LAMMPS Documentation.....	1
16 Mar 2018 version.....	1
Version info:.....	1
1. Introduction.....	5
1.1 What is LAMMPS.....	5
1.2 LAMMPS features.....	6
1.3 LAMMPS non-features.....	9
1.4 Open source distribution.....	11
1.5 Acknowledgments and citations.....	12
2. Getting Started.....	14
2.1 What's in the LAMMPS distribution.....	14
2.2 Making LAMMPS.....	15
2.3 Making LAMMPS with optional packages.....	25
2.4 Building LAMMPS as a library.....	29
2.5 Running LAMMPS.....	31
2.6 Command-line options.....	33
2.7 LAMMPS screen output.....	40
2.8 Tips for users of previous LAMMPS versions.....	43
3. Commands.....	45
3.1 LAMMPS input script.....	45
3.2 Parsing rules.....	46
3.3 Input script structure.....	48
3.4 Commands listed by category.....	49
3.5 Individual commands.....	50
Fix styles.....	51
Compute styles.....	52
Pair_style potentials.....	52
Bond_style potentials.....	54
Angle_style potentials.....	54
Dihedral_style potentials.....	55
Improper_style potentials.....	55
Kspace solvers.....	55
4. Packages.....	57
ASPHERE package.....	60
BODY package.....	61
CLASS2 package.....	61
COLLOID package.....	62
COMPRESS package.....	63
CORESHELL package.....	63
DIPOLE package.....	64
GPU package.....	64
GRANULAR package.....	66
KIM package.....	66
KOKKOS package.....	68
KSPACE package.....	69
LATTE package.....	70
MANYBODY package.....	71
MC package.....	72

Table of Contents

MEAM package.....	72
MISC package.....	73
MOLECULE package.....	74
MPIIO package.....	74
MSCG package.....	75
OPT package.....	76
PERI package.....	77
POEMS package.....	77
PYTHON package.....	78
QEQ package.....	79
REAX package.....	79
REPLICA package.....	80
RIGID package.....	81
SHOCK package.....	82
SNAP package.....	82
SRD package.....	83
VORONOI package.....	83
USER-ATC package.....	84
USER-AWPMD package.....	85
USER-CGDNA package.....	86
USER-CGSDK package.....	87
USER-COLVARS package.....	87
USER-DIFFRACTION package.....	88
USER-DPD package.....	89
USER-DRUDE package.....	90
USER-EFF package.....	90
USER-FEP package.....	91
USER-H5MD package.....	92
USER-INTEL package.....	93
USER-LB package.....	94
USER-MGPT package.....	94
USER-MISC package.....	95
USER-MANIFOLD package.....	96
USER-MEAMC package.....	96
USER-MESO package.....	97
USER-MOFFF package.....	97
USER-MOLFILE package.....	98
USER-NETCDF package.....	99
USER-OMP package.....	100
USER-PHONON package.....	101
USER-QMMM package.....	101
USER-QTB package.....	102
USER-QUIP package.....	103
USER-REAXC package.....	104
USER-SMD package.....	104
USER-SMTBQ package.....	105
USER-SPH package.....	106
USER-TALLY package.....	106

Table of Contents

USER-UEF package.....	107
USER-VTK package.....	107
5. Accelerating LAMMPS performance.....	109
5.1 Measuring performance.....	109
5.2 General strategies.....	110
5.3 Packages with optimized styles.....	111
5.4 Comparison of various accelerator packages.....	114
6. How-to discussions.....	145
6.1 Restarting a simulation.....	145
6.2 2d simulations.....	147
6.3 CHARMM, AMBER, and DREIDING force fields.....	147
6.4 Running multiple simulations from one input script.....	149
6.5 Multi-replica simulations.....	150
6.6 Granular models.....	151
6.7 TIP3P water model.....	152
6.8 TIP4P water model.....	153
6.9 SPC water model.....	155
6.10 Coupling LAMMPS to other codes.....	156
6.11 Visualizing LAMMPS snapshots.....	157
6.12 Triclinic (non-orthogonal) simulation boxes.....	157
6.13 NEMD simulations.....	163
6.14 Finite-size spherical and aspherical particles.....	163
6.15 Output from LAMMPS (thermo, dumps, computes, fixes, variables).....	167
6.16 Thermostatting, barostatting, and computing temperature.....	172
6.17 Walls.....	175
6.18 Elastic constants.....	176
6.19 Library interface to LAMMPS.....	177
6.20 Calculating thermal conductivity.....	180
6.21 Calculating viscosity.....	181
6.22 Calculating a diffusion coefficient.....	183
6.23 Using chunks to calculate system properties.....	183
6.24 Setting parameters for the kspace_style ppm/disp command.....	186
6.25 Polarizable models.....	188
6.26 Adiabatic core/shell model.....	189
6.27 Drude induced dipoles.....	192
7. Example problems.....	195
Lowercase directories.....	195
Uppercase directories.....	197
8. Performance & scalability.....	198
9. Additional tools.....	200
amber2lmp tool.....	200
binary2txt tool.....	200
ch2lmp tool.....	201
chain tool.....	201
colvars tools.....	201
createatoms tool.....	202
doxygen tool.....	202

Table of Contents

drude tool.....	202
eam database tool.....	202
eam generate tool.....	203
eff tool.....	203
emacs tool.....	203
fep tool.....	203
i-pi tool.....	203
ipp tool.....	204
kate tool.....	204
lmp2arc tool.....	204
lmp2cfg tool.....	204
matlab tool.....	204
micelle2d tool.....	205
moltemplate tool.....	205
msi2lmp tool.....	205
phonon tool.....	205
polybond tool.....	206
pymol_sphere tool.....	206
python tool.....	206
reax tool.....	206
smd tool.....	207
vim tool.....	207
xmgrace tool.....	207
10. Modifying & extending LAMMPS.....	208
10.1 Atom styles.....	210
10.2 Bond, angle, dihedral, improper potentials.....	211
10.3 Compute styles.....	212
10.4 Dump styles.....	213
10.5 Dump custom output options.....	213
10.6 Fix styles.....	213
10.7 Input script commands.....	216
10.8 Kspace computations.....	216
10.9 Minimization styles.....	216
10.10 Pairwise potentials.....	217
10.11 Region styles.....	217
10.12 Body styles.....	218
10.13 Thermodynamic output options.....	218
10.14 Variable options.....	219
10.15 Submitting new features for inclusion in LAMMPS.....	219
11. Python interface to LAMMPS.....	224
11.1 Overview of running LAMMPS from Python.....	225
11.2 Overview of using Python from a LAMMPS script.....	226
11.3 Building LAMMPS as a shared library.....	227
11.4 Installing the Python wrapper into Python.....	227
11.5 Extending Python with MPI to run in parallel.....	228
11.6 Testing the Python-LAMMPS interface.....	231
11.7 Using LAMMPS from Python.....	233
11.8 Example Python scripts that use LAMMPS.....	237

Table of Contents

11.9 PyLammps interface.....	238
12. Errors.....	239
12.1 Common problems.....	239
12.2 Reporting bugs.....	241
12.3 Error & warning messages.....	241
Errors:.....	241
Warnings:.....	353
13. Future and history.....	365
13.1 Coming attractions.....	365
13.2 Past versions.....	365
Tutorials.....	368
Using LAMMPS with Bash on Windows.....	369
Installing Bash on Windows.....	369
Compiling LAMMPS in Bash on Windows.....	376
Tutorial for Thermalized Drude oscillators in LAMMPS.....	379
LAMMPS GitHub tutorial.....	387
PyLammps Tutorial.....	403
Overview.....	403
Quick Start.....	403
Creating a new instance of PyLammps.....	404
Commands.....	405
System state.....	405
Working with LAMMPS variables.....	406
Retrieving the value of an arbitrary LAMMPS expressions.....	406
Accessing atom data.....	407
Evaluating thermo data.....	407
Error handling with PyLammps.....	407
Using PyLammps in IPython notebooks and Jupyter.....	408
IPyLammps Examples.....	408
Using PyLammps and mpi4py (Experimental).....	413
Feedback and Contributing.....	413
Body particles.....	415
Manifolds (surfaces).....	421
LAMMPS Commands.....	423
angle_coeff command.....	424
angle_style command.....	426
atom_modify command.....	428
atom_style command.....	431
balance command.....	437
bond_coeff command.....	446
bond_style command.....	448
bond_write command.....	450
boundary command.....	451
box command.....	453
change_box command.....	454

Table of Contents

LAMMPS Commands

clear command.....	460
comm_modify command.....	461
comm_style command.....	464
compute command.....	465
compute_modify command.....	470
create_atoms command.....	472
create_bonds command.....	478
create_box command.....	482
delete_atoms command.....	485
delete_bonds command.....	488
dielectric command.....	491
dihedral_coeff command.....	492
dihedral_style command.....	494
dimension command.....	497
displace_atoms command.....	498
dump command.....	501
dump vtk command.....	501
dump h5md command.....	501
dump molfile command.....	501
dump netcdf command.....	501
dump image command.....	501
dump movie command.....	501
dump h5md command.....	512
dump image command.....	514
dump movie command.....	514
dump_modify command.....	526
dump molfile command.....	541
dump netcdf command.....	543
dump netcdf/mpio command.....	543
dump vtk command.....	545
dump cfg/uef command.....	548
echo command.....	549
fix command.....	550
fix_modify command.....	556
group command.....	558
group2ndx command.....	563
ndx2group command.....	563
if command.....	565
improper_coeff command.....	569
improper_style command.....	571
include command.....	573
info command.....	574
jump command.....	577
kspace_modify command.....	580
kspace_style command.....	586
label command.....	593
lattice command.....	594

Table of Contents

LAMMPS Commands

log command.....	599
mass command.....	600
min_modify command.....	602
min_style command.....	604
minimize command.....	606
molecule command.....	611
neb command.....	619
neigh_modify command.....	626
neighbor command.....	630
newton command.....	632
next command.....	633
package command.....	636
pair_coeff command.....	646
pair_modify command.....	649
pair_style command.....	654
pair_write command.....	659
partition command.....	661
prd command.....	663
print command.....	669
processors command.....	671
python command.....	677
quit command.....	685
read_data command.....	686
read_dump command.....	706
read_restart command.....	712
region command.....	717
replicate command.....	724
rerun command.....	726
reset_timestep command.....	730
restart command.....	731
run command.....	734
run_style command.....	738
set command.....	743
shell command.....	751
special_bonds command.....	753
suffix command.....	757
tad command.....	759
temper command.....	764
temper/grem command.....	767
temper/npt command.....	769
thermo command.....	771
thermo_modify command.....	772
thermo_style command.....	775
timer command.....	782
timestep command.....	785
uncompute command.....	786
undump command.....	787

Table of Contents

LAMMPS Commands

unfix command.....	788
units command.....	789
variable command.....	794
Numbers, constants, and thermo keywords.....	802
Math Operators.....	802
Math Functions.....	803
Group and Region Functions.....	805
Special Functions.....	806
Feature Functions.....	807
Atom Values and Vectors.....	808
Compute References.....	809
Fix References.....	810
Variable References.....	811
velocity command.....	816
write_coeff command.....	821
write_data command.....	822
write_dump command.....	824
write_restart command.....	826
fix adapt command.....	828
fix adapt/fep command.....	833
fix addforce command.....	838
fix addtorque command.....	841
fix append/atoms command.....	843
fix atom/swap command.....	845
fix ave/atom command.....	848
fix ave/chunk command.....	851
fix ave/correlate command.....	859
fix ave/correlate/long command.....	865
fix ave/histo command.....	868
fix ave/histo/weight command.....	868
fix ave/time command.....	874
fix aveforce command.....	880
fix balance command.....	882
fix bond/break command.....	889
fix bond/create command.....	892
fix bond/swap command.....	896
fix box/relax command.....	900
fix cmap command.....	906
fix colvars command.....	909
fix controller command.....	912
fix deform command.....	916
fix deform/kk command.....	916
fix deposit command.....	926
fix dpd/energy command.....	931
fix dpd/energy/kk command.....	931
fix edpd/source command.....	933
fix tdpd/source command.....	933

Table of Contents

LAMMPS Commands

fix drag command.....	935
fix drude command.....	936
fix drude/transform/direct command.....	937
fix drude/transform/inverse command.....	937
fix dt/reset command.....	940
fix efield command.....	942
fix ehex command.....	945
fix enforce2d command.....	948
fix eos/cv command.....	950
fix eos/table command.....	951
fix eos/table/rx command.....	953
fix eos/table/rx/kk command.....	953
fix evaporate command.....	957
fix external command.....	959
fix filter/corotate command.....	962
fix flow/gauss command.....	964
fix freeze command.....	967
fix gcmc command.....	969
fix gld command.....	977
fix gle command.....	980
fix gravity command.....	983
fix gravity/omp command.....	983
fix grem command.....	986
fix halt command.....	988
fix heat command.....	991
fix ind command.....	994
fix indent command.....	997
fix ipi command.....	1001
fix langevin command.....	1003
fix langevin/kk command.....	1003
fix langevin/drude command.....	1009
fix langevin/eff command.....	1013
fix latte command.....	1015
fix lb/fluid command.....	1019
fix lb/momentum command.....	1026
fix lb/pc command.....	1028
fix lb/rigid/pc/sphere command.....	1029
fix lb/viscous command.....	1032
fix lineforce command.....	1034
fix manifoldforce command.....	1035
fix meso command.....	1036
fix meso/stationary command.....	1037
fix momentum command.....	1038
fix momentum/kk command.....	1038
fix move command.....	1040
fix mscg command.....	1044
fix msst command.....	1047

LAMMPS Documentation

16 Mar 2018 version

Version info:

The LAMMPS "version" is the date when it was released, such as 1 May 2010. LAMMPS is updated continuously. Whenever we fix a bug or add a feature, we release it immediately, and post a notice on [this page of the WWW site](#). Every 2-4 months one of the incremental releases is subjected to more thorough testing and labeled as a *stable* version.

Each dated copy of LAMMPS contains all the features and bug-fixes up to and including that version date. The version date is printed to the screen and logfile every time you run LAMMPS. It is also in the file `src/version.h` and in the LAMMPS directory name created when you unpack a tarball, and at the top of the first page of the manual (this page).

- If you browse the HTML doc pages on the LAMMPS WWW site, they always describe the most current **development** version of LAMMPS.
- If you browse the HTML doc pages included in your tarball, they describe the version you have.
- The [PDF file](#) on the WWW site or in the tarball is updated about once per month. This is because it is large, and we don't want it to be part of every patch.
- There is also a [Developer.pdf](#) file in the doc directory, which describes the internal structure and algorithms of LAMMPS.

LAMMPS stands for Large-scale Atomic/Molecular Massively Parallel Simulator.

LAMMPS is a classical molecular dynamics simulation code designed to run efficiently on parallel computers. It was developed at Sandia National Laboratories, a US Department of Energy facility, with funding from the DOE. It is an open-source code, distributed freely under the terms of the GNU Public License (GPL).

The current core group of LAMMPS developers is at Sandia National Labs and Temple University:

- [Steve Plimpton](#), sjplimp at sandia.gov
- Aidan Thompson, athomps at sandia.gov
- Stan Moore, stamoor at sandia.gov
- [Axel Kohlmeyer](#), akohlmey at gmail.com

Past core developers include Paul Crozier, Ray Shan and Mark Stevens, all at Sandia. The **LAMMPS home page** at <http://lammps.sandia.gov> has more information about the code and its uses. Interaction with external LAMMPS developers, bug reports and feature requests are mainly coordinated through the [LAMMPS project on GitHub](#). The lammps.org domain, currently hosting [public continuous integration testing](#) and [precompiled Linux RPM and Windows installer packages](#) is located at Temple University and managed by Richard Berger, richard.berger at temple.edu.

LAMMPS Users Manual

The LAMMPS documentation is organized into the following sections. If you find errors or omissions in this manual or have suggestions for useful information to add, please send an email to the developers so we can improve the LAMMPS documentation.

Once you are familiar with LAMMPS, you may want to bookmark [this page](#) at `Section_commands.html#comm` since it gives quick access to documentation for all LAMMPS commands.

1. Introduction

This section provides an overview of what LAMMPS can and can't do, describes what it means for LAMMPS to be an open-source code, and acknowledges the funding and people who have contributed to LAMMPS over the years.

- 1.1 [What is LAMMPS](#)
 - 1.2 [LAMMPS features](#)
 - 1.3 [LAMMPS non-features](#)
 - 1.4 [Open source distribution](#)
 - 1.5 [Acknowledgments and citations](#)
-

1.1 What is LAMMPS

LAMMPS is a classical molecular dynamics code that models an ensemble of particles in a liquid, solid, or gaseous state. It can model atomic, polymeric, biological, metallic, granular, and coarse-grained systems using a variety of force fields and boundary conditions.

For examples of LAMMPS simulations, see the Publications page of the [LAMMPS WWW Site](#).

LAMMPS runs efficiently on single-processor desktop or laptop machines, but is designed for parallel computers. It will run on any parallel machine that compiles C++ and supports the [MPI](#) message-passing library. This includes distributed- or shared-memory parallel machines and Beowulf-style clusters.

LAMMPS can model systems with only a few particles up to millions or billions. See [Section 8](#) for information on LAMMPS performance and scalability, or the Benchmarks section of the [LAMMPS WWW Site](#).

LAMMPS is a freely-available open-source code, distributed under the terms of the [GNU Public License](#), which means you can use or modify the code however you wish. See [this section](#) for a brief discussion of the open-source philosophy.

LAMMPS is designed to be easy to modify or extend with new capabilities, such as new force fields, atom types, boundary conditions, or diagnostics. See [Section 10](#) for more details.

The current version of LAMMPS is written in C++. Earlier versions were written in F77 and F90. See [Section 13](#) for more information on different versions. All versions can be downloaded from the [LAMMPS WWW Site](#).

LAMMPS was originally developed under a US Department of Energy CRADA (Cooperative Research and Development Agreement) between two DOE labs and 3

LAMMPS Users Manual

companies. It is distributed by [Sandia National Labs](#). See [this section](#) for more information on LAMMPS funding and individuals who have contributed to LAMMPS.

In the most general sense, LAMMPS integrates Newton's equations of motion for collections of atoms, molecules, or macroscopic particles that interact via short- or long-range forces with a variety of initial and/or boundary conditions. For computational efficiency LAMMPS uses neighbor lists to keep track of nearby particles. The lists are optimized for systems with particles that are repulsive at short distances, so that the local density of particles never becomes too large. On parallel machines, LAMMPS uses spatial-decomposition techniques to partition the simulation domain into small 3d sub-domains, one of which is assigned to each processor. Processors communicate and store "ghost" atom information for atoms that border their sub-domain. LAMMPS is most efficient (in a parallel sense) for systems whose particles fill a 3d rectangular box with roughly uniform density. Papers with technical details of the algorithms used in LAMMPS are listed in [this section](#).

1.2 LAMMPS features

This section highlights LAMMPS features, with pointers to specific commands which give more details. If LAMMPS doesn't have your favorite interatomic potential, boundary condition, or atom type, see [Section 10](#), which describes how you can add it to LAMMPS.

General features

- runs on a single processor or in parallel
- distributed-memory message-passing parallelism (MPI)
- spatial-decomposition of simulation domain for parallelism
- open-source distribution
- highly portable C++
- optional libraries used: MPI and single-processor FFT
- GPU (CUDA and OpenCL), Intel(R) Xeon Phi(TM) coprocessors, and OpenMP support for many code features
- easy to extend with new features and functionality
- runs from an input script
- syntax for defining and using variables and formulas
- syntax for looping over runs and breaking out of loops
- run one or multiple simulations simultaneously (in parallel) from one script
- build as library, invoke LAMMPS thru library interface or provided Python wrapper
- couple with other codes: LAMMPS calls other code, other code calls LAMMPS, umbrella code calls both

Particle and model types

([atom style](#) command)

- atoms
- coarse-grained particles (e.g. bead-spring polymers)
- united-atom polymers or organic molecules

LAMMPS Users Manual

- all-atom polymers, organic molecules, proteins, DNA
- metals
- granular materials
- coarse-grained mesoscale models
- finite-size spherical and ellipsoidal particles
- finite-size line segment (2d) and triangle (3d) particles
- point dipole particles
- rigid collections of particles
- hybrid combinations of these

Force fields

([pair style](#), [bond style](#), [angle style](#), [dihedral style](#), [improper style](#), [kspace style](#) commands)

- pairwise potentials: Lennard-Jones, Buckingham, Morse, Born-Mayer-Huggins, Yukawa, soft, class 2 (COMPASS), hydrogen bond, tabulated
- charged pairwise potentials: Coulombic, point-dipole
- manybody potentials: EAM, Finnis/Sinclair EAM, modified EAM (MEAM), embedded ion method (EIM), EDIP, ADP, Stillinger-Weber, Tersoff, REBO, AIREBO, ReaxFF, COMB, SNAP, Streitz-Mintmire, 3-body polymorphic
- long-range interactions for charge, point-dipoles, and LJ dispersion: Ewald, Wolf, PPPM (similar to particle-mesh Ewald)
- polarization models: [QEq](#), [core/shell model](#), [Drude dipole model](#)
- charge equilibration (QEq via dynamic, point, shielded, Slater methods)
- coarse-grained potentials: DPD, GayBerne, REsquared, colloidal, DLVO
- mesoscopic potentials: granular, Peridynamics, SPH
- electron force field (eFF, AWPMD)
- bond potentials: harmonic, FENE, Morse, nonlinear, class 2, quartic (breakable)
- angle potentials: harmonic, CHARMM, cosine, cosine/squared, cosine/periodic, class 2 (COMPASS)
- dihedral potentials: harmonic, CHARMM, multi-harmonic, helix, class 2 (COMPASS), OPLS
- improper potentials: harmonic, cvff, umbrella, class 2 (COMPASS)
- polymer potentials: all-atom, united-atom, bead-spring, breakable
- water potentials: TIP3P, TIP4P, SPC
- implicit solvent potentials: hydrodynamic lubrication, Debye
- force-field compatibility with common CHARMM, AMBER, DREIDING, OPLS, GROMACS, COMPASS options
- access to [KIM archive](#) of potentials via [pair kim](#)
- hybrid potentials: multiple pair, bond, angle, dihedral, improper potentials can be used in one simulation
- overlaid potentials: superposition of multiple pair potentials

Atom creation

([read_data](#), [lattice](#), [create_atoms](#), [delete_atoms](#), [displace_atoms](#), [replicate](#) commands)

- read in atom coords from files
- create atoms on one or more lattices (e.g. grain boundaries)
- delete geometric or logical groups of atoms (e.g. voids)

LAMMPS Users Manual

- replicate existing atoms multiple times
- displace atoms

Ensembles, constraints, and boundary conditions

([fix](#) command)

- 2d or 3d systems
- orthogonal or non-orthogonal (triclinic symmetry) simulation domains
- constant NVE, NVT, NPT, NPH, Parinello/Rahman integrators
- thermostating options for groups and geometric regions of atoms
- pressure control via Nose/Hoover or Berendsen barostatting in 1 to 3 dimensions
- simulation box deformation (tensile and shear)
- harmonic (umbrella) constraint forces
- rigid body constraints
- SHAKE bond and angle constraints
- Monte Carlo bond breaking, formation, swapping
- atom/molecule insertion and deletion
- walls of various kinds
- non-equilibrium molecular dynamics (NEMD)
- variety of additional boundary conditions and constraints

Integrators

([run](#), [run_style](#), [minimize](#) commands)

- velocity-Verlet integrator
- Brownian dynamics
- rigid body integration
- energy minimization via conjugate gradient or steepest descent relaxation
- rRESPA hierarchical timestepping
- rerun command for post-processing of dump files

Diagnostics

- see the various flavors of the [fix](#) and [compute](#) commands

Output

([dump](#), [restart](#) commands)

- log file of thermodynamic info
- text dump files of atom coords, velocities, other per-atom quantities
- binary restart files
- parallel I/O of dump and restart files
- per-atom quantities (energy, stress, centro-symmetry parameter, CNA, etc)
- user-defined system-wide (log file) or per-atom (dump file) calculations
- spatial and time averaging of per-atom quantities
- time averaging of system-wide quantities
- atom snapshots in native, XYZ, XTC, DCD, CFG formats

LAMMPS Users Manual

Multi-replica models

[nudged elastic band](#) [parallel replica dynamics](#) [temperature accelerated dynamics](#)
[parallel tempering](#)

Pre- and post-processing

- Various pre- and post-processing serial tools are packaged with LAMMPS; see these [doc pages](#).
- Our group has also written and released a separate toolkit called [Pizza.py](#) which provides tools for doing setup, analysis, plotting, and visualization for LAMMPS simulations. Pizza.py is written in [Python](#) and is available for download from [the Pizza.py WWW site](#).

Specialized features

LAMMPS can be built with optional packages which implement a variety of additional capabilities. An overview of all the packages is [given here](#).

These are some LAMMPS capabilities which you may not think of as typical classical molecular dynamics options:

- [static](#) and [dynamic load-balancing](#)
- [generalized aspherical particles](#)
- [stochastic rotation dynamics \(SRD\)](#)
- [real-time visualization and interactive MD](#)
- calculate [virtual diffraction patterns](#)
- [atom-to-continuum coupling](#) with finite elements
- coupled rigid body integration via the [POEMS](#) library
- [QM/MM coupling](#)
- [path-integral molecular dynamics \(PIMD\)](#) and [this as well](#)
- Monte Carlo via [GCMC](#) and [tfMC atom swapping](#) and [bond swapping](#)
- [Direct Simulation Monte Carlo](#) for low-density fluids
- [Peridynamics mesoscale modeling](#)
- [Lattice Boltzmann fluid](#)
- [targeted](#) and [steered](#) molecular dynamics
- [two-temperature electron model](#)

1.3 LAMMPS non-features

LAMMPS is designed to efficiently compute Newton's equations of motion for a system of interacting particles. Many of the tools needed to pre- and post-process the data for such simulations are not included in the LAMMPS kernel for several reasons:

- the desire to keep LAMMPS simple
- they are not parallel operations
- other codes already do them
- limited development resources

Specifically, LAMMPS itself does not:

LAMMPS Users Manual

- run thru a GUI
- build molecular systems
- assign force-field coefficients automatically
- perform sophisticated analyses of your MD simulation
- visualize your MD simulation
- plot your output data

A few tools for pre- and post-processing tasks are provided as part of the LAMMPS package; they are described in [this section](#). However, many people use other codes or write their own tools for these tasks.

As noted above, our group has also written and released a separate toolkit called [Pizza.py](#) which addresses some of the listed bullets. It provides tools for doing setup, analysis, plotting, and visualization for LAMMPS simulations. Pizza.py is written in [Python](#) and is available for download from [the Pizza.py WWW site](#).

LAMMPS requires as input a list of initial atom coordinates and types, molecular topology information, and force-field coefficients assigned to all atoms and bonds. LAMMPS will not build molecular systems and assign force-field parameters for you.

For atomic systems LAMMPS provides a [create_atoms](#) command which places atoms on solid-state lattices (fcc, bcc, user-defined, etc). Assigning small numbers of force field coefficients can be done via the [pair coeff](#), [bond coeff](#), [angle coeff](#), etc commands. For molecular systems or more complicated simulation geometries, users typically use another code as a builder and convert its output to LAMMPS input format, or write their own code to generate atom coordinate and molecular topology for LAMMPS to read in.

For complicated molecular systems (e.g. a protein), a multitude of topology information and hundreds of force-field coefficients must typically be specified. We suggest you use a program like [CHARMM](#) or [AMBER](#) or other molecular builders to setup such problems and dump its information to a file. You can then reformat the file as LAMMPS input. Some of the tools in [this section](#) can assist in this process.

Similarly, LAMMPS creates output files in a simple format. Most users post-process these files with their own analysis tools or re-format them for input into other programs, including visualization packages. If you are convinced you need to compute something on-the-fly as LAMMPS runs, see [Section 10](#) for a discussion of how you can use the [dump](#) and [compute](#) and [fix](#) commands to print out data of your choosing. Keep in mind that complicated computations can slow down the molecular dynamics timestepping, particularly if the computations are not parallel, so it is often better to leave such analysis to post-processing codes.

For high-quality visualization we recommend the following packages:

- [VMD](#)
- [AtomEye](#)
- [OVITO](#)
- [ParaView](#)
- [PyMol](#)
- [Raster3d](#)

LAMMPS Users Manual

- [RasMol](#)

Other features that LAMMPS does not yet (and may never) support are discussed in [Section 13](#).

Finally, these are freely-available molecular dynamics codes, most of them parallel, which may be well-suited to the problems you want to model. They can also be used in conjunction with LAMMPS to perform complementary modeling tasks.

- [CHARMM](#)
- [AMBER](#)
- [NAMD](#)
- [NWCHEM](#)
- [DL_POLY](#)
- [Tinker](#)

CHARMM, AMBER, NAMD, NWCHEM, and Tinker are designed primarily for modeling biological molecules. CHARMM and AMBER use atom-decomposition (replicated-data) strategies for parallelism; NAMD and NWCHEM use spatial-decomposition approaches, similar to LAMMPS. Tinker is a serial code. DL_POLY includes potentials for a variety of biological and non-biological materials; both a replicated-data and spatial-decomposition version exist.

1.4 Open source distribution

LAMMPS comes with no warranty of any kind. As each source file states in its header, it is a copyrighted code that is distributed free-of-charge, under the terms of the [GNU Public License](#) (GPL). This is often referred to as open-source distribution - see www.gnu.org or www.opensource.org for more details. The legal text of the GPL is in the LICENSE file that is included in the LAMMPS distribution.

Here is a summary of what the GPL means for LAMMPS users:

- (1) Anyone is free to use, modify, or extend LAMMPS in any way they choose, including for commercial purposes.
- (2) If you distribute a modified version of LAMMPS, it must remain open-source, meaning you distribute it under the terms of the GPL. You should clearly annotate such a code as a derivative version of LAMMPS.
- (3) If you release any code that includes LAMMPS source code, then it must also be open-sourced, meaning you distribute it under the terms of the GPL.
- (4) If you give LAMMPS files to someone else, the GPL LICENSE file and source file headers (including the copyright and GPL notices) should remain part of the code.

In the spirit of an open-source code, these are various ways you can contribute to making LAMMPS better. You can send email to the [developers](#) on any of these items.

LAMMPS Users Manual

- Point prospective users to the [LAMMPS WWW Site](#). Mention it in talks or link to it from your WWW site.
 - If you find an error or omission in this manual or on the [LAMMPS WWW Site](#), or have a suggestion for something to clarify or include, send an email to the [developers](#).
 - If you find a bug, [Section 12.2](#) describes how to report it.
 - If you publish a paper using LAMMPS results, send the citation (and any cool pictures or movies if you like) to add to the Publications, Pictures, and Movies pages of the [LAMMPS WWW Site](#), with links and attributions back to you.
 - Create a new Makefile.machine that can be added to the src/MAKE directory.
 - The tools sub-directory of the LAMMPS distribution has various stand-alone codes for pre- and post-processing of LAMMPS data. More details are given in [Section 9](#). If you write a new tool that users will find useful, it can be added to the LAMMPS distribution.
 - LAMMPS is designed to be easy to extend with new code for features like potentials, boundary conditions, diagnostic computations, etc. [This section](#) gives details. If you add a feature of general interest, it can be added to the LAMMPS distribution.
 - The Benchmark page of the [LAMMPS WWW Site](#) lists LAMMPS performance on various platforms. The files needed to run the benchmarks are part of the LAMMPS distribution. If your machine is sufficiently different from those listed, your timing data can be added to the page.
 - You can send feedback for the User Comments page of the [LAMMPS WWW Site](#). It might be added to the page. No promises.
 - Cash. Small denominations, unmarked bills preferred. Paper sack OK. Leave on desk. VISA also accepted. Chocolate chip cookies encouraged.
-

1.5 Acknowledgments and citations

LAMMPS development has been funded by the [US Department of Energy](#) (DOE), through its CRADA, LDRD, ASCI, and Genomes-to-Life programs and its [OASCR](#) and [OBER](#) offices.

Specifically, work on the latest version was funded in part by the US Department of Energy's Genomics:GTL program (www.doegenomestolife.org) under the [project](#), "Carbon Sequestration in Synechococcus Sp.: From Molecular Machines to Hierarchical Modeling".

The following paper describe the basic parallel algorithms used in LAMMPS. If you use LAMMPS results in your published work, please cite this paper and include a pointer to the [LAMMPS WWW Site](#) (<http://lammps.sandia.gov>):

S. Plimpton, **Fast Parallel Algorithms for Short-Range Molecular Dynamics**, J Comp Phys, 117, 1-19 (1995).

Other papers describing specific algorithms used in LAMMPS are listed under the [Citing LAMMPS link](#) of the LAMMPS WWW page.

The [Publications link](#) on the LAMMPS WWW page lists papers that have cited LAMMPS. If your paper is not listed there for some reason, feel free to send us the info. If the simulations in your paper produced cool pictures or animations, we'll be

LAMMPS Users Manual

pleased to add them to the [Pictures](#) or [Movies](#) pages of the LAMMPS WWW site.

The primary LAMMPS developers are at Sandia National Labs and Temple University:

- Steve Plimpton, [sjplimp at sandia.gov](mailto:sjplimp@sandia.gov)
- Aidan Thompson, [athomps at sandia.gov](mailto:athomps@sandia.gov)
- Stan Moore, [stamoor at sandia.gov](mailto:stamoor@sandia.gov)
- Axel Kohlmeyer, [akohlmey at gmail.com](mailto:akohlmey@gmail.com)

Past primary developers include Paul Crozier and Mark Stevens, both at Sandia, and Ray Shan, now at Materials Design.

The following folks are responsible for significant contributions to the code, or other aspects of the LAMMPS development effort. Many of the packages they have written are somewhat unique to LAMMPS and the code would not be as general-purpose as it is without their expertise and efforts.

- Axel Kohlmeyer (Temple U), [akohlmey at gmail.com](mailto:akohlmey@gmail.com), SVN and Git repositories, indefatigable mail list responder, USER-CGSDK, USER-OMP, USER-COLVARS, USER-MOLFILE, USER-QMMM, USER-TALLY, and COMPRESS packages
- Roy Pollock (LLNL), Ewald and PPPM solvers
- Mike Brown (ORNL), [brownw at ornl.gov](mailto:brownw@ornl.gov), GPU and USER-INTEL package
- Greg Wagner (Sandia), [gjwagne at sandia.gov](mailto:gjwagne@sandia.gov), MEAM package for MEAM potential
- Mike Parks (Sandia), [mlparks at sandia.gov](mailto:mlparks@sandia.gov), PERI package for Peridynamics
- Rudra Mukherjee (JPL), [Rudranarayan.M.Mukherjee at jpl.nasa.gov](mailto:Rudranarayan.M.Mukherjee@jpl.nasa.gov), POEMS package for articulated rigid body motion
- Reese Jones (Sandia) and collaborators, [rjones at sandia.gov](mailto:rjones@sandia.gov), USER-ATC package for atom/continuum coupling
- Ilya Valuev (JIHT), [valuev at physik.hu-berlin.de](mailto:valuev@physik.hu-berlin.de), USER-AWPMD package for wave-packet MD
- Christian Trott (U Tech Ilmenau), [christian.trott at tu-ilmenau.de](mailto:christian.trott@tu-ilmenau.de), USER-CUDA and KOKKOS packages
- Andres Jaramillo-Botero (Caltech), [ajaramil at wag.caltech.edu](mailto:ajaramil@wag.caltech.edu), USER-EFF package for electron force field
- Christoph Kloss (JKU), [Christoph.Kloss at jku.at](mailto:Christoph.Kloss@jku.at), USER-LIGGGHTS package for granular models and granular/fluid coupling
- Metin Aktulga (LBL), [hmaktulga at lbl.gov](mailto:hmaktulga@lbl.gov), USER-REAXC package for C version of ReaxFF
- Georg Gunzenmuller (EMI), [georg.ganzenmueller at emi.fhg.de](mailto:georg.ganzenmueller@emi.fhg.de), USER-SMD and USER-SPH packages
- Colin Denniston (U Western Ontario), [cdennist at uwo.ca](mailto:cdennist@uwo.ca), USER-LB package

As discussed in [Section 13](#), LAMMPS originated as a cooperative project between DOE labs and industrial partners. Folks involved in the design and testing of the original version of LAMMPS were the following:

- John Carpenter (Mayo Clinic, formerly at Cray Research)
- Terry Stouch (Lexicon Pharmaceuticals, formerly at Bristol Myers Squibb)
- Steve Lustig (Dupont)
- Jim Belak (LLNL)

2. Getting Started

This section describes how to build and run LAMMPS, for both new and experienced users.

- [2.1 What's in the LAMMPS distribution](#)
 - [2.2 Making LAMMPS](#)
 - [2.3 Making LAMMPS with optional packages](#)
 - [2.4 Building LAMMPS as a library](#)
 - [2.5 Running LAMMPS](#)
 - [2.6 Command-line options](#)
 - [2.7 Screen output](#)
 - [2.8 Tips for users of previous versions](#)
-

2.1 What's in the LAMMPS distribution

When you download a LAMMPS tarball you will need to unzip and untar the downloaded file with the following commands, after placing the tarball in an appropriate directory.

```
tar -xzvf lammps*.tar.gz
```

This will create a LAMMPS directory containing two files and several sub-directories:

README	text file
LICENSE	the GNU General Public License (GPL)
bench	benchmark problems
doc	documentation
examples	simple test problems
potentials	embedded atom method (EAM) potential files
src	source files
tools	pre- and post-processing tools

Note that the [download page](#) also has links to download pre-build Windows installers, as well as pre-built packages for several widely used Linux distributions. It also has instructions for how to download/install LAMMPS for Macs (via Homebrew), and to download and update LAMMPS from SVN and Git repositories, which gives you access to the up-to-date sources that are used by the LAMMPS core developers.

The Windows and Linux packages for serial or parallel include only selected packages and bug-fixes/upgrades listed on [this page](#) up to a certain date, as stated on the download page. If you want an executable with non-included packages or that is more current, then you'll need to build LAMMPS yourself, as discussed in the next section.

Skip to the [Running LAMMPS](#) sections for info on how to launch a LAMMPS Windows executable on a Windows box.

2.2 Making LAMMPS

This section has the following sub-sections:

2.2.1 [Read this first](#)

2.2.3 [Common errors that can occur when making LAMMPS](#)

2.2.4 [Additional build tips](#)

2.2.5 [Building for a Mac](#)

2.2.6 [Building for Windows](#)

Read this first

If you want to avoid building LAMMPS yourself, read the preceding section about options available for downloading and installing executables. Details are discussed on the [download](#) page.

Building LAMMPS can be simple or not-so-simple. If all you need are the default packages installed in LAMMPS, and MPI is already installed on your machine, or you just want to run LAMMPS in serial, then you can typically use the Makefile.mpi or Makefile.serial files in src/MAKE by typing one of these lines (from the src dir):

```
make mpi
make serial
```

Note that on a facility supercomputer, there are often "modules" loaded in your environment that provide the compilers and MPI you should use. In this case, the "mpicxx" compile/link command in Makefile.mpi should simply work by accessing those modules.

It may be the case that one of the other Makefile.machine files in the src/MAKE sub-directories is a better match to your system (type "make" to see a list), you can use it as-is by typing (for example):

```
make stampede
```

If any of these builds (with an existing Makefile.machine) works on your system, then you're done!

If you need to install an optional package with a LAMMPS command you want to use, and the package does not depend on an extra library, you can simply type

```
make name
```

before invoking (or re-invoking) the above steps. "Name" is the lower-case name of the package, e.g. replica or user-misc.

If you want to do one of the following:

- use a LAMMPS command that requires an extra library (e.g. [dump image](#))

LAMMPS Users Manual

- build with a package that requires an extra library
- build with an accelerator package that requires special compiler/linker settings
- run on a machine that has its own compilers, settings, or libraries

then building LAMMPS is more complicated. You may need to find where extra libraries exist on your machine or install them if they don't. You may need to build extra libraries that are included in the LAMMPS distribution, before building LAMMPS itself. You may need to edit a Makefile.machine file to make it compatible with your system.

Please read the following sections carefully. If you are not comfortable with makefiles, or building codes on a Unix platform, or running an MPI job on your machine, please find a local expert to help you. Many compilation, linking, and run problems users experience are often not LAMMPS issues - they are peculiar to the user's system, compilers, libraries, etc. Such questions are better answered by a local expert.

If you have a build problem that you are convinced is a LAMMPS issue (e.g. the compiler complains about a line of LAMMPS source code), then please post the issue to the [LAMMPS mail list](#).

If you succeed in building LAMMPS on a new kind of machine, for which there isn't a similar machine Makefile included in the src/MAKE/MACHINES directory, then send it to the developers and we can include it in the LAMMPS distribution.

Steps to build a LAMMPS executable

Step 0

The src directory contains the C++ source and header files for LAMMPS. It also contains a top-level Makefile and a MAKE sub-directory with low-level Makefile.* files for many systems and machines. See the src/MAKE/README file for a quick overview of what files are available and what sub-directories they are in.

The src/MAKE dir has a few files that should work as-is on many platforms. The src/MAKE/OPTIONS dir has more that invoke additional compiler, MPI, and other setting options commonly used by LAMMPS, to illustrate their syntax. The src/MAKE/MACHINES dir has many more that have been tweaked or optimized for specific machines. These files are all good starting points if you find you need to change them for your machine. Put any file you edit into the src/MAKE/MINE directory and it will be never be touched by any LAMMPS updates.

>From within the src directory, type "make" or "gmake". You should see a list of available choices from src/MAKE and all of its sub-directories. If one of those has the options you want or is the machine you want, you can type a command like:

```
make mpi
```

or

```
make serial
```

LAMMPS Users Manual

or

```
gmake mac
```

Note that the corresponding Makefile.machine can exist in src/MAKE or any of its sub-directories. If a file with the same name appears in multiple places (not a good idea), the order they are used is as follows: src/MAKE/MINE, src/MAKE, src/MAKE/OPTIONS, src/MAKE/MACHINES. This gives preference to a file you have created/edited and put in src/MAKE/MINE.

Note that on a multi-processor or multi-core platform you can launch a parallel make, by using the "-j" switch with the make command, which will build LAMMPS more quickly.

If you get no errors and an executable like **lmp_mpi** or **lmp_serial** or **lmp_mac** is produced, then you're done; it's your lucky day.

Note that by default only a few of LAMMPS optional packages are installed. To build LAMMPS with optional packages, see [this section](#) below.

Step 1

If Step 0 did not work, you will need to create a low-level Makefile for your machine, like Makefile.foo. You should make a copy of an existing Makefile.* in src/MAKE or one of its sub-directories as a starting point. The only portions of the file you need to edit are the first line, the "compiler/linker settings" section, and the "LAMMPS-specific settings" section. When it works, put the edited file in src/MAKE/MINE and it will not be altered by any future LAMMPS updates.

Step 2

Change the first line of Makefile.foo to list the word "foo" after the "#", and whatever other options it will set. This is the line you will see if you just type "make".

Step 3

The "compiler/linker settings" section lists compiler and linker settings for your C++ compiler, including optimization flags. You can use g++, the open-source GNU compiler, which is available on all Unix systems. You can also use mpicxx which will typically be available if MPI is installed on your system, though you should check which actual compiler it wraps. Vendor compilers often produce faster code. On boxes with Intel CPUs, we suggest using the Intel icc compiler, which can be downloaded from [Intel's compiler site](#).

If building a C++ code on your machine requires additional libraries, then you should list them as part of the LIB variable. You should not need to do this if you use mpicxx.

The DEPFLAGS setting is what triggers the C++ compiler to create a dependency list for a source file. This speeds re-compilation when source (*.cpp) or header (*.h) files are edited. Some compilers do not support dependency file creation, or may use a different switch than -D. GNU g++ and Intel icc works with -D. If your compiler can't create dependency files, then you'll need to create a Makefile.foo patterned after

LAMMPS Users Manual

Makefile.storm, which uses different rules that do not involve dependency files. Note that when you build LAMMPS for the first time on a new platform, a long list of *.d files will be printed out rapidly. This is not an error; it is the Makefile doing its normal creation of dependencies.

Step 4

The "system-specific settings" section has several parts. Note that if you change any -D setting in this section, you should do a full re-compile, after typing "make clean" (which will describe different clean options).

The LMP_INC variable is used to include options that turn on ifdefs within the LAMMPS code. The options that are currently recognized are:

- -DLAMMPS_GZIP
- -DLAMMPS_JPEG
- -DLAMMPS_PNG
- -DLAMMPS_FFMPEG
- -DLAMMPS_MEMALIGN
- -DLAMMPS_SMALLBIG
- -DLAMMPS_BIGBIG
- -DLAMMPS_SMALLSMALL
- -DLAMMPS_LONGLONG_TO_LONG
- -DLAMMPS_EXCEPTIONS
- -DPACK_ARRAY
- -DPACK_POINTER
- -DPACK_MEMCPY

The read_data and dump commands will read/write gzipped files if you compile with -DLAMMPS_GZIP. It requires that your machine supports the "popen()" function in the standard runtime library and that a gzip executable can be found by LAMMPS during a run.

NOTE: on some clusters with high-speed networks, using the fork() library calls (required by popen()) can interfere with the fast communication library and lead to simulations using compressed output or input to hang or crash. For selected operations, compressed file I/O is also available using a compression library instead, which are provided in the COMPRESS package. For more details about compiling LAMMPS with packages, please see below.

If you use -DLAMMPS_JPEG, the [dump image](#) command will be able to write out JPEG image files. For JPEG files, you must also link LAMMPS with a JPEG library, as described below. If you use -DLAMMPS_PNG, the [dump image](#) command will be able to write out PNG image files. For PNG files, you must also link LAMMPS with a PNG library, as described below. If neither of those two defines are used, LAMMPS will only be able to write out uncompressed PPM image files.

If you use -DLAMMPS_FFMPEG, the [dump movie](#) command will be available to support on-the-fly generation of rendered movies the need to store intermediate image files. It requires that your machines supports the "popen" function in the standard runtime library and that an FFmpeg executable can be found by LAMMPS during the

LAMMPS Users Manual

run.

NOTE: Similar to the note above, this option can conflict with high-speed networks, because it uses `popen()`.

Using `-DLAMMPS_MEMALIGN=` enables the use of the `posix_memalign()` call instead of `malloc()` when large chunks of memory are allocated by LAMMPS. This can help to make more efficient use of vector instructions of modern CPUs, since dynamically allocated memory has to be aligned on larger than default byte boundaries (e.g. 16 bytes instead of 8 bytes on x86 type platforms) for optimal performance.

Use at most one of the `-DLAMMPS_SMALLBIG`, `-DLAMMPS_BIGBIG`, `-DLAMMPS_SMALLSMALL` settings. The default is `-DLAMMPS_SMALLBIG`. These settings refer to use of 4-byte (small) vs 8-byte (big) integers within LAMMPS, as specified in `src/lmptype.h`. The only reason to use the `BIGBIG` setting is to enable simulation of huge molecular systems (which store bond topology info) with more than 2 billion atoms, or to track the image flags of moving atoms that wrap around a periodic box more than 512 times. Normally, the only reason to use `SMALLSMALL` is if your machine does not support 64-bit integers, though you can use `SMALLSMALL` setting if you are running in serial or on a desktop machine or small cluster where you will never run large systems or for long time (more than 2 billion atoms, more than 2 billion timesteps). See the [Additional build tips](#) section below for more details on these settings.

Note that the USER-ATC package is not currently compatible with `-DLAMMPS_BIGBIG`. Also the GPU package requires the `lib/gpu` library to be compiled with the same setting, or the link will fail.

The `-DLAMMPS_LONGLONG_TO_LONG` setting may be needed if your system or MPI version does not recognize "long long" data types. In this case a "long" data type is likely already 64-bits, in which case this setting will convert to that data type.

The `-DLAMMPS_EXCEPTIONS` setting can be used to activate alternative versions of error handling inside of LAMMPS. This is useful when external codes drive LAMMPS as a library. Using this option, LAMMPS errors do not kill the caller. Instead, the call stack is unwound and control returns to the caller. The library interface provides the `lammops_has_error()` and `lammops_get_last_error_message()` functions to detect and find out more about a LAMMPS error.

Using one of the `-DPACK_ARRAY`, `-DPACK_POINTER`, and `-DPACK_MEMCPY` options can make for faster parallel FFTs (in the PPPM solver) on some platforms. The `-DPACK_ARRAY` setting is the default. See the [k-space style](#) command for info about PPPM. See Step 6 below for info about building LAMMPS with an FFT library.

Step 5

The 3 MPI variables are used to specify an MPI library to build LAMMPS with. Note that you do not need to set these if you use the MPI compiler `mpicxx` for your CC and LINK setting in the section above. The MPI wrapper knows where to find the needed files.

LAMMPS Users Manual

If you want LAMMPS to run in parallel, you must have an MPI library installed on your platform. If MPI is installed on your system in the usual place (under /usr/local), you also may not need to specify these 3 variables, assuming /usr/local is in your path. On some large parallel machines which use "modules" for their compile/link environments, you may simply need to include the correct module in your build environment, before building LAMMPS. Or the parallel machine may have a vendor-provided MPI which the compiler has no trouble finding.

Failing this, these 3 variables can be used to specify where the mpi.h file (MPI_INC) and the MPI library file (MPI_PATH) are found and the name of the library file (MPI_LIB).

If you are installing MPI yourself, we recommend Argonne's MPICH2 or OpenMPI. MPICH can be downloaded from the [Argonne MPI site](#). OpenMPI can be downloaded from the [OpenMPI site](#). Other MPI packages should also work. If you are running on a big parallel platform, your system people or the vendor should have already installed a version of MPI, which is likely to be faster than a self-installed MPICH or OpenMPI, so find out how to build and link with it. If you use MPICH or OpenMPI, you will have to configure and build it for your platform. The MPI configure script should have compiler options to enable you to use the same compiler you are using for the LAMMPS build, which can avoid problems that can arise when linking LAMMPS to the MPI library.

If you just want to run LAMMPS on a single processor, you can use the dummy MPI library provided in src/STUBS, since you don't need a true MPI library installed on your system. See src/MAKE/Makefile.serial for how to specify the 3 MPI variables in this case. You will also need to build the STUBS library for your platform before making LAMMPS itself. Note that if you are building with src/MAKE/Makefile.serial, e.g. by typing "make serial", then the STUBS library is built for you.

To build the STUBS library from the src directory, type "make mpi-stubs", or from the src/STUBS dir, type "make". This should create a libmpi_stubs.a file suitable for linking to LAMMPS. If the build fails, you will need to edit the STUBS/Makefile for your platform.

The file STUBS/mpi.c provides a CPU timer function called MPI_Wtime() that calls gettimeofday() . If your system doesn't support gettimeofday() , you'll need to insert code to call another timer. Note that the ANSI-standard function clock() rolls over after an hour or so, and is therefore insufficient for timing long LAMMPS simulations.

Step 6

The 3 FFT variables allow you to specify an FFT library which LAMMPS uses (for performing 1d FFTs) when running the particle-particle particle-mesh (PPPM) option for long-range Coulombics via the [kspace_style](#) command.

LAMMPS supports common open-source or vendor-supplied FFT libraries for this purpose. If you leave these 3 variables blank, LAMMPS will use the open-source [KISS FFT library](#), which is included in the LAMMPS distribution. This library is portable to all platforms and for typical LAMMPS simulations is almost as fast as FFTW or vendor optimized libraries. If you are not including the KSPACE package in your build, you

LAMMPS Users Manual

can also leave the 3 variables blank.

Otherwise, select which kinds of FFTs to use as part of the `FFT_INC` setting by a switch of the form `-DFFT_XXX`. Recommended values for `XXX` are: `MKL` or `FFTW3`. `FFTW2` and `NONE` are supported as legacy options. Selecting `-DFFT_FFTW` will use the `FFTW3` library and `-DFFT_NONE` will use the `KISS` library described above.

You may also need to set the `FFT_INC`, `FFT_PATH`, and `FFT_LIB` variables, so the compiler and linker can find the needed FFT header and library files. Note that on some large parallel machines which use "modules" for their compile/link environments, you may simply need to include the correct module in your build environment. Or the parallel machine may have a vendor-provided FFT library which the compiler has no trouble finding. See the `src/MAKE/OPTIONS/Makefile.fftw` file for an example of how to specify these variables to use the `FFTW3` library.

`FFTW` is fast, portable library that should also work on any platform and typically be faster than `KISS FFT`. You can download it from www.fftw.org. Both the legacy version 2.1.X and the newer 3.X versions are supported as `-DFFT_FFTW2` or `-DFFT_FFTW3`. Building `FFTW` for your box should be as simple as `./configure; make; make install`. The install command typically requires root privileges (e.g. invoke it via `sudo`), unless you specify a local directory with the `--prefix` option of `configure`. Type `./configure --help` to see various options.

If you wish to have `FFTW` support for single-precision FFTs (see below about `-DFFT_SINGLE`) in addition to the default double-precision FFTs, you will need to build `FFTW` a second time for single-precision. For `FFTW3`, do this via:

```
make clean
./configure --enable-single; make; make install
```

which should produce the additional library `libfftw3f.a`.

For `FFTW2`, do this:

```
make clean
./configure --enable-float --enable-type-prefix; make; make install
```

which should produce the additional library `libsfftw.a` and additional include file `sfftw.a`. Note that on some platforms `FFTW2` has been pre-installed for both single- and double-precision, and may already have these files as well as `libdfft.a` and `dfft.h` for double precision.

The `FFT_INC` variable also allows for a `-DFFT_SINGLE` setting that will use single-precision FFTs with `PPPM`, which can speed-up long-range calculations, particularly in parallel or on GPUs. Fourier transform and related `PPPM` operations are somewhat insensitive to floating point truncation errors and thus do not always need to be performed in double precision. Using the `-DFFT_SINGLE` setting trades off a little accuracy for reduced memory use and parallel communication costs for transposing 3d FFT data. Note that single precision FFTs have only been tested with the `FFTW3`, `FFTW2`, `MKL`, and `KISS FFT` options.

LAMMPS Users Manual

When using `-DFFT_SINGLE` with `FFTW3` or `FFTW2`, you need to build `FFTW` with support for single-precision, as explained above. For `FFTW3` you also need to include `-lfftw3f` with the `FFT_LIB` setting, in addition to `-lfftw3`. For `FFTW2`, you also need to specify `-DFFT_SIZE` with the `FFT_INC` setting and `-lsfftw` with the `FFT_LIB` setting (in place of `-lfftw`). Similarly, if `FFTW2` has been pre-installed with an explicit double-precision library (`libdfft.a` and not the default `libfftw.a`), then you can specify `-DFFT_SIZE` (and not `-DFFT_SINGLE`), and specify `-ldfftw` to use double-precision FFTs.

Step 7

The 3 `JPG` variables allow you to specify a `JPEG` and/or `PNG` library which `LAMMPS` uses when writing out `JPEG` or `PNG` files via the [dump image](#) command. These can be left blank if you do not use the `-DLAMMPS_JPEG` or `-DLAMMPS_PNG` switches discussed above in Step 4, since in that case `JPEG/PNG` output will be disabled.

A standard `JPEG` library usually goes by the name `libjpeg.a` or `libjpeg.so` and has an associated header file `jpeglib.h`. Whichever `JPEG` library you have on your platform, you'll need to set the appropriate `JPG_INC`, `JPG_PATH`, and `JPG_LIB` variables, so that the compiler and linker can find it.

A standard `PNG` library usually goes by the name `libpng.a` or `libpng.so` and has an associated header file `png.h`. Whichever `PNG` library you have on your platform, you'll need to set the appropriate `JPG_INC`, `JPG_PATH`, and `JPG_LIB` variables, so that the compiler and linker can find it.

As before, if these header and library files are in the usual place on your machine, you may not need to set these variables.

Step 8

Note that by default only a few of `LAMMPS` optional packages are installed. To build `LAMMPS` with optional packages, see [this section](#) below, before proceeding to Step 9.

Step 9

That's it. Once you have a correct `Makefile.foo`, and you have pre-built any other needed libraries (e.g. `MPI`, `FFT`, etc) all you need to do from the `src` directory is type something like this:

```
make foo
make -j N foo
gmake foo
gmake -j N foo
```

The `-j` or `-j N` switches perform a parallel build which can be much faster, depending on how many cores your compilation machine has. `N` is the number of cores the build runs on.

You should get the executable `lmp_foo` when the build is complete.

Errors that can occur when making `LAMMPS` :h5

LAMMPS Users Manual

If an error occurs when building LAMMPS, the compiler or linker will state very explicitly what the problem is. The error message should give you a hint as to which of the steps above has failed, and what you need to do in order to fix it. Building a code with a Makefile is a very logical process. The compiler and linker need to find the appropriate files and those files need to be compatible with LAMMPS settings and source files. When a make fails, there is usually a very simple reason, which you or a local expert will need to fix.

Here are two non-obvious errors that can occur:

(1) If the make command breaks immediately with errors that indicate it can't find files with a "*" in their names, this can be because your machine's native make doesn't support wildcard expansion in a makefile. Try gmake instead of make. If that doesn't work, try using a -f switch with your make command to use a pre-generated Makefile.list which explicitly lists all the needed files, e.g.

```
make makelist
make -f Makefile.list linux
gmake -f Makefile.list mac
```

The first "make" command will create a current Makefile.list with all the file names in your src dir. The 2nd "make" command (make or gmake) will use it to build LAMMPS. Note that you should include/exclude any desired optional packages before using the "make makelist" command.

(2) If you get an error that says something like 'identifier "atoll" is undefined', then your machine does not support "long long" integers. Try using the -DLAMMPS_LONGLONG_TO_LONG setting described above in Step 4.

Additional build tips

Building LAMMPS for multiple platforms.

You can make LAMMPS for multiple platforms from the same src directory. Each target creates its own object sub-directory called Obj_target where it stores the system-specific *.o files.

Cleaning up.

Typing "make clean-all" or "make clean-machine" will delete *.o object files created when LAMMPS is built, for either all builds or for a particular machine.

Changing the LAMMPS size limits via -DLAMMPS_SMALLBIG or -DLAMMPS_BIGBIG or -DLAMMPS_SMALLSMALL

As explained above, any of these 3 settings can be specified on the LMP_INC line in your low-level src/MAKE/Makefile.foo.

The default is -DLAMMPS_SMALLBIG which allows for systems with up to 2^{63} atoms and 2^{63} timesteps (about $9e18$). The atom limit is for atomic systems which do not store bond topology info and thus do not require atom IDs. If you use atom IDs for atomic systems (which is the default) or if you use a molecular model, which stores bond topology info and thus requires atom IDs, the limit is 2^{31} atoms (about 2

LAMMPS Users Manual

billion). This is because the IDs are stored in 32-bit integers.

Likewise, with this setting, the 3 image flags for each atom (see the [dump](#) doc page for a discussion) are stored in a 32-bit integer, which means the atoms can only wrap around a periodic box (in each dimension) at most 512 times. If atoms move through the periodic box more than this many times, the image flags will "roll over", e.g. from 511 to -512, which can cause diagnostics like the mean-squared displacement, as calculated by the [compute msd](#) command, to be faulty.

To allow for larger atomic systems with atom IDs or larger molecular systems or larger image flags, compile with `-DLAMMPS_BIGBIG`. This stores atom IDs and image flags in 64-bit integers. This enables atomic or molecular systems with atom IDs of up to 2^{63} atoms (about $9e18$). And image flags will not "roll over" until they reach $2^{20} = 1048576$.

If your system does not support 8-byte integers, you will need to compile with the `-DLAMMPS_SMALLSMALL` setting. This will restrict the total number of atoms (for atomic or molecular systems) and timesteps to 2^{31} (about 2 billion). Image flags will roll over at $2^9 = 512$.

Note that in `src/lmptype.h` there are definitions of all these data types as well as the MPI data types associated with them. The MPI types need to be consistent with the associated C data types, or else LAMMPS will generate a run-time error. As far as we know, the settings defined in `src/lmptype.h` are portable and work on every current system.

In all cases, the size of problem that can be run on a per-processor basis is limited by 4-byte integer storage to 2^{31} atoms per processor (about 2 billion). This should not normally be a limitation since such a problem would have a huge per-processor memory footprint due to neighbor lists and would run very slowly in terms of CPU secs/timestep.

Building for a Mac

OS X is a derivative of BSD Unix, so it should just work. See the `src/MAKE/MACHINES/Makefile.mac` and `Makefile.mac_mpi` files.

Building for Windows

If you want to build a Windows version of LAMMPS, you can build it yourself, but it may require some effort. LAMMPS expects a Unix-like build environment for the default build procedure. This can be done using either Cygwin or MinGW; the latter also exists as a ready-to-use Linux-to-Windows cross-compiler in several Linux distributions. In these cases, you can do the installation after installing several unix-style commands like `make`, `grep`, `sed` and `bash` with some shell utilities.

For Cygwin and the MinGW cross-compilers, suitable makefiles are provided in `src/MAKE/MACHINES`. When using other compilers, like Visual C++ or Intel compilers for Windows, you may have to implement your own build system. Due to differences between the Windows OS and Windows system libraries to Unix-like environments like Linux or MacOS, when compiling for Windows a few adjustments

LAMMPS Users Manual

may be needed:

- Do **not** set the `-DLAMMPS_MEMALIGN` define (see `LMP_INC` makefile variable)
- Add `-lwsock32 -lpsapi` to the linker flags (see `LIB` makefile variable)
- Try adding `-static-libgcc` or `-static` or both to the linker flags when your LAMMPS executable complains about missing `.dll` files

Since none of the current LAMMPS core developers has significant experience building executables on Windows, we are happy to distribute contributed instructions and modifications to improve the situation, but we cannot provide support for those.

With the so-called "Anniversary Update" to Windows 10, there is a Ubuntu Linux subsystem available for Windows, that can be installed and then used to compile/install LAMMPS as if you are running on a Ubuntu Linux system instead of Windows.

As an alternative, you can download pre-compiled installer packages from packages.lammps.org/windows.html. These executables are built with most optional packages included and the download includes documentation, potential files, some tools and many examples, but no source code.

2.3 Making LAMMPS with optional packages

This section has the following sub-sections:

- 2.3.1 [Package basics](#)
- 2.3.2 [Including/excluding packages](#)
- 2.3.3 [Packages that require extra libraries](#)

Package basics:

The source code for LAMMPS is structured as a set of core files which are always included, plus optional packages. Packages are groups of files that enable a specific set of features. For example, force fields for molecular systems or granular systems are in packages.

[Section 4](#) in the manual has details about all the packages, which come in two flavors: **standard** and **user** packages. It also has specific instructions for building LAMMPS with any package which requires an extra library. General instructions are below.

You can see the list of all packages by typing "make package" from within the `src` directory of the LAMMPS distribution. It will also list various make commands that can be used to manage packages.

If you use a command in a LAMMPS input script that is part of a package, you must have built LAMMPS with that package, else you will get an error that the style is invalid or the command is unknown. Every command's doc page specifies if it is part of a package. You can type

```
lmp_machine -h
```

LAMMPS Users Manual

to run your executable with the optional `-h` [command-line switch](#) for "help", which will list the styles and commands known to your executable, and immediately exit.

Including/excluding packages

To use (or not use) a package you must install it (or un-install it) before building LAMMPS. From the src directory, this is as simple as:

```
make yes-colloid
make mpi
```

or

```
make no-user-omp
make mpi
```

NOTE: You should NOT install/un-install packages and build LAMMPS in a single make command using multiple targets, e.g. `make yes-colloid mpi`. This is because the make procedure creates a list of source files that will be out-of-date for the build if the package configuration changes within the same command.

Any package can be installed or not in a LAMMPS build, independent of all other packages. However, some packages include files derived from files in other packages. LAMMPS checks for this and does the right thing. I.e. individual files are only included if their dependencies are already included. Likewise, if a package is excluded, other files dependent on that package are also excluded.

NOTE: The one exception is that we do not recommend building with both the KOKKOS package installed and any of the other acceleration packages (GPU, OPT, USER-INTEL, USER-OMP) also installed. This is because of how Kokkos sometimes builds using a wrapper compiler which can make it difficult to invoke all the compile/link flags correctly for both Kokkos and non-Kokkos files.

If you will never run simulations that use the features in a particular packages, there is no reason to include it in your build. For some packages, this will keep you from having to build extra libraries, and will also produce a smaller executable which may run a bit faster.

When you download a LAMMPS tarball, three packages are pre-installed in the src directory -- KSPACE, MANYBODY, MOLECULE -- because they are so commonly used. When you download LAMMPS source files from the SVN or Git repositories, no packages are pre-installed.

Packages are installed or un-installed by typing

```
make yes-name
make no-name
```

where "name" is the name of the package in lower-case, e.g. `name = kspace` for the KSPACE package or `name = user-atc` for the USER-ATC package. You can also type any of these commands:

LAMMPS Users Manual

make yes-all	install all packages
make no-all	un-install all packages
make yes-standard or make yes-std	install standard packages
make no-standard or make no-std	un-install standard packages
make yes-user	install user packages
make no-user	un-install user packages
make yes-lib	install packages that require extra libraries
make no-lib	un-install packages that require extra libraries
make yes-ext	install packages that require external libraries
make no-ext	un-install packages that require external libraries

which install/un-install various sets of packages. Typing "make package" will list all the these commands.

NOTE: Installing or un-installing a package works by simply moving files back and forth between the main src directory and sub-directories with the package name (e.g. src/KSPACE, src/USER-ATC), so that the files are included or excluded when LAMMPS is built. After you have installed or un-installed a package, you must re-build LAMMPS for the action to take effect.

The following make commands help manage files that exist in both the src directory and in package sub-directories. You do not normally need to use these commands unless you are editing LAMMPS files or have downloaded a patch from the LAMMPS web site.

Typing "make package-status" or "make ps" will show which packages are currently installed. For those that are installed, it will list any files that are different in the src directory and package sub-directory.

Typing "make package-installed" or "make pi" will list which packages are currently installed, without listing the status of packages that are not installed.

Typing "make package-update" or "make pu" will overwrite src files with files from the package sub-directories if the package is installed. It should be used after a patch has been applied, since patches only update the files in the package sub-directory, but not the src files.

Typing "make package-overwrite" will overwrite files in the package sub-directories with src files.

Typing "make package-diff" lists all differences between these files.

Again, just type "make package" to see all of the package-related make options.

Packages that require extra libraries

A few of the standard and user packages require extra libraries. See [Section 4](#) for two tables of packages which indicate which ones require libraries. For each such package, the Section 4 doc page gives details on how to build the extra library, including how to download it if necessary. The basic ideas are summarized here.

LAMMPS Users Manual

System libraries:

Packages in the tables [Section 4](#) with a "sys" in the last column link to system libraries that typically already exist on your machine. E.g. the python package links to a system Python library. If your machine does not have the required library, you will have to download and install it on your machine, in either the system or user space.

Internal libraries:

Packages in the tables [Section 4](#) with an "int" in the last column link to internal libraries whose source code is included with LAMMPS, in the lib/name directory where name is the package name. You must first build the library in that directory before building LAMMPS with that package installed. E.g. the gpu package links to a library you build in the lib/gpu dir. You can often do the build in one step by typing "make lib-name args=..." from the src dir, with appropriate arguments. You can leave off the args to see a help message. See [Section 4](#) for details for each package.

External libraries:

Packages in the tables [Section 4](#) with an "ext" in the last column link to external libraries whose source code is not included with LAMMPS. You must first download and install the library before building LAMMPS with that package installed. E.g. the voronoi package links to the freely available [Voro++ library](#). You can often do the download/build in one step by typing "make lib-name args=..." from the src dir, with appropriate arguments. You can leave off the args to see a help message. See [Section 4](#) for details for each package.

Possible errors:

There are various common errors which can occur when building extra libraries or when building LAMMPS with packages that require the extra libraries.

If you cannot build the extra library itself successfully, you may need to edit or create an appropriate Makefile for your machine, e.g. with appropriate compiler or system settings. Provided makefiles are typically in the lib/name directory. E.g. see the Makefile.* files in lib/gpu.

The LAMMPS build often uses settings in a lib/name/Makefile.lammps file which either exists in the LAMMPS distribution or is created or copied from a lib/name/Makefile.lammps.* file when the library is built. If those settings are not correct for your machine you will need to edit or create an appropriate Makefile.lammps file.

Package-specific details for these steps are given in [Section 4](#) and in README files in the lib/name directories.

Compiler options needed for accelerator packages:

Several packages contain code that is optimized for specific hardware, e.g. CPU, KNL, or GPU. These are the OPT, GPU, KOKKOS, USER-INTEL, and USER-OMP packages. Compiling and linking the source files in these accelerator packages for optimal

LAMMPS Users Manual

performance requires specific settings in the Makefile.machine file you use.

A summary of the Makefile.machine settings needed for each of these packages is given in [Section 4](#). More info is given on the doc pages that describe each package in detail:

5.3.1 [USER-INTEL package](#)

5.3.2 [GPU package](#)

5.3.3 [KOKKOS package](#)

5.3.4 [USER-OMP package](#)

5.3.5 [OPT package](#)

You can also use or examine the following machine Makefiles in src/MAKE/OPTIONS, which include the settings. Note that the USER-INTEL and KOKKOS packages can use settings that build LAMMPS for different hardware. The USER-INTEL package can be compiled for Intel CPUs and KNLs; the KOKKOS package builds for CPUs (OpenMP), GPUs (CUDA), and Intel KNLs.

- Makefile.intel_cpu
- Makefile.intel_phi
- Makefile.kokkos_omp
- Makefile.kokkos_cuda_mpi
- Makefile.kokkos_phi
- Makefile.omp
- Makefile.opt

2.4 Building LAMMPS as a library

LAMMPS can be built as either a static or shared library, which can then be called from another application or a scripting language. See [this section](#) for more info on coupling LAMMPS to other codes. See [this section](#) for more info on wrapping and running LAMMPS from Python.

Static library

To build LAMMPS as a static library (*.a file on Linux), type

```
make foo mode=lib
```

where foo is the machine name. This kind of library is typically used to statically link a driver application to LAMMPS, so that you can insure all dependencies are satisfied at compile time. This will use the ARCHIVE and ARFLAGS settings in src/MAKE/Makefile.foo. The build will create the file liblammps_foo.a which another application can link to. It will also create a soft link liblammps.a, which will point to the most recently built static library.

Shared library

To build LAMMPS as a shared library (*.so file on Linux), which can be dynamically loaded, e.g. from Python, type

LAMMPS Users Manual

```
make foo mode=shlib
```

where foo is the machine name. This kind of library is required when wrapping LAMMPS with Python; see [Section 11](#) for details. This will use the SHFLAGS and SHLIBFLAGS settings in src/MAKE/Makefile.foo and perform the build in the directory Obj_shared_foo. This is so that each file can be compiled with the -fPIC flag which is required for inclusion in a shared library. The build will create the file liblammeps_foo.so which another application can link to dynamically. It will also create a soft link liblammeps.so, which will point to the most recently built shared library. This is the file the Python wrapper loads by default.

Note that for a shared library to be usable by a calling program, all the auxiliary libraries it depends on must also exist as shared libraries. This will be the case for libraries included with LAMMPS, such as the dummy MPI library in src/STUBS or any package libraries in lib/packages, since they are always built as shared libraries using the -fPIC switch. However, if a library like MPI or FFTW does not exist as a shared library, the shared library build will generate an error. This means you will need to install a shared library version of the auxiliary library. The build instructions for the library should tell you how to do this.

Here is an example of such errors when the system FFTW or provided lib/colvars library have not been built as shared libraries:

```
/usr/bin/ld: /usr/local/lib/libfftw3.a(mapflags.o): relocation
R_X86_64_32 against '.rodata' can not be used when making a shared
object; recompile with -fPIC
/usr/local/lib/libfftw3.a: could not read symbols: Bad value

/usr/bin/ld: ../../lib/colvars/libcolvars.a(colvarmodule.o):
relocation R_X86_64_32 against '__pthread_key_create' can not be used
when making a shared object; recompile with -fPIC
../../lib/colvars/libcolvars.a: error adding symbols: Bad value
```

As an example, here is how to build and install the [MPICH library](#), a popular open-source version of MPI, distributed by Argonne National Labs, as a shared library in the default /usr/local/lib location:

```
./configure --enable-shared
make
make install
```

You may need to use "sudo make install" in place of the last line if you do not have write privileges for /usr/local/lib. The end result should be the file /usr/local/lib/libmpich.so.

Additional requirement for using a shared library:

The operating system finds shared libraries to load at run-time using the environment variable LD_LIBRARY_PATH. So you may wish to copy the file src/liblammeps.so or src/liblammeps_g++.so (for example) to a place the system can find it by default, such as /usr/local/lib, or you may wish to add the LAMMPS src directory to LD_LIBRARY_PATH, so that the current version of the shared library is always available to programs that use it.

LAMMPS Users Manual

For the csh or tcsh shells, you would add something like this to your ~/.cshrc file:

```
setenv LD_LIBRARY_PATH ${LD_LIBRARY_PATH}:/home/sjplimp/lammps/src
```

Calling the LAMMPS library

Either flavor of library (static or shared) allows one or more LAMMPS objects to be instantiated from the calling program.

When used from a C++ program, all of LAMMPS is wrapped in a LAMMPS_NS namespace; you can safely use any of its classes and methods from within the calling code, as needed.

When used from a C or Fortran program or a scripting language like Python, the library has a simple function-style interface, provided in src/library.cpp and src/library.h.

See the sample codes in examples/COUPLE/simple for examples of C++ and C and Fortran codes that invoke LAMMPS thru its library interface. There are other examples as well in the COUPLE directory which are discussed in [Section 6.10](#) of the manual. See [Section 11](#) of the manual for a description of the Python wrapper provided with LAMMPS that operates through the LAMMPS library interface.

The files src/library.cpp and library.h define the C-style API for using LAMMPS as a library. See [Section 6.19](#) of the manual for a description of the interface and how to extend it for your needs.

2.5 Running LAMMPS

By default, LAMMPS runs by reading commands from standard input. Thus if you run the LAMMPS executable by itself, e.g.

```
lmp_linux
```

it will simply wait, expecting commands from the keyboard. Typically you should put commands in an input script and use I/O redirection, e.g.

```
lmp_linux <in.file
```

For parallel environments this should also work. If it does not, use the '-in' command-line switch, e.g.

```
lmp_linux -in in.file
```

[This section](#) describes how input scripts are structured and what commands they contain.

You can test LAMMPS on any of the sample inputs provided in the examples or bench directory. Input scripts are named in.* and sample outputs are named log.*.name.P where name is a machine and P is the number of processors it was run on.

LAMMPS Users Manual

Here is how you might run a standard Lennard-Jones benchmark on a Linux box, using `mpirun` to launch a parallel job:

```
cd src
make linux
cp lmp_linux ../bench
cd ../bench
mpirun -np 4 lmp_linux -in in.lj
```

See [this page](#) for timings for this and the other benchmarks on various platforms. Note that some of the example scripts require LAMMPS to be built with one or more of its optional packages.

On a Windows box, you can skip making LAMMPS and simply download an installer package from [here](#)

For running the non-MPI executable, follow these steps:

- Get a command prompt by going to Start->Run... , then typing "cmd".
- Move to the directory where you have your input, e.g. a copy of the **in.lj** input from the bench folder. (e.g. by typing: `cd "Documents"`).
- At the command prompt, type "`lmp_serial -in in.lj`", replacing **in.lj** with the name of your LAMMPS input script.

The serial executable includes support for multi-threading parallelization from the styles in the USER-OMP packages.

To run with, e.g. 4 threads, type "`lmp_serial -in in.lj -pk omp 4 -sf omp`"

For the MPI version, which allows you to run LAMMPS under Windows with the more general message passing parallel library (LAMMPS has been designed from ground up to use MPI efficiently), follow these steps:

- Download and install a compatible MPI library binary package: for 32-bit Windows [mpich2-1.4.1p1-win-ia32.msi](#) and for 64-bit Windows [mpich2-1.4.1p1-win-x86-64.msi](#)

The LAMMPS Windows installer packages will automatically adjust your path for the default location of this MPI package. After the installation of the MPICH2 software, it needs to be integrated into the system. For this you need to start a Command Prompt in *Administrator Mode* (right click on the icon and select it). Change into the MPICH2 installation directory, then into the subdirectory **bin** and execute **smpd.exe -install**. Exit the command window.

- Get a new, regular command prompt by going to Start->Run... , then typing "cmd".
- Move to the directory where you have your input file (e.g. by typing: `cd "Documents"`).

Then type something like this:

```
mpiexec -localonly 4 lmp_mpi -in in.lj
```

LAMMPS Users Manual

or

```
mpiexec -np 4 lmp_mpi -in in.lj
```

- replacing **in.lj** with the name of your LAMMPS input script. For the latter case, you may be prompted to enter your password.
- In this mode, output may not immediately show up on the screen, so if your input script takes a long time to execute, you may need to be patient before the output shows up.

The parallel executable can also run on a single processor by typing something like:

```
lmp_mpi -in in.lj
```

And the parallel executable also includes OpenMP multi-threading, which can be combined with MPI using something like:

```
mpiexec -localonly 2 lmp_mpi -in in.lj -pk omp 2 -sf omp
```

The screen output from LAMMPS is described in a section below. As it runs, LAMMPS also writes a log.lammps file with the same information.

Note that this sequence of commands copies the LAMMPS executable (`lmp_linux`) to the directory with the input files. This may not be necessary, but some versions of MPI reset the working directory to where the executable is, rather than leave it as the directory where you launch `mpirun` from (if you launch `lmp_linux` on its own and not under `mpirun`). If that happens, LAMMPS will look for additional input files and write its output files to the executable directory, rather than your working directory, which is probably not what you want.

If LAMMPS encounters errors in the input script or while running a simulation it will print an ERROR message and stop or a WARNING message and continue. See [Section 12](#) for a discussion of the various kinds of errors LAMMPS can or can't detect, a list of all ERROR and WARNING messages, and what to do about them.

LAMMPS can run a problem on any number of processors, including a single processor. In theory you should get identical answers on any number of processors and on any machine. In practice, numerical round-off can cause slight differences and eventual divergence of molecular dynamics phase space trajectories.

LAMMPS can run as large a problem as will fit in the physical memory of one or more processors. If you run out of memory, you must run on more processors or setup a smaller problem.

2.6 Command-line options

At run time, LAMMPS recognizes several optional command-line switches which may be used in any order. Either the full word or a one-or-two letter abbreviation can be used:

- `-e` or `-echo`

LAMMPS Users Manual

- -h or -help
- -i or -in
- -k or -kokkos
- -l or -log
- -nc or -nocite
- -pk or -package
- -p or -partition
- -pl or -plog
- -ps or -pscreen
- -r or -restart
- -ro or -reorder
- -sc or -screen
- -sf or -suffix
- -v or -var

For example, `lmp_ibm` might be launched as follows:

```
mpirun -np 16 lmp_ibm -v f tmp.out -l my.log -sc none -in in.alloy
mpirun -np 16 lmp_ibm -var f tmp.out -log my.log -screen none -in in.alloy
```

Here are the details on the options:

-echo style

Set the style of command echoing. The style can be *none* or *screen* or *log* or *both*. Depending on the style, each command read from the input script will be echoed to the screen and/or logfile. This can be useful to figure out which line of your script is causing an input error. The default value is *log*. The echo style can also be set by using the `echo` command in the input script itself.

-help

Print a brief help summary and a list of options compiled into this executable for each LAMMPS style (`atom_style`, `fix`, `compute`, `pair_style`, `bond_style`, etc). This can tell you if the command you want to use was included via the appropriate package at compile time. LAMMPS will print the info and immediately exit if this switch is used.

-in file

Specify a file to use as an input script. This is an optional switch when running LAMMPS in one-partition mode. If it is not specified, LAMMPS reads its script from standard input, typically from a script via I/O redirection; e.g. `lmp_linux < in.run`. I/O redirection should also work in parallel, but if it does not (in the unlikely case that an MPI implementation does not support it), then use the `-in` flag. Note that this is a required switch when running LAMMPS in multi-partition mode, since multiple processors cannot all read from `stdin`.

-kokkos on/off keyword/value ...

Explicitly enable or disable KOKKOS support, as provided by the KOKKOS package. Even if LAMMPS is built with this package, as described above in [Section 2.3](#), this switch must be set to enable running with the KOKKOS-enabled styles the package

LAMMPS Users Manual

provides. If the switch is not set (the default), LAMMPS will operate as if the KOKKOS package were not installed; i.e. you can run standard LAMMPS or with the GPU or USER-OMP packages, for testing or benchmarking purposes.

Additional optional keyword/value pairs can be specified which determine how Kokkos will use the underlying hardware on your platform. These settings apply to each MPI task you launch via the "mpirun" or "mpiexec" command. You may choose to run one or more MPI tasks per physical node. Note that if you are running on a desktop machine, you typically have one physical node. On a cluster or supercomputer there may be dozens or 1000s of physical nodes.

Either the full word or an abbreviation can be used for the keywords. Note that the keywords do not use a leading minus sign. I.e. the keyword is "t", not "-t". Also note that each of the keywords has a default setting. Example of when to use these options and what settings to use on different platforms is given in [Section 5.3](#).

- d or device
- g or gpus
- t or threads
- n or numa

device Nd

This option is only relevant if you built LAMMPS with CUDA=yes, you have more than one GPU per node, and if you are running with only one MPI task per node. The Nd setting is the ID of the GPU on the node to run on. By default Nd = 0. If you have multiple GPUs per node, they have consecutive IDs numbered as 0,1,2,etc. This setting allows you to launch multiple independent jobs on the node, each with a single MPI task per node, and assign each job to run on a different GPU.

gpus Ng Ns

This option is only relevant if you built LAMMPS with CUDA=yes, you have more than one GPU per node, and you are running with multiple MPI tasks per node (up to one per GPU). The Ng setting is how many GPUs you will use. The Ns setting is optional. If set, it is the ID of a GPU to skip when assigning MPI tasks to GPUs. This may be useful if your desktop system reserves one GPU to drive the screen and the rest are intended for computational work like running LAMMPS. By default Ng = 1 and Ns is not set.

Depending on which flavor of MPI you are running, LAMMPS will look for one of these 3 environment variables

```
SLURM_LOCALID (various MPI variants compiled with SLURM support)
MV2_COMM_WORLD_LOCAL_RANK (Mvapich)
OMPI_COMM_WORLD_LOCAL_RANK (OpenMPI)
```

which are initialized by the "srun", "mpirun" or "mpiexec" commands. The environment variable setting for each MPI rank is used to assign a unique GPU ID to the MPI task.

threads Nt

LAMMPS Users Manual

This option assigns N_t number of threads to each MPI task for performing work when Kokkos is executing in OpenMP or pthreads mode. The default is $N_t = 1$, which essentially runs in MPI-only mode. If there are N_p MPI tasks per physical node, you generally want $N_p * N_t =$ the number of physical cores per node, to use your available hardware optimally. This also sets the number of threads used by the host when LAMMPS is compiled with `CUDA=yes`.

`numa Nm`

This option is only relevant when using pthreads with hwloc support. In this case N_m defines the number of NUMA regions (typically sockets) on a node which will be utilized by a single MPI rank. By default $N_m = 1$. If this option is used the total number of worker-threads per MPI rank is $\text{threads} * \text{numa}$. Currently it is always almost better to assign at least one MPI rank per NUMA region, and leave `numa` set to its default value of 1. This is because letting a single process span multiple NUMA regions induces a significant amount of cross NUMA data traffic which is slow.

`-log file`

Specify a log file for LAMMPS to write status information to. In one-partition mode, if the switch is not used, LAMMPS writes to the file `log.lammps`. If this switch is used, LAMMPS writes to the specified file. In multi-partition mode, if the switch is not used, a `log.lammps` file is created with hi-level status information. Each partition also writes to a `log.lammps.N` file where N is the partition ID. If the switch is specified in multi-partition mode, the hi-level logfile is named "file" and each partition also logs information to a `file.N`. For both one-partition and multi-partition mode, if the specified file is "none", then no log files are created. Using a [log](#) command in the input script will override this setting. Option `-plog` will override the name of the partition log files `file.N`.

`-nocite`

Disable writing the `log.cite` file which is normally written to list references for specific cite-able features used during a LAMMPS run. See the [citation page](#) for more details.

`-package style args`

Invoke the [package](#) command with `style` and `args`. The syntax is the same as if the command appeared at the top of the input script. For example `"-package gpu 2"` or `"-pk gpu 2"` is the same as [package gpu 2](#) in the input script. The possible styles and args are documented on the [package](#) doc page. This switch can be used multiple times, e.g. to set options for the USER-INTEL and USER-OMP packages which can be used together.

Along with the `"-suffix"` command-line switch, this is a convenient mechanism for invoking accelerator packages and their options without having to edit an input script.

`-partition 8x2 4 5 ...`

Invoke LAMMPS in multi-partition mode. When LAMMPS is run on P processors and this switch is not used, LAMMPS runs in one partition, i.e. all P processors run a single simulation. If this switch is used, the P processors are split into separate

LAMMPS Users Manual

partitions and each partition runs its own simulation. The arguments to the switch specify the number of processors in each partition. Arguments of the form $M \times N$ mean M partitions, each with N processors. Arguments of the form N mean a single partition with N processors. The sum of processors in all partitions must equal P . Thus the command "-partition 8x2 4 5" has 10 partitions and runs on a total of 25 processors.

Running with multiple partitions can be useful for running [multi-replica simulations](#), where each replica runs on one or a few processors. Note that with MPI installed on a machine (e.g. your desktop), you can run on more (virtual) processors than you have physical processors.

To run multiple independent simulations from one input script, using multiple partitions, see [Section 6.4](#) of the manual. World- and universe-style [variables](#) are useful in this context.

-plog file

Specify the base name for the partition log files, so partition N writes log information to file. N . If file is none, then no partition log files are created. This overrides the filename specified in the -log command-line option. This option is useful when working with large numbers of partitions, allowing the partition log files to be suppressed (-plog none) or placed in a sub-directory (-plog replica_files/log.lammps) If this option is not used the log file for partition N is log.lammps. N or whatever is specified by the -log command-line option.

-pscreen file

Specify the base name for the partition screen file, so partition N writes screen information to file. N . If file is none, then no partition screen files are created. This overrides the filename specified in the -screen command-line option. This option is useful when working with large numbers of partitions, allowing the partition screen files to be suppressed (-pscreen none) or placed in a sub-directory (-pscreen replica_files/screen). If this option is not used the screen file for partition N is screen. N or whatever is specified by the -screen command-line option.

-restart restartfile *remap* datafile keyword value ...

Convert the restart file into a data file and immediately exit. This is the same operation as if the following 2-line input script were run:

```
read_restart restartfile remap
write_data datafile keyword value ...
```

Note that the specified restartfile and datafile can have wild-card characters ("*", "%") as described by the [read_restart](#) and [write_data](#) commands. But a filename such as file.* will need to be enclosed in quotes to avoid shell expansion of the "*" character.

Note that following restartfile, the optional flag *remap* can be used. This has the same effect as adding it to the [read_restart](#) command, as explained on its doc page. This is only useful if the reading of the restart file triggers an error that atoms have been lost. In that case, use of the remap flag should allow the data file to still be produced.

LAMMPS Users Manual

Also note that following datafile, the same optional keyword/value pairs can be listed as used by the [write_data](#) command.

```
-reorder nth N
-reorder custom filename
```

Reorder the processors in the MPI communicator used to instantiate LAMMPS, in one of several ways. The original MPI communicator ranks all P processors from 0 to P-1. The mapping of these ranks to physical processors is done by MPI before LAMMPS begins. It may be useful in some cases to alter the rank order. E.g. to insure that cores within each node are ranked in a desired order. Or when using the [run_style verlet/split](#) command with 2 partitions to insure that a specific Kspace processor (in the 2nd partition) is matched up with a specific set of processors in the 1st partition. See the [Section 5](#) doc pages for more details.

If the keyword *nth* is used with a setting *N*, then it means every Nth processor will be moved to the end of the ranking. This is useful when using the [run_style verlet/split](#) command with 2 partitions via the `-partition` command-line switch. The first set of processors will be in the first partition, the 2nd set in the 2nd partition. The `-reorder` command-line switch can alter this so that the 1st N procs in the 1st partition and one proc in the 2nd partition will be ordered consecutively, e.g. as the cores on one physical node. This can boost performance. For example, if you use `"-reorder nth 4"` and `"-partition 9 3"` and you are running on 12 processors, the processors will be reordered from

```
0 1 2 3 4 5 6 7 8 9 10 11
```

to

```
0 1 2 4 5 6 8 9 10 3 7 11
```

so that the processors in each partition will be

```
0 1 2 4 5 6 8 9 10
3 7 11
```

See the "processors" command for how to insure processors from each partition could then be grouped optimally for quad-core nodes.

If the keyword is *custom*, then a file that specifies a permutation of the processor ranks is also specified. The format of the reorder file is as follows. Any number of initial blank or comment lines (starting with a "#" character) can be present. These should be followed by P lines of the form:

```
I J
```

where P is the number of processors LAMMPS was launched with. Note that if running in multi-partition mode (see the `-partition` switch above) P is the total number of processors in all partitions. The I and J values describe a permutation of the P processors. Every I and J should be values from 0 to P-1 inclusive. In the set of P I values, every proc ID should appear exactly once. Ditto for the set of P J values. A single I,J pairing means that the physical processor with rank I in the original MPI

LAMMPS Users Manual

communicator will have rank J in the reordered communicator.

Note that rank ordering can also be specified by many MPI implementations, either by environment variables that specify how to order physical processors, or by config files that specify what physical processors to assign to each MPI rank. The `-reorder` switch simply gives you a portable way to do this without relying on MPI itself. See the [processors out](#) command for how to output info on the final assignment of physical processors to the LAMMPS simulation domain.

`-screen file`

Specify a file for LAMMPS to write its screen information to. In one-partition mode, if the switch is not used, LAMMPS writes to the screen. If this switch is used, LAMMPS writes to the specified file instead and you will see no screen output. In multi-partition mode, if the switch is not used, hi-level status information is written to the screen. Each partition also writes to a screen.N file where N is the partition ID. If the switch is specified in multi-partition mode, the hi-level screen dump is named "file" and each partition also writes screen information to a file.N. For both one-partition and multi-partition mode, if the specified file is "none", then no screen output is performed. Option `-pscreen` will override the name of the partition screen files file.N.

`-suffix style args`

Use variants of various styles if they exist. The specified style can be *cuda*, *gpu*, *intel*, *kk*, *omp*, *opt*, or *hybrid*. These refer to optional packages that LAMMPS can be built with, as described above in [Section 2.3](#). The "gpu" style corresponds to the GPU package, the "intel" style to the USER-INTEL package, the "kk" style to the KOKKOS package, the "opt" style to the OPT package, and the "omp" style to the USER-OMP package. The hybrid style is the only style that accepts arguments. It allows for two packages to be specified. The first package specified is the default and will be used if it is available. If no style is available for the first package, the style for the second package will be used if available. For example, `-suffix hybrid intel omp` will use styles from the USER-INTEL package if they are installed and available, but styles for the USER-OMP package otherwise.

Along with the `-package` command-line switch, this is a convenient mechanism for invoking accelerator packages and their options without having to edit an input script.

As an example, all of the packages provide a [pair_style lj/cut](#) variant, with style names `lj/cut/gpu`, `lj/cut/intel`, `lj/cut/kk`, `lj/cut/omp`, and `lj/cut/opt`. A variant style can be specified explicitly in your input script, e.g. `pair_style lj/cut/gpu`. If the `-suffix` switch is used the specified suffix (`gpu,intel,kk,omp,opt`) is automatically appended whenever your input script command creates a new [atom](#), [pair](#), [fix](#), [compute](#), or [run](#) style. If the variant version does not exist, the standard version is created.

For the GPU package, using this command-line switch also invokes the default GPU settings, as if the command `package gpu 1` were used at the top of your input script. These settings can be changed by using the `-package gpu` command-line switch or the [package gpu](#) command in your script.

LAMMPS Users Manual

For the USER-INTEL package, using this command-line switch also invokes the default USER-INTEL settings, as if the command "package intel 1" were used at the top of your input script. These settings can be changed by using the "-package intel" command-line switch or the [package intel](#) command in your script. If the USER-OMP package is also installed, the hybrid style with "intel omp" arguments can be used to make the omp suffix a second choice, if a requested style is not available in the USER-INTEL package. It will also invoke the default USER-OMP settings, as if the command "package omp 0" were used at the top of your input script. These settings can be changed by using the "-package omp" command-line switch or the [package omp](#) command in your script.

For the KOKKOS package, using this command-line switch also invokes the default KOKKOS settings, as if the command "package kokkos" were used at the top of your input script. These settings can be changed by using the "-package kokkos" command-line switch or the [package kokkos](#) command in your script.

For the OMP package, using this command-line switch also invokes the default OMP settings, as if the command "package omp 0" were used at the top of your input script. These settings can be changed by using the "-package omp" command-line switch or the [package omp](#) command in your script.

The [suffix](#) command can also be used within an input script to set a suffix, or to turn off or back on any suffix setting made via the command line.

```
-var name value1 value2 ...
```

Specify a variable that will be defined for substitution purposes when the input script is read. This switch can be used multiple times to define multiple variables. "Name" is the variable name which can be a single character (referenced as \$x in the input script) or a full string (referenced as \${abc}). An [index-style variable](#) will be created and populated with the subsequent values, e.g. a set of filenames. Using this command-line option is equivalent to putting the line "variable name index value1 value2 ..." at the beginning of the input script. Defining an index variable as a command-line argument overrides any setting for the same index variable in the input script, since index variables cannot be re-defined. See the [variable](#) command for more info on defining index and other kinds of variables and [this section](#) for more info on using variables in input scripts.

NOTE: Currently, the command-line parser looks for arguments that start with "-" to indicate new switches. Thus you cannot specify multiple variable values if any of them start with a "-", e.g. a negative numeric value. It is OK if the first value1 starts with a "-", since it is automatically skipped.

2.7 LAMMPS screen output

As LAMMPS reads an input script, it prints information to both the screen and a log file about significant actions it takes to setup a simulation. When the simulation is ready to begin, LAMMPS performs various initializations and prints the amount of memory (in MBytes per processor) that the simulation requires. It also prints details of the initial thermodynamic state of the system. During the run itself, thermodynamic information is printed periodically, every few timesteps. When the run concludes,

LAMMPS Users Manual

LAMMPS prints the final thermodynamic state and a total run time for the simulation. It then appends statistics about the CPU time and storage requirements for the simulation. An example set of statistics is shown here:

Loop time of 2.81192 on 4 procs for 300 steps with 2004 atoms

Performance: 18.436 ns/day 1.302 hours/ns 106.689 timesteps/s
97.0% CPU use with 4 MPI tasks x no OpenMP threads

MPI task timings breakdown:

Section	min time	avg time	max time	%varavg	%total
Pair	1.9808	2.0134	2.0318	1.4	71.60
Bond	0.0021894	0.0060319	0.010058	4.7	0.21
Kspace	0.3207	0.3366	0.36616	3.1	11.97
Neigh	0.28411	0.28464	0.28516	0.1	10.12

Modify	0.086606	0.086631	0.086668	0.0	3.08
Other		0.007178			0.26

Nlocal: 501 ave 508 max 490 min
Histogram: 1 0 0 0 0 0 1 1 0 1
Nghost: 6586.25 ave 6628 max 6548 min
Histogram: 1 0 1 0 0 0 1 0 0 1
Neighs: 177007 ave 180562 max 170212 min
Histogram: 1 0 0 0 0 0 0 1 1 1

Total # of neighbors = 708028
Ave neighs/atom = 353.307
Ave special neighs/atom = 2.34032
Neighbor list builds = 26
Dangerous builds = 0

The first section provides a global loop timing summary. The *loop time* is the total wall time for the section. The *Performance* line is provided for convenience to help predicting the number of loop continuations required and for comparing performance with other, similar MD codes. The *CPU use* line provides the CPU utilization per MPI task; it should be close to 100% times the number of OpenMP threads (or 1 of no OpenMP). Lower numbers correspond to delays due to file I/O or insufficient thread utilization.

The MPI task section gives the breakdown of the CPU run time (in seconds) into major categories:

- *Pair* stands for all non-bonded force computation
- *Bond* stands for bonded interactions: bonds, angles, dihedrals, impropers
- *Kspace* stands for reciprocal space interactions: Ewald, PPPM, MSM
- *Neigh* stands for neighbor list construction
- *Comm* stands for communicating atoms and their properties
- *Output* stands for writing dumps and thermo output
- *Modify* stands for fixes and computes called by them
- *Other* is the remaining time

LAMMPS Users Manual

For each category, there is a breakdown of the least, average and most amount of wall time a processor spent on this section. Also you have the variation from the average time. Together these numbers allow to gauge the amount of load imbalance in this segment of the calculation. Ideally the difference between minimum, maximum and average is small and thus the variation from the average close to zero. The final column shows the percentage of the total loop time is spent in this section.

When using the [timer full](#) setting, an additional column is present that also prints the CPU utilization in percent. In addition, when using *timer full* and the [package omp](#) command are active, a similar timing summary of time spent in threaded regions to monitor thread utilization and load balance is provided. A new entry is the *Reduce* section, which lists the time spent in reducing the per-thread data elements to the storage for non-threaded computation. These thread timings are taking from the first MPI rank only and thus, as the breakdown for MPI tasks can change from MPI rank to MPI rank, this breakdown can be very different for individual ranks. Here is an example output for this section:

```
Thread timings breakdown (MPI rank 0):
Total threaded time 0.6846 / 90.6%
Section | min time | avg time | max time | %varavg | %total
-----|-----|-----|-----|-----|-----
Pair    | 0.5127   | 0.5147   | 0.5167   | 0.3     | 75.18
Bond    | 0.0043139 | 0.0046779 | 0.0050418 | 0.5     | 0.68
Kspace  | 0.070572  | 0.074541  | 0.07851  | 1.5     | 10.89
Neigh   | 0.084778  | 0.086969  | 0.089161  | 0.7     | 12.70
Reduce  | 0.0036485 | 0.003737  | 0.0038254 | 0.1     | 0.55
```

The third section lists the number of owned atoms (Nlocal), ghost atoms (Nghost), and pair-wise neighbors stored per processor. The max and min values give the spread of these values across processors with a 10-bin histogram showing the distribution. The total number of histogram counts is equal to the number of processors.

The last section gives aggregate statistics for pair-wise neighbors and special neighbors that LAMMPS keeps track of (see the [special_bonds](#) command). The number of times neighbor lists were rebuilt during the run is given as well as the number of potentially "dangerous" rebuilds. If atom movement triggered neighbor list rebuilding (see the [neigh_modify](#) command), then dangerous reneighborings are those that were triggered on the first timestep atom movement was checked for. If this count is non-zero you may wish to reduce the delay factor to insure no force interactions are missed by atoms moving beyond the neighbor skin distance before a rebuild takes place.

If an energy minimization was performed via the [minimize](#) command, additional information is printed, e.g.

```
Minimization stats:
Stopping criterion = linesearch alpha is zero
Energy initial, next-to-last, final =
  -6372.3765206      -8328.46998942      -8328.46998942
Force two-norm initial, final = 1059.36 5.36874
Force max component initial, final = 58.6026 1.46872
Final line search alpha, max atom move = 2.7842e-10 4.0892e-10
Iterations, force evaluations = 701 1516
```

LAMMPS Users Manual

The first line prints the criterion that determined the minimization to be completed. The third line lists the initial and final energy, as well as the energy on the next-to-last iteration. The next 2 lines give a measure of the gradient of the energy (force on all atoms). The 2-norm is the "length" of this force vector; the inf-norm is the largest component. Then some information about the line search and statistics on how many iterations and force-evaluations the minimizer required. Multiple force evaluations are typically done at each iteration to perform a 1d line minimization in the search direction.

If a [kspace_style](#) long-range Coulombics solve was performed during the run (PPPM, Ewald), then additional information is printed, e.g.

```
FFT time (% of Kspce) = 0.200313 (8.34477)
FFT Gflps 3d 1d-only = 2.31074 9.19989
```

The first line gives the time spent doing 3d FFTs (4 per timestep) and the fraction it represents of the total KSpace time (listed above). Each 3d FFT requires computation (3 sets of 1d FFTs) and communication (transposes). The total flops performed is $5N\log_2(N)$, where N is the number of points in the 3d grid. The FFTs are timed with and without the communication and a Gflop rate is computed. The 3d rate is with communication; the 1d rate is without (just the 1d FFTs). Thus you can estimate what fraction of your FFT time was spent in communication, roughly 75% in the example above.

2.8 Tips for users of previous LAMMPS versions

The current C++ began with a complete rewrite of LAMMPS 2001, which was written in F90. Features of earlier versions of LAMMPS are listed in [Section 13](#). The F90 and F77 versions (2001 and 99) are also freely distributed as open-source codes; check the [LAMMPS WWW Site](#) for distribution information if you prefer those versions. The 99 and 2001 versions are no longer under active development; they do not have all the features of C++ LAMMPS.

If you are a previous user of LAMMPS 2001, these are the most significant changes you will notice in C++ LAMMPS:

- (1) The names and arguments of many input script commands have changed. All commands are now a single word (e.g. `read_data` instead of `read data`).
- (2) All the functionality of LAMMPS 2001 is included in C++ LAMMPS, but you may need to specify the relevant commands in different ways.
- (3) The format of the data file can be streamlined for some problems. See the [read_data](#) command for details. The data file section "Nonbond Coeff" has been renamed to "Pair Coeff" in C++ LAMMPS.
- (4) Binary restart files written by LAMMPS 2001 cannot be read by C++ LAMMPS with a [read_restart](#) command. This is because they were output by F90 which writes in a different binary format than C or C++ writes or reads. Use the `restart2data` tool provided with LAMMPS 2001 to convert the 2001 restart file to a text data file. Then edit the data file as necessary before using the C++ LAMMPS [read_data](#) command to

LAMMPS Users Manual

read it in.

(5) There are numerous small numerical changes in C++ LAMMPS that mean you will not get identical answers when comparing to a 2001 run. However, your initial thermodynamic energy and MD trajectory should be close if you have setup the problem for both codes the same.

3. Commands

This section describes how a LAMMPS input script is formatted and the input script commands used to define a LAMMPS simulation.

- [3.1 LAMMPS input script](#)
 - [3.2 Parsing rules](#)
 - [3.3 Input script structure](#)
 - [3.4 Commands listed by category](#)
 - [3.5 Commands listed alphabetically](#)
-

3.1 LAMMPS input script

LAMMPS executes by reading commands from a input script (text file), one line at a time. When the input script ends, LAMMPS exits. Each command causes LAMMPS to take some action. It may set an internal variable, read in a file, or run a simulation. Most commands have default settings, which means you only need to use the command if you wish to change the default.

In many cases, the ordering of commands in an input script is not important. However the following rules apply:

(1) LAMMPS does not read your entire input script and then perform a simulation with all the settings. Rather, the input script is read one line at a time and each command takes effect when it is read. Thus this sequence of commands:

```
timestep 0.5
run      100
run      100
```

does something different than this sequence:

```
run      100
timestep 0.5
run      100
```

In the first case, the specified timestep (0.5 fmsec) is used for two simulations of 100 timesteps each. In the 2nd case, the default timestep (1.0 fmsec) is used for the 1st 100 step simulation and a 0.5 fmsec timestep is used for the 2nd one.

(2) Some commands are only valid when they follow other commands. For example you cannot set the temperature of a group of atoms until atoms have been defined and a group command is used to define which atoms belong to the group.

(3) Sometimes command B will use values that can be set by command A. This means command A must precede command B in the input script if it is to have the desired

LAMMPS Users Manual

effect. For example, the [read_data](#) command initializes the system by setting up the simulation box and assigning atoms to processors. If default values are not desired, the [processors](#) and [boundary](#) commands need to be used before [read_data](#) to tell LAMMPS how to map processors to the simulation box.

Many input script errors are detected by LAMMPS and an ERROR or WARNING message is printed. [This section](#) gives more information on what errors mean. The documentation for each command lists restrictions on how the command can be used.

3.2 Parsing rules

Each non-blank line in the input script is treated as a command. LAMMPS commands are case sensitive. Command names are lower-case, as are specified command arguments. Upper case letters may be used in file names or user-chosen ID strings.

Here is how each line in the input script is parsed by LAMMPS:

(1) If the last printable character on the line is a "&" character, the command is assumed to continue on the next line. The next line is concatenated to the previous line by removing the "&" character and line break. This allows long commands to be continued across two or more lines. See the discussion of triple quotes in (6) for how to continue a command across multiple line without using "&" characters.

(2) All characters from the first "#" character onward are treated as comment and discarded. See an exception in (6). Note that a comment after a trailing "&" character will prevent the command from continuing on the next line. Also note that for multi-line commands a single leading "#" will comment out the entire command.

(3) The line is searched repeatedly for \$ characters, which indicate variables that are replaced with a text string. See an exception in (6).

If the \$ is followed by curly brackets, then the variable name is the text inside the curly brackets. If no curly brackets follow the \$, then the variable name is the single character immediately following the \$. Thus `${myTemp}` and `$x` refer to variable names "myTemp" and "x".

How the variable is converted to a text string depends on what style of variable it is; see the [variable](#) doc page for details. It can be a variable that stores multiple text strings, and return one of them. The returned text string can be multiple "words" (space separated) which will then be interpreted as multiple arguments in the input command. The variable can also store a numeric formula which will be evaluated and its numeric result returned as a string.

As a special case, if the \$ is followed by parenthesis, then the text inside the parenthesis is treated as an "immediate" variable and evaluated as an [equal-style variable](#). This is a way to use numeric formulas in an input script without having to assign them to variable names. For example, these 3 input script lines:

```
variable X equal (xlo+xhi)/2+sqrt(v_area)
region 1 block $X 2 INF INF EDGE EDGE
```

LAMMPS Users Manual

```
variable X delete
```

can be replaced by

```
region 1 block $((xlo+xhi)/2+sqrt(v_area)) 2 INF INF EDGE EDGE
```

so that you do not have to define (or discard) a temporary variable X.

Note that neither the curly-bracket or immediate form of variables can contain nested \$ characters for other variables to substitute for. Thus you cannot do this:

```
variable      a equal 2
variable      b2 equal 4
print         "B2 = ${b$a}"
```

Nor can you specify this $$(x-1.0)$ for an immediate variable, but you could use $(v_x-1.0)$, since the latter is valid syntax for an [equal-style variable](#).

See the [variable](#) command for more details of how strings are assigned to variables and evaluated, and how they can be used in input script commands.

(4) The line is broken into "words" separated by whitespace (tabs, spaces). Note that words can thus contain letters, digits, underscores, or punctuation characters.

(5) The first word is the command name. All successive words in the line are arguments.

(6) If you want text with spaces to be treated as a single argument, it can be enclosed in either single or double or triple quotes. A long single argument enclosed in single or double quotes can span multiple lines if the "&" character is used, as described above. When the lines are concatenated together (and the "&" characters and line breaks removed), the text will become a single line. If you want multiple lines of an argument to retain their line breaks, the text can be enclosed in triple quotes, in which case "&" characters are not needed. For example:

```
print "Volume = $v"
print 'Volume = $v'
if "${steps} > 1000" then quit
variable a string "red green blue &
                  purple orange cyan"
print ""
System volume = $v
System temperature = $t
""
```

In each case, the single, double, or triple quotes are removed when the single argument they enclose is stored internally.

See the [dump modify format](#), [print](#), [if](#), and [python](#) commands for examples.

A "#" or "\$" character that is between quotes will not be treated as a comment indicator in (2) or substituted for as a variable in (3).

NOTE: If the argument is itself a command that requires a quoted argument (e.g. using a [print](#) command as part of an [if](#) or [run every](#) command), then single, double, or triple quotes can be nested in the usual manner. See the doc pages for those commands for examples. Only one of level of nesting is allowed, but that should be sufficient for most use cases.

3.3 Input script structure

This section describes the structure of a typical LAMMPS input script. The "examples" directory in the LAMMPS distribution contains many sample input scripts; the corresponding problems are discussed in [Section 7](#), and animated on the [LAMMPS WWW Site](#).

A LAMMPS input script typically has 4 parts:

1. Initialization
2. Atom definition
3. Settings
4. Run a simulation

The last 2 parts can be repeated as many times as desired. I.e. run a simulation, change some settings, run some more, etc. Each of the 4 parts is now described in more detail. Remember that almost all the commands need only be used if a non-default value is desired.

(1) Initialization

Set parameters that need to be defined before atoms are created or read-in from a file.

The relevant commands are [units](#), [dimension](#), [newton](#), [processors](#), [boundary](#), [atom_style](#), [atom_modify](#).

If force-field parameters appear in the files that will be read, these commands tell LAMMPS what kinds of force fields are being used: [pair_style](#), [bond_style](#), [angle_style](#), [dihedral_style](#), [improper_style](#).

(2) Atom definition

There are 3 ways to define atoms in LAMMPS. Read them in from a data or restart file via the [read_data](#) or [read_restart](#) commands. These files can contain molecular topology information. Or create atoms on a lattice (with no molecular topology), using these commands: [lattice](#), [region](#), [create_box](#), [create_atoms](#). The entire set of atoms can be duplicated to make a larger simulation using the [replicate](#) command.

(3) Settings

Once atoms and molecular topology are defined, a variety of settings can be specified: force field coefficients, simulation parameters, output options, etc.

LAMMPS Users Manual

Force field coefficients are set by these commands (they can also be set in the read-in files): [pair_coeff](#), [bond_coeff](#), [angle_coeff](#), [dihedral_coeff](#), [improper_coeff](#), [kspace_style](#), [dielectric](#), [special_bonds](#).

Various simulation parameters are set by these commands: [neighbor](#), [neigh_modify](#), [group](#), [timestep](#), [reset_timestep](#), [run_style](#), [min_style](#), [min_modify](#).

Fixes impose a variety of boundary conditions, time integration, and diagnostic options. The [fix](#) command comes in many flavors.

Various computations can be specified for execution during a simulation using the [compute](#), [compute_modify](#), and [variable](#) commands.

Output options are set by the [thermo](#), [dump](#), and [restart](#) commands.

(4) Run a simulation

A molecular dynamics simulation is run using the [run](#) command. Energy minimization (molecular statics) is performed using the [minimize](#) command. A parallel tempering (replica-exchange) simulation can be run using the [temper](#) command.

3.4 Commands listed by category

This section lists core LAMMPS commands, grouped by category. The [next section](#) lists all commands alphabetically. The next section also includes (long) lists of style options for entries that appear in the following categories as a single command ([fix](#), [compute](#), [pair](#), etc). Commands that are added by user packages are not included in the categories here, but they are in the next section.

Initialization:

[newton](#), [package](#), [processors](#), [suffix](#), [units](#)

Setup simulation box:

[boundary](#), [box](#), [change_box](#), [create_box](#), [dimension](#), [lattice](#), [region](#)

Setup atoms:

[atom_modify](#), [atom_style](#), [balance](#), [create_atoms](#), [create_bonds](#), [delete_atoms](#), [delete_bonds](#), [displace_atoms](#), [group](#), [mass](#), [molecule](#), [read_data](#), [read_dump](#), [read_restart](#), [replicate](#), [set](#), [velocity](#)

Force fields:

[angle_coeff](#), [angle_style](#), [bond_coeff](#), [bond_style](#), [bond_write](#), [dielectric](#), [dihedral_coeff](#), [dihedral_style](#), [improper_coeff](#), [improper_style](#), [kspace_modify](#), [kspace_style](#), [pair_coeff](#), [pair_modify](#), [pair_style](#), [pair_write](#), [special_bonds](#)

Settings:

LAMMPS Users Manual

[comm_modify](#), [comm_style](#), [info](#), [min_modify](#), [min_style](#), [neigh_modify](#), [neighbor](#), [partition](#), [reset_timestep](#), [run_style](#), [timer](#), [timestep](#)

Operations within timestepping (fixes) and diagnostics (computes):

[compute](#), [compute_modify](#), [fix](#), [fix_modify](#), [uncompute](#), [unfix](#)

Output:

[dump_image](#), [dump_movie](#), [dump](#), [dump_modify](#), [restart](#), [thermo](#), [thermo_modify](#), [thermo_style](#), [undump](#), [write_coeff](#), [write_data](#), [write_dump](#), [write_restart](#)

Actions:

[minimize](#), [neb](#), [prd](#), [rerun](#), [run](#), [tad](#), [temper](#)

Input script control:

[clear](#), [echo](#), [if](#), [include](#), [jump](#), [label](#), [log](#), [next](#), [print](#), [python](#), [quit](#), [shell](#), [variable](#)

3.5 Individual commands

This section lists all LAMMPS commands alphabetically, with a separate listing below of styles within certain commands. The [previous section](#) lists the same commands, grouped by category. Note that some style options for some commands are part of specific LAMMPS packages, which means they cannot be used unless the package was included when LAMMPS was built. Not all packages are included in a default LAMMPS build. These dependencies are listed as Restrictions in the command's documentation.

angle_coeff	angle_style	atom_modify	atom_style	balance	bond_coeff
bond_style	bond_write	boundary	box	change_box	clear
comm_modify	comm_style	compute	compute_modify	create_atoms	create_bonds
create_box	delete_atoms	delete_bonds	dielectric	dihedral_coeff	dihedral_style
dimension	displace_atoms	dump	dump_image	dump_modify	dump_movie
echo	fix	fix_modify	group	if	info
improper_coeff	improper_style	include	jump	kspace_modify	kspace_style
label	lattice	log	mass	minimize	min_modify
min_style	molecule	neb	neigh_modify	neighbor	newton
next	package	pair_coeff	pair_modify	pair_style	pair_write
partition	prd	print	processors	python	quit
read_data	read_dump	read_restart	region	replicate	rerun
reset_timestep	restart	run	run_style	set	shell
special_bonds	suffix	tad	temper	thermo	thermo_modify
thermo_style	timer	timestep	uncompute	undump	unfix
units	variable	velocity	write_coeff	write_data	write_dump
write_restart					

LAMMPS Users Manual

These are additional commands in USER packages, which can be used if LAMMPS is built with the appropriate package.

dump netcdf	dump netcdf/mpiio	dump vtk
group2ndx	ndx2group	temper/grem
temper/npt		

Fix styles

See the [fix](#) command for one-line descriptions of each style or click on the style itself for a full description. Some of the styles have accelerated versions, which can be used if LAMMPS is built with the [appropriate accelerated package](#). This is indicated by additional letters in parenthesis: g = GPU, i = USER-INTEL, k = KOKKOS, o = USER-OMP, t = OPT.

addforce	append/atoms	atom/swap	aveforce	ave/atom	ave/chunk
ave/histo/weight	ave/time	balance	bond/break	bond/create	bond/swap
controller	deform (k)	deposit	drag	dt/reset	efield
evaporate	external	freeze	gcmc	gld	gravity (o)

pppm/stagger	pppm/tip4p (o)		

4. Packages

This section gives an overview of the optional packages that extend LAMMPS functionality with instructions on how to build LAMMPS with each of them. Packages are groups of files that enable a specific set of features. For example, force fields for molecular systems or granular systems are in packages. You can see the list of all packages and "make" commands to manage them by typing "make package" from within the src directory of the LAMMPS distribution. [Section 2.3](#) gives general info on how to install and un-install packages as part of the LAMMPS build process.

There are two kinds of packages in LAMMPS, standard and user packages:

- [Table of standard packages](#)
- [Table of user packages](#)

Either of these kinds of packages may work as is, may require some additional code compiled located in the lib folder, or may require an external library to be downloaded, compiled, installed, and LAMMPS configured to know about its location and additional compiler flags. You can often do the build of the internal or external libraries in one step by typing "make lib-name args='...'" from the src dir, with appropriate arguments included in args='...'. If you just type "make lib-name" you should see a help message about supported flags and some examples. For more details about this, please study the tables below and the sections about the individual packages.

Standard packages are supported by the LAMMPS developers and are written in a syntax and style consistent with the rest of LAMMPS. This means the developers will answer questions about them, debug and fix them if necessary, and keep them compatible with future changes to LAMMPS.

User packages have been contributed by users, and begin with the "user" prefix. If they are a single command (single file), they are typically in the user-misc package. User packages don't necessarily meet the requirements of the standard packages. This means the developers will try to keep things working and usually can answer technical questions about compiling the package. If you have problems using a feature provided in a user package, you may need to contact the contributor directly to get help. Information on how to submit additions you make to LAMMPS as single files or as a standard or user package are given in [this section](#) of the manual.

Following the next two tables is a sub-section for each package. It lists authors (if applicable) and summarizes the package contents. It has specific instructions on how to install the package, including (if necessary) downloading or building any extra library it requires. It also gives links to documentation, example scripts, and pictures/movies (if available) that illustrate use of the package.

NOTE: To see the complete list of commands a package adds to LAMMPS, just look at the files in its src directory, e.g. "ls src/GRANULAR". Files with names that start with

LAMMPS Users Manual

fix, compute, atom, pair, bond, angle, etc correspond to commands with the same style names.

In these two tables, the "Example" column is a sub-directory in the examples directory of the distribution which has an input script that uses the package. E.g. "peptide" refers to the examples/peptide directory; USER/atc refers to the examples/USER/atc directory. The "Library" column indicates whether an extra library is needed to build and use the package:

- dash = no library
- sys = system library: you likely have it on your machine
- int = internal library: provided with LAMMPS, but you may need to build it
- ext = external library: you will need to download and install it on your machine

Standard packages

Package	Description	Doc page	Example	Library
ASPHERE	aspherical particle models	Section 6.6.14	ellipse	-
BODY	body-style particles	body	body	-
CLASS2	class 2 force fields	pair_style lj/class2	-	-
COLLOID	colloidal particles	atom_style colloid	colloid	-

USER-MOFFF	styles for MOF-FF force field	pair_style buck6d/coul/gauss	USER/mofff	-
USER-MOLFILE	VMD molfile plug-ins	dump molfile	-	ext
USER-NETCDF	dump output via NetCDF	dump netcdf	-	ext
USER-OMP	OpenMP-enabled styles	Section 5.3.4	Benchmarks	-
USER-PHONON	phonon dynamical matrix	fix phonon	USER/phonon	-
USER-QMMM	QM/MM coupling	fix qmmm	USER/qmmm	ext
USER-QTB	quantum nuclear effects	fix qtb fix qbmsst	qtb	-
USER-QUIP	QUIP/libatoms interface	pair_style quip	USER/quip	ext
USER-REAXC	ReaxFF potential (C/C++)	pair_style reaxc	reax	-
USER-SMD	smoothed Mach dynamics	SMD User Guide	USER/smd	ext
USER-SMTBQ	second moment tight binding QEq potential	pair_style smtbq	USER/smtbq	-
USER-SPH	smoothed particle hydrodynamics	SPH User Guide	USER/sph	-
USER-TALLY	pairwise tally computes	compute XXX/tally	USER/tally	-
USER-UEF	extensional flow	fix nvt/uef	USER/uef	-
USER-VTK	dump output via VTK	compute vtk	-	ext

ASPHERE package

Contents:

Computes, time-integration fixes, and pair styles for aspherical particle models including ellipsoids, 2d lines, and 3d triangles.

Install or un-install:

```
make yes-asphere  
make machine
```

```
make no-asphere  
make machine
```

Supporting info:

- src/ASPHERE: filenames -> commands
 - [Section 6.14](#)
 - [pair_style gayberne](#)
 - [pair_style resquared](#)
 - [doc/PDF/pair_gayberne_extra.pdf](#)
 - [doc/PDF/pair_resquared_extra.pdf](#)
 - examples/ASPHERE
 - examples/ellipse
 - <http://lammps.sandia.gov/movies.html#line>
 - <http://lammps.sandia.gov/movies.html#tri>
-

BODY package

Contents:

Body-style particles with internal structure. Computes, time-integration fixes, pair styles, as well as the body styles themselves. See the [body](#) doc page for an overview.

Install or un-install:

```
make yes-body  
make machine
```

```
make no-body  
make machine
```

Supporting info:

- src/BODY filenames -> commands
 - [body](#)
 - [atom_style body](#)
 - [fix nve/body](#)
 - [pair_style body](#)
 - examples/body
-

CLASS2 package

Contents:

LAMMPS Users Manual

Bond, angle, dihedral, improper, and pair styles for the COMPASS CLASS2 molecular force field.

Install or un-install:

```
make yes-class2  
make machine
```

```
make no-class2  
make machine
```

Supporting info:

- src/CLASS2: filenames -> commands
 - [bond_style class2](#)
 - [angle_style class2](#)
 - [dihedral_style class2](#)
 - [improper_style class2](#)
 - [pair_style lj/class2](#)
-

COLLOID package

Contents:

Coarse-grained finite-size colloidal particles. Pair styles and fix wall styles for colloidal interactions. Includes the Fast Lubrication Dynamics (FLD) method for hydrodynamic interactions, which is a simplified approximation to Stokesian dynamics.

Authors: This package includes Fast Lubrication Dynamics pair styles which were created by Amit Kumar and Michael Bybee from Jonathan Higdon's group at UIUC.

Install or un-install:

```
make yes-colloid  
make machine
```

```
make no-colloid  
make machine
```

Supporting info:

- src/COLLOID: filenames -> commands
 - [fix wall/colloid](#)
 - [pair_style colloid](#)
 - [pair_style yukawa/colloid](#)
 - [pair_style brownian](#)
 - [pair_style lubricate](#)
 - [pair_style lubricateU](#)
 - [examples/colloid](#)
 - [examples/srd](#)
-

COMPRESS package

Contents:

Compressed output of dump files via the zlib compression library, using dump styles with a "gz" in their style name.

To use this package you must have the zlib compression library available on your system.

Author: Axel Kohlmeyer (Temple U).

Install or un-install:

Note that building with this package assumes you have the zlib compression library available on your system. The LAMMPS build uses the settings in the `lib/compress/Makefile.lammps` file in the compile/link process. You should only need to edit this file if the LAMMPS build fails on your system.

```
make yes-compress
make machine
```

```
make no-compress
make machine
```

Supporting info:

- `src/COMPRESS`: filenames -> commands
 - `src/COMPRESS/README`
 - `lib/compress/README`
 - [dump atom/gz](#)
 - [dump cfg/gz](#)
 - [dump custom/gz](#)
 - [dump xyz/gz](#)
-

CORESHELL package

Contents:

Compute and pair styles that implement the adiabatic core/shell model for polarizability. The pair styles augment Born, Buckingham, and Lennard-Jones styles with core/shell capabilities. The [compute temp/cs](#) command calculates the temperature of a system with core/shell particles. See [Section 6.26](#) for an overview of how to use this package.

Author: Hendrik Heenen (Technical U of Munich).

Install or un-install:

```
make yes-coreshell
make machine
```

```
make no-coreshell
make machine
```

Supporting info:

- src/CORESHELL: filenames -> commands
 - [Section 6.26](#)
 - [Section 6.25](#)
 - [compute temp/cs](#)
 - [pair_style born/coul/long/cs](#)
 - [pair_style buck/coul/long/cs](#)
 - [pair_style lj/cut/coul/long/cs](#)
 - [examples/coreshell](#)
-

DIPOLE package

Contents:

An atom style and several pair styles for point dipole models with short-range or long-range interactions.

Install or un-install:

```
make yes-dipole
make machine
```

```
make no-dipole
make machine
```

Supporting info:

- src/DIPOLE: filenames -> commands
 - [atom_style dipole](#)
 - [pair_style lj/cut/dipole/cut](#)
 - [pair_style lj/cut/dipole/long](#)
 - [pair_style lj/long/dipole/long](#)
 - [examples/dipole](#)
-

GPU package

Contents:

Dozens of pair styles and a version of the PPPM long-range Coulombic solver optimized for GPUs. All such styles have a "gpu" as a suffix in their style name. The GPU code can be compiled with either CUDA or OpenCL, however the OpenCL variants are no longer actively maintained and only the CUDA versions are regularly tested. [Section 5.3.1](#) gives details of what hardware and GPU software is required on your system, and details on how to build and use this package. Its styles can be invoked at run time via the "-sf gpu" or "-suffix gpu" [command-line switches](#). See also

LAMMPS Users Manual

the [KOKKOS](#) package, which has GPU-enabled styles.

Authors: Mike Brown (Intel) while at Sandia and ORNL and Trung Nguyen (Northwestern U) while at ORNL.

Install or un-install:

Before building LAMMPS with this package, you must first build the GPU library in lib/gpu from a set of provided C and CUDA files. You can do this manually if you prefer; follow the instructions in lib/gpu/README. Please note, that the GPU library uses MPI calls, so you have to make certain to use the same MPI library (or the STUBS library) settings as the main LAMMPS code. That same applies to the -DLAMMPS_BIGBIG, -DLAMMPS_SMALLBIG, or -DLAMMPS_SMALLSMALL define.

You can also do it in one step from the lammeps/src dir, using a command like these, which simply invoke the lib/gpu/Install.py script with the specified args:

```
make lib-gpu                # print help message
make lib-gpu args="-b"      # build GPU library with default Makefile.linux
make lib-gpu args="-m xk7 -p single -o xk7.single" # create new Makefile.xk7.single, altered t
make lib-gpu args="-m mpi -p mixed -b" # build GPU library with mixed precision using settings
```

Note that this procedure through the '-m machine' flag starts with one of the existing Makefile.machine files in lib/gpu. For your convenience, machine makefiles for "mpi" and "serial" are provided, which have the same settings as the corresponding machine makefiles in the main LAMMPS source folder. In addition you can alter 4 important settings in that Makefile, via the -h, -a, -p, -e switches, and also save a copy of the new Makefile, if desired:

- CUDA_HOME = where NVIDIA CUDA software is installed on your system
- CUDA_ARCH = what GPU hardware you have (see help message for details)
- CUDA_PRECISION = precision (double, mixed, single)
- EXTRAMAKE = which Makefile.lammps.* file to copy to Makefile.lammps

If the library build is successful, at least 3 files should be created: lib/gpu/libgpu.a, lib/gpu/nvc_get_devices, and lib/gpu/Makefile.lammps. The latter has settings that enable LAMMPS to link with CUDA libraries. If the settings in Makefile.lammps for your machine are not correct, the LAMMPS build will fail, and lib/gpu/Makefile.lammps may need to be edited.

You can then install/un-install the package and build LAMMPS in the usual manner:

```
make yes-gpu
make machine
```

```
make no-gpu
make machine
```

NOTE: If you re-build the GPU library in lib/gpu, you should always un-install the GPU package, then re-install it and re-build LAMMPS. This is because the compilation of files in the GPU package use the library settings from the lib/gpu/Makefile.machine used to build the GPU library.

GRANULAR package

Contents:

Pair styles and fixes for finite-size granular particles, which interact with each other and boundaries via frictional and dissipative potentials.

Install or un-install:

```
make yes-granular  
make machine
```

```
make no-granular  
make machine
```

KIM package

Contents:

LAMMPS Users Manual

A [pair_style kim](#) command which is a wrapper on the Knowledge Base for Interatomic Models (KIM) repository of interatomic potentials, enabling any of them to be used in LAMMPS simulations.

To use this package you must have the KIM library available on your system.

Information about the KIM project can be found at its website: <https://openkim.org>. The KIM project is led by Ellad Tadmor and Ryan Elliott (U Minnesota) and James Sethna (Cornell U).

Authors: Ryan Elliott (U Minnesota) is the main developer for the KIM API which the [pair_style kim](#) command uses. He developed the pair style in collaboration with Valeriu Smirichinski (U Minnesota).

Install or un-install:

Before building LAMMPS with this package, you must first download and build the KIM library and include the KIM models that you want to use. You can do this manually if you prefer; follow the instructions in `lib/kim/README`. You can also do it in one step from the `lammmps/src` dir, using a command like these, which simply invoke the `lib/kim/Install.py` script with the specified args.

```
make lib-kim                # print help message
make lib-kim args="-b "    # (re-)install KIM API lib with only example models
make lib-kim args="-b -a Glue_Ercolessi_Adams_Al_MO_324507536345_001" # ditto plus one model
make lib-kim args="-b -a everything" # install KIM API lib with all models
make lib-kim args="-n -a EAM_Dynamo_Ackland_W_MO_141627196590_002" # add one model or more
make lib-kim args="-p /usr/local/kim-api" # use an existing KIM API installation at the provided path
make lib-kim args="-p /usr/local/kim-api -a EAM_Dynamo_Ackland_W_MO_141627196590_002" # ditto
```

Note that in LAMMPS lingo, a KIM model driver is a pair style (e.g. EAM or Tersoff). A KIM model is a pair style for a particular element or alloy and set of parameters, e.g. EAM for Cu with a specific EAM potential file. Also note that installing the KIM API library with all its models, may take around 30 min to build. Of course you only need to do that once.

See the list of KIM model drivers here:

<https://openkim.org/kim-items/model-drivers/alphabetical>

See the list of all KIM models here:

<https://openkim.org/kim-items/models/by-model-drivers>

See the list of example KIM models included by default here:

<https://openkim.org/kim-api> in the "What is in the KIM API source package?" section

You can then install/un-install the package and build LAMMPS in the usual manner:

```
make yes-kim
make machine
```

```
make no-kim
make machine
```

Supporting info:

- src/KIM: filenames -> commands
 - src/KIM/README
 - lib/kim/README
 - [pair_style kim](#)
 - examples/kim
-

KOKKOS package

Contents:

Dozens of atom, pair, bond, angle, dihedral, improper, fix, compute styles adapted to compile using the Kokkos library which can convert them to OpenMP or CUDA code so that they run efficiently on multicore CPUs, KNLs, or GPUs. All the styles have a "kk" as a suffix in their style name. [Section 5.3.3](#) gives details of what hardware and software is required on your system, and how to build and use this package. Its styles can be invoked at run time via the "-sf kk" or "-suffix kk" [command-line switches](#). Also see the [GPU](#), [OPT](#), [USER-INTEL](#), and [USER-OMP](#) packages, which have styles optimized for CPUs, KNLs, and GPUs.

You must have a C++11 compatible compiler to use this package.

Authors: The KOKKOS package was created primarily by Christian Trott and Stan Moore (Sandia), with contributions from other folks as well. It uses the open-source [Kokkos library](#) which was developed by Carter Edwards, Christian Trott, and others at Sandia, and which is included in the LAMMPS distribution in lib/kokkos.

Install or un-install:

For the KOKKOS package, you have 3 choices when building. You can build with either CPU or KNL or GPU support. Each choice requires additional settings in your Makefile.machine for the KOKKOS_DEVICES and KOKKOS_ARCH settings. See the src/MAKE/OPTIONS/Makefile.kokkos* files for examples.

For multicore CPUs using OpenMP:

```
KOKKOS_DEVICES = OpenMP
KOKKOS_ARCH = HSW          # HSW = Haswell, SNB = SandyBridge, BDW = Broadwell, etc
```

For Intel KNLs using OpenMP:

```
KOKKOS_DEVICES = OpenMP
KOKKOS_ARCH = KNL
```

For NVIDIA GPUs using CUDA:

```
KOKKOS_DEVICES = Cuda
KOKKOS_ARCH = Pascal60,Power8    # P100 hosted by an IBM Power8, etc
KOKKOS_ARCH = Kepler37,Power8   # K80 hosted by an IBM Power8, etc
```

LAMMPS Users Manual

For GPUs, you also need these 2 lines in your Makefile.machine before the CC line is defined, in this case for use with OpenMPI mpicxx. The 2 lines define a nvcc wrapper compiler, which will use nvcc for compiling CUDA files or use a C++ compiler for non-Kokkos, non-CUDA files.

```
KOKKOS_ABSOLUTE_PATH = $(shell cd $(KOKKOS_PATH); pwd)
export OMPI_CXX = $(KOKKOS_ABSOLUTE_PATH)/config/nvcc_wrapper
CC = mpicxx
```

Once you have an appropriate Makefile.machine, you can install/un-install the package and build LAMMPS in the usual manner. Note that you cannot build one executable to run on multiple hardware targets (CPU or KNL or GPU). You need to build LAMMPS once for each hardware target, to produce a separate executable. Also note that we do not recommend building with other acceleration packages installed (GPU, OPT, USER-INTEL, USER-OMP) when also building with KOKKOS.

```
make yes-kokkos
make machine
```

```
make no-kokkos
make machine
```

Supporting info:

KSPACE package

Contents:

A variety of long-range Coulombic solvers, as well as pair styles which compute the corresponding short-range pairwise Coulombic interactions. These include Ewald, particle-particle particle-mesh (PPPM), and multilevel summation method (MSM) solvers.

Install or un-install:

Building with this package requires a 1d FFT library be present on your system for use by the PPPM solvers. This can be the KISS FFT library provided with LAMMPS, 3rd party libraries like FFTW, or a vendor-supplied FFT library. See step 6 of [Section 2.2.2](#) of the manual for details on how to select different FFT options in your machine

LAMMPS Users Manual

Makefile.

```
make yes-kSPACE
make machine
```

```
make no-kSPACE
make machine
```

-

LATTE package

Contents:

A `fix` command which wraps the LATTE DFTB code, so that molecular dynamics can be run with LAMMPS using density-functional tight-binding quantum forces calculated by LATTE.

More information on LATTE can be found at this web site:

<https://github.com/lanl/LATTE>. A brief technical description is given with the `fix latte` command.

Authors: Christian Negre (LANL) and Steve Plimpton (Sandia). LATTE itself is developed at Los Alamos National Laboratory by Marc Cawkwell, Anders Niklasson, and Christian Negre.

Install or un-install:

Before building LAMMPS with this package, you must first download and build the LATTE library. You can do this manually if you prefer; follow the instructions in `lib/latte/README`. You can also do it in one step from the `lammps/src` dir, using a command like these, which simply invokes the `lib/latte/Install.py` script with the specified args:

```
make lib-latte # print help message
make lib-latte args="-b" # download and build in lib/latte/LATTE-master
make lib-latte args="-p $HOME/latte" # use existing LATTE installation in $HOME/latte
make lib-latte args="-b -m gfortran" # download and build in lib/latte and
# copy Makefile.lammps.gfortran to Makefile.lammps
```

LAMMPS Users Manual

Note that 3 symbolic (soft) links, "includelink" and "liblink" and "filelink.o", are created in lib/latte to point into the LATTE home dir. When LAMMPS builds in src it will use these links. You should also check that the Makefile.lammps file you create is appropriate for the compiler you use on your system to build LATTE.

You can then install/un-install the package and build LAMMPS in the usual manner:

```
make yes-latte
make machine
```

```
make no-latte
make machine
```

Supporting info:

- src/LATTE: filenames -> commands
 - src/LATTE/README
 - lib/latte/README
 - [fix latte](#)
 - examples/latte
 - [LAMMPS-LATTE tutorial](#)
-

MANYBODY package

Contents:

A variety of manybody and bond-order potentials. These include (AI)REBO, BOP, EAM, EIM, Stillinger-Weber, and Tersoff potentials.

Install or un-install:

```
make yes-manybody
make machine
```

```
make no-manybody
make machine
```

Supporting info:

- src/MANYBODY: filenames -> commands
 - Pair Styles section of [Section 3.5](#)
 - examples/comb
 - examples/eim
 - examples/nb3d
 - examples/shear
 - examples/streitz
 - examples/vashishta
 - bench/in.eam
-

MC package

Contents:

Several fixes and a pair style that have Monte Carlo (MC) or MC-like attributes. These include fixes for creating, breaking, and swapping bonds, for performing atomic swaps, and performing grand-canonical MC (GCMC) in conjunction with dynamics.

Install or un-install:

```
make yes-mc
make machine
```

```
make no-mc
make machine
```

Supporting info:

- src/MC: filenames -> commands
 - [fix atom/swap](#)
 - [fix bond/break](#)
 - [fix bond/create](#)
 - [fix bond/swap](#)
 - [fix gcmc](#)
 - [pair_style dsmc](#)
 - <http://lammps.sandia.gov/movies.html#gcmc>
-

MEAM package

Contents:

A pair style for the modified embedded atom (MEAM) potential.

Please note that the MEAM package has been superseded by the [USER-MEAMC](#) package, which is a direct translation of the MEAM package to C++. USER-MEAMC contains additional optimizations making it run faster than MEAM on most machines, while providing the identical features and USER interface.

Author: Greg Wagner (Northwestern U) while at Sandia.

Install or un-install:

Before building LAMMPS with this package, you must first build the MEAM library in lib/meam. You can do this manually if you prefer; follow the instructions in lib/meam/README. You can also do it in one step from the lammps/src dir, using a command like these, which simply invoke the lib/meam/Install.py script with the specified args:

```
make lib-meam          # print help message
make lib-meam args="-m mpi" # build with default Fortran compiler compatible with your MPI T
make lib-meam args="-m serial" # build with compiler compatible with "make serial" (GNU Fortran
```

LAMMPS Users Manual

```
make lib-meam args="-m ifort" # build with Intel Fortran compiler using Makefile.ifort
```

The build should produce two files: lib/meam/libmeam.a and lib/meam/Makefile.lammps. The latter is copied from an existing Makefile.lammps.* and has settings needed to link C++ (LAMMPS) with Fortran (MEAM library). Typically the two compilers used for LAMMPS and the MEAM library need to be consistent (e.g. both Intel or both GNU compilers). If necessary, you can edit/create a new lib/meam/Makefile.machine file for your system, which should define an EXTRAMAKE variable to specify a corresponding Makefile.lammps.machine file.

You can then install/un-install the package and build LAMMPS in the usual manner:

```
make yes-meam  
make machine
```

```
make no-meam  
make machine
```

NOTE: You should test building the MEAM library with both the Intel and GNU compilers to see if a simulation runs faster with one versus the other on your system.

Supporting info:

- src/MEAM: filenames -> commands
 - src/meam/README
 - lib/meam/README
 - [pair_style meam](#)
 - examples/meam
-

MISC package

Contents:

A variety of compute, fix, pair, dump styles with specialized capabilities that don't align with other packages. Do a directory listing, "ls src/MISC", to see the list of commands.

NOTE: the MISC package contains styles that require using the -restrict flag, when compiling with Intel compilers.

Install or un-install:

```
make yes-misc  
make machine
```

```
make no-misc  
make machine
```

Supporting info:

- src/MISC: filenames -> commands

LAMMPS Users Manual

-

MOLECULE package

Contents:

A large number of atom, pair, bond, angle, dihedral, improper styles that are used to model molecular systems with fixed covalent bonds. The pair styles include the Dreiding (hydrogen-bonding) and CHARMM force fields, and a TIP4P water model.

Install or un-install:

```
make yes-molecule
make machine
```

```
make no-molecule
make machine
```

Supporting info:

- [src/MOLECULE: filenames -> commands](#)
 - [atom_style](#)
 - [bond_style](#)
 - [angle_style](#)
 - [dihedral_style](#)
 - [improper_style](#)

-

MPIIO package

Contents:

LAMMPS Users Manual

Support for parallel output/input of dump and restart files via the MPIIO library. It adds [dump styles](#) with a "mpiio" in their style name. Restart files with an ".mpiio" suffix are also written and read in parallel.

Install or un-install:

Note that MPIIO is part of the standard message-passing interface (MPI) library, so you should not need any additional compiler or link settings, beyond what LAMMPS normally uses for MPI on your system.

```
make yes-mpiio
make machine
```

```
make no-mpiio
make machine
```

Supporting info:

- src/MPIIO: filenames -> commands
 - [dump](#)
 - [restart](#)
 - [write_restart](#)
 - [read_restart](#)
-

MSCG package

Contents:

A [fix mscg](#) command which can parameterize a Multi-Scale Coarse-Graining (MSCG) model using the open-source [MS-CG library](#).

To use this package you must have the MS-CG library available on your system.

Authors: The fix was written by Lauren Abbott (Sandia). The MS-CG library was developed by Jacob Wagner in Greg Voth's group at the University of Chicago.

Install or un-install:

Before building LAMMPS with this package, you must first download and build the MS-CG library. Building the MS-CG library and using it from LAMMPS requires a C++11 compatible compiler and that the GSL (GNU Scientific Library) headers and libraries are installed on your machine. See the lib/mscg/README and MSCG/Install files for more details.

Assuming these libraries are in place, you can do the download and build of MS-CG manually if you prefer; follow the instructions in lib/mscg/README. You can also do it in one step from the lammeps/src dir, using a command like these, which simply invoke the lib/mscg/Install.py script with the specified args:

```
make lib-mscg          # print help message
make lib-mscg args="-b -m serial" # download and build in lib/mscg/MSCG-release-master
```

LAMMPS Users Manual

```
make lib-mscg args="-b -m mpi" # with the settings compatible with "make serial"
                                # download and build in lib/mscg/MSCG-release-master
make lib-mscg args="-p /usr/local/mscg-release" # with the settings compatible with "make mpi"
                                                # use the existing MS-CG installation in /usr/
```

Note that 2 symbolic (soft) links, "includelink" and "liblink", will be created in lib/mscg to point to the MS-CG src/installation dir. When LAMMPS is built in src it will use these links. You should not need to edit the lib/mscg/Makefile.lammps file.

You can then install/un-install the package and build LAMMPS in the usual manner:

```
make yes-mscg
make machine
```

```
make no-mscg
make machine
```

Supporting info:

- src/MSCG: filenames -> commands
 - src/MSCG/README
 - lib/mscg/README
 - examples/mscg
-

OPT package

Contents:

A handful of pair styles which are optimized for improved CPU performance on single or multiple cores. These include EAM, LJ, CHARMM, and Morse potentials. The styles have an "opt" suffix in their style name. [Section 5.3.5](#) gives details of how to build and use this package. Its styles can be invoked at run time via the "-sf opt" or "-suffix opt" [command-line switches](#). See also the [KOKKOS](#), [USER-INTEL](#), and [USER-OMP](#) packages, which have styles optimized for CPU performance.

Authors: James Fischer (High Performance Technologies), David Richie, and Vincent Natoli (Stone Ridge Technolgy).

Install or un-install:

```
make yes-opt
make machine
```

```
make no-opt
make machine
```

NOTE: The compile flag "-restrict" must be used to build LAMMPS with the OPT package when using Intel compilers. It should be added to the CCFLAGS line of your Makefile.machine. See Makefile.opt in src/MAKE/OPTIONS for an example.

- CCFLAGS: add -restrict for Intel compilers

Supporting info:

- src/OPT: filenames -> commands
 - [Section 5.3](#)
 - [Section 5.3.5](#)
 - [Section 2.6 -sf opt](#)
 - Pair Styles section of [Section 3.5](#) for pair styles followed by (t)
 - [Benchmarks page](#) of web site
-

PERI package

Contents:

An atom style, several pair styles which implement different Peridynamics materials models, and several computes which calculate diagnostics. Peridynamics is a particle-based meshless continuum model.

Authors: The original package was created by Mike Parks (Sandia). Additional Peridynamics models were added by Rezwanur Rahman and John Foster (UTSA).

Install or un-install:

```
make yes-peri  
make machine
```

```
make no-peri  
make machine
```

Supporting info:

 - <http://lammps.sandia.gov/movies.html#peri>
-

POEMS package

Contents:

A fix that wraps the Parallelizable Open source Efficient Multibody Software (POEMS) library, which is able to simulate the dynamics of articulated body systems. These are systems with multiple rigid bodies (collections of particles) whose motion is coupled by connections at hinge points.

LAMMPS Users Manual

Author: Rudra Mukherjee (JPL) while at RPI.

Install or un-install:

Before building LAMMPS with this package, you must first build the POEMS library in lib/poems. You can do this manually if you prefer; follow the instructions in lib/poems/README. You can also do it in one step from the lammeps/src dir, using a command like these, which simply invoke the lib/poems/Install.py script with the specified args:

```
make lib-poems          # print help message
make lib-poems args="-m serial" # build with GNU g++ compiler (settings as with "make serial")
make lib-poems args="-m mpi"   # build with default MPI C++ compiler (settings as with "make serial")
make lib-poems args="-m icc"   # build with Intel icc compiler
```

The build should produce two files: lib/poems/libpoems.a and lib/poems/Makefile.lammps. The latter is copied from an existing Makefile.lammps.* and has settings needed to build LAMMPS with the POEMS library (though typically the settings are just blank). If necessary, you can edit/create a new lib/poems/Makefile.machine file for your system, which should define an EXTRAMAKE variable to specify a corresponding Makefile.lammps.machine file.

You can then install/un-install the package and build LAMMPS in the usual manner:

```
make yes-poems
make machine
```

```
make no-meam
make machine
```

Supporting info:

- src/POEMS: filenames -> commands
- src/POEMS/README
- lib/poems/README
- [fix poems](#)
- examples/rigid

PYTHON package

Contents:

A [python](#) command which allow you to execute Python code from a LAMMPS input script. The code can be in a separate file or embedded in the input script itself. See [Section 11.2](#) for an overview of using Python from LAMMPS in this manner and the entire section for other ways to use LAMMPS and Python together.

Install or un-install:

```
make yes-python
make machine
```

LAMMPS Users Manual

```
make no-python  
make machine
```

NOTE: Building with the PYTHON package assumes you have a Python shared library available on your system, which needs to be a Python 2 version, 2.6 or later. Python 3 is not yet supported. See the lib/python/README for more details. Note that the build uses the lib/python/Makefile.lammps file in the compile/link process. You should only need to create a new Makefile.lammps.* file (and copy it to Makefile.lammps) if the LAMMPS build fails.

Supporting info:

- src/PYTHON: filenames -> commands
 - [Section 11](#)
 - lib/python/README
 - examples/python
-

QEQ package

Contents:

Several fixes for performing charge equilibration (QEq) via different algorithms. These can be used with pair styles that perform QEq as part of their formulation.

Install or un-install:

```
make yes-qeq  
make machine
```

```
make no-qeq  
make machine
```

Supporting info:

- src/QEQ: filenames -> commands
 - [fix qeq/*](#)
 - examples/qeq
 - examples/streitz
-

REAX package

Contents:

A pair style which wraps a Fortran library which implements the ReaxFF potential, which is a universal reactive force field. See the [USER-REAXC package](#) for an alternate implementation in C/C++. Also a [fix reax/bonds](#) command for monitoring molecules as bonds are created and destroyed.

Author: Aidan Thompson (Sandia).

LAMMPS Users Manual

Install or un-install:

Before building LAMMPS with this package, you must first build the REAX library in lib/reax. You can do this manually if you prefer; follow the instructions in lib/reax/README. You can also do it in one step from the lammps/src dir, using a command like these, which simply invoke the lib/reax/Install.py script with the specified args:

```
make lib-reax                # print help message
make lib-reax args="-m serial" # build with GNU Fortran compiler (settings as with "make ser
make lib-reax args="-m mpi"   # build with default MPI Fortran compiler (settings as with "
make lib-reax args="-m ifort" # build with Intel ifort compiler
```

The build should produce two files: lib/reax/libreax.a and lib/reax/Makefile.lammps. The latter is copied from an existing Makefile.lammps.* and has settings needed to link C++ (LAMMPS) with Fortran (REAX library). Typically the two compilers used for LAMMPS and the REAX library need to be consistent (e.g. both Intel or both GNU compilers). If necessary, you can edit/create a new lib/reax/Makefile.machine file for your system, which should define an EXTRAMAKE variable to specify a corresponding Makefile.lammps.machine file.

You can then install/un-install the package and build LAMMPS in the usual manner:

```
make yes-reax
make machine
```

```
make no-reax
make machine
```

Supporting info:

- src/REAX: filenames -> commands
- lib/reax/README
- [pair_style reax](#)
- [fix reax/bonds](#)
- examples/reax

REPLICA package

Contents:

A collection of multi-replica methods which can be used when running multiple LAMMPS simulations (replicas). See [Section 6.5](#) for an overview of how to run multi-replica simulations in LAMMPS. Methods in the package include nudged elastic band (NEB), parallel replica dynamics (PRD), temperature accelerated dynamics (TAD), parallel tempering, and a verlet/split algorithm for performing long-range Coulombics on one set of processors, and the remainder of the force field calculation on another set.

Install or un-install:

LAMMPS Users Manual

RIGID package

Contents:

Fixes which enforce rigid constraints on collections of atoms or particles. This includes SHAKE and RATTLE, as well as various rigid-body integrators for a few large bodies or many small bodies. Also several computes which calculate properties of rigid bodies.

To install/build:

```
make yes-rigid  
make machine
```

To un-install/re-build:

```
make no-rigid  
make machine
```

Supporting info:

- src/RIGID: filenames -> commands

 - [fix append/atoms](#)
 - [fix msst](#)
 - [fix np Hug](#)
 - [fix wall/piston](#)
 - examples/hugoniostat
 - examples/msst
-

SNAP package

Contents:

A pair style for the spectral neighbor analysis potential (SNAP). SNAP is methodology for deriving a highly accurate classical potential fit to a large archive of quantum mechanical (DFT) data. Also several computes which analyze attributes of the potential.

Author: Aidan Thompson (Sandia).

Install or un-install:

```
make yes-snap  
make machine
```

```
make no-snap  
make machine
```

Supporting info:

- src/SNAP: filenames -> commands
- [pair_style snap](#)
- [compute sna/atom](#)
- [compute snad/atom](#)
- [compute snav/atom](#)
- examples/snap

SRD package

Contents:

A pair of fixes which implement the Stochastic Rotation Dynamics (SRD) method for coarse-graining of a solvent, typically around large colloidal particles.

To install/build:

```
make yes-srd
make machine
```

To un-install/re-build:

```
make no-srd
make machine
```

Supporting info:

-

VORONOI package

Contents:

A compute command which calculates the Voronoi tessellation of a collection of atoms by wrapping the [Voro++ library](#). This can be used to calculate the local volume of each atom or its near neighbors.

To use this package you must have the Voro++ library available on your system.

Author: Daniel Schwen (INL) while at LANL. The open-source Voro++ library was written by Chris Rycroft (Harvard U) while at UC Berkeley and LBNL.

Install or un-install:

Before building LAMMPS with this package, you must first download and build the Voro++ library. You can do this manually if you prefer; follow the instructions in `lib/voronoi/README`. You can also do it in one step from the `lammps/src` dir, using a command like these, which simply invoke the `lib/voronoi/Install.py` script with the specified args:

LAMMPS Users Manual

```
make lib-voronoi          # print help message
make lib-voronoi args="-b" # download and build the default version in lib/voronoi
```

Note that 2 symbolic (soft) links, "includelink" and "liblink", are created in lib/voronoi to point to the Voropp src dir. When LAMMPS builds in src it will use these links. You should not need to edit the lib/voronoi/Makefile.lammps file.

You can then install/un-install the package and build LAMMPS in the usual manner:

```
make yes-voronoi
make machine
```

```
make no-voronoi
make machine
```

Supporting info:

- src/VORONOI: filenames -> commands
 - src/VORONOI/README
 - lib/voronoi/README
 - [compute voronoi/atom](#)
 - examples/voronoi
-
-

USER-ATC package

Contents:

ATC stands for atoms-to-continuum. This package implements a [fix atc](#) command to either couple molecular dynamics with continuum finite element equations or perform on-the-fly conversion of atomic information to continuum fields.

Authors: Reese Jones, Jeremy Templeton, Jon Zimmerman (Sandia).

Install or un-install:

Before building LAMMPS with this package, you must first build the ATC library in lib/atc. You can do this manually if you prefer; follow the instructions in lib/atc/README. You can also do it in one step from the lammps/src dir, using a command like these, which simply invoke the lib/atc/Install.py script with the specified args:

```
make lib-atc          # print help message
make lib-atc args="-m serial" # build with GNU g++ compiler and MPI STUBS (settings as with
make lib-atc args="-m mpi"   # build with default MPI compiler (settings as with "make mpi
make lib-atc args="-m icc"   # build with Intel icc compiler
```

The build should produce two files: lib/atc/libatc.a and lib/atc/Makefile.lammps. The latter is copied from an existing Makefile.lammps.* and has settings needed to build LAMMPS with the ATC library. If necessary, you can edit/create a new lib/atc/Makefile.machine file for your system, which should define an EXTRAMAKE

LAMMPS Users Manual

variable to specify a corresponding Makefile.lammps.machine file.

Note that the Makefile.lammps file has settings for the BLAS and LAPACK linear algebra libraries. As explained in lib/atc/README these can either exist on your system, or you can use the files provided in lib/linalg. In the latter case you also need to build the library in lib/linalg with a command like these:

```
make lib-linalg # print help message
make lib-linalg args="-m serial" # build with GNU Fortran compiler (settings as with "make s
make lib-linalg args="-m mpi" # build with default MPI Fortran compiler (settings as with
make lib-linalg args="-m gfortran" # build with GNU Fortran compiler
```

You can then install/un-install the package and build LAMMPS in the usual manner:

```
make yes-user-atc
make machine
```

```
make no-user-atc
make machine
```

Supporting info:

- src/USER-ATC: filenames -> commands
- src/USER-ATC/README
- [fix atc](#)
- examples/USER/atc
- <http://lammps.sandia.gov/pictures.html#atc>

USER-AWPMD package

Contents:

AWPMD stands for Antisymmetrized Wave Packet Molecular Dynamics. This package implements an atom, pair, and fix style which allows electrons to be treated as explicit particles in a classical molecular dynamics model.

Author: Ilya Valuev (JIHT, Russia).

Install or un-install:

Before building LAMMPS with this package, you must first build the AWPMD library in lib/awpmd. You can do this manually if you prefer; follow the instructions in lib/awpmd/README. You can also do it in one step from the lammps/src dir, using a command like these, which simply invoke the lib/awpmd/Install.py script with the specified args:

```
make lib-awpmd # print help message
make lib-awpmd args="-m serial" # build with GNU g++ compiler and MPI STUBS (settings as with
make lib-awpmd args="-m mpi" # build with default MPI compiler (settings as with "make mpi
make lib-awpmd args="-m icc" # build with Intel icc compiler
```

LAMMPS Users Manual

The build should produce two files: lib/awpmd/libawpmd.a and lib/awpmd/Makefile.lammps. The latter is copied from an existing Makefile.lammps.* and has settings needed to build LAMMPS with the AWPMD library. If necessary, you can edit/create a new lib/awpmd/Makefile.machine file for your system, which should define an EXTRAMAKE variable to specify a corresponding Makefile.lammps.machine file.

Note that the Makefile.lammps file has settings for the BLAS and LAPACK linear algebra libraries. As explained in lib/awpmd/README these can either exist on your system, or you can use the files provided in lib/linalg. In the latter case you also need to build the library in lib/linalg with a command like these:

```
make lib-linalg          # print help message
make lib-linalg args="-m serial" # build with GNU Fortran compiler (settings as with "make s
make lib-linalg args="-m mpi"   # build with default MPI Fortran compiler (settings as with
make lib-linalg args="-m gfortran" # build with GNU Fortran compiler
```

You can then install/un-install the package and build LAMMPS in the usual manner:

```
make yes-user-awpmd
make machine
```

```
make no-user-awpmd
make machine
```

Supporting info:

- src/USER-AWPMD: filenames -> commands
 - src/USER-AWPMD/README
 - [pair_style awpmd/cut](#)
 - examples/USER/awpmd
-

USER-CGDNA package

Contents:

Several pair styles, a bond style, and integration fixes for coarse-grained models of single- and double-stranded DNA based on the oxDNA model of Doye, Louis and Ouldridge at the University of Oxford. This includes Langevin-type rigid-body integrators with improved stability.

Author: Oliver Henrich (University of Strathclyde, Glasgow).

Install or un-install:

```
make yes-user-cgdna
make machine
```

```
make no-user-cgdna
make machine
```

Supporting info:

LAMMPS Users Manual

- src/USER-CGDNA: filenames -> commands
 - /src/USER-CGDNA/README
 - [pair_style oxdna/*](#)
 - [pair_style oxdna2/*](#)
 - [bond_style oxdna/*](#)
 - [bond_style oxdna2/*](#)
 - [fix nve/dotc/langevin](#)
-

USER-CGSDK package

Contents:

Several pair styles and an angle style which implement the coarse-grained SDK model of Shinoda, DeVane, and Klein which enables simulation of ionic liquids, electrolytes, lipids and charged amino acids.

Author: Axel Kohlmeyer (Temple U).

Install or un-install:

```
make yes-user-cgsdk
make machine
```

```
make no-user-cgsdk
make machine
```

Supporting info:

- src/USER-CGSDK: filenames -> commands
 - src/USER-CGSDK/README
 - [pair_style lj/sdk/*](#)
 - [angle_style sdk](#)
 - examples/USER/cgsdk
 - <http://lammps.sandia.gov/pictures.html#cg>
-

USER-COLVARS package

Contents:

COLVARS stands for collective variables, which can be used to implement various enhanced sampling methods, including Adaptive Biasing Force, Metadynamics, Steered MD, Umbrella Sampling and Restraints. A [fix colvars](#) command is implemented which wraps a COLVARS library, which implements these methods. simulations.

Authors: The COLVARS library is written and maintained by Giacomo Fiorin (ICMS, Temple University, Philadelphia, PA, USA) and Jerome Henin (LISM, CNRS, Marseille, France), originally for the NAMD MD code, but with portability in mind. Axel Kohlmeyer (Temple U) provided the interface to LAMMPS.

LAMMPS Users Manual

Install or un-install:

Before building LAMMPS with this package, you must first build the COLVARS library in lib/colvars. You can do this manually if you prefer; follow the instructions in lib/colvars/README. You can also do it in one step from the lammps/src dir, using a command like these, which simply invoke the lib/colvars/Install.py script with the specified args:

```
make lib-colvars                # print help message
make lib-colvars args="-m serial" # build with GNU g++ compiler (settings as with "make ser
make lib-colvars args="-m mpi"   # build with default MPI compiler (settings as with "make
make lib-colvars args="-m g++-debug" # build with GNU g++ compiler and colvars debugging enabl
```

The build should produce two files: lib/colvars/libcolvars.a and lib/colvars/Makefile.lammps. The latter is copied from an existing Makefile.lammps.* and has settings needed to build LAMMPS with the COLVARS library (though typically the settings are just blank). If necessary, you can edit/create a new lib/colvars/Makefile.machine file for your system, which should define an EXTRAMAKE variable to specify a corresponding Makefile.lammps.machine file.

You can then install/un-install the package and build LAMMPS in the usual manner:

```
make yes-user-colvars
make machine
```

```
make no-user-colvars
make machine
```

Supporting info:

- [doc/PDF/colvars-refman-lammps.pdf](#)
- src/USER-COLVARS/README
- lib/colvars/README
- [fix colvars](#)
- examples/USER/colvars

USER-DIFFRACTION package

Contents:

Two computes and a fix for calculating x-ray and electron diffraction intensities based on kinematic diffraction theory.

Author: Shawn Coleman while at the U Arkansas.

Install or un-install:

```
make yes-user-diffraction
make machine
```

```
make no-user-diffraction
```

make machine

Supporting info:

- src/USER-DIFFRACTION: filenames -> commands
 - [compute saed](#)
 - [compute xrd](#)
 - [fix saed/vtk](#)
 - examples/USER/diffraction
-

USER-DPD package

Contents:

DPD stands for dissipative particle dynamics. This package implements coarse-grained DPD-based models for energetic, reactive molecular crystalline materials. It includes many pair styles specific to these systems, including for reactive DPD, where each particle has internal state for multiple species and a coupled set of chemical reaction ODEs are integrated each timestep. Highly accurate time integrators for isothermal, isoenergetic, isobaric and isenthalpic conditions are included. These enable long timesteps via the Shardlow splitting algorithm.

Authors: Jim Larentzos (ARL), Tim Mattox (Engility Corp), and and John Brennan (ARL).

Install or un-install:

```
make yes-user-dpd
make machine
```

```
make no-user-dpd
make machine
```

Supporting info:

- src/USER-DPD: filenames -> commands
- /src/USER-DPD/README
- [compute dpd](#)
- [compute dpd/atom](#)
- [fix eos/cv](#)
- [fix eos/table](#)

USER-DRUDE package

Contents:

Fixes, pair styles, and a compute to simulate thermalized Drude oscillators as a model of polarization. See [Section 6.27](#) for an overview of how to use the package. There are auxiliary tools for using this package in tools/drude.

Authors: Alain Dequidt (U Blaise Pascal Clermont-Ferrand), Julien Devemy (CNRS), and Agilio Padua (U Blaise Pascal).

Install or un-install:

```
make yes-user-drude
make machine
```

```
make no-user-drude
make machine
```

Supporting info:

- src/USER-DRUDE: filenames -> commands

 - tools/drude
-

USER-EFF package

Contents:

EFF stands for electron force field which allows a classical MD code to model electrons as particles of variable radius. This package contains atom, pair, fix and compute styles which implement the eFF as described in A. Jaramillo-Botero, J. Su, Q. An, and W.A. Goddard III, JCC, 2010. The eFF potential was first introduced by Su and Goddard, in 2007. There are auxiliary tools for using this package in tools/eff; see its README file.

Author: Andres Jaramillo-Botero (CalTech).

Install or un-install:

LAMMPS Users Manual

```
make yes-user-eff  
make machine
```

```
make no-user-eff  
make machine
```

Supporting info:

- src/USER-EFF: filenames -> commands
 - src/USER-EFF/README
 - [atom_style electron](#)
 - [fix nve/eff](#)

 - examples/USER/eff
 - tools/eff/README
 - tools/eff
 - <http://lammps.sandia.gov/movies.html#eff>
-

USER-FEP package

Contents:

FEP stands for free energy perturbation. This package provides methods for performing FEP simulations by using a [fix adapt/fep](#) command with soft-core pair potentials, which have a "soft" in their style name. There are auxiliary tools for using this package in tools/fep; see its README file.

Author: Agilio Padua (Universite Blaise Pascal Clermont-Ferrand)

Install or un-install:

```
make yes-user-fep  
make machine
```

```
make no-user-fep  
make machine
```

Supporting info:

- src/USER-FEP: filenames -> commands
- src/USER-FEP/README
- [fix adapt/fep](#)
- [compute fep](#)
- [pair_style */soft](#)
- examples/USER/fep
- tools/fep/README

USER-H5MD package

Contents:

H5MD stands for HDF5 for MD. [HDF5](#) is a portable, binary, self-describing file format, used by many scientific simulations. H5MD is a format for molecular simulations, built on top of HDF5. This package implements a [dump h5md](#) command to output LAMMPS snapshots in this format.

To use this package you must have the HDF5 library available on your system.

Author: Pierre de Buyl (KU Leuven) created both the package and the H5MD format.

Install or un-install:

Note that to follow these steps to compile and link to the CH5MD library, you need the standard HDF5 software package installed on your system, which should include the h5cc compiler and the HDF5 library.

Before building LAMMPS with this package, you must first build the CH5MD library in lib/h5md. You can do this manually if you prefer; follow the instructions in lib/h5md/README. You can also do it in one step from the lammeps/src dir, using a command like these, which simply invoke the lib/h5md/Install.py script with the specified args:

```
make lib-h5md                # print help message
make lib-hm5d args="-m h5cc" # build with h5cc compiler
```

The build should produce two files: lib/h5md/libch5md.a and lib/h5md/Makefile.lammps. The latter is copied from an existing Makefile.lammps.* and has settings needed to build LAMMPS with the system HDF5 library. If necessary, you can edit/create a new lib/h5md/Makefile.machine file for your system, which should define an EXTRAMAKE variable to specify a corresponding Makefile.lammps.machine file.

You can then install/un-install the package and build LAMMPS in the usual manner:

```
make yes-user-h5md
make machine
```

```
make no-user-h5md
make machine
```

Supporting info:

- src/USER-H5MD: filenames -> commands
- src/USER-H5MD/README
- lib/h5md/README
- [dump h5md](#)

USER-INTEL package

Contents:

Dozens of pair, fix, bond, angle, dihedral, improper, and kspace styles which are optimized for Intel CPUs and KNLs (Knights Landing). All of them have an "intel" in their style name. [Section 5.3.2](#) gives details of what hardware and compilers are required on your system, and how to build and use this package. Its styles can be invoked at run time via the "-sf intel" or "-suffix intel" [command-line switches](#). Also see the [KOKKOS](#), [OPT](#), and [USER-OMP](#) packages, which have styles optimized for CPUs and KNLs.

You need to have an Intel compiler, version 14 or higher to take full advantage of this package. While compilation with GNU compilers is supported, performance will be suboptimal.

NOTE: the USER-INTEL package contains styles that require using the -restrict flag, when compiling with Intel compilers.

Author: Mike Brown (Intel).

Install or un-install:

For the USER-INTEL package, you have 2 choices when building. You can build with either CPU or KNL support. Each choice requires additional settings in your Makefile.machine for CCFLAGS and LINKFLAGS and optimized malloc libraries. See the src/MAKE/OPTIONS/Makefile.intel_cpu and src/MAKE/OPTIONS/Makefile.knl files for examples.

For CPUs:

```
OPTFLAGS = -xHost -O2 -fp-model fast=2 -no-prec-div -qoverride-limits
CCFLAGS = -g -qopenmp -DLAMMPS_MEMALIGN=64 -no-offload -fno-alias -ansi-alias -restrict s
LINKFLAGS = -g -qopenmp $(OPTFLAGS)
LIB = -ltbbmalloc -ltbbmalloc_proxy
```

For KNLs:

```
OPTFLAGS = -xMIC-AVX512 -O2 -fp-model fast=2 -no-prec-div -qoverride-limits
CCFLAGS = -g -qopenmp -DLAMMPS_MEMALIGN=64 -no-offload -fno-alias -ansi-alias -restrict s
LINKFLAGS = -g -qopenmp $(OPTFLAGS)
LIB = -ltbbmalloc
```

Once you have an appropriate Makefile.machine, you can install/un-install the package and build LAMMPS in the usual manner. Note that you cannot build one executable to run on multiple hardware targets (Intel CPUs or KNL). You need to build LAMMPS once for each hardware target, to produce a separate executable.

You should also typically install the USER-OMP package, as it can be used in tandem with the USER-INTEL package to good effect, as explained in [Section 5.3.2](#).

LAMMPS Users Manual

```
make yes-user-intel yes-user-omp  
make machine
```

```
make no-user-intel no-user-omp  
make machine
```

 - src/USER-LB/README
 - [fix lb/fluid](#)
 - [fix lb/momentum](#)
 - [fix lb/viscous](#)
 - examples/USER/lb
-

USER-MGPT package

Contents:

LAMMPS Users Manual

A pair style which provides a fast implementation of the quantum-based MGPT multi-ion potentials. The MGPT or model GPT method derives from first-principles DFT-based generalized pseudopotential theory (GPT) through a series of systematic approximations valid for mid-period transition metals with nearly half-filled d bands. The MGPT method was originally developed by John Moriarty at LLNL. The pair style in this package calculates forces and energies using an optimized matrix-MGPT algorithm due to Tomas Oppelstrup at LLNL.

Authors: Tomas Oppelstrup and John Moriarty (LLNL).

Install or un-install:

```
make yes-user-mgpt  
make machine
```

```
make no-user-mgpt  
make machine
```

Supporting info:

- src/USER-MGPT: filenames -> commands
 - src/USER-MGPT/README
 - [pair_style mgpt](#)
 - examples/USER/mgpt
-

USER-MISC package

Contents:

A potpourri of (mostly) unrelated features contributed to LAMMPS by users. Each feature is a single fix, compute, pair, bond, angle, dihedral, improper, or command style.

Authors: The author for each style in the package is listed in the src/USER-MISC/README file.

Install or un-install:

```
make yes-user-misc  
make machine
```

```
make no-user-misc  
make machine
```

Supporting info:

- src/USER-MISC: filenames -> commands
 - src/USER-MISC/README
 - one doc page per individual command listed in src/USER-MISC/README
 - examples/USER/misc
-

USER-MANIFOLD package

Contents:

Several fixes and a "manifold" class which enable simulations of particles constrained to a manifold (a 2D surface within the 3D simulation box). This is done by applying the RATTLE constraint algorithm to formulate single-particle constraint functions $g(x_i, y_i, z_i) = 0$ and their derivative (i.e. the normal of the manifold) $n = \text{grad}(g)$.

Author: Stefan Paquay (until 2017: Eindhoven University of Technology (TU/e), The Netherlands; since 2017: Brandeis University, Waltham, MA, USA)

Install or un-install:

```
make yes-user-manifold
make machine
```

```
make no-user-manifold
make machine
```

Supporting info:

- src/USER-MANIFOLD: filenames -> commands
 - src/USER-MANIFOLD/README
 - [doc/manifolds](#)
 - [fix manifoldforce](#)
 - [fix nve/manifold/rattle](#)
 - [fix nvt/manifold/rattle](#)
 - examples/USER/manifold
 - <http://lammps.sandia.gov/movies.html#manifold>
-

USER-MEAMC package

Contents:

A pair style for the modified embedded atom (MEAM) potential translated from the Fortran version in the [MEAM](#) package to plain C++. In contrast to the MEAM package, no library needs to be compiled and the pair style can be instantiated multiple times.

Author: Sebastian Huetter, (Otto-von-Guericke University Magdeburg) based on the Fortran version of Greg Wagner (Northwestern U) while at Sandia.

Install or un-install:

```
make yes-user-meamc
make machine
```

```
make no-user-meamc
make machine
```

Supporting info:

- src/USER-MEAMC: filenames -> commands
 - src/USER-MEAMC/README
 - [pair_style meam/c](#)
 - examples/meam
-

USER-MESO package

Contents:

Several extensions of the the dissipative particle dynamics (DPD) method. Specifically, energy-conserving DPD (eDPD) that can model non-isothermal processes, many-body DPD (mDPD) for simulating vapor-liquid coexistence, and transport DPD (tDPD) for modeling advection-diffusion-reaction systems. The equations of motion of these DPD extensions are integrated through a modified velocity-Verlet (MVV) algorithm.

Author: Zhen Li (Division of Applied Mathematics, Brown University)

Install or un-install:

```
make yes-user-meso
make machine
```

```
make no-user-meso
make machine
```

Supporting info:

 - src/USER-MESO/README
 - [atom_style edpd](#)
 - [pair_style edpd](#)
 - [pair_style mdpd](#)
 - [pair_style tdpd](#)
 - [fix mvv/dpd](#)
 - examples/USER/meso
 - <http://lammeps.sandia.gov/movies.html#mesodpd>
-

USER-MOFFF package

Contents:

Pair, angle and improper styles needed to employ the MOF-FF force field by Schmid and coworkers with LAMMPS. MOF-FF is a first principles derived force field with the primary aim to simulate MOFs and related porous framework materials, using spherical Gaussian charges. It is described in S. Bureekaew et al., Phys. Stat. Sol. B 2013, 250, 1128-1141. For the usage of MOF-FF see the example in the example directory as well as the [MOF+](#) website.

LAMMPS Users Manual

Author: Hendrik Heenen (Technical U of Munich), Rochus Schmid (Ruhr-University Bochum).

Install or un-install:

```
make yes-user-mofff
make machine
```

```
make no-user-mofff
make machine
```

Supporting info:

USER-MOLFILE package

Contents:

A [dump molfile](#) command which uses molfile plugins that are bundled with the [VMD](#) molecular visualization and analysis program, to enable LAMMPS to dump snapshots in formats compatible with various molecular simulation tools.

To use this package you must have the desired VMD plugins available on your system.

Note that this package only provides the interface code, not the plugins themselves, which will be accessed when requesting a specific plugin via the [dump molfile](#) command. Plugins can be obtained from a VMD installation which has to match the platform that you are using to compile LAMMPS for. By adding plugins to VMD, support for new file formats can be added to LAMMPS (or VMD or other programs that use them) without having to recompile the application itself. More information about the VMD molfile plugins can be found at <http://www.ks.uiuc.edu/Research/vmd/plugins/molfile>.

Author: Axel Kohlmeyer (Temple U).

Install or un-install:

Note that the lib/molfile/Makefile.lammps file has a setting for a dynamic loading library libdl.a that should be typically present on all systems, which is required for LAMMPS to link with this package. If the setting is not valid for your system, you will need to edit the Makefile.lammps file. See lib/molfile/README and lib/molfile/Makefile.lammps for details.

```
make yes-user-molfile
```

LAMMPS Users Manual

```
make machine
```

```
make no-user-molfile  
make machine
```

Supporting info:

 - lib/molfile/README
 - [dump molfile](#)
-

USER-NETCDF package

Contents:

Dump styles for writing NetCDF formatted dump files. NetCDF is a portable, binary, self-describing file format developed on top of HDF5. The file contents follow the AMBER NetCDF trajectory conventions (<http://ambermd.org/netcdf/nctrjaj.shtml>), but include extensions.

To use this package you must have the NetCDF library available on your system.

Note that NetCDF files can be directly visualized with the following tools:

- [Ovito](#) (Ovito supports the AMBER convention and the extensions mentioned above)
- [VMD](#)
- [AtomEye](#) (the libAtoms version of AtomEye contains a NetCDF reader not present in the standard distribution)

Author: Lars Pastewka (Karlsruhe Institute of Technology).

Install or un-install:

Note that to follow these steps, you need the standard NetCDF software package installed on your system. The lib/netcdf/Makefile.lammps file has settings for NetCDF include and library files that LAMMPS needs to compile and link with this package. If the settings are not valid for your system, you will need to edit the Makefile.lammps file. See lib/netcdf/README for details.

```
make yes-user-netcdf  
make machine
```

```
make no-user-netcdf  
make machine
```

Supporting info:

- src/USER-NETCDF/README

- [lib/netcdf/README](#)
 - [dump netcdf](#)
-

USER-OMP package

Contents:

Hundreds of pair, fix, compute, bond, angle, dihedral, improper, and kspace styles which are altered to enable threading on many-core CPUs via OpenMP directives. All of them have an "omp" in their style name. [Section 5.3.4](#) gives details of what hardware and compilers are required on your system, and how to build and use this package. Its styles can be invoked at run time via the "-sf omp" or "-suffix omp" [command-line switches](#). Also see the [KOKKOS](#), [OPT](#), and [USER-INTEL](#) packages, which have styles optimized for CPUs.

Author: Axel Kohlmeyer (Temple U).

NOTE: To enable multi-threading support the compile flag "-fopenmp" and the link flag "-fopenmp" (for GNU compilers, you have to look up the equivalent flags for other compilers) must be used to build LAMMPS. When using Intel compilers, also the "-restrict" flag is required. The USER-OMP package can be compiled without enabling OpenMP; then all code will be compiled as serial and the only improvement over the regular styles are some data access optimization. These flags should be added to the CCFLAGS and LINKFLAGS lines of your Makefile.machine. See [src/MAKE/OPTIONS/Makefile.omp](#) for an example.

Once you have an appropriate Makefile.machine, you can install/un-install the package and build LAMMPS in the usual manner:

Install or un-install:

```
make yes-user-omp  
make machine
```

```
make no-user-omp  
make machine
```

- CCFLAGS: add -fopenmp (and -restrict when using Intel compilers)
- LINKFLAGS: add -fopenmp

Supporting info:

USER-PHONON package

Contents:

A [fix phonon](#) command that calculates dynamical matrices, which can then be used to compute phonon dispersion relations, directly from molecular dynamics simulations.

Author: Ling-Ti Kong (Shanghai Jiao Tong University).

Install or un-install:

```
make yes-user-phonon
make machine
```

```
make no-user-phonon
make machine
```

Supporting info:

- src/USER-PHONON: filenames -> commands
 - src/USER-PHONON/README
 - [fix phonon](#)
 - examples/USER/phonon
-

USER-QMMM package

Contents:

A [fix qmmm](#) command which allows LAMMPS to be used in a QM/MM simulation, currently only in combination with the [Quantum ESPRESSO](#) package.

To use this package you must have Quantum ESPRESSO available on your system.

The current implementation only supports an ONIOM style mechanical coupling to the Quantum ESPRESSO plane wave DFT package. Electrostatic coupling is in preparation and the interface has been written in a manner that coupling to other QM codes should be possible without changes to LAMMPS itself.

Author: Axel Kohlmeyer (Temple U).

Install or un-install:

Before building LAMMPS with this package, you must first build the QMMM library in lib/qmmm. You can do this manually if you prefer; follow the first two steps explained in lib/qmmm/README. You can also do it in one step from the lammps/src dir, using a command like these, which simply invoke the lib/qmmm/Install.py script with the specified args:

LAMMPS Users Manual

```
make lib-qmmm # print help message
make lib-qmmm args="-m serial" # build with GNU Fortran compiler (settings as in "make ser
make lib-qmmm args="-m mpi" # build with default MPI compiler (settings as in "make mpi
make lib-qmmm args="-m gfortran" # build with GNU Fortran compiler
```

The build should produce two files: lib/qmmm/libqmmm.a and lib/qmmm/Makefile.lammps. The latter is copied from an existing Makefile.lammps.* and has settings needed to build LAMMPS with the QMMM library (though typically the settings are just blank). If necessary, you can edit/create a new lib/qmmm/Makefile.machine file for your system, which should define an EXTRAMAKE variable to specify a corresponding Makefile.lammps.machine file.

You can then install/un-install the package and build LAMMPS in the usual manner:

```
make yes-user-qmmm
make machine
```

```
make no-user-qmmm
make machine
```

NOTE: The LAMMPS executable these steps produce is not yet functional for a QM/MM simulation. You must also build Quantum ESPRESSO and create a new executable which links LAMMPS and Quantum ESPRESSO together. These are steps 3 and 4 described in the lib/qmmm/README file.

Supporting info:

- src/USER-QMMM: filenames -> commands
- src/USER-QMMM/README
- lib/qmmm/README
- [fix phonon](#)
- lib/qmmm/example-ec/README
- lib/qmmm/example-mc/README

USER-QTB package

Contents:

Two fixes which provide a self-consistent quantum treatment of vibrational modes in a classical molecular dynamics simulation. By coupling the MD simulation to a colored thermostat, it introduces zero point energy into the system, altering the energy power spectrum and the heat capacity to account for their quantum nature. This is useful when modeling systems at temperatures lower than their classical limits or when temperatures ramp across the classical limits in a simulation.

Author: Yuan Shen (Stanford U).

Install or un-install:

```
make yes-user-qtb
make machine
```

LAMMPS Users Manual

```
make no-user-qtb
make machine
```

Supporting info:

- src/USER-QTB: filenames -> commands
 - src/USER-QTB/README
 - [fix qtb](#)
 - [fix qbmsst](#)
 - examples/USER/qtbt
-

USER-QUIP package

Contents:

A [pair_style quip](#) command which wraps the [QUIP libAtoms library](#), which includes a variety of interatomic potentials, including Gaussian Approximation Potential (GAP) models developed by the Cambridge University group.

To use this package you must have the QUIP libAtoms library available on your system.

Author: Albert Bartok (Cambridge University)

Install or un-install:

Note that to follow these steps to compile and link to the QUIP library, you must first download and build QUIP on your systems. It can be obtained from GitHub. See step 1 and step 1.1 in the lib/quip/README file for details on how to do this. Note that it requires setting two environment variables, QUIP_ROOT and QUIP_ARCH, which will be accessed by the lib/quip/Makefile.lammps file which is used when you compile and link LAMMPS with this package. You should only need to edit this file if the LAMMPS build can not use its settings to successfully build on your system.

You can then install/un-install the package and build LAMMPS in the usual manner:

```
make yes-user-quip
make machine
```

```
make no-user-quip
make machine
```

Supporting info:

- src/USER-QUIP: filenames -> commands
 - src/USER-QUIP/README
 - [pair_style quip](#)
 - examples/USER/quip
-

USER-REAXC package

Contents:

A pair style which implements the ReaxFF potential in C/C++ (in contrast to the [REAX package](#) and its Fortran library). ReaxFF is universal reactive force field. See the `src/USER-REAXC/README` file for more info on differences between the two packages. Also two fixes for monitoring molecules as bonds are created and destroyed.

Author: Hasan Metin Aktulga (MSU) while at Purdue University.

Install or un-install:

```
make yes-user-reaxc  
make machine
```

```
make no-user-reaxc  
make machine
```

Supporting info:

- `src/USER-REAXC`: filenames -> commands
 - `src/USER-REAXC/README`
 - [pair_style reax/c](#)
 - [fix reax/c/bonds](#)
 - [fix reax/c/species](#)
 - `examples/reax`
-

USER-SMD package

Contents:

An atom style, fixes, computes, and several pair styles which implements smoothed Mach dynamics (SMD) for solids, which is a model related to smoothed particle hydrodynamics (SPH) for liquids (see the [USER-SPH package](#)).

This package solves solids mechanics problems via a state of the art stabilized meshless method with hourglass control. It can specify hydrostatic interactions independently from material strength models, i.e. pressure and deviatoric stresses are separated. It provides many material models (Johnson-Cook, plasticity with hardening, Mie-Grueneisen, Polynomial EOS) and allows new material models to be added. It implements rigid boundary conditions (walls) which can be specified as surface geometries from *.STL files.

Author: Georg Ganzenmuller (Fraunhofer-Institute for High-Speed Dynamics, Ernst Mach Institute, Germany).

Install or un-install:

LAMMPS Users Manual

Before building LAMMPS with this package, you must first download the Eigen library. Eigen is a template library, so you do not need to build it, just download it. You can do this manually if you prefer; follow the instructions in lib/smd/README. You can also do it in one step from the lammops/src dir, using a command like these, which simply invoke the lib/smd/Install.py script with the specified args:

```
make lib-smd                                # print help message
make lib-smd args="-b"                      # download and build in default lib/smd/eigen-eigen-...
make lib-smd args="-p /usr/include/eigen3"  # use existing Eigen installation in /usr/include
```

Note that a symbolic (soft) link named "includelink" is created in lib/smd to point to the Eigen dir. When LAMMPS builds it will use this link. You should not need to edit the lib/smd/Makefile.lammps file.

You can then install/un-install the package and build LAMMPS in the usual manner:

```
make yes-user-smd
make machine
```

```
make no-user-smd
make machine
```

Supporting info:

- src/USER-SMD: filenames -> commands
 - src/USER-SMD/README
 - doc/PDF/SMD_LAMMPS_userguide.pdf
 - examples/USER/smd
 - <http://lammops.sandia.gov/movies.html#smd>
-

USER-SMTBQ package

Contents:

A pair style which implements a Second Moment Tight Binding model with QEq charge equilibration (SMTBQ) potential for the description of ionocovalent bonds in oxides.

Authors: Nicolas Salles, Emile Maras, Olivier Politano, and Robert Tetot (LAAS-CNRS, France).

Install or un-install:

```
make yes-user-smtbq
make machine
```

```
make no-user-smtbq
make machine
```

Supporting info:

LAMMPS Users Manual

- src/USER-SMTBQ: filenames -> commands

-

USER-SPH package

Contents:

An atom style, fixes, computes, and several pair styles which implements smoothed particle hydrodynamics (SPH) for liquids. See the related [USER-SMD package](#) package for smooth Mach dynamics (SMD) for solids.

This package contains ideal gas, Lennard-Jones equation of states, Tait, and full support for complete (i.e. internal-energy dependent) equations of state. It allows for plain or Monaghans XSPH integration of the equations of motion. It has options for density continuity or density summation to propagate the density field. It has [set](#) command options to set the internal energy and density of particles from the input script and allows the same quantities to be output with thermodynamic output or to dump files via the [compute property/atom](#) command.

Author: Georg Ganzenmuller (Fraunhofer-Institute for High-Speed Dynamics, Ernst Mach Institute, Germany).

Install or un-install:

```
make yes-user-sph
make machine
```

```
make no-user-sph
make machine
```

Supporting info:

 - src/USER-SPH/README
 - doc/PDF/SPH_LAMMPS_userguide.pdf
 - examples/USER/sph
 - <http://lammeps.sandia.gov/movies.html#sph>
-

USER-TALLY package

Contents:

Several compute styles that can be called when pairwise interactions are calculated to tally information (forces, heat flux, energy, stress, etc) about individual interactions.

Author: Axel Kohlmeyer (Temple U).

Install or un-install:

```
make yes-user-tally
make machine
```

```
make no-user-tally
make machine
```

Supporting info:

- src/USER-TALLY: filenames -> commands
 - src/USER-TALLY/README
 - [compute */tally](#)
 - examples/USER/tally
-

USER-UEF package

Contents:

A fix style for the integration of the equations of motion under extensional flow with proper boundary conditions, as well as several supporting compute styles and an output option.

Author: David Nicholson (MIT).

Install or un-install:

```
make yes-user-uef
make machine
```

```
make no-user-uef
make machine
```

Supporting info:

- src/USER-UEF: filenames -> commands
 - src/USER-UEF/README
 - [fix nvt/uef](#)
 - [fix npt/uef](#)
 - [compute pressure/uef](#)
 - [compute temp/uef](#)
 - [dump cfg/uef](#)
 - examples/uef
-

USER-VTK package

Contents:

A [dump vtk](#) command which outputs snapshot info in the [VTK format](#), enabling visualization by [Paraview](#) or other visualization packages.

LAMMPS Users Manual

To use this package you must have VTK library available on your system.

Authors: Richard Berger (JKU) and Daniel Queteschiner (DCS Computing).

Install or un-install:

The lib/vtk/Makefile.lammps file has settings for accessing VTK files and its library, which are required for LAMMPS to build and link with this package. If the settings are not valid for your system, check if one of the other lib/vtk/Makefile.lammps.* files is compatible and copy it to Makefile.lammps. If none of the provided files work, you will need to edit the Makefile.lammps file.

You can then install/un-install the package and build LAMMPS in the usual manner:

```
make yes-user-vtk  
make machine
```

```
make no-user-vtk  
make machine
```

Supporting info:

- src/USER-VTK: filenames -> commands
- src/USER-VTK/README
- lib/vtk/README
- [dump vtk](#)

5. Accelerating LAMMPS performance

This section describes various methods for improving LAMMPS performance for different classes of problems running on different kinds of machines.

There are two thrusts to the discussion that follows. The first is using code options that implement alternate algorithms that can speed-up a simulation. The second is to use one of the several accelerator packages provided with LAMMPS that contain code optimized for certain kinds of hardware, including multi-core CPUs, GPUs, and Intel Xeon Phi coprocessors.

- [5.1 Measuring performance](#)
- [5.2 Algorithms and code options to boost performance](#)
- [5.3 Accelerator packages with optimized styles](#)
 - [5.3.1 GPU package](#)
 - [5.3.2 USER-INTEL package](#)
 - [5.3.3 KOKKOS package](#)
 - [5.3.4 USER-OMP package](#)
 - [5.3.5 OPT package](#)
- [5.4 Comparison of various accelerator packages](#)

The [Benchmark page](#) of the LAMMPS web site gives performance results for the various accelerator packages discussed in Section 5.2, for several of the standard LAMMPS benchmark problems, as a function of problem size and number of compute nodes, on different hardware platforms.

5.1 Measuring performance

Before trying to make your simulation run faster, you should understand how it currently performs and where the bottlenecks are.

The best way to do this is run the your system (actual number of atoms) for a modest number of timesteps (say 100 steps) on several different processor counts, including a single processor if possible. Do this for an equilibrium version of your system, so that the 100-step timings are representative of a much longer run. There is typically no need to run for 1000s of timesteps to get accurate timings; you can simply extrapolate from short runs.

For the set of runs, look at the timing data printed to the screen and log file at the end of each LAMMPS run. [This section](#) of the manual has an overview.

Running on one (or a few processors) should give a good estimate of the serial performance and what portions of the timestep are taking the most time. Running the same problem on a few different processor counts should give an estimate of parallel scalability. I.e. if the simulation runs 16x faster on 16 processors, its 100% parallel efficient; if it runs 8x faster on 16 processors, it's 50% efficient.

LAMMPS Users Manual

The most important data to look at in the timing info is the timing breakdown and relative percentages. For example, trying different options for speeding up the long-range solvers will have little impact if they only consume 10% of the run time. If the pairwise time is dominating, you may want to look at GPU or OMP versions of the pair style, as discussed below. Comparing how the percentages change as you increase the processor count gives you a sense of how different operations within the timestep are scaling. Note that if you are running with a Kspace solver, there is additional output on the breakdown of the Kspace time. For PPPM, this includes the fraction spent on FFTs, which can be communication intensive.

Another important detail in the timing info are the histograms of atoms counts and neighbor counts. If these vary widely across processors, you have a load-imbalance issue. This often results in inaccurate relative timing data, because processors have to wait when communication occurs for other processors to catch up. Thus the reported times for "Communication" or "Other" may be higher than they really are, due to load-imbalance. If this is an issue, you can uncomment the `MPI_Barrier()` lines in `src/timer.cpp`, and recompile LAMMPS, to obtain synchronized timings.

5.2 General strategies

NOTE: this section 5.2 is still a work in progress

Here is a list of general ideas for improving simulation performance. Most of them are only applicable to certain models and certain bottlenecks in the current performance, so let the timing data you generate be your guide. It is hard, if not impossible, to predict how much difference these options will make, since it is a function of problem size, number of processors used, and your machine. There is no substitute for identifying performance bottlenecks, and trying out various options.

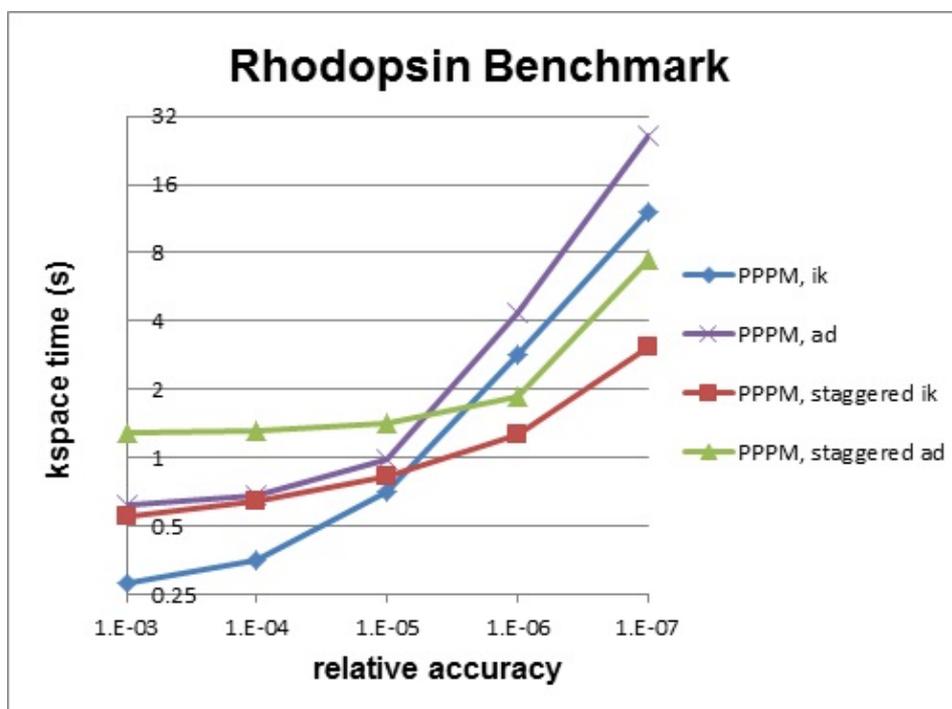

- rRESPA
- 2-FFT PPPM
- Staggered PPPM
- single vs double PPPM
- partial charge PPPM
- verlet/split run style
- processor command for proc layout and numa layout
- load-balancing: balance and fix balance

2-FFT PPPM, also called *analytic differentiation* or *ad* PPPM, uses 2 FFTs instead of the 4 FFTs used by the default *ik differentiation* PPPM. However, 2-FFT PPPM also requires a slightly larger mesh size to achieve the same accuracy as 4-FFT PPPM. For problems where the FFT cost is the performance bottleneck (typically large problems running on many processors), 2-FFT PPPM may be faster than 4-FFT PPPM.

Staggered PPPM performs calculations using two different meshes, one shifted slightly with respect to the other. This can reduce force aliasing errors and increase the accuracy of the method, but also doubles the amount of work required. For high relative accuracy, using staggered PPPM allows one to half the mesh size in each dimension as compared to regular PPPM, which can give around a 4x speedup in the kspace time. However, for low relative accuracy, using staggered PPPM gives little benefit and can be up to 2x slower in the kspace time. For example, the rhodopsin

LAMMPS Users Manual

benchmark was run on a single processor, and results for kspace time vs. relative accuracy for the different methods are shown in the figure below. For this system, staggered PPPM (using ik differentiation) becomes useful when using a relative accuracy of slightly greater than $1e-5$ and above.

NOTE: Using staggered PPPM may not give the same increase in accuracy of energy and pressure as it does in forces, so some caution must be used if energy and/or pressure are quantities of interest, such as when using a barostat.

5.3 Packages with optimized styles

Accelerated versions of various [pair_style](#), [fixes](#), [computes](#), and other commands have been added to LAMMPS, which will typically run faster than the standard non-accelerated versions. Some require appropriate hardware to be present on your system, e.g. GPUs or Intel Xeon Phi coprocessors.

All of these commands are in packages provided with LAMMPS. An overview of packages is give in [Section packages](#).

These are the accelerator packages currently in LAMMPS, either as standard or user packages:

GPU Package	for NVIDIA GPUs as well as OpenCL support
USER-INTEL Package	for Intel CPUs and Intel Xeon Phi
KOKKOS Package	for Nvidia GPUs, Intel Xeon Phi, and OpenMP threading
USER-OMP Package	for OpenMP threading and generic CPU optimizations
OPT Package	generic CPU optimizations

Inverting this list, LAMMPS currently has acceleration support for three kinds of

LAMMPS Users Manual

hardware, via the listed packages:

Many-core CPUs	USER-INTEL , KOKKOS , USER-OMP , OPT packages
NVIDIA GPUs	GPU , KOKKOS packages
Intel Phi	USER-INTEL , KOKKOS packages

Which package is fastest for your hardware may depend on the size problem you are running and what commands (accelerated and non-accelerated) are invoked by your input script. While these doc pages include performance guidelines, there is no substitute for trying out the different packages appropriate to your hardware.

Any accelerated style has the same name as the corresponding standard style, except that a suffix is appended. Otherwise, the syntax for the command that uses the style is identical, their functionality is the same, and the numerical results it produces should also be the same, except for precision and round-off effects.

For example, all of these styles are accelerated variants of the Lennard-Jones [pair_style lj/cut](#):

- [pair_style lj/cut/gpu](#)
- [pair_style lj/cut/intel](#)
- [pair_style lj/cut/kk](#)
- [pair_style lj/cut/omp](#)
- [pair_style lj/cut/opt](#)

To see what accelerate styles are currently available, see [Section 3.5](#) of the manual. The doc pages for individual commands (e.g. [pair lj/cut](#) or [fix nve](#)) also list any accelerated variants available for that style.

To use an accelerator package in LAMMPS, and one or more of the styles it provides, follow these general steps. Details vary from package to package and are explained in the individual accelerator doc pages, listed above:

build the accelerator library	only for GPU package
install the accelerator package	make yes-opt, make yes-user-intel, etc
add compile/link flags to Makefile.machine in src/MAKE	only for USER-INTEL , KOKKOS , USER-OMP , OPT packages
re-build LAMMPS	make machine
prepare and test a regular LAMMPS simulation	<code>lmp_machine -in in.script; mpirun -np 32 lmp_machine -in in.script</code>
enable specific accelerator support via '-k on' command-line switch ,	only needed for KOKKOS package
set any needed options for the package via "-pk" command-line switch or package command,	only if defaults need to be changed
use accelerated styles in your input via "-sf" command-line switch or suffix command	<code>lmp_machine -in in.script -sf gpu</code>

Note that the first 4 steps can be done as a single command with suitable make command invocations. This is discussed in [Section 4](#) of the manual, and its use is

LAMMPS Users Manual

illustrated in the individual accelerator sections. Typically these steps only need to be done once, to create an executable that uses one or more accelerator packages.

The last 4 steps can all be done from the command-line when LAMMPS is launched, without changing your input script, as illustrated in the individual accelerator sections. Or you can add [package](#) and [suffix](#) commands to your input script.

NOTE: With a few exceptions, you can build a single LAMMPS executable with all its accelerator packages installed. Note however that the USER-INTEL and KOKKOS packages require you to choose one of their hardware options when building for a specific platform. I.e. CPU or Phi option for the USER-INTEL package. Or the OpenMP, Cuda, or Phi option for the KOKKOS package.

These are the exceptions. You cannot build a single executable with:

- both the USER-INTEL Phi and KOKKOS Phi options
- the USER-INTEL Phi or Kokkos Phi option, and the GPU package

See the [examples/accelerate/README](#) and `make.list` files for sample `Make.py` commands that build LAMMPS with any or all of the accelerator packages. As an example, here is a command that builds with all the GPU related packages installed (GPU, KOKKOS with Cuda), including settings to build the needed auxiliary GPU libraries for Kepler GPUs:

```
Make.py -j 16 -p omp gpu kokkos -cc nvcc wrap=mpi -gpu mode=double arch=35 -kokkos cuda arch=
```

The `examples/accelerate` directory also has input scripts that can be used with all of the accelerator packages. See its `README` file for details.

Likewise, the `bench` directory has `FERMI` and `KEPLER` and `PHI` sub-directories with `Make.py` commands and input scripts for using all the accelerator packages on various machines. See the `README` files in those dirs.

As mentioned above, the [Benchmark page](#) of the LAMMPS web site gives performance results for the various accelerator packages for several of the standard LAMMPS benchmark problems, as a function of problem size and number of compute nodes, on different hardware platforms.

Here is a brief summary of what the various packages provide. Details are in the individual accelerator sections.

- Styles with a "gpu" suffix are part of the GPU package, and can be run on NVIDIA GPUs. The speed-up on a GPU depends on a variety of factors, discussed in the accelerator sections.
- Styles with an "intel" suffix are part of the USER-INTEL package. These styles support vectorized single and mixed precision calculations, in addition to full double precision. In extreme cases, this can provide speedups over 3.5x on CPUs. The package also supports acceleration in "offload" mode to Intel(R) Xeon Phi(TM) coprocessors. This can result in additional speedup over 2x depending on the hardware configuration.

LAMMPS Users Manual

- Styles with a "kk" suffix are part of the KOKKOS package, and can be run using OpenMP on multicore CPUs, on an NVIDIA GPU, or on an Intel Xeon Phi in "native" mode. The speed-up depends on a variety of factors, as discussed on the KOKKOS accelerator page.
- Styles with an "omp" suffix are part of the USER-OMP package and allow a pair-style to be run in multi-threaded mode using OpenMP. This can be useful on nodes with high-core counts when using less MPI processes than cores is advantageous, e.g. when running with PPPM so that FFTs are run on fewer MPI processors or when the many MPI tasks would overload the available bandwidth for communication.
- Styles with an "opt" suffix are part of the OPT package and typically speed-up the pairwise calculations of your simulation by 5-25% on a CPU.

The individual accelerator package doc pages explain:

- what hardware and software the accelerated package requires
- how to build LAMMPS with the accelerated package
- how to run with the accelerated package either via command-line switches or modifying the input script
- speed-ups to expect
- guidelines for best performance
- restrictions

5.4 Comparison of various accelerator packages

NOTE: this section still needs to be re-worked with additional KOKKOS and USER-INTEL information.

The next section compares and contrasts the various accelerator options, since there are multiple ways to perform OpenMP threading, run on GPUs, and run on Intel Xeon Phi coprocessors.

All 3 of these packages accelerate a LAMMPS calculation using NVIDIA hardware, but they do it in different ways.

As a consequence, for a particular simulation on specific hardware, one package may be faster than the other. We give guidelines below, but the best way to determine which package is faster for your input script is to try both of them on your machine. See the benchmarking section below for examples where this has been done.

Guidelines for using each package optimally:

- The GPU package allows you to assign multiple CPUs (cores) to a single GPU (a common configuration for "hybrid" nodes that contain multicore CPU(s) and GPU(s)) and works effectively in this mode.
- The GPU package moves per-atom data (coordinates, forces) back-and-forth between the CPU and GPU every timestep. The KOKKOS/CUDA package only does this on timesteps when a CPU calculation is required (e.g. to invoke a fix or compute that is non-GPU-ized). Hence, if you can formulate your input script to only use GPU-ized fixes and computes, and avoid doing I/O too often (thermo output, dump file snapshots, restart files), then the data transfer cost of the

LAMMPS Users Manual

KOKKOS/CUDA package can be very low, causing it to run faster than the GPU package.

- The GPU package is often faster than the KOKKOS/CUDA package, if the number of atoms per GPU is smaller. The crossover point, in terms of atoms/GPU at which the KOKKOS/CUDA package becomes faster depends strongly on the pair style. For example, for a simple Lennard Jones system the crossover (in single precision) is often about 50K-100K atoms per GPU. When performing double precision calculations the crossover point can be significantly smaller.
- Both packages compute bonded interactions (bonds, angles, etc) on the CPU. If the GPU package is running with several MPI processes assigned to one GPU, the cost of computing the bonded interactions is spread across more CPUs and hence the GPU package can run faster.
- When using the GPU package with multiple CPUs assigned to one GPU, its performance depends to some extent on high bandwidth between the CPUs and the GPU. Hence its performance is affected if full 16 PCIe lanes are not available for each GPU. In HPC environments this can be the case if S2050/70 servers are used, where two devices generally share one PCIe 2.0 16x slot. Also many multi-GPU mainboards do not provide full 16 lanes to each of the PCIe 2.0 16x slots.

Differences between the two packages:

- The GPU package accelerates only pair force, neighbor list, and PPPM calculations.
- The GPU package requires neighbor lists to be built on the CPU when using exclusion lists, hybrid pair styles, or a triclinic simulation box.

[Return to Section accelerate overview](#)

5.3.1 GPU package

The GPU package was developed by Mike Brown at ORNL and his collaborators, particularly Trung Nguyen (ORNL). It provides GPU versions of many pair styles, including the 3-body Stillinger-Weber pair style, and for [kspace_style pppm](#) for long-range Coulombics. It has the following general features:

- It is designed to exploit common GPU hardware configurations where one or more GPUs are coupled to many cores of one or more multi-core CPUs, e.g. within a node of a parallel machine.
- Atom-based data (e.g. coordinates, forces) moves back-and-forth between the CPU(s) and GPU every timestep.
- Neighbor lists can be built on the CPU or on the GPU
- The charge assignment and force interpolation portions of PPPM can be run on the GPU. The FFT portion, which requires MPI communication between processors, runs on the CPU.
- Asynchronous force computations can be performed simultaneously on the CPU(s) and GPU.
- It allows for GPU computations to be performed in single or double precision, or in mixed-mode precision, where pairwise forces are computed in single precision, but accumulated into double-precision force vectors.
- LAMMPS-specific code is in the GPU package. It makes calls to a generic GPU library in the lib/gpu directory. This library provides NVIDIA support as well as more general OpenCL support, so that the same functionality can eventually be supported on a variety of GPU hardware.

Here is a quick overview of how to enable and use the GPU package:

- build the library in lib/gpu for your GPU hardware with the desired precision settings
- install the GPU package and build LAMMPS as usual
- use the mpirun command to set the number of MPI tasks/node which determines the number of MPI tasks/GPU
- specify the # of GPUs per node
- use GPU styles in your input script

The latter two steps can be done using the "-pk gpu" and "-sf gpu" [command-line switches](#) respectively. Or the effect of the "-pk" or "-sf" switches can be duplicated by adding the [package gpu](#) or [suffix gpu](#) commands respectively to your input script.

Required hardware/software:

To use this package, you currently need to have an NVIDIA GPU and install the NVIDIA CUDA software on your system:

- Check if you have an NVIDIA GPU: `cat /proc/driver/nvidia/gpus/0/information`

LAMMPS Users Manual

- Go to http://www.nvidia.com/object/cuda_get.html
- Install a driver and toolkit appropriate for your system (SDK is not necessary)
- Run `lammeps/lib/gpu/nvc_get_devices` (after building the GPU library, see below) to list supported devices and properties

Building LAMMPS with the GPU package:

This requires two steps (a,b): build the GPU library, then build LAMMPS with the GPU package.

You can do both these steps in one line as described in [Section 4](#) of the manual.

Or you can follow these two (a,b) steps:

(a) Build the GPU library

The GPU library is in `lammeps/lib/gpu`. Select a `Makefile.machine` (in `lib/gpu`) appropriate for your system. You should pay special attention to 3 settings in this makefile.

- `CUDA_HOME` = needs to be where NVIDIA CUDA software is installed on your system
- `CUDA_ARCH` = needs to be appropriate to your GPUs
- `CUDA_PREC` = precision (double, mixed, single) you desire

See `lib/gpu/Makefile.linux.double` for examples of the `ARCH` settings for different GPU choices, e.g. Fermi vs Kepler. It also lists the possible precision settings:

```
CUDA_PREC = -D_SINGLE_SINGLE # single precision for all calculations
CUDA_PREC = -D_DOUBLE_DOUBLE # double precision for all calculations
CUDA_PREC = -D_SINGLE_DOUBLE # accumulation of forces, etc, in double
```

The last setting is the mixed mode referred to above. Note that your GPU must support double precision to use either the 2nd or 3rd of these settings.

To build the library, type:

```
make -f Makefile.machine
```

If successful, it will produce the files `libgpu.a` and `Makefile.lammeps`.

The latter file has 3 settings that need to be appropriate for the paths and settings for the CUDA system software on your machine. `Makefile.lammeps` is a copy of the file specified by the `EXTRAMAKE` setting in `Makefile.machine`. You can change `EXTRAMAKE` or create your own `Makefile.lammeps.machine` if needed.

Note that to change the precision of the GPU library, you need to re-build the entire library. Do a "clean" first, e.g. `"make -f Makefile.linux clean"`, followed by the make command above.

(b) Build LAMMPS with the GPU package

LAMMPS Users Manual

```
cd lammeps/src
make yes-gpu
make machine
```

No additional compile/link flags are needed in Makefile.machine.

Note that if you change the GPU library precision (discussed above) and rebuild the GPU library, then you also need to re-install the GPU package and re-build LAMMPS, so that all affected files are re-compiled and linked to the new GPU library.

Run with the GPU package from the command line:

The `mpirun` or `mpiexec` command sets the total number of MPI tasks used by LAMMPS (one or multiple per compute node) and the number of MPI tasks used per node. E.g. the `mpirun` command in MPICH does this via its `-np` and `-ppn` switches. Ditto for OpenMPI via `-np` and `-npernode`.

When using the GPU package, you cannot assign more than one GPU to a single MPI task. However multiple MPI tasks can share the same GPU, and in many cases it will be more efficient to run this way. Likewise it may be more efficient to use less MPI tasks/node than the available # of CPU cores. Assignment of multiple MPI tasks to a GPU will happen automatically if you create more MPI tasks/node than there are GPUs/node. E.g. with 8 MPI tasks/node and 2 GPUs, each GPU will be shared by 4 MPI tasks.

Use the `"-sf gpu"` [command-line switch](#), which will automatically append `"gpu"` to styles that support it. Use the `"-pk gpu Ng"` [command-line switch](#) to set `Ng = # of GPUs/node to use`.

```
lmp_machine -sf gpu -pk gpu 1 -in in.script # 1 MPI task uses 1 GPU
mpirun -np 12 lmp_machine -sf gpu -pk gpu 2 -in in.script # 12 MPI tasks share 2 GPUs
mpirun -np 48 -ppn 12 lmp_machine -sf gpu -pk gpu 2 -in in.script # ditto on 4 16-core nodes
```

Note that if the `"-sf gpu"` switch is used, it also issues a default [package gpu 1](#) command, which sets the number of GPUs/node to 1.

Using the `"-pk"` switch explicitly allows for setting of the number of GPUs/node to use and additional options. Its syntax is the same as same as the `"package gpu"` command. See the [package](#) command doc page for details, including the default values used for all its options if it is not specified.

Note that the default for the [package gpu](#) command is to set the Newton flag to "off" pairwise interactions. It does not affect the setting for bonded interactions (LAMMPS default is "on"). The "off" setting for pairwise interaction is currently required for GPU package pair styles.

Or run with the GPU package by editing an input script:

The discussion above for the `mpirun/mpiexec` command, MPI tasks/node, and use of multiple MPI tasks/GPU is the same.

LAMMPS Users Manual

Use the [suffix gpu](#) command, or you can explicitly add an "gpu" suffix to individual styles in your input script, e.g.

```
pair_style lj/cut/gpu 2.5
```

You must also use the [package gpu](#) command to enable the GPU package, unless the "-sf gpu" or "-pk gpu" [command-line switches](#) were used. It specifies the number of GPUs/node to use, as well as other options.

Speed-ups to expect:

The performance of a GPU versus a multi-core CPU is a function of your hardware, which pair style is used, the number of atoms/GPU, and the precision used on the GPU (double, single, mixed).

See the [Benchmark page](#) of the LAMMPS web site for performance of the GPU package on various hardware, including the Titan HPC platform at ORNL.

You should also experiment with how many MPI tasks per GPU to use to give the best performance for your problem and machine. This is also a function of the problem size and the pair style being using. Likewise, you should experiment with the precision setting for the GPU library to see if single or mixed precision will give accurate results, since they will typically be faster.

Guidelines for best performance:

- Using multiple MPI tasks per GPU will often give the best performance, as allowed by most multi-core CPU/GPU configurations.
- If the number of particles per MPI task is small (e.g. 100s of particles), it can be more efficient to run with fewer MPI tasks per GPU, even if you do not use all the cores on the compute node.
- The [package gpu](#) command has several options for tuning performance. Neighbor lists can be built on the GPU or CPU. Force calculations can be dynamically balanced across the CPU cores and GPUs. GPU-specific settings can be made which can be optimized for different hardware. See the [package](#) command doc page for details.
- As described by the [package gpu](#) command, GPU accelerated pair styles can perform computations asynchronously with CPU computations. The "Pair" time reported by LAMMPS will be the maximum of the time required to complete the CPU pair style computations and the time required to complete the GPU pair style computations. Any time spent for GPU-enabled pair styles for computations that run simultaneously with [bond](#), [angle](#), [dihedral](#), [improper](#), and [long-range](#) calculations will not be included in the "Pair" time.
- When the *mode* setting for the [package gpu](#) command is *force/neighbor*, the time for neighbor list calculations on the GPU will be added into the "Pair" time, not the "Neighbor" time. An additional breakdown of the times required for various tasks on the GPU (data copy, neighbor calculations, force computations, etc) are output only with the LAMMPS screen output (not in the log file) at the end of each run. These timings represent total time spent on the GPU for each routine, regardless of asynchronous CPU calculations.

LAMMPS Users Manual

- The output section "GPU Time Info (average)" reports "Max Mem / Proc". This is the maximum memory used at one time on the GPU for data storage by a single MPI process.

Restrictions:

None.

[Return to Section accelerate overview](#)

5.3.2 USER-INTEL package

The USER-INTEL package is maintained by Mike Brown at Intel Corporation. It provides two methods for accelerating simulations, depending on the hardware you have. The first is acceleration on Intel CPUs by running in single, mixed, or double precision with vectorization. The second is acceleration on Intel Xeon Phi coprocessors via offloading neighbor list and non-bonded force calculations to the Phi. The same C++ code is used in both cases. When offloading to a coprocessor from a CPU, the same routine is run twice, once on the CPU and once with an offload flag. This allows LAMMPS to run on the CPU cores and coprocessor cores simultaneously.

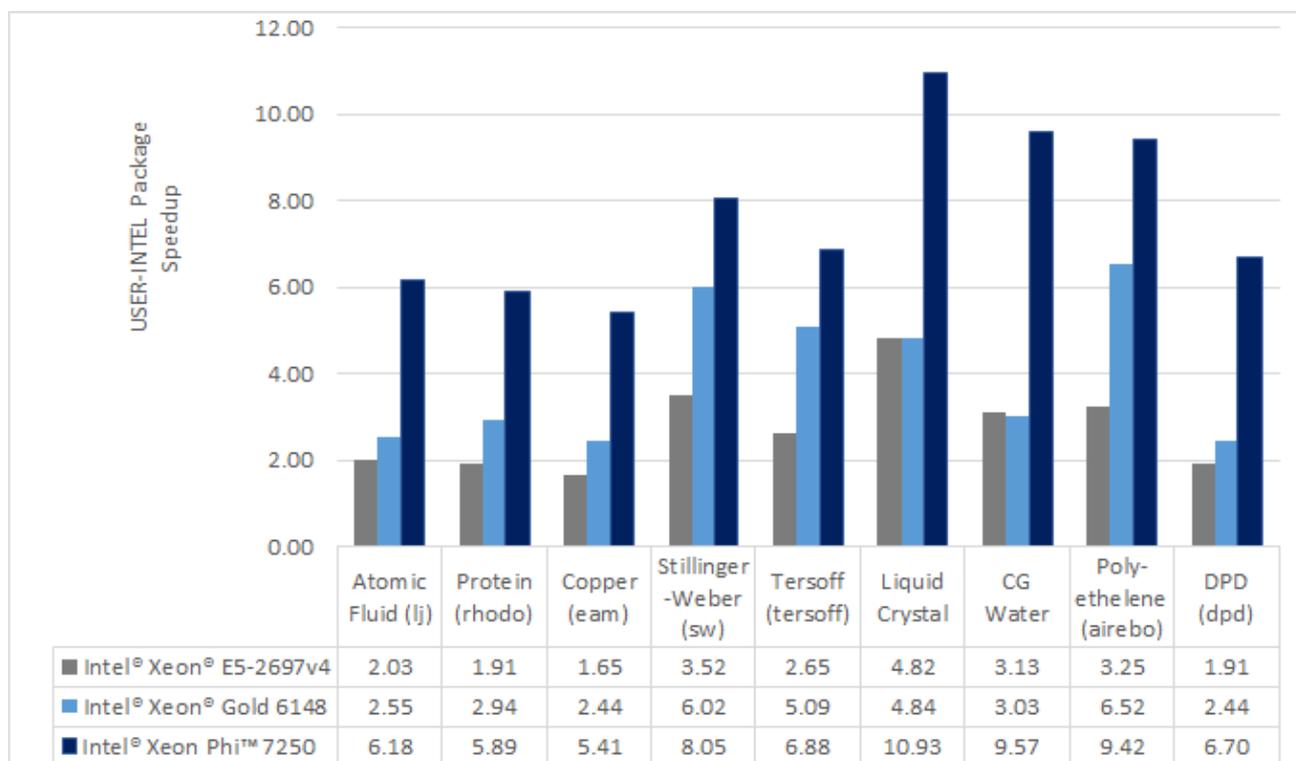

Currently Available USER-INTEL Styles:

- Angle Styles: charmm, harmonic
- Bond Styles: fene, fourier, harmonic
- Dihedral Styles: charmm, harmonic, opls
- Fixes: nve, npt, nvt, nvt/sllod, nve/asphere
- Improper Styles: cvff, harmonic
- Pair Styles: airebo, airebo/morse, buck/coul/cut, buck/coul/long, buck, dpd, eam, eam/alloy, eam/fs, gayberne, lj/charmm/coul/charmm, lj/charmm/coul/long, lj/cut, lj/cut/coul/long, lj/long/coul/long, rebo, sw, tersoff
- K-Space Styles: pppm, pppm/disp

Speed-ups to expect:

The speedups will depend on your simulation, the hardware, which styles are used, the number of atoms, and the floating-point precision mode. Performance improvements are shown compared to LAMMPS *without using other acceleration packages* as these are under active development (and subject to performance changes). The measurements were performed using the input files available in the src/USER-INTEL/TEST directory with the provided run script. These are scalable in size; the results given are with 512K particles (524K for Liquid Crystal). Most of the simulations are standard LAMMPS benchmarks (indicated by the filename extension in parenthesis) with modifications to the run length and to add a warmup run (for use with offload benchmarks).

LAMMPS Users Manual

Results are speedups obtained on Intel Xeon E5-2697v4 processors (code-named Broadwell), Intel Xeon Phi 7250 processors (code-named Knights Landing), and Intel Xeon Gold 6148 processors (code-named Skylake) with "June 2017" LAMMPS built with Intel Parallel Studio 2017 update 2. Results are with 1 MPI task per physical core. See *src/USER-INTEL/TEST/README* for the raw simulation rates and instructions to reproduce.

Accuracy and order of operations:

In most molecular dynamics software, parallelization parameters (# of MPI, OpenMP, and vectorization) can change the results due to changing the order of operations with finite-precision calculations. The USER-INTEL package is deterministic. This means that the results should be reproducible from run to run with the *same* parallel configurations and when using deterministic libraries or library settings (MPI, OpenMP, FFT). However, there are differences in the USER-INTEL package that can change the order of operations compared to LAMMPS without acceleration:

- Neighbor lists can be created in a different order
- Bins used for sorting atoms can be oriented differently
- The default stencil order for PPPM is 7. By default, LAMMPS will calculate other PPPM parameters to fit the desired accuracy with this order
- The *newton* setting applies to all atoms, not just atoms shared between MPI tasks
- Vectorization can change the order for adding pairwise forces
- When using the `-DLMP_USE_MKL_RNG` define (all included intel optimized makefiles do) at build time, the random number generator for dissipative particle dynamics (pair style dpd/intel) uses the Mersenne Twister generator included in the Intel MKL library (that should be more robust than the default

LAMMPS Users Manual

Masaglia random number generator)

The precision mode (described below) used with the USER-INTEL package can change the *accuracy* of the calculations. For the default *mixed* precision option, calculations between pairs or triplets of atoms are performed in single precision, intended to be within the inherent error of MD simulations. All accumulation is performed in double precision to prevent the error from growing with the number of atoms in the simulation. *Single* precision mode should not be used without appropriate validation.

Quick Start for Experienced Users:

LAMMPS should be built with the USER-INTEL package installed. Simulations should be run with 1 MPI task per physical *core*, not *hardware thread*.

- Edit src/MAKE/OPTIONS/Makefile.intel_cpu_intelmpi as necessary.
- Set the environment variable KMP_BLOCKTIME=0
- "-pk intel 0 omp \$t -sf intel" added to LAMMPS command-line
- \$t should be 2 for Intel Xeon CPUs and 2 or 4 for Intel Xeon Phi
- For some of the simple 2-body potentials without long-range electrostatics, performance and scalability can be better with the "newton off" setting added to the input script
- For simulations on higher node counts, add "processors * * * grid numa" to the beginning of the input script for better scalability
- If using *kpace_style ppm* in the input script, add "kpace_modify diff ad" for better performance

For Intel Xeon Phi CPUs:

- Runs should be performed using MCDRAM.

For simulations using *kpace_style ppm* on Intel CPUs supporting AVX-512:

- Add "kpace_modify diff ad" to the input script
- The command-line option should be changed to "-pk intel 0 omp \$r lrt yes -sf intel" where \$r is the number of threads minus 1.
- Do not use thread affinity (set KMP_AFFINITY=none)
- The "newton off" setting may provide better scalability

For Intel Xeon Phi coprocessors (Offload):

- Edit src/MAKE/OPTIONS/Makefile.intel_coprocessor as necessary
- "-pk intel N omp 1" added to command-line where N is the number of coprocessors per node.

Required hardware/software:

In order to use offload to coprocessors, an Intel Xeon Phi coprocessor and an Intel compiler are required. For this, the recommended version of the Intel compiler is 14.0.1.106 or versions 15.0.2.044 and higher.

LAMMPS Users Manual

Although any compiler can be used with the USER-INTEL package, currently, vectorization directives are disabled by default when not using Intel compilers due to lack of standard support and observations of decreased performance. The OpenMP standard now supports directives for vectorization and we plan to transition the code to this standard once it is available in most compilers. We expect this to allow improved performance and support with other compilers.

For Intel Xeon Phi x200 series processors (code-named Knights Landing), there are multiple configuration options for the hardware. For best performance, we recommend that the MCDRAM is configured in "Flat" mode and with the cluster mode set to "Quadrant" or "SNC4". "Cache" mode can also be used, although the performance might be slightly lower.

Notes about Simultaneous Multithreading:

Modern CPUs often support Simultaneous Multithreading (SMT). On Intel processors, this is called Hyper-Threading (HT) technology. SMT is hardware support for running multiple threads efficiently on a single core. *Hardware threads* or *logical cores* are often used to refer to the number of threads that are supported in hardware. For example, the Intel Xeon E5-2697v4 processor is described as having 36 cores and 72 threads. This means that 36 MPI processes or OpenMP threads can run simultaneously on separate cores, but that up to 72 MPI processes or OpenMP threads can be running on the CPU without costly operating system context switches.

Molecular dynamics simulations will often run faster when making use of SMT. If a thread becomes stalled, for example because it is waiting on data that has not yet arrived from memory, another thread can start running so that the CPU pipeline is still being used efficiently. Although benefits can be seen by launching a MPI task for every hardware thread, for multinode simulations, we recommend that OpenMP threads are used for SMT instead, either with the USER-INTEL package, [USER-OMP package](#), or [KOKKOS package](#). In the example above, up to 36X speedups can be observed by using all 36 physical cores with LAMMPS. By using all 72 hardware threads, an additional 10-30% performance gain can be achieved.

The BIOS on many platforms allows SMT to be disabled, however, we do not recommend this on modern processors as there is little to no benefit for any software package in most cases. The operating system will report every hardware thread as a separate core allowing one to determine the number of hardware threads available. On Linux systems, this information can normally be obtained with:

```
cat /proc/cpuinfo
```

Building LAMMPS with the USER-INTEL package:

NOTE: See the src/USER-INTEL/README file for additional flags that might be needed for best performance on Intel server processors code-named "Skylake".

The USER-INTEL package must be installed into the source directory:

```
make yes-user-intel
```

LAMMPS Users Manual

Several example Makefiles for building with the Intel compiler are included with LAMMPS in the `src/MAKE/OPTIONS/` directory:

```
Makefile.intel_cpu_intelmpi # Intel Compiler, Intel MPI, No Offload
Makefile.knl                # Intel Compiler, Intel MPI, No Offload
Makefile.intel_cpu_mpich    # Intel Compiler, MPICH, No Offload
Makefile.intel_cpu_openmpi  # Intel Compiler, OpenMPI, No Offload
Makefile.intel_coprocessor  # Intel Compiler, Intel MPI, Offload
```

`Makefile.knl` is identical to `Makefile.intel_cpu_intelmpi` except that it explicitly specifies that vectorization should be for Intel Xeon Phi x200 processors making it easier to cross-compile. For users with recent installations of Intel Parallel Studio, the process can be as simple as:

```
make yes-user-intel
source /opt/intel/parallel_studio_xe_2016.3.067/psxevars.sh
# or psxevars.csh for C-shell
make intel_cpu_intelmpi
```

Alternatively this can be done as a single command with suitable make command invocations. This is discussed in [Section 4](#) of the manual.

Note that if you build with support for a Phi coprocessor, the same binary can be used on nodes with or without coprocessors installed. However, if you do not have coprocessors on your system, building without offload support will produce a smaller binary.

The general requirements for Makefiles with the USER-INTEL package are as follows. When using Intel compilers, `"-restrict"` is required and `"-qopenmp"` is highly recommended for `CCFLAGS` and `LINKFLAGS`. `CCFLAGS` should include `"-DLMP_INTEL_USELRT"` (unless POSIX Threads are not supported in the build environment) and `"-DLMP_USE_MKL_RNG"` (unless Intel Math Kernel Library (MKL) is not available in the build environment). For Intel compilers, `LIB` should include `"-ltbbmalloc"` or if the library is not available, `"-DLMP_INTEL_NO_TBB"` can be added to `CCFLAGS`. For builds supporting offload, `"-DLMP_INTEL_OFFLOAD"` is required for `CCFLAGS` and `"-qoffload"` is required for `LINKFLAGS`. Other recommended `CCFLAG` options for best performance are `"-O2 -fno-alias -ansi-alias -qoverride-limits fp-model fast=2 -no-prec-div"`.

NOTE: The vectorization and math capabilities can differ depending on the CPU. For Intel compilers, the `"-x"` flag specifies the type of processor for which to optimize. `"-xHost"` specifies that the compiler should build for the processor used for compiling. For Intel Xeon Phi x200 series processors, this option is `"-xMIC-AVX512"`. For fourth generation Intel Xeon (v4/Broadwell) processors, `"-xCORE-AVX2"` should be used. For older Intel Xeon processors, `"-xAVX"` will perform best in general for the different simulations in LAMMPS. The default in most of the example Makefiles is to use `"-xHost"`, however this should not be used when cross-compiling.

Running LAMMPS with the USER-INTEL package:

Running LAMMPS with the USER-INTEL package is similar to normal use with the exceptions that one should 1) specify that LAMMPS should use the USER-INTEL

LAMMPS Users Manual

package, 2) specify the number of OpenMP threads, and 3) optionally specify the specific LAMMPS styles that should use the USER-INTEL package. 1) and 2) can be performed from the command-line or by editing the input script. 3) requires editing the input script. Advanced performance tuning options are also described below to get the best performance.

When running on a single node (including runs using offload to a coprocessor), best performance is normally obtained by using 1 MPI task per physical core and additional OpenMP threads with SMT. For Intel Xeon processors, 2 OpenMP threads should be used for SMT. For Intel Xeon Phi CPUs, 2 or 4 OpenMP threads should be used (best choice depends on the simulation). In cases where the user specifies that LRT mode is used (described below), 1 or 3 OpenMP threads should be used. For multi-node runs, using 1 MPI task per physical core will often perform best, however, depending on the machine and scale, users might get better performance by decreasing the number of MPI tasks and using more OpenMP threads. For performance, the product of the number of MPI tasks and OpenMP threads should not exceed the number of available hardware threads in almost all cases.

NOTE: Setting core affinity is often used to pin MPI tasks and OpenMP threads to a core or group of cores so that memory access can be uniform. Unless disabled at build time, affinity for MPI tasks and OpenMP threads on the host (CPU) will be set by default on the host *when using offload to a coprocessor*. In this case, it is unnecessary to use other methods to control affinity (e.g. taskset, numactl, I_MPI_PIN_DOMAIN, etc.). This can be disabled with the *no_affinity* option to the [package intel](#) command or by disabling the option at build time (by adding `-DINTEL_OFFLOAD_NOAFFINITY` to the CCFLAGS line of your Makefile). Disabling this option is not recommended, especially when running on a machine with Intel Hyper-Threading technology disabled.

Run with the USER-INTEL package from the command line:

To enable USER-INTEL optimizations for all available styles used in the input script, the `"-sf intel"` [command-line switch](#) can be used without any requirement for editing the input script. This switch will automatically append "intel" to styles that support it. It also invokes a default command: [package intel 1](#). This package command is used to set options for the USER-INTEL package. The default package command will specify that USER-INTEL calculations are performed in mixed precision, that the number of OpenMP threads is specified by the `OMP_NUM_THREADS` environment variable, and that if coprocessors are present and the binary was built with offload support, that 1 coprocessor per node will be used with automatic balancing of work between the CPU and the coprocessor.

You can specify different options for the USER-INTEL package by using the `"-pk intel Nphi"` [command-line switch](#) with keyword/value pairs as specified in the documentation. Here, `Nphi` = # of Xeon Phi coprocessors/node (ignored without offload support). Common options to the USER-INTEL package include *omp* to override any `OMP_NUM_THREADS` setting and specify the number of OpenMP threads, *mode* to set the floating-point precision mode, and *lrt* to enable Long-Range Thread mode as described below. See the [package intel](#) command for details, including the default values used for all its options if not specified, and how to set the number of OpenMP threads via the `OMP_NUM_THREADS` environment variable if

LAMMPS Users Manual

desired.

Examples (see documentation for your MPI/Machine for differences in launching MPI applications):

```
mpirun -np 72 -ppn 36 lmp_machine -sf intel -in in.script # 2 r
mpirun -np 72 -ppn 36 lmp_machine -sf intel -in in.script -pk intel 0 omp 2 mode double # Dor
```

Or run with the USER-INTEL package by editing an input script:

As an alternative to adding command-line arguments, the input script can be edited to enable the USER-INTEL package. This requires adding the [package intel](#) command to the top of the input script. For the second example above, this would be:

```
package intel 0 omp 2 mode double
```

To enable the USER-INTEL package only for individual styles, you can add an "intel" suffix to the individual style, e.g.:

```
pair_style lj/cut/intel 2.5
```

Alternatively, the [suffix intel](#) command can be added to the input script to enable USER-INTEL styles for the commands that follow in the input script.

Tuning for Performance:

NOTE: The USER-INTEL package will perform better with modifications to the input script when [PPPM](#) is used: [kspace_modify diff ad](#) should be added to the input script.

Long-Range Thread (LRT) mode is an option to the [package intel](#) command that can improve performance when using [PPPM](#) for long-range electrostatics on processors with SMT. It generates an extra pthread for each MPI task. The thread is dedicated to performing some of the PPPM calculations and MPI communications. This feature requires setting the preprocessor flag `-DLMP_INTEL_USELRT` in the makefile when compiling LAMMPS. It is unset in the default makefiles (*Makefile.mpi* and *Makefile.serial*) but it is set in all makefiles tuned for the USER-INTEL package. On Intel Xeon Phi x200 series CPUs, the LRT feature will likely improve performance, even on a single node. On Intel Xeon processors, using this mode might result in better performance when using multiple nodes, depending on the specific machine configuration. To enable LRT mode, specify that the number of OpenMP threads is one less than would normally be used for the run and add the "lrt yes" option to the "-pk" command-line suffix or "package intel" command. For example, if a run would normally perform best with "-pk intel 0 omp 4", instead use "-pk intel 0 omp 3 lrt yes". When using LRT, you should set the environment variable "KMP_AFFINITY=none". LRT mode is not supported when using offload.

NOTE: Changing the [newton](#) setting to off can improve performance and/or scalability for simple 2-body potentials such as lj/cut or when using LRT mode on processors supporting AVX-512.

Not all styles are supported in the USER-INTEL package. You can mix the

LAMMPS Users Manual

USER-INTEL package with styles from the [OPT](#) package or the [USER-OMP package](#). Of course, this requires that these packages were installed at build time. This can be performed automatically by using "-sf hybrid intel opt" or "-sf hybrid intel omp" command-line options. Alternatively, the "opt" and "omp" suffixes can be appended manually in the input script. For the latter, the [package omp](#) command must be in the input script or the "-pk omp Nt" [command-line switch](#) must be used where Nt is the number of OpenMP threads. The number of OpenMP threads should not be set differently for the different packages. Note that the [suffix hybrid intel omp](#) command can also be used within the input script to automatically append the "omp" suffix to styles when USER-INTEL styles are not available.

NOTE: For simulations on higher node counts, add [processors * * * grid numa](#) to the beginning of the input script for better scalability.

When running on many nodes, performance might be better when using fewer OpenMP threads and more MPI tasks. This will depend on the simulation and the machine. Using the [verlet/split](#) run style might also give better performance for simulations with [PPPM](#) electrostatics. Note that this is an alternative to LRT mode and the two cannot be used together.

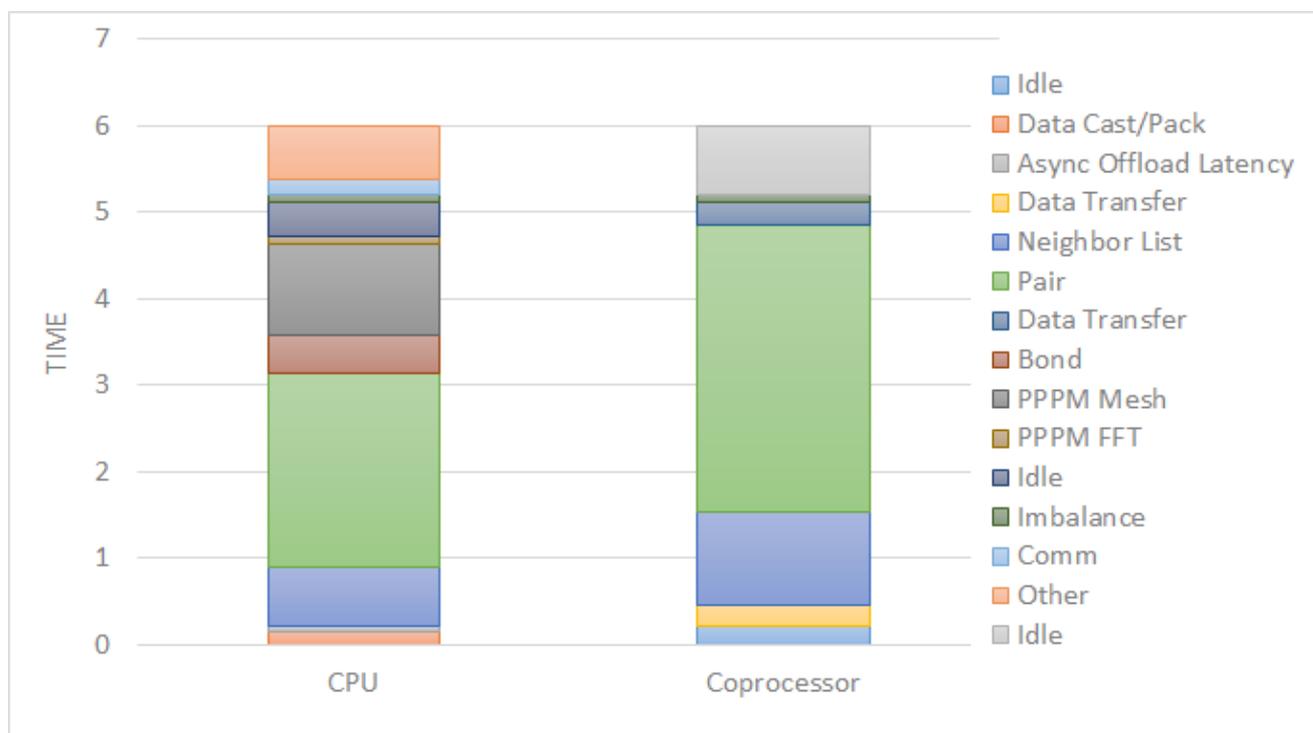

Currently, when using Intel MPI with Intel Xeon Phi x200 series CPUs, better performance might be obtained by setting the environment variable "I_MPI_SHM_LMT=shm" for Linux kernels that do not yet have full support for AVX-512. Runs on Intel Xeon Phi x200 series processors will always perform better using MCDRAM. Please consult your system documentation for the best approach to specify that MPI runs are performed in MCDRAM.

Tuning for Offload Performance:

The default settings for offload should give good performance.

When using LAMMPS with offload to Intel coprocessors, best performance will typically be achieved with concurrent calculations performed on both the CPU and the coprocessor. This is achieved by offloading only a fraction of the neighbor and pair computations to the coprocessor or using [hybrid](#) pair styles where only one style uses the "intel" suffix. For simulations with long-range electrostatics or bond, angle, dihedral, improper calculations, computation and data transfer to the coprocessor will run concurrently with computations and MPI communications for these calculations on the host CPU. This is illustrated in the figure below for the rhodopsin protein benchmark running on E5-2697v2 processors with a Intel Xeon Phi 7120p coprocessor. In this plot, the vertical axis is time and routines running at the same time are running concurrently on both the host and the coprocessor.

LAMMPS Users Manual

The fraction of the offloaded work is controlled by the *balance* keyword in the [package intel](#) command. A balance of 0 runs all calculations on the CPU. A balance of 1 runs all supported calculations on the coprocessor. A balance of 0.5 runs half of the calculations on the coprocessor. Setting the balance to -1 (the default) will enable dynamic load balancing that continuously adjusts the fraction of offloaded work throughout the simulation. Because data transfer cannot be timed, this option typically produces results within 5 to 10 percent of the optimal fixed balance.

If running short benchmark runs with dynamic load balancing, adding a short warm-up run (10-20 steps) will allow the load-balancer to find a near-optimal setting that will carry over to additional runs.

The default for the [package intel](#) command is to have all the MPI tasks on a given compute node use a single Xeon Phi coprocessor. In general, running with a large number of MPI tasks on each node will perform best with offload. Each MPI task will automatically get affinity to a subset of the hardware threads available on the coprocessor. For example, if your card has 61 cores, with 60 cores available for offload and 4 hardware threads per core (240 total threads), running with 24 MPI tasks per node will cause each MPI task to use a subset of 10 threads on the coprocessor. Fine tuning of the number of threads to use per MPI task or the number of threads to use per core can be accomplished with keyword settings of the [package intel](#) command.

The USER-INTEL package has two modes for deciding which atoms will be handled by the coprocessor. This choice is controlled with the *ghost* keyword of the [package intel](#) command. When set to 0, ghost atoms (atoms at the borders between MPI tasks) are not offloaded to the card. This allows for overlap of MPI communication of forces with computation on the coprocessor when the [newton](#) setting is "on". The default is dependent on the style being used, however, better performance may be achieved by

LAMMPS Users Manual

setting this option explicitly.

When using offload with CPU Hyper-Threading disabled, it may help performance to use fewer MPI tasks and OpenMP threads than available cores. This is due to the fact that additional threads are generated internally to handle the asynchronous offload tasks.

If pair computations are being offloaded to an Intel Xeon Phi coprocessor, a diagnostic line is printed to the screen (not to the log file), during the setup phase of a run, indicating that offload mode is being used and indicating the number of coprocessor threads per MPI task. Additionally, an offload timing summary is printed at the end of each run. When offloading, the frequency for [atom sorting](#) is changed to 1 so that the per-atom data is effectively sorted at every rebuild of the neighbor lists. All the available coprocessor threads on each Phi will be divided among MPI tasks, unless the *tptask* option of the "-pk intel" [command-line switch](#) is used to limit the coprocessor threads per MPI task.

Restrictions:

When offloading to a coprocessor, [hybrid](#) styles that require skip lists for neighbor builds cannot be offloaded. Using [hybrid/overlay](#) is allowed. Only one intel accelerated style may be used with hybrid styles. [Special bonds](#) exclusion lists are not currently supported with offload, however, the same effect can often be accomplished by setting cutoffs for excluded atom types to 0. None of the pair styles in the USER-INTEL package currently support the "inner", "middle", "outer" options for rRESPA integration via the [run_style respa](#) command; only the "pair" option is supported.

[Return to Section accelerate overview](#)

5.3.3 KOKKOS package

Kokkos is a templated C++ library that provides abstractions to allow a single implementation of an application kernel (e.g. a pair style) to run efficiently on different kinds of hardware, such as GPUs, Intel Xeon Phis, or many-core CPUs. Kokkos maps the C++ kernel onto different backend languages such as CUDA, OpenMP, or Pthreads. The Kokkos library also provides data abstractions to adjust (at compile time) the memory layout of data structures like 2d and 3d arrays to optimize performance on different hardware. For more information on Kokkos, see [Github](#). Kokkos is part of [Trilinos](#). The Kokkos library was written primarily by Carter Edwards, Christian Trott, and Dan Sunderland (all Sandia).

The LAMMPS KOKKOS package contains versions of pair, fix, and atom styles that use data structures and macros provided by the Kokkos library, which is included with LAMMPS in `/lib/kokkos`. The KOKKOS package was developed primarily by Christian Trott (Sandia) and Stan Moore (Sandia) with contributions of various styles by others, including Sikandar Mashayak (UIUC), Ray Shan (Sandia), and Dan Ibanez (Sandia). For more information on developing using Kokkos abstractions see the Kokkos programmers' guide at `/lib/kokkos/doc/Kokkos_PG.pdf`.

Kokkos currently provides support for 3 modes of execution (per MPI task). These are Serial (MPI-only for CPUs and Intel Phi), OpenMP (threading for many-core CPUs and Intel Phi), and CUDA (for NVIDIA GPUs). You choose the mode at build time to produce an executable compatible with specific hardware.

Building LAMMPS with the KOKKOS package:

NOTE: Kokkos support within LAMMPS must be built with a C++11 compatible compiler. This means GCC version 4.7.2 or later, Intel 14.0.4 or later, or Clang 3.5.2 or later is required.

The recommended method of building the KOKKOS package is to start with the provided Kokkos Makefiles in `/src/MAKE/OPTIONS/`. You may need to modify the `KOKKOS_ARCH` variable in the Makefile to match your specific hardware. For example:

- for Sandy Bridge CPUs, set `KOKKOS_ARCH=SNB`
- for Broadwell CPUs, set `KOKKOS_ARCH=BWD`
- for K80 GPUs, set `KOKKOS_ARCH=Kepler37`
- for P100 GPUs and Power8 CPUs, set `KOKKOS_ARCH=Pascal60,Power8`

See the **Advanced Kokkos Options** section below for a listing of all `KOKKOS_ARCH` options.

Compile for CPU-only (MPI only, no threading):

LAMMPS Users Manual

use a C++11 compatible compiler and set KOKKOS_ARCH variable in /src/MAKE/OPTIONS/Makefile.kokkos_mpi_only as described above. Then do the following:

```
cd lammeps/src
make yes-kokkos
make kokkos_mpi_only
```

Compile for CPU-only (MPI plus OpenMP threading):

NOTE: To build with Kokkos support for OpenMP threading, your compiler must support the OpenMP interface. You should have one or more multi-core CPUs so that multiple threads can be launched by each MPI task running on a CPU.

use a C++11 compatible compiler and set KOKKOS_ARCH variable in /src/MAKE/OPTIONS/Makefile.kokkos_omp as described above. Then do the following:

```
cd lammeps/src
make yes-kokkos
make kokkos_omp
```

Compile for Intel KNL Xeon Phi (Intel Compiler, OpenMPI):

use a C++11 compatible compiler and do the following:

```
cd lammeps/src
make yes-kokkos
make kokkos_phi
```

Compile for CPUs and GPUs (with OpenMPI or MPICH):

NOTE: To build with Kokkos support for NVIDIA GPUs, NVIDIA CUDA software version 7.5 or later must be installed on your system. See the discussion for the [GPU](#) package for details of how to check and do this.

use a C++11 compatible compiler and set KOKKOS_ARCH variable in /src/MAKE/OPTIONS/Makefile.kokkos_cuda_mpi for both GPU and CPU as described above. Then do the following:

```
cd lammeps/src
make yes-kokkos
make kokkos_cuda_mpi
```

Alternative Methods of Compiling:

Alternatively, the KOKKOS package can be built by specifying Kokkos variables on the make command line. For example:

```
make mpi KOKKOS_DEVICES=OpenMP KOKKOS_ARCH=SNB      # set the KOKKOS_DEVICES and KOKKOS_ARCH variables
make kokkos_cuda_mpi KOKKOS_ARCH=Pascal60,Power8    # set the KOKKOS_ARCH variable explicitly
```

Setting the KOKKOS_DEVICES and KOKKOS_ARCH variables on the make command line requires a GNU-compatible make command. Try "gmake" if your system's

LAMMPS Users Manual

standard make complains.

NOTE: If you build using make line variables and re-build LAMMPS twice with different KOKKOS options and the **same** target, then you **must** perform a "make clean-all" or "make clean-machine" before each build. This is to force all the KOKKOS-dependent files to be re-compiled with the new options.

Running LAMMPS with the KOKKOS package:

All Kokkos operations occur within the context of an individual MPI task running on a single node of the machine. The total number of MPI tasks used by LAMMPS (one or multiple per compute node) is set in the usual manner via the mpirun or mpiexec commands, and is independent of Kokkos. E.g. the mpirun command in OpenMPI does this via its -np and -npnnode switches. Ditto for MPICH via -np and -ppn.

Running on a multi-core CPU:

Here is a quick overview of how to use the KOKKOS package for CPU acceleration, assuming one or more 16-core nodes.

```
mpirun -np 16 lmp_kokkos_mpi_only -k on -sf kk -in in.lj          # 1 node, 16 MPI tasks/node, 16 MPI tasks
mpirun -np 2 -ppn 1 lmp_kokkos_omp -k on t 16 -sf kk -in in.lj # 2 nodes, 1 MPI task/node, 16 MPI tasks
mpirun -np 2 lmp_kokkos_omp -k on t 8 -sf kk -in in.lj         # 1 node, 2 MPI tasks/node, 8 MPI tasks
mpirun -np 32 -ppn 4 lmp_kokkos_omp -k on t 4 -sf kk -in in.lj # 8 nodes, 4 MPI tasks/node, 4 MPI tasks
```

To run using the KOKKOS package, use the "-k on", "-sf kk" and "-pk kokkos" [command-line switches](#) in your mpirun command. You must use the "-k on" [command-line switch](#) to enable the KOKKOS package. It takes additional arguments for hardware settings appropriate to your system. Those arguments are [documented here](#). For OpenMP use:

```
-k on t Nt
```

The "t Nt" option specifies how many OpenMP threads per MPI task to use with a node. The default is Nt = 1, which is MPI-only mode. Note that the product of MPI tasks * OpenMP threads/task should not exceed the physical number of cores (on a node), otherwise performance will suffer. If hyperthreading is enabled, then the product of MPI tasks * OpenMP threads/task should not exceed the physical number of cores * hardware threads. The "-k on" switch also issues a "package kokkos" command (with no additional arguments) which sets various KOKKOS options to default values, as discussed on the [package](#) command doc page.

The "-sf kk" [command-line switch](#) will automatically append the "/kk" suffix to styles that support it. In this manner no modification to the input script is needed. Alternatively, one can run with the KOKKOS package by editing the input script as described below.

NOTE: The default for the [package kokkos](#) command is to use "full" neighbor lists and set the Newton flag to "off" for both pairwise and bonded interactions. However, when running on CPUs, it will typically be faster to use "half" neighbor lists and set the Newton flag to "on", just as is the case for non-accelerated pair styles. It can also be faster to use non-threaded communication. Use the "-pk kokkos" [command-line switch](#)

LAMMPS Users Manual

to change the default [package kokkos](#) options. See its doc page for details and default settings. Experimenting with its options can provide a speed-up for specific calculations. For example:

```
mpirun -np 16 lmp_kokkos_mpi_only -k on -sf kk -pk kokkos newton on neigh half comm no -in in.l
```

If the [newton](#) command is used in the input script, it can also override the Newton flag defaults.

Core and Thread Affinity:

When using multi-threading, it is important for performance to bind both MPI tasks to physical cores, and threads to physical cores, so they do not migrate during a simulation.

If you are not certain MPI tasks are being bound (check the defaults for your MPI installation), binding can be forced with these flags:

```
OpenMPI 1.8: mpirun -np 2 --bind-to socket --map-by socket ./lmp_openmpi ...
Mvapich2 2.0: mpiexec -np 2 --bind-to socket --map-by socket ./lmp_mvapich ...
```

For binding threads with KOKKOS OpenMP, use thread affinity environment variables to force binding. With OpenMP 3.1 (gcc 4.7 or later, intel 12 or later) setting the environment variable `OMP_PROC_BIND=true` should be sufficient. In general, for best performance with OpenMP 4.0 or better set `OMP_PROC_BIND=spread` and `OMP_PLACES=threads`. For binding threads with the KOKKOS pthreads option, compile LAMMPS the `KOKKOS HWLOC=yes` option as described below.

Running on Knight's Landing (KNL) Intel Xeon Phi:

Here is a quick overview of how to use the KOKKOS package for the Intel Knight's Landing (KNL) Xeon Phi:

KNL Intel Phi chips have 68 physical cores. Typically 1 to 4 cores are reserved for the OS, and only 64 or 66 cores are used. Each core has 4 hyperthreads, so there are effectively $N = 256$ (4×64) or $N = 264$ (4×66) cores to run on. The product of MPI tasks * OpenMP threads/task should not exceed this limit, otherwise performance will suffer. Note that with the KOKKOS package you do not need to specify how many KNLs there are per node; each KNL is simply treated as running some number of MPI tasks.

Examples of mpirun commands that follow these rules are shown below.

```
Intel KNL node with 68 cores (272 threads/node via 4x hardware threading):
mpirun -np 64 lmp_kokkos_phi -k on t 4 -sf kk -in in.lj      # 1 node, 64 MPI tasks/node, 4 thr
mpirun -np 66 lmp_kokkos_phi -k on t 4 -sf kk -in in.lj      # 1 node, 66 MPI tasks/node, 4 thr
mpirun -np 32 lmp_kokkos_phi -k on t 8 -sf kk -in in.lj      # 1 node, 32 MPI tasks/node, 8 thr
mpirun -np 512 -ppn 64 lmp_kokkos_phi -k on t 4 -sf kk -in in.lj # 8 nodes, 64 MPI tasks/node,
```

The `-np` setting of the mpirun command sets the number of MPI tasks/node. The `"-k on t Nt"` command-line switch sets the number of threads/task as `Nt`. The product of these two values should be `N`, i.e. 256 or 264.

LAMMPS Users Manual

NOTE: The default for the [package kokkos](#) command is to use "full" neighbor lists and set the Newton flag to "off" for both pairwise and bonded interactions. When running on KNL, this will typically be best for pair-wise potentials. For manybody potentials, using "half" neighbor lists and setting the Newton flag to "on" may be faster. It can also be faster to use non-threaded communication. Use the "-pk kokkos" [command-line switch](#) to change the default [package kokkos](#) options. See its doc page for details and default settings. Experimenting with its options can provide a speed-up for specific calculations. For example:

```
mpirun -np 64 lmp_kokkos_phi -k on t 4 -sf kk -pk kokkos comm no -in in.lj # Newton off,
mpirun -np 64 lmp_kokkos_phi -k on t 4 -sf kk -pk kokkos newton on neigh half comm no -in in.r
```

NOTE: MPI tasks and threads should be bound to cores as described above for CPUs.

NOTE: To build with Kokkos support for Intel Xeon Phi coprocessors such as Knight's Corner (KNC), your system must be configured to use them in "native" mode, not "offload" mode like the USER-INTEL package supports.

Running on GPUs:

Use the "-k" [command-line switch](#) to specify the number of GPUs per node. Typically the -np setting of the mpirun command should set the number of MPI tasks/node to be equal to the # of physical GPUs on the node. You can assign multiple MPI tasks to the same GPU with the KOKKOS package, but this is usually only faster if significant portions of the input script have not been ported to use Kokkos. Using CUDA MPS is recommended in this scenario. As above for multi-core CPUs (and no GPU), if N is the number of physical cores/node, then the number of MPI tasks/node should not exceed N.

```
-k on g Ng
```

Here are examples of how to use the KOKKOS package for GPUs, assuming one or more nodes, each with two GPUs:

```
mpirun -np 2 lmp_kokkos_cuda_openmpi -k on g 2 -sf kk -in in.lj # 1 node, 2 MPI task
mpirun -np 32 -ppn 2 lmp_kokkos_cuda_openmpi -k on g 2 -sf kk -in in.lj # 16 nodes, 2 MPI task
```

NOTE: The default for the [package kokkos](#) command is to use "full" neighbor lists and set the Newton flag to "off" for both pairwise and bonded interactions, along with threaded communication. When running on Maxwell or Kepler GPUs, this will typically be best. For Pascal GPUs, using "half" neighbor lists and setting the Newton flag to "on" may be faster. For many pair styles, setting the neighbor binsize equal to the ghost atom cutoff will give speedup. Use the "-pk kokkos" [command-line switch](#) to change the default [package kokkos](#) options. See its doc page for details and default settings. Experimenting with its options can provide a speed-up for specific calculations. For example:

```
mpirun -np 2 lmp_kokkos_cuda_openmpi -k on g 2 -sf kk -pk kokkos binsize 2.8 -in in.lj # 9
mpirun -np 2 lmp_kokkos_cuda_openmpi -k on g 2 -sf kk -pk kokkos newton on neigh half binsize 2
```

NOTE: For good performance of the KOKKOS package on GPUs, you must have Kepler generation GPUs (or later). The Kokkos library exploits texture cache options not

LAMMPS Users Manual

supported by Telsa generation GPUs (or older).

NOTE: When using a GPU, you will achieve the best performance if your input script does not use fix or compute styles which are not yet Kokkos-enabled. This allows data to stay on the GPU for multiple timesteps, without being copied back to the host CPU. Invoking a non-Kokkos fix or compute, or performing I/O for [thermo](#) or [dump](#) output will cause data to be copied back to the CPU incurring a performance penalty.

NOTE: To get an accurate timing breakdown between time spend in pair, kspace, etc., you must set the environment variable `CUDA_LAUNCH_BLOCKING=1`. However, this will reduce performance and is not recommended for production runs.

Run with the KOKKOS package by editing an input script:

Alternatively the effect of the "-sf" or "-pk" switches can be duplicated by adding the [package kokkos](#) or [suffix kk](#) commands to your input script.

The discussion above for building LAMMPS with the KOKKOS package, the `mpirun/mpirun` command, and setting appropriate thread are the same.

You must still use the "-k on" [command-line switch](#) to enable the KOKKOS package, and specify its additional arguments for hardware options appropriate to your system, as documented above.

You can use the [suffix kk](#) command, or you can explicitly add a "kk" suffix to individual styles in your input script, e.g.

```
pair_style lj/cut/kk 2.5
```

You only need to use the [package kokkos](#) command if you wish to change any of its option defaults, as set by the "-k on" [command-line switch](#).

Using OpenMP threading and CUDA together (experimental):

With the KOKKOS package, both OpenMP multi-threading and GPUs can be used together in a few special cases. In the Makefile, the `KOKKOS_DEVICES` variable must include both "Cuda" and "OpenMP", as is the case for `/src/MAKE/OPTIONS/Makefile.kokkos_cuda_mpi`

```
KOKKOS_DEVICES=Cuda,OpenMP
```

The suffix "/kk" is equivalent to "/kk/device", and for Kokkos CUDA, using the "-sf kk" in the command line gives the default CUDA version everywhere. However, if the "/kk/host" suffix is added to a specific style in the input script, the Kokkos OpenMP (CPU) version of that specific style will be used instead. Set the number of OpenMP threads as "t Nt" and the number of GPUs as "g Ng"

```
-k on t Nt g Ng
```

For example, the command to run with 1 GPU and 8 OpenMP threads is then:

```
mpirun -np 1 lmp_kokkos_cuda_openmpi -in in.lj -k on g 1 t 8 -sf kk
```

LAMMPS Users Manual

Conversely, if the "-sf kk/host" is used in the command line and then the "/kk" or "/kk/device" suffix is added to a specific style in your input script, then only that specific style will run on the GPU while everything else will run on the CPU in OpenMP mode. Note that the execution of the CPU and GPU styles will NOT overlap, except for a special case:

A kspace style and/or molecular topology (bonds, angles, etc.) running on the host CPU can overlap with a pair style running on the GPU. First compile with "--default-stream per-thread" added to CCFLAGS in the Kokkos CUDA Makefile. Then explicitly use the "/kk/host" suffix for kspace and bonds, angles, etc. in the input file and the "kk" suffix (equal to "kk/device") on the command line. Also make sure the environment variable CUDA_LAUNCH_BLOCKING is not set to "1" so CPU/GPU overlap can occur.

Speed-ups to expect:

The performance of KOKKOS running in different modes is a function of your hardware, which KOKKOS-enable styles are used, and the problem size.

Generally speaking, the following rules of thumb apply:

- When running on CPUs only, with a single thread per MPI task, performance of a KOKKOS style is somewhere between the standard (un-accelerated) styles (MPI-only mode), and those provided by the USER-OMP package. However the difference between all 3 is small (less than 20%).
- When running on CPUs only, with multiple threads per MPI task, performance of a KOKKOS style is a bit slower than the USER-OMP package.
- When running large number of atoms per GPU, KOKKOS is typically faster than the GPU package.
- When running on Intel hardware, KOKKOS is not as fast as the USER-INTEL package, which is optimized for that hardware.

See the [Benchmark page](#) of the LAMMPS web site for performance of the KOKKOS package on different hardware.

Advanced Kokkos options:

There are other allowed options when building with the KOKKOS package. As above, they can be set either as variables on the make command line or in Makefile.machine. This is the full list of options, including those discussed above. Each takes a value shown below. The default value is listed, which is set in the /lib/kokkos/Makefile.kokkos file.

- KOKKOS_DEVICES, values = *Serial, OpenMP, Pthreads, Cuda*, default = *OpenMP*
- KOKKOS_ARCH, values = *KNC, SNB, HSW, Kepler30, Kepler32, Kepler35, Kepler37, Maxwell50, Maxwell52, Maxwell53, Pascal60, Pascal61, ARMv80, ARMv81, ARMv81, ARMv8-ThunderX, BGQ, Power7, Power8, Power9, KNL, BDW, SKX*, default = *none*
- KOKKOS_DEBUG, values = *yes, no*, default = *no*

LAMMPS Users Manual

- KOKKOS_USE_TPLS, values = *hwloc*, *librt*, *experimental_memkind*, default = *none*
- KOKKOS_CXX_STANDARD, values = *c++11*, *c++1z*, default = *c++11*
- KOKKOS_OPTIONS, values = *aggressive_vectorization*, *disable_profiling*, default = *none*
- KOKKOS_CUDA_OPTIONS, values = *force_uvm*, *use_ldg*, *rdc*, *enable_lambda*, default = *enable_lambda*

KOKKOS_DEVICES sets the parallelization method used for Kokkos code (within LAMMPS). KOKKOS_DEVICES=Serial means that no threading will be used. KOKKOS_DEVICES=OpenMP means that OpenMP threading will be used. KOKKOS_DEVICES=Pthreads means that pthreads will be used. KOKKOS_DEVICES=Cuda means an NVIDIA GPU running CUDA will be used.

KOKKOS_ARCH enables compiler switches needed when compiling for a specific hardware:

- ARMv80 = ARMv8.0 Compatible CPU
- ARMv81 = ARMv8.1 Compatible CPU
- ARMv8-ThunderX = ARMv8 Cavium ThunderX CPU
- SNB = Intel Sandy/Ivy Bridge CPUs
- HSW = Intel Haswell CPUs
- BDW = Intel Broadwell Xeon E-class CPUs
- SKX = Intel Sky Lake Xeon E-class HPC CPUs (AVX512)
- KNC = Intel Knights Corner Xeon Phi
- KNL = Intel Knights Landing Xeon Phi
- Kepler30 = NVIDIA Kepler generation CC 3.0
- Kepler32 = NVIDIA Kepler generation CC 3.2
- Kepler35 = NVIDIA Kepler generation CC 3.5
- Kepler37 = NVIDIA Kepler generation CC 3.7
- Maxwell50 = NVIDIA Maxwell generation CC 5.0
- Maxwell52 = NVIDIA Maxwell generation CC 5.2
- Maxwell53 = NVIDIA Maxwell generation CC 5.3
- Pascal60 = NVIDIA Pascal generation CC 6.0
- Pascal61 = NVIDIA Pascal generation CC 6.1
- BGQ = IBM Blue Gene/Q CPUs
- Power8 = IBM POWER8 CPUs
- Power9 = IBM POWER9 CPUs

KOKKOS_USE_TPLS=hwloc binds threads to hardware cores, so they do not migrate during a simulation. KOKKOS_USE_TPLS=hwloc should always be used if running with KOKKOS_DEVICES=Pthreads for pthreads. It is not necessary for KOKKOS_DEVICES=OpenMP for OpenMP, because OpenMP provides alternative methods via environment variables for binding threads to hardware cores. More info on binding threads to cores is given in [Section 5.3](#).

KOKKOS_USE_TPLS=librt enables use of a more accurate timer mechanism on most Unix platforms. This library is not available on all platforms.

KOKKOS_DEBUG is only useful when developing a Kokkos-enabled style within LAMMPS. KOKKOS_DEBUG=yes enables printing of run-time debugging information

LAMMPS Users Manual

that can be useful. It also enables runtime bounds checking on Kokkos data structures.

KOKKOS_CXX_STANDARD and KOKKOS_OPTIONS are typically not changed when building LAMMPS.

KOKKOS_CUDA_OPTIONS are additional options for CUDA. The LAMMPS KOKKOS package must be compiled with the *enable_lambda* option when using GPUs.

Restrictions:

Currently, there are no precision options with the KOKKOS package. All compilation and computation is performed in double precision.

[Return to Section 5 overview](#)

5.3.4 USER-OMP package

The USER-OMP package was developed by Axel Kohlmeyer at Temple University. It provides multi-threaded versions of most pair styles, nearly all bonded styles (bond, angle, dihedral, improper), several Kspace styles, and a few fix styles. The package currently uses the OpenMP interface for multi-threading.

Here is a quick overview of how to use the USER-OMP package, assuming one or more 16-core nodes. More details follow.

use -fopenmp with CCFLAGS and LINKFLAGS in Makefile.machine

```
make yes-user-omp
```

```
make mpi
```

```
# build with USER-OMP package, if settings added to
```

```
make omp
```

```
# or Makefile.omp already has settings
```

```
lmp_mpi -sf omp -pk omp 16 <in.script
```

```
# 1 MPI task, 16 threads
```

```
mpirun -np 4 lmp_mpi -sf omp -pk omp 4 -in in.script
```

```
# 4 MPI tasks, 4 threads/task
```

```
mpirun -np 32 -ppn 4 lmp_mpi -sf omp -pk omp 4 -in in.script
```

```
# 8 nodes, 4 MPI tasks/node, 4 t
```

Required hardware/software:

Your compiler must support the OpenMP interface. You should have one or more multi-core CPUs so that multiple threads can be launched by each MPI task running on a CPU.

Building LAMMPS with the USER-OMP package:

The lines above illustrate how to include/build with the USER-OMP package in two steps, using the "make" command. Or how to do it with one command as described in [Section 4](#) of the manual.

Note that the CCFLAGS and LINKFLAGS settings in Makefile.machine must include "-fopenmp". Likewise, if you use an Intel compiler, the CCFLAGS setting must include "-restrict".

Run with the USER-OMP package from the command line:

The mpirun or mpiexec command sets the total number of MPI tasks used by LAMMPS (one or multiple per compute node) and the number of MPI tasks used per node. E.g. the mpirun command in MPICH does this via its -np and -ppn switches. Ditto for OpenMPI via -np and -npernode.

You need to choose how many OpenMP threads per MPI task will be used by the USER-OMP package. Note that the product of MPI tasks * threads/task should not exceed the physical number of cores (on a node), otherwise performance will suffer.

LAMMPS Users Manual

As in the lines above, use the "-sf omp" [command-line switch](#), which will automatically append "omp" to styles that support it. The "-sf omp" switch also issues a default [package omp 0](#) command, which will set the number of threads per MPI task via the OMP_NUM_THREADS environment variable.

You can also use the "-pk omp Nt" [command-line switch](#), to explicitly set Nt = # of OpenMP threads per MPI task to use, as well as additional options. Its syntax is the same as the [package omp](#) command whose doc page gives details, including the default values used if it is not specified. It also gives more details on how to set the number of threads via the OMP_NUM_THREADS environment variable.

Or run with the USER-OMP package by editing an input script:

The discussion above for the mpirun/mpixexec command, MPI tasks/node, and threads/MPI task is the same.

Use the [suffix omp](#) command, or you can explicitly add an "omp" suffix to individual styles in your input script, e.g.

```
pair_style lj/cut/omp 2.5
```

You must also use the [package omp](#) command to enable the USER-OMP package. When you do this you also specify how many threads per MPI task to use. The command doc page explains other options and how to set the number of threads via the OMP_NUM_THREADS environment variable.

Speed-ups to expect:

Depending on which styles are accelerated, you should look for a reduction in the "Pair time", "Bond time", "KSpace time", and "Loop time" values printed at the end of a run.

You may see a small performance advantage (5 to 20%) when running a USER-OMP style (in serial or parallel) with a single thread per MPI task, versus running standard LAMMPS with its standard un-accelerated styles (in serial or all-MPI parallelization with 1 task/core). This is because many of the USER-OMP styles contain similar optimizations to those used in the OPT package, described in [Section 5.3.5](#).

With multiple threads/task, the optimal choice of number of MPI tasks/node and OpenMP threads/task can vary a lot and should always be tested via benchmark runs for a specific simulation running on a specific machine, paying attention to guidelines discussed in the next sub-section.

A description of the multi-threading strategy used in the USER-OMP package and some performance examples are [presented here](#)

Guidelines for best performance:

For many problems on current generation CPUs, running the USER-OMP package with a single thread/task is faster than running with multiple threads/task. This is because the MPI parallelization in LAMMPS is often more efficient than

LAMMPS Users Manual

multi-threading as implemented in the USER-OMP package. The parallel efficiency (in a threaded sense) also varies for different USER-OMP styles.

Using multiple threads/task can be more effective under the following circumstances:

- Individual compute nodes have a significant number of CPU cores but the CPU itself has limited memory bandwidth, e.g. for Intel Xeon 53xx (Clovertown) and 54xx (Harpertown) quad-core processors. Running one MPI task per CPU core will result in significant performance degradation, so that running with 4 or even only 2 MPI tasks per node is faster. Running in hybrid MPI+OpenMP mode will reduce the inter-node communication bandwidth contention in the same way, but offers an additional speedup by utilizing the otherwise idle CPU cores.
- The interconnect used for MPI communication does not provide sufficient bandwidth for a large number of MPI tasks per node. For example, this applies to running over gigabit ethernet or on Cray XT4 or XT5 series supercomputers. As in the aforementioned case, this effect worsens when using an increasing number of nodes.
- The system has a spatially inhomogeneous particle density which does not map well to the [domain decomposition scheme](#) or [load-balancing](#) options that LAMMPS provides. This is because multi-threading achieves parallelism over the number of particles, not via their distribution in space.
- A machine is being used in "capability mode", i.e. near the point where MPI parallelism is maxed out. For example, this can happen when using the [PPPM solver](#) for long-range electrostatics on large numbers of nodes. The scaling of the KSpace calculation (see the [kspace_style](#) command) becomes the performance-limiting factor. Using multi-threading allows less MPI tasks to be invoked and can speed-up the long-range solver, while increasing overall performance by parallelizing the pairwise and bonded calculations via OpenMP. Likewise additional speedup can be sometimes be achieved by increasing the length of the Coulombic cutoff and thus reducing the work done by the long-range solver. Using the [run_style verlet/split](#) command, which is compatible with the USER-OMP package, is an alternative way to reduce the number of MPI tasks assigned to the KSpace calculation.

Additional performance tips are as follows:

- The best parallel efficiency from *omp* styles is typically achieved when there is at least one MPI task per physical CPU chip, i.e. socket or die.
- It is usually most efficient to restrict threading to a single socket, i.e. use one or more MPI task per socket.
- NOTE: By default, several current MPI implementations use a processor affinity setting that restricts each MPI task to a single CPU core. Using multi-threading in this mode will force all threads to share the one core and thus is likely to be counterproductive. Instead, binding MPI tasks to a (multi-core) socket, should solve this issue.

Restrictions:

None.

[Return to Section accelerate overview](#)

5.3.5 OPT package

The OPT package was developed by James Fischer (High Performance Technologies), David Richie, and Vincent Natoli (Stone Ridge Technologies). It contains a handful of pair styles whose compute() methods were rewritten in C++ templated form to reduce the overhead due to if tests and other conditional code.

Here is a quick overview of how to use the OPT package. More details follow.

```
make yes-opt
make mpi                # build with the OPT package

lmp_mpi -sf opt -in in.script      # run in serial
mpirun -np 4 lmp_mpi -sf opt -in in.script  # run in parallel
```

Required hardware/software:

None.

Building LAMMPS with the OPT package:

The lines above illustrate how to build LAMMPS with the OPT package in two steps, using the "make" command. Or how to do it with one command as described in [Section 4](#) of the manual.

Note that if you use an Intel compiler to build with the OPT package, the CCFLAGS setting in your Makefile.machine must include "-restrict".

Run with the OPT package from the command line:

As in the lines above, use the "-sf opt" [command-line switch](#), which will automatically append "opt" to styles that support it.

Or run with the OPT package by editing an input script:

Use the [suffix opt](#) command, or you can explicitly add an "opt" suffix to individual styles in your input script, e.g.

```
pair_style lj/cut/opt 2.5
```

Speed-ups to expect:

You should see a reduction in the "Pair time" value printed at the end of a run. On most machines for reasonable problem sizes, it will be a 5 to 20% savings.

Guidelines for best performance:

LAMMPS Users Manual

Just try out an OPT pair style to see how it performs.

Restrictions:

None.

6. How-to discussions

This section describes how to perform common tasks using LAMMPS.

The example input scripts included in the LAMMPS distribution and highlighted in [Section 7](#) also show how to setup and run various kinds of simulations.

6.1 Restarting a simulation

There are 3 ways to continue a long LAMMPS simulation. Multiple `run` commands can be used in the same input script. Each run will continue from where the previous run left off. Or binary restart files can be saved to disk using the `restart` command. At a later time, these binary files can be read via a `read_restart` command in a new script. Or they can be converted to text data files using the `-r` [command-line switch](#) and read by a `read_data` command in a new script.

LAMMPS Users Manual

Here we give examples of 2 scripts that read either a binary restart file or a converted data file and then issue a new run command to continue where the previous run left off. They illustrate what settings must be made in the new script. Details are discussed in the documentation for the [read_restart](#) and [read_data](#) commands.

Look at the *in.chain* input script provided in the *bench* directory of the LAMMPS distribution to see the original script that these 2 scripts are based on. If that script had the line

```
restart          50 tmp.restart
```

added to it, it would produce 2 binary restart files (tmp.restart.50 and tmp.restart.100) as it ran.

This script could be used to read the 1st restart file and re-run the last 50 timesteps:

```
read_restart    tmp.restart.50

neighbor        0.4 bin
neigh_modify    every 1 delay 1

fix             1 all nve
fix             2 all langevin 1.0 1.0 10.0 904297

timestep        0.012

run             50
```

Note that the following commands do not need to be repeated because their settings are included in the restart file: *units*, *atom_style*, *special_bonds*, *pair_style*, *bond_style*. However these commands do need to be used, since their settings are not in the restart file: *neighbor*, *fix*, *timestep*.

If you actually use this script to perform a restarted run, you will notice that the thermodynamic data match at step 50 (if you also put a "thermo 50" command in the original script), but do not match at step 100. This is because the [fix langevin](#) command uses random numbers in a way that does not allow for perfect restarts.

As an alternate approach, the restart file could be converted to a data file as follows:

```
lmp_g++ -r tmp.restart.50 tmp.restart.data
```

Then, this script could be used to re-run the last 50 steps:

```
units           lj
atom_style      bond
pair_style      lj/cut 1.12
pair_modify     shift yes
bond_style      fene
special_bonds   0.0 1.0 1.0

read_data       tmp.restart.data

neighbor        0.4 bin
```

LAMMPS Users Manual

```
neigh_modify    every 1 delay 1

fix             1 all nve
fix             2 all langevin 1.0 1.0 10.0 904297

timestep        0.012

reset_timestep  50
run             50
```

Note that nearly all the settings specified in the original *in.chain* script must be repeated, except the *pair_coeff* and *bond_coeff* commands since the new data file lists the force field coefficients. Also, the [reset timestep](#) command is used to tell LAMMPS the current timestep. This value is stored in restart files, but not in data files.

6.2 2d simulations

Use the [dimension](#) command to specify a 2d simulation.

Make the simulation box periodic in z via the [boundary](#) command. This is the default.

If using the [create box](#) command to define a simulation box, set the z dimensions narrow, but finite, so that the *create_atoms* command will tile the 3d simulation box with a single z plane of atoms - e.g.

```
create box 1 -10 10 -10 10 -0.25 0.25
```

If using the [read data](#) command to read in a file of atom coordinates, set the "zlo zhi" values to be finite but narrow, similar to the *create_box* command settings just described. For each atom in the file, assign a z coordinate so it falls inside the z-boundaries of the box - e.g. 0.0.

Use the [fix enforce2d](#) command as the last defined fix to insure that the z-components of velocities and forces are zeroed out every timestep. The reason to make it the last fix is so that any forces induced by other fixes will be zeroed out.

Many of the example input scripts included in the LAMMPS distribution are for 2d models.

NOTE: Some models in LAMMPS treat particles as finite-size spheres, as opposed to point particles. See the [atom_style sphere](#) and [fix nve/sphere](#) commands for details. By default, for 2d simulations, such particles will still be modeled as 3d spheres, not 2d discs (circles), meaning their moment of inertia will be that of a sphere. If you wish to model them as 2d discs, see the [set density/disc](#) command and the *disc* option for the [fix nve/sphere](#), [fix nvt/sphere](#), [fix nph/sphere](#), [fix npt/sphere](#) commands.

6.3 CHARMM, AMBER, and DREIDING force fields

A force field has 2 parts: the formulas that define it and the coefficients used for a particular system. Here we only discuss formulas implemented in LAMMPS that

LAMMPS Users Manual

correspond to formulas commonly used in the CHARMM, AMBER, and DREIDING force fields. Setting coefficients is done in the input data file via the [read_data](#) command or in the input script with commands like [pair_coeff](#) or [bond_coeff](#). See [Section 9](#) for additional tools that can use CHARMM or AMBER to assign force field coefficients and convert their output into LAMMPS input.

See [\(MacKerell\)](#) for a description of the CHARMM force field. See [\(Cornell\)](#) for a description of the AMBER force field.

These style choices compute force field formulas that are consistent with common options in CHARMM or AMBER. See each command's documentation for the formula it computes.

- [bond_style](#) harmonic
- [angle_style](#) charmm
- [dihedral_style](#) charmmfsh
- [dihedral_style](#) charmm
- [pair_style](#) lj/charmmfsw/coul/charmmfsh
- [pair_style](#) lj/charmmfsw/coul/long
- [pair_style](#) lj/charmm/coul/charmm
- [pair_style](#) lj/charmm/coul/charmm/implicit
- [pair_style](#) lj/charmm/coul/long

- [special_bonds](#) charmm
- [special_bonds](#) amber

NOTE: For CHARMM, newer *charmmfsw* or *charmmfsh* styles were released in March 2017. We recommend they be used instead of the older *charmm* styles. See discussion of the differences on the [pair charmm](#) and [dihedral charmm](#) doc pages.

DREIDING is a generic force field developed by the [Goddard group](#) at Caltech and is useful for predicting structures and dynamics of organic, biological and main-group inorganic molecules. The philosophy in DREIDING is to use general force constants and geometry parameters based on simple hybridization considerations, rather than individual force constants and geometric parameters that depend on the particular combinations of atoms involved in the bond, angle, or torsion terms. DREIDING has an [explicit hydrogen bond term](#) to describe interactions involving a hydrogen atom on very electronegative atoms (N, O, F).

See [\(Mayo\)](#) for a description of the DREIDING force field

These style choices compute force field formulas that are consistent with the DREIDING force field. See each command's documentation for the formula it computes.

- [bond_style](#) harmonic
- [bond_style](#) morse

- [angle_style](#) harmonic
- [angle_style](#) cosine
- [angle_style](#) cosine/periodic

- [dihedral_style](#) charmm
 - [improper_style](#) umbrella

 - [pair_style](#) buck
 - [pair_style](#) buck/coul/cut
 - [pair_style](#) buck/coul/long
 - [pair_style](#) lj/cut
 - [pair_style](#) lj/cut/coul/cut
 - [pair_style](#) lj/cut/coul/long

 - [pair_style](#) hbond/dreiding/lj
 - [pair_style](#) hbond/dreiding/morse

 - [special_bonds](#) dreiding
-

6.4 Running multiple simulations from one input script

This can be done in several ways. See the documentation for individual commands for more details on how these examples work.

If "multiple simulations" means continue a previous simulation for more timesteps, then you simply use the [run](#) command multiple times. For example, this script

```
units lj
atom_style atomic
read_data data.lj
run 10000
run 10000
run 10000
run 10000
run 10000
```

would run 5 successive simulations of the same system for a total of 50,000 timesteps.

If you wish to run totally different simulations, one after the other, the [clear](#) command can be used in between them to re-initialize LAMMPS. For example, this script

```
units lj
atom_style atomic
read_data data.lj
run 10000
clear
units lj
atom_style atomic
read_data data.lj.new
run 10000
```

would run 2 independent simulations, one after the other.

For large numbers of independent simulations, you can use [variables](#) and the [next](#) and [jump](#) commands to loop over the same input script multiple times with different settings. For example, this script, named in.polymer

LAMMPS Users Manual

```
variable d index run1 run2 run3 run4 run5 run6 run7 run8
shell cd $d
read_data data.polymer
run 10000
shell cd ..
clear
next d
jump in.polymer
```

would run 8 simulations in different directories, using a data.polymer file in each directory. The same concept could be used to run the same system at 8 different temperatures, using a temperature variable and storing the output in different log and dump files, for example

```
variable a loop 8
variable t index 0.8 0.85 0.9 0.95 1.0 1.05 1.1 1.15
log log.$a
read_data data.polymer
velocity all create $t 352839
fix 1 all nvt $t $t 100.0
dump 1 all atom 1000 dump.$a
run 100000
clear
next t
next a
jump in.polymer
```

All of the above examples work whether you are running on 1 or multiple processors, but assumed you are running LAMMPS on a single partition of processors. LAMMPS can be run on multiple partitions via the "-partition" command-line switch as described in [this section](#) of the manual.

In the last 2 examples, if LAMMPS were run on 3 partitions, the same scripts could be used if the "index" and "loop" variables were replaced with *universe*-style variables, as described in the [variable](#) command. Also, the "next t" and "next a" commands would need to be replaced with a single "next a t" command. With these modifications, the 8 simulations of each script would run on the 3 partitions one after the other until all were finished. Initially, 3 simulations would be started simultaneously, one on each partition. When one finished, that partition would then start the 4th simulation, and so forth, until all 8 were completed.

6.5 Multi-replica simulations

Several commands in LAMMPS run multi-replica simulations, meaning that multiple instances (replicas) of your simulation are run simultaneously, with small amounts of data exchanged between replicas periodically.

These are the relevant commands:

- [neb](#) for nudged elastic band calculations
- [prd](#) for parallel replica dynamics
- [tad](#) for temperature accelerated dynamics
- [temper](#) for parallel tempering

LAMMPS Users Manual

- [fix pimd](#) for path-integral molecular dynamics (PIMD)

NEB is a method for finding transition states and barrier energies. PRD and TAD are methods for performing accelerated dynamics to find and perform infrequent events. Parallel tempering or replica exchange runs different replicas at a series of temperature to facilitate rare-event sampling.

These commands can only be used if LAMMPS was built with the REPLICA package. See the [Making LAMMPS](#) section for more info on packages.

PIMD runs different replicas whose individual particles are coupled together by springs to model a system or ring-polymers.

This commands can only be used if LAMMPS was built with the USER-MISC package. See the [Making LAMMPS](#) section for more info on packages.

In all these cases, you must run with one or more processors per replica. The processors assigned to each replica are determined at run-time by using the [-partition command-line switch](#) to launch LAMMPS on multiple partitions, which in this context are the same as replicas. E.g. these commands:

```
mpirun -np 16 lmp_linux -partition 8x2 -in in.temper
mpirun -np 8 lmp_linux -partition 8x1 -in in.neb
```

would each run 8 replicas, on either 16 or 8 processors. Note the use of the [-in command-line switch](#) to specify the input script which is required when running in multi-replica mode.

Also note that with MPI installed on a machine (e.g. your desktop), you can run on more (virtual) processors than you have physical processors. Thus the above commands could be run on a single-processor (or few-processor) desktop so that you can run a multi-replica simulation on more replicas than you have physical processors.

6.6 Granular models

Granular system are composed of spherical particles with a diameter, as opposed to point particles. This means they have an angular velocity and torque can be imparted to them to cause them to rotate.

To run a simulation of a granular model, you will want to use the following commands:

- [atom_style sphere](#)
- [fix nve/sphere](#)
- [fix gravity](#)

This compute

- [compute erotate/sphere](#)

calculates rotational kinetic energy which can be [output with thermodynamic info](#).

LAMMPS Users Manual

Use one of these 3 pair potentials, which compute forces and torques between interacting pairs of particles:

- [pair_style gran/history](#)
- [pair_style gran/no_history](#)
- [pair_style gran/hertzian](#)

These commands implement fix options specific to granular systems:

- [fix freeze](#)
- [fix pour](#)
- [fix viscous](#)
- [fix wall/gran](#)

The fix style *freeze* zeroes both the force and torque of frozen atoms, and should be used for granular system instead of the fix style *setforce*.

For computational efficiency, you can eliminate needless pairwise computations between frozen atoms by using this command:

- [neigh_modify exclude](#)

NOTE: By default, for 2d systems, granular particles are still modeled as 3d spheres, not 2d discs (circles), meaning their moment of inertia will be the same as in 3d. If you wish to model granular particles in 2d as 2d discs, see the note on this topic in [Section 6.2](#), where 2d simulations are discussed.

6.7 TIP3P water model

The TIP3P water model as implemented in CHARMM ([MacKerell](#)) specifies a 3-site rigid water molecule with charges and Lennard-Jones parameters assigned to each of the 3 atoms. In LAMMPS the [fix shake](#) command can be used to hold the two O-H bonds and the H-O-H angle rigid. A bond style of *harmonic* and an angle style of *harmonic* or *charmm* should also be used.

These are the additional parameters (in real units) to set for O and H atoms and the water molecule to run a rigid TIP3P-CHARMM model with a cutoff. The K values can be used if a flexible TIP3P model (without fix shake) is desired. If the LJ epsilon and sigma for HH and OH are set to 0.0, it corresponds to the original 1983 TIP3P model ([Jorgensen](#)).

O mass = 15.9994
H mass = 1.008
O charge = -0.834
H charge = 0.417
LJ epsilon of OO = 0.1521
LJ sigma of OO = 3.1507
LJ epsilon of HH = 0.0460
LJ sigma of HH = 0.4000
LJ epsilon of OH = 0.0836

LAMMPS Users Manual

LJ sigma of OH = 1.7753
K of OH bond = 450
r0 of OH bond = 0.9572
K of HOH angle = 55
theta of HOH angle = 104.52

These are the parameters to use for TIP3P with a long-range Coulombic solver (e.g. Ewald or PPPM in LAMMPS), see ([Price](#)) for details:

O mass = 15.9994
H mass = 1.008
O charge = -0.830
H charge = 0.415
LJ epsilon of OO = 0.102
LJ sigma of OO = 3.188
LJ epsilon, sigma of OH, HH = 0.0
K of OH bond = 450
r0 of OH bond = 0.9572
K of HOH angle = 55
theta of HOH angle = 104.52

Wikipedia also has a nice article on [water models](#).

6.8 TIP4P water model

The four-point TIP4P rigid water model extends the traditional three-point TIP3P model by adding an additional site, usually massless, where the charge associated with the oxygen atom is placed. This site M is located at a fixed distance away from the oxygen along the bisector of the HOH bond angle. A bond style of *harmonic* and an angle style of *harmonic* or *charmm* should also be used.

A TIP4P model is run with LAMMPS using either this command for a cutoff model:

```
pair_style lj/cut/tip4p/cut
```

or these two commands for a long-range model:

- [pair_style lj/cut/tip4p/long](#)
- [kspace_style pppm/tip4p](#)

For both models, the bond lengths and bond angles should be held fixed using the [fix shake](#) command.

These are the additional parameters (in real units) to set for O and H atoms and the water molecule to run a rigid TIP4P model with a cutoff ([Jorgensen](#)). Note that the OM distance is specified in the [pair_style](#) command, not as part of the pair coefficients.

O mass = 15.9994
H mass = 1.008
O charge = -1.040

LAMMPS Users Manual

H charge = 0.520
r0 of OH bond = 0.9572
theta of HOH angle = 104.52
OM distance = 0.15
LJ epsilon of O-O = 0.1550
LJ sigma of O-O = 3.1536
LJ epsilon, sigma of OH, HH = 0.0
Coulombic cutoff = 8.5

For the TIP4/Ice model (J Chem Phys, 122, 234511 (2005);
<http://dx.doi.org/10.1063/1.1931662>) these values can be used:

O mass = 15.9994
H mass = 1.008
O charge = -1.1794
H charge = 0.5897
r0 of OH bond = 0.9572
theta of HOH angle = 104.52
OM distance = 0.1577
LJ epsilon of O-O = 0.21084
LJ sigma of O-O = 3.1668
LJ epsilon, sigma of OH, HH = 0.0
Coulombic cutoff = 8.5

For the TIP4P/2005 model (J Chem Phys, 123, 234505 (2005);
<http://dx.doi.org/10.1063/1.2121687>), these values can be used:

O mass = 15.9994
H mass = 1.008
O charge = -1.1128
H charge = 0.5564
r0 of OH bond = 0.9572
theta of HOH angle = 104.52
OM distance = 0.1546
LJ epsilon of O-O = 0.1852
LJ sigma of O-O = 3.1589
LJ epsilon, sigma of OH, HH = 0.0
Coulombic cutoff = 8.5

These are the parameters to use for TIP4P with a long-range Coulombic solver (e.g. Ewald or PPPM in LAMMPS):

O mass = 15.9994
H mass = 1.008
O charge = -1.0484
H charge = 0.5242
r0 of OH bond = 0.9572
theta of HOH angle = 104.52
OM distance = 0.1250
LJ epsilon of O-O = 0.16275
LJ sigma of O-O = 3.16435

LJ epsilon, sigma of OH, HH = 0.0

Note that when using the TIP4P pair style, the neighbor list cutoff for Coulomb interactions is effectively extended by a distance $2 * (\text{OM distance})$, to account for the offset distance of the fictitious charges on O atoms in water molecules. Thus it is typically best in an efficiency sense to use a LJ cutoff $\geq \text{Coulomb cutoff} + 2 * (\text{OM distance})$, to shrink the size of the neighbor list. This leads to slightly larger cost for the long-range calculation, so you can test the trade-off for your model. The OM distance and the LJ and Coulombic cutoffs are set in the `pair_style lj/cut/tip4p/long` command.

Wikipedia also has a nice article on [water models](#).

6.9 SPC water model

The SPC water model specifies a 3-site rigid water molecule with charges and Lennard-Jones parameters assigned to each of the 3 atoms. In LAMMPS the `fix shake` command can be used to hold the two O-H bonds and the H-O-H angle rigid. A bond style of *harmonic* and an angle style of *harmonic* or *charmm* should also be used.

These are the additional parameters (in real units) to set for O and H atoms and the water molecule to run a rigid SPC model.

O mass = 15.9994
H mass = 1.008
O charge = -0.820
H charge = 0.410
LJ epsilon of OO = 0.1553
LJ sigma of OO = 3.166
LJ epsilon, sigma of OH, HH = 0.0
r0 of OH bond = 1.0
theta of HOH angle = 109.47

Note that as originally proposed, the SPC model was run with a 9 Angstrom cutoff for both LJ and Coulombic terms. It can also be used with long-range Coulombics (Ewald or PPPM in LAMMPS), without changing any of the parameters above, though it becomes a different model in that mode of usage.

The SPC/E (extended) water model is the same, except the partial charge assignments change:

O charge = -0.8476
H charge = 0.4238

See the [\(Berendsen\)](#) reference for more details on both the SPC and SPC/E models.

Wikipedia also has a nice article on [water models](#).

6.10 Coupling LAMMPS to other codes

LAMMPS is designed to allow it to be coupled to other codes. For example, a quantum mechanics code might compute forces on a subset of atoms and pass those forces to LAMMPS. Or a continuum finite element (FE) simulation might use atom positions as boundary conditions on FE nodal points, compute a FE solution, and return interpolated forces on MD atoms.

LAMMPS can be coupled to other codes in at least 3 ways. Each has advantages and disadvantages, which you'll have to think about in the context of your application.

(1) Define a new [fix](#) command that calls the other code. In this scenario, LAMMPS is the driver code. During its timestepping, the fix is invoked, and can make library calls to the other code, which has been linked to LAMMPS as a library. This is the way the [POEMS](#) package that performs constrained rigid-body motion on groups of atoms is hooked to LAMMPS. See the [fix poems](#) command for more details. See [this section](#) of the documentation for info on how to add a new fix to LAMMPS.

(2) Define a new LAMMPS command that calls the other code. This is conceptually similar to method (1), but in this case LAMMPS and the other code are on a more equal footing. Note that now the other code is not called during the timestepping of a LAMMPS run, but between runs. The LAMMPS input script can be used to alternate LAMMPS runs with calls to the other code, invoked via the new command. The [run](#) command facilitates this with its *every* option, which makes it easy to run a few steps, invoke the command, run a few steps, invoke the command, etc.

In this scenario, the other code can be called as a library, as in (1), or it could be a stand-alone code, invoked by a `system()` call made by the command (assuming your parallel machine allows one or more processors to start up another program). In the latter case the stand-alone code could communicate with LAMMPS thru files that the command writes and reads.

See [Section 10](#) of the documentation for how to add a new command to LAMMPS.

(3) Use LAMMPS as a library called by another code. In this case the other code is the driver and calls LAMMPS as needed. Or a wrapper code could link and call both LAMMPS and another code as libraries. Again, the [run](#) command has options that allow it to be invoked with minimal overhead (no setup or clean-up) if you wish to do multiple short runs, driven by another program.

Examples of driver codes that call LAMMPS as a library are included in the `examples/COUPLE` directory of the LAMMPS distribution; see `examples/COUPLE/README` for more details:

- `simple`: simple driver programs in C++ and C which invoke LAMMPS as a library
- `lammps_quest`: coupling of LAMMPS and [Quest](#), to run classical MD with quantum forces calculated by a density functional code
- `lammps_spparks`: coupling of LAMMPS and [SPPARKS](#), to couple a kinetic Monte Carlo model for grain growth using MD to calculate strain induced across grain boundaries

LAMMPS Users Manual

[This section](#) of the documentation describes how to build LAMMPS as a library. Once this is done, you can interface with LAMMPS either via C++, C, Fortran, or Python (or any other language that supports a vanilla C-like interface). For example, from C++ you could create one (or more) "instances" of LAMMPS, pass it an input script to process, or execute individual commands, all by invoking the correct class methods in LAMMPS. From C or Fortran you can make function calls to do the same things. See [Section 11](#) of the manual for a description of the Python wrapper provided with LAMMPS that operates through the LAMMPS library interface.

The files `src/library.cpp` and `library.h` contain the C-style interface to LAMMPS. See [Section 6.19](#) of the manual for a description of the interface and how to extend it for your needs.

Note that the `lammeps_open()` function that creates an instance of LAMMPS takes an MPI communicator as an argument. This means that instance of LAMMPS will run on the set of processors in the communicator. Thus the calling code can run LAMMPS on all or a subset of processors. For example, a wrapper script might decide to alternate between LAMMPS and another code, allowing them both to run on all the processors. Or it might allocate half the processors to LAMMPS and half to the other code and run both codes simultaneously before syncing them up periodically. Or it might instantiate multiple instances of LAMMPS to perform different calculations.

6.11 Visualizing LAMMPS snapshots

LAMMPS itself does not do visualization, but snapshots from LAMMPS simulations can be visualized (and analyzed) in a variety of ways.

LAMMPS snapshots are created by the [dump](#) command which can create files in several formats. The native LAMMPS dump format is a text file (see "dump atom" or "dump custom") which can be visualized by several popular visualization tools. The [dump image](#) and [dump movie](#) styles can output internally rendered images and convert a sequence of them to a movie during the MD run. Several programs included with LAMMPS as auxiliary tools can convert between LAMMPS format files and other formats. See the [Section 9](#) doc page for details.

A Python-based toolkit distributed by our group can read native LAMMPS dump files, including custom dump files with additional columns of user-specified atom information, and convert them to various formats or pipe them into visualization software directly. See the [Pizza.py WWW site](#) for details. Specifically, `Pizza.py` can convert LAMMPS dump files into PDB, XYZ, [Ensignt](#), and VTK formats. `Pizza.py` can pipe LAMMPS dump files directly into the Raster3d and RasMol visualization programs. `Pizza.py` has tools that do interactive 3d OpenGL visualization and one that creates SVG images of dump file snapshots.

6.12 Triclinic (non-orthogonal) simulation boxes

By default, LAMMPS uses an orthogonal simulation box to encompass the particles. The [boundary](#) command sets the boundary conditions of the box (periodic,

LAMMPS Users Manual

non-periodic, etc). The orthogonal box has its "origin" at (x_{lo}, y_{lo}, z_{lo}) and is defined by 3 edge vectors starting from the origin given by $\mathbf{a} = (x_{hi} - x_{lo}, 0, 0)$; $\mathbf{b} = (0, y_{hi} - y_{lo}, 0)$; $\mathbf{c} = (0, 0, z_{hi} - z_{lo})$. The 6 parameters $(x_{lo}, x_{hi}, y_{lo}, y_{hi}, z_{lo}, z_{hi})$ are defined at the time the simulation box is created, e.g. by the `create_box` or `read_data` or `read_restart` commands. Additionally, LAMMPS defines box size parameters l_x, l_y, l_z where $l_x = x_{hi} - x_{lo}$, and similarly in the y and z dimensions. The 6 parameters, as well as l_x, l_y, l_z , can be output via the `thermo_style custom` command.

LAMMPS also allows simulations to be performed in triclinic (non-orthogonal) simulation boxes shaped as a parallelepiped with triclinic symmetry. The parallelepiped has its "origin" at (x_{lo}, y_{lo}, z_{lo}) and is defined by 3 edge vectors starting from the origin given by $\mathbf{a} = (x_{hi} - x_{lo}, 0, 0)$; $\mathbf{b} = (x_y, y_{hi} - y_{lo}, 0)$; $\mathbf{c} = (x_z, y_z, z_{hi} - z_{lo})$. x_y, x_z, y_z can be 0.0 or positive or negative values and are called "tilt factors" because they are the amount of displacement applied to faces of an originally orthogonal box to transform it into the parallelepiped. In LAMMPS the triclinic simulation box edge vectors \mathbf{a} , \mathbf{b} , and \mathbf{c} cannot be arbitrary vectors. As indicated, \mathbf{a} must lie on the positive x axis. \mathbf{b} must lie in the xy plane, with strictly positive y component. \mathbf{c} may have any orientation with strictly positive z component. The requirement that \mathbf{a} , \mathbf{b} , and \mathbf{c} have strictly positive x , y , and z components, respectively, ensures that \mathbf{a} , \mathbf{b} , and \mathbf{c} form a complete right-handed basis. These restrictions impose no loss of generality, since it is possible to rotate/invert any set of 3 crystal basis vectors so that they conform to the restrictions.

For example, assume that the 3 vectors $\mathbf{A}, \mathbf{B}, \mathbf{C}$ are the edge vectors of a general parallelepiped, where there is no restriction on $\mathbf{A}, \mathbf{B}, \mathbf{C}$ other than they form a complete right-handed basis i.e. $\mathbf{A} \times \mathbf{B} \cdot \mathbf{C} > 0$. The equivalent LAMMPS $\mathbf{a}, \mathbf{b}, \mathbf{c}$ are a linear rotation of \mathbf{A} , \mathbf{B} , and \mathbf{C} and can be computed as follows:

$$\begin{aligned}
 (\mathbf{a} \quad \mathbf{b} \quad \mathbf{c}) &= \begin{pmatrix} a_x & b_x & c_x \\ 0 & b_y & c_y \\ 0 & 0 & c_z \end{pmatrix} \\
 a_x &= A \\
 b_x &= \mathbf{B} \cdot \hat{\mathbf{A}} = B \cos \gamma \\
 b_y &= |\hat{\mathbf{A}} \times \mathbf{B}| = B \sin \gamma = \sqrt{B^2 - b_x^2} \\
 c_x &= \mathbf{C} \cdot \hat{\mathbf{A}} = C \cos \beta \\
 c_y &= \mathbf{C} \cdot (\widehat{\mathbf{A} \times \mathbf{B}}) \times \hat{\mathbf{A}} = \frac{\mathbf{B} \cdot \mathbf{C} - b_x c_x}{b_y} \\
 c_z &= |\mathbf{C} \cdot (\widehat{\mathbf{A} \times \mathbf{B}})| = \sqrt{C^2 - c_x^2 - c_y^2}
 \end{aligned}$$

where $A = |\mathbf{A}|$ indicates the scalar length of \mathbf{A} . The hat symbol ($\hat{}$) indicates the corresponding unit vector. *beta* and *gamma* are angles between the vectors described below. Note that by construction, \mathbf{a} , \mathbf{b} , and \mathbf{c} have strictly positive x, y, and z components, respectively. If it should happen that \mathbf{A} , \mathbf{B} , and \mathbf{C} form a left-handed basis, then the above equations are not valid for \mathbf{c} . In this case, it is necessary to first apply an inversion. This can be achieved by interchanging two basis vectors or by changing the sign of one of them.

For consistency, the same rotation/inversion applied to the basis vectors must also be applied to atom positions, velocities, and any other vector quantities. This can be conveniently achieved by first converting to fractional coordinates in the old basis and then converting to distance coordinates in the new basis. The transformation is given by the following equation:

$$\mathbf{x} = (\mathbf{a} \quad \mathbf{b} \quad \mathbf{c}) \cdot \frac{1}{V} \begin{pmatrix} \mathbf{B} \times \mathbf{C} \\ \mathbf{C} \times \mathbf{A} \\ \mathbf{A} \times \mathbf{B} \end{pmatrix} \cdot \mathbf{X}$$

LAMMPS Users Manual

where V is the volume of the box, \mathbf{X} is the original vector quantity and \mathbf{x} is the vector in the LAMMPS basis.

There is no requirement that a triclinic box be periodic in any dimension, though it typically should be in at least the 2nd dimension of the tilt (y in xy) if you want to enforce a shift in periodic boundary conditions across that boundary. Some commands that work with triclinic boxes, e.g. the [fix deform](#) and [fix npt](#) commands, require periodicity or non-shrink-wrap boundary conditions in specific dimensions. See the command doc pages for details.

The 9 parameters (xlo,xhi,ylo,yhi,zlo,zhi,xy,xz,yz) are defined at the time the simulation box is created. This happens in one of 3 ways. If the [create_box](#) command is used with a region of style *prism*, then a triclinic box is setup. See the [region](#) command for details. If the [read_data](#) command is used to define the simulation box, and the header of the data file contains a line with the "xy xz yz" keyword, then a triclinic box is setup. See the [read_data](#) command for details. Finally, if the [read_restart](#) command reads a restart file which was written from a simulation using a triclinic box, then a triclinic box will be setup for the restarted simulation.

Note that you can define a triclinic box with all 3 tilt factors = 0.0, so that it is initially orthogonal. This is necessary if the box will become non-orthogonal, e.g. due to the [fix npt](#) or [fix deform](#) commands. Alternatively, you can use the [change_box](#) command to convert a simulation box from orthogonal to triclinic and vice versa.

As with orthogonal boxes, LAMMPS defines triclinic box size parameters lx,ly,lz where $lx = xhi - xlo$, and similarly in the y and z dimensions. The 9 parameters, as well as lx,ly,lz, can be output via the [thermo_style custom](#) command.

To avoid extremely tilted boxes (which would be computationally inefficient), LAMMPS normally requires that no tilt factor can skew the box more than half the distance of the parallel box length, which is the 1st dimension in the tilt factor (x for xz). This is required both when the simulation box is created, e.g. via the [create_box](#) or [read_data](#) commands, as well as when the box shape changes dynamically during a simulation, e.g. via the [fix deform](#) or [fix npt](#) commands.

For example, if $xlo = 2$ and $xhi = 12$, then the x box length is 10 and the xy tilt factor must be between -5 and 5. Similarly, both xz and yz must be between $-(xhi - xlo)/2$ and $+(yhi - ylo)/2$. Note that this is not a limitation, since if the maximum tilt factor is 5 (as in this example), then configurations with tilt = ..., -15, -5, 5, 15, 25, ... are geometrically all equivalent. If the box tilt exceeds this limit during a dynamics run (e.g. via the [fix deform](#) command), then the box is "flipped" to an equivalent shape with a tilt factor within the bounds, so the run can continue. See the [fix deform](#) doc page for further details.

One exception to this rule is if the 1st dimension in the tilt factor (x for xy) is non-periodic. In that case, the limits on the tilt factor are not enforced, since flipping the box in that dimension does not change the atom positions due to non-periodicity. In this mode, if you tilt the system to extreme angles, the simulation will simply become inefficient, due to the highly skewed simulation box.

LAMMPS Users Manual

The limitation on not creating a simulation box with a tilt factor skewing the box more than half the distance of the parallel box length can be overridden via the `box` command. Setting the `tilt` keyword to `large` allows any tilt factors to be specified.

Box flips that may occur using the `fix deform` or `fix npt` commands can be turned off using the `flip no` option with either of the commands.

Note that if a simulation box has a large tilt factor, LAMMPS will run less efficiently, due to the large volume of communication needed to acquire ghost atoms around a processor's irregular-shaped sub-domain. For extreme values of tilt, LAMMPS may also lose atoms and generate an error.

Triclinic crystal structures are often defined using three lattice constants a , b , and c , and three angles α , β and γ . Note that in this nomenclature, the a , b , and c lattice constants are the scalar lengths of the edge vectors \mathbf{a} , \mathbf{b} , and \mathbf{c} defined above. The relationship between these 6 quantities ($a,b,c,\alpha,\beta,\gamma$) and the LAMMPS box sizes $(lx,ly,lz) = (xhi-xlo,yhi-ylo,zhi-zlo)$ and tilt factors (xy,xz,yz) is as follows:

$$\begin{aligned} a &= lx \\ b^2 &= ly^2 + xy^2 \\ c^2 &= lz^2 + xz^2 + yz^2 \\ \cos \alpha &= \frac{xy * xz + ly * yz}{b * c} \\ \cos \beta &= \frac{xz}{c} \\ \cos \gamma &= \frac{xy}{b} \end{aligned}$$

The inverse relationship can be written as follows:

LAMMPS Users Manual

$$\begin{aligned}l_x &= a \\xy &= b \cos \gamma \\xz &= c \cos \beta \\ly^2 &= b^2 - xy^2 \\yz &= \frac{b * c \cos \alpha - xy * xz}{ly} \\lz^2 &= c^2 - xz^2 - yz^2\end{aligned}$$

The values of a , b , c , α , β , and γ can be printed out or accessed by computes using the [thermo_style custom](#) keywords *cella*, *cellb*, *cellc*, *cellalpha*, *cellbeta*, *cellgamma*, respectively.

As discussed on the [dump](#) command doc page, when the BOX BOUNDS for a snapshot is written to a dump file for a triclinic box, an orthogonal bounding box which encloses the triclinic simulation box is output, along with the 3 tilt factors (xy , xz , yz) of the triclinic box, formatted as follows:

```
ITEM: BOX BOUNDS xy xz yz
xlo_bound xhi_bound xy
ylo_bound yhi_bound xz
zlo_bound zhi_bound yz
```

This bounding box is convenient for many visualization programs and is calculated from the 9 triclinic box parameters ($xlo, xhi, ylo, yhi, zlo, zhi, xy, xz, yz$) as follows:

```
xlo_bound = xlo + MIN(0.0, xy, xz, xy+xz)
xhi_bound = xhi + MAX(0.0, xy, xz, xy+xz)
ylo_bound = ylo + MIN(0.0, yz)
yhi_bound = yhi + MAX(0.0, yz)
zlo_bound = zlo
zhi_bound = zhi
```

These formulas can be inverted if you need to convert the bounding box back into the triclinic box parameters, e.g. $xlo = xlo_bound - MIN(0.0, xy, xz, xy+xz)$.

One use of triclinic simulation boxes is to model solid-state crystals with triclinic symmetry. The [lattice](#) command can be used with non-orthogonal basis vectors to define a lattice that will tile a triclinic simulation box via the [create_atoms](#) command.

A second use is to run Parinello-Rahman dynamics via the [fix npt](#) command, which will adjust the xy , xz , yz tilt factors to compensate for off-diagonal components of the pressure tensor. The analog for an [energy minimization](#) is the [fix box/relax](#) command.

A third use is to shear a bulk solid to study the response of the material. The [fix deform](#) command can be used for this purpose. It allows dynamic control of the xy, xz, yz tilt factors as a simulation runs. This is discussed in the next section on non-equilibrium MD (NEMD) simulations.

6.13 NEMD simulations

Non-equilibrium molecular dynamics or NEMD simulations are typically used to measure a fluid's rheological properties such as viscosity. In LAMMPS, such simulations can be performed by first setting up a non-orthogonal simulation box (see the preceding Howto section).

A shear strain can be applied to the simulation box at a desired strain rate by using the [fix deform](#) command. The [fix nvt/sllod](#) command can be used to thermostat the sheared fluid and integrate the SLLD equations of motion for the system. Fix nvt/sllod uses [compute temp/deform](#) to compute a thermal temperature by subtracting out the streaming velocity of the shearing atoms. The velocity profile or other properties of the fluid can be monitored via the [fix ave/chunk](#) command.

As discussed in the previous section on non-orthogonal simulation boxes, the amount of tilt or skew that can be applied is limited by LAMMPS for computational efficiency to be 1/2 of the parallel box length. However, [fix deform](#) can continuously strain a box by an arbitrary amount. As discussed in the [fix deform](#) command, when the tilt value reaches a limit, the box is flipped to the opposite limit which is an equivalent tiling of periodic space. The strain rate can then continue to change as before. In a long NEMD simulation these box re-shaping events may occur many times.

In a NEMD simulation, the "remap" option of [fix deform](#) should be set to "remap v", since that is what [fix nvt/sllod](#) assumes to generate a velocity profile consistent with the applied shear strain rate.

An alternative method for calculating viscosities is provided via the [fix viscosity](#) command.

NEMD simulations can also be used to measure transport properties of a fluid through a pore or channel. Simulations of steady-state flow can be performed using the [fix flow/gauss](#) command.

6.14 Finite-size spherical and aspherical particles

Typical MD models treat atoms or particles as point masses. Sometimes it is desirable to have a model with finite-size particles such as spheroids or ellipsoids or generalized aspherical bodies. The difference is that such particles have a moment of inertia, rotational energy, and angular momentum. Rotation is induced by torque coming from interactions with other particles.

LAMMPS has several options for running simulations with these kinds of particles. The following aspects are discussed in turn:

LAMMPS Users Manual

- atom styles
- pair potentials
- time integration
- computes, thermodynamics, and dump output
- rigid bodies composed of finite-size particles

Example input scripts for these kinds of models are in the `body`, `colloid`, `dipole`, `ellipse`, `line`, `peri`, `pour`, and `tri` directories of the [examples directory](#) in the LAMMPS distribution.

Atom styles

There are several [atom styles](#) that allow for definition of finite-size particles: `sphere`, `dipole`, `ellipsoid`, `line`, `tri`, `peri`, and `body`.

The `sphere` style defines particles that are spheroids and each particle can have a unique diameter and mass (or density). These particles store an angular velocity (ω) and can be acted upon by torque. The "set" command can be used to modify the diameter and mass of individual particles, after then are created.

The `dipole` style does not actually define finite-size particles, but is often used in conjunction with spherical particles, via a command like

```
atom_style hybrid sphere dipole
```

This is because when dipoles interact with each other, they induce torques, and a particle must be finite-size (i.e. have a moment of inertia) in order to respond and rotate. See the [atom_style dipole](#) command for details. The "set" command can be used to modify the orientation and length of the dipole moment of individual particles, after then are created.

The `ellipsoid` style defines particles that are ellipsoids and thus can be aspherical. Each particle has a shape, specified by 3 diameters, and mass (or density). These particles store an angular momentum and their orientation (quaternion), and can be acted upon by torque. They do not store an angular velocity (ω), which can be in a different direction than angular momentum, rather they compute it as needed. The "set" command can be used to modify the diameter, orientation, and mass of individual particles, after then are created. It also has a brief explanation of what quaternions are.

The `line` style defines line segment particles with two end points and a mass (or density). They can be used in 2d simulations, and they can be joined together to form rigid bodies which represent arbitrary polygons.

The `tri` style defines triangular particles with three corner points and a mass (or density). They can be used in 3d simulations, and they can be joined together to form rigid bodies which represent arbitrary particles with a triangulated surface.

The `peri` style is used with [Peridynamic models](#) and defines particles as having a volume, that is used internally in the [pair_style peri](#) potentials.

LAMMPS Users Manual

The body style allows for definition of particles which can represent complex entities, such as surface meshes of discrete points, collections of sub-particles, deformable objects, etc. The body style is discussed in more detail on the [body](#) doc page.

Note that if one of these atom styles is used (or multiple styles via the [atom_style hybrid](#) command), not all particles in the system are required to be finite-size or aspherical.

For example, in the ellipsoid style, if the 3 shape parameters are set to the same value, the particle will be a sphere rather than an ellipsoid. If the 3 shape parameters are all set to 0.0 or if the diameter is set to 0.0, it will be a point particle. In the line or tri style, if the lineflag or triflag is specified as 0, then it will be a point particle.

Some of the pair styles used to compute pairwise interactions between finite-size particles also compute the correct interaction with point particles as well, e.g. the interaction between a point particle and a finite-size particle or between two point particles. If necessary, [pair_style hybrid](#) can be used to insure the correct interactions are computed for the appropriate style of interactions. Likewise, using groups to partition particles (ellipsoids versus spheres versus point particles) will allow you to use the appropriate time integrators and temperature computations for each class of particles. See the doc pages for various commands for details.

Also note that for [2d simulations](#), atom styles sphere and ellipsoid still use 3d particles, rather than as circular disks or ellipses. This means they have the same moment of inertia as the 3d object. When temperature is computed, the correct degrees of freedom are used for rotation in a 2d versus 3d system.

Pair potentials

When a system with finite-size particles is defined, the particles will only rotate and experience torque if the force field computes such interactions. These are the various [pair styles](#) that generate torque:

- [pair_style gran/history](#)
- [pair_style gran/hertzian](#)
- [pair_style gran/no_history](#)
- [pair_style dipole/cut](#)
- [pair_style gayberne](#)
- [pair_style resquared](#)
- [pair_style brownian](#)
- [pair_style lubricate](#)
- [pair_style line/lj](#)
- [pair_style tri/lj](#)
- [pair_style body](#)

The granular pair styles are used with spherical particles. The dipole pair style is used with the dipole atom style, which could be applied to spherical or ellipsoidal particles. The GayBerne and REsquared potentials require ellipsoidal particles, though they will also work if the 3 shape parameters are the same (a sphere). The Brownian and lubrication potentials are used with spherical particles. The line, tri, and body potentials are used with line segment, triangular, and body particles respectively.

Time integration

There are several fixes that perform time integration on finite-size spherical particles, meaning the integrators update the rotational orientation and angular velocity or angular momentum of the particles:

- [fix nve/sphere](#)
- [fix nvt/sphere](#)
- [fix npt/sphere](#)

Likewise, there are 3 fixes that perform time integration on ellipsoidal particles:

- [fix nve/asphere](#)
- [fix nvt/asphere](#)
- [fix npt/asphere](#)

The advantage of these fixes is that those which thermostat the particles include the rotational degrees of freedom in the temperature calculation and thermostating. The [fix langevin](#) command can also be used with its *omega* or *angmom* options to thermostat the rotational degrees of freedom for spherical or ellipsoidal particles. Other thermostating fixes only operate on the translational kinetic energy of finite-size particles.

These fixes perform constant NVE time integration on line segment, triangular, and body particles:

- [fix nve/line](#)
- [fix nve/tri](#)
- [fix nve/body](#)

Note that for mixtures of point and finite-size particles, these integration fixes can only be used with [groups](#) which contain finite-size particles.

Computes, thermodynamics, and dump output

There are several computes that calculate the temperature or rotational energy of spherical or ellipsoidal particles:

- [compute temp/sphere](#)
- [compute temp/asphere](#)
- [compute erotate/sphere](#)
- [compute erotate/asphere](#)

These include rotational degrees of freedom in their computation. If you wish the thermodynamic output of temperature or pressure to use one of these computes (e.g. for a system entirely composed of finite-size particles), then the compute can be defined and the [thermo_modify](#) command used. Note that by default thermodynamic quantities will be calculated with a temperature that only includes translational degrees of freedom. See the [thermo_style](#) command for details.

These commands can be used to output various attributes of finite-size particles:

- [dump custom](#)
- [compute property/atom](#)
- [dump local](#)
- [compute body/local](#)

Attributes include the dipole moment, the angular velocity, the angular momentum, the quaternion, the torque, the end-point and corner-point coordinates (for line and tri particles), and sub-particle attributes of body particles.

Rigid bodies composed of finite-size particles

The [fix rigid](#) command treats a collection of particles as a rigid body, computes its inertia tensor, sums the total force and torque on the rigid body each timestep due to forces on its constituent particles, and integrates the motion of the rigid body.

If any of the constituent particles of a rigid body are finite-size particles (spheres or ellipsoids or line segments or triangles), then their contribution to the inertia tensor of the body is different than if they were point particles. This means the rotational dynamics of the rigid body will be different. Thus a model of a dimer is different if the dimer consists of two point masses versus two spheroids, even if the two particles have the same mass. Finite-size particles that experience torque due to their interaction with other particles will also impart that torque to a rigid body they are part of.

See the "fix rigid" command for example of complex rigid-body models it is possible to define in LAMMPS.

Note that the [fix shake](#) command can also be used to treat 2, 3, or 4 particles as a rigid body, but it always assumes the particles are point masses.

Also note that body particles cannot be modeled with the [fix rigid](#) command. Body particles are treated by LAMMPS as single particles, though they can store internal state, such as a list of sub-particles. Individual body particles are typically treated as rigid bodies, and their motion integrated with a command like [fix nve/body](#). Interactions between pairs of body particles are computed via a command like [pair_style body](#).

6.15 Output from LAMMPS (thermo, dumps, computes, fixes, variables)

There are four basic kinds of LAMMPS output:

- [Thermodynamic output](#), which is a list of quantities printed every few timesteps to the screen and logfile.
- [Dump files](#), which contain snapshots of atoms and various per-atom values and are written at a specified frequency.
- Certain fixes can output user-specified quantities to files: [fix ave/time](#) for time averaging, [fix ave/chunk](#) for spatial or other averaging, and [fix print](#) for single-line output of [variables](#). Fix print can also output to the screen.
- [Restart files](#).

LAMMPS Users Manual

A simulation prints one set of thermodynamic output and (optionally) restart files. It can generate any number of dump files and fix output files, depending on what [dump](#) and [fix](#) commands you specify.

As discussed below, LAMMPS gives you a variety of ways to determine what quantities are computed and printed when the thermodynamics, dump, or fix commands listed above perform output. Throughout this discussion, note that users can also [add their own computes and fixes to LAMMPS](#) which can then generate values that can then be output with these commands.

The following sub-sections discuss different LAMMPS command related to output and the kind of data they operate on and produce:

- [Global/per-atom/local data](#)
- [Scalar/vector/array data](#)
- [Thermodynamic output](#)
- [Dump file output](#)
- [Fixes that write output files](#)
- [Computes that process output quantities](#)
- [Fixes that process output quantities](#)
- [Computes that generate values to output](#)
- [Fixes that generate values to output](#)
- [Variables that generate values to output](#)
- [Summary table of output options and data flow between commands](#)

Global/per-atom/local data

Various output-related commands work with three different styles of data: global, per-atom, or local. A global datum is one or more system-wide values, e.g. the temperature of the system. A per-atom datum is one or more values per atom, e.g. the kinetic energy of each atom. Local datums are calculated by each processor based on the atoms it owns, but there may be zero or more per atom, e.g. a list of bond distances.

Scalar/vector/array data

Global, per-atom, and local datums can each come in three kinds: a single scalar value, a vector of values, or a 2d array of values. The doc page for a "compute" or "fix" or "variable" that generates data will specify both the style and kind of data it produces, e.g. a per-atom vector.

When a quantity is accessed, as in many of the output commands discussed below, it can be referenced via the following bracket notation, where ID in this case is the ID of a compute. The leading "c_" would be replaced by "f_" for a fix, or "v_" for a variable:

c_ID	entire scalar, vector, or array
c_ID[I]	one element of vector, one column of array
c_ID[I][J]	one element of array

In other words, using one bracket reduces the dimension of the data once (vector -> scalar, array -> vector). Using two brackets reduces the dimension twice (array ->

LAMMPS Users Manual

scalar). Thus a command that uses scalar values as input can typically also process elements of a vector or array.

Thermodynamic output

The frequency and format of thermodynamic output is set by the [thermo](#), [thermo_style](#), and [thermo_modify](#) commands. The [thermo_style](#) command also specifies what values are calculated and written out. Pre-defined keywords can be specified (e.g. [press](#), [etotal](#), etc). Three additional kinds of keywords can also be specified ([c_ID](#), [f_ID](#), [v_name](#)), where a [compute](#) or [fix](#) or [variable](#) provides the value to be output. In each case, the compute, fix, or variable must generate global values for input to the [thermo_style custom](#) command.

Note that thermodynamic output values can be "extensive" or "intensive". The former scale with the number of atoms in the system (e.g. total energy), the latter do not (e.g. temperature). The setting for [thermo_modify norm](#) determines whether extensive quantities are normalized or not. Computes and fixes produce either extensive or intensive values; see their individual doc pages for details. [Equal-style variables](#) produce only intensive values; you can include a division by "natoms" in the formula if desired, to make an extensive calculation produce an intensive result.

Dump file output

Dump file output is specified by the [dump](#) and [dump_modify](#) commands. There are several pre-defined formats ([dump atom](#), [dump xtc](#), etc).

There is also a [dump custom](#) format where the user specifies what values are output with each atom. Pre-defined atom attributes can be specified ([id](#), [x](#), [fx](#), etc). Three additional kinds of keywords can also be specified ([c_ID](#), [f_ID](#), [v_name](#)), where a [compute](#) or [fix](#) or [variable](#) provides the values to be output. In each case, the compute, fix, or variable must generate per-atom values for input to the [dump custom](#) command.

There is also a [dump local](#) format where the user specifies what local values to output. A pre-defined index keyword can be specified to enumerate the local values. Two additional kinds of keywords can also be specified ([c_ID](#), [f_ID](#)), where a [compute](#) or [fix](#) or [variable](#) provides the values to be output. In each case, the compute or fix must generate local values for input to the [dump local](#) command.

Fixes that write output files

Several fixes take various quantities as input and can write output files: [fix ave/time](#), [fix ave/chunk](#), [fix ave/histo](#), [fix ave/correlate](#), and [fix print](#).

The [fix ave/time](#) command enables direct output to a file and/or time-averaging of global scalars or vectors. The user specifies one or more quantities as input. These can be global [compute](#) values, global [fix](#) values, or [variables](#) of any style except the atom style which produces per-atom values. Since a variable can refer to keywords used by the [thermo_style custom](#) command (like [temp](#) or [press](#)) and individual per-atom values, a wide variety of quantities can be time averaged and/or output in this way. If the inputs are one or more scalar values, then the fix generate a global

LAMMPS Users Manual

scalar or vector of output. If the inputs are one or more vector values, then the `fix` generates a global vector or array of output. The time-averaged output of this `fix` can also be used as input to other output commands.

The `fix ave/chunk` command enables direct output to a file of chunk-averaged per-atom quantities like those output in dump files. Chunks can represent spatial bins or other collections of atoms, e.g. individual molecules. The per-atom quantities can be atom density (mass or number) or atom attributes such as position, velocity, force. They can also be per-atom quantities calculated by a `compute`, by a `fix`, or by an atom-style `variable`. The chunk-averaged output of this `fix` can also be used as input to other output commands.

The `fix ave/histo` command enables direct output to a file of histogrammed quantities, which can be global or per-atom or local quantities. The histogram output of this `fix` can also be used as input to other output commands.

The `fix ave/correlate` command enables direct output to a file of time-correlated quantities, which can be global values. The correlation matrix output of this `fix` can also be used as input to other output commands.

The `fix print` command can generate a line of output written to the screen and log file or to a separate file, periodically during a running simulation. The line can contain one or more `variable` values for any style variable except the vector or atom styles). As explained above, variables themselves can contain references to global values generated by `thermodynamic keywords`, `computes`, `fixes`, or other `variables`, or to per-atom values for a specific atom. Thus the `fix print` command is a means to output a wide variety of quantities separate from normal thermodynamic or dump file output.

Computes that process output quantities

The `compute reduce` and `compute reduce/region` commands take one or more per-atom or local vector quantities as inputs and "reduce" them (sum, min, max, ave) to scalar quantities. These are produced as output values which can be used as input to other output commands.

The `compute slice` command take one or more global vector or array quantities as inputs and extracts a subset of their values to create a new vector or array. These are produced as output values which can be used as input to other output commands.

The `compute property/atom` command takes a list of one or more pre-defined atom attributes (id, x, fx, etc) and stores the values in a per-atom vector or array. These are produced as output values which can be used as input to other output commands. The list of atom attributes is the same as for the `dump custom` command.

The `compute property/local` command takes a list of one or more pre-defined local attributes (bond info, angle info, etc) and stores the values in a local vector or array. These are produced as output values which can be used as input to other output commands.

LAMMPS Users Manual

Fixes that process output quantities

The [fix vector](#) command can create global vectors as output from global scalars as input, accumulating them one element at a time.

The [fix ave/atom](#) command performs time-averaging of per-atom vectors. The per-atom quantities can be atom attributes such as position, velocity, force. They can also be per-atom quantities calculated by a [compute](#), by a [fix](#), or by an atom-style [variable](#). The time-averaged per-atom output of this fix can be used as input to other output commands.

The [fix store/state](#) command can archive one or more per-atom attributes at a particular time, so that the old values can be used in a future calculation or output. The list of atom attributes is the same as for the [dump custom](#) command, including per-atom quantities calculated by a [compute](#), by a [fix](#), or by an atom-style [variable](#). The output of this fix can be used as input to other output commands.

Computes that generate values to output

Every [compute](#) in LAMMPS produces either global or per-atom or local values. The values can be scalars or vectors or arrays of data. These values can be output using the other commands described in this section. The doc page for each compute command describes what it produces. Computes that produce per-atom or local values have the word "atom" or "local" in their style name. Computes without the word "atom" or "local" produce global values.

Fixes that generate values to output

Some [fixes](#) in LAMMPS produces either global or per-atom or local values which can be accessed by other commands. The values can be scalars or vectors or arrays of data. These values can be output using the other commands described in this section. The doc page for each fix command tells whether it produces any output quantities and describes them.

Variables that generate values to output

[Variables](#) defined in an input script can store one or more strings. But equal-style, vector-style, and atom-style or atomfile-style variables generate a global scalar value, global vector or values, or a per-atom vector, respectively, when accessed. The formulas used to define these variables can contain references to the thermodynamic keywords and to global and per-atom data generated by computes, fixes, and other variables. The values generated by variables can be used as input to and thus output by the other commands described in this section.

Summary table of output options and data flow between commands

This table summarizes the various commands that can be used for generating output from LAMMPS. Each command produces output data of some kind and/or writes data to a file. Most of the commands can take data from other commands as input. Thus you can link many of these commands together in pipeline form, where data produced by one command is used as input to another command and eventually written to the screen or to a file. Note that to hook two commands together the output and input

LAMMPS Users Manual

data types must match, e.g. global/per-atom/local data and scalar/vector/array data.

Also note that, as described above, when a command takes a scalar as input, that could be an element of a vector or array. Likewise a vector input could be a column of an array.

Command	Input	Output
thermo_style custom	global scalars	screen, log file
dump custom	per-atom vectors	dump file
dump local	local vectors	dump file
fix print	global scalar from variable	screen, file
print	global scalar from variable	screen
computes	N/A	global/per-atom/local scalar/vector/array
fixes	N/A	global/per-atom/local scalar/vector/array
variables	global scalars and vectors, per-atom vectors	global scalar and vector, per-atom vector
compute reduce	per-atom/local vectors	global scalar/vector
compute slice	global vectors/arrays	global vector/array
compute property/atom	per-atom vectors	per-atom vector/array
compute property/local	local vectors	local vector/array
fix vector	global scalars	global vector
fix ave/atom	per-atom vectors	per-atom vector/array
fix ave/time	global scalars/vectors	global scalar/vector/array, file
fix ave/chunk	per-atom vectors	global array, file
fix ave/histo	global/per-atom/local scalars and vectors	global array, file
fix ave/correlate	global scalars	global array, file
fix store/state	per-atom vectors	per-atom vector/array

6.16 Thermostatting, barostatting, and computing temperature

Thermostatting means controlling the temperature of particles in an MD simulation. Barostatting means controlling the pressure. Since the pressure includes a kinetic component due to particle velocities, both these operations require calculation of the temperature. Typically a target temperature (T) and/or pressure (P) is specified by the user, and the thermostat or barostat attempts to equilibrate the system to the requested T and/or P.

Temperature is computed as kinetic energy divided by some number of degrees of freedom (and the Boltzmann constant). Since kinetic energy is a function of particle

LAMMPS Users Manual

velocity, there is often a need to distinguish between a particle's advection velocity (due to some aggregate motion of particles) and its thermal velocity. The sum of the two is the particle's total velocity, but the latter is often what is wanted to compute a temperature.

LAMMPS has several options for computing temperatures, any of which can be used in thermostating and barostatting. These [compute commands](#) calculate temperature, and the [compute pressure](#) command calculates pressure.

- [compute temp](#)
- [compute temp/sphere](#)
- [compute temp/asphere](#)
- [compute temp/com](#)
- [compute temp/deform](#)
- [compute temp/partial](#)
- [compute temp/profile](#)
- [compute temp/ramp](#)
- [compute temp/region](#)

All but the first 3 calculate velocity biases directly (e.g. advection velocities) that are removed when computing the thermal temperature. [Compute temp/sphere](#) and [compute temp/asphere](#) compute kinetic energy for finite-size particles that includes rotational degrees of freedom. They both allow for velocity biases indirectly, via an optional extra argument, another temperature compute that subtracts a velocity bias. This allows the translational velocity of spherical or aspherical particles to be adjusted in prescribed ways.

Thermostating in LAMMPS is performed by [fixes](#), or in one case by a pair style. Several thermostating fixes are available: Nose-Hoover (nvt), Berendsen, CSVR, Langevin, and direct rescaling (temp/rescale). Dissipative particle dynamics (DPD) thermostating can be invoked via the *dpd/tstat* pair style:

- [fix nvt](#)
- [fix nvt/sphere](#)
- [fix nvt/asphere](#)
- [fix nvt/sllod](#)
- [fix temp/berendsen](#)
- [fix temp/csvr](#)
- [fix langevin](#)
- [fix temp/rescale](#)
- [pair_style dpd/tstat](#)

[Fix nvt](#) only thermostats the translational velocity of particles. [Fix nvt/sllod](#) also does this, except that it subtracts out a velocity bias due to a deforming box and integrates the SLLD equations of motion. See the [NEMD simulations](#) section of this page for further details. [Fix nvt/sphere](#) and [fix nvt/asphere](#) thermostat not only translation velocities but also rotational velocities for spherical and aspherical particles.

DPD thermostating alters pairwise interactions in a manner analogous to the per-particle thermostating of [fix langevin](#).

LAMMPS Users Manual

Any of the thermostating fixes can use temperature computes that remove bias which has two effects. First, the current calculated temperature, which is compared to the requested target temperature, is calculated with the velocity bias removed. Second, the thermostat adjusts only the thermal temperature component of the particle's velocities, which are the velocities with the bias removed. The removed bias is then added back to the adjusted velocities. See the doc pages for the individual fixes and for the [fix_modify](#) command for instructions on how to assign a temperature compute to a thermostating fix. For example, you can apply a thermostat to only the x and z components of velocity by using it in conjunction with [compute temp/partial](#). Of you could thermostat only the thermal temperature of a streaming flow of particles without affecting the streaming velocity, by using [compute temp/profile](#).

NOTE: Only the nvt fixes perform time integration, meaning they update the velocities and positions of particles due to forces and velocities respectively. The other thermostat fixes only adjust velocities; they do NOT perform time integration updates. Thus they should be used in conjunction with a constant NVE integration fix such as these:

- [fix nve](#)
- [fix nve/sphere](#)
- [fix nve/asphere](#)

Barostatting in LAMMPS is also performed by [fixes](#). Two barostatting methods are currently available: Nose-Hoover (npt and nph) and Berendsen:

- [fix npt](#)
- [fix npt/sphere](#)
- [fix npt/asphere](#)
- [fix nph](#)
- [fix press/berendsen](#)

The [fix npt](#) commands include a Nose-Hoover thermostat and barostat. [Fix nph](#) is just a Nose/Hoover barostat; it does no thermostating. Both [fix nph](#) and [fix press/berendsen](#) can be used in conjunction with any of the thermostating fixes.

As with the thermostats, [fix npt](#) and [fix nph](#) only use translational motion of the particles in computing T and P and performing thermo/barostatting. [Fix npt/sphere](#) and [fix npt/asphere](#) thermo/barostat using not only translation velocities but also rotational velocities for spherical and aspherical particles.

All of the barostatting fixes use the [compute pressure](#) compute to calculate a current pressure. By default, this compute is created with a simple [compute temp](#) (see the last argument of the [compute pressure](#) command), which is used to calculate the kinetic component of the pressure. The barostatting fixes can also use temperature computes that remove bias for the purpose of computing the kinetic component which contributes to the current pressure. See the doc pages for the individual fixes and for the [fix_modify](#) command for instructions on how to assign a temperature or pressure compute to a barostatting fix.

NOTE: As with the thermostats, the Nose/Hoover methods ([fix npt](#) and [fix nph](#)) perform time integration. [Fix press/berendsen](#) does NOT, so it should be used with

one of the constant NVE fixes or with one of the NVT fixes.

Finally, thermodynamic output, which can be setup via the [thermo_style](#) command, often includes temperature and pressure values. As explained on the doc page for the [thermo_style](#) command, the default T and P are setup by the thermo command itself. They are NOT the ones associated with any thermostatting or barostatting fix you have defined or with any compute that calculates a temperature or pressure. Thus if you want to view these values of T and P, you need to specify them explicitly via a [thermo_style custom](#) command. Or you can use the [thermo_modify](#) command to re-define what temperature or pressure compute is used for default thermodynamic output.

6.17 Walls

Walls in an MD simulation are typically used to bound particle motion, i.e. to serve as a boundary condition.

Walls in LAMMPS can be of rough (made of particles) or idealized surfaces. Ideal walls can be smooth, generating forces only in the normal direction, or frictional, generating forces also in the tangential direction.

Rough walls, built of particles, can be created in various ways. The particles themselves can be generated like any other particle, via the [lattice](#) and [create_atoms](#) commands, or read in via the [read_data](#) command.

Their motion can be constrained by many different commands, so that they do not move at all, move together as a group at constant velocity or in response to a net force acting on them, move in a prescribed fashion (e.g. rotate around a point), etc. Note that if a time integration fix like [fix nve](#) or [fix nvt](#) is not used with the group that contains wall particles, their positions and velocities will not be updated.

- [fix aveforce](#) - set force on particles to average value, so they move together
- [fix setforce](#) - set force on particles to a value, e.g. 0.0
- [fix freeze](#) - freeze particles for use as granular walls
- [fix nve/noforce](#) - advect particles by their velocity, but without force
- [fix move](#) - prescribe motion of particles by a linear velocity, oscillation, rotation, variable

The [fix move](#) command offers the most generality, since the motion of individual particles can be specified with [variable](#) formula which depends on time and/or the particle position.

For rough walls, it may be useful to turn off pairwise interactions between wall particles via the [neigh_modify exclude](#) command.

Rough walls can also be created by specifying frozen particles that do not move and do not interact with mobile particles, and then tethering other particles to the fixed particles, via a [bond](#). The bonded particles do interact with other mobile particles.

LAMMPS Users Manual

Idealized walls can be specified via several `fix` commands. `Fix wall/gran` creates frictional walls for use with granular particles; all the other commands create smooth walls.

- `fix wall/reflect` - reflective flat walls
- `fix wall/lj93` - flat walls, with Lennard-Jones 9/3 potential
- `fix wall/lj126` - flat walls, with Lennard-Jones 12/6 potential
- `fix wall/colloid` - flat walls, with `pair_style colloid` potential
- `fix wall/harmonic` - flat walls, with repulsive harmonic spring potential
- `fix wall/region` - use region surface as wall
- `fix wall/gran` - flat or curved walls with `pair_style granular` potential

The `lj93`, `lj126`, `colloid`, and `harmonic` styles all allow the flat walls to move with a constant velocity, or oscillate in time. The `fix wall/region` command offers the most generality, since the region surface is treated as a wall, and the geometry of the region can be a simple primitive volume (e.g. a sphere, or cube, or plane), or a complex volume made from the union and intersection of primitive volumes. `Regions` can also specify a volume "interior" or "exterior" to the specified primitive shape or *union* or *intersection*. `Regions` can also be "dynamic" meaning they move with constant velocity, oscillate, or rotate.

The only frictional idealized walls currently in LAMMPS are flat or curved surfaces specified by the `fix wall/gran` command. At some point we plan to allow region surfaces to be used as frictional walls, as well as triangulated surfaces.

6.18 Elastic constants

Elastic constants characterize the stiffness of a material. The formal definition is provided by the linear relation that holds between the stress and strain tensors in the limit of infinitesimal deformation. In tensor notation, this is expressed as $s_{ij} = C_{ijkl} * e_{kl}$, where the repeated indices imply summation. s_{ij} are the elements of the symmetric stress tensor. e_{kl} are the elements of the symmetric strain tensor. C_{ijkl} are the elements of the fourth rank tensor of elastic constants. In three dimensions, this tensor has $3^4=81$ elements. Using Voigt notation, the tensor can be written as a 6x6 matrix, where C_{ij} is now the derivative of s_i w.r.t. e_j . Because s_i is itself a derivative w.r.t. e_i , it follows that C_{ij} is also symmetric, with at most $7*6/2 = 21$ distinct elements.

At zero temperature, it is easy to estimate these derivatives by deforming the simulation box in one of the six directions using the `change_box` command and measuring the change in the stress tensor. A general-purpose script that does this is given in the examples/elastic directory described in [this section](#).

Calculating elastic constants at finite temperature is more challenging, because it is necessary to run a simulation that performs time averages of differential properties. One way to do this is to measure the change in average stress tensor in an NVT simulations when the cell volume undergoes a finite deformation. In order to balance the systematic and statistical errors in this method, the magnitude of the deformation must be chosen judiciously, and care must be taken to fully equilibrate the deformed cell before sampling the stress tensor. Another approach is to sample the triclinic cell

fluctuations that occur in an NPT simulation. This method can also be slow to converge and requires careful post-processing ([Shinoda](#))

6.19 Library interface to LAMMPS

As described in [Section 2.5](#), LAMMPS can be built as a library, so that it can be called by another code, used in a [coupled manner](#) with other codes, or driven through a [Python interface](#).

All of these methodologies use a C-style interface to LAMMPS that is provided in the files `src/library.cpp` and `src/library.h`. The functions therein have a C-style argument list, but contain C++ code you could write yourself in a C++ application that was invoking LAMMPS directly. The C++ code in the functions illustrates how to invoke internal LAMMPS operations. Note that LAMMPS classes are defined within a LAMMPS namespace (`LAMMPS_NS`) if you use them from another C++ application.

`Library.cpp` contains these functions for creating and destroying an instance of LAMMPS and sending it commands to execute. See the documentation in the `src/library.cpp` file for details:

```
void lammps_open(int, char **, MPI_Comm, void **)
void lammps_open_no_mpi(int, char **, void **)
void lammps_close(void *)
int lammps_version(void *)
void lammps_file(void *, char *)
char *lammps_command(void *, char *)
void lammps_commands_list(void *, int, char **)
void lammps_commands_string(void *, char *)
void lammps_free(void *)
```

The `lammps_open()` function is used to initialize LAMMPS, passing in a list of strings as if they were [command-line arguments](#) when LAMMPS is run in stand-alone mode from the command line, and a MPI communicator for LAMMPS to run under. It returns a ptr to the LAMMPS object that is created, and which is used in subsequent library calls. The `lammps_open()` function can be called multiple times, to create multiple instances of LAMMPS.

LAMMPS will run on the set of processors in the communicator. This means the calling code can run LAMMPS on all or a subset of processors. For example, a wrapper script might decide to alternate between LAMMPS and another code, allowing them both to run on all the processors. Or it might allocate half the processors to LAMMPS and half to the other code and run both codes simultaneously before syncing them up periodically. Or it might instantiate multiple instances of LAMMPS to perform different calculations.

The `lammps_open_no_mpi()` function is similar except that no MPI communicator is passed from the caller. Instead, `MPI_COMM_WORLD` is used to instantiate LAMMPS, and MPI is initialized if necessary.

The `lammps_close()` function is used to shut down an instance of LAMMPS and free all its memory.

LAMMPS Users Manual

The `lammeps_version()` function can be used to determine the specific version of the underlying LAMMPS code. This is particularly useful when loading LAMMPS as a shared library via `dlopen()`. The code using the library interface can then use this information to adapt to changes to the LAMMPS command syntax between versions. The returned LAMMPS version code is an integer (e.g. 2 Sep 2015 results in 20150902) that grows with every new LAMMPS version.

The `lammeps_file()`, `lammeps_command()`, `lammeps_commands_list()`, and `lammeps_commands_string()` functions are used to pass one or more commands to LAMMPS to execute, the same as if they were coming from an input script.

Via these functions, the calling code can read or generate a series of LAMMPS commands one or multiple at a time and pass it thru the library interface to setup a problem and then run it in stages. The caller can interleave the command function calls with operations it performs, calls to extract information from or set information within LAMMPS, or calls to another code's library.

The `lammeps_file()` function passes the filename of an input script. The `lammeps_command()` function passes a single command as a string. The `lammeps_commands_list()` function passes multiple commands in a `char**` list. In both `lammeps_command()` and `lammeps_commands_list()`, individual commands may or may not have a trailing newline. The `lammeps_commands_string()` function passes multiple commands concatenated into one long string, separated by newline characters. In both `lammeps_commands_list()` and `lammeps_commands_string()`, a single command can be spread across multiple lines, if the last printable character of all but the last line is "&", the same as if the lines appeared in an input script.

The `lammeps_free()` function is a clean-up function to free memory that the library allocated previously via other function calls. See comments in `src/library.cpp` file for which other functions need this clean-up.

`Library.cpp` also contains these functions for extracting information from LAMMPS and setting value within LAMMPS. Again, see the documentation in the `src/library.cpp` file for details, including which quantities can be queried by name:

```
void *lammeps_extract_global(void *, char *)
void lammeps_extract_box(void *, double *, double *,
                        double *, double *, double *, int *, int *)
void *lammeps_extract_atom(void *, char *)
void *lammeps_extract_compute(void *, char *, int, int)
void *lammeps_extract_fix(void *, char *, int, int, int, int)
void *lammeps_extract_variable(void *, char *, char *)

void lammeps_reset_box(void *, double *, double *, double, double, double)
int lammeps_set_variable(void *, char *, char *)

double lammeps_get_thermo(void *, char *)
int lammeps_get_natoms(void *)
void lammeps_gather_atoms(void *, double *)
void lammeps_scatter_atoms(void *, double *)

void lammeps_create_atoms(void *, int, tagint *, int *, double *, double *,
                        imageint *, int)
```

LAMMPS Users Manual

The `extract` functions return a pointer to various global or per-atom quantities stored in LAMMPS or to values calculated by a `compute`, `fix`, or `variable`. The pointer returned by the `extract_global()` function can be used as a permanent reference to a value which may change. For the `extract_atom()` method, see the `extract()` method in the `src/atom.cpp` file for a list of valid per-atom properties. New names could easily be added if the property you want is not listed. For the other `extract` functions, the underlying storage may be reallocated as LAMMPS runs, so you need to re-call the function to assure a current pointer or returned value(s).

The `lammeps_reset_box()` function resets the size and shape of the simulation box, e.g. as part of restoring a previously extracted and saved state of a simulation.

The `lammeps_set_variable()` function can set an existing string-style variable to a new string value, so that subsequent LAMMPS commands can access the variable.

The `lammeps_get_thermo()` function returns the current value of a thermo keyword as a double precision value.

The `lammeps_get_natoms()` function returns the total number of atoms in the system and can be used by the caller to allocate space for the `lammeps_gather_atoms()` and `lammeps_scatter_atoms()` functions. The `gather` function collects peratom info of the requested type (atom coords, types, forces, etc) from all processors, orders them by atom ID, and returns a full list to each calling processor. The `scatter` function does the inverse. It distributes the same peratom values, passed by the caller, to each atom owned by individual processors. Both methods are thus a means to extract or assign (overwrite) any peratom quantities within LAMMPS. See the `extract()` method in the `src/atom.cpp` file for a list of valid per-atom properties. New names could easily be added if the property you want is not listed. A special treatment is applied for accessing image flags via the "image" property. Image flags are stored in a packed format with all three image flags stored in a single integer. When signaling to access the image flags as 3 individual values per atom instead of 1, the data is transparently packed or unpacked by the library interface.

The `lammeps_create_atoms()` function takes a list of N atoms as input with atom types and coords (required), an optionally atom IDs and velocities and image flags. It uses the coords of each atom to assign it as a new atom to the processor that owns it. This function is useful to add atoms to a simulation or (in tandem with `lammeps_reset_box()`) to restore a previously extracted and saved state of a simulation. Additional properties for the new atoms can then be assigned via the `lammeps_scatter_atoms()` or `lammeps_extract_atom()` functions.

The `examples/COUPLE` and `python` directories have example C++ and C and Python codes which show how a driver code can link to LAMMPS as a library, run LAMMPS on a subset of processors, grab data from LAMMPS, change it, and put it back into LAMMPS.

NOTE: You can write code for additional functions as needed to define how your code talks to LAMMPS and add them to `src/library.cpp` and `src/library.h`, as well as to the [Python interface](#). The added functions can access or change any LAMMPS data you wish.

6.20 Calculating thermal conductivity

The thermal conductivity κ of a material can be measured in at least 4 ways using various options in LAMMPS. See the examples/KAPPA directory for scripts that implement the 4 methods discussed here for a simple Lennard-Jones fluid model. Also, see [this section](#) of the manual for an analogous discussion for viscosity.

The thermal conductivity tensor κ is a measure of the propensity of a material to transmit heat energy in a diffusive manner as given by Fourier's law

$$J = -\kappa \text{grad}(T)$$

where J is the heat flux in units of energy per area per time and $\text{grad}(T)$ is the spatial gradient of temperature. The thermal conductivity thus has units of energy per distance per time per degree K and is often approximated as an isotropic quantity, i.e. as a scalar.

The first method is to setup two thermostatted regions at opposite ends of a simulation box, or one in the middle and one at the end of a periodic box. By holding the two regions at different temperatures with a [thermostatting fix](#), the energy added to the hot region should equal the energy subtracted from the cold region and be proportional to the heat flux moving between the regions. See the papers by [Ikeshoji and Hafskjold](#) and [Wirnsberger et al](#) for details of this idea. Note that thermostatting fixes such as [fix nvt](#), [fix langevin](#), and [fix temp/rescale](#) store the cumulative energy they add/subtract.

Alternatively, as a second method, the [fix heat](#) or [fix ehex](#) commands can be used in place of thermostats on each of two regions to add/subtract specified amounts of energy to both regions. In both cases, the resulting temperatures of the two regions can be monitored with the "compute temp/region" command and the temperature profile of the intermediate region can be monitored with the [fix ave/chunk](#) and [compute ke/atom](#) commands.

The third method is to perform a reverse non-equilibrium MD simulation using the [fix thermal/conductivity](#) command which implements the rNEMD algorithm of Muller-Plathe. Kinetic energy is swapped between atoms in two different layers of the simulation box. This induces a temperature gradient between the two layers which can be monitored with the [fix ave/chunk](#) and [compute ke/atom](#) commands. The [fix thermal/conductivity](#) tallies the cumulative energy transfer that it performs. See the [fix thermal/conductivity](#) command for details.

The fourth method is based on the Green-Kubo (GK) formula which relates the ensemble average of the auto-correlation of the heat flux to κ . The heat flux can be calculated from the fluctuations of per-atom potential and kinetic energies and per-atom stress tensor in a steady-state equilibrated simulation. This is in contrast to the two preceding non-equilibrium methods, where energy flows continuously between hot and cold regions of the simulation box.

The [compute heat/flux](#) command can calculate the needed heat flux and describes how to implement the Green_Kubo formalism using additional LAMMPS commands, such as the [fix ave/correlate](#) command to calculate the needed auto-correlation. See the doc

page for the [compute heat/flux](#) command for an example input script that calculates the thermal conductivity of solid Ar via the GK formalism.

6.21 Calculating viscosity

The shear viscosity η of a fluid can be measured in at least 5 ways using various options in LAMMPS. See the examples/VISCOSITY directory for scripts that implement the 5 methods discussed here for a simple Lennard-Jones fluid model. Also, see [this section](#) of the manual for an analogous discussion for thermal conductivity.

η is a measure of the propensity of a fluid to transmit momentum in a direction perpendicular to the direction of velocity or momentum flow. Alternatively it is the resistance the fluid has to being sheared. It is given by

$$J = -\eta \text{grad}(V_{\text{stream}})$$

where J is the momentum flux in units of momentum per area per time. and $\text{grad}(V_{\text{stream}})$ is the spatial gradient of the velocity of the fluid moving in another direction, normal to the area through which the momentum flows. Viscosity thus has units of pressure-time.

The first method is to perform a non-equilibrium MD (NEMD) simulation by shearing the simulation box via the [fix deform](#) command, and using the [fix nvt/sllod](#) command to thermostat the fluid via the SLLD equations of motion. Alternatively, as a second method, one or more moving walls can be used to shear the fluid in between them, again with some kind of thermostat that modifies only the thermal (non-shearing) components of velocity to prevent the fluid from heating up.

In both cases, the velocity profile setup in the fluid by this procedure can be monitored by the [fix ave/chunk](#) command, which determines $\text{grad}(V_{\text{stream}})$ in the equation above. E.g. the derivative in the y-direction of the V_x component of fluid motion or $\text{grad}(V_{\text{stream}}) = dV_x/dy$. The P_{xy} off-diagonal component of the pressure or stress tensor, as calculated by the [compute pressure](#) command, can also be monitored, which is the J term in the equation above. See [this section](#) of the manual for details on NEMD simulations.

The third method is to perform a reverse non-equilibrium MD simulation using the [fix viscosity](#) command which implements the rNEMD algorithm of Muller-Plathe. Momentum in one dimension is swapped between atoms in two different layers of the simulation box in a different dimension. This induces a velocity gradient which can be monitored with the [fix ave/chunk](#) command. The [fix](#) tallies the cumulative momentum transfer that it performs. See the [fix viscosity](#) command for details.

The fourth method is based on the Green-Kubo (GK) formula which relates the ensemble average of the auto-correlation of the stress/pressure tensor to η . This can be done in a fully equilibrated simulation which is in contrast to the two preceding non-equilibrium methods, where momentum flows continuously through the simulation box.

LAMMPS Users Manual

Here is an example input script that calculates the viscosity of liquid Ar via the GK formalism:

```

```

The fifth method is related to the above Green-Kubo method, but uses the Einstein formulation, analogous to the Einstein mean-square-displacement formulation for self-diffusivity. The time-integrated momentum fluxes play the role of Cartesian coordinates, whose mean-square displacement increases linearly with time at sufficiently long times.

6.22 Calculating a diffusion coefficient

The diffusion coefficient D of a material can be measured in at least 2 ways using various options in LAMMPS. See the examples/DIFFUSE directory for scripts that implement the 2 methods discussed here for a simple Lennard-Jones fluid model.

The first method is to measure the mean-squared displacement (MSD) of the system, via the [compute msd](#) command. The slope of the MSD versus time is proportional to the diffusion coefficient. The instantaneous MSD values can be accumulated in a vector via the [fix vector](#) command, and a line fit to the vector to compute its slope via the [variable slope](#) function, and thus extract D .

The second method is to measure the velocity auto-correlation function (VACF) of the system, via the [compute vacf](#) command. The time-integral of the VACF is proportional to the diffusion coefficient. The instantaneous VACF values can be accumulated in a vector via the [fix vector](#) command, and time integrated via the [variable trap](#) function, and thus extract D .

6.23 Using chunks to calculate system properties

In LAMMPS, "chunks" are collections of atoms, as defined by the [compute chunk/atom](#) command, which assigns each atom to a chunk ID (or to no chunk at all). The number of chunks and the assignment of chunk IDs to atoms can be static or change over time. Examples of "chunks" are molecules or spatial bins or atoms with similar values (e.g. coordination number or potential energy).

The per-atom chunk IDs can be used as input to two other kinds of commands, to calculate various properties of a system:

- [fix ave/chunk](#)
- any of the [compute */chunk](#) commands

Here, each of the 3 kinds of chunk-related commands is briefly overviewed. Then some examples are given of how to compute different properties with chunk commands.

Compute chunk/atom command:

This compute can assign atoms to chunks of various styles. Only atoms in the specified group and optional specified region are assigned to a chunk. Here are some possible chunk definitions:

LAMMPS Users Manual

atoms in same molecule	chunk ID = molecule ID
atoms of same atom type	chunk ID = atom type
all atoms with same atom property (charge, radius, etc)	chunk ID = output of compute property/atom
atoms in same cluster	chunk ID = output of compute cluster/atom command
atoms in same spatial bin	chunk ID = bin ID
atoms in same rigid body	chunk ID = molecule ID used to define rigid bodies
atoms with similar potential energy	chunk ID = output of compute pe/atom
atoms with same local defect structure	chunk ID = output of compute centro/atom or compute coord/atom command

Note that chunk IDs are integer values, so for atom properties or computes that produce a floating point value, they will be truncated to an integer. You could also use the compute in a variable that scales the floating point value to spread it across multiple integers.

Spatial bins can be of various kinds, e.g. 1d bins = slabs, 2d bins = pencils, 3d bins = boxes, spherical bins, cylindrical bins.

This compute also calculates the number of chunks *Nchunk*, which is used by other commands to tally per-chunk data. *Nchunk* can be a static value or change over time (e.g. the number of clusters). The chunk ID for an individual atom can also be static (e.g. a molecule ID), or dynamic (e.g. what spatial bin an atom is in as it moves).

Note that this compute allows the per-atom output of other [computes](#), [fixes](#), and [variables](#) to be used to define chunk IDs for each atom. This means you can write your own compute or fix to output a per-atom quantity to use as chunk ID. See [Section 10](#) of the documentation for how to do this. You can also define a [per-atom variable](#) in the input script that uses a formula to generate a chunk ID for each atom.

Fix ave/chunk command:

This fix takes the ID of a [compute chunk/atom](#) command as input. For each chunk, it then sums one or more specified per-atom values over the atoms in each chunk. The per-atom values can be any atom property, such as velocity, force, charge, potential energy, kinetic energy, stress, etc. Additional keywords are defined for per-chunk properties like density and temperature. More generally any per-atom value generated by other [computes](#), [fixes](#), and [per-atom variables](#), can be summed over atoms in each chunk.

Similar to other averaging fixes, this fix allows the summed per-chunk values to be time-averaged in various ways, and output to a file. The fix produces a global array as output with one row of values per chunk.

LAMMPS Users Manual

Compute */chunk commands:

Currently the following computes operate on chunks of atoms to produce per-chunk values.

- [compute com/chunk](#)
- [compute gyration/chunk](#)
- [compute inertia/chunk](#)
- [compute msd/chunk](#)
- [compute property/chunk](#)
- [compute temp/chunk](#)
- [compute torque/chunk](#)
- [compute vcm/chunk](#)

They each take the ID of a [compute chunk/atom](#) command as input. As their names indicate, they calculate the center-of-mass, radius of gyration, moments of inertia, mean-squared displacement, temperature, torque, and velocity of center-of-mass for each chunk of atoms. The [compute property/chunk](#) command can tally the count of atoms in each chunk and extract other per-chunk properties.

The reason these various calculations are not part of the [fix ave/chunk command](#), is that each requires a more complicated operation than simply summing and averaging over per-atom values in each chunk. For example, many of them require calculation of a center of mass, which requires summing mass*position over the atoms and then dividing by summed mass.

All of these computes produce a global vector or global array as output, with one or more values per chunk. They can be used in various ways:

- As input to the [fix ave/time](#) command, which can write the values to a file and optionally time average them.
- As input to the [fix ave/histo](#) command to histogram values across chunks. E.g. a histogram of cluster sizes or molecule diffusion rates.
- As input to special functions of [equal-style variables](#), like `sum()` and `max()`. E.g. to find the largest cluster or fastest diffusing molecule.

Example calculations with chunks

Here are examples using chunk commands to calculate various properties:

(1) Average velocity in each of 1000 2d spatial bins:

```
compute cc1 all chunk/atom bin/2d x 0.0 0.1 y lower 0.01 units reduced
fix 1 all ave/chunk 100 10 1000 cc1 vx vy file tmp.out
```

(2) Temperature in each spatial bin, after subtracting a flow velocity:

```
compute cc1 all chunk/atom bin/2d x 0.0 0.1 y lower 0.1 units reduced
compute vbias all temp/profile 1 0 0 y 10
fix 1 all ave/chunk 100 10 1000 cc1 temp bias vbias file tmp.out
```

(3) Center of mass of each molecule:

LAMMPS Users Manual

```
compute cc1 all chunk/atom molecule
compute myChunk all com/chunk cc1
fix 1 all ave/time 100 1 100 c_myChunk[*] file tmp.out mode vector
```

(4) Total force on each molecule and ave/max across all molecules:

```
compute cc1 all chunk/atom molecule
fix 1 all ave/chunk 1000 1 1000 cc1 fx fy fz file tmp.out
variable xave equal ave(f_1[2])
variable xmax equal max(f_1[2])
thermo 1000
thermo_style custom step temp v_xave v_xmax
```

(5) Histogram of cluster sizes:

```
compute cluster all cluster/atom 1.0
compute cc1 all chunk/atom c_cluster compress yes
compute size all property/chunk cc1 count
fix 1 all ave/histo 100 1 100 0 20 20 c_size mode vector ave running beyond ignore file tmp.his
```

6.24 Setting parameters for the `kspace_style ppm/disp` command

The PPPM method computes interactions by splitting the pair potential into two parts, one of which is computed in a normal pairwise fashion, the so-called real-space part, and one of which is computed using the Fourier transform, the so called reciprocal-space or kspace part. For both parts, the potential is not computed exactly but is approximated. Thus, there is an error in both parts of the computation, the real-space and the kspace error. The just mentioned facts are true both for the PPPM for Coulomb as well as dispersion interactions. The deciding difference - and also the reason why the parameters for ppm/disp have to be selected with more care - is the impact of the errors on the results: The kspace error of the PPPM for Coulomb and dispersion interaction and the real-space error of the PPPM for Coulomb interaction have the character of noise. In contrast, the real-space error of the PPPM for dispersion has a clear physical interpretation: the underprediction of cohesion. As a consequence, the real-space error has a much stronger effect than the kspace error on simulation results for ppm/disp. Parameters must thus be chosen in a way that this error is much smaller than the kspace error.

When using ppm/disp and not making any specifications on the PPPM parameters via the kspace modify command, parameters will be tuned such that the real-space error and the kspace error are equal. This will result in simulations that are either inaccurate or slow, both of which is not desirable. For selecting parameters for the ppm/disp that provide fast and accurate simulations, there are two approaches, which both have their up- and downsides.

The first approach is to set desired real-space and kspace accuracies via the `kspace_modify force/disp/real` and `kspace_modify force/disp/kspace` commands. Note that the accuracies have to be specified in force units and are thus dependent on the chosen unit settings. For real units, 0.0001 and 0.002 seem to provide reasonable accurate and efficient computations for the real-space and kspace accuracies. 0.002 and 0.05 work well for most systems using lj units. PPPM parameters will be generated based on the desired accuracies. The upside of this approach is that it

LAMMPS Users Manual

usually provides a good set of parameters and will work for both the *kpspace_modify diff ad* and *kpspace_modify diff ik* options. The downside of the method is that setting the PPPM parameters will take some time during the initialization of the simulation.

The second approach is to set the parameters for the *pppm/disp* explicitly using the *kpspace_modify mesh/disp*, *kpspace_modify order/disp*, and *kpspace_modify gewald/disp* commands. This approach requires a more experienced user who understands well the impact of the choice of parameters on the simulation accuracy and performance. This approach provides a fast initialization of the simulation. However, it is sensitive to errors: A combination of parameters that will perform well for one system might result in far-from-optimal conditions for other simulations. For example, parameters that provide accurate and fast computations for all-atomistic force fields can provide insufficient accuracy or united-atomistic force fields (which is related to that the latter typically have larger dispersion coefficients).

To avoid inaccurate or inefficient simulations, the *pppm/disp* stops simulations with an error message if no action is taken to control the PPPM parameters. If the automatic parameter generation is desired and real-space and *kpspace* accuracies are desired to be equal, this error message can be suppressed using the *kpspace_modify disp/auto yes* command.

A reasonable approach that combines the upsides of both methods is to make the first run using the *kpspace_modify force/disp/real* and *kpspace_modify force/disp/kpspace* commands, write down the PPPM parameters from the output, and specify these parameters using the second approach in subsequent runs (which have the same composition, force field, and approximately the same volume).

Concerning the performance of the *pppm/disp* there are two more things to consider. The first is that when using the *pppm/disp*, the cutoff parameter does no longer affect the accuracy of the simulation (subject to that *gewald/disp* is adjusted when changing the cutoff). The performance can thus be increased by examining different values for the cutoff parameter. A lower bound for the cutoff is only set by the truncation error of the repulsive term of pair potentials.

The second is that the mixing rule of the pair style has an impact on the computation time when using the *pppm/disp*. Fastest computations are achieved when using the geometric mixing rule. Using the arithmetic mixing rule substantially increases the computational cost. The computational overhead can be reduced using the *kpspace_modify mix/disp geom* and *kpspace_modify splittol* commands. The first command simply enforces geometric mixing of the dispersion coefficients in *kpspace* computations. This introduces some error in the computations but will also significantly speed-up the simulations. The second keyword sets the accuracy with which the dispersion coefficients are approximated using a matrix factorization approach. This may result in better accuracy than using the first command, but will usually also not provide an equally good increase of efficiency.

Finally, *pppm/disp* can also be used when no mixing rules apply. This can be achieved using the *kpspace_modify mix/disp none* command. Note that the code does not check automatically whether any mixing rule is fulfilled. If mixing rules do not apply, the user will have to specify this command explicitly.

6.25 Polarizable models

In polarizable force fields the charge distributions in molecules and materials respond to their electrostatic environments. Polarizable systems can be simulated in LAMMPS using three methods:

- the fluctuating charge method, implemented in the [QEQ](#) package,
- the adiabatic core-shell method, implemented in the [CORESHELL](#) package,
- the thermalized Drude dipole method, implemented in the [USER-DRUDE](#) package.

The fluctuating charge method calculates instantaneous charges on interacting atoms based on the electronegativity equalization principle. It is implemented in the [fix qeq](#) which is available in several variants. It is a relatively efficient technique since no additional particles are introduced. This method allows for charge transfer between molecules or atom groups. However, because the charges are located at the interaction sites, off-plane components of polarization cannot be represented in planar molecules or atom groups.

The two other methods share the same basic idea: polarizable atoms are split into one core atom and one satellite particle (called shell or Drude particle) attached to it by a harmonic spring. Both atoms bear a charge and they represent collectively an induced electric dipole. These techniques are computationally more expensive than the QEQ method because of additional particles and bonds. These two charge-on-spring methods differ in certain features, with the core-shell model being normally used for ionic/crystalline materials, whereas the so-called Drude model is normally used for molecular systems and fluid states.

The core-shell model is applicable to crystalline materials where the high symmetry around each site leads to stable trajectories of the core-shell pairs. However, bonded atoms in molecules can be so close that a core would interact too strongly or even capture the Drude particle of a neighbor. The Drude dipole model is relatively more complex in order to remediate this and other issues. Specifically, the Drude model includes specific thermostating of the core-Drude pairs and short-range damping of the induced dipoles.

The three polarization methods can be implemented through a self-consistent calculation of charges or induced dipoles at each timestep. In the fluctuating charge scheme this is done by the matrix inversion method in [fix qeq/point](#), but for core-shell or Drude-dipoles the relaxed-dipoles technique would require a slow iterative procedure. These self-consistent solutions yield accurate trajectories since the additional degrees of freedom representing polarization are massless. An alternative is to attribute a mass to the additional degrees of freedom and perform time integration using an extended Lagrangian technique. For the fluctuating charge scheme this is done by [fix qeq/dynamic](#), and for the charge-on-spring models by the methods outlined in the next two sections. The assignment of masses to the additional degrees of freedom can lead to unphysical trajectories if care is not exerted in choosing the parameters of the polarizable models and the simulation conditions.

In the core-shell model the vibration of the shells is kept faster than the ionic vibrations to mimic the fast response of the polarizable electrons. But in molecular

systems thermalizing the core-Drude pairs at temperatures comparable to the rest of the simulation leads to several problems (kinetic energy transfer, too short a timestep, etc.) In order to avoid these problems the relative motion of the Drude particles with respect to their cores is kept "cold" so the vibration of the core-Drude pairs is very slow, approaching the self-consistent regime. In both models the temperature is regulated using the velocities of the center of mass of core+shell (or Drude) pairs, but in the Drude model the actual relative core-Drude particle motion is thermostated separately as well.

6.26 Adiabatic core/shell model

The adiabatic core-shell model by [Mitchell and Fincham](#) is a simple method for adding polarizability to a system. In order to mimic the electron shell of an ion, a satellite particle is attached to it. This way the ions are split into a core and a shell where the latter is meant to react to the electrostatic environment inducing polarizability.

Technically, shells are attached to the cores by a spring force $f = k*r$ where k is a parametrized spring constant and r is the distance between the core and the shell. The charges of the core and the shell add up to the ion charge, thus $q(\text{ion}) = q(\text{core}) + q(\text{shell})$. This setup introduces the ion polarizability (α) given by $\alpha = q(\text{shell})^2 / k$. In a similar fashion the mass of the ion is distributed on the core and the shell with the core having the larger mass.

To run this model in LAMMPS, `atom_style full` can be used since atom charge and bonds are needed. Each kind of core/shell pair requires two atom types and a bond type. The core and shell of a core/shell pair should be bonded to each other with a harmonic bond that provides the spring force. For example, a data file for NaCl, as found in `examples/coreshell`, has this format:

```

432 atoms # core and shell atoms
216 bonds # number of core/shell springs

4 atom types # 2 cores and 2 shells for Na and Cl
2 bond types

0.0 24.09597 xlo xhi
0.0 24.09597 ylo yhi
0.0 24.09597 zlo zhi

Masses # core/shell mass ratio = 0.1

1 20.690784 # Na core
2 31.90500 # Cl core
3 2.298976 # Na shell
4 3.54500 # Cl shell

Atoms

1 1 2 1.5005 0.00000000 0.00000000 0.00000000 # core of core/shell pair 1
2 1 4 -2.5005 0.00000000 0.00000000 0.00000000 # shell of core/shell pair 1
3 2 1 1.5056 4.01599500 4.01599500 4.01599500 # core of core/shell pair 2
4 2 3 -0.5056 4.01599500 4.01599500 4.01599500 # shell of core/shell pair 2
(...)
```

LAMMPS Users Manual

```
Bonds # Bond topology for spring forces

1 2 1 2 # spring for core/shell pair 1
2 2 3 4 # spring for core/shell pair 2
(...)
```

Non-Coulombic (e.g. Lennard-Jones) pairwise interactions are only defined between the shells. Coulombic interactions are defined between all cores and shells. If desired, additional bonds can be specified between cores.

The [special_bonds](#) command should be used to turn-off the Coulombic interaction within core/shell pairs, since that interaction is set by the bond spring. This is done using the [special_bonds](#) command with a 1-2 weight = 0.0, which is the default value. It needs to be considered whether one has to adjust the [special_bonds](#) weighting according to the molecular topology since the interactions of the shells are bypassed over an extra bond.

Note that this core/shell implementation does not require all ions to be polarized. One can mix core/shell pairs and ions without a satellite particle if desired.

Since the core/shell model permits distances of $r = 0.0$ between the core and shell, a pair style with a "cs" suffix needs to be used to implement a valid long-range Coulombic correction. Several such pair styles are provided in the CORESHELL package. See [this doc page](#) for details. All of the core/shell enabled pair styles require the use of a long-range Coulombic solver, as specified by the [kspace_style](#) command. Either the PPPM or Ewald solvers can be used.

For the NaCl example problem, these pair style and bond style settings are used:

```
pair_style      born/coul/long/cs 20.0 20.0
pair_coeff      * *      0.0 1.000  0.00 0.00  0.00
pair_coeff      3 3      487.0 0.23768 0.00 1.05  0.50 #Na-Na
pair_coeff      3 4     145134.0 0.23768 0.00 6.99  8.70 #Na-Cl
pair_coeff      4 4     405774.0 0.23768 0.00 72.40 145.40 #Cl-Cl

bond_style      harmonic
bond_coeff      1 63.014 0.0
bond_coeff      2 25.724 0.0
```

When running dynamics with the adiabatic core/shell model, the following issues should be considered. The relative motion of the core and shell particles corresponds to the polarization, hereby an instantaneous relaxation of the shells is approximated and a fast core/shell spring frequency ensures a nearly constant internal kinetic energy during the simulation. Thermostats can alter this polarization behaviour, by scaling the internal kinetic energy, meaning the shell will not react freely to its electrostatic environment. Therefore it is typically desirable to decouple the relative motion of the core/shell pair, which is an imaginary degree of freedom, from the real physical system. To do that, the [compute temp/cs](#) command can be used, in conjunction with any of the thermostat fixes, such as [fix nvt](#) or [fix langevin](#). This compute uses the center-of-mass velocity of the core/shell pairs to calculate a temperature, and insures that velocity is what is rescaled for thermostatting purposes. This compute also works for a system with both core/shell pairs and non-polarized ions (ions without an attached satellite particle). The [compute temp/cs](#) command requires

LAMMPS Users Manual

input of two groups, one for the core atoms, another for the shell atoms. Non-polarized ions which might also be included in the treated system should not be included into either of these groups, they are taken into account by the *group-ID* (2nd argument) of the compute. The groups can be defined using the [group type](#) command. Note that to perform thermostating using this definition of temperature, the [fix modify temp](#) command should be used to assign the compute to the thermostat fix. Likewise the [thermo_modify temp](#) command can be used to make this temperature be output for the overall system.

For the NaCl example, this can be done as follows:

```
group cores type 1 2
group shells type 3 4
compute CSequ all temp/cs cores shells
fix thermostatequ all nve # integrator as needed for the berendsen
fix_thermo_berendsen all temp/berendsen 1427 1427 0.4 # thermostat for the true physical system
thermo_modify temp CSequ # output of center-of-mass derived temperature
```

The pressure for the core/shell system is computed via the regular LAMMPS convention by [treating the cores and shells as individual particles](#). For the thermo output of the pressure as well as for the application of a barostat, it is necessary to use an additional [pressure](#) compute based on the default [temperature](#) and specifying it as a second argument in [fix modify](#) and [thermo_modify](#) resulting in:

```
(...)
compute CSequ all temp/cs cores shells
compute thermo_press_lmp all pressure thermo_temp # pressure for individual particles
thermo_modify temp CSequ press thermo_press_lmp # modify thermo to regular pressure
fix_press_bar all npt temp 300 300 0.04 iso 0 0 0.4
fix_modify press_bar temp CSequ press thermo_press_lmp # pressure modification for correct kinetic energy
```

If [compute temp/cs](#) is used, the decoupled relative motion of the core and the shell should in theory be stable. However numerical fluctuation can introduce a small momentum to the system, which is noticeable over long trajectories. Therefore it is recommendable to use the [fix momentum](#) command in combination with [compute temp/cs](#) when equilibrating the system to prevent any drift.

When initializing the velocities of a system with core/shell pairs, it is also desirable to not introduce energy into the relative motion of the core/shell particles, but only assign a center-of-mass velocity to the pairs. This can be done by using the *bias* keyword of the [velocity create](#) command and assigning the [compute temp/cs](#) command to the *temp* keyword of the [velocity](#) command, e.g.

```
velocity all create 1427 134 bias yes temp CSequ
velocity all scale 1427 temp CSequ
```

To maintain the correct polarizability of the core/shell pairs, the kinetic energy of the internal motion shall remain nearly constant. Therefore the choice of spring force and mass ratio need to ensure much faster relative motion of the 2 atoms within the core/shell pair than their center-of-mass velocity. This allows the shells to effectively react instantaneously to the electrostatic environment and limits energy transfer to or from the core/shell oscillators. This fast movement also dictates the timestep that can

be used.

The primary literature of the adiabatic core/shell model suggests that the fast relative motion of the core/shell pairs only allows negligible energy transfer to the environment. The mentioned energy transfer will typically lead to a small drift in total energy over time. This internal energy can be monitored using the `compute chunk/atom` and `compute temp/chunk` commands. The internal kinetic energies of each core/shell pair can then be summed using the `sum()` special function of the `variable` command. Or they can be time/averaged and output using the `fix ave/time` command. To use these commands, each core/shell pair must be defined as a "chunk". If each core/shell pair is defined as its own molecule, the molecule ID can be used to define the chunks. If cores are bonded to each other to form larger molecules, the chunks can be identified by the `fix property/atom` via assigning a core/shell ID to each atom using a special field in the data file read by the `read_data` command. This field can then be accessed by the `compute property/atom` command, to use as input to the `compute chunk/atom` command to define the core/shell pairs as chunks.

For example if core/shell pairs are the only molecules:

```
read_data NaCl_CS_x0.1_prop.data
compute prop all property/atom molecule
compute cs_chunk all chunk/atom c_prop
compute csthern all temp/chunk cs_chunk temp internal com yes cdof 3.0 # note the chosen dof
fix ave_chunk all ave/time 10 1 10 c_csthern file chunk.dump mode vector
```

For example if core/shell pairs and other molecules are present:

```
fix csinfo all property/atom i_CSID # property/atom command
read_data NaCl_CS_x0.1_prop.data fix csinfo NULL CS-Info # atom property added in the data-file
compute prop all property/atom i_CSID
(...)
```

The additional section in the data file would be formatted like this:

```
CS-Info # header of additional section

1 1 # column 1 = atom ID, column 2 = core/shell ID
2 1
3 2
4 2
5 3
6 3
7 4
8 4
(...)
```

6.27 Drude induced dipoles

The thermalized Drude model, similarly to the `core-shell` model, represents induced dipoles by a pair of charges (the core atom and the Drude particle) connected by a harmonic spring. The Drude model has a number of features aimed at its use in molecular systems ([Lamoureux and Roux](#)):

LAMMPS Users Manual

- Thermostating of the additional degrees of freedom associated with the induced dipoles at very low temperature, in terms of the reduced coordinates of the Drude particles with respect to their cores. This makes the trajectory close to that of relaxed induced dipoles.
- Consistent definition of 1-2 to 1-4 neighbors. A core-Drude particle pair represents a single (polarizable) atom, so the special screening factors in a covalent structure should be the same for the core and the Drude particle. Drude particles have to inherit the 1-2, 1-3, 1-4 special neighbor relations from their respective cores.
- Stabilization of the interactions between induced dipoles. Drude dipoles on covalently bonded atoms interact too strongly due to the short distances, so an atom may capture the Drude particle of a neighbor, or the induced dipoles within the same molecule may align too much. To avoid this, damping at short range can be done by Thole functions (for which there are physical grounds). This Thole damping is applied to the point charges composing the induced dipole (the charge of the Drude particle and the opposite charge on the core, not to the total charge of the core atom).

A detailed tutorial covering the usage of Drude induced dipoles in LAMMPS is [available here](#).

As with the core-shell model, the cores and Drude particles should appear in the data file as standard atoms. The same holds for the springs between them, which are described by standard harmonic bonds. The nature of the atoms (core, Drude particle or non-polarizable) is specified via the [fix drude](#) command. The special list of neighbors is automatically refactored to account for the equivalence of core and Drude particles as regards special 1-2 to 1-4 screening. It may be necessary to use the *extra/special/per/atom* keyword of the [read_data](#) command. If using [fix shake](#), make sure no Drude particle is in this fix group.

There are two ways to thermostat the Drude particles at a low temperature: use either [fix langevin/drude](#) for a Langevin thermostat, or [fix drude/transform/*](#) for a Nose-Hoover thermostat. The former requires use of the command [comm_modify vel yes](#). The latter requires two separate integration fixes like *nvt* or *npt*. The correct temperatures of the reduced degrees of freedom can be calculated using the [compute temp/drude](#). This requires also to use the command *comm_modify vel yes*.

Short-range damping of the induced dipole interactions can be achieved using Thole functions through the [pair style thole](#) in [pair_style hybrid/overlay](#) with a Coulomb pair style. It may be useful to use *coul/long/cs* or similar from the CORESHELL package if the core and Drude particle come too close, which can cause numerical issues.

7. Example problems

The LAMMPS distribution includes an examples sub-directory with many sample problems. Many are 2d models that run quickly and are straightforward to visualize, requiring at most a couple of minutes to run on a desktop machine. Each problem has an input script (in.*) and produces a log file (log.*) when it runs. Some use a data file (data.*) of initial coordinates as additional input. A few sample log file runs on different machines and different numbers of processors are included in the directories to compare your answers to. E.g. a log file like log.date.crack.foo.P means the "crack" example was run on P processors of machine "foo" on that date (i.e. with that version of LAMMPS).

Many of the input files have commented-out lines for creating dump files and image files.

If you uncomment the [dump](#) command in the input script, a text dump file will be produced, which can be animated by various [visualization programs](#).

If you uncomment the [dump image](#) command in the input script, and assuming you have built LAMMPS with a JPG library, JPG snapshot images will be produced when the simulation runs. They can be quickly post-processed into a movie using commands described on the [dump image](#) doc page.

Animations of many of the examples can be viewed on the Movies section of the [LAMMPS web site](#).

There are two kinds of sub-directories in the examples dir. Lowercase dirs contain one or a few simple, quick-to-run problems. Uppercase dirs contain up to several complex scripts that illustrate a particular kind of simulation method or model. Some of these run for longer times, e.g. to measure a particular quantity.

Lists of both kinds of directories are given below.

Lowercase directories

accelerate	run with various acceleration options (OpenMP, GPU, Phi)
airebo	polyethylene with AIREBO potential
balance	dynamic load balancing, 2d system
body	body particles, 2d system
cmap	CMAP 5-body contributions to CHARMM force field
colloid	big colloid particles in a small particle solvent, 2d system
comb	models using the COMB potential
coreshell	core/shell model using CORESHELL package
controller	use of fix controller as a thermostat
crack	crack propagation in a 2d solid

LAMMPS Users Manual

deposit	deposit atoms and molecules on a surface
dipole	point dipolar particles, 2d system
dreiding	methanol via Dreiding FF
eim	NaCl using the EIM potential
ellipse	ellipsoidal particles in spherical solvent, 2d system
flow	Couette and Poiseuille flow in a 2d channel
friction	frictional contact of spherical asperities between 2d surfaces
gcmc	Grand Canonical Monte Carlo (GCMC) via the fix gcmc command
granregion	use of fix wall/region/gran as boundary on granular particles
hugoniostat	Hugoniostat shock dynamics
indent	spherical indenter into a 2d solid
kim	use of potentials in Knowledge Base for Interatomic Models (KIM)
meam	MEAM test for SiC and shear (same as shear examples)
melt	rapid melt of 3d LJ system
micelle	self-assembly of small lipid-like molecules into 2d bilayers
min	energy minimization of 2d LJ melt
mscg	parameterize a multi-scale coarse-graining (MSCG) model
msst	MSST shock dynamics
nb3b	use of nonbonded 3-body harmonic pair style
neb	nudged elastic band (NEB) calculation for barrier finding
nemd	non-equilibrium MD of 2d sheared system
obstacle	flow around two voids in a 2d channel
peptide	dynamics of a small solvated peptide chain (5-mer)
peri	Peridynamic model of cylinder impacted by indenter
pour	pouring of granular particles into a 3d box, then chute flow
prd	parallel replica dynamics of vacancy diffusion in bulk Si
python	using embedded Python in a LAMMPS input script
qeq	use of the QEQ package for charge equilibration
reax	RDX and TATB models using the ReaxFF
rigid	rigid bodies modeled as independent or coupled
shear	sideways shear applied to 2d solid, with and without a void
snap	NVE dynamics for BCC tantalum crystal using SNAP potential
srd	stochastic rotation dynamics (SRD) particles as solvent
streitz	use of Streitz/Mintmire potential with charge equilibration
tad	temperature-accelerated dynamics of vacancy diffusion in bulk Si
vashishta	use of the Vashishta potential
voronoi	Voronoi tessellation via compute voronoi/atom command

Here is how you can run and visualize one of the sample problems:

```
cd indent
cp ../../src/lmp_linux .           # copy LAMMPS executable to this dir
lmp_linux -in in.indent            # run the problem
```

LAMMPS Users Manual

Running the simulation produces the files *dump.indent* and *log.lammps*. You can visualize the dump file of snapshots with a variety of 3rd-party tools highlighted on the [Visualization](#) page of the LAMMPS web site.

If you uncomment the [dump image](#) line(s) in the input script a series of JPG images will be produced by the run (assuming you built LAMMPS with JPG support; see [Section 2.2](#) for details). These can be viewed individually or turned into a movie or animated by tools like ImageMagick or QuickTime or various Windows-based tools. See the [dump image](#) doc page for more details. E.g. this Imagemagick command would create a GIF file suitable for viewing in a browser.

```
% convert -loop 1 *.jpg foo.gif
```

Uppercase directories

ASPHERE	various aspherical particle models, using ellipsoids, rigid bodies, line/triangle particles, etc
COUPLE	examples of how to use LAMMPS as a library
DIFFUSE	compute diffusion coefficients via several methods
ELASTIC	compute elastic constants at zero temperature
ELASTIC_T	compute elastic constants at finite temperature
KAPPA	compute thermal conductivity via several methods
MC	using LAMMPS in a Monte Carlo mode to relax the energy of a system
USER	examples for USER packages and USER-contributed commands
VISCOSITY	compute viscosity via several methods

Nearly all of these directories have README files which give more details on how to understand and use their contents.

The USER directory has a large number of sub-directories which correspond by name to a USER package. They contain scripts that illustrate how to use the command(s) provided in that package. Many of the sub-directories have their own README files which give further instructions. See the [Section 4](#) doc page for more info on specific USER packages.

8. Performance & scalability

Current LAMMPS performance is discussed on the Benchmarks page of the [LAMMPS WWW Site](#) where CPU timings and parallel efficiencies are listed. The page has several sections, which are briefly described below:

- CPU performance on 5 standard problems, strong and weak scaling
- GPU and Xeon Phi performance on same and related problems
- Comparison of cost of interatomic potentials
- Performance of huge, billion-atom problems

The 5 standard problems are as follow:

1. LJ = atomic fluid, Lennard-Jones potential with 2.5 sigma cutoff (55 neighbors per atom), NVE integration
2. Chain = bead-spring polymer melt of 100-mer chains, FENE bonds and LJ pairwise interactions with a $2^{(1/6)}$ sigma cutoff (5 neighbors per atom), NVE integration
3. EAM = metallic solid, Cu EAM potential with 4.95 Angstrom cutoff (45 neighbors per atom), NVE integration
4. Chute = granular chute flow, frictional history potential with 1.1 sigma cutoff (7 neighbors per atom), NVE integration
5. Rhodo = rhodopsin protein in solvated lipid bilayer, CHARMM force field with a 10 Angstrom LJ cutoff (440 neighbors per atom), particle-particle particle-mesh (PPPM) for long-range Coulombics, NPT integration

Input files for these 5 problems are provided in the bench directory of the LAMMPS distribution. Each has 32,000 atoms and runs for 100 timesteps. The size of the problem (number of atoms) can be varied using command-line switches as described in the bench/README file. This is an easy way to test performance and either strong or weak scalability on your machine.

The bench directory includes a few log.* files that show performance of these 5 problems on 1 or 4 cores of Linux desktop. The bench/FERMI and bench/KEPLER dirs have input files and scripts and instructions for running the same (or similar) problems using OpenMP or GPU or Xeon Phi acceleration options. See the README files in those dirs and the [Section 5.3](#) doc pages for instructions on how to build LAMMPS and run on that kind of hardware.

The bench/POTENTIALS directory has input files which correspond to the table of results on the [Potentials](#) section of the Benchmarks web page. So you can also run those test problems on your machine.

The [billion-atom](#) section of the Benchmarks web page has performance data for very large benchmark runs of simple Lennard-Jones (LJ) models, which use the bench/in.lj input script.

LAMMPS Users Manual

For all the benchmarks, a useful metric is the CPU cost per atom per timestep. Since performance scales roughly linearly with problem size and timesteps for all LAMMPS models (i.e. interatomic or coarse-grained potentials), the run time of any problem using the same model (atom style, force field, cutoff, etc) can then be estimated.

Performance on a parallel machine can also be predicted from one-core or one-node timings if the parallel efficiency can be estimated. The communication bandwidth and latency of a particular parallel machine affects the efficiency. On most machines LAMMPS will give parallel efficiencies on these benchmarks above 50% so long as the number of atoms/core is a few 100 or greater, and closer to 100% for large numbers of atoms/core. This is for all-MPI mode with one MPI task per core. For nodes with accelerator options or hardware (OpenMP, GPU, Phi), you should first measure single node performance. Then you can estimate parallel performance for multi-node runs using the same logic as for all-MPI mode, except that now you will typically need many more atoms/node to achieve good scalability.

9. Additional tools

LAMMPS is designed to be a computational kernel for performing molecular dynamics computations. Additional pre- and post-processing steps are often necessary to setup and analyze a simulation. A list of such tools can be found on the LAMMPS home page at <http://lammps.sandia.gov/prepost.html>

A few additional tools are provided with the LAMMPS distribution and are described in this section.

Our group has also written and released a separate toolkit called [Pizza.py](#) which provides tools for doing setup, analysis, plotting, and visualization for LAMMPS simulations. Pizza.py is written in [Python](#) and is available for download from [the Pizza.py WWW site](#).

Note that many users write their own setup or analysis tools or use other existing codes and convert their output to a LAMMPS input format or vice versa. The tools listed here are included in the LAMMPS distribution as examples of auxiliary tools. Some of them are not actively supported by Sandia, as they were contributed by LAMMPS users. If you have problems using them, we can direct you to the authors.

The source code for each of these codes is in the tools sub-directory of the LAMMPS distribution. There is a Makefile (which you may need to edit for your platform) which will build several of the tools which reside in that directory. Most of them are larger packages in their own sub-directories with their own Makefiles and/or README files.

[amber2lmp](#) [binary2txt](#) [ch2lmp](#) [chain](#) [colvars](#) [createatoms](#) [doxygen](#) [drude](#) [eam](#) [database](#) [eam](#) [generate](#) [eff](#) [emacs](#) [fep](#) [i-pi](#) [ipp](#) [kate](#) [lmp2arc](#) [lmp2cfg](#) [matlab](#) [micelle2d](#) [moltemplate](#) [msi2lmp](#) [phonon](#) [polybond](#) [pymol_asphere](#) [python](#) [reax](#) [smd](#) [vim](#) [xmgrace](#)

amber2lmp tool

The `amber2lmp` sub-directory contains two Python scripts for converting files back-and-forth between the AMBER MD code and LAMMPS. See the README file in `amber2lmp` for more information.

These tools were written by Keir Novik while he was at Queen Mary University of London. Keir is no longer there and cannot support these tools which are out-of-date with respect to the current LAMMPS version (and maybe with respect to AMBER as well). Since we don't use these tools at Sandia, you'll need to experiment with them and make necessary modifications yourself.

binary2txt tool

The file `binary2txt.cpp` converts one or more binary LAMMPS dump file into ASCII text files. The syntax for running the tool is

LAMMPS Users Manual

```
binary2txt file1 file2 ...
```

which creates file1.txt, file2.txt, etc. This tool must be compiled on a platform that can read the binary file created by a LAMMPS run, since binary files are not compatible across all platforms.

ch2lmp tool

The ch2lmp sub-directory contains tools for converting files back-and-forth between the CHARMM MD code and LAMMPS.

They are intended to make it easy to use CHARMM as a builder and as a post-processor for LAMMPS. Using charmm2lammeps.pl, you can convert a PDB file with associated CHARMM info, including CHARMM force field data, into its LAMMPS equivalent. Support for the CMAP correction of CHARMM22 and later is available as an option. This tool can also add solvent water molecules and Na⁺ or Cl⁻ ions to the system. Using lammeps2pdb.pl you can convert LAMMPS atom dumps into PDB files.

See the README file in the ch2lmp sub-directory for more information.

These tools were created by Pieter in't Veld (pjintve at sandia.gov) and Paul Crozier (pscrozi at sandia.gov) at Sandia.

CMAP support added and tested by Xiaohu Hu (hux2 at ornl.gov) and Robert A. Latour (latourr at clemson.edu), David Hyde-Volpe, and Tigran Abramyan, (Clemson University) and Chris Lorenz (chris.lorenz at kcl.ac.uk), King's College London.

chain tool

The file chain.f creates a LAMMPS data file containing bead-spring polymer chains and/or monomer solvent atoms. It uses a text file containing chain definition parameters as an input. The created chains and solvent atoms can strongly overlap, so LAMMPS needs to run the system initially with a "soft" pair potential to un-overlap it. The syntax for running the tool is

```
chain <def.chain > data.file
```

See the def.chain or def.chain.ab files in the tools directory for examples of definition files. This tool was used to create the system for the [chain benchmark](#).

colvars tools

The colvars directory contains a collection of tools for postprocessing data produced by the colvars collective variable library. To compile the tools, edit the makefile for your system and run "make".

Please report problems and issues the colvars library and its tools at:
<https://github.com/colvars/colvars/issues>

abf_integrate:

LAMMPS Users Manual

MC-based integration of multidimensional free energy gradient Version 20110511

Syntax: `./abf_integrate <filename > [-n <nsteps >] [-t <temp >] [-m [0|1] (metadynamics)] [-h`

The LAMMPS interface to the colvars collective variable library, as well as these tools, were created by Axel Kohlmeyer (akohlmey at gmail.com) at ICTP, Italy.

createatoms tool

The tools/createatoms directory contains a Fortran program called createAtoms.f which can generate a variety of interesting crystal structures and geometries and output the resulting list of atom coordinates in LAMMPS or other formats.

See the included Manual.pdf for details.

The tool is authored by Xiaowang Zhou (Sandia), xzhou at sandia.gov.

doxygen tool

The tools/doxygen directory contains a shell script called doxygen.sh which can generate a call graph and API lists using the [Doxygen software](#).

See the included README file for details.

The tool is authored by Nandor Tamaskovics, numericalfreedom at gmail.com.

drude tool

The tools/drude directory contains a Python script called polarizer.py which can add Drude oscillators to a LAMMPS data file in the required format.

See the header of the polarizer.py file for details.

The tool is authored by Agilio Padua and Alain Dequidt: agilio.padua at univ-bpclermont.fr, alain.dequidt at univ-bpclermont.fr

eam database tool

The tools/eam_database directory contains a Fortran program that will generate EAM alloy setfl potential files for any combination of 16 elements: Cu, Ag, Au, Ni, Pd, Pt, Al, Pb, Fe, Mo, Ta, W, Mg, Co, Ti, Zr. The files can then be used with the [pair_style eam/alloy](#) command.

The tool is authored by Xiaowang Zhou (Sandia), xzhou at sandia.gov, and is based on his paper:

X. W. Zhou, R. A. Johnson, and H. N. G. Wadley, Phys. Rev. B, 69, 144113 (2004).

eam generate tool

The tools/eam_generate directory contains several one-file C programs that convert an analytic formula into a tabulated [embedded atom method \(EAM\)](#) setfl potential file. The potentials they produce are in the potentials directory, and can be used with the [pair_style eam/alloy](#) command.

The source files and potentials were provided by Gerolf Ziegenhain (gerolf at ziegenhain.com).

eff tool

The tools/eff directory contains various scripts for generating structures and post-processing output for simulations using the electron force field (eFF).

These tools were provided by Andres Jaramillo-Botero at CalTech (ajaramil at wag.caltech.edu).

emacs tool

The tools/emacs directory contains a Lips add-on file for Emacs that enables a lammeps-mode for editing of input scripts when using Emacs, with various highlighting options setup.

These tools were provided by Aidan Thompson at Sandia (athomps at sandia.gov).

fep tool

The tools/fep directory contains Python scripts useful for post-processing results from performing free-energy perturbation simulations using the USER-FEP package.

The scripts were contributed by Agilio Padua (Universite Blaise Pascal Clermont-Ferrand), agilio.padua at univ-bpclermont.fr.

See README file in the tools/fep directory.

i-pi tool

The tools/i-pi directory contains a version of the i-PI package, with all the LAMMPS-unrelated files removed. It is provided so that it can be used with the [fix ipi](#) command to perform path-integral molecular dynamics (PIMD).

The i-PI package was created and is maintained by Michele Ceriotti, michele.ceriotti at gmail.com, to interface to a variety of molecular dynamics codes.

See the tools/i-pi/manual.pdf file for an overview of i-PI, and the [fix ipi](#) doc page for further details on running PIMD calculations with LAMMPS.

ipp tool

The tools/ipp directory contains a Perl script ipp which can be used to facilitate the creation of a complicated file (say, a lammmps input script or tools/createatoms input file) using a template file.

ipp was created and is maintained by Reese Jones (Sandia), rjones at sandia.gov.

See two examples in the tools/ipp directory. One of them is for the tools/createatoms tool's input file.

kate tool

The file in the tools/kate directory is an add-on to the Kate editor in the KDE suite that allow syntax highlighting of LAMMPS input scripts. See the README.txt file for details.

The file was provided by Alessandro Luigi Sellerio (alessandro.sellerio at ieni.cnr.it).

Imp2arc tool

The Imp2arc sub-directory contains a tool for converting LAMMPS output files to the format for Accelrys' Insight MD code (formerly MSI/Biosym and its Discover MD code). See the README file for more information.

This tool was written by John Carpenter (Cray), Michael Peachey (Cray), and Steve Lustig (Dupont). John is now at the Mayo Clinic (jec at mayo.edu), but still fields questions about the tool.

This tool was updated for the current LAMMPS C++ version by Jeff Greathouse at Sandia (jagreat at sandia.gov).

Imp2cfg tool

The Imp2cfg sub-directory contains a tool for converting LAMMPS output files into a series of *.cfg files which can be read into the [AtomEye](#) visualizer. See the README file for more information.

This tool was written by Ara Kooser at Sandia (askoose at sandia.gov).

matlab tool

The matlab sub-directory contains several [MATLAB](#) scripts for post-processing LAMMPS output. The scripts include readers for log and dump files, a reader for EAM potential files, and a converter that reads LAMMPS dump files and produces CFG files that can be visualized with the [AtomEye](#) visualizer.

See the README.pdf file for more information.

LAMMPS Users Manual

These scripts were written by Arun Subramanian at Purdue Univ (asubrama at purdue.edu).

micelle2d tool

The file micelle2d.f creates a LAMMPS data file containing short lipid chains in a monomer solution. It uses a text file containing lipid definition parameters as an input. The created molecules and solvent atoms can strongly overlap, so LAMMPS needs to run the system initially with a "soft" pair potential to un-overlap it. The syntax for running the tool is

```
micelle2d <def.micelle2d > data.file
```

See the def.micelle2d file in the tools directory for an example of a definition file. This tool was used to create the system for the [micelle example](#).

moltemplate tool

The moltemplate sub-directory contains a Python-based tool for building molecular systems based on a text-file description, and creating LAMMPS data files that encode their molecular topology as lists of bonds, angles, dihedrals, etc. See the README.TXT file for more information.

This tool was written by Andrew Jewett (jewett.aj at gmail.com), who supports it. It has its own WWW page at <http://moltemplate.org>.

msi2lmp tool

The msi2lmp sub-directory contains a tool for creating LAMMPS template input and data files from BIOVIA's Materias Studio files (formerly Accelrys' Insight MD code, formerly MSI/Biosym and its Discover MD code).

This tool was written by John Carpenter (Cray), Michael Peachey (Cray), and Steve Lustig (Dupont). Several people contributed changes to remove bugs and adapt its output to changes in LAMMPS.

This tool has several known limitations and is no longer under active development, so there are no changes except for the occasional bugfix.

See the README file in the tools/msi2lmp folder for more information.

phonon tool

The phonon sub-directory contains a post-processing tool useful for analyzing the output of the [fix phonon](#) command in the USER-PHONON package.

See the README file for instruction on building the tool and what library it needs. And see the examples/USER/phonon directory for example problems that can be post-processed with this tool.

LAMMPS Users Manual

This tool was written by Ling-Ti Kong at Shanghai Jiao Tong University.

polybond tool

The polybond sub-directory contains a Python-based tool useful for performing "programmable polymer bonding". The Python file `lmpsdata.py` provides a "Lmpsdata" class with various methods which can be invoked by a user-written Python script to create data files with complex bonding topologies.

See the `Manual.pdf` for details and example scripts.

This tool was written by Zachary Kraus at Georgia Tech.

pymol_asphere tool

The `pymol_asphere` sub-directory contains a tool for converting a LAMMPS dump file that contains orientation info for ellipsoidal particles into an input file for the [PyMol visualization package](#) or its [open source variant](#).

Specifically, the tool triangulates the ellipsoids so they can be viewed as true ellipsoidal particles within PyMol. See the `README` and `examples` directory within `pymol_asphere` for more information.

This tool was written by Mike Brown at Sandia.

python tool

The `python` sub-directory contains several Python scripts that perform common LAMMPS post-processing tasks, such as:

- extract thermodynamic info from a log file as columns of numbers
- plot two columns of thermodynamic info from a log file using GnuPlot
- sort the snapshots in a dump file by atom ID
- convert multiple [NEB](#) dump files into one dump file for viz
- convert dump files into XYZ, CFG, or PDB format for viz by other packages

These are simple scripts built on [Pizza.py](#) modules. See the `README` for more info on `Pizza.py` and how to use these scripts.

reax tool

The `reax` sub-directory contains stand-alone codes that can post-process the output of the `fix reax/bonds` command from a LAMMPS simulation using [ReaxFF](#). See the `README.txt` file for more info.

These tools were written by Aidan Thompson at Sandia.

smd tool

The smd sub-directory contains a C++ file `dump2vtk_tris.cpp` and Makefile which can be compiled and used to convert triangle output files created by the Smooth-Mach Dynamics (USER-SMD) package into a VTK-compatible unstructured grid file. It could then be read in and visualized by VTK.

See the header of `dump2vtk.cpp` for more details.

This tool was written by the USER-SMD package author, Georg Ganzenmuller at the Fraunhofer-Institute for High-Speed Dynamics, Ernst Mach Institute in Germany (`georg.ganzenmueller at emi.fhg.de`).

vim tool

The files in the `tools/vim` directory are add-ons to the VIM editor that allow easier editing of LAMMPS input scripts. See the `README.txt` file for details.

These files were provided by Gerolf Ziegenhain (`gerolf at ziegenhain.com`)

xmgrace tool

The files in the `tools/xmgrace` directory can be used to plot the thermodynamic data in LAMMPS log files via the `xmgrace` plotting package. There are several tools in the directory that can be used in post-processing mode. The `lammplot.cpp` file can be compiled and used to create plots from the current state of a running LAMMPS simulation.

See the `README` file for details.

These files were provided by Vikas Varshney (`vv0210 at gmail.com`)

10. Modifying & extending LAMMPS

This section describes how to customize LAMMPS by modifying and extending its source code.

- 10.1 [Atom styles](#)
- 10.2 [Bond, angle, dihedral, improper potentials](#)
- 10.3 [Compute styles](#)
- 10.4 [Dump styles](#)
- 10.5 [Dump custom output options](#)
- 10.6 [Fix styles](#) which include integrators, temperature and pressure control, force constraints, boundary conditions, diagnostic output, etc
- 10.7 [Input script commands](#)
- 10.8 [Kspace computations](#)
- 10.9 [Minimization styles](#)
- 10.10 [Pairwise potentials](#)
- 10.11 [Region styles](#)
- 10.12 [Body styles](#)
- 10.13 [Thermodynamic output options](#)
- 10.14 [Variable options](#)
- 10.15 [Submitting new features for inclusion in LAMMPS](#)

LAMMPS is designed in a modular fashion so as to be easy to modify and extend with new functionality. In fact, about 75% of its source code is files added in this fashion.

In this section, changes and additions users can make are listed along with minimal instructions. If you add a new feature to LAMMPS and think it will be of interest to general users, we encourage you to submit it to the developers for inclusion in the released version of LAMMPS. Information about how to do this is provided [below](#).

The best way to add a new feature is to find a similar feature in LAMMPS and look at the corresponding source and header files to figure out what it does. You will need some knowledge of C++ to be able to understand the hi-level structure of LAMMPS and its class organization, but functions (class methods) that do actual computations are written in vanilla C-style code and operate on simple C-style data structures (vectors and arrays).

Most of the new features described in this section require you to write a new C++ derived class (except for exceptions described below, where you can make small edits to existing files). Creating a new class requires 2 files, a source code file (*.cpp) and a header file (*.h). The derived class must provide certain methods to work as a new option. Depending on how different your new feature is compared to existing features, you can either derive from the base class itself, or from a derived class that already exists. Enabling LAMMPS to invoke the new class is as simple as putting the two source files in the src dir and re-building LAMMPS.

The advantage of C++ and its object-orientation is that all the code and variables

LAMMPS Users Manual

needed to define the new feature are in the 2 files you write, and thus shouldn't make the rest of LAMMPS more complex or cause side-effect bugs.

Here is a concrete example. Suppose you write 2 files `pair_foo.cpp` and `pair_foo.h` that define a new class `PairFoo` that computes pairwise potentials described in the classic 1997 [paper](#) by Foo, et al. If you wish to invoke those potentials in a LAMMPS input script with a command like

```
pair_style foo 0.1 3.5
```

then your `pair_foo.h` file should be structured as follows:

```
#ifndef PAIR_CLASS
PairStyle(foo,PairFoo)
#else
...
(class definition for PairFoo)
...
#endif
```

where "foo" is the style keyword in the `pair_style` command, and `PairFoo` is the class name defined in your `pair_foo.cpp` and `pair_foo.h` files.

When you re-build LAMMPS, your new pairwise potential becomes part of the executable and can be invoked with a `pair_style` command like the example above. Arguments like 0.1 and 3.5 can be defined and processed by your new class.

As illustrated by this pairwise example, many kinds of options are referred to in the LAMMPS documentation as the "style" of a particular command.

The instructions below give the header file for the base class that these styles are derived from. Public variables in that file are ones used and set by the derived classes which are also used by the base class. Sometimes they are also used by the rest of LAMMPS. Virtual functions in the base class header file which are set = 0 are ones you must define in your new derived class to give it the functionality LAMMPS expects. Virtual functions that are not set to 0 are functions you can optionally define.

Additionally, new output options can be added directly to the `thermo.cpp`, `dump_custom.cpp`, and `variable.cpp` files as explained below.

Here are additional guidelines for modifying LAMMPS and adding new functionality:

- Think about whether what you want to do would be better as a pre- or post-processing step. Many computations are more easily and more quickly done that way.
- Don't do anything within the timestepping of a run that isn't parallel. E.g. don't accumulate a bunch of data on a single processor and analyze it. You run the risk of seriously degrading the parallel efficiency.
- If your new feature reads arguments or writes output, make sure you follow the unit conventions discussed by the [units](#) command.
- If you add something you think is truly useful and doesn't impact LAMMPS performance when it isn't used, send an email to the [developers](#). We might be

interested in adding it to the LAMMPS distribution. See further details on this at the bottom of this page.

10.1 Atom styles

Classes that define an [atom style](#) are derived from the AtomVec class and managed by the Atom class. The atom style determines what attributes are associated with an atom. A new atom style can be created if one of the existing atom styles does not define all the attributes you need to store and communicate with atoms.

Atom_vec_atomic.cpp is a simple example of an atom style.

Here is a brief description of methods you define in your new derived class. See atom_vec.h for details.

init	one time setup (optional)
grow	re-allocate atom arrays to longer lengths (required)
grow_reset	make array pointers in Atom and AtomVec classes consistent (required)
copy	copy info for one atom to another atom's array locations (required)
pack_comm	store an atom's info in a buffer communicated every timestep (required)
pack_comm_vel	add velocity info to communication buffer (required)
pack_comm_hybrid	store extra info unique to this atom style (optional)
unpack_comm	retrieve an atom's info from the buffer (required)
unpack_comm_vel	also retrieve velocity info (required)
unpack_comm_hybrid	retrieve extra info unique to this atom style (optional)
pack_reverse	store an atom's info in a buffer communicating partial forces (required)
pack_reverse_hybrid	store extra info unique to this atom style (optional)
unpack_reverse	retrieve an atom's info from the buffer (required)
unpack_reverse_hybrid	retrieve extra info unique to this atom style (optional)
pack_border	store an atom's info in a buffer communicated on neighbor re-builds (required)
pack_border_vel	add velocity info to buffer (required)
pack_border_hybrid	store extra info unique to this atom style (optional)
unpack_border	retrieve an atom's info from the buffer (required)
unpack_border_vel	also retrieve velocity info (required)
unpack_border_hybrid	retrieve extra info unique to this atom style (optional)
pack_exchange	store all an atom's info to migrate to another processor (required)
unpack_exchange	retrieve an atom's info from the buffer (required)

LAMMPS Users Manual

size_restart	number of restart quantities associated with proc's atoms (required)
pack_restart	pack atom quantities into a buffer (required)
unpack_restart	unpack atom quantities from a buffer (required)
create_atom	create an individual atom of this style (required)
data_atom	parse an atom line from the data file (required)
data_atom_hybrid	parse additional atom info unique to this atom style (optional)
data_vel	parse one line of velocity information from data file (optional)
data_vel_hybrid	parse additional velocity data unique to this atom style (optional)
memory_usage	tally memory allocated by atom arrays (required)

The constructor of the derived class sets values for several variables that you must set when defining a new atom style, which are documented in `atom_vec.h`. New atom arrays are defined in `atom.cpp`. Search for the word "customize" and you will find locations you will need to modify.

NOTE: It is possible to add some attributes, such as a molecule ID, to atom styles that do not have them via the [fix property/atom](#) command. This command also allows new custom attributes consisting of extra integer or floating-point values to be added to atoms. See the [fix property/atom](#) doc page for examples of cases where this is useful and details on how to initialize, access, and output the custom values.

New [pair styles](#), [fixes](#), or [computes](#) can be added to LAMMPS, as discussed below. The code for these classes can use the per-atom properties defined by `fix property/atom`. The Atom class has a `find_custom()` method that is useful in this context:

```
int index = atom->find_custom(char *name, int &flag);
```

The "name" of a custom attribute, as specified in the [fix property/atom](#) command, is checked to verify that it exists and its index is returned. The method also sets `flag = 0/1` depending on whether it is an integer or floating-point attribute. The vector of values associated with the attribute can then be accessed using the returned index as

```
int *ivector = atom->ivector[index];  
double *dvector = atom->dvector[index];
```

Ivector or dvector are vectors of length `Nlocal = # of owned atoms`, which store the attributes of individual atoms.

10.2 Bond, angle, dihedral, improper potentials

Classes that compute molecular interactions are derived from the Bond, Angle, Dihedral, and Improper classes. New styles can be created to add new potentials to LAMMPS.

`Bond_harmonic.cpp` is the simplest example of a bond style. Ditto for the harmonic forms of the angle, dihedral, and improper style commands.

LAMMPS Users Manual

Here is a brief description of common methods you define in your new derived class. See `bond.h`, `angle.h`, `dihedral.h`, and `improper.h` for details and specific additional methods.

<code>init</code>	check if all coefficients are set, calls <i>init style</i> (optional)
<code>init_style</code>	check if style specific conditions are met (optional)
<code>compute</code>	compute the molecular interactions (required)
<code>settings</code>	apply global settings for all types (optional)
<code>coeff</code>	set coefficients for one type (required)
<code>equilibrium_distance</code>	length of bond, used by SHAKE (required, bond only)
<code>equilibrium_angle</code>	opening of angle, used by SHAKE (required, angle only)
<code>write & read_restart</code>	writes/reads coeffs to restart files (required)
<code>single</code>	force and energy of a single bond or angle (required, bond or angle only)
<code>memory_usage</code>	tally memory allocated by the style (optional)

10.3 Compute styles

Classes that compute scalar and vector quantities like temperature and the pressure tensor, as well as classes that compute per-atom quantities like kinetic energy and the centro-symmetry parameter are derived from the Compute class. New styles can be created to add new calculations to LAMMPS.

`Compute_temp.cpp` is a simple example of computing a scalar temperature. `Compute_ke_atom.cpp` is a simple example of computing per-atom kinetic energy.

Here is a brief description of methods you define in your new derived class. See `compute.h` for details.

<code>init</code>	perform one time setup (required)
<code>init_list</code>	neighbor list setup, if needed (optional)
<code>compute_scalar</code>	compute a scalar quantity (optional)
<code>compute_vector</code>	compute a vector of quantities (optional)
<code>compute_peratom</code>	compute one or more quantities per atom (optional)
<code>compute_local</code>	compute one or more quantities per processor (optional)
<code>pack_comm</code>	pack a buffer with items to communicate (optional)
<code>unpack_comm</code>	unpack the buffer (optional)
<code>pack_reverse</code>	pack a buffer with items to reverse communicate (optional)
<code>unpack_reverse</code>	unpack the buffer (optional)
<code>remove_bias</code>	remove velocity bias from one atom (optional)
<code>remove_bias_all</code>	remove velocity bias from all atoms in group (optional)
<code>restore_bias</code>	restore velocity bias for one atom after <code>remove_bias</code> (optional)
<code>restore_bias_all</code>	same as before, but for all atoms in group (optional)
<code>pair_tally_callback</code>	callback function for <i>tally</i> -style computes (optional).

memory_usage	tally memory usage (optional)
--------------	-------------------------------

Tally-style computes are a special case, as their computation is done in two stages: the callback function is registered with the pair style and then called from the `Pair::ev_tally()` function, which is called for each pair after force and energy has been computed for this pair. Then the tallied values are retrieved with the standard `compute_scalar` or `compute_vector` or `compute_peratom` methods. The USER-TALLY package provides *examples_compute_tally.html* for utilizing this mechanism.

10.4 Dump styles

10.5 Dump custom output options

Classes that dump per-atom info to files are derived from the Dump class. To dump new quantities or in a new format, a new derived dump class can be added, but it is typically simpler to modify the DumpCustom class contained in the `dump_custom.cpp` file.

`Dump_atom.cpp` is a simple example of a derived dump class.

Here is a brief description of methods you define in your new derived class. See `dump.h` for details.

<code>write_header</code>	write the header section of a snapshot of atoms
<code>count</code>	count the number of lines a processor will output
<code>pack</code>	pack a proc's output data into a buffer
<code>write_data</code>	write a proc's data to a file

See the [dump](#) command and its *custom* style for a list of keywords for atom information that can already be dumped by DumpCustom. It includes options to dump per-atom info from Compute classes, so adding a new derived Compute class is one way to calculate new quantities to dump.

Alternatively, you can add new keywords to the dump custom command. Search for the word "customize" in `dump_custom.cpp` to see the half-dozen or so locations where code will need to be added.

10.6 Fix styles

In LAMMPS, a "fix" is any operation that is computed during timestepping that alters some property of the system. Essentially everything that happens during a simulation besides force computation, neighbor list construction, and output, is a "fix". This includes time integration (update of coordinates and velocities), force constraints or boundary conditions (SHAKE or walls), and diagnostics (compute a diffusion coefficient). New styles can be created to add new options to LAMMPS.

`Fix_setforce.cpp` is a simple example of setting forces on atoms to prescribed values. There are dozens of fix options already in LAMMPS; choose one as a template that is

LAMMPS Users Manual

similar to what you want to implement.

Here is a brief description of methods you can define in your new derived class. See `fix.h` for details.

<code>setmask</code>	determines when the fix is called during the timestep (required)
<code>init</code>	initialization before a run (optional)
<code>setup_pre_exchange</code>	called before atom exchange in setup (optional)
<code>setup_pre_force</code>	called before force computation in setup (optional)
<code>setup</code>	called immediately before the 1st timestep and after forces are computed (optional)
<code>min_setup_pre_force</code>	like <code>setup_pre_force</code> , but for minimizations instead of MD runs (optional)
<code>min_setup</code>	like <code>setup</code> , but for minimizations instead of MD runs (optional)
<code>initial_integrate</code>	called at very beginning of each timestep (optional)
<code>pre_exchange</code>	called before atom exchange on re-neighboring steps (optional)
<code>pre_neighbor</code>	called before neighbor list build (optional)
<code>pre_force</code>	called before pair & molecular forces are computed (optional)
<code>post_force</code>	called after pair & molecular forces are computed and communicated (optional)
<code>final_integrate</code>	called at end of each timestep (optional)
<code>end_of_step</code>	called at very end of timestep (optional)
<code>write_restart</code>	dumps fix info to restart file (optional)
<code>restart</code>	uses info from restart file to re-initialize the fix (optional)
<code>grow_arrays</code>	allocate memory for atom-based arrays used by fix (optional)
<code>copy_arrays</code>	copy atom info when an atom migrates to a new processor (optional)
<code>pack_exchange</code>	store atom's data in a buffer (optional)
<code>unpack_exchange</code>	retrieve atom's data from a buffer (optional)
<code>pack_restart</code>	store atom's data for writing to restart file (optional)
<code>unpack_restart</code>	retrieve atom's data from a restart file buffer (optional)
<code>size_restart</code>	size of atom's data (optional)
<code>maxsize_restart</code>	max size of atom's data (optional)
<code>setup_pre_force_respa</code>	same as <code>setup_pre_force</code> , but for rRESPA (optional)
<code>initial_integrate_respa</code>	same as <code>initial_integrate</code> , but for rRESPA (optional)
<code>post_integrate_respa</code>	called after the first half integration step is done in rRESPA (optional)
<code>pre_force_respa</code>	same as <code>pre_force</code> , but for rRESPA (optional)
<code>post_force_respa</code>	same as <code>post_force</code> , but for rRESPA (optional)
<code>final_integrate_respa</code>	same as <code>final_integrate</code> , but for rRESPA (optional)
<code>min_pre_force</code>	called after pair & molecular forces are computed in minimizer (optional)

LAMMPS Users Manual

min_post_force	called after pair & molecular forces are computed and communicated in minimizer (optional)
min_store	store extra data for linesearch based minimization on a LIFO stack (optional)
min_pushstore	push the minimization LIFO stack one element down (optional)
min_popstore	pop the minimization LIFO stack one element up (optional)
min_clearstore	clear minimization LIFO stack (optional)
min_step	reset or move forward on line search minimization (optional)
min_dof	report number of degrees of freedom <i>added</i> by this fix in minimization (optional)
max_alpha	report maximum allowed step size during linesearch minimization (optional)
pack_comm	pack a buffer to communicate a per-atom quantity (optional)
unpack_comm	unpack a buffer to communicate a per-atom quantity (optional)
pack_reverse_comm	pack a buffer to reverse communicate a per-atom quantity (optional)
unpack_reverse_comm	unpack a buffer to reverse communicate a per-atom quantity (optional)
dof	report number of degrees of freedom <i>removed</i> by this fix during MD (optional)
compute_scalar	return a global scalar property that the fix computes (optional)
compute_vector	return a component of a vector property that the fix computes (optional)
compute_array	return a component of an array property that the fix computes (optional)
deform	called when the box size is changed (optional)
reset_target	called when a change of the target temperature is requested during a run (optional)
reset_dt	is called when a change of the time step is requested during a run (optional)
modify_param	called when a fix_modify request is executed (optional)
memory_usage	report memory used by fix (optional)
thermo	compute quantities for thermodynamic output (optional)

Typically, only a small fraction of these methods are defined for a particular fix. Setmask is mandatory, as it determines when the fix will be invoked during the timestep. Fixes that perform time integration (*nve*, *nvt*, *npt*) implement `initial_integrate()` and `final_integrate()` to perform velocity Verlet updates. Fixes that constrain forces implement `post_force()`.

Fixes that perform diagnostics typically implement `end_of_step()`. For an `end_of_step` fix, one of your fix arguments must be the variable "nevery" which is used to determine when to call the fix and you must set this variable in the constructor of your fix. By convention, this is the first argument the fix defines (after the ID, group-ID, style).

LAMMPS Users Manual

If the fix needs to store information for each atom that persists from timestep to timestep, it can manage that memory and migrate the info with the atoms as they move from processors to processor by implementing the `grow_arrays`, `copy_arrays`, `pack_exchange`, and `unpack_exchange` methods. Similarly, the `pack_restart` and `unpack_restart` methods can be implemented to store information about the fix in restart files. If you wish an integrator or force constraint fix to work with rRESPA (see the [run_style](#) command), the `initial_integrate`, `post_force_integrate`, and `final_integrate_respa` methods can be implemented. The thermo method enables a fix to contribute values to thermodynamic output, as printed quantities and/or to be summed to the potential energy of the system.

10.7 Input script commands

New commands can be added to LAMMPS input scripts by adding new classes that have a "command" method. For example, the `create_atoms`, `read_data`, `velocity`, and `run` commands are all implemented in this fashion. When such a command is encountered in the LAMMPS input script, LAMMPS simply creates a class with the corresponding name, invokes the "command" method of the class, and passes it the arguments from the input script. The command method can perform whatever operations it wishes on LAMMPS data structures.

The single method your new class must define is as follows:

command	operations performed by the new command
---------	---

Of course, the new class can define other methods and variables as needed.

10.8 Kspace computations

Classes that compute long-range Coulombic interactions via K-space representations (Ewald, PPPM) are derived from the `KSpace` class. New styles can be created to add new K-space options to LAMMPS.

`Ewald.cpp` is an example of computing K-space interactions.

Here is a brief description of methods you define in your new derived class. See `kpace.h` for details.

<code>init</code>	initialize the calculation before a run
<code>setup</code>	computation before the 1st timestep of a run
<code>compute</code>	every-timestep computation
<code>memory_usage</code>	tally of memory usage

10.9 Minimization styles

Classes that perform energy minimization derived from the `Min` class. New styles can be created to add new minimization algorithms to LAMMPS.

LAMMPS Users Manual

Min_cg.cpp is an example of conjugate gradient minimization.

Here is a brief description of methods you define in your new derived class. See min.h for details.

init	initialize the minimization before a run
run	perform the minimization
memory_usage	tally of memory usage

10.10 Pairwise potentials

Classes that compute pairwise interactions are derived from the Pair class. In LAMMPS, pairwise calculation include manybody potentials such as EAM or Tersoff where particles interact without a static bond topology. New styles can be created to add new pair potentials to LAMMPS.

Pair_lj_cut.cpp is a simple example of a Pair class, though it includes some optional methods to enable its use with rRESPA.

Here is a brief description of the class methods in pair.h:

compute	workhorse routine that computes pairwise interactions
settings	reads the input script line with arguments you define
coeff	set coefficients for one i,j type pair
init_one	perform initialization for one i,j type pair
init_style	initialization specific to this pair style
write & read_restart	write/read i,j pair coeffs to restart files
write & read_restart_settings	write/read global settings to restart files
single	force and energy of a single pairwise interaction between 2 atoms
compute_inner/middle/outer	versions of compute used by rRESPA

The inner/middle/outer routines are optional.

10.11 Region styles

Classes that define geometric regions are derived from the Region class. Regions are used elsewhere in LAMMPS to group atoms, delete atoms to create a void, insert atoms in a specified region, etc. New styles can be created to add new region shapes to LAMMPS.

Region_sphere.cpp is an example of a spherical region.

Here is a brief description of methods you define in your new derived class. See region.h for details.

inside	determine whether a point is in the region
--------	--

LAMMPS Users Manual

surface_interior	determine if a point is within a cutoff distance inside of surc
surface_exterior	determine if a point is within a cutoff distance outside of surf
shape_update	change region shape if set by time-dependent variable

10.12 Body styles

Classes that define body particles are derived from the Body class. Body particles can represent complex entities, such as surface meshes of discrete points, collections of sub-particles, deformable objects, etc.

See [Section 6.14](#) of the manual for an overview of using body particles and the [body](#) doc page for details on the various body styles LAMMPS supports. New styles can be created to add new kinds of body particles to LAMMPS.

Body_nparticle.cpp is an example of a body particle that is treated as a rigid body containing N sub-particles.

Here is a brief description of methods you define in your new derived class. See body.h for details.

data_body	process a line from the Bodies section of a data file
noutrow	number of sub-particles output is generated for
noutcol	number of values per-sub-particle output is generated for
output	output values for the Mth sub-particle
pack_comm_body	body attributes to communicate every timestep
unpack_comm_body	unpacking of those attributes
pack_border_body	body attributes to communicate when reneighboring is done
unpack_border_body	unpacking of those attributes

10.13 Thermodynamic output options

There is one class that computes and prints thermodynamic information to the screen and log file; see the file thermo.cpp.

There are two styles defined in thermo.cpp: "one" and "multi". There is also a flexible "custom" style which allows the user to explicitly list keywords for quantities to print when thermodynamic info is output. See the [thermo_style](#) command for a list of defined quantities.

The thermo styles (one, multi, etc) are simply lists of keywords. Adding a new style thus only requires defining a new list of keywords. Search for the word "customize" with references to "thermo style" in thermo.cpp to see the two locations where code will need to be added.

New keywords can also be added to thermo.cpp to compute new quantities for output. Search for the word "customize" with references to "keyword" in thermo.cpp to see

the several locations where code will need to be added.

Note that the [thermo_style custom](#) command already allows for thermo output of quantities calculated by [fixes](#), [computes](#), and [variables](#). Thus, it may be simpler to compute what you wish via one of those constructs, than by adding a new keyword to the thermo command.

10.14 Variable options

There is one class that computes and stores [variable](#) information in LAMMPS; see the file `variable.cpp`. The value associated with a variable can be periodically printed to the screen via the [print](#), [fix print](#), or [thermo_style custom](#) commands. Variables of style "equal" can compute complex equations that involve the following types of arguments:

```
thermo keywords = ke, vol, atoms, ...
other variables = v_a, v_myvar, ...
math functions = div(x,y), mult(x,y), add(x,y), ...
group functions = mass(group), xcm(group,x), ...
atom values = x[123], y[3], vx[34], ...
compute values = c_mytemp[0], c_thermo_press[3], ...
```

Adding keywords for the [thermo_style custom](#) command (which can then be accessed by variables) was discussed [here](#) on this page.

Adding a new math function of one or two arguments can be done by editing one section of the `Variable::evaluate()` method. Search for the word "customize" to find the appropriate location.

Adding a new group function can be done by editing one section of the `Variable::evaluate()` method. Search for the word "customize" to find the appropriate location. You may need to add a new method to the Group class as well (see the `group.cpp` file).

Accessing a new atom-based vector can be done by editing one section of the `Variable::evaluate()` method. Search for the word "customize" to find the appropriate location.

Adding new [compute styles](#) (whose calculated values can then be accessed by variables) was discussed [here](#) on this page.

10.15 Submitting new features for inclusion in LAMMPS

We encourage users to submit new features or modifications for LAMMPS to [the core developers](#) so they can be added to the LAMMPS distribution. The preferred way to manage and coordinate this is as of Fall 2016 via the LAMMPS project on [GitHub](#). An alternative is to contact the LAMMPS developers or the indicated developer of a package or feature directly and send in your contribution via e-mail.

LAMMPS Users Manual

For any larger modifications or programming project, you are encouraged to contact the LAMMPS developers ahead of time, in order to discuss implementation strategies and coding guidelines, that will make it easier to integrate your contribution and result in less work for everybody involved. You are also encouraged to search through the list of [open issues on GitHub](#) and submit a new issue for a planned feature, so you would not duplicate the work of others (and possibly get scooped by them) or have your work duplicated by others.

How quickly your contribution will be integrated depends largely on how much effort it will cause to integrate and test it, how much it requires changes to the core codebase, and of how much interest it is to the larger LAMMPS community. Please see below for a checklist of typical requirements. Once you have prepared everything, see [this tutorial](#) for instructions on how to submit your changes or new files through a GitHub pull request. If you prefer to submit patches or full files, you should first make certain, that your code works correctly with the latest patch-level version of LAMMPS and contains all bugfixes from it. Then create a gzipped tar file of all changed or added files or a corresponding patch file using 'diff -u' or 'diff -c' and compress it with gzip. Please only use gzip compression, as this works well on all platforms.

If the new features/files are broadly useful we may add them as core files to LAMMPS or as part of a [standard package](#). Else we will add them as a user-contributed file or package. Examples of user packages are in src sub-directories that start with USER. The USER-MISC package is simply a collection of (mostly) unrelated single files, which is the simplest way to have your contribution quickly added to the LAMMPS distribution. You can see a list of the both standard and user packages by typing "make package" in the LAMMPS src directory.

Note that by providing us files to release, you are agreeing to make them open-source, i.e. we can release them under the terms of the GPL, used as a license for the rest of LAMMPS. See [Section 1.4](#) for details.

With user packages and files, all we are really providing (aside from the fame and fortune that accompanies having your name in the source code and on the [Authors page](#) of the [LAMMPS WWW site](#)), is a means for you to distribute your work to the LAMMPS user community, and a mechanism for others to easily try out your new feature. This may help you find bugs or make contact with new collaborators. Note that you're also implicitly agreeing to support your code which means answer questions, fix bugs, and maintain it if LAMMPS changes in some way that breaks it (an unusual event).

NOTE: If you prefer to actively develop and support your add-on feature yourself, then you may wish to make it available for download from your own website, as a user package that LAMMPS users can add to their copy of LAMMPS. See the [Offsite LAMMPS packages and tools](#) page of the LAMMPS web site for examples of groups that do this. We are happy to advertise your package and web site from that page. Simply email the [developers](#) with info about your package and we will post it there.

The previous sections of this doc page describe how to add new "style" files of various kinds to LAMMPS. Packages are simply collections of one or more new class files which are invoked as a new style within a LAMMPS input script. If designed correctly, these additions typically do not require changes to the main core of LAMMPS; they

LAMMPS Users Manual

are simply add-on files. If you think your new feature requires non-trivial changes in core LAMMPS files, you'll need to [communicate with the developers](#), since we may or may not want to make those changes. An example of a trivial change is making a parent-class method "virtual" when you derive a new child class from it.

Here is a checklist of steps you need to follow to submit a single file or user package for our consideration. Following these steps will save both you and us time. See existing files in packages in the src dir for examples. If you are uncertain, please ask.

- All source files you provide must compile with the most current version of LAMMPS with multiple configurations. In particular you need to test compiling LAMMPS from scratch with `-DLAMMPS_BIGBIG` set in addition to the default `-DLAMMPS_SMALLBIG` setting. Your code will need to work correctly in serial and in parallel using MPI.
- For consistency with the rest of LAMMPS and especially, if you want your contribution(s) to be added to main LAMMPS code or one of its standard packages, it needs to be written in a style compatible with other LAMMPS source files. This means: 2-character indentation per level, **no tabs**, no lines over 80 characters. I/O is done via the C-style `stdio` library, class header files should not import any system headers outside `<`, STL containers should be avoided in headers, and forward declarations used where possible or needed. All added code should be placed into the `LAMMPS_NS` namespace or a sub-namespace; global or static variables should be avoided, as they conflict with the modular nature of LAMMPS and the C++ class structure. Header files must **not** import namespaces with *using*. This all is so the developers can more easily understand, integrate, and maintain your contribution and reduce conflicts with other parts of LAMMPS. This basically means that the code accesses data structures, performs its operations, and is formatted similar to other LAMMPS source files, including the use of the error class for error and warning messages.
- If you want your contribution to be added as a user-contributed feature, and it's a single file (actually a *.cpp and *.h file) it can rapidly be added to the USER-MISC directory. Send us the one-line entry to add to the USER-MISC/README file in that dir, along with the 2 source files. You can do this multiple times if you wish to contribute several individual features.
- If you want your contribution to be added as a user-contribution and it is several related features, it is probably best to make it a user package directory with a name like USER-FOO. In addition to your new files, the directory should contain a README text file. The README should contain your name and contact information and a brief description of what your new package does. If your files depend on other LAMMPS style files also being installed (e.g. because your file is a derived class from the other LAMMPS class), then an Install.sh file is also needed to check for those dependencies. See other README and Install.sh files in other USER directories as examples. Send us a tarball of this USER-FOO directory.
- Your new source files need to have the LAMMPS copyright, GPL notice, and your name and email address at the top, like other user-contributed LAMMPS source files. They need to create a class that is inside the LAMMPS namespace. If the file is for one of the USER packages, including USER-MISC, then we are not as picky about the coding style (see above). I.e. the files do not need to be in the same stylistic format and syntax as other LAMMPS files, though that would

LAMMPS Users Manual

be nice for developers as well as users who try to read your code.

- You **must** also create a **documentation** file for each new command or style you are adding to LAMMPS. For simplicity and convenience, the documentation of groups of closely related commands or styles may be combined into a single file. This will be one file for a single-file feature. For a package, it might be several files. These are simple text files with a specific markup language, that are then auto-converted to HTML and PDF. The tools for this conversion are included in the source distribution, and the translation can be as simple as doing "make html pdf" in the doc folder. Thus the documentation source files must be in the same format and style as other *.txt files in the lammeps/doc/src directory for similar commands and styles; use one or more of them as a starting point. A description of the markup can also be found in [lammeps/doc/utills/txt2html/README.html](#) As appropriate, the text files can include links to equations (see doc/Eqs/*.tex for examples, we auto-create the associated JPG files), or figures (see doc/JPG for examples), or even additional PDF files with further details (see doc/PDF for examples). The doc page should also include literature citations as appropriate; see the bottom of doc/fix_nh.txt for examples and the earlier part of the same file for how to format the cite itself. The "Restrictions" section of the doc page should indicate that your command is only available if LAMMPS is built with the appropriate USER-MISC or USER-FOO package. See other user package doc files for examples of how to do this. The prerequisite for building the HTML format files are Python 3.x and virtualenv, the requirement for generating the PDF format manual is the [htmldoc](#) software. Please run at least "make html" and carefully inspect and proofread the resulting HTML format doc page before submitting your code.
- For a new package (or even a single command) you should include one or more example scripts demonstrating its use. These should run in no more than a couple minutes, even on a single processor, and not require large data files as input. See directories under examples/USER for examples of input scripts other users provided for their packages. These example inputs are also required for validating memory accesses and testing for memory leaks with valgrind
- If there is a paper of yours describing your feature (either the algorithm/science behind the feature itself, or its initial usage, or its implementation in LAMMPS), you can add the citation to the *.cpp source file. See [src/USER-EFF/atom_vec_electron.cpp](#) for an example. A LaTeX citation is stored in a variable at the top of the file and a single line of code that references the variable is added to the constructor of the class. Whenever a user invokes your feature from their input script, this will cause LAMMPS to output the citation to a log.cite file and prompt the user to examine the file. Note that you should only use this for a paper you or your group authored. E.g. adding a cite in the code for a paper by Nose and Hoover if you write a fix that implements their integrator is not the intended usage. That kind of citation should just be in the doc page you provide.

Finally, as a general rule-of-thumb, the more clear and self-explanatory you make your documentation and README files, and the easier you make it for people to get started, e.g. by providing example scripts, the more likely it is that users will try out your new feature.

LAMMPS Users Manual

11. Python interface to LAMMPS

LAMMPS can work together with Python in three ways. First, Python can wrap LAMMPS through the [LAMMPS library interface](#), so that a Python script can create one or more instances of LAMMPS and launch one or more simulations. In Python lingo, this is "extending" Python with LAMMPS.

Second, the low-level Python interface can be used indirectly through the PyLammps and IPyLammps wrapper classes in Python. These wrappers try to simplify the usage of LAMMPS in Python by providing an object-based interface to common LAMMPS functionality. It also reduces the amount of code necessary to parameterize LAMMPS scripts through Python and makes variables and computes directly accessible. See [PyLammps interface](#) for more details.

Third, LAMMPS can use the Python interpreter, so that a LAMMPS input script can invoke Python code, and pass information back-and-forth between the input script and Python functions you write. The Python code can also callback to LAMMPS to query or change its attributes. In Python lingo, this is "embedding" Python in LAMMPS.

This section describes how to use these three approaches.

- [11.1 Overview of running LAMMPS from Python](#)
- [11.2 Overview of using Python from a LAMMPS script](#)
- [11.3 Building LAMMPS as a shared library](#)
- [11.4 Installing the Python wrapper into Python](#)
- [11.5 Extending Python with MPI to run in parallel](#)
- [11.6 Testing the Python-LAMMPS interface](#)
- [11.7 Using LAMMPS from Python](#)
- [11.8 Example Python scripts that use LAMMPS](#)
- [11.9 PyLammps interface](#)

If you are not familiar with it, [Python](#) is a powerful scripting and programming language which can essentially do anything that faster, lower-level languages like C or C++ can do, but typically with much fewer lines of code. When used in embedded mode, Python can perform operations that the simplistic LAMMPS input script syntax cannot. Python can be also be used as a "glue" language to drive a program through its library interface, or to hook multiple pieces of software together, such as a simulation package plus a visualization package, or to run a coupled multiscale or multiphysics model.

See [Section 6.10](#) of the manual and the couple directory of the distribution for more ideas about coupling LAMMPS to other codes. See [Section 6.19](#) for a description of the LAMMPS library interface provided in `src/library.cpp` and `src/library.h`, and how to extend it for your needs. As described below, that interface is what is exposed to Python either when calling LAMMPS from Python or when calling Python from a LAMMPS input script and then calling back to LAMMPS from Python code. The library interface is designed to be easy to add functions to. Thus the Python interface to

LAMMPS Users Manual

LAMMPS is also easy to extend as well.

If you create interesting Python scripts that run LAMMPS or interesting Python functions that can be called from a LAMMPS input script, that you think would be useful to other users, please [email them to the developers](#). We can include them in the LAMMPS distribution.

11.1 Overview of running LAMMPS from Python

The LAMMPS distribution includes a python directory with all you need to run LAMMPS from Python. The python/lammps.py file wraps the LAMMPS library interface, with one wrapper function per LAMMPS library function. This file makes it is possible to do the following either from a Python script, or interactively from a Python prompt: create one or more instances of LAMMPS, invoke LAMMPS commands or give it an input script, run LAMMPS incrementally, extract LAMMPS results, an modify internal LAMMPS variables. From a Python script you can do this in serial or parallel. Running Python interactively in parallel does not generally work, unless you have a version of Python that extends standard Python to enable multiple instances of Python to read what you type.

To do all of this, you must first build LAMMPS as a shared library, then insure that your Python can find the python/lammps.py file and the shared library. These steps are explained in subsequent sections 11.3 and 11.4. Sections 11.5 and 11.6 discuss using MPI from a parallel Python program and how to test that you are ready to use LAMMPS from Python. Section 11.7 lists all the functions in the current LAMMPS library interface and how to call them from Python.

Section 11.8 gives some examples of coupling LAMMPS to other tools via Python. For example, LAMMPS can easily be coupled to a GUI or other visualization tools that display graphs or animations in real time as LAMMPS runs. Examples of such scripts are included in the python directory.

Two advantages of using Python to run LAMMPS are how concise the language is, and that it can be run interactively, enabling rapid development and debugging of programs. If you use it to mostly invoke costly operations within LAMMPS, such as running a simulation for a reasonable number of timesteps, then the overhead cost of invoking LAMMPS thru Python will be negligible.

The Python wrapper for LAMMPS uses the amazing and magical (to me) "ctypes" package in Python, which auto-generates the interface code needed between Python and a set of C interface routines for a library. Ctypes is part of standard Python for versions 2.5 and later. You can check which version of Python you have installed, by simply typing "python" at a shell prompt.

11.2 Overview of using Python from a LAMMPS script

LAMMPS has several commands which can be used to invoke Python code directly from an input script:

- [python](#)
- [variable python](#)
- [fix python/invoke](#)
- [pair_style python](#)

The [python](#) command which can be used to define and execute a Python function that you write the code for. The Python function can also be assigned to a LAMMPS python-style variable via the [variable](#) command. Each time the variable is evaluated, either in the LAMMPS input script itself, or by another LAMMPS command that uses the variable, this will trigger the Python function to be invoked.

The Python code for the function can be included directly in the input script or in an auxiliary file. The function can have arguments which are mapped to LAMMPS variables (also defined in the input script) and it can return a value to a LAMMPS variable. This is thus a mechanism for your input script to pass information to a piece of Python code, ask Python to execute the code, and return information to your input script.

Note that a Python function can be arbitrarily complex. It can import other Python modules, instantiate Python classes, call other Python functions, etc. The Python code that you provide can contain more code than the single function. It can contain other functions or Python classes, as well as global variables or other mechanisms for storing state between calls from LAMMPS to the function.

The Python function you provide can consist of "pure" Python code that only performs operations provided by standard Python. However, the Python function can also "call back" to LAMMPS through its Python-wrapped library interface, in the manner described in the previous section 11.1. This means it can issue LAMMPS input script commands or query and set internal LAMMPS state. As an example, this can be useful in an input script to create a more complex loop with branching logic, than can be created using the simple looping and branching logic enabled by the [next](#) and [if](#) commands.

See the [python](#) doc page and the [variable](#) doc page for its python-style variables for more info, including examples of Python code you can write for both pure Python operations and callbacks to LAMMPS.

The [fix python/invoke](#) command can execute Python code at selected timesteps during a simulation run.

The [pair_style python](#) command allows you to define pairwise potentials as python code which encodes a single pairwise interaction. This is useful for rapid-development and debugging of a new potential.

To use any of these commands, you only need to build LAMMPS with the PYTHON package installed:

LAMMPS Users Manual

```
make yes-python
make machine
```

Note that this will link LAMMPS with the Python library on your system, which typically requires several auxiliary system libraries to also be linked. The list of these libraries and the paths to find them are specified in the `lib/python/Makefile.lammps` file. You need to insure that file contains the correct information for your version of Python and your machine to successfully build LAMMPS. See the `lib/python/README` file for more info.

If you want to write Python code with callbacks to LAMMPS, then you must also follow the steps overviewed in the preceding section (11.1) for running LAMMPS from Python. I.e. you must build LAMMPS as a shared library and insure that Python can find the `python/lammps.py` file and the shared library.

11.3 Building LAMMPS as a shared library

Instructions on how to build LAMMPS as a shared library are given in [Section 2.4](#). A shared library is one that is dynamically loadable, which is what Python requires to wrap LAMMPS. On Linux this is a library file that ends in `".so"`, not `".a"`.

From the `src` directory, type

```
make foo mode=shlib
```

where `foo` is the machine target name, such as `linux` or `g++` or `serial`. This should create the file `liblammps_foo.so` in the `src` directory, as well as a soft link `liblammps.so`, which is what the Python wrapper will load by default. Note that if you are building multiple machine versions of the shared library, the soft link is always set to the most recently built version.

NOTE: If you are building LAMMPS with an MPI or FFT library or other auxiliary libraries (used by various packages), then all of these extra libraries must also be shared libraries. If the LAMMPS shared-library build fails with an error complaining about this, see [Section 2.4](#) for more details.

11.4 Installing the Python wrapper into Python

For Python to invoke LAMMPS, there are 2 files it needs to know about:

- `python/lammps.py`
- `src/liblammps.so`

`Lammps.py` is the Python wrapper on the LAMMPS library interface. `Liblammps.so` is the shared LAMMPS library that Python loads, as described above.

You can insure Python can find these files in one of two ways:

- set two environment variables

LAMMPS Users Manual

- run the python/install.py script

If you set the paths to these files as environment variables, you only have to do it once. For the csh or tcsh shells, add something like this to your ~/.cshrc file, one line for each of the two files:

```
setenv PYTHONPATH ${PYTHONPATH}:/home/sjplimp/lammps/python
setenv LD_LIBRARY_PATH ${LD_LIBRARY_PATH}:/home/sjplimp/lammps/src
```

If you use the python/install.py script, you need to invoke it every time you rebuild LAMMPS (as a shared library) or make changes to the python/lammps.py file.

You can invoke install.py from the python directory as

```
% python install.py [libdir] [pydir]
```

The optional libdir is where to copy the LAMMPS shared library to; the default is /usr/local/lib. The optional pydir is where to copy the lammps.py file to; the default is the site-packages directory of the version of Python that is running the install script.

Note that libdir must be a location that is in your default LD_LIBRARY_PATH, like /usr/local/lib or /usr/lib. And pydir must be a location that Python looks in by default for imported modules, like its site-packages dir. If you want to copy these files to non-standard locations, such as within your own user space, you will need to set your PYTHONPATH and LD_LIBRARY_PATH environment variables accordingly, as above.

If the install.py script does not allow you to copy files into system directories, prefix the python command with "sudo". If you do this, make sure that the Python that root runs is the same as the Python you run. E.g. you may need to do something like

```
% sudo /usr/local/bin/python install.py [libdir] [pydir]
```

You can also invoke install.py from the make command in the src directory as

```
% make install-python
```

In this mode you cannot append optional arguments. Again, you may need to prefix this with "sudo". In this mode you cannot control which Python is invoked by root.

Note that if you want Python to be able to load different versions of the LAMMPS shared library (see [this section](#) below), you will need to manually copy files like liblammps_g++.so into the appropriate system directory. This is not needed if you set the LD_LIBRARY_PATH environment variable as described above.

11.5 Extending Python with MPI to run in parallel

If you wish to run LAMMPS in parallel from Python, you need to extend your Python with an interface to MPI. This also allows you to make MPI calls directly from Python in your script, if you desire.

LAMMPS Users Manual

There are several Python packages available that purport to wrap MPI as a library and allow MPI functions to be called from Python. However, development on most of them seems to be halted except on:

- [mpi4py](#)
- [PyPar](#)

Both packages, PyPar and mpi4py have been successfully tested with LAMMPS. PyPar is simpler and easy to set up and use, but supports only a subset of MPI. Mpi4py is more MPI-feature complete, but also a bit more complex to use. As of version 2.0.0, mpi4py is the only python MPI wrapper that allows passing a custom MPI communicator to the LAMMPS constructor, which means one can easily run one or more LAMMPS instances on subsets of the total MPI ranks.

PyPar requires the ubiquitous [Numpy package](#) be installed in your Python. After launching Python, type

```
import numpy
```

to see if it is installed. If not, here is how to install it (version 1.3.0b1 as of April 2009). Unpack the numpy tarball and from its top-level directory, type

```
python setup.py build
sudo python setup.py install
```

The "sudo" is only needed if required to copy Numpy files into your Python distribution's site-packages directory.

To install PyPar (version pypar-2.1.4_94 as of Aug 2012), unpack it and from its "source" directory, type

```
python setup.py build
sudo python setup.py install
```

Again, the "sudo" is only needed if required to copy PyPar files into your Python distribution's site-packages directory.

If you have successfully installed PyPar, you should be able to run Python and type

```
import pypar
```

without error. You should also be able to run python in parallel on a simple test script

```
% mpirun -np 4 python test.py
```

where test.py contains the lines

```
import pypar
print "Proc %d out of %d procs" % (pypar.rank(),pypar.size())
```

and see one line of output for each processor you run on.

LAMMPS Users Manual

NOTE: To use PyPar and LAMMPS in parallel from Python, you must insure both are using the same version of MPI. If you only have one MPI installed on your system, this is not an issue, but it can be if you have multiple MPIs. Your LAMMPS build is explicit about which MPI it is using, since you specify the details in your lo-level src/MAKE/Makefile.foo file. PyPar uses the "mpicc" command to find information about the MPI it uses to build against. And it tries to load "libmpi.so" from the LD_LIBRARY_PATH. This may or may not find the MPI library that LAMMPS is using. If you have problems running both PyPar and LAMMPS together, this is an issue you may need to address, e.g. by moving other MPI installations so that PyPar finds the right one.

To install mpi4py (version mpi4py-2.0.0 as of Oct 2015), unpack it and from its main directory, type

```
python setup.py build
sudo python setup.py install
```

Again, the "sudo" is only needed if required to copy mpi4py files into your Python distribution's site-packages directory. To install with user privilege into the user local directory type

```
python setup.py install --user
```

If you have successfully installed mpi4py, you should be able to run Python and type

```
from mpi4py import MPI
```

without error. You should also be able to run python in parallel on a simple test script

```
% mpirun -np 4 python test.py
```

where test.py contains the lines

```
from mpi4py import MPI
comm = MPI.COMM_WORLD
print "Proc %d out of %d procs" % (comm.Get_rank(),comm.Get_size())
```

and see one line of output for each processor you run on.

NOTE: To use mpi4py and LAMMPS in parallel from Python, you must insure both are using the same version of MPI. If you only have one MPI installed on your system, this is not an issue, but it can be if you have multiple MPIs. Your LAMMPS build is explicit about which MPI it is using, since you specify the details in your lo-level src/MAKE/Makefile.foo file. Mpi4py uses the "mpicc" command to find information about the MPI it uses to build against. And it tries to load "libmpi.so" from the LD_LIBRARY_PATH. This may or may not find the MPI library that LAMMPS is using. If you have problems running both mpi4py and LAMMPS together, this is an issue you may need to address, e.g. by moving other MPI installations so that mpi4py finds the right one.

LAMMPS Users Manual

11.6 Testing the Python-LAMMPS interface

To test if LAMMPS is callable from Python, launch Python interactively and type:

```
>>> from lammps import lammps
>>> lmp = lammps()
```

If you get no errors, you're ready to use LAMMPS from Python. If the 2nd command fails, the most common error to see is

```
OSError: Could not load LAMMPS dynamic library
```

which means Python was unable to load the LAMMPS shared library. This typically occurs if the system can't find the LAMMPS shared library or one of the auxiliary shared libraries it depends on, or if something about the library is incompatible with your Python. The error message should give you an indication of what went wrong.

You can also test the load directly in Python as follows, without first importing from the lammps.py file:

```
>>> from ctypes import CDLL
>>> CDLL("liblammps.so")
```

If an error occurs, carefully go thru the steps in [Section 2.4](#) and above about building a shared library and about insuring Python can find the necessary two files it needs.

Test LAMMPS and Python in serial:

To run a LAMMPS test in serial, type these lines into Python interactively from the bench directory:

```
>>> from lammps import lammps
>>> lmp = lammps()
>>> lmp.file("in.lj")
```

Or put the same lines in the file test.py and run it as

```
% python test.py
```

Either way, you should see the results of running the in.lj benchmark on a single processor appear on the screen, the same as if you had typed something like:

```
lmp_g++ -in in.lj
```

Test LAMMPS and Python in parallel:

To run LAMMPS in parallel, assuming you have installed the [PyPar](#) package as discussed above, create a test.py file containing these lines:

```
import pypar
from lammps import lammps
lmp = lammps()
lmp.file("in.lj")
print "Proc %d out of %d procs has" % (pypar.rank(),pypar.size()),lmp
```

LAMMPS Users Manual

```
pypar.finalize()
```

To run LAMMPS in parallel, assuming you have installed the [mpi4py](#) package as discussed above, create a test.py file containing these lines:

```
from mpi4py import MPI
from lammmps import lammmps
lmp = lammmps()
lmp.file("in.lj")
me = MPI.COMM_WORLD.Get_rank()
nprocs = MPI.COMM_WORLD.Get_size()
print "Proc %d out of %d procs has" % (me,nprocs),lmp
MPI.Finalize()
```

You can either script in parallel as:

```
% mpirun -np 4 python test.py
```

and you should see the same output as if you had typed

```
% mpirun -np 4 lmp_g++ -in in.lj
```

Note that if you leave out the 3 lines from test.py that specify PyPar commands you will instantiate and run LAMMPS independently on each of the P processors specified in the mpirun command. In this case you should get 4 sets of output, each showing that a LAMMPS run was made on a single processor, instead of one set of output showing that LAMMPS ran on 4 processors. If the 1-processor outputs occur, it means that PyPar is not working correctly.

Also note that once you import the PyPar module, PyPar initializes MPI for you, and you can use MPI calls directly in your Python script, as described in the PyPar documentation. The last line of your Python script should be pypar.finalize(), to insure MPI is shut down correctly.

Running Python scripts:

Note that any Python script (not just for LAMMPS) can be invoked in one of several ways:

```
% python foo.script
% python -i foo.script
% foo.script
```

The last command requires that the first line of the script be something like this:

```
#!/usr/local/bin/python
#!/usr/local/bin/python -i
```

where the path points to where you have Python installed, and that you have made the script file executable:

```
% chmod +x foo.script
```

LAMMPS Users Manual

Without the "-i" flag, Python will exit when the script finishes. With the "-i" flag, you will be left in the Python interpreter when the script finishes, so you can type subsequent commands. As mentioned above, you can only run Python interactively when running Python on a single processor, not in parallel.

11.7 Using LAMMPS from Python

As described above, the Python interface to LAMMPS consists of a Python "lammeps" module, the source code for which is in python/lammeps.py, which creates a "lammeps" object, with a set of methods that can be invoked on that object. The sample Python code below assumes you have first imported the "lammeps" module in your Python script, as follows:

```
from lammeps import lammeps
```

These are the methods defined by the lammeps module. If you look at the files src/library.cpp and src/library.h you will see that they correspond one-to-one with calls you can make to the LAMMPS library from a C++ or C or Fortran program, and which are described in [Section 6.19](#) of the manual.

```
lmp = lammeps()           # create a LAMMPS object using the default liblammeps.so library
                          # 4 optional args are allowed: name, cmdargs, ptr, comm
lmp = lammeps(ptr=lmp_ptr) # use lmp_ptr as previously created LAMMPS object
lmp = lammeps(comm=split) # create a LAMMPS object with a custom communicator, requires mpi4py 2
lmp = lammeps(name="g++")  # create a LAMMPS object using the liblammeps_g++.so library
lmp = lammeps(name="g++",cmdargs=list) # add LAMMPS command-line args, e.g. list = ["-echo",']

lmp.close()              # destroy a LAMMPS object

version = lmp.version() # return the numerical version id, e.g. LAMMPS 2 Sep 2015
-> 20150902

lmp.file(file)           # run an entire input script, file = "in.lj"
lmp.command(cmd)         # invoke a single LAMMPS command, cmd = "run 100"

lmp.commands_list(cmdlist) # invoke commands in cmdlist = "run 10", "run 20"
lmp.commands_string(multicmd) # invoke commands in multicmd = "run 10\nrun 20"

xlo = lmp.extract_global(name,type) # extract a global quantity
                                     # name = "boxxlo", "nlocal", etc
                                     # type = 0 = int
                                     #       1 = double

coords = lmp.extract_atom(name,type) # extract a per-atom quantity
                                     # name = "x", "type", etc
                                     # type = 0 = vector of ints
                                     #       1 = array of ints
                                     #       2 = vector of doubles
                                     #       3 = array of doubles

eng = lmp.extract_compute(id,style,type) # extract value(s) from a compute
v3 = lmp.extract_fix(id,style,type,i,j) # extract value(s) from a fix
```

LAMMPS Users Manual

```
# id = ID of compute or fix
# style = 0 = global data
#         1 = per-atom data
#         2 = local data
# type = 0 = scalar
#         1 = vector
#         2 = array
# i,j = indices of value in global vector or array

var = lmp.extract_variable(name,group,flag) # extract value(s) from a variable
# name = name of variable
# group = group ID (ignored for equal-style variable)
# flag = 0 = equal-style variable
#       1 = atom-style variable

flag = lmp.set_variable(name,value) # set existing named string-style variable to
value, flag = 0 if successful value = lmp.get_thermo(name) # return current value of a
thermo keyword

natoms = lmp.get_natoms() # total # of atoms as int
data = lmp.gather_atoms(name,type,count) # return per-atom property of all atoms gathered into
# name = "x", "charge", "type", etc
# count = # of per-atom values, 1 or 3, etc
lmp.scatter_atoms(name,type,count,data) # scatter per-atom property to all atoms from data,
# name = "x", "charge", "type", etc
# count = # of per-atom values, 1 or 3, etc
```

The lines

```
from lammps import lammps
lmp = lammps()
```

create an instance of LAMMPS, wrapped in a Python class by the lammps Python module, and return an instance of the Python class as lmp. It is used to make all subsequent calls to the LAMMPS library.

Additional arguments to lammps() can be used to tell Python the name of the shared library to load or to pass arguments to the LAMMPS instance, the same as if LAMMPS were launched from a command-line prompt.

If the ptr argument is set like this:

```
lmp = lammps(ptr=lmpptr)
```

then lmpptr must be an argument passed to Python via the LAMMPS [python](#) command, when it is used to define a Python function that is invoked by the LAMMPS input script. This mode of using Python with LAMMPS is described above in 11.2. The variable lmpptr refers to the instance of LAMMPS that called the embedded Python interpreter. Using it as an argument to lammps() allows the returned Python class instance "lmp" to make calls to that instance of LAMMPS. See the [python](#) command doc page for examples using this syntax.

Note that you can create multiple LAMMPS objects in your Python script, and coordinate and run multiple simulations, e.g.

LAMMPS Users Manual

```
from lammops import lammops
lmp1 = lammops()
lmp2 = lammops()
lmp1.file("in.file1")
lmp2.file("in.file2")
```

The `file()`, `command()`, `commands_list()`, `commands_string()` methods allow an input script, a single command, or multiple commands to be invoked.

The `extract_global()`, `extract_atom()`, `extract_compute()`, `extract_fix()`, and `extract_variable()` methods return values or pointers to data structures internal to LAMMPS.

For `extract_global()` see the `src/library.cpp` file for the list of valid names. New names could easily be added. A double or integer is returned. You need to specify the appropriate data type via the `type` argument.

For `extract_atom()`, a pointer to internal LAMMPS atom-based data is returned, which you can use via normal Python subscripting. See the `extract()` method in the `src/atom.cpp` file for a list of valid names. Again, new names could easily be added if the property you want is not listed. A pointer to a vector of doubles or integers, or a pointer to an array of doubles (`double **`) or integers (`int **`) is returned. You need to specify the appropriate data type via the `type` argument.

For `extract_compute()` and `extract_fix()`, the global, per-atom, or local data calculated by the `compute` or `fix` can be accessed. What is returned depends on whether the `compute` or `fix` calculates a scalar or vector or array. For a scalar, a single double value is returned. If the `compute` or `fix` calculates a vector or array, a pointer to the internal LAMMPS data is returned, which you can use via normal Python subscripting. The one exception is that for a `fix` that calculates a global vector or array, a single double value from the vector or array is returned, indexed by `I` (vector) or `I` and `J` (array). `I, J` are zero-based indices. The `I, J` arguments can be left out if not needed. See [Section 6.15](#) of the manual for a discussion of global, per-atom, and local data, and of scalar, vector, and array data types. See the doc pages for individual [computes](#) and [fixes](#) for a description of what they calculate and store.

For `extract_variable()`, an [equal-style or atom-style variable](#) is evaluated and its result returned.

For equal-style variables a single double value is returned and the `group` argument is ignored. For atom-style variables, a vector of doubles is returned, one value per atom, which you can use via normal Python subscripting. The values will be zero for atoms not in the specified group.

The `get_natoms()` method returns the total number of atoms in the simulation, as an `int`.

The `gather_atoms()` method allows any per-atom property (coordinates, velocities, etc) to be extracted from LAMMPS. It returns a ctypes vector of ints or doubles as specified by `type`, of length `count*natoms`, for the named property for all atoms in the simulation. The data is ordered by `count` and then by atom ID. See the `extract()` method in the `src/atom.cpp` file for a list of valid names. Again, new names could

LAMMPS Users Manual

easily be added if the property you want is missing. The vector can be used via normal Python subscripting. If atom IDs are not consecutively ordered within LAMMPS, a None is returned as indication of an error. A special treatment is applied for image flags stored in the "image" property. All three image flags are stored in a packed format in a single integer, so count would be 1 to retrieve that integer, however also a count value of 3 can be used and then the image flags will be unpacked into 3 individual integers, ordered in a similar fashion as coordinates.

Note that the data structure `gather_atoms("x")` returns is different from the data structure returned by `extract_atom("x")` in four ways. (1) `Gather_atoms()` returns a vector which you index as `x[i]`; `extract_atom()` returns an array which you index as `x[i][j]`. (2) `Gather_atoms()` orders the atoms by atom ID while `extract_atom()` does not. (3) `Gather_atoms()` returns a list of all atoms in the simulation; `extract_atoms()` returns just the atoms local to each processor. (4) Finally, the `gather_atoms()` data structure is a copy of the atom coords stored internally in LAMMPS, whereas `extract_atom()` returns an array that effectively points directly to the internal data. This means you can change values inside LAMMPS from Python by assigning a new values to the `extract_atom()` array. To do this with the `gather_atoms()` vector, you need to change values in the vector, then invoke the `scatter_atoms()` method.

The `scatter_atoms()` method allows any per-atom property (coordinates, velocities, etc) to be inserted into LAMMPS, overwriting the current property. It takes a vector of ints or doubles as specified by type, of length `count*natoms`, for the named property for all atoms in the simulation. The data should be ordered by count and then by atom ID. See the `extract()` method in the `src/atom.cpp` file for a list of valid names. Again, new names could easily be added if the property you want is missing. It uses the vector of data to overwrite the corresponding properties for each atom inside LAMMPS. This requires LAMMPS to have its "map" option enabled; see the [atom_modify](#) command for details. If it is not, or if atom IDs are not consecutively ordered, no coordinates are reset. Similar as for `gather_atoms()` a special treatment is applied for image flags, which can be provided in packed (`count = 1`) or unpacked (`count = 3`) format and in the latter case, they will be packed before applied to atoms.

The array of coordinates passed to `scatter_atoms()` must be a ctypes vector of ints or doubles, allocated and initialized something like this:

```
from ctypes import *
natoms = lmp.get_natoms()
n3 = 3*natoms
x = (n3*c_double)()
x[0] = x coord of atom with ID 1
x[1] = y coord of atom with ID 1
x[2] = z coord of atom with ID 1
x[3] = x coord of atom with ID 2
...
x[n3-1] = z coord of atom with ID natoms
lmp.scatter_atoms("x",1,3,x)
```

Alternatively, you can just change values in the vector returned by `gather_atoms("x",1,3)`, since it is a ctypes vector of doubles.

As noted above, these Python class methods correspond one-to-one with the functions

LAMMPS Users Manual

in the LAMMPS library interface in `src/library.cpp` and `library.h`. This means you can extend the Python wrapper via the following steps:

- Add a new interface function to `src/library.cpp` and `src/library.h`.
- Rebuild LAMMPS as a shared library.
- Add a wrapper method to `python/lammps.py` for this interface function.
- You should now be able to invoke the new interface function from a Python script. Isn't ctypes amazing?

11.8 Example Python scripts that use LAMMPS

These are the Python scripts included as demos in the `python/examples` directory of the LAMMPS distribution, to illustrate the kinds of things that are possible when Python wraps LAMMPS. If you create your own scripts, send them to us and we can include them in the LAMMPS distribution.

<code>trivial.py</code>	read/run a LAMMPS input script thru Python
<code>demo.py</code>	invoke various LAMMPS library interface routines
<code>simple.py</code>	run in parallel
similar to <code>examples/COUPLE/simple/simple.cpp</code>	<code>split.py</code>
same as <code>simple.py</code> but running in parallel on a subset of procs	<code>gui.py</code>
GUI go/stop/temperature-slider to control LAMMPS	<code>plot.py</code>
real-time temperature plot with GnuPlot via <code>Pizza.py</code>	<code>viz_tool.py</code>
real-time viz via some viz package	<code>vizplotgui_tool.py</code>
combination of <code>viz_tool.py</code> and <code>plot.py</code> and <code>gui.py</code>	

For the `viz_tool.py` and `vizplotgui_tool.py` commands, replace "tool" with "gl" or "atomeye" or "pymol" or "vmd", depending on what visualization package you have installed.

Note that for GL, you need to be able to run the `Pizza.py` GL tool, which is included in the `pizza` sub-directory. See the [Pizza.py doc pages](#) for more info:

Note that for AtomEye, you need version 3, and there is a line in the scripts that specifies the path and name of the executable. See the AtomEye WWW pages [here](#) or [here](#) for more details:

<http://mt.seas.upenn.edu/Archive/Graphics/A>
<http://mt.seas.upenn.edu/Archive/Graphics/A3/A3.html>

The latter link is to AtomEye 3 which has the scriping capability needed by these Python scripts.

LAMMPS Users Manual

Note that for PyMol, you need to have built and installed the open-source version of PyMol in your Python, so that you can import it from a Python script. See the PyMol WWW pages [here](#) or [here](#) for more details:

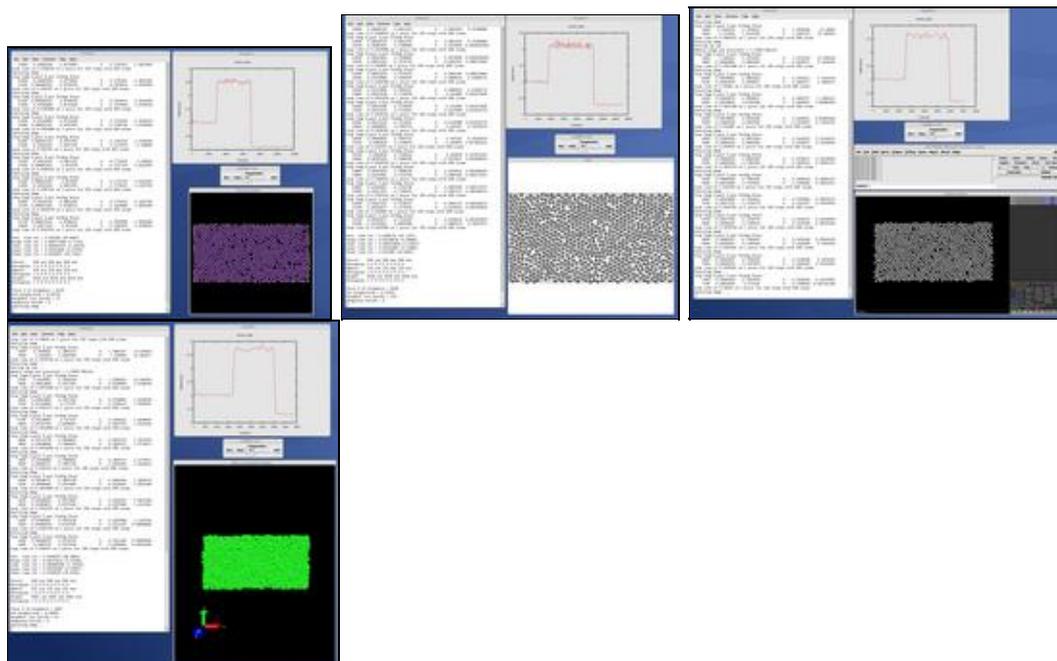

<http://www.pymol.org>
http://sourceforge.net/scm/?type=svn&group_id=4546

The latter link is to the open-source version.

Note that for VMD, you need a fairly current version (1.8.7 works for me) and there are some lines in the `pizza/vmd.py` script for 4 PIZZA variables that have to match the VMD installation on your system.

See the `python/README` file for instructions on how to run them and the source code for individual scripts for comments about what they do.

Here are screenshots of the `vizplotgui_tool.py` script in action for different visualization package options. Click to see larger images:

11.9 PyLammps interface

Please see the [PyLammps Tutorial](#).

12. Errors

This section describes the errors you can encounter when using LAMMPS, either conceptually, or as printed out by the program.

12.1 [Common problems](#)

12.2 [Reporting bugs](#)

12.3 [Error & warning messages](#)

12.1 Common problems

If two LAMMPS runs do not produce the exact same answer on different machines or different numbers of processors, this is typically not a bug. In theory you should get identical answers on any number of processors and on any machine. In practice, numerical round-off can cause slight differences and eventual divergence of molecular dynamics phase space trajectories within a few 100s or few 1000s of timesteps. However, the statistical properties of the two runs (e.g. average energy or temperature) should still be the same.

If the [velocity](#) command is used to set initial atom velocities, a particular atom can be assigned a different velocity when the problem is run on a different number of processors or on different machines. If this happens, the phase space trajectories of the two simulations will rapidly diverge. See the discussion of the *loop* option in the [velocity](#) command for details and options that avoid this issue.

Similarly, the [create_atoms](#) command generates a lattice of atoms. For the same physical system, the ordering and numbering of atoms by atom ID may be different depending on the number of processors.

Some commands use random number generators which may be setup to produce different random number streams on each processor and hence will produce different effects when run on different numbers of processors. A commonly-used example is the [fix langevin](#) command for thermostating.

A LAMMPS simulation typically has two stages, setup and run. Most LAMMPS errors are detected at setup time; others like a bond stretching too far may not occur until the middle of a run.

LAMMPS tries to flag errors and print informative error messages so you can fix the problem. For most errors it will also print the last input script command that it was processing. Of course, LAMMPS cannot figure out your physics or numerical mistakes, like choosing too big a timestep, specifying erroneous force field coefficients, or putting 2 atoms on top of each other! If you run into errors that LAMMPS doesn't catch that you think it should flag, please send an email to the [developers](#).

LAMMPS Users Manual

If you get an error message about an invalid command in your input script, you can determine what command is causing the problem by looking in the `log.lammps` file or using the [echo command](#) to see it on the screen. If you get an error like "Invalid ... style", with ... being fix, compute, pair, etc, it means that you mistyped the style name or that the command is part of an optional package which was not compiled into your executable. The list of available styles in your executable can be listed by using [the -h command-line argument](#). The installation and compilation of optional packages is explained in the [installation instructions](#).

For a given command, LAMMPS expects certain arguments in a specified order. If you mess this up, LAMMPS will often flag the error, but it may also simply read a bogus argument and assign a value that is valid, but not what you wanted. E.g. trying to read the string "abc" as an integer value of 0. Careful reading of the associated doc page for the command should allow you to fix these problems. In most cases, where LAMMPS expects to read a number, either integer or floating point, it performs a stringent test on whether the provided input actually is an integer or floating-point number, respectively, and reject the input with an error message (for instance, when an integer is required, but a floating-point number 1.0 is provided):

```
ERROR: Expected integer parameter in input script or data file
```

Some commands allow for using variable references in place of numeric constants so that the value can be evaluated and may change over the course of a run. This is typically done with the syntax `v_name` for a parameter, where name is the name of the variable. On the other hand, immediate variable expansion with the syntax `$name` is performed while reading the input and before parsing commands,

NOTE: Using a variable reference (i.e. `v_name`) is only allowed if the documentation of the corresponding command explicitly says it is.

Generally, LAMMPS will print a message to the screen and logfile and exit gracefully when it encounters a fatal error. Sometimes it will print a WARNING to the screen and logfile and continue on; you can decide if the WARNING is important or not. A WARNING message that is generated in the middle of a run is only printed to the screen, not to the logfile, to avoid cluttering up thermodynamic output. If LAMMPS crashes or hangs without spitting out an error message first then it could be a bug (see [this section](#)) or one of the following cases:

LAMMPS runs in the available memory a processor allows to be allocated. Most reasonable MD runs are compute limited, not memory limited, so this shouldn't be a bottleneck on most platforms. Almost all large memory allocations in the code are done via C-style `malloc`'s which will generate an error message if you run out of memory. Smaller chunks of memory are allocated via C++ "new" statements. If you are unlucky you could run out of memory just when one of these small requests is made, in which case the code will crash or hang (in parallel), since LAMMPS doesn't trap on those errors.

Illegal arithmetic can cause LAMMPS to run slow or crash. This is typically due to invalid physics and numerics that your simulation is computing. If you see wild thermodynamic values or NaN values in your LAMMPS output, something is wrong with your simulation. If you suspect this is happening, it is a good idea to print out

LAMMPS Users Manual

thermodynamic info frequently (e.g. every timestep) via the [thermo](#) so you can monitor what is happening. Visualizing the atom movement is also a good idea to insure your model is behaving as you expect.

In parallel, one way LAMMPS can hang is due to how different MPI implementations handle buffering of messages. If the code hangs without an error message, it may be that you need to specify an MPI setting or two (usually via an environment variable) to enable buffering or boost the sizes of messages that can be buffered.

12.2 Reporting bugs

If you are confident that you have found a bug in LAMMPS, follow these steps.

Check the [New features and bug fixes](#) section of the [LAMMPS WWW site](#) to see if the bug has already been reported or fixed or the [Unfixed bug](#) to see if a fix is pending.

Check the [mailing list](#) to see if it has been discussed before.

If not, send an email to the mailing list describing the problem with any ideas you have as to what is causing it or where in the code the problem might be. The developers will ask for more info if needed, such as an input script or data files.

The most useful thing you can do to help us fix the bug is to isolate the problem. Run it on the smallest number of atoms and fewest number of processors and with the simplest input script that reproduces the bug and try to identify what command or combination of commands is causing the problem.

As a last resort, you can send an email directly to the [developers](#).

12.3 Error & warning messages

These are two alphabetic lists of the [ERROR](#) and [WARNING](#) messages LAMMPS prints out and the reason why. If the explanation here is not sufficient, the documentation for the offending command may help. Error and warning messages also list the source file and line number where the error was generated. For example, this message

```
ERROR: Illegal velocity command (velocity.cpp:78)
```

means that line #78 in the file src/velocity.cpp generated the error. Looking in the source code may help you figure out what went wrong.

Note that error messages from [user-contributed packages](#) are not listed here. If such an error occurs and is not self-explanatory, you'll need to look in the source code or contact the author of the package.

Errors:

1-3 bond count is inconsistent

An inconsistency was detected when computing the number of 1-3 neighbors for

LAMMPS Users Manual

each atom. This likely means something is wrong with the bond topologies you have defined.

1-4 bond count is inconsistent

An inconsistency was detected when computing the number of 1-4 neighbors for each atom. This likely means something is wrong with the bond topologies you have defined.

Accelerator sharing is not currently supported on system

Multiple MPI processes cannot share the accelerator on your system. For NVIDIA GPUs, see the `nvidia-smi` command to change this setting.

All angle coeffs are not set

All angle coefficients must be set in the data file or by the `angle_coeff` command before running a simulation.

All atom IDs = 0 but atom_modify id = yes

Self-explanatory.

All atoms of a swapped type must have same charge.

Self-explanatory.

All atoms of a swapped type must have the same charge.

Self-explanatory.

All bond coeffs are not set

All bond coefficients must be set in the data file or by the `bond_coeff` command before running a simulation.

All dihedral coeffs are not set

All dihedral coefficients must be set in the data file or by the `dihedral_coeff` command before running a simulation.

All improper coeffs are not set

All improper coefficients must be set in the data file or by the `improper_coeff` command before running a simulation.

All masses are not set

For atom styles that define masses for each atom type, all masses must be set in the data file or by the `mass` command before running a simulation. They must also be set before using the `velocity` command.

All mol IDs should be set for fix gcmc group atoms

The molecule flag is on, yet not all molecule ids in the fix group have been set to non-zero positive values by the user. This is an error since all atoms in the fix gcmc group are eligible for deletion, rotation, and translation and therefore must have valid molecule ids.

All pair coeffs are not set

All pair coefficients must be set in the data file or by the `pair_coeff` command before running a simulation.

All read_dump x,y,z fields must be specified for scaled, triclinic coords

For triclinic boxes and scaled coordinates you must specify all 3 of the `x,y,z` fields, else LAMMPS cannot reconstruct the unscaled coordinates.

All universe/uloop variables must have same # of values

Self-explanatory.

All variables in next command must be same style

Self-explanatory.

Angle atom missing in delete_bonds

The `delete_bonds` command cannot find one or more atoms in a particular angle on a particular processor. The pairwise cutoff is too short or the atoms are too far apart to make a valid angle.

Angle atom missing in set command

LAMMPS Users Manual

The set command cannot find one or more atoms in a particular angle on a particular processor. The pairwise cutoff is too short or the atoms are too far apart to make a valid angle.

Angle atoms %d %d %d missing on proc %d at step %ld

One or more of 3 atoms needed to compute a particular angle are missing on this processor. Typically this is because the pairwise cutoff is set too short or the angle has blown apart and an atom is too far away.

Angle atoms missing on proc %d at step %ld

One or more of 3 atoms needed to compute a particular angle are missing on this processor. Typically this is because the pairwise cutoff is set too short or the angle has blown apart and an atom is too far away.

Angle coeff for hybrid has invalid style

Angle style hybrid uses another angle style as one of its coefficients. The angle style used in the angle_coeff command or read from a restart file is not recognized.

Angle coeffs are not set

No angle coefficients have been assigned in the data file or via the angle_coeff command.

Angle extent > half of periodic box length

This error was detected by the neigh_modify check yes setting. It is an error because the angle atoms are so far apart it is ambiguous how it should be defined.

Angle potential must be defined for SHAKE

When shaking angles, an angle_style potential must be used.

Angle style hybrid cannot have hybrid as an argument

Self-explanatory.

Angle style hybrid cannot have none as an argument

Self-explanatory.

Angle style hybrid cannot use same angle style twice

Self-explanatory.

Angle table must range from 0 to 180 degrees

Self-explanatory.

Angle table parameters did not set N

List of angle table parameters must include N setting.

Angle_coeff command before angle_style is defined

Coefficients cannot be set in the data file or via the angle_coeff command until an angle_style has been assigned.

Angle_coeff command before simulation box is defined

The angle_coeff command cannot be used before a read_data, read_restart, or create_box command.

Angle_coeff command when no angles allowed

The chosen atom style does not allow for angles to be defined.

Angle_style command when no angles allowed

The chosen atom style does not allow for angles to be defined.

Angles assigned incorrectly

Angles read in from the data file were not assigned correctly to atoms. This means there is something invalid about the topology definitions.

Angles defined but no angle types

The data file header lists angles but no angle types.

Append boundary must be shrink/minimum

LAMMPS Users Manual

The boundary style of the face where atoms are added must be of type m (shrink/minimum).

Arccos of invalid value in variable formula

Argument of arccos() must be between -1 and 1.

Arcsin of invalid value in variable formula

Argument of arcsin() must be between -1 and 1.

Assigning body parameters to non-body atom

Self-explanatory.

Assigning ellipsoid parameters to non-ellipsoid atom

Self-explanatory.

Assigning line parameters to non-line atom

Self-explanatory.

Assigning quat to non-body atom

Self-explanatory.

Assigning tri parameters to non-tri atom

Self-explanatory.

At least one atom of each swapped type must be present to define charges.

Self-explanatory.

Atom IDs must be consecutive for velocity create loop all

Self-explanatory.

Atom IDs must be used for molecular systems

Atom IDs are used to identify and find partner atoms in bonds.

Atom count changed in fix neb

This is not allowed in a NEB calculation.

Atom count is inconsistent, cannot write data file

The sum of atoms across processors does not equal the global number of atoms. Probably some atoms have been lost.

Atom count is inconsistent, cannot write restart file

Sum of atoms across processors does not equal initial total count. This is probably because you have lost some atoms.

Atom in too many rigid bodies - boost MAXBODY

Fix poems has a parameter MAXBODY (in fix_poems.cpp) which determines the maximum number of rigid bodies a single atom can belong to (i.e. a multibody joint). The bodies you have defined exceed this limit.

Atom sort did not operate correctly

This is an internal LAMMPS error. Please report it to the developers.

Atom sorting has bin size = 0.0

The neighbor cutoff is being used as the bin size, but it is zero. Thus you must explicitly list a bin size in the atom_modify sort command or turn off sorting.

Atom style hybrid cannot have hybrid as an argument

Self-explanatory.

Atom style hybrid cannot use same atom style twice

Self-explanatory.

Atom style template molecule must have atom types

The defined molecule(s) does not specify atom types.

Atom style was redefined after using fix property/atom

This is not allowed.

Atom type must be zero in fix gcmc mol command

Self-explanatory.

Atom vector in equal-style variable formula

LAMMPS Users Manual

Atom vectors generate one value per atom which is not allowed in an equal-style variable.

Atom-style variable in equal-style variable formula

Atom-style variables generate one value per atom which is not allowed in an equal-style variable.

Atom_modify id command after simulation box is defined

The atom_modify id command cannot be used after a read_data, read_restart, or create_box command.

Atom_modify map command after simulation box is defined

The atom_modify map command cannot be used after a read_data, read_restart, or create_box command.

Atom_modify sort and first options cannot be used together

Self-explanatory.

Atom_style command after simulation box is defined

The atom_style command cannot be used after a read_data, read_restart, or create_box command.

Atom_style line can only be used in 2d simulations

Self-explanatory.

Atom_style tri can only be used in 3d simulations

Self-explanatory.

Atomfile variable could not read values

Check the file assigned to the variable.

Atomfile variable in equal-style variable formula

Self-explanatory.

Atomfile-style variable in equal-style variable formula

Self-explanatory.

Attempt to pop empty stack in fix box/relax

Internal LAMMPS error. Please report it to the developers.

Attempt to push beyond stack limit in fix box/relax

Internal LAMMPS error. Please report it to the developers.

Attempting to rescale a 0.0 temperature

Cannot rescale a temperature that is already 0.0.

Bad FENE bond

Two atoms in a FENE bond have become so far apart that the bond cannot be computed.

Bad TIP4P angle type for PPPM/TIP4P

Specified angle type is not valid.

Bad TIP4P angle type for PPPMDisp/TIP4P

Specified angle type is not valid.

Bad TIP4P bond type for PPPM/TIP4P

Specified bond type is not valid.

Bad TIP4P bond type for PPPMDisp/TIP4P

Specified bond type is not valid.

Bad fix ID in fix append/atoms command

The value of the fix_id for keyword spatial must start with 'f_'.

Bad grid of processors

The 3d grid of processors defined by the processors command does not match the number of processors LAMMPS is being run on.

Bad kspace_modify kmax/ewald parameter

Kspace_modify values for the kmax/ewald keyword must be integers > 0

Bad kspace_modify slab parameter

LAMMPS Users Manual

- Kspace_modify* value for the slab/volume keyword must be ≥ 2.0 .
- Bad matrix inversion in mldivide3*
This error should not occur unless the matrix is badly formed.
- Bad principal moments*
Fix rigid did not compute the principal moments of inertia of a rigid group of atoms correctly.
- Bad quadratic solve for particle/line collision*
This is an internal error. It should normally not occur.
- Bad quadratic solve for particle/tri collision*
This is an internal error. It should normally not occur.
- Bad real space Coulomb cutoff in fix tune/kspace*
Fix tune/kspace tried to find the optimal real space Coulomb cutoff using the Newton-Raphson method, but found a non-positive or NaN cutoff
- Balance command before simulation box is defined*
The balance command cannot be used before a `read_data`, `read_restart`, or `create_box` command.
- Balance produced bad splits*
This should not occur. It means two or more cutting plane locations are on top of each other or out of order. Report the problem to the developers.
- Balance rcb cannot be used with comm_style brick*
`Comm_style tiled` must be used instead.
- Balance shift string is invalid*
The string can only contain the characters "x", "y", or "z".
- Bias compute does not calculate a velocity bias*
The specified compute must compute a bias for temperature.
- Bias compute does not calculate temperature*
The specified compute must compute temperature.
- Bias compute group does not match compute group*
The specified compute must operate on the same group as the parent compute.
- Big particle in fix srd cannot be point particle*
Big particles must be extended spheroids or ellipsoids.
- Bigint setting in lmptype.h is invalid*
Size of bigint is less than size of tagint.
- Bigint setting in lmptype.h is not compatible*
Format of bigint stored in restart file is not consistent with LAMMPS version you are running. See the settings in `src/lmptype.h`
- Bitmapped lookup tables require int/float be same size*
Cannot use pair tables on this machine, because of word sizes. Use the `pair_modify` command with `table 0` instead.
- Bitmapped table in file does not match requested table*
Setting for bitmapped table in `pair_coeff` command must match table in file exactly.
- Bitmapped table is incorrect length in table file*
Number of table entries is not a correct power of 2.
- Bond and angle potentials must be defined for TIP4P*
Cannot use TIP4P pair potential unless bond and angle potentials are defined.
- Bond atom missing in box size check*
The 2nd atoms needed to compute a particular bond is missing on this processor. Typically this is because the pairwise cutoff is set too short or the bond has blown apart and an atom is too far away.
- Bond atom missing in delete_bonds*

LAMMPS Users Manual

The `delete_bonds` command cannot find one or more atoms in a particular bond on a particular processor. The pairwise cutoff is too short or the atoms are too far apart to make a valid bond.

Bond atom missing in image check

The 2nd atom in a particular bond is missing on this processor. Typically this is because the pairwise cutoff is set too short or the bond has blown apart and an atom is too far away.

Bond atom missing in set command

The set command cannot find one or more atoms in a particular bond on a particular processor. The pairwise cutoff is too short or the atoms are too far apart to make a valid bond.

Bond atoms %d %d missing on proc %d at step %ld

The 2nd atom needed to compute a particular bond is missing on this processor. Typically this is because the pairwise cutoff is set too short or the bond has blown apart and an atom is too far away.

Bond atoms missing on proc %d at step %ld

The 2nd atom needed to compute a particular bond is missing on this processor. Typically this is because the pairwise cutoff is set too short or the bond has blown apart and an atom is too far away.

Bond coeff for hybrid has invalid style

Bond style hybrid uses another bond style as one of its coefficients. The bond style used in the `bond_coeff` command or read from a restart file is not recognized.

Bond coeffs are not set

No bond coefficients have been assigned in the data file or via the `bond_coeff` command.

Bond extent > half of periodic box length

This error was detected by the `neigh_modify` check yes setting. It is an error because the bond atoms are so far apart it is ambiguous how it should be defined.

Bond potential must be defined for SHAKE

Cannot use fix shake unless bond potential is defined.

Bond style hybrid cannot have hybrid as an argument

Self-explanatory.

Bond style hybrid cannot have none as an argument

Self-explanatory.

Bond style hybrid cannot use same bond style twice

Self-explanatory.

Bond style quartic cannot be used with 3,4-body interactions

No angle, dihedral, or improper styles can be defined when using bond style quartic.

Bond style quartic cannot be used with atom style template

This bond style can change the bond topology which is not allowed with this atom style.

Bond style quartic requires special_bonds = 1,1,1

This is a restriction of the current bond quartic implementation.

Bond table parameters did not set N

List of bond table parameters must include N setting.

Bond table values are not increasing

The values in the tabulated file must be monotonically increasing.

BondAngle coeff for hybrid angle has invalid format

LAMMPS Users Manual

- No "ba" field should appear in data file entry.
BondBond coeff for hybrid angle has invalid format
No "bb" field should appear in data file entry.
- Bond_coeff command before bond_style is defined*
Coefficients cannot be set in the data file or via the bond_coeff command until an bond_style has been assigned.
- Bond_coeff command before simulation box is defined*
The bond_coeff command cannot be used before a read_data, read_restart, or create_box command.
- Bond_coeff command when no bonds allowed*
The chosen atom style does not allow for bonds to be defined.
- Bond_style command when no bonds allowed*
The chosen atom style does not allow for bonds to be defined.
- Bonds assigned incorrectly*
Bonds read in from the data file were not assigned correctly to atoms. This means there is something invalid about the topology definitions.
- Bonds defined but no bond types*
The data file header lists bonds but no bond types.
- Both restart files must use % or neither*
Self-explanatory.
- Both restart files must use MPI-IO or neither*
Self-explanatory.
- Both sides of boundary must be periodic*
Cannot specify a boundary as periodic only on the lo or hi side. Must be periodic on both sides.
- Boundary command after simulation box is defined*
The boundary command cannot be used after a read_data, read_restart, or create_box command.
- Box bounds are invalid*
The box boundaries specified in the read_data file are invalid. The lo value must be less than the hi value for all 3 dimensions.
- Box command after simulation box is defined*
The box command cannot be used after a read_data, read_restart, or create_box command.
- CPU neighbor lists must be used for ellipsoid/sphere mix.*
When using Gay-Berne or RE-squared pair styles with both ellipsoidal and spherical particles, the neighbor list must be built on the CPU
- Can not specify Pxy/Pxz/Pyz in fix box/relax with non-triclinic box*
Only triclinic boxes can be used with off-diagonal pressure components. See the region prism command for details.
- Can not specify Pxy/Pxz/Pyz in fix nvt/npt/nph with non-triclinic box*
Only triclinic boxes can be used with off-diagonal pressure components. See the region prism command for details.
- Can only use -plog with multiple partitions*
Self-explanatory. See doc page discussion of command-line switches.
- Can only use -pscreen with multiple partitions*
Self-explanatory. See doc page discussion of command-line switches.
- Can only use Kokkos supported regions with Kokkos package*
Self-explanatory.
- Can only use NEB with 1-processor replicas*
This is current restriction for NEB as implemented in LAMMPS.

LAMMPS Users Manual

Can only use TAD with 1-processor replicas for NEB

This is current restriction for NEB as implemented in LAMMPS.

Cannot (yet) do analytic differentiation with pppm/gpu

This is a current restriction of this command.

Cannot (yet) request ghost atoms with Kokkos half neighbor list

This feature is not yet supported.

Cannot (yet) use 'electron' units with dipoles

This feature is not yet supported.

Cannot (yet) use Ewald with triclinic box and slab correction

This feature is not yet supported.

Cannot (yet) use K-space slab correction with compute group/group for triclinic systems

This option is not yet supported.

Cannot (yet) use MSM with 2d simulation

This feature is not yet supported.

Cannot (yet) use PPPM with triclinic box and TIP4P

This feature is not yet supported.

Cannot (yet) use PPPM with triclinic box and kspace_modify diff ad

This feature is not yet supported.

Cannot (yet) use PPPM with triclinic box and slab correction

This feature is not yet supported.

Cannot (yet) use kspace slab correction with long-range dipoles and non-neutral systems or per-atom energy

This feature is not yet supported.

Cannot (yet) use kspace_modify diff ad with compute group/group

This option is not yet supported.

Cannot (yet) use kspace_style pppm/stagger with triclinic systems

This feature is not yet supported.

Cannot (yet) use molecular templates with Kokkos

Self-explanatory.

Cannot (yet) use respa with Kokkos

Self-explanatory.

Cannot (yet) use rigid bodies with fix deform and Kokkos

Self-explanatory.

Cannot (yet) use rigid bodies with fix nh and Kokkos

Self-explanatory.

Cannot (yet) use single precision with MSM (remove -DFFT_SINGLE from Makefile and recompile)

Single precision cannot be used with MSM.

Cannot add atoms to fix move variable

Atoms can not be added afterwards to this fix option.

Cannot append atoms to a triclinic box

The simulation box must be defined with edges aligned with the Cartesian axes.

Cannot balance in z dimension for 2d simulation

Self-explanatory.

Cannot change box ortho/triclinic with certain fixes defined

This is because those fixes store the shape of the box. You need to use unfix to discard the fix, change the box, then redefine a new fix.

Cannot change box ortho/triclinic with dumps defined

This is because some dumps store the shape of the box. You need to use undump to discard the dump, change the box, then redefine a new dump.

LAMMPS Users Manual

Cannot change box tilt factors for orthogonal box

Cannot use tilt factors unless the simulation box is non-orthogonal.

Cannot change box to orthogonal when tilt is non-zero

Self-explanatory.

Cannot change box z boundary to nonperiodic for a 2d simulation

Self-explanatory.

Cannot change dump_modify every for dump dcd

The frequency of writing dump dcd snapshots cannot be changed.

Cannot change dump_modify every for dump xtc

The frequency of writing dump xtc snapshots cannot be changed.

Cannot change timestep once fix srd is setup

This is because various SRD properties depend on the timestep size.

Cannot change timestep with fix pour

This is because fix pour pre-computes the time delay for particles to fall out of the insertion volume due to gravity.

Cannot change to comm_style brick from tiled layout

Self-explanatory.

Cannot change_box after reading restart file with per-atom info

This is because the restart file info cannot be migrated with the atoms. You can get around this by performing a 0-timestep run which will assign the restart file info to actual atoms.

Cannot change_box in xz or yz for 2d simulation

Self-explanatory.

Cannot change_box in z dimension for 2d simulation

Self-explanatory.

Cannot clear group all

This operation is not allowed.

Cannot close restart file - MPI error: %s

This error was generated by MPI when reading/writing an MPI-IO restart file.

Cannot compute initial g_ewald_disp

LAMMPS failed to compute an initial guess for the PPPM_disp g_ewald_6 factor that partitions the computation between real space and k-space for Dispersion interactions.

Cannot create an atom map unless atoms have IDs

The simulation requires a mapping from global atom IDs to local atoms, but the atoms that have been defined have no IDs.

Cannot create atoms with undefined lattice

Must use the lattice command before using the create_atoms command.

Cannot create/grow a vector/array of pointers for %s

LAMMPS code is making an illegal call to the templated memory allocators, to create a vector or array of pointers.

Cannot create_atoms after reading restart file with per-atom info

The per-atom info was stored to be used when by a fix that you may re-define. If you add atoms before re-defining the fix, then there will not be a correct amount of per-atom info.

Cannot create_box after simulation box is defined

A simulation box can only be defined once.

Cannot currently use pair reax with pair hybrid

This is not yet supported.

Cannot currently use ppm/gpu with fix balance.

Self-explanatory.

LAMMPS Users Manual

Cannot delete group all

Self-explanatory.

Cannot delete group currently used by a compute

Self-explanatory.

Cannot delete group currently used by a dump

Self-explanatory.

Cannot delete group currently used by a fix

Self-explanatory.

Cannot delete group currently used by atom_modify first

Self-explanatory.

Cannot delete_atoms bond yes for non-molecular systems

Self-explanatory.

Cannot displace_atoms after reading restart file with per-atom info

This is because the restart file info cannot be migrated with the atoms. You can get around this by performing a 0-timestep run which will assign the restart file info to actual atoms.

Cannot do GCMC on atoms in atom_modify first group

This is a restriction due to the way atoms are organized in a list to enable the atom_modify first command.

Cannot do atom/swap on atoms in atom_modify first group

This is a restriction due to the way atoms are organized in a list to enable the atom_modify first command.

Cannot dump sort on atom IDs with no atom IDs defined

Self-explanatory.

Cannot dump sort when multiple dump files are written

In this mode, each processor dumps its atoms to a file, so no sorting is allowed.

Cannot embed Python when also extending Python with LAMMPS

When running LAMMPS via Python through the LAMMPS library interface you cannot also use the input script python command.

Cannot evaporate atoms in atom_modify first group

This is a restriction due to the way atoms are organized in a list to enable the atom_modify first command.

Cannot find_create_bonds group ID

Self-explanatory.

Cannot find_delete_bonds group ID

Group ID used in the delete_bonds command does not exist.

Cannot find specified group ID for core particles

Self-explanatory.

Cannot find specified group ID for shell particles

Self-explanatory.

Cannot have both pair_modify shift and tail set to yes

These 2 options are contradictory.

Cannot intersect groups using a dynamic group

This operation is not allowed.

Cannot mix molecular and molecule template atom styles

Self-explanatory.

Cannot open -reorder file

Self-explanatory.

Cannot open ADP potential file %s

The specified ADP potential file cannot be opened. Check that the path and name are correct.

LAMMPS Users Manual

Cannot open AIREBO potential file %s

The specified AIREBO potential file cannot be opened. Check that the path and name are correct.

Cannot open BOP potential file %s

The specified BOP potential file cannot be opened. Check that the path and name are correct.

Cannot open COMB potential file %s

The specified COMB potential file cannot be opened. Check that the path and name are correct.

Cannot open COMB3 lib.comb3 file

The COMB3 library file cannot be opened. Check that the path and name are correct.

Cannot open COMB3 potential file %s

The specified COMB3 potential file cannot be opened. Check that the path and name are correct.

Cannot open EAM potential file %s

The specified EAM potential file cannot be opened. Check that the path and name are correct.

Cannot open EIM potential file %s

The specified EIM potential file cannot be opened. Check that the path and name are correct.

Cannot open LCBOP potential file %s

The specified LCBOP potential file cannot be opened. Check that the path and name are correct.

Cannot open MEAM potential file %s

The specified MEAM potential file cannot be opened. Check that the path and name are correct.

Cannot open SNAP coefficient file %s

The specified SNAP coefficient file cannot be opened. Check that the path and name are correct.

Cannot open SNAP parameter file %s

The specified SNAP parameter file cannot be opened. Check that the path and name are correct.

Cannot open Stillinger-Weber potential file %s

The specified SW potential file cannot be opened. Check that the path and name are correct.

Cannot open Tersoff potential file %s

The specified potential file cannot be opened. Check that the path and name are correct.

Cannot open Vashishta potential file %s

The specified Vashishta potential file cannot be opened. Check that the path and name are correct.

Cannot open balance output file

Self-explanatory.

Cannot open coul/streitz potential file %s

The specified coul/streitz potential file cannot be opened. Check that the path and name are correct.

Cannot open custom file

Self-explanatory.

Cannot open data file %s

The specified file cannot be opened. Check that the path and name are correct.

LAMMPS Users Manual

Cannot open dir to search for restart file

Using a "*" in the name of the restart file will open the current directory to search for matching file names.

Cannot open dump file

Self-explanatory.

Cannot open dump file %s

The output file for the dump command cannot be opened. Check that the path and name are correct.

Cannot open file %s

The specified file cannot be opened. Check that the path and name are correct. If the file is a compressed file, also check that the gzip executable can be found and run.

Cannot open file variable file %s

The specified file cannot be opened. Check that the path and name are correct.

Cannot open fix ave/chunk file %s

The specified file cannot be opened. Check that the path and name are correct.

Cannot open fix ave/correlate file %s

The specified file cannot be opened. Check that the path and name are correct.

Cannot open fix ave/histo file %s

The specified file cannot be opened. Check that the path and name are correct.

Cannot open fix ave/spatial file %s

The specified file cannot be opened. Check that the path and name are correct.

Cannot open fix ave/time file %s

The specified file cannot be opened. Check that the path and name are correct.

Cannot open fix balance output file

Self-explanatory.

Cannot open fix poems file %s

The specified file cannot be opened. Check that the path and name are correct.

Cannot open fix print file %s

The output file generated by the fix print command cannot be opened

Cannot open fix qeq parameter file %s

The specified file cannot be opened. Check that the path and name are correct.

Cannot open fix qeq/comb file %s

The output file for the fix qeq/combs command cannot be opened. Check that the path and name are correct.

Cannot open fix reax/bonds file %s

The output file for the fix reax/bonds command cannot be opened. Check that the path and name are correct.

Cannot open fix rigid infile %s

The specified file cannot be opened. Check that the path and name are correct.

Cannot open fix rigid restart file %s

The specified file cannot be opened. Check that the path and name are correct.

Cannot open fix rigid/small infile %s

The specified file cannot be opened. Check that the path and name are correct.

Cannot open fix tmd file %s

The output file for the fix tmd command cannot be opened. Check that the path and name are correct.

Cannot open fix ttm file %s

The output file for the fix ttm command cannot be opened. Check that the path and name are correct.

Cannot open gzipped file

LAMMPS Users Manual

LAMMPS was compiled without support for reading and writing gzipped files through a pipeline to the gzip program with `-DLAMMPS_GZIP`.

Cannot open input script %s

Self-explanatory.

Cannot open log.cite file

This file is created when you use some LAMMPS features, to indicate what paper you should cite on behalf of those who implemented the feature. Check that you have write privileges into the directory you are running in.

Cannot open log.lammps for writing

The default LAMMPS log file cannot be opened. Check that the directory you are running in allows for files to be created.

Cannot open logfile

The LAMMPS log file named in a command-line argument cannot be opened. Check that the path and name are correct.

Cannot open logfile %s

The LAMMPS log file specified in the input script cannot be opened. Check that the path and name are correct.

Cannot open molecule file %s

The specified file cannot be opened. Check that the path and name are correct.

Cannot open nb3b/harmonic potential file %s

The specified potential file cannot be opened. Check that the path and name are correct.

Cannot open pair_write file

The specified output file for pair energies and forces cannot be opened. Check that the path and name are correct.

Cannot open polymorphic potential file %s

The specified polymorphic potential file cannot be opened. Check that the path and name are correct.

Cannot open print file %s

Self-explanatory.

Cannot open processors output file

Self-explanatory.

Cannot open restart file %s

Self-explanatory.

Cannot open restart file for reading - MPI error: %s

This error was generated by MPI when reading/writing an MPI-IO restart file.

Cannot open restart file for writing - MPI error: %s

This error was generated by MPI when reading/writing an MPI-IO restart file.

Cannot open screen file

The screen file specified as a command-line argument cannot be opened. Check that the directory you are running in allows for files to be created.

Cannot open temporary file for world counter.

Self-explanatory.

Cannot open universe log file

For a multi-partition run, the master log file cannot be opened. Check that the directory you are running in allows for files to be created.

Cannot open universe screen file

For a multi-partition run, the master screen file cannot be opened. Check that the directory you are running in allows for files to be created.

Cannot read from restart file - MPI error: %s

This error was generated by MPI when reading/writing an MPI-IO restart file.

LAMMPS Users Manual

Cannot read_data without add keyword after simulation box is defined

Self-explanatory.

Cannot read_restart after simulation box is defined

The read_restart command cannot be used after a read_data, read_restart, or create_box command.

Cannot redefine variable as a different style

An equal-style variable can be re-defined but only if it was originally an equal-style variable.

Cannot replicate 2d simulation in z dimension

The replicate command cannot replicate a 2d simulation in the z dimension.

Cannot replicate with fixes that store atom quantities

Either fixes are defined that create and store atom-based vectors or a restart file was read which included atom-based vectors for fixes. The replicate command cannot duplicate that information for new atoms. You should use the replicate command before fixes are applied to the system.

Cannot reset timestep with a dynamic region defined

Dynamic regions (see the region command) have a time dependence. Thus you cannot change the timestep when one or more of these are defined.

Cannot reset timestep with a time-dependent fix defined

You cannot reset the timestep when a fix that keeps track of elapsed time is in place.

Cannot run 2d simulation with nonperiodic Z dimension

Use the boundary command to make the z dimension periodic in order to run a 2d simulation.

Cannot set bond topology types for atom style template

The bond, angle, etc types cannot be changed for this atom style since they are static settings in the molecule template files.

Cannot set both respa pair and inner/middle/outer

In the rRESPA integrator, you must compute pairwise potentials either all together (pair), or in pieces (inner/middle/outer). You can't do both.

Cannot set cutoff/multi before simulation box is defined

Self-explanatory.

Cannot set dpd/theta for this atom style

Self-explanatory.

Cannot set dump_modify flush for dump xtc

Self-explanatory.

Cannot set mass for this atom style

This atom style does not support mass settings for each atom type. Instead they are defined on a per-atom basis in the data file.

Cannot set meso/cv for this atom style

Self-explanatory.

Cannot set meso/e for this atom style

Self-explanatory.

Cannot set meso/rho for this atom style

Self-explanatory.

Cannot set non-zero image flag for non-periodic dimension

Self-explanatory.

Cannot set non-zero z velocity for 2d simulation

Self-explanatory.

Cannot set quaternion for atom that has none

Self-explanatory.

LAMMPS Users Manual

Cannot set quaternion with xy components for 2d system

Self-explanatory.

Cannot set respa hybrid and any of pair/inner/middle/outer

In the rRESPA integrator, you must compute pairwise potentials either all together (pair), with different cutoff regions (inner/middle/outer), or per hybrid sub-style (hybrid). You cannot mix those.

Cannot set respa middle without inner/outer

In the rRESPA integrator, you must define both a inner and outer setting in order to use a middle setting.

Cannot set restart file size - MPI error: %s

This error was generated by MPI when reading/writing an MPI-IO restart file.

Cannot set smd/contact/radius for this atom style

Self-explanatory.

Cannot set smd/mass/density for this atom style

Self-explanatory.

Cannot set temperature for fix rigid/nph

The temp keyword cannot be specified.

Cannot set theta for atom that is not a line

Self-explanatory.

Cannot set this attribute for this atom style

The attribute being set does not exist for the defined atom style.

Cannot set variable z velocity for 2d simulation

Self-explanatory.

Cannot skew triclinic box in z for 2d simulation

Self-explanatory.

Cannot subtract groups using a dynamic group

This operation is not allowed.

Cannot union groups using a dynamic group

This operation is not allowed.

Cannot use -cuda on and -kokkos on together

This is not allowed since both packages can use GPUs.

Cannot use -cuda on without USER-CUDA installed

The USER-CUDA package must be installed via "make yes-user-cuda" before LAMMPS is built.

Cannot use -kokkos on without KOKKOS installed

Self-explanatory.

Cannot use -reorder after -partition

Self-explanatory. See doc page discussion of command-line switches.

Cannot use Ewald with 2d simulation

The kspace style ewald cannot be used in 2d simulations. You can use 2d Ewald in a 3d simulation; see the kspace_modify command.

Cannot use Ewald/disp solver on system with no charge, dipole, or LJ particles

No atoms in system have a non-zero charge or dipole, or are LJ particles.

Change charges/dipoles or change options of the kspace solver/pair style.

Cannot use EwaldDisp with 2d simulation

This is a current restriction of this command.

Cannot use GPU package with USER-CUDA package enabled

You cannot use both the GPU and USER-CUDA packages together. Use one or the other.

Cannot use Kokkos pair style with rRESPA inner/middle

Self-explanatory.

LAMMPS Users Manual

Cannot use NEB unless atom map exists

Use the `atom_modify` command to create an atom map.

Cannot use NEB with a single replica

Self-explanatory.

Cannot use NEB with atom_modify sort enabled

This is current restriction for NEB implemented in LAMMPS.

Cannot use PPPM with 2d simulation

The `kspace` style `pppm` cannot be used in 2d simulations. You can use 2d PPPM in a 3d simulation; see the `kspace_modify` command.

Cannot use PPPMDisp with 2d simulation

The `kspace` style `pppm/disp` cannot be used in 2d simulations. You can use 2d `pppm/disp` in a 3d simulation; see the `kspace_modify` command.

Cannot use PRD with a changing box

The current box dimensions are not copied between replicas

Cannot use PRD with a time-dependent fix defined

PRD alters the timestep in ways that will mess up these fixes.

Cannot use PRD with a time-dependent region defined

PRD alters the timestep in ways that will mess up these regions.

Cannot use PRD with atom_modify sort enabled

This is a current restriction of PRD. You must turn off sorting, which is enabled by default, via the `atom_modify` command.

Cannot use PRD with multi-processor replicas unless atom map exists

Use the `atom_modify` command to create an atom map.

Cannot use TAD unless atom map exists for NEB

See `atom_modify` map command to set this.

Cannot use TAD with a single replica for NEB

NEB requires multiple replicas.

Cannot use TAD with atom_modify sort enabled for NEB

This is a current restriction of NEB.

Cannot use a damped dynamics min style with fix box/relax

This is a current restriction in LAMMPS. Use another minimizer style.

Cannot use a damped dynamics min style with per-atom DOF

This is a current restriction in LAMMPS. Use another minimizer style.

Cannot use append/atoms in periodic dimension

The boundary style of the face where atoms are added can not be of type `p` (periodic).

Cannot use atomfile-style variable unless atom map exists

Self-explanatory. See the `atom_modify` command to create a map.

Cannot use both com and bias with compute temp/chunk

Self-explanatory.

Cannot use chosen neighbor list style with buck/coul/cut/kk

Self-explanatory.

Cannot use chosen neighbor list style with buck/coul/long/kk

Self-explanatory.

Cannot use chosen neighbor list style with buck/kk

That style is not supported by Kokkos.

Cannot use chosen neighbor list style with coul/cut/kk

That style is not supported by Kokkos.

Cannot use chosen neighbor list style with coul/debye/kk

Self-explanatory.

Cannot use chosen neighbor list style with coul/dsf/kk

LAMMPS Users Manual

That style is not supported by Kokkos.
Cannot use chosen neighbor list style with coul/wolf/kk
That style is not supported by Kokkos.
Cannot use chosen neighbor list style with lj/charmm/coul/charmm/implicit/kk
Self-explanatory.
Cannot use chosen neighbor list style with lj/charmm/coul/charmm/kk
Self-explanatory.
Cannot use chosen neighbor list style with lj/charmm/coul/long/kk
Self-explanatory.
Cannot use chosen neighbor list style with lj/class2/coul/cut/kk
Self-explanatory.
Cannot use chosen neighbor list style with lj/class2/coul/long/kk
Self-explanatory.
Cannot use chosen neighbor list style with lj/class2/kk
Self-explanatory.
Cannot use chosen neighbor list style with lj/cut/coul/cut/kk
That style is not supported by Kokkos.
Cannot use chosen neighbor list style with lj/cut/coul/debye/kk
Self-explanatory.
Cannot use chosen neighbor list style with lj/cut/coul/long/kk
That style is not supported by Kokkos.
Cannot use chosen neighbor list style with lj/cut/kk
That style is not supported by Kokkos.
Cannot use chosen neighbor list style with lj/expand/kk
Self-explanatory.
Cannot use chosen neighbor list style with lj/gromacs/coul/gromacs/kk
Self-explanatory.
Cannot use chosen neighbor list style with lj/gromacs/kk
Self-explanatory.
Cannot use chosen neighbor list style with lj/sdk/kk
That style is not supported by Kokkos.
Cannot use chosen neighbor list style with pair eam/kk
That style is not supported by Kokkos.
Cannot use chosen neighbor list style with pair eam/kk/alloy
Self-explanatory.
Cannot use chosen neighbor list style with pair eam/kk/fs
Self-explanatory.
Cannot use chosen neighbor list style with pair sw/kk
Self-explanatory.
Cannot use chosen neighbor list style with tersoff/kk
Self-explanatory.
Cannot use chosen neighbor list style with tersoff/zbl/kk
Self-explanatory.
Cannot use compute chunk/atom bin z for 2d model
Self-explanatory.
Cannot use compute cluster/atom unless atoms have IDs
Atom IDs are used to identify clusters.
Cannot use create_atoms rotate unless single style
Self-explanatory.
Cannot use create_bonds unless atoms have IDs

LAMMPS Users Manual

This command requires a mapping from global atom IDs to local atoms, but the atoms that have been defined have no IDs.

Cannot use create_bonds with non-molecular system

Self-explanatory.

Cannot use cwiggle in variable formula between runs

This is a function of elapsed time.

Cannot use delete_atoms bond yes with atom_style template

This is because the bonds for that atom style are hardwired in the molecule template.

Cannot use delete_atoms unless atoms have IDs

Your atoms do not have IDs, so the delete_atoms command cannot be used.

Cannot use delete_bonds with non-molecular system

Your choice of atom style does not have bonds.

Cannot use dump_modify fileper without % in dump file name

Self-explanatory.

Cannot use dump_modify nfile without % in dump file name

Self-explanatory.

Cannot use dynamic group with fix adapt atom

This is not yet supported.

Cannot use fix TMD unless atom map exists

Using this fix requires the ability to lookup an atom index, which is provided by an atom map. An atom map does not exist (by default) for non-molecular problems. Using the atom_modify map command will force an atom map to be created.

Cannot use fix ave/spatial z for 2 dimensional model

Self-explanatory.

Cannot use fix bond/break with non-molecular systems

Only systems with bonds that can be changed can be used. Atom_style template does not qualify.

Cannot use fix bond/create with non-molecular systems

Only systems with bonds that can be changed can be used. Atom_style template does not qualify.

Cannot use fix bond/swap with non-molecular systems

Only systems with bonds that can be changed can be used. Atom_style template does not qualify.

Cannot use fix box/relax on a 2nd non-periodic dimension

When specifying an off-diagonal pressure component, the 2nd of the two dimensions must be periodic. E.g. if the xy component is specified, then the y dimension must be periodic.

Cannot use fix box/relax on a non-periodic dimension

When specifying a diagonal pressure component, the dimension must be periodic.

Cannot use fix box/relax with both relaxation and scaling on a tilt factor

When specifying scaling on a tilt factor component, that component can not also be controlled by the barostat. E.g. if scalexy yes is specified and also keyword tri or xy, this is wrong.

Cannot use fix box/relax with tilt factor scaling on a 2nd non-periodic dimension

When specifying scaling on a tilt factor component, the 2nd of the two dimensions must be periodic. E.g. if the xy component is specified, then the y dimension must be periodic.

Cannot use fix deform on a shrink-wrapped boundary

LAMMPS Users Manual

- The x, y, z options cannot be applied to shrink-wrapped dimensions.
Cannot use fix deform tilt on a shrink-wrapped 2nd dim
This is because the shrink-wrapping will change the value of the strain implied by the tilt factor.
- Cannot use fix deform trape on a box with zero tilt*
The trape style alters the current strain.
- Cannot use fix deposit rigid and not molecule*
Self-explanatory.
- Cannot use fix deposit rigid and shake*
These two attributes are conflicting.
- Cannot use fix deposit shake and not molecule*
Self-explanatory.
- Cannot use fix enforce2d with 3d simulation*
Self-explanatory.
- Cannot use fix gcmc in a 2d simulation*
Fix gcmc is set up to run in 3d only. No 2d simulations with fix gcmc are allowed.
- Cannot use fix gcmc shake and not molecule*
Self-explanatory.
- Cannot use fix msst without per-type mass defined*
Self-explanatory.
- Cannot use fix npt and fix deform on same component of stress tensor*
This would be changing the same box dimension twice.
- Cannot use fix nvt/npt/nph on a 2nd non-periodic dimension*
When specifying an off-diagonal pressure component, the 2nd of the two dimensions must be periodic. E.g. if the xy component is specified, then the y dimension must be periodic.
- Cannot use fix nvt/npt/nph on a non-periodic dimension*
When specifying a diagonal pressure component, the dimension must be periodic.
- Cannot use fix nvt/npt/nph with both xy dynamics and xy scaling*
Self-explanatory.
- Cannot use fix nvt/npt/nph with both xz dynamics and xz scaling*
Self-explanatory.
- Cannot use fix nvt/npt/nph with both yz dynamics and yz scaling*
Self-explanatory.
- Cannot use fix nvt/npt/nph with xy scaling when y is non-periodic dimension*
The 2nd dimension in the barostatted tilt factor must be periodic.
- Cannot use fix nvt/npt/nph with xz scaling when z is non-periodic dimension*
The 2nd dimension in the barostatted tilt factor must be periodic.
- Cannot use fix nvt/npt/nph with yz scaling when z is non-periodic dimension*
The 2nd dimension in the barostatted tilt factor must be periodic.
- Cannot use fix pour rigid and not molecule*
Self-explanatory.
- Cannot use fix pour rigid and shake*
These two attributes are conflicting.
- Cannot use fix pour shake and not molecule*
Self-explanatory.
- Cannot use fix pour with triclinic box*
This option is not yet supported.
- Cannot use fix press/berendsen and fix deform on same component of stress tensor*

LAMMPS Users Manual

These commands both change the box size/shape, so you cannot use both together.

Cannot use fix press/berendsen on a non-periodic dimension

Self-explanatory.

Cannot use fix press/berendsen with triclinic box

Self-explanatory.

Cannot use fix reax/bonds without pair_style reax

Self-explanatory.

Cannot use fix rigid npt/nph and fix deform on same component of stress tensor

This would be changing the same box dimension twice.

Cannot use fix rigid npt/nph on a non-periodic dimension

When specifying a diagonal pressure component, the dimension must be periodic.

Cannot use fix rigid/small npt/nph on a non-periodic dimension

When specifying a diagonal pressure component, the dimension must be periodic.

Cannot use fix shake with non-molecular system

Your choice of atom style does not have bonds.

Cannot use fix ttm with 2d simulation

This is a current restriction of this fix due to the grid it creates.

Cannot use fix ttm with triclinic box

This is a current restriction of this fix due to the grid it creates.

Cannot use fix tune/kspace without a kspace style

Self-explanatory.

Cannot use fix tune/kspace without a pair style

This fix (tune/kspace) can only be used when a pair style has been specified.

Cannot use fix wall in periodic dimension

Self-explanatory.

Cannot use fix wall zlo/zhi for a 2d simulation

Self-explanatory.

Cannot use fix wall/reflect in periodic dimension

Self-explanatory.

Cannot use fix wall/reflect zlo/zhi for a 2d simulation

Self-explanatory.

Cannot use fix wall/srd in periodic dimension

Self-explanatory.

Cannot use fix wall/srd more than once

Nor is there a need to since multiple walls can be specified in one command.

Cannot use fix wall/srd without fix srd

Self-explanatory.

Cannot use fix wall/srd zlo/zhi for a 2d simulation

Self-explanatory.

Cannot use fix_deposit unless atoms have IDs

Self-explanatory.

Cannot use fix_pour unless atoms have IDs

Self-explanatory.

Cannot use include command within an if command

Self-explanatory.

Cannot use lines with fix srd unless overlap is set

This is because line segments are connected to each other.

Cannot use multiple fix wall commands with pair brownian

LAMMPS Users Manual

- Self-explanatory.
- Cannot use multiple fix wall commands with pair lubricate*
Self-explanatory.
- Cannot use multiple fix wall commands with pair lubricate/poly*
Self-explanatory.
- Cannot use multiple fix wall commands with pair lubricateU*
Self-explanatory.
- Cannot use neigh_modify exclude with GPU neighbor builds*
This is a current limitation of the GPU implementation in LAMMPS.
- Cannot use neighbor bins - box size << cutoff*
Too many neighbor bins will be created. This typically happens when the simulation box is very small in some dimension, compared to the neighbor cutoff. Use the "nsq" style instead of "bin" style.
- Cannot use newton pair with beck/gpu pair style*
Self-explanatory.
- Cannot use newton pair with born/coul/long/gpu pair style*
Self-explanatory.
- Cannot use newton pair with born/coul/wolf/gpu pair style*
Self-explanatory.
- Cannot use newton pair with born/gpu pair style*
Self-explanatory.
- Cannot use newton pair with buck/coul/cut/gpu pair style*
Self-explanatory.
- Cannot use newton pair with buck/coul/long/gpu pair style*
Self-explanatory.
- Cannot use newton pair with buck/gpu pair style*
Self-explanatory.
- Cannot use newton pair with colloid/gpu pair style*
Self-explanatory.
- Cannot use newton pair with coul/cut/gpu pair style*
Self-explanatory.
- Cannot use newton pair with coul/debye/gpu pair style*
Self-explanatory.
- Cannot use newton pair with coul/dsf/gpu pair style*
Self-explanatory.
- Cannot use newton pair with coul/long/gpu pair style*
Self-explanatory.
- Cannot use newton pair with dipole/cut/gpu pair style*
Self-explanatory.
- Cannot use newton pair with dipole/sf/gpu pair style*
Self-explanatory.
- Cannot use newton pair with dpd/gpu pair style*
Self-explanatory.
- Cannot use newton pair with dpd/tstat/gpu pair style*
Self-explanatory.
- Cannot use newton pair with eam/alloy/gpu pair style*
Self-explanatory.
- Cannot use newton pair with eam/fs/gpu pair style*
Self-explanatory.
- Cannot use newton pair with eam/gpu pair style*
Self-explanatory.

LAMMPS Users Manual

Cannot use newton pair with gauss/gpu pair style
Self-explanatory.

Cannot use newton pair with gayberne/gpu pair style
Self-explanatory.

Cannot use newton pair with lj/charmm/coul/long/gpu pair style
Self-explanatory.

Cannot use newton pair with lj/class2/coul/long/gpu pair style

Self-explanatory.

Cannot use newton pair with mie/cut/gpu pair style
Self-explanatory.

Cannot use newton pair with morse/gpu pair style
Self-explanatory.

Cannot use newton pair with resquared/gpu pair style
Self-explanatory.

Cannot use newton pair with soft/gpu pair style
Self-explanatory.

Cannot use newton pair with table/gpu pair style
Self-explanatory.

Cannot use newton pair with yukawa/colloid/gpu pair style
Self-explanatory.

Cannot use newton pair with yukawa/gpu pair style
Self-explanatory.

Cannot use newton pair with zbl/gpu pair style
Self-explanatory.

Cannot use non-zero forces in an energy minimization

LAMMPS Users Manual

- Fix setforce cannot be used in this manner. Use fix addforce instead.
- Cannot use nonperiodic boundares with fix ttm*
This fix requires a fully periodic simulation box.
- Cannot use nonperiodic boundaries with Ewald*
For kspace style ewald, all 3 dimensions must have periodic boundaries unless you use the kspace_modify command to define a 2d slab with a non-periodic z dimension.
- Cannot use nonperiodic boundaries with EwaldDisp*
For kspace style ewald/disp, all 3 dimensions must have periodic boundaries unless you use the kspace_modify command to define a 2d slab with a non-periodic z dimension.
- Cannot use nonperiodic boundaries with PPPM*
For kspace style ppm, all 3 dimensions must have periodic boundaries unless you use the kspace_modify command to define a 2d slab with a non-periodic z dimension.
- Cannot use nonperiodic boundaries with PPPMDisp*
For kspace style ppm/disp, all 3 dimensions must have periodic boundaries unless you use the kspace_modify command to define a 2d slab with a non-periodic z dimension.
- Cannot use order greater than 8 with ppm/gpu.*
Self-explanatory.
- Cannot use package gpu neigh yes with triclinic box*
This is a current restriction in LAMMPS.
- Cannot use pair hybrid with GPU neighbor list builds*
Neighbor list builds must be done on the CPU for this pair style.
- Cannot use pair tail corrections with 2d simulations*
The correction factors are only currently defined for 3d systems.
- Cannot use processors part command without using partitions*
See the command-line -partition switch.
- Cannot use ramp in variable formula between runs*
This is because the ramp() function is time dependent.
- Cannot use read_data add before simulation box is defined*
Self-explanatory.
- Cannot use read_data extra with add flag*
Self-explanatory.
- Cannot use read_data offset without add flag*
Self-explanatory.
- Cannot use read_data shift without add flag*
Self-explanatory.
- Cannot use region INF or EDGE when box does not exist*
Regions that extend to the box boundaries can only be used after the create_box command has been used.
- Cannot use set atom with no atom IDs defined*
Atom IDs are not defined, so they cannot be used to identify an atom.
- Cannot use set mol with no molecule IDs defined*
Self-explanatory.
- Cannot use swiggle in variable formula between runs*
This is a function of elapsed time.
- Cannot use tris with fix srd unless overlap is set*
This is because triangles are connected to each other.
- Cannot use variable energy with constant efield in fix efield*

LAMMPS Users Manual

- LAMMPS computes the energy itself when the E-field is constant.
- Cannot use variable energy with constant force in fix addforce*
This is because for constant force, LAMMPS can compute the change in energy directly.
- Cannot use variable every setting for dump dcd*
The format of DCD dump files requires snapshots be output at a constant frequency.
- Cannot use variable every setting for dump xtc*
The format of this file requires snapshots at regular intervals.
- Cannot use vdisplace in variable formula between runs*
This is a function of elapsed time.
- Cannot use velocity bias command without temp keyword*
Self-explanatory.
- Cannot use velocity create loop all unless atoms have IDs*
Atoms in the simulation to do not have IDs, so this style of velocity creation cannot be performed.
- Cannot use wall in periodic dimension*
Self-explanatory.
- Cannot use write_restart fileper without % in restart file name*
Self-explanatory.
- Cannot use write_restart nfile without % in restart file name*
Self-explanatory.
- Cannot wiggle and shear fix wall/gran*
Cannot specify both options at the same time.
- Cannot write to restart file - MPI error: %s*
This error was generated by MPI when reading/writing an MPI-IO restart file.
- Cannot yet use KSpace solver with grid with comm style tiled*
This is current restriction in LAMMPS.
- Cannot yet use comm_style tiled with multi-mode comm*
Self-explanatory.
- Cannot yet use comm_style tiled with triclinic box*
Self-explanatory.
- Cannot yet use compute tally with Kokkos*
This feature is not yet supported.
- Cannot yet use fix bond/break with this improper style*
This is a current restriction in LAMMPS.
- Cannot yet use fix bond/create with this improper style*
This is a current restriction in LAMMPS.
- Cannot yet use minimize with Kokkos*
This feature is not yet supported.
- Cannot yet use pair hybrid with Kokkos*
This feature is not yet supported.
- Cannot zero Langevin force of 0 atoms*
The group has zero atoms, so you cannot request its force be zeroed.
- Cannot zero gld force for zero atoms*
There are no atoms currently in the group.
- Cannot zero momentum of no atoms*
Self-explanatory.
- Change_box command before simulation box is defined*
Self-explanatory.
- Change_box volume used incorrectly*

LAMMPS Users Manual

The "dim volume" option must be used immediately following one or two settings for "dim1 ..." (and optionally "dim2 ...") and must be for a different dimension, i.e. $\text{dim} \neq \text{dim1}$ and $\text{dim} \neq \text{dim2}$.

Chunk/atom compute does not exist for compute angmom/chunk
Self-explanatory.

Chunk/atom compute does not exist for compute com/chunk
Self-explanatory.

Chunk/atom compute does not exist for compute gyration/chunk
Self-explanatory.

Chunk/atom compute does not exist for compute inertia/chunk
Self-explanatory.

Chunk/atom compute does not exist for compute msd/chunk
Self-explanatory.

Chunk/atom compute does not exist for compute omega/chunk
Self-explanatory.

Chunk/atom compute does not exist for compute property/chunk
Self-explanatory.

Chunk/atom compute does not exist for compute temp/chunk
Self-explanatory.

Chunk/atom compute does not exist for compute torque/chunk
Self-explanatory.

Chunk/atom compute does not exist for compute vcm/chunk
Self-explanatory.

Chunk/atom compute does not exist for fix ave/chunk
Self-explanatory.

Comm tiled invalid index in box drop brick
Internal error check in comm_style tiled which should not occur. Contact the developers.

Comm tiled mis-match in box drop brick
Internal error check in comm_style tiled which should not occur. Contact the developers.

Comm_modify group != atom_modify first group
Self-explanatory.

Communication cutoff for comm_style tiled cannot exceed periodic box length
Self-explanatory.

Communication cutoff too small for SNAP micro load balancing
This can happen if you change the neighbor skin after your pair_style command or if your box dimensions grow during a run. You can set the cutoff explicitly via the comm_modify cutoff command.

Compute %s does not allow use of dynamic group
Dynamic groups have not yet been enabled for this compute.

Compute ID for compute chunk /atom does not exist
Self-explanatory.

Compute ID for compute chunk/atom does not exist
Self-explanatory.

Compute ID for compute reduce does not exist
Self-explanatory.

Compute ID for compute slice does not exist
Self-explanatory.

Compute ID for fix ave/atom does not exist
Self-explanatory.

LAMMPS Users Manual

- Compute ID for fix ave/chunk does not exist*
Self-explanatory.
- Compute ID for fix ave/correlate does not exist*
Self-explanatory.
- Compute ID for fix ave/histo does not exist*
Self-explanatory.
- Compute ID for fix ave/spatial does not exist*
Self-explanatory.
- Compute ID for fix ave/time does not exist*
Self-explanatory.
- Compute ID for fix store/state does not exist*
Self-explanatory.
- Compute ID for fix vector does not exist*
Self-explanatory.
- Compute ID must be alphanumeric or underscore characters*
Self-explanatory.
- Compute angle/local used when angles are not allowed*
The atom style does not support angles.
- Compute angmom/chunk does not use chunk/atom compute*
The style of the specified compute is not chunk/atom.
- Compute body/local requires atom style body*
Self-explanatory.
- Compute bond/local used when bonds are not allowed*
The atom style does not support bonds.
- Compute centro/atom requires a pair style be defined*
This is because the computation of the centro-symmetry values uses a pairwise neighbor list.
- Compute chunk/atom bin/cylinder radius is too large for periodic box*
Radius cannot be bigger than 1/2 of a non-axis periodic dimension.
- Compute chunk/atom bin/sphere radius is too large for periodic box*
Radius cannot be bigger than 1/2 of any periodic dimension.
- Compute chunk/atom compute array is accessed out-of-range*
The index for the array is out of bounds.
- Compute chunk/atom compute does not calculate a per-atom array*
Self-explanatory.
- Compute chunk/atom compute does not calculate a per-atom vector*
Self-explanatory.
- Compute chunk/atom compute does not calculate per-atom values*
Self-explanatory.
- Compute chunk/atom cylinder axis must be z for 2d*
Self-explanatory.
- Compute chunk/atom fix array is accessed out-of-range*
the index for the array is out of bounds.
- Compute chunk/atom fix does not calculate a per-atom array*
Self-explanatory.
- Compute chunk/atom fix does not calculate a per-atom vector*
Self-explanatory.
- Compute chunk/atom fix does not calculate per-atom values*
Self-explanatory.
- Compute chunk/atom for triclinic boxes requires units reduced*
Self-explanatory.

LAMMPS Users Manual

Compute chunk/atom ids once but nchunk is not once

You cannot assign chunks IDs to atom permanently if the number of chunks may change.

Compute chunk/atom molecule for non-molecular system

Self-explanatory.

Compute chunk/atom sphere z origin must be 0.0 for 2d

Self-explanatory.

Compute chunk/atom stores no IDs for compute property/chunk

It will only store IDs if its compress option is enabled.

Compute chunk/atom stores no coord1 for compute property/chunk

Only certain binning options for compute chunk/atom store coordinates.

Compute chunk/atom stores no coord2 for compute property/chunk

Only certain binning options for compute chunk/atom store coordinates.

Compute chunk/atom stores no coord3 for compute property/chunk

Only certain binning options for compute chunk/atom store coordinates.

Compute chunk/atom variable is not atom-style variable

Self-explanatory.

Compute chunk/atom without bins cannot use discard mixed

That discard option only applies to the binning styles.

Compute cluster/atom cutoff is longer than pairwise cutoff

Cannot identify clusters beyond cutoff.

Compute cluster/atom requires a pair style be defined

This is so that the pair style defines a cutoff distance which is used to find clusters.

Compute cna/atom cutoff is longer than pairwise cutoff

Self-explanatory.

Compute cna/atom requires a pair style be defined

Self-explanatory.

Compute com/chunk does not use chunk/atom compute

The style of the specified compute is not chunk/atom.

Compute contact/atom requires a pair style be defined

Self-explanatory.

Compute contact/atom requires atom style sphere

Self-explanatory.

Compute coord/atom cutoff is longer than pairwise cutoff

Cannot compute coordination at distances longer than the pair cutoff, since those atoms are not in the neighbor list.

Compute coord/atom requires a pair style be defined

Self-explanatory.

Compute damage/atom requires peridynamic potential

Damage is a Peridynamic-specific metric. It requires you to be running a Peridynamics simulation.

Compute dihedral/local used when dihedrals are not allowed

The atom style does not support dihedrals.

Compute dilatation/atom cannot be used with this pair style

Self-explanatory.

Compute dilatation/atom requires Peridynamic pair style

Self-explanatory.

Compute does not allow an extra compute or fix to be reset

This is an internal LAMMPS error. Please report it to the developers.

Compute erotate/asphere requires atom style ellipsoid or line or tri

LAMMPS Users Manual

- Self-explanatory.
- Compute erotate/asphere requires extended particles*
This compute cannot be used with point particles.
- Compute erotate/rigid with non-rigid fix-ID*
Self-explanatory.
- Compute erotate/sphere requires atom style sphere*
Self-explanatory.
- Compute erotate/sphere/atom requires atom style sphere*
Self-explanatory.
- Compute event/displace has invalid fix event assigned*
This is an internal LAMMPS error. Please report it to the developers.
- Compute group/group group ID does not exist*
Self-explanatory.
- Compute gyration/chunk does not use chunk/atom compute*
The style of the specified compute is not chunk/atom.
- Compute heat/flux compute ID does not compute ke/atom*
Self-explanatory.
- Compute heat/flux compute ID does not compute pe/atom*
Self-explanatory.
- Compute heat/flux compute ID does not compute stress/atom*
Self-explanatory.
- Compute hexorder/atom cutoff is longer than pairwise cutoff*
Cannot compute order parameter beyond cutoff.
- Compute hexorder/atom requires a pair style be defined*
Self-explanatory.
- Compute improper/local used when impropers are not allowed*
The atom style does not support impropers.
- Compute inertia/chunk does not use chunk/atom compute*
The style of the specified compute is not chunk/atom.
- Compute ke/rigid with non-rigid fix-ID*
Self-explanatory.
- Compute msd/chunk does not use chunk/atom compute*
The style of the specified compute is not chunk/atom.
- Compute msd/chunk nchunk is not static*
This is required because the MSD cannot be computed consistently if the number of chunks is changing. Compute chunk/atom allows setting nchunk to be static.
- Compute nve/asphere requires atom style ellipsoid*
Self-explanatory.
- Compute nvt/nph/npt asphere requires atom style ellipsoid*
Self-explanatory.
- Compute nvt/nph/npt body requires atom style body*
Self-explanatory.
- Compute omega/chunk does not use chunk/atom compute*
The style of the specified compute is not chunk/atom.
- Compute orientorder/atom cutoff is longer than pairwise cutoff*
Cannot compute order parameter beyond cutoff.
- Compute orientorder/atom requires a pair style be defined*
Self-explanatory.
- Compute pair must use group all*
Pair styles accumulate energy on all atoms.

LAMMPS Users Manual

Compute pe must use group all

Energies computed by potentials (pair, bond, etc) are computed on all atoms.

Compute plasticity/atom cannot be used with this pair style

Self-explanatory.

Compute plasticity/atom requires Peridynamic pair style

Self-explanatory.

Compute pressure must use group all

Virial contributions computed by potentials (pair, bond, etc) are computed on all atoms.

Compute pressure requires temperature ID to include kinetic energy

The keflag cannot be used unless a temperature compute is provided.

Compute pressure temperature ID does not compute temperature

The compute ID assigned to a pressure computation must compute temperature.

Compute property/atom floating point vector does not exist

The command is accessing a vector added by the fix property/atom command, that does not exist.

Compute property/atom for atom property that isn't allocated

Self-explanatory.

Compute property/atom integer vector does not exist

The command is accessing a vector added by the fix property/atom command, that does not exist.

Compute property/chunk does not use chunk/atom compute

The style of the specified compute is not chunk/atom.

Compute property/local cannot use these inputs together

Only inputs that generate the same number of datums can be used together. E.g. bond and angle quantities cannot be mixed.

Compute property/local does not (yet) work with atom_style template

Self-explanatory.

Compute property/local for property that isn't allocated

Self-explanatory.

Compute rdf requires a pair style be defined

Self-explanatory.

Compute reduce compute array is accessed out-of-range

An index for the array is out of bounds.

Compute reduce compute calculates global values

A compute that calculates peratom or local values is required.

Compute reduce compute does not calculate a local array

Self-explanatory.

Compute reduce compute does not calculate a local vector

Self-explanatory.

Compute reduce compute does not calculate a per-atom array

Self-explanatory.

Compute reduce compute does not calculate a per-atom vector

Self-explanatory.

Compute reduce fix array is accessed out-of-range

An index for the array is out of bounds.

Compute reduce fix calculates global values

A fix that calculates peratom or local values is required.

Compute reduce fix does not calculate a local array

Self-explanatory.

LAMMPS Users Manual

- Compute reduce fix does not calculate a local vector*
Self-explanatory.
- Compute reduce fix does not calculate a per-atom array*
Self-explanatory.
- Compute reduce fix does not calculate a per-atom vector*
Self-explanatory.
- Compute reduce replace requires min or max mode*
Self-explanatory.
- Compute reduce variable is not atom-style variable*
Self-explanatory.
- Compute slice compute array is accessed out-of-range*
An index for the array is out of bounds.
- Compute slice compute does not calculate a global array*
Self-explanatory.
- Compute slice compute does not calculate a global vector*
Self-explanatory.
- Compute slice compute does not calculate global vector or array*
Self-explanatory.
- Compute slice compute vector is accessed out-of-range*
The index for the vector is out of bounds.
- Compute slice fix array is accessed out-of-range*
An index for the array is out of bounds.
- Compute slice fix does not calculate a global array*
Self-explanatory.
- Compute slice fix does not calculate a global vector*
Self-explanatory.
- Compute slice fix does not calculate global vector or array*
Self-explanatory.
- Compute slice fix vector is accessed out-of-range*
The index for the vector is out of bounds.
- Compute sna/atom cutoff is longer than pairwise cutoff*
Self-explanatory.
- Compute sna/atom requires a pair style be defined*
Self-explanatory.
- Compute snad/atom cutoff is longer than pairwise cutoff*
Self-explanatory.
- Compute snad/atom requires a pair style be defined*
Self-explanatory.
- Compute snav/atom cutoff is longer than pairwise cutoff*
Self-explanatory.
- Compute snav/atom requires a pair style be defined*
Self-explanatory.
- Compute stress/atom temperature ID does not compute temperature*
The specified compute must compute temperature.
- Compute temp/asphere requires atom style ellipsoid*
Self-explanatory.
- Compute temp/asphere requires extended particles*
This compute cannot be used with point particles.
- Compute temp/body requires atom style body*
Self-explanatory.
- Compute temp/body requires bodies*

LAMMPS Users Manual

- This compute can only be applied to body particles.
- Compute temp/chunk does not use chunk/atom compute*
The style of the specified compute is not chunk/atom.
- Compute temp/cs requires ghost atoms store velocity*
Use the comm_modify vel yes command to enable this.
- Compute temp/cs used when bonds are not allowed*
This compute only works on pairs of bonded particles.
- Compute temp/partial cannot use vz for 2d systemx*
Self-explanatory.
- Compute temp/profile cannot bin z for 2d systems*
Self-explanatory.
- Compute temp/profile cannot use vz for 2d systemx*
Self-explanatory.
- Compute temp/sphere requires atom style sphere*
Self-explanatory.
- Compute ti kspace style does not exist*
Self-explanatory.
- Compute ti pair style does not exist*
Self-explanatory.
- Compute ti tail when pair style does not compute tail corrections*
Self-explanatory.
- Compute torque/chunk does not use chunk/atom compute*
The style of the specified compute is not chunk/atom.
- Compute used in dump between runs is not current*
The compute was not invoked on the current timestep, therefore it cannot be used in a dump between runs.
- Compute used in variable between runs is not current*
Computes cannot be invoked by a variable in between runs. Thus they must have been evaluated on the last timestep of the previous run in order for their value(s) to be accessed. See the doc page for the variable command for more info.
- Compute used in variable thermo keyword between runs is not current*
Some thermo keywords rely on a compute to calculate their value(s). Computes cannot be invoked by a variable in between runs. Thus they must have been evaluated on the last timestep of the previous run in order for their value(s) to be accessed. See the doc page for the variable command for more info.
- Compute vcm/chunk does not use chunk/atom compute*
The style of the specified compute is not chunk/atom.
- Computed temperature for fix temp/berendsen cannot be 0.0*
Self-explanatory.
- Computed temperature for fix temp/rescale cannot be 0.0*
Cannot rescale the temperature to a new value if the current temperature is 0.0.
- Core/shell partner atom not found*
Could not find one of the atoms in the bond pair.
- Core/shell partners were not all found*
Could not find or more atoms in the bond pairs.
- Could not adjust g_ewald_6*
The Newton-Raphson solver failed to converge to a good value for g_ewald. This error should not occur for typical problems. Please send an email to the developers.

LAMMPS Users Manual

Could not compute g_ewald

The Newton-Raphson solver failed to converge to a good value for g_ewald. This error should not occur for typical problems. Please send an email to the developers.

Could not compute grid size

The code is unable to compute a grid size consistent with the desired accuracy. This error should not occur for typical problems. Please send an email to the developers.

Could not compute grid size for Coulomb interaction

The code is unable to compute a grid size consistent with the desired accuracy. This error should not occur for typical problems. Please send an email to the developers.

Could not compute grid size for Dispersion

The code is unable to compute a grid size consistent with the desired accuracy. This error should not occur for typical problems. Please send an email to the developers.

Could not create 3d FFT plan

The FFT setup for the PPPM solver failed, typically due to lack of memory. This is an unusual error. Check the size of the FFT grid you are requesting.

Could not create 3d grid of processors

The specified constraints did not allow a Px by Py by Pz grid to be created where $P_x * P_y * P_z = P =$ total number of processors.

Could not create 3d remap plan

The FFT setup in pppm failed.

Could not create Python function arguments

This is an internal Python error, possibly because the number of inputs to the function is too large.

Could not create numa grid of processors

The specified constraints did not allow this style of grid to be created. Usually this is because the total processor count is not a multiple of the cores/node or the user specified processor count is > 1 in one of the dimensions.

Could not create twolevel 3d grid of processors

The specified constraints did not allow this style of grid to be created.

Could not evaluate Python function input variable

Self-explanatory.

Could not find Python function

The provided Python code was run successfully, but it not define a callable function with the required name.

Could not find atom_modify first group ID

Self-explanatory.

Could not find change_box group ID

Group ID used in the change_box command does not exist.

Could not find compute ID for PRD

Self-explanatory.

Could not find compute ID for TAD

Self-explanatory.

Could not find compute ID for temperature bias

Self-explanatory.

Could not find compute ID to delete

Self-explanatory.

Could not find compute displace/atom fix ID

LAMMPS Users Manual

- Self-explanatory.

Self-explanatory.
- Could not find dump modify fix ID*
Self-explanatory.
- Could not find dump modify variable name*
Self-explanatory.

LAMMPS Users Manual

Could not find fix ID to delete

Self-explanatory.

Could not find fix adapt storage fix ID

This should not happen unless you explicitly deleted a secondary fix that fix adapt created internally.

Could not find fix gcmc exclusion group ID

Self-explanatory.

Could not find fix gcmc rotation group ID

Self-explanatory.

Could not find fix group ID

A group ID used in the fix command does not exist.

Could not find fix msst compute ID

Self-explanatory.

Could not find fix poems group ID

A group ID used in the fix poems command does not exist.

Could not find fix recenter group ID

A group ID used in the fix recenter command does not exist.

Could not find fix rigid group ID

A group ID used in the fix rigid command does not exist.

Could not find fix srd group ID

Self-explanatory.

Could not find fix_modify ID

A fix ID used in the fix_modify command does not exist.

Could not find fix_modify pressure ID

The compute ID for computing pressure does not exist.

Could not find fix_modify temperature ID

The compute ID for computing temperature does not exist.

Could not find group clear group ID

Self-explanatory.

Could not find group delete group ID

Self-explanatory.

Could not find pair fix ID

A fix is created internally by the pair style to store shear history information. You cannot delete it.

Could not find set group ID

Group ID specified in set command does not exist.

Could not find specified fix gcmc group ID

Self-explanatory.

Could not find thermo compute ID

Compute ID specified in thermo_style command does not exist.

Could not find thermo custom compute ID

The compute ID needed by thermo style custom to compute a requested quantity does not exist.

Could not find thermo custom fix ID

The fix ID needed by thermo style custom to compute a requested quantity does not exist.

Could not find thermo custom variable name

Self-explanatory.

Could not find thermo fix ID

Fix ID specified in thermo_style command does not exist.

Could not find thermo variable name

LAMMPS Users Manual

- Self-explanatory.
- Could not find thermo_modify pressure ID*
The compute ID needed by thermo style custom to compute pressure does not exist.
- Could not find thermo_modify temperature ID*
The compute ID needed by thermo style custom to compute temperature does not exist.
- Could not find undump ID*
A dump ID used in the undump command does not exist.
- Could not find velocity group ID*
A group ID used in the velocity command does not exist.
- Could not find velocity temperature ID*
The compute ID needed by the velocity command to compute temperature does not exist.
- Could not find/initialize a specified accelerator device*
Could not initialize at least one of the devices specified for the gpu package
- Could not grab element entry from EIM potential file*
Self-explanatory
- Could not grab global entry from EIM potential file*
Self-explanatory.
- Could not grab pair entry from EIM potential file*
Self-explanatory.
- Could not initialize embedded Python*
The main module in Python was not accessible.
- Could not open Python file*
The specified file of Python code cannot be opened. Check that the path and name are correct.
- Could not process Python file*
The Python code in the specified file was not run successfully by Python, probably due to errors in the Python code.
- Could not process Python string*
The Python code in the here string was not run successfully by Python, probably due to errors in the Python code.
- Coulomb PPPMDisp order has been reduced below minorder*
The default minimum order is 2. This can be reset by the kspace_modify minorder command.
- Coulomb cut not supported in pair_style buck/long/coul/coul*
Must use long-range Coulombic interactions.
- Coulomb cut not supported in pair_style lj/long/coul/long*
Must use long-range Coulombic interactions.
- Coulomb cut not supported in pair_style lj/long/tip4p/long*
Must use long-range Coulombic interactions.
- Coulomb cutoffs of pair hybrid sub-styles do not match*
If using a Kspace solver, all Coulomb cutoffs of long pair styles must be the same.
- Coulombic cut not supported in pair_style lj/long/dipole/long*
Must use long-range Coulombic interactions.
- Could not find dump_modify ID*
Self-explanatory.
- Create_atoms command before simulation box is defined*

LAMMPS Users Manual

The `create_atoms` command cannot be used before a `read_data`, `read_restart`, or `create_box` command.

Create_atoms_molecule has atom IDs, but system does not

The `atom_style id` command can be used to force atom IDs to be stored.

Create_atoms_molecule must have atom types

The defined molecule does not specify atom types.

Create_atoms_molecule must have coordinates

The defined molecule does not specify coordinates.

Create_atoms_region ID does not exist

A region ID used in the `create_atoms` command does not exist.

Create_bonds command before simulation box is defined

Self-explanatory.

Create_bonds command requires no kspace_style be defined

This is so that atom pairs that are already bonded to not appear in the neighbor list.

Create_bonds command requires special_bonds 1-2 weights be 0.0

This is so that atom pairs that are already bonded to not appear in the neighbor list.

Create_bonds max distance > neighbor cutoff

Can only create bonds for atom pairs that will be in neighbor list.

Create_bonds requires a pair style be defined

Self-explanatory.

Create_box region ID does not exist

Self-explanatory.

Create_box region does not support a bounding box

Not all regions represent bounded volumes. You cannot use such a region with the `create_box` command.

Custom floating point vector for fix store/state does not exist

The command is accessing a vector added by the `fix property/atom` command, that does not exist.

Custom integer vector for fix store/state does not exist

The command is accessing a vector added by the `fix property/atom` command, that does not exist.

Custom per-atom property ID is not floating point

Self-explanatory.

Custom per-atom property ID is not integer

Self-explanatory.

Cut-offs missing in pair_style lj/long/dipole/long

Self-explanatory.

Cutoffs missing in pair_style buck/long/coul/long

Self-explanatory.

Cutoffs missing in pair_style lj/long/coul/long

Self-explanatory.

Cyclic loop in joint connections

Fix poems cannot (yet) work with coupled bodies whose joints connect the bodies in a ring (or cycle).

Degenerate lattice primitive vectors

Invalid set of 3 lattice vectors for `lattice` command.

Delete region ID does not exist

Self-explanatory.

Delete_atoms command before simulation box is defined

LAMMPS Users Manual

The `delete_atoms` command cannot be used before a `read_data`, `read_restart`, or `create_box` command.

Delete_atoms_cutoff > max_neighbor_cutoff

Can only delete atoms in atom pairs that will be in neighbor list.

Delete_atoms_mol yes requires atom attribute molecule

Cannot use this option with a non-molecular system.

Delete_atoms requires a pair style be defined

This is because atom deletion within a cutoff uses a pairwise neighbor list.

Delete_bonds command before simulation box is defined

The `delete_bonds` command cannot be used before a `read_data`, `read_restart`, or `create_box` command.

Delete_bonds command with no atoms existing

No atoms are yet defined so the `delete_bonds` command cannot be used.

Deposition region extends outside simulation box

Self-explanatory.

Did not assign all atoms correctly

Atoms read in from a data file were not assigned correctly to processors. This is likely due to some atom coordinates being outside a non-periodic simulation box.

Did not assign all restart atoms correctly

Atoms read in from the restart file were not assigned correctly to processors. This is likely due to some atom coordinates being outside a non-periodic simulation box. Normally this should not happen. You may wish to use the "remap" option on the `read_restart` command to see if this helps.

Did not find all elements in MEAM library file

The requested elements were not found in the MEAM file.

Did not find fix shake partner info

Could not find bond partners implied by `fix shake` command. This error can be triggered if the `delete_bonds` command was used before `fix shake`, and it removed bonds without resetting the 1-2, 1-3, 1-4 weighting list via the special keyword.

Did not find keyword in table file

Keyword used in `pair_coeff` command was not found in table file.

Did not set pressure for fix rigid/nph

The `press` keyword must be specified.

Did not set temp for fix rigid/nvt/small

Self-explanatory.

Did not set temp or press for fix rigid/npt/small

Self-explanatory.

Did not set temperature for fix rigid/nvt

The `temp` keyword must be specified.

Did not set temperature or pressure for fix rigid/npt

The `temp` and `press` keywords must be specified.

Dihedral atom missing in delete_bonds

The `delete_bonds` command cannot find one or more atoms in a particular dihedral on a particular processor. The pairwise cutoff is too short or the atoms are too far apart to make a valid dihedral.

Dihedral atom missing in set command

The `set` command cannot find one or more atoms in a particular dihedral on a particular processor. The pairwise cutoff is too short or the atoms are too far apart to make a valid dihedral.

LAMMPS Users Manual

Dihedral atoms %d %d %d %d missing on proc %d at step %ld

One or more of 4 atoms needed to compute a particular dihedral are missing on this processor. Typically this is because the pairwise cutoff is set too short or the dihedral has blown apart and an atom is too far away.

Dihedral atoms missing on proc %d at step %ld

One or more of 4 atoms needed to compute a particular dihedral are missing on this processor. Typically this is because the pairwise cutoff is set too short or the dihedral has blown apart and an atom is too far away.

Dihedral charmm is incompatible with Pair style

Dihedral style charmm must be used with a pair style charmm in order for the 1-4 epsilon/sigma parameters to be defined.

Dihedral coeff for hybrid has invalid style

Dihedral style hybrid uses another dihedral style as one of its coefficients. The dihedral style used in the dihedral_coeff command or read from a restart file is not recognized.

Dihedral coeffs are not set

No dihedral coefficients have been assigned in the data file or via the dihedral_coeff command.

Dihedral style hybrid cannot have hybrid as an argument

Self-explanatory.

Dihedral style hybrid cannot have none as an argument

Self-explanatory.

Dihedral style hybrid cannot use same dihedral style twice

Self-explanatory.

Dihedral/improper extent > half of periodic box length

This error was detected by the neigh_modify check yes setting. It is an error because the dihedral atoms are so far apart it is ambiguous how it should be defined.

Dihedral_coeff command before dihedral_style is defined

Coefficients cannot be set in the data file or via the dihedral_coeff command until an dihedral_style has been assigned.

Dihedral_coeff command before simulation box is defined

The dihedral_coeff command cannot be used before a read_data, read_restart, or create_box command.

Dihedral_coeff command when no divedrals allowed

The chosen atom style does not allow for divedrals to be defined.

Dihedral_style command when no divedrals allowed

The chosen atom style does not allow for divedrals to be defined.

Divedrals assigned incorrectly

Divedrals read in from the data file were not assigned correctly to atoms. This means there is something invalid about the topology definitions.

Divedrals defined but no dihedral types

The data file header lists divedrals but no dihedral types.

Dimension command after simulation box is defined

The dimension command cannot be used after a read_data, read_restart, or create_box command.

Dispersion PPPMDisp order has been reduced below minorder

The default minimum order is 2. This can be reset by the kspace_modify minorder command.

Displace_atoms command before simulation box is defined

LAMMPS Users Manual

The `displace_atoms` command cannot be used before a `read_data`, `read_restart`, or `create_box` command.

Distance must be > 0 for compute event/displace

Self-explanatory.

Divide by 0 in influence function

This should not normally occur. It is likely a problem with your model.

Divide by 0 in influence function of pair peri/lps

This should not normally occur. It is likely a problem with your model.

Divide by 0 in variable formula

Self-explanatory.

Domain too large for neighbor bins

The domain has become extremely large so that neighbor bins cannot be used. Most likely, one or more atoms have been blown out of the simulation box to a great distance.

Double precision is not supported on this accelerator

Self-explanatory

Dump atom/gz only writes compressed files

The dump atom/gz output file name must have a .gz suffix.

Dump cfg arguments can not mix xs|ys|zs with xsu|ysu|zsu

Self-explanatory.

Dump cfg arguments must start with 'mass type xs ys zs' or 'mass type xsu ysu zsu'

This is a requirement of the CFG output format. See the dump cfg doc page for more details.

Dump cfg requires one snapshot per file

Use the wildcard "*" character in the filename.

Dump cfg/gz only writes compressed files

The dump cfg/gz output file name must have a .gz suffix.

Dump custom and fix not computed at compatible times

The fix must produce per-atom quantities on timesteps that dump custom needs them.

Dump custom compute does not calculate per-atom array

Self-explanatory.

Dump custom compute does not calculate per-atom vector

Self-explanatory.

Dump custom compute does not compute per-atom info

Self-explanatory.

Dump custom compute vector is accessed out-of-range

Self-explanatory.

Dump custom fix does not compute per-atom array

Self-explanatory.

Dump custom fix does not compute per-atom info

Self-explanatory.

Dump custom fix does not compute per-atom vector

Self-explanatory.

Dump custom fix vector is accessed out-of-range

Self-explanatory.

Dump custom variable is not atom-style variable

Only atom-style variables generate per-atom quantities, needed for dump output.

Dump custom/gz only writes compressed files

The dump custom/gz output file name must have a .gz suffix.

LAMMPS Users Manual

- Dump dcd of non-matching # of atoms*
Every snapshot written by dump dcd must contain the same # of atoms.
- Dump dcd requires sorting by atom ID*
Use the dump_modify sort command to enable this.
- Dump every variable returned a bad timestep*
The variable must return a timestep greater than the current timestep.
- Dump file MPI-IO output not allowed with % in filename*
This is because a % signifies one file per processor and MPI-IO creates one large file for all processors.
- Dump file does not contain requested snapshot*
Self-explanatory.
- Dump file is incorrectly formatted*
Self-explanatory.
- Dump image body yes requires atom style body*
Self-explanatory.
- Dump image bond not allowed with no bond types*
Self-explanatory.
- Dump image cannot perform sorting*
Self-explanatory.
- Dump image line requires atom style line*
Self-explanatory.
- Dump image persp option is not yet supported*
Self-explanatory.
- Dump image requires one snapshot per file*
Use a "*" in the filename.
- Dump image tri requires atom style tri*
Self-explanatory.
- Dump local and fix not computed at compatible times*
The fix must produce per-atom quantities on timesteps that dump local needs them.
- Dump local attributes contain no compute or fix*
Self-explanatory.
- Dump local cannot sort by atom ID*
This is because dump local does not really dump per-atom info.
- Dump local compute does not calculate local array*
Self-explanatory.
- Dump local compute does not calculate local vector*
Self-explanatory.
- Dump local compute does not compute local info*
Self-explanatory.
- Dump local compute vector is accessed out-of-range*
Self-explanatory.
- Dump local count is not consistent across input fields*
Every column of output must be the same length.
- Dump local fix does not compute local array*
Self-explanatory.
- Dump local fix does not compute local info*
Self-explanatory.
- Dump local fix does not compute local vector*
Self-explanatory.
- Dump local fix vector is accessed out-of-range*

LAMMPS Users Manual

- Self-explanatory.
- Dump modify bcolor not allowed with no bond types*
Self-explanatory.
- Dump modify bdiam not allowed with no bond types*
Self-explanatory.
- Dump modify compute ID does not compute per-atom array*
Self-explanatory.
- Dump modify compute ID does not compute per-atom info*
Self-explanatory.
- Dump modify compute ID does not compute per-atom vector*
Self-explanatory.
- Dump modify compute ID vector is not large enough*
Self-explanatory.
- Dump modify element names do not match atom types*
Number of element names must equal number of atom types.
- Dump modify fix ID does not compute per-atom array*
Self-explanatory.
- Dump modify fix ID does not compute per-atom info*
Self-explanatory.
- Dump modify fix ID does not compute per-atom vector*
Self-explanatory.
- Dump modify fix ID vector is not large enough*
Self-explanatory.
- Dump modify variable is not atom-style variable*
Self-explanatory.
- Dump sort column is invalid*
Self-explanatory.
- Dump xtc requires sorting by atom ID*
Use the `dump_modify sort` command to enable this.
- Dump xyz/gz only writes compressed files*
The `dump xyz/gz` output file name must have a `.gz` suffix.
- Dump_modify buffer yes not allowed for this style*
Self-explanatory.
- Dump_modify format string is too short*
There are more fields to be dumped in a line of output than your format string specifies.
- Dump_modify region ID does not exist*
Self-explanatory.
- Dumping an atom property that isn't allocated*
The chosen atom style does not define the per-atom quantity being dumped.
- Duplicate atom IDs exist*
Self-explanatory.
- Duplicate fields in read_dump command*
Self-explanatory.
- Duplicate particle in PeriDynamic bond - simulation box is too small*
This is likely because your box length is shorter than 2 times the bond length.
- Electronic temperature dropped below zero*
Something has gone wrong with the `fix ttm` electron temperature model.
- Element not defined in potential file*
The specified element is not in the potential file.
- Empty brackets in variable*

LAMMPS Users Manual

There is no variable syntax that uses empty brackets. Check the variable doc page.

Energy was not tallied on needed timestep

You are using a thermo keyword that requires potentials to have tallied energy, but they didn't on this timestep. See the variable doc page for ideas on how to make this work.

Epsilon or sigma reference not set by pair style in PPPMDisp

Self-explanatory.

Epsilon or sigma reference not set by pair style in ewald/n

The pair style is not providing the needed epsilon or sigma values.

Error in vdw spline: inner radius > outer radius

A pre-tabulated spline is invalid. Likely a problem with the potential parameters.

Error writing averaged chunk data

Something in the output to the file triggered an error.

Error writing file header

Something in the output to the file triggered an error.

Error writing out correlation data

Something in the output to the file triggered an error.

Error writing out histogram data

Something in the output to the file triggered an error.

Error writing out time averaged data

Something in the output to the file triggered an error.

Failed to allocate %ld bytes for array %s

Your LAMMPS simulation has run out of memory. You need to run a smaller simulation or on more processors.

Failed to open FFmpeg pipeline to file %s

The specified file cannot be opened. Check that the path and name are correct and writable and that the FFmpeg executable can be found and run.

Failed to reallocate %ld bytes for array %s

Your LAMMPS simulation has run out of memory. You need to run a smaller simulation or on more processors.

Fewer SRD bins than processors in some dimension

This is not allowed. Make your SRD bin size smaller.

File variable could not read value

Check the file assigned to the variable.

Final box dimension due to fix deform is < 0.0

Self-explanatory.

Fix %s does not allow use of dynamic group

Dynamic groups have not yet been enabled for this fix.

Fix ID for compute chunk/atom does not exist

Self-explanatory.

Fix ID for compute erotate/rigid does not exist

Self-explanatory.

Fix ID for compute ke/rigid does not exist

Self-explanatory.

Fix ID for compute reduce does not exist

Self-explanatory.

Fix ID for compute slice does not exist

Self-explanatory.

Fix ID for fix ave/atom does not exist

- Self-explanatory.
- Fix ID for fix ave/chunk does not exist*
Self-explanatory.

Self-explanatory.
- Fix ID for fix ave/time does not exist*
Self-explanatory.
- Fix ID for fix store/state does not exist*
Self-explanatory
- Fix ID for fix vector does not exist*
Self-explanatory.
- Fix ID for read_data does not exist*
Self-explanatory.
- Fix ID for velocity does not exist*
Self-explanatory.
- Fix ID must be alphanumeric or underscore characters*
Self-explanatory.
- Fix SRD: bad bin assignment for SRD advection*
Something has gone wrong in your SRD model; try using more conservative settings.
- Fix SRD: bad search bin assignment*
Something has gone wrong in your SRD model; try using more conservative settings.
- Fix SRD: bad stencil bin for big particle*
Something has gone wrong in your SRD model; try using more conservative settings.
- Fix SRD: too many big particles in bin*
Reset the ATOMPERBIN parameter at the top of fix_srd.cpp to a larger value, and re-compile the code.
- Fix SRD: too many walls in bin*
This should not happen unless your system has been setup incorrectly.
- Fix adapt interface to this pair style not supported*
New coding for the pair style would need to be done.
- Fix adapt kspace style does not exist*
Self-explanatory.
- Fix adapt pair style does not exist*
Self-explanatory
- Fix adapt pair style param not supported*
The pair style does not know about the parameter you specified.
- Fix adapt requires atom attribute charge*
The atom style being used does not specify an atom charge.
- Fix adapt requires atom attribute diameter*
The atom style being used does not specify an atom diameter.
- Fix adapt type pair range is not valid for pair hybrid sub-style*
Self-explanatory.
- Fix append/atoms requires a lattice be defined*
Use the lattice command for this purpose.

LAMMPS Users Manual

- Fix ave/atom compute array is accessed out-of-range*
Self-explanatory.
- Fix ave/atom compute does not calculate a per-atom array*
Self-explanatory.
- Fix ave/atom compute does not calculate a per-atom vector*
A compute used by fix ave/atom must generate per-atom values.
- Fix ave/atom compute does not calculate per-atom values*
A compute used by fix ave/atom must generate per-atom values.
- Fix ave/atom fix array is accessed out-of-range*
Self-explanatory.
- Fix ave/atom fix does not calculate a per-atom array*
Self-explanatory.
- Fix ave/atom fix does not calculate a per-atom vector*
A fix used by fix ave/atom must generate per-atom values.
- Fix ave/atom fix does not calculate per-atom values*
A fix used by fix ave/atom must generate per-atom values.
- Fix ave/atom variable is not atom-style variable*
A variable used by fix ave/atom must generate per-atom values.
- Fix ave/chunk compute does not calculate a per-atom array*
Self-explanatory.
- Fix ave/chunk compute does not calculate a per-atom vector*
Self-explanatory.
- Fix ave/chunk compute does not calculate per-atom values*
Self-explanatory.
- Fix ave/chunk compute vector is accessed out-of-range*
Self-explanatory.
- Fix ave/chunk does not use chunk/atom compute*
The specified compute is not for a compute chunk/atom command.
- Fix ave/chunk fix does not calculate a per-atom array*
Self-explanatory.
- Fix ave/chunk fix does not calculate a per-atom vector*
Self-explanatory.
- Fix ave/chunk fix does not calculate per-atom values*
Self-explanatory.
- Fix ave/chunk fix vector is accessed out-of-range*
Self-explanatory.
- Fix ave/chunk variable is not atom-style variable*
Self-explanatory.
- Fix ave/correlate compute does not calculate a scalar*
Self-explanatory.
- Fix ave/correlate compute does not calculate a vector*
Self-explanatory.
- Fix ave/correlate compute vector is accessed out-of-range*
The index for the vector is out of bounds.
- Fix ave/correlate fix does not calculate a scalar*
Self-explanatory.
- Fix ave/correlate fix does not calculate a vector*
Self-explanatory.
- Fix ave/correlate fix vector is accessed out-of-range*
The index for the vector is out of bounds.
- Fix ave/correlate variable is not equal-style variable*

LAMMPS Users Manual

Self-explanatory.
Fix ave/histo fix does not calculate per-atom values
Self-explanatory.
Fix ave/histo fix vector is accessed out-of-range
Self-explanatory.
Fix ave/histo input is invalid compute
Self-explanatory.

LAMMPS Users Manual

Fix ave/histo input is invalid fix

Self-explanatory.

Fix ave/histo input is invalid variable

Self-explanatory.

Fix ave/histo inputs are not all global, peratom, or local

All inputs in a single fix ave/histo command must be of the same style.

Fix ave/histo/weight value and weight vector lengths do not match

Self-explanatory.

Fix ave/spatial compute does not calculate a per-atom array

Self-explanatory.

Fix ave/spatial compute does not calculate a per-atom vector

A compute used by fix ave/spatial must generate per-atom values.

Fix ave/spatial compute does not calculate per-atom values

A compute used by fix ave/spatial must generate per-atom values.

Fix ave/spatial compute vector is accessed out-of-range

The index for the vector is out of bounds.

Fix ave/spatial fix does not calculate a per-atom array

Self-explanatory.

Fix ave/spatial fix does not calculate a per-atom vector

A fix used by fix ave/spatial must generate per-atom values.

Fix ave/spatial fix does not calculate per-atom values

A fix used by fix ave/spatial must generate per-atom values.

Fix ave/spatial fix vector is accessed out-of-range

The index for the vector is out of bounds.

Fix ave/spatial for triclinic boxes requires units reduced

Self-explanatory.

Fix ave/spatial settings invalid with changing box size

If the box size changes, only the units reduced option can be used.

Fix ave/spatial variable is not atom-style variable

A variable used by fix ave/spatial must generate per-atom values.

Fix ave/time cannot set output array intensive/extensive from these inputs

One of more of the vector inputs has individual elements which are flagged as intensive or extensive. Such an input cannot be flagged as all intensive/extensive when turned into an array by fix ave/time.

Fix ave/time cannot use variable with vector mode

Variables produce scalar values.

Fix ave/time columns are inconsistent lengths

Self-explanatory.

Fix ave/time compute array is accessed out-of-range

An index for the array is out of bounds.

Fix ave/time compute does not calculate a scalar

Self-explanatory.

Fix ave/time compute does not calculate a vector

Self-explanatory.

Fix ave/time compute does not calculate an array

Self-explanatory.

Fix ave/time compute vector is accessed out-of-range

The index for the vector is out of bounds.

Fix ave/time fix array cannot be variable length

Self-explanatory.

Fix ave/time fix array is accessed out-of-range

LAMMPS Users Manual

- An index for the array is out of bounds.
Fix ave/time fix does not calculate a scalar
Self-explanatory.
- Fix ave/time fix does not calculate a vector*
Self-explanatory.
- Fix ave/time fix does not calculate an array*
Self-explanatory.
- Fix ave/time fix vector cannot be variable length*
Self-explanatory.
- Fix ave/time fix vector is accessed out-of-range*
The index for the vector is out of bounds.
- Fix ave/time variable is not equal-style variable*
Self-explanatory.
- Fix balance rcb cannot be used with comm_style brick*
Comm_style tiled must be used instead.
- Fix balance shift string is invalid*
The string can only contain the characters "x", "y", or "z".
- Fix bond/break needs ghost atoms from further away*
This is because the fix needs to walk bonds to a certain distance to acquire needed info, The comm_modify cutoff command can be used to extend the communication range.
- Fix bond/create angle type is invalid*
Self-explanatory.
- Fix bond/create cutoff is longer than pairwise cutoff*
This is not allowed because bond creation is done using the pairwise neighbor list.
- Fix bond/create dihedral type is invalid*
Self-explanatory.
- Fix bond/create improper type is invalid*
Self-explanatory.
- Fix bond/create induced too many angles/dihedrals/impropers per atom*
See the read_data command for info on using the "extra/angle/per/atom", (or dihedral, improper) keywords to allow for additional angles, dihedrals, and impropers to be formed.
- Fix bond/create needs ghost atoms from further away*
This is because the fix needs to walk bonds to a certain distance to acquire needed info, The comm_modify cutoff command can be used to extend the communication range.
- Fix bond/swap cannot use dihedral or improper styles*
These styles cannot be defined when using this fix.
- Fix bond/swap requires pair and bond styles*
Self-explanatory.
- Fix bond/swap requires special_bonds = 0,1,1*
Self-explanatory.
- Fix box/relax generated negative box length*
The pressure being applied is likely too large. Try applying it incrementally, to build to the high pressure.
- Fix command before simulation box is defined*
The fix command cannot be used before a read_data, read_restart, or create_box command.
- Fix deform cannot use yz variable with xy*

LAMMPS Users Manual

The yz setting cannot be a variable if xy deformation is also specified. This is because LAMMPS cannot determine if the yz setting will induce a box flip which would be invalid if xy is also changing.

Fix deform is changing yz too much with xy

When both yz and xy are changing, it induces changes in xz if the box must flip from one tilt extreme to another. Thus it is not allowed for yz to grow so much that a flip is induced.

Fix deform tilt factors require triclinic box

Cannot deform the tilt factors of a simulation box unless it is a triclinic (non-orthogonal) box.

Fix deform volume setting is invalid

Cannot use volume style unless other dimensions are being controlled.

Fix deposit and fix rigid/small not using same molecule template ID

Self-explanatory.

Fix deposit and fix shake not using same molecule template ID

Self-explanatory.

Fix deposit molecule must have atom types

The defined molecule does not specify atom types.

Fix deposit molecule must have coordinates

The defined molecule does not specify coordinates.

Fix deposit molecule template ID must be same as atom_style template ID

When using atom_style template, you cannot deposit molecules that are not in that template.

Fix deposit region cannot be dynamic

Only static regions can be used with fix deposit.

Fix deposit region does not support a bounding box

Not all regions represent bounded volumes. You cannot use such a region with the fix deposit command.

Fix deposit shake fix does not exist

Self-explanatory.

Fix efield requires atom attribute q or mu

The atom style defined does not have this attribute.

Fix efield with dipoles cannot use atom-style variables

This option is not supported.

Fix evaporate molecule requires atom attribute molecule

The atom style being used does not define a molecule ID.

Fix external callback function not set

This must be done by an external program in order to use this fix.

Fix for fix ave/atom not computed at compatible time

Fixes generate their values on specific timesteps. Fix ave/atom is requesting a value on a non-allowed timestep.

Fix for fix ave/chunk not computed at compatible time

Fixes generate their values on specific timesteps. Fix ave/chunk is requesting a value on a non-allowed timestep.

Fix for fix ave/correlate not computed at compatible time

Fixes generate their values on specific timesteps. Fix ave/correlate is requesting a value on a non-allowed timestep.

Fix for fix ave/histo not computed at compatible time

Fixes generate their values on specific timesteps. Fix ave/histo is requesting a value on a non-allowed timestep.

Fix for fix ave/spatial not computed at compatible time

LAMMPS Users Manual

Fixes generate their values on specific timesteps. Fix ave/spatial is requesting a value on a non-allowed timestep.

Fix for fix ave/time not computed at compatible time

Fixes generate their values on specific timesteps. Fix ave/time is requesting a value on a non-allowed timestep.

Fix for fix store/state not computed at compatible time

Fixes generate their values on specific timesteps. Fix store/state is requesting a value on a non-allowed timestep.

Fix for fix vector not computed at compatible time

Fixes generate their values on specific timesteps. Fix vector is requesting a value on a non-allowed timestep.

Fix freeze requires atom attribute torque

The atom style defined does not have this attribute.

Fix gcmc and fix shake not using same molecule template ID

Self-explanatory.

Fix gcmc atom has charge, but atom style does not

Self-explanatory.

Fix gcmc cannot exchange individual atoms belonging to a molecule

This is an error since you should not delete only one atom of a molecule. The user has specified atomic (non-molecular) gas exchanges, but an atom belonging to a molecule could be deleted.

Fix gcmc does not (yet) work with atom_style template

Self-explanatory.

Fix gcmc molecule command requires that atoms have molecule attributes

Should not choose the gcmc molecule feature if no molecules are being simulated. The general molecule flag is off, but gcmc's molecule flag is on.

Fix gcmc molecule has charges, but atom style does not

Self-explanatory.

Fix gcmc molecule must have atom types

The defined molecule does not specify atom types.

Fix gcmc molecule must have coordinates

The defined molecule does not specify coordinates.

Fix gcmc molecule template ID must be same as atom_style template ID

When using atom_style template, you cannot insert molecules that are not in that template.

Fix gcmc put atom outside box

This should not normally happen. Contact the developers.

Fix gcmc ran out of available atom IDs

See the setting for tagint in the src/lmptype.h file.

Fix gcmc ran out of available molecule IDs

See the setting for tagint in the src/lmptype.h file.

Fix gcmc region cannot be dynamic

Only static regions can be used with fix gcmc.

Fix gcmc region does not support a bounding box

Not all regions represent bounded volumes. You cannot use such a region with the fix gcmc command.

Fix gcmc region extends outside simulation box

Self-explanatory.

Fix gcmc shake fix does not exist

Self-explanatory.

Fix gld c coefficients must be ≥ 0

- Self-explanatory.
- Fix gld needs more prony series coefficients*
Self-explanatory.
- Fix gld prony terms must be > 0*
Self-explanatory.
- Fix gld series type must be pprony for now*
Self-explanatory.
- Fix gld start temperature must be >= 0*
Self-explanatory.
- Fix gld stop temperature must be >= 0*
Self-explanatory.
- Fix gld tau coefficients must be > 0*
Self-explanatory.
- Fix heat group has no atoms*
Self-explanatory.
- Fix heat kinetic energy of an atom went negative*
This will cause the velocity rescaling about to be performed by fix heat to be invalid.
- Fix heat kinetic energy went negative*
This will cause the velocity rescaling about to be performed by fix heat to be invalid.
- Fix in variable not computed at compatible time*
Fixes generate their values on specific timesteps. The variable is requesting the values on a non-allowed timestep.
- Fix langevin angmom is not yet implemented with kokkos*
This option is not yet available.
- Fix langevin angmom requires atom style ellipsoid*
Self-explanatory.
- Fix langevin angmom requires extended particles*
This fix option cannot be used with point particles.
- Fix langevin omega is not yet implemented with kokkos*
This option is not yet available.
- Fix langevin omega requires atom style sphere*
Self-explanatory.
- Fix langevin omega requires extended particles*
One of the particles has radius 0.0.
- Fix langevin period must be > 0.0*
The time window for temperature relaxation must be > 0
- Fix langevin variable returned negative temperature*
Self-explanatory.
- Fix momentum group has no atoms*
Self-explanatory.
- Fix move cannot define z or vz variable for 2d problem*
Self-explanatory.
- Fix move cannot rotate around non z-axis for 2d problem*
Self-explanatory.
- Fix move cannot set linear z motion for 2d problem*
Self-explanatory.
- Fix move cannot set wiggle z motion for 2d problem*
Self-explanatory.
- Fix msst compute ID does not compute potential energy*

LAMMPS Users Manual

Self-explanatory.

Fix msst compute ID does not compute pressure

Self-explanatory.

Fix msst compute ID does not compute temperature

Self-explanatory.

Fix msst requires a periodic box

Self-explanatory.

Fix msst tscale must satisfy $0 \leq tscale < 1$

Self-explanatory.

Fix npt/nph has tilted box too far in one step - periodic cell is too far from equilibrium state

Self-explanatory. The change in the box tilt is too extreme on a short timescale.

Fix nve/asphere requires extended particles

This fix can only be used for particles with a shape setting.

Fix nve/asphere/noforce requires atom style ellipsoid

Self-explanatory.

Fix nve/asphere/noforce requires extended particles

One of the particles is not an ellipsoid.

Fix nve/body requires atom style body

Self-explanatory.

Fix nve/body requires bodies

This fix can only be used for particles that are bodies.

Fix nve/line can only be used for 2d simulations

Self-explanatory.

Fix nve/line requires atom style line

Self-explanatory.

Fix nve/line requires line particles

Self-explanatory.

Fix nve/sphere dipole requires atom attribute mu

An atom style with this attribute is needed.

Fix nve/sphere requires atom style sphere

Self-explanatory.

Fix nve/sphere requires extended particles

This fix can only be used for particles of a finite size.

Fix nve/tri can only be used for 3d simulations

Self-explanatory.

Fix nve/tri requires atom style tri

Self-explanatory.

Fix nve/tri requires tri particles

Self-explanatory.

Fix nvt/nph/npt asphere requires extended particles

The shape setting for a particle in the fix group has shape = 0.0, which means it is a point particle.

Fix nvt/nph/npt body requires bodies

Self-explanatory.

Fix nvt/nph/npt sphere requires atom style sphere

Self-explanatory.

Fix nvt/npt/nph damping parameters must be > 0.0

Self-explanatory.

Fix nvt/npt/nph dilate group ID does not exist

Self-explanatory.

LAMMPS Users Manual

Fix nvt/sphere requires extended particles

This fix can only be used for particles of a finite size.

Fix orient/fcc file open failed

The fix orient/fcc command could not open a specified file.

Fix orient/fcc file read failed

The fix orient/fcc command could not read the needed parameters from a specified file.

Fix orient/fcc found self twice

The neighbor lists used by fix orient/fcc are messed up. If this error occurs, it is likely a bug, so send an email to the [developers](#).

Fix peri neigh does not exist

Somehow a fix that the pair style defines has been deleted.

Fix pour and fix rigid/small not using same molecule template ID

Self-explanatory.

Fix pour and fix shake not using same molecule template ID

Self-explanatory.

Fix pour insertion count per timestep is 0

Self-explanatory.

Fix pour molecule must have atom types

The defined molecule does not specify atom types.

Fix pour molecule must have coordinates

The defined molecule does not specify coordinates.

Fix pour molecule template ID must be same as atom style template ID

When using atom_style template, you cannot pour molecules that are not in that template.

Fix pour polydisperse fractions do not sum to 1.0

Self-explanatory.

Fix pour region ID does not exist

Self-explanatory.

Fix pour region cannot be dynamic

Only static regions can be used with fix pour.

Fix pour region does not support a bounding box

Not all regions represent bounded volumes. You cannot use such a region with the fix pour command.

Fix pour requires atom attributes radius, rmass

The atom style defined does not have these attributes.

Fix pour rigid fix does not exist

Self-explanatory.

Fix pour shake fix does not exist

Self-explanatory.

Fix press/berendsen damping parameters must be > 0.0

Self-explanatory.

Fix property/atom cannot specify mol twice

Self-explanatory.

Fix property/atom cannot specify q twice

Self-explanatory.

Fix property/atom mol when atom_style already has molecule attribute

Self-explanatory.

Fix property/atom q when atom_style already has charge attribute

Self-explanatory.

Fix property/atom vector name already exists

LAMMPS Users Manual

- The name for an integer or floating-point vector must be unique.
- Fix qeq has negative upper Taper radius cutoff*
Self-explanatory.
- Fix qeq/comb group has no atoms*
Self-explanatory.
- Fix qeq/comb requires atom attribute q*
An atom style with charge must be used to perform charge equilibration.
- Fix qeq/dynamic group has no atoms*
Self-explanatory.
- Fix qeq/dynamic requires atom attribute q*
Self-explanatory.
- Fix qeq/fire group has no atoms*
Self-explanatory.
- Fix qeq/fire requires atom attribute q*
Self-explanatory.
- Fix qeq/point group has no atoms*
Self-explanatory.
- Fix qeq/point has insufficient QEq matrix size*
Occurs when number of neighbor atoms for an atom increased too much during a run. Increase SAFE_ZONE and MIN_CAP in fix_qeq.h and recompile.
- Fix qeq/point requires atom attribute q*
Self-explanatory.
- Fix qeq/shielded group has no atoms*
Self-explanatory.
- Fix qeq/shielded has insufficient QEq matrix size*
Occurs when number of neighbor atoms for an atom increased too much during a run. Increase SAFE_ZONE and MIN_CAP in fix_qeq.h and recompile.
- Fix qeq/shielded requires atom attribute q*
Self-explanatory.
- Fix qeq/slater could not extract params from pair coul/streitz*
This should not happen unless pair coul/streitz has been altered.
- Fix qeq/slater group has no atoms*
Self-explanatory.
- Fix qeq/slater has insufficient QEq matrix size*
Occurs when number of neighbor atoms for an atom increased too much during a run. Increase SAFE_ZONE and MIN_CAP in fix_qeq.h and recompile.
- Fix qeq/slater requires atom attribute q*
Self-explanatory.
- Fix reax/bonds numbonds > nsbmax_most*
The limit of the number of bonds expected by the ReaxFF force field was exceeded.
- Fix recenter group has no atoms*
Self-explanatory.
- Fix restrain requires an atom map, see atom_modify*
Self-explanatory.
- Fix rigid atom has non-zero image flag in a non-periodic dimension*
Image flags for non-periodic dimensions should not be set.
- Fix rigid file has no lines*
Self-explanatory.
- Fix rigid langevin period must be > 0.0*
Self-explanatory.

LAMMPS Users Manual

- Fix rigid molecule requires atom attribute molecule*
Self-explanatory.
- Fix rigid npt/nph dilate group ID does not exist*
Self-explanatory.
- Fix rigid npt/nph does not yet allow triclinic box*
This is a current restriction in LAMMPS.
- Fix rigid npt/nph period must be > 0.0*
Self-explanatory.
- Fix rigid npt/small t_chain should not be less than 1*
Self-explanatory.
- Fix rigid npt/small t_order must be 3 or 5*
Self-explanatory.
- Fix rigid nvt/npt/nph damping parameters must be > 0.0*
Self-explanatory.
- Fix rigid nvt/small t_chain should not be less than 1*
Self-explanatory.
- Fix rigid nvt/small t_iter should not be less than 1*
Self-explanatory.
- Fix rigid nvt/small t_order must be 3 or 5*
Self-explanatory.
- Fix rigid xy torque cannot be on for 2d simulation*
Self-explanatory.
- Fix rigid z force cannot be on for 2d simulation*
Self-explanatory.
- Fix rigid/npt period must be > 0.0*
Self-explanatory.
- Fix rigid/npt temperature order must be 3 or 5*
Self-explanatory.
- Fix rigid/npt/small period must be > 0.0*
Self-explanatory.
- Fix rigid/nvt period must be > 0.0*
Self-explanatory.
- Fix rigid/nvt temperature order must be 3 or 5*
Self-explanatory.
- Fix rigid/nvt/small period must be > 0.0*
Self-explanatory.
- Fix rigid/small atom has non-zero image flag in a non-periodic dimension*
Image flags for non-periodic dimensions should not be set.
- Fix rigid/small langevin period must be > 0.0*
Self-explanatory.
- Fix rigid/small molecule must have atom types*
The defined molecule does not specify atom types.
- Fix rigid/small molecule must have coordinates*
The defined molecule does not specify coordinates.
- Fix rigid/small npt/nph period must be > 0.0*
Self-explanatory.
- Fix rigid/small nvt/npt/nph damping parameters must be > 0.0*
Self-explanatory.
- Fix rigid/small nvt/npt/nph dilate group ID does not exist*
Self-explanatory.
- Fix rigid/small requires an atom map, see atom_modify*

LAMMPS Users Manual

- Self-explanatory.
- Fix rigid/small requires atom attribute molecule*
Self-explanatory.
- Fix rigid: Bad principal moments*
The principal moments of inertia computed for a rigid body are not within the required tolerances.
- Fix shake cannot be used with minimization*
Cannot use fix shake while doing an energy minimization since it turns off bonds that should contribute to the energy.
- Fix shake molecule template must have shake info*
The defined molecule does not specify SHAKE information.
- Fix spring couple group ID does not exist*
Self-explanatory.
- Fix srd can only currently be used with comm_style brick*
This is a current restriction in LAMMPS.
- Fix srd lamda must be ≥ 0.6 of SRD grid size*
This is a requirement for accuracy reasons.
- Fix srd no-slip requires atom attribute torque*
This is because the SRD collisions will impart torque to the solute particles.
- Fix srd requires SRD particles all have same mass*
Self-explanatory.
- Fix srd requires ghost atoms store velocity*
Use the comm_modify vel yes command to enable this.
- Fix srd requires newton pair on*
Self-explanatory.
- Fix store/state compute array is accessed out-of-range*
Self-explanatory.
- Fix store/state compute does not calculate a per-atom array*
The compute calculates a per-atom vector.
- Fix store/state compute does not calculate a per-atom vector*
The compute calculates a per-atom vector.
- Fix store/state compute does not calculate per-atom values*
Computes that calculate global or local quantities cannot be used with fix store/state.
- Fix store/state fix array is accessed out-of-range*
Self-explanatory.
- Fix store/state fix does not calculate a per-atom array*
The fix calculates a per-atom vector.
- Fix store/state fix does not calculate a per-atom vector*
The fix calculates a per-atom array.
- Fix store/state fix does not calculate per-atom values*
Fixes that calculate global or local quantities cannot be used with fix store/state.
- Fix store/state for atom property that isn't allocated*
Self-explanatory.
- Fix store/state variable is not atom-style variable*
Only atom-style variables calculate per-atom quantities.
- Fix temp/berendsen period must be > 0.0*
Self-explanatory.
- Fix temp/berendsen variable returned negative temperature*
Self-explanatory.

LAMMPS Users Manual

Fix temp/csld is not compatible with fix rattle or fix shake

These two commands cannot currently be used together with fix temp/csld.

Fix temp/csld variable returned negative temperature

Self-explanatory.

Fix temp/csvr variable returned negative temperature

Self-explanatory.

Fix temp/rescale variable returned negative temperature

Self-explanatory.

Fix tfmc displacement length must be > 0

Self-explanatory.

Fix tfmc is not compatible with fix shake

These two commands cannot currently be used together.

Fix tfmc temperature must be > 0

Self-explanatory.

Fix thermal/conductivity swap value must be positive

Self-explanatory.

Fix tmd must come after integration fixes

Any fix tmd command must appear in the input script after all time integration fixes (nve, nvt, npt). See the fix tmd documentation for details.

Fix ttm electron temperatures must be > 0.0

Self-explanatory.

Fix ttm electronic_density must be > 0.0

Self-explanatory.

Fix ttm electronic_specific_heat must be > 0.0

Self-explanatory.

Fix ttm electronic_thermal_conductivity must be >= 0.0

Self-explanatory.

Fix ttm gamma_p must be > 0.0

Self-explanatory.

Fix ttm gamma_s must be >= 0.0

Self-explanatory.

Fix ttm number of nodes must be > 0

Self-explanatory.

Fix ttm v_0 must be >= 0.0

Self-explanatory.

Fix used in compute chunk/atom not computed at compatible time

The chunk/atom compute cannot query the output of the fix on a timestep it is needed.

Fix used in compute reduce not computed at compatible time

Fixes generate their values on specific timesteps. Compute reduce is requesting a value on a non-allowed timestep.

Fix used in compute slice not computed at compatible time

Fixes generate their values on specific timesteps. Compute slice is requesting a value on a non-allowed timestep.

Fix vector cannot set output array intensive/extensive from these inputs

The inputs to the command have conflicting intensive/extensive attributes. You need to use more than one fix vector command.

Fix vector compute does not calculate a scalar

Self-explanatory.

Fix vector compute does not calculate a vector

Self-explanatory.

LAMMPS Users Manual

- Fix vector compute vector is accessed out-of-range*
Self-explanatory.
- Fix vector fix does not calculate a scalar*
Self-explanatory.
- Fix vector fix does not calculate a vector*
Self-explanatory.
- Fix vector fix vector is accessed out-of-range*
Self-explanatory.
- Fix vector variable is not equal-style variable*
Self-explanatory.
- Fix viscosity swap value must be positive*
Self-explanatory.
- Fix viscosity vtarget value must be positive*
Self-explanatory.
- Fix wall cutoff ≤ 0.0*
Self-explanatory.
- Fix wall/colloid requires atom style sphere*
Self-explanatory.
- Fix wall/colloid requires extended particles*
One of the particles has radius 0.0.
- Fix wall/gran is incompatible with Pair style*
Must use a granular pair style to define the parameters needed for this fix.
- Fix wall/gran requires atom style sphere*
Self-explanatory.
- Fix wall/piston command only available at zlo*
The face keyword must be zlo.
- Fix wall/region colloid requires atom style sphere*
Self-explanatory.
- Fix wall/region colloid requires extended particles*
One of the particles has radius 0.0.
- Fix wall/region cutoff ≤ 0.0*
Self-explanatory.
- Fix_modify pressure ID does not compute pressure*
The compute ID assigned to the fix must compute pressure.
- Fix_modify temperature ID does not compute temperature*
The compute ID assigned to the fix must compute temperature.
- For triclinic deformation, specified target stress must be hydrostatic*
Triclinic pressure control is allowed using the tri keyword, but non-hydrostatic pressure control can not be used in this case.
- Found no restart file matching pattern*
When using a "*" in the restart file name, no matching file was found.
- GPU library not compiled for this accelerator*
Self-explanatory.
- GPU package does not (yet) work with atom_style template*
Self-explanatory.
- GPU particle split must be set to 1 for this pair style.*
For this pair style, you cannot run part of the force calculation on the host. See the package command.
- GPU split param must be positive for hybrid pair styles*
See the package gpu command.
- GPUs are requested but Kokkos has not been compiled for CUDA*

LAMMPS Users Manual

- Recompile Kokkos with CUDA support to use GPUs.
- Ghost velocity forward comm not yet implemented with Kokkos*
This is a current restriction.
- Gmask function in equal-style variable formula*
Gmask is per-atom operation.
- Gravity changed since fix pour was created*
The gravity vector defined by fix gravity must be static.
- Gravity must point in -y to use with fix pour in 2d*
Self-explanatory.
- Gravity must point in -z to use with fix pour in 3d*
Self-explanatory.
- Grmask function in equal-style variable formula*
Grmask is per-atom operation.
- Group ID does not exist*
A group ID used in the group command does not exist.
- Group ID in variable formula does not exist*
Self-explanatory.
- Group all cannot be made dynamic*
This operation is not allowed.
- Group command before simulation box is defined*
The group command cannot be used before a read_data, read_restart, or create_box command.
- Group dynamic cannot reference itself*
Self-explanatory.
- Group dynamic parent group cannot be dynamic*
Self-explanatory.
- Group dynamic parent group does not exist*
Self-explanatory.
- Group region ID does not exist*
A region ID used in the group command does not exist.
- If read_dump purges it cannot replace or trim*
These operations are not compatible. See the read_dump doc page for details.
- Illegal ... command*
Self-explanatory. Check the input script syntax and compare to the documentation for the command. You can use -echo screen as a command-line option when running LAMMPS to see the offending line.
- Illegal COMB parameter*
One or more of the coefficients defined in the potential file is invalid.
- Illegal COMB3 parameter*
One or more of the coefficients defined in the potential file is invalid.
- Illegal Stillinger-Weber parameter*
One or more of the coefficients defined in the potential file is invalid.
- Illegal Tersoff parameter*
One or more of the coefficients defined in the potential file is invalid.
- Illegal Vashishta parameter*
One or more of the coefficients defined in the potential file is invalid.
- Illegal compute voronoi/atom command (occupation and (surface or edges))*
Self-explanatory.
- Illegal coul/streitz parameter*
One or more of the coefficients defined in the potential file is invalid.
- Illegal dump_modify sfactor value (must be > 0.0)*

LAMMPS Users Manual

- Self-explanatory.
- Illegal dump_modify tfactor value (must be > 0.0)*
Self-explanatory.
- Illegal fix gcmc gas mass <= 0*
The computed mass of the designated gas molecule or atom type was less than or equal to zero.
- Illegal fix tfmc random seed*
Seeds can only be nonzero positive integers.
- Illegal fix wall/piston velocity*
The piston velocity must be positive.
- Illegal integrate style*
Self-explanatory.
- Illegal nb3b/harmonic parameter*
One or more of the coefficients defined in the potential file is invalid.
- Illegal number of angle table entries*
There must be at least 2 table entries.
- Illegal number of bond table entries*
There must be at least 2 table entries.
- Illegal number of pair table entries*
There must be at least 2 table entries.
- Illegal or unset periodicity in restart*
This error should not normally occur unless the restart file is invalid.
- Illegal range increment value*
The increment must be ≥ 1 .
- Illegal simulation box*
The lower bound of the simulation box is greater than the upper bound.
- Illegal size double vector read requested*
This error should not normally occur unless the restart file is invalid.
- Illegal size integer vector read requested*
This error should not normally occur unless the restart file is invalid.
- Illegal size string or corrupt restart*
This error should not normally occur unless the restart file is invalid.
- Imageint setting in lmptype.h is invalid*
Imageint must be as large or larger than smallint.
- Imageint setting in lmptype.h is not compatible*
Format of imageint stored in restart file is not consistent with LAMMPS version you are running. See the settings in src/lmptype.h
- Improper atom missing in delete_bonds*
The delete_bonds command cannot find one or more atoms in a particular improper on a particular processor. The pairwise cutoff is too short or the atoms are too far apart to make a valid improper.
- Improper atom missing in set command*
The set command cannot find one or more atoms in a particular improper on a particular processor. The pairwise cutoff is too short or the atoms are too far apart to make a valid improper.
- Improper atoms %d %d %d %d missing on proc %d at step %ld*
One or more of 4 atoms needed to compute a particular improper are missing on this processor. Typically this is because the pairwise cutoff is set too short or the improper has blown apart and an atom is too far away.
- Improper atoms missing on proc %d at step %ld*

LAMMPS Users Manual

One or more of 4 atoms needed to compute a particular improper are missing on this processor. Typically this is because the pairwise cutoff is set too short or the improper has blown apart and an atom is too far away.

Improper coeff for hybrid has invalid style

Improper style hybrid uses another improper style as one of its coefficients. The improper style used in the `improper_coeff` command or read from a restart file is not recognized.

Improper coeffs are not set

No improper coefficients have been assigned in the data file or via the `improper_coeff` command.

Improper style hybrid cannot have hybrid as an argument

Self-explanatory.

Improper style hybrid cannot have none as an argument

Self-explanatory.

Improper style hybrid cannot use same improper style twice

Self-explanatory.

Improper_coeff command before improper_style is defined

Coefficients cannot be set in the data file or via the `improper_coeff` command until an `improper_style` has been assigned.

Improper_coeff command before simulation box is defined

The `improper_coeff` command cannot be used before a `read_data`, `read_restart`, or `create_box` command.

Improper_coeff command when no impropers allowed

The chosen atom style does not allow for impropers to be defined.

Improper_style command when no impropers allowed

The chosen atom style does not allow for impropers to be defined.

Impropers assigned incorrectly

Impropers read in from the data file were not assigned correctly to atoms. This means there is something invalid about the topology definitions.

Impropers defined but no improper types

The data file header lists improper but no improper types.

Incomplete use of variables in create_atoms command

The `var` and `set` options must be used together.

Inconsistent iparam/jparam values in fix bond/create command

If `itype` and `jtype` are the same, then their `maxbond` and `newtype` settings must also be the same.

Inconsistent line segment in data file

The end points of the line segment are not equal distances from the center point which is the atom coordinate.

Inconsistent triangle in data file

The centroid of the triangle as defined by the corner points is not the atom coordinate.

Inconsistent use of finite-size particles by molecule template molecules

Not all of the molecules define a radius for their constituent particles.

Incorrect # of floating-point values in Bodies section of data file

See doc page for body style.

Incorrect # of integer values in Bodies section of data file

See doc page for body style.

Incorrect %s format in data file

A section of the data file being read by `fix property/atom` does not have the correct number of values per line.

LAMMPS Users Manual

Incorrect SNAP parameter file

The file cannot be parsed correctly, check its internal syntax.

Incorrect args for angle coefficients

Self-explanatory. Check the input script or data file.

Incorrect args for bond coefficients

Self-explanatory. Check the input script or data file.

Incorrect args for dihedral coefficients

Self-explanatory. Check the input script or data file.

Incorrect args for improper coefficients

Self-explanatory. Check the input script or data file.

Incorrect args for pair coefficients

Self-explanatory. Check the input script or data file.

Incorrect args in pair_style command

Self-explanatory.

Incorrect atom format in data file

Number of values per atom line in the data file is not consistent with the atom style.

Incorrect atom format in neb file

The number of fields per line is not what expected.

Incorrect bonus data format in data file

See the read_data doc page for a description of how various kinds of bonus data must be formatted for certain atom styles.

Incorrect boundaries with slab Ewald

Must have periodic x,y dimensions and non-periodic z dimension to use 2d slab option with Ewald.

Incorrect boundaries with slab EwaldDisp

Must have periodic x,y dimensions and non-periodic z dimension to use 2d slab option with Ewald.

Incorrect boundaries with slab PPPM

Must have periodic x,y dimensions and non-periodic z dimension to use 2d slab option with PPPM.

Incorrect boundaries with slab PPPMDisp

Must have periodic x,y dimensions and non-periodic z dimension to use 2d slab option with ppm/disp.

Incorrect element names in ADP potential file

The element names in the ADP file do not match those requested.

Incorrect element names in EAM potential file

The element names in the EAM file do not match those requested.

Incorrect format in COMB potential file

Incorrect number of words per line in the potential file.

Incorrect format in COMB3 potential file

Incorrect number of words per line in the potential file.

Incorrect format in MEAM potential file

Incorrect number of words per line in the potential file.

Incorrect format in SNAP coefficient file

Incorrect number of words per line in the coefficient file.

Incorrect format in SNAP parameter file

Incorrect number of words per line in the parameter file.

Incorrect format in Stillinger-Weber potential file

Incorrect number of words per line in the potential file.

Incorrect format in TMD target file

LAMMPS Users Manual

- Format of file read by fix tmd command is incorrect.
- Incorrect format in Tersoff potential file*
Incorrect number of words per line in the potential file.
- Incorrect format in Vashishta potential file*
Incorrect number of words per line in the potential file.
- Incorrect format in coul/streitz potential file*
Incorrect number of words per line in the potential file.
- Incorrect format in nb3b/harmonic potential file*
Incorrect number of words per line in the potential file.
- Incorrect integer value in Bodies section of data file*
See doc page for body style.
- Incorrect multiplicity arg for dihedral coefficients*
Self-explanatory. Check the input script or data file.
- Incorrect number of elements in potential file*
Self-explanatory.
- Incorrect rigid body format in fix rigid file*
The number of fields per line is not what expected.
- Incorrect rigid body format in fix rigid/small file*
The number of fields per line is not what expected.
- Incorrect sign arg for dihedral coefficients*
Self-explanatory. Check the input script or data file.
- Incorrect table format check for element types*
Self-explanatory.
- Incorrect velocity format in data file*
Each atom style defines a format for the Velocity section of the data file. The read-in lines do not match.
- Incorrect weight arg for dihedral coefficients*
Self-explanatory. Check the input script or data file.
- Index between variable brackets must be positive*
Self-explanatory.
- Indexed per-atom vector in variable formula without atom map*
Accessing a value from an atom vector requires the ability to lookup an atom index, which is provided by an atom map. An atom map does not exist (by default) for non-molecular problems. Using the atom_modify map command will force an atom map to be created.
- Initial temperatures not all set in fix ttm*
Self-explanatory.
- Input line quote not followed by whitespace*
An end quote must be followed by whitespace.
- Insertion region extends outside simulation box*
Self-explanatory.
- Insufficient Jacobi rotations for POEMS body*
Eigensolve for rigid body was not sufficiently accurate.
- Insufficient Jacobi rotations for body nparticle*
Eigensolve for rigid body was not sufficiently accurate.
- Insufficient Jacobi rotations for rigid body*
Eigensolve for rigid body was not sufficiently accurate.
- Insufficient Jacobi rotations for rigid molecule*
Eigensolve for rigid body was not sufficiently accurate.
- Insufficient Jacobi rotations for triangle*

LAMMPS Users Manual

The calculation of the inertia tensor of the triangle failed. This should not happen if it is a reasonably shaped triangle.

Insufficient memory on accelerator

There is insufficient memory on one of the devices specified for the gpu package

Internal error in atom_style body

This error should not occur. Contact the developers.

Invalid -reorder N value

Self-explanatory.

Invalid Angles section in molecule file

Invalid Dihedrals section in molecule file

Self-explanatory.

Invalid Impropers section in molecule file

Self-explanatory.

Invalid Kokkos command-line args

Self-explanatory. See Section 2.7 of the manual for details.

Invalid LAMMPS restart file

The file does not appear to be a LAMMPS restart file since it doesn't contain the correct magic string at the beginning.

Invalid Masses section in molecule file

Self-explanatory.

Invalid REAX atom type

There is a mis-match between LAMMPS atom types and the elements listed in the ReaxFF force field file.

Invalid Special Bond Counts section in molecule file

Self-explanatory.

Invalid Types section in molecule file

Self-explanatory.

Invalid angle count in molecule file

Self-explanatory.

Invalid angle table length

Length must be 2 or greater.

Invalid angle type in Angles section of data file

Angle type must be positive integer and within range of specified angle types.

Invalid angle type in Angles section of molecule file

Self-explanatory.

Invalid angle type index for fix shake

Self-explanatory.

Invalid args for non-hybrid pair coefficients

"NULL" is only supported in pair_coeff calls when using pair hybrid

LAMMPS Users Manual

Invalid argument to factorial %d

N must be ≥ 0 and ≤ 167 , otherwise the factorial result is too large.

Invalid atom ID in %s section of data file

An atom in a section of the data file being read by fix property/atom has an invalid atom ID that is ≤ 0 or $>$ the maximum existing atom ID.

Invalid atom ID in Angles section of data file

Atom IDs must be positive integers and within range of defined atoms.

Invalid atom ID in Angles section of molecule file

Self-explanatory.

Invalid atom ID in Atoms section of data file

Atom IDs must be positive integers.

Invalid atom ID in Bodies section of data file

Atom IDs must be positive integers and within range of defined atoms.

Invalid atom ID in Bonds section of data file

Atom IDs must be positive integers and within range of defined atoms.

Invalid atom ID in Bonds section of molecule file

Self-explanatory.

Invalid atom ID in Bonus section of data file

Atom IDs must be positive integers and within range of defined atoms.

Invalid atom ID in Dihedrals section of data file

Atom IDs must be positive integers and within range of defined atoms.

Invalid atom ID in Impropers section of data file

Atom IDs must be positive integers and within range of defined atoms.

Invalid atom ID in Velocities section of data file

Atom IDs must be positive integers and within range of defined atoms.

Invalid atom ID in dihedrals section of molecule file

Self-explanatory.

Invalid atom ID in impropers section of molecule file

Self-explanatory.

Invalid atom ID in variable file

Self-explanatory.

Invalid atom IDs in neb file

An ID in the file was not found in the system.

Invalid atom diameter in molecule file

Diameters must be ≥ 0.0 .

Invalid atom mass for fix shake

Mass specified in fix shake command must be > 0.0 .

Invalid atom mass in molecule file

Masses must be > 0.0 .

Invalid atom type in Atoms section of data file

Atom types must range from 1 to specified # of types.

Invalid atom type in create_atoms command

The create_box command specified the range of valid atom types. An invalid type is being requested.

Invalid atom type in create_atoms mol command

The atom types in the defined molecule are added to the value specified in the create_atoms command, as an offset. The final value for each atom must be between 1 to N, where N is the number of atom types.

Invalid atom type in fix atom/swap command

The atom type specified in the atom/swap command does not exist.

Invalid atom type in fix bond/create command

LAMMPS Users Manual

Self-explanatory.

Invalid atom type in fix deposit command

Self-explanatory.

Invalid atom type in fix deposit mol command

The atom types in the defined molecule are added to the value specified in the `create_atoms` command, as an offset. The final value for each atom must be between 1 to N, where N is the number of atom types.

Invalid atom type in fix gcmc command

The atom type specified in the `gcmc` command does not exist.

Invalid atom type in fix pour command

Self-explanatory.

Invalid atom type in fix pour mol command

The atom types in the defined molecule are added to the value specified in the `create_atoms` command, as an offset. The final value for each atom must be between 1 to N, where N is the number of atom types.

Invalid atom type in molecule file

Atom types must range from 1 to specified # of types.

Invalid atom type in neighbor exclusion list

Atom types must range from 1 to Ntypes inclusive.

Invalid atom type index for fix shake

Atom types must range from 1 to Ntypes inclusive.

Invalid atom types in pair_write command

Atom types must range from 1 to Ntypes inclusive.

Invalid atom vector in variable formula

The atom vector is not recognized.

Invalid atom_style body command

No body style argument was provided.

Invalid atom_style command

Self-explanatory.

Invalid attribute in dump custom command

Self-explanatory.

Invalid attribute in dump local command

Self-explanatory.

Invalid attribute in dump modify command

Self-explanatory.

Invalid basis setting in create_atoms command

The basis index must be between 1 to N where N is the number of basis atoms in the lattice. The type index must be between 1 to N where N is the number of atom types.

Invalid basis setting in fix append/atoms command

The basis index must be between 1 to N where N is the number of basis atoms in the lattice. The type index must be between 1 to N where N is the number of atom types.

Invalid bin bounds in compute chunk/atom

The lo/hi values are inconsistent.

Invalid bin bounds in fix ave/spatial

The lo/hi values are inconsistent.

Invalid body nparticle command

Arguments in atom-style command are not correct.

Invalid bond count in molecule file

Self-explanatory.

LAMMPS Users Manual

Invalid bond table length

Length must be 2 or greater.

Invalid bond type in Bonds section of data file

Bond type must be positive integer and within range of specified bond types.

Invalid bond type in Bonds section of molecule file

Self-explanatory.

Invalid bond type in create_bonds command

Self-explanatory.

Invalid bond type in fix bond/break command

Self-explanatory.

Invalid bond type in fix bond/create command

Self-explanatory.

Invalid bond type index for fix shake

Self-explanatory. Check the fix shake command in the input script.

Invalid coeffs for this dihedral style

Cannot set class 2 coeffs in data file for this dihedral style.

Invalid color in dump_modify command

The specified color name was not in the list of recognized colors. See the dump_modify doc page.

Invalid color map min/max values

The min/max values are not consistent with either each other or with values in the color map.

Invalid command-line argument

One or more command-line arguments is invalid. Check the syntax of the command you are using to launch LAMMPS.

Invalid compute ID in variable formula

The compute is not recognized.

Invalid create_atoms rotation vector for 2d model

The rotation vector can only have a z component.

Invalid custom OpenCL parameter string.

There are not enough or too many parameters in the custom string for package GPU.

Invalid cutoff in comm_modify command

Specified cutoff must be ≥ 0.0 .

Invalid cutoffs in pair_write command

Inner cutoff must be larger than 0.0 and less than outer cutoff.

Invalid d1 or d2 value for pair colloid coeff

Neither d1 or d2 can be < 0 .

Invalid data file section: Angle Coeffs

Atom style does not allow angles.

Invalid data file section: AngleAngle Coeffs

Atom style does not allow improper.

Invalid data file section: AngleAngleTorsion Coeffs

Atom style does not allow dihedrals.

Invalid data file section: AngleTorsion Coeffs

Atom style does not allow dihedrals.

Invalid data file section: Angles

Atom style does not allow angles.

Invalid data file section: Bodies

Atom style does not allow bodies.

Invalid data file section: Bond Coeffs

LAMMPS Users Manual

- Atom style does not allow bonds.
Invalid data file section: BondAngle Coeffs
- Atom style does not allow angles.
Invalid data file section: BondBond Coeffs
- Atom style does not allow angles.
Invalid data file section: BondBond13 Coeffs
- Atom style does not allow dihedrals.
Invalid data file section: Bonds
- Atom style does not allow bonds.
Invalid data file section: Dihedral Coeffs
- Atom style does not allow dihedrals.
Invalid data file section: Dihedrals
- Atom style does not allow dihedrals.
Invalid data file section: Ellipsoids
- Atom style does not allow ellipsoids.
Invalid data file section: EndBondTorsion Coeffs
- Atom style does not allow dihedrals.
Invalid data file section: Improper Coeffs
- Atom style does not allow improper.
Invalid data file section: Impropers
- Atom style does not allow improper.
Invalid data file section: Lines
- Atom style does not allow lines.
Invalid data file section: MiddleBondTorsion Coeffs
- Atom style does not allow dihedrals.
Invalid data file section: Triangles
- Atom style does not allow triangles.
Invalid delta_conf in tad command
- The value must be between 0 and 1 inclusive.
- Invalid density in Atoms section of data file*
- Density value cannot be ≤ 0.0 .
- Invalid density in set command*
- Density must be > 0.0 .
- Invalid diameter in set command*
- Self-explanatory.
- Invalid dihedral count in molecule file*
- Self-explanatory.
- Invalid dihedral type in Dihedrals section of data file*
- Dihedral type must be positive integer and within range of specified dihedral types.
- Invalid dihedral type in dihedrals section of molecule file*
- Self-explanatory.
- Invalid dipole length in set command*
- Self-explanatory.
- Invalid displace_atoms rotate axis for 2d*
- Axis must be in z direction.
- Invalid dump dcd filename*
- Filenames used with the dump dcd style cannot be binary or compressed or cause multiple files to be written.
- Invalid dump frequency*
- Dump frequency must be 1 or greater.

LAMMPS Users Manual

Invalid dump image element name

The specified element name was not in the standard list of elements. See the `dump_modify` doc page.

Invalid dump image filename

The file produced by `dump image` cannot be binary and must be for a single processor.

Invalid dump image persp value

Persp value must be ≥ 0.0 .

Invalid dump image theta value

Theta must be between 0.0 and 180.0 inclusive.

Invalid dump image zoom value

Zoom value must be > 0.0 .

Invalid dump movie filename

The file produced by `dump movie` cannot be binary or compressed and must be a single file for a single processor.

Invalid dump xtc filename

Filenames used with the `dump xtc` style cannot be binary or compressed or cause multiple files to be written.

Invalid dump xyz filename

Filenames used with the `dump xyz` style cannot be binary or cause files to be written by each processor.

Invalid dump_modify threshold operator

Operator keyword used for threshold specification is not recognized.

Invalid entry in -reorder file

Self-explanatory.

Invalid fix ID in variable formula

The fix is not recognized.

Invalid fix ave/time off column

Self-explanatory.

Invalid fix box/relax command for a 2d simulation

Fix `box/relax` styles involving the z dimension cannot be used in a 2d simulation.

Invalid fix box/relax command pressure settings

If multiple dimensions are coupled, those dimensions must be specified.

Invalid fix box/relax pressure settings

Settings for coupled dimensions must be the same.

Invalid fix nvt/npt/nph command for a 2d simulation

Cannot control z dimension in a 2d model.

Invalid fix nvt/npt/nph command pressure settings

If multiple dimensions are coupled, those dimensions must be specified.

Invalid fix nvt/npt/nph pressure settings

Settings for coupled dimensions must be the same.

Invalid fix press/berendsen for a 2d simulation

The z component of pressure cannot be controlled for a 2d model.

Invalid fix press/berendsen pressure settings

Settings for coupled dimensions must be the same.

Invalid fix qeq parameter file

Element index $>$ number of atom types.

Invalid fix rigid npt/nph command for a 2d simulation

Cannot control z dimension in a 2d model.

Invalid fix rigid npt/nph command pressure settings

If multiple dimensions are coupled, those dimensions must be specified.

LAMMPS Users Manual

- Invalid fix rigid/small npt/nph command for a 2d simulation*
Cannot control z dimension in a 2d model.
- Invalid fix rigid/small npt/nph command pressure settings*
If multiple dimensions are coupled, those dimensions must be specified.
- Invalid flag in force field section of restart file*
Unrecognized entry in restart file.
- Invalid flag in header section of restart file*
Unrecognized entry in restart file.
- Invalid flag in peratom section of restart file*
The format of this section of the file is not correct.
- Invalid flag in type arrays section of restart file*
Unrecognized entry in restart file.
- Invalid frequency in temper command*
Nevery must be > 0.
- Invalid group ID in neigh_modify command*
A group ID used in the neigh_modify command does not exist.
- Invalid group function in variable formula*
Group function is not recognized.
- Invalid group in comm_modify command*
Self-explanatory.
- Invalid image up vector*
Up vector cannot be (0,0,0).
- Invalid immediate variable*
Syntax of immediate value is incorrect.
- Invalid improper count in molecule file*
Self-explanatory.
- Invalid improper type in Improvers section of data file*
Improper type must be positive integer and within range of specified improper types.
- Invalid improper type in improvers section of molecule file*
Self-explanatory.
- Invalid index for non-body particles in compute body/local command*
Only indices 1,2,3 can be used for non-body particles.
- Invalid index in compute body/local command*
Self-explanatory.
- Invalid is_active() function in variable formula*
Self-explanatory.
- Invalid is_available() function in variable formula*
Self-explanatory.
- Invalid is_defined() function in variable formula*
Self-explanatory.
- Invalid keyword in angle table parameters*
Self-explanatory.
- Invalid keyword in bond table parameters*
Self-explanatory.
- Invalid keyword in compute angle/local command*
Self-explanatory.
- Invalid keyword in compute bond/local command*
Self-explanatory.
- Invalid keyword in compute dihedral/local command*
Self-explanatory.

LAMMPS Users Manual

- Invalid keyword in compute improper/local command*
Self-explanatory.
- Invalid keyword in compute pair/local command*
Self-explanatory.
- Invalid keyword in compute property/atom command*
Self-explanatory.
- Invalid keyword in compute property/chunk command*
Self-explanatory.
- Invalid keyword in compute property/local command*
Self-explanatory.
- Invalid keyword in dump cfg command*
Self-explanatory.
- Invalid keyword in pair table parameters*
Keyword used in list of table parameters is not recognized.
- Invalid length in set command*
Self-explanatory.
- Invalid mass in set command*
Self-explanatory.
- Invalid mass line in data file*
Self-explanatory.
- Invalid mass value*
Self-explanatory.
- Invalid math function in variable formula*
Self-explanatory.
- Invalid math/group/special function in variable formula*
Self-explanatory.
- Invalid option in lattice command for non-custom style*
Certain lattice keywords are not supported unless the lattice style is "custom".
- Invalid order of forces within respa levels*
For respa, ordering of force computations within respa levels must obey certain rules. E.g. bonds cannot be compute less frequently than angles, pairwise forces cannot be computed less frequently than kspace, etc.
- Invalid pair table cutoff*
Cutoffs in pair_coeff command are not valid with read-in pair table.
- Invalid pair table length*
Length of read-in pair table is invalid
- Invalid param file for fix qeq/shielded*
Invalid value of gamma.
- Invalid param file for fix qeq/slater*
Zeta value is 0.0.
- Invalid partitions in processors part command*
Valid partitions are numbered 1 to N and the sender and receiver cannot be the same partition.
- Invalid python command*
Self-explanatory. Check the input script syntax and compare to the documentation for the command. You can use -echo screen as a command-line option when running LAMMPS to see the offending line.
- Invalid radius in Atoms section of data file*
Radius must be ≥ 0.0 .
- Invalid random number seed in fix ttm command*
Random number seed must be > 0 .

LAMMPS Users Manual

Invalid random number seed in set command

Random number seed must be > 0.

Invalid replace values in compute reduce

Self-explanatory.

Invalid rigid body ID in fix rigid file

The ID does not match the number of an existing ID of rigid bodies that are defined by the fix rigid command.

Invalid rigid body ID in fix rigid/small file

The ID does not match the number of an existing ID of rigid bodies that are defined by the fix rigid/small command.

Invalid run command N value

The number of timesteps must fit in a 32-bit integer. If you want to run for more steps than this, perform multiple shorter runs.

Invalid run command start/stop value

Self-explanatory.

Invalid run command upto value

Self-explanatory.

Invalid seed for Marsaglia random # generator

The initial seed for this random number generator must be a positive integer less than or equal to 900 million.

Invalid seed for Park random # generator

The initial seed for this random number generator must be a positive integer.

Invalid shake angle type in molecule file

Self-explanatory.

Invalid shake atom in molecule file

Self-explanatory.

Invalid shake bond type in molecule file

Self-explanatory.

Invalid shake flag in molecule file

Self-explanatory.

Invalid shape in Ellipsoids section of data file

Self-explanatory.

Invalid shape in Triangles section of data file

Two or more of the triangle corners are duplicate points.

Invalid shape in set command

Self-explanatory.

Invalid shear direction for fix wall/gran

Self-explanatory.

Invalid special atom index in molecule file

Self-explanatory.

Invalid special function in variable formula

Self-explanatory.

Invalid style in pair_write command

Self-explanatory. Check the input script.

Invalid syntax in variable formula

Self-explanatory.

Invalid t_event in prd command

Self-explanatory.

Invalid t_event in tad command

The value must be greater than 0.

Invalid template atom in Atoms section of data file

LAMMPS Users Manual

The atom indices must be between 1 to N, where N is the number of atoms in the template molecule the atom belongs to.

Invalid template index in Atoms section of data file

The template indices must be between 1 to N, where N is the number of molecules in the template.

Invalid thermo keyword in variable formula

The keyword is not recognized.

Invalid threads_per_atom specified.

For 3-body potentials on the GPU, the threads_per_atom setting cannot be greater than 4 for NVIDIA GPUs.

Invalid timestep reset for fix ave/atom

Resetting the timestep has invalidated the sequence of timesteps this fix needs to process.

Invalid timestep reset for fix ave/chunk

Resetting the timestep has invalidated the sequence of timesteps this fix needs to process.

Invalid timestep reset for fix ave/correlate

Resetting the timestep has invalidated the sequence of timesteps this fix needs to process.

Invalid timestep reset for fix ave/histo

Resetting the timestep has invalidated the sequence of timesteps this fix needs to process.

Invalid timestep reset for fix ave/spatial

Resetting the timestep has invalidated the sequence of timesteps this fix needs to process.

Invalid timestep reset for fix ave/time

Resetting the timestep has invalidated the sequence of timesteps this fix needs to process.

Invalid tmax in tad command

The value must be greater than 0.0.

Invalid type for mass set

Mass command must set a type from 1-N where N is the number of atom types.

Invalid use of library file() function

This function is called thru the library interface. This error should not occur. Contact the developers if it does.

Invalid value in set command

The value specified for the setting is invalid, likely because it is too small or too large.

Invalid variable evaluation in variable formula

A variable used in a formula could not be evaluated.

Invalid variable in next command

Self-explanatory.

Invalid variable name

Variable name used in an input script line is invalid.

Invalid variable name in variable formula

Variable name is not recognized.

Invalid variable style in special function next

Only file-style or atomfile-style variables can be used with next().

Invalid variable style with next command

Variable styles *equal* and *world* cannot be used in a next command.

Invalid volume in set command

LAMMPS Users Manual

- Volume must be > 0.0 .
- Invalid wiggle direction for fix wall/gran*
Self-explanatory.
- Invoked angle equil angle on angle style none*
Self-explanatory.
- Invoked angle single on angle style none*
Self-explanatory.
- Invoked bond equil distance on bond style none*
Self-explanatory.
- Invoked bond single on bond style none*
Self-explanatory.
- Invoked pair single on pair style none*
A command (e.g. a dump) attempted to invoke the single() function on a pair style none, which is illegal. You are probably attempting to compute per-atom quantities with an undefined pair style.
- Invoking coulombic in pair style lj/coul requires atom attribute q*
The atom style defined does not have this attribute.
- Invoking coulombic in pair style lj/long/dipole/long requires atom attribute q*
The atom style defined does not have these attributes.
- KIM neighbor iterator exceeded range*
This should not happen. It likely indicates a bug in the KIM implementation of the interatomic potential where it is requesting neighbors incorrectly.
- KOKKOS package does not yet support comm_style tiled*
Self-explanatory.
- KOKKOS package requires a kokkos enabled atom_style*
Self-explanatory.
- KSpace accuracy must be > 0*
The kspace accuracy designated in the input must be greater than zero.
- KSpace accuracy too large to estimate G vector*
Reduce the accuracy request or specify gwald explicitly via the kspace_modify command.
- KSpace accuracy too low*
Requested accuracy must be less than 1.0.
- KSpace solver requires a pair style*
No pair style is defined.
- KSpace style does not yet support triclinic geometries*
The specified kspace style does not allow for non-orthogonal simulation boxes.
- KSpace style has not yet been set*
Cannot use kspace_modify command until a kspace style is set.
- KSpace style is incompatible with Pair style*
Setting a kspace style requires that a pair style with matching long-range Coulombic or dispersion components be used.
- Keyword %s in MEAM parameter file not recognized*
Self-explanatory.
- Kokkos has been compiled for CUDA but no GPUs are requested*
One or more GPUs must be used when Kokkos is compiled for CUDA.
- Kspace style does not support compute group/group*
Self-explanatory.
- Kspace style ppm/disp/tip4p requires newton on*
Self-explanatory.
- Kspace style ppm/tip4p requires newton on*

LAMMPS Users Manual

Self-explanatory.

Kspace style requires atom attribute q

The atom style defined does not have these attributes.

Kspace_modify eigtol must be smaller than one

Self-explanatory.

LAMMPS is not built with Python embedded

This is done by including the PYTHON package before LAMMPS is built. This is required to use python-style variables.

LAMMPS unit_style lj not supported by KIM models

Self-explanatory. Check the input script or data file.

LJ6 off not supported in pair_style buck/long/coul/long

Self-explanatory.

Label wasn't found in input script

Self-explanatory.

Lattice orient vectors are not orthogonal

The three specified lattice orientation vectors must be mutually orthogonal.

Lattice orient vectors are not right-handed

The three specified lattice orientation vectors must create a right-handed coordinate system such that $a_1 \text{ cross } a_2 = a_3$.

Lattice primitive vectors are collinear

The specified lattice primitive vectors do not form a unit cell with non-zero volume.

Lattice settings are not compatible with 2d simulation

One or more of the specified lattice vectors has a non-zero z component.

Lattice spacings are invalid

Each x,y,z spacing must be > 0 .

Lattice style incompatible with simulation dimension

2d simulation can use sq, sq2, or hex lattice. 3d simulation can use sc, bcc, or fcc lattice.

Log of zero/negative value in variable formula

Self-explanatory.

Lost atoms via balance: original %ld current %ld

This should not occur. Report the problem to the developers.

Lost atoms: original %ld current %ld

Lost atoms are checked for each time thermo output is done. See the thermo_modify lost command for options. Lost atoms usually indicate bad dynamics, e.g. atoms have been blown far out of the simulation box, or moved further than one processor's sub-domain away before reneighboring.

MEAM library error %d

A call to the MEAM Fortran library returned an error.

MPI_LMP_BIGINT and bigint in lmptype.h are not compatible

The size of the MPI datatype does not match the size of a bigint.

MPI_LMP_TAGINT and tagint in lmptype.h are not compatible

The size of the MPI datatype does not match the size of a tagint.

MSM can only currently be used with comm_style brick

This is a current restriction in LAMMPS.

MSM grid is too large

The global MSM grid is larger than OFFSET in one or more dimensions.

OFFSET is currently set to 16384. You likely need to decrease the requested accuracy.

MSM order must be 4, 6, 8, or 10

LAMMPS Users Manual

This is a limitation of the MSM implementation in LAMMPS: the MSM order can only be 4, 6, 8, or 10.

Mass command before simulation box is defined

The mass command cannot be used before a read_data, read_restart, or create_box command.

Matrix factorization to split dispersion coefficients failed

This should not normally happen. Contact the developers.

Min_style command before simulation box is defined

The min_style command cannot be used before a read_data, read_restart, or create_box command.

Minimization could not find thermo_pe compute

This compute is created by the thermo command. It must have been explicitly deleted by a uncompute command.

Minimize command before simulation box is defined

The minimize command cannot be used before a read_data, read_restart, or create_box command.

Mismatched brackets in variable

Self-explanatory.

Mismatched compute in variable formula

A compute is referenced incorrectly or a compute that produces per-atom values is used in an equal-style variable formula.

Mismatched fix in variable formula

A fix is referenced incorrectly or a fix that produces per-atom values is used in an equal-style variable formula.

Mismatched variable in variable formula

A variable is referenced incorrectly or an atom-style variable that produces per-atom values is used in an equal-style variable formula.

Modulo 0 in variable formula

Self-explanatory.

Molecule IDs too large for compute chunk/atom

The IDs must not be larger than can be stored in a 32-bit integer since chunk IDs are 32-bit integers.

Molecule auto special bond generation overflow

Counts exceed maxspecial setting for other atoms in system.

Molecule file has angles but no nangles setting

Self-explanatory.

Molecule file has body params but no setting for them

Self-explanatory.

Molecule file has bonds but no nbonds setting

Self-explanatory.

Molecule file has dihedrals but no ndihedrals setting

Self-explanatory.

Molecule file has impropers but no nimpropers setting

Self-explanatory.

Molecule file has no Body Doubles section

Self-explanatory.

Molecule file has no Body Integers section

Self-explanatory.

Molecule file has special flags but no bonds

Self-explanatory.

Molecule file needs both Special Bond sections

- Self-explanatory.
- Molecule file requires atom style body*
Self-explanatory.
- Molecule file shake flags not before shake atoms*
The order of the two sections is important.
- Molecule file shake flags not before shake bonds*
The order of the two sections is important.
- Molecule file shake info is incomplete*
All 3 SHAKE sections are needed.
- Molecule file special list does not match special count*
The number of values in an atom's special list does not match count.
- Molecule file z center-of-mass must be 0.0 for 2d*
Self-explanatory.
- Molecule file z coord must be 0.0 for 2d*
Self-explanatory.
- Molecule natoms must be 1 for body particle*
Self-explanatory.
- Molecule sizescale must be 1.0 for body particle*
Self-explanatory.
- Molecule template ID for atom_style template does not exist*
Self-explanatory.
- Molecule template ID for create_atoms does not exist*
Self-explanatory.
- Molecule template ID for fix deposit does not exist*
Self-explanatory.
- Molecule template ID for fix gcmc does not exist*
Self-explanatory.
- Molecule template ID for fix pour does not exist*
Self-explanatory.
- Molecule template ID for fix rigid/small does not exist*
Self-explanatory.
- Molecule template ID for fix shake does not exist*
Self-explanatory.
- Molecule template ID must be alphanumeric or underscore characters*
Self-explanatory.
- Molecule topology/atom exceeds system topology/atom*
The number of bonds, angles, etc per-atom in the molecule exceeds the system setting. See the create_box command for how to specify these values.
- Molecule topology type exceeds system topology type*
The number of bond, angle, etc types in the molecule exceeds the system setting. See the create_box command for how to specify these values.
- More than one fix deform*
Only one fix deform can be defined at a time.
- More than one fix freeze*
Only one of these fixes can be defined, since the granular pair potentials access it.
- More than one fix shake*
Only one fix shake can be defined.
- Mu not allowed when not using semi-grand in fix atom/swap command*
Self-explanatory.
- Must define angle_style before Angle Coeffs*

LAMMPS Users Manual

- Must use an `angle_style` command before reading a data file that defines Angle Coeffs.
- Must define `angle_style` before `BondAngle Coeffs`*
Must use an `angle_style` command before reading a data file that defines Angle Coeffs.
- Must define `angle_style` before `BondBond Coeffs`*
Must use an `angle_style` command before reading a data file that defines Angle Coeffs.
- Must define `bond_style` before `Bond Coeffs`*
Must use a `bond_style` command before reading a data file that defines Bond Coeffs.
- Must define `dihedral_style` before `AngleAngleTorsion Coeffs`*
Must use a `dihedral_style` command before reading a data file that defines AngleAngleTorsion Coeffs.
- Must define `dihedral_style` before `AngleTorsion Coeffs`*
Must use a `dihedral_style` command before reading a data file that defines AngleTorsion Coeffs.
- Must define `dihedral_style` before `BondBond13 Coeffs`*
Must use a `dihedral_style` command before reading a data file that defines BondBond13 Coeffs.
- Must define `dihedral_style` before `Dihedral Coeffs`*
Must use a `dihedral_style` command before reading a data file that defines Dihedral Coeffs.
- Must define `dihedral_style` before `EndBondTorsion Coeffs`*
Must use a `dihedral_style` command before reading a data file that defines EndBondTorsion Coeffs.
- Must define `dihedral_style` before `MiddleBondTorsion Coeffs`*
Must use a `dihedral_style` command before reading a data file that defines MiddleBondTorsion Coeffs.
- Must define `improper_style` before `AngleAngle Coeffs`*
Must use an `improper_style` command before reading a data file that defines AngleAngle Coeffs.
- Must define `improper_style` before `Improper Coeffs`*
Must use an `improper_style` command before reading a data file that defines Improper Coeffs.
- Must define `pair_style` before `Pair Coeffs`*
Must use a `pair_style` command before reading a data file that defines Pair Coeffs.
- Must define `pair_style` before `PairIJ Coeffs`*
Must use a `pair_style` command before reading a data file that defines PairIJ Coeffs.
- Must have more than one processor partition to `temper`*
Cannot use the `temper` command with only one processor partition. Use the `-partition` command-line option.
- Must read `Atoms` before `Angles`*
The `Atoms` section of a data file must come before an `Angles` section.
- Must read `Atoms` before `Bodies`*
The `Atoms` section of a data file must come before a `Bodies` section.
- Must read `Atoms` before `Bonds`*
The `Atoms` section of a data file must come before a `Bonds` section.
- Must read `Atoms` before `Dihedrals`*

LAMMPS Users Manual

- The Atoms section of a data file must come before a Dihedrals section.
- Must read Atoms before Ellipsoids*
The Atoms section of a data file must come before a Ellipsoids section.
- Must read Atoms before Impropers*
The Atoms section of a data file must come before an Impropers section.
- Must read Atoms before Lines*
The Atoms section of a data file must come before a Lines section.
- Must read Atoms before Triangles*
The Atoms section of a data file must come before a Triangles section.
- Must read Atoms before Velocities*
The Atoms section of a data file must come before a Velocities section.
- Must set both respa inner and outer*
Cannot use just the inner or outer option with respa without using the other.
- Must set number of threads via package omp command*
Because you are using the USER-OMP package, set the number of threads via its settings, not by the pair_style snap nthreads setting.
- Must shrink-wrap piston boundary*
The boundary style of the face where the piston is applied must be of type s (shrink-wrapped).
- Must specify a region in fix deposit*
The region keyword must be specified with this fix.
- Must specify a region in fix pour*
Self-explanatory.
- Must specify at least 2 types in fix atom/swap command*
Self-explanatory.
- Must use 'kspace_modify pressure/scalar no' for rRESPA with kspace_style MSM*
The kspace scalar pressure option cannot (yet) be used with rRESPA.
- Must use 'kspace_modify pressure/scalar no' for tensor components with kspace_style msm*
Otherwise MSM will compute only a scalar pressure. See the kspace_modify command for details on this setting.
- Must use 'kspace_modify pressure/scalar no' to obtain per-atom virial with kspace_style MSM*
The kspace scalar pressure option cannot be used to obtain per-atom virial.
- Must use 'kspace_modify pressure/scalar no' with GPU MSM Pair styles*
The kspace scalar pressure option is not (yet) compatible with GPU MSM Pair styles.
- Must use 'kspace_modify pressure/scalar no' with kspace_style msm/cg*
The kspace scalar pressure option is not compatible with kspace_style msm/cg.
- Must use -in switch with multiple partitions*
A multi-partition simulation cannot read the input script from stdin. The -in command-line option must be used to specify a file.
- Must use Kokkos half/thread or full neighbor list with threads or GPUs*
Using Kokkos half-neighbor lists with threading is not allowed.
- Must use a block or cylinder region with fix pour*
Self-explanatory.
- Must use a block region with fix pour for 2d simulations*
Self-explanatory.
- Must use a bond style with TIP4P potential*
TIP4P potentials assume bond lengths in water are constrained by a fix shake command.

LAMMPS Users Manual

Must use a molecular atom style with fix poems molecule
Self-explanatory.

Must use a z-axis cylinder region with fix pour
Self-explanatory.

Must use an angle style with TIP4P potential
TIP4P potentials assume angles in water are constrained by a fix shake command.

Must use atom map style array with Kokkos
See the atom_modify map command.

Must use atom style with molecule IDs with fix bond/swap
Self-explanatory.

Must use pair_style comb or comb3 with fix qeq/comb
Self-explanatory.

Must use variable energy with fix addforce
Must define an energy variable when applying a dynamic force during minimization.

Must use variable energy with fix efield
You must define an energy when performing a minimization with a variable E-field.

NEB command before simulation box is defined
Self-explanatory.

NEB requires damped dynamics minimizer
Use a different minimization style.

NEB requires use of fix neb
Self-explanatory.

NL ramp in wall/piston only implemented in zlo for now
The ramp keyword can only be used for piston applied to face zlo.

Need nswaptypes mu values in fix atom/swap command
Self-explanatory.

Needed bonus data not in data file
Some atom styles require bonus data. See the read_data doc page for details.

Needed molecular topology not in data file
The header of the data file indicated bonds, angles, etc would be included, but they are not present.

Neigh_modify exclude molecule requires atom attribute molecule
Self-explanatory.

Neigh_modify include group != atom_modify first group
Self-explanatory.

Neighbor delay must be 0 or multiple of every setting
The delay and every parameters set via the neigh_modify command are inconsistent. If the delay setting is non-zero, then it must be a multiple of the every setting.

Neighbor include group not allowed with ghost neighbors
This is a current restriction within LAMMPS.

Neighbor list overflow, boost neigh_modify one
There are too many neighbors of a single atom. Use the neigh_modify command to increase the max number of neighbors allowed for one atom. You may also want to boost the page size.

Neighbor multi not yet enabled for ghost neighbors
This is a current restriction within LAMMPS.

Neighbor multi not yet enabled for granular

LAMMPS Users Manual

Self-explanatory.

Neighbor multi not yet enabled for rRESPA

Self-explanatory.

Neighbor page size must be ≥ 10 x the one atom setting

This is required to prevent wasting too much memory.

New atom IDs exceed maximum allowed ID

See the setting for tagint in the src/lmptype.h file.

New bond exceeded bonds per atom in create_bonds

See the read_data command for info on using the "extra/bond/per/atom" keyword to allow for additional bonds to be formed

New bond exceeded bonds per atom in fix bond/create

See the read_data command for info on using the "extra/bond/per/atom" keyword to allow for additional bonds to be formed

New bond exceeded special list size in fix bond/create

See the "read_data extra/special/per/atom" command (or the "create_box extra/special/per/atom" command) for info on how to leave space in the special bonds list to allow for additional bonds to be formed.

Newton bond change after simulation box is defined

The newton command cannot be used to change the newton bond value after a read_data, read_restart, or create_box command.

Next command must list all universe and uloop variables

This is to insure they stay in sync.

No Kspace style defined for compute group/group

Self-explanatory.

No OpenMP support compiled in

An OpenMP flag is set, but LAMMPS was not built with OpenMP support.

No angle style is defined for compute angle/local

Self-explanatory.

No angles allowed with this atom style

Self-explanatory.

No atoms in data file

The header of the data file indicated that atoms would be included, but they are not present.

No basis atoms in lattice

Basis atoms must be defined for lattice style user.

No bodies allowed with this atom style

Self-explanatory. Check data file.

No bond style is defined for compute bond/local

Self-explanatory.

No bonds allowed with this atom style

Self-explanatory.

No box information in dump. You have to use 'box no'

Self-explanatory.

No count or invalid atom count in molecule file

The number of atoms must be specified.

No dihedral style is defined for compute dihedral/local

Self-explanatory.

No dihedrals allowed with this atom style

Self-explanatory.

No dump custom arguments specified

LAMMPS Users Manual

The dump custom command requires that atom quantities be specified to output to dump file.

No dump local arguments specified

Self-explanatory.

No ellipsoids allowed with this atom style

Self-explanatory. Check data file.

No fix gravity defined for fix pour

Gravity is required to use fix pour.

No improper style is defined for compute improper/local

Self-explanatory.

No impropers allowed with this atom style

Self-explanatory.

No input values for fix ave/spatial

Self-explanatory.

No lines allowed with this atom style

Self-explanatory. Check data file.

No matching element in ADP potential file

The ADP potential file does not contain elements that match the requested elements.

No matching element in EAM potential file

The EAM potential file does not contain elements that match the requested elements.

No molecule topology allowed with atom style template

The data file cannot specify the number of bonds, angles, etc, because this info is inferred from the molecule templates.

No overlap of box and region for create_atoms

Self-explanatory.

No pair coul/streitz for fix qeq/slater

These commands must be used together.

No pair hbond/dreiding coefficients set

Self-explanatory.

No pair style defined for compute group/group

Cannot calculate group interactions without a pair style defined.

No pair style is defined for compute pair/local

Self-explanatory.

No pair style is defined for compute property/local

Self-explanatory.

No rigid bodies defined

The fix specification did not end up defining any rigid bodies.

No triangles allowed with this atom style

Self-explanatory. Check data file.

No values in fix ave/chunk command

Self-explanatory.

No values in fix ave/time command

Self-explanatory.

Non digit character between brackets in variable

Self-explanatory.

Non integer # of swaps in temper command

Swap frequency in temper command must evenly divide the total # of timesteps.

Non-numeric box dimensions - simulation unstable

LAMMPS Users Manual

- The box size has apparently blown up.
Non-zero atom IDs with atom_modify id = no
Self-explanatory.
- Non-zero read_data shift z value for 2d simulation*
Self-explanatory.
- Nprocs not a multiple of N for -reorder*
Self-explanatory.
- Number of core atoms != number of shell atoms*
There must be a one-to-one pairing of core and shell atoms.
- Numeric index is out of bounds*
A command with an argument that specifies an integer or range of integers is using a value that is less than 1 or greater than the maximum allowed limit.
- One or more Atom IDs is negative*
Atom IDs must be positive integers.
- One or more atom IDs is too big*
The limit on atom IDs is set by the SMALLBIG, BIGBIG, SMALLSMALL setting in your Makefile. See Section_start 2.2 of the manual for more details.
- One or more atom IDs is zero*
Either all atoms IDs must be zero or none of them.
- One or more atoms belong to multiple rigid bodies*
Two or more rigid bodies defined by the fix rigid command cannot contain the same atom.
- One or more rigid bodies are a single particle*
Self-explanatory.
- One or zero atoms in rigid body*
Any rigid body defined by the fix rigid command must contain 2 or more atoms.
- Only 2 types allowed when not using semi-grand in fix atom/swap command*
Self-explanatory.
- Only one cut-off allowed when requesting all long*
Self-explanatory.
- Only one cutoff allowed when requesting all long*
Self-explanatory.
- Only zhi currently implemented for fix append/atoms*
Self-explanatory.
- Out of range atoms - cannot compute MSM*
One or more atoms are attempting to map their charge to a MSM grid point that is not owned by a processor. This is likely for one of two reasons, both of them bad. First, it may mean that an atom near the boundary of a processor's sub-domain has moved more than 1/2 the [neighbor skin distance](#) without neighbor lists being rebuilt and atoms being migrated to new processors. This also means you may be missing pairwise interactions that need to be computed. The solution is to change the re-neighboring criteria via the [neigh_modify](#) command. The safest settings are "delay 0 every 1 check yes". Second, it may mean that an atom has moved far outside a processor's sub-domain or even the entire simulation box. This indicates bad physics, e.g. due to highly overlapping atoms, too large a timestep, etc.
- Out of range atoms - cannot compute PPPM*
One or more atoms are attempting to map their charge to a PPPM grid point that is not owned by a processor. This is likely for one of two reasons, both of them bad. First, it may mean that an atom near the boundary of a processor's sub-domain has moved more than 1/2 the [neighbor skin distance](#) without

LAMMPS Users Manual

neighbor lists being rebuilt and atoms being migrated to new processors. This also means you may be missing pairwise interactions that need to be computed. The solution is to change the re-neighboring criteria via the [neigh_modify](#) command. The safest settings are "delay 0 every 1 check yes". Second, it may mean that an atom has moved far outside a processor's sub-domain or even the entire simulation box. This indicates bad physics, e.g. due to highly overlapping atoms, too large a timestep, etc.

Out of range atoms - cannot compute PPPMDisp

One or more atoms are attempting to map their charge to a PPPM grid point that is not owned by a processor. This is likely for one of two reasons, both of them bad. First, it may mean that an atom near the boundary of a processor's sub-domain has moved more than 1/2 the [neighbor skin distance](#) without neighbor lists being rebuilt and atoms being migrated to new processors. This also means you may be missing pairwise interactions that need to be computed. The solution is to change the re-neighboring criteria via the [neigh_modify](#) command. The safest settings are "delay 0 every 1 check yes". Second, it may mean that an atom has moved far outside a processor's sub-domain or even the entire simulation box. This indicates bad physics, e.g. due to highly overlapping atoms, too large a timestep, etc.

Overflow of allocated fix vector storage

This should not normally happen if the fix correctly calculated how long the vector will grow to. Contact the developers.

Overlapping large/large in pair colloid

This potential is infinite when there is an overlap.

Overlapping small/large in pair colloid

This potential is infinite when there is an overlap.

POEMS fix must come before NPT/NPH fix

NPT/NPH fix must be defined in input script after all poems fixes, else the fix contribution to the pressure virial is incorrect.

PPPM can only currently be used with comm_style brick

This is a current restriction in LAMMPS.

PPPM grid is too large

The global PPPM grid is larger than OFFSET in one or more dimensions. OFFSET is currently set to 4096. You likely need to decrease the requested accuracy.

PPPM grid stencil extends beyond nearest neighbor processor

This is not allowed if the kspace_modify overlap setting is no.

PPPM order < minimum allowed order

The default minimum order is 2. This can be reset by the kspace_modify minorder command.

PPPM order cannot be < 2 or > than %d

This is a limitation of the PPPM implementation in LAMMPS.

PPPMDisp Coulomb grid is too large

The global PPPM grid is larger than OFFSET in one or more dimensions. OFFSET is currently set to 4096. You likely need to decrease the requested accuracy.

PPPMDisp Dispersion grid is too large

The global PPPM grid is larger than OFFSET in one or more dimensions. OFFSET is currently set to 4096. You likely need to decrease the requested accuracy.

PPPMDisp can only currently be used with comm_style brick

LAMMPS Users Manual

This is a current restriction in LAMMPS.

PPPMDisp coulomb order cannot be greater than %d

This is a limitation of the PPPM implementation in LAMMPS.

PPPMDisp used but no parameters set, for further information please see the ppm/disp documentation

An efficient and accurate usage of the ppm/disp requires settings via the kspace_modify command. Please see the ppm/disp documentation for further instructions.

PRD command before simulation box is defined

The prd command cannot be used before a read_data, read_restart, or create_box command.

PRD nsteps must be multiple of t_event

Self-explanatory.

PRD t_corr must be multiple of t_event

Self-explanatory.

Package command after simulation box is defined

The package command cannot be used after a read_data, read_restart, or create_box command.

Package cuda command without USER-CUDA package enabled

The USER-CUDA package must be installed via "make yes-user-cuda" before LAMMPS is built, and the "-c on" must be used to enable the package.

Package gpu command without GPU package installed

The GPU package must be installed via "make yes-gpu" before LAMMPS is built.

Package intel command without USER-INTEL package installed

The USER-INTEL package must be installed via "make yes-user-intel" before LAMMPS is built.

Package kokkos command without KOKKOS package enabled

The KOKKOS package must be installed via "make yes-kokkos" before LAMMPS is built, and the "-k on" must be used to enable the package.

Package omp command without USER-OMP package installed

The USER-OMP package must be installed via "make yes-user-omp" before LAMMPS is built.

Pair body requires atom style body

Self-explanatory.

Pair body requires body style nparticle

This pair style is specific to the nparticle body style.

Pair brownian requires atom style sphere

Self-explanatory.

Pair brownian requires extended particles

One of the particles has radius 0.0.

Pair brownian requires monodisperse particles

All particles must be the same finite size.

Pair brownian/poly requires atom style sphere

Self-explanatory.

Pair brownian/poly requires extended particles

One of the particles has radius 0.0.

Pair brownian/poly requires newton pair off

Self-explanatory.

Pair coeff for hybrid has invalid style

Style in pair coeff must have been listed in pair_style command.

Pair coul/wolf requires atom attribute q

LAMMPS Users Manual

- The atom style defined does not have this attribute.
- Pair cutoff < Respa interior cutoff*
One or more pairwise cutoffs are too short to use with the specified rRESPA cutoffs.
- Pair dipole/cut requires atom attributes q, mu, torque*
The atom style defined does not have these attributes.
- Pair dipole/cut/gpu requires atom attributes q, mu, torque*
The atom style defined does not have this attribute.
- Pair dipole/long requires atom attributes q, mu, torque*
The atom style defined does not have these attributes.
- Pair dipole/sf/gpu requires atom attributes q, mu, torque*
The atom style defined does not one or more of these attributes.
- Pair distance < table inner cutoff*
Two atoms are closer together than the pairwise table allows.
- Pair distance > table outer cutoff*
Two atoms are further apart than the pairwise table allows.
- Pair dpd requires ghost atoms store velocity*
Use the comm_modify vel yes command to enable this.
- Pair gayberne epsilon a,b,c coeffs are not all set*
Each atom type involved in pair_style gayberne must have these 3 coefficients set at least once.
- Pair gayberne requires atom style ellipsoid*
Self-explanatory.
- Pair gayberne requires atoms with same type have same shape*
Self-explanatory.
- Pair gayberne/gpu requires atom style ellipsoid*
Self-explanatory.
- Pair gayberne/gpu requires atoms with same type have same shape*
Self-explanatory.
- Pair granular requires atom attributes radius, rmass*
The atom style defined does not have these attributes.
- Pair granular requires ghost atoms store velocity*
Use the comm_modify vel yes command to enable this.
- Pair granular with shear history requires newton pair off*
This is a current restriction of the implementation of pair granular styles with history.
- Pair hybrid single calls do not support per sub-style special bond values*
Self-explanatory.
- Pair hybrid sub-style does not support single call*
You are attempting to invoke a single() call on a pair style that doesn't support it.
- Pair hybrid sub-style is not used*
No pair_coeff command used a sub-style specified in the pair_style command.
- Pair inner cutoff < Respa interior cutoff*
One or more pairwise cutoffs are too short to use with the specified rRESPA cutoffs.
- Pair inner cutoff >= Pair outer cutoff*
The specified cutoffs for the pair style are inconsistent.
- Pair line/lj requires atom style line*
Self-explanatory.
- Pair lj/long/dipole/long requires atom attributes mu, torque*

LAMMPS Users Manual

- The atom style defined does not have these attributes.
- Pair lubricate requires atom style sphere*
Self-explanatory.
- Pair lubricate requires ghost atoms store velocity*
Use the `comm_modify vel yes` command to enable this.
- Pair lubricate requires monodisperse particles*
All particles must be the same finite size.
- Pair lubricate/poly requires atom style sphere*
Self-explanatory.
- Pair lubricate/poly requires extended particles*
One of the particles has radius 0.0.
- Pair lubricate/poly requires ghost atoms store velocity*
Use the `comm_modify vel yes` command to enable this.
- Pair lubricate/poly requires newton pair off*
Self-explanatory.
- Pair lubricateU requires atom style sphere*
Self-explanatory.
- Pair lubricateU requires ghost atoms store velocity*
Use the `comm_modify vel yes` command to enable this.
- Pair lubricateU requires monodisperse particles*
All particles must be the same finite size.
- Pair lubricateU/poly requires ghost atoms store velocity*
Use the `comm_modify vel yes` command to enable this.
- Pair lubricateU/poly requires newton pair off*
Self-explanatory.
- Pair peri lattice is not identical in x, y, and z*
The lattice defined by the `lattice` command must be cubic.
- Pair peri requires a lattice be defined*
Use the `lattice` command for this purpose.
- Pair peri requires an atom map, see atom_modify*
Even for atomic systems, an atom map is required to find Peridynamic bonds.
Use the `atom_modify` command to define one.
- Pair resquared epsilon a,b,c coeffs are not all set*
Self-explanatory.
- Pair resquared epsilon and sigma coeffs are not all set*
Self-explanatory.
- Pair resquared requires atom style ellipsoid*
Self-explanatory.
- Pair resquared requires atoms with same type have same shape*
Self-explanatory.
- Pair resquared/gpu requires atom style ellipsoid*
Self-explanatory.
- Pair resquared/gpu requires atoms with same type have same shape*
Self-explanatory.
- Pair style AIREBO requires atom IDs*
This is a requirement to use the AIREBO potential.
- Pair style AIREBO requires newton pair on*
See the `newton` command. This is a restriction to use the AIREBO potential.
- Pair style BOP requires atom IDs*
This is a requirement to use the BOP potential.
- Pair style BOP requires newton pair on*

LAMMPS Users Manual

- See the newton command. This is a restriction to use the BOP potential.
- Pair style COMB requires atom IDs*
This is a requirement to use the AIREBO potential.
- Pair style COMB requires atom attribute q*
Self-explanatory.
- Pair style COMB requires newton pair on*
See the newton command. This is a restriction to use the COMB potential.
- Pair style COMB3 requires atom IDs*
This is a requirement to use the COMB3 potential.
- Pair style COMB3 requires atom attribute q*
Self-explanatory.
- Pair style COMB3 requires newton pair on*
See the newton command. This is a restriction to use the COMB3 potential.
- Pair style LCBOP requires atom IDs*
This is a requirement to use the LCBOP potential.
- Pair style LCBOP requires newton pair on*
See the newton command. This is a restriction to use the Tersoff potential.
- Pair style MEAM requires newton pair on*
See the newton command. This is a restriction to use the MEAM potential.
- Pair style SNAP requires newton pair on*
See the newton command. This is a restriction to use the SNAP potential.
- Pair style Stillinger-Weber requires atom IDs*
This is a requirement to use the SW potential.
- Pair style Stillinger-Weber requires newton pair on*
See the newton command. This is a restriction to use the SW potential.
- Pair style Tersoff requires atom IDs*
This is a requirement to use the Tersoff potential.
- Pair style Tersoff requires newton pair on*
See the newton command. This is a restriction to use the Tersoff potential.
- Pair style Vashishta requires atom IDs*
This is a requirement to use the Vashishta potential.
- Pair style Vashishta requires newton pair on*
See the newton command. This is a restriction to use the Vashishta potential.
- Pair style bop requires comm ghost cutoff at least 3x larger than %g*
Use the communicate ghost command to set this. See the pair bop doc page for more details.
- Pair style born/coul/long requires atom attribute q*
An atom style that defines this attribute must be used.
- Pair style born/coul/long/gpu requires atom attribute q*
The atom style defined does not have this attribute.
- Pair style born/coul/wolf requires atom attribute q*
The atom style defined does not have this attribute.
- Pair style buck/coul/cut requires atom attribute q*
The atom style defined does not have this attribute.
- Pair style buck/coul/long requires atom attribute q*
The atom style defined does not have these attributes.
- Pair style buck/coul/long/gpu requires atom attribute q*
The atom style defined does not have this attribute.
- Pair style buck/long/coul/long requires atom attribute q*
The atom style defined does not have this attribute.
- Pair style coul/cut requires atom attribute q*

LAMMPS Users Manual

- The atom style defined does not have these attributes.
- Pair style coul/cut/gpu requires atom attribute q*
The atom style defined does not have this attribute.
- Pair style coul/debye/gpu requires atom attribute q*
The atom style defined does not have this attribute.
- Pair style coul/dsf requires atom attribute q*
The atom style defined does not have this attribute.
- Pair style coul/dsf/gpu requires atom attribute q*
The atom style defined does not have this attribute.
- Pair style coul/long/gpu requires atom attribute q*
The atom style defined does not have these attributes.
- Pair style coul/streitz requires atom attribute q*
Self-explanatory.
- Pair style does not have extra field requested by compute pair/local*
The pair style does not support the pN value requested by the compute pair/local command.
- Pair style does not support bond_style quartic*
The pair style does not have a single() function, so it can not be invoked by bond_style quartic.
- Pair style does not support compute group/group*
The pair_style does not have a single() function, so it cannot be invoked by the compute group/group command.
- Pair style does not support compute pair/local*
The pair style does not have a single() function, so it can not be invoked by compute pair/local.
- Pair style does not support compute property/local*
The pair style does not have a single() function, so it can not be invoked by fix bond/swap.
- Pair style does not support fix bond/swap*
The pair style does not have a single() function, so it can not be invoked by fix bond/swap.
- Pair style does not support pair_write*
The pair style does not have a single() function, so it can not be invoked by pair write.
- Pair style does not support rRESPA inner/middle/outer*
You are attempting to use rRESPA options with a pair style that does not support them.
- Pair style granular with history requires atoms have IDs*
Atoms in the simulation do not have IDs, so history effects cannot be tracked by the granular pair potential.
- Pair style hbond/dreiding requires an atom map, see atom_modify*
Self-explanatory.
- Pair style hbond/dreiding requires atom IDs*
Self-explanatory.
- Pair style hbond/dreiding requires molecular system*
Self-explanatory.
- Pair style hbond/dreiding requires newton pair on*
See the newton command for details.
- Pair style hybrid cannot have hybrid as an argument*
Self-explanatory.
- Pair style hybrid cannot have none as an argument*

LAMMPS Users Manual

Self-explanatory.

Pair style is incompatible with KSpace style

If a pair style with a long-range Coulombic component is selected, then a kspace style must also be used.

Pair style is incompatible with TIP4P KSpace style

The pair style does not have the requires TIP4P settings.

Pair style lj/charmm/coul/charmm requires atom attribute q

The atom style defined does not have these attributes.

Pair style lj/charmm/coul/long requires atom attribute q

The atom style defined does not have these attributes.

Pair style lj/charmm/coul/long/gpu requires atom attribute q

The atom style defined does not have this attribute.

Pair style lj/class2/coul/cut requires atom attribute q

The atom style defined does not have this attribute.

Pair style lj/class2/coul/long requires atom attribute q

The atom style defined does not have this attribute.

Pair style lj/class2/coul/long/gpu requires atom attribute q

The atom style defined does not have this attribute.

Pair style lj/cut/coul/cut requires atom attribute q

The atom style defined does not have this attribute.

Pair style lj/cut/coul/cut/gpu requires atom attribute q

The atom style defined does not have this attribute.

Pair style lj/cut/coul/debye/gpu requires atom attribute q

The atom style defined does not have this attribute.

Pair style lj/cut/coul/dsf requires atom attribute q

The atom style defined does not have these attributes.

Pair style lj/cut/coul/dsf/gpu requires atom attribute q

The atom style defined does not have this attribute.

Pair style lj/cut/coul/long requires atom attribute q

The atom style defined does not have this attribute.

Pair style lj/cut/coul/long/gpu requires atom attribute q

The atom style defined does not have this attribute.

Pair style lj/cut/tip4p/cut requires atom IDs

This is a requirement to use this potential.

Pair style lj/cut/tip4p/cut requires atom attribute q

The atom style defined does not have this attribute.

Pair style lj/cut/tip4p/cut requires newton pair on

See the newton command. This is a restriction to use this potential.

Pair style lj/cut/tip4p/long requires atom IDs

There are no atom IDs defined in the system and the TIP4P potential requires them to find O,H atoms with a water molecule.

Pair style lj/cut/tip4p/long requires atom attribute q

The atom style defined does not have these attributes.

Pair style lj/cut/tip4p/long requires newton pair on

This is because the computation of constraint forces within a water molecule adds forces to atoms owned by other processors.

Pair style lj/gromacs/coul/gromacs requires atom attribute q

An atom_style with this attribute is needed.

Pair style lj/long/dipole/long does not currently support respa

This feature is not yet supported.

Pair style lj/long/tip4p/long requires atom IDs

LAMMPS Users Manual

There are no atom IDs defined in the system and the TIP4P potential requires them to find O,H atoms with a water molecule.

Pair style lj/long/tip4p/long requires atom attribute q

The atom style defined does not have these attributes.

Pair style lj/long/tip4p/long requires newton pair on

This is because the computation of constraint forces within a water molecule adds forces to atoms owned by other processors.

Pair style lj/sdk/coul/long/gpu requires atom attribute q

The atom style defined does not have this attribute.

Pair style nb3b/harmonic requires atom IDs

This is a requirement to use this potential.

Pair style nb3b/harmonic requires newton pair on

See the newton command. This is a restriction to use this potential.

Pair style nm/cut/coul/cut requires atom attribute q

The atom style defined does not have this attribute.

Pair style nm/cut/coul/long requires atom attribute q

The atom style defined does not have this attribute.

Pair style peri requires atom style peri

Self-explanatory.

Pair style polymorphic requires atom IDs

This is a requirement to use the polymorphic potential.

Pair style polymorphic requires newton pair on

See the newton command. This is a restriction to use the polymorphic potential.

Pair style reax requires atom IDs

This is a requirement to use the ReaxFF potential.

Pair style reax requires atom attribute q

The atom style defined does not have this attribute.

Pair style reax requires newton pair on

This is a requirement to use the ReaxFF potential.

Pair style requires a KSpace style

No kspace style is defined.

Pair style requires use of kspace_style ewald/disp

Self-explanatory.

Pair style sw/gpu requires atom IDs

This is a requirement to use this potential.

Pair style sw/gpu requires newton pair off

See the newton command. This is a restriction to use this potential.

Pair style vashishta/gpu requires atom IDs

This is a requirement to use this potential.

Pair style vashishta/gpu requires newton pair off

See the newton command. This is a restriction to use this potential.

Pair style tersoff/gpu requires atom IDs

This is a requirement to use the tersoff/gpu potential.

Pair style tersoff/gpu requires newton pair off

See the newton command. This is a restriction to use this pair style.

Pair style tip4p/cut requires atom IDs

This is a requirement to use this potential.

Pair style tip4p/cut requires atom attribute q

The atom style defined does not have this attribute.

Pair style tip4p/cut requires newton pair on

See the newton command. This is a restriction to use this potential.

LAMMPS Users Manual

Pair style tip4p/long requires atom IDs

There are no atom IDs defined in the system and the TIP4P potential requires them to find O,H atoms with a water molecule.

Pair style tip4p/long requires atom attribute q

The atom style defined does not have these attributes.

Pair style tip4p/long requires newton pair on

This is because the computation of constraint forces within a water molecule adds forces to atoms owned by other processors.

Pair table cutoffs must all be equal to use with KSpace

When using pair style table with a long-range KSpace solver, the cutoffs for all atom type pairs must all be the same, since the long-range solver starts at that cutoff.

Pair table parameters did not set N

List of pair table parameters must include N setting.

Pair tersoff/zbl requires metal or real units

This is a current restriction of this pair potential.

Pair tersoff/zbl/kk requires metal or real units

This is a current restriction of this pair potential.

Pair tri/lj requires atom style tri

Self-explanatory.

Pair yukawa/colloid requires atom style sphere

Self-explanatory.

Pair yukawa/colloid requires atoms with same type have same radius

Self-explanatory.

Pair yukawa/colloid/gpu requires atom style sphere

Self-explanatory.

PairKIM only works with 3D problems

This is a current limitation.

Pair_coeff command before pair_style is defined

Self-explanatory.

Pair_coeff command before simulation box is defined

The pair_coeff command cannot be used before a read_data, read_restart, or create_box command.

Pair_modify command before pair_style is defined

Self-explanatory.

Pair_modify special setting for pair hybrid incompatible with global special_bonds setting

Cannot override a setting of 0.0 or 1.0 or change a setting between 0.0 and 1.0.

Pair_write command before pair_style is defined

Self-explanatory.

Particle on or inside fix wall surface

Particles must be "exterior" to the wall in order for energy/force to be calculated.

Particle outside surface of region used in fix wall/region

Particles must be inside the region for energy/force to be calculated. A particle outside the region generates an error.

Per-atom compute in equal-style variable formula

Equal-style variables cannot use per-atom quantities.

Per-atom energy was not tallied on needed timestep

You are using a thermo keyword that requires potentials to have tallied energy, but they didn't on this timestep. See the variable doc page for ideas on how to

make this work.

Per-atom fix in equal-style variable formula

Equal-style variables cannot use per-atom quantities.

Per-atom virial was not tallied on needed timestep

You are using a thermo keyword that requires potentials to have tallied the virial, but they didn't on this timestep. See the variable doc page for ideas on how to make this work.

Per-processor system is too big

The number of owned atoms plus ghost atoms on a single processor must fit in 32-bit integer.

Potential energy ID for fix neb does not exist

Self-explanatory.

Potential energy ID for fix nvt/nph/npt does not exist

A compute for potential energy must be defined.

Potential file has duplicate entry

The potential file has more than one entry for the same element.

Potential file is missing an entry

The potential file does not have a needed entry.

Power by 0 in variable formula

Self-explanatory.

Pressure ID for fix box/relax does not exist

The compute ID needed to compute pressure for the fix does not exist.

Pressure ID for fix modify does not exist

Self-explanatory.

Pressure ID for fix npt/nph does not exist

Self-explanatory.

Pressure ID for fix press/berendsen does not exist

The compute ID needed to compute pressure for the fix does not exist.

Pressure ID for fix rigid npt/nph does not exist

Self-explanatory.

Pressure ID for thermo does not exist

The compute ID needed to compute pressure for thermodynamics does not exist.

Pressure control can not be used with fix nvt

Self-explanatory.

Pressure control can not be used with fix nvt/asphere

Self-explanatory.

Pressure control can not be used with fix nvt/body

Self-explanatory.

Pressure control can not be used with fix nvt/sllod

Self-explanatory.

Pressure control can not be used with fix nvt/sphere

Self-explanatory.

Pressure control must be used with fix nph

Self-explanatory.

Pressure control must be used with fix nph/asphere

Self-explanatory.

Pressure control must be used with fix nph/body

Self-explanatory.

Pressure control must be used with fix nph/small

Self-explanatory.

LAMMPS Users Manual

- Pressure control must be used with fix nph/sphere*
Self-explanatory.
- Pressure control must be used with fix nphug*
A pressure control keyword (iso, aniso, tri, x, y, or z) must be provided.
- Pressure control must be used with fix npt*
Self-explanatory.
- Pressure control must be used with fix npt/asphere*
Self-explanatory.
- Pressure control must be used with fix npt/body*
Self-explanatory.
- Pressure control must be used with fix npt/sphere*
Self-explanatory.
- Processor count in z must be 1 for 2d simulation*
Self-explanatory.
- Processor partitions do not match number of allocated processors*
The total number of processors in all partitions must match the number of processors LAMMPS is running on.
- Processors command after simulation box is defined*
The processors command cannot be used after a read_data, read_restart, or create_box command.
- Processors custom grid file is inconsistent*
The vales in the custom file are not consistent with the number of processors you are running on or the Px,Py,Pz settings of the processors command. Or there was not a setting for every processor.
- Processors grid numa and map style are incompatible*
Using numa for gstyle in the processors command requires using cart for the map option.
- Processors part option and grid style are incompatible*
Cannot use gstyle numa or custom with the part option.
- Processors twogrid requires proc count be a multiple of core count*
Self-explanatory.
- Pstart and Pstop must have the same value*
Self-explanatory.
- Python function evaluation failed*
The Python function did not run successfully and/or did not return a value (if it is supposed to return a value). This is probably due to some error condition in the function.
- Python function is not callable*
The provided Python code was run successfully, but it not define a callable function with the required name.
- Python invoke of undefined function*
Cannot invoke a function that has not been previously defined.
- Python variable does not match Python function*
This matching is defined by the python-style variable and the python command.
- Python variable has no function*
No python command was used to define the function associated with the python-style variable.
- QEQ with 'newton pair off' not supported*
See the newton command. This is a restriction to use the QEQ fixes.
- R0 < 0 for fix spring command*
Equilibrium spring length is invalid.

LAMMPS Users Manual

- RATTLE coordinate constraints are not satisfied up to desired tolerance*
Self-explanatory.
- RATTLE determinant = 0.0*
The determinant of the matrix being solved for a single cluster specified by the fix rattle command is numerically invalid.
- RATTLE failed*
Certain constraints were not satisfied.
- RATTLE velocity constraints are not satisfied up to desired tolerance*
Self-explanatory.
- Read data add offset is too big*
It cannot be larger than the size of atom IDs, e.g. the maximum 32-bit integer.
- Read dump of atom property that isn't allocated*
Self-explanatory.
- Read rerun dump file timestep > specified stop*
Self-explanatory.
- Read restart MPI-IO input not allowed with % in filename*
This is because a % signifies one file per processor and MPI-IO creates one large file for all processors.
- Read_data shrink wrap did not assign all atoms correctly*
This is typically because the box-size specified in the data file is large compared to the actual extent of atoms in a shrink-wrapped dimension. When LAMMPS shrink-wraps the box atoms will be lost if the processor they are re-assigned to is too far away. Choose a box size closer to the actual extent of the atoms.
- Read_dump command before simulation box is defined*
The read_dump command cannot be used before a read_data, read_restart, or create_box command.
- Read_dump field not found in dump file*
Self-explanatory.
- Read_dump triclinic status does not match simulation*
Both the dump snapshot and the current LAMMPS simulation must be using either an orthogonal or triclinic box.
- Read_dump xyz fields do not have consistent scaling/wrapping*
Self-explanatory.
- Reading from MPI-IO filename when MPIIO package is not installed*
Self-explanatory.
- Reax_defs.h setting for NATDEF is too small*
Edit the setting in the ReaxFF library and re-compile the library and re-build LAMMPS.
- Reax_defs.h setting for NNEIGHMAXDEF is too small*
Edit the setting in the ReaxFF library and re-compile the library and re-build LAMMPS.
- Receiving partition in processors part command is already a receiver*
Cannot specify a partition to be a receiver twice.
- Region ID for compute chunk/atom does not exist*
Self-explanatory.
- Region ID for compute reduce/region does not exist*
Self-explanatory.
- Region ID for compute temp/region does not exist*
Self-explanatory.
- Region ID for dump custom does not exist*
Self-explanatory.

Region ID for fix addforce does not exist

Self-explanatory.

Region ID for fix atom/swap does not exist

Self-explanatory.

Region ID for fix ave/spatial does not exist

Self-explanatory.

Region ID for fix aveforce does not exist

Self-explanatory.

Region ID for fix deposit does not exist

Self-explanatory.

Region ID for fix efield does not exist

Self-explanatory.

Region ID for fix evaporate does not exist

Self-explanatory.

Region ID for fix gcmc does not exist

Self-explanatory.

Region ID for fix heat does not exist

Self-explanatory.

Region ID for fix setforce does not exist

Self-explanatory.

Region ID for fix wall/region does not exist

Self-explanatory.

Region ID for group dynamic does not exist

Self-explanatory.

Region ID in variable formula does not exist

Self-explanatory.

Region cannot have 0 length rotation vector

Self-explanatory.

Region for fix oneway does not exist

Self-explanatory.

Region intersect region ID does not exist

Self-explanatory.

Region union or intersect cannot be dynamic

The sub-regions can be dynamic, but not the combined region.

Region union region ID does not exist

One or more of the region IDs specified by the region union command does not exist.

Replacing a fix, but new style != old style

A fix ID can be used a 2nd time, but only if the style matches the previous fix. In this case it is assumed you wish to reset a fix's parameters. This error may mean you are mistakenly re-using a fix ID when you do not intend to.

Replicate command before simulation box is defined

The replicate command cannot be used before a read_data, read_restart, or create_box command.

Replicate did not assign all atoms correctly

Atoms replicated by the replicate command were not assigned correctly to processors. This is likely due to some atom coordinates being outside a non-periodic simulation box.

Replicated system atom IDs are too big

See the setting for tagint in the src/lmptype.h file.

Replicated system is too big

LAMMPS Users Manual

- See the setting for `bigint` in the `src/lmptype.h` file.
- Required border comm not yet implemented with Kokkos*
There are various limitations in the communication options supported by Kokkos.
- Rerun command before simulation box is defined*
The `rerun` command cannot be used before a `read_data`, `read_restart`, or `create_box` command.
- Rerun dump file does not contain requested snapshot*
Self-explanatory.
- Resetting timestep size is not allowed with fix move*
This is because `fix move` is moving atoms based on elapsed time.
- Respa inner cutoffs are invalid*
The first cutoff must be \leq the second cutoff.
- Respa levels must be ≥ 1*
Self-explanatory.
- Respa middle cutoffs are invalid*
The first cutoff must be \leq the second cutoff.
- Restart file MPI-IO output not allowed with % in filename*
This is because a `%` signifies one file per processor and MPI-IO creates one large file for all processors.
- Restart file byte ordering is not recognized*
The file does not appear to be a LAMMPS restart file since it doesn't contain a recognized byte-ordering flag at the beginning.
- Restart file byte ordering is swapped*
The file was written on a machine with different byte-ordering than the machine you are reading it on. Convert it to a text data file instead, on the machine you wrote it on.
- Restart file incompatible with current version*
This is probably because you are trying to read a file created with a version of LAMMPS that is too old compared to the current version. Use your older version of LAMMPS and convert the restart file to a data file.
- Restart file is a MPI-IO file*
The file is inconsistent with the filename you specified for it.
- Restart file is a multi-proc file*
The file is inconsistent with the filename you specified for it.
- Restart file is not a MPI-IO file*
The file is inconsistent with the filename you specified for it.
- Restart file is not a multi-proc file*
The file is inconsistent with the filename you specified for it.
- Restart variable returned a bad timestep*
The variable must return a timestep greater than the current timestep.
- Restrain atoms %d %d %d %d missing on proc %d at step %ld*
The 4 atoms in a restrain dihedral specified by the `fix restrain` command are not all accessible to a processor. This probably means an atom has moved too far.
- Restrain atoms %d %d %d missing on proc %d at step %ld*
The 3 atoms in a restrain angle specified by the `fix restrain` command are not all accessible to a processor. This probably means an atom has moved too far.
- Restrain atoms %d %d missing on proc %d at step %ld*
The 2 atoms in a restrain bond specified by the `fix restrain` command are not all accessible to a processor. This probably means an atom has moved too far.
- Reuse of compute ID*

LAMMPS Users Manual

A compute ID cannot be used twice.

Reuse of dump ID

A dump ID cannot be used twice.

Reuse of molecule template ID

The template IDs must be unique.

Reuse of region ID

A region ID cannot be used twice.

Rigid body atoms %d %d missing on proc %d at step %ld

This means that an atom cannot find the atom that owns the rigid body it is part of, or vice versa. The solution is to use the communicate cutoff command to insure ghost atoms are acquired from far enough away to encompass the max distance printed when the fix rigid/small command was invoked.

Rigid body has degenerate moment of inertia

Fix poems will only work with bodies (collections of atoms) that have non-zero principal moments of inertia. This means they must be 3 or more non-collinear atoms, even with joint atoms removed.

Rigid fix must come before NPT/NPH fix

NPT/NPH fix must be defined in input script after all rigid fixes, else the rigid fix contribution to the pressure virial is incorrect.

Rmask function in equal-style variable formula

Rmask is per-atom operation.

Run command before simulation box is defined

The run command cannot be used before a read_data, read_restart, or create_box command.

Run command start value is after start of run

Self-explanatory.

Run command stop value is before end of run

Self-explanatory.

Run_style command before simulation box is defined

The run_style command cannot be used before a read_data, read_restart, or create_box command.

SRD bin size for fix srd differs from user request

Fix SRD had to adjust the bin size to fit the simulation box. See the cubic keyword if you want this message to be an error vs warning.

SRD bins for fix srd are not cubic enough

The bin shape is not within tolerance of cubic. See the cubic keyword if you want this message to be an error vs warning.

SRD particle %d started inside big particle %d on step %ld bounce %d

See the inside keyword if you want this message to be an error vs warning.

SRD particle %d started inside wall %d on step %ld bounce %d

See the inside keyword if you want this message to be an error vs warning.

Same dimension twice in fix ave/spatial

Self-explanatory.

Sending partition in processors part command is already a sender

Cannot specify a partition to be a sender twice.

Set command before simulation box is defined

The set command cannot be used before a read_data, read_restart, or create_box command.

Set command floating point vector does not exist

Self-explanatory.

Set command integer vector does not exist

LAMMPS Users Manual

Self-explanatory.

Set command with no atoms existing

No atoms are yet defined so the set command cannot be used.

Set region ID does not exist

Region ID specified in set command does not exist.

Shake angles have different bond types

All 3-atom angle-constrained SHAKE clusters specified by the fix shake command that are the same angle type, must also have the same bond types for the 2 bonds in the angle.

Shake atoms %d %d %d %d missing on proc %d at step %ld

The 4 atoms in a single shake cluster specified by the fix shake command are not all accessible to a processor. This probably means an atom has moved too far.

Shake atoms %d %d %d missing on proc %d at step %ld

The 3 atoms in a single shake cluster specified by the fix shake command are not all accessible to a processor. This probably means an atom has moved too far.

Shake atoms %d %d missing on proc %d at step %ld

The 2 atoms in a single shake cluster specified by the fix shake command are not all accessible to a processor. This probably means an atom has moved too far.

Shake cluster of more than 4 atoms

A single cluster specified by the fix shake command can have no more than 4 atoms.

Shake clusters are connected

A single cluster specified by the fix shake command must have a single central atom with up to 3 other atoms bonded to it.

Shake determinant = 0.0

The determinant of the matrix being solved for a single cluster specified by the fix shake command is numerically invalid.

Shake fix must come before NPT/NPH fix

NPT fix must be defined in input script after SHAKE fix, else the SHAKE fix contribution to the pressure virial is incorrect.

Shear history overflow, boost neigh_modify one

There are too many neighbors of a single atom. Use the neigh_modify command to increase the max number of neighbors allowed for one atom. You may also want to boost the page size.

Small to big integers are not sized correctly

This error occurs when the sizes of smallint, imageint, tagint, bigint, as defined in src/lmptype.h are not what is expected. Contact the developers if this occurs.

Smallint setting in lmptype.h is invalid

It has to be the size of an integer.

Smallint setting in lmptype.h is not compatible

Smallint stored in restart file is not consistent with LAMMPS version you are running.

Special list size exceeded in fix bond/create

See the "read_data extra/special/per/atom" command (or the "create_box extra/special/per/atom" command) for info on how to leave space in the special bonds list to allow for additional bonds to be formed.

Specified processors != physical processors

LAMMPS Users Manual

- The 3d grid of processors defined by the processors command does not match the number of processors LAMMPS is being run on.
- Specified target stress must be uniaxial or hydrostatic*
Self-explanatory.
- Sqrt of negative value in variable formula*
Self-explanatory.
- Subsequent read data induced too many angles per atom*
See the extra/angle/per/atom keyword for the create_box or the read_data command to set this limit larger
- Subsequent read data induced too many bonds per atom*
See the extra/bond/per/atom keyword for the create_box or the read_data command to set this limit larger
- Subsequent read data induced too many dihedrals per atom*
See the extra/dihedral/per/atom keyword for the create_box or the read_data command to set this limit larger
- Subsequent read data induced too many impropers per atom*
See the extra/improper/per/atom keyword for the create_box or the read_data command to set this limit larger
- Substitution for illegal variable*
Input script line contained a variable that could not be substituted for.
- Support for writing images in JPEG format not included*
LAMMPS was not built with the -DLAMMPS_JPEG switch in the Makefile.
- Support for writing images in PNG format not included*
LAMMPS was not built with the -DLAMMPS_PNG switch in the Makefile.
- Support for writing movies not included*
LAMMPS was not built with the -DLAMMPS_FFMPEG switch in the Makefile
- System in data file is too big*
See the setting for bigint in the src/lmptype.h file.
- System is not charge neutral, net charge = %g*
The total charge on all atoms on the system is not 0.0. For some KSpace solvers this is an error.
- TAD nsteps must be multiple of t_event*
Self-explanatory.
- TIP4P hydrogen has incorrect atom type*
The TIP4P pairwise computation found an H atom whose type does not agree with the specified H type.
- TIP4P hydrogen is missing*
The TIP4P pairwise computation failed to find the correct H atom within a water molecule.
- TMD target file did not list all group atoms*
The target file for the fix tmd command did not list all atoms in the fix group.
- Tad command before simulation box is defined*
Self-explanatory.
- Tagint setting in lmptype.h is invalid*
Tagint must be as large or larger than smallint.
- Tagint setting in lmptype.h is not compatible*
Format of tagint stored in restart file is not consistent with LAMMPS version you are running. See the settings in src/lmptype.h
- Target pressure for fix rigid/nph cannot be < 0.0*
Self-explanatory.
- Target pressure for fix rigid/npt/small cannot be < 0.0*

LAMMPS Users Manual

- Self-explanatory.
- Target temperature for fix nvt/npt/nph cannot be 0.0*
Self-explanatory.
- Target temperature for fix rigid/npt cannot be 0.0*
Self-explanatory.
- Target temperature for fix rigid/npt/small cannot be 0.0*
Self-explanatory.
- Target temperature for fix rigid/nvt cannot be 0.0*
Self-explanatory.
- Target temperature for fix rigid/nvt/small cannot be 0.0*
Self-explanatory.
- Temper command before simulation box is defined*
The temper command cannot be used before a read_data, read_restart, or create_box command.
- Temperature ID for fix bond/swap does not exist*
Self-explanatory.
- Temperature ID for fix box/relax does not exist*
Self-explanatory.
- Temperature ID for fix nvt/npt does not exist*
Self-explanatory.
- Temperature ID for fix press/berendsen does not exist*
Self-explanatory.
- Temperature ID for fix rigid nvt/npt/nph does not exist*
Self-explanatory.
- Temperature ID for fix temp/berendsen does not exist*
Self-explanatory.
- Temperature ID for fix temp/csld does not exist*
Self-explanatory.
- Temperature ID for fix temp/csvr does not exist*
Self-explanatory.
- Temperature ID for fix temp/rescale does not exist*
Self-explanatory.
- Temperature compute degrees of freedom < 0*
This should not happen if you are calculating the temperature on a valid set of atoms.
- Temperature control can not be used with fix nph*
Self-explanatory.
- Temperature control can not be used with fix nph/asphere*
Self-explanatory.
- Temperature control can not be used with fix nph/body*
Self-explanatory.
- Temperature control can not be used with fix nph/sphere*
Self-explanatory.
- Temperature control must be used with fix nphug*
The temp keyword must be provided.
- Temperature control must be used with fix npt*
Self-explanatory.
- Temperature control must be used with fix npt/asphere*
Self-explanatory.
- Temperature control must be used with fix npt/body*
Self-explanatory.

LAMMPS Users Manual

- Temperature control must be used with fix npt/sphere*
Self-explanatory.
- Temperature control must be used with fix nvt*
Self-explanatory.
- Temperature control must be used with fix nvt/asphere*
Self-explanatory.
- Temperature control must be used with fix nvt/body*
Self-explanatory.
- Temperature control must be used with fix nvt/sllod*
Self-explanatory.
- Temperature control must be used with fix nvt/sphere*
Self-explanatory.
- Temperature control must not be used with fix nph/small*
Self-explanatory.
- Temperature for fix nvt/sllod does not have a bias*
The specified compute must compute temperature with a bias.
- Tempering could not find thermo_pe compute*
This compute is created by the thermo command. It must have been explicitly deleted by a uncompute command.
- Tempering fix ID is not defined*
The fix ID specified by the temper command does not exist.
- Tempering temperature fix is not valid*
The fix specified by the temper command is not one that controls temperature (nvt or langevin).
- Test_descriptor_string already allocated*
This is an internal error. Contact the developers.
- The package gpu command is required for gpu styles*
Self-explanatory.
- Thermo and fix not computed at compatible times*
Fixes generate values on specific timesteps. The thermo output does not match these timesteps.
- Thermo compute array is accessed out-of-range*
Self-explanatory.
- Thermo compute does not compute array*
Self-explanatory.
- Thermo compute does not compute scalar*
Self-explanatory.
- Thermo compute does not compute vector*
Self-explanatory.
- Thermo compute vector is accessed out-of-range*
Self-explanatory.
- Thermo custom variable cannot be indexed*
Self-explanatory.
- Thermo custom variable is not equal-style variable*
Only equal-style variables can be output with thermodynamics, not atom-style variables.
- Thermo every variable returned a bad timestep*
The variable must return a timestep greater than the current timestep.
- Thermo fix array is accessed out-of-range*
Self-explanatory.
- Thermo fix does not compute array*

- Self-explanatory.
- Thermo fix does not compute scalar*
Self-explanatory.
- Thermo fix does not compute vector*
Self-explanatory.
- Thermo fix vector is accessed out-of-range*
Self-explanatory.
- Thermo keyword in variable requires thermo to use/init pe*
You are using a thermo keyword in a variable that requires potential energy to be calculated, but your thermo output does not use it. Add it to your thermo output.
- Thermo keyword in variable requires thermo to use/init press*
You are using a thermo keyword in a variable that requires pressure to be calculated, but your thermo output does not use it. Add it to your thermo output.
- Thermo keyword in variable requires thermo to use/init temp*
You are using a thermo keyword in a variable that requires temperature to be calculated, but your thermo output does not use it. Add it to your thermo output.
- Thermo style does not use press*
Cannot use thermo_modify to set this parameter since the thermo_style is not computing this quantity.
- Thermo style does not use temp*
Cannot use thermo_modify to set this parameter since the thermo_style is not computing this quantity.
- Thermo_modify every variable returned a bad timestep*
The returned timestep is less than or equal to the current timestep.
- Thermo_modify int format does not contain d character*
Self-explanatory.
- Thermo_modify pressure ID does not compute pressure*
The specified compute ID does not compute pressure.
- Thermo_modify temperature ID does not compute temperature*
The specified compute ID does not compute temperature.
- Thermo_style command before simulation box is defined*
The thermo_style command cannot be used before a read_data, read_restart, or create_box command.
- This variable thermo keyword cannot be used between runs*
Keywords that refer to time (such as cpu, elapsed) do not make sense in between runs.
- Threshold for an atom property that isn't allocated*
A dump threshold has been requested on a quantity that is not defined by the atom style used in this simulation.
- Timestep must be ≥ 0*
Specified timestep is invalid.
- Too big a problem to use velocity create loop all*
The system size must fit in a 32-bit integer to use this option.
- Too big a timestep for dump dcd*
The timestep must fit in a 32-bit integer to use this dump style.
- Too big a timestep for dump xtc*
The timestep must fit in a 32-bit integer to use this dump style.
- Too few bits for lookup table*

LAMMPS Users Manual

- Table size specified via `pair_modify` command does not work with your machine's floating point representation.
- Too few lines in %s section of data file*
Self-explanatory.
- Too few values in body lines in data file*
Self-explanatory.
- Too few values in body section of molecule file*
Self-explanatory.
- Too many -pk arguments in command line*
The string formed by concatenating the arguments is too long. Use a package command in the input script instead.
- Too many MSM grid levels*
The max number of MSM grid levels is hardwired to 10.
- Too many args in variable function*
More args are used than any variable function allows.
- Too many atom pairs for pair bop*
The number of atomic pairs exceeds the expected number. Check your atomic structure to ensure that it is realistic.
- Too many atom sorting bins*
This is likely due to an immense simulation box that has blown up to a large size.
- Too many atom triplets for pair bop*
The number of three atom groups for angle determinations exceeds the expected number. Check your atomic structure to ensure that it is realistic.
- Too many atoms for dump dcd*
The system size must fit in a 32-bit integer to use this dump style.
- Too many atoms for dump xtc*
The system size must fit in a 32-bit integer to use this dump style.
- Too many atoms to dump sort*
Cannot sort when running with more than 2^{31} atoms.
- Too many exponent bits for lookup table*
Table size specified via `pair_modify` command does not work with your machine's floating point representation.
- Too many groups*
The maximum number of atom groups (including the "all" group) is given by `MAX_GROUP` in `group.cpp` and is 32.
- Too many iterations*
You must use a number of iterations that fit in a 32-bit integer for minimization.
- Too many lines in one body in data file - boost MAXBODY*
`MAXBODY` is a setting at the top of the `src/read_data.cpp` file. Set it larger and re-compile the code.
- Too many local+ghost atoms for neighbor list*
The number of `nlocal + nghost` atoms on a processor is limited by the size of a 32-bit integer with 2 bits removed for masking 1-2, 1-3, 1-4 neighbors.
- Too many mantissa bits for lookup table*
Table size specified via `pair_modify` command does not work with your machine's floating point representation.
- Too many masses for fix shake*
The `fix shake` command cannot list more masses than there are atom types.
- Too many molecules for fix poems*
The limit is $2^{31} = \sim 2$ billion molecules.

LAMMPS Users Manual

Too many molecules for fix rigid

The limit is $2^{31} = \sim 2$ billion molecules.

Too many neighbor bins

This is likely due to an immense simulation box that has blown up to a large size.

Too many timesteps

The cumulative timesteps must fit in a 64-bit integer.

Too many timesteps for NEB

You must use a number of timesteps that fit in a 32-bit integer for NEB.

Too many total atoms

See the setting for bigint in the src/lmptype.h file.

Too many total bits for bitmapped lookup table

Table size specified via pair_modify command is too large. Note that a value of N generates a 2^N size table.

Too many values in body lines in data file

Self-explanatory.

Too many values in body section of molecule file

Self-explanatory.

Too much buffered per-proc info for dump

The size of the buffered string must fit in a 32-bit integer for a dump.

Too much per-proc info for dump

Number of local atoms times number of columns must fit in a 32-bit integer for dump.

Tree structure in joint connections

Fix poems cannot (yet) work with coupled bodies whose joints connect the bodies in a tree structure.

Triclinic box skew is too large

The displacement in a skewed direction must be less than half the box length in that dimension. E.g. the xy tilt must be between -half and +half of the x box length. This constraint can be relaxed by using the box tilt command.

Tried to convert a double to int, but input_double > INT_MAX

Self-explanatory.

Trying to build an occasional neighbor list before initialization completed

This is not allowed. Source code caller needs to be modified.

Two fix ave commands using same compute chunk/atom command in incompatible ways

They are both attempting to "lock" the chunk/atom command so that the chunk assignments persist for some number of timesteps, but are doing it in different ways.

Two groups cannot be the same in fix spring couple

Self-explanatory.

USER-CUDA mode requires CUDA variant of min style

CUDA mode is enabled, so the min style must include a cuda suffix.

USER-CUDA mode requires CUDA variant of run style

CUDA mode is enabled, so the run style must include a cuda suffix.

USER-CUDA package does not yet support comm_style tiled

Self-explanatory.

USER-CUDA package requires a cuda enabled atom_style

Self-explanatory.

Unable to initialize accelerator for use

There was a problem initializing an accelerator for the gpu package

LAMMPS Users Manual

Unbalanced quotes in input line

No matching end double quote was found following a leading double quote.

Unexpected end of -reorder file

Self-explanatory.

Unexpected end of AngleCoeffs section

Read a blank line.

Unexpected end of BondCoeffs section

Read a blank line.

Unexpected end of DihedralCoeffs section

Read a blank line.

Unexpected end of ImproperCoeffs section

Read a blank line.

Unexpected end of PairCoeffs section

Read a blank line.

Unexpected end of custom file

Self-explanatory.

Unexpected end of data file

LAMMPS hit the end of the data file while attempting to read a section.

Something is wrong with the format of the data file.

Unexpected end of dump file

A read operation from the file failed.

Unexpected end of fix rigid file

A read operation from the file failed.

Unexpected end of fix rigid/small file

A read operation from the file failed.

Unexpected end of molecule file

Self-explanatory.

Unexpected end of neb file

A read operation from the file failed.

Units command after simulation box is defined

The units command cannot be used after a read_data, read_restart, or create_box command.

Universe/uloop variable count < # of partitions

A universe or uloop style variable must specify a number of values \geq to the number of processor partitions.

Unknown angle style

The choice of angle style is unknown.

Unknown atom style

The choice of atom style is unknown.

Unknown body style

The choice of body style is unknown.

Unknown bond style

The choice of bond style is unknown.

Unknown category for info is_active()

Self-explanatory.

Unknown category for info is_available()

Self-explanatory.

Unknown category for info is_defined()

Self-explanatory.

Unknown command: %s

The command is not known to LAMMPS. Check the input script.

LAMMPS Users Manual

Unknown compute style

The choice of compute style is unknown.

Unknown dihedral style

The choice of dihedral style is unknown.

Unknown dump reader style

The choice of dump reader style via the format keyword is unknown.

Unknown dump style

The choice of dump style is unknown.

Unknown error in GPU library

Self-explanatory.

Unknown fix style

The choice of fix style is unknown.

Unknown identifier in data file: %s

A section of the data file cannot be read by LAMMPS.

Unknown improper style

The choice of improper style is unknown.

Unknown keyword in thermo_style custom command

One or more specified keywords are not recognized.

Unknown kspace style

The choice of kspace style is unknown.

Self-explanatory.

Unknown table style in bond style table

Self-explanatory.

Unknown table style in pair_style command

Style of table is invalid for use with pair_style table command.

Unknown unit_style

Self-explanatory. Check the input script or data file.

Unrecognized lattice type in MEAM file 1

The lattice type in an entry of the MEAM library file is not valid.

Unrecognized lattice type in MEAM file 2

The lattice type in an entry of the MEAM parameter file is not valid.

Unrecognized pair style in compute pair command

Self-explanatory.

Unrecognized virial argument in pair_style command

Only two options are supported: LAMMPSvirial and KIMvirial

Unsupported mixing rule in kspace_style ewald/disp

LAMMPS Users Manual

Only geometric mixing is supported.

Unsupported order in kspace_style ewald/disp

Only $1/r^6$ dispersion or dipole terms are supported.

Unsupported order in kspace_style pppm/disp, pair_style %s

Only pair styles with $1/r$ and $1/r^6$ dependence are currently supported.

Use cutoff keyword to set cutoff in single mode

Mode is single so cutoff/multi keyword cannot be used.

Use cutoff/multi keyword to set cutoff in multi mode

Mode is multi so cutoff keyword cannot be used.

Using fix nvt/sllod with inconsistent fix deform remap option

Fix nvt/sllod requires that deforming atoms have a velocity profile provided by "remap v" as a fix deform option.

Using fix nvt/sllod with no fix deform defined

Self-explanatory.

Using fix srd with inconsistent fix deform remap option

When shearing the box in an SRD simulation, the remap v option for fix deform needs to be used.

Using pair lubricate with inconsistent fix deform remap option

Must use remap v option with fix deform with this pair style.

Using pair lubricate/poly with inconsistent fix deform remap option

If fix deform is used, the remap v option is required.

Using suffix cuda without USER-CUDA package enabled

Self-explanatory.

Using suffix gpu without GPU package installed

Self-explanatory.

Using suffix intel without USER-INTEL package installed

Self-explanatory.

Using suffix kk without KOKKOS package enabled

Self-explanatory.

Using suffix omp without USER-OMP package installed

Self-explanatory.

Using update dipole flag requires atom attribute mu

Self-explanatory.

Using update dipole flag requires atom style sphere

Self-explanatory.

Variable ID in variable formula does not exist

Self-explanatory.

Variable atom ID is too large

Specified ID is larger than the maximum allowed atom ID.

Variable evaluation before simulation box is defined

Cannot evaluate a compute or fix or atom-based value in a variable before the simulation has been setup.

Variable evaluation in fix wall gave bad value

The returned value for epsilon or sigma < 0.0 .

Variable evaluation in region gave bad value

Variable returned a radius < 0.0 .

Variable for compute ti is invalid style

Self-explanatory.

Variable for create_atoms is invalid style

The variables must be equal-style variables.

Variable for displace_atoms is invalid style

LAMMPS Users Manual

- It must be an equal-style or atom-style variable.
- Variable for dump every is invalid style*
Only equal-style variables can be used.
- Variable for dump image center is invalid style*
Must be an equal-style variable.
- Variable for dump image persp is invalid style*
Must be an equal-style variable.
- Variable for dump image phi is invalid style*
Must be an equal-style variable.
- Variable for dump image theta is invalid style*
Must be an equal-style variable.
- Variable for dump image zoom is invalid style*
Must be an equal-style variable.
- Variable for fix adapt is invalid style*
Only equal-style variables can be used.
- Variable for fix addforce is invalid style*
Self-explanatory.
- Variable for fix aveforce is invalid style*
Only equal-style variables can be used.
- Variable for fix deform is invalid style*
The variable must be an equal-style variable.
- Variable for fix efield is invalid style*
The variable must be an equal- or atom-style variable.
- Variable for fix gravity is invalid style*
Only equal-style variables can be used.
- Variable for fix heat is invalid style*
Only equal-style or atom-style variables can be used.
- Variable for fix indent is invalid style*
Only equal-style variables can be used.
- Variable for fix indent is not equal style*
Only equal-style variables can be used.
- Variable for fix langevin is invalid style*
It must be an equal-style variable.
- Variable for fix move is invalid style*
Only equal-style variables can be used.
- Variable for fix setforce is invalid style*
Only equal-style variables can be used.
- Variable for fix temp/berendsen is invalid style*
Only equal-style variables can be used.
- Variable for fix temp/csld is invalid style*
Only equal-style variables can be used.
- Variable for fix temp/csvr is invalid style*
Only equal-style variables can be used.
- Variable for fix temp/rescale is invalid style*
Only equal-style variables can be used.
- Variable for fix wall is invalid style*
Only equal-style variables can be used.
- Variable for fix wall/reflect is invalid style*
Only equal-style variables can be used.
- Variable for fix wall/srd is invalid style*
Only equal-style variables can be used.

LAMMPS Users Manual

Variable for group dynamic is invalid style

The variable must be an atom-style variable.

Variable for group is invalid style

Only atom-style variables can be used.

Variable for region cylinder is invalid style

Only equal-style variables are allowed.

Variable for region is invalid style

Only equal-style variables can be used.

Variable for region is not equal style

Self-explanatory.

Variable for region sphere is invalid style

Only equal-style variables are allowed.

Variable for restart is invalid style

Only equal-style variables can be used.

Variable for set command is invalid style

Only atom-style variables can be used.

Variable for thermo every is invalid style

Only equal-style variables can be used.

Variable for velocity set is invalid style

Only atom-style variables can be used.

Variable for voronoi radius is not atom style

Self-explanatory.

Variable formula compute array is accessed out-of-range

Self-explanatory.

Velocity command before simulation box is defined

The velocity command cannot be used before a read_data, read_restart, or create_box command.

Velocity command with no atoms existing

A velocity command has been used, but no atoms yet exist.

Velocity ramp in z for a 2d problem

Self-explanatory.

Velocity rigid used with non-rigid fix-ID

Self-explanatory.

Velocity temperature ID does calculate a velocity bias

The specified compute must compute a bias for temperature.

Velocity temperature ID does not compute temperature

The compute ID given to the velocity command must compute temperature.

Verlet/split can only currently be used with comm_style brick

This is a current restriction in LAMMPS.

Verlet/split does not yet support TIP4P

This is a current limitation.

Verlet/split requires 2 partitions

See the -partition command-line switch.

LAMMPS Users Manual

Verlet/split requires Rspace partition layout be multiple of Kspace partition layout in each dim

This is controlled by the processors command.

Verlet/split requires Rspace partition size be multiple of Kspace partition size

This is so there is an equal number of Rspace processors for every Kspace processor.

Virial was not tallied on needed timestep

You are using a thermo keyword that requires potentials to have tallied the virial, but they didn't on this timestep. See the variable doc page for ideas on how to make this work.

Voro++ error: narea and neigh have a different size

This error is returned by the Voro++ library.

Wall defined twice in fix wall command

Self-explanatory.

Wall defined twice in fix wall/reflect command

Self-explanatory.

Wall defined twice in fix wall/srd command

Self-explanatory.

Water H epsilon must be 0.0 for pair style lj/cut/tip4p/cut

This is because LAMMPS does not compute the Lennard-Jones interactions with these particles for efficiency reasons.

Water H epsilon must be 0.0 for pair style lj/cut/tip4p/long

This is because LAMMPS does not compute the Lennard-Jones interactions with these particles for efficiency reasons.

Water H epsilon must be 0.0 for pair style lj/long/tip4p/long

This is because LAMMPS does not compute the Lennard-Jones interactions with these particles for efficiency reasons.

World variable count doesn't match # of partitions

A world-style variable must specify a number of values equal to the number of processor partitions.

Write_data command before simulation box is defined

Self-explanatory.

Write_restart command before simulation box is defined

The write_restart command cannot be used before a read_data, read_restart, or create_box command.

Writing to MPI-IO filename when MPIIO package is not installed

Self-explanatory.

Zero length rotation vector with displace_atoms

Self-explanatory.

Zero-length lattice orient vector

Self-explanatory.

Warnings:

Adjusting Coulombic cutoff for MSM, new cutoff = %g

The adjust/cutoff command is turned on and the Coulombic cutoff has been adjusted to match the user-specified accuracy.

Angle atoms missing at step %ld

LAMMPS Users Manual

One or more of 3 atoms needed to compute a particular angle are missing on this processor. Typically this is because the pairwise cutoff is set too short or the angle has blown apart and an atom is too far away.

Angle style in data file differs from currently defined angle style
Self-explanatory.

Atom style in data file differs from currently defined atom style
Self-explanatory.

Bond atom missing in box size check

The 2nd atoms needed to compute a particular bond is missing on this processor. Typically this is because the pairwise cutoff is set too short or the bond has blown apart and an atom is too far away.

Bond atom missing in image check

The 2nd atom in a particular bond is missing on this processor. Typically this is because the pairwise cutoff is set too short or the bond has blown apart and an atom is too far away.

Bond atoms missing at step %ld

The 2nd atom needed to compute a particular bond is missing on this processor. Typically this is because the pairwise cutoff is set too short or the bond has blown apart and an atom is too far away.

Bond style in data file differs from currently defined bond style
Self-explanatory.

Bond/angle/dihedral extent > half of periodic box length

This is a restriction because LAMMPS can be confused about which image of an atom in the bonded interaction is the correct one to use. "Extent" in this context means the maximum end-to-end length of the bond/angle/dihedral. LAMMPS computes this by taking the maximum bond length, multiplying by the number of bonds in the interaction (e.g. 3 for a dihedral) and adding a small amount of stretch.

Both groups in compute group/group have a net charge; the Kspace boundary correction to energy will be non-zero

Self-explanatory.

Calling write_dump before a full system init.

The write_dump command is used before the system has been fully initialized as part of a 'run' or 'minimize' command. Not all dump styles and features are fully supported at this point and thus the command may fail or produce incomplete or incorrect output. Insert a "run 0" command, if a full system init is required.

Cannot count rigid body degrees-of-freedom before bodies are fully initialized

This means the temperature associated with the rigid bodies may be incorrect on this timestep.

Cannot count rigid body degrees-of-freedom before bodies are initialized

This means the temperature associated with the rigid bodies may be incorrect on this timestep.

Cannot include log terms without 1/r terms; setting flagHI to 1

Self-explanatory.

Cannot include log terms without 1/r terms; setting flagHI to 1.

Self-explanatory.

Charges are set, but coulombic solver is not used

Self-explanatory.

Charges did not converge at step %ld: %lg

Self-explanatory.

Communication cutoff is too small for SNAP micro load balancing, increased to %lf

LAMMPS Users Manual

Self-explanatory.

Compute `cna/atom cutoff` may be too large to find ghost atom neighbors

The neighbor cutoff used may not encompass enough ghost atoms to perform this operation correctly.

Computing temperature of portions of rigid bodies

The group defined by the temperature compute does not encompass all the atoms in one or more rigid bodies, so the change in degrees-of-freedom for the atoms in those partial rigid bodies will not be accounted for.

Create `bonds max distance > minimum neighbor cutoff`

This means atom pairs for some atom types may not be in the neighbor list and thus no bond can be created between them.

Delete `atoms cutoff > minimum neighbor cutoff`

This means atom pairs for some atom types may not be in the neighbor list and thus an atom in that pair cannot be deleted.

Dihedral atoms missing at step %ld

One or more of 4 atoms needed to compute a particular dihedral are missing on this processor. Typically this is because the pairwise cutoff is set too short or the dihedral has blown apart and an atom is too far away.

Dihedral problem

Conformation of the 4 listed dihedral atoms is extreme; you may want to check your simulation geometry.

Dihedral problem: %d %ld %d %d %d %d

Conformation of the 4 listed dihedral atoms is extreme; you may want to check your simulation geometry.

Dihedral style in data file differs from currently defined dihedral style

Self-explanatory.

Dump `dcd/xtc timestamp` may be wrong with `fix dt/reset`

If the fix changes the timestep, the dump dcd file will not reflect the change.

Energy due to X extra global DOFs will be included in minimizer energies

When using fixes like box/relax, the potential energy used by the minimizer is augmented by an additional energy provided by the fix. Thus the printed converged energy may be different from the total potential energy.

Energy tally does not account for 'zero yes'

The energy removed by using the 'zero yes' flag is not accounted for in the energy tally and thus energy conservation cannot be monitored in this case.

Estimated error in splitting of dispersion coeffs is %g

Error is greater than 0.0001 percent.

Ewald/disp Newton solver failed, using old method to estimate `g_ewald`

Self-explanatory. Choosing a different cutoff value may help.

FENE bond too long

A FENE bond has stretched dangerously far. Its interaction strength will be truncated to attempt to prevent the bond from blowing up.

FENE bond too long: %ld %d %d %g

A FENE bond has stretched dangerously far. Its interaction strength will be truncated to attempt to prevent the bond from blowing up.

FENE bond too long: %ld %g

A FENE bond has stretched dangerously far. Its interaction strength will be truncated to attempt to prevent the bond from blowing up.

Fix SRD walls overlap but `fix srd overlap` not set

You likely want to set this in your input script.

Fix bond/swap will ignore defined angles

LAMMPS Users Manual

See the doc page for fix bond/swap for more info on this restriction.

Fix deposit near setting < possible overlap separation %g

This test is performed for finite size particles with a diameter, not for point particles. The near setting is smaller than the particle diameter which can lead to overlaps.

Fix evaporate may delete atom with non-zero molecule ID

This is probably an error, since you should not delete only one atom of a molecule.

Fix gcmc using full_energy option

Fix gcmc has automatically turned on the full_energy option since it is required for systems like the one specified by the user. User input included one or more of the following: kspace, triclinic, a hybrid pair style, an eam pair style, or no "single" function for the pair style.

Fix property/atom mol or charge w/out ghost communication

A model typically needs these properties defined for ghost atoms.

Fix qeq CG convergence failed (%g) after %d iterations at %ld step

Self-explanatory.

Fix qeq has non-zero lower Taper radius cutoff

Absolute value must be ≤ 0.01 .

Fix qeq has very low Taper radius cutoff

Value should typically be ≥ 5.0 .

Fix qeq/dynamic tolerance may be too small for damped dynamics

Self-explanatory.

Fix qeq/fire tolerance may be too small for damped fires

Self-explanatory.

Fix rattle should come after all other integration fixes

This fix is designed to work after all other integration fixes change atom positions. Thus it should be the last integration fix specified. If not, it will not satisfy the desired constraints as well as it otherwise would.

Fix recenter should come after all other integration fixes

Other fixes may change the position of the center-of-mass, so fix recenter should come last.

Fix srd SRD moves may trigger frequent reneighboring

This is because the SRD particles may move long distances.

Fix srd grid size > 1/4 of big particle diameter

This may cause accuracy problems.

Fix srd particle moved outside valid domain

This may indicate a problem with your simulation parameters.

Fix srd particles may move > big particle diameter

This may cause accuracy problems.

Fix srd viscosity < 0.0 due to low SRD density

This may cause accuracy problems.

Fix thermal/conductivity comes before fix ave/spatial

The order of these 2 fixes in your input script is such that fix thermal/conductivity comes first. If you are using fix ave/spatial to measure the temperature profile induced by fix viscosity, then this may cause a glitch in the profile since you are averaging immediately after swaps have occurred. Flipping the order of the 2 fixes typically helps.

Fix viscosity comes before fix ave/spatial

The order of these 2 fixes in your input script is such that fix viscosity comes first. If you are using fix ave/spatial to measure the velocity profile induced by

LAMMPS Users Manual

fix viscosity, then this may cause a glitch in the profile since you are averaging immediately after swaps have occurred. Flipping the order of the 2 fixes typically helps.

Fixes cannot send data in Kokkos communication, switching to classic communication
This is current restriction with Kokkos.

For better accuracy use 'pair_modify table 0'

The user-specified force accuracy cannot be achieved unless the table feature is disabled by using 'pair_modify table 0'.

Geometric mixing assumed for $1/r^6$ coefficients

Self-explanatory.

Group for fix_modify temp != fix group

The fix_modify command is specifying a temperature computation that computes a temperature on a different group of atoms than the fix itself operates on. This is probably not what you want to do.

H matrix size has been exceeded: m_fill=%d H.m=%d\n

This is the size of the matrix.

Ignoring unknown or incorrect info command flag

Self-explanatory. An unknown argument was given to the info command.

Compare your input with the documentation.

Improper atoms missing at step %ld

One or more of 4 atoms needed to compute a particular improper are missing on this processor. Typically this is because the pairwise cutoff is set too short or the improper has blown apart and an atom is too far away.

Improper problem: %d %d %d %d %d %d

Conformation of the 4 listed improper atoms is extreme; you may want to check your simulation geometry.

Improper style in data file differs from currently defined improper style

Self-explanatory.

Inconsistent image flags

The image flags for a pair on bonded atoms appear to be inconsistent.

Inconsistent means that when the coordinates of the two atoms are unwrapped using the image flags, the two atoms are far apart. Specifically they are further apart than half a periodic box length. Or they are more than a box length apart in a non-periodic dimension. This is usually due to the initial data file not having correct image flags for the 2 atoms in a bond that straddles a periodic boundary. They should be different by 1 in that case. This is a warning because inconsistent image flags will not cause problems for dynamics or most LAMMPS simulations. However they can cause problems when such atoms are used with the fix rigid or replicate commands. Note that if you have an infinite periodic crystal with bonds then it is impossible to have fully consistent image flags, since some bonds will cross periodic boundaries and connect two atoms with the same image flag.

KIM Model does not provide 'energy'; Potential energy will be zero

Self-explanatory.

KIM Model does not provide 'forces'; Forces will be zero

Self-explanatory.

KIM Model does not provide 'particleEnergy'; energy per atom will be zero

Self-explanatory.

KIM Model does not provide 'particleVirial'; virial per atom will be zero

Self-explanatory.

Kspace_modify slab param < 2.0 may cause unphysical behavior

LAMMPS Users Manual

The `kpace_modify slab` parameter should be larger to insure periodic grids padded with empty space do not overlap.

Less insertions than requested

The `fix pour` command was unsuccessful at finding open space for as many particles as it tried to insert.

Library error in `lammps_gather_atoms`

This library function cannot be used if atom IDs are not defined or are not consecutively numbered.

Library error in `lammps_scatter_atoms`

This library function cannot be used if atom IDs are not defined or are not consecutively numbered, or if no atom map is defined. See the `atom_modify` command for details about atom maps.

Lost atoms via `change_box`: original %ld current %ld

The command options you have used caused atoms to be lost.

Lost atoms via `displace_atoms`: original %ld current %ld

The command options you have used caused atoms to be lost.

Lost atoms: original %ld current %ld

Lost atoms are checked for each time thermo output is done. See the `thermo_modify lost` command for options. Lost atoms usually indicate bad dynamics, e.g. atoms have been blown far out of the simulation box, or moved further than one processor's sub-domain away before reneighboring.

MSM mesh too small, increasing to 2 points in each direction

Self-explanatory.

Mismatch between velocity and compute groups

The temperature computation used by the `velocity` command will not be on the same group of atoms that velocities are being set for.

Mixing forced for lj coefficients

Self-explanatory.

Molecule attributes do not match system attributes

An attribute is specified (e.g. diameter, charge) that is not defined for the specified atom style.

Molecule has bond topology but no special bond settings

This means the bonded atoms will not be excluded in pair-wise interactions.

Molecule template for `create_atoms` has multiple molecules

The `create_atoms` command will only create molecules of a single type, i.e. the first molecule in the template.

Molecule template for `fix gcmc` has multiple molecules

The `fix gcmc` command will only create molecules of a single type, i.e. the first molecule in the template.

Molecule template for `fix shake` has multiple molecules

The `fix shake` command will only recognize molecules of a single type, i.e. the first molecule in the template.

More than one compute centro/atom

It is not efficient to use `compute centro/atom` more than once.

More than one compute cluster/atom

It is not efficient to use `compute cluster/atom` more than once.

More than one compute cna/atom defined

It is not efficient to use `compute cna/atom` more than once.

More than one compute contact/atom

It is not efficient to use `compute contact/atom` more than once.

More than one compute coord/atom

LAMMPS Users Manual

- It is not efficient to use compute coord/atom more than once.
- More than one compute damage/atom*
It is not efficient to use compute ke/atom more than once.
- More than one compute dilatation/atom*
Self-explanatory.
- More than one compute erotate/sphere/atom*
It is not efficient to use compute erorate/sphere/atom more than once.
- More than one compute hexorder/atom*
It is not efficient to use compute hexorder/atom more than once.
- More than one compute ke/atom*
It is not efficient to use compute ke/atom more than once.
- More than one compute orientorder/atom*
It is not efficient to use compute orientorder/atom more than once.
- More than one compute plasticity/atom*
Self-explanatory.
- More than one compute sna/atom*
Self-explanatory.
- More than one compute snad/atom*
Self-explanatory.
- More than one compute snav/atom*
Self-explanatory.
- More than one fix poems*
It is not efficient to use fix poems more than once.
- More than one fix rigid*
It is not efficient to use fix rigid more than once.
- Neighbor exclusions used with KSpace solver may give inconsistent Coulombic energies*
This is because excluding specific pair interactions also excludes them from long-range interactions which may not be the desired effect. The special_bonds command handles this consistently by insuring excluded (or weighted) 1-2, 1-3, 1-4 interactions are treated consistently by both the short-range pair style and the long-range solver. This is not done for exclusions of charged atom pairs via the neigh_modify exclude command.
- New thermo_style command, previous thermo_modify settings will be lost*
If a thermo_style command is used after a thermo_modify command, the settings changed by the thermo_modify command will be reset to their default values. This is because the thermo_modify command acts on the currently defined thermo style, and a thermo_style command creates a new style.
- No Kspace calculation with verlet/split*
The 2nd partition performs a kspace calculation so the kspace_style command must be used.
- No automatic unit conversion to XTC file format conventions possible for units lj*
This means no scaling will be performed.
- No fixes defined, atoms won't move*
If you are not using a fix like nve, nvt, npt then atom velocities and coordinates will not be updated during timestepping.
- No joints between rigid bodies, use fix rigid instead*
The bodies defined by fix poems are not connected by joints. POEMS will integrate the body motion, but it would be more efficient to use fix rigid.
- Not using real units with pair reax*

LAMMPS Users Manual

This is most likely an error, unless you have created your own ReaxFF parameter file in a different set of units.

Number of MSM mesh points changed to be a multiple of 2

MSM requires that the number of grid points in each direction be a multiple of two and the number of grid points in one or more directions have been adjusted to meet this requirement.

OMP_NUM_THREADS environment is not set.

This environment variable must be set appropriately to use the USER-OMP package.

One or more atoms are time integrated more than once

This is probably an error since you typically do not want to advance the positions or velocities of an atom more than once per timestep.

One or more chunks do not contain all atoms in molecule

This may not be what you intended.

One or more dynamic groups may not be updated at correct point in timestep

If there are other fixes that act immediately after the initial stage of time integration within a timestep (i.e. after atoms move), then the command that sets up the dynamic group should appear after those fixes. This will insure that dynamic group assignments are made after all atoms have moved.

One or more respa levels compute no forces

This is computationally inefficient.

Pair COMB charge %.10f with force %.10f hit max barrier

Something is possibly wrong with your model.

Pair COMB charge %.10f with force %.10f hit min barrier

Something is possibly wrong with your model.

Pair brownian needs newton pair on for momentum conservation

Self-explanatory.

Pair dpd needs newton pair on for momentum conservation

Self-explanatory.

Pair dsmc: num_of_collisions > number_of_A

Collision model in DSMC is breaking down.

Pair dsmc: num_of_collisions > number_of_B

Collision model in DSMC is breaking down.

Pair style in data file differs from currently defined pair style

Self-explanatory.

Particle deposition was unsuccessful

The fix deposit command was not able to insert as many atoms as needed. The requested volume fraction may be too high, or other atoms may be in the insertion region.

Proc sub-domain size < neighbor skin, could lead to lost atoms

The decomposition of the physical domain (likely due to load balancing) has led to a processor's sub-domain being smaller than the neighbor skin in one or more dimensions. Since reneighboring is triggered by atoms moving the skin distance, this may lead to lost atoms, if an atom moves all the way across a neighboring processor's sub-domain before reneighboring is triggered.

Reducing PPPM order b/c stencil extends beyond nearest neighbor processor

This may lead to a larger grid than desired. See the `kpspace_modify overlap` command to prevent changing of the PPPM order.

Reducing PPPMDisp Coulomb order b/c stencil extends beyond neighbor processor

This may lead to a larger grid than desired. See the `kpspace_modify overlap` command to prevent changing of the PPPM order.

LAMMPS Users Manual

Reducing PPPMDisp dispersion order b/c stencil extends beyond neighbor processor
This may lead to a larger grid than desired. See the `kspace_modify overlap` command to prevent changing of the PPPM order.

Replacing a fix, but new group != old group

The ID and style of a fix match for a fix you are changing with a fix command, but the new group you are specifying does not match the old group.

Replicating in a non-periodic dimension

The parameters for a replicate command will cause a non-periodic dimension to be replicated; this may cause unwanted behavior.

Resetting reneighboring criteria during PRD

A PRD simulation requires that `neigh_modify` settings be `delay = 0`, `every = 1`, `check = yes`. Since these settings were not in place, LAMMPS changed them and will restore them to their original values after the PRD simulation.

Resetting reneighboring criteria during TAD

A TAD simulation requires that `neigh_modify` settings be `delay = 0`, `every = 1`, `check = yes`. Since these settings were not in place, LAMMPS changed them and will restore them to their original values after the PRD simulation.

Resetting reneighboring criteria during minimization

Minimization requires that `neigh_modify` settings be `delay = 0`, `every = 1`, `check = yes`. Since these settings were not in place, LAMMPS changed them and will restore them to their original values after the minimization.

Restart file used different # of processors

The restart file was written out by a LAMMPS simulation running on a different number of processors. Due to round-off, the trajectories of your restarted simulation may diverge a little more quickly than if you ran on the same # of processors.

Restart file used different 3d processor grid

The restart file was written out by a LAMMPS simulation running on a different 3d grid of processors. Due to round-off, the trajectories of your restarted simulation may diverge a little more quickly than if you ran on the same # of processors.

Restart file used different boundary settings, using restart file values

Your input script cannot change these restart file settings.

Restart file used different newton bond setting, using restart file value

The restart file value will override the setting in the input script.

Restart file used different newton pair setting, using input script value

The input script value will override the setting in the restart file.

Restrain problem: %d %d %d %d %d %d

Conformation of the 4 listed dihedral atoms is extreme; you may want to check your simulation geometry.

Running PRD with only one replica

This is allowed, but you will get no parallel speed-up.

SRD bin shifting turned on due to small lamda

This is done to try to preserve accuracy.

SRD bin size for fix srd differs from user request

Fix SRD had to adjust the bin size to fit the simulation box. See the `cubic` keyword if you want this message to be an error vs warning.

SRD bins for fix srd are not cubic enough

The bin shape is not within tolerance of cubic. See the `cubic` keyword if you want this message to be an error vs warning.

SRD particle %d started inside big particle %d on step %d bounce %d

LAMMPS Users Manual

See the inside keyword if you want this message to be an error vs warning.
SRD particle %d started inside wall %d on step %ld bounce %d

See the inside keyword if you want this message to be an error vs warning.
Shake determinant < 0.0

The determinant of the quadratic equation being solved for a single cluster specified by the fix shake command is numerically suspect. LAMMPS will set it to 0.0 and continue.

Shell command '%s' failed with error '%s'
Self-explanatory.

Shell command returned with non-zero status
This may indicate the shell command did not operate as expected.

Should not allow rigid bodies to bounce off relecting walls
LAMMPS allows this, but their dynamics are not computed correctly.

Should not use fix nve/limit with fix shake or fix rattle
This will lead to invalid constraint forces in the SHAKE/RATTLE computation.

Simulations might be very slow because of large number of structure factors
Self-explanatory.

Slab correction not needed for MSM
Slab correction is intended to be used with Ewald or PPPM and is not needed by MSM.

System is not charge neutral, net charge = %g
The total charge on all atoms on the system is not 0.0. For some KSpace solvers this is only a warning.

Table inner cutoff >= outer cutoff
You specified an inner cutoff for a Coulombic table that is longer than the global cutoff. Probably not what you wanted.

Temperature for MSST is not for group all
User-assigned temperature to MSST fix does not compute temperature for all atoms. Since MSST computes a global pressure, the kinetic energy contribution from the temperature is assumed to also be for all atoms. Thus the pressure used by MSST could be inaccurate.

Temperature for NPT is not for group all
User-assigned temperature to NPT fix does not compute temperature for all atoms. Since NPT computes a global pressure, the kinetic energy contribution from the temperature is assumed to also be for all atoms. Thus the pressure used by NPT could be inaccurate.

Temperature for fix modify is not for group all
The temperature compute is being used with a pressure calculation which does operate on group all, so this may be inconsistent.

Temperature for thermo pressure is not for group all
User-assigned temperature to thermo via the thermo_modify command does not compute temperature for all atoms. Since thermo computes a global pressure, the kinetic energy contribution from the temperature is assumed to also be for all atoms. Thus the pressure printed by thermo could be inaccurate.

The fix ave/spatial command has been replaced by the more flexible fix ave/chunk and compute chunk/atom commands -- fix ave/spatial will be removed in the summer of 2015

Self-explanatory.

The minimizer does not re-orient dipoles when using fix efield
This means that only the atom coordinates will be minimized, not the orientation of the dipoles.

LAMMPS Users Manual

Too many common neighbors in CNA %d times

More than the maximum # of neighbors was found multiple times. This was unexpected.

Too many inner timesteps in fix ttm

Self-explanatory.

Too many neighbors in CNA for %d atoms

More than the maximum # of neighbors was found multiple times. This was unexpected.

Triclinic box skew is large

The displacement in a skewed direction is normally required to be less than half the box length in that dimension. E.g. the xy tilt must be between -half and +half of the x box length. You have relaxed the constraint using the box tilt command, but the warning means that a LAMMPS simulation may be inefficient as a result.

Use special bonds = 0,1,1 with bond style fene

Most FENE models need this setting for the special_bonds command.

Use special bonds = 0,1,1 with bond style fene/expand

Most FENE models need this setting for the special_bonds command.

Using a manybody potential with bonds/angles/dihedrals and special_bond exclusions

This is likely not what you want to do. The exclusion settings will eliminate neighbors in the neighbor list, which the manybody potential needs to calculate its terms correctly.

Using compute temp/deform with inconsistent fix deform remap option

Fix nvt/sllod assumes deforming atoms have a velocity profile provided by "remap v" or "remap none" as a fix deform option.

Using compute temp/deform with no fix deform defined

This is probably an error, since it makes little sense to use compute temp/deform in this case.

Using fix srd with box deformation but no SRD thermostat

The deformation will heat the SRD particles so this can be dangerous.

Using kspace solver on system with no charge

Self-explanatory.

Using largest cut-off for lj/long/dipole/long long long

Self-explanatory.

Using largest cutoff for buck/long/coul/long

Self-explanatory.

Using largest cutoff for lj/long/coul/long

Self-explanatory.

Using largest cutoff for pair_style lj/long/tip4p/long

Self-explanatory.

Using package gpu without any pair style defined

Self-explanatory.

Using pair potential shift with pair_modify compute no

The shift effects will thus not be computed.

Using pair tail corrections with nonperiodic system

This is probably a bogus thing to do, since tail corrections are computed by integrating the density of a periodic system out to infinity.

Using pair tail corrections with pair_modify compute no

The tail corrections will thus not be computed.

pair_style reax is now deprecated and will soon be retired. Users should switch to pair_style reax/c

LAMMPS Users Manual

Self-explanatory.

13. Future and history

This section lists features we plan to add to LAMMPS, features of previous versions of LAMMPS, and features of other parallel molecular dynamics codes our group has distributed.

13.1 [Coming attractions](#)

13.2 [Past versions](#)

13.1 Coming attractions

As of summer 2016 we are using the [LAMMPS project issue tracker on GitHub](#) for keeping track of suggested, planned or pending new features. This includes discussions of how to best implement them, or why they would be useful. Especially if a planned or proposed feature is non-trivial to add, e.g. because it requires changes to some of the core classes of LAMMPS, people planning to contribute a new feature to LAMMPS are encouraged to submit an issue about their planned implementation this way in order to receive feedback from the LAMMPS core developers. They will provide suggestions about the validity of the proposed approach and possible improvements, pitfalls or alternatives.

Please see some of the closed issues for examples of how to suggest code enhancements, submit proposed changes, or report possible bugs and how they are resolved.

As an alternative to using GitHub, you may e-mail the [core developers](#) or send an e-mail to the [LAMMPS Mail list](#) if you want to have your suggestion added to the list.

13.2 Past versions

LAMMPS development began in the mid 1990s under a cooperative research & development agreement (CRADA) between two DOE labs (Sandia and LLNL) and 3 companies (Cray, Bristol Myers Squibb, and Dupont). The goal was to develop a large-scale parallel classical MD code; the coding effort was led by Steve Plimpton at Sandia.

After the CRADA ended, a final F77 version, LAMMPS 99, was released. As development of LAMMPS continued at Sandia, its memory management was converted to F90; a final F90 version was released as LAMMPS 2001.

The current LAMMPS is a rewrite in C++ and was first publicly released as an open source code in 2004. It includes many new features beyond those in LAMMPS 99 or 2001. It also includes features from older parallel MD codes written at Sandia, namely ParaDyn, Warp, and GranFlow (see below).

LAMMPS Users Manual

In late 2006 we began merging new capabilities into LAMMPS that were developed by Aidan Thompson at Sandia for his MD code GRASP, which has a parallel framework similar to LAMMPS. Most notably, these have included many-body potentials - Stillinger-Weber, Tersoff, ReaxFF - and the associated charge-equilibration routines needed for ReaxFF.

The [History link](#) on the LAMMPS WWW page gives a timeline of features added to the C++ open-source version of LAMMPS over the last several years.

These older codes are available for download from the [LAMMPS WWW site](#), except for Warp & GranFlow which were primarily used internally. A brief listing of their features is given here.

LAMMPS 2001

- F90 + MPI
- dynamic memory
- spatial-decomposition parallelism
- NVE, NVT, NPT, NPH, rRESPA integrators
- LJ and Coulombic pairwise force fields
- all-atom, united-atom, bead-spring polymer force fields
- CHARMM-compatible force fields
- class 2 force fields
- 3d/2d Ewald & PPPM
- various force and temperature constraints
- SHAKE
- Hessian-free truncated-Newton minimizer
- user-defined diagnostics

LAMMPS 99

- F77 + MPI
- static memory allocation
- spatial-decomposition parallelism
- most of the LAMMPS 2001 features with a few exceptions
- no 2d Ewald & PPPM
- molecular force fields are missing a few CHARMM terms
- no SHAKE

Warp

- F90 + MPI
- spatial-decomposition parallelism
- embedded atom method (EAM) metal potentials + LJ
- lattice and grain-boundary atom creation
- NVE, NVT integrators
- boundary conditions for applying shear stresses
- temperature controls for actively sheared systems
- per-atom energy and centro-symmetry computation and output

ParaDyn

LAMMPS Users Manual

- F77 + MPI
- atom- and force-decomposition parallelism
- embedded atom method (EAM) metal potentials
- lattice atom creation
- NVE, NVT, NPT integrators
- all serial DYNAMO features for controls and constraints

GranFlow

- F90 + MPI
- spatial-decomposition parallelism
- frictional granular potentials
- NVE integrator
- boundary conditions for granular flow and packing and walls
- particle insertion

Tutorials

The following pages contain some in-depth tutorials for selected topics, that did not fit into any other place in the manual.

Using LAMMPS with Bash on Windows

written by Richard Berger

Starting with Windows 10 you can install Linux tools directly in Windows. This allows you to compile LAMMPS following the same procedure as on a real Ubuntu Linux installation. Software can be easily installed using the package manager via apt-get and all files are accessible in both the Windows Explorer and your Linux shell (bash). This avoids switching to a different operating system or installing a virtual machine. Everything runs on Windows.

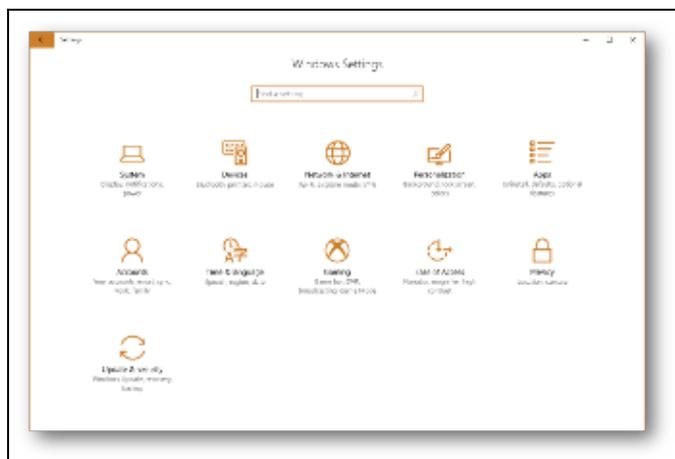

Installing Bash on Windows

Prerequisites

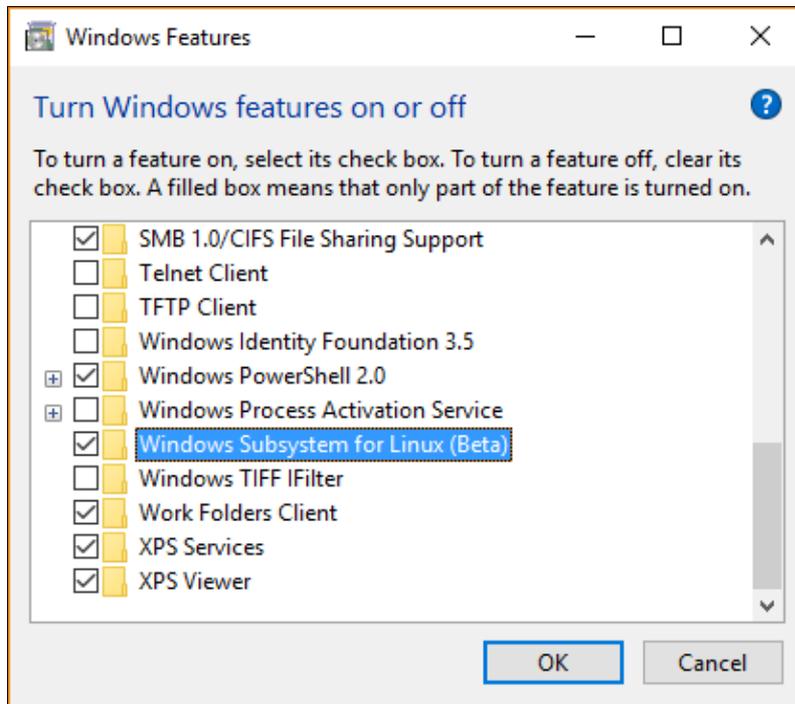

- Windows 10 (64bit only)
- Latest updates installed

Enable developer mode

You enable this feature by first opening Windows Settings and enabling Developer mode. Go to the Windows settings and search for "developer". This will allow you to install software which comes from outside of the Windows Store. You might be prompted to reboot your compute. Please do so.

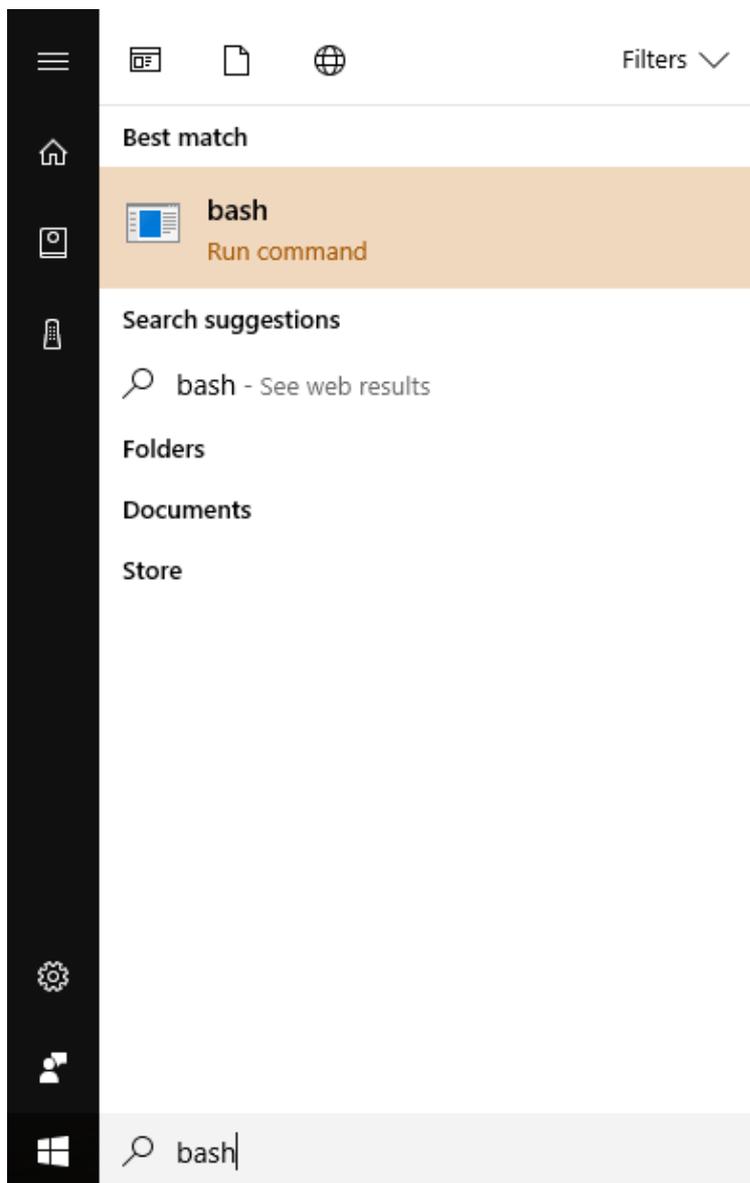

LAMMPS Users Manual

Install Bash for Windows

After installation completes, type "bash" in the Windows Start menu search. Select the first found option. This will launch a command-line window which will prompt you about installing Ubuntu on Windows. Confirm with "y" and press enter. This will then download Ubuntu for Windows.

LAMMPS Users Manual

LAMMPS Users Manual

C:\Windows\System32\bash.exe

```
-- Beta feature --  
This will install Ubuntu on Windows, distributed by Canonical  
and licensed under its terms available here:  
https://aka.ms/uowterms  
Type "y" to continue:
```

During installation, you will be asked for a new password. This will be used for installing new software and running commands with sudo.

LAMMPS Users Manual

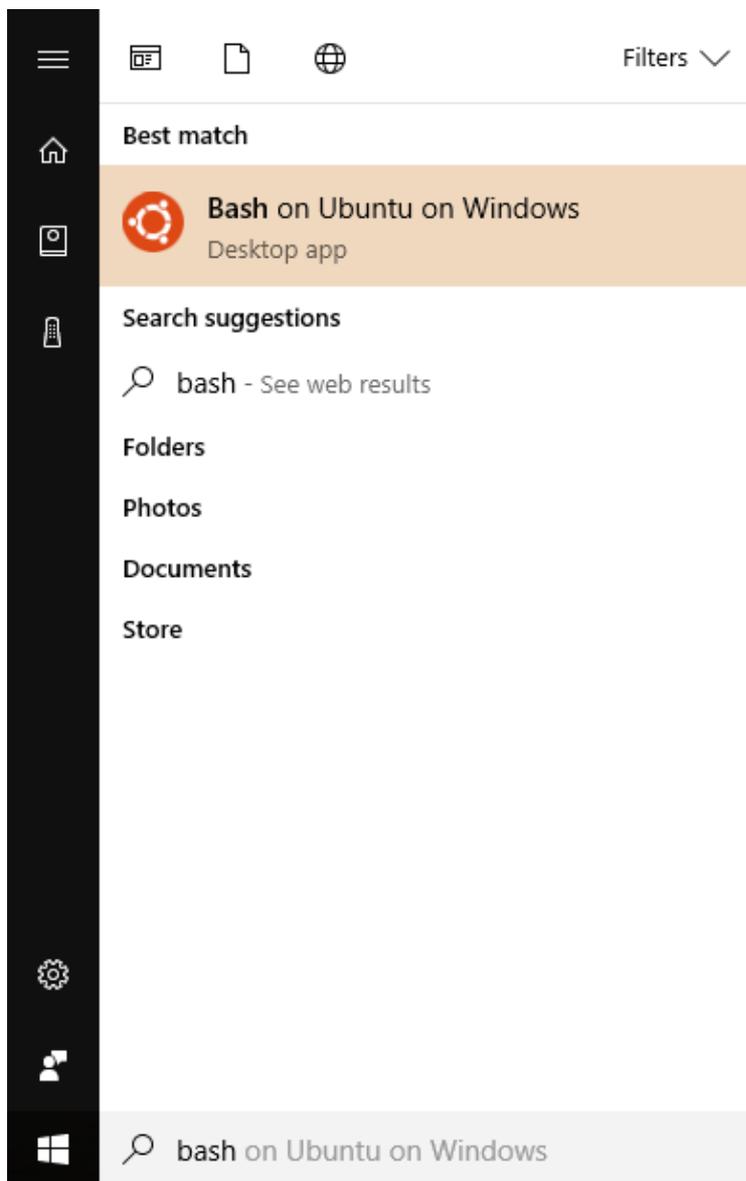

```

Compiling LAMMPS in Bash on Windows

The installation of LAMMPS in this environment is identical to working inside of a real Ubuntu Linux installation. At the time writing, it uses Ubuntu 16.04.

Installing prerequisite packages

First upgrade all existing packages using

```
sudo apt update  
sudo apt upgrade -y
```

Next install the following packages, which include compilers and libraries needed for various LAMMPS features:

```
sudo apt install -y build-essential ccache gfortran openmpi-bin libopenmpi-dev libfftw3-dev lib
```

Files in Ubuntu on Windows

When you launch "Bash on Ubuntu on Windows" you will start out in your Linux user home directory `/home/username`. You can access your Windows user directory using the `/mnt/c/Users/username` folder.

LAMMPS Users Manual

Download LAMMPS

Obtain a copy of the LAMMPS code and go into it using "cd"

Option 1: Downloading LAMMPS tarball using wget

```
wget http://lammps.sandia.gov/tars/lammps-stable.tar.gz
tar xvzf lammps-stable.tar.gz
cd lammps-31Mar17
```

Option 2: Obtaining LAMMPS code from GitHub

```
git clone https://github.com/lammps/lammps.git
cd lammps
```

Compiling LAMMPS

At this point you can compile LAMMPS like on Ubuntu Linux.

Compiling serial version

```
cd src/
make -j 4 serial
```

This will create an executable called `lmp_serial` in the `src/` directory

Compiling MPI version

```
cd src/
make -j 4 mpi
```

This will create an executable called `lmp_mpi` in the `src/` directory

Finally, please note the absolute path of your `src` folder. You can get this using

```
pwd
```

or

```
echo $PWD
```

To run any examples you need the location of the executable. For now, let us save this location in a temporary variable

```
LAMMPS_DIR=$PWD
```

Running an example script

Once compiled you can execute some of the LAMMPS examples. Switch into the `examples/melt` folder

```
cd ../examples/melt
```

LAMMPS Users Manual

The full path of the serial executable is `$LAMMPS_DIR/lmp_serial`, while the mpi version is `$LAMMPS_DIR/lmp_mpi`. You can run the melt example with either version as follows:

```
$LAMMPS_DIR/lmp_serial -in in.melt
```

or

```
mpirun -np 4 $LAMMPS_DIR/lmp_mpi -in in.melt
```

Note the use of our variable `$LAMMPS_DIR`, which expands into the full path of the LAMMPS src folder we saved earlier.

Adding your executable directory to your PATH

You can avoid having to type the full path of your LAMMPS binary by adding its parent folder to the PATH environment variable as follows:

```
export PATH=$LAMMPS_DIR:$PATH
```

Input scripts can then be run like this:

```
lmp_serial -in in.melt
```

or

```
mpirun -np 4 lmp_mpi -in in.melt
```

However, this PATH variable will not persist if you close your bash window. To persist this setting edit the `$HOME/.bashrc` file using your favorite editor and add this line

```
export PATH=/full/path/to/your/lammps/src:$PATH
```

Example:

For an executable `lmp_serial` with a full path

```
/home/richard/lammps/src/lmp_serial
```

the PATH variable should be

```
export PATH=/home/richard/lammps/src:$PATH
```

NOTE: This should give you a jump start when trying to run LAMMPS on Windows. To become effective in this environment I encourage you to look into Linux tutorials explaining Bash and Basic Unix commands (e.g., [Linux Journey](#))

Tutorial for Thermalized Drude oscillators in LAMMPS

This tutorial explains how to use Drude oscillators in LAMMPS to simulate polarizable systems using the USER-DRUDE package. As an illustration, the input files for a simulation of 250 phenol molecules are documented. First of all, LAMMPS has to be compiled with the USER-DRUDE package activated. Then, the data file and input scripts have to be modified to include the Drude dipoles and how to handle them.

Overview of Drude induced dipoles

Polarizable atoms acquire an induced electric dipole moment under the action of an external electric field, for example the electric field created by the surrounding particles. Drude oscillators represent these dipoles by two fixed charges: the core (DC) and the Drude particle (DP) bound by a harmonic potential. The Drude particle can be thought of as the electron cloud whose center can be displaced from the position of the corresponding nucleus.

The sum of the masses of a core-Drude pair should be the mass of the initial (unsplit) atom, $(m_C + m_D = m)$. The sum of their charges should be the charge of the initial (unsplit) atom, $(q_C + q_D = q)$. A harmonic potential between the core and Drude partners should be present, with force constant (k_D) and an equilibrium distance of zero. The (half-)stiffness of the [harmonic bond](#) $(K_D = k_D/2)$ and the Drude charge (q_D) are related to the atom polarizability (α) by

$$K_D = \frac{1}{2} \frac{q_D^2}{\alpha}$$

Ideally, the mass of the Drude particle should be small, and the stiffness of the harmonic bond should be large, so that the Drude particle remains close to the core. The values of Drude mass, Drude charge, and force constant can be chosen following different strategies, as in the following examples of polarizable force fields:

- [Lamoureux and Roux](#) suggest adopting a global half-stiffness, $(K_D) = 500$ kcal/(mol Ang $(\text{\AA})^2$) - which corresponds to a force constant $(k_D) = 4184$ kJ/(mol Ang $(\text{\AA})^2$) - for all types of core-Drude bond, a global mass $(m_D) = 0.4$ g/mol (or u) for all types of Drude particles, and to calculate the Drude charges for individual atom types from the atom polarizabilities using equation (1). This choice is followed in the polarizable CHARMM force field.
- Alternately [Schroeder and Steinhauser](#) suggest adopting a global charge $(q_D) = -1.0e$ and a global mass $(m_D) = 0.1$ g/mol (or u) for all Drude particles, and to calculate the force constant for each type of core-Drude bond from equation (1). The timesteps used by these authors are between 0.5 and 2 fs, with the degrees of freedom of the Drude oscillators kept cold at 1 K.
- In both these force fields hydrogen atoms are treated as non-polarizable.

The motion of the Drude particles can be calculated by minimizing the energy of the induced dipoles at each timestep, by an iterative, self-consistent procedure. The Drude particles can be massless and therefore do not contribute to the kinetic energy. However, the relaxed method is computational slow. An extended-lagrangian method

LAMMPS Users Manual

can be used to calculate the positions of the Drude particles, but this requires them to have mass. It is important in this case to decouple the degrees of freedom associated with the Drude oscillators from those of the normal atoms. Thermalizing the Drude dipoles at temperatures comparable to the rest of the simulation leads to several problems (kinetic energy transfer, very short timestep, etc.), which can be remediate by the "cold Drude" technique ([Lamoureux and Roux](#)).

Two closely related models are used to represent polarization through "charges on a spring": the core-shell model and the Drude model. Although the basic idea is the same, the core-shell model is normally used for ionic/crystalline materials, whereas the Drude model is normally used for molecular systems and fluid states. In ionic crystals the symmetry around each ion and the distance between them are such that the core-shell model is sufficiently stable. But to be applicable to molecular/covalent systems the Drude model includes two important features:

1. The possibility to thermostat the additional degrees of freedom associated with the induced dipoles at very low temperature, in terms of the reduced coordinates of the Drude particles with respect to their cores. This makes the trajectory close to that of relaxed induced dipoles.
2. The Drude dipoles on covalently bonded atoms interact too strongly due to the short distances, so an atom may capture the Drude particle (shell) of a neighbor, or the induced dipoles within the same molecule may align too much. To avoid this, damping at short of the interactions between the point charges composing the induced dipole can be done by [Thole](#) functions.

Preparation of the data file

The data file is similar to a standard LAMMPS data file for *atom_style full*. The DPs and the *harmonic bonds* connecting them to their DC should appear in the data file as normal atoms and bonds.

You can use the *polarizer* tool (Python script distributed with the USER-DRUDE package) to convert a non-polarizable data file (here *data.102494.lmp*) to a polarizable data file (*data-p.lmp*)

```
polarizer -q -f phenol.dff data.102494.lmp data-p.lmp
```

This will automatically insert the new atoms and bonds. The masses and charges of DCs and DPs are computed from *phenol.dff*, as well as the DC-DP bond constants. The file *phenol.dff* contains the polarizabilities of the atom types and the mass of the Drude particles, for instance:

```
# units: kJ/mol, A, deg
# kforce is in the form k/2 r_D^2
# type  m_D/u   q_D/e   k_D   alpha/A3   thole
OH      0.4     -1.0   4184.0  0.63     0.67
CA      0.4     -1.0   4184.0  1.36     2.51
CAI     0.4     -1.0   4184.0  1.09     2.51
```

The hydrogen atoms are absent from this file, so they will be treated as non-polarizable atoms. In the non-polarizable data file *data.102494.lmp*, atom names corresponding to the atom type numbers have to be specified as comments at the end

LAMMPS Users Manual

of lines of the *Masses* section. You probably need to edit it to add these names. It should look like

Masses

```
1 12.011 # CAI
2 12.011 # CA
3 15.999 # OH
4 1.008 # HA
5 1.008 # HO
```

Basic input file

The atom style should be set to (or derive from) *full*, so that you can define atomic charges and molecular bonds, angles, dihedrals...

The *polarizer* tool also outputs certain lines related to the input script (the use of these lines will be explained below). In order for LAMMPS to recognize that you are using Drude oscillators, you should use the fix *drude*. The command is

```
fix DRUDE all drude C C C N N D D D
```

The N, C, D following the *drude* keyword have the following meaning: There is one tag for each atom type. This tag is C for DCs, D for DPs and N for non-polarizable atoms. Here the atom types 1 to 3 (C and O atoms) are DC, atom types 4 and 5 (H atoms) are non-polarizable and the atom types 6 to 8 are the newly created DPs.

By recognizing the fix *drude*, LAMMPS will find and store matching DC-DP pairs and will treat DP as equivalent to their DC in the *special bonds* relations. It may be necessary to extend the space for storing such special relations. In this case extra space should be reserved by using the *extra/special/per/atom* keyword of either the [read_data](#) or [create_box](#) command. With our phenol, there is 1 more special neighbor for which space is required. Otherwise LAMMPS crashes and gives the required value.

```
read_data data-p.lmp extra/special/per/atom 1
```

Let us assume we want to run a simple NVT simulation at 300 K. Note that Drude oscillators need to be thermalized at a low temperature in order to approximate a self-consistent field (SCF), therefore it is not possible to simulate an NVE ensemble with this package. Since dipoles are approximated by a charged DC-DP pair, the *pair_style* must include Coulomb interactions, for instance *lj/cut/coul/long* with *kpspace_style ppm*. For example, with a cutoff of 10. and a precision 1.e-4:

```
pair_style lj/cut/coul/long 10.0
kpspace_style ppm 1.0e-4
```

As compared to the non-polarizable input file, *pair_coeff* lines need to be added for the DPs. Since the DPs have no Lennard-Jones interactions, their *epsilon* is 0. so the only *pair_coeff* line that needs to be added is

```
pair_coeff * 6* 0.0 0.0 # All-DPs
```

LAMMPS Users Manual

Now for the thermalization, the simplest choice is to use the [fix langevin/drude](#).

```
fix LANG all langevin/drude 300. 100 12435 1. 20 13977
```

This applies a Langevin thermostat at temperature 300. to the centers of mass of the DC-DP pairs, with relaxation time 100 and with random seed 12345. This fix applies also a Langevin thermostat at temperature 1. to the relative motion of the DPs around their DCs, with relaxation time 20 and random seed 13977. Only the DCs and non-polarizable atoms need to be in this fix's group. LAMMPS will thermostate the DPs together with their DC. For this, ghost atoms need to know their velocities. Thus you need to add the following command:

```
comm_modify vel yes
```

In order to avoid that the center of mass of the whole system drifts due to the random forces of the Langevin thermostat on DCs, you can add the *zero yes* option at the end of the fix line.

If the fix *shake* is used to constrain the C-H bonds, it should be invoked after the fix *langevin/drude* for more accuracy.

```
fix SHAKE ATOMS shake 0.0001 20 0 t 4 5
```

NOTE: The group of the fix *shake* must not include the DPs. If the group *ATOMS* is defined by non-DPs atom types, you could use

Since the fix *langevin/drude* does not perform time integration (just modification of forces but no position/velocity updates), the fix *nve* should be used in conjunction.

```
fix NVE all nve
```

Finally, do not forget to update the atom type elements if you use them in a *dump_modify ... element ...* command, by adding the element type of the DPs. Here for instance

```
dump DUMP all custom 10 dump.lampstrj id mol type element x y z ix iy iz
dump_modify DUMP element C C O H H D D D
```

The input file should now be ready for use!

You will notice that the global temperature *thermo_temp* computed by LAMMPS is not 300. K as wanted. This is because LAMMPS treats DPs as standard atoms in his default compute. If you want to output the temperatures of the DC-DP pair centers of mass and of the DPs relative to their DCs, you should use the [compute temp_drude](#)

```
compute TDRUDE all temp/drude
```

And then output the correct temperatures of the Drude oscillators using *thermo_style custom* with respectively *c_TDRUDE[1]* and *c_TDRUDE[2]*. These should be close to 300.0 and 1.0 on average.

```
thermo_style custom step temp c_TDRUDE[1] c_TDRUDE[2]
```

Thole screening

Dipolar interactions represented by point charges on springs may not be stable, for example if the atomic polarizability is too high for instance, a DP can escape from its DC and be captured by another DC, which makes the force and energy diverge and the simulation crash. Even without reaching this extreme case, the correlation between nearby dipoles on the same molecule may be exaggerated. Often, special bond relations prevent bonded neighboring atoms to see the charge of each other's DP, so that the problem does not always appear. It is possible to use screened dipole dipole interactions by using the *pair_style thole*. This is implemented as a correction to the Coulomb pair_styles, which dampens at short distance the interactions between the charges representing the induced dipoles. It is to be used as *hybrid/overlay* with any standard *coul* pair style. In our example, we would use

```
pair_style hybrid/overlay lj/cut/coul/long 10.0 thole 2.6 10.0
```

This tells LAMMPS that we are using two pair_styles. The first one is as above (*lj/cut/coul/long 10.0*). The second one is a *thole* pair_style with default screening factor 2.6 (Noskov) and cutoff 10.0.

Since *hybrid/overlay* does not support mixing rules, the interaction coefficients of all the pairs of atom types with $i < j$ should be explicitly defined. The output of the *polarizer* script can be used to complete the *pair_coeff* section of the input file. In our example, this will look like:

```
pair_coeff 1 1 lj/cut/coul/long 0.0700 3.550
pair_coeff 1 2 lj/cut/coul/long 0.0700 3.550
pair_coeff 1 3 lj/cut/coul/long 0.1091 3.310
pair_coeff 1 4 lj/cut/coul/long 0.0458 2.985
pair_coeff 2 2 lj/cut/coul/long 0.0700 3.550
pair_coeff 2 3 lj/cut/coul/long 0.1091 3.310
pair_coeff 2 4 lj/cut/coul/long 0.0458 2.985
pair_coeff 3 3 lj/cut/coul/long 0.1700 3.070
pair_coeff 3 4 lj/cut/coul/long 0.0714 2.745
pair_coeff 4 4 lj/cut/coul/long 0.0300 2.420
pair_coeff * 5 lj/cut/coul/long 0.0000 0.000
pair_coeff * 6* lj/cut/coul/long 0.0000 0.000
pair_coeff 1 1 thole 1.090 2.510
pair_coeff 1 2 thole 1.218 2.510
pair_coeff 1 3 thole 0.829 1.590
pair_coeff 1 6 thole 1.090 2.510
pair_coeff 1 7 thole 1.218 2.510
pair_coeff 1 8 thole 0.829 1.590
pair_coeff 2 2 thole 1.360 2.510
pair_coeff 2 3 thole 0.926 1.590
pair_coeff 2 6 thole 1.218 2.510
pair_coeff 2 7 thole 1.360 2.510
pair_coeff 2 8 thole 0.926 1.590
pair_coeff 3 3 thole 0.630 0.670
pair_coeff 3 6 thole 0.829 1.590
pair_coeff 3 7 thole 0.926 1.590
pair_coeff 3 8 thole 0.630 0.670
pair_coeff 6 6 thole 1.090 2.510
pair_coeff 6 7 thole 1.218 2.510
pair_coeff 6 8 thole 0.829 1.590
```

LAMMPS Users Manual

```
pair_coeff 7 7 thole 1.360 2.510
pair_coeff 7 8 thole 0.926 1.590
pair_coeff 8 8 thole 0.630 0.670
```

For the *thole* pair style the coefficients are

1. the atom polarizability in units of cubic length
2. the screening factor of the Thole function (optional, default value specified by the `pair_style` command)
3. the cutoff (optional, default value defined by the `pair_style` command)

The special neighbors have charge-charge and charge-dipole interactions screened by the *coul* factors of the *special_bonds* command (0.0, 0.0, and 0.5 in the example above). Without using the `pair_style thole`, dipole-dipole interactions are screened by the same factor. By using the `pair_style thole`, dipole-dipole interactions are screened by Thole's function, whatever their special relationship (except within each DC-DP pair of course). Consider for example 1-2 neighbors: using the `pair_style thole`, their dipoles will see each other (despite the *coul* factor being 0.) and the interactions between these dipoles will be damped by Thole's function.

Thermostats and barostats

Using a Nose-Hoover barostat with the *langevin/drude* thermostat is straightforward using `fix nph` instead of `nve`. For example:

```
fix NPH all nph iso 1. 1. 500
```

It is also possible to use a Nose-Hoover instead of a Langevin thermostat. This requires to use [fix drude/transform](#) just before and after the time integration fixes. The `fix drude/transform/direct` converts the atomic masses, positions, velocities and forces into a reduced representation, where the DCs transform into the centers of mass of the DC-DP pairs and the DPs transform into their relative position with respect to their DC. The `fix drude/transform/inverse` performs the reverse transformation. For a NVT simulation, with the DCs and atoms at 300 K and the DPs at 1 K relative to their DC one would use

```
fix DIRECT all drude/transform/direct
fix NVT1 ATOMS nvt temp 300. 300. 100
fix NVT2 DRUDES nvt temp 1. 1. 20
fix INVERSE all drude/transform/inverse
```

For our phenol example, the groups would be defined as

```
group ATOMS type 1 2 3 4 5 # DCs and non-polarizable atoms
group CORES type 1 2 3 # DCs
group DRUDES type 6 7 8 # DPs
```

Note that with the fixes *drude/transform*, it is not required to specify `comm_modify vel yes` because the fixes do it anyway (several times and for the forces also). To avoid the flying ice cube artifact ([Lamoureux](#)), where the atoms progressively freeze and the center of mass of the whole system drifts faster and faster, the `fix momentum` can be used. For instance:

LAMMPS Users Manual

```
fix MOMENTUM all momentum 100 linear 1 1 1
```

It is a bit more tricky to run a NPT simulation with Nose-Hoover barostat and thermostat. First, the volume should be integrated only once. So the fix for DCs and atoms should be *npt* while the fix for DPs should be *nvt* (or vice versa). Second, the *fix npt* computes a global pressure and thus a global temperature whatever the fix group. We do want the pressure to correspond to the whole system, but we want the temperature to correspond to the fix group only. We must then use the *fix_modify* command for this. In the end, the block of instructions for thermostating and barostating will look like

```
compute TATOMS ATOMS temp
fix DIRECT all drude/transform/direct
fix NPT ATOMS npt temp 300. 300. 100 iso 1. 1. 500
fix_modify NPT temp TATOMS press thermo_press
fix NVT DRUDES nvt temp 1. 1. 20
fix INVERSE all drude/transform/inverse
```

Rigid bodies

You may want to simulate molecules as rigid bodies (but polarizable). Common cases are water models such as [SWM4-NDP](#), which is a kind of polarizable TIP4P water. The rigid bodies and the DPs should be integrated separately, even with the Langevin thermostat. Let us review the different thermostats and ensemble combinations.

NVT ensemble using Langevin thermostat:

```
comm_modify vel yes
fix LANG all langevin/drude 300. 100 12435 1. 20 13977
fix RIGID ATOMS rigid/nve/small molecule
fix NVE DRUDES nve
```

NVT ensemble using Nose-Hoover thermostat:

```
fix DIRECT all drude/transform/direct
fix RIGID ATOMS rigid/nvt/small molecule temp 300. 300. 100
fix NVT DRUDES nvt temp 1. 1. 20
fix INVERSE all drude/transform/inverse
```

NPT ensemble with Langevin thermostat:

```
comm_modify vel yes
fix LANG all langevin/drude 300. 100 12435 1. 20 13977
fix RIGID ATOMS rigid/nph/small molecule iso 1. 1. 500
fix NVE DRUDES nve
```

NPT ensemble using Nose-Hoover thermostat:

```
compute TATOM ATOMS temp
fix DIRECT all drude/transform/direct
fix RIGID ATOMS rigid/npt/small molecule temp 300. 300. 100 iso 1. 1. 500
fix_modify RIGID temp TATOM press thermo_press
fix NVT DRUDES nvt temp 1. 1. 20
fix INVERSE all drude/transform/inverse
```

LAMMPS GitHub tutorial

written by **Stefan Paquay**

This document describes the process of how to use GitHub to integrate changes or additions you have made to LAMMPS into the official LAMMPS distribution. It uses the process of updating this very tutorial as an example to describe the individual steps and options. You need to be familiar with git and you may want to have a look at the [Git book](#) to reacquaint yourself with some of the more advanced git features used below.

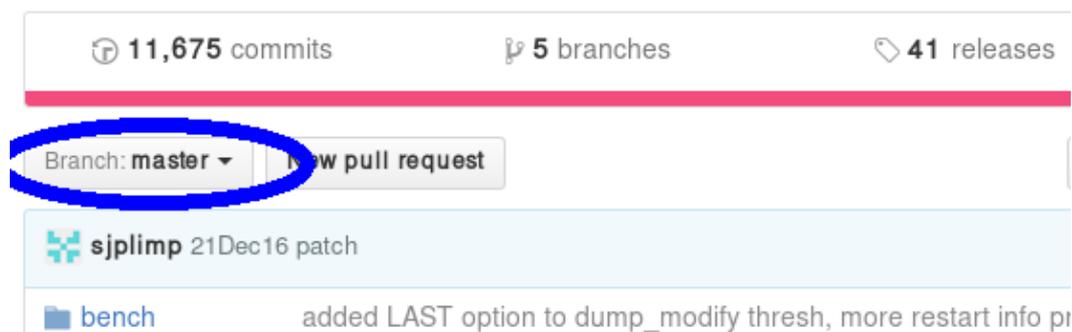

As of fall 2016, submitting contributions to LAMMPS via pull requests on GitHub is the preferred option for integrating contributed features or improvements to LAMMPS, as it significantly reduces the amount of work required by the LAMMPS developers. Consequently, creating a pull request will increase your chances to have your contribution included and will reduce the time until the integration is complete. For more information on the requirements to have your code included into LAMMPS please see [Section 10.15](#)

Making an account

First of all, you need a GitHub account. This is fairly simple, just go to [GitHub](#) and create an account by clicking the "Sign up for GitHub" button. Once your account is created, you can sign in by clicking the button in the top left and filling in your username or e-mail address and password.

Forking the repository

To get changes into LAMMPS, you need to first fork the `lammps/lammps` repository on GitHub. At the time of writing, *master* is the preferred target branch. Thus go to [LAMMPS on GitHub](#) and make sure branch is set to "master", as shown in the figure below.

If it is not, use the button to change it to *master*. Once it is, use the fork button to create a fork.

This will create a fork (which is essentially a copy, but uses less resources) of the LAMMPS repository under your own GitHub account. You can make changes in this fork and later file *pull requests* to allow the upstream repository to merge changes from your own fork into the one we just forked from (or others that were forked from the same repository). At the same time, you can set things up, so you can include changes from upstream into your repository and thus keep it in sync with the ongoing LAMMPS development.

Adding changes to your own fork

Additions to the upstream version of LAMMPS are handled using *feature branches*. For every new feature, a so-called feature branch is created, which contains only those modification relevant to one specific feature. For example, adding a single fix would consist of creating a branch with only the fix header and source file and nothing else. It is explained in more detail here: [feature branch workflow](#).

Feature branches

First of all, create a clone of your version on github on your local machine via HTTPS:

```
$ git clone https://github.com/
```

or, if you have set up your GitHub account for using SSH keys, via SSH:

```
$ git clone git@github.com:
```

You can find the proper URL by clicking the "Clone or download"-button:

teret2 Merged stuffs.

Commit	Message
	Merge remote branch 'lammps-ro/master' into lammps-icm
	Updated docs.

The above command copies ("clones") the git repository to your local machine to a directory with the name you chose. If none is given, it will default to "lammps". Typical names are "mylammps" or something similar.

You can use this local clone to make changes and test them without interfering with the repository on Github.

To pull changes from upstream into this copy, you can go to the directory and use git pull:

```
$ cd mylammps
$ git checkout master
$ git pull https://github.com/lammps/lammps
```

You can also add this URL as a remote:

```
$ git remote add lammps_upstream https://www.github.com/lammps/lammps
```

At this point, you typically make a feature branch from the updated master branch for the feature you want to work on. This tutorial contains the workflow that updated this tutorial, and hence we will call the branch "github-tutorial-update":

```
$ git checkout -b github-tutorial-update master
```

Now that we have changed branches, we can make our changes to our local repository. Just remember that if you want to start working on another, unrelated

LAMMPS Users Manual

feature, you should switch branches!

After changes are made

After everything is done, add the files to the branch and commit them:

```
$ git add doc/src/tutorial_github.txt
$ git add doc/src/JPG/tutorial*.png
```

IMPORTANT NOTE: Do not use *git commit -a* (or *git add -A*). The *-a* flag (or *-A* flag) will automatically include all modified or new files and that is rarely the behavior you want. It can easily lead to accidentally adding unrelated and unwanted changes into the repository. Instead it is preferable to explicitly use *git add*, *git rm*, *git mv* for adding, removing, renaming individual files, respectively, and then *git commit* to finalize the commit. Carefully check all pending changes with *git status* before committing them. If you find doing this on the command line too tedious, consider using a GUI, for example the one included in git distributions written in Tk, i.e. use *git gui* (on some Linux distributions it may be required to install an additional package to use it).

After adding all files, the change set can be committed with some useful message that explains the change.

```
$ git commit -m 'Finally updated the github tutorial'
```

After the commit, the changes can be pushed to the same branch on GitHub:

```
$ git push
```

Git will ask you for your user name and password on GitHub if you have not configured anything. If your local branch is not present on Github yet, it will ask you to add it by running

```
$ git push --set-upstream origin github-tutorial-update
```

If you correctly type your user name and password, the feature branch should be added to your fork on GitHub.

If you want to make really sure you push to the right repository (which is good practice), you can provide it explicitly:

```
$ git push origin
```

or using an explicit URL:

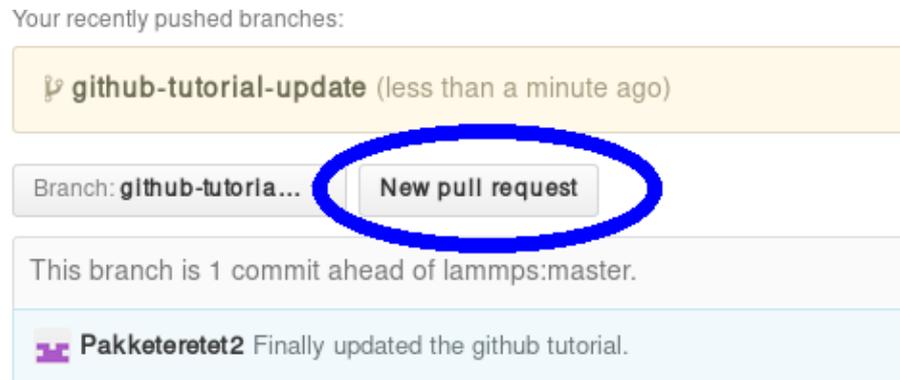

```
$ git push git@github.com:Pakketeretet2/lammps.git
```

Filing a pull request

Up to this point in the tutorial, all changes were to *your* clones of LAMMPS. Eventually, however, you want this feature to be included into the official LAMMPS version. To do this, you will want to file a pull request by clicking on the "New pull

LAMMPS Users Manual

request" button:

Make sure that the current branch is set to the correct one, which, in this case, is "github-tutorial-update". If done correctly, the only changes you will see are those that were made on this branch.

This will open up a new window that lists changes made to the repository. If you are just adding new files, there is not much to do, but I suppose merge conflicts are to be resolved here if there are changes in existing files. If all changes can automatically be merged, green text at the top will say so and you can click the "Create pull request" button, see image.

Open a pull request

Create a new pull request by comparing changes across two branches. If you need to, you can also [compare across forks](#).

The screenshot shows the GitHub pull request creation form. At the top, there are dropdown menus for the fork, base branch, and head branch. A green checkmark and the text "Able to merge. These branches can be automatically merged." are circled in blue. Below the form title "GitHub tutorial update", there are tabs for "Write" and "Preview", and a rich text editor toolbar. A large text area for comments is present, with the placeholder text "Leave a comment". Below the comment area, there is a checkbox labeled "Allow edits from maintainers. Learn more" which is checked. A green "Create pull request" button is circled in blue.

Before creating the pull request, make sure the short title is accurate and add a comment with details about your pull request. Here you write what your modifications do and why they should be incorporated upstream.

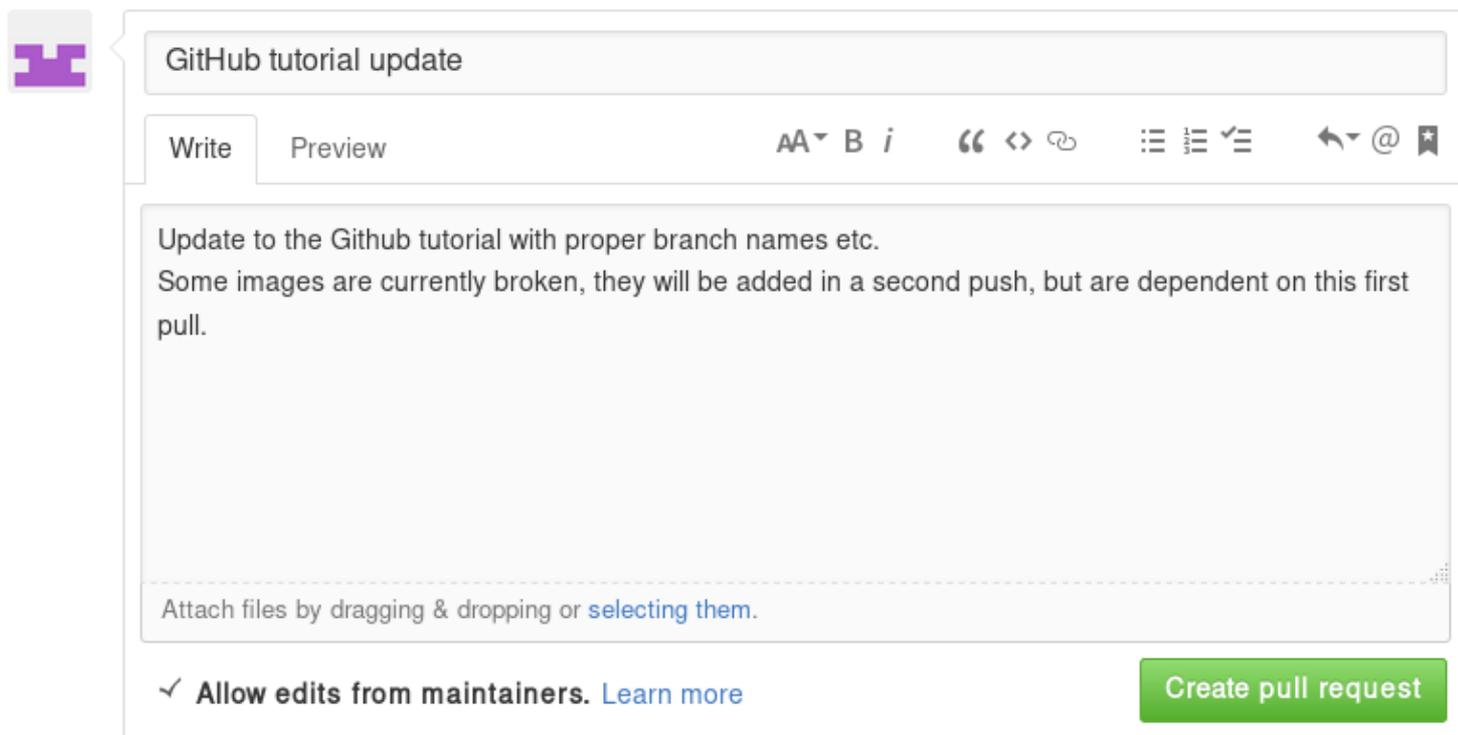

Note the checkbox that says "Allow edits from maintainers". This is checked by default checkbox (although in my version of Firefox, only the checkmark is visible):

This is a close-up of the bottom part of the pull request form. It shows the text "Attach files by dragging & dropping or selecting them." followed by a checked checkbox labeled "Allow edits from maintainers. Learn more". The checkbox and its label are circled in blue. To the right is the green "Create pull request" button.

LAMMPS Users Manual

If it is checked, maintainers can immediately add their own edits to the pull request. This helps the inclusion of your branch significantly, as simple/trivial changes can be added directly to your pull request branch by the LAMMPS maintainers. The alternative would be that they make changes on their own version of the branch and file a reverse pull request to you. Just leave this box checked unless you have a very good reason not to.

Now just write some nice comments and click on "Create pull request".

GitHub tutorial update

AA B i “ <> 🔗 ☰ ☷ ✓ ↶ @ 🚩

Update to the Github tutorial with proper branch names etc.
Some images are currently broken, they will be added in a second push, but are dependent on this first pull.

Attach files by dragging & dropping or [selecting them](#).

Allow edits from maintainers. [Learn more](#)

Create pull request

After filing a pull request

NOTE: When you submit a pull request (or ask for a pull request) for the first time, you will receive an invitation to become a LAMMPS project collaborator. Please accept this invite as being a collaborator will simplify certain administrative tasks and will probably speed up the merging of your feature, too.

You will notice that after filing the pull request, some checks are performed automatically:

GitHub tutorial update #315

 Open **Pakketeretet2** wants to merge 2 commits into `lammps:master` from `Pakketeretet2:github-tutorial-updat`

 Conversation **0**  Commits **2**  Files changed **5**

Pakketeretet2 commented a minute ago

Collaborator + 😊 ✎

Update to the Github tutorial with proper branch names etc.
Some images are currently broken, they will be added in a second push, but are dependent on this first pull.

 **Pakketeretet2** added some commits 18 minutes ago

-   Finally updated the github tutorial. 391ab76
-   Almost done with the tutorial now 4d98bbd

Add more commits by pushing to the `github-tutorial-update` branch on `Pakketeretet2/lammps`.

 **Some checks haven't completed yet** [Hide all checks](#)

Only those with [write access](#) to this repository can merge pull requests.

 Merge pull request You're not [authorized](#) to merge this pull request.

If all is fine, you will see this:

LAMMPS Users Manual

Add more commits by pushing to the `github-tutorial-update` branch on `Pakketeret2/lammps`.

 **All checks have passed** [Show all checks](#)
3 successful checks

 **This pull request can be automatically merged by project collaborators**
Only those with [write access](#) to this repository can merge pull requests.

 **Merge pull request** You're not [authorized](#) to merge this pull request.

If any of the checks are failing, your pull request will not be processed, as your changes may break compilation for certain configurations or may not merge cleanly. It is your responsibility to remove the reason(s) for the failed test(s). If you need help with this, please contact the LAMMPS developers by adding a comment explaining your problems with resolving the failed tests.

A few further interesting things (can) happen to pull requests before they are included.

Additional changes

First of all, any additional changes you push into your branch in your repository will automatically become part of the pull request:

 **Pakketeret2** added some commits 2 days ago

-   Finally updated the github tutorial. 391ab76
-   Almost done with the tutorial now ✓ 4d98bbd
-   Second update round to text and images, a third will follow after suc... ✓ 2c7feal
-   Small changes to tutorial text. 18b12ef

This means you can add changes that should be part of the feature after filing the pull request, which is useful in case you have forgotten them, or if a developer has requested that something needs to be changed before the feature can be accepted into the official LAMMPS version. After each push, the automated checks are run again.

Assignees

There is an assignee label for pull requests. If the request has not been reviewed by any developer yet, it is not assigned to anyone. After revision, a developer can choose to assign it to either a) you, b) a LAMMPS developer (including him/herself) or c)

LAMMPS Users Manual

Steve Plimpton (sjplimp).

- Case a) happens if changes are required on your part
- Case b) means that at the moment, it is being tested and reviewed by a LAMMPS developer with the expectation that some changes would be required. After the review, the developer can choose to implement changes directly or suggest them to you.
- Case c) means that the pull request has been assigned to the lead developer Steve Plimpton and means it is considered ready for merging.

In this case, Axel assigned the tutorial to Steve:

Update to the Github tutorial with proper branch names etc.

Some images are currently broken, they will be added in a second push, but are dependent on this first push.

Reverse pull requests

Sometimes, however, you might not feel comfortable having other people push changes into your own branch, or maybe the maintainers are not sure their idea was the right one. In such a case, they can make changes, reassign you as the assignee,

LAMMPS Users Manual

and file a "reverse pull request", i.e. file a pull request in your GitHub repository to include changes in the branch, that you have submitted as a pull request yourself. In that case, you can choose to merge their changes back into your branch, possibly make additional changes or corrections and proceed from there. It looks something like this:

For some reason, the highlighted button didn't work in my case, but I can go to my own repository and merge the pull request from there:

The screenshot shows a GitHub pull request page for the repository 'Pakketeretet2 / lammeps', which is a fork of 'lammeps/lammeps'. The page title is 'some formatting updates and text rewrites for your pull request #1'. A green 'Open' button indicates that 'akohlmey' wants to merge 1 commit into 'Pakketeretet2:github-tutorial-update' from 'akohlmey:pull-315'. Below the title, there are tabs for 'Conversation' (0), 'Commits' (1), and 'Files changed' (1). A comment from 'akohlmey' dated 2 days ago states: 'Here are some additional changes for your lammeps/#315 pull request. It updates the "do not use git add -a" paragraph and some formatting improvements.' Below the comment, a commit is listed: 'some formatting updates and text rewrites in the "do not use git add ...' with commit hash 'fe14158'. At the bottom, a green box with a checkmark icon contains the message: 'This branch has no conflicts with the base branch. Merging can be performed automatically.' Below this message is a green button labeled 'Merge pull request' with a dropdown arrow, followed by the text 'or view [command line instructions](#).' The entire merge confirmation box is highlighted with a blue rounded rectangle.

Be sure to check the changes to see if you agree with them by clicking on the tab button:

some formatting updates and text rewrites for your pull request #1

 akohlmey commented 2 days ago +😊✎

Here are some additional changes for your lammps/#315 pull request. It updates the "do not use git add -a" paragraph and some formatting improvements.

  some formatting updates and text rewrites in the "do not use git add ..." fe14158

 Pakketeret2 commented 26 seconds ago Owner +😊✎✕

Thanks Axel, will merge after a review.

  **This branch has no conflicts with the base branch**
Merging can be performed automatically.

 Merge pull request ▼ or view [command line instructions](#).

In this case, most of it is changes in the markup and a short rewrite of Axel's explanation of the "git gui" and "git add" commands.

LAMMPS Users Manual

```
ng :pre
113 $ git add doc/src/JPG
114
115 +IMPORTANT NOTE: Do not
116 +automatically include
117 +behavior you want. It
118 +and unwanted changes in
119 +explicitly use `git add
120 +renaming files, respect
121 +commit. If you find do
122 +consider using a GUI, f
123 +written in Tk, i.e. use
124 +be required to install
125
126 +After adding all files,
127 +useful message that exp
128
129 $ git commit -m 'Fina
130
can be committed with some useful message
the github tutorial' :pre
automatically become part of the pull request:
anges.png)
216
217 :c,image(JPG/tutorial_a
```

Because the changes are OK with us, we are going to merge by clicking on "Merge pull request". After a merge it looks like this:

The screenshot shows a GitHub pull request interface. At the top, a comment from user 'Pakketeret2' is displayed, stating 'Thanks Axel, will merge after a review.' Below the comment, a merge action is shown: 'Pakketeret2 merged commit 1310438 into Pakketeret2:github-tutorial-update'. At the bottom, a notification banner reads 'Avoid bugs by automatically running your tests.' with a 'Learn more' link.

Now, since in the meantime our local text for the tutorial also changed, we need to pull Axel's change back into our branch, and merge them:

LAMMPS Users Manual

```
$ git add tutorial_github.txt
$ git add JPG/tutorial_reverse_pull_request*.png
$ git commit -m "Updated text and images on reverse pull requests"
$ git pull
```

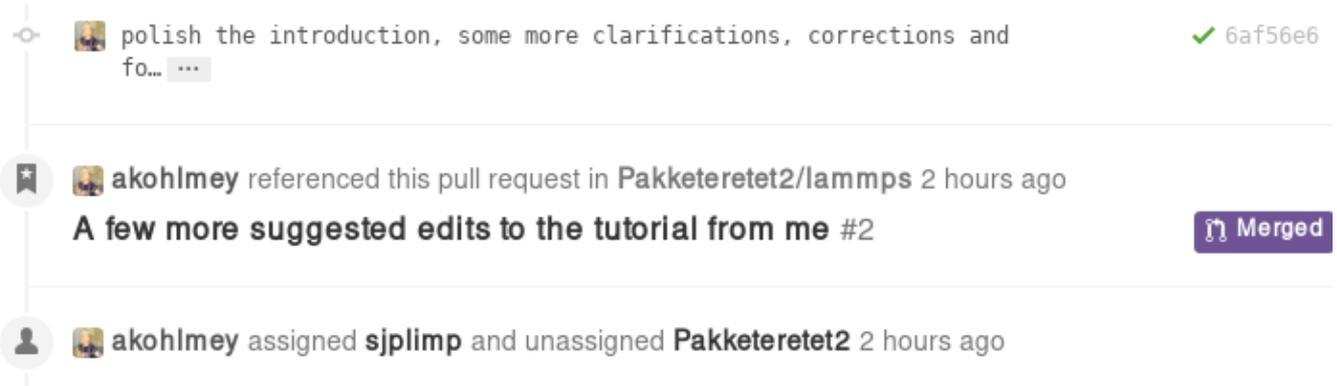

In this case, the merge was painless because git could auto-merge:

```
[ stefan@phys8250 src ] % git pull
Auto-merging doc/src/tutorial_github.txt
Waiting for Emacs...
Merge made by the 'recursive' strategy.
 doc/src/tutorial_github.txt | 68 ++++++-----
 1 file changed, 37 insertions(+), 31 deletions(-)
[ stefan@phys8250 src ] %
```

With Axel's changes merged in and some final text updates, our feature branch is now perfect as far as we are concerned, so we are going to commit and push again:

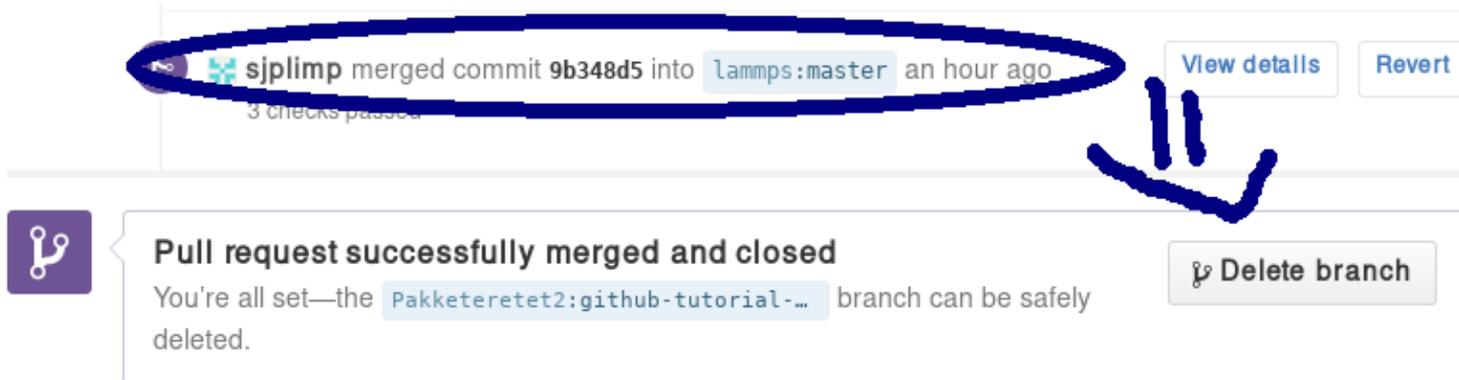

```
$ git add tutorial_github.txt
$ git add JPG/tutorial_reverse_pull_request6.png
$ git commit -m "Merged Axel's suggestions and updated text"
$ git push git@github.com:Pakketeretet2/lammps
```

This merge also shows up on the lammps Github page:

After a merge

When everything is fine, the feature branch is merged into the master branch:

LAMMPS Users Manual

Now one question remains: What to do with the feature branch that got merged into upstream?

It is in principle safe to delete them from your own fork. This helps keep it a bit more tidy. Note that you first have to switch to another branch!

```
$ git checkout master
$ git pull master
$ git branch -d github-tutorial-update
```

If you do not pull first, it is not really a problem but git will warn you at the next statement that you are deleting a local branch that was not yet fully merged into HEAD. This is because git does not yet know your branch just got merged into LAMMPS upstream. If you first delete and then pull, everything should still be fine.

Finally, if you delete the branch locally, you might want to push this to your remote(s) as well:

```
$ git push origin :github-tutorial-update
```

Recent changes in the workflow

Some changes to the workflow are not captured in this tutorial. For example, in addition to the master branch, to which all new features should be submitted, there is now also an "unstable" and a "stable" branch; these have the same content as "master", but are only updated after a patch release or stable release was made. Furthermore, the naming of the patches now follow the pattern "patch_" to simplify comparisons between releases. Finally, all patches and submissions are subject to automatic testing and code checks to make sure they at the very least compile.

PyLammps Tutorial

Overview

PyLammps is a Python wrapper class which can be created on its own or use an existing lammps Python object. It creates a simpler, Python-like interface to common LAMMPS functionality. Unlike the original flat C-types interface, it exposes a discoverable API. It no longer requires knowledge of the underlying C++ code implementation. Finally, the IPyLammps wrapper builds on top of PyLammps and adds some additional features for IPython integration into IPython notebooks, e.g. for embedded visualization output from dump/image.

Comparison of lammps and PyLammps interfaces

lammps.lammps

- uses C-Types
- direct memory access to native C++ data
- provides functions to send and receive data to LAMMPS
- requires knowledge of how LAMMPS internally works (C pointers, etc)

lammps.PyLammps

- higher-level abstraction built on top of original C-Types interface
- manipulation of Python objects
- communication with LAMMPS is hidden from API user
- shorter, more concise Python
- better IPython integration, designed for quick prototyping

Quick Start

System-wide Installation

Step 1: Building LAMMPS as a shared library

To use LAMMPS inside of Python it has to be compiled as shared library. This library is then loaded by the Python interface. In this example we enable the MOLECULE package and compile LAMMPS with C++ exceptions, PNG, JPEG and FFMPEG output support enabled.

```
cd $LAMMPS_DIR/src
```

```
# add packages if necessary  
make yes-MOLECULE
```

```
# compile shared library using Makefile
```

```
make mpi mode=shlib LMP_INC="-DLAMMPS_PNG -DLAMMPS_JPEG -DLAMMPS_FFMPEG -DLAMMPS_EXCEPTIONS" JP
```

LAMMPS Users Manual

Step 2: Installing the LAMMPS Python package

PyLammps is part of the lammps Python package. To install it simply install that package into your current Python installation.

```
cd $LAMMPS_DIR/python
python install.py
```

NOTE: Recompiling the shared library requires reinstalling the Python package

Installation inside of a virtualenv

You can use virtualenv to create a custom Python environment specifically tuned for your workflow.

Benefits of using a virtualenv

- isolation of your system Python installation from your development installation
- installation can happen in your user directory without root access (useful for HPC clusters)
- installing packages through pip allows you to get newer versions of packages than e.g., through apt-get or yum package managers (and without root access)
- you can even install specific old versions of a package if necessary

Prerequisite (e.g. on Ubuntu)

```
apt-get install python-virtualenv
```

Creating a virtualenv with lammps installed

```
# create virtualenv name 'testing'

# activate 'testing' environment
source testing/bin/activate

# install LAMMPS package in virtualenv
(testing) cd $LAMMPS_DIR/python
(testing) python install.py

# install other useful packages
(testing) pip install matplotlib jupyter mpi4py

...

# return to original shell
(testing) deactivate
```

Creating a new instance of PyLammps

To create a PyLammps object you need to first import the class from the lammps module. By using the default constructor, a new *lammps* instance is created.

```
from lammps import PyLammps
L = PyLammps()
```

LAMMPS Users Manual

You can also initialize PyLammps on top of this existing *lammps* object:

```
from lammps import lammps, PyLammps
lmp = lammps()
L = PyLammps(ptr=lmp)
```

Commands

Sending a LAMMPS command with the existing library interfaces is done using the command method of the lammps object instance.

For instance, let's take the following LAMMPS command:

```
region box block 0 10 0 5 -0.5 0.5
```

In the original interface this command can be executed with the following Python code if *L* was a lammps instance:

```
L.command("region box block 0 10 0 5 -0.5 0.5")
```

With the PyLammps interface, any command can be split up into arbitrary parts separated by whitespace, passed as individual arguments to a region method.

```
L.region("box block", 0, 10, 0, 5, -0.5, 0.5)
```

Note that each parameter is set as Python literal floating-point number. In the PyLammps interface, each command takes an arbitrary parameter list and transparently merges it to a single command string, separating individual parameters by whitespace.

The benefit of this approach is avoiding redundant command calls and easier parameterization. In the original interface parametrization needed to be done manually by creating formatted strings.

```
L.command("region box block %f %f %f %f %f %f" % (xlo, xhi, ylo, yhi, zlo, zhi))
```

In contrast, methods of PyLammps accept parameters directly and will convert them automatically to a final command string.

```
L.region("box block", xlo, xhi, ylo, yhi, zlo, zhi)
```

System state

In addition to dispatching commands directly through the PyLammps object, it also provides several properties which allow you to query the system state.

`L.system`

Is a dictionary describing the system such as the bounding box or number of atoms

`L.system.xlo`, `L.system.xhi`

bounding box limits along x-axis

`L.system.ylo`, `L.system.yhi`

LAMMPS Users Manual

- bounding box limits along y-axis
- L.system.zlo, L.system.zhi
 - bounding box limits along z-axis
- L.communication
 - configuration of communication subsystem, such as the number of threads or processors
- L.communication.nthreads
 - number of threads used by each LAMMPS process
- L.communication.nprocs
 - number of MPI processes used by LAMMPS
- L.fixes
 - List of fixes in the current system
- L.computes
 - List of active computes in the current system
- L.dump
 - List of active dumps in the current system
- L.groups
 - List of groups present in the current system

Working with LAMMPS variables

LAMMPS variables can be both defined and accessed via the PyLammps interface.

To define a variable you can use the [variable](#) command:

```
L.variable("a index 2")
```

A dictionary of all variables is returned by L.variables

you can access an individual variable by retrieving a variable object from the L.variables dictionary by name

```
a = L.variables['a']
```

The variable value can then be easily read and written by accessing the value property of this object.

```
print(a.value)
a.value = 4
```

Retrieving the value of an arbitrary LAMMPS expressions

LAMMPS expressions can be immediately evaluated by using the eval method. The passed string parameter can be any expression containing global thermo values, variables, compute or fix data.

```
result = L.eval("ke") # kinetic energy
result = L.eval("pe") # potential energy
```

```
result = L.eval("v_t/2.0")
```

Accessing atom data

All atoms in the current simulation can be accessed by using the `L.atoms` list. Each element of this list is an object which exposes its properties (id, type, position, velocity, force, etc.).

```
# access first atom
L.atoms[0].id
L.atoms[0].type
```

```
# access second atom
L.atoms[1].position
L.atoms[1].velocity
L.atoms[1].force
```

Some properties can also be used to set:

```
# set position in 2D simulation
L.atoms[0].position = (1.0, 0.0)
```

```
# set position in 3D simulation
L.atoms[0].position = (1.0, 0.0, 1.)
```

Evaluating thermo data

Each simulation run usually produces thermo output based on system state, computes, fixes or variables. The trajectories of these values can be queried after a run via the `L.runs` list. This list contains a growing list of run data. The first element is the output of the first run, the second element that of the second run.

```
L.run(1000)
L.runs[0] # data of first 1000 time steps
```

```
L.run(1000)
L.runs[1] # data of second 1000 time steps
```

Each run contains a dictionary of all trajectories. Each trajectory is accessible through its thermo name:

```
L.runs[0].step # list of time steps in first run
L.runs[0].ke   # list of kinetic energy values in first run
```

Together with matplotlib plotting data out of LAMMPS becomes simple:

```
import matplotlib.pyplot as plt
```

```
steps = L.runs[0].step
ke     = L.runs[0].ke
plt.plot(steps, ke)
```

Error handling with PyLammps

Compiling the shared library with C++ exception support provides a better error handling experience. Without exceptions the LAMMPS code will terminate the current

LAMMPS Users Manual

Python process with an error message. C++ exceptions allow capturing them on the C++ side and rethrowing them on the Python side. This way you can handle LAMMPS errors through the Python exception handling mechanism.

IMPORTANT NOTE: Capturing a LAMMPS exception in Python can still mean that the current LAMMPS process is in an illegal state and must be terminated. It is advised to save your data and terminate the Python instance as quickly as possible.

Using PyLammps in IPython notebooks and Jupyter

If the LAMMPS Python package is installed for the same Python interpreter as IPython, you can use PyLammps directly inside of an IPython notebook inside of Jupyter. Jupyter is a powerful integrated development environment (IDE) for many dynamic languages like Python, Julia and others, which operates inside of any web browser. Besides auto-completion and syntax highlighting it allows you to create formatted documents using Markup, mathematical formulas, graphics and animations intermixed with executable Python code. It is a great format for tutorials and showcasing your latest research.

To launch an instance of Jupyter simply run the following command inside your Python environment (this assumes you followed the Quick Start instructions):

```
jupyter notebook
```

IPyLammps Examples

Examples of IPython notebooks can be found in the `python/examples/pylammps` subdirectory. To open these notebooks launch *jupyter notebook* inside this directory and navigate to one of them. If you compiled and installed a LAMMPS shared library with exceptions, PNG, JPEG and FFMPEG support you should be able to rerun all of these notebooks.

Validating a dihedral potential

This example showcases how an IPython Notebook can be used to compare a simple LAMMPS simulation of a harmonic dihedral potential to its analytical solution. Four atoms are placed in the simulation and the dihedral potential is applied on them using a datafile. Then one of the atoms is rotated along the central axis by setting its position from Python, which changes the dihedral angle.

```
phi = [d * math.pi / 180 for d in range(360)]

pos = [(1.0, math.cos(p), math.sin(p)) for p in phi]

pe = []
for p in pos:
    L.atoms[3].position = p
    L.run(0)
    pe.append(L.eval("pe"))
```

By evaluating the potential energy for each position we can verify that trajectory with the analytical formula. To compare both solutions, we plot both trajectories over each

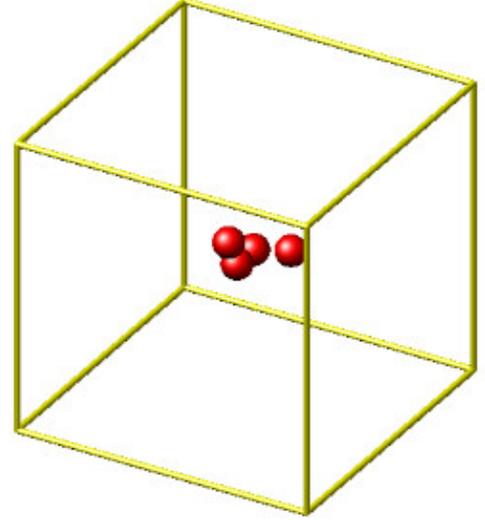

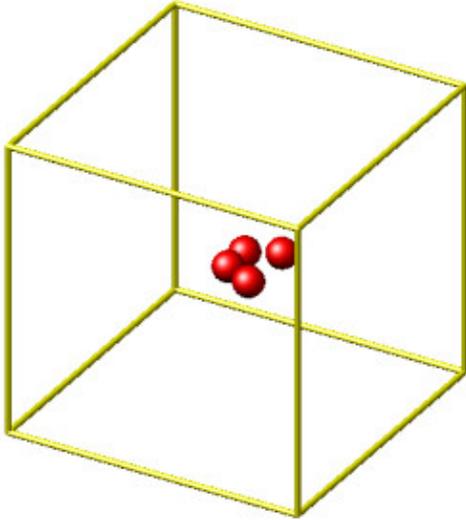

LAMMPS Users Manual

other using matplotlib, which embeds the generated plot inside the IPython notebook.

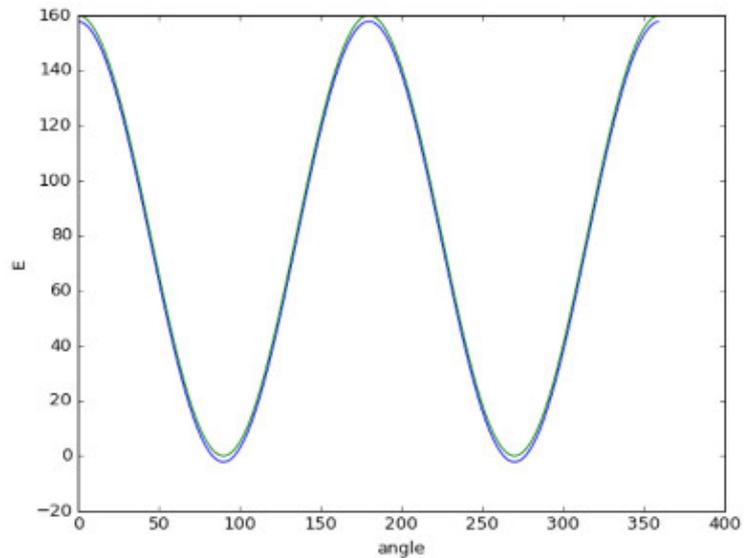

```
age(zoom=1.0)
```

```
In [14]: L.image(zoom=1.0)
```

```
Out[14]:
```

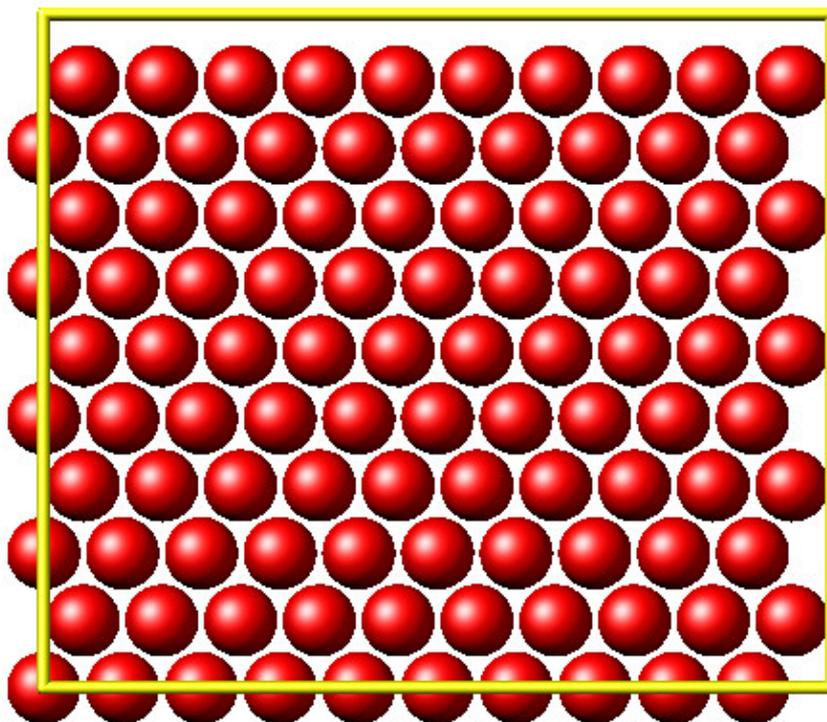

```
In [27]: plt.plot(range(360), pe, range(360), E_analytical)
plt.xlabel('angle')
plt.ylabel('E')
```

Running a Monte Carlo relaxation

This second example shows how to use PyLammps to create a 2D Monte Carlo Relaxation simulation, computing and plotting energy terms and even embedding video output.

Initially, a 2D system is created in a state with minimal energy.

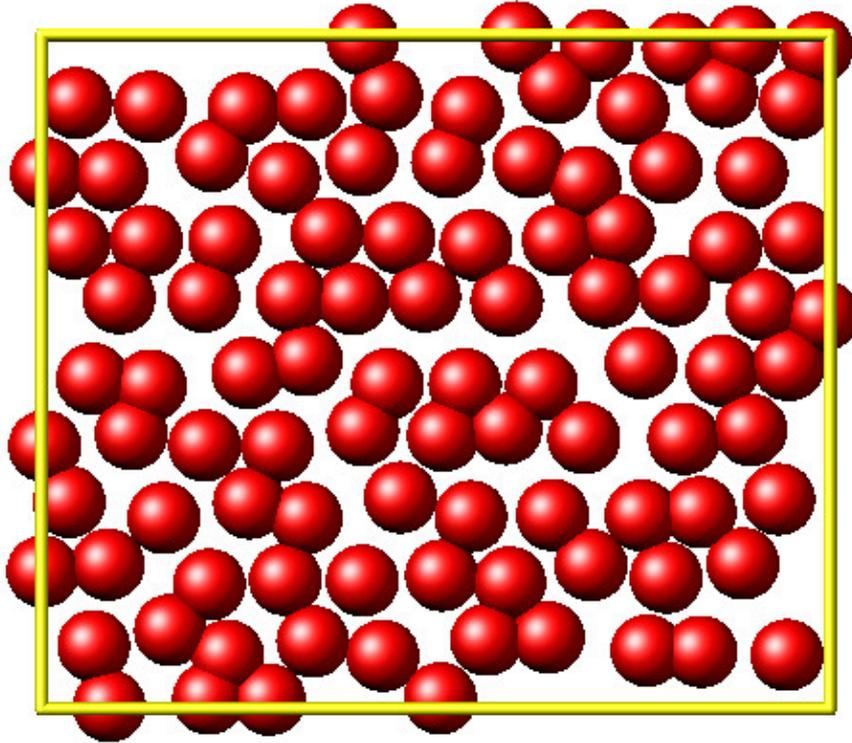

It is then disordered by moving each atom by a random delta.

```
random.seed(27848)  
deltaperturb = 0.2
```

```
for i in range(L.system.natoms):  
    x, y = L.atoms[i].position  
    dx = deltaperturb * random.uniform(-1, 1)  
    dy = deltaperturb * random.uniform(-1, 1)  
    L.atoms[i].position = (x+dx, y+dy)
```

```
L.run(0)
```

Finally, the Monte Carlo algorithm is implemented in Python. It continuously moves random atoms by a random delta and only accepts certain moves.

```
estart = L.eval("pe")
elast = estart

naccept = 0
energies = [estart]

niterations = 3000
deltamove = 0.1
kT = 0.05

natoms = L.system.natoms

for i in range(niterations):
    iatom = random.randrange(0, natoms)
    current_atom = L.atoms[iatom]

    x0, y0 = current_atom.position

    dx = deltamove * random.uniform(-1, 1)
    dy = deltamove * random.uniform(-1, 1)

    current_atom.position = (x0+dx, y0+dy)

L.run(1, "pre no post no")

e = L.eval("pe")
```

LAMMPS Users Manual

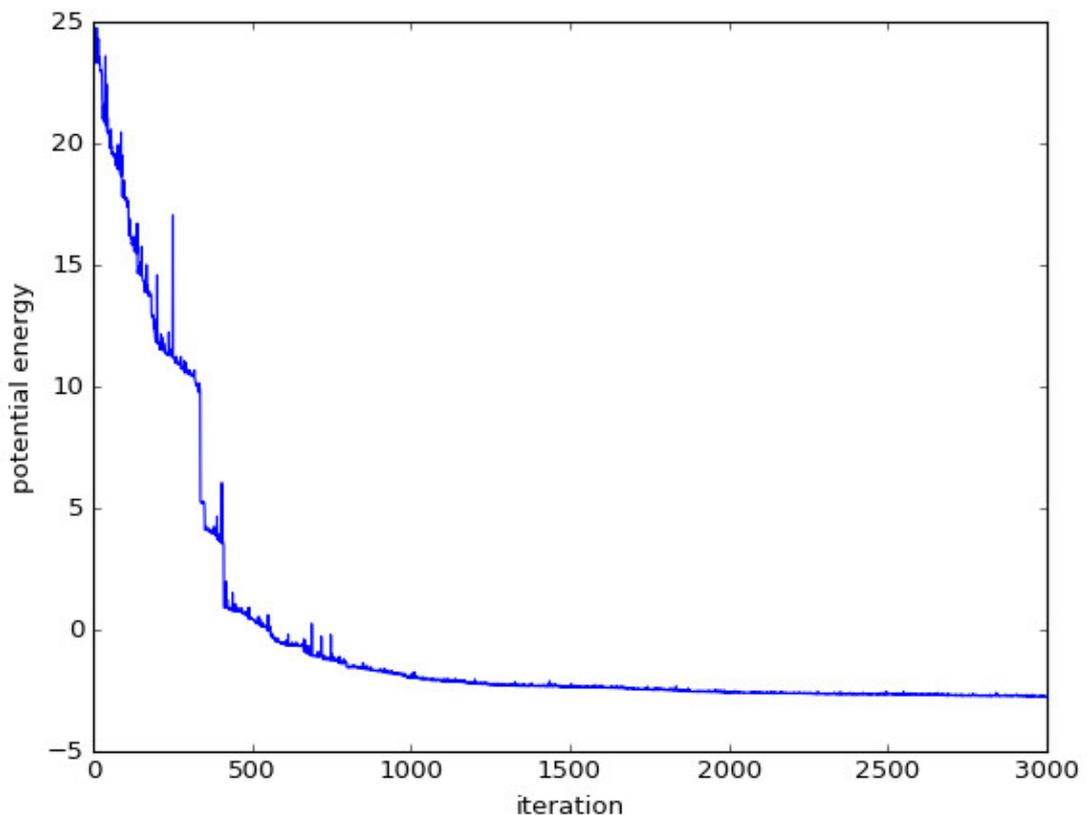

```
energies.append(e)

if e <= elast:
    naccept += 1
    elast = e
elif random.random() <= math.exp(natoms*(elast-e)/kT):
    naccept += 1
    elast = e
else:
    current_atom.position = (x0, y0)
```

The energies of each iteration are collected in a Python list and finally plotted using matplotlib.

```
In [20]: plt.xlabel('iteration')
plt.ylabel('potential energy')
plt.plot(energies)
```

Figure 1

```
Out[20]: [<matplotlib.lines.Line2D at 0x7f26a40123c8>]
```

LAMMPS Users Manual

The IPython notebook also shows how to use dump commands and embed video files inside of the IPython notebook.

Using PyLammps and mpi4py (Experimental)

PyLammps can be run in parallel using mpi4py. This python package can be installed using

```
pip install mpi4py
```

The following is a short example which reads in an existing LAMMPS input file and executes it in parallel. You can find in.melt in the examples/melt folder.

```
from mpi4py import MPI
from lammps import PyLammps

L = PyLammps()
L.file("in.melt")

if MPI.COMM_WORLD.rank == 0:
    print("Potential energy: ", L.eval("pe"))

MPI.Finalize()
```

To run this script (melt.py) in parallel using 4 MPI processes we invoke the following mpirun command:

```
mpirun -np 4 python melt.py
```

IMPORTANT NOTE: Any command must be executed by all MPI processes. However, evaluations and querying the system state is only available on rank 0.

Feedback and Contributing

If you find this Python interface useful, please feel free to provide feedback and ideas on how to improve it to Richard Berger (richard.berger@temple.edu). We also want to encourage people to write tutorial style IPython notebooks showcasing LAMMPS usage and maybe their latest research results.

LAMMPS Users Manual

[LAMMPS WWW Site](#) - [LAMMPS Documentation](#) - [LAMMPS Commands](#)

Body particles

Overview:

This doc page is not about a LAMMPS input script command, but about body particles, which are generalized finite-size particles. Individual body particles can represent complex entities, such as surface meshes of discrete points, collections of sub-particles, deformable objects, etc. Note that other kinds of finite-size spherical and aspherical particles are also supported by LAMMPS, such as spheres, ellipsoids, line segments, and triangles, but they are simpler entities than body particles. See [Section 6.14](#) for a general overview of all these particle types.

Body particles are used via the [atom_style body](#) command. It takes a body style as an argument. The current body styles supported by LAMMPS are as follows. The name in the first column is used as the *bstyle* argument for the [atom_style body](#) command.

<i>nparticle</i>	rigid body with N sub-particles
<i>rounded/polygon</i>	2d convex polygon with N vertices

The body style determines what attributes are stored for each body and thus how they can be used to compute pairwise body/body or bond/non-body (point particle) interactions. More details of each style are described below.

NOTE: The rounded/polygon style listed in the table above and described below has not yet been released in LAMMPS. It will be soon.

We hope to add more styles in the future. See [Section 10.12](#) for details on how to add a new body style to the code.

When to use body particles:

You should not use body particles to model a rigid body made of simpler particles (e.g. point, sphere, ellipsoid, line segment, triangular particles), if the interaction between pairs of rigid bodies is just the summation of pairwise interactions between the simpler particles. LAMMPS already supports this kind of model via the [fix rigid](#) command. Any of the numerous pair styles that compute interactions between simpler particles can be used. The [fix rigid](#) command time integrates the motion of the rigid bodies. All of the standard LAMMPS commands for thermostating, adding constraints, performing output, etc will operate as expected on the simple particles.

By contrast, when body particles are used, LAMMPS treats an entire body as a single particle for purposes of computing pairwise interactions, building neighbor lists, migrating particles between processors, outputting particles to a dump file, etc. This means that interactions between pairs of bodies or between a body and non-body (point) particle need to be encoded in an appropriate pair style. If such a pair style were to mimic the [fix rigid](#) model, it would need to loop over the entire collection of interactions between pairs of simple particles within the two bodies, each time a single body/body interaction was computed.

Thus it only makes sense to use body particles and develop such a pair style, when

LAMMPS Users Manual

particle/particle interactions are more complex than what the [fix rigid](#) command can already calculate. For example, if particles have one or more of the following attributes:

- represented by a surface mesh
- represented by a collection of geometric entities (e.g. planes + spheres)
- deformable
- internal stress that induces fragmentation

then the interaction between pairs of particles is likely to be more complex than the summation of simple sub-particle interactions. An example is contact or frictional forces between particles with planar surfaces that inter-penetrate.

These are additional LAMMPS commands that can be used with body particles of different styles

fix nve/body	integrate motion of a body particle in NVE ensemble
fix nvt/body	ditto for NVT ensemble
fix npt/body	ditto for NPT ensemble
fix nph/body	ditto for NPH ensemble
compute body/local	store sub-particle attributes of a body particle
compute temp/body	compute temperature of body particles
dump local	output sub-particle attributes of a body particle
dump image	output body particle attributes as an image

The pair styles defined for use with specific body styles are listed in the sections below.

Specifics of body style *nparticle*:

The *nparticle* body style represents body particles as a rigid body with a variable number N of sub-particles. It is provided as a vanilla, prototypical example of a body particle, although as mentioned above, the [fix rigid](#) command already duplicates its functionality.

The `atom_style body` command for this body style takes two additional arguments:

```
atom_style body nparticle Nmin Nmax
Nmin = minimum # of sub-particles in any body in the system
Nmax = maximum # of sub-particles in any body in the system
```

The N_{min} and N_{max} arguments are used to bound the size of data structures used internally by each particle.

When the [read_data](#) command reads a data file for this body style, the following information must be provided for each entry in the *Bodies* section of the data file:

```
atom-ID 1 M
N
ixx iyy izz ixy ixz iyz
x1 y1 z1
```

...
xN yN zN

N is the number of sub-particles in the body particle. $M = 6 + 3*N$. The integer line has a single value N. The floating point line(s) list 6 moments of inertia followed by the coordinates of the N sub-particles (x1 to zN) as 3N values. These values can be listed on as many lines as you wish; see the [read_data](#) command for more details.

The 6 moments of inertia (ixx,iyy,izz,ixy,ixz,iyz) should be the values consistent with the current orientation of the rigid body around its center of mass. The values are with respect to the simulation box XYZ axes, not with respect to the principal axes of the rigid body itself. LAMMPS performs the latter calculation internally. The coordinates of each sub-particle are specified as its x,y,z displacement from the center-of-mass of the body particle. The center-of-mass position of the particle is specified by the x,y,z values in the *Atoms* section of the data file, as is the total mass of the body particle.

The [pair_style body](#) command can be used with this body style to compute body/body and body/non-body interactions.

For output purposes via the [compute body/local](#) and [dump local](#) commands, this body style produces one datum for each of the N sub-particles in a body particle. The datum has 3 values:

1 = x position of sub-particle
2 = y position of sub-particle
3 = z position of sub-particle

These values are the current position of the sub-particle within the simulation domain, not a displacement from the center-of-mass (COM) of the body particle itself. These values are calculated using the current COM and orientation of the body particle.

For images created by the [dump image](#) command, if the *body* keyword is set, then each body particle is drawn as a collection of spheres, one for each sub-particle. The size of each sphere is determined by the *bflag1* parameter for the *body* keyword. The *bflag2* argument is ignored.

Specifics of body style rounded/polygon:

NOTE: Aug 2016 - This body style has not yet been added to LAMMPS. The info below is a placeholder.

The *rounded/polygon* body style represents body particles as a convex polygon with a variable number $N > 2$ of vertices, which can only be used for 2d models. One example use of this body style is for 2d discrete element models, as described in [Fraige](#). Similar to body style *nparticle*, the *atom_style* body command for this body style takes two additional arguments:

`atom_style body rounded/polygon Nmin Nmax`
Nmin = minimum # of vertices in any body in the system
Nmax = maximum # of vertices in any body in the system

LAMMPS Users Manual

The `Nmin` and `Nmax` arguments are used to bound the size of data structures used internally by each particle.

When the `read_data` command reads a data file for this body style, the following information must be provided for each entry in the *Bodies* section of the data file:

```
atom-ID 1 M
N
ixx iyy izz ixy ixz iyz
x1 y1 z1
...
xN yN zN
i j j k k ...
radius
```

`N` is the number of vertices in the body particle. $M = 6 + 3*N + 2*N + 1$. The integer line has a single value `N`. The floating point line(s) list 6 moments of inertia followed by the coordinates of the `N` vertices (`x1` to `zN`) as $3N$ values, followed by $2N$ vertex indices corresponding to the end points of the `N` edges, followed by a single radius value = the smallest circle encompassing the polygon. That last value is used to facilitate the body/body contact detection. These floating-point values can be listed on as many lines as you wish; see the `read_data` command for more details.

The 6 moments of inertia (`ixx,iyy,izz,ixy,ixz,iyz`) should be the values consistent with the current orientation of the rigid body around its center of mass. The values are with respect to the simulation box `XYZ` axes, not with respect to the principal axes of the rigid body itself. LAMMPS performs the latter calculation internally. The coordinates of each vertex are specified as its `x,y,z` displacement from the center-of-mass of the body particle. The center-of-mass position of the particle is specified by the `x,y,z` values in the *Atoms* section of the data file.

For example, the following information would specify a square particles whose edge length is $\sqrt{2}$:

```
3 1 27
4
1 1 4 0 0 0
-0.7071 -0.7071 0
-0.7071 0.7071 0
0.7071 0.7071 0
0.7071 -0.7071 0
0 1 1 2 2 3 3 0
1.0
```

The `pair_style body/rounded/polygon` command can be used with this body style to compute body/body interactions.

For output purposes via the `compute body/local` and `dump local` commands, this body style produces one datum for each of the `N` sub-particles in a body particle. The datum has 3 values:

```
1 = x position of vertex
2 = y position of vertex
3 = z position of vertex
```

LAMMPS Users Manual

These values are the current position of the vertex within the simulation domain, not a displacement from the center-of-mass (COM) of the body particle itself. These values are calculated using the current COM and orientation of the body particle.

For images created by the [dump image](#) command, if the *body* keyword is set, then each body particle is drawn as a convex polygon consisting of N line segments. Note that the line segments are drawn between the N vertices, which does not correspond exactly to the physical extent of the body (because the [pair_style rounded/polygon](#) defines finite-size spheres at those point and the line segments between the spheres are tangent to the spheres). The drawn diameter of each line segment is determined by the *bflag1* parameter for the *body* keyword. The *bflag2* argument is ignored.

Manifolds (surfaces)

Overview:

This doc page is not about a LAMMPS input script command, but about manifolds, which are generalized surfaces, as defined and used by the USER-MANIFOLD package, to track particle motion on the manifolds. See the src/USER-MANIFOLD/README file for more details about the package and its commands.

Below is a list of currently supported manifolds by the USER-MANIFOLD package, their parameters and a short description of them. The parameters listed here are in the same order as they should be passed to the relevant fixes.

<i>manifold</i>	<i>parameters</i>	<i>equation</i>	<i>description</i>
cylinder	R	$x^2 + y^2 - R^2 = 0$	Cylinder along z-axis, axis going through (0,0,0)
cylinder_dent	R l a	$x^2 + y^2 - r(z)^2 = 0$, $r(x) = R$ if $ z > l$, $r(z) = R - a*(1 + \cos(z/l))/2$ otherwise	A cylinder with a dent around $z = 0$
dumbbell	a A B c	$-(x^2 + y^2) + (a^2 - z^2/c^2) * (1 + (A*\sin(B*z^2))^4) = 0$	A dumbbell
ellipsoid	a b c	$(x/a)^2 + (y/b)^2 + (z/c)^2 = 0$	An ellipsoid
gaussian_bump	A l rc1 rc2	if($x < rc1$) -z + A * exp($-x^2 / (2 l^2)$); else if($x < rc2$) -z + a + b*x + c*x^2 + d*x^3; else z	A Gaussian bump at $x = y = 0$, smoothly tapered to a flat plane $z = 0$.
plane	a b c x0 y0 z0	$a*(x-x0) + b*(y-y0) + c*(z-z0) = 0$	A plane with normal (a,b,c) going through point (x0,y0,z0)
plane_wiggle	a w	$z - a*\sin(w*x) = 0$	A plane with a sinusoidal modulation on z along x.
sphere	R	$x^2 + y^2 + z^2 - R^2 = 0$	A sphere of radius R
supersphere	R q	$ x ^q + y ^q + z ^q - R^q = 0$	A supersphere of hyperradius R
spine	a, A, B, B2, c	$-(x^2 + y^2) + (a^2 - z^2/f(z)^2)*(1 + (A*\sin(g(z)*z^2))^4)$, $f(z) = c$ if $z > 0$, 1 otherwise; $g(z) = B$ if $z > 0$, B2 otherwise	An approximation to a dendritic spine
spine_two	a, A, B, B2, c	$-(x^2 + y^2) + (a^2 - z^2/f(z)^2)*(1 + (A*\sin(g(z)*z^2))^2)$, $f(z) = c$ if $z > 0$, 1 otherwise; $g(z) = B$	Another approximation to a dendritic spine

LAMMPS Users Manual

		if $z > 0$, $B2$ otherwise	
thylakoid	wB LB lB	Various, see (Paquay)	A model grana thylakoid consisting of two block-like compartments connected by a bridge of width wB, length LB and taper length lB
torus	R r	$(R - \sqrt{x^2 + y^2})^2 + z^2 - r^2$	A torus with large radius R and small radius r, centered on (0,0,0)

(Paquay) Paquay and Kusters, Biophys. J., 110, 6, (2016). preprint available at [arXiv:1411.3019](https://arxiv.org/abs/1411.3019).

LAMMPS Commands

The following pages contain the detailed documentation of all LAMMPS commands included in this version of LAMMPS. Generic commands are listed first (in alphabetical order) followed by command categories like compute styles or pair styles and so on.

The documentation for the USER-ATC package `fix_modify` commands follow at the very end of this manual.

angle_coeff command

Syntax:

```
angle_coeff N args
```

- N = angle type (see asterisk form below)
- args = coefficients for one or more angle types

Examples:

```
angle_coeff 1 300.0 107.0  
angle_coeff * 5.0  
angle_coeff 2*10 5.0
```

Description:

Specify the angle force field coefficients for one or more angle types. The number and meaning of the coefficients depends on the angle style. Angle coefficients can also be set in the data file read by the [read_data](#) command or in a restart file.

N can be specified in one of two ways. An explicit numeric value can be used, as in the 1st example above. Or a wild-card asterisk can be used to set the coefficients for multiple angle types. This takes the form "*" or "*n" or "n*" or "m*n". If N = the number of angle types, then an asterisk with no numeric values means all types from 1 to N. A leading asterisk means all types from 1 to n (inclusive). A trailing asterisk means all types from n to N (inclusive). A middle asterisk means all types from m to n (inclusive).

Note that using an `angle_coeff` command can override a previous setting for the same angle type. For example, these commands set the coeffs for all angle types, then overwrite the coeffs for just angle type 2:

```
angle_coeff * 200.0 107.0 1.2  
angle_coeff 2 50.0 107.0
```

A line in a data file that specifies angle coefficients uses the exact same format as the arguments of the `angle_coeff` command in an input script, except that wild-card asterisks should not be used since coefficients for all N types must be listed in the file. For example, under the "Angle Coeffs" section of a data file, the line that corresponds to the 1st example above would be listed as

```
1 300.0 107.0
```

The [angle_style class2](#) is an exception to this rule, in that an additional argument is used in the input script to allow specification of the cross-term coefficients. See its doc page for details.

Here is an alphabetic list of angle styles defined in LAMMPS. Click on the style to

LAMMPS Users Manual

display the formula it computes and coefficients specified by the associated [angle_coeff](#) command.

Note that there are also additional angle styles submitted by users which are included in the LAMMPS distribution. The list of these with links to the individual styles are given in the angle section of [this page](#).

- [angle_style none](#) - turn off angle interactions
- [angle_style hybrid](#) - define multiple styles of angle interactions

- [angle_style charmm](#) - CHARMM angle
- [angle_style class2](#) - COMPASS (class 2) angle
- [angle_style cosine](#) - cosine angle potential
- [angle_style cosine/delta](#) - difference of cosines angle potential
- [angle_style cosine/periodic](#) - DREIDING angle
- [angle_style cosine/squared](#) - cosine squared angle potential
- [angle_style harmonic](#) - harmonic angle
- [angle_style table](#) - tabulated by angle

Restrictions:

This command must come after the simulation box is defined by a [read_data](#), [read_restart](#), or [create_box](#) command.

An angle style must be defined before any angle coefficients are set, either in the input script or in a data file.

Related commands:

[angle_style](#)

Default: none

angle_style command

Syntax:

```
angle_style style
```

- style = *none* or *hybrid* or *charmm* or *class2* or *cosine* or *cosine/squared* or *harmonic*

Examples:

```
angle_style harmonic  
angle_style charmm  
angle_style hybrid harmonic cosine
```

Description:

Set the formula(s) LAMMPS uses to compute angle interactions between triplets of atoms, which remain in force for the duration of the simulation. The list of angle triplets is read in by a [read_data](#) or [read_restart](#) command from a data or restart file.

Hybrid models where angles are computed using different angle potentials can be setup using the *hybrid* angle style.

The coefficients associated with a angle style can be specified in a data or restart file or via the [angle_coeff](#) command.

All angle potentials store their coefficient data in binary restart files which means `angle_style` and [angle_coeff](#) commands do not need to be re-specified in an input script that restarts a simulation. See the [read_restart](#) command for details on how to do this. The one exception is that `angle_style hybrid` only stores the list of sub-styles in the restart file; angle coefficients need to be re-specified.

NOTE: When both an angle and pair style is defined, the [special_bonds](#) command often needs to be used to turn off (or weight) the pairwise interaction that would otherwise exist between 3 bonded atoms.

In the formulas listed for each angle style, *theta* is the angle between the 3 atoms in the angle.

Here is an alphabetic list of angle styles defined in LAMMPS. Click on the style to display the formula it computes and coefficients specified by the associated [angle_coeff](#) command.

Note that there are also additional angle styles submitted by users which are included in the LAMMPS distribution. The list of these with links to the individual styles are given in the angle section of [this page](#).

- [angle_style none](#) - turn off angle interactions

LAMMPS Users Manual

- [angle_style zero](#) - topology but no interactions
 - [angle_style hybrid](#) - define multiple styles of angle interactions

 - [angle_style charmm](#) - CHARMM angle
 - [angle_style class2](#) - COMPASS (class 2) angle
 - [angle_style cosine](#) - cosine angle potential
 - [angle_style cosine/delta](#) - difference of cosines angle potential
 - [angle_style cosine/periodic](#) - DREIDING angle
 - [angle_style cosine/squared](#) - cosine squared angle potential
 - [angle_style harmonic](#) - harmonic angle
 - [angle_style table](#) - tabulated by angle
-

Restrictions:

Angle styles can only be set for atom_styles that allow angles to be defined.

Most angle styles are part of the MOLECULE package. They are only enabled if LAMMPS was built with that package. See the [Making LAMMPS](#) section for more info on packages. The doc pages for individual bond potentials tell if it is part of a package.

Related commands:

[angle_coeff](#)

Default:

angle_style none

atom_modify command

Syntax:

```
atom_modify keyword values ...
```

- one or more keyword/value pairs may be appended
- keyword = *id* or *map* or *first* or *sort*

```

id value = yes or no
map value = yes or array or hash
first value = group-ID = group whose atoms will appear first in internal atom lists
sort values = Nfreq binsize
                Nfreq = sort atoms spatially every this many time steps
                binsize = bin size for spatial sorting (distance units)

```

Examples:

```

atom_modify map yes
atom_modify map hash sort 10000 2.0
atom_modify first colloid

```

Description:

Modify certain attributes of atoms defined and stored within LAMMPS, in addition to what is specified by the [atom_style](#) command. The *id* and *map* keywords must be specified before a simulation box is defined; other keywords can be specified any time.

The *id* keyword determines whether non-zero atom IDs can be assigned to each atom. If the value is *yes*, which is the default, IDs are assigned, whether you use the [create_atoms](#) or [read_data](#) or [read_restart](#) commands to initialize atoms. If the value is *no* the IDs for all atoms are assumed to be 0.

If atom IDs are used, they must all be positive integers. They should also be unique, though LAMMPS does not check for this. Typically they should also be consecutively numbered (from 1 to Natoms), though this is not required. Molecular [atom styles](#) are those that store bond topology information (styles bond, angle, molecular, full). These styles require atom IDs since the IDs are used to encode the topology. Some other LAMMPS commands also require the use of atom IDs. E.g. some many-body pair styles use them to avoid double computation of the I-J interaction between two atoms.

The only reason not to use atom IDs is if you are running an atomic simulation so large that IDs cannot be uniquely assigned. For a default LAMMPS build this limit is 2^{31} or about 2 billion atoms. However, even in this case, you can use 64-bit atom IDs, allowing 2^{63} or about $9e18$ atoms, if you build LAMMPS with the -DLAMMPS_BIGBIG switch. This is described in [Section 2.2](#) of the manual. If atom IDs are not used, they must be specified as 0 for all atoms, e.g. in a data or restart file.

The *map* keyword determines how atoms with specific IDs are found when required. An example are the bond (angle, etc) methods which need to find the local index of an

LAMMPS Users Manual

atom with a specific global ID which is a bond (angle, etc) partner. LAMMPS performs this operation efficiently by creating a "map", which is either an *array* or *hash* table, as descibed below.

When the *map* keyword is not specified in your input script, LAMMPS only creates a map for [atom_styles](#) for molecular systems which have permanent bonds (angles, etc). No map is created for atomic systems, since it is normally not needed. However some LAMMPS commands require a map, even for atomic systems, and will generate an error if one does not exist. The *map* keyword thus allows you to force the creation of a map. The *yes* value will create either an *array* or *hash* style map, as explained in the next paragraph. The *array* and *hash* values create an atom-style or hash-style map respectively.

For an *array*-style map, each processor stores a lookup table of length N, where N is the largest atom ID in the system. This is a fast, simple method for many simulations, but requires too much memory for large simulations. For a *hash*-style map, a hash table is created on each processor, which finds an atom ID in constant time (independent of the global number of atom IDs). It can be slightly slower than the *array* map, but its memory cost is proportional to the number of atoms owned by a processor, i.e. N/P when N is the total number of atoms in the system and P is the number of processors.

The *first* keyword allows a [group](#) to be specified whose atoms will be maintained as the first atoms in each processor's list of owned atoms. This is only useful when the specified group is a small fraction of all the atoms, and there are other operations LAMMPS is performing that will be sped-up significantly by being able to loop over the smaller set of atoms. Otherwise the reordering required by this option will be a net slow-down. The [neigh_modify include](#) and [comm_modify group](#) commands are two examples of commands that require this setting to work efficiently. Several [fixes](#), most notably time integration fixes like [fix nve](#), also take advantage of this setting if the group they operate on is the group specified by this command. Note that specifying "all" as the group-ID effectively turns off the *first* option.

It is OK to use the *first* keyword with a group that has not yet been defined, e.g. to use the [atom_modify first](#) command at the beginning of your input script. LAMMPS does not use the group until a simulation is run.

The *sort* keyword turns on a spatial sorting or reordering of atoms within each processor's sub-domain every *Nfreq* timesteps. If *Nfreq* is set to 0, then sorting is turned off. Sorting can improve cache performance and thus speed-up a LAMMPS simulation, as discussed in a paper by [\(Meloni\)](#). Its efficacy depends on the problem size (atoms/processor), how quickly the system becomes disordered, and various other factors. As a general rule, sorting is typically more effective at speeding up simulations of liquids as opposed to solids. In tests we have done, the speed-up can range from zero to 3-4x.

Reordering is performed every *Nfreq* timesteps during a dynamics run or iterations during a minimization. More precisely, reordering occurs at the first reneighboring that occurs after the target timestep. The reordering is performed locally by each processor, using bins of the specified *binsize*. If *binsize* is set to 0.0, then a binsize equal to half the [neighbor](#) cutoff distance (force cutoff plus skin distance) is used,

LAMMPS Users Manual

which is a reasonable value. After the atoms have been binned, they are reordered so that atoms in the same bin are adjacent to each other in the processor's 1d list of atoms.

The goal of this procedure is for atoms to put atoms close to each other in the processor's one-dimensional list of atoms that are also near to each other spatially. This can improve cache performance when pairwise interactions and neighbor lists are computed. Note that if bins are too small, there will be few atoms/bin. Likewise if bins are too large, there will be many atoms/bin. In both cases, the goal of cache locality will be undermined.

NOTE: Running a simulation with sorting on versus off should not change the simulation results in a statistical sense. However, a different ordering will induce round-off differences, which will lead to diverging trajectories over time when comparing two simulations. Various commands, particularly those which use random numbers (e.g. [velocity create](#), and [fix langevin](#)), may generate (statistically identical) results which depend on the order in which atoms are processed. The order of atoms in a [dump](#) file will also typically change if sorting is enabled.

Restrictions:

The *first* and *sort* options cannot be used together. Since sorting is on by default, it will be turned off if the *first* keyword is used with a group-ID that is not "all".

Related commands: none

Default:

By default, *id* is yes. By default, atomic systems (no bond topology info) do not use a map. For molecular systems (with bond topology info), a map is used. The default map style is array if no atom ID is larger than 1 million, otherwise the default is hash. By default, a "first" group is not defined. By default, sorting is enabled with a frequency of 1000 and a binsize of 0.0, which means the neighbor cutoff will be used to set the bin size.

(Meloni) Meloni, Rosati and Colombo, J Chem Phys, 126, 121102 (2007).

atom_style command

Syntax:

```
atom_style style args
```

- *style* = *angle* or *atomic* or *body* or *bond* or *charge* or *dipole* or *dpd* or *edpd* or *mdpd* or *tdpd* or *electron* or *ellipsoid* or *full* or *line* or *meso* or *molecular* or *peri* or *smd* or *sphere* or *tri* or *template* or *hybrid*

args = none for any style except the following

body args = *bstyle* *bstyle-args*

bstyle = style of body particles

bstyle-args = additional arguments specific to the *bstyle*
see the [body](#) doc page for details

tdpd arg = *Nspecies*

Nspecies = # of chemical species

template arg = *template-ID*

template-ID = ID of molecule template specified in a separate [molecule](#) command

hybrid args = list of one or more sub-styles, each with their args

- accelerated styles (with same args) = *angle/kk* or *atomic/kk* or *bond/kk* or *charge/kk* or *full/kk* or *molecular/kk*

Examples:

```
atom_style atomic
atom_style bond
atom_style full
atom_style body nparticle 2 10
atom_style hybrid charge bond
atom_style hybrid charge body nparticle 2 5
atom_style template myMols
atom_style tdpd 2
```

Description:

Define what style of atoms to use in a simulation. This determines what attributes are associated with the atoms. This command must be used before a simulation is setup via a [read_data](#), [read_restart](#), or [create_box](#) command.

NOTE: Many of the atom styles discussed here are only enabled if LAMMPS was built with a specific package, as listed below in the Restrictions section.

Once a style is assigned, it cannot be changed, so use a style general enough to encompass all attributes. E.g. with style *bond*, angular terms cannot be used or added later to the model. It is OK to use a style more general than needed, though it may be slightly inefficient.

The choice of style affects what quantities are stored by each atom, what quantities are communicated between processors to enable forces to be computed, and what quantities are listed in the data file read by the [read_data](#) command.

LAMMPS Users Manual

These are the additional attributes of each style and the typical kinds of physical systems they are used to model. All styles store coordinates, velocities, atom IDs and types. See the [read_data](#), [create_atoms](#), and [set](#) commands for info on how to set these various quantities.

<i>angle</i>	bonds and angles	bead-spring polymers with stiffness
<i>atomic</i>	only the default values	coarse-grain liquids, solids, metals
<i>body</i>	mass, inertia moments, quaternion, angular momentum	arbitrary bodies
<i>bond</i>	bonds	bead-spring polymers
<i>charge</i>	charge	atomic system with charges
<i>dipole</i>	charge and dipole moment	system with dipolar particles
<i>dpd</i>	internal temperature and internal energies	DPD particles
<i>edpd</i>	temperature and heat capacity	eDPD particles
<i>mdpd</i>	density	mDPD particles
<i>tdpd</i>	chemical concentration	tDPD particles
<i>electron</i>	charge and spin and eradius	electronic force field
<i>ellipsoid</i>	shape, quaternion, angular momentum	aspherical particles
<i>full</i>	molecular + charge	bio-molecules
<i>line</i>	end points, angular velocity	rigid bodies
<i>meso</i>	rho, e, cv	SPH particles
<i>molecular</i>	bonds, angles, dihedrals, impropers	uncharged molecules
<i>peri</i>	mass, volume	mesoscopic Peridynamic models
<i>smd</i>	volume, kernel diameter, contact radius, mass	solid and fluid SPH particles
<i>sphere</i>	diameter, mass, angular velocity	granular models
<i>template</i>	template index, template atom	small molecules with fixed topology
<i>tri</i>	corner points, angular momentum	rigid bodies
<i>wavepacket</i>	charge, spin, eradius, etag, cs re, cs im	AWPMD

NOTE: It is possible to add some attributes, such as a molecule ID, to atom styles that do not have them via the [fix property/atom](#) command. This command also allows new custom attributes consisting of extra integer or floating-point values to be added to atoms. See the [fix property/atom](#) doc page for examples of cases where this is useful and details on how to initialize, access, and output the custom values.

All of the above styles define point particles, except the *sphere*, *ellipsoid*, *electron*, *peri*, *wavepacket*, *line*, *tri*, and *body* styles, which define finite-size particles. See [Section 6.14](#) for an overview of using finite-size particle models with LAMMPS.

All of the point-particle styles assign mass to particles on a per-type basis, using the [mass](#) command. The finite-size particle styles assign mass to individual particles on a per-particle basis.

LAMMPS Users Manual

For the *sphere* style, the particles are spheres and each stores a per-particle diameter and mass. If the diameter > 0.0, the particle is a finite-size sphere. If the diameter = 0.0, it is a point particle. Note that by use of the *disc* keyword with the [fix nve/sphere](#), [fix nvt/sphere](#), [fix nph/sphere](#), [fix npt/sphere](#) commands, spheres can be effectively treated as 2d discs for a 2d simulation if desired. See also the [set density/disc](#) command.

For the *ellipsoid* style, the particles are ellipsoids and each stores a flag which indicates whether it is a finite-size ellipsoid or a point particle. If it is an ellipsoid, it also stores a shape vector with the 3 diameters of the ellipsoid and a quaternion 4-vector with its orientation.

For the *dipole* style, a point dipole is defined for each point particle. Note that if you wish the particles to be finite-size spheres as in a Stockmayer potential for a dipolar fluid, so that the particles can rotate due to dipole-dipole interactions, then you need to use `atom_style hybrid sphere dipole`, which will assign both a diameter and dipole moment to each particle.

For the *electron* style, the particles representing electrons are 3d Gaussians with a specified position and bandwidth or uncertainty in position, which is represented by the `eradius = electron size`.

For the *peri* style, the particles are spherical and each stores a per-particle mass and volume.

The *dpd* style is for dissipative particle dynamics (DPD) particles. Note that it is part of the USER-DPD package, and is not for use with the [pair_style dpd](#) or [dpd/stat](#) commands, which can simply use `atom_style atomic`. `atom_style dpd` extends DPD particle properties with internal temperature (`dpdTheta`), internal conductive energy (`uCond`), internal mechanical energy (`uMech`), and internal chemical energy (`uChem`).

The *edpd* style is for energy-conserving dissipative particle dynamics (eDPD) particles which store a temperature (`edpd_temp`), and heat capacity (`edpd_cv`).

The *mdpd* style is for many-body dissipative particle dynamics (mDPD) particles which store a density (`rho`) for considering density-dependent many-body interactions.

The *tdpd* style is for transport dissipative particle dynamics (tDPD) particles which store a set of chemical concentration. An integer "`cc_species`" is required to specify the number of chemical species involved in a tDPD system.

The *meso* style is for smoothed particle hydrodynamics (SPH) particles which store a density (`rho`), energy (`e`), and heat capacity (`cv`).

The *smd* style is for a general formulation of Smooth Particle Hydrodynamics. Both fluids and solids can be modeled. Particles store the mass and volume of an integration point, a kernel diameter used for calculating the field variables (e.g. stress and deformation) and a contact radius for calculating repulsive forces which prevent individual physical bodies from penetrating each other.

LAMMPS Users Manual

The *wavepacket* style is similar to *electron*, but the electrons may consist of several Gaussian wave packets, summed up with coefficients $cs = (cs_re, cs_im)$. Each of the wave packets is treated as a separate particle in LAMMPS, wave packets belonging to the same electron must have identical *etag* values.

For the *line* style, the particles are idealized line segments and each stores a per-particle mass and length and orientation (i.e. the end points of the line segment).

For the *tri* style, the particles are planar triangles and each stores a per-particle mass and size and orientation (i.e. the corner points of the triangle).

The *template* style allows molecular topology (bonds, angles, etc) to be defined via a molecule template using the [molecule](#) command. The template stores one or more molecules with a single copy of the topology info (bonds, angles, etc) of each. Individual atoms only store a template index and template atom to identify which molecule and which atom-within-the-molecule they represent. Using the *template* style instead of the *bond*, *angle*, *molecular* styles can save memory for systems comprised of a large number of small molecules, all of a single type (or small number of types). See the paper by Grime and Voth, in [\(Grime\)](#), for examples of how this can be advantageous for large-scale coarse-grained systems.

NOTE: When using the *template* style with a [molecule template](#) that contains multiple molecules, you should insure the atom types, bond types, *angle_types*, etc in all the molecules are consistent. E.g. if one molecule represents H₂O and another CO₂, then you probably do not want each molecule file to define 2 atom types and a single bond type, because they will conflict with each other when a mixture system of H₂O and CO₂ molecules is defined, e.g. by the [read_data](#) command. Rather the H₂O molecule should define atom types 1 and 2, and bond type 1. And the CO₂ molecule should define atom types 3 and 4 (or atom types 3 and 2 if a single oxygen type is desired), and bond type 2.

For the *body* style, the particles are arbitrary bodies with internal attributes defined by the "style" of the bodies, which is specified by the *bstyle* argument. Body particles can represent complex entities, such as surface meshes of discrete points, collections of sub-particles, deformable objects, etc.

The [body](#) doc page describes the body styles LAMMPS currently supports, and provides more details as to the kind of body particles they represent. For all styles, each body particle stores moments of inertia and a quaternion 4-vector, so that its orientation and position can be time integrated due to forces and torques.

Note that there may be additional arguments required along with the *bstyle* specification, in the *atom_style* body command. These arguments are described in the [body](#) doc page.

Typically, simulations require only a single (non-hybrid) atom style. If some atoms in the simulation do not have all the properties defined by a particular style, use the simplest style that defines all the needed properties by any atom. For example, if some atoms in a simulation are charged, but others are not, use the *charge* style. If some atoms have bonds, but others do not, use the *bond* style.

LAMMPS Users Manual

The only scenario where the *hybrid* style is needed is if there is no single style which defines all needed properties of all atoms. For example, as mentioned above, if you want dipolar particles which will rotate due to torque, you need to use "atom_style hybrid sphere dipole". When a hybrid style is used, atoms store and communicate the union of all quantities implied by the individual styles.

When using the *hybrid* style, you cannot combine the *template* style with another molecular style that stores bond,angle,etc info on a per-atom basis.

LAMMPS can be extended with new atom styles as well as new body styles; see [this section](#).

Styles with a *kk* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed in [Section 5](#) of the manual. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

Note that other acceleration packages in LAMMPS, specifically the GPU, USER-INTEL, USER-OMP, and OPT packages do not use accelerated atom styles.

The accelerated styles are part of the KOKKOS package. They are only enabled if LAMMPS was built with those packages. See the [Making LAMMPS](#) section for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the [-suffix command-line switch](#) when you invoke LAMMPS, or you can use the [suffix](#) command in your input script.

See [Section 5](#) of the manual for more instructions on how to use the accelerated styles effectively.

Restrictions:

This command cannot be used after the simulation box is defined by a [read_data](#) or [create_box](#) command.

Many of the styles listed above are only enabled if LAMMPS was built with a specific package, as listed below. See the [Making LAMMPS](#) section for more info.

The *angle*, *bond*, *full*, *molecular*, and *template* styles are part of the MOLECULE package.

The *line* and *tri* styles are part of the ASPHERE package.

The *body* style is part of the BODY package.

The *dipole* style is part of the DIPOLE package.

The *peri* style is part of the PERI package for Peridynamics.

LAMMPS Users Manual

The *electron* style is part of the USER-EFF package for [electronic force fields](#).

The *dpd* style is part of the USER-DPD package for dissipative particle dynamics (DPD).

The *edpd*, *mdpd*, and *tdpd* styles are part of the USER-MESO package for energy-conserving dissipative particle dynamics (eDPD), many-body dissipative particle dynamics (mDPD), and transport dissipative particle dynamics (tDPD), respectively.

The *meso* style is part of the USER-SPH package for smoothed particle hydrodynamics (SPH). See [this PDF guide](#) to using SPH in LAMMPS.

The *wavepacket* style is part of the USER-AWPMD package for the [antisymmetrized wave packet MD method](#).

Default:

`atom_style atomic`

(Grime) Grime and Voth, to appear in J Chem Theory & Computation (2014).

balance command

Syntax:

balance thresh style args ... keyword args ...

- thresh = imbalance threshold that must be exceeded to perform a re-balance
- one style/arg pair can be used (or multiple for x,y,z)
- style = x or y or z or *shift* or *rcb*

x args = *uniform* or Px-1 numbers between 0 and 1
uniform = evenly spaced cuts between processors in x dimension
 numbers = Px-1 ascending values between 0 and 1, Px - # of processors in x dimension
 x can be specified together with y or z
 y args = *uniform* or Py-1 numbers between 0 and 1
uniform = evenly spaced cuts between processors in y dimension
 numbers = Py-1 ascending values between 0 and 1, Py - # of processors in y dimension
 y can be specified together with x or z
 z args = *uniform* or Pz-1 numbers between 0 and 1
uniform = evenly spaced cuts between processors in z dimension
 numbers = Pz-1 ascending values between 0 and 1, Pz - # of processors in z dimension
 z can be specified together with x or y
shift args = dimstr Niter stopthresh
 dimstr = sequence of letters containing "x" or "y" or "z", each not more than once
 Niter = # of times to iterate within each dimension of dimstr sequence
 stopthresh = stop balancing when this imbalance threshold is reached
rcb args = none

- zero or more keyword/arg pairs may be appended
- keyword = *weight* or *out*

weight style args = use weighted particle counts for the balancing
 style = *group* or *neigh* or *time* or *var* or *store*
group args = Ngroup group1 weight1 group2 weight2 ...
 Ngroup = number of groups with assigned weights
 group1, group2, ... = group IDs
 weight1, weight2, ... = corresponding weight factors
neigh factor = compute weight based on number of neighbors
 factor = scaling factor (> 0)
time factor = compute weight based on time spend computing
 factor = scaling factor (> 0)
var name = take weight from atom-style variable
 name = name of the atom-style variable
store name = store weight in custom atom property defined by [fix property/atom](#) command
 name = atom property name (without d_ prefix)
out arg = filename
 filename = write each processor's sub-domain to a file

Examples:

```
balance 0.9 x uniform y 0.4 0.5 0.6
balance 1.2 shift xz 5 1.1
balance 1.0 shift xz 5 1.1
balance 1.1 rcb
balance 1.0 shift x 10 1.1 weight group 2 fast 0.5 slow 2.0
balance 1.0 shift x 10 1.1 weight time 0.8 weight neigh 0.5 weight store balance
```

```
balance 1.0 shift x 20 1.0 out tmp.balance
```

Description:

This command adjusts the size and shape of processor sub-domains within the simulation box, to attempt to balance the number of atoms or particles and thus indirectly the computational cost (load) more evenly across processors. The load balancing is "static" in the sense that this command performs the balancing once, before or between simulations. The processor sub-domains will then remain static during the subsequent run. To perform "dynamic" balancing, see the [fix balance](#) command, which can adjust processor sub-domain sizes and shapes on-the-fly during a run.

Load-balancing is typically most useful if the particles in the simulation box have a spatially-varying density distribution or when the computational cost varies significantly between different particles. E.g. a model of a vapor/liquid interface, or a solid with an irregular-shaped geometry containing void regions, or [hybrid pair style simulations](#) which combine pair styles with different computational cost. In these cases, the LAMMPS default of dividing the simulation box volume into a regular-spaced grid of 3d bricks, with one equal-volume sub-domain per processor, may assign numbers of particles per processor in a way that the computational effort varies significantly. This can lead to poor performance when the simulation is run in parallel.

The balancing can be performed with or without per-particle weighting. With no weighting, the balancing attempts to assign an equal number of particles to each processor. With weighting, the balancing attempts to assign an equal aggregate computational weight to each processor, which typically induces a different number of atoms assigned to each processor. Details on the various weighting options and examples for how they can be used are [given below](#).

Note that the [processors](#) command allows some control over how the box volume is split across processors. Specifically, for a P_x by P_y by P_z grid of processors, it allows choice of P_x , P_y , and P_z , subject to the constraint that $P_x * P_y * P_z = P$, the total number of processors. This is sufficient to achieve good load-balance for some problems on some processor counts. However, all the processor sub-domains will still have the same shape and same volume.

The requested load-balancing operation is only performed if the current "imbalance factor" in particles owned by each processor exceeds the specified *thresh* parameter. The imbalance factor is defined as the maximum number of particles (or weight) owned by any processor, divided by the average number of particles (or weight) per processor. Thus an imbalance factor of 1.0 is perfect balance.

As an example, for 10000 particles running on 10 processors, if the most heavily loaded processor has 1200 particles, then the factor is 1.2, meaning there is a 20% imbalance. Note that a re-balance can be forced even if the current balance is perfect (1.0) by specifying a *thresh* < 1.0.

NOTE: Balancing is performed even if the imbalance factor does not exceed the *thresh* parameter if a "grid" style is specified when the current partitioning is "tiled". The

LAMMPS Users Manual

meaning of "grid" vs "tiled" is explained below. This is to allow forcing of the partitioning to "grid" so that the `comm_style brick` command can then be used to replace a current `comm_style tiled` setting.

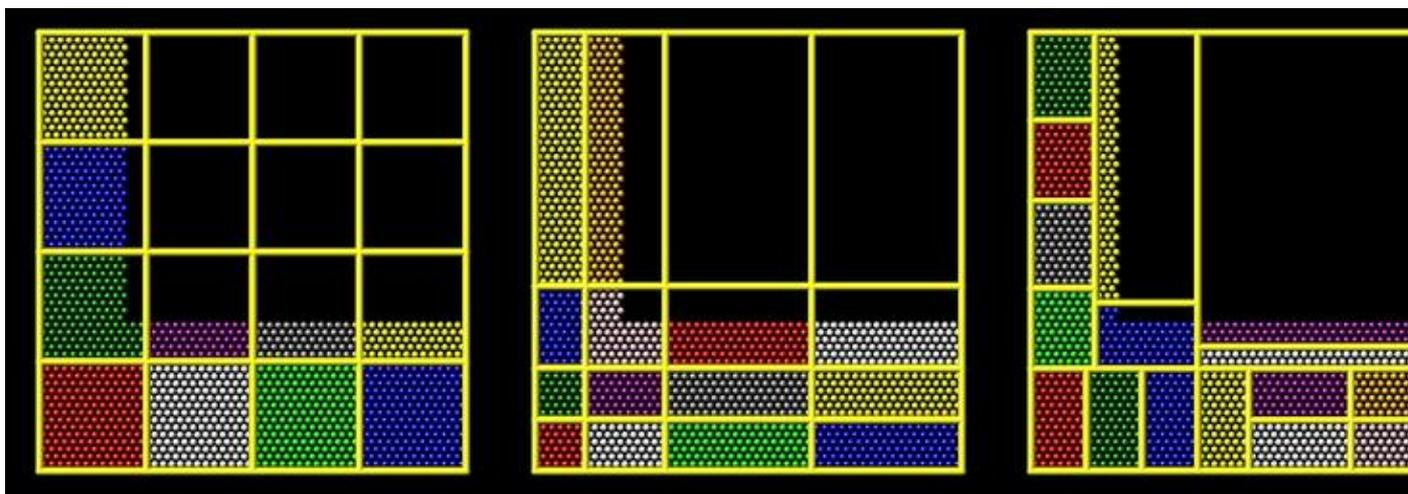

When the `balance` command completes, it prints statistics about the result, including the change in the imbalance factor and the change in the maximum number of particles on any processor. For "grid" methods (defined below) that create a logical 3d grid of processors, the positions of all cutting planes in each of the 3 dimensions (as fractions of the box length) are also printed.

NOTE: This command attempts to minimize the imbalance factor, as defined above. But depending on the method a perfect balance (1.0) may not be achieved. For example, "grid" methods (defined below) that create a logical 3d grid cannot achieve perfect balance for many irregular distributions of particles. Likewise, if a portion of the system is a perfect lattice, e.g. the initial system is generated by the `create_atoms` command, then "grid" methods may be unable to achieve exact balance. This is because entire lattice planes will be owned or not owned by a single processor.

NOTE: The imbalance factor is also an estimate of the maximum speed-up you can hope to achieve by running a perfectly balanced simulation versus an imbalanced one. In the example above, the 10000 particle simulation could run up to 20% faster if it were perfectly balanced, versus when imbalanced. However, computational cost is not strictly proportional to particle count, and changing the relative size and shape of processor sub-domains may lead to additional computational and communication overheads, e.g. in the PPPM solver used via the `kpace_style` command. Thus you should benchmark the run times of a simulation before and after balancing.

The method used to perform a load balance is specified by one of the listed styles (or more in the case of x,y,z), which are described in detail below. There are 2 kinds of styles.

The x , y , z , and *shift* styles are "grid" methods which produce a logical 3d grid of processors. They operate by changing the cutting planes (or lines) between processors in 3d (or 2d), to adjust the volume (area in 2d) assigned to each processor, as in the following 2d diagram where processor sub-domains are shown and particles are colored by the processor that owns them. The leftmost diagram is the default partitioning of the simulation box across processors (one sub-box for each of 16 processors); the middle diagram is after a "grid" method has been applied.

The *rcb* style is a "tiling" method which does not produce a logical 3d grid of processors. Rather it tiles the simulation domain with rectangular sub-boxes of varying size and shape in an irregular fashion so as to have equal numbers of particles (or weight) in each sub-box, as in the rightmost diagram above.

The "grid" methods can be used with either of the `comm_style` command options, *brick* or *tiled*. The "tiling" methods can only be used with `comm_style tiled`. Note that it can be useful to use a "grid" method with `comm_style tiled` to return the domain partitioning to a logical 3d grid of processors so that "comm_style brick" can afterwards be specified for subsequent `run` commands.

When a "grid" method is specified, the current domain partitioning can be either a logical 3d grid or a tiled partitioning. In the former case, the current logical 3d grid is used as a starting point and changes are made to improve the imbalance factor. In the latter case, the tiled partitioning is discarded and a logical 3d grid is created with uniform spacing in all dimensions. This becomes the starting point for the balancing operation.

When a "tiling" method is specified, the current domain partitioning ("grid" or "tiled") is ignored, and a new partitioning is computed from scratch.

The *x*, *y*, and *z* styles invoke a "grid" method for balancing, as described above. Note that any or all of these 3 styles can be specified together, one after the other, but they cannot be used with any other style. This style adjusts the position of cutting planes between processor sub-domains in specific dimensions. Only the specified dimensions are altered.

The *uniform* argument spaces the planes evenly, as in the left diagrams above. The *numeric* argument requires listing $P_s - 1$ numbers that specify the position of the cutting planes. This requires knowing $P_s = P_x$ or P_y or $P_z =$ the number of processors assigned by LAMMPS to the relevant dimension. This assignment is made (and the P_x , P_y , P_z values printed out) when the simulation box is created by the "create_box" or "read_data" or "read_restart" command and is influenced by the settings of the `processors` command.

LAMMPS Users Manual

Each of the numeric values must be between 0 and 1, and they must be listed in ascending order. They represent the fractional position of the cutting place. The left (or lower) edge of the box is 0.0, and the right (or upper) edge is 1.0. Neither of these values is specified. Only the interior Ps-1 positions are specified. Thus if there are 2 processors in the x dimension, you specify a single value such as 0.75, which would make the left processor's sub-domain 3x larger than the right processor's sub-domain.

The *shift* style invokes a "grid" method for balancing, as described above. It changes the positions of cutting planes between processors in an iterative fashion, seeking to reduce the imbalance factor, similar to how the `fix balance shift` command operates.

The *dimstr* argument is a string of characters, each of which must be an "x" or "y" or "z". Each character can appear zero or one time, since there is no advantage to balancing on a dimension more than once. You should normally only list dimensions where you expect there to be a density variation in the particles.

Balancing proceeds by adjusting the cutting planes in each of the dimensions listed in *dimstr*, one dimension at a time. For a single dimension, the balancing operation (described below) is iterated on up to *Niter* times. After each dimension finishes, the imbalance factor is re-computed, and the balancing operation halts if the *stopthresh* criterion is met.

A rebalance operation in a single dimension is performed using a recursive multisectioning algorithm, where the position of each cutting plane (line in 2d) in the dimension is adjusted independently. This is similar to a recursive bisectioning for a single value, except that the bounds used for each bisectioning take advantage of information from neighboring cuts if possible. At each iteration, the count of particles on either side of each plane is tallied. If the counts do not match the target value for the plane, the position of the cut is adjusted to be halfway between a low and high bound. The low and high bounds are adjusted on each iteration, using new count information, so that they become closer together over time. Thus as the recursion progresses, the count of particles on either side of the plane gets closer to the target value.

Once the rebalancing is complete and final processor sub-domains assigned, particles are migrated to their new owning processor, and the balance procedure ends.

NOTE: At each rebalance operation, the bisectioning for each cutting plane (line in 2d) typically starts with low and high bounds separated by the extent of a processor's sub-domain in one dimension. The size of this bracketing region shrinks by 1/2 every iteration. Thus if *Niter* is specified as 10, the cutting plane will typically be positioned to 1 part in 1000 accuracy (relative to the perfect target position). For *Niter* = 20, it will be accurate to 1 part in a million. Thus there is no need to set *Niter* to a large value. LAMMPS will check if the threshold accuracy is reached (in a dimension) is less iterations than *Niter* and exit early. However, *Niter* should also not be set too small, since it will take roughly the same number of iterations to converge even if the cutting plane is initially close to the target value.

The *rcb* style invokes a "tiled" method for balancing, as described above. It performs a recursive coordinate bisectioning (RCB) of the simulation domain. The basic idea is as

follows.

The simulation domain is cut into 2 boxes by an axis-aligned cut in one of the dimensions, leaving one new sub-box on either side of the cut. Which dimension is chosen for the cut depends on the particle (weight) distribution within the parent box. Normally the longest dimension of the box is cut, but if all (or most) of the particles are at one end of the box, a cut may be performed in another dimension to induce sub-boxes that are more cube-ish (3d) or square-ish (2d) in shape.

After the cut is made, all the processors are also partitioned into 2 groups, half assigned to the box on the lower side of the cut, and half to the box on the upper side. (If the processor count is odd, one side gets an extra processor.) The cut is positioned so that the number of (weighted) particles in the lower box is exactly the number that the processors assigned to that box should own for load balance to be perfect. This also makes load balance for the upper box perfect. The positioning of the cut is done iteratively, by a bisectioning method (median search). Note that counting particles on either side of the cut requires communication between all processors at each iteration.

That is the procedure for the first cut. Subsequent cuts are made recursively, in exactly the same manner. The subset of processors assigned to each box make a new cut in one dimension of that box, splitting the box, the subset of processors, and the particles in the box in two. The recursion continues until every processor is assigned a sub-box of the entire simulation domain, and owns the (weighted) particles in that sub-box.

This sub-section describes how to perform weighted load balancing using the *weight* keyword.

By default, all particles have a weight of 1.0, which means each particle is assumed to require the same amount of computation during a timestep. There are, however, scenarios where this is not a good assumption. Measuring the computational cost for each particle accurately would be impractical and slow down the computation. Instead the *weight* keyword implements several ways to influence the per-particle weights empirically by properties readily available or using the user's knowledge of the system. Note that the absolute value of the weights are not important; only their relative ratios affect which particle is assigned to which processor. A particle with a weight of 2.5 is assumed to require 5x more computational than a particle with a weight of 0.5. For all the options below the weight assigned to a particle must be a positive value; an error will be generated if a weight is ≤ 0.0 .

Below is a list of possible weight options with a short description of their usage and some example scenarios where they might be applicable. It is possible to apply multiple weight flags and the weightings they induce will be combined through multiplication. Most of the time, however, it is sufficient to use just one method.

The *group* weight style assigns weight factors to specified [groups](#) of particles. The *group* style keyword is followed by the number of groups, then pairs of group IDs and the corresponding weight factor. If a particle belongs to none of the specified groups, its weight is not changed. If it belongs to multiple groups, its weight is the product of the weight factors.

LAMMPS Users Manual

This weight style is useful in combination with pair style [hybrid](#), e.g. when combining a more costly manybody potential with a fast pair-wise potential. It is also useful when using [run_style respa](#) where some portions of the system have many bonded interactions and others none. It assumes that the computational cost for each group remains constant over time. This is a purely empirical weighting, so a series test runs to tune the assigned weight factors for optimal performance is recommended.

The *neigh* weight style assigns the same weight to each particle owned by a processor based on the total count of neighbors in the neighbor list owned by that processor. The motivation is that more neighbors means a higher computational cost. The style does not use neighbors per atom to assign a unique weight to each atom, because that value can vary depending on how the neighbor list is built.

The *factor* setting is applied as an overall scale factor to the *neigh* weights which allows adjustment of their impact on the balancing operation. The specified *factor* value must be positive. A value > 1.0 will increase the weights so that the ratio of max weight to min weight increases by *factor*. A value < 1.0 will decrease the weights so that the ratio of max weight to min weight decreases by *factor*. In both cases the intermediate weight values increase/decrease proportionally as well. A value $= 1.0$ has no effect on the *neigh* weights. As a rule of thumb, we have found a *factor* of about 0.8 often results in the best performance, since the number of neighbors is likely to overestimate the ideal weight.

This weight style is useful for systems where there are different cutoffs used for different pairs of interactions, or the density fluctuates, or a large number of particles are in the vicinity of a wall, or a combination of these effects. If a simulation uses multiple neighbor lists, this weight style will use the first suitable neighbor list it finds. It will not request or compute a new list. A warning will be issued if there is no suitable neighbor list available or if it is not current, e.g. if the *balance* command is used before a [run](#) or [minimize](#) command is used, in which case the neighbor list may not yet have been built. In this case no weights are computed. Inserting a [run 0 post no](#) command before issuing the *balance* command, may be a workaround for this case, as it will induce the neighbor list to be built.

The *time* weight style uses [timer data](#) to estimate weights. It assigns the same weight to each particle owned by a processor based on the total computational time spent by that processor. See details below on what time window is used. It uses the same timing information as is used for the [MPI task timing breakdown](#), namely, for sections *Pair*, *Bond*, *Kspace*, and *Neigh*. The time spent in those portions of the timestep are measured for each MPI rank, summed, then divided by the number of particles owned by that processor. I.e. the weight is an effective CPU time/particle averaged over the particles on that processor.

The *factor* setting is applied as an overall scale factor to the *time* weights which allows adjustment of their impact on the balancing operation. The specified *factor* value must be positive. A value > 1.0 will increase the weights so that the ratio of max weight to min weight increases by *factor*. A value < 1.0 will decrease the weights so that the ratio of max weight to min weight decreases by *factor*. In both cases the intermediate weight values increase/decrease proportionally as well. A value $= 1.0$ has no effect on the *time* weights. As a rule of thumb, effective values to use are typically between 0.5 and 1.2. Note that the timer quantities mentioned above can be affected

LAMMPS Users Manual

by communication which occurs in the middle of the operations, e.g. pair styles with intermediate exchange of data within the force computation, and likewise for KSpace solves.

When using the *time* weight style with the *balance* command, the timing data is taken from the preceding run command, i.e. the timings are for the entire previous run. For the *fix balance* command the timing data is for only the timesteps since the last balancing operation was performed. If timing information for the required sections is not available, e.g. at the beginning of a run, or when the [timer](#) command is set to either *loop* or *off*, a warning is issued. In this case no weights are computed.

NOTE: The *time* weight style is the most generic option, and should be tried first, unless the *group* style is easily applicable. However, since the computed cost function is averaged over all particles on a processor, the weights may not be highly accurate. This style can also be effective as a secondary weight in combination with either *group* or *neigh* to offset some of inaccuracies in either of those heuristics.

The *var* weight style assigns per-particle weights by evaluating an [atom-style variable](#) specified by *name*. This is provided as a more flexible alternative to the *group* weight style, allowing definition of a more complex heuristics based on information (global and per atom) available inside of LAMMPS. For example, atom-style variables can reference the position of a particle, its velocity, the volume of its Voronoi cell, etc.

The *store* weight style does not compute a weight factor. Instead it stores the current accumulated weights in a custom per-atom property specified by *name*. This must be a property defined as *d_name* via the [fix property/atom](#) command. Note that these custom per-atom properties can be output in a [dump](#) file, so this is a way to examine, debug, or visualize the per-particle weights computed during the load-balancing operation.

The *out* keyword writes a text file to the specified *filename* with the results of the balancing operation. The file contains the bounds of the sub-domain for each processor after the balancing operation completes. The format of the file is compatible with the [Pizza.py mdump](#) tool which has support for manipulating and visualizing mesh files. An example is shown here for a balancing by 4 processors for a 2d problem:

```
ITEM: TIMESTEP
0
ITEM: NUMBER OF NODES
16
ITEM: BOX BOUNDS
0 10
0 10
0 10
ITEM: NODES
1 1 0 0 0
2 1 5 0 0
3 1 5 5 0
4 1 0 5 0
5 1 5 0 0
6 1 10 0 0
7 1 10 5 0
8 1 5 5 0
```

LAMMPS Users Manual

```
9 1 0 5 0
10 1 5 5 0
11 1 5 10 0
12 1 10 5 0
13 1 5 5 0
14 1 10 5 0
15 1 10 10 0
16 1 5 10 0
ITEM: TIMESTEP
0
ITEM: NUMBER OF SQUARES
4
ITEM: SQUARES
1 1 1 2 3 4
2 1 5 6 7 8
3 1 9 10 11 12
4 1 13 14 15 16
```

The coordinates of all the vertices are listed in the NODES section, 5 per processor. Note that the 4 sub-domains share vertices, so there will be duplicate nodes in the list.

The "SQUARES" section lists the node IDs of the 4 vertices in a rectangle for each processor (1 to 4).

For a 3d problem, the syntax is similar with 8 vertices listed for each processor, instead of 4, and "SQUARES" replaced by "CUBES".

Restrictions:

For 2d simulations, the *z* style cannot be used. Nor can a "z" appear in *dimstr* for the *shift* style.

Related commands:

[group](#), [processors](#), [fix balance](#)

Default: none

bond_coeff command

Syntax:

```
bond_coeff N args
```

- N = bond type (see asterisk form below)
- args = coefficients for one or more bond types

Examples:

```
bond_coeff 5 80.0 1.2
bond_coeff * 30.0 1.5 1.0 1.0
bond_coeff 1*4 30.0 1.5 1.0 1.0
bond_coeff 1 harmonic 200.0 1.0
```

Description:

Specify the bond force field coefficients for one or more bond types. The number and meaning of the coefficients depends on the bond style. Bond coefficients can also be set in the data file read by the [read_data](#) command or in a restart file.

N can be specified in one of two ways. An explicit numeric value can be used, as in the 1st example above. Or a wild-card asterisk can be used to set the coefficients for multiple bond types. This takes the form "*" or "*n" or "n*" or "m*n". If N = the number of bond types, then an asterisk with no numeric values means all types from 1 to N. A leading asterisk means all types from 1 to n (inclusive). A trailing asterisk means all types from n to N (inclusive). A middle asterisk means all types from m to n (inclusive).

Note that using a `bond_coeff` command can override a previous setting for the same bond type. For example, these commands set the coeffs for all bond types, then overwrite the coeffs for just bond type 2:

```
bond_coeff * 100.0 1.2
bond_coeff 2 200.0 1.2
```

A line in a data file that specifies bond coefficients uses the exact same format as the arguments of the `bond_coeff` command in an input script, except that wild-card asterisks should not be used since coefficients for all N types must be listed in the file. For example, under the "Bond Coeffs" section of a data file, the line that corresponds to the 1st example above would be listed as

```
5 80.0 1.2
```

Here is an alphabetic list of bond styles defined in LAMMPS. Click on the style to display the formula it computes and coefficients specified by the associated [bond_coeff](#) command.

LAMMPS Users Manual

Note that here are also additional bond styles submitted by users which are included in the LAMMPS distribution. The list of these with links to the individual styles are given in the bond section of [this page](#).

- [bond_style none](#) - turn off bonded interactions
 - [bond_style hybrid](#) - define multiple styles of bond interactions

 - [bond_style class2](#) - COMPASS (class 2) bond
 - [bond_style fene](#) - FENE (finite-extensible non-linear elastic) bond
 - [bond_style fene/expand](#) - FENE bonds with variable size particles
 - [bond_style harmonic](#) - harmonic bond
 - [bond_style morse](#) - Morse bond
 - [bond_style nonlinear](#) - nonlinear bond
 - [bond_style quartic](#) - breakable quartic bond
 - [bond_style table](#) - tabulated by bond length
-

Restrictions:

This command must come after the simulation box is defined by a [read_data](#), [read_restart](#), or [create_box](#) command.

A bond style must be defined before any bond coefficients are set, either in the input script or in a data file.

Related commands:

[bond_style](#)

Default: none

bond_style command

Syntax:

```
bond_style style args
```

- style = *none* or *hybrid* or *class2* or *fene* or *fene/expand* or *harmonic* or *morse* or *nonlinear* or *quartic*

```
args = none for any style except hybrid  
hybrid args = list of one or more styles
```

Examples:

```
bond_style harmonic  
bond_style fene  
bond_style hybrid harmonic fene
```

Description:

Set the formula(s) LAMMPS uses to compute bond interactions between pairs of atoms. In LAMMPS, a bond differs from a pairwise interaction, which are set via the [pair_style](#) command. Bonds are defined between specified pairs of atoms and remain in force for the duration of the simulation (unless the bond breaks which is possible in some bond potentials). The list of bonded atoms is read in by a [read_data](#) or [read_restart](#) command from a data or restart file. By contrast, pair potentials are typically defined between all pairs of atoms within a cutoff distance and the set of active interactions changes over time.

Hybrid models where bonds are computed using different bond potentials can be setup using the *hybrid* bond style.

The coefficients associated with a bond style can be specified in a data or restart file or via the [bond_coeff](#) command.

All bond potentials store their coefficient data in binary restart files which means `bond_style` and `bond_coeff` commands do not need to be re-specified in an input script that restarts a simulation. See the [read_restart](#) command for details on how to do this. The one exception is that `bond_style hybrid` only stores the list of sub-styles in the restart file; bond coefficients need to be re-specified.

NOTE: When both a bond and pair style is defined, the [special_bonds](#) command often needs to be used to turn off (or weight) the pairwise interaction that would otherwise exist between 2 bonded atoms.

In the formulas listed for each bond style, r is the distance between the 2 atoms in the bond.

LAMMPS Users Manual

Here is an alphabetic list of bond styles defined in LAMMPS. Click on the style to display the formula it computes and coefficients specified by the associated [bond_coeff](#) command.

Note that there are also additional bond styles submitted by users which are included in the LAMMPS distribution. The list of these with links to the individual styles are given in the bond section of [this page](#).

- [bond_style none](#) - turn off bonded interactions
- [bond_style zero](#) - topology but no interactions
- [bond_style hybrid](#) - define multiple styles of bond interactions

- [bond_style class2](#) - COMPASS (class 2) bond
- [bond_style fene](#) - FENE (finite-extensible non-linear elastic) bond
- [bond_style fene/expand](#) - FENE bonds with variable size particles
- [bond_style harmonic](#) - harmonic bond
- [bond_style morse](#) - Morse bond
- [bond_style nonlinear](#) - nonlinear bond
- [bond_style quartic](#) - breakable quartic bond
- [bond_style table](#) - tabulated by bond length

Restrictions:

Bond styles can only be set for atom styles that allow bonds to be defined.

Most bond styles are part of the MOLECULE package. They are only enabled if LAMMPS was built with that package. See the [Making LAMMPS](#) section for more info on packages. The doc pages for individual bond potentials tell if it is part of a package.

Related commands:

[bond_coeff](#), [delete_bonds](#)

Default:

`bond_style none`

bond_write command

Syntax:

```
bond_write btype N inner outer file keyword itype jtype
```

- btype = bond types
- N = # of values
- inner,outer = inner and outer bond length (distance units)
- file = name of file to write values to
- keyword = section name in file for this set of tabulated values
- itype,jtype = 2 atom types (optional)
-

Examples:

```
bond_write 1 500 0.5 3.5 table.txt Harmonic_1  
bond_write 3 1000 0.1 6.0 table.txt Morse
```

Description:

Write energy and force values to a file as a function of distance for the currently defined bond potential. This is useful for plotting the potential function or otherwise debugging its values. If the file already exists, the table of values is appended to the end of the file to allow multiple tables of energy and force to be included in one file.

The energy and force values are computed at distances from inner to outer for 2 interacting atoms forming a bond of type btype, using the appropriate [bond_coeff](#) coefficients. N evenly spaced distances are used.

For example, for N = 7, inner = 1.0, and outer = 4.0, values are computed at r = 1.0, 1.5, 2.0, 2.5, 3.0, 3.5, 4.0.

The file is written in the format used as input for the [bond_style table](#) option with *keyword* as the section name. Each line written to the file lists an index number (1-N), a distance (in distance units), an energy (in energy units), and a force (in force units).

Restrictions:

All force field coefficients for bond and other kinds of interactions must be set before this command can be invoked.

Due to how the bond force is computed, an inner value > 0.0 must be specified even if the potential has a finite value at r = 0.0.

Related commands:

[bond_style table](#), [bond_style](#), [bond_coeff](#)

Default: none

boundary command

Syntax:

```
boundary x y z
```

- $x,y,z = p$ or s or f or m , one or two letters

p is periodic
 f is non-periodic and fixed
 s is non-periodic and shrink-wrapped
 m is non-periodic and shrink-wrapped with a minimum value

Examples:

```
boundary p p f
boundary p fs p
boundary s f fm
```

Description:

Set the style of boundaries for the global simulation box in each dimension. A single letter assigns the same style to both the lower and upper face of the box. Two letters assigns the first style to the lower face and the second style to the upper face. The initial size of the simulation box is set by the [read_data](#), [read_restart](#), or [create_box](#) commands.

The style p means the box is periodic, so that particles interact across the boundary, and they can exit one end of the box and re-enter the other end. A periodic dimension can change in size due to constant pressure boundary conditions or box deformation (see the [fix npt](#) and [fix deform](#) commands). The p style must be applied to both faces of a dimension.

The styles f , s , and m mean the box is non-periodic, so that particles do not interact across the boundary and do not move from one side of the box to the other.

For style f , the position of the face is fixed. If an atom moves outside the face it will be deleted on the next timestep that reneighboring occurs. This will typically generate an error unless you have set the [thermo_modify lost](#) option to allow for lost atoms.

For style s , the position of the face is set so as to encompass the atoms in that dimension (shrink-wrapping), no matter how far they move. Note that when the difference between the current box dimensions and the shrink-wrap box dimensions is large, this can lead to lost atoms at the beginning of a run when running in parallel. This is due to the large change in the (global) box dimensions also causing significant changes in the individual sub-domain sizes. If these changes are farther than the communication cutoff, atoms will be lost. This is best addressed by setting initial box dimensions to match the shrink-wrapped dimensions more closely, by using m style boundaries (see below).

LAMMPS Users Manual

For style *m*, shrink-wrapping occurs, but is bounded by the value specified in the data or restart file or set by the [create_box](#) command. For example, if the upper z face has a value of 50.0 in the data file, the face will always be positioned at 50.0 or above, even if the maximum z-extent of all the atoms becomes less than 50.0. This can be useful if you start a simulation with an empty box or if you wish to leave room on one side of the box, e.g. for atoms to evaporate from a surface.

For triclinic (non-orthogonal) simulation boxes, if the 2nd dimension of a tilt factor (e.g. *y* for *xy*) is periodic, then the periodicity is enforced with the tilt factor offset. If the 1st dimension is shrink-wrapped, then the shrink wrapping is applied to the tilted box face, to encompass the atoms. E.g. for a positive *xy* tilt, the *xlo* and *xhi* faces of the box are planes tilting in the +*y* direction as *y* increases. These tilted planes are shrink-wrapped around the atoms to determine the *x* extent of the box.

See [Section 6.12](#) of the doc pages for a geometric description of triclinic boxes, as defined by LAMMPS, and how to transform these parameters to and from other commonly used triclinic representations.

Restrictions:

This command cannot be used after the simulation box is defined by a [read_data](#) or [create_box](#) command or [read_restart](#) command. See the [change_box](#) command for how to change the simulation box boundaries after it has been defined.

For 2d simulations, the *z* dimension must be periodic.

Related commands:

See the [thermo_modify](#) command for a discussion of lost atoms.

Default:

boundary p p p

box command

Syntax:

```
box keyword value ...
```

- one or more keyword/value pairs may be appended
- keyword = *tilt*

tilt value = *small* or *large*

Examples:

```
box tilt large  
box tilt small
```

Description:

Set attributes of the simulation box.

For triclinic (non-orthogonal) simulation boxes, the *tilt* keyword allows simulation domains to be created with arbitrary tilt factors, e.g. via the [create_box](#) or [read_data](#) commands. Tilt factors determine how skewed the triclinic box is; see [this section](#) of the manual for a discussion of triclinic boxes in LAMMPS.

LAMMPS normally requires that no tilt factor can skew the box more than half the distance of the parallel box length, which is the 1st dimension in the tilt factor (x for xz). If *tilt* is set to *small*, which is the default, then an error will be generated if a box is created which exceeds this limit. If *tilt* is set to *large*, then no limit is enforced. You can create a box with any tilt factors you wish.

Note that if a simulation box has a large tilt factor, LAMMPS will run less efficiently, due to the large volume of communication needed to acquire ghost atoms around a processor's irregular-shaped sub-domain. For extreme values of tilt, LAMMPS may also lose atoms and generate an error.

Restrictions:

This command cannot be used after the simulation box is defined by a [read_data](#) or [create_box](#) command or [read_restart](#) command.

Related commands: none

Default:

The default value is *tilt* = *small*.

change_box command

Syntax:

change_box group-ID parameter args ... keyword args ...

- group-ID = ID of group of atoms to (optionally) displace
- one or more parameter/arg pairs may be appended

parameter = *x* or *y* or *z* or *xy* or *xz* or *yz* or *boundary* or *ortho* or *triclinic* or *set* or *remap*

x, y, z args = style value(s)

style = *final* or *delta* or *scale* or *volume*

final values = lo hi

lo hi = box boundaries after displacement (distance units)

delta values = dlo dhi

dlo dhi = change in box boundaries after displacement (distance units)

scale values = factor

factor = multiplicative factor for change in box length after displacement

volume value = none = adjust this dim to preserve volume of system

xy, xz, yz args = style value

style = *final* or *delta*

final value = tilt

tilt = tilt factor after displacement (distance units)

delta value = dtilt

dtilt = change in tilt factor after displacement (distance units)

boundary args = *x y z*

x,y,z = *p* or *s* or *f* or *m*, one or two letters

p is periodic

f is non-periodic and fixed

s is non-periodic and shrink-wrapped

m is non-periodic and shrink-wrapped with a minimum value

ortho args = none = change box to orthogonal

triclinic args = none = change box to triclinic

set args = none = store state of current box

remap args = none = remap atom coords from last saved state to current box

- zero or more keyword/value pairs may be appended

- keyword = *units*

units value = *lattice* or *box*

lattice = distances are defined in lattice units

box = distances are defined in simulation box units

Examples:

```
change_box all xy final -2.0 z final 0.0 5.0 boundary p p f remap units box
```

```
change_box all x scale 1.1 y volume z volume remap
```

Description:

Change the volume and/or shape and/or boundary conditions for the simulation box. Orthogonal simulation boxes have 3 adjustable size parameters (*x,y,z*). Triclinic (non-orthogonal) simulation boxes have 6 adjustable size/shape parameters (*x,y,z,xy,xz,yz*). Any or all of them can be adjusted independently by this command. Thus it can be used to expand or contract a box, or to apply a shear strain to a

LAMMPS Users Manual

non-orthogonal box. It can also be used to change the boundary conditions for the simulation box, similar to the [boundary](#) command.

The size and shape of the initial simulation box are specified by the [create_box](#) or [read_data](#) or [read_restart](#) command used to setup the simulation. The size and shape may be altered by subsequent runs, e.g. by use of the [fix npt](#) or [fix deform](#) commands. The [create_box](#), [read_data](#), and [read_restart](#) commands also determine whether the simulation box is orthogonal or triclinic and their doc pages explain the meaning of the xy,xz,yz tilt factors.

See [Section 6.12](#) of the doc pages for a geometric description of triclinic boxes, as defined by LAMMPS, and how to transform these parameters to and from other commonly used triclinic representations.

The keywords used in this command are applied sequentially to the simulation box and the atoms in it, in the order specified.

Before the sequence of keywords are invoked, the current box size/shape is stored, in case a *remap* keyword is used to map the atom coordinates from a previously stored box size/shape to the current one.

After all the keywords have been processed, any shrink-wrap boundary conditions are invoked (see the [boundary](#) command) which may change simulation box boundaries, and atoms are migrated to new owning processors.

NOTE: This means that you cannot use the [change_box](#) command to enlarge a shrink-wrapped box, e.g. to make room to insert more atoms via the [create_atoms](#) command, because the simulation box will be re-shrink-wrapped before the [change_box](#) command completes. Instead you could do something like this, assuming the simulation box is non-periodic and atoms extend from 0 to 20 in all dimensions:

```
change_box all x final -10 20
create_atoms 1 single -5 5 5      # this will fail to insert an atom

change_box all x final -10 20 boundary f s s
create_atoms 1 single -5 5 5
change_box all boundary s s s      # this will work
```

NOTE: Unlike the earlier "displace_box" version of this command, atom remapping is NOT performed by default. This command allows remapping to be done in a more general way, exactly when you specify it (zero or more times) in the sequence of transformations. Thus if you do not use the *remap* keyword, atom coordinates will not be changed even if the box size/shape changes. If a uniformly strained state is desired, the *remap* keyword should be specified.

NOTE: It is possible to lose atoms with this command. E.g. by changing the box without remapping the atoms, and having atoms end up outside of non-periodic boundaries. It is also possible to alter bonds between atoms straddling a boundary in bad ways. E.g. by converting a boundary from periodic to non-periodic. It is also possible when remapping atoms to put them (nearly) on top of each other. E.g. by converting a boundary from non-periodic to periodic. All of these will typically lead to bad dynamics and/or generate error messages.

LAMMPS Users Manual

NOTE: The simulation box size/shape can be changed by arbitrarily large amounts by this command. This is not a problem, except that the mapping of processors to the simulation box is not changed from its initial 3d configuration; see the [processors](#) command. Thus, if the box size/shape changes dramatically, the mapping of processors to the simulation box may not end up as optimal as the initial mapping attempted to be.

NOTE: Because the keywords used in this command are applied one at a time to the simulation box and the atoms in it, care must be taken with triclinic cells to avoid exceeding the limits on skew after each transformation in the sequence. If skew is exceeded before the final transformation this can be avoided by changing the order of the sequence, or breaking the transformation into two or more smaller transformations. For more information on the allowed limits for box skew see the discussion on triclinic boxes on [this page](#).

For the *x*, *y*, and *z* parameters, this is the meaning of their styles and values.

For style *final*, the final lo and hi box boundaries of a dimension are specified. The values can be in lattice or box distance units. See the discussion of the units keyword below.

For style *delta*, plus or minus changes in the lo/hi box boundaries of a dimension are specified. The values can be in lattice or box distance units. See the discussion of the units keyword below.

For style *scale*, a multiplicative factor to apply to the box length of a dimension is specified. For example, if the initial box length is 10, and the factor is 1.1, then the final box length will be 11. A factor less than 1.0 means compression.

The *volume* style changes the specified dimension in such a way that the overall box volume remains constant with respect to the operation performed by the preceding keyword. The *volume* style can only be used following a keyword that changed the volume, which is any of the *x*, *y*, *z* keywords. If the preceding keyword "key" had a *volume* style, then both it and the current keyword apply to the keyword preceding "key". I.e. this sequence of keywords is allowed:

```
change_box all x scale 1.1 y volume z volume
```

The *volume* style changes the associated dimension so that the overall box volume is unchanged relative to its value before the preceding keyword was invoked.

If the following command is used, then the *z* box length will shrink by the same 1.1 factor the *x* box length was increased by:

```
change_box all x scale 1.1 z volume
```

If the following command is used, then the *y,z* box lengths will each shrink by $\sqrt{1.1}$ to keep the volume constant. In this case, the *y,z* box lengths shrink so as to keep their relative aspect ratio constant:

```
change_box all"x scale 1.1 y volume z volume
```

LAMMPS Users Manual

If the following command is used, then the final box will be a factor of 10% larger in x and y, and a factor of 21% smaller in z, so as to keep the volume constant:

```
change_box all x scale 1.1 z volume y scale 1.1 z volume
```

NOTE: For solids or liquids, when one dimension of the box is expanded, it may be physically undesirable to hold the other 2 box lengths constant since that implies a density change. For solids, adjusting the other dimensions via the *volume* style may make physical sense (just as for a liquid), but may not be correct for materials and potentials whose Poisson ratio is not 0.5.

For the *scale* and *volume* styles, the box length is expanded or compressed around its mid point.

For the *xy*, *xz*, and *yz* parameters, this is the meaning of their styles and values. Note that changing the tilt factors of a triclinic box does not change its volume.

For style *final*, the final tilt factor is specified. The value can be in lattice or box distance units. See the discussion of the units keyword below.

For style *delta*, a plus or minus change in the tilt factor is specified. The value can be in lattice or box distance units. See the discussion of the units keyword below.

All of these styles change the *xy*, *xz*, *yz* tilt factors. In LAMMPS, tilt factors (*xy*,*xz*,*yz*) for triclinic boxes are required to be no more than half the distance of the parallel box length. For example, if *xlo* = 2 and *xhi* = 12, then the x box length is 10 and the *xy* tilt factor must be between -5 and 5. Similarly, both *xz* and *yz* must be between $-(xhi-xlo)/2$ and $+(yhi-ylo)/2$. Note that this is not a limitation, since if the maximum tilt factor is 5 (as in this example), then configurations with tilt = ..., -15, -5, 5, 15, 25, ... are all equivalent. Any tilt factor specified by this command must be within these limits.

The *boundary* keyword takes arguments that have exactly the same meaning as they do for the [boundary](#) command. In each dimension, a single letter assigns the same style to both the lower and upper face of the box. Two letters assigns the first style to the lower face and the second style to the upper face.

The style *p* means the box is periodic; the other styles mean non-periodic. For style *f*, the position of the face is fixed. For style *s*, the position of the face is set so as to encompass the atoms in that dimension (shrink-wrapping), no matter how far they move. For style *m*, shrink-wrapping occurs, but is bounded by the current box edge in that dimension, so that the box will become no smaller. See the [boundary](#) command for more explanation of these style options.

Note that the "boundary" command itself can only be used before the simulation box is defined via a [read_data](#) or [create_box](#) or [read_restart](#) command. This command allows the boundary conditions to be changed later in your input script. Also note that the [read_restart](#) will change boundary conditions to match what is stored in the restart file. So if you wish to change them, you should use the `change_box` command after the `read_restart` command.

The *ortho* and *triclinic* keywords convert the simulation box to be orthogonal or triclinic (non-orthogonal). See [this section](#) for a discussion of how non-orthogonal boxes are represented in LAMMPS.

The simulation box is defined as either orthogonal or triclinic when it is created via the [create_box](#), [read_data](#), or [read_restart](#) commands.

These keywords allow you to toggle the existing simulation box from orthogonal to triclinic and vice versa. For example, an initial equilibration simulation can be run in an orthogonal box, the box can be toggled to triclinic, and then a [non-equilibrium MD \(NEMD\) simulation](#) can be run with deformation via the [fix deform](#) command.

If the simulation box is currently triclinic and has non-zero tilt in xy, yz, or xz, then it cannot be converted to an orthogonal box.

The *set* keyword saves the current box size/shape. This can be useful if you wish to use the *remap* keyword more than once or if you wish it to be applied to an intermediate box size/shape in a sequence of keyword operations. Note that the box size/shape is saved before any of the keywords are processed, i.e. the box size/shape at the time the [create_box](#) command is encountered in the input script.

The *remap* keyword remaps atom coordinates from the last saved box size/shape to the current box state. For example, if you stretch the box in the x dimension or tilt it in the xy plane via the *x* and *xy* keywords, then the *remap* command will dilate or tilt the atoms to conform to the new box size/shape, as if the atoms moved with the box as it deformed.

Note that this operation is performed without regard to periodic boundaries. Also, any shrink-wrapping of non-periodic boundaries (see the [boundary](#) command) occurs after all keywords, including this one, have been processed.

Only atoms in the specified group are remapped.

The *units* keyword determines the meaning of the distance units used to define various arguments. A *box* value selects standard distance units as defined by the [units](#) command, e.g. Angstroms for *units = real* or *metal*. A *lattice* value means the distance units are in lattice spacings. The [lattice](#) command must have been previously used to define the lattice spacing.

Restrictions:

If you use the *ortho* or *triclinic* keywords, then at the point in the input script when this command is issued, no [dumps](#) can be active, nor can a [fix deform](#) be active. This is because these commands test whether the simulation box is orthogonal when they are first issued. Note that these commands can be used in your script before a [change_box](#) command is issued, so long as an [undump](#) or [unfix](#) command is also used to turn them off.

Related commands:

[fix deform](#), [boundary](#)

Default:

The option default is units = lattice.

clear command

Syntax:

```
clear
```

Examples:

```
(commands for 1st simulation)
clear
(commands for 2nd simulation)
```

Description:

This command deletes all atoms, restores all settings to their default values, and frees all memory allocated by LAMMPS. Once a clear command has been executed, it is almost as if LAMMPS were starting over, with only the exceptions noted below. This command enables multiple jobs to be run sequentially from one input script.

These settings are not affected by a clear command: the working directory ([shell](#) command), log file status ([log](#) command), echo status ([echo](#) command), and input script variables ([variable](#) command).

Restrictions: none

Related commands: none

Default: none

comm_modify command

Syntax:

```
comm_modify keyword value ...
```

- zero or more keyword/value pairs may be appended
- keyword = *mode* or *cutoff* or *cutoff/multi* or *group* or *vel*

```

mode value = single or multi = communicate atoms within a single or multiple distances
cutoff value = Rcut (distance units) = communicate atoms from this far away
cutoff/multi type value
    type = atom type or type range (supports asterisk notation)
    value = Rcut (distance units) = communicate atoms for selected types from this far
group value = group-ID = only communicate atoms in the group
vel value = yes or no = do or do not communicate velocity info with ghost atoms

```

Examples:

```

comm_modify mode multi
comm_modify mode multi group solvent
comm_modify mode multi cutoff/multi 1 10.0 cutoff/multi 2*4 15.0
comm_modify vel yes
comm_modify mode single cutoff 5.0 vel yes
comm_modify cutoff/multi * 0.0

```

Description:

This command sets parameters that affect the inter-processor communication of atom information that occurs each timestep as coordinates and other properties are exchanged between neighboring processors and stored as properties of ghost atoms.

NOTE: These options apply to the currently defined comm style. When you specify a [comm_style](#) command, all communication settings are restored to their default values, including those previously reset by a `comm_modify` command. Thus if your input script specifies a `comm_style` command, you should use the `comm_modify` command after it.

The *mode* keyword determines whether a single or multiple cutoff distances are used to determine which atoms to communicate.

The default mode is *single* which means each processor acquires information for ghost atoms that are within a single distance from its sub-domain. The distance is by default the maximum of the neighbor cutoff across all atom type pairs.

For many systems this is an efficient algorithm, but for systems with widely varying cutoffs for different type pairs, the *multi* mode can be faster. In this case, each atom type is assigned its own distance cutoff for communication purposes, and fewer atoms will be communicated. See the [neighbor multi](#) command for a neighbor list construction option that may also be beneficial for simulations of this kind.

LAMMPS Users Manual

The *cutoff* keyword allows you to extend the ghost cutoff distance for communication mode *single*, which is the distance from the borders of a processor's sub-domain at which ghost atoms are acquired from other processors. By default the ghost cutoff = neighbor cutoff = pairwise force cutoff + neighbor skin. See the [neighbor](#) command for more information about the skin distance. If the specified Rcut is greater than the neighbor cutoff, then extra ghost atoms will be acquired. If the provided cutoff is smaller, the provided value will be ignored and the ghost cutoff is set to the neighbor cutoff. Specifying a cutoff value of 0.0 will reset any previous value to the default.

The *cutoff/multi* option is equivalent to *cutoff*, but applies to communication mode *multi* instead. Since in this case the communication cutoffs are determined per atom type, a type specifier is needed and cutoff for one or multiple types can be extended. Also ranges of types using the usual asterisk notation can be given.

These are simulation scenarios in which it may be useful or even necessary to set a ghost cutoff > neighbor cutoff:

- a single polymer chain with bond interactions, but no pairwise interactions
- bonded interactions (e.g. dihedrals) extend further than the pairwise cutoff
- ghost atoms beyond the pairwise cutoff are needed for some computation

In the first scenario, a pairwise potential is not defined. Thus the pairwise neighbor cutoff will be 0.0. But ghost atoms are still needed for computing bond, angle, etc interactions between atoms on different processors, or when the interaction straddles a periodic boundary.

The appropriate ghost cutoff depends on the [newton bond](#) setting. For *newton bond off*, the distance needs to be the furthest distance between any two atoms in the bond, angle, etc. E.g. the distance between 1-4 atoms in a dihedral. For *newton bond on*, the distance between the central atom in the bond, angle, etc and any other atom is sufficient. E.g. the distance between 2-4 atoms in a dihedral.

In the second scenario, a pairwise potential is defined, but its neighbor cutoff is not sufficiently long enough to enable bond, angle, etc terms to be computed. As in the previous scenario, an appropriate ghost cutoff should be set.

In the last scenario, a [fix](#) or [compute](#) or [pairwise potential](#) needs to calculate with ghost atoms beyond the normal pairwise cutoff for some computation it performs (e.g. locate neighbors of ghost atoms in a multibody pair potential). Setting the ghost cutoff appropriately can insure it will find the needed atoms.

NOTE: In these scenarios, if you do not set the ghost cutoff long enough, and if there is only one processor in a periodic dimension (e.g. you are running in serial), then LAMMPS may "find" the atom it is looking for (e.g. the partner atom in a bond), that is on the far side of the simulation box, across a periodic boundary. This will typically lead to bad dynamics (i.e. the bond length is now the simulation box length). To detect if this is happening, see the [neigh_modify cluster](#) command.

The *group* keyword will limit communication to atoms in the specified group. This can be useful for models where no ghost atoms are needed for some kinds of particles. All atoms (not just those in the specified group) will still migrate to new processors as

LAMMPS Users Manual

they move. The group specified with this option must also be specified via the [atom_modify first](#) command.

The *vel* keyword enables velocity information to be communicated with ghost particles. Depending on the [atom_style](#), velocity info includes the translational velocity, angular velocity, and angular momentum of a particle. If the *vel* option is set to *yes*, then ghost atoms store these quantities; if *no* then they do not. The *yes* setting is needed by some pair styles which require the velocity state of both the I and J particles to compute a pairwise I,J interaction, as well as by some compute and fix commands.

Note that if the [fix deform](#) command is being used with its "remap v" option enabled, then the velocities for ghost atoms (in the fix deform group) mirrored across a periodic boundary will also include components due to any velocity shift that occurs across that boundary (e.g. due to dilation or shear).

Restrictions:

Communication mode *multi* is currently only available for [comm_style brick](#).

Related commands:

[comm_style](#), [neighbor](#)

Default:

The option defaults are mode = single, group = all, cutoff = 0.0, vel = no. The cutoff default of 0.0 means that ghost cutoff = neighbor cutoff = pairwise force cutoff + neighbor skin.

comm_style command

Syntax:

```
comm_style style
```

- style = *brick* or *tiled*

Examples:

```
comm_style brick  
comm_style tiled
```

Description:

This command sets the style of inter-processor communication of atom information that occurs each timestep as coordinates and other properties are exchanged between neighboring processors and stored as properties of ghost atoms.

For the default *brick* style, the domain decomposition used by LAMMPS to partition the simulation box must be a regular 3d grid of bricks, one per processor. Each processor communicates with its 6 Cartesian neighbors in the grid to acquire information for nearby atoms.

For the *tiled* style, a more general domain decomposition can be used, as triggered by the [balance](#) or [fix balance](#) commands. The simulation box can be partitioned into non-overlapping rectangular-shaped "tiles" of varying sizes and shapes. Again there is one tile per processor. To acquire information for nearby atoms, communication must now be done with a more complex pattern of neighboring processors.

Note that this command does not actually define a partitioning of the simulation box (a domain decomposition), rather it determines what kinds of decompositions are allowed and the pattern of communication used to enable the decomposition. A decomposition is created when the simulation box is first created, via the [create_box](#) or [read_data](#) or [read_restart](#) commands. For both the *brick* and *tiled* styles, the initial decomposition will be the same, as described by [create_box](#) and [processors](#) commands. The decomposition can be changed via the [balance](#) or [fix balance](#) commands.

Restrictions: none

Related commands:

[comm_modify](#), [processors](#), [balance](#), [fix balance](#)

Default:

The default style is brick.

compute command

Syntax:

```
compute ID group-ID style args
```

- ID = user-assigned name for the computation
- group-ID = ID of the group of atoms to perform the computation on
- style = one of a list of possible style names (see below)
- args = arguments used by a particular style

Examples:

```
compute 1 all temp  
compute newtemp flow temp/partial 1 1 0  
compute 3 all ke/atom
```

Description:

Define a computation that will be performed on a group of atoms. Quantities calculated by a compute are instantaneous values, meaning they are calculated from information about atoms on the current timestep or iteration, though a compute may internally store some information about a previous state of the system. Defining a compute does not perform a computation. Instead computes are invoked by other LAMMPS commands as needed, e.g. to calculate a temperature needed for a thermostat fix or to generate thermodynamic or dump file output. See this [howto section](#) for a summary of various LAMMPS output options, many of which involve computes.

The ID of a compute can only contain alphanumeric characters and underscores.

Computes calculate one of three styles of quantities: global, per-atom, or local. A global quantity is one or more system-wide values, e.g. the temperature of the system. A per-atom quantity is one or more values per atom, e.g. the kinetic energy of each atom. Per-atom values are set to 0.0 for atoms not in the specified compute group. Local quantities are calculated by each processor based on the atoms it owns, but there may be zero or more per atom, e.g. a list of bond distances. Computes that produce per-atom quantities have the word "atom" in their style, e.g. *ke/atom*. Computes that produce local quantities have the word "local" in their style, e.g. *bond/local*. Styles with neither "atom" or "local" in their style produce global quantities.

Note that a single compute produces either global or per-atom or local quantities, but never more than one of these (with only a few exceptions, as documented by individual compute commands).

Global, per-atom, and local quantities each come in three kinds: a single scalar value, a vector of values, or a 2d array of values. The doc page for each compute describes the style and kind of values it produces, e.g. a per-atom vector. Some computes

LAMMPS Users Manual

produce more than one kind of a single style, e.g. a global scalar and a global vector.

When a compute quantity is accessed, as in many of the output commands discussed below, it can be referenced via the following bracket notation, where ID is the ID of the compute:

c_ID	entire scalar, vector, or array
c_ID[I]	one element of vector, one column of array
c_ID[I][J]	one element of array

In other words, using one bracket reduces the dimension of the quantity once (vector -> scalar, array -> vector). Using two brackets reduces the dimension twice (array -> scalar). Thus a command that uses scalar compute values as input can also process elements of a vector or array.

Note that commands and [variables](#) which use compute quantities typically do not allow for all kinds, e.g. a command may require a vector of values, not a scalar. This means there is no ambiguity about referring to a compute quantity as c_ID even if it produces, for example, both a scalar and vector. The doc pages for various commands explain the details.

In LAMMPS, the values generated by a compute can be used in several ways:

- The results of computes that calculate a global temperature or pressure can be used by fixes that do thermostating or barostating or when atom velocities are created.
- Global values can be output via the [thermo_style custom](#) or [fix ave/time](#) command. Or the values can be referenced in a [variable equal](#) or [variable atom](#) command.
- Per-atom values can be output via the [dump custom](#) command. Or they can be time-averaged via the [fix ave/atom](#) command or reduced by the [compute reduce](#) command. Or the per-atom values can be referenced in an [atom-style variable](#).
- Local values can be reduced by the [compute reduce](#) command, or histogrammed by the [fix ave/histo](#) command, or output by the [dump local](#) command.

The results of computes that calculate global quantities can be either "intensive" or "extensive" values. Intensive means the value is independent of the number of atoms in the simulation, e.g. temperature. Extensive means the value scales with the number of atoms in the simulation, e.g. total rotational kinetic energy. [Thermodynamic output](#) will normalize extensive values by the number of atoms in the system, depending on the "thermo_modify norm" setting. It will not normalize intensive values. If a compute value is accessed in another way, e.g. by a [variable](#), you may want to know whether it is an intensive or extensive value. See the doc page for individual computes for further info.

LAMMPS creates its own computes internally for thermodynamic output. Three computes are always created, named "thermo_temp", "thermo_press", and "thermo_pe", as if these commands had been invoked in the input script:

```
compute thermo_temp all temp
```

LAMMPS Users Manual

```
compute thermo_press all pressure thermo_temp
compute thermo_pe all pe
```

Additional computes for other quantities are created if the thermo style requires it. See the documentation for the [thermo_style](#) command.

Fixes that calculate temperature or pressure, i.e. for thermostating or barostatting, may also create computes. These are discussed in the documentation for specific [fix](#) commands.

In all these cases, the default computes LAMMPS creates can be replaced by computes defined by the user in the input script, as described by the [thermo_modify](#) and [fix modify](#) commands.

Properties of either a default or user-defined compute can be modified via the [compute_modify](#) command.

Computes can be deleted with the [uncompute](#) command.

Code for new computes can be added to LAMMPS (see [this section](#) of the manual) and the results of their calculations accessed in the various ways described above.

Each compute style has its own doc page which describes its arguments and what it does. Here is an alphabetic list of compute styles available in LAMMPS. They are also given in more compact form in the Compute section of [this page](#).

There are also additional compute styles (not listed here) submitted by users which are included in the LAMMPS distribution. The list of these with links to the individual styles are given in the compute section of [this page](#).

- [aggregate/atom](#) - aggregate ID for each atom
- [angle/local](#) - theta and energy of each angle
- [angmom/chunk](#) - angular momentum for each chunk
- [body/local](#) - attributes of body sub-particles
- [bond](#) - values computed by a bond style
- [bond/local](#) - distance and energy of each bond
- [centro/atom](#) - centro-symmetry parameter for each atom
- [chunk/atom](#) - assign chunk IDs to each atom
- [cluster/atom](#) - cluster ID for each atom
- [cna/atom](#) - common neighbor analysis (CNA) for each atom
- [com](#) - center-of-mass of group of atoms
- [com/chunk](#) - center-of-mass for each chunk
- [contact/atom](#) - contact count for each spherical particle
- [coord/atom](#) - coordination number for each atom
- [damage/atom](#) - Peridynamic damage for each atom
- [dihedral/local](#) - angle of each dihedral
- [dilatation/atom](#) - Peridynamic dilatation for each atom
- [displace/atom](#) - displacement of each atom
- [erotate/asphere](#) - rotational energy of aspherical particles
- [erotate/rigid](#) - rotational energy of rigid bodies
- [erotate/sphere](#) - rotational energy of spherical particles

LAMMPS Users Manual

- [erotate/sphere/atom](#) - rotational energy for each spherical particle
- [event/displace](#) - detect event on atom displacement
- [fragment/atom](#) - fragment ID for each atom
- [group/group](#) - energy/force between two groups of atoms
- [gyration](#) - radius of gyration of group of atoms
- [gyration/chunk](#) - radius of gyration for each chunk
- [heat/flux](#) - heat flux through a group of atoms
- [hexorder/atom](#) - bond orientational order parameter q_6
- [improper/local](#) - angle of each improper
- [inertia/chunk](#) - inertia tensor for each chunk
- [ke](#) - translational kinetic energy
- [ke/atom](#) - kinetic energy for each atom
- [ke/rigid](#) - translational kinetic energy of rigid bodies
- [msd](#) - mean-squared displacement of group of atoms
- [msd/chunk](#) - mean-squared displacement for each chunk
- [msd/nongauss](#) - MSD and non-Gaussian parameter of group of atoms
- [omega/chunk](#) - angular velocity for each chunk
- [orientorder/atom](#) - Steinhardt bond orientational order parameters Q_l
- [pair](#) - values computed by a pair style
- [pair/local](#) - distance/energy/force of each pairwise interaction
- [pe](#) - potential energy
- [pe/atom](#) - potential energy for each atom
- [plasticity/atom](#) - Peridynamic plasticity for each atom
- [pressure](#) - total pressure and pressure tensor
- [property/atom](#) - convert atom attributes to per-atom vectors/arrays
- [property/local](#) - convert local attributes to localvectors/arrays
- [property/chunk](#) - extract various per-chunk attributes
- [rdf](#) - radial distribution function $g(r)$ histogram of group of atoms
- [reduce](#) - combine per-atom quantities into a single global value
- [reduce/region](#) - same as compute reduce, within a region
- [rigid/local](#) - extract rigid body attributes
- [slice](#) - extract values from global vector or array
- [sna/atom](#) - calculate bispectrum coefficients for each atom
- [snad/atom](#) - derivative of bispectrum coefficients for each atom
- [snav/atom](#) - virial contribution from bispectrum coefficients for each atom
- [stress/atom](#) - stress tensor for each atom
- [temp](#) - temperature of group of atoms
- [temp/asphere](#) - temperature of aspherical particles
- [temp/body](#) - temperature of body particles
- [temp/chunk](#) - temperature of each chunk
- [temp/com](#) - temperature after subtracting center-of-mass velocity
- [temp/deform](#) - temperature excluding box deformation velocity
- [temp/partial](#) - temperature excluding one or more dimensions of velocity
- [temp/profile](#) - temperature excluding a binned velocity profile
- [temp/ramp](#) - temperature excluding ramped velocity component
- [temp/region](#) - temperature of a region of atoms
- [temp/sphere](#) - temperature of spherical particles
- [ti](#) - thermodynamic integration free energy values
- [torque/chunk](#) - torque applied on each chunk
- [vacf](#) - velocity-autocorrelation function of group of atoms
- [vcm/chunk](#) - velocity of center-of-mass for each chunk

LAMMPS Users Manual

- [voronoi/atom](#) - Voronoi volume and neighbors for each atom

There are also additional compute styles submitted by users which are included in the LAMMPS distribution. The list of these with links to the individual styles are given in the compute section of [this page](#).

There are also additional accelerated compute styles included in the LAMMPS distribution for faster performance on CPUs and GPUs. The list of these with links to the individual styles are given in the pair section of [this page](#).

Restrictions: none

Related commands:

[uncompute](#), [compute_modify](#), [fix ave/atom](#), [fix ave/time](#), [fix ave/histo](#)

Default: none

compute_modify command

Syntax:

```
compute_modify compute-ID keyword value ...
```

- compute-ID = ID of the compute to modify
- one or more keyword/value pairs may be listed
- keyword = *extra/dof* or *extra* or *dynamic/dof* or *dynamic*

```
extra/dof value = N
```

```
  N = # of extra degrees of freedom to subtract
```

```
  extra syntax is identical to extra/dof, will be disabled at some point
```

```
dynamic/dof value = yes or no
```

```
  yes/no = do or do not recompute the number of degrees of freedom (DOF) contributing
```

```
  dynamic syntax is identical to dynamic/dof, will be disabled at some point
```

Examples:

```
compute_modify myTemp extra/dof 0
compute_modify newtemp dynamic/dof yes extra/dof 600
```

Description:

Modify one or more parameters of a previously defined compute. Not all compute styles support all parameters.

The *extra/dof* or *extra* keyword refers to how many degrees-of-freedom are subtracted (typically from 3N) as a normalizing factor in a temperature computation. Only computes that compute a temperature use this option. The default is 2 or 3 for [2d or 3d systems](#) which is a correction factor for an ensemble of velocities with zero total linear momentum. For compute temp/partial, if one or more velocity components are excluded, the value used for *extra* is scaled accordingly. You can use a negative number for the *extra* parameter if you need to add degrees-of-freedom. See the [compute temp/asphere](#) command for an example.

The *dynamic/dof* or *dynamic* keyword determines whether the number of atoms N in the compute group and their associated degrees of freedom are re-computed each time a temperature is computed. Only compute styles that calculate a temperature use this option. By default, N and their DOF are assumed to be constant. If you are adding atoms or molecules to the system (see the [fix pour](#), [fix deposit](#), and [fix gcmc](#) commands) or expect atoms or molecules to be lost (e.g. due to exiting the simulation box or via [fix evaporate](#)), then this option should be used to insure the temperature is correctly normalized.

NOTE: The *extra* and *dynamic* keywords should not be used as they are deprecated (March 2017) and will eventually be disabled. Instead, use the equivalent *extra/dof* and *dynamic/dof* keywords.

Restrictions: none

Related commands:

[compute](#)

Default:

The option defaults are `extra/dof = 2` or `3` for 2d or 3d systems and `dynamic/dof = no`.

create_atoms command

Syntax:

```
create_atoms type style args keyword values ...
```

- `type` = atom type (1-Ntypes) of atoms to create (offset for molecule creation)
- `style` = *box* or *region* or *single* or *random*

```
box args = none
```

```
region args = region-ID
```

```
region-ID = particles will only be created if contained in the region
```

```
single args = x y z
```

```
x,y,z = coordinates of a single particle (distance units)
```

```
random args = N seed region-ID
```

```
N = number of particles to create
```

```
seed = random # seed (positive integer)
```

```
region-ID = create atoms within this region, use NULL for entire simulation box
```

- zero or more keyword/value pairs may be appended
- `keyword` = *mol* or *basis* or *remap* or *var* or *set* or *units*

```
mol value = template-ID seed
```

```
template-ID = ID of molecule template specified in a separate molecule command
```

```
seed = random # seed (positive integer)
```

```
basis values = M itype
```

```
M = which basis atom
```

```
itype = atom type (1-N) to assign to this basis atom
```

```
remap value = yes or no
```

```
var value = name = variable name to evaluate for test of atom creation
```

```
set values = dim name
```

```
dim = x or y or z
```

```
name = name of variable to set with x, y, or z atom position
```

```
rotate values = theta Rx Ry Rz
```

```
theta = rotation angle for single molecule (degrees)
```

```
Rx,Ry,Rz = rotation vector for single molecule
```

```
units value = lattice or box
```

```
lattice = the geometry is defined in lattice units
```

```
box = the geometry is defined in simulation box units
```

Examples:

```
create_atoms 1 box
create_atoms 3 region regsphere basis 2 3
create_atoms 3 single 0 0 5
create_atoms 1 box var v set x xpos set y ypos
```

Description:

This command creates atoms (or molecules) on a lattice, or a single atom (or molecule), or a random collection of atoms (or molecules), as an alternative to reading in their coordinates explicitly via a [read_data](#) or [read_restart](#) command. A simulation box must already exist, which is typically created via the [create_box](#) command. Before using this command, a lattice must also be defined using the [lattice](#) command, unless you specify the *single* style with `units = box` or the *random* style. For the remainder of

LAMMPS Users Manual

this doc page, a created atom or molecule is referred to as a "particle".

If created particles are individual atoms, they are assigned the specified atom *type*, though this can be altered via the *basis* keyword as discussed below. If molecules are being created, the type of each atom in the created molecule is specified in the file read by the [molecule](#) command, and those values are added to the specified atom *type*. E.g. if *type* = 2, and the file specifies atom types 1,2,3, then each created molecule will have atom types 3,4,5.

For the *box* style, the `create_atoms` command fills the entire simulation box with particles on the lattice. If your simulation box is periodic, you should insure its size is a multiple of the lattice spacings, to avoid unwanted atom overlaps at the box boundaries. If your box is periodic and a multiple of the lattice spacing in a particular dimension, LAMMPS is careful to put exactly one particle at the boundary (on either side of the box), not zero or two.

For the *region* style, a geometric volume is filled with particles on the lattice. This volume what is inside the simulation box and is also consistent with the region volume. See the [region](#) command for details. Note that a region can be specified so that its "volume" is either inside or outside a geometric boundary. Also note that if your region is the same size as a periodic simulation box (in some dimension), LAMMPS does not implement the same logic described above as for the *box* style, to insure exactly one particle at periodic boundaries. If this is what you desire, you should either use the *box* style, or tweak the region size to get precisely the particles you want.

For the *single* style, a single particle is added to the system at the specified coordinates. This can be useful for debugging purposes or to create a tiny system with a handful of particles at specified positions.

For the *random* style, *N* particles are added to the system at randomly generated coordinates, which can be useful for generating an amorphous system. The particles are created one by one using the specified random number *seed*, resulting in the same set of particles coordinates, independent of how many processors are being used in the simulation. If the *region-ID* argument is specified as NULL, then the created particles will be anywhere in the simulation box. If a *region-ID* is specified, a geometric volume is filled which is both inside the simulation box and is also consistent with the region volume. See the [region](#) command for details. Note that a region can be specified so that its "volume" is either inside or outside a geometric boundary.

NOTE: Particles generated by the *random* style will typically be highly overlapped which will cause many interatomic potentials to compute large energies and forces. Thus you should either perform an [energy minimization](#) or run dynamics with [fix nve/limit](#) to equilibrate such a system, before running normal dynamics.

Note that this command adds particles to those that already exist. This means it can be used to add particles to a system previously read in from a data or restart file. Or the `create_atoms` command can be used multiple times, to add multiple sets of particles to the simulation. For example, grain boundaries can be created, by interleaving `create_atoms` with [lattice](#) commands specifying different orientations. By

LAMMPS Users Manual

using the `create_atoms` command in conjunction with the `delete_atoms` command, reasonably complex geometries can be created, or a protein can be solvated with a surrounding box of water molecules.

In all these cases, care should be taken to insure that new atoms do not overlap existing atoms inappropriately, especially if molecules are being added. The `delete_atoms` command can be used to remove overlapping atoms or molecules.

NOTE: You cannot use any of the styles explained above to create atoms that are outside the simulation box; they will just be ignored by LAMMPS. This is true even if you are using shrink-wrapped box boundaries, as specified by the `boundary` command. However, you can first use the `change_box` command to temporarily expand the box, then add atoms via `create_atoms`, then finally use `change_box` command again if needed to re-shrink-wrap the new atoms. See the `change_box` doc page for an example of how to do this, using the `create_atoms single` style to insert a new atom outside the current simulation box.

Individual atoms are inserted by this command, unless the `mol` keyword is used. It specifies a *template-ID* previously defined using the `molecule` command, which reads a file that defines the molecule. The coordinates, atom types, charges, etc, as well as any bond/angle/etc and special neighbor information for the molecule can be specified in the molecule file. See the `molecule` command for details. The only settings required to be in this file are the coordinates and types of atoms in the molecule.

Using a lattice to add molecules, e.g. via the `box` or `region` or `single` styles, is exactly the same as adding atoms on lattice points, except that entire molecules are added at each point, i.e. on the point defined by each basis atom in the unit cell as it tiles the simulation box or region. This is done by placing the geometric center of the molecule at the lattice point, and giving the molecule a random orientation about the point. The random *seed* specified with the `mol` keyword is used for this operation, and the random numbers generated by each processor are different. This means the coordinates of individual atoms (in the molecules) will be different when running on different numbers of processors, unlike when atoms are being created in parallel.

Also note that because of the random rotations, it may be important to use a lattice with a large enough spacing that adjacent molecules will not overlap, regardless of their relative orientations.

NOTE: If the `create_box` command is used to create the simulation box, followed by the `create_atoms` command with its `mol` option for adding molecules, then you typically need to use the optional keywords allowed by the `create_box` command for extra bonds (angles,etc) or extra special neighbors. This is because by default, the `create_box` command sets up a non-molecular system which doesn't allow molecules to be added.

This is the meaning of the other allowed keywords.

The `basis` keyword is only used when atoms (not molecules) are being created. It specifies an atom type that will be assigned to specific basis atoms as they are created. See the `lattice` command for specifics on how basis atoms are defined for the

LAMMPS Users Manual

unit cell of the lattice. By default, all created atoms are assigned the argument *type* as their atom type.

The *remap* keyword only applies to the *single* style. If it is set to *yes*, then if the specified position is outside the simulation box, it will be mapped back into the box, assuming the relevant dimensions are periodic. If it is set to *no*, no remapping is done and no particle is created if its position is outside the box.

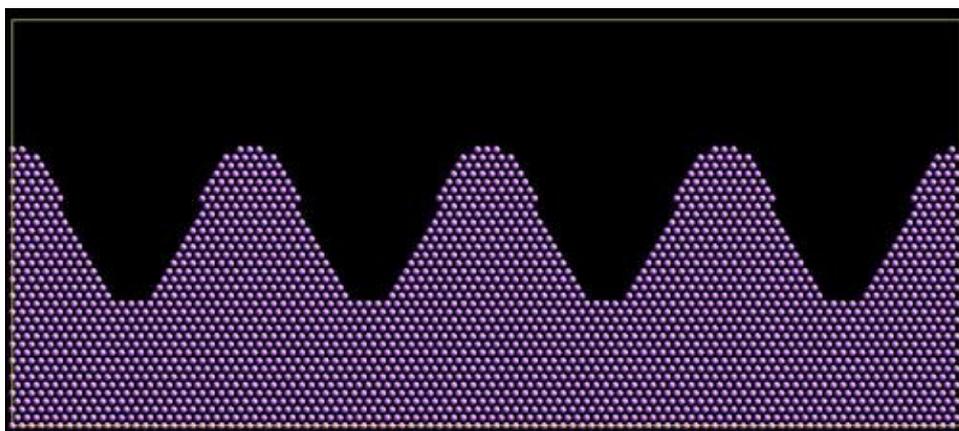

The *var* and *set* keywords can be used together to provide a criterion for accepting or rejecting the addition of an individual atom, based on its coordinates. The *name* specified for the *var* keyword is the name of an [equal-style variable](#) which should evaluate to a zero or non-zero value based on one or two or three variables which will store the x, y, or z coordinates of an atom (one variable per coordinate). If used, these other variables must be [internal-style variables](#) defined in the input script; their initial numeric value can be anything. They must be internal-style variables, because this command resets their values directly. The *set* keyword is used to identify the names of these other variables, one variable for the x-coordinate of a created atom, one for y, and one for z.

When an atom is created, its x,y,z coordinates become the values for any *set* variable that is defined. The *var* variable is then evaluated. If the returned value is 0.0, the atom is not created. If it is non-zero, the atom is created.

As an example, these commands can be used in a 2d simulation, to create a sinusoidal surface. Note that the surface is "rough" due to individual lattice points being "above" or "below" the mathematical expression for the sinusoidal curve. If a finer lattice were used, the sinusoid would appear to be "smoother". Also note the use of the "xlat" and "ylat" [thermo_style](#) keywords which convert lattice spacings to distance. Click on the image for a larger version.

```
dimension      2
variable       x equal 100
variable       y equal 25
lattice        hex 0.8442
region         box block 0 $x 0 $y -0.5 0.5
create_box    1 box

variable       xx internal 0.0
variable       yy internal 0.0
variable       v equal "(0.2*v_y*ylat * cos(v_xx/xlat * 2.0*PI*4.0/v_x) + 0.5*v_y*ylat - v_yy)"
create_atoms  1 box var v set x xx set y yy
write_dump    all atom sinusoid.lammpstrj
```

The *rotate* keyword can only be used with the *single* style and when adding a single molecule. It allows to specify the orientation at which the molecule is inserted. The axis of rotation is determined by the rotation vector (R_x, R_y, R_z) that goes through the insertion point. The specified *theta* determines the angle of rotation around that axis. Note that the direction of rotation for the atoms around the rotation axis is consistent with the right-hand rule: if your right-hand's thumb points along R , then your fingers wrap around the axis in the direction of rotation.

The *units* keyword determines the meaning of the distance units used to specify the coordinates of the one particle created by the *single* style. A *box* value selects standard distance units as defined by the [units](#) command, e.g. Angstroms for `units = real` or metal. A *lattice* value means the distance units are in lattice spacings.

Atom IDs are assigned to created atoms in the following way. The collection of created atoms are assigned consecutive IDs that start immediately following the largest atom ID existing before the `create_atoms` command was invoked. When a simulation is performed on different numbers of processors, there is no guarantee a particular created atom will be assigned the same ID. If molecules are being created, molecule IDs are assigned to created molecules in a similar fashion.

Aside from their ID, atom type, and xyz position, other properties of created atoms are set to default values, depending on which quantities are defined by the chosen [atom style](#). See the [atom style](#) command for more details. See the [set](#) and [velocity](#) commands for info on how to change these values.

- charge = 0.0
- dipole moment magnitude = 0.0
- diameter = 1.0
- shape = 0.0 0.0 0.0
- density = 1.0
- volume = 1.0
- velocity = 0.0 0.0 0.0
- angular velocity = 0.0 0.0 0.0
- angular momentum = 0.0 0.0 0.0
- quaternion = (1,0,0,0)
- bonds, angles, dihedrals, impropers = none

LAMMPS Users Manual

If molecules are being created, these defaults can be overridden by values specified in the file read by the [molecule](#) command. E.g. the file typically defines bonds (angles,etc) between atoms in the molecule, and can optionally define charges on each atom.

Note that the *sphere* atom style sets the default particle diameter to 1.0 as well as the density. This means the mass for the particle is not 1.0, but is $\text{PI}/6 * \text{diameter}^3 = 0.5236$.

Note that the *ellipsoid* atom style sets the default particle shape to (0.0 0.0 0.0) and the density to 1.0 which means it is a point particle, not an ellipsoid, and has a mass of 1.0.

Note that the *peri* style sets the default volume and density to 1.0 and thus also set the mass for the particle to 1.0.

The [set](#) command can be used to override many of these default settings.

Restrictions:

An [atom_style](#) must be previously defined to use this command.

A rotation vector specified for a single molecule must be in the z-direction for a 2d model.

Related commands:

[lattice](#), [region](#), [create_box](#), [read_data](#), [read_restart](#)

Default:

The default for the *basis* keyword is that all created atoms are assigned the argument *type* as their atom type (when single atoms are being created). The other defaults are *remap* = no, *rotate* = random, and *units* = lattice.

create_bonds command

Syntax:

```
create_bonds style args ... keyword value ...
```

- *style* = *many* or *single/bond* or *single/angle* or *single/dihedral*

```
many args = group-ID group2-ID btype rmin rmax
  group-ID = ID of first group
  group2-ID = ID of second group, bonds will be between atoms in the 2 groups
  btype = bond type of created bonds
  rmin = minimum distance between pair of atoms to bond together
  rmax = maximum distance between pair of atoms to bond together
single/bond args = btype batom1 batom2
  btype = bond type of new bond
  batom1,batom2 = atom IDs for two atoms in bond
single/angle args = atype aatom1 aatom2 aatom3
  atype = bond type of new angle
  aatom1,aatom2,aatom3 = atom IDs for three atoms in angle
single/dihedral args = dtype datom1 datom2 datom3 datom4
  dtype = bond type of new dihedral
  datom1,datom2,datom3,datom4 = atom IDs for four atoms in dihedral
```

- zero or more keyword/value pairs may be appended
- *keyword* = *special*

```
special value = yes or no
```

Examples:

```
create_bonds many all all 1 1.0 1.2
create_bonds many surf solvent 3 2.0 2.4
create_bond single/bond 1 1 2
create_bond single/angle 5 52 98 107 special no
```

Description:

Create bonds between pairs of atoms that meet a specified distance criteria. Or create a single bond, angle, or dihedral between 2, 3, or 4 specified atoms.

The new bond (angle, dihedral) interactions will then be computed during a simulation by the bond (angle, dihedral) potential defined by the [bond_style](#), [bond_coeff](#), [angle_style](#), [angle_coeff](#), [dihedral_style](#), [dihedral_coeff](#) commands.

The *many* style is useful for adding bonds to a system, e.g. between nearest neighbors in a lattice of atoms, without having to enumerate all the bonds in the data file read by the [read_data](#) command.

The *single* styles are useful for adding bonds, angles, dihedrals to a system incrementally, then continuing a simulation.

LAMMPS Users Manual

Note that this command does not auto-create any angle or dihedral interactions when a bond is added. Nor does it auto-create any bonds when an angle or dihedral is added. Or auto-create any angles when a dihedral is added. Thus the flexibility of this command is limited. It can be used several times to create different types of bond at different distances. But it cannot typically auto-create all the bonds or angles or dihedral that would normally be defined in a data file for a complex system of molecules.

NOTE: If the system has no bonds (angles, dihedrals) to begin with, or if more bonds per atom are being added than currently exist, then you must insure that the number of bond types and the maximum number of bonds per atom are set to large enough values. And similarly for angles and dihedrals. Otherwise an error may occur when too many bonds (angles, dihedrals) are added to an atom. If the [read_data](#) command is used to define the system, these parameters can be set via the "bond types" and "extra bond per atom" fields in the header section of the data file. If the [create_box](#) command is used to define the system, these 2 parameters can be set via its optional "bond/types" and "extra/bond/per/atom" arguments. And similarly for angles and dihedrals. See the doc pages for these 2 commands for details.

The *many* style will create bonds between pairs of atoms I,J where I is in one of the two specified groups, and J is in the other. The two groups can be the same, e.g. group "all". The created bonds will be of bond type *btype*, where *btype* must be a value between 1 and the number of bond types defined.

For a bond to be created, an I,J pair of atoms must be a distance D apart such that $rmin \leq D \leq rmax$.

The following settings must have been made in an input script before this style is used:

- [special_bonds](#) weight for 1-2 interactions must be 0.0
- a [pair_style](#) must be defined
- no [kspace_style](#) defined
- minimum [pair_style](#) cutoff + [neighbor](#) skin $\geq rmax$

These settings are required so that a neighbor list can be created to search for nearby atoms. Pairs of atoms that are already bonded cannot appear in the neighbor list, to avoid creation of duplicate bonds. The neighbor list for all atom type pairs must also extend to a distance that encompasses the *rmax* for new bonds to create.

An additional requirement for this style is that your system must be ready to perform a simulation. This means, for example, that all [pair_style](#) coefficients be set via the [pair_coeff](#) command. A [bond_style](#) command and all bond coefficients must also be set, even if no bonds exist before this command is invoked. This is because the building of neighbor list requires initialization and setup of a simulation, similar to what a [run](#) command would require.

Note that you can change any of these settings after this command executes, e.g. if you wish to use long-range Coulombic interactions via the [kspace_style](#) command for your subsequent simulation.

The *single/bond* style creates a single bond of type *btype* between two atoms with IDs *batom1* and *batom2*. *Btype* must be a value between 1 and the number of bond types defined.

The *single/angle* style creates a single angle of type *atype* between three atoms with IDs *aatom1*, *aatom2*, and *aatom3*. The ordering of the atoms is the same as in the *Angles* section of a data file read by the [read_data](#) command. I.e. the 3 atoms are ordered linearly within the angle; the central atom is *aatom2*. *Atype* must be a value between 1 and the number of angle types defined.

The *single/dihedral* style creates a single dihedral of type *btype* between two atoms with IDs *batom1* and *batom2*. The ordering of the atoms is the same as in the *Dihedrals* section of a data file read by the [read_data](#) command. I.e. the 4 atoms are ordered linearly within the dihedral. *Dtype* must be a value between 1 and the number of dihedral types defined.

The keyword *special* controls whether an internal list of special bonds is created after one or more bonds, or a single angle or dihedral is added to the system.

The default value is *yes*. A value of *no* cannot be used with the *many* style.

This is an expensive operation since the bond topology for the system must be walked to find all 1-2, 1-3, 1-4 interactions to store in an internal list, which is used when pairwise interactions are weighted; see the [special_bonds](#) command for details.

Thus if you are adding a few bonds or a large list of angles all at the same time, by using this command repeatedly, it is more efficient to only trigger the internal list to be created once, after the last bond (or angle, or dihedral) is added:

```
create_bonds single/bond 5 52 98 special no
create_bonds single/bond 5 73 74 special no
...
create_bonds single/bond 5 17 386 special no
create_bonds single/bond 4 112 183 special yes
```

Note that you MUST insure the internal list is re-built after the last bond (angle, dihedral) is added, before performing a simulation. Otherwise pairwise interactions will not be properly excluded or weighted. LAMMPS does NOT check that you have done this correctly.

Restrictions:

This command cannot be used with molecular systems defined using molecule template files via the [molecule](#) and [atom_style template](#) commands.

Related commands:

[create_atoms](#), [delete_bonds](#)

Default:

The keyword default is special = yes.

create_box command

Syntax:

```
create_box N region-ID keyword value ...
```

- N = # of atom types to use in this simulation
- region-ID = ID of region to use as simulation domain
- zero or more keyword/value pairs may be appended
- keyword = *bond/types* or *angle/types* or *dihedral/types* or *improper/types* or *extra/bond/per/atom* or *extra/angle/per/atom* or *extra/dihedral/per/atom* or *extra/improper/per/atom*

```

bond/types value = # of bond types
angle/types value = # of angle types
dihedral/types value = # of dihedral types
improper/types value = # of improper types
extra/bond/per/atom value = # of bonds per atom
extra/angle/per/atom value = # of angles per atom
extra/dihedral/per/atom value = # of dihedrals per atom
extra/improper/per/atom value = # of improvers per atom
extra/special/per/atom value = # of special neighbors per atom

```

Examples:

```

create_box 2 mybox
create_box 2 mybox bond/types 2 extra/bond/per/atom 1

```

Description:

This command creates a simulation box based on the specified region. Thus a [region](#) command must first be used to define a geometric domain. It also partitions the simulation box into a regular 3d grid of rectangular bricks, one per processor, based on the number of processors being used and the settings of the [processors](#) command. The partitioning can later be changed by the [balance](#) or [fix balance](#) commands.

The argument N is the number of atom types that will be used in the simulation.

If the region is not of style *prism*, then LAMMPS encloses the region (block, sphere, etc) with an axis-aligned orthogonal bounding box which becomes the simulation domain.

If the region is of style *prism*, LAMMPS creates a non-orthogonal simulation domain shaped as a parallelepiped with triclinic symmetry. As defined by the [region prism](#) command, the parallelepiped has its "origin" at (xlo,ylo,zlo) and is defined by 3 edge vectors starting from the origin given by $A = (xhi-xlo,0,0)$; $B = (xy,yhi-ylo,0)$; $C = (xz,yz,zhi-zlo)$. Xy,xz,yz can be 0.0 or positive or negative values and are called "tilt factors" because they are the amount of displacement applied to faces of an originally orthogonal box to transform it into the parallelepiped.

LAMMPS Users Manual

By default, a *prism* region used with the `create_box` command must have tilt factors (xy, xz, yz) that do not skew the box more than half the distance of the parallel box length. For example, if $xlo = 2$ and $xhi = 12$, then the x box length is 10 and the xy tilt factor must be between -5 and 5. Similarly, both xz and yz must be between $-(xhi-xlo)/2$ and $+(yhi-ylo)/2$. Note that this is not a limitation, since if the maximum tilt factor is 5 (as in this example), then configurations with tilt = ..., -15, -5, 5, 15, 25, ... are all geometrically equivalent. If you wish to define a box with tilt factors that exceed these limits, you can use the `box tilt` command, with a setting of *large*; a setting of *small* is the default.

See [Section 6.12](#) of the doc pages for a geometric description of triclinic boxes, as defined by LAMMPS, and how to transform these parameters to and from other commonly used triclinic representations.

When a prism region is used, the simulation domain should normally be periodic in the dimension that the tilt is applied to, which is given by the second dimension of the tilt factor (e.g. y for xy tilt). This is so that pairs of atoms interacting across that boundary will have one of them shifted by the tilt factor. Periodicity is set by the `boundary` command. For example, if the xy tilt factor is non-zero, then the y dimension should be periodic. Similarly, the z dimension should be periodic if xz or yz is non-zero. LAMMPS does not require this periodicity, but you may lose atoms if this is not the case.

Also note that if your simulation will tilt the box, e.g. via the `fix deform` command, the simulation box must be setup to be triclinic, even if the tilt factors are initially 0.0. You can also change an orthogonal box to a triclinic box or vice versa by using the `change box` command with its *ortho* and *triclinic* options.

NOTE: If the system is non-periodic (in a dimension), then you should not make the lo/hi box dimensions (as defined in your `region` command) radically smaller/larger than the extent of the atoms you eventually plan to create, e.g. via the `create_atoms` command. For example, if your atoms extend from 0 to 50, you should not specify the box bounds as -10000 and 10000. This is because as described above, LAMMPS uses the specified box size to layout the 3d grid of processors. A huge (mostly empty) box will be sub-optimal for performance when using "fixed" boundary conditions (see the `boundary` command). When using "shrink-wrap" boundary conditions (see the `boundary` command), a huge (mostly empty) box may cause a parallel simulation to lose atoms the first time that LAMMPS shrink-wraps the box around the atoms.

The optional keywords can be used to create a system that allows for bond (angle, dihedral, improper) interactions, or for molecules with special 1-2, 1-3, 1-4 neighbors to be added later. These optional keywords serve the same purpose as the analogous keywords that can be used in a data file which are recognized by the `read_data` command when it sets up a system.

Note that if these keywords are not used, then the `create_box` command creates an atomic (non-molecular) simulation that does not allow bonds between pairs of atoms to be defined, or a `bond potential` to be specified, or for molecules with special neighbors to be added to the system by commands such as `create_atoms mol`, `fix deposit` or `fix pour`.

LAMMPS Users Manual

As an example, see the examples/deposit/in.deposit.molecule script, which deposits molecules onto a substrate. Initially there are no molecules in the system, but they are added later by the `fix deposit` command. The `create_box` command in the script uses the `bond/types` and `extra/bond/per/atom` keywords to allow this. If the added molecule contained more than 1 special bond (allowed by default), an `extra/special/per/atom` keyword would also need to be specified.

Restrictions:

An `atom_style` and `region` must have been previously defined to use this command.

Related commands:

`read_data`, `create_atoms`, `region`

Default: none

delete_atoms command

Syntax:

```
delete_atoms style args keyword value ...
```

- *style* = *group* or *region* or *overlap* or *porosity*

group args = group-ID

region args = region-ID

overlap args = cutoff group1-ID group2-ID

cutoff = delete one atom from pairs of atoms within the cutoff (distance units)

group1-ID = one atom in pair must be in this group

group2-ID = other atom in pair must be in this group

porosity args = region-ID fraction seed

region-ID = region within which to perform deletions

fraction = delete this fraction of atoms

seed = random number seed (positive integer)

- zero or more keyword/value pairs may be appended

- keyword = *compress* or *bond* or *mol*

compress value = *no* or *yes*

bond value = *no* or *yes*

mol value = *no* or *yes*

Examples:

```
delete_atoms group edge
delete_atoms region sphere compress no
delete_atoms overlap 0.3 all all
delete_atoms overlap 0.5 solvent colloid
delete_atoms porosity cube 0.1 482793 bond yes
```

Description:

Delete the specified atoms. This command can be used to carve out voids from a block of material or to delete created atoms that are too close to each other (e.g. at a grain boundary).

For style *group*, all atoms belonging to the group are deleted.

For style *region*, all atoms in the region volume are deleted. Additional atoms can be deleted if they are in a molecule for which one or more atoms were deleted within the region; see the *mol* keyword discussion below.

For style *overlap* pairs of atoms whose distance of separation is within the specified cutoff distance are searched for, and one of the 2 atoms is deleted. Only pairs where one of the two atoms is in the first group specified and the other atom is in the second group are considered. The atom that is in the first group is the one that is deleted.

Note that it is OK for the two group IDs to be the same (e.g. group *all*), or for some atoms to be members of both groups. In these cases, either atom in the pair may be

LAMMPS Users Manual

deleted. Also note that if there are atoms which are members of both groups, the only guarantee is that at the end of the deletion operation, enough deletions will have occurred that no atom pairs within the cutoff will remain (subject to the group restriction). There is no guarantee that the minimum number of atoms will be deleted, or that the same atoms will be deleted when running on different numbers of processors.

For style *porosity* a specified *fraction* of atoms are deleted within the specified region. For example, if fraction is 0.1, then 10% of the atoms will be deleted. The atoms to delete are chosen randomly. There is no guarantee that the exact fraction of atoms will be deleted, or that the same atoms will be deleted when running on different numbers of processors.

If the *compress* keyword is set to *yes*, then after atoms are deleted, then atom IDs are re-assigned so that they run from 1 to the number of atoms in the system. Note that this is not done for molecular systems (see the [atom_style](#) command), regardless of the *compress* setting, since it would foul up the bond connectivity that has already been assigned.

A molecular system with fixed bonds, angles, dihedrals, or improper interactions, is one where the topology of the interactions is typically defined in the data file read by the [read_data](#) command, and where the interactions themselves are defined with the [bond_style](#), [angle_style](#), etc commands. If you delete atoms from such a system, you must be careful not to end up with bonded interactions that are stored by remaining atoms but which include deleted atoms. This will cause LAMMPS to generate a "missing atoms" error when the bonded interaction is computed. The *bond* and *mol* keywords offer two ways to do that.

If the *bond* keyword is set to *yes* then any bond or angle or dihedral or improper interaction that includes a deleted atom is also removed from the lists of such interactions stored by non-deleted atoms. Note that simply deleting interactions due to dangling bonds (e.g. at a surface) may result in an inaccurate or invalid model for the remaining atoms.

If the *mol* keyword is set to *yes*, then for every atom that is deleted, all other atoms in the same molecule (with the same molecule ID) will also be deleted. This is not done for atoms with molecule ID = 0, since such an ID is assumed to flag isolated atoms that are not part of molecules.

NOTE: The molecule deletion operation is invoked after all individual atoms have been deleted using the rules described above for each style. This means additional atoms may be deleted that are not in the group or region, that are not required by the overlap cutoff criterion, or that will create a higher fraction of porosity than was requested.

Restrictions:

The *overlap* styles requires inter-processor communication to acquire ghost atoms and build a neighbor list. This means that your system must be ready to perform a simulation before using this command (force fields setup, atom masses set, etc). Since a neighbor list is used to find overlapping atom pairs, it also means that you must

LAMMPS Users Manual

define a [pair style](#) with the minimum force cutoff distance between any pair of atoms types (plus the [neighbor skin](#)) \geq the specified overlap cutoff.

If the [special_bonds](#) command is used with a setting of 0, then a pair of bonded atoms (1-2, 1-3, or 1-4) will not appear in the neighbor list, and thus will not be considered for deletion by the *overlap* styles. You probably don't want to be deleting one atom in a bonded pair anyway.

The *bond yes* option cannot be used with molecular systems defined using molecule template files via the [molecule](#) and [atom_style template](#) commands.

Related commands:

[create_atoms](#)

Default:

The option defaults are `compress = yes`, `bond = no`, `mol = no`.

delete_bonds command

Syntax:

```
delete_bonds group-ID style arg keyword ...
```

- group-ID = group ID
- style = *multi* or *atom* or *bond* or *angle* or *dihedral* or *improper* or *stats*

multi arg = none

atom arg = an atom type or range of types (see below)

bond arg = a bond type or range of types (see below)

angle arg = an angle type or range of types (see below)

dihedral arg = a dihedral type or range of types (see below)

improper arg = an improper type or range of types (see below)

stats arg = none

- zero or more keywords may be appended
- keyword = *any* or *undo* or *remove* or *special*

Examples:

```
delete_bonds frozen multi remove
delete_bonds all atom 4 special
delete_bonds all bond 0*3 special
delete_bonds all stats
```

Description:

Turn off (or on) molecular topology interactions, i.e. bonds, angles, dihedrals, impropers. This command is useful for deleting interactions that have been previously turned off by bond-breaking potentials. It is also useful for turning off topology interactions between frozen or rigid atoms. Pairwise interactions can be turned off via the [neigh_modify exclude](#) command. The [fix shake](#) command also effectively turns off certain bond and angle interactions.

For all styles, by default, an interaction is only turned off (or on) if all the atoms involved are in the specified group. See the *any* keyword to change the behavior.

Several of the styles (*atom*, *bond*, *angle*, *dihedral*, *improper*) take a *type* as an argument. The specified *type* should be an integer from 0 to N, where N is the number of relevant types (atom types, bond types, etc). A value of 0 is only relevant for style *bond*; see details below. In all cases, a wildcard asterisk can be used in place of or in conjunction with the *type* argument to specify a range of types. This takes the form "*" or "*n" or "n*" or "m*n". If N = the number of types, then an asterisk with no numeric values means all types from 0 to N. A leading asterisk means all types from 0 to n (inclusive). A trailing asterisk means all types from n to N (inclusive). A middle asterisk means all types from m to n (inclusive). Note that it is fine to include a type of 0 for non-bond styles; it will simply be ignored.

For style *multi* all bond, angle, dihedral, and improper interactions of any type,

involving atoms in the group, are turned off.

Style *atom* is the same as style *multi* except that in addition, one or more of the atoms involved in the bond, angle, dihedral, or improper interaction must also be of the specified atom type.

For style *bond*, only bonds are candidates for turn-off, and the bond must also be of the specified type. Styles *angle*, *dihedral*, and *improper* are treated similarly.

For style *bond*, you can set the type to 0 to delete bonds that have been previously broken by a bond-breaking potential (which sets the bond type to 0 when a bond is broken); e.g. see the [bond_style quartic](#) command.

For style *stats* no interactions are turned off (or on); the status of all interactions in the specified group is simply reported. This is useful for diagnostic purposes if bonds have been turned off by a bond-breaking potential during a previous run.

The default behavior of the `delete_bonds` command is to turn off interactions by toggling their type to a negative value, but not to permanently remove the interaction. E.g. a `bond_type` of 2 is set to -2. The neighbor list creation routines will not include such an interaction in their interaction lists. The default is also to not alter the list of 1-2, 1-3, 1-4 neighbors computed by the [special_bonds](#) command and used to weight pairwise force and energy calculations. This means that pairwise computations will proceed as if the bond (or angle, etc) were still turned on.

Several keywords can be appended to the argument list to alter the default behaviors.

The *any* keyword changes the requirement that all atoms in the bond (angle, etc) must be in the specified group in order to turn-off the interaction. Instead, if any of the atoms in the interaction are in the specified group, it will be turned off (or on if the *undo* keyword is used).

The *undo* keyword inverts the `delete_bonds` command so that the specified bonds, angles, etc are turned on if they are currently turned off. This means a negative value is toggled to positive. For example, for style *angle*, if *type* is specified as 2, then all angles with current type = -2, are reset to type = 2. Note that the [fix shake](#) command also sets bond and angle types negative, so this option should not be used on those interactions.

The *remove* keyword is invoked at the end of the `delete_bonds` operation. It causes turned-off bonds (angles, etc) to be removed from each atom's data structure and then adjusts the global bond (angle, etc) counts accordingly. Removal is a permanent change; removed bonds cannot be turned back on via the *undo* keyword. Removal does not alter the pairwise 1-2, 1-3, 1-4 weighting list.

The *special* keyword is invoked at the end of the `delete_bonds` operation, after (optional) removal. It re-computes the pairwise 1-2, 1-3, 1-4 weighting list. The weighting list computation treats turned-off bonds the same as turned-on. Thus, turned-off bonds must be removed if you wish to change the weighting list.

LAMMPS Users Manual

Note that the choice of *remove* and *special* options affects how 1-2, 1-3, 1-4 pairwise interactions will be computed across bonds that have been modified by the `delete_bonds` command.

Restrictions:

This command requires inter-processor communication to acquire ghost atoms, to coordinate the deleting of bonds, angles, etc between atoms shared by multiple processors. This means that your system must be ready to perform a simulation before using this command (force fields setup, atom masses set, etc). Just as would be needed to run dynamics, the force field you define should define a cutoff (e.g. through a [pair_style](#) command) which is long enough for a processor to acquire the ghost atoms its needs to compute bond, angle, etc interactions.

If deleted bonds (angles, etc) are removed but the 1-2, 1-3, 1-4 weighting list is not recomputed, this can cause a later [fix shake](#) command to fail due to an atom's bonds being inconsistent with the weighting list. This should only happen if the group used in the `fix` command includes both atoms in the bond, in which case you probably should be recomputing the weighting list.

Related commands:

[neigh_modify](#) `exclude`, [special_bonds](#), [fix shake](#)

Default: none

dielectric command

Syntax:

```
dielectric value
```

- value = dielectric constant

Examples:

```
dielectric 2.0
```

Description:

Set the dielectric constant for Coulombic interactions (pairwise and long-range) to this value. The constant is unitless, since it is used to reduce the strength of the interactions. The value is used in the denominator of the formulas for Coulombic interactions - e.g. a value of 4.0 reduces the Coulombic interactions to 25% of their default strength. See the [pair_style](#) command for more details.

Restrictions: none

Related commands:

[pair_style](#)

Default:

```
dielectric 1.0
```

dihedral_coeff command

Syntax:

```
dihedral_coeff N args
```

- N = dihedral type (see asterisk form below)
- args = coefficients for one or more dihedral types

Examples:

```
dihedral_coeff 1 80.0 1 3  
dihedral_coeff * 80.0 1 3 0.5  
dihedral_coeff 2* 80.0 1 3 0.5
```

Description:

Specify the dihedral force field coefficients for one or more dihedral types. The number and meaning of the coefficients depends on the dihedral style. Dihedral coefficients can also be set in the data file read by the [read_data](#) command or in a restart file.

N can be specified in one of two ways. An explicit numeric value can be used, as in the 1st example above. Or a wild-card asterisk can be used to set the coefficients for multiple dihedral types. This takes the form "*" or "*n" or "n*" or "m*n". If N = the number of dihedral types, then an asterisk with no numeric values means all types from 1 to N. A leading asterisk means all types from 1 to n (inclusive). A trailing asterisk means all types from n to N (inclusive). A middle asterisk means all types from m to n (inclusive).

Note that using a `dihedral_coeff` command can override a previous setting for the same dihedral type. For example, these commands set the coeffs for all dihedral types, then overwrite the coeffs for just dihedral type 2:

```
dihedral_coeff * 80.0 1 3  
dihedral_coeff 2 200.0 1 3
```

A line in a data file that specifies dihedral coefficients uses the exact same format as the arguments of the `dihedral_coeff` command in an input script, except that wild-card asterisks should not be used since coefficients for all N types must be listed in the file. For example, under the "Dihedral Coeffs" section of a data file, the line that corresponds to the 1st example above would be listed as

```
1 80.0 1 3
```

The [dihedral_style class2](#) is an exception to this rule, in that an additional argument is used in the input script to allow specification of the cross-term coefficients. See its doc page for details.

LAMMPS Users Manual

NOTE: When comparing the formulas and coefficients for various LAMMPS dihedral styles with dihedral equations defined by other force fields, note that some force field implementations divide/multiply the energy prefactor K by the multiple number of torsions that contain the J-K bond in an I-J-K-L torsion. LAMMPS does not do this, i.e. the listed dihedral equation applies to each individual dihedral. Thus you need to define K appropriately to account for this difference if necessary.

Here is an alphabetic list of dihedral styles defined in LAMMPS. Click on the style to display the formula it computes and coefficients specified by the associated [dihedral_coeff](#) command.

Note that there are also additional dihedral styles submitted by users which are included in the LAMMPS distribution. The list of these with links to the individual styles are given in the dihedral section of [this page](#).

- [dihedral_style none](#) - turn off dihedral interactions
 - [dihedral_style hybrid](#) - define multiple styles of dihedral interactions

 - [dihedral_style charmm](#) - CHARMM dihedral
 - [dihedral_style class2](#) - COMPASS (class 2) dihedral
 - [dihedral_style harmonic](#) - harmonic dihedral
 - [dihedral_style helix](#) - helix dihedral
 - [dihedral_style multi/harmonic](#) - multi-harmonic dihedral
 - [dihedral_style opls](#) - OPLS dihedral
-

Restrictions:

This command must come after the simulation box is defined by a [read_data](#), [read_restart](#), or [create_box](#) command.

A dihedral style must be defined before any dihedral coefficients are set, either in the input script or in a data file.

Related commands:

[dihedral_style](#)

Default: none

dihedral_style command

Syntax:

```
dihedral_style style
```

- style = *none* or *hybrid* or *charmm* or *class2* or *harmonic* or *helix* or *multi/harmonic* or *opls*

Examples:

```
dihedral_style harmonic  
dihedral_style multi/harmonic  
dihedral_style hybrid harmonic charmm
```

Description:

Set the formula(s) LAMMPS uses to compute dihedral interactions between quadruplets of atoms, which remain in force for the duration of the simulation. The list of dihedral quadruplets is read in by a [read_data](#) or [read_restart](#) command from a data or restart file.

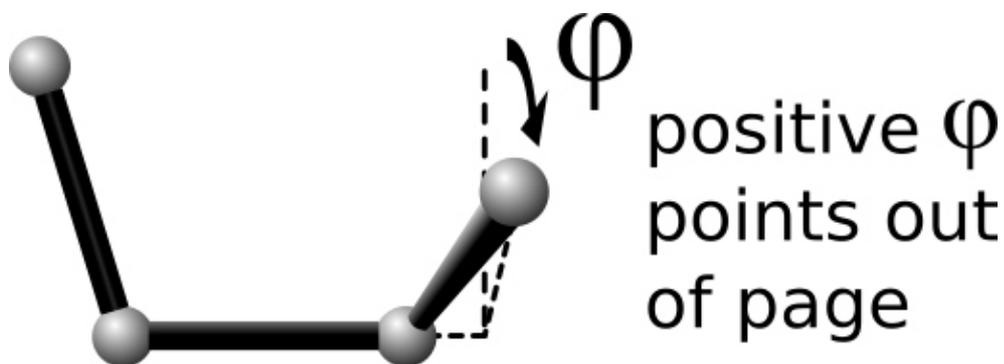

Hybrid models where dihedrals are computed using different dihedral potentials can be setup using the *hybrid* dihedral style.

The coefficients associated with a dihedral style can be specified in a data or restart file or via the [dihedral_coeff](#) command.

All dihedral potentials store their coefficient data in binary restart files which means `dihedral_style` and [dihedral_coeff](#) commands do not need to be re-specified in an input script that restarts a simulation. See the [read_restart](#) command for details on how to do this. The one exception is that `dihedral_style hybrid` only stores the list of sub-styles in the restart file; dihedral coefficients need to be re-specified.

NOTE: When both a dihedral and pair style is defined, the [special_bonds](#) command often needs to be used to turn off (or weight) the pairwise interaction that would otherwise exist between 4 bonded atoms.

In the formulas listed for each dihedral style, *phi* is the torsional angle defined by the quadruplet of atoms. This angle has a sign convention as shown in this diagram:

where the I,J,K,L ordering of the 4 atoms that define the dihedral is from left to right.

This sign convention effects several of the dihedral styles listed below (e.g. charmm, helix) in the sense that the energy formula depends on the sign of phi, which may be reflected in the value of the coefficients you specify.

NOTE: When comparing the formulas and coefficients for various LAMMPS dihedral styles with dihedral equations defined by other force fields, note that some force field implementations divide/multiply the energy prefactor K by the multiple number of torsions that contain the J-K bond in an I-J-K-L torsion. LAMMPS does not do this, i.e. the listed dihedral equation applies to each individual dihedral. Thus you need to define K appropriately via the [dihedral_coeff](#) command to account for this difference if necessary.

Here is an alphabetic list of dihedral styles defined in LAMMPS. Click on the style to display the formula it computes and coefficients specified by the associated [dihedral_coeff](#) command.

Note that there are also additional dihedral styles submitted by users which are included in the LAMMPS distribution. The list of these with links to the individual styles are given in the dihedral section of [this page](#).

- [dihedral_style none](#) - turn off dihedral interactions
- [dihedral_style zero](#) - topology but no interactions
- [dihedral_style hybrid](#) - define multiple styles of dihedral interactions

- [dihedral_style charmm](#) - CHARMM dihedral
- [dihedral_style class2](#) - COMPASS (class 2) dihedral
- [dihedral_style harmonic](#) - harmonic dihedral
- [dihedral_style helix](#) - helix dihedral
- [dihedral_style multi/harmonic](#) - multi-harmonic dihedral
- [dihedral_style opl](#) - OPLS dihedral

Restrictions:

Dihedral styles can only be set for atom styles that allow dihedrals to be defined.

Most dihedral styles are part of the MOLECULE package. They are only enabled if LAMMPS was built with that package. See the [Making LAMMPS](#) section for more info

LAMMPS Users Manual

on packages. The doc pages for individual dihedral potentials tell if it is part of a package.

Related commands:

[dihedral_coeff](#)

Default:

dihedral_style none

dimension command

Syntax:

```
dimension N
```

- N = 2 or 3

Examples:

```
dimension 2
```

Description:

Set the dimensionality of the simulation. By default LAMMPS runs 3d simulations. To run a 2d simulation, this command should be used prior to setting up a simulation box via the [create_box](#) or [read_data](#) commands. Restart files also store this setting.

See the discussion in [Section 6](#) for additional instructions on how to run 2d simulations.

NOTE: Some models in LAMMPS treat particles as finite-size spheres or ellipsoids, as opposed to point particles. In 2d, the particles will still be spheres or ellipsoids, not circular disks or ellipses, meaning their moment of inertia will be the same as in 3d.

Restrictions:

This command must be used before the simulation box is defined by a [read_data](#) or [create_box](#) command.

Related commands:

[fix enforce2d](#)

```

- group-ID = ID of group of atoms to displace
- style = *move* or *ramp* or *random* or *rotate*

```

move args = delx dely delz
    delx,dely,delz = distance to displace in each dimension (distance units)
    any of delx,dely,delz can be a variable (see below)
ramp args = ddim dlo dhi dim clo chi
    ddim = x or y or z
    dlo,dhi = displacement distance between dlo and dhi (distance units)
    dim = x or y or z
    clo,chi = lower and upper bound of domain to displace (distance units)
random args = dx dy dz seed
    dx,dy,dz = random displacement magnitude in each dimension (distance units)
    seed = random # seed (positive integer)
rotate args = Px Py Pz Rx Ry Rz theta
    Px,Py,Pz = origin point of axis of rotation (distance units)
    Rx,Ry,Rz = axis of rotation vector
    theta = angle of rotation (degrees)

```

- zero or more keyword/value pairs may be appended

```

keyword = units
value = box or lattice

```

Examples:

```

displace_atoms top move 0 -5 0 units box
displace_atoms flow ramp x 0.0 5.0 y 2.0 20.5

```

Description:

Displace a group of atoms. This can be used to move atoms a large distance before beginning a simulation or to randomize atoms initially on a lattice. For example, in a shear simulation, an initial strain can be imposed on the system. Or two groups of atoms can be brought into closer proximity.

The *move* style displaces the group of atoms by the specified 3d displacement vector. Any of the 3 quantities defining the vector components can be specified as an equal-style or atom-style [variable](#). If the value is a variable, it should be specified as `v_name`, where name is the variable name. In this case, the variable will be evaluated, and its value(s) used for the displacement(s). The scale factor implied by the *units* keyword will also be applied to the variable result.

Equal-style variables can specify formulas with various mathematical functions, and include [thermo_style](#) command keywords for the simulation box parameters and timestep and elapsed time. Atom-style variables can specify the same formulas as equal-style variables but can also include per-atom values, such as atom coordinates

LAMMPS Users Manual

or per-atom values read from a file. Note that if the variable references other [compute](#) or [fix](#) commands, those values must be up-to-date for the current timestep. See the "Variable Accuracy" section of the [variable](#) doc page for more details.

The *ramp* style displaces atoms a variable amount in one dimension depending on the atom's coordinate in a (possibly) different dimension. For example, the second example command displaces atoms in the x-direction an amount between 0.0 and 5.0 distance units. Each atom's displacement depends on the fractional distance its y coordinate is between 2.0 and 20.5. Atoms with y-coordinates outside those bounds will be moved the minimum (0.0) or maximum (5.0) amount.

The *random* style independently moves each atom in the group by a random displacement, uniformly sampled from a value between -dx and +dx in the x dimension, and similarly for y and z. Random numbers are used in such a way that the displacement of a particular atom is the same, regardless of how many processors are being used.

The *rotate* style rotates each atom in the group by the angle *theta* around a rotation axis $R = (R_x, R_y, R_z)$ that goes thru a point $P = (P_x, P_y, P_z)$. The direction of rotation for the atoms around the rotation axis is consistent with the right-hand rule: if your right-hand thumb points along R , then your fingers wrap around the axis in the direction of positive theta.

If the defined [atom_style](#) assigns an orientation to each atom ([atom styles](#) ellipsoid, line, tri, body), then that property is also updated appropriately to correspond to the atom's rotation.

Distance units for displacements and the origin point of the *rotate* style are determined by the setting of *box* or *lattice* for the *units* keyword. *Box* means distance units as defined by the [units](#) command - e.g. Angstroms for *real* units. *Lattice* means distance units are in lattice spacings. The [lattice](#) command must have been previously used to define the lattice spacing.

NOTE: Care should be taken not to move atoms on top of other atoms. After the move, atoms are remapped into the periodic simulation box if needed, and any shrink-wrap boundary conditions (see the [boundary](#) command) are enforced which may change the box size. Other than this effect, this command does not change the size or shape of the simulation box. See the [change_box](#) command if that effect is desired.

NOTE: Atoms can be moved arbitrarily long distances by this command. If the simulation box is non-periodic and shrink-wrapped (see the [boundary](#) command), this can change its size or shape. This is not a problem, except that the mapping of processors to the simulation box is not changed by this command from its initial 3d configuration; see the [processors](#) command. Thus, if the box size/shape changes dramatically, the mapping of processors to the simulation box may not end up as optimal as the initial mapping attempted to be.

Restrictions:

For a 2d simulation, only rotations around the a vector parallel to the z-axis are

allowed.

Description:

Dump a snapshot of atom quantities to one or more files every N timesteps in one of several styles. The *image* and *movie* styles are the exception: the *image* style renders a JPG, PNG, or PPM image file of the atom configuration every N timesteps while the *movie* style combines and compresses them into a movie file; both are discussed in detail on the [dump image](#) doc page. The timesteps on which dump output is written can also be controlled by a variable. See the [dump_modify every](#) command.

Only information for atoms in the specified group is dumped. The [dump_modify thresh and region](#) commands can also alter what atoms are included. Not all styles support all these options; see details below.

As described below, the filename determines the kind of output (text or binary or gzipped, one big file or one per timestep, one big file or multiple smaller files).

NOTE: Because periodic boundary conditions are enforced only on timesteps when neighbor lists are rebuilt, the coordinates of an atom written to a dump file may be slightly outside the simulation box. Re-neighbor timesteps will not typically coincide with the timesteps dump snapshots are written. See the [dump_modify pbc](#) command if you wish to force coordinates to be strictly inside the simulation box.

NOTE: Unless the [dump_modify sort](#) option is invoked, the lines of atom information written to dump files (typically one line per atom) will be in an indeterminate order for each snapshot. This is even true when running on a single processor, if the [atom_modify sort](#) option is on, which it is by default. In this case atoms are re-ordered periodically during a simulation, due to spatial sorting. It is also true when running in parallel, because data for a single snapshot is collected from multiple processors, each of which owns a subset of the atoms.

For the *atom*, *custom*, *cfg*, and *local* styles, sorting is off by default. For the *dcd*, *xtc*, *xyz*, and *molfile* styles, sorting by atom ID is on by default. See the [dump_modify](#) doc page for details.

The *atom/gz*, *cfg/gz*, *custom/gz*, and *xyz/gz* styles are identical in command syntax to the corresponding styles without "gz", however, they generate compressed files using the zlib library. Thus the filename suffix ".gz" is mandatory. This is an alternative approach to writing compressed files via a pipe, as done by the regular dump styles, which may be required on clusters where the interface to the high-speed network disallows using the fork() library call (which is needed for a pipe). For the remainder of this doc page, you should thus consider the *atom* and *atom/gz* styles (etc) to be inter-changeable, with the exception of the required filename suffix.

As explained below, the *atom/mpio*, *cfg/mpio*, *custom/mpio*, and *xyz/mpio* styles are identical in command syntax and in the format of the dump files they create, to the corresponding styles without "mpio", except the single dump file they produce is written in parallel via the MPI-IO library. For the remainder of this doc page, you should thus consider the *atom* and *atom/mpio* styles (etc) to be inter-changeable. The one exception is how the filename is specified for the MPI-IO styles, as explained below.

LAMMPS Users Manual

The precision of values output to text-based dump files can be controlled by the [dump_modify format](#) command and its options.

The *style* keyword determines what atom quantities are written to the file and in what format. Settings made via the [dump_modify](#) command can also alter the format of individual values and the file itself.

The *atom*, *local*, and *custom* styles create files in a simple text format that is self-explanatory when viewing a dump file. Many of the LAMMPS [post-processing tools](#), including [Pizza.py](#), work with this format, as does the [rerun](#) command.

For post-processing purposes the *atom*, *local*, and *custom* text files are self-describing in the following sense.

The dimensions of the simulation box are included in each snapshot. For an orthogonal simulation box this information is formatted as:

```
ITEM: BOX BOUNDS xx yy zz
xlo xhi
ylo yhi
zlo zhi
```

where xlo,xhi are the maximum extents of the simulation box in the x-dimension, and similarly for y and z. The "xx yy zz" represent 6 characters that encode the style of boundary for each of the 6 simulation box boundaries (xlo,xhi and ylo,yhi and zlo,zhi). Each of the 6 characters is either p = periodic, f = fixed, s = shrink wrap, or m = shrink wrapped with a minimum value. See the [boundary](#) command for details.

For triclinic simulation boxes (non-orthogonal), an orthogonal bounding box which encloses the triclinic simulation box is output, along with the 3 tilt factors (xy, xz, yz) of the triclinic box, formatted as follows:

```
ITEM: BOX BOUNDS xy xz yz xx yy zz
xlo_bound xhi_bound xy
ylo_bound yhi_bound xz
zlo_bound zhi_bound yz
```

The presence of the text "xy xz yz" in the ITEM line indicates that the 3 tilt factors will be included on each of the 3 following lines. This bounding box is convenient for many visualization programs. The meaning of the 6 character flags for "xx yy zz" is the same as above.

Note that the first two numbers on each line are now xlo_bound instead of xlo, etc, since they represent a bounding box. See [this section](#) of the doc pages for a geometric description of triclinic boxes, as defined by LAMMPS, simple formulas for how the 6 bounding box extents (xlo_bound,xhi_bound,etc) are calculated from the triclinic parameters, and how to transform those parameters to and from other commonly used triclinic representations.

The "ITEM: ATOMS" line in each snapshot lists column descriptors for the per-atom lines that follow. For example, the descriptors would be "id type xs ys zs" for the default *atom* style, and would be the atom attributes you specify in the dump

LAMMPS Users Manual

command for the *custom* style.

For style *atom*, atom coordinates are written to the file, along with the atom ID and atom type. By default, atom coords are written in a scaled format (from 0 to 1). I.e. an x value of 0.25 means the atom is at a location 1/4 of the distance from xlo to xhi of the box boundaries. The format can be changed to unscaled coords via the [dump_modify](#) settings. Image flags can also be added for each atom via [dump_modify](#).

Style *custom* allows you to specify a list of atom attributes to be written to the dump file for each atom. Possible attributes are listed above and will appear in the order specified. You cannot specify a quantity that is not defined for a particular simulation - such as *q* for atom style *bond*, since that atom style doesn't assign charges. Dumps occur at the very end of a timestep, so atom attributes will include effects due to fixes that are applied during the timestep. An explanation of the possible dump custom attributes is given below.

For style *local*, local output generated by [computes](#) and [fixes](#) is used to generate lines of output that is written to the dump file. This local data is typically calculated by each processor based on the atoms it owns, but there may be zero or more entities per atom, e.g. a list of bond distances. An explanation of the possible dump local attributes is given below. Note that by using input from the [compute property/local](#) command with [dump local](#), it is possible to generate information on bonds, angles, etc that can be cut and pasted directly into a data file read by the [read_data](#) command.

Style *cfg* has the same command syntax as style *custom* and writes extended CFG format files, as used by the [AtomEye](#) visualization package. Since the extended CFG format uses a single snapshot of the system per file, a wildcard "*" must be included in the filename, as discussed below. The list of atom attributes for style *cfg* must begin with either "mass type xs ys zs" or "mass type xsu ysu zsu" since these quantities are needed to write the CFG files in the appropriate format (though the "mass" and "type" fields do not appear explicitly in the file). Any remaining attributes will be stored as "auxiliary properties" in the CFG files. Note that you will typically want to use the [dump_modify element](#) command with CFG-formatted files, to associate element names with atom types, so that AtomEye can render atoms appropriately. When unwrapped coordinates *xsu*, *ysu*, and *zsu* are requested, the nominal AtomEye periodic cell dimensions are expanded by a large factor UNWRAPEXPAND = 10.0, which ensures atoms that are displayed correctly for up to UNWRAPEXPAND/2 periodic boundary crossings in any direction. Beyond this, AtomEye will rewrap the unwrapped coordinates. The expansion causes the atoms to be drawn farther away from the viewer, but it is easy to zoom the atoms closer, and the interatomic distances are unaffected.

The *dcd* style writes DCD files, a standard atomic trajectory format used by the CHARMM, NAMD, and Xplor molecular dynamics packages. DCD files are binary and thus may not be portable to different machines. The number of atoms per snapshot cannot change with the *dcd* style. The *unwrap* option of the [dump_modify](#) command allows DCD coordinates to be written "unwrapped" by the image flags for each atom. Unwrapped means that if the atom has passed through a periodic boundary one or more times, the value is printed for what the coordinate would be if it had not been wrapped back into the periodic box. Note that these coordinates may thus be far outside the box size stored with the snapshot.

LAMMPS Users Manual

The *xtc* style writes XTC files, a compressed trajectory format used by the GROMACS molecular dynamics package, and described [here](#). The precision used in XTC files can be adjusted via the [dump_modify](#) command. The default value of 1000 means that coordinates are stored to 1/1000 nanometer accuracy. XTC files are portable binary files written in the NFS XDR data format, so that any machine which supports XDR should be able to read them. The number of atoms per snapshot cannot change with the *xtc* style. The *unwrap* option of the [dump_modify](#) command allows XTC coordinates to be written "unwrapped" by the image flags for each atom. Unwrapped means that if the atom has passed thru a periodic boundary one or more times, the value is printed for what the coordinate would be if it had not been wrapped back into the periodic box. Note that these coordinates may thus be far outside the box size stored with the snapshot.

The *xyz* style writes XYZ files, which is a simple text-based coordinate format that many codes can read. Specifically it has a line with the number of atoms, then a comment line that is usually ignored followed by one line per atom with the atom type and the x-, y-, and z-coordinate of that atom. You can use the [dump_modify element](#) option to change the output from using the (numerical) atom type to an element name (or some other label). This will help many visualization programs to guess bonds and colors.

Note that *atom*, *custom*, *dcd*, *xtc*, and *xyz* style dump files can be read directly by [VMD](#), a popular molecular viewing program.

Dumps are performed on timesteps that are a multiple of N (including timestep 0) and on the last timestep of a minimization if the minimization converges. Note that this means a dump will not be performed on the initial timestep after the dump command is invoked, if the current timestep is not a multiple of N. This behavior can be changed via the [dump_modify first](#) command, which can also be useful if the dump command is invoked after a minimization ended on an arbitrary timestep. N can be changed between runs by using the [dump_modify every](#) command (not allowed for *dcd* style). The [dump_modify every](#) command also allows a variable to be used to determine the sequence of timesteps on which dump files are written. In this mode a dump on the first timestep of a run will also not be written unless the [dump_modify first](#) command is used.

The specified filename determines how the dump file(s) is written. The default is to write one large text file, which is opened when the dump command is invoked and closed when an [undump](#) command is used or when LAMMPS exits. For the *dcd* and *xtc* styles, this is a single large binary file.

Dump filenames can contain two wildcard characters. If a "*" character appears in the filename, then one file per snapshot is written and the "*" character is replaced with the timestep value. For example, tmp.dump.* becomes tmp.dump.0, tmp.dump.10000, tmp.dump.20000, etc. This option is not available for the *dcd* and *xtc* styles. Note that the [dump_modify pad](#) command can be used to insure all timestep numbers are the same length (e.g. 00010), which can make it easier to read a series of dump files in order with some post-processing tools.

If a "%" character appears in the filename, then each of P processors writes a portion of the dump file, and the "%" character is replaced with the processor ID from 0 to

LAMMPS Users Manual

P-1. For example, `tmp.dump.%` becomes `tmp.dump.0`, `tmp.dump.1`, ... `tmp.dump.P-1`, etc. This creates smaller files and can be a fast mode of output on parallel machines that support parallel I/O for output. This option is not available for the *dcd*, *xtc*, and *xyz* styles.

By default, P = the number of processors meaning one file per processor, but P can be set to a smaller value via the *nfile* or *fileper* keywords of the [dump_modify](#) command. These options can be the most efficient way of writing out dump files when running on large numbers of processors.

Note that using the "*" and "%" characters together can produce a large number of small dump files!

For the *atom/mpiio*, *cfg/mpiio*, *custom/mpiio*, and *xyz/mpiio* styles, a single dump file is written in parallel via the MPI-IO library, which is part of the MPI standard for versions 2.0 and above. Using MPI-IO requires two steps. First, build LAMMPS with its MPIIO package installed, e.g.

```
make yes-mpiio    # installs the MPIIO package
make mpi         # build LAMMPS for your platform
```

Second, use a dump filename which contains ".mpiio". Note that it does not have to end in ".mpiio", just contain those characters. Unlike MPI-IO restart files, which must be both written and read using MPI-IO, the dump files produced by these MPI-IO styles are identical in format to the files produced by their non-MPI-IO style counterparts. This means you can write a dump file using MPI-IO and use the [read_dump](#) command or perform other post-processing, just as if the dump file was not written using MPI-IO.

Note that MPI-IO dump files are one large file which all processors write to. You thus cannot use the "%" wildcard character described above in the filename since that specifies generation of multiple files. You can use the ".bin" suffix described below in an MPI-IO dump file; again this file will be written in parallel and have the same binary format as if it were written without MPI-IO.

If the filename ends with ".bin", the dump file (or files, if "*" or "%" is also used) is written in binary format. A binary dump file will be about the same size as a text version, but will typically write out much faster. Of course, when post-processing, you will need to convert it back to text format (see the [binary2txt tool](#)) or write your own code to read the binary file. The format of the binary file can be understood by looking at the `tools/binary2txt.cpp` file. This option is only available for the *atom* and *custom* styles.

If the filename ends with ".gz", the dump file (or files, if "*" or "%" is also used) is written in gzipped format. A gzipped dump file will be about 3x smaller than the text version, but will also take longer to write. This option is not available for the *dcd* and *xtc* styles.

Note that in the discussion which follows, for styles which can reference values from a compute or fix, like the *custom*, *cfg*, or *local* styles, the bracketed index I can be specified using a wildcard asterisk with the index to effectively specify multiple

LAMMPS Users Manual

values. This takes the form "*" or "*n" or "n*" or "m*n". If N = the size of the vector (for *mode* = scalar) or the number of columns in the array (for *mode* = vector), then an asterisk with no numeric values means all indices from 1 to N. A leading asterisk means all indices from 1 to n (inclusive). A trailing asterisk means all indices from n to N (inclusive). A middle asterisk means all indices from m to n (inclusive).

Using a wildcard is the same as if the individual columns of the array had been listed one by one. E.g. these 2 dump commands are equivalent, since the [compute stress/atom](#) command creates a per-atom array with 6 columns:

```
compute myPress all stress/atom NULL
dump 2 all custom 100 tmp.dump id myPress[*]
dump 2 all custom 100 tmp.dump id myPress[1] myPress[2] myPress[3] &
                                     myPress[4] myPress[5] myPress[6]
```

This section explains the local attributes that can be specified as part of the *local* style.

The *index* attribute can be used to generate an index number from 1 to N for each line written into the dump file, where N is the total number of local datums from all processors, or lines of output that will appear in the snapshot. Note that because data from different processors depend on what atoms they currently own, and atoms migrate between processor, there is no guarantee that the same index will be used for the same info (e.g. a particular bond) in successive snapshots.

The *c_ID* and *c_ID[I]* attributes allow local vectors or arrays calculated by a [compute](#) to be output. The ID in the attribute should be replaced by the actual ID of the compute that has been defined previously in the input script. See the [compute](#) command for details. There are computes for calculating local information such as indices, types, and energies for bonds and angles.

Note that computes which calculate global or per-atom quantities, as opposed to local quantities, cannot be output in a dump local command. Instead, global quantities can be output by the [thermo_style custom](#) command, and per-atom quantities can be output by the dump custom command.

If *c_ID* is used as a attribute, then the local vector calculated by the compute is printed. If *c_ID[I]* is used, then I must be in the range from 1-M, which will print the Ith column of the local array with M columns calculated by the compute. See the discussion above for how I can be specified with a wildcard asterisk to effectively specify multiple values.

The *f_ID* and *f_ID[I]* attributes allow local vectors or arrays calculated by a [fix](#) to be output. The ID in the attribute should be replaced by the actual ID of the fix that has been defined previously in the input script.

If *f_ID* is used as a attribute, then the local vector calculated by the fix is printed. If *f_ID[I]* is used, then I must be in the range from 1-M, which will print the Ith column of the local with M columns calculated by the fix. See the discussion above for how I can be specified with a wildcard asterisk to effectively specify multiple values.

LAMMPS Users Manual

Here is an example of how to dump bond info for a system, including the distance and energy of each bond:

```
compute 1 all property/local batom1 batom2 btype
compute 2 all bond/local dist eng
dump 1 all local 1000 tmp.dump index c_1[1] c_1[2] c_1[3] c_2[1] c_2[2]
```

This section explains the atom attributes that can be specified as part of the *custom* and *cfg* styles.

The *id*, *mol*, *proc*, *procp1*, *type*, *element*, *mass*, *vx*, *vy*, *vz*, *fx*, *fy*, *fz*, *q* attributes are self-explanatory.

Id is the atom ID. *Mol* is the molecule ID, included in the data file for molecular systems. *Proc* is the ID of the processor (0 to Nprocs-1) that currently owns the atom. *Procp1* is the proc ID+1, which can be convenient in place of a *type* attribute (1 to Ntypes) for coloring atoms in a visualization program. *Type* is the atom type (1 to Ntypes). *Element* is typically the chemical name of an element, which you must assign to each type via the [dump_modify element](#) command. More generally, it can be any string you wish to associated with an atom type. *Mass* is the atom mass. *Vx*, *vy*, *vz*, *fx*, *fy*, *fz*, and *q* are components of atom velocity and force and atomic charge.

There are several options for outputting atom coordinates. The *x*, *y*, *z* attributes write atom coordinates "unscaled", in the appropriate distance [units](#) (Angstroms, sigma, etc). Use *xs*, *ys*, *zs* if you want the coordinates "scaled" to the box size, so that each value is 0.0 to 1.0. If the simulation box is triclinic (tilted), then all atom coords will still be between 0.0 and 1.0. I.e. actual unscaled (x,y,z) = $x_s*A + y_s*B + z_s*C$, where (A,B,C) are the non-orthogonal vectors of the simulation box edges, as discussed in [Section 6.12](#).

Use *xu*, *yu*, *zu* if you want the coordinates "unwrapped" by the image flags for each atom. Unwrapped means that if the atom has passed thru a periodic boundary one or more times, the value is printed for what the coordinate would be if it had not been wrapped back into the periodic box. Note that using *xu*, *yu*, *zu* means that the coordinate values may be far outside the box bounds printed with the snapshot. Using *xsu*, *ysu*, *zsu* is similar to using *xu*, *yu*, *zu*, except that the unwrapped coordinates are scaled by the box size. Atoms that have passed through a periodic boundary will have the corresponding coordinate increased or decreased by 1.0.

The image flags can be printed directly using the *ix*, *iy*, *iz* attributes. For periodic dimensions, they specify which image of the simulation box the atom is considered to be in. An image of 0 means it is inside the box as defined. A value of 2 means add 2 box lengths to get the true value. A value of -1 means subtract 1 box length to get the true value. LAMMPS updates these flags as atoms cross periodic boundaries during the simulation.

The *mux*, *muy*, *muz* attributes are specific to dipolar systems defined with an atom style of *dipole*. They give the orientation of the atom's point dipole moment. The *mu* attribute gives the magnitude of the atom's dipole moment.

LAMMPS Users Manual

The *radius* and *diameter* attributes are specific to spherical particles that have a finite size, such as those defined with an atom style of *sphere*.

The *omegax*, *omegay*, and *omegaz* attributes are specific to finite-size spherical particles that have an angular velocity. Only certain atom styles, such as *sphere* define this quantity.

The *angmomx*, *angmomy*, and *angmomz* attributes are specific to finite-size aspherical particles that have an angular momentum. Only the *ellipsoid* atom style defines this quantity.

The *tqx*, *tqy*, *tqz* attributes are for finite-size particles that can sustain a rotational torque due to interactions with other particles.

The *c_ID* and *c_ID[I]* attributes allow per-atom vectors or arrays calculated by a [compute](#) to be output. The ID in the attribute should be replaced by the actual ID of the compute that has been defined previously in the input script. See the [compute](#) command for details. There are computes for calculating the per-atom energy, stress, centro-symmetry parameter, and coordination number of individual atoms.

Note that computes which calculate global or local quantities, as opposed to per-atom quantities, cannot be output in a dump custom command. Instead, global quantities can be output by the [thermo_style custom](#) command, and local quantities can be output by the dump local command.

If *c_ID* is used as a attribute, then the per-atom vector calculated by the compute is printed. If *c_ID[I]* is used, then I must be in the range from 1-M, which will print the Ith column of the per-atom array with M columns calculated by the compute. See the discussion above for how I can be specified with a wildcard asterisk to effectively specify multiple values.

The *f_ID* and *f_ID[I]* attributes allow vector or array per-atom quantities calculated by a [fix](#) to be output. The ID in the attribute should be replaced by the actual ID of the fix that has been defined previously in the input script. The [fix ave/atom](#) command is one that calculates per-atom quantities. Since it can time-average per-atom quantities produced by any [compute](#), [fix](#), or atom-style [variable](#), this allows those time-averaged results to be written to a dump file.

If *f_ID* is used as a attribute, then the per-atom vector calculated by the fix is printed. If *f_ID[I]* is used, then I must be in the range from 1-M, which will print the Ith column of the per-atom array with M columns calculated by the fix. See the discussion above for how I can be specified with a wildcard asterisk to effectively specify multiple values.

The *v_name* attribute allows per-atom vectors calculated by a [variable](#) to be output. The name in the attribute should be replaced by the actual name of the variable that has been defined previously in the input script. Only an atom-style variable can be referenced, since it is the only style that generates per-atom values. Variables of style *atom* can reference individual atom attributes, per-atom atom attributes, thermodynamic keywords, or invoke other computes, fixes, or variables when they are evaluated, so this is a very general means of creating quantities to output to a dump

file.

The *d_name* and *i_name* attributes allow to output custom per atom floating point or integer properties that are managed by [fix property/atom](#).

See [Section 10](#) of the manual for information on how to add new compute and fix styles to LAMMPS to calculate per-atom quantities which could then be output into dump files.

Restrictions:

To write gzipped dump files, you must either compile LAMMPS with the `-DLAMMPS_GZIP` option or use the styles from the COMPRESS package - see the [Making LAMMPS](#) section of the documentation.

The *atom/gz*, *cfg/gz*, *custom/gz*, and *xyz/gz* styles are part of the COMPRESS package. They are only enabled if LAMMPS was built with that package. See the [Making LAMMPS](#) section for more info.

The *atom/mpii*, *cfg/mpii*, *custom/mpii*, and *xyz/mpii* styles are part of the MPIIO package. They are only enabled if LAMMPS was built with that package. See the [Making LAMMPS](#) section for more info.

The *xtc* style is part of the MISC package. It is only enabled if LAMMPS was built with that package. See the [Making LAMMPS](#) section for more info.

Related commands:

[dump h5md](#), [dump image](#), [dump molfile](#), [dump_modify](#), [undump](#)

Default:

The defaults for the *image* and *movie* styles are listed on the [dump image](#) doc page.

dump h5md command

Syntax:

```
dump ID group-ID h5md N file.h5 args
```

- ID = user-assigned name for the dump
- group-ID = ID of the group of atoms to be imaged
- h5md = style of dump command (other styles *atom* or *cfg* or *dcd* or *xtc* or *xyz* or *local* or *custom* are discussed on the [dump](#) doc page)
- N = dump every this many timesteps
- file.h5 = name of file to write to

```
args = list of data elements to dump, with their dump "subintervals"
position options
image
velocity options
force options
species options
file_from ID: do not open a new file, re-use the already opened file from dump ID
box value = yes or no
create_group value = yes or no
author value = quoted string
```

Note that at least one element must be specified and image may only be present if position is specified first.

For the elements *position*, *velocity*, *force* and *species*, a sub-interval may be specified to write the data only every N_{element} iterations of the dump (i.e. every $N * N_{\text{element}}$ time steps). This is specified by this option directly following the element declaration:

```
every N_element
```

Examples:

```
dump h5md1 all h5md 100 dump_h5md.h5 position image
dump h5md1 all h5md 100 dump_h5md.h5 position velocity every 10
dump h5md1 all h5md 100 dump_h5md.h5 velocity author "John Doe"
```

Description:

Dump a snapshot of atom coordinates every N timesteps in the [HDF5](#) based [H5MD](#) file format ([de Buyl](#)). HDF5 files are binary, portable and self-describing. This dump style will write only one file, on the root node.

Several dumps may write to the same file, by using *file_from* and referring to a previously defined dump. Several groups may also be stored within the same file by defining several dumps. A dump that refers (via *file_from*) to an already open dump ID and that concerns another particle group must specify *create_group yes*.

LAMMPS Users Manual

Each data element is written every $N*N_element$ steps. For *image*, no subinterval is needed as it must be present at the same interval as *position*. *image* must be given after *position* in any case. The box information (edges in each dimension) is stored at the same interval than the *position* element, if present. Else it is stored every N steps.

NOTE: Because periodic boundary conditions are enforced only on timesteps when neighbor lists are rebuilt, the coordinates of an atom written to a dump file may be slightly outside the simulation box.

Use from write_dump:

It is possible to use this dump style with the [write_dump](#) command. In this case, the subintervals must not be set at all. The `write_dump` command can be used either to create a new file or to add current data to an existing dump file by using the *file_from* keyword.

Typically, the *species* data is fixed. The following two commands store the position data every 100 timesteps, with the image data, and store once the species data in the same file.

```
dump h5md1 all h5md 100 dump.h5 position image
write_dump all h5md dump.h5 file_from h5md1 species
```

Restrictions:

The number of atoms per snapshot cannot change with the h5md style. The position data is stored wrapped (box boundaries not enforced, see note above). Only orthogonal domains are currently supported. This is a limitation of the present dump h5md command and not of H5MD itself.

The *h5md* dump style is part of the USER-H5MD package. It is only enabled if LAMMPS was built with that package. See the [Making LAMMPS](#) section for more info. It also requires (i) building the ch5md library provided with LAMMPS (See the [Making LAMMPS](#) section for more info.) and (ii) having the [HDF5](#) library installed (C bindings are sufficient) on your system. The library ch5md is compiled with the h5cc wrapper provided by the HDF5 library.

dump image command

dump movie command

Syntax:

```
dump ID group-ID style N file color diameter keyword value ...
```

- ID = user-assigned name for the dump
- group-ID = ID of the group of atoms to be imaged
- style = *image* or *movie* = style of dump command (other styles *atom* or *cfg* or *dcd* or *xtc* or *xyz* or *local* or *custom* are discussed on the [dump](#) doc page)
- N = dump every this many timesteps
- file = name of file to write image to
- color = atom attribute that determines color of each atom
- diameter = atom attribute that determines size of each atom
- zero or more keyword/value pairs may be appended
- keyword = *atom* or *adiam* or *bond* or *line* or *tri* or *body* or *fix* or *size* or *view* or *center* or *up* or *zoom* or *persp* or *box* or *axes* or *subbox* or *shiny* or *ssao*

```
atom = yes/no = do or do not draw atoms
adiam size = numeric value for atom diameter (distance units)
bond values = color width = color and width of bonds
  color = atom or type or none
  width = number or atom or type or none
  number = numeric value for bond width (distance units)
line = color width
  color = type
  width = numeric value for line width (distance units)
tri = color tflag width
  color = type
  tflag = 1 for just triangle, 2 for just tri edges, 3 for both
  width = numeric value for triangle edge width (distance units)
body = color bflag1 bflag2
  color = type
  bflag1,bflag2 = 2 numeric flags to affect how bodies are drawn
fix = fixID color fflag1 fflag2
  fixID = ID of fix that generates objects to draw
  color = type
  fflag1,fflag2 = 2 numeric flags to affect how fix objects are drawn
size values = width height = size of images
  width = width of image in # of pixels
  height = height of image in # of pixels
view values = theta phi = view of simulation box
  theta = view angle from +z axis (degrees)
  phi = azimuthal view angle (degrees)
  theta or phi can be a variable (see below)
center values = flag Cx Cy Cz = center point of image
  flag = "s" for static, "d" for dynamic
  Cx,Cy,Cz = center point of image as fraction of box dimension (0.5 = center of box)
  Cx,Cy,Cz can be variables (see below)
up values = Ux Uy Uz = direction that is "up" in image
  Ux,Uy,Uz = components of up vector
  Ux,Uy,Uz can be variables (see below)
```

LAMMPS Users Manual

zoom value = *zfactor* = size that simulation box appears in image
 zfactor = scale image size by factor > 1 to enlarge, factor <1 to shrink
 zfactor can be a variable (see below)
persp value = *pfactor* = amount of "perspective" in image
 pfactor = amount of perspective (0 = none, <1 = some, > 1 = highly skewed)
 pfactor can be a variable (see below)
box values = yes/no *diam* = draw outline of simulation box
 yes/no = do or do not draw simulation box lines
 diam = diameter of box lines as fraction of shortest box length
axes values = yes/no *length* *diam* = draw xyz axes
 yes/no = do or do not draw xyz axes lines next to simulation box
 length = length of axes lines as fraction of respective box lengths
 diam = diameter of axes lines as fraction of shortest box length
subbox values = yes/no *diam* = draw outline of processor sub-domains
 yes/no = do or do not draw sub-domain lines
 diam = diameter of sub-domain lines as fraction of shortest box length
shiny value = *sfactor* = shininess of spheres and cylinders
 sfactor = shininess of spheres and cylinders from 0.0 to 1.0
ssao value = yes/no *seed* *dfactor* = SSAO depth shading
 yes/no = turn depth shading on/off
 seed = random # seed (positive integer)
 dfactor = strength of shading from 0.0 to 1.0

Examples:

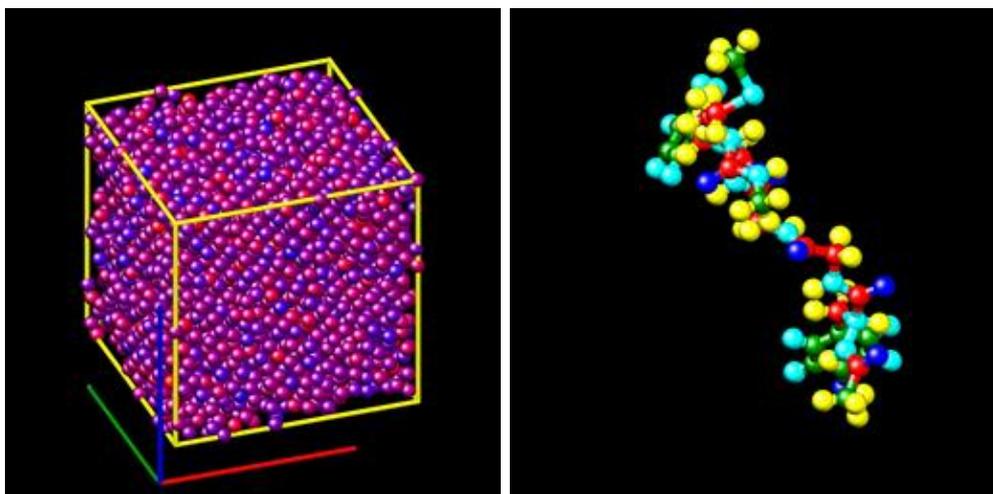

```
dump d0 all image 100 dump.*.jpg type type
dump d1 mobile image 500 snap.*.png element element ssao yes 4539 0.6
dump d2 all image 200 img-*.ppm type type zoom 2.5 adiam 1.5 size 1280 720
dump m0 all movie 1000 movie.mpg type type size 640 480
dump m1 all movie 1000 movie.avi type type size 640 480
dump m2 all movie 100 movie.m4v type type zoom 1.8 adiam v_value size 1280 720
```

Description:

Dump a high-quality rendered image of the atom configuration every N timesteps and save the images either as a sequence of JPEG or PNG or PPM files, or as a single movie file. The options for this command as well as the [dump_modify](#) command control what is included in the image or movie and how it appears. A series of such images can easily be manually converted into an animated movie of your simulation or the process can be automated without writing the intermediate files using the `dump movie` style; see further details below. Other dump styles store snapshots of numerical data associated with atoms in various formats, as discussed on the [dump](#) doc page.

Note that a set of images or a movie can be made after a simulation has been run, using the [rerun](#) command to read snapshots from an existing dump file, and using these dump commands in the rerun script to generate the images/movie.

Here are two sample images, rendered as 1024x1024 JPEG files. Click to see the full-size images:

Only atoms in the specified group are rendered in the image. The [dump_modify region](#) and [thresh](#) commands can also alter what atoms are included in the image.

The filename suffix determines whether a JPEG, PNG, or PPM file is created with the *image* dump style. If the suffix is ".jpg" or ".jpeg", then a JPEG format file is created, if the suffix is ".png", then a PNG format is created, else a PPM (aka NETPBM) format file is created. The JPEG and PNG files are binary; PPM has a text mode header followed by binary data. JPEG images have lossy compression; PNG has lossless compression; and PPM files are uncompressed but can be compressed with gzip, if LAMMPS has been compiled with -DLAMMPS_GZIP and a ".gz" suffix is used.

Similarly, the format of the resulting movie is chosen with the *movie* dump style. This is handled by the underlying FFmpeg converter and thus details have to be looked up in the FFmpeg documentation. Typical examples are: .avi, .mpg, .m4v, .mp4, .mkv, .flv, .mov, .gif. Additional settings of the movie compression like bitrate and framerate can be set using the [dump_modify](#) command.

To write out JPEG and PNG format files, you must build LAMMPS with support for the corresponding JPEG or PNG library. To convert images into movies, LAMMPS has to be compiled with the -DLAMMPS_FFMPEG flag. See [this section](#) of the manual for instructions on how to do this.

NOTE: Because periodic boundary conditions are enforced only on timesteps when neighbor lists are rebuilt, the coordinates of an atom in the image may be slightly outside the simulation box.

Dumps are performed on timesteps that are a multiple of N (including timestep 0) and on the last timestep of a minimization if the minimization converges. Note that this means a dump will not be performed on the initial timestep after the dump command is invoked, if the current timestep is not a multiple of N. This behavior can be changed via the [dump_modify first](#) command, which can be useful if the dump command is invoked after a minimization ended on an arbitrary timestep. N can be changed between runs by using the [dump_modify every](#) command.

Dump *image* filenames must contain a wildcard character "*", so that one image file per snapshot is written. The "*" character is replaced with the timestep value. For example, tmp.dump.*.jpg becomes tmp.dump.0.jpg, tmp.dump.10000.jpg,

LAMMPS Users Manual

tmp.dump.20000.jpg, etc. Note that the [dump_modify pad](#) command can be used to insure all timestep numbers are the same length (e.g. 00010), which can make it easier to convert a series of images into a movie in the correct ordering.

Dump *movie* filenames on the other hand, must not have any wildcard character since only one file combining all images into a single movie will be written by the movie encoder.

The *color* and *diameter* settings determine the color and size of atoms rendered in the image. They can be any atom attribute defined for the [dump custom](#) command, including *type* and *element*. This includes per-atom quantities calculated by a [compute](#), [fix](#), or [variable](#), which are prefixed by "c_", "f_", or "v_" respectively. Note that the *diameter* setting can be overridden with a numeric value applied to all atoms by the optional *adiam* keyword.

If *type* is specified for the *color* setting, then the color of each atom is determined by its atom type. By default the mapping of types to colors is as follows:

- type 1 = red
- type 2 = green
- type 3 = blue
- type 4 = yellow
- type 5 = aqua
- type 6 = cyan

and repeats itself for types > 6. This mapping can be changed by the [dump_modify acolor](#) command.

If *type* is specified for the *diameter* setting then the diameter of each atom is determined by its atom type. By default all types have diameter 1.0. This mapping can be changed by the [dump_modify adiam](#) command.

If *element* is specified for the *color* and/or *diameter* setting, then the color and/or diameter of each atom is determined by which element it is, which in turn is specified by the element-to-type mapping specified by the "dump_modify element" command. By default every atom type is C (carbon). Every element has a color and diameter associated with it, which is the same as the colors and sizes used by the [AtomEye](#) visualization package.

If other atom attributes are used for the *color* or *diameter* settings, they are interpreted in the following way.

If "vx", for example, is used as the *color* setting, then the color of the atom will depend on the x-component of its velocity. The association of a per-atom value with a specific color is determined by a "color map", which can be specified via the [dump_modify](#) command. The basic idea is that the atom-attribute will be within a range of values, and every value within the range is mapped to a specific color. Depending on how the color map is defined, that mapping can take place via interpolation so that a value of -3.2 is halfway between "red" and "blue", or discretely so that the value of -3.2 is "orange".

LAMMPS Users Manual

If "vx", for example, is used as the *diameter* setting, then the atom will be rendered using the x-component of its velocity as the diameter. If the per-atom value ≤ 0.0 , then the atom will not be drawn. Note that finite-size spherical particles, as defined by [atom_style sphere](#) define a per-particle radius or diameter, which can be used as the *diameter* setting.

The various keywords listed above control how the image is rendered. As listed below, all of the keywords have defaults, most of which you will likely not need to change. The [dump modify](#) also has options specific to the dump image style, particularly for assigning colors to atoms, bonds, and other image features.

The *atom* keyword allow you to turn off the drawing of all atoms, if the specified value is *no*. Note that this will not turn off the drawing of particles that are represented as lines, triangles, or bodies, as discussed below. These particles can be drawn separately if the *line*, *tri*, or *body* keywords are used.

The *adiam* keyword allows you to override the *diameter* setting to set a single numeric *size*. All atoms will be drawn with that diameter, e.g. 1.5, which is in whatever distance [units](#) the input script defines, e.g. Angstroms.

The *bond* keyword allows to you to alter how bonds are drawn. A bond is only drawn if both atoms in the bond are being drawn due to being in the specified group and due to other selection criteria (e.g. region, threshold settings of the [dump_modify](#) command). By default, bonds are drawn if they are defined in the input data file as read by the [read_data](#) command. Using *none* for both the bond *color* and *width* value will turn off the drawing of all bonds.

If *atom* is specified for the bond *color* value, then each bond is drawn in 2 halves, with the color of each half being the color of the atom at that end of the bond.

If *type* is specified for the *color* value, then the color of each bond is determined by its bond type. By default the mapping of bond types to colors is as follows:

- type 1 = red
- type 2 = green
- type 3 = blue
- type 4 = yellow
- type 5 = aqua
- type 6 = cyan

and repeats itself for bond types > 6 . This mapping can be changed by the [dump_modify bcolor](#) command.

The bond *width* value can be a numeric value or *atom* or *type* (or *none* as indicated above).

If a numeric value is specified, then all bonds will be drawn as cylinders with that diameter, e.g. 1.0, which is in whatever distance [units](#) the input script defines, e.g. Angstroms.

LAMMPS Users Manual

If *atom* is specified for the *width* value, then each bond will be drawn with a width corresponding to the minimum diameter of the 2 atoms in the bond.

If *type* is specified for the *width* value then the diameter of each bond is determined by its bond type. By default all types have diameter 0.5. This mapping can be changed by the [dump_modify bdiam](#) command.

The *line* keyword can be used when [atom_style line](#) is used to define particles as line segments, and will draw them as lines. If this keyword is not used, such particles will be drawn as spheres, the same as if they were regular atoms. The only setting currently allowed for the *color* value is *type*, which will color the lines according to the atom type of the particle. By default the mapping of types to colors is as follows:

- type 1 = red
- type 2 = green
- type 3 = blue
- type 4 = yellow
- type 5 = aqua
- type 6 = cyan

and repeats itself for types > 6. There is not yet an option to change this via the [dump_modify](#) command.

The *line width* can only be a numeric value, which specifies that all lines will be drawn as cylinders with that diameter, e.g. 1.0, which is in whatever distance [units](#) the input script defines, e.g. Angstroms.

The *tri* keyword can be used when [atom_style tri](#) is used to define particles as triangles, and will draw them as triangles or edges (3 lines) or both, depending on the setting for *tflag*. If edges are drawn, the *width* setting determines the diameters of the line segments. If this keyword is not used, triangle particles will be drawn as spheres, the same as if they were regular atoms. The only setting currently allowed for the *color* value is *type*, which will color the triangles according to the atom type of the particle. By default the mapping of types to colors is as follows:

- type 1 = red
- type 2 = green
- type 3 = blue
- type 4 = yellow
- type 5 = aqua
- type 6 = cyan

and repeats itself for types > 6. There is not yet an option to change this via the [dump_modify](#) command.

The *body* keyword can be used when [atom_style body](#) is used to define body particles with internal state (e.g. sub-particles), and will draw them in a manner specific to the body style. If this keyword is not used, such particles will be drawn as spheres, the same as if they were regular atoms.

LAMMPS Users Manual

The [body](#) doc page describes the body styles LAMMPS currently supports, and provides more details as to the kind of body particles they represent and how they are drawn by this dump image command. For all the body styles, individual atoms can be either a body particle or a usual point (non-body) particle. Non-body particles will be drawn the same way they would be as a regular atom. The *bflag1* and *bflag2* settings are numerical values which are passed to the body style to affect how the drawing of a body particle is done. See the [body](#) doc page for a description of what these parameters mean for each body style.

The only setting currently allowed for the *color* value is *type*, which will color the body particles according to the atom type of the particle. By default the mapping of types to colors is as follows:

- type 1 = red
- type 2 = green
- type 3 = blue
- type 4 = yellow
- type 5 = aqua
- type 6 = cyan

and repeats itself for types > 6. There is not yet an option to change this via the [dump_modify](#) command.

The *fix* keyword can be used with a [fix](#) that produces objects to be drawn. An example is the [fix surface/global](#) command which can draw lines or triangles for 2d/3d simulations.

NOTE: Aug 2016 - The [fix surface/global](#) command is not yet added to LAMMPS.

The *fflag1* and *fflag2* settings are numerical values which are passed to the *fix* to affect how the drawing of its objects is done. See the individual *fix* doc page for a description of what these parameters mean for a particular *fix*.

The only setting currently allowed for the *color* value is *type*, which will color the *fix* objects according to their type. By default the mapping of types to colors is as follows:

- type 1 = red
- type 2 = green
- type 3 = blue
- type 4 = yellow
- type 5 = aqua
- type 6 = cyan

and repeats itself for types > 6. There is not yet an option to change this via the [dump_modify](#) command.

The *size* keyword sets the width and height of the created images, i.e. the number of pixels in each direction.

LAMMPS Users Manual

The *view*, *center*, *up*, *zoom*, and *persp* values determine how 3d simulation space is mapped to the 2d plane of the image. Basically they control how the simulation box appears in the image.

All of the *view*, *center*, *up*, *zoom*, and *persp* values can be specified as numeric quantities, whose meaning is explained below. Any of them can also be specified as an [equal-style variable](#), by using `v_name` as the value, where "name" is the variable name. In this case the variable will be evaluated on the timestep each image is created to create a new value. If the equal-style variable is time-dependent, this is a means of changing the way the simulation box appears from image to image, effectively doing a pan or fly-by view of your simulation.

The *view* keyword determines the viewpoint from which the simulation box is viewed, looking towards the *center* point. The *theta* value is the vertical angle from the +z axis, and must be an angle from 0 to 180 degrees. The *phi* value is an azimuthal angle around the z axis and can be positive or negative. A value of 0.0 is a view along the +x axis, towards the *center* point. If *theta* or *phi* are specified via variables, then the variable values should be in degrees.

The *center* keyword determines the point in simulation space that will be at the center of the image. *Cx*, *Cy*, and *Cz* are specified as fractions of the box dimensions, so that (0.5,0.5,0.5) is the center of the simulation box. These values do not have to be between 0.0 and 1.0, if you want the simulation box to be offset from the center of the image. Note, however, that if you choose strange values for *Cx*, *Cy*, or *Cz* you may get a blank image. Internally, *Cx*, *Cy*, and *Cz* are converted into a point in simulation space. If *flag* is set to "s" for static, then this conversion is done once, at the time the dump command is issued. If *flag* is set to "d" for dynamic then the conversion is performed every time a new image is created. If the box size or shape is changing, this will adjust the center point in simulation space.

The *up* keyword determines what direction in simulation space will be "up" in the image. Internally it is stored as a vector that is in the plane perpendicular to the view vector implied by the *theta* and *phi* values, and which is also in the plane defined by the view vector and user-specified up vector. Thus this internal vector is computed from the user-specified *up* vector as

```
up_internal = view cross (up cross view)
```

This means the only restriction on the specified *up* vector is that it cannot be parallel to the *view* vector, implied by the *theta* and *phi* values.

The *zoom* keyword scales the size of the simulation box as it appears in the image. The default *zfactor* value of 1 should display an image mostly filled by the atoms in the simulation box. A *zfactor* > 1 will make the simulation box larger; a *zfactor* < 1 will make it smaller. *Zfactor* must be a value > 0.0.

The *persp* keyword determines how much depth perspective is present in the image. Depth perspective makes lines that are parallel in simulation space appear non-parallel in the image. A *pfactor* value of 0.0 means that parallel lines will meet at infinity (1.0/pfactor), which is an orthographic rendering with no perspective. A *pfactor* value between 0.0 and 1.0 will introduce more perspective. A *pfactor* value >

LAMMPS Users Manual

1 will create a highly skewed image with a large amount of perspective.

NOTE: The *persp* keyword is not yet supported as an option.

The *box* keyword determines if and how the simulation box boundaries are rendered as thin cylinders in the image. If *no* is set, then the box boundaries are not drawn and the *diam* setting is ignored. If *yes* is set, the 12 edges of the box are drawn, with a diameter that is a fraction of the shortest box length in *x,y,z* (for 3d) or *x,y* (for 2d). The color of the box boundaries can be set with the `dump_modify boxcolor` command.

The *axes* keyword determines if and how the coordinate axes are rendered as thin cylinders in the image. If *no* is set, then the axes are not drawn and the *length* and *diam* settings are ignored. If *yes* is set, 3 thin cylinders are drawn to represent the *x,y,z* axes in colors red,green,blue. The origin of these cylinders will be offset from the lower left corner of the box by 10%. The *length* setting determines how long the cylinders will be as a fraction of the respective box lengths. The *diam* setting determines their thickness as a fraction of the shortest box length in *x,y,z* (for 3d) or *x,y* (for 2d).

The *subbox* keyword determines if and how processor sub-domain boundaries are rendered as thin cylinders in the image. If *no* is set (default), then the sub-domain boundaries are not drawn and the *diam* setting is ignored. If *yes* is set, the 12 edges of each processor sub-domain are drawn, with a diameter that is a fraction of the shortest box length in *x,y,z* (for 3d) or *x,y* (for 2d). The color of the sub-domain boundaries can be set with the `dump_modify boxcolor` command.

The *shiny* keyword determines how shiny the objects rendered in the image will appear. The *sfactor* value must be a value $0.0 \leq sfactor \leq 1.0$, where *sfactor* = 1 is a highly reflective surface and *sfactor* = 0 is a rough non-shiny surface.

The *ssao* keyword turns on/off a screen space ambient occlusion (SSAO) model for depth shading. If *yes* is set, then atoms further away from the viewer are darkened via a randomized process, which is perceived as depth. The calculation of this effect can increase the cost of computing the image by roughly 2x. The strength of the effect can be scaled by the *dfactor* parameter. If *no* is set, no depth shading is performed.

A series of JPEG, PNG, or PPM images can be converted into a movie file and then played as a movie using commonly available tools. Using `dump style movie` automates this step and avoids the intermediate step of writing (many) image snapshot file. But LAMMPS has to be compiled with `-DLAMMPS_FFmpeg` and an FFmpeg executable have to be installed.

To manually convert JPEG, PNG or PPM files into an animated GIF or MPEG or other movie file you can use:

- a) Use the ImageMagick convert program.

```
% convert *.jpg foo.gif
% convert -loop 1 *.ppm foo.mpg
```

LAMMPS Users Manual

Animated GIF files from ImageMagick are unoptimized. You can use a program like gifsicle to optimize and massively shrink them. MPEG files created by ImageMagick are in MPEG-1 format with rather inefficient compression and low quality.

- b) Use QuickTime.

Select "Open Image Sequence" under the File menu Load the images into QuickTime to animate them Select "Export" under the File menu Save the movie as a QuickTime movie (*.mov) or in another format. QuickTime can generate very high quality and efficiently compressed movie files. Some of the supported formats require to buy a license and some are not readable on all platforms until specific runtime libraries are installed.

- c) Use FFmpeg

FFmpeg is a command line tool that is available on many platforms and allows extremely flexible encoding and decoding of movies.

```
cat snap.*.jpg | ffmpeg -y -f image2pipe -c:v mjpeg -i - -b:v 2000k movie.m4v
cat snap.*.ppm | ffmpeg -y -f image2pipe -c:v ppm -i - -b:v 2400k movie.avi
```

Frontends for FFmpeg exist for multiple platforms. For more information see the [FFmpeg homepage](#)

Play the movie:

- a) Use your browser to view an animated GIF movie.

Select "Open File" under the File menu Load the animated GIF file

- b) Use the freely available mplayer or ffplay tool to view a movie. Both are available for multiple OSes and support a large variety of file formats and decoders.

```
% mplayer foo.mpg
% ffplay bar.avi
```

- c) Use the [Pizza.py animate tool](#), which works directly on a series of image files.

```
a = animate("foo*.jpg")
```

- d) QuickTime and other Windows- or MacOS-based media players can obviously play movie files directly. Similarly for corresponding tools bundled with Linux desktop environments. However, due to licensing issues with some file formats, the formats may require installing additional libraries, purchasing a license, or may not be supported.
-

See [Section 10](#) of the manual for information on how to add new compute and fix styles to LAMMPS to calculate per-atom quantities which could then be output into dump files.

Restrictions:

To write JPEG images, you must use the `-DLAMMPS_JPEG` switch when building LAMMPS and link with a JPEG library. To write PNG images, you must use the

LAMMPS Users Manual

-DLAMMPS_PNG switch when building LAMMPS and link with a PNG library.

To write *movie* dumps, you must use the -DLAMMPS_FFMPEG switch when building LAMMPS and have the FFmpeg executable available on the machine where LAMMPS is being run. Typically it's name is lowercase, i.e. ffmpeg.

See the [Making LAMMPS](#) section of the documentation for details on how to compile with optional switches.

Note that since FFmpeg is run as an external program via a pipe, LAMMPS has limited control over its execution and no knowledge about errors and warnings printed by it. Those warnings and error messages will be printed to the screen only. Due to the way image data is communicated to FFmpeg, it will often print the message

```
pipe:: Input/output error
```

which can be safely ignored. Other warnings and errors have to be addressed according to the FFmpeg documentation. One known issue is that certain movie file formats (e.g. MPEG level 1 and 2 format streams) have video bandwidth limits that can be crossed when rendering too large of image sizes. Typical warnings look like this:

```
[mpeg @ 0x98b5e0] packet too large, ignoring buffer limits to mux it
[mpeg @ 0x98b5e0] buffer underflow st=0 bufi=281407 size=285018
[mpeg @ 0x98b5e0] buffer underflow st=0 bufi=283448 size=285018
```

In this case it is recommended to either reduce the size of the image or encode in a different format that is also supported by your copy of FFmpeg, and which does not have this limitation (e.g. .avi, .mkv, mp4).

Related commands:

[dump](#), [dump_modify](#), [undump](#)

Default:

The defaults for the keywords are as follows:

- `adiam` = not specified (use diameter setting)
- `atom` = yes
- `bond` = none none (if no bonds in system)
- `bond` = atom 0.5 (if bonds in system)
- `size` = 512 512
- `view` = 60 30 (for 3d)
- `view` = 0 0 (for 2d)
- `center` = s 0.5 0.5 0.5
- `up` = 0 0 1 (for 3d)
- `up` = 0 1 0 (for 2d)
- `zoom` = 1.0
- `persp` = 0.0

LAMMPS Users Manual

- box = yes 0.02
- axes = no 0.0 0.0
- subbox no 0.0
- shiny = 1.0
- ssao = no

dump_modify command

Syntax:

dump_modify dump-ID keyword values ...

- dump-ID = ID of dump to modify
- one or more keyword/value pairs may be appended
- these keywords apply to various dump styles
- keyword = *append* or *at* or *buffer* or *element* or *every* or *fileper* or *first* or *flush* or *format* or *image* or *label* or *nfile* or *pad* or *precision* or *region* or *scale* or *sort* or *thresh* or *unwrap*

append arg = *yes* or *no*

at arg = N

N = index of frame written upon first dump

buffer arg = *yes* or *no*

element args = E1 E2 ... EN, where N = # of atom types

E1,...,EN = element name, e.g. C or Fe or Ga

every arg = N

N = dump every this many timesteps

N can be a variable (see below)

fileper arg = Np

Np = write one file for every this many processors

first arg = *yes* or *no*

format args = *line* string, *int* string, *float* string, M string, or *none*

string = C-style format string

M = integer from 1 to N, where N = # of per-atom quantities being output

flush arg = *yes* or *no*

image arg = *yes* or *no*

label arg = string

string = character string (e.g. BONDS) to use in header of dump local file

nfile arg = Nf

Nf = write this many files, one from each of Nf processors

pad arg = Nchar = # of characters to convert timestep to

pbcs arg = *yes* or *no* = remap atoms via periodic boundary conditions

precision arg = power-of-10 value from 10 to 1000000

region arg = region-ID or "none"

scale arg = *yes* or *no*

sfactor arg = coordinate scaling factor (> 0.0)

thermo arg = *yes* or *no*

tfactor arg = time scaling factor (> 0.0)

sort arg = *off* or *id* or N or -N

off = no sorting of per-atom lines within a snapshot

id = sort per-atom lines by atom ID

N = sort per-atom lines in ascending order by the Nth column

-N = sort per-atom lines in descending order by the Nth column

thresh args = attribute operator value

attribute = same attributes (x,fy,etotal,sxx,etc) used by dump custom style

operator = "

- these keywords apply only to the *image* and *movie* styles
- keyword = *acolor* or *adiam* or *amap* or *backcolor* or *bcolor* or *bdiam* or *boxcolor* or *color* or *bitrate* or *framerate*

acolor args = type color

LAMMPS Users Manual

type = atom type or range of types (see below)
color = name of color or color1/color2/...

adiam args = type diam
type = atom type or range of types (see below)
diam = diameter of atoms of that type (distance units)

amap args = lo hi style delta N entry1 entry2 ... entryN
lo = number or *min* = lower bound of range of color map
hi = number or *max* = upper bound of range of color map
style = 2 letters = "c" or "d" or "s" plus "a" or "f"
"c" for continuous
"d" for discrete
"s" for sequential
"a" for absolute
"f" for fractional
delta = binsize (only used for style "s", otherwise ignored)
binsize = range is divided into bins of this width
N = # of subsequent entries
entry = value color (for continuous style)
value = number or *min* or *max* = single value within range
color = name of color used for that value
entry = lo hi color (for discrete style)
lo/hi = number or *min* or *max* = lower/upper bound of subset of range
color = name of color used for that subset of values
entry = color (for sequential style)
color = name of color used for a bin of values

backcolor arg = color
color = name of color for background

bcolor args = type color
type = bond type or range of types (see below)
color = name of color or color1/color2/...

bdiam args = type diam
type = bond type or range of types (see below)
diam = diameter of bonds of that type (distance units)

boxcolor arg = color
color = name of color for simulation box lines and processor sub-domain lines

color args = name R G B
name = name of color
R,G,B = red/green/blue numeric values from 0.0 to 1.0

bitrate arg = rate
rate = target bitrate for movie in kbps

framerate arg = fps
fps = frames per second for movie

Examples:

```
dump_modify 1 format line "%d %d %20.15g %g %g" scale yes
dump_modify 1 format float %20.15g scale yes
dump_modify myDump image yes scale no flush yes
dump_modify 1 region mySphere thresh x <0.0 thresh epair >= 3.2
dump_modify xtcdump precision 10000 sfactor 0.1
dump_modify 1 every 1000 nfile 20
dump_modify 1 every v_myVar
dump_modify 1 amap min max cf 0.0 3 min green 0.5 yellow max blue boxcolor red
```

Description:

Modify the parameters of a previously defined dump command. Not all parameters are relevant to all dump styles.

LAMMPS Users Manual

As explained on the [dump](#) doc page, the *atom/mpiio*, *custom/mpiio*, and *xyz/mpiio* dump styles are identical in command syntax and in the format of the dump files they create, to the corresponding styles without "mpiio", except the single dump file they produce is written in parallel via the MPI-IO library. Thus if a `dump_modify` option below is valid for the *atom* style, it is also valid for the *atom/mpiio* style, and similarly for the other styles which allow for use of MPI-IO.

These keywords apply to various dump styles, including the [dump image](#) and [dump movie](#) styles. The description gives details.

The *append* keyword applies to all dump styles except *cfg* and *xtc* and *dcd*. It also applies only to text output files, not to binary or gzipped or image/movie files. If specified as *yes*, then dump snapshots are appended to the end of an existing dump file. If specified as *no*, then a new dump file will be created which will overwrite an existing file with the same name.

The *at* keyword only applies to the *netcdf* dump style. It can only be used if the *append yes* keyword is also used. The *N* argument is the index of which frame to append to. A negative value can be specified for *N*, which means a frame counted from the end of the file. The *at* keyword can only be used if the `dump_modify` command is before the first command that causes dump snapshots to be output, e.g. a [run](#) or [minimize](#) command. Once the dump file has been opened, this keyword has no further effect.

The *buffer* keyword applies only to dump styles *atom*, *cfg*, *custom*, *local*, and *xyz*. It also applies only to text output files, not to binary or gzipped files. If specified as *yes*, which is the default, then each processor writes its output into an internal text buffer, which is then sent to the processor(s) which perform file writes, and written by those processor(s) as one large chunk of text. If specified as *no*, each processor sends its per-atom data in binary format to the processor(s) which perform file writes, and those processor(s) format and write it line by line into the output file.

The buffering mode is typically faster since each processor does the relatively expensive task of formatting the output for its own atoms. However it requires about twice the memory (per processor) for the extra buffering.

The *element* keyword applies only to the dump *cfg*, *xyz*, and *image* styles. It associates element names (e.g. H, C, Fe) with LAMMPS atom types. See the list of element names at the bottom of this page.

In the case of dump *cfg*, this allows the [AtomEye](#) visualization package to read the dump file and render atoms with the appropriate size and color.

In the case of dump *image*, the output images will follow the same [AtomEye](#) convention. An element name is specified for each atom type (1 to Ntype) in the simulation. The same element name can be given to multiple atom types.

In the case of *xyz* format dumps, there are no restrictions to what label can be used as an element name. Any whitespace separated text will be accepted.

LAMMPS Users Manual

The *every* keyword changes the dump frequency originally specified by the `dump` command to a new value. The *every* keyword can be specified in one of two ways. It can be a numeric value in which case it must be > 0 . Or it can be an [equal-style variable](#), which should be specified as `v_name`, where `name` is the variable name.

In this case, the variable is evaluated at the beginning of a run to determine the next timestep at which a dump snapshot will be written out. On that timestep the variable will be evaluated again to determine the next timestep, etc. Thus the variable should return timestep values. See the `stagger()` and `logfreq()` and `stride()` math functions for [equal-style variables](#), as examples of useful functions to use in this context. Other similar math functions could easily be added as options for [equal-style variables](#). Also see the `next()` function, which allows use of a file-style variable which reads successive values from a file, each time the variable is evaluated. Used with the *every* keyword, if the file contains a list of ascending timesteps, you can output snapshots whenever you wish.

Note that when using the variable option with the *every* keyword, you need to use the *first* option if you want an initial snapshot written to the dump file. The *every* keyword cannot be used with the dump *dcd* style.

For example, the following commands will write snapshots at timesteps 0,10,20,30,100,200,300,1000,2000,etc:

```
variable      s equal logfreq(10,3,10)
dump          1 all atom 100 tmp.dump
dump_modify  1 every v_s first yes
```

The following commands would write snapshots at the timesteps listed in file `tmp.times`:

```
variable      f file tmp.times
variable      s equal next(f)
dump          1 all atom 100 tmp.dump
dump_modify  1 every v_s
```

NOTE: When using a file-style variable with the *every* keyword, the file of timesteps must list a first timestep that is beyond the current timestep (e.g. it cannot be 0). And it must list one or more timesteps beyond the length of the run you perform. This is because the dump command will generate an error if the next timestep it reads from the file is not a value greater than the current timestep. Thus if you wanted output on steps 0,15,100 of a 100-timestep run, the file should contain the values 15,100,101 and you should also use the `dump_modify first` command. Any final value > 100 could be used in place of 101.

The *first* keyword determines whether a dump snapshot is written on the very first timestep after the dump command is invoked. This will always occur if the current timestep is a multiple of `N`, the frequency specified in the `dump` command, including timestep 0. But if this is not the case, a dump snapshot will only be written if the setting of this keyword is *yes*. If it is *no*, which is the default, then it will not be written.

LAMMPS Users Manual

The *flush* keyword determines whether a flush operation is invoked after a dump snapshot is written to the dump file. A flush insures the output in that file is current (no buffering by the OS), even if LAMMPS halts before the simulation completes. Flushes cannot be performed with dump style *xtc*.

The *format* keyword can be used to change the default numeric format output by the text-based dump styles: *atom*, *custom*, *cfg*, and *xyz* styles, and their MPIIO variants. Only the *line* or *none* options can be used with the *atom* and *xyz* styles.

All the specified format strings are C-style formats, e.g. as used by the C/C++ `printf()` command. The *line* keyword takes a single argument which is the format string for an entire line of output for each atom (do not include a trailing "\n"), with N fields, which you must enclose in quotes if it is more than one field. The *int* and *float* keywords take a single format argument and are applied to all integer or floating-point quantities output. The setting for *M string* also takes a single format argument which is used for the Mth value output in each line, e.g. the 5th column is output in high precision for "format 5 %20.15g".

NOTE: When using the *line* keyword for the *cfg* style, the first two fields (atom ID and type) are not actually written into the CFG file, however you must include formats for them in the format string.

The *format* keyword can be used multiple times. The precedence is that for each value in a line of output, the *M* format (if specified) is used, else the *int* or *float* setting (if specified) is used, else the *line* setting (if specified) for that value is used, else the default setting is used. A setting of *none* clears all previous settings, reverting all values to their default format.

NOTE: Atom and molecule IDs are stored internally as 4-byte or 8-byte signed integers, depending on how LAMMPS was compiled. When specifying the *format int* option you can use a "%d"-style format identifier in the format string and LAMMPS will convert this to the corresponding 8-byte form if it is needed when outputting those values. However, when specifying the *line* option or *format M string* option for those values, you should specify a format string appropriate for an 8-byte signed integer, e.g. one with "%ld", if LAMMPS was compiled with the `-DLAMMPS_BIGBIG` option for 8-byte IDs.

NOTE: Any value written to a text-based dump file that is a per-atom quantity calculated by a `compute` or `fix` is stored internally as a floating-point value. If the value is actually an integer and you wish it to appear in the text dump file as a (large) integer, then you need to use an appropriate format. For example, these commands:

```
compute      1 all property/local batom1 batom2
dump         1 all local 100 tmp.bonds index c_1[1] c_1[2]
dump_modify 1 format "%d %0.0f %0.0f"
```

will output the two atom IDs for atoms in each bond as integers. If the `dump_modify` command were omitted, they would appear as floating-point values, assuming they were large integers (more than 6 digits). The "index" keyword should use the "%d" format since it is not generated by a `compute` or `fix`, and is stored internally as an integer.

The *fileper* keyword is documented below with the *nfile* keyword.

The *image* keyword applies only to the dump *atom* style. If the image value is *yes*, 3 flags are appended to each atom's coords which are the absolute box image of the atom in each dimension. For example, an x image flag of -2 with a normalized coord of 0.5 means the atom is in the center of the box, but has passed thru the box boundary 2 times and is really 2 box lengths to the left of its current coordinate. Note that for dump style *custom* these various values can be printed in the dump file by using the appropriate atom attributes in the dump command itself.

The *label* keyword applies only to the dump *local* style. When it writes local information, such as bond or angle topology to a dump file, it will use the specified *label* to format the header. By default this includes 2 lines:

```
ITEM: NUMBER OF ENTRIES  
ITEM: ENTRIES ...
```

The word "ENTRIES" will be replaced with the string specified, e.g. BONDS or ANGLES.

The *nfile* or *fileper* keywords can be used in conjunction with the "%" wildcard character in the specified dump file name, for all dump styles except the *dcd*, *image*, *movie*, *xtc*, and *xyz* styles (for which "%" is not allowed). As explained on the [dump](#) command doc page, the "%" character causes the dump file to be written in pieces, one piece for each of P processors. By default P = the number of processors the simulation is running on. The *nfile* or *fileper* keyword can be used to set P to a smaller value, which can be more efficient when running on a large number of processors.

The *nfile* keyword sets P to the specified Nf value. For example, if Nf = 4, and the simulation is running on 100 processors, 4 files will be written, by processors 0,25,50,75. Each will collect information from itself and the next 24 processors and write it to a dump file.

For the *fileper* keyword, the specified value of Np means write one file for every Np processors. For example, if Np = 4, every 4th processor (0,4,8,12,etc) will collect information from itself and the next 3 processors and write it to a dump file.

The *pad* keyword only applies when the dump filename is specified with a wildcard "*" character which becomes the timestep. If *pad* is 0, which is the default, the timestep is converted into a string of unpadding length, e.g. 100 or 12000 or 2000000. When *pad* is specified with *Nchar* > 0, the string is padded with leading zeroes so they are all the same length = *Nchar*. For example, pad 7 would yield 0000100, 0012000, 2000000. This can be useful so that post-processing programs can easily read the files in ascending timestep order.

The *pbz* keyword applies to all the dump styles. As explained on the [dump](#) doc page, atom coordinates in a dump file may be slightly outside the simulation box. This is because periodic boundary conditions are enforced only on timesteps when neighbor lists are rebuilt, which will not typically coincide with the timesteps dump snapshots

LAMMPS Users Manual

are written. If the setting of this keyword is set to *yes*, then all atoms will be remapped to the periodic box before the snapshot is written, then restored to their original position. If it is set to *no* they will not be. The *no* setting is the default because it requires no extra computation.

The *precision* keyword only applies to the dump *xtc* style. A specified value of N means that coordinates are stored to 1/N nanometer accuracy, e.g. for N = 1000, the coordinates are written to 1/1000 nanometer accuracy.

The *sfactor* and *tfactor* keywords only apply to the dump *xtc* style. They allow customization of the unit conversion factors used when writing to XTC files. By default they are initialized for whatever [units](#) style is being used, to write out coordinates in nanometers and time in picoseconds. I.e. for *real* units, LAMMPS defines *sfactor* = 0.1 and *tfactor* = 0.001, since the Angstroms and fmsec used by *real* units are 0.1 nm and 0.001 psec respectively. If you are using a units system with distance and time units far from nm and psec, you may wish to write XTC files with different units, since the compression algorithm used in XTC files is most effective when the typical magnitude of position data is between 10.0 and 0.1.

The *thermo* keyword (*netcdf* only) triggers writing of [thermo](#) information to the dump file alongside per-atom data. The data included in the dump file is identical to the data specified by [thermo_style](#).

The *region* keyword only applies to the dump *custom*, *cfg*, *image*, and *movie* styles. If specified, only atoms in the region will be written to the dump file or included in the image/movie. Only one region can be applied as a filter (the last one specified). See the [region](#) command for more details. Note that a region can be defined as the "inside" or "outside" of a geometric shape, and it can be the "union" or "intersection" of a series of simpler regions.

The *scale* keyword applies only to the dump *atom* style. A scale value of *yes* means atom coords are written in normalized units from 0.0 to 1.0 in each box dimension. If the simulation box is triclinic (tilted), then all atom coords will still be between 0.0 and 1.0. A value of *no* means they are written in absolute distance units (e.g. Angstroms or sigma).

The *sort* keyword determines whether lines of per-atom output in a snapshot are sorted or not. A sort value of *off* means they will typically be written in indeterminate order, either in serial or parallel. This is the case even in serial if the [atom_modify sort](#) option is turned on, which it is by default, to improve performance. A sort value of *id* means sort the output by atom ID. A sort value of N or -N means sort the output by the value in the Nth column of per-atom info in either ascending or descending order.

The dump *local* style cannot be sorted by atom ID, since there are typically multiple lines of output per atom. Some dump styles, such as *dcd* and *xtc*, require sorting by atom ID to format the output file correctly. If multiple processors are writing the dump file, via the "%" wildcard in the dump filename, then sorting cannot be performed.

LAMMPS Users Manual

NOTE: Unless it is required by the dump style, sorting dump file output requires extra overhead in terms of CPU and communication cost, as well as memory, versus unsorted output.

The *thresh* keyword only applies to the dump *custom*, *cfg*, *image*, and *movie* styles. Multiple thresholds can be specified. Specifying *none* turns off all threshold criteria. If thresholds are specified, only atoms whose attributes meet all the threshold criteria are written to the dump file or included in the image. The possible attributes that can be tested for are the same as those that can be specified in the [dump custom](#) command, with the exception of the *element* attribute, since it is not a numeric value. Note that a different attributes can be used than those output by the [dump custom](#) command. E.g. you can output the coordinates and stress of atoms whose energy is above some threshold.

If an atom-style variable is used as the attribute, then it can produce continuous numeric values or effective Boolean 0/1 values which may be useful for the comparison operator. Boolean values can be generated by variable formulas that use comparison or Boolean math operators or special functions like `gmask()` and `rmask()` and `grmask()`. See the [variable](#) command doc page for details.

The specified value must be a simple numeric value or the word LAST. If LAST is used, it refers to the value of the attribute the last time the dump command was invoked to produce a snapshot. This is a way to only dump atoms whose attribute has changed (or not changed). Three examples follow.

```
dump_modify ... thresh ix != LAST
```

This will dump atoms which have crossed the periodic x boundary of the simulation box since the last dump. (Note that atoms that crossed once and then crossed back between the two dump timesteps would not be included.)

```
region foo sphere 10 20 10 15 variable inregion atom rmask(foo) dump_modify ...  
thresh v_inregion |^ LAST
```

This will dump atoms which crossed the boundary of the spherical region since the last dump.

```
variable charge atom "(q > 0.5) || (q < -0.5)" dump_modify ... thresh v_charge |^ LAST
```

This will dump atoms whose charge has changed from an absolute value less than 1/2 to greater than 1/2 (or vice versa) since the last dump. E.g. due to reactions and subsequent charge equilibration in a reactive force field.

The choice of operators listed above are the usual comparison operators. The XOR operation (exclusive or) is also included as "|^". In this context, XOR means that if either the attribute or value is 0.0 and the other is non-zero, then the result is "true" and the threshold criterion is met. Otherwise it is not met.

The *unwrap* keyword only applies to the dump *dcd* and *xtc* styles. If set to *yes*, coordinates will be written "unwrapped" by the image flags for each atom. Unwrapped means that if the atom has passed thru a periodic boundary one or more times, the

value is printed for what the coordinate would be if it had not been wrapped back into the periodic box. Note that these coordinates may thus be far outside the box size stored with the snapshot.

These keywords apply only to the [dump image](#) and [dump movie](#) styles. Any keyword that affects an image, also affects a movie, since the movie is simply a collection of images. Some of the keywords only affect the [dump movie](#) style. The descriptions give details.

The *acolor* keyword can be used with the [dump image](#) command, when its atom color setting is *type*, to set the color that atoms of each type will be drawn in the image.

The specified *type* should be an integer from 1 to N_{types} = the number of atom types. A wildcard asterisk can be used in place of or in conjunction with the *type* argument to specify a range of atom types. This takes the form "*" or "*n" or "n*" or "m*n". If N = the number of atom types, then an asterisk with no numeric values means all types from 1 to N . A leading asterisk means all types from 1 to n (inclusive). A trailing asterisk means all types from n to N (inclusive). A middle asterisk means all types from m to n (inclusive).

The specified *color* can be a single color which is any of the 140 pre-defined colors (see below) or a color name defined by the `dump_modify color` option. Or it can be two or more colors separated by a "/" character, e.g. red/green/blue. In the former case, that color is assigned to all the specified atom types. In the latter case, the list of colors are assigned in a round-robin fashion to each of the specified atom types.

The *adiam* keyword can be used with the [dump image](#) command, when its atom diameter setting is *type*, to set the size that atoms of each type will be drawn in the image. The specified *type* should be an integer from 1 to N_{types} . As with the *acolor* keyword, a wildcard asterisk can be used as part of the *type* argument to specify a range of atom types. The specified *diam* is the size in whatever distance [units](#) the input script is using, e.g. Angstroms.

The *amap* keyword can be used with the [dump image](#) command, with its *atom* keyword, when its atom setting is an atom-attribute, to setup a color map. The color map is used to assign a specific RGB (red/green/blue) color value to an individual atom when it is drawn, based on the atom's attribute, which is a numeric value, e.g. its x-component of velocity if the atom-attribute "vx" was specified.

The basic idea of a color map is that the atom-attribute will be within a range of values, and that range is associated with a series of colors (e.g. red, blue, green). An atom's specific value (vx = -3.2) can then mapped to the series of colors (e.g. halfway between red and blue), and a specific color is determined via an interpolation procedure.

There are many possible options for the color map, enabled by the *amap* keyword. Here are the details.

LAMMPS Users Manual

The *lo* and *hi* settings determine the range of values allowed for the atom attribute. If numeric values are used for *lo* and/or *hi*, then values that are lower/higher than that value are set to the value. I.e. the range is static. If *lo* is specified as *min* or *hi* as *max* then the range is dynamic, and the lower and/or upper bound will be calculated each time an image is drawn, based on the set of atoms being visualized.

The *style* setting is two letters, such as "ca". The first letter is either "c" for continuous, "d" for discrete, or "s" for sequential. The second letter is either "a" for absolute, or "f" for fractional.

A continuous color map is one in which the color changes continuously from value to value within the range. A discrete color map is one in which discrete colors are assigned to sub-ranges of values within the range. A sequential color map is one in which discrete colors are assigned to a sequence of sub-ranges of values covering the entire range.

An absolute color map is one in which the values to which colors are assigned are specified explicitly as values within the range. A fractional color map is one in which the values to which colors are assigned are specified as a fractional portion of the range. For example if the range is from -10.0 to 10.0, and the color red is to be assigned to atoms with a value of 5.0, then for an absolute color map the number 5.0 would be used. But for a fractional map, the number 0.75 would be used since 5.0 is 3/4 of the way from -10.0 to 10.0.

The *delta* setting must be specified for all styles, but is only used for the sequential style; otherwise the value is ignored. It specifies the bin size to use within the range for assigning consecutive colors to. For example, if the range is from -10.0 to 10.0 and a *delta* of 1.0 is used, then 20 colors will be assigned to the range. The first will be from $-10.0 \leq \text{color1} < -9.0$, then 2nd from $-9.0 \leq \text{color2} < -8.0$, etc.

The *N* setting is how many entries follow. The format of the entries depends on whether the color map style is continuous, discrete or sequential. In all cases the *color* setting can be any of the 140 pre-defined colors (see below) or a color name defined by the `dump_modify color` option.

For continuous color maps, each entry has a *value* and a *color*. The *value* is either a number within the range of values or *min* or *max*. The *value* of the first entry must be *min* and the *value* of the last entry must be *max*. Any entries in between must have increasing values. Note that numeric values can be specified either as absolute numbers or as fractions (0.0 to 1.0) of the range, depending on the "a" or "f" in the style setting for the color map.

Here is how the entries are used to determine the color of an individual atom, given the value *X* of its atom attribute. *X* will fall between 2 of the entry values. The color of the atom is linearly interpolated (in each of the RGB values) between the 2 colors associated with those entries. For example, if $X = -5.0$ and the 2 surrounding entries are "red" at -10.0 and "blue" at 0.0, then the atom's color will be halfway between "red" and "blue", which happens to be "purple".

For discrete color maps, each entry has a *lo* and *hi* value and a *color*. The *lo* and *hi* settings are either numbers within the range of values or *lo* can be *min* or *hi* can be

LAMMPS Users Manual

max. The *lo* and *hi* settings of the last entry must be *min* and *max*. Other entries can have any *lo* and *hi* values and the sub-ranges of different values can overlap. Note that numeric *lo* and *hi* values can be specified either as absolute numbers or as fractions (0.0 to 1.0) of the range, depending on the "a" or "f" in the style setting for the color map.

Here is how the entries are used to determine the color of an individual atom, given the value *X* of its atom attribute. The entries are scanned from first to last. The first time that $lo \leq X \leq hi$, *X* is assigned the color associated with that entry. You can think of the last entry as assigning a default color (since it will always be matched by *X*), and the earlier entries as colors that override the default. Also note that no interpolation of a color RGB is done. All atoms will be drawn with one of the colors in the list of entries.

For sequential color maps, each entry has only a *color*. Here is how the entries are used to determine the color of an individual atom, given the value *X* of its atom attribute. The range is partitioned into *N* bins of width *binsize*. Thus *X* will fall in a specific bin from 1 to *N*, say the *M*th bin. If it falls on a boundary between 2 bins, it is considered to be in the higher of the 2 bins. Each bin is assigned a color from the *E* entries. If $E < N$, then the colors are repeated. For example if 2 entries with colors red and green are specified, then the odd numbered bins will be red and the even bins green. The color of the atom is the color of its bin. Note that the sequential color map is really a shorthand way of defining a discrete color map without having to specify where all the bin boundaries are.

Here is an example of using a sequential color map to color all the atoms in individual molecules with a different color. See the examples/pour/in.pour.2d.molecule input script for an example of how this is used.

```
variable          colors string &
                  "red green blue yellow white &
                  purple pink orange lime gray"
variable          mol atom mol%10
dump              1 all image 250 image.*.jpg v_mol type &
                  zoom 1.6 adiam 1.5
dump_modify       1 pad 5 amap 0 10 sa 1 10 ${colors}
```

In this case, 10 colors are defined, and molecule IDs are mapped to one of the colors, even if there are 1000s of molecules.

The *backcolor* sets the background color of the images. The color name can be any of the 140 pre-defined colors (see below) or a color name defined by the `dump_modify` color option.

The *bcolor* keyword can be used with the `dump image` command, with its *bond* keyword, when its color setting is *type*, to set the color that bonds of each type will be drawn in the image.

The specified *type* should be an integer from 1 to $N_{bondtypes}$ = the number of bond types. A wildcard asterisk can be used in place of or in conjunction with the *type* argument to specify a range of bond types. This takes the form "*" or "*n" or "n*" or "m*n". If *N* = the number of bond types, then an asterisk with no numeric values

LAMMPS Users Manual

means all types from 1 to N. A leading asterisk means all types from 1 to n (inclusive). A trailing asterisk means all types from n to N (inclusive). A middle asterisk means all types from m to n (inclusive).

The specified *color* can be a single color which is any of the 140 pre-defined colors (see below) or a color name defined by the `dump_modify` color option. Or it can be two or more colors separated by a "/" character, e.g. red/green/blue. In the former case, that color is assigned to all the specified bond types. In the latter case, the list of colors are assigned in a round-robin fashion to each of the specified bond types.

The *bdiam* keyword can be used with the `dump image` command, with its *bond* keyword, when its *diam* setting is *type*, to set the diameter that bonds of each type will be drawn in the image. The specified *type* should be an integer from 1 to Nbondtypes. As with the *bcolor* keyword, a wildcard asterisk can be used as part of the *type* argument to specify a range of bond types. The specified *diam* is the size in whatever distance *units* you are using, e.g. Angstroms.

The *bitrate* keyword can be used with the `dump movie` command to define the size of the resulting movie file and its quality via setting how many kbits per second are to be used for the movie file. Higher bitrates require less compression and will result in higher quality movies. The quality is also determined by the compression format and encoder. The default setting is 2000 kbit/s, which will result in average quality with older compression formats.

NOTE: Not all movie file formats supported by `dump movie` allow the bitrate to be set. If not, the setting is silently ignored.

The *boxcolor* keyword sets the color of the simulation box drawn around the atoms in each image as well as the color of processor sub-domain boundaries. See the "dump image box" command for how to specify that a box be drawn via the *box* keyword, and the sub-domain boundaries via the *subbox* keyword. The color name can be any of the 140 pre-defined colors (see below) or a color name defined by the `dump_modify` color option.

The *color* keyword allows definition of a new color name, in addition to the 140-predefined colors (see below), and associates 3 red/green/blue RGB values with that color name. The color name can then be used with any other `dump_modify` keyword that takes a color name as a value. The RGB values should each be floating point values between 0.0 and 1.0 inclusive.

When a color name is converted to RGB values, the user-defined color names are searched first, then the 140 pre-defined color names. This means you can also use the *color* keyword to overwrite one of the pre-defined color names with new RGB values.

The *framerate* keyword can be used with the `dump movie` command to define the duration of the resulting movie file. Movie files written by the `dump movie` command have a default frame rate of 24 frames per second and the images generated will be converted at that rate. Thus a sequence of 1000 dump images will result in a movie of about 42 seconds. To make a movie run longer you can either generate images more frequently or lower the frame rate. To speed a movie up, you can do the inverse. Using

LAMMPS Users Manual

a frame rate higher than 24 is not recommended, as it will result in simply dropping the rendered images. It is more efficient to dump images less frequently.

Restrictions: none

Related commands:

[dump](#), [dump image](#), [undump](#)

Default:

The option defaults are

- `append` = no
- `buffer` = yes for dump styles *atom*, *custom*, *loca*, and *xyz*
- `element` = "C" for every atom type
- `every` = whatever it was set to via the [dump](#) command
- `fileper` = # of processors
- `first` = no
- `flush` = yes
- `format` = %d and %g for each integer or floating point value
- `image` = no
- `label` = ENTRIES
- `nfile` = 1
- `pad` = 0
- `pbcb` = no
- `precision` = 1000
- `region` = none

- `bdial` = * 0.5
- `bitrate` = 2000
- `boxcolor` = yellow
- `color` = 140 color names are pre-defined as listed below
- `framerate` = 24

These are the standard 109 element names that LAMMPS pre-defines for use with the [dump image](#) and `dump_modify` commands.

- 1-10 = "H", "He", "Li", "Be", "B", "C", "N", "O", "F", "Ne"

LAMMPS Users Manual

- 11-20 = "Na", "Mg", "Al", "Si", "P", "S", "Cl", "Ar", "K", "Ca"
- 21-30 = "Sc", "Ti", "V", "Cr", "Mn", "Fe", "Co", "Ni", "Cu", "Zn"
- 31-40 = "Ga", "Ge", "As", "Se", "Br", "Kr", "Rb", "Sr", "Y", "Zr"
- 41-50 = "Nb", "Mo", "Tc", "Ru", "Rh", "Pd", "Ag", "Cd", "In", "Sn"
- 51-60 = "Sb", "Te", "I", "Xe", "Cs", "Ba", "La", "Ce", "Pr", "Nd"
- 61-70 = "Pm", "Sm", "Eu", "Gd", "Tb", "Dy", "Ho", "Er", "Tm", "Yb"
- 71-80 = "Lu", "Hf", "Ta", "W", "Re", "Os", "Ir", "Pt", "Au", "Hg"
- 81-90 = "Tl", "Pb", "Bi", "Po", "At", "Rn", "Fr", "Ra", "Ac", "Th"
- 91-100 = "Pa", "U", "Np", "Pu", "Am", "Cm", "Bk", "Cf", "Es", "Fm"
- 101-109 = "Md", "No", "Lr", "Rf", "Db", "Sg", "Bh", "Hs", "Mt"

These are the 140 colors that LAMMPS pre-defines for use with the [dump image](#) and `dump_modify` commands. Additional colors can be defined with the `dump_modify color` command. The 3 numbers listed for each name are the RGB (red/green/blue) values. Divide each value by 255 to get the equivalent 0.0 to 1.0 value.

dump molfile command

Syntax:

```
dump ID group-ID molfile N file format path
```

- ID = user-assigned name for the dump
- group-ID = ID of the group of atoms to be imaged
- molfile = style of dump command (other styles *atom* or *cfg* or *dcd* or *xtc* or *xyz* or *local* or *custom* are discussed on the [dump](#) doc page)
- N = dump every this many timesteps
- file = name of file to write to
- format = file format to be used
- path = file path with plugins (optional)

Examples:

```
dump mf1 all molfile 10 melt1.xml hoond  
dump mf2 all molfile 10 melt2-*.pdb pdb .  
dump mf3 all molfile 50 melt3.xyz xyz ./home/akohlmeier/vmd/plugins/LINUX/molfile
```

Description:

Dump a snapshot of atom coordinates and selected additional quantities to one or more files every N timesteps in one of several formats. Only information for atoms in the specified group is dumped. This specific dump style uses molfile plugins that are bundled with the [VMD](#) molecular visualization and analysis program.

Unless the filename contains a * character, the output will be written to one single file with the specified format. Otherwise there will be one file per snapshot and the * will be replaced by the time step number when the snapshot is written.

NOTE: Because periodic boundary conditions are enforced only on timesteps when neighbor lists are rebuilt, the coordinates of an atom written to a dump file may be slightly outside the simulation box.

The molfile plugin API has a few restrictions that have to be honored by this dump style: the number of atoms must not change, the atoms must be sorted, outside of the coordinates no change in atom properties (like type, mass, charge) will be recorded.

The *format* keyword determines what format is used to write out the dump. For this to work, LAMMPS must be able to find and load a compatible molfile plugin that supports this format. Settings made via the [dump_modify](#) command can alter per atom properties like element names.

The *path* keyword determines which in directories. This is a "path" like other search paths, i.e. it can contain multiple directories separated by a colon (or semi-colon on windows). This keyword is optional and default to ".", the current directory.

LAMMPS Users Manual

The *unwrap* option of the [dump_modify](#) command allows coordinates to be written "unwrapped" by the image flags for each atom. Unwrapped means that if the atom has passed through a periodic boundary one or more times, the value is printed for what the coordinate would be if it had not been wrapped back into the periodic box. Note that these coordinates may thus be far outside the box size stored with the snapshot.

Dumps are performed on timesteps that are a multiple of N (including timestep 0) and on the last timestep of a minimization if the minimization converges. Note that this means a dump will not be performed on the initial timestep after the dump command is invoked, if the current timestep is not a multiple of N. This behavior can be changed via the [dump_modify first](#) command, which can be useful if the dump command is invoked after a minimization ended on an arbitrary timestep. N can be changed between runs by using the [dump_modify every](#) command. The [dump_modify every](#) command also allows a variable to be used to determine the sequence of timesteps on which dump files are written.

Restrictions:

The *molfile* dump style is part of the USER-MOLFILE package. It is only enabled if LAMMPS was built with that package. See the [Making LAMMPS](#) section for more info.

Molfile plugins provide a consistent programming interface to read and write file formats commonly used in molecular simulations. The USER-MOLFILE package only provides the interface code, not the plugins. These can be obtained from a VMD installation which has to match the platform that you are using to compile LAMMPS for. By adding plugins to VMD, support for new file formats can be added to LAMMPS (or VMD or other programs that use them) without having to recompile the application itself. The plugins are installed in the directory: `/plugins/molfile`

NOTE: while the programming interface (API) to the plugins is backward compatible, the binary interface (ABI) has been changing over time, so it is necessary to compile this package with the plugin header files from VMD that match the binary plugins. These header files in the directory: `/plugins/include` For convenience, the package ships with a set of header files that are compatible with VMD 1.9 and 1.9.1 (June 2012)

Related commands:

[dump](#), [dump_modify](#), [undump](#)

Default:

The default path is ".". All other properties have to be specified.

dump netcdf command

dump netcdf/mpiio command

Syntax:

```
dump ID group-ID netcdf N file args
dump ID group-ID netcdf/mpiio N file args
```

- ID = user-assigned name for the dump
- group-ID = ID of the group of atoms to be imaged
- *netcdf* or *netcdf/mpiio* = style of dump command (other styles *atom* or *cfg* or *dcd* or *xtc* or *xyz* or *local* or *custom* are discussed on the [dump](#) doc page)
- N = dump every this many timesteps
- file = name of file to write dump info to
- args = list of atom attributes, same as for [dump_style custom](#)

Examples:

```
dump 1 all netcdf 100 traj.nc type x y z vx vy vz
dump_modify 1 append yes at -1 thermo yes
dump 1 all netcdf/mpiio 1000 traj.nc id type x y z
dump 1 all netcdf 1000 traj.*.nc id type x y z
```

Description:

Dump a snapshot of atom coordinates every N timesteps in Amber-style NetCDF file format. NetCDF files are binary, portable and self-describing. This dump style will write only one file on the root node. The dump style *netcdf* uses the [standard NetCDF library](#). All data is collected on one processor and then written to the dump file. Dump style *netcdf/mpiio* uses the [parallel NetCDF library](#) and MPI-IO to write to the dump file in parallel; it has better performance on a larger number of processors. Note that style *netcdf* outputs all atoms sorted by atom tag while style *netcdf/mpiio* outputs atoms in order of their MPI rank.

NetCDF files can be directly visualized via the following tools:

Ovito (<http://www.ovito.org/>). Ovito supports the AMBER convention and all extensions of this dump style.

- VMD (<http://www.ks.uiuc.edu/Research/vmd/>).
- AtomEye (<http://www.libatoms.org/>). The libAtoms version of AtomEye contains a NetCDF reader that is not present in the standard distribution of AtomEye.

In addition to per-atom data, [thermo](#) data can be included in the dump file. The data included in the dump file is identical to the data specified by [thermo_style](#).

Restrictions:

LAMMPS Users Manual

The *netcdf* and *netcdf/mpiio* dump styles are part of the USER-NETCDF package. They are only enabled if LAMMPS was built with that package. See the [Making LAMMPS](#) section for more info.

Related commands:

[dump](#), [dump_modify](#), [undump](#)

dump vtk command

Syntax:

```
dump ID group-ID vtk N file args
```

- ID = user-assigned name for the dump
- group-ID = ID of the group of atoms to be dumped
- vtk = style of dump command (other styles *atom* or *cfg* or *dcd* or *xtc* or *xyz* or *local* or *custom* are discussed on the [dump](#) doc page)
- N = dump every this many timesteps
- file = name of file to write dump info to
- args = same as arguments for [dump_style custom](#)

Examples:

```
dump dmpvtk all vtk 100 dump*.myforce.vtk id type vx fx
dump dmpvtp flow vtk 100 dump*.*.displace.vtp id type c_myD[1] c_myD[2] c_myD[3] v_ke
```

Description:

Dump a snapshot of atom quantities to one or more files every N timesteps in a format readable by the [VTK visualization toolkit](#) or other visualization tools that use it, e.g. [ParaView](#). The timesteps on which dump output is written can also be controlled by a variable; see the [dump_modify every](#) command for details.

This dump style is similar to [dump_style custom](#) but uses the VTK library to write data to VTK simple legacy or XML format depending on the filename extension specified for the dump file. This can be either **.vtk* for the legacy format or **.vtp* and **.vtu*, respectively, for XML format; see the [VTK homepage](#) for a detailed description of these formats. Since this naming convention conflicts with the way binary output is usually specified (see below), the [dump_modify binary](#) command allows setting of a binary option for this dump style explicitly.

Only information for atoms in the specified group is dumped. The [dump_modify thresh and region](#) commands can also alter what atoms are included; see details below.

As described below, special characters ("***", "*%*") in the filename determine the kind of output.

IMPORTANT NOTE: Because periodic boundary conditions are enforced only on timesteps when neighbor lists are rebuilt, the coordinates of an atom written to a dump file may be slightly outside the simulation box.

IMPORTANT NOTE: Unless the [dump_modify sort](#) option is invoked, the lines of atom information written to dump files will be in an indeterminate order for each snapshot. This is even true when running on a single processor, if the [atom_modify sort](#) option is on, which it is by default. In this case atoms are re-ordered periodically during a simulation, due to spatial sorting. It is also true when running in parallel, because

LAMMPS Users Manual

data for a single snapshot is collected from multiple processors, each of which owns a subset of the atoms.

For the *vtk* style, sorting is off by default. See the [dump_modify](#) doc page for details.

The dimensions of the simulation box are written to a separate file for each snapshot (either in legacy VTK or XML format depending on the format of the main dump file) with the suffix *_boundingBox* appended to the given dump filename.

For an orthogonal simulation box this information is saved as a rectilinear grid (legacy *.vtk* or *.vtr* XML format).

Triclinic simulation boxes (non-orthogonal) are saved as hexahedrons in either legacy *.vtk* or *.vtu* XML format.

Style *vtk* allows you to specify a list of atom attributes to be written to the dump file for each atom. The list of possible attributes is the same as for the [dump_style custom](#) command; see its doc page for a listing and an explanation of each attribute.

NOTE: Since position data is required to write VTK files the atom attributes "x y z" do not have to be specified explicitly; they will be included in the dump file regardless. Also, in contrast to the *custom* style, the specified *vtk* attributes are rearranged to ensure correct ordering of vector components (except for *computes* and *fixes* - these have to be given in the right order) and duplicate entries are removed.

The VTK format uses a single snapshot of the system per file, thus a wildcard "*" must be included in the filename, as discussed below. Otherwise the dump files will get overwritten with the new snapshot each time.

Dumps are performed on timesteps that are a multiple of N (including timestep 0) and on the last timestep of a minimization if the minimization converges. Note that this means a dump will not be performed on the initial timestep after the dump command is invoked, if the current timestep is not a multiple of N. This behavior can be changed via the [dump_modify first](#) command, which can also be useful if the dump command is invoked after a minimization ended on an arbitrary timestep. N can be changed between runs by using the [dump_modify every](#) command. The [dump_modify every](#) command also allows a variable to be used to determine the sequence of timesteps on which dump files are written. In this mode a dump on the first timestep of a run will also not be written unless the [dump_modify first](#) command is used.

Dump filenames can contain two wildcard characters. If a "*" character appears in the filename, then one file per snapshot is written and the "*" character is replaced with the timestep value. For example, *tmp.dump*.vtk* becomes *tmp.dump0.vtk*, *tmp.dump10000.vtk*, *tmp.dump20000.vtk*, etc. Note that the [dump_modify pad](#) command can be used to insure all timestep numbers are the same length (e.g. 00010), which can make it easier to read a series of dump files in order with some post-processing tools.

If a "%" character appears in the filename, then each of P processors writes a portion of the dump file, and the "%" character is replaced with the processor ID from 0 to P-1

LAMMPS Users Manual

preceded by an underscore character. For example, `tmp.dump%.vtp` becomes `tmp.dump_0.vtp`, `tmp.dump_1.vtp`, ... `tmp.dump_P-1.vtp`, etc. This creates smaller files and can be a fast mode of output on parallel machines that support parallel I/O for output.

By default, P = the number of processors meaning one file per processor, but P can be set to a smaller value via the *nfile* or *fileper* keywords of the [dump_modify](#) command. These options can be the most efficient way of writing out dump files when running on large numbers of processors.

For the legacy VTK format "%" is ignored and $P = 1$, i.e., only processor 0 does write files.

Note that using the "*" and "%" characters together can produce a large number of small dump files!

If *dump_modify binary* is used, the dump file (or files, if "*" or "%" is also used) is written in binary format. A binary dump file will be about the same size as a text version, but will typically write out much faster.

Restrictions:

The *vtk* style does not support writing of gzipped dump files.

The *vtk* dump style is part of the USER-VTK package. It is only enabled if LAMMPS was built with that package. See the [Making LAMMPS](#) section for more info.

To use this dump style, you also must link to the VTK library. See the info in `lib/vtk/README` and insure the `Makefile.lammps` file in that directory is appropriate for your machine.

The *vtk* dump style supports neither buffering or custom format strings.

Related commands:

[dump](#), [dump image](#), [dump_modify](#), [undump](#)

Default:

By default, files are written in ASCII format. If the file extension is not one of `.vtk`, `.vtp` or `.vtu`, the legacy VTK file format is used.

dump cfg/uef command

Syntax:

```
dump ID group-ID cfg/uef N file mass type xs ys zs args
```

- ID = user-assigned name for the dump
- group-ID = ID of the group of atoms to be dumped
- N = dump every this many timesteps
- file = name of file to write dump info to

args = same as args for [dump custom](#)

Examples:

```
dump 1 all cfg/uef 10 dump.*.cfg mass type xs ys zs  
dump 2 all cfg/uef 100 dump.*.cfg mass type xs ys zs id c_stress
```

Description:

This command is used to dump atomic coordinates in the reference frame of the applied flow field when [fix nvt/uef](#) or [fix npt/uef](#) or is used. Only the atomic coordinates and frame-invariant scalar quantities will be in the flow frame. If velocities are selected as output, for example, they will not be in the same reference frame as the atomic positions.

Restrictions:

This fix is part of the USER-UEF package. It is only enabled if LAMMPS was built with that package. See the [Making LAMMPS](#) section for more info.

This command can only be used when [fix nvt/uef](#) or [fix npt/uef](#) is active.

Related commands:

[dump](#), [fix nvt/uef](#)

Default: none

echo command

Syntax:

```
echo style
```

- style = *none* or *screen* or *log* or *both*

Examples:

```
echo both  
echo log
```

Description:

This command determines whether LAMMPS echoes each input script command to the screen and/or log file as it is read and processed. If an input script has errors, it can be useful to look at echoed output to see the last command processed.

The [command-line switch](#) `-echo` can be used in place of this command.

Restrictions: none

Related commands: none

Default:

```
echo log
```

fix command

Syntax:

```
fix ID group-ID style args
```

- ID = user-assigned name for the fix
- group-ID = ID of the group of atoms to apply the fix to
- style = one of a long list of possible style names (see below)
- args = arguments used by a particular style

Examples:

```
fix 1 all nve  
fix 3 all nvt temp 300.0 300.0 0.01  
fix mine top setforce 0.0 NULL 0.0
```

Description:

Set a fix that will be applied to a group of atoms. In LAMMPS, a "fix" is any operation that is applied to the system during timestepping or minimization. Examples include updating of atom positions and velocities due to time integration, controlling temperature, applying constraint forces to atoms, enforcing boundary conditions, computing diagnostics, etc. There are dozens of fixes defined in LAMMPS and new ones can be added; see [this section](#) for a discussion.

Fixes perform their operations at different stages of the timestep. If 2 or more fixes operate at the same stage of the timestep, they are invoked in the order they were specified in the input script.

The ID of a fix can only contain alphanumeric characters and underscores.

Fixes can be deleted with the [unfix](#) command.

NOTE: The [unfix](#) command is the only way to turn off a fix; simply specifying a new fix with a similar style will not turn off the first one. This is especially important to realize for integration fixes. For example, using a [fix nve](#) command for a second run after using a [fix nvt](#) command for the first run, will not cancel out the NVT time integration invoked by the "fix nvt" command. Thus two time integrators would be in place!

If you specify a new fix with the same ID and style as an existing fix, the old fix is deleted and the new one is created (presumably with new settings). This is the same as if an "unfix" command were first performed on the old fix, except that the new fix is kept in the same order relative to the existing fixes as the old one originally was. Note that this operation also wipes out any additional changes made to the old fix via the [fix_modify](#) command.

The [fix modify](#) command allows settings for some fixes to be reset. See the doc page for individual fixes for details.

LAMMPS Users Manual

Some fixes store an internal "state" which is written to binary restart files via the [restart](#) or [write_restart](#) commands. This allows the fix to continue on with its calculations in a restarted simulation. See the [read_restart](#) command for info on how to re-specify a fix in an input script that reads a restart file. See the doc pages for individual fixes for info on which ones can be restarted.

Some fixes calculate one of three styles of quantities: global, per-atom, or local, which can be used by other commands or output as described below. A global quantity is one or more system-wide values, e.g. the energy of a wall interacting with particles. A per-atom quantity is one or more values per atom, e.g. the displacement vector for each atom since time 0. Per-atom values are set to 0.0 for atoms not in the specified fix group. Local quantities are calculated by each processor based on the atoms it owns, but there may be zero or more per atoms.

Note that a single fix may produce either global or per-atom or local quantities (or none at all), but never more than one of these.

Global, per-atom, and local quantities each come in three kinds: a single scalar value, a vector of values, or a 2d array of values. The doc page for each fix describes the style and kind of values it produces, e.g. a per-atom vector. Some fixes produce more than one kind of a single style, e.g. a global scalar and a global vector.

When a fix quantity is accessed, as in many of the output commands discussed below, it can be referenced via the following bracket notation, where ID is the ID of the fix:

f_ID	entire scalar, vector, or array
f_ID[I]	one element of vector, one column of array
f_ID[I][J]	one element of array

In other words, using one bracket reduces the dimension of the quantity once (vector -> scalar, array -> vector). Using two brackets reduces the dimension twice (array -> scalar). Thus a command that uses scalar fix values as input can also process elements of a vector or array.

Note that commands and [variables](#) which use fix quantities typically do not allow for all kinds, e.g. a command may require a vector of values, not a scalar. This means there is no ambiguity about referring to a fix quantity as f_ID even if it produces, for example, both a scalar and vector. The doc pages for various commands explain the details.

In LAMMPS, the values generated by a fix can be used in several ways:

- Global values can be output via the [thermo_style custom](#) or [fix ave/time](#) command. Or the values can be referenced in a [variable equal](#) or [variable atom](#) command.
- Per-atom values can be output via the [dump custom](#) command. Or they can be time-averaged via the [fix ave/atom](#) command or reduced by the [compute reduce](#) command. Or the per-atom values can be referenced in an [atom-style variable](#).
- Local values can be reduced by the [compute reduce](#) command, or histogrammed by the [fix ave/histo](#) command.

LAMMPS Users Manual

See this [howto section](#) for a summary of various LAMMPS output options, many of which involve fixes.

The results of fixes that calculate global quantities can be either "intensive" or "extensive" values. Intensive means the value is independent of the number of atoms in the simulation, e.g. temperature. Extensive means the value scales with the number of atoms in the simulation, e.g. total rotational kinetic energy. [Thermodynamic output](#) will normalize extensive values by the number of atoms in the system, depending on the "thermo_modify norm" setting. It will not normalize intensive values. If a fix value is accessed in another way, e.g. by a [variable](#), you may want to know whether it is an intensive or extensive value. See the doc page for individual fixes for further info.

Each fix style has its own documentation page which describes its arguments and what it does, as listed below. Here is an alphabetic list of fix styles available in LAMMPS. They are also given in more compact form in the Fix section of [this page](#).

There are also additional fix styles (not listed here) submitted by users which are included in the LAMMPS distribution. The list of these with links to the individual styles are given in the fix section of [this page](#).

- [adapt](#) - change a simulation parameter over time
- [addforce](#) - add a force to each atom
- [append/atoms](#) - append atoms to a running simulation
- [atom/swap](#) - Monte Carlo atom type swapping
- [aveforce](#) - add an averaged force to each atom
- [ave/atom](#) - compute per-atom time-averaged quantities
- [ave/chunk](#) - compute per-chunk time-averaged quantities
- [ave/correlate](#) - compute/output time correlations
- [ave/histo](#) - compute/output time-averaged histograms
- [ave/time](#) - compute/output global time-averaged quantities
- [balance](#) - perform dynamic load-balancing
- [bond/break](#) - break bonds on the fly
- [bond/create](#) - create bonds on the fly
- [bond/swap](#) - Monte Carlo bond swapping
- [box/relax](#) - relax box size during energy minimization
- [deform](#) - change the simulation box size/shape
- [deposit](#) - add new atoms above a surface
- [drag](#) - drag atoms towards a defined coordinate
- [dt/reset](#) - reset the timestep based on velocity, forces
- [efield](#) - impose electric field on system
- [ehex](#) - enhanced heat exchange algorithm
- [enforce2d](#) - zero out z-dimension velocity and force
- [evaporate](#) - remove atoms from simulation periodically
- [external](#) - callback to an external driver program
- [freeze](#) - freeze atoms in a granular simulation
- [gcmc](#) - grand canonical insertions/deletions
- [gld](#) - generalized Langevin dynamics integrator
- [gravity](#) - add gravity to atoms in a granular simulation
- [halt](#) - terminate a dynamics run or minimization
- [heat](#) - add/subtract momentum-conserving heat
- [indent](#) - impose force due to an indenter

LAMMPS Users Manual

- [latte](#) - wrapper on LATTE density-functional tight-binding code
- [langevin](#) - Langevin temperature control
- [lineforce](#) - constrain atoms to move in a line
- [momentum](#) - zero the linear and/or angular momentum of a group of atoms
- [move](#) - move atoms in a prescribed fashion
- [msst](#) - multi-scale shock technique (MSST) integration
- [neb](#) - nudged elastic band (NEB) spring forces
- [nph](#) - constant NPH time integration via Nose/Hoover
- [nphug](#) - constant-stress Hugonostat integration
- [nph/asphere](#) - NPH for aspherical particles
- [nph/body](#) - NPH for body particles
- [nph/sphere](#) - NPH for spherical particles
- [npt](#) - constant NPT time integration via Nose/Hoover
- [npt/asphere](#) - NPT for aspherical particles
- [npt/body](#) - NPT for body particles
- [npt/sphere](#) - NPT for spherical particles
- [nve](#) - constant NVE time integration
- [nve/asphere](#) - NVE for aspherical particles
- [nve/asphere/noforce](#) - NVE for aspherical particles without forces"
- [nve/body](#) - NVE for body particles
- [nve/limit](#) - NVE with limited step length
- [nve/line](#) - NVE for line segments
- [nve/noforce](#) - NVE without forces (v only)
- [nve/sphere](#) - NVE for spherical particles
- [nve/tri](#) - NVE for triangles
- [nvt](#) - constant NVT time integration via Nose/Hoover
- [nvt/asphere](#) - NVT for aspherical particles
- [nvt/body](#) - NVT for body particles
- [nvt/sllod](#) - NVT for NEMD with SLLOD equations
- [nvt/sphere](#) - NVT for spherical particles
- [oneway](#) - constrain particles on move in one direction
- [orient/bcc](#) - add grain boundary migration force for BCC
- [orient/fcc](#) - add grain boundary migration force for FCC
- [planeforce](#) - constrain atoms to move in a plane
- [poems](#) - constrain clusters of atoms to move as coupled rigid bodies
- [pour](#) - pour new atoms/molecules into a granular simulation domain
- [press/berendsen](#) - pressure control by Berendsen barostat
- [print](#) - print text and variables during a simulation
- [property/atom](#) - add customized per-atom values
- [qeq/comb](#) - charge equilibration for COMB potential [qeq/dynamic](#) - charge equilibration via dynamic method [qeq/fire](#) - charge equilibration via FIRE minimizer [qeq/point](#) - charge equilibration via point method [qeq/shielded](#) - charge equilibration via shielded method [qeq/slater](#) - charge equilibration via Slater method [rattle](#) - RATTLE constraints on bonds and/or angles
- [reax/bonds](#) - write out ReaxFF bond information [recenter](#) - constrain the center-of-mass position of a group of atoms
- [restrain](#) - constrain a bond, angle, dihedral
- [rigid](#) - constrain one or more clusters of atoms to move as a rigid body with NVE integration
- [rigid/nph](#) - constrain one or more clusters of atoms to move as a rigid body with NPH integration

LAMMPS Users Manual

- [rigid/npt](#) - constrain one or more clusters of atoms to move as a rigid body with NPT integration
- [rigid/nve](#) - constrain one or more clusters of atoms to move as a rigid body with alternate NVE integration
- [rigid/nvt](#) - constrain one or more clusters of atoms to move as a rigid body with NVT integration
- [rigid/small](#) - constrain many small clusters of atoms to move as a rigid body with NVE integration
- [rigid/small/nph](#) - constrain many small clusters of atoms to move as a rigid body with NPH integration
- [rigid/small/npt](#) - constrain many small clusters of atoms to move as a rigid body with NPT integration
- [rigid/small/nve](#) - constrain many small clusters of atoms to move as a rigid body with alternate NVE integration
- [rigid/small/nvt](#) - constrain many small clusters of atoms to move as a rigid body with NVT integration
- [setforce](#) - set the force on each atom
- [shake](#) - SHAKE constraints on bonds and/or angles
- [spring](#) - apply harmonic spring force to group of atoms
- [spring/chunk](#) - apply harmonic spring force to each chunk of atoms
- [spring/rg](#) - spring on radius of gyration of group of atoms
- [spring/self](#) - spring from each atom to its origin
- [srd](#) - stochastic rotation dynamics (SRD)
- [store/force](#) - store force on each atom
- [store/state](#) - store attributes for each atom
- [temp/berendsen](#) - temperature control by Berendsen thermostat
- [temp/csld](#) - canonical sampling thermostat with Langevin dynamics
- [temp/csvr](#) - canonical sampling thermostat with Hamiltonian dynamics
- [temp/rescale](#) - temperature control by velocity rescaling
- [tfmc](#) - perform force-bias Monte Carlo with time-stamped method
- [thermal/conductivity](#) - Muller-Plathe kinetic energy exchange for thermal conductivity calculation
- [tmd](#) - guide a group of atoms to a new configuration
- [ttm](#) - two-temperature model for electronic/atomic coupling
- [tune/kpace](#) - auto-tune KSpace parameters
- [vector](#) - accumulate a global vector every N timesteps
- [viscosity](#) - Muller-Plathe momentum exchange for viscosity calculation
- [viscous](#) - viscous damping for granular simulations
- [wall/colloid](#) - Lennard-Jones wall interacting with finite-size particles
- [wall/gran](#) - frictional wall(s) for granular simulations
- [wall/harmonic](#) - harmonic spring wall
- [wall/lj1043](#) - Lennard-Jones 10-4-3 wall
- [wall/lj126](#) - Lennard-Jones 12-6 wall
- [wall/lj93](#) - Lennard-Jones 9-3 wall
- [wall/piston](#) - moving reflective piston wall
- [wall/reflect](#) - reflecting wall(s)
- [wall/region](#) - use region surface as wall
- [wall/srd](#) - slip/no-slip wall for SRD particles

Restrictions:

LAMMPS Users Manual

Some fix styles are part of specific packages. They are only enabled if LAMMPS was built with that package. See the [Making LAMMPS](#) section for more info on packages. The doc pages for individual fixes tell if it is part of a package.

Related commands:

[unfix](#), [fix_modify](#)

Default: none

fix_modify command

Syntax:

```
fix_modify fix-ID keyword value ...
```

- fix-ID = ID of the fix to modify
- one or more keyword/value pairs may be appended
- keyword = *temp* or *press* or *energy* or *virial* or *respa* or *dynamic/dof*

temp value = compute ID that calculates a temperature

press value = compute ID that calculates a pressure

energy value = *yes* or *no*

virial value = *yes* or *no*

respa value = 1 to *max respa level* or 0 (for outermost level)

dynamic/dof value = *yes* or *no*

yes/no = do or do not recompute the number of degrees of freedom (DOF) contributing

Examples:

```
fix_modify 3 temp myTemp press myPress
fix_modify 1 energy yes
fix_modify tether respa 2
```

Description:

Modify one or more parameters of a previously defined fix. Only specific fix styles support specific parameters. See the doc pages for individual fix commands for info on which ones support which `fix_modify` parameters.

The *temp* keyword is used to determine how a fix computes temperature. The specified compute ID must have been previously defined by the user via the [compute](#) command and it must be a style of compute that calculates a temperature. All fixes that compute temperatures define their own compute by default, as described in their documentation. Thus this option allows the user to override the default method for computing T.

The *press* keyword is used to determine how a fix computes pressure. The specified compute ID must have been previously defined by the user via the [compute](#) command and it must be a style of compute that calculates a pressure. All fixes that compute pressures define their own compute by default, as described in their documentation. Thus this option allows the user to override the default method for computing P.

The *energy* keyword can be used with fixes that support it. *energy yes* adds a contribution to the potential energy of the system. The fix's global and per-atom energy is included in the calculation performed by the [compute pe](#) or [compute pe/atom](#) commands. See the [thermo_style](#) command for info on how potential energy is output. For fixes that tally a global energy, it can be printed by using the keyword `f_ID` in the `thermo_style` custom command, where ID is the fix-ID of the appropriate fix.

LAMMPS Users Manual

NOTE: You must also specify the *energy yes* setting for a fix if you are using it when performing an [energy minimization](#) and if you want the energy and forces it produces to be part of the optimization criteria.

The *virial* keyword can be used with fixes that support it. *virial yes* adds a contribution to the virial of the system. The fix's global and per-atom virial is included in the calculation performed by the [compute pressure](#) or [compute stress/atom](#) commands. See the [thermo_style](#) command for info on how pressure is output.

NOTE: You must specify the *virial yes* setting for a fix if you are doing [box relaxation](#) and if you want virial contribution of the fix to be part of the relaxation criteria, although this seems unlikely.

NOTE: This option is only supported by fixes that explicitly say so. For some of these (e.g. the [fix shake](#) command) the default setting is *virial yes*, for others it is *virial no*.

For fixes that set or modify forces, it may be possible to select at which [r-RESPA](#) level the fix operates via the *respa* keyword. The RESPA level at which the fix is active can be selected. This is a number ranging from 1 to the number of levels. If the RESPA level is larger than the current maximum, the outermost level will be used, which is also the default setting. This default can be restored using a value of 0 for the RESPA level. The affected fix has to be enabled to support this feature; if not, *fix_modify* will report an error. Active fixes with a custom RESPA level setting are reported with their specified level at the beginning of a r-RESPA run.

The *dynamic/dof* keyword determines whether the number of atoms N in the fix group and their associated degrees of freedom are re-computed each time a temperature is computed. Only fix styles that calculate their own internal temperature use this option. Currently this is only the [fix rigid/nvt/small](#) and [fix rigid/npt/small](#) commands for the purpose of thermostating rigid body translation and rotation. By default, N and their DOF are assumed to be constant. If you are adding atoms or molecules to the system (see the [fix pour](#), [fix deposit](#), and [fix gcmc](#) commands) or expect atoms or molecules to be lost (e.g. due to exiting the simulation box or via [fix evaporate](#)), then this option should be used to insure the temperature is correctly normalized.

NOTE: Other thermostating fixes, such as [fix nvt](#), do not use the *dynamic/dof* keyword because they use a temperature compute to calculate temperature. See the [compute_modify dynamic/dof](#) command for a similar way to insure correct temperature normalization for those thermostats.

Restrictions: none

Related commands:

[fix](#), [compute temp](#), [compute pressure](#), [thermo_style](#)

Default:

The option defaults are temp = ID defined by fix, press = ID defined by fix, energy = no, virial = different for each fix style, respa = 0.

group command

Syntax:

```
group ID style args
```

- ID = user-defined name of the group
- style = *delete* or *clear* or *empty* or *region* or *type* or *id* or *molecule* or *variable* or *include* or *subtract* or *union* or *intersect* or *dynamic* or *static*

```
delete = no args
clear = no args
empty = no args
region args = region-ID
type or id or molecule
args = list of one or more atom types, atom IDs, or molecule IDs
any entry in list can be a sequence formatted as A:B or A:B:C where
A = starting index, B = ending index,
C = increment between indices, 1 if not specified
args = logical value
logical = "
```

Examples:

```
group edge region regstrip
group water type 3 4
group sub id 10 25 50
group sub id 10 25 50 500:1000
group sub id 100:10000:10
group sub id <= 150
group polyA molecule 50 250
group hienergy variable eng
group hienergy include molecule
group boundary subtract all a2 a3
group boundary union lower upper
group boundary intersect upper flow
group boundary delete
group mine dynamic all region myRegion every 100
```

Description:

Identify a collection of atoms as belonging to a group. The group ID can then be used in other commands such as [fix](#), [compute](#), [dump](#), or [velocity](#) to act on those atoms together.

If the group ID already exists, the group command adds the specified atoms to the group.

NOTE: By default groups are static, meaning the atoms are permanently assigned to the group. For example, if the *region* style is used to assign atoms to a group, the atoms will remain in the group even if they later move out of the region. As explained below, the *dynamic* style can be used to make a group dynamic so that a periodic determination is made as to which atoms are in the group. Since many LAMMPS

LAMMPS Users Manual

commands operate on groups of atoms, you should think carefully about whether making a group dynamic makes sense for your model.

A group with the ID *all* is predefined. All atoms belong to this group. This group cannot be deleted, or made dynamic.

The *delete* style removes the named group and un-assigns all atoms that were assigned to that group. Since there is a restriction (see below) that no more than 32 groups can be defined at any time, the *delete* style allows you to remove groups that are no longer needed, so that more can be specified. You cannot delete a group if it has been used to define a current [fix](#) or [compute](#) or [dump](#).

The *clear* style un-assigns all atoms that were assigned to that group. This may be dangerous to do during a simulation run, e.g. using the [run every](#) command if a [fix](#) or [compute](#) or other operation expects the atoms in the group to remain constant, but LAMMPS does not check for this.

The *empty* style creates an empty group, which is useful for commands like [fix gcmc](#) or with complex scripts that add atoms to a group.

The *region* style puts all atoms in the region volume into the group. Note that this is a static one-time assignment. The atoms remain assigned (or not assigned) to the group even in they later move out of the region volume.

The *type*, *id*, and *molecule* styles put all atoms with the specified atom types, atom IDs, or molecule IDs into the group. These 3 styles can use arguments specified in one of two formats.

The first format is a list of values (types or IDs). For example, the 2nd command in the examples above puts all atoms of type 3 or 4 into the group named *water*. Each entry in the list can be a colon-separated sequence A:B or A:B:C, as in two of the examples above. A "sequence" generates a sequence of values (types or IDs), with an optional increment. The first example with 500:1000 has the default increment of 1 and would add all atom IDs from 500 to 1000 (inclusive) to the group *sub*, along with 10,25,50 since they also appear in the list of values. The second example with 100:10000:10 uses an increment of 10 and would thus would add atoms IDs 100,110,120, ... 9990,10000 to the group *sub*.

The second format is a *logical* followed by one or two values (type or ID). The 7 valid logicals are listed above. All the logicals except *between* take a single argument. The 3rd example above adds all atoms with IDs from 1 to 150 to the group named *sub*. The *between* logical means "between" and takes 2 arguments. The 4th example above adds all atoms belonging to molecules with IDs from 50 to 250 (inclusive) to the group named *polyA*.

The *variable* style evaluates a variable to determine which atoms to add to the group. It must be an [atom-style variable](#) previously defined in the input script. If the variable evaluates to a non-zero value for a particular atom, then that atom is added to the specified group.

LAMMPS Users Manual

Atom-style variables can specify formulas that include thermodynamic quantities, per-atom values such as atom coordinates, or per-atom quantities calculated by computes, fixes, or other variables. They can also include Boolean logic where 2 numeric values are compared to yield a 1 or 0 (effectively a true or false). Thus using the *variable* style, is a general way to flag specific atoms to include or exclude from a group.

For example, these lines define a variable "eatom" that calculates the potential energy of each atom and includes it in the group if its potential energy is above the threshold value -3.0.

```
compute      1 all pe/atom
compute      2 all reduce sum c_1
thermo_style custom step temp pe c_2
run          0

variable     eatom atom "c_1 > -3.0"
group       hienergy variable eatom
```

Note that these lines

```
compute      2 all reduce sum c_1
thermo_style custom step temp pe c_2
run          0
```

are necessary to insure that the "eatom" variable is current when the group command invokes it. Because the eatom variable computes the per-atom energy via the pe/atom compute, it will only be current if a run has been performed which evaluated pairwise energies, and the pe/atom compute was actually invoked during the run. Printing the thermodynamic info for compute 2 insures that this is the case, since it sums the pe/atom compute values (in the reduce compute) to output them to the screen. See the "Variable Accuracy" section of the [variable](#) doc page for more details on insuring that variables are current when they are evaluated between runs.

The *include molecule* style with its arg *molecule* adds atoms to a group that have the same molecule ID as atoms already in the group. The molecule ID = 0 is ignored in this operation, since it is assumed to flag isolated atoms that are not part of molecules. An example of where this operation is useful is if the *region* style has been used previously to add atoms to a group that are within a geometric region. If molecules straddle the region boundary, then atoms outside the region that are part of molecules with atoms inside the region will not be in the group. Using the group command a 2nd time with *include molecule* will add those atoms that are outside the region to the group.

NOTE: The *include molecule* operation is relatively expensive in a parallel sense. This is because it requires communication of relevant molecule IDs between all the processors and each processor to loop over its atoms once per processor, to compare its atoms to the list of molecule IDs from every other processor. Hence it scales as N, rather than N/P as most of the group operations do, where N is the number of atoms, and P is the number of processors.

LAMMPS Users Manual

The *subtract* style takes a list of two or more existing group names as arguments. All atoms that belong to the 1st group, but not to any of the other groups are added to the specified group.

The *union* style takes a list of one or more existing group names as arguments. All atoms that belong to any of the listed groups are added to the specified group.

The *intersect* style takes a list of two or more existing group names as arguments. Atoms that belong to every one of the listed groups are added to the specified group.

The *dynamic* style flags an existing or new group as dynamic. This means atoms will be (re)assigned to the group periodically as a simulation runs. This is in contrast to static groups where atoms are permanently assigned to the group. The way the assignment occurs is as follows. Only atoms in the group specified as the parent group via the parent-ID are assigned to the dynamic group before the following conditions are applied. If the *region* keyword is used, atoms not in the specified region are removed from the dynamic group. If the *var* keyword is used, the variable name must be an atom-style or atomfile-style variable. The variable is evaluated and atoms whose per-atom values are 0.0, are removed from the dynamic group. If the *property* keyword is used, the per-atom property name must be a previously defined per-atom property. The per-atom property is evaluated and atoms whose values are 0.0 are removed from the dynamic group, otherwise they are added to the group.

The assignment of atoms to a dynamic group is done at the beginning of each run and on every timestep that is a multiple of N , which is the argument for the *every* keyword ($N = 1$ is the default). For an energy minimization, via the [minimize](#) command, an assignment is made at the beginning of the minimization, but not during the iterations of the minimizer.

The point in the timestep at which atoms are assigned to a dynamic group is after the initial stage of velocity Verlet time integration has been performed, and before neighbor lists or forces are computed. This is the point in the timestep where atom positions have just changed due to the time integration, so the region criterion should be accurate, if applied.

NOTE: If the *region* keyword is used to determine what atoms are in the dynamic group, atoms can move outside of the simulation box between reneighboring events. Thus if you want to include all atoms on the left side of the simulation box, you probably want to set the left boundary of the region to be outside the simulation box by some reasonable amount (e.g. up to the cutoff of the potential), else they may be excluded from the dynamic region.

Here is an example of using a dynamic group to shrink the set of atoms being integrated by using a spherical region with a variable radius (shrinking from 18 to 5 over the course of the run). This could be used to model a quench of the system, freezing atoms outside the shrinking sphere, then converting the remaining atoms to a static group and running further.

```
variable          nsteps equal 5000
variable          rad equal 18-(step/v_nsteps)*(18-5)
region            ss sphere 20 20 0 v_rad
```

LAMMPS Users Manual

```
group          mobile dynamic all region ss
fix            1 mobile nve
run            ${nsteps}
group          mobile static
run            ${nsteps}
```

NOTE: All fixes and computes take a group ID as an argument, but they do not all allow for use of a dynamic group. If you get an error message that this is not allowed, but feel that it should be for the fix or compute in question, then please post your reasoning to the LAMMPS mail list and we can change it.

The *static* style removes the setting for a dynamic group, converting it to a static group (the default). The atoms in the static group are those currently in the dynamic group.

Restrictions:

There can be no more than 32 groups defined at one time, including "all".

The parent group of a dynamic group cannot itself be a dynamic group.

Related commands:

[dump](#), [fix](#), [region](#), [velocity](#)

Default:

All atoms belong to the "all" group.

group2ndx command

ndx2group command

Syntax:

```
group2ndx file group-ID ...  
ndx2group file group-ID ...
```

- file = name of index file to write out or read in
- zero or more group IDs may be appended

Examples:

```
group2ndx allindex.ndx  
group2ndx someindex.ndx upper lower mobile  
ndx2group someindex.ndx  
ndx2group someindex.ndx mobile
```

Description:

Write or read a Gromacs style index file in text format that associates atom IDs with the corresponding group definitions. This index file can be used with in combination with Gromacs analysis tools or to import group definitions into the [fix colvars](#) input file. It can also be used to save and restore group definitions for static groups.

The *group2ndx* command will write group definitions to an index file. Without specifying any group IDs, all groups will be written to the index file. When specifying group IDs, only those groups will be written to the index file. In order to follow the Gromacs conventions, the group *all* will be renamed to *System* in the index file.

The *ndx2group* command will create or update group definitions from those stored in an index file. Without specifying any group IDs, all groups except *System* will be read from the index file and the corresponding groups recreated. If a group of the same name already exists, it will be completely reset. When specifying group IDs, those groups, if present, will be read from the index file and restored.

Restrictions:

This command requires that atoms have atom IDs, since this is the information that is written to the index file.

These commands are part of the USER-COLVARS package. They are only enabled if LAMMPS was built with that package. See the [Making LAMMPS](#) section for more info.

Related commands:

[group](#), [dump](#), [fix colvars](#)

Default: none

if command

Syntax:

```
if boolean then t1 t2 ... elif boolean f1 f2 ... elif boolean f1 f2 ... else e1 e2 ...
```

- `boolean` = a Boolean expression evaluated as TRUE or FALSE (see below)
- `then` = required word
- `t1,t2,...,tN` = one or more LAMMPS commands to execute if condition is met, each enclosed in quotes
- `elif` = optional word, can appear multiple times
- `f1,f2,...,fN` = one or more LAMMPS commands to execute if elif condition is met, each enclosed in quotes (optional arguments)
- `else` = optional argument
- `e1,e2,...,eN` = one or more LAMMPS commands to execute if no condition is met, each enclosed in quotes (optional arguments)

Examples:

```
if "${steps} > 1000" then quit
if "${myString} == a10" then quit
if "$x <= $y" then "print X is smaller = $x" else "print Y is smaller = $y"
if "(${eng} > 0.0) || ($n <1000)" then &
  "timestep 0.005" &
elif $n
```

Description:

This command provides an if-then-else capability within an input script. A Boolean expression is evaluated and the result is TRUE or FALSE. Note that as in the examples above, the expression can contain variables, as defined by the [variable](#) command, which will be evaluated as part of the expression. Thus a user-defined formula that reflects the current state of the simulation can be used to issue one or more new commands.

If the result of the Boolean expression is TRUE, then one or more commands (`t1`, `t2`, ..., `tN`) are executed. If it is FALSE, then Boolean expressions associated with successive `elif` keywords are evaluated until one is found to be true, in which case its commands (`f1`, `f2`, ..., `fN`) are executed. If no Boolean expression is TRUE, then the commands associated with the `else` keyword, namely (`e1`, `e2`, ..., `eN`), are executed. The `elif` and `else` keywords and their associated commands are optional. If they aren't specified and the initial Boolean expression is FALSE, then no commands are executed.

The syntax for Boolean expressions is described below.

Each command (`t1`, `f1`, `e1`, etc) can be any valid LAMMPS input script command, except an [include](#) command, which is not allowed. If the command is more than one word, it must be enclosed in quotes, so it will be treated as a single argument, as in the examples above.

LAMMPS Users Manual

NOTE: If a command itself requires a quoted argument (e.g. a [print](#) command), then double and single quotes can be used and nested in the usual manner, as in the examples above and below. See [Section 3.2](#) of the manual for more details on using quotes in arguments. Only one of level of nesting is allowed, but that should be sufficient for most use cases.

Note that by using the line continuation character "&", the if command can be spread across many lines, though it is still a single command:

```
if "$a <$b" then &
  "print 'Minimum value = $a'" &
  "run 1000" &
else &
  'print "Minimum value = $b"' &
  "minimize 0.001 0.001 1000 10000"
```

Note that if one of the commands to execute is [quit](#), as in the first example above, then executing the command will cause LAMMPS to halt.

Note that by jumping to a label in the same input script, the if command can be used to break out of a loop. See the [variable delete](#) command for info on how to delete the associated loop variable, so that it can be re-used later in the input script.

Here is an example of a loop which checks every 1000 steps if the system temperature has reached a certain value, and if so, breaks out of the loop to finish the run. Note that any variable could be checked, so long as it is current on the timestep when the run completes. As explained on the [variable](#) doc page, this can be insured by including the variable in thermodynamic output.

```
variable myTemp equal temp
label loop
variable a loop 1000
run 1000
if "${myTemp} <300.0" then "jump SELF break"
next a
jump SELF loop
label break
print "ALL DONE"
```

Here is an example of a double loop which uses the if and [jump](#) commands to break out of the inner loop when a condition is met, then continues iterating thru the outer loop.

```
label      loopa
variable  a loop 5
  label   loopb
  variable b loop 5
  print   "A,B = $a,$b"
  run     10000
  if      "$b > 2" then "jump SELF break"
  next    b
  jump    in.script loopb
label     break
variable  b delete
next     a
jump     SELF loopa
```

The Boolean expressions for the `if` and `elif` keywords have a C-like syntax. Note that each expression is a single argument within the `if` command. Thus if you want to include spaces in the expression for clarity, you must enclose the entire expression in quotes.

An expression is built out of numbers (which start with a digit or period or minus sign) or strings (which start with a letter and can contain alphanumeric characters or underscores):

```
0.2, 100, 1.0e20, -15.4, etc
InP, myString, a123, ab_23_cd, etc
```

and Boolean operators:

```
A == B, A != B, A < B, A <= B, A > B, A >= B, A && B, A || B, A ^ B, !A
```

Each `A` and `B` is a number or string or a variable reference like `$a` or `${abc}`, or `A` or `B` can be another Boolean expression.

If a variable is used it can produce a number when evaluated, like an [equal-style variable](#). Or it can produce a string, like an [index-style variable](#). For an individual Boolean operator, `A` and `B` must both be numbers or must both be strings. You cannot compare a number to a string.

Expressions are evaluated left to right and have the usual C-style precedence: the unary logical NOT operator `!` has the highest precedence, the 4 relational operators `<`, `<=`, `>`, and `>=` are next; the two remaining relational operators `==` and `!=` are next; then the logical AND operator `&&`; and finally the logical OR operator `||` and logical XOR (exclusive or) operator `^` have the lowest precedence. Parenthesis can be used to group one or more portions of an expression and/or enforce a different order of evaluation than what would occur with the default precedence.

When the 6 relational operators (first 6 in list above) compare 2 numbers, they return either a 1.0 or 0.0 depending on whether the relationship between `A` and `B` is TRUE or FALSE. When the 6 relational operators compare 2 strings, they also return a 1.0 or 0.0 for TRUE or FALSE, but the comparison is done by the C function `strcmp()`.

When the 3 logical operators (last 3 in list above) compare 2 numbers, they also return either a 1.0 or 0.0 depending on whether the relationship between `A` and `B` is TRUE or FALSE (or just `A`). The logical AND operator will return 1.0 if both its arguments are non-zero, else it returns 0.0. The logical OR operator will return 1.0 if either of its arguments is non-zero, else it returns 0.0. The logical XOR operator will return 1.0 if one of its arguments is zero and the other non-zero, else it returns 0.0. The logical NOT operator returns 1.0 if its argument is 0.0, else it returns 0.0. The 3 logical operators can only be used to operate on numbers, not on strings.

The overall Boolean expression produces a TRUE result if the result is non-zero. If the result is zero, the expression result is FALSE.

Restrictions: none

Related commands:

[variable](#), [print](#)

Default: none

improper_coeff command

Syntax:

```
improper_coeff N args
```

- N = improper type (see asterisk form below)
- args = coefficients for one or more improper types

Examples:

```
improper_coeff 1 300.0 0.0  
improper_coeff * 80.2 -1 2  
improper_coeff *4 80.2 -1 2
```

Description:

Specify the improper force field coefficients for one or more improper types. The number and meaning of the coefficients depends on the improper style. Improper coefficients can also be set in the data file read by the [read_data](#) command or in a restart file.

N can be specified in one of two ways. An explicit numeric value can be used, as in the 1st example above. Or a wild-card asterisk can be used to set the coefficients for multiple improper types. This takes the form "*" or "*n" or "n*" or "m*n". If N = the number of improper types, then an asterisk with no numeric values means all types from 1 to N. A leading asterisk means all types from 1 to n (inclusive). A trailing asterisk means all types from n to N (inclusive). A middle asterisk means all types from m to n (inclusive).

Note that using an `improper_coeff` command can override a previous setting for the same improper type. For example, these commands set the coeffs for all improper types, then overwrite the coeffs for just improper type 2:

```
improper_coeff * 300.0 0.0  
improper_coeff 2 50.0 0.0
```

A line in a data file that specifies improper coefficients uses the exact same format as the arguments of the `improper_coeff` command in an input script, except that wild-card asterisks should not be used since coefficients for all N types must be listed in the file. For example, under the "Improper Coeffs" section of a data file, the line that corresponds to the 1st example above would be listed as

```
1 300.0 0.0
```

The [improper_style class2](#) is an exception to this rule, in that an additional argument is used in the input script to allow specification of the cross-term coefficients. See its doc page for details.

LAMMPS Users Manual

Here is an alphabetic list of improper styles defined in LAMMPS. Click on the style to display the formula it computes and coefficients specified by the associated [improper_coeff](#) command.

Note that there are also additional improper styles submitted by users which are included in the LAMMPS distribution. The list of these with links to the individual styles are given in the improper section of [this page](#).

- [improper_style none](#) - turn off improper interactions
 - [improper_style hybrid](#) - define multiple styles of improper interactions

 - [improper_style class2](#) - COMPASS (class 2) improper
 - [improper_style cvff](#) - CVFF improper
 - [improper_style harmonic](#) - harmonic improper
 - [improper_style umbrella](#) - DREIDING improper
-

Restrictions:

This command must come after the simulation box is defined by a [read_data](#), [read_restart](#), or [create_box](#) command.

An improper style must be defined before any improper coefficients are set, either in the input script or in a data file.

Related commands:

[improper_style](#)

Default: none

improper_style command

Syntax:

```
improper_style style
```

- style = *none* or *hybrid* or *class2* or *cvff* or *harmonic*

Examples:

```
improper_style harmonic  
improper_style cvff  
improper_style hybrid cvff harmonic
```

Description:

Set the formula(s) LAMMPS uses to compute improper interactions between quadruplets of atoms, which remain in force for the duration of the simulation. The list of improper quadruplets is read in by a [read_data](#) or [read_restart](#) command from a data or restart file. Note that the ordering of the 4 atoms in an improper quadruplet determines the definition of the improper angle used in the formula for each style. See the doc pages of individual styles for details.

Hybrid models where improvers are computed using different improper potentials can be setup using the *hybrid* improper style.

The coefficients associated with an improper style can be specified in a data or restart file or via the [improper_coeff](#) command.

All improper potentials store their coefficient data in binary restart files which means `improper_style` and [improper_coeff](#) commands do not need to be re-specified in an input script that restarts a simulation. See the [read_restart](#) command for details on how to do this. The one exception is that `improper_style hybrid` only stores the list of sub-styles in the restart file; improper coefficients need to be re-specified.

NOTE: When both an improper and pair style is defined, the [special_bonds](#) command often needs to be used to turn off (or weight) the pairwise interaction that would otherwise exist between a group of 4 bonded atoms.

Here is an alphabetic list of improper styles defined in LAMMPS. Click on the style to display the formula it computes and coefficients specified by the associated [improper_coeff](#) command.

Note that there are also additional improper styles submitted by users which are included in the LAMMPS distribution. The list of these with links to the individual styles are given in the improper section of [this page](#).

- [improper_style none](#) - turn off improper interactions
- [improper_style zero](#) - topology but no interactions

LAMMPS Users Manual

- [improper_style hybrid](#) - define multiple styles of improper interactions
 - [improper_style class2](#) - COMPASS (class 2) improper
 - [improper_style cvff](#) - CVFF improper
 - [improper_style harmonic](#) - harmonic improper
 - [improper_style umbrella](#) - DREIDING improper
-

Restrictions:

Improper styles can only be set for atom_style choices that allow improper to be defined.

Most improper styles are part of the MOLECULE package. They are only enabled if LAMMPS was built with that package. See the [Making LAMMPS](#) section for more info on packages. The doc pages for individual improper potentials tell if it is part of a package.

Related commands:

[improper_coeff](#)

Default:

`improper_style none`

include command

Syntax:

```
include file
```

- file = filename of new input script to switch to

Examples:

```
include newfile  
include in.run2
```

Description:

This command opens a new input script file and begins reading LAMMPS commands from that file. When the new file is finished, the original file is returned to. Include files can be nested as deeply as desired. If input script A includes script B, and B includes A, then LAMMPS could run for a long time.

If the filename is a variable (see the [variable](#) command), different processor partitions can run different input scripts.

Restrictions: none

Related commands:

[variable](#), [jump](#)

Default: none

info command

Syntax:

info args

- args = one or more of the following keywords: *out*, *all*, *system*, *memory*, *communication*, *computes*, *dumps*, *fixes*, *groups*, *regions*, *variables*, *coeffs*, *styles*, *time*, or *configuration*
- *out* values = *screen*, *log*, *append* filename, *overwrite* filename
- *styles* values = *all*, *angle*, *atom*, *bond*, *compute*, *command*, *dump*, *dihedral*, *fix*, *improper*, *integrate*, *kspace*, *minimize*, *pair*, *region*

Examples:

```
info system
info groups computes variables
info all out log
info all out append info.txt
info styles all
info styles atom
```

Description:

Print out information about the current internal state of the running LAMMPS process. This can be helpful when debugging or validating complex input scripts. Several output categories are available and one or more output category may be requested.

The *out* flag controls where the output is sent. It can only be sent to one target. By default this is the screen, if it is active. The *log* argument selects the log file instead. With the *append* and *overwrite* option, followed by a filename, the output is written to that file, which is either appended to or overwritten, respectively.

The *all* flag activates printing all categories listed below.

The *configuration* category prints some information about the LAMMPS version as well as architecture and OS it is run on.

The *memory* category prints some information about the current memory allocation of MPI rank 0 (this is the amount of dynamically allocated memory reported by LAMMPS classes). Where supported, also some OS specific information about the size of the reserved memory pool size (this is where `malloc()` and the new operator request memory from) and the maximum resident set size is reported (this is the maximum amount of physical memory occupied so far).

The *system* category prints a general system overview listing. This includes the unit style, atom style, number of atoms, bonds, angles, dihedrals, and improper and the number of the respective types, box dimensions and properties, force computing styles and more.

LAMMPS Users Manual

The *communication* category prints a variety of information about communication and parallelization: the MPI library version level, the number of MPI ranks and OpenMP threads, the communication style and layout, the processor grid dimensions, ghost atom communication mode, cutoff, and related settings.

The *computes* category prints a list of all currently defined computes, their IDs and styles and groups they operate on.

The *dumps* category prints a list of all currently active dumps, their IDs, styles, filenames, groups, and dump frequencies.

The *fixes* category prints a list of all currently defined fixes, their IDs and styles and groups they operate on.

The *groups* category prints a list of all currently defined groups.

The *regions* category prints a list of all currently defined regions, their IDs and styles and whether "inside" or "outside" atoms are selected.

The *variables* category prints a list of all currently defined variables, their names, styles, definition and last computed value, if available.

The *coeffs* category prints a list for each defined force style (pair, bond, angle, dihedral, improper) indicating which of the corresponding coefficients have been set. This can be very helpful to debug error messages like "All pair coeffs are not set".

The *styles* category prints the list of styles available in the current LAMMPS binary. It supports one of the following options to control which category of styles is printed out:

- all
- angle
- atom
- bond
- compute
- command
- dump
- dihedral
- fix
- improper
- integrate
- kspace
- minimize
- pair
- region

The *time* category prints the accumulated CPU and wall time for the process that writes output (usually MPI rank 0).

Restrictions: none

Related commands:

print

Default:

The *out* option has the default *screen*.

The *styles* option has the default *all*.

jump command

Syntax:

```
jump file label
```

- file = filename of new input script to switch to
- label = optional label within file to jump to

Examples:

```
jump newfile  
jump in.run2 runloop  
jump SELF runloop
```

Description:

This command closes the current input script file, opens the file with the specified name, and begins reading LAMMPS commands from that file. Unlike the [include](#) command, the original file is not returned to, although by using multiple jump commands it is possible to chain from file to file or back to the original file.

If the word "SELF" is used for the filename, then the current input script is re-opened and read again.

NOTE: The SELF option is not guaranteed to work when the current input script is being read through stdin (standard input), e.g.

```
lmp_g++ <in.script
```

since the SELF option invokes the C-library `rewind()` call, which may not be supported for stdin on some systems or by some MPI implementations. This can be worked around by using the [-in command-line argument](#), e.g.

```
lmp_g++ -in in.script
```

or by using the [-var command-line argument](#) to pass the script name as a variable to the input script. In the latter case, a [variable](#) called "fname" could be used in place of SELF, e.g.

```
lmp_g++ -var fname in.script <in.script
```

The 2nd argument to the jump command is optional. If specified, it is treated as a label and the new file is scanned (without executing commands) until the label is found, and commands are executed from that point forward. This can be used to loop over a portion of the input script, as in this example. These commands perform 10 runs, each of 10000 steps, and create 10 dump files named file.1, file.2, etc. The [next](#) command is used to exit the loop after 10 iterations. When the "a" variable has been incremented for the tenth time, it will cause the next jump command to be skipped.

LAMMPS Users Manual

```
variable a loop 10
label loop
dump 1 all atom 100 file.$a
run 10000
undump 1
next a
jump in.lj loop
```

If the jump *file* argument is a variable, the jump command can be used to cause different processor partitions to run different input scripts. In this example, LAMMPS is run on 40 processors, with 4 partitions of 10 procs each. An in.file containing the example variable and jump command will cause each partition to run a different simulation.

```
mpirun -np 40 lmp_ibm -partition 4x10 -in in.file
```

```
variable f world script.1 script.2 script.3 script.4
jump $f
```

Here is an example of a loop which checks every 1000 steps if the system temperature has reached a certain value, and if so, breaks out of the loop to finish the run. Note that any variable could be checked, so long as it is current on the timestep when the run completes. As explained on the [variable](#) doc page, this can be insured by including the variable in thermodynamic output.

```
variable myTemp equal temp
label loop
variable a loop 1000
run 1000
if "${myTemp} <300.0" then "jump SELF break"
next a
jump SELF loop
label break
print "ALL DONE"
```

Here is an example of a double loop which uses the if and [jump](#) commands to break out of the inner loop when a condition is met, then continues iterating thru the outer loop.

```
label      loopa
variable  a loop 5
  label   loopb
  variable b loop 5
  print   "A,B = $a,$b"
  run     10000
  if      "$b > 2" then "jump SELF break"
  next    b
  jump    in.script loopb
label     break
variable  b delete
next     a
jump     SELF loopa
```

Restrictions:

LAMMPS Users Manual

If you jump to a file and it does not contain the specified label, LAMMPS will come to the end of the file and exit.

Related commands:

[variable](#), [include](#), [label](#), [next](#)

Default: none

kspace_modify command

Syntax:

kspace_modify keyword value ...

- one or more keyword/value pairs may be listed

keyword = *mesh* or *order* or *order/disp* or *mix/disp* or *overlap* or *minorder* or *force* or *gewald*
mesh value = x y z
 x,y,z = grid size in each dimension for long-range Coulombics
mesh/disp value = x y z
 x,y,z = grid size in each dimension for 1/r⁶ dispersion
order value = N
 N = extent of Gaussian for PPPM or MSM mapping of charge to grid
order/disp value = N
 N = extent of Gaussian for PPPM mapping of dispersion term to grid
mix/disp value = *pair* or *geom* or *none*
overlap = *yes* or *no* = whether the grid stencil for PPPM is allowed to overlap into more than one cell
minorder value = M
 M = min allowed extent of Gaussian when auto-adjusting to minimize grid communication
force value = accuracy (force units)
gewald value = rinv (1/distance units)
 rinv = G-ewald parameter for Coulombics
gewald/disp value = rinv (1/distance units)
 rinv = G-ewald parameter for dispersion
slab value = *volfactor* or *nozforce*
 volfactor = ratio of the total extended volume used in the 2d approximation compared with the volume of the simulation domain
 nozforce turns off kspace forces in the z direction
compute value = *yes* or *no*
cutoff/adjust value = *yes* or *no*
pressure/scalar value = *yes* or *no*
fftbench value = *yes* or *no*
collective value = *yes* or *no*
diff value = *ad* or *ik* = 2 or 4 FFTs for PPPM in smoothed or non-smoothed mode
kmax/ewald value = kx ky kz
 kx,ky,kz = number of Ewald sum kspace vectors in each dimension
force/disp/real value = accuracy (force units)
force/disp/kspace value = accuracy (force units)
splittol value = tol
 tol = relative size of two eigenvalues (see discussion below)
disp/auto value = *yes* or *no*

Examples:

```
kspace_modify mesh 24 24 30 order 6
kspace_modify slab 3.0
```

Description:

Set parameters used by the kspace solvers defined by the [kspace_style](#) command. Not all parameters are relevant to all kspace styles.

LAMMPS Users Manual

The *mesh* keyword sets the grid size for kspace style *pppm* or *msm*. In the case of PPPM, this is the FFT mesh, and each dimension must be factorizable into powers of 2, 3, and 5. In the case of MSM, this is the finest scale real-space mesh, and each dimension must be factorizable into powers of 2. When this option is not set, the PPPM or MSM solver chooses its own grid size, consistent with the user-specified accuracy and pairwise cutoff. Values for x,y,z of 0,0,0 unset the option.

The *mesh/disp* keyword sets the grid size for kspace style *pppm/disp*. This is the FFT mesh for long-range dispersion and each dimension must be factorizable into powers of 2, 3, and 5. When this option is not set, the PPPM solver chooses its own grid size, consistent with the user-specified accuracy and pairwise cutoff. Values for x,y,z of 0,0,0 unset the option.

The *order* keyword determines how many grid spacings an atom's charge extends when it is mapped to the grid in kspace style *pppm* or *msm*. The default for this parameter is 5 for PPPM and 8 for MSM, which means each charge spans 5 or 8 grid cells in each dimension, respectively. For the LAMMPS implementation of MSM, the order can range from 4 to 10 and must be even. For PPPM, the minimum allowed setting is 2 and the maximum allowed setting is 7. The larger the value of this parameter, the smaller that LAMMPS will set the grid size, to achieve the requested accuracy. Conversely, the smaller the order value, the larger the grid size will be. Note that there is an inherent trade-off involved: a small grid will lower the cost of FFTs or MSM direct sum, but a larger order parameter will increase the cost of interpolating charge/fields to/from the grid.

The *order/disp* keyword determines how many grid spacings an atom's dispersion term extends when it is mapped to the grid in kspace style *pppm/disp*. It has the same meaning as the *order* setting for Coulombics.

The *overlap* keyword can be used in conjunction with the *minorder* keyword with the PPPM styles to adjust the amount of communication that occurs when values on the FFT grid are exchanged between processors. This communication is distinct from the communication inherent in the parallel FFTs themselves, and is required because processors interpolate charge and field values using grid point values owned by neighboring processors (i.e. ghost point communication). If the *overlap* keyword is set to *yes* then this communication is allowed to extend beyond nearest-neighbor processors, e.g. when using lots of processors on a small problem. If it is set to *no* then the communication will be limited to nearest-neighbor processors and the *order* setting will be reduced if necessary, as explained by the *minorder* keyword discussion. The *overlap* keyword is always set to *yes* in MSM.

The *minorder* keyword allows LAMMPS to reduce the *order* setting if necessary to keep the communication of ghost grid point limited to exchanges between nearest-neighbor processors. See the discussion of the *overlap* keyword for details. If the *overlap* keyword is set to *yes*, which is the default, this is never needed. If it set to *no* and overlap occurs, then LAMMPS will reduce the order setting, one step at a time, until the ghost grid overlap only extends to nearest neighbor processors. The *minorder* keyword limits how small the *order* setting can become. The minimum allowed value for PPPM is 2, which is the default. If *minorder* is set to the same value as *order* then no reduction is allowed, and LAMMPS will generate an error if the grid communication is non-nearest-neighbor and *overlap* is set to *no*. The *minorder*

LAMMPS Users Manual

keyword is not currently supported in MSM.

The PPPM order parameter may be reset by LAMMPS when it sets up the FFT grid if the implied grid stencil extends beyond the grid cells owned by neighboring processors. Typically this will only occur when small problems are run on large numbers of processors. A warning will be generated indicating the order parameter is being reduced to allow LAMMPS to run the problem. Automatic adjustment of the order parameter is not supported in MSM.

The *force* keyword overrides the relative accuracy parameter set by the [kspace_style](#) command with an absolute accuracy. The accuracy determines the RMS error in per-atom forces calculated by the long-range solver and is thus specified in force units. A negative value for the accuracy setting means to use the relative accuracy parameter. The accuracy setting is used in conjunction with the pairwise cutoff to determine the number of K-space vectors for style *ewald*, the FFT grid size for style *pppm*, or the real space grid size for style *msm*.

The *gewald* keyword sets the value of the Ewald or PPPM G-ewald parameter for charge as *rinv* in reciprocal distance units. Without this setting, LAMMPS chooses the parameter automatically as a function of cutoff, precision, grid spacing, etc. This means it can vary from one simulation to the next which may not be desirable for matching a KSpace solver to a pre-tabulated pairwise potential. This setting can also be useful if Ewald or PPPM fails to choose a good grid spacing and G-ewald parameter automatically. If the value is set to 0.0, LAMMPS will choose the G-ewald parameter automatically. MSM does not use the *gewald* parameter.

The *gewald/disp* keyword sets the value of the Ewald or PPPM G-ewald parameter for dispersion as *rinv* in reciprocal distance units. It has the same meaning as the *gewald* setting for Coulombics.

The *slab* keyword allows an Ewald or PPPM solver to be used for a systems that are periodic in x,y but non-periodic in z - a [boundary](#) setting of "boundary p p f". This is done by treating the system as if it were periodic in z, but inserting empty volume between atom slabs and removing dipole inter-slab interactions so that slab-slab interactions are effectively turned off. The volfactor value sets the ratio of the extended dimension in z divided by the actual dimension in z. The recommended value is 3.0. A larger value is inefficient; a smaller value introduces unwanted slab-slab interactions. The use of fixed boundaries in z means that the user must prevent particle migration beyond the initial z-bounds, typically by providing a wall-style fix. The methodology behind the *slab* option is explained in the paper by [\(Yeh\)](#). The *slab* option is also extended to non-neutral systems [\(Ballenegger\)](#).

An alternative slab option can be invoked with the *nozforce* keyword in lieu of the volfactor. This turns off all kspace forces in the z direction. The *nozforce* option is not supported by MSM. For MSM, any combination of periodic, non-periodic, or shrink-wrapped boundaries can be set using [boundary](#) (the slab approximation is not needed). The *slab* keyword is not currently supported by Ewald or PPPM when using a triclinic simulation cell. The slab correction has also been extended to point dipole interactions [\(Klapp\)](#) in [kspace_style ewald/disp](#).

LAMMPS Users Manual

NOTE: If you wish to apply an electric field in the Z-direction, in conjunction with the *slab* keyword, you should do it by adding explicit charged particles to the +/- Z surfaces. If you do it via the `fix efield` command, it will not give the correct dielectric constant due to the Yeh/Berkowitz (Yeh) correction not being compatible with how `fix efield` works.

The *compute* keyword allows Kspace computations to be turned off, even though a `kspace_style` is defined. This is not useful for running a real simulation, but can be useful for debugging purposes or for computing only partial forces that do not include the Kspace contribution. You can also do this by simply not defining a `kspace_style`, but a Kspace-compatible `pair_style` requires a kspace style to be defined. This keyword gives you that option.

The *cutoff/adjust* keyword applies only to MSM. If this option is turned on, the Coulombic cutoff will be automatically adjusted at the beginning of the run to give the desired estimated error. Other cutoffs such as LJ will not be affected. If the grid is not set using the *mesh* command, this command will also attempt to use the optimal grid that minimizes cost using an estimate given by (Hardy). Note that this cost estimate is not exact, somewhat experimental, and still may not yield the optimal parameters.

The *pressure/scalar* keyword applies only to MSM. If this option is turned on, only the scalar pressure (i.e. $(P_{xx} + P_{yy} + P_{zz})/3.0$) will be computed, which can be used, for example, to run an isotropic barostat. Computing the full pressure tensor with MSM is expensive, and this option provides a faster alternative. The scalar pressure is computed using a relationship between the Coulombic energy and pressure (Hummer) instead of using the virial equation. This option cannot be used to access individual components of the pressure tensor, to compute per-atom virial, or with suffix `kspace/pair` styles of MSM, like OMP or GPU.

The *fftbench* keyword applies only to PPPM. It is off by default. If this option is turned on, LAMMPS will perform a short FFT benchmark computation and report its timings, and will thus finish a some seconds later than it would if this option were off.

The *collective* keyword applies only to PPPM. It is set to *no* by default, except on IBM BlueGene machines. If this option is set to *yes*, LAMMPS will use MPI collective operations to remap data for 3d-FFT operations instead of the default point-to-point communication. This is faster on IBM BlueGene machines, and may also be faster on other machines if they have an efficient implementation of MPI collective operations and adequate hardware.

The *diff* keyword specifies the differentiation scheme used by the PPPM method to compute forces on particles given electrostatic potentials on the PPPM mesh. The *ik* approach is the default for PPPM and is the original formulation used in (Hockney). It performs differentiation in Kspace, and uses 3 FFTs to transfer each component of the computed fields back to real space for total of 4 FFTs per timestep.

The analytic differentiation *ad* approach uses only 1 FFT to transfer information back to real space for a total of 2 FFTs per timestep. It then performs analytic differentiation on the single quantity to generate the 3 components of the electric field at each grid point. This is sometimes referred to as "smoothed" PPPM. This approach requires a somewhat larger PPPM mesh to achieve the same accuracy as the *ik*

LAMMPS Users Manual

method. Currently, only the *ik* method (default) can be used for a triclinic simulation cell with PPPM. The *ad* method is always used for MSM.

NOTE: Currently, not all PPPM styles support the *ad* option. Support for those PPPM variants will be added later.

The *kmax/ewald* keyword sets the number of kspace vectors in each dimension for kspace style *ewald*. The three values must be positive integers, or else (0,0,0), which unsets the option. When this option is not set, the Ewald sum scheme chooses its own kspace vectors, consistent with the user-specified accuracy and pairwise cutoff. In any case, if kspace style *ewald* is invoked, the values used are printed to the screen and the log file at the start of the run.

With the *mix/disp* keyword one can select the mixing rule for the dispersion coefficients. With *pair*, the dispersion coefficients of unlike types are computed as indicated with [pair_modify](#). With *geom*, geometric mixing is enforced on the dispersion coefficients in the kspace coefficients. When using the arithmetic mixing rule, this will speed-up the simulations but introduces some error in the force computations, as shown in ([Wennberg](#)). With *none*, it is assumed that no mixing rule is applicable. Splitting of the dispersion coefficients will be performed as described in ([Isele-Holder](#)). This splitting can be influenced with the *splittol* keywords. Only the eigenvalues that are larger than *tol* compared to the largest eigenvalues are included. Using this keywords the original matrix of dispersion coefficients is approximated. This leads to faster computations, but the accuracy in the reciprocal space computations of the dispersion part is decreased.

The *force/disp/real* and *force/disp/kspace* keywords set the force accuracy for the real and space computations for the dispersion part of *pppm/disp*. As shown in ([Isele-Holder](#)), optimal performance and accuracy in the results is obtained when these values are different.

The *disp/auto* option controls whether the *pppm/disp* is allowed to generate PPPM parameters automatically. If set to *no*, parameters have to be specified using the *gewald/disp*, *mesh/disp*, *force/disp/real* or *force/disp/kspace* keywords, or the code will stop with an error message. When this option is set to *yes*, the error message will not appear and the simulation will start. For a typical application, using the automatic parameter generation will provide simulations that are either inaccurate or slow. Using this option is thus not recommended. For guidelines on how to obtain good parameters, see the [How-To](#) discussion.

kspace_style none
```

Description:

Define a long-range solver for LAMMPS to use each timestep to compute long-range Coulombic interactions or long-range $1/r^6$ interactions. Most of the long-range solvers perform their computation in K-space, hence the name of this command.

When such a solver is used in conjunction with an appropriate pair style, the cutoff for Coulombic or $1/r^N$ interactions is effectively infinite. If the Coulombic case, this means each charge in the system interacts with charges in an infinite array of periodic images of the simulation domain.

Note that using a long-range solver requires use of a matching [pair style](#) to perform consistent short-range pairwise calculations. This means that the name of the pair style contains a matching keyword to the name of the KSpace style, as in this table:

Pair style	KSpace style
coul/long	ewald or ppm
coul/msm	msm
lj/long or buck/long	disp (for dispersion)
tip4p/long	tip4p

The *ewald* style performs a standard Ewald summation as described in any solid-state physics text.

The *ewald/disp* style adds a long-range dispersion sum option for $1/r^6$ potentials and is useful for simulation of interfaces ([Veld](#)). It also performs standard Coulombic Ewald summations, but in a more efficient manner than the *ewald* style. The $1/r^6$ capability means that Lennard-Jones or Buckingham potentials can be used without a cutoff, i.e. they become full long-range potentials. The *ewald/disp* style can also be used with point-dipoles ([Toukmaji](#)) and is currently the only kspace solver in LAMMPS with this capability.

The *pppm* style invokes a particle-particle particle-mesh solver ([Hockney](#)) which maps atom charge to a 3d mesh, uses 3d FFTs to solve Poisson's equation on the mesh, then interpolates electric fields on the mesh points back to the atoms. It is closely related to the particle-mesh Ewald technique (PME) ([Darden](#)) used in AMBER and CHARMM. The cost of traditional Ewald summation scales as $N^{3/2}$ where N is the number of atoms in the system. The PPPM solver scales as $N \log(N)$ due to the FFTs, so it is almost always a faster choice ([Pollock](#)).

The *pppm/cg* style is identical to the *pppm* style except that it has an optimization for systems where most particles are uncharged. Similarly the *msm/cg* style implements the same optimization for *msm*. The optional *smallq* argument defines the cutoff for

LAMMPS Users Manual

the absolute charge value which determines whether a particle is considered charged or not. Its default value is 1.0e-5.

The *pppm/tip4p* style is identical to the *pppm* style except that it adds a charge at the massless 4th site in each TIP4P water molecule. It should be used with [pair styles](#) with a *tip4p/long* in their style name.

The *pppm/stagger* style performs calculations using two different meshes, one shifted slightly with respect to the other. This can reduce force aliasing errors and increase the accuracy of the method for a given mesh size. Or a coarser mesh can be used for the same target accuracy, which saves CPU time. However, there is a trade-off since FFTs on two meshes are now performed which increases the computation required. See [\(Cerutti\)](#), [\(Neelov\)](#), and [\(Hockney\)](#) for details of the method.

For high relative accuracy, using staggered PPPM allows the mesh size to be reduced by a factor of 2 in each dimension as compared to regular PPPM (for the same target accuracy). This can give up to a 4x speedup in the KSpace time (8x less mesh points, 2x more expensive). However, for low relative accuracy, the staggered PPPM mesh size may be essentially the same as for regular PPPM, which means the method will be up to 2x slower in the KSpace time (simply 2x more expensive). For more details and timings, see [Section 5](#).

NOTE: Using *pppm/stagger* may not give the same increase in the accuracy of energy and pressure as it does in forces, so some caution must be used if energy and/or pressure are quantities of interest, such as when using a barostat.

The *pppm/disp* and *pppm/disp/tip4p* styles add a mesh-based long-range dispersion sum option for $1/r^6$ potentials ([Isele-Holder](#)), similar to the *ewald/disp* style. The $1/r^6$ capability means that Lennard-Jones or Buckingham potentials can be used without a cutoff, i.e. they become full long-range potentials.

For these styles, you will possibly want to adjust the default choice of parameters by using the [kpace_modify](#) command. This can be done by either choosing the Ewald and grid parameters, or by specifying separate accuracies for the real and kspace calculations. When not making any settings, the simulation will stop with an error message. Further information on the influence of the parameters and how to choose them is described in [\(Isele-Holder\)](#), [\(Isele-Holder2\)](#) and the [How-To](#) discussion.

NOTE: All of the PPPM styles can be used with single-precision FFTs by using the compiler switch `-DFFT_SINGLE` for the `FFT_INC` setting in your lo-level Makefile. This setting also changes some of the PPPM operations (e.g. mapping charge to mesh and interpolating electric fields to particles) to be performed in single precision. This option can speed-up long-range calculations, particularly in parallel or on GPUs. The use of the `-DFFT_SINGLE` flag is discussed in [this section](#) of the manual. MSM does not currently support the `-DFFT_SINGLE` compiler switch.

The *msm* style invokes a multi-level summation method MSM solver, [\(Hardy\)](#) or [\(Hardy2\)](#), which maps atom charge to a 3d mesh, and uses a multi-level hierarchy of coarser and coarser meshes on which direct coulomb solves are done. This method does not use FFTs and scales as N . It may therefore be faster than the other K-space

LAMMPS Users Manual

solvers for relatively large problems when running on large core counts. MSM can also be used for non-periodic boundary conditions and for mixed periodic and non-periodic boundaries.

MSM is most competitive versus Ewald and PPPM when only relatively low accuracy forces, about $1e-4$ relative error or less accurate, are needed. Note that use of a larger coulomb cutoff (i.e. 15 angstroms instead of 10 angstroms) provides better MSM accuracy for both the real space and grid computed forces.

Currently calculation of the full pressure tensor in MSM is expensive. Using the [kspace_modify pressure/scalar yes](#) command provides a less expensive way to compute the scalar pressure $(P_{xx} + P_{yy} + P_{zz})/3.0$. The scalar pressure can be used, for example, to run an isotropic barostat. If the full pressure tensor is needed, then calculating the pressure at every timestep or using a fixed pressure simulation with MSM will cause the code to run slower.

The specified *accuracy* determines the relative RMS error in per-atom forces calculated by the long-range solver. It is set as a dimensionless number, relative to the force that two unit point charges (e.g. 2 monovalent ions) exert on each other at a distance of 1 Angstrom. This reference value was chosen as representative of the magnitude of electrostatic forces in atomic systems. Thus an accuracy value of $1.0e-4$ means that the RMS error will be a factor of 10000 smaller than the reference force.

The accuracy setting is used in conjunction with the pairwise cutoff to determine the number of K-space vectors for style *ewald* or the grid size for style *pppm* or *msm*.

Note that style *pppm* only computes the grid size at the beginning of a simulation, so if the length or triclinic tilt of the simulation cell increases dramatically during the course of the simulation, the accuracy of the simulation may degrade. Likewise, if the [kspace_modify slab](#) option is used with shrink-wrap boundaries in the z-dimension, and the box size changes dramatically in z. For example, for a triclinic system with all three tilt factors set to the maximum limit, the PPPM grid should be increased roughly by a factor of 1.5 in the y direction and 2.0 in the z direction as compared to the same system using a cubic orthogonal simulation cell. One way to handle this issue if you have a long simulation where the box size changes dramatically, is to break it into shorter simulations (multiple [run](#) commands). This works because the grid size is re-computed at the beginning of each run. Another way to ensure the described accuracy requirement is met is to run a short simulation at the maximum expected tilt or length, note the required grid size, and then use the [kspace_modify mesh](#) command to manually set the PPPM grid size to this value for the long run. The simulation then will be "too accurate" for some portion of the run.

RMS force errors in real space for *ewald* and *pppm* are estimated using equation 18 of (Kolafa), which is also referenced as equation 9 of (Petersen). RMS force errors in K-space for *ewald* are estimated using equation 11 of (Petersen), which is similar to equation 32 of (Kolafa). RMS force errors in K-space for *pppm* are estimated using equation 38 of (Deserno). RMS force errors for *msm* are estimated using ideas from chapter 3 of (Hardy), with equation 3.197 of particular note. When using *msm* with non-periodic boundary conditions, it is expected that the error estimation will be too pessimistic. RMS force errors for dipoles when using *ewald/disp* are estimated using equations 33 and 46 of (Wang).

LAMMPS Users Manual

See the [kspace_modify](#) command for additional options of the K-space solvers that can be set, including a *force* option for setting an absolute RMS error in forces, as opposed to a relative RMS error.

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed in [Section 5](#) of the manual. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

More specifically, the *pppm/gpu* style performs charge assignment and force interpolation calculations on the GPU. These processes are performed either in single or double precision, depending on whether the `-DFFT_SINGLE` setting was specified in your lo-level Makefile, as discussed above. The FFTs themselves are still calculated on the CPU. If *pppm/gpu* is used with a GPU-enabled pair style, part of the PPPM calculation can be performed concurrently on the GPU while other calculations for non-bonded and bonded force calculation are performed on the CPU.

The *pppm/kk* style also performs charge assignment and force interpolation calculations on the GPU while the FFTs themselves are calculated on the CPU in non-threaded mode.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP, and OPT packages respectively. They are only enabled if LAMMPS was built with those packages. See the [Making LAMMPS](#) section for more info.

See [Section 5](#) of the manual for more instructions on how to use the accelerated styles effectively.

Restrictions:

Note that the long-range electrostatic solvers in LAMMPS assume conducting metal (tin foil) boundary conditions for both charge and dipole interactions. Vacuum boundary conditions are not currently supported.

The *ewald/disp*, *ewald*, *pppm*, and *msm* styles support non-orthogonal (triclinic symmetry) simulation boxes. However, triclinic simulation cells may not yet be supported by suffix versions of these styles.

All of the *kspace* styles are part of the KSPACE package. They are only enabled if LAMMPS was built with that package. See the [Making LAMMPS](#) section for more info. Note that the KSPACE package is installed by default.

For MSM, a simulation must be 3d and one can use any combination of periodic, non-periodic, or shrink-wrapped boundaries (specified using the [boundary](#) command).

For Ewald and PPPM, a simulation must be 3d and periodic in all dimensions. The only exception is if the slab option is set with [kspace_modify](#), in which case the xy dimensions must be periodic and the z dimension must be non-periodic.

label command

Syntax:

```
label ID
```

- ID = string used as label name

Examples:

```
label xyz  
label loop
```

Description:

Label this line of the input script with the chosen ID. Unless a `jump` command was used previously, this does nothing. But if a `jump` command was used with a label argument to begin invoking this script file, then all command lines in the script prior to this line will be ignored. I.e. execution of the script will begin at this line. This is useful for looping over a section of the input script as discussed in the `jump` command.

basis 0.0 0.0 0.0 basis 0.5 0.5 0.5
lattice none 2.0
```

Description:

Define a lattice for use by other commands. In LAMMPS, a lattice is simply a set of points in space, determined by a unit cell with basis atoms, that is replicated infinitely in all dimensions. The arguments of the lattice command can be used to define a wide variety of crystallographic lattices.

A lattice is used by LAMMPS in two ways. First, the [create_atoms](#) command creates atoms on the lattice points inside the simulation box. Note that the [create_atoms](#) command allows different atom types to be assigned to different basis atoms of the lattice. Second, the lattice spacing in the x,y,z dimensions implied by the lattice, can be used by other commands as distance units (e.g. [create_box](#), [region](#) and [velocity](#)), which are often convenient to use when the underlying problem geometry is atoms on a lattice.

The lattice style must be consistent with the dimension of the simulation - see the [dimension](#) command. Styles *sc* or *bcc* or *fcc* or *hcp* or *diamond* are for 3d problems.

LAMMPS Users Manual

Styles *sq* or *sq2* or *hex* are for 2d problems. Style *custom* can be used for either 2d or 3d problems.

A lattice consists of a unit cell, a set of basis atoms within that cell, and a set of transformation parameters (scale, origin, orient) that map the unit cell into the simulation box. The vectors a_1, a_2, a_3 are the edge vectors of the unit cell. This is the nomenclature for "primitive" vectors in solid-state crystallography, but in LAMMPS the unit cell they determine does not have to be a "primitive cell" of minimum volume.

Note that the lattice command can be used multiple times in an input script. Each time it is invoked, the lattice attributes are re-defined and are used for all subsequent commands (that use lattice attributes). For example, a sequence of lattice, [region](#), and [create_atoms](#) commands can be repeated multiple times to build a poly-crystalline model with different geometric regions populated with atoms in different lattice orientations.

A lattice of style *none* does not define a unit cell and basis set, so it cannot be used with the [create_atoms](#) command. However it does define a lattice spacing via the specified scale parameter. As explained above the lattice spacings in x,y,z can be used by other commands as distance units. No additional keyword/value pairs can be specified for the *none* style. By default, a "lattice none 1.0" is defined, which means the lattice spacing is the same as one distance unit, as defined by the [units](#) command.

Lattices of style *sc*, *fcc*, *bcc*, and *diamond* are 3d lattices that define a cubic unit cell with edge length = 1.0. This means $a_1 = 1\ 0\ 0$, $a_2 = 0\ 1\ 0$, and $a_3 = 0\ 0\ 1$. Style *hcp* has $a_1 = 1\ 0\ 0$, $a_2 = 0\ \sqrt{3}\ 0$, and $a_3 = 0\ 0\ \sqrt{8/3}$. The placement of the basis atoms within the unit cell are described in any solid-state physics text. A *sc* lattice has 1 basis atom at the lower-left-bottom corner of the cube. A *bcc* lattice has 2 basis atoms, one at the corner and one at the center of the cube. A *fcc* lattice has 4 basis atoms, one at the corner and 3 at the cube face centers. A *hcp* lattice has 4 basis atoms, two in the $z = 0$ plane and 2 in the $z = 0.5$ plane. A *diamond* lattice has 8 basis atoms.

Lattices of style *sq* and *sq2* are 2d lattices that define a square unit cell with edge length = 1.0. This means $a_1 = 1\ 0\ 0$ and $a_2 = 0\ 1\ 0$. A *sq* lattice has 1 basis atom at the lower-left corner of the square. A *sq2* lattice has 2 basis atoms, one at the corner and one at the center of the square. A *hex* style is also a 2d lattice, but the unit cell is rectangular, with $a_1 = 1\ 0\ 0$ and $a_2 = 0\ \sqrt{3}\ 0$. It has 2 basis atoms, one at the corner and one at the center of the rectangle.

A lattice of style *custom* allows you to specify a_1 , a_2 , a_3 , and a list of basis atoms to put in the unit cell. By default, a_1 and a_2 and a_3 are 3 orthogonal unit vectors (edges of a unit cube). But you can specify them to be of any length and non-orthogonal to each other, so that they describe a tilted parallelepiped. Via the *basis* keyword you add atoms, one at a time, to the unit cell. Its arguments are fractional coordinates ($0.0 \leq x,y,z < 1.0$). The position vector x of a basis atom within the unit cell is thus a linear combination of the the unit cell's 3 edge vectors, i.e. $x = b_x a_1 + b_y a_2 + b_z a_3$, where b_x, b_y, b_z are the 3 values specified for the *basis* keyword.

This sub-section discusses the arguments that determine how the idealized unit cell is

LAMMPS Users Manual

transformed into a lattice of points within the simulation box.

The *scale* argument determines how the size of the unit cell will be scaled when mapping it into the simulation box. I.e. it determines a multiplicative factor to apply to the unit cell, to convert it to a lattice of the desired size and distance units in the simulation box. The meaning of the *scale* argument depends on the [units](#) being used in your simulation.

For all unit styles except *lj*, the scale argument is specified in the distance units defined by the unit style. For example, in *real* or *metal* units, if the unit cell is a unit cube with edge length 1.0, specifying *scale* = 3.52 would create a cubic lattice with a spacing of 3.52 Angstroms. In *cgs* units, the spacing would be 3.52 cm.

For unit style *lj*, the scale argument is the Lennard-Jones reduced density, typically written as ρ^* . LAMMPS converts this value into the multiplicative factor via the formula $\text{factor}^{\text{dim}} = \rho/\rho^*$, where $\rho = N/V$ with V = the volume of the lattice unit cell and N = the number of basis atoms in the unit cell (described below), and $\text{dim} = 2$ or 3 for the dimensionality of the simulation. Effectively, this means that if LJ particles of size $\sigma = 1.0$ are used in the simulation, the lattice of particles will be at the desired reduced density.

The *origin* option specifies how the unit cell will be shifted or translated when mapping it into the simulation box. The *x,y,z* values are fractional values ($0.0 \leq x,y,z < 1.0$) meaning shift the lattice by a fraction of the lattice spacing in each dimension. The meaning of "lattice spacing" is discussed below.

The *orient* option specifies how the unit cell will be rotated when mapping it into the simulation box. The *dim* argument is one of the 3 coordinate axes in the simulation box. The other 3 arguments are the crystallographic direction in the lattice that you want to orient along that axis, specified as integers. E.g. "orient x 2 1 0" means the x-axis in the simulation box will be the [210] lattice direction, and similarly for y and z. The 3 lattice directions you specify do not have to be unit vectors, but they must be mutually orthogonal and obey the right-hand rule, i.e. (X cross Y) points in the Z direction.

NOTE: The preceding paragraph describing lattice directions is only valid for orthogonal cubic unit cells (or square in 2d). If you are using a *hcp* or *hex* lattice or the more general lattice style *custom* with non-orthogonal *a1,a2,a3* vectors, then you should think of the 3 *orient* vectors as creating a 3x3 rotation matrix which is applied to *a1,a2,a3* to rotate the original unit cell to a new orientation in the simulation box.

Several LAMMPS commands have the option to use distance units that are inferred from "lattice spacings" in the *x,y,z* box directions. E.g. the [region](#) command can create a block of size 10x20x20, where 10 means 10 lattice spacings in the x direction.

NOTE: Though they are called lattice spacings, all the commands that have a "units lattice" option, simply use the 3 values as scale factors on the distance units defined by the [units](#) command. Thus if you do not like the lattice spacings computed by LAMMPS (e.g. for a non-orthogonal or rotated unit cell), you can define the 3 values to be whatever you wish, via the *spacing* option.

LAMMPS Users Manual

If the *spacing* option is not specified, the lattice spacings are computed by LAMMPS in the following way. A unit cell of the lattice is mapped into the simulation box (scaled and rotated), so that it now has (perhaps) a modified size and orientation. The lattice spacing in X is defined as the difference between the min/max extent of the x coordinates of the 8 corner points of the modified unit cell (4 in 2d). Similarly, the Y and Z lattice spacings are defined as the difference in the min/max of the y and z coordinates.

Note that if the unit cell is orthogonal with axis-aligned edges (no rotation via the *orient* keyword), then the lattice spacings in each dimension are simply the scale factor (described above) multiplied by the length of a_1, a_2, a_3 . Thus a *hex* style lattice with a scale factor of 3.0 Angstroms, would have a lattice spacing of 3.0 in x and $3*\sqrt{3.0}$ in y.

NOTE: For non-orthogonal unit cells and/or when a rotation is applied via the *orient* keyword, then the lattice spacings computed by LAMMPS are typically less intuitive. In particular, in these cases, there is no guarantee that a particular lattice spacing is an integer multiple of the periodicity of the lattice in that direction. Thus, if you create an orthogonal periodic simulation box whose size in a dimension is a multiple of the lattice spacing, and then fill it with atoms via the [create_atoms](#) command, you will NOT necessarily create a periodic system. I.e. atoms may overlap incorrectly at the faces of the simulation box.

The *spacing* option sets the 3 lattice spacings directly. All must be non-zero (use 1.0 for dz in a 2d simulation). The specified values are multiplied by the multiplicative factor described above that is associated with the scale factor. Thus a spacing of 1.0 means one unit cell edge length independent of the scale factor. As mentioned above, this option can be useful if the spacings LAMMPS computes are inconvenient to use in subsequent commands, which can be the case for non-orthogonal or rotated lattices.

Note that whenever the lattice command is used, the values of the lattice spacings LAMMPS calculates are printed out. Thus their effect in commands that use the spacings should be decipherable.

Example commands for generating a Wurtzite crystal (courtesy of Aidan Thompson), with its 8 atom unit cell.

```
variable a equal 4.340330
variable b equal $a*sqrt(3.0)
variable c equal $a*sqrt(8.0/3.0)

variable 1_3 equal 1.0/3.0
variable 2_3 equal 2.0/3.0
variable 1_6 equal 1.0/6.0
variable 5_6 equal 5.0/6.0
variable 1_12 equal 1.0/12.0
variable 5_12 equal 5.0/12.0

Restrictions:

The *a1,a2,a3,basis* keywords can only be used with style *custom*.

Related commands:

[dimension](#), [create_atoms](#), [region](#)

Default:

```
lattice none 1.0
```

For other lattice styles, the option defaults are *origin* = 0.0 0.0 0.0, *orient* = x 1 0 0, *orient* = y 0 1 0, *orient* = z 0 0 1, *a1* = 1 0 0, *a2* = 0 1 0, and *a3* = 0 0 1.

log command

Syntax:

```
log file keyword
```

- file = name of new logfile
- keyword = *append* if output should be appended to logfile (optional)

Examples:

```
log log.equil  
log log.equil append
```

Description:

This command closes the current LAMMPS log file, opens a new file with the specified name, and begins logging information to it. If the specified file name is *none*, then no new log file is opened. If the optional keyword *append* is specified, then output will be appended to an existing log file, instead of overwriting it.

If multiple processor partitions are being used, the file name should be a variable, so that different processors do not attempt to write to the same log file.

The file "log.lammps" is the default log file for a LAMMPS run. The name of the initial log file can also be set by the command-line switch `-log`. See [Section 2.6](#) for details.

Restrictions: none

Related commands: none

Default:

The default LAMMPS log file is named log.lammps

mass command

Syntax:

```
mass I value
```

- I = atom type (see asterisk form below)
- value = mass

Examples:

```
mass 1 1.0  
mass * 62.5  
mass 2* 62.5
```

Description:

Set the mass for all atoms of one or more atom types. Per-type mass values can also be set in the [read_data](#) data file using the "Masses" keyword. See the [units](#) command for what mass units to use.

The I index can be specified in one of two ways. An explicit numeric value can be used, as in the 1st example above. Or a wild-card asterisk can be used to set the mass for multiple atom types. This takes the form "*" or "*n" or "n*" or "m*n". If N = the number of atom types, then an asterisk with no numeric values means all types from 1 to N. A leading asterisk means all types from 1 to n (inclusive). A trailing asterisk means all types from n to N (inclusive). A middle asterisk means all types from m to n (inclusive).

A line in a [data file](#) that follows the "Masses" keyword specifies mass using the same format as the arguments of the mass command in an input script, except that no wild-card asterisk can be used. For example, under the "Masses" section of a data file, the line that corresponds to the 1st example above would be listed as

```
1 1.0
```

Note that the mass command can only be used if the [atom style](#) requires per-type atom mass to be set. Currently, all but the *sphere* and *ellipsoid* and *peri* styles do. They require mass to be set for individual particles, not types. Per-atom masses are defined in the data file read by the [read_data](#) command, or set to default values by the [create_atoms](#) command. Per-atom masses can also be set to new values by the [set mass](#) or [set density](#) commands.

Also note that [pair_style eam](#) and [pair_style bop](#) commands define the masses of atom types in their respective potential files, in which case the mass command is normally not used.

If you define a [hybrid atom style](#) which includes one (or more) sub-styles which require per-type mass and one (or more) sub-styles which require per-atom mass, then

LAMMPS Users Manual

you must define both. However, in this case the per-type mass will be ignored; only the per-atom mass will be used by LAMMPS.

Restrictions:

This command must come after the simulation box is defined by a [read_data](#), [read_restart](#), or [create_box](#) command.

All masses must be defined before a simulation is run. They must also all be defined before a [velocity](#) or [fix shake](#) command is used.

The mass assigned to any type or atom must be > 0.0 .

Related commands: none

Default: none

min_modify command

Syntax:

min_modify keyword values ...

- one or more keyword/value pairs may be listed

```
keyword = dmax or line  
  dmax value = max  
    max = maximum distance for line search to move (distance units)  
  line value = backtrack or quadratic or forcezero  
    backtrack,quadratic,forcezero = style of linesearch to use
```

Examples:

```
min_modify dmax 0.2
```

Description:

This command sets parameters that affect the energy minimization algorithms selected by the [min_style](#) command. The various settings may affect the convergence rate and overall number of force evaluations required by a minimization, so users can experiment with these parameters to tune their minimizations.

The *cg* and *sd* minimization styles have an outer iteration and an inner iteration which is steps along a one-dimensional line search in a particular search direction. The *dmax* parameter is how far any atom can move in a single line search in any dimension (x, y, or z). For the *quickmin* and *fire* minimization styles, the *dmax* setting is how far any atom can move in a single iteration (timestep). Thus a value of 0.1 in real [units](#) means no atom will move further than 0.1 Angstroms in a single outer iteration. This prevents highly overlapped atoms from being moved long distances (e.g. through another atom) due to large forces.

The choice of line search algorithm for the *cg* and *sd* minimization styles can be selected via the *line* keyword. The default *quadratic* line search algorithm starts out using the robust backtracking method described below. However, once the system gets close to a local minimum and the linesearch steps get small, so that the energy is approximately quadratic in the step length, it uses the estimated location of zero gradient as the linesearch step, provided the energy change is downhill. This becomes more efficient than backtracking for highly-converged relaxations. The *forcezero* line search algorithm is similar to *quadratic*. It may be more efficient than *quadratic* on some systems.

The backtracking search is robust and should always find a local energy minimum. However, it will "converge" when it can no longer reduce the energy of the system. Individual atom forces may still be larger than desired at this point, because the energy change is measured as the difference of two large values (energy before and energy after) and that difference may be smaller than machine epsilon even if atoms could move in the gradient direction to reduce forces further.

LAMMPS Users Manual

Restrictions: none

Related commands:

[min_style](#), [minimize](#)

Default:

The option defaults are $dmax = 0.1$ and $line = quadratic$.

min_style command

Syntax:

```
min_style style
```

- style = *cg* or *hftn* or *sd* or *quickmin* or *fire*

Examples:

```
min_style cg  
min_style fire
```

Description:

Choose a minimization algorithm to use when a [minimize](#) command is performed.

Style *cg* is the Polak-Ribiere version of the conjugate gradient (CG) algorithm. At each iteration the force gradient is combined with the previous iteration information to compute a new search direction perpendicular (conjugate) to the previous search direction. The PR variant affects how the direction is chosen and how the CG method is restarted when it ceases to make progress. The PR variant is thought to be the most effective CG choice for most problems.

Style *hftn* is a Hessian-free truncated Newton algorithm. At each iteration a quadratic model of the energy potential is solved by a conjugate gradient inner iteration. The Hessian (second derivatives) of the energy is not formed directly, but approximated in each conjugate search direction by a finite difference directional derivative. When close to an energy minimum, the algorithm behaves like a Newton method and exhibits a quadratic convergence rate to high accuracy. In most cases the behavior of *hftn* is similar to *cg*, but it offers an alternative if *cg* seems to perform poorly. This style is not affected by the [min_modify](#) command.

Style *sd* is a steepest descent algorithm. At each iteration, the search direction is set to the downhill direction corresponding to the force vector (negative gradient of energy). Typically, steepest descent will not converge as quickly as CG, but may be more robust in some situations.

Style *quickmin* is a damped dynamics method described in ([Sheppard](#)), where the damping parameter is related to the projection of the velocity vector along the current force vector for each atom. The velocity of each atom is initialized to 0.0 by this style, at the beginning of a minimization.

Style *fire* is a damped dynamics method described in ([Bitzek](#)), which is similar to *quickmin* but adds a variable timestep and alters the projection operation to maintain components of the velocity non-parallel to the current force vector. The velocity of each atom is initialized to 0.0 by this style, at the beginning of a minimization.

LAMMPS Users Manual

Either the *quickmin* and *fire* styles are useful in the context of nudged elastic band (NEB) calculations via the [neb](#) command.

NOTE: The damped dynamic minimizers use whatever timestep you have defined via the [timestep](#) command. Often they will converge more quickly if you use a timestep about 10x larger than you would normally use for dynamics simulations.

NOTE: The *quickmin*, *fire*, and *hftn* styles do not yet support the use of the [fix box/relax](#) command or minimizations involving the electron radius in [eFF](#) models.

Restrictions: none

Related commands:

[min_modify](#), [minimize](#), [neb](#)

Default:

`min_style cg`

(Sheppard) Sheppard, Terrell, Henkelman, J Chem Phys, 128, 134106 (2008). See ref 1 in this paper for original reference to Qmin in Jonsson, Mills, Jacobsen.

minimize command

Syntax:

```
minimize etol ftol maxiter maxeval
```

- etol = stopping tolerance for energy (unitless)
- ftol = stopping tolerance for force (force units)
- maxiter = max iterations of minimizer
- maxeval = max number of force/energy evaluations

Examples:

```
minimize 1.0e-4 1.0e-6 100 1000  
minimize 0.0 1.0e-8 1000 100000
```

Description:

Perform an energy minimization of the system, by iteratively adjusting atom coordinates. Iterations are terminated when one of the stopping criteria is satisfied. At that point the configuration will hopefully be in local potential energy minimum. More precisely, the configuration should approximate a critical point for the objective function (see below), which may or may not be a local minimum.

The minimization algorithm used is set by the [min_style](#) command. Other options are set by the [min_modify](#) command. Minimize commands can be interspersed with [run](#) commands to alternate between relaxation and dynamics. The minimizers bound the distance atoms move in one iteration, so that you can relax systems with highly overlapped atoms (large energies and forces) by pushing the atoms off of each other.

Alternate means of relaxing a system are to run dynamics with a small or [limited timestep](#). Or dynamics can be run using [fix viscous](#) to impose a damping force that slowly drains all kinetic energy from the system. The [pair_style soft](#) potential can be used to un-overlap atoms while running dynamics.

Note that you can minimize some atoms in the system while holding the coordinates of other atoms fixed by applying [fix setforce](#) to the other atoms. See a fuller discussion of using fixes while minimizing below.

The [minimization styles](#) *cg*, *sd*, and *hftn* involves an outer iteration loop which sets the search direction along which atom coordinates are changed. An inner iteration is then performed using a line search algorithm. The line search typically evaluates forces and energies several times to set new coordinates. Currently, a backtracking algorithm is used which may not be optimal in terms of the number of force evaluations performed, but appears to be more robust than previous line searches we've tried. The backtracking method is described in Nocedal and Wright's Numerical Optimization (Procedure 3.1 on p 41).

LAMMPS Users Manual

The [minimization styles](#) *quickmin* and *fire* perform damped dynamics using an Euler integration step. Thus they require a [timestep](#) be defined.

NOTE: The damped dynamic minimizers use whatever timestep you have defined via the [timestep](#) command. Often they will converge more quickly if you use a timestep about 10x larger than you would normally use for dynamics simulations.

In all cases, the objective function being minimized is the total potential energy of the system as a function of the N atom coordinates:

$$\mathcal{E}(r_1, r_2, \dots, r_N) = \sum_{i,j} E_{pair}(r_i, r_j) + \sum_{ij} E_{bond}(r_i, r_j) + \sum_{ijk} E_{angle}(r_i, r_j, r_k) + \sum_{ijkl} E_{dihedral}(r_i, r_j, r_k, r_l) + \sum_{ijkl} E_{improper}(r_i, r_j, r_k, r_l) + \sum_i E_{fix}$$

where the first term is the sum of all non-bonded [pairwise interactions](#) including [long-range Coulombic interactions](#), the 2nd thru 5th terms are [bond](#), [angle](#), [dihedral](#), and [improper](#) interactions respectively, and the last term is energy due to [fixes](#) which can act as constraints or apply force to atoms, such as thru interaction with a wall. See the discussion below about how fix commands affect minimization.

The starting point for the minimization is the current configuration of the atoms.

The minimization procedure stops if any of several criteria are met:

- the change in energy between outer iterations is less than *etol*
- the 2-norm (length) of the global force vector is less than the *ftol*
- the line search fails because the step distance backtracks to 0.0
- the number of outer iterations or timesteps exceeds *maxiter*
- the number of total force evaluations exceeds *maxeval*

NOTE: You can also use the [fix halt](#) command to specify a general criterion for exiting a minimization, that is a calculation performed on the state of the current system, as defined by an [equal-style variable](#).

For the first criterion, the specified energy tolerance *etol* is unitless; it is met when the energy change between successive iterations divided by the energy magnitude is less than or equal to the tolerance. For example, a setting of 1.0e-4 for *etol* means an energy tolerance of one part in 10⁴. For the damped dynamics minimizers this check is not performed for a few steps after velocities are reset to 0, otherwise the minimizer would prematurely converge.

For the second criterion, the specified force tolerance *ftol* is in force units, since it is the length of the global force vector for all atoms, e.g. a vector of size 3N for N atoms. Since many of the components will be near zero after minimization, you can think of *ftol* as an upper bound on the final force on any component of any atom. For example, a setting of 1.0e-4 for *ftol* means no x, y, or z component of force on any atom will be

LAMMPS Users Manual

larger than 1.0e-4 (in force units) after minimization.

Either or both of the *etol* and *ftol* values can be set to 0.0, in which case some other criterion will terminate the minimization.

During a minimization, the outer iteration count is treated as a timestep. Output is triggered by this timestep, e.g. thermodynamic output or dump and restart files.

Using the `thermo_style custom` command with the *fmax* or *fnorm* keywords can be useful for monitoring the progress of the minimization. Note that these outputs will be calculated only from forces on the atoms, and will not include any extra degrees of freedom, such as from the `fix box/relax` command.

Following minimization, a statistical summary is printed that lists which convergence criterion caused the minimizer to stop, as well as information about the energy, force, final line search, and iteration counts. An example is as follows:

```
Minimization stats:
Stopping criterion = max iterations
Energy initial, next-to-last, final =
    -0.626828169302    -2.82642039062    -2.82643549739
Force two-norm initial, final = 2052.1 91.9642
Force max component initial, final = 346.048 9.78056
Final line search alpha, max atom move = 2.23899e-06 2.18986e-05
Iterations, force evaluations = 2000 12724
```

The 3 energy values are for before and after the minimization and on the next-to-last iteration. This is what the *etol* parameter checks.

The two-norm force values are the length of the global force vector before and after minimization. This is what the *ftol* parameter checks.

The max-component force values are the absolute value of the largest component (x,y,z) in the global force vector, i.e. the infinity-norm of the force vector.

The alpha parameter for the line-search, when multiplied by the max force component (on the last iteration), gives the max distance any atom moved during the last iteration. Alpha will be 0.0 if the line search could not reduce the energy. Even if alpha is non-zero, if the "max atom move" distance is tiny compared to typical atom coordinates, then it is possible the last iteration effectively caused no atom movement and thus the evaluated energy did not change and the minimizer terminated. Said another way, even with non-zero forces, it's possible the effect of those forces is to move atoms a distance less than machine precision, so that the energy cannot be further reduced.

The iterations and force evaluation values are what is checked by the *maxiter* and *maxeval* parameters.

NOTE: There are several force fields in LAMMPS which have discontinuities or other approximations which may prevent you from performing an energy minimization to high tolerances. For example, you should use a `pair style` that goes to 0.0 at the cutoff distance when performing minimization (even if you later change it when running

LAMMPS Users Manual

dynamics). If you do not do this, the total energy of the system will have discontinuities when the relative distance between any pair of atoms changes from cutoff+epsilon to cutoff-epsilon and the minimizer may behave poorly. Some of the manybody potentials use splines and other internal cutoffs that inherently have this problem. The [long-range Coulombic styles](#) (PPPM, Ewald) are approximate to within the user-specified tolerance, which means their energy and forces may not agree to a higher precision than the Kspace-specified tolerance. In all these cases, the minimizer may give up and stop before finding a minimum to the specified energy or force tolerance.

Note that a cutoff Lennard-Jones potential (and others) can be shifted so that its energy is 0.0 at the cutoff via the [pair_modify](#) command. See the doc pages for individual [pair styles](#) for details. Note that Coulombic potentials always have a cutoff, unless versions with a long-range component are used (e.g. [pair_style lj/cut/coul/long](#)). The CHARMM potentials go to 0.0 at the cutoff (e.g. [pair_style lj/charmm/coul/charmm](#)), as do the GROMACS potentials (e.g. [pair_style lj/gromacs](#)).

If a soft potential ([pair_style soft](#)) is used the Astop value is used for the prefactor (no time dependence).

The [fix box/relax](#) command can be used to apply an external pressure to the simulation box and allow it to shrink/expand during the minimization.

Only a few other fixes (typically those that apply force constraints) are invoked during minimization. See the doc pages for individual [fix](#) commands to see which ones are relevant. Current examples of fixes that can be used include:

- [fix addforce](#)
- [fix addtorque](#)
- [fix efield](#)
- [fix enforce2d](#)
- [fix indent](#)
- [fix lineforce](#)
- [fix planeforce](#)
- [fix setforce](#)
- [fix spring](#)
- [fix spring/self](#)
- [fix viscous](#)
- [fix wall](#)
- [fix wall/region](#)

NOTE: Some fixes which are invoked during minimization have an associated potential energy. For that energy to be included in the total potential energy of the system (the quantity being minimized), you MUST enable the [fix_modify energy](#) option for that fix. The doc pages for individual [fix](#) commands specify if this should be done.

Restrictions:

Features that are not yet implemented are listed here, in case someone knows how they could be coded:

LAMMPS Users Manual

It is an error to use [fix shake](#) with minimization because it turns off bonds that should be included in the potential energy of the system. The effect of a fix shake can be approximated during a minimization by using stiff spring constants for the bonds and/or angles that would normally be constrained by the SHAKE algorithm.

[Fix rigid](#) is also not supported by minimization. It is not an error to have it defined, but the energy minimization will not keep the defined body(s) rigid during the minimization. Note that if bonds, angles, etc internal to a rigid body have been turned off (e.g. via [neigh_modify exclude](#)), they will not contribute to the potential energy which is probably not what is desired.

Pair potentials that produce torque on a particle (e.g. [granular potentials](#) or the [GayBerne potential](#) for ellipsoidal particles) are not relaxed by a minimization. More specifically, radial relaxations are induced, but no rotations are induced by a minimization, so such a system will not fully relax.

molecule C02 co2.txt boff 3 aoff 2
molecule 1 mymol.txt offset 6 9 18 23 14
molecule objects file.1 scale 1.5 file.1 scale 2.0 file.2 scale 1.3
```

Description:

Define a molecule template that can be used as part of other LAMMPS commands, typically to define a collection of particles as a bonded molecule or a rigid body. Commands that currently use molecule templates include:

- [fix deposit](#)
- [fix pour](#)
- [fix rigid/small](#)
- [fix shake](#)
- [fix gcmc](#)
- [create_atoms](#)
- [atom_style template](#)

LAMMPS Users Manual

The ID of a molecule template can only contain alphanumeric characters and underscores.

A single template can contain multiple molecules, listed one per file. Some of the commands listed above currently use only the first molecule in the template, and will issue a warning if the template contains multiple molecules. The [atom_style template](#) command allows multiple-molecule templates to define a system with more than one templated molecule.

Each filename can be followed by optional keywords which are applied only to the molecule in the file as used in this template. This is to make it easy to use the same molecule file in different molecule templates or in different simulations. You can specify the same file multiple times with different optional keywords.

The *offset*, *toff*, *aoff*, *doff*, *ioff* keywords add the specified offset values to the atom types, bond types, angle types, dihedral types, and/or improper types as they are read from the molecule file. E.g. if *toff* = 2, and the file uses atom types 1,2,3, then each created molecule will have atom types 3,4,5. For the *offset* keyword, all five offset values must be specified, but individual values will be ignored if the molecule template does not use that attribute (e.g. no bonds).

The *scale* keyword scales the size of the molecule. This can be useful for modeling polydisperse granular rigid bodies. The scale factor is applied to each of these properties in the molecule file, if they are defined: the individual particle coordinates (Coords section), the individual mass of each particle (Masses section), the individual diameters of each particle (Diameters section), the total mass of the molecule (header keyword = mass), the center-of-mass of the molecule (header keyword = com), and the moments of inertia of the molecule (header keyword = inertia).

NOTE: The molecule command can be used to define molecules with bonds, angles, dihedrals, improper, or special bond lists of neighbors within a molecular topology, so that you can later add the molecules to your simulation, via one or more of the commands listed above. If such molecules do not already exist when LAMMPS creates the simulation box, via the [create_box](#) or [read_data](#) command, when you later add them you may overflow the pre-allocated data structures which store molecular topology information with each atom, and an error will be generated. Both the [create_box](#) command and the data files read by the [read_data](#) command have "extra" options which insure space is allocated for storing topology info for molecules that are added later.

The format of an individual molecule file is similar to the data file read by the [read_data](#) commands, and is as follows.

A molecule file has a header and a body. The header appears first. The first line of the header is always skipped; it typically contains a description of the file. Then lines are read one at a time. Lines can have a trailing comment starting with '#' that is ignored. If the line is blank (only whitespace after comment is deleted), it is skipped. If the line contains a header keyword, the corresponding value(s) is read from the line. If it doesn't contain a header keyword, the line begins the body of the file.

LAMMPS Users Manual

The body of the file contains zero or more sections. The first line of a section has only a keyword. The next line is skipped. The remaining lines of the section contain values. The number of lines depends on the section keyword as described below. Zero or more blank lines can be used between sections. Sections can appear in any order, with a few exceptions as noted below.

These are the recognized header keywords. Header lines can come in any order. The numeric value(s) are read from the beginning of the line. The keyword should appear at the end of the line. All these settings have default values, as explained below. A line need only appear if the value(s) are different than the default.

- *N atoms* = # of atoms N in molecule, default = 0
- *Nb bonds* = # of bonds Nb in molecule, default = 0
- *Na angles* = # of angles Na in molecule, default = 0
- *Nd dihedrals* = # of dihedrals Nd in molecule, default = 0
- *Ni impropers* = # of impropers Ni in molecule, default = 0
- *Mtotal mass* = total mass of molecule
- *Xc Yc Zc com* = coordinates of center-of-mass of molecule
- *Ixx Iyy Izz Ixy Ixz Iyz inertia* = 6 components of inertia tensor of molecule

For *mass*, *com*, and *inertia*, the default is for LAMMPS to calculate this quantity itself if needed, assuming the molecule consists of a set of point particles or finite-size particles (with a non-zero diameter) that do not overlap. If finite-size particles in the molecule do overlap, LAMMPS will not account for the overlap effects when calculating any of these 3 quantities, so you should pre-compute them yourself and list the values in the file.

The mass and center-of-mass coordinates (*Xc*,*Yc*,*Zc*) are self-explanatory. The 6 moments of inertia (*ixx*,*iyy*,*izz*,*ixy*,*ixz*,*iyz*) should be the values consistent with the current orientation of the rigid body around its center of mass. The values are with respect to the simulation box XYZ axes, not with respect to the principal axes of the rigid body itself. LAMMPS performs the latter calculation internally.

These are the allowed section keywords for the body of the file.

- *Coords, Types, Charges, Diameters, Masses* = atom-property sections
- *Bonds, Angles, Dihedrals, Impropers* = molecular topology sections
- *Special Bond Counts, Special Bonds* = special neighbor info
- *Shake Flags, Shake Atoms, Shake Bond Types* = SHAKE info

If a Bonds section is specified then the Special Bond Counts and Special Bonds sections can also be used, if desired, to explicitly list the 1-2, 1-3, 1-4 neighbors within the molecule topology (see details below). This is optional since if these sections are not included, LAMMPS will auto-generate this information. Note that LAMMPS uses this info to properly exclude or weight bonded pairwise interactions between bonded atoms. See the [special_bonds](#) command for more details. One reason to list the special bond info explicitly is for the [thermalized Drude oscillator model](#) which treats the bonds between nuclear cores and Drude electrons in a different manner.

NOTE: Whether a section is required depends on how the molecule template is used by other LAMMPS commands. For example, to add a molecule via the [fix deposit](#)

LAMMPS Users Manual

command, the Coords and Types sections are required. To add a rigid body via the [fix pour](#) command, the Bonds (Angles, etc) sections are not required, since the molecule will be treated as a rigid body. Some sections are optional. For example, the [fix pour](#) command can be used to add "molecules" which are clusters of finite-size granular particles. If the Diameters section is not specified, each particle in the molecule will have a default diameter of 1.0. See the doc pages for LAMMPS commands that use molecule templates for more details.

Each section is listed below in alphabetic order. The format of each section is described including the number of lines it must contain and rules (if any) for whether it can appear in the data file. In each case the ID is ignored; it is simply included for readability, and should be a number from 1 to Nlines for the section, indicating which atom (or bond, etc) the entry applies to. The lines are assumed to be listed in order from 1 to Nlines, but LAMMPS does not check for this.

Coords section:

- one line per atom
 - line syntax: ID x y z
 - x,y,z = coordinate of atom
-

Types section:

- one line per atom
 - line syntax: ID type
 - type = atom type of atom
-

Charges section:

- one line per atom
- line syntax: ID q
- q = charge on atom

This section is only allowed for [atom styles](#) that support charge. If this section is not included, the default charge on each atom in the molecule is 0.0.

Diameters section:

- one line per atom
- line syntax: ID diam
- diam = diameter of atom

This section is only allowed for [atom styles](#) that support finite-size spherical particles, e.g. atom_style sphere. If not listed, the default diameter of each atom in the molecule is 1.0.

Masses section:

- one line per atom
- line syntax: ID mass

LAMMPS Users Manual

- mass = mass of atom

This section is only allowed for [atom styles](#) that support per-atom mass, as opposed to per-type mass. See the [mass](#) command for details. If this section is not included, the default mass for each atom is derived from its volume (see [Diameters](#) section) and a default density of 1.0, in [units](#) of mass/volume.

Bonds section:

- one line per bond
- line syntax: ID type atom1 atom2
- type = bond type (1-Nbondtype)
- atom1,atom2 = IDs of atoms in bond

The IDs for the two atoms in each bond should be values from 1 to Natoms, where Natoms = # of atoms in the molecule.

Angles section:

- one line per angle
- line syntax: ID type atom1 atom2 atom3
- type = angle type (1-Nangletype)
- atom1,atom2,atom3 = IDs of atoms in angle

The IDs for the three atoms in each angle should be values from 1 to Natoms, where Natoms = # of atoms in the molecule. The 3 atoms are ordered linearly within the angle. Thus the central atom (around which the angle is computed) is the atom2 in the list.

Dihedrals section:

- one line per dihedral
- line syntax: ID type atom1 atom2 atom3 atom4
- type = dihedral type (1-Ndihedralttype)
- atom1,atom2,atom3,atom4 = IDs of atoms in dihedral

The IDs for the four atoms in each dihedral should be values from 1 to Natoms, where Natoms = # of atoms in the molecule. The 4 atoms are ordered linearly within the dihedral.

Impropers section:

- one line per improper
- line syntax: ID type atom1 atom2 atom3 atom4
- type = improper type (1-Nimproprtype)
- atom1,atom2,atom3,atom4 = IDs of atoms in improper

The IDs for the four atoms in each improper should be values from 1 to Natoms, where Natoms = # of atoms in the molecule. The ordering of the 4 atoms determines the definition of the improper angle used in the formula for the defined [improper](#)

[style](#). See the doc pages for individual styles for details.

Special Bond Counts section:

- one line per atom
- line syntax: ID N1 N2 N3
- N1 = # of 1-2 bonds
- N2 = # of 1-3 bonds
- N3 = # of 1-4 bonds

N1, N2, N3 are the number of 1-2, 1-3, 1-4 neighbors respectively of this atom within the topology of the molecule. See the [special_bonds](#) doc page for more discussion of 1-2, 1-3, 1-4 neighbors. If this section appears, the Special Bonds section must also appear.

As explained above, LAMMPS will auto-generate this information if this section is not specified. If specified, this section will override what would be auto-generated.

Special Bonds section:

- one line per atom
- line syntax: ID a b c d ...
- a,b,c,d,... = IDs of atoms in N1+N2+N3 special bonds

A, b, c, d, etc are the IDs of the n1+n2+n3 atoms that are 1-2, 1-3, 1-4 neighbors of this atom. The IDs should be values from 1 to Natoms, where Natoms = # of atoms in the molecule. The first N1 values should be the 1-2 neighbors, the next N2 should be the 1-3 neighbors, the last N3 should be the 1-4 neighbors. No atom ID should appear more than once. See the [special_bonds](#) doc page for more discussion of 1-2, 1-3, 1-4 neighbors. If this section appears, the Special Bond Counts section must also appear.

As explained above, LAMMPS will auto-generate this information if this section is not specified. If specified, this section will override what would be auto-generated.

Shake Flags section:

- one line per atom
- line syntax: ID flag
- flag = 0,1,2,3,4

This section is only needed when molecules created using the template will be constrained by SHAKE via the "fix shake" command. The other two Shake sections must also appear in the file, following this one.

The meaning of the flag for each atom is as follows. See the [fix shake](#) doc page for a further description of SHAKE clusters.

- 0 = not part of a SHAKE cluster
- 1 = part of a SHAKE angle cluster (two bonds and the angle they form)
- 2 = part of a 2-atom SHAKE cluster with a single bond

LAMMPS Users Manual

- 3 = part of a 3-atom SHAKE cluster with two bonds
 - 4 = part of a 4-atom SHAKE cluster with three bonds
-

Shake Atoms section:

- one line per atom
- line syntax: ID a b c d
- a,b,c,d = IDs of atoms in cluster

This section is only needed when molecules created using the template will be constrained by SHAKE via the "fix shake" command. The other two Shake sections must also appear in the file.

The a,b,c,d values are atom IDs (from 1 to Natoms) for all the atoms in the SHAKE cluster that this atom belongs to. The number of values that must appear is determined by the shake flag for the atom (see the Shake Flags section above). All atoms in a particular cluster should list their a,b,c,d values identically.

If flag = 0, no a,b,c,d values are listed on the line, just the (ignored) ID.

If flag = 1, a,b,c are listed, where a = ID of central atom in the angle, and b,c the other two atoms in the angle.

If flag = 2, a,b are listed, where a = ID of atom in bond with the the lowest ID, and b = ID of atom in bond with the highest ID.

If flag = 3, a,b,c are listed, where a = ID of central atom, and b,c = IDs of other two atoms bonded to the central atom.

If flag = 4, a,b,c,d are listed, where a = ID of central atom, and b,c,d = IDs of other three atoms bonded to the central atom.

See the [fix shake](#) doc page for a further description of SHAKE clusters.

Shake Bond Types section:

- one line per atom
- line syntax: ID a b c
- a,b,c = bond types (or angle type) of bonds (or angle) in cluster

This section is only needed when molecules created using the template will be constrained by SHAKE via the "fix shake" command. The other two Shake sections must also appear in the file.

The a,b,c values are bond types (from 1 to Nbondtypes) for all bonds in the SHAKE cluster that this atom belongs to. The number of values that must appear is determined by the shake flag for the atom (see the Shake Flags section above). All atoms in a particular cluster should list their a,b,c values identically.

If flag = 0, no a,b,c values are listed on the line, just the (ignored) ID.

LAMMPS Users Manual

If flag = 1, a,b,c are listed, where a = bondtype of the bond between the central atom and the first non-central atom (value b in the Shake Atoms section), b = bondtype of the bond between the central atom and the 2nd non-central atom (value c in the Shake Atoms section), and c = the angle type (1 to Nangletypes) of the angle between the 3 atoms.

If flag = 2, only a is listed, where a = bondtype of the bond between the 2 atoms in the cluster.

If flag = 3, a,b are listed, where a = bondtype of the bond between the central atom and the first non-central atom (value b in the Shake Atoms section), and b = bondtype of the bond between the central atom and the 2nd non-central atom (value c in the Shake Atoms section).

If flag = 4, a,b,c are listed, where a = bondtype of the bond between the central atom and the first non-central atom (value b in the Shake Atoms section), b = bondtype of the bond between the central atom and the 2nd non-central atom (value c in the Shake Atoms section), and c = bondtype of the bond between the central atom and the 3rd non-central atom (value d in the Shake Atoms section).

See the [fix shake](#) doc page for a further description of SHAKE clusters.

Restrictions: none

Related commands:

[fix deposit](#), [fix pour](#), [fix gcmc](#)

Default:

The default keywords values are offset 0 0 0 0 0 and scale = 1.0.

neb command

Syntax:

```
neb etol ftol N1 N2 Nevery file-style arg keyword
```

- etol = stopping tolerance for energy (energy units)
- ftol = stopping tolerance for force (force units)
- N1 = max # of iterations (timesteps) to run initial NEB
- N2 = max # of iterations (timesteps) to run barrier-climbing NEB
- Nevery = print replica energies and reaction coordinates every this many timesteps
- file-style = *final* or *each* or *none*

```
final arg = filename
  filename = file with initial coords for final replica
  coords for intermediate replicas are linearly interpolated
  between first and last replica
each arg = filename
  filename = unique filename for each replica (except first)
  with its initial coords
none arg = no argument all replicas assumed to already have
  their initial coords
```

keyword = *verbose*

Examples:

```
neb 0.1 0.0 1000 500 50 final coords.final
neb 0.0 0.001 1000 500 50 each coords.initial.$i
neb 0.0 0.001 1000 500 50 none verbose
```

Description:

Perform a nudged elastic band (NEB) calculation using multiple replicas of a system. Two or more replicas must be used; the first and last are the end points of the transition path.

NEB is a method for finding both the atomic configurations and height of the energy barrier associated with a transition state, e.g. for an atom to perform a diffusive hop from one energy basin to another in a coordinated fashion with its neighbors. The implementation in LAMMPS follows the discussion in these 4 papers: ([HenkelmanA](#)), ([HenkelmanB](#)), ([Nakano](#)) and ([Maras](#)).

Each replica runs on a partition of one or more processors. Processor partitions are defined at run-time using the `-partition` command-line switch; see [Section 2.6](#) of the manual. Note that if you have MPI installed, you can run a multi-replica simulation with more replicas (partitions) than you have physical processors, e.g you can run a 10-replica simulation on just one or two processors. You will simply not get the performance speed-up you would see with one or more physical processors per replica. See [Section 6.5](#) of the manual for further discussion.

LAMMPS Users Manual

NOTE: As explained below, a NEB calculation performs a damped dynamics minimization across all the replicas. The minimizer uses whatever timestep you have defined in your input script, via the `timestep` command. Often NEB will converge more quickly if you use a timestep about 10x larger than you would normally use for dynamics simulations.

When a NEB calculation is performed, it is assumed that each replica is running the same system, though LAMMPS does not check for this. I.e. the simulation domain, the number of atoms, the interaction potentials, and the starting configuration when the `neb` command is issued should be the same for every replica.

In a NEB calculation each replica is connected to other replicas by inter-replica nudging forces. These forces are imposed by the `fix neb` command, which must be used in conjunction with the `neb` command. The group used to define the `fix neb` command defines the NEB atoms which are the only ones that inter-replica springs are applied to. If the group does not include all atoms, then non-NEB atoms have no inter-replica springs and the forces they feel and their motion is computed in the usual way due only to other atoms within their replica. Conceptually, the non-NEB atoms provide a background force field for the NEB atoms. They can be allowed to move during the NEB minimization procedure (which will typically induce different coordinates for non-NEB atoms in different replicas), or held fixed using other LAMMPS commands such as `fix setforce`. Note that the `partition` command can be used to invoke a command on a subset of the replicas, e.g. if you wish to hold NEB or non-NEB atoms fixed in only the end-point replicas.

The initial atomic configuration for each of the replicas can be specified in different manners via the `file-style` setting, as discussed below. Only atoms whose initial coordinates should differ from the current configuration need be specified.

Conceptually, the initial and final configurations for the first replica should be states on either side of an energy barrier.

As explained below, the initial configurations of intermediate replicas can be atomic coordinates interpolated in a linear fashion between the first and last replicas. This is often adequate for simple transitions. For more complex transitions, it may lead to slow convergence or even bad results if the minimum energy path (MEP, see below) of states over the barrier cannot be correctly converged to from such an initial path. In this case, you will want to generate initial states for the intermediate replicas that are geometrically closer to the MEP and read them in.

For a `file-style` setting of `final`, a filename is specified which contains atomic coordinates for zero or more atoms, in the format described below. For each atom that appears in the file, the new coordinates are assigned to that atom in the final replica. Each intermediate replica also assigns a new position to that atom in an interpolated manner. This is done by using the current position of the atom as the starting point and the read-in position as the final point. The distance between them is calculated, and the new position is assigned to be a fraction of the distance. E.g. if there are 10 replicas, the 2nd replica will assign a position that is 10% of the distance along a line between the starting and final point, and the 9th replica will assign a position that is 90% of the distance along the line. Note that for this procedure to produce consistent coordinates across all the replicas, the current coordinates need to be the same in all

LAMMPS Users Manual

replicas. LAMMPS does not check for this, but invalid initial configurations will likely result if it is not the case.

NOTE: The "distance" between the starting and final point is calculated in a minimum-image sense for a periodic simulation box. This means that if the two positions are on opposite sides of a box (periodic in that dimension), the distance between them will be small, because the periodic image of one of the atoms is close to the other. Similarly, even if the assigned position resulting from the interpolation is outside the periodic box, the atom will be wrapped back into the box when the NEB calculation begins.

For a *file-style* setting of *each*, a filename is specified which is assumed to be unique to each replica. This can be done by using a variable in the filename, e.g.

```
variable i equal part
neb 0.0 0.001 1000 500 50 each coords.initial.$i
```

which in this case will substitute the partition ID (0 to N-1) for the variable I, which is also effectively the replica ID. See the [variable](#) command for other options, such as using *world-*, *universe-*, or *uloop-style* variables.

Each replica (except the first replica) will read its file, formatted as described below, and for any atom that appears in the file, assign the specified coordinates to its atom. The various files do not need to contain the same set of atoms.

For a *file-style* setting of *none*, no filename is specified. Each replica is assumed to already be in its initial configuration at the time the *neb* command is issued. This allows each replica to define its own configuration by reading a replica-specific data or restart or dump file, via the [read_data](#), [read_restart](#), or [read_dump](#) commands. The replica-specific names of these files can be specified as in the discussion above for the *each* file-style. Also see the section below for how a NEB calculation can produce restart files, so that a long calculation can be restarted if needed.

NOTE: None of the *file-style* settings change the initial configuration of any atom in the first replica. The first replica must thus be in the correct initial configuration at the time the *neb* command is issued.

A NEB calculation proceeds in two stages, each of which is a minimization procedure, performed via damped dynamics. To enable this, you must first define a damped dynamics [min_style](#), such as *quickmin* or *fire*. The *cg*, *sd*, and *hftn* styles cannot be used, since they perform iterative line searches in their inner loop, which cannot be easily synchronized across multiple replicas.

The minimizer tolerances for energy and force are set by *etol* and *ftol*, the same as for the [minimize](#) command.

A non-zero *etol* means that the NEB calculation will terminate if the energy criterion is met by every replica. The energies being compared to *etol* do not include any contribution from the inter-replica nudging forces, since these are non-conservative. A non-zero *ftol* means that the NEB calculation will terminate if the force criterion is met by every replica. The forces being compared to *ftol* include the inter-replica

nudging forces.

The maximum number of iterations in each stage is set by *N1* and *N2*. These are effectively timestep counts since each iteration of damped dynamics is like a single timestep in a dynamics [run](#). During both stages, the potential energy of each replica and its normalized distance along the reaction path (reaction coordinate RD) will be printed to the screen and log file every *Nevery* timesteps. The RD is 0 and 1 for the first and last replica. For intermediate replicas, it is the cumulative distance (normalized by the total cumulative distance) between adjacent replicas, where "distance" is defined as the length of the 3N-vector of differences in atomic coordinates, where N is the number of NEB atoms involved in the transition. These outputs allow you to monitor NEB's progress in finding a good energy barrier. *N1* and *N2* must both be multiples of *Nevery*.

In the first stage of NEB, the set of replicas should converge toward a minimum energy path (MEP) of conformational states that transition over a barrier. The MEP for a transition is defined as a sequence of 3N-dimensional states, each of which has a potential energy gradient parallel to the MEP itself. The configuration of highest energy along a MEP corresponds to a saddle point. The replica states will also be roughly equally spaced along the MEP due to the inter-replica nudging force added by the [fix neb](#) command.

In the second stage of NEB, the replica with the highest energy is selected and the inter-replica forces on it are converted to a force that drives its atom coordinates to the top or saddle point of the barrier, via the barrier-climbing calculation described in ([HenkelmanB](#)). As before, the other replicas rearrange themselves along the MEP so as to be roughly equally spaced.

When both stages are complete, if the NEB calculation was successful, the configurations of the replicas should be along (close to) the MEP and the replica with the highest energy should be an atomic configuration at (close to) the saddle point of the transition. The potential energies for the set of replicas represents the energy profile of the transition along the MEP.

A few other settings in your input script are required or advised to perform a NEB calculation. See the NOTE about the choice of timestep at the beginning of this doc page.

An atom map must be defined which it is not by default for [atom_style atomic](#) problems. The [atom_modify map](#) command can be used to do this.

The minimizers in LAMMPS operate on all atoms in your system, even non-NEB atoms, as defined above. To prevent non-NEB atoms from moving during the minimization, you should use the [fix setforce](#) command to set the force on each of those atoms to 0.0. This is not required, and may not even be desired in some cases, but if those atoms move too far (e.g. because the initial state of your system was not well-minimized), it can cause problems for the NEB procedure.

The damped dynamics [minimizers](#), such as *quickmin* and *fire*), adjust the position and velocity of the atoms via an Euler integration step. Thus you must define an appropriate [timestep](#) to use with NEB. As mentioned above, NEB will often converge

LAMMPS Users Manual

more quickly if you use a timestep about 10x larger than you would normally use for dynamics simulations.

Each file read by the `neb` command containing atomic coordinates used to initialize one or more replicas must be formatted as follows.

The file can be ASCII text or a gzipped text file (detected by a `.gz` suffix). The file can contain initial blank lines or comment lines starting with `"#"` which are ignored. The first non-blank, non-comment line should list `N` = the number of lines to follow. The `N` successive lines contain the following information:

```
ID1 x1 y1 z1
ID2 x2 y2 z2
...
IDN xN yN zN
```

The fields are the atom ID, followed by the `x,y,z` coordinates. The lines can be listed in any order. Additional trailing information on the line is OK, such as a comment.

Note that for a typical NEB calculation you do not need to specify initial coordinates for very many atoms to produce differing starting and final replicas whose intermediate replicas will converge to the energy barrier. Typically only new coordinates for atoms geometrically near the barrier need be specified.

Also note there is no requirement that the atoms in the file correspond to the NEB atoms in the group defined by the `fix neb` command. Not every NEB atom need be in the file, and non-NEB atoms can be listed in the file.

Four kinds of output can be generated during a NEB calculation: energy barrier statistics, thermodynamic output by each replica, dump files, and restart files.

When running with multiple partitions (each of which is a replica in this case), the print-out to the screen and master `log.lammps` file contains a line of output, printed once every *Nevery* timesteps. It contains the timestep, the maximum force per replica, the maximum force per atom (in any replica), potential gradients in the initial, final, and climbing replicas, the forward and backward energy barriers, the total reaction coordinate (RDT), and the normalized reaction coordinate and potential energy of each replica.

The "maximum force per replica" is the two-norm of the `3N`-length force vector for the atoms in each replica, maximized across replicas, which is what the `ftol` setting is checking against. In this case, `N` is all the atoms in each replica. The "maximum force per atom" is the maximum force component of any atom in any replica. The potential gradients are the two-norm of the `3N`-length force vector solely due to the interaction potential i.e. without adding in inter-replica forces.

The "reaction coordinate" (RD) for each replica is the two-norm of the `3N`-length vector of distances between its atoms and the preceding replica's atoms, added to the RD of the preceding replica. The RD of the first replica `RD1 = 0.0`; the RD of the final replica `RDN = RDT`, the total reaction coordinate. The normalized RDs are divided by `RDT`, so that they form a monotonically increasing sequence from zero to one. When

LAMMPS Users Manual

computing RD, N only includes the atoms being operated on by the fix neb command.

The forward (reverse) energy barrier is the potential energy of the highest replica minus the energy of the first (last) replica.

Supplementary information for all replicas can be printed out to the screen and master log.lammps file by adding the verbose keyword. This information include the following. The "path angle" (pathangle) for the replica i which is the angle between the $3N$ -length vectors $(R_{i-1} - R_i)$ and $(R_{i+1} - R_i)$ (where R_i is the atomic coordinates of replica i). A "path angle" of 180 indicates that replicas $i-1$, i and $i+1$ are aligned. "angletangrad" is the angle between the $3N$ -length tangent vector and the $3N$ -length force vector at image i . The tangent vector is calculated as in (HenkelmanA) for all intermediate replicas and at $R_2 - R_1$ and $R_M - R_{M-1}$ for the first and last replica, respectively. "anglegrad" is the angle between the $3N$ -length energy gradient vector of replica i and that of replica $i+1$. It is not defined for the final replica and reads nan. gradV is the norm of the energy gradient of image i . ReplicaForce is the two-norm of the $3N$ -length force vector (including nudging forces) for replica i . MaxAtomForce is the maximum force component of any atom in replica i .

When a NEB calculation does not converge properly, the supplementary information can help understanding what is going wrong. For instance when the path angle becomes accute the definition of tangent used in the NEB calculation is questionable and the NEB cannot may diverge (Maras).

When running on multiple partitions, LAMMPS produces additional log files for each partition, e.g. log.lammps.0, log.lammps.1, etc. For a NEB calculation, these contain the thermodynamic output for each replica.

If `dump` commands in the input script define a filename that includes a *universe* or *uloop* style `variable`, then one dump file (per dump command) will be created for each replica. At the end of the NEB calculation, the final snapshot in each file will contain the sequence of snapshots that transition the system over the energy barrier. Earlier snapshots will show the convergence of the replicas to the MEP.

Likewise, `restart` filenames can be specified with a *universe* or *uloop* style `variable`, to generate restart files for each replica. These may be useful if the NEB calculation fails to converge properly to the MEP, and you wish to restart the calculation from an intermediate point with altered parameters.

There are 2 Python scripts provided in the tools/python directory, `neb_combine.py` and `neb_final.py`, which are useful in analyzing output from a NEB calculation. Assume a NEB simulation with M replicas, and the NEB atoms labeled with a specific atom type.

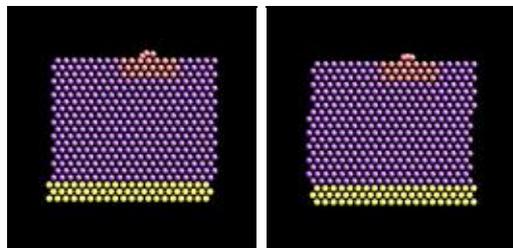

The `neb_combine.py` script extracts atom coords for the NEB atoms from all M dump files and creates a single dump file where each snapshot contains the NEB atoms from all the replicas and one copy of non-NEB atoms from the first replica (presumed to be identical in other replicas). This can be visualized/animated to see how the NEB atoms relax as the NEB calculation proceeds.

The `neb_final.py` script extracts the final snapshot from each of the M dump files to create a single dump file with M snapshots. This can be visualized to watch the system

LAMMPS Users Manual

make its transition over the energy barrier.

To illustrate, here are images from the final snapshot produced by the `neb_combine.py` script run on the dump files produced by the two example input scripts in `examples/neb`. Click on them to see a larger image.

Restrictions:

This command can only be used if LAMMPS was built with the REPLICAs package. See the [Making LAMMPS](#) section for more info on packages.

neigh_modify command

Syntax:

neigh_modify keyword values ...

- one or more keyword/value pairs may be listed

keyword = *delay* or *every* or *check* or *once* or *cluster* or *include* or *exclude* or *page* or *one*

delay value = N

N = delay building until this many steps since last build

every value = M

M = build neighbor list every this many steps

check value = *yes* or *no*

yes = only build if some atom has moved half the skin distance or more

no = always build on 1st step that *every* and *delay* are satisfied

once

yes = only build neighbor list once at start of run and never rebuild

no = rebuild neighbor list according to other settings

cluster

yes = check bond,angle,etc neighbor list for nearby clusters

no = do not check bond,angle,etc neighbor list for nearby clusters

include value = group-ID

group-ID = only build pair neighbor lists for atoms in this group

exclude values:

type M N

M,N = exclude if one atom in pair is type M, other is type N

group group1-ID group2-ID

group1-ID,group2-ID = exclude if one atom is in 1st group, other in 2nd

molecule/intra group-ID

group-ID = exclude if both atoms are in the same molecule and in group

molecule/inter group-ID

group-ID = exclude if both atoms are in different molecules and in group

none

delete all exclude settings

page value = N

N = number of pairs stored in a single neighbor page

one value = N

N = max number of neighbors of one atom

binsize value = size

size = bin size for neighbor list construction (distance units)

Examples:

```
neigh_modify every 2 delay 10 check yes page 100000
```

```
neigh_modify exclude type 2 3
```

```
neigh_modify exclude group frozen frozen check no
```

```
neigh_modify exclude group residue1 chain3
```

```
neigh_modify exclude molecule/intra rigid
```

Description:

This command sets parameters that affect the building and use of pairwise neighbor lists. Depending on what pair interactions and other commands are defined, a simulation may require one or more neighbor lists.

LAMMPS Users Manual

The *every*, *delay*, *check*, and *once* options affect how often lists are built as a simulation runs. The *delay* setting means never build new lists until at least N steps after the previous build. The *every* setting means build lists every M steps (after the delay has passed). If the *check* setting is *no*, the lists are built on the first step that satisfies the *delay* and *every* settings. If the *check* setting is *yes*, then the *every* and *delay* settings determine when a build may possibly be performed, but an actual build only occurs if some atom has moved more than half the skin distance (specified in the [neighbor](#) command) since the last build.

If the *once* setting is *yes*, then the neighbor list is only built once at the beginning of each run, and never rebuilt, except on steps when a restart file is written, or steps when a fix forces a rebuild to occur (e.g. fixes that create or delete atoms, such as [fix deposit](#) or [fix evaporate](#)). This setting should only be made if you are certain atoms will not move far enough that the neighbor list should be rebuilt, e.g. running a simulation of a cold crystal. Note that it is not that expensive to check if neighbor lists should be rebuilt.

When the rRESPA integrator is used (see the [run_style](#) command), the *every* and *delay* parameters refer to the longest (outermost) timestep.

The *cluster* option does a sanity test every time neighbor lists are built for bond, angle, dihedral, and improper interactions, to check that each set of 2, 3, or 4 atoms is a cluster of nearby atoms. It does this by computing the distance between pairs of atoms in the interaction and insuring they are not further apart than half the periodic box length. If they are, an error is generated, since the interaction would be computed between far-away atoms instead of their nearby periodic images. The only way this should happen is if the pairwise cutoff is so short that atoms that are part of the same interaction are not communicated as ghost atoms. This is an unusual model (e.g. no pair interactions at all) and the problem can be fixed by use of the [comm_modify cutoff](#) command. Note that to save time, the default *cluster* setting is *no*, so that this check is not performed.

The *include* option limits the building of pairwise neighbor lists to atoms in the specified group. This can be useful for models where a large portion of the simulation is particles that do not interact with other particles or with each other via pairwise interactions. The group specified with this option must also be specified via the [atom_modify first](#) command. Note that specifying "all" as the group-ID effectively turns off the *include* option.

The *exclude* option turns off pairwise interactions between certain pairs of atoms, by not including them in the neighbor list. These are sample scenarios where this is useful:

- In crack simulations, pairwise interactions can be shut off between 2 slabs of atoms to effectively create a crack.
- When a large collection of atoms is treated as frozen, interactions between those atoms can be turned off to save needless computation. E.g. Using the [fix setforce](#) command to freeze a wall or portion of a bio-molecule.
- When one or more rigid bodies are specified, interactions within each body can be turned off to save needless computation. See the [fix rigid](#) command for more details.

LAMMPS Users Manual

The *exclude type* option turns off the pairwise interaction if one atom is of type M and the other of type N. M can equal N. The *exclude group* option turns off the interaction if one atom is in the first group and the other is the second. Group1-ID can equal group2-ID. The *exclude molecule/intra* option turns off the interaction if both atoms are in the specified group and in the same molecule, as determined by their molecule ID. The *exclude molecule/inter* turns off the interaction between pairs of atoms that have different molecule IDs and are both in the specified group.

Each of the exclude options can be specified multiple times. The *exclude type* option is the most efficient option to use; it requires only a single check, no matter how many times it has been specified. The other exclude options are more expensive if specified multiple times; they require one check for each time they have been specified.

Note that the exclude options only affect pairwise interactions; see the [delete_bonds](#) command for information on turning off bond interactions.

NOTE: Excluding pairwise interactions will not work correctly when also using a long-range solver via the [kspace_style](#) command. LAMMPS will give a warning to this effect. This is because the short-range pairwise interaction needs to subtract off a term from the total energy for pairs whose short-range interaction is excluded, to compensate for how the long-range solver treats the interaction. This is done correctly for pairwise interactions that are excluded (or weighted) via the [special_bonds](#) command. But it is not done for interactions that are excluded via these `neigh_modify` exclude options.

The *page* and *one* options affect how memory is allocated for the neighbor lists. For most simulations the default settings for these options are fine, but if a very large problem is being run or a very long cutoff is being used, these parameters can be tuned. The indices of neighboring atoms are stored in "pages", which are allocated one after another as they fill up. The size of each page is set by the *page* value. A new page is allocated when the next atom's neighbors could potentially overflow the list. This threshold is set by the *one* value which tells LAMMPS the maximum number of neighbor's one atom can have.

NOTE: LAMMPS can crash without an error message if the number of neighbors for a single particle is larger than the *page* setting, which means it is much, much larger than the *one* setting. This is because LAMMPS doesn't error check these limits for every pairwise interaction (too costly), but only after all the particle's neighbors have been found. This problem usually means something is very wrong with the way you've setup your problem (particle spacing, cutoff length, neighbor skin distance, etc). If you really expect that many neighbors per particle, then boost the *one* and *page* settings accordingly.

The *binsize* option allows you to specify what size of bins will be used in neighbor list construction to sort and find neighboring atoms. By default, for [neighbor style bin](#), LAMMPS uses bins that are 1/2 the size of the maximum pair cutoff. For [neighbor style multi](#), the bins are 1/2 the size of the minimum pair cutoff. Typically these are good values values for minimizing the time for neighbor list construction. This setting overrides the default. If you make it too big, there is little overhead due to looping over bins, but more atoms are checked. If you make it too small, the optimal number of atoms is checked, but bin overhead goes up. If you set the binsize to 0.0, LAMMPS

LAMMPS Users Manual

will use the default binsize of 1/2 the cutoff.

Restrictions:

If the "delay" setting is non-zero, then it must be a multiple of the "every" setting.

The molecule/intra and molecule/inter exclude options can only be used with atom styles that define molecule IDs.

The value of the *page* setting must be at least 10x larger than the *one* setting. This insures neighbor pages are not mostly empty space.

Related commands:

[neighbor](#), [delete_bonds](#)

Default:

The option defaults are delay = 10, every = 1, check = yes, once = no, cluster = no, include = all (same as no include option defined), exclude = none, page = 100000, one = 2000, and binsize = 0.0.

neighbor command

Syntax:

```
neighbor skin style
```

- skin = extra distance beyond force cutoff (distance units)
- style = *bin* or *nsq* or *multi*

Examples:

```
neighbor 0.3 bin  
neighbor 2.0 nsq
```

Description:

This command sets parameters that affect the building of pairwise neighbor lists. All atom pairs within a neighbor cutoff distance equal to the their force cutoff plus the *skin* distance are stored in the list. Typically, the larger the skin distance, the less often neighbor lists need to be built, but more pairs must be checked for possible force interactions every timestep. The default value for *skin* depends on the choice of units for the simulation; see the default values below.

The *skin* distance is also used to determine how often atoms migrate to new processors if the *check* option of the [neigh_modify](#) command is set to *yes*. Atoms are migrated (communicated) to new processors on the same timestep that neighbor lists are re-built.

The *style* value selects what algorithm is used to build the list. The *bin* style creates the list by binning which is an operation that scales linearly with N/P, the number of atoms per processor where N = total number of atoms and P = number of processors. It is almost always faster than the *nsq* style which scales as (N/P)². For unsolvated small molecules in a non-periodic box, the *nsq* choice can sometimes be faster. Either style should give the same answers.

The *multi* style is a modified binning algorithm that is useful for systems with a wide range of cutoff distances, e.g. due to different size particles. For the *bin* style, the bin size is set to 1/2 of the largest cutoff distance between any pair of atom types and a single set of bins is defined to search over for all atom types. This can be inefficient if one pair of types has a very long cutoff, but other type pairs have a much shorter cutoff. For style *multi* the bin size is set to 1/2 of the shortest cutoff distance and multiple sets of bins are defined to search over for different atom types. This imposes some extra setup overhead, but the searches themselves may be much faster for the short-cutoff cases. See the [comm_modify mode multi](#) command for a communication option option that may also be beneficial for simulations of this kind.

The [neigh_modify](#) command has additional options that control how often neighbor lists are built and which pairs are stored in the list.

LAMMPS Users Manual

When a run is finished, counts of the number of neighbors stored in the pairwise list and the number of times neighbor lists were built are printed to the screen and log file. See [this section](#) for details.

Restrictions: none

Related commands:

[neigh_modify](#), [units](#), [comm_modify](#)

Default:

0.3 bin for units = lj, skin = 0.3 sigma

2.0 bin for units = real or metal, skin = 2.0 Angstroms

0.001 bin for units = si, skin = 0.001 meters = 1.0 mm

0.1 bin for units = cgs, skin = 0.1 cm = 1.0 mm

newton command

Syntax:

```
newton flag  
newton flag1 flag2
```

- flag = *on* or *off* for both pairwise and bonded interactions
- flag1 = *on* or *off* for pairwise interactions
- flag2 = *on* or *off* for bonded interactions

Examples:

```
newton off  
newton on off
```

Description:

This command turns Newton's 3rd law *on* or *off* for pairwise and bonded interactions. For most problems, setting Newton's 3rd law to *on* means a modest savings in computation at the cost of two times more communication. Whether this is faster depends on problem size, force cutoff lengths, a machine's compute/communication ratio, and how many processors are being used.

Setting the pairwise newton flag to *off* means that if two interacting atoms are on different processors, both processors compute their interaction and the resulting force information is not communicated. Similarly, for bonded interactions, newton *off* means that if a bond, angle, dihedral, or improper interaction contains atoms on 2 or more processors, the interaction is computed by each processor.

LAMMPS should produce the same answers for any newton flag settings, except for round-off issues.

With [run_style respa](#) and only bonded interactions (bond, angle, etc) computed in the innermost timestep, it may be faster to turn newton *off* for bonded interactions, to avoid extra communication in the innermost loop.

Restrictions:

The newton bond setting cannot be changed after the simulation box is defined by a [read_data](#) or [create_box](#) command.

Related commands:

[run_style respa](#)

Default:

```
newton on
```

next command

Syntax:

```
next variables
```

- variables = one or more variable names

Examples:

```
next x  
next a t x myTemp
```

Description:

This command is used with variables defined by the [variable](#) command. It assigns the next value to the variable from the list of values defined for that variable by the [variable](#) command. Thus when that variable is subsequently substituted for in an input script command, the new value is used.

See the [variable](#) command for info on how to define and use different kinds of variables in LAMMPS input scripts. If a variable name is a single lower-case character from "a" to "z", it can be used in an input script command as \$a or \$z. If it is multiple letters, it can be used as \${myTemp}.

If multiple variables are used as arguments to the *next* command, then all must be of the same variable style: *index*, *loop*, *file*, *universe*, or *uloop*. An exception is that *universe*- and *uloop*-style variables can be mixed in the same *next* command.

All the variables specified with the *next* command are incremented by one value from their respective list of values. A *file*-style variable reads the next line from its associated file. An *atomfile*-style variable reads the next set of lines (one per atom) from its associated file. *String*- or *atom*- or *equal*- or *world*-style variables cannot be used with the *next* command, since they only store a single value.

When any of the variables in the *next* command has no more values, a flag is set that causes the input script to skip the next [jump](#) command encountered. This enables a loop containing a *next* command to exit. As explained in the [variable](#) command, the variable that has exhausted its values is also deleted. This allows it to be used and re-defined later in the input script. *File*-style and *atomfile*-style variables are exhausted when the end-of-file is reached.

When the *next* command is used with *index*- or *loop*-style variables, the next value is assigned to the variable for all processors. When the *next* command is used with *file*-style variables, the next line is read from its file and the string assigned to the variable. When the *next* command is used with *atomfile*-style variables, the next set of per-atom values is read from its file and assigned to the variable.

LAMMPS Users Manual

When the next command is used with *universe*- or *uloop*-style variables, all *universe*- or *uloop*-style variables must be listed in the next command. This is because of the manner in which the incrementing is done, using a single lock file for all variables. The next value (for each variable) is assigned to whichever processor partition executes the command first. All processors in the partition are assigned the same value(s). Running LAMMPS on multiple partitions of processors via the "-partition" command-line switch is described in [this section](#) of the manual. *Universe*- and *uloop*-style variables are incremented using the files "tmp.lammps.variable" and "tmp.lammps.variable.lock" which you will see in your directory during and after such a LAMMPS run.

Here is an example of running a series of simulations using the next command with an *index*-style variable. If this input script is named in.polymer, 8 simulations would be run using data files from directories run1 thru run8.

```
variable d index run1 run2 run3 run4 run5 run6 run7 run8
shell cd $d
read_data data.polymer
run 10000
shell cd ..
clear
next d
jump in.polymer
```

If the variable "d" were of style *universe*, and the same in.polymer input script were run on 3 partitions of processors, then the first 3 simulations would begin, one on each set of processors. Whichever partition finished first, it would assign variable "d" the 4th value and run another simulation, and so forth until all 8 simulations were finished.

Jump and next commands can also be nested to enable multi-level loops. For example, this script will run 15 simulations in a double loop.

```
variable i loop 3
  variable j loop 5
  clear
  ...
  read_data data.polymer.$i$j
  print Running simulation $i.$j
  run 10000
  next j
  jump in.script
next i
jump in.script
```

Here is an example of a double loop which uses the [if](#) and [jump](#) commands to break out of the inner loop when a condition is met, then continues iterating thru the outer loop.

```
label      loopa
variable  a loop 5
label     loopb
variable  b loop 5
print    "A,B = $a,$b"
run      10000
```

LAMMPS Users Manual

```
if      $b > 2 then "jump in.script break"
next    b
jump    in.script loopb
label   break
variable b delete

next    a
jump    in.script loopa
```

Restrictions:

As described above.

Related commands:

[jump](#), [include](#), [shell](#), [variable](#),

package kokkos neigh half comm device  
package omp 0 neigh no  
package omp 4  
package intel 1  
package intel 2 omp 4 mode mixed balance 0.5
```

Description:

This command invokes package-specific settings for the various accelerator packages available in LAMMPS. Currently the following packages use settings from this command: GPU, USER-INTEL, KOKKOS, and USER-OMP.

If this command is specified in an input script, it must be near the top of the script, before the simulation box has been defined. This is because it specifies settings that the accelerator packages use in their initialization, before a simulation is defined.

This command can also be specified from the command-line when launching LAMMPS, using the "-pk" [command-line switch](#). The syntax is exactly the same as when used in an input script.

Note that all of the accelerator packages require the package command to be specified (except the OPT package), if the package is to be used in a simulation (LAMMPS can be built with an accelerator package without using it in a particular simulation). However, in all cases, a default version of the command is typically

LAMMPS Users Manual

invoked by other accelerator settings.

The KOKKOS package requires a "-k on" [command-line switch](#) respectively, which invokes a "package kokkos" command with default settings.

For the GPU, USER-INTEL, and USER-OMP packages, if a "-sf gpu" or "-sf intel" or "-sf omp" [command-line switch](#) is used to auto-append accelerator suffixes to various styles in the input script, then those switches also invoke a "package gpu", "package intel", or "package omp" command with default settings.

NOTE: A package command for a particular style can be invoked multiple times when a simulation is setup, e.g. by the "-c on", "-k on", "-sf", and "-pk" [command-line switches](#), and by using this command in an input script. Each time it is used all of the style options are set, either to default values or to specified settings. I.e. settings from previous invocations do not persist across multiple invocations.

See the [Section 5.3](#) section of the manual for more details about using the various accelerator packages for speeding up LAMMPS simulations.

The *gpu* style invokes settings associated with the use of the GPU package.

The *Ngpu* argument sets the number of GPUs per node. There must be at least as many MPI tasks per node as GPUs, as set by the mpirun or mpiexec command. If there are more MPI tasks (per node) than GPUs, multiple MPI tasks will share each GPU.

Optional keyword/value pairs can also be specified. Each has a default value as listed below.

The *neigh* keyword specifies where neighbor lists for pair style computation will be built. If *neigh* is *yes*, which is the default, neighbor list building is performed on the GPU. If *neigh* is *no*, neighbor list building is performed on the CPU. GPU neighbor list building currently cannot be used with a triclinic box. GPU neighbor list calculation currently cannot be used with [hybrid](#) pair styles. GPU neighbor lists are not compatible with commands that are not GPU-enabled. When a non-GPU enabled command requires a neighbor list, it will also be built on the CPU. In these cases, it will typically be more efficient to only use CPU neighbor list builds.

The *newton* keyword sets the Newton flags for pairwise (not bonded) interactions to *off* or *on*, the same as the [newton](#) command allows. Currently, only an *off* value is allowed, since all the GPU package pair styles require this setting. This means more computation is done, but less communication. In the future a value of *on* may be allowed, so the *newton* keyword is included as an option for compatibility with the package command for other accelerator styles. Note that the newton setting for bonded interactions is not affected by this keyword.

The *binsize* keyword sets the size of bins used to bin atoms in neighbor list builds performed on the GPU, if *neigh* = *yes* is set. If *binsize* is set to 0.0 (the default), then bins = the size of the pairwise cutoff + neighbor skin distance. This is 2x larger than the LAMMPS default used for neighbor list building on the CPU. This will be close to optimal for the GPU, so you do not normally need to use this keyword. Note that if you use a longer-than-usual pairwise cutoff, e.g. to allow for a smaller fraction of KSpace

LAMMPS Users Manual

work with a [long-range Coulombic solver](#) because the GPU is faster at performing pairwise interactions, then it may be optimal to make the *binsize* smaller than the default. For example, with a cutoff of $20 \cdot \sigma$ in LJ [units](#) and a neighbor skin distance of σ , a *binsize* = $5.25 \cdot \sigma$ can be more efficient than the default.

The *split* keyword can be used for load balancing force calculations between CPU and GPU cores in GPU-enabled pair styles. If $0 < \textit{split} < 1.0$, a fixed fraction of particles is offloaded to the GPU while force calculation for the other particles occurs simultaneously on the CPU. If *split* < 0.0, the optimal fraction (based on CPU and GPU timings) is calculated every 25 timesteps, i.e. dynamic load-balancing across the CPU and GPU is performed. If *split* = 1.0, all force calculations for GPU accelerated pair styles are performed on the GPU. In this case, other [hybrid](#) pair interactions, [bond](#), [angle](#), [dihedral](#), [improper](#), and [long-range](#) calculations can be performed on the CPU while the GPU is performing force calculations for the GPU-enabled pair style. If all CPU force computations complete before the GPU completes, LAMMPS will block until the GPU has finished before continuing the timestep.

As an example, if you have two GPUs per node and 8 CPU cores per node, and would like to run on 4 nodes (32 cores) with dynamic balancing of force calculation across CPU and GPU cores, you could specify

```
mpirun -np 32 -sf gpu -in in.script      # launch command
package gpu 2 split -1                  # input script command
```

In this case, all CPU cores and GPU devices on the nodes would be utilized. Each GPU device would be shared by 4 CPU cores. The CPU cores would perform force calculations for some fraction of the particles at the same time the GPUs performed force calculation for the other particles.

The *gpuID* keyword allows selection of which GPUs on each node will be used for a simulation. The *first* and *last* values specify the GPU IDs to use (from 0 to $\text{Ngpu}-1$). By default, *first* = 0 and *last* = $\text{Ngpu}-1$, so that all GPUs are used, assuming *Ngpu* is set to the number of physical GPUs. If you only wish to use a subset, set *Ngpu* to a smaller number and *first/last* to a sub-range of the available GPUs.

The *tpa* keyword sets the number of GPU thread per atom used to perform force calculations. With a default value of 1, the number of threads will be chosen based on the pair style, however, the value can be set explicitly with this keyword to fine-tune performance. For large cutoffs or with a small number of particles per GPU, increasing the value can improve performance. The number of threads per atom must be a power of 2 and currently cannot be greater than 32.

The *device* keyword can be used to tune parameters optimized for a specific accelerator, when using OpenCL. For CUDA, the *device* keyword is ignored. Currently, the device type is limited to NVIDIA Kepler, NVIDIA Fermi, AMD Cypress, or a generic device. More devices may be added later. The default device type can be specified when building LAMMPS with the GPU library, via settings in the `lib/gpu/Makefile` that is used.

The *blocksize* keyword allows you to tweak the number of threads used per thread block. This number should be a multiple of 32 (for GPUs) and its maximum depends on

LAMMPS Users Manual

the specific GPU hardware. Typical choices are 64, 128, or 256. A larger blocksize increases occupancy of individual GPU cores, but reduces the total number of thread blocks, thus may lead to load imbalance.

The *intel* style invokes settings associated with the use of the USER-INTEL package. All of its settings, except the *omp* and *mode* keywords, are ignored if LAMMPS was not built with Xeon Phi coprocessor support. All of its settings, including the *omp* and *mode* keyword are applicable if LAMMPS was built with coprocessor support.

The *Nphi* argument sets the number of coprocessors per node. This can be set to any value, including 0, if LAMMPS was not built with coprocessor support.

Optional keyword/value pairs can also be specified. Each has a default value as listed below.

The *omp* keyword determines the number of OpenMP threads allocated for each MPI task when any portion of the interactions computed by a USER-INTEL pair style are run on the CPU. This can be the case even if LAMMPS was built with coprocessor support; see the *balance* keyword discussion below. If you are running with less MPI tasks/node than there are CPUs, it can be advantageous to use OpenMP threading on the CPUs.

NOTE: The *omp* keyword has nothing to do with coprocessor threads on the Xeon Phi; see the *tpc* and *tptask* keywords below for a discussion of coprocessor threads.

The *Nthread* value for the *omp* keyword sets the number of OpenMP threads allocated for each MPI task. Setting *Nthread* = 0 (the default) instructs LAMMPS to use whatever value is the default for the given OpenMP environment. This is usually determined via the *OMP_NUM_THREADS* environment variable or the compiler runtime, which is usually a value of 1.

For more details, including examples of how to set the *OMP_NUM_THREADS* environment variable, see the discussion of the *Nthreads* setting on this doc page for the "package omp" command. *Nthreads* is a required argument for the USER-OMP package. Its meaning is exactly the same for the USER-INTEL package.

NOTE: If you build LAMMPS with both the USER-INTEL and USER-OMP packages, be aware that both packages allow setting of the *Nthreads* value via their package commands, but there is only a single global *Nthreads* value used by OpenMP. Thus if both package commands are invoked, you should insure the two values are consistent. If they are not, the last one invoked will take precedence, for both packages. Also note that if the "-sf hybrid intel omp" [command-line](#)> switch is used, it invokes a "package intel" command, followed by a "package omp" command, both with a setting of *Nthreads* = 0.

The *mode* keyword determines the precision mode to use for computing pair style forces, either on the CPU or on the coprocessor, when using a USER-INTEL supported [pair style](#). It can take a value of *single*, *mixed* which is the default, or *double*. *Single* means single precision is used for the entire force calculation. *Mixed* means forces between a pair of atoms are computed in single precision, but accumulated and stored in double precision, including storage of forces, torques, energies, and virial

LAMMPS Users Manual

quantities. *Double* means double precision is used for the entire force calculation.

The *lrt* keyword can be used to enable "Long Range Thread (LRT)" mode. It can take a value of *yes* to enable and *no* to disable. LRT mode generates an extra thread (in addition to any OpenMP threads specified with the OMP_NUM_THREADS environment variable or the *omp* keyword). The extra thread is dedicated for performing part of the [PPPM solver](#) computations and communications. This can improve parallel performance on processors supporting Simultaneous Multithreading (SMT) such as Hyperthreading on Intel processors. In this mode, one additional thread is generated per MPI process. LAMMPS will generate a warning in the case that more threads are used than available in SMT hardware on a node. If the PPPM solver from the USER-INTEL package is not used, then the LRT setting is ignored and no extra threads are generated. Enabling LRT will replace the [run_style](#) with the *verlet/lrt/intel* style that is identical to the default *verlet* style aside from supporting the LRT feature. This feature requires setting the preprocessor flag `-DLMP_INTEL_USELRT` in the makefile when compiling LAMMPS.

The *balance* keyword sets the fraction of [pair style](#) work offloaded to the coprocessor for split values between 0.0 and 1.0 inclusive. While this fraction of work is running on the coprocessor, other calculations will run on the host, including neighbor and pair calculations that are not offloaded, as well as angle, bond, dihedral, kspace, and some MPI communications. If *split* is set to -1, the fraction of work is dynamically adjusted automatically throughout the run. This typically give performance within 5 to 10 percent of the optimal fixed fraction.

The *ghost* keyword determines whether or not ghost atoms, i.e. atoms at the boundaries of processor sub-domains, are offloaded for neighbor and force calculations. When the value = "no", ghost atoms are not offloaded. This option can reduce the amount of data transfer with the coprocessor and can also overlap MPI communication of forces with computation on the coprocessor when the [newton pair](#) setting is "on". When the value = "yes", ghost atoms are offloaded. In some cases this can provide better performance, especially if the *balance* fraction is high.

The *tpc* keyword sets the max # of coprocessor threads *Ntpc* that will run on each core of the coprocessor. The default value = 4, which is the number of hardware threads per core supported by the current generation Xeon Phi chips.

The *tptask* keyword sets the max # of coprocessor threads (Ntptask assigned to each MPI task. The default value = 240, which is the total # of threads an entire current generation Xeon Phi chip can run (240 = 60 cores * 4 threads/core). This means each MPI task assigned to the Phi will enough threads for the chip to run the max allowed, even if only 1 MPI task is assigned. If 8 MPI tasks are assigned to the Phi, each will run with 30 threads. If you wish to limit the number of threads per MPI task, set *tptask* to a smaller value. E.g. for *tptask* = 16, if 8 MPI tasks are assigned, each will run with 16 threads, for a total of 128.

Note that the default settings for *tpc* and *tptask* are fine for most problems, regardless of how many MPI tasks you assign to a Phi.

The *no_affinity* keyword will turn off automatic setting of core affinity for MPI tasks and OpenMP threads on the host when using offload to a coprocessor. Affinity settings

LAMMPS Users Manual

are used when possible to prevent MPI tasks and OpenMP threads from being on separate NUMA domains and to prevent offload threads from interfering with other processes/threads used for LAMMPS.

The *kokkos* style invokes settings associated with the use of the KOKKOS package.

All of the settings are optional keyword/value pairs. Each has a default value as listed below.

The *neigh* keyword determines how neighbor lists are built. A value of *half* uses a thread-safe variant of half-neighbor lists, the same as used by most pair styles in LAMMPS.

A value of *full* uses a full neighbor lists and is the default. This performs twice as much computation as the *half* option, however that is often a win because it is thread-safe and doesn't require atomic operations in the calculation of pair forces. For that reason, *full* is the default setting. However, when running in MPI-only mode with 1 thread per MPI task, *half* neighbor lists will typically be faster, just as it is for non-accelerated pair styles. Similarly, the *neigh/req* keyword determines how neighbor lists are built for [fix req/reax/kk](#). If not explicitly set, the value of *neigh/req* will match *neigh*.

The *newton* keyword sets the Newton flags for pairwise and bonded interactions to *off* or *on*, the same as the [newton](#) command allows. The default is *off* because this will almost always give better performance for the KOKKOS package. This means more computation is done, but less communication. However, when running in MPI-only mode with 1 thread per MPI task, a value of *on* will typically be faster, just as it is for non-accelerated pair styles.

The *binsize* keyword sets the size of bins used to bin atoms in neighbor list builds. The same value can be set by the [neigh_modify binsize](#) command. Making it an option in the package *kokkos* command allows it to be set from the command line. The default value is 0.0, which means the LAMMPS default will be used, which is $\text{bins} = 1/2$ the size of the pairwise cutoff + neighbor skin distance. This is fine when neighbor lists are built on the CPU. For GPU builds, a 2x larger binsize equal to the pairwise cutoff + neighbor skin, is often faster, which can be set by this keyword. Note that if you use a longer-than-usual pairwise cutoff, e.g. to allow for a smaller fraction of KSpace work with a [long-range Coulombic solver](#) because the GPU is faster at performing pairwise interactions, then this rule of thumb may give too large a binsize.

The *comm* and *comm/exchange* and *comm/forward* and *comm/reverse* keywords determine whether the host or device performs the packing and unpacking of data when communicating per-atom data between processors. "Exchange" communication happens only on timesteps that neighbor lists are rebuilt. The data is only for atoms that migrate to new processors. "Forward" communication happens every timestep. "Reverse" communication happens every timestep if the *newton* option is on. The data is for atom coordinates and any other atom properties that needs to be updated for ghost atoms owned by each processor.

The *comm* keyword is simply a short-cut to set the same value for both the *comm/exchange* and *comm/forward* and *comm/reverse* keywords.

LAMMPS Users Manual

The value options for all 3 keywords are *no* or *host* or *device*. A value of *no* means to use the standard non-KOKKOS method of packing/unpacking data for the communication. A value of *host* means to use the host, typically a multi-core CPU, and perform the packing/unpacking in parallel with threads. A value of *device* means to use the device, typically a GPU, to perform the packing/unpacking operation.

The optimal choice for these keywords depends on the input script and the hardware used. The *no* value is useful for verifying that the Kokkos-based *host* and *device* values are working correctly. It may also be the fastest choice when using Kokkos styles in MPI-only mode (i.e. with a thread count of 1).

When running on CPUs or Xeon Phi, the *host* and *device* values work identically. When using GPUs, the *device* value will typically be optimal if all of your styles used in your input script are supported by the KOKKOS package. In this case data can stay on the GPU for many timesteps without being moved between the host and GPU, if you use the *device* value. This requires that your MPI is able to access GPU memory directly. Currently that is true for OpenMPI 1.8 (or later versions), Mvapich2 1.9 (or later), and CrayMPI. If your script uses styles (e.g. *fixes*) which are not yet supported by the KOKKOS package, then data has to be move between the host and device anyway, so it is typically faster to let the host handle communication, by using the *host* value. Using *host* instead of *no* will enable use of multiple threads to pack/unpack communicated data.

The *omp* style invokes settings associated with the use of the USER-OMP package.

The *Nthread* argument sets the number of OpenMP threads allocated for each MPI task. For example, if your system has nodes with dual quad-core processors, it has a total of 8 cores per node. You could use two MPI tasks per node (e.g. using the *-ppn* option of the *mpirun* command in MPICH or *-npernode* in OpenMPI), and set *Nthreads* = 4. This would use all 8 cores on each node. Note that the product of MPI tasks * threads/task should not exceed the physical number of cores (on a node), otherwise performance will suffer.

Setting *Nthread* = 0 instructs LAMMPS to use whatever value is the default for the given OpenMP environment. This is usually determined via the *OMP_NUM_THREADS* environment variable or the compiler runtime. Note that in most cases the default for OpenMP capable compilers is to use one thread for each available CPU core when *OMP_NUM_THREADS* is not explicitly set, which can lead to poor performance.

Here are examples of how to set the environment variable when launching LAMMPS:

```
env OMP_NUM_THREADS=4 lmp_machine -sf omp -in in.script
env OMP_NUM_THREADS=2 mpirun -np 2 lmp_machine -sf omp -in in.script
mpirun -x OMP_NUM_THREADS=2 -np 2 lmp_machine -sf omp -in in.script
```

or you can set it permanently in your shell's start-up script. All three of these examples use a total of 4 CPU cores.

Note that different MPI implementations have different ways of passing the *OMP_NUM_THREADS* environment variable to all MPI processes. The 2nd example line above is for MPICH; the 3rd example line with *-x* is for OpenMPI. Check your MPI

documentation for additional details.

What combination of threads and MPI tasks gives the best performance is difficult to predict and can depend on many components of your input. Not all features of LAMMPS support OpenMP threading via the USER-OMP package and the parallel efficiency can be very different, too.

Optional keyword/value pairs can also be specified. Each has a default value as listed below.

The *neigh* keyword specifies whether neighbor list building will be multi-threaded in addition to force calculations. If *neigh* is set to *no* then neighbor list calculation is performed only by MPI tasks with no OpenMP threading. If *mode* is *yes* (the default), a multi-threaded neighbor list build is used. Using *neigh = yes* is almost always faster and should produce identical neighbor lists at the expense of using more memory. Specifically, neighbor list pages are allocated for all threads at the same time and each thread works within its own pages.

Restrictions:

This command cannot be used after the simulation box is defined by a [read_data](#) or [create_box](#) command.

The gpu style of this command can only be invoked if LAMMPS was built with the GPU package. See the [Making LAMMPS](#) section for more info.

The intel style of this command can only be invoked if LAMMPS was built with the USER-INTEL package. See the [Making LAMMPS](#) section for more info.

The kk style of this command can only be invoked if LAMMPS was built with the KOKKOS package. See the [Making LAMMPS](#) section for more info.

The omp style of this command can only be invoked if LAMMPS was built with the USER-OMP package. See the [Making LAMMPS](#) section for more info.

Related commands:

[suffix](#), ["-pk" command-line setting](#)

Default:

For the GPU package, the default is $N_{\text{gpu}} = 1$ and the option defaults are *neigh = yes*, *newton = off*, *binsize = 0.0*, *split = 1.0*, *gpuID = 0* to $N_{\text{gpu}}-1$, *tpa = 1*, and *device = not used*. These settings are made automatically if the ["-sf gpu" command-line switch](#) is used. If it is not used, you must invoke the package *gpu* command in your input script or via the ["-pk gpu" command-line switch](#).

For the USER-INTEL package, the default is $N_{\text{phi}} = 1$ and the option defaults are *omp = 0*, *mode = mixed*, *lrt = no*, *balance = -1*, *tpc = 4*, *tptask = 240*. The default ghost option is determined by the pair style being used. This value is output to the screen in the offload report at the end of each run. Note that all of these settings, except "omp"

LAMMPS Users Manual

and "mode", are ignored if LAMMPS was not built with Xeon Phi coprocessor support. These settings are made automatically if the "-sf intel" [command-line switch](#) is used. If it is not used, you must invoke the package intel command in your input script or via the "-pk intel" [command-line switch](#).

For the KOKKOS package, the option defaults neigh = full, neigh/qq = full, newton = off, binsize = 0.0, and comm = device. These settings are made automatically by the required "-k on" [command-line switch](#). You can change them by using the package kokkos command in your input script or via the "-pk kokkos" [command-line switch](#).

For the OMP package, the default is Nthreads = 0 and the option defaults are neigh = yes. These settings are made automatically if the "-sf omp" [command-line switch](#) is used. If it is not used, you must invoke the package omp command in your input script or via the "-pk omp" [command-line switch](#).

pair_coeff command

Syntax:

```
pair_coeff I J args
```

- I,J = atom types (see asterisk form below)
- args = coefficients for one or more pairs of atom types

Examples:

```
pair_coeff 1 2 1.0 1.0 2.5
pair_coeff 2 * 1.0 1.0
pair_coeff 3* 1*2 1.0 1.0 2.5
pair_coeff * * 1.0 1.0
pair_coeff * * nialhjea 1 1 2
pair_coeff * 3 morse.table ENTRY1
pair_coeff 1 2 lj/cut 1.0 1.0 2.5 (for pair_style hybrid)
```

Description:

Specify the pairwise force field coefficients for one or more pairs of atom types. The number and meaning of the coefficients depends on the pair style. Pair coefficients can also be set in the data file read by the [read_data](#) command or in a restart file.

I and J can be specified in one of two ways. Explicit numeric values can be used for each, as in the 1st example above. $I \leq J$ is required. LAMMPS sets the coefficients for the symmetric J,I interaction to the same values.

A wildcard asterisk can be used in place of or in conjunction with the I,J arguments to set the coefficients for multiple pairs of atom types. This takes the form "*" or "*n" or "n*" or "m*n". If N = the number of atom types, then an asterisk with no numeric values means all types from 1 to N. A leading asterisk means all types from 1 to n (inclusive). A trailing asterisk means all types from n to N (inclusive). A middle asterisk means all types from m to n (inclusive). Note that only type pairs with $I \leq J$ are considered; if asterisks imply type pairs where $J < I$, they are ignored.

Note that a pair_coeff command can override a previous setting for the same I,J pair. For example, these commands set the coeffs for all I,J pairs, then overwrite the coeffs for just the I,J = 2,3 pair:

```
pair_coeff * * 1.0 1.0 2.5
pair_coeff 2 3 2.0 1.0 1.12
```

A line in a data file that specifies pair coefficients uses the exact same format as the arguments of the pair_coeff command in an input script, with the exception of the I,J type arguments. In each line of the "Pair Coeffs" section of a data file, only a single type I is specified, which sets the coefficients for type I interacting with type I. This is because the section has exactly N lines, where N = the number of atom types. For this reason, the wild-card asterisk should also not be used as part of the I argument. Thus

LAMMPS Users Manual

in a data file, the line corresponding to the 1st example above would be listed as

```
2 1.0 1.0 2.5
```

For many potentials, if coefficients for type pairs with $I \neq J$ are not set explicitly by a `pair_coeff` command, the values are inferred from the I,I and J,J settings by mixing rules; see the [pair_modify](#) command for a discussion. Details on this option as it pertains to individual potentials are described on the doc page for the potential.

Many pair styles, typically for many-body potentials, use tabulated potential files as input, when specifying the `pair_coeff` command. Potential files provided with LAMMPS are in the potentials directory of the distribution. For some potentials, such as EAM, other archives of suitable files can be found on the Web. They can be used with LAMMPS so long as they are in the format LAMMPS expects, as discussed on the individual doc pages.

When a `pair_coeff` command using a potential file is specified, LAMMPS looks for the potential file in 2 places. First it looks in the location specified. E.g. if the file is specified as "niu3.eam", it is looked for in the current working directory. If it is specified as "../potentials/niu3.eam", then it is looked for in the potentials directory, assuming it is a sister directory of the current working directory. If the file is not found, it is then looked for in the directory specified by the LAMMPS_POTENTIALS environment variable. Thus if this is set to the potentials directory in the LAMMPS distro, then you can use those files from anywhere on your system, without copying them into your working directory. Environment variables are set in different ways for different shells. Here are example settings for

csh, tcsh:

```
% setenv LAMMPS_POTENTIALS /path/to/lammps/potentials
```

bash:

```
% export LAMMPS_POTENTIALS=/path/to/lammps/potentials
```

Windows:

```
% set LAMMPS_POTENTIALS="C:\\Path to LAMMPS\\Potentials"
```

The alphabetic list of pair styles defined in LAMMPS is given on the [pair_style](#) doc page. They are also given in more compact form in the pair section of [this page](#).

Click on the style to display the formula it computes, arguments specified in the `pair_style` command, and coefficients specified by the associated `pair_coeff` command.

Note that there are also additional pair styles (not listed on the [pair_style](#) doc page) submitted by users which are included in the LAMMPS distribution. The list of these with links to the individual styles are given in the pair section of [this page](#).

There are also additional accelerated pair styles (not listed on the [pair_style](#) doc page) included in the LAMMPS distribution for faster performance on CPUs and GPUs. The

list of these with links to the individual styles are given in the pair section of [this page](#).

Restrictions:

This command must come after the simulation box is defined by a [read_data](#), [read_restart](#), or [create_box](#) command.

[pair_style](#), [pair_modify](#), [read_data](#), [read_restart](#), [pair_write](#)

Default: none

pair_modify command

Syntax:

```
pair_modify keyword values ...
```

- one or more keyword/value pairs may be listed
- keyword = *pair* or *shift* or *mix* or *table* or *table/disp* or *tabinner* or *tabinner/disp* or *tail* or *compute*

```
pair values = sub-style N special which wt1 wt2 wt3
              or sub-style N compute/tally flag
sub-style = sub-style of pair hybrid
N = which instance of sub-style (only if sub-style is used multiple times)
special which wt1 wt2 wt3 = override special_bonds settings (optional)
  which = lj/coul or lj or coul
  w1,w2,w3 = 1-2, 1-3, and 1-4 weights from 0.0 to 1.0 inclusive
compute/tally flag = yes or no
mix value = geometric or arithmetic or sixthpower
shift value = yes or no
table value = N
  2^N = # of values in table
table/disp value = N
  2^N = # of values in table
tabinner value = cutoff
  cutoff = inner cutoff at which to begin table (distance units)
tabinner/disp value = cutoff
  cutoff = inner cutoff at which to begin table (distance units)
tail value = yes or no
compute value = yes or no
```

Examples:

```
pair_modify shift yes mix geometric
pair_modify tail yes
pair_modify table 12
pair_modify pair lj/cut compute no
pair_modify pair tersoff compute/tally no
pair_modify pair lj/cut/coul/long 1 special lj/coul 0.0 0.0 0.0
```

Description:

Modify the parameters of the currently defined pair style. Not all parameters are relevant to all pair styles.

If used, the *pair* keyword must appear first in the list of keywords. It can only be used with the [hybrid](#) and [hybrid/overlay](#) pair styles. It means that all the following parameters will only be modified for the specified sub-style. If the sub-style is defined multiple times, then an additional numeric argument *N* must also be specified, which is a number from 1 to *M* where *M* is the number of times the sub-style was listed in the [pair_style hybrid](#) command. The extra number indicates which instance of the sub-style the remaining keywords will be applied to. Note that if the *pair* keyword is not used, and the pair style is *hybrid* or *hybrid/overlay*, then all the specified keywords

will be applied to all sub-styles.

The *special* and *compute/tally* keywords can **only** be used in conjunction with the *pair* keyword and must directly follow it. *special* allows to override the [special_bonds](#) settings for the specified sub-style. *compute/tally* allows to disable or enable registering [compute */tally](#) computes for a given sub-style. More details are given below.

The *mix* keyword affects pair coefficients for interactions between atoms of type I and J, when $I \neq J$ and the coefficients are not explicitly set in the input script. Note that coefficients for $I = J$ must be set explicitly, either in the input script via the "pair_coeff" command or in the "Pair Coeffs" section of the [data file](#). For some pair styles it is not necessary to specify coefficients when $I \neq J$, since a "mixing" rule will create them from the I,I and J,J settings. The pair_modify *mix* value determines what formulas are used to compute the mixed coefficients. In each case, the cutoff distance is mixed the same way as sigma.

Note that not all pair styles support mixing. Also, some mix options are not available for certain pair styles. See the doc page for individual pair styles for those restrictions. Note also that the [pair_coeff](#) command also can be to directly set coefficients for a specific $I \neq J$ pairing, in which case no mixing is performed.

mix geometric

```
epsilon_ij = sqrt(epsilon_i * epsilon_j)
sigma_ij = sqrt(sigma_i * sigma_j)
```

mix arithmetic

```
epsilon_ij = sqrt(epsilon_i * epsilon_j)
sigma_ij = (sigma_i + sigma_j) / 2
```

mix sixthpower

```
epsilon_ij = (2 * sqrt(epsilon_i*epsilon_j) * sigma_i^3 * sigma_j^3) /
             (sigma_i^6 + sigma_j^6)
sigma_ij = ((sigma_i**6 + sigma_j**6) / 2) ^ (1/6)
```

The *shift* keyword determines whether a Lennard-Jones potential is shifted at its cutoff to 0.0. If so, this adds an energy term to each pairwise interaction which will be included in the thermodynamic output, but does not affect pair forces or atom trajectories. See the doc page for individual pair styles to see which ones support this option.

The *table* and *table/disp* keywords apply to pair styles with a long-range Coulombic term or long-range dispersion term respectively; see the doc page for individual styles to see which potentials support these options. If N is non-zero, a table of length 2^N is pre-computed for forces and energies, which can shrink their computational cost by up to a factor of 2. The table is indexed via a bit-mapping technique ([Wolff](#)) and a linear interpolation is performed between adjacent table values. In our experiments with different table styles (lookup, linear, spline), this method typically gave the best performance in terms of speed and accuracy.

LAMMPS Users Manual

The choice of table length is a tradeoff in accuracy versus speed. A larger N yields more accurate force computations, but requires more memory which can slow down the computation due to cache misses. A reasonable value of N is between 8 and 16. The default value of 12 (table of length 4096) gives approximately the same accuracy as the no-table ($N = 0$) option. For $N = 0$, forces and energies are computed directly, using a polynomial fit for the needed $\text{erfc}()$ function evaluation, which is what earlier versions of LAMMPS did. Values greater than 16 typically slow down the simulation and will not improve accuracy; values from 1 to 8 give unreliable results.

The *tabinner* and *tabinner/disp* keywords set an inner cutoff above which the pairwise computation is done by table lookup (if tables are invoked), for the corresponding Coulombic and dispersion tables discussed with the *table* and *table/disp* keywords. The smaller the cutoff is set, the less accurate the table becomes (for a given number of table values), which can require use of larger tables. The default cutoff value is $\text{sqrt}(2.0)$ distance units which means nearly all pairwise interactions are computed via table lookup for simulations with "real" units, but some close pairs may be computed directly (non-table) for simulations with "lj" units.

When the *tail* keyword is set to *yes*, certain pair styles will add a long-range VanderWaals tail "correction" to the energy and pressure. These corrections are bookkeeping terms which do not affect dynamics, unless a constant-pressure simulation is being performed. See the doc page for individual styles to see which support this option. These corrections are included in the calculation and printing of thermodynamic quantities (see the [thermo_style](#) command). Their effect will also be included in constant NPT or NPH simulations where the pressure influences the simulation box dimensions (e.g. the [fix npt](#) and [fix nph](#) commands). The formulas used for the long-range corrections come from equation 5 of [\(Sun\)](#).

NOTE: The tail correction terms are computed at the beginning of each run, using the current atom counts of each atom type. If atoms are deleted (or lost) or created during a simulation, e.g. via the [fix gcmc](#) command, the correction factors are not re-computed. If you expect the counts to change dramatically, you can break a run into a series of shorter runs so that the correction factors are re-computed more frequently.

Several additional assumptions are inherent in using tail corrections, including the following:

- The simulated system is a 3d bulk homogeneous liquid. This option should not be used for systems that are non-liquid, 2d, have a slab geometry (only 2d periodic), or inhomogeneous.
- $G(r)$, the radial distribution function (rdf), is unity beyond the cutoff, so a fairly large cutoff should be used (i.e. 2.5 sigma for an LJ fluid), and it is probably a good idea to verify this assumption by checking the rdf. The rdf is not exactly unity beyond the cutoff for each pair of interaction types, so the tail correction is necessarily an approximation.

The tail corrections are computed at the beginning of each simulation run. If the number of atoms changes during the run, e.g. due to atoms leaving the simulation domain, or use of the [fix gcmc](#) command, then the corrections are not updated to reflect the changed atom count. If this is a large effect in your

LAMMPS Users Manual

simulation, you should break the long run into several short runs, so that the correction factors are re-computed multiple times.

- Thermophysical properties obtained from calculations with this option enabled will not be thermodynamically consistent with the truncated force-field that was used. In other words, atoms do not feel any LJ pair interactions beyond the cutoff, but the energy and pressure reported by the simulation include an estimated contribution from those interactions.

The *compute* keyword allows pairwise computations to be turned off, even though a [pair_style](#) is defined. This is not useful for running a real simulation, but can be useful for debugging purposes or for performing a [rerun](#) simulation, when you only wish to compute partial forces that do not include the pairwise contribution.

Two examples are as follows. First, this option allows you to perform a simulation with [pair_style hybrid](#) with only a subset of the hybrid sub-styles enabled. Second, this option allows you to perform a simulation with only long-range interactions but no short-range pairwise interactions. Doing this by simply not defining a pair style will not work, because the [kspace_style](#) command requires a Kspace-compatible pair style be defined.

The *special* keyword allows to override the 1-2, 1-3, and 1-4 exclusion settings for individual sub-styles of a [hybrid pair style](#). It requires 4 arguments similar to the [special_bonds](#) command, *which* and *wt1,wt2,wt3*. The *which* argument can be *lj* to change the Lennard-Jones settings, *coul* to change the Coulombic settings, or *lj/coul* to change both to the same set of 3 values. The *wt1,wt2,wt3* values are numeric weights from 0.0 to 1.0 inclusive, for the 1-2, 1-3, and 1-4 bond topology neighbors, respectively. The *special* keyword can only be used in conjunction with the *pair* keyword and has to directly follow it.

NOTE: The global settings specified by the [special_bonds](#) command affect the construction of neighbor lists. Weights of 0.0 (for 1-2, 1-3, or 1-4 neighbors) exclude those pairs from the neighbor list entirely. Weights of 1.0 store the neighbor with no weighting applied. Thus only global values different from exactly 0.0 or 1.0 can be overridden and an error is generated if the requested setting is not compatible with the global setting. Substituting 1.0e-10 for 0.0 and 0.9999999999 for 1.0 is usually a sufficient workaround in this case without causing a significant error.

The *compute/tally* keyword takes exactly 1 argument (*no* or *yes*), and allows to selectively disable or enable processing of the various [compute */tally](#) styles for a given [pair hybrid or hybrid/overlay](#) sub-style.

NOTE: Any "pair_modify pair compute/tally" command must be issued **before** the corresponding compute style is defined.

Restrictions: none

You cannot use *shift yes* with *tail yes*, since those are conflicting options. You cannot use *tail yes* with 2d simulations.

Related commands:

LAMMPS Users Manual

`pair_style`, `>pair_style hybrid`, `pair_coeff`, `thermo_style`, `compute */tally`

Default:

The option defaults are `mix = geometric`, `shift = no`, `table = 12`, `tabinner = sqrt(2.0)`, `tail = no`, and `compute = yes`.

Note that some pair styles perform mixing, but only a certain style of mixing. See the doc pages for individual pair styles for details.

(Sun) Sun, J Phys Chem B, 102, 7338-7364 (1998).

pair_style command

Syntax:

```
pair_style style args
```

- style = one of the styles from the list below
- args = arguments used by a particular style

Examples:

```
pair_style lj/cut 2.5
pair_style eam/alloy
pair_style hybrid lj/charmm/coul/long 10.0 eam
pair_style table linear 1000
pair_style none
```

Description:

Set the formula(s) LAMMPS uses to compute pairwise interactions. In LAMMPS, pair potentials are defined between pairs of atoms that are within a cutoff distance and the set of active interactions typically changes over time. See the [bond_style](#) command to define potentials between pairs of bonded atoms, which typically remain in place for the duration of a simulation.

In LAMMPS, pairwise force fields encompass a variety of interactions, some of which include many-body effects, e.g. EAM, Stillinger-Weber, Tersoff, REBO potentials. They are still classified as "pairwise" potentials because the set of interacting atoms changes with time (unlike molecular bonds) and thus a neighbor list is used to find nearby interacting atoms.

Hybrid models where specified pairs of atom types interact via different pair potentials can be setup using the *hybrid* pair style.

The coefficients associated with a pair style are typically set for each pair of atom types, and are specified by the [pair_coeff](#) command or read from a file by the [read_data](#) or [read_restart](#) commands.

The [pair_modify](#) command sets options for mixing of type I-J interaction coefficients and adding energy offsets or tail corrections to Lennard-Jones potentials. Details on these options as they pertain to individual potentials are described on the doc page for the potential. Likewise, info on whether the potential information is stored in a [restart file](#) is listed on the potential doc page.

In the formulas listed for each pair style, E is the energy of a pairwise interaction between two atoms separated by a distance r . The force between the atoms is the negative derivative of this expression.

If the `pair_style` command has a cutoff argument, it sets global cutoffs for all pairs of

LAMMPS Users Manual

atom types. The distance(s) can be smaller or larger than the dimensions of the simulation box.

Typically, the global cutoff value can be overridden for a specific pair of atom types by the [pair_coeff](#) command. The pair style settings (including global cutoffs) can be changed by a subsequent [pair_style](#) command using the same style. This will reset the cutoffs for all atom type pairs, including those previously set explicitly by a [pair_coeff](#) command. The exceptions to this are that [pair_style table](#) and [pair_style hybrid](#) settings cannot be reset. A new [pair_style](#) command for these styles will wipe out all previously specified [pair_coeff](#) values.

Here is an alphabetic list of pair styles defined in LAMMPS. They are also given in more compact form in the pair section of [this page](#).

Click on the style to display the formula it computes, arguments specified in the [pair_style](#) command, and coefficients specified by the associated [pair_coeff](#) command.

There are also additional pair styles (not listed here) submitted by users which are included in the LAMMPS distribution. The list of these with links to the individual styles are given in the pair section of [this page](#).

There are also additional accelerated pair styles (not listed here) included in the LAMMPS distribution for faster performance on CPUs and GPUs. The list of these with links to the individual styles are given in the pair section of [this page](#).

- [pair_style none](#) - turn off pairwise interactions
- [pair_style hybrid](#) - multiple styles of pairwise interactions
- [pair_style hybrid/overlay](#) - multiple styles of superposed pairwise interactions
- [pair_style zero](#) - neighbor list but no interactions

- [pair_style adp](#) - angular dependent potential (ADP) of Mishin

Restrictions:

LAMMPS Users Manual

This command must be used before any coefficients are set by the [pair_coeff](#), [read_data](#), or [read_restart](#) commands.

Some pair styles are part of specific packages. They are only enabled if LAMMPS was built with that package. See the [Making LAMMPS](#) section for more info on packages. The doc pages for individual pair potentials tell if it is part of a package.

Related commands:

[pair_coeff](#), [read_data](#), [pair_modify](#), [kspace_style](#), [dielectric](#), [pair_write](#)

Default:

`pair_style none`

pair_write command

Syntax:

```
pair_write itype jtype N style inner outer file keyword Qi Qj
```

- itype,jtype = 2 atom types
- N = # of values
- style = *r* or *rsq* or *bitmap*
- inner,outer = inner and outer cutoff (distance units)
- file = name of file to write values to
- keyword = section name in file for this set of tabulated values
- Qi,Qj = 2 atom charges (charge units) (optional)

Examples:

```
pair_write 1 3 500 r 1.0 10.0 table.txt LJ
pair_write 1 1 1000 rsq 2.0 8.0 table.txt Yukawa_1_1 -0.5 0.5
```

Description:

Write energy and force values to a file as a function of distance for the currently defined pair potential. This is useful for plotting the potential function or otherwise debugging its values. If the file already exists, the table of values is appended to the end of the file to allow multiple tables of energy and force to be included in one file.

The energy and force values are computed at distances from inner to outer for 2 interacting atoms of type itype and jtype, using the appropriate [pair_coeff](#) coefficients. If the style is *r*, then N distances are used, evenly spaced in r; if the style is *rsq*, N distances are used, evenly spaced in r^2 .

For example, for N = 7, style = *r*, inner = 1.0, and outer = 4.0, values are computed at $r = 1.0, 1.5, 2.0, 2.5, 3.0, 3.5, 4.0$.

If the style is *bitmap*, then 2^N values are written to the file in a format and order consistent with how they are read in by the [pair_coeff](#) command for pair style *table*. For reasonable accuracy in a bitmapped table, choose $N \geq 12$, an *inner* value that is smaller than the distance of closest approach of 2 atoms, and an *outer* value \leq cutoff of the potential.

If the pair potential is computed between charged atoms, the charges of the pair of interacting atoms can optionally be specified. If not specified, values of $Q_i = Q_j = 1.0$ are used.

The file is written in the format used as input for the [pair_style table](#) option with *keyword* as the section name. Each line written to the file lists an index number (1-N), a distance (in distance units), an energy (in energy units), and a force (in force units).

Restrictions:

LAMMPS Users Manual

All force field coefficients for pair and other kinds of interactions must be set before this command can be invoked.

Due to how the pairwise force is computed, an inner value > 0.0 must be specified even if the potential has a finite value at $r = 0.0$.

For EAM potentials, the `pair_write` command only tabulates the pairwise portion of the potential, not the embedding portion.

Related commands:

[pair_style table](#), [pair_style](#), [pair_coeff](#)

Default: none

partition command

Syntax:

```
partition style N command ...
```

- style = *yes* or *no*
- N = partition number (see asterisk form below)
- command = any LAMMPS command

Examples:

```
partition yes 1 processors 4 10 6
partition no 5 print "Active partition"
partition yes *5 fix all nve
partition yes 6* fix all nvt temp 1.0 1.0 0.1
```

Description:

This command invokes the specified command on a subset of the partitions of processors you have defined via the `-partition` command-line switch. See [Section 2.6](#) for an explanation of the switch.

Normally, every input script command in your script is invoked by every partition. This behavior can be modified by defining world- or universe-style [variables](#) that have different values for each partition. This mechanism can be used to cause your script to jump to different input script files on different partitions, if such a variable is used in a [jump](#) command.

The "partition" command is another mechanism for having an input script operate differently on different partitions. It is basically a prefix on any LAMMPS command. The command will only be invoked on the partition(s) specified by the *style* and *N* arguments.

If the *style* is *yes*, the command will be invoked on any partition which matches the *N* argument. If the *style* is *no* the command will be invoked on all the partitions which do not match the *Np* argument.

Partitions are numbered from 1 to *Np*, where *Np* is the number of partitions specified by the [-partition command-line switch](#).

N can be specified in one of two ways. An explicit numeric value can be used, as in the 1st example above. Or a wild-card asterisk can be used to span a range of partition numbers. This takes the form "*" or "*n" or "n*" or "m*n". An asterisk with no numeric values means all partitions from 1 to *Np*. A leading asterisk means all partitions from 1 to *n* (inclusive). A trailing asterisk means all partitions from *n* to *Np* (inclusive). A middle asterisk means all partitions from *m* to *n* (inclusive).

LAMMPS Users Manual

This command can be useful for the "run_style verlet/split" command which imposed requirements on how the [processors](#) command lays out a 3d grid of processors in each of 2 partitions.

Restrictions: none

Related commands:

[run_style verlet/split](#)

Default: none

prd command

Syntax:

```
prd N t_event n_dephase t_dephase t_correlate compute-ID seed keyword value ...
```

- N = # of timesteps to run (not including dephasing/quenching)
- t_event = timestep interval between event checks
- n_dephase = number of velocity randomizations to perform in each dephase run
- t_dephase = number of timesteps to run dynamics after each velocity randomization during dephase
- t_correlate = number of timesteps within which 2 consecutive events are considered to be correlated
- compute-ID = ID of the compute used for event detection
- random_seed = random # seed (positive integer)
- zero or more keyword/value pairs may be appended
- keyword = *min* or *temp* or *vel*

```
min values = etol ftol maxiter maxeval
  etol = stopping tolerance for energy, used in quenching
  ftol = stopping tolerance for force, used in quenching
  maxiter = max iterations of minimize, used in quenching
  maxeval = max number of force/energy evaluations, used in quenching
temp value = Tdephase
  Tdephase = target temperature for velocity randomization, used in dephasing
vel values = loop dist
  loop = all or local or geom, used in dephasing
  dist = uniform or gaussian, used in dephasing
time value = steps or clock
  steps = simulation runs for N timesteps on each replica (default)
  clock = simulation runs for N timesteps across all replicas
```

Examples:

```
prd 5000 100 10 10 100 1 54982
prd 5000 100 10 10 100 1 54982 min 0.1 0.1 100 200
```

Description:

Run a parallel replica dynamics (PRD) simulation using multiple replicas of a system. One or more replicas can be used. The total number of steps *N* to run can be interpreted in one of two ways; see discussion of the *time* keyword below.

PRD is described in [this paper](#) by Art Voter. It is a method for performing accelerated dynamics that is suitable for infrequent-event systems that obey first-order kinetics. A good overview of accelerated dynamics methods for such systems is given in [this review paper](#) from the same group. To quote from the paper: "The dynamical evolution is characterized by vibrational excursions within a potential basin, punctuated by occasional transitions between basins." The transition probability is characterized by $p(t) = k \cdot \exp(-kt)$ where *k* is the rate constant. Running multiple replicas gives an effective enhancement in the timescale spanned by the multiple simulations, while

LAMMPS Users Manual

waiting for an event to occur.

Each replica runs on a partition of one or more processors. Processor partitions are defined at run-time using the `-partition` command-line switch; see [Section 2.6](#) of the manual. Note that if you have MPI installed, you can run a multi-replica simulation with more replicas (partitions) than you have physical processors, e.g you can run a 10-replica simulation on one or two processors. However for PRD, this makes little sense, since running a replica on virtual instead of physical processors, offers no effective parallel speed-up in searching for infrequent events. See [Section 6.5](#) of the manual for further discussion.

When a PRD simulation is performed, it is assumed that each replica is running the same model, though LAMMPS does not check for this. I.e. the simulation domain, the number of atoms, the interaction potentials, etc should be the same for every replica.

A PRD run has several stages, which are repeated each time an "event" occurs in one of the replicas, as defined below. The logic for a PRD run is as follows:

```
while (time remains):
  dephase for n_dephase*t_dephase steps
  until (event occurs on some replica):
    run dynamics for t_event steps
    quench
    check for uncorrelated event on any replica
  until (no correlated event occurs):
    run dynamics for t_correlate steps
    quench
    check for correlated event on this replica
  event replica shares state with all replicas
```

Before this loop begins, the state of the system on replica 0 is shared with all replicas, so that all replicas begin from the same initial state. The first potential energy basin is identified by quenching (an energy minimization, see below) the initial state and storing the resulting coordinates for reference.

In the first stage, dephasing is performed by each replica independently to eliminate correlations between replicas. This is done by choosing a random set of velocities, based on the *random_seed* that is specified, and running *t_dephase* timesteps of dynamics. This is repeated *n_dephase* times. At each of the *n_dephase* stages, if an event occurs during the *t_dephase* steps of dynamics for a particular replica, the replica repeats the stage until no event occurs.

If the *temp* keyword is not specified, the target temperature for velocity randomization for each replica is the current temperature of that replica. Otherwise, it is the specified *Tdephase* temperature. The style of velocity randomization is controlled using the keyword *vel* with arguments that have the same meaning as their counterparts in the [velocity](#) command.

In the second stage, each replica runs dynamics continuously, stopping every *t_event* steps to check if a transition event has occurred. This check is performed by quenching the system and comparing the resulting atom coordinates to the coordinates from the previous basin. The first time through the PRD loop, the "previous basin" is the set of quenched coordinates from the initial state of the system.

LAMMPS Users Manual

A quench is an energy minimization and is performed by whichever algorithm has been defined by the `min_style` command. Minimization parameters may be set via the `min_modify` command and by the `min` keyword of the PRD command. The latter are the settings that would be used with the `minimize` command. Note that typically, you do not need to perform a highly-converged minimization to detect a transition event.

The event check is performed by a compute with the specified *compute-ID*. Currently there is only one compute that works with the PRD command, which is the `compute event/displace` command. Other event-checking computes may be added. `Compute event/displace` checks whether any atom in the compute group has moved further than a specified threshold distance. If so, an "event" has occurred.

In the third stage, the replica on which the event occurred (event replica) continues to run dynamics to search for correlated events. This is done by running dynamics for $t_{correlate}$ steps, quenching every t_{event} steps, and checking if another event has occurred.

The first time no correlated event occurs, the final state of the event replica is shared with all replicas, the new basin reference coordinates are updated with the quenched state, and the outer loop begins again. While the replica event is searching for correlated events, all the other replicas also run dynamics and event checking with the same schedule, but the final states are always overwritten by the state of the event replica.

The outer loop of the pseudo-code above continues until N steps of dynamics have been performed. Note that N only includes the dynamics of stages 2 and 3, not the steps taken during dephasing or the minimization iterations of quenching. The specified N is interpreted in one of two ways, depending on the *time* keyword. If the *time* value is *steps*, which is the default, then each replica runs for N timesteps. If the *time* value is *clock*, then the simulation runs until N aggregate timesteps across all replicas have elapsed. This aggregate time is the "clock" time defined below, which typically advances nearly M times faster than the timestepping on a single replica, where M is the number of replicas.

Four kinds of output can be generated during a PRD run: event statistics, thermodynamic output by each replica, dump files, and restart files.

When running with multiple partitions (each of which is a replica in this case), the print-out to the screen and master log.lammps file is limited to event statistics. Note that if a PRD run is performed on only a single replica then the event statistics will be intermixed with the usual thermodynamic output discussed below.

The quantities printed each time an event occurs are the timestep, CPU time, clock, event number, a correlation flag, the number of coincident events, and the replica number of the chosen event.

The timestep is the usual LAMMPS timestep, except that time does not advance during dephasing or quenches, but only during dynamics. Note that there are two kinds of dynamics in the PRD loop listed above that contribute to this timestepping. The first is when all replicas are performing independent dynamics, waiting for an event to occur. The second is when correlated events are being searched for, but only one replica is

running dynamics.

The CPU time is the total elapsed time on each processor, since the start of the PRD run.

The clock is the same as the timestep except that it advances by M steps per timestep during the first kind of dynamics when the M replicas are running independently. The clock advances by only 1 step per timestep during the second kind of dynamics, when only a single replica is checking for a correlated event. Thus "clock" time represents the aggregate time (in steps) that has effectively elapsed during a PRD simulation on M replicas. If most of the PRD run is spent in the second stage of the loop above, searching for infrequent events, then the clock will advance nearly M times faster than it would if a single replica was running. Note the clock time between successive events should be drawn from $p(t)$.

The event number is a counter that increments with each event, whether it is uncorrelated or correlated.

The correlation flag will be 0 when an uncorrelated event occurs during the second stage of the loop listed above, i.e. when all replicas are running independently. The correlation flag will be 1 when a correlated event occurs during the third stage of the loop listed above, i.e. when only one replica is running dynamics.

When more than one replica detects an event at the end of the same event check (every t_{event} steps) during the second stage, then one of them is chosen at random. The number of coincident events is the number of replicas that detected an event. Normally, this value should be 1. If it is often greater than 1, then either the number of replicas is too large, or t_{event} is too large.

The replica number is the ID of the replica (from 0 to $M-1$) in which the event occurred.

When running on multiple partitions, LAMMPS produces additional log files for each partition, e.g. `log.lammps.0`, `log.lammps.1`, etc. For the PRD command, these contain the thermodynamic output for each replica. You will see short runs and minimizations corresponding to the dynamics and quench operations of the loop listed above. The timestep will be reset appropriately depending on whether the operation advances time or not.

After the PRD command completes, timing statistics for the PRD run are printed in each replica's log file, giving a breakdown of how much CPU time was spent in each stage (dephasing, dynamics, quenching, etc).

Any [dump files](#) defined in the input script, will be written to during a PRD run at timesteps corresponding to both uncorrelated and correlated events. This means the requested dump frequency in the `dump` command is ignored. There will be one dump file (per dump command) created for all partitions.

The atom coordinates of the dump snapshot are those of the minimum energy configuration resulting from quenching following a transition event. The timesteps

LAMMPS Users Manual

written into the dump files correspond to the timestep at which the event occurred and NOT the clock. A dump snapshot corresponding to the initial minimum state used for event detection is written to the dump file at the beginning of each PRD run.

If the [restart](#) command is used, a single restart file for all the partitions is generated, which allows a PRD run to be continued by a new input script in the usual manner.

The restart file is generated at the end of the loop listed above. If no correlated events are found, this means it contains a snapshot of the system at time $T + t_correlate$, where T is the time at which the uncorrelated event occurred. If correlated events were found, then it contains a snapshot of the system at time $T + t_correlate$, where T is the time of the last correlated event.

The restart frequency specified in the [restart](#) command is interpreted differently when performing a PRD run. It does not mean the timestep interval between restart files. Instead it means an event interval for uncorrelated events. Thus a frequency of 1 means write a restart file every time an uncorrelated event occurs. A frequency of 10 means write a restart file every 10th uncorrelated event.

When an input script reads a restart file from a previous PRD run, the new script can be run on a different number of replicas or processors. However, it is assumed that $t_correlate$ in the new PRD command is the same as it was previously. If not, the calculation of the "clock" value for the first event in the new run will be slightly off.

Restrictions:

This command can only be used if LAMMPS was built with the REPLICAS package. See the [Making LAMMPS](#) section for more info on packages.

The N and $t_correlate$ settings must be integer multiples of t_event .

Runs restarted from restart file written during a PRD run will not produce identical results due to changes in the random numbers used for dephasing.

This command cannot be used when any fixes are defined that keep track of elapsed time to perform time-dependent operations. Examples include the "ave" fixes such as [fix ave/chunk](#). Also [fix dt/reset](#) and [fix deposit](#).

Related commands:

[compute event/displace](#), [min_modify](#), [min_style](#), [run_style](#), [minimize](#), [velocity](#), [temper](#), [neb](#), [tad](#)

Default:

The option defaults are `min = 0.1 0.1 40 50`, no temp setting, `vel = geom gaussian`, and `time = steps`.

print command

Syntax:

```
print string keyword value
```

- string = text string to print, which may contain variables
- zero or more keyword/value pairs may be appended
- keyword = *file* or *append* or *screen* or *universe*

```
file value = filename
append value = filename
screen value = yes or no
universe value = yes or no
```

Examples:

```
print "Done with equilibration" file info.dat
print Vol=$v append info.dat screen no
print "The system volume is now $v"
print 'The system volume is now $v'
print "NEB calculation 1 complete" screen no universe yes
print ""
System volume = $v
System temperature = $t
""
```

Description:

Print a text string to the screen and logfile. The text string must be a single argument, so if it is one line but more than one word, it should be enclosed in single or double quotes. To generate multiple lines of output, the string can be enclosed in triple quotes, as in the last example above. If the text string contains variables, they will be evaluated and their current values printed.

If the *file* or *append* keyword is used, a filename is specified to which the output will be written. If *file* is used, then the filename is overwritten if it already exists. If *append* is used, then the filename is appended to if it already exists, or created if it does not exist.

If the *screen* keyword is used, output to the screen and logfile can be turned on or off as desired.

If the *universe* keyword is used, output to the global screen and logfile can be turned on or off as desired. In multi-partition calculations, the *screen* option and the corresponding output only apply to the screen and logfile of the individual partition.

If you want the print command to be executed multiple times (with changing variable values), there are 3 options. First, consider using the [fix print](#) command, which will print a string periodically during a simulation. Second, the print command can be used as an argument to the *every* option of the [run](#) command. Third, the print

LAMMPS Users Manual

command could appear in a section of the input script that is looped over (see the [jump](#) and [next](#) commands).

See the [variable](#) command for a description of *equal* style variables which are typically the most useful ones to use with the print command. Equal-style variables can calculate formulas involving mathematical operations, atom properties, group properties, thermodynamic properties, global values calculated by a [compute](#) or [fix](#), or references to other [variables](#).

Restrictions: none

Related commands:

[fix print](#), [variable](#)

Default:

The option defaults are no file output, screen = yes, and universe = no.

processors command

Syntax:

```
processors Px Py Pz keyword args ...
```

- Px,Py,Pz = # of processors in each dimension of 3d grid overlaying the simulation domain
- zero or more keyword/arg pairs may be appended
- keyword = *grid* or *map* or *part* or *file*

```
grid arg = gstyle params ...
```

```
  gstyle = onelevel or twolevel or numa or custom
```

```
  onelevel params = none
```

```
  twolevel params = Nc Cx Cy Cz
```

```
    Nc = number of cores per node
```

```
    Cx,Cy,Cz = # of cores in each dimension of 3d sub-grid assigned to each node
```

```
  numa params = none
```

```
  custom params = infile
```

```
    infile = file containing grid layout
```

```
map arg = cart or cart/reorder or xyz or xzy or yxz or yzx or zxy or zyx
```

```
  cart = use MPI_Cart() methods to map processors to 3d grid with reorder = 0
```

```
  cart/reorder = use MPI_Cart() methods to map processors to 3d grid with reorder = 1
```

```
  xyz,xzy,yxz,yzx,zxy,zyx = map processors to 3d grid in IJK ordering
```

```
numa arg = none
```

```
part args = Psend Precv cstyle
```

```
  Psend = partition # (1 to Np) which will send its processor layout
```

```
  Precv = partition # (1 to Np) which will recv the processor layout
```

```
  cstyle = multiple
```

```
    multiple = Psend grid will be multiple of Precv grid in each dimension
```

```
file arg = outfile
```

```
  outfile = name of file to write 3d grid of processors to
```

Examples:

```
processors * * 5
processors 2 4 4
processors * * 8 map xyz
processors * * * grid numa
processors * * * grid twolevel 4 * * 1
processors 4 8 16 grid custom myfile
processors * * * part 1 2 multiple
```

Description:

Specify how processors are mapped as a regular 3d grid to the global simulation box. The mapping involves 2 steps. First if there are P processors it means choosing a factorization $P = P_x$ by P_y by P_z so that there are P_x processors in the x dimension, and similarly for the y and z dimensions. Second, the P processors are mapped to the regular 3d grid. The arguments to this command control each of these 2 steps.

The P_x , P_y , P_z parameters affect the factorization. Any of the 3 parameters can be specified with an asterisk "*", which means LAMMPS will choose the number of

LAMMPS Users Manual

processors in that dimension of the grid. It will do this based on the size and shape of the global simulation box so as to minimize the surface-to-volume ratio of each processor's sub-domain.

Choosing explicit values for Px or Py or Pz can be used to override the default manner in which LAMMPS will create the regular 3d grid of processors, if it is known to be sub-optimal for a particular problem. E.g. a problem where the extent of atoms will change dramatically in a particular dimension over the course of the simulation.

The product of Px, Py, Pz must equal P, the total # of processors LAMMPS is running on. For a [2d simulation](#), Pz must equal 1.

Note that if you run on a prime number of processors P, then a grid such as 1 x P x 1 will be required, which may incur extra communication costs due to the high surface area of each processor's sub-domain.

Also note that if multiple partitions are being used then P is the number of processors in this partition; see [this section](#) for an explanation of the `-partition` command-line switch. Also note that you can prefix the `processors` command with the [partition](#) command to easily specify different Px,Py,Pz values for different partitions.

You can use the [partition](#) command to specify different processor grids for different partitions, e.g.

```
partition yes 1 processors 4 4 4
partition yes 2 processors 2 3 2
```

NOTE: This command only affects the initial regular 3d grid created when the simulation box is first specified via a [create_box](#) or [read_data](#) or [read_restart](#) command. Or if the simulation box is re-created via the [replicate](#) command. The same regular grid is initially created, regardless of which [comm_style](#) command is in effect.

If load-balancing is never invoked via the [balance](#) or [fix balance](#) commands, then the initial regular grid will persist for all simulations. If balancing is performed, some of the methods invoked by those commands retain the logical topology of the initial 3d grid, and the mapping of processors to the grid specified by the `processors` command. However the grid spacings in different dimensions may change, so that processors own sub-domains of different sizes. If the [comm_style tiled](#) command is used, methods invoked by the balancing commands may discard the 3d grid of processors and tile the simulation domain with sub-domains of different sizes and shapes which no longer have a logical 3d connectivity. If that occurs, all the information specified by the `processors` command is ignored.

The *grid* keyword affects the factorization of P into Px,Py,Pz and it can also affect how the P processor IDs are mapped to the 3d grid of processors.

The *onelevel* style creates a 3d grid that is compatible with the Px,Py,Pz settings, and which minimizes the surface-to-volume ratio of each processor's sub-domain, as described above. The mapping of processors to the grid is determined by the *map* keyword setting.

LAMMPS Users Manual

The *twolevel* style can be used on machines with multicore nodes to minimize off-node communication. It insures that contiguous sub-sections of the 3d grid are assigned to all the cores of a node. For example if N_c is 4, then 2x2x1 or 2x1x2 or 1x2x2 sub-sections of the 3d grid will correspond to the cores of each node. This affects both the factorization and mapping steps.

The C_x , C_y , C_z settings are similar to the P_x , P_y , P_z settings, only their product should equal N_c . Any of the 3 parameters can be specified with an asterisk "*", which means LAMMPS will choose the number of cores in that dimension of the node's sub-grid. As with P_x, P_y, P_z , it will do this based on the size and shape of the global simulation box so as to minimize the surface-to-volume ratio of each processor's sub-domain.

NOTE: For the *twolevel* style to work correctly, it assumes the MPI ranks of processors LAMMPS is running on are ordered by core and then by node. E.g. if you are running on 2 quad-core nodes, for a total of 8 processors, then it assumes processors 0,1,2,3 are on node 1, and processors 4,5,6,7 are on node 2. This is the default rank ordering for most MPI implementations, but some MPIs provide options for this ordering, e.g. via environment variable settings.

The *numa* style operates similar to the *twolevel* keyword except that it auto-detects which cores are running on which nodes. Currently, it does this in only 2 levels, but it may be extended in the future to account for socket topology and other non-uniform memory access (NUMA) costs. It also uses a different algorithm than the *twolevel* keyword for doing the two-level factorization of the simulation box into a 3d processor grid to minimize off-node communication, and it does its own MPI-based mapping of nodes and cores to the regular 3d grid. Thus it may produce a different layout of the processors than the *twolevel* options.

The *numa* style will give an error if the number of MPI processes is not divisible by the number of cores used per node, or any of the P_x or P_y or P_z values is greater than 1.

NOTE: Unlike the *twolevel* style, the *numa* style does not require any particular ordering of MPI ranks in order to work correctly. This is because it auto-detects which processes are running on which nodes.

The *custom* style uses the file *infile* to define both the 3d factorization and the mapping of processors to the grid.

The file should have the following format. Any number of initial blank or comment lines (starting with a "#" character) can be present. The first non-blank, non-comment line should have 3 values:

P_x P_y P_z

These must be compatible with the total number of processors and the P_x , P_y , P_z settings of the processors command.

This line should be immediately followed by $P = P_x * P_y * P_z$ lines of the form:

ID I J K

LAMMPS Users Manual

where ID is a processor ID (from 0 to P-1) and I,J,K are the processors location in the 3d grid. I must be a number from 1 to Px (inclusive) and similarly for J and K. The P lines can be listed in any order, but no processor ID should appear more than once.

The *map* keyword affects how the P processor IDs (from 0 to P-1) are mapped to the 3d grid of processors. It is only used by the *onelevel* and *twolevel* grid settings.

The *cart* style uses the family of MPI Cartesian functions to perform the mapping, namely `MPI_Cart_create()`, `MPI_Cart_get()`, `MPI_Cart_shift()`, and `MPI_Cart_rank()`. It invokes the `MPI_Cart_create()` function with its `reorder` flag = 0, so that MPI is not free to reorder the processors.

The *cart/reorder* style does the same thing as the *cart* style except it sets the `reorder` flag to 1, so that MPI can reorder processors if it desires.

The *xyz*, *xzy*, *yxz*, *yzx*, *zxy*, and *zyx* styles are all similar. If the style is IJK, then it maps the P processors to the grid so that the processor ID in the I direction varies fastest, the processor ID in the J direction varies next fastest, and the processor ID in the K direction varies slowest. For example, if you select style *xyz* and you have a 2x2x2 grid of 8 processors, the assignments of the 8 octants of the simulation domain will be:

```
proc 0 = lo x, lo y, lo z octant
proc 1 = hi x, lo y, lo z octant
proc 2 = lo x, hi y, lo z octant
proc 3 = hi x, hi y, lo z octant
proc 4 = lo x, lo y, hi z octant
proc 5 = hi x, lo y, hi z octant
proc 6 = lo x, hi y, hi z octant
proc 7 = hi x, hi y, hi z octant
```

Note that, in principle, an MPI implementation on a particular machine should be aware of both the machine's network topology and the specific subset of processors and nodes that were assigned to your simulation. Thus its `MPI_Cart` calls can optimize the assignment of MPI processes to the 3d grid to minimize communication costs. In practice, however, few if any MPI implementations actually do this. So it is likely that the *cart* and *cart/reorder* styles simply give the same result as one of the IJK styles.

Also note, that for the *twolevel* grid style, the *map* setting is used to first map the nodes to the 3d grid, then again to the cores within each node. For the latter step, the *cart* and *cart/reorder* styles are not supported, so an *xyz* style is used in their place.

The *part* keyword affects the factorization of P into Px,Py,Pz.

It can be useful when running in multi-partition mode, e.g. with the [run_style verlet/split](#) command. It specifies a dependency between a sending partition *Psend* and a receiving partition *Precv* which is enforced when each is setting up their own mapping of their processors to the simulation box. Each of *Psend* and *Precv* must be integers from 1 to Np, where Np is the number of partitions you have defined via the [-partition command-line switch](#).

A "dependency" means that the sending partition will create its regular 3d grid as Px by Py by Pz and after it has done this, it will send the Px,Py,Pz values to the receiving

LAMMPS Users Manual

partition. The receiving partition will wait to receive these values before creating its own regular 3d grid and will use the sender's P_x, P_y, P_z values as a constraint. The nature of the constraint is determined by the *cstyle* argument.

For a *cstyle* of *multiple*, each dimension of the sender's processor grid is required to be an integer multiple of the corresponding dimension in the receiver's processor grid. This is a requirement of the [run_style verlet/split](#) command.

For example, assume the sending partition creates a 4x6x10 grid = 240 processor grid. If the receiving partition is running on 80 processors, it could create a 4x2x10 grid, but it will not create a 2x4x10 grid, since in the y-dimension, 6 is not an integer multiple of 4.

NOTE: If you use the [partition](#) command to invoke different "processors" commands on different partitions, and you also use the *part* keyword, then you must insure that both the sending and receiving partitions invoke the "processors" command that connects the 2 partitions via the *part* keyword. LAMMPS cannot easily check for this, but your simulation will likely hang in its setup phase if this error has been made.

The *file* keyword writes the mapping of the factorization of P processors and their mapping to the 3d grid to the specified file *outfile*. This is useful to check that you assigned physical processors in the manner you desired, which can be tricky to figure out, especially when running on multiple partitions or on, a multicore machine or when the processor ranks were reordered by use of the [-reorder command-line switch](#) or due to use of MPI-specific launch options such as a config file.

If you have multiple partitions you should insure that each one writes to a different file, e.g. using a [world-style variable](#) for the filename. The file has a self-explanatory header, followed by one-line per processor in this format:

```
world-ID universe-ID original-ID: I J K: name
```

The IDs are the processor's rank in this simulation (the world), the universe (of multiple simulations), and the original MPI communicator used to instantiate LAMMPS, respectively. The world and universe IDs will only be different if you are running on more than one partition; see the [-partition command-line switch](#). The universe and original IDs will only be different if you used the [-reorder command-line switch](#) to reorder the processors differently than their rank in the original communicator LAMMPS was instantiated with.

I,J,K are the indices of the processor in the regular 3d grid, each from 1 to N_d , where N_d is the number of processors in that dimension of the grid.

The *name* is what is returned by a call to `MPI_Get_processor_name()` and should represent an identifier relevant to the physical processors in your machine. Note that depending on the MPI implementation, multiple cores can have the same *name*.

Restrictions:

This command cannot be used after the simulation box is defined by a [read_data](#) or

LAMMPS Users Manual

[create_box](#) command. It can be used before a restart file is read to change the 3d processor grid from what is specified in the restart file.

The *grid numa* keyword only currently works with the *map cart* option.

The *part* keyword (for the receiving partition) only works with the *grid onelevel* or *grid twolevel* options.

Related commands:

[partition](#), [-reorder](#) command-line switch

Default:

The option defaults are Px Py Pz = * * *, grid = onelevel, and map = cart.

python command

Syntax:

```
python func keyword args ...
```

- func = name of Python function
- one or more keyword/args pairs must be appended

```
keyword = invoke or input or return or format or length or file or here or exists or source
invoke arg = none = invoke the previously defined Python function
input args = N i1 i2 ... iN
    N = # of inputs to function
    i1,...,iN = value, SELF, or LAMMPS variable name
        value = integer number, floating point number, or string
        SELF = reference to LAMMPS itself which can be accessed by Python function
        variable = v_name, where name = name of LAMMPS variable, e.g. v_abc
return arg = varReturn
    varReturn = v_name = LAMMPS variable name which return value of function will be assigned
format arg = fstring with M characters
    M = N if no return value, where N = # of inputs
    M = N+1 if there is a return value
    fstring = each character (i,f,s,p) corresponds in order to an input or return value
    'i' = integer, 'f' = floating point, 's' = string, 'p' = SELF
length arg = Nlen
    Nlen = max length of string returned from Python function
file arg = filename
    filename = file of Python code, which defines func
here arg = inline
    inline = one or more lines of Python code which defines func
    must be a single argument, typically enclosed between triple quotes

    lmp = lammps(ptr=lmp_ptr)
```

```
# loop N times, increasing cutoff each time
```

LAMMPS Users Manual

```
for i in range(N):
    cut = cut0 + i*0.1
    lmp.set_variable("cut",cut)           # set a variable in LAMMPS
    lmp.command("pair_style lj/cut ${cut}") # LAMMPS commands
    lmp.command("pair_coeff * * 1.0 1.0")
    lmp.command("run 100")
"""
```

Description:

Define a Python function or execute a previously defined function or execute some arbitrary python code. Arguments, including LAMMPS variables, can be passed to the function from the LAMMPS input script and a value returned by the Python function to a LAMMPS variable. The Python code for the function can be included directly in the input script or in a separate Python file. The function can be standard Python code or it can make "callbacks" to LAMMPS through its library interface to query or set internal values within LAMMPS. This is a powerful mechanism for performing complex operations in a LAMMPS input script that are not possible with the simple input script and variable syntax which LAMMPS defines. Thus your input script can operate more like a true programming language.

Use of this command requires building LAMMPS with the PYTHON package which links to the Python library so that the Python interpreter is embedded in LAMMPS. More details about this process are given below.

There are two ways to invoke a Python function once it has been defined. One is using the *invoke* keyword. The other is to assign the function to a [python-style variable](#) defined in your input script. Whenever the variable is evaluated, it will execute the Python function to assign a value to the variable. Note that variables can be evaluated in many different ways within LAMMPS. They can be substituted for directly in an input script. Or they can be passed to various commands as arguments, so that the variable is evaluated during a simulation run.

A broader overview of how Python can be used with LAMMPS is given in [Section 11](#). There is an `examples/python` directory which illustrates use of the `python` command.

The *func* setting specifies the name of the Python function. The code for the function is defined using the *file* or *here* keywords as explained below. In case of the *source* keyword, the name of the function is ignored.

If the *invoke* keyword is used, no other keywords can be used, and a previous python command must have defined the Python function referenced by this command. This invokes the Python function with the previously defined arguments and return value processed as explained below. You can invoke the function as many times as you wish in your input script.

If the *source* keyword is used, no other keywords can be used. The argument can be a filename or a string with python commands, either on a single line enclosed in quotes, or as multiple lines enclosed in triple quotes. These python commands will be passed to the python interpreter and executed immediately without registering a python function for future execution.

LAMMPS Users Manual

The *input* keyword defines how many arguments N the Python function expects. If it takes no arguments, then the *input* keyword should not be used. Each argument can be specified directly as a value, e.g. 6 or 3.14159 or abc (a string of characters). The type of each argument is specified by the *format* keyword as explained below, so that Python will know how to interpret the value. If the word SELF is used for an argument it has a special meaning. A pointer is passed to the Python function which it converts into a reference to LAMMPS itself. This enables the function to call back to LAMMPS through its library interface as explained below. This allows the Python function to query or set values internal to LAMMPS which can affect the subsequent execution of the input script. A LAMMPS variable can also be used as an argument, specified as v_name , where "name" is the name of the variable. Any style of LAMMPS variable can be used, as defined by the [variable](#) command. Each time the Python function is invoked, the LAMMPS variable is evaluated and its value is passed to the Python function.

The *return* keyword is only needed if the Python function returns a value. The specified *varReturn* must be of the form v_name , where "name" is the name of a python-style LAMMPS variable, defined by the [variable](#) command. The Python function can return a numeric or string value, as specified by the *format* keyword.

As explained on the [variable](#) doc page, the definition of a python-style variable associates a Python function name with the variable. This must match the *func* setting for this command. For example these two commands would be self-consistent:

```
variable foo python myMultiply
python myMultiply return v_foo format f file funcs.py
```

The two commands can appear in either order in the input script so long as both are specified before the Python function is invoked for the first time.

The *format* keyword must be used if the *input* or *return* keyword is used. It defines an *fstring* with M characters, where $M = \text{sum of number of inputs and outputs}$. The order of characters corresponds to the N inputs, followed by the return value (if it exists). Each character must be one of the following: "i" for integer, "f" for floating point, "s" for string, or "p" for SELF. Each character defines the type of the corresponding input or output value of the Python function and affects the type conversion that is performed internally as data is passed back and forth between LAMMPS and Python. Note that it is permissible to use a [python-style variable](#) in a LAMMPS command that allows for an equal-style variable as an argument, but only if the output of the Python function is flagged as a numeric value ("i" or "f") via the *format* keyword.

If the *return* keyword is used and the *format* keyword specifies the output as a string, then the default maximum length of that string is 63 characters (64-1 for the string terminator). If you want to return a longer string, the *length* keyword can be specified with its *Nlen* value set to a larger number (the code allocates space for $Nlen+1$ to include the string terminator). If the Python function generates a string longer than the default 63 or the specified *Nlen*, it will be truncated.

Either the *file*, *here*, or *exists* keyword must be used, but only one of them. These keywords specify what Python code to load into the Python interpreter. The *file* keyword gives the name of a file, which should end with a ".py" suffix, which contains

LAMMPS Users Manual

Python code. The code will be immediately loaded into and run in the "main" module of the Python interpreter. Note that Python code which contains a function definition does not "execute" the function when it is run; it simply defines the function so that it can be invoked later.

The *here* keyword does the same thing, except that the Python code follows as a single argument to the *here* keyword. This can be done using triple quotes as delimiters, as in the examples above. This allows Python code to be listed verbatim in your input script, with proper indentation, blank lines, and comments, as desired. See [Section 3.2](#), for an explanation of how triple quotes can be used as part of input script syntax.

The *exists* keyword takes no argument. It means that Python code containing the required Python function defined by the *func* setting, is assumed to have been previously loaded by another python command.

Note that the Python code that is loaded and run must contain a function with the specified *func* name. To operate properly when later invoked, the function code must match the *input* and *return* and *format* keywords specified by the python command. Otherwise Python will generate an error.

This section describes how Python code can be written to work with LAMMPS.

Whether you load Python code from a file or directly from your input script, via the *file* and *here* keywords, the code can be identical. It must be indented properly as Python requires. It can contain comments or blank lines. If the code is in your input script, it cannot however contain triple-quoted Python strings, since that will conflict with the triple-quote parsing that the LAMMPS input script performs.

All the Python code you specify via one or more python commands is loaded into the Python "main" module, i.e. `__main__`. The code can define global variables or statements that are outside of function definitions. It can contain multiple functions, only one of which matches the *func* setting in the python command. This means you can use the *file* keyword once to load several functions, and the *exists* keyword thereafter in subsequent python commands to access the other functions previously loaded.

A Python function you define (or more generally, the code you load) can import other Python modules or classes, it can make calls to other system functions or functions you define, and it can access or modify global variables (in the "main" module) which will persist between successive function calls. The latter can be useful, for example, to prevent a function from being invoke multiple times per timestep by different commands in a LAMMPS input script that access the returned python-style variable associated with the function. For example, consider this function loaded with two global variables defined outside the function:

```
nsteplast = -1
nvaluelast = 0

def expensive(nstep):
    global nsteplast, nvaluelast
    if nstep == nsteplast: return nvaluelast
    nsteplast = nstep
```

LAMMPS Users Manual

```
# perform complicated calculation
nvalue = ...
nvaluelast = nvalue
return nvalue
```

Nsteplast stores the previous timestep the function was invoked (passed as an argument to the function). Nvaluelast stores the return value computed on the last function invocation. If the function is invoked again on the same timestep, the previous value is simply returned, without re-computing it. The "global" statement inside the Python function allows it to overwrite the global variables.

Note that if you load Python code multiple times (via multiple python commands), you can overwrite previously loaded variables and functions if you are not careful. E.g. if the code above were loaded twice, the global variables would be re-initialized, which might not be what you want. Likewise, if a function with the same name exists in two chunks of Python code you load, the function loaded second will override the function loaded first.

It's important to realize that if you are running LAMMPS in parallel, each MPI task will load the Python interpreter and execute a local copy of the Python function(s) you define. There is no connection between the Python interpreters running on different processors. This implies three important things.

First, if you put a print statement in your Python function, you will see P copies of the output, when running on P processors. If the prints occur at (nearly) the same time, the P copies of the output may be mixed together. Welcome to the world of parallel programming and debugging.

Second, if your Python code loads modules that are not pre-loaded by the Python library, then it will load the module from disk. This may be a bottleneck if 1000s of processors try to load a module at the same time. On some large supercomputers, loading of modules from disk by Python may be disabled. In this case you would need to pre-build a Python library that has the required modules pre-loaded and link LAMMPS with that library.

Third, if your Python code calls back to LAMMPS (discussed in the next section) and causes LAMMPS to perform an MPI operation requires global communication (e.g. via MPI_Allreduce), such as computing the global temperature of the system, then you must insure all your Python functions (running independently on different processors) call back to LAMMPS. Otherwise the code may hang.

Your Python function can "call back" to LAMMPS through its library interface, if you use the SELF input to pass Python a pointer to LAMMPS. The mechanism for doing this in your Python function is as follows:

```
def foo(lmp_ptr,...):
    from lammps import lammps
    lmp = lammps(ptr=lmp_ptr)
    lmp.command('print "Hello from inside Python"')
    ...
```

LAMMPS Users Manual

The function definition must include a variable (`lmpptr` in this case) which corresponds to `SELF` in the python command. The first line of the function imports the Python module `lammeps.py` in the python dir of the distribution. The second line creates a Python object "lmp" which wraps the instance of LAMMPS that called the function. The "ptr=lmpptr" argument is what makes that happen. The third line invokes the `command()` function in the LAMMPS library interface. It takes a single string argument which is a LAMMPS input script command for LAMMPS to execute, the same as if it appeared in your input script. In this case, LAMMPS should output

```
Hello from inside Python
```

to the screen and log file. Note that since the LAMMPS print command itself takes a string in quotes as its argument, the Python string must be delimited with a different style of quotes.

[Section 11.7](#) describes the syntax for how Python wraps the various functions included in the LAMMPS library interface.

A more interesting example is in the `examples/python/in.python` script which loads and runs the following function from `examples/python/funcs.py`:

```
def loop(N,cut0,thresh,lmpptr):
    print "LOOP ARGS",N,cut0,thresh,lmpptr
    from lammeps import lammeps
    lmp = lammeps(ptr=lmpptr)
    natoms = lmp.get_natoms()

    for i in range(N):
        cut = cut0 + i*0.1

        lmp.set_variable("cut",cut)           # set a variable in LAMMPS
        lmp.command("pair_style lj/cut ${cut}") # LAMMPS command
        #lmp.command("pair_style lj/cut %d" % cut) # LAMMPS command option

        lmp.command("pair_coeff * * 1.0 1.0") # ditto
        lmp.command("run 10")                # ditto
        pe = lmp.extract_compute("thermo_pe",0,0) # extract total PE from LAMMPS
        print "PE",pe/natoms,thresh
        if pe/natoms <thresh: return
```

with these input script commands:

```
python      loop input 4 10 1.0 -4.0 SELF format iffp file funcs.py
python      loop invoke
```

This has the effect of looping over a series of 10 short runs (10 timesteps each) where the pair style cutoff is increased from a value of 1.0 in distance units, in increments of 0.1. The looping stops when the per-atom potential energy falls below a threshold of -4.0 in energy units. More generally, Python can be used to implement a loop with complex logic, much more so than can be created using the LAMMPS [jump](#) and [if](#) commands.

Several LAMMPS library functions are called from the loop function. `Get_natoms()` returns the number of atoms in the simulation, so that it can be used to normalize the

LAMMPS Users Manual

potential energy that is returned by `extract_compute()` for the "thermo_pe" compute that is defined by default for LAMMPS thermodynamic output. `Set_variable()` sets the value of a string variable defined in LAMMPS. This library function is a useful way for a Python function to return multiple values to LAMMPS, more than the single value that can be passed back via a return statement. This cutoff value in the "cut" variable is then substituted (by LAMMPS) in the `pair_style` command that is executed next. Alternatively, the "LAMMPS command option" line could be used in place of the 2 preceding lines, to have Python insert the value into the LAMMPS command string.

NOTE: When using the callback mechanism just described, recognize that there are some operations you should not attempt because LAMMPS cannot execute them correctly. If the Python function is invoked between runs in the LAMMPS input script, then it should be OK to invoke any LAMMPS input script command via the library interface `command()` or `file()` functions, so long as the command would work if it were executed in the LAMMPS input script directly at the same point.

However, a Python function can also be invoked during a run, whenever an associated LAMMPS variable it is assigned to is evaluated. If the variable is an input argument to another LAMMPS command (e.g. [fix setforce](#)), then the Python function will be invoked inside the class for that command, in one of its methods that is invoked in the middle of a timestep. You cannot execute arbitrary input script commands from the Python function (again, via the `command()` or `file()` functions) at that point in the run and expect it to work. Other library functions such as those that invoke computes or other variables may have hidden side effects as well. In these cases, LAMMPS has no simple way to check that something illogical is being attempted.

The same applies to Python functions called during a simulation run at each time step using [fix python/invoke](#).

If you run Python code directly on your workstation, either interactively or by using Python to launch a Python script stored in a file, and your code has an error, you will typically see informative error messages. That is not the case when you run Python code from LAMMPS using an embedded Python interpreter. The code will typically fail silently. LAMMPS will catch some errors but cannot tell you where in the Python code the problem occurred. For example, if the Python code cannot be loaded and run because it has syntax or other logic errors, you may get an error from Python pointing to the offending line, or you may get one of these generic errors from LAMMPS:

```
Could not process Python file
Could not process Python string
```

When the Python function is invoked, if it does not return properly, you will typically get this generic error from LAMMPS:

```
Python function evaluation failed
```

Here are three suggestions for debugging your Python code while running it under LAMMPS.

First, don't run it under LAMMPS, at least to start with! Debug it using plain Python. Load and invoke your function, pass it arguments, check return values, etc.

LAMMPS Users Manual

Second, add Python print statements to the function to check how far it gets and intermediate values it calculates. See the discussion above about printing from Python when running in parallel.

Third, use Python exception handling. For example, say this statement in your Python function is failing, because you have not initialized the variable foo:

```
foo += 1
```

If you put one (or more) statements inside a "try" statement, like this:

```
import exceptions
print "Inside simple function"
try:
    foo += 1      # one or more statements here
except Exception, e:
    print "F00 error:",e
```

then you will get this message printed to the screen:

```
F00 error: local variable 'foo' referenced before assignment
```

If there is no error in the try statements, then nothing is printed. Either way the function continues on (unless you put a return or sys.exit() in the except clause).

Restrictions:

This command is part of the PYTHON package. It is only enabled if LAMMPS was built with that package. See the [Making LAMMPS](#) section for more info.

Building LAMMPS with the PYTHON package will link LAMMPS with the Python library on your system. Settings to enable this are in the lib/python/Makefile.lammps file. See the lib/python/README file for information on those settings.

If you use Python code which calls back to LAMMPS, via the SELF input argument explained above, there is an extra step required when building LAMMPS. LAMMPS must also be built as a shared library and your Python function must be able to load the Python module in python/lammps.py that wraps the LAMMPS library interface. These are the same steps required to use Python by itself to wrap LAMMPS. Details on these steps are explained in [Section python](#). Note that it is important that the stand-alone LAMMPS executable and the LAMMPS shared library be consistent (built from the same source code files) in order for this to work. If the two have been built at different times using different source files, problems may occur.

Related commands:

[shell](#), [variable](#), [fix python/invoke](#)

Default: none

quit command

Syntax:

```
quit status
```

status = numerical exit status (optional)

Examples:

```
quit  
if "$n > 10000" then "quit 1"
```

Description:

This command causes LAMMPS to exit, after shutting down all output cleanly.

It can be used as a debug statement in an input script, to terminate the script at some intermediate point.

It can also be used as an invoked command inside the "then" or "else" portion of an [if](#) command.

The optional status argument is an integer which signals the return status to a program calling LAMMPS. A return status of 0 usually indicates success. A status != 0 is failure, where the specified value can be used to distinguish the kind of error, e.g. where in the input script the quit was invoked. If not specified, a status of 0 is returned.

Restrictions: none

Related commands:

[if](#)

Default: none

read_data command

Syntax:

```
read_data file keyword args ...
```

- file = name of data file to read in
- zero or more keyword/arg pairs may be appended
- keyword = *add* or *offset* or *shift* or *extra/atom/types* or *extra/bond/types* or *extra/angle/types* or *extra/dihedral/types* or *extra/improper/types* or *extra/bond/per/atom* or *extra/angle/per/atom* or *extra/dihedral/per/atom* or *extra/improper/per/atom* or *group* or *nocoeff* or *fix*

add arg = *append* or *IDoffset* or *IDoffset MOLOffset* or *merge*

append = add new atoms with atom IDs appended to current IDs

IDoffset = add new atoms with atom IDs having *IDoffset* added

MOLOffset = add new atoms with molecule IDs having *MOLOffset* added (only when molecule IDs are used)

merge = add new atoms with their atom IDs (and molecule IDs) unchanged

offset args = *toff* *boff* *aoff* *doff* *ioff*

toff = offset to add to atom types

boff = offset to add to bond types

aoff = offset to add to angle types

doff = offset to add to dihedral types

ioff = offset to add to improper types

shift args = *Sx* *Sy* *Sz*

Sx,Sy,Sz = distance to shift atoms when adding to system (distance units)

extra/atom/types arg = # of extra atom types

extra/bond/types arg = # of extra bond types

extra/angle/types arg = # of extra angle types

extra/dihedral/types arg = # of extra dihedral types

extra/improper/types arg = # of extra improper types

extra/bond/per/atom arg = leave space for this many new bonds per atom

extra/angle/per/atom arg = leave space for this many new angles per atom

extra/dihedral/per/atom arg = leave space for this many new dihedrals per atom

extra/improper/per/atom arg = leave space for this many new improper per atom

extra/special/per/atom arg = leave space for extra 1-2,1-3,1-4 interactions per atom

group args = *groupID*

groupID = add atoms in data file to this group

nocoeff = ignore force field parameters

fix args = *fix-ID* *header-string* *section-string*

fix-ID = ID of *fix* to process header lines and sections of data file

header-string = header lines containing this string will be passed to *fix*

section-string = section names with this string will be passed to *fix*

Examples:

```
read_data data.lj
```

```
read_data ../run7/data.polymer.gz
```

```
read_data data.protein fix mycmap crossterm CMAP
```

```
read_data data.water add append offset 3 1 1 1 1 shift 0.0 0.0 50.0
```

```
read_data data.water add merge 1 group solvent
```

Description:

LAMMPS Users Manual

Read in a data file containing information LAMMPS needs to run a simulation. The file can be ASCII text or a gzipped text file (detected by a .gz suffix). This is one of 3 ways to specify initial atom coordinates; see the [read_restart](#) and [create_atoms](#) commands for alternative methods. Also see the explanation of the [-restart command-line switch](#) which can convert a restart file to a data file.

This command can be used multiple times to add new atoms and their properties to an existing system by using the *add*, *offset*, and *shift* keywords. See more details below, which includes the use case for the *extra* keywords.

The *group* keyword adds all the atoms in the data file to the specified group-ID. The group will be created if it does not already exist. This is useful if you are reading multiple data files and wish to put sets of atoms into different groups so they can be operated on later. E.g. a group of added atoms can be moved to new positions via the [displace_atoms](#) command. Note that atoms read from the data file are also always added to the "all" group. The [group](#) command discusses atom groups, as used in LAMMPS.

The *nocoeff* keyword tells `read_data` to ignore force field parameters. The various *Coeff* sections are still read and have to have the correct number of lines, but they are not applied. This also allows to read a data file without having any pair, bond, angle, dihedral or improper styles defined, or to read a data file for a different force field.

The use of the *fix* keyword is discussed below.

Reading multiple data files

The `read_data` command can be used multiple times with the same or different data files to build up a complex system from components contained in individual data files. For example one data file could contain fluid in a confined domain; a second could contain wall atoms, and the second file could be read a third time to create a wall on the other side of the fluid. The third set of atoms could be rotated to an opposing direction using the [displace_atoms](#) command, after the third `read_data` command is used.

The *add*, *offset*, *shift*, *extra*, and *group* keywords are useful in this context.

If a simulation box does not yet exist, the *add* keyword cannot be used; the `read_data` command is being used for the first time. If a simulation box does exist, due to using the [create_box](#) command, or a previous `read_data` command, then the *add* keyword must be used.

NOTE: The simulation box size (xlo to xhi, ylo to yhi, zlo to zhi) in the new data file will be merged with the existing simulation box to create a large enough box in each dimension to contain both the existing and new atoms. Each box dimension never shrinks due to this merge operation, it only stays the same or grows. Care must be used if you are growing the existing simulation box in a periodic dimension. If there are existing atoms with bonds that straddle that periodic boundary, then the atoms may become far apart if the box size grows. This will separate the atoms in the bond, which can lead to "lost" bond atoms or bad dynamics.

LAMMPS Users Manual

The three choices for the *add* argument affect how the atom IDs and molecule IDs of atoms in the data file are treated. If *append* is specified, atoms in the data file are added to the current system, with their atom IDs reset so that an atomID = M in the data file becomes atomID = N+M, where N is the largest atom ID in the current system. This rule is applied to all occurrences of atom IDs in the data file, e.g. in the Velocity or Bonds section. This is also done for molecule IDs, if the atom style does support molecule IDs or they are enabled via *fix property/atom*. If *IDoffset* is specified, then *IDoffset* is a numeric value is given, e.g. 1000, so that an atomID = M in the data file becomes atomID = 1000+M. For systems with enabled molecule IDs, another numerical argument *MOLoffset* is required representing the equivalent offset for molecule IDs. If *merge* is specified, the data file atoms are added to the current system without changing their IDs. They are assumed to merge (without duplication) with the currently defined atoms. It is up to you to insure there are no multiply defined atom IDs, as LAMMPS only performs an incomplete check that this is the case by insuring the resulting max atomID \geq the number of atoms. For molecule IDs, there is no check done at all.

The *offset* and *shift* keywords can only be used if the *add* keyword is also specified.

The *offset* keyword adds the specified offset values to the atom types, bond types, angle types, dihedral types, and improper types as they are read from the data file. E.g. if *toff* = 2, and the file uses atom types 1,2,3, then the added atoms will have atom types 3,4,5. These offsets apply to all occurrences of types in the data file, e.g. for the Atoms or Masses or Pair Coeffs or Bond Coeffs sections. This makes it easy to use atoms and molecules and their attributes from a data file in different simulations, where you want their types (atom, bond, angle, etc) to be different depending on what other types already exist. All five offset values must be specified, but individual values will be ignored if the data file does not use that attribute (e.g. no bonds).

The *shift* keyword can be used to specify an (Sx, Sy, Sz) displacement applied to the coordinates of each atom. Sz must be 0.0 for a 2d simulation. This is a mechanism for adding structured collections of atoms at different locations within the simulation box, to build up a complex geometry. It is up to you to insure atoms do not end up overlapping unphysically which would lead to bad dynamics. Note that the [displace_atoms](#) command can be used to move a subset of atoms after they have been read from a data file. Likewise, the [delete_atoms](#) command can be used to remove overlapping atoms. Note that the shift values (Sx, Sy, Sz) are also added to the simulation box information (xlo, xhi, ylo, yhi, zlo, zhi) in the data file to shift its boundaries. E.g. $xlo_new = xlo + Sx$, $xhi_new = xhi + Sx$.

The *extra* keywords can only be used the first time the *read_data* command is used. They are useful if you intend to add new atom, bond, angle, etc types later with additional *read_data* commands. This is because the maximum number of allowed atom, bond, angle, etc types is set by LAMMPS when the system is first initialized. If you do not use the *extra* keywords, then the number of these types will be limited to what appears in the first data file you read. For example, if the first data file is a solid substrate of Si, it will likely specify a single atom type. If you read a second data file with a different material (water molecules) that sit on top of the substrate, you will want to use different atom types for those atoms. You can only do this if you set the *extra/atom/types* keyword to a sufficiently large value when reading the substrate data file. Note that use of the *extra* keywords also allows each data file to contain sections

LAMMPS Users Manual

like Masses or Pair Coeffs or Bond Coeffs which are sized appropriately for the number of types in that data file. If the *offset* keyword is used appropriately when each data file is read, the values in those sections will be stored correctly in the larger data structures allocated by the use of the *extra* keywords. E.g. the substrate file can list mass and pair coefficients for type 1 silicon atoms. The water file can list mass and pair coefficients for type 1 and type 2 hydrogen and oxygen atoms. Use of the *extra* and *offset* keywords will store those mass and pair coefficient values appropriately in data structures that allow for 3 atom types (Si, H, O). Of course, you would still need to specify coefficients for H/Si and O/Si interactions in your input script to have a complete pairwise interaction model.

An alternative to using the *extra* keywords with the `read_data` command, is to use the `create_box` command to initialize the simulation box and all the various type limits you need via its *extra* keywords. Then use the `read_data` command one or more times to populate the system with atoms, bonds, angles, etc, using the *offset* keyword if desired to alter types used in the various data files you read.

Format of a data file

The structure of the data file is important, though many settings and sections are optional or can come in any order. See the examples directory for sample data files for different problems.

A data file has a header and a body. The header appears first. The first line of the header is always skipped; it typically contains a description of the file. Then lines are read one at a time. Lines can have a trailing comment starting with '#' that is ignored. If the line is blank (only whitespace after comment is deleted), it is skipped. If the line contains a header keyword, the corresponding value(s) is read from the line. If it doesn't contain a header keyword, the line begins the body of the file.

The body of the file contains zero or more sections. The first line of a section has only a keyword. This line can have a trailing comment starting with '#' that is either ignored or can be used to check for a style match, as described below. The next line is skipped. The remaining lines of the section contain values. The number of lines depends on the section keyword as described below. Zero or more blank lines can be used between sections. Sections can appear in any order, with a few exceptions as noted below.

The keyword *fix* can be used one or more times. Each usage specifies a fix that will be used to process a specific portion of the data file. Any header line containing *header-string* and any section with a name containing *section-string* will be passed to the specified fix. See the `fix property/atom` command for an example of a fix that operates in this manner. The doc page for the fix defines the syntax of the header line(s) and section(s) that it reads from the data file. Note that the *header-string* can be specified as NULL, in which case no header lines are passed to the fix. This means that it can infer the length of its Section from standard header settings, such as the number of atoms.

The formatting of individual lines in the data file (indentation, spacing between words and numbers) is not important except that header and section keywords (e.g. atoms, xlo xhi, Masses, Bond Coeffs) must be capitalized as shown and can't have extra white

space between their words - e.g. two spaces or a tab between the 2 words in "xlo xhi" or the 2 words in "Bond Coeffs", is not valid.

Format of the header of a data file

These are the recognized header keywords. Header lines can come in any order. The value(s) are read from the beginning of the line. Thus the keyword *atoms* should be in a line like "1000 atoms"; the keyword *ylo yhi* should be in a line like "-10.0 10.0 ylo yhi"; the keyword *xy xz yz* should be in a line like "0.0 5.0 6.0 xy xz yz". All these settings have a default value of 0, except the lo/hi box size defaults are -0.5 and 0.5. A line need only appear if the value is different than the default.

- *atoms* = # of atoms in system

- *extra special per atom* = leave space for this many new special bonds per atom (deprecated, use extra/special/per/atom keyword)
- *ellipsoids* = # of ellipsoids in system
- *lines* = # of line segments in system
- *triangles* = # of triangles in system
- *bodies* = # of bodies in system
- *xlo xhi* = simulation box boundaries in x dimension
- *ylo yhi* = simulation box boundaries in y dimension
- *zlo zhi* = simulation box boundaries in z dimension
- *xy xz yz* = simulation box tilt factors for triclinic system

The initial simulation box size is determined by the lo/hi settings. In any dimension, the system may be periodic or non-periodic; see the [boundary](#) command. When the simulation box is created it is also partitioned into a regular 3d grid of rectangular bricks, one per processor, based on the number of processors being used and the settings of the [processors](#) command. The partitioning can later be changed by the [balance](#) or [fix balance](#) commands.

If the *xy xz yz* line does not appear, LAMMPS will set up an axis-aligned (orthogonal) simulation box. If the line does appear, LAMMPS creates a non-orthogonal simulation domain shaped as a parallelepiped with triclinic symmetry. The parallelepiped has its

LAMMPS Users Manual

"origin" at (x_{lo}, y_{lo}, z_{lo}) and is defined by 3 edge vectors starting from the origin given by $A = (x_{hi} - x_{lo}, 0, 0)$; $B = (x_y, y_{hi} - y_{lo}, 0)$; $C = (x_z, y_z, z_{hi} - z_{lo})$. x_y, x_z, y_z can be 0.0 or positive or negative values and are called "tilt factors" because they are the amount of displacement applied to faces of an originally orthogonal box to transform it into the parallelepiped.

By default, the tilt factors (x_y, x_z, y_z) can not skew the box more than half the distance of the corresponding parallel box length. For example, if $x_{lo} = 2$ and $x_{hi} = 12$, then the x box length is 10 and the xy tilt factor must be between -5 and 5. Similarly, both x_z and y_z must be between $-(x_{hi} - x_{lo})/2$ and $+(y_{hi} - y_{lo})/2$. Note that this is not a limitation, since if the maximum tilt factor is 5 (as in this example), then configurations with tilt = ..., -15, -5, 5, 15, 25, ... are all geometrically equivalent. If you wish to define a box with tilt factors that exceed these limits, you can use the [box tilt](#) command, with a setting of *large*; a setting of *small* is the default.

See [Section 6.12](#) of the doc pages for a geometric description of triclinic boxes, as defined by LAMMPS, and how to transform these parameters to and from other commonly used triclinic representations.

When a triclinic system is used, the simulation domain should normally be periodic in the dimension that the tilt is applied to, which is given by the second dimension of the tilt factor (e.g. y for xy tilt). This is so that pairs of atoms interacting across that boundary will have one of them shifted by the tilt factor. Periodicity is set by the [boundary](#) command. For example, if the xy tilt factor is non-zero, then the y dimension should be periodic. Similarly, the z dimension should be periodic if x_z or y_z is non-zero. LAMMPS does not require this periodicity, but you may lose atoms if this is not the case.

Also note that if your simulation will tilt the box, e.g. via the [fix deform](#) command, the simulation box must be setup to be triclinic, even if the tilt factors are initially 0.0. You can also change an orthogonal box to a triclinic box or vice versa by using the [change box](#) command with its *ortho* and *triclinic* options.

For 2d simulations, the z_{lo} z_{hi} values should be set to bound the z coords for atoms that appear in the file; the default of -0.5 0.5 is valid if all z coords are 0.0. For 2d triclinic simulations, the x_z and y_z tilt factors must be 0.0.

If the system is periodic (in a dimension), then atom coordinates can be outside the bounds (in that dimension); they will be remapped (in a periodic sense) back inside the box. Note that if the *add* option is being used to add atoms to a simulation box that already exists, this periodic remapping will be performed using simulation box bounds that are the union of the existing box and the box boundaries in the new data file.

NOTE: If the system is non-periodic (in a dimension), then all atoms in the data file must have coordinates (in that dimension) that are "greater than or equal to" the lo value and "less than or equal to" the hi value. If the non-periodic dimension is of style "fixed" (see the [boundary](#) command), then the atom coords must be strictly "less than" the hi value, due to the way LAMMPS assign atoms to processors. Note that you should not make the lo/hi values radically smaller/larger than the extent of the atoms. For example, if your atoms extend from 0 to 50, you should not specify the box bounds as -10000 and 10000. This is because LAMMPS uses the specified box size to layout

LAMMPS Users Manual

the 3d grid of processors. A huge (mostly empty) box will be sub-optimal for performance when using "fixed" boundary conditions (see the [boundary](#) command). When using "shrink-wrap" boundary conditions (see the [boundary](#) command), a huge (mostly empty) box may cause a parallel simulation to lose atoms when LAMMPS shrink-wraps the box around the atoms. The `read_data` command will generate an error in this case.

The "extra bond per atom" setting (angle, dihedral, improper) is only needed if new bonds (angles, dihedrals, improper) will be added to the system when a simulation runs, e.g. by using the [fix bond/create](#) command. Using this header flag is deprecated; please use the `extra/bond/per/atom` keyword (and correspondingly for angles, dihedrals and improper) in the `read_data` command instead. Either will pre-allocate space in LAMMPS data structures for storing the new bonds (angles, dihedrals, improper).

The "extra special per atom" setting is typically only needed if new bonds/angles/etc will be added to the system, e.g. by using the [fix bond/create](#) command. Or if entire new molecules will be added to the system, e.g. by using the [fix deposit](#) or [fix pour](#) commands, which will have more special 1-2,1-3,1-4 neighbors than any other molecules defined in the data file. Using this header flag is deprecated; please use the `extra/special/per/atom` keyword instead. Using this setting will pre-allocate space in the LAMMPS data structures for storing these neighbors. See the [special_bonds](#) and [molecule](#) doc pages for more discussion of 1-2,1-3,1-4 neighbors.

NOTE: All of the "extra" settings are only applied in the first data file read and when no simulation box has yet been created; as soon as the simulation box is created (and `read_data` implies that), these settings are *locked* and cannot be changed anymore. Please see the description of the `add` keyword above for reading multiple data files. If they appear in later data files, they are ignored.

The "ellipsoids" and "lines" and "triangles" and "bodies" settings are only used with [atom_style ellipsoid or line or tri or body](#) and specify how many of the atoms are finite-size ellipsoids or lines or triangles or bodies; the remainder are point particles. See the discussion of `ellipsoidflag` and the *Ellipsoids* section below. See the discussion of `lineflag` and the *Lines* section below. See the discussion of `triangleflag` and the *Triangles* section below. See the discussion of `bodyflag` and the *Bodies* section below.

NOTE: For [atom_style template](#), the molecular topology (bonds,angles,etc) is contained in the molecule templates read-in by the [molecule](#) command. This means you cannot set the *bonds*, *angles*, etc header keywords in the data file, nor can you define *Bonds*, *Angles*, etc sections as discussed below. You can set the *bond types*, *angle types*, etc header keywords, though it is not necessary. If specified, they must match the maximum values defined in any of the template molecules.

Format of the body of a data file

These are the section keywords for the body of the file.

- *Atoms, Velocities, Masses, Ellipsoids, Lines, Triangles, Bodies* = atom-property sections
- *Bonds, Angles, Dihedrals, Improper* = molecular topology sections

LAMMPS Users Manual

- *Pair Coeffs, PairIJ Coeffs, Bond Coeffs, Angle Coeffs, Dihedral Coeffs, Improper Coeffs* = force field sections
- *BondBond Coeffs, BondAngle Coeffs, MiddleBondTorsion Coeffs, EndBondTorsion Coeffs, AngleTorsion Coeffs, AngleAngleTorsion Coeffs, BondBond13 Coeffs, AngleAngle Coeffs* = class 2 force field sections

These keywords will check an appended comment for a match with the currently defined style:

- *Atoms, Pair Coeffs, PairIJ Coeffs, Bond Coeffs, Angle Coeffs, Dihedral Coeffs, Improper Coeffs*

For example, these lines:

```
Atoms # sphere
Pair Coeffs # lj/cut
```

will check if the currently-defined `atom_style` is *sphere*, and the current `pair_style` is *lj/cut*. If not, LAMMPS will issue a warning to indicate that the data file section likely does not contain the correct number or type of parameters expected for the currently-defined style.

Each section is listed below in alphabetic order. The format of each section is described including the number of lines it must contain and rules (if any) for where it can appear in the data file.

Any individual line in the various sections can have a trailing comment starting with "#" for annotation purposes. E.g. in the Atoms section:

```
10 1 17 -1.0 10.0 5.0 6.0 # salt ion
```

Angle Coeffs section:

- one line per angle type
 - line syntax: ID coeffs
- ID = angle type (1-N)
coeffs = list of coeffs
- example:

```
6 70 108.5 0 0
```

The number and meaning of the coefficients are specific to the defined angle style. See the `angle_style` and `angle_coeff` commands for details. Coefficients can also be set via the `angle_coeff` command in the input script.

AngleAngle Coeffs section:

- one line per improper type
- line syntax: ID coeffs

ID = improper type (1-N)

LAMMPS Users Manual

coeffs = list of coeffs (see [improper_coeff](#))

AngleAngleTorsion Coeffs section:

- one line per dihedral type
- line syntax: ID coeffs

ID = dihedral type (1-N)
coeffs = list of coeffs (see [dihedral_coeff](#))

Angles section:

- one line per angle
- line syntax: ID type atom1 atom2 atom3

ID = number of angle (1-Nangles)
type = angle type (1-Nangletype)
atom1,atom2,atom3 = IDs of 1st,2nd,3rd atoms in angle

example:

```
2 2 17 29 430
```

The 3 atoms are ordered linearly within the angle. Thus the central atom (around which the angle is computed) is the atom2 in the list. E.g. H,O,H for a water molecule. The *Angles* section must appear after the *Atoms* section. All values in this section must be integers (1, not 1.0).

AngleTorsion Coeffs section:

- one line per dihedral type
- line syntax: ID coeffs

ID = dihedral type (1-N)
coeffs = list of coeffs (see [dihedral_coeff](#))

Atoms section:

- one line per atom
- line syntax: depends on atom style

An *Atoms* section must appear in the data file if natoms > 0 in the header section. The atoms can be listed in any order. These are the line formats for each [atom style](#) in LAMMPS. As discussed below, each line can optionally have 3 flags (nx,ny,nz) appended to it, which indicate which image of a periodic simulation box the atom is in. These may be important to include for some kinds of analysis.

angle	atom-ID molecule-ID atom-type x y z
atomic	atom-ID atom-type x y z
body	atom-ID atom-type bodyflag mass x y z
bond	atom-ID molecule-ID atom-type x y z

LAMMPS Users Manual

charge	atom-ID atom-type q x y z
dipole	atom-ID atom-type q x y z mux muy muz
dpd	atom-ID atom-type theta x y z
edpd	atom-ID atom-type edpd_temp edpd_cv x y z
mdpd	atom-ID atom-type rho x y z
tdpd	atom-ID atom-type x y z cc1 cc2 ... ccNspecies
electron	atom-ID atom-type q spin eradius x y z
ellipsoid	atom-ID atom-type ellipsoidflag density x y z
full	atom-ID molecule-ID atom-type q x y z
line	atom-ID molecule-ID atom-type lineflag density x y z
meso	atom-ID atom-type rho e cv x y z
molecular	atom-ID molecule-ID atom-type x y z
peri	atom-ID atom-type volume density x y z
smd	atom-ID atom-type molecule volume mass kernel-radius contact-radius x y z
sphere	atom-ID atom-type diameter density x y z
template	atom-ID molecule-ID template-index template-atom atom-type x y z
tri	atom-ID molecule-ID atom-type triangleflag density x y z
wavepacket	atom-ID atom-type charge spin eradius etag cs_re cs_im x y z
hybrid	atom-ID atom-type x y z sub-style1 sub-style2 ...

The per-atom values have these meanings and units, listed alphabetically:

- atom-ID = integer ID of atom
- atom-type = type of atom (1-Ntype)
- bodyflag = 1 for body particles, 0 for point particles
- cc = chemical concentration for tDPD particles for each species (mole/volume units)
- contact-radius = ??? (distance units)
- cs_re,cs_im = real/imaginary parts of wavepacket coefficients
- cv = heat capacity (need units) for SPH particles
- density = density of particle (mass/distance³ or mass/distance² or mass/distance units, depending on dimensionality of particle)
- diameter = diameter of spherical atom (distance units)
- e = energy (need units) for SPH particles
- edpd_temp = temperature for eDPD particles (temperature units)
- edpd_cv = volumetric heat capacity for eDPD particles (energy/temperature/volume units)
- ellipsoidflag = 1 for ellipsoidal particles, 0 for point particles
- eradius = electron radius (or fixed-core radius)
- etag = integer ID of electron that each wavepacket belongs to
- kernel-radius = ??? (distance units)
- lineflag = 1 for line segment particles, 0 for point or spherical particles
- mass = mass of particle (mass units)
- molecule-ID = integer ID of molecule the atom belongs to
- mux,muy,muz = components of dipole moment of atom (dipole units)
- q = charge on atom (charge units)
- rho = density (need units) for SPH particles

LAMMPS Users Manual

- spin = electron spin (+1/-1), 0 = nuclei, 2 = fixed-core, 3 = pseudo-cores (i.e. ECP)
- template-atom = which atom within a template molecule the atom is
- template-index = which molecule within the molecule template the atom is part of
- theta = internal temperature of a DPD particle
- triangleflag = 1 for triangular particles, 0 for point or spherical particles
- volume = volume of Peridynamic particle (distance³ units)
- x,y,z = coordinates of atom (distance units)

The units for these quantities depend on the unit style; see the [units](#) command for details.

For 2d simulations specify z as 0.0, or a value within the *zlo zhi* setting in the data file header.

The atom-ID is used to identify the atom throughout the simulation and in dump files. Normally, it is a unique value from 1 to Natoms for each atom. Unique values larger than Natoms can be used, but they will cause extra memory to be allocated on each processor, if an atom map array is used, but not if an atom map hash is used; see the [atom_modify](#) command for details. If an atom map is not used (e.g. an atomic system with no bonds), and you don't care if unique atom IDs appear in dump files, then the atom-IDs can all be set to 0.

The molecule ID is a 2nd identifier attached to an atom. Normally, it is a number from 1 to N, identifying which molecule the atom belongs to. It can be 0 if it is an unbonded atom or if you don't care to keep track of molecule assignments.

The diameter specifies the size of a finite-size spherical particle. It can be set to 0.0, which means that atom is a point particle.

The ellipsoidflag, lineflag, triangleflag, and bodyflag determine whether the particle is a finite-size ellipsoid or line or triangle or body of finite size, or whether the particle is a point particle. Additional attributes must be defined for each ellipsoid, line, triangle, or body in the corresponding *Ellipsoids*, *Lines*, *Triangles*, or *Bodies* section.

The *template-index* and *template-atom* are only defined used by [atom_style template](#). In this case the [molecule](#) command is used to define a molecule template which contains one or more molecules. If an atom belongs to one of those molecules, its *template-index* and *template-atom* are both set to positive integers; if not the values are both 0. The *template-index* is which molecule (1 to Nmols) the atom belongs to. The *template-atom* is which atom (1 to Natoms) within the molecule the atom is.

Some pair styles and fixes and computes that operate on finite-size particles allow for a mixture of finite-size and point particles. See the doc pages of individual commands for details.

For finite-size particles, the density is used in conjunction with the particle volume to set the mass of each particle as mass = density * volume. In this context, volume can be a 3d quantity (for spheres or ellipsoids), a 2d quantity (for triangles), or a 1d quantity (for line segments). If the volume is 0.0, meaning a point particle, then the

LAMMPS Users Manual

density value is used as the mass. One exception is for the body atom style, in which case the mass of each particle (body or point particle) is specified explicitly. This is because the volume of the body is unknown.

Note that for 2d simulations of spheres, this command will treat them as spheres when converting density to mass. However, they can also be modeled as 2d discs (circles) if the `set density/disc` command is used to reset their mass after the `read_data` command is used. A `disc` keyword can also be used with time integration fixes, such as `fix nve/sphere` and `fix nvt/sphere` to time integrate their motion as 2d discs (not 3d spheres), by changing their moment of inertia.

For `atom_style hybrid`, following the 5 initial values (ID,type,x,y,z), specific values for each sub-style must be listed. The order of the sub-styles is the same as they were listed in the `atom_style` command. The sub-style specific values are those that are not the 5 standard ones (ID,type,x,y,z). For example, for the "charge" sub-style, a "q" value would appear. For the "full" sub-style, a "molecule-ID" and "q" would appear. These are listed in the same order they appear as listed above. Thus if

```
atom_style hybrid charge sphere
```

were used in the input script, each atom line would have these fields:

```
atom-ID atom-type x y z q diameter density
```

Note that if a non-standard value is defined by multiple sub-styles, it must appear multiple times in the atom line. E.g. the atom line for `atom_style hybrid dipole full` would list "q" twice:

```
atom-ID atom-type x y z q mux muy myz molecule-ID q
```

Atom lines specify the (x,y,z) coordinates of atoms. These can be inside or outside the simulation box. When the data file is read, LAMMPS wraps coordinates outside the box back into the box for dimensions that are periodic. As discussed above, if an atom is outside the box in a non-periodic dimension, it will be lost.

LAMMPS always stores atom coordinates as values which are inside the simulation box. It also stores 3 flags which indicate which image of the simulation box (in each dimension) the atom would be in if its coordinates were unwrapped across periodic boundaries. An image flag of 0 means the atom is still inside the box when unwrapped. A value of 2 means add 2 box lengths to get the unwrapped coordinate. A value of -1 means subtract 1 box length to get the unwrapped coordinate. LAMMPS updates these flags as atoms cross periodic boundaries during the simulation. The `dump` command can output atom atom coordinates in wrapped or unwrapped form, as well as the 3 image flags.

In the data file, atom lines (all lines or none of them) can optionally list 3 trailing integer values (nx,ny,nz), which are used to initialize the atom's image flags. If nx,ny,nz values are not listed in the data file, LAMMPS initializes them to 0. Note that the image flags are immediately updated if an atom's coordinates need to wrapped back into the simulation box.

LAMMPS Users Manual

It is only important to set image flags correctly in a data file if a simulation model relies on unwrapped coordinates for some calculation; otherwise they can be left unspecified. Examples of LAMMPS commands that use unwrapped coordinates internally are as follows:

- Atoms in a rigid body (see [fix rigid](#), [fix rigid/small](#)) must have consistent image flags, so that when the atoms are unwrapped, they are near each other, i.e. as a single body.
- If the [replicate](#) command is used to generate a larger system, image flags must be consistent for bonded atoms when the bond crosses a periodic boundary. I.e. the values of the image flags should be different by 1 (in the appropriate dimension) for the two atoms in such a bond.
- If you plan to [dump](#) image flags and perform post-analysis that will unwrap atom coordinates, it may be important that a continued run (restarted from a data file) begins with image flags that are consistent with the previous run.

NOTE: If your system is an infinite periodic crystal with bonds then it is impossible to have fully consistent image flags. This is because some bonds will cross periodic boundaries and connect two atoms with the same image flag.

Atom velocities and other atom quantities not defined above are set to 0.0 when the *Atoms* section is read. Velocities can be set later by a *Velocities* section in the data file or by a [velocity](#) or [set](#) command in the input script.

Bodies section:

- one or more lines per body
 - first line syntax: atom-ID Ninteger Ndouble
- Ninteger = # of integer quantities for this particle
Ndouble = # of floating-point quantities for this particle
- 0 or more integer lines with total of Ninteger values
 - 0 or more double lines with total of Ndouble values
 - example:

```
12 3 6
2 3 2
1.0 2.0 3.0 1.0 2.0 4.0
```

- example:

```
12 0 14
1.0 2.0 3.0 1.0 2.0 4.0 1.0
2.0 3.0 1.0 2.0 4.0 4.0 2.0
```

The *Bodies* section must appear if [atom_style body](#) is used and any atoms listed in the *Atoms* section have a bodyflag = 1. The number of bodies should be specified in the header section via the "bodies" keyword.

Each body can have a variable number of integer and/or floating-point values. The number and meaning of the values is defined by the body style, as described in the [body](#) doc page. The body style is given as an argument to the [atom_style body](#) command.

LAMMPS Users Manual

The Ninteger and Ndouble values determine how many integer and floating-point values are specified for this particle. Ninteger and Ndouble can be as large as needed and can be different for every body. Integer values are then listed next on subsequent lines. Lines are read one at a time until Ninteger values are read. Floating-point values follow on subsequent lines, Again lines are read one at a time until Ndouble values are read. Note that if there are no values of a particular type, no lines appear for that type.

The *Bodies* section must appear after the *Atoms* section.

Bond Coeffs section:

- one line per bond type
- line syntax: ID coeffs

ID = bond type (1-N)
coeffs = list of coeffs

- example:

```
4 250 1.49
```

The number and meaning of the coefficients are specific to the defined bond style. See the [bond_style](#) and [bond_coeff](#) commands for details. Coefficients can also be set via the [bond_coeff](#) command in the input script.

BondAngle Coeffs section:

- one line per angle type
- line syntax: ID coeffs

ID = angle type (1-N)
coeffs = list of coeffs (see class 2 section of [angle_coeff](#))

BondBond Coeffs section:

- one line per angle type
- line syntax: ID coeffs

ID = angle type (1-N)
coeffs = list of coeffs (see class 2 section of [angle_coeff](#))

BondBond13 Coeffs section:

- one line per dihedral type
- line syntax: ID coeffs

ID = dihedral type (1-N)
coeffs = list of coeffs (see class 2 section of [dihedral_coeff](#))

Bonds section:

LAMMPS Users Manual

- one line per bond
- line syntax: ID type atom1 atom2

```
ID = bond number (1-Nbonds)
type = bond type (1-Nbondtype)
atom1,atom2 = IDs of 1st,2nd atoms in bond
```

- example:

```
12 3 17 29
```

The *Bonds* section must appear after the *Atoms* section. All values in this section must be integers (1, not 1.0).

Dihedral Coeffs section:

- one line per dihedral type
- line syntax: ID coeffs

```
ID = dihedral type (1-N)
coeffs = list of coeffs
```

- example:

```
3 0.6 1 0 1
```

The number and meaning of the coefficients are specific to the defined dihedral style. See the [dihedral_style](#) and [dihedral_coeff](#) commands for details. Coefficients can also be set via the [dihedral_coeff](#) command in the input script.

Dihedrals section:

- one line per dihedral
- line syntax: ID type atom1 atom2 atom3 atom4

```
ID = number of dihedral (1-Ndihedrals)
type = dihedral type (1-Ndihedralttype)
atom1,atom2,atom3,atom4 = IDs of 1st,2nd,3rd,4th atoms in dihedral
```

- example:

```
12 4 17 29 30 21
```

The 4 atoms are ordered linearly within the dihedral. The *Dihedrals* section must appear after the *Atoms* section. All values in this section must be integers (1, not 1.0).

Ellipsoids section:

- one line per ellipsoid
- line syntax: atom-ID shapex shapey shapez quatw quati quatj quatk

```
atom-ID = ID of atom which is an ellipsoid
shapex,shapey,shapez = 3 diameters of ellipsoid (distance units)
quatw,quati,quatj,quatk = quaternion components for orientation of atom
```

- example:

LAMMPS Users Manual

12 1 2 1 1 0 0 0

The *Ellipsoids* section must appear if [atom_style ellipsoid](#) is used and any atoms are listed in the *Atoms* section with an `ellipsoidflag = 1`. The number of ellipsoids should be specified in the header section via the "ellipsoids" keyword.

The 3 shape values specify the 3 diameters or aspect ratios of a finite-size ellipsoidal particle, when it is oriented along the 3 coordinate axes. They must all be non-zero values.

The values *quatw*, *quati*, *quatj*, and *quatk* set the orientation of the atom as a quaternion (4-vector). Note that the shape attributes specify the aspect ratios of an ellipsoidal particle, which is oriented by default with its x-axis along the simulation box's x-axis, and similarly for y and z. If this body is rotated (via the right-hand rule) by an angle θ around a unit vector (a,b,c) , then the quaternion that represents its new orientation is given by $(\cos(\theta/2), a*\sin(\theta/2), b*\sin(\theta/2), c*\sin(\theta/2))$. These 4 components are *quatw*, *quati*, *quatj*, and *quatk* as specified above. LAMMPS normalizes each atom's quaternion in case (a,b,c) is not specified as a unit vector.

The *Ellipsoids* section must appear after the *Atoms* section.

EndBondTorsion Coeffs section:

- one line per dihedral type
- line syntax: ID coeffs

ID = dihedral type (1-N)
coeffs = list of coeffs (see class 2 section of [dihedral_coeff](#))

Improper Coeffs section:

- one line per improper type
- line syntax: ID coeffs

ID = improper type (1-N)
coeffs = list of coeffs

- example:

```
2 20 0.0548311
```

The number and meaning of the coefficients are specific to the defined improper style. See the [improper_style](#) and [improper_coeff](#) commands for details. Coefficients can also be set via the [improper_coeff](#) command in the input script.

Impropers section:

- one line per improper
- line syntax: ID type atom1 atom2 atom3 atom4

ID = number of improper (1-Nimpropers)
type = improper type (1-Nimproptype)
atom1,atom2,atom3,atom4 = IDs of 1st,2nd,3rd,4th atoms in improper

LAMMPS Users Manual

- example:

```
12 3 17 29 13 100
```

The ordering of the 4 atoms determines the definition of the improper angle used in the formula for each [improper style](#). See the doc pages for individual styles for details.

The *Impropers* section must appear after the *Atoms* section. All values in this section must be integers (1, not 1.0).

Lines section:

- one line per line segment
- line syntax: atom-ID x1 y1 x2 y2

```
atom-ID = ID of atom which is a line segment
x1,y1 = 1st end point
x2,y2 = 2nd end point
```

- example:

```
12 1.0 0.0 2.0 0.0
```

The *Lines* section must appear if [atom_style line](#) is used and any atoms are listed in the *Atoms* section with a lineflag = 1. The number of lines should be specified in the header section via the "lines" keyword.

The 2 end points are the end points of the line segment. The ordering of the 2 points should be such that using a right-hand rule to cross the line segment with a unit vector in the +z direction, gives an "outward" normal vector perpendicular to the line segment. I.e. normal = (c2-c1) x (0,0,1). This orientation may be important for defining some interactions.

The *Lines* section must appear after the *Atoms* section.

Masses section:

- one line per atom type
- line syntax: ID mass

```
ID = atom type (1-N)
mass = mass value
```

- example:

```
3 1.01
```

This defines the mass of each atom type. This can also be set via the [mass](#) command in the input script. This section cannot be used for atom styles that define a mass for individual atoms - e.g. [atom_style sphere](#).

MiddleBondTorsion Coeffs section:

- one line per dihedral type

LAMMPS Users Manual

- line syntax: ID coeffs

```
ID = dihedral type (1-N)
coeffs = list of coeffs (see class 2 section of dihedral\_coeff)
```

Pair Coeffs section:

- one line per atom type
- line syntax: ID coeffs

```
ID = atom type (1-N)
coeffs = list of coeffs
```

- example:

```
3 0.022 2.35197 0.022 2.35197
```

The number and meaning of the coefficients are specific to the defined pair style. See the [pair_style](#) and [pair_coeff](#) commands for details. Since pair coefficients for types $I \neq J$ are not specified, these will be generated automatically by the pair style's mixing rule. See the individual [pair_style](#) doc pages and the [pair_modify mix](#) command for details. Pair coefficients can also be set via the [pair_coeff](#) command in the input script.

PairIJ Coeffs section:

- one line per pair of atom types for all I,J with $I \leq J$
- line syntax: ID1 ID2 coeffs

```
ID1 = atom type I = 1-N
ID2 = atom type J = I-N, with  $I \leq J$ 
coeffs = list of coeffs
```

- examples:

```
3 3 0.022 2.35197 0.022 2.35197
3 5 0.022 2.35197 0.022 2.35197
```

This section must have $N*(N+1)/2$ lines where $N = \#$ of atom types. The number and meaning of the coefficients are specific to the defined pair style. See the [pair_style](#) and [pair_coeff](#) commands for details. Since pair coefficients for types $I \neq J$ are all specified, these values will turn off the default mixing rule defined by the pair style. See the individual [pair_style](#) doc pages and the [pair_modify mix](#) command for details. Pair coefficients can also be set via the [pair_coeff](#) command in the input script.

Triangles section:

- one line per triangle
- line syntax: atom-ID x1 y1 z1 x2 y2 z2 x3 y3 z3

```
atom-ID = ID of atom which is a line segment
x1,y1,z1 = 1st corner point
x2,y2,z2 = 2nd corner point
x3,y3,z3 = 3rd corner point
```

- example:

LAMMPS Users Manual

12 0.0 0.0 0.0 2.0 0.0 1.0 0.0 2.0 1.0

The *Triangles* section must appear if [atom_style tri](#) is used and any atoms are listed in the *Atoms* section with a `triangleflag = 1`. The number of lines should be specified in the header section via the "triangles" keyword.

The 3 corner points are the corner points of the triangle. The ordering of the 3 points should be such that using a right-hand rule to go from point1 to point2 to point3 gives an "outward" normal vector to the face of the triangle. I.e. $\text{normal} = (c2-c1) \times (c3-c1)$. This orientation may be important for defining some interactions.

The *Triangles* section must appear after the *Atoms* section.

Velocities section:

- one line per atom
- line syntax: depends on atom style

all styles except those listed	atom-ID vx vy vz
electron	atom-ID vx vy vz ervel
ellipsoid	atom-ID vx vy vz lx ly lz
sphere	atom-ID vx vy vz wx wy wz
hybrid	atom-ID vx vy vz sub-style1 sub-style2 ...

where the keywords have these meanings:

vx,vy,vz = translational velocity of atom lx,ly,lz = angular momentum of aspherical atom wx,wy,wz = angular velocity of spherical atom ervel = electron radial velocity (0 for fixed-core):ul

The velocity lines can appear in any order. This section can only be used after an *Atoms* section. This is because the *Atoms* section must have assigned a unique atom ID to each atom so that velocities can be assigned to them.

Vx, vy, vz, and ervel are in [units](#) of velocity. Lx, ly, lz are in units of angular momentum (distance-velocity-mass). Wx, Wy, Wz are in units of angular velocity (radians/time).

For `atom_style hybrid`, following the 4 initial values (ID,vx,vy,vz), specific values for each sub-style must be listed. The order of the sub-styles is the same as they were listed in the [atom_style](#) command. The sub-style specific values are those that are not the 5 standard ones (ID,vx,vy,vz). For example, for the "sphere" sub-style, "wx", "wy", "wz" values would appear. These are listed in the same order they appear as listed above. Thus if

```
atom_style hybrid electron sphere
```

were used in the input script, each velocity line would have these fields:

```
atom-ID vx vy vz ervel wx wy wz
```

LAMMPS Users Manual

Translational velocities can also be set by the [velocity](#) command in the input script.

Restrictions:

To read gzipped data files, you must compile LAMMPS with the `-DLAMMPS_GZIP` option - see the [Making LAMMPS](#) section of the documentation.

Related commands:

[read_dump](#), [read_restart](#), [create_atoms](#), [write_data](#)

Default:

The default for all the *extra* keywords is 0.

read_dump command

Syntax:

```
read_dump file Nstep field1 field2 ... keyword values ...
```

- file = name of dump file to read
 - Nstep = snapshot timestep to read from file
 - one or more fields may be appended
- field = x or y or z or vx or vy or vz or q or ix or iy or iz or fx or fy or fz
 x,y,z = atom coordinates
 vx,vy,vz = velocity components
 q = charge
 ix,iy,iz = image flags in each dimension
 fx,fy,fz = force components
- zero or more keyword/value pairs may be appended
 - keyword = *box* or *replace* or *purge* or *trim* or *add* or *label* or *scaled* or *wrapped* or *format*

box value = *yes* or *no* = replace simulation box with dump box
replace value = *yes* or *no* = overwrite atoms with dump atoms
purge value = *yes* or *no* = delete all atoms before adding dump atoms
trim value = *yes* or *no* = trim atoms not in dump snapshot
add value = *yes* or *no* = add new dump atoms to system
label value = field column
 field = one of the listed fields or *id* or *type*
 column = label on corresponding column in dump file
scaled value = *yes* or *no* = coords in dump file are scaled/unscaled
wrapped value = *yes* or *no* = coords in dump file are wrapped/unwrapped
format values = format of dump file, must be last keyword if used
native = native LAMMPS dump file
xyz = XYZ file
molfile style path = VMD molfile plugin interface
 style = *dcd* or *xyz* or others supported by molfile plugins
 path = optional path for location of molfile plugins

Examples:

```
read_dump dump.file 5000 x y z
read_dump dump.xyz 5 x y z box no format xyz
read_dump dump.xyz 10 x y z box no format molfile xyz "../plugins"
read_dump dump.dcd 0 x y z box yes format molfile dcd
read_dump dump.file 1000 x y z vx vy vz box yes format molfile lammstrj /usr/local/lib/vmd/plu
read_dump dump.file 5000 x y vx vy trim yes
read_dump ../run7/dump.file.gz 10000 x y z box yes
read_dump dump.xyz 10 x y z box no format molfile xyz ../plugins
read_dump dump.dcd 0 x y z format molfile dcd
read_dump dump.file 1000 x y z vx vy vz format molfile lammstrj /usr/local/lib/vmd/plugins/LI
```

Description:

Read atom information from a dump file to overwrite the current atom coordinates, and optionally the atom velocities and image flags and the simulation box dimensions.

LAMMPS Users Manual

This is useful for restarting a run from a particular snapshot in a dump file. See the [read_restart](#) and [read_data](#) commands for alternative methods to do this. Also see the [rerun](#) command for a means of reading multiple snapshots from a dump file.

Note that a simulation box must already be defined before using the `read_dump` command. This can be done by the [create_box](#), [read_data](#), or [read_restart](#) commands. The `read_dump` command can reset the simulation box dimensions, as explained below.

Also note that reading per-atom information from a dump snapshot is limited to the atom coordinates, velocities and image flags, as explained below. Other atom properties, which may be necessary to run a valid simulation, such as atom charge, or bond topology information for a molecular system, are not read from (or even contained in) dump files. Thus this auxiliary information should be defined in the usual way, e.g. in a data file read in by a [read_data](#) command, before using the `read_dump` command, or by the [set](#) command, after the dump snapshot is read.

If the dump filename specified as *file* ends with ".gz", the dump file is read in gzipped format. You cannot (yet) read a dump file that was written in binary format with a ".bin" suffix, or to multiple files via the "%" option in the dump file name. See the [dump](#) command for details.

The format of the dump file is selected through the *format* keyword. If specified, it must be the last keyword used, since all remaining arguments are passed on to the dump reader. The *native* format is for native LAMMPS dump files, written with a [dump_atom](#) or [dump_custom](#) command. The *xyz* format is for generic XYZ formatted dump files. These formats take no additional values.

The *molfile* format supports reading data through using the [VMD](#) molfile plugin interface. This dump reader format is only available, if the USER-MOLFILE package has been installed when compiling LAMMPS.

The *molfile* format takes one or two additional values. The *style* value determines the file format to be used and can be any format that the molfile plugins support, such as DCD or XYZ. Note that DCD dump files can be written by LAMMPS via the [dump_dcd](#) command. The *path* value specifies a list of directories which LAMMPS will search for the molfile plugins appropriate to the specified *style*. The syntax of the *path* value is like other search paths: it can contain multiple directories separated by a colon (or semi-colon on windows). The *path* keyword is optional and defaults to ".", i.e. the current directory.

Support for other dump format readers may be added in the future.

Global information is first read from the dump file, namely timestep and box information.

The dump file is scanned for a snapshot with a time stamp that matches the specified *Nstep*. This means the LAMMPS timestep the dump file snapshot was written on for the *native* format. Note that the *xyz* and *molfile* formats do not store the timestep. For these formats, timesteps are numbered logically, in a sequential manner, starting from

LAMMPS Users Manual

0. Thus to access the 10th snapshot in an *xyz* or *molfile* formatted dump file, use *Nstep* = 9.

The dimensions of the simulation box for the selected snapshot are also read; see the *box* keyword discussion below. For the *native* format, an error is generated if the snapshot is for a triclinic box and the current simulation box is orthogonal or vice versa. A warning will be generated if the snapshot box boundary conditions (periodic, shrink-wrapped, etc) do not match the current simulation boundary conditions, but the boundary condition information in the snapshot is otherwise ignored. See the "boundary" command for more details.

For the *xyz* format, no information about the box is available, so you must set the *box* flag to *no*. See details below.

For the *molfile* format, reading simulation box information is typically supported, but the location of the simulation box origin is lost and no explicit information about periodicity or orthogonal/triclinic box shape is available. The USER-MOLFILE package makes a best effort to guess based on heuristics, but this may not always work perfectly.

Per-atom information from the dump file snapshot is then read from the dump file snapshot. This corresponds to the specified *fields* listed in the *read_dump* command. It is an error to specify a z-dimension field, namely *z*, *vz*, or *iz*, for a 2d simulation.

For dump files in *native* format, each column of per-atom data has a text label listed in the file. A matching label for each field must appear, e.g. the label "vy" for the field *vy*. For the *x*, *y*, *z* fields any of the following labels are considered a match:

```
x, xs, xu, xsu for field x
y, ys, yu, ysu for field y
z, zs, zu, zsu for field z
```

The meaning of *xs* (scaled), *xu* (unwrapped), and *xsu* (scaled and unwrapped) is explained on the [dump](#) command doc page. These labels are searched for in the list of column labels in the dump file, in order, until a match is found.

The dump file must also contain atom IDs, with a column label of "id".

If the *add* keyword is specified with a value of *yes*, as discussed below, the dump file must contain atom types, with a column label of "type".

If a column label you want to read from the dump file is not a match to a specified field, the *label* keyword can be used to specify the specific column label from the dump file to associate with that field. An example is if a time-averaged coordinate is written to the dump file via the [fix ave/atom](#) command. The column will then have a label corresponding to the fix-ID rather than "x" or "xs". The *label* keyword can also be used to specify new column labels for fields *id* and *type*.

For dump files in *xyz* format, only the *x*, *y*, and *z* fields are supported. The dump file does not store atom IDs, so these are assigned consecutively to the atoms as they appear in the dump file, starting from 1. Thus you should insure that order of atoms is

LAMMPS Users Manual

consistent from snapshot to snapshot in the XYZ dump file. See the [dump_modify sort](#) command if the XYZ dump file was written by LAMMPS.

For dump files in *molfile* format, the *x*, *y*, *z*, *vx*, *vy*, and *vz* fields can be specified. However, not all molfile formats store velocities, or their respective plugins may not support reading of velocities. The molfile dump files do not store atom IDs, so these are assigned consecutively to the atoms as they appear in the dump file, starting from 1. Thus you should insure that order of atoms are consistent from snapshot to snapshot in the molfile dump file. See the [dump_modify sort](#) command if the dump file was written by LAMMPS.

Information from the dump file snapshot is used to overwrite or replace properties of the current system. There are various options for how this is done, determined by the specified fields and optional keywords.

The timestep of the snapshot becomes the current timestep for the simulation. See the [reset_timestep](#) command if you wish to change this after the dump snapshot is read.

If the *box* keyword is specified with a *yes* value, then the current simulation box dimensions are replaced by the dump snapshot box dimensions. If the *box* keyword is specified with a *no* value, the current simulation box is unchanged.

If the *purge* keyword is specified with a *yes* value, then all current atoms in the system are deleted before any of the operations invoked by the *replace*, *trim*, or *add* keywords take place.

If the *replace* keyword is specified with a *yes* value, then atoms with IDs that are in both the current system and the dump snapshot have their properties overwritten by field values. If the *replace* keyword is specified with a *no* value, atoms with IDs that are in both the current system and the dump snapshot are not modified.

If the *trim* keyword is specified with a *yes* value, then atoms with IDs that are in the current system but not in the dump snapshot are deleted. These atoms are unaffected if the *trim* keyword is specified with a *no* value.

If the *add* keyword is specified with a *yes* value, then atoms with IDs that are in the dump snapshot, but not in the current system are added to the system. These dump atoms are ignored if the *add* keyword is specified with a *no* value.

Note that atoms added via the *add* keyword will have only the attributes read from the dump file due to the *field* arguments. If *x* or *y* or *z* is not specified as a field, a value of 0.0 is used for added atoms. Added atoms must have an atom type, so this value must appear in the dump file.

Any other attributes (e.g. charge or particle diameter for spherical particles) will be set to default values, the same as if the [create_atoms](#) command were used.

Note that atom IDs are not preserved for new dump snapshot atoms added via the *add* keyword. The procedure for assigning new atom IDs to added atoms is the same as is described for the [create_atoms](#) command.

Atom coordinates read from the dump file are first converted into unscaled coordinates, relative to the box dimensions of the snapshot. These coordinates are then be assigned to an existing or new atom in the current simulation. The coordinates will then be remapped to the simulation box, whether it is the original box or the dump snapshot box. If periodic boundary conditions apply, this means the atom will be remapped back into the simulation box if necessary. If shrink-wrap boundary conditions apply, the new coordinates may change the simulation box dimensions. If fixed boundary conditions apply, the atom will be lost if it is outside the simulation box.

For *native* format dump files, the 3 xyz image flags for an atom in the dump file are set to the corresponding values appearing in the dump file if the *ix*, *iy*, *iz* fields are specified. If not specified, the image flags for replaced atoms are not changed and image flags for new atoms are set to default values. If coordinates read from the dump file are in unwrapped format (e.g. *xu*) then the image flags for read-in atoms are also set to default values. The remapping procedure described in the previous paragraph will then change images flags for all atoms (old and new) if periodic boundary conditions are applied to remap an atom back into the simulation box.

NOTE: If you get a warning about inconsistent image flags after reading in a dump snapshot, it means one or more pairs of bonded atoms now have inconsistent image flags. As discussed in [Section errors](#) this may or may not cause problems for subsequent simulations, One way this can happen is if you read image flag fields from the dump file but do not also use the dump file box parameters.

LAMMPS knows how to compute unscaled and remapped coordinates for the snapshot column labels discussed above, e.g. *x*, *xs*, *xu*, *xsu*. If another column label is assigned to the *x* or *y* or *z* field via the *label* keyword, e.g. for coordinates output by the [fix ave/atom](#) command, then LAMMPS needs to know whether the coordinate information in the dump file is scaled and/or wrapped. This can be set via the *scaled* and *wrapped* keywords. Note that the value of the *scaled* and *wrapped* keywords is ignored for fields *x* or *y* or *z* if the *label* keyword is not used to assign a column label to that field.

The scaled/unscaled and wrapped/unwrapped setting must be identical for any of the *x*, *y*, *z* fields that are specified. Thus you cannot read *xs* and *yu* from the dump file. Also, if the dump file coordinates are scaled and the simulation box is triclinic, then all 3 of the *x*, *y*, *z* fields must be specified, since they are all needed to generate absolute, unscaled coordinates.

Restrictions:

To read gzipped dump files, you must compile LAMMPS with the `-DLAMMPS_GZIP` option - see the [Making LAMMPS](#) section of the documentation.

The *molfile* dump file formats are part of the USER-MOLFILE package. They are only enabled if LAMMPS was built with that packages. See the [Making LAMMPS](#) section for more info.

Related commands:

LAMMPS Users Manual

[dump](#), [dump molfile](#), [read_data](#), [read_restart](#), [rerun](#)

Default:

The option defaults are box = yes, replace = yes, purge = no, trim = no, add = no, scaled = no, wrapped = yes, and format = native.

read_restart command

Syntax:

```
read_restart file flag
```

- file = name of binary restart file to read in
- flag = remap (optional)

Examples:

```
read_restart save.10000
read_restart save.10000 remap
read_restart restart.*
read_restart restart.*.mpio
read_restart poly.*.% remap
```

Description:

Read in a previously saved system configuration from a restart file. This allows continuation of a previous run. Details about what information is stored (and not stored) in a restart file is given below. Basically this operation will re-create the simulation box with all its atoms and their attributes as well as some related global settings, at the point in time it was written to the restart file by a previous simulation. The simulation box will be partitioned into a regular 3d grid of rectangular bricks, one per processor, based on the number of processors in the current simulation and the settings of the [processors](#) command. The partitioning can later be changed by the [balance](#) or [fix balance](#) commands.

NOTE: Normally, restart files are written by the [restart](#) or [write_restart](#) commands so that all atoms in the restart file are inside the simulation box. If this is not the case, the `read_restart` command will print an error that atoms were "lost" when the file is read. This error should be reported to the LAMMPS developers so the invalid writing of the restart file can be fixed. If you still wish to use the restart file, the optional *remap* flag can be appended to the `read_restart` command. This should avoid the error, by explicitly remapping each atom back into the simulation box, updating image flags for the atom appropriately.

Restart files are saved in binary format to enable exact restarts, meaning that the trajectories of a restarted run will precisely match those produced by the original run had it continued on.

Several things can prevent exact restarts due to round-off effects, in which case the trajectories in the 2 runs will slowly diverge. These include running on a different number of processors or changing certain settings such as those set by the [newton](#) or [processors](#) commands. LAMMPS will issue a warning in these cases.

Certain fixes will not restart exactly, though they should provide statistically similar results. These include [fix shake](#) and [fix langevin](#).

LAMMPS Users Manual

Certain pair styles will not restart exactly, though they should provide statistically similar results. This is because the forces they compute depend on atom velocities, which are used at half-step values every timestep when forces are computed. When a run restarts, forces are initially evaluated with a full-step velocity, which is different than if the run had continued. These pair styles include [granular pair styles](#), [pair dpd](#), and [pair lubricate](#).

If a restarted run is immediately different than the run which produced the restart file, it could be a LAMMPS bug, so consider [reporting it](#) if you think the behavior is wrong.

Because restart files are binary, they may not be portable to other machines. In this case, you can use the [-restart command-line switch](#) to convert a restart file to a data file.

Similar to how restart files are written (see the [write_restart](#) and [restart](#) commands), the restart filename can contain two wild-card characters. If a "*" appears in the filename, the directory is searched for all filenames that match the pattern where "*" is replaced with a timestep value. The file with the largest timestep value is read in. Thus, this effectively means, read the latest restart file. It's useful if you want your script to continue a run from where it left off. See the [run](#) command and its "upto" option for how to specify the run command so it doesn't need to be changed either.

If a "%" character appears in the restart filename, LAMMPS expects a set of multiple files to exist. The [restart](#) and [write_restart](#) commands explain how such sets are created. `read_restart` will first read a filename where "%" is replaced by "base". This file tells LAMMPS how many processors created the set and how many files are in it. `read_restart` then reads the additional files. For example, if the restart file was specified as `save.%` when it was written, then `read_restart` reads the files `save.base`, `save.0`, `save.1`, ... `save.P-1`, where P is the number of processors that created the restart file.

Note that P could be the total number of processors in the previous simulation, or some subset of those processors, if the `fileper` or `nfile` options were used when the restart file was written; see the [restart](#) and [write_restart](#) commands for details. The processors in the current LAMMPS simulation share the work of reading these files; each reads a roughly equal subset of the files. The number of processors which created the set can be different the number of processors in the current LAMMPS simulation. This can be a fast mode of input on parallel machines that support parallel I/O.

A restart file can also be read in parallel as one large binary file via the MPI-IO library, assuming it was also written with MPI-IO. MPI-IO is part of the MPI standard for versions 2.0 and above. Using MPI-IO requires two steps. First, build LAMMPS with its MPIIO package installed, e.g.

```
make yes-mpiio    # installs the MPIIO package
make mpi          # build LAMMPS for your platform
```

Second, use a restart filename which contains ".mpiio". Note that it does not have to end in ".mpiio", just contain those characters. Unlike MPI-IO dump files, a particular

LAMMPS Users Manual

restart file must be both written and read using MPI-IO.

Here is the list of information included in a restart file, which means these quantities do not need to be re-specified in the input script that reads the restart file, though you can redefine many of these settings after the restart file is read.

- [units](#)
- [newton bond](#) (see discussion of newton command below)
- [atom style](#) and [atom_modify](#) settings id, map, sort
- [comm style](#) and [comm_modify](#) settings mode, cutoff, vel
- [timestep](#)
- simulation box size and shape and [boundary](#) settings
- atom [group](#) definitions
- per-type atom settings such as [mass](#)
- per-atom attributes including their group assignments and molecular topology attributes (bonds, angles, etc)
- force field styles ([pair](#), [bond](#), [angle](#), etc)
- force field coefficients ([pair](#), [bond](#), [angle](#), etc) in some cases (see below)
- [pair_modify](#) settings, except the compute option
- [special_bonds](#) settings

Here is a list of information not stored in a restart file, which means you must re-issue these commands in your input script, after reading the restart file.

- [newton pair](#) (see discussion of newton command below)
- [fix](#) commands (see below)
- [compute](#) commands (see below)
- [variable](#) commands
- [region](#) commands
- [neighbor list](#) criteria including [neigh_modify](#) settings
- [kspace_style](#) and [kspace_modify](#) settings
- info for [thermodynamic](#), [dump](#), or [restart](#) output

The [newton](#) command has two settings, one for pairwise interactions, the other for bonded. Both settings are stored in the restart file. For the bond setting, the value in the file will overwrite the current value (at the time the `read_restart` command is issued) and warn if the two values are not the same and the current value is not the default. For the pair setting, the value in the file will not overwrite the current value (so that you can override the previous run's value), but a warning is issued if the two values are not the same and the current value is not the default.

Note that some force field styles (`pair`, `bond`, `angle`, etc) do not store their coefficient info in restart files. Typically these are many-body or tabulated potentials which read their parameters from separate files. In these cases you will need to re-specify the [pair_coeff](#), [bond_coeff](#), etc commands in your restart input script. The doc pages for individual force field styles mention if this is the case. This is also true of [pair_style hybrid](#) (`bond hybrid`, `angle hybrid`, etc) commands; they do not store coefficient info.

As indicated in the above list, the [fixes](#) used for a simulation are not stored in the restart file. This means the new input script should specify all fixes it will use. However, note that some fixes store an internal "state" which is written to the restart

LAMMPS Users Manual

file. This allows the fix to continue on with its calculations in a restarted simulation. To re-enable such a fix, the fix command in the new input script must be of the same style and use the same fix-ID as was used in the input script that wrote the restart file.

If a match is found, LAMMPS prints a message indicating that the fix is being re-enabled. If no match is found before the first run or minimization is performed by the new script, the "state" information for the saved fix is discarded. At the time the discard occurs, LAMMPS will also print a list of fixes for which the information is being discarded. See the doc pages for individual fixes for info on which ones can be restarted in this manner. Note that fixes which are created internally by other LAMMPS commands (computes, fixes, etc) will have style names which are all-capitalized, and IDs which are generated internally.

Likewise, the [computes](#) used for a simulation are not stored in the restart file. This means the new input script should specify all computes it will use. However, some computes create a fix internally to store "state" information that persists from timestep to timestep. An example is the [compute msd](#) command which uses a fix to store a reference coordinate for each atom, so that a displacement can be calculated at any later time. If the compute command in the new input script uses the same compute-ID and group-ID as was used in the input script that wrote the restart file, then it will create the same fix in the restarted run. This means the re-created fix will be re-enabled with the stored state information as described in the previous paragraph, so that the compute can continue its calculations in a consistent manner.

NOTE: There are a handful of commands which can be used before or between runs which may require a system initialization. Examples include the "balance", "displace_atoms", "delete_atoms", "set" (some options), and "velocity" (some options) commands. This is because they can migrate atoms to new processors. Thus they will also discard unused "state" information from fixes. You will know the discard has occurred because a list of discarded fixes will be printed to the screen and log file, as explained above. This means that if you wish to retain that info in a restarted run, you must re-specify the relevant fixes and computes (which create fixes) before those commands are used.

Some pair styles, like the [granular pair styles](#), also use a fix to store "state" information that persists from timestep to timestep. In the case of granular potentials, it is contact information between pairs of touching particles. This info will also be re-enabled in the restart script, assuming you re-use the same granular pair style.

LAMMPS allows bond interactions (angle, etc) to be turned off or deleted in various ways, which can affect how their info is stored in a restart file.

If bonds (angles, etc) have been turned off by the [fix shake](#) or [delete_bonds](#) command, their info will be written to a restart file as if they are turned on. This means they will need to be turned off again in a new run after the restart file is read.

Bonds that are broken (e.g. by a bond-breaking potential) are written to the restart file as broken bonds with a type of 0. Thus these bonds will still be broken when the restart file is read.

LAMMPS Users Manual

Bonds that have been broken by the [fix bond/break](#) command have disappeared from the system. No information about these bonds is written to the restart file.

Restrictions:

To write and read restart files in parallel with MPI-IO, the MPIIO package must be installed.

Related commands:

[read_data](#), [read_dump](#), [write_restart](#), [restart](#)

Default: none

region command

Syntax:

region ID style args keyword arg ...

- ID = user-assigned name for the region
- style = *delete* or *block* or *cone* or *cylinder* or *plane* or *prism* or *sphere* or *union* or *intersect*

delete = no args

block args = xlo xhi ylo yhi zlo zhi

xlo,xhi,ylo,yhi,zlo,zhi = bounds of block in all dimensions (distance units)

cone args = dim c1 c2 radlo radhi lo hi

dim = x or y or z = axis of cone

c1,c2 = coords of cone axis in other 2 dimensions (distance units)

radlo,radhi = cone radii at lo and hi end (distance units)

lo,hi = bounds of cone in dim (distance units)

cylinder args = dim c1 c2 radius lo hi

dim = x or y or z = axis of cylinder

c1,c2 = coords of cylinder axis in other 2 dimensions (distance units)

radius = cylinder radius (distance units)

radius can be a variable (see below)

lo,hi = bounds of cylinder in dim (distance units)

plane args = px py pz nx ny nz

px,py,pz = point on the plane (distance units)

nx,ny,nz = direction normal to plane (distance units)

prism args = xlo xhi ylo yhi zlo zhi xy xz yz

xlo,xhi,ylo,yhi,zlo,zhi = bounds of untilted prism (distance units)

xy = distance to tilt y in x direction (distance units)

xz = distance to tilt z in x direction (distance units)

yz = distance to tilt z in y direction (distance units)

sphere args = x y z radius

x,y,z = center of sphere (distance units)

radius = radius of sphere (distance units)

radius can be a variable (see below)

union args = N reg-ID1 reg-ID2 ...

N = # of regions to follow, must be 2 or greater

reg-ID1,reg-ID2, ... = IDs of regions to join together

intersect args = N reg-ID1 reg-ID2 ...

N = # of regions to follow, must be 2 or greater

reg-ID1,reg-ID2, ... = IDs of regions to intersect

- zero or more keyword/arg pairs may be appended
- keyword = *side* or *units* or *move* or *rotate* or *open*

side value = *in* or *out*

in = the region is inside the specified geometry

out = the region is outside the specified geometry

units value = *lattice* or *box*

lattice = the geometry is defined in lattice units

box = the geometry is defined in simulation box units

move args = v_x v_y v_z

v_x,v_y,v_z = equal-style variables for x,y,z displacement of region over time

rotate args = v_theta Px Py Pz Rx Ry Rz

v_theta = equal-style variable for rotation of region over time (in radians)

Px,Py,Pz = origin for axis of rotation (distance units)

LAMMPS Users Manual

Rx,Ry,Rz = axis of rotation vector
open value = integer from 1-6 corresponding to face index (see below)

- accelerated styles (with same args) = *block/kk*

Examples:

```
region 1 block -3.0 5.0 INF 10.0 INF INF
region 2 sphere 0.0 0.0 0.0 5 side out
region void cylinder y 2 3 5 -5.0 EDGE units box
region 1 prism 0 10 0 10 0 10 2 0 0
region outside union 4 side1 side2 side3 side4
region 2 sphere 0.0 0.0 0.0 5 side out move v_left v_up NULL
region openbox block 0 10 0 10 0 10 open 5 open 6 units box
region funnel cone z 10 10 2 5 0 10 open 1 units box
```

Description:

This command defines a geometric region of space. Various other commands use regions. For example, the region can be filled with atoms via the [create_atoms](#) command. Or a bounding box around the region, can be used to define the simulation box via the [create_box](#) command. Or the atoms in the region can be identified as a group via the [group](#) command, or deleted via the [delete_atoms](#) command. Or the surface of the region can be used as a boundary wall via the [fix wall/region](#) command.

Commands which use regions typically test whether an atom's position is contained in the region or not. For this purpose, coordinates exactly on the region boundary are considered to be interior to the region. This means, for example, for a spherical region, an atom on the sphere surface would be part of the region if the sphere were defined with the *side in* keyword, but would not be part of the region if it were defined using the *side out* keyword. See more details on the *side* keyword below.

Normally, regions in LAMMPS are "static", meaning their geometric extent does not change with time. If the *move* or *rotate* keyword is used, as described below, the region becomes "dynamic", meaning it's location or orientation changes with time. This may be useful, for example, when thermostating a region, via the [compute temp/region](#) command, or when the [fix wall/region](#) command uses a region surface as a bounding wall on particle motion, i.e. a rotating container.

The *delete* style removes the named region. Since there is little overhead to defining extra regions, there is normally no need to do this, unless you are defining and discarding large numbers of regions in your input script.

The lo/hi values for *block* or *cone* or *cylinder* or *prism* styles can be specified as EDGE or INF. EDGE means they extend all the way to the global simulation box boundary. Note that this is the current box boundary; if the box changes size during a simulation, the region does not. INF means a large negative or positive number (1.0e20), so it should encompass the simulation box even if it changes size. If a region is defined before the simulation box has been created (via [create_box](#) or [read_data](#) or [read_restart](#) commands), then an EDGE or INF parameter cannot be used. For a *prism* region, a non-zero tilt factor in any pair of dimensions cannot be used if both the lo/hi values in either of those dimensions are INF. E.g. if the xy tilt is non-zero, then xlo and xhi cannot both be INF, nor can ylo and yhi.

LAMMPS Users Manual

NOTE: Regions in LAMMPS do not get wrapped across periodic boundaries, as specified by the [boundary](#) command. For example, a spherical region that is defined so that it overlaps a periodic boundary is not treated as 2 half-spheres, one on either side of the simulation box.

NOTE: Regions in LAMMPS are always 3d geometric objects, regardless of whether the [dimension](#) of a simulation is 2d or 3d. Thus when using regions in a 2d simulation, you should be careful to define the region so that its intersection with the 2d x-y plane of the simulation has the 2d geometric extent you want.

For style *cone*, an axis-aligned cone is defined which is like a *cylinder* except that two different radii (one at each end) can be defined. Either of the radii (but not both) can be 0.0.

For style *cone* and *cylinder*, the *c1,c2* params are coordinates in the 2 other dimensions besides the cylinder axis dimension. For $\text{dim} = x$, $c1/c2 = y/z$; for $\text{dim} = y$, $c1/c2 = x/z$; for $\text{dim} = z$, $c1/c2 = x/y$. Thus the third example above specifies a cylinder with its axis in the y-direction located at $x = 2.0$ and $z = 3.0$, with a radius of 5.0, and extending in the y-direction from -5.0 to the upper box boundary.

For style *plane*, a plane is defined which contain the point (px,py,pz) and has a normal vector (nx,ny,nz) . The normal vector does not have to be of unit length. The "inside" of the plane is the half-space in the direction of the normal vector; see the discussion of the *side* option below.

For style *prism*, a parallelepiped is defined (it's too hard to spell parallelepiped in an input script!). The parallelepiped has its "origin" at (xlo,ylo,zlo) and is defined by 3 edge vectors starting from the origin given by $A = (xhi-xlo,0,0)$; $B = (xy,yhi-ylo,0)$; $C = (xz,yz,zhi-zlo)$. Xy,xz,yz can be 0.0 or positive or negative values and are called "tilt factors" because they are the amount of displacement applied to faces of an originally orthogonal box to transform it into the parallelepiped.

A prism region that will be used with the [create_box](#) command to define a triclinic simulation box must have tilt factors (xy,xz,yz) that do not skew the box more than half the distance of corresponding the parallel box length. For example, if $xlo = 2$ and $xhi = 12$, then the x box length is 10 and the xy tilt factor must be between -5 and 5. Similarly, both xz and yz must be between $-(xhi-xlo)/2$ and $+(yhi-ylo)/2$. Note that this is not a limitation, since if the maximum tilt factor is 5 (as in this example), then configurations with tilt = ..., -15, -5, 5, 15, 25, ... are all geometrically equivalent.

The *radius* value for style *sphere* and *cylinder* can be specified as an equal-style [variable](#). If the value is a variable, it should be specified as v_name , where name is the variable name. In this case, the variable will be evaluated each timestep, and its value used to determine the radius of the region.

Equal-style variables can specify formulas with various mathematical functions, and include [thermo_style](#) command keywords for the simulation box parameters and timestep and elapsed time. Thus it is easy to specify a time-dependent radius.

See [Section 6.12](#) of the doc pages for a geometric description of triclinic boxes, as defined by LAMMPS, and how to transform these parameters to and from other

commonly used triclinic representations.

The *union* style creates a region consisting of the volume of all the listed regions combined. The *intersect* style creates a region consisting of the volume that is common to all the listed regions.

NOTE: The *union* and *intersect* regions operate by invoking methods from their list of sub-regions. Thus you cannot delete the sub-regions after defining a *union* or *intersection* region.

The *side* keyword determines whether the region is considered to be inside or outside of the specified geometry. Using this keyword in conjunction with *union* and *intersect* regions, complex geometries can be built up. For example, if the interior of two spheres were each defined as regions, and a *union* style with *side* = out was constructed listing the region-IDs of the 2 spheres, the resulting region would be all the volume in the simulation box that was outside both of the spheres.

The *units* keyword determines the meaning of the distance units used to define the region for any argument above listed as having distance units. It also affects the scaling of the velocity vector specified with the *vel* keyword, the amplitude vector specified with the *wiggle* keyword, and the rotation point specified with the *rotate* keyword, since they each involve a distance metric.

A *box* value selects standard distance units as defined by the [units](#) command, e.g. Angstroms for *units* = real or metal. A *lattice* value means the distance units are in lattice spacings. The [lattice](#) command must have been previously used to define the lattice spacings which are used as follows:

- For style *block*, the lattice spacing in dimension x is applied to xlo and xhi, similarly the spacings in dimensions y,z are applied to ylo/yhi and zlo/zhi.
 - For style *cone*, the lattice spacing in argument *dim* is applied to lo and hi. The spacings in the two radial dimensions are applied to c1 and c2. The two cone radii are scaled by the lattice spacing in the dimension corresponding to c1.
 - For style *cylinder*, the lattice spacing in argument *dim* is applied to lo and hi. The spacings in the two radial dimensions are applied to c1 and c2. The cylinder radius is scaled by the lattice spacing in the dimension corresponding to c1.
 - For style *plane*, the lattice spacing in dimension x is applied to px and nx, similarly the spacings in dimensions y,z are applied to py/ny and pz/nz.
 - For style *prism*, the lattice spacing in dimension x is applied to xlo and xhi, similarly for ylo/yhi and zlo/zhi. The lattice spacing in dimension x is applied to xy and xz, and the spacing in dimension y to yz.
 - For style *sphere*, the lattice spacing in dimensions x,y,z are applied to the sphere center x,y,z. The spacing in dimension x is applied to the sphere radius.
-

If the *move* or *rotate* keywords are used, the region is "dynamic", meaning its location or orientation changes with time. These keywords cannot be used with a *union* or *intersect* style region. Instead, the keywords should be used to make the individual sub-regions of the *union* or *intersect* region dynamic. Normally, each sub-region should be "dynamic" in the same manner (e.g. rotate around the same point), though this is not a requirement.

LAMMPS Users Manual

The *move* keyword allows one or more [equal-style variables](#) to be used to specify the x,y,z displacement of the region, typically as a function of time. A variable is specified as *v_name*, where name is the variable name. Any of the three variables can be specified as NULL, in which case no displacement is calculated in that dimension.

Note that equal-style variables can specify formulas with various mathematical functions, and include [thermo_style](#) command keywords for the simulation box parameters and timestep and elapsed time. Thus it is easy to specify a region displacement that change as a function of time or spans consecutive runs in a continuous fashion. For the latter, see the *start* and *stop* keywords of the [run](#) command and the *elaplong* keyword of [thermo_style custom](#) for details.

For example, these commands would displace a region from its initial position, in the positive x direction, effectively at a constant velocity:

```
variable dx equal ramp(0,10)
region 2 sphere 10.0 10.0 0.0 5 move v_dx NULL NULL
```

Note that the initial displacement is 0.0, though that is not required.

Either of these variables would "wiggle" the region back and forth in the y direction:

```
variable dy equal swiggle(0,5,100)
variable dysame equal 5*sin(2*PI*elaplong*dt/100)
region 2 sphere 10.0 10.0 0.0 5 move NULL v_dy NULL
```

The *rotate* keyword rotates the region around a rotation axis $R = (R_x, R_y, R_z)$ that goes thru a point $P = (P_x, P_y, P_z)$. The rotation angle is calculated, presumably as a function of time, by a variable specified as *v_theta*, where theta is the variable name. The variable should generate its result in radians. The direction of rotation for the region around the rotation axis is consistent with the right-hand rule: if your right-hand thumb points along R , then your fingers wrap around the axis in the direction of rotation.

The *move* and *rotate* keywords can be used together. In this case, the displacement specified by the *move* keyword is applied to the P point of the *rotate* keyword.

The *open* keyword can be used (multiple times) to indicate that one or more faces of the region are ignored for purposes of particle/wall interactions. This keyword is only relevant for regions used by the *fix wall/region* and *fix wall/gran/region* commands. It can be used to create "open" containers where only some of the region faces are walls. For example, a funnel can be created with a *cone* style region that has an open face at the smaller radius for particles to flow out, or at the larger radius for pouring particles into the cone, or both.

Note that using the *open* keyword partly overrides the *side* keyword, since both exterior and interior surfaces of an open region are tested for particle contacts. The exception to this is a *union* or *intersect* region which includes an open sub-region. In that case the *side* keyword is still used to define the union/intersect region volume, and the *open* settings are only applied to the individual sub-regions that use them.

LAMMPS Users Manual

The indices specified as part of the *open* keyword have the following meanings:

For style *block*, indices 1-6 correspond to the xlo, xhi, ylo, yhi, zlo, zhi surfaces of the block. I.e. 1 is the yz plane at $x = xlo$, 2 is the yz-plane at $x = xhi$, 3 is the xz plane at $y = ylo$, 4 is the xz plane at $y = yhi$, 5 is the xy plane at $z = zlo$, 6 is the xy plane at $z = zhi$. In the second-to-last example above, the region is a box open at both xy planes.

For style *prism*, values 1-6 have the same mapping as for style *block*. I.e. in an untilted *prism*, *open* indices correspond to the xlo, xhi, ylo, yhi, zlo, zhi surfaces.

For style *cylinder*, index 1 corresponds to the flat end cap at the low coordinate along the cylinder axis, index 2 corresponds to the high-coordinate flat end cap along the cylinder axis, and index 3 is the curved cylinder surface. For example, a *cylinder* region with *open 1 open 2* keywords will be open at both ends (e.g. a section of pipe), regardless of the cylinder orientation.

For style *cone*, the mapping is the same as for style *cylinder*. Index 1 is the low-coordinate flat end cap, index 2 is the high-coordinate flat end cap, and index 3 is the curved cone surface. In the last example above, a *cone* region is defined along the z-axis that is open at the zlo value (e.g. for use as a funnel).

For all other styles, the *open* keyword is ignored. As indicated above, this includes the *intersect* and *union* regions, though their sub-regions can be defined with the *open* keyword.

Styles with a *kk* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed in [Section 5](#) of the manual. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

The code using the region (such as a fix or compute) must also be supported by Kokkos or no acceleration will occur. Currently, only *block* style regions are supported by Kokkos.

These accelerated styles are part of the Kokkos package. They are only enabled if LAMMPS was built with that package. See the [Making LAMMPS](#) section for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the [-suffix command-line switch](#) when you invoke LAMMPS, or you can use the [suffix](#) command in your input script.

See [Section 5](#) of the manual for more instructions on how to use the accelerated styles effectively.

Restrictions:

A prism cannot be of 0.0 thickness in any dimension; use a small z thickness for 2d simulations. For 2d simulations, the xz and yz parameters must be 0.0.

Related commands:

[lattice](#), [create_atoms](#), [delete_atoms](#), [group](#)

Default:

The option defaults are side = in, units = lattice, and no move or rotation.

replicate command

Syntax:

```
replicate nx ny nz keyword
```

nx,ny,nz = replication factors in each dimension

- optional *keyword* = *bbox* *bbox* = only check atoms in replicas that overlap with a processor's subdomain

Examples:

```
replicate 2 3 2
```

Description:

Replicate the current simulation one or more times in each dimension. For example, replication factors of 2,2,2 will create a simulation with 8x as many atoms by doubling the simulation domain in each dimension. A replication factor of 1 in a dimension leaves the simulation domain unchanged. When the new simulation box is created it is also partitioned into a regular 3d grid of rectangular bricks, one per processor, based on the number of processors being used and the settings of the [processors](#) command. The partitioning can later be changed by the [balance](#) or [fix balance](#) commands.

All properties of the atoms are replicated, including their velocities, which may or may not be desirable. New atom IDs are assigned to new atoms, as are molecule IDs. Bonds and other topology interactions are created between pairs of new atoms as well as between old and new atoms. This is done by using the image flag for each atom to "unwrap" it out of the periodic box before replicating it.

This means that any molecular bond you specify in the original data file that crosses a periodic boundary should be between two atoms with image flags that differ by 1. This will allow the bond to be unwrapped appropriately.

The optional keyword *bbox* uses a bounding box to only check atoms in replicas that overlap with a processor's subdomain when assigning atoms to processors, and thus can result in substantial speedups for calculations using a large number of processors. It does require temporarily using more memory.

Restrictions:

A 2d simulation cannot be replicated in the z dimension.

If a simulation is non-periodic in a dimension, care should be used when replicating it in that dimension, as it may put atoms nearly on top of each other.

NOTE: You cannot use the replicate command on a system which has a molecule that spans the box and is bonded to itself across a periodic boundary, so that the molecule is effectively a loop. A simple example would be a linear polymer chain that spans the

LAMMPS Users Manual

simulation box and bonds back to itself across the periodic boundary. More realistic examples would be a CNT (meant to be an infinitely long CNT) or a graphene sheet or a bulk periodic crystal where there are explicit bonds specified between near neighbors. (Note that this only applies to systems that have permanent bonds as specified in the data file. A CNT that is just atoms modeled with the [AIREBO potential](#) has no such permanent bonds, so it can be replicated.) The reason replication does not work with those systems is that the image flag settings described above cannot be made consistent. I.e. it is not possible to define images flags so that when every pair of bonded atoms is unwrapped (using the image flags), they will be close to each other. The only way the replicate command could work in this scenario is for it to break a bond, insert more atoms, and re-connect the loop for the larger simulation box. But it is not clever enough to do this. So you will have to construct a larger version of your molecule as a pre-processing step and input a new data file to LAMMPS.

If the current simulation was read in from a restart file (before a run is performed), there must not be any fix information stored in the file for individual atoms. Similarly, no fixes can be defined at the time the replicate command is used that require vectors of atom information to be stored. This is because the replicate command does not know how to replicate that information for new atoms it creates. To work around this restriction, restart files may be converted into data files and fixes may be undefined via the [unfix](#) command before and redefined after the replicate command.

Related commands: none

Default: none

rerun command

Syntax:

```
rerun file1 file2 ... keyword args ...
```

- file1,file2,... = dump file(s) to read
- one or more keywords may be appended, keyword *dump* must appear and be last

```
keyword = first or last or every or skip or start or stop or dump
first args = Nfirst
    Nfirst = dump timestep to start on
last args = Nlast
    Nlast = dumptimestep to stop on
every args = Nevery
    Nevery = read snapshots matching every this many timesteps
skip args = Nskip
    Nskip = read one out of every Nskip snapshots
start args = Nstart
    Nstart = timestep on which pseudo run will start
stop args = Nstop
    Nstop = timestep to which pseudo run will end
dump args = same as read\_dump command starting with its field arguments
```

Examples:

```
rerun dump.file dump x y z vx vy vz
rerun dump1.txt dump2.txt first 10000 every 1000 dump x y z
rerun dump.vels dump x y z vx vy vz box yes format molfile lammprj
rerun dump.dcd dump x y z box no format molfile dcd
rerun ../run7/dump.file.gz skip 2 dump x y z box yes
```

Description:

Perform a pseudo simulation run where atom information is read one snapshot at a time from a dump file(s), and energies and forces are computed on the snapshot to produce thermodynamic or other output.

This can be useful in the following kinds of scenarios, after an initial simulation produced the dump file:

- Compute the energy and forces of snapshots using a different potential.
- Calculate one or more diagnostic quantities on the snapshots that weren't computed in the initial run. These can also be computed with settings not used in the initial run, e.g. computing an RDF via the [compute rdf](#) command with a longer cutoff than was used initially.
- Calculate the portion of per-atom forces resulting from a subset of the potential. E.g. compute only Coulombic forces. This can be done by only defining only a Coulombic pair style in the rerun script. Doing this in the original script would result in different (bad) dynamics.

LAMMPS Users Manual

Conceptually, using the rerun command is like running an input script that has a loop in it (see the [next](#) and [jump](#) commands). Each iteration of the loop reads one snapshot from the dump file via the [read_dump](#) command, sets the timestep to the appropriate value, and then invokes a [run](#) command for zero timesteps to simply compute energy and forces, and any other [thermodynamic output](#) or diagnostic info you have defined. This computation also invokes any fixes you have defined that apply constraints to the system, such as [fix shake](#) or [fix indent](#).

Note that a simulation box must already be defined before using the rerun command. This can be done by the [create_box](#), [read_data](#), or [read_restart](#) commands.

Also note that reading per-atom information from dump snapshots is limited to the atom coordinates, velocities and image flags as explained in the [read_dump](#) command. Other atom properties, which may be necessary to compute energies and forces, such as atom charge, or bond topology information for a molecular system, are not read from (or even contained in) dump files. Thus this auxiliary information should be defined in the usual way, e.g. in a data file read in by a [read_data](#) command, before using the rerun command.

If more than one dump file is specified, the dump files are read one after the other. It is assumed that snapshot timesteps will be in ascending order. If a snapshot is encountered that is not in ascending order, it will cause the rerun command to complete.

The *first*, *last*, *every*, *skip* keywords determine which snapshots are read from the dump file(s). Snapshots are skipped until they have a timestamp $\geq N_{first}$. When a snapshot with a timestamp $> N_{last}$ is encountered, the rerun command finishes. Note below that the defaults for *first* and *last* are to read all snapshots. If the *every* keyword is set to a value > 0 , then only snapshots with timestamps that are a multiple of N_{every} are read (the first snapshot is always read). If $N_{every} = 0$, then this criterion is ignored, i.e. every snapshot is read that meets the other criteria. If the *skip* keyword is used, then after the first snapshot is read, every N th snapshot is read, where $N = N_{skip}$. E.g. if $N_{skip} = 3$, then only 1 out of every 3 snapshots is read, assuming the snapshot timestamp is also consistent with the other criteria.

The *start* and *stop* keywords do not affect which snapshots are read from the dump file(s). Rather, they have the same meaning that they do for the [run](#) command. They only need to be defined if (a) you are using a [fix](#) command that changes some value over time, and (b) you want the reference point for elapsed time (from start to stop) to be different than the *first* and *last* settings. See the doc page for individual fixes to see which ones can be used with the *start/stop* keywords. Note that if you define neither of the *start/stop* or *first/last* keywords, then LAMMPS treats the pseudo run as going from 0 to a huge value (effectively infinity). This means that any quantity that a fix scales as a fraction of elapsed time in the run, will essentially remain at its initial value. Also note that an error will occur if you read a snapshot from the dump file with a timestep value larger than the *stop* setting you have specified.

The *dump* keyword is required and must be the last keyword specified. Its arguments are passed internally to the [read_dump](#) command. The first argument following the *dump* keyword should be the *field1* argument of the [read_dump](#) command. See the [read_dump](#) doc page for details on the various options it allows for extracting

LAMMPS Users Manual

information from the dump file snapshots, and for using that information to alter the LAMMPS simulation.

In general, a LAMMPS input script that uses a rerun command can include and perform all the usual operations of an input script that uses the [run](#) command. There are a few exceptions and points to consider, as discussed here.

Fixes that perform time integration, such as [fix nve](#) or [fix npt](#) are not invoked, since no time integration is performed. Fixes that perturb or constrain the forces on atoms will be invoked, just as they would during a normal run. Examples are [fix indent](#) and [fix langevin](#). So you should think carefully as to whether that makes sense for the manner in which you are reprocessing the dump snapshots.

If you only want the rerun script to perform analyses that do not involve pair interactions, such as use [compute msd](#) to calculate displacements over time, you do not need to define a [pair style](#), which may also mean neighbor lists will not need to be calculated which saves time. The [comm_modify cutoff](#) command can also be used to insure ghost atoms are acquired from far enough away for operations like bond and angle evaluations, if no pair style is being used.

Every time a snapshot is read, the timestep for the simulation is reset, as if the [reset timestep](#) command were used. This command has some restrictions as to what fixes can be defined. See its doc page for details. For example, the [fix deposit](#) and [fix dt/reset](#) fixes are in this category. They also make no sense to use with a rerun command.

If time-averaging fixes like [fix ave/time](#) are used, they are invoked on timesteps that are a function of their *Nevery*, *Nrepeat*, and *Nfreq* settings. As an example, see the [fix ave/time](#) doc page for details. You must insure those settings are consistent with the snapshot timestamps that are read from the dump file(s). If an averaging fix is not invoked on a timestep it expects to be, LAMMPS will flag an error.

The various forms of LAMMPS output, as defined by the [thermo_style](#), [thermo](#), [dump](#), and [restart](#) commands occur on specific timesteps. If successive dump snapshots skip those timesteps, then no output will be produced. E.g. if you request thermodynamic output every 100 steps, but the dump file snapshots are every 1000 steps, then you will only see thermodynamic output every 1000 steps.

Restrictions:

To read gzipped dump files, you must compile LAMMPS with the `-DLAMMPS_GZIP` option - see the [Making LAMMPS](#) section of the documentation.

Related commands:

[read_dump](#)

Default:

The option defaults are first = 0, last = a huge value (effectively infinity), start = same

LAMMPS Users Manual

as first, stop = same as last, every = 0, skip = 1;

reset_timestep command

Syntax:

```
reset_timestep N
```

- N = timestep number

Examples:

```
reset_timestep 0  
reset_timestep 4000000
```

Description:

Set the timestep counter to the specified value. This command normally comes after the timestep has been set by reading a restart file via the [read_restart](#) command, or a previous simulation advanced the timestep.

The [read_data](#) and [create_box](#) commands set the timestep to 0; the [read_restart](#) command sets the timestep to the value it had when the restart file was written.

Restrictions: none

This command cannot be used when any fixes are defined that keep track of elapsed time to perform certain kinds of time-dependent operations. Examples are the [fix deposit](#) and [fix dt/reset](#) commands. The former adds atoms on specific timesteps. The latter keeps track of accumulated time.

Various fixes use the current timestep to calculate related quantities. If the timestep is reset, this may produce unexpected behavior, but LAMMPS allows the fixes to be defined even if the timestep is reset. For example, commands which thermostat the system, e.g. [fix nvt](#), allow you to specify a target temperature which ramps from Tstart to Tstop which may persist over several runs. If you change the timestep, you may induce an instantaneous change in the target temperature.

Resetting the timestep clears flags for [computes](#) that may have calculated some quantity from a previous run. This means these quantity cannot be accessed by a variable in between runs until a new run is performed. See the [variable](#) command for more details.

Related commands:

[rerun](#)

Default: none

restart command

Syntax:

```
restart 0
restart N root keyword value ...
restart N file1 file2 keyword value ...
```

- N = write a restart file every this many timesteps
- N can be a variable (see below)
- root = filename to which timestep # is appended
- file1,file2 = two full filenames, toggle between them when writing file
- zero or more keyword/value pairs may be appended
- keyword = *fileper* or *nfile*

```
fileper arg = Np
      Np = write one file for every this many processors
nfile arg = Nf
      Nf = write this many files, one from each of Nf processors
```

Examples:

```
restart 0
restart 1000 poly.restart
restart 1000 poly.restart.mpio
restart 1000 restart.*.equil
restart 10000 poly.%.1 poly.%.2 nfile 10
restart v_mystep poly.restart
```

Description:

Write out a binary restart file with the current state of the simulation every so many timesteps, in either or both of two modes, as a run proceeds. A value of 0 means do not write out any restart files. The two modes are as follows. If one filename is specified, a series of filenames will be created which include the timestep in the filename. If two filenames are specified, only 2 restart files will be created, with those names. LAMMPS will toggle between the 2 names as it writes successive restart files.

Note that you can specify the restart command twice, once with a single filename and once with two filenames. This would allow you, for example, to write out archival restart files every 100000 steps using a single filename, and more frequent temporary restart files every 1000 steps, using two filenames. Using restart 0 will turn off both modes of output.

Similar to [dump](#) files, the restart filename(s) can contain two wild-card characters.

If a "*" appears in the single filename, it is replaced with the current timestep value. This is only recognized when a single filename is used (not when toggling back and forth). Thus, the 3rd example above creates restart files as follows: restart.1000.equil, restart.2000.equil, etc. If a single filename is used with no "*", then the timestep value is appended. E.g. the 2nd example above creates restart files as follows:

LAMMPS Users Manual

poly.restart.1000, poly.restart.2000, etc.

If a "%" character appears in the restart filename(s), then one file is written for each processor and the "%" character is replaced with the processor ID from 0 to P-1. An additional file with the "%" replaced by "base" is also written, which contains global information. For example, the files written on step 1000 for filename restart.% would be restart.base.1000, restart.0.1000, restart.1.1000, ..., restart.P-1.1000. This creates smaller files and can be a fast mode of output and subsequent input on parallel machines that support parallel I/O. The optional *fileper* and *nfile* keywords discussed below can alter the number of files written.

The restart file can also be written in parallel as one large binary file via the MPI-IO library, which is part of the MPI standard for versions 2.0 and above. Using MPI-IO requires two steps. First, build LAMMPS with its MPIIO package installed, e.g.

```
make yes-mpiio    # installs the MPIIO package
make mpi         # build LAMMPS for your platform
```

Second, use a restart filename which contains ".mpiio". Note that it does not have to end in ".mpiio", just contain those characters. Unlike MPI-IO dump files, a particular restart file must be both written and read using MPI-IO.

Restart files are written on timesteps that are a multiple of N but not on the first timestep of a run or minimization. You can use the [write_restart](#) command to write a restart file before a run begins. A restart file is not written on the last timestep of a run unless it is a multiple of N. A restart file is written on the last timestep of a minimization if $N > 0$ and the minimization converges.

Instead of a numeric value, N can be specified as an [equal-style variable](#), which should be specified as `v_name`, where name is the variable name. In this case, the variable is evaluated at the beginning of a run to determine the next timestep at which a restart file will be written out. On that timestep, the variable will be evaluated again to determine the next timestep, etc. Thus the variable should return timestep values. See the `stagger()` and `logfreq()` and `stride()` math functions for [equal-style variables](#), as examples of useful functions to use in this context. Other similar math functions could easily be added as options for [equal-style variables](#).

For example, the following commands will write restart files every step from 1100 to 1200, and could be useful for debugging a simulation where something goes wrong at step 1163:

```
variable          s equal stride(1100,1200,1)
restart           v_s tmp.restart
```

See the [read_restart](#) command for information about what is stored in a restart file.

Restart files can be read by a [read_restart](#) command to restart a simulation from a particular state. Because the file is binary (to enable exact restarts), it may not be readable on another machine. In this case, you can use the [-r command-line switch](#) to convert a restart file to a data file.

LAMMPS Users Manual

NOTE: Although the purpose of restart files is to enable restarting a simulation from where it left off, not all information about a simulation is stored in the file. For example, the list of fixes that were specified during the initial run is not stored, which means the new input script must specify any fixes you want to use. Even when restart information is stored in the file, as it is for some fixes, commands may need to be re-specified in the new input script, in order to re-use that information. See the [read_restart](#) command for information about what is stored in a restart file.

The optional *nfile* or *fileper* keywords can be used in conjunction with the "%" wildcard character in the specified restart file name(s). As explained above, the "%" character causes the restart file to be written in pieces, one piece for each of P processors. By default P = the number of processors the simulation is running on. The *nfile* or *fileper* keyword can be used to set P to a smaller value, which can be more efficient when running on a large number of processors.

The *nfile* keyword sets P to the specified Nf value. For example, if Nf = 4, and the simulation is running on 100 processors, 4 files will be written, by processors 0,25,50,75. Each will collect information from itself and the next 24 processors and write it to a restart file.

For the *fileper* keyword, the specified value of Np means write one file for every Np processors. For example, if Np = 4, every 4th processor (0,4,8,12,etc) will collect information from itself and the next 3 processors and write it to a restart file.

Restrictions:

To write and read restart files in parallel with MPI-IO, the MPIIO package must be installed.

Related commands:

[write_restart](#), [read_restart](#)

Default:

restart 0

run command

Syntax:

```
run N keyword values ...
```

- N = # of timesteps
- zero or more keyword/value pairs may be appended
- keyword = *upto* or *start* or *stop* or *pre* or *post* or *every*

```
upto value = none
```

```
start value = N1
```

```
  N1 = timestep at which 1st run started
```

```
stop value = N2
```

```
  N2 = timestep at which last run will end
```

```
pre value = no or yes
```

```
post value = no or yes
```

```
every values = M c1 c2 ...
```

```
  M = break the run into M-timestep segments and invoke one or more commands between e
```

```
  c1,c2,...,cN = one or more LAMMPS commands, each enclosed in quotes
```

```
  c1 = NULL means no command will be invoked
```

Examples:

```
run 10000
run 1000000 upto
run 100 start 0 stop 1000
run 1000 pre no post yes
run 100000 start 0 stop 1000000 every 1000 "print 'Protein Rg = $r'"
run 100000 every 1000 NULL
```

Description:

Run or continue dynamics for a specified number of timesteps.

When the [run style](#) is *respa*, N refers to outer loop (largest) timesteps.

A value of N = 0 is acceptable; only the thermodynamics of the system are computed and printed without taking a timestep.

The *upto* keyword means to perform a run starting at the current timestep up to the specified timestep. E.g. if the current timestep is 10,000 and "run 100000 upto" is used, then an additional 90,000 timesteps will be run. This can be useful for very long runs on a machine that allocates chunks of time and terminate your job when time is exceeded. If you need to restart your script multiple times (reading in the last restart file), you can keep restarting your script with the same run command until the simulation finally completes.

The *start* or *stop* keywords can be used if multiple runs are being performed and you want a [fix](#) command that changes some value over time (e.g. temperature) to make the change across the entire set of runs and not just a single run. See the doc page for

LAMMPS Users Manual

individual fixes to see which ones can be used with the *start/stop* keywords.

For example, consider this fix followed by 10 run commands:

```
fix          1 all nvt 200.0 300.0 1.0
run          1000 start 0 stop 10000
run          1000 start 0 stop 10000
...
run          1000 start 0 stop 10000
```

The NVT fix ramps the target temperature from 200.0 to 300.0 during a run. If the run commands did not have the start/stop keywords (just "run 1000"), then the temperature would ramp from 200.0 to 300.0 during the 1000 steps of each run. With the start/stop keywords, the ramping takes place over the 10000 steps of all runs together.

The *pre* and *post* keywords can be used to streamline the setup, clean-up, and associated output to the screen that happens before and after a run. This can be useful if you wish to do many short runs in succession (e.g. LAMMPS is being called as a library which is doing other computations between successive short LAMMPS runs).

By default (*pre* and *post* = yes), LAMMPS creates neighbor lists, computes forces, and imposes fix constraints before every run. And after every run it gathers and prints timings statistics. If a run is just a continuation of a previous run (i.e. no settings are changed), the initial computation is not necessary; the old neighbor list is still valid as are the forces. So if *pre* is specified as "no" then the initial setup is skipped, except for printing thermodynamic info. Note that if *pre* is set to "no" for the very 1st run LAMMPS performs, then it is overridden, since the initial setup computations must be done.

NOTE: If your input script changes the system between 2 runs, then the initial setup must be performed to insure the change is recognized by all parts of the code that are affected. Examples are adding a [fix](#) or [dump](#) or [compute](#), changing a [neighbor](#) list parameter, or writing restart file which can migrate atoms between processors. LAMMPS has no easy way to check if this has happened, but it is an error to use the *pre no* option in this case.

If *post* is specified as "no", the full timing summary is skipped; only a one-line summary timing is printed.

The *every* keyword provides a means of breaking a LAMMPS run into a series of shorter runs. Optionally, one or more LAMMPS commands (c1, c2, ..., cN) will be executed in between the short runs. If used, the *every* keyword must be the last keyword, since it has a variable number of arguments. Each of the trailing arguments is a single LAMMPS command, and each command should be enclosed in quotes, so that the entire command will be treated as a single argument. This will also prevent any variables in the command from being evaluated until it is executed multiple times during the run. Note that if a command itself needs one of its arguments quoted (e.g. the [print](#) command), then you can use a combination of single and double quotes, as in the example above or below.

LAMMPS Users Manual

The *every* keyword is a means to avoid listing a long series of runs and interleaving commands in your input script. For example, a [print](#) command could be invoked or a [fix](#) could be redefined, e.g. to reset a thermostat temperature. Or this could be useful for invoking a command you have added to LAMMPS that wraps some other code (e.g. as a library) to perform a computation periodically during a long LAMMPS run. See [this section](#) of the documentation for info about how to add new commands to LAMMPS. See [this section](#) of the documentation for ideas about how to couple LAMMPS to other codes.

With the *every* option, N total steps are simulated, in shorter runs of M steps each. After each M-length run, the specified commands are invoked. If only a single command is specified as NULL, then no command is invoked. Thus these lines:

```
variable q equal x[100]
run 6000 every 2000 "print 'Coord = $q'"
```

are the equivalent of:

```
variable q equal x[100]
run 2000
print "Coord = $q"
run 2000
print "Coord = $q"
run 2000
print "Coord = $q"
```

which does 3 runs of 2000 steps and prints the x-coordinate of a particular atom between runs. Note that the variable "\$q" will be evaluated afresh each time the print command is executed.

Note that by using the line continuation character "&", the run every command can be spread across many lines, though it is still a single command:

```
run 100000 every 1000 &
  "print 'Minimum value = $a'" &
  "print 'Maximum value = $b'" &
  "print 'Temp = $c'" &
  "print 'Press = $d'"
```

If the *pre* and *post* options are set to "no" when used with the *every* keyword, then the 1st run will do the full setup and the last run will print the full timing summary, but these operations will be skipped for intermediate runs.

NOTE: You might wish to specify a command that exits the run by jumping out of the loop, e.g.

```
variable t equal temp
run 10000 every 100 "if '$t <300.0' then 'jump SELF afterrun'"
```

However, this will not work. The run command simply executes each command one at a time each time it pauses, then continues the run.

Instead, you should use the [fix halt](#) command, which has additional options for how to

exit the run.

Restrictions:

When not using the *upto* keyword, the number of specified timesteps N must fit in a signed 32-bit integer, so you are limited to slightly more than 2 billion steps (2^{31}) in a single run. When using *upto*, N can be larger than a signed 32-bit integer, however the difference between N and the current timestep must still be no larger than 2^{31} steps.

However, with or without the *upto* keyword, you can perform successive runs to run a simulation for any number of steps (ok, up to 2^{63} total steps). I.e. the timestep counter within LAMMPS is a 64-bit signed integer.

Related commands:

[minimize](#), [run_style](#), [temper](#), [fix halt](#)

Default:

The option defaults are `start = the current timestep`, `stop = current timestep + N`, `pre = yes`, and `post = yes`.

run_style command

Syntax:

run_style style args

- style = *verlet* or *verlet/split* or *respa* or *respa/omp*

```

verlet args = none
verlet/split args = none
respa args = N n1 n2 ... keyword values ...
  N = # of levels of rRESPA
  n1, n2, ... = loop factors between rRESPA levels (N-1 values)
  zero or more keyword/value pairings may be appended to the loop factors
  keyword = bond or angle or dihedral or improper or
            pair or inner or middle or outer or hybrid or kspace
  bond value = M
    M = which level (1-N) to compute bond forces in
  angle value = M
    M = which level (1-N) to compute angle forces in
  dihedral value = M
    M = which level (1-N) to compute dihedral forces in
  improper value = M
    M = which level (1-N) to compute improper forces in
  pair value = M
    M = which level (1-N) to compute pair forces in
  inner values = M cut1 cut2
    M = which level (1-N) to compute pair inner forces in
    cut1 = inner cutoff between pair inner and
           pair middle or outer (distance units)
    cut2 = outer cutoff between pair inner and
           pair middle or outer (distance units)
  middle values = M cut1 cut2
    M = which level (1-N) to compute pair middle forces in
    cut1 = inner cutoff between pair middle and pair outer (distance units)
    cut2 = outer cutoff between pair middle and pair outer (distance units)
  outer value = M
    M = which level (1-N) to compute pair outer forces in
  hybrid values = M1 M2 ... (as many values as there are hybrid sub-styles)
    M1 = which level (1-N) to compute the first pair_style hybrid sub-style in
    M2 = which level (1-N) to compute the second pair_style hybrid sub-style in
    M3, etc
  kspace value = M
    M = which level (1-N) to compute kspace forces in

```

Examples:

```

run_style verlet
run_style respa 4 2 2 2 bond 1 dihedral 2 pair 3 kspace 4
run_style respa 4 2 2 2 bond 1 dihedral 2 inner 3 5.0 6.0 outer 4 kspace 4
run_style respa 3 4 2 bond 1 hybrid 2 2 1 kspace 3

```

Description:

LAMMPS Users Manual

Choose the style of time integrator used for molecular dynamics simulations performed by LAMMPS.

The *verlet* style is a standard velocity-Verlet integrator.

The *verlet/split* style is also a velocity-Verlet integrator, but it splits the force calculation within each timestep over 2 partitions of processors. See [Section 2.6](#) for an explanation of the `-partition` command-line switch.

Specifically, this style performs all computation except the `kspace_style` portion of the force field on the 1st partition. This include the `pair style`, `bond style`, `neighbor list building`, `fixes` including time integration, and output. The `kspace_style` portion of the calculation is performed on the 2nd partition.

This is most useful for the PPPM `kspace_style` when its performance on a large number of processors degrades due to the cost of communication in its 3d FFTs. In this scenario, splitting your P total processors into 2 subsets of processors, P_1 in the 1st partition and P_2 in the 2nd partition, can enable your simulation to run faster. This is because the long-range forces in PPPM can be calculated at the same time as pair-wise and bonded forces are being calculated, and the FFTs can actually speed up when running on fewer processors.

To use this style, you must define 2 partitions where P_1 is a multiple of P_2 . Typically having P_1 be 3x larger than P_2 is a good choice. The 3d processor layouts in each partition must overlay in the following sense. If P_1 is a P_{x1} by P_{y1} by P_{z1} grid, and $P_2 = P_{x2}$ by P_{y2} by P_{z2} , then P_{x1} must be an integer multiple of P_{x2} , and similarly for P_{y1} a multiple of P_{y2} , and P_{z1} a multiple of P_{z2} .

Typically the best way to do this is to let the 1st partition choose its own optimal layout, then require the 2nd partition's layout to match the integer multiple constraint. See the `processors` command with its `part` keyword for a way to control this, e.g.

```
processors * * * part 1 2 multiple
```

You can also use the `partition` command to explicitly specify the processor layout on each partition. E.g. for 2 partitions of 60 and 15 processors each:

```
partition yes 1 processors 3 4 5  
partition yes 2 processors 3 1 5
```

When you run in 2-partition mode with the *verlet/split* style, the thermodynamic data for the entire simulation will be output to the log and screen file of the 1st partition, which are `log.lammps.0` and `screen.0` by default; see the [-plog and -pscreen command-line switches](#) to change this. The log and screen file for the 2nd partition will not contain thermodynamic output beyond the 1st timestep of the run.

See [Section 5](#) of the manual for performance details of the speed-up offered by the *verlet/split* style. One important performance consideration is the assignment of logical processors in the 2 partitions to the physical cores of a parallel machine. The `processors` command has options to support this, and strategies are discussed in

Section 5 of the manual.

The *respa* style implements the rRESPA multi-timescale integrator (Tuckerman) with N hierarchical levels, where level 1 is the innermost loop (shortest timestep) and level N is the outermost loop (largest timestep). The loop factor arguments specify what the looping factor is between levels. N1 specifies the number of iterations of level 1 for a single iteration of level 2, N2 is the iterations of level 2 per iteration of level 3, etc. N-1 looping parameters must be specified.

The *timestep* command sets the timestep for the outermost rRESPA level. Thus if the example command above for a 4-level rRESPA had an outer timestep of 4.0 fmsec, the inner timestep would be 8x smaller or 0.5 fmsec. All other LAMMPS commands that specify number of timesteps (e.g. *neigh_modify* parameters, *dump* every N timesteps, etc) refer to the outermost timesteps.

The rRESPA keywords enable you to specify at what level of the hierarchy various forces will be computed. If not specified, the defaults are that bond forces are computed at level 1 (innermost loop), angle forces are computed where bond forces are, dihedral forces are computed where angle forces are, improper forces are computed where dihedral forces are, pair forces are computed at the outermost level, and kspace forces are computed where pair forces are. The inner, middle, outer forces have no defaults.

For fixes that support it, the rRESPA level at which a given fix is active, can be selected through the *fix_modify* command.

The *inner* and *middle* keywords take additional arguments for cutoffs that are used by the pairwise force computations. If the 2 cutoffs for *inner* are 5.0 and 6.0, this means that all pairs up to 6.0 apart are computed by the inner force. Those between 5.0 and 6.0 have their force go ramped to 0.0 so the overlap with the next regime (middle or outer) is smooth. The next regime (middle or outer) will compute forces for all pairs from 5.0 outward, with those from 5.0 to 6.0 having their value ramped in an inverse manner.

Only some pair potentials support the use of the *inner* and *middle* and *outer* keywords. If not, only the *pair* keyword can be used with that pair style, meaning all pairwise forces are computed at the same rRESPA level. See the doc pages for individual pair styles for details.

Another option for using pair potentials with rRESPA is with the *hybrid* keyword, which requires the use of the *pair_style hybrid or hybrid/overlay* command. In this scenario, different sub-styles of the hybrid pair style are evaluated at different rRESPA levels. This can be useful, for example, to set different timesteps for hybrid coarse-grained/all-atom models. The *hybrid* keyword requires as many level assignments as there are hybrid substyles, which assigns each sub-style to a rRESPA level, following their order of definition in the *pair_style* command. Since the *hybrid* keyword operates on pair style computations, it is mutually exclusive with either the *pair* or the *inner/middle/outer* keywords.

When using rRESPA (or for any MD simulation) care must be taken to choose a timestep size(s) that insures the Hamiltonian for the chosen ensemble is conserved.

LAMMPS Users Manual

For the constant NVE ensemble, total energy must be conserved. Unfortunately, it is difficult to know *a priori* how well energy will be conserved, and a fairly long test simulation (~ 10 ps) is usually necessary in order to verify that no long-term drift in energy occurs with the trial set of parameters.

With that caveat, a few rules-of-thumb may be useful in selecting *respa* settings. The following applies mostly to biomolecular simulations using the CHARMM or a similar all-atom force field, but the concepts are adaptable to other problems. Without SHAKE, bonds involving hydrogen atoms exhibit high-frequency vibrations and require a timestep on the order of 0.5 fmsec in order to conserve energy. The relatively inexpensive force computations for the bonds, angles, impropers, and dihedrals can be computed on this innermost 0.5 fmsec step. The outermost timestep cannot be greater than 4.0 fmsec without risking energy drift. Smooth switching of forces between the levels of the rRESPA hierarchy is also necessary to avoid drift, and a 1-2 angstrom "healing distance" (the distance between the outer and inner cutoffs) works reasonably well. We thus recommend the following settings for use of the *respa* style without SHAKE in biomolecular simulations:

```
timestep 4.0
run_style respa 4 2 2 2 inner 2 4.5 6.0 middle 3 8.0 10.0 outer 4
```

With these settings, users can expect good energy conservation and roughly a 2.5 fold speedup over the *verlet* style with a 0.5 fmsec timestep.

If SHAKE is used with the *respa* style, time reversibility is lost, but substantially longer time steps can be achieved. For biomolecular simulations using the CHARMM or similar all-atom force field, bonds involving hydrogen atoms exhibit high frequency vibrations and require a time step on the order of 0.5 fmsec in order to conserve energy. These high frequency modes also limit the outer time step sizes since the modes are coupled. It is therefore desirable to use SHAKE with *respa* in order to freeze out these high frequency motions and increase the size of the time steps in the *respa* hierarchy. The following settings can be used for biomolecular simulations with SHAKE and rRESPA:

```
fix          2 all shake 0.000001 500 0 m 1.0 a 1
timestep     4.0
run_style    respa 2 2 inner 1 4.0 5.0 outer 2
```

With these settings, users can expect good energy conservation and roughly a 1.5 fold speedup over the *verlet* style with SHAKE and a 2.0 fmsec timestep.

For non-biomolecular simulations, the *respa* style can be advantageous if there is a clear separation of time scales - fast and slow modes in the simulation. Even a LJ system can benefit from rRESPA if the interactions are divided by the inner, middle and outer keywords. A 2-fold or more speedup can be obtained while maintaining good energy conservation. In real units, for a pure LJ fluid at liquid density, with a sigma of 3.0 angstroms, and epsilon of 0.1 Kcal/mol, the following settings seem to work well:

```
timestep 36.0
run_style respa 3 3 4 inner 1 3.0 4.0 middle 2 6.0 7.0 outer 3
```

LAMMPS Users Manual

The *respa/omp* style is a variant of *respa* adapted for use with pair, bond, angle, dihedral, improper, or kspace styles with an *omp* suffix. It is functionally equivalent to *respa* but performs additional operations required for managing *omp* styles. For more on *omp* styles see the [Section 5](#) of the manual. Accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

You can specify *respa/omp* explicitly in your input script, or you can use the [-suffix command-line switch](#) when you invoke LAMMPS, or you can use the [suffix](#) command in your input script.

See [Section 5](#) of the manual for more instructions on how to use the accelerated styles effectively.

Restrictions:

The *verlet/split* style can only be used if LAMMPS was built with the REPLIC package. Correspondingly the *respa/omp* style is available only if the USER-OMP package was included. See the [Making LAMMPS](#) section for more info on packages.

Whenever using rRESPA, the user should experiment with trade-offs in speed and accuracy for their system, and verify that they are conserving energy to adequate precision.

LAMMPS Users Manual

angmom values = Lx Ly Lz
Lx,Ly,Lz = components of angular momentum vector (distance-mass-velocity units)
any of Lx,Ly,Lz can be an atom-style variable (see below)

omega values = Wx Wy Wz
Wx,Wy,Wz = components of angular velocity vector (radians/time units)
any of wx,wy,wz can be an atom-style variable (see below)

mass value = per-atom mass (mass units)
value can be an atom-style variable (see below)

density value = particle density for a sphere or ellipsoid (mass/distance³ units), or
value can be an atom-style variable (see below)

density/disc value = particle density for a 2d disc or ellipse (mass/distance² units)
value can be an atom-style variable (see below)

volume value = particle volume for Peridynamic particle (distance³ units)
value can be an atom-style variable (see below)

image nx ny nz
nx,ny,nz = which periodic image of the simulation box the atom is in
any of nx,ny,nz can be an atom-style variable (see below)

bond value = bond type for all bonds between selected atoms

angle value = angle type for all angles between selected atoms

dihedral value = dihedral type for all dihedrals between selected atoms

improper value = improper type for all improvers between selected atoms

meso/e value = energy of SPH particles (need units)
value can be an atom-style variable (see below)

meso/cv value = heat capacity of SPH particles (need units)
value can be an atom-style variable (see below)

meso/rho value = density of SPH particles (need units)
value can be an atom-style variable (see below)

smd/contact/radius = radius for short range interactions, i.e. contact and friction
value can be an atom-style variable (see below)

smd/mass/density = set particle mass based on volume by providing a mass density
value can be an atom-style variable (see below)

dpd/theta value = internal temperature of DPD particles (temperature units)
value can be an atom-style variable (see below)
value can be NULL which sets internal temp of each particle to KE temp

edpd/temp value = temperature of eDPD particles (temperature units)
value can be an atom-style variable (see below)

edpd/cv value = volumetric heat capacity of eDPD particles (energy/temperature/volume)
value can be an atom-style variable (see below)

cc values = index cc
index = index of a chemical species (1 to Nspecies)
cc = chemical concentration of tDPD particles for a species (mole/volume units)

i_name value = value for custom integer vector with name

d_name value = value for custom floating-point vector with name

Examples:

```
set group solvent type 2
set group solvent type/fraction 2 0.5 12393
set group edge bond 4
set region half charge 0.5
set type 3 charge 0.5
set type 1*3 charge 0.5
set atom * charge v_atomfile
set atom 100*200 x 0.5 y 1.0
set atom 1492 type 3
```

Description:

Set one or more properties of one or more atoms. Since atom properties are initially

LAMMPS Users Manual

assigned by the [read_data](#), [read_restart](#) or [create_atoms](#) commands, this command changes those assignments. This can be useful for overriding the default values assigned by the [create_atoms](#) command (e.g. charge = 0.0). It can be useful for altering pairwise and molecular force interactions, since force-field coefficients are defined in terms of types. It can be used to change the labeling of atoms by atom type or molecule ID when they are output in [dump](#) files. It can also be useful for debugging purposes; i.e. positioning an atom at a precise location to compute subsequent forces or energy.

Note that the *style* and *ID* arguments determine which atoms have their properties reset. The remaining keywords specify which properties to reset and what the new values are. Some strings like *type* or *mol* can be used as a style and/or a keyword.

This section describes how to select which atoms to change the properties of, via the *style* and *ID* arguments.

The style *atom* selects all the atoms in a range of atom IDs. The style *type* selects all the atoms in a range of types. The style *mol* selects all the atoms in a range of molecule IDs.

In each of the range cases, the range can be specified as a single numeric value, or a wildcard asterisk can be used to specify a range of values. This takes the form "*" or "*n" or "n*" or "m*n". For example, for the style *type*, if N = the number of atom types, then an asterisk with no numeric values means all types from 1 to N. A leading asterisk means all types from 1 to n (inclusive). A trailing asterisk means all types from n to N (inclusive). A middle asterisk means all types from m to n (inclusive). For all the styles except *mol*, the lowest value for the wildcard is 1; for *mol* it is 0.

The style *group* selects all the atoms in the specified group. The style *region* selects all the atoms in the specified geometric region. See the [group](#) and [region](#) commands for details of how to specify a group or region.

This section describes the keyword options for which properties to change, for the selected atoms.

Note that except where explicitly prohibited below, all of the keywords allow an [atom-style or atomfile-style variable](#) to be used as the specified value(s). If the value is a variable, it should be specified as *v_name*, where name is the variable name. In this case, the variable will be evaluated, and its resulting per-atom value used to determine the value assigned to each selected atom. Note that the per-atom value from the variable will be ignored for atoms that are not selected via the *style* and *ID* settings explained above. A simple way to use per-atom values from the variable to reset a property for all atoms is to use style *atom* with *ID* = "*"; this selects all atom IDs.

Atom-style variables can specify formulas with various mathematical functions, and include [thermo_style](#) command keywords for the simulation box parameters and timestep and elapsed time. They can also include per-atom values, such as atom coordinates. Thus it is easy to specify a time-dependent or spatially-dependent set of per-atom values. As explained on the [variable](#) doc page, atomfile-style variables can be

LAMMPS Users Manual

used in place of atom-style variables, and thus as arguments to the set command. Atomfile-style variables read their per-atoms values from a file.

NOTE: Atom-style and atomfile-style variables return floating point per-atom values. If the values are assigned to an integer variable, such as the molecule ID, then the floating point value is truncated to its integer portion, e.g. a value of 2.6 would become 2.

Keyword *type* sets the atom type for all selected atoms. The specified value must be from 1 to *ntypes*, where *ntypes* was set by the [create_box](#) command or the *atom types* field in the header of the data file read by the [read_data](#) command.

Keyword *type/fraction* sets the atom type for a fraction of the selected atoms. The actual number of atoms changed is not guaranteed to be exactly the requested fraction, but should be statistically close. Random numbers are used in such a way that a particular atom is changed or not changed, regardless of how many processors are being used. This keyword does not allow use of an atom-style variable.

Keyword *mol* sets the molecule ID for all selected atoms. The [atom style](#) being used must support the use of molecule IDs.

Keywords *x*, *y*, *z*, and *charge* set the coordinates or charge of all selected atoms. For *charge*, the [atom style](#) being used must support the use of atomic charge.

Keyword *dipole* uses the specified x,y,z values as components of a vector to set as the orientation of the dipole moment vectors of the selected atoms. The magnitude of the dipole moment is set by the length of this orientation vector.

Keyword *dipole/random* randomizes the orientation of the dipole moment vectors for the selected atoms and sets the magnitude of each to the specified *Dlen* value. For 2d systems, the z component of the orientation is set to 0.0. Random numbers are used in such a way that the orientation of a particular atom is the same, regardless of how many processors are being used. This keyword does not allow use of an atom-style variable.

Keyword *quat* uses the specified values to create a quaternion (4-vector) that represents the orientation of the selected atoms. The particles must define a quaternion for their orientation (e.g. ellipsoids, triangles, body particles) as defined by the [atom_style](#) command. Note that particles defined by [atom_style ellipsoid](#) have 3 shape parameters. The 3 values must be non-zero for each particle set by this command. They are used to specify the aspect ratios of an ellipsoidal particle, which is oriented by default with its x-axis along the simulation box's x-axis, and similarly for y and z. If this body is rotated (via the right-hand rule) by an angle *theta* around a unit rotation vector (a,b,c), then the quaternion that represents its new orientation is given by $(\cos(\theta/2), a*\sin(\theta/2), b*\sin(\theta/2), c*\sin(\theta/2))$. The *theta* and a,b,c values are the arguments to the *quat* keyword. LAMMPS normalizes the quaternion in case (a,b,c) was not specified as a unit vector. For 2d systems, the a,b,c values are ignored, since a rotation vector of (0,0,1) is the only valid choice.

Keyword *quat/random* randomizes the orientation of the quaternion for the selected atoms. The particles must define a quaternion for their orientation (e.g. ellipsoids,

LAMMPS Users Manual

triangles, body particles) as defined by the [atom_style](#) command. Random numbers are used in such a way that the orientation of a particular atom is the same, regardless of how many processors are being used. For 2d systems, only orientations in the xy plane are generated. As with keyword *quat*, for ellipsoidal particles, the 3 shape values must be non-zero for each particle set by this command. This keyword does not allow use of an atom-style variable.

Keyword *diameter* sets the size of the selected atoms. The particles must be finite-size spheres as defined by the [atom_style sphere](#) command. The diameter of a particle can be set to 0.0, which means they will be treated as point particles. Note that this command does not adjust the particle mass, even if it was defined with a density, e.g. via the [read_data](#) command.

Keyword *shape* sets the size and shape of the selected atoms. The particles must be ellipsoids as defined by the [atom_style ellipsoid](#) command. The S_x , S_y , S_z settings are the 3 diameters of the ellipsoid in each direction. All 3 can be set to the same value, which means the ellipsoid is effectively a sphere. They can also all be set to 0.0 which means the particle will be treated as a point particle. Note that this command does not adjust the particle mass, even if it was defined with a density, e.g. via the [read_data](#) command.

Keyword *length* sets the length of selected atoms. The particles must be line segments as defined by the [atom_style line](#) command. If the specified value is non-zero the line segment is (re)set to a length = the specified value, centered around the particle position, with an orientation along the x-axis. If the specified value is 0.0, the particle will become a point particle. Note that this command does not adjust the particle mass, even if it was defined with a density, e.g. via the [read_data](#) command.

Keyword *tri* sets the size of selected atoms. The particles must be triangles as defined by the [atom_style tri](#) command. If the specified value is non-zero the triangle is (re)set to be an equilateral triangle in the xy plane with side length = the specified value, with a centroid at the particle position, with its base parallel to the x axis, and the y-axis running from the center of the base to the top point of the triangle. If the specified value is 0.0, the particle will become a point particle. Note that this command does not adjust the particle mass, even if it was defined with a density, e.g. via the [read_data](#) command.

Keyword *theta* sets the orientation of selected atoms. The particles must be line segments as defined by the [atom_style line](#) command. The specified value is used to set the orientation angle of the line segments with respect to the x axis.

Keyword *theta/random* randomizes the orientation of theta for the selected atoms. The particles must be line segments as defined by the [atom_style line](#) command. Random numbers are used in such a way that the orientation of a particular atom is the same, regardless of how many processors are being used. This keyword does not allow use of an atom-style variable.

Keyword *angmom* sets the angular momentum of selected atoms. The particles must be ellipsoids as defined by the [atom_style ellipsoid](#) command or triangles as defined by the [atom_style tri](#) command. The angular momentum vector of the particles is set to the 3 specified components.

LAMMPS Users Manual

Keyword *omega* sets the angular velocity of selected atoms. The particles must be spheres as defined by the [atom_style sphere](#) `atom_style.html` command. The angular velocity vector of the particles is set to the 3 specified components.

Keyword *mass* sets the mass of all selected particles. The particles must have a per-atom mass attribute, as defined by the [atom_style](#) command. See the "mass" command for how to set mass values on a per-type basis.

Keyword *density* or *density/disc* also sets the mass of all selected particles, but in a different way. The particles must have a per-atom mass attribute, as defined by the [atom_style](#) command. If the atom has a radius attribute (see [atom_style sphere](#)) and its radius is non-zero, its mass is set from the density and particle volume for 3d systems (the input density is assumed to be in mass/distance³ units). For 2d, the default is for LAMMPS to model particles with a radius attribute as spheres. However, if the *density/disc* keyword is used, then they can be modeled as 2d discs (circles). Their mass is set from the density and particle area (the input density is assumed to be in mass/distance² units).

If the atom has a shape attribute (see [atom_style ellipsoid](#)) and its 3 shape parameters are non-zero, then its mass is set from the density and particle volume (the input density is assumed to be in mass/distance³ units). The *density/disc* keyword has no effect; it does not (yet) treat 3d ellipsoids as 2d ellipses.

If the atom has a length attribute (see [atom_style line](#)) and its length is non-zero, then its mass is set from the density and line segment length (the input density is assumed to be in mass/distance units). If the atom has an area attribute (see [atom_style tri](#)) and its area is non-zero, then its mass is set from the density and triangle area (the input density is assumed to be in mass/distance² units).

If none of these cases are valid, then the mass is set to the density value directly (the input density is assumed to be in mass units).

Keyword *volume* sets the volume of all selected particles. Currently, only the [atom_style peri](#) command defines particles with a volume attribute. Note that this command does not adjust the particle mass.

Keyword *image* sets which image of the simulation box the atom is considered to be in. An image of 0 means it is inside the box as defined. A value of 2 means add 2 box lengths to get the true value. A value of -1 means subtract 1 box length to get the true value. LAMMPS updates these flags as atoms cross periodic boundaries during the simulation. The flags can be output with atom snapshots via the [dump](#) command. If a value of NULL is specified for any of nx,ny,nz, then the current image value for that dimension is unchanged. For non-periodic dimensions only a value of 0 can be specified. This command can be useful after a system has been equilibrated and atoms have diffused one or more box lengths in various directions. This command can then reset the image values for atoms so that they are effectively inside the simulation box, e.g if a diffusion coefficient is about to be measured via the [compute msd](#) command. Care should be taken not to reset the image flags of two atoms in a bond to the same value if the bond straddles a periodic boundary (rather they should be different by +/- 1). This will not affect the dynamics of a simulation, but may mess up analysis of the trajectories if a LAMMPS diagnostic or your own analysis relies on the image flags to

LAMMPS Users Manual

unwrap a molecule which straddles the periodic box.

Keywords *bond*, *angle*, *dihedral*, and *improper*, set the bond type (angle type, etc) of all bonds (angles, etc) of selected atoms to the specified value from 1 to nbondtypes (nangletypes, etc). All atoms in a particular bond (angle, etc) must be selected atoms in order for the change to be made. The value of nbondtype (nangletypes, etc) was set by the *bond types* (*angle types*, etc) field in the header of the data file read by the [read_data](#) command. These keywords do not allow use of an atom-style variable.

Keywords *meso/e*, *meso/cv*, and *meso/rho* set the energy, heat capacity, and density of smoothed particle hydrodynamics (SPH) particles. See [this PDF guide](#) to using SPH in LAMMPS.

Keyword *smd/mass/density* sets the mass of all selected particles, but it is only applicable to the Smooth Mach Dynamics package USER-SMD. It assumes that the particle volume has already been correctly set and calculates particle mass from the provided mass density value.

Keyword *smd/contact/radius* only applies to simulations with the Smooth Mach Dynamics package USER-SMD. It sets an interaction radius for computing short-range interactions, e.g. repulsive forces to prevent different individual physical bodies from penetrating each other. Note that the SPH smoothing kernel diameter used for computing long range, nonlocal interactions, is set using the *diameter* keyword.

Keyword *dpd/theta* sets the internal temperature of a DPD particle as defined by the USER-DPD package. If the specified value is a number it must be ≥ 0.0 . If the specified value is NULL, then the kinetic temperature T_{kin} of each particle is computed as $\frac{3}{2} k T_{kin} = KE = \frac{1}{2} m v^2 = \frac{1}{2} m (v_x^2 + v_y^2 + v_z^2)$. Each particle's internal temperature is set to T_{kin} . If the specified value is an atom-style variable, then the variable is evaluated for each particle. If a value ≥ 0.0 , the internal temperature is set to that value. If it is < 0.0 , the computation of T_{kin} is performed and the internal temperature is set to that value.

Keywords *edpd/temp* and *edpd/cv* set the temperature and volumetric heat capacity of an eDPD particle as defined by the USER-MESO package. Currently, only [atom_style edpd](#) defines particles with these attributes. The values for the temperature and heat capacity must be positive.

Keyword *cc* sets the chemical concentration of a tDPD particle for a specified species as defined by the USER-MESO package. Currently, only [atom_style tdpd](#) defines particles with this attribute. An integer for "index" selects a chemical species (1 to Nspecies) where Nspecies is set by the [atom_style](#) command. The value for the chemical concentration must be ≥ 0.0 .

Keywords *i_name* and *d_name* refer to custom integer and floating-point properties that have been added to each atom via the [fix property/atom](#) command. When that command is used specific names are given to each attribute which are what is specified as the "name" portion of *i_name* or *d_name*.

Restrictions:

LAMMPS Users Manual

You cannot set an atom attribute (e.g. *mol* or *q* or *volume*) if the [atom_style](#) does not have that attribute.

This command requires inter-processor communication to coordinate the setting of bond types (angle types, etc). This means that your system must be ready to perform a simulation before using one of these keywords (force fields set, atom mass set, etc). This is not necessary for other keywords.

Using the *region* style with the bond (angle, etc) keywords can give unpredictable results if there are bonds (angles, etc) that straddle periodic boundaries. This is because the region may only extend up to the boundary and partner atoms in the bond (angle, etc) may have coordinates outside the simulation box if they are ghost atoms.

Related commands:

[create_box](#), [create_atoms](#), [read_data](#)

Default: none

shell command

Syntax:

```
shell cmd args
```

- `cmd` = `cd` or `mkdir` or `mv` or `rm` or `rmdir` or `putenv` or arbitrary command

```
cd arg = dir
    dir = directory to change to
mkdir args = dir1 dir2 ...
    dir1,dir2 = one or more directories to create
mv args = old new
    old = old filename
    new = new filename
rm args = file1 file2 ...
    file1,file2 = one or more filenames to delete
rmdir args = dir1 dir2 ...
    dir1,dir2 = one or more directories to delete
putenv args = var1=value1 var2=value2
    var=value = one of more definitions of environment variables
anything else is passed as a command to the shell for direct execution
```

Examples:

```
shell cd sub1
shell cd ..
shell mkdir tmp1 tmp2 tmp3
shell rmdir tmp1
shell mv log.lammps hold/log.1
shell rm TMP/file1 TMP/file2
shell putenv LAMMPS_POTENTIALS=../../potentials
shell my_setup file1 10 file2
shell my_post_process 100 dump.out
```

Description:

Execute a shell command. A few simple file-based shell commands are supported directly, in Unix-style syntax. Any command not listed above is passed as-is to the C-library `system()` call, which invokes the command in a shell.

This is means to invoke other commands from your input script. For example, you can move files around in preparation for the next section of the input script. Or you can run a program that pre-processes data for input into LAMMPS. Or you can run a program that post-processes LAMMPS output data.

With the exception of `cd`, all commands, including ones invoked via a `system()` call, are executed by only a single processor, so that files/directories are not being manipulated by multiple processors.

The `cd` cmd executes the Unix "cd" command to change the working directory. All subsequent LAMMPS commands that read/write files will use the new directory. All

LAMMPS Users Manual

processors execute this command.

The *mkdir* cmd executes the Unix "mkdir" command to create one or more directories.

The *mv* cmd executes the Unix "mv" command to rename a file and/or move it to a new directory.

The *rm* cmd executes the Unix "rm" command to remove one or more files.

The *rmdir* cmd executes the Unix "rmdir" command to remove one or more directories. A directory must be empty to be successfully removed.

The *putenv* cmd defines or updates an environment variable directly. Since this command does not pass through the shell, no shell variable expansion or globbing is performed, only the usual substitution for LAMMPS variables defined with the [variable](#) command is performed. The resulting string is then used literally.

Any other cmd is passed as-is to the shell along with its arguments as one string, invoked by the C-library system() call. For example, these lines in your input script:

```
variable n equal 10
variable foo string file2
shell my_setup file1 $n ${foo}
```

would be the same as invoking

```
% my_setup file1 10 file2
```

from a command-line prompt. The executable program "my_setup" is run with 3 arguments: file1 10 file2.

Restrictions:

LAMMPS does not detect errors or print warnings when any of these commands execute. E.g. if the specified directory does not exist, executing the *cd* command will silently do nothing.

Related commands: none

Default: none

special_bonds command

Syntax:

```
special_bonds keyword values ...
```

- one or more keyword/value pairs may be appended
- keyword = *amber* or *charmm* or *dreiding* or *fene* or *lj/coul* or *lj* or *coul* or *angle* or *dihedral* or *extra*

```
amber values = none
charmm values = none
dreiding values = none
fene values = none
lj/coul values = w1,w2,w3
  w1,w2,w3 = weights (0.0 to 1.0) on pairwise Lennard-Jones and Coulombic interactions
lj values = w1,w2,w3
  w1,w2,w3 = weights (0.0 to 1.0) on pairwise Lennard-Jones interactions
coul values = w1,w2,w3
  w1,w2,w3 = weights (0.0 to 1.0) on pairwise Coulombic interactions
angle value = yes or no
dihedral value = yes or no
```

Examples:

```
special_bonds amber
special_bonds charmm
special_bonds fene dihedral no
special_bonds lj/coul 0.0 0.0 0.5 angle yes dihedral yes
special_bonds lj 0.0 0.0 0.5 coul 0.0 0.0 0.0 dihedral yes
```

Description:

Set weighting coefficients for pairwise energy and force contributions between pairs of atoms that are also permanently bonded to each other, either directly or via one or two intermediate bonds. These weighting factors are used by nearly all [pair styles](#) in LAMMPS that compute simple pairwise interactions. Permanent bonds between atoms are specified by defining the bond topology in the data file read by the [read_data](#) command. Typically a [bond_style](#) command is also used to define a bond potential. The rationale for using these weighting factors is that the interaction between a pair of bonded atoms is all (or mostly) specified by the bond, angle, dihedral potentials, and thus the non-bonded Lennard-Jones or Coulombic interaction between the pair of atoms should be excluded (or reduced by a weighting factor).

NOTE: These weighting factors are NOT used by [pair styles](#) that compute many-body interactions, since the "bonds" that result from such interactions are not permanent, but are created and broken dynamically as atom conformations change. Examples of pair styles in this category are EAM, MEAM, Stillinger-Weber, Tersoff, COMB, AIREBO, and ReaxFF. In fact, it generally makes no sense to define permanent bonds between atoms that interact via these potentials, though such bonds may exist elsewhere in your system, e.g. when using the [pair_style hybrid](#) command. Thus

LAMMPS Users Manual

LAMMPS ignores `special_bonds` settings when manybody potentials are calculated. Please note, that the existence of explicit bonds for atoms that are described by a manybody potential will alter the neighborlist and thus can render the computation of those interactions invalid, since those pairs are not only used to determine direct pairwise interactions but also neighbors of neighbors and more. The recommended course of action is to remove such bonds, or - if that is not possible - use a `special_bonds` setting of 1.0 1.0 1.0.

NOTE: Unlike some commands in LAMMPS, you cannot use this command multiple times in an incremental fashion: e.g. to first set the LJ settings and then the Coulombic ones. Each time you use this command it sets all the coefficients to default values and only overrides the one you specify, so you should set all the options you need each time you use it. See more details at the bottom of this page.

The Coulomb factors are applied to any Coulomb (charge interaction) term that the potential calculates. The LJ factors are applied to the remaining terms that the potential calculates, whether they represent LJ interactions or not. The weighting factors are a scaling pre-factor on the energy and force between the pair of atoms. A value of 1.0 means include the full interaction; a value of 0.0 means exclude it completely.

The 1st of the 3 coefficients (LJ or Coulombic) is the weighting factor on 1-2 atom pairs, which are pairs of atoms directly bonded to each other. The 2nd coefficient is the weighting factor on 1-3 atom pairs which are those separated by 2 bonds (e.g. the two H atoms in a water molecule). The 3rd coefficient is the weighting factor on 1-4 atom pairs which are those separated by 3 bonds (e.g. the 1st and 4th atoms in a dihedral interaction). Thus if the 1-2 coefficient is set to 0.0, then the pairwise interaction is effectively turned off for all pairs of atoms bonded to each other. If it is set to 1.0, then that interaction will be at full strength.

NOTE: For purposes of computing weighted pairwise interactions, 1-3 and 1-4 interactions are not defined from the list of angles or dihedrals used by the simulation. Rather, they are inferred topologically from the set of bonds specified when the simulation is defined from a data or restart file (see [read_data](#) or [read_restart](#) commands). Thus the set of 1-2,1-3,1-4 interactions that the weights apply to is the same whether angle and dihedral potentials are computed or not, and remains the same even if bonds are constrained, or turned off, or removed during a simulation.

The two exceptions to this rule are (a) if the `angle` or `dihedral` keywords are set to `yes` (see below), or (b) if the [delete_bonds](#) command is used with the `special` option that recomputes the 1-2,1-3,1-4 topologies after bonds are deleted; see the [delete_bonds](#) command for more details.

The `amber` keyword sets the 3 coefficients to 0.0, 0.0, 0.5 for LJ interactions and to 0.0, 0.0, 0.8333 for Coulombic interactions, which is the default for a commonly used version of the AMBER force field, where the last value is really 5/6. See [\(Cornell\)](#) for a description of the AMBER force field.

The `charmm` keyword sets the 3 coefficients to 0.0, 0.0, 0.0 for both LJ and Coulombic interactions, which is the default for a commonly used version of the CHARMM force field. Note that in pair styles `lj/charmm/coul/charmm` and `lj/charmm/coul/long` the 1-4

LAMMPS Users Manual

coefficients are defined explicitly, and these pairwise contributions are computed as part of the charmm dihedral style - see the [pair_coeff](#) and [dihedral_style](#) commands for more information. See [\(MacKerell\)](#) for a description of the CHARMM force field.

The *dreiding* keyword sets the 3 coefficients to 0.0, 0.0, 1.0 for both LJ and Coulombic interactions, which is the default for the Dreiding force field, as discussed in [\(Mayo\)](#).

The *fene* keyword sets the 3 coefficients to 0.0, 1.0, 1.0 for both LJ and Coulombic interactions, which is consistent with a coarse-grained polymer model with [FENE bonds](#). See [\(Kremer\)](#) for a description of FENE bonds.

The *lj/coul*, *lj*, and *coul* keywords allow the 3 coefficients to be set explicitly. The *lj/coul* keyword sets both the LJ and Coulombic coefficients to the same 3 values. The *lj* and *coul* keywords only set either the LJ or Coulombic coefficients. Use both of them if you wish to set the LJ coefficients to different values than the Coulombic coefficients.

The *angle* keyword allows the 1-3 weighting factor to be ignored for individual atom pairs if they are not listed as the first and last atoms in any angle defined in the simulation or as 1,3 or 2,4 atoms in any dihedral defined in the simulation. For example, imagine the 1-3 weighting factor is set to 0.5 and you have a linear molecule with 4 atoms and bonds as follows: 1-2-3-4. If your data file defines 1-2-3 as an angle, but does not define 2-3-4 as an angle or 1-2-3-4 as a dihedral, then the pairwise interaction between atoms 1 and 3 will always be weighted by 0.5, but different force fields use different rules for weighting the pairwise interaction between atoms 2 and 4. If the *angle* keyword is specified as *yes*, then the pairwise interaction between atoms 2 and 4 will be unaffected (full weighting of 1.0). If the *angle* keyword is specified as *no* which is the default, then the 2,4 interaction will also be weighted by 0.5.

The *dihedral* keyword allows the 1-4 weighting factor to be ignored for individual atom pairs if they are not listed as the first and last atoms in any dihedral defined in the simulation. For example, imagine the 1-4 weighting factor is set to 0.5 and you have a linear molecule with 5 atoms and bonds as follows: 1-2-3-4-5. If your data file defines 1-2-3-4 as a dihedral, but does not define 2-3-4-5 as a dihedral, then the pairwise interaction between atoms 1 and 4 will always be weighted by 0.5, but different force fields use different rules for weighting the pairwise interaction between atoms 2 and 5. If the *dihedral* keyword is specified as *yes*, then the pairwise interaction between atoms 2 and 5 will be unaffected (full weighting of 1.0). If the *dihedral* keyword is specified as *no* which is the default, then the 2,5 interaction will also be weighted by 0.5.

NOTE: LAMMPS stores and maintains a data structure with a list of the 1st, 2nd, and 3rd neighbors of each atom (within the bond topology of the system). If new bonds are created (or molecules added containing atoms with more special neighbors), the size of this list needs to grow. Note that adding a single bond always adds a new 1st neighbor but may also induce **many** new 2nd and 3rd neighbors, depending on the molecular topology of your system. Using the *extra/special/per/atom* keyword to either [read_data](#) or [create_box](#) reserves empty space in the list for this N additional 1st, 2nd, or 3rd neighbors to be added. If you do not do this, you may get an error when bonds (or molecules) are added.

NOTE: If you reuse this command in an input script, you should set all the options you need each time. This command cannot be used a 2nd time incrementally. E.g. these two commands:

```
special_bonds lj 0.0 1.0 1.0 special_bonds coul 0.0 0.0 1.0
```

are not the same as

```
special_bonds lj 0.0 1.0 1.0 coul 0.0 0.0 1.0
```

In the first case you end up with (after the 2nd command):

```
LJ: 0.0 0.0 0.0 Coul: coul 0.0 0.0 1.0
```

because the LJ settings are reset to their default values each time the command is issued.

suffix command

Syntax:

```
suffix style args
```

- style = *off* or *on* or *gpu* or *intel* or *kk* or *omp* or *opt* or *hybrid*
- args = for hybrid style, default suffix to be used and alternative suffix

Examples:

```
suffix off
suffix on
suffix gpu
suffix intel
suffix hybrid intel omp
suffix kk
```

Description:

This command allows you to use variants of various styles if they exist. In that respect it operates the same as the [-suffix command-line switch](#). It also has options to turn off or back on any suffix setting made via the command line.

The specified style can be *gpu*, *intel*, *kk*, *omp*, *opt* or *hybrid*. These refer to optional packages that LAMMPS can be built with, as described in [this section of the manual](#). The "gpu" style corresponds to the GPU package, the "intel" style to the USER-INTEL package, the "kk" style to the KOKKOS package, the "omp" style to the USER-OMP package, and the "opt" style to the OPT package.

These are the variants these packages provide:

- GPU = a handful of pair styles and the PPPM `kpace_style`, optimized to run on one or more GPUs or multicore CPU/GPU nodes
- USER-INTEL = a collection of pair styles and neighbor routines optimized to run in single, mixed, or double precision on CPUs and Intel(R) Xeon Phi(TM) coprocessors.
- KOKKOS = a collection of atom, pair, and fix styles optimized to run using the Kokkos library on various kinds of hardware, including GPUs via CUDA and many-core chips via OpenMP or threading.
- USER-OMP = a collection of pair, bond, angle, dihedral, improper, `kpace`, compute, and fix styles with support for OpenMP multi-threading
- OPT = a handful of pair styles, cache-optimized for faster CPU performance
- HYBRID = a combination of two packages can be specified (see below)

As an example, all of the packages provide a [pair_style lj/cut](#) variant, with style names `lj/cut/opt`, `lj/cut/omp`, `lj/cut/gpu`, `lj/cut/intel`, or `lj/cut/kk`. A variant styles can be specified explicitly in your input script, e.g. `pair_style lj/cut/gpu`. If the suffix command is used with the appropriate style, you do not need to modify your input script. The specified suffix (`opt,omp,gpu,intel,kk`) is automatically appended whenever your input

LAMMPS Users Manual

script command creates a new [atom](#), [pair](#), [bond](#), [angle](#), [dihedral](#), [improper](#), [kpace](#), [fix](#), [compute](#), or [run](#) style. If the variant version does not exist, the standard version is created.

For "hybrid", two packages are specified. The first is used whenever available. If a style with the first suffix is not available, the style with the suffix for the second package will be used if available. For example, "hybrid intel omp" will use styles from the USER-INTEL package as a first choice and styles from the USER-OMP package as a second choice if no USER-INTEL variant is available.

If the specified style is *off*, then any previously specified suffix is temporarily disabled, whether it was specified by a command-line switch or a previous suffix command. If the specified style is *on*, a disabled suffix is turned back on. The use of these 2 commands lets your input script use a standard LAMMPS style (i.e. a non-accelerated variant), which can be useful for testing or benchmarking purposes. Of course this is also possible by not using any suffix commands, and explicitly appending or not appending the suffix to the relevant commands in your input script.

NOTE: The default [run_style](#) verlet is invoked prior to reading the input script and is therefore not affected by a suffix command in the input script. The KOKKOS package requires "run_style verlet/kk", so when using the KOKKOS package it is necessary to either use the command line "-sf kk" command or add an explicit "run_style verlet" command to the input script.

Restrictions: none

[Command-line switch -suffix](#)

Default: none

tad command

Syntax:

```
tad N t_event T_lo T_hi delta tmax compute-ID keyword value ...
```

- N = # of timesteps to run (not including dephasing/quenching)
- t_event = timestep interval between event checks
- T_lo = temperature at which event times are desired
- T_hi = temperature at which MD simulation is performed
- delta = desired confidence level for stopping criterion
- tmax = reciprocal of lowest expected preexponential factor (time units)
- compute-ID = ID of the compute used for event detection
- zero or more keyword/value pairs may be appended
- keyword = *min* or *neb* or *min_style* or *neb_style* or *neb_log*

```
min values = etol ftol maxiter maxeval
  etol = stopping tolerance for energy (energy units)
  ftol = stopping tolerance for force (force units)
  maxiter = max iterations of minimize
  maxeval = max number of force/energy evaluations
neb values = ftol N1 N2 Nevery
  etol = stopping tolerance for energy (energy units)
  ftol = stopping tolerance for force (force units)
  N1 = max # of iterations (timesteps) to run initial NEB
  N2 = max # of iterations (timesteps) to run barrier-climbing NEB
  Nevery = print NEB statistics every this many timesteps
neb_style value = quickmin or fire
neb_step value = dtneb
  dtneb = timestep for NEB damped dynamics minimization
neb_log value = file where NEB statistics are printed
```

Examples:

```
tad 2000 50 1800 2300 0.01 0.01 event
tad 2000 50 1800 2300 0.01 0.01 event &
  min 1e-05 1e-05 100 100 &
  neb 0.0 0.01 200 200 20 &
  min_style cg &
  neb_style fire &
  neb_log log.neb
```

Description:

Run a temperature accelerated dynamics (TAD) simulation. This method requires two or more partitions to perform NEB transition state searches.

TAD is described in [this paper](#) by Art Voter. It is a method that uses accelerated dynamics at an elevated temperature to generate results at a specified lower temperature. A good overview of accelerated dynamics methods for such systems is given in [this review paper](#) from the same group. In general, these methods assume that the long-time dynamics is dominated by infrequent events i.e. the system is is

LAMMPS Users Manual

confined to low energy basins for long periods, punctuated by brief, randomly-occurring transitions to adjacent basins. TAD is suitable for infrequent-event systems, where in addition, the transition kinetics are well-approximated by harmonic transition state theory (hTST). In hTST, the temperature dependence of transition rates follows the Arrhenius relation. As a consequence a set of event times generated in a high-temperature simulation can be mapped to a set of much longer estimated times in the low-temperature system. However, because this mapping involves the energy barrier of the transition event, which is different for each event, the first event at the high temperature may not be the earliest event at the low temperature. TAD handles this by first generating a set of possible events from the current basin. After each event, the simulation is reflected backwards into the current basin. This is repeated until the stopping criterion is satisfied, at which point the event with the earliest low-temperature occurrence time is selected. The stopping criterion is that the confidence measure be greater than $1-\delta$. The confidence measure is the probability that no earlier low-temperature event will occur at some later time in the high-temperature simulation. hTST provides an lower bound for this probability, based on the user-specified minimum pre-exponential factor (reciprocal of t_{max}).

In order to estimate the energy barrier for each event, the TAD method invokes the [NEB](#) method. Each NEB replica runs on a partition of processors. The current NEB implementation in LAMMPS restricts you to having exactly one processor per replica. For more information, see the documentation for the [neb](#) command. In the current LAMMPS implementation of TAD, all the non-NEB TAD operations are performed on the first partition, while the other partitions remain idle. See [Section 6.5](#) of the manual for further discussion of multi-replica simulations.

A TAD run has several stages, which are repeated each time an event is performed. The logic for a TAD run is as follows:

```
while (time remains):
  while (time <tstop):
    until (event occurs):
      run dynamics for  $t_{event}$  steps
      quench
      run neb calculation using all replicas
      compute  $t_{lo}$  from energy barrier
      update earliest event
      update tstop
      reflect back into current basin
    execute earliest event
```

Before this outer loop begins, the initial potential energy basin is identified by quenching (an energy minimization, see below) the initial state and storing the resulting coordinates for reference.

Inside the inner loop, dynamics is run continuously according to whatever integrator has been specified by the user, stopping every t_{event} steps to check if a transition event has occurred. This check is performed by quenching the system and comparing the resulting atom coordinates to the coordinates from the previous basin.

A quench is an energy minimization and is performed by whichever algorithm has been defined by the [min_style](#) command; its default is the CG minimizer. The tolerances and limits for each quench can be set by the *min* keyword. Note that

LAMMPS Users Manual

typically, you do not need to perform a highly-converged minimization to detect a transition event.

The event check is performed by a compute with the specified *compute-ID*. Currently there is only one compute that works with the TAD command, which is the `compute event/displace` command. Other event-checking computes may be added. `Compute event/displace` checks whether any atom in the compute group has moved further than a specified threshold distance. If so, an "event" has occurred.

The NEB calculation is similar to that invoked by the `neb` command, except that the final state is generated internally, instead of being read in from a file. The style of minimization performed by NEB is determined by the *neb_style* keyword and must be a damped dynamics minimizer. The tolerances and limits for each NEB calculation can be set by the *neb* keyword. As discussed on the `neb`, it is often advantageous to use a larger timestep for NEB than for normal dynamics. Since the size of the timestep set by the `timestep` command is used by TAD for performing dynamics, there is a *neb_step* keyword which can be used to set a larger timestep for each NEB calculation if desired.

A key aspect of the TAD method is setting the stopping criterion appropriately. If this criterion is too conservative, then many events must be generated before one is finally executed. Conversely, if this criterion is too aggressive, high-entropy high-barrier events will be over-sampled, while low-entropy low-barrier events will be under-sampled. If the lowest pre-exponential factor is known fairly accurately, then it can be used to estimate *t_{max}*, and the value of *delta* can be set to the desired confidence level e.g. *delta* = 0.05 corresponds to 95% confidence. However, for systems where the dynamics are not well characterized (the most common case), it will be necessary to experiment with the values of *delta* and *t_{max}* to get a good trade-off between accuracy and performance.

A second key aspect is the choice of *t_{hi}*. A larger value greatly increases the rate at which new events are generated. However, too large a value introduces errors due to anharmonicity (not accounted for within hTST). Once again, for any given system, experimentation is necessary to determine the best value of *t_{hi}*.

Five kinds of output can be generated during a TAD run: event statistics, NEB statistics, thermodynamic output by each replica, dump files, and restart files.

Event statistics are printed to the screen and master log.lammps file each time an event is executed. The quantities are the timestep, CPU time, global event number *N*, local event number *M*, event status, energy barrier, time margin, *t_{lo}* and *delt_lo*. The timestep is the usual LAMMPS timestep, which corresponds to the high-temperature time at which the event was detected, in units of timestep. The CPU time is the total processor time since the start of the TAD run. The global event number *N* is a counter that increments with each executed event. The local event number *M* is a counter that resets to zero upon entering each new basin. The event status is *E* when an event is executed, and is *D* for an event that is detected, while *DF* is for a detected event that is also the earliest (first) event at the low temperature.

The time margin is the ratio of the high temperature time in the current basin to the

LAMMPS Users Manual

stopping time. This last number can be used to judge whether the stopping time is too short or too long (see above).

t_{lo} is the low-temperature event time when the current basin was entered, in units of timestep. $delt_{lo}$ is the time of each detected event, measured relative to t_{lo} . $delt_{lo}$ is equal to the high-temperature time since entering the current basin, scaled by an exponential factor that depends on the hi/lo temperature ratio and the energy barrier for that event.

On lines for executed events, with status *E*, the global event number is incremented by one, the local event number and time margin are reset to zero, while the global event number, energy barrier, and $delt_{lo}$ match the last event with status *DF* in the immediately preceding block of detected events. The low-temperature event time t_{lo} is incremented by $delt_{lo}$.

NEB statistics are written to the file specified by the *neb_log* keyword. If the keyword value is "none", then no NEB statistics are printed out. The statistics are written every *Nevery* timesteps. See the [neb](#) command for a full description of the NEB statistics. When invoked from TAD, NEB statistics are never printed to the screen.

Because the NEB calculation must run on multiple partitions, LAMMPS produces additional screen and log files for each partition, e.g. `log.lammps.0`, `log.lammps.1`, etc. For the TAD command, these contain the thermodynamic output of each NEB replica. In addition, the log file for the first partition, `log.lammps.0`, will contain thermodynamic output from short runs and minimizations corresponding to the dynamics and quench operations, as well as a line for each new detected event, as described above.

After the TAD command completes, timing statistics for the TAD run are printed in each replica's log file, giving a breakdown of how much CPU time was spent in each stage (NEB, dynamics, quenching, etc).

Any [dump files](#) defined in the input script will be written to during a TAD run at timesteps when an event is executed. This means the requested dump frequency in the [dump](#) command is ignored. There will be one dump file (per dump command) created for all partitions. The atom coordinates of the dump snapshot are those of the minimum energy configuration resulting from quenching following the executed event. The timesteps written into the dump files correspond to the timestep at which the event occurred and NOT the clock. A dump snapshot corresponding to the initial minimum state used for event detection is written to the dump file at the beginning of each TAD run.

If the [restart](#) command is used, a single restart file for all the partitions is generated, which allows a TAD run to be continued by a new input script in the usual manner. The restart file is generated after an event is executed. The restart file contains a snapshot of the system in the new quenched state, including the event number and the low-temperature time. The restart frequency specified in the [restart](#) command is interpreted differently when performing a TAD run. It does not mean the timestep interval between restart files. Instead it means an event interval for executed events. Thus a frequency of 1 means write a restart file every time an event is executed. A frequency of 10 means write a restart file every 10th executed event. When an input

LAMMPS Users Manual

script reads a restart file from a previous TAD run, the new script can be run on a different number of replicas or processors.

Note that within a single state, the dynamics will typically temporarily continue beyond the event that is ultimately chosen, until the stopping criterion is satisfied. When the event is eventually executed, the timestep counter is reset to the value when the event was detected. Similarly, after each quench and NEB minimization, the timestep counter is reset to the value at the start of the minimization. This means that the timesteps listed in the replica log files do not always increase monotonically. However, the timestep values printed to the master log file, dump files, and restart files are always monotonically increasing.

Restrictions:

This command can only be used if LAMMPS was built with the REPLICCA package. See the [Making LAMMPS](#) section for more info on packages.

N setting must be integer multiple of t_{event} .

Runs restarted from restart files written during a TAD run will only produce identical results if the user-specified integrator supports exact restarts. So [fix nvt](#) will produce an exact restart, but [fix langevin](#) will not.

This command cannot be used when any fixes are defined that keep track of elapsed time to perform time-dependent operations. Examples include the "ave" fixes such as [fix ave/chunk](#). Also [fix dt/reset](#) and [fix deposit](#).

Related commands:

[compute event/displace](#), [min_modify](#), [min_style](#), [run_style](#), [minimize](#), [temper](#), [neb](#), [prd](#)

Default:

The option defaults are $min = 0.1\ 0.1\ 40\ 50$, $neb = 0.01\ 100\ 100\ 10$, $neb_style = quickmin$, $neb_step =$ the same timestep set by the [timestep](#) command, and $neb_log = "none"$.

(Voter2000) Sorensen and Voter, J Chem Phys, 112, 9599 (2000)

(Voter2002) Voter, Montalenti, Germann, Annual Review of Materials Research 32, 321 (2002).

temper command

Syntax:

```
temper N M temp fix-ID seed1 seed2 index
```

- N = total # of timesteps to run
- M = attempt a tempering swap every this many steps
- temp = initial temperature for this ensemble
- fix-ID = ID of the fix that will control temperature during the run
- seed1 = random # seed used to decide on adjacent temperature to partner with
- seed2 = random # seed for Boltzmann factor in Metropolis swap
- index = which temperature (0 to N-1) I am simulating (optional)

Examples:

```
temper 100000 100 $t tempfix 0 58728
temper 40000 100 $t tempfix 0 32285 $w
```

Description:

Run a parallel tempering or replica exchange simulation using multiple replicas (ensembles) of a system. Two or more replicas must be used.

Each replica runs on a partition of one or more processors. Processor partitions are defined at run-time using the `-partition` command-line switch; see [Section 2.6](#) of the manual. Note that if you have MPI installed, you can run a multi-replica simulation with more replicas (partitions) than you have physical processors, e.g you can run a 10-replica simulation on one or two processors. You will simply not get the performance speed-up you would see with one or more physical processors per replica. See [this section](#) of the manual for further discussion.

Each replica's temperature is controlled at a different value by a fix with *fix-ID* that controls temperature. Most thermostat fix styles (with and without included time integration) are supported. The command will print an error message and abort, if the chosen fix is unsupported. The desired temperature is specified by *temp*, which is typically a variable previously set in the input script, so that each partition is assigned a different temperature. See the [variable](#) command for more details. For example:

```
variable t world 300.0 310.0 320.0 330.0
fix myfix all nvt temp $t $t 100.0
temper 100000 100 $t myfix 3847 58382
```

would define 4 temperatures, and assign one of them to the thermostat used by each replica, and to the temper command.

As the tempering simulation runs for N timesteps, a temperature swap between adjacent ensembles will be attempted every M timesteps. If *seed1* is 0, then the swap attempts will alternate between odd and even pairings. If *seed1* is non-zero then it is

LAMMPS Users Manual

used as a seed in a random number generator to randomly choose an odd or even pairing each time. Each attempted swap of temperatures is either accepted or rejected based on a Boltzmann-weighted Metropolis criterion which uses *seed2* in the random number generator.

As a tempering run proceeds, multiple log files and screen output files are created, one per replica. By default these files are named `log.lammps.M` and `screen.M` where `M` is the replica number from 0 to `N-1`, with `N = # of replicas`. See the [section on command-line switches](#) for info on how to change these names.

The main screen and log file (`log.lammps`) will list information about which temperature is assigned to each replica at each thermodynamic output timestep. E.g. for a simulation with 16 replicas:

```
Running on 16 partitions of processors
Step T0 T1 T2 T3 T4 T5 T6 T7 T8 T9 T10 T11 T12 T13 T14 T15
0     0 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15
500   1 0 3 2 5 4 6 7 8 9 10 11 12 13 14 15
1000  2 0 4 1 5 3 6 7 8 9 10 11 12 14 13 15
1500  2 1 4 0 5 3 6 7 9 8 10 11 12 14 13 15
2000  2 1 3 0 6 4 5 7 10 8 9 11 12 14 13 15
2500  2 1 3 0 6 4 5 7 11 8 9 10 12 14 13 15
...
```

The column headings `T0` to `TN-1` mean which temperature is currently assigned to the replica 0 to `N-1`. Thus the columns represent replicas and the value in each column is its temperature (also numbered 0 to `N-1`). For example, a 0 in the 4th column (column `T3`, step 2500) means that the 4th replica is assigned temperature 0, i.e. the lowest temperature. You can verify this time sequence of temperature assignments for the `N`th replica by comparing the `N`th column of screen output to the thermodynamic data in the corresponding `log.lammps.N` or `screen.N` files as time proceeds.

You can have each replica create its own dump file in the following manner:

```
variable rep world 0 1 2 3 4 5 6 7
dump 1 all atom 1000 dump.temper.$rep
```

NOTE: Each replica's dump file will contain a continuous trajectory for its atoms where the temperature varies over time as swaps take place involving that replica. If you want a series of dump files, each with snapshots (from all replicas) that are all at a single temperature, then you will need to post-process the dump files using the information from the `log.lammps` file. E.g. you could produce one dump file with snapshots at 300K (from all replicas), another with snapshots at 310K, etc. Note that these new dump files will not contain "continuous trajectories" for individual atoms, because two successive snapshots (in time) may be from different replicas.

The last argument *index* in the `temper` command is optional and is used when restarting a tempering run from a set of restart files (one for each replica) which had previously swapped to new temperatures. The *index* value (from 0 to `N-1`, where `N` is the # of replicas) identifies which temperature the replica was simulating on the timestep the restart files were written. Obviously, this argument must be a variable so that each partition has the correct value. Set the variable to the `N` values listed in the log file for the previous run for the replica temperatures at that timestep. For example

LAMMPS Users Manual

if the log file listed the following for a simulation with 5 replicas:

```
500000 2 4 0 1 3
```

then a setting of

```
variable w world 2 4 0 1 3
```

would be used to restart the run with a tempering command like the example above with \$w as the last argument.

Restrictions:

This command can only be used if LAMMPS was built with the REPLICCA package. See the [Making LAMMPS](#) section for more info on packages.

Related commands:

[variable](#), [prd](#), [neb](#)

Default: none

temper/grem command

Syntax:

```
temper/grem N M lambda fix-ID thermostat-ID seed1 seed2 index
```

- N = total # of timesteps to run
- M = attempt a tempering swap every this many steps
- lambda = initial lambda for this ensemble
- fix-ID = ID of fix_grem
- thermostat-ID = ID of the thermostat that controls kinetic temperature
- seed1 = random # seed used to decide on adjacent temperature to partner with
- seed2 = random # seed for Boltzmann factor in Metropolis swap
- index = which temperature (0 to N-1) I am simulating (optional)

Examples:

```
temper/grem 100000 1000 $lambda fxgREM fxnvt 0 58728
temper/grem 40000 100 $lambda fxgREM fxnpt 0 32285 $walkers
```

Description:

Run a parallel tempering or replica exchange simulation in LAMMPS partition mode using multiple generalized replicas (ensembles) of a system defined by [fix grem](#), which stands for the generalized replica exchange method (gREM) originally developed by [\(Kim\)](#). It uses non-Boltzmann ensembles to sample over first order phase transitions. This is done by defining replicas with an enthalpy dependent effective temperature

Two or more replicas must be used. See the [temper](#) command for an explanation of how to run replicas on multiple partitions of one or more processors.

This command is a modification of the [temper](#) command and has the same dependencies, restraints, and input variables which are discussed there in greater detail.

Instead of temperature, this command performs replica exchanges in lambda as per the generalized ensemble enforced by [fix grem](#). The desired lambda is specified by *lambda*, which is typically a variable previously set in the input script, so that each partition is assigned a different temperature. See the [variable](#) command for more details. For example:

```
variable lambda world 400 420 440 460
fix fxnvt all nvt temp 300.0 300.0 100.0
fix fxgREM all grem $lambda -0.05 -50000 fxnvt
temper 100000 100 $lambda fxgREM fxnvt 3847 58382
```

would define 4 lambdas with constant kinetic temperature but unique generalized temperature, and assign one of them to [fix grem](#) used by each replica, and to the grem command.

LAMMPS Users Manual

As the gREM simulation runs for N timesteps, a swap between adjacent ensembles will be attempted every M timesteps. If *seed1* is 0, then the swap attempts will alternate between odd and even pairings. If *seed1* is non-zero then it is used as a seed in a random number generator to randomly choose an odd or even pairing each time. Each attempted swap of temperatures is either accepted or rejected based on a Metropolis criterion, derived for gREM by (Kim), which uses *seed2* in the random number generator.

File management works identical to the [temper](#) command. Dump files created by this fix contain continuous trajectories and require post-processing to obtain per-replica information.

The last argument *index* in the grem command is optional and is used when restarting a run from a set of restart files (one for each replica) which had previously swapped to new lambda. This is done using a variable. For example if the log file listed the following for a simulation with 5 replicas:

```
500000 2 4 0 1 3
```

then a setting of

```
variable walkers world 2 4 0 1 3
```

would be used to restart the run with a grem command like the example above with *\$walkers* as the last argument. This functionality is identical to [temper](#).

Restrictions:

This command can only be used if LAMMPS was built with the USER-MISC package. See the [Making LAMMPS](#) section for more info on packages.

This command must be used with [fix grem](#).

Related commands:

[fix grem](#), [temper](#), [variable](#)

Default: none

temper/npt command

Syntax:

```
temper/npt N M temp fix-ID seed1 seed2 pressure index
```

- N = total # of timesteps to run
- M = attempt a tempering swap every this many steps
- temp = initial temperature for this ensemble
- fix-ID = ID of the fix that will control temperature and pressure during the run
- seed1 = random # seed used to decide on adjacent temperature to partner with
- seed2 = random # seed for Boltzmann factor in Metropolis swap
- pressure = setpoint pressure for the ensemble
- index = which temperature (0 to N-1) I am simulating (optional)

Examples:

```
temper/npt 100000 100 $t nptfix 0 58728 1  
temper/npt 2500000 1000 300 nptfix 0 32285 $p  
temper/npt 5000000 2000 $t nptfix 0 12523 1 $w
```

Description:

Run a parallel tempering or replica exchange simulation using multiple replicas (ensembles) of a system in the isothermal-isobaric (NPT) ensemble. The command `temper/npt` works like [temper](#) but requires running replicas in the NPT ensemble instead of the canonical (NVT) ensemble and allows for pressure to be set in the ensembles. These multiple ensembles can run in parallel at different temperatures or different pressures. The acceptance criteria for `temper/npt` is specific to the NPT ensemble and can be found in references ([Okabe](#)) and ([Mori](#)).

Apart from the difference in acceptance criteria and the specification of pressure, this command works much like the [temper](#) command. See the documentation on [temper](#) for information on how the parallel tempering is handled in general.

Restrictions:

This command can only be used if LAMMPS was built with the USER-MISC package. See the [Making LAMMPS](#) section for more info on packages.

This command should be used with a fix that maintains the isothermal-isobaric (NPT) ensemble.

Related commands:

[temper](#), [variable](#), [fix_npt](#)

Default: none

thermo command

Syntax:

```
thermo N
```

- N = output thermodynamics every N timesteps
- N can be a variable (see below)

Examples:

```
thermo 100
```

Description:

Compute and print thermodynamic info (e.g. temperature, energy, pressure) on timesteps that are a multiple of N and at the beginning and end of a simulation. A value of 0 will only print thermodynamics at the beginning and end.

The content and format of what is printed is controlled by the [thermo_style](#) and [thermo_modify](#) commands.

Instead of a numeric value, N can be specified as an [equal-style variable](#), which should be specified as `v_name`, where name is the variable name. In this case, the variable is evaluated at the beginning of a run to determine the next timestep at which thermodynamic info will be written out. On that timestep, the variable will be evaluated again to determine the next timestep, etc. Thus the variable should return timestep values. See the [stagger\(\)](#) and [logfreq\(\)](#) and [stride\(\)](#) math functions for [equal-style variables](#), as examples of useful functions to use in this context. Other similar math functions could easily be added as options for [equal-style variables](#).

For example, the following commands will output thermodynamic info at timesteps 0,10,20,30,100,200,300,1000,2000,etc:

```
variable          s equal logfreq(10,3,10)
thermo            v_s
```

Restrictions: none

Related commands:

[thermo_style](#), [thermo_modify](#)

Default:

```
thermo 0
```

thermo_modify command

Syntax:

```
thermo_modify keyword value ...
```

- one or more keyword/value pairs may be listed

```
keyword = lost or lost/bond or norm or flush or line or format or temp or press:l
lost value = error or warn or ignore
lost/bond value = error or warn or ignore
norm value = yes or no
flush value = yes or no
line value = one or multi
format values = line string, int string, float string, M string, or none
  string = C-style format string
  M = integer from 1 to N, where N = # of quantities being output
temp value = compute ID that calculates a temperature
press value = compute ID that calculates a pressure
```

Examples:

```
thermo_modify lost ignore flush yes
thermo_modify temp myTemp format 3 %15.8g
thermo_modify temp myTemp format line "%ld %g %g %15.8g"
thermo_modify line multi format float %g
```

Description:

Set options for how thermodynamic information is computed and printed by LAMMPS.

NOTE: These options apply to the currently defined thermo style. When you specify a [thermo_style](#) command, all thermodynamic settings are restored to their default values, including those previously reset by a thermo_modify command. Thus if your input script specifies a thermo_style command, you should use the thermo_modify command after it.

The *lost* keyword determines whether LAMMPS checks for lost atoms each time it computes thermodynamics and what it does if atoms are lost. An atom can be "lost" if it moves across a non-periodic simulation box [boundary](#) or if it moves more than a box length outside the simulation domain (or more than a processor sub-domain length) before reneighboring occurs. The latter case is typically due to bad dynamics, e.g. too large a timestep or huge forces and velocities. If the value is *ignore*, LAMMPS does not check for lost atoms. If the value is *error* or *warn*, LAMMPS checks and either issues an error or warning. The code will exit with an error and continue with a warning. A warning will only be issued once, the first time an atom is lost. This can be a useful debugging option.

The *lost/bond* keyword determines whether LAMMPS throws an error or not if an atom in a bonded interaction (bond, angle, etc) cannot be found when it creates bonded neighbor lists. By default this is a fatal error. However in some scenarios it

LAMMPS Users Manual

may be desirable to only issue a warning or ignore it and skip the computation of the missing bond, angle, etc. An example would be when gas molecules in a vapor are drifting out of the box through a fixed boundary condition (see the [boundary](#) command). In this case one atom may be deleted before the rest of the molecule is, on a later timestep.

The *norm* keyword determines whether various thermodynamic output values are normalized by the number of atoms or not, depending on whether it is set to *yes* or *no*. Different unit styles have different defaults for this setting (see below). Even if *norm* is set to *yes*, a value is only normalized if it is an "extensive" quantity, meaning that it scales with the number of atoms in the system. For the thermo keywords described by the doc page for the [thermo_style](#) command, all energy-related keywords are extensive, such as *pe* or *ebond* or *enthalpy*. Other keywords such as *temp* or *press* are "intensive" meaning their value is independent (in a statistical sense) of the number of atoms in the system and thus are never normalized. For thermodynamic output values extracted from *fixes* and *computes* in a [thermo_style custom](#) command, the doc page for the individual [fix](#) or [compute](#) lists whether the value is "extensive" or "intensive" and thus whether it is normalized. Thermodynamic output values calculated by a variable formula are assumed to be "intensive" and thus are never normalized. You can always include a divide by the number of atoms in the variable formula if this is not the case.

The *flush* keyword invokes a flush operation after thermodynamic info is written to the log file. This insures the output in that file is current (no buffering by the OS), even if LAMMPS halts before the simulation completes.

The *line* keyword determines whether thermodynamics will be output as a series of numeric values on one line or in a multi-line format with 3 quantities with text strings per line and a dashed-line header containing the timestep and CPU time. This modify option overrides the *one* and *multi* thermo_style settings.

The *format* keyword can be used to change the default numeric format of any of quantities the [thermo_style](#) command outputs. All the specified format strings are C-style formats, e.g. as used by the C/C++ `printf()` command. The *line* keyword takes a single argument which is the format string for the entire line of thermo output, with N fields, which you must enclose in quotes if it is more than one field. The *int* and *float* keywords take a single format argument and are applied to all integer or floating-point quantities output. The setting for *M string* also takes a single format argument which is used for the Mth value output in each line, e.g. the 5th column is output in high precision for "format 5 %20.15g".

The *format* keyword can be used multiple times. The precedence is that for each value in a line of output, the *M* format (if specified) is used, else the *int* or *float* setting (if specified) is used, else the *line* setting (if specified) for that value is used, else the default setting is used. A setting of *none* clears all previous settings, reverting all values to their default format.

NOTE: The thermo output values *step* and *atoms* are stored internally as 8-byte signed integers, rather than the usual 4-byte signed integers. When specifying the *format int* option you can use a "%d"-style format identifier in the format string and LAMMPS will convert this to the corresponding 8-byte form when it is applied to those

LAMMPS Users Manual

keywords. However, when specifying the *line* option or *format M string* option for *step* and *natoms*, you should specify a format string appropriate for an 8-byte signed integer, e.g. one with "%ld".

The *temp* keyword is used to determine how thermodynamic temperature is calculated, which is used by all thermo quantities that require a temperature ("temp", "press", "ke", "etotal", "enthalpy", "pxx", etc). The specified compute ID must have been previously defined by the user via the [compute](#) command and it must be a style of compute that calculates a temperature. As described in the [thermo_style](#) command, thermo output uses a default compute for temperature with ID = *thermo_temp*. This option allows the user to override the default.

The *press* keyword is used to determine how thermodynamic pressure is calculated, which is used by all thermo quantities that require a pressure ("press", "enthalpy", "pxx", etc). The specified compute ID must have been previously defined by the user via the [compute](#) command and it must be a style of compute that calculates a pressure. As described in the [thermo_style](#) command, thermo output uses a default compute for pressure with ID = *thermo_press*. This option allows the user to override the default.

NOTE: If both the *temp* and *press* keywords are used in a single *thermo_modify* command (or in two separate commands), then the order in which the keywords are specified is important. Note that a [pressure compute](#) defines its own temperature compute as an argument when it is specified. The *temp* keyword will override this (for the pressure compute being used by thermodynamics), but only if the *temp* keyword comes after the *press* keyword. If the *temp* keyword comes before the *press* keyword, then the new pressure compute specified by the *press* keyword will be unaffected by the *temp* setting.

Restrictions: none

Related commands:

[thermo](#), [thermo_style](#)

Default:

The option defaults are *lost* = error, *norm* = yes for unit style of *lj*, *norm* = no for unit style of *real* and *metal*, *flush* = no, and *temp/press* = compute IDs defined by *thermo_style*.

The defaults for the *line* and *format* options depend on the thermo style. For styles "one" and "custom", the *line* and *format* defaults are "one", "%8d", and "%12.8g". For style "multi", the *line* and *format* defaults are "multi", "%8d", and "%14.4f".

thermo_style command

Syntax:

thermo_style style args

- style = *one* or *multi* or *custom*
- args = list of arguments for a particular style

one args = none

multi args = none

custom args = list of keywords

possible keywords = step, elapsed, elaplong, dt, time,
 cpu, tpcpu, spcpu, cpuremain, part, timeremain,
 atoms, temp, press, pe, ke, etotal, enthalpy,

 c_ID, c_ID[I], c_ID[I][J],
 f_ID, f_ID[I], f_ID[I][J],
 v_name, v_name[I]

step = timestep

elapsed = timesteps since start of this run

elaplong = timesteps since start of initial run in a series of runs

dt = timestep size

time = simulation time

cpu = elapsed CPU time in seconds since start of this run

tpcpu = time per CPU second

spcpu = timesteps per CPU second

cpuremain = estimated CPU time remaining in run

part = which partition (0 to Npartition-1) this is

timeremain = remaining time in seconds on timer timeout.

atoms = # of atoms

temp = temperature

press = pressure

pe = total potential energy

ke = kinetic energy

etotal = total energy (pe + ke)

enthalpy = enthalpy (etotal + press*vol)

evdwl = VanderWaal pairwise energy (includes etail)

ecoul = Coulombic pairwise energy

epair = pairwise energy (evdwl + ecoul + elong)

ebond = bond energy

eangle = angle energy

edihed = dihedral energy

eimp = improper energy

emol = molecular energy (ebond + eangle + edihed + eimp)

elong = long-range kspace energy

etail = VanderWaal energy long-range tail correction

vol = volume

density = mass density of system

lx,ly,lz = box lengths in x,y,z

LAMMPS Users Manual

```
xlo,xhi,ylo,yhi,zlo,zhi = box boundaries
xy,xz,yz = box tilt for triclinic (non-orthogonal) simulation boxes
xlat,ylat,zlat = lattice spacings as calculated by lattice command

f_ID[I][J] = I,J component of global array calculated by a fix with ID
v_name = value calculated by an equal-style variable with name
v_name[I] = value calculated by a vector-style variable with name
```

Examples:

```
thermo_style multi
thermo_style custom step temp pe etotal press vol
thermo_style custom step temp etotal c_myTemp v_abc
thermo_style custom step temp etotal c_myTemp[*] v_abc
```

Description:

Set the style and content for printing thermodynamic data to the screen and log file.

Style *one* prints a one-line summary of thermodynamic info that is the equivalent of "thermo_style custom step temp epair emol etotal press". The line contains only numeric values.

Style *multi* prints a multiple-line listing of thermodynamic info that is the equivalent of "thermo_style custom etotal ke temp pe ebond eangle edihed eimp evdwl ecoul elong press". The listing contains numeric values and a string ID for each quantity.

Style *custom* is the most general setting and allows you to specify which of the keywords listed above you want printed on each thermodynamic timestep. Note that the keywords `c_ID`, `f_ID`, `v_name` are references to [computes](#), [fixes](#), and equal-style [variables](#) that have been defined elsewhere in the input script or can even be new styles which users have added to LAMMPS (see the [Section 10](#) section of the documentation). Thus the *custom* style provides a flexible means of outputting essentially any desired quantity as a simulation proceeds.

All styles except *custom* have *vol* appended to their list of outputs if the simulation box volume changes during the simulation.

The values printed by the various keywords are instantaneous values, calculated on the current timestep. Time-averaged quantities, which include values from previous timesteps, can be output by using the `f_ID` keyword and accessing a fix that does time-averaging such as the [fix ave/time](#) command.

LAMMPS Users Manual

Options invoked by the [thermo_modify](#) command can be used to set the one- or multi-line format of the print-out, the normalization of thermodynamic output (total values versus per-atom values for extensive quantities (ones which scale with the number of atoms in the system)), and the numeric precision of each printed value.

NOTE: When you use a "thermo_style" command, all thermodynamic settings are restored to their default values, including those previously set by a [thermo_modify](#) command. Thus if your input script specifies a thermo_style command, you should use the thermo_modify command after it.

Several of the thermodynamic quantities require a temperature to be computed: "temp", "press", "ke", "etotal", "enthalpy", "pxx", etc. By default this is done by using a *temperature* compute which is created when LAMMPS starts up, as if this command had been issued:

```
compute thermo_temp all temp
```

See the [compute temp](#) command for details. Note that the ID of this compute is *thermo_temp* and the group is *all*. You can change the attributes of this temperature (e.g. its degrees-of-freedom) via the [compute_modify](#) command. Alternatively, you can directly assign a new compute (that calculates temperature) which you have defined, to be used for calculating any thermodynamic quantity that requires a temperature. This is done via the [thermo_modify](#) command.

Several of the thermodynamic quantities require a pressure to be computed: "press", "enthalpy", "pxx", etc. By default this is done by using a *pressure* compute which is created when LAMMPS starts up, as if this command had been issued:

```
compute thermo_press all pressure thermo_temp
```

See the [compute pressure](#) command for details. Note that the ID of this compute is *thermo_press* and the group is *all*. You can change the attributes of this pressure via the [compute_modify](#) command. Alternatively, you can directly assign a new compute (that calculates pressure) which you have defined, to be used for calculating any thermodynamic quantity that requires a pressure. This is done via the [thermo_modify](#) command.

Several of the thermodynamic quantities require a potential energy to be computed: "pe", "etotal", "ebond", etc. This is done by using a *pe* compute which is created when LAMMPS starts up, as if this command had been issued:

```
compute thermo_pe all pe
```

See the [compute pe](#) command for details. Note that the ID of this compute is *thermo_pe* and the group is *all*. You can change the attributes of this potential energy via the [compute_modify](#) command.

The kinetic energy of the system *ke* is inferred from the temperature of the system with $1/2 k_B T$ of energy for each degree of freedom. Thus, using different [compute commands](#) for calculating temperature, via the [thermo_modify temp](#) command, may yield different kinetic energies, since different computes that calculate temperature

can subtract out different non-thermal components of velocity and/or include different degrees of freedom (translational, rotational, etc).

The potential energy of the system pe will include contributions from fixes if the [fix_modify thermo](#) option is set for a fix that calculates such a contribution. For example, the [fix wall/lj93](#) fix calculates the energy of atoms interacting with the wall. See the doc pages for "individual fixes" to see which ones contribute.

A long-range tail correction $etail$ for the VanderWaal pairwise energy will be non-zero only if the [pair_modify tail](#) option is turned on. The $etail$ contribution is included in $evdwl$, $epair$, pe , and $etotal$, and the corresponding tail correction to the pressure is included in $press$ and pxx , pyy , etc.

The $step$, $elapsed$, and $elaplong$ keywords refer to timestep count. $Step$ is the current timestep, or iteration count when a [minimization](#) is being performed. $Elapsed$ is the number of timesteps elapsed since the beginning of this run. $Elaplong$ is the number of timesteps elapsed since the beginning of an initial run in a series of runs. See the $start$ and $stop$ keywords for the [run](#) for info on how to invoke a series of runs that keep track of an initial starting time. If these keywords are not used, then $elapsed$ and $elaplong$ are the same value.

The dt keyword is the current timestep size in time [units](#). The $time$ keyword is the current elapsed simulation time, also in time [units](#), which is simply ($step*dt$) if the timestep size has not changed and the timestep has not been reset. If the timestep has changed (e.g. via [fix dt/reset](#)) or the timestep has been reset (e.g. via the "reset_timestep" command), then the simulation time is effectively a cumulative value up to the current point.

The cpu keyword is elapsed CPU seconds since the beginning of this run. The $tpcpu$ and $spcpu$ keywords are measures of how fast your simulation is currently running. The $tpcpu$ keyword is simulation time per CPU second, where simulation time is in time [units](#). E.g. for metal units, the $tpcpu$ value would be picoseconds per CPU second. The $spcpu$ keyword is the number of timesteps per CPU second. Both quantities are on-the-fly metrics, measured relative to the last time they were invoked. Thus if you are printing out thermodynamic output every 100 timesteps, the two keywords will continually output the time and timestep rate for the last 100 steps. The $tpcpu$ keyword does not attempt to track any changes in timestep size, e.g. due to using the [fix dt/reset](#) command.

The $cpuremain$ keyword estimates the CPU time remaining in the current run, based on the time elapsed thus far. It will only be a good estimate if the CPU time/timestep for the rest of the run is similar to the preceding timesteps. On the initial timestep the value will be 0.0 since there is no history to estimate from. For a minimization run performed by the "minimize" command, the estimate is based on the $maxiter$ parameter, assuming the minimization will proceed for the maximum number of allowed iterations.

The $part$ keyword is useful for multi-replica or multi-partition simulations to indicate which partition this output and this file corresponds to, or for use in a [variable](#) to append to a filename for output specific to this partition. See [Section 2.6](#) of the manual for details on running in multi-partition mode.

LAMMPS Users Manual

The *timeremain* keyword returns the remaining seconds when a timeout has been configured via the [timer timeout](#) command. If the timeout timer is inactive, the value of this keyword is 0.0 and if the timer is expired, it is negative. This allows for example to exit loops cleanly, if the timeout is expired with:

```
if "$(timeremain) <0.0" then "quit 0"
```

The *fmax* and *fnorm* keywords are useful for monitoring the progress of an [energy minimization](#). The *fmax* keyword calculates the maximum force in any dimension on any atom in the system, or the infinity-norm of the force vector for the system. The *fnorm* keyword calculates the 2-norm or length of the force vector.

The *nbuild* and *ndanger* keywords are useful for monitoring neighbor list builds during a run. Note that both these values are also printed with the end-of-run statistics. The *nbuild* keyword is the number of re-builds during the current run. The *ndanger* keyword is the number of re-builds that LAMMPS considered potentially "dangerous". If atom movement triggered neighbor list rebuilding (see the [neigh_modify](#) command), then dangerous reneighborings are those that were triggered on the first timestep atom movement was checked for. If this count is non-zero you may wish to reduce the delay factor to insure no force interactions are missed by atoms moving beyond the neighbor skin distance before a rebuild takes place.

The keywords *cella*, *cellb*, *cellc*, *cellalpha*, *cellbeta*, *cellgamma*, correspond to the usual crystallographic quantities that define the periodic unit cell of a crystal. See [this section](#) of the doc pages for a geometric description of triclinic periodic cells, including a precise definition of these quantities in terms of the internal LAMMPS cell dimensions *lx*, *ly*, *lz*, *yz*, *xz*, *xy*.

For output values from a `compute` or `fix`, the bracketed index *I* used to index a vector, as in `c_ID[I]` or `f_ID[I]`, can be specified using a wildcard asterisk with the index to effectively specify multiple values. This takes the form "*" or "*n" or "n*" or "m*n". If *N* = the size of the vector (for *mode* = scalar) or the number of columns in the array (for *mode* = vector), then an asterisk with no numeric values means all indices from 1 to *N*. A leading asterisk means all indices from 1 to *n* (inclusive). A trailing asterisk means all indices from *n* to *N* (inclusive). A middle asterisk means all indices from *m* to *n* (inclusive).

Using a wildcard is the same as if the individual elements of the vector had been listed one by one. E.g. these 2 `thermo_style` commands are equivalent, since the [compute temp](#) command creates a global vector with 6 values.

```
compute myTemp all temp
thermo_style custom step temp etotal c_myTemp[*]
thermo_style custom step temp etotal &
    c_myTemp[1] c_myTemp[2] c_myTemp[3] &
    c_myTemp[4] c_myTemp[5] c_myTemp[6]
```

The `c_ID` and `c_ID[I]` and `c_ID[I][J]` keywords allow global values calculated by a `compute` to be output. As discussed on the [compute](#) doc page, computes can calculate global, per-atom, or local values. Only global values can be referenced by this command. However, per-atom `compute` values for an individual atom can be

referenced in a [variable](#) and the variable referenced by `thermo_style custom`, as discussed below. See the discussion above for how the `I` in `c_ID[I]` can be specified with a wildcard asterisk to effectively specify multiple values from a global compute vector.

The ID in the keyword should be replaced by the actual ID of a compute that has been defined elsewhere in the input script. See the [compute](#) command for details. If the compute calculates a global scalar, vector, or array, then the keyword formats with 0, 1, or 2 brackets will reference a scalar value from the compute.

Note that some computes calculate "intensive" global quantities like temperature; others calculate "extensive" global quantities like kinetic energy that are summed over all atoms in the compute group. Intensive quantities are printed directly without normalization by `thermo_style custom`. Extensive quantities may be normalized by the total number of atoms in the simulation (NOT the number of atoms in the compute group) when output, depending on the [thermo_modify norm](#) option being used.

The `f_ID` and `f_ID[I]` and `f_ID[I][J]` keywords allow global values calculated by a fix to be output. As discussed on the [fix](#) doc page, fixes can calculate global, per-atom, or local values. Only global values can be referenced by this command. However, per-atom fix values can be referenced for an individual atom in a [variable](#) and the variable referenced by `thermo_style custom`, as discussed below. See the discussion above for how the `I` in `f_ID[I]` can be specified with a wildcard asterisk to effectively specify multiple values from a global fix vector.

The ID in the keyword should be replaced by the actual ID of a fix that has been defined elsewhere in the input script. See the [fix](#) command for details. If the fix calculates a global scalar, vector, or array, then the keyword formats with 0, 1, or 2 brackets will reference a scalar value from the fix.

Note that some fixes calculate "intensive" global quantities like timestep size; others calculate "extensive" global quantities like energy that are summed over all atoms in the fix group. Intensive quantities are printed directly without normalization by `thermo_style custom`. Extensive quantities may be normalized by the total number of atoms in the simulation (NOT the number of atoms in the fix group) when output, depending on the [thermo_modify norm](#) option being used.

The `v_name` keyword allow the current value of a variable to be output. The name in the keyword should be replaced by the variable name that has been defined elsewhere in the input script. Only equal-style and vector-style variables can be referenced; the latter requires a bracketed term to specify the `I`th element of the vector calculated by the variable. However, an atom-style variable can be referenced for an individual atom by an equal-style variable and that variable referenced. See the [variable](#) command for details. Variables of style `equal` and `vector` and `atom` define a formula which can reference per-atom properties or thermodynamic keywords, or they can invoke other computes, fixes, or variables when evaluated, so this is a very general means of creating thermodynamic output.

Note that equal-style and vector-style variables are assumed to produce "intensive" global quantities, which are thus printed as-is, without normalization by `thermo_style custom`. You can include a division by "natoms" in the variable formula if this is not the

case.

thermo_style one

timer command

Syntax:

timer args

- *args* = one or more of *off* or *loop* or *normal* or *full* or *sync* or *nosync* or *timeout* or *every*

off = do not collect or print any timing information
loop = collect only the total time for the simulation loop
normal = collect timer information broken down by sections (default)
full = like *normal* but also include CPU and thread utilization
sync = explicitly synchronize MPI tasks between sections
nosync = do not synchronize MPI tasks between sections (default)
timeout elapse = set walltime limit to *elapse*
every Ncheck = perform timeout check every *Ncheck* steps

Examples:

```
timer full sync
timer timeout 2:00:00 every 100
timer loop
```

Description:

Select the level of detail at which LAMMPS performs its CPU timings. Multiple keywords can be specified with the *timer* command. For keywords that are mutually exclusive, the last one specified takes precedence.

During a simulation run LAMMPS collects information about how much time is spent in different sections of the code and thus can provide information for determining performance and load imbalance problems. This can be done at different levels of detail and accuracy. For more information about the timing output, see this [discussion of screen output in Section 2.7](#).

The *off* setting will turn all time measurements off. The *loop* setting will only measure the total time for a run and not collect any detailed per section information. With the *normal* setting, timing information for portions of the timestep (pairwise calculations, neighbor list construction, output, etc) are collected as well as information about load imbalances for those sections across processors. The *full* setting adds information about CPU utilization and thread utilization, when multi-threading is enabled.

With the *sync* setting, all MPI tasks are synchronized at each timer call which measures load imbalance for each section more accurately, though it can also slow down the simulation by prohibiting overlapping independent computations on different MPI ranks Using the *nosync* setting (which is the default) turns this synchronization off.

LAMMPS Users Manual

With the *timeout* keyword a walltime limit can be imposed, that affects the [run](#) and [minimize](#) commands. This can be convenient when calculations have to comply with execution time limits, e.g. when running under a batch system when you want to maximize the utilization of the batch time slot, especially for runs where the time per timestep varies much and thus it becomes difficult to predict how many steps a simulation can perform for a given walltime limit. This also applies for difficult to converge minimizations. The *timeout* *elapse* value should be somewhat smaller than the maximum wall time requested from the batch system, as there is usually some overhead to launch jobs, and it is advisable to write out a restart after terminating a run due to a timeout.

The *timeout* timer starts when the command is issued. When the time limit is reached, the run or energy minimization will exit on the next step or iteration that is a multiple of the *Ncheck* value which can be set with the *every* keyword. Default is checking every 10 steps. After the timer timeout has expired all subsequent run or minimize commands in the input script will be skipped. The remaining time or timer status can be accessed with the [thermo](#) variable *timeremain*, which will be zero, if the timeout is inactive (default setting), it will be negative, if the timeout time is expired and positive if there is time remaining and in this case the value of the variable are the number of seconds remaining.

When the *timeout* key word is used a second time, the timer is restarted with a new time limit. The *timeout* *elapse* value can be specified as *off* or *unlimited* to impose a no timeout condition (which is the default). The *elapse* setting can be specified as a single number for seconds, two numbers separated by a colon (MM:SS) for minutes and seconds, or as three numbers separated by colons for hours, minutes, and seconds (H:MM:SS).

The *every* keyword sets how frequently during a run or energy minimization the wall clock will be checked. This check count applies to the outer iterations or time steps during minimizations or [r-RESPA runs](#), respectively. Checking for timeout too often, can slow a calculation down. Checking too infrequently can make the timeout measurement less accurate, with the run being stopped later than desired.

NOTE: Using the *full* and *sync* options provides the most detailed and accurate timing information, but can also have a negative performance impact due to the overhead of the many required system calls. It is thus recommended to use these settings only when testing tests to identify performance bottlenecks. For calculations with few atoms or a very large number of processors, even the *normal* setting can have a measurable negative performance impact. In those cases you can just use the *loop* or *off* setting.

LAMMPS Users Manual

```
timer timeout off  
timer every 10
```

timestep command

Syntax:

```
timestep dt
```

- dt = timestep size (time units)

Examples:

```
timestep 2.0
timestep 0.003
```

Description:

Set the timestep size for subsequent molecular dynamics simulations. See the [units](#) command for the time units associated with each choice of units that LAMMPS supports.

The default value for the timestep size also depends on the choice of units for the simulation; see the default values below.

When the [run style](#) is *respa*, dt is the timestep for the outer loop (largest) timestep.

Default: none

units command

Syntax:

```
units style
```

- style = *lj* or *real* or *metal* or *si* or *cgs* or *electron* or *micro* or *nano*

Examples:

```
units metal  
units lj
```

Description:

This command sets the style of units used for a simulation. It determines the units of all quantities specified in the input script and data file, as well as quantities output to the screen, log file, and dump files. Typically, this command is used at the very beginning of an input script.

For all units except *lj*, LAMMPS uses physical constants from www.physics.nist.gov. For the definition of Kcal in real units, LAMMPS uses the thermochemical calorie = 4.184 J.

The choice you make for units simply sets some internal conversion factors within LAMMPS. This means that any simulation you perform for one choice of units can be duplicated with any other unit setting LAMMPS supports. In this context "duplicate" means the particles will have identical trajectories and all output generated by the simulation will be identical. This will be the case for some number of timesteps until round-off effects accumulate, since the conversion factors for two different unit systems are not identical to infinite precision.

To perform the same simulation in a different set of units you must change all the unit-based input parameters in your input script and other input files (data file, potential files, etc) correctly to the new units. And you must correctly convert all output from the new units to the old units when comparing to the original results. That is often not simple to do.

For style *lj*, all quantities are unitless. Without loss of generality, LAMMPS sets the fundamental quantities mass, sigma, epsilon, and the Boltzmann constant = 1. The masses, distances, energies you specify are multiples of these fundamental values. The formulas relating the reduced or unitless quantity (with an asterisk) to the same quantity with units is also given. Thus you can use the mass & sigma & epsilon values for a specific material and convert the results from a unitless LJ simulation into physical quantities.

- mass = mass or m
- distance = sigma, where $x^* = x / \text{sigma}$
- time = tau, where $t^* = t (\text{epsilon} / m / \text{sigma}^2)^{1/2}$

LAMMPS Users Manual

- energy = epsilon, where $E^* = E / \text{epsilon}$
- velocity = sigma/tau, where $v^* = v \text{ tau} / \text{sigma}$
- force = epsilon/sigma, where $f^* = f \text{ sigma} / \text{epsilon}$
- torque = epsilon, where $t^* = t / \text{epsilon}$
- temperature = reduced LJ temperature, where $T^* = T \text{ Kb} / \text{epsilon}$
- pressure = reduced LJ pressure, where $P^* = P \text{ sigma}^3 / \text{epsilon}$
- dynamic viscosity = reduced LJ viscosity, where $\eta^* = \eta \text{ sigma}^3 / \text{epsilon} / \text{tau}$
- charge = reduced LJ charge, where $q^* = q / (4 \text{ pi perm0 sigma epsilon})^{1/2}$
- dipole = reduced LJ dipole, moment where $\mu^* = \mu / (4 \text{ pi perm0 sigma}^3 \text{ epsilon})^{1/2}$
- electric field = force/charge, where $E^* = E (4 \text{ pi perm0 sigma epsilon})^{1/2} \text{ sigma} / \text{epsilon}$
- density = mass/volume, where $\rho^* = \rho \text{ sigma}^{\text{dim}}$

Note that for LJ units, the default mode of thermodynamic output via the [thermo_style](#) command is to normalize all extensive quantities by the number of atoms. E.g. potential energy is extensive because it is summed over atoms, so it is output as energy/atom. Temperature is intensive since it is already normalized by the number of atoms, so it is output as-is. This behavior can be changed via the [thermo_modify norm](#) command.

For style *real*, these are the units:

- mass = grams/mole
- distance = Angstroms
- time = femtoseconds
- energy = Kcal/mole
- velocity = Angstroms/femtosecond
- force = Kcal/mole-Angstrom
- torque = Kcal/mole
- temperature = Kelvin
- pressure = atmospheres
- dynamic viscosity = Poise
- charge = multiple of electron charge (1.0 is a proton)
- dipole = charge*Angstroms
- electric field = volts/Angstrom
- density = gram/cm^{dim}

For style *metal*, these are the units:

- mass = grams/mole
- distance = Angstroms
- time = picoseconds
- energy = eV
- velocity = Angstroms/picosecond
- force = eV/Angstrom
- torque = eV
- temperature = Kelvin
- pressure = bars
- dynamic viscosity = Poise

LAMMPS Users Manual

- charge = multiple of electron charge (1.0 is a proton)
- dipole = charge*Angstroms
- electric field = volts/Angstrom
- density = gram/cm^{dim}

For style *si*, these are the units:

- mass = kilograms
- distance = meters
- time = seconds
- energy = Joules
- velocity = meters/second
- force = Newtons
- torque = Newton-meters
- temperature = Kelvin
- pressure = Pascals
- dynamic viscosity = Pascal*second
- charge = Coulombs (1.6021765e-19 is a proton)
- dipole = Coulombs*meters
- electric field = volts/meter
- density = kilograms/meter^{dim}

For style *cgs*, these are the units:

- mass = grams
- distance = centimeters
- time = seconds
- energy = ergs
- velocity = centimeters/second
- force = dynes
- torque = dyne-centimeters
- temperature = Kelvin
- pressure = dyne/cm² or barye = 1.0e-6 bars
- dynamic viscosity = Poise
- charge = statcoulombs or esu (4.8032044e-10 is a proton)
- dipole = statcoul-cm = 10¹⁸ debye
- electric field = statvolt/cm or dyne/esu
- density = grams/cm^{dim}

For style *electron*, these are the units:

- mass = atomic mass units
- distance = Bohr
- time = femtoseconds
- energy = Hartrees
- velocity = Bohr/atomic time units [1.03275e-15 seconds]
- force = Hartrees/Bohr
- temperature = Kelvin
- pressure = Pascals
- charge = multiple of electron charge (1.0 is a proton)
- dipole moment = Debye

LAMMPS Users Manual

- electric field = volts/cm

For style *micro*, these are the units:

- mass = picograms
- distance = micrometers
- time = microseconds
- energy = picogram-micrometer²/microsecond²
- velocity = micrometers/microsecond
- force = picogram-micrometer/microsecond²
- torque = picogram-micrometer²/microsecond²
- temperature = Kelvin
- pressure = picogram/(micrometer-microsecond²)
- dynamic viscosity = picogram/(micrometer-microsecond)
- charge = picocoulombs (1.6021765e-7 is a proton)
- dipole = picocoulomb-micrometer
- electric field = volt/micrometer
- density = picograms/micrometer^{dim}

For style *nano*, these are the units:

- mass = attograms
- distance = nanometers
- time = nanoseconds
- energy = attogram-nanometer²/nanosecond²
- velocity = nanometers/nanosecond
- force = attogram-nanometer/nanosecond²
- torque = attogram-nanometer²/nanosecond²
- temperature = Kelvin
- pressure = attogram/(nanometer-nanosecond²)
- dynamic viscosity = attogram/(nanometer-nanosecond)
- charge = multiple of electron charge (1.0 is a proton)
- dipole = charge-nanometer
- electric field = volt/nanometer
- density = attograms/nanometer^{dim}

The units command also sets the timestep size and neighbor skin distance to default values for each style:

- For style *lj* these are dt = 0.005 tau and skin = 0.3 sigma.
- For style *real* these are dt = 1.0 fmsec and skin = 2.0 Angstroms.
- For style *metal* these are dt = 0.001 psec and skin = 2.0 Angstroms.
- For style *si* these are dt = 1.0e-8 sec and skin = 0.001 meters.
- For style *cgs* these are dt = 1.0e-8 sec and skin = 0.1 cm.
- For style *electron* these are dt = 0.001 fmsec and skin = 2.0 Bohr.
- For style *micro* these are dt = 2.0 microsec and skin = 0.1 micrometers.
- For style *nano* these are dt = 0.00045 nanosec and skin = 0.1 nanometers.

```

Description:

This command assigns one or more strings to a variable name for evaluation later in the input script or during a simulation.

Variables can thus be useful in several contexts. A variable can be defined and then referenced elsewhere in an input script to become part of a new input command. For variable styles that store multiple strings, the [next](#) command can be used to increment which string is assigned to the variable. Variables of style *equal* store a formula which when evaluated produces a single numeric value which can be output either directly (see the [print](#), [fix print](#), and [run every](#) commands) or as part of thermodynamic output (see the [thermo_style](#) command), or used as input to an averaging fix (see the [fix ave/time](#) command). Variables of style *vector* store a formula which produces a vector of such values which can be used as input to various averaging fixes, or elements of which can be part of thermodynamic output. Variables of style *atom* store a formula which when evaluated produces one numeric value per atom which can be output to a dump file (see the [dump custom](#) command) or used as input to an averaging fix (see the [fix ave/chunk](#) and [fix ave/atom](#) commands). Variables of style *atomfile* can be used anywhere in an input script that atom-style variables are used; they get their per-atom values from a file rather than from a formula. Variables of style *python* can be hooked to Python functions using code you provide, so that the variable gets its value from the evaluation of the Python code. Variables of style *internal* are used by a few commands which set their value directly.

LAMMPS Users Manual

NOTE: As discussed in [Section 3.2](#) of the manual, an input script can use "immediate" variables, specified as \$(formula) with parenthesis, where the formula has the same syntax as equal-style variables described on this page. This is a convenient way to evaluate a formula immediately without using the variable command to define a named variable and then evaluate that variable. See below for a more detailed discussion of this feature.

In the discussion that follows, the "name" of the variable is the arbitrary string that is the 1st argument in the variable command. This name can only contain alphanumeric characters and underscores. The "string" is one or more of the subsequent arguments. The "string" can be simple text as in the 1st example above, it can contain other variables as in the 2nd example, or it can be a formula as in the 3rd example. The "value" is the numeric quantity resulting from evaluation of the string. Note that the same string can generate different values when it is evaluated at different times during a simulation.

NOTE: When an input script line is encountered that defines a variable of style *equal* or *vector* or *atom* or *python* that contains a formula or Python code, the formula is NOT immediately evaluated. It will be evaluated every time when the variable is **used** instead. If you simply want to evaluate a formula in place you can use as so-called. See the section below about "Immediate Evaluation of Variables" for more details on the topic. This is also true of a *format* style variable since it evaluates another variable when it is invoked.

Variables of style *equal* and *vector* and *atom* can be used as inputs to various other commands which evaluate their formulas as needed, e.g. at different timesteps during a [run](#).

Variables of style *internal* can be used in place of an equal-style variable, except by commands that set the value stored by the internal-style variable. Thus any command that states it can use an equal-style variable as an argument, can also use an internal-style variable. This means that when the command evaluates the variable, it will use the value set (internally) by another command.

Variables of style *python* can be used in place of an equal-style variable so long as the associated Python function, as defined by the [python](#) command, returns a numeric value. Thus any command that states it can use an equal-style variable as an argument, can also use such a python-style variable. This means that when the LAMMPS command evaluates the variable, the Python function will be executed.

NOTE: When a variable command is encountered in the input script and the variable name has already been specified, the command is ignored. This means variables can NOT be re-defined in an input script (with two exceptions, read further). This is to allow an input script to be processed multiple times without resetting the variables; see the [jump](#) or [include](#) commands. It also means that using the [command-line switch -var](#) will override a corresponding index variable setting in the input script.

There are two exceptions to this rule. First, variables of style *string*, *getenv*, *internal*, *equal*, *vector*, *atom*, and *python* ARE redefined each time the command is encountered. This allows these style of variables to be redefined multiple times in an input script. In a loop, this means the formula associated with an *equal* or *atom* style

LAMMPS Users Manual

variable can change if it contains a substitution for another variable, e.g. \$x or v_x.

Second, as described below, if a variable is iterated on to the end of its list of strings via the `next` command, it is removed from the list of active variables, and is thus available to be re-defined in a subsequent variable command. The `delete` style does the same thing.

[This section](#) of the manual explains how occurrences of a variable name in an input script line are replaced by the variable's string. The variable name can be referenced as \$x if the name "x" is a single character, or as \${LoopVar} if the name "LoopVar" is one or more characters.

As described below, for variable styles *index*, *loop*, *file*, *universe*, and *uloop*, which string is assigned to a variable can be incremented via the `next` command. When there are no more strings to assign, the variable is exhausted and a flag is set that causes the next `jump` command encountered in the input script to be skipped. This enables the construction of simple loops in the input script that are iterated over and then exited from.

As explained above, an exhausted variable can be re-used in an input script. The `delete` style also removes the variable, the same as if it were exhausted, allowing it to be redefined later in the input script or when the input script is looped over. This can be useful when breaking out of a loop via the `if` and `jump` commands before the variable would become exhausted. For example,

```
label      loop
variable   a loop 5
print      "A = $a"
if         "$a > 2" then "jump in.script break"
next       a
jump       in.script loop
label      break
variable   a delete
```

This section describes how all the various variable styles are defined and what they store. Except for the *equal* and *vector* and *atom* styles, which are explained in the next section.

Many of the styles store one or more strings. Note that a single string can contain spaces (multiple words), if it is enclosed in quotes in the variable command. When the variable is substituted for in another input script command, its returned string will then be interpreted as multiple arguments in the expanded command.

For the *index* style, one or more strings are specified. Initially, the 1st string is assigned to the variable. Each time a `next` command is used with the variable name, the next string is assigned. All processors assign the same string to the variable.

Index style variables with a single string value can also be set by using the command-line switch `-var`; see [this section](#) for details.

The *loop* style is identical to the *index* style except that the strings are the integers from 1 to N inclusive, if only one argument N is specified. This allows generation of a

LAMMPS Users Manual

long list of runs (e.g. 1000) without having to list N strings in the input script. Initially, the string "1" is assigned to the variable. Each time a [next](#) command is used with the variable name, the next string ("2", "3", etc) is assigned. All processors assign the same string to the variable. The *loop* style can also be specified with two arguments N1 and N2. In this case the loop runs from N1 to N2 inclusive, and the string N1 is initially assigned to the variable. $N1 \leq N2$ and $N2 \geq 0$ is required.

For the *world* style, one or more strings are specified. There must be one string for each processor partition or "world". See [this section](#) of the manual for information on running LAMMPS with multiple partitions via the "-partition" command-line switch. This variable command assigns one string to each world. All processors in the world are assigned the same string. The next command cannot be used with *equal* style variables, since there is only one value per world. This style of variable is useful when you wish to run different simulations on different partitions, or when performing a parallel tempering simulation (see the [temper](#) command), to assign different temperatures to different partitions.

For the *universe* style, one or more strings are specified. There must be at least as many strings as there are processor partitions or "worlds". See [this page](#) for information on running LAMMPS with multiple partitions via the "-partition" command-line switch. This variable command initially assigns one string to each world. When a [next](#) command is encountered using this variable, the first processor partition to encounter it, is assigned the next available string. This continues until all the variable strings are consumed. Thus, this command can be used to run 50 simulations on 8 processor partitions. The simulations will be run one after the other on whatever partition becomes available, until they are all finished. *Universe* style variables are incremented using the files "tmp.lammps.variable" and "tmp.lammps.variable.lock" which you will see in your directory during such a LAMMPS run.

The *uloop* style is identical to the *universe* style except that the strings are the integers from 1 to N. This allows generation of long list of runs (e.g. 1000) without having to list N strings in the input script.

For the *string* style, a single string is assigned to the variable. The only difference between this and using the *index* style with a single string is that a variable with *string* style can be redefined. E.g. by another command later in the input script, or if the script is read again in a loop.

For the *format* style, an equal-style variable is specified along with a C-style format string, e.g. "%f" or "%.10g", which must be appropriate for formatting a double-precision floating-point value. This allows an equal-style variable to be formatted specifically for output as a string, e.g. by the [print](#) command, if the default format "%.15g" has too much precision.

For the *getenv* style, a single string is assigned to the variable which should be the name of an environment variable. When the variable is evaluated, it returns the value of the environment variable, or an empty string if it not defined. This style of variable can be used to adapt the behavior of LAMMPS input scripts via environment variable settings, or to retrieve information that has been previously stored with the [shell putenv](#) command. Note that because environment variable settings are stored by the

LAMMPS Users Manual

operating systems, they persist beyond a `clear` command.

For the *file* style, a filename is provided which contains a list of strings to assign to the variable, one per line. The strings can be numeric values if desired. See the discussion of the `next()` function below for equal-style variables, which will convert the string of a file-style variable into a numeric value in a formula.

When a file-style variable is defined, the file is opened and the string on the first line is read and stored with the variable. This means the variable can then be evaluated as many times as desired and will return that string. There are two ways to cause the next string from the file to be read: use the `next` command or the `next()` function in an equal- or atom-style variable, as discussed below.

The rules for formatting the file are as follows. A comment character "#" can be used anywhere on a line; text starting with the comment character is stripped. Blank lines are skipped. The first "word" of a non-blank line, delimited by white space, is the "string" assigned to the variable.

For the *atomfile* style, a filename is provided which contains one or more sets of values, to assign on a per-atom basis to the variable. The format of the file is described below.

When an atomfile-style variable is defined, the file is opened and the first set of per-atom values are read and stored with the variable. This means the variable can then be evaluated as many times as desired and will return those values. There are two ways to cause the next set of per-atom values from the file to be read: use the `next` command or the `next()` function in an atom-style variable, as discussed below.

The rules for formatting the file are as follows. Each time a set of per-atom values is read, a non-blank line is searched for in the file. A comment character "#" can be used anywhere on a line; text starting with the comment character is stripped. Blank lines are skipped. The first "word" of a non-blank line, delimited by white space, is read as the count N of per-atom lines to immediately follow. N can be the total number of atoms in the system, or only a subset. The next N lines have the following format

```
ID value
```

where ID is an atom ID and value is the per-atom numeric value that will be assigned to that atom. IDs can be listed in any order.

NOTE: Every time a set of per-atom lines is read, the value for all atoms is first set to 0.0. Thus values for atoms whose ID does not appear in the set, will remain 0.0.

For the *python* style a Python function name is provided. This needs to match a function name specified in a `python` command which returns a value to this variable as defined by its `return` keyword. For example these two commands would be self-consistent:

```
variable foo python myMultiply
python myMultiply return v_foo format f file funcs.py
```

LAMMPS Users Manual

The two commands can appear in either order so long as both are specified before the Python function is invoked for the first time.

Each time the variable is evaluated, the associated Python function is invoked, and the value it returns is also returned by the variable. Since the Python function can use other LAMMPS variables as input, or query internal LAMMPS quantities to perform its computation, this means the variable can return a different value each time it is evaluated.

The type of value stored in the variable is determined by the *format* keyword of the `python` command. It can be an integer (i), floating point (f), or string (s) value. As mentioned above, if it is a numeric value (integer or floating point), then the python-style variable can be used in place of an equal-style variable anywhere in an input script, e.g. as an argument to another command that allows for equal-style variables.

For the *internal* style a numeric value is provided. This value will be assigned to the variable until a LAMMPS command sets it to a new value. There are currently only two LAMMPS commands that require *internal* variables as inputs, because they reset them: `create_atoms` and `fix controller`. As mentioned above, an internal-style variable can be used in place of an equal-style variable anywhere else in an input script, e.g. as an argument to another command that allows for equal-style variables.

For the *equal* and *vector* and *atom* styles, a single string is specified which represents a formula that will be evaluated afresh each time the variable is used. If you want spaces in the string, enclose it in double quotes so the parser will treat it as a single argument. For *equal*-style variables the formula computes a scalar quantity, which becomes the value of the variable whenever it is evaluated. For *vector*-style variables the formula must compute a vector of quantities, which becomes the value of the variable whenever it is evaluated. The calculated vector can be on length one, but it cannot be a simple scalar value like that produced by an equal-style compute. I.e. the formula for a vector-style variable must have at least one quantity in it that refers to a global vector produced by a compute, fix, or other vector-style variable. For *atom*-style variables the formula computes one quantity for each atom whenever it is evaluated.

Note that *equal*, *vector*, and *atom* variables can produce different values at different stages of the input script or at different times during a run. For example, if an *equal* variable is used in a `fix print` command, different values could be printed each timestep it was invoked. If you want a variable to be evaluated immediately, so that the result is stored by the variable instead of the string, see the section below on "Immediate Evaluation of Variables".

The next command cannot be used with *equal* or *vector* or *atom* style variables, since there is only one string.

The formula for an *equal*, *vector*, or *atom* variable can contain a variety of quantities. The syntax for each kind of quantity is simple, but multiple quantities can be nested and combined in various ways to build up formulas of arbitrary complexity. For example, this is a valid (though strange) variable formula:

```
variable x equal "pe + c_MyTemp / vol^(1/3)"
```

LAMMPS Users Manual

Specifically, a formula can contain numbers, constants, thermo keywords, math operators, math functions, group functions, region functions, atom values, atom vectors, compute references, fix references, and references to other variables.

Number	0.2, 100, 1.0e20, -15.4, etc
Constant	PI, version, on, off, true, false, yes, no
Thermo keywords	vol, pe, ebond, etc
Math operators	(), -x, x+y, x-y, x*y, x/y, x^y, x%y, x == y, x != y, x < y, x <= y, x > y, x >= y, x && y, x y, x ^ y, !x
Math functions	sqrt(x), exp(x), ln(x), log(x), abs(x), sin(x), cos(x), tan(x), asin(x), acos(x), atan(x), atan2(y,x), random(x,y,z), normal(x,y,z), ceil(x), floor(x), round(x), ramp(x,y), stagger(x,y), logfreq(x,y,z), logfreq2(x,y,z), stride(x,y,z), stride2(x,y,z,a,b,c), vdisplace(x,y), swiggle(x,y,z), cwiggle(x,y,z)
Group functions	count(ID), mass(ID), charge(ID), xcm(ID,dim), vcm(ID,dim), fcm(ID,dim), bound(ID,dir), gyration(ID), ke(ID), angmom(ID,dim), torque(ID,dim), inertia(ID,dimdim), omega(ID,dim)
Region functions	count(ID,IDR), mass(ID,IDR), charge(ID,IDR), xcm(ID,dim,IDR), vcm(ID,dim,IDR), fcm(ID,dim,IDR), bound(ID,dir,IDR), gyration(ID,IDR), ke(ID,IDR), angmom(ID,dim,IDR), torque(ID,dim,IDR), inertia(ID,dimdim,IDR), omega(ID,dim,IDR)
Special functions	sum(x), min(x), max(x), ave(x), trap(x), slope(x), gmask(x), rmask(x), grmask(x,y), next(x)
Atom values	id[i], mass[i], type[i], mol[i], x[i], y[i], z[i], vx[i], vy[i], vz[i], fx[i], fy[i], fz[i], q[i]
Atom vectors	id, mass, type, mol, x, y, z, vx, vy, vz, fx, fy, fz, q
Compute references	c_ID, c_ID[i], c_ID[i][j], C_ID, C_ID[i]
Fix references	f_ID, f_ID[i], f_ID[i][j], F_ID, F_ID[i]
Other variables	v_name, v_name[i]

Most of the formula elements produce a scalar value. Some produce a global or per-atom vector of values. Global vectors can be produced by computes or fixes or by other vector-style variables. Per-atom vectors are produced by atom vectors, compute references that represent a per-atom vector, fix references that represent a per-atom vector, and variables that are atom-style variables. Math functions that operate on scalar values produce a scalar value; math function that operate on global or per-atom vectors do so element-by-element and produce a global or per-atom vector.

A formula for equal-style variables cannot use any formula element that produces a global or per-atom vector. A formula for a vector-style variable can use formula elements that produce either a scalar value or a global vector value, but cannot use a formula element that produces a per-atom vector. A formula for an atom-style variable can use formula elements that produce either a scalar value or a per-atom vector, but not one that produces a global vector. Atom-style variables are evaluated by other

LAMMPS Users Manual

commands that define a [group](#) on which they operate, e.g. a [dump](#) or [compute](#) or [fix](#) command. When they invoke the atom-style variable, only atoms in the group are included in the formula evaluation. The variable evaluates to 0.0 for atoms not in the group.

Numbers, constants, and thermo keywords

Numbers can contain digits, scientific notation (3.0e20,3.0e-20,3.0E20,3.0E-20), and leading minus signs.

Constants are set at compile time and cannot be changed. *PI* will return the number 3.14159265358979323846; *on*, *true* or *yes* will return 1.0; *off*, *false* or *no* will return 0.0; *version* will return a numeric version code of the current LAMMPS version (e.g. version 2 Sep 2015 will return the number 20150902). The corresponding value for newer versions of LAMMPS will be larger, for older versions of LAMMPS will be smaller. This can be used to have input scripts adapt automatically to LAMMPS versions, when non-backwards compatible syntax changes are introduced. Here is an illustrative example (which will not work, since the *version* has been introduced more recently):

```
if $(version
```

The thermo keywords allowed in a formula are those defined by the [thermo_style custom](#) command. Thermo keywords that require a [compute](#) to calculate their values such as "temp" or "press", use computes stored and invoked by the [thermo_style](#) command. This means that you can only use those keywords in a variable if the style you are using with the [thermo_style](#) command (and the thermo keywords associated with that style) also define and use the needed compute. Note that some thermo keywords use a compute indirectly to calculate their value (e.g. the enthalpy keyword uses temp, pe, and pressure). If a variable is evaluated directly in an input script (not during a run), then the values accessed by the thermo keyword must be current. See the discussion below about "Variable Accuracy".

Math Operators

Math operators are written in the usual way, where the "x" and "y" in the examples can themselves be arbitrarily complex formulas, as in the examples above. In this syntax, "x" and "y" can be scalar values or per-atom vectors. For example, "ke/natoms" is the division of two scalars, where "vy+vz" is the element-by-element sum of two per-atom vectors of y and z velocities.

Operators are evaluated left to right and have the usual C-style precedence: unary minus and unary logical NOT operator "!" have the highest precedence, exponentiation "^" is next; multiplication and division and the modulo operator "%" are next; addition and subtraction are next; the 4 relational operators "", and ">=" are next; the two remaining relational operators "==" and "!=" are next; then the logical AND operator "&&"; and finally the logical OR operator "||" and logical XOR (exclusive or) operator "|^" have the lowest precedence. Parenthesis can be used to group one or more portions of a formula and/or enforce a different order of evaluation than what would occur with the default precedence.

NOTE: Because a unary minus is higher precedence than exponentiation, the formula -2^2 will evaluate to 4, not -4. This convention is compatible with some programming languages, but not others. As mentioned, this behavior can be easily overridden with parenthesis; the formula $-(2^2)$ will evaluate to -4.

The 6 relational operators return either a 1.0 or 0.0 depending on whether the relationship between x and y is TRUE or FALSE. For example the expression x

These relational and logical operators can be used as a masking or selection operation in a formula. For example, the number of atoms whose properties satisfy one or more criteria could be calculated by taking the returned per-atom vector of ones and zeroes and passing it to the `compute reduce` command.

Math Functions

Math functions are specified as keywords followed by one or more parenthesized arguments "x", "y", "z", each of which can themselves be arbitrarily complex formulas. In this syntax, the arguments can represent scalar values or global vectors or per-atom vectors. In the latter case, the math operation is performed on each element of the vector. For example, `sqrt(natoms)` is the `sqrt()` of a scalar, where `sqrt(y*z)` yields a per-atom vector with each element being the `sqrt()` of the product of one atom's y and z coordinates.

Most of the math functions perform obvious operations. The `ln()` is the natural log; `log()` is the base 10 log.

The `random(x,y,z)` function takes 3 arguments: x = lo, y = hi, and z = seed. It generates a uniform random number between lo and hi. The `normal(x,y,z)` function also takes 3 arguments: x = mu, y = sigma, and z = seed. It generates a Gaussian variate centered on mu with variance σ^2 . In both cases the seed is used the first time the internal random number generator is invoked, to initialize it. For equal-style and vector-style variables, every processor uses the same seed so that they each generate the same sequence of random numbers. For atom-style variables, a unique seed is created for each processor, based on the specified seed. This effectively generates a different random number for each atom being looped over in the atom-style variable.

NOTE: Internally, there is just one random number generator for all equal-style and vector-style variables and another one for all atom-style variables. If you define multiple variables (of each style) which use the `random()` or `normal()` math functions, then the internal random number generators will only be initialized once, which means only one of the specified seeds will determine the sequence of generated random numbers.

The `ceil()`, `floor()`, and `round()` functions are those in the C math library. `Ceil()` is the smallest integer not less than its argument. `Floor()` is the largest integer not greater than its argument. `Round()` is the nearest integer to its argument.

The `ramp(x,y)` function uses the current timestep to generate a value linearly interpolated between the specified x,y values over the course of a run, according to this formula:

LAMMPS Users Manual

$\text{value} = x + (y-x) * (\text{timestep}-\text{startstep}) / (\text{stopstep}-\text{startstep})$

The run begins on *startstep* and ends on *stopstep*. *Startstep* and *stopstep* can span multiple runs, using the *start* and *stop* keywords of the [run](#) command. See the [run](#) command for details of how to do this.

The [stagger\(x,y\)](#) function uses the current timestep to generate a new timestep. $X, y > 0$ and $x > y$ are required. The generated timesteps increase in a staggered fashion, as the sequence $x, x+y, 2x, 2x+y, 3x, 3x+y, \text{etc.}$ For any current timestep, the next timestep in the sequence is returned. Thus if [stagger\(1000,100\)](#) is used in a variable by the [dump_modify every](#) command, it will generate the sequence of output timesteps:

100, 1000, 1100, 2000, 2100, 3000, etc

The [logfreq\(x,y,z\)](#) function uses the current timestep to generate a new timestep. $X, y, z > 0$ and $y < z$ are required. The generated timesteps are on a base- z logarithmic scale, starting with x , and the y value is how many of the $z-1$ possible timesteps within one logarithmic interval are generated. I.e. the timesteps follow the sequence $x, 2x, 3x, \dots, y*x, x*z, 2x*z, 3x*z, \dots, y*x*z, x*z^2, 2x*z^2, \text{etc.}$ For any current timestep, the next timestep in the sequence is returned. Thus if [logfreq\(100,4,10\)](#) is used in a variable by the [dump_modify every](#) command, it will generate this sequence of output timesteps:

100, 200, 300, 400, 1000, 2000, 3000, 4000, 10000, 20000, etc

The [logfreq2\(x,y,z\)](#) function is similar to [logfreq](#), except a single logarithmic interval is divided into y equally-spaced timesteps and all of them are output. $Y < z$ is not required. Thus, if [logfreq2\(100,18,10\)](#) is used in a variable by the [dump_modify every](#) command, then the interval between 100 and 1000 is divided as $900/18 = 50$ steps, and it will generate the sequence of output timesteps:

100, 150, 200, . . . 950, 1000, 1500, 2000, . . . 9500, 10000, 15000, etc

The [stride\(x,y,z\)](#) function uses the current timestep to generate a new timestep. $X, y \geq 0$ and $z > 0$ and $x \leq y$ are required. The generated timesteps increase in increments of z , from x to y , i.e. it generates the sequence $x, x+z, x+2z, \dots, y$. If $y-x$ is not a multiple of z , then similar to the way a for loop operates, the last value will be one that does not exceed y . For any current timestep, the next timestep in the sequence is returned. Thus if [stride\(1000,2000,100\)](#) is used in a variable by the [dump_modify every](#) command, it will generate the sequence of output timesteps:

1000, 1100, 1200, . . . , 1900, 2000

The [stride2\(x,y,z,a,b,c\)](#) function is similar to the [stride\(\)](#) function except it generates two sets of strided timesteps, one at a coarser level and one at a finer level. Thus it is useful for debugging, e.g. to produce output every timestep at the point in simulation when a problem occurs. $X, y \geq 0$ and $z > 0$ and $x \leq y$ are required, as are $a, b \geq 0$ and $c > 0$ and $a < b$. Also, $a \geq x$ and $b \leq y$ are required so that the second stride is inside the first. The generated timesteps increase in increments of z , starting at x , until a is reached. At that point the timestep increases in increments of c , from a to b , then after b , increments by z are resumed until y is reached. For any current timestep, the next timestep in the sequence is returned. Thus if

LAMMPS Users Manual

`stride2(1000,2000,100,1350,1360,1)` is used in a variable by the `dump_modify every` command, it will generate the sequence of output timesteps:

```
1000,1100,1200,1300,1350,1351,1352, ... 1359,1360,1400,1500, ... ,2000
```

The `vdisplace(x,y)` function takes 2 arguments: $x = \text{value0}$ and $y = \text{velocity}$, and uses the elapsed time to change the value by a linear displacement due to the applied velocity over the course of a run, according to this formula:

$$\text{value} = \text{value0} + \text{velocity} * (\text{timestep} - \text{startstep}) * \text{dt}$$

where $\text{dt} = \text{the timestep size}$.

The run begins on `startstep`. `Startstep` can span multiple runs, using the `start` keyword of the `run` command. See the `run` command for details of how to do this. Note that the `thermo_style` keyword `elaplong = timestep-startstep`.

The `swiggle(x,y,z)` and `cwiggle(x,y,z)` functions each take 3 arguments: $x = \text{value0}$, $y = \text{amplitude}$, $z = \text{period}$. They use the elapsed time to oscillate the value by a `sin()` or `cos()` function over the course of a run, according to one of these formulas, where $\omega = 2 \text{ PI} / \text{period}$:

$$\begin{aligned} \text{value} &= \text{value0} + \text{Amplitude} * \sin(\omega * (\text{timestep} - \text{startstep}) * \text{dt}) \\ \text{value} &= \text{value0} + \text{Amplitude} * (1 - \cos(\omega * (\text{timestep} - \text{startstep}) * \text{dt})) \end{aligned}$$

where $\text{dt} = \text{the timestep size}$.

The run begins on `startstep`. `Startstep` can span multiple runs, using the `start` keyword of the `run` command. See the `run` command for details of how to do this. Note that the `thermo_style` keyword `elaplong = timestep-startstep`.

Group and Region Functions

Group functions are specified as keywords followed by one or two parenthesized arguments. The first argument *ID* is the group-ID. The *dim* argument, if it exists, is x or y or z . The *dir* argument, if it exists, is *xmin*, *xmax*, *ymin*, *ymax*, *zmin*, or *zmax*. The *dimdim* argument, if it exists, is *xx* or *yy* or *zz* or *xy* or *yz* or *xz*.

The group function `count()` is the number of atoms in the group. The group functions `mass()` and `charge()` are the total mass and charge of the group. `Xcm()` and `vcm()` return components of the position and velocity of the center of mass of the group. `Fcm()` returns a component of the total force on the group of atoms. `Bound()` returns the min/max of a particular coordinate for all atoms in the group. `Gyration()` computes the radius-of-gyration of the group of atoms. See the `compute gyration` command for a definition of the formula. `Angmom()` returns components of the angular momentum of the group of atoms around its center of mass. `Torque()` returns components of the torque on the group of atoms around its center of mass, based on current forces on the atoms. `Inertia()` returns one of 6 components of the symmetric inertia tensor of the group of atoms around its center of mass, ordered as *Ixx*, *Iyy*, *Izz*, *Ixy*, *Iyz*, *Ixz*. `Omega()` returns components of the angular velocity of the group of atoms around its center of mass.

Region functions are specified exactly the same way as group functions except they take an extra final argument *IDR* which is the region ID. The function is computed for all atoms that are in both the group and the region. If the group is "all", then the only criteria for atom inclusion is that it be in the region.

Special Functions

Special functions take specific kinds of arguments, meaning their arguments cannot be formulas themselves.

The `sum(x)`, `min(x)`, `max(x)`, `ave(x)`, `trap(x)`, and `slope(x)` functions each take 1 argument which is of the form "c_ID" or "c_ID[N]" or "f_ID" or "f_ID[N]" or "v_name". The first two are computes and the second two are fixes; the ID in the reference should be replaced by the ID of a compute or fix defined elsewhere in the input script. The compute or fix must produce either a global vector or array. If it produces a global vector, then the notation without "[N]" should be used. If it produces a global array, then the notation with "[N]" should be used, when N is an integer, to specify which column of the global array is being referenced. The last form of argument "v_name" is for a vector-style variable where "name" is replaced by the name of the variable.

These functions operate on a global vector of inputs and reduce it to a single scalar value. This is analogous to the operation of the `compute reduce` command, which performs similar operations on per-atom and local vectors.

The `sum()` function calculates the sum of all the vector elements. The `min()` and `max()` functions find the minimum and maximum element respectively. The `ave()` function is the same as `sum()` except that it divides the result by the length of the vector.

The `trap()` function is the same as `sum()` except the first and last elements are multiplied by a weighting factor of 1/2 when performing the sum. This effectively implements an integration via the trapezoidal rule on the global vector of data. I.e. consider a set of points, equally spaced by 1 in their x coordinate: (1,V1), (2,V2), ..., (N,VN), where the V_i are the values in the global vector of length N. The integral from 1 to N of these points is `trap()`. When appropriately normalized by the timestep size, this function is useful for calculating integrals of time-series data, like that generated by the `fix ave/correlate` command.

The `slope()` function uses linear regression to fit a line to the set of points, equally spaced by 1 in their x coordinate: (1,V1), (2,V2), ..., (N,VN), where the V_i are the values in the global vector of length N. The returned value is the slope of the line. If the line has a single point or is vertical, it returns 1.0e20.

The `gmask(x)` function takes 1 argument which is a group ID. It can only be used in atom-style variables. It returns a 1 for atoms that are in the group, and a 0 for atoms that are not.

The `rmask(x)` function takes 1 argument which is a region ID. It can only be used in atom-style variables. It returns a 1 for atoms that are in the geometric region, and a 0 for atoms that are not.

LAMMPS Users Manual

The `grmask(x,y)` function takes 2 arguments. The first is a group ID, and the second is a region ID. It can only be used in atom-style variables. It returns a 1 for atoms that are in both the group and region, and a 0 for atoms that are not in both.

The `next(x)` function takes 1 argument which is a variable ID (not "v_foo", just "foo"). It must be for a file-style or atomfile-style variable. Each time the `next()` function is invoked (i.e. each time the equal-style or atom-style variable is evaluated), the following steps occur.

For file-style variables, the current string value stored by the file-style variable is converted to a numeric value and returned by the function. And the next string value in the file is read and stored. Note that if the line previously read from the file was not a numeric string, then it will typically evaluate to 0.0, which is likely not what you want.

For atomfile-style variables, the current per-atom values stored by the atomfile-style variable are returned by the function. And the next set of per-atom values in the file is read and stored.

Since file-style and atomfile-style variables read and store the first line of the file or first set of per-atoms values when they are defined in the input script, these are the value(s) that will be returned the first time the `next()` function is invoked. If `next()` is invoked more times than there are lines or sets of lines in the file, the variable is deleted, similar to how the `next` command operates.

Feature Functions

Feature functions allow to probe the running LAMMPS executable for whether specific features are either active, defined, or available. The functions take two arguments, a *category* and a corresponding *argument*. The arguments are strings thus cannot be formulas themselves (only \$-style immediate variable expansion is possible). Return value is either 1.0 or 0.0 depending on whether the function evaluates to true or false, respectively.

The `is_active()` function allows to query for active settings which are grouped by categories. Currently supported categories and arguments are:

- *package* (argument = *cuda* or *gpu* or *intel* or *kokkos* or *omp*)
- *newton* (argument = *pair* or *bond* or *any*)
- *pair* (argument = *single* or *respa* or *manybody* or *tail* or *shift*)
- *comm_style* (argument = *brick* or *tiled*)
- *min_style* (argument = any of the compiled in minimizer styles)
- *run_style* (argument = any of the compiled in run styles)
- *atom_style* (argument = any of the compiled in atom styles)
- *pair_style* (argument = any of the compiled in pair styles)
- *bond_style* (argument = any of the compiled in bond styles)
- *angle_style* (argument = any of the compiled in angle styles)
- *dihedral_style* (argument = any of the compiled in dihedral styles)
- *improper_style* (argument = any of the compiled in improper styles)
- *kspace_style* (argument = any of the compiled in kspace styles)

LAMMPS Users Manual

Most of the settings are self-explanatory, the *single* argument in the *pair* category allows to check whether a pair style supports a `Pair::single()` function as needed by `compute group/group` and others features or LAMMPS, *respa* allows to check whether the inner/middle/outer mode of r-RESPA is supported. In the various style categories, the checking is also done using suffix flags, if available and enabled.

Example 1: disable use of suffix for `pppm` when using GPU package (i.e. run it on the CPU concurrently to running the pair style on the GPU), but do use the suffix otherwise (e.g. with `USER-OMP`).

```
pair_style lj/cut/coul/long 14.0
if $(is_active(package,gpu)) then "suffix off"
kspace_style pppm
```

Example 2: use r-RESPA with inner/outer cutoff, if supported by pair style, otherwise fall back to using pair and reducing the outer time step

```
timestep $(2.0*(1.0+is_active(pair,respa)))
if $(is_active(pair,respa)) then "run_style respa 4 3 2 2 improper 1 inner 2 5.5 7.0 outer 3 1"
```

The `is_defined()` function allows to query categories like *compute*, *dump*, *fix*, *group*, *region*, and *variable* whether an entry with the provided name or id is defined.

The `is_available(category,name)` function allows to query whether a specific optional feature is available, i.e. compiled in. This currently works for the following categories: *command*, *compute*, *fix*, *pair_style* and *feature*. For all categories except *command* and *feature* also appending active suffixes is tried before reporting failure.

The *feature* category is used to check the availability of compiled in features such as GZIP support, PNG support, JPEG support, FFMPEG support, and C++ exceptions for error handling. Corresponding values for name are *gzip*, *png*, *jpeg*, *ffmpeg* and *exceptions*.

This enables writing input scripts which only dump using a given format if the compiled binary supports it.

```
if "$(is_available(feature,png))" then "print 'PNG supported'" else "print 'PNG not supported'"
```

```
if "$(is_available(feature,ffmpeg))" then "dump 3 all movie 25 movie.mp4 type type zoom 1.6 adia"
```

Atom Values and Vectors

Atom values take an integer argument *I* from 1 to *N*, where *I* is the atom-ID, e.g. `x[243]`, which means use the *x* coordinate of the atom with ID = 243. Or they can take a variable name, specified as `v_name`, where name is the name of the variable, like `x[v_myIndex]`. The variable can be of any style except *vector* or *atom* or *atomfile* variables. The variable is evaluated and the result is expected to be numeric and is cast to an integer (i.e. 3.4 becomes 3), to use as an index, which must be a value from 1 to *N*. Note that a "formula" cannot be used as the argument between the brackets, e.g. `x[243+10]` or `x[v_myIndex+1]` are not allowed. To do this a single variable can be defined that contains the needed formula.

LAMMPS Users Manual

Note that the $0 < \text{atom-ID} \leq N$, where N is the largest atom ID in the system. If an ID is specified for an atom that does not currently exist, then the generated value is 0.0.

Atom vectors generate one value per atom, so that a reference like "vx" means the x-component of each atom's velocity will be used when evaluating the variable.

The meaning of the different atom values and vectors is mostly self-explanatory. *Mol* refers to the molecule ID of an atom, and is only defined if an [atom_style](#) is being used that defines molecule IDs.

Note that many other atom attributes can be used as inputs to a variable by using the [compute property/atom](#) command and then specifying a quantity from that compute.

Compute References

Compute references access quantities calculated by a [compute](#). The ID in the reference should be replaced by the ID of a compute defined elsewhere in the input script. As discussed in the doc page for the [compute](#) command, computes can produce global, per-atom, or local values. Only global and per-atom values can be used in a variable. Computes can also produce a scalar, vector, or array.

An equal-style variable can only use scalar values, which means a global scalar, or an element of a global or per-atom vector or array. A vector-style variable can use scalar values or a global vector of values, or a column of a global array of values. Atom-style variables can use global scalar values. They can also use per-atom vector values, or a column of a per-atom array. See the doc pages for individual computes to see what kind of values they produce.

Examples of different kinds of compute references are as follows. There is typically no ambiguity (see exception below) as to what a reference means, since computes only produce either global or per-atom quantities, never both.

c_ID	global scalar, or per-atom vector
c_ID[I]	Ith element of global vector, or atom I's value in per-atom vector, or Ith column from per-atom array
c_ID[I][J]	I,J element of global array, or atom I's Jth value in per-atom array

For I and J indices, integers can be specified or a variable name, specified as *v_name*, where name is the name of the variable. The rules for this syntax are the same as for the "Atom Values and Vectors" discussion above.

One source of ambiguity for compute references is when a vector-style variable refers to a compute that produces both a global scalar and a global vector. Consider a compute with ID "foo" that does this, referenced as follows by variable "a", where "myVec" is another vector-style variable:

```
variable a vector c_foo*v_myVec
```

The reference "c_foo" could refer to either the global scalar or global vector produced by compute "foo". In this case, "c_foo" will always refer to the global scalar, and

"C_foo" can be used to reference the global vector. Similarly if the compute produces both a global vector and global array, then "c_foo[I]" will always refer to an element of the global vector, and "C_foo[I]" can be used to reference the Ith column of the global array.

Note that if a variable containing a compute is evaluated directly in an input script (not during a run), then the values accessed by the compute must be current. See the discussion below about "Variable Accuracy".

Fix References

Fix references access quantities calculated by a [fix](#). The ID in the reference should be replaced by the ID of a fix defined elsewhere in the input script. As discussed in the doc page for the [fix](#) command, fixes can produce global, per-atom, or local values. Only global and per-atom values can be used in a variable. Fixes can also produce a scalar, vector, or array. An equal-style variable can only use scalar values, which means a global scalar, or an element of a global or per-atom vector or array. Atom-style variables can use the same scalar values. They can also use per-atom vector values. A vector value can be a per-atom vector itself, or a column of an per-atom array. See the doc pages for individual fixes to see what kind of values they produce.

The different kinds of fix references are exactly the same as the compute references listed in the above table, where "c_" is replaced by "f_". Again, there is typically no ambiguity (see exception below) as to what a reference means, since fixes only produce either global or per-atom quantities, never both.

f ID	global scalar, or per-atom vector
f_ID[I]	Ith element of global vector, or atom I's value in per-atom vector, or Ith column from per-atom array
f_ID[I][J]	I,J element of global array, or atom I's Jth value in per-atom array

For I and J indices, integers can be specified or a variable name, specified as v_name, where name is the name of the variable. The rules for this syntax are the same as for the "Atom Values and Vectors" discussion above.

One source of ambiguity for fix references is the same ambiguity discussed for compute references above. Namely when a vector-style variable refers to a fix that produces both a global scalar and a global vector. The solution is the same as for compute references. For a fix with ID "foo", "f_foo" will always refer to the global scalar, and "F_foo" can be used to reference the global vector. And similarly for distinguishing between a fix's global vector versus global array with "f_foo[I]" versus "F_foo[I]".

Note that if a variable containing a fix is evaluated directly in an input script (not during a run), then the values accessed by the fix should be current. See the discussion below about "Variable Accuracy".

Note that some fixes only generate quantities on certain timesteps. If a variable attempts to access the fix on non-allowed timesteps, an error is generated. For example, the [fix ave/time](#) command may only generate averaged quantities every 100

steps. See the doc pages for individual fix commands for details.

Variable References

Variable references access quantities stored or calculated by other variables, which will cause those variables to be evaluated. The name in the reference should be replaced by the name of a variable defined elsewhere in the input script.

As discussed on this doc page, equal-style variables generate a single global numeric value, vector-style variables generate a vector of global numeric values, and atom-style and atomfile-style variables generate a per-atom vector of numeric values. All other variables store one or more strings.

The formula for an equal-style variable can use any style of variable including a vector_style or atom-style or atomfile-style. For these 3 styles, a subscript must be used to access a single value from the vector-, atom-, or atomfile-style variable. If a string-storing variable is used, the string is converted to a numeric value. Note that this will typically produce a 0.0 if the string is not a numeric string, which is likely not what you want.

The formula for a vector-style variable can use any style of variable, including atom-style or atomfile-style variables. For these 2 styles, a subscript must be used to access a single value from the atom-, or atomfile-style variable.

The formula for an atom-style variable can use any style of variable, including other atom-style or atomfile-style variables. If it uses a vector-style variable, a subscript must be used to access a single value from the vector-style variable.

Examples of different kinds of variable references are as follows. There is no ambiguity as to what a reference means, since variables produce only a global scalar or global vector or per-atom vector.

v_name	global scalar from equal-style variable
v_name	global vector from vector-style variable
v_name	per-atom vector from atom-style or atomfile-style variable
v_name[I]	Ith element of a global vector from vector-style variable
v_name[I]	value of atom with ID = I from atom-style or atomfile-style variable

For the I index, an integer can be specified or a variable name, specified as v_name, where name is the name of the variable. The rules for this syntax are the same as for the "Atom Values and Vectors" discussion above.

Immediate Evaluation of Variables:

If you want an equal-style variable to be evaluated immediately, it may be the case that you do not need to define a variable at all. See [Section 3.2](#) of the manual, which describes the use of "immediate" variables in an input script, specified as \$(formula) with parenthesis, where the formula has the same syntax as equal-style variables described on this page. This effectively evaluates a formula immediately without using the variable command to define a named variable.

LAMMPS Users Manual

More generally, there is a difference between referencing a variable with a leading \$ sign (e.g. \$x or \${abc}) versus with a leading "v_" (e.g. v_x or v_abc). The former can be used in any input script command, including a variable command. The input script parser evaluates the reference variable immediately and substitutes its value into the command. As explained in [Section 3.2](#) for "Parsing rules", you can also use un-named "immediate" variables for this purpose. For example, a string like this $((x_{lo}+x_{hi})/2+\sqrt{v_{area}})$ in an input script command evaluates the string between the parenthesis as an equal-style variable formula.

Referencing a variable with a leading "v_" is an optional or required kind of argument for some commands (e.g. the [fix ave/chunk](#) or [dump custom](#) or [thermo_style](#) commands) if you wish it to evaluate a variable periodically during a run. It can also be used in a variable formula if you wish to reference a second variable. The second variable will be evaluated whenever the first variable is evaluated.

As an example, suppose you use this command in your input script to define the variable "v" as

```
variable v equal vol
```

before a run where the simulation box size changes. You might think this will assign the initial volume to the variable "v". That is not the case. Rather it assigns a formula which evaluates the volume (using the [thermo_style](#) keyword "vol") to the variable "v". If you use the variable "v" in some other command like [fix ave/time](#) then the current volume of the box will be evaluated continuously during the run.

If you want to store the initial volume of the system, you can do it this way:

```
variable v equal vol
variable v0 equal $v
```

The second command will force "v" to be evaluated (yielding the initial volume) and assign that value to the variable "v0". Thus the command

```
thermo_style custom step v_v v_v0
```

would print out both the current and initial volume periodically during the run.

Note that it is a mistake to enclose a variable formula in double quotes if it contains variables preceded by \$ signs. For example,

```
variable vratio equal "${vfinal}/${v0}"
```

This is because the quotes prevent variable substitution (see [this section](#) on parsing input script commands), and thus an error will occur when the formula for "vratio" is evaluated later.

Variable Accuracy:

Obviously, LAMMPS attempts to evaluate variables containing formulas (*equal* and *atom* style variables) accurately whenever the evaluation is performed. Depending on

LAMMPS Users Manual

what is included in the formula, this may require invoking a `compute`, either directly or indirectly via a thermo keyword, or accessing a value previously calculated by a `compute`, or accessing a value calculated and stored by a `fix`. If the `compute` is one that calculates the pressure or energy of the system, then these quantities need to be tallied during the evaluation of the interatomic potentials (pair, bond, etc) on timesteps that the variable will need the values.

LAMMPS keeps track of all of this during a `run` or `energy minimization`. An error will be generated if you attempt to evaluate a variable on timesteps when it cannot produce accurate values. For example, if a `thermo_style custom` command prints a variable which accesses values stored by a `fix ave/time` command and the timesteps on which thermo output is generated are not multiples of the averaging frequency used in the `fix` command, then an error will occur.

An input script can also request variables be evaluated before or after or in between runs, e.g. by including them in a `print` command. In this case, if a `compute` is needed to evaluate a variable (either directly or indirectly), LAMMPS will not invoke the `compute`, but it will use a value previously calculated by the `compute`, and can do this only if it was invoked on the current timestep. Fixes will always provide a quantity needed by a variable, but the quantity may or may not be current. This leads to one of three kinds of behavior:

(1) The variable may be evaluated accurately. If it contains references to a `compute` or `fix`, and these values were calculated on the last timestep of a preceding run, then they will be accessed and used by the variable and the result will be accurate.

(2) LAMMPS may not be able to evaluate the variable and will generate an error message stating so. For example, if the variable requires a quantity from a `compute` that has not been invoked on the current timestep, LAMMPS will generate an error. This means, for example, that such a variable cannot be evaluated before the first run has occurred. Likewise, in between runs, a variable containing a `compute` cannot be evaluated unless the `compute` was invoked on the last timestep of the preceding run, e.g. by thermodynamic output.

One way to get around this problem is to perform a 0-timestep run before using the variable. For example, these commands

```
variable t equal temp
print "Initial temperature = $t"
run 1000
```

will generate an error if the run is the first run specified in the input script, because generating a value for the "t" variable requires a `compute` for calculating the temperature to be invoked.

However, this sequence of commands would be fine:

```
run 0
variable t equal temp
print "Initial temperature = $t"
run 1000
```

LAMMPS Users Manual

The 0-timestep run initializes and invokes various computes, including the one for temperature, so that the value it stores is current and can be accessed by the variable "t" after the run has completed. Note that a 0-timestep run does not alter the state of the system, so it does not change the input state for the 1000-timestep run that follows. Also note that the 0-timestep run must actually use and invoke the compute in question (e.g. via [thermo](#) or [dump](#) output) in order for it to enable the compute to be used in a variable after the run. Thus if you are trying to print a variable that uses a compute you have defined, you can insure it is invoked on the last timestep of the preceding run by including it in thermodynamic output.

Unlike computes, [fixes](#) will never generate an error if their values are accessed by a variable in between runs. They always return some value to the variable. However, the value may not be what you expect if the fix has not yet calculated the quantity of interest or it is not current. For example, the [fix indent](#) command stores the force on the indenter. But this is not computed until a run is performed. Thus if a variable attempts to print this value before the first run, zeroes will be output. Again, performing a 0-timestep run before printing the variable has the desired effect.

(3) The variable may be evaluated incorrectly and LAMMPS may have no way to detect this has occurred. Consider the following sequence of commands:

```
pair_coeff 1 1 1.0 1.0
run 1000
pair_coeff 1 1 1.5 1.0
variable e equal pe
print "Final potential energy = $e"
```

The first run is performed using one setting for the pairwise potential defined by the [pair_style](#) and [pair_coeff](#) commands. The potential energy is evaluated on the final timestep and stored by the [compute pe](#) compute (this is done by the [thermo_style](#) command). Then a pair coefficient is changed, altering the potential energy of the system. When the potential energy is printed via the "e" variable, LAMMPS will use the potential energy value stored by the [compute pe](#) compute, thinking it is current. There are many other commands which could alter the state of the system between runs, causing a variable to evaluate incorrectly.

The solution to this issue is the same as for case (2) above, namely perform a 0-timestep run before the variable is evaluated to insure the system is up-to-date. For example, this sequence of commands would print a potential energy that reflected the changed pairwise coefficient:

```
pair_coeff 1 1 1.0 1.0
run 1000
pair_coeff 1 1 1.5 1.0
run 0
variable e equal pe
print "Final potential energy = $e"
```

Restrictions:

Indexing any formula element by global atom ID, such as an atom value, requires the [atom style](#) to use a global mapping in order to look up the vector indices. By default,

LAMMPS Users Manual

only atom styles with molecular information create global maps. The [atom_modify map](#) command can override the default, e.g. for atomic-style atom styles.

All *universe*- and *uloop*-style variables defined in an input script must have the same number of values.

Related commands:

[next](#), [jump](#), [include](#), [temper](#), [fix print](#), [print](#)

Default: none

velocity command

Syntax:

velocity group-ID style args keyword value ...

- group-ID = ID of group of atoms whose velocity will be changed
- style = *create* or *set* or *scale* or *ramp* or *zero*

```

create args = temp seed
  temp = temperature value (temperature units)
  seed = random # seed (positive integer)
set args = vx vy vz
  vx,vy,vz = velocity value or NULL (velocity units)
  any of vx,vy,vz can be a variable (see below)
scale arg = temp
  temp = temperature value (temperature units)
ramp args = vdim vlo vhi dim clo chi
  vdim = vx or vy or vz
  vlo,vhi = lower and upper velocity value (velocity units)
  dim = x or y or z
  clo,chi = lower and upper coordinate bound (distance units)
zero arg = linear or angular
  linear = zero the linear momentum
  angular = zero the angular momentum

```

- zero or more keyword/value pairs may be appended
- keyword = *dist* or *sum* or *mom* or *rot* or *temp* or *bias* or *loop* or *units*

```

dist value = uniform or gaussian
sum value = no or yes
mom value = no or yes
rot value = no or yes
temp value = temperature compute ID
bias value = no or yes
loop value = all or local or geom
rigid value = fix-ID
  fix-ID = ID of rigid body fix
units value = box or lattice

```

Examples:

```

velocity all create 300.0 4928459 rot yes dist gaussian
velocity border set NULL 4.0 v_vz sum yes units box
velocity flow scale 300.0
velocity flow ramp vx 0.0 5.0 y 5 25 temp mytemp
velocity all zero linear

```

Description:

Set or change the velocities of a group of atoms in one of several styles. For each style, there are required arguments and optional keyword/value parameters. Not all options are used by each style. Each option has a default as listed below.

LAMMPS Users Manual

The *create* style generates an ensemble of velocities using a random number generator with the specified seed at the specified temperature.

The *set* style sets the velocities of all atoms in the group to the specified values. If any component is specified as NULL, then it is not set. Any of the vx,vy,vz velocity components can be specified as an equal-style or atom-style [variable](#). If the value is a variable, it should be specified as v_name, where name is the variable name. In this case, the variable will be evaluated, and its value used to determine the velocity component. Note that if a variable is used, the velocity it calculates must be in box units, not lattice units; see the discussion of the *units* keyword below.

Equal-style variables can specify formulas with various mathematical functions, and include [thermo_style](#) command keywords for the simulation box parameters or other parameters.

Atom-style variables can specify the same formulas as equal-style variables but can also include per-atom values, such as atom coordinates. Thus it is easy to specify a spatially-dependent velocity field.

The *scale* style computes the current temperature of the group of atoms and then rescales the velocities to the specified temperature.

The *ramp* style is similar to that used by the [compute temp/ramp](#) command. Velocities ramped uniformly from v_{lo} to v_{hi} are applied to dimension vx, or vy, or vz. The value assigned to a particular atom depends on its relative coordinate value (in dim) from clo to chi. For the example above, an atom with y-coordinate of 10 (1/4 of the way from 5 to 25), would be assigned a x-velocity of 1.25 (1/4 of the way from 0.0 to 5.0). Atoms outside the coordinate bounds (less than 5 or greater than 25 in this case), are assigned velocities equal to v_{lo} or v_{hi} (0.0 or 5.0 in this case).

The *zero* style adjusts the velocities of the group of atoms so that the aggregate linear or angular momentum is zero. No other changes are made to the velocities of the atoms. If the *rigid* option is specified (see below), then the zeroing is performed on individual rigid bodies, as defined by the [fix rigid](#) or [fix rigid/small](#) commands. In other words, zero linear will set the linear momentum of each rigid body to zero, and zero angular will set the angular momentum of each rigid body to zero. This is done by adjusting the velocities of the atoms in each rigid body.

All temperatures specified in the velocity command are in temperature units; see the [units](#) command. The units of velocities and coordinates depend on whether the *units* keyword is set to *box* or *lattice*, as discussed below.

For all styles, no atoms are assigned z-component velocities if the simulation is 2d; see the [dimension](#) command.

The keyword/value options are used in the following ways by the various styles.

The *dist* keyword is used by *create*. The ensemble of generated velocities can be a *uniform* distribution from some minimum to maximum value, scaled to produce the requested temperature. Or it can be a *gaussian* distribution with a mean of 0.0 and a sigma scaled to produce the requested temperature.

LAMMPS Users Manual

The *sum* keyword is used by all styles, except *zero*. The new velocities will be added to the existing ones if *sum* = *yes*, or will replace them if *sum* = *no*.

The *mom* and *rot* keywords are used by *create*. If *mom* = *yes*, the linear momentum of the newly created ensemble of velocities is zeroed; if *rot* = *yes*, the angular momentum is zeroed.

*line

If specified, the *temp* keyword is used by *create* and *scale* to specify a [compute](#) that calculates temperature in a desired way, e.g. by first subtracting out a velocity bias, as discussed in [Section 6.16](#) of the doc pages. If this keyword is not specified, *create* and *scale* calculate temperature using a compute that is defined internally as follows:

```
compute velocity_temp group-ID temp
```

where group-ID is the same ID used in the velocity command. i.e. the group of atoms whose velocity is being altered. This compute is deleted when the velocity command is finished. See the [compute temp](#) command for details. If the calculated temperature should have degrees-of-freedom removed due to fix constraints (e.g. SHAKE or rigid-body constraints), then the appropriate fix command must be specified before the velocity command is issued.

The *bias* keyword with a *yes* setting is used by *create* and *scale*, but only if the *temp* keyword is also used to specify a [compute](#) that calculates temperature in a desired way. If the temperature compute also calculates a velocity bias, the the bias is subtracted from atom velocities before the *create* and *scale* operations are performed. After the operations, the bias is added back to the atom velocities. See [Section 6.16](#) of the doc pages for more discussion of temperature computes with biases. Note that the velocity bias is only applied to atoms in the temperature compute specified with the *temp* keyword.

As an example, assume atoms are currently streaming in a flow direction (which could be separately initialized with the *ramp* style), and you wish to initialize their thermal velocity to a desired temperature. In this context thermal velocity means the per-particle velocity that remains when the streaming velocity is subtracted. This can be done using the *create* style with the *temp* keyword specifying the ID of a [compute temp/ramp](#) or [compute temp/profile](#) command, and the *bias* keyword set to a *yes* value.

The *loop* keyword is used by *create* in the following ways.

If *loop* = *all*, then each processor loops over all atoms in the simulation to create velocities, but only stores velocities for atoms it owns. This can be a slow loop for a large simulation. If atoms were read from a data file, the velocity assigned to a particular atom will be the same, independent of how many processors are being used. This will not be the case if atoms were created using the [create_atoms](#) command, since atom IDs will likely be assigned to atoms differently.

If *loop* = *local*, then each processor loops over only its atoms to produce velocities. The random number seed is adjusted to give a different set of velocities on each

LAMMPS Users Manual

processor. This is a fast loop, but the velocity assigned to a particular atom will depend on which processor owns it. Thus the results will always be different when a simulation is run on a different number of processors.

If `loop = geom`, then each processor loops over only its atoms. For each atom a unique random number seed is created, based on the atom's xyz coordinates. A velocity is generated using that seed. This is a fast loop and the velocity assigned to a particular atom will be the same, independent of how many processors are used. However, the set of generated velocities may be more correlated than if the *all* or *local* keywords are used.

Note that the *loop geom* keyword will not necessarily assign identical velocities for two simulations run on different machines. This is because the computations based on xyz coordinates are sensitive to tiny differences in the double-precision value for a coordinate as stored on a particular machine.

The *rigid* keyword only has meaning when used with the *zero* style. It allows specification of a fix-ID for one of the [rigid-body fix](#) variants which defines a set of rigid bodies. The zeroing of linear or angular momentum is then performed for each rigid body defined by the fix, as described above.

The *units* keyword is used by *set* and *ramp*. If `units = box`, the velocities and coordinates specified in the velocity command are in the standard units described by the [units](#) command (e.g. Angstroms/fmsec for real units). If `units = lattice`, velocities are in units of lattice spacings per time (e.g. spacings/fmsec) and coordinates are in lattice spacings. The [lattice](#) command must have been previously used to define the lattice spacing.

Restrictions:

Assigning a temperature via the *create* style to a system with [rigid bodies](#) or [SHAKE constraints](#) may not have the desired outcome for two reasons. First, the velocity command can be invoked before all of the relevant fixes are created and initialized and the number of adjusted degrees of freedom (DOFs) is known. Thus it is not possible to compute the target temperature correctly. Second, the assigned velocities may be partially canceled when constraints are first enforced, leading to a different temperature than desired. A workaround for this is to perform a `run 0` command, which insures all DOFs are accounted for properly, and then rescale the temperature to the desired value before performing a simulation. For example:

```
velocity all create 300.0 12345
run 0 # temperature may not be 300K
velocity all scale 300.0 # now it should be
```

Related commands:

[fix rigid](#), [fix shake](#), [lattice](#)

Default:

LAMMPS Users Manual

The keyword defaults are `dist = uniform`, `sum = no`, `mom = yes`, `rot = no`, `bias = no`, `loop = all`, and `units = lattice`. The `temp` and `rigid` keywords are not defined by default.

write_coeff command

Syntax:

```
write_coeff file
```

file = name of data file to write out

Examples:

```
write_coeff polymer.coeff
```

Description:

Write a text format file with the currently defined force field coefficients in a way, that it can be read by LAMMPS with the [include](#) command. In combination with the [nocoeff](#) option of [write_data](#) this can be used to move the Coeffs sections from a data file into a separate file.

NOTE: The `write_coeff` command is not yet fully implemented in two respects. First, some pair styles do not yet write their coefficient information into the coeff file. This means you will need to specify that information in your input script that reads the data file, via the [pair_coeff](#) command.

Restrictions:

none

Related commands:

[read_data](#), [write_restart](#), [write_data](#)

write_data command

Syntax:

```
write_data file keyword value ...
```

- file = name of data file to write out
- zero or more keyword/value pairs may be appended
- keyword = *pair* or *nocoeff*

```

nocoeff = do not write out force field info
pair value = ii or ij
  ii = write one line of pair coefficient info per atom type
  ij = write one line of pair coefficient info per IJ atom type pair

```

Examples:

```
write_data data.polymer
write_data data.*
```

Description:

Write a data file in text format of the current state of the simulation. Data files can be read by the [read_data](#) command to begin a simulation. The [read_data](#) command also describes their format.

Similar to [dump](#) files, the data filename can contain a "*" wild-card character. The "*" is replaced with the current timestep value.

NOTE: The write-data command is not yet fully implemented in two respects. First, most pair styles do not yet write their coefficient information into the data file. This means you will need to specify that information in your input script that reads the data file, via the [pair_coeff](#) command. Second, a few of the [atom styles](#) (body, ellipsoid, line, tri) that store auxiliary "bonus" information about aspherical particles, do not yet write the bonus info into the data file. Both these functionalities will be added to the [write_data](#) command later.

Because a data file is in text format, if you use a data file written out by this command to restart a simulation, the initial state of the new run will be slightly different than the final state of the old run (when the file was written) which was represented internally by LAMMPS in binary format. A new simulation which reads the data file will thus typically diverge from a simulation that continued in the original input script.

If you want to do more exact restarts, using binary files, see the [restart](#), [write_restart](#), and [read_restart](#) commands. You can also convert binary restart files to text data files, after a simulation has run, using the [-r command-line switch](#).

NOTE: Only limited information about a simulation is stored in a data file. For example, no information about atom [groups](#) and [fixes](#) are stored. [Binary restart files](#) store more information.

LAMMPS Users Manual

Bond interactions (angle, etc) that have been turned off by the [fix shake](#) or [delete_bonds](#) command will be written to a data file as if they are turned on. This means they will need to be turned off again in a new run after the data file is read.

Bonds that are broken (e.g. by a bond-breaking potential) are not written to the data file. Thus these bonds will not exist when the data file is read.

The *nocoeff* keyword requests that no force field parameters should be written to the data file. This can be very helpful, if one wants to make significant changes to the force field or if the parameters are read in separately anyway, e.g. from an include file.

The *pair* keyword lets you specify in what format the pair coefficient information is written into the data file. If the value is specified as *ii*, then one line per atom type is written, to specify the coefficients for each of the $I=J$ interactions. This means that no cross-interactions for $I \neq J$ will be specified in the data file and the pair style will apply its mixing rule, as documented on individual [pair_style](#) doc pages. Of course this behavior can be overridden in the input script after reading the data file, by specifying additional [pair_coeff](#) commands for any desired I,J pairs.

If the value is specified as *ij*, then one line of coefficients is written for all I,J pairs where $I \leq J$. These coefficients will include any specific settings made in the input script up to that point. The presence of these $I \neq J$ coefficients in the data file will effectively turn off the default mixing rule for the pair style. Again, the coefficient values in the data file can be overridden in the input script after reading the data file, by specifying additional [pair_coeff](#) commands for any desired I,J pairs.

Restrictions:

This command requires inter-processor communication to migrate atoms before the data file is written. This means that your system must be ready to perform a simulation before using this command (force fields setup, atom masses initialized, etc).

Related commands:

[read_data](#), [write_restart](#)

Default:

The option defaults are `pair = ii`.

write_dump command

Syntax:

```
write_dump group-ID style file dump-args modify dump_modify-args
```

- group-ID = ID of the group of atoms to be dumped
- style = any of the supported [dump styles](#)
- file = name of file to write dump info to
- dump-args = any additional args needed for a particular [dump style](#)
- modify = all args after this keyword are passed to [dump_modify](#) (optional)
- dump_modify-args = args for [dump_modify](#) (optional)

Examples:

```
write_dump all atom dump.atom
write_dump subgroup atom dump.run.bin
write_dump all custom dump.myforce.* id type x y vx fx
write_dump flow custom dump.%.myforce id type c_myF[3] v_ke modify sort id
write_dump all xyz system.xyz modify sort id element O H
write_dump all image snap*.jpg type type size 960 960 modify bgcolor white
write_dump all image snap*.jpg element element &
    bond atom 0.3 shiny 0.1 ssao yes 6345 0.2 size 1600 1600 &
    modify bgcolor white element C C O H N C C C O H H S O H
```

Description:

Dump a single snapshot of atom quantities to one or more files for the current state of the system. This is a one-time immediate operation, in contrast to the [dump](#) command which will set up a dump style to write out snapshots periodically during a running simulation.

The syntax for this command is mostly identical to that of the [dump](#) and [dump_modify](#) commands as if they were concatenated together, with the following exceptions: There is no need for a dump ID or dump frequency and the keyword *modify* is added. The latter is so that the full range of [dump_modify](#) options can be specified for the single snapshot, just as they can be for multiple snapshots. The *modify* keyword separates the arguments that would normally be passed to the *dump* command from those that would be given the *dump_modify*. Both support optional arguments and thus LAMMPS needs to be able to cleanly separate the two sets of args.

Note that if the specified filename uses wildcard characters "*" or "%", as supported by the [dump](#) command, they will operate in the same fashion to create the new filename(s). Normally, [dump image](#) files require a filename with a "*" character for the timestep. That is not the case for the `write_dump` command; no wildcard "*" character is necessary.

Restrictions:

LAMMPS Users Manual

All restrictions for the [dump](#) and [dump_modify](#) commands apply to this command as well, with the exception of the [dump image](#) filename not requiring a wildcard "*" character, as noted above.

Since dumps are normally written during a [run](#) or [energy minimization](#), the simulation has to be ready to run before this command can be used. Similarly, if the dump requires information from a compute, fix, or variable, the information needs to have been calculated for the current timestep (e.g. by a prior run), else LAMMPS will generate an error message.

For example, it is not possible to dump per-atom energy with this command before a run has been performed, since no energies and forces have yet been calculated. See the [variable](#) doc page section on Variable Accuracy for more information on this topic.

Related commands:

[dump](#), [dump image](#), [dump_modify](#)

Default:

The defaults are listed on the doc pages for the [dump](#) and [dump image](#) and [dump_modify](#) commands.

write_restart command

Syntax:

```
write_restart file keyword value ...
```

- file = name of file to write restart information to
- zero or more keyword/value pairs may be appended
- keyword = *fileper* or *nfile*

```
fileper arg = Np
    Np = write one file for every this many processors
nfile arg = Nf
    Nf = write this many files, one from each of Nf processors
```

Examples:

```
write_restart restart.equil
write_restart restart.equil.mpio
write_restart poly.%.* nfile 10
```

Description:

Write a binary restart file of the current state of the simulation.

During a long simulation, the [restart](#) command is typically used to output restart files periodically. The `write_restart` command is useful after a minimization or whenever you wish to write out a single current restart file.

Similar to [dump](#) files, the restart filename can contain two wild-card characters. If a "*" appears in the filename, it is replaced with the current timestep value. If a "%" character appears in the filename, then one file is written by each processor and the "%" character is replaced with the processor ID from 0 to P-1. An additional file with the "%" replaced by "base" is also written, which contains global information. For example, the files written for filename `restart.%` would be `restart.base`, `restart.0`, `restart.1`, ... `restart.P-1`. This creates smaller files and can be a fast mode of output and subsequent input on parallel machines that support parallel I/O. The optional *fileper* and *nfile* keywords discussed below can alter the number of files written.

The restart file can also be written in parallel as one large binary file via the MPI-IO library, which is part of the MPI standard for versions 2.0 and above. Using MPI-IO requires two steps. First, build LAMMPS with its MPIIO package installed, e.g.

```
make yes-mpiio    # installs the MPIIO package
make mpi          # build LAMMPS for your platform
```

Second, use a restart filename which contains ".mpio". Note that it does not have to end in ".mpio", just contain those characters. Unlike MPI-IO dump files, a particular restart file must be both written and read using MPI-IO.

LAMMPS Users Manual

Restart files can be read by a [read_restart](#) command to restart a simulation from a particular state. Because the file is binary (to enable exact restarts), it may not be readable on another machine. In this case, you can use the [-r command-line switch](#) to convert a restart file to a data file.

NOTE: Although the purpose of restart files is to enable restarting a simulation from where it left off, not all information about a simulation is stored in the file. For example, the list of fixes that were specified during the initial run is not stored, which means the new input script must specify any fixes you want to use. Even when restart information is stored in the file, as it is for some fixes, commands may need to be re-specified in the new input script, in order to re-use that information. Details are usually given in the documentation of the respective command. Also, see the [read_restart](#) command for general information about what is stored in a restart file.

The optional *nfile* or *fileper* keywords can be used in conjunction with the "%" wildcard character in the specified restart file name. As explained above, the "%" character causes the restart file to be written in pieces, one piece for each of P processors. By default P = the number of processors the simulation is running on. The *nfile* or *fileper* keyword can be used to set P to a smaller value, which can be more efficient when running on a large number of processors.

The *nfile* keyword sets P to the specified Nf value. For example, if Nf = 4, and the simulation is running on 100 processors, 4 files will be written, by processors 0,25,50,75. Each will collect information from itself and the next 24 processors and write it to a restart file.

For the *fileper* keyword, the specified value of Np means write one file for every Np processors. For example, if Np = 4, every 4th processor (0,4,8,12,etc) will collect information from itself and the next 3 processors and write it to a restart file.

Restrictions:

This command requires inter-processor communication to migrate atoms before the restart file is written. This means that your system must be ready to perform a simulation before using this command (force fields setup, atom masses initialized, etc).

To write and read restart files in parallel with MPI-IO, the MPIIO package must be installed.

Related commands:

[restart](#), [read_restart](#), [write_data](#)

Default: none

fix adapt command

Syntax:

```
fix ID group-ID adapt N attribute args ... keyword value ...
```

- ID, group-ID are documented in [fix](#) command
- adapt = style name of this fix command
- N = adapt simulation settings every this many timesteps
- one or more attribute/arg pairs may be appended
- attribute = *pair* or *kspace* or *atom*

```
pair args = pstyle pparam I J v_name
  pstyle = pair style name, e.g. lj/cut
  pparam = parameter to adapt over time
  I,J = type pair(s) to set parameter for
  v_name = variable with name that calculates value of pparam
bond args = bstyle bparam I v_name
  bstyle = bond style name, e.g. harmonic
  bparam = parameter to adapt over time
  I = type bond to set parameter for
  v_name = variable with name that calculates value of bparam
kspace arg = v_name
  v_name = variable with name that calculates scale factor on K-space terms
atom args = aparam v_name
  aparam = parameter to adapt over time
  v_name = variable with name that calculates value of aparam
```

- zero or more keyword/value pairs may be appended
- keyword = *scale* or *reset*

```
scale value = no or yes
  no = the variable value is the new setting
  yes = the variable value multiplies the original setting
reset value = no or yes
  no = values will remain altered at the end of a run
  yes = reset altered values to their original values at the end of a run
```

Examples:

```
fix 1 all adapt 1 pair soft a 1 1 v_prefactor
fix 1 all adapt 1 pair soft a 2* 3 v_prefactor
fix 1 all adapt 1 pair lj/cut epsilon * * v_scale1 coul/cut scale 3 3 v_scale2 scale yes reset
fix 1 all adapt 10 atom diameter v_size
```

```
variable ramp_up equal "ramp(0.01,0.5)"
fix stretch all adapt 1 bond harmonic r0 1 v_ramp_up
```

Description:

Change or adapt one or more specific simulation attributes or settings over time as a simulation runs. Pair potential and K-space and atom attributes which can be varied by this fix are discussed below. Many other fixes can also be used to time-vary simulation parameters, e.g. the "fix deform" command will change the simulation box

LAMMPS Users Manual

size/shape and the "fix move" command will change atom positions and velocities in a prescribed manner. Also note that many commands allow variables as arguments for specific parameters, if described in that manner on their doc pages. An equal-style variable can calculate a time-dependent quantity, so this is another way to vary a simulation parameter over time.

If N is specified as 0, the specified attributes are only changed once, before the simulation begins. This is all that is needed if the associated variables are not time-dependent. If $N > 0$, then changes are made every N steps during the simulation, presumably with a variable that is time-dependent.

Depending on the value of the *reset* keyword, attributes changed by this fix will or will not be reset back to their original values at the end of a simulation. Even if *reset* is specified as *yes*, a restart file written during a simulation will contain the modified settings.

If the *scale* keyword is set to *no*, then the value the parameter is set to will be whatever the variable generates. If the *scale* keyword is set to *yes*, then the value of the altered parameter will be the initial value of that parameter multiplied by whatever the variable generates. I.e. the variable is now a "scale factor" applied in (presumably) a time-varying fashion to the parameter.

Note that whether *scale* is *no* or *yes*, internally, the parameters themselves are actually altered by this fix. Make sure you use the *reset yes* option if you want the parameters to be restored to their initial values after the run.

The *pair* keyword enables various parameters of potentials defined by the [pair_style](#) command to be changed, if the pair style supports it. Note that the [pair_style](#) and [pair_coeff](#) commands must be used in the usual manner to specify these parameters initially; the fix adapt command simply overrides the parameters.

The *pstyle* argument is the name of the pair style. If [pair_style hybrid](#) or [pair_style hybrid/overlay](#) is used, *pstyle* should be a sub-style name. If there are multiple sub-styles using the same pair style, then *pstyle* should be specified as "style:N" where N is which instance of the pair style you wish to adapt, e.g. the first, second, etc. For example, *pstyle* could be specified as "soft" or "lubricate" or "lj/cut:1" or "lj/cut:2". The *pparam* argument is the name of the parameter to change. This is the current list of pair styles and parameters that can be varied by this fix. See the doc pages for individual pair styles and their energy formulas for the meaning of these parameters:

born	a,b,c	type pairs
buck	a,c	type pairs
coul/cut	scale	type pairs
coul/debye	scale	type pairs
coul/long	scale	type pairs
eam, eam/alloy, eam/fs	scale	type pairs
lj/cut	epsilon,sigma	type pairs
lj/expand	epsilon,sigma,delta	type pairs
lj/sf/dipole/sf	epsilon,sigma,scale	type pairs

LAMMPS Users Manual

lubricate	mu	global
gauss	a	type pairs
morse	d0,r0,alpha	type pairs
soft	a	type pairs
kim	PARAM_FREE_*#58i,j,...	global

NOTE: It is easy to add new pairwise potentials and their parameters to this list. All it typically takes is adding an extract() method to the pair_*.cpp file associated with the potential.

Some parameters are global settings for the pair style, e.g. the viscosity setting "mu" for [pair_style lubricate](#). For [pair_style kim](#), all free parameters supported by the KIM Model are available (e.g., PARAM_FREE_sigmas provided by the LennardJones612_Universal_MO_826355984548_001 Model). If the free parameter corresponds to an array, then the particular array element to be adapted must be specified (e.g., "PARAM_FREE_sigmas:10", to adapt the tenth entry of the sigmas array). Other parameters apply to atom type pairs within the pair style, e.g. the prefactor "a" for [pair_style soft](#).

Note that for many of the potentials, the parameter that can be varied is effectively a prefactor on the entire energy expression for the potential, e.g. the lj/cut epsilon. The parameters listed as "scale" are exactly that, since the energy expression for the [coul/cut](#) potential (for example) has no labeled prefactor in its formula. To apply an effective prefactor to some potentials, multiple parameters need to be altered. For example, the [Buckingham potential](#) needs both the A and C terms altered together. To scale the Buckingham potential, you should thus list the pair style twice, once for A and once for C.

If a type pair parameter is specified, the *I* and *J* settings should be specified to indicate which type pairs to apply it to. If a global parameter is specified, the *I* and *J* settings still need to be specified, but are ignored.

Similar to the [pair_coeff command](#), I and J can be specified in one of two ways. Explicit numeric values can be used for each, as in the 1st example above. $I \leq J$ is required. LAMMPS sets the coefficients for the symmetric J,I interaction to the same values.

A wild-card asterisk can be used in place of or in conjunction with the I,J arguments to set the coefficients for multiple pairs of atom types. This takes the form "*" or "*n" or "n*" or "m*n". If N = the number of atom types, then an asterisk with no numeric values means all types from 1 to N. A leading asterisk means all types from 1 to n (inclusive). A trailing asterisk means all types from n to N (inclusive). A middle asterisk means all types from m to n (inclusive). Note that only type pairs with $I \leq J$ are considered; if asterisks imply type pairs where $J < I$, they are ignored.

IMPOTANT NOTE: If [pair_style hybrid or hybrid/overlay](#) is being used, then the *pstyle* will be a sub-style name. You must specify I,J arguments that correspond to type pair values defined (via the [pair_coeff](#) command) for that sub-style.

The *v_name* argument for keyword *pair* is the name of an [equal-style variable](#) which will be evaluated each time this fix is invoked to set the parameter to a new value. It

LAMMPS Users Manual

should be specified as `v_name`, where `name` is the variable name. Equal-style variables can specify formulas with various mathematical functions, and include [thermo_style](#) command keywords for the simulation box parameters and timestep and elapsed time. Thus it is easy to specify parameters that change as a function of time or span consecutive runs in a continuous fashion. For the latter, see the *start* and *stop* keywords of the [run](#) command and the *elaplong* keyword of [thermo_style custom](#) for details.

For example, these commands would change the prefactor coefficient of the [pair_style soft](#) potential from 10.0 to 30.0 in a linear fashion over the course of a simulation:

```
variable prefactor equal ramp(10,30)
fix 1 all adapt 1 pair soft a * * v_prefactor
```

The *bond* keyword uses the specified variable to change the value of a bond coefficient over time, very similar to how the *pair* keyword operates. The only difference is that now a bond coefficient for a given bond type is adapted.

Currently *bond* does not support `bond_style hybrid` nor `bond_style hybrid/overlay` as bond styles. The only bonds that currently are working with `fix_adapt` are

harmonic	<code>k,r0</code>	type bonds
--------------------------	-------------------	------------

The *kspace* keyword used the specified variable as a scale factor on the energy, forces, virial calculated by whatever K-Space solver is defined by the [kspace_style](#) command. If the variable has a value of 1.0, then the solver is unaltered.

The *kspace* keyword works this way whether the *scale* keyword is set to *no* or *yes*.

The *atom* keyword enables various atom properties to be changed. The *aparam* argument is the name of the parameter to change. This is the current list of atom parameters that can be varied by this fix:

- charge = charge on particle
- diameter = diameter of particle

The *v_name* argument of the *atom* keyword is the name of an [equal-style variable](#) which will be evaluated each time this fix is invoked to set the parameter to a new value. It should be specified as `v_name`, where `name` is the variable name. See the discussion above describing the formulas associated with equal-style variables. The new value is assigned to the corresponding attribute for all atoms in the fix group.

NOTE: The *atom* keyword works this way whether the *scale* keyword is set to *no* or *yes*. I.e. the use of *scale yes* is not yet supported by the *atom* keyword.

If the atom parameter is *diameter* and per-atom density and per-atom mass are defined for particles (e.g. [atom_style granular](#)), then the mass of each particle is also changed when the diameter changes (density is assumed to stay constant).

For example, these commands would shrink the diameter of all granular particles in

LAMMPS Users Manual

the "center" group from 1.0 to 0.1 in a linear fashion over the course of a 1000-step simulation:

```
variable size equal ramp(1.0,0.1)
fix 1 center adapt 10 atom diameter v_size
```

Restart, fix_modify, output, run start/stop, minimize info:

No information about this fix is written to [binary restart files](#). None of the [fix_modify](#) options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various [output commands](#). No parameter of this fix can be used with the *start/stop* keywords of the [run](#) command. This fix is not invoked during [energy minimization](#).

For [rRESPA time integration](#), this fix changes parameters on the outermost rRESPA level.

```

```
fix 1 all adapt/fep 10 atom diameter 1 v_size
```

Description:

Change or adapt one or more specific simulation attributes or settings over time as a simulation runs.

This is an enhanced version of the [fix adapt](#) command with two differences,

- It is possible to modify the charges of chosen atom types only, instead of scaling all the charges in the system.

LAMMPS Users Manual

- There is a new option *after* for better compatibility with "fix ave/time".

This version is suited for free energy calculations using [compute ti](#) or [compute fep](#).

If N is specified as 0, the specified attributes are only changed once, before the simulation begins. This is all that is needed if the associated variables are not time-dependent. If $N > 0$, then changes are made every N steps during the simulation, presumably with a variable that is time-dependent.

Depending on the value of the *reset* keyword, attributes changed by this fix will or will not be reset back to their original values at the end of a simulation. Even if *reset* is specified as *yes*, a restart file written during a simulation will contain the modified settings.

If the *scale* keyword is set to *no*, then the value the parameter is set to will be whatever the variable generates. If the *scale* keyword is set to *yes*, then the value of the altered parameter will be the initial value of that parameter multiplied by whatever the variable generates. I.e. the variable is now a "scale factor" applied in (presumably) a time-varying fashion to the parameter. Internally, the parameters themselves are actually altered; make sure you use the *reset yes* option if you want the parameters to be restored to their initial values after the run.

If the *after* keyword is set to *yes*, then the parameters are changed one timestep after the multiple of N . In this manner, if a fix such as "fix ave/time" is used to calculate averages at every N timesteps, all the contributions to the average will be obtained with the same values of the parameters.

The *pair* keyword enables various parameters of potentials defined by the [pair_style](#) command to be changed, if the pair style supports it. Note that the [pair_style](#) and [pair_coeff](#) commands must be used in the usual manner to specify these parameters initially; the fix adapt command simply overrides the parameters.

The *pstyle* argument is the name of the pair style. If [pair_style hybrid or hybrid/overlay](#) is used, *pstyle* should be a sub-style name. For example, *pstyle* could be specified as "soft" or "lubricate". The *pparam* argument is the name of the parameter to change. This is the current list of pair styles and parameters that can be varied by this fix. See the doc pages for individual pair styles and their energy formulas for the meaning of these parameters:

born	a,b,c	type pairs
buck	a,c	type pairs
coul/cut	scale	type pairs
coul/debye	scale	type pairs
coul/long	scale	type pairs
lj/cut	epsilon,sigma	type pairs
lj/expand	epsilon,sigma,delta	type pairs
lubricate	mu	global
gauss	a	type pairs

LAMMPS Users Manual

<code>soft</code>	<code>a</code>	type pairs
-------------------	----------------	------------

NOTE: It is easy to add new potentials and their parameters to this list. All it typically takes is adding an `extract()` method to the `pair_*.cpp` file associated with the potential.

Some parameters are global settings for the pair style, e.g. the viscosity setting "`mu`" for [pair_style lubricate](#). Other parameters apply to atom type pairs within the pair style, e.g. the prefactor "`a`" for [pair_style soft](#).

Note that for many of the potentials, the parameter that can be varied is effectively a prefactor on the entire energy expression for the potential, e.g. the `lj/cut` `epsilon`. The parameters listed as "scale" are exactly that, since the energy expression for the [coul/cut](#) potential (for example) has no labeled prefactor in its formula. To apply an effective prefactor to some potentials, multiple parameters need to be altered. For example, the [Buckingham potential](#) needs both the A and C terms altered together. To scale the Buckingham potential, you should thus list the pair style twice, once for A and once for C.

If a type pair parameter is specified, the *I* and *J* settings should be specified to indicate which type pairs to apply it to. If a global parameter is specified, the *I* and *J* settings still need to be specified, but are ignored.

Similar to the [pair_coeff command](#), *I* and *J* can be specified in one of two ways. Explicit numeric values can be used for each, as in the 1st example above. $I \leq J$ is required. LAMMPS sets the coefficients for the symmetric *J,I* interaction to the same values.

A wild-card asterisk can be used in place of or in conjunction with the *I,J* arguments to set the coefficients for multiple pairs of atom types. This takes the form "*" or "*n" or "n*" or "m*n". If *N* = the number of atom types, then an asterisk with no numeric values means all types from 1 to *N*. A leading asterisk means all types from 1 to *n* (inclusive). A trailing asterisk means all types from *n* to *N* (inclusive). A middle asterisk means all types from *m* to *n* (inclusive). Note that only type pairs with $I \leq J$ are considered; if asterisks imply type pairs where $J < I$, they are ignored.

IMPOTANT NOTE: If [pair_style hybrid](#) or [hybrid/overlay](#) is being used, then the *pstyle* will be a sub-style name. You must specify *I,J* arguments that correspond to type pair values defined (via the [pair_coeff](#) command) for that sub-style.

The *v_name* argument for keyword *pair* is the name of an [equal-style variable](#) which will be evaluated each time this fix is invoked to set the parameter to a new value. It should be specified as *v_name*, where *name* is the variable name. Equal-style variables can specify formulas with various mathematical functions, and include [thermo_style](#) command keywords for the simulation box parameters and timestep and elapsed time. Thus it is easy to specify parameters that change as a function of time or span consecutive runs in a continuous fashion. For the latter, see the *start* and *stop* keywords of the [run](#) command and the *elaplong* keyword of [thermo_style custom](#) for details.

For example, these commands would change the prefactor coefficient of the [pair_style soft](#) potential from 10.0 to 30.0 in a linear fashion over the course of a simulation:

LAMMPS Users Manual

```
variable prefactor equal ramp(10,30)
fix 1 all adapt 1 pair soft a * * v_prefactor
```

The *kspace* keyword used the specified variable as a scale factor on the energy, forces, virial calculated by whatever K-Space solver is defined by the [kspace_style](#) command. If the variable has a value of 1.0, then the solver is unaltered.

The *kspace* keyword works this way whether the *scale* keyword is set to *no* or *yes*.

The *atom* keyword enables various atom properties to be changed. The *aparam* argument is the name of the parameter to change. This is the current list of atom parameters that can be varied by this fix:

- charge = charge on particle
- diameter = diameter of particle

The *I* argument indicates which atom types are affected. A wild-card asterisk can be used in place of or in conjunction with the *I* argument to set the coefficients for multiple atom types.

The *v_name* argument of the *atom* keyword is the name of an [equal-style variable](#) which will be evaluated each time this fix is invoked to set the parameter to a new value. It should be specified as *v_name*, where *name* is the variable name. See the discussion above describing the formulas associated with equal-style variables. The new value is assigned to the corresponding attribute for all atoms in the fix group.

If the atom parameter is *diameter* and per-atom density and per-atom mass are defined for particles (e.g. [atom_style granular](#)), then the mass of each particle is also changed when the diameter changes (density is assumed to stay constant).

For example, these commands would shrink the diameter of all granular particles in the "center" group from 1.0 to 0.1 in a linear fashion over the course of a 1000-step simulation:

```
variable size equal ramp(1.0,0.1)
fix 1 center adapt 10 atom diameter * v_size
```

For [rRESPA time integration](#), this fix changes parameters on the outermost rRESPA level.

Restart, fix_modify, output, run start/stop, minimize info:

No information about this fix is written to [binary restart files](#). None of the [fix_modify](#) options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various [output commands](#). No parameter of this fix can be used with the *start/stop* keywords of the [run](#) command. This fix is not invoked during [energy minimization](#).

Restrictions: none

Default:

The option defaults are scale = no, reset = no, after = no.

fix addforce command

Syntax:

```
fix ID group-ID addforce fx fy fz keyword value ...
```

- ID, group-ID are documented in [fix](#) command
- addforce = style name of this fix command
- fx,fy,fz = force component values (force units)

any of fx,fy,fz can be a variable (see below)

- zero or more keyword/value pairs may be appended to args
- keyword = *every* or *region* or *energy*

every value = *Nevery*

Nevery = add force every this many timesteps

region value = region-ID

region-ID = ID of region atoms must be in to have added force

energy value = *v_name*

v_name = variable with name that calculates the potential energy of each atom in the

Examples:

```
fix kick flow addforce 1.0 0.0 0.0
fix kick flow addforce 1.0 0.0 v_oscillate
fix ff boundary addforce 0.0 0.0 v_push energy v_espace
```

Description:

Add fx,fy,fz to the corresponding component of force for each atom in the group. This command can be used to give an additional push to atoms in a simulation, such as for a simulation of Poiseuille flow in a channel.

Any of the 3 quantities defining the force components can be specified as an equal-style or atom-style [variable](#), namely *fx*, *fy*, *fz*. If the value is a variable, it should be specified as *v_name*, where name is the variable name. In this case, the variable will be evaluated each timestep, and its value(s) used to determine the force component.

Equal-style variables can specify formulas with various mathematical functions, and include [thermo_style](#) command keywords for the simulation box parameters and timestep and elapsed time. Thus it is easy to specify a time-dependent force field.

Atom-style variables can specify the same formulas as equal-style variables but can also include per-atom values, such as atom coordinates. Thus it is easy to specify a spatially-dependent force field with optional time-dependence as well.

If the *every* keyword is used, the *Nevery* setting determines how often the forces are applied. The default value is 1, for every timestep.

LAMMPS Users Manual

If the *region* keyword is used, the atom must also be in the specified geometric [region](#) in order to have force added to it.

Adding a force to atoms implies a change in their potential energy as they move due to the applied force field. For dynamics via the "run" command, this energy can be optionally added to the system's potential energy for thermodynamic output (see below). For energy minimization via the "minimize" command, this energy must be added to the system's potential energy to formulate a self-consistent minimization problem (see below).

The *energy* keyword is not allowed if the added force is a constant vector $F = (f_x, f_y, f_z)$, with all components defined as numeric constants and not as variables. This is because LAMMPS can compute the energy for each atom directly as $E = -x \cdot F = -(x \cdot f_x + y \cdot f_y + z \cdot f_z)$, so that $-\text{Grad}(E) = F$.

The *energy* keyword is optional if the added force is defined with one or more variables, and if you are performing dynamics via the [run](#) command. If the keyword is not used, LAMMPS will set the energy to 0.0, which is typically fine for dynamics.

The *energy* keyword is required if the added force is defined with one or more variables, and you are performing energy minimization via the "minimize" command. The keyword specifies the name of an atom-style [variable](#) which is used to compute the energy of each atom as function of its position. Like variables used for f_x , f_y , f_z , the energy variable is specified as `v_name`, where name is the variable name.

Note that when the *energy* keyword is used during an energy minimization, you must insure that the formula defined for the atom-style [variable](#) is consistent with the force variable formulas, i.e. that $-\text{Grad}(E) = F$. For example, if the force were a spring-like $F = kx$, then the energy formula should be $E = -0.5kx^2$. If you don't do this correctly, the minimization will not converge properly.

Styles with a suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed in [Section 5](#) of the manual. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Making LAMMPS](#) section for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the [-suffix command-line switch](#) when you invoke LAMMPS, or you can use the [suffix](#) command in your input script.

See [Section 5](#) of the manual for more instructions on how to use the accelerated styles effectively.

Restart, fix_modify, output, run start/stop, minimize info:

LAMMPS Users Manual

No information about this fix is written to [binary restart files](#).

The [fix_modify energy](#) option is supported by this fix to add the potential "energy" inferred by the added force to the system's potential energy as part of [thermodynamic output](#). This is a fictitious quantity but is needed so that the [minimize](#) command can include the forces added by this fix in a consistent manner. I.e. there is a decrease in potential energy when atoms move in the direction of the added force.

The [fix_modify virial](#) option is supported by this fix to add the contribution due to the added forces on atoms to the system's virial as part of [thermodynamic output](#). The default is *virial no*

The [fix_modify respa](#) option is supported by this fix. This allows to set at which level of the [r-RESPA](#) integrator the fix is adding its forces. Default is the outermost level.

This fix computes a global scalar and a global 3-vector of forces, which can be accessed by various [output commands](#). The scalar is the potential energy discussed above. The vector is the total force on the group of atoms before the forces on individual atoms are changed by the fix. The scalar and vector values calculated by this fix are "extensive".

No parameter of this fix can be used with the *start/stop* keywords of the [run](#) command.

The forces due to this fix are imposed during an energy minimization, invoked by the [minimize](#) command. You should not specify force components with a variable that has time-dependence for use with a minimizer, since the minimizer increments the timestep as the iteration count during the minimization.

NOTE: If you want the fictitious potential energy associated with the added forces to be included in the total potential energy of the system (the quantity being minimized), you MUST enable the [fix_modify energy](#) option for this fix.

Restrictions: none

Related commands:

[fix setforce](#), [fix aveforce](#)

Default:

The option default for the every keyword is $every = 1$.

fix addtorque command

Syntax:

```
fix ID group-ID addtorque Tx Ty Tz
```

- ID, group-ID are documented in [fix](#) command
- addtorque = style name of this fix command
- Tx,Ty,Tz = torque component values (torque units)
- any of Tx,Ty,Tz can be a variable (see below)

Examples:

```
fix kick bead addtorque 2.0 3.0 5.0  
fix kick bead addtorque 0.0 0.0 v_oscillate
```

Description:

Add a set of forces to each atom in the group such that:

- the components of the total torque applied on the group (around its center of mass) are Tx,Ty,Tz
- the group would move as a rigid body in the absence of other forces.

This command can be used to drive a group of atoms into rotation.

Any of the 3 quantities defining the torque components can be specified as an equal-style [variable](#), namely T_x , T_y , T_z . If the value is a variable, it should be specified as `v_name`, where name is the variable name. In this case, the variable will be evaluated each timestep, and its value used to determine the torque component.

Equal-style variables can specify formulas with various mathematical functions, and include [thermo_style](#) command keywords for the simulation box parameters and timestep and elapsed time. Thus it is easy to specify a time-dependent torque.

Restart, fix_modify, output, run start/stop, minimize info:

No information about this fix is written to [binary restart files](#).

The [fix_modify](#) *energy* option is supported by this fix to add the potential "energy" inferred by the added forces to the system's potential energy as part of [thermodynamic output](#). This is a fictitious quantity but is needed so that the [minimize](#) command can include the forces added by this fix in a consistent manner. I.e. there is a decrease in potential energy when atoms move in the direction of the added forces.

The [fix_modify](#) *respa* option is supported by this fix. This allows to set at which level of the [r-RESPA](#) integrator the fix is adding its torque. Default is the outermost level.

LAMMPS Users Manual

This fix computes a global scalar and a global 3-vector, which can be accessed by various [output commands](#). The scalar is the potential energy discussed above. The vector is the total torque on the group of atoms before the forces on individual atoms are changed by the fix. The scalar and vector values calculated by this fix are "extensive".

No parameter of this fix can be used with the *start/stop* keywords of the [run](#) command.

The forces due to this fix are imposed during an energy minimization, invoked by the [minimize](#) command. You should not specify force components with a variable that has time-dependence for use with a minimizer, since the minimizer increments the timestep as the iteration count during the minimization.

Restrictions:

This fix is part of the USER-MISC package. It is only enabled if LAMMPS was built with that package. See the [Making LAMMPS](#) section for more info.

Related commands:

[fix addforce](#)

Default: none

fix append/atoms command

Syntax:

```
fix ID group-ID append/atoms face ... keyword value ...
```

- ID, group-ID are documented in [fix](#) command
- append/atoms = style name of this fix command
- face = *zhi*
- zero or more keyword/value pairs may be appended
- keyword = *basis* or *size* or *freq* or *temp* or *random* or *units*

basis values = M itype

M = which basis atom

itype = atom type (1-N) to assign to this basis atom

size args = Lz

Lz = z size of lattice region appended in a single event(distance units)

freq args = freq

freq = the number of timesteps between append events

temp args = target damp seed extent

target = target temperature for the region between zhi-extent and zhi (temperature units)

damp = damping parameter (time units)

seed = random number seed for langevin kicks

extent = extent of thermostated region (distance units)

random args = xmax ymax zmax seed

xmax, ymax, zmax = maximum displacement in particular direction (distance units)

seed = random number seed for random displacement

units value = *lattice* or *box*

lattice = the wall position is defined in lattice units

box = the wall position is defined in simulation box units

Examples:

```
fix 1 all append/atoms zhi size 5.0 freq 295 units lattice
fix 4 all append/atoms zhi size 15.0 freq 5 units box
fix A all append/atoms zhi size 1.0 freq 1000 units lattice
```

Description:

This fix creates atoms on a lattice, appended on the zhi edge of the system box. This can be useful when a shock or wave is propagating from zlo. This allows the system to grow with time to accommodate an expanding wave. A simulation box must already exist, which is typically created via the [create_box](#) command. Before using this command, a lattice must also be defined using the [lattice](#) command.

This fix will automatically freeze atoms on the zhi edge of the system, so that overlaps are avoided when new atoms are appended.

The *basis* keyword specifies an atom type that will be assigned to specific basis atoms as they are created. See the [lattice](#) command for specifics on how basis atoms are defined for the unit cell of the lattice. By default, all created atoms are assigned type = 1 unless this keyword specifies differently.

LAMMPS Users Manual

The *size* keyword defines the size in z of the chunk of material to be added.

The *random* keyword will give the atoms random displacements around their lattice points to simulate some initial temperature.

The *temp* keyword will cause a region to be thermostated with a Langevin thermostat on the zhi boundary. The size of the region is measured from zhi and is set with the *extent* argument.

The *units* keyword determines the meaning of the distance units used to define a wall position, but only when a numeric constant is used. A *box* value selects standard distance units as defined by the [units](#) command, e.g. Angstroms for units = real or metal. A *lattice* value means the distance units are in lattice spacings. The [lattice](#) command must have been previously used to define the lattice spacings.

Restart, fix_modify, output, run start/stop, minimize info:

No information about this fix is written to [binary restart files](#). None of the [fix_modify](#) options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various [output commands](#). No parameter of this fix can be used with the *start/stop* keywords of the [run](#) command. This fix is not invoked during [energy minimization](#).

Restrictions:

This fix style is part of the SHOCK package. It is only enabled if LAMMPS was built with that package. See the [Making LAMMPS](#) section for more info.

The boundary on which atoms are added with *append/atoms* must be *shrink/minimum*. The opposite boundary may be any boundary type other than periodic.

Related commands:

[fix wall/piston](#) command

Default:

The keyword defaults are *size* = 0.0, *freq* = 0, *units* = lattice. All added atoms are of type 1 unless the *basis* keyword is used.

fix atom/swap command

Syntax:

```
fix ID group-ID atom/swap N X seed T keyword values ...
```

- ID, group-ID are documented in [fix](#) command
- atom/swap = style name of this fix command
- N = invoke this fix every N steps
- X = number of swaps to attempt every N steps
- seed = random # seed (positive integer)
- T = scaling temperature of the MC swaps (temperature units)
- one or more keyword/value pairs may be appended to args
- keyword = *types* or *mu* or *ke* or *semi-grand* or *region*

```
types values = two or more atom types
mu values = chemical potential of swap types (energy units)
ke value = no or yes
  no = no conservation of kinetic energy after atom swaps
  yes = kinetic energy is conserved after atom swaps
semi-grand value = no or yes
  no = particle type counts and fractions conserved
  yes = semi-grand canonical ensemble, particle fractions not conserved
region value = region-ID
  region-ID = ID of region to use as an exchange/move volume
```

Examples:

```
fix 2 all atom/swap 1 1 29494 300.0 ke no types 1 2
fix myFix all atom/swap 100 1 12345 298.0 region my_swap_region types 5 6
fix SGMC all atom/swap 1 100 345 1.0 semi-grand yes types 1 2 3 mu 0.0 4.3 -5.0
```

Description:

This fix performs Monte Carlo swaps of atoms of one given atom type with atoms of the other given atom types. The specified T is used in the Metropolis criterion dictating swap probabilities.

Perform X swaps of atoms of one type with atoms of another type according to a Monte Carlo probability. Swap candidates must be in the fix group, must be in the region (if specified), and must be of one of the listed types. Swaps are attempted between candidates that are chosen randomly with equal probability among the candidate atoms. Swaps are not attempted between atoms of the same type since nothing would happen.

All atoms in the simulation domain can be moved using regular time integration displacements, e.g. via [fix nvt](#), resulting in a hybrid MC+MD simulation. A smaller-than-usual timestep size may be needed when running such a hybrid simulation, especially if the swapped atoms are not well equilibrated.

The *types* keyword is required. At least two atom types must be specified.

LAMMPS Users Manual

The *ke* keyword can be set to *no* to turn off kinetic energy conservation for swaps. The default is *yes*, which means that swapped atoms have their velocities scaled by the ratio of the masses of the swapped atom types. This ensures that the kinetic energy of each atom is the same after the swap as it was before the swap, even though the atom masses have changed.

The *semi-grand* keyword can be set to *yes* to switch to the semi-grand canonical ensemble as discussed in (Sadigh). This means that the total number of each particle type does not need to be conserved. The default is *no*, which means that the only kind of swap allowed exchanges an atom of one type with an atom of a different given type. In other words, the relative mole fractions of the swapped atoms remains constant. Whereas in the semi-grand canonical ensemble, the composition of the system can change. Note that when using *semi-grand*, atoms in the *fix* group whose type is not listed in the *types* keyword are ineligible for attempted conversion. An attempt is made to switch the selected atom (if eligible) to one of the other listed types with equal probability. Acceptance of each attempt depends upon the Metropolis criterion.

The *mu* keyword allows users to specify chemical potentials. This is required and allowed only when using *semi-grand*. All chemical potentials are absolute, so there is one for each swap type listed following the *types* keyword. In semi-grand canonical ensemble simulations the chemical composition of the system is controlled by the difference in these values. So shifting all values by a constant amount will have no effect on the simulation.

This command may optionally use the *region* keyword to define swap volume. The specified region must have been previously defined with a [region](#) command. It must be defined with *side = in*. Swap attempts occur only between atoms that are both within the specified region. Swaps are not otherwise attempted.

You should ensure you do not swap atoms belonging to a molecule, or LAMMPS will soon generate an error when it tries to find those atoms. LAMMPS will warn you if any of the atoms eligible for swapping have a non-zero molecule ID, but does not check for this at the time of swapping.

If not using *semi-grand* this *fix* checks to ensure all atoms of the given types have the same atomic charge. LAMMPS doesn't enforce this in general, but it is needed for this *fix* to simplify the swapping procedure. Successful swaps will swap the atom type and charge of the swapped atoms. Conversely, when using *semi-grand*, it is assumed that all the atom types involved in switches have the same charge. Otherwise, charge would not be conserved. As a consequence, no checks on atomic charges are performed, and successful switches update the atom type but not the atom charge. While it is possible to use *semi-grand* with groups of atoms that have different charges, these charges will not be changed when the atom types change.

Since this *fix* computes total potential energies before and after proposed swaps, so even complicated potential energy calculations are OK, including the following:

- long-range electrostatics (k-space)
- many body pair styles
- hybrid pair styles
- eam pair styles

LAMMPS Users Manual

- triclinic systems
- need to include potential energy contributions from other fixes

Some fixes have an associated potential energy. Examples of such fixes include: [efield](#), [gravity](#), [addforce](#), [langevin](#), [restrain](#), [temp/berendsen](#), [temp/rescale](#), and [wall](#) fixes. For that energy to be included in the total potential energy of the system (the quantity used when performing GCMC moves), you MUST enable the [fix_modify energy](#) option for that fix. The doc pages for individual [fix](#) commands specify if this should be done.

Restart, fix_modify, output, run start/stop, minimize info:

This fix writes the state of the fix to [binary restart files](#). This includes information about the random number generator seed, the next timestep for MC exchanges, etc. See the [read_restart](#) command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

None of the [fix_modify](#) options are relevant to this fix.

This fix computes a global vector of length 2, which can be accessed by various [output commands](#). The vector values are the following global cumulative quantities:

- 1 = swap attempts
- 2 = swap successes

The vector values calculated by this fix are "extensive".

No parameter of this fix can be used with the *start/stop* keywords of the [run](#) command. This fix is not invoked during [energy minimization](#).

Restrictions:

This fix is part of the MC package. It is only enabled if LAMMPS was built with that package. See the [Making LAMMPS](#) section for more info.

Related commands:

[fix nvt](#), [neighbor](#), [fix deposit](#), [fix evaporate](#), [delete_atoms](#), [fix gcmc](#)

Default:

The option defaults are ke = yes, semi-grand = no, mu = 0.0 for all atom types.

(Sadigh) B Sadigh, P Erhart, A Stukowski, A Caro, E Martinez, and L Zepeda-Ruiz, Phys. Rev. B, 85, 184203 (2012).

fix ave/atom command

Syntax:

```
fix ID group-ID ave/atom Nevery Nrepeat Nfreq value1 value2 ...
```

- ID, group-ID are documented in [fix](#) command
- ave/atom = style name of this fix command
- Nevery = use input values every this many timesteps
- Nrepeat = # of times to use input values for calculating averages
- Nfreq = calculate averages every this many timesteps one or more input values can be listed
- value = x, y, z, vx, vy, vz, fx, fy, fz, c_ID, c_ID[i], f_ID, f_ID[i], v_name

x,y,z,vx,vy,vz,fx,fy,fz = atom attribute (position, velocity, force component)

c_ID = per-atom vector calculated by a compute with ID

c_ID[I] = Ith column of per-atom array calculated by a compute with ID, I can include

f_ID = per-atom vector calculated by a fix with ID

f_ID[I] = Ith column of per-atom array calculated by a fix with ID, I can include wild

v_name = per-atom vector calculated by an atom-style variable with name

Examples:

```
fix 1 all ave/atom 1 100 100 vx vy vz
fix 1 all ave/atom 10 20 1000 c_my_stress[1]
fix 1 all ave/atom 10 20 1000 c_my_stress[*]
```

Description:

Use one or more per-atom vectors as inputs every few timesteps, and average them atom by atom over longer timescales. The resulting per-atom averages can be used by other [output commands](#) such as the [fix ave/chunk](#) or [dump custom](#) commands.

The group specified with the command means only atoms within the group have their averages computed. Results are set to 0.0 for atoms not in the group.

Each input value can be an atom attribute (position, velocity, force component) or can be the result of a [compute](#) or [fix](#) or the evaluation of an atom-style [variable](#). In the latter cases, the compute, fix, or variable must produce a per-atom vector, not a global quantity or local quantity. If you wish to time-average global quantities from a compute, fix, or variable, then see the [fix ave/time](#) command.

Each per-atom value of each input vector is averaged independently.

[Computes](#) that produce per-atom vectors or arrays are those which have the word *atom* in their style name. See the doc pages for individual [fixes](#) to determine which ones produce per-atom vectors or arrays. [Variables](#) of style *atom* are the only ones that can be used with this fix since they produce per-atom vectors.

LAMMPS Users Manual

Note that for values from a `compute` or `fix`, the bracketed index *I* can be specified using a wildcard asterisk with the index to effectively specify multiple values. This takes the form "*" or "*n" or "n*" or "m*n". If *N* = the size of the vector (for *mode* = scalar) or the number of columns in the array (for *mode* = vector), then an asterisk with no numeric values means all indices from 1 to *N*. A leading asterisk means all indices from 1 to *n* (inclusive). A trailing asterisk means all indices from *n* to *N* (inclusive). A middle asterisk means all indices from *m* to *n* (inclusive).

Using a wildcard is the same as if the individual columns of the array had been listed one by one. E.g. these 2 `fix ave/atom` commands are equivalent, since the `compute stress/atom` command creates a per-atom array with 6 columns:

```
compute my_stress all stress/atom NULL
fix 1 all ave/atom 10 20 1000 c_my_stress[*]
fix 1 all ave/atom 10 20 1000 c_my_stress[1] c_my_stress[1] &
                                c_my_stress[3] c_my_stress[4] &
                                c_my_stress[5] c_my_stress[6]
```

The *Nevery*, *Nrepeat*, and *Nfreq* arguments specify on what timesteps the input values will be used in order to contribute to the average. The final averaged quantities are generated on timesteps that are a multiple of *Nfreq*. The average is over *Nrepeat* quantities, computed in the preceding portion of the simulation every *Nevery* timesteps. *Nfreq* must be a multiple of *Nevery* and *Nevery* must be non-zero even if *Nrepeat* is 1. Also, the timesteps contributing to the average value cannot overlap, i.e. *Nrepeat***Nevery* can not exceed *Nfreq*.

For example, if *Nevery*=2, *Nrepeat*=6, and *Nfreq*=100, then values on timesteps 90,92,94,96,98,100 will be used to compute the final average on timestep 100. Similarly for timesteps 190,192,194,196,198,200 on timestep 200, etc.

The atom attribute values (*x,y,z,vx,vy,vz,fx,fy,fz*) are self-explanatory. Note that other atom attributes can be used as inputs to this `fix` by using the `compute property/atom` command and then specifying an input value from that `compute`.

NOTE: The *x,y,z* attributes are values that are re-wrapped inside the periodic box whenever an atom crosses a periodic boundary. Thus if you time average an atom that spends half its time on either side of the periodic box, you will get a value in the middle of the box. If this is not what you want, consider averaging unwrapped coordinates, which can be provided by the `compute property/atom` command via its *xu,yu,zu* attributes.

If a value begins with "c_", a `compute` ID must follow which has been previously defined in the input script. If no bracketed term is appended, the per-atom vector calculated by the `compute` is used. If a bracketed term containing an index *I* is appended, the *I*th column of the per-atom array calculated by the `compute` is used. Users can also write code for their own `compute` styles and [add them to LAMMPS](#). See the discussion above for how *I* can be specified with a wildcard asterisk to effectively specify multiple values.

If a value begins with "f_", a `fix` ID must follow which has been previously defined in the input script. If no bracketed term is appended, the per-atom vector calculated by

LAMMPS Users Manual

the fix is used. If a bracketed term containing an index I is appended, the I th column of the per-atom array calculated by the fix is used. Note that some fixes only produce their values on certain timesteps, which must be compatible with *Nevery*, else an error will result. Users can also write code for their own fix styles and [add them to LAMMPS](#). See the discussion above for how I can be specified with a wildcard asterisk to effectively specify multiple values.

If a value begins with "v_", a variable name must follow which has been previously defined in the input script as an [atom-style variable](#). Variables of style *atom* can reference thermodynamic keywords, or invoke other computes, fixes, or variables when they are evaluated, so this is a very general means of generating per-atom quantities to time average.

Restart, fix_modify, output, run start/stop, minimize info:

No information about this fix is written to [binary restart files](#). None of the [fix_modify](#) options are relevant to this fix. No global scalar or vector quantities are stored by this fix for access by various [output commands](#).

This fix produces a per-atom vector or array which can be accessed by various [output commands](#). A vector is produced if only a single quantity is averaged by this fix. If two or more quantities are averaged, then an array of values is produced. The per-atom values can only be accessed on timesteps that are multiples of *Nfreq* since that is when averaging is performed.

No parameter of this fix can be used with the *start/stop* keywords of the [run](#) command. This fix is not invoked during [energy minimization](#).

fix ave/chunk command

Syntax:

```
fix ID group-ID ave/chunk Nevery Nrepeat Nfreq chunkID value1 value2 ... keyword args ...
```

- ID, group-ID are documented in [fix](#) command
- ave/chunk = style name of this fix command
- Nevery = use input values every this many timesteps
- Nrepeat = # of times to use input values for calculating averages
- Nfreq = calculate averages every this many timesteps
- chunkID = ID of [compute chunk/atom](#) command
- one or more input values can be listed
- value = vx, vy, vz, fx, fy, fz, density/mass, density/number, temp, c_ID, c_ID[I], f_ID, f_ID[I], v_name

vx,vy,vz,fx,fy,fz = atom attribute (velocity, force component)

density/number, density/mass = number or mass density

temp = temperature

c_ID = per-atom vector calculated by a compute with ID

c_ID[I] = Ith column of per-atom array calculated by a compute with ID, I can include

f_ID = per-atom vector calculated by a fix with ID

f_ID[I] = Ith column of per-atom array calculated by a fix with ID, I can include wild

v_name = per-atom vector calculated by an atom-style variable with name

- zero or more keyword/arg pairs may be appended
- keyword = *norm* or *ave* or *bias* or *adof* or *cdof* or *file* or *overwrite* or *title1* or *title2* or *title3*

norm arg = *all* or *sample* or *none* = how output on *Nfreq* steps is normalized

all = output is sum of atoms across all *Nrepeat* samples, divided by atom count

sample = output is sum of *Nrepeat* sample averages, divided by *Nrepeat*

none = output is sum of *Nrepeat* sample sums, divided by *Nrepeat*

ave args = *one* or *running* or *window M*

one = output new average value every *Nfreq* steps

running = output cumulative average of all previous *Nfreq* steps

window M = output average of *M* most recent *Nfreq* steps

bias arg = bias-ID

bias-ID = ID of a temperature compute that removes a velocity bias for temperature c

adof value = dof_per_atom

dof_per_atom = define this many degrees-of-freedom per atom for temperature calculat

cdof value = dof_per_chunk

dof_per_chunk = define this many degrees-of-freedom per chunk for temperature calcul

file arg = filename

filename = file to write results to

overwrite arg = *none* = overwrite output file with only latest output

format arg = string

string = C-style format string

title1 arg = string

string = text to print as 1st line of output file

title2 arg = string

string = text to print as 2nd line of output file

title3 arg = string

string = text to print as 3rd line of output file

LAMMPS Users Manual

Examples:

```
fix 1 all ave/chunk 10000 1 10000 binchunk c_myCentro title1 "My output values"
fix 1 flow ave/chunk 100 10 1000 molchunk vx vz norm sample file vel.profile
fix 1 flow ave/chunk 100 5 1000 binchunk density/mass ave running
fix 1 flow ave/chunk 100 5 1000 binchunk density/mass ave running
```

NOTE:

If you are trying to replace a deprecated `fix ave/spatial` command with the newer, more flexible `fix ave/chunk` and [compute chunk/atom](#) commands, you simply need to split the `fix ave/spatial` arguments across the two new commands. For example, this command:

```
fix 1 flow ave/spatial 100 10 1000 y 0.0 1.0 vx vz norm sample file vel.profile
```

could be replaced by:

```
compute ccl flow chunk/atom bin/ld y 0.0 1.0
fix 1 flow ave/chunk 100 10 1000 ccl vx vz norm sample file vel.profile
```

Description:

Use one or more per-atom vectors as inputs every few timesteps, sum the values over the atoms in each chunk at each timestep, then average the per-chunk values over longer timescales. The resulting chunk averages can be used by other [output commands](#) such as [thermo_style custom](#), and can also be written to a file.

In LAMMPS, chunks are collections of atoms defined by a [compute chunk/atom](#) command, which assigns each atom to a single chunk (or no chunk). The ID for this command is specified as `chunkID`. For example, a single chunk could be the atoms in a molecule or atoms in a spatial bin. See the [compute chunk/atom](#) doc page and [Section 6.23](#) for details of how chunks can be defined and examples of how they can be used to measure properties of a system.

Note that only atoms in the specified group contribute to the summing and averaging calculations. The [compute chunk/atom](#) command defines its own group as well as an optional region. Atoms will have a chunk ID = 0, meaning they belong to no chunk, if they are not in that group or region. Thus you can specify the "all" group for this command if you simply want to use the chunk definitions provided by `chunkID`.

Each specified per-atom value can be an atom attribute (position, velocity, force component), a mass or number density, or the result of a [compute](#) or [fix](#) or the evaluation of an atom-style [variable](#). In the latter cases, the `compute`, `fix`, or `variable` must produce a per-atom quantity, not a global quantity. Note that the [compute property/atom](#) command provides access to any attribute defined and stored by atoms. If you wish to time-average global quantities from a `compute`, `fix`, or `variable`, then see the [fix ave/time](#) command.

The per-atom values of each input vector are summed and averaged independently of the per-atom values in other input vectors.

LAMMPS Users Manual

Computes that produce per-atom quantities are those which have the word *atom* in their style name. See the doc pages for individual **fixes** to determine which ones produce per-atom quantities. **Variables** of style *atom* are the only ones that can be used with this fix since all other styles of variable produce global quantities.

Note that for values from a compute or fix, the bracketed index *I* can be specified using a wildcard asterisk with the index to effectively specify multiple values. This takes the form "*" or "*n" or "n*" or "m*n". If *N* = the size of the vector (for *mode* = scalar) or the number of columns in the array (for *mode* = vector), then an asterisk with no numeric values means all indices from 1 to *N*. A leading asterisk means all indices from 1 to *n* (inclusive). A trailing asterisk means all indices from *n* to *N* (inclusive). A middle asterisk means all indices from *m* to *n* (inclusive).

Using a wildcard is the same as if the individual columns of the array had been listed one by one. E.g. these 2 fix ave/chunk commands are equivalent, since the **compute property/atom** command creates, in this case, a per-atom array with 3 columns:

```
compute myAng all property/atom angmomx angmomz  
fix 1 all ave/chunk 100 1 100 ccl c_myAng[*] file tmp.angmom  
fix 2 all ave/chunk 100 1 100 ccl c_myAng[1] c_myAng[2] c_myAng[3] file tmp.angmom
```

NOTE: This fix works by creating an array of size *Nchunk* by *Nvalues* on each processor. *Nchunk* is the number of chunks which is defined by the **compute chunk/atom** command. *Nvalues* is the number of input values specified. Each processor loops over its atoms, tallying its values to the appropriate chunk. Then the entire array is summed across all processors. This means that using a large number of chunks will incur an overhead in memory and computational cost (summing across processors), so be careful to define a reasonable number of chunks.

The *Nevery*, *Nrepeat*, and *Nfreq* arguments specify on what timesteps the input values will be accessed and contribute to the average. The final averaged quantities are generated on timesteps that are a multiples of *Nfreq*. The average is over *Nrepeat* quantities, computed in the preceding portion of the simulation every *Nevery* timesteps. *Nfreq* must be a multiple of *Nevery* and *Nevery* must be non-zero even if *Nrepeat* is 1. Also, the timesteps contributing to the average value cannot overlap, i.e. $Nrepeat * Nevery$ can not exceed *Nfreq*.

For example, if *Nevery*=2, *Nrepeat*=6, and *Nfreq*=100, then values on timesteps 90,92,94,96,98,100 will be used to compute the final average on timestep 100. Similarly for timesteps 190,192,194,196,198,200 on timestep 200, etc. If *Nrepeat*=1 and *Nfreq* = 100, then no time averaging is done; values are simply generated on timesteps 100,200,etc.

Each input value can also be averaged over the atoms in each chunk. The way the averaging is done across the *Nrepeat* timesteps to produce output on the *Nfreq* timesteps, and across multiple *Nfreq* outputs, is determined by the *norm* and *ave* keyword settings, as discussed below.

NOTE: To perform per-chunk averaging within a *Nfreq* time window, the number of chunks *Nchunk* defined by the **compute chunk/atom** command must remain constant. If the *ave* keyword is set to *running* or *window* then *Nchunk* must remain constant for

the duration of the simulation. This fix forces the chunk/atom compute specified by chunkID to hold *Nchunk* constant for the appropriate time windows, by not allowing it to re-calculate *Nchunk*, which can also affect how it assigns chunk IDs to atoms. This is particularly important to understand if the chunks defined by the [compute chunk/atom](#) command are spatial bins. If its *units* keyword is set to *box* or *lattice*, then the number of bins *Nchunk* and size of each bin will be fixed over the *Nfreq* time window, which can affect which atoms are discarded if the simulation box size changes. If its *units* keyword is set to *reduced*, then the number of bins *Nchunk* will still be fixed, but the size of each bin can vary at each timestep if the simulation box size changes, e.g. for an NPT simulation.

The atom attribute values (vx,vy,vz,fx,fy,fz) are self-explanatory. As noted above, any other atom attributes can be used as input values to this fix by using the [compute property/atom](#) command and then specifying an input value from that compute.

The *density/number* value means the number density is computed for each chunk, i.e. number/volume. The *density/mass* value means the mass density is computed for each chunk, i.e. total-mass/volume. The output values are in units of 1/volume or density (mass/volume). See the [units](#) command doc page for the definition of density for each choice of units, e.g. gram/cm³. If the chunks defined by the [compute chunk/atom](#) command are spatial bins, the volume is the bin volume. Otherwise it is the volume of the entire simulation box.

The *temp* value means the temperature is computed for each chunk, by the formula $KE = DOF/2 k T$, where $KE =$ total kinetic energy of the chunk of atoms (sum of $1/2 m v^2$), $DOF =$ the total number of degrees of freedom for all atoms in the chunk, $k =$ Boltzmann constant, and $T =$ temperature.

The DOF is calculated as $N*adof + cdof$, where $N =$ number of atoms in the chunk, $adof =$ degrees of freedom per atom, and $cdof =$ degrees of freedom per chunk. By default $adof = 2$ or $3 =$ dimensionality of system, as set via the [dimension](#) command, and $cdof = 0.0$. This gives the usual formula for temperature.

Note that currently this temperature only includes translational degrees of freedom for each atom. No rotational degrees of freedom are included for finite-size particles. Also no degrees of freedom are subtracted for any velocity bias or constraints that are applied, such as [compute temp/partial](#), or [fix shake](#) or [fix rigid](#). This is because those degrees of freedom (e.g. a constrained bond) could apply to sets of atoms that are both included and excluded from a specific chunk, and hence the concept is somewhat ill-defined. In some cases, you can use the *adof* and *cdof* keywords to adjust the calculated degrees of freedom appropriately, as explained below.

Also note that a bias can be subtracted from atom velocities before they are used in the above formula for KE , by using the *bias* keyword. This allows, for example, a thermal temperature to be computed after removal of a flow velocity profile.

Note that the per-chunk temperature calculated by this fix and the [compute temp/chunk](#) command can be different. The compute calculates the temperature for each chunk for a single snapshot. This fix can do that but can also time average those values over many snapshots, or it can compute a temperature as if the atoms in the chunk on different timesteps were collected together as one set of atoms to calculate

their temperature. The compute allows the center-of-mass velocity of each chunk to be subtracted before calculating the temperature; this fix does not.

If a value begins with "c_", a compute ID must follow which has been previously defined in the input script. If no bracketed integer is appended, the per-atom vector calculated by the compute is used. If a bracketed integer is appended, the Ith column of the per-atom array calculated by the compute is used. Users can also write code for their own compute styles and [add them to LAMMPS](#). See the discussion above for how I can be specified with a wildcard asterisk to effectively specify multiple values.

If a value begins with "f_", a fix ID must follow which has been previously defined in the input script. If no bracketed integer is appended, the per-atom vector calculated by the fix is used. If a bracketed integer is appended, the Ith column of the per-atom array calculated by the fix is used. Note that some fixes only produce their values on certain timesteps, which must be compatible with *Nevery*, else an error results. Users can also write code for their own fix styles and [add them to LAMMPS](#). See the discussion above for how I can be specified with a wildcard asterisk to effectively specify multiple values.

If a value begins with "v_", a variable name must follow which has been previously defined in the input script. Variables of style *atom* can reference thermodynamic keywords and various per-atom attributes, or invoke other computes, fixes, or variables when they are evaluated, so this is a very general means of generating per-atom quantities to average within chunks.

Additional optional keywords also affect the operation of this fix and its outputs.

The *norm* keyword affects how averaging is done for the per-chunk values that are output every *Nfreq* timesteps.

If the *norm* setting is *all*, which is the default, a chunk value is summed over all atoms in all *Nrepeat* samples, as is the count of atoms in the chunk. The averaged output value for the chunk on the *Nfreq* timesteps is Total-sum / Total-count. In other words it is an average over atoms across the entire *Nfreq* timescale. For the *density/number* and *density/mass* values, the volume (bin volume or system volume) used in the final normalization will be the volume at the final *Nfreq* timestep.

If the *norm* setting is *sample*, the chunk value is summed over atoms for each sample, as is the count, and an "average sample value" is computed for each sample, i.e. Sample-sum / Sample-count. The output value for the chunk on the *Nfreq* timesteps is the average of the *Nrepeat* "average sample values", i.e. the sum of *Nrepeat* "average sample values" divided by *Nrepeat*. In other words it is an average of an average. For the *density/number* and *density/mass* values, the volume (bin volume or system volume) used in the per-sample normalization will be the current volume at each sampling step.

If the *norm* setting is *none*, a similar computation as for the *sample* setting is done, except the individual "average sample values" are "summed sample values". A summed sample value is simply the chunk value summed over atoms in the sample, without dividing by the number of atoms in the sample. The output value for the chunk on the *Nfreq* timesteps is the average of the *Nrepeat* "summed sample values", i.e. the

LAMMPS Users Manual

sum of $Nrepeat$ "summed sample values" divided by $Nrepeat$. For the *density/number* and *density/mass* values, the volume (bin volume or system volume) used in the per-sample sum normalization will be the current volume at each sampling step.

The *ave* keyword determines how the per-chunk values produced every $Nfreq$ steps are averaged with values produced on previous steps that were multiples of $Nfreq$, before they are accessed by another output command or written to a file.

If the *ave* setting is *one*, which is the default, then the chunk values produced on timesteps that are multiples of $Nfreq$ are independent of each other; they are output as-is without further averaging.

If the *ave* setting is *running*, then the chunk values produced on timesteps that are multiples of $Nfreq$ are summed and averaged in a cumulative sense before being output. Each output chunk value is thus the average of the chunk value produced on that timestep with all preceding values for the same chunk. This running average begins when the *fix* is defined; it can only be restarted by deleting the *fix* via the [unfix](#) command, or re-defining the *fix* by re-specifying it.

If the *ave* setting is *window*, then the chunk values produced on timesteps that are multiples of $Nfreq$ are summed and averaged within a moving "window" of time, so that the last M values for the same chunk are used to produce the output. E.g. if $M = 3$ and $Nfreq = 1000$, then the output on step 10000 will be the average of the individual chunk values on steps 8000,9000,10000. Outputs on early steps will average over less than M values if they are not available.

The *bias* keyword specifies the ID of a temperature compute that removes a "bias" velocity from each atom, specified as *bias-ID*. It is only used when the *temp* value is calculated, to compute the thermal temperature of each chunk after the translational kinetic energy components have been altered in a prescribed way, e.g. to remove a flow velocity profile. See the doc pages for individual computes that calculate a temperature to see which ones implement a bias.

The *adof* and *cdof* keywords define the values used in the degree of freedom (DOF) formula described above for temperature calculation for each chunk. They are only used when the *temp* value is calculated. They can be used to calculate a more appropriate temperature for some kinds of chunks. Here are 3 examples:

If spatially binned chunks contain some number of water molecules and [fix shake](#) is used to make each molecule rigid, then you could calculate a temperature with 6 degrees of freedom (DOF) (3 translational, 3 rotational) per molecule by setting *adof* to 2.0.

If [compute temp/partial](#) is used with the *bias* keyword to only allow the x component of velocity to contribute to the temperature, then *adof* = 1.0 would be appropriate.

If each chunk consists of a large molecule, with some number of its bonds constrained by [fix shake](#) or the entire molecule by [fix rigid/small](#), *adof* = 0.0 and *cdof* could be set to the remaining degrees of freedom for the entire molecule (entire chunk in this case), e.g. 6 for 3d, or 3 for 2d, for a rigid molecule.

LAMMPS Users Manual

The *file* keyword allows a filename to be specified. Every *Nfreq* timesteps, a section of chunk info will be written to a text file in the following format. A line with the timestep and number of chunks is written. Then one line per chunk is written, containing the chunk ID (1-Nchunk), an optional original ID value, optional coordinate values for chunks that represent spatial bins, the number of atoms in the chunk, and one or more calculated values. More explanation of the optional values is given below. The number of values in each line corresponds to the number of values specified in the *fix ave/chunk* command. The number of atoms and the value(s) are summed or average quantities, as explained above.

The *overwrite* keyword will continuously overwrite the output file with the latest output, so that it only contains one timestep worth of output. This option can only be used with the *ave running* setting.

The *format* keyword sets the numeric format of each value when it is printed to a file via the *file* keyword. Note that all values are floating point quantities. The default format is `%g`. You can specify a higher precision if desired, e.g. `%20.16g`.

The *title1* and *title2* and *title3* keywords allow specification of the strings that will be printed as the first 3 lines of the output file, assuming the *file* keyword was used. LAMMPS uses default values for each of these, so they do not need to be specified.

By default, these header lines are as follows:

```
# Chunk-averaged data for fix ID and group name
# Timestep Number-of-chunks
# Chunk (OrigID) (Coord1) (Coord2) (Coord3) Ncount value1 value2 ...
```

In the first line, ID and name are replaced with the fix-ID and group name. The second line describes the two values that are printed at the first of each section of output. In the third line the values are replaced with the appropriate value names, e.g. `fx` or `c_myCompute2`.

The words in parenthesis only appear with corresponding columns if the chunk style specified for the [compute chunk/atom](#) command supports them. The OrigID column is only used if the *compress* keyword was set to *yes* for the [compute chunk/atom](#) command. This means that the original chunk IDs (e.g. molecule IDs) will have been compressed to remove chunk IDs with no atoms assigned to them. Thus a compressed chunk ID of 3 may correspond to an original chunk ID or molecule ID of 415. The OrigID column will list 415 for the 3rd chunk.

The CoordN columns only appear if a *binning* style was used in the [compute chunk/atom](#) command. For *bin/1d*, *bin/2d*, and *bin/3d* styles the column values are the center point of the bin in the corresponding dimension. Just Coord1 is used for *bin/1d*, Coord2 is added for *bin/2d*, Coord3 is added for *bin/3d*. For *bin/sphere*, just Coord1 is used, and it is the radial coordinate. For *bin/cylinder*, Coord1 and Coord2 are used. Coord1 is the radial coordinate (away from the cylinder axis), and coord2 is the coordinate along the cylinder axis.

Note that if the value of the *units* keyword used in the [compute chunk/atom command](#) is *box* or *lattice*, the coordinate values will be in distance [units](#). If the value of the

LAMMPS Users Manual

units keyword is *reduced*, the coordinate values will be in unitless reduced units (0-1). This is not true for the *Coord1* value of style *bin/sphere* or *bin/cylinder* which both represent radial dimensions. Those values are always in distance [units](#).

Restart, fix_modify, output, run start/stop, minimize info:

No information about this fix is written to [binary restart files](#). None of the [fix_modify](#) options are relevant to this fix.

This fix computes a global array of values which can be accessed by various [output commands](#). The values can only be accessed on timesteps that are multiples of *Nfreq* since that is when averaging is performed. The global array has # of rows = the number of chunks *Nchunk* as calculated by the specified [compute chunk/atom](#) command. The # of columns = $M+1+N_{\text{values}}$, where $M = 1$ to 4 , depending on whether the optional columns for *OrigID* and *CoordN* are used, as explained above. Following the optional columns, the next column contains the count of atoms in the chunk, and the remaining columns are the *Nvalue* quantities. When the array is accessed with a row *I* that exceeds the current number of chunks, than a 0.0 is returned by the fix instead of an error, since the number of chunks can vary as a simulation runs depending on how that value is computed by the [compute chunk/atom](#) command.

The array values calculated by this fix are treated as "intensive", since they are typically already normalized by the count of atoms in each chunk.

No parameter of this fix can be used with the *start/stop* keywords of the [run](#) command. This fix is not invoked during [energy minimization](#).

Restrictions: none

Related commands:

[compute](#), [fix ave/atom](#), [fix ave/histo](#), [fix ave/time](#), [variable](#), [fix ave/correlate](#)

```
fix 1 all ave/correlate 5 100 1000 c_myTemp file temp.correlate
```

```
fix 1 all ave/correlate 1 50 10000 &
```

```
  c_thermo_press[1] c_thermo_press[2] c_thermo_press[3] &
```

```
  type upper ave running title1 "My correlation data"
```

```
fix 1 all ave/correlate 1 50 10000 c_thermo_press[*]
```

Description:

Use one or more global scalar values as inputs every few timesteps, calculate time correlations between them at varying time intervals, and average the correlation data over longer timescales. The resulting correlation values can be time integrated by [variables](#) or used by other [output commands](#) such as [thermo_style custom](#), and can also be written to a file. See the [fix ave/correlate/long](#) command for an alternate method for computing correlation functions efficiently over very long time windows.

The group specified with this command is ignored. However, note that specified values may represent calculations performed by computes and fixes which store their own "group" definitions.

Each listed value can be the result of a [compute](#) or [fix](#) or the evaluation of an equal-style or vector-style [variable](#). In each case, the compute, fix, or variable must produce a global quantity, not a per-atom or local quantity. If you wish to spatial- or time-average or histogram per-atom quantities from a compute, fix, or variable, then see the [fix ave/chunk](#), [fix ave/atom](#), or [fix ave/histo](#) commands. If you wish to convert a per-atom quantity into a single global value, see the [compute reduce](#) command.

The input values must either be all scalars. What kinds of correlations between input values are calculated is determined by the *type* keyword as discussed below.

[Computes](#) that produce global quantities are those which do not have the word *atom* in their style name. Only a few [fixes](#) produce global quantities. See the doc pages for individual fixes for info on which ones produce such values. [Variables](#) of style *equal* and *vector* are the only ones that can be used with this fix. Variables of style *atom* cannot be used, since they produce per-atom values.

Note that for values from a compute or fix, the bracketed index *I* can be specified using a wildcard asterisk with the index to effectively specify multiple values. This takes the form "*" or "*n" or "n*" or "m*n". If *N* = the size of the vector (for *mode* = scalar) or the number of columns in the array (for *mode* = vector), then an asterisk with no numeric values means all indices from 1 to *N*. A leading asterisk means all indices from 1 to *n* (inclusive). A trailing asterisk means all indices from *n* to *N* (inclusive). A middle asterisk means all indices from *m* to *n* (inclusive).

Using a wildcard is the same as if the individual elements of the vector had been listed one by one. E.g. these 2 fix ave/correlate commands are equivalent, since the [compute pressure](#) command creates a global vector with 6 values.

```
compute myPress all pressure NULL
fix 1 all ave/correlate 1 50 10000 c_myPress[*]
fix 1 all ave/correlate 1 50 10000 &
      c_myPress[1] c_myPress[2] c_myPress[3] &
      c_myPress[4] c_myPress[5] c_myPress[6]
```

The *Nevery*, *Nrepeat*, and *Nfreq* arguments specify on what timesteps the input values will be used to calculate correlation data. The input values are sampled every *Nevery*

LAMMPS Users Manual

timesteps. The correlation data for the preceding samples is computed on timesteps that are a multiple of *Nfreq*. Consider a set of samples from some initial time up to an output timestep. The initial time could be the beginning of the simulation or the last output time; see the *ave* keyword for options. For the set of samples, the correlation value *Cij* is calculated as:

$$C_{ij}(\text{delta}) = \text{ave}(V_i(t) * V_j(t + \text{delta}))$$

which is the correlation value between input values *V_i* and *V_j*, separated by time *delta*. Note that the second value *V_j* in the pair is always the one sampled at the later time. The *ave()* represents an average over every pair of samples in the set that are separated by time *delta*. The maximum *delta* used is of size $(Nrepeat-1) * Nevery$. Thus the correlation between a pair of input values yields *Nrepeat* correlation datums:

$$C_{ij}(0), C_{ij}(Nevery), C_{ij}(2 * Nevery), \dots, C_{ij}((Nrepeat-1) * Nevery)$$

For example, if *Nevery*=5, *Nrepeat*=6, and *Nfreq*=100, then values on timesteps 0,5,10,15,...,100 will be used to compute the final averages on timestep 100. Six averages will be computed: *Cij*(0), *Cij*(5), *Cij*(10), *Cij*(15), *Cij*(20), and *Cij*(25). *Cij*(10) on timestep 100 will be the average of 19 samples, namely *V_i*(0)**V_j*(10), *V_i*(5)**V_j*(15), *V_i*(10)**V_j*(20), *V_i*(15)**V_j*(25), ..., *V_i*(85)**V_j*(95), *V_i*(90)**V_j*(100).

Nfreq must be a multiple of *Nevery*; *Nevery* and *Nrepeat* must be non-zero. Also, if the *ave* keyword is set to *one* which is the default, then $Nfreq \geq (Nrepeat-1) * Nevery$ is required.

If a value begins with "c_", a compute ID must follow which has been previously defined in the input script. If no bracketed term is appended, the global scalar calculated by the compute is used. If a bracketed term is appended, the *I*th element of the global vector calculated by the compute is used. See the discussion above for how *I* can be specified with a wildcard asterisk to effectively specify multiple values.

Note that there is a [compute reduce](#) command which can sum per-atom quantities into a global scalar or vector which can thus be accessed by *fix ave/correlate*. Or it can be a compute defined not in your input script, but by [thermodynamic output](#) or other fixes such as [fix nvt](#) or [fix temp/rescale](#). See the doc pages for these commands which give the IDs of these computes. Users can also write code for their own compute styles and [add them to LAMMPS](#).

If a value begins with "f_", a fix ID must follow which has been previously defined in the input script. If no bracketed term is appended, the global scalar calculated by the *fix* is used. If a bracketed term is appended, the *I*th element of the global vector calculated by the *fix* is used. See the discussion above for how *I* can be specified with a wildcard asterisk to effectively specify multiple values.

Note that some fixes only produce their values on certain timesteps, which must be compatible with *Nevery*, else an error will result. Users can also write code for their own fix styles and [add them to LAMMPS](#).

If a value begins with "v_", a variable name must follow which has been previously defined in the input script. Only equal-style or vector-style variables can be

LAMMPS Users Manual

referenced; the latter requires a bracketed term to specify the i th element of the vector calculated by the variable. See the [variable](#) command for details. Note that variables of style *equal* or *vector* define a formula which can reference individual atom properties or thermodynamic keywords, or they can invoke other computes, fixes, or variables when they are evaluated, so this is a very general means of specifying quantities to time correlate.

Additional optional keywords also affect the operation of this fix.

The *type* keyword determines which pairs of input values are correlated with each other. For N input values V_i , for $i = 1$ to N , let the number of pairs = N_{pair} . Note that the second value in the pair $V_i(t) \cdot V_j(t+\delta t)$ is always the one sampled at the later time.

- If *type* is set to *auto* then each input value is correlated with itself. I.e. $C_{ii} = V_i \cdot V_i$, for $i = 1$ to N , so $N_{\text{pair}} = N$.
- If *type* is set to *upper* then each input value is correlated with every succeeding value. I.e. $C_{ij} = V_i \cdot V_j$, for $i < j$, so $N_{\text{pair}} = N \cdot (N-1) / 2$.
- If *type* is set to *lower* then each input value is correlated with every preceding value. I.e. $C_{ij} = V_i \cdot V_j$, for $i > j$, so $N_{\text{pair}} = N \cdot (N-1) / 2$.
- If *type* is set to *auto/upper* then each input value is correlated with itself and every succeeding value. I.e. $C_{ij} = V_i \cdot V_j$, for $i \geq j$, so $N_{\text{pair}} = N \cdot (N+1) / 2$.
- If *type* is set to *auto/lower* then each input value is correlated with itself and every preceding value. I.e. $C_{ij} = V_i \cdot V_j$, for $i \leq j$, so $N_{\text{pair}} = N \cdot (N+1) / 2$.
- If *type* is set to *full* then each input value is correlated with itself and every other value. I.e. $C_{ij} = V_i \cdot V_j$, for $i, j = 1, N$ so $N_{\text{pair}} = N^2$.

The *ave* keyword determines what happens to the accumulation of correlation samples every *Nfreq* timesteps. If the *ave* setting is *one*, then the accumulation is restarted or zeroed every *Nfreq* timesteps. Thus the outputs on successive *Nfreq* timesteps are essentially independent of each other. The exception is that the $C_{ij}(0) = V_i(T) \cdot V_j(T)$ value at a timestep T , where T is a multiple of *Nfreq*, contributes to the correlation output both at time T and at time $T+Nfreq$.

If the *ave* setting is *running*, then the accumulation is never zeroed. Thus the output of correlation data at any timestep is the average over samples accumulated every *Nevery* steps since the fix was defined. It can only be restarted by deleting the fix via the [unfix](#) command, or by re-defining the fix by re-specifying it.

The *start* keyword specifies what timestep the accumulation of correlation samples will begin on. The default is step 0. Setting it to a larger value can avoid adding non-equilibrated data to the correlation averages.

The *prefactor* keyword specifies a constant which will be used as a multiplier on the correlation data after it is averaged. It is effectively a scale factor on $V_i \cdot V_j$, which can be used to account for the size of the time window or other unit conversions.

The *file* keyword allows a filename to be specified. Every *Nfreq* steps, an array of correlation data is written to the file. The number of rows is *Nrepeat*, as described above. The number of columns is the $N_{\text{pair}}+2$, also as described above. Thus the file ends up to be a series of these array sections.

LAMMPS Users Manual

The *overwrite* keyword will continuously overwrite the output file with the latest output, so that it only contains one timestep worth of output. This option can only be used with the *ave running* setting.

The *title1* and *title2* and *title3* keywords allow specification of the strings that will be printed as the first 3 lines of the output file, assuming the *file* keyword was used. LAMMPS uses default values for each of these, so they do not need to be specified.

By default, these header lines are as follows:

```
# Time-correlated data for fix ID
# TimeStep Number-of-time-windows
# Index TimeDelta Ncount valueI*valueJ valueI*valueJ ...
```

In the first line, ID is replaced with the fix-ID. The second line describes the two values that are printed at the first of each section of output. In the third line the value pairs are replaced with the appropriate fields from the fix *ave/correlate* command.

Let S_{ij} = a set of time correlation data for input values I and J, namely the *Nrepeat* values:

$$S_{ij} = C_{ij}(0), C_{ij}(N_{\text{every}}), C_{ij}(2*N_{\text{every}}), \dots, C_{ij}(*N_{\text{repeat}}-1)*N_{\text{every}}$$

As explained below, these datums are output as one column of a global array, which is effectively the correlation matrix.

The *trap* function defined for [equal-style variables](#) can be used to perform a time integration of this vector of datums, using a trapezoidal rule. This is useful for calculating various quantities which can be derived from time correlation data. If a normalization factor is needed for the time integration, it can be included in the variable formula or via the *prefactor* keyword.

Restart, fix_modify, output, run start/stop, minimize info:

No information about this fix is written to [binary restart files](#). None of the [fix_modify](#) options are relevant to this fix.

This fix computes a global array of values which can be accessed by various [output commands](#). The values can only be accessed on timesteps that are multiples of *Nfreq* since that is when averaging is performed. The global array has # of rows = *Nrepeat* and # of columns = *Npair*+2. The first column has the time delta (in timesteps) between the pairs of input values used to calculate the correlation, as described above. The 2nd column has the number of samples contributing to the correlation average, as described above. The remaining *Npair* columns are for I,J pairs of the *N* input values, as determined by the *type* keyword, as described above.

- For *type* = *auto*, the *Npair* = *N* columns are ordered: C11, C22, ..., CNN.
- For *type* = *upper*, the *Npair* = $N*(N-1)/2$ columns are ordered: C12, C13, ..., C1N, C23, ..., C2N, C34, ..., CN-1N.
- For *type* = *lower*, the *Npair* = $N*(N-1)/2$ columns are ordered: C21, C31, C32, C41, C42, C43, ..., CN1, CN2, ..., CNN-1.

LAMMPS Users Manual

- For *type = auto/upper*, the $N_{\text{pair}} = N(N+1)/2$ columns are ordered: C11, C12, C13, ..., C1N, C22, C23, ..., C2N, C33, C34, ..., CN-1N, CNN.
- For *type = auto/lower*, the $N_{\text{pair}} = N(N+1)/2$ columns are ordered: C11, C21, C22, C31, C32, C33, C41, ..., C44, CN1, CN2, ..., CNN-1, CNN.
- For *type = full*, the $N_{\text{pair}} = N^2$ columns are ordered: C11, C12, ..., C1N, C21, C22, ..., C2N, C31, ..., C3N, ..., CN1, ..., CNN-1, CNN.

The array values calculated by this fix are treated as intensive. If you need to divide them by the number of atoms, you must do this in a later processing step, e.g. when using them in a [variable](#).

No parameter of this fix can be used with the *start/stop* keywords of the [run](#) command. This fix is not invoked during [energy minimization](#).

  type upper title1 "My correlation data" nlen 15 ncount 3
```

Description:

LAMMPS Users Manual

This fix is similar in spirit and syntax to the [fix ave/correlate](#). However, this fix allows the efficient calculation of time correlation functions on the fly over extremely long time windows without too much CPU overhead, using a multiple-tau method ([Ramirez](#)) that decreases the resolution of the stored correlation function with time.

The group specified with this command is ignored. However, note that specified values may represent calculations performed by computes and fixes which store their own "group" definitions.

Each listed value can be the result of a compute or fix or the evaluation of an equal-style variable. See the [fix ave/correlate](#) doc page for details.

The *Nevery* and *Nfreq* arguments specify on what timesteps the input values will be used to calculate correlation data, and the frequency with which the time correlation functions will be output to a file. Note that there is no *Nrepeat* argument, unlike the [fix ave/correlate](#) command.

The optional keywords *ncorr*, *nlen*, and *ncount* are unique to this command and determine the number of correlation points calculated and the memory and CPU overhead used by this calculation. *Nlen* and *ncount* determine the amount of averaging done at longer correlation times. The default values *nlen=16*, *ncount=2* ensure that the systematic error of the multiple-tau correlator is always below the level of the statistical error of a typical simulation (which depends on the ensemble size and the simulation length).

The maximum correlation time (in time steps) that can be reached is given by the formula $(nlen-1) * ncount^{(ncorr-1)}$. Longer correlation times are discarded and not calculated. With the default values of the parameters (*ncorr=20*, *nlen=16* and *ncount=2*), this corresponds to 7864320 time steps. If longer correlation times are needed, the value of *ncorr* should be increased. Using *nlen=16* and *ncount=2*, with *ncorr=30*, the maximum number of steps that can be correlated is 80530636808. If *ncorr=40*, correlation times in excess of 8e12 time steps can be calculated.

The total memory needed for each correlation pair is roughly $4*ncorr*nlen*8$ bytes. With the default values of the parameters, this corresponds to about 10 KB.

For the meaning of the additional optional keywords, see the [fix ave/correlate](#) doc page.

Restart, fix_modify, output, run start/stop, minimize info:

Since this fix is intended for the calculation of time correlation functions over very long MD simulations, the information about this fix is written automatically to binary restart files, so that the time correlation calculation can continue in subsequent simulations. None of the *fix_modify* options are relevant to this fix.

No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during energy minimization.

Restrictions:

LAMMPS Users Manual

This compute is part of the USER-MISC package. It is only enabled if LAMMPS was built with that package. See the [Making LAMMPS](#) section for more info.

```

Description:

Use one or more values as inputs every few timesteps to create a single histogram. The histogram can then be averaged over longer timescales. The resulting histogram can be used by other [output commands](#), and can also be written to a file. The `fix ave/histo/weight` command has identical syntax to `fix ave/histo`, except that exactly two values must be specified. See details below.

The group specified with this command is ignored for global and local input values. For per-atom input values, only atoms in the group contribute to the histogram. Note that regardless of the specified group, specified values may represent calculations performed by computes and fixes which store their own "group" definition.

A histogram is simply a count of the number of values that fall within a histogram bin. *Nbins* are defined, with even spacing between *lo* and *hi*. Values that fall outside the *lo/hi* bounds can be treated in different ways; see the discussion of the *beyond* keyword below.

Each input value can be an atom attribute (position, velocity, force component) or can be the result of a [compute](#) or [fix](#) or the evaluation of an equal-style or vector-style or atom-style [variable](#). The set of input values can be either all global, all per-atom, or all local quantities. Inputs of different kinds (e.g. global and per-atom) cannot be mixed. Atom attributes are per-atom vector values. See the doc page for individual "compute" and "fix" commands to see what kinds of quantities they generate.

Note that the output of this command is a single histogram for all input values combined together, not one histogram per input value. See below for details on the format of the output of this `fix`.

The input values must either be all scalars or all vectors (or arrays), depending on the setting of the *mode* keyword.

If *mode* = scalar, then the input values must be scalars, or vectors with a bracketed term appended, indicating the *I*th value of the vector is used.

If *mode* = vector, then the input values must be vectors, or arrays with a bracketed term appended, indicating the *I*th column of the array is used.

Note that for values from a `compute` or `fix`, the bracketed index *I* can be specified using a wildcard asterisk with the index to effectively specify multiple values. This takes the form "*" or "*n" or "n*" or "m*n". If *N* = the size of the vector (for *mode* = scalar) or the number of columns in the array (for *mode* = vector), then an asterisk with no numeric values means all indices from 1 to *N*. A leading asterisk means all indices from 1 to *n* (inclusive). A trailing asterisk means all indices from *n* to *N* (inclusive). A middle asterisk means all indices from *m* to *n* (inclusive).

LAMMPS Users Manual

Using a wildcard is the same as if the individual elements of the vector or columns of the array had been listed one by one. E.g. these 2 fix ave/histo commands are equivalent, since the [compute com/chunk](#) command creates a global array with 3 columns:

```
compute myCOM all com/chunk
fix 1 all ave/histo 100 1 100 c_myCOM[*] file tmp1.com mode vector
fix 2 all ave/histo 100 1 100 c_myCOM[1] c_myCOM[2] c_myCOM[3] file tmp2.com mode vector
```

If the fix ave/histo/weight command is used, exactly two values must be specified. If the values are vectors, they must be the same length. The first value (a scalar or vector) is what is histogrammed into bins, in the same manner the fix ave/histo command operates. The second value (a scalar or vector) is used as a "weight". This means that instead of each value tallying a "1" to its bin, the corresponding weight is tallied. E.g. The Nth entry (weight) in the second vector is tallied to the bin corresponding to the Nth entry in the first vector.

The *Nevery*, *Nrepeat*, and *Nfreq* arguments specify on what timesteps the input values will be used in order to contribute to the histogram. The final histogram is generated on timesteps that are multiple of *Nfreq*. It is averaged over *Nrepeat* histograms, computed in the preceding portion of the simulation every *Nevery* timesteps. *Nfreq* must be a multiple of *Nevery* and *Nevery* must be non-zero even if *Nrepeat* is 1. Also, the timesteps contributing to the histogram value cannot overlap, i.e. $Nrepeat * Nevery$ can not exceed *Nfreq*.

For example, if *Nevery*=2, *Nrepeat*=6, and *Nfreq*=100, then input values on timesteps 90,92,94,96,98,100 will be used to compute the final histogram on timestep 100. Similarly for timesteps 190,192,194,196,198,200 on timestep 200, etc. If *Nrepeat*=1 and *Nfreq* = 100, then no time averaging of the histogram is done; a histogram is simply generated on timesteps 100,200,etc.

The atom attribute values (x,y,z,vx,vy,vz,fx,fy,fz) are self-explanatory. Note that other atom attributes can be used as inputs to this fix by using the [compute property/atom](#) command and then specifying an input value from that compute.

If a value begins with "c_", a compute ID must follow which has been previously defined in the input script. If *mode* = scalar, then if no bracketed term is appended, the global scalar calculated by the compute is used. If a bracketed term is appended, the Ith element of the global vector calculated by the compute is used. If *mode* = vector, then if no bracketed term is appended, the global or per-atom or local vector calculated by the compute is used. If a bracketed term is appended, the Ith column of the global or per-atom or local array calculated by the compute is used. See the discussion above for how I can be specified with a wildcard asterisk to effectively specify multiple values.

Note that there is a [compute reduce](#) command which can sum per-atom quantities into a global scalar or vector which can thus be accessed by fix ave/histo. Or it can be a compute defined not in your input script, but by [thermodynamic output](#) or other fixes such as [fix nvt](#) or [fix temp/rescale](#). See the doc pages for these commands which give the IDs of these computes. Users can also write code for their own compute styles and [add them to LAMMPS](#).

LAMMPS Users Manual

If a value begins with "f_", a fix ID must follow which has been previously defined in the input script. If *mode* = scalar, then if no bracketed term is appended, the global scalar calculated by the fix is used. If a bracketed term is appended, the Ith element of the global vector calculated by the fix is used. If *mode* = vector, then if no bracketed term is appended, the global or per-atom or local vector calculated by the fix is used. If a bracketed term is appended, the Ith column of the global or per-atom or local array calculated by the fix is used. See the discussion above for how I can be specified with a wildcard asterisk to effectively specify multiple values.

Note that some fixes only produce their values on certain timesteps, which must be compatible with *Nevery*, else an error will result. Users can also write code for their own fix styles and [add them to LAMMPS](#).

If a value begins with "v_", a variable name must follow which has been previously defined in the input script. If *mode* = scalar, then only equal-style or vector-style variables can be used, which both produce global values. In this mode, a vector-style variable requires a bracketed term to specify the Ith element of the vector calculated by the variable. If *mode* = vector, then only vector-style or atom-style variables can be used, which produce a global or per-atom vector respectively. The vector-style variable must be used without a bracketed term. See the [variable](#) command for details.

Note that variables of style *equal*, *vector*, and *atom* define a formula which can reference individual atom properties or thermodynamic keywords, or they can invoke other computes, fixes, or variables when they are evaluated, so this is a very general means of specifying quantities to histogram.

Additional optional keywords also affect the operation of this fix.

If the *mode* keyword is set to *scalar*, then all input values must be global scalars, or elements of global vectors. If the *mode* keyword is set to *vector*, then all input values must be global or per-atom or local vectors, or columns of global or per-atom or local arrays.

The *beyond* keyword determines how input values that fall outside the *lo* to *hi* bounds are treated. Values such that $lo \leq \text{value} \leq hi$ are assigned to one bin. Values on a bin boundary are assigned to the lower of the 2 bins. If *beyond* is set to *ignore* then values $< lo$ and values $> hi$ are ignored, i.e. they are not binned. If *beyond* is set to *end* then values $< lo$ are counted in the first bin and values $> hi$ are counted in the last bin. If *beyond* is set to *extend* then two extra bins are created, so that there are $N_{bins}+2$ total bins. Values $< lo$ are counted in the first bin and values $> hi$ are counted in the last bin ($N_{bins}+1$). Values between *lo* and *hi* (inclusive) are counted in bins 2 thru $N_{bins}+1$. The "coordinate" stored and printed for these two extra bins is *lo* and *hi*.

The *ave* keyword determines how the histogram produced every *Nfreq* steps are averaged with histograms produced on previous steps that were multiples of *Nfreq*, before they are accessed by another output command or written to a file.

If the *ave* setting is *one*, then the histograms produced on timesteps that are multiples of *Nfreq* are independent of each other; they are output as-is without further

averaging.

If the *ave* setting is *running*, then the histograms produced on timesteps that are multiples of *Nfreq* are summed and averaged in a cumulative sense before being output. Each bin value in the histogram is thus the average of the bin value produced on that timestep with all preceding values for the same bin. This running average begins when the fix is defined; it can only be restarted by deleting the fix via the `unfix` command, or by re-defining the fix by re-specifying it.

If the *ave* setting is *window*, then the histograms produced on timesteps that are multiples of *Nfreq* are summed within a moving "window" of time, so that the last *M* histograms are used to produce the output. E.g. if $M = 3$ and $Nfreq = 1000$, then the output on step 10000 will be the combined histogram of the individual histograms on steps 8000,9000,10000. Outputs on early steps will be sums over less than *M* histograms if they are not available.

The *start* keyword specifies what timestep histogramming will begin on. The default is step 0. Often input values can be 0.0 at time 0, so setting *start* to a larger value can avoid including a 0.0 in a running or windowed histogram.

The *file* keyword allows a filename to be specified. Every *Nfreq* steps, one histogram is written to the file. This includes a leading line that contains the timestep, number of bins, the total count of values contributing to the histogram, the count of values that were not histogrammed (see the *beyond* keyword), the minimum value encountered, and the maximum value encountered. The min/max values include values that were not histogrammed. Following the leading line, one line per bin is written into the file. Each line contains the bin #, the coordinate for the center of the bin (between *lo* and *hi*), the count of values in the bin, and the normalized count. The normalized count is the bin count divided by the total count (not including values not histogrammed), so that the normalized values sum to 1.0 across all bins.

The *overwrite* keyword will continuously overwrite the output file with the latest output, so that it only contains one timestep worth of output. This option can only be used with the *ave running* setting.

The *title1* and *title2* and *title3* keywords allow specification of the strings that will be printed as the first 3 lines of the output file, assuming the *file* keyword was used. LAMMPS uses default values for each of these, so they do not need to be specified.

By default, these header lines are as follows:

```
# Histogram for fix ID
# TimeStep Number-of-bins Total-counts Missing-counts Min-value Max-value
# Bin Coord Count Count/Total
```

In the first line, ID is replaced with the fix-ID. The second line describes the six values that are printed at the first of each section of output. The third describes the 4 values printed for each bin in the histogram.

Restart, fix_modify, output, run start/stop, minimize info:

LAMMPS Users Manual

No information about this fix is written to [binary restart files](#). None of the [fix_modify](#) options are relevant to this fix.

This fix produces a global vector and global array which can be accessed by various [output commands](#). The values can only be accessed on timesteps that are multiples of *Nfreq* since that is when a histogram is generated. The global vector has 4 values:

- 1 = total counts in the histogram
- 2 = values that were not histogrammed (see *beyond* keyword)
- 3 = min value of all input values, including ones not histogrammed
- 4 = max value of all input values, including ones not histogrammed

The global array has # of rows = Nbins and # of columns = 3. The first column has the bin coordinate, the 2nd column has the count of values in that histogram bin, and the 3rd column has the bin count divided by the total count (not including missing counts), so that the values in the 3rd column sum to 1.0.

The vector and array values calculated by this fix are all treated as intensive. If this is not the case, e.g. due to histogramming per-atom input values, then you will need to account for that when interpreting the values produced by this fix.

No parameter of this fix can be used with the *start/stop* keywords of the [run](#) command. This fix is not invoked during [energy minimization](#).

Restrictions: none

Related commands:

[compute](#), [fix ave/atom](#), [fix ave/chunk](#), [fix ave/time](#), [variable](#), [fix ave/correlate](#),

Default: none

The option defaults are mode = scalar, ave = one, start = 0, no file output, beyond = ignore, and title 1,2,3 = strings as described above.

fix ave/time command

Syntax:

```
fix ID group-ID ave/time Nevery Nrepeat Nfreq value1 value2 ... keyword args ...
```

- ID, group-ID are documented in [fix](#) command
- ave/time = style name of this fix command
- Nevery = use input values every this many timesteps
- Nrepeat = # of times to use input values for calculating averages
- Nfreq = calculate averages every this many timesteps
- one or more input values can be listed
- value = c_ID, c_ID[N], f_ID, f_ID[N], v_name

c_ID = global scalar or vector calculated by a compute with ID

c_ID[I] = Ith component of global vector or Ith column of global array calculated by a

f_ID = global scalar or vector calculated by a fix with ID

f_ID[I] = Ith component of global vector or Ith column of global array calculated by a

v_name = value(s) calculated by an equal-style or vector-style variable with name

v_name[I] = value calculated by a vector-style variable with name

- zero or more keyword/arg pairs may be appended
- keyword = *mode* or *file* or *ave* or *start* or *off* or *overwrite* or *title1* or *title2* or *title3*

mode arg = *scalar* or *vector*

scalar = all input values are global scalars

vector = all input values are global vectors or global arrays

ave args = *one* or *running* or *window M*

one = output a new average value every Nfreq steps

running = output cumulative average of all previous Nfreq steps

window M = output average of M most recent Nfreq steps

start args = Nstart

Nstart = start averaging on this timestep

off arg = M = do not average this value

M = value # from 1 to Nvalues

file arg = filename

filename = name of file to output time averages to

overwrite arg = none = overwrite output file with only latest output

format arg = string

string = C-style format string

title1 arg = string

string = text to print as 1st line of output file

title2 arg = string

string = text to print as 2nd line of output file

title3 arg = string

string = text to print as 3rd line of output file, only for vector mode

Examples:

```
fix 1 all ave/time 100 5 1000 c_myTemp c_thermo_temp file temp.profile
```

```
fix 1 all ave/time 100 5 1000 c_thermo_press[2] ave window 20 &  
title1 "My output values"
```

```
fix 1 all ave/time 100 5 1000 c_thermo_press[*]
```

```
fix 1 all ave/time 1 100 1000 f_indent f_indent[1] file temp.indent off 1
```

Description:

Use one or more global values as inputs every few timesteps, and average them over longer timescales. The resulting averages can be used by other [output commands](#) such as [thermo_style custom](#), and can also be written to a file. Note that if no time averaging is done, this command can be used as a convenient way to simply output one or more global values to a file.

The group specified with this command is ignored. However, note that specified values may represent calculations performed by `compute` and `fix` which store their own "group" definitions.

Each listed value can be the result of a [compute](#) or [fix](#) or the evaluation of an equal-style or vector-style [variable](#). In each case, the `compute`, `fix`, or `variable` must produce a global quantity, not a per-atom or local quantity. If you wish to spatial- or time-average or histogram per-atom quantities from a `compute`, `fix`, or `variable`, then see the [fix ave/chunk](#), [fix ave/atom](#), or [fix ave/histo](#) commands. If you wish to sum a per-atom quantity into a single global quantity, see the [compute reduce](#) command.

[Computes](#) that produce global quantities are those which do not have the word *atom* in their style name. Only a few [fixes](#) produce global quantities. See the doc pages for individual `fixes` for info on which ones produce such values. [Variables](#) of style *equal* and *vector* are the only ones that can be used with this `fix`. Variables of style *atom* cannot be used, since they produce per-atom values.

The input values must either be all scalars or all vectors depending on the setting of the *mode* keyword. In both cases, the averaging is performed independently on each input value. I.e. each input scalar is averaged independently or each element of each input vector is averaged independently.

If *mode* = scalar, then the input values must be scalars, or vectors with a bracketed term appended, indicating the Ith value of the vector is used.

If *mode* = vector, then the input values must be vectors, or arrays with a bracketed term appended, indicating the Ith column of the array is used. All vectors must be the same length, which is the length of the vector or number of rows in the array.

Note that for values from a `compute` or `fix`, the bracketed index I can be specified using a wildcard asterisk with the index to effectively specify multiple values. This takes the form "*" or "*n" or "n*" or "m*n". If N = the size of the vector (for *mode* = scalar) or the number of columns in the array (for *mode* = vector), then an asterisk with no numeric values means all indices from 1 to N. A leading asterisk means all indices from 1 to n (inclusive). A trailing asterisk means all indices from n to N (inclusive). A middle asterisk means all indices from m to n (inclusive).

Using a wildcard is the same as if the individual elements of the vector or columns of the array had been listed one by one. E.g. these 2 `fix ave/time` commands are equivalent, since the [compute rdf](#) command creates, in this case, a global array with 3 columns, each of length 50:

```
compute myRDF all rdf 50 1 2
```

LAMMPS Users Manual

```
fix 1 all ave/time 100 1 100 c_myRDF[*] file tmp1.rdf mode vector
fix 2 all ave/time 100 1 100 c_myRDF[1] c_myRDF[2] c_myRDF[3] file tmp2.rdf mode vector
```

The *Nevery*, *Nrepeat*, and *Nfreq* arguments specify on what timesteps the input values will be used in order to contribute to the average. The final averaged quantities are generated on timesteps that are a multiple of *Nfreq*. The average is over *Nrepeat* quantities, computed in the preceding portion of the simulation every *Nevery* timesteps. *Nfreq* must be a multiple of *Nevery* and *Nevery* must be non-zero even if *Nrepeat* is 1. Also, the timesteps contributing to the average value cannot overlap, i.e. $Nrepeat * Nevery$ can not exceed *Nfreq*.

For example, if *Nevery*=2, *Nrepeat*=6, and *Nfreq*=100, then values on timesteps 90,92,94,96,98,100 will be used to compute the final average on timestep 100. Similarly for timesteps 190,192,194,196,198,200 on timestep 200, etc. If *Nrepeat*=1 and *Nfreq* = 100, then no time averaging is done; values are simply generated on timesteps 100,200,etc.
