        .postSticky(new SlideChangedEvent(resourceId));
}
```

(from [Presentation/MultiDisplay/app/src/main/java/com/commonsware/android/preso/slides/MainActivity.java](#))

PresentationActivity, in turn, registers for that sticky event and shows that slide, or the first slide if there is no such event:

```
package com.commonsware.android.preso.slides;

import android.app.Activity;
import android.os.Bundle;
import android.support.annotation.Nullable;
import android.widget.ImageView;
import org.greenrobot.eventbus.EventBus;
import org.greenrobot.eventbus.Subscribe;
import org.greenrobot.eventbus.ThreadMode;

public class PresentationActivity extends Activity {
    private ImageView slide;

    @Override
    protected void onCreate(@Nullable Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.activity_preso);

        slide=(ImageView)findViewById(R.id.slide);

        MainActivity.SlideChangedEvent event=
            EventBus.getDefault().getStickyEvent(MainActivity.SlideChangedEvent.class);

        if (event==null) {
            slide.setImageResource(R.drawable.img0);
        }
    }

    @Override
    protected void onStart() {
        super.onStart();

        EventBus.getDefault().register(this);
    }

    @Override
    protected void onStop() {
        EventBus.getDefault().unregister(this);

        super.onStop();
    }
}
```

MULTI-WINDOW SUPPORT

```
@Subscribe(sticky = true, threadMode = ThreadMode.MAIN)
public void onSlideChanged(MainActivity.SlideChangedEvent event) {
    slide.setImageResource(event.resourceId);
}
}
```

(from [Presentation/MultiDisplay/app/src/main/java/com/commonsware/android/preso/slides/PresentationActivity.java](#))

Using a sticky event means that MainActivity does not really care if PresentationActivity is currently available or not. It just fires off the events, knowing that whenever PresentationActivity is started, it can pick up the latest such event, plus any new ones raised while PresentationActivity is around.

Not only can use multi-display mode as a replacement for Presentation, but you can do something that was never officially supported with Presentation: control the external display while allowing some other activity to take over the primary display. This is illustrated in the [Presentation/MultiDisplayDetached](#) sample app. This is a clone of the MultiDisplay one, but set up where MainActivity goes away after kicking off the presentation.

MainActivity has the same action bar items as before, but this time, when the user starts the presentation, we handle that event slightly differently:

```
@Override
public boolean onOptionsItemSelected(MenuItem item) {
    switch (item.getItemId()) {
        case R.id.present:
            Intent i =
                new Intent(this, PresentationActivity.class)
                    .addFlags(Intent.FLAG_ACTIVITY_NEW_TASK|Intent.FLAG_ACTIVITY_MULTIPLE_TASK);
            Bundle opts=ActivityOptions
                .makeBasic()
                .setLaunchDisplayId(presoDisplay.getDisplayId())
                .toBundle();

            startActivity(i, opts);
            showNotification();
            finish();

            break;

        case R.id.first:
            pager.setCurrentItem(0);
            break;

        case R.id.last:
            pager.setCurrentItem(adapter.getCount() - 1);
            break;
    }

    return(super.onOptionsItemSelected(item));
}
```

MULTI-WINDOW SUPPORT

(from [Presentation/MultiDisplayDetached/app/src/main/java/com/commonsware/android/preso/slides/MainActivity.java](#))

After starting the `PresentationActivity` in multi-display mode, we `finish()` the `MainActivity`. However, we also call `showNotification()`, which brings up a `Notification` to use to control the slides:

```
private void showNotification() {
    NotificationCompat.Builder b=
        new NotificationCompat.Builder(this)
            .setOngoing(true)
            .setContentTitle("Presentation!")
            .setSmallIcon(android.R.drawable.stat_notify_more)
            .addAction(android.R.drawable.ic_media_previous,
                getString(R.string.action_previous), buildPreviousPendingIntent())
            .addAction(android.R.drawable.ic_media_next,
                getString(R.string.action_next), buildNextPendingIntent())
            .addAction(android.R.drawable.ic_media_pause,
                getString(R.string.action_stop), buildStopPendingIntent());

    NotificationManager mgr=
        (NotificationManager) getSystemService(NOTIFICATION_SERVICE);

    mgr.notify(1337, b.build());
}

private PendingIntent buildPreviousPendingIntent() {
    Intent i=new Intent(this, ControlReceiver.class).putExtra(EXTRA_DELTA, -1);

    return(PendingIntent.getBroadcast(this, PI_PREVIOUS, i, 0));
}

private PendingIntent buildNextPendingIntent() {
    Intent i=new Intent(this, ControlReceiver.class).putExtra(EXTRA_DELTA, 1);

    return(PendingIntent.getBroadcast(this, PI_NEXT, i, 0));
}

private PendingIntent buildStopPendingIntent() {
    Intent i=new Intent(this, ControlReceiver.class).putExtra(EXTRA_STOP, true);

    return(PendingIntent.getBroadcast(this, PI_STOP, i, 0));
}
```

(from [Presentation/MultiDisplayDetached/app/src/main/java/com/commonsware/android/preso/slides/MainActivity.java](#))

Those broadcasts go to a `ControlReceiver`, which is registered in the manifest and simply forwards those broadcasts on an event bus:

```
package com.commonsware.android.preso.slides;

import android.content.BroadcastReceiver;
import android.content.Context;
import android.content.Intent;
import org.greenrobot.eventbus.EventBus;
```

MULTI-WINDOW SUPPORT

```
public class ControlReceiver extends BroadcastReceiver {
    static final String EXTRA_DELTA="delta";
    static final String EXTRA_STOP="orMyMomWillShoot";

    @Override
    public void onReceive(Context context, Intent intent) {
        EventBus.getDefault().post(intent);
    }
}
```

(from [Presentation/MultiDisplayDetached/app/src/main/java/com/commonsware/android/preso/slides/ControlReceiver.java](#))

PresentationActivity can then listen for that event, along with the SlidePositionEvent, using each to update the visible slide:

```
@Subscribe(sticky=true, threadMode=ThreadMode.MAIN)
public void onSlideChanged(SlidePositionEvent event) {
    position=event.position;
    updateSlide();
}

@Subscribe(threadMode=ThreadMode.MAIN)
public void onBroadcast(Intent i) {
    if (i.getBooleanExtra(EXTRA_STOP, false)) {
        ((NotificationManager) getSystemService(NOTIFICATION_SERVICE)).cancelAll();
        finish();
    }
    else {
        int delta=i.getIntExtra(EXTRA_DELTA, 0);

        if (position+delta>=0 && position+delta<SlidesAdapter.SLIDES.length) {
            position+=delta;
            updateSlide();
        }
    }
}

private void updateSlide() {
    slide.setImageResource(SlidesAdapter.SLIDES[position]);
}
```

(from [Presentation/MultiDisplayDetached/app/src/main/java/com/commonsware/android/preso/slides/PresentationActivity.java](#))

The result is that the slides remain visible — and controllable via the Notification — even though MainActivity is gone:

MULTI-WINDOW SUPPORT

Advanced ConstraintLayout

The [original chapter on ConstraintLayout](#) covered some basic uses of this container class, particularly how it can be used in the place of classic containers like `LinearLayout` and `RelativeLayout`. In this chapter, we will explore other features that `ConstraintLayout` offers and other use cases for this container.

This chapter examines some more layouts from the [Containers/Sampler](#) sample project.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book, particularly the [original chapter on ConstraintLayout](#).

Disclosing Your Bias

For a given axis, there are roughly three models for how you use constraints for a given widget:

- Anchor one side of the widget to something based upon that axis (e.g., `app:layout_constraintStart_toStartOf="parent"`)
- Anchor both sides of the widget to something based upon that axis, with the size on that axis (e.g., `android:layout_width` for the horizontal axis) set to `0dp`
- Anchor both sides of the widget to something based upon that axis, with the size on that axis set to `wrap_content` or some non-zero dimension

ADVANCED CONSTRAINTLAYOUT

In the first case, the widget is simply attached to the anchor point, taking any margins into account. In the second case, the widget is stretched between the two anchor points.

The default for the third case is for the widget to be centered within the available space between the two anchor points, assuming that its size on that axis is smaller than the available space. However, we can use “bias” to slide the widget along that axis away from the center point, so it appears closer to one end than the other.

Centering a widget within a RelativeLayout is a matter of using `android:layout_centerInParent="true"`:

```
<?xml version="1.0" encoding="utf-8"?>
<RelativeLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent">

    <Button
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:layout_centerInParent="true"
        android:text="@string/button" />

</RelativeLayout>
```

(from [Containers/Sampler/app/src/main/res/layout/center_rl.xml](#))

Centering a widget within a ConstraintLayout is more verbose, requiring you to anchor all four sides of the widget to the four edges of the ConstraintLayout:

```
<?xml version="1.0" encoding="utf-8"?>
<android.support.constraint.ConstraintLayout
    xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:app="http://schemas.android.com/apk/res-auto"
    android:layout_width="match_parent"
    android:layout_height="match_parent">

    <Button
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:text="@string/button"
        app:layout_constraintBottom_toBottomOf="parent"
        app:layout_constraintEnd_toEndOf="parent"
        app:layout_constraintStart_toStartOf="parent"
        app:layout_constraintTop_toTopOf="parent" />
```

ADVANCED CONSTRAINTLAYOUT

```
</android.support.constraint.ConstraintLayout>
```

(from [Containers/Sampler/app/src/main/res/layout/center_cl.xml](#))

However, that verbosity also allows us to apply biases, via `app:layout_constraintHorizontal_bias` and `app:layout_constraintVertical_bias`:

```
<?xml version="1.0" encoding="utf-8"?>
<android.support.constraint.ConstraintLayout xmlns:tools="http://schemas.android.com/tools"
    xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:app="http://schemas.android.com/apk/res-auto"
    android:layout_width="match_parent"
    android:layout_height="match_parent">

    <Button
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:text="@string/button"
        app:layout_constraintBottom_toBottomOf="parent"
        app:layout_constraintEnd_toEndOf="parent"
        app:layout_constraintHorizontal_bias="0.33"
        app:layout_constraintStart_toStartOf="parent"
        app:layout_constraintTop_toTopOf="parent"
        app:layout_constraintVertical_bias="0.32999998"
        tools:layout_editor_absoluteX="98dp" />

</android.support.constraint.ConstraintLayout>
```

(from [Containers/Sampler/app/src/main/res/layout/bias_cl.xml](#))

The default values for the biases are 0.5, meaning that the center point of the widget is centered evenly between the two anchor points. A bias of less than 0.5 slides the widget towards the beginning of that axis (towards the start size of the horizontal axis or the top of the vertical axis). A bias of higher than 0.5 slides the widget towards the end of that axis.

So, for bias values of 0.33 along each axis, the Button is slid towards the start and top:

Figure 450: Bias Sample, Using ConstraintLayout

It is impractical to replicate this using the classic container classes. LinearLayout comes closest, using something like this:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:orientation="vertical"
    android:weightSum="100">

    <View
        android:layout_width="match_parent"
        android:layout_height="0dp"
        android:layout_weight="33" />

    <LinearLayout
        android:layout_width="match_parent"
        android:layout_height="0dp"
        android:layout_weight="67"
        android:orientation="horizontal"
        android:weightSum="100">

        <View
            android:layout_width="0dp"
```

ADVANCED CONSTRAINTLAYOUT

```
        android:layout_height="match_parent"
        android:layout_weight="33" />

        <Button
            android:layout_width="wrap_content"
            android:layout_height="wrap_content"
            android:text="@string/button" />
    </LinearLayout>
</LinearLayout>
```

(from [Containers/Sampler/app/src/main/res/layout/bias_ll.xml](#))

Here, we use empty View widgets as spacers, along with weights to get the proportions the way that we want. However, this puts a *corner* of the Button at the appropriate location, not its center. So, compared to the ConstraintLayout approach, the LinearLayout implementation is a bit closer to the center:

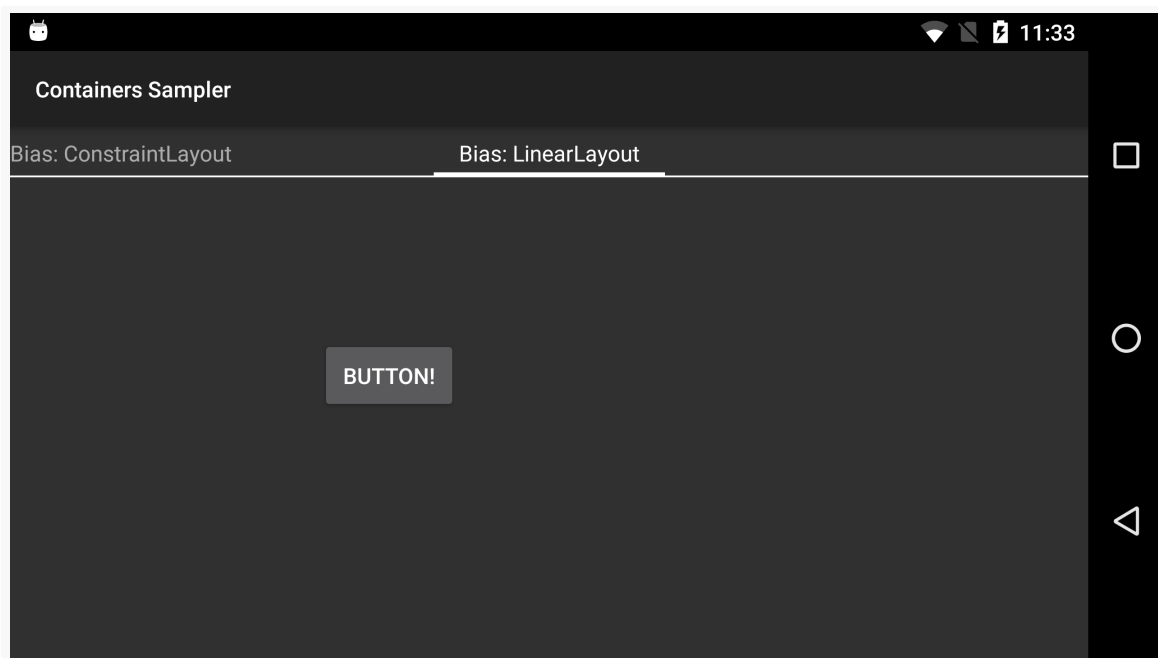

Figure 451: Bias Sample, Using LinearLayout

ConstraintLayout biases are not limited to constraints placed against the ConstraintLayout edges. You can apply biases based on constraints tied to guidelines or other widgets as well:

```
<?xml version="1.0" encoding="utf-8"?>
<android.support.constraint.ConstraintLayout xmlns:android="http://schemas.android.com/apk/res/android"
```

ADVANCED CONSTRAINTLAYOUT

```
xmlns:app="http://schemas.android.com/apk/res-auto"
android:layout_width="match_parent"
android:layout_height="match_parent">

<Button
    android:id="@+id/button3"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:text="@string/button"
    app:layout_constraintBottom_toBottomOf="parent"
    app:layout_constraintEnd_toEndOf="@+id/guideline"
    app:layout_constraintHorizontal_bias="0.1"
    app:layout_constraintLeft_toLeftOf="parent"
    app:layout_constraintRight_toRightOf="@+id/guideline"
    app:layout_constraintStart_toStartOf="parent"
    app:layout_constraintTop_toTopOf="parent"
    app:layout_constraintVertical_bias="0.25" />

<android.support.constraint.Guideline
    android:id="@+id/guideline"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:orientation="vertical"
    app:layout_constraintGuide_percent=".50" />

<Button
    android:id="@+id/button2"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:text="@string/btn_other"
    app:layout_constraintHorizontal_bias="0.8"
    app:layout_constraintLeft_toRightOf="@+id/button3"
    app:layout_constraintRight_toRightOf="parent"
    app:layout_constraintTop_toTopOf="@+id/button3" />

</android.support.constraint.ConstraintLayout>
```

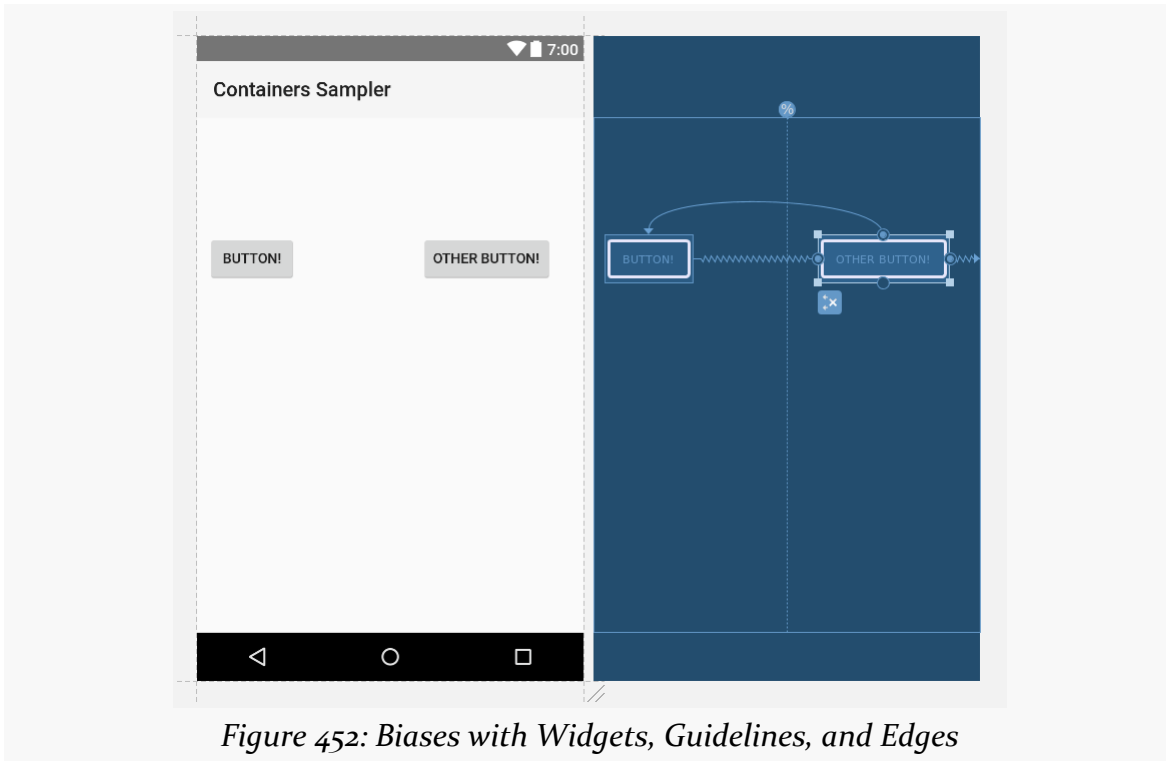

(from [Containers/Sampler/app/src/main/res/layout/bias_peers.cl.xml](#))

Here we have a `ConstraintLayout` with two buttons. The “Button!” button has two biases:

- A vertical bias to place it at the 25% mark from the top
- A horizontal bias to place it at the 10% mark between the screen edge and a center `Guideline`

The “Other Button!” button has a horizontal bias to place it at the 80% mark between the edge of the first button and the screen edge.

The buttons are positioned with those biases applied:

The configuration tool atop the Attributes pane lets you control the bias, by adjusting the slider for the bias to apply to that particular axis:

Centering Yourself

Sometimes, we want to have one widget be centered upon another widget. This could be in either direction: horizontal centering or vertical centering.

ADVANCED CONSTRAINTLAYOUT

The classic way to approximate this would involve you wrapping those two widgets in a container, then use `android:layout_gravity` to ask each of those widgets to center itself within the container:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:orientation="vertical">

    <Button
        android:id="@+id/button"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:layout_gravity="center_horizontal"
        android:layout_marginTop="16dp"
        android:text="@string/button" />

    <Button
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:layout_gravity="center_horizontal"
        android:layout_marginTop="16dp"
        android:text="@string/another_button" />

</LinearLayout>
```

(from [Containers/Sampler/app/src/main/res/layout/center_align_ll.xml](#))

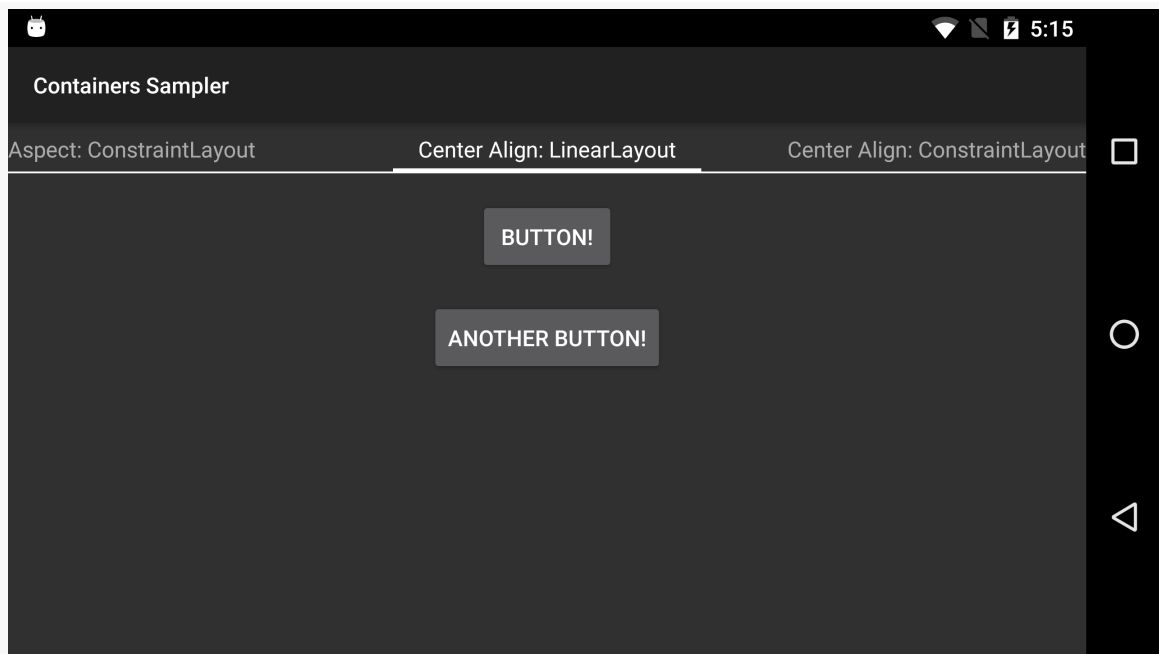

Figure 454: Center Alignment, Using LinearLayout

However, this approach has flaws:

- This actually centers the smaller widget on the larger one. In this case, the bottom Button has a larger caption, and so the smaller (top) Button is centered within the larger (bottom) Button.
- It requires that the two widgets be wrapped in a container, which may make it more difficult for those widgets to be positioned overall within the layout. They have to be moved in unison, rather than treated separately (other than for the center alignment aspect). This extra container also consumes heap size, rendering time, etc.

Using ConstraintLayout, we can just have rules that enforce the center alignment, along with all the rest of our rules, without the need for the additional container.

The trick is to simply have the dependent widget constrain its edges to match the edges of the independent widget. So, if we wanted to say that the bottom Button should be centered on the top Button, we get this:

```
<?xml version="1.0" encoding="utf-8"?>
<android.support.constraint.ConstraintLayout
    xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:app="http://schemas.android.com/apk/res-auto"
```

ADVANCED CONSTRAINTLAYOUT

```
android:layout_width="wrap_content"
android:layout_height="wrap_content">

<Button
    android:id="@+id/button"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:layout_marginTop="16dp"
    android:text="@string/button"
    app:layout_constraintEnd_toEndOf="parent"
    app:layout_constraintStart_toStartOf="parent"
    app:layout_constraintTop_toTopOf="parent" />

<Button
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:layout_marginTop="16dp"
    android:text="@string/another_button"
    app:layout_constraintEnd_toEndOf="@id/button"
    app:layout_constraintStart_toStartOf="@id/button"
    app:layout_constraintTop_toBottomOf="@id/button" />

</android.support.constraint.ConstraintLayout>
```

(from [Containers/Sampler/app/src/main/res/layout/center_align_cl.xml](#))

The top Button centers itself within the ConstraintLayout and anchors itself to the top of the ConstraintLayout.

The bottom Button uses `app:layout_constraintStart_toStartOf` and `app:layout_constraintEnd_toEndOf` to align its edges with those of the top Button. However, its width is set to `wrap_content`, so the *size* of the Button will not change. Instead, those rules are treated as meaning that the bottom Button should be centered on the top Button.

In essence, both Button widgets are doing the same thing: using `app:layout_constraintStart_toStartOf` and `app:layout_constraintEnd_toEndOf` to center themselves. The difference is that the top Button is centering itself inside the ConstraintLayout, while the bottom Button is centering itself on the top Button.

Figure 455: Center Alignment, Using ConstraintLayout

Assuming that we are putting the `ConstraintLayout` to other good uses, managing the position and size of other widgets, we are avoiding having a dedicated container for these two widgets. This has the potential to be more efficient and more flexible.

Keeping Things Proportional

Occasionally, we have a widget that we want to have a particular aspect ratio. That is relatively unusual. Perhaps the most common case is an `ImageView`, where you know in advance what the aspect ratio of the image is and you want to have the `ImageView` be sized to match.

`ConstraintLayout` offers an `app:layout_constraintDimensionRatio` that can help here.

To use the dimension ratio constraint, you need to pick one axis to have a known size (e.g., `wrap_content`). The other axis needs a size of `0dp`. Then, `app:layout_constraintDimensionRatio` will scale the widget along the `0dp` axis to match the specified aspect ratio:

```
<?xml version="1.0" encoding="utf-8"?>
<android.support.constraint.ConstraintLayout
```

ADVANCED CONSTRAINTLAYOUT

```
xmlns:android="http://schemas.android.com/apk/res/android"
xmlns:app="http://schemas.android.com/apk/res-auto"
android:layout_width="match_parent"
android:layout_height="match_parent">

<ImageView
    android:layout_width="wrap_content"
    android:layout_height="0dp"
    android:src="@drawable/freedom_tower"
    app:layout_constraintBottom_toBottomOf="parent"
    app:layout_constraintDimensionRatio="4:3"
    app:layout_constraintEnd_toEndOf="parent"
    app:layout_constraintStart_toStartOf="parent"
    app:layout_constraintTop_toTopOf="parent" />

</android.support.constraint.ConstraintLayout>
```

(from [Containers/Sampler/app/src/main/res/layout/aspect_cl.xml](#))

Alternatively, you could have *both* axes have a size of 0dp, and use an H, or W, prefix on the ratio to indicate which axis is the one that should be constrained (e.g., W,4:3).

Constraining the ConstraintLayout Size

Sometimes, your ConstraintLayout dimensions (android:layout_width and/or android:layout_height) are set to specific dimensions, ideally via a dimension resource. Sometimes, they are set to match_parent. And, sometimes, they are set to wrap_content. Those all work as expected.

However, sometimes, you would like wrap_content behavior, but only to certain extents. You want the ConstraintLayout to size itself based on its contents, but:

- You want to cap its size, perhaps to help prevent adjacent content from being clipped by the screen edge or being squished into too small of a space, or
- You want to prevent it from being *too* small, if the contents are small, because other aspects of the ConstraintLayout (e.g., background) are important and might not be visible at small size

To that end, ConstraintLayout offers the following attributes:

If This Is wrap_content...	Then You Can Use
android:layout_width	android:minWidth and android:maxWidth
android:layout_height	android:minHeight and android:maxHeight

Each takes a dimension and works pretty much as you might expect from the attribute names.

Chains, Without the Whips

Chains represent a linked series of widgets in a row or column inside of a ConstraintLayout. You can then set up some rules for how the entire chain should be rendered, such as how to handle whitespace between those widgets.

How Do We Set up a Chain?

A chain is an implicit structure. There is no `app:chainId` or similar mechanism to identify chains.

Rather, a chain is defined any time there are 2 widgets with mutual constraints, such as the left side of one widget being tied to the right side of the other widget, and vice-versa.

A chain itself can be as many widgets as needed, so long as pair-wise they have the mutual constraints. So, for example, here is a chain containing three Button widgets:

```
<Button
  android:id="@+id/button1a"
  android:layout_width="wrap_content"
  android:layout_height="wrap_content"
  android:text="1"
  app:layout_constraintBottom_toBottomOf="parent"
  app:layout_constraintHorizontal_chainStyle="spread"
  app:layout_constraintLeft_toLeftOf="parent"
  app:layout_constraintRight_toLeftOf="@+id/button2a"
  app:layout_constraintStart_toStartOf="parent"
  app:layout_constraintTop_toTopOf="parent"
  app:layout_constraintVertical_bias="0.1" />

<Button
  android:id="@+id/button2a"
  android:layout_width="wrap_content"
  android:layout_height="wrap_content"
  android:text="2"
```

ADVANCED CONSTRAINTLAYOUT

```
app:layout_constraintBaseline_toBaselineOf="@+id/button1a"  
app:layout_constraintLeft_toRightOf="@+id/button1a"  
app:layout_constraintRight_toLeftOf="@+id/button3a" />  
  
<Button  
  android:id="@+id/button3a"  
  android:layout_width="wrap_content"  
  android:layout_height="wrap_content"  
  android:text="3"  
  app:layout_constraintBaseline_toBaselineOf="@+id/button2a"  
  app:layout_constraintLeft_toRightOf="@+id/button2a"  
  app:layout_constraintRight_toRightOf="parent" />
```

(from [Containers/Sampler/app/src/main/res/layout/chains.cl.xml](#))

button1a and button2a have their horizontal constraints connected to each other, as do button2a and button3a. Hence, the three widgets represent a single chain.

Styles of Chains

Configuring a chain comes in part by adding a “chain style” attribute to the head of the chain. The head is defined as the left-most widget in a horizontal chain (e.g., button1a) or the top-most widget in a vertical chain.

Spread

If you do not otherwise specify on a chain, the chain style is “spread”. By default, this means that whitespace should be allocated between the widgets in the chain and outside the ends of the chain. And, by default, that allocation is even, so the space between each widget in the chain is the same, and the same amount of space appears outside the chain on either side.

That’s what we get from the chain shown above:

The chain head (button1a) has `app:layout_constraintHorizontal_chainStyle="spread"` to positively declare that

ADVANCED CONSTRAINTLAYOUT

this chain has a spread style, though this is unnecessary, as this is the default chain behavior.

Spread-Inside

A `spread_inside` chain style is similar to `spread`, except that there is no whitespace added to either end of the chain. All whitespace goes between the pairs of widgets.

Figure 457: Spread-Inside Chain

Packed

Conversely, a packed chain style puts all the whitespace on either end of the chain, having the widgets directly adjacent to each other:

Figure 458: Packed Chain

Chains and Biases

Spread and packed chains — ones where there is whitespace outside the chain — respond to biases, where a bias slides the entire chain to a given side by allocating the whitespace non-equally.

For example, here is a biased packed chain:

```
<Button
    android:id="@+id/button1e"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:text="1"
    app:layout_constraintBottom_toBottomOf="parent"
    app:layout_constraintHorizontal_bias="0.8"
    app:layout_constraintHorizontal_chainStyle="packed"
    app:layout_constraintLeft_toLeftOf="parent"
    app:layout_constraintRight_toLeftOf="@+id/button2e"
    app:layout_constraintStart_toStartOf="parent"
```

ADVANCED CONSTRAINTLAYOUT

```
app:layout_constraintTop_toTopOf="parent"
app:layout_constraintVertical_bias="0.9" />

<Button
    android:id="@+id/button2e"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:text="2"
    app:layout_constraintBaseline_toBaselineOf="@+id/button1e"
    app:layout_constraintLeft_toRightOf="@+id/button1e"
    app:layout_constraintRight_toLeftOf="@+id/button3e" />

<Button
    android:id="@+id/button3e"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:text="3"
    app:layout_constraintBaseline_toBaselineOf="@+id/button2e"
    app:layout_constraintLeft_toRightOf="@+id/button2e"
    app:layout_constraintRight_toRightOf="parent" />
```

(from [Containers/Sampler/app/src/main/res/layout/chains_cl.xml](#))

Here, the chain head has `app:layout_constraintHorizontal_bias="0.8"`, sliding the entire packed chain to the right:

Figure 459: Packed Chain with Horizontal Bias

Chains and Weights

Spread and spread-inside chains — ones where there is whitespace inside the chain — respond to weights, reminiscent of the weights used with `LinearLayout`.

Simply marking the widget as having a width (or height, for vertical chains) of `0dp` causes that widget to absorb the whitespace:

```
<Button
    android:id="@+id/button1c"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:text="1"
```

ADVANCED CONSTRAINTLAYOUT

```
app:layout_constraintBottom_toBottomOf="parent"
app:layout_constraintHorizontal_chainStyle="spread_inside"
app:layout_constraintLeft_toLeftOf="parent"
app:layout_constraintRight_toLeftOf="@+id/button2c"
app:layout_constraintStart_toStartOf="parent"
app:layout_constraintTop_toTopOf="parent"
app:layout_constraintVertical_bias="0.5" />

<Button
    android:id="@+id/button2c"
    android:layout_width="0dp"
    android:layout_height="wrap_content"
    android:text="2"
    app:layout_constraintBaseline_toBaselineOf="@+id/button1c"
    app:layout_constraintLeft_toRightOf="@+id/button1c"
    app:layout_constraintRight_toLeftOf="@+id/button3c" />

<Button
    android:id="@+id/button3c"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:text="3"
    app:layout_constraintBaseline_toBaselineOf="@+id/button2c"
    app:layout_constraintLeft_toRightOf="@+id/button2c"
    app:layout_constraintRight_toRightOf="parent" />
```

(from [Containers/Sampler/app/src/main/res/layout/chains_cl.xml](#))

Figure 460: Spread-Inside Chain, With Middle Button Filling Space

If two or more widgets use 0dp this way, they will divide the space equally, by default. Using `app:layout_constraintHorizontal_weight` or `app:layout_constraintVertical_weight` on the affected widgets can be used to divide the space on a weighted basis (e.g., giving one widget twice the space of another).

What If We're GONE?

For most container classes, marking a widget's visibility as GONE totally removes it from everything regarding the measurement and layout of the container. It is as if

ADVANCED CONSTRAINTLAYOUT

the widget never existed, though you are in position to “add it back in” simply by making it `VISIBLE`.

`ConstraintLayout` handles this slightly differently. Widgets that are `GONE` are treated as having no size (width and height of 0) and having no margins. However, `ConstraintLayout` will still honor constraints tied to those `GONE` widgets, taking into account their zero-size and zero-margin status. This allows your constraints to still work, rather than breaking entirely.

The zero size is non-negotiable. However, it is possible that you may still want margins to be taken into account. To that end, there are attributes like `app:layout_goneMarginStart` that you can use. As the attribute name suggests, these provide margins to be used when the widget itself is marked as `GONE`. You could set these to the same value as you used for the corresponding normal margin, perhaps using [the data binding framework](#) to have one attribute value reference the other attribute value and reduce duplication. You could even set the `GONE` margins to be something entirely different, if that made sense in your scenario (e.g., half of the normal margin).

GridLayout

In 2011, Google added `GridLayout` to our roster of available container classes (a.k.a., layout managers). `GridLayout` is an attempt to make setting up complex Android layouts a bit easier, particularly with an eye towards working well with IDE graphical layout editors. In this chapter, we will examine why `GridLayout` was added and how we can use it in our projects.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book.

Issues with the Classic Containers

Most layouts are implemented using a combination of `LinearLayout`, `RelativeLayout`, and `TableLayout`. Almost everything you would want to be able to create can be accomplished using one, or sometimes more than one, of those containers.

However, there are issues with the classic containers. The two most prominent might be the over-reliance upon nested containers and issues with drag-and-drop GUI building capability.

Nested Containers

`LinearLayout` and `TableLayout` suffer from a tendency to put too many containers inside of other containers. For example, implementing some sort of 2x2 grid would involve:

GRIDLAYOUT

- A vertical `LinearLayout` holding onto a pair of horizontal `LinearLayout`s, or
- A `TableLayout` holding onto a pair of `TableRows`

On the surface, this does not seem that bad. And, in many cases, it is not that bad.

However, views and containers are relatively heavyweight items. They consume a fair bit of heap space, and when it comes time to lay them out on the screen, they consume a fair bit of processing power. In particular, the fact that a container can hold onto *any* type of widget or container means that it is difficult to optimize common scenarios (e.g., a 2x2 grid) for faster processing. Instead, a container treats its children more or less as “black boxes”, requiring lots of method invocations up and down the call stack to calculate sizes and complete the layout process.

Moreover, the call stack itself can be an issue. The stack size of the main application thread has historically been rather small (8KB was the last reported value). If you have a complex UI, with more than ~15 nested containers, you are likely to run into a `StackOverflowError`. Android itself will contribute some of these containers, exacerbating this problem.

`RelativeLayout`, by comparison, can implement some UI patterns without any nested containers, simply by positioning widgets relative to the container’s bounds and relative to each other.

Drag-and-Drop

Where `RelativeLayout` falls down is with the drag-and-drop capability of the graphical layout editor in IDEs like Android Studio.

When you release the mouse button when dropping a widget into the preview area, the tools need to determine what that really means in terms of layout rules.

`LinearLayout` works fairly well: it will either insert your widget in between two other widgets or add it to the end of the row or column you dropped into. `TableLayout` behaves similarly.

`RelativeLayout`, though, has a more difficult time guessing what particular combination of rules you really mean by this particular drop target. Are you trying to attach the widget to another widget? If so, which one? Are you trying to attach the widget to the bounds of the `RelativeLayout`? While sometimes it will guess properly, sometimes it will not, with potentially confusing results. It is reasonably

likely that you will need to tweak the layout rules manually, either via the Attributes pane or via the raw XML.

The New Contender: GridLayout

GridLayout tries to cull the best of the capabilities of the classic containers and drop as many of their limitations as possible.

GridLayout works a bit like `TableLayout`, insofar as it sets things up in a grid, with rows and columns, where the row and column sizes are computed based upon what is placed into those rows and columns. However, unlike `TableLayout`, which relies upon a separate `TableRow` container to manage the rows, `GridLayout` takes the `RelativeLayout` approach of putting rules on the individual widgets (or containers) in the grid, where those rules steer the layout processing. For example, with `GridLayout`, widgets can declare specifically which row and column they should slot into.

`GridLayout` also goes a bit beyond what `TableLayout` offers in terms of capabilities. Notably, it supports row spans as well as column spans, whereas `TableRow` only supports a column span. This gives you greater flexibility when designing your layout to fit the grid-style positioning rules. You can also:

- Explicitly state how many columns there are, rather than having that value be inferred by row contents
- Allow Android to determine where to place a widget without specifying any row or column, with it finding the next available set of grid cells capable of holding the widget, based upon its requested row span and column span values
- Have control over orientation: whereas `TableLayout` always was a column of rows, you could have a `GridLayout` be a row of columns, if that makes implementing the design easier
- And so on

GridLayout and the Android Support Package

`GridLayout` was natively added to the Android SDK in API Level 14 (Android 4.0). Fortunately, the Android Support package has a backport of `GridLayout`. However, the backport is not in one of the JAR files, such as `support-v4`, as `GridLayout` requires some resources. Hence, it is in an Android library project that you must add to your project, known as `gridlayout-v7`.

GRIDLAYOUT

Android Studio users can simply add a implementation 'com.android.support:gridlayout-v7:...' statement to their top-level dependencies closure, for some version identified by So long as those users have the Android Support Repository set up in the SDK Manager, Gradle will be able to find and incorporate the artifact.

When using the backported GridLayout, you will need to declare another XML namespace in your layout XML resources. That namespace will be `http://schemas.android.com/apk/res-auto`. If you use an IDE to add the GridLayout to the layout resource, it will automatically add this namespace, under the prefix of `app`, such as:

```
<android.support.v7.widget.GridLayout
    xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:app="http://schemas.android.com/apk/res-auto"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    app:columnCount="2">
</android.support.v7.widget.GridLayout>
```

That namespace is required for GridLayout-specific attributes. For example, we can have a `columnCount` attribute, indicating how many columns the GridLayout should contain. For the native API Level 14 GridLayout, that attribute would be `android:columnCount`. For the backport, it will be `app:columnCount`, assuming that you gave the namespace the prefix of `app`.

When citing GridLayout-specific attributes, the rest of this chapter will use the `app` prefix, to clarify which attributes need that prefix for the backport. If you are using the native API Level 14 implementation of GridLayout, and you are manually working with the XML, just remember to use `android` as a prefix instead of `app`.

The sample app shows *both* the native and the backport implementations of GridLayout: on API Level 14+ devices/emulators it will use native implementations from `res/layout-v14/`, and it will use the backport on older environments.

Our Test App

To look at a series of GridLayout-based layouts, let's turn our attention to the [GridLayout/Sampler](#) sample project. This has the same ViewPager and PagerTabStrip as did the second sample app from [the chapter on ViewPager](#). However, rather than use a list of 10 EditText widgets managed by fragments, in this

GRIDLAYOUT

case, our fragments will manage layouts containing GridLayout. Each page of our pager will contain a TrivialFragment, whose contents are based on a Sample class that is a simple pair of a layout resource ID and a string resource ID for the fragment's title:

```
package com.commonware.android.gridlayout;

class Sample {
    int layoutId;
    int titleId;

    Sample(int layoutId, int titleId) {
        this.layoutId=layoutId;
        this.titleId=titleId;
    }
}
```

(from [GridLayout/Sampler/app/src/main/java/com/commonware/android/gridlayout/Sample.java](#))

Our revised SampleAdapter maintains a static ArrayList of these Sample objects, one per layout we wish to examine, and uses those values to populate our ViewPager title:

```
package com.commonware.android.gridlayout;

import android.app.Fragment;
import android.app.FragmentManager;
import android.content.Context;
import android.support.v13.app.FragmentPagerAdapter;
import java.util.ArrayList;

public class SampleAdapter extends FragmentPagerAdapter {
    static ArrayList<Sample> SAMPLES=new ArrayList<Sample>();
    private Context ctxt=null;

    static {
        SAMPLES.add(new Sample(R.layout.row, R.string.row));
        SAMPLES.add(new Sample(R.layout.column, R.string.column));
        SAMPLES.add(new Sample(R.layout.table, R.string.table));
        SAMPLES.add(new Sample(R.layout.table_flex, R.string.flexible_table));
        SAMPLES.add(new Sample(R.layout.implicit, R.string.implicit));
        SAMPLES.add(new Sample(R.layout.spans, R.string.spans));
    }

    public SampleAdapter(Context ctxt, FragmentManager mgr) {
        super(mgr);
        this.ctxt=ctxt;
    }
}
```

GRIDLAYOUT

```
}

@Override
public int getCount() {
    return(SAMPLES.size());
}

@Override
public Fragment getItem(int position) {
    return(TrivialFragment.newInstance(getSample(position).layoutId));
}

@Override
public String getPageTitle(int position) {
    return(ctxt.getString(getSample(position).titleId));
}

private Sample getSample(int position) {
    return(SAMPLES.get(position));
}
}
```

(from [GridLayout/Sampler/app/src/main/java/com/commonsware/android/gridlayout/SampleAdapter.java](#))

TrivialFragment just inflates our desired layout, having received the layout resource ID as a parameter to its factory method:

```
package com.commonsware.android.gridlayout;

import android.app.Fragment;
import android.os.Bundle;
import android.view.LayoutInflater;
import android.view.View;
import android.view.ViewGroup;

public class TrivialFragment extends Fragment {
    private static final String KEY_LAYOUT_ID="layoutId";

    static TrivialFragment newInstance(int layoutId) {
        TrivialFragment frag=new TrivialFragment();
        Bundle args=new Bundle();

        args.putInt(KEY_LAYOUT_ID, layoutId);
        frag.setArguments(args);

        return(frag);
    }
}
```

GRIDLAYOUT

```
@Override
public View onCreateView(LayoutInflater inflater,
    ViewGroup container,
    Bundle savedInstanceState) {
    return(inflater.inflate(getArguments().getInt(KEY_LAYOUT_ID, -1),
        container, false));
}
}
```

(from [GridLayout/Sampler/app/src/main/java/com/commonsware/android/gridlayout/TrivialFragment.java](#))

Note that if you load this project from the GitHub repository, you will need to update it for your copy of the GridLayout library project.

Replacing the Classics

Let's first examine the behavior of GridLayout by seeing how it can replace some of the classic layouts we would get from LinearLayout and TableLayout. Each of the following sub-sections will examine one GridLayout-based layout XML resource, how it can be constructed, and what the result looks like when viewed in the sample project.

Horizontal LinearLayout

The classic way to create a row of widgets is to use a horizontal LinearLayout. The LinearLayout will put each of its children, one after the next, within the row.

The GridLayout equivalent is to specify one that has an `app:columnCount` equal to the number of widgets in the row. Then, each widget will have `app:layout_column` set to its specific column index (starting at 0) and `app:layout_row` set to 0, as seen in `res/layout/row.xml`:

```
<android.support.v7.widget.GridLayout xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:app="http://schemas.android.com/apk/res-auto"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    app:columnCount="2">

    <Button
        app:layout_column="0"
        app:layout_row="0"
        android:text="@string/button"/>

    <Button
        app:layout_column="1"
        app:layout_row="0"
        android:text="@string/button"/>
</android.support.v7.widget.GridLayout>
```

GRIDLAYOUT

```
</android.support.v7.widget.GridLayout>
```

(from [GridLayout/Sampler/app/src/main/res/layout/row.xml](#))

Unlike `LinearLayout`, though, we do not specify sizes of the children, in terms of `android:layout_width` and `android:layout_height`. `GridLayout` works a bit like `TableLayout` in this regard, supplying default values for these attributes. In the case of `GridLayout`, the defaults are `wrap_content`, and this cannot be overridden (akin to the behavior of immediate children of a `TableRow`). Instead, you will control size via row and column spans, as will be illustrated later in this chapter.

Given the above layout, we get:

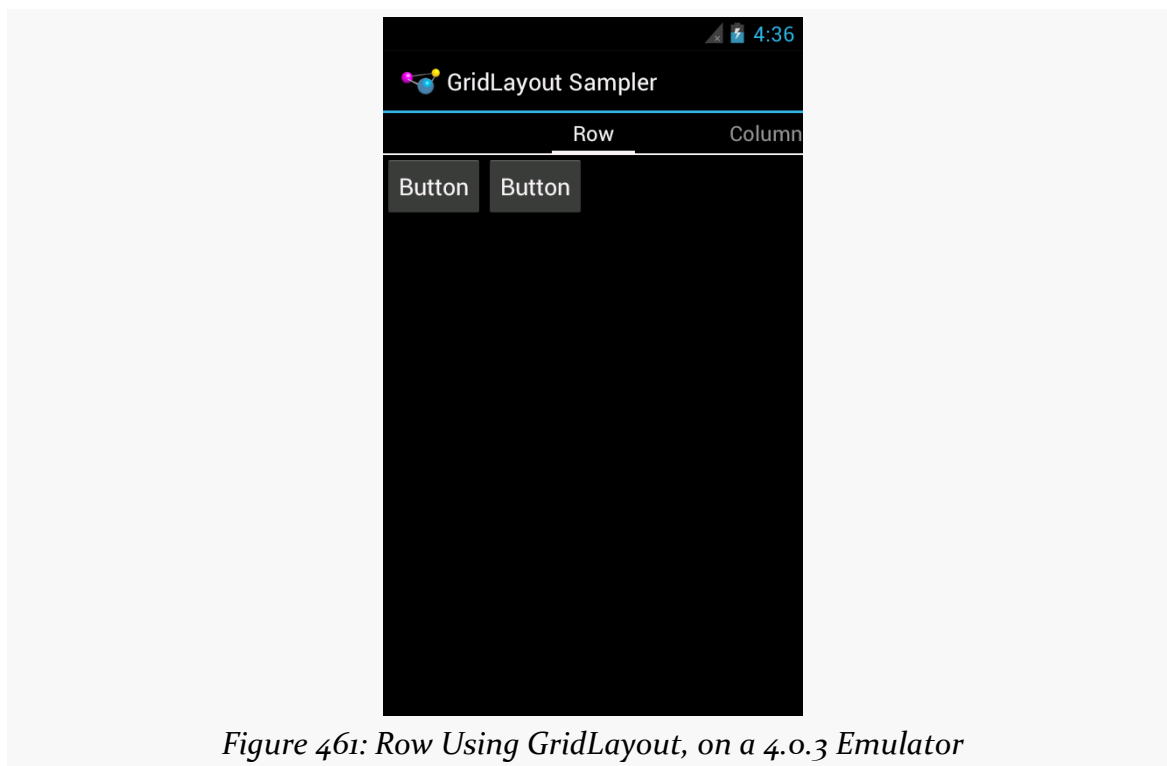

Figure 461: Row Using GridLayout, on a 4.0.3 Emulator

Vertical LinearLayout

Similarly, the conventional way you would specify a column is to use a vertical `LinearLayout`, which would position its children one after the next. The `GridLayout` equivalent would be to have `app:columnCount` set to 1, and to place the widgets in each required row via `app:layout_row` attributes, as seen in `res/layout/column.xml`:

GRIDLAYOUT

```
<android.support.v7.widget.GridLayout xmlns:android="http://schemas.android.com/apk/res/android"
  xmlns:app="http://schemas.android.com/apk/res-auto"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  app:columnCount="1">

  <Button
    app:layout_column="0"
    app:layout_row="0"
    android:text="@string/button"/>

  <Button
    app:layout_column="0"
    app:layout_row="1"
    android:text="@string/button"/>

</android.support.v7.widget.GridLayout>
```

(from [GridLayout/Sampler/app/src/main/res/layout/column.xml](#))

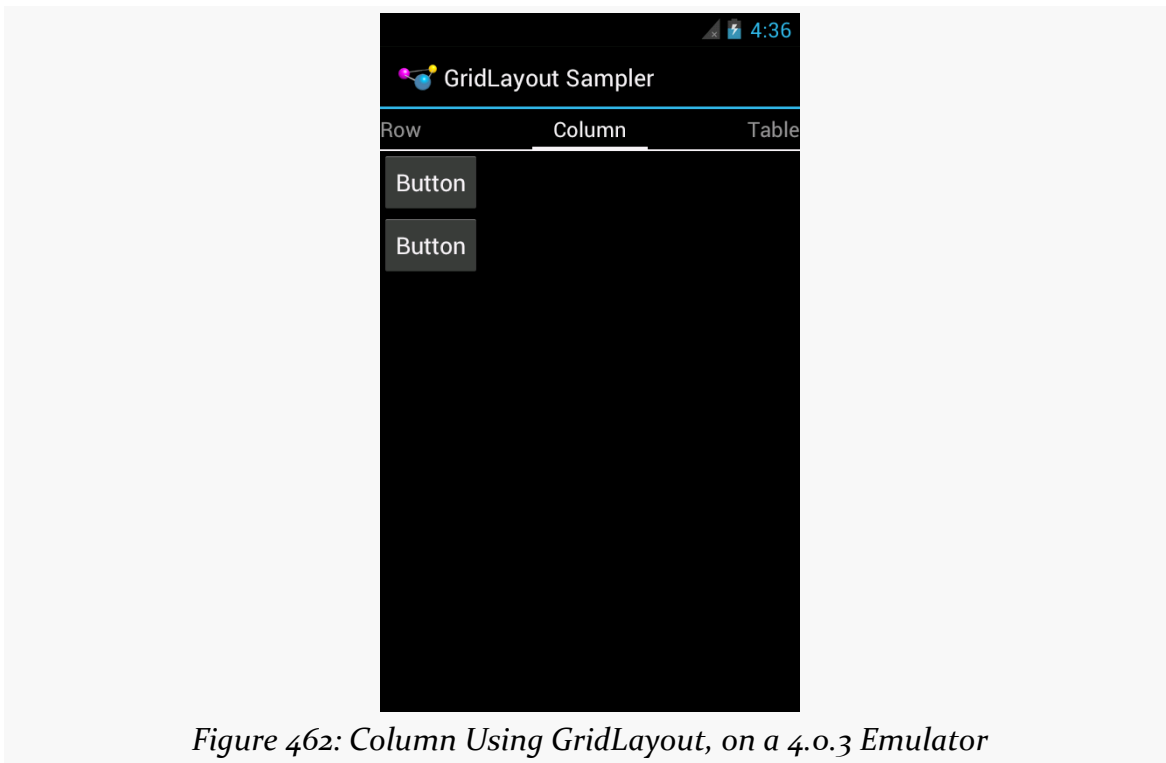

Figure 462: Column Using GridLayout, on a 4.0.3 Emulator

All that being said, it is still probably better to use `LinearLayout` in these cases, rather than mess with `GridLayout`.

TableLayout

The big key to a `TableLayout` is column width, where columns expand to fill their contents, assuming there is sufficient room in the table. `GridLayout` also expands its columns to address the sizes of its contents.

For example, here is a simple 2x2 table, with `TextView` widgets in the left column and `EditText` widgets in the right column, as seen in `res/layout/table.xml`:

```
<android.support.v7.widget.GridLayout xmlns:android="http://schemas.android.com/apk/res/android"
  xmlns:app="http://schemas.android.com/apk/res-auto"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  app:columnCount="2">

  <TextView
    app:layout_column="0"
    app:layout_row="0"
    android:text="@string/name"
    android:textAppearance="?android:attr/textAppearanceLarge" />

  <EditText
    app:layout_column="1"
    app:layout_row="0"
    android:inputType="textPersonName">

    <requestFocus/>
  </EditText>

  <TextView
    app:layout_column="0"
    app:layout_row="1"
    android:text="@string/address"
    android:textAppearance="?android:attr/textAppearanceLarge" />

  <EditText
    app:layout_column="1"
    app:layout_row="1"
    android:inputType="textPostalAddress" />

</android.support.v7.widget.GridLayout>
```

(from [GridLayout/Sampler/app/src/main/res/layout/table.xml](#))

However, our `EditText` widgets are small, because nothing is causing them to fill the available space. To do that, we can use `android:layout_gravity`, to ask the `GridLayout` to let the widgets fill the available horizontal space, as seen in `res/layout/table_flex.xml`:

```
<android.support.v7.widget.GridLayout xmlns:android="http://schemas.android.com/apk/res/android"
  xmlns:app="http://schemas.android.com/apk/res-auto"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
```

GRIDLAYOUT

```
app:columnCount="2">

<TextView
  app:layout_column="0"
  app:layout_row="0"
  android:text="@string/name"
  android:textAppearance="?android:attr/textAppearanceLarge"/>

<EditText
  app:layout_column="1"
  app:layout_row="0"
  app:layout_gravity="fill_horizontal"
  android:inputType="textPersonName">

  <requestFocus/>
</EditText>

<TextView
  app:layout_column="0"
  app:layout_row="1"
  android:text="@string/address"
  android:textAppearance="?android:attr/textAppearanceLarge"/>

<EditText
  app:layout_column="1"
  app:layout_row="1"
  app:layout_gravity="fill_horizontal"
  android:inputType="textPostalAddress"/>

</android.support.v7.widget.GridLayout>
```

(from [GridLayout/Sampler/app/src/main/res/layout/table_flex.xml](#))

This allows the `EditText` widgets to fill the width of the column:

GRIDLAYOUT

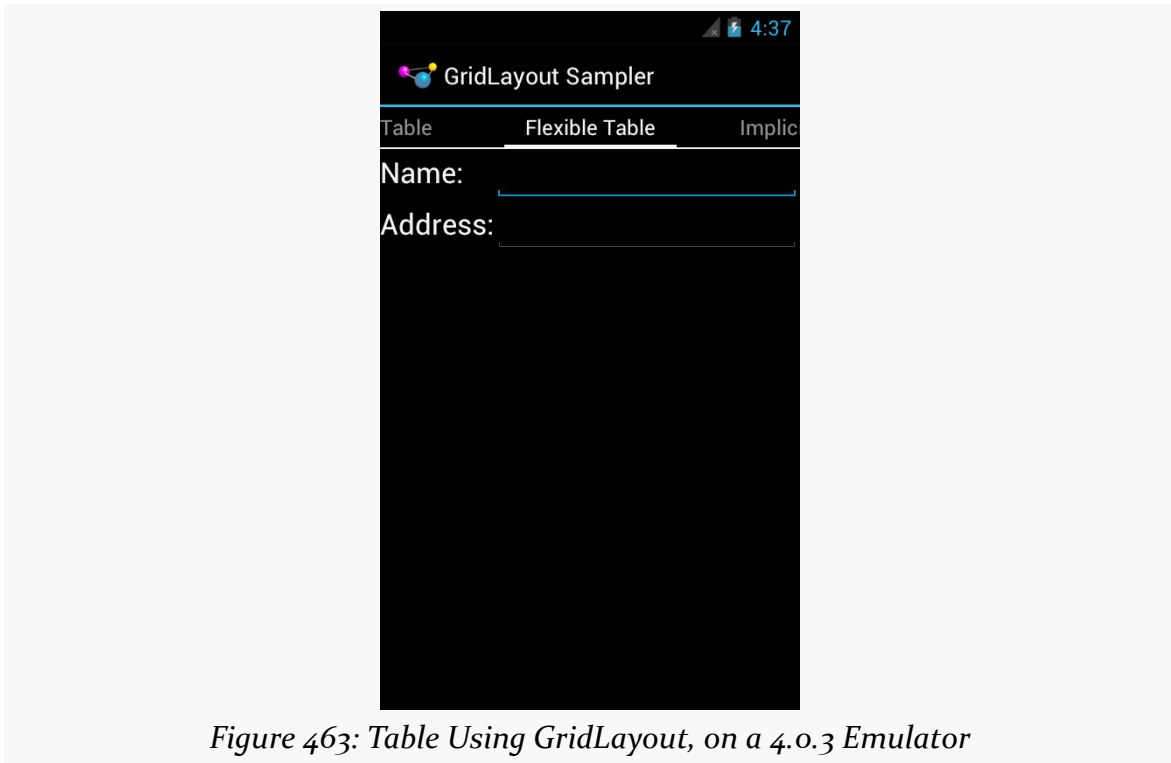

Figure 463: Table Using GridLayout, on a 4.0.3 Emulator

That holds true regardless of how wide that column is:

Figure 464: Table Using GridLayout, in Landscape, on a 4.0.3 Emulator

Implicit Rows and Columns

While all the previous samples showed the row and column of each widget being defined explicitly via `app:layout_row` and `app:layout_column` attributes, that is not your only option.

If you have `app:columnCount` on the `GridLayout` element itself, you can allow `GridLayout` to assign rows and columns. In this respect, `GridLayout` behaves a bit like a “flow layout”: it assigns widgets to cells in the first row, starting from the first column and working its way across, wrapping to the next row when it runs out of room. This makes for a more terse layout file, at the cost of perhaps introducing a bit of confusion when you add or remove a widget and everything after it in the layout file shifts location.

For example, `res/layout/implicit.xml` is the same as `res/layout/table_flex.xml`, except that it skips the `app:layout_row` and `app:layout_column` attributes, allowing `GridLayout` to assign the positions:

```
<android.support.v7.widget.GridLayout xmlns:android="http://schemas.android.com/apk/res/android"
  xmlns:app="http://schemas.android.com/apk/res-auto"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  app:columnCount="2"
  app:orientation="horizontal">

  <TextView
    android:text="@string/name"
    android:textAppearance="?android:attr/textAppearanceLarge"/>

  <EditText
    app:layout_gravity="fill_horizontal"
    android:inputType="textPersonName">

    <requestFocus/>
  </EditText>

  <TextView
    android:text="@string/address"
    android:textAppearance="?android:attr/textAppearanceLarge"/>

  <EditText
    app:layout_gravity="fill_horizontal"
    android:inputType="textPostalAddress"/>

</android.support.v7.widget.GridLayout>
```

(from [GridLayout/Sampler/app/src/main/res/layout/implicit.xml](#))

Visually, this sample is identical to the last one:

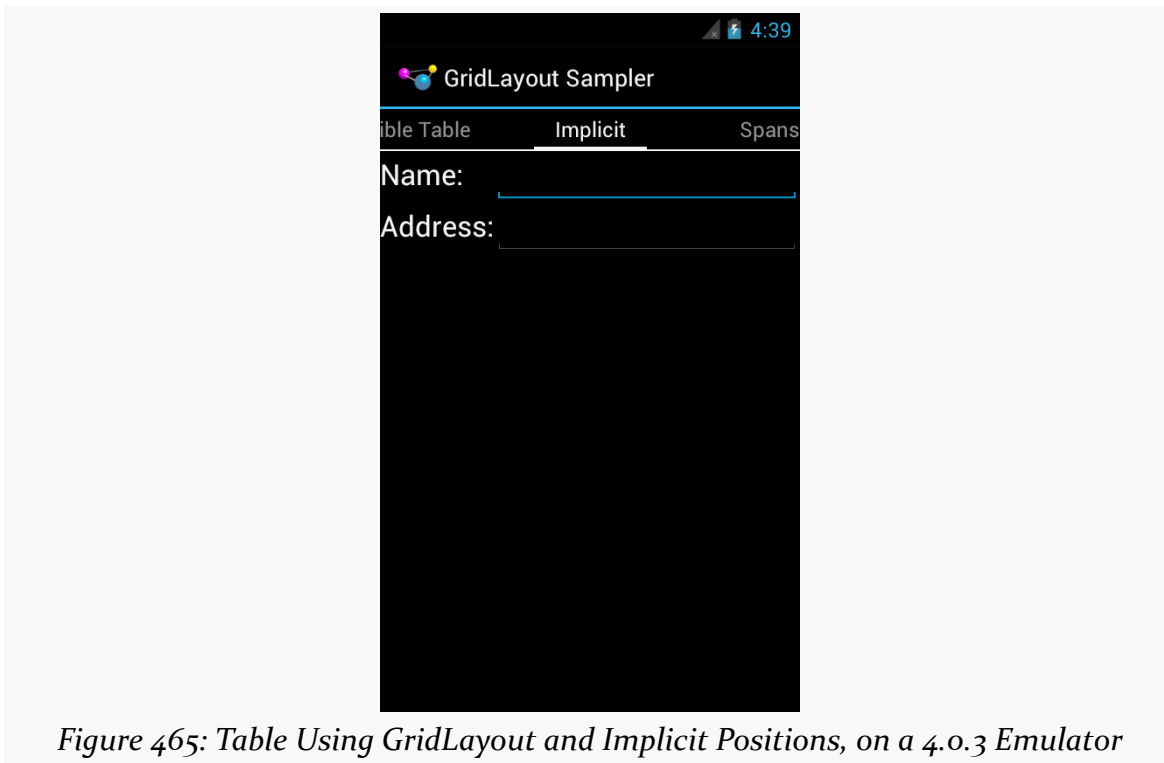

Figure 465: Table Using GridLayout and Implicit Positions, on a 4.0.3 Emulator

The “across columns, then down rows” model holds for GridLayout in the default orientation: horizontal. You can add an `app:orientation` attribute to the GridLayout, setting it to vertical. Then, based on an `app:rowCount` value, GridLayout will automatically assign positions, working down the first column, then across to the next column when it runs out of rows.

Row and Column Spans

Like `TableLayout`, `GridLayout` supports the notion of column spans. You can use `app:layout_columnSpan` to indicate how many columns a particular widget should span in the resulting grid.

However, `GridLayout` also supports row spans, in the form of `app:layout_rowSpan` attributes. A widget can span rows, columns, or both, as needed.

If you are using implicit positions, per the previous section, `GridLayout` will seek the next available space that has sufficient rows and columns for a widget’s set of spans.

GRIDLAYOUT

For example, the following diagram depicts five buttons placed in a GridLayout with various spans, and an attempt to add a sixth button that should span two columns:

Figure 466: Span Sample (image courtesy of Android Open Source Project)

Assuming the first five buttons were added in sequence and with implicit positioning, GridLayout ordinarily would drop the sixth button into the fourth column of the third row. However, there is only a one-column-wide space available there, given that the third button intrudes into the third row. Hence, GridLayout will skip over the smaller space and put the sixth button into the sixth column in the third row.

A GridLayout-based layout that implements the above diagram can be found in `res/layout/spans.xml`:

```
<android.support.v7.widget.GridLayout xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:app="http://schemas.android.com/apk/res-auto"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    app:columnCount="9"
    app:orientation="horizontal"
    app:rowCount="5">

    <Button
        app:layout_gravity="fill"
        app:layout_columnSpan="2"
        app:layout_rowSpan="2"
        android:text="@string/string_1"/>

    <Button
        app:layout_gravity="fill_horizontal"
        app:layout_columnSpan="2"
        android:text="@string/string_2"/>

    <Button
        app:layout_gravity="fill_vertical"
        app:layout_rowSpan="4"
        android:text="@string/string_3"/>
```

GRIDLAYOUT

```
<Button
    app:layout_gravity="fill"
    app:layout_columnSpan="3"
    app:layout_rowSpan="2"
    android:text="@string/string_4"/>

<Button
    app:layout_gravity="fill_horizontal"
    app:layout_columnSpan="3"
    android:text="@string/string_5"/>

<Button
    app:layout_gravity="fill_horizontal"
    app:layout_columnSpan="2"
    android:text="@string/string_6"/>

<android.support.v7.widget.Space
    android:layout_width="36dp"
    app:layout_column="0"
    app:layout_row="4"/>

<android.support.v7.widget.Space
    android:layout_width="36dp"
    app:layout_column="1"
    app:layout_row="4"/>

<android.support.v7.widget.Space
    android:layout_width="36dp"
    app:layout_column="2"
    app:layout_row="4"/>

<android.support.v7.widget.Space
    android:layout_width="36dp"
    app:layout_column="3"
    app:layout_row="4"/>

<android.support.v7.widget.Space
    android:layout_width="36dp"
    app:layout_column="4"
    app:layout_row="4"/>

<android.support.v7.widget.Space
    android:layout_width="36dp"
    app:layout_column="5"
    app:layout_row="4"/>

<android.support.v7.widget.Space
    android:layout_width="36dp"
    app:layout_column="6"
    app:layout_row="4"/>

<android.support.v7.widget.Space
    android:layout_width="36dp"
    app:layout_column="7"
    app:layout_row="4"/>

<android.support.v7.widget.Space
    android:layout_height="36dp"
    app:layout_column="8"/>
```

GRIDLAYOUT

```
    app:layout_row="0" />

    <android.support.v7.widget.Space
        android:layout_height="36dp"
        app:layout_column="8"
        app:layout_row="1" />

    <android.support.v7.widget.Space
        android:layout_height="36dp"
        app:layout_column="8"
        app:layout_row="2" />

    <android.support.v7.widget.Space
        android:layout_height="36dp"
        app:layout_column="8"
        app:layout_row="3" />

    <android.support.v7.widget.Space
        android:layout_height="36dp"
        app:layout_column="8"
        app:layout_row="4" />

</android.support.v7.widget.GridLayout>
```

(from [GridLayout/Sampler/app/src/main/res/layout/spans.xml](#))

This layout shows one of the limitations of `GridLayout`: its columns and rows will have a size of 0 by default. Hence, to ensure that each row and column has a minimum size, this layout uses `Space` elements (in an eighth column and fifth row) to establish those minimums. This makes the layout file fairly verbose, but it gives the desired results:

GRIDLAYOUT

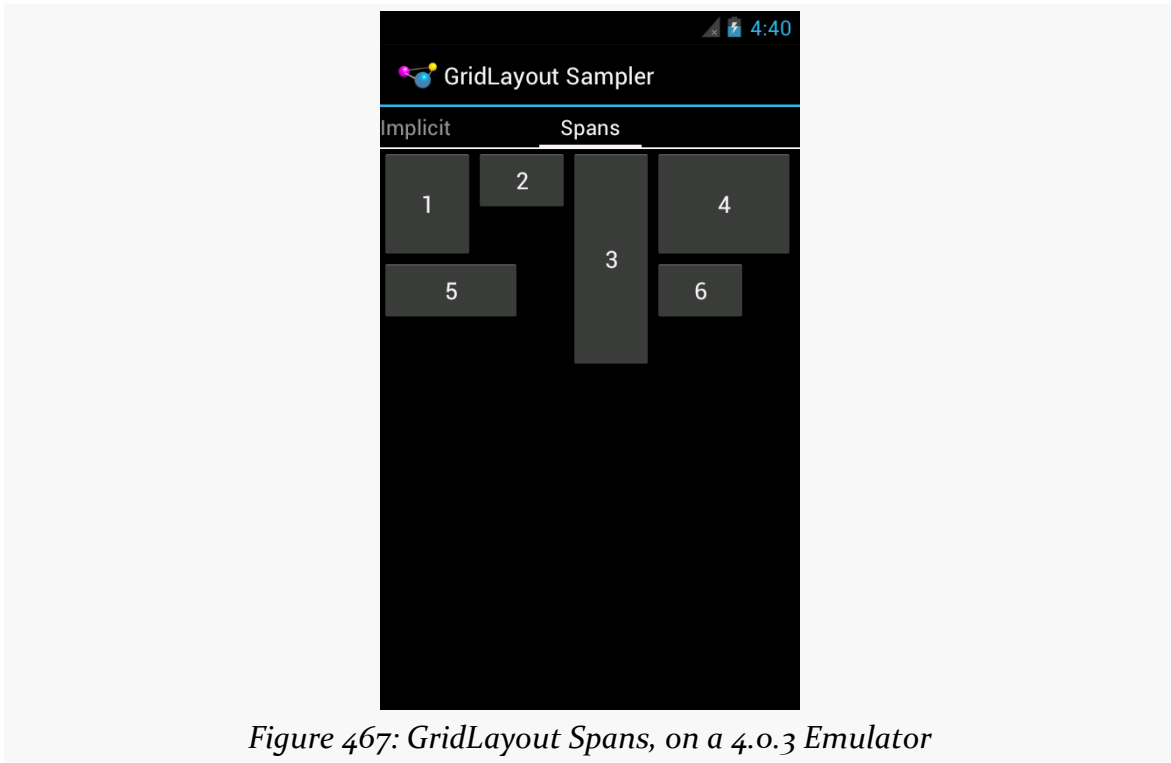

Figure 467: GridLayout Spans, on a 4.0.3 Emulator

However, the fixed-sized Space elements break the fluidity of the layout:

Figure 468: GridLayout Spans, in Landscape, on a 4.0.3 Emulator

GRIDLAYOUT

Perhaps someday someone will create a PercentSpace widget, occupying a percentage of the parent's size, that could be used instead.

The author would like to give thanks to [those on Stack Overflow who assisted in getting the span layout to work](#).

Dialogs and DialogFragments

Generally speaking, modal dialogs are considered to offer poor UX, particularly on mobile devices. You want to give the user more choices, not fewer, and so locking them into “deal with this dialog right now, or else” is not especially friendly. That being said, from time to time, there will be cases where that sort of modal interface is necessary, and to help with that, Android does have a dialog framework that you can use.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book.

DatePickerDialog and TimePickerDialog

Android has a pair of built-in dialogs that handle the common operations of allowing the user to select a date (`DatePickerDialog`) or a time (`TimePickerDialog`). These are simply dialog wrappers around the [DatePicker](#) and [TimePicker](#) widgets, as are described in this book’s Widget Catalog.

The `DatePickerDialog` allows you to set the starting date for the selection, in the form of a year, month, and day of month value. Note that the month runs from 0 for January through 11 for December. Most importantly, both let you provide a callback object (`OnDateChangeListener` or `OnDateSetListener`) where you are informed of a new date selected by the user. It is up to you to store that date someplace, particularly if you are using the dialog, since there is no other way for you to get at the chosen date later on.

Similarly, `TimePickerDialog` lets you:

- Set the initial time the user can adjust, in the form of an hour (0 through 23) and a minute (0 through 59)
- Indicate if the selection should be in 12-hour mode with an AM/PM toggle, or in 24-hour mode (what in the US is thought of as “military time” and what in much of the rest of the world is thought of as “the way times are supposed to be”)
- Provide a callback object (`OnTimeChangeListener` or `OnTimeSetListener`) to be notified of when the user has chosen a new time, which is supplied to you in the form of an hour and minute

For example, from the [Dialogs/Chrono](#) sample project, here’s a trivial layout containing a label and two buttons — the buttons will pop up the dialog flavors of the date and time pickers:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout
  xmlns:android="http://schemas.android.com/apk/res/android"
  android:orientation="vertical"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  >
  <TextView android:id="@+id/dateAndTime"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    />
  <Button android:id="@+id/dateBtn"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:text="Set the Date"
    android:onClick="chooseDate"
    />
  <Button android:id="@+id/timeBtn"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:text="Set the Time"
    android:onClick="chooseTime"
    />
</LinearLayout>
```

(from [Dialogs/Chrono/app/src/main/res/layout/main.xml](#))

The more interesting stuff comes in the Java source:

DIALOGS AND DIALOGFRAGMENTS

```
package com.commonware.android.chrono;

import android.app.Activity;
import android.app.DatePickerDialog;
import android.app.TimePickerDialog;
import android.os.Bundle;
import android.text.format.DateUtils;
import android.view.View;
import android.widget.DatePicker;
import android.widget.TextView;
import android.widget.TimePicker;
import java.util.Calendar;

public class ChronoDemo extends Activity {
    TextView dateAndTimeLabel;
    Calendar dateAndTime=Calendar.getInstance();

    @Override
    public void onCreate(Bundle state) {
        super.onCreate(state);
        setContentView(R.layout.main);

        dateAndTimeLabel=(TextView)findViewById(R.id.dateAndTime);

        updateLabel();
    }

    public void chooseDate(View v) {
        new DatePickerDialog(this, d,
            dateAndTime.get(Calendar.YEAR),
            dateAndTime.get(Calendar.MONTH),
            dateAndTime.get(Calendar.DAY_OF_MONTH))

            .show();
    }

    public void chooseTime(View v) {
        new TimePickerDialog(this, t,
            dateAndTime.get(Calendar.HOUR_OF_DAY),
            dateAndTime.get(Calendar.MINUTE),
            true)

            .show();
    }

    private void updateLabel() {
        dateAndTimeLabel
            .setText(DateUtils
                .formatDateTime(this,
                    dateAndTime.getTimeInMillis(),
                    DateUtils.FORMAT_SHOW_DATE|DateUtils.FORMAT_SHOW_TIME));
    }

    DatePickerDialog.OnDateSetListener d=new DatePickerDialog.OnDateSetListener() {
        public void onDateSet(DatePicker view, int year, int monthOfYear,
            int dayOfMonth) {
            dateAndTime.set(Calendar.YEAR, year);
            dateAndTime.set(Calendar.MONTH, monthOfYear);
            dateAndTime.set(Calendar.DAY_OF_MONTH, dayOfMonth);
            updateLabel();
        }
    };
};
```

DIALOGS AND DIALOGFRAGMENTS

```
TimePickerDialog.OnTimeSetListener t=new TimePickerDialog.OnTimeSetListener() {
    public void onTimeSet(TimePicker view, int hourOfDay,
        int minute) {
        dateAndTime.set(Calendar.HOUR_OF_DAY, hourOfDay);
        dateAndTime.set(Calendar.MINUTE, minute);
        updateLabel();
    }
};
}
```

(from [Dialogs/Chrono/app/src/main/java/com/commonsware/android/chrono/ChronoDemo.java](#))

The “model” for this activity is just a Calendar instance, initially set to be the current date and time. In the `updateLabel()` method, we take the current Calendar, format it using `DateUtils` and `formatDateTime()`, and put it in the `TextView`. The nice thing about using Android’s `DateUtils` class is that it will format dates and times using the user’s choice of date formatting, determined through the Settings application.

Each button has a corresponding method that will get control when the user clicks it (`chooseDate()` and `chooseTime()`). When the button is clicked, either a `DatePickerDialog` or a `TimePickerDialog` is shown. In the case of the `DatePickerDialog`, we give it an `OnDateSetListener` callback that updates the Calendar with the new date (year, month, day of month). We also give the dialog the last-selected date, getting the values out of the Calendar. In the case of the `TimePickerDialog`, it gets an `OnTimeSetListener` callback to update the time portion of the Calendar, the last-selected time, and a true indicating we want 24-hour mode on the time selector

With all this wired together, the resulting activity looks like this:

DIALOGS AND DIALOGFRAGMENTS

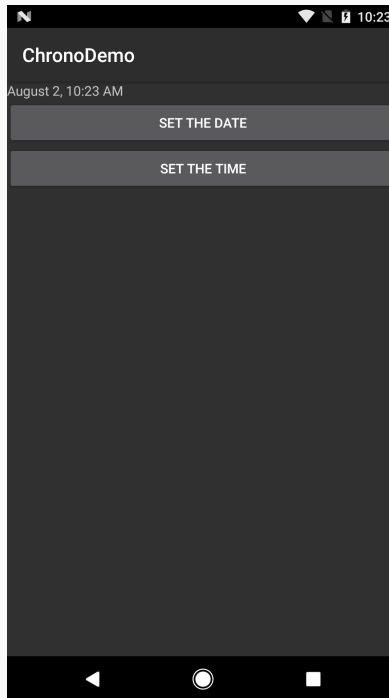

Figure 469: ChronoDemo, As Initially Launched, on Android 7.1

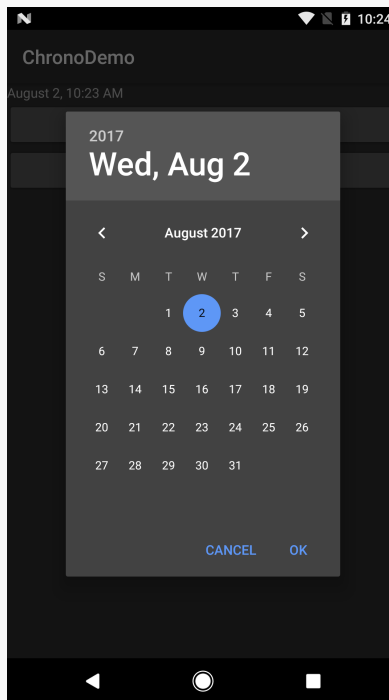

Figure 470: ChronoDemo, Showing DatePickerDialog

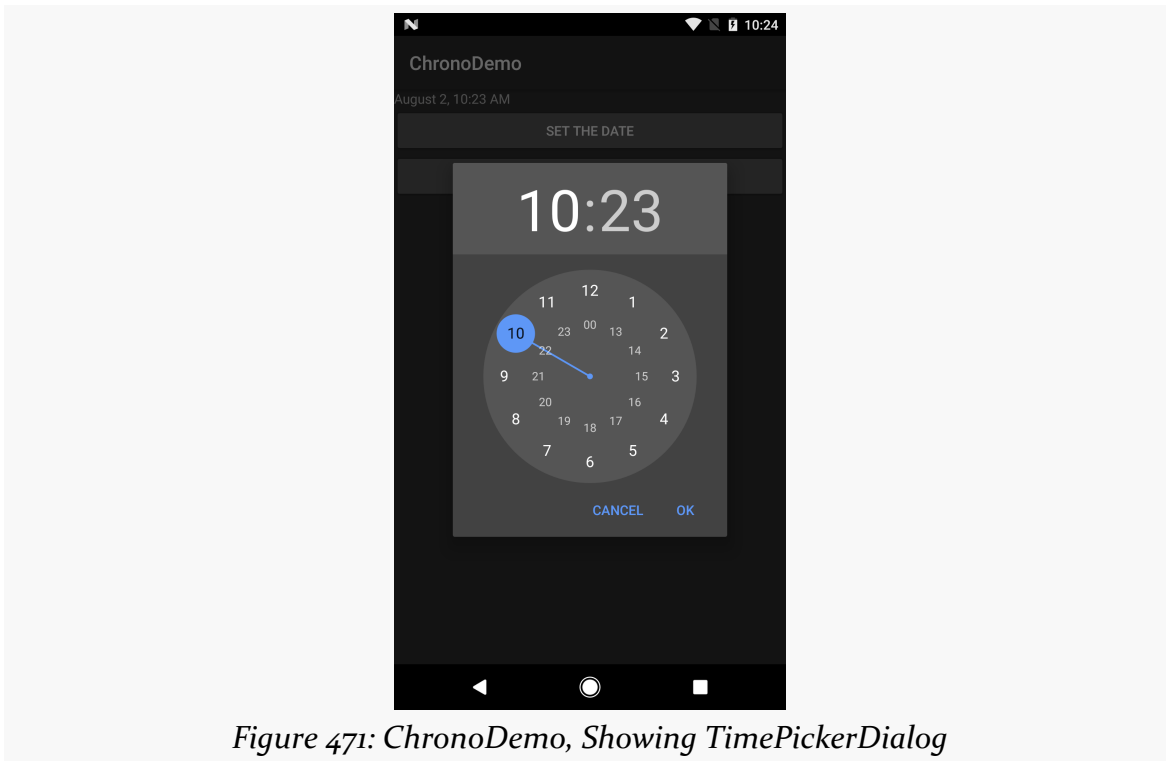

Figure 471: ChronoDemo, Showing TimePickerDialog

Changes and Bugs

Android 4.1 through 4.4 have some changes in behavior from what came before and what came after.

First, the “Cancel” button was removed, unless you specifically add a negative button listener to the underlying DatePicker or TimePicker widget:

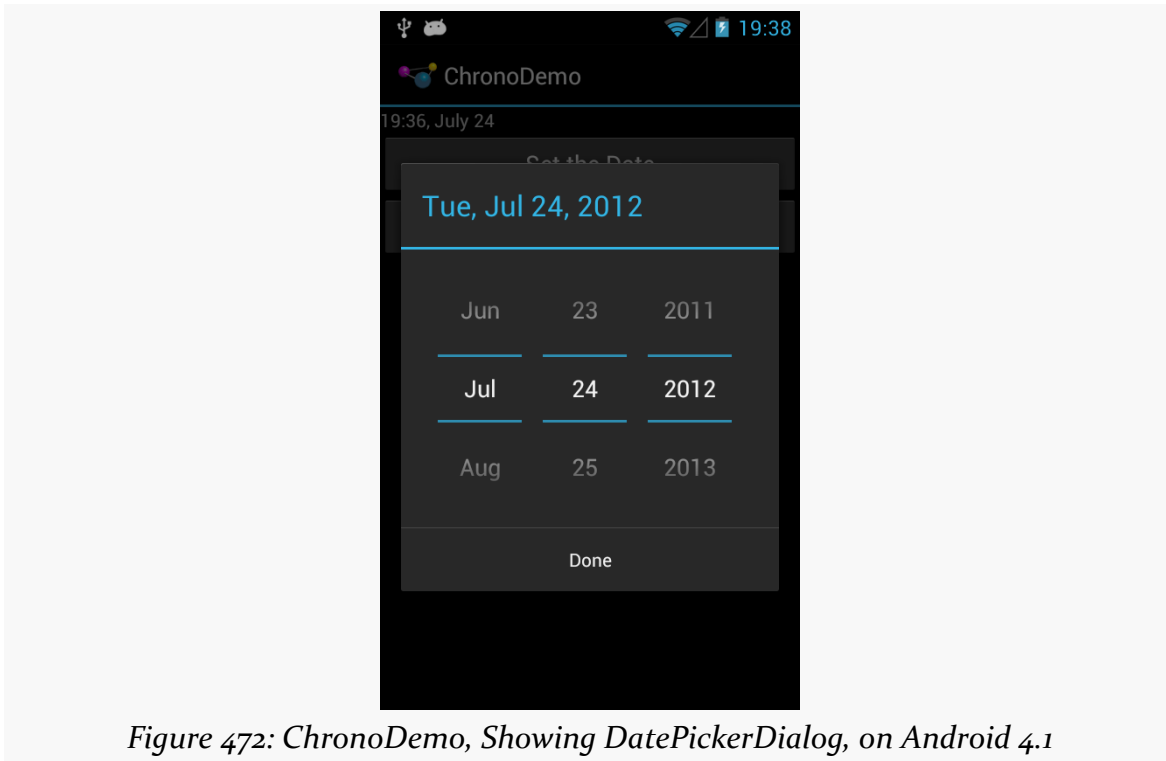

Figure 472: ChronoDemo, Showing DatePickerDialog, on Android 4.1

The user can press BACK to exit the dialog, so all functionality is still there, but you may need to craft your documentation to accommodate this difference. And, on Android 5.0+, the Cancel button returned.

Second, your `OnDateSetListener` or `OnTimeSetListener` will be called an extra time. If the user presses BACK to leave the dialog, your `onDateSet()` or `onTimeSet()` will be called. If the user clicks the positive button of the dialog, you are called *twice*. There is a workaround [documented on Stack Overflow](#). This too was repaired in Android 5.0.

AlertDialog

For your own custom dialogs, you could extend the `Dialog` base class, as do `DatePickerDialog` and `TimePickerDialog`. More commonly, though, developers create custom dialogs via `AlertDialog`, in large part due to the existence of `AlertDialog.Builder`. This builder class allows you to construct a custom dialog using a single (albeit long) Java statement, rather than having to create your own custom subclass. Builder offers a series of methods to configure an `AlertDialog`, each method returning the Builder for easy chaining.

Commonly-used configuration methods on Builder include:

- `setMessage()` if you want the “body” of the dialog to be a simple textual message, from either a supplied String or a supplied string resource ID.
- `setTitle()` and `setIcon()`, to configure the text and/or icon to appear in the title bar of the dialog box.
- `setPositiveButton()`, `setNegativeButton()`, and `setNeutralButton()`, to indicate which button(s) should appear across the bottom of the dialog, where they should be positioned (left, center, or right, respectively), what their captions should be, and what logic should be invoked when the button is clicked (besides dismissing the dialog).

Calling `create()` on the Builder will give you the `AlertDialog`, built according to your specifications. You can use additional methods on `AlertDialog` itself to perhaps configure things beyond what Builder happens to support.

Note, though, that calling `create()` does not actually display the dialog. The modern way to display the dialog is to tie it to a `DialogFragment`, as will be discussed in the next section.

DialogFragments

One challenge with dialogs comes with configuration changes, notably screen rotations. If they pivot the device from portrait to landscape (or vice versa), presumably the dialog should remain on the screen after the change. However, since Android wants to destroy and recreate the activity, that would have dire impacts on your dialog.

Pre-fragments, Android had a “managed dialog” facility that would attempt to help with this. However, with the introduction of fragments came the `DialogFragment`, which handles the configuration change process.

You have two ways of supplying the dialog to the `DialogFragment`:

1. You can override `onCreateDialog()` and return a `Dialog`, such as `AlertDialog` created via an `AlertDialog.Builder`
2. You can override `onCreateView()`, as you would with an ordinary fragment, and the `View` that you return will be placed inside of a dialog

DIALOGS AND DIALOGFRAGMENTS

The [Dialogs/DialogFragment](#) sample project demonstrates the use of a DialogFragment in conjunction with an AlertDialog in this fashion.

Here is our DialogFragment, named SampleDialogFragment:

```
package com.commonsware.android.dlgfrag;

import android.app.AlertDialog;
import android.app.Dialog;
import android.app.DialogFragment;
import android.content.DialogInterface;
import android.os.Bundle;
import android.util.Log;
import android.view.View;
import android.widget.EditText;
import android.widget.Toast;

public class SampleDialogFragment extends DialogFragment implements
    DialogInterface.OnClickListener {
    private View form=null;

    @Override
    public Dialog onCreateDialog(Bundle savedInstanceState) {
        form=
            getActivity().getLayoutInflater()
                .inflate(R.layout.dialog, null);

        AlertDialog.Builder builder=new AlertDialog.Builder(getActivity());

        return(builder.setTitle(R.string.dlg_title).setView(form)
            .setPositiveButton(android.R.string.ok, this)
            .setNegativeButton(android.R.string.cancel, null).create());
    }

    @Override
    public void onClick(DialogInterface dialog, int which) {
        String template=getActivity().getString(R.string.toast);
        EditText name=(EditText)form.findViewById(R.id.title);
        EditText value=(EditText)form.findViewById(R.id.value);
        String msg=
            String.format(template, name.getText().toString(),
                value.getText().toString());

        Toast.makeText(getActivity(), msg, Toast.LENGTH_LONG).show();
    }

    @Override
```

DIALOGS AND DIALOGFRAGMENTS

```
public void onDismiss(DialogInterface unused) {
    super.onDismiss(unused);

    Log.d(getClass().getSimpleName(), "Goodbye!");
}

@Override
public void onCancel(DialogInterface unused) {
    super.onCancel(unused);

    Toast.makeText(getActivity(), R.string.back, Toast.LENGTH_LONG).show();
}
}
```

(from [Dialogs/DialogFragment/app/src/main/java/com/commonsware/android/dlfrag/SampleDialogFragment.java](#))

In `onCreateDialog()`, we inflate a custom layout (`R.layout.dialog`) that consists of some `TextView` labels and `EditText` fields:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:orientation="vertical">

    <LinearLayout
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:layout_margin="4dp"
        android:orientation="horizontal">

        <TextView
            android:layout_width="wrap_content"
            android:layout_height="wrap_content"
            android:text="@string/display_name"/>

        <EditText
            android:id="@+id/title"
            android:layout_width="match_parent"
            android:layout_height="wrap_content"
            android:inputType="text"/>
    </LinearLayout>

    <LinearLayout
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:layout_margin="4dp"
        android:orientation="horizontal">
```

DIALOGS AND DIALOGFRAGMENTS

```
<TextView
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:text="@string/value" />

<EditText
    android:id="@+id/value"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:inputType="number" />
</LinearLayout>

</LinearLayout>
```

(from [Dialogs/DialogFragment/app/src/main/res/layout/dialog.xml](#))

We then create an instance of `AlertDialog.Builder`, then start configuring the dialog by calling a series of methods on the Builder:

- `setTitle()` to supply the text to appear in the title bar of the dialog
- `setView()` to define the contents of the dialog, in the form of our inflated View
- `setPositiveButton()` to define the caption of one button (set here to the Android-supplied “OK” string resource) and to arrange to get control when that button is clicked (via this as the second parameter and our activity implementing `DialogInterface.OnClickListener`)
- `setNegativeButton()` to define the caption of the other button (set here to the Android-supplied “Cancel” resource)

We do not supply a listener to `setNegativeButton()`, because we do not need one in this case. Whenever the user clicks on *any* of the buttons, the dialog will be dismissed automatically. Hence, you only need a listener if you intend to do something special beyond dismissing the dialog when a button is clicked.

At that point, we call `create()` to construct the actual `AlertDialog` instance and hand that back to Android.

If the user taps our positive button, we are called with `onClick()` and can collect information from our form and do something with it, in this case displaying a Toast.

We also override:

DIALOGS AND DIALOGFRAGMENTS

- `onCancel()`, which is called if the user presses the BACK button to exit the dialog
- `onDismiss()`, which is called whenever the dialog goes away for any reason (BACK or a button click)

Our activity (`MainActivity`), has a big button tied to a `showMe()` method, which calls `show()` on a newly-created instance of our `SampleDialogFragment`:

```
public void showMe(View v) {  
    new SampleDialogFragment().show(getFragmentManager(), "sample");  
}
```

(from [Dialogs/DialogFragment/app/src/main/java/com/commonsware/android/dlgfrag/MainActivity.java](#))

The second parameter to `show()` is a tag that can be used to retrieve this fragment again later from the `FragmentManager` via `findFragmentByTag()`.

When you click the big button in the activity, our dialog is displayed:

Figure 473: SampleDialogFragment, As Initially Launched, on Android 4.0.3

Android will handle the configuration change, and so long as our dialog uses typical widgets like `EditText`, the standard configuration change logic will carry our data forward from the old activity's dialog to the new activity's dialog.

DialogFragment: The Other Flavor

If you do not override `onCreateDialog()`, Android will assume that you want the `View` returned by `onCreateView()` to be poured into an ordinary `Dialog`, which `DialogFragment` will create for you automatically.

One advantage of this approach is that you can selectively show the fragment as a dialog *or* show it as a regular fragment as part of your main UI.

To show the fragment as a dialog, use the same `show()` technique as was outlined in the previous section. To display the fragment as part of the main UI, use a `FragmentManager` to `add()` it, the way you would for any other dynamic fragment.

This is one alternative to the normal fragment approach of having dedicated activities for each fragment on smaller screen sizes.

We will also see this approach used when we try to apply fragments to display content on a secondary screen using Android 4.2's `Presentation` class, covered [elsewhere in this book](#).

Dialogs: Modal, Not Blocking

Dialogs in Android are modal in terms of UI. The user cannot proceed in your activity until they complete or dismiss the dialog.

Dialogs in Android are not blocking in terms of the programming model. When you call `show()` to display a dialog — either directly or by means of adding a `DialogFragment` to the screen — this is not a blocking call. The dialog will be displayed sometime after the call to `show()`, asynchronously. You use callbacks, such as the button event listeners, to find out about events going on with respect to the dialog that you care about.

This runs counter to a couple of GUI toolkits, where displaying the dialog blocks the thread that does the displaying. In those toolkits, the call to `show()` would not return until the dialog had been displayed and dealt with by the user. That being

DIALOGS AND DIALOGFRAGMENTS

said, most modern GUI toolkits take the approach Android does and have dialogs be non-blocking. Some developers try to figure out some way of hacking a blocking approach on top of Android's non-blocking dialogs — their time would be far better spent learning modern event-driven programming.

Advanced ListViews

The humble `ListView` is the backbone of many an Android application. On phone-sized screens, the screen may be dominated by a single `ListView`, to allow the user to choose something to examine in more detail (e.g., pick a contact). On larger screens, the `ListView` may be shown side-by-side with the details of the selected item, to minimize the “pogo stick” effect seen on phones as users bounce back and forth between the list and the details.

While we have covered the basics of `ListView` in the core chapters of this book, there is a lot more that you can do if you so choose, to make your lists that much more interesting — this chapter will cover some of these techniques.

Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly [the one on `Adapter` and `AdapterView`](#).

Multiple Row Types, and Self Inflation

When we originally looked at `ListView`, we had all of our rows come from a common layout. Hence, while the data in each row would vary, the row structure itself would be consistent for all rows. This is very easy to set up, but it is not always what you want. Sometimes, you want a mix of row structures, such as header rows versus detail rows, or detail rows that vary a bit in structure based on the data:

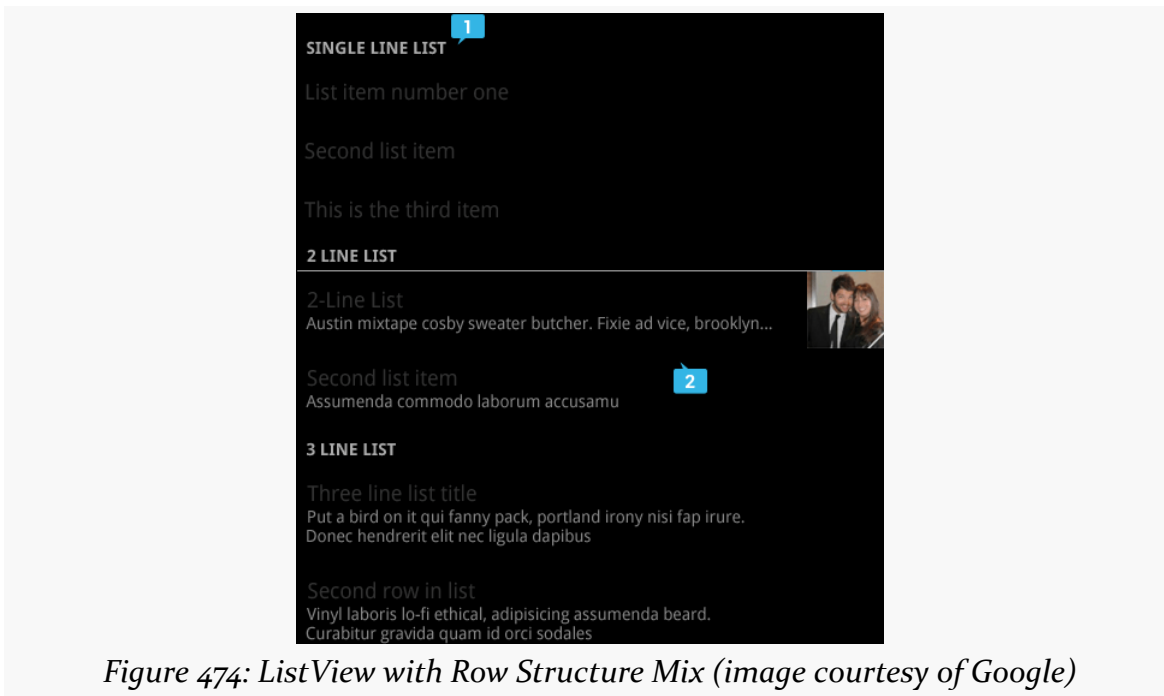

Figure 474: ListView with Row Structure Mix (image courtesy of Google)

Here, we see some header rows (e.g., “SINGLE LINE LIST”) along with detail rows. While the detail rows visually vary a bit, they might still be all inflated from the same layout, simply making some pieces (second line of text, thumbnail, etc.) visible or invisible as needed. However, the header rows are sufficiently visually distinct that they really ought to come from separate layouts.

The good news is that Android supports multiple row types. However, this comes at a cost: you will need to handle the row creation yourself, rather than chaining to the superclass.

Our sample project, [Selection/HeaderDetailList](#) will demonstrate this, along with showing how you can create your own custom adapter straight from BaseAdapter, for data models that do not quite line up with what Android supports natively.

Our Data Model and Planned UI

The HeaderDetailList project is based on the ViewHolderDemo project from [the chapter on ListView](#). However, this time, we have our list of 25 Latin words broken down into five groups of five, as seen in the HeaderDetailList activity:

```
private static final String[][] items= {  
    { "lorem", "ipsum", "dolor", "sit", "amet" },
```

ADVANCED LISTVIEWS

```
{ "consectetuer", "adipiscing", "elit", "morbi", "vel" },  
{ "ligula", "vitae", "arcu", "aliquet", "mollis" },  
{ "etiam", "vel", "erat", "placerat", "ante" },  
{ "porttitor", "sodales", "pellentesque", "augue", "purus" } };
```

(from [Selection/HeaderDetailList/app/src/main/java/com/commonsware/android/headerdetail/HeaderDetailListDemo.java](#))

We want to display a header row for each batch:

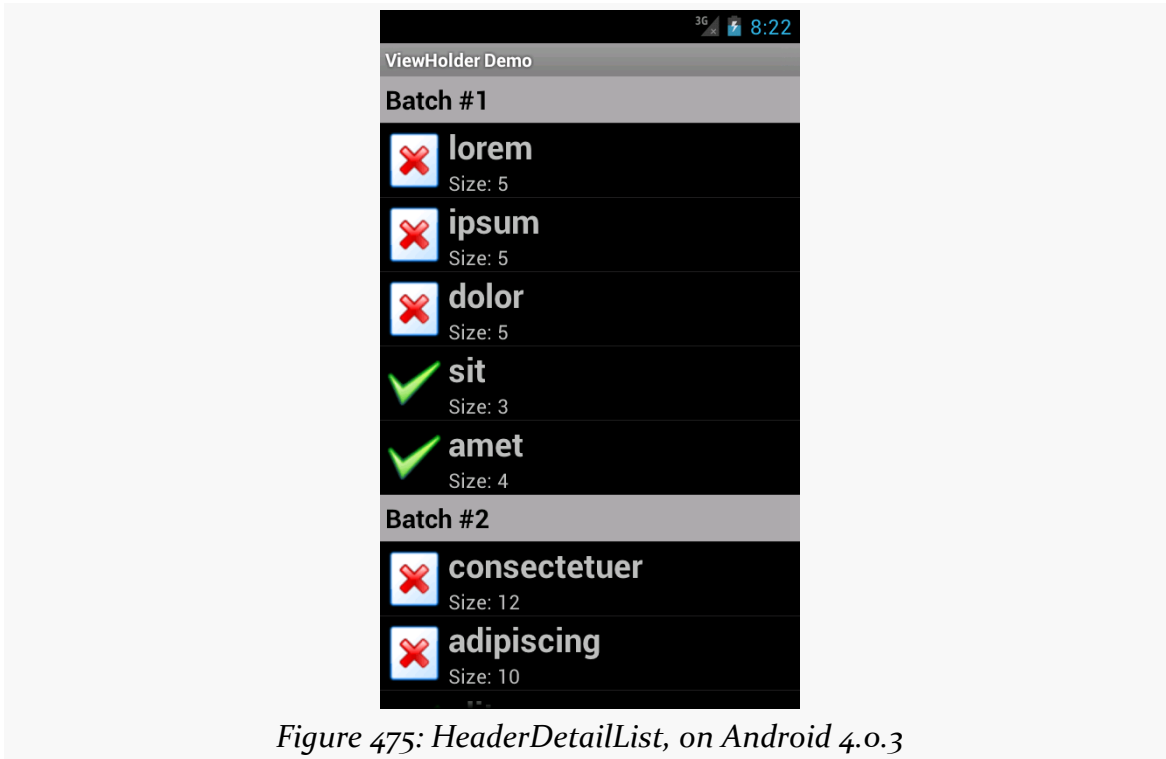

Figure 475: HeaderDetailList, on Android 4.0.3

The Basic BaseAdapter

Once again, we have a custom ListAdapter named IconicAdapter. However, this time, instead of inheriting from ArrayAdapter, or even CursorAdapter, we are inheriting from BaseAdapter. As the name suggests, BaseAdapter is a basic implementation of the ListAdapter interface, with stock implementations of many of the ListAdapter methods. However, BaseAdapter is abstract, and so there are a few methods that we need to implement:

- `getCount()` returns the total number of rows that would be in the list. In our case, we total up the sizes of each of the batches, plus add one for each batch for our header rows:

ADVANCED LISTVIEWS

```
@Override
public int getCount() {
    int count=0;

    for (String[] batch : items) {
        count+=1 + batch.length;
    }

    return(count);
}
```

(from [Selection/HeaderDetailList/app/src/main/java/com/commonsware/android/headerdetail/HeaderDetailListDemo.java](#))

- `getItem()` needs to return the data model for a given position, passed in as the typical `int` index. An `ArrayAdapter` would return the value out of the array at that index; a `CursorAdapter` would return the `Cursor` positioned at that row. In our case, we will return one of two objects: either the `String` for rows that are to display a Latin word, or an `Integer` containing our batch's index for rows that are to be a header:

```
@Override
public Object getItem(int position) {
    int offset=position;
    int batchSize=0;

    for (String[] batch : items) {
        if (offset == 0) {
            return(Integer.valueOf(batchIndex));
        }

        offset--;

        if (offset < batch.length) {
            return(batch[offset]);
        }

        offset-=batch.length;
        batchSize++;
    }

    throw new IllegalArgumentException("Invalid position: "
        + String.valueOf(position));
}
```

(from [Selection/HeaderDetailList/app/src/main/java/com/commonsware/android/headerdetail/HeaderDetailListDemo.java](#))

ADVANCED LISTVIEWS

- `getItemId()` needs to return a unique long value for a given position. A `CursorAdapter` would find the `_id` value in the `Cursor` for that position and return it. In our case, lacking anything else, we simply return the position itself:

```
@Override
public long getItemId(int position) {
    return(position);
}
```

(from [Selection/HeaderDetailList/app/src/main/java/com/commonsware/android/headerdetail/HeaderDetailListDemo.java](#))

- `getView()`, which returns the `View` to use for a given row. This is the method that we overrode on our `IconicAdapter` in some previous incarnations to tailor the way the rows were populated. Our `getView()` implementation will be a bit more complex in this case, due to our multiple-row-type requirement, so we will examine it a bit later in this section.

Requesting Multiple Row Types

The methods listed above are the abstract ones that you have no choice but to implement yourself. Anything else on the `ListAdapter` interface that you wish to override you can, to replace the stub implementation supplied by `BaseAdapter`.

If you wish to have more than one type of row, there are two such methods that you will wish to override:

- `getViewTypeCount()` needs to return the number of distinct row types you will use. In our case, there are just two:

```
@Override
public int getViewTypeCount() {
    return(2);
}
```

(from [Selection/HeaderDetailList/app/src/main/java/com/commonsware/android/headerdetail/HeaderDetailListDemo.java](#))

- `getItemViewType()` needs to return a value from 0 to `getViewTypeCount()-1`, indicating the index of the particular row type to use for a particular row position. In our case, we need to return different values for headers (0) and detail rows (1). To determine which is which, we use `getItem()` — if we get an `Integer` back, we need to use a header row for that position:

ADVANCED LISTVIEWS

```
@Override
public int getItemViewType(int position) {
    if (getItem(position) instanceof Integer) {
        return(0);
    }

    return(1);
}
```

(from [Selection/HeaderDetailList/app/src/main/java/com/commonsware/android/headerdetail/HeaderDetailListDemo.java](#))

The reason for supplying this information is for row recycling. The View that is passed into `getView()` is either null or a row that we had previously created that has scrolled off the screen. By passing us this now-unused View, Android is asking us to reuse it if possible. By specifying the row type for each position, Android will ensure that it hands us the right type of row for recycling — we will not be passed in a header row to recycle when we need to be returning a detail row, for example.

Creating and Recycling the Rows

Our `getView()` implementation, then, needs to have two key enhancements over previous versions:

1. We need to create the rows ourselves, particularly using the appropriate layout for the required row type (header or detail)
2. We need to recycle the rows when they are provided, as this has a **major** impact on the scrolling speed of our `ListView`

To help simplify the logic, we will have `getView()` focus on the detail rows, with a separate `getHeaderView()` to create/recycle and populate the header rows. Our `getView()` determines up front whether the row required is a header and, if so, delegates the work to `getHeaderView()`:

```
@Override
public View getView(int position, View convertView, ViewGroup parent) {
    if (getItemViewType(position) == 0) {
        return(getHeaderView(position, convertView, parent));
    }

    View row=convertView;

    if (row == null) {
        row=getLayoutInflater().inflate(R.layout.row, parent, false);
    }
}
```

ADVANCED LISTVIEWS

```
ViewHolder holder=(ViewHolder)row.getTag();

if (holder == null) {
    holder=new ViewHolder(row);
    row.setTag(holder);
}

String word=(String)getItem(position);

if (word.length() > 4) {
    holder.icon.setImageResource(R.drawable.delete);
}
else {
    holder.icon.setImageResource(R.drawable.ok);
}

holder.label.setText(word);
holder.size.setText(String.format(getString(R.string.size_template),
                                word.length()));

return(row);
}
```

(from [Selection/HeaderDetailList/app/src/main/java/com/commonsware/android/headerdetail/HeaderDetailListDemo.java](#))

Assuming that we are to create a detail row, we then check to see if we were passed in a non-null View. If we were passed in null, we cannot recycle that row, so we have to inflate a new one via a call to `inflate()` on a `LayoutInflater` we get via `getLayoutInflater()`. But, if we were passed in an actual View to recycle, we can skip this step.

From here, the `getView()` implementation is largely the way it was before, including dealing with the `ViewHolder`. The only change of significance is that we have to manage the `label` `TextView` ourselves — before, we chained to the superclass and let `ArrayAdapter` handle that. So our `ViewHolder` now has a `label` data member with our `label` `TextView`, and we fill it in along with the `size` and `icon`. Also, we use `getItem()` to retrieve our Latin word, so it can find the right word for the given position out of our various word batches.

Our `getHeaderView()` does much the same thing, except it uses `getItem()` to retrieve our batch index, and we use that for constructing our header:

```
private View getHeaderView(int position, View convertView,
                          ViewGroup parent) {
```

```
View row=convertView;

if (row == null) {
    row=getLayoutInflater().inflate(R.layout.header, parent, false);
}

Integer batchIndex=(Integer)getItem(position);
TextView label=(TextView)row.findViewById(R.id.label);

label.setText(String.format(getString(R.string.batch),
                            1 + batchIndex.intValue()));

return(row);
}
```

(from [Selection/HeaderDetailList/app/src/main/java/com/commonsware/android/headerdetail/HeaderDetailListDemo.java](#))

Choice Modes and the Activated Style

In [the chapter on large-screen strategies](#), we saw the EU4You sample application, and we mentioned that the ListView formatted its rows as “activated” to represent the current selection, when the ListView was side-by-side with the details.

In [the chapter on styles](#), we saw an example of an “activated” style that referred to a device-specific color to use for an activated background. It just so happens that this is the same style that we used in EU4You.

Hence, the recipe for using activated notation for a ListView adjacent to details on the last-clicked-upon ListView row is:

- Use CHOICE_MODE_SINGLE (or android:choiceMode="singleChoice") on the ListView.
- Have a style resource, in res/values-v11/, that references the device-specific activated background:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
  <style name="activated" parent="android:Theme.Holo">
    <item name="android:background">?android:attr/activatedBackgroundIndicator</item>
  </style>
</resources>
```

- Have the same style resource also defined in res/values if you are supporting pre-Honeycomb devices, where you skip the parent and the

background color override, as neither of those specific values existed before API Level 11:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
  <style name="activated">
  </style>
</resources>
```

- Use that style as the background of your `ListView` row (e.g., `style="@style/activated"`)

Android will automatically color the row background based upon the last row clicked, instead of checking a `RadioButton` as you might ordinarily see with `CHOICE_MODE_SINGLE` lists.

Custom Mutable Row Contents

Lists with pretty icons next to them are all fine and well. But, can we create `ListView` widgets whose rows contain interactive child widgets instead of just passive widgets like `TextView` and `ImageView`? For example, there is a `RatingBar` widget that allows users to assign a rating by clicking on a set of star icons. Could we combine the `RatingBar` with text in order to allow people to scroll a list of, say, songs and rate them right inside the list?

There is good news and bad news.

The good news is that interactive widgets in rows work just fine. The bad news is that it is a little tricky, specifically when it comes to taking action when the interactive widget's state changes (e.g., a value is typed into a field). We need to store that state somewhere, since our `RatingBar` widget will be recycled when the `ListView` is scrolled. We need to be able to set the `RatingBar` state based upon the actual word we are viewing as the `RatingBar` is recycled, and we need to save the state when it changes so it can be restored when this particular row is scrolled back into view.

What makes this interesting is that, by default, the `RatingBar` has absolutely no idea what item in the `ArrayAdapter` it represents. After all, the `RatingBar` is just a widget, used in a row of a `ListView`. We need to teach the rows which item in the `ArrayAdapter` they are currently displaying, so when their `RatingBar` is checked, they know which item's state to modify.

ADVANCED LISTVIEWS

So, let's see how this is done, using the activity in the [Selection/RateList](#) sample project. We will use the same basic classes as in most of our ListView samples, where we are showing a list of Latin words. In this case, you can rate the words on a three-star rating. Words given a top rating are put in all caps:

```
package com.commonsware.android.ratelist;

import android.app.ListActivity;
import android.os.Bundle;
import android.view.View;
import android.view.ViewGroup;
import android.widget.ArrayAdapter;
import android.widget.LinearLayout;
import android.widget.RatingBar;
import android.widget.TextView;
import java.util.ArrayList;

public class RateListDemo extends ListActivity {
    private static final String[] items={"lorem", "ipsum", "dolor",
        "sit", "amet",
        "consectetuer", "adipiscing", "elit", "morbi", "vel",
        "ligula", "vitae", "arcu", "aliquet", "mollis",
        "etiam", "vel", "erat", "placerat", "ante",
        "porttitor", "sodales", "pellentesque", "augue", "purus"};

    @Override
    public void onCreate(Bundle state) {
        super.onCreate(state);

        ArrayList<RowModel> list=new ArrayList<RowModel>();

        for (String s : items) {
            list.add(new RowModel(s));
        }

        setListAdapter(new RatingAdapter(list));
    }

    private RowModel getModel(int position) {
        return(((RatingAdapter)getListAdapter()).getItem(position));
    }

    class RatingAdapter extends ArrayAdapter<RowModel> {
        RatingAdapter(ArrayList<RowModel> list) {
            super(RateListDemo.this, R.layout.row, R.id.label, list);
        }
    }
}
```

ADVANCED LISTVIEWS

```
public View getView(int position, View convertView,
                    ViewGroup parent) {
    View row=super.getView(position, convertView, parent);
    RatingBar bar=(RatingBar)row.getTag();

    if (bar==null) {
        bar=(RatingBar)row.findViewById(R.id.rate);
        row.setTag(bar);

        RatingBar.OnRatingBarChangeListener l=
            new RatingBar.OnRatingBarChangeListener() {
                public void onRatingChanged(RatingBar ratingBar,
                                           float rating,
                                           boolean fromTouch) {
                    Integer myPosition=(Integer)ratingBar.getTag();
                    RowModel model=getModel(myPosition);

                    model.rating=rating;

                    LinearLayout parent=(LinearLayout)ratingBar.getParent();
                    TextView label=(TextView)parent.findViewById(R.id.label);

                    label.setText(model.toString());
                }
            };

        bar.setOnRatingBarChangeListener(l);
    }

    RowModel model=getModel(position);

    bar.setTag(Integer.valueOf(position));
    bar.setRating(model.rating);

    return(row);
}

class RowModel {
    String label;
    float rating=2.0f;

    RowModel(String label) {
        this.label=label;
    }

    public String toString() {
        if (rating>=3.0) {
```

ADVANCED LISTVIEWS

```
        return(label.toUpperCase());
    }

    return(label);
}
}
```

(from [Selection/RateList/app/src/main/java/com/commonsware/android/ratelist/RateListDemo.java](#))

Here is what is different in this activity and `getView()` implementation than in earlier, simpler samples:

1. While we are still using `String` array items as the list of Latin words, rather than pour that `String` array straight into an `ArrayAdapter`, we turn it into a list of `RowModel` objects. `RowModel` is the mutable model: it holds the Latin word plus the current rating. In a real system, these might be objects populated from a database, and the properties would have more business meaning.
2. Utility methods like `onListItemClick()` had to be updated to reflect the change from a pure-`String` model to use a `RowModel`.
3. The `ArrayAdapter` subclass (`RatingAdapter`), in `getView()`, lets `ArrayAdapter` inflate and recycle the row, then checks to see if we have a `ViewHolder` in the row's tag. If not, we create a new `ViewHolder` and associate it with the row. For the row's `RatingBar`, we add an anonymous `onRatingChanged()` listener that looks at the row's tag (`getTag()`) and converts that into an `Integer`, representing the position within the `ArrayAdapter` that this row is displaying. Using that, the rating bar can get the actual `RowModel` for the row and update the model based upon the new state of the rating bar. It also updates the text adjacent to the `RatingBar` when checked to match the rating bar state.
4. We always make sure that the `RatingBar` has the proper contents and has a tag (via `setTag()`) pointing to the position in the adapter the row is displaying.

The row layout is very simple: just a `RatingBar` and a `TextView` inside a `LinearLayout`:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:orientation="horizontal"
```

ADVANCED LISTVIEWS

```
>  
<RatingBar  
    android:id="@+id/rate"  
    android:layout_width="wrap_content"  
    android:layout_height="wrap_content"  
    android:numStars="3"  
    android:stepSize="1"  
    android:rating="2" />  
<TextView  
    android:id="@+id/label"  
    android:padding="2dip"  
    android:textSize="18sp"  
    android:layout_gravity="left|center_vertical"  
    android:layout_width="match_parent"  
    android:layout_height="wrap_content"/>  
</LinearLayout>
```

(from [Selection/RateList/app/src/main/res/layout/row.xml](#))

And the result is what you would expect, visually:

Figure 476: RateList, As Initially Shown

This includes the toggled rating bars turning their words into all caps:

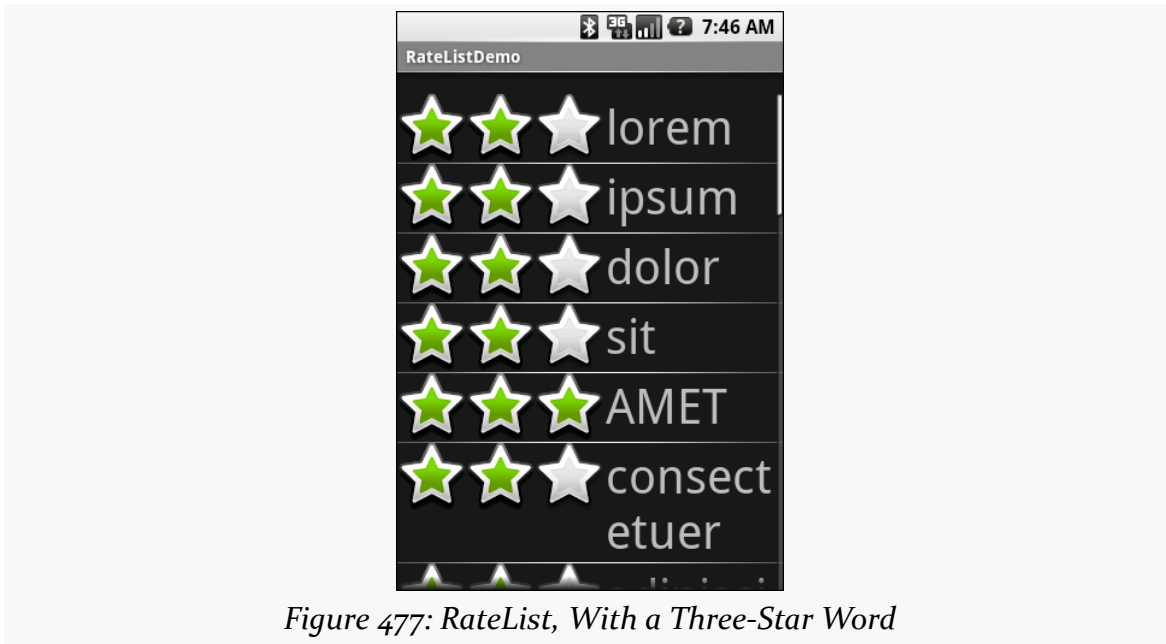

Figure 477: RateList, With a Three-Star Word

From Head To Toe

Perhaps you do not need section headers scattered throughout your list. If you only need extra “fake rows” at the beginning or end of your list, you can use header and footer views.

`ListView` supports `addHeaderView()` and `addFooterView()` methods that allow you to add `View` objects to the beginning and end of the list, respectively. These `View` objects otherwise behave like regular rows, in that they are part of the scrolled area and will scroll off the screen if the list is long enough. If you want fixed headers or footers, rather than put them in the `ListView` itself, put them outside the `ListView`, perhaps using a `LinearLayout`.

To demonstrate header and footer views, take a peek at the [Selection/HeaderFooter](#) sample project, particularly the `HeaderFooterDemo` class:

```
package com.commonware.android.header;

import java.util.Arrays;
import java.util.Collections;
import java.util.List;
import android.app.ListActivity;
import android.os.Bundle;
import android.os.SystemClock;
```

ADVANCED LISTVIEWS

```
import android.view.View;
import android.widget.AdapterView;
import android.widget.Button;
import android.widget.TextView;

public class HeaderFooterDemo extends ListActivity {
    private static String[] items={"lorem", "ipsum", "dolor",
        "sit", "amet", "consectetuer",
        "adipiscing", "elit", "morbi",
        "vel", "ligula", "vitae",
        "arcu", "aliquet", "mollis",
        "etiam", "vel", "erat",
        "placerat", "ante",
        "porttitor", "sodales",
        "pellentesque", "augue",
        "purus"};

    private long startTime=SystemClock.uptimeMillis();
    private boolean areWeDeadYet=false;

    @Override
    public void onCreate(Bundle state) {
        super.onCreate(state);
        setContentView(R.layout.main);
        getListView().addHeaderView(buildHeader());
        getListView().addFooterView(buildFooter());
        setListAdapter(new ArrayAdapter<String>(this,
            android.R.layout.simple_list_item_1,
            items));
    }

    @Override
    public void onDestroy() {
        super.onDestroy();

        areWeDeadYet=true;
    }

    private View buildHeader() {
        Button btn=new Button(this);

        btn.setText("Randomize!");
        btn.setOnClickListener(new View.OnClickListener() {
            public void onClick(View v) {
                List<String> list=Arrays.asList(items);

                Collections.shuffle(list);

                setListAdapter(new ArrayAdapter<String>(HeaderFooterDemo.this,
```

ADVANCED LISTVIEWS

```
        android.R.layout.simple_list_item_1,
        list));
    }
});

return(btn);
}

private View buildFooter() {
    TextView txt=new TextView(this);

    updateFooter(txt);

    return(txt);
}

private void updateFooter(final TextView txt) {
    long runtime=(SystemClock.uptimeMillis()-startTime)/1000;

    txt.setText(String.valueOf(runtime)+" seconds since activity launched");

    if (!areWeDeadYet) {
        getListView().postDelayed(new Runnable() {
            public void run() {
                updateFooter(txt);
            }
        }, 1000);
    }
}
}
```

(from [Selection/HeaderFooter/app/src/main/java/com/commonsware/android/header/HeaderFooterDemo.java](#))

Here, we add a header View built via `buildHeader()`, returning a Button that, when clicked, will shuffle the contents of the list. We also add a footer View built via `buildFooter()`, returning a TextView that shows how long the activity has been running, updated every second. The list itself is the ever-popular list of *lorem ipsum* words.

When initially displayed, the header is visible but the footer is not, because the list is too long:

ADVANCED LISTVIEWS

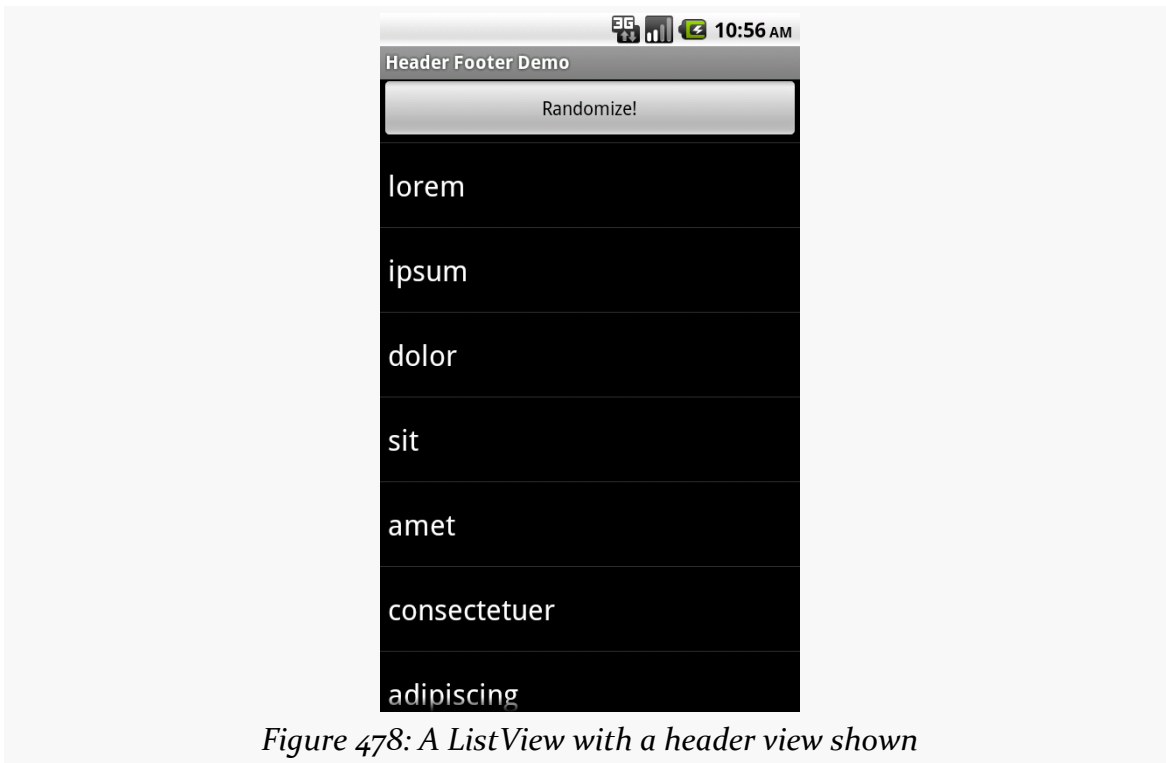

Figure 478: A ListView with a header view shown

If you scroll downward, the header will slide off the top, and eventually the footer will scroll into view:

ADVANCED LISTVIEWS

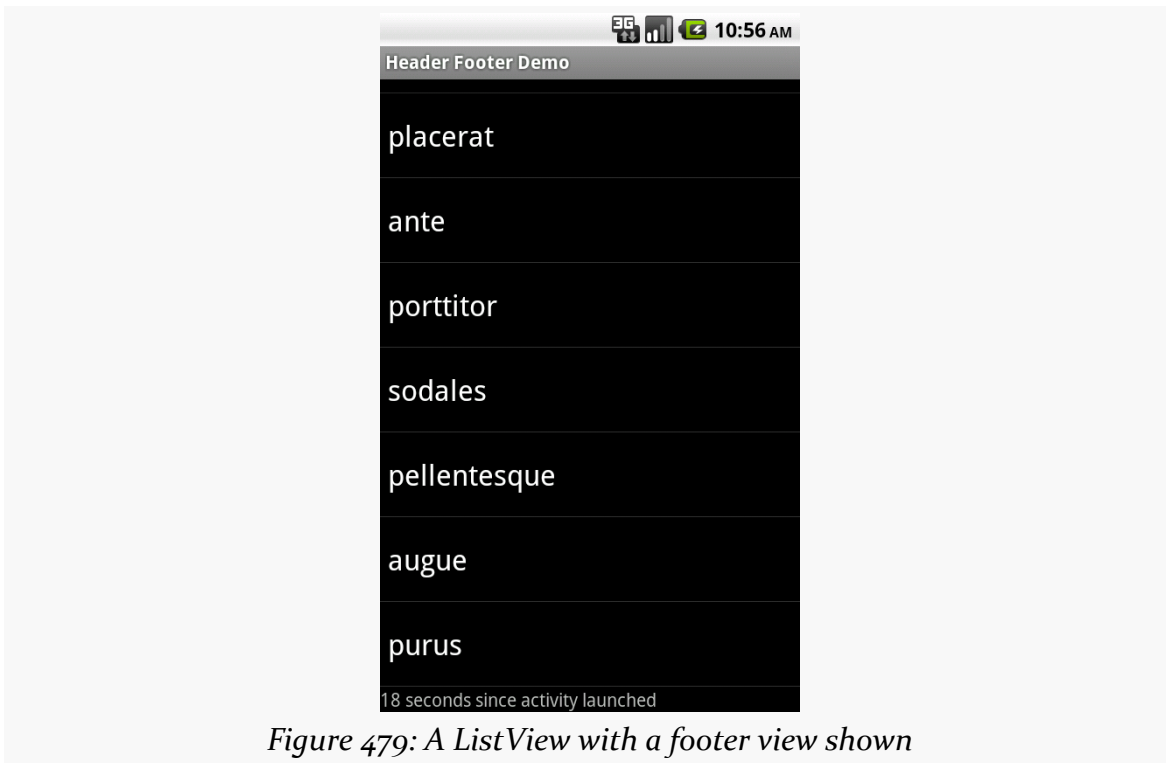

Figure 479: A ListView with a footer view shown

Enter RecyclerView

RecyclerView is a more powerful (and more complex) replacement for ListView and GridView. You can read more about [what it does and how you can use it](#).

Action Modes

If you have spent much time on an Android 3.0+ device, then you probably have run into a curious phenomenon. Sometimes, when you select an item in a list or other widget, the action bar magically transforms from its normal look:

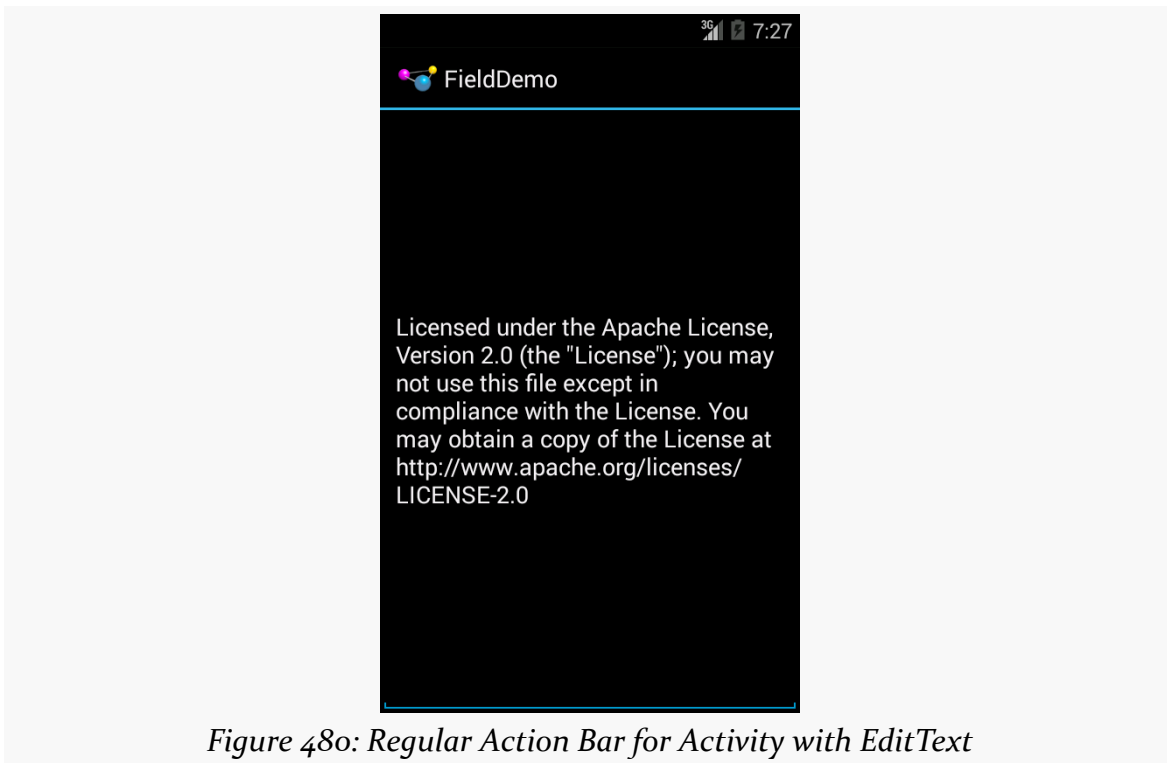

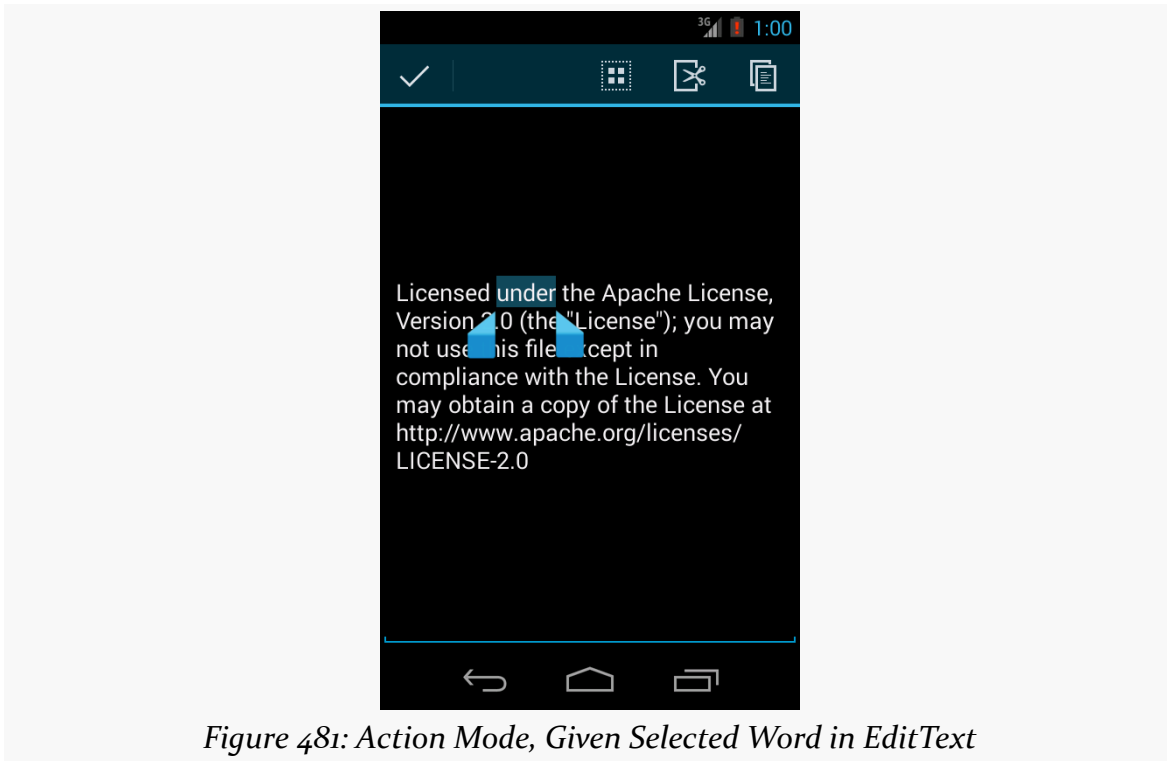

Figure 480: Regular Action Bar for Activity with EditText

to one designed to perform operations on what you have selected:

The good news is that this is not some sort of magic limited only to built-in widgets like `EditText`. You too can have this effect in your application, by triggering an “action mode”.

In this chapter, we will explore how you can set up and respond to action modes.

Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly [the one on the action bar](#).

A Matter of Context

Most desktop operating systems have had the notion of a “context menu” for some time, typically triggered by a click of the right mouse button. In particular, a right-click over some selected item might bring up a context menu of operations to perform on that item:

- Selecting text in a text editor, then right-clicking, might bring up a context menu for cut/copy/paste of the text
- Right-clicking over a file in some sort of file explorer might bring up a context menu for cut/copy/paste of the file
- Etc.

Android supports context menus, driven by a long-tap on a widget rather than a right-click. You will find a few applications that offer such menus, particularly on lists of things. However, context menus are a very old UI design pattern in Android, and modern apps rarely use them.

Instead, contextual operations are raised via an action mode, so when the user specifies a context (e.g., selects a word in an `EditText`), the action bar changes to show operations relevant for the selection.

Manual Action Modes

A common pattern will be to activate an action mode when the user checks off something in a multiple-choice `ListView`. If you want to go that route, there is some built-in scaffolding to make that work, described [later in this chapter](#).

You can, if you wish, move the action bar into an action mode whenever you want. This would be particularly important if your UI is not based on a `ListView`. For example, tapping on an image in a `GridView` might activate it and move you into an action mode for operations upon that particular image.

In this section, we will examine the [ActionMode/ManualNative](#) sample project. This is another variation on the “show a list of Latin words in a list” sample used elsewhere in this book.

Choosing Your Trigger

As mentioned above, selecting a word or passage in an `EditText` (e.g., via a long-tap) brings up an action mode for cut/copy/paste operations. Other apps might bring up an action mode when you check an item in a checklist. Yet others might bring up an action mode when you long-tap on an item in a regular list. And so on.

You will need to choose, for your own UI, what trigger mechanism will bring up an action mode. It should be some trigger that makes it obvious to the user what the action mode will be acting upon. For example:

ACTION MODES

- If the user long-taps on an item in a `GridView`, bring up an action mode, and treat future taps on `GridView` items as adding or removing items from the “selection” while that action mode is visible
- If the user “rubber-bands” some figures in your vector art drawing `View`, bring up an action mode for operations on those figures (e.g., rotate, resize)
- And so on

In the case of the sample project, we stick with the classic long-tap on a `ListView` row to bring up an action mode:

```
@Override
public void onCreate(Bundle state) {
    super.onCreate(state);

    initAdapter();
    getListView().setLongClickable(true);
    getListView().setChoiceMode(ListView.CHOICE_MODE_SINGLE);
    getListView().setOnItemLongClickListener(new ActionModeHelper(
                                                this,
                                                getListView()));
}
```

(from [ActionMode/ManualNative/app/src/main/java/com/commonsware/android/actionmode/ActionModeDemo.java](#))

Starting the Action Mode

Starting an action mode is trivially easy: just call `startActionMode()` on your `Activity`, passing in an implementation of `ActionMode.Callback`, which will be called with various lifecycle methods for the action mode itself.

In the case of the `ActionMode` sample project, `ActionModeHelper` – our `OnItemLongClickListener` from the preceding section – also is our `ActionMode.Callback` implementation. Hence, when the user long-clicks on an item in the `ListView`, the `ActionModeHelper` establishes itself as the action mode:

```
@Override
public boolean onItemLongClick(AdapterView<?> view, View row,
                                int position, long id) {
    modeView.clearChoices();
    modeView.setItemChecked(position, true);

    if (activeMode == null) {
        activeMode=host.startActionMode(this);
    }

    return(true);
}
```

ACTION MODES

(from [ActionMode/ManualNative/app/src/main/java/com/commonsware/android/actionmode/ActionModeHelper.java](#))

Note that `startActionMode()` returns an `ActionMode` object, which we can use later on to configure the mode's behavior, by stashing it in an `actionMode` data member.

Also, we make the long-clicked-upon item be “checked”, to show which item the action mode will act upon. Our row layout will make a checked row show up with the “activated” style, courtesy of Android's `simple_list_item_activated_1` stock layout.

Also note that we only start the action mode if it is not already started.

Implementing the Action Mode

The real logic behind the action mode lies in your `ActionMode.Callback` implementation. It is in these four lifecycle methods where you define what the action mode should look like and what should happen when choices are made in it.

`onCreateActionMode()`

The `onCreateActionMode()` method will be called shortly after you call `startActionMode()`. Here, you get to define what goes in the action mode. You get the `ActionMode` object itself (in case you do not already have a reference to it). More importantly, you are passed a `Menu` object, just as you get in `onCreateOptionsMenu()`. And, just like with `onCreateOptionsMenu()`, you can inflate a menu resource into the `Menu` object to define the contents of the action mode:

```
@Override
public boolean onCreateActionMode(ActionMode mode, Menu menu) {
    MenuInflater inflater=host.getMenuInflater();

    inflater.inflate(R.menu.context, menu);
    mode.setTitle(R.string.context_title);

    return(true);
}
```

(from [ActionMode/ManualNative/app/src/main/java/com/commonsware/android/actionmode/ActionModeHelper.java](#))

In addition to inflating our menu resource into the action mode's menu, we also set the title of the `ActionMode`, which shows up to the right of the Done button:

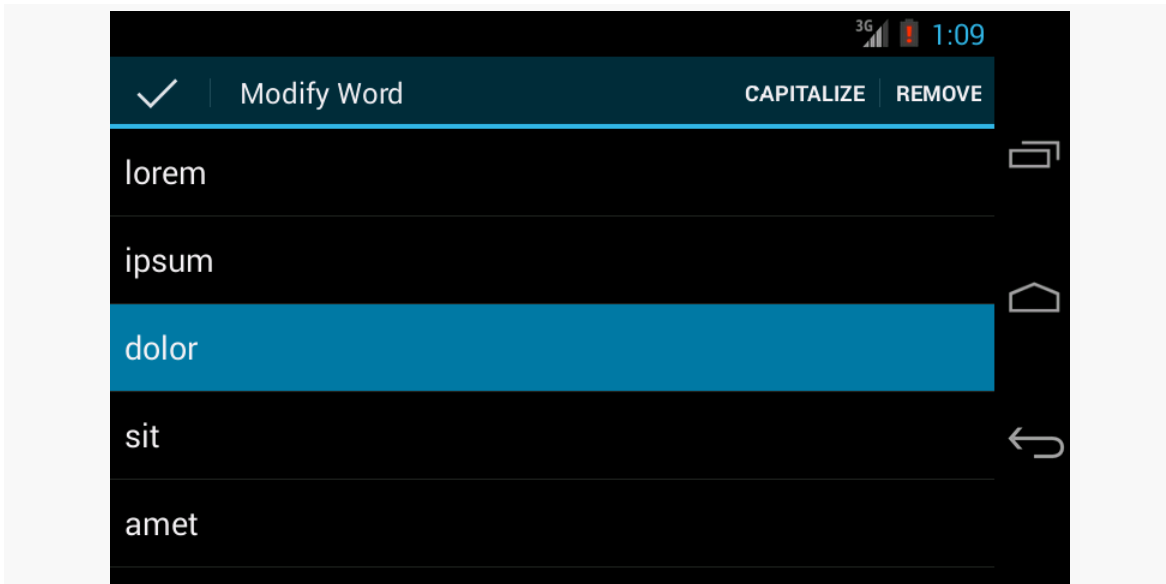

Figure 482: The ManualNative Sample App, Showing an Action Mode

onPrepareActionMode()

If you determine that you need to change the contents of your action mode, you can call `invalidate()` on the `ActionMode` object. That, in turn, will trigger a call to `onPrepareActionMode()`, where you once again have an opportunity to configure the `Menu` object. If you do make changes, return `true` — otherwise, return `false`. In the case of `ActionModeHelper`, we take the latter approach:

```
@Override
public boolean onPrepareActionMode(ActionMode mode, Menu menu) {
    return(false);
}
```

(from [ActionMode/ManualNative/app/src/main/java/com/commonsware/android/actionmode/ActionModeHelper.java](#))

onActionItemClicked()

Just as `onCreateActionMode()` is the action mode analogue to `onCreateOptionsMenu()`, `onActionItemClicked()` is the action mode analogue to `onOptionsItemSelected()`. This will be called if the user clicks on something related to your action mode. You are passed in the corresponding `MenuItem` object (plus the `ActionMode` itself), and you can take whatever steps are necessary to do whatever the work is.

ACTION MODES

On the `ActionModeDemo` class, we have the business logic for handling the data-change operations in a `performAction()` method:

```
public boolean performAction(int itemId, int position) {
    switch (itemId) {
        case R.id.cap:
            String word=words.get(position);

            word=word.toUpperCase();

            adapter.remove(words.get(position));
            adapter.insert(word, position);

            return(true);

        case R.id.remove:
            adapter.remove(words.get(position));

            return(true);
    }

    return(false);
}
```

(from [ActionMode/ManualNative/app/src/main/java/com/commonsware/android/actionmode/ActionModeDemo.java](#))

And, the `onActionItemClicked()` method calls `performAction()`:

```
@Override
public boolean onActionItemClicked(ActionMode mode, MenuItem item) {
    boolean result=
        host.performAction(item.getItemId(),
            modeView.getCheckedItemPosition());

    if (item.getItemId() == R.id.remove) {
        activeMode.finish();
    }

    return(result);
}
```

(from [ActionMode/ManualNative/app/src/main/java/com/commonsware/android/actionmode/ActionModeHelper.java](#))

`onActionItemClicked()` also dismisses the action mode if the user chose the “remove” item, since the action mode is no longer needed. You get rid of an active action mode by calling `finish()` on it.

onDestroyActionMode()

The `onDestroyActionMode()` callback will be invoked when the action mode goes away, for any reason, such as:

1. The user clicks the Done button on the left
2. The user clicks the BACK button
3. You call `finish()` on the `ActionMode`

Here, you can do any necessary cleanup. `ActionModeHelper` tries to clean things up, notably the “checked” state of the last item long-tapped-upon:

```
@Override
public void onDestroyActionMode(ActionMode mode) {
    activeMode=null;
    modeView.clearChoices();
    modeView.requestLayout();
}
```

(from [ActionMode/ManualNative/app/src/main/java/com/commonsware/android/actionmode/ActionModeHelper.java](#))

However, for reasons that are not yet clear, `clearChoices()` does not update the UI when called from `onDestroyActionMode()` unless you also call `requestLayout()`.

Multiple-Choice-Modal Action Modes

For many cases, the best user experience will be for you to have a multiple-choice `ListView`, where checking items in that list enables an action mode for performing operations on the checked items. For this scenario, API Level 11+ has a built-in `ListView` choice mode, `CHOICE_MODE_MULTIPLE_MODAL`, that automatically sets up an `ActionMode` for you as the user checks and unchecks items.

To see how this works, let’s examine the [ActionMode/ActionModeMC](#) sample project. This is the same project as in the preceding section, but altered to have a multiple-choice `ListView`, utilizing an action mode on API Level 11+.

Once again, in `onCreate()`, we need to set up the smarts for our `ListView`. This time, though, we will use `CHOICE_MODE_MULTIPLE_MODAL`:

```
@Override
public void onCreate(Bundle state) {
    super.onCreate(state);
```

ACTION MODES

```
initAdapter();

getListView().setChoiceMode(ListView.CHOICE_MODE_MULTIPLE_MODAL);
getListView().setMultiChoiceModeListener(new HCMultiChoiceModeListener(
    this, getListView()));
}
```

(from [ActionMode/ActionModeMC/app/src/main/java/com/commonsware/android/actionmodemc/ActionModeDemo.java](#))

We enable `CHOICE_MODE_MULTIPLE_MODAL` for the `ListView`, and register an instance of an `HCMultiChoiceModeListener` object via `setMultiChoiceModeListener()`. This object is an implementation of the `MultiChoiceModeListener` interface that we will examine shortly.

Since we now may have multiple checked items, our `performAction()` method must take this into account, capitalizing or removing all checked words:

```
public boolean performActions(MenuItem item) {
    SparseBooleanArray checked=getListView().getCheckedItemPositions();

    switch (item.getItemId()) {
        case R.id.cap:
            for (int i=0; i < checked.size(); i++) {
                if (checked.valueAt(i)) {
                    int position=checked.keyAt(i);
                    String word=words.get(position);

                    word=word.toUpperCase(Locale.ENGLISH);

                    adapter.remove(words.get(position));
                    adapter.insert(word, position);
                }
            }

            return(true);

        case R.id.remove:
            ArrayList<Integer> positions=new ArrayList<Integer>();

            for (int i=0; i < checked.size(); i++) {
                if (checked.valueAt(i)) {
                    positions.add(checked.keyAt(i));
                }
            }

            Collections.sort(positions, Collections.reverseOrder());
    }
}
```

ACTION MODES

```
    for (int position : positions) {
        adapter.remove(words.get(position));
    }

    getListView().clearChoices();

    return(true);
}

return(false);
}
```

(from [ActionMode/ActionModeMC/app/src/main/java/com/commonsware/android/actionmodemc/ActionModeDemo.java](#))

MultiChoiceModeListener extends the ActionMode.Callback interface we used with our manual action mode earlier in this book. Hence, we need to implement all the standard ActionMode.Callback methods, plus a new onItemCheckedStateChanged() method introduced by MultiChoiceModeListener:

```
package com.commonsware.android.actionmodemc;

import android.annotation.TargetApi;
import android.os.Build;
import android.view.ActionMode;
import android.view.Menu;
import android.view.MenuInflater;
import android.view.MenuItem;
import android.widget.AbsListView;
import android.widget.ListView;

@TargetApi(Build.VERSION_CODES.HONEYCOMB)
public class HCMultiChoiceModeListener implements
    AbsListView.MultiChoiceModeListener {
    ActionModeDemo host;
    ActionMode activeMode;
    ListView lv;

    HCMultiChoiceModeListener(ActionModeDemo host, ListView lv) {
        this.host=host;
        this.lv=lv;
    }

    @Override
    public boolean onCreateActionMode(ActionMode mode, Menu menu) {
        MenuInflater inflater=host.getMenuInflater();
```

ACTION MODES

```
inflater.inflate(R.menu.context, menu);
mode.setTitle(R.string.context_title);
mode.setSubtitle("(1)");
activeMode=mode;

return(true);
}

@Override
public boolean onPrepareActionMode(ActionMode mode, Menu menu) {
    return(false);
}

@Override
public boolean onActionItemClicked(ActionMode mode, MenuItem item) {
    boolean result=host.performActions(item);

    updateSubtitle(activeMode);

    return(result);
}

@Override
public void onDestroyActionMode(ActionMode mode) {
    activeMode=null;
}

@Override
public void onItemCheckedStateChanged(ActionMode mode, int position,
                                       long id, boolean checked) {
    updateSubtitle(mode);
}

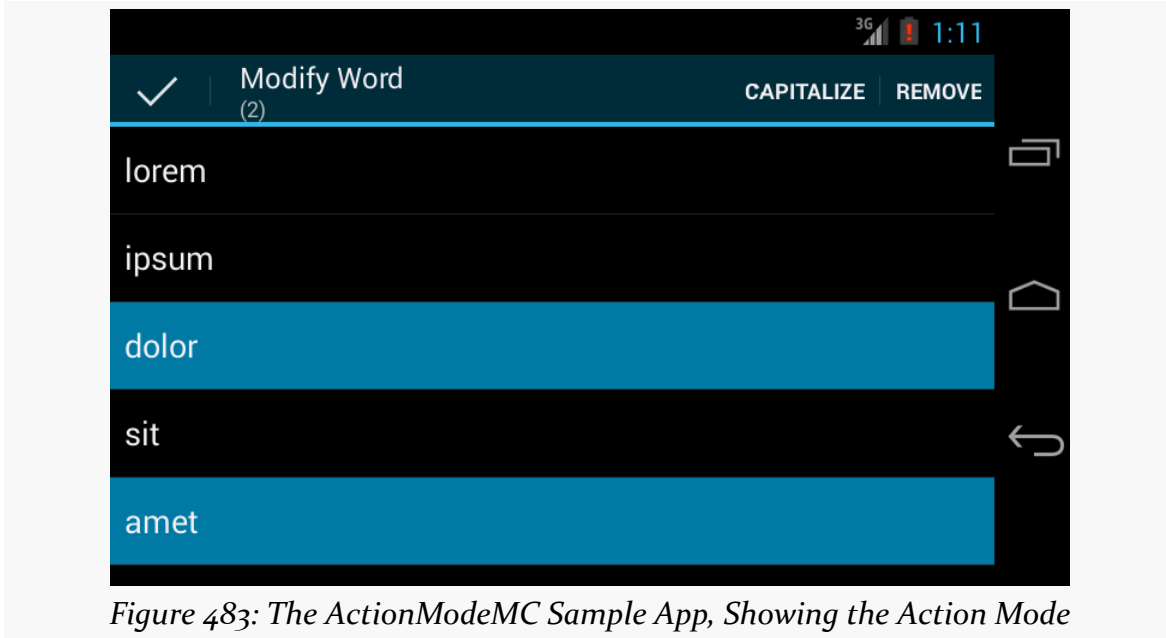

private void updateSubtitle(ActionMode mode) {
    mode.setSubtitle("(" + lv.getCheckedItemCount() + ")");
}
}
```

(from [ActionMode/ActionModeMC/app/src/main/java/com/commonsware/android/actionmodemc/HCMultiChoiceModeListener.java](#))

Android will automatically start our action mode for us when the user checks the first item in the list, using our `MultiChoiceModeListener` as the callback. Android will also automatically finish the action mode if the user unchecks all previously-checked items.

In `onCreateActionMode()`, we populate the menu, plus set up a title and subtitle on the `ActionMode`. The subtitle appears below the title, as you might expect. In this

case, we are indicating how many words are checked and therefore will be affected by the actions the user chooses in the action mode:

Then, in `onActionItemClicked()`, we both call `performActions()` to affect the desired changes, plus update the subtitle in case the user removed words (which means they are no longer checked).

The new `onItemCheckedStateChanged()` will be called whenever the user checks or unchecks an item, up until the last item is unchecked. `HCMultiChoiceModeListener` simply updates the subtitle to reflect the new count of checked items.

On the whole, using `CHOICE_MODE_MULTIPLE_MODAL` is simpler than setting up your own trigger mechanism and managing the action mode yourself. That being said, both are completely valid options, which is particularly important for situations where a multiple-choice `ListView` is not the desired user interface.

Long-Click To Initiate an Action Mode

However, rather than having checkboxes or the like always in the `ListView`, a more modern approach is to move into multiple-selection mode based on a long-click. Before then, clicks on rows behave like with any other `ListView`, but after a long-

ACTION MODES

click, the action mode appears and the user can tap on rows to select which of them to operate upon.

The [ActionMode/LongPress](#) sample project is a variation on the preceding project, with some slight simplifications, and adopting the long-click as the means to enter the action mode.

Setting Up the Listeners

In `onCreate()`, we set up listeners for both a long click (via `setOnItemLongClickListener()`) and for multiple-choice mode (via `setMultiChoiceModeListener()`). Both times, we supply the activity as the listener, as it implements the appropriate interfaces:

```
getListView().setOnItemLongClickListener(this);
getListView().setMultiChoiceModeListener(this);
```

(from [ActionMode/LongPress/app/src/main/java/com/commonsware/android/actionmode/longpress/ActionModeDemo.java](#))

Handling the Long Click

By default, the `ListView` is in no-choice mode, where clicks on rows simply trigger `onItemClickListener()` or the equivalent. However, if the user long-clicks on a row, our `onItemLongClick()` method will be called, and we can both switch into multiple-choice mode and mark the long-clicked row as being checked:

```
@Override
public boolean onItemLongClick(AdapterView<?> parent, View view,
                                int position, long id) {
    getListView().setChoiceMode(ListView.CHOICE_MODE_MULTIPLE_MODAL);
    getListView().setItemChecked(position, true);

    return true;
}
```

(from [ActionMode/LongPress/app/src/main/java/com/commonsware/android/actionmode/longpress/ActionModeDemo.java](#))

At this point, the action mode will also start up, courtesy of having called `setMultiChoiceModeListener()`.

Addressing Configuration Changes

If we undergo a configuration change, we want:

ACTION MODES

1. To keep the current set of words, including any that were added
2. To keep the action mode going, if the user had long-clicked to enter the action mode
3. To keep our checked item states, if the action mode is active

Keeping the checked item states will be handled for us by the built-in instance-state management of `ListView` and `ListActivity`. However, the rest we need to handle ourselves. So, we have an `onSaveInstanceState()` implementation in the activity, which saves the current choice mode, plus the current word list:

```
@Override
public void onSaveInstanceState(Bundle state) {
    super.onSaveInstanceState(state);
    state.putInt(STATE_CHOICE_MODE, getListView().getChoiceMode());
    state.putStringArrayList(STATE_MODEL, words);
}
```

(from [ActionMode/LongPress/app/src/main/java/com/commonsware/android/actionmode/longpress/ActionModeDemo.java](#))

Plus, in `onCreate()`, after setting up the listeners, we set up the choice mode of the `ListView` based upon the passed in instance state `Bundle`, if there is one:

```
@Override
public void onCreate(Bundle state) {
    super.onCreate(state);

    if (state == null) {
        initAdapter(null);
    }
    else {
        initAdapter(state.getStringArrayList(STATE_MODEL));
    }

    getListView().setOnItemLongClickListener(this);
    getListView().setMultiChoiceModeListener(this);

    int choiceMode=
        (state == null ? ListView.CHOICE_MODE_NONE
         : state.getInt(STATE_CHOICE_MODE));

    getListView().setChoiceMode(choiceMode);
}
```

(from [ActionMode/LongPress/app/src/main/java/com/commonsware/android/actionmode/longpress/ActionModeDemo.java](#))

Once we call `setChoiceMode()` with the previous activity instance's choice mode, if that was `CHOICE_MODE_MULTIPLE_MODAL`, Android will automatically open up the action mode again and restore our checked items.

Resetting the Choice Mode

Where things get a bit interesting is when the user dismisses the action mode, at which point we need to move back to no-choice mode.

You might think that this would merely be a matter of calling `setChoiceMode()` on the `ListView`, asking for `CHOICE_MODE_NONE`. Indeed, that is part of the solution. However, there are two problems:

1. If you call that in `onDestroyActionMode()` directly, you wind up with infinite recursion and a `StackOverflowError`, as changing the choice mode while the action mode is still technically active will cause it to destroy the action mode again.
2. Switching the choice mode back to “none” enables some optimizations within `ListView` that ignore the checked state of our rows. However, those rows still already checked will show up as activated, even after calling `setChoiceMode()` to return to the normal “none” mode. `clearChoices()` also does not have a worthwhile effect, for whatever reason.

Hence, in `onDestroyActionMode()`, not only do we need to call `setChoiceMode()`, but we need to “smack around” the `ListView` enough to get it to clear our checked rows, and the easiest way to do that is to call `setAdapter()` on it, passing in its existing adapter:

```
@Override
public void onDestroyActionMode(ActionMode mode) {
    if (activeMode != null) {
        activeMode=null;
        getListView().setChoiceMode(ListView.CHOICE_MODE_NONE);
        getListView().setAdapter(getListView().getAdapter());
    }
}
```

(from [ActionMode/LongPress/app/src/main/java/com/commonsware/android/actionmode/longpress/ActionModeDemo.java](#))

And, we only do that while our action mode is active (i.e., `activeMode` is not `null`), to avoid the infinite recursion.

This is a bit clunky, but it works.

The Results

When initially launched, the activity looks like a simple `ListActivity`:

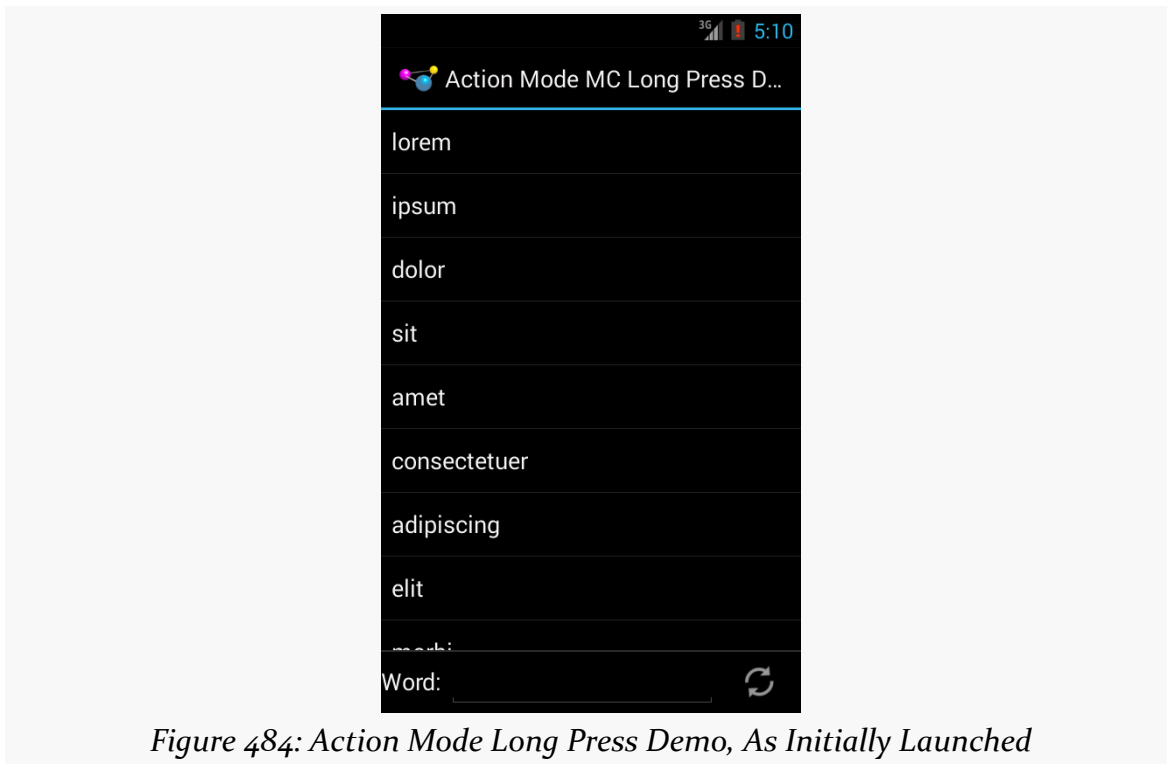

Figure 484: Action Mode Long Press Demo, As Initially Launched

Tapping on a row provides the normal momentary highlight.

However, if the user long-clicks a row, we move into the action mode and a multiple-choice `ListView`:

ACTION MODES

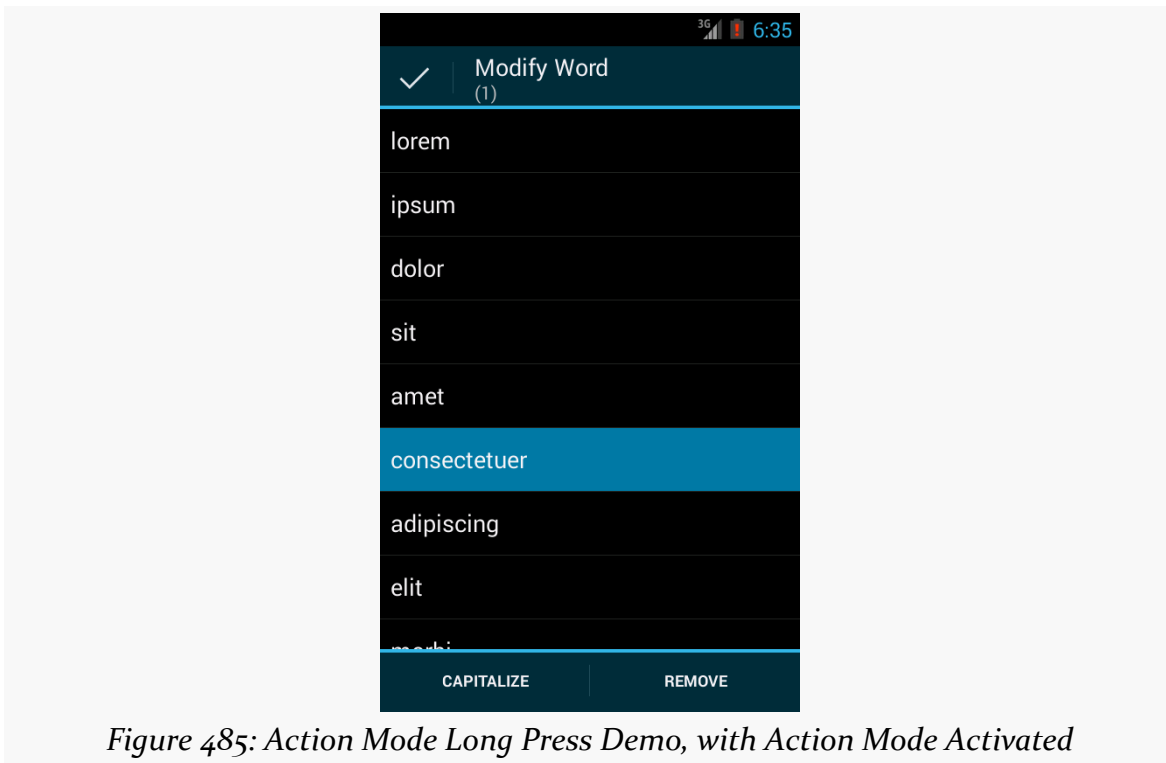

Figure 485: Action Mode Long Press Demo, with Action Mode Activated

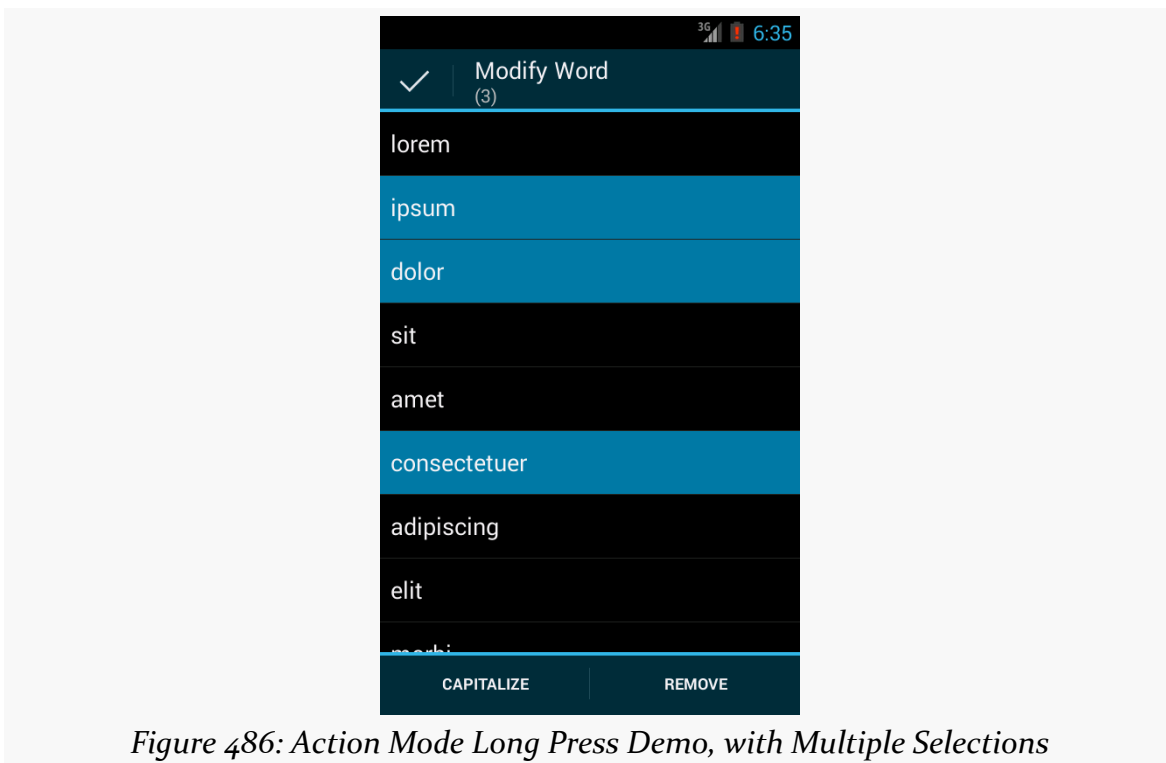

Figure 486: Action Mode Long Press Demo, with Multiple Selections

ACTION MODES

Dismissing the action mode returns the `ListView` to normal operation.

Other Advanced Action Bar Techniques

The action bar offers a number of other features that developers can take advantage of, ones that do not necessarily fit into the other chapters. Hence, this chapter is a “catch all” for other things you may wish to do with your action bar. Note that this chapter is focused on the native action bar, not the [AppCompat](#) backport.

Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly [the one on the action bar](#).

Action Layouts

What happens if you want something other than a button to appear as an action bar item? Suppose you want a field instead?

Fortunately, this is supported. Otherwise, this would be a completely pointless section of the book.

You can specify `android:actionLayout` on an `<item>` element in a menu resource. This will point to a reference to a layout XML resource that you want to have inflated into the action bar instead of a toolbar button. Then, in `onCreateOptionsMenu()`, you can call `findMenuItem()` on the `Menu` to retrieve the `MenuItem` associated with this `<item>` element, then call `getActionView()` to retrieve the root of your inflated layout. At that point, you can hook up event listeners to the widgets in that layout, as needed.

Obviously, since the action bar is only so big, you will need to be judicious about your use of space.

Action Views and Action Providers

If all you need is a single widget to replace the toolbar button, rather than a whole layout resource, you can use `android:actionViewClass` instead of `android:actionLayout`. In `android:actionViewClass`, you provide the fully-qualified class name of the widget that you wish to use to replace the toolbar button. You still use `getActionView()` to retrieve a reference to this at runtime.

If the widget you use implements the `CollapsibleActionView` interface, then it has an additional behavior: the ability to collapse into a standard toolbar button or expand into its normal mode. The only example of this in the current Android SDK is `SearchView`, which can expand into a field for searching or collapse into a simple search icon (magnifying glass) as needed. We will see more about `SearchView`, and how it behaves as a `CollapsibleActionView`, [later in this chapter](#).

Yet another possible toolbar button replacement is an action provider. Whereas an action view or action layout provide the UI, and your code provides the handling of touch events, an action provider is an “all-in-one” solution. It is designed to be configured, then used by the user without any required additional intervention by the developer. That being said, an action provider can have its own listener interfaces to let developers know about various events that have occurred. The two primary implementations of the `ActionProvider` base class are:

- `MediaRouteActionProvider`, covered [later elsewhere in the book](#), is used to allow users to control the destination for media, such as routing audio to Bluetooth headphones instead of the device speaker or playing content back on a Chromecast
- `ShareActionProvider` can simplify sharing content via `ACTION_SEND`, as is covered [elsewhere in the book](#)

To use an `ActionProvider`, you add the `android:actionProviderClass` attribute to an `<item>` in the `<menu>` resource, providing the fully-qualified class name of the `ActionProvider` implementation. You can call `getActionProvider()` on the `MenuItem` to retrieve the `ActionProvider` instance, for configuration at runtime.

Searching with SearchView

Many apps employ a SearchView in their action bar. The user typically sees the search icon as a regular toolbar button:

Figure 487: SearchView Demo, Showing Collapsed Action View

Tapping that opens a search field, taking over more of the action bar:

Figure 488: SearchView Demo, Showing Expanded Action View

Typing something in initiates some sort of search, as defined by the activity that is using the SearchView. BACK or the app icon in the action bar will “collapse” the SearchView back into its iconified state.

The [ActionBar/SearchView](#) sample project, profiled in this section, shows how you can use SearchView within your app. This sample is a clone of one of the previous action bar samples, where we have the list of 25 words, hosted in a ListFragment, with action bar items to add a word and reset the word list. In this section, we will augment the sample with a SearchView and a filtered ListView.

SearchView... in the Menu Resource

The project’s menu resource (res/menu/actions.xml) contains a regular action item (reset), an action item employing an action layout (add), and an action item containing our SearchView (search):

```
<?xml version="1.0" encoding="utf-8"?>
<menu xmlns:android="http://schemas.android.com/apk/res/android">

  <item
    android:id="@+id/search"
    android:actionViewClass="android.widget.SearchView"
    android:icon="@drawable/ic_action_search"
    android:showAsAction="ifRoom|collapseActionView"
    android:title="@string/filter">
```

OTHER ADVANCED ACTION BAR TECHNIQUES

```
</item>
</menu>
```

(from [ActionBar/SearchView/app/src/main/res/menu/actions.xml](#))

Note that the search item not only has `android:actionViewClass="android.widget.SearchView"` to tie in our action view, but it also has `android:showAsAction="ifRoom|collapseActionView"`, to indicate that this action view should support collapsing and expanding.

SearchView... in the Action Bar Configuration

In `onCreateOptionsMenu()` of our `ActionBarFragment`, in addition to inflating the menu resource and calling a `configureActionItem()` method to configure the add action layout, we now also call a `configureSearchView()` method to configure the `SearchView`:

```
@Override
public void onCreateOptionsMenu(Menu menu, MenuInflater inflater) {
    inflater.inflate(R.menu.actions, menu);

    configureSearchView(menu);

    super.onCreateOptionsMenu(menu, inflater);
}
```

(from [ActionBar/SearchView/app/src/main/java/com/commonsware/android/ab/search/ActionBarFragment.java](#))

In `configureSearchView()`, surprisingly enough, we configure the `SearchView`:

```
private void configureSearchView(Menu menu) {
    MenuItem search=menu.findItem(R.id.search);

    sv=(SearchView)search.getActionView();
    sv.setOnQueryTextListener(this);
    sv.setOnCloseListener(this);
    sv.setSubmitButtonEnabled(false);
    sv.setIconifiedByDefault(true);

    if (initialQuery != null) {
        sv.setIconified(false);
        search.expandActionView();
        sv.setQuery(initialQuery, true);
    }
}
```

OTHER ADVANCED ACTION BAR TECHNIQUES

(from [ActionBar/SearchView/app/src/main/java/com/commonsware/android/ab/search/ActionBarFragment.java](#))

Specifically, we:

- Register our fragment as the `QueryTextListener` and the `OnCloseListener`, which will be covered in greater detail [later in this chapter](#)
- Disable the submit button, as we will be using the `SearchView` for filtering rather than querying
- Indicate that the `SearchView` should be collapsed (“iconified”) as the default state

Also, our fragment has an `initialQuery` data member, and if that is not null, we expand the `SearchView` and fill in `initialQuery` as the query to be shown in the `SearchView`, also submitting it.

`initialQuery` comes from our configuration change logic, as if the user fills in something in the `SearchView` in one configuration (e.g., portrait), we do not want to lose it on a configuration change (e.g., to landscape). In our `onSaveInstanceState()` method, we save both the query from the `SearchView` and the words currently in our list:

```
@Override
public void onSaveInstanceState(Bundle state) {
    super.onSaveInstanceState(state);

    if (!sv.isIconified()) {
        state.putCharSequence(STATE_QUERY, sv.getQuery());
    }

    state.putStringArrayList(STATE_MODEL, words);
}
```

(from [ActionBar/SearchView/app/src/main/java/com/commonsware/android/ab/search/ActionBarFragment.java](#))

In `onActivityCreated()`, we use the saved `InstanceState` `Bundle` to populate the adapter with the previous set of words, plus store the old `SearchView`'s query in `initialQuery`:

```
@Override
public void onActivityCreated(Bundle savedInstanceState) {
    super.onActivityCreated(savedInstanceState);

    if (savedInstanceState == null) {
        initAdapter(null);
    }
}
```

OTHER ADVANCED ACTION BAR TECHNIQUES

```
}  
else {  
    initAdapter(savedInstanceState.getStringArrayList(STATE_MODEL));  
    initialQuery=savedInstanceState.getCharSequence(STATE_QUERY);  
}  
  
setHasOptionsMenu(true);  
}
```

(from [ActionBar/SearchView/app/src/main/java/com/commonsware/android/ab/search/ActionBarFragment.java](#))

Hence, on a configuration change, by the time `configureSearchView()` is called, we will have our `initialQuery`, if there is one, and we can set up the UI to be the same as it was in the old configuration.

SearchView... And Filtering a ListView

The `ActionBarFragment` implements the `SearchView.OnQueryTextListener` and `SearchView.OnCloseListener` interfaces, which is why we can pass this to `setOnQueryTextListener()` and `setOnCloseListener()` in `configureSearchView()`.

Those two interfaces require a total of three methods, described below.

onQueryTextChange()

The `onQueryTextChange()` method — required by `SearchView.OnQueryTextListener` — will be called whenever the user has changed the contents of the expanded `SearchView`, such as by typing a character. This is used when you want to employ the `SearchView` for filtering, updating the filter as the user types, rather than for searching, in which case you would wait until the user “submits” the search request.

Our implementation takes advantage of `ArrayAdapter`’s built-in filtering capability:

```
@Override  
public boolean onQueryTextChange(String newText) {  
    if (TextUtils.isEmpty(newText)) {  
        adapter.getFilter().filter("");  
    }  
    else {  
        adapter.getFilter().filter(newText.toString());  
    }  
}
```

OTHER ADVANCED ACTION BAR TECHNIQUES

```
return(true);  
}
```

(from [ActionBar/SearchView/app/src/main/java/com/commonsware/android/ab/search/ActionBarFragment.java](#))

Adapters that implement the `Filterable` interface can be filtered, automatically restricting the displayed items to ones that match the filter. Calling `getFilter()` on a `Filterable` returns a `Filter`. The default implementation of a `Filter` filters on the leading characters of `toString()` of `getItem()` from the Adapter. Hence, filtering an `ArrayAdapter` on our roster of 25 words, where the filter string is 'm', would show `morbi` and `mollis` but skip `amet`, let alone other words not beginning with m.

So, our `onQueryTextChange()` method simply updates the `Filter` with whatever the user has typed into the `SearchView`, setting the filter to the empty string if the `SearchView` is either empty or has null contents.

onQueryTextSubmit()

The `onQueryTextSubmit()` method — required by `SearchView.OnQueryTextListener` — would be called if the user tapped on the submit button within the expanded `SearchView`, to ask us to perform the search. In this sample, we have disabled that button, as we are filtering our list on the fly, rather than performing a query once the `SearchView` is filled out. Hence, `ActionBarFragment` has a do-nothing implementation of `onQueryTextSubmit()`, simply returning `false` to indicate that we have not consumed the event:

```
@Override  
public boolean onQueryTextSubmit(String query) {  
    return(false);  
}
```

(from [ActionBar/SearchView/app/src/main/java/com/commonsware/android/ab/search/ActionBarFragment.java](#))

The chapter on advanced database techniques has [a section on full-text indexing](#), and the sample app in that chapter demonstrates the use of the submit button in a `SearchView` and `onQueryTextSubmit()`.

onClose()

The `onClose()` method — required by `SearchView.OnCloseListener` — in theory will be called when the `SearchView` is collapsed. Here, we simply clear out the filter

OTHER ADVANCED ACTION BAR TECHNIQUES

that we are using to limit the contents of the `ListView`, plus return `true` to say that we have handled the event:

```
@Override
public boolean onClose() {
    adapter.getFilter().filter("");

    return(true);
}
```

(from [ActionBar/SearchView/app/src/main/java/com/commonsware/android/ab/search/ActionBarFragment.java](#))

According to the `SearchView` source code, it will only be called if:

- The query text is empty, and
- The `SearchView` is iconified by default (`setIconifiedByDefault(true)`)

In practice, not even that works very well.

Hence, if you really need to find out when the `SearchView` is collapsed, you will probably need to use the more generic `OnActionExpandListener` interface, attached to the `SearchView` via `setOnActionExpandListener().onMenuItemActionCollapse()` should be called when the `SearchView` is collapsed. This also works for other types of collapsible action views, not just `SearchView`.

SearchView... From the User's Perspective

If the user taps on the search icon, then starts typing into the `SearchView`'s editing area, the `ListView` is filtered based upon the typed-in prefix:

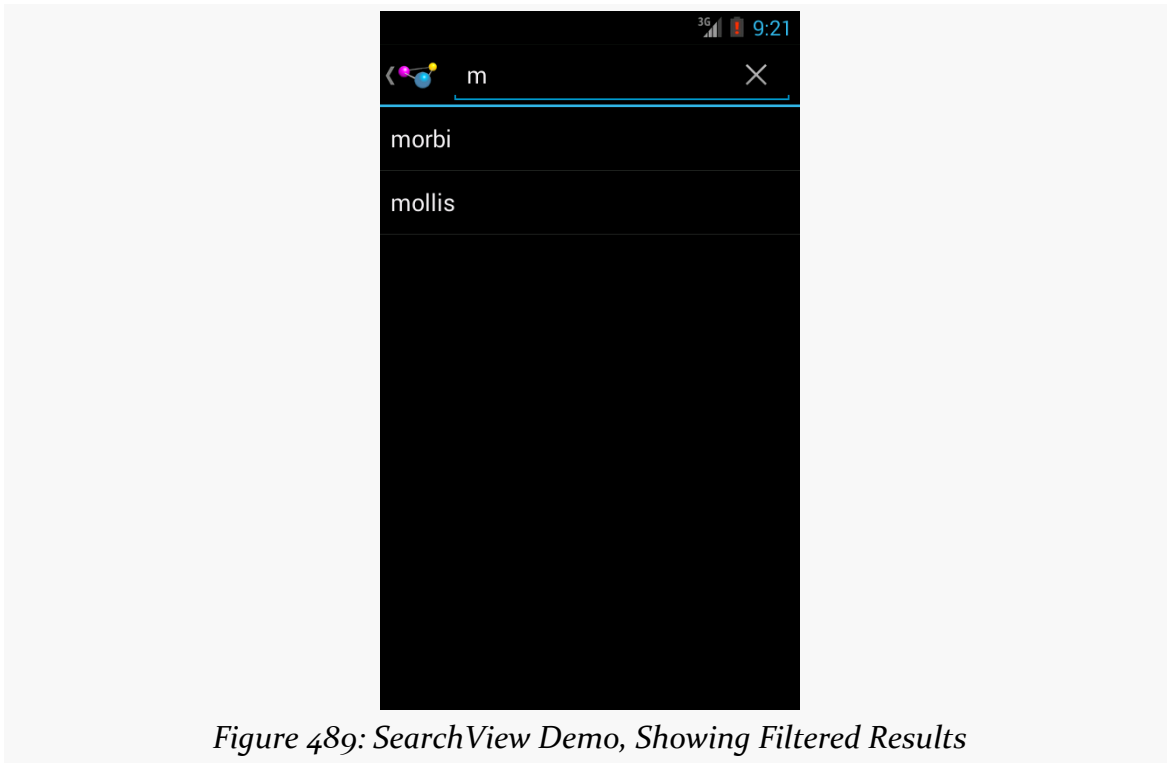

Figure 489: SearchView Demo, Showing Filtered Results

Floating Action Bars

By default, your action bar will be separate from the main content area of your activity. Normally, that is what you want.

But, sometimes, you may want to have the action bar(s) float over the top of your activity, as can be seen in Google Maps:

OTHER ADVANCED ACTION BAR TECHNIQUES

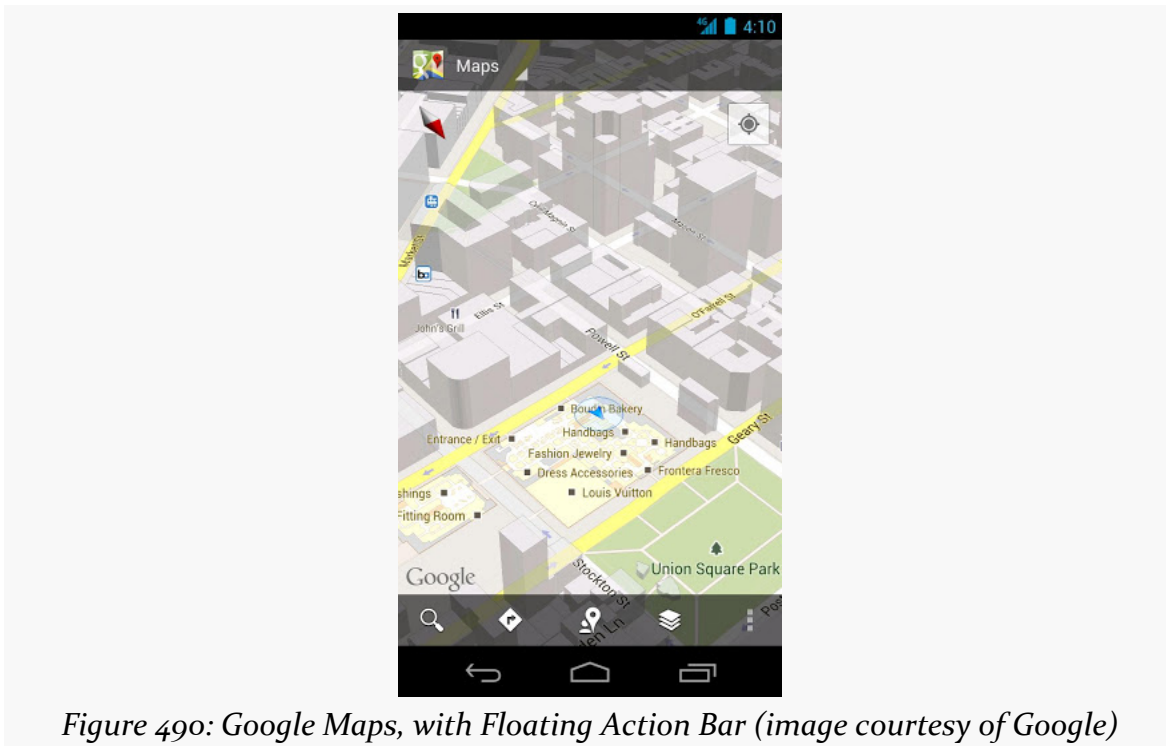

Figure 490: Google Maps, with Floating Action Bar (image courtesy of Google)

To accomplish this, you can use `FEATURE_ACTION_BAR_OVERLAY`, as is illustrated in the [ActionBar/OverlayNative](#) sample project.

This is nearly identical to the `ActionBar/ActionBarDemoNative` sample project, with just a few changes, mostly in the `onCreate()` method of our activity:

```
@Override
public void onCreate(Bundle state) {
    super.onCreate(state);

    getWindow().requestFeature(Window.FEATURE_ACTION_BAR_OVERLAY);

    initAdapter();

    Drawable d=
        getResources().getDrawable(R.drawable.action_bar_background);

    getActionBar().setBackgroundDrawable(d);
}
```

(from [ActionBar/OverlayNative/app/src/main/java/com/commonsware/android/actionbaroverlay/ActionBarDemoActivity.java](#))

In addition to the original logic, we:

OTHER ADVANCED ACTION BAR TECHNIQUES

- Call `requestFeature()` on our `Window` (obtained via a call to `getWindow()`), asking for `FEATURE_ACTION_BAR_OVERLAY`
- Call `setBackgroundDrawable()` on our `ActionBar`, supplying a reference to a drawable resource to use for the background of the floating action bar

The drawable resource is a `ShapeDrawable`, defined in XML:

```
<?xml version="1.0" encoding="utf-8"?>
<shape xmlns:android="http://schemas.android.com/apk/res/android"
    android:shape="rectangle">

    <solid android:color="#AAFFFFFF"/>

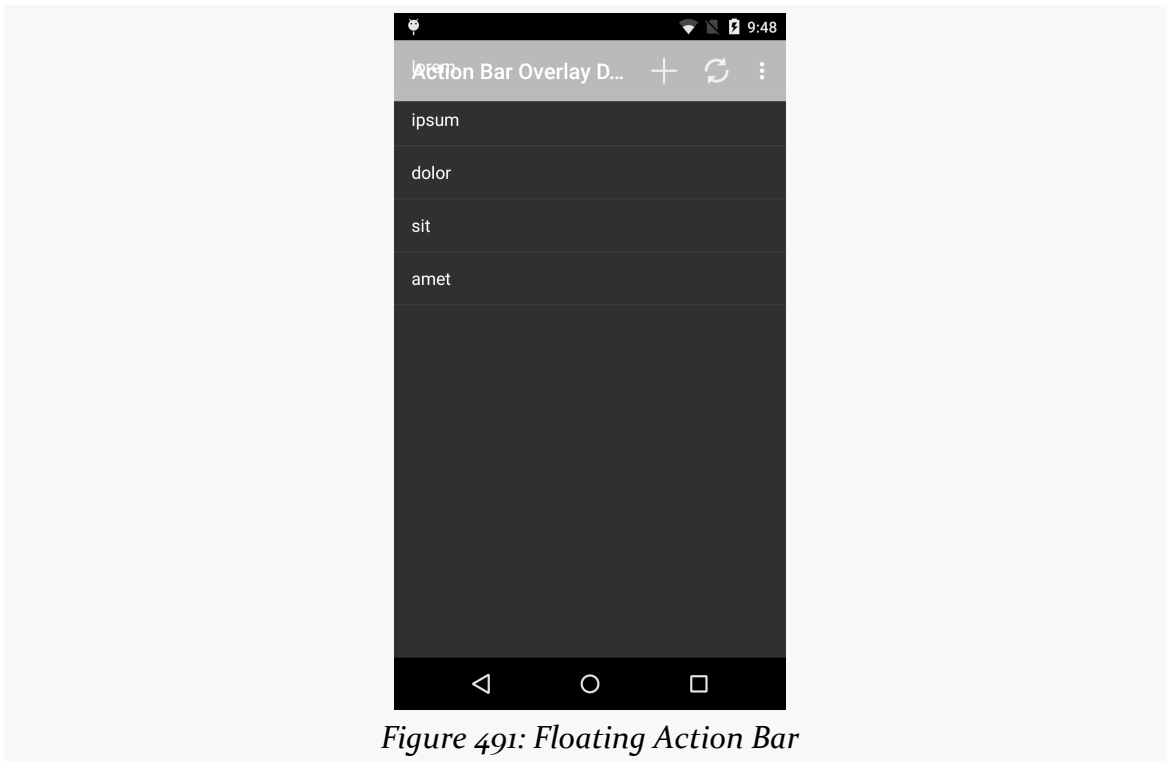

</shape>
```

(from [ActionBar/OverlayNative/app/src/main/res/drawable/action_bar_background.xml](#))

We will discuss `ShapeDrawable` in much greater detail [later in this book](#) . For the moment, take it on faith that our resource is defining a rectangle, with a translucent white fill. The alpha channel (AA) for our translucence is important, so the user can see a bit of our activity underneath the floating action bar.

The result is that our action bars float over the top of the list:

OTHER ADVANCED ACTION BAR TECHNIQUES

In this case, the effect is not very good, as the words will blend in too strongly with the overlaid action bars. However, that is a question of organizing the screen content and using this overlay feature only in cases where you will see good results, such as in the Google Maps example shown above.

Toolbar

Android 5.0 introduced a `Toolbar` widget, offering functionality akin to the action bar, but in the form of a `ViewGroup` that can be positioned where you need it. You can even use a `Toolbar` as an outright replacement for the action bar, for cases where you need a bit more control over the action bar implementation than you get by default.

In this chapter, we will explore the use of `Toolbar`. Note that [an upcoming chapter](#) will cover the use of [a backport of `Toolbar`](#) that works back to API Level 7... albeit with some issues.

Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly [the one on the action bar](#).

Note that the examples in this chapter are clones of a couple from the core chapters. This chapter's prose was written assuming that you were familiar with those samples, so you may need to go back and review them as needed.

One of the samples relies upon using a custom `Parcelable` class, which is covered [in another chapter](#).

Basic `Toolbar` Mechanics

As noted earlier, a `Toolbar` is an ordinary `ViewGroup`. While it does not support placing arbitrary children in it the way a `LinearLayout` might, it otherwise can be used like any other `ViewGroup`. In particular, you can put it in a layout resource and

position it wherever it makes sense, such as in a lower quadrant of a tablet-sized screen, tied to some specific part of your UI.

However, the `Toolbar` is not the action bar... at least, not by default. As such, you will use somewhat different methods for interacting with it, particularly for dealing with menu items:

- You will call `inflateMenu()` when you want to pour action items into the menu, as a counterpart to the work you do in `onCreateOptionsMenu()` for the action bar
- You will call `setOnMenuItemClickListener()` to set a listener to be invoked when the user taps on a menu item in the `Toolbar`, as a counterpart to the work you do in `onOptionsItemSelected()`

A `Toolbar` does not automatically adopt much in the way of styling from your activity's theme. In particular, it does not set the background color to be the primary color of a `Theme.Material` theme, the way the action bar does. However, whether via a style resource, XML attributes in a layout file, or Java code, you can affect these same sorts of capabilities.

Use Case #1: Split Action Bar

In Android 4.x, and in the original implementation of [the `appcompat-v7` action bar backport](#), we had the notion of the “split action bar”. On phone-sized screens in portrait orientation, the action bar could easily get too crowded. We could opt into having a split action bar in these cases, where action items and the overflow would go into a bar at the bottom of the screen, leaving the top for the app's title, icon, and navigation items.

However, `Theme.Material` and modern editions of `appcompat-v7` have dropped support for the split action bar. To achieve the same basic effect, you can use a `Toolbar` that you position yourself at the bottom of the screen.

The [Toolbar/SplitActionBar](#) sample project demonstrates both the original Android 4.x way of getting a split action bar and using `Toolbar` to get the same basic visual effect on Android 5.0+. This is a clone of the `ActionBar/VersionedColor` sample app from [a previous chapter](#), supporting a tinted action bar on Android 4.x (via a custom theme based off of `Theme.Holo`) and Android 5.0+ (via a custom theme based off of `Theme.Material`).

Enabling Stock Android 4.x Behavior

Getting a split action bar on Android 4.x was easy: just add `android:uiOptions="splitActionBarWhenNarrow"` to the `<activity>` or `<application>` in the manifest. Putting it on `<application>` will affect the default for all activities; putting it on a single `<activity>` affects only that activity.

The sample app's manifest uses `android:uiOptions="splitActionBarWhenNarrow"` on the one-and-only activity:

```
<activity
  android:name="ActionBarDemoActivity"
  android:label="@string/app_name"
  android:uiOptions="splitActionBarWhenNarrow">
  <intent-filter>
    <action android:name="android.intent.action.MAIN"/>

    <category android:name="android.intent.category.LAUNCHER"/>
  </intent-filter>
</activity>
```

(from [Toolbar/SplitActionBar/app/src/main/AndroidManifest.xml](#))

The result is, as the name suggests, a split action bar:

TOOLBAR

Figure 492: Split Action Bar on Android 4.3

Note that the bottom bar retains the tinting rules applied via our theme, created via [the Action Bar Style Generator](#).

Adding the Toolbar

Since Toolbar is an ordinary ViewGroup, we can put one in a layout resource, such as `res/layout-v21/main.xml`:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout
    xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:orientation="vertical">

    <ListView
        android:id="@android:id/list"
        android:layout_width="match_parent"
        android:layout_height="0dp"
        android:layout_weight="1"/>

    <Toolbar
```

TOOLBAR

```
    android:id="@+id/toolbar"
    style="@style/SplitActionBar"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"/>
</LinearLayout>
```

(from [Toolbar/SplitActionBar/app/src/main/res/layout-v21/main.xml](#))

Here, we allocate `wrap_content` height for the Toolbar and give all remaining space to the `ListView` (by means of `android:layout_weight="1"` and no weight on the Toolbar).

The style attribute on the Toolbar points to a custom style resource, in `res/values-v21/styles.xml`:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
    <style name="Theme.Apptheme" parent="android:Theme.Material">
        <item name="android:colorPrimary">@color/primary</item>
        <item name="android:colorPrimaryDark">@color/primary_dark</item>
        <item name="android:colorAccent">@color/accent</item>
    </style>
    <style name="SplitActionBar">
        <item name="android:background">@color/primary</item>
    </style>
</resources>
```

(from [Toolbar/SplitActionBar/app/src/main/res/values-v21/styles.xml](#))

This sets the background color of the Toolbar to be the same background color that we are using for the `colorPrimary` tint for our `Theme.Material`-based custom theme. By default, Toolbar has a black background, despite setting `colorPrimary` on the theme.

Using the Layout

In `onCreate()` of the activity, we load up the layout file if we are on Android 5.0 or higher:

```
@Override
public void onCreate(Bundle state) {
    super.onCreate(state);

    if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.LOLLIPOP) {
```

TOOLBAR

```
    setContentView(R.layout.main);
}

    initAdapter();
}
```

(from [Toolbar/SplitActionBar/app/src/main/java/com/commonsware/android/toolbar/sab/ActionBarDemoActivity.java](#))

Note that we could have had a separate `res/layout/main.xml` resource, containing just the `ListView`. Then, we could call `setContentView()` regardless of API level, with the resource system pulling in the right one based on the device's API level. In this case, since we are using `ListActivity`, we do not need a layout for Android 4.x. Having two lines of Java versus a separate layout resource is a tradeoff that could be made either way.

This gives us a `Toolbar`, but by default it will be empty, making it less than useful.

Populating and Using the Toolbar

On Android 4.x, we can just implement `onCreateOptionsMenu()` and `onOptionsItemSelected()`, and the items will work, whether we chose a split action bar or not. On Android 5.0+, we need to explicitly put the action bar items into the `Toolbar` and explicitly register a listener to find out when those items are tapped.

We handle all of that in `onCreateOptionsMenu()` itself, using different behavior based on API level:

```
@Override
public boolean onCreateOptionsMenu(Menu menu) {
    if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.LOLLIPOP) {
        Toolbar tb = (Toolbar) findViewById(R.id.toolbar);

        tb.inflateMenu(R.menu.actions);
        tb.setOnMenuItemClickListener(new Toolbar.OnMenuItemClickListener() {
            @Override
            public boolean onMenuItemClick(MenuItem item) {
                return onOptionsItemSelected(item);
            }
        });
    }
    else {
        getMenuInflater().inflate(R.menu.actions, menu);
    }
}
```

TOOLBAR

```
return(super.onCreateOptionsMenu(menu));  
}
```

(from [Toolbar/SplitActionBar/app/src/main/java/com/commonsware/android/toolbar/sab/ActionBarDemoActivity.java](#))

If we are on an Android 4.x device, we just `inflate()` a menu resource into the supplied `Menu` for the action bar. If we are on an Android 5.0+ device, we:

- Retrieve the `Toolbar` from the inflated layout
- Inflate our menu resource into the `Toolbar` via `inflateMenu()`
- Register an `OnMenuItemClickListener` with the `Toolbar`, routing the menu item click over to our `onOptionsItemSelected()` method, so we can have one common implementation of logic for handling action items that are either in the action bar or the `Toolbar`

Results and Changes

Running this sample on Android 5.0+ gives us a split “action bar” implemented as a `Toolbar`:

One significant visual difference is the horizontal placement of the action items. In a true split action bar, they are evenly spaced across the bar. In a Toolbar, they are flush right (or, more accurately, flush “end”, to handle right-to-left languages). There is nothing built into Toolbar to spread the items out. While there are [hacks to make this happen](#), they rely on internal implementation of Toolbar and may prove unreliable over time.

Use Case #2: Contextual Actions

Sometimes, the reason to consider a Toolbar is that you want the user to have an easier time performing actions that pertain to a part of the UI, instead of the whole UI. This is particularly the case on tablet-sized screens, where the visual gap between parts of your UI and the top action bar may be substantial.

As an example, the [Toolbar/EU4YouToolbar](#) sample project is based on the EU4You samples from [the chapter on large-screen strategies](#). There, we had a master/detail pattern with a list of member nations of the EU as the master and the mobile Wikipedia page as the detail.

EU4YouToolbar makes a few changes:

- On tablets, it splits the detail area, to show a larger rendition of the country’s flag, to go along with the mobile Wikipedia page.
- It adds navigational controls, so as the user browses the Web through the webView in our UI, the user can go forward and backwards in their browsing history, plus reload the current page. On smaller screens, where the webView fills the screen, these controls are in the action bar:

TOOLBAR

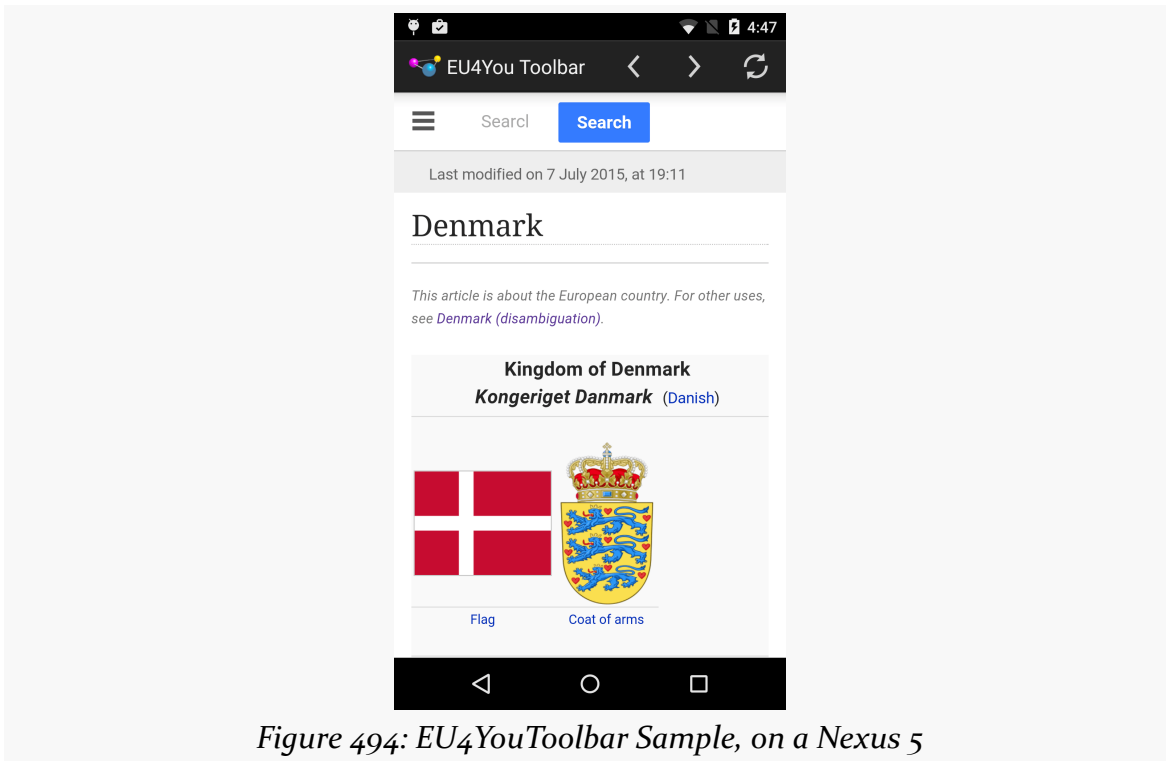

Figure 494: EU4YouToolbar Sample, on a Nexus 5

On larger screens, these controls are in a Toolbar placed immediately above the WebView:

TOOLBAR

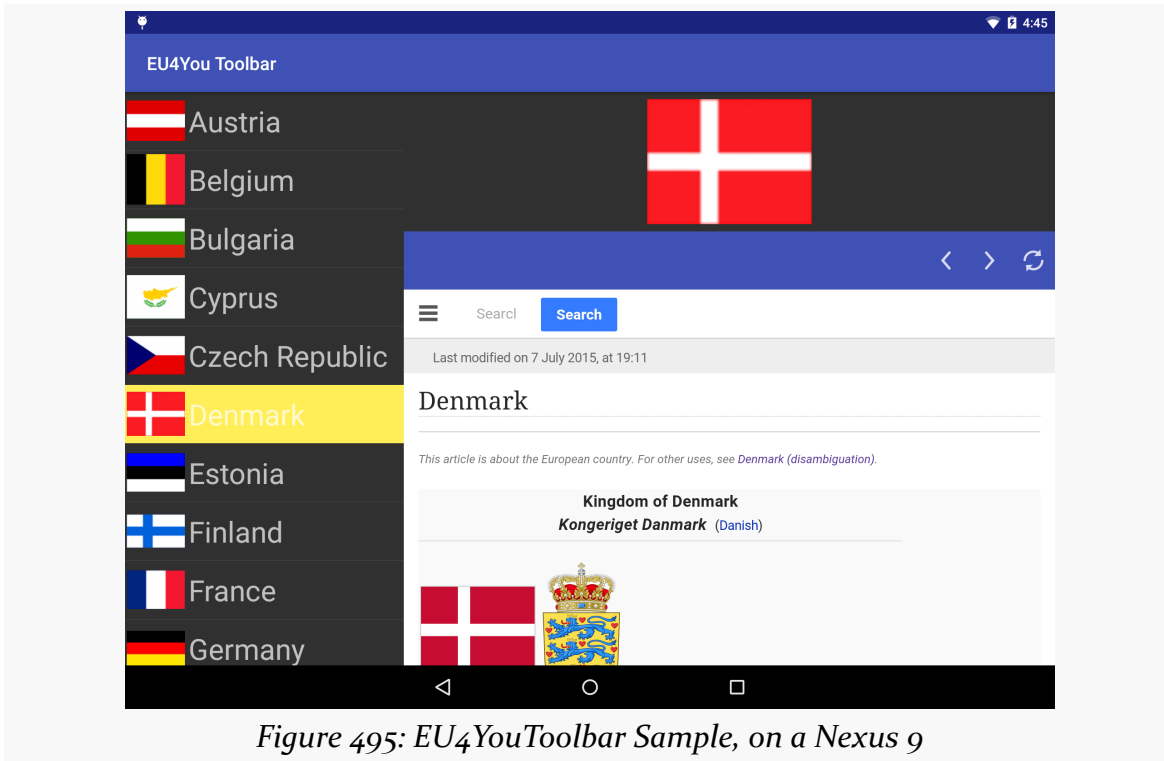

Figure 495: EU4YouToolbar Sample, on a Nexus 9

To keep things a bit simpler, this project has a `minSdkVersion` of 21, so we do not need to fuss with backwards compatibility. In truth, this would not be too difficult, requiring a different large-screen detail layout (that lacks the `Toolbar`) and falling back to having the navigational controls in the action bar if we cannot find a `Toolbar`.

The original sample used a `WebViewFragment` subclass (`DetailFragment`) to display the detail, and it supplied its own `WebView`. Now, we may want to show a flag (`ImageView`) and `Toolbar` as well, so we need our own layouts. Normally, we still only show a `WebView`:

```
<?xml version="1.0" encoding="utf-8"?>
<WebView
  xmlns:android="http://schemas.android.com/apk/res/android"
  android:id="@+id/webview"
  android:layout_width="match_parent"
  android:layout_height="match_parent">
</WebView>
```

(from [Toolbar/EU4YouToolbar/app/src/main/res/layout/details.xml](#))

TOOLBAR

However, on 720dp or larger screens, we add in an `ImageView` for the flag and a `Toolbar` for the navigational controls:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout
  xmlns:android="http://schemas.android.com/apk/res/android"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  android:orientation="vertical">

  <ImageView
    android:id="@+id/flag"
    android:layout_width="match_parent"
    android:layout_height="0dp"
    android:layout_margin="8dp"
    android:layout_weight="1"
    android:scaleType="fitCenter"/>

  <Toolbar
    android:id="@+id/toolbar"
    style="@style/Toolbar"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"/>

  <WebView
    android:id="@+id/webview"
    android:layout_width="match_parent"
    android:layout_height="0dp"
    android:layout_weight="3"/>

</LinearLayout>
```

(from [Toolbar/EU4YouToolbar/app/src/main/res/layout-w720dp/details.xml](#))

That layout gives the `Toolbar` a style of `@style/Toolbar`, which sets the background color of the `Toolbar` to be the primary color used by our overall theme:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
  <style name="Theme.Apptheme" parent="android:Theme.Material">
    <item name="android:colorPrimary">@color/primary</item>
    <item name="android:colorPrimaryDark">@color/primary_dark</item>
    <item name="android:colorAccent">@color/accent</item>
  </style>
  <style name="Toolbar">
    <item name="android:background">@color/primary</item>
  </style>
</resources>
```

TOOLBAR

```
</style>
</resources>
```

(from [Toolbar/EU4YouToolbar/app/src/main/res/values-v21/styles.xml](#))

Originally, our `DetailFragment` only needed the mobile Wikipedia URL as a data model. Now, though, we also need to know the image resource to use for the flag. While we could handle this as two separate bits of data (e.g., two extras to use with `DetailActivity`), another approach would be to pass the `Country` as the data model. However, that requires `Country` [to be Parcelable](#), so we need to add some code to `Country` to fulfill the `Parcelable` contract:

```
protected Country(Parcel in) {
    name = in.readInt();
    flag = in.readInt();
    url = in.readInt();
}

@Override
public int describeContents() {
    return 0;
}

@Override
public void writeToParcel(Parcel dest, int flags) {
    dest.writeInt(name);
    dest.writeInt(flag);
    dest.writeInt(url);
}

@SuppressWarnings("unused")
public static final Parcelable.Creator<Country> CREATOR = new Parcelable.Creator<Country>() {
    @Override
    public Country createFromParcel(Parcel in) {
        return new Country(in);
    }

    @Override
    public Country[] newArray(int size) {
        return new Country[size];
    }
};
```

(from [Toolbar/EU4YouToolbar/app/src/main/java/com/commonsware/android/eu4youtb/Country.java](#))

The `onCountrySelected()` method of the `EU4You` activity — which is called when the user taps on a country in the “master” list — now passes the `Country` itself over to the `DetailFragment`, whether directly or by means of starting the `DetailsActivity`:

```
@Override
public void onCountrySelected(Country c) {
```

TOOLBAR

```
if (details != null && details.isVisible()) {
    details.showCountry(c);
}
else {
    Intent i=new Intent(this, DetailsActivity.class);

    i.putExtra(DetailsActivity.EXTRA_COUNTRY, c);
    startActivity(i);
}
}
```

(from [Toolbar/EU4YouToolbar/app/src/main/java/com/commonsware/android/eu4youtb/EU4You.java](#))

DetailsActivity just turns around and invokes the same showCountry() method on DetailsFragment that EU4You uses when the DetailsFragment is hosted directly in EU4You:

```
package com.commonsware.android.eu4youtb;

import android.app.Activity;
import android.os.Bundle;

public class DetailsActivity extends Activity {
    public static final String EXTRA_COUNTRY=
        "com.commonsware.android.eu4you.EXTRA_COUNTRY";
    private Country c=null;
    private DetailsFragment details=null;

    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        details=(DetailsFragment)getFragmentManager()
            .findFragmentById(android.R.id.content);

        if (details == null) {
            details=new DetailsFragment();

            getFragmentManager().beginTransaction()
                .add(android.R.id.content, details)
                .commit();
        }

        c=getIntent().getParcelableExtra(EXTRA_COUNTRY);
    }

    @Override
```

TOOLBAR

```
public void onResume() {
    super.onResume();

    details.showCountry(c);
}
}
```

(from [Toolbar/EU4YouToolbar/app/src/main/java/com/commonsware/android/eu4youtb/DetailsActivity.java](#))

For the navigation controls, we need a menu resource. So, we define a webview menu resource that contains action bar items to go back in the browsing history, go forward in the browsing history, or reload the current page:

```
<?xml version="1.0" encoding="utf-8"?>
<menu xmlns:android="http://schemas.android.com/apk/res/android">
    <item
        android:id="@+id/back"
        android:title="@string/menu_back"
        android:icon="@drawable/ic_action_back"
        android:showAsAction="ifRoom"/>
    <item
        android:id="@+id/fwd"
        android:title="@string/menu_fwd"
        android:icon="@drawable/ic_action_fwd"
        android:showAsAction="ifRoom"/>
    <item
        android:id="@+id/reload"
        android:title="@string/menu_reload"
        android:icon="@drawable/ic_action_reload"
        android:showAsAction="ifRoom"/>
</menu>
```

(from [Toolbar/EU4YouToolbar/app/src/main/res/menu/webview.xml](#))

Most of the changes, not surprisingly, reside in `DetailsFragment`, which now must manage the flag's `ImageView`, the `Toolbar` (when it exists), the action bar items (when the `Toolbar` does not exist), and the behaviors to be invoked when any of those toolbar/action bar items are invoked.

`DetailsFragment` is no longer a `WebViewFragment`, as we need our own layout. While `ListFragment` supports subclasses inflating a layout (so long as the layout has a `ListView` named `@android:id/list`), `WebViewFragment` does not. So, we inherit from the stock `Fragment` class instead and have an `onCreateView()` method that inflates our desired layout:

TOOLBAR

```
@Override
public View onCreateView(LayoutInflater inflater, ViewGroup container, Bundle savedInstanceState) {
    View result=inflater.inflate(R.layout.details, container, false);

    webView=(WebView)result.findViewById(R.id.webview);
    flag=(ImageView)result.findViewById(R.id.flag);
    toolbar=(Toolbar)result.findViewById(R.id.toolbar);

    if (toolbar==null) {
        setHasOptionsMenu(true);
    }
    else {
        toolbar.inflateMenu(R.menu.webview);
        getNavItems(toolbar.getMenu());
        toolbar.setOnMenuItemClickListener(this);
    }

    return(result);
}
```

(from [Toolbar/EU4YouToolbar/app/src/main/java/com/commonsware/android/eu4youth/DetailsFragment.java](#))

Here, we inflate that details layout resource and retrieve our three main widgets (webView, flag, and toolbar). However, there are two versions of that layout resource, one for larger screens and one for smaller screens. Only the larger screen has a Toolbar; the plan is for smaller screens to use the action bar instead. Hence, toolbar may be null.

If toolbar is null, we call `setHasOptionsMenu(true)`, to opt into this fragment participating in the action bar. If the toolbar is not null, we have it inflate a menu resource via `inflateMenu()`, and we set the fragment itself up to be the listener for click events via `setOnMenuItemClickListener()`.

In between those two steps, we call `getNavItems()`, passing the Menu object that the Toolbar is using:

```
private void getNavItems(Menu menu) {
    navBack=menu.findItem(R.id.back);
    navForward=menu.findItem(R.id.fwd);
    navReload=menu.findItem(R.id.reload);

    updateNav();
}
```

(from [Toolbar/EU4YouToolbar/app/src/main/java/com/commonsware/android/eu4youth/DetailsFragment.java](#))

Here, we retrieve our three toolbar items, stashing them as fields in the fragment class. We also call `updateNav()`:

TOOLBAR

```
private void updateNav() {
    navBack.setEnabled(webView.canGoBack());
    navForward.setEnabled(webView.canGoForward());
    navReload.setEnabled(webView.getUrl()!=null);
}
```

(from [Toolbar/EU4YouToolbar/app/src/main/java/com/commonsware/android/eu4youth/DetailsFragment.java](#))

`updateNav()` updates the enabled state for each of those three toolbar items, based upon the state of the `WebView`. If we can navigate back (`canGoBack()` returns `true`), we enable the back toolbar item, and so on. There is no `canReload()` method, so we substitute a check to see if the URL in the `WebView` (via `getUrl()`) is `null`.

Since we called `setOnMenuItemClickListener()` on the `Toolbar`, indicating that the fragment itself is the listener, the fragment needs to implement the `Toolbar.OnMenuItemClickListener` interface. That requires an implementation of a `onMenuItemClick()` method. In our case, as with the previous example, we delegate that to `onOptionsItemSelected()`:

```
@Override
public boolean onMenuItemClick(MenuItem item) {
    return(onOptionsItemSelected(item));
}
```

(from [Toolbar/EU4YouToolbar/app/src/main/java/com/commonsware/android/eu4youth/DetailsFragment.java](#))

`onOptionsItemSelected()`, along with `onCreateOptionsMenu()`, will also be used if toolbar was `null` and we called `setHasOptionsMenu(true)` to use the action bar. So, we have a mostly-typical implementation of those methods, where `onOptionsItemSelected()` happens to be used both for the action bar and the `Toolbar` scenarios:

```
@Override
public void onCreateOptionsMenu(Menu menu, MenuInflater inflater) {
    inflater.inflate(R.menu.webview, menu);
    getNavItems(menu);

    super.onCreateOptionsMenu(menu, inflater);
}

@Override
public boolean onOptionsItemSelected(MenuItem item) {
    switch(item.getItemId()) {
        case R.id.back:
            if (webView.canGoBack()) {
```

TOOLBAR

```
        webView.goBack();
    }
    break;

    case R.id.fwd:
        if (webView.canGoForward()) {
            webView.goForward();
        }
        break;

    case R.id.reload:
        webView.reload();
        break;

    default:
        return(super.onOptionsItemSelected(item));
}

return(true);
}
```

(from [Toolbar/EU4YouToolbar/app/src/main/java/com/commonsware/android/eu4youth/DetailsFragment.java](#))

Note that in `onCreateOptionsMenu()`, we call `getNavItems()`, passing in the `Menu` supplied to `onCreateOptionsMenu()`. Hence, no matter whether we are using the action bar or a `Toolbar` to host the navigation items, we have those `MenuItem` objects as fields.

The `onOptionsItemSelected()` implementation just calls appropriate methods on `WebView` tied to the particular `MenuItem`, such as `canGoBack()` and `goBack()` if the user taps the “back” `MenuItem`.

This gives us the visual result that we want. However, with the code as shown so far, the toolbar items would not change state as the user browses in the `WebView`. Their enabled states are only set when the fragment is set up. We also need to update those states as the user browses.

To handle this, we attach a `URLHandler` subclass of `WebViewClient` to the `WebView` in the `onViewCreated()` method:

```
@Override
public void onViewCreated(View view, Bundle savedInstanceState) {
    super.onViewCreated(view, savedInstanceState);
```

TOOLBAR

```
webView.setWebViewClient(new URLHandler());
}
```

(from [Toolbar/EU4YouToolbar/app/src/main/java/com/commonsware/android/eu4youth/DetailsFragment.java](#))

(note: this work could have been done in `onCreateView()`, but some of this code was ported from a sample app that used `WebViewFragment`, where we would not have an `onCreateView()` method)

Partly, `URLHandler` is responsible for ensuring that all clicks on links keep the user within the `WebView`, via a `shouldOverrideUrlLoading()` implementation. Partly, `URLHandler` is responsible for calling `updateNav()` when it appears that the navigation state of the `WebView` has changed. Unfortunately, there is no canonical place to update those navigation items, so we hook into three methods and hope for the best: `onPageStarted()`, `onPageFinished()`, and `doUpdateVisitedHistory()`:

```
private class URLHandler extends WebViewClient {
    @Override
    public void onPageStarted(WebView view, String url, Bitmap favicon) {
        super.onPageStarted(view, url, favicon);

        updateNav();
    }

    @Override
    public void onPageFinished(WebView view, String url) {
        super.onPageFinished(view, url);

        updateNav();
    }

    @Override
    public void doUpdateVisitedHistory(WebView view, String url, boolean isReload) {
        super.doUpdateVisitedHistory(view, url, isReload);

        updateNav();
    }
}
```

(from [Toolbar/EU4YouToolbar/app/src/main/java/com/commonsware/android/eu4youth/DetailsFragment.java](#))

Now, assuming that those two hooks are sufficient, our back, forward, and reload navigation items will be enabled or disabled as appropriate as the user navigates within our app and the `WebView`.

Use Case #3: Replacement Action Bar

Another thing that you can do with a `Toolbar` is make it serve as your action bar. The net effect is that you can position your activity's action bar wherever you like,

TOOLBAR

rather than have it be anchored at the top of the screen. Also, you can control the Toolbar more than you can the original action bar, for things like animations. For example, if you have seen apps where the action bar slides out of the way while you are scrolling down a list, only to return when you scroll back up the list, that could be accomplished via a Toolbar as your action bar.

The basic mechanics of making a Toolbar serve as the action bar are not especially difficult. Primarily, you need to inherit from `Theme.Material.NoActionBar` (to suppress the regular action bar) and call `setActionBar()` to attach your Toolbar to the activity to serve as the activity's action bar. As with all Toolbar-specific code, this will only work on API Level 21+, though the `appcompat-v7` backport offers similar capabilities.

The [Toolbar/SplitActionBar2](#) sample project is a clone of the `SplitActionBar` project from earlier in this chapter, except that the Toolbar is set up to serve as the activity's action bar.

Our activity's theme (`Theme.Apptheme`) now inherits from `Theme.Material.NoActionBar`:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
  <style name="Theme.Apptheme" parent="android:Theme.Material.NoActionBar">
    <item name="android:colorPrimary">@color/primary</item>
    <item name="android:colorPrimaryDark">@color/primary_dark</item>
    <item name="android:colorAccent">@color/accent</item>
  </style>
  <style name="SplitActionBar">
    <item name="android:background">@color/primary</item>
  </style>
</resources>
```

(from [Toolbar/SplitActionBar2/app/src/main/res/values-v21/styles.xml](#))

The `build.gradle` file sets the `minSdkVersion` to 21, so we dispense with the backwards-compatibility checks. So, in `onCreate()`, rather than conditionally using `main.xml` as our layout, we always use it, followed by a call to `setSupportActionBar()`:

```
@Override
public void onCreate(Bundle state) {
    super.onCreate(state);

    setContentView(R.layout.main);
    setSupportActionBar((Toolbar)findViewById(R.id.toolbar));
}
```

TOOLBAR

```
initAdapter();  
}
```

(from [Toolbar/SplitActionBarz/app/src/main/java/com/commonsware/android/toolbar/sabz/ActionBarDemoActivity.java](#))

Our `onCreateOptionsMenu()` can also dispense with the conditional check to see if we are on API Level 21+. However, since we are using the `Toolbar` as our action bar, we can simply populate the action bar normally, and it will affect the `Toolbar`:

```
@Override  
public boolean onCreateOptionsMenu(Menu menu) {  
    getMenuInflater().inflate(R.menu.actions, menu);  
  
    return(super.onCreateOptionsMenu(menu));  
}
```

(from [Toolbar/SplitActionBarz/app/src/main/java/com/commonsware/android/toolbar/sabz/ActionBarDemoActivity.java](#))

The result is that we have a regular action bar, with its normal contents (e.g., title), but positioned where we put the `Toolbar`, at the bottom of the screen, where it used to serve as the bottom half of the split action bar:

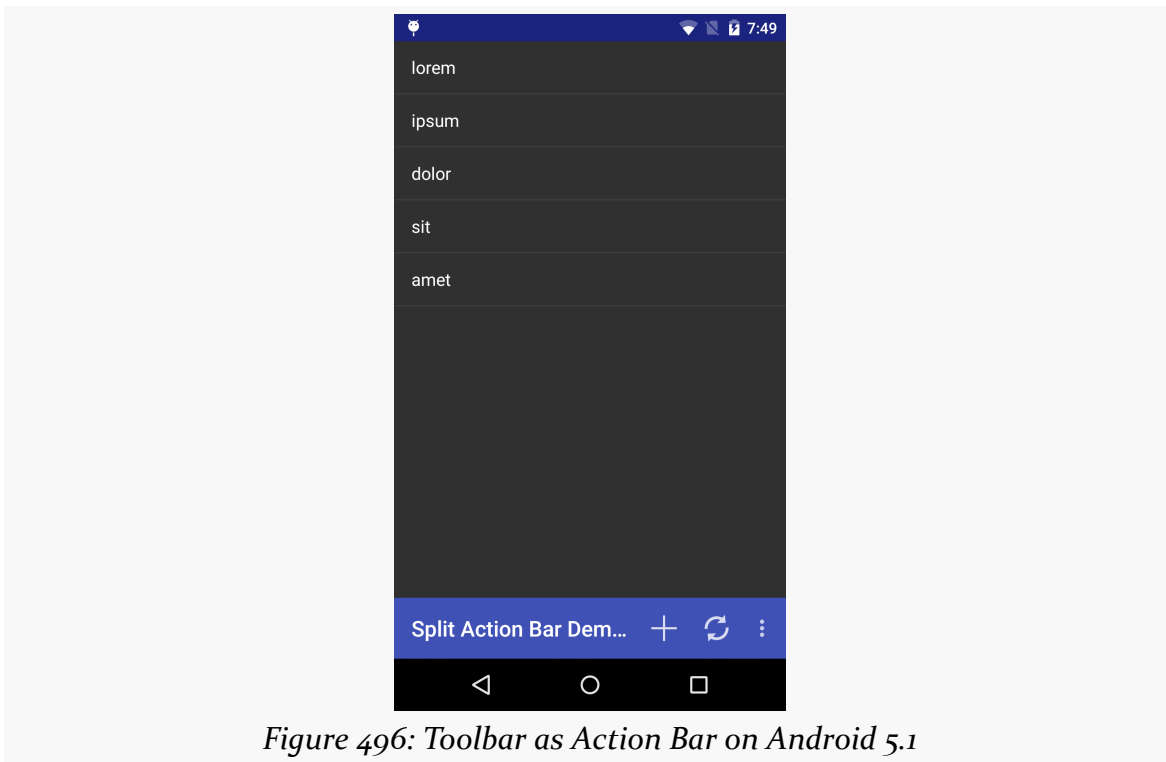

Figure 496: Toolbar as Action Bar on Android 5.1

AppCompat: The Official Action Bar Backport

Approximately 30 months after Google added the action bar to Android 3.0, Google released a backport for previous devices. Referred to here as AppCompat or, `appcompat-v7` (after its library name), this adds action bar support to Android apps, going all the way back to API Level 7.

The `appcompat-v7` Android Support Package artifact houses AppCompat. Version 21 and higher of this artifact change the way that AppCompat looks, to try to not only backport the action bar, but to backport a bit of the Material Design aesthetic.

This chapter will outline why you might want to use AppCompat and how to employ it in your Android applications.

Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly [the one on the action bar](#).

Ummmm... Why?

You might wonder why we would bother with any of it. AppCompat is not required, and apps can work fine without it. And, in truth, most apps will be just fine using the native action bar implementation.

That being said, you may find some pressures nudging you towards using an action bar backport, and AppCompat specifically.

Why an Action Bar Backport?

If your `minSdkVersion` is 11 or higher, you have an action bar on all Android versions that your app supports.

If, however, your `minSdkVersion` is below 11, by default you will get the old-style options menu on Android 1.x/2.x devices. That is not a crime. However, the action bar design pattern had been used in various Android apps prior to Android 3.0's formalization of the pattern. Many apps that users will see on older devices will have an action bar, courtesy of one of the backports. By adopting a backport, you will gain a measure of consistency in your UX across Android versions that you would otherwise miss by falling back to the options menu.

You might also adopt a backport because something else is steering you to use AppCompat, and therefore you elect to use it for those reasons.

Why AppCompat?

AppCompat is a somewhat controversial library nowadays. It did not start that way when it was released in the Summer of 2013. But Google has been rather aggressive about trying to get developers to use AppCompat, and that aggressiveness has had its downsides.

Supported

The #1 reason for using AppCompat is because you decided, for other reasons, that you wanted an action bar backport, and AppCompat right now is the primary supported option.

The original backport, `ActionBarSherlock`, was officially deprecated by its author (Jake Wharton), who is steering you towards the native action bar or AppCompat as alternatives. While this does not prevent you from using `ActionBarSherlock`, it is probably not a great choice today given that Google is supporting AppCompat.

Materialistic

The current version of AppCompat does not only give you an action bar. It gives you an action bar that looks like the one that you get from `Theme.Material`. It also will attempt to apply your accent color to select widgets, the way Android 5.0 and

Theme.Material do, to make your app abide a bit more by the Material Design aesthetic.

[Whether or not this is a good thing is up to you.](#)

Consistent

One hidden advantage of using AppCompat, particularly in concert with the fragments backport, is consistency across Android versions. By using the native action bar and fragments, you are at some risk of inconsistent behavior based upon:

- Android OS version, due to bug fixes, deprecations, and the like
- Manufacturer or ROM modder tweaks to the native implementations, which you do not control

Having your action bar and fragments be in a library in your app isolates you from those changes. AppCompat always uses its own implementation, so any changes in the native implementation will not affect your app.

This comes at a cost of additional complexity and APK size.

Forced

Some things in the Android development ecosystem, like official support for the `MediaRouteActionProvider`, only work with the AppCompat action bar, as Google has either not shipped or has deprecated their native alternatives.

You may find some “cross-ports” of those things that work with the native action bar, but those are unlikely to be as well-supported as Google’s own editions.

Also, new projects created via Android Studio basically shove `appcompat-v7` down your throat. This is why this book’s tutorials have you start by importing an existing project, so you do not have to rip `appcompat-v7` and its references out by the roots to start a new project.

While it is theoretically possible that Google itself will eventually offer native action bar implementations of those things, it is unlikely. Hence, if you determine that you need one of those, you may be more inclined to use AppCompat, even if you do not need it for any other reason.

The Basics of Using AppCompatActivity

The recipe for using the AppCompatActivity action bar requires no new skills beyond what you have learned so far in this book. However, there are some subtle and not-so-subtle differences in the approaches AppCompatActivity takes when compared to the native action bar.

To see the basic differences, we will take a look at the [AppCompatActivity/ActionBar](#) sample project. This is a port of the `fragments-and-action-bar` sample from [earlier in the book](#), where we have replaced the native action bar with AppCompatActivity.

The Library Project

AppCompatActivity is provided by the `appcompat-v7` Android library project, part of the Android Support Package. Just add the implementation `'com.android.support:appcompat-v7:...'` line to your dependencies closure, replacing `...` with a suitable version number of the library. That will take care of downloading the library and adding it to your project.

To get the material effects described in this chapter, you will want to use version 21 or higher of `appcompat-v7` (e.g., `com.android.support:appcompat-v7:22.2.0`). And, due to a particular name change that we will examine shortly, using version 22 or higher is probably a good idea.

But, more importantly, you *really* want version 23 or higher. There are [changes to ART](#) – the Android runtime used on Android 5.0+ — that apparently will break the older versions of `appcompat-v7` when running on Android 6.0+ devices.

Your Build Settings

If you are using version 22 or higher of AppCompatActivity, your build target must be API Level 22 or higher. Basically, for the Android Support libraries, your `compileSdkVersion` should match the major version of the library.

In Android Studio and the Android Gradle Plugin, this would be the `compileSdkVersion` found in your `build.gradle` file. In Eclipse, this would be the API level chosen in `Project > Properties > Android`.

Your Theme

Rather than using `Theme.Holo` or `Theme.Material`, when using `AppCompatActivity` you will use `Theme.AppCompat`, whether you use that theme directly or create your own custom theme inheriting from it. There is also `Theme.AppCompat.Light` and `Theme.AppCompat.Light.DarkActionBar`, mirroring their native counterparts.

```
<application
    android:allowBackup="false"
    android:icon="@drawable/ic_launcher"
    android:label="@string/app_name"
    android:theme="@style/Theme.AppCompat">
```

(from [AppCompatActivity/ActionBar/app/src/main/AndroidManifest.xml](#))

Your Menu Resources

Where things start to get a bit strange with `AppCompatActivity` comes with our menu resources. `AppCompatActivity` forces you to use a *different namespace* for any action bar-related attributes, those added in API Level 11 or higher.

So, we started with:

```
<?xml version="1.0" encoding="utf-8"?>
<menu xmlns:android="http://schemas.android.com/apk/res/android">

    <item
        android:id="@+id/add"
        android:icon="@drawable/ic_action_new"
        android:showAsAction="always"
        android:title="@string/add"/>
    <item
        android:id="@+id/reset"
        android:icon="@drawable/ic_action_refresh"
        android:showAsAction="always|withText"
        android:title="@string/reset"/>

</menu>
```

(from [Fragments/ActionBarNative/app/src/main/res/menu/actions.xml](#))

and we had to change it to:

```
<?xml version="1.0" encoding="utf-8"?>
<menu
```

```
xmlns:android="http://schemas.android.com/apk/res/android"
xmlns:app="http://schemas.android.com/apk/res-auto">

<item
    android:id="@+id/add"
    android:icon="@drawable/ic_action_new"
    app:showAsAction="always"
    android:title="@string/add"/>
<item
    android:id="@+id/reset"
    android:icon="@drawable/ic_action_refresh"
    app:showAsAction="always|withText"
    android:title="@string/reset"/>
<item
    android:id="@+id/about"
    android:icon="@drawable/ic_action_about"
    app:showAsAction="never"
    android:title="@string/about">
</item>
</menu>
```

(from [AppCompatActivity/src/main/res/menu/actions.xml](#))

Note that we have a new `xmlns:app="http://schemas.android.com/apk/res-auto"` namespace declaration in the root `<menu>` element, and that namespace is used for the `app:showAsAction` attribute. The actual prefix name, here shown as `app`, can be whatever you want. It just has to be unique within the document and a valid XML namespace prefix (e.g., no whitespace).

Your Activity and Fragments

We have to inherit from an `AppCompatActivity` class to use `AppCompatActivity`. `AppCompatActivity` itself inherits from `FragmentActivity`, and so we can use the Android Support Package's backport of fragments without issue, so you have access to backported versions of `Fragment`, `ListFragment`, etc.

NOTE: Prior to version 22 of `appcompat-v7`, you would inherit from an `ActionBarActivity` class. That class is still available for backwards compatibility, but you are recommended to inherit from `AppCompatActivity` instead.

However, note that there are no other analogues of `AppCompatActivity` for other scenarios, such as `ListActivity`. In principle, you should be able to make your own mash-ups of `AppCompatActivity` and other base activity classes, though the proof of

APPCOMPAT: THE OFFICIAL ACTION BAR BACKPORT

this is left as an exercise for the reader. The sample app just uses AppCompatActivity directly for showing a ListView:

```
package com.commonware.android.inflation;

import android.os.Bundle;
import android.support.v7.app.AppCompatActivity;
import android.view.Menu;
import android.view.MenuItem;
import android.widget.ArrayAdapter;
import android.widget.ListAdapter;
import android.widget.ListView;
import android.widget.Toast;
import java.util.ArrayList;

public class ActionBarDemoActivity extends AppCompatActivity {
    private static final String[] items= { "lorem", "ipsum", "dolor",
        "sit", "amet", "consectetuer", "adipiscing", "elit", "morbi",
        "vel", "ligula", "vitae", "arcu", "aliquet", "mollis", "etiam",
        "vel", "erat", "placerat", "ante", "porttitor", "sodales",
        "pellentesque", "augue", "purus" };
    private ArrayList<String> words=null;
    private ArrayAdapter<String> adapter=null;

    @Override
    public void onCreate(Bundle state) {
        super.onCreate(state);

        setContentView(R.layout.list_content_simple);
        initAdapter();
    }

    @Override
    public boolean onCreateOptionsMenu(Menu menu) {
        getMenuInflater().inflate(R.menu.actions, menu);

        return(super.onCreateOptionsMenu(menu));
    }

    @Override
    public boolean onOptionsItemSelected(MenuItem item) {
        switch(item.getItemId()) {
            case R.id.add:
                addWord();

                return(true);
        }
    }
}
```

```
        case R.id.reset:
            initAdapter();

            return(true);

        case R.id.about:
            Toast.makeText(this, R.string.about_toast, Toast.LENGTH_LONG)
                .show();

            return(true);
    }

    return(super.onOptionsItemSelected(item));
}

private void initAdapter() {
    words=new ArrayList<String>();

    for (int i=0;i<5;i++) {
        words.add(items[i]);
    }

    adapter=
        new ArrayAdapter<String>(this,
                                android.R.layout.simple_list_item_1,
                                words);

    setListAdapter(adapter);
}

private void addWord() {
    if (adapter.getCount()<items.length) {
        adapter.add(items[adapter.getCount()]);
    }
}

private void setListAdapter(ListAdapter la) {
    ((ListView)findViewById(android.R.id.list)).setAdapter(la);
}
}
```

(from [AppCompat/ActionBar/app/src/main/java/com/commonsware/android/inflation/ActionBarDemoActivity.java](https://github.com/android/android-support-v4-appcompat/blob/master/src/main/java/com/commonsware/android/inflation/ActionBarDemoActivity.java))

The layout, `res/layout/list_content_simple.xml`, is cloned from the one used by `ListActivity` itself:

```
<?xml version="1.0" encoding="utf-8"?>
<!--
```

APPCOMPAT: THE OFFICIAL ACTION BAR BACKPORT

```

*/
-->
<ListView xmlns:android="http://schemas.android.com/apk/res/android" android:id="@android:id/list"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:drawSelectorOnTop="false"
/>
```

(from [AppCompat/ActionBar/app/src/main/res/layout/list_content_simple.xml](#))

Your Callback Methods

In many cases, your `onCreateOptionsMenu()` and `onOptionsItemSelected()` methods will be the same for AppCompat as they would be for a regular Android app.

However, if you do need to manipulate action bar-specific attributes of your inflated menu resources, you will be unable to do so directly. The workaround is to use `MenuCompat` and `MenuItemCompat`, from the Android Support package, to give you access to newer `Menu` and `MenuItem` features in a backwards-compatible fashion.

Your Results

Visually, the results are very similar to what we get from `Theme.Material`, whether we run on Android 5.0 itself:

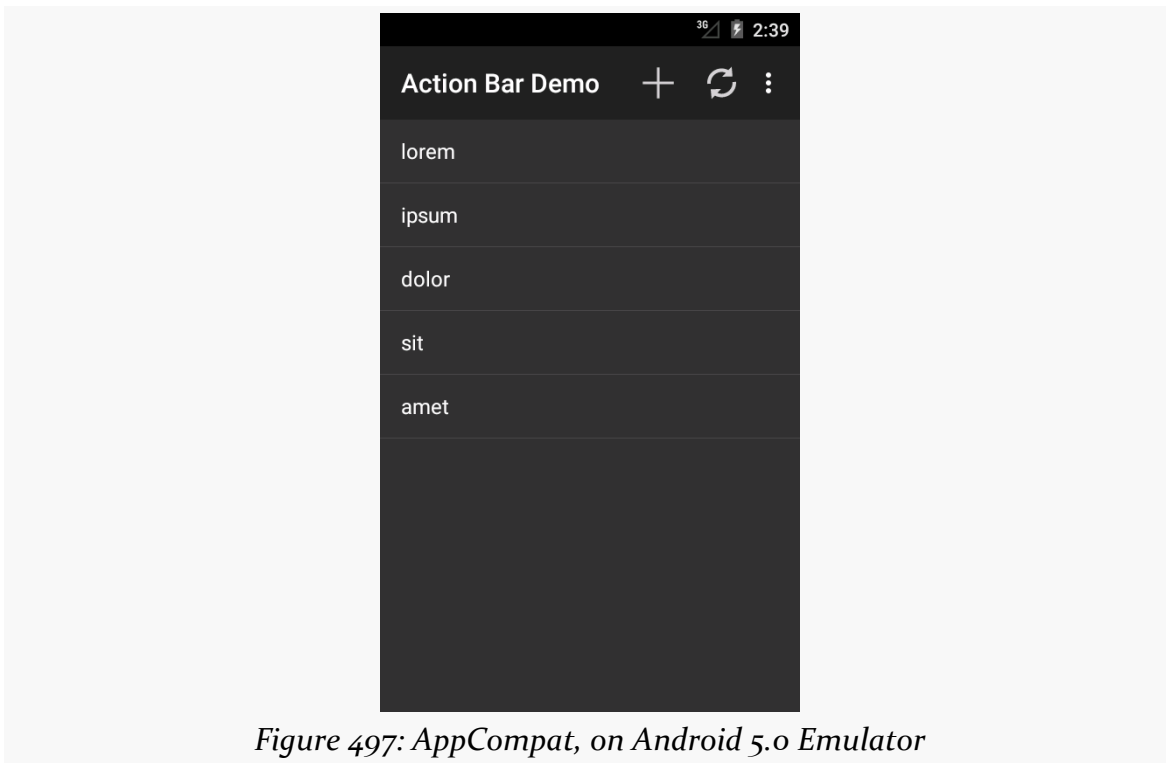

Figure 497: AppCompatActivity, on Android 5.0 Emulator

...or on something older, like an Android 4.1 emulator:

Figure 498: AppCompatActivity, on Android 4.1 Emulator

Other AppCompatActivity Effects

While the above recipe will give you the basics, you can go a lot further with AppCompatActivity, just as you can with the native action bar. Generally speaking, AppCompatActivity's backport includes all of the capabilities of the native action bar.

The biggest key is that when working with AppCompatActivity, if you need to access your ActionBar instance, call `getSupportActionBar()`, not `getActionBar()`. The latter will compile, but it will return null at runtime, as you are disabling the native action bar and using AppCompatActivity's instead.

Tinting

The same basic tinting rules that apply for `Theme.Material` apply for `Theme.AppCompat` and AppCompatActivity, with two noteworthy differences.

First, the theme attributes do not have the android prefix, but instead are just the bare names (e.g., `colorPrimary`). So, in the [AppCompatActivity/ActionBarColor](#) sample project, the style resource becomes:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
  <style name="Theme.Apptheme" parent="Theme.AppCompat">
    <item name="colorPrimary">@color/primary</item>
    <item name="colorPrimaryDark">@color/primary_dark</item>
    <item name="colorAccent">@color/accent</item>
  </style>
</resources>
```

(from [AppCompat/ActionBarColor/app/src/main/res/values/styles.xml](https://github.com/ActionBarColor/app/src/main/res/values/styles.xml))

Second, not all widgets will have their colors affected by the theme. As of version 22 of `appcompat-v7`, the roster is limited to:

- `AutoCompleteTextView`
- `Button`
- `CheckBox`
- `CheckedTextView`
- `EditText`
- `MultiAutoCompleteTextView`
- `RadioButton`
- `RatingBar`
- `Spinner`
- `TextView`

Also, `Switch` adopts the colors, if you use the `SwitchCompat` backport discussed in the next section.

In the [AppCompat/Basic](#) directory you will find projects mirroring those from the `BasicMaterial` directory. In `BasicMaterial`, we saw how widgets were tinted based on a `Theme.Material`-based theme; in `AppCompat/Basic`, you will see how widgets are tinted based upon a `Theme.AppCompat`-based theme.

Switch Backport

As mentioned above, there is an official backport of the `Switch` widget, known as `SwitchCompat`, added to the `appcompat-v7` library. This works back to API Level 7, as does everything in `appcompat-v7`. And, for better or worse, it provides a backport of the Material Design implementation of a `Switch`. So, rather than the `Theme.Holo.ON/OFF` toggle, we get the unlabeled “looks like a really tiny `SeekBar`” widget:

Figure 499: SwitchCompat, on an Android 4.3 Emulator

The above screenshot comes from the [AppCompat/Basic/Switch](#) sample project, which uses a layout specifying the SwitchCompat widget:

```
<?xml version="1.0" encoding="utf-8"?>
<android.support.v7.widget.SwitchCompat
    xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/toggle"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content" />
```

(from [AppCompat/Basic/Switch/app/src/main/res/layout/main.xml](#))

Also note that SwitchCompat only works inside an AppCompatActivity. It is not a general backport of Switch that can be used in any activity.

Overlay

AppCompat supports the same basic sort of [floating action bar](#) that is supported by the native action bar implementation. There are two slight changes in the recipe:

APPCOMPAT: THE OFFICIAL ACTION BAR BACKPORT

- Use `supportRequestWindowFeature()`, rather than `requestWindowFeature()`, to request `Window.FEATURE_ACTION_BAR_OVERLAY`
- Use `getSupportActionBar()`, rather than `getActionBar()`, to set the background

This is illustrated in `onCreate()` of the `ActionBarDemoActivity` version found in the [AppCompat/Overlay](#) sample project:

```
@Override
public void onCreate(Bundle state) {
    super.onCreate(state);

    supportRequestWindowFeature(Window.FEATURE_ACTION_BAR_OVERLAY);

    setContentView(R.layout.list_content_simple);

    initAdapter();

    Drawable d=
        getResources().getDrawable(R.drawable.action_bar_background);

    getSupportActionBar().setBackgroundDrawable(d);
    getSupportActionBar().setSplitBackgroundDrawable(d);
}
```

(from [AppCompat/Overlay/app/src/main/java/com/commonsware/android/actionbaroverlay/ActionBarDemoActivity.java](#))

And, you get the same basic results as with the native action bar:

Figure 500: AppCompatActivity with FEATURE_ACTION_BAR_OVERLAY on an Android 4.3 Emulator

SearchView

AppCompatActivity has its own implementation of SearchView, as `android.support.v7.widget.SearchView`. To use it, switch to that class in your menu resource, then use `MenuItemCompat.getActionView()` to retrieve the instance after your menu resource has been inflated.

For example, the [AppCompatActivity/SearchView](#) sample project uses the AppCompatActivity implementation of SearchView in its `res/menu/actions.xml` file:

```
<?xml version="1.0" encoding="utf-8"?>
<menu
  xmlns:android="http://schemas.android.com/apk/res/android"
  xmlns:app="http://schemas.android.com/apk/res-auto">

  <item
    android:id="@+id/search"
    app:actionViewClass="android.support.v7.widget.SearchView"
    android:icon="@drawable/ic_action_search"
    app:showAsAction="ifRoom|collapseActionView">
```

```
    android:title="@string/filter">
  </item>

</menu>
```

(from [AppCompat/SearchView/app/src/main/res/menu/actions.xml](#))

Then, in `onCreateOptionsMenu()`, `ActionBarFragment` calls out to a private `configureSearchView()` method that retrieves the `SearchView` and sets it up, much as you saw with the native implementation of `SearchView` from [earlier in this book](#):

```
private void configureSearchView(Menu menu) {
    MenuItem search=menu.findItem(R.id.search);

    sv=(SearchView)MenuItemCompat.getActionView(search);
    sv.setOnQueryTextListener(this);
    sv.setOnCloseListener(this);
    sv.setSubmitButtonEnabled(false);
    sv.setIconifiedByDefault(true);

    if (initialQuery != null) {
        sv.setIconified(false);
        search.expandActionView();
        sv.setQuery(initialQuery, true);
    }
}
```

(from [AppCompat/SearchView/app/src/main/java/com/commonsware/android/ab/search/ActionBarFragment.java](#))

The resulting `SearchView` is tied into `AppCompat` and offers a Material Design-esque look, applying your tints when opened:

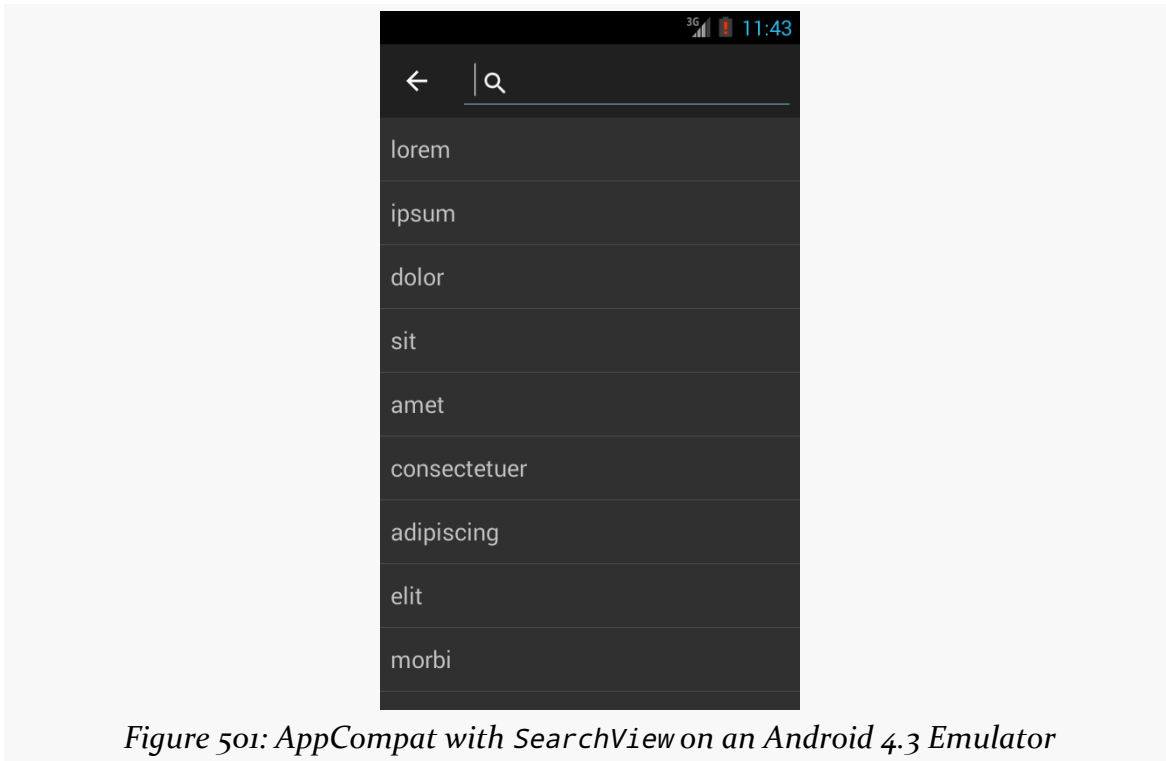

Figure 501: AppCompatActivity with SearchView on an Android 4.3 Emulator

ShareActionProvider

Similarly, AppCompatActivity has its own implementation of ShareActionProvider, as `android.support.v7.widget.ShareActionProvider`. The recipe for using it resembles that of using SearchView:

- Refer to the AppCompatActivity edition of the class in your menu resource
- Use `MenuItemCompat.getActionProvider()` to retrieve your ShareActionProvider instance after inflating the menu resource, to configure and use it

The [AppCompatActivity/Share](#) sample project is a clone of the ShareActionProvider project described [elsewhere in the book](#), converted to use AppCompatActivity and its edition of ShareActionProvider.

Toolbar and AppCompatActivity

AppCompatActivity has its own backport of [the Toolbar widget](#). By and large, you use it in much the same way as you use the native Toolbar. On the plus side, the backported

APPCOMPAT: THE OFFICIAL ACTION BAR BACKPORT

Toolbar works back to API Level 7, allowing you to take advantage of this on much older devices. However, it requires you to be using AppCompatActivity — you cannot use the backported Toolbar with a regular activity.

The [Toolbar/SplitActionBarCompat](#) sample project is a clone of the Toolbar/SplitActionBar sample. That sample uses the native Toolbar to replicate [the “split action bar” pattern](#), where there is a second “action bar” at the bottom of the screen, for actions that would not fit in the regular action bar. This clone uses the AppCompatActivity backport of Toolbar, and that requires some changes.

First, we now depend upon `appcompat-v7` in the `app/` module’s `build.gradle` file:

```
apply plugin: 'com.android.application'

dependencies {
    implementation 'com.android.support:appcompat-v7:22.2.1'
}

android {
    compileSdkVersion 22
    buildToolsVersion '26.0.2'

    defaultConfig {
        minSdkVersion 14
        targetSdkVersion 22
    }
}
```

(from [Toolbar/SplitActionBarCompat/app/build.gradle](#))

Our styles and themes change to use `Theme.AppCompat` as a base:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>

    <style name="Theme.Apptheme" parent="Theme.AppCompat">
        <item name="colorPrimary">@color/primary</item>
        <item name="colorPrimaryDark">@color/primary_dark</item>
        <item name="colorAccent">@color/accent</item>
    </style>

    <style name="SplitActionBar">
        <item name="background">@color/primary</item>
    </style>
</resources>
```

APPCOMPAT: THE OFFICIAL ACTION BAR BACKPORT

(from [Toolbar/SplitActionBarCompat/app/src/main/res/values/styles.xml](#))

Note that the `SplitActionBar` style, like `Theme.AppTheme`, drops the `android:` from the name attributes. That is because our `Toolbar` now comes from a library, and so we are no longer using system-defined attributes, but rather library-defined attributes.

The layout resource simply fully-qualifies the class name for the `Toolbar` widget to refer to the one from `AppCompatActivity`:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout
  xmlns:android="http://schemas.android.com/apk/res/android"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  android:orientation="vertical">

  <ListView
    android:id="@android:id/list"
    android:layout_width="match_parent"
    android:layout_height="0dp"
    android:layout_weight="1"/>

  <android.support.v7.widget.Toolbar
    android:id="@+id/toolbar"
    style="@style/SplitActionBar"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"/>

</LinearLayout>
```

(from [Toolbar/SplitActionBarCompat/app/src/main/res/layout/main.xml](#))

`ActionBarDemoActivity` now needs to inherit from `AppCompatActivity`, rather than `ListActivity`. That means we no longer have any scenario in which we will get a `ListView` “for free” — we always have to inflate our layout resource:

```
@Override
public void onCreate(Bundle state) {
    super.onCreate(state);

    setContentView(R.layout.main);
    initAdapter();
}
```

(from [Toolbar/SplitActionBarCompat/app/src/main/java/com/commonsware/android/toolbar/sabc/ActionBarDemoActivity.java](#))

APPCOMPAT: THE OFFICIAL ACTION BAR BACKPORT

This also means we need our own `setListAdapter()` method, since we are no longer inheriting one:

```
private void setListAdapter(ListAdapter adapter) {  
    ListView lv=(ListView)findViewById(android.R.id.list);  
  
    lv.setAdapter(adapter);  
}
```

(from [Toolbar/SplitActionBarCompat/app/src/main/java/com/commonsware/android/toolbar/sabc/ActionBarDemoActivity.java](#))

The only other change is to the `Toolbar` import statement, to pull in the backport:

```
import android.support.v7.widget.Toolbar;
```

(from [Toolbar/SplitActionBarCompat/app/src/main/java/com/commonsware/android/toolbar/sabc/ActionBarDemoActivity.java](#))

The result is visually very similar to what we would have had on Android 5.0+, but it works back to API Level 7:

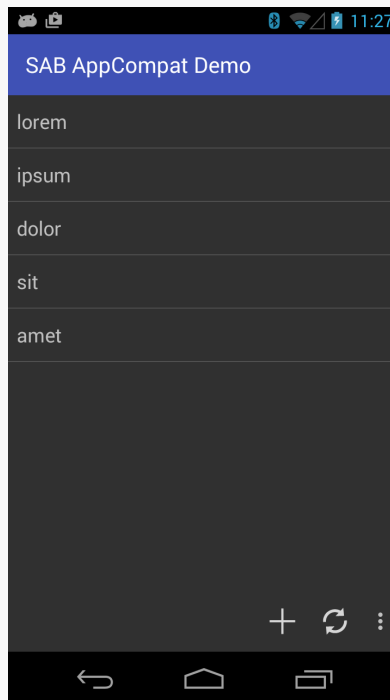

Figure 502: AppCompat Toolbar Backport, as a Split Action Bar

To Material, or Not to Material

(the following is adapted from [one of the author's blog posts](#))

There has been a lot of discussion regarding the adoption of Material Design aesthetics in Android apps. Newcomers to Android might conclude that Material Design must be The Most Important Thing in Android Development and therefore should be pursued immediately at all costs.

[Not everybody shares this opinion](#)

With that in mind, here are the author's recommendations on what to consider with Material Design:

DO start considering the effects of Material Design upon your Android app. Theme.Material is the dominant theme on Android 5.0 devices, and it should remain the dominant theme on future Android versions, at least for a while. There will be hundreds of millions of these devices in use, eventually, and you will want your app to look like “it belongs” on those devices. On those devices, not only will Google's apps be employing Theme.Material, but manufacturer-supplied apps should do so as well. While not everything on the device may necessarily adopt this theme, more than enough will that your app may stand out somewhat if your app does not and the user thinks that it should.

DON'T blindly assume that you should be using a Material-ish look on all versions of Android. Your objective should be having an app that looks like it belongs on the device. Material-themed apps are highly unlikely to achieve majority status, let alone dominance, on pre-Android 5.0 releases. After all, device manufacturers are not going to be shipping Material-themed updates to built-in apps *en masse*, and there are plenty of apps out there that are still using pre-Holo themes. This is all on top of app that have no identifiable Android theme (e.g., most games). Certainly, there will be Material-themed apps running on Android 4.x devices, courtesy of Google and some other developers. But there will be enough Holo-themed apps that your app will not look out of place on Android 4.x any time soon, if ever. Hence, you have your choice of adopting Material Design across the board or not — user pressure is unlikely to be a major criterion any time soon.

DON'T fall victim to the “our app must look the same across all devices” mindset. Again, your app should look like it belongs on the device, which is why trying to ape an iOS look-and-feel on Android is rarely a good move. Most people do not have two

APPCOMPAT: THE OFFICIAL ACTION BAR BACKPORT

Android devices, and only a small subset of those will have an Android 5.x device and an Android 4.x (or older) device. Hence, most of the people who will care about your app appearing identical on those devices will be in your meeting room discussing the issue. Few of your users will notice — they want an app that works, does what the user wants, and looks like it belongs on their device.

DO consider whether adopting Material Design across the board may offer *engineering* benefits. For example, if you have been heavily customizing widget colors in a `Ho1o`-based theme, the tinting options provided by `appcompat-v7` may simplify your app a fair bit, reducing APK size, maintenance costs after the Material conversion, etc. Since your users are unlikely to be terribly concerned one way or the other, engineering considerations may help to “tip the scales” in one direction or another.

DON'T blindly assume that `appcompat-v7` will result in a simpler app, or that it should be the basis for all new apps. `appcompat-v7` has had a history of bugs. Not all of those bugs are Google's fault (e.g., the Samsung device issue was really caused by a screwy decision on Samsung's part), but that comes as cold comfort to developers trying to distribute `appcompat-v7` apps. And, if you are comfortable with using themes based on `Theme.Ho1o` for pre-Android 5.0 devices, `appcompat-v7` may be much more of an impediment than an advance. `appcompat-v7` is a tool, not a religion — use it where it clearly adds value *to you and your app*.

DO start planning for Google's next major theme overhaul. Google, of course, is portraying Material Design as being The One True UI Design. Google will probably get irritated when people point out that `Theme.Material` is the third major theme in the six-year production history of Android, and so assuming that `Theme.Material` is “the be-all and end-all” of themes is unrealistic. Whether the next-generation theme is a refinement on Material Design or a larger overhaul remains to be seen. But you should be taking into account that we may well wind up going through this same process in, say, early 2018. The more you can isolate the theme-related changes from the rest of your app, the more likely it is that you will be able to accommodate future theme changes with less work.

The Android Design Support Library

In 2014, to much fanfare, Google released their first edition of [the Material Design guidelines](#).

What was missing was an actual implementation of most of these guidelines.

Beyond the obvious question of “how do you know that it will work well if you have not tried it?”, it put Android developers in the unenviable position of being pressured to make their apps “look more material” without having anything really to do that.

In the months that followed Google I/O 2014, various developers took this implementation gap as a challenge and created their own implementations of many bits of Material Design. Much of this was released in the form of open source components, easily added to an app via dependencies added to a project’s `build.gradle` file (at least, for Android Studio developers and other Gradle users).

In 2015, to a bit less fanfare, Google [released](#) the Android Design Support Library. The vision is that this would be the official implementation of many Material Design core components, like floating action buttons (FABs), snackbars, and the like.

This chapter explores some components from the Android Design Support Library. This chapter also explores some independent implementations of the same components, particularly ones that seem to be superior to what Google is offering at present.

Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly [the one on the action bar](#). You also should read the chapter on [the appcompat-v7 action bar backport](#).

Note that the examples in this chapter are clones of a couple from the core chapters. This chapter's prose was written assuming that you were familiar with those samples, so you may need to go back and review them as needed.

One of the book samples makes use of [the animator framework](#).

GUIs and the Support Package

Many developers think that the libraries in the Android Support Package are purely backports. They then get confused when they realize that certain classes, like `ViewPager`, are not part of the core Android framework for any API level and exist only in the Android Support Package.

In truth, a lot of what is in the Android Support Package consists of backports: fragments, the action bar, `NotificationCompat`, and so on. However, the Android Support Package really consists of code that Google wants to make available to developers that can be used right away, even on older devices.

Many pieces of the Android Support Package are GUI-related, yet are not backports:

- `support-v4` and `support-v13` have the aforementioned `ViewPager`
- `cardview-v7` has `CardView`
- `recyclerview-v7` has `RecyclerView`
- `leanback-v17` has classes for “the ten-foot UI” approach used for Android apps appearing on televisions, such as via Android TV boxes

Now, we can add the Android Design Support Library to that list. Right now, this library is focused on Material Design components, and that is likely to remain its near-term focus. It remains to be seen if other GUI components, not specifically tied to Material Design, wind up in the Android Design Support Library, in `support-v4/support-v13`, or in other libraries.

Adding the Library... and What Comes With It

On the surface, Android Studio users can simply add `com.android.support:design:...` (for some version number for ..., such as 25.1.1) as a dependency:

```
implementation 'com.android.support:design:25.1.1'
```

However, this library has a transitive dependency that pulls in `appcompat-v7`. Most pieces of the Android Design Support Library do indeed seem to require that you use `appcompat-v7`, using `Theme.AppCompat`, `AppCompatActivity`, and friends. This is true even if you planned on using `Theme.Material` itself, with a `minSdkVersion` of 21 or higher.

There are two ways to work around this `appcompat-v7` requirement:

- Use a third-party implementation of the same GUI element
- Use CWAC-CrossPort, described in the next section

Introducing CWAC-CrossPort

[CWAC-CrossPort](#) is a library, published by the author of this book, that contains a subset of the GUI elements from the Design Support library. All references to `appcompat-v7` have been removed, replaced with equivalents from `Theme.Material`. As such, you can use CWAC-CrossPort on apps with a `minSdkVersion` of 21 or higher, to get the Material Design elements from the Design Support library, but without the `appcompat-v7` baggage.

CWAC-CrossPort does not include *everything* from the Design Support library, but it does include most of it.

As with the rest of the CWAC libraries, using it requires that you add the CWAC artifact repository to your Gradle configuration:

```
repositories {  
    maven {  
        url "https://s3.amazonaws.com/repo.commonsware.com"  
    }  
}
```

Then, add a dependency on the artifact itself, for some version:

```
dependencies {  
    implementation 'com.commonsware.cwac:crossport:0.1.0'  
}
```

Snackbars: Sweeter than Toasts

The Toast has been in Android since the beginning. It allows you to pop up a message to show the user, one that does not interfere with the rest of your activity layout. And, it is fairly easy to use.

However, some people get burned by Toast:

- A Toast is modeless, so you cannot get user input via a Toast
- Because a Toast is modeless, it is time-limited, and therefore the user might never see your message, because the user is not glancing at the screen during the short window your Toast is visible
- A Toast is a separate window from the window that is displaying your activity, so your Toast will remain visible even if the user navigates to some other activity, which can be annoying at times

The Material Design guidelines instead call for the use of a “snackbar”, and the Design Support Library offers a Snackbar implementation of this UI pattern. In contrast to a Toast:

- A Snackbar is part of your activity’s UI, and so it can collect input from the user, while it is around, usually in the form of some sort of “action”
- A Snackbar can be time-limited (for information notices) or durable (for errors or getting user input)
- While a Snackbar is part of your activity (and will go away when the user leaves your activity), you do not have to declare it in your layout files

With that in mind, let’s take a look at some use cases for a Snackbar and how they can be implemented.

Alerts

The quintessential reason to use a Toast was to display a simple message to the user. You can use a Snackbar in the same role, with most of the same code.

Snackbar has a static `make()` method, mirroring the `makeText()` method on Toast. `make()` takes three parameters, only slightly different from those on `makeText()`:

1. A View in the activity that wishes to show the Snackbar
2. The message, in the form of a CharSequence (e.g., a String) or a string resource ID
3. The duration of the Snackbar, which is either `Snackbar.LENGTH_SHORT`, `Snackbar.LENGTH_LONG`, or possibly something else (the documentation is inconsistent on this point)

As with `makeText()` on `Toast`, simply calling `make()` on `Snackbar` creates a `Snackbar` object for you, but does not display anything. You need to call `show()` on the `Snackbar` instance to get it to appear.

The [DesignSupport/Snackbar](#) sample project is a clone of the `Threads/AsyncDemo` sample from earlier in the book. The app shows a list of 25 Latin words, progressively added to the list via an `AsyncTask`. When the list is fully populated, the original sample would display a `Toast`, from `onPostExecute()` of the `AsyncTask`.

The revised sample substitutes a `Snackbar`:

```
@Override
protected void onPostExecute(Void unused) {
    Snackbar.make(getListView(), R.string.done,
        Snackbar.LENGTH_LONG).show();

    task=null;
}
```

(from [DesignSupport/Snackbar/app/src/main/java/com/commonsware/android/snackbar/async/AsyncDemoFragment.java](#))

On phone-sized screens, the `Snackbar` will be centered along the bottom:

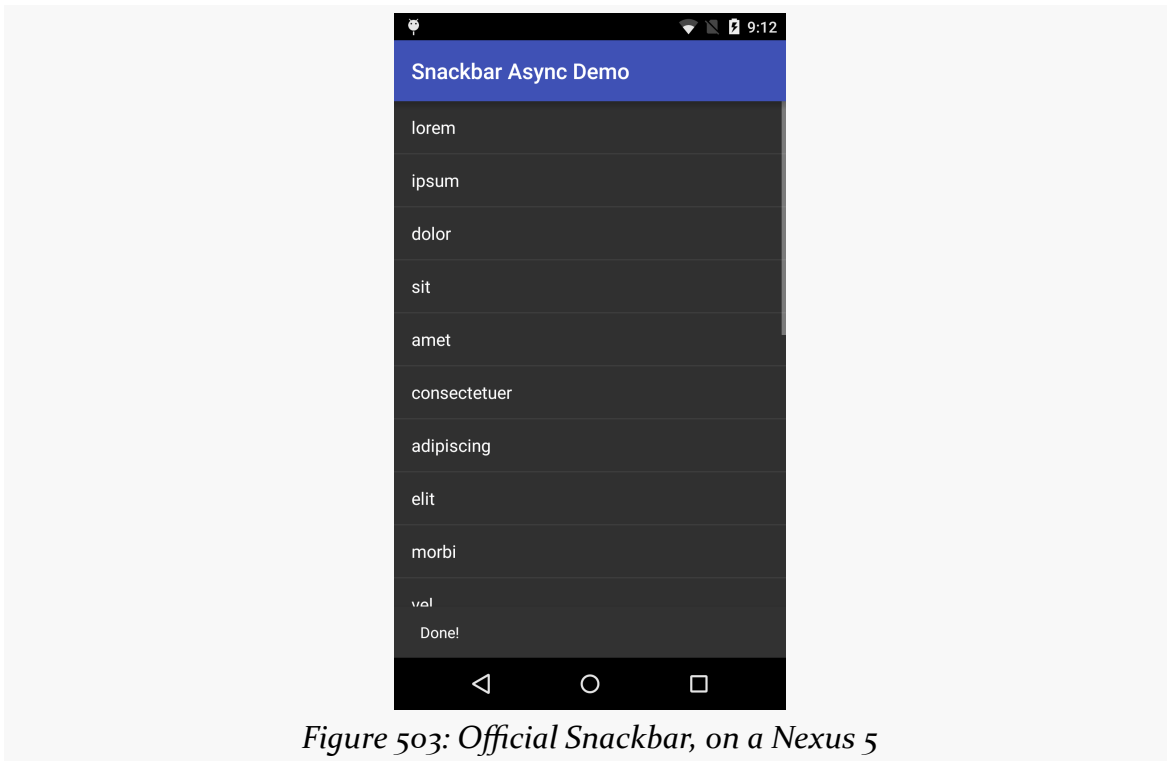

Figure 503: Official Snackbar, on a Nexus 5

On tablet-sized screens, the Snackbar will appear at the bottom but off to the side:

Figure 504: Official Snackbar, on a Nexus 7

Unfortunately, there does not seem to be much support for styling the look of the Snackbar. To do this manually, you can obtain the actual `View` for the Snackbar via `getView()`. While you should make few assumptions about what this `View` actually is, you should be able to call setters on that `View` to change things like background colors.

Also note that the user can get rid of a Snackbar via a swipe gesture, in addition to allowing the Snackbar to time out on its own. This is not possible with `Toast`, as a `Toast` is modeless.

Action Bars. No, Not Those Action Bars.

We can expand upon the user interaction with a Snackbar by adding an action to it. To do this, just call `setAction()` on the Snackbar after creating it, passing in the display string for the action (what the user will see on the Snackbar) and a `View.OnClickListener` that will get control when the user taps on that action. The look and feel of the action is up to the Snackbar implementation.

The [DesignSupport/SnackbarAction](#) sample project is a clone of the previous sample, adding one of these actions. Specifically, once the list is loaded, we want a

“Restart” action to clear the list and load it again. Perhaps the user found loading the list to be exciting and wishes to see it happen all over again.

To that end, we should pull out the work of loading our list into a `loadModel()` method that can be used from multiple places:

```
private void loadModel() {
    task=new AddStringTask();
    task.execute();
}
```

(from [DesignSupport/SnackbarAction/app/src/main/java/com/commonsware/android/snackbar/action/AsyncDemoFragment.java](#))

The `onCreate()` method now delegates to `loadModel()`:

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    setRetainInstance(true);

    adapter=
        new ArrayAdapter<String>(getActivity(),
            android.R.layout.simple_list_item_1,
            model);

    loadModel();
}
```

(from [DesignSupport/SnackbarAction/app/src/main/java/com/commonsware/android/snackbar/action/AsyncDemoFragment.java](#))

And, more importantly for this section, we also call `loadModel()` from the `View.OnClickListener` of the action that we add to our Snackbar:

```
@Override
protected void onPostExecute(Void unused) {
    Snackbar munchie=Snackbar.make(getListView(), R.string.done,
        Snackbar.LENGTH_LONG);

    munchie.setAction(R.string.snackbar_action_restart,
        new View.OnClickListener() {
            @Override
            public void onClick(View view) {
                adapter.clear();
                loadModel();
            }
        });
}
```

THE ANDROID DESIGN SUPPORT LIBRARY

```
munchie.show();  
  
task=null;  
}
```

(from [DesignSupport/SnackbarAction/app/src/main/java/com/commonsware/android/snackbar/action/AsyncDemoFragment.java](#))

The action will appear on the Snackbar itself, both on phones:

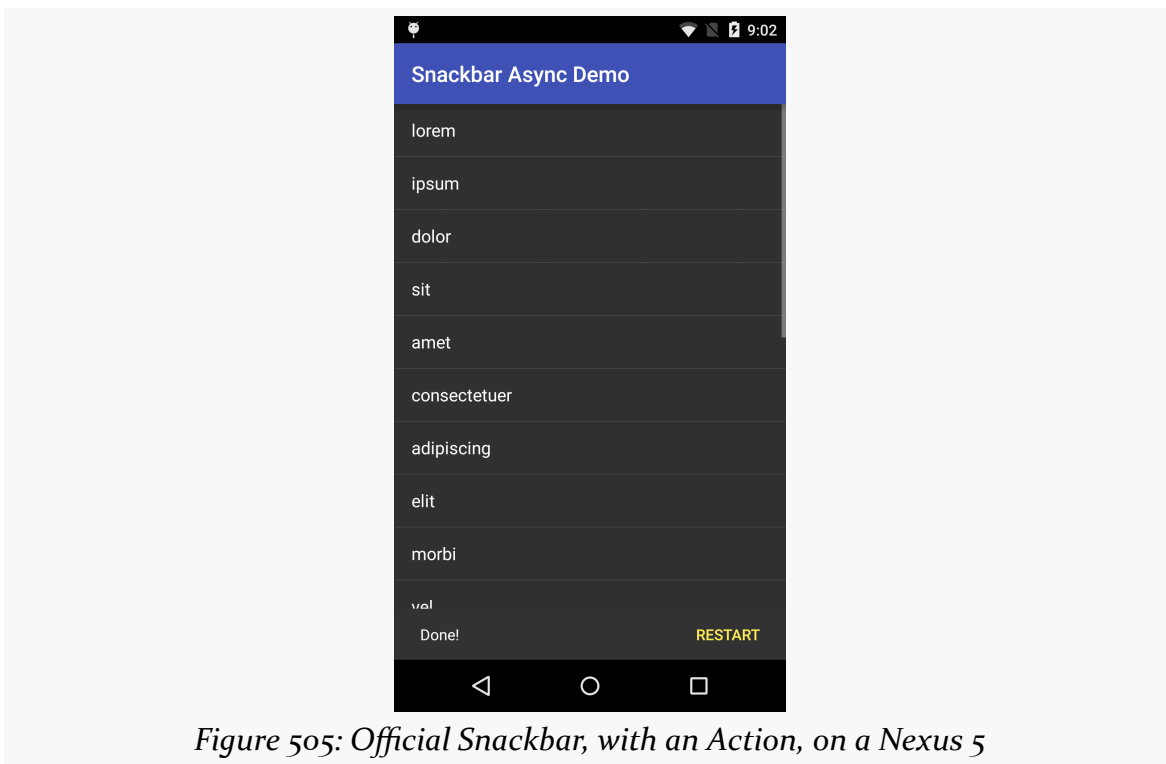

Figure 505: Official Snackbar, with an Action, on a Nexus 5

...and on tablets:

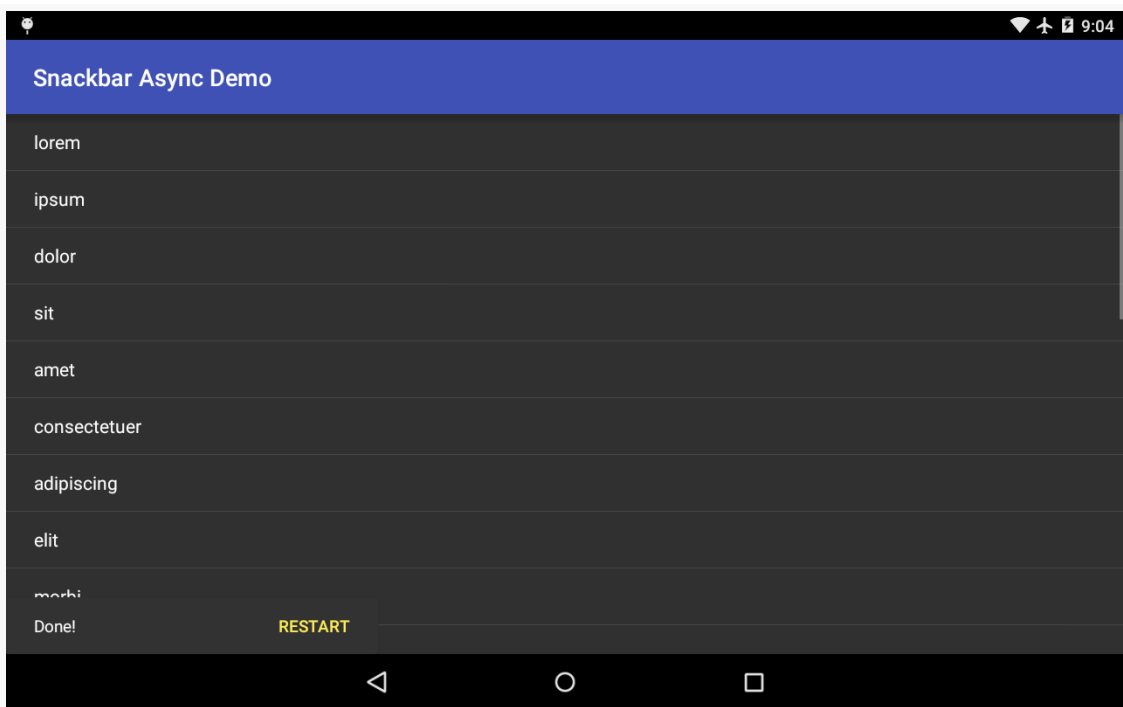

Figure 506: Official Snackbar, with an Action, on Nexus 7

Tapping the action triggers the listener, which in our case clears the list and starts the load all over again.

CWAC-CrossPort

CWAC-CrossPort supports Snackbar, with all the same features as are in the original Design Support implementation. The [DesignSupport/SnackbarActionCP](#) sample project is a clone of the previous sample, where we have migrated to CWAC-CrossPort.

Our app/build.gradle file not only adds the CWAC-CrossPort dependency, but it sets the minSdkVersion to 21:

```
apply plugin: 'com.android.application'

repositories {
    maven {
        url "https://s3.amazonaws.com/repo.commonsware.com"
    }
}
```

THE ANDROID DESIGN SUPPORT LIBRARY

```
dependencies {
    implementation 'com.commonware.cwac:crossport:0.2.0'
}

android {
    compileSdkVersion 26
    buildToolsVersion '26.0.2'

    defaultConfig {
        minSdkVersion 21
        targetSdkVersion 26
        applicationId 'com.commonware.android.snackbar.action.crossport'
    }
}
```

(from [DesignSupport/SnackbarActionCP/app/build.gradle](#))

Removing appcompat-v7 has rippling effects across the rest of the code:

- We switch to inheriting from `Theme.Material.Light.DarkActionBar` in `Theme.Apptheme`, replacing the former `Theme.AppCompat` theme
- We change the theme colors to use the `android:` prefix (e.g., `android:colorPrimary`), instead of the bare names used by `appcompat-v7`
- Our activity now just inherits from `Activity`, instead of `AppCompatActivity`
- Our fragment now just inherits from `android.app.Fragment`, instead of `android.support.v4.app.Fragment`
- Our `Snackbar` import is now for `com.commonware.cwac.crossport.design.widget.Snackbar`

Otherwise, the code is identical, and we get identical results, though with an inverse them and adjusted title bar, to help distinguish the original from the CWAC-CrossPort edition:

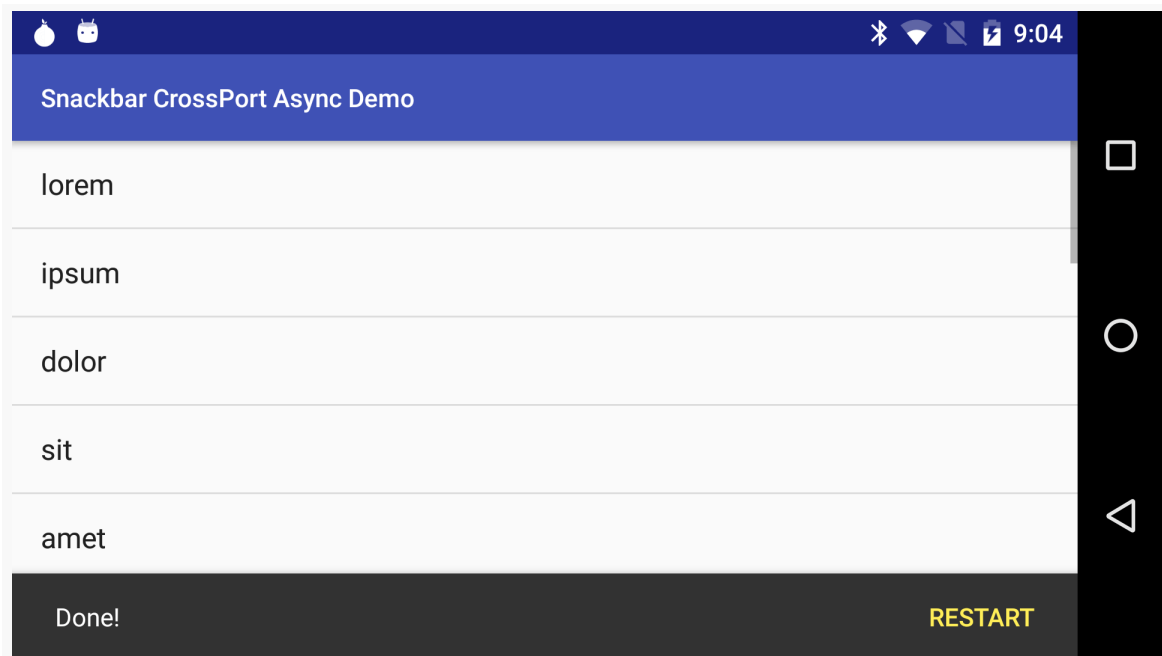

Figure 507: CWAC-CrossPort Snackbar

Absolutely FABulous

Perhaps no single element of the Material Design aesthetic has gotten more attention than has the floating action button, or FAB. These are round buttons, usually floating towards the bottom of the screen over top of the main UI:

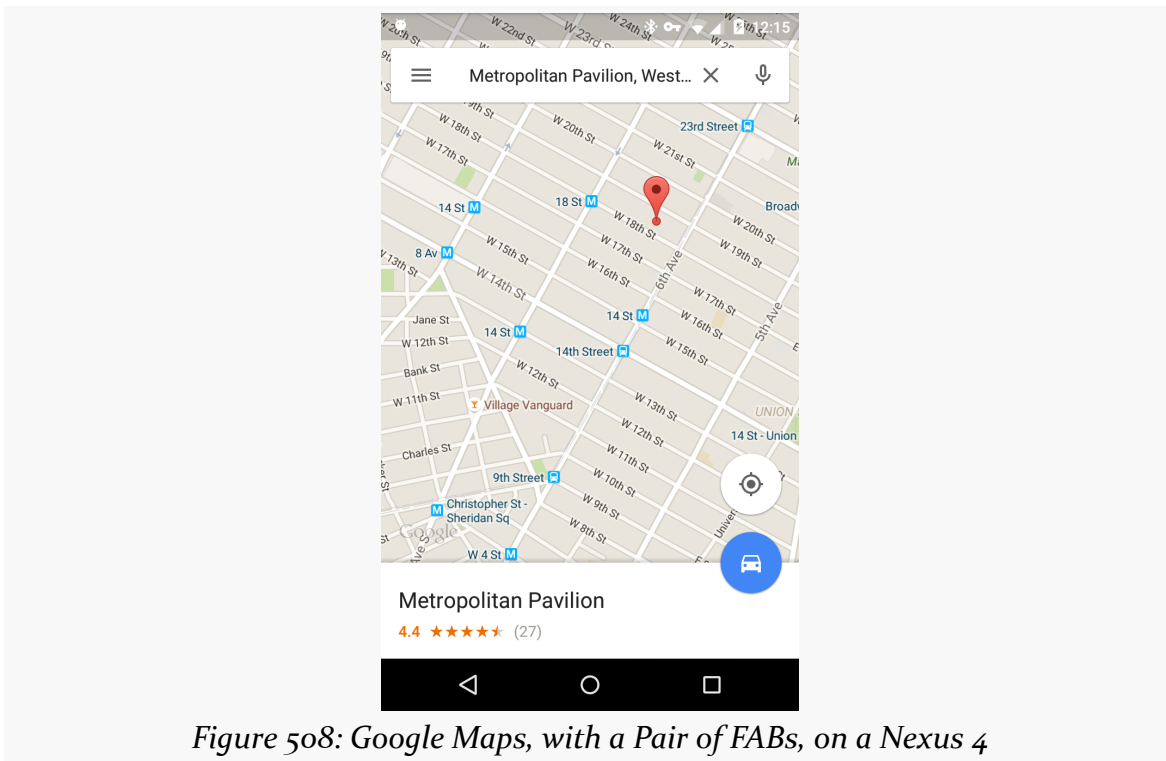

Figure 508: Google Maps, with a Pair of FABs, on a Nexus 4

The job of the FAB is to provide rapid access to the primary action that users might take on that particular screen. Typically, in a master/detail sort of UI, the FAB will allow creating a new item for the collection:

- A voice recording app showing a list of previous recordings might have a FAB to make a new recording
- A blood pressure monitoring app showing a list of previous readings might have a FAB to take a new reading
- A to-do list app showing the current tasks might have a FAB to add a new task

However, the FAB does not have to be an “add” operation. The only real limitation is that it should be a screen-level operation, not affecting only some selected item on that screen. So, for example, in the video recording app example, you would not use a FAB to play back one of the existing videos... at least on a screen listing those videos. If tapping a video in that list brings up some sort of detail screen, *that* screen could possibly have a FAB to play back the video.

The Design Support library has a rudimentary FAB implementation, and there are third-party alternatives that either add power or solve other FAB-related problems.

FAB Mechanics

In many respects, setting up a FAB is not that different from setting up any other widget: put it in your layout, positioned where you want it, then access it in Java code to set up listeners. In particular, Google's FAB implementation supports a `View.OnClickListener` much like a regular `Button`.

The [DesignSupport/FAB](#) sample project is a clone of the first `Snackbar` sample from earlier in this chapter. The second `Snackbar` sample added a “restart” action to the `Snackbar`. In this sample, we instead have a “restart” action on a FAB.

Before, we did not need a layout resource for the `AsyncDemoFragment`, as it was an ordinary `ListFragment` and therefore would supply a `ListView` automatically. However, this time, we want to have a FAB as well, so we need our own layout file:

```
<?xml version="1.0" encoding="utf-8"?>
<RelativeLayout
    xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent">

    <ListView
        android:id="@android:id/list"
        android:layout_width="match_parent"
        android:layout_height="match_parent"
        android:drawSelectorOnTop="false"
        />

    <android.support.design.widget.FloatingActionButton
        android:id="@+id/refresh"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:src="@drawable/ic_refresh_black_24dp"
        android:layout_marginRight="@dimen/fab_margin"
        android:layout_marginBottom="@dimen/fab_margin"
        android:layout_alignParentBottom="true"
        android:layout_alignParentRight="true"/>

</RelativeLayout>
```

(from [DesignSupport/FAB/app/src/main/res/layout/main.xml](#))

Here, the FAB (a.k.a., `android.support.design.widget.FloatingActionButton`) is later in a `RelativeLayout` than is the `ListView`, so the FAB will have higher elevation

THE ANDROID DESIGN SUPPORT LIBRARY

and will appear to float over the `ListView`. The `android:src` attribute points to a drawable resource, much like how that attribute works on an `ImageButton`.

However, the interesting bit is the pair of margin attributes (`android:layout_marginRight` and `android:layout_marginBottom`). They point to a `fab_margin` dimension resource, one with some specific values required due to bugs (or curious implementation choices) in Google's FAB implementation.

By default, the `fab_margin` in `res/values/dimens.xml` is used, which has a dimension of `0dp`:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
  <dimen name="fab_margin">0dp</dimen>
</resources>
```

(from [DesignSupport/FAB/app/src/main/res/values/dimens.xml](#))

You might think that this would cause the FAB to be slammed up against the side and bottom of the `RelativeLayout`. However, the FAB has built-in margins... on older devices.

But, for whatever reason, on API Level 21+, that automatic margin vanishes. So, we have another definition of `fab_margin`, in `res/values-v21/dimens.xml`, setting it to `16dp`:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
  <dimen name="fab_margin">16dp</dimen>
</resources>
```

(from [DesignSupport/FAB/app/src/main/res/values-v21/dimens.xml](#))

Furthermore, Google's Material Design docs state that there should be `24dp` margin on tablets, not `16dp`. So, we have a *third* definition of `fab_margin`, in `res/values-sw720dp-v21`, to set the margin to `24dp`:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
  <dimen name="fab_margin">24dp</dimen>
</resources>
```

(from [DesignSupport/FAB/app/src/main/res/values-sw720dp-v21/dimens.xml](#))

THE ANDROID DESIGN SUPPORT LIBRARY

It is possible that a full implementation of this would need a fourth `fab_margin` value, for Android 4.x tablets, where `fab_margin` would be set to something that gives a 24dp margin but takes into account the automatic margin that the FAB seems to have prior to API Level 21. This sample avoids this, going with the automatic margin on all tablets, regardless of API level.

The Java code is fairly straightforward, retrieving the FAB in `onViewCreated()` and hooking up a `View.OnClickListener` to the FAB, where that listener is the `AsyncDemoFragment` itself:

```
@Override
public void onViewCreated(View v, Bundle savedInstanceState) {
    super.onViewCreated(v, savedInstanceState);

    getListView().setScrollbarFadingEnabled(false);
    setListAdapter(adapter);

    FloatingActionButton fab=(FloatingActionButton)v.findViewById(R.id.refresh);

    fab.setOnClickListener(this);
}
```

(from [DesignSupport/FAB/app/src/main/java/com/commonsware/android/fab/async/AsyncDemoFragment.java](#))

In `onClick()`, if the `AsyncTask` is still running, we `cancel()` it. Then, we clear the list and kick off a fresh task via the same sort of `loadModel()` method as seen in the second `Snackbar` example:

```
@Override
public void onClick(View view) {
    if (task!=null) {
        task.cancel(false);
    }

    adapter.clear();
    loadModel();
}

void loadModel() {
    task=new AddStringTask();
    task.execute();
}
```

(from [DesignSupport/FAB/app/src/main/java/com/commonsware/android/fab/async/AsyncDemoFragment.java](#))

This gives us our FAB on Android 4.x devices:

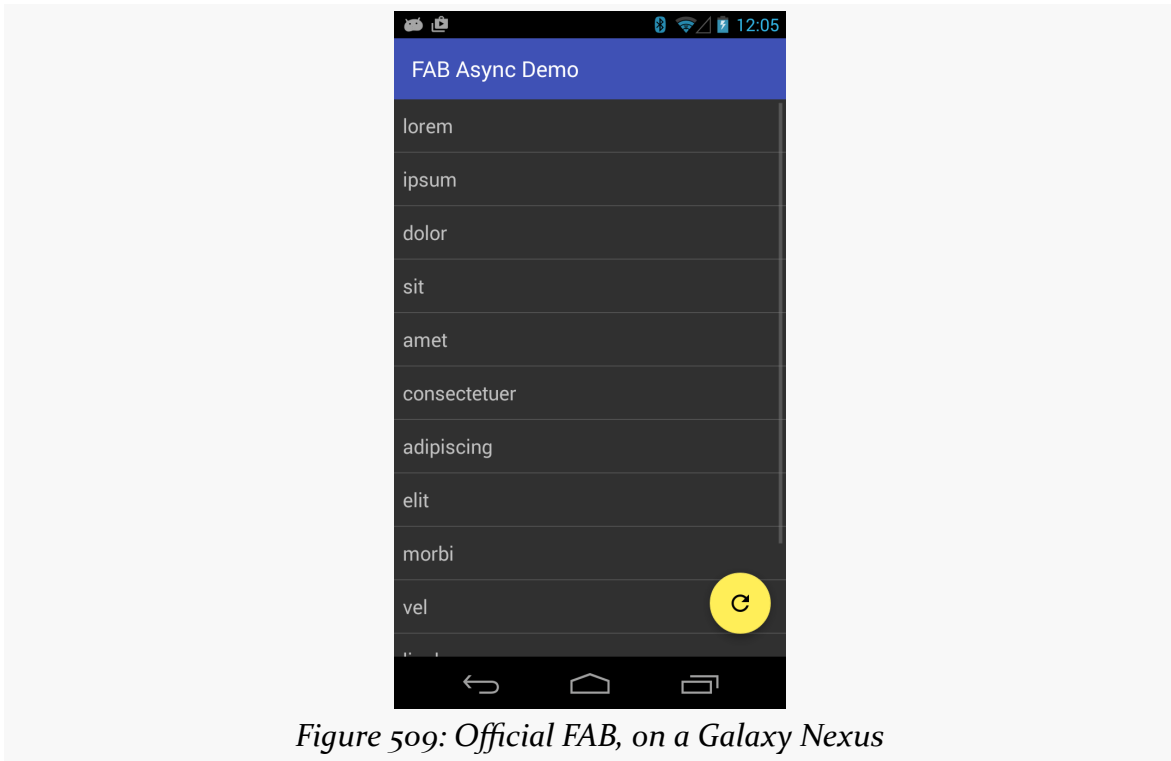

Figure 509: Official FAB, on a Galaxy Nexus

...on Android 5.x phones:

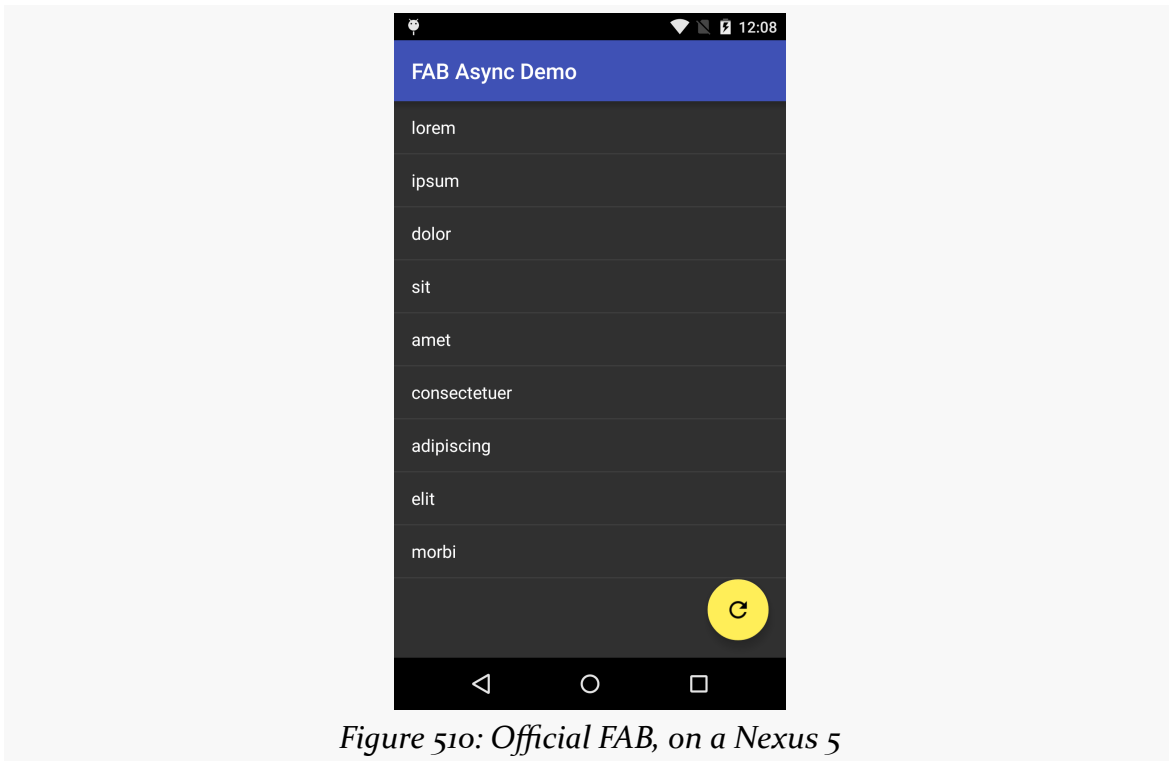

Figure 510: Official FAB, on a Nexus 5

...and on Android 5.x tablets:

Coordinating with Snackbars

However, what the above screenshots do *not* illustrate is what happens when our Snackbar appears:

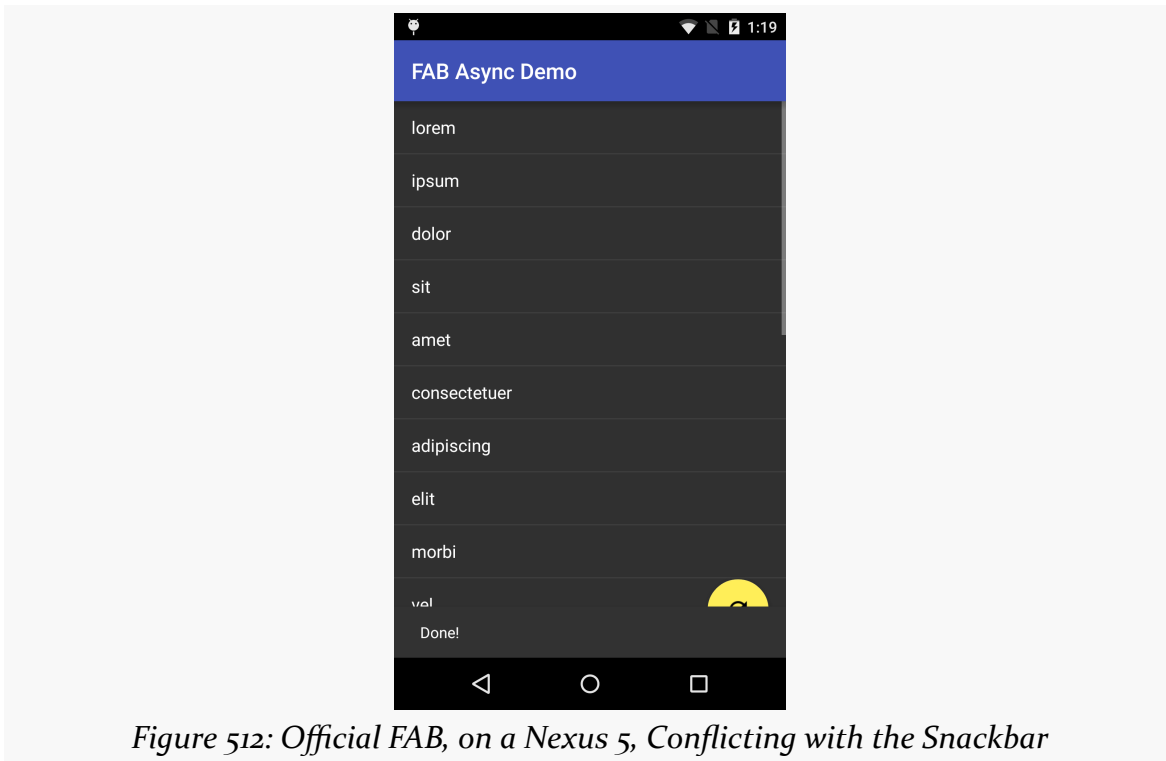

Figure 512: Official FAB, on a Nexus 5, Conflicting with the Snackbar

The fact that the Snackbar overlaps the FAB should not be much of a surprise. After all, the Snackbar overlaps the ListView as well. A Toast would also overlap the list and FAB. Hence, to some extent, the fact that there is this lack of coordination between the Snackbar and the FAB seems to be fairly normal.

That being said, the Design Support library has a container designed for coordinating between different children as those children animate and scroll. This container — `CoordinatorLayout` — is a subclass of `FrameLayout`, meaning other than Z-axis ordering (elevation) and gravity, it has no other notable layout rules. It merely exists to perform this sort of coordination.

As it turns out, `CoordinatorLayout` has special awareness of Snackbar and the FAB, so simply using `CoordinatorLayout` will cause the FAB to slide upwards to make room for the Snackbar.

The [DesignSupport/CoordinatedFAB](#) sample project is a clone of the previous FAB example, except that we switch from a `RelativeLayout` root container to a `CoordinatorLayout`:

THE ANDROID DESIGN SUPPORT LIBRARY

```
<?xml version="1.0" encoding="utf-8"?>
<android.support.design.widget.CoordinatorLayout
    xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent">

    <ListView
        android:id="@android:id/list"
        android:layout_width="match_parent"
        android:layout_height="match_parent"
        android:drawSelectorOnTop="false"
        />

    <android.support.design.widget.FloatingActionButton
        android:id="@+id/refresh"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:layout_gravity="bottom|right"
        android:layout_marginBottom="@dimen/fab_margin"
        android:layout_marginRight="@dimen/fab_margin"
        android:src="@drawable/ic_refresh_black_24dp"/>

</android.support.design.widget.CoordinatorLayout>
```

(from [DesignSupport/CoordinatedFAB/app/src/main/res/layout/main.xml](#))

Since `CoordinatorLayout` is based on `FrameLayout`, not `RelativeLayout`, we have to adjust the layout rules on the FAB to match, using `android:layout_gravity` to position the FAB towards the bottom right corner.

With no other changes, we now get coordinated movements of the FAB and the Snackbar as the Snackbar appears and disappears:

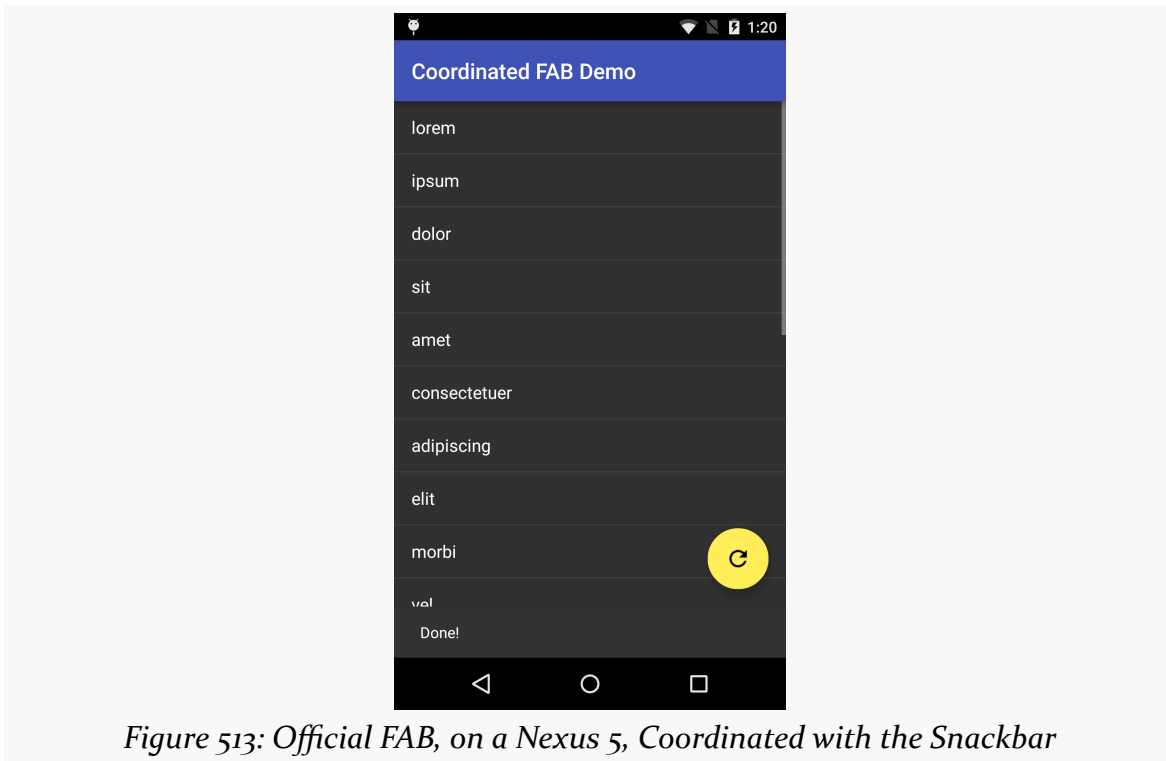

Figure 513: Official FAB, on a Nexus 5, Coordinated with the Snackbar

CWAC-CrossPort

CWAC-CrossPort also has ports of `FloatingActionButton` and `CoordinatorLayout`, as can be seen in the [DesignSupport/CoordinatedFABCP](#) sample project.

In addition to the sorts of changes needed before (e.g., replace `appcompat-v7` with `crossport`, change imports, change the theme), our layout now uses `crossport` classes:

```
<?xml version="1.0" encoding="utf-8"?>
<com.commonware.cwac.crossport.design.widget.CoordinatorLayout
  xmlns:android="http://schemas.android.com/apk/res/android"
  android:layout_width="match_parent"
  android:layout_height="match_parent">

  <ListView
    android:id="@android:id/list"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:drawSelectorOnTop="false"
  />
```

```
<com.commonsware.cwac.crossport.design.widget.FloatingActionButton
    android:id="@+id/refresh"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:layout_gravity="bottom|right"
    android:layout_marginBottom="@dimen/fab_margin"
    android:layout_marginRight="@dimen/fab_margin"
    android:src="@drawable/ic_refresh_black_24dp"/>

</com.commonsware.cwac.crossport.design.widget.CoordinatorLayout>
```

(from [DesignSupport/CoordinatedFABCP/app/src/main/res/layout/main.xml](#))

And, as before, we get the same results as with the official implements, just without the appcompat-v7 overhead:

Third-Party FABs... and FAMs

The Design Support implementation of a FAB works, and it works nicely “out of the box” with CoordinatorLayout. However, it implements only a subset of the Material Design FAB capabilities, let alone related structures like the floating action menu (FAM).

As a result, there are [many FAB projects listed on the Android Arsenal](#), offering other implementations of a FAB. The author of this book uses [the Clans FAB implementation](#), in part because it offers support for the FAM pattern as well:

Figure 515: CWAC-Cam2 CameraActivity, Showing Clans FAB and FAM

Figure 516: CWAC-Cam2 CameraActivity, Showing Clans FAB and FAM, with FAM Open

The [DesignSupport/FABClans](#) sample project is a clone of the original FAB sample shown above, where the Clans FAB implementation is used, along with a FAM.

The layout now switches to show the FAB, the FAM, and a smaller FAB that appears when the FAM is opened:

```
<?xml version="1.0" encoding="utf-8"?>
<RelativeLayout
    xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:fab="http://schemas.android.com/apk/res-auto"
    android:layout_width="match_parent"
    android:layout_height="match_parent">

    <ListView
        android:id="@android:id/list"
        android:layout_width="match_parent"
        android:layout_height="match_parent"
        android:drawSelectorOnTop="false"
        />

    <com.github.clans.fab.FloatingActionButton
        android:id="@+id/refresh"
        android:layout_width="wrap_content"
```

```
        android:layout_height="wrap_content"
        android:src="@drawable/ic_refresh_black_24dp"
        android:layout_marginBottom="@dimen/fab_margin"
        android:layout_marginRight="@dimen/fab_margin"
        android:layout_alignParentBottom="true"
        android:layout_alignParentRight="true"/>

<com.github.clans.fab.FloatingActionMenu
    android:id="@+id/settings"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:layout_above="@id/refresh"
    android:layout_alignRight="@id/refresh"
    android:layout_marginBottom="@dimen/fam_bottom_margin"
    fab:menu_colorNormal="@color/fam"
    fab:menu_colorPressed="@color/fam_pressed"
    fab:menu_icon="@drawable/ic_action_settings">

    <com.github.clans.fab.FloatingActionButton
        android:id="@+id/settings_item"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:src="@drawable/ic_switch_camera"
        fab:fab_colorNormal="@color/fam"
        fab:fab_colorPressed="@color/fam_pressed"
        fab:fab_size="mini"/>

</com.github.clans.fab.FloatingActionMenu>

</RelativeLayout>
```

(from [DesignSupport/FABClans/app/src/main/res/layout/main.xml](#))

In terms of the primary FAB, the element is largely the same, other than changing the class to be `com.github.clans.fab.FloatingActionButton`.

Below that in the layout XML is a `com.github.clans.fab.FloatingActionMenu`. This is a FAB that knows how to show and hide a menu of secondary FABs when clicked. In this case, we set it to appear above the FAB with 4dp of margin between them. In addition, we set the colors for the normal and pressed states, pointing to a pair of color resources:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
    <color name="primary">#3f51b5</color>
    <color name="primary_dark">#1a237e</color>
    <color name="accent">#ffee58</color>
```

```
<color name="fam">#fafafa</color>
<color name="fam_pressed">#f1f1f1</color>
</resources>
```

(from [DesignSupport/FABClans/app/src/main/res/values/colors.xml](#))

Also, for whatever reason, the icon for the FAM is not handled via the `android:src` attribute used for the FAB, but instead via a `fab:menu_icon` attribute.

The children of the FAM are supposed to be FABs that will appear and disappear as the FAM is clicked on. For this, we use `fab:fab_size="mini"` for the smaller FAB, in addition to tailoring the color.

In `onViewCreated()`, we get our hands on the main FAB and set up the `View.OnClickListener`, just as we did with the Design Support edition of the FAB. However, we also retrieve the FAM and call a `changeMenuIconAnimation()` method:

```
@Override
public void onViewCreated(View v, Bundle savedInstanceState) {
    super.onViewCreated(v, savedInstanceState);

    getListView().setScrollbarFadingEnabled(false);
    setListAdapter(adapter);

    FloatingActionButton fab=(FloatingActionButton)v.findViewById(R.id.refresh);

    fab.setOnClickListener(this);

    changeMenuIconAnimation((FloatingActionMenu)v.findViewById(R.id.settings));
}
```

(from [DesignSupport/FABClans/app/src/main/java/com/commonsware/android/fab/clans/AsyncDemoFragment.java](#))

The recommended visual effect when tapping on a FAM is not only to show the menu, but also to change the icon to a close icon, to indicate that tapping the FAM again will close the menu. Unfortunately, the Clans FAM implementation does not do this automatically. The `changeMenuIconAnimation()` method sets it up, using a combination of the Android SDK animator framework and hooks provided by the FAM for the `AnimatorSet` to be invoked when the user toggles the FAM between open and closed:

```
// based on https://goo.gl/3IUM8K

private void changeMenuIconAnimation(final FloatingActionMenu menu) {
    AnimatorSet set=new AnimatorSet();
    final ImageView v=menu.getMenuIconView();
    ObjectAnimator scaleOutX=ObjectAnimator.ofFloat(v, "scaleX", 1.0f, 0.2f);
    ObjectAnimator scaleOutY=ObjectAnimator.ofFloat(v, "scaleY", 1.0f, 0.2f);
```

THE ANDROID DESIGN SUPPORT LIBRARY

```
ObjectAnimator scaleX=ObjectAnimator.ofFloat(v, "scaleX", 0.2f, 1.0f);
ObjectAnimator scaleY=ObjectAnimator.ofFloat(v, "scaleY", 0.2f, 1.0f);

scaleOutX.setDuration(50);
scaleOutY.setDuration(50);

scaleInX.setDuration(150);
scaleInY.setDuration(150);
scaleInX.addListener(new AnimatorListenerAdapter() {
    @Override
    public void onAnimationStart(Animator animation) {
        v.setImageResource(menu.isOpened()
            ? R.drawable.ic_action_settings
            : R.drawable.ic_close);
    }
});

set.play(scaleOutX).with(scaleOutY);
set.play(scaleInX).with(scaleInY).after(scaleOutX);
set.setInterpolator(new OvershootInterpolator(2));
menu.setIconToggleAnimatorSet(set);
}
```

(from [DesignSupport/FABClans/app/src/main/java/com/commonsware/android/fab/clans/AsyncDemoFragment.java](https://github.com/CommonsWare/android-fab-clans/blob/master/AsyncDemoFragment.java))

Here, we:

- Create an AnimatorSet
- Create four ObjectAnimator instances, for scaling the size of something on both axes, for both scaling out (shrinking) and scaling in (growing)
- Configure the durations of each of those scale animator instances
- Add a listener to one animator to toggle the drawable used for the icon when the animation begins
- Configure the animator set to scale the old drawable out, then switch to the new icon and scale that drawable in, with an OvershootInterpolator for a bit of a “bounce” effect
- Tell the FAM to use that AnimatorSet each time the user taps the FAM

In principle, we should also be setting up a View.OnClickListener on the mini FAB that is inside the menu, as usually the point behind having a FAM is to respond to taps on those menu items. This is skipped in this sample in the interests of simplicity.

The resulting UI shows the FAB and the FAM, much like those from the CWAC-Cam2 library shown earlier in this section:

Figure 517: FABClans Sample, Showing Clans FAB and FAM

Figure 518: FABClans Sample, Showing Clans FAB and FAM, with FAM Open

Third-Party FAB Add-Ons

In addition to complete FAB and FAM implementations, developers have been publishing libraries that add on other Material Design features to existing FAB implementations, such as:

- Wrapping [a progress bar around a FAB](#), perhaps to show the progress of some work triggered by a previous click on the FAB
- Using a [“material sheet”](#) or a [“floating action toolbar”](#) as an alternative to the FAM pattern

As usual, the Android Arsenal has [a category devoted to FABs](#) that is worth checking out.

Material Tabs with TabLayout

Android has had a myriad of tab implementations over the years:

- TabHost and TabWidget
- FragmentTabHost and TabWidget
- the now-deprecated action bar tabs
- PagerTabStrip, used in conjunction with a ViewPager

The Design Support library adds yet another tab implementation: TabLayout. Specifically, this implementation’s claim to fame is a faithful implementation of a subset of Google’s Material Design guidelines for how tabs should look and behave.

TabLayout can be used with or without a ViewPager. If you elect to skip the ViewPager, TabLayout works in a form reminiscent of action bar tabs, where it is responsible for the tab UI and you are responsible for updating the rest of your UI based upon the chosen tab (e.g., commit a FragmentTransaction). If you elect to use a ViewPager, TabLayout can lightly integrate with the ViewPager, so navigating by one means (e.g., swiping the pager) updates the other UI (e.g., changing the selected tab).

From a layout standpoint, you use TabLayout much like you would use TabWidget: put it where the tabs should go. Since Material Design wants the tabs on top, that means that typically you would put TabLayout inside a vertical LinearLayout, with the actual tabbed content beneath the TabLayout.

THE ANDROID DESIGN SUPPORT LIBRARY

This is illustrated in the [DesignSupport/TabLayout](#) sample project. It is based on the original ViewPager samples, showing a set of editors in pages, this time using a TabLayout as the tab implementation (as opposed to PagerTabStrip or the TabPagerIndicator from the ViewPagerIndicator library).

The layout loaded by the activity has a setup much as described above: a vertical LinearLayout wrapped around a TabLayout and our ViewPager:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:orientation="vertical">

    <android.support.design.widget.TabLayout
        android:id="@+id/tabs"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"/>

    <android.support.v4.view.ViewPager
        android:id="@+id/pager"
        android:layout_width="match_parent"
        android:layout_height="match_parent">
    </android.support.v4.view.ViewPager>
</LinearLayout>
```

(from [DesignSupport/TabLayout/app/src/main/res/layout/main.xml](#))

TabLayout can have its tabs operate in one of two modes: fixed and scrollable. With fixed tabs, all tabs will be on the screen at all times, where they divide the available horizontal space between them. This works fine for just a few tabs. But for lots of tabs, each tab becomes very small, making it unlikely that the user can read the tab caption. Scrollable tabs each take up as much room as their caption requires, and if the roster of tabs becomes too wide for the screen, the user can swipe the tabs.

The sample app demonstrates both of these approaches, using a checkable action bar item to toggle between three editors with fixed tabs or ten editors with scrollable tabs. The default state is to be in fixed-tab mode:

```
<?xml version="1.0" encoding="utf-8"?>
<menu xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:app="http://schemas.android.com/apk/res-auto">
    <item
        android:id="@+id/fixed"
        android:title="@string/menu_fixed"
```

THE ANDROID DESIGN SUPPORT LIBRARY

```
    android:checkable="true"
    android:checked="true"
    app:showAsAction="never"/>
</menu>
```

(from [DesignSupport/TabLayout/app/src/main/res/menu/actions.xml](#))

The entire app was switched over to use AppCompatActivity and the fragment backport, as that is what the Design Support library requires. Beyond that, the EditorFragment is pretty much unchanged from the original implementations, just showing a large EditText widget with a hint based on the page number.

Our PagerAdapter — SamplePagerAdapter — has one change beyond the switch to the fragment backport. To accommodate switching between fixed and scrollable tabs, rather than hard-coding the number of pages, the adapter offers a setPageCount() method to stipulate the number of pages. The page count defaults to 3.

```
package com.commonware.android.tablayout;

import android.content.Context;
import android.support.v4.app.Fragment;
import android.support.v4.app.FragmentManager;
import android.support.v4.app.FragmentPagerAdapter;

public class SampleAdapter extends FragmentPagerAdapter {
    private final Context ctxt;
    private int pageCount=3;

    public SampleAdapter(Context ctxt, FragmentManager mgr) {
        super(mgr);

        this.ctxt=ctxt;
    }

    @Override
    public int getCount() {
        return(pageCount);
    }

    @Override
    public Fragment getItem(int position) {
        return(EditorFragment.newInstance(position));
    }

    @Override
```

THE ANDROID DESIGN SUPPORT LIBRARY

```
public String getPageTitle(int position) {
    return(EditorFragment.getTitle(ctxt, position));
}

void setPageCount(int pageCount) {
    this.pageCount=pageCount;
}
}
```

(from [DesignSupport/TabLayout/app/src/main/java/com/commonsware/android/tablayout/SampleAdapter.java](#))

In MainActivity, in onCreate(), we set up the ViewPager and the TabLayout:

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.main);

    pager=(ViewPager)findViewById(R.id.pager);
    adapter=new SampleAdapter(this, getSupportFragmentManager());
    pager.setAdapter(adapter);

    tabs=(TabLayout)findViewById(R.id.tabs);
    tabs.setupWithViewPager(pager);
    tabs.setTabMode(TabLayout.MODE_FIXED);
}
```

(from [DesignSupport/TabLayout/app/src/main/java/com/commonsware/android/tablayout/MainActivity.java](#))

The bulk of the TabLayout setup work is handled with one call to `setupWithViewPager()`. This:

- Creates one tab for every page, based on whatever the PagerAdapter in the ViewPager is reporting at the time of this call
- Sets up the appropriate listeners, so that taps on a tab switches pages in the ViewPager, and swipes between pages update the selected tab

We also call `setTabMode(TabLayout.MODE_FIXED)`, as we are going with fixed tabs at the outset.

This gives us our three tabs:

Figure 519: TabLayout Sample, As Initially Launched, Showing Three Fixed Tabs

But we also have that menu resource, to allow the user to switch between fixed and scrollable tabs. We `inflate()` that resource in `onCreateOptionsMenu()` as usual, and we handle the checked state change in `onOptionsItemSelected()`:

```
@Override
public boolean onCreateOptionsMenu(Menu menu) {
    getMenuInflater().inflate(R.menu.actions, menu);

    return(super.onCreateOptionsMenu(menu));
}

@Override
public boolean onOptionsItemSelected(MenuItem item) {
    if (item.getItemId()==R.id.fixed) {
        item.setChecked(!item.isChecked());

        if (item.isChecked()) {
            adapter.setPageCount(3);
            tabs.setTabMode(TabLayout.MODE_FIXED);
        }
        else {
            adapter.setPageCount(10);
            tabs.setTabMode(TabLayout.MODE_SCROLLABLE);
        }
    }
}
```

```
    }

    adapter.notifyDataSetChanged();

    if (pager.getCurrentItem() >= 3) {
        pager.setCurrentItem(2);
    }

    return(true);
}

return(super.onOptionsItemSelected(item));
}
```

(from [DesignSupport/TabLayout/app/src/main/java/com/commonsware/android/tabl原因/MainActivity.java](https://github.com/androidx/androidx/blob/master/designsupport/src/main/java/com/commonsware/android/tabl原因/MainActivity.java))

If the user taps on our checkable overflow item, we invert the item’s checked state (which, unfortunately, does not happen automatically). Then, we call `setPageCount()` on the `SampleAdapter` and `setTabMode()` on the `TabLayout` based on the now-current checked state, to either have three fixed tabs or ten scrollable tabs.

Changing the page count of the `SampleAdapter` requires calling `notifyDataSetChanged()` to alert the `ViewPager` that the data set changed and it needs to repaint. However, while the associated `TabLayout` repaints, the selected page is left alone. That is fine when going from 3 pages to 10, but it could be a problem when going from 10 pages to 3, if the selected page is after those three. So, we use `setCurrentItem()` to manually move the selection to the last valid page, if that situation occurs.

Clicking on the “Fixed” checkable overflow item, and thereby unchecking it from its initial checked state, gives us ten scrollable tabs:

Figure 520: TabLayout Sample, Showing Scrollable Tabs

Note that while this particular sample app shows `TabLayout` working with a `ViewPager`, a `ViewPager` is not required to be able to use `TabLayout`. You can simply have the `TabLayout` plus your own system for whatever the tabs switch in your UI. Then, you can use methods like `addTab()` and `setOnTabSelectedListener()` to set up tabs and find out when the user taps on them, so you can adjust your UI to match the selected tab. That being said, many users may come to expect that they can horizontally swipe to move between pages of content, and so definitely consider using a `ViewPager` if practical.

CWAC-CrossPort

CWAC-CrossPort has a port of `TabLayout`. The [DesignSupport/TabLayoutCP](#) sample project is identical to the `DesignSupport/TabLayout` sample app, except that it uses CWAC-CrossPort. The same sorts of modifications as seen earlier in this chapter are required, such as changing the layout to refer to the appropriate package for the ported `TabLayout`:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
```

```
        android:layout_height="match_parent"
        android:orientation="vertical">

<com.commonsware.cwac.crossport.design.widget.TabLayout
    android:id="@+id/tabs"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"/>

<android.support.v4.view.ViewPager
    android:id="@+id/pager"
    android:layout_width="match_parent"
    android:layout_height="match_parent">
</android.support.v4.view.ViewPager>
</LinearLayout>
```

(from [DesignSupport/TabLayoutCP/app/src/main/res/layout/main.xml](#))

In this particular sample, since we are using menu resources, we have one additional change to make: switching from `app:showAsAction` to `android:showAsAction`, as we are using the native action bar:

```
<?xml version="1.0" encoding="utf-8"?>
<menu xmlns:android="http://schemas.android.com/apk/res/android"
      xmlns:app="http://schemas.android.com/apk/res-auto">
    <item
        android:id="@+id/fixed"
        android:title="@string/menu_fixed"
        android:checkable="true"
        android:checked="true"
        android:showAsAction="never"/>
</menu>
```

(from [DesignSupport/TabLayoutCP/app/src/main/res/menu/actions.xml](#))

Third-Party Material Tabs

There are [other implementations of Material Design-inspired tabs](#), including ones that do not have the `appcompat-v7` requirement.

One that seems to work fairly well is [Karim Frenn's MaterialTabs](#). Not only can it work with native fragments and the native action bar, but it also adds features that `TabLayout` lacks, like:

- Continuous synchronization with the `ViewPager` (though there is a bug related to that, which we will examine shortly)

THE ANDROID DESIGN SUPPORT LIBRARY

- More customization options, including custom fonts or even custom views for the tabs

On the other hand, `MaterialTabs` is limited to working with a `ViewPager`. It does not presently offer an API for adding tabs manually and responding to tab selection.

The [DesignSupport/TabLayoutPizza](#) sample project is so named because Mr. Frenn's GitHub account is named pizza. This project is a clone of the `TabLayout` sample, but it substitutes in `MaterialTabs` as the tab implementation.

In the app/ module's `build.gradle` file, we replace the `com.android.support:design` dependency with one for `MaterialTabs` and one for `com.android.support:support-v13`. The latter is so we can use native fragments for our pages in the `ViewPager`; `MaterialTabs` itself depends upon `support-v4`.

```
apply plugin: 'com.android.application'

dependencies {
    implementation 'io.karim:materialtabs:2.0.2'
    implementation 'com.android.support:support-v13:22.2.1'
}

android {
    compileSdkVersion 22
    buildToolsVersion '26.0.2'

    defaultConfig {
        minSdkVersion 15
        targetSdkVersion 18
    }
}
```

(from [DesignSupport/TabLayoutPizza/app/build.gradle](#))

`EditorFragment` and `SampleAdapter` are unchanged from the previous sample, except that they now use native fragments rather than the fragments backport.

The layout for `MainActivity` (`main.xml`) now has a `io.karim.MaterialTabs` widget instead of a `TabLayout`:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:app="http://schemas.android.com/apk/res-auto"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
```

```
        android:orientation="vertical">

<io.karim.MaterialTabs
    android:id="@+id/tabs"
    android:layout_width="match_parent"
    android:layout_height="48dp"
    app:mtIndicatorColor="@color/accent"
    app:mtSameWeightTabs="true"/>

<android.support.v4.view.ViewPager
    android:id="@+id/pager"
    android:layout_width="match_parent"
    android:layout_height="match_parent">
</android.support.v4.view.ViewPager>
</LinearLayout>
```

(from [DesignSupport/TabLayoutPizza/app/src/main/res/layout/main.xml](#))

`MaterialTabs` has a lot of custom attributes that you can set. Here, we use two:

1. `app:mtIndicatorColor` provides the color to use for the bar that indicates the selected tab.
2. `app:mtSameWeightTabs` says that if all tabs can fit on the screen, give them all the same weight, to provide the same sort of look as we get with the fixed mode with `TabLayout`. Note that `MaterialTabs` does not require manually switching modes, as it automatically switches into a scrollable mode when the number of tabs exceeds the available space.

Setting up `MaterialTabs` is then just a matter of calling `setViewPager()` on the `MaterialTabs` object to connect the tabs to the pager:

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.main);

    pager=(ViewPager)findViewById(R.id.pager);
    adapter=new SampleAdapter(this, getFragmentManager());
    pager.setAdapter(adapter);

    MaterialTabs tabs=(MaterialTabs)findViewById(R.id.tabs);
    tabs.setViewPager(pager);
}
```

(from [DesignSupport/TabLayoutPizza/app/src/main/java/com/commonsware/android/tablayout/pizza/MainActivity.java](#))

THE ANDROID DESIGN SUPPORT LIBRARY

Since `MaterialTabs` *does* pay attention to when the `PagerAdapter` is called with `notifyDataSetChanged()`, ideally switching between “fixed” and “scrollable” would just be a matter of setting the number of pages (via `setPageCount()`) and calling `notifyDataSetChanged()`. Unfortunately, `MaterialTabs` 2.0.2 has [a bug when you reduce the number of pages](#), and the workaround gets a bit tricky:

```
@Override
public boolean onOptionsItemSelected(MenuItem item) {
    if (item.getItemId()==R.id.fixed) {
        item.setChecked(!item.isChecked());

        if (item.isChecked()) {
            if (pager.getCurrentItem()>2) {
                pager.setCurrentItem(2);
            }

            pager.postDelayed(new Runnable() {
                @Override
                public void run() {
                    adapter.setPageCount(3);
                    adapter.notifyDataSetChanged();
                }
            }, 100);
        }
        else {
            adapter.setPageCount(10);
            adapter.notifyDataSetChanged();
        }

        return(true);
    }

    return(super.onOptionsItemSelected(item));
}
```

(from [DesignSupport/TabLayoutPizza/app/src/main/java/com/commonsware/android/tablayout/pizza/MainActivity.java](#))

`TabLayout`, when you call `setTabsFromViewPager()`, always resets your current tab to the first tab. This sucks, as the user loses her place when we add pages (or remove pages but the selected tab still exists), but at least it is reliable.

`MaterialTabs`, on the other hand, crashes if the selected tab no longer exists due to a reduction in page count. To work around this, we have to manually set the current tab to a safe tab by calling `setCurrentItem()` on the `ViewPager`, before we try changing the page count. Worse, we have to postpone the actual page count change

until after `setCurrentItem()` affects the `ViewPager` and the `MaterialTabs` objects. Hopefully, in the future, the `postDelayed()` call will no longer be needed here.

Visually, the results are pretty much the same as you get with `TabLayout`, just with the native action bar and fragments:

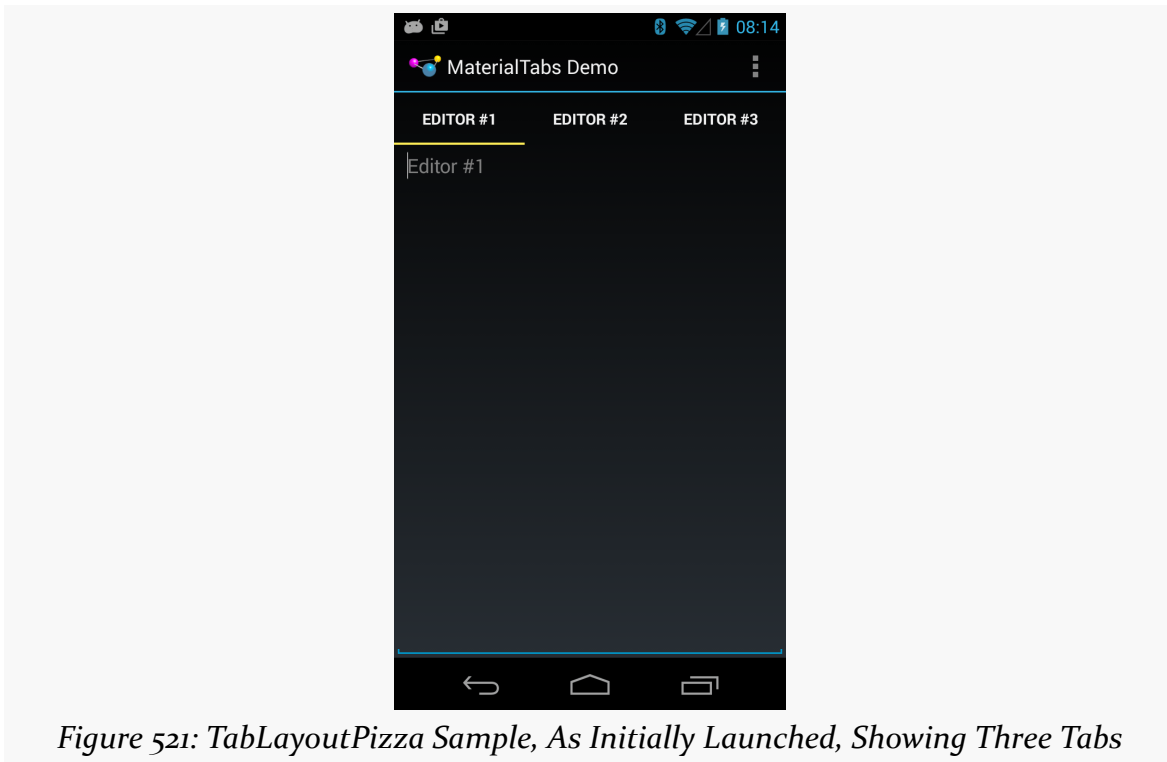

Figure 521: TabLayoutPizza Sample, As Initially Launched, Showing Three Tabs

Figure 522: TabLayoutPizza Sample, As Initially Launched, Showing Ten Tabs

Floating Labels

The `EditText` widget supports the `android:hint` attribute. The hint is shown in the `EditText` when the `EditText` is otherwise empty. However, if the `EditText` has actual text in it (whether typed by the user, loaded from a database, or whatever), the hint is not shown. This saves screen space compared to having a `TextView` label always visible; the hint itself serves as the label.

However, the hint-as-label pattern has a major drawback: the hint is not visible if there is text in the `EditText`. In the long term, as the user learns your UI, this is not a big problem. However, particularly early on, the user might look at a filled-in field and wonder what that field is for. This is even more likely in cases where the user is not the one who typed the text into the field in the first place, such as editing a database entry pulled from a server, where somebody (or something) else had created the entry in the first place.

The “floating label” pattern starts with a hint in the field. However, when the field is used, the hint animates out of the field itself and “floats” above the field in a shrunken form. This way, the label is always visible. However, in its smaller floating

state, it takes up less screen space, yet while the field is otherwise empty, we can take advantage of that space to offer a “full-size” label instead.

The Design Support library offers `TextInputLayout` as a way of implementing the floating label pattern. This is not a subclass of `EditText`, but rather a `ViewGroup` that is wrapped around the `EditText`. This is convenient, insofar as it allows developers to use other `EditText` subclasses and still get the floating-label behavior.

`TextInputLayout` also supports an error state, where we can optionally show an error message below the `EditText`, such as an indication of an invalid bit of data entry.

Using `TextInputLayout`

The [DesignSupport/FloatingLabel](#) sample project is a clone of [an earlier sample](#) where we allowed the user to enter in a URL and then, upon a button click, would parse the URL into a `Uri`, wrap that in an `ACTION_VIEW` Intent, then try to start an activity for that Intent.

The original sample’s layout looks like:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:orientation="vertical">

    <EditText
        android:id="@+id/url"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:hint="@string/url"
        android:inputType="textUri"/>

    <Button
        android:id="@+id/browse"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:onClick="showMe"
        android:text="@string/show_me"/>

</LinearLayout>
```

(from [Activities/LaunchWeb/app/src/main/res/layout/main.xml](#))

In this revised sample, the original EditText is augmented with a TextInputLayout:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:orientation="vertical">

    <Button
        android:id="@+id/browse"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:onClick="showMe"
        android:text="@string/show_me">

        <requestFocus/>
    </Button>

    <android.support.design.widget.TextInputLayout
        android:id="@+id/til"
        android:layout_width="match_parent"
        android:layout_height="wrap_content">

        <EditText
            android:id="@+id/url"
            android:layout_width="match_parent"
            android:layout_height="wrap_content"
            android:hint="@string/url"
            android:inputType="textUri" />
    </android.support.design.widget.TextInputLayout>

</LinearLayout>
```

(from [DesignSupport/FloatingLabel/app/src/main/res/layout/main.xml](#))

You will notice that there are a few changes here:

- The EditText is wrapped by an `android.support.design.widget.TextInputLayout` container that provides the actual floating label itself
- The Button is moved ahead of the EditText, in terms of the top-down organization of our vertical LinearLayout
- The Button has a `<requestFocus/>` child element, indicating to Android that this widget should get the focus first

THE ANDROID DESIGN SUPPORT LIBRARY

Those latter two changes are due to one major limitation with `TextInputLayout`: the hint moves out of the `EditText` into the floating position when *either* there is text in the `EditText` *or* the `EditText` gains the focus. Strangely, simply putting the `Button` before the `EditText` is insufficient, as is simply adding `<requestFocus/>` on the `Button`. Both have to be implemented to cause the `TextInputLayout` to show the hint in its default location at the outset.

The Java code is also augmented a bit from the original sample, to take advantage of the error-reporting feature of `TextInputLayout`:

```
package com.commonware.android.design.til;

import android.content.Intent;
import android.net.Uri;
import android.os.Bundle;
import android.support.design.widget.TextInputLayout;
import android.support.v7.app.AppCompatActivity;
import android.util.Patterns;
import android.view.View;
import android.widget.EditText;

public class LaunchDemo extends AppCompatActivity {
    private TextInputLayout til;

    @Override
    public void onCreate(Bundle state) {
        super.onCreate(state);
        setContentView(R.layout.main);

        til=(TextInputLayout)findViewById(R.id.til);
        til.setErrorEnabled(true);
    }

    public void showMe(View v) {
        EditText urlField=(EditText)findViewById(R.id.url);
        String url=urlField.getText().toString();

        if (Patterns.WEB_URL.matcher(url).matches()) {
            startActivity(new Intent(Intent.ACTION_VIEW, Uri.parse(url)));
        }
        else {
            til.setError(getString(R.string.til_error));
        }
    }
}
```

(from [DesignSupport/FloatingLabel/app/src/main/java/com/commonsware/android/design/til/LaunchDemo.java](#))

The Patterns class in Android contains a series of stock regular expressions. One, WEB_URL, is designed to see if the URL that was entered looks like a Web URL. When the user taps the button, if the pattern matches what the user entered in the field, we go ahead and try to start the activity. If not, we show an error.

To show the error, we need to do two things:

1. Up front, we call `setErrorEnabled()`, to tell `TextInputLayout` to reserve some space for an error message
2. At the point where we want to show the error, we call `setError()` on the `TextInputLayout`

When we run the app, the `TextInputLayout` leaves the hint in the `EditText` itself, as the `EditText` is empty and does not have the focus:

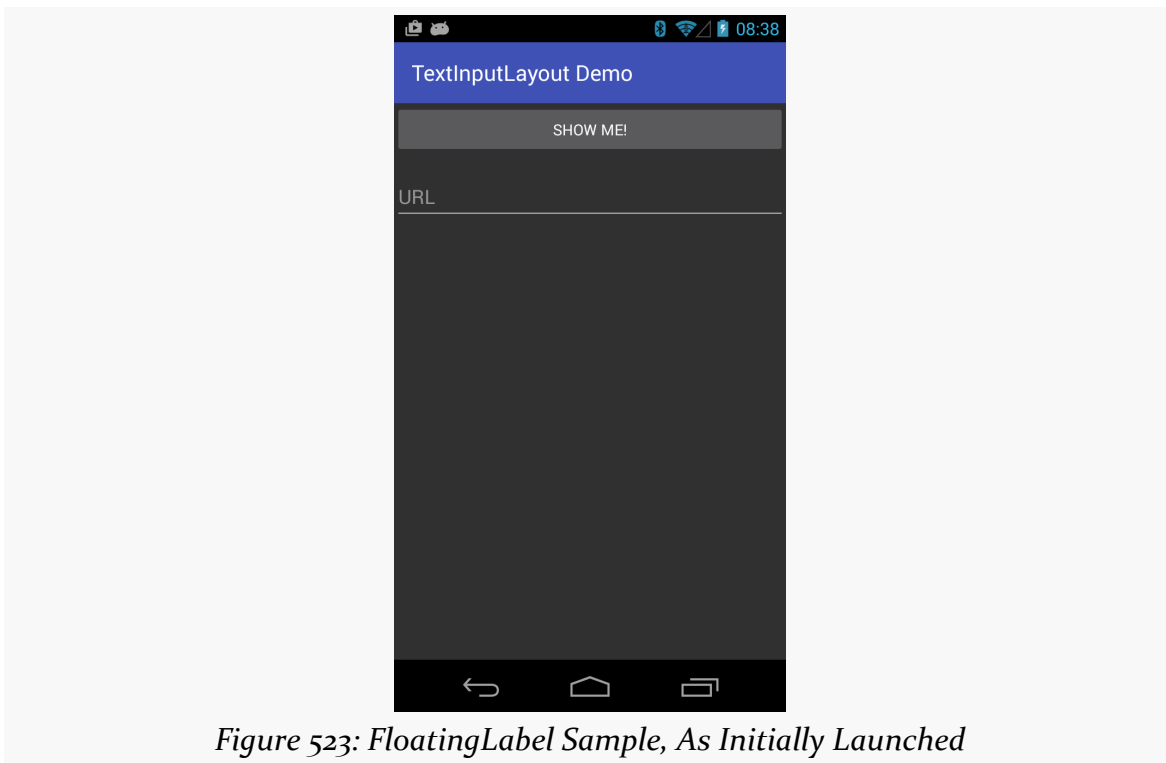

Figure 523: FloatingLabel Sample, As Initially Launched

Once the user taps on the field, though, the hint “floats” above the `EditText`:

Figure 524: FloatingLabel Sample, After Focus Change

And, if the user tries entering an invalid URL, the error message appears when the user taps the button to try to visit the invalid URL:

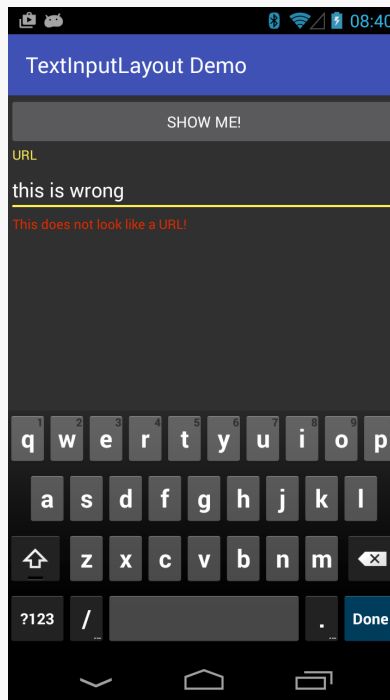

Figure 525: FloatingLabel Sample, After Erroneous Data Entry

CWAC-CrossPort

CWAC-CrossPort has a port of `TextInputLayout` and `TextInputEditText`, the latter being the `EditText` subclass that actually winds up being used with a `TextInputLayout`.

The [DesignSupport/FloatingLabelCP](#) sample project is a port of the `FloatingLabel` sample, converted to using CWAC-CrossPort. The standard sorts of changes seen earlier in this chapter, such as artifact dependencies and themes, are needed. In addition, the layout needs to change to use the CWAC-CrossPort editions of the classes:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:orientation="vertical">

    <Button
        android:id="@+id/browse"
        android:layout_width="match_parent"
```

```
        android:layout_height="wrap_content"
        android:onClick="showMe"
        android:text="@string/show_me">

        <requestFocus />
    </Button>

    <com.commonsware.cwac.crossport.design.widget.TextInputLayout
        android:id="@+id/til"
        android:layout_width="match_parent"
        android:layout_height="wrap_content">

        <com.commonsware.cwac.crossport.design.widget.TextInputEditText
            android:id="@+id/url"
            android:layout_width="match_parent"
            android:layout_height="wrap_content"
            android:hint="@string/url"
            android:inputType="textUri" />
    </com.commonsware.cwac.crossport.design.widget.TextInputLayout>
</LinearLayout>
```

(from [DesignSupport/FloatingLabelCP/app/src/main/res/layout/main.xml](#))

Third-Party Floating Labels

As with the rest of the Design Support library, `TextInputLayout` requires `appcompat-v7`. There are [other implementations of the floating label pattern](#) that do not require `appcompat-v7`, or perhaps offer additional features that you may want.

[FloatLabeledEditText](#) is one such implementation. It lacks the error message capability of `TextInputLayout`. However:

- It only floats the hint when there is text in the `EditText` widget, not when the `EditText` gets the focus, and
- It does not require `appcompat-v7`

The [DesignSupport/FloatingLabelNative](#) sample project is a clone of the previous sample, where the `TextInputLayout` is replaced by a `FloatLabeledEditText`:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:orientation="vertical">
```

```
<com.wrapp.floatlabeledittext.FloatLabeledEditText
  android:id="@+id/t1l"
  android:layout_width="match_parent"
  android:layout_height="wrap_content">

  <EditText
    android:id="@+id/url"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:hint="@string/url"
    android:inputType="textUri"/>
</com.wrapp.floatlabeledittext.FloatLabeledEditText>

<Button
  android:id="@+id/browse"
  android:layout_width="match_parent"
  android:layout_height="wrap_content"
  android:onClick="showMe"
  android:text="@string/show_me"/>

</LinearLayout>
```

(from [DesignSupport/FloatingLabelNative/app/src/main/res/layout/main.xml](#))

As with `TextInputLayout`, `FloatLabeledEditText` is a decorating container around a regular `EditText`. Here, since the hint is left alone when the `EditText` gets focus, we have it back in its original position at the top of the form.

Visually, it is fairly similar to `TextInputLayout`, albeit with the native action bar:

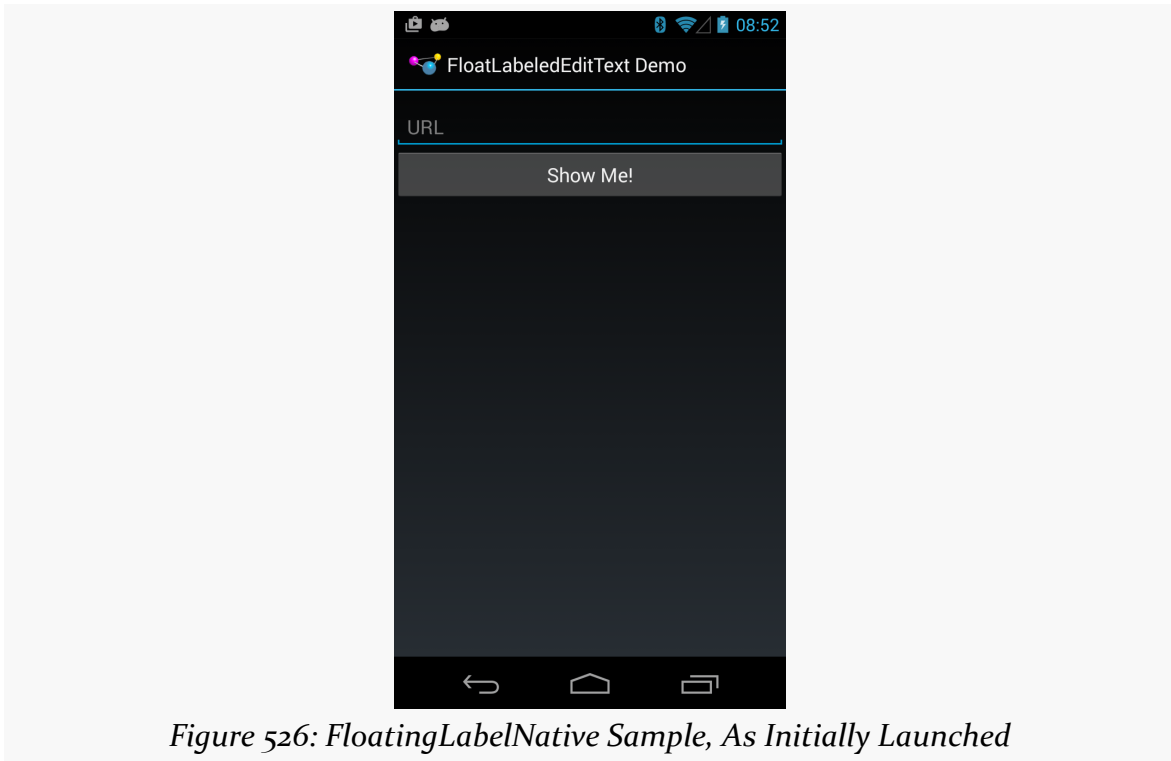

Figure 526: FloatingLabelNative Sample, As Initially Launched

Implementing a Navigation Drawer

Each year brings a new design pattern in Android that takes the development community by storm. In 2011, it was the [action bar](#). In 2012, it was [ViewPager](#). In 2013, it was the navigation drawer.

This chapter covers that navigation drawer pattern: what it is, where you use it, and how you implement it, using a `DrawerLayout` class supplied by the Android Support package.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book. In addition, one section ties into [the chapter on action modes](#).

What is a Navigation Drawer?

Complex apps often require complex navigation, to get to all of the different areas of the app. And, in many cases, that navigation is tied to nouns, reflecting different types of content, more so than verbs, reflecting operations to be performed against a particular piece of content. Verbs are actions, and can usually go in the action bar as action bar items (e.g., toolbar-style buttons). Nouns *could* be put in the action bar as well as items, though having a mixed bunch of nouns and verbs makes the action bar item roster inconsistent.

Back before the action bar, the “go-to” design pattern for navigation was the so-called “dashboard”:

IMPLEMENTING A NAVIGATION DRAWER

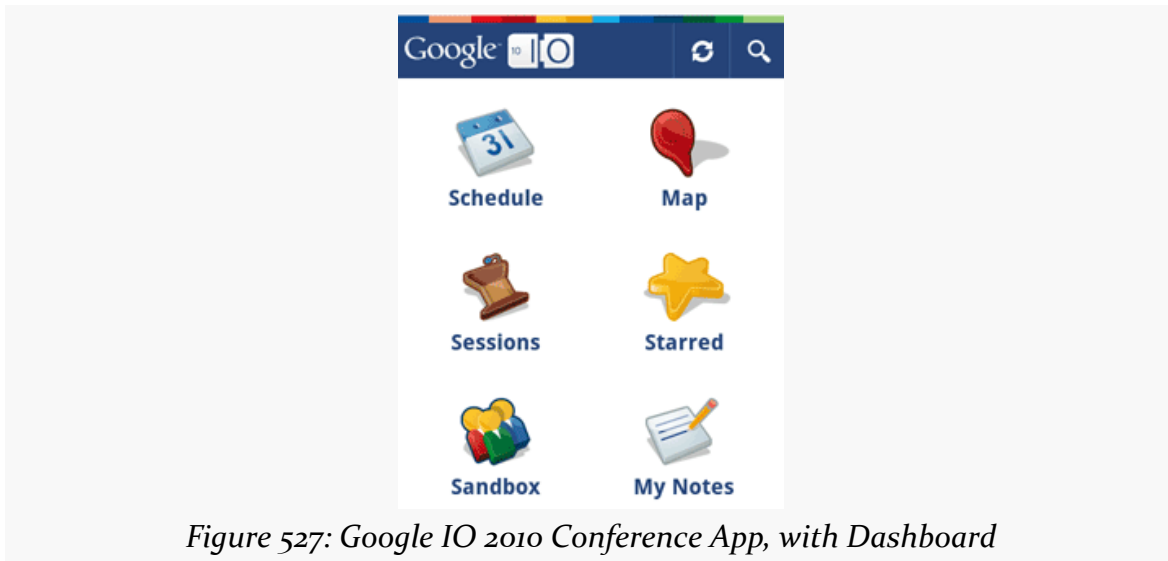

Figure 527: Google IO 2010 Conference App, with Dashboard

But this took up the whole screen and was therefore only available as the “home” activity of an app.

The navigation drawer, or “sliding menu”, pattern has the same sort of content navigation options available in a drawer that slides out from the side of the screen:

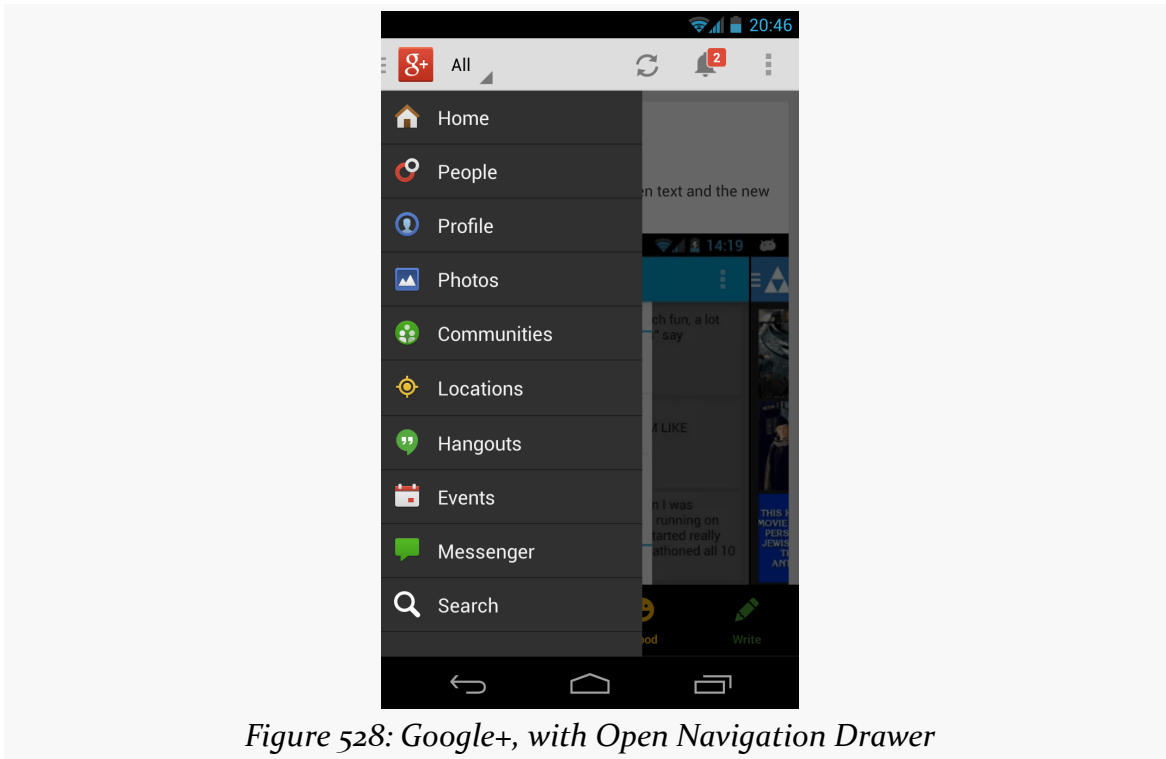

Figure 528: Google+, with Open Navigation Drawer

The drawer can be accessed from many, if not all, activities in the app, to allow the user to get wherever they need to from wherever they happen to be.

A Simple Navigation Drawer

The good news is that Google released an implementation of the navigation drawer pattern, called `DrawerLayout`, in the Android Support package (`support-v4` and `support-v13`).

The bad news is that it still takes a bit of work to get this integrated with your app.

This section will review the [NavDrawer/Simple](#) sample project, that shows a fairly simplistic integration of a `DrawerLayout` into an activity.

The Activity Layout

The root element of your activity layout, for an activity using `DrawerLayout`, is `DrawerLayout` itself:

IMPLEMENTING A NAVIGATION DRAWER

```
<android.support.v4.widget.DrawerLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/drawer_layout"
    android:layout_width="match_parent"
    android:layout_height="match_parent">

    <FrameLayout
        android:id="@+id/content"
        android:layout_width="match_parent"
        android:layout_height="match_parent" />

    <ListView
        android:id="@+id/drawer"
        android:layout_width="240dp"
        android:layout_height="match_parent"
        android:layout_gravity="start"
        android:background="#111"
        android:choiceMode="singleChoice"
        android:divider="@android:color/transparent"
        android:dividerHeight="0dp" />

</android.support.v4.widget.DrawerLayout>
```

(from [NavDrawer/Simple/app/src/main/res/layout/activity_main.xml](#))

DrawerLayout itself is rather unremarkable in the layout resource: you size and position it, usually to fill the screen. It needs to have precisely two child elements:

1. The first child represents the “real” activity content
2. The second child represents the contents of the drawer that can be opened and closed

If you are adapting an existing activity to use the DrawerLayout, that first child could well be an `<include>` element pointing to your existing activity layout resource, so that you can leave it undisturbed and just point your activity to start with this new DrawerLayout resource.

There are a couple of attributes in the children that are important for proper DrawerLayout operation:

- The second child — often a `ListView` — needs to have its `android:layout_gravity` set to indicate what side of the screen the drawer will slide out from. Typically this will be `left` (or `start` if you are on API Level 17+ and are taking advantage of the RTL layout support).
- The second child also specifies its `android:layout_width` to indicate the size of the drawer when opened. This should *not* be the full width of the screen, and the [Android design guidelines](#) suggest a width between 240dp and 320dp.

The ActionBarDrawerToggle

The `onCreate()` method of `MainActivity` is responsible for setting up the drawer, as well as the activity's main content:

```
@Override
protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.activity_main);

    if (getFragmentManager().findFragmentById(R.id.content) == null) {
        showLorem();
    }

    ListView drawer=(ListView)findViewById(R.id.drawer);

    drawer.setAdapter(new ArrayAdapter<String>(
        this,
        R.layout.drawer_row,
        getResources().getStringArray(R.array.drawer_rows)));

    drawer.setOnItemClickListener(this);

    drawerLayout=(DrawerLayout)findViewById(R.id.drawer_layout);
    toggle=
        new ActionBarDrawerToggle(this, drawerLayout,
            R.drawable.ic_drawer,
            R.string.drawer_open,
            R.string.drawer_close);

    drawerLayout.setDrawerListener(toggle);
    getActionBar().setDisplayHomeAsUpEnabled(true);
    getActionBar().setHomeButtonEnabled(true);
}
```

(from [NavDrawer/Simple/app/src/main/java/com/commonsware/android/drawer/simple/MainActivity.java](#))

In terms of the content, if the `FrameLayout` placed in the layout resource is empty, we call `showLorem()` to lazy-create a `LoremFragment` (a `ListFragment` with 25 Latin words) and run a `FragmentManager` to display it:

```
private void showLorem() {
    if (lorem == null) {
        lorem=new LoremFragment();
    }

    if (!lorem.isVisible()) {
        getFragmentManager().beginTransaction()
            .replace(R.id.content, lorem).commit();
    }
}
```

(from [NavDrawer/Simple/app/src/main/java/com/commonsware/android/drawer/simple/MainActivity.java](#))

IMPLEMENTING A NAVIGATION DRAWER

`onCreate()` then retrieves the `ListView`, sets the contents of the list to be a `<string-array>` resource named `drawer_rows`, and sets up the activity itself to respond to clicks on the list.

`onCreate()` then sets up an `ActionBarDrawerToggle`. This allows the app icon on the left of the action bar to open and close the navigation drawer. The `ActionBarDrawerToggle` constructor takes five parameters:

- The Activity as a Context
- The `DrawerLayout` widget to be managed by this toggle
- The icon to superimpose on the app icon to indicate that there is a toggle
- String resources for the open and close operations, for accessibility

The sample app uses icons from Google’s discontinued “Action Bar Icon Pack” for the third parameter. In addition, the [Android Asset Studio](#) offers a way for you to customize the navigation drawer indicator artwork for other themes.

In addition to creating the toggle instance, we need to:

- Associate it with the `DrawerLayout`, by calling `setDrawerListener()` on it
- Enable the app icon via `setHomeButtonEnabled()` and enable it for “up” navigation via `setDisplayHomeAsUpEnabled()`
- Forward the `onPostExecute()`, `onConfigurationChanged()`, and `onOptionsItemSelected()` activity callback methods on to the toggle:

```
@Override
protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    toggle.syncState();
}

@Override
public void onConfigurationChanged(Configuration newConfig) {
    super.onConfigurationChanged(newConfig);

    toggle.onConfigurationChanged(newConfig);
}

@Override
public boolean onOptionsItemSelected(MenuItem item) {
    if (toggle.onOptionsItemSelected(item)) {
        return(true);
    }
}
```

IMPLEMENTING A NAVIGATION DRAWER

```
return(super.onOptionsItemSelected(item));  
}
```

(from [NavDrawer/Simple/app/src/main/java/com/commonsware/android/drawer/simple/MainActivity.java](#))

Without any additional work, launching the app will show the “mini hamburger” navigation drawer icon in the action bar:

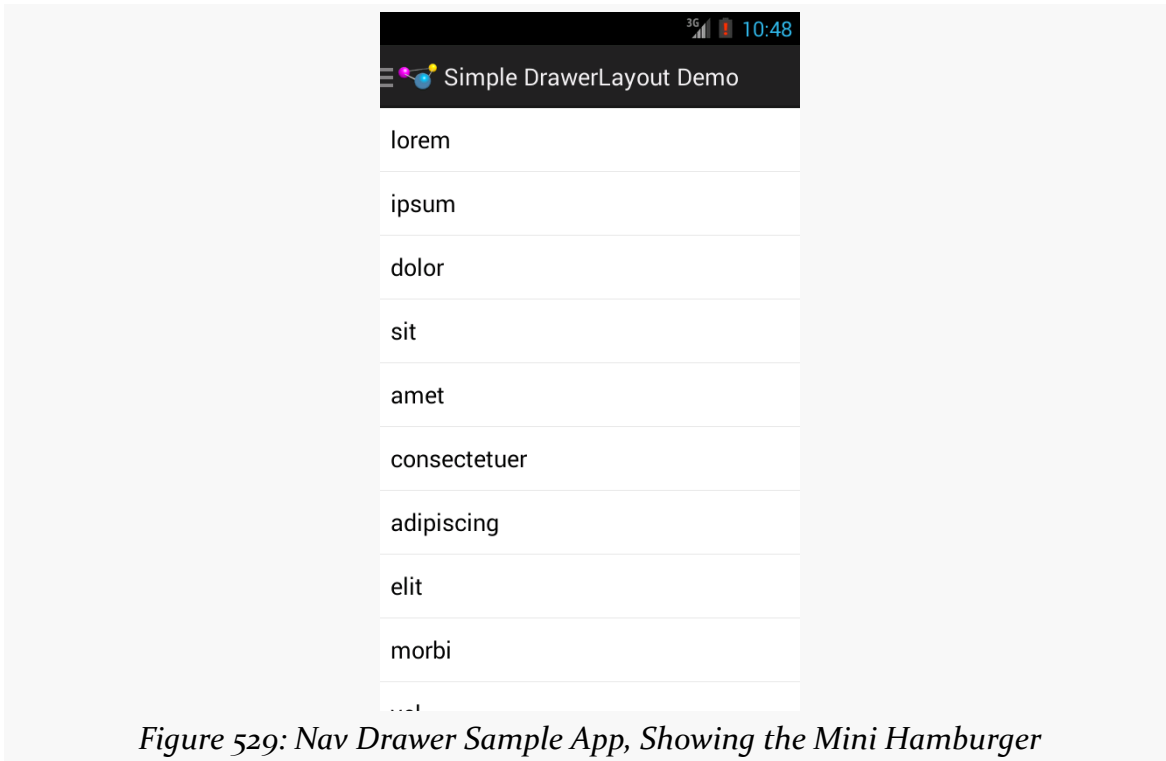

Figure 529: Nav Drawer Sample App, Showing the Mini Hamburger

Tapping the app icon will open the drawer:

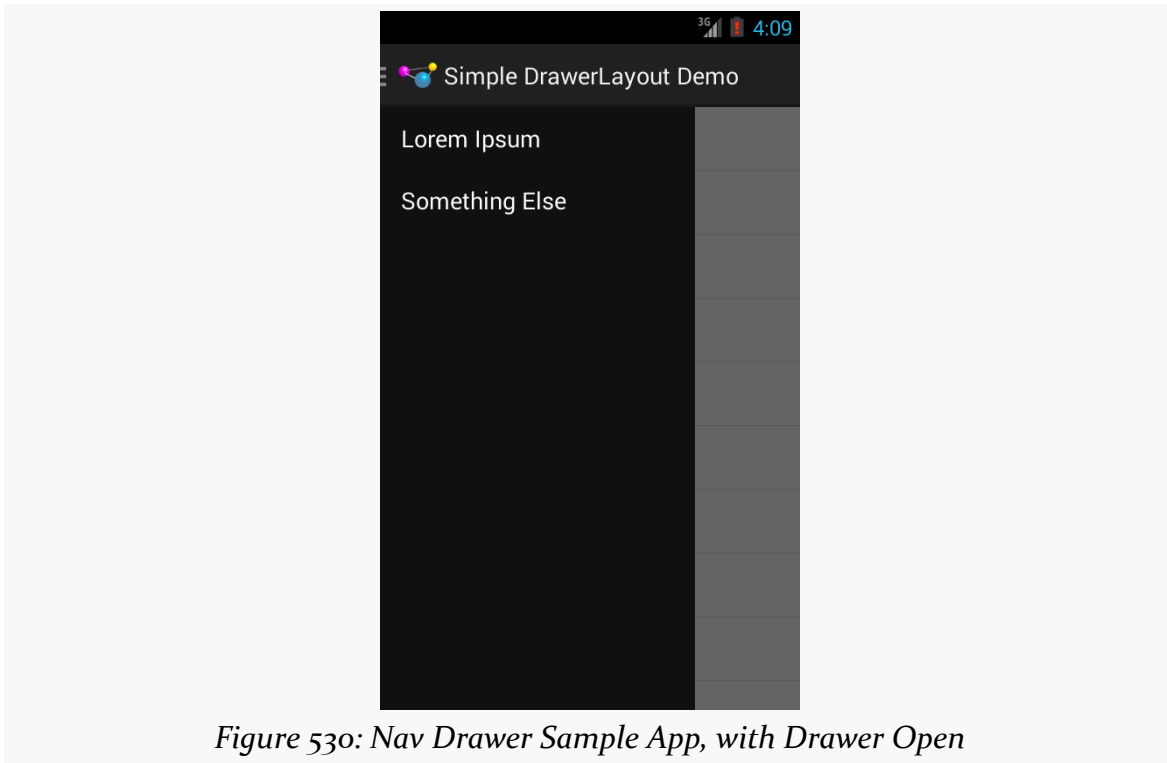

Figure 530: Nav Drawer Sample App, with Drawer Open

The drawer slides over the content, rather than pushing the content away, which is why we do not see the words peeking out on the right side of the screen.

Tapping the app icon again will close the drawer.

The user can also open the drawer via gestures. A bezel swipe from the left side will open the drawer, and swiping the open drawer right to left will close it. In addition, tapping and holding on the left edge of the content will cause the drawer to “peek” open by a handful of pixels, to hint to the user that there may be something that they can access by swiping from the left.

NOTE: This implementation of `ActionBarDrawerToggle` is officially deprecated as of the 21.0.0 version of the Android Support library. However, it is still necessary, at this time, for using `DrawerLayout` with the native action bar.

The Actions on Navigation Clicks

Of course, a navigation drawer is useless unless we do something when the user interacts with it, clicking on list rows in this case.

IMPLEMENTING A NAVIGATION DRAWER

Our list is very simple, with just two elements. The app simply toggles between two fragments based upon the list item click:

```
@Override
public void onItemClick(AdapterView<?> listView, View row,
                        int position, long id) {
    if (position == 0) {
        showLorem();
    }
    else {
        showContent();
    }

    drawerLayout.closeDrawers();
}
```

(from [NavDrawer/Simple/app/src/main/java/com/commonsware/android/drawer/simple/MainActivity.java](#))

We also close the drawer, using `closeDrawers()`, as otherwise the `DrawerLayout` is unaware that the user chose something and that we should return to the content.

Alternative Row Layouts

The rows in the sample app's `ListView` were fairly conventional. Rows in a nav drawer should be fairly simple, as you are merely trying to lead the users to pieces of content, not present content itself.

That being said, the navigation options can have a bit more to them than what the sample app showed. The [Android design guidelines](#) will steer you in the direction of how best to style:

- Rows with leading icons
- Rows with trailing badges (e.g., unread message counts)
- Expandable sections (e.g., less-important items but still worth having in the drawer)
- Dividers, to help organize groups of related rows

IMPLEMENTING A NAVIGATION DRAWER

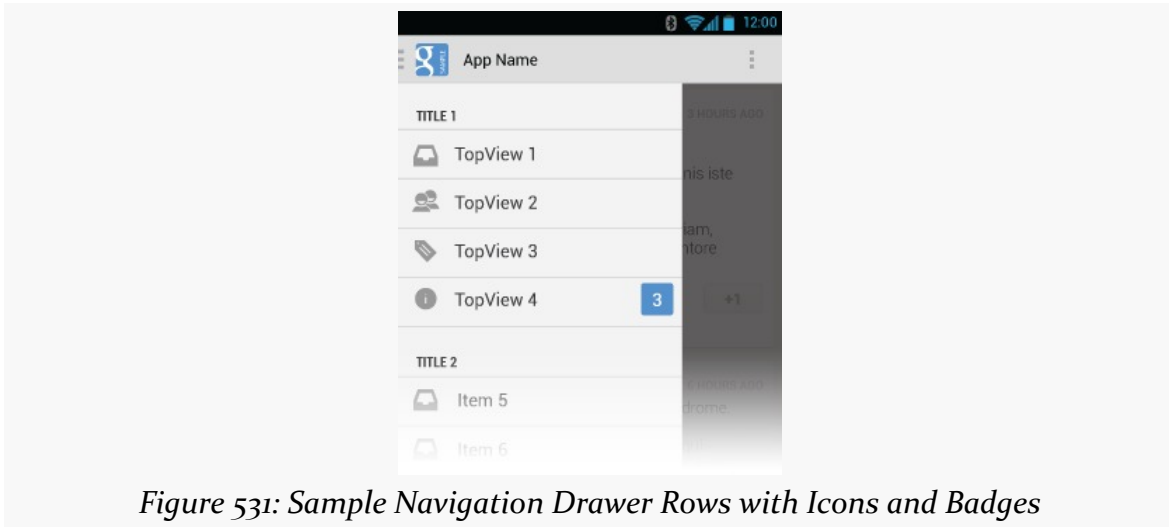

Figure 531: Sample Navigation Drawer Rows with Icons and Badges

You will see other apps experiment with other capabilities. For example, Gmail used to use `RadioButton` widgets for the accounts:

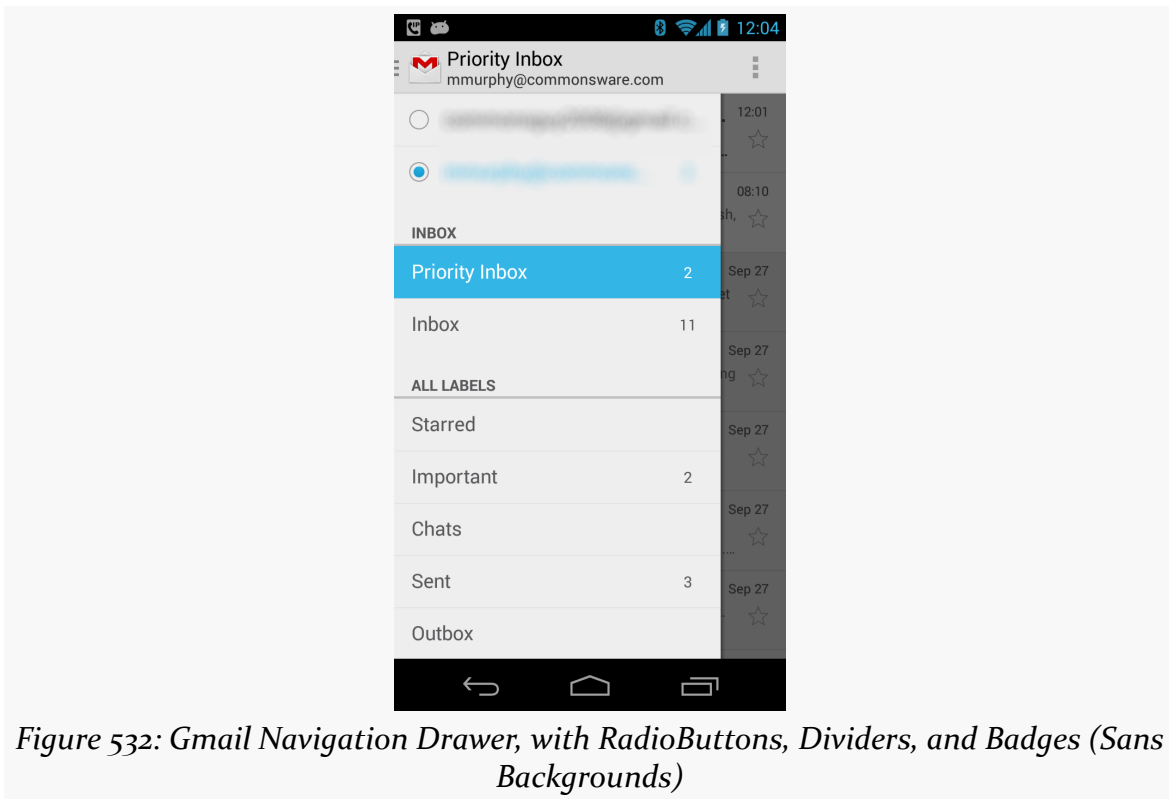

Figure 532: Gmail Navigation Drawer, with RadioButtons, Dividers, and Badges (Sans Backgrounds)

That being said, the closer you can stick with the official design guidelines, the better off you will tend to be, in terms of meeting user expectations and not encountering rendering or click event oddities with `DrawerLayout`.

Additional Considerations

Beyond putting the right things into the navigation drawer, there are some other things that you will need to take into account, particularly as your navigation drawer interacts with the rest of the activity and overall application.

Highlighting the Current Location

If the user opens the navigation drawer, and they are already at one of the navigation destinations shown in the drawer, that destination should show up with the activated state, to indicate to the user that she is already there. Conversely, if the user has drilled down into some part of your application that does *not* have a corresponding entry in the navigation drawer, the navigation drawer should show no activated entry.

One way to handle this is to keep the `ListView` updated as the user navigates (whether through the navigation drawer or by other means), selecting and de-selecting items as needed.

The row layout used in the original sample, culled from [Google's DrawerLayout sample code](#), already has the activated background:

```
<android.support.v4.widget.DrawerLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/drawer_layout"
    android:layout_width="match_parent"
    android:layout_height="match_parent">

    <FrameLayout
        android:id="@+id/content"
        android:layout_width="match_parent"
        android:layout_height="match_parent"/>

    <ListView
        android:id="@+id/drawer"
        android:layout_width="240dp"
        android:layout_height="match_parent"
        android:layout_gravity="start"
        android:background="#111"
        android:choiceMode="singleChoice"
        android:divider="@android:color/transparent"
        android:dividerHeight="0dp"/>

</android.support.v4.widget.DrawerLayout>
```

IMPLEMENTING A NAVIGATION DRAWER

(from [NavDrawer/Simple/app/src/main/res/layout/activity_main.xml](#))

However, we were not using it in that sample, so the drawer `ListView` did not give the user any indication that they had already navigated to a navigable destination. But, we have the [NavDrawer/Activated](#) sample project, a clone of the original sample, that adds this activation capability, and demonstrates the headaches it causes.

First, as part of our `onCreate()` work in `MainActivity`, we need to configure the `ListView` to work in single-choice mode (the `ListView` engine behind the activated state), along with the rest of the `ListView` setup:

```
@Override
protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.activity_main);

    drawer=(ListView)findViewById(R.id.drawer);
    drawer.setChoiceMode(ListView.CHOICE_MODE_SINGLE);

    String[] rows=getResources().getStringArray(R.array.drawer_rows);

    drawer.setAdapter(new ArrayAdapter<String>(this,
                                                R.layout.drawer_row,
                                                rows));

    drawer.setOnItemClickListener(this);

    drawerLayout=(DrawerLayout)findViewById(R.id.drawer_layout);
    toggle=
        new ActionBarDrawerToggle(this, drawerLayout,
                                R.drawable.ic_drawer,
                                R.string.drawer_open,
                                R.string.drawer_close);

    drawerLayout.setDrawerListener(toggle);
    getActionBar().setDisplayHomeAsUpEnabled(true);
    getActionBar().setHomeButtonEnabled(true);

    getFragmentManager().addOnBackStackChangedListener(this);

    if (getFragmentManager().findFragmentById(R.id.content) == null) {
        showLorem();
    }
}
```

(from [NavDrawer/Activated/app/src/main/java/com/commonsware/android/drawer/activated/MainActivity.java](#))

IMPLEMENTING A NAVIGATION DRAWER

Our showLorem() method now will post() a Runnable, named onNavChange, after it calls commit() on its FragmentTransaction:

```
private void showLorem() {
    if (lorem == null) {
        lorem=new LoremFragment();
    }

    if (!lorem.isVisible()) {
        getFragmentManager().popBackStack();
        getFragmentManager().beginTransaction()
            .replace(R.id.content, lorem).commit();
        drawer.post(onNavChange);
    }
}
```

(from [NavDrawer/Activated/app/src/main/java/com/commonsware/android/drawer/activated/MainActivity.java](#))

That magic onNavChange Runnable simply sees what fragment is presently visible and updates the checked item in the nav drawer's ListView to match:

```
private Runnable onNavChange=new Runnable() {
    @Override
    public void run() {
        if (lorem != null && lorem.isVisible()) {
            drawer.setItemChecked(0, true);
        }
        else if (content != null && content.isVisible()) {
            drawer.setItemChecked(1, true);
        }
        else {
            int toClear=drawer.getCheckedItemPosition();

            if (toClear >= 0) {
                drawer.setItemChecked(toClear, false);
            }
        }
    }
};
```

(from [NavDrawer/Activated/app/src/main/java/com/commonsware/android/drawer/activated/MainActivity.java](#))

By using post(), we schedule the Runnable to be executed after the fragment change has occurred. Ideally, we would somehow more explicitly attach the Runnable to the FragmentTransaction, but [that does not appear to be an option](#).

IMPLEMENTING A NAVIGATION DRAWER

Since we call `showLorem()` in `onCreate()`, this causes our navigation drawer to show that we are in `LoremFragment` when the activity first starts up:

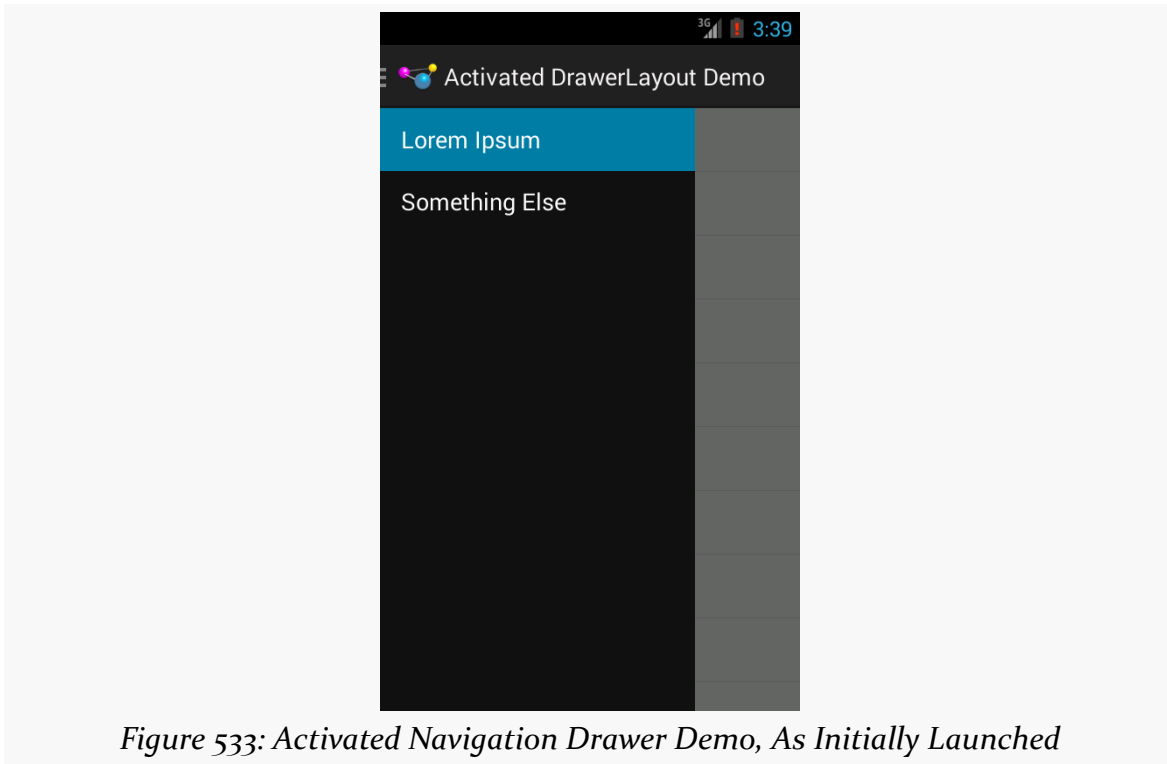

Figure 533: Activated Navigation Drawer Demo, As Initially Launched

The natural behavior of a single-choice `ListView` will check the row that we tap upon, and so when the user taps on an entry in the navigation drawer, it automatically becomes activated. This means we do not have to do our own work for that.

If *everything* in your app is represented by an entry in the navigation drawer, your work is done. However, most likely, there are parts of your app that do not directly map to entries in the navigation drawer... and that is where things get a wee bit complex.

To demonstrate this, we need a bit more to our UI. So, we make `LoremFragment` use the contract pattern, seen elsewhere in the book. We override `onListItemClick()` to call a `wordClicked()` method on the contract, to let the hosting activity know about that UI operation:

```
package com.commonware.android.drawer.activated;
import android.os.Bundle;
```

IMPLEMENTING A NAVIGATION DRAWER

```
import android.view.View;
import android.widget.ArrayAdapter;
import android.widget.ListView;

public class LoremFragment extends ContractListFragment<LoremFragment.Contract> {
    private static final String[] items= { "lorem", "ipsum", "dolor",
        "sit", "amet", "consectetuer", "adipiscing", "elit", "morbi",
        "vel", "ligula", "vitae", "arcu", "aliquet", "mollis", "etiam",
        "vel", "erat", "placerat", "ante", "porttitor", "sodales",
        "pellentesque", "augue", "purus" };

    @Override
    public void onActivityCreated(Bundle savedInstanceState) {
        super.onActivityCreated(savedInstanceState);

        setListAdapter(new ArrayAdapter<String>(
            getActivity(),
            android.R.layout.simple_list_item_1,
            items));
    }

    @Override
    public void onListItemClick(ListView l, View v, int position, long id) {
        getContract().wordClicked();
    }

    interface Contract {
        void wordClicked();
    }
}
```

(from [NavDrawer/Activated/app/src/main/java/com/commonsware/android/drawer/activated/LoremFragment.java](#))

We also create a StuffFragment that displays a simple message:

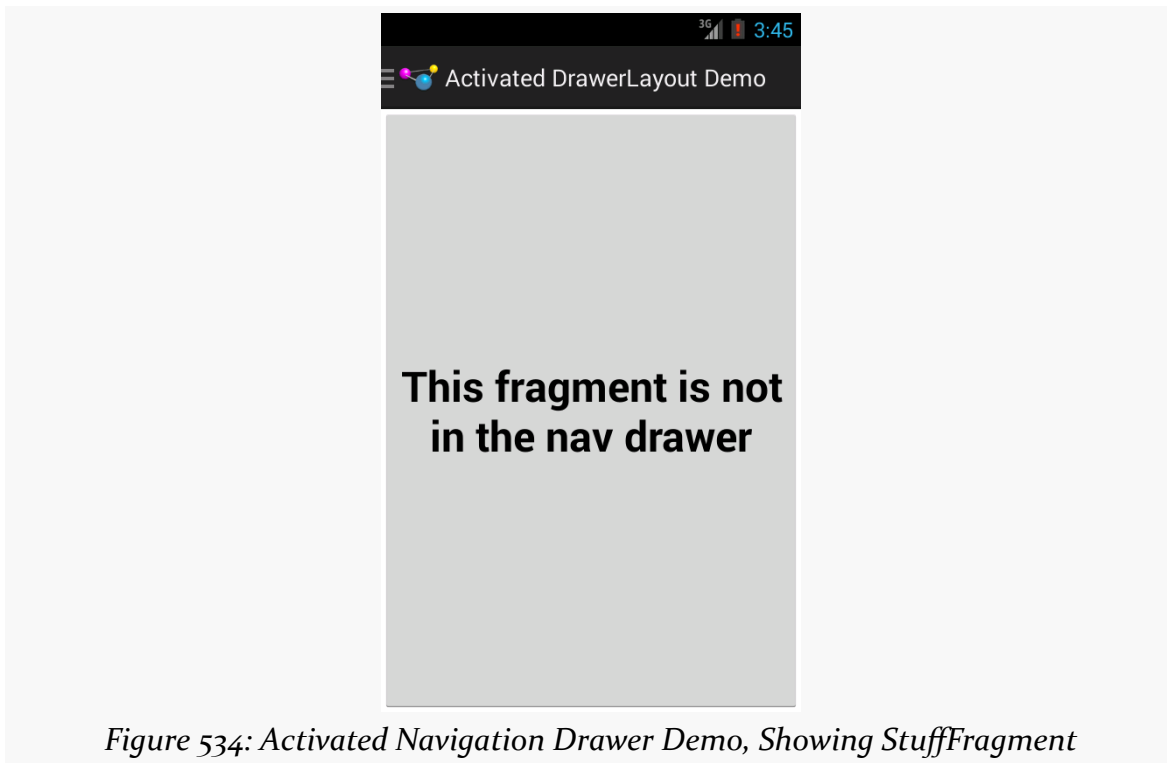

Figure 534: Activated Navigation Drawer Demo, Showing StuffFragment

The idea is that clicking on a word in the LoremFragment should bring up the StuffFragment, as if this were a master/detail implementation.

The implementation of `wordClicked()` in `MainActivity` does indeed show a `StuffFragment` (while also adding it to the back stack), but it also needs to make the drawer `ListView` have no checked items, reflecting the fact that the UI state does not reflect one of the navigation destinations:

```
@Override
public void wordClicked() {
    if (stuff == null) {
        stuff=new StuffFragment();
    }

    getFragmentManager().beginTransaction()
        .replace(R.id.content, stuff)
        .addToBackStack(null).commit();
    drawer.post(onNavChange);
}
```

(from [NavDrawer/Activated/app/src/main/java/com/commonsware/android/drawer/activated/MainActivity.java](#))

IMPLEMENTING A NAVIGATION DRAWER

Note that we also post() the onNavChange Runnable here as well.

The result is that when we do tap on a word in the list, the StuffFragment appears, but the navigation drawer shows no activated row:

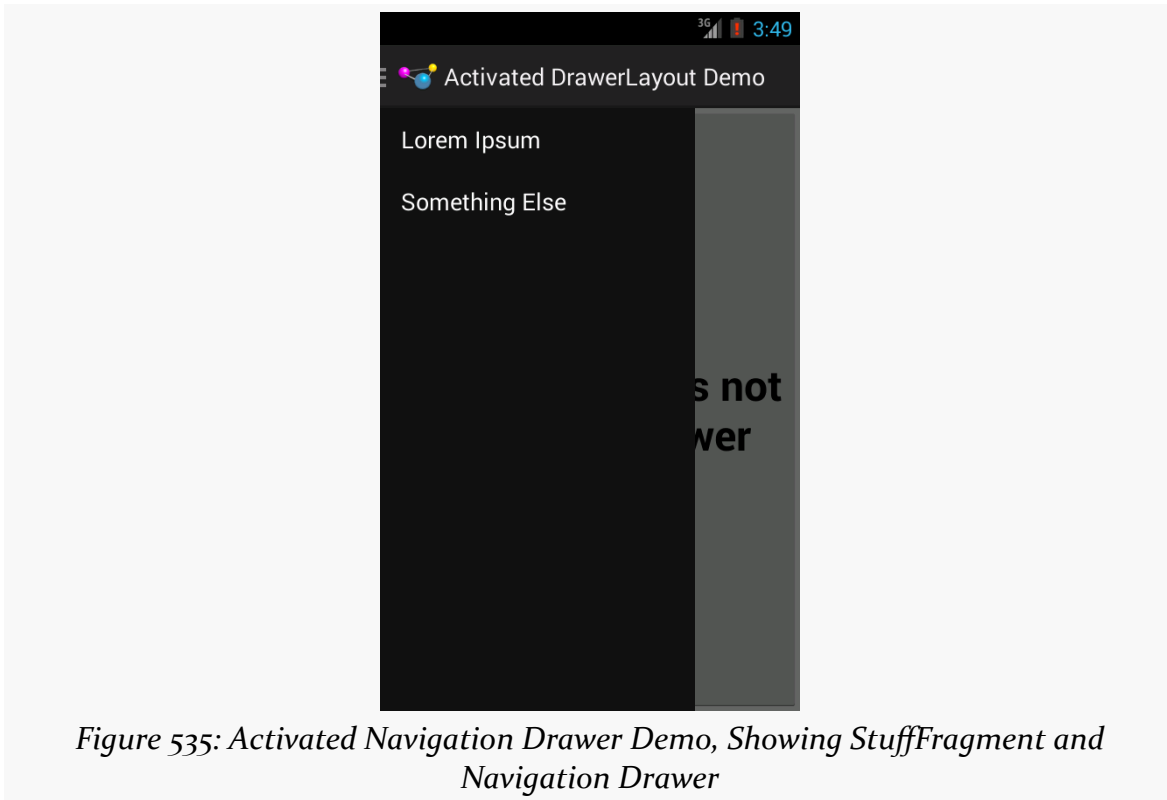

Figure 535: Activated Navigation Drawer Demo, Showing StuffFragment and Navigation Drawer

However, since we manually cleared the checked state, we now need to re-check a row if the user navigates back to one of the other fragments. There are two ways the user could return to one of those other fragments: via the navigation drawer, or via the BACK button (popping our transaction off the back stack).

If they navigate to one of the other fragments via the navigation drawer, the appropriate row will be activated automatically by the user's click event. However, we need to consider what to do about that transaction hanging around the back stack from before. One option is to remove it, so the other fragments behave as they do normally, where BACK exits the activity. That is a matter of calling `popBackStack()` on the `FragmentManager` as part of showing one of the fragments, such as the `showContent()` method that shows the `ContentFragment`:

IMPLEMENTING A NAVIGATION DRAWER

```
private void showContent() {
    if (content == null) {
        content=new ContentFragment();
    }

    if (!content.isVisible()) {
        getFragmentManager().popBackStack();
        getFragmentManager().beginTransaction()
            .replace(R.id.content, content).commit();
        drawer.post(onNavChange);
    }
}
```

(from [NavDrawer/Activated/app/src/main/java/com/commonsware/android/drawer/activated/MainActivity.java](#))

If the user presses the BACK button, having the earlier fragment reappear happens automatically. However, we need to fix up the navigation drawer to show the proper row as being activated. To do that, we implement `OnBackStackChangeListener` on `MainActivity` and call `addOnBackStackChangeListener()` on the `FragmentManager` in the `onCreate()` initialization work. That way, `onBackStackChanged()` will be called when there is a change in the state of the back stack. Then, it is merely a matter of calling `post()` for `onNavChanged` again, to update the nav drawer:

```
@Override
public void onBackStackChanged() {
    drawer.post(onNavChange);
}
```

(from [NavDrawer/Activated/app/src/main/java/com/commonsware/android/drawer/activated/MainActivity.java](#))

Hiding Context-Specific Action Bar Items

Another Google design guideline that makes sense, but adds complexity, is to only show action bar items that pertain to the entire application while the navigation drawer is visible. So, for example, a “Help” action bar item should remain visible, to allow users to switch over to that. But an “Edit” action bar item, to edit something in the main activity, should be hidden while the navigation drawer is visible.

The navigation drawer is effectively an application-level construct, even if we wind up implementing it on a per-activity basis due to the way Android user interfaces are constructed. Hence, the action bar items with the drawer open should pertain to the same scope that the drawer itself does: the application, not a particular activity or fragment inside of it.

Also, on phone-sized screens, the user may not be able to see much of the underlying UI, as the drawer itself will occlude most of it. They may not remember exactly what was showing, and therefore may forget what that “Delete” action bar item would actually delete. Hiding such a context-specific item, while the drawer is open, is safer.

The converse, of course, is that when the drawer closes, you will need to show once again the items that you hid when the drawer opened.

`DrawerLayout` supports a `DrawerListener`, an instance of which you can attach to the drawer itself, to be notified of when the drawer opens and closes, so you can adjust your action bar items to match.

Interacting with an Action Mode

You may be using your own custom [action modes](#) (a.k.a., contextual action bars), such as allowing the user to perform operations on multiple selections in a `ListView`.

Since the navigation drawer is tied to the application as a whole, not necessarily just the current activity or the selections in it, Google’s recommendation is for you to temporarily dismiss the action mode when the navigation drawer is opened. This will allow the action bar to show items of relevance to the app, not to the selection. If the user navigates elsewhere using the navigation drawer, you would leave the action mode dismissed. If the user slides the navigation drawer closed, though, you could re-enable the action mode, tied back into the multiple selections the user has already made.

Advertising Your Drawer

Users who have spent some time with Android will have a decent shot at recognizing that tapping the action bar item adorned with the nav drawer artwork will open a drawer. However, not all users will necessarily make that connection, particularly users relatively new to Android.

As noted earlier in this chapter, `DrawerLayout` implements the “peek” pattern, where a long-tap on the edge of the screen will cause the drawer to open just a bit, to hint that there is something that can be opened with a swipe gesture. This is nice and subtle, but perhaps too subtle, as users are not necessarily likely to tap-and-hold on the screen edge just to see if something interesting happens.

Another possibility is to have the drawer open automatically, either the first time that your app is launched, or every time your app is launched until you detect that the user has manually opened the drawer (e.g., by adding a `DrawerListener` and watching for `onDrawerSlide()` and `onDrawerOpened()` events not triggered by you). On the plus side, this puts the drawer “front and center”, so the user cannot miss it. Once the user taps in your activity (inside or outside of the drawer), the drawer will close with the animated slide to the edge. The hope is that the user will either eventually realize that they can bezel-swipe to get that drawer open, or they will learn about the action bar option (where you have it). This works if the drawer is fairly useful, relative to what the activity would be displaying by default. If, however, the drawer pales in comparison to the main activity view, forcing the drawer open may reduce, not improve, usability.

What Should Not Be in the Drawer

Your navigation drawer should only provide access to the major areas of content in your app. If you do not have many “major areas of content in your app”, reconsider having a navigation drawer, and use something else (e.g., `ViewPager` with a tabbed indicator) to get to what content you have.

Also, there are certain things that should not go into a navigation drawer:

- Actions (verbs) generally do not belong in the navigation drawer. “Edit”, “Save”, and so forth belong as action bar items, or perhaps as part of an action mode, not in the navigation drawer.
- Content itself does not belong in the navigation drawer. Bits of metadata, in the form of badges and similar sorts of indicators, are fine, to hint to the user about the content that is available in that area of your app. But the navigation drawer is not meant to be the “master” in the master/detail pattern, nor is it some sort of “sidebar” of additional content that you just want to have hidden away.
- Low-priority areas of your app, particularly those that are traditionally in the action bar, should not be in the navigation drawer. “Help” and “About” are classic examples. “Settings” is another, though the line starts to get a bit fuzzy (while “Settings” might be something traditional for the action bar, “Accounts” is not). The overflow menu of an action bar is a fine place to have those sorts of areas be available to the user without cluttering up the primary action bar or the navigation drawer.

Independent Implementations

The navigation drawer pattern did not begin with the introduction of `DrawerLayout`. There have been many independent implementations of such a “sliding menu” that pre-dated `DrawerLayout` and the Android design guidelines for navigation drawers. Examples include:

- Jeremy Feinstein’s [SlidingMenu](#)
- 6Wunderkinder’s [Sliding Layer](#)
- David Scott’s [RibbonMenu](#)

Just bear in mind that these implementations do not necessarily adhere to everything in the design guidelines, requiring you to perhaps make modifications or simply ignore those guidelines as needed.

RecyclerView

Visually representing collections of items is an important aspect of many mobile apps. The classic Android implementation of this was the `AdapterView` family of widgets: `ListView`, `GridView`, `Spinner`, and so on. However, they had their limitations, particularly with respect to advanced capabilities like animating changes in the list contents.

In 2014, Google released `RecyclerView`, via the Android Support package. Developers can add the `recyclerview-v7` to their projects and use `RecyclerView` as a replacement for most of the `AdapterView` family. `RecyclerView` was written from the ground up to be a more flexible container, with lots of hooks and delegation to allow behaviors to be plugged in.

This had two major impacts:

1. `RecyclerView` is indeed much more powerful than its `AdapterView` counterparts
2. `RecyclerView`, out of the box, is nearly useless, and wiring together enough stuff to even replicate basic `ListView/GridView` functionality takes quite a bit of code

In this chapter, we will review `RecyclerView` from the ground up, starting with basic operation. Many of the `ListView` samples from elsewhere in the book will be replicated here, to see how to pull off the same things with `RecyclerView`. And, we will explore some of the additional capabilities that make `RecyclerView` perhaps worth the effort on high-end Android applications.

Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly the one on [AdapterView and adapters](#).

One section involves the use of [custom XML drawables](#). Another section demonstrates using content pulled from [the MediaStore ContentProvider](#).

This chapter also covers things like [action modes](#) and other [advanced ListView techniques](#).

AdapterView and its Discontents

AdapterView, and particularly its ListView and GridView subclasses, serve important roles in Android application development. And, for basic scenarios, they work reasonably well.

However, there are issues.

Perhaps the biggest tactical issue is that updating an AdapterView tends to be an all-or-nothing affair. If there is a change to the model data — new rows added, existing rows removed, or data changes that might affect the AdapterView presentation — the only well-supported solution is to call `notifyDataSetChanged()` and have the AdapterView rebuild itself. This is slow and can have impacts on things like choice states. And, if you wanted to get really elaborate about your changes, and use animated effects to show where rows got added or removed, that was halfway to impossible.

Strategically, AdapterView, AbsListView (the immediate parent of ListView and GridView), and ListView are large piles of code that resemble [pasta](#) to many outsiders. There are so many responsibilities piled into these classes that maintainability was a challenge for Google and extensibility was a dream more than a reality.

Enter RecyclerView

RecyclerView is designed to correct those sorts of flaws.

RecyclerView, on its own, does very little other than help manage view recycling (e.g., row recycling of a vertical list). It delegates almost everything else to other classes, such as:

- a layout manager, responsible for organizing the views into various structures (vertical list, grid, staggered grid, etc.)
- an item decorator, responsible for applying effects and light positioning to the views, such as adding divider lines between rows in a vertical list
- an item animator, responsible for animated effects as the model data changes

This is on top of the adapters and view holders that were the hallmarks of conventional AdapterView usage.

Because things like layout managers are handled via abstract classes and replaceable concrete implementations, third-party developers can contribute options for developers to use, just as Google does. [Later in this chapter](#), we will explore some of these contributions.

On the flip side, though, RecyclerView does *much* less “out of the box” than does ListView or GridView. Not everything that is missing is supplied anywhere in the `recyclerview-v7` library, requiring that you either roll a bunch of code yourself or rely upon those third-party libraries to get anything much done.

A Trivial List

Back in the original chapter on [AdapterView and adapters](#), we had the Selection/Dynamic sample app. This app would display a list of 25 Latin words, each with the word’s length and an accompanying icon (different for short and long words):

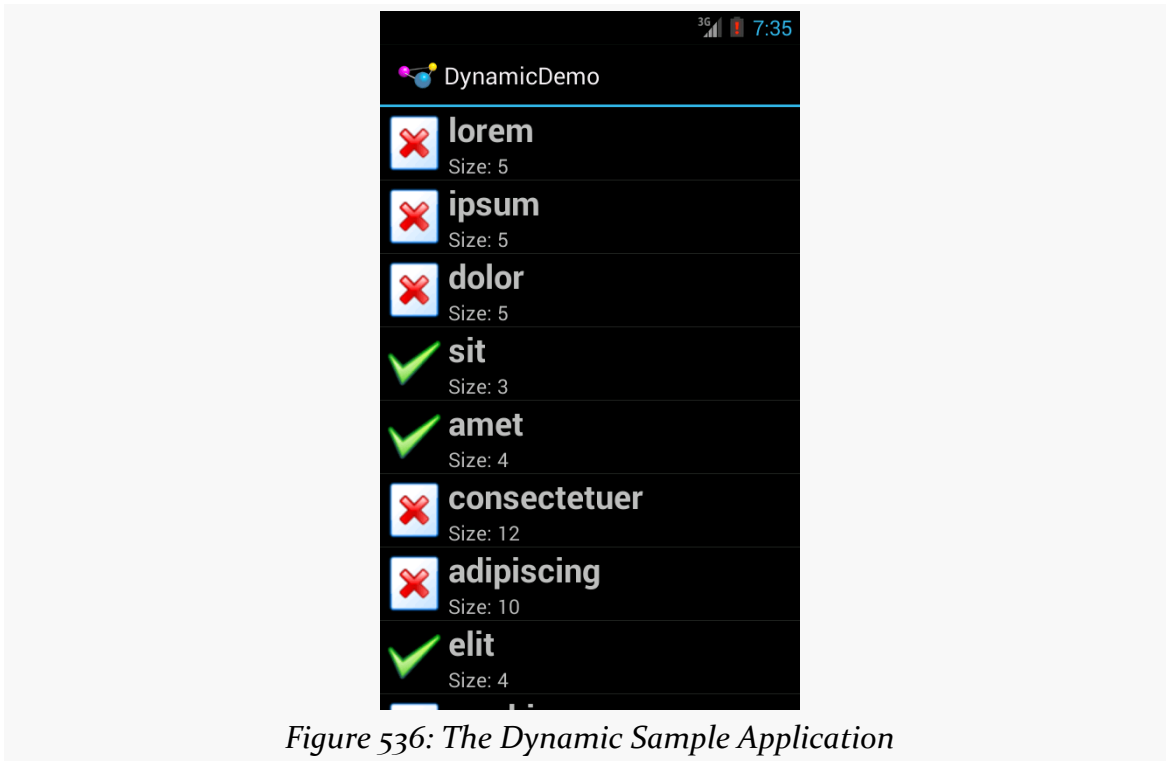

Figure 536: The Dynamic Sample Application

Here, we will review the [RecyclerView/SimpleList](#) sample project, which is a first pass at porting the Selection/Dynamic demo over to use RecyclerView.

The Dependency

Any project that wishes to use RecyclerView needs to have access to the `recyclerview-v7` library from the Android Support package. Android Studio users can simply have a reference to it in the top-level dependencies closure:

```
apply plugin: 'com.android.application'

dependencies {
    implementation 'com.android.support:recyclerview-v7:22.2.0'
}

android {
    compileSdkVersion 22
    buildToolsVersion '26.0.2'
}
```

(from [RecyclerView/SimpleList/app/build.gradle](#))

However, if you are using `recyclerview-v7`, you want to use version 23 or higher of that library. There are [changes to ART](#) – the Android runtime used on Android 5.0+ — that apparently will break the older versions of `recyclerview-v7` when running on Android 6.0+ devices.

A RecyclerViewActivity

With `ListView`, we could use `ListActivity`, to isolate some of the `ListView`-management code. There is no `RecyclerViewActivity` in the `recyclerview-v7` library... but we can create one:

```
package com.commonware.android.recyclerview.simplelist;

import android.app.Activity;
import android.support.v7.widget.RecyclerView;

public class RecyclerViewActivity extends Activity {
    private RecyclerView rv=null;

    public void setAdapter(RecyclerView.Adapter adapter) {
        getRecyclerView().setAdapter(adapter);
    }

    public RecyclerView.Adapter getAdapter() {
        return(getRecyclerView().getAdapter());
    }

    public void setLayoutManager(RecyclerView.LayoutManager mgr) {
        getRecyclerView().setLayoutManager(mgr);
    }

    public RecyclerView getRecyclerView() {
        if (rv==null) {
            rv=new RecyclerView(this);
            rv.setHasFixedSize(true);
            setContentView(rv);
        }

        return(rv);
    }
}
```

(from [RecyclerView/SimpleList/app/src/main/java/com/commonware/android/recyclerview/simplelist/RecyclerViewActivity.java](#))

The important part is the `getRecyclerView()` method. Here, if we have not already initialized the `RecyclerView`, we create an instance of it and set it as the activity's

RECYCLERVIEW

content view via `setContentview()`. Along the way, we call `setHasFixedSize(true)` on the `RecyclerView`, to tell it that its size should not be changing based upon the contents of the adapter. This knowledge can help `RecyclerView` operate more efficiently.

The `RecyclerViewActivity` also has `getAdapter()` and `setAdapter()` analogues for their `ListActivity` counterparts. We will explore the differences in the adapter classes [later in this section](#). We also have a `setLayoutManager()` convenience method, that just calls `setLayoutManager()` on the underlying `RecyclerView` — we will see what a layout manager is in the context of `RecyclerView` [in the next section](#).

There are other features of `ListActivity` that are not mirrored here in `RecyclerViewActivity`, just to keep `RecyclerViewActivity` short. Notably, `ListActivity` supports either inflating a custom layout that contains the `ListView` or creating its own. `RecyclerViewActivity` does not support this, though it could with some minor extensions.

The LayoutManager

The “real” activity of the project is `MainActivity`, which consists of a single method: `onCreate()`

```
@Override
public void onCreate(Bundle state) {
    super.onCreate(state);

    setLayoutManager(new LinearLayoutManager(this));
    setAdapter(new IconicAdapter());
}
```

(from [RecyclerView/SimpleList/app/src/main/java/com/commonsware/android/recyclerview/simplelist/MainActivity.java](#))

After chaining to the superclass, the first thing we do is call `setLayoutManager()`, which will associate a `RecyclerView.LayoutManager` with our `RecyclerView`. Specifically, we are using a `LinearLayoutManager`.

`ListView` has the notion of a vertically-scrolling list of rows “baked into” its implementation. Similarly, `GridView` has the notion of a two-dimensional vertically-scrolling grid “baked into” its implementation. `RecyclerView`, on the other hand, knows absolutely nothing about how to lay out its children. That work is delegated to a `RecyclerView.LayoutManager`, so that different approaches can be plugged in as needed.

RECYCLERVIEW

There are three concrete subclasses of the abstract `RecyclerView.LayoutManager` base class that ship with `recyclerview-v7`:

- `LinearLayoutManager`, which implements a vertically-scrolling list, akin to `ListView`
- `GridLayoutManager`, which implements a two-dimensional vertically-scrolling list, akin to `GridView`
- `StaggeredGridLayoutManager`, which implements a “staggered grid”, which has columns of cells like a `GridView`, but where the cells do not have to all have the same size

In addition, it is eminently possible to create your own `RecyclerView.LayoutManager`, or use ones from third-party libraries.

In this example, though, we stick with a simple `LinearLayoutManager`, as we are attempting to replicate the functionality of a `ListView`.

The Adapter

Our `onCreate()` method also calls `setAdapter()`, to associate an `RecyclerView.Adapter` with our `RecyclerView` (specifically, a revised version of our `IconicAdapter` from the original `Selection/Dynamic` sample app). As with the `AdapterView` family, `RecyclerView` uses an adapter to help convert our model data into visual representations. However, the implementation of a `RecyclerView.Adapter` is substantially different from a classic `ListAdapter` for use with `ListView` or `GridView`.

Reminiscent of `ArrayAdapter`, a `RecyclerView.Adapter` uses generics, and we declare what sort of stuff we are adapting. However, `ArrayAdapter` uses the generic to describe the model data. `RecyclerView.Adapter` instead uses the generic to identify a `ViewHolder` that will be responsible for doing the work to actually tie model data to row widgets:

```
class IconicAdapter extends RecyclerView.Adapter<ViewHolder> {
    @Override
    public ViewHolder onCreateViewHolder(ViewGroup parent, int viewType) {
        return(new ViewHolder(getLayoutInflater()
            .inflate(R.layout.row, parent, false)));
    }

    @Override
    public void onBindViewHolder(ViewHolder holder, int position) {
```

RECYCLERVIEW

```
holder.bindModel(items[position]);
}

@Override
public int getItemCount() {
    return(items.length);
}
}
```

(from [RecyclerView/SimpleList/app/src/main/java/com/commonsware/android/recyclerview/simplelist/MainActivity.java](#))

In our case, IconicAdapter is using a RowHolder class that we will examine in [the next section](#).

A RecyclerView.Adapter has three abstract methods that need to be implemented.

One is getItemCount(), which fills the same role as does getCount() with a ListAdapter, indicating how many items there will be in the RecyclerView. In the case of IconicAdapter, this is based on the length of the items static array of String objects, same as it was with IconicAdapter in the Selection/Dynamic sample app:

```
private static final String[] items={"lorem", "ipsum", "dolor",
    "sit", "amet",
    "consectetuer", "adipiscing", "elit", "morbi", "vel",
    "ligula", "vitae", "arcu", "aliquet", "mollis",
    "etiam", "vel", "erat", "placerat", "ante",
    "porttitor", "sodales", "pellentesque", "augue", "purus"};
```

(from [RecyclerView/SimpleList/app/src/main/java/com/commonsware/android/recyclerview/simplelist/MainActivity.java](#))

The other two methods are onCreateViewHolder() and onBindViewHolder(). These are a bit reminiscent of the newView() and bindView() methods that are used by a CursorAdapter. However, rather than working directly with views, onCreateViewHolder() and onBindViewHolder() work with ViewHolder objects, as a formalization of the view holder pattern seen originally in [the chapter on selection widgets](#).

onCreateViewHolder(), as the name suggests, needs to create, configure, and return a ViewHolder for a particular row of our list. It is passed two parameters:

- a ViewGroup that will hold the views managed by the holder, mostly for use with layout inflation, and

RECYCLERVIEW

- an int that is the particular view type we are using, for cases where we have [multiple view types](#)

The IconicAdapter implementation inflates our row view (R.layout.row) and passes it to the ViewHolder constructor, returning the resulting ViewHolder.

onBindViewHolder() is responsible for updating a ViewHolder based upon the model data for a certain position. IconicAdapter handles this by passing the model into a private bindModel() method implemented on ViewHolder.

There are many other methods you could override on RecyclerView.Adapter, and we will see a few of those later in this chapter. But, for a simple list, these three will suffice.

The ViewHolder

The RecyclerView.ViewHolder is responsible for binding data as needed from our model into the widgets for a row in our list:

```
static class ViewHolder extends RecyclerView.ViewHolder {
    TextView label=null;
    TextView size=null;
    ImageView icon=null;
    String template=null;

    ViewHolder(View row) {
        super(row);

        label=(TextView)row.findViewById(R.id.label);
        size=(TextView)row.findViewById(R.id.size);
        icon=(ImageView)row.findViewById(R.id.icon);

        template=size.getContext().getString(R.string.size_template);
    }

    void bindModel(String item) {
        label.setText(item);
        size.setText(String.format(template, item.length()));

        if (item.length()>4) {
            icon.setImageResource(R.drawable.delete);
        }
        else {
            icon.setImageResource(R.drawable.ok);
        }
    }
}
```

RECYCLERVIEW

```
}  
}
```

(from [RecyclerView/SimpleList/app/src/main/java/com/commonsware/android/recyclerview/simplelist/MainActivity.java](#))

However, other than needing to use the base class of `RecyclerView.ViewHolder`, there is no other particular protocol that is mandated between the adapter and the view holder. You can invent your own API. Here, we use the `RowHolder` constructor to pass in the row View, where the constructor retrieves the individual widgets and sets up our string resource template. Then, a private `bindModel()` method takes our model object (a `String`) and binds it to the row's widgets, applying our business rules along the way.

The Results

As the project name suggests, this gives us a simple list:

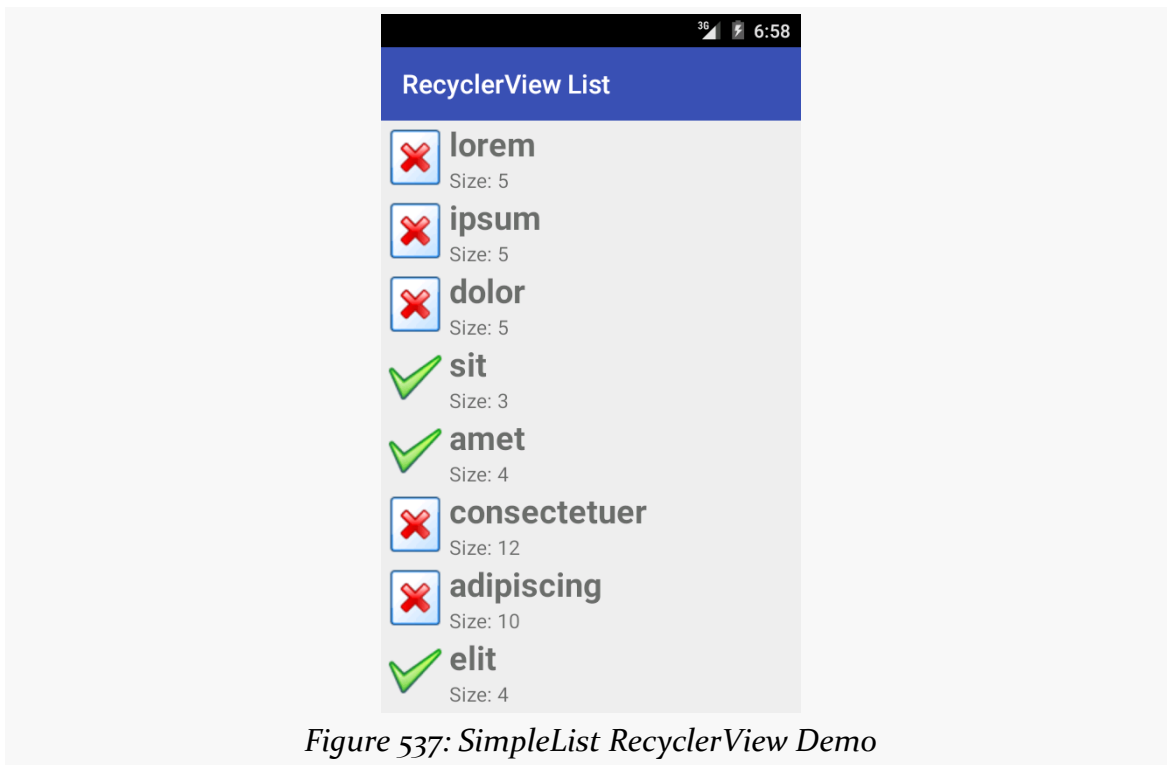

Figure 537: SimpleList RecyclerView Demo

As with `ListView`, `RecyclerView` (along with the `RecyclerView.LayoutManager`) handles the vertical scrolling through our available rows.

What's Missing?

However, we are lacking two things that we had in the Selection/Dynamic edition of this sample that used a `ListView`.

First, there are no dividers between the rows. That may not be a huge issue for this particular row layout, but other layouts may need more assistance in visually separating one row from the next. We will explore ways of accomplishing this [in the next section](#).

Second, we are missing click events. The user can tap on rows as much as she wants. Not only will the user not get any visual feedback from those taps, but we have no `setOnClickListener()` to find out about those taps. We will explore how to fill in this gap [later in the chapter](#).

`RecyclerView` also lacks a variety of other things that we could get from a `ListView`, that we happen to not be using in this sample, such as:

- choice modes, for checklists and such
- header and footer views
- any concept of a “selected” row
- filter support
- and so on

We will explore some of those and how to address them in this chapter.

Divider Options

There are two main approaches for visually separating items in a `RecyclerView`:

1. Ensure that this is handled via the layout itself, such as using a `CardView`
2. Use a `RecyclerView.ItemDecoration` to apply a common divider between items

Both of these techniques will be covered in this chapter.

CardView

Cards are a popular visual metaphor in mobile development. Dividing content collections (or aspects of a larger piece of content) into cards makes it clearer how

RECYCLERVIEW

you can reorganize that content to fit various screen sizes and orientations. In some cases, you might have a single column of cards, while in other cases, you have cards arranged more laterally.

In 2014, Google released `cardview-v7`, another library in the Android Support package, that offers a `CardView`. `CardView` is a simple subclass of `FrameLayout`, designed to provide a card UI, consisting of a rounded rectangle and a drop shadow. In particular, `CardView` will use Android 5.0's default drop shadows based on widget elevation, while offering emulated drop shadows on earlier Android releases. This way, you can get a reasonably consistent look going back to API Level 7.

To use this, you will have to add the `cardview-v7` library to your app project. Android Studio users can just add a dependency on the `cardview-v7` artifact in the Android Support repository, as seen in the [RecyclerView/CardViewList](#) sample project:

```
dependencies {
    implementation 'com.android.support:recyclerview-v7:22.2.0'
    implementation 'com.android.support:cardview-v7:22.2.0'
}
```

(from [RecyclerView/CardViewList/app/build.gradle](#))

Then, you can wrap your row layout in a `CardView` (or, more accurately, in an `android.support.v7.widget.CardView`):

```
<?xml version="1.0" encoding="utf-8"?>
<android.support.v7.widget.CardView
    xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:cardview="http://schemas.android.com/apk/res-auto"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:layout_margin="4dp"
    cardview:cardCornerRadius="4dp">

    <LinearLayout
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:orientation="horizontal">

        <ImageView
            android:id="@+id/icon"
            android:layout_width="wrap_content"
            android:layout_height="wrap_content"
            android:layout_gravity="center_vertical">
```

RECYCLERVIEW

```
        android:padding="2dip"
        android:src="@drawable/ok"
        android:contentDescription="@string/icon"/>

<LinearLayout
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:orientation="vertical">

    <TextView
        android:id="@+id/label"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:textSize="25sp"
        android:textStyle="bold"/>

    <TextView
        android:id="@+id/size"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:textSize="15sp"/>
</LinearLayout>

</LinearLayout>
</android.support.v7.widget.CardView>
```

(from [RecyclerView/CardViewList/app/src/main/res/layout/row.xml](#))

With no other code changes from the original RecyclerView/SimpleList sample, we get this:

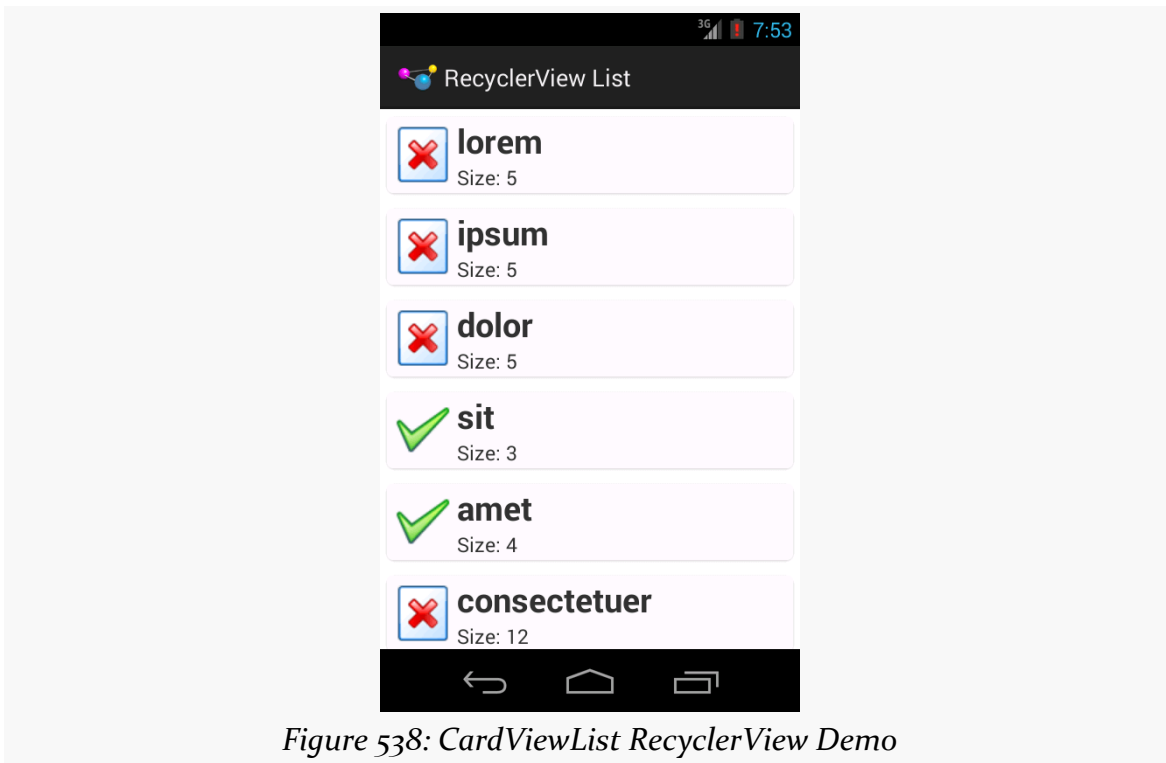

Figure 538: CardViewList RecyclerView Demo

Note that drop shadows from CardView may not show up on Android 5.0+ emulators, particularly if you have Host GPU mode disabled in the emulator AVD. The CardView itself will work fine, just without the drop shadow effect.

Manual

A CardView may not be an appropriate visual approach for your list. Perhaps you want a regular divider, like we had with ListView.divi While that is possible, it is not especially straightforward.

RecyclerView considers things like dividers to be “item decorations”. There is a RecyclerView.ItemDecoration abstract class that you can extend to handle item decoration, and you can attach such a decoration to a RecyclerView via addItemDecoration(). As the name suggests, you can have more than one decorator if needed.

Originally, Google did not bother to provide any concrete implementation of such a decoration. However, they eventually added a DividerItemDecoration class that you can use for a simple, “out of the box” divider.

DividerItemDecoration

The [RecyclerView/DividerList](#) sample project demonstrates the use of `DividerItemDecoration`... which consists of a single call to `addItemDecoration()`:

```
@Override
public void onCreate(Bundle state) {
    super.onCreate(state);

    setLayoutManager(new LinearLayoutManager(this));

    getRecyclerView()
        .addItemDecoration(new DividerItemDecoration(this, LinearLayoutManager.VERTICAL));
    setAdapter(new IconicAdapter());
}
```

(from [RecyclerView/DividerList/app/src/main/java/com/commonsware/android/recyclerview/divider/MainActivity.java](#))

The `DividerItemDecoration` constructor just takes a `Context` and the orientation to use. Here, though, the orientation refers to *the orientation of the RecyclerView*. You might think that using `LinearLayoutManager.VERTICAL` here would mean that the divider would be drawn vertically. Instead, it means that the `RecyclerView` scrolls vertically, so dividers are drawn horizontally.

While `DividerItemDecoration` has a few configuration options — notably, a `setDrawable()` method to override the default artwork to use for the divider — the “out of the box” implementation largely matches the look of the `ListView` divider:

RECYCLERVIEW

DIY Decorators

As noted above, originally `recyclerview-v7` did not come with an actual divider. A few enterprising developers experimented with this, leading to solutions like [this one, published as a GitHub gist](#). The [RecyclerView/ManualDividerList](#) sample project demonstrates the use of such a decoration. It may be that what you want for a decorator is more complex than what `DividerItemDecoration` can offer, and so implementing your own decorator may be necessary.

First, we will need a drawable resource for the divider itself:

```
<?xml version="1.0" encoding="utf-8"?>
<shape xmlns:android="http://schemas.android.com/apk/res/android"
    android:shape="rectangle">

    <size
        android:width="1dp"
        android:height="1dp" />

    <solid android:color="@color/divider" />
</shape>
```

RECYCLERVIEW

```
</shape>
```

(from [RecyclerView/ManualDividerList/app/src/main/res/drawable/item_divider.xml](#))

This is a ShapeDrawable, as is covered in [the chapter on drawables](#). The big thing is the solid fill, here pointing to a color resource for the color to use for that fill:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
  <color name="divider">#ffaafaaa</color>
</resources>
```

(from [RecyclerView/ManualDividerList/app/src/main/res/values/colors.xml](#))

The ShapeDrawable is given a size of 1dp square. In reality, it will be resized on the fly by the decorator to fill the width of the RecyclerView.

Note that there is nothing especially magic about using this particular drawable. You could have a gradient fill to have the divider taper off towards the ends and be solid in the middle. Or, you could use a nine-patch PNG file, a VectorDrawable on Android 5.0+, or anything else that will resize well.

Next, we need a RecyclerView.ItemDecoration implementation, such as the sample project's HorizontalDividerItemDecoration:

```
package com.commonware.android.recyclerview.manualdivider;

import android.graphics.Canvas;
import android.graphics.drawable.Drawable;
import android.support.v7.widget.RecyclerView;
import android.view.View;

// inspired by https://gist.github.com/polbins/e37206fbc444207c0e92

public class HorizontalDividerItemDecoration extends RecyclerView.ItemDecoration {
    private Drawable divider;

    public HorizontalDividerItemDecoration(Drawable divider) {
        this.divider=divider.mutate();
    }

    @Override
    public void onDrawOver(Canvas c, RecyclerView parent, RecyclerView.State state) {
        int left=parent.getPaddingLeft();
        int right=parent.getWidth()-parent.getPaddingRight();

        int childCount=parent.getChildCount();

        for (int i=0; i<childCount-1; i++) {
            View child=parent.getChildAt(i);
```

RECYCLERVIEW

```
RecyclerView.LayoutParams params=
    (RecyclerView.LayoutParams)child.getLayoutParams();

int top=child.getBottom()+params.bottomMargin;
int bottom=top+divider.getIntrinsicHeight();

divider.setBounds(left, top, right, bottom);
divider.draw(c);
}
}
```

(from [RecyclerView/ManualDividerList/app/src/main/java/com/commonsware/android/recyclerview/manualdivider/HorizontalDividerItemDecoration.java](#))

This class takes the Drawable that is the divider as input, so it can be used for different dividers as needed. `HorizontalDividerItemDecoration` calls `mutate()` on the Drawable to get a Drawable that can be changed independently of any original instance of the Drawable. This is important when using Drawable resources, as the Drawable instances get reused for other references to the same resource, so changing the core Drawable itself (e.g., via a `setBounds()` call) is unsafe.

The main logic of `HorizontalDividerItemDecoration` resides in the `onDrawOver()` method. This will be called to let us draw over top of the items in the `RecyclerView`. Here we:

- Determine the left and right extents to draw, relative to the left and right edges of the `RecyclerView`, but subtracting the padding, so that we only draw inside of that padding
- Iterate over the child views of the `RecyclerView`, find the vertical location for that divider, resize the divider to fit the desired space, and then draw the divider on the supplied Canvas, skipping the last child so we do not draw a divider at the bottom of the list

Using that bit of magic, then, is merely a matter of attaching our `HorizontalDividerItemDecoration` to our `RecyclerView`, done here in `onCreate()` of `MainActivity`:

```
@Override
public void onCreate(Bundle state) {
    super.onCreate(state);

    setLayoutManager(new LinearLayoutManager(this));

    Drawable divider=getResources().getDrawable(R.drawable.item_divider);

    getRecyclerView().addItemDecoration(new HorizontalDividerItemDecoration(divider));
    setAdapter(new IconicAdapter());
}
```

RECYCLERVIEW

(from [RecyclerView/ManualDividerList/app/src/main/java/com/commonsware/android/recyclerview/manualdivider/MainActivity.java](#))

The rest of the sample project is a clone of the original `SimpleList` sample project from the beginning of this chapter.

The result is that we have a divider drawn between the children:

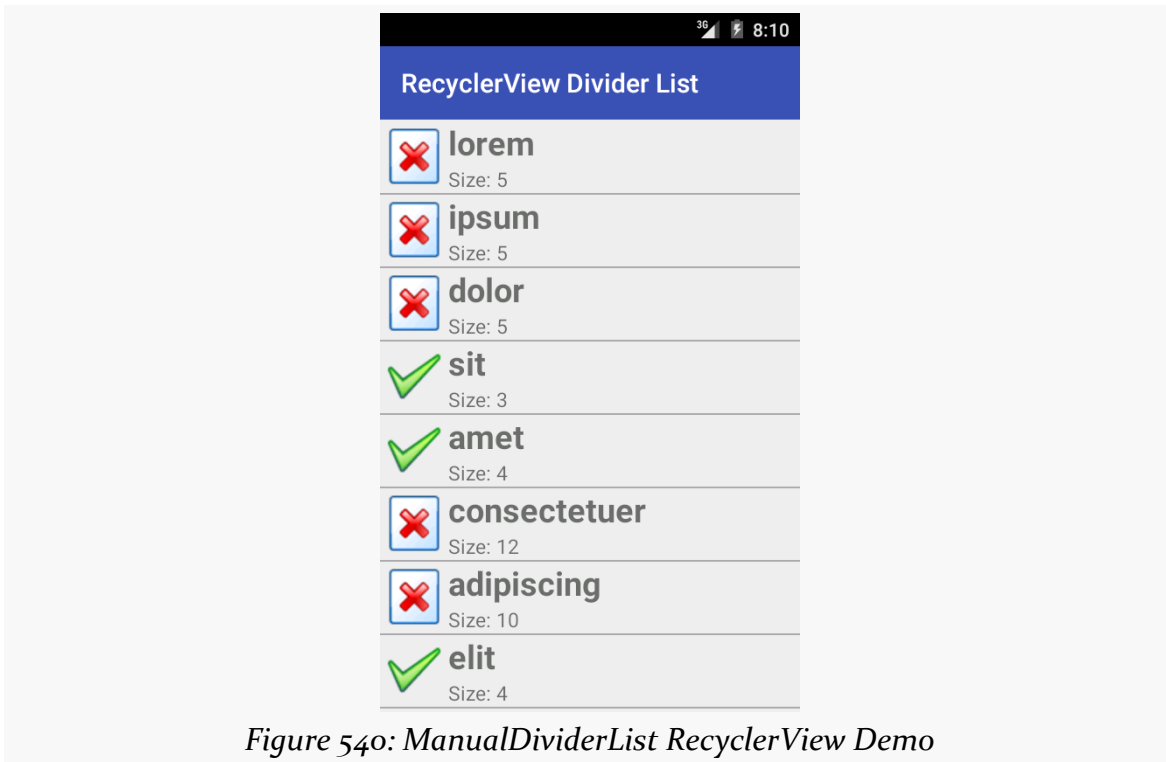

Figure 540: ManualDividerList RecyclerView Demo

Handling Click Events

However, having nice dividers does not address the larger problem: responding to input.

The `RecyclerView` vision, overall, is that `RecyclerView` itself has nothing much to do with input, other than scrolling. Anything having to do with users clicking things and triggering some sort of response is the responsibility of the views inside the `RecyclerView`, such as the rows in a list-style `RecyclerView`.

This has its benefits. Clickable widgets, like a `RatingBar`, in a `ListView` row had long been in conflict with click events on rows themselves. Getting rows that can be clicked, with row contents that can also be clicked, gets a bit tricky at times. With

RecyclerView, you are in more explicit control over how this sort of thing gets handled... because you are the one setting up all of the on-click handling logic.

Of course, that does not help the users much. Users do not care what bit of code is responsible for input. Users simply want to provide the input. If you present them with a vertically-scrolling list-style UI, they will attempt to click on rows in the list and will expect some sort of outcome.

The RecyclerView approach, though, means that you are largely on your own for handling that input. This requires yet more code that, in an ideal world, would be offered as an “out of the box” option by RecyclerView.

Responding to Clicks

At its core, responding to clicks is a matter of setting an `OnClickListener` on the appropriate Views.

So, for example, the [RecyclerView/CardClickList](#) sample project is a clone of the `CardViewList` sample, where we call `setOnClickListener()` on the row View in the `RecyclerView.ViewHolder`, now renamed `RowController`:

```
package com.commonware.android.recyclerview.cardclicklist;

import android.support.v7.widget.RecyclerView;
import android.view.View;
import android.widget.ImageView;
import android.widget.TextView;
import android.widget.Toast;

class RowController extends RecyclerView.ViewHolder
    implements View.OnClickListener {
    TextView label=null;
    TextView size=null;
    ImageView icon=null;
    String template=null;

    RowController(View row) {
        super(row);

        label=(TextView)row.findViewById(R.id.label);
        size=(TextView)row.findViewById(R.id.size);
        icon=(ImageView)row.findViewById(R.id.icon);

        template=size.getContext().getString(R.string.size_template);
    }
}
```

```
        row.setOnClickListener(this);
    }

    @Override
    public void onClick(View v) {
        Toast.makeText(v.getContext(),
            String.format("Clicked on position %d", getAdapterPosition()),
            Toast.LENGTH_SHORT).show();
    }

    void bindModel(String item) {
        label.setText(item);
        size.setText(String.format(template, item.length()));

        if (item.length() > 4) {
            icon.setImageResource(R.drawable.delete);
        }
        else {
            icon.setImageResource(R.drawable.ok);
        }
    }
}
```

(from [RecyclerView/CardClickList/app/src/main/java/com/commonsware/android/recyclerview/cardclicklist/RowController.java](#))

In this sample, all the `onClick()` method does is show a Toast. However, you could:

- Raise an event on an event bus, or
- Call a method on some supplied interface (e.g., passed into the `RowController` constructor) to delegate the event to a higher-order controller, or
- Whatever else might be needed

In this case, since none of the widgets in the row are interactive and might consume click events themselves, the user can tap anywhere on the row, and the Toast will appear. If you have more complex scenarios — such as a checklist where you have a `CheckBox` in the rows — you can decide for yourself how to handle click events on different parts of the row. We will see checklists in action [later in this chapter](#).

Visual Impact of Clicks

However, if you run the `CardClickList` sample, you will notice one major remaining flaw: there is no visual feedback to the user about the click event. Yes, the Toast appears, but users are used to seeing some sort of transient state change in the row

itself on a click, such as a flash of color. Once again, we have the ability to control this as we see fit... by having the responsibility to make it happen at all.

There are a few approaches to this problem, such as the ones outlined in this section.

Option #1: Translucent Selector on Top

An approach that Mark Allison suggested in [his Styling Android blog](#) mimics the `drawSelectorOnTop` approach available to `ListView`. Using something like a `FrameLayout`, you layer a translucent selector atop the rows, where the selector implements the click feedback.

The [RecyclerView/CardRippleList](#) sample project is a clone of `CardClickList` that takes Mr. Allison's approach. The revised `row.xml` takes advantage of the fact that `CardView` is a subclass of `FrameLayout`, so it layers a plain `View` atop the `LinearLayout` that is the core content of the row:

```
<?xml version="1.0" encoding="utf-8"?>
<android.support.v7.widget.CardView
    xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:cardview="http://schemas.android.com/apk/res-auto"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:layout_margin="4dp"
    cardview:cardCornerRadius="4dp">

    <LinearLayout
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:orientation="horizontal">

        <ImageView
            android:id="@+id/icon"
            android:layout_width="wrap_content"
            android:layout_height="wrap_content"
            android:layout_gravity="center_vertical"
            android:padding="2dip"
            android:src="@drawable/ok"
            android:contentDescription="@string/icon"/>

        <LinearLayout
            android:layout_width="match_parent"
            android:layout_height="wrap_content"
            android:orientation="vertical">
```

```
<TextView
    android:id="@+id/label"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:textSize="25sp"
    android:textStyle="bold"/>

<TextView
    android:id="@+id/size"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:textSize="15sp"/>
</LinearLayout>

</LinearLayout>

<View
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:background="?android:attr/selectableItemBackground" />

</android.support.v7.widget.CardView>
```

(from [RecyclerView/CardRippleList/app/src/main/res/layout/row.xml](#))

The background of that View is the `selectableItemBackground` from the current theme. On apps using `Theme`, this will give you an orange flash. On apps using `Theme.Holo`, this will give you a blue flash. On apps using `Theme.Material`, this will give you a ripple animation. And, of course, you can supply your own override value for `selectableItemBackground` to use your own `StateListDrawable` instead.

The downside of this approach is that the View is higher on the Z axis than is the rest of the row content. In this case, since the rest of the row content is non-interactive, this is not a problem. However, if we elect to put interactive widgets in the rows — such as `CheckBox` widgets to implement a checklist — now our View will prevent the user from interacting with those widgets.

Option #2: Background Selector

Another approach would be to apply the `selectableItemBackground` to our existing row content, rather than to some separate selector widget that overlays the row content. This is the approach taken in the [RecyclerView/CardRippleList2](#) sample

RECYCLERVIEW

project. Here, the `selectableItemBackground` is applied to the `LinearLayout` inside of the `CardView`:

```
<?xml version="1.0" encoding="utf-8"?>
<android.support.v7.widget.CardView
    xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:cardview="http://schemas.android.com/apk/res-auto"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:layout_margin="4dp"
    cardview:cardCornerRadius="4dp">

    <LinearLayout
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:orientation="horizontal"
        android:background="?android:attr/selectableItemBackground">

        <ImageView
            android:id="@+id/icon"
            android:layout_width="wrap_content"
            android:layout_height="wrap_content"
            android:layout_gravity="center_vertical"
            android:padding="2dip"
            android:src="@drawable/ok"
            android:contentDescription="@string/icon"/>

        <LinearLayout
            android:layout_width="match_parent"
            android:layout_height="wrap_content"
            android:orientation="vertical">

            <TextView
                android:id="@+id/label"
                android:layout_width="wrap_content"
                android:layout_height="wrap_content"
                android:textSize="25sp"
                android:textStyle="bold"/>

            <TextView
                android:id="@+id/size"
                android:layout_width="wrap_content"
                android:layout_height="wrap_content"
                android:textSize="15sp"/>
        </LinearLayout>
    </LinearLayout>
</CardView>
```

```
</android.support.v7.widget.CardView>
```

(from [RecyclerView/CardRippleList2/app/src/main/res/layout/row.xml](#))

For non-interactive widgets, like our TextViews and ImageView, touch events will get propagated to the LinearLayout, which will trigger the changes in the state of the StateListDrawable that is the LinearLayout background. Yet, if we change the rows to have interactive widgets, those widgets will still be able to process their own touch events, as we will see [later in this chapter](#).

However, particularly for this sample app, the visual effect is largely the same as with CardRippleList: the user will get click feedback based upon the selectableItemBackground in use given the activity's theme.

Option #3: Controlled Ripple Emanation Point

There is one problem with both click event implementations, though: the ripples on Android 5.0 start in the center of each row. According to the Material Design rules, the ripples should start where the touch event occurs, so they seem to flow outward from the finger. This was addressed in Android 5.1, but was a bug in Android 5.0

To fix this, you need to use the `setHotspot()` method, added to Drawable in API Level 21. `setHotspot()` provides to the drawable a “hot spot”, and RippleDrawable apparently uses this as the emanation point for the ripple effect. `setHotspot()` takes a pair of float values, presumably with an eye towards using `setHotspot()` inside of an `OnTouchListener`, as the `MotionEvent` reports X/Y positions of the touch event with float values.

The [RecyclerView/CardRippleList3](#) sample project is a clone of CardRipple2 that adds this feature.

The row layout is the same as before. However, in `RowController`, when setting up the row, we register an `OnTouchListener`, to find out the low-level `MotionEvent` of when the user touches our row:

```
RowController(View row) {  
    super(row);  
  
    label=(TextView)row.findViewById(R.id.label);  
    size=(TextView)row.findViewById(R.id.size);  
    icon=(ImageView)row.findViewById(R.id.icon);  
}
```

RECYCLERVIEW

```
template=size.getContext().getString(R.string.size_template);

row.setOnClickListener(this);

if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.LOLLIPOP) {
    row.setOnTouchListener(new View.OnTouchListener() {
        @TargetApi(Build.VERSION_CODES.LOLLIPOP)
        @Override
        public boolean onTouch(View v, MotionEvent event) {
            v
                .findViewById(R.id.row_content)
                .getBackground()
                .setHotspot(event.getX(), event.getY());

            return(false);
        }
    });
}
```

(from [RecyclerView/CardRippleList3/app/src/main/java/com/commonsware/android/recyclerview/cardripplelist3/RowController.java](#))

We only bother registering this listener on API Level 21+, as there is no `setHotspot()` method on prior versions of Android and therefore no need for the listener. However, *if* we are on an Android 5.0+ device, we intercept the touch event, pass it along to `setHotspot()` on the background Drawable, and return `false` to ensure that regular touch event processing proceeds.

The effect is subtle and may be difficult for you to discern. But, if you look at the touch events in slow motion (e.g., screen record a session, then examine the resulting video frame-by-frame), you will see that the ripple effect appears to emanate from the touch point, rather than from the row's center as before. And, since this logic is only used on API Level 21+, older devices are unaffected.

What About Cursors?

So far, our model data has been a simple static array. Often times, though, we need to be working with model data culled from a database or ContentProvider. It may be that, for other reasons, we want to convert the Cursor we get back from queries into an array of ordinary Java objects. However, there is nothing stopping us from using a Cursor more directly as the model for a RecyclerView.

The `RecyclerView.Adapter` is responsible for teaching the `RecyclerView.ViewHolder` the model data to bind against. The

RECYCLERVIEW

RecyclerView.Adapter base class is oblivious to how that model data is organized: array, ArrayList, Cursor, JSONArray, etc. And the actual bind-the-data logic for the RecyclerView.ViewHolder is our responsibility — again, the base class is oblivious to where the data is coming from. Hence, we can create our own protocol for passing the model data for the needed position from the RecyclerView.Adapter to the RecyclerView.ViewHolder. If we want to use a Cursor as the vehicle for doing this, we are welcome to do so.

This is illustrated in the [RecyclerView/VideoList](#) sample project, which is a clone of the VideoList project introduced in [the chapter on the MediaStore ContentProvider](#). In the original sample, the list was a ListView; in this sample, the list is a RecyclerView.

The core “plumbing” of the app is akin to the previous RecyclerView samples, such as using RecyclerViewActivity for handling getting the RecyclerView on the screen. However, our row layout is now based on the original VideoList row:

```
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:orientation="horizontal"
    android:padding="8dp"
    android:background="?android:attr/selectableItemBackground">

    <ImageView
        android:id="@+id/thumbnail"
        android:layout_width="64dp"
        android:layout_height="64dp"
        android:contentDescription="@string/thumbnail"/>

    <TextView
        android:id="@android:id/text1"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:layout_marginLeft="8dp"
        android:layout_gravity="center_vertical"
        android:textSize="24sp"/>

</LinearLayout>
```

(from [RecyclerView/VideoList/app/src/main/res/layout/row.xml](#))

However, as we will now be accessing media, we need the READ_EXTERNAL_STORAGE permission, so we request that in the manifest:

RECYCLERVIEW

```
<?xml version="1.0"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
    package="com.commonware.android.recyclerview.videolist"
    android:versionCode="1"
    android:versionName="1.0">

    <supports-screens
        android:anyDensity="true"
        android:largeScreens="true"
        android:normalScreens="true"
        android:smallScreens="true"/>

    <uses-permission android:name="android.permission.READ_EXTERNAL_STORAGE" />

    <application
        android:icon="@drawable/ic_launcher"
        android:theme="@style/Theme.Apptheme">
        <activity
            android:name=".MainActivity"
            android:label="@string/app_name">
            <intent-filter>
                <action android:name="android.intent.action.MAIN"/>

                <category android:name="android.intent.category.LAUNCHER"/>
            </intent-filter>
        </activity>
    </application>
</manifest>
```

(from [RecyclerView/VideoList/app/src/main/AndroidManifest.xml](#))

And our app/build.gradle file gives us a targetSdkVersion of 23, requiring us to deal with runtime permissions on Android 6.0+:

```
apply plugin: 'com.android.application'

dependencies {
    implementation 'com.android.support.recyclerview-v7:23.4.0'
    implementation 'com.squareup.picasso:picasso:2.5.2'
}

android {
    compileSdkVersion 23
    buildToolsVersion '26.0.2'

    defaultConfig {
        minSdkVersion 15
    }
}
```

RECYCLERVIEW

```
        targetSdkVersion 23
    }
}
```

(from [RecyclerView/VideoList/app/build.gradle](#))

`onCreate()` sets up the empty `RecyclerView` with a `LinearLayoutManager` and a `VideoAdapter` (that we will examine shortly). However, we also confirm whether we have `READ_EXTERNAL_STORAGE` already — if yes, we call `loadVideos()` to get the videos. If we do not have permission, and we are not in the middle of requesting permission, we ask for permission using `requestPermissions()`:

```
private static final String STATE_IN_PERMISSION="inPermission";
private static final int REQUEST_PERMS=137;
private boolean isInPermission=false;

@Override
public void onCreate(Bundle state) {
    super.onCreate(state);

    setLayoutManager(new LinearLayoutManager(this));
    setAdapter(new VideoAdapter());

    if (state!=null) {
        isInPermission=
            state.getBoolean(STATE_IN_PERMISSION, false);
    }

    if (hasFilesPermission()) {
        loadVideos();
    }
    else if (!isInPermission) {
        isInPermission=true;

        ActivityCompat.requestPermissions(this,
            new String[] {Manifest.permission.READ_EXTERNAL_STORAGE},
            REQUEST_PERMS);
    }
}
```

(from [RecyclerView/VideoList/app/src/main/java/com/commonsware/android/recyclerview/videolist/MainActivity.java](#))

`hasFilesPermission()` just uses `checkSelfPermission()` to see whether we can read external storage:

```
private boolean hasFilesPermission() {
    return(ContextCompat.checkSelfPermission(this,
```

RECYCLERVIEW

```
Manifest.permission.READ_EXTERNAL_STORAGE)==  
PackageManager.PERMISSION_GRANTED);  
}
```

(from [RecyclerView/VideoList/app/src/main/java/com/commonsware/android/recyclerview/videolist/MainActivity.java](#))

We then call `loadVideos()` once we have permission, plus keep track of whether or not we are in the process of requesting permissions (so we do not raise the permission dialog again if we undergo a configuration change while the permission dialog is already on-screen):

```
@Override  
protected void onSaveInstanceState(Bundle outState) {  
    super.onSaveInstanceState(outState);  
  
    outState.putBoolean(STATE_IN_PERMISSION, isInPermission);  
}  
  
@Override  
public void onRequestPermissionsResult(int requestCode,  
                                       String[] permissions,  
                                       int[] grantResults) {  
  
    isInPermission=false;  
  
    if (requestCode==REQUEST_PERMS) {  
        if (hasFilesPermission()) {  
            loadVideos();  
        }  
        else {  
            finish(); // denied permission, so we're done  
        }  
    }  
}
```

(from [RecyclerView/VideoList/app/src/main/java/com/commonsware/android/recyclerview/videolist/MainActivity.java](#))

`loadVideos()` just calls `initLoader()` to request that we load the videos from the MediaStore:

```
private void loadVideos() {  
    getLoaderManager().initLoader(0, null, this);  
}
```

(from [RecyclerView/VideoList/app/src/main/java/com/commonsware/android/recyclerview/videolist/MainActivity.java](#))

RECYCLERVIEW

The CursorLoader logic, for getting details about videos from the MediaStore, is pretty much the same as before, other than providing the Cursor to the VideoAdapter when it is ready:

```
@Override
public Loader<Cursor> onCreateLoader(int arg0, Bundle arg1) {
    return(new CursorLoader(this,
        MediaStore.Video.Media.EXTERNAL_CONTENT_URI,
        null, null, null,
        MediaStore.Video.Media.TITLE));
}

@Override
public void onLoadFinished(Loader<Cursor> loader, Cursor c) {
    ((VideoAdapter)getAdapter()).setVideos(c);
}

@Override
public void onLoaderReset(Loader<Cursor> loader) {
    ((VideoAdapter)getAdapter()).setVideos(null);
}
```

(from [RecyclerView/VideoList/app/src/main/java/com/commonsware/android/recyclerview/videlist/MainActivity.java](#))

VideoAdapter is another subclass of RecyclerView.Adapter, this time with smarts for dealing with a Cursor as the source of model data:

```
class VideoAdapter extends RecyclerView.Adapter<RowController> {
    Cursor videos=null;

    @Override
    public RowController onCreateViewHolder(ViewGroup parent, int viewType) {
        return(new RowController(getLayoutInflater()
            .inflate(R.layout.row, parent, false)));
    }

    void setVideos(Cursor videos) {
        this.videos=videos;
        notifyDataSetChanged();
    }

    @Override
    public void onBindViewHolder(RowController holder, int position) {
        videos.moveToPosition(position);
        holder.bindModel(videos);
    }
}
```

RECYCLERVIEW

```
@Override
public int getItemCount() {
    if (videos==null) {
        return(0);
    }

    return(videos.getCount());
}
}
```

(from [RecyclerView/VideoList/app/src/main/java/com/commonsware/android/recyclerview/videolist/MainActivity.java](#))

Specifically:

- `getItemCount()` returns the count of videos from the Cursor, or 0 if the Cursor is null (mimicking the behavior of CursorAdapter, which also treats a null Cursor as merely being one that has no rows)
- `onCreateViewHolder()` creates the RowController
- `onBindViewHolder()` moves the Cursor to the desired position, then passes the Cursor over to the RowController

Also note that we have a `setVideos()` method that is used to associate our Cursor of video information with the adapter. This also triggers a call to `notifyDataSetChanged()`, to ensure that the RecyclerView knows that our model has changed and it should re-render its contents.

The RowController constructor retrieves the necessary widgets from the row and setting up an OnClickListener:

```
RowController(View row) {
    super(row);

    title=(TextView)row.findViewById(android.R.id.text1);
    thumbnail=(ImageView)row.findViewById(R.id.thumbnail);

    row.setOnClickListener(this);
}
```

(from [RecyclerView/VideoList/app/src/main/java/com/commonsware/android/recyclerview/videolist/RowController.java](#))

The `bindModel()` method invoked by `onBindViewHolder()` on VideoAdapter uses the same basic logic from the original VideoList sample to populate the row widgets, plus holds onto the Uri and MIME type of the video in data members for the current row:

RECYCLERVIEW

```
void bindModel(Cursor row) {
    title.setText(row.getString(
        row.getColumnIndex(MediaStore.Video.Media.TITLE)));

    videoUri=
        ContentUris.withAppendedId(
            MediaStore.Video.Media.EXTERNAL_CONTENT_URI,
            row.getInt(row.getColumnIndex(MediaStore.Video.Media._ID)));

    Picasso.with(thumbnail.getContext())
        .load(videoUri.toString())
        .fit().centerCrop()
        .placeholder(R.drawable.ic_media_video_poster)
        .into(thumbnail);

    int uriColumn=row.getColumnIndex(MediaStore.Video.Media.DATA);
    int mimeTypeColumn=
        row.getColumnIndex(MediaStore.Video.Media.MIME_TYPE);

    videoMimeType=row.getString(mimeTypeColumn);
}
```

(from [RecyclerView/VideoList/app/src/main/java/com/commonsware/android/recyclerview/videlist/RowController.java](#))

The `onClick()` method uses those saved `Uri` and `MIME` type values for starting up the activity to play the selected video:

```
@Override
public void onClick(View v) {
    Intent i=new Intent(Intent.ACTION_VIEW);

    i.setDataAndType(videoUri, videoMimeType);
    title.getContext().startActivity(i);
}
```

(from [RecyclerView/VideoList/app/src/main/java/com/commonsware/android/recyclerview/videlist/RowController.java](#))

Other than the lack of dividers, the UI is very similar to the original `VideoList`.

This sample app is used as the basis for many other samples in this book, such as the [drag-and-drop examples](#).

Grids

So far, we have focused on one visual representation of our collection of model data: a vertically-scrolling list. In the `AdapterView` family, a given `AdapterView` subclass

has a specific visual representation (`ListView` for a vertically-scrolling list, `GridView` for a two-dimensional grid, etc.). With `RecyclerView`, the choice of layout manager determines most of the visual representation, and so switching from a list to a grid can be as simple as a single-line change to our code.

The key, though, is the word *can* in the previous sentence. Depending upon what you want to do, a grid-styled `RecyclerView` can be more complicated, simply because you now have two dimensions' worth of power and configuration to play with.

A Simple Grid

Making a `RecyclerView` use a grid is a matter of swapping out `LinearLayoutManager` for `GridLayoutManager`. In the [RecyclerView/Grid](#) sample project, you will see a clone of the `CardRippleList3` sample app, where we are now using `GridLayoutManager` in `onCreate()` of `MainActivity`:

```
@Override
public void onCreate(Bundle state) {
    super.onCreate(state);

    setLayoutManager(new GridLayoutManager(this, 2));
    setAdapter(new IconicAdapter());
}
```

(from [RecyclerView/Grid/app/src/main/java/com/commonsware/android/recyclerview/grid/MainActivity.java](#))

`GridLayoutManager` takes a number of “spans”, as well as a `Context`, as constructor parameters. In the simple case, as is with this app, “spans” will equate to “columns”: each item returned by the `RecyclerView.Adapter` will go into a single-row, single-span cell.

In our case, we requested two spans, and so our result resides in two columns:

RECYCLERVIEW

In this case, this is a “true” grid, with rows and columns of cells. Hence, the height of a row is determined by the tallest cell in that row. The “amet” cell in the left column of the third row is taller than required because of the word-wrap of the “consectetuer” cell in the right column of the same row, for example. [Later in this chapter](#), we will examine yet another option, `StaggeredGridLayoutManager`, where cells do not necessarily line up neatly in rows.

Choosing the Number of Columns

If we rotate the screen for the above sample, you will see that the cells fit a bit better, since they are really repurposed list-style rows:

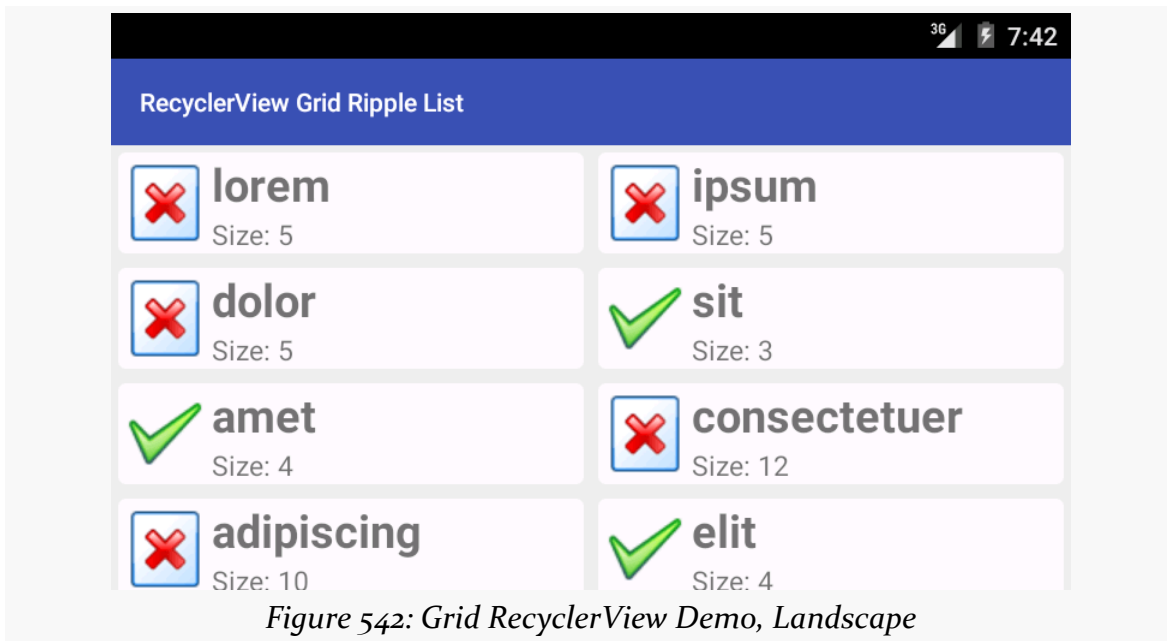

Figure 542: Grid RecyclerView Demo, Landscape

However, some apps may have smaller per-cell content. Plus, we have tablets to consider, and perhaps even televisions. It may be that you want to determine how many spans to use based on screen size and orientation.

One approach for doing that would be to use integer resources. You could have a `res/values/integers.xml` file with `<integer>` elements, giving the integer a name (name attribute) and value (text of the `<integer>` node). You could also have `res/values-w600dp/integers.xml` or other variations of the resource, where you provide different values to use for different screen sizes. Then, at runtime, call `getResources().getInteger()` to retrieve the correct value of the resource to use for the current device, and use that in your `GridLayoutManager` constructor. Now, you are in control over how many columns there are, by controlling how many spans are supplied to the constructor.

Another approach, [suggested by Chiu-Ki Chan](#), is to create a subclass of `RecyclerView`, on which you provide a custom attribute for a desired approximate column width. Then, in your subclass' `onMeasure()` method, you can *calculate* the number of spans to use to give you the desired column width.

Of course, another way to take advantage of screen space is to grow the cells. By default, they will grow evenly, as each cell takes up one span, and the spans are evenly sized. However, you can change that behavior, by attaching a `GridLayoutManager.SpanSizeLookup` to the `GridLayoutManager`. The

`GridLayoutManager.SpanSizeLookup` is responsible for indicating, for a given item's position, how many spans it should take up in the grid. We will examine how this works [later in this chapter](#).

Varying the Items

So far, all of the items in the `RecyclerView` have had the same basic structure, just with varying content in the widgets in those items. But, it is entirely possible that we will want to have some items be more substantively different, based on different layouts. `ListView` and kin handle this via `getViewTypeCount()` and `getItemViewType()` in the `ListAdapter`. `RecyclerView` and `RecyclerView.Adapter` offer a similar mechanism, including their own variant of the `getItemViewType()` method. In this section, we will examine how this works, both with lists and grids.

A List with Headers

There are many cases where we want to have a list with some sort of section headers. The look of the headers usually is substantially different than the look of the rest of the rows, and therefore the best way to handle this is to teach the adapter about multiple row types.

This can be seen in the [RecyclerView/HeaderList](#) sample project. This is a clone of a similar project for `ListView`, where we want to put the 25 Latin words into 5 groups of 5 words each, with each group getting its own header.

Hence, our model data is now a two-dimensional `String` array:

```
private static final String[][] items= {
    { "lorem", "ipsum", "dolor", "sit", "amet" },
    { "consectetuer", "adipiscing", "elit", "morbi", "vel" },
    { "ligula", "vitae", "arcu", "aliquet", "mollis" },
    { "etiam", "vel", "erat", "placerat", "ante" },
    { "porttitor", "sodales", "pellentesque", "augue", "purus" } };
```

(from [RecyclerView/HeaderList/app/src/main/java/com/commonsware/android/recyclerview/headerlist/MainActivity.java](#))

Our `getItemCount()` method now needs to take into account the headers, as well as the regular rows. There is one header row per batch of items, and so `getItemCount()` sums up the sizes of the batches with the extra header rows:

```
@Override
public int getItemCount() {
```

RECYCLERVIEW

```
int count=0;

for (String[] batch : items) {
    count+=1 + batch.length;
}

return(count);
}
```

(from [RecyclerView/HeaderList/app/src/main/java/com/commonsware/android/recyclerview/headerlist/MainActivity.java](#))

In order to teach RecyclerView about our different rows, we need to implement `getItemViewType()`. Unlike its counterpart on `ListAdapter`, `getItemViewType()` can return *any* int value, so long as it is unique for the row type. In fact, the recommendation is to use dedicated ID resources to ensure that uniqueness.

To that end, we define two ID resources, in a `res/values/ids.xml` file:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
    <item type="id" name="header"/>
    <item type="id" name="detail"/>
</resources>
```

(from [RecyclerView/HeaderList/app/src/main/res/values/ids.xml](#))

Then, `getItemViewType()` can return `R.id.header` or `R.id.detail` to identify the two row types, and specifically which row type corresponds to the supplied position:

```
@Override
public int getItemViewType(int position) {
    if (getItem(position) instanceof Integer) {
        return(R.id.header);
    }

    return(R.id.detail);
}

private Object getItem(int position) {
    int offset=position;
    int batchSize=0;

    for (String[] batch : items) {
        if (offset == 0) {
            return(Integer.valueOf(batchIndex));
        }
    }
}
```

RECYCLERVIEW

```
offset--;

if (offset < batch.length) {
    return(batch[offset]);
}

offset-=batch.length;
batchIndex++;
}

throw new IllegalArgumentException("Invalid position: "
    + String.valueOf(position));
}
```

(from [RecyclerView/HeaderList/app/src/main/java/com/commonsware/android/recyclerview/headerlist/MainActivity.java](#))

This leverages a copy of the `getItem()` method from the original `ListView` version of this sample, which returns an `Integer` for a header item (identifying which header it is) and a `String` for detail item (identifying what Latin word to use). Note that `getItem()` is not part of the `RecyclerView.Adapter` protocol, but you are certainly welcome to have one if you want it.

In `onCreateViewHolder()`, we can now start paying attention to the second parameter, which we have been studiously ignoring until now. That value, `viewType`, will be a value that we returned from `getItemViewType()`, and it indicates what sort of `RecyclerView.ViewHolder` we should return. In our case, there are only two possibilities, and so we just inflate the appropriate layout and use a dedicated controller class (`HeaderController` for headers, `RowController` for detail):

```
@Override
public RecyclerView.ViewHolder onCreateViewHolder(ViewGroup parent, int viewType) {
    if (viewType==R.id.detail) {
        return(new RowController(getLayoutInflater()
            .inflate(R.layout.row, parent, false)));
    }

    return(new HeaderController(getLayoutInflater()
        .inflate(R.layout.header, parent, false)));
}
```

(from [RecyclerView/HeaderList/app/src/main/java/com/commonsware/android/recyclerview/headerlist/MainActivity.java](#))

Similarly, our binding logic in `onBindViewHolder()` needs to route the right sort of model information to the proper controller:

```
@Override
public void onBindViewHolder(RecyclerView.ViewHolder holder, int position) {
```

RECYCLERVIEW

```
    if (holder instanceof RowController) {
        ((RowController)holder).bindModel((String)getItem(position));
    }
    else {
        ((HeaderController)holder).bindModel((Integer)getItem(position));
    }
}
```

(from [RecyclerView/HeaderList/app/src/main/java/com/commonsware/android/recyclerview/headerlist/MainActivity.java](#))

RowController is the same sort of setup as we have had in past examples. HeaderController is too, though it is far simpler, as we have only one widget needing to be updated (a TextView named label) and we do not care about click events:

```
package com.commonsware.android.recyclerview.headerlist;

import android.support.v7.widget.RecyclerView;
import android.view.View;
import android.widget.TextView;

class HeaderController extends RecyclerView.ViewHolder {
    TextView label=null;
    String template=null;

    HeaderController(View row) {
        super(row);

        label=(TextView)row.findViewById(R.id.label);

        template=label.getContext().getString(R.string.header_template);
    }

    void bindModel(Integer headerIndex) {
        label.setText(String.format(template, headerIndex.intValue()+1));
    }
}
```

(from [RecyclerView/HeaderList/app/src/main/java/com/commonsware/android/recyclerview/headerlist/HeaderController.java](#))

The results are header rows with one look-and-feel, and detail rows with a different look-and-feel:

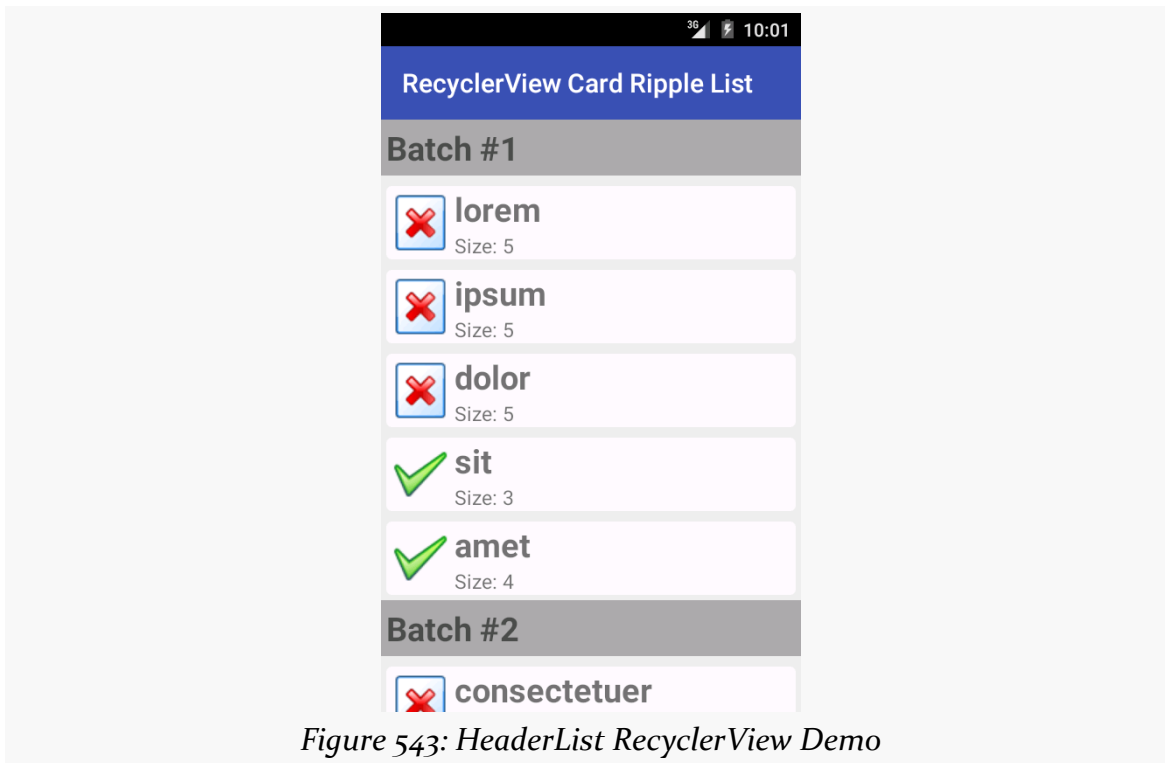

Figure 543: HeaderList RecyclerView Demo

A Grid-Style Table

In the discussion of RecyclerView grids, we saw that one way to take advantage of larger screens is to have more cells, in part by having more spans across the screen.

Another way to take advantage of screen space is to grow the cells. By default, they will grow evenly, as each cell takes up one span, and the spans are evenly sizes. However, you can change that behavior, by attaching a `GridLayoutManager.SpanSizeLookup` to the `GridLayoutManager`. The `GridLayoutManager.SpanSizeLookup` is responsible for indicating, for a given item's position, how many spans it should take up in the grid.

One way of employing a `GridLayoutManager.SpanSizeLookup` is to make a table. If you want a table, but the user should only be able to select rows, that would be a matter of using a `LinearLayoutManager` and setting up the rows with "cells" that are of consistent size per row. For example, each row could be a horizontal `LinearLayout`, where the "column" widths are determined using `android:layout_weight`. But sometimes you want a table where individual cells can be clicked upon (or selected via a five-way navigation option, like a trackball). In this case, `GridLayoutManager.SpanSizeLookup` will let you indicate, for a "column" of

RECYCLERVIEW

your output, how many spans the cell should take up. By using a consistent number of spans for each column, you can get the same sort of weighted column width that you might get with `LinearLayout`-based rows in a `LinearLayoutManager`-powered `RecyclerView`.

And that will make a lot more sense (hopefully) when you see an example.

The [RecyclerView/VideoTable](#) sample project is a clone of the `VideoList` sample project from earlier in the chapter, with a few changes:

- We are going to use a `GridLayoutManager`, yet still organize our output into logical rows, by having three cells per row (title, thumbnail, and video duration)
- We are going to use `GridLayoutManager.SpanSizeLookup` to control the widths of each column in our grid
- Because our cells have varying content (`ImageView` in one, `TextView` in others), we will use different controllers for those cells, each optimized for handling that cell's sort of content

The two columns that will hold text (title and video duration) will use the following layout:

```
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:orientation="horizontal"
    android:padding="8dp"
    android:background="?android:attr/selectableItemBackground">

    <TextView
        android:id="@android:id/text1"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:layout_marginLeft="8dp"
        android:layout_gravity="center_vertical"
        android:textSize="24sp"/>
</LinearLayout>
```

(from [RecyclerView/VideoTable/app/src/main/res/layout/label.xml](#))

The `LinearLayout` root element may seem superfluous, but we are using it for the `selectableItemBackground`, to provide a response when the cell is clicked upon.

Similarly, we have a layout dedicated to the thumbnail:

RECYCLERVIEW

```
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:orientation="horizontal"
    android:padding="8dp"
    android:background="?android:attr/selectableItemBackground">

    <ImageView
        android:id="@+id/thumbnail"
        android:layout_width="96dp"
        android:layout_height="72dp"
        android:contentDescription="@string/thumbnail"/>

</LinearLayout>
```

(from [RecyclerView/VideoTable/app/src/main/res/layout/thumbnail.xml](#))

onCreate() of MainActivity is largely the same as before. This time, though, we are creating an instance of a ColumnWeightSpanSizeLookup class and using it for two things:

1. Calling its getTotalSpans() to tell the GridLayoutManager how many spans to use
2. Using it as a GridLayoutManager.SpanSizeLookup, attaching it to the GridLayoutManager via setSpanSizeLookup():

```
ColumnWeightSpanSizeLookup spanSizer=new ColumnWeightSpanSizeLookup(COLUMN_WEIGHTS);
GridLayoutManager mgr=new GridLayoutManager(this, spanSizer.getTotalSpans());

mgr.setSpanSizeLookup(spanSizer);
setLayoutManager(mgr);
setAdapter(new VideoAdapter());
```

(from [RecyclerView/VideoTable/app/src/main/java/com/commonsware/android/recyclerview/videtable/MainActivity.java](#))

The latter point means that ColumnWeightSpanSizeLookup is a subclass of the abstract GridLayoutManager.SpanSizeLookup base class. The one method that you need to override in a GridLayoutManager.SpanSizeLookup subclass is getSpanSize(). Given an item's position, getSpanSize() returns the number of spans that the item's cell should... um... span.

(we overload the word “span” a lot in Android...)

ColumnWeightSpanSizeLookup handles this via a set of column weights, which it gets as an int array in the constructor. onCreate() referenced a COLUMN_WEIGHTS static data member for the weights:

RECYCLERVIEW

```
private static final int[] COLUMN_WEIGHTS={1, 4, 1};
```

(from [RecyclerView/VideoTable/app/src/main/java/com/commonsware/android/recyclerview/videotable/MainActivity.java](#))

This int array tells us both how many columns there are and how wide each column should be, in terms of spans.

Converting the position to a column index is a matter of applying the modulo (%) operator, so the implementation of `getSpanSize()` on `ColumnWeightSpanSizeLookup` just returns the `columnWeights` value for the desired column:

```
package com.commonsware.android.recyclerview.videotable;

import android.support.v7.widget.GridLayoutManager;

class ColumnWeightSpanSizeLookup extends GridLayoutManager.SpanSizeLookup {
    private final int[] columnWeights;

    ColumnWeightSpanSizeLookup(int[] columnWeights) {
        this.columnWeights=columnWeights;
    }

    @Override
    public int getSpanSize(int position) {
        return(columnWeights[position % columnWeights.length]);
    }

    int getTotalSpans() {
        int sum=0;

        for (int weight : columnWeights) {
            sum+=weight;
        }

        return(sum);
    }
}
```

(from [RecyclerView/VideoTable/app/src/main/java/com/commonsware/android/recyclerview/videotable/ColumnWeightSpanSizeLookup.java](#))

`getTotalSpans()` is a convenience method, to sum all of the column weights. That is how many spans the `GridLayoutManager` will use overall, with each column getting its specific number of spans based upon the int array. Note that while we hard-coded the int array values in this case, there is nothing stopping us from using

RECYCLERVIEW

<integer-array> resources to pull these values out of the Java code, and perhaps even vary them by screen size or other configuration variations.

All of that will set up our grid with the correct number of spans and the right number of spans to use per column of the output. The combination will give us the row structure, as each row's worth of columns uses all of the spans for that row, forcing `GridLayoutManager` to put subsequent items on the next row.

The rest of the project is focused on having different widgets for those different cells, using `getItemViewType()` and so on.

The `VideoAdapter` implementation of `getItemViewType()` simply returns the position modulo 3, to return a unique value (in this case, 0, 1, or 2):

```
@Override
public int getItemViewType(int position) {
    return(position % 3);
}
```

(from [RecyclerView/VideoTable/app/src/main/java/com/commonsware/android/recyclerview/videotable/MainActivity.java](#))

`getItemCount()` takes into account that there are three cells per video, and so the number of items being managed by this adapter is triple the number of videos:

```
@Override
public int getItemCount() {
    if (videos==null) {
        return(0);
    }

    return(videos.getCount()*3);
}
```

(from [RecyclerView/VideoTable/app/src/main/java/com/commonsware/android/recyclerview/videotable/MainActivity.java](#))

The `onCreateViewHolder()` and `onBindViewHolder()` methods take into account those three item types, using a `VideoThumbnailController` or a `VideoTextController` depending on the item type. Both of those classes will inherit from a `BaseVideoController`, which defines a `bindModel()` method that `onBindViewHolder()` can use:

```
@Override
public BaseVideoController onCreateViewHolder(ViewGroup parent, int viewType) {
    BaseVideoController result=null;

    switch(viewType) {
```

RECYCLERVIEW

```
case 0:
    result=new VideoThumbnailController(getLayoutInflater()
        .inflate(R.layout.thumbnail,
            parent, false));
    break;

case 1:
    int cursorColumn=videos.getColumnIndex(MediaStore.Video.VideoColumns.DISPLAY_NAME);

    result=new VideoTextController(getLayoutInflater()
        .inflate(R.layout.label,
            parent, false),
        android.R.id.text1,
        cursorColumn);

    break;

case 2:
    cursorColumn=videos.getColumnIndex(MediaStore.Video.VideoColumns.DURATION);

    result=new VideoTextController(getLayoutInflater()
        .inflate(R.layout.label,
            parent, false),
        android.R.id.text1,
        cursorColumn);

    break;
}

return(result);
}

@Override
public void onBindViewHolder(BaseVideoController holder, int position) {
    videos.moveToPosition(position/3);
    holder.bindModel(videos);
}
```

(from [RecyclerView/VideoTable/app/src/main/java/com/commonsware/android/recyclerview/videtable/MainActivity.java](#))

BaseVideoController handles click events on the cell, along with collecting the Uri and MIME type of the video to use on click events:

```
package com.commonsware.android.recyclerview.videtable;

import android.content.ContentUris;
import android.content.Intent;
import android.database.Cursor;
import android.net.Uri;
import android.provider.MediaStore;
import android.support.v7.widget.RecyclerView;
import android.view.View;

abstract class BaseVideoController extends RecyclerView.ViewHolder
    implements View.OnClickListener {
    private Uri videoUri=null;
    private String videoMimeType=null;
```

RECYCLERVIEW

```
BaseVideoController(View cell) {
    super(cell);

    cell.setOnClickListener(this);
}

@Override
public void onClick(View v) {
    Intent i=new Intent(Intent.ACTION_VIEW);

    i.setDataAndType(videoUri, videoMimeType);
    itemView.getContext().startActivity(i);
}

void bindModel(Cursor row) {
    int mimeTypeColumn=
        row.getColumnIndex(MediaStore.Video.Media.MIME_TYPE);

    videoUri=ContentUris.withAppendedId(
        MediaStore.Video.Media.EXTERNAL_CONTENT_URI,
        row.getInt(row.getColumnIndex(MediaStore.Video.Media._ID)));
    videoMimeType=row.getString(mimeTypeColumn);
}
}
```

(from [RecyclerView/VideoTable/app/src/main/java/com/commonsware/android/recyclerview/videotable/BaseVideoController.java](#))

VideoTextController extends BaseVideoController and handles binding some column from the MediaStore Cursor to a TextView with some ID:

```
package com.commonsware.android.recyclerview.videotable;

import android.database.Cursor;
import android.view.View;
import android.widget.TextView;

class VideoTextController extends BaseVideoController {
    private TextView label=null;
    private int cursorColumn;

    VideoTextController(View cell, int labelId, int cursorColumn) {
        super(cell);
        this.cursorColumn=cursorColumn;

        label=(TextView)cell.findViewById(labelId);
    }
}
```

RECYCLERVIEW

```
@Override
void bindModel(Cursor row) {
    super.bindModel(row);

    label.setText(row.getString(cursorColumn));
}
}
```

(from [RecyclerView/VideoTable/app/src/main/java/com/commonsware/android/recyclerview/videotable/VideoTextController.java](#))

VideoThumbnailController handles using Picasso to get the video thumbnail asynchronously and binding it to an ImageView in the inflated cell View:

```
package com.commonsware.android.recyclerview.videotable;

import android.content.ContentUri;
import android.database.Cursor;
import android.net.Uri;
import android.provider.MediaStore;
import android.view.View;
import android.widget.ImageView;
import com.squareup.picasso.Picasso;

class VideoThumbnailController extends BaseVideoController {
    private ImageView thumbnail=null;

    VideoThumbnailController(View cell) {
        super(cell);

        thumbnail=(ImageView)cell.findViewById(R.id.thumbnail);
    }

    @Override
    void bindModel(Cursor row) {
        super.bindModel(row);

        Uri video=
            ContentUri.withAppendedId(
                MediaStore.Video.Media.EXTERNAL_CONTENT_URI,
                row.getInt(row.getColumnIndex(MediaStore.Video.Media._ID)));

        Picasso.with(thumbnail.getContext())
            .load(video.toString())
            .fit().centerCrop()
            .placeholder(R.drawable.ic_media_video_poster)
            .into(thumbnail);
    }
}
```

RECYCLERVIEW

(from [RecyclerView/VideoTable/app/src/main/java/com/commonsware/android/recyclerview/videotable/VideoThumbnailController.java](#))

The result is the same information as was in the original `VideoList` demo, but organized into a table, where each cell is clickable:

The duration is returned by `MediaStore` in milliseconds, which is not a great choice to present directly to the user. An improved version of this app might use a dedicated `RecyclerView.ViewHolder` that would convert the millisecond count into a duration measured in hours, minutes, and seconds (e.g., shown as `HH:MM:SS` to the user).

Also note that the cell sizes are purely driven by their weights, which will not necessarily handle all content in all configurations very well. The chosen weights barely work on a 10" tablet in portrait, for example:

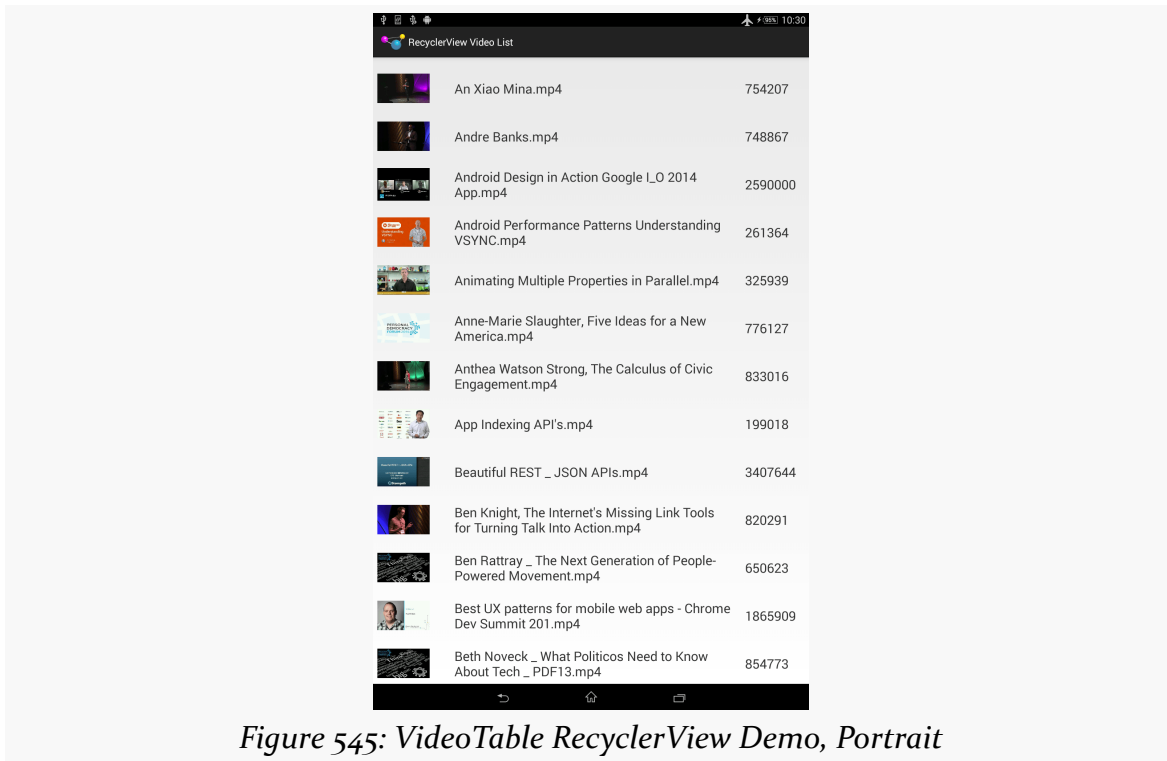

Figure 545: VideoTable RecyclerView Demo, Portrait

Mutable Row Contents

So far, all of the items we have used have been display-only. At most, they might respond to click events, along the lines of clicking a `ListView` row or `GridView` cell.

But, what about choice modes?

`ListView` and `GridView` — by way of their common `AbsListView` ancestor — have the concept of choice modes, where the user can “check” and “uncheck” items, and the list or grid will keep track of those states.

Well, as with lots of other things involving `RecyclerView`, `RecyclerView` does not offer choice modes... though you can implement that yourself. The [RecyclerView/ChoiceList](#) sample project turns our list-style `RecyclerView` into a checklist, with `CheckBox` widgets in each row, where the `RecyclerView.Adapter` will keep track of the `CheckBox` checked states for us.

First, we need to add a `CheckBox` to the row:

RECYCLERVIEW

```
<?xml version="1.0" encoding="utf-8"?>
<android.support.v7.widget.CardView
    xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:cardview="http://schemas.android.com/apk/res-auto"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:layout_margin="4dp"
    cardview:cardCornerRadius="4dp">

    <LinearLayout
        android:id="@+id/row_content"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:orientation="horizontal"
        android:background="?android:attr/selectableItemBackground">

        <ImageView
            android:id="@+id/icon"
            android:layout_width="wrap_content"
            android:layout_height="wrap_content"
            android:layout_gravity="center_vertical"
            android:padding="2dip"
            android:src="@drawable/ok"
            android:contentDescription="@string/icon"/>

        <LinearLayout
            android:layout_width="0dip"
            android:layout_height="wrap_content"
            android:layout_weight="1"
            android:orientation="vertical">

            <TextView
                android:id="@+id/label"
                android:layout_width="wrap_content"
                android:layout_height="wrap_content"
                android:textSize="25sp"
                android:textStyle="bold"/>

            <TextView
                android:id="@+id/size"
                android:layout_width="wrap_content"
                android:layout_height="wrap_content"
                android:textSize="15sp"/>
        </LinearLayout>

        <CheckBox
            android:layout_width="wrap_content"
            android:layout_height="wrap_content"

```

RECYCLERVIEW

```
        android:id="@+id/cb"
        android:layout_gravity="center_vertical"/>

</LinearLayout>
</android.support.v7.widget.CardView>
```

(from [RecyclerView/ChoiceList/app/src/main/res/layout/row.xml](#))

Our IconicAdapter is only slightly different than before:

- it inherits from a ChoiceCapableAdapter that we will examine shortly, and
- it supplies a MultiChoiceMode instance to ChoiceCapableAdapter as part of chaining to the ChoiceCapableAdapter constructor

```
class IconicAdapter extends ChoiceCapableAdapter<RowController> {
    IconicAdapter() {
        super(new MultiChoiceMode());
    }

    @Override
    public RowController onCreateViewHolder(ViewGroup parent, int viewType) {
        return(new RowController(this, getLayoutInflater()
            .inflate(R.layout.row, parent, false)));
    }

    @Override
    public void onBindViewHolder(RowController holder, int position) {
        holder.bindModel(items[position]);
    }

    @Override
    public int getItemCount() {
        return(items.length);
    }
}
```

(from [RecyclerView/ChoiceList/app/src/main/java/com/commonsware/android/recyclerview/choicelist/MainActivity.java](#))

ChoiceCapableAdapter is simply a RecyclerView.Adapter that knows how to handle choice modes, as implemented via the ChoiceMode interface:

```
package com.commonsware.android.recyclerview.choicelist;

import android.os.Bundle;

public interface ChoiceMode {
    void setChecked(int position, boolean isChecked);
}
```

RECYCLERVIEW

```
boolean isChecked(int position);
void onSaveInstanceState(Bundle state);
void onRestoreInstanceState(Bundle state);
}
```

(from [RecyclerView/ChoiceList/app/src/main/java/com/commonsware/android/recyclerview/choicelist/ChoiceMode.java](#))

A `ChoiceMode` is effectively a strategy class, responsible for tracking the checked states, not only for the current `ChoiceCapableAdapter` instance, but for future ones created as part of a configuration change. It requires four methods:

- `setChecked()` and `isChecked()` are getters and setters for whether or not a given position is checked
- `onSaveInstanceState()` and `onRestoreInstanceState()` manage storing and restoring those check states from the saved instance state `Bundle` of an activity or fragment

This project uses a `MultiChoiceMode` implementation of `ChoiceMode`:

```
package com.commonsware.android.recyclerview.choicelist;

import android.os.Bundle;

public class MultiChoiceMode implements ChoiceMode {
    private static final String STATE_CHECK_STATES="checkStates";
    private ParcelableSparseBooleanArray checkStates=new ParcelableSparseBooleanArray();

    @Override
    public void setChecked(int position, boolean isChecked) {
        checkStates.put(position, isChecked);
    }

    @Override
    public boolean isChecked(int position) {
        return(checkStates.get(position, false));
    }

    @Override
    public void onSaveInstanceState(Bundle state) {
        state.putParcelable(STATE_CHECK_STATES, checkStates);
    }

    @Override
    public void onRestoreInstanceState(Bundle state) {
        checkStates=state.getParcelable(STATE_CHECK_STATES);
    }
}
```

(from [RecyclerView/ChoiceList/app/src/main/java/com/commonsware/android/recyclerview/choicelist/MultiChoiceMode.java](#))

`MultiChoiceMode`, in turn, is mostly handled by a `ParcelableSparseBooleanArray`. `SparseBooleanArray` is a class, supplied in the Android SDK, that is a space-efficient

RECYCLERVIEW

mapping of int values to boolean values, as opposed to using a HashMap and having to convert those primitives to Integer and Boolean objects. However, for inexplicable reasons, SparseBooleanArray was not [implemented to be Parcelable](#), and therefore it cannot be stored in a Bundle. ParcelableSparseBooleanArray is a subclass of SparseBooleanArray that handles the Parcelable aspects:

```
package com.commonware.android.recyclerview.choicelist;

import android.os.Parcel;
import android.os.Parcelable;
import android.util.SparseBooleanArray;

public class ParcelableSparseBooleanArray extends SparseBooleanArray
    implements Parcelable {
    public static Parcelable.Creator<ParcelableSparseBooleanArray> CREATOR
        =new Parcelable.Creator<ParcelableSparseBooleanArray>() {
        @Override
        public ParcelableSparseBooleanArray createFromParcel(Parcel source) {
            return(new ParcelableSparseBooleanArray(source));
        }

        @Override
        public ParcelableSparseBooleanArray[] newArray(int size) {
            return(new ParcelableSparseBooleanArray[size]);
        }
    };

    public ParcelableSparseBooleanArray() {
        super();
    }

    private ParcelableSparseBooleanArray(Parcel source) {
        int size=source.readInt();

        for (int i=0; i < size; i++) {
            put(source.readInt(), (Boolean)source.readValue(null));
        }
    }

    @Override
    public int describeContents() {
        return(0);
    }

    @Override
    public void writeToParcel(Parcel dest, int flags) {
        dest.writeInt(size());
    }
}
```

RECYCLERVIEW

```
    for (int i=0;i<size();i++) {
        dest.writeInt(keyAt(i));
        dest.writeValue(valueAt(i));
    }
}
```

(from [RecyclerView/ChoiceList/app/src/main/java/com/commonsware/android/recyclerview/choicelist/ParcelableSparseBooleanArray.java](#))

The net effect is that `MultiChoiceMode`, by means of `ParcelableSparseBooleanArray`, can track the checked/unchecked states of particular item position values.

`ChoiceCapableAdapter`, then, is a `RecyclerView.ViewHolder` that surfaces a `ChoiceMode` implementation:

```
package com.commonsware.android.recyclerview.choicelist;

import android.os.Bundle;
import android.support.v7.widget.RecyclerView;

abstract public class
    ChoiceCapableAdapter<T extends RecyclerView.ViewHolder>
    extends RecyclerView.Adapter<T> {
    private final ChoiceMode choiceMode;

    public ChoiceCapableAdapter(ChoiceMode choiceMode) {
        super();
        this.choiceMode=choiceMode;
    }

    void onChecked(int position, boolean isChecked) {
        choiceMode.setChecked(position, isChecked);
    }

    boolean isChecked(int position) {
        return(choiceMode.isChecked(position));
    }

    void onSaveInstanceState(Bundle state) {
        choiceMode.onSaveInstanceState(state);
    }

    void onRestoreInstanceState(Bundle state) {
        choiceMode.onRestoreInstanceState(state);
    }
}
```

RECYCLERVIEW

```
}  
}
```

(from [RecyclerView/ChoiceList/app/src/main/java/com/commonsware/android/recyclerview/choicelist/ChoiceCapableAdapter.java](#))

The methods exposed by ChoiceCapableAdapter can then be used by outside parties. Specifically, MainActivity delegates onSaveInstanceState() and onRestoreInstanceState() to ChoiceCapableAdapter, so checked states can span configuration changes and the like. Plus, RowController can hook up on OnCheckedChangeListener and to update ChoiceCapableAdapter based on the state of checkbox changes:

```
package com.commonsware.android.recyclerview.choicelist;  
  
import android.annotation.TargetApi;  
import android.os.Build;  
import android.support.v7.widget.RecyclerView;  
import android.view.MotionEvent;  
import android.view.View;  
import android.widget.CheckBox;  
import android.widget.CompoundButton;  
import android.widget.ImageView;  
import android.widget.TextView;  
import android.widget.Toast;  
  
class RowController extends RecyclerView.ViewHolder  
    implements View.OnClickListener, CompoundButton.OnCheckedChangeListener {  
    private ChoiceCapableAdapter adapter;  
    private TextView label=null;  
    private TextView size=null;  
    private ImageView icon=null;  
    private String template=null;  
    private CheckBox cb=null;  
  
    RowController(ChoiceCapableAdapter adapter, View row) {  
        super(row);  
  
        this.adapter=adapter;  
        label=(TextView)row.findViewById(R.id.label);  
        size=(TextView)row.findViewById(R.id.size);  
        icon=(ImageView)row.findViewById(R.id.icon);  
        cb=(CheckBox)row.findViewById(R.id.cb);  
  
        template=size.getContext().getString(R.string.size_template);  
  
        row.setOnClickListener(this);  
    }  
}
```

RECYCLERVIEW

```
if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.LOLLIPOP) {
    row.setOnTouchListener(new View.OnTouchListener() {
        @TargetApi(Build.VERSION_CODES.LOLLIPOP)
        @Override
        public boolean onTouch(View v, MotionEvent event) {
            v
                .findViewById(R.id.row_content)
                .getBackground()
                .setHotspot(event.getX(), event.getY());

            return(false);
        }
    });
}

cb.setOnCheckedChangeListener(this);
}

@Override
public void onClick(View v) {
    Toast.makeText(v.getContext(),
        String.format("Clicked on position %d", getAdapterPosition()),
        Toast.LENGTH_SHORT).show();
}

@Override
public void onCheckedChanged(CompoundButton buttonView, boolean isChecked) {
    adapter.onChecked(getAdapterPosition(), isChecked);
}

void bindModel(String item) {
    label.setText(item);
    size.setText(String.format(template, item.length()));

    if (item.length()>4) {
        icon.setImageResource(R.drawable.delete);
    }
    else {
        icon.setImageResource(R.drawable.ok);
    }

    cb.setChecked(adapter.isChecked(getAdapterPosition()));
}
}
```

(from [RecyclerView/ChoiceList/app/src/main/java/com/commonsware/android/recyclerview/choicelist/RowController.java](https://github.com/CommonWare/android-recyclerview-choicelist/blob/master/app/src/main/java/com/commonsware/android/recyclerview/choicelist/RowController.java))

RECYCLERVIEW

Here, `bindModel()` updates the `CheckBox` based upon the `ChoiceCapableAdapter` `isChecked()` value for the `RecyclerView.ViewHolder` position (obtained via `getPosition()`). And, `onCheckedChanged()` updates the `ChoiceCapableAdapter` to keep track of whether this position is checked or unchecked, to handle row recycling, configuration changes, etc.

The result is much as you would expect: a version of our same sort of UI as before, except that if the user clicks the `CheckBox`, instead of the rest of the row, the `CheckBox` toggles its checked state, and that state survives row recycling, configuration changes, and so on:

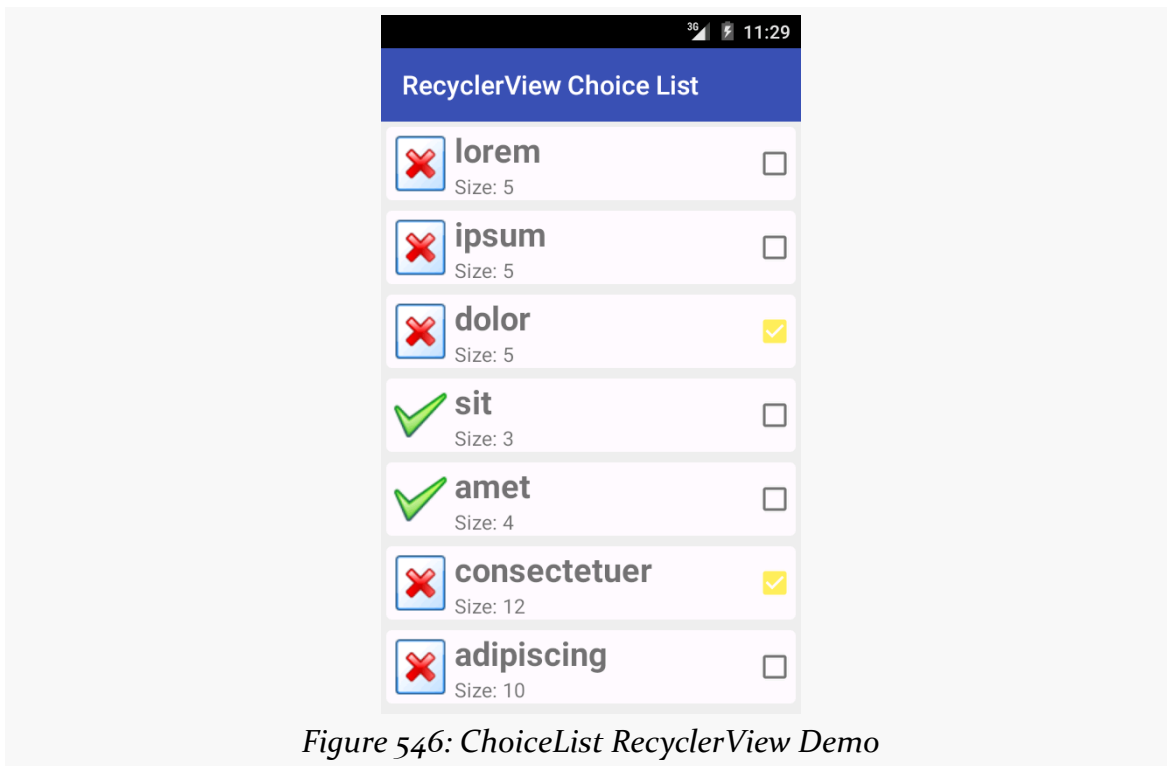

Figure 546: ChoiceList RecyclerView Demo

Note that since this sample is using `Theme.Material` on Android 5.0+ devices, and since the screenshot is from an Android 5.0 emulator, the `CheckBox` styling is based on the accent color, here shown as bright yellow.

Switching to the Activated Style

Also note that `ChoiceCapableAdapter`, `MultiChoiceMode`, and `kin` are oblivious to *how* the user is informed about what is checked and unchecked. `RowController` in

RECYCLERVIEW

the previous sample happens to use a `CheckBox`. `RowController` could use some other widget, like a `Switch`.

Another approach is to use the activated state. Once again, this is the sort of thing that is automatically handled for us by `ListView` and its choice modes, but with some minor tweaks, we can get our `RowController` to use this approach. This is shown in the [RecyclerView/ActivatedList](#) sample project.

First, we need to give our row a background that has a `StateListDrawable` that supports the activated state. The simplest approach — and the one traditionally used with `ListView` — is to set up an activated style with the stock theme-supplied background drawable, then apply that style to the row.

So, this sample app defines `activated` in `res/values/styles.xml`:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>

  <style name="Theme.Apptheme" parent="@android:style/Theme.Holo.Light.DarkActionBar">
  </style>

  <style name="activated" parent="Theme.Apptheme">
    <item name="android:background">?android:attr/activatedBackgroundIndicator</item>
  </style>
</resources>
```

(from [RecyclerView/ActivatedList/app/src/main/res/values/styles.xml](#))

Note that `activated` inherits from `Theme.Apptheme`. This means that we will get the `Theme.Holo`-flavored background normally, but on API Level 21+, we will get the `Theme.Material`-flavored background, courtesy of a `res/values-v21/styles.xml` override of `Theme.Apptheme`:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
  <style name="Theme.Apptheme" parent="android:Theme.Material.Light.DarkActionBar">
    <item name="android:colorPrimary">@color/primary</item>
    <item name="android:colorPrimaryDark">@color/primary_dark</item>
    <item name="android:colorAccent">@color/accent</item>
  </style>
</resources>
```

(from [RecyclerView/ActivatedList/app/src/main/res/values-v21/styles.xml](#))

Our row layout now dumps the `CardView` (whose own background may conflict with the activated one) and applies the `activated` style to the root `LinearLayout`:

RECYCLERVIEW

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout
  xmlns:android="http://schemas.android.com/apk/res/android"
  android:layout_width="match_parent"
  android:layout_height="wrap_content"
  android:orientation="horizontal"
  style="@style/activated">

  <ImageView
    android:id="@+id/icon"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:layout_gravity="center_vertical"
    android:padding="2dip"
    android:src="@drawable/ok"
    android:contentDescription="@string/icon"/>

  <LinearLayout
    android:layout_width="0dip"
    android:layout_height="wrap_content"
    android:layout_weight="1"
    android:orientation="vertical">

    <TextView
      android:id="@+id/label"
      android:layout_width="wrap_content"
      android:layout_height="wrap_content"
      android:textSize="25sp"
      android:textStyle="bold"/>

    <TextView
      android:id="@+id/size"
      android:layout_width="wrap_content"
      android:layout_height="wrap_content"
      android:textSize="15sp"/>
  </LinearLayout>
</LinearLayout>
```

(from [RecyclerView/ActivatedList/app/src/main/res/layout/row.xml](#))

The row also no longer has the CheckBox, as it is no longer needed.

RowController now uses the OnClickListener interface to respond to clicks and use that to toggle the activated state for that row:

RECYCLERVIEW

```
@Override
public void onClick(View v) {
    boolean isCheckedNow=adapter.isChecked(getAdapterPosition());

    adapter.onChecked(getAdapterPosition(), !isCheckedNow);
    row.setActivated(!isCheckedNow);
}
```

(from [RecyclerView/ActivatedList/app/src/main/java/com/commonsware/android/recyclerview/activatedlist/RowController.java](#))

`setActivated()`, applied to a `View`, indicates that it is (or is not) activated, affecting anything in that `View` that depends upon that state, such as the background.

Similarly, `bindModel()` uses `setActivated()` to update the activated state when binding our data:

```
void bindModel(String item) {
    label.setText(item);
    size.setText(String.format(template, item.length()));

    if (item.length()>4) {
        icon.setImageResource(R.drawable.delete);
    }
    else {
        icon.setImageResource(R.drawable.ok);
    }

    row.setActivated(adapter.isChecked(getAdapterPosition()));
}
```

(from [RecyclerView/ActivatedList/app/src/main/java/com/commonsware/android/recyclerview/activatedlist/RowController.java](#))

Everything else is the same as the original `CheckBox` version of the sample. But now, the “checked” state is indicated by the activated highlight:

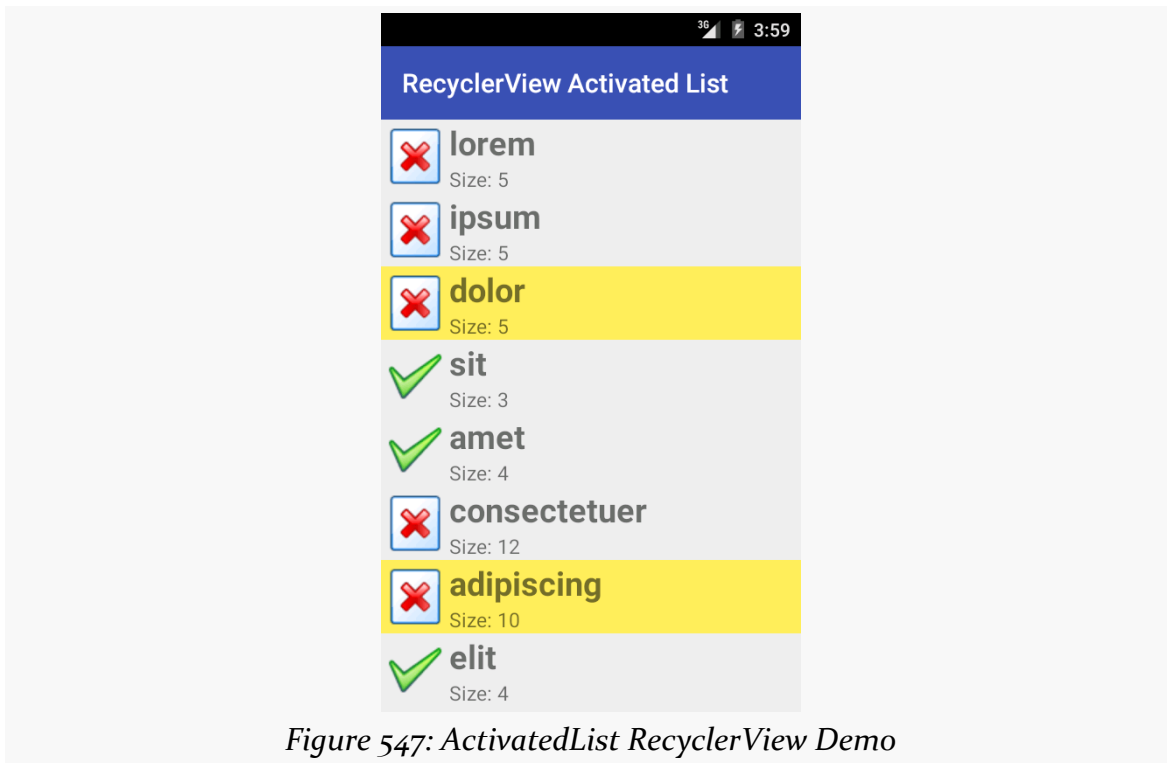

Figure 547: ActivatedList RecyclerView Demo

And, since this demo is running on Android 5.0, the activated highlight color is the accent color, which in this case is set to be yellow.

But, What About Single-Choice?

Both of the preceding examples illustrate multiple-choice behavior. Sometimes, though, single-choice behavior is the better option. For example, in a master-detail structure, in dual-pane mode (e.g., tablets, where the master and the detail are both visible), you probably normally want single-choice mode.

That is certainly possible, though, once again, RecyclerView does not offer it. It also adds a wrinkle: how do we arrange to uncheck a previously-checked item, when the user checks another item? Like `RadioButton` widgets in a `RadioGroup`, we need to ensure that only one item at a time is checked, and that will require us to update the UI of the formerly-checked-but-now-unchecked item.

With some tweaks, the last sample project, where we used the activated state for a multiple-choice list, can be revised to limit the user to a single choice. Those tweaks are illustrated in the [RecyclerView/SingleActivatedList](#) sample project.

RECYCLERVIEW

The ChoiceMode interface now has two new methods:

1. `isSingleChoice()` will return true for a single-choice ChoiceMode strategy, false otherwise
2. `getCheckedPosition()` will return the position of whatever the currently-checked item is

```
package com.commonware.android.recyclerview.singleactivatedlist;

import android.os.Bundle;

public interface ChoiceMode {
    boolean isSingleChoice();
    int getCheckedPosition();
    void setChecked(int position, boolean isChecked);
    boolean isChecked(int position);
    void onSaveInstanceState(Bundle state);
    void onRestoreInstanceState(Bundle state);
}
```

(from [RecyclerView/SingleActivatedList/app/src/main/java/com/commonware/android/recyclerview/singleactivatedlist/ChoiceMode.java](#))

SingleChoiceMode is now our implementation of ChoiceMode:

```
package com.commonware.android.recyclerview.singleactivatedlist;

import android.os.Bundle;

public class SingleChoiceMode implements ChoiceMode {
    private static final String STATE_CHECKED="checkedPosition";
    private int checkedPosition=-1;

    @Override
    public boolean isSingleChoice() {
        return(true);
    }

    @Override
    public int getCheckedPosition() {
        return(checkedPosition);
    }

    @Override
    public void setChecked(int position, boolean isChecked) {
        if (isChecked) {
            checkedPosition=position;
        }
    }
}
```

RECYCLERVIEW

```
    }
    else if (isChecked(position)) {
        checkedPosition=-1;
    }
}

@Override
public boolean isChecked(int position) {
    return(checkedPosition==position);
}

@Override
public void onSaveInstanceState(Bundle state) {
    state.putInt(STATE_CHECKED, checkedPosition);
}

@Override
public void onRestoreInstanceState(Bundle state) {
    checkedPosition=state.getInt(STATE_CHECKED, -1);
}
}
```

(from [RecyclerView/SingleActivatedList/app/src/main/java/com/commonsware/android/recyclerview/singleactivatedlist/SingleChoiceMode.java](#))

SingleChoiceMode tracks the currently-checked position, using -1 to indicate no position is checked. Of note, if a position was checked, then `setChecked()` unchecks it, SingleChoiceMode goes back to -1 and indicates that there is no currently-checked position.

ChoiceCapableAdapter also has a couple of modifications. First, it now accepts the RecyclerView itself as a constructor parameter, holding onto it in an `rv` data member. And, `onChecked()` needs to be modified to take care of removing the activated state from whatever item had been previously checked when some new item is checked:

```
package com.commonsware.android.recyclerview.singleactivatedlist;

import android.os.Bundle;
import android.support.v7.widget.RecyclerView;

abstract public class
    ChoiceCapableAdapter<T extends RecyclerView.ViewHolder>
    extends RecyclerView.Adapter<T> {
    private final ChoiceMode choiceMode;
    private final RecyclerView rv;
```

RECYCLERVIEW

```
public ChoiceCapableAdapter(RecyclerView rv,
                             ChoiceMode choiceMode) {
    super();
    this.rv=rv;
    this.choiceMode=choiceMode;
}

void onChecked(int position, boolean isChecked) {
    if (choiceMode.isSingleChoice()) {
        int checked=choiceMode.getCheckedPosition();

        if (checked>=0) {
            RowController row=
                (RowController)rv.findViewByIdForAdapterPosition(checked);

            if (row!=null) {
                row.setChecked(false);
            }
        }
    }

    choiceMode.setChecked(position, isChecked);
}

boolean isChecked(int position) {
    return(choiceMode.isChecked(position));
}

void onSaveInstanceState(Bundle state) {
    choiceMode.onSaveInstanceState(state);
}

void onRestoreInstanceState(Bundle state) {
    choiceMode.onRestoreInstanceState(state);
}

@Override
public void onViewAttachedToWindow(T holder) {
    super.onViewAttachedToWindow(holder);

    if (holder.getAdapterPosition()!=choiceMode.getCheckedPosition()) {
        ((RowController)holder).setChecked(false);
    }
}
}
```

RECYCLERVIEW

(from [RecyclerView/SingleActivatedList/app/src/main/java/com/commonsware/android/recyclerview/singleactivatedlist/ChoiceCapableAdapter.java](#))

To do that, `onChecked()` asks the `ChoiceMode` if it is single choice. If yes, it gets the last checked position. If that position is plausible (0 or higher), it gets the `RecyclerView.ViewHolder` for that position via `findViewHolderForAdapterPosition()`, called on the `RecyclerView`. If this returns something other than null, then it must be a `RowController`, and so `onChecked()` calls `setChecked(false)` on that row to remove the activated state.

`findViewHolderForAdapterPosition()` and `findViewHolderForLayoutPosition()` replace the now-deprecated `findViewHolderForPosition()` method. All three methods do the same basic thing: given a position, return the `ViewHolder` for that position, if any. `findViewHolderForPosition()` and `findViewHolderForLayoutPosition()` have the same implementation, at least at the present time. The primary thing that `findViewHolderForAdapterPosition()` does differently is it always returns null if the data has been changed (e.g., `notifyDataSetChanged()` was called on the adapter) but those changes have not yet been laid out. In this sample app, that difference is academic, but `findViewHolderForAdapterPosition()` probably is a safer choice for most use cases.

However, these `find...()` methods have a wrinkle: they only return a `ViewHolder` if the row is *visible*. If the `ViewHolder` is cached, but not visible, `find...()` will still not return it. This causes a problem where we need to de-select a row that is not visible (and so `find...()` does not work) but will not be re-bound using `onBindViewHolder()` (as the `ViewHolder` is already set up). This requires us to implement `onViewAttachedToWindow()` — called whenever a `ViewHolder` contents are actually attached as children to the `RelativeLayout` — and update the checked state there, as a fallback.

(and many thanks to Mahmoud Abou-Eita for [reporting that problem](#))

`setChecked()` did not exist in the previous sample, as the activated state was handled purely internally to `RowController`. So, now `RowController` has a `setChecked()` method to toggle the activated state:

```
void setChecked(boolean isChecked) {
    row.setActivated(isChecked);
}
```

(from [RecyclerView/SingleActivatedList/app/src/main/java/com/commonsware/android/recyclerview/singleactivatedlist/RowController.java](#))

RECYCLERVIEW

MainActivity now must supply the RecyclerView to the IconicAdapter in onCreate():

```
@Override
public void onCreate(Bundle state) {
    super.onCreate(state);

    setLayoutManager(new LinearLayoutManager(this));
    adapter=new IconicAdapter(getRecyclerView());
    setAdapter(adapter);
}
```

(from [RecyclerView/SingleActivatedList/app/src/main/java/com/commonsware/android/recyclerview/singleactivatedlist/MainActivity.java](https://github.com/commonsware/android-recyclerview/singleactivatedlist/MainActivity.java))

...so that IconicAdapter() can supply it to the ChoiceCapableAdapter superclass constructor:

```
IconicAdapter(RecyclerView rv) {
    super(rv, new SingleChoiceMode());
}
```

(from [RecyclerView/SingleActivatedList/app/src/main/java/com/commonsware/android/recyclerview/singleactivatedlist/MainActivity.java](https://github.com/commonsware/android-recyclerview/singleactivatedlist/MainActivity.java))

Visually, the results are identical to the previous example, except that at most only one item can be checked at a time. The key is the phrase “at most” — this implementation allows the user to tap on a checked item to uncheck it. This may be fine, as your app may simply hide the detail in this scenario, still allowing the user to interact with action bar items (e.g., a “create new model” item). If you wanted to prevent that, have SingleChoiceMode *not* set checkedPosition to -1 when the user taps on a previously-checked item, to leave the currently-checked position intact.

Keyboard Navigation

If you try using the RecyclerView/SingleActivatedList app — or any of the sample apps presented so far — on a device that has a physical keyboard or five-way navigation option (e.g., D-pad), you will find that RecyclerView has no built-in keyboard navigation. This is in contrast with standard AdapterView classes like ListView, where key events are handled automatically. Once again, if you want the behavior, you have to add it yourself.

The exact details of what you want to do when the user tries navigating with a keyboard will vary, based on lots of things:

RECYCLERVIEW

- What sort of layout manager are you using? If it is a list, you only need to worry about moving up and down, while if it is a grid, you will need to handle movement along both axes.
- Do you have focusable widgets in your RecyclerView items? If so, how will navigation between those widgets blend with navigation through the RecyclerView overall?
- Are you using any sort of “selection” or “choice” model? If so, do you want keyboard navigation to change the choice? Or, do you want keyboard navigation to only make a choice when the user does something special (e.g., presses an Enter key or a center D-pad button), with the two-way or four-way navigation showing up as something separate from the user’s choice?

The [RecyclerView/SingleActivatedListKB](#) sample project is a clone of the SingleActivatedList sample, except that we now support keyboard events. Specifically, the user can use the up and down arrow keys to change the selected row in the list. This is perhaps the simplest scenario:

- We have no focusable widgets, so key events can just change the selected row
- It is just a list, so we only need to worry about two directions, not four
- We want either zero or one selected row, and so we do not need to have a distinction between navigation and selection, as we might with a multiple-choice list

And, the best part is that we only need to change ChoiceCapableAdapter — the rest of the app can remain unchanged.

First, we override another method on RecyclerView.Adapter: `onAttachedToRecyclerView()`. As the name suggests, this method is called when our adapter is assigned to a RecyclerView instance. Here, if we are in single-choice mode, we register an `OnKeyListener` on the RecyclerView itself, to find out when it receives key events:

```
// inspired by http://stackoverflow.com/a/28838834/115145

@Override
public void onAttachedToRecyclerView(RecyclerView rv) {
    super.onAttachedToRecyclerView(rv);

    if (choiceMode.isSingleChoice()) {
        rv.setOnKeyListener(new View.OnKeyListener() {
            @Override
```

RECYCLERVIEW

```
public boolean onKeyDown(View v, int keyCode, KeyEvent event) {
    if (event.getAction()==KeyEvent.ACTION_DOWN) {
        switch (keyCode) {
            case KeyEvent.KEYCODE_DPAD_DOWN:
                return(chooseNext());
            case KeyEvent.KEYCODE_DPAD_UP:
                return(choosePrevious());
        }
    }

    return(false);
}
});
}
```

(from [RecyclerView/SingleActivatedListKB/app/src/main/java/com/commonsware/android/recyclerview/singleactivatedlist/ChoiceCapableAdapter.java](#))

When the user presses down either the up or down arrow key (or equivalents on a D-pad), we call out to private `choosePrevious()` and `chooseNext()` methods, which will return `true` if we moved the selection in that direction, `false` otherwise. If the key event is not one of those, we return `false` to indicate that we are not consuming the key event.

The `choosePrevious()` and `chooseNext()` methods are responsible for determining what our next selection should be, assuming that the selection can change in the designated direction:

```
private boolean chooseNext() {
    long now=System.currentTimeMillis();
    boolean result=false;

    if (lastDownKeyTime==-1 || now-lastDownKeyTime>KEY_TIME_DELTA) {
        lastDownKeyTime=now;
        lastUpKeyTime=-1L;

        int checked=choiceMode.getCheckedPosition();

        if (checked<0) {
            onChecked(0, true, true);
            result=true;
        }
        else if (checked<getItemCount()-1) {
            onChecked(checked+1, true, true);
            result=true;
        }
    }
}
```

RECYCLERVIEW

```
}

return(result);
}

private boolean choosePrevious() {
    long now=System.currentTimeMillis();
    boolean result=false;

    if (lastUpKeyTime==-1 || now-lastUpKeyTime>KEY_TIME_DELTA) {
        lastUpKeyTime=now;
        lastDownKeyTime=-1L;

        int checked=choiceMode.getCheckedPosition();

        if (checked>0) {
            onChecked(checked-1, true, true);
            result=true;
        }
        else if (checked<0) {
            onChecked(0, true, true);
            result=true;
        }
    }

    return(result);
}
```

(from [RecyclerView/SingleActivatedListKB/app/src/main/java/com/commonsware/android/recyclerview/singleactivatedlist/ChoiceCapableAdapter.java](#))

In both cases, we find out what the current selection is. If it is a negative number, we do not have a selection yet, so we select the first row. Otherwise, if we can still move in the desired direction, add or subtract one from the current selection.

However, in this crude implementation, we need to slow down how frequently we change the selection. Simply changing which row is highlighted is fast, but if the list has to scroll to uncover that row, doing too many of those too quickly results in a “smearing” effect. The simplest way to avoid that smearing is to limit how many consecutive identical key events we process (e.g., user holds down an arrow key).

The approach taken in this code is to track the last time we were called to process an arrow key event for each direction, in `lastUpKeyTime` and `lastDownKeyTime` fields. We use `-1` to indicate that we have not just processed another one of that type. If, when we get a key event, either the related time value is `-1` or is within `KEY_TIME_DELTA` of now, we go ahead and update the checked position (if needed),

RECYCLERVIEW

plus update the times. `KEY_TIME_DELTA` is defined as 250, limiting us to four updates per second.

We change the current selection, where needed, via a call to a new three-parameter `onChecked()` method:

```
void onChecked(int position, boolean isChecked) {
    onChecked(position, isChecked, false);
}

void onChecked(int position, boolean isChecked, boolean updateUI) {
    if (choiceMode.isSingleChoice()) {
        int checked=choiceMode.getCheckedPosition();

        if (checked>=0) {
            RowController row=
                (RowController)rv.findViewByIdForAdapterPosition(checked);

            if (row!=null) {
                row.setChecked(false);
            }
        }
    }

    choiceMode.setChecked(position, isChecked);

    if (updateUI) {
        notifyItemChanged(position);
        rv.scrollToPosition(position);
    }
}
```

(from [RecyclerView/SingleActivatedListKB/app/src/main/java/com/commonsware/android/recyclerview/singleactivatedlist/ChoiceCapableAdapter.java](#))

The third parameter indicates if we need to update the UI or not. For touchscreen events, activating rows and such is enough to ensure that the UI is properly updated. With key events, we need to:

- Make sure that Android is going to repaint the affected row and pick up the change in the activated state (`notifyItemChanged()`), and
- Make sure that the user can see the affected row, since they key event might now select a row that is not visible on the screen (`scrollToPosition()`)

Action Modes

Another thing that `ListView` gave us was support for action modes. In particular, the “multiple-choice modal” setting would automatically start and finish an action mode for us.

And, once again, `RecyclerView` has no hooks for action modes, though you can do it yourself if desired. We have to manually start and destroy the action mode, in addition to responding to the user’s interaction with the action mode (tapping on items, or dismissing the action mode manually).

Where things get interesting is in the connection between checked items and the action mode. There are two UX rules:

1. When there are no checked items, there should be no action mode
2. When there is no action mode, there should be no checked items

You might think that those two rules are the same, and to some extent they are. They are phrased this way to emphasize the state changes that are involved:

- When the user checks an item, an action mode should appear
- When the user unchecks the last checked item, and therefore there are no more checked items, the action mode should disappear
- When the user dismisses the action mode (e.g., presses BACK), all checked items should become unchecked

Handling these transitions takes a bit of work, demonstrated in the [RecyclerView/ActionModeList](#) sample project. This is a clone of the `ChoiceList` sample from earlier, augmented with an action mode when 1+ items are checked. The action mode logic is largely cloned from one of the book’s action mode samples, where we want to allow the user to capitalize or remove the checked items.

Once again, we have some tweaks to `ChoiceMode`, adding two methods:

1. `getCheckedCount()`, to return the number of checked items, which we will use for the subtitle of the action mode
2. `clearChecks()`, to uncheck all checked items

```
package com.commonware.android.recyclerview.actionmodelist;

import android.os.Bundle;
```

RECYCLERVIEW

```
public interface ChoiceMode {
    void setChecked(int position, boolean isChecked);
    boolean isChecked(int position);
    void onSaveInstanceState(Bundle state);
    void onRestoreInstanceState(Bundle state);
    int getCheckedCount();
    void clearChecks();
}
```

(from [RecyclerView/ActionModelList/app/src/main/java/com/commonsware/android/recyclerview/actionmodelist/ChoiceMode.java](#))

MultiChoiceMode implements those, plus adds a subtle change to `setChecked()`. Previous editions of MultiChoiceMode would simply put the checked state boolean into the `ParcelableSparseBooleanArray`, with `false` as a default value for any position not in the array. Now, we specifically *remove* items that are unchecked, so the only items in the `ParcelableSparseBooleanArray` are those that are checked. This makes `getCheckedCount()` and `clearChecks()` very simple to implement:

```
package com.commonsware.android.recyclerview.actionmodelist;

import android.os.Bundle;

public class MultiChoiceMode implements ChoiceMode {
    private static final String STATE_CHECK_STATES="checkStates";
    private ParcelableSparseBooleanArray checkStates=new ParcelableSparseBooleanArray();

    @Override
    public void setChecked(int position, boolean isChecked) {
        if (isChecked) {
            checkStates.put(position, isChecked);
        }
        else {
            checkStates.delete(position);
        }
    }

    @Override
    public boolean isChecked(int position) {
        return(checkStates.get(position, false));
    }

    @Override
    public void onSaveInstanceState(Bundle state) {
        state.putParcelable(STATE_CHECK_STATES, checkStates);
    }

    @Override
    public void onRestoreInstanceState(Bundle state) {
        checkStates=state.getParcelable(STATE_CHECK_STATES);
    }

    @Override
    public int getCheckedCount() {
        return(checkStates.size());
    }
}
```

RECYCLERVIEW

```
}  
  
@Override  
public void clearChecks() {  
    checkStates.clear();  
}  
}
```

(from [RecyclerView/ActionModeList/app/src/main/java/com/commonsware/android/recyclerview/actionmodelist/MultiChoiceMode.java](#))

ChoiceCapableAdapter exposes the two new ChoiceMode capabilities to its subclasses:

```
package com.commonsware.android.recyclerview.actionmodelist;  
  
import android.os.Bundle;  
import android.support.v7.widget.RecyclerView;  
  
abstract public class  
    ChoiceCapableAdapter<T extends RecyclerView.ViewHolder>  
        extends RecyclerView.Adapter<T> {  
    private final ChoiceMode choiceMode;  
  
    public ChoiceCapableAdapter(ChoiceMode choiceMode) {  
        super();  
        this.choiceMode=choiceMode;  
    }  
  
    void onChecked(int position, boolean isChecked) {  
        choiceMode.setChecked(position, isChecked);  
    }  
  
    boolean isChecked(int position) {  
        return(choiceMode.isChecked(position));  
    }  
  
    void onSaveInstanceState(Bundle state) {  
        choiceMode.onSaveInstanceState(state);  
    }  
  
    void onRestoreInstanceState(Bundle state) {  
        choiceMode.onRestoreInstanceState(state);  
    }  
  
    int getCheckedCount() {  
        return(choiceMode.getCheckedCount());  
    }  
}
```

RECYCLERVIEW

```
void clearChecks() {
    choiceMode.clearChecks();
}
}
```

(from [RecyclerView/ActionModeList/app/src/main/java/com/commonsware/android/recyclerview/actionmodelist/ChoiceCapableAdapter.java](#))

IconicAdapter now not only extends ChoiceCapableAdapter, but it implements the ActionMode.Callback interface, and therefore will be responsible for managing the action mode:

```
class IconicAdapter extends ChoiceCapableAdapter<RowController>
    implements ActionMode.Callback {
```

(from [RecyclerView/ActionModeList/app/src/main/java/com/commonsware/android/recyclerview/actionmodelist/MainActivity.java](#))

IconicAdapter now overrides onChecked(), normally just handled by ChoiceCapableAdapter. In addition to chaining to the superclass for standard behavior, IconicAdapter manages the action mode:

- If we do not have any checked items, and we have an active action mode, finish() that action mode, as the user has unchecked the last checked item and the action mode is no longer needed
- Otherwise, update the subtitle, and if we are checking an item (isChecked is true), and if we do not already have an action mode going (tracked by an activeMode data member), start the action mode using startActionMode()

```
@Override
void onChecked(int position, boolean isChecked) {
    super.onChecked(position, isChecked);

    if (getCheckedCount()==0 && activeMode!=null) {
        activeMode.finish();
    }
    else {
        updateSubtitle(activeMode);

        if (isChecked) {
            if (activeMode==null) {
                activeMode=startActionMode(this);
            }
        }
    }
}
}
```

RECYCLERVIEW

(from [RecyclerView/ActionModelList/app/src/main/java/com/commonsware/android/recyclerview/actionmodelist/MainActivity.java](#))

Because `IconicAdapter` implements `ActionMode.Callback`, it needs to implement the methods required by that interface. This includes:

- `onCreateActionMode()`, to set up the action mode
- `onPrepareActionMode()`, just because it is required by the interface
- `onActionItemClicked()`, where we should do some real work, but for the moment just have a `TODO` comment
- `onDestroyActionMode()`, where we make sure that all checked items are unchecked (`clearChecks()`) and tell the `RecyclerView.Adapter` that the data set changed, to force a repaint of all the visible rows, so they will now reflect the fact that they are no longer checked

```
@Override
public boolean onCreateActionMode(ActionMode mode, Menu menu) {
    MenuInflater inflater=getMenuInflater();

    inflater.inflate(R.menu.context, menu);
    mode.setTitle(R.string.context_title);
    activeMode=mode;
    updateSubtitle(activeMode);

    return(true);
}

@Override
public boolean onPrepareActionMode(ActionMode mode, Menu menu) {
    return(false);
}

@Override
public boolean onActionItemClicked(ActionMode mode, MenuItem item) {
    // TODO: do something based on the action

    updateSubtitle(activeMode);

    return(true);
}

@Override
public void onDestroyActionMode(ActionMode mode) {
    if (activeMode != null) {
        activeMode=null;
        clearChecks();
        notifyDataSetChanged();
    }
}
```

RECYCLERVIEW

```
}  
}
```

(from [RecyclerView/ActionModeList/app/src/main/java/com/commonsware/android/recyclerview/actionmodelist/MainActivity.java](#))

The `updateSubtitle()` method, referred to by some of the previous methods, just updates the subtitle of the action mode to reflect the current count of checked items:

```
private void updateSubtitle(ActionMode mode) {  
    if (mode!=null) {  
        mode.setSubtitle("(" + getCheckedCount() + ")");  
    }  
}
```

(from [RecyclerView/ActionModeList/app/src/main/java/com/commonsware/android/recyclerview/actionmodelist/MainActivity.java](#))

The resulting app looks a lot like the original `ChoiceList` sample, until we check one or more items, at which point the action mode appears:

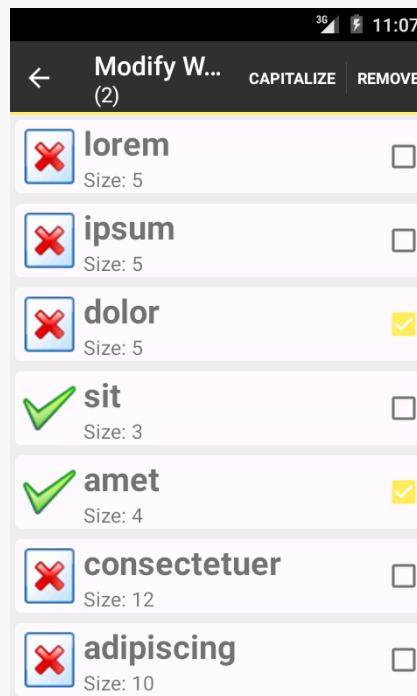

Figure 548: `ActionModeList` RecyclerView Demo

Changing the Contents

The obvious problem with the preceding sample is that we are not actually doing anything in response to user clicks on action mode items. We really should be capitalizing and/or removing words. However, this involves modifying the model data and how that model data is being visually displayed by the RecyclerView.

The less-obvious problem is that we are calling `notifyDataSetChanged()` when the action mode is dismissed, to force a full repaint of the RecyclerView contents. While this works, it is overkill, as probably only a subset of the visible items are checked. Ideally, we would only update the specific positions that were checked and now, with the action mode finished, are unchecked. We could find the affected `RowController` instances, using `findViewHolderByPosition()` on `RecyclerView`, as we did in the single-choice list sample. But, really, updating the checked state is just another manifestation of the same problem that capitalizing or removing words causes: we need to ensure that the RecyclerView depicts the current model state, ideally with minimum work.

So, let's see how this is accomplished, by looking at the [RecyclerView/ActionModeList2](#) sample project. As the name suggests, this is a clone of the `ActionModeList` shown in the preceding section. This time, we will fully implement `onActionItemClicked()` and allow our model data to be mutable.

Updating Existing Contents

With `AdapterView` and `Adapter` classes based on `BaseAdapter`, the only way we had to tell the `AdapterView` about model data changes was `notifyDataSetChanged()`. This would trigger a rebuild of the entire `AdapterView`, which is slow and expensive.

While `RecyclerView.Adapter` has its own `notifyDataSetChanged()`, that is really for total reloads of the model data, such as having gotten a fresh `Cursor` from a database and not knowing exactly what the changes are. If you are driving the changes yourself from the UI — and particularly if your model data is something like an `ArrayList` of model objects — you can use methods on `RecyclerView.Adapter` that are more fine-grained than is `notifyDataSetChanged()`.

If an item was updated in place — such as a word now being capitalized — you can use `notifyItemChanged()` on `RecyclerView.Adapter` to point out the specific position that changed. Alternatives include:

RECYCLERVIEW

- `notifyItemMoved()`, to indicate that an item is still in the model data but now is in a new position
- `notifyItemRangeChanged()`, to indicate a range of positions that were modified, instead of having to repeatedly call `notifyItemChanged()`

`ActionModeList2` uses `notifyItemChanged()` when the user capitalizes words, to get those items repainted, if needed. It may not be needed immediately, if one or more of those items are not presently visible within the `RecyclerView`.

However, so far, our model data has been a static `String` array, and now we need a mutable model. So, we take the same approach as the `ListView` action mode samples use, converting our model to be an `ArrayList` that happens to be populated by a static `String` array.

The `items` data member of `MainActivity` is now an `ArrayList` of `String`, with the static `String` array being converted into `ORIGINAL_ITEMS`:

```
private static final String[] ORIGINAL_ITEMS={"lorem", "ipsum", "dolor",
    "sit", "amet",
    "consectetuer", "adipiscing", "elit", "morbi", "vel",
    "ligula", "vitae", "arcu", "aliquet", "mollis",
    "etiam", "vel", "erat", "placerat", "ante",
    "porttitor", "sodales", "pellentesque", "augue", "purus"};
private ArrayList<String> items;
```

(from [RecyclerView/ActionModeList2/app/src/main/java/com/commonsware/android/recyclerview/actionmodelist2/MainActivity.java](#))

Places that used to refer to `items` now use a private `getItems()` method, which lazy-instantiates the list if needed:

```
private ArrayList<String> getItems() {
    if (items==null) {
        items=new ArrayList<String>();

        for (String s : ORIGINAL_ITEMS) {
            items.add(s);
        }
    }

    return(items);
}
```

(from [RecyclerView/ActionModeList2/app/src/main/java/com/commonsware/android/recyclerview/actionmodelist2/MainActivity.java](#))

RECYCLERVIEW

We also need to ensure that we hold onto the items across configuration changes, since those items could be changed by the user. So, our `onSaveInstanceState()` and `onRestoreInstanceState()` methods on `MainActivity` now handle that chore, in addition to their original behavior of having the `ChoiceCapableAdapter` persist checked states:

```
@Override
public void onSaveInstanceState(Bundle state) {
    adapter.onSaveInstanceState(state);
    state.putStringArrayList(STATE_ITEMS, items);
}

@Override
public void onRestoreInstanceState(Bundle state) {
    adapter.onRestoreInstanceState(state);
    items=state.getStringArrayList(STATE_ITEMS);
}
```

(from [RecyclerView/ActionModeList2/app/src/main/java/com/commonsware/android/recyclerview/actionmodelist2/MainActivity.java](#))

(here, `STATE_ITEMS` is a static data member, serving as the constant key for the `Bundle` entry)

In order to be able to capitalize or remove the checked words from the list, we need to know which ones are checked. Rather than expose that data directly, `ChoiceMode` now has a `visitChecks()` method, where we can supply a `Visitor` to be invoked for every checked position:

```
package com.commonsware.android.recyclerview.actionmodelist2;

import android.os.Bundle;

public interface ChoiceMode {
    void setChecked(int position, boolean isChecked);
    boolean isChecked(int position);
    void onSaveInstanceState(Bundle state);
    void onRestoreInstanceState(Bundle state);
    int getCheckedCount();
    void clearChecks();
    void visitChecks(Visitor v);

    public interface Visitor {
        void onCheckedPosition(int position);
    }
}
```

RECYCLERVIEW

(from [RecyclerView/ActionModeList2/app/src/main/java/com/commonsware/android/recyclerview/actionmodelist2/ChoiceMode.java](#))

MultiChoiceMode implements `visitChecks()` by iterating over a *copy* of the `checkStates` `ParcelableSparseBooleanArray`. That way, if the visitor modifies `checkStates` (e.g., unchecks a position), our loop is unaffected.

```
@Override
public void visitChecks(Visitor v) {
    SparseBooleanArray copy=checkStates.clone();

    for (int i=0;i<copy.size();i++) {
        v.onCheckedPosition(copy.keyAt(i));
    }
}
```

(from [RecyclerView/ActionModeList2/app/src/main/java/com/commonsware/android/recyclerview/actionmodelist2/MultiChoiceMode.java](#))

`visitChecks()` is also exposed by `ChoiceCapableAdapter`, as are all the other methods on `ChoiceMode`.

Now, `IconicAdapter` can capitalize the words, by using `visitChecks()`:

```
case R.id.cap:
    visitChecks(new ChoiceMode.Visitor() {
        @Override
        public void onCheckedPosition(int position) {
            String word=getItems().get(position);

            word=word.toUpperCase(Locale.ENGLISH);
            getItems().set(position, word);
            notifyItemChanged(position);
        }
    });
    break;
```

(from [RecyclerView/ActionModeList2/app/src/main/java/com/commonsware/android/recyclerview/actionmodelist2/MainActivity.java](#))

Here, for each checked item, we capitalize the word, replace the original word with its capitalized equivalent, and call `notifyItemChanged()` to let the `RecyclerView` know that this position had its model data changed and therefore should be repainted, if needed.

We also use `visitChecks()` now in `onDestroyActionMode()`, to avoid the `notifyDataSetChanged()` call:

RECYCLERVIEW

```
@Override
public void onDestroyActionMode(ActionMode mode) {
    if (activeMode != null) {
        activeMode=null;
        visitChecks(new ChoiceMode.Visitor() {
            @Override
            public void onCheckedPosition(int position) {
                onChecked(position, false);
                notifyItemChanged(position);
            }
        });
    }
}
```

(from [RecyclerView/ActionModeList2/app/src/main/java/com/commonsware/android/recyclerview/actionmodelist2/MainActivity.java](#))

Each item that was checked is unchecked, and we use `notifyItemChanged()` to ensure that the item is repainted if needed.

Now, checking some items and choosing “CAPITALIZE” from the action mode will capitalize those words:

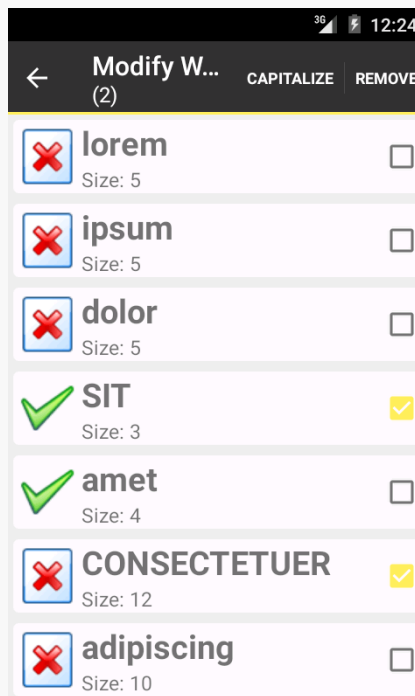

Figure 549: ActionModeList2 RecyclerView Demo, with Capitalized Words

Adding and Removing Items

There are also methods on RecyclerView.Adapter to specifically call out when you are adding or removing items from the adapter. Not only does this cause the RecyclerView to update itself, but it will animate the changes, if the relevant position(s) are visible.

Specifically, you can call:

- `notifyItemInserted()`, to indicate that a new item was inserted at a specified position, with everything else moving one position later in the roster
- `notifyItemRangeInserted()`, to insert several items in a block
- `notifyItemRemoved()`, to indicate a position that had an item removed from the roster, with later items moving up to take over earlier positions
- `notifyItemRangeRemoved()`, to remove several items in a block

The ActionModeList2 sample uses `notifyItemRemoved()` as part of its handling of the remove action mode item:

```
case R.id.remove:
    final ArrayList<Integer> positions=new ArrayList<Integer>();

    visitChecks(new ChoiceMode.Visitor() {
        @Override
        public void onCheckedPosition(int position) {
            positions.add(position);
        }
    });

    Collections.sort(positions, Collections.reverseOrder());

    for (int position : positions) {
        getItem().remove(position);
        notifyItemRemoved(position);
    }

    clearChecks();
    activeMode.finish();
    break;
```

(from [RecyclerView/ActionModeList2/app/src/main/java/com/commonsware/android/recyclerview/actionmodelist2/MainActivity.java](#))

RECYCLERVIEW

Because items slide up to take over vacated positions, when removing items, it is important to remove the lowest items first and work your way up the roster. That is why this code:

- Aggregates the list of positions that are checked
- Sorts the checked items in reverse order
- Iterates over the checked items, removing each from the `ArrayList` and calling `notifyItemRemoved()` to inform the adapter that the old item at this position is now gone
- Clears all of the checks from the `ChoiceMode` (as all checked items are now removed) and finishes the action mode (as there are no more checked items)

The result is that when the user removes items, they rapidly fade out, then later items in the list slide up to occupy the now-vacated space. If you would prefer to use other animations, you can do so, by creating your own subclass of `RecyclerView.ItemAnimator` and attaching it to the `RecyclerView` with `setItemAnimator()`.

The Order of Things

Version 22+ of `recyclerview-v7` offers `SortedList`. On the surface, the class appears to be a regular `List` that offers sorting. However, it also has a callback interface designed to be tied into `RecyclerView`, so that changes made to the `SortedList` can be reflected in the `RecyclerView` itself, complete with animations, optional batched processing, and so on.

This is illustrated in the [RecyclerView/SortedList](#) sample project. Along the way, we will also see how to use `RecyclerView` in a fragment and how to populate `RecyclerView` from the background thread.

The Gradle Change

This project requires version 22 or higher of `recyclerview-v7`, as the original v21 release of `recyclerview-v7` did not have `SortedList`. So, the Gradle build file requests something appropriate:

```
implementation 'com.android.support:recyclerview-v7:22.2.0'  
implementation 'com.android.support:cardview-v7:22.2.0'
```

(from [RecyclerView/SortedList/app/build.gradle](#))

RECYCLERVIEW

Note that it pulls in the same version of `cardview-v7`. In general, it is best to try to keep Android Support package libraries in sync, at least in terms of major versions. Similarly, it is best to have the `compileSdkVersion` match the major library version, as the library may be conditionally using APIs made available in that version of Android. Hence, the project also has `compileSdkVersion` (and `buildTools`) set to pull from v22:

```
compileSdkVersion 22
buildToolsVersion '26.0.2'
```

(from [RecyclerView/SortedList/app/build.gradle](#))

The RecyclerViewFragment

Prior samples in this chapter used a `RecyclerViewActivity` for basic `RecyclerView` setup. However, in this sample, we want to use a retained fragment for managing the `AsyncTask`, which suggests putting the `RecyclerView` in a fragment, rather than having it be managed directly by the activity.

So, this project has a reworking of `RecyclerViewActivity` into `RecyclerViewFragment`:

```
package com.commonware.android.recyclerview.sorted;

import android.app.Fragment;
import android.os.Bundle;
import android.support.v7.widget.RecyclerView;
import android.view.LayoutInflater;
import android.view.View;
import android.view.ViewGroup;

public class RecyclerViewFragment extends Fragment {
    @Override
    public View onCreateView(LayoutInflater inflater, ViewGroup container,
        Bundle savedInstanceState) {
        RecyclerView rv=new RecyclerView(getActivity());

        rv.setHasFixedSize(true);

        return(rv);
    }

    public void setAdapter(RecyclerView.Adapter adapter) {
        getRecyclerView().setAdapter(adapter);
    }
}
```

RECYCLERVIEW

```
public RecyclerView.Adapter getAdapter() {
    return(getRecyclerView().getAdapter());
}

public void setLayoutManager(RecyclerView.LayoutManager mgr) {
    getRecyclerView().setLayoutManager(mgr);
}

public RecyclerView getRecyclerView() {
    return((RecyclerView)getView());
}
}
```

(from [RecyclerView/SortedList/app/src/main/java/com/commonsware/android/recyclerview/sorted/RecyclerViewFragment.java](#))

Basically, what had been in `onCreate()` mostly moves into `onCreateView()`, where we set up the `RecyclerView`. The rest of the core API is unchanged.

The project has `SortedFragment`, which extends `RecyclerViewFragment` and handles loading of the data — we will examine more of it later in this chapter.

The revised `MainActivity` then just loads up `SortedFragment` via a `FragmentManager`:

```
package com.commonsware.android.recyclerview.sorted;

import android.app.Activity;
import android.os.Bundle;

public class MainActivity extends Activity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        if (getFragmentManager().findFragmentById(android.R.id.content) == null) {
            getFragmentManager().beginTransaction()
                .add(android.R.id.content,
                    new SortedFragment()).commit();
        }
    }
}
```

(from [RecyclerView/SortedList/app/src/main/java/com/commonsware/android/recyclerview/sorted/MainActivity.java](#))

The SortedFragment

Most of SortedFragment is reminiscent of the original AsyncTask demo from [the chapter on threads](#), mashed up with one of the CardView/RecyclerView samples from earlier in this chapter. However, the SortedList gets weaved throughout.

The SortedList

The model in the original AsyncTask demo was a simple ArrayList. Now it is a SortedList, initialized in onCreate() of the SortedFragment:

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    setRetainInstance(true);

    model=new SortedList<String>(String.class, sortCallback);

    task=new AddStringTask();
    task.execute();
}
```

(from [RecyclerView/SortedList/app/src/main/java/com/commonsware/android/recyclerview/sorted/SortedFragment.java](#))

The SortedList constructor takes two parameters:

- the Java class object for the models inside the list (in this case, String.class)
- a SortedList.Callback object that will be invoked when the model changes based on List APIs (e.g., add(), insert(), remove())

There is an optional third parameter for the capacity, unused in this sample.

We will take a peek at the SortedList.Callback implementation, named sortCallback, shortly.

The IconicAdapter

The IconicAdapter from earlier RecyclerView samples worked directly off of the static array of String values. Now, we want it to work off of the model SortedList.

RECYCLERVIEW

Hence, `onBindViewHolder()` and `getItemCount()` need to be modified to refer to appropriate methods on the model:

```
class IconicAdapter extends RecyclerView.Adapter<RowController> {
    @Override
    public RowController onCreateViewHolder(ViewGroup parent, int viewType) {
        return(new RowController(getActivity().getLayoutInflater()
            .inflate(R.layout.row, parent, false)));
    }

    @Override
    public void onBindViewHolder(RowController holder, int position) {
        holder.bindModel(model.get(position));
    }

    @Override
    public int getItemCount() {
        return(model.size());
    }
}
```

(from [RecyclerView/SortedList/app/src/main/java/com/commonsware/android/recyclerview/sorted/SortedFragment.java](#))

Also note that when we create the adapter in `onViewCreated()`, that we hold onto it in an adapter data member of the fragment:

```
@Override
public void onViewCreated(View view, Bundle savedInstanceState) {
    super.onViewCreated(view, savedInstanceState);

    setLayoutManager(new LinearLayoutManager(getActivity()));
    adapter=new IconicAdapter();
    setAdapter(adapter);
}
```

(from [RecyclerView/SortedList/app/src/main/java/com/commonsware/android/recyclerview/sorted/SortedFragment.java](#))

The SortedList.Callback

The job of the `SortedList.Callback` is to serve as the bridge between the `SortedList` and the `RecyclerView.Adapter`.

`SortedList`, as the name suggests, sorts its contents. That means that any change to the `SortedList` contents can have different impacts on the `RecyclerView`. For example, while an `add()` to an `ArrayList` would just add a new row to the end of the

RECYCLERVIEW

RecyclerView, an `add()` on `SortedList` might need to insert a row in the middle of the `RecyclerView`, to maintain the sorted order.

Hence, your `SortedList.Callback` is responsible for two things:

- Helping with the sorting itself, by comparing elements
- Passing information about how the sorting is done out to the `RecyclerView.Adapter`, so the appropriate moves can be made there, complete with animations

With that in mind, here is the `sortedCB` implementation of `SortedList.Callback`:

```
private SortedList.Callback<String> sortCallback=new SortedList.Callback<String>() {
    @Override
    public int compare(String o1, String o2) {
        return o1.compareTo(o2);
    }

    @Override
    public boolean areContentsTheSame(String oldItem, String newItem) {
        return(areItemsTheSame(oldItem, newItem));
    }

    @Override
    public boolean areItemsTheSame(String oldItem, String newItem) {
        return(compare(oldItem, newItem)==0);
    }

    @Override
    public void onInserted(int position, int count) {
        adapter.notifyItemRangeInserted(position, count);
    }

    @Override
    public void onRemoved(int position, int count) {
        adapter.notifyItemRangeRemoved(position, count);
    }

    @Override
    public void onMoved(int fromPosition, int toPosition) {
        adapter.notifyItemMoved(fromPosition, toPosition);
    }

    @Override
    public void onChanged(int position, int count) {
        adapter.notifyItemRangeChanged(position, count);
    }
};
```

(from [RecyclerView/SortedList/app/src/main/java/com/commonsware/android/recyclerview/sorted/SortedFragment.java](#))

The first method is your standard sort of `compare()` comparison method, as you might implement on a `Comparator`. It should return zero if the two model objects

are the same from a sorting standpoint, a negative number if the first parameter sorts before the second parameter, or a positive number if the first parameter sorts after the second parameter.

Then there are two similarly-named methods that serve as more-or-less replacements for the `equals()` that you might have on a `Comparator`: `areContentsTheSame()` and `areItemsTheSame()`.

`areItemsTheSame()` should return `true` if the two passed-in values represent the same actual logical item. In the case of `SortedFragment`, that is simply whether or not the strings are equal. But, with a more complex data model, you might be comparing primary keys or some other form of immutable identifier.

`areContentsTheSame()` should return `true` if the visual representation of the items look the same, as this will be used to optimize the changes made to the `RecyclerView`.

For example, suppose a shopping cart fragment wanted to use `SortedList`. Further suppose that if you added three boxes of laundry detergent to the cart, rather than having one row in the list with “Quantity: 3”, you were representing them as three rows in the `RecyclerView`. In this case:

- `compare()` returns a value to indicate the sorting rules of those shopping cart items, perhaps based on the title of the item
- `areItemsTheSame()` might return `false` for any combination of these three items, as they are logically distinct rows within the `RecyclerView`
- `areContentsTheSame()` might return `true` for any combination of these three items, as while they are three separate line items, each is visually identical in terms of what the `RecyclerView` rows look like

In many cases, `areContentsTheSame()` can simply invoke `areItemsTheSame()`, under the premise that different items *probably* have different visual representations. That is what is done in this sample, where `areItemsTheSame()` in turn uses `compare()` to see whether or not the items are the same.

Finally, there are four `on...()` methods that are simply forwarded along to their `RecyclerView.Adapter` counterparts, so changes to the `SortedList` make the corresponding changes to the `RecyclerView` contents.

Note that there is a `SortedListAdapterCallback` that takes a `RecyclerView.Adapter` as a constructor parameter and handles the `on...()` methods for you. However,

RECYCLERVIEW

since we want to retain the `SortedList` across configuration changes, and since `SortedList` does not allow us to change the `SortedList.Callback` object, we cannot readily switch the `SortedList` to the new fragment and new adapter after a configuration change.

The AsyncTask

The `AddStringTask` is the same as with the original `AsyncTask` sample, except that now it adds the words to the `SortedList`, which (via its `Callback`) will update the `RecyclerView`:

```
private class AddStringTask extends AsyncTask<Void, String, Void> {
    @Override
    protected Void doInBackground(Void... unused) {
        for (String item : items) {
            if (isCancelled())
                break;

            publishProgress(item);
            SystemClock.sleep(400);
        }

        return(null);
    }

    @Override
    protected void onProgressUpdate(String... item) {
        if (!isCancelled()) {
            model.add(item[0]);
        }
    }

    @Override
    protected void onPostExecute(Void unused) {
        Toast.makeText(getActivity(), R.string.done, Toast.LENGTH_SHORT)
            .show();

        task=null;
    }
}
```

(from [RecyclerView/SortedList/app/src/main/java/com/commonsware/android/recyclerview/sorted/SortedFragment.java](#))

The Results

If you run this sample, you will see the words be added to the list, every 400ms. However, in the original `ListView`-based sample, new rows were appended to the end, and so you would not see new rows appear after the `ListView` space was filled. In this sample, the Latin words are sorted by `SortedList`, and you will see them animate into position at the appropriate spots as they are added. In the end, you get the same look as in earlier `CardView`-based `RecyclerView` implementations, except that the words are sorted:

Other Bits of Goodness

To quote the infamous American infomercial line: “But wait! There’s more!”

In addition to `LinearLayoutManager` and `GridLayoutManager`, there is `StaggeredGridLayoutManager`. With a vertically-scrolling `GridLayoutManager`, rows are all a consistent height, but the cell widths might vary. With a vertically-scrolling `StaggeredGridLayoutManager`, the columns are all the same width, but the cell heights might vary.

All three of the standard layout managers support horizontal operation as well, through a `boolean` on a constructor. In these cases, the content will scroll horizontally, rather than vertically. This eliminates the need for third-party horizontal `ListView` implementations and the like.

And, of course, you can implement your own `RecyclerView.LayoutManager`, avoiding any of the built-in ones.

Animating the Deltas Using DiffUtil

`SortedList` is interesting, but it is inflexible. For example, you cannot readily change the sort order, without completely replacing the `SortedList`.

Moreover, it assumes that the changes that you want to make are simply to keep a list in sorted order. There are plenty of other possible changes to your data set that might occur, such as from the results of some Web service call to synchronize your local data with that on a server. You would have to somehow perform your own “diff” on the data shown in your `RecyclerView` and the new roster of data, to determine what changed, what did not change, and how those changes affect things like item positions within the list or grid.

Fortunately, the 25.0.0+ version of `recyclerview-v7` gives you another tool: `DiffUtil`. This handles everything cited in the last sentence of the previous paragraph. You hand it two collections (old and new), plus an object that can help determine what the changes are (one reminiscent of a `SortedList.Callback`). It gives you a results object that, in turn, can update the `RecyclerView` to affect those changes.

The [Java8/VideoLambda](#) sample project is yet another rendition of the “list of videos” sample app from earlier in this chapter. However, it shows the list in sorted order, but using `DiffUtil` rather than `SortedList`. This allows us to offer the user the ability to change the sort order (ascending or descending).

Model

The original version of this sample used a `Cursor` directly, wrapping it in a `RecyclerView.Adapter`. That is fine, but we cannot readily sort a `Cursor`. It is simpler to convert the `Cursor` into a list of model objects, so we can sort the list.

RECYCLERVIEW

To that end, the VideoLambda sample app has a Video class, with a constructor that can populate itself from a Cursor positioned on a valid row:

```
package com.commonware.android.recyclerview.videolist;

import android.content.ContentUris;
import android.database.Cursor;
import android.net.Uri;
import android.provider.MediaStore;

class Video implements Comparable<Video> {
    final String title;
    final Uri videoUri;
    final String mimeType;

    Video(Cursor row) {
        this.title=
            row.getString(row.getColumnIndex(MediaStore.Video.Media.TITLE));
        this.videoUri=ContentUris.withAppendedId(
            MediaStore.Video.Media.EXTERNAL_CONTENT_URI,
            row.getInt(row.getColumnIndex(MediaStore.Video.Media._ID)));
        this.mimeType=
            row.getString(row.getColumnIndex(MediaStore.Video.Media.MIME_TYPE));
    }

    @Override
    public boolean equals(Object obj) {
        if (!(obj instanceof Video)) {
            return(false);
        }

        return(videoUri.equals(((Video)obj).videoUri));
    }

    @Override
    public int hashCode() {
        return(videoUri.hashCode());
    }

    @Override
    public int compareTo(Video video) {
        return(title.compareTo(video.title));
    }
}
```

(from [Java8/VideoLambda/app/src/main/java/com/commonware/android/recyclerview/videolist/Video.java](https://github.com/CommonWare/VideoLambda/blob/master/app/src/main/java/com/commonware/android/recyclerview/videolist/Video.java))

RECYCLERVIEW

Note that `Video` has an implementation of `equals()` considering two `Video` objects to be equal if they point to the same `Uri`. That will be important when we use `DiffUtil`, as `DiffUtil` (and our helper code) need to know when two `Video` objects logically represent the same video.

`Video` also implements `Comparable` and therefore has a `compareTo()` method, implemented by comparing the titles of the videos. This will be used as part of our sorting logic.

The `VideoAdapter` has a `setVideos()` method, taking a `Cursor` that we loaded from the `MediaStore`, as before. However, now `VideoAdapter` does not hold that `Cursor` in a field. Rather, it holds an `ArrayList` of `Video` objects as the `videos` field, with `setVideos()` handling the conversion of data from the `Cursor` into the `Video` objects:

```
void setVideos(Cursor c) {
    if (c==null) {
        videos=null;
        notifyDataSetChanged();
    }
    else {
        ArrayList<Video> temp=new ArrayList<>();

        while (c.moveToNext()) {
            temp.add(new Video(c));
        }

        if (videos==null) {
            videos=new ArrayList<>();
        }

        sortAndApply(temp);
    }
}
```

@Override

(from [Java8/VideoLambda/app/src/main/java/com/commonsware/android/recyclerview/videolist/MainActivity.java](#))

We will see the `sortAndApply()` method, and understand what the `temp` local variable is all about, a bit later in this section. For now, take it on faith that:

- If the `Cursor` is null (e.g., `onLoaderReset()` was called), we null out the `videos` field and call `notifyDataSetChanged()`, to let the `RecyclerView` know that our entire roster of videos changed

- If the Cursor is not null, we convert it into an ArrayList of Video objects, then use `sortAndApply()` to update the RecyclerView

The Menu

The other time we need to sort the videos is if the user chooses to switch from ascending to descending sort (or back again).

The app has a menu resource with a checkable menu `<item>`, named `sort`, that the user will be able to use to toggle the sort order:

```
<?xml version="1.0" encoding="utf-8"?>
<menu xmlns:android="http://schemas.android.com/apk/res/android">
  <item
    android:id="@+id/sort"
    android:checkable="true"
    android:checked="true"
    android:enabled="false"
    android:showAsAction="never"
    android:title="@string/sort_ascending" />
</menu>
```

(from [Java8/VideoLambda/app/src/main/res/menu/actions.xml](#))

Note that it is disabled initially. When the app starts up, we do not yet have our videos, since they need to be loaded from the MediaStore. Hence, we keep the item disabled until the videos are ready.

In the activity's `onCreateOptionsMenu()` method, we inflate the resource, get the sort MenuItem, hold onto it in a field (also named `sort`), and enable it if the VideoAdapter happens to already have some videos:

```
@Override
public boolean onCreateOptionsMenu(Menu menu) {
    getMenuInflater().inflate(R.menu.actions, menu);
    sort=menu.findItem(R.id.sort);
    sort.setEnabled(adapter.getItemCount()>0);

    return(super.onCreateOptionsMenu(menu));
}
```

(from [Java8/VideoLambda/app/src/main/java/com/commonsware/android/recyclerview/videolist/MainActivity.java](#))

Then, in `onOptionsItemSelected()`, if the user taps on this action bar item, we toggle its checked state, then tell the VideoAdapter to `sort()` based upon that state:

RECYCLERVIEW

```
@Override
public boolean onOptionsItemSelected(MenuItem item) {
    if (item.getItemId()==R.id.sort) {
        item.setChecked(!item.isChecked());
        adapter.sort(item.isChecked());

        return(true);
    }

    return(super.onOptionsItemSelected(item));
}
```

(from [Java8/VideoLambda/app/src/main/java/com/commonsware/android/recyclerview/videolist/MainActivity.java](#))

sort(), in turn, keeps track of the current sort order, then calls the same sortAndApply() that we did in setVideos():

```
        sortAscending=checked;
        sortAndApply(new ArrayList<>(videos));
    }
}
}
```

(from [Java8/VideoLambda/app/src/main/java/com/commonsware/android/recyclerview/videolist/MainActivity.java](#))

The Diff-ing

The job of sortAndApply() is to do what the name suggests: sort the videos and apply the sorted list to the RecyclerView. In principle, there are two possible scenarios:

1. We are showing the videos for the very first time
2. We are showing the videos again, after a re-sort, or perhaps after a new video was scanned by the MediaStore, triggering the Loader framework to hand us a fresh Cursor

Fortunately, we can handle both the same way:

```
        Collections.sort(newVideos,
            (one, two) -> one.compareTo(two));
    }
    else {
        Collections.sort(newVideos,
            (one, two) -> two.compareTo(one));
    }
```

RECYCLERVIEW

```
    }

    DiffUtil.Callback cb=new SimpleCallback<>(videos, newVideos);
    DiffUtil.DiffResult result=DiffUtil.calculateDiff(cb, true);

    videos=newVideos;
    result.dispatchUpdatesTo(this);
}

private void sort(boolean checked) {
```

(from [Java8/VideoLambda/app/src/main/java/com/commonsware/android/recyclerview/videolist/MainActivity.java](#))

The new list of videos is the newVideos parameter to sortAndApply(). Based on the sortAscending value, we use Collections.sort() to sort the newVideos list... using a Java 8 lambda expression. Lambda expressions are covered [elsewhere in the book](#). However, we could just sort using an anonymous inner class implementation of Comparator, such as this for sorting in ascending order:

```
Collections.sort(temp, new Comparator<Video>() {
    @Override
    public int compare(Video one, Video two) {
        return(one.compareTo(two));
    }
});
```

Given the newly-sorted list, we create an instance of a DiffUtil.Callback object, called SimpleCallback. We will see its implementation shortly. Its role is to help DiffUtil calculate the nature of the changes to list of videos, comparing what is in the RecyclerView now (videos) with what we want the RecyclerView to show (newVideos).

That DiffUtil.Callback object is passed to the calculateDiff() method on DiffUtil. The second parameter — true — indicates whether or not objects in the list may have moved. Sometimes, we know that the updates do not move objects around in the list, but merely insert new ones or remove existing ones. In such cases, calculateDiff() can optimize its tracking algorithm to run more efficiently. In our case, we most definitely are changing the positions of existing objects, and therefore we need to pass true.

In principle, calculateDiff() should be called on a background thread. For long lists and complicated comparisons, calculateDiff() could take long enough that you might [exhibit some jank](#) by taking up too much time on the main application

thread. In this case, the comparisons are cheap, and hopefully you do not have too many videos on your test device.

The result of `calculateDiff()` is a `DiffUtil.DiffResult` object. After updating our video field to be the sorted `newVideos` collection, we call `dispatchUpdatesTo()` on the `DiffResult`, to have it apply the changes to the `VideoAdapter`. We need to update videos first because `dispatchUpdatesTo()` may trigger fresh `onBindViewHolder()` calls, and we need to make sure that we are using the newly-sorted list for those.

The SimpleCallback

`SimpleCallback`, as the name suggests, is a naive implementation of `DiffUtil.Callback`:

```
package com.commonware.android.recyclerview.videolist;

import android.support.v7.util.DiffUtil;
import java.util.ArrayList;

class SimpleCallback<T extends Comparable> extends DiffUtil.Callback {
    private final ArrayList<T> oldItems;
    private final ArrayList<T> newItems;

    public SimpleCallback(ArrayList<T> oldItems,
        ArrayList<T> newItems) {
        this.oldItems=oldItems;
        this.newItems=newItems;
    }

    @Override
    public int getOldListSize() {
        return(oldItems.size());
    }

    @Override
    public int getNewListSize() {
        return(newItems.size());
    }

    @Override
    public boolean areItemsTheSame(int oldItemPosition,
        int newItemPosition) {
        return(oldItems.get(oldItemPosition)
            .equals(newItems.get(newItemPosition)));
    }
}
```

RECYCLERVIEW

```
}  
  
@Override  
public boolean areContentsTheSame(int oldItemPosition,  
                                  int newItemPosition) {  
    return(oldItems.get(oldItemPosition)  
           .compareTo(newItems.get(newItemPosition))==0);  
}  
}
```

(from [Java8/VideoLambda/app/src/main/java/com/commonsware/android/recyclerview/videolist/SimpleCallback.java](#))

Any `DiffUtil.Callback` needs to implement four key abstract methods:

- `getOldListSize()` and `getNewListSize()`, which return pretty much what their names would indicate
- `areItemsTheSame()`, where you need to indicate if a particular item from the old list (identified by position) represents the same logical entity as does a particular item from the new list (also identified by position)
- `areContentsTheSame()`, where you need to indicate if objects from the old and new list (identified by positions) are similar enough that the user would not notice a visual difference

Those latter two methods basically fill the same roles as do methods of the same names on a `SortedList.Callback`.

In the case of `SimpleCallback`, `areItemsTheSame()` uses `equals()`. Since `Video` implements `equals()` to compare the `video Uri` values, `areItemsTheSame()` will return `true` if the two `Video` objects point to the same video.

`areContentsTheSame()` leverages `compareTo()`, which compares the titles of the videos. If `compareTo()` return `0`, the titles are the same, and so `areContentsTheSame()` returns `true` to indicate that the visual representation of the videos is the same. This might not actually be the case, as we are showing the video thumbnails in the rows, and so it is possible that we have two videos that have the same title but different thumbnails. In that case, `DiffUtil` might not cause `RecyclerView` to redraw one or the other row. An alternative approach would be to have `areContentsTheSame()` simply return the value of `areItemsTheSame()`. This covers the thumbnails issue, at the expense of possibly doing some unnecessary shuffling of `RecyclerView` items, for cases where we have two videos with identical titles and thumbnails. It will be up to you, in your own app, to determine the best implementation of `areContentsTheSame()` based on your UI.

The March of the Libraries

By this point in time, you may be wailing in anguish and rending your garments over how much is involved in getting RecyclerView going.

(pro tip: do not rend your garments in public, to avoid running afoul of indecency laws)

There is little doubt that RecyclerView is the epitome of “some assembly required”. However, other developers have come to the forefront with libraries that can help fill in these gaps without you having to roll all the code yourself.

Note that the author has not tried many of these libraries, and listing them here neither is an endorsement of these libraries nor a knock on any libraries not listed here.

DynamicRecyclerView

The [DynamicRecyclerView library](#) offers:

- Drag and drop reordering of items, via a simple custom `OnItemTouchListener` implementation
- An implementation of the horizontal “swipe-to-dismiss” UI pattern, also via a custom `OnItemTouchListener` implementation
- An implementation of choice modes, akin to those shown in this chapter
- An implementation of click-style events, by handling them as touch events using yet another custom `OnItemTouchListener` implementation

Advanced RecyclerView

The [Advanced RecyclerView library](#) offers its own drag-and-drop and swipe-to-dismiss implementations. Rather than using `OnItemTouchListener` implementations, you implement certain interfaces on your `RecyclerView.Adapter` and `RecyclerView.ViewHolder` classes to support drag-and-drop and/or swipe-to-dismiss, plus work with “manager” classes to tie the support together.

It also supports an expandable item, where clicking on the item expands or collapses a set of views vertically beneath the item, offering an approach for using RecyclerView to replace `ExpandableListView`. And, it has a few item decorators, including a basic divider implementation.

SuperRecyclerView

The [SuperRecyclerView library](#) has its own swipe-to-dismiss implementation. It also supports the “swipe layout” pattern, where a horizontal swipe gesture slides out the main view and uncovers a set of contextual operations on the item.

It also offers:

- scrollbars (which are not enabled on RecyclerView)
- progress bars and/or empty views to handle the asynchronous loading of data
- an “endless” or “infinite scrolling” implementation, where when the user scrolls to the bottom of the data, you get a chance to go load more data
- sticky headers, where as the user scrolls, the top-most header remains pinned to the top of the RecyclerView, until replaced by a new header that scrolls to the top

However, this library requires that you inherit from a custom RecyclerView subclass.

FlexibleDivider

The [FlexibleDivider library](#) does just one thing: provides dividers. However, it offers *deep* support for dividers, where you can easily control all sorts of aspects, from color and width to margins and path effects (e.g., dashed lines versus solid lines).

The [RecyclerView/FlexDividerList](#) sample project is a clone of the `ManualDividerList` sample from earlier in the chapter, where the dividers are now provided by the FlexibleDivider library, which is loaded via the `build.gradle` file:

```
dependencies {  
    implementation 'com.android.support:recyclerview-v7:22.2.0'  
    implementation 'com.yqritc:recyclerview-flexibledivider:1.0.1'  
}
```

(from [RecyclerView/FlexDividerList/app/build.gradle](#))

Then, we use the library’s `HorizontalDividerItemDecoration` to set up our dividers:

```
@Override  
public void onCreate(Bundle state) {  
    super.onCreate(state);  
  
    setLayoutManager(new LinearLayoutManager(this));  
}
```

RECYCLERVIEW

```
RecyclerView.ItemDecoration decor=  
    new HorizontalDividerItemDecoration.Builder(this)  
        .color(getResources().getColor(R.color.primary))  
        .build();  
  
getRecyclerView().addItemDecoration(decor);  
setAdapter(new IconicAdapter());  
}
```

(from [RecyclerView/FlexDividerList/app/src/main/java/com/commonsware/android/recyclerview/flexdivider/MainActivity.java](#))

The results are a solid blue divider:

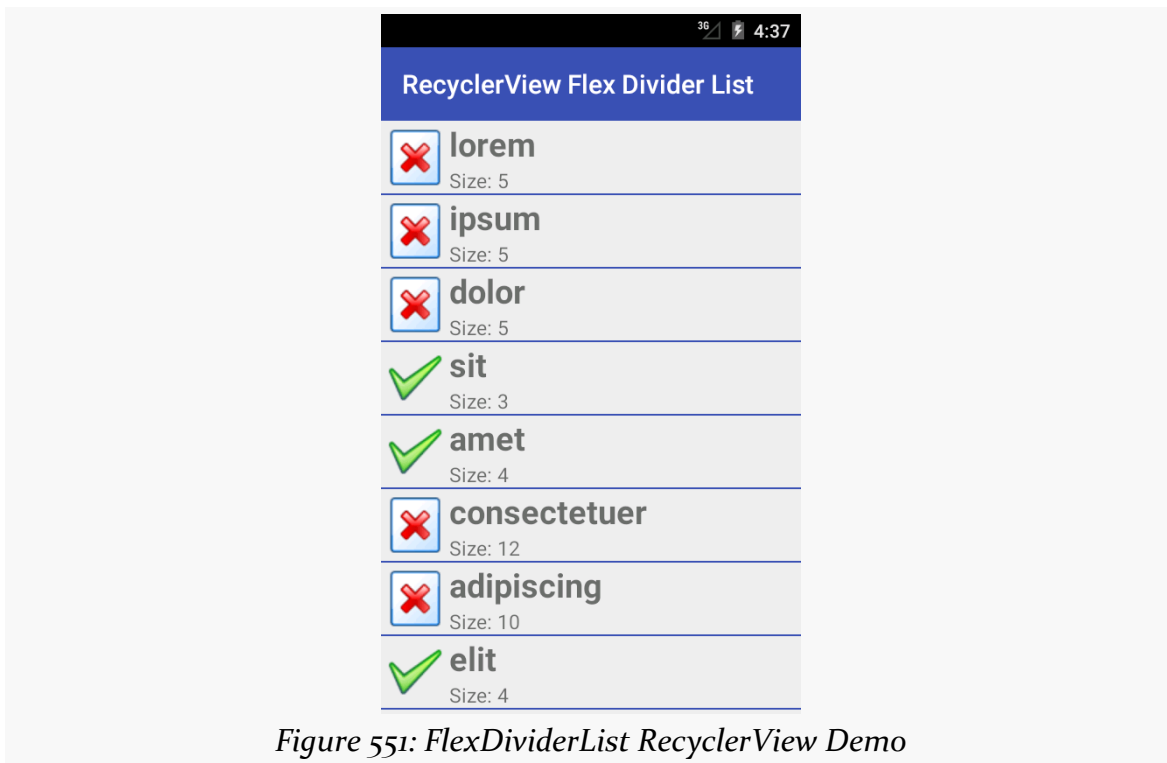

Figure 551: FlexDividerList RecyclerView Demo

Of course, through the library, you can change a lot more about the divider than just its color, through its builder-style API.

Expandable Rows

A common pattern in vertically-scrolling lists is to have the rows expand and contract when clicked. This allows you to have more information inline in the list, without always taking up all of the vertical space that the information might require.

This might not sound very hard: just toggle the visibility of some widgets, perhaps using an animation.

However, what we really want is that when a row is expanded, that the entirety of the expanded row is visible, assuming that there is sufficient screen space for it. Otherwise, if the user happens to expand some row at the bottom of the list, the user might not realize that more information is available off the bottom of the screen.

Making this work requires knowing where the row is in the list, how much space will be required when it is expanded, whether the expanded row will fit given the RecyclerView size, and how to scroll the RecyclerView to make the row fit if needed.

That sounds complicated.

And so, we turn to a library: the `ExpandableLayout` provided by [com.github.SilenceDut:ExpandableLayout](https://github.com/SilenceDut/ExpandableLayout). This library is demonstrated in the [RecyclerView/ExpandableRow](#) sample project. However, this sample project makes extensive use of [the data binding framework](#), so you may wish to read that chapter before continuing with this section.

This app is another “list the recent questions on Stack Overflow” apps that have been profiled elsewhere in the book, starting with [the chapter on Internet access](#). In this case, we are using a RecyclerView for the list, with the data binding framework populating the rows.

A Stack Overflow question has [lots of possible pieces of data](#), far more than we would want to display in a RecyclerView row. Even showing a subset of this information would make for a really long list, as each row would be fairly large. So, instead, we will use `ExpandableLayout` to show the title, owner’s avatar, and question score all the time and show the tags, view count, and answer count after the user taps on a row. Since we are “stealing” the click event to expand and collapse the row, we cannot use it for anything else, so we also want a “View” button in the expanded area, to allow the user to view the Stack Overflow question on the Stack Overflow Web site.

Our `build.gradle` file pulls in libraries for accessing the Stack Exchange API (Retrofit and Picasso), libraries for displaying the results (`recyclerview-v7` and `cardview-v7`), plus `ExpandableLayout`:

RECYCLERVIEW

```
apply plugin: 'com.android.application'

repositories {
    maven { url "https://jitpack.io" }
}

dependencies {
    implementation 'com.squareup.picasso:picasso:2.5.2'
    implementation 'com.squareup.retrofit:retrofit:1.9.0'
    implementation 'com.android.support:recyclerview-v7:24.1.1'
    implementation 'com.android.support:cardview-v7:24.1.1'
    implementation 'com.github.SilenceDut:ExpandableLayout:1.2.0'
}

android {
    compileSdkVersion 24
    buildToolsVersion '26.0.2'

    defaultConfig {
        minSdkVersion 15
        targetSdkVersion 24
        versionCode 1
        versionName "1.0"
        applicationId "com.commonware.android.databind.expandable"
    }

    dataBinding {
        enabled = true
    }
}
```

(from [RecyclerView/ExpandableRow/app/build.gradle](#))

An `ExpandableLayout` contains two children. The first child will be shown all the time, while the second child represents the additional content to be shown when the `ExpandableLayout` is expanded. So, our `res/layout/row.xml` resource contains an `ExpandableLayout`, wrapping around the desired UI. The `ExpandableLayout` itself is wrapped in a `CardView` for formatting, and the whole thing is inside a `<layout>` for the data binding framework:

```
<?xml version="1.0" encoding="utf-8"?>
<layout xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:app="http://schemas.android.com/apk/res-auto">

    <data>

    <import type="android.text.Html" />
```

RECYCLERVIEW

```
<import type="android.text.TextUtils" />

<variable
    name="question"
    type="com.commonware.android.databind.basic.Question" />

<variable
    name="controller"
    type="com.commonware.android.databind.basic.QuestionController" />
</data>

<android.support.v7.widget.CardView
    xmlns:cardview="http://schemas.android.com/apk/res-auto"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:layout_margin="4dp"
    cardview:cardCornerRadius="4dp">

    <com.silencedut.expandablelayout.ExpandableLayout
        android:id="@+id/row_content"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:background="?android:attr/selectableItemBackground"
        android:onTouch="@{controller::onTouch}"
        app:expWithParentScroll="true">

        <LinearLayout
            android:layout_width="match_parent"
            android:layout_height="wrap_content"
            android:orientation="horizontal">

            <ImageView
                android:id="@+id/icon"
                android:layout_width="@dimen/icon"
                android:layout_height="@dimen/icon"
                android:layout_gravity="center_vertical"
                android:contentDescription="@string/icon"
                android:padding="8dp"
                app:error="@{@drawable/owner_error}"
                app:imageUrl="@{question.owner.profileImage}"
                app:placeholder="@{@drawable/owner_placeholder}" />

            <TextView
                android:id="@+id/title"
                android:layout_width="0dp"
                android:layout_height="wrap_content"
                android:layout_gravity="left|center_vertical"
                android:layout_weight="1"
                android:text="@{Html.fromHtml(question.title)}"
                android:textSize="20sp" />

            <TextView
                android:id="@+id/score"
                android:layout_width="wrap_content"
                android:layout_height="wrap_content"
                android:layout_gravity="center_vertical"
                android:layout_marginLeft="8dp"
                android:layout_marginRight="8dp"
                android:text="@{Integer.toString(question.score)}">

        </LinearLayout>

    </com.silencedut.expandablelayout.ExpandableLayout>

</android.support.v7.widget.CardView>
```

RECYCLERVIEW

```
        android:textSize="40sp"
        android:textStyle="bold" />

</LinearLayout>

<LinearLayout
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:orientation="horizontal"
    android:padding="8dp">

    <LinearLayout
        android:layout_width="0dp"
        android:layout_height="wrap_content"
        android:layout_weight="1"
        android:orientation="vertical">

        <TextView
            android:layout_width="wrap_content"
            android:layout_height="wrap_content"
            android:ellipsize="end"
            android:maxLines="1"
            android:text="@{string/tags+" "+TextUtils.join(", ", question.tags)}' />

        <TextView
            android:layout_width="wrap_content"
            android:layout_height="wrap_content"
            android:text="@{string/views+" "+question.viewCount}' />

        <TextView
            android:layout_width="wrap_content"
            android:layout_height="wrap_content"
            android:text="@{string/answers+" "+question.answerCount}' />

    </LinearLayout>

    <Button
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:onClick="@{()->controller.showQuestion(context, question)}"
        android:text="@string/btn_view" />
</LinearLayout>
</com.silencedut.expandablelayout.ExpandableLayout>
</android.support.v7.widget.CardView>
</layout>
```

(from [RecyclerView/ExpandableRow/app/src/main/res/layout/row.xml](#))

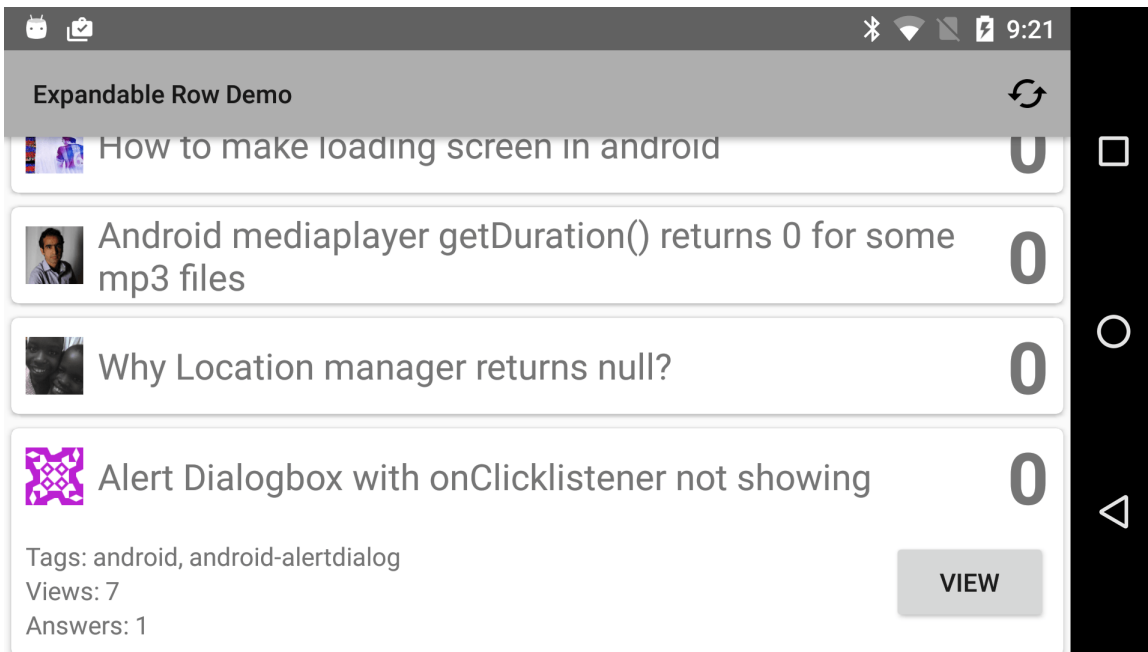

We do not need to do anything to teach `ExpandableLayout` to expand and collapse based upon click events, as that is built into the class. However, we do opt into one optional feature, via `app:expWithParentScroll="true"`. This indicates that we want to scroll the parent (here, referring to the `RecyclerView`) to allow the expanded `ExpandableLayout` to be fully visible where possible.

When the activity is launched, the rows are collapsed:

RECYCLERVIEW

Tapping on one expands it to show the rest of the content, including scrolling the RecyclerView so it is visible:

Advanced RecyclerView

RecyclerView is the “Swiss army knife” of Android selection widgets. You can use it for a wide range of scenarios, well beyond what classic AdapterView widgets — like ListView or GridView — could handle.

In this chapter, we will “go outside the (AdapterView) box” and explore some advanced uses of RecyclerView.

Prerequisites

Understanding this chapter requires that you have read [the preceding chapter](#), on RecyclerView.

RecyclerView as Pager

ViewPager has been used for horizontally-swiped page-at-a-time user interfaces since its debut in 2011.

However, ViewPager is not that flexible:

- You can only swipe horizontally. It has no `setSwipeDirection()` or similar method to switch to vertical swiping.
- It was designed to work with fragments as pages. While `PagerAdapter` itself can work with views as pages, even the minimum required API is difficult to understand. And using fragments as pages means that you may wind up in cases with nested fragments, which adds to the complexity.
- While `PagerAdapter` has enough hooks to allow you to add and remove pages on the fly, neither `FragmentPagerAdapter` nor

FragmentManager support this use case, requiring you to roll your own PagerAdapter implementation.

And so on.

However, as it turns out, RecyclerView can be readily adapted to serve as a ViewPager replacement. Instead of a PagerAdapter, you use an ordinary RecyclerView.Adapter, where your pages are simple views. RecyclerView itself is far more flexible than is ViewPager, giving you a stronger foundation for more advanced paging scenarios.

Using RecyclerViewPager

The original solution for using RecyclerView as a ViewPager replacement came in the form of a third-party library, `com.github.lsjwzh.RecyclerViewPager`. This library offers a `RecyclerViewPager` subclass of `RecyclerView` that offers the page-at-a-time swiping metaphor.

The [RecyclerViewPager/PlainRVP](#) sample project illustrates its use. This is another rendition of the `io-EditText-widgets` pager that was used in [the chapter on ViewPager](#), swapping in `RecyclerViewPager` for the `ViewPager`.

Adding the Dependency

The `com.github.lsjwzh.RecyclerViewPager` library is not on JCenter or Maven Central. Instead, it is on `jitpack.io`, an artifact repository that builds artifacts directly from GitHub source repositories. So, to use this library, we need to add `jitpack.io` as a repository, in addition to adding the `RecyclerViewPager` library itself:

```
apply plugin: 'com.android.application'

repositories {
    maven { url "https://jitpack.io" }
}

dependencies {
    implementation 'com.android.support:recyclerview-v7:25.1.0'
    implementation 'com.github.lsjwzh.RecyclerViewPager:lib:v1.1.2'
}

android {
```

ADVANCED RECYCLERVIEW

```
compileSdkVersion 25
buildToolsVersion '26.0.2'

defaultConfig {
    minSdkVersion 15
    targetSdkVersion 25
}
}
```

(from [RecyclerViewPager/PlainRVP/app/build.gradle](#))

Using the Widget

In the equivalent ViewPager sample app, the main.xml layout resource held the ViewPager. In this sample, it holds the RecyclerViewPager (or, more accurately, the `com.lsjwzh.widget.recyclerviewpager.RecyclerViewPager`, since the class name needs to be fully-qualified since it is coming from a library):

```
<?xml version="1.0" encoding="utf-8"?>
<com.lsjwzh.widget.recyclerviewpager.RecyclerViewPager android:id="@+id/pager"
    xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:app="http://schemas.android.com/apk/res-auto"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:clipToPadding="false"
    android:layout_margin="@dimen/pager_padding"
    app:rvp_singlePageFling="true"
    app:rvp_triggerOffset="0.1" />
```

(from [RecyclerViewPager/PlainRVP/app/src/main/res/layout/main.xml](#))

The `app:rvp_singlePageFling` indicates that we want to limit the user to switch one page at a time, rather than a long fling gesture resulting in moving through many pages at once. The `app:rvp_triggerOffset` attribute is undocumented but appears to control how much of a swipe gesture is necessary to trigger a page change.

Populating the Pages

With ViewPager, you supply the pages via a PagerAdapter, typically a FragmentPagerAdapter or a FragmentStatePagerAdapter. With RecyclerViewPager, you supply the pages via a RecyclerView.Adapter, just as you would with any other RecyclerView.

ADVANCED RECYCLERVIEW

So, in `onCreate()` of the `MainActivity`, we get the `RecyclerViewPager`, hand it a horizontal `LinearLayoutManager`, create a `PagerAdapter`, and attach that `PagerAdapter` to the `RecyclerViewPager`:

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.main);

    RecyclerViewPager pager=(RecyclerViewPager) findViewById(R.id.pager);

    pager.setLayoutManager(new LinearLayoutManager(this,
        LinearLayoutManager.HORIZONTAL, false));
    adapter=new PagerAdapter(pager, getLayoutInflater());
    pager.setAdapter(adapter);
}
```

(from [RecyclerViewPager/PlainRVP/app/src/main/java/com/commonsware/android/rvp/MainActivity.java](#))

By using a horizontal `LinearLayoutManager`, the `RecyclerViewPager` will behave akin to a regular `ViewPager`, with navigation occurring via horizontal swipes. Want a vertical `ViewPager`? Replace the horizontal `LinearLayoutManager` with a vertical one, and you are set.

Our `PagerAdapter` is a `RecyclerView.Adapter`, for a `RecyclerView.ViewHolder` named `PageController`. The basic setup for `PagerAdapter` is not that different than any other `RecyclerView.Adapter`:

- We create a `PageController` in `onCreateViewHolder()`
- We populate that `PageController` with model data in `onBindViewHolder()`
- We indicate how many items there are in `getItemCount()`

```
class PagerAdapter extends RecyclerView.Adapter<PageController> {
    private static final String STATE_BUFFERS="buffers";
    private static final int PAGE_COUNT=10;
    private final RecyclerViewPager pager;
    private final LayoutInflater inflater;
    private ArrayList<String> buffers=new ArrayList<>();

    PagerAdapter(RecyclerViewPager pager, LayoutInflater inflater) {
        this.pager=pager;
        this.inflater=inflater;

        for (int i=0;i<10;i++) {
            buffers.add("");
        }
    }

    @Override
```

ADVANCED RECYCLERVIEW

```
public PageController onCreateViewHolder(ViewGroup parent, int viewType) {
    return(new PageController(inflater.inflate(R.layout.editor, parent, false)));
}

@Override
public void onBindViewHolder(PageController holder, int position) {
    holder.setText(bufers.get(position));
}

@Override
public int getItemCount() {
    return(PAGE_COUNT);
}
```

(from [RecyclerViewPager/PlainRVP/app/src/main/java/com/commonsware/android/rvp/PageAdapter.java](#))

In this case, our model data is an `ArrayList` of `String` objects, representing the text that the user enters into each page's `EditText`. `PAGE_COUNT` caps the number of editors (and pages) at 10, and so we initialize 10 buffers in the `PageAdapter` constructor.

The layout used for the pages — inflated by `onCreateViewHolder()` — is just a full-page multi-line `EditText` widget:

```
<EditText xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/editor"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:inputType="textMultiLine"
    android:gravity="left|top"
/>
```

(from [RecyclerViewPager/PlainRVP/app/src/main/res/layout/editor.xml](#))

`PageController` is a fairly basic `RecyclerView.ViewHolder`, wrapping our `EditText` and offering a getter and setter for manipulating the text in the editor:

```
package com.commonsware.android.rvp;

import android.support.v7.widget.RecyclerView;
import android.view.View;
import android.widget.EditText;

class PageController extends RecyclerView.ViewHolder {
    private final EditText editor;

    PageController(View itemView) {
        super(itemView);
    }
}
```

ADVANCED RECYCLERVIEW

```
        editor=(EditText)itemView.findViewById(R.id.editor);
    }

    void setText(String text) {
        editor.setText(text);
        editor.setHint(editor.getContext().getString(R.string.hint,
            getAdapterPosition()+1));
    }

    String getText() {
        return(editor.getText().toString());
    }
}
```

(from [RecyclerViewPager/PlainRVP/app/src/main/java/com/commonsware/android/rvp/PageController.java](#))

In case the buffer is empty (as it is at the outset), we also set the hint of the EditText to be the current page's index, adding one to adjust the range to start at 1 rather than 0. The hint text itself is in a string resource, with a %d placeholder for the page number:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
    <string name="app_name">RVP Demo</string>
    <string name="hint">Editor #<int>d</int></string>
</resources>
```

(from [RecyclerViewPager/PlainRVP/app/src/main/res/values/strings.xml](#))

We use the N-parameter `getString()` method to not only retrieve the hint string resource but run it through `String.format()` to populate the placeholders, in this case using `getAdapterPosition()` to determine our page number.

Dealing with Recycling

RecyclerView wants to recycle its items. That is in contrast to how the stock PagerAdapter implementation work:

- FragmentPagerAdapter holds onto every fragment created due to the user's navigation
- FragmentStatePagerAdapter holds onto some fragments, but lets others get garbage-collected, to minimize memory consumption

ADVANCED RECYCLERVIEW

If our pages were read-only, we would not have to worry about recycling. This is how many RecyclerView implementations work — they just focus on binding the right data into the right RecyclerView.ViewHolder at the right time, based on calls to onBindViewHolder in the RecyclerView.Adapter.

However, when the RecyclerView items are interactive, we need to make sure that we hold onto the changed data, rather than having it be overwritten when we bind fresh data into the recycled item's views.

In PageAdapter, we handle this by overriding onViewDetachedFromWindow(), which is called when the views of a PageController are no longer part of our activity's window. Typically, this will occur as part of scrolling. In our case, we use this opportunity to grab the current contents of that EditText widget and update our buffers data model to match:

```
@Override
public void onViewDetachedFromWindow(PageController holder) {
    super.onViewDetachedFromWindow(holder);

    buffers.set(holder.getAdapterPosition(), holder.getText());
}
```

(from [RecyclerViewPager/PlainRVP/app/src/main/java/com/commonsware/android/rvp/PageAdapter.java](#))

Alternatively, you could aim to deal with this more in “real time”, such as by using a TextWatcher to update the model as the user types. That adds a fair bit of overhead, though.

Dealing with Configuration Changes

We need to make sure that we do not lose what the user types into the pages when we undergo a configuration change. Since our model is a simple ArrayList of String objects, we can use the saved instance state Bundle to hold onto the in-flight information.

A RecyclerView.Adapter does not have its own onSaveInstanceState() method, but we can add one, then call it from MainActivity:

```
@Override
protected void onSaveInstanceState(Bundle state) {
    super.onSaveInstanceState(state);

    Bundle adapterState=new Bundle();
```

ADVANCED RECYCLERVIEW

```
adapter.onSaveInstanceState(adapterState);
state.putBundle(STATE_ADAPTER, adapterState);
}
```

(from [RecyclerViewPager/PlainRVP/app/src/main/java/com/commonsware/android/rvp/MainActivity.java](#))

Here, `MainActivity` provides a fresh `Bundle` to the adapter. This way, values that the adapter wishes to save in the instance state will not collide with anything else the activity would want to save in the instance state, due to accidental key collisions. In this case, this may well be superfluous, but it is a worthwhile practice.

The challenge in our `PageAdapter` is that buffers only has text from those `PageController` objects that have been recycled. That will not include the currently-visible page or possibly some adjacent pages.

So, we iterate over all pages and call `findViewHolderForAdapterPosition()` on the `RecyclerView` itself. This will return `null` for any positions for which no `PageController` is presently allocated, or the `PageController` for the position for those positions that are actively being used. For those latter ones, we update the buffers to reflect whatever is in the `EditText` widgets, saving that into the instance state `Bundle`:

```
void onSaveInstanceState(Bundle state) {
    for (int i=0;i<PAGE_COUNT;i++) {
        PageController holder=
            (PageController)pager.findViewHolderForAdapterPosition(i);

        if (holder!=null) {
            buffers.set(i, holder.getText());
        }
    }

    state.putStringArrayList(STATE_BUFFERS, buffers);
}
```

(from [RecyclerViewPager/PlainRVP/app/src/main/java/com/commonsware/android/rvp/PageAdapter.java](#))

`MainActivity` has a corresponding `onRestoreInstanceState()` method:

```
@Override
protected void onRestoreInstanceState(Bundle state) {
    super.onRestoreInstanceState(state);
}
```

ADVANCED RECYCLERVIEW

```
adapter.onRestoreInstanceState(state.getBundle(STATE_ADAPTER));  
}
```

(from [RecyclerViewPager/PlainRVP/app/src/main/java/com/commonsware/android/rvp/MainActivity.java](#))

That delegates the work to the `onRestoreInstanceState()` method on the `PagerAdapter`:

```
void onRestoreInstanceState(Bundle state) {  
    buffers=state.getStringArrayList(STATE_BUFFERS);  
}
```

(from [RecyclerViewPager/PlainRVP/app/src/main/java/com/commonsware/android/rvp/PageAdapter.java](#))

This sets up our buffers for use in populating pages again.

Using SnapHelper

`RecyclerViewPager` was first released in 2014. Since then, `RecyclerView` and its supporting classes have evolved. Now, you can get much of the functionality of `RecyclerViewPager` with an ordinary `RecyclerView`, with the assistance of `SnapHelper`. As Lisa Wray profiled in [a droidcon NYC 2016 presentation](#), `SnapHelper` is a utility class that forces swipe gestures to “snap” to certain locations or boundaries. And, there is a `PagerSnapHelper` that, in conjunction with properly-configured `RecyclerView` and items, gives you `ViewPager`-like behavior.

The [RecyclerViewPager/PlainSnap](#) sample project is a clone of the `PlainRVP` sample, except that the `RecyclerViewPager` is replaced by a `RecyclerView` and a `PagerSnapHelper`.

There are three requirements of `PagerSnapHelper`. Two are tied to the layouts: both the `RecyclerView` and its items need to have `match_parent` for `android:layout_width` and `android:layout_height`. That was how `PlainRVP` was set up already, though `PlainSnap` swaps in a `RecyclerView` for the `RecyclerViewPager` in `main.xml`:

```
<?xml version="1.0" encoding="utf-8"?>  
<android.support.v7.widget.RecyclerView android:id="@+id/pager"  
    xmlns:android="http://schemas.android.com/apk/res/android"  
    android:layout_width="match_parent"  
    android:layout_height="match_parent"  
    android:layout_margin="@dimen/pager_padding"  
    android:clipToPadding="false" />
```

ADVANCED RECYCLERVIEW

(from [RecyclerViewPager/PlainSnap/app/src/main/res/layout/main.xml](#))

The other requirement is that we create an instance of PagerSnapHelper and call `attachToRecyclerView()` on it, supplying our `RecyclerView`. This is handled in an updated `MainActivity`:

```
package com.commonsware.android.rvp;

import android.app.Activity;
import android.os.Bundle;
import android.support.v7.widget.LinearLayoutManager;
import android.support.v7.widget.PagerSnapHelper;
import android.support.v7.widget.RecyclerView;
import android.support.v7.widget.SnapHelper;

public class MainActivity extends Activity {
    private static final String STATE_ADAPTER="adapter";
    private final SnapHelper snapperCarr=new PagerSnapHelper();
    private PageAdapter adapter;

    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.main);

        RecyclerView pager=(RecyclerView)findViewById(R.id.pager);

        pager.setLayoutManager(new LinearLayoutManager(this,
            LinearLayoutManager.HORIZONTAL, false));
        snapperCarr.attachToRecyclerView(pager);

        adapter=new PageAdapter(pager, getLayoutInflater());
        pager.setAdapter(adapter);
    }

    @Override
    protected void onSaveInstanceState(Bundle state) {
        super.onSaveInstanceState(state);

        Bundle adapterState=new Bundle();

        adapter.onSaveInstanceState(adapterState);
        state.putBundle(STATE_ADAPTER, adapterState);
    }

    @Override
    protected void onRestoreInstanceState(Bundle state) {
```

ADVANCED RECYCLERVIEW

```
super.onRestoreInstanceState(state);  
  
adapter.onRestoreInstanceState(state.getBundle(STATE_ADAPTER));  
}  
}
```

(from [RecyclerViewPager/PlainSnap/app/src/main/java/com/commonsware/android/rvp/MainActivity.java](#))

We hold onto the PagerSnapHelper in a field, to ensure that it will not be garbage-collected unexpectedly. *Probably* the PagerSnapHelper has sufficient connections to the RecyclerView to ensure that it will stay around as long as its associated RecyclerView does, but that is not apparent from the API or the documentation.

Beyond that, we configure the RecyclerView much as we had configured the RecyclerViewPager, and our PageAdapter and PageController are largely unaffected by the UI switch. In the end, we wind up once again with page-at-a-time horizontal swiping, though this time we can skip the third-party library.

Adding Tabs

Many times, with a pager-style interface, we want an indicator to help the user understand where they are within the range of pages offered by the pager. One of the more popular indicator styles is tabs, as those also provide an alternative navigation option, with the user tapping on tabs to switch to particular pages.

For adding tabs to a RecyclerView-powered pager, you need a tab implementation that is not tied inextricably to ViewPager, the way PagerTabStrip is. At the same time, you need one that is not tied inextricably to some other particular UI setup, the way that FragmentTabHost is. Instead, you need tabs that “stick to their knitting” and focus solely on handling the tab UI, giving you the hooks necessary to update your UI based on tab changes, and to update the tabs based on other UI changes.

TabLayout, from [the Design Support library](#), is one such tab implementation. While it offers hooks into ViewPager, those are optional. You have two main options for using TabLayout:

1. Literally use the version from the Design Support library, which will require you to use appcompat-v7. This works back to API Level 7, as does RecyclerView itself.
2. Use the TabLayout from [the CWAC-CrossPort library](#), which is the official TabLayout code, with all references to appcompat-v7 replaced by references

ADVANCED RECYCLERVIEW

to `Theme.Material` and related native items. However, this limits this cross-ported `TabLayout` to API Level 21 and higher (Android 5.0).

The [RecyclerViewPager/TabSnap](#) sample project is a clone of the `PlainSnap` sample, with tabs added, via the `TabLayout` from `CWAC-CrossPort`. As a result, we need the `CWAC-CrossPort` dependency and need to raise our `minSdkVersion` to 21:

```
apply plugin: 'com.android.application'

repositories {
    maven {
        url "https://s3.amazonaws.com/repo.commonsware.com"
    }
}

dependencies {
    implementation 'com.android.support:recyclerview-v7:25.1.0'
    implementation 'com.commonsware.cwac:crossport:0.0.2'
}

android {
    compileSdkVersion 25
    buildToolsVersion '26.0.2'

    defaultConfig {
        minSdkVersion 21
        targetSdkVersion 25
        applicationId 'com.commonsware.cwac.rvp.tabsnap'
    }
}
```

(from [RecyclerViewPager/TabSnap/app/build.gradle](#))

The tabs themselves can then go above the `RecyclerView`, in a vertical `LinearLayout`:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    xmlns:app="http://schemas.android.com/apk/res-auto"
    android:orientation="vertical">

    <com.commonsware.cwac.crossport.design.widget.TabLayout
        android:id="@+id/tabs"
        android:layout_width="match_parent"
```

ADVANCED RECYCLERVIEW

```
        android:layout_height="wrap_content"
        app:tabMode="scrollable" />

<android.support.v7.widget.RecyclerView
    android:id="@+id/pager"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:layout_margin="@dimen/pager_padding"
    android:clipToPadding="false" />
</LinearLayout>
```

(from [RecyclerViewPager/TabSnap/app/src/main/res/layout/main.xml](#))

Next, we need to set up the tab contents in `onCreate()` of `MainActivity`. To do that, we get our hands on the `TabLayout` using `findViewById()`, then iterate through the items in the `PagerAdapter` to set up tabs for each:

```
final TabLayout tabs=(TabLayout)findViewById(R.id.tabs);

for (int i=0;i<adapter.getItemCount();i++) {
    tabs.addTab(tabs.newTab().setText(adapter.getTabText(this, i)));
}
```

(from [RecyclerViewPager/TabSnap/app/src/main/java/com/commonsware/android/rvp/MainActivity.java](#))

We ask the `PagerAdapter` for the text to show in the tab, via a `getTabText()` method:

```
String getTabText(Context ctxt, int position) {
    return(PageController.getTitle(ctxt, position));
}
```

(from [RecyclerViewPager/TabSnap/app/src/main/java/com/commonsware/android/rvp/PageAdapter.java](#))

That, in turn, delegates to a static version of the `getTitle()` method on `PageController`, to fill in the string resource template with the proper page number:

```
static String getTitle(Context ctxt, int position) {
    return(ctxt.getString(R.string.hint, position+1));
}
```

(from [RecyclerViewPager/TabSnap/app/src/main/java/com/commonsware/android/rvp/PageController.java](#))

We now need to add code in `onCreate()` of `MainActivity` to tie the navigation together:

- When the user taps a tab, we need to update the pager

ADVANCED RECYCLERVIEW

- When the user swipes the pager, we need to update the tabs to show the new selection

This is handled by event listeners:

```
tabs.addTabSelectedListener(new TabLayout.OnTabSelectedListener() {
    @Override
    public void onTabSelected(TabLayout.Tab tab) {
        pager.smoothScrollToPosition(tab.getPosition());
    }

    @Override
    public void onTabUnselected(TabLayout.Tab tab) {
        // unused
    }

    @Override
    public void onTabReselected(TabLayout.Tab tab) {
        // unused
    }
});

pager.setOnScrollListener(new RecyclerView.OnScrollListener() {
    @Override
    public void onScrolled(RecyclerView recyclerView, int dx, int dy) {
        int tab=layoutManager.findFirstCompletelyVisibleItemPosition();

        if (tab>=0 && tab<tabs.getTabCount()) {
            tabs.getTabAt(tab).select();
        }
    }
});
```

(from [RecyclerViewPager/TabSnap/app/src/main/java/com/commonsware/android/rvp/MainActivity.java](#))

When a tab is selected, our anonymous `TabLayout.OnTabSelectedListener` implementation will get control in `onTabSelected()`. There, we tell the `RecyclerView` to scroll to show a particular position, tied to the position of the selected tab.

Similarly, when the user scrolls the pager, we need to update the tabs to show the new selection. To do that, we take advantage of the `findFirstCompletelyVisibleItemPosition()` method on `LinearLayoutManager`. As the (lengthy) method name suggests, this returns the position of the first item that is completely visible within the pager. This might return `-1`, if we are in the middle of

a swipe, as no item may be *completely* visible at that point. But, once we get a plausible value, we tell the `TabLayout` to select that tab.

`RecyclerViewPager` has a more sophisticated algorithm for integrating with the official Design Support library implementation of `TabLayout`. `RecyclerViewPager` calculates the position of the tab highlight, based upon the current swipe position, and updates that. This provides visual feedback within the tabs while the swipe is going on. The approach shown in the sample app has the effect of only updating the tabs once the swipe is completed.

Changing the Mix of Pages

A major problem with `ViewPager` — or, more accurately, the stock `PagerAdapter` implementations — was when we wanted to add, move, or remove pages on the fly, such as by the user tapping some sort of “add tab” action bar item. To pull this off required a custom `PagerAdapter`, as neither `FragmentPagerAdapter` nor `FragmentStatePagerAdapter` were well-suited for this scenario.

`RecyclerView` can readily handle such changes in its roster of items, and so we can add, move, and remove pages easily enough. However, it does require a somewhat more elaborate example, not so much due to `RecyclerView`, but for the rest of our business logic. For example, all the prior samples hard-coded `getItemCount()` to return 10 (by way of a `PAGE_COUNT` value), and that will no longer be the case as we add and remove pages.

The [RecyclerViewPager/DynSnap](#) sample project is a clone of the `TabSnap` sample, with four action bar items, to add, “split”, swap, and remove pages.

Using a Richer Model

In our previous samples, the tab title was tied to the tab position. That worked well, since our tabs all had fixed positions. Now, though, we want to add, move, and remove tabs, which means the positions of the existing tabs will change. We do not want to change the tab titles just because the positions change, as that will be very confusing for the user. So, our data model is more than just the text that the user types in — now it needs to include the title associated with that text.

To that end, `DynSnap` sets up an actual model object, called `EditBuffer`, to track both of those values:

ADVANCED RECYCLERVIEW

```
package com.commonware.android.rvp;

import android.os.Parcel;
import android.os.Parcelable;

class EditBuffer implements Parcelable {
    private String prose;
    final private String title;

    EditBuffer(String title) {
        this(title, "");
    }

    EditBuffer(String title, String prose) {
        this.prose=prose;
        this.title=title;
    }

    protected EditBuffer(Parcel in) {
        prose=in.readString();
        title=in.readString();
    }

    @Override
    public String toString() {
        return(title);
    }

    String getProse() {
        return(prose);
    }

    void setProse(String prose) {
        this.prose=prose;
    }

    @Override
    public int describeContents() {
        return 0;
    }

    @Override
    public void writeToParcel(Parcel dest, int flags) {
        dest.writeString(prose);
        dest.writeString(title);
    }

    @SuppressWarnings("unused")
```

ADVANCED RECYCLERVIEW

```
public static final Parcelable.Creator<EditBuffer> CREATOR=
    new Parcelable.Creator<EditBuffer>() {
        @Override
        public EditBuffer createFromParcel(Parcel in) {
            return(new EditBuffer(in));
        }

        @Override
        public EditBuffer[] newArray(int size) {
            return(new EditBuffer[size]);
        }
    };
}
```

(from [RecyclerViewPager/DynSnap/app/src/main/java/com/commonsware/android/rvp/EditBuffer.java](#))

EditBuffer is Parcelable, so we will be able to hold onto this information in the saved instance state Bundle, for dealing with configuration changes.

The buffers field in PageAdapter now is an ArrayList of EditBuffer objects, and our original constructor and other methods are updated to match that:

```
PageAdapter(RecyclerView pager, LayoutInflater inflater) {
    this.pager=pager;
    this.inflater=inflater;

    for (int i=0;i<10;i++) {
        buffers.add(new EditBuffer(getNextTitle()));
    }
}

@Override
public PageController onCreateViewHolder(ViewGroup parent, int viewType) {
    return(new PageController(inflater.inflate(R.layout.editor, parent, false)));
}

@Override
public void onBindViewHolder(PageController holder, int position) {
    holder.setText(buffers.get(position).getProse());
    holder.setTitle(buffers.get(position).toString());
}

@Override
public int getItemCount() {
    return(buffers.size());
}

String getTabText(int position) {
    return(buffers.get(position).toString());
}

@Override
public void onViewDetachedFromWindow(PageController holder) {
```

ADVANCED RECYCLERVIEW

```
super.onViewDetachedFromWindow(holder);

if (holder.getAdapterPosition() >= 0) {
    buffers.get(holder.getAdapterPosition()).setProse(holder.getText());
}
}

private String getNextTitle() {
    return(pager.getContext().getString(R.string.hint, nextTabNumber++));
}

void onSaveInstanceState(Bundle state) {
    for (int i=0; i<getItemCount(); i++) {
        updateProse(i);
    }

    state.putParcelableArrayList(STATE_BUFFERS, buffers);
}

void onRestoreInstanceState(Bundle state) {
    buffers=state.getParcelableArrayList(STATE_BUFFERS);
}
}
```

(from [RecyclerViewPager/DynSnap/app/src/main/java/com/commonsware/android/rvp/PageAdapter.java](#))

We pull out the “update-the-EditBuffer-based-on-the-holder-contents” logic into a separate `updateProse()` method, that we will reuse elsewhere:

```
private void updateProse(int position) {
    PageController holder=
        (PageController)pager.findViewByIdForAdapterPosition(position);

    if (holder!=null) {
        buffers.get(position).setProse(holder.getText());
    }
}
}
```

(from [RecyclerViewPager/DynSnap/app/src/main/java/com/commonsware/android/rvp/PageAdapter.java](#))

Also note that when we set up the buffers in the constructor, we call a `getNextTitle()` method. This tracks the number of titles that we have generated, via a `nextTabNumber` field, and creates a new title with a new number on each call. This further decouples our tab titles from any concept of tab positions.

Adding Action Bar Items

We have four vector assets in `res/drawable/` for our four action bar items:

```
<menu xmlns:android="http://schemas.android.com/apk/res/android">
    <item
        android:id="@+id/add"
```

ADVANCED RECYCLERVIEW

```
    android:icon="@drawable/ic_add_white_24dp"
    android:showAsAction="ifRoom"
    android:title="@string/menu_add" />
<item
    android:id="@+id/split"
    android:icon="@drawable/ic_split_white_24dp"
    android:showAsAction="ifRoom"
    android:title="@string/menu_split" />
<item
    android:id="@+id/swap"
    android:icon="@drawable/ic_swap_white_24dp"
    android:showAsAction="ifRoom"
    android:title="@string/menu_swap" />
<item
    android:id="@+id/remove"
    android:icon="@drawable/ic_remove_white_24dp"
    android:showAsAction="ifRoom"
    android:title="@string/menu_remove" />
</menu>
```

(from [RecyclerViewPager/DynSnap/app/src/main/res/menu/actions.xml](#))

Those items get inflated and applied in MainActivity:

```
@Override
public boolean onCreateOptionsMenu(Menu menu) {
    getMenuInflater().inflate(R.menu.actions, menu);
    remove=menu.findItem(R.id.remove);

    return(super.onCreateOptionsMenu(menu));
}

@Override
public boolean onOptionsItemSelected(MenuItem item) {
    switch(item.getItemId()) {
        case R.id.add:
            add();
            return(true);

        case R.id.split:
            split();
            return(true);

        case R.id.swap:
            swap();
            return(true);

        case R.id.remove:
```

ADVANCED RECYCLERVIEW

```
        remove();
        return(true);
    }

    return(super.onOptionsItemSelected(item));
}
```

(from [RecyclerViewPager/DynSnap/app/src/main/java/com/commonsware/android/rvp/MainActivity.java](#))

Each of the items gets tied to its own dedicated method (e.g., `R.id.add` triggers a call to `add()`).

Note that we find and hold onto the `remove MenuItem`, caching its value in a field. We are going to need to disable this `MenuItem` when we can no longer allow the user to remove pages. In the case of this app, we prevent the user from removing all the pages, so once we are down to our last page, we need to disable the `MenuItem`, re-enabling it when the user adds new pages.

Adding Pages

The “add” and “split” operations both do the same thing: add a page. One difference is where they add it. “Add” adds a page before the current one. “Split” adds a page after the current one.

The `add()` and `split()` methods therefore do very similar things:

- Determine where the new tab’s position will be
- Tell the adapter to do its work for managing the data model and pager
- Adds a new tab for the new position
- Updates the `remove MenuItem`, in case it had been disabled and should now be enabled

```
private void add() {
    int current=getCurrentPosition();

    adapter.insert(current);
    tabs.addTab(tabs.newTab().setText(adapter.getTabText(current)), current);
    updateRemoveMenuItem();
}

private void split() {
    int newPosition=getCurrentPosition()+1;

    adapter.clone(newPosition-1);
    tabs.addTab(tabs.newTab().setText(adapter.getTabText(newPosition)), newPosition);
    updateRemoveMenuItem();
}
```

ADVANCED RECYCLERVIEW

(from [RecyclerViewPager/DynSnap/app/src/main/java/com/commonsware/android/rvp/MainActivity.java](#))

Here, `updateRemoveMenuItem()` simply sets the enabled state of the remove item based on our page count:

```
private void updateRemoveMenuItem() {
    remove.setEnabled(adapter.getItemCount()>1);
}
```

(from [RecyclerViewPager/DynSnap/app/src/main/java/com/commonsware/android/rvp/MainActivity.java](#))

Another difference between “add” and “split” is what the new page has for content. “Add” adds an empty page. “Split” clones the prose from the selected page and puts that prose in the new page as well.

That is why `add()` on `MainActivity` calls an `insert()` method on `PageAdapter` and `split()` calls `clone()`, because the `PageAdapter` has different behavior for each:

```
void insert(int position) {
    buffers.add(position, new EditBuffer(getNextTitle()));
    notifyItemInserted(position);
}

void clone(int position) {
    updateProse(position);

    EditBuffer newBuffer=new EditBuffer(getNextTitle(),
        buffers.get(position).getProse());

    buffers.add(position+1, newBuffer);
    notifyItemInserted(position+1);
}
```

(from [RecyclerViewPager/DynSnap/app/src/main/java/com/commonsware/android/rvp/PageAdapter.java](#))

In both cases, a new `EditBuffer` gets added to the buffers, and we call `notifyItemInserted()` to let the `RecyclerView` know of the data model change. In the case of `clone()`, we also update the `EditBuffer` for the page to be cloned, then use that data to populate the new `EditBuffer`.

Moving Pages

The `swap()` method on `MainActivity` flips the positions of two pages. Normally, this will be the active tab and the next tab, but if the active tab is the *last* tab, the pair will be the active tab and the previous tab.

ADVANCED RECYCLERVIEW

Hence, `swap()` identifies the right pair of positions, tells the `PagerAdapter` to swap the contents, then swaps the titles of the two affected tabs:

```
private void swap() {
    int first=getCurrentPosition();
    int second;

    if (first>=adapter.getItemCount()-1) {
        second=first;
        first--;
    }
    else {
        second=first+1;
    }

    adapter.swap(first, second);

    TabLayout.Tab firstTab=tabs.getTabAt(first);
    TabLayout.Tab secondTab=tabs.getTabAt(second);
    CharSequence firstText=firstTab.getText();

    firstTab.setText(secondTab.getText());
    secondTab.setText(firstText);
}
```

(from [RecyclerViewPager/DynSnap/app/src/main/java/com/commonsware/android/rvp/MainActivity.java](#))

The `swap()` method on `PagerAdapter` needs to do three things:

- Update the buffers to reflect the swapped pages
- Update the existing `PageController` objects for those pages, if they exist
- Tell the `RecyclerView` that the contents of these two positions changed, to ensure that they get redrawn

```
void swap(int first, int second) {
    EditBuffer firstBuffer=buffers.get(first);
    EditBuffer secondBuffer=buffers.get(second);

    buffers.set(first, secondBuffer);
    buffers.set(second, firstBuffer);

    PageController holder=
        (PageController)pager.findViewHolderForAdapterPosition(first);

    if (holder!=null) {
        holder.setText(secondBuffer.getProse());
    }
}
```

ADVANCED RECYCLERVIEW

```
}

holder=(PageController)pager.findViewByIdForAdapterPosition(second);

if (holder!=null) {
    holder.setText(firstBuffer.getProse());
}

notifyItemChanged(first);
notifyItemChanged(second);
}
```

(from [RecyclerViewPager/DynSnap/app/src/main/java/com/commonsware/android/rvp/PageAdapter.java](#))

Removing Pages

Removing a page involves:

- Removing the EditBuffer from the data model
- Removing the associated item in the RecyclerView
- Removing the associated tab
- Updating the remove MenuItem, if we are down to our last page

The latter two tasks are handled by `remove()` on MainActivity:

```
private void remove() {
    final int current=getCurrentPosition();

    tabs.removeTabAt(current);
    adapter.remove(current);

    if (current<adapter.getItemCount()) {
        pager.scrollToPosition(current);
    }

    updateRemoveMenuItem();
}
```

(from [RecyclerViewPager/DynSnap/app/src/main/java/com/commonsware/android/rvp/MainActivity.java](#))

The former two tasks are handled by `remove()` on PageAdapter:

```
void remove(int position) {
    buffers.remove(position);
    notifyItemRemoved(position);
}
```

(from [RecyclerViewPager/DynSnap/app/src/main/java/com/commonsware/android/rvp/PageAdapter.java](#))

Declaring a LayoutManager in the Layout

The typical way of setting up a `LayoutManager` is to call `setLayoutManager()` on the `RecyclerView`. There may be no choice in some cases, if the `LayoutManager` that you wish to use has a custom constructor that you need.

However, in some cases, where the `LayoutManager` has adequate setters to configure it beyond the constructor, you can set up the `LayoutManager` in your layout resource file. Just add the `app:layoutManager` attribute to the `RecyclerView` element, with the value being:

- the bare class name of a standard `LayoutManager`, such as `LinearLayoutManager`, or
- the fully-qualified class name of some custom `LayoutManager`, one that you wrote or are using from a library

The app XML namespace (`xmlns:app="http://schemas.android.com/apk/res-auto"`) can be added to the layout resource file by an Android Studio quick-fix.

Transcript Mode

“Transcript mode” with `ListView` means that the `ListView` automatically scrolls to keep the bottom entries in view. This is useful for things like chat transcripts, where you want to append new messages and show those new messages to the user, and the new messages (traditionally) go below older messages. This approach — using `setTranscriptMode()` — has been used a couple of times in this book, such as in [the chapter profiling various event bus implementations](#).

`RecyclerView` also supports this approach, though it is set up somewhat differently.

The [RecyclerView/Transcript](#) sample project is a clone of the [EventBus/GreenRobot3](#) sample project, where the `ListView` is replaced by a `RecyclerView`.

In a layout resource, we declare our `RecyclerView`, with a few interesting attributes:

```
<?xml version="1.0" encoding="utf-8"?>
<android.support.v7.widget.RecyclerView android:id="@+id/transcript"
    xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:app="http://schemas.android.com/apk/res-auto"
```

ADVANCED RECYCLERVIEW

```
android:layout_width="match_parent"  
android:layout_height="match_parent"  
app:layoutManager="LinearLayoutManager"  
app:reverseLayout="true"  
app:stackFromEnd="true" />
```

(from [RecyclerView/Transcript/app/src/main/res/layout/main.xml](#))

Specifically, we have:

- `app:layoutManager` defines the layout manager that we want to use, in this case a `LinearLayoutManager`
- `app:reverseLayout="true"` and `app:stackFromEnd="true"`, which combine to give us a transcript-style effect

Note that those latter two attributes are actually documented on `LinearLayoutManager`, not on `RecyclerView` (and, even then, they are largely undocumented). Those attributes may not work with other layout managers (e.g., `GridLayoutManager`).

Beyond that, the rest of the code works pretty much as the original sample app did, except that we need to substitute in `RecyclerView` equivalents for the `ListView` functionality. So, for example, rather than inheriting from `ListViewFragment`, the `EventLogFragment` is now a regular `Fragment`, where we inflate our layout in `onCreateView()` and attach its `EventLogAdapter` in `onViewCreated()`:

```
@Nullable  
@Override  
public View onCreateView(LayoutInflater inflater, ViewGroup container,  
                          Bundle savedInstanceState) {  
    return(inflater.inflate(R.layout.main, container, false));  
}  
  
@Override  
public void onViewCreated(View view, Bundle savedInstanceState) {  
    super.onViewCreated(view, savedInstanceState);  
  
    if (adapter==null) {  
        adapter=new EventLogAdapter();  
    }  
  
    RecyclerView transcript=(RecyclerView)view.findViewById(R.id.transcript);  
  
    transcript.setAdapter(adapter);  
}
```

ADVANCED RECYCLERVIEW

(from [RecyclerView/Transcript/app/src/main/java/com/commonsware/android/rv/transcript/EventLogFragment.java](#))

The old ArrayAdapter is gone, so EventLogAdapter is now a RecyclerView.Adapter, managing a series of RowHolder objects for our rows:

```
class EventLogAdapter extends RecyclerView.Adapter<RowHolder> {
    private final ArrayList<RandomEvent> events=new ArrayList<>();

    @Override
    public RowHolder onCreateViewHolder(ViewGroup parent,
                                       int viewType) {
        View row=
            getActivity()
                .getLayoutInflater()
                .inflate(android.R.layout.simple_list_item_1, parent, false);

        return(new RowHolder(row));
    }

    @Override
    public void onBindViewHolder(RowHolder holder,
                               int position) {
        holder.bind(events.get(position));
    }

    @Override
    public int getItemCount() {
        return(events.size());
    }

    void add(RandomEvent event) {
        events.add(event);
        notifyItemInserted(getItemCount());
    }
}

static class RowHolder extends RecyclerView.ViewHolder {
    private static final DateFormat fmt=
        new SimpleDateFormat("HH:mm:ss", Locale.US);
    private final TextView tv;

    RowHolder(View itemView) {
        super(itemView);

        tv=(TextView)itemView.findViewById(android.R.id.text1);
    }
}
```

ADVANCED RECYCLERVIEW

```
void bind(RandomEvent event) {
    tv.setText(String.format("%s = %x", fmt.format(event.when),
        event.value));
}
}
```

(from [RecyclerView/Transcript/app/src/main/java/com/commonsware/android/rv/transcript/EventLogFragment.java](#))

And, when we get a `RandomEvent`, we `add()` that to our `EventLogAdapter`, which adds it to its array of events and updates the `RecyclerView` to match:

```
@Subscribe(threadMode = ThreadMode.MAIN)
public void onRandomEvent(final RandomEvent event) {
    adapter.add(event);
}
```

(from [RecyclerView/Transcript/app/src/main/java/com/commonsware/android/rv/transcript/EventLogFragment.java](#))

Advanced Uses of WebView

Android uses the WebKit browser engine as the foundation for both its Browser application and the WebView embeddable browsing widget. The Browser application, of course, is something Android users can interact with directly; the WebView widget is something you can integrate into your own applications for places where an HTML interface might be useful.

[Earlier in this book](#), we saw a simple integration of a WebView into an Android activity, with the activity dictating what the browsing widget displayed and how it responded to links.

Here, we will expand on this theme, and show how to more tightly integrate the Java environment of an Android application with the JavaScript environment of WebKit.

Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly the one [covering WebView](#). Some of the samples [use locationManager](#) for obtaining a GPS fix.

Friends with Benefits

When you integrate a WebView into your activity, you can control what Web pages are displayed, whether they are from a local provider or come from over the Internet, what should happen when a link is clicked, and so forth. And between WebView, WebViewClient, and WebSettings, you can control a fair bit about how the embedded browser behaves. Yet, by default, the browser itself is just a browser,

capable of showing Web pages and interacting with Web sites, but otherwise gaining nothing from being hosted by an Android application.

However, WebView offers a few options for more tightly integrating the Java and JavaScript realms, so Web content can call into your app to get data to display, and your app can push data into the Web page for JavaScript to render.

Unfortunately, the techniques for doing this have changed over the years. Partially that is due to changes in WebView, particularly starting with Android 4.4. But, some of the changes are due to security issues, particularly when you are loading arbitrary content, such as Web-based ads from an ad network, into your WebView.

The following sections will go over four separate sample apps. All do the same thing: provide data about the ambient light level, using the [sensor](#) on the phone or tablet, to the Web page for rendering. The differences are whether we are pushing data from Java into JavaScript (e.g., as the light level changes), or whether we are pulling data from Java using JavaScript (e.g., in response to a user tapping on something in the Web page). Also, we will see two approaches to push and two approaches to pull.

JavaScript Calling Java: addJavascriptInterface()

The `addJavascriptInterface()` method on `WebView` allows you to inject a Java object into the `WebView`, exposing its methods, so they can be called by JavaScript loaded by the Web content in the `WebView` itself.

Now you have the power to provide access to a wide range of Android features and capabilities to your `WebView`-hosted content. If you can access it from your activity, and if you can wrap it in something convenient for use by JavaScript, your Web pages can access it as well.

The [WebKit/SensorPull](#) sample project demonstrates using `addJavascriptInterface()` to pull light sensor data into a Web page to display to the user.

For all four of these sample apps, the UI is just a `WebView`:

```
<?xml version="1.0" encoding="utf-8"?>
<WebView android:id="@+id/webkit"
  xmlns:android="http://schemas.android.com/apk/res/android"
  android:layout_width="match_parent"
  android:layout_height="match_parent">
```

ADVANCED USES OF WEBVIEW

```
</WebView>
```

(from [WebKit/SensorPull/app/src/main/res/layout/main.xml](#))

In onCreate(), we set things up:

```
@SuppressWarnings({"AddJavascriptInterface", "SetJavaScriptEnabled"})
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.main);

    mgr=(SensorManager) getSystemService(Context.SENSOR_SERVICE);
    light=mgr.getDefaultSensor(Sensor.TYPE_LIGHT);

    ww=(WebView) findViewById(R.id.webkit);
    ww.getSettings().setJavaScriptEnabled(true);
    ww.addJavascriptInterface(jsInterface, "LIGHT_SENSOR");
    ww.loadUrl("file:///android_asset/index.html");
}
```

(from [WebKit/SensorPull/app/src/main/java/com/commonware/android/webkit/bridge/MainActivity.java](#))

Specifically, we:

- Get a SensorManager and the appropriate Sensor for measuring ambient light levels, saving those in fields
- Get our WebView via findViewById()
- Enable JavaScript (which comes disabled by default), using getSettings() and setJavaScriptEnabled(true)
- Call addJavascriptInterface(), and
- Load a Web page from assets (which we will examine shortly)

Because we are enabling JavaScript, Lint will complain that this poses security risks, so onCreate() has a @SuppressWarnings annotation for SetJavaScriptEnabled to indicate that we are aware of the risks. Similarly, because we are calling addJavascriptInterface(), Lint will complain that this poses even more security risks. So, @SuppressWarnings suppresses both the SetJavaScriptEnabled warning and the AddJavascriptInterface warning.

Also, you may notice that there is a significant debate within the Android SDK as to whether the “s” in “JavaScript” gets capitalized or not. In general, it does, but addJavascriptInterface() shipped in API Level 1 with a lowercase “s” in its name,

ADVANCED USES OF WEBVIEW

and so that method, and variations of it (e.g., the `AddJavascriptInterface` annotation) will use a lowercase “s”. Eventually, you just get used to this.

`addJavascriptInterface()` takes two parameters: a Java object to inject into the JavaScript of the Web page, and a String that is the name by which JavaScript can reference that object. So, we have a `jsInterface` object that JavaScript can reference via `LIGHT_SENSOR`.

`jsInterface` is an instance of `JSInterface`, a static nested class inside `MainActivity`:

```
private static class JSInterface {
    float lux=0.0f;

    private void updateLux(float lux) {
        this.lux=lux;
    }

    @JavascriptInterface
    public String getLux() {
        return(String.format(Locale.US, "{\"lux\": %f}", lux));
    }
}
```

(from [WebKit/SensorPull/app/src/main/java/com/commonsware/android/webkit/bridge/MainActivity.java](#))

It just has a getter and setter around the current light level, which is a float named `lux` (referring to the unit of brightness used for the values coming from the ambient light sensor). The getter, however, has two interesting traits:

- It returns a String, representing a JSON object wrapped around the `lux` value
- It is annotated with `@JavascriptInterface`

This annotation is required of apps with `android:targetSdkVersion` set to 17 or higher, though it is a good idea to start using it anyway. With such an `android:targetSdkVersion`, in an app running on an Android 4.2 or higher device, *only* public methods with the `@JavascriptInterface` annotation will be accessible by JavaScript code. On earlier devices, or with an earlier `android:targetSdkVersion`, *all* public methods on the `JSInterface` object would be accessible by JavaScript, including those inherited from superclasses like `Object`. Note that your build target (i.e., `compileSdkVersion` in Android Studio) will need to be Android 4.2 or higher in order to reference the `@JavascriptInterface` annotation.

ADVANCED USES OF WEBVIEW

The reason for returning a JSON object (in string form), rather than just the float, is for two reasons:

1. For more complex APIs, you cannot pass into JavaScript an arbitrary Java object. All return types from `@JavascriptInterface` objects need to be something that JavaScript can use, and a simple way to do that is to create data structures in JSON.
2. float did not seem to work well as a return type, as it always seemed to turn into 0.0 on the JavaScript side, for unknown reasons

We register with the `SensorManager` to find out when the light level changes, via `registerListener()` (in `onStart()`) and `unregisterListener()` (in `onStop()`):

```
@Override
protected void onStart() {
    super.onStart();

    mgr.registerListener(this, light, SensorManager.SENSOR_DELAY_UI);
}

@Override
protected void onStop() {
    mgr.unregisterListener(this);

    super.onStop();
}
```

(from [WebKit/SensorPull/app/src/main/java/com/commonware/android/webkit/bridge/MainActivity.java](#))

That, in turn, will trigger a call to `onSensorChanged()` when the light level changes. There, we pass the light level (the first float out of the values array from the `SensorEvent`) to the `JsInterface` instance, ready to be retrieved by the JavaScript code in our Web page:

```
@Override
public void onSensorChanged(SensorEvent sensorEvent) {
    jsInterface.updateLux(sensorEvent.values[0]);
}

@Override
public void onAccuracyChanged(Sensor sensor, int i) {
    // unused
}
```

(from [WebKit/SensorPull/app/src/main/java/com/commonware/android/webkit/bridge/MainActivity.java](#))

ADVANCED USES OF WEBVIEW

In the Web page, we set it up to show the current light level, starting with a value of 0.0. When the user taps on the Light Level caption, we call a `pull()` JavaScript function, which:

- Calls our `getLux()` method on the `LIGHT_SENSOR` global object
- Parses our JSON into a JavaScript object
- Calls an `update_lux()` function to update the lux span with the new light level

```
<html>
<head>
<title>Android Light Sensor Demo</title>
<script language="javascript">
  function update_lux(lux) {
    document.getElementById("lux").innerHTML=lux;
  }

  function pull() {
    var result=JSON.parse(LIGHT_SENSOR.getLux());

    update_lux(result.lux);
  }
</script>
</head>
<body>
<p><b><a onClick="pull()">Light Level</a>: </b><span id="lux">0.0</span> lux</p>
</body>
</html>
```

(from [WebKit/SensorPull/app/src/main/assets/index.html](#))

If you run the app, you get our trivial Web page in the WebView:

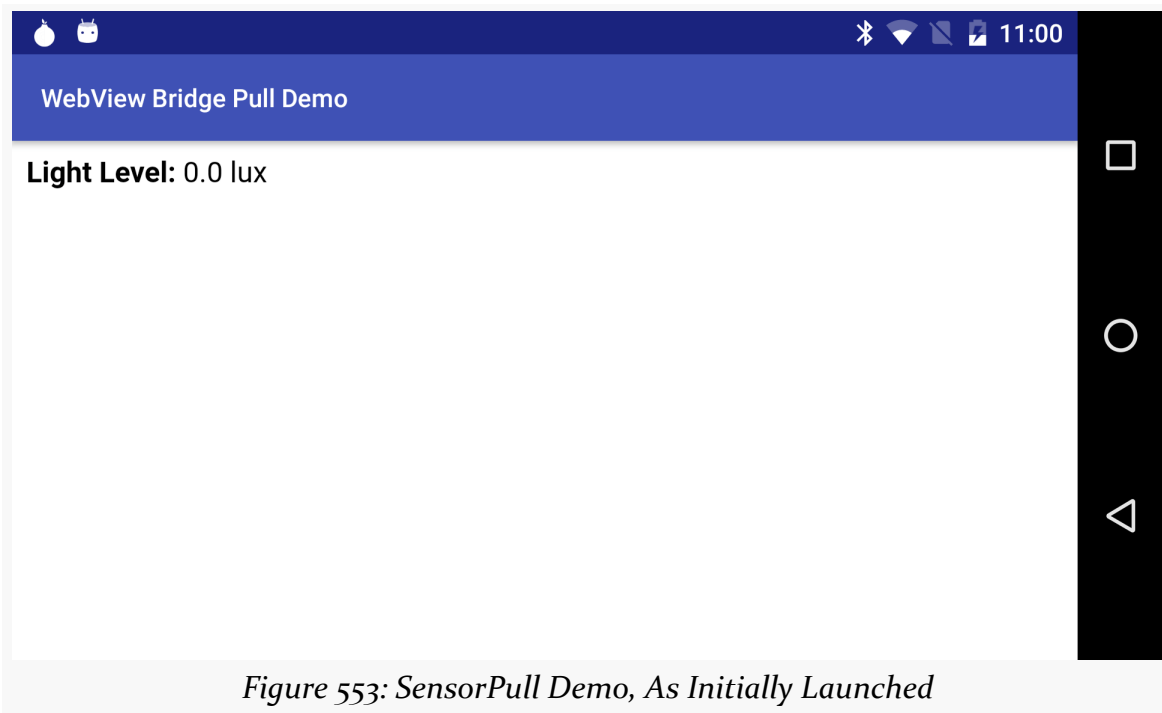

Figure 553: SensorPull Demo, As Initially Launched

Tapping on the words “Light Level” will cause JavaScript to request the light level, updating the page to match:

Figure 554: SensorPull Demo, Showing Light Level

Note that this sample app will only work on devices with an ambient light sensor. It is rather likely that the app will crash spectacularly on devices lacking such a sensor.

Unfortunately, `addJavascriptInterface()` opens up a number of security issues, outlined [later in this chapter](#). Where possible, avoid the use of this API.

Java Calling JavaScript: `loadUrl()` and `evaluateJavascript()`

Now that we have seen how JavaScript can call into Java, it would be nice if Java could somehow call out to JavaScript. Well, as luck would have it, we can do that too. This is a good thing, otherwise, this would be a really weak section of the book.

What is unusual is how you call out to JavaScript. One might imagine there would be an `evaluateJavaScript()` counterpart to `addJavascriptInterface()`, where you could supply some JavaScript source and have it executed within the context of the currently-loaded Web page.

Actually, there *is* such a method on Android 4.4. However, earlier versions of Android lacked that method. Instead, on older versions of Android, given your snippet of JavaScript source to execute, you call `loadUrl()` on your `WebView`, as if you

ADVANCED USES OF WEBVIEW

were going to load a Web page, but you put `javascript:` in front of your code and use that as the “address” to load.

If you have ever created a “bookmarklet” for a desktop Web browser, you will recognize this technique as being the Android analogue – the `javascript:` prefix tells the browser to treat the rest of the address as JavaScript source, injected into the currently-viewed Web page.

The [WebKit/SensorPush](#) sample project expands upon the SensorPull app. This time, though, in addition to pulling via `addJavascriptInterface()`, we support pushing light levels as sensor readings come in.

That comes courtesy of a revised `onSensorChanged()` method:

```
@Override
public void onSensorChanged(SensorEvent sensorEvent) {
    float lux=sensorEvent.values[0];

    jsInterface.updateLux(lux);

    String js=String.format(Locale.US, "update_lux(%f)", lux);

    if (Build.VERSION.SDK_INT>=Build.VERSION_CODES.KITKAT) {
        ww.evaluateJavascript(js, null);
    }
    else {
        ww.loadUrl("javascript:"+js);
    }
}
```

(from [WebKit/SensorPush/app/src/main/java/com/commonsware/android/webkit/bridge/MainActivity.java](#))

Before, we just updated the `JsInterface` object with the new light level. Now, we also format a JavaScript call to `update_lux()`, supplying our light level. Then, based on Android OS version (`Build.VERSION.SDK_INT`), we either call `evaluateJavascript()` or `loadUrl()`, the latter also employing the `javascript:` scheme.

Because we had pulled out `update_lux()` as a separate function before, our HTML and JavaScript does not need to change at all:

```
<html>
<head>
<title>Android Light Sensor Demo</title>
<script language="javascript">
```

ADVANCED USES OF WEBVIEW

```
function update_lux(lux) {
    document.getElementById("lux").innerHTML=lux;
}

function pull() {
    var result=JSON.parse(LIGHT_SENSOR.getLux());

    update_lux(result.lux);
}
</script>
</head>
<body>
<p><b><a onClick="pull()">Light Level</a>: </b><span id="lux">0.0</span> lux</p>
</body>
</html>
```

(from [WebKit/SensorPush/app/src/main/assets/index.html](#))

If you run this sample app, you will find that the Web page updates in real time as you wave your hand in front of the light sensor, shine a light on that sensor, etc.

Java Calling JavaScript: WebMessage

Both of those techniques have worked since API Level 1. But, as mentioned, `addJavascriptInterface()` has security issues. Also, `evaluateJavascript()` (or its `loadUrl()` equivalent) requires the Java code to know what functions are available in the Web page. That may tie the Java and JavaScript more tightly than you might like.

Android 6.0 introduced another pair of options for communicating between Java and JavaScript — `WebMessage` and `WebMessagePort` — that try to eliminate these issues.

The simpler of the two approaches is `WebMessage`. Instead of calling `evaluateJavascript()` or `loadUrl()`, you create a `WebMessage` object and call `postWebMessage()` to deliver it to the JavaScript in your Web page. So, in the [WebKit/SensorMessage](#) sample project, we have an updated `onSensorChanged()` method that does this:

```
@Override
public void onSensorChanged(SensorEvent sensorEvent) {
    float lux=sensorEvent.values[0];

    jsInterface.updateLux(lux);

    String js=String.format(Locale.US, "update_lux(%f)", lux);

    if (Build.VERSION.SDK_INT>=Build.VERSION_CODES.M) {
```

ADVANCED USES OF WEBVIEW

```
        ww.postMessage(new WebMessage(jsInterface.getLux()),
            Uri.EMPTY);
    }
    else if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.KITKAT) {
        ww.evaluateJavascript(js, null);
    }
    else {
        ww.loadUrl("javascript:"+js);
    }
}
```

(from [WebKit/SensorMessage/app/src/main/java/com/commonsware/android/webkit/bridge/MainActivity.java](#))

The `WebMessage` constructor that we are using here takes a simple string that is the content of the message. In this case, it is the JSON object wrapping our light level in lux, using the same `getLux()` method that JavaScript can call on our `JsInterface` instance that we registered via `addJavascriptInterface()`.

`postWebMessage()` takes two parameters. The first is the `WebMessage` to deliver to the page. The other is supposed to be the `Uri` of the Web page. This is supposed to be used to confirm that you are sending the message to the page that you think you are sending it to.

Unfortunately, this is not behaving especially well.

It only works as advertised for `http/https` URLs, or for data that you load using `loadDataWithBaseURL()` and supply some `http` or `https` URL. If you load from a file URL, as we are doing here, you cannot use the actual URL. Instead, you have to use `Uri.EMPTY`, which is a “wildcard” that skips over this test, which is what we use here. Apparently, this is all [working as intended](#).

To receive these messages, our JavaScript needs to define an `onmessage()` global function:

```
<html>
<head>
<title>Android Light Sensor Demo</title>
<script language="javascript">
    function update_lux(lux) {
        document.getElementById("lux").innerHTML=lux;
    }

    function parse(json) {
        var result=JSON.parse(json);

        update_lux(result.lux);
    }
}
```

ADVANCED USES OF WEBVIEW

```
function pull() {
    parse(LIGHT_SENSOR.getLux());
}

onmessage = function (e) {
    parse(e.data);
}
</script>
</head>
<body>
<p><b><a onClick="pull()">Light Level</a>: </b><span id="lux">0.0</span> lux</p>
</body>
</html>
```

(from [WebKit/SensorMessage/app/src/main/assets/index.html](#))

This receives the HTML Web message equivalent of the `WebMessage` that we posted. The data field on the supplied event object (e in the sample) contains our string. So, we turn around and `parse()` it, just as we would `parse()` the JSON we got from calling `getLux()` on our `LIGHT_SENSOR`.

If you run this sample app on an Android 6.0+ device, you should get the same results as with `SensorPush`, where the light level changes automatically. However, in this case, we will be using code that relies upon `WebMessage` and `postWebMessage()`, instead of `evaluateJavascript()` or `loadUrl()`. In particular, our Java code does not need to know anything about the internal workings of the JavaScript (e.g., function names) — it just passes over the message and relies on the JavaScript to have registered itself appropriately to receive the message.

JavaScript Calling Java: `WebMessagePort`

What would be nice is to use this `WebMessage` system to be able to replace `addJavaScriptInterface()` and allow JavaScript to call back into Java. This is possible, but it is fairly complex.

For our Java code to receive messages sent to it from JavaScript, we need to do three things:

1. Call `createWebMessageChannel()` on the `WebView`. This creates a private communications channel between us and our target Web page. It returns a two-element `WebMessagePort` array. Index 0 of that array is our end of the channel; index 1 is the JavaScript end of the channel.

ADVANCED USES OF WEBVIEW

2. Call `setWebMessageCallback()` on our `WebMessagePort`, supplying a `WebMessageCallback` that will be called with `onMessage()` when a message arrives on the port from JavaScript.
3. Send the other `WebMessagePort` to JavaScript using a `WebMessage`.

In the [WebKit/SensorPort](#) sample project, this is handled by an `initPort()` method:

```
@TargetApi(Build.VERSION_CODES.M)
private void initPort() {
    final WebMessagePort[] channel=webView.createWebMessageChannel();

    port=channel[0];
    port.setWebMessageCallback(new WebMessagePort.WebMessageCallback() {
        @Override
        public void onMessage(WebMessagePort port, WebMessage message) {
            postLux();
        }
    });

    webView.postMessage(new WebMessage("", new WebMessagePort[]{channel[1]}),
        Uri.EMPTY);
}
```

(from [WebKit/SensorPort/app/src/main/java/com/commonsware/android/webkit/bridge/MainActivity.java](#))

The `WebMessage` constructor that we use this time takes two parameters: an arbitrary string (here, just set to "", as we are not using it) and a one-element `WebMessagePort` array containing the JavaScript end of the communications channel.

However, we cannot do any of this work until the Web page is ready to be used. Otherwise, the JavaScript code will not receive our `WebMessage`, since it is not yet ready.

So, we have to postpone calling `initPort()` until a `WebViewClient` is called with `onPageFinished()`, as we do in `onCreate()`:

```
@SuppressWarnings({"AddJavascriptInterface", "SetJavaScriptEnabled"})
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.main);

    mgr=(SensorManager) getSystemService(Context.SENSOR_SERVICE);
    light=mgr.getDefaultSensor(Sensor.TYPE_LIGHT);
}
```

ADVANCED USES OF WEBVIEW

```
    wv=(WebView)findViewById(R.id.webkit);
    wv.getSettings().setJavaScriptEnabled(true);
    wv.addJavascriptInterface(jsInterface, "LIGHT_SENSOR");

    if (Build.VERSION.SDK_INT>=Build.VERSION_CODES.M) {
        wv.setWebViewClient(new WebViewClient() {
            @Override
            public void onPageFinished(WebView view, String url) {
                initPort();
            }
        });
    }

    wv.loadUrl(URL);
}
```

(from [WebKit/SensorPort/app/src/main/java/com/commonsware/android/webkit/bridge/MainActivity.java](#))

Our `WebMessageCallback`, upon receipt of a `WebMessage` from the JavaScript, calls a `postLux()` method. We are just using the existence of the message as a “ping” from the JavaScript to Java, asking for us to send it the ambient light level. So, in `postLux()`, we create a `WebMessage` and send it to JavaScript... but not via the `postWebMessage()` method on `WebView`. Instead, we use *our* end of the `WebMessagePort` communications channel, calling `postMessage()` on it, in a `postLux()` method:

```
@TargetApi(Build.VERSION_CODES.M)
private void postLux() {
    port.postMessage(new WebMessage(jsInterface.getLux()));
}
```

(from [WebKit/SensorPort/app/src/main/java/com/commonsware/android/webkit/bridge/MainActivity.java](#))

So, when the JavaScript sends a `WebMessage` to Java, Java sends a `WebMessage` right back, supplying the light level JSON.

To prove that this is working, this sample comments out the automated push of the light level in `onSensorChanged()` — ordinarily, we would call `postLux()` to push over the light level when we get it:

```
@Override
public void onSensorChanged(SensorEvent sensorEvent) {
    float lux=sensorEvent.values[0];

    jsInterface.updateLux(lux);
}
```

ADVANCED USES OF WEBVIEW

```
String js=String.format(Locale.US, "update_lux(%f)", lux);

if (Build.VERSION.SDK_INT>=Build.VERSION_CODES.M) {
    // postLux();
}
else if (Build.VERSION.SDK_INT>=Build.VERSION_CODES.KITKAT) {
    ww.evaluateJavascript(js, null);
}
else {
    ww.loadUrl("javascript:"+js);
}
}
```

(from [WebKit/SensorPort/app/src/main/java/com/commonware/android/webkit/bridge/MainActivity.java](#))

In JavaScript, our onmessage global function is now a bit more complex as well. We get our end of the communications channel by retrieving our port from ports on the event delivered to onmessage(). Then, we register an onmessage function *on that port*, which is how we receive the light levels that Java delivers via postMessage() on its WebMessagePort. When the user taps the label, we call a pull() function in JavaScript, that calls postMessage() on the port, supplying some string as a message (here, hardcoded as "ping" and ignored by our Java code):

```
<html>
<head>
<title>Android Light Sensor Demo</title>
<script language="javascript">
    function update_lux(lux) {
        document.getElementById("lux").innerHTML=lux;
    }

    function parse(json) {
        var result=JSON.parse(json);

        update_lux(result.lux);
    }

    var port;

    function pull() {
        port.postMessage("ping");
    }

    onmessage = function (e) {
        port = e.ports[0];

        port.onmessage = function (f) {
            parse(f.data);
        }
    }
</script>
</head>
<body>
```

ADVANCED USES OF WEBVIEW

```
<p><b><a onClick="pull()">Light Level</a>: </b><span id="lux">0.0</span> lux</p>
</body>
</html>
```

(from WebKit/SensorPort/app/src/main/assets/index.html)

If you run this sample on Android 6.0+, and you tap the “Light Level” label, you will get the light level, delivered by means of our `WebMessagePort`-based communications channel.

(NOTE: the author would like to thank Diego Torres Milano for his assistance in [finding out how this stuff works](#)).

Navigating the Waters

There is no navigation toolbar with the `WebView` widget. This allows you to use it in places where such a toolbar would be pointless and a waste of screen real estate. That being said, if you want to offer navigational capabilities, you can, but you have to supply the UI. `WebView` offers ways to perform garden-variety browser navigation, including:

- `reload()` to refresh the currently-viewed Web page
- `goBack()` to go back one step in the browser history, and `canGoBack()` to determine if there is any history to go back to
- `goForward()` to go forward one step in the browser history, and `canGoForward()` to determine if there is any history to go forward to
- `goBackOrForward()` to go backwards or forwards in the browser history, where negative numbers represent a count of steps to go backwards, and positive numbers represent how many steps to go forwards
- `canGoBackOrForward()` to see if the browser can go backwards or forwards the stated number of steps (following the same positive/negative convention as `goBackOrForward()`)
- `clearCache()` to clear the browser resource cache and `clearHistory()` to clear the browsing history

Settings, Preferences, and Options (Oh, My!)

With your favorite desktop Web browser, you have some sort of “settings” or “preferences” or “options” window. Between that and the toolbar controls, you can tweak and twiddle the behavior of your browser, from preferred fonts to the behavior of JavaScript.

Similarly, you can adjust the settings of your `WebView` widget as you see fit, via the `WebSettings` instance returned from calling the widget's `getSettings()` method.

There are lots of options on `WebSettings` to play with. Most appear fairly esoteric (e.g., `setFontFamily()`). However, here are some that you may find more useful:

- Control the font sizing via `setDefaultFontSize()` (to use a point size) or `setTextSize()` (to use constants indicating relative sizes like `LARGER` and `SMALLEST`)
- Control Web site rendering via `setUserAgent()`, so you can supply your own user agent string to make the Web server think you are a desktop browser, another mobile device (e.g., iPhone), or whatever. The settings you change are not persistent, so you should store them somewhere (such as via the Android preferences engine) if you are allowing your users to determine the settings, versus hard-wiring the settings in your application.

Security and Your WebView

More so than normal widgets, `WebView` opens up potential security issues, just as a Web browser could. If all you are doing is displaying your own content, the risks are minimal. If, on the other hand, you are displaying content from third parties, it is possible that their content is malicious in a way that can compromise your app's security, to your users' detriment.

Rogue JavaScript Risks

If you call `setJavaScriptEnabled(true)` on your `WebSettings`, you are allowing JavaScript code to be loaded and executed by `WebView`. In many cases, this is essential to get your content to render properly (e.g., the JavaScript is issuing AJAX calls). However, if you did not write the scripts, you do not know what they might be doing. If there are flaws in `WebView` — such as those discussed in the next sections — then your users may be at risk.

Even in the absence of such bugs, JavaScript can always:

- Consume so much CPU that it represents an attempt at a denial-of-service attack on the user's device
- Access anything the user enters into the Web page

- Access anything you enter into the Web page, using approaches as `javascript: URLs` or `evaluateJavaScript()`

The `addJavaScriptInterface()` Bugs

Another way that rogue JavaScript can attack users is if you use `addJavaScriptInterface()` to allow JavaScript code to call out to a Java object that you supply.

As was noted [earlier in this chapter](#), when `addJavaScriptInterface()` was introduced, there is this `@JavaScriptInterface` annotation that we should apply to the methods we want JavaScript to be able to call on the object we supply via `addJavaScriptInterface()`. This is because of a bug in the `addJavaScriptInterface()` implementation, whereby on 4.1 and below *any* method on the Java object could be called by JavaScript. This includes methods like `getClass()`... which in turn would allow JavaScript to use `Class.forName()` to get at arbitrary stuff. This was used by various bits of malware.

Hence, using `addJavaScriptInterface()` on Android 4.1 and below is rather risky, if you are loading arbitrary third-party JavaScript. If you have the means of examining that JavaScript (e.g., you are loading the scripts yourself), you might perform some simple scans of it to see if they appear to be doing anything unfortunate with your Java object that you injected into JavaScript via `addJavaScriptInterface()`.

Worse, Android sometimes also injects its *own* objects, without our requesting them.

In particular, [this security bug](#) points out that, through Android 4.3, if users have enabled an accessibility service, Android automatically injects objects into `WebView`, using `addJavaScriptInterface()`, named `accessibility` and `accessibilityTraversal`. So, even if you do not inject any objects yourself via `addJavaScriptInterface()`, your `WebView` may be at risk. The security researchers who uncovered this attack vector suggest using `removeJavaScriptInterface()` to specifically get rid of those objects.

The Same-Origin Policy Bug

Due to a bizarre bug in the parsing of URLs, it is possible for JavaScript code to violate the “same-origin policy” of a `WebView` on Android 4.3 and earlier.

Quoting [Wikipedia](#) from September 2014:

ADVANCED USES OF WEBVIEW

the same-origin policy is an important concept in the web application security model. The policy permits scripts running on pages originating from the same site — a combination of scheme, hostname, and port number — to access each other's DOM with no specific restrictions, but prevents access to DOM on different sites... This mechanism bears a particular significance for modern web applications that extensively depend on HTTP cookies to maintain authenticated user sessions, as servers act based on the HTTP cookie information to reveal sensitive information or take state-changing actions. A strict separation between content provided by unrelated sites must be maintained on the client side to prevent the loss of data confidentiality or integrity.

All modern Web browsers implement the same-origin policy (SOP)... but there can be bugs. A security researcher disclosed that the original AOSP Browser application [failed to implement the SOP properly](#), when a `javascript: URL` has a null byte before the `j` in `javascript`. And while the report was focused on the AOSP Browser app, the problem really lies with `WebView`.

To see this in action, load `https://commonsware.com/misc/sop-demo.html` in the AOSP Browser app on Android 4.3 or lower. This Web page consists of:

```
<html>
<head>
<title>WebView SOP Test</title>
</head>
<body>
<h1>WebView SOP Test</h1>
<iframe name="test" src="http://developer.android.com"></iframe>
<input type="button" value="test"
onclick="window.open('\u0000javascript:alert(document.domain)','test')">
</body>
</html>
```

It is derived from a similar example found in [the blog post outlining the security flaw](#).

In an SOP-compliant browser, clicking the button will have no effect. In the AOSP Browser app, clicking the button shows the domain name of the document in the `iframe`. And, loading this HTML into a `WebView` has the same effect.

Part of the `WebView` overhaul in Android 4.4 — replacing the original implementation with a new one backed by Chromium — had the effect of fixing this bug, whether intentionally or inadvertently.

There is no obvious mitigation approach for this bug, insofar as for the attack shown above, none of the callbacks on `WebViewClient` or `WebChromeClient` seem to allow us to intercept this URL before its JavaScript is executed. If you are loading HTML yourself from a third party, you might consider scanning that HTML for obvious signs of the attack (e.g., regular expression check for `\u0000javascript`), but that will be limited at best. Beyond that, try to limit the content in a `WebView` to be from only one origin, so that there is nothing for attackers to obtain via this bug.

Also note that the security researcher who found this bug has also found [another SOP violation](#), suggesting that mitigation strategies may be impractical.

Android 8.0 WebView Changes

`WebView`, as Android developers use it, is really a facade API, as of Android 5.0. Previously, the `WebView` implementation was part of the Android framework. Nowadays, the implementation is delegated to the Android System `WebView`, which allows Google to update the `WebView` implementation without relying upon manufacturers to distribute firmware updates.

Hence, to some extent, `WebView` continuously changes, as the Android System `WebView` app gets updated a few times per year.

However, it is only in a new version of Android that Google changes the API or the general approach taken by a `WebView` implementation. In Android 8.0, two significant changes arrived: multi-process mode and support for banning of cleartext traffic.

Multi-Process Mode

Historically, `WebView` code ran in your app's regular process. Because we often load JavaScript into a `WebView`, having the `WebView` in our process would raise the risks of `WebView` bugs. If JavaScript could cause arbitrary code to execute in our own process, it would have whatever rights our own application code does, including everything for which we have runtime permissions.

Android 7.0 added a developer option for moving the `WebView` execution to a separate process, and that is now standard on Android 8.0. As the documentation describes it, "Web content is handled in a separate, isolated process from the containing app's process for enhanced security."

In principle, this should not require code changes. However, this is a significant architectural change, and so it is worthwhile to fully test your WebView usage on Android 8.0+, to make sure nothing breaks compared with that same code running on Android 7.1 or older devices.

Honors Cleartext Traffic Setting

If your app has a `targetSdkVersion` over 25, and in your [network security configuration](#) you banned cleartext traffic, WebView will honor that setting on Android 8.0+. On older devices, WebView ignores the network security configuration, and it appears that it still ignores the rest of the configuration (e.g., certificate pinning).

However, this allows you to block the accidental transmission of data over unencrypted channels. Most apps doing network I/O should ban cleartext traffic, at least for debug builds, to identify where they are accidentally using a plain http URL. Apps for which security is a priority might also ban cleartext traffic for release builds.

The [WebKit/BrowserSecure](#) sample project demonstrates this. It has a network security configuration XML file that bans cleartext traffic:

```
<?xml version="1.0" encoding="utf-8"?>
<network-security-config>
  <base-config cleartextTrafficPermitted="false">
    <trust-anchors>
      <certificates src="system" />
    </trust-anchors>
  </base-config>
</network-security-config>
```

(from [WebKit/BrowserSecure/app/src/main/res/xml/net_security_config.xml](#))

It applies that configuration in the manifest via the `android:networkSecurityConfig` attribute on the `<application>` element:

```
<application
  android:allowBackup="false"
  android:icon="@drawable/ic_launcher"
  android:label="@string/app_name"
  android:networkSecurityConfig="@xml/net_security_config">
  <activity android:name=".BrowserDemo1">
    <intent-filter>
      <action android:name="android.intent.action.MAIN" />
```

ADVANCED USES OF WEBVIEW

```
        <category android:name="android.intent.category.LAUNCHER" />
    </intent-filter>
</activity>
</application>
```

(from [WebKit/BrowserSecure/app/src/main/AndroidManifest.xml](#))

The activity just loads up a plain HTTP-served Web page:

```
package com.commonware.android.browser1;

import android.app.Activity;
import android.os.Bundle;
import android.webkit.WebView;

public class BrowserDemo1 extends Activity {
    WebView browser;

    @Override
    public void onCreate(Bundle state) {
        super.onCreate(state);
        setContentView(R.layout.main);

        browser=(WebView)findViewById(R.id.webkit);
        browser.loadUrl("http://www.andglobe.com");
    }
}
```

(from [WebKit/BrowserSecure/app/src/main/java/com/commonware/android/browser1/BrowserDemo1.java](#))

The project is set up to target 26:

```
apply plugin: 'com.android.application'

android {
    compileSdkVersion 25
    buildToolsVersion '26.0.2'

    defaultConfig {
        minSdkVersion 25
        targetSdkVersion 26
        applicationId 'com.commonware.android.browser.secure'
    }
}
```

(from [WebKit/BrowserSecure/app/build.gradle](#))

If you change that to have it target 25, the app will run “normally” on Android 8.0, showing the designated Web page. But, with a `targetSdkVersion` set at 26, the `WebView` will not show that page, as it would be loaded over a cleartext (HTTP) connection:

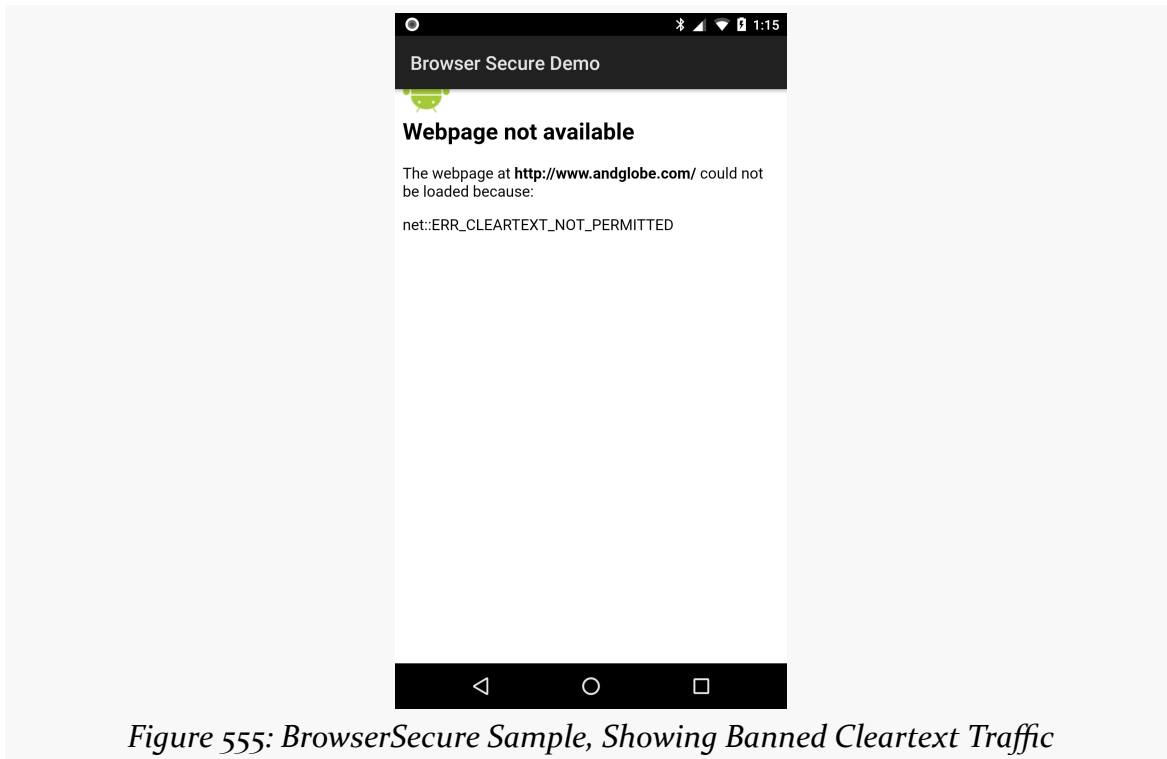

Figure 555: BrowserSecure Sample, Showing Banned Cleartext Traffic

Chrome Custom Tabs

Chrome custom tabs serve as middle ground between using a `WebView` in your own app and launching a URL into a separate Web browser.

With a `WebView`, you have complete control over the overall user experience within your app. However, your `WebView` is decoupled from any other browser the user may be using on the device. Conversely, launching URLs into the user’s chosen browser gives the user their normal browsing experience, but you have no control over the user experience, as the user is now in the browser app, not your app.

With Chrome custom tabs, while Chrome is handling the URL, it will allow you limited control over the action bar (color and custom actions). It also simplifies some things that you might otherwise have had to handle yourself, such as pre-

ADVANCED USES OF WEBVIEW

fetching a Web page to be able to quickly switch to it. Basic integration is also fairly easy, coming in the form of extras on the same sort of ACTION_VIEW Intent that you might have used for launching the URL in a standalone browser.

At the same time, there are some concerns:

- [The documentation](#) states that there is a “Shared Cookie Jar and permissions model so users don’t have to log in to sites they are already connected to, or re-grant permissions they have already granted”, which would require significant testing to ensure that you are not leaking information into Chrome that might be somehow delivered to other sites (including Google).
- While it uses an ACTION_VIEW Intent, and so the user can choose to view the URL in a different browser, you will not get the custom integration in that case. This may be fine, but you will need to make sure that from a marketing and documentation standpoint you handle both the case where the user chooses Chrome (and you get the “custom tab”) and the case where the user chooses something else.
- Since any app could handle the ACTION_VIEW Intent, you need to take into account that any information in the custom extras, like the PendingIntent to use for an custom action bar item, is stuff that you are willing for *arbitrary* apps to get their hands on. Do not assume that your communications will solely be with Chrome.

The Input Method Framework

We think of Android devices as having “soft keyboards”. The official term for this is that Android devices offer one or more “input method editors” (or “input methods” for short). These input methods allow for text entry on a touchscreen, avoiding the need for a physical keyboard. Note, though, that “text entry” does not necessarily imply an on-screen keyboard equivalent — for example, the old PalmOS Graffiti text entry system is [available as an app on the Play Store](#).

While it is possible to create custom input method editors — as the authors of Graffiti Pro did — this chapter is focused more on how ordinary app developers are affected by input methods, and how an app can help steer the behavior of the input method to benefit the user.

Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly the [section covering the `EditText` widget](#).

Keyboards, Hard and Soft

Some Android devices have a hardware keyboard that is visible some of the time (when it is slid out). A few Android devices have a hardware keyboard that is always visible (so-called “bar” or “slab” phones). Most Android devices, though, have no hardware keyboard at all.

The IMF handles all of these scenarios. In short, if there is no hardware keyboard, an input method editor (IME) will be available to the user when they tap on an enabled `EditText`.

This requires no code changes to your application... if the default functionality of the IME is what you want. Fortunately, Android is fairly smart about guessing what you want, so it may be you can just test with the IME but otherwise make no specific code changes.

Of course, the keyboard may not quite behave how you would like. For example, in the Basic/Field sample project, the `FieldDemo` activity has the IME overlaying the multiple-line `EditText`:

Figure 556: The input method editor, as seen in the FieldDemo sample application

It would be nice to have more control over how this appears, and for other behavior of the IME. Fortunately, the framework as a whole gives you many options for this, as is described over the bulk of this chapter.

Tailored To Your Needs

Android 1.1 and earlier offered many attributes on `EditText` widgets to control their style of input, such as `android:password` to indicate a field should be for password entry (shrouding the password keystrokes from prying eyes). Starting in Android 1.5, with the IMF, many of these have been combined into a single `android:inputType` attribute.

The `android:inputType` attribute takes a class plus modifiers, in a pipe-delimited list (where `|` is the pipe character). The class generally describes what the user is

THE INPUT METHOD FRAMEWORK

allowed to input, and this determines the basic set of keys available on the soft keyboard. The available classes are:

1. text (the default)
2. number
3. phone
4. datetime
5. date
6. time

Many of these classes offer one or more modifiers, to further refine what the user will be entering. To help explain those, take a look at the `res/layout/main.xml` file from the [InputMethod/IMEDemo1](#) project:

```
<?xml version="1.0" encoding="utf-8"?>
<TableLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:stretchColumns="1"
    >
    <TableRow>
        <TextView
            android:text="No special rules:"
        />
        <EditText
        />
    </TableRow>
    <TableRow>
        <TextView
            android:text="Email address:"
        />
        <EditText
            android:inputType="text|textEmailAddress"
        />
    </TableRow>
    <TableRow>
        <TextView
            android:text="Signed decimal number:"
        />
        <EditText
            android:inputType="number|numberSigned|numberDecimal"
        />
    </TableRow>
    <TableRow>
        <TextView
```

THE INPUT METHOD FRAMEWORK

```
        android:text="Date:"
    />
    <EditText
        android:inputType="date"
    />
</TableRow>
<TableRow>
    <TextView
        android:text="Multi-line text:"
    />
    <EditText
        android:inputType="text|textMultiLine|textAutoCorrect"
        android:minLines="3"
        android:gravity="top"
    />
</TableRow>
</TableLayout>
```

(from [InputMethod/IMEDemo/app/src/main/res/layout/main.xml](#))

Here, you will see a `TableLayout` containing five rows, each demonstrating a slightly different flavor of `EditText`:

- One has no attributes at all on the `EditText`, meaning you get a plain text entry field
- One has `android:inputType = "text|textEmailAddress"`, meaning it is text entry, but specifically seeks an email address
- One allows for signed decimal numeric input, via `android:inputType = "number|numberSigned|numberDecimal"`
- One is set up to allow for data entry of a date (`android:inputType = "date"`)
- The last allows for multi-line input with auto-correction of probable spelling errors (`android:inputType = "text|textMultiLine|textAutoCorrect"`)

The class and modifiers tailor the keyboard. So, a plain text entry field results in a plain soft keyboard:

THE INPUT METHOD FRAMEWORK

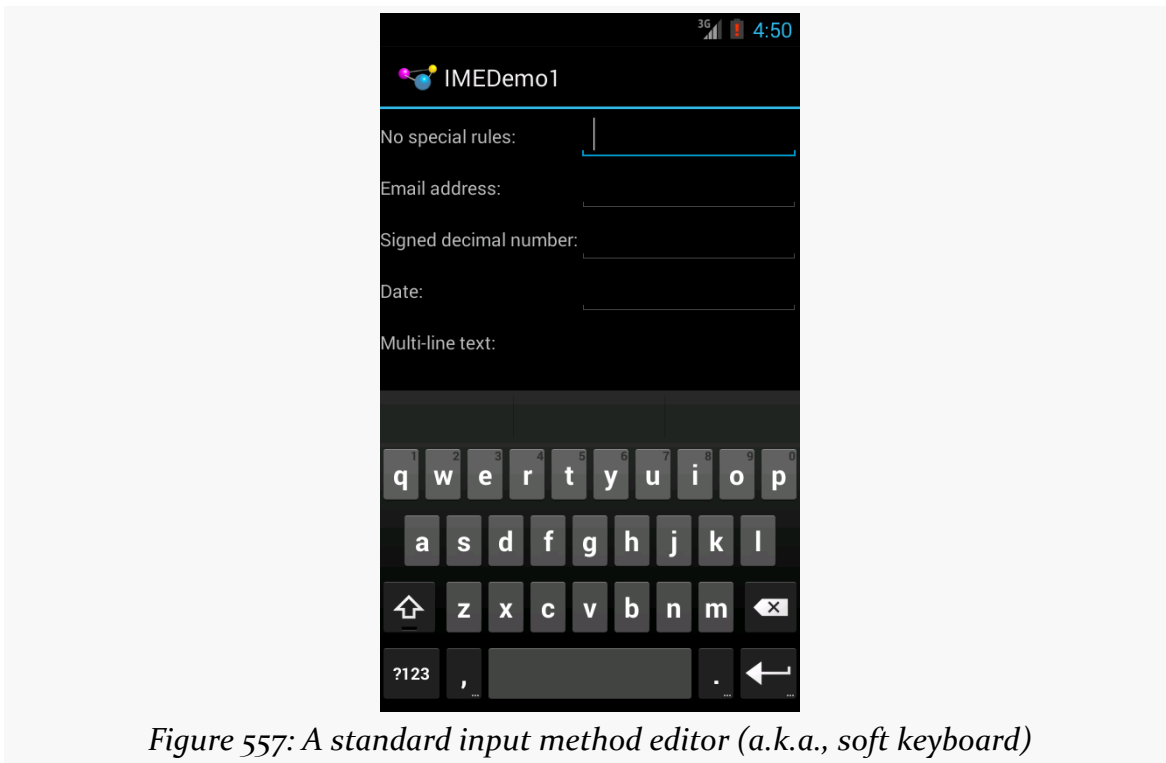

Figure 557: A standard input method editor (a.k.a., soft keyboard)

An email address field might put the @ symbol on the soft keyboard, perhaps at the cost of a smaller spacebar, depending on the keyboard implementation:

Figure 558: The input method editor for email addresses

Note, though, that this behavior is specific to the input method editor. Some editors might put an @ sign on the primary keyboard for an email field. Some might put a “.com” button on the primary keyboard. Some might not react at all. It is up to the implementation of the input method editor — all you can do is supply the hint.

Numbers and dates restrict the keys to numeric keys, plus a set of symbols that may or may not be valid on a given field:

Figure 559: The input method editor for signed decimal numbers

And so on.

By choosing the appropriate `android:inputType`, you can give the user a soft keyboard that best suits what it is they should be entering.

Tell Android Where It Can Go

You may have noticed a subtle difference between the first and second input method editors, beyond the addition of the @ key. If you look in the lower-right corner of the soft keyboard, the second field's editor has a "Next" button, while the first field's editor has a newline button.

This points out two things:

- `EditText` widgets are multi-line by default if you do not specify `android:inputType`
- You can control what goes on with that lower-right-hand button, called the action key

THE INPUT METHOD FRAMEWORK

By default, on an `EditText` where you have specified `android:inputType`, the action key will be “Next”, moving you to the next `EditText` in sequence, or “Done”, if you are on the last `EditText` on the screen. You can manually stipulate what the action key will be labeled via the `android:imeOptions` attribute. For example, in the `res/layout/main.xml` from the [InputMethod/IMEDemo2](#) sample project, you will see an augmented version of the previous example, where two input fields specify what their action key should look like:

```
<?xml version="1.0" encoding="utf-8"?>
<ScrollView xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
>
    <TableLayout
        android:layout_width="match_parent"
        android:layout_height="match_parent"
        android:stretchColumns="1"
    >
        <TableRow>
            <TextView
                android:text="No special rules:"
            />
            <EditText
            />
        </TableRow>
        <TableRow>
            <TextView
                android:text="Email address:"
            />
            <EditText
                android:inputType="text|textEmailAddress"
                android:imeOptions="actionSend"
            />
        </TableRow>
        <TableRow>
            <TextView
                android:text="Signed decimal number:"
            />
            <EditText
                android:inputType="number|numberSigned|numberDecimal"
                android:imeOptions="actionDone"
            />
        </TableRow>
        <TableRow>
            <TextView
                android:text="Date:"
```

```
    />
    <EditText
        android:inputType="date"
    />
</TableRow>
<TableRow>
    <TextView
        android:text="Multi-line text:"
    />
    <EditText
        android:inputType="text|textMultiLine|textAutoCorrect"
        android:minLines="3"
        android:gravity="top"
    />
</TableRow>
</TableLayout>
</ScrollView>
```

(from [InputMethod/IMEDemo2/app/src/main/res/layout/main.xml](#))

Here, we attach a “Send” action to the action key for the email address (`android:imeOptions = "actionSend"`), and the “Done” action on the middle field (`android:imeOptions = "actionDone"`).

By default, “Next” will move the focus to the next `EditText` and “Done” will close up the input method editor. However, for those, or for any other ones like “Send”, you can use `setOnEditorActionListener()` on `EditText` (technically, on the `TextView` superclass) to get control when the action key is clicked or the user presses the `<Enter>` key. You are provided with a flag indicating the desired action (e.g., `IME_ACTION_SEND`), and you can then do something to handle that request (e.g., send an email to the supplied email address).

If you need more control over the action button, you can set:

- `android:imeActionId`, which provides a custom value for the `actionId` that is passed to `onEditorAction()` of your `OnEditorActionListener`
- `android:imeActionLabel`, where you provide your own caption for the button (bearing in mind that your desired caption may or may not fit)

Fitting In

You will notice that the `IMEDemo2` layout shown above has another difference from its `IMEDemo1` predecessor: the use of a `ScrollView` container wrapping the `TableLayout`.

THE INPUT METHOD FRAMEWORK

This ties into another level of control you have over the input method editors: what happens to your activity's own layout when the input method editor appears?

There are three possibilities, depending on circumstances:

1. Android can “pan” your activity, effectively sliding the whole layout up to accommodate the input method editor, or overlaying your layout, depending on whether the `EditText` being edited is at the top or bottom. This has the effect of hiding some portion of your UI.
2. Android can resize your activity, effectively causing it to shrink to a smaller screen dimension, allowing the input method editor to sit below the activity itself. This is great when the layout can readily be shrunk (e.g., it is dominated by a list or multi-line input field that does not need the whole screen to be functional).
3. In landscape mode, Android may display the input method editor full-screen, obscuring your entire activity. This allows for a bigger keyboard and generally easier data entry.

Android controls the full-screen option purely on its own. And, by default, Android will choose between pan and resize modes depending on what your layout looks like. If you want to specifically choose between pan and resize, you can do so via an `android:windowSoftInputMode` attribute on the `<activity>` element in your `AndroidManifest.xml` file. For example, here is the manifest from `IMEDemo2`:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
    package="com.commonware.android.imf.two"
    android:versionCode="1"
    android:versionName="1.0">

    <supports-screens
        android:anyDensity="true"
        android:largeScreens="true"
        android:normalScreens="true"
        android:smallScreens="true"/>

    <uses-sdk
        android:minSdkVersion="7"
        android:targetSdkVersion="11"/>

    <application
        android:icon="@drawable/ic_launcher"
        android:label="@string/app_name">
        <activity
```

THE INPUT METHOD FRAMEWORK

```
android:name=".IMEDemo2"
android:label="@string/app_name"
android:windowSoftInputMode="adjustResize">
<intent-filter>
  <action android:name="android.intent.action.MAIN"/>

  <category android:name="android.intent.category.LAUNCHER"/>
</intent-filter>
</activity>
</application>

</manifest>
```

(from [InputMethod/IMEDemo2/app/src/main/AndroidManifest.xml](#))

Because we specified `resize`, Android will shrink our layout to accommodate the input method editor. With the `ScrollView` in place, this means the scrollbar will appear as needed when the user is scrolling:

Figure 560: The shrunken, scrollable layout

Jane, Stop This Crazy Thing!

Sometimes, you need the input method editor to just go away. For example, if you make the action button be “Search”, the user tapping that button will not automatically hide the editor.

To hide the editor, you will need to make a call to the `InputMethodManager`, a system service that controls these input method editors:

```
InputMethodManager  
mgr=(InputMethodManager)getSystemService(INPUT_METHOD_SERVICE);  
mgr.hideSoftInputFromWindow(fld.getWindowToken(), 0);
```

(where `fld` is the `EditText` whose input method editor you want to hide)

Fonts and Text

Inevitably, you'll get the question "hey, can we change this font?" when doing application development. The answer depends on what fonts come with the platform, whether you can add other fonts, and how to apply them to the widget or whatever needs the font change.

Android is no different. It comes with some fonts plus a means for adding new fonts. Though, as with any new environment, there are a few idiosyncrasies to deal with.

Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly the one on [files](#).

Love The One You're With

Android natively knows three fonts, by the shorthand names of "sans", "serif", and "monospace". For Android 1.x, 2.x, and 3.x, these fonts are actually the Droid series of fonts, created for the Open Handset Alliance by [Ascender](#). A new font set, Roboto, is used in Android 4.x and beyond, though the look of the font changed somewhat in Android 5.0.

For those fonts, you can just reference them in your layout XML, if you choose, such as the following layout from the [Fonts/FontSampler](#) sample project:

```
<?xml version="1.0" encoding="utf-8"?>
<TableLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
```

FONTS AND TEXT

```
android:stretchColumns="1">

<TableRow>

  <TextView
    android:layout_marginRight="4dip"
    android:text="@string/label_sans"
    android:textSize="20sp" />

  <TextView
    android:id="@+id/sans"
    android:text="@string/hello_world"
    android:textSize="20sp"
    android:typeface="sans" />
</TableRow>

<TableRow>

  <TextView
    android:layout_marginRight="4dip"
    android:text="@string/label_serif"
    android:textSize="20sp" />

  <TextView
    android:id="@+id/serif"
    android:text="@string/hello_world"
    android:textSize="20sp"
    android:typeface="serif" />
</TableRow>

<TableRow>

  <TextView
    android:layout_marginRight="4dip"
    android:text="@string/label_monospace"
    android:textSize="20sp" />

  <TextView
    android:id="@+id/monospace"
    android:text="@string/hello_world"
    android:textSize="20sp"
    android:typeface="monospace" />
</TableRow>

<TableRow>

  <TextView
    android:layout_marginRight="4dip"
```

FONTS AND TEXT

```
        android:text="@string/label_custom"
        android:textSize="20sp" />

<TextView
    android:id="@+id/custom"
    android:text="@string/hello_world"
    android:textSize="20sp" />
</TableRow>

<TableRow android:id="@+id/filerow">

    <TextView
        android:layout_marginRight="4dip"
        android:text="@string/label_custom_from_file"
        android:textSize="20sp" />

    <TextView
        android:id="@+id/file"
        android:text="@string/hello_world"
        android:textSize="20sp" />
</TableRow>
</TableLayout>
```

(from [Fonts/FontSampler/app/src/main/res/layout/main.xml](#))

This layout builds a table showing short samples of five fonts. Notice how the first three have the `android:typeface` attribute, whose value is one of the three built-in font faces (e.g., “sans”).

The three built-in fonts are very nice. However, it may be that a designer, or a manager, or a customer wants a different font than one of those three. Or perhaps you want to use a font for specialized purposes, such as an image font instead of a series of PNG graphics.

The easiest way to accomplish this is to package the desired font(s) with your application. To do this, simply create an `assets/` folder in the project root, and put your TrueType (TTF) fonts in the assets. You might, for example, create `assets/fonts/` and put your TTF files in there. Note that Android has some support for OpenType (OTF) fonts, as well.

Then, you need to tell your widgets to use that font. Unfortunately, you can no longer use layout XML for this, since the XML does not know about any fonts you may have tucked away as an application asset. Instead, you need to make the change in Java code:

FONTS AND TEXT

```
package com.commonware.android.fonts;

import android.app.Activity;
import android.graphics.Typeface;
import android.os.Bundle;
import android.os.Environment;
import android.view.View;
import android.widget.TextView;
import java.io.File;

public class FontSampler extends Activity {
    @Override
    public void onCreate(Bundle state) {
        super.onCreate(state);
        setContentView(R.layout.main);

        TextView tv=(TextView)findViewById(R.id.custom);
        Typeface face=
            Typeface.createFromAsset(getAssets(), "fonts/HandmadeTypewriter.ttf");

        tv.setTypeface(face);

        File font=
            new File(Environment.getExternalStorageDirectory(), "MgOpenCosmeticaBold.ttf");

        if (font.exists()) {
            tv=(TextView)findViewById(R.id.file);
            face=Typeface.createFromFile(font);

            tv.setTypeface(face);
        }
        else {
            findViewById(R.id.filerow).setVisibility(View.GONE);
        }
    }
}
```

(from [Fonts/FontSampler/app/src/main/java/com/commonware/android/fonts/FontSampler.java](#))

Here we grab the `TextView` for our “custom” sample, then create a `Typeface` object via the static `createFromAsset()` builder method. This takes the application’s `AssetManager` (from `getAssets()`) and a path within your `assets/` directory to the font you want.

Then, it is just a matter of telling the `TextView` to `setTypeface()`, providing the `Typeface` you just created. In this case, we are using the [Handmade Typewriter](#) font.

You can also load a font out of a local file and use it. The benefit is that you can customize your fonts after your application has been distributed. On the other hand, you have to somehow arrange to get the font onto the device. But just as you can get a `Typeface` via `createFromAsset()`, you can get a `Typeface` via `createFromFile()`. In our `FontSampler`, we look in the root of “external storage” (typically the SD card) for

the MgOpenCosmeticaBold TrueType font file, and if it is found, we use it for the fifth row of the table. Otherwise, we hide that row.

The results?

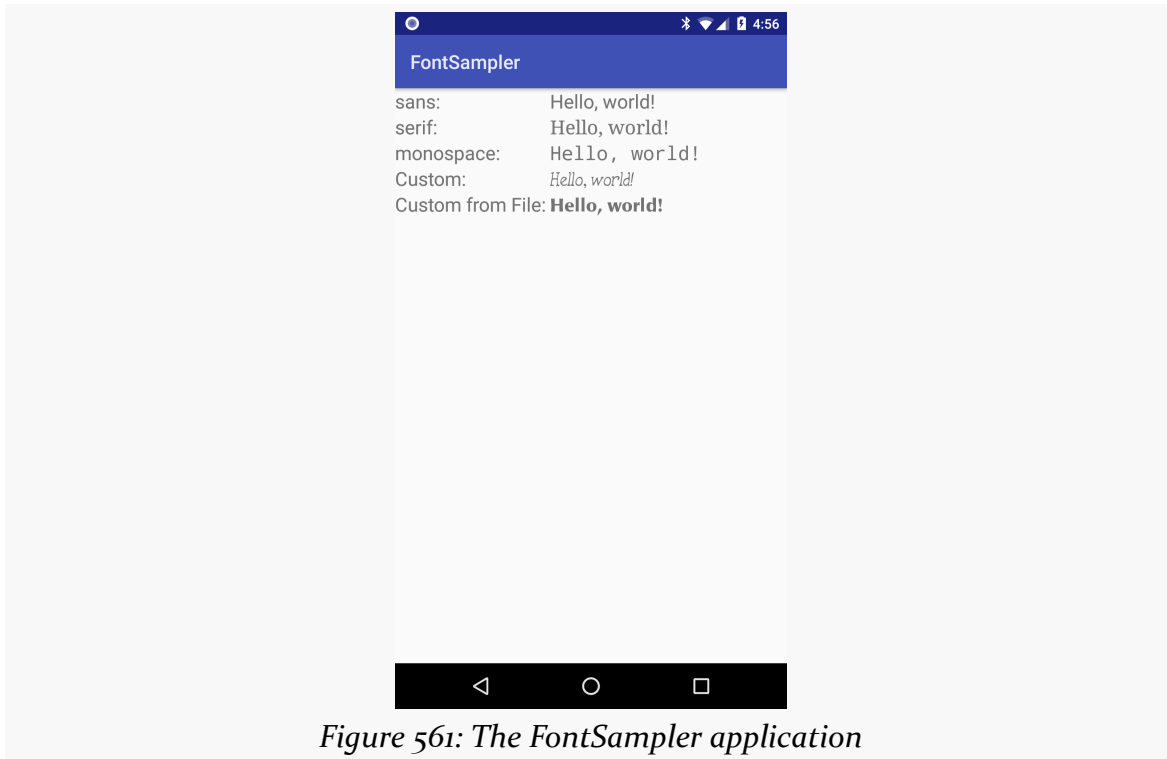

Figure 561: The FontSampler application

Note that Android does not seem to like all TrueType fonts. When Android dislikes a custom font, rather than raise an `Exception`, it seems to substitute Droid Sans (“sans”) quietly. So, if you try to use a different font and it does not seem to be working, it may be that the font in question is incompatible with Android, for whatever reason.

Yeah, But Do We Really Have To Do This in Java?

One common complaint with font handling in Android is that you have to apply a custom font on a per-widget basis in Java code.

This gets old quickly.

It is not too bad with just a single `TextView`. But for a whole activity, or a whole application, changing all of the relevant `TextView` widgets (and descendents, like `Button`) gets to be a bit tedious.

While there are “traverse the widget hierarchy and fix up the fonts” code snippets available, you are probably better served using a third-party library, like Christopher Jenkins’ [Calligraphy](#), which lets you define custom fonts in layout XML files or style resources.

Here a Glyph, There a Glyph

TrueType fonts can be rather pudgy, particularly if they support an extensive subset of the available Unicode characters. The Handmade Typewriter font used above runs over 70KB; the DejaVu free fonts can run upwards of 500KB apiece. Even compressed, these add bulk to your application, so be careful not to go overboard with custom fonts, lest your application take up too much room on your users’ phones.

Conversely, bear in mind that fonts may not have all of the glyphs that you need. As an example, let us talk about the ellipsis.

Android’s `TextView` class has the built-in ability to “ellipsize” text, truncating it and adding an ellipsis if the text is longer than the available space. You can use this via the `android:ellipsize` attribute, for example. This works fairly well, at least for single-line text.

The ellipsis that Android uses is not three periods. Rather it uses an actual ellipsis character, where the three dots are contained in a single glyph. Hence, any font that you use in a `TextView` where you also use the “ellipsizing” feature will need the ellipsis glyph.

Beyond that, though, Android pads out the string that gets rendered on-screen, such that the length (in characters) is the same before and after “ellipsizing”. To make this work, Android replaces one character with the ellipsis, and replaces all other removed characters with the Unicode character ‘ZERO WIDTH NO-BREAK SPACE’ (U+FEFF). This means the “extra” characters after the ellipsis do not take up any visible space on screen, yet they can be part of the string.

However, this means any custom fonts you use for `TextView` widgets that you use with `android:ellipsize` must also support this special Unicode character. Not all

fonts do, and you will get artifacts in the on-screen representation of your shortened strings if your font lacks this character (e.g., rogue X's appear at the end of the line).

And, of course, Android's international deployment means your font must handle any language your users might be looking to enter, perhaps through a language-specific input method editor.

Hence, while using custom fonts in Android is very possible, there are many potential problems, and so you must weigh carefully the benefits of the custom fonts versus their potential costs.

Auto-Sizing TextView

Text comes in all lengths.

Sometimes, when showing text in a `TextView`, we can allow that text to word-wrap and extend vertically. Other times, though, that proves to be impractical, such as when using a `TextView` as a label for another widget. However, even in those times, the text to be shown may vary in length by a significant amount. Translations of the label's text might range from a couple of kanji in Japanese to a 20-letter word in German or Icelandic.

One long-standing solution to that problem has been to use an auto-sizing `TextView`. Here, what is being "auto-sized" is the size of the font used for the text, to keep the `TextView` at a fixed dimension regardless of translation. It is up to the developer to ensure that for a given screen size and translation that the font does not wind up being too small to be read.

However, Android itself never had a widget for this, so developers would rely instead upon third-party or home-grown implementations.

Android 8.0 adds this sort of auto-sizing capability to `TextView` itself (and, by extension, subclasses like `Button`). You have two main approaches for implementing this:

- Set `android:autoSizeTextType="uniform"` on the `TextView` to engage auto-size capability. Then, use `android:autoSizeMinTextSize` and `android:autoSizeMaxTextSize` to set the lower and upper bounds for the text size, where Android can choose any size in between those. If you also add `android:autoSizeStepGranularity`, you can choose the increments in

FONTS AND TEXT

which Android will move between the ends of the text size range (the default is 1px).

- Set `android:autoSizeTextType="uniform"` on the `TextView`, as in the above option. Then, instead of providing the starting and ending values of a range, use an `<array>` resource to define specific sizes that you want to support, then use `android:autoSizePresetSizes` to point to that resource. This is a bit more difficult to set up, as you need to define the array resource, but it may simplify testing, as you are in complete control over the possible sizes.

To make this work, you need to constrain the size of the `TextView`, so that it does not expand to fill all available space. That might be through having both axes set to `wrap_content`, but have the container holding the `TextView` limit how big the `TextView` can get. It might be through `TextView`-specific configuration, such as `android:maxLines`. Or, it might be through setting the size of the axes to be some specific dimension or `match_parent`.

The [Basic/AutoSize](#) sample project illustrates the use of both forms of `android:autoSizeTextType`.

The activity's layout consists of an `EditText`, a pair of `TextView` widgets, and a pair of divider lines (horizontal `View` widgets with background and margin), all inside of a vertical `LinearLayout`:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:tools="http://schemas.android.com/tools"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:orientation="vertical"
    tools:context="com.commonware.android.autosize.MainActivity">

    <EditText
        android:id="@+id/input"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:layout_margin="4dp"
        android:hint="@string/hint_input" />

    <View
        android:layout_width="match_parent"
        android:layout_height="2dp"
        android:layout_margin="4dp"
        android:background="@android:color/black" />
```

FONTS AND TEXT

```
<TextView
    android:id="@+id/granular"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:layout_margin="4dp"
    android:autoSizeMaxTextSize="40sp"
    android:autoSizeMinTextSize="5sp"
    android:autoSizeStepGranularity="5sp"
    android:autoSizeTextType="uniform"
    android:maxLines="1" />

<View
    android:layout_width="match_parent"
    android:layout_height="2dp"
    android:layout_margin="4dp"
    android:background="@android:color/black" />

<TextView
    android:id="@+id/steps"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:layout_margin="4dp"
    android:autoSizePresetSizes="@array/autosize_sizes"
    android:autoSizeTextType="uniform"
    android:maxLines="1" />

</LinearLayout>
```

(from [Basic/AutoSize/app/src/main/res/layout/activity_main.xml](#))

Both TextView widgets have `android:autoSizeTextType` set to `uniform`. The top one uses `android:autoSizeMinTextSize`, `android:autoSizeMaxTextSize`, and `android:autoSizeStepGranularity` to allow the text size to float between 5sp and 40sp in 5sp increments. The bottom one uses `android:autoSizePresetSizes` to tie in an array resource for the valid sizes to use:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
    <array name="autosize_sizes">
        <item>10sp</item>
        <item>12sp</item>
        <item>14sp</item>
        <item>16sp</item>
        <item>18sp</item>
        <item>20sp</item>
    </array>
</resources>
```

FONTS AND TEXT

(from [Basic/AutoSize/app/src/main/res/values/arrays.xml](#))

Here, the size can float between 10sp and 20sp in 2sp increments. However, there is no requirement that the sizes increment in a uniform fashion when using the array approach.

The MainActivity that uses the layout sets up a TextWatcher on the EditText and copies what you enter into the two TextView widgets, to allow you to experiment in real time with changes in the text size:

```
EditText input=(EditText)findViewById(R.id.input);
final TextView granular=(TextView)findViewById(R.id.granular);
final TextView steps=(TextView)findViewById(R.id.steps);

input.addTextChangedListener(new TextWatcher() {
    @Override
    public void beforeTextChanged(CharSequence charSequence, int i, int i1,
        int i2) {
        // unused
    }

    @Override
    public void onTextChanged(CharSequence charSequence, int i, int i1,
        int i2) {
        // unused
    }

    @Override
    public void afterTextChanged(Editable editable) {
        granular.setText(editable.toString());
        steps.setText(editable.toString());
    }
});
}
```

(from [Basic/AutoSize/app/src/main/java/com/commonsware/android/autosize/MainActivity.java](#))

When you run the app, initially the EditText and corresponding TextView widgets have no text. If you start typing, you will see your text appear in the TextView widgets:

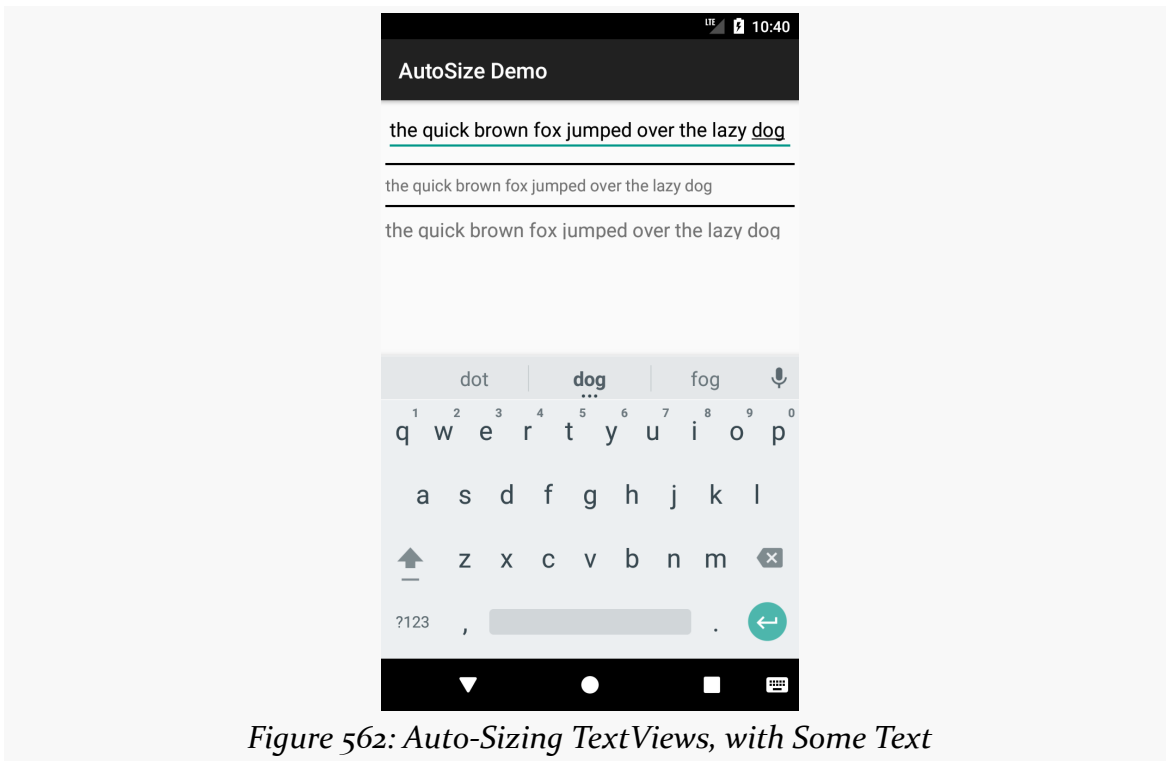

Figure 562: Auto-Sizing TextViews, with Some Text

As you continue typing, the text size decreases:

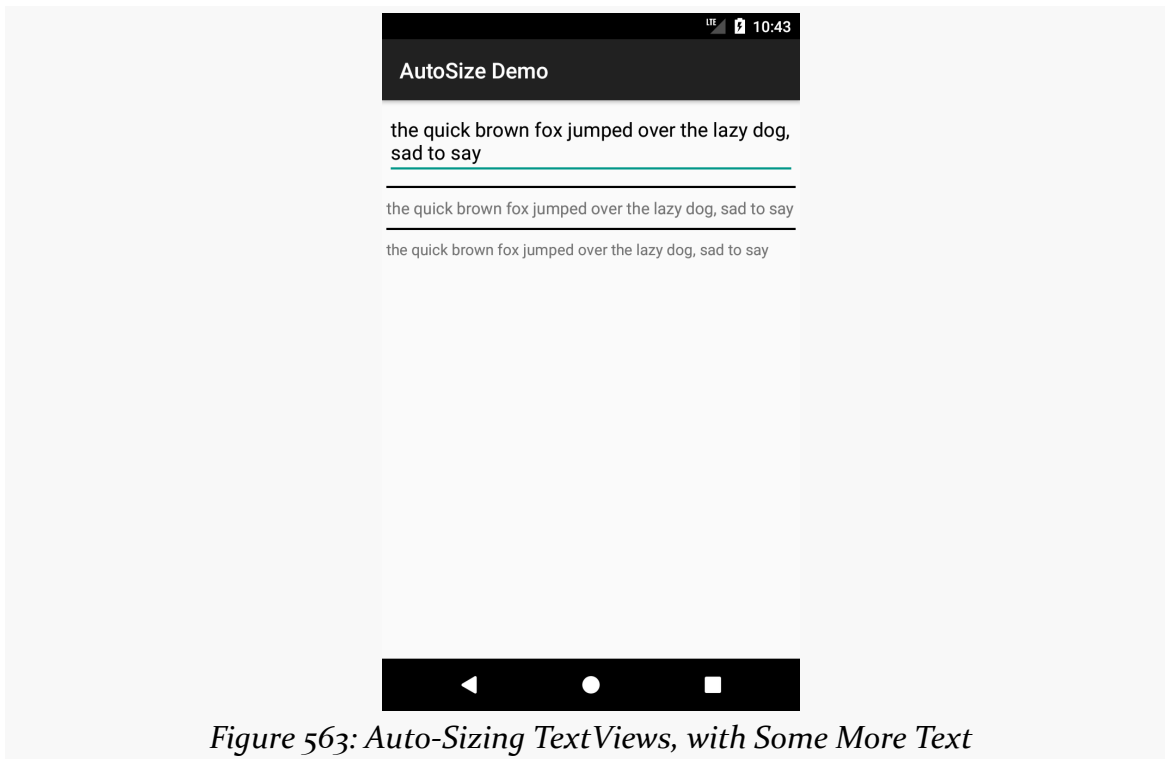

Figure 563: Auto-Sizing TextViews, with Some More Text

If you are using `appcompat-v7`, there are equivalent capabilities added to its wrapper backport of `TextView`.

Justified Text

If you are reading the PDF edition of this book, its paragraphs do not use justified text. If you are reading the Kindle edition of this book — at least when using the Amazon Kindle app for Android — its paragraphs do use justified text.

Justified text is when text (e.g., in the middle of a paragraph) fills the entire line, usually with bits of extra space added between the words to get them to neatly fill the available horizontal space.

For years, `TextView` never supported justified text, though you could get it through [third-party libraries](#).

In Android 8.0+, you can now enable justified text on a `TextView` via `setJustify()`. At the present time, the documentation does not show an `android:justify` attribute, though, [with luck](#), it will be added in a future update.

Plain text is so, well, plain.

Fortunately, Android has fairly extensive support for formatted text, before you need to break out something as heavy-weight as `WebView`. However, some of this rich text support has been shrouded in mystery, particularly how you would allow users to edit formatted text.

This chapter will explain how the rich text support in Android works and how you can take advantage of it, with particular emphasis on some open source projects to help you do just that.

Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly the ones on [basic widgets](#) and the [input method framework](#).

The Span Concept

You may have noticed that many methods in Android accept or return a `CharSequence`. The `CharSequence` interface is little used in traditional Java, if for no other reason than there are relatively few implementations of it outside of `String`. However, in Android, `CharSequence` becomes much more important, because of a sub-interface named `Spanned`.

`Spanned` defines sequences of characters (`CharSequence`) that contain *inline markup rules*. These rules — mostly instances of `CharacterStyle` and `ParagraphStyle` subclasses — indicate whether the “spanned” portion of the characters should be

rendered in an alternate font, or be turned into a hyperlink, or have other effects applied to them.

Methods that take a `CharSequence` as a parameter, therefore, can work equally well with `String` objects as well as objects that implement `Spanned`.

Implementations

The base interface for rich-text `CharSequence` objects is `Spanned`. This is used for any `CharSequence` that has inline markup rules, and it defines methods for retrieving markup rules applied to portions of the underlying text.

The primary concrete implementation of `Spanned` is `SpannedString`. `SpannedString`, like `String`, is immutable — you cannot change either the text or the formatting of a `SpannedString`.

There is also the `Spannable` sub-interface of `Spanned`. `Spannable` is used for any `CharSequence` with inline markup rules that can be modified, and it defines the methods for modifying the formatting. There is a corresponding `SpannableString` implementation.

Finally, there is a related `Editable` interface, which is for a `CharSequence` that can have its *text* modified in-place. `SpannableStringBuilder` implements both `Editable` and `Spannable`, for modifying text and formatting at the same time.

TextView and Spanned

One of the most important uses of `Spanned` objects is with `TextView`. `TextView` is capable of rendering a `Spanned`, complete with all of the specified formatting. So, if you have a `Spanned` that indicates that the third word should be rendered in italics, `TextView` will faithfully italicize that word.

`TextView`, of course, is an ancestor of many other widgets, from `EditText` to `Button` to `CheckBox`. Each of those, therefore, can use and render `Spannable` objects. The fact that `EditText` has the ability to render `Spanned` objects — and even allow them to be edited — is key for allowing users to enter rich text themselves as part of your UI.

Available Spans

As noted above, the markup rules come in the form of instances of base classes known as `CharacterStyle` and `ParagraphStyle`. Despite those names, most of the SDK-supplied subclasses of `CharacterStyle` and `ParagraphStyle` end in `Span` (not `Style`), and so you will likely see references to these as “spans” as often as “styles”. That also helps minimize confusion between character styles and style resources.

There are well over a dozen supplied `CharacterStyle` subclasses, including:

1. `ForegroundColorSpan` and `BackgroundColorSpan` for coloring text
2. `StyleSpan`, `TextAppearanceSpan`, `TypefaceSpan`, `UnderlineSpan`, and `StrikethroughSpan` for affecting the true “style” of text
3. `AbsoluteSizeSpan`, `RelativeSizeSpan`, `SuperscriptSpan`, and `SubscriptSpan` for affecting the size (and, in some cases, vertical position) of the text

And so on. Similarly, `ParagraphStyle` has subclasses like `BulletSpan` for bulleted lists.

You can implement your own custom subclasses of `CharacterStyle` and `ParagraphStyle`, though the book does not cover this subject at this time.

Loading Rich Text

Spanned objects do not appear by magic. Plenty of things in Java will give you ordinary strings, from XML and JSON parsers to loading data out of a database to simply hard-coding string constants. However, there are only a few ways that you as a developer will get a `Spanned` complete with formatting, and that includes you creating such a `Spanned` yourself by hand.

String Resource

The primary way most developers get a `Spanned` object into their application is via a string resource. String resources support inline markup in the form of HTML tags. Bold (``), italics (`<i>`), and underline (`<u>`) are officially supported, such as:

```
<string name="welcome">Welcome to <b>Android</b>!</string>
```

When you retrieve the string resource via `getText()`, you get back a `CharSequence` that represents a `Spanned` object with the markup rules in place.

HTML

The next-most common way to get a `Spanned` object is to use `Html.fromHtml()`. This parses an HTML string and returns a `Spanned` object, with all recognized tags converted into corresponding spans. You might use this for text loaded from a database, retrieved from a Web service call, extracted from an RSS feed, etc.

Unfortunately, the list of tags that `fromHtml()` understands is undocumented. Based upon the source code to `fromHtml()`, the following seem safe:

- ``
- ``
- `<big>`
- `<blockquote>`
- `
`
- `<cite>`
- `<dfn>`
- `<div align="...">`
- ``
- ``
- `<h1>`
- `<h2>`
- `<h3>`
- `<h4>`
- `<h5>`
- `<h6>`
- `<i>`
- ``
- `<p>`
- `<small>`
- ``
- `<sub>`
- `<sup>`
- `<tt>`
- `<u>`

However, do bear in mind that these are undocumented and therefore are subject to change. Also note that `fromHtml()` is perhaps slower than you might think, particularly for longer strings.

You might also wind up using some other support code to get your HTML. For example, some data sources might publish text formatted as [Markdown](#) — Stack Overflow, GitHub, etc. use this extensively. Markdown can be converted to HTML, through any number of available Java libraries or via [CWAC-AndDown](#), which wraps the native [hoedown](#) Markdown-to-HTML converter for maximum speed. CWAC-AndDown will be explored in a bit more detail in [the chapter on the NDK](#).

From EditText

The reason why so much sample code calls `getText()` followed by `toString()` on an `EditText` widget is because `EditText` is going to return an `Editable` object from `getText()`, not a simple string. That's because, in theory, `EditText` could be returning something with formatting applied. The call to `toString()` simply strips out any potential formatting as part of giving you back a `String`.

However, you could elect to use the `Editable` object (presumably a `SpannableStringBuilder`) if you wanted, such as for pouring the entered text into a `TextView`, complete with any formatting that might have wound up on the entered text.

Actually getting formatting applied to the contents of an `EditText` is covered [later in this chapter](#).

Manually

You are welcome to create a `SpannableString` via its constructor, supplying the text that you wish to display, then calling various methods on `SpannableString` to format it. We will see an example of this [later in this chapter](#).

Or, you are welcome to create a `SpannableStringBuilder` via its constructor. In some respects, `SpannableStringBuilder` works like the classic `StringBuilder` — you call `append()` to add more text. However, `SpannableStringBuilder` also offers `delete()`, `insert()`, and `replace()` methods to modify portions of the existing content. It also supports the same methods that `SpannableString` does, via the `Spannable` interface, for applying formatting rules to portions of text.

Editing Rich Text

If the `Spannable` you wound up with is a `SpannedString`, it is what it is — you cannot change it. If, however, you have a `SpannableString`, that can be modified by you, or by the user. Of course, allowing the user to modify a `Spannable` gets a wee bit tricky, and is why the `RichEditText` project was born.

RichEditText

If you load a `Spannable` into an `EditText`, the formatting will not only be displayed, but it will be part of the editing experience. For example, if the phrase “**the fox jumped**” is in bold, and the user adds in more words to make it “**the quick brown fox jumped**”, the additional words will also be in boldface. That is because the user is modifying text in the middle of a defined span, and so therefore the adjusted text is rendered according to that span.

The biggest problem is that `EditText` alone has no mechanism to allow users to *change* formatting. Perhaps someday it will have options for that. In the meantime, though, `RichEditText` is designed to fill that gap.

[RichEditText is a CWAC project](#) that offers a reasonably convenient API for applying, toggling, or removing effects applied to the current selected text. You have your choice of creating your own UI for this (e.g., implementing a toolbar) or enabling an extension to the `EditText` action modes to allow the users to format the text.

More information on using `RichEditText` can be found on [the project site](#).

Manually

`Spannable` offers two methods for modifying its formatting: `setSpan()` to apply formatting, and `removeSpan()` to get rid of an existing span. And, since `Spannable` extends `Spanned`, a `Spannable` also has `getSpans()`, to return existing spans of a current type within a certain range of characters in the text. These methods, along with others on `Spanned`, allow you to get and set whatever formatting you wish to apply on a `Spannable` object, such as a `SpannableString`.

For example, let’s take a look at the [RichText/Search](#) sample project. Here, we are going to load some text into a `TextView`, then allow the user to enter a search string

RICH TEXT

in an `EditText`, and we will use the `Spannable` methods to highlight the search string occurrences inside the text in the `TextView`.

Our layout is simply an `EditText` atop a `TextView` (wrapped in a `ScrollView`):

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:orientation="vertical">

    <EditText
        android:id="@+id/search"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:singleLine="true">

        <requestFocus/>
    </EditText>

    <ScrollView
        android:id="@+id/scroll"
        android:layout_width="match_parent"
        android:layout_height="match_parent">

        <TextView
            android:id="@+id/prose"
            android:layout_width="match_parent"
            android:layout_height="wrap_content"
            android:text="@string/address"
            android:textAppearance="?android:attr/textAppearanceMedium" />
    </ScrollView>
</LinearLayout>
```

(from [RichText/Search/app/src/main/res/layout/main.xml](#))

We pre-fill the `TextView` with a string resource (`@string/address`), which in this project is the text of Lincoln's Gettysburg Address, with a bit of inline markup (e.g., "Four score and seven years ago" italicized). So, when we fire up the project at the outset, we see the formatted prose from the string resource:

RICH TEXT

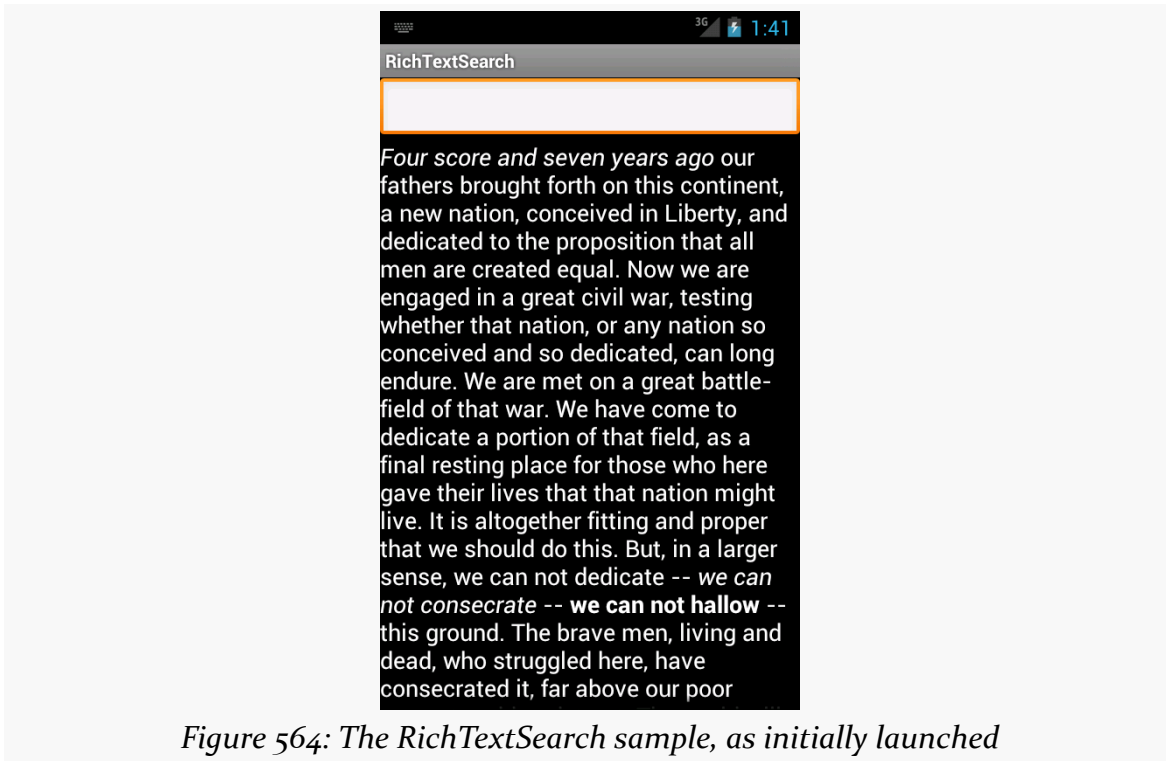

Figure 564: The RichTextSearch sample, as initially launched

In `onCreate()` of our activity, we find the `EditText` widget and designate the activity itself as being an `OnEditorActionListener` for the `EditText`:

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.main);

    search=(EditText)findViewById(R.id.search);
    search.setOnEditorActionListener(this);
}
```

(from [RichText/Search/app/src/main/java/com/commonsware/android/rich/search/RichTextSearchActivity.java](#))

That means when the user presses <Enter>, we will get control in an `onEditorAction()` method. There, we pass the search text to a private `searchFor()` method, plus ensure that the input method editor is hidden (if one was used to fill in the search text):

```
@Override
public boolean onEditorAction(TextView v, int actionId, KeyEvent event) {
    if (event == null || event.getAction() == KeyEvent.ACTION_UP) {
```

RICH TEXT

```
searchFor(search.getText().toString());

InputMethodManager imm=
    (InputMethodManager) getSystemService(INPUT_METHOD_SERVICE);

imm.hideSoftInputFromWindow(v.getWindowToken(), 0);
}

return(true);
}
```

(from [RichText/Search/app/src/main/java/com/commonsware/android/rich/search/RichTextSearchActivity.java](#))

The `searchFor()` method is where the formatting is applied to our search text:

```
private void searchFor(String text) {
    TextView prose=(TextView)findViewById(R.id.prose);
    Spannable raw=new SpannableString(prose.getText());
    BackgroundColorSpan[] spans=raw.getSpans(0,
                                           raw.length(),
                                           BackgroundColorSpan.class);

    for (BackgroundColorSpan span : spans) {
        raw.removeSpan(span);
    }

    int index=TextUtils.indexOf(raw, text);

    while (index >= 0) {
        raw.setSpan(new BackgroundColorSpan(0xFF8B008B), index, index
            + text.length(), Spanned.SPAN_EXCLUSIVE_EXCLUSIVE);
        index=TextUtils.indexOf(raw, text, index + text.length());
    }

    prose.setText(raw);
}
```

(from [RichText/Search/app/src/main/java/com/commonsware/android/rich/search/RichTextSearchActivity.java](#))

First, we get a `Spannable` object out of the `TextView`. While an `EditText` returns an `Editable` from `getText()`, `getText()` on a `TextView` returns a `CharSequence`. In particular, the first time we execute `searchFor()`, `getText()` will return a `SpannedString`, as that is what a string resource turns into. However, that is not modifiable, so we convert it into a `SpannableString` so we can apply formatting to it. An optimization would be to see if `getText()` returns something implementing `Spannable` and then just using it directly.

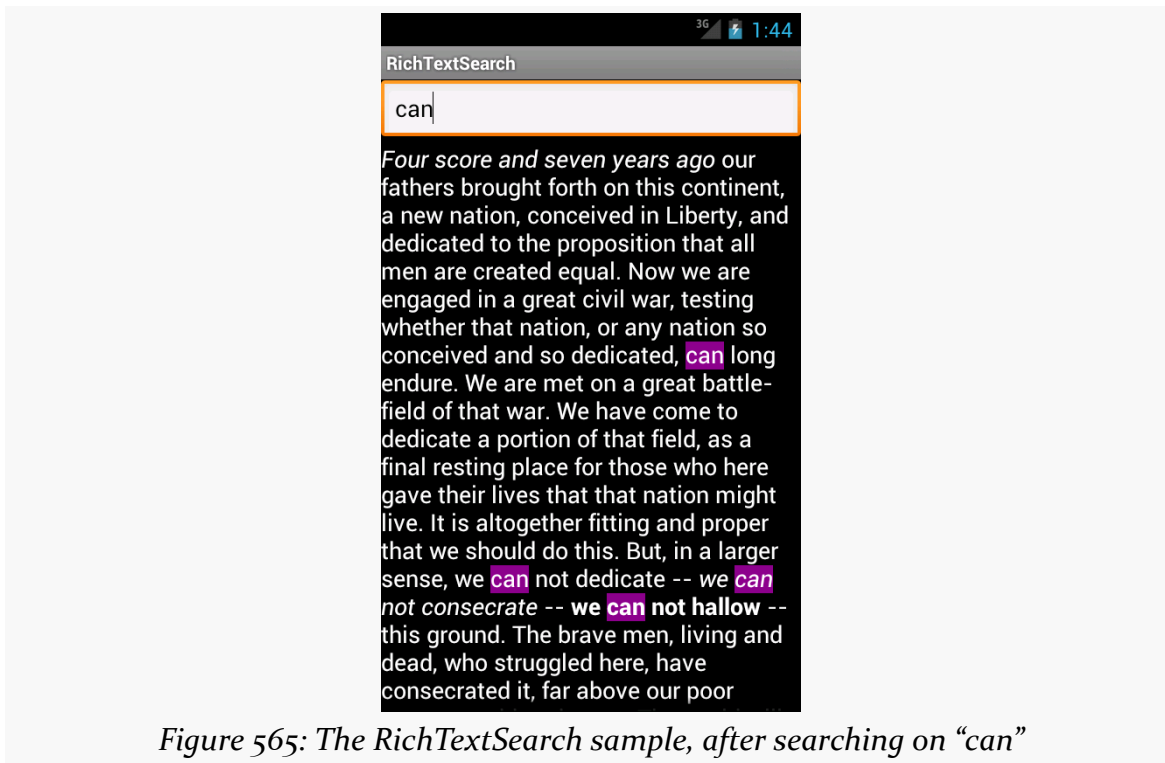

RICH TEXT

We want to highlight the search terms using a `BackgroundColorSpan`. However, that means we first need to get rid of any existing `BackgroundColorSpan` objects applied to the prose from a previous search — otherwise, we would keep highlighting more and more of the prose. So, we use `getSpans()` to find all `BackgroundColorSpan` objects anywhere in the prose (from index 0 through the length of the text). For each that we find, we call `removeSpan()` to get rid of it from our `Spannable`.

Then, we use `indexOf()` on `TextUtils` to find the first occurrence of whatever the user typed into the `EditText`. If we find it, we create a new `BackgroundColorSpan` and apply it to the matching portion of the prose using `setSpan()`. The last parameter to `setSpan()` is a flag, indicating what should happen if text is inserted at either the starting or ending point. In our case, the text itself is remaining constant, so the flag does not matter much – here, we use `SPAN_EXCLUSIVE_EXCLUSIVE`, which would mean that the span would not cover any text inserted at the starting or ending point of the span.

We then continue using `indexOf()` to find any remaining occurrences of the search text. Once we are done modifying our `Spannable`, we put it into the `TextView` via `setText()`.

The result is that all matching substrings are highlighted in a purple/magenta shade:

Saving Rich Text

SpannableString and SpannedString are not Serializable. There is no built-in way to persist them directly.

However, `Html.toHtml()` will convert a Spanned object into corresponding HTML, for all `CharacterStyle` and `ParagraphStyle` objects that can be readily converted into HTML. You can then persist the resulting HTML any place you would persist a `String` (e.g., database column).

In principle, you could create other similar conversion code, such as something to take a Spanned and return the corresponding Markdown source.

Manipulating Rich Text

The `TextUtils` class has many utility methods that manipulate a `CharSequence`, to allow you to do things that you might ordinarily have done just with methods on `String`. These utility methods will work with any `CharSequence`, including `SpannedString` and `SpannableString`.

RICH TEXT

Some are specifically aimed at Spanned objects, such as `copySpansFrom()` (to apply formatting from one `CharSequence` onto another). Some are clones of `String` equivalents, such as `split()`, `join()`, and `substring()`. Yet others are designed for developers using the Canvas 2D drawing API, such as `ellipsize()` and `commaEllipsize()` for intelligently truncating messages.

Animators

Users like things that move. Or fade, spin, or otherwise offer a dynamic experience.

Much of the time, such animations are handled for us by the framework. We do not have to worry about sliding rows in a `ListView` when the user scrolls, or as the user pans around a `ViewPager`, and so forth.

However, sometimes, we will need to add our own animations, where we want effects that either are not provided by the framework innately or are simply different (e.g., want something to slide off the bottom of the screen, rather than off the left edge).

Android had an [animation framework](#) back in the beginning, one that is still available for you today. However, Android 3.0 introduced a new *animator* framework that is going to be Android's primary focus for animated effects going forward. Many, but not all, of the animator framework capabilities are available to us as developers via a backport.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book. Also, you should read the chapter on [custom views](#), to be able to make sense of one of the samples.

ViewPropertyAnimator

Let's say that you want to fade out a widget, instead of simply setting its visibility to `INVISIBLE` or `GONE`.

For a widget whose name is `v`, on API Level 11 or higher, that is as simple as:

```
v.animate().alpha(0);
```

Here, “alpha” refers to the “alpha channel”. An alpha of 1 is normal opacity, while an alpha of 0 is completely transparent, with values in between representing various levels of translucence.

That may seem rather simple. The good news is, it *really* is that easy. Of course, there is a lot more you can do here, and you might have to worry about supporting older Android versions, and we need to think about things other than fading widgets in and out, and so forth.

First, though, let’s consider what is really going on when we call `animate()` on a widget on API Level 11+.

Native Implementation

The call to `animate()` returns an instance of `ViewPropertyAnimator`. This object allows us to build up a description of an animation to be performed, such as calling `alpha()` to change the alpha channel value. `ViewPropertyAnimator` uses a so-called [fluent interface](#), much like the various builder classes (e.g., `Notification.Builder`) — calling a method on a `ViewPropertyAnimator()` usually returns the `ViewPropertyAnimator` itself. This allows you to build up an animation via a chained series of method calls, starting with that call to `animate()` on the widget.

You will note that we do not end the chain of method calls with something like a `start()` method. `ViewPropertyAnimator` will automatically arrange to start the animation once we return control of the main application thread back to the framework. Hence, we do not have to explicitly start the animation.

You will also notice that we did not indicate any particulars about how the animation should be accomplished, beyond stating the ending alpha channel value of 0. `ViewPropertyAnimator` will use some standard defaults for the animation, such as a default duration, to determine how quickly Android changes the alpha value from its starting point to 0. Most of those particulars can be overridden from their defaults via additional methods called on our `ViewPropertyAnimator`, such as `setDuration()` to provide a duration in milliseconds.

There are four standard animations that `ViewPropertyAnimator` can perform:

ANIMATORS

1. Changes in alpha channel values, for fading widgets in and out
2. Changes in widget position, by altering the X and Y values of the upper-left corner of the widget, from wherever on the screen it used to be to some new value
3. Changes in the widget's rotation, around any of the three axes
4. Changes in the widget's size, where Android can scale the widget by some percentage to expand or shrink it

We will see an example of changing a widget's position, using the `translationXBy()` method, [later in this chapter](#).

You are welcome to use more than one animation effect simultaneously, such as using both `alpha()` and `translationXBy()` to slide a widget horizontally and have it fade in or out.

There are other aspects of the animation that you can control. By default, the animation happens linearly — if we are sliding 500 pixels in 500ms, the widget will move evenly at 1 pixel/ms. However, you can specify a different “interpolator” to override that default linear behavior (e.g., start slow and accelerate as the animation proceeds). You can attach a listener object to find out about when the animation starts and ends. And, you can specify `withLayer()` to indicate that Android should try to more aggressively use hardware acceleration for an animation, a concept that we will get into in greater detail [later in this chapter](#).

To see this in action, take a look at the [Animation/AnimatorFade](#) sample app.

The app consists of a single activity (MainActivity). It uses a layout that is dominated by a single `TextView` widget, whose ID is `fadee`:

```
<RelativeLayout xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:tools="http://schemas.android.com/tools"
    android:layout_width="match_parent"
    android:layout_height="match_parent">

    <TextView
        android:id="@+id/fadee"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:layout_centerHorizontal="true"
        android:layout_centerVertical="true"
        android:text="@string/fading_out"
        android:textAppearance="?android:attr/textAppearanceLarge"
        tools:context=".MainActivity"/>
```

ANIMATORS

```
</RelativeLayout>
```

(from [Animation/AnimatorFade/app/src/main/res/layout/activity_main.xml](#))

In `onCreate()`, we load up the layout and get our hands on the `fadee` widget:

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.activity_main);

    fadee=(TextView)findViewById(R.id.fadee);
}
```

(from [Animation/AnimatorFade/app/src/main/java/com/commonsware/android/animator/fade/MainActivity.java](#))

`MainActivity` itself implements `Runnable`, and our `run()` method will perform some animated effects:

```
@Override
public void run() {
    if (fadingOut) {
        fadee.animate().alpha(0).setDuration(PERIOD);
        fadee.setText(R.string.fading_out);
    }
    else {
        fadee.animate().alpha(1).setDuration(PERIOD);
        fadee.setText(R.string.coming_back);
    }

    fadingOut=!fadingOut;

    fadee.postDelayed(this, PERIOD);
}
```

(from [Animation/AnimatorFade/app/src/main/java/com/commonsware/android/animator/fade/MainActivity.java](#))

Specifically, we use `ViewPropertyAnimator` to fade out the `TextView` over a certain period (`fadee.animate().alpha(0).setDuration(PERIOD);`) and set its caption to a value indicating that we are fading out. If we are to be fading back in, we perform the opposite animation and set the caption to a different value. We then flip the `fadingOut` boolean for the next pass and use `postDelayed()` to reschedule ourselves to run after the period has elapsed.

ANIMATORS

To complete the process, we run() our code initially in onStop() and cancel the postDelayed() loop in onStart():

```
@Override
public void onStart() {
    super.onStart();

    run();
}

@Override
public void onStop() {
    fadee.removeCallbacks(this);

    super.onStop();
}
```

(from [Animation/AnimatorFade/app/src/main/java/com/commonsware/android/animator/fade/MainActivity.java](#))

The result is that the TextView smoothly fades out and in, alternating captions as it goes.

However, it would be really unpleasant if all this animator goodness worked only on API Level 11+. Fortunately for us, somebody wrote a backport.

Backport Via NineOldAndroids

Jake Wharton wrote [NineOldAndroids](#). This is, in effect, a backport of ViewPropertyAnimator and its underpinnings. There are some slight changes in how you use it, because NineOldAndroids is simply a library. It cannot add methods to existing classes (like adding animate() to View), nor can it add capabilities that the underlying firmware simply lacks. But, it may cover many of your animator needs, even if the name is somewhat inexplicable, and it works going all the way back to API Level 1, ensuring that it will cover any Android release that you care about.

NineOldAndroids is an Android library project. Android Studio users can add a implementation statement to their dependencies closure in build.gradle to pull in com.nineoldandroids:library:... (for some version indicated by ...).

Since NineOldAndroids cannot add animate() to View, the recommended approach is to use a somewhat obscure feature of Java: imported static methods. An import static statement, referencing a particular static method of a class, makes that method available as if it were a static method on the class that you are writing, or as

ANIMATORS

some sort of global function. `NineOldAndroids` has an `animate()` method that you can import this way, so instead of `v.animate()`, you use `animate(v)` to accomplish the same end. Everything else is the same, except perhaps some imports, to reference `NineOldAndroids` instead of the native classes.

You can see this in the [Animation/AnimatorFadeBC](#) sample app.

In addition to having the `NineOldAndroids` JAR in `libs/`, the only difference between this edition and the previous sample is in how the animation is set up. Instead of lines like:

```
fadee.animate().alpha(0).setDuration(PERIOD);
```

we have:

```
animate(fadee).alpha(0).setDuration(PERIOD);
```

This takes advantage of our static import:

```
import static com.nineoldandroids.view.ViewPropertyAnimator.animate;
```

If the static import makes you queasy, you are welcome to simply import the `com.nineoldandroids.view.ViewPropertyAnimator` class, rather than the static method, and call the `animate()` method on `ViewPropertyAnimator`:

```
ViewPropertyAnimator.animate(fadee).alpha(0).setDuration(PERIOD);
```

The Foundation: Value and Object Animators

`ViewPropertyAnimator` itself is a layer atop of a more primitive set of animators, known as value and object animators.

A `ValueAnimator` handles the core logic of transitioning some value, from an old to a new value, over a period of time. `ValueAnimator` offers replaceable “interpolators”, which will determine how the values change from start to finish over the animation period (e.g., start slowly, accelerate, then end slowly). `ValueAnimator` also handles the concept of a “repeat mode”, to indicate if the animation should simply happen once, a fixed number of times, or should infinitely repeat (and, in the latter cases, whether it does so always transitioning from start to finish or if it reverses direction on alternate passes, going from finish back to start).

ANIMATORS

What `ValueAnimator` does *not* do is actually change anything. It is merely computing the different values based on time. You can call `getAnimatedValue()` to find out the value at any point in time, or you can call `addUpdateListener()` to register a listener object that will be notified of each change in the value, so that change can be applied somewhere.

Hence, what tends to be a bit more popular is `ObjectAnimator`, a subclass of `ValueAnimator` that automatically applies the new values. `ObjectAnimator` does this by calling a setter method on some object, where you supply the object and the “property name” used to derive the getter and setter method names. For example, if you request a property name of `foo`, `ObjectAnimator` will try to call `getFoo()` and `setFoo()` methods on your supplied object.

As with `ViewPropertyAnimator`, `ValueAnimator` and `ObjectAnimator` are implemented natively in API Level 11 and are available via the `NineOldAndroids` backport as well.

To see what `ObjectAnimator` looks like in practice, let us examine the [Animation/ObjectAnimator](#) sample app.

Once again, our activity’s layout is pretty much just a centered `TextView`, here named `word`:

```
<RelativeLayout xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:tools="http://schemas.android.com/tools"
    android:layout_width="match_parent"
    android:layout_height="match_parent">

    <TextView
        android:id="@+id/word"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:layout_centerHorizontal="true"
        android:layout_centerVertical="true"
        android:textAppearance="?android:attr/textAppearanceLarge"
        tools:context=".MainActivity"/>

</RelativeLayout>
```

(from [Animation/ObjectAnimator/app/src/main/res/layout/activity_main.xml](#))

The objective of our activity is to iterate through 25 words, showing one at a time in the `TextView`:

ANIMATORS

```
package com.commonware.android animator.obj;

import android.app.Activity;
import android.os.Bundle;
import android.widget.TextView;
import com.nineoldandroids.animation.ObjectAnimator;
import com.nineoldandroids.animation.ValueAnimator;

public class MainActivity extends Activity {
    private static final String[] items= { "lorem", "ipsum", "dolor",
        "sit", "amet", "consectetuer", "adipiscing", "elit", "morbi",
        "vel", "ligula", "vitae", "arcu", "aliquet", "mollis", "etiam",
        "vel", "erat", "placerat", "ante", "porttitor", "sodales",
        "pellentesque", "augue", "purus" };
    private TextView word=null;
    int position=0;

    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.activity_main);

        word=(TextView)findViewById(R.id.word);

        ValueAnimator positionAnim = ObjectAnimator.ofInt(this, "wordPosition", 0, 24);
        positionAnim.setDuration(12500);
        positionAnim.setRepeatCount(ValueAnimator.INFINITE);
        positionAnim.setRepeatMode(ValueAnimator.RESTART);
        positionAnim.start();
    }

    public void setWordPosition(int position) {
        this.position=position;
        word.setText(items[position]);
    }

    public int getWordPosition() {
        return(position);
    }
}
```

(from [Animation/ObjectAnimator/app/src/main/java/com/commonware/android/animator/obj/MainActivity.java](#))

To accomplish this, we use NineOldAndroids version of ObjectAnimator, saying that we wish to “animate” the wordPosition property of the activity itself, from 0 to 24. We configure the animation to run for 12.5 seconds (i.e., 500ms per word) and to repeat indefinitely by restarting the animation from the beginning on each pass. We then call start() to kick off the animation.

For this to work, though, we need getWordPosition() and setWordPosition() accessor methods for the theoretical wordPosition property. In our case, the “word position” is simply an integer data member of the activity, which we return in getWordPosition() and update in setWordPosition(). However, we also update the TextView in setWordPosition(), to display the word at that position.

The net effect is that words appear in our `TextView`, changing on average every 500ms.

Animating Custom Types

In the previous section, we animated an `int` property of an `Activity`. That works, because Android knows how to compute `int` values between the start and end position, through simple math.

But, what if we wanted to animate something that is not a simple number? For example, what if we want to animate a `Color`, or a `LatLng` from [Maps V2](#), or a `TastyTreat` class of our own design?

So long as we can perform the calculations, we can animate a type of anything we want, using `TypeEvaluator` and `ofObject()` on `ObjectAnimator`.

A `TypeEvaluator` is a simple interface, containing a single method that we need to override: `evaluate()`. However, `TypeEvaluator` uses generics, and so our implementation will actually be of some concrete class (e.g., a `TypeEvaluator` of `TastyTreat`). Our job in `evaluate()` is to return a value of our designated type (e.g., `TastyTreat`) given three inputs:

1. The initial value for our animation range, in the form of our designated type
2. The end value for our animation range, in the form of our designated type
3. The fraction along that range that represents how much we have moved from the initial value to the end value

Note that the fraction is not limited to being between 0 and 1, as certain interpolators (e.g., an overshoot interpolator) might result in a fraction being negative (e.g., we overshoot past the initial value) or greater than one (e.g., we overshoot past the end value).

For example, to have a `TypeEvaluator` of `Color`, we might have `evaluate()` generate a new `Color` instance based upon applying the fraction to the initial and end red, green, blue, and alpha channels.

To use a `TypeEvaluator`, instead of `ofInt()`, `ofFloat()`, or similar simple factory methods on `ObjectAnimator`, we use `ofObject()`. `ofObject()` takes the object to be animated, the property to be animated, the `TypeEvaluator` to assist in the actual

animation, and the final value of the animation (or, optionally, a series of waypoints to be animated along).

A flavor of `ofObject()` that takes the property name — akin to the `wordPosition` of `Int()` used in the previous section — has been around since API Level 11. API Level 14 added an `ofObject()` method that takes a `Property` value instead of the name of the property. This version has the added benefit of type-safety, as it can ensure that your object to be animated, `TypeEvaluator`, and final position are all of the same type.

You can see an example of using `TypeEvaluator` this way in [the chapter on Maps V2](#), as we animate the movement of a map marker from a starting point to an ending point.

Hardware Acceleration

Animated effects operate much more smoothly with hardware acceleration. There are two facets to employing hardware acceleration for animations: enabling it overall and directing its use for the animations themselves.

Hardware acceleration is enabled overall on Android devices running Android 4.0 or higher (API Level 14). On Android 3.x, hardware acceleration is available but is disabled by default — use `android:hardwareAccelerated="true"` in your `<application>` or `<activity>` element in the manifest to enable it on those versions. Hardware acceleration for 2D graphics operations like widget animations is not available on older versions of Android.

While this will provide some benefit across the board, you may also wish to consider rendering animated widgets or containers in an off-screen buffer, or “hardware layer”, that then gets applied to the screen via the GPU. In particular, the GPU can apply certain animated transformations to a hardware layer without forcing software to redraw the widgets or containers (e.g., what happens when you `invalidate()` them). As it turns out, these GPU-enhanced transformations match the ones supported by `ViewPropertyAnimator`:

1. Changes in alpha channel values, for fading widgets in and out
2. Changes in widget position, by altering the X and Y values of the upper-left corner of the widget, from wherever on the screen it used to be to some new value
3. Changes in the widget’s rotation, around any of the three axes

4. Changes in the widget's size, where Android can scale the widget by some percentage to expand or shrink it

By having the widget be rendered in a hardware layer, these `ViewPropertyAnimator` operations are significantly more efficient than before.

However, since hardware layers take up video memory, generally you do not want to keep a widget or container in a hardware layer indefinitely. Instead, the recommended approach is to have the widget or container be rendered in a hardware layer only while the animation is ongoing, by calling `setLayerType()` for `LAYER_TYPE_HARDWARE` before the animation begins, then calling `setLayerType()` for `LAYER_TYPE_NONE` (i.e., return to default behavior) when the animation completes. Or, for `ViewPropertyAnimator` on API Level 16 and higher, use `withLayer()` in the fluent interface to have it apply the hardware layer automatically just for the animation duration.

We will see examples of using hardware acceleration this way in the next section.

The Three-Fragment Problem

The original tablet implementation of Gmail organized its landscape main activity into two panes, one on the left taking up ~30% of the screen, and one on the right taking up the remainder:

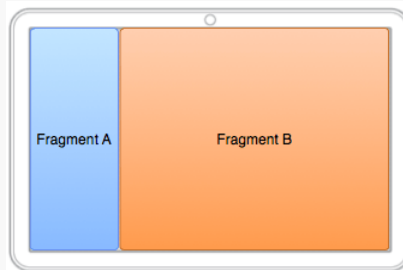

Figure 566: Gmail Fragments (image courtesy of Google and AOSP)

Gmail had a very specific navigation mode in its main activity when viewed in landscape on a tablet, where upon some UI event (e.g., tapping on something in the right-hand area):

- The original left-hand fragment (Fragment A) slid off the screen to the left

ANIMATORS

- The original right-hand fragment (Fragment B) slid to the left edge of the screen and shrunk to take up the spot vacated by Fragment A
- Another fragment (Fragment C) slid in from the right side of the screen and expanded to take up the spot vacated by Fragment B

And a BACK button press reversed this operation.

This is a bit tricky to set up, leading to the author of this book posting [a question on Stack Overflow to get input](#). Here, we will examine one of the results of that discussion, based in large part on the implementation of the AOSP Email app, which has a similar navigation flow. The other answers on that question may have merit in other scenarios as well.

You can see one approach for implementing the three-pane solution in the [Animation/ThreePane](#) sample app.

The ThreePaneLayout

The logic to handle the animated effects is encapsulated in a `ThreePaneLayout` class. It is designed to be used in a layout XML resource where you supply the contents of the three panes, sizing the first two as you want, with the third “pane” having zero width at the outset:

```
<com.commonware.android.anim.threepane.ThreePaneLayout xmlns:android="http://schemas.android.com/apk/res/
android"
  xmlns:tools="http://schemas.android.com/tools"
  android:id="@+id/root"
  android:layout_width="match_parent"
  android:layout_height="match_parent">

  <FrameLayout
    android:id="@+id/left"
    android:layout_width="0dp"
    android:layout_height="match_parent"
    android:layout_weight="3"/>

  <FrameLayout
    android:id="@+id/middle"
    android:layout_width="0dp"
    android:layout_height="match_parent"
    android:layout_weight="7"/>

  <Button
    android:layout_width="0dp"
    android:layout_height="match_parent" />

</com.commonware.android.anim.threepane.ThreePaneLayout>
```

(from [Animation/ThreePane/app/src/main/res/layout/activity_main.xml](#))

ANIMATORS

ThreePaneLayout itself is a subclass of LinearLayout, set up to always be horizontal, regardless of what might be set in the layout XML resource.

```
public ThreePaneLayout(Context context, AttributeSet attrs) {
    super(context, attrs);
    initSelf();
}

void initSelf() {
    setOrientation(HORIZONTAL);
}
```

(from [Animation/ThreePane/app/src/main/java/com/commonsware/android/anim/threepane/ThreePaneLayout.java](#))

When the layout finishes inflating, we grab the three panes (defined as the first three children of the container) and stash them in data members named `left`, `middle`, and `right`, with matching getter methods:

```
@Override
public void onFinishInflate() {
    super.onFinishInflate();

    left=getChildAt(0);
    middle=getChildAt(1);
    right=getChildAt(2);
}

public View getLeftView() {
    return(left);
}

public View getMiddleView() {
    return(middle);
}

public View getRightView() {
    return(right);
}
```

(from [Animation/ThreePane/app/src/main/java/com/commonsware/android/anim/threepane/ThreePaneLayout.java](#))

The major operational API, from the standpoint of an activity using ThreePaneLayout, is `hideLeft()` and `showLeft()`. `hideLeft()` will switch from showing the left and middle widgets in their original size and position to showing the middle and right widgets wherever left and middle had been originally. `showLeft()` reverses the operation.

ANIMATORS

The problem is that, initially, we do not know where the widgets are or how big they are, as that should be able to be set from the layout XML resource and are not known until the ThreePaneLayout is actually applied to the screen. Hence, we lazy-retrieve those values in `hideLeft()`, plus remove any weights that had been originally defined, setting the actual pixel widths on the widgets instead:

```
public void hideLeft() {
    if (leftWidth == -1) {
        leftWidth=left.getWidth();
        middleWidthNormal=middle.getWidth();
        resetWidget(left, leftWidth);
        resetWidget(middle, middleWidthNormal);
        resetWidget(right, middleWidthNormal);
        requestLayout();
    }

    translateWidgets(-1 * leftWidth, left, middle, right);

    ObjectAnimator.ofInt(this, "middleWidth", middleWidthNormal,
        leftWidth).setDuration(ANIM_DURATION).start();
}
```

(from [Animation/ThreePane/app/src/main/java/com/commonsware/android/anim/threepane/ThreePaneLayout.java](#))

The work to change the weights into widths is handled in `resetWidget()`:

```
private void resetWidget(View v, int width) {
    LinearLayout.LayoutParams p=
        (LinearLayout.LayoutParams)v.getLayoutParams();

    p.width=width;
    p.weight=0;
}
```

(from [Animation/ThreePane/app/src/main/java/com/commonsware/android/anim/threepane/ThreePaneLayout.java](#))

After the lazy-initialization and widget cleanup, we perform the two animations. `translateWidgets()` will slide each of our three widgets to the left by the width of the left widget, using a `ViewPropertyAnimator` and a hardware layer:

```
private void translateWidgets(int deltaX, View... views) {
    for (final View v : views) {
        v.setLayerType(View.LAYER_TYPE_HARDWARE, null);

        v.animate().translationXBy(deltaX).setDuration(ANIM_DURATION)
            .setListener(new AnimatorListenerAdapter() {
```

ANIMATORS

```
@Override
public void onAnimationEnd(Animator animation) {
    v.setLayerType(View.LAYER_TYPE_NONE, null);
}
});
}
```

(from [Animation/ThreePane/app/src/main/java/com/commonsware/android/anim/threepane/ThreePaneLayout.java](#))

The resize animation — to set the middle size to be what left had been — is handled via an `ObjectAnimator`, for a theoretical property of `middleWidth` on `ThreePaneLayout`. That is backed by a `setMiddleWidth()` method that adjusts the width property of the middle widget's `LayoutParams` and triggers a redraw:

```
@SuppressWarnings("unused")
private void setMiddleWidth(int value) {
    middle.getLayoutParams().width=value;
    requestLayout();
}
```

(from [Animation/ThreePane/app/src/main/java/com/commonsware/android/anim/threepane/ThreePaneLayout.java](#))

The `showLeft()` method simply performs those two animations in reverse:

```
public void showLeft() {
    translateWidgets(leftWidth, left, middle, right);

    ObjectAnimator.ofInt(this, "middleWidth", leftWidth,
        middleWidthNormal).setDuration(ANIM_DURATION)
        .start();
}
```

(from [Animation/ThreePane/app/src/main/java/com/commonsware/android/anim/threepane/ThreePaneLayout.java](#))

Using the ThreePaneLayout

The sample app uses one activity (`MainActivity`) and one fragment (`SimpleListFragment`) to set up and use the `ThreePaneLayout`. The objective is a UI that roughly mirrors that of the AOSP Email app: a list on the left, a list in the middle (whose contents are based on the item chosen in the left list), and something else on the right (whose contents are based on the item chosen in the middle list).

ANIMATORS

SimpleListFragment is used for both lists. Its newInstance() factory method is handed the list of strings to display. SimpleListFragment just loads those into its ListView, also setting up CHOICE_MODE_SINGLE for use with the activated style, and routing all clicks on the list to the MainActivity that hosts the fragment:

```
package com.commonware.android.anim.threepane;

import android.app.ListFragment;
import android.os.Bundle;
import android.view.View;
import android.widget.AdapterView;
import android.widget.AdapterView.OnItemClickListener;
import android.widget.ArrayAdapter;
import android.widget.ListView;
import java.util.ArrayList;
import java.util.Arrays;

public class SimpleListFragment extends ListFragment {
    private static final String KEY_CONTENTS="contents";

    public static SimpleListFragment newInstance(String[] contents) {
        return(new SimpleListFragment(new ArrayList<String>(Arrays.asList(contents))));
    }

    public static SimpleListFragment newInstance(ArrayList<String> contents) {
        SimpleListFragment result=new SimpleListFragment();
        Bundle args=new Bundle();

        args.putStringArrayList(KEY_CONTENTS, contents);
        result.setArguments(args);

        return(result);
    }

    @Override
    public void onActivityCreated(Bundle savedInstanceState) {
        super.onActivityCreated(savedInstanceState);

        getListView().setChoiceMode(ListView.CHOICE_MODE_SINGLE);
        setContents(getArguments().getStringArrayList(KEY_CONTENTS));
    }

    @Override
    public void onItemClick(ListView l, View v, int position, long id) {
        ((MainActivity)getActivity()).onItemClick(this, position);
    }

    void setContents(ArrayList<String> contents) {
        setListAdapter(new ArrayAdapter<String>(
```

ANIMATORS

```
        getActivity(),  
        R.layout.simple_list_item_1,  
        contents));  
    }  
}
```

(from [Animation/ThreePane/app/src/main/java/com/commonsware/android/anim/threepane/SimpleListFragment.java](#))

MainActivity populates the left `FrameLayout` with a `SimpleListFragment` in `onCreate()`, if the fragment does not already exist (e.g., from a configuration change). When an item in the left list is clicked, MainActivity populates the middle `FrameLayout`. When an item in the middle list is clicked, it sets the caption of the right `Button` and uses `hideLeft()` to animate that `Button` onto the screen, hiding the left list. If the user presses `BACK`, and our left list is not showing, MainActivity calls `showLeft()` to reverse the animation:

```
package com.commonsware.android.anim.threepane;  
  
import android.app.Activity;  
import android.os.Bundle;  
import android.widget.Button;  
import java.util.ArrayList;  
  
public class MainActivity extends Activity {  
    private static final String KEY_MIDDLE_CONTENTS="middleContents";  
    private static final String[] items= { "lorem", "ipsum", "dolor",  
        "sit", "amet", "consectetuer", "adipiscing", "elit", "morbi",  
        "vel", "ligula", "vitae", "arcu", "aliquet", "mollis", "etiam",  
        "vel", "erat", "placerat", "ante", "porttitor", "sodales",  
        "pellentesque", "augue", "purus" };  
    private boolean isLeftShowing=true;  
    private SimpleListFragment middleFragment=null;  
    private ArrayList<String> middleContents=null;  
    private ThreePaneLayout root=null;  
  
    @Override  
    public void onCreate(Bundle savedInstanceState) {  
        super.onCreate(savedInstanceState);  
        setContentView(R.layout.activity_main);  
  
        root=(ThreePaneLayout)findViewById(R.id.root);  
  
        if (getFragmentManager().findFragmentById(R.id.left) == null) {  
            getFragmentManager().beginTransaction()  
                .add(R.id.left,  
                    SimpleListFragment.newInstance(items))  
                .commit();  
        }  
    }  
}
```

ANIMATORS

```
    }

    middleFragment=
        (SimpleListFragment)getFragmentManager().findFragmentById(R.id.middle);
}

@Override
public void onBackPressed() {
    if (!isLeftShowing) {
        root.showLeft();
        isLeftShowing=true;
    }
    else {
        super.onBackPressed();
    }
}

@Override
protected void onSaveInstanceState(Bundle outState) {
    super.onSaveInstanceState(outState);

    outState.putStringArrayList(KEY_MIDDLE_CONTENTS, middleContents);
}

@Override
protected void onRestoreInstanceState(Bundle inState) {
    middleContents=inState.getStringArrayList(KEY_MIDDLE_CONTENTS);
}

void onItemClick(SimpleListFragment fragment, int position) {
    if (fragment == middleFragment) {
        ((Button)root.getRightView()).setText(middleContents.get(position));

        if (isLeftShowing) {
            root.hideLeft();
            isLeftShowing=false;
        }
    }
    else {
        middleContents=new ArrayList<String>();

        for (int i=0; i < 20; i++) {
            middleContents.add(items[position] + " #" + i);
        }

        if (getFragmentManager().findFragmentById(R.id.middle) == null) {
            middleFragment=SimpleListFragment.newInstance(middleContents);
            getFragmentManager().beginTransaction()
```

ANIMATORS

```
        .add(R.id.middle, middleFragment).commit();
    }
    else {
        middleFragment.setContents(middleContents);
    }
}
}
```

(from [Animation/ThreePane/app/src/main/java/com/commonsware/android/anim/threepane/MainActivity.java](#))

The Results

If you run this app on a landscape tablet running API Level 11 or higher, you start off with a single list of words on the left:

Clicking on a word brings up a second list, taking up the rest of the screen, with numbered entries based upon the clicked-upon word:

ANIMATORS

Clicking on an entry in the second list starts the animation, sliding the first list off to the left, sliding the second list into the space vacated by the first list, and sliding in a “detail view” into the right portion of the screen:

ANIMATORS

Figure 569: ThreePane, After Clicking a Numbered Word

Pressing BACK once will reverse the animation, restoring you to the two-list perspective.

The Backport

The ThreePane sample described above uses the native API Level 11 version of the animator framework and the native implementation of fragments. However, the same approach can work using the Android Support package's version of fragments and NineOldAndroids. You can see this in the [Animation/ThreePaneBC](#) sample app.

Besides changing the import statements and adding the NineOldAndroids JAR file, the only other changes of substance were:

- Using `ViewPropertyAnimator.animate(v)` instead of `v.animate()` in `translateWidgets()`
- Conditionally setting the hardware acceleration layers via `setLayerType()` in `translateWidgets()` based upon API level, as that method was only added in API Level 11

The smoothness of animations, though, will vary by hardware capabilities. For example, on a first-generation Kindle Fire, running Android 2.3, the backport works but is not especially smooth, while the animations are very smooth on more modern hardware where hardware acceleration can be applied.

The Problems

As we will see in [the chapter on “jank”](#), there is some stutter in the rendering of this app. Fixing it requires removing the animated change in the width of the middle pane, which in turn makes the animation itself look worse. More details on the analysis can be found in [the “jank” chapter](#).

Legacy Animations

Before `ViewPropertyAnimator` and the rest of [the animator framework](#) were added in API Level 11, we had the original `Animation` base class and specialized animations based upon it, like `TranslateAnimation` for movement and `AlphaAnimation` for fades. On the whole, you will want to try to use the animator framework where possible, as the new system is more powerful and efficient than the legacy `Animation` approach. However, particularly for apps where the `NineOldAndroids` backport is insufficient, you may wish to use the legacy framework.

After an overview of the role of the [animation](#) framework, we go in-depth to animate the [movement](#) of a widget across the screen. We then look at [alpha animations](#), for fading widgets in and out. We then see how you can get control during the [lifecycle](#) of an animation, how to control the [acceleration](#) of animations, and how to [group](#) animations together for parallel execution. Finally, we see how the same framework can now be used to control the animation for the switching of [activities](#).

Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly the ones on [basic resources](#) and [basic widgets](#). Also, you should read the chapter on [custom views](#).

It's Not Just For Toons Anymore

Android has a package of classes (`android.view.animation`) dedicated to animating the movement and behavior of widgets.

They center around an `Animation` base class that describes what is to be done. Built-in animations exist to move a widget (`TranslateAnimation`), change the transparency of a widget (`AlphaAnimation`), revolve a widget (`RotateAnimation`), and resize a widget (`ScaleAnimation`). There is even a way to aggregate animations together into a composite `Animation` called an `AnimationSet`. Later sections in this chapter will examine the use of several of these animations.

Given that you have an animation, to apply it, you have two main options:

1. You may be using a container that supports animating its contents, such as a `ViewFlipper` or `TextSwitcher`. These are typically subclasses of `ViewAnimator` and let you define the “in” and “out” animations to apply. For example, with a `ViewFlipper`, you can specify how it flips between `Views` in terms of what animation is used to animate “out” the currently-visible `View` and what animation is used to animate “in” the replacement `View`.
2. You can simply tell any `View` to `startAnimation()`, given the `Animation` to apply to itself. This is the technique we will be seeing used in the examples in this chapter.

A Quirky Translation

Animation takes some getting used to. Frequently, it takes a fair bit of experimentation to get it all working as you wish. This is particularly true of `TranslateAnimation`, as not everything about it is intuitive, even to authors of Android books.

Mechanics of Translation

The simple constructor for `TranslateAnimation` takes four parameters describing how the widget should move: the before and after `X` offsets from the current position, and the before and after `Y` offsets from the current position. The Android documentation refers to these as `fromXDelta`, `toXDelta`, `fromYDelta`, and `toYDelta`.

In Android’s pixel-space, an (X, Y) coordinate of $(0, 0)$ represents the upper-left corner of the screen. Hence, if `toXDelta` is greater than `fromXDelta`, the widget will move to the right, if `toYDelta` is greater than `fromYDelta`, the widget will move down, and so on.

Imagining a Sliding Panel

Some Android applications employ a sliding panel, one that is off-screen most of the time but can be called up by the user (e.g., via a menu) when desired. When anchored at the bottom of the screen, you get a container that slides up from the bottom and slides down and out when being removed.

One way to implement such a panel is to have a container (e.g., a `LinearLayout`) whose contents are absent (`INVISIBLE`) when the panel is closed and is present (`VISIBLE`) when the drawer is open. If we simply toggled `setVisibility()` using the aforementioned values, though, the panel would wink open and closed immediately, without any sort of animation. So, instead, we want to:

1. Make the panel visible and animate it up from the bottom of the screen when we open the panel
2. Animate it down to the bottom of the screen and make the panel invisible when we close the panel

The Aftermath

This brings up a key point with respect to `TranslateAnimation`: the animation temporarily moves the widget, but if you want the widget to stay where it is when the animation is over, you have to handle that yourself. Otherwise, the widget will snap back to its original position when the animation completes.

In the case of the panel opening, we handle that via the transition from `INVISIBLE` to `VISIBLE`. Technically speaking, the panel is always “open”, in that we are not, in the end, changing its position. But when the body of the panel is `INVISIBLE`, it takes up no space on the screen; when we make it `VISIBLE`, it takes up whatever space it is supposed to.

Later in this chapter, we will cover how to use animation listeners to accomplish this end for closing the panel.

Introducing `SlidingPanel`

With all that said, turn your attention to the [Animation/SlidingPanel](#) sample project and, in particular, the `SlidingPanel` class.

LEGACY ANIMATIONS

This class implements a layout that works as a panel, anchored to the bottom of the screen. A `toggle()` method can be called by the activity to hide or show the panel. The panel itself is a `LinearLayout`, so you can put whatever contents you want in there.

We use two flavors of `TranslateAnimation`, one for opening the panel and one for closing it.

Here is the opening animation:

```
anim=new TranslateAnimation(0.0f, 0.0f,  
                           getHeight(),  
                           0.0f);
```

(from [Animation/SlidingPanel/app/src/main/java/com/commonsware/android/anim/SlidingPanel.java](#))

Our `fromXDelta` and `toXDelta` are both 0, since we are not shifting the panel's position along the horizontal axis. Our `fromYDelta` is the panel's height according to its layout parameters (representing how big we want the panel to be), because we want the panel to start the animation at the bottom of the screen; our `toYDelta` is 0 because we want the panel to be at its "natural" open position at the end of the animation.

Conversely, here is the closing animation:

```
anim=new TranslateAnimation(0.0f, 0.0f, 0.0f,  
                           getHeight());
```

(from [Animation/SlidingPanel/app/src/main/java/com/commonsware/android/anim/SlidingPanel.java](#))

It has the same basic structure, except the Y values are reversed, since we want the panel to start open and animate to a closed position.

The result is a container that can be closed:

Figure 570: The SlidingPanel sample application, with the panel closed

... or open, in this case toggled via a menu choice in the SlidingPanelDemo activity:

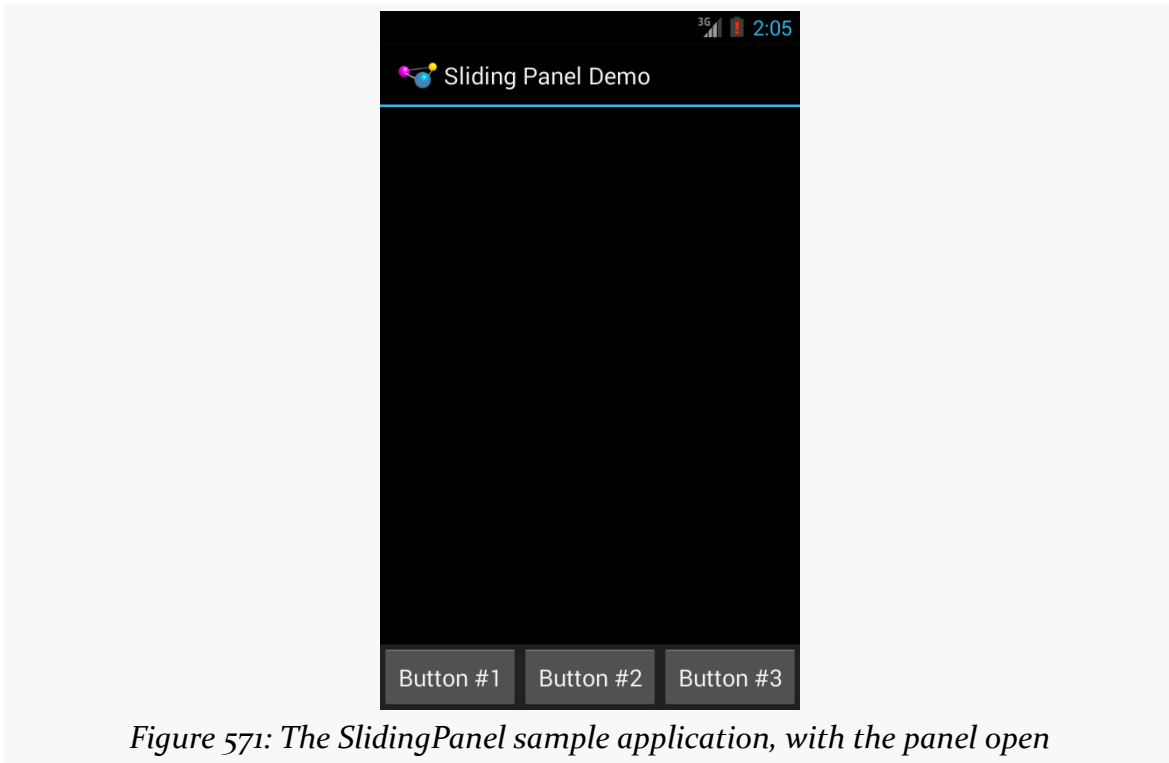

Figure 571: The SlidingPanel sample application, with the panel open

Using the Animation

When setting up an animation, you also need to indicate how long the animation should take. This is done by calling `setDuration()` on the animation, providing the desired length of time in milliseconds.

When we are ready with the animation, we simply call `startAnimation()` on the `SlidingPanel` itself, causing it to move as specified by the `TranslateAnimation` instance.

Fading To Black. Or Some Other Color.

`AlphaAnimation` allows you to fade a widget in or out by making it less or more transparent. The greater the transparency, the more the widget appears to be “fading”.

Alpha Numbers

You may be used to alpha channels, when used in #AARRGGBB color notation, or perhaps when working with alpha-capable image formats like PNG.

Similarly, `AlphaAnimation` allows you to change the alpha channel for an entire widget, from fully-solid to fully-transparent.

In Android, a float value of 1.0 indicates a fully-solid widget, while a value of 0.0 indicates a fully-transparent widget. Values in between, of course, represent various amounts of transparency.

Hence, it is common for an `AlphaAnimation` to either start at 1.0 and smoothly change the alpha to 0.0 (a fade) or vice versa.

Animations in XML

With `TranslateAnimation`, we showed how to construct the animation in Java source code. One can also create animation resources, which define the animations using XML. This is similar to the process for defining layouts, albeit much simpler.

For example, there is a second animation project, [Animation/SlidingPanelEx](#), which demonstrates a panel that fades out as it is closed. In there, you will find a `res/anim/` directory, which is where animation resources should reside. In there, you will find `fade.xml`:

```
<?xml version="1.0" encoding="utf-8"?>
<alpha xmlns:android="http://schemas.android.com/apk/res/android"
    android:fromAlpha="1.0"
    android:toAlpha="0.0" />
```

(from [Animation/SlidingPanelEx/app/src/main/res/anim/fade.xml](#))

The name of the root element indicates the type of animation (in this case, alpha for an `AlphaAnimation`). The attributes specify the characteristics of the animation, in this case a fade from 1.0 to 0.0 on the alpha channel.

This XML is the same as calling `new AlphaAnimation(1.0f, 0.0f)` in Java.

Using XML Animations

To make use of XML-defined animations, you need to inflate them, much as you might inflate a View or Menu resource. This is accomplished by using the `loadAnimation()` static method on the `AnimationUtils` class, seen here in our `SlidingPanel` constructor:

```
public SlidingPanel(final Context ctxt, AttributeSet attrs) {
    super(ctxt, attrs);

    TypedArray a=ctxt.obtainStyledAttributes(attrs,
                                           R.styleable.SlidingPanel,
                                           0, 0);

    speed=a.getInt(R.styleable.SlidingPanel_speed, 300);

    a.recycle();

    fadeOut=AnimationUtils.loadAnimation(ctxt, R.anim.fade);
}
```

(from [Animation/SlidingPanelEx/app/src/main/java/com/commonsware/android/anim2/SlidingPanel.java](#))

Here, we are loading our fade animation, given a `Context`. This is being put into an `Animation` variable, so we neither know nor care that this particular XML that we are loading defines an `AlphaAnimation` instead of, say, a `RotateAnimation`.

When It's All Said And Done

Sometimes, you need to take action when an animation completes.

For example, when we close the panel, we want to use a `TranslationAnimation` to slide it down from the open position to closed... then *keep* it closed. With the system used in `SlidingPanel`, keeping the panel closed is a matter of calling `setVisibility()` on the contents with `INVISIBLE`.

However, you cannot do that when the animation begins; otherwise, the panel is gone by the time you try to animate its motion.

Instead, you need to arrange to have it become invisible when the animation ends. To do that, you use an animation listener.

LEGACY ANIMATIONS

An animation listener is simply an instance of the `AnimationListener` interface, provided to an animation via `setAnimationListener()`. The listener will be invoked when the animation starts, ends, or repeats (the latter courtesy of `CycleInterpolator`, discussed later in this chapter). You can put logic in the `onAnimationEnd()` callback in the listener to take action when the animation finishes.

For example, here is the `AnimationListener` for `SlidingPanel`:

```
Animation.AnimationListener collapseListener=new Animation.AnimationListener() {
    public void onAnimationEnd(Animation animation) {
        setVisibility(View.INVISIBLE);
    }

    public void onAnimationRepeat(Animation animation) {
        // not needed
    }

    public void onAnimationStart(Animation animation) {
        // not needed
    }
};
```

(from [Animation/SlidingPanel/app/src/main/java/com/commonsware/android/anim/SlidingPanel.java](#))

All we do is set our content's visibility to be `INVISIBLE`, thereby closing the panel.

Loose Fill

You will see attributes, available on `Animation`, named `android:fillEnabled` and `android:fillAfter`. Reading those, you may think that you can dispense with the `AnimationListener` and just use those to arrange to have your widget wind up being “permanently” in the state represented by the end of the animation. All you would have to do is set each of those to true in your animation XML (or the equivalent in Java), and you would be set.

At least for `TranslateAnimation`, you would be mistaken.

It actually will look like it works — the animated widgets will be drawn in their new location. However, if those widgets are clickable, they will not be clicked in their new location, but rather in their old one. This, of course, is not terribly useful.

Hence, even though it is annoying, you will want to use the `AnimationListener` techniques described in this chapter.

Hit The Accelerator

In addition to the `Animation` classes themselves, Android also provides a set of `Interpolator` classes. These provide instructions for how an animation is supposed to behave during its operating period.

For example, the `AccelerateInterpolator` indicates that, during the duration of an animation, the rate of change of the animation should begin slowly and accelerate until the end. When applied to a `TranslateAnimation`, for example, the sliding movement will start out slowly and pick up speed until the movement is complete.

There are several implementations of the `Interpolator` interface besides `AccelerateInterpolator`, including:

1. `AccelerateDecelerateInterpolator`, which starts slowly, picks up speed in the middle, and slows down again at the end
2. `DecelerateInterpolator`, which starts quickly and slows down towards the end
3. `LinearInterpolator`, the default, which indicates the animation should proceed smoothly from start to finish
4. `CycleInterpolator`, which repeats an animation for a number of cycles, following the `AccelerateDecelerateInterpolator` pattern (slow, then fast, then slow)

To apply an interpolator to an animation, simply call `setInterpolator()` on the animation with the `Interpolator` instance, such as the following line from `SlidingPanel`:

```
anim.setInterpolator(new AccelerateInterpolator(1.0f));
```

(from [Animation/SlidingPanel/app/src/main/java/com/commonsware/android/anim/SlidingPanel.java](#))

You can also specify one of the stock interpolators via the `android:interpolator` attribute in your animation XML file.

Animate. Set. Match.

For the `Animation/SlidingPanelEx` project, though, we want the panel to slide open, but also fade when it slides closed. This implies two animations working at the same time (a fade and a slide). Android supports this via the `AnimationSet` class.

LEGACY ANIMATIONS

An `AnimationSet` is itself an `Animation` implementation. Following the composite design pattern, it simply cascades the major `Animation` events to each of the animations in the set.

To create a set, just create an `AnimationSet` instance, add the animations, and configure the set. For example, here is the logic from the `SlidingPanel` implementation in `Animation/SlidingPanelEx`:

```
public void toggle() {
    TranslateAnimation anim=null;
    AnimationSet set=new AnimationSet(true);

    isOpen=!isOpen;

    if (isOpen) {
        setVisibility(View.VISIBLE);
        anim=new TranslateAnimation(0.0f, 0.0f,
                                   getHeight(),
                                   0.0f);
    }
    else {
        anim=new TranslateAnimation(0.0f, 0.0f, 0.0f,
                                   getHeight());
        anim.setAnimationListener(collapseListener);
        set.addAnimation(fadeOut);
    }

    set.addAnimation(anim);
    set.setDuration(speed);
    set.setInterpolator(new AccelerateInterpolator(1.0f));
    startAnimation(set);
}
```

(from [Animation/SlidingPanelEx/app/src/main/java/com/commonsware/android/anim2/SlidingPanel.java](#))

If the panel is to be opened, we make the contents visible (so we can animate the motion upwards), and create a `TranslateAnimation` for the upward movement. If the panel is to be closed, we create a `TranslateAnimation` for the downward movement, but also add a pre-defined `AlphaAnimation` (`fadeOut`) to an `AnimationSet`. In either case, we add the `TranslateAnimation` to the set, give the set a duration and interpolator, and run the animation.

Active Animations

Starting with Android 1.5, users could indicate if they wanted to have inter-activity animations: a slide-in/slide-out effect as they switched from activity to activity. However, at that time, they could merely toggle this setting on or off, and applications had no control over these animations whatsoever.

Starting in Android 2.0, though, developers have a bit more control. Specifically:

1. Developers can call `overridePendingTransition()` on an Activity, typically after calling `startActivity()` to launch another activity or `finish()` to close up the current activity. The `overridePendingTransition()` indicates an in/out animation pair that should be applied as control passes from this activity to the next one, whether that one is being started (`startActivity()`) or is the one previous on the stack (`finish()`).
2. Developers can start an activity via an Intent containing the `FLAG_ACTIVITY_NO_ANIMATION` flag. As the name suggests, this flag requests that animations on the transitions involving this activity be suppressed.

These are prioritized as follows:

- Any call to `overridePendingTransition()` is always taken into account
- Lacking that, `FLAG_ACTIVITY_NO_ANIMATION` will be taken into account
- In the normal case, where neither of the two are used, whatever the user's preference, via the Settings application, is applied

Custom Drawables

Many times, our artwork can simply be some PNG or JPEG files, perhaps with different variations in different resource directories by density.

Sometimes, though, we need something more.

In addition to supporting standard PNG and JPEG files, Android has a number of custom drawable resource formats — mostly written in XML — that handle specific scenarios.

For example, you may wish to customize “the background” of a Button, but a Button really has several different background images for different circumstances (normal, pressed, focused, disabled, etc.). Android has a certain type of drawable resource that aggregates other drawable resources, indicating which of those other resources should be used in different circumstances (e.g., for a normal button use X, for a disabled button use Y).

In this chapter, we will explore these non-traditional types of “drawables” and how you can use them within your apps.

Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly the ones on [basic resources](#), [basic widgets](#), and [vector drawables](#).

Having read the chapters on [animators](#) and [legacy animations](#) would be useful.

Where Do These Things Go?

All of the drawables described in this chapter, unless otherwise noted, are density-independent. Hence, they do not normally go in a density-dependent directories like `res/drawable-hdpi/`. However, that still leaves three possible candidates: `res/drawable-nodpi/`, `res/drawable-anydpi/`, and the unadorned `res/drawable/`.

nodpi: Fallback

A drawable in `res/drawable-nodpi/` is valid for any screen density. However, if there is another drawable with the same base name in a density-specific directory, and the device running your app happens to have that screen density, the density-specific resource will be used. As a result, `-nodpi` becomes a fallback, to be used in cases where you do not have something specific for a density.

For example, suppose that we have `res/drawable-nodpi/foo.xml` and `res/drawable-xxhdpi/foo.png`. An `-xxhdpi` device would use the PNG; all other devices would use the XML.

anydpi: Takeover

A drawable in `res/drawable-anydpi/` also is valid for any screen density. However, in this case, the `-anydpi` variant trumps any density-specific variant.

For example, suppose that we have `res/drawable-anydpi/foo.xml` and `res/drawable-xxhdpi/foo.png`. **All devices** would use the XML, even `-xxhdpi` devices.

For this reason, often you will see `-anydpi` used in conjunction with other qualifiers. A popular one will be `-v21`, to restrict the resources to be used on API Level 21+ devices.

No Qualifier: Just Say “WTF?”

`res/drawable/` is a synonym for `res/drawable-mdpi/`, for backwards compatibility with *really* old Android apps, written before we had density-specific resources. Hence, `res/drawable/` is not really an appropriate choice for density-independent drawables.

Alas, Android Studio may put some drawables here, for uncertain reasons.

So long as there are no other resources with the same basename, the choice made by Android Studio's developers is unlikely to cause any harm.

ColorDrawable

The simplest XML drawable format, by far, is for `ColorDrawable`. Not surprisingly, this defines a `Drawable` that is a solid color.

So, you can have a `res/drawable/thing.xml` file, containing something like this:

```
<color xmlns:android="http://schemas.android.com/apk/res/android"
    android:color="#80FF00FF"/>
```

From there, you can use `@drawable/thing` or `R.drawable.thing` in the same places that you would use any other drawable resource.

Note that a `ColorDrawable` is different than a color resource. A color resource (e.g., `res/values/colors.xml`) specifies a color. A `ColorDrawable` resource defines a `Drawable` of a color. A `ColorDrawable` resource is welcome to reference a color defined by a color resource, though:

```
<color xmlns:android="http://schemas.android.com/apk/res/android"
    android:color="@color/primary_dark"/>
```

AnimationDrawable

The original way of doing animation on the Web was via the animated GIF. An individual GIF file could contain many frames, and the browser would switch between those frames to display a basic animated effect. This was used by Web designers for things both good (animated progress “spinners”) and bad (“hit the monkey” ad banners).

Android, on the whole, does not support animated GIF files, certainly not as regular images for use with widgets like `ImageView`.

However, there are times where having this sort of frame-by-frame animation would be useful. For example, in [another chapter](#), we will look at `ProgressBar`, which is Android's primary way of demonstrating progress of background work. You may wish to customize the “spinning wheel” image that Android uses by default, to match your app's color scheme, or to spin your company logo, or whatever. On the

CUSTOM DRAWABLES

Web, particularly on older browsers, you might use an animated GIF for that. On Android, you still could, though it would require a [third-party library](#) or some fairly heavyweight solutions (e.g., WebView, Movie).

Another possibility is to use an AnimationDrawable. AnimationDrawable has the net effect of an animated GIF:

- You define a series of images that serve as the frames of the animation
- You define how long each of those images should be on the screen
- You define whether the animation should loop back to the beginning after it reaches the end or not

However, rather than encoding all of this in an animated GIF, you instead encode this information in an XML file, stored as a drawable resource.

XML-encoded drawable resources are typically stored in a drawable directory that does *not* contain density information, such as `res/drawable/`. That is because the XML-encoded drawable resources are density-invariant: they behave the same regardless of density. Those, like the AnimationDrawable, that refer to other images might well refer to other images that are stored in density-dependent resource directories, but the XML-encoded drawable itself is independent of density.

An AnimationDrawable is defined as in XML with a root `<animation-list>` element, containing a series of `<item>` elements for each frame:

```
<animation-list xmlns:android="http://schemas.android.com/apk/res/android"
    android:oneshot="true">
    <item android:drawable="@drawable/frame1" android:duration="250" />
    <item android:drawable="@drawable/frame2" android:duration="250" />
    <item android:drawable="@drawable/frame3" android:duration="250" />
    <item android:drawable="@drawable/frame4" android:duration="250" />
</animation-list>
```

The root `<animation-list>` element can have an `android:oneshot` attribute, indicating whether the animation should repeat after displaying the last frame (false) or stop (true).

The `<item>` elements have `android:drawable` attributes pointing to the individual images for the individual frames. Usually these frames are PNG or JPEG files, but you refer to them as drawable resources, using `@drawable` syntax, so Android can find the right image based upon the density (or other characteristics) of the current device. The `<item>` elements also need an `android:duration` attribute, specifying

CUSTOM DRAWABLES

the time in milliseconds that this frame should be on the screen. While the above example has all durations the same, that is not required.

For example, the Android OS uses `AnimationDrawable` resources in a few places. One is for the download icon used in a Notification for use with `DownloadManager` and similar situations. That drawable resource – `stat_sys_download.xml` — looks like this:

```
<?xml version="1.0" encoding="utf-8"?>
<!--
/* //device/apps/common/res/drawable/status_icon_background.xml
**
** Copyright 2008, The Android Open Source Project
**
** Licensed under the Apache License, Version 2.0 (the "License");
** you may not use this file except in compliance with the License.
** You may obtain a copy of the License at
**
**     http://www.apache.org/licenses/LICENSE-2.0
**
** Unless required by applicable law or agreed to in writing, software
** distributed under the License is distributed on an "AS IS" BASIS,
** WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
** See the License for the specific language governing permissions and
** limitations under the License.
*/
-->
<animation-list
    xmlns:android="http://schemas.android.com/apk/res/android"
    android:oneshot="false">
    <item android:drawable="@drawable/stat_sys_download_anim0" android:duration="200"
    />
    <item android:drawable="@drawable/stat_sys_download_anim1" android:duration="200"
    />
    <item android:drawable="@drawable/stat_sys_download_anim2" android:duration="200"
    />
    <item android:drawable="@drawable/stat_sys_download_anim3" android:duration="200"
    />
    <item android:drawable="@drawable/stat_sys_download_anim4" android:duration="200"
    />
    <item android:drawable="@drawable/stat_sys_download_anim5" android:duration="200"
    />
</animation-list>
```

Here, we have a repeating animation (`android:oneshot="false"`), consisting of six frames, each on the screen for 200 milliseconds.

By specifying an `AnimationDrawable` in your `Notification` for its icon, you too can have this sort of animated effect. Of course, the animation is “fire and forget”: other than by removing or replacing the `Notification`, you cannot affect the animation in any other way.

Animated GIF Conversion

It may be that you have an animated GIF that you would like to use as the basis for your `AnimationDrawable`. If you have passing familiarity with Ruby, the author of this book has published [a Ruby script, named `gif2animdraw`](#), that automates the conversion.

To use `gif2animdraw`, in addition to the script itself and a Ruby interpreter, you will need the `RMagick`, `slop`, and `builder` gems. Note that `RMagick`, in turn, will require `ImageMagick` libraries and therefore is a bit more complicated to install than is your ordinary gem.

On Linux environments, you can also `chmod` the script to run it directly; otherwise, you would run it via the `ruby` command.

The script takes four command-line switches:

- `-i` should point to the GIF file to be converted
- `-o` should point to the root output directory, which typically would be a project’s `res/` directory
- `-d` should have, as a value, one of the Android density bucket names (e.g., `hdpi`); this will be used as the density for the frames of the GIF
- Optionally, include `--oneshot` to indicate that this should be a one-shot animation, not a repeating one

The results will be:

- A `drawable/` directory underneath your supplied root, containing a file with the same name as the GIF file, but with a `.xml` extension, representing the `AnimationDrawable` itself
- A `drawable-XXXX/` directory, where `XXXX` is your stated density, containing each frame of the animated GIF, as a PNG file, with a sequentially numbered filename based on the GIF’s filename

StateListDrawable

Another XML-defined drawable resource, the `StateListDrawable`, is key if you want to have different images when widgets are in different states.

As outlined in the introduction to this chapter, what makes a `Button` visually be a `Button` is its background. To handle different looks for the `Button` background for different states (normal, pressed, disabled, etc.), the standard `Button` background is a `StateListDrawable`, one that looks something like this:

```
<?xml version="1.0" encoding="utf-8"?>
<!-- Copyright (C) 2008 The Android Open Source Project

Licensed under the Apache License, Version 2.0 (the "License");
you may not use this file except in compliance with the License.
You may obtain a copy of the License at

    http://www.apache.org/licenses/LICENSE-2.0

Unless required by applicable law or agreed to in writing, software
distributed under the License is distributed on an "AS IS" BASIS,
WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
See the License for the specific language governing permissions and
limitations under the License.
-->
<selector xmlns:android="http://schemas.android.com/apk/res/android">
    <item android:state_window_focused="false" android:state_enabled="true"
        android:drawable="@drawable/btn_default_normal" />
    <item android:state_window_focused="false" android:state_enabled="false"
        android:drawable="@drawable/btn_default_normal_disable" />
    <item android:state_pressed="true"
        android:drawable="@drawable/btn_default_pressed" />
    <item android:state_focused="true" android:state_enabled="true"
        android:drawable="@drawable/btn_default_selected" />
    <item android:state_enabled="true"
        android:drawable="@drawable/btn_default_normal" />
    <item android:state_focused="true"
        android:drawable="@drawable/btn_default_normal_disable_focused" />
    <item
        android:drawable="@drawable/btn_default_normal_disable" />
</selector>
```

The XML has a `<selector>` root element, indicating this is a `StateListDrawable`. The `<item>` elements inside the root describe what `Drawable` resource should be

used if the `StateListDrawable` is being used in some state. For example, if the “window” (think activity or dialog) does not have the focus (`android:state_window_focused="false"`) and the Button is enabled (`android:state_enabled="true"`), then we use the `@drawable/btn_default_normal` Drawable resource. That resource, as it turns out, is a nine-patch PNG file, described [later in this chapter](#).

Android applies each rule in turn, top-down, to find the Drawable to use for a given state of the `StateListDrawable`. The last rule has no `android:state_*` attributes, meaning it is the overall default image to use if none of the other rules match.

So, if you want to change the background of a Button, you need to:

- Copy the above resource, found in your Android SDK as `res/drawable/btn_default.xml` inside any of the `platforms/` directories, into your project
- Copy each of the Button state nine-patch images into your project
- Modify whichever of those nine-patch images you want, to affect the visual change you seek
- If need be, tweak the states and images defined in the `StateListDrawable` XML you copied
- Reference the local `StateListDrawable` as the background for your Button

The backgrounds of most widgets that have backgrounds by default will use a `StateListDrawable`. Searching a platform version’s `res/drawable/` directory for XML files containing `<selector>` elements comes up with a rather long list.

ColorStateList

A `ColorStateList` is analogous to a `StateListDrawable`, in that it defines states and identifies what should be used for a given state. Whereas `StateListDrawable` ties states to drawables, `ColorStateList` ties states to colors. This allows you to, say, change the color of some text based upon whether that text is drawn in a widget that is being pressed, or has the focus, or is disabled. If you tailor the background of a text-based widget using a `StateListDrawable`, you may well wind up tailoring the foreground text using a `ColorStateList`.

While this chapter mentions `ColorStateList`, technically a `ColorStateList` is not a Drawable. You do not use it in methods that take drawables or in widget XML attributes that take drawables. Rather, there are other methods and other attributes that take a `ColorStateList`, such as `android:textColor`.

CUSTOM DRAWABLES

Similarly, while you can define a `ColorStateList` in XML, you do not do so in a `res/drawable/` resource directory, but rather a `res/color/` resource directory. Beyond that, though, a `ColorStateList` XML resource looks a lot like a `StateListDrawable` XML resource, such as this definition of `@android:color/primary_text_dark` from Android 4.4:

```
<?xml version="1.0" encoding="utf-8"?>
<!-- Copyright (C) 2008 The Android Open Source Project

Licensed under the Apache License, Version 2.0 (the "License");
you may not use this file except in compliance with the License.
You may obtain a copy of the License at

    http://www.apache.org/licenses/LICENSE-2.0

Unless required by applicable law or agreed to in writing, software
distributed under the License is distributed on an "AS IS" BASIS,
WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
See the License for the specific language governing permissions and
limitations under the License.
-->

<selector xmlns:android="http://schemas.android.com/apk/res/android">
  <item android:state_enabled="false" android:color="@android:color/
bright_foreground_dark_disabled"/>
  <item android:state_window_focused="false" android:color="@android:color/
bright_foreground_dark"/>
  <item android:state_pressed="true" android:color="@android:color/
bright_foreground_dark_inverse"/>
  <item android:state_selected="true" android:color="@android:color/
bright_foreground_dark_inverse"/>
  <item android:state_activated="true" android:color="@android:color/
bright_foreground_dark_inverse"/>
  <item android:color="@android:color/bright_foreground_dark"/> <!-- not selected
-->
</selector>
```

Based upon the state, the `ColorStateList` pulls in a separate resource to define the actual color. Those colors, in turn, are defined via `<color>` elements in `res/values/colors.xml` as color resources, or are pulled in from system-defined colors (`@android:color/...` syntax):

```
<color name="background_dark">#ff000000</color>
<color name="background_light">#ffffffff</color>
<color name="bright_foreground_dark">@android:color/background_light</color>
<color name="bright_foreground_light">@android:color/background_dark</color>
```

```
<color name="bright_foreground_dark_disabled">#80ffffff</color>
<color name="bright_foreground_light_disabled">#80000000</color>
<color name="bright_foreground_dark_inverse">@android:color/
bright_foreground_light</color>
<color name="bright_foreground_light_inverse">@android:color/
bright_foreground_dark</color>
```

LayerDrawable

A LayerDrawable basically stacks a bunch of other drawables on top of each other. Later drawables are drawn on top of earlier drawables, much as later children of a RelativeLayout are drawn on top of earlier children.

Typically, you will create a LayerDrawable via a <layer-list> XML drawable resource.

For example, a ToggleButton widget has a LayerDrawable as its background:

```
?xml version="1.0" encoding="utf-8"?>
<!-- Copyright (C) 2008 The Android Open Source Project

Licensed under the Apache License, Version 2.0 (the "License");
you may not use this file except in compliance with the License.
You may obtain a copy of the License at

    http://www.apache.org/licenses/LICENSE-2.0

Unless required by applicable law or agreed to in writing, software
distributed under the License is distributed on an "AS IS" BASIS,
WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
See the License for the specific language governing permissions and
limitations under the License.
-->

<layer-list xmlns:android="http://schemas.android.com/apk/res/android">
    <item android:id="@+android:id/background" android:drawable="@android:drawable/
btn_default_small" />
    <item android:id="@+android:id/toggle" android:drawable="@android:drawable/
btn_toggle" />
</layer-list>
```

This LayerDrawable draws two images on top of each other. One is a standard small button background (@android:drawable/btn_default_small). The other is the

actual face of the toggle itself — a `StateListDrawable` that uses different images for checked and unchecked states.

In the `<layer-list>`, you can have several `<item>` elements. Each `<item>` element usually will need an `android:drawable` attribute, pointing to the drawable that should be drawn. Optionally, you can assign ID values to the items via `android:id` attributes, much like you would do for widgets in a layout XML resource. Later on, you can call `findDrawableByLayerId()` on the `LayerDrawable` to retrieve an individual `Drawable` representing the layer, given its `android:id` value.

There are also `android:left`, `android:right`, `android:top`, and `android:bottom` attributes, which you can use to provide dimension values to offset an image within the layered set. For example, you could use `android:left` to inset one of the layers by a certain number of pixels (or dp or whatever).

By default, the layers in the `LayerDrawable` are scaled to fit the size of whatever `View` is holding them (e.g., the size of the `ToggleButton` using the `LayerDrawable` as a background). To prevent this, you can skip the `android:drawable` attribute, and instead nest a `<bitmap>` element inside the `<item>`, where you can provide an `android:gravity` attribute to control how the image should be handled relative to its containing `View`. We will get more into nested `<bitmap>` elements [later in this chapter](#).

TransitionDrawable

A `TransitionDrawable` is a `LayerDrawable` with one added feature: for a two-layer drawable, it can smoothly transition from showing one layer to another on top.

For example, you may have noticed that when you tap-and-hold on a row in a `ListView` that the selector highlight has an animated effect, slowly shifting colors from the color used for a simple click to one signifying that you have long-clicked the row. Android accomplishes this via a `TransitionDrawable`, set up as a `<transition>` XML drawable resource:

```
<?xml version="1.0" encoding="utf-8"?>
<!-- Copyright (C) 2008 The Android Open Source Project

Licensed under the Apache License, Version 2.0 (the "License");
you may not use this file except in compliance with the License.
You may obtain a copy of the License at
```

CUSTOM DRAWABLES

```
    http://www.apache.org/licenses/LICENSE-2.0

    Unless required by applicable law or agreed to in writing, software
    distributed under the License is distributed on an "AS IS" BASIS,
    WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
    See the License for the specific language governing permissions and
    limitations under the License.
-->

<transition xmlns:android="http://schemas.android.com/apk/res/android">
    <item android:drawable="@android:drawable/list_selector_background_pressed" />
    <item android:drawable="@android:drawable/list_selector_background_longpress" />
</transition>
```

The `TransitionDrawable` object has a `startTransition()` method that you can use, that will have Android smoothly switch from the first drawable to the second. You specify the duration of the transition as a number of milliseconds passed to `startTransition()`. There are also options to reverse the transition, set up more of a cross-fade effect, and the like.

LevelListDrawable

A `LevelListDrawable` is similar in some respects to a `StateListDrawable`, insofar as one specific item from the “list drawable” will be displayed based upon certain conditions. In the case of `StateListDrawable`, the conditions are based upon the state of the widget using the drawable (e.g., checked, pressed, disabled). In the case of `LevelListDrawable`, it is merely an integer level.

For example, the status or system bar of your average Android device has an icon indicating the battery charge level. That is actually implemented as a `LevelListDrawable`, via an XML resource containing a root `<level-list>` element:

```
<?xml version="1.0" encoding="utf-8"?>
<!--
/* //device/apps/common/res/drawable/stat_sys_battery.xml
**
** Copyright 2007, The Android Open Source Project
**
** Licensed under the Apache License, Version 2.0 (the "License");
** you may not use this file except in compliance with the License.
** You may obtain a copy of the License at
**
**     http://www.apache.org/licenses/LICENSE-2.0
**
```

CUSTOM DRAWABLES

```
** Unless required by applicable law or agreed to in writing, software  
** distributed under the License is distributed on an "AS IS" BASIS,  
** WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.  
** See the License for the specific language governing permissions and  
** limitations under the License.  
*/  
-->  
  
<level-list xmlns:android="http://schemas.android.com/apk/res/android">  
  <item android:maxLevel="4" android:drawable="@android:drawable/  
stat_sys_battery_0" />  
  <item android:maxLevel="15" android:drawable="@android:drawable/  
stat_sys_battery_15" />  
  <item android:maxLevel="35" android:drawable="@android:drawable/  
stat_sys_battery_28" />  
  <item android:maxLevel="49" android:drawable="@android:drawable/  
stat_sys_battery_43" />  
  <item android:maxLevel="60" android:drawable="@android:drawable/  
stat_sys_battery_57" />  
  <item android:maxLevel="75" android:drawable="@android:drawable/  
stat_sys_battery_71" />  
  <item android:maxLevel="90" android:drawable="@android:drawable/  
stat_sys_battery_85" />  
  <item android:maxLevel="100" android:drawable="@android:drawable/  
stat_sys_battery_100" />  
</level-list>
```

This `LevelListDrawable` has eight items, whose `android:drawable` attributes point to specific other drawable resources (in this case, standard PNG files with different implementations for different densities). Each `<item>` has an `android:maxLevel` value. When someone calls `setLevel()` on the `Drawable` or `setImageLevel()` on the `ImageView`, Android will choose the item with the lowest `maxLevel` that meets or exceeds the requested level, and show that. In the case of the battery icon, when the battery level changes, the status bar picks up that change and calls `setImageLevel()` with the battery charge percentage (expressed as an integer from 0-100) — that, in turn, triggers the right PNG file to be displayed.

Another use of `LevelListDrawable` is with a `RemoteViews`, such as for an [app widget](#). The `setImageLevel()` method is “remotable”, despite not being directly part of the `RemoteViews` API. Hence, given that you use a `LevelListDrawable` in your app widget’s layout, you should be able to use `setInt()` with a method name of “setImageLevel” to have the app widget update to display the proper image.

ScaleDrawable and ClipDrawable

A ScaleDrawable does pretty much what its name suggests: it scales another drawable. A ClipDrawable does pretty much what *its* name suggests: it clips another drawable.

How they do this, and how you control it, requires a bit more explanation.

Like LevelListDrawable, ScaleDrawable and ClipDrawable leverage the `setLevel()` method on Drawable (or the `setImageLevel()` method on ImageView). Whereas LevelListDrawable uses this to choose an individual image out of a set of possible images, ScaleDrawable and ClipDrawable use the level to control how much an image should be scaled or clipped. For this, they support a range of levels from 0 to 10000.

Scaling

For a level of 0, ScaleDrawable will not draw anything. For a level from 1 to 10000, ScaleDrawable will scale an image from a configurable minimum size to the bounds of the View to which the drawable is applied.

The amount of scaling is determined by `android:scaleHeight` and `android:scaleWidth` attributes:

```
<?xml version="1.0" encoding="utf-8"?>
<scale xmlns:android="http://schemas.android.com/apk/res/android"
    android:drawable="@android:drawable/btn_default"
    android:scaleGravity="left|top"
    android:scaleHeight="50%"
    android:scaleWidth="50%" />
```

(from [Drawable/ScaleClip/app/src/main/res/drawable/scale.xml](http://android.googlesource.com/platform/manifest/+/android-4.0.4_r1/res/drawable/scale.xml))

The above ScaleDrawable (denoted by the `<scale>` root element) says that we should scale both height and width of the underlying drawable to 50% of the available space for the drawable, when the level is at its maximum (10000).

Note that you do not have to scale along both dimensions. If, for example, you kept `android:scaleWidth` but deleted `android:scaleHeight`, `setImageLevel()` would control the scaled width of the underlying image (provided via `android:drawable`) but not the height.

The `android:scaleGravity` attribute indicates where the scaled image should reside within the available space (the 10000 level, determined by the bounds of the View to which the drawable is applied). The value shown above, `center`, keeps the image centered within the available space, and shrinks or expands it around the center. A value of `left|top` would keep the image in the upper-left corner of the space, having the visual effect of moving the lower-right corner based upon the supplied level.

Clipping

Scaling proportionally reduces the height and/or width of an image. Clipping, on the other hand, chops off part of the height or width of the image.

```
<clip xmlns:android="http://schemas.android.com/apk/res/android"
    android:clipOrientation="horizontal"
    android:drawable="@drawable/btn_default_normal"
    android:gravity="left"/>
```

(from [Drawable/ScaleClip/app/src/main/res/drawable/clip.xml](#))

In this sample `ClipDrawable` (indicated by the `<clip>` root element), we are going to allow the level to chop off part of the image indicated by the `android:drawable` attribute. Our `android:clipOrientation`, set to `horizontal`, means we are going to chop off part of the width (`vertical` would have us chop off part of the height). The amount that is going to be chopped off is the level you supply (e.g., `setImageLevel()`) divided by 10000. Hence, a level of 5000 will chop off 0.5 (a.k.a., 50%) of the image.

Where in the image the clipping occurs is determined by the `android:gravity` attribute. An `android:clipOrientation` of `horizontal` and an `android:gravity` of `left`, as in the sample drawable above, means that the left side of the image is retained, and the image will be clipped on the right. Specifying `right` instead of `left` would reverse that, clipping the image from the right, while `center` would clip equally from both sides. There are other gravity values as well, such as `top` and `bottom` values to be used with a vertical orientation.

Seeing It In Action

To see these effects, take a look at the [Drawable/ScaleClip](#) sample project. This is derived from [an earlier example](#) showing how to use `ViewPager` with `PagerTabStrip`. In that example, we had 10 tabs, each being a large `EditText` widget. In this example, we have 2 tabs, “Scale” and “Clip”, both using the same layout:

CUSTOM DRAWABLES

```
<RelativeLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent">

    <ImageView
        android:id="@+id/image"
        android:layout_width="150dp"
        android:layout_height="150dp"
        android:layout_centerHorizontal="true"
        android:layout_marginTop="20dp"
        android:scaleType="fitXY"/>

    <SeekBar
        android:id="@+id/level"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:layout_alignParentBottom="true"
        android:layout_marginBottom="20dp"
        android:layout_marginLeft="20dp"
        android:layout_marginRight="20dp"
        android:max="10000"
        android:progress="10000"/>

</RelativeLayout>
```

(from [Drawable/ScaleClip/app/src/main/res/layout/scaleclip.xml](#))

This is simply a 150dp square `ImageView` towards the top of the screen and a `SeekBar` towards the bottom of the screen. The `SeekBar` will be used to control the level applied to a `ScaleDrawable` and `ClipDrawable`, which is why we have `android:max` set to 10000. We also have our “progress” (original `SeekBar` value) set to 10000, so the bar’s thumb will be fully slid over to the right at the outset.

The fragments that we will use for the tabs both inherit from a common abstract `FragmentBase` class:

```
package com.commonware.android.scaleclip;

import android.app.Fragment;
import android.os.Bundle;
import android.view.LayoutInflater;
import android.view.View;
import android.view.ViewGroup;
import android.widget.ImageView;
import android.widget.SeekBar;

abstract public class FragmentBase extends Fragment implements
```

CUSTOM DRAWABLES

```
SeekBar.OnSeekBarChangeListener {
abstract void setBackgroundImage(ImageView image);

private ImageView image=null;

@Override
public View onCreateView(LayoutInflater inflater,
                        ViewGroup container,
                        Bundle savedInstanceState) {
    setRetainInstance(true);

    View result=inflater.inflate(R.layout.scaleclip, container, false);
    SeekBar bar=((SeekBar)result.findViewById(R.id.level));

    bar.setOnSeekBarChangeListener(this);
    image=(ImageView)result.findViewById(R.id.image);
    setBackgroundImage(image);
    image.setImageLevel(bar.getProgress());

    return(result);
}

@Override
public void onProgressChanged(SeekBar seekBar, int progress,
                             boolean fromUser) {
    image.setImageLevel(progress);
}

@Override
public void onStartTrackingTouch(SeekBar seekBar) {
    // no-op
}

@Override
public void onStopTrackingTouch(SeekBar seekBar) {
    // no-op
}
}
```

(from [Drawable/ScaleClip/app/src/main/java/com/commonware/android/scaleclip/FragmentBase.java](#))

In `onCreateView()`, we inflate the above layout file, hook up the fragment itself to be the listener for SeekBar change events, call the subclass' `setBackgroundImage()` method to populate the `ImageView` with an image, and set the `ImageView`'s level to be the initial value of the SeekBar. When the SeekBar value changes, our `onProgressChanged()` method will adjust the level.

CUSTOM DRAWABLES

The concrete subclasses — `ScaleFragment` and `ClipFragment` — simply populate the `ImageView` with the `ScaleDrawable` and `ClipDrawable` resources shown earlier in this section:

```
package com.commonware.android.scaleclip;

import android.widget.ImageView;

public class ScaleFragment extends FragmentBase {
    @Override
    void setBackgroundImage(ImageView image) {
        image.setImageResource(R.drawable.scale);
    }
}
```

(from [Drawable/ScaleClip/app/src/main/java/com/commonware/android/scaleclip/ScaleFragment.java](#))

```
package com.commonware.android.scaleclip;

import android.widget.ImageView;

public class ClipFragment extends FragmentBase {
    @Override
    void setBackgroundImage(ImageView image) {
        image.setImageResource(R.drawable.clip);
    }
}
```

(from [Drawable/ScaleClip/app/src/main/java/com/commonware/android/scaleclip/ClipFragment.java](#))

Those two drawables based their scaling and clipping on `res/drawable-xdpi/btn_default_normal.9.png`. This is a slightly-modified copy of the default button background, and is a nine-patch PNG file. We will discuss nine-patch PNG files [later in this chapter](#) — suffice it to say for now that it is a PNG file with rules about how it should be stretched.

Our scale tab starts off showing the full image:

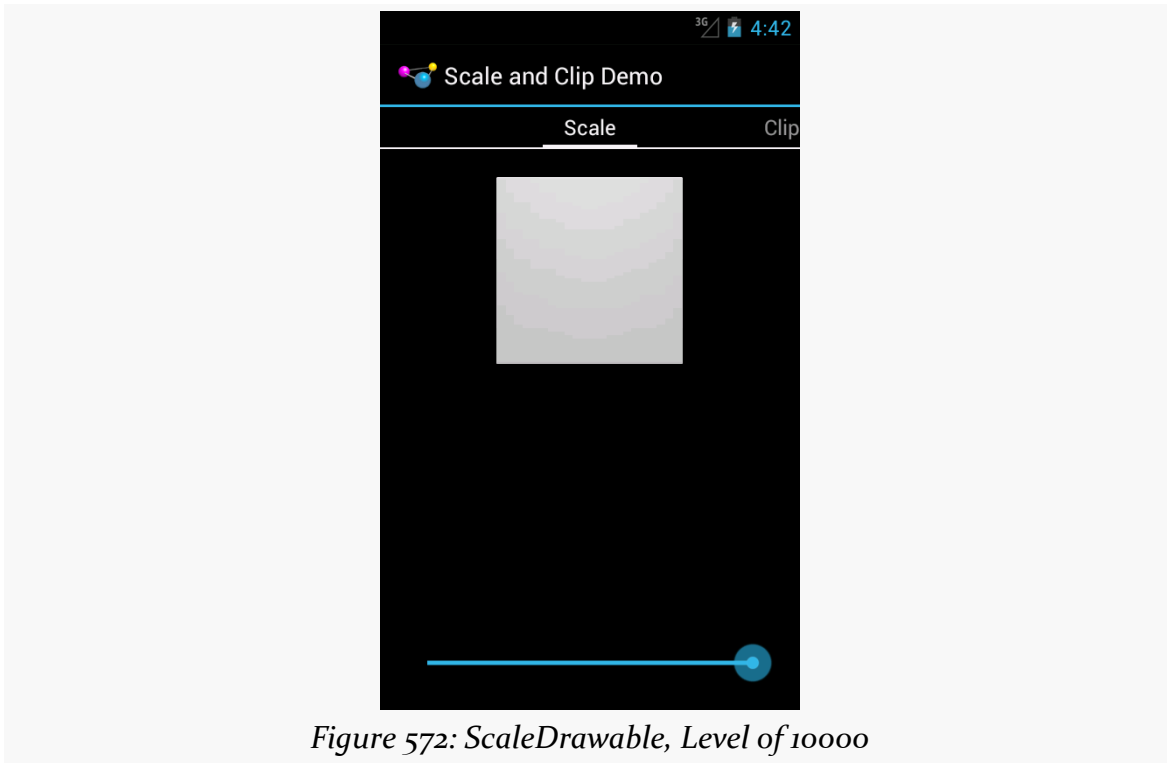

Figure 572: ScaleDrawable, Level of 10000

As we start sliding the SeekBar thumb to the left, the image shrinks progressively:

CUSTOM DRAWABLES

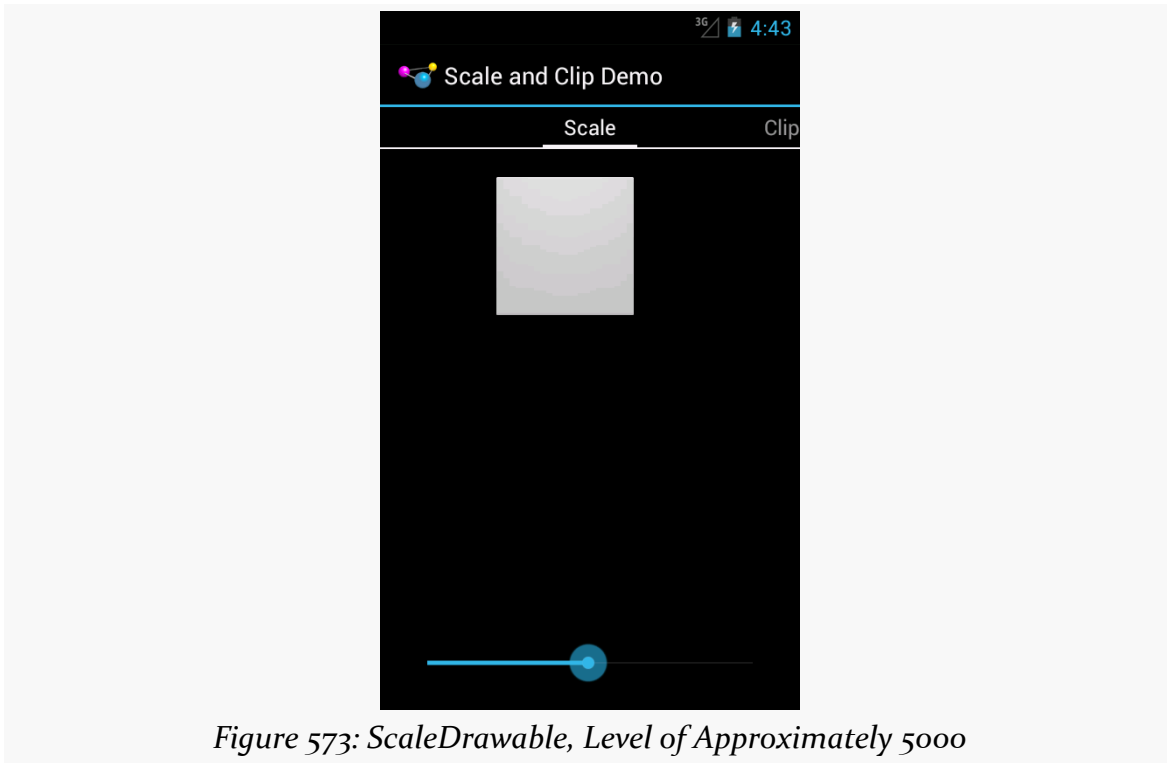

Figure 573: ScaleDrawable, Level of Approximately 5000

It eventually tends towards the 50% level specified in our `android:scaleHeight` and `android:scaleWidth` values:

Figure 574: ScaleDrawable, Level of Approximately 100

Sliding it all the way to the left, though, causes the image to vanish.

The ClipDrawable starts off looking much like the ScaleDrawable:

CUSTOM DRAWABLES

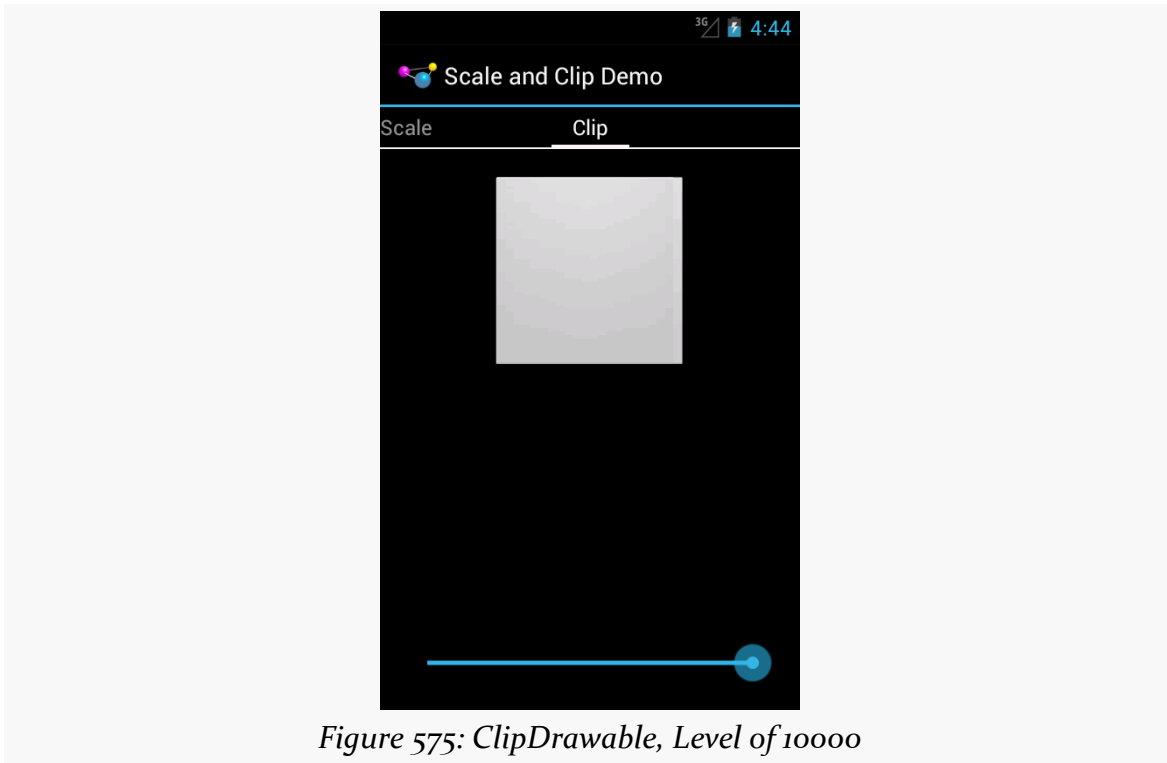

Figure 575: ClipDrawable, Level of 10000

As we slide the SeekBar to the left, the right side of the image gets clipped:

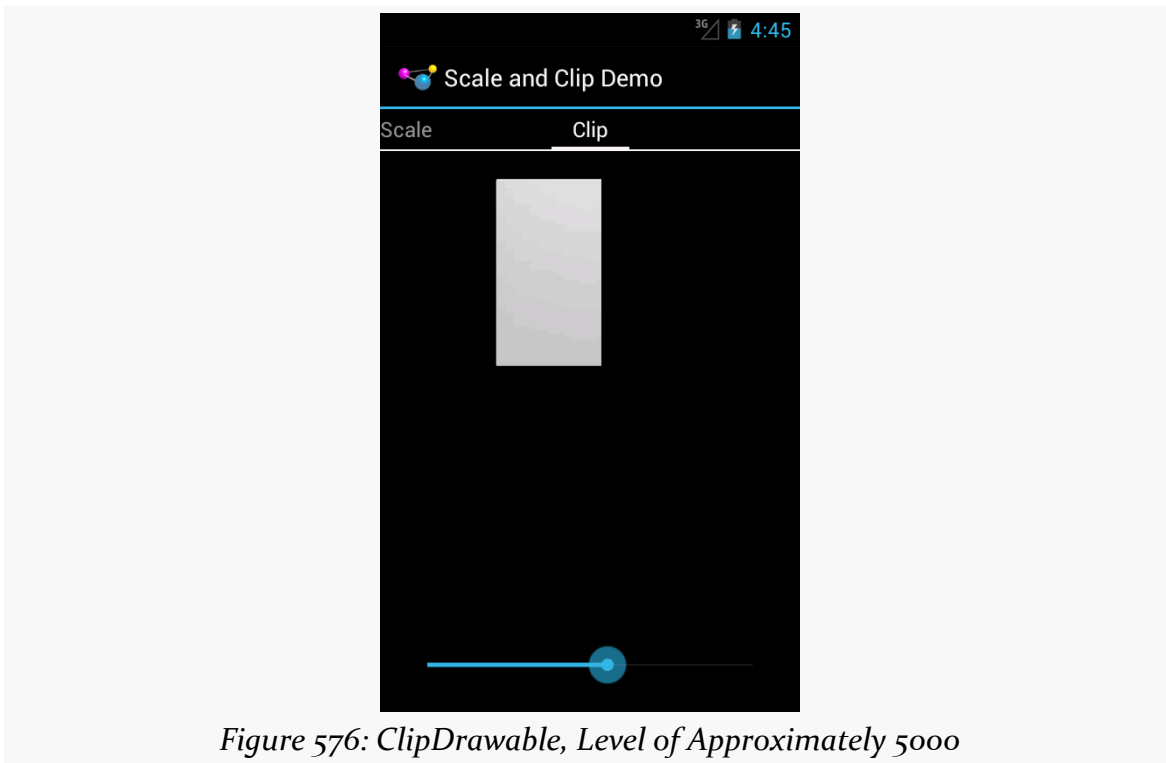

Figure 576: ClipDrawable, Level of Approximately 5000

InsetDrawable

An InsetDrawable allows you to apply insets on any side (or all sides) of some other drawable resource. The use case cited in [the documentation](#) is “This is used when a View needs a background that is smaller than the View’s actual bounds”. However, at the present time, nothing in the Android open source code uses this particular type of resource, or even the Java class.

In principle, though, you could have an XML drawable resource that looked like this:

```
<?xml version="1.0" encoding="utf-8"?>
<inset xmlns:android="http://schemas.android.com/apk/res/android"
    android:drawable="@drawable/something_or_another"
    android:insetLeft="20dp"
    android:insetTop="10dp" />
```

When used as the background for some View, for example, Android would pull in the something_or_another resource and effectively add 20dp of left margin and 10dp of top margin on the background when calculating its size and drawing it on the screen.

ShapeDrawable

ShapeDrawable is the original approach to implementing limited vector art on Android. It gives you what amounts to a very tiny subset of SVG, for creating simple vector art shapes.

The root element of a ShapeDrawable resource is `<shape>`, which may have child elements, along with attributes, to configure what gets rendered on the screen when the drawable is applied.

This section will review the elements and attributes available to you, with sample drawables (and screenshots) culled from the [Drawable/Shape](#) sample project.

This is a “sampler” project, designed to depict a number of ShapeDrawables. To accomplish this, we will use action bar tabs. Our activity (MainActivity) has a pair of static int arrays, one pointing at string resources to use for tab captions, the other pointing at corresponding drawable resources:

```
package com.commonware.android.shape;

import android.app.ActionBar;
import android.app.ActionBar.Tab;
import android.app.ActionBar.TabListener;
import android.app.Activity;
import android.app.FragmentTransaction;
import android.os.Bundle;
import android.widget.ImageView;

public class MainActivity extends Activity implements TabListener {
    private static final int TABS[] = { R.string.solid, R.string.gradient,
        R.string.border, R.string.rounded, R.string.ring,
        R.string.layered };
    private static final int DRAWABLES[] = { R.drawable.rectangle,
        R.drawable.gradient, R.drawable.border, R.drawable.rounded,
        R.drawable.ring, R.drawable.layered };
    private ImageView image=null;

    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.activity_main);

        image=(ImageView)findViewById(R.id.image);
    }
}
```

CUSTOM DRAWABLES

```
ActionBar bar=getActionBar();
bar.setNavigationMode(ActionBar.NAVIGATION_MODE_TABS);

for (int i=0; i < TABS.length; i++) {
    bar.addTab(bar.newTab().setText(getString(TABS[i]))
        .setTabListener(this));
}

@Override
public void onTabSelected(Tab tab, FragmentTransaction ft) {
    image.setImageResource(DRAWABLES[tab.getPosition()]);
}

@Override
public void onTabUnselected(Tab tab, FragmentTransaction ft) {
    // no-op
}

@Override
public void onTabReselected(Tab tab, FragmentTransaction ft) {
    // no-op
}
}
```

(from [Drawable/Shape/app/src/main/java/com/commonsware/android/shape/MainActivity.java](#))

In `onCreate()`, we toggle the `ActionBar` into tab-navigation mode, then iterate over the arrays and add one tab per element.

Our layout is an `ImageView`, named `image`, centered on the screen, taking up 80% of the horizontal space, plus has 20dp of top and bottom margin:

```
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:tools="http://schemas.android.com/tools"
    android:id="@+id/LinearLayout1"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:orientation="horizontal"
    android:gravity="center"
    android:weightSum="10">

    <ImageView
        android:id="@+id/image"
        android:src="@drawable/rectangle"
        android:layout_width="0dp"
        android:layout_height="match_parent"
```

CUSTOM DRAWABLES

```
android:layout_marginTop="20dp"  
android:layout_marginBottom="20dp"  
android:layout_gravity="center"  
android:layout_weight="8"/>
```

```
</LinearLayout>
```

(from [Drawable/Shape/app/src/main/res/layout/activity_main.xml](#))

In our activity's `onTabSelected()` — implemented because the activity is the `TabListener` for our tabs — we get the position of our tab and fill in the appropriate drawable into the `ImageView`.

Given that, let's take a look at how to construct a `ShapeDrawable`, along with some sample drawables.

<shape>

Your root element, not surprisingly, is `<shape>`.

The primary thing that you will define on the `<shape>` element is the redundantly-named `android:shape` attribute, to define what sort of shape you want:

- `line` (a shape with no interior)
- `oval` (also for ellipses)
- `rectangle` (including rounded rectangles)
- `ring` (for partially-filled circles)

There are some other attributes available on `<shape>` for a `ring`, which we will examine [later in this chapter](#).

<solid>

Your shape will usually require some sort of fill, to say what color goes in the shape. There are two types of fills: `solid` and `gradient`.

For a `solid` fill, add a `<solid>` child element to the `<shape>`, with an `android:color` attribute indicating what color to use. As with most places in Android, this can either be a literal color or a reference to a color resource.

So, for example, we can specify a solid red rectangle as:

CUSTOM DRAWABLES

```
<?xml version="1.0" encoding="utf-8"?>
<shape xmlns:android="http://schemas.android.com/apk/res/android"
    android:shape="rectangle">
    <solid android:color="#FFAA0000" />
</shape>
```

(from [Drawable/Shape/app/src/main/res/drawable/rectangle.xml](#))

This gives us the following visual result:

Figure 577: ShapeDrawable, Solid Red Rectangle

<gradient>

Your alternative fill is a gradient. The nice thing about gradients with ShapeDrawable is that they are generated at runtime from the specifications in the ShapeDrawable, and therefore will be smooth. Gradients that appear in PNG files and the like, if stretched, will tend to have a banding effect.

Gradient fills are defined via a <gradient> child element of the <shape> element.

The simplest way to set up a gradient is to use three attributes:

CUSTOM DRAWABLES

- `android:startColor` and `android:endColor`, to specify the starting and ending colors of the gradient, respectively, and
- `android:angle`, to specify what direction the gradient “flows” in

The angle must be a multiple of 45 degrees. 0 degrees is left-to-right, 90 degrees is bottom-to-top, 180 degrees is right-to-left, and 270 degrees is top-to-bottom.

So, for example, we could change our rectangle to have a gradient fill, from red to blue, with red at the top, via:

```
<?xml version="1.0" encoding="utf-8"?>
<shape xmlns:android="http://schemas.android.com/apk/res/android"
    android:shape="rectangle">

    <gradient
        android:angle="270"
        android:endColor="#FF0000FF"
        android:startColor="#FFFFFF0000" />

</shape>
```

(from [Drawable/Shape/app/src/main/res/drawable/gradient.xml](#))

That gives us:

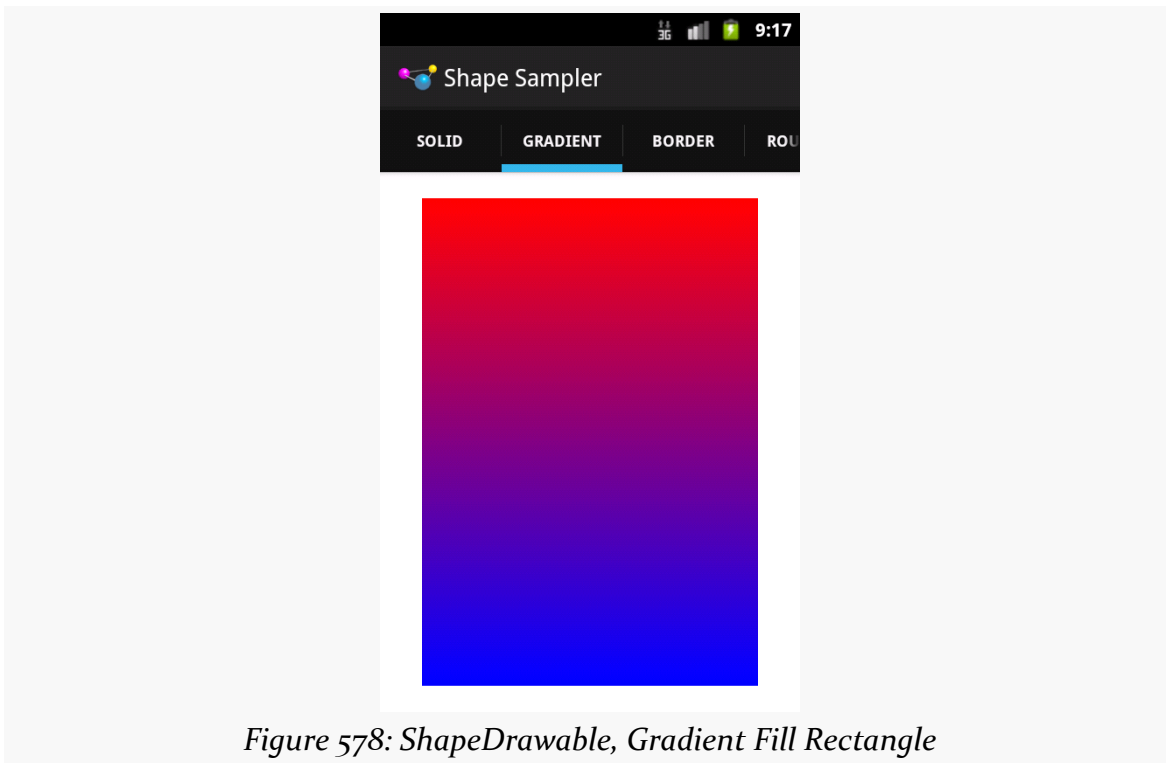

Figure 578: ShapeDrawable, Gradient Fill Rectangle

We will examine some other gradient options in the section on rings, [later in this chapter](#).

<stroke>

If you want a separate color for a border around your shape, you can use the `<stroke>` element, as a child of the `<shape>` element, to configure one.

There are four attributes that you can declare. The two that you will probably always use are `android:color` (to indicate the color of the border) and `android:width` (to indicate the thickness of the border). By default, using just those two will give you a solid line around the edge of your shape.

If you would prefer a dashed border, you can add in `android:dashWidth` (to indicate how long each dash segment should be) and `android:dashGap` (to indicate how long the gaps between dash segments should be).

So, for example, we can add a dashed border to our gradient rectangle via a suitable `<stroke>` element:

CUSTOM DRAWABLES

```
<?xml version="1.0" encoding="utf-8"?>
<shape xmlns:android="http://schemas.android.com/apk/res/android"
    android:shape="rectangle">

    <gradient
        android:angle="270"
        android:endColor="#FF0000FF"
        android:startColor="#FFFF0000" />

    <stroke
        android:width="2dp"
        android:dashGap="4dp"
        android:dashWidth="20dp"
        android:color="#FF000000" />

</shape>
```

(from [Drawable/Shape/app/src/main/res/drawable/border.xml](#))

This gives us:

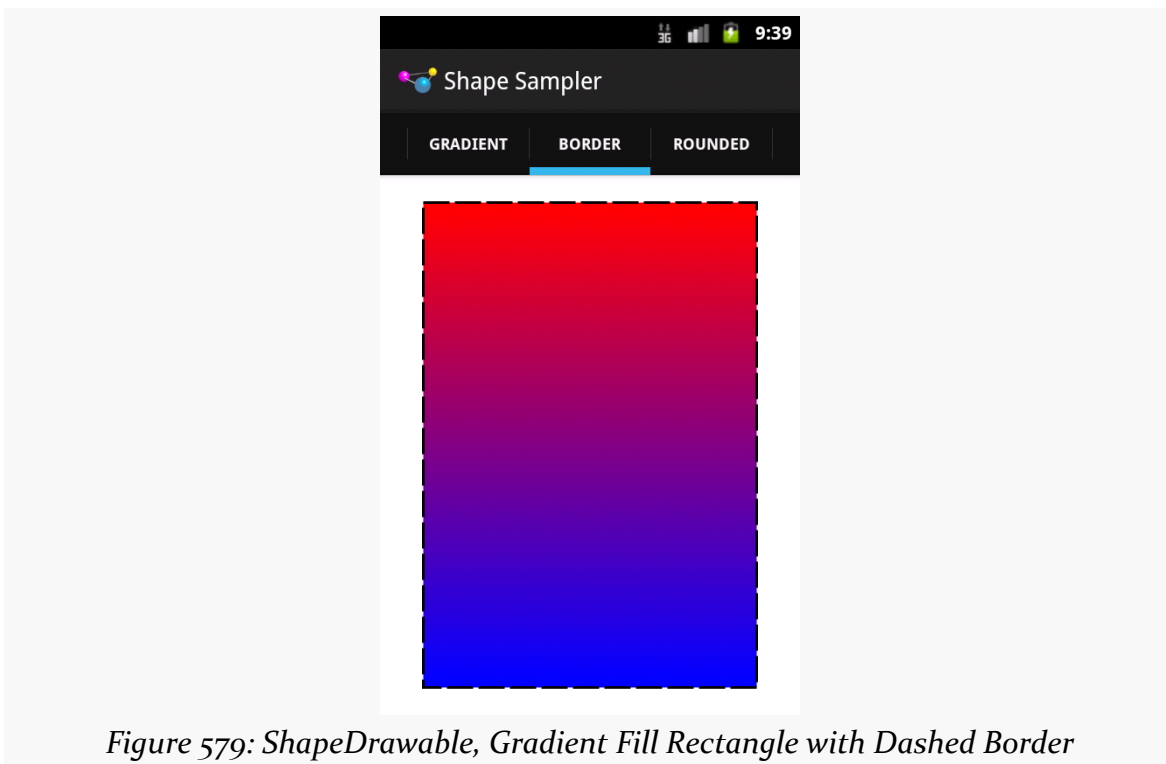

Figure 579: ShapeDrawable, Gradient Fill Rectangle with Dashed Border

<corners>

If we are implementing a rectangle shape, but we really want it to be a rounded rectangle, we can add a <corners> element as a child of the <shape> element. You can specify the radius to apply to the corners, either for all corners (e.g., `android:radius`), or for individual corners (e.g., `android:topLeftRadius`). Here, “radius” basically means the size of the circle that should implement the corner, where a radius of `0dp` would indicate the default square corner.

So, if we wanted to add rounded corners to our gradient-filled, dash-outlined rectangle, we could use this:

```
<?xml version="1.0" encoding="utf-8"?>
<shape xmlns:android="http://schemas.android.com/apk/res/android"
    android:shape="rectangle">

    <gradient
        android:angle="270"
        android:endColor="#FF0000FF"
        android:startColor="#FFFF0000" />

    <stroke
        android:dashGap="4dp"
        android:dashWidth="20dp"
        android:width="2dp"
        android:color="#FF000000" />

    <corners android:radius="8dp" />

</shape>
```

(from [Drawable/Shape/app/src/main/res/drawable/rounded.xml](#))

This gives us the following:

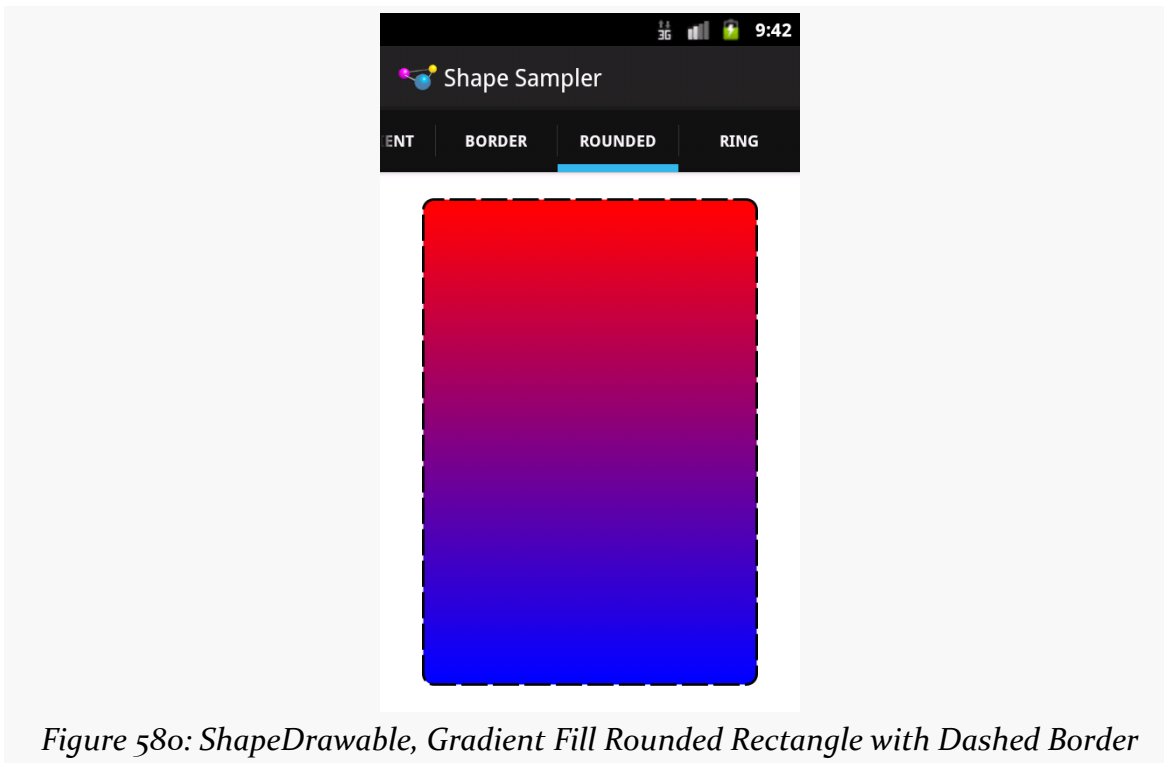

Figure 580: *ShapeDrawable*, Gradient Fill Rounded Rectangle with Dashed Border

<padding> and <size>

There are also `<padding>` and `<size>` elements that you can add, that specify padding to put on the various sides and the overall size of the drawable. More often than not, you would actually handle this on the `ImageView` or other widget that is using your drawable, but if you would prefer to define those things in the drawable itself, you are welcome to do so.

Put a Ring On It

Rings are a bit more complicated, in large part because they are not completely filled. With a ring, the “fill” is filling what goes in the ring itself, not the “hole” in the center of the ring. This means that we need to teach Android more about how that “hole” is supposed to be set up.

To do that, we need to provide two pieces of information:

1. How big the inner radius should be, where by “inner radius” Android means “the radius of the hole”
2. How thick the ring should be

CUSTOM DRAWABLES

The ring will then be drawn based upon that inner radius and thickness.

You might wonder, “well, where does the size of the actual drawable come into play?” After all, if we specify an inner radius of 20dp and a thickness of 10dp, that would give us an outer radius of 30dp, for a total width of 60dp... regardless of how big the actual drawable is.

And that is completely correct.

However, for both the inner radius and the thickness, you have two choices of how to specify their values:

1. As actual sizes (dimensions or references to dimension resources)
2. As ratios to the overall drawable width (defined by `<size>` or the widget that is using the drawable)

This gives us four total attributes to choose from, to be placed on the `<shape>` element for ring drawables:

1. `android:innerRadius`
2. `android:innerRadiusRatio`
3. `android:thickness`
4. `android:thicknessRatio`

Therefore, if you want the ring’s size to be based on the size of the drawable, you would use `innerRadiusRatio`, `thicknessRatio`, or both.

The other thing about rings is that they are round. Hence, a default linear gradient fill — going from one side of the drawable to another — may not be what you really want. You can control the type of gradient fill to use via the `android:type` attribute on the `<gradient>` element. There are three possible values:

1. `linear` (the default behavior)
2. `radial`, where the gradient starts from the center (or another point that you define) and changes color from that center to the edges
3. `sweep`, where the gradient revolves clockwise in a circle, starting from whatever `android:angle` you specify (or 0, meaning “east”, as the default)

So, for example, take a look at the following `ShapeDrawable`:

```
<?xml version="1.0" encoding="utf-8"?>
<shape xmlns:android="http://schemas.android.com/apk/res/android"
```

CUSTOM DRAWABLES

```
android:innerRadiusRatio="3"
android:shape="ring"
android:thickness="15dp"
android:useLevel="false">

<gradient
  android:centerColor="#4c737373"
  android:endColor="#ff9933CC"
  android:startColor="#4c737373"
  android:type="sweep"/>

</shape>
```

(from [Drawable/Shape/app/src/main/res/drawable/ring.xml](#))

Here, we:

- Declare that our shape is a ring
- Indicate that the distance between the inner radius and the outer radius of the ring should be 15dp
- Indicate that there is a 3:1 ratio between the width of the image and the radius of the “hole” in the ring
- Indicate that the fill should be a gradient that sweeps clockwise from the default angle of 0
- Indicate that the first half of the gradient (start to center) should remain a constant color
- Indicate that the second half of the gradient (center to end) should change color from gray to purple

We also have `android:useLevel="false"` in the `<shape>` element. For unknown reasons, this is required for rings but not for other types of shapes.

This gives us:

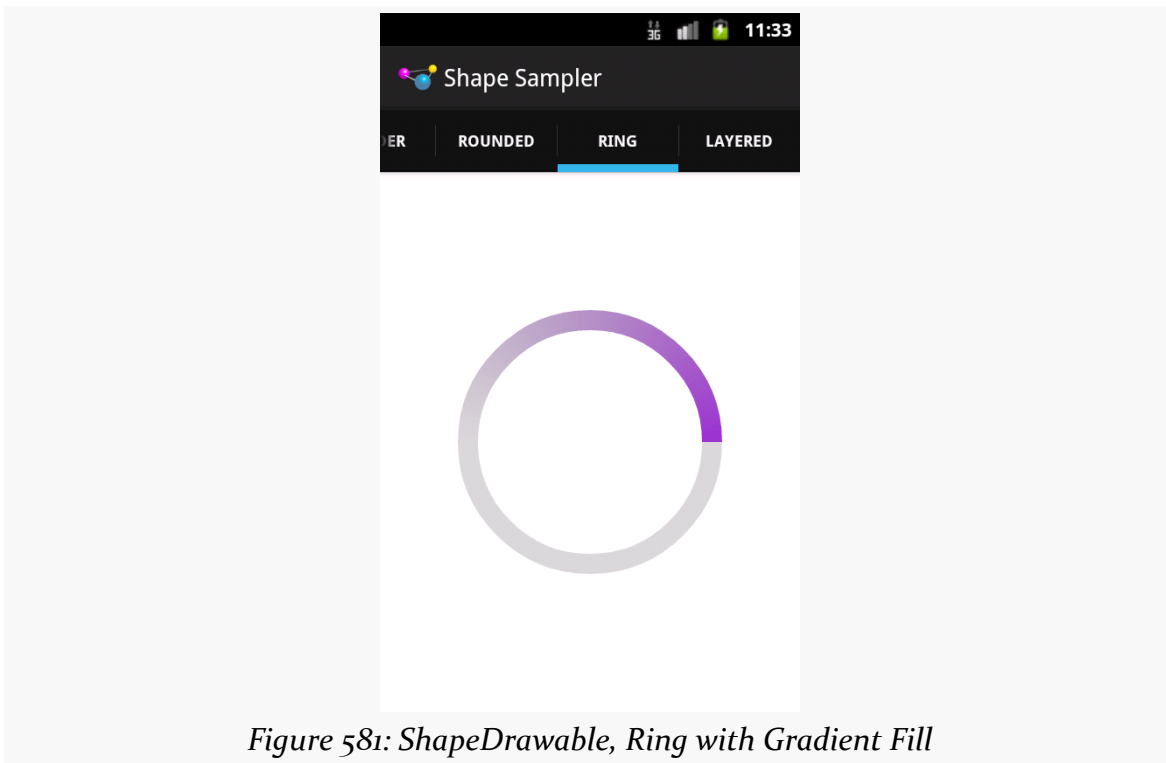

Figure 581: ShapeDrawable, Ring with Gradient Fill

BitmapDrawable

Having an XML drawable format named `BitmapDrawable` may seem like a contradiction in terms. However, `BitmapDrawable` is not an XML representation of a bitmap, but rather an XML representation of operations to perform on an actual bitmap.

The big thing that `BitmapDrawable` offers is `android:tileMode`, which turns a single bitmap into a repeating bitmap. The bitmap is tiled, horizontally and vertically, using a tiling mode that you specify.

This is demonstrated in the [Drawable/TileMode](#) sample project.

Our activity's layout is just a `LinearLayout`, set to fill the screen:

```
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
  xmlns:tools="http://schemas.android.com/tools"
  android:id="@+id/widget"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
```

CUSTOM DRAWABLES

```
    android:orientation="horizontal">
</LinearLayout>
```

(from [Drawable/TileMode/app/src/main/res/layout/activity_main.xml](#))

Our activity populates action bar tabs, where it applies a particular background image to the LinearLayout (known as `R.id.widget`) based on the selected tab:

```
package com.commonware.android.tilemode;

import android.app.ActionBar;
import android.app.ActionBar.Tab;
import android.app.ActionBar.TabListener;
import android.app.Activity;
import android.app.FragmentTransaction;
import android.os.Bundle;
import android.view.View;

public class MainActivity extends Activity implements TabListener {
    private static final int TABS[] = { R.string._default, R.string.clamp,
        R.string.repeat, R.string.mirror };
    private static final int DRAWABLES[] = { R.drawable._default,
        R.drawable.clamp, R.drawable.repeat, R.drawable.mirror };
    private View widget=null;

    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.activity_main);

        widget=findViewById(R.id.widget);

        ActionBar bar=getActionBar();
        bar.setNavigationMode(ActionBar.NAVIGATION_MODE_TABS);

        for (int i=0; i < TABS.length; i++) {
            bar.addTab(bar.newTab().setText(getString(TABS[i]))
                .setTabListener(this));
        }
    }

    @Override
    public void onTabSelected(Tab tab, FragmentTransaction ft) {
        widget.setBackgroundResource(DRAWABLES[tab.getPosition()]);
    }

    @Override
```

CUSTOM DRAWABLES

```
public void onTabUnselected(Tab tab, FragmentTransaction ft) {  
    // no-op  
}  
  
@Override  
public void onTabReselected(Tab tab, FragmentTransaction ft) {  
    // no-op  
}  
}
```

(from [Drawable/TileMode/app/src/main/java/com/commonsware/android/tilemode/MainActivity.java](#))

The `res/drawable/_default.xml` resource, used on the first tab, is an unadorned `BitmapDrawable` resource, where our `<bitmap>` element simply has an `android:src` attribute pointing to a bitmap to be used for this `BitmapDrawable`:

```
<bitmap xmlns:android="http://schemas.android.com/apk/res/android"  
    android:src="@drawable/hatch"/>
```

(from [Drawable/TileMode/app/src/main/res/drawable/_default.xml](#))

Since we have not specified a tile mode, the image is stretched to fill the size of our `LinearLayout` when serving as its background:

Figure 582: BitmapDrawable, Without android:tileMode

CUSTOM DRAWABLES

The `res/drawable/clamp.xml` resource, used on the second tab, adds `android:tileMode="clamp"`:

```
<bitmap xmlns:android="http://schemas.android.com/apk/res/android"
  android:src="@drawable/hatch"
  android:tileMode="clamp"/>
```

(from [Drawable/TileMode/app/src/main/res/drawable/clamp.xml](#))

This causes the right-most column of pixels and the bottom-most row of pixels to be repeated to fill the available space:

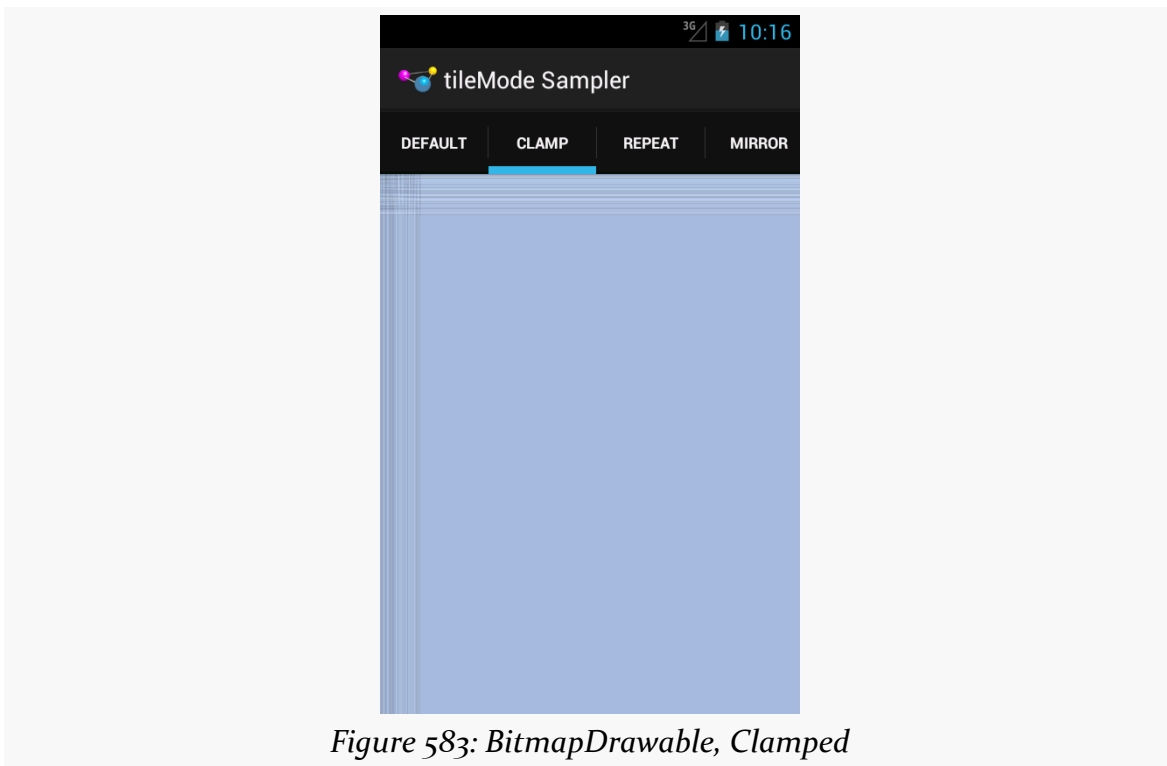

Figure 583: BitmapDrawable, Clamped

Zooming in on the upper-left portion of our `LinearLayout` demonstrates this:

The `res/drawable/repeat.xml` resource, used on the third tab, employs `android:tileMode="repeat"`:

```
<bitmap xmlns:android="http://schemas.android.com/apk/res/android"
  android:src="@drawable/hatch"
  android:tileMode="repeat"/>
```

(from [Drawable/TileMode/app/src/main/res/drawable/repeat.xml](#))

Here, the image is simply repeated *in toto* to fill the available space, rather than only its lower-right edges:

CUSTOM DRAWABLES

Figure 585: BitmapDrawable, Repeated

Zooming in on an arbitrary chunk of the LinearLayout shows this effect:

Figure 586: Portion of BitmapDrawable, Repeated

CUSTOM DRAWABLES

The `res/drawable/mirror.xml` resource, used on the fourth tab, uses `android:tileMode="mirror"`:

```
<bitmap xmlns:android="http://schemas.android.com/apk/res/android"
  android:src="@drawable/hatch"
  android:tileMode="mirror"/>
```

(from [Drawable/TileMode/app/src/main/res/drawable/mirror.xml](#))

Here, the image is repeated, but alternately mirrored along the repeating axis. So, it is flipped horizontally for each repeat along the horizontal axis, and it is flipped vertically for each repeat along the vertical axis:

Zooming in on an arbitrary chunk of the `LinearLayout` shows this effect:

Figure 588: Portion of BitmapDrawable, Mirrored

Composite Drawables

Let's say that we wanted to have a pair of ShapeDrawable images, one superimposed on another. Since a single ShapeDrawable defines only one shape, we would need something else to assist with stacking the images.

One possibility would be to use a LayerDrawable, creating three total resources:

1. The first ShapeDrawable, in its own resource file
2. The second ShapeDrawable, in its own resource file
3. The LayerDrawable, holding references to the two ShapeDrawable resources

And this will certainly work. But you have an alternative: put all of it into a single drawable resource.

An `android:drawable` attribute in an `<item>` element can be replaced by child elements representing another drawable structure. Hence, rather than having a LayerDrawable with two `<item>` elements pointing to other drawable resources, we could have those same `<item>` elements *contain* the other drawable XML structures, and thereby cut our number of files from 3 to 1.

For example, we could have something like this:

```
<?xml version="1.0" encoding="utf-8"?>
<layer-list xmlns:android="http://schemas.android.com/apk/res/android">

  <item>
    <shape android:shape="rectangle">
      <gradient
```

CUSTOM DRAWABLES

```
        android:angle="270"
        android:endColor="#FF0000FF"
        android:startColor="#FFFFFF000" />

        <stroke
            android:dashGap="4dp"
            android:dashWidth="20dp"
            android:width="2dp"
            android:color="#FF000000" />

        <corners android:radius="8dp" />
    </shape>
</item>
<item>
    <shape
        android:innerRadiusRatio="3"
        android:shape="ring"
        android:thickness="15dp"
        android:useLevel="false">
        <gradient
            android:endColor="#FFFFFFF"
            android:startColor="#ff000000"
            android:type="sweep" />
    </shape>
</item>
</layer-list>
```

(from [Drawable/Shape/app/src/main/res/drawable/layered.xml](#))

This is a LayerDrawable, layering two ShapeDrawable structures. The first ShapeDrawable is our dash-bordered, gradient-filled, rounded rectangle from before. The second ShapeDrawable is a ring with a simple gradient sweep fill, from black to white.

This gives us:

CUSTOM DRAWABLES

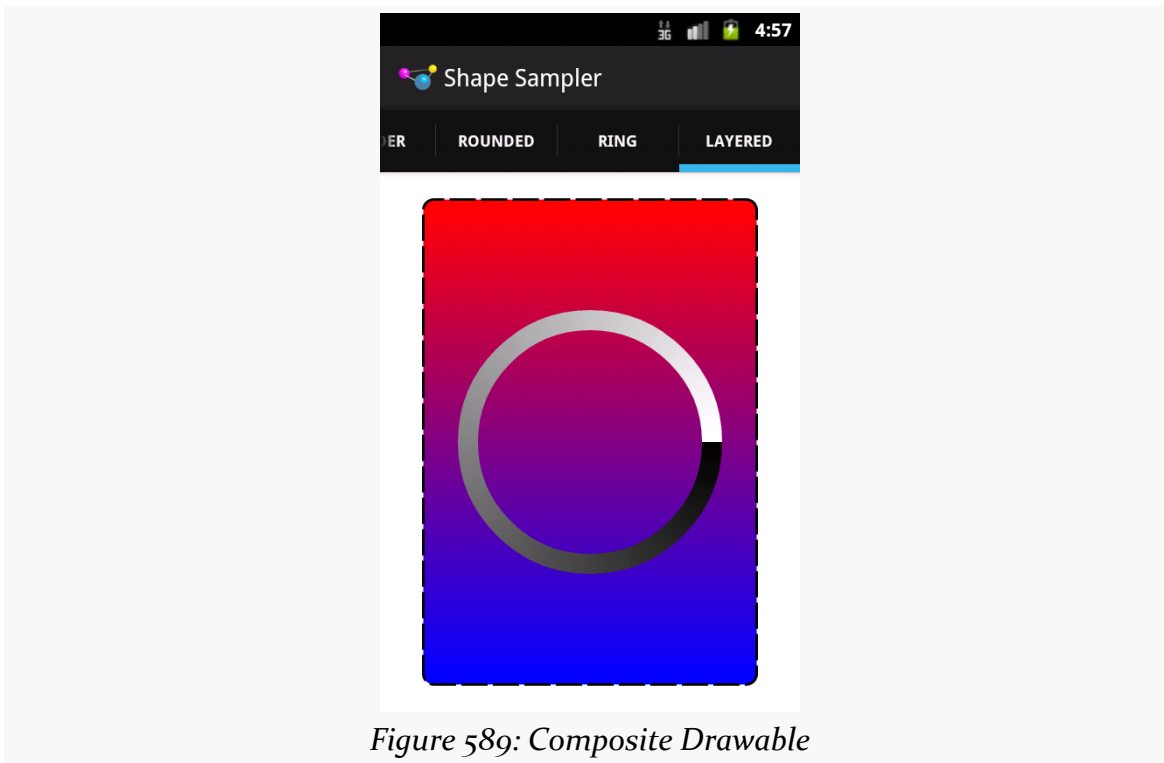

Figure 589: Composite Drawable

Hence, any of the drawable XML structures other than ShapeDrawable can, in their `<item>` elements, hold any drawable XML structure, instead of pointing to another separate resource.

Android uses this trick as well. For example, the stock ProgressBar image is based off of a LayerDrawable wrapped around three ShapeDrawable structures:

```

                    android:angle="270"
                />
            </shape>
        </clip>
    </item>
</layer-list>
```

We will get into how this works with a `ProgressBar` in [a separate chapter](#).

A Stitch In Time Saves Nine

Most of the types of non-traditional drawable resources you can create in Android are described in XML... but not all.

As you read through the Android documentation, you no doubt ran into references to “nine-patch” or “9-patch” and wondered what Android had to do with [quilting](#). Rest assured, you will not need to take up needlework to be an effective Android developer.

If, however, you are looking to create backgrounds for resizable widgets, like a `Button`, you may wish to work with nine-patch images.

As the Android documentation states, a nine-patch is “a PNG image in which you define stretchable sections that Android will resize to fit the object at display time to accommodate variable sized sections, such as text strings”. By using a specially-created PNG file, Android can avoid trying to use vector-based formats (e.g., `ShapeDrawable`) and their associated overhead when trying to create a background at runtime. Yet, at the same time, Android can still resize the background to handle whatever you want to put inside of it, such as the text of a `Button`.

In this section, we will cover some of the basics of nine-patch graphics, including how to customize and apply them to your own Android layouts.

Note that nine-patch PNG files, while they provide stretching rules, are still somewhat dependent upon density. You may wish to have different versions of your nine-patch PNG files for different densities, and therefore these images should be put in density-specific resource directories (e.g., `res/drawable-hdpi/`).

The Name and the Border

Nine-patch graphics are PNG files whose names end in `.9.png`. This means they can be edited using normal graphics tools, but Android knows to apply nine-patch rules to their use.

What makes a nine-patch graphic different than an ordinary PNG is a one-pixel-wide border surrounding the image. When drawn, Android will remove that border, showing only the stretched rendition of what lies inside the border. The border is

used as a control channel, providing instructions to Android for how to deal with stretching the image to fit its contents.

Padding and the Box

Along the right and bottom sides, you can draw one-pixel-wide black lines to indicate the “padding box”. Android will stretch the image such that the contents of the widget will fit inside that padding box.

For example, suppose we are using a nine-patch as the background of a Button. When you set the text to appear in the button (e.g., “Hello, world!”), Android will compute the size of that text, in terms of width and height in pixels. Then, it will stretch the nine-patch image such that the text will reside inside the padding box. What lies outside the padding box forms the border of the button, typically a rounded rectangle of some form.

Stretch Zones

To tell Android where on the image to actually do the stretching, draw one-pixel-wide black lines on the top and left sides of the image. Android will scale the graphic only in those areas — areas outside the stretch zones are not stretched.

Perhaps the most common pattern is the center-stretch, where the middle portions of the image on both axes are considered stretchable, but the edges are not:

Here, the stretch zones will be stretched just enough for the contents to fit in the padding box. The edges of the graphic are left unstretched.

Some additional rules to bear in mind:

1. If you have multiple discrete stretch zones along an axis (e.g., two zones separated by whitespace), Android will stretch both of them but keep them in their current proportions. So, if the first zone is twice as wide as the second zone in the original graphic, the first zone will be twice as wide as the second zone in the stretched graphic.

2. If you leave out the control lines for the padding box, it is assumed that the padding box and the stretch zones are one and the same.

Tooling

Android Studio has a nine-patch PNG editor, based on the now-discontinued `draw9patch` utility used previously by Android app developers. To work with this tool:

- If you have a regular PNG that you want to convert into a nine-patch PNG, right-click over it and choose “Create 9-patch file” from the context menu
- If you already have a nine-patch PNG (with the `.9.png` extension), or you created one using “Create 9-patch file”, just double-click on the image to bring it up in a nine-patch editor

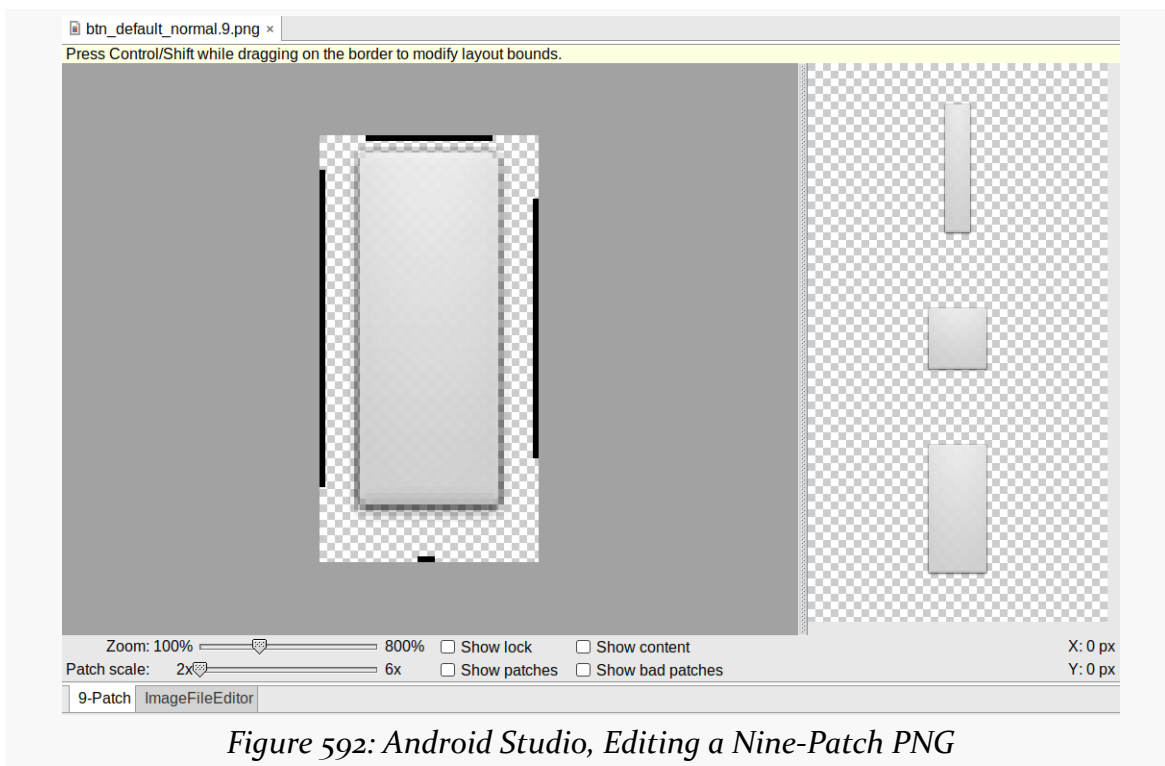

Figure 592: Android Studio, Editing a Nine-Patch PNG

While a regular graphics editor would allow you to draw any color on any pixel, the nine-patch editor limits you to drawing or erasing pixels in the control area:

- Set a pixel (making it black) by clicking on it
- Clear a pixel by shift-clicking on it

If you attempt to draw inside the main image area itself, you will be blocked.

On the right, you will see samples of the image in various stretched sizes, so you can see the impact as you change the stretchable zones and padding box.

While this is convenient for working with the nine-patch nature of the image, you will still need some other graphics editor to create or modify the body of the image itself. For example, the image shown above, from the [Drawable/NinePatch](#) project, is a modified version of a nine-patch graphic from the SDK's [ApiDemos](#), where the GIMP was used to add the neon green stripe across the bottom portion of the image.

Using Nine-Patch Images

Nine-patch images are most commonly used as backgrounds, as illustrated by the following layout from the [Drawable/NinePatch](#) sample project:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:orientation="vertical"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    >
    <TableLayout
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:stretchColumns="1"
    >
    <TableRow
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
    >
        <TextView
            android:layout_width="wrap_content"
            android:layout_height="wrap_content"
            android:layout_gravity="center_vertical"
            android:text="Horizontal:"
        />
        <SeekBar android:id="@+id/horizontal"
            android:layout_width="match_parent"
            android:layout_height="wrap_content"
        />
    </TableRow>
    <TableRow
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
```

CUSTOM DRAWABLES

```
>
  <TextView
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:layout_gravity="center_vertical"
    android:text="Vertical:"
  />
  <SeekBar android:id="@+id/vertical"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
  />
</TableRow>
</TableLayout>
<LinearLayout
  android:orientation="vertical"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  >
  <Button android:id="@+id/resize"
    android:layout_width="96px"
    android:layout_height="96px"
    android:text="Hi!"
    android:textSize="10sp"
    android:background="@drawable/button"
  />
</LinearLayout>
</LinearLayout>
```

(from [Drawable/NinePatch/app/src/main/res/layout/main.xml](#))

Here, we have two SeekBar widgets, labeled for the horizontal and vertical axes, plus a Button set up with our nine-patch graphic as its background (android:background = "@drawable/button").

The NinePatchDemo activity then uses the two SeekBar widgets to let the user control how large the button should be drawn on-screen, starting from an initial size of 64px square:

```
package com.commonware.android.ninepatch;

import android.app.Activity;
import android.os.Bundle;
import android.view.View;
import android.view.ViewGroup;
import android.widget.LinearLayout;
import android.widget.SeekBar;

public class NinePatchDemo extends Activity {
    SeekBar horizontal=null;
```

CUSTOM DRAWABLES

```
SeekBar vertical=null;
View thingToResize=null;

@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.main);

    thingToResize=findViewById(R.id.resize);

    horizontal=(SeekBar)findViewById(R.id.horizontal);
    vertical=(SeekBar)findViewById(R.id.vertical);

    horizontal.setMax(144); // 240 less 96 starting size
    vertical.setMax(144); // keep it square @ max

    horizontal.setOnSeekBarChangeListener(h);
    vertical.setOnSeekBarChangeListener(v);
}

SeekBar.OnSeekBarChangeListener h=new SeekBar.OnSeekBarChangeListener() {
    public void onProgressChanged(SeekBar seekBar,
        int progress,
        boolean fromTouch) {
        ViewGroup.LayoutParams old=thingToResize.getLayoutParams();
        ViewGroup.LayoutParams current=new LinearLayout.LayoutParams(64+progress,
            old.height);

        thingToResize.setLayoutParams(current);
    }

    public void onStartTrackingTouch(SeekBar seekBar) {
        // unused
    }

    public void onStopTrackingTouch(SeekBar seekBar) {
        // unused
    }
};

SeekBar.OnSeekBarChangeListener v=new SeekBar.OnSeekBarChangeListener() {
    public void onProgressChanged(SeekBar seekBar,
        int progress,
        boolean fromTouch) {
        ViewGroup.LayoutParams old=thingToResize.getLayoutParams();
        ViewGroup.LayoutParams current=new LinearLayout.LayoutParams(old.width,
            64+progress);

        thingToResize.setLayoutParams(current);
    }

    public void onStartTrackingTouch(SeekBar seekBar) {
        // unused
    }

    public void onStopTrackingTouch(SeekBar seekBar) {
        // unused
    }
};
}
```

CUSTOM DRAWABLES

(from [Drawable/NinePatch/app/src/main/java/com/commonsware/android/ninepatch/NinePatchDemo.java](#))

The result is an application that can be used much like the right pane of `draw9patch`, to see how the nine-patch graphic looks on an actual device or emulator in various sizes:

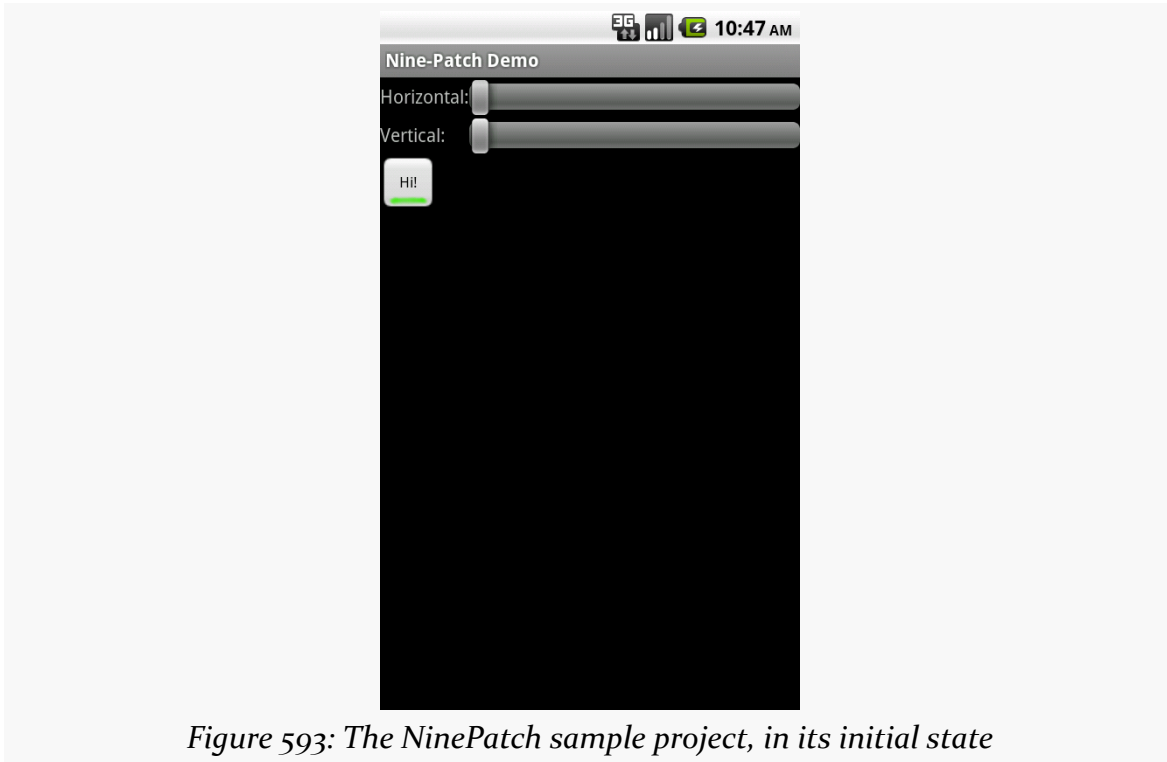

Figure 593: The NinePatch sample project, in its initial state

Mapping with Maps V2

One of Google's most popular services — after search, of course – is Google Maps, where you can find everything from the nearest pizza parlor to directions from New York City to San Francisco (only 2,905 miles!) to street views and satellite imagery.

Android has had mapping capability from the beginning, with an API available to us as developers to bake maps into our apps. However, as we will [see shortly](#), that original API was getting a bit stale.

In December 2012, Google released a long-awaited update to the mapping capabilities available to Android app developers. The original mapping solution, now known as the Maps V1, worked but had serious limitations. The new mapping solution, known as Maps V2, offers greater power and greater ease of handling common situations, though it too has its rough edges.

Prerequisites

Understanding this chapter requires that you have read the core chapters, along with [the chapter on drawables](#). Also, one of the samples involves [location tracking](#), and another of the samples involves the use of [the animator framework](#).

One section involves the use of Picasso, covered in [the chapter on Internet access](#).

This chapter also makes the occasional reference back to Maps V1 for comparisons, mostly for the benefit of developers already familiar with Maps V1 and looking to migrate to Maps V2. However, prior experience with Maps V1 is not necessary to understand this chapter.

A Brief History of Mapping on Android

Back in the dawn of Android, we were given the Maps SDK add-on. This would allow us to load a firmware-hosted mapping library into our applications, then embed maps into our activities, by means of a `MapView` widget.

And it worked.

More importantly, from the standpoint of users, the results from our apps were visually indistinguishable from the built-in Maps application available on devices that had the Maps SDK add-on.

This was the case through most of 2009. Eventually, though, the Google Maps team wanted to update the Maps application... but, for whatever reason, the decision was made to *not* update the Maps SDK add-on as well. At this point, the Google Maps team effectively forked the Maps SDK add-on, causing the Maps application to diverge from what other Android app developers could deliver. Over time, this feature gap became quite pronounced.

The release of Android 3.0 in early 2011 compounded the problems. Now, we needed to consider using fragments to help manage our code and deliver solutions to all screen sizes. Alas, while we could add maps to our fragments, we could only do so on API Level 11 or higher — the fragments backport from the Android Support package did not work with the Maps SDK add-on.

The release of Maps V2 helped all of this significantly. Now we have proper map support for native and backported versions of the fragment framework. We also have a look and feel that is closer to what the Maps application itself supports. While we still cannot reach feature parity with the Maps application, our SDK apps can at least look like they belong on the same device as the Maps application.

More importantly, as of the time of this writing, Maps V1 is no longer an option for new developers. Those who already have Maps V1 API keys can use Maps V1, but no new Maps V1 API keys are being offered. That leaves you with either using Maps V2 or [some alternative mapping solution](#).

Where You Can Use Maps V2

Many devices will be able to use Maps V2... but not all. Notably:

- Devices need to support OpenGL ES 2.0+, to handle the new vector-based tiles that Maps V2 uses. [Over 99% of Android devices](#) in use today that support the Play Store (or its “Android Market” predecessor) also support OpenGL ES 2.0+.
- Devices will need an update to the Play Services Framework that accompanies the Play Store. Devices that do not have the Play Store — either because they are forever stuck on the old Android Market or, like the Kindle Fire, never had Play Store support in the first place — will be unable to use Maps V2.

[Later in this chapter](#), we will look at other mapping libraries that you could use instead of either of Google’s mapping solutions.

Licensing Terms for Maps V2

As with the original Maps SDK add-on, to use Maps V2, you must agree to [a terms of service agreement](#) to be authorized to embed Google Maps within your application. If you intend to use Maps V2, you should review these terms closely, as they place many restrictions on developers. The most notorious of these is that you cannot use Maps V2 to create an application that offers “real time navigation or route guidance, including but not limited to turn-by-turn route guidance that is synchronized to the position of a user’s sensor-enabled device.”

If you find these terms to be an issue for your application, you may need to consider [alternative mapping solutions](#).

What You Need to Start

If you wish to use Maps V2 in one or more of your Android applications, this section will outline what you need to get started.

Your Signing Key Fingerprint(s)

As with the legacy Maps SDK add-on, you will need fingerprints of your app signing keys, to tie your apps to your Google account and the API keys you will be generating. However, unlike the legacy Maps SDK add-on, the fingerprints you will be using will be created using the SHA-1 hash algorithm, rather than MD5.

MAPPING WITH MAPS V2

First, you will need to know where the keystore is for your signing key. For a production keystore that you created yourself for your production apps, you should know where it is located already. For the debug keystore, used by default during development, the location is dependent upon operating system:

- macOS and Linux: `~/.android/debug.keystore`
- Windows XP: `C:\Documents and Settings\%USER\.android\debug.keystore`
- Windows Vista and Windows 7: `C:\Users\%USER\.android\debug.keystore`

(where `%USER` is your Windows user name)

You will then need to run the `keytool` command, to dump information related to this keystore. The `keytool` command is in your Java SDK, not the Android SDK. You will need to run this from a command line (e.g., Command Prompt in Windows). The specific command to run is:

```
keytool -list -v -keystore ... -alias androiddebugkey -storepass android -keypass android
```

where the `...` is replaced by the path to your debug keystore, enclosed in quotation marks if the path contains spaces. For your production keystore, you would supply your own alias and passwords.

This should emit output akin to:

```
Alias name: androiddebugkey
Creation date: Aug 7, 2011
Entry type: PrivateKeyEntry
Certificate chain length: 1
Certificate[1]:
Owner: CN=Android Debug, O=Android, C=US
Issuer: CN=Android Debug, O=Android, C=US
Serial number: 4e3f2684
Valid from: Sun Aug 07 19:57:56 EDT 2011 until: Tue Jul 30 19:57:56 EDT 2041
Certificate fingerprints:
  MD5:  98:84:0E:36:F0:B3:48:9C:CD:13:EB:C6:D8:7F:F3:B1
  SHA1: E6:C5:81:EB:8A:F4:35:B0:04:84:3E:6E:C3:88:BD:B2:66:52:E7:09
Signature algorithm name: SHA1withRSA
Version: 3
```

You will need to make note of the SHA1 entry (see third line from the bottom of the above sample).

Your Google Account

To sign up for an API key, you need a Google account. Ideally, this account would be the same one you intend to use for submitting apps to the Play Store (if, indeed, you intend to do so).

Your API Key

Given that you are logged into the aforementioned Google account, you can visit [the Google Cloud Console](#) to request access to the Maps V2 API. They have a tendency to keep changing this set of pages, but these instructions were good as of late February 2014:

- Create a project via the “Create project” option, if you have not done so already for something else (e.g., [GCM](#))
- Open your project, then select “APIs & auth” from the left navigation bar, and in there select “APIs”
- Sift through the various APIs until you find “Google Maps Android API v2”, then toggle that on
- Agree to the Terms of Service that appears when you try to toggle on Maps V2 access
- Click “Credentials” in the left navigation bar
- Click the “CREATE NEW KEY” button
- In the popup dialog, choose “Android key”
- In the fields that appear once you chose “Android key”, fill in your app’s package name and your SHA1 fingerprint, then click the “Create” button

This will give you an “API key” that you will need for your application.

If you wish to have more than one app use Maps V2, you can click “Edit allowed Android applications” for a key, to return to the dialog where you can paste in another SHA1 fingerprint and package name, separated by a semicolon. Or, if you prefer, you can create new keys for each application.

For apps that are in (or going to) production, you will need to supply both the debug and production SHA1 fingerprints with your package name. By doing this on the same key, you will use the same API key string for both debug and production builds, which simplifies things a fair bit over the separate API keys you would have used with the legacy Maps SDK add-on.

Also note that a single API key seems to only support a few fingerprint/package pairs. If you try adding a new pair, and the form ignores you, you will need to set up a separate API key for additional pairs.

The Play Services Library

You also need to set up the Google Play Services library for use with your app.

While this used to be published via a separate “Google Repository” that you had to download to your development machine, nowadays, it is part of Google’s overall public Maven repository, the one that `google()` points to in your `build.gradle` files. Most likely, your project is already set up to use this repository.

If so, all you need to do is add a dependency on `com.google.android.gms:play-services-maps` for some likely version (e.g., `com.google.android.gms:play-services-maps:11.6.2`) to your dependencies closure.

Note, though, that starting with version `10.x`, the `minSdkVersion` imposed by the Play Services libraries is `14`. If your desired `minSdkVersion` is lower than that, you will need to remain on older versions of the Play Services libraries.

The Book Samples... And You!

If you wish to try to run the book samples outlined in this chapter, you will need to replace the Maps V2 API key in the manifest with your own.

Setting Up a Basic Map

With that preparation work completed, now you can start working on projects that use the Maps V2 API. In this section, we will review the [MapsV2/Basic](#) sample project, which simply brings up a Maps V2 map of the world.

The Dependency

Android Studio users need an entry in their top-level dependencies closure to pull in the Play Services SDK artifact:

MAPPING WITH MAPS V2

```
dependencies {  
    implementation 'com.google.android.gms:play-services-maps:11.6.2'  
}
```

(from [MapsV2/Basic/app/build.gradle](#))

The Project Setup and the Manifest

This project uses Maps V2, and so it has a reference to that library project.

Our manifest file is fairly traditional, though there are a number of elements in it that are required by Maps V2:

```
<?xml version="1.0" encoding="utf-8"?>  
<manifest package="com.commonware.android.mapsv2.basic"  
    xmlns:android="http://schemas.android.com/apk/res/android"  
    android:versionCode="1"  
    android:versionName="1.0">  
  
    <uses-permission  
        android:name="android.permission.WRITE_EXTERNAL_STORAGE"  
        android:maxSdkVersion="22" />  
  
    <uses-feature  
        android:glEsVersion="0x00020000"  
        android:required="false" />  
  
    <application  
        android:allowBackup="false"  
        android:icon="@drawable/ic_launcher"  
        android:label="@string/app_name">  
        <activity  
            android:name="MainActivity"  
            android:label="@string/app_name">  
            <intent-filter>  
                <action android:name="android.intent.action.MAIN" />  
  
                <category android:name="android.intent.category.LAUNCHER" />  
            </intent-filter>  
        </activity>  
  
        <meta-data  
            android:name="com.google.android.maps.v2.API_KEY"  
            android:value="AIzaSyC4iyT46cB00IdKGcy5EmAxK5uCOQX20y8" />  
  
        <meta-data  
            android:name="com.google.android.gms.version"
```

MAPPING WITH MAPS V2

```
    android:value="@integer/google_play_services_version" />
</application>
</manifest>
```

(from [MapsV2/Basic/app/src/main/AndroidManifest.xml](#))

Specifically:

- We need the `WRITE_EXTERNAL_STORAGE` permissions, but only on Android 5.1 and below, so we can use `android:maxSdkVersion="22"` to only request that permission on older devices
- We need a `<meta-data>` element, with a name of `com.google.android.maps.v2.API_KEY`, whose value is the API key we got from the Google APIs Console for use with this particular package name.
- We can have a second `<meta-data>` element, with a name of `com.google.android.gms.version`, with a value of the `@integer/google_play_services_version` (an integer resource supplied by the Play Services SDK library project). Starting with version 8.1.0 of the Maps V2 library, this element is not essential, as it will be added automatically to our manifest via [the manifest merger process](#). However, code written for older versions of Maps V2 than 8.1.0 will need the element, and there is no particular harm in having it.

We also should include a `<uses-feature>` element for OpenGL ES 2.0. If your app absolutely must be able to run Maps V2, have `android:required="true"` (or drop the `android:required` attribute entirely, as `true` is the default), which will force devices to have OpenGL ES 2.0 to run your app. If your app will gracefully degrade for devices incapable of running Maps V2, use `android:required="false"`, as is shown in the sample.

Beyond those items, everything else in this project is based on what the app needs, more so than what Maps V2 needs. Note, though, that the Play Services SDK library project will add additional items to our manifest, notably requests for a few other permissions, like `INTERNET`. Also note that we used to need to define and use a custom permission, based upon our app's package name and ending in `MAPS_RECEIVE`. This is not required as of Play Services 3.1.59 and the "rev 8" release of the Play Services SDK.

The Play Services Detection

In the fullness of time, all devices that are capable of using Maps V2 will already have the on-device portion of this logic, known as the “Google Play services” app.

However, it is entirely possible, in the short term, that you will encounter devices that are capable of using Maps V2 (e.g., they have OpenGL ES 2.0 or higher), but do not have the “Google Play services” app from the Play Store, and therefore you cannot actually *use* Maps V2 in your app.

This is a departure from the Maps V1 approach, where either the device shipped with maps capability, or it did not, and nothing (legally) could be done to change that state.

To determine whether or not the Maps V2 API is available to you, the best option is to call the `isGooglePlayServicesAvailable()` static method on the `GooglePlayServicesUtil` utility class supplied by the Play Services library. This will return an `int`, with a value of `ConnectionResult.SUCCESS` if Maps V2 can be used right away.

Actually assisting the user to get Maps V2 set up all the way is conceivable but is also bug-riddled and annoying. The `MapsV2/Basic` sample app has an `AbstractMapActivity` base class that is designed to hide most of this annoyance from you. If you wish to know the details of how this works, we will cover it [later in this chapter](#).

The Fragment and Activity

Our main activity — `MainActivity` — extends from the aforementioned `AbstractMapActivity` and simply overrides `onCreate()`, as most activities do:

```
package com.commonware.android.mapsv2.basic;

import android.os.Bundle;

public class MainActivity extends AbstractMapActivity {
    @Override
    protected void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        if (readyToGo()) {
            setContentView(R.layout.activity_main);
        }
    }
}
```

MAPPING WITH MAPS V2

```
}  
}  
}
```

(from [MapsV2/Basic/app/src/main/java/com/commonsware/android/mapsv2/basic/MainActivity.java](#))

We call `setContentView()` to load up the `activity_main` layout resource:

```
<fragment xmlns:android="http://schemas.android.com/apk/res/android"  
    android:id="@+id/map"  
    android:layout_width="match_parent"  
    android:layout_height="match_parent"  
    class="com.google.android.gms.maps.MapFragment" />
```

(from [MapsV2/Basic/app/src/main/res/layout/activity_main.xml](#))

That resource, in turn, has a `<fragment>` element pointing to a `com.google.android.gms.maps.MapFragment` class supplied by the Play Services library. This is a fragment that knows how to display a Maps V2 map. There is a corresponding `com.google.android.gms.maps.SupportMapFragment` class for use with the fragments backport from the Android Support library.

You will notice, though, that we only call `setContentView()` if a `readyToGo()` method returns `true`. The `readyToGo()` method is supplied by the `AbstractMapActivity` class and returns `true` if we are safe to go ahead and use Maps V2, `false` otherwise. In the `false` case, `AbstractMapActivity` will be taking care of trying to get Maps V2 going, and we need do nothing further.

The Result

When you run the app, assuming that Maps V2 is ready for use, you will get a basic map showing a good-sized chunk of the planet:

MAPPING WITH MAPS V2

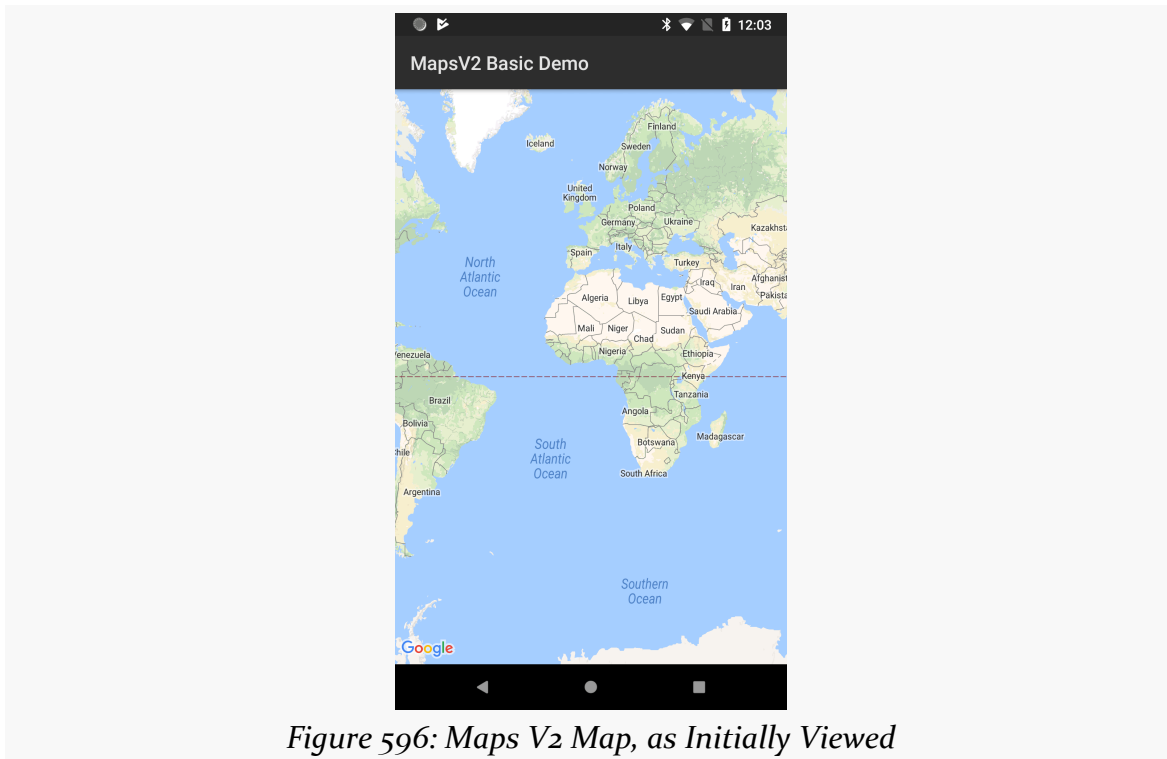

Figure 596: Maps V2 Map, as Initially Viewed

If your Maps V2 API key is incorrect, or you do not have this app’s package name set up for that key in the Google APIs Console, you will get an “Authorization failure” error message in Logcat, and you will get a blank map, akin to the behavior seen in Maps V1 when you had an invalid `android:apiKey` attribute on the `MapView`.

Playing with the Map

Showing a map of a good-sized chunk of the planet is nice, and it is entirely possible that is precisely what you wanted to show the user. If, on the other hand, you wanted to show the user something else — another location, a closer look, etc. — you will need to further configure your map, via a `GoogleMap` object.

To see how this is done, take a look at the [MapsV2/NooYawk](#) sample application. This is a clone of `MapsV2/Basic` that adds in logic to center and zoom the map over a portion of New York City.

The `onCreate()` method of the revised `MapActivity` is now a bit more involved:

```
@Override
protected void onCreate(Bundle savedInstanceState) {
```

MAPPING WITH MAPS V2

```
super.onCreate(savedInstanceState);

if (readyToGo()) {
    setContentView(R.layout.activity_main);

    MapFragment mapFrag=
        (MapFragment)getFragmentManager().findFragmentById(R.id.map);

    if (savedInstanceState == null) {
        mapFrag.getMapAsync(this);
    }
}
}
```

(from [MapsV2/NooYawk/app/src/main/java/com/commonsware/android/mapsv2/nooyawk/MainActivity.java](#))

After calling `setContentView()`, we can retrieve our `MapFragment` via `findFragmentById()`, no different than any other static fragment.

Then, if `savedInstanceState` is `null` — meaning that the activity is not being recreated, but instead is being created from scratch — we call `getMapAsync()` on the `MapFragment`. This triggers some asynchronous work to set up a `GoogleMap` object. `getMapAsync()` takes an implementation of `OnMapReadyCallback` as a parameter. In this case, `OnMapReadyCallback` is implemented on the activity itself.

That `GoogleMap` object will then be delivered to us in `onMapReady()`. Most of our work in configuring the map will be accomplished by calling methods on this `GoogleMap` object:

```
@Override
public void onMapReady(GoogleMap map) {
    CameraUpdate center=
        CameraUpdateFactory.newLatLng(new LatLng(40.76793169992044,
            -73.98180484771729));
    CameraUpdate zoom=CameraUpdateFactory.zoomTo(15);

    map.moveCamera(center);
    map.animateCamera(zoom);
}
```

(from [MapsV2/NooYawk/app/src/main/java/com/commonsware/android/mapsv2/nooyawk/MainActivity.java](#))

To change where the map is centered, we can create a `CameraUpdate` object from the `CameraUpdateFactory` (“camera” in this case referring to the position of the user’s virtual eyes with respect to the surface of the Earth). The `newLatLng()` factory

method on `CameraUpdateFactory` will give us a `CameraUpdate` object that can re-center the map over a supplied latitude and longitude. Those coordinates are encapsulated in a `LatLng` object and are maintained as decimal degrees as Java `float` or `double` values (as opposed to the Maps V1 `GeoPoint`, which used integer microdegrees).

To change the zoom level of the map, we need another `CameraUpdate` object, this time from the `zoomTo()` factory method on `CameraUpdateFactory`. As with Maps V1, the zoom levels start at 1 and zoom in by powers of two. As you will see, a value of 15 gives you a nice block-level view of a city like New York City.

To actually apply these changes to the map, we have two methods on `GoogleMap`:

1. `moveCamera()` will perform a “smash cut” and immediately change the map based upon the supplied `CameraUpdate`
2. `animateCamera()` will smoothly animate the map from its original state to the new state supplied by the `CameraUpdate`

In our case, we immediately shift to the proper position, but then zoom in from the default zoom level to 15, giving us a map centered over Columbus Circle, in the southwest corner of Central Park in Manhattan:

Figure 597: Maps V2 Centered Over Columbus Circle, New York City

Note that you might want to do both actions simultaneously, rather than have one be animated and one not as in this sample. In that case, you can manually create a `CameraPosition` object that describes the desired center, zoom, etc., then use the `newCameraPosition()` method on `CameraUpdateFactory` to get a `CameraUpdate` instance that will apply all of those changes.

Map Tiles

The map, by default, shows the normal tile set. `setMapType()` on the `GoogleMap` allows you to switch to satellite, hybrid (satellite view plus place labels), or terrain tile sets.

Placing Simple Markers

For markers — push-pins and the like — you simply hand markers to the `GoogleMap` for display, as is illustrated in the [MapsV2/Markers](#) sample application. This is a clone of `MapsV2/NooYawk`, with four markers for four landmarks within Manhattan.

MAPPING WITH MAPS V2

Our `onCreate()` method on `MainActivity` now always invokes `getMapAsync()`, not just when the activity is first created. However, we still check `savedInstanceState` and set a new `needsInit` boolean data member to `true` if `savedInstanceState` is `null`:

```
@Override
protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    if (readyToGo()) {
        setContentView(R.layout.activity_main);

        MapFragment mapFrag=
            (MapFragment)getFragmentManager().findFragmentById(R.id.map);

        if (savedInstanceState == null) {
            needsInit=true;
        }

        mapFrag.getMapAsync(this);
    }
}
```

(from [MapsV2/Markers/app/src/main/java/com/commonsware/android/mapsv2/markers/MainActivity.java](#))

Our `onMapReady()` method performs the camera adjustments if `needsInit` is `true`. It also has four additional statements – calls to a private `addMarker()` method to define the four landmarks:

```
@Override
public void onMapReady(GoogleMap map) {
    if (needsInit) {
        CameraUpdate center=
            CameraUpdateFactory.newLatLng(new LatLng(40.76793169992044,
                -73.98180484771729));

        CameraUpdate zoom=CameraUpdateFactory.zoomTo(15);

        map.moveCamera(center);
        map.animateCamera(zoom);
    }

    addMarker(map, 40.748963847316034, -73.96807193756104,
        R.string.un, R.string.united_nations);
    addMarker(map, 40.76866299974387, -73.98268461227417,
        R.string.lincoln_center,
        R.string.lincoln_center_snippet);
    addMarker(map, 40.765136435316755, -73.97989511489868,
```

MAPPING WITH MAPS V2

```
R.string.carnegie_hall, R.string.practice_x3);
addMarker(map, 40.70686417491799, -74.01572942733765,
R.string.downtown_club, R.string.heisman_trophy);
}
```

(from [MapsV2/Markers/app/src/main/java/com/commonsware/android/mapsv2/markers/MainActivity.java](#))

The `addMarker()` method on our `MainActivity` adds markers by creating a `MarkerOptions` object and passing it to the `addMarker()` on `GoogleMap`. `MarkerOptions` offers a so-called “fluent” interface, with a series of methods to affect one aspect of the `MarkerOptions`, each of which returns the `MarkerOptions` object itself. That way, configuring a `MarkerOptions` is a chained series of method calls:

```
private void addMarker(GoogleMap map, double lat, double lon,
    int title, int snippet) {
    map.addMarker(new MarkerOptions().position(new LatLng(lat, lon))
        .title(getString(title))
        .snippet(getString(snippet)));
}
```

(from [MapsV2/Markers/app/src/main/java/com/commonsware/android/mapsv2/markers/MainActivity.java](#))

Here, we:

- Set the `position()` of the marker, in the form of another `LatLng` object
- Set the `title()` and `snippet()` of the marker to be a pair of strings loaded from string resources

We will see other methods available on `MarkerOptions` in upcoming sections of this chapter.

`addMarker()` on `GoogleMap` returns an actual `Marker` object, which we could hold onto to change certain aspects of it later on (e.g., its title). In the case of this sample, we ignore this.

Now, you may be wondering why we set up the markers on every `onMapReady()` invocation, not just in the `needsInit` block. That is because while a `MapFragment` retains its camera information (center, zoom, etc.) on a configuration change, it does *not* retain its markers. Hence, we need to re-establish the markers in all calls to `onCreate()`, not just the very first one.

With no other changes, we get a version of the map that shows markers at our designated locations:

MAPPING WITH MAPS V2

Initially, we only see two markers, as the other two are outside the current center position and zoom level of the map. If the user changes the center or zoom, markers will come and go as needed:

MAPPING WITH MAPS V2

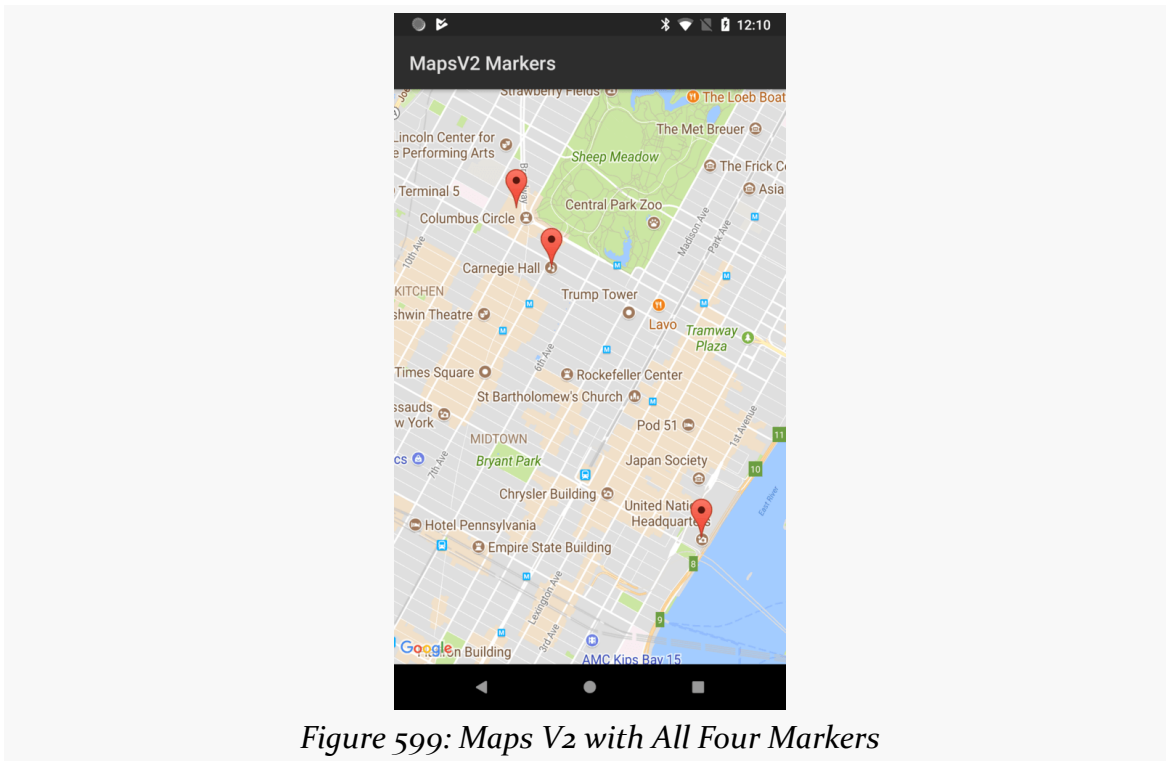

Figure 599: Maps V2 with All Four Markers

We do not need to worry about managing the markers ourselves, so long as the GoogleMap performance is adequate. It is likely that dumping 10,000 markers into a GoogleMap will still result in sluggish responses, though, so you may need to add and remove markers yourself based upon what portion of the world the user happens to be examining in the map at the moment.

Seeing All the Markers

When you add markers to a map, there is no guarantee that the markers will be visible given the map's current center position and zoom level. In fact, it is entirely possible that you add a bunch of markers and *none* are visible, so the user may not realize that the markers were added.

There is a way that you can center and zoom the map to show some set of markers, based on their positions. You get to choose the markers: all of them, the four nearest markers, etc.

MAPPING WITH MAPS V2

We can see how this works in the [MapsV2/Bounds](#) sample application. This is a clone of MapsV2/Markers from the previous section, with reworked code to show all four markers when the map is first displayed.

The key to making this work is a `LatLngBounds` object. This represents a bounding box that contains all `LatLng` locations handed to the `LatLngBounds`. To build up a `LatLngBounds`, you can use the `LatLngBounds.Builder` class. So, our revised `MainActivity` has a `LatLngBounds.Builder` private data member:

```
private LatLngBounds.Builder builder=new LatLngBounds.Builder();
```

(from [MapsV2/Bounds/app/src/main/java/com/commonsware/android/mapsv2/markers/MainActivity.java](#))

Our revised `addMarker()` method adds the `LatLng` values from our markers as they are added to the map:

```
private void addMarker(GoogleMap map, double lat, double lon,
                       int title, int snippet) {
    Marker marker=
        map.addMarker(new MarkerOptions().position(new LatLng(lat, lon))
                     .title(getString(title))
                     .snippet(getString(snippet)));

    builder.include(marker.getPosition());
}
```

(from [MapsV2/Bounds/app/src/main/java/com/commonsware/android/mapsv2/markers/MainActivity.java](#))

Finally, the revised `onMapReady()` moves the `CameraUpdateFactory` work until after all four of the `addMarker()` calls and changes it a bit:

```
@Override
public void onMapReady(final GoogleMap map) {
    addMarker(map, 40.748963847316034, -73.96807193756104,
              R.string.un, R.string.united_nations);
    addMarker(map, 40.76866299974387, -73.98268461227417,
              R.string.lincoln_center,
              R.string.lincoln_center_snippet);
    addMarker(map, 40.765136435316755, -73.97989511489868,
              R.string.carnegie_hall, R.string.practice_x3);
    addMarker(map, 40.70686417491799, -74.01572942733765,
              R.string.downtown_club, R.string.heisman_trophy);

    if (needsInit) {
        findViewById(android.R.id.content).post(new Runnable() {
            @Override
```

MAPPING WITH MAPS V2

```
public void run() {
    CameraUpdate allTheThings=
        CameraUpdateFactory.newLatLngBounds(builder.build(), 32);

    map.moveCamera(allTheThings);
}
});
}
```

(from [MapsV2/Bounds/app/src/main/java/com/commonsware/android/mapsv2/markers/MainActivity.java](#))

Specifically, we:

- Ask the `LatLngBounds.Builder` to `build()` the `LatLngBounds`
- Pass that to the `newLatLngBounds()` method on `CameraUpdateFactory`, along with an inset value in pixels (all `LatLng` locations will be that many pixels in from the edges, or more)
- Use `moveCamera()` to center and zoom the map based upon the resulting `CameraUpdate`

All of this is done in a `Runnable` which we `post()` to a `View` (here, the `FrameLayout` of our activity supplied by Android as `android.R.id.content`). `GoogleMap` cannot ensure that all of our markers are visible until it knows how big the map is, and that is not known until the map is rendered to the screen. `post()` will add our work to the end of the main application thread's work queue. The `Runnable` will not be run until after the map is on the screen, at which time the `CameraUpdate` can work.

Flattening and Rotating Markers

Markers, by default, appear to be “push pins” pressed into the surface of the map. This is not necessarily obvious with the default top-down perspective of the map camera. But, if you use a two-finger vertical swiping gesture, you can change the camera tilt, and that will illustrate the “push pin” effect a bit better:

MAPPING WITH MAPS V2

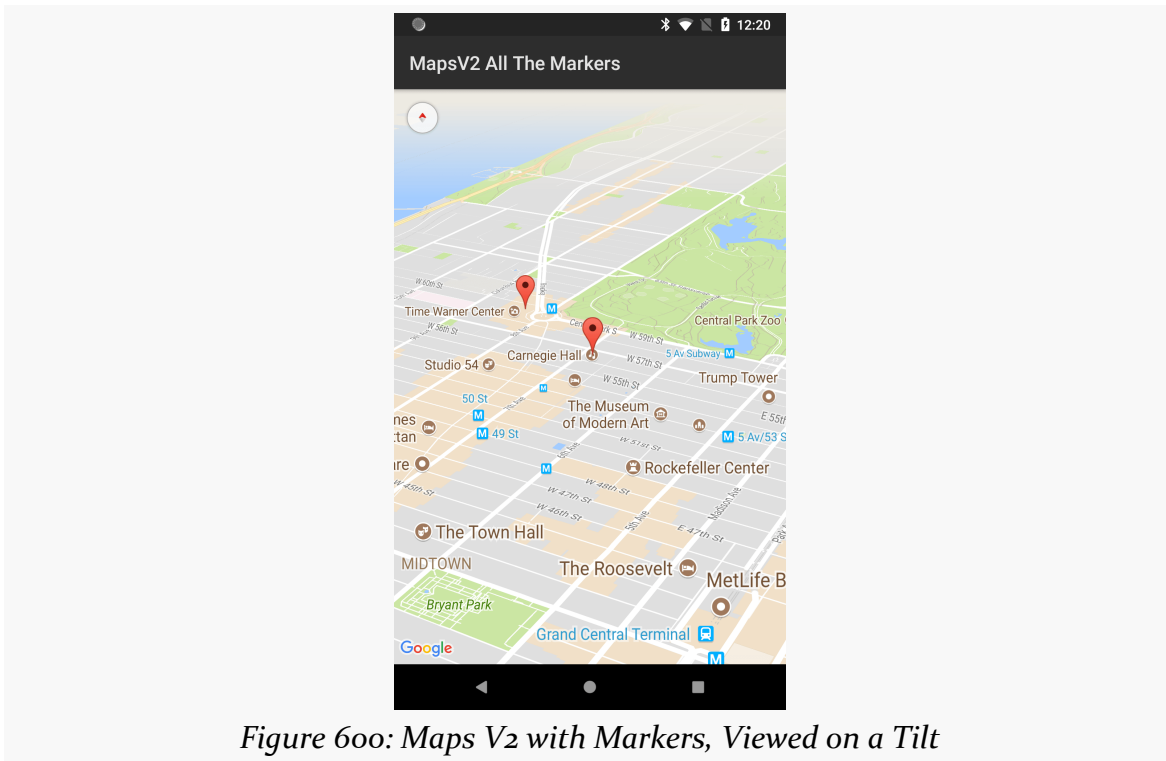

Figure 600: Maps V2 with Markers, Viewed on a Tilt

However, you have options for flat markers and rotated markers.

A flat marker is one that is flat on the map. In other words, rather than theoretically rising out of the Z axis of the map, the marker is kept on the X-Y plane:

MAPPING WITH MAPS V2

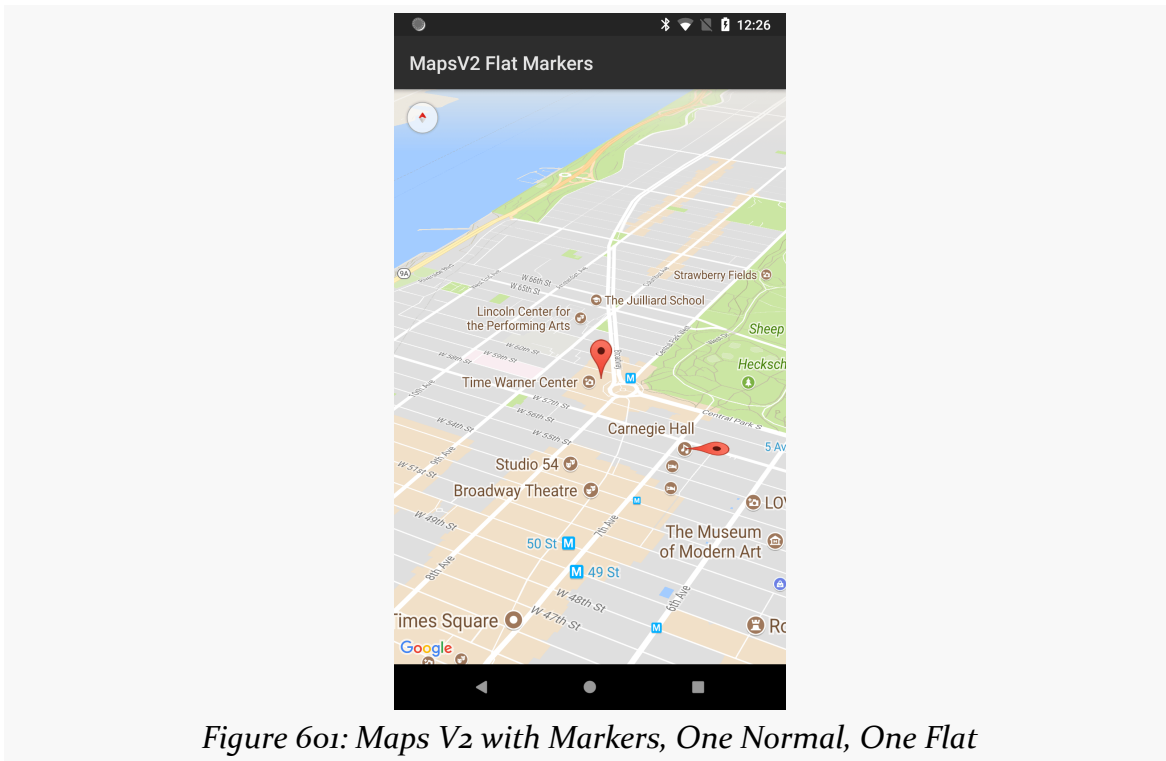

Figure 601: Maps V2 with Markers, One Normal, One Flat

It is also possible to rotate a marker. The flat marker in the previous screenshot is rotated 90 degrees from its normal “bulb on the north side” orientation. The following screenshot shows another flat marker, rotated 270 degrees from normal:

MAPPING WITH MAPS V2

Figure 6o2: Maps V2 with Markers, Flat and Rotated

These features can be handy for providing pointers in a particular direction, such as indicating not only the location to make a turn, but what direction to turn at that location.

These capabilities are courtesy of `flat()` and `rotation()` methods on `MarkerOptions`, plus corresponding getters and setters on `Marker` itself. To see how this works, let's examine the [MapsV2/FlatMarkers](#) sample application. This is a clone of `MapsV2/Markers`, with markers applied using different values for `flat()` and `rotation()`.

Specifically, our own `addMarker()` helper method now takes and applies a boolean parameter for `flat` (`true` means it is flat, `false` means normal behavior), as well as a float parameter for `rotation` (a value between 0 and 360 for the rotation off the default in degrees):

```
private void addMarker(GoogleMap map, double lat, double lon,
    int title, int snippet, boolean flat,
    float rotation) {
    map.addMarker(new MarkerOptions().position(new LatLng(lat, lon))
        .title(getString(title))
        .snippet(getString(snippet))
```

MAPPING WITH MAPS V2

```
        .flat(flat).rotation(rotation));  
    }
```

(from [MapsV2/FlatMarkers/app/src/main/java/com/commonsware/android/mapsv2/flatmarkers/MainActivity.java](#))

When we call `addMarker()`, we supply corresponding values:

```
addMarker(map, 40.748963847316034, -73.96807193756104,  
          R.string.un, R.string.united_nations, false, 180);  
addMarker(map, 40.76866299974387, -73.98268461227417,  
          R.string.lincoln_center,  
          R.string.lincoln_center_snippet, false, 0);  
addMarker(map, 40.765136435316755, -73.97989511489868,  
          R.string.carnegie_hall, R.string.practice_x3, true, 90);  
addMarker(map, 40.70686417491799, -74.01572942733765,  
          R.string.downtown_club, R.string.heisman_trophy, true,  
          270);
```

(from [MapsV2/FlatMarkers/app/src/main/java/com/commonsware/android/mapsv2/flatmarkers/MainActivity.java](#))

Sprucing Up Your “Info Windows”

If the user taps on one of the markers from the preceding sample, Android will automatically display a popup, known as an “info window”:

MAPPING WITH MAPS V2

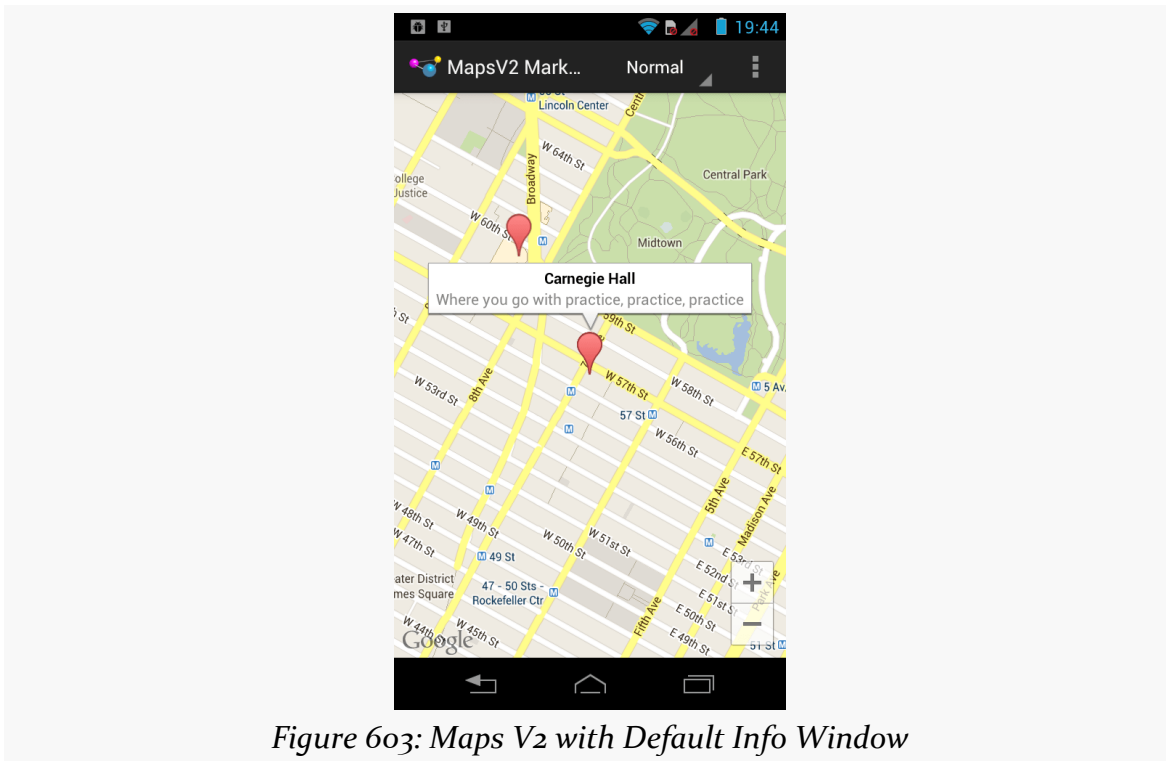

Figure 603: Maps V2 with Default Info Window

You can tailor that “info window” if desired, either replacing just the interior portion (leaving the bounding border with its caret intact) or replacing the entire window. However, in the interests of memory conservation, you do not hand new View widgets to the MarkerOptions object. Instead, you can provide an adapter that will be called when info windows (or their contents) are required.

To see how this works, we can examine the [MapsV2/Popups](#) sample application. This is a clone of MapsV2/Markers, where we are using our own layout file for the contents of the info windows, from the popup.xml layout resource:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:orientation="horizontal">

    <ImageView
        android:id="@+id/icon"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:layout_gravity="center_vertical"
        android:padding="2dip"
```

MAPPING WITH MAPS V2

```
    android:src="@drawable/ic_launcher"
    android:contentDescription="@string/icon"/>

<LinearLayout
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:orientation="vertical">

    <TextView
        android:id="@+id/title"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:textSize="25sp"
        android:textStyle="bold"/>

    <TextView
        android:id="@+id/snippet"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:textSize="15sp"/>
</LinearLayout>
</LinearLayout>
```

(from [MapsV2/Popups/app/src/main/res/layout/popup.xml](#))

Here, we will show the title and snippet in our own chosen font size and weight, plus show the launcher icon on the left.

To use this layout, we must create an `InfoWindowAdapter` implementation — in the case of this sample project, that is found in the `PopupAdapter` class:

```
package com.commonware.android.mapsv2.popups;

import android.annotation.SuppressLint;
import android.view.LayoutInflater;
import android.view.View;
import android.widget.TextView;
import com.google.android.gms.maps.GoogleMap.InfoWindowAdapter;
import com.google.android.gms.maps.model.Marker;

class PopupAdapter implements InfoWindowAdapter {
    private View popup=null;
    private LayoutInflater inflater=null;

    PopupAdapter(LayoutInflater inflater) {
        this.inflater=inflater;
    }
}
```

MAPPING WITH MAPS V2

```
}

@Override
public View getInfoWindow(Marker marker) {
    return(null);
}

@SuppressLint("InflateParams")
@Override
public View getInfoContents(Marker marker) {
    if (popup == null) {
        popup=inflater.inflate(R.layout.popup, null);
    }

    TextView tv=(TextView)popup.findViewById(R.id.title);

    tv.setText(marker.getTitle());
    tv=(TextView)popup.findViewById(R.id.snippet);
    tv.setText(marker.getSnippet());

    return(popup);
}
}
```

(from [MapsV2/Popups/app/src/main/java/com/commonsware/android/mapsv2/popups/PopupAdapter.java](#))

When an info window is to be displayed, Android will first call `getInfoWindow()` on our `InfoWindowAdapter`, passing in the `Marker` whose info window is needed. If we return a `View` here, that will be used for the entire info window. If, instead, we return `null`, Android will call `getInfoContents()`, passing in the same `Marker` object. If we return a `View` here, Android will use that as the “body” of the info window, with Android supplying the border. If we return `null`, the default info window is displayed. This way, we can conditionally do any of the three possibilities (replace the window, replace the contents, or accept the default).

In our case, `getInfoContents()` will inflate the `popup.xml` layout and populate the two `TextView` widgets with the title and snippet from the `Marker`. However, we cache the inflated layout and reuse it on the second and subsequent calls to `getInfoContents()`. Despite the “adapter” name conjuring up visions of `ListAdapter` and having multiple outstanding views, `InfoWindowAdapter` will only ever use one `View` at a time. Hence, rather than inflate our layout each time we need to show the info window, we can safely reuse the previously-used `View`.

MAPPING WITH MAPS V2

Then, we just need to tell the GoogleMap to use our InfoWindowAdapter, via a call to `setInfoWindowAdapter()`, such as this statement from `onMapReady()` of our new edition of `MainActivity`:

```
map.setInfoWindowAdapter(new PopupAdapter(getLayoutInflater()));
```

(from [MapsV2/Popups/app/src/main/java/com/commonsware/android/mapsv2/popups/MainActivity.java](#))

Now, when the user taps on a marker, they will get our customized info window:

We can also call `setOnInfoWindowClickListener()` on our `GoogleMap`, passing in an implementation of the `OnInfoWindowClickListener` interface, to find out when the user taps on the info window. In the case of `MainActivity`, we set up the activity itself to implement that interface and be the listener:

```
map.setOnInfoWindowClickListener(this);
```

(from [MapsV2/Popups/app/src/main/java/com/commonsware/android/mapsv2/popups/MainActivity.java](#))

This requires us to implement an `onInfoWindowClick()` method, where we are passed the `Marker` representing the tapped-upon info window:

```
@Override
public void onInfoWindowClick(Marker marker) {
    Toast.makeText(this, marker.getTitle(), Toast.LENGTH_LONG).show();
}
```

MAPPING WITH MAPS V2

(from [MapsV2/Popups/app/src/main/java/com/commonsware/android/mapsv2/popups/MainActivity.java](#))

Here, we just display a Toast with the title of the Marker when the user taps an info window:

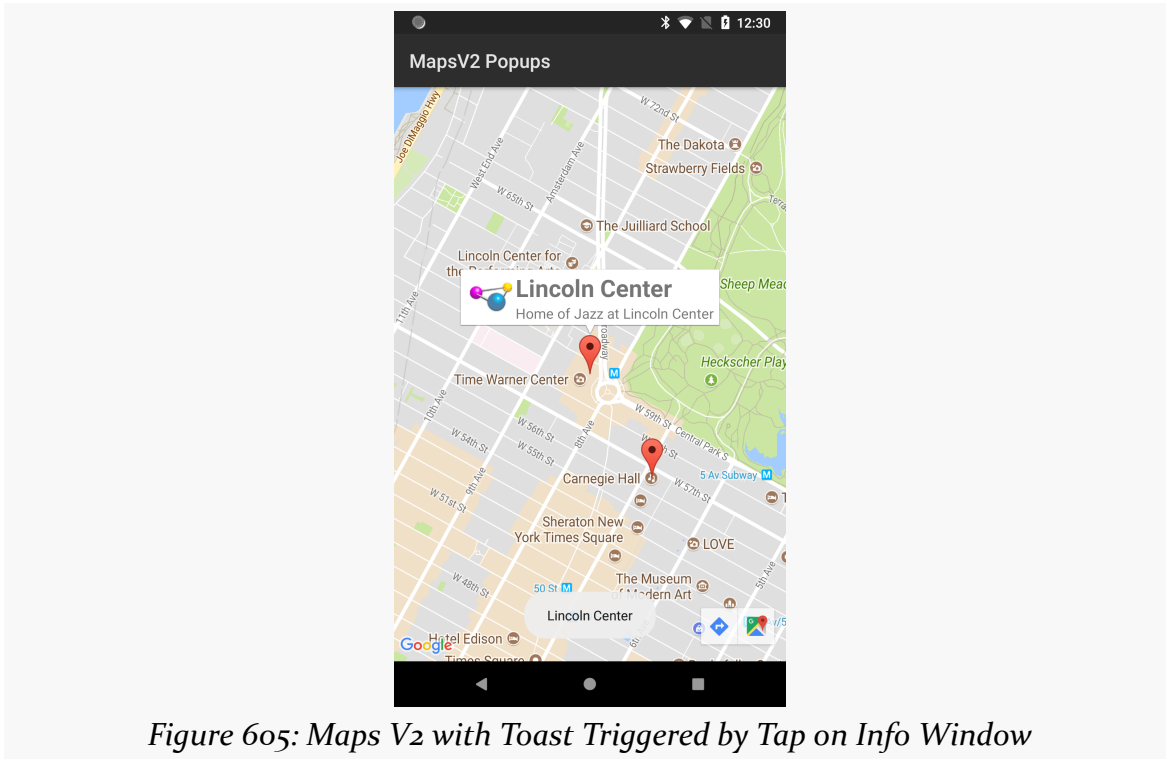

Figure 605: Maps V2 with Toast Triggered by Tap on Info Window

Note that, according to the documentation, you can only find out about taps on the entire info window. Indeed, if you try setting up click listeners on the widgets in your custom layout, you will find that they are not called. This is because the View you return for the info window is converted into a Bitmap, which is then displayed. Presumably, this is to steer developers in the direction of making larger tap targets, rather than expecting users to tap tiny elements within an info window. On the other hand, if your design calls for a large info window containing several navigation options, you will need to either re-think your design or avoid the info window system. We will see how to find out about taps on markers more directly [later in this chapter](#).

Images and Your Info Window

The Bitmap approach that Maps V2 uses for the info window introduces an additional challenge: updating the info window itself. Normally, we would just

update the individual widgets in the info window, the way we might update widgets in an already-visible row in a `ListView`. However, that is not an option here, as our widgets are discarded almost immediately.

One particular occurrence of this problem comes when you want to show an image in the info window. If the image is a resource, or is already in memory, showing it is not a big problem, as you can just populate your `ImageView` in your info window with it. However, if the image is a file (or, worse, needs to be downloaded), you want to load the image asynchronously. However, if you kick off some background thread, like an `AsyncTask`, to retrieve the image, you will return from your `InfoWindowAdapter` method long before the task is complete. Your info window will show whatever placeholder image you used; the image you loaded will never be seen, even if you update your original `ImageView`.

There are two solutions to this problem.

The best solution, by far, is to have the images before you need them, wherever possible. For example, if you are showing a map with 25 markers, for which you need 25 thumbnail images, start downloading those images while you are showing the map. With luck, at the point in time when the user taps on a marker to show the info window, you will have your image already.

However, this approach will not work well if:

- You need a ridiculous number of images, or
- You need images, but they need to be downloaded full-sized and turned into thumbnails locally, as that might consume quite a bit of bandwidth, or
- Your last name is Murphy, and therefore the user taps on an info window before you have had a chance to prepare its image

The workaround is to make note of the `Marker` the user tapped upon to open its info window, then call `showInfoWindow()` on that `Marker` to cause the info window to be redisplayed once you have your image, triggering calls to your `InfoWindowAdapter`. There, you can see that your image cache includes the image that you need, and you can apply it to the info window.

The problem *here* is that it is possible that the user tapped on another marker, after the first one, while you were busily fetching and loading the image. Hence, rather than blindly calling `showInfoWindow()` on the `Marker`, you should call `isInfoWindowShown()` first, and only call `showInfoWindow()` to force the refresh if `isInfoWindowShown()` returns `true`. Otherwise, some other marker's info window is

MAPPING WITH MAPS V2

shown. The user is not expecting this earlier info window to somehow magically reappear.

All of this is a pain. It can be made a bit less of a pain by use of an image fetching-and-caching library like [Picasso](#). We can see how this can be applied by looking at the [MapsV2/ImagePopups](#) sample application. This is a clone of MapsV2/Popups, with some additions to handle lazy-populating an info window based upon a downloaded image.

First, since we are going to be generating some thumbnails based on downloaded imagery, it helps to establish a fixed-size ImageView for our icon. So, this project has a pair of dimension resources, for the image height and width:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
  <dimen name="icon_width">96dp</dimen>
  <dimen name="icon_height">64dp</dimen>
</resources>
```

(from [MapsV2/ImagePopups/app/src/main/res/values/dimens.xml](#))

Those are then used in a revised version of the popup layout resource:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
  android:layout_width="match_parent"
  android:layout_height="wrap_content"
  android:orientation="horizontal">

  <ImageView
    android:id="@+id/icon"
    android:layout_width="@dimen/icon_width"
    android:layout_height="@dimen/icon_height"
    android:padding="2dip"
    android:src="@drawable/ic_launcher"
    android:contentDescription="@string/icon"/>

  <LinearLayout
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:layout_gravity="center_vertical"
    android:orientation="vertical">

    <TextView
      android:id="@+id/title"
```

MAPPING WITH MAPS V2

```
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:textSize="25sp"
        android:textStyle="bold"/>

        <TextView
            android:id="@+id/snippet"
            android:layout_width="wrap_content"
            android:layout_height="wrap_content"
            android:textSize="15sp"/>
    </LinearLayout>
</LinearLayout>
```

(from [MapsV2/ImagePopups/app/src/main/res/layout/popup.xml](#))

We need some way of keeping track of what images should be used for each marker. This is somewhat annoying to implement, as we cannot subclass `Marker`, since it is marked as `final` and cannot be extended. However, we can use `getId()` on a `Marker` to obtain a unique ID, and we can use that as the key to additional model data. We will examine variations on this technique [later in this chapter](#). For now, this sample gets away with a simple `HashMap`, mapping the string ID of a `Marker` to a `Uri` representing an image to be shown for that `Marker`'s info window:

```
private HashMap<String, Uri> images=new HashMap<String, Uri>();
```

(from [MapsV2/ImagePopups/app/src/main/java/com/commonsware/android/mapsv2/imagepopups/MainActivity.java](#))

Our private `addMarker()` method now takes a `String` name of an image, and it adds a `Uri` pointing to that image to the `HashMap`, keyed by the ID of the generated `Marker`:

```
private void addMarker(GoogleMap map, double lat, double lon,
                      int title, int snippet, String image) {
    Marker marker=
        map.addMarker(new MarkerOptions().position(new LatLng(lat, lon))
                      .title(getString(title))
                      .snippet(getString(snippet)));

    if (image != null) {
        images.put(marker.getId(),
                  Uri.parse("http://misc.commonsware.com/mapsv2/"
                            + image));
    }
}
```

(from [MapsV2/ImagePopups/app/src/main/java/com/commonsware/android/mapsv2/imagepopups/MainActivity.java](#))

MAPPING WITH MAPS V2

For three of our markers, we pass in actual filenames; for a fourth, null is used, indicating that there is no suitable image for use:

```
addMarker(map, 40.748963847316034, -73.96807193756104,
          R.string.un, R.string.united_nations, "UN_HQ.jpg");
addMarker(map, 40.76866299974387, -73.98268461227417,
          R.string.lincoln_center,
          R.string.lincoln_center_snippet,
          "Avery_Fisher_Hall.jpg");
addMarker(map, 40.765136435316755, -73.97989511489868,
          R.string.carnegie_hall, R.string.practice_x3,
          "Carnegie_Hall.jpg");
addMarker(map, 40.70686417491799, -74.01572942733765,
          R.string.downtown_club, R.string.heisman_trophy, null);
```

(from [MapsV2/ImagePopups/app/src/main/java/com/commonsware/android/mapsv2/imagepopups/MainActivity.java](#))

Note that the three images being used in this chapter come from Wikipedia. One is public domain, the others are licensed under the Creative Commons Attribution 1.0 license. Those two are a picture of [Avery Fisher Hall](#), part of the Lincoln Center for the Performing Arts (courtesy of [Geographer](#)) and the other is a picture of [the United Nations building](#) (courtesy of [WorldIslandInfo](#)).

The PopupAdapter needs access to these images. It will also need access to a Context, for use with Picasso. So, PopupAdapter now has data members for these, which are passed into a revised version of its constructor by MainActivity. That constructor not only holds onto the new objects, but it retrieves the values of the dimension resources for our images, converted by Android into pixels for the screen density of the device that we are running on:

```
PopupAdapter(Context ctxt, LayoutInflater inflater,
             HashMap<String, Uri> images) {
    this.ctxt=ctxt;
    this.inflater=inflater;
    this.images=images;

    iconWidth=
        ctxt.getResources().getDimensionPixelSize(R.dimen.icon_width);
    iconHeight=
        ctxt.getResources().getDimensionPixelSize(R.dimen.icon_height);
}
```

(from [MapsV2/ImagePopups/app/src/main/java/com/commonsware/android/mapsv2/imagepopups/PopupAdapter.java](#))

MAPPING WITH MAPS V2

The revised `getInfoContents()` method is significantly more complicated than was its predecessor:

```
@SuppressWarnings("InflateParams")
@Override
public View getInfoContents(Marker marker) {
    if (popup == null) {
        popup=inflater.inflate(R.layout.popup, null);
    }

    if (lastMarker == null
        || !lastMarker.getId().equals(marker.getId())) {
        lastMarker=marker;

        TextView tv=(TextView)popup.findViewById(R.id.title);

        tv.setText(marker.getTitle());
        tv=(TextView)popup.findViewById(R.id.snippet);
        tv.setText(marker.getSnippet());

        Uri image=images.get(marker.getId());
        ImageView icon=(ImageView)popup.findViewById(R.id.icon);

        if (image == null) {
            icon.setVisibility(View.GONE);
        }
        else {
            Picasso.with(ctxt).load(image).resize(iconWidth, iconHeight)
                .centerCrop().noFade()
                .placeholder(R.drawable.placeholder)
                .into(icon, new MarkerCallback(marker));
        }
    }

    return(popup);
}
```

(from [MapsV2/ImagePopups/app/src/main/java/com/commonsware/android/mapsv2/imagepopups/PopupAdapter.java](#))

We track the last Marker that we have processed in a `lastMarker` data member. Initially, of course, that will be `null`. If it is, or if the Marker passed into `getInfoContents()` is a different one (based on the `getId()` value), then we populate the popup View. This includes fetching the `Uri` from the `HashMap` of `Uri` values (given the Marker ID). If there is no `Uri`, `getInfoContents()` marks the `ImageView` as `GONE`, so it will not take up space in the popup. If, however, there is an image `Uri`, `getInfoContents()` asks Picasso to “do its thing”:

MAPPING WITH MAPS V2

- Load the image from the Uri
- Resize the image to be the desired dimensions for the ImageView, center-cropping to keep the right aspect ratio
- Skip the fade-in animation that is normally applied when Picasso populates an ImageView (as the Maps V2 Bitmap is generated before the animation completes, resulting in a washed-out image)
- Use a particular placeholder drawable resource while the image is loading
- Populate the ImageView with the results, specifying a MarkerCallback to be notified of the results

MarkerCallback, as an implementation of Picasso's Callback interface, needs onError() and onSuccess() methods. onError() just dumps a message to Logcat, while onSuccess() refreshes the info window, via a call to showInfoWindow() on the Marker, if that info window is still showing:

```
static class MarkerCallback implements Callback {
    Marker marker=null;

    MarkerCallback(Marker marker) {
        this.marker=marker;
    }

    @Override
    public void onError() {
        Log.e(getClass().getSimpleName(), "Error loading thumbnail!");
    }

    @Override
    public void onSuccess() {
        if (marker != null && marker.isInfoWindowShown()) {
            marker.showInfoWindow();
        }
    }
}
```

(from [MapsV2/ImagePopups/app/src/main/java/com/commonsware/android/mapsv2/imagepopups/PopupAdapter.java](#))

If you run this sample app, you will see the popup with a placeholder image at first, quickly being replaced by the thumbnail supplied by Picasso:

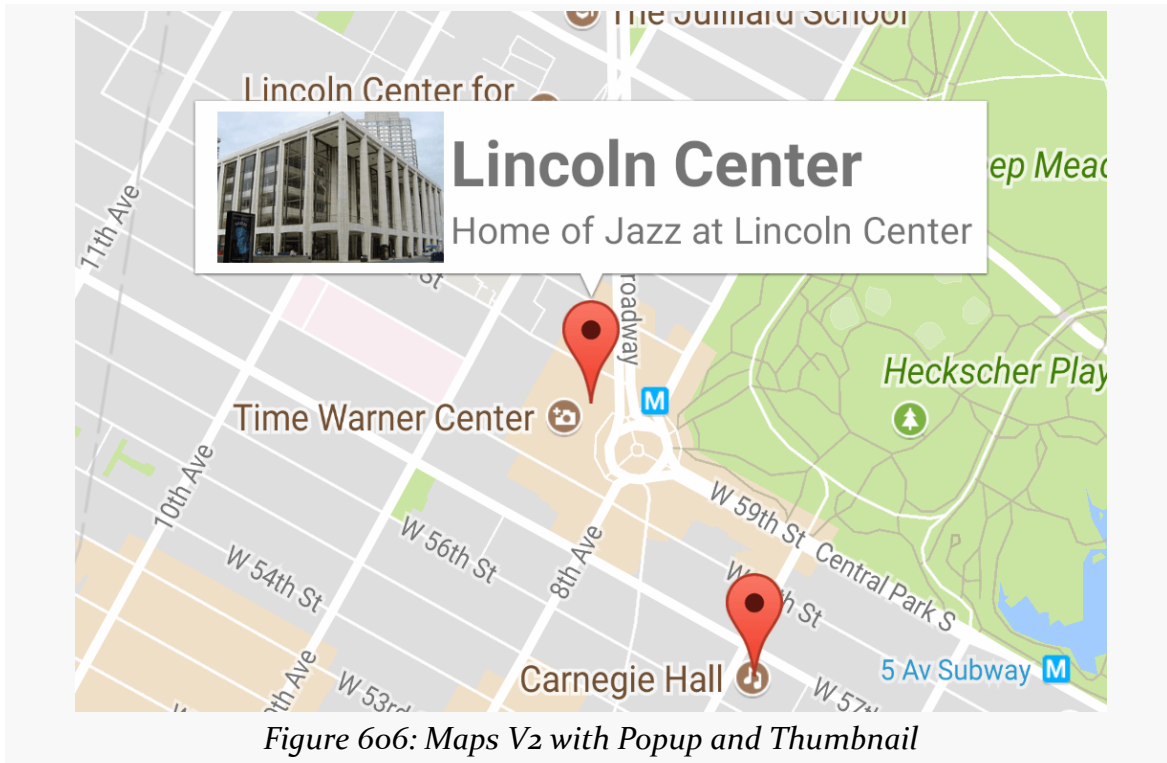

Figure 6o6: Maps V2 with Popup and Thumbnail

Setting the Marker Icon

Maps V2 includes a stock marker icon that looks a lot like the standard Google Maps marker. You have three major choices for what to use for your own markers:

1. Stick with the stock icon, which is the default behavior
2. Change the stock icon to a different hue
3. Replace the stock icon with your own from an asset, resource, file, or in-memory Bitmap

To indicate that you want a different icon than the stock one, use the `icon()` method on the `MarkerOptions` fluent interface. This takes a `BitmapDescriptor`, which you get from one of a series of static methods on the `BitmapDescriptorFactory` class.

For example, you might have a revised version of the `addMarker()` method of `MainActivity` that took a hue — a value from 0 to 360 representing different colors along a color wheel. 0 represents red, 120 represents green, and 240 represents blue, with different shades in between. There is a series of `HUE_` constants defined on

MAPPING WITH MAPS V2

BitmapDescriptorFactory, plus a defaultMarker() method that takes a hue as a parameter and returns a BitmapDescriptor that will use the stock icon, colored to the specified hue:

```
private void addMarker(GoogleMap map, double lat, double lon,
                       int title, int snippet, int hue) {
    map.addMarker(new MarkerOptions().position(new LatLng(lat, lon))
                 .title(getString(title))
                 .snippet(getString(snippet))
                 .icon(BitmapDescriptorFactory.defaultMarker(hue)));
}
```

(from [MapsV2/Taps/app/src/main/java/com/commonsware/android/mapsv2/taps/MainActivity.java](#))

This could then be used to give you different colors per marker, or by category of marker, etc.:

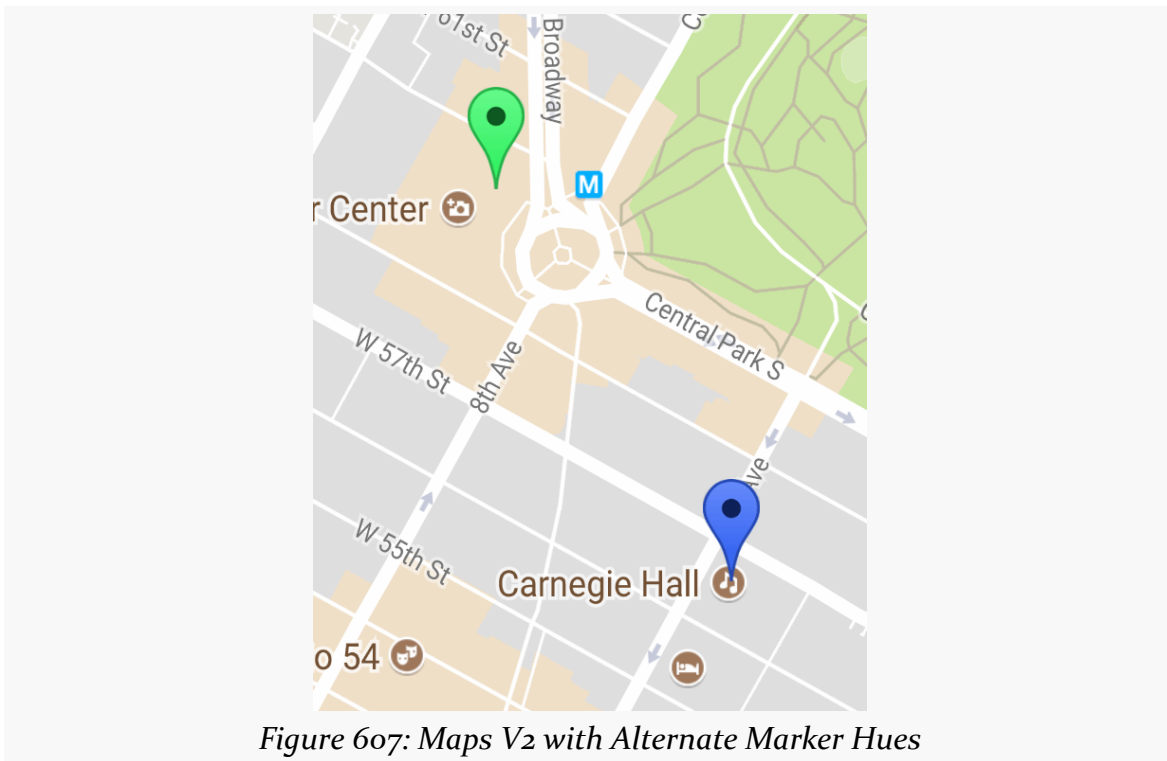

Figure 607: Maps V2 with Alternate Marker Hues

Note that you can modify the icon at runtime via the setIcon() method on the Marker returned by addMarker() method on GoogleMap.

However, you cannot draw the marker directly yourself, the way you might have with Maps V1. What you *can* do is draw to a Bitmap-backed Canvas object, then use the

resulting Bitmap with BitmapFactoryDescriptor and its fromBitmap() factory method.

Responding to Taps

Perhaps we would like to find out when a user taps on one of our markers, instead of displaying an info window. Maybe we want to have some other UI response to that tap in our app.

To do that, simply create an implementation of the OnMarkerClickListener interface and attach it to the GoogleMap via setOnMarkerClickListener(). You will then be called with onMarkerClick() when the user taps on a marker, and you are passed the Marker object in question. If you return true, you are indicating that you are handling the event; returning false means that default handling (the info window) should be done.

You can see this, plus the multi-colored markers, in the [MapsV2/Taps](#) sample application. This takes MapsV2/Popups and adds a Toast when the user taps a marker, in addition to displaying the info window:

```
@Override
public boolean onMarkerClick(Marker marker) {
    Toast.makeText(this, marker.getTitle(), Toast.LENGTH_LONG).show();

    return(false);
}
```

(from [MapsV2/Taps/app/src/main/java/com/commonsware/android/mapsv2/taps/MainActivity.java](#))

MAPPING WITH MAPS V2

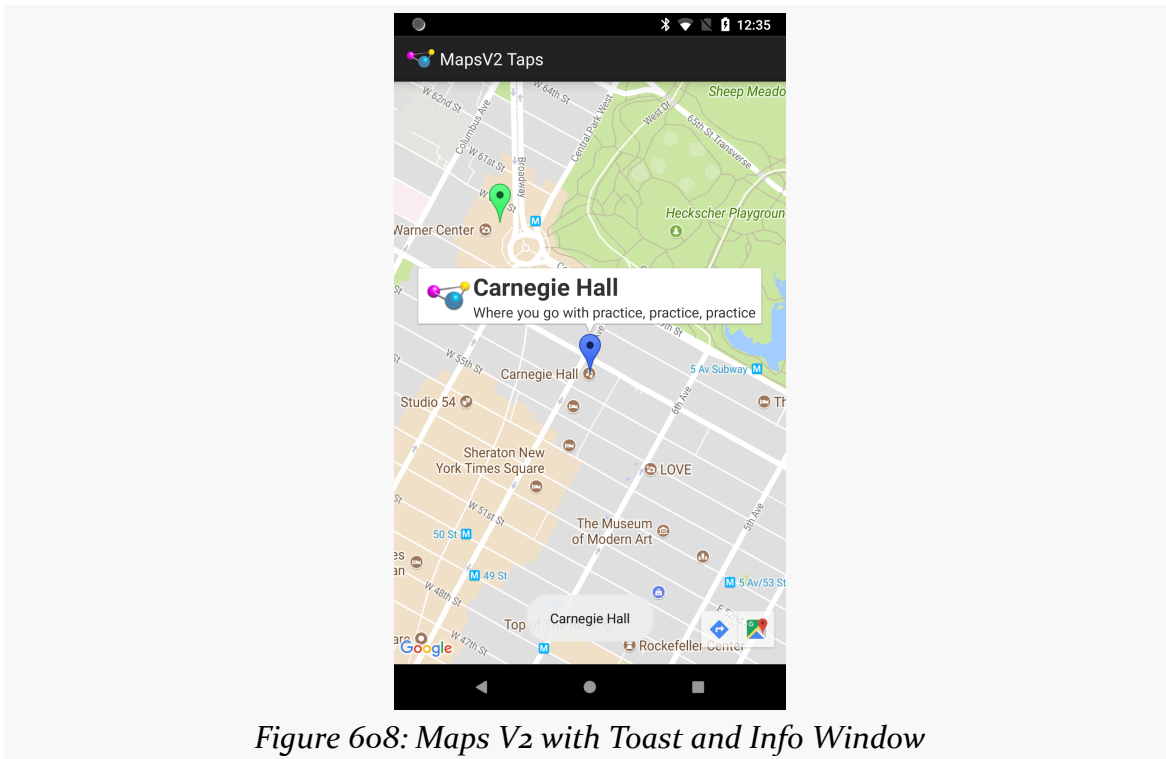

Figure 6o8: Maps V2 with Toast and Info Window

Our call to `setOnMarkerClickListener()` is up in the `onMapReady()` method of `MainActivity`:

```
map.setOnMarkerClickListener(this);
```

(from [MapsV2/Taps/app/src/main/java/com/commonsware/android/mapsv2/taps/MainActivity.java](https://github.com/commonsware/android-mapsv2/taps/MainActivity.java))

Dragging Markers

By default, markers are not draggable. But, if you call `draggable(true)` on your `MarkerOptions` when creating the marker — or call `setDraggable(true)` on the `Marker` later on — Android will automatically support drag-and-drop. The user can tap-and-hold on the marker to enable drag mode, then slide the marker around the map.

Note that at the present time, this functionality is a little odd. When you tap-and-hold the marker, with drag mode enabled, the marker initially jumps away from its original position. The user can reposition the marker to any desired location, and the marker will seem to “drop” where the user requests. Why the marker makes the sudden shift at the outset, using the default marker settings, is unclear.

MAPPING WITH MAPS V2

Of course, your code may need to know about drag-and-drop events, such as to update your own data model to reflect the newly-chosen location. You can register an `OnMarkerDragListener` that will be notified of the start of the drag, where the marker slides during the drag, and where the marker is dropped at the end of the drag.

You can see all of this in the [MapsV2/Drag](#) sample application, which is a clone of `MapsV2/Popup` with drag-and-drop enabled.

To enable drag-and-drop, we just chain `draggable(true)` onto the series of calls on our `MarkerOptions` when creating the markers:

```
private void addMarker(GoogleMap map, double lat, double lon,
                      int title, int snippet) {
    map.addMarker(new MarkerOptions().position(new LatLng(lat, lon))
                 .title(getString(title))
                 .snippet(getString(snippet))
                 .draggable(true));
}
```

(from [MapsV2/Drag/app/src/main/java/com/commonsware/android/mapsv2/drag/MainActivity.java](#))

We also register `MainActivity` as being the drag listener, up in `onMapReady()`:

```
map.setOnMarkerDragListener(this);
```

(from [MapsV2/Drag/app/src/main/java/com/commonsware/android/mapsv2/drag/MainActivity.java](#))

That requires `MainActivity` to implement `OnMarkerDragListener`, which in turn requires three methods to be defined: `onMarkerDragStart()`, `onMarkerDrag()`, and `onMarkerDragEnd()`:

```
@Override
public void onMarkerDragStart(Marker marker) {
    LatLng position=marker.getPosition();

    Log.d(getClass().getSimpleName(), String.format("Drag from %f:%f",
                                                    position.latitude,
                                                    position.longitude));
}

@Override
public void onMarkerDrag(Marker marker) {
    LatLng position=marker.getPosition();
}
```

MAPPING WITH MAPS V2

```
Log.d(getClass().getSimpleName(),
      String.format("Dragging to %f:%f", position.latitude,
                    position.longitude));
}

@Override
public void onMarkerDragEnd(Marker marker) {
    LatLng position=marker.getPosition();

    Log.d(getClass().getSimpleName(), String.format("Dragged to %f:%f",
            position.latitude,
            position.longitude));
}
```

(from [MapsV2/Drag/app/src/main/java/com/commonsware/android/mapsv2/drag/MainActivity.java](#))

Here, we just dump the information about the new marker position in Logcat.

So, if you run this app and drag-and-drop a marker, you will see output in Logcat akin to:

```
12-19 13:10:36.442: D/MainActivity(22510): Drag from 40.770876:-73.982499
12-19 13:10:36.892: D/MainActivity(22510): Dragging to 40.770876:-73.981593
12-19 13:10:36.912: D/MainActivity(22510): Dragging to 40.770795:-73.981352
12-19 13:10:36.932: D/MainActivity(22510): Dragging to 40.770754:-73.981141
.
.
.
12-19 13:10:38.292: D/MainActivity(22510): Dragging to 40.769596:-73.983615
12-19 13:10:38.372: D/MainActivity(22510): Dragged to 40.769596:-73.983615
```

The actual list of events was much longer, as `onMarkerDrag()` is called a *lot*, so the ... in the Logcat entries above reflect another 50 or so lines for a drag-and-drop that took a couple of seconds.

Also, up in `onCreate()`, we retain our `MapFragment` across configuration changes via `setRetainInstance(true)`:

```
mapFrag.setRetainInstance(true);
```

(from [MapsV2/Drag/app/src/main/java/com/commonsware/android/mapsv2/drag/MainActivity.java](#))

Retaining the fragment instance causes the fragment to keep our markers in their moved positions, rather than resetting them to their original positions.

The “Final” Limitations

In Maps V2, not only do you not create Marker objects directly yourself, but Marker is marked as final and cannot be extended. Hence, you cannot use a Marker directly to hold model data.

However, Marker does have getId(), an immutable identifier for the Marker. We can use that as a key for a HashMap that allows us to get at additional model data associated with the Marker.

You can see this approach in the [MapsV2/Models](#) sample application, which is a clone of MapsV2/Popup where we use the ID in just this fashion.

Our simplified model is merely the data we poured into our Marker objects in the original MapsV2/Popup project:

```
package com.commonware.android.mapsv2.model;

import android.content.Context;

public class Model {
    String title;
    String snippet;
    double lat;
    double lon;

    Model(Context ctxt, double lat, double lon, int title,
          int snippet) {
        this.title=ctxt.getString(title);
        this.snippet=ctxt.getString(snippet);
        this.lat=lat;
        this.lon=lon;
    }

    String getTitle() {
        return(title);
    }

    String getSnippet() {
        return(snippet);
    }

    double getLatitude() {
        return(lat);
    }
}
```

MAPPING WITH MAPS V2

```
double getLongitude() {  
    return(lon);  
}  
}
```

(from [MapsV2/Models/app/src/main/java/com/commonsware/android/mapsv2/model/Model.java](#))

Our activity holds onto a `HashMap` of these `Model` objects, with the map keyed by the Marker ID (a `String`):

```
private HashMap<String, Model> models=new HashMap<String, Model>();
```

(from [MapsV2/Models/app/src/main/java/com/commonsware/android/mapsv2/model/MainActivity.java](#))

Of course, a real application would have a much more elaborate setup than this.

We then arrange to populate our map with Marker objects created from our `Model` objects, moving the add-the-markers-to-the-map logic to an `addMarkers()` method:

```
private void addMarkers(GoogleMap map) {  
    Model model=  
        new Model(this, 40.748963847316034, -73.96807193756104,  
                  R.string.un, R.string.united_nations);  
  
    models.put(addMarkerForModel(map, model).getId(), model);  
  
    model=  
        new Model(this, 40.76866299974387, -73.98268461227417,  
                  R.string.lincoln_center,  
                  R.string.lincoln_center_snippet);  
    models.put(addMarkerForModel(map, model).getId(), model);  
  
    model=  
        new Model(this, 40.765136435316755, -73.97989511489868,  
                  R.string.carnegie_hall, R.string.practice_x3);  
    models.put(addMarkerForModel(map, model).getId(), model);  
  
    model=  
        new Model(this, 40.70686417491799, -74.01572942733765,  
                  R.string.downtown_club, R.string.heisman_trophy);  
    models.put(addMarkerForModel(map, model).getId(), model);  
}  
  
private Marker addMarkerForModel(GoogleMap map, Model model) {  
    LatLng position=  
        new LatLng(model.getLatitude(), model.getLongitude());
```

MAPPING WITH MAPS V2

```
return(map.addMarker(new MarkerOptions().position(position)
                    .title(model.getTitle())
                    .snippet(model.getSnippet())));
}
```

(from [MapsV2/Models/app/src/main/java/com/commonsware/android/mapsv2/model/MainActivity.java](#))

Notice that `addMarkerForModel()` returns the Marker, and we use `getId()` on that Marker as the key when adding a Model to the HashMap.

Our `PopupAdapter` gets the data for the info window from the Model (though, in truth, in this case, it could have gotten the data from the Marker itself, since we did not add more information to the info window):

```
package com.commonsware.android.mapsv2.model;

import android.view.LayoutInflater;
import android.view.View;
import android.widget.TextView;
import java.util.HashMap;
import com.google.android.gms.maps.GoogleMap.InfoWindowAdapter;
import com.google.android.gms.maps.model.Marker;

class PopupAdapter implements InfoWindowAdapter {
    LayoutInflater inflater=null;
    HashMap<String, Model> models=null;

    PopupAdapter(LayoutInflater inflater, HashMap<String, Model> models) {
        this.inflater=inflater;
        this.models=models;
    }

    @Override
    public View getInfoWindow(Marker marker) {
        return(null);
    }

    @Override
    public View getInfoContents(Marker marker) {
        View popup=inflater.inflate(R.layout.popup, null);

        TextView tv=(TextView)popup.findViewById(R.id.title);

        tv.setText(models.get(marker.getId()).getTitle());
        tv=(TextView)popup.findViewById(R.id.snippet);
    }
}
```

MAPPING WITH MAPS V2

```
tv.setText(models.get(marker.getId()).getSnippet());  
  
return(popup);  
}  
}
```

(from [MapsV2/Models/app/src/main/java/com/commonsware/android/mapsv2/model/PopupAdapter.java](#))

Visually, this is indistinguishable from the original MapsV2/Popups project. Of course, a real app would have more complex models, perhaps containing more discrete information for a more complex info window.

A Bit More About IPC

IPC is not only a problem in terms of disappearing Marker objects.

If you run a Maps V2 app under [Traceview](#), to see what methods get called and how much time everything takes, you will see that many, many operations with GoogleMap do little in your process, but instead make synchronous calls to a Play Services process to do the real work. You need to avoid manipulating your GoogleMap in time-sensitive portions of your code.

Finding the User

Many times, the user is looking at a map to figure out where they are. Perhaps they are lost. Perhaps their spouse or significant other thinks that they are lost. Perhaps they think that they were teleported somewhere (e.g., a North African desert) after turning a [“frozen wheel”](#) in an icy cavern beneath an island, and therefore are *really* lost. Stranger things have happened.

(well, OK, perhaps not)

Regardless, it is often useful to help point out to the user their current location. That is a matter of adding a suitable location permission (e.g., ACCESS_FINE_LOCATION) and calling `setMyLocationEnabled(true)` on your GoogleMap. This activates a layer that will highlight their location, with the user having an option of having the “camera” (i.e., their perspective on the map) reposition itself to their location and move as they move. This latter capability is activated by a small icon in the upper right of the map.

MAPPING WITH MAPS V2

You can see this in operation in the [MapsV2/MyLocation](#) sample application, which is a clone of MapsV2/Popup with standard location tracking enabled.

All we do is call two additional methods on our `GoogleMap` in `onCreate()`:

- `setMyLocationEnabled()`, indicating that we want the “my location” layer added and automatic tracking to be enabled, and
- `setOnMyLocationChangeListener()`, indicating that we *also* want to be notified about changes in the user position

```
map.setMyLocationEnabled(true);
map.setOnMyLocationChangeListener(this);
```

(from [MapsV2/MyLocation/app/src/main/java/com/commonsware/android/mapsv2/mylocation/MainActivity.java](#))

That latter method also requires our activity to implement the `OnMyLocationChangeListener` interface, which in turn requires us to implement the `onMyLocationChange()` method, which will be called when Maps V2 gets a new location fix:

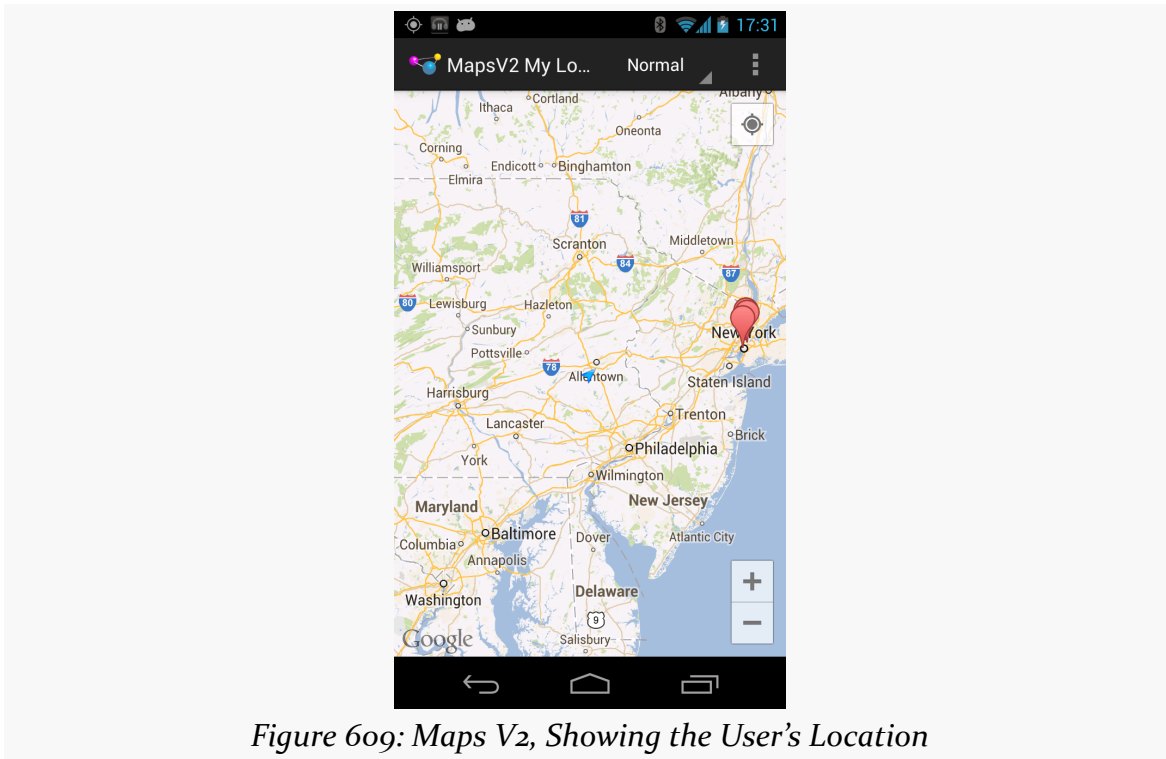

```
@Override
public void onMyLocationChange(Location lastKnownLocation) {
    Log.d(getClass().getSimpleName(),
        String.format("%f:%f", lastKnownLocation.getLatitude(),
            lastKnownLocation.getLongitude()));
}
```

(from [MapsV2/MyLocation/app/src/main/java/com/commonsware/android/mapsv2/mylocation/MainActivity.java](#))

Here, we simply log the location to Logcat.

This is nice and easy, giving us our my-location overlay and arrow indicating the user’s location and orientation:

MAPPING WITH MAPS V2

However, there are three problems here. First, `setOnMyLocationChangeListener()` is now deprecated, as Google would prefer that you directly request the locations through [the `LocationClient` available from Play Services](#).

Second, there does not appear to be a way to *force* camera tracking of the user's position — you are reliant upon the user tapping that icon. You also have no control over the nature of the location provider that is used.

However, there is a workaround for this, proposed in [a Stack Overflow answer](#) – provide your own location data and update the camera yourself, by means of `setLocationSource()`. `setLocationSource()` lets you push locations to the `GoogleMap`, making other adjustments (e.g., camera position) along the way.

To see how this works, take a peek at the [MapsV2/Location](#) sample application, which is a clone of `MapsV2/Popup` with custom location tracking enabled.

Along with adding `ACCESS_FINE_LOCATION` to the manifest, this sample project adds some lines to the `onMapReady()` implementation of `MainActivity` to configure the `GoogleMap`:

MAPPING WITH MAPS V2

```
locMgr=(LocationManager)getSystemService(LOCATION_SERVICE);
crit.setAccuracy(Criteria.ACCURACY_FINE);
locMgr.requestLocationUpdates(0L, 0.0f, crit, this, null);

map.setLocationSource(this);
map.setMyLocationEnabled(true);
map.getUiSettings().setMyLocationButtonEnabled(false);
```

(from [MapsV2/Location/app/src/main/java/com/commonsware/android/mapsv2/location/MainActivity.java](#))

The first three lines get access to a `LocationManager`, indicate that a `Criteria` object (initialized as a data member) should require fine accuracy, and request location updates. These come from the [location tracking](#) subsystem in Android.

The next two lines register our activity as being the source of location data and turns on location tracking in the `GoogleMap`, so the user's position will be marked on the map.

The last line disables the user's control over whether the camera position tracks their movement, since we want that to always be on in this case.

In `onResume()` and `onPause()` of `MainActivity`, we enable and disable getting location updates, as is typical of an activity needing location data. However, we also tell the `GoogleMap` that we are going to supply it with location data, rather than it having to obtain location data itself:

```
@Override
public void onResume() {
    super.onResume();

    if (locMgr!=null) {
        locMgr.requestLocationUpdates(0L, 0.0f, crit, this, null);
    }

    if (map!=null) {
        map.setLocationSource(this);
    }
}

@Override
public void onPause() {
    map.setLocationSource(null);
    locMgr.removeUpdates(this);
}
```

MAPPING WITH MAPS V2

```
super.onPause();  
}
```

(from [MapsV2/Location/app/src/main/java/com/commonsware/android/mapsv2/location/MainActivity.java](#))

Note that we are blindly assuming that we will get location data. A production-grade app would put in better smarts to confirm that we will actually learn our location via this Criteria (e.g., the user does not have all location providers disabled).

Also note that because the map initialization is now happening on a background thread, `onResume()` might be called before `onMapReady()`, and so `onResume()` has to check to see if we already have a `LocationManager` and `GoogleMap` before proceeding.

The call to `setLocationSource()` — both in `onMapReady()` and `onResume()` — tells `GoogleMap` that our `MainActivity` itself is to be the source of location data. This requires `MainActivity` to implement the `LocationSource` interface, requiring us to implement `activate()` and `deactivate()` methods:

```
@Override  
public void activate(OnLocationChangeListener listener) {  
    this.mapLocationListener=listener;  
}  
  
@Override  
public void deactivate() {  
    this.mapLocationListener=null;  
}
```

(from [MapsV2/Location/app/src/main/java/com/commonsware/android/mapsv2/location/MainActivity.java](#))

`activate()` provides us with an `OnLocationChangeListener`, from `GoogleMap`, to which we need to pass location data as we get it. `deactivate()` indicates that we should no longer attempt to contact that listener. In addition to holding onto that listener (or removing our reference to it when deactivated), we also take this opportunity to request and remove location updates.

The `onLocationChanged()` method — where we get our location fixes from `LocationManager` via the `LocationListener` interface — must pass the location along to the `GoogleMap`-supplied `OnLocationChangeListener`, if we have such a listener available:

```
@Override  
public void onLocationChanged(Location location) {  
    if (mapLocationListener != null) {
```

MAPPING WITH MAPS V2

```
mapLocationListener.onLocationChanged(location);

LatLng latLng=
    new LatLng(location.getLatitude(), location.getLongitude());
CameraUpdate cu=CameraUpdateFactory.newLatLng(latLng);

map.animateCamera(cu);
}
}
```

(from [MapsV2/Location/app/src/main/java/com/commonsware/android/mapsv2/location/MainActivity.java](#))

Here, we also create a `CameraUpdate` representing the new location and animate that update, to have the map slide over to the new location, centering the camera on the user's updated position.

The net effect of all of this is that the map continuously re-centers itself to show the user's position, which `GoogleMap` is highlighting on the map for us.

Dealing with Runtime Permissions

The previous section claimed three problems with the `MyLocation` sample, yet only explained two of them. That is because the third problem is shared by the `Location` sample as well: the apps are oblivious to [Android 6.0's runtime permissions system](#).

Both samples have a `targetSdkVersion` of 22. They will install just fine on an Android 6.0 device, triggering the classic "accept all permissions at install time" dialog if installed by any means other than development tools. However, this also means that the apps will not know if the user goes into Settings and revokes the app's access to location data. Besides, *eventually* something will force your hand to have a `targetSdkVersion` of 23 or higher, and that will require you to adopt the new runtime permission system, whether you like it or not.

The [MapsV2/MyLocationMNC](#) sample application is nearly identical to the `MyLocation` sample, except that it has a `targetSdkVersion` of 23 and it makes limited use of the runtime permission system.

`onCreate()` of `MainActivity` now looks radically different:

```
@Override
protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
}
```

MAPPING WITH MAPS V2

```
if (savedInstanceState==null) {
    needsInit=true;
}
else {
    isInPermission=
        savedInstanceState.getBoolean(STATE_IN_PERMISSION, false);
}

onCreateForRealz(canGetLocation());
}
```

(from [MapsV2/MyLocationMNC/app/src/main/java/com/commonsware/android/mapsv2/mylocation/MainActivity.java](#))

Most of the original business logic from `onCreate()` has been moved into `onCreateForRealz()`. That method takes a boolean parameter, indicating whether or not we have permission to access the user's location. Here, we get that from a `canGetLocation()` method that, in turn, uses `ContextCompat.checkSelfPermission()` to see if we hold `ACCESS_FINE_LOCATION`:

```
private boolean canGetLocation() {
    return(ContextCompat.checkSelfPermission(this,
        Manifest.permission.ACCESS_FINE_LOCATION)==
        PackageManager.PERMISSION_GRANTED);
}
```

(from [MapsV2/MyLocationMNC/app/src/main/java/com/commonsware/android/mapsv2/mylocation/MainActivity.java](#))

If we can work with locations, `onCreateForRealz()` will do what `onCreate()` used to do: call `readyToGo()` and, if we are ready to go, bring up the map:

```
private void onCreateForRealz(boolean canGetLocation) {
    if (canGetLocation) {
        if (readyToGo()) {
            setContentView(R.layout.activity_main);

            MapFragment mapFrag=
                (MapFragment)getManager().findFragmentById(
                    R.id.map);

            mapFrag.getMapAsync(this);
        }
    }
    else if (!isInPermission) {
        isInPermission=true;

        ActivityCompat.requestPermissions(this,
            new String[] {Manifest.permission.ACCESS_FINE_LOCATION},
```

MAPPING WITH MAPS V2

```
    REQUEST_PERMS);  
    }  
}
```

(from [MapsV2/MyLocationMNC/app/src/main/java/com/commonsware/android/maps2/mylocation/MainActivity.java](#))

If we do not have access to the user's location, this particular sample app is not that interesting, so we will ask the user for permission, via a call to `ActivityCompat.requestPermissions()`. This will eventually trigger a call to `onRequestPermissionsResult()`:

```
@Override  
public void onRequestPermissionsResult(int requestCode,  
                                     String[] permissions,  
                                     int[] grantResults) {  
  
    isInPermission=false;  
  
    if (requestCode==REQUEST_PERMS) {  
        if (canGetLocation()) {  
            onCreateForRealz(true);  
        }  
        else {  
            finish(); // denied permission, so we're done  
        }  
    }  
}
```

(from [MapsV2/MyLocationMNC/app/src/main/java/com/commonsware/android/maps2/mylocation/MainActivity.java](#))

Here, if we can now get the location, we go ahead and run through `onCreateForRealz()` again, to initialize the map. If, however, the user denied us the right to access the location, we `finish()` and exit the activity outright. One could argue that a better approach would be to show the map and simply not call `setMyLocationEnabled(true)` or `setOnMyLocationChangeListener()`. That would be another approach to dealing with the missing permission, and it is probably the better option if your primary goal was to just show a map.

Throughout this code, you have seen references to an `isInPermission` field. This tracks whether or not we are in the middle of requesting a permission:

- It is initialized to `false` in the activity
- It is set to `true` just before calling `requestPermissions()`
- It is set back to `false` in `onRequestPermissionsResult()`
- It is saved across configuration changes via `onSaveInstanceState()` and is retrieved from that state in `onCreate()`:

MAPPING WITH MAPS V2

```
@Override
protected void onSaveInstanceState(Bundle outState) {
    super.onSaveInstanceState(outState);

    outState.putBoolean(STATE_IN_PERMISSION, isInPermission);
}
```

(from [MapsV2/MyLocationMNC/app/src/main/java/com/commonsware/android/mapsv2/mylocation/MainActivity.java](#))

(where STATE_IN_PERMISSION is a static final String to use as a key for the Bundle value)

This allows us to check whether or not we are in the middle of requesting permissions already in onCreateForRealz() and avoid popping up the permission-request dialog twice if the user rotates the screen while the first dialog is up, then denies the permission.

Also note that we are not taking any steps here to leverage ActivityCompat.showShowRequestPermissionRationale(), in case the user denied the permission on some previous run of our app, but then ran the app again. You could do something for that here, such as pop up a dialog and call requestPermissions() afterwards.

Drawing Lines and Areas

If you wanted to draw on a map in the Maps V1 framework, you created an Overlay and drew upon it. This forced you to handle low-level drawing work yourself, as you were handed a Canvas object and had to handle all the lines, fills, and so forth yourself.

Maps V2 offers a different approach. Free-form drawing is still conceivable, though it appears to have to be handled in the form of tile overlays instead of map overlays. However, for the simpler cases of drawing lines and areas, Maps V2 has built-in polyline, polygon, and circle support. You tell the GoogleMap what needs to be drawn, and it handles drawing it, both initially and as the map is zoomed or panned. A polyline is a line connecting a series of points; a polygon is a region defined by a series of corners. A circle, from the standpoint of Maps V2, is defined by a center coordinate and a radius.

We can see polylines and polygons on a GoogleMap in the [MapsV2/Polyl](#) sample application, which is a clone of MapsV2/Popup with two additions:

MAPPING WITH MAPS V2

- A polyline connecting the locations of our four markers
- A polygon enclosing the area of Manhattan known as the Garment District (bounded by 34th Street, 42nd Street, Fifth Avenue, and Ninth Avenue)

To draw those, we simply add a few lines to `onMapReady()` of `MainActivity`:

```
PolylineOptions line=
    new PolylineOptions().add(new LatLng(40.70686417491799,
        -74.01572942733765),
        new LatLng(40.76866299974387,
        -73.98268461227417),
        new LatLng(40.765136435316755,
        -73.97989511489868),
        new LatLng(40.748963847316034,
        -73.96807193756104))
        .width(5).color(Color.RED);

map.addPolyline(line);

PolygonOptions area=
    new PolygonOptions().add(new LatLng(40.748429, -73.984573),
        new LatLng(40.753393, -73.996311),
        new LatLng(40.758393, -73.992705),
        new LatLng(40.753484, -73.980882))
        .strokeColor(Color.BLUE);

map.addPolygon(area);
```

(from [MapsV2/Poly/app/src/main/java/com/commonsware/android/mapsv2/poly/MainActivity.java](#))

The API for adding polylines and polygons is reminiscent of the API for adding markers: define an `...Options` object with the characteristics of the item to be drawn, then call an `add...()` method on `GoogleMap` to add the item.

So, to add a polyline, we create a `PolylineOptions` object. Using its fluent interface, we `add()` a series of `LatLng` objects, representing the points to be connected by the line. We also specify the line width in *pixels* via `width()` and the color of the line via `color()`. If we had several lines that might overlap, we could specify the `zIndex()`, where higher indexes indicate lines to be drawn over the top of lines with lower indexes. We add the polyline to the map by passing our `PolylineOptions` to `addPolyline()` on `GoogleMap`.

This gives us a line connecting the four markers, with `GoogleMap` handling the details of where the line should be drawn on the screen given the current map center and zoom levels:

MAPPING WITH MAPS V2

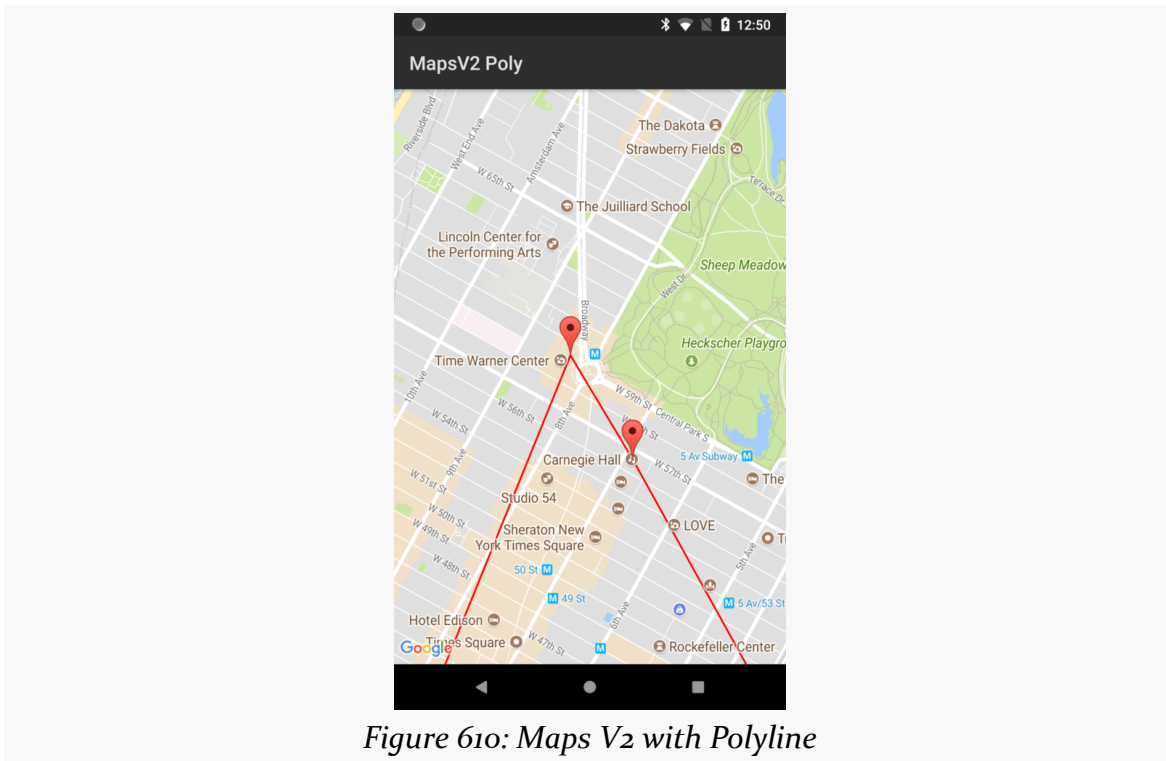

Figure 610: Maps V₂ with Polyline

Note that the polyline is drawn using a flat Mercator projection by default. For most maps, that is perfectly fine. If your map will be showing countries and continents, rather than city blocks, you might want to call `geodesic(true)` on the `PolylineOptions`, to have the line drawn on a geodesic curve, reflecting the spherical nature of the Earth ([dissenting opinions on that](#) notwithstanding).

Similarly, we create a `PolygonOptions` object, configure it, and pass it to `addPolygon` for our Garment District box. The `add()` method on `PolygonOptions` will take the corners of our polygon, automatically enclosing that region. We also specify the `strokeColor()`. We could have specified a `fillColor()` (default is transparent), `strokeWidth()` (default is 10 pixels), `zIndex()`, and `geodesic()`.

If we run the app and pan the map down to the south a bit, we see our polygon:

MAPPING WITH MAPS V2

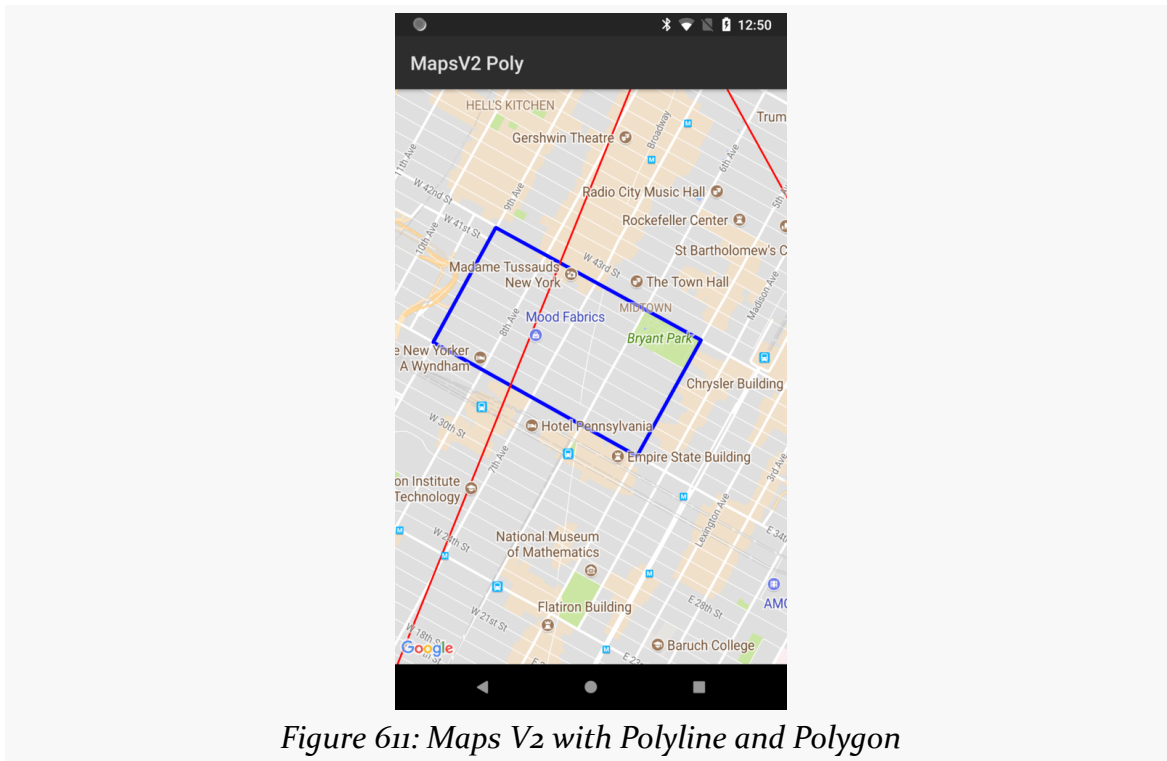

Figure 611: Maps V2 with Polyline and Polygon

As with the polyline, Android automatically handles drawing what is needed based on map center and zoom levels.

Note that, as with markers, we need to re-add the polylines and polygons after a configuration change, as the GoogleMap does not retain that information.

Gestures and Controls

By default, standard gestures and controls are enabled on your map:

- The user can change zoom level either by + and - buttons or via “pinch-to-zoom” gestures
- The user can change the center of the map via simple swipe gestures
- The user can change the camera tilt via two-finger vertical swipes, so instead of a traditional top-down perspective, the user can see things on an angle
- The user can change the orientation of the map via a two-finger rotating swipe, to change the typical “north is to the top of the map” to some other orientation

You can obtain a `UiSettings` object from your `GoogleMap` via `getUiSettings()` to disable these features, if desired:

- `setRotateGesturesEnabled()`
- `setScrollGesturesEnabled()` (for panning the map)
- `setTiltGesturesEnabled()`
- `setZoomControlsEnabled()` (for the + and - buttons)
- `setZoomGesturesEnabled()` (for pinch-to-zoom)

There is also `setAllGesturesEnabled()` to toggle on or off all gesture-based map control. This is roughly analogous to the `android:clickable` attribute on the Maps V1 edition of `MapView`.

There is also `setCompassEnabled()`, to indicate if a compass should be shown if the user changes the map orientation via a rotate gesture.

Tracking Camera Changes

If you have gestures enabled, the user can change the perspective of the map, referred to as changing the camera position. You may need to know about these changes, to perform various operations in your app based upon what is presently visible on the screen.

Originally, to find out when the camera position changes, you could call `setOnCameraChangeListener()` on the `GoogleMap`, supplying an implementation of `OnCameraChangeListener`, which would be called with `onCameraChange()` as the user pans, zooms, or tilts the map. This approach was deprecated and replaced with a series of listeners:

- `OnCameraMoveStartedListener`, invoked when the user starts moving the map
- `OnCameraMoveListener`, invoked when the user continues moving the map after having originally started moving it, all in one gesture
- `OnCameraIdleListener`, invoked when the user stops moving the map (e.g., lifts up their finger or stylus)
- `OnCameraMoveCanceledListener`, invoked if you do something programmatically to interrupt the camera movement

MAPPING WITH MAPS V2

To see how this works, we can take a quick peek at the [MapsV2/Camera](#) sample application, which is a clone of MapsV2/Popup with camera position tracking enabled.

Late in `onMapReady()` of `MainActivity`, we call a series of setter methods on the `GoogleMap` to associate `MainActivity` itself as the listener for these events:

```
map.setOnCameraMoveStartedListener(this);
map.setOnCameraMoveListener(this);
map.setOnCameraMoveCanceledListener(this);
map.setOnCameraIdleListener(this);
```

(from [MapsV2/Camera/app/src/main/java/com/commonsware/android/mapsv2/camera/MainActivity.java](#))

This requires `MainActivity` to implement all four of those listener interfaces:

```
public class MainActivity extends AbstractMapActivity implements
    OnMapReadyCallback, OnInfoWindowClickListener,
    OnCameraMoveStartedListener,
    OnCameraMoveListener,
    OnCameraMoveCanceledListener,
    OnCameraIdleListener {
```

(from [MapsV2/Camera/app/src/main/java/com/commonsware/android/mapsv2/camera/MainActivity.java](#))

And, this requires `MainActivity` to implement the callback method for each of those listeners:

Listener Interface	Event Method
<code>OnCameraMoveStartedListener</code>	<code>onCameraMoveStarted(int i)</code>
<code>OnCameraMoveListener</code>	<code>onCameraMove()</code>
<code>OnCameraIdleListener</code>	<code>onCameraIdle()</code>
<code>OnCameraMoveCanceledListener</code>	<code>onCameraMoveCanceled()</code>

```
@Override
public void onCameraIdle() {
    CameraPosition position=map.getCameraPosition();

    Log.d("onCameraIdle",
        String.format("lat: %f, lon: %f, zoom: %f, tilt: %f",
            position.target.latitude,
            position.target.longitude, position.zoom,
            position.tilt));
}
```

MAPPING WITH MAPS V2

```
@Override
public void onCameraMoveCanceled() {
    CameraPosition position=map.getCameraPosition();

    Log.d("onCameraMoveCanceled",
        String.format("lat: %f, lon: %f, zoom: %f, tilt: %f",
            position.target.latitude,
            position.target.longitude, position.zoom,
            position.tilt));
}

@Override
public void onCameraMove() {
    CameraPosition position=map.getCameraPosition();

    Log.d("onCameraMove",
        String.format("lat: %f, lon: %f, zoom: %f, tilt: %f",
            position.target.latitude,
            position.target.longitude, position.zoom,
            position.tilt));
}

@Override
public void onCameraMoveStarted(int i) {
    CameraPosition position=map.getCameraPosition();

    Log.d("onCameraMoveStarted",
        String.format("lat: %f, lon: %f, zoom: %f, tilt: %f",
            position.target.latitude,
            position.target.longitude, position.zoom,
            position.tilt));
}
```

(from [MapsV2/Camera/app/src/main/java/com/commonsware/android/mapsv2/camera/MainActivity.java](#))

Here, we just log a message to Logcat on each camera position change, logging:

- the latitude and longitude of the map center, obtained from the target LatLng data member of the CameraPosition object supplied to onCameraChange(),
- the zoom level of the map, from the zoom data member of CameraPosition, and
- the tilt of the map, in degrees, from the tilt data member of CameraPosition

MAPPING WITH MAPS V2

As a result, if you run this app and play around with the various gestures, you get a series of Logcat messages with the results:

```
10-08 12:13:54.449 28718-28718/com.commonware.android.mapsv2.camera D/
onCameraMoveStarted: lat: 40.771664, lon: -73.986067, zoom: 15.000000, tilt: 0.000000
10-08 12:13:54.453 28718-28718/com.commonware.android.mapsv2.camera D/onCameraMove:
lat: 40.771773, lon: -73.985717, zoom: 15.000000, tilt: 0.000000
10-08 12:13:54.483 28718-28718/com.commonware.android.mapsv2.camera D/onCameraMove:
lat: 40.771805, lon: -73.985701, zoom: 15.000000, tilt: 0.000000
10-08 12:13:54.500 28718-28718/com.commonware.android.mapsv2.camera D/onCameraMove:
lat: 40.771843, lon: -73.985669, zoom: 15.000000, tilt: 0.000000
.
.
.
10-08 12:13:57.001 28718-28718/com.commonware.android.mapsv2.camera D/onCameraIdle:
lat: 40.774540, lon: -73.985632, zoom: 15.000000, tilt: 0.000000
```

Note that `onCameraMoveStarted()` will be invoked for three reasons:

1. The user started panning, tilting, or rotating the map, or used a pinch-to-zoom gesture
2. The user did something else that triggered a camera change, such as tapping the “my location” button to move the camera to their current location
3. You did something programmatically to change the camera position

The parameter passed into `onCameraMoveStarted()` will contain a reason code (e.g., `REASON_GESTURE`) to help you distinguish these cases, if that level of detail is needed by your app.

Maps in Fragments and Pagers

One key limitation of Maps V1 was that you could only have one `MapView` instance per *process*. Presumably, the proprietary code at the heart of the Maps SDK add-on used static data members for some state management, ones that would get messed up if there were two or more `MapView` widgets in active use.

Fortunately, Maps V2 gets rid of this restriction. You are welcome to have multiple `MapFragment` objects if that makes sense. Maps are relatively memory-intensive, so you should not be planning on having dozens or hundreds of them in use at a time, but you can have more than one.

MAPPING WITH MAPS V2

To showcase this, the [MapsV2/Pager](#) sample application hosts 10 MapFragment instances as pages in a ViewPager. The bulk of the application is a clone of one of the ViewPager samples from [the chapter on ViewPager](#).

Having maps in a ViewPager presents a bit of a problem, in terms of interpreting horizontal swipe events. Normally, ViewPager handles those itself. However, that would mean that the user cannot pan the map horizontally, which makes using the map somewhat challenging. In this sample, we will augment the ViewPager with logic to allow horizontal swiping on the maps and on the tab strip.

Our activity inflates a layout that contains our ViewPager along with a PagerTabStrip:

```
<?xml version="1.0" encoding="utf-8"?>
<com.commonsware.android.mapsv2.pager.MapAwarePager xmlns:android="http://schemas.android.com/apk/res/
android"
    android:id="@+id/pager"
    android:layout_width="match_parent"
    android:layout_height="match_parent">

    <android.support.v4.view.PagerTabStrip
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:layout_gravity="top"/>

</com.commonsware.android.mapsv2.pager.MapAwarePager>
```

(from [MapsV2/Pager/app/src/main/res/layout/activity_main.xml](#))

However, you will note that this is not ViewPager, but rather MapAwarePager, a custom subclass of ViewPager that we will examine shortly.

MainActivity then populates the MapAwarePager with an instance of a MapPagerAdapter:

```
package com.commonsware.android.mapsv2.pager;

import android.os.Bundle;
import android.support.v4.view.PagerAdapter;
import android.support.v4.view.ViewPager;

public class MainActivity extends AbstractMapActivity {
    @Override
    protected void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        if (readyToGo()) {
            setContentView(R.layout.activity_main);
        }
    }
}
```

MAPPING WITH MAPS V2

```
ViewPager pager=(ViewPager)findViewById(R.id.pager);

pager.setAdapter(buildAdapter());
}
}

private PagerAdapter buildAdapter() {
    return(new MapPagerAdapter(this, getFragmentManager()));
}
}
```

(from [MapsV2/Pager/app/src/main/java/com/commonsware/android/mapsv2/pager/MainActivity.java](#))

MapPagerAdapter is a `FragmentStatePagerAdapter`, not a `FragmentPagerAdapter`. This means that as the user swipes through our `ViewPager`, the adapter has the right to discard old fragments when it creates new ones. This helps reduce the overall memory footprint of our activity.

```
package com.commonsware.android.mapsv2.pager;

import android.content.Context;
import android.app.Fragment;
import android.app.FragmentManager;
import android.support.v13.app.FragmentStatePagerAdapter;

public class MapPagerAdapter extends FragmentStatePagerAdapter {
    Context ctxt=null;

    public MapPagerAdapter(Context ctxt, FragmentManager mgr) {
        super(mgr);
        this.ctxt=ctxt;
    }

    @Override
    public int getCount() {
        return(10);
    }

    @Override
    public Fragment getItem(int position) {
        return(new PageMapFragment());
    }

    @Override
    public String getPageTitle(int position) {
        return(ctxt.getString(R.string.map_page_title) + String.valueOf(position + 1));
    }
}
```

(from [MapsV2/Pager/app/src/main/java/com/commonsware/android/mapsv2/pager/MapPagerAdapter.java](#))

MAPPING WITH MAPS V2

MapPagerAdapter declares that there should be ten pages (in `getCount()`) and returns an instance of `PageMapFragment` for each page. `PageMapFragment` is a subclass of `MapFragment`, and so is responsible for displaying our map:

```
package com.commonsware.android.mapsv2.pager;

import android.os.Bundle;
import com.google.android.gms.maps.CameraUpdate;
import com.google.android.gms.maps.CameraUpdateFactory;
import com.google.android.gms.maps.GoogleMap;
import com.google.android.gms.maps.MapFragment;
import com.google.android.gms.maps.OnMapReadyCallback;
import com.google.android.gms.maps.model.LatLng;
import com.google.android.gms.maps.model.MarkerOptions;

public class PageMapFragment extends MapFragment implements
    OnMapReadyCallback {
    private boolean needsInit=false;

    @Override
    public void onActivityCreated(Bundle savedInstanceState) {
        super.onActivityCreated(savedInstanceState);

        if (savedInstanceState == null) {
            needsInit=true;
        }

        getMapAsync(this);
    }

    @Override
    public void onMapReady(final GoogleMap map) {
        if (needsInit) {
            CameraUpdate center=
                CameraUpdateFactory.newLatLng(new LatLng(40.76793169992044,
                    -73.98180484771729));

            CameraUpdate zoom=CameraUpdateFactory.zoomTo(15);

            map.moveCamera(center);
            map.animateCamera(zoom);
        }

        addMarker(map, 40.748963847316034, -73.96807193756104, R.string.un,
            R.string.united_nations);
        addMarker(map, 40.76866299974387, -73.98268461227417,
            R.string.lincoln_center, R.string.lincoln_center_snippet);
        addMarker(map, 40.765136435316755, -73.97989511489868,
```

MAPPING WITH MAPS V2

```
        R.string.carnegie_hall, R.string.practice_x3);
    addMarker(map, 40.70686417491799, -74.01572942733765,
        R.string.downtown_club, R.string.heisman_trophy);
}

private void addMarker(GoogleMap map, double lat, double lon,
    int title, int snippet) {
    map.addMarker(new MarkerOptions().position(new LatLng(lat, lon))
        .title(getString(title))
        .snippet(getString(snippet)));
}
}
```

(from [MapsV2/Pager/app/src/main/java/com/commonsware/android/mapsv2/pager/PageMapFragment.java](#))

If we simply wanted to display an unconfigured map, we could just have `MapPageAdapter` create and return instances of `MapFragment` directly. If we want to configure our map, though, we need to get control when the `GoogleMap` object is ready for use. One way to do that is to extend `MapFragment` and override `onActivityCreated()` and call `getMapAsync()` there to begin the whole get-the-`GoogleMap`-loaded process. In `onMapReady()`, we can then go ahead and configure the map much as we have done in previous examples, just from within the fragment itself rather than from the hosting activity.

`MapAwarePager` overrides one key method of `ViewPager`: `canScroll()`:

```
package com.commonsware.android.mapsv2.pager;

import android.content.Context;
import android.support.v4.view.PagerTabStrip;
import android.support.v4.view.ViewPager;
import android.util.AttributeSet;
import android.view.SurfaceView;
import android.view.View;

public class MapAwarePager extends ViewPager {
    public MapAwarePager(Context context, AttributeSet attrs) {
        super(context, attrs);
    }

    @Override
    protected boolean canScroll(View v, boolean checkV, int dx, int x,
        int y) {
        if (v instanceof SurfaceView || v instanceof PagerTabStrip) {
            return(true);
        }
    }
}
```

MAPPING WITH MAPS V2

```
return(super.canScroll(v, checkV, dx, x, y));
}
}
```

(from [MapsV2/Pager/app/src/main/java/com/commonsware/android/mapsv2/pager/MapAwarePager.java](#))

`canScroll()` should return true if the View (and specifically the supplied X and Y coordinates within that View) can be scrolled horizontally, false otherwise. In our case, we want to say that the map and the tab strip are each scrollable horizontally. As it turns out, the passed-in View for our MapFragment will be the map if it is a subclass of SurfaceView (determined by trial and error on the author's part, with hopes for a more authoritative solution in a future edition of the Maps V2 API). So, if the passed-in View is either a SurfaceView or a PagerTabStrip, we return true, otherwise we default to normal logic.

The result is a series of independent maps, one per page:

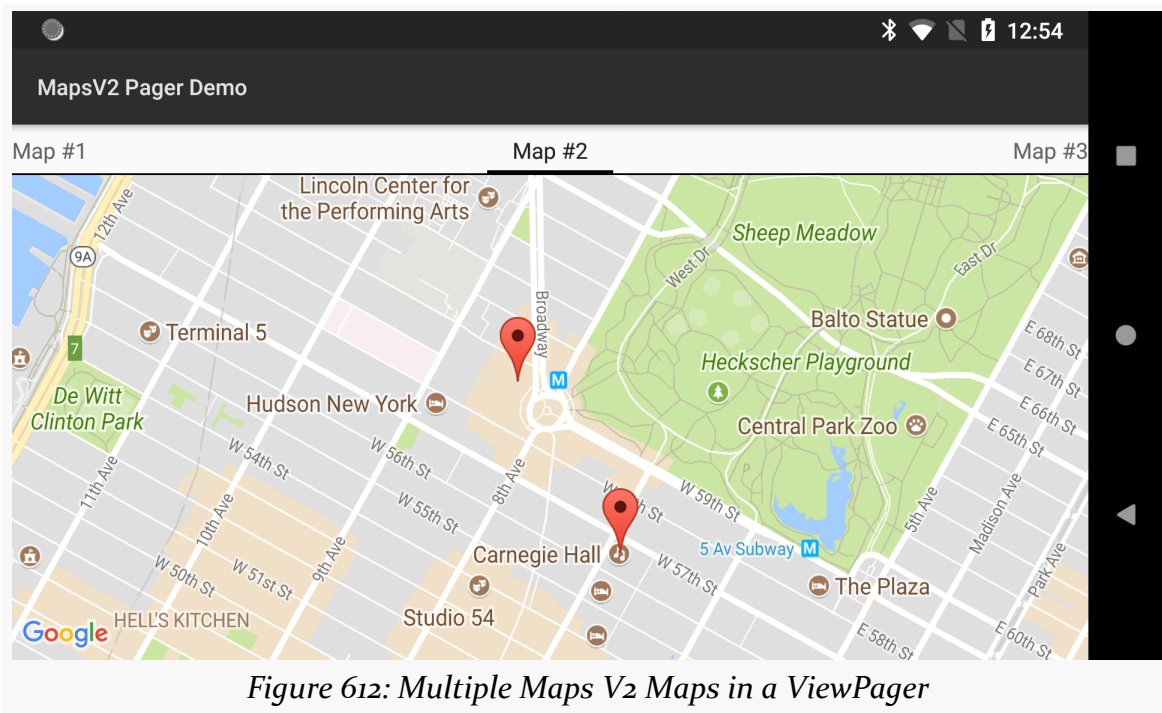

Figure 612: Multiple Maps V2 Maps in a ViewPager

Each map is independent: if the user pans or zooms one map, that has no impact on any of the other pages. Panning the maps horizontally works; to move between pages, use the tab strip.

Animating Marker Movement

Markers, by default, are static, unless you make them be draggable, and then only the user can drag them.

However, you are welcome to update the position of a Marker at any point, by calling `setPosition()` and supplying a new `LatLng`. The Marker then will jump to that position.

But what if you want to animate the movement of a Marker from its current position to a new one? Maps V2 does not offer anything “out of the box” for implementing this, but Google demonstrated approaches for this in [a “DevBytes” video](#) and related [bit of code in a GitHub Gist](#). This section will cover the technique appropriate for API Level 14+, including a full working sample (the Gist shows code but not its usage).

Problem #1: Animating a LatLng

The position of a Marker is a `LatLng`, as we have seen previously. `LatLng` is not a simple number, and so the animator framework needs our assistance to animate them. Specifically, we need a `TypeEvaluator` for `LatLng`, with our `evaluate()` method taking the initial and end positions and computing another `LatLng` representing the fraction position between those other positions. This concept was introduced back in [the chapter on the animator framework](#).

A simple approach to computing the fractional `LatLng` would be to apply the fraction to the latitude and the longitude as Java double values:

```
LatLng interpolate(float fraction, LatLng initial, LatLng end) {
    double lat = (end.latitude - initial.latitude) * fraction + initial.latitude;
    double lng = (end.longitude - initial.longitude) * fraction + initial.longitude;

    return(new LatLng(lat, lng));
}
```

That would work reasonably well for fairly close points, such as animating a marker within a city. However, animating markers across longer distances means that we have to take into account some geographic realities that a simple calculation will miss.

Problem #2: The Earth Is Not Flat (Really!)

One bit of reality is that the Earth is round. The above calculation assumes that the Earth is flat. Calculating “great circle” positions requires a fair bit of spherical trigonometry, known to cause loss of hair in software developers.

Hence, ideally, we will use somebody’s existing debugged algorithm for that.

Problem #3: 180 Equals –180, At Least For Longitude

The other problem is that longitudes wrap around, as 180 degrees longitude is equivalent to –180 degrees longitude, and longitudinal values are considered to be between 180 and –180. In cases where we would not cross 180 degrees longitude, this is not an issue. However, a simple calculation might miss this and wind up having our animation “take the long way” (e.g., animating from –175 degrees longitude to 175 degrees longitude by going 350 degrees around the Earth, rather than just 10 degrees and crossing the International Date Line).

Introducing Some Googly Assistance

Google themselves have released a [utility library for Maps V2](#). It offers polyline and polygon decoding, primarily for interoperability with other location-related Google services like the Google Directions API. The `SphericalUtil` class handles all of the nasty math for computing distances along the surface of the Earth and related calculations. It also offers `BubbleIconFactory`, which makes it easy to create marker icons that look a bit like info windows (complete with border and caret) wrapping around a bit of text or an icon.

In our case, we can use `SphericalUtil` to handle Problem #2 and Problem #3, interpolating the location between two `LatLng` values, taking the curvature of the Earth and longitude idiosyncrasies into account.

Seeing This in Action

The [MapsV2/Animator](#) sample project is a modified version of the `MapsV2/Markers` project, adding in the notion of animating a marker from its original position (Lincoln Center) to a new position (Penn Station) within Manhattan.

Since we want to use the Google map utility library, we need to add it as a dependency. Android Studio users can simply add implementation

MAPPING WITH MAPS V2

'com.google.maps.android:android-maps-utils:0.3.4' (or a higher version) to the dependencies closure.

We need to know where our starting and ending position for the animation will be, in terms of `LatLng` objects. Since those have no dependencies upon a `Context` or anything, we can simply declare them as `static final` values:

```
private static final LatLng PENN_STATION=new LatLng(40.749972,  
                                                    -73.992319);  
private static final LatLng LINCOLN_CENTER=  
    new LatLng(40.76866299974387, -73.98268461227417);
```

(from [MapsV2/Animator/app/src/main/java/com/commonsware/android/mapsv2/animator/MainActivity.java](#))

We will also need the actual `Marker` object created when we add our starting position (`LINCOLN_CENTER`) to the map. So far, we have ignored the `Marker` returned by `addMarker()` on `GoogleMap`, but now we need that. So, our own `addMarker()` method now returns this value:

```
private Marker addMarker(GoogleMap map, double lat, double lon,  
                        int title, int snippet) {  
    return(map.addMarker(new MarkerOptions().position(new LatLng(lat,  
                                                                lon))  
                        .title(getString(title))  
                        .snippet(getString(snippet))));  
}
```

(from [MapsV2/Animator/app/src/main/java/com/commonsware/android/mapsv2/animator/MainActivity.java](#))

We also now have a `markerToAnimate` data member of the activity, for our `Marker`, which we populate from our modified `addMarker()` method:

```
addMarker(map, 40.748963847316034, -73.96807193756104,  
          R.string.un, R.string.united_nations);  
markerToAnimate=  
    addMarker(map, LINCOLN_CENTER.latitude,  
              LINCOLN_CENTER.longitude, R.string.lincoln_center,  
              R.string.lincoln_center_snippet);  
addMarker(map, 40.765136435316755, -73.97989511489868,  
          R.string.carnegie_hall, R.string.practice_x3);  
addMarker(map, 40.70686417491799, -74.01572942733765,  
          R.string.downtown_club, R.string.heisman_trophy);
```

(from [MapsV2/Animator/app/src/main/java/com/commonsware/android/mapsv2/animator/MainActivity.java](#))

MAPPING WITH MAPS V2

To make the sample work repeatedly, it would be nice to support bi-directional animation, starting with animating from Lincoln Center to Penn Station, then reversing the animation to go back to Lincoln Center. That means that we need to know, for any particular animation, where the end position should be. So, we track a `LatLng` for the next end position, surprisingly named `nextAnimationEnd`, initializing it to be `PENN_STATION` (since we are starting at the outset at `LINCOLN_CENTER`):

```
private LatLng nextAnimationEnd=PENN_STATION;
```

(from [MapsV2/Animator/app/src/main/java/com/commonsware/android/mapsv2/animator/MainActivity.java](#))

Next, we need to give the user a means of actually requesting the animation to run. To do that, we define a new menu XML resource for an animate menu item (using the directions icon for lack of a better handy icon):

```
<menu xmlns:android="http://schemas.android.com/apk/res/android">
    <item
        android:id="@+id/animate"
        android:icon="@android:drawable/ic_menu_directions"
        android:showAsAction="ifRoom"
        android:title="@string/animate"/>
</menu>
```

(from [MapsV2/Animator/app/src/main/res/menu/animate.xml](#))

We then load that menu resource in an overridden `onCreateOptionsMenu()` and direct the click event to an `animateMarker()` method in `onOptionsItemSelected()`:

```
@Override
public boolean onCreateOptionsMenu(Menu menu) {
    getMenuInflater().inflate(R.menu.animate, menu);

    return(super.onCreateOptionsMenu(menu));
}

@Override
public boolean onOptionsItemSelected(MenuItem item) {
    if (item.getItemId() == R.id.animate) {
        animateMarker();

        return(true);
    }
}
```

MAPPING WITH MAPS V2

```
return(super.onOptionsItemSelected(item));  
}
```

(from [MapsV2/Animator/app/src/main/java/com/commonsware/android/mapsv2/animator/MainActivity.java](#))

In `animateMarker()`, we need to do two things:

1. Actually run the animation
2. Ensure that the camera position is such that the animation will actually be visible, as it is pointless to animate a marker between two points if the currently-viewed portion of the map does not show those points

To handle the camera position, we need to use `moveCamera()` with a `CameraUpdate` from `CameraUpdateFactory`, as we used to set the initial camera position and zoom level. To handle the case where we want one or more points to be visible, we can use the `newLatLngBounds()` method on `CameraUpdateFactory`. This takes a `LatLngBounds` describing the area that needs to be visible, plus a padding amount in pixels for where that area should be inset within the map.

Of course, this implies that we have a `LatLngBounds`.

Since `LatLngBounds` also does not depend upon a `Context` or much of anything, we can define one of those as a static `final` data member, using a `LatLngBounds.Builder` instance:

```
private static final LatLngBounds bounds=  
    new LatLngBounds.Builder().include(LINCOLN_CENTER)  
        .include(PENN_STATION).build();
```

(from [MapsV2/Animator/app/src/main/java/com/commonsware/android/mapsv2/animator/MainActivity.java](#))

A `LatLngBounds.Builder` takes one or more `LatLng` objects — passed in via `include()` — then constructs a `LatLngBounds` that encompasses all of those points via `build()`.

Our `animateMarker()` method then starts off by using `moveCamera()` to reset the camera to show that defined region:

```
private void animateMarker() {  
    map.moveCamera(CameraUpdateFactory.newLatLngBounds(bounds, 48));  
  
    Property<Marker, LatLng> property=  
        Property.of(Marker.class, LatLng.class, "position");  
    ObjectAnimator animator=
```

MAPPING WITH MAPS V2

```
ObjectAnimator.ofObject(markerToAnimate, property,
                       new LatLngEvaluator(), nextAnimationEnd);
animator.setDuration(2000);
animator.start();

if (nextAnimationEnd == LINCOLN_CENTER) {
    nextAnimationEnd=PENN_STATION;
}
else {
    nextAnimationEnd=LINCOLN_CENTER;
}
}
```

(from [MapsV2/Animator/app/src/main/java/com/commonsware/android/mapsv2/animator/MainActivity.java](#))

Then, we need to set up the animation. To do this, we will use the object animator framework, specifically an `ObjectAnimator`. We know the `Marker` that we want to animate (`markerToAnimate`) and we know where we want to animate it to (`nextAnimationEnd`). What we need is to indicate the property to animate on this object, plus provide help to actually animate a `LatLng`.

To specify the property, we could just pass in the name of the property ("position"). However, in `animateMarker()`, we set up a `Property` object via the static `of()` factory method. This makes our use of `ofObject()` more type-safe, as `Property` will help enforce that we are animating a `Marker` using `LatLng` values.

To animate `LatLng` values, we need a `TypeEvaluator` for `LatLng`, here defined as a static inner class named `LatLngEvaluator`:

```
private static class LatLngEvaluator implements TypeEvaluator<LatLng> {
    @Override
    public LatLng evaluate(float fraction, LatLng startValue,
                          LatLng endValue) {
        return(SphericalUtil.interpolate(startValue, endValue, fraction));
    }
}
```

(from [MapsV2/Animator/app/src/main/java/com/commonsware/android/mapsv2/animator/MainActivity.java](#))

Our `evaluate()` method turns around and calls the static `interpolate()` method on `SphericalUtil`, supplied by Google's map utility library. `interpolate()` handles all the nasty spherical trigonometry and stuff, so we do not have to.

We then set the duration of the animation to be two seconds, and start the animation.

Finally, to reverse the animation for the next request, `animateMarker()` resets the value of `nextAnimationEnd` to be `PENN_STATION` or `LINCOLN_CENTER`, wherever we will animate to next.

Honoring Traffic Rules, Like “Drive Only On Streets”

You will notice that our animation ignores other aspects of reality, such as buildings that might be in the way. Sometimes, that is appropriate, such as animating the movement of:

- a bird
- a plane
- [a costumed superhero with independent flight capability](#)

Sometimes, though, we need to take into account those obstacles, such as animating the movement of:

- a pedestrian
- a car
- [a costumed superhero “flying” by means of swinging between buildings using dynamically-generated cables of either natural or synthetic origin](#)

However, to do this implies that we know where the obstacles are. Or, more accurately, we would need to animate the marker along known good waypoints, such as streets.

The animation would not be especially difficult, as `ofObject()` can take a series of waypoints. However, we would need to find those waypoints, and there is nothing in Maps V2 itself that supplies this data.

Maps, of the Indoor Variety

The good news is that Maps V2 supports Google’s indoor maps, for those venues for which Google has indoor map data.

The bad news is that for some reason, only one map at a time supports indoor maps. The default will be that the first map you create will support indoor maps, and others will not.

To see if a given map offers indoor map capability, you can call `isIndoorEnabled()` on `GoogleMap`. To toggle this capability, call `setIndoorEnabled()`.

Taking a Snapshot of a Map

Once a map is drawn, you can take a snapshot of it, converting the viewed map into a `Bitmap` object. This is designed to take an image of the map and use it in places where a `MapFragment`, or even a `MapView`, cannot go, such as:

- Things tied to a `RemoteViews`, such as a custom `Notification`
- Thumbnails of maps, for an app that allows users to manipulate several maps at once

The `GoogleMap` object has two flavors of a `snapshot()` method. Both take a `SnapshotReadyCallback` object. You will need to supply an instance of something implementing the `SnapshotReadyCallback` interface, overriding `onSnapshotReady()`, where you will receive your `Bitmap`.

One flavor of `snapshot()` takes just the `SnapshotReadyCallback`; the other also takes a `Bitmap` of the proper dimensions, such as a previous snapshot `Bitmap` that you want to recycle. Using the latter `snapshot()` is recommended where possible, so you do not need to allocate new `Bitmap` objects on each `snapshot()` call.

Note that `snapshot()` will only work once the map is actually rendered. So, for example, calling `snapshot()` from `onCreate()` of your activity will fail, because the map has not been rendered yet. `snapshot()` is designed to be called based upon user input, either to manually capture a snapshot or based on navigation (e.g., tapping on a `ListView` item triggers saving a snapshot of the current map as a thumbnail before changing the map contents).

Also, the documentation for `snapshot()` contains the following:

Note: Images of the map must not be transmitted to your servers, or otherwise used outside of the application. If you need to send a map to another application or user, send data that allows them to reconstruct the map for the new user instead of a snapshot.

As this statement may be tied to the terms and conditions of your use of Maps V2, you should talk with qualified legal counsel before:

- Saving a snapshot to external storage
- Sharing a snapshot via ACTION_SEND
- Sending a snapshot to your server

or similar operations.

MapFragment vs. MapView

So far, all the examples shown in this chapter use MapFragment. In most cases, this is the right thing to use.

However, there may be places where you really want to use a View, rather than a Fragment, for your maps.

The good news is that Maps V2 does have a MapView. MapFragment usually handles creating and managing the MapView for you, but you can, if you wish, avoid MapFragment and manage the MapView yourself.

The biggest limitation is that you need to forward the lifecycle methods from your activity or fragment on to the MapView, calling onCreate(), onResume(), onPause(), onDestroy(), and onSaveInstanceState() on the MapView. Normally, MapFragment would do that for you, saving you the trouble.

Also note that while MapView is a ViewGroup, you are not allowed to add child widgets to it.

About That AbstractMapActivity Class...

Early on, we hand-waved our way past the AbstractMapActivity that all of our MainActivity classes inherit from, and we skirted past the readyToGo() method that we were calling. Also, you may have noticed that our app has an action bar overflow item, that we do not seem to be creating in MainActivity.

Now, it is time to dive into what is going on in our AbstractMapActivity implementations.

The readyToGo() method in AbstractMapActivity is designed to help us determine if Maps V2 is “ready to go” and, if not, to help the user perhaps fix their device such that Maps V2 will work in the future:

MAPPING WITH MAPS V2

```
protected boolean readyToGo() {
    GoogleApiAvailability checker=
        GoogleApiAvailability.getInstance();

    int status=checker.isGooglePlayServicesAvailable(this);

    if (status == ConnectionResult.SUCCESS) {
        if (getVersionFromPackageManager(this)>=2) {
            return(true);
        }
        else {
            Toast.makeText(this, R.string.no_maps, Toast.LENGTH_LONG).show();
            finish();
        }
    }
    else if (checker.isUserResolvableError(status)) {
        AlertDialogFragment.newInstance(status)
            .show(getFragmentManager(),
                TAG_ERROR_DIALOG_FRAGMENT);
    }
    else {
        Toast.makeText(this, R.string.no_maps, Toast.LENGTH_LONG).show();
        finish();
    }

    return(false);
}
```

(from [MapsV2/Basic/app/src/main/java/com/commonsware/android/mapsv2/basic/AbstractMapActivity.java](https://android.googlesource.com/platform/cts/+/master/tests/tests/graphics/src/android/opengl/cts/))

Determining the availability of Maps V2 — or anything in the Play Services SDK — is handled through an instance of `GoogleApiAvailability`. You get a singleton instance of this class via its static `getInstance()` method.

First, we call `isGooglePlayServicesAvailable()` method on the `GoogleApiAvailability` singleton. This will return an integer indicating whether Maps V2 is available for our use or not.

If the return value is `ConnectionResult.SUCCESS` — meaning Maps V2 is indeed available to us – we check to see if OpenGL ES is version 2.0 or higher, as we did not require that in the manifest. There are a few ways in Android to check the OpenGL ES version. This sample uses some code from the Compatibility Test Suite (CTS), examining `PackageManager` to determine the major level:

```
// following from
// https://android.googlesource.com/platform/cts/+/master/tests/tests/graphics/src/android/opengl/cts/
```

(from [MapsV2/Basic/app/src/main/java/com/commonsware/android/mapsv2/basic/AbstractMapActivity.java](#))

If the major version is 2 or higher, we return true from `readyToGo()`, so `MainActivity` knows to continue on setting up the map. If the major version is 1, we display a `Toast` — a production-grade app would do something else to let the user know of the problem, most likely.

But, what if `isGooglePlayServicesAvailable()` returns something else?

MAPPING WITH MAPS V2

There are two major possibilities here:

1. The error is something that the user might be able to rectify, such as by downloading the Google Play Services app from the Play Store
2. The error is something that the user cannot recover from

We can distinguish these two cases by calling `isUserResolvableError()` on the `GoogleApiAvailability` singleton, passing in the value we received from `isGooglePlayServicesAvailable()`. This will return `true` if the user might be able to fix the problem, `false` otherwise.

In the false case, the user is just out of luck, so we display a `Toast` to alert them of this fact, then `finish()` the activity and return `false`, so `MainActivity` skips over the rest of its work.

In the true case, we can display something to the user to prompt them to fix the problem. One way to do that is to use a dialog obtained from Google code, by calling the static `getErrorDialog()` method on a `GoogleApiAvailability` singleton. In our case, we wrap that in a `DialogFragment` named `ErrorDialogFragment`, implemented as a static inner class of `AbstractMapActivity`:

```
public static class ErrorDialogFragment extends DialogFragment {
    static final String ARG_ERROR_CODE="errorCode";

    static ErrorDialogFragment newInstance(int errorCode) {
        Bundle args=new Bundle();
        ErrorDialogFragment result=new ErrorDialogFragment();

        args.putInt(ARG_ERROR_CODE, errorCode);
        result.setArguments(args);

        return(result);
    }

    @Override
    public Dialog onCreateDialog(Bundle savedInstanceState) {
        Bundle args=getArguments();
        GoogleApiAvailability checker=
            GoogleApiAvailability.getInstance();

        return(checker.getErrorDialog(getActivity(),
            args.getInt(ARG_ERROR_CODE), 0));
    }
}
```

MAPPING WITH MAPS V2

```
@Override
public void onDismiss(DialogInterface dlg) {
    if (getActivity() != null) {
        getActivity().finish();
    }
}
}
```

(from [MapsV2/Basic/app/src/main/java/com/commonsware/android/mapsv2/basic/AbstractMapActivity.java](#))

While the code and comments around `getErrorDialog()` suggest that there is some way for us to find out if the user performed actions that fix the problem, this code does not seem to work well in practice. After all, downloading Google Play Services is asynchronous, so even if the user returns to our app, it is entirely likely that Maps V2 is still unavailable. As a result, when the user is done with the dialog, we `finish()` the activity, forcing the user to start it again if and when they are done downloading Google Play Services.

Testing this code requires an older device, one in which the “Google Play services” app can be uninstalled... if it can be installed at all.

As it turns out, not all Android devices support the Play Store, or the Google Play Services by extension. Notably, if the device [lacks the Play Store](#), `isUserRecoverableError()` returns true, even though the user cannot recover from this situation (except perhaps via a firmware update).

(An earlier problem where `getErrorDialog()` [could return null](#) even for cases where the error is supposedly user-recoverable has been fixed)

Helper Libraries for Maps V2

Many developers have been busy writing libraries that help in the development of Maps V2 applications, beyond Google’s own utility library mentioned in [the section on animating markers](#).

Perhaps the most expansive of these is [the Android Maps Extensions library](#). The big thing that this library offers is marker clustering, where as the user zooms out, individual markers are replaced by a marker representing a cluster, so you avoid flooding a small area with too many individual markers:

MAPPING WITH MAPS V2

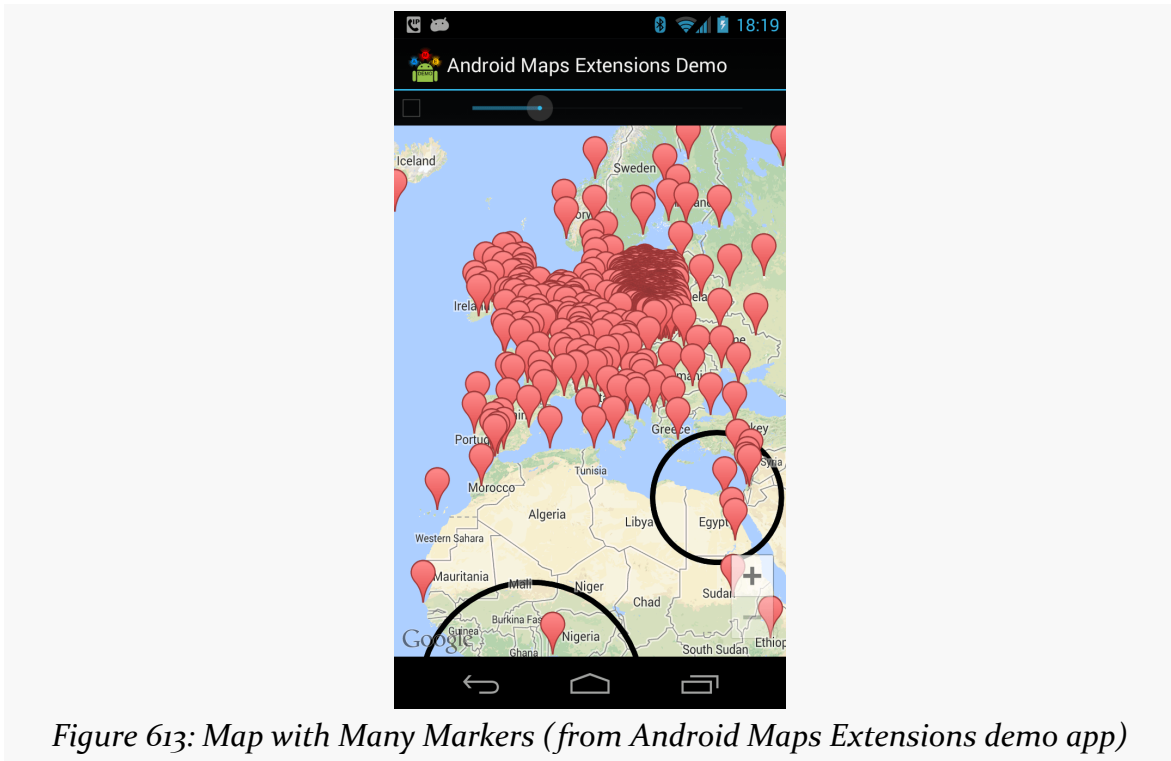

Figure 613: Map with Many Markers (from Android Maps Extensions demo app)

MAPPING WITH MAPS V2

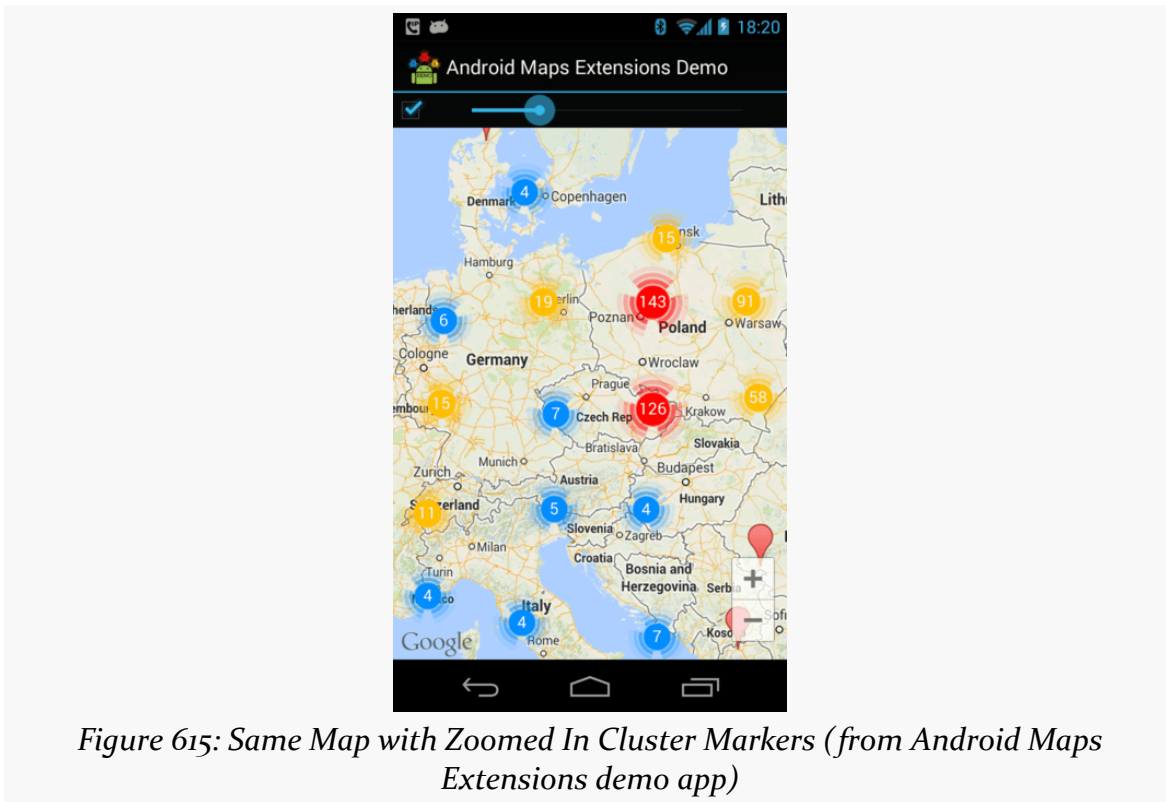

Figure 614: Same Map with Cluster Markers (from Android Maps Extensions demo app)

MAPPING WITH MAPS V2

This library wraps the Maps V2 classes, allowing the library to offer extensions to the standard Maps V2 API, including:

- Associating your own data with Marker, Polygon, Polyline, and other classes, to tie them back to your models
- Getters to retrieve previously-defined markers, etc.
- Etc.

Another library offering marker clustering is [clusterkraf](#), from Two Toasters.

The clusterkraf library can optionally integrate with [Cyril Mottier's Polaris2 library](#). His original Polaris library aimed to provide more features to Maps V1; Polaris2 fills a similar role for Maps V2. At this time, Polaris2 is a smaller library, simply because Maps V2 handles much of what Polaris provided. Polaris2, like Android Maps Extensions, wraps the Maps V2 API with its own classes, in lieu of subclassing (since most Maps V2 classes are marked final). Of note, Polaris2 offers reset() methods on many of the . . .Options classes (e.g., MarkerOptions), and offers constants for the minimum and maximum valid latitude and longitude.

Problems with Maps V2 at Runtime

Portions of the logic that powers your Maps V2 `MapFragment` are supplied by the Google Play Services app. As a result, many operations with Maps V2, such as manipulating markers, require IPC calls between your app and Google Play Services. If those IPC calls are synchronous, they will add a bit of overhead to your app — enough that you will want to avoid them in time-critical pieces of code, tight loops, and the like.

Problems with Maps V2 Deployment

Of course, the key question is: should you be using Maps V2 at all?

Google thinks so, as they have [turned off access to new API keys for Maps V1](#). That makes ongoing development of Maps V1 solutions a bit risky, as you cannot create new API keys for new signing keys, such as if you need to replace your debug keystore.

However, Maps V2 has some deployment limitations at this time. While 99.8+% of Android devices that have the Play Store have the requisite OpenGL ES 2.0+, some devices that have a suitable OpenGL ES version may not have the Play Store or otherwise be unable to get Google Play Services, required for using Maps V2. The `isGooglePlayServicesAvailable()` approach advocated by Google can help determine this at runtime, though this approach used to have some bugs, and it still cannot always help you recover from this problem.

And, as the next section illustrates, not every Android device supports Maps V2, because not every device supports Google Play Services.

What Non-Compliant Devices Show

If your app tries to bring up Maps V2 on a device that cannot possibly have the Play Services Framework — such as a Kindle Fire — the user will see an error dialog:

Google Play services

Google Play services, which some of your applications rely on, is not supported by your device. Please contact the manufacturer for assistance.

OK

Figure 616: Maps V2 Error on Kindle Fire

For those devices, you will need to consider some alternative source of maps.

Mapping Alternatives

Beyond using Maps V2 or Maps V1, you may need to consider other mapping alternatives. The Google mapping APIs are only available on Android devices that have the Maps SDK add-on (Maps V1) or Google Play Services (Maps V2). Not all devices have those. And, the limitations of Maps V2 deployment and the deprecation of Maps V1 may convince you that relying upon Google for maps is not safe at the present time.

The most common native replacement for Google's mapping is [OpenStreetMap](#), which to some extent is "the Wikipedia of maps". [OSMDroid](#) is a library that provides a Maps V1-ish API for embedding OpenStreetMap-based maps into your application.

Another solution is to integrate Web-based Google maps into your app, the same way that you might embed them into your Web site. An activity hosting a `WebView` can display a Web-based Google Map, for example.

Certain devices may have access to other native mapping solutions. For example, Amazon has published [their own maps API](#) for use with the Kindle Fire.

Crafting Your Own Views

One of the classic forms of code reuse is the GUI widget. Since the advent of Microsoft Windows — and, to some extent, even earlier — developers have been creating their own widgets to extend an existing widget set. These range from 16-bit Windows “custom controls” to 32-bit Windows OCX components to the innumerable widgets available for Java Swing and SWT, and beyond. Android lets you craft your own widgets as well, such as extending an existing widget with a new UI or new behaviors.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book.

Pick Your Poison

You have five major options for creating a custom `View` class.

First, your “custom `View` class” might really only be custom `Drawable` resources. Many widgets can adopt a radically different look and feel just with replacement graphics. For example, you might think that these toggle buttons from the Android 2.1 Google Maps application are some fancy custom widget:

Figure 617: Google Maps navigation toggle buttons

In reality, those are just radio buttons with replacement images.

Second, your custom View class might be a simple subclass of an existing widget, where you override some behaviors or otherwise inject your own logic. Unfortunately, most of the built-in Android widgets are not really designed for this sort of simple subclassing, so you may be disappointed in how well this particular technique works.

Third, your custom View class might be a composite widget — akin to an activity's contents, complete with layout and such, but encapsulated in its own class. This allows you to create something more elaborate than you will just by tweaking resources. We will see this later in the chapter with `ColorMixer`.

Fourth, you might want to implement your own layout manager, if your GUI rules do not fit well with `RelativeLayout`, `TableLayout`, or other built-in containers. For example, you might want to create a layout manager that more closely mirrors the “box model” approach taken by XUL and Flex, or you might want to create one that mirrors Swing's `FlowLayout` (laying widgets out horizontally until there is no more room on the current row, then start a new row).

Finally, you might want to do something totally different, where you need to draw the widget yourself. For example, the `ColorMixer` widget uses `SeekBar` widgets to control the mix of red, blue, and green. But, you might create a `ColorWheel` widget that draws a spectrum gradient, detects touch events, and lets the user pick a color that way.

Some of these techniques are fairly simple; others are fairly complex. All share some common traits, such as widget-defined attributes, that we will see throughout the remainder of this chapter.

Colors, Mixed How You Like Them

The classic way for a user to pick a color in a GUI is to use a color wheel like this one:

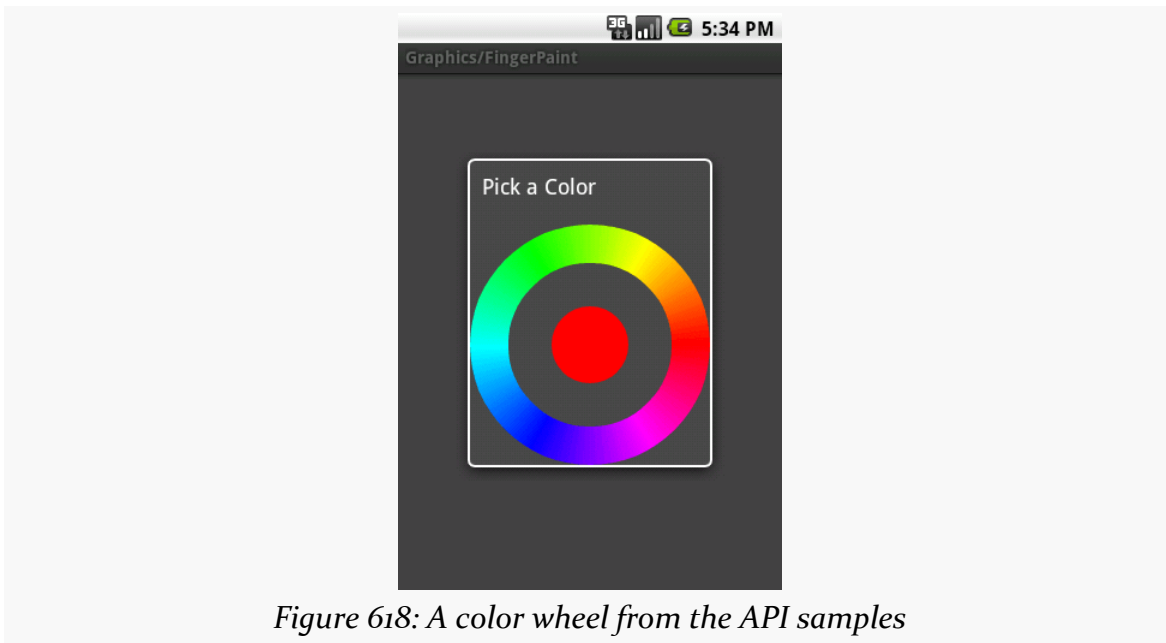

Figure 618: A color wheel from the API samples

There is even code to make one in the [API samples](#).

However, a color wheel like that is difficult to manipulate on a touch screen, particularly a capacitive touchscreen designed for finger input. Fingers are great for gross touch events and lousy for selecting a particular color pixel.

Another approach is to use a mixer, with sliders to control the red, green, and blue values:

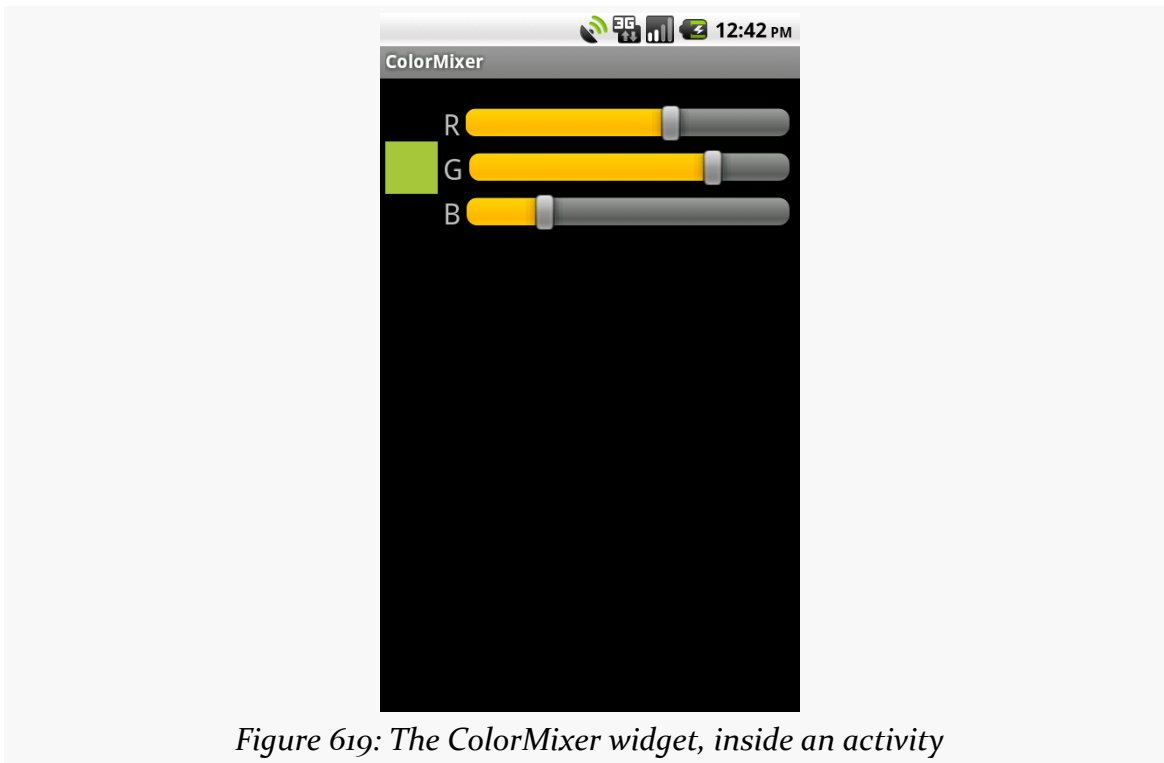

Figure 619: The ColorMixer widget, inside an activity

That is the custom widget you will see in this section, based on the code in the [Views/ColorMixer](#) sample project.

The Layout

ColorMixer is a composite widget, meaning that its contents are created from other widgets and containers. Hence, we can use a layout file to describe what the widget should look like.

The layout to be used for the widget is not that much: three SeekBar widgets (to control the colors), three TextView widgets (to label the colors), and one plain View (the “swatch” on the left that shows what the currently selected color is). Here is the file, found in `res/layout/mixer.xml` in the Views/ColorMixer project:

```
<?xml version="1.0" encoding="utf-8"?>
<merge xmlns:android="http://schemas.android.com/apk/res/android">
  <View android:id="@+id/swatch"
        android:layout_width="40dip"
        android:layout_height="40dip"
        android:layout_alignParentLeft="true"
        android:layout_centerVertical="true"
  />
  <TextView android:id="@+id/r"
            android:layout_width="wrap_content"
            android:layout_height="wrap_content"
            android:layout_toRightOf="@+id/swatch"
            android:layout_alignTop="@+id/swatch"
            android:layout_alignLeft="@+id/swatch"
            android:layout_alignParentRight="true"
            android:layout_alignParentBottom="true"
            android:text="R"
  />
  <SeekBar android:id="@+id/r_slider"
            android:layout_width="fill_parent"
            android:layout_height="wrap_content"
            android:layout_toRightOf="@+id/r"
            android:layout_alignTop="@+id/r"
            android:layout_alignLeft="@+id/r"
            android:layout_alignParentRight="true"
            android:layout_alignParentBottom="true"
  />
  <TextView android:id="@+id/g"
            android:layout_width="wrap_content"
            android:layout_height="wrap_content"
            android:layout_toRightOf="@+id/swatch"
            android:layout_alignTop="@+id/swatch"
            android:layout_alignLeft="@+id/swatch"
            android:layout_alignParentRight="true"
            android:layout_alignParentBottom="true"
            android:text="G"
  />
  <SeekBar android:id="@+id/g_slider"
            android:layout_width="fill_parent"
            android:layout_height="wrap_content"
            android:layout_toRightOf="@+id/g"
            android:layout_alignTop="@+id/g"
            android:layout_alignLeft="@+id/g"
            android:layout_alignParentRight="true"
            android:layout_alignParentBottom="true"
  />
  <TextView android:id="@+id/b"
            android:layout_width="wrap_content"
            android:layout_height="wrap_content"
            android:layout_toRightOf="@+id/swatch"
            android:layout_alignTop="@+id/swatch"
            android:layout_alignLeft="@+id/swatch"
            android:layout_alignParentRight="true"
            android:layout_alignParentBottom="true"
            android:text="B"
  />
  <SeekBar android:id="@+id/b_slider"
            android:layout_width="fill_parent"
            android:layout_height="wrap_content"
            android:layout_toRightOf="@+id/b"
            android:layout_alignTop="@+id/b"
            android:layout_alignLeft="@+id/b"
            android:layout_alignParentRight="true"
            android:layout_alignParentBottom="true"
  />
</merge>
```

CRAFTING YOUR OWN VIEWS

```
    android:layout_marginLeft="4dip"
  />
  <TextView android:id="@+id/redLabel"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:layout_alignTop="@id/swatch"
    android:layout_toRightOf="@id/swatch"
    android:layout_marginLeft="4dip"

    android:layout_marginLeft="4dip"
    android:layout_marginRight="8dip"
  />
</merge>
```

(from [Views/ColorMixer/app/src/main/res/layout/mixer.xml](#))

One thing that is a bit interesting about this layout, though, is the root element: `<merge>`. A `<merge>` layout is a bag of widgets that can be poured into some other container. The layout rules on the children of `<merge>` are then used in conjunction with whatever container they are added to. As we will see shortly, `ColorMixer` itself inherits from `RelativeLayout`, and the children of the `<merge>` element will become children of `ColorMixer` in Java. Basically, the `<merge>` element is only there because XML files need a single root — otherwise, the `<merge>` element itself is ignored in the layout.

The Attributes

Widgets usually have attributes that you can set in the XML file, such as the `android:src` attribute you can specify on an `ImageButton` widget. You can create your own custom attributes that can be used in your custom widget, by creating a `res/values/attrs.xml` file containing `declare-styleable` resources to specify them.

For example, here is the attributes file for `ColorMixer`:

```
<resources>
  <declare-styleable name="ColorMixer">
    <attr name="initialColor" format="color" />
  </declare-styleable>
</resources>
```

(from [Views/ColorMixer/app/src/main/res/values/attrs.xml](#))

The `declare-styleable` element describes what attributes are available on the widget class specified in the `name` attribute — in our case, `ColorMixer`. Inside `declare-styleable` you can have one or more `attr` elements, each indicating the name of an attribute (e.g., `initialColor`) and what data format the attribute has (e.g., `color`). The data type will help with compile-time validation and in getting any supplied values for this attribute parsed into the appropriate type at runtime.

Here, we indicate there is only one attribute: `initialColor`, which will hold the initial color we want the mixer set to when it first appears.

There are many possible values for the `format` attribute in an `attr` element, including:

1. `boolean`
2. `color`
3. `dimension`
4. `float`
5. `fraction`
6. `integer`
7. `reference` (which means a reference to another resource, such as a `Drawable`)
8. `string`

You can even support multiple formats for an attribute, by separating the values with a pipe (e.g., `reference|color`).

The Class

Our `ColorMixer` class, a subclass of `RelativeLayout`, will take those attributes and provide the actual custom widget implementation, for use in activities.

Constructor Flavors

A `View` has three possible constructors:

1. One takes just a `Context`, which usually will be an `Activity`
2. One takes a `Context` and an `AttributeSet`, the latter of which represents the attributes supplied via layout XML
3. One takes a `Context`, an `AttributeSet`, and the default style to apply to the attributes

If you are expecting to use your custom widget in layout XML files, you will need to implement the second constructor and chain to the superclass. If you want to use styles with your custom widget when declared in layout XML files, you will need to implement the third constructor and chain to the superclass. If you want developers to create instances of your `View` class in Java code directly, you probably should implement the first constructor and, again, chain to the superclass.

CRAFTING YOUR OWN VIEWS

In the case of `ColorMixer`, all three constructors are implemented, eventually routing to the three-parameter edition, which initializes our widget. Below, you will see the first two of those constructors, with the third coming up in the next section:

```
public ColorMixer(Context context) {
    this(context, null);
}

public ColorMixer(Context context, AttributeSet attrs) {
    this(context, attrs, 0);
}
```

(from [Views/ColorMixer/app/src/main/java/com/commonsware/android/colormixer/ColorMixer.java](#))

Using the Attributes

The `ColorMixer` has a starting color — after all, the `SeekBar` widgets and `swatch View` have to show something. Developers can, if they wish, set that color via a `setColor()` method:

```
public void setColor(int color) {
    red.setProgress(Color.red(color));
    green.setProgress(Color.green(color));
    blue.setProgress(Color.blue(color));
    swatch.setBackgroundColor(color);
}
```

(from [Views/ColorMixer/app/src/main/java/com/commonsware/android/colormixer/ColorMixer.java](#))

If, however, we want developers to be able to use layout XML, we need to get the value of `initialColor` out of the supplied `AttributeSet`. In `ColorMixer`, this is handled in the three-parameter constructor:

```
public ColorMixer(Context context, AttributeSet attrs, int defStyle) {
    super(context, attrs, defStyle);

    ((Activity)getContext())
        .getLayoutInflater()
        .inflate(R.layout.mixer, this, true);

    swatch=findViewById(R.id.swatch);

    red=(SeekBar)findViewById(R.id.red);
    red.setMax(0xFF);
    red.setOnSeekBarChangeListener(onMix);
}
```

CRAFTING YOUR OWN VIEWS

```
green=(SeekBar)findViewById(R.id.green);
green.setMax(0xFF);
green.setOnSeekBarChangeListener(onMix);

blue=(SeekBar)findViewById(R.id.blue);
blue.setMax(0xFF);
blue.setOnSeekBarChangeListener(onMix);

if (attrs!=null) {
    TypedArray a=getContext()
                .obtainStyledAttributes(attrs,
                                        R.styleable.ColorMixer,
                                        0, 0);

    setColor(a.getInt(R.styleable.ColorMixer_initialColor,
                    0xFFA4C639));
    a.recycle();
}
}
```

(from [Views/ColorMixer/app/src/main/java/com/commonsware/android/colormixer/ColorMixer.java](#))

There are three steps for getting attribute values:

- Get a TypedArray conversion of the AttributeSet by calling `obtainStyledAttributes()` on our Context, supplying it the AttributeSet and the ID of our styleable resource (in this case, `R.styleable.ColorMixer`, since we set the name of the declare-styleable element to be `ColorMixer`)
- Use the TypedArray to access specific attributes of interest, by calling an appropriate getter (e.g., `getInt()`) with the ID of the specific attribute to fetch (`R.styleable.ColorMixer_initialColor`)
- Recycle the TypedArray when done, via a call to `recycle()`, to make the object available to Android for use with other widgets via an object pool (versus creating new instances every time)

Note that the name of any given attribute, from the standpoint of TypedArray, is the name of the styleable resource (`R.styleable.ColorMixer`) concatenated with an underscore and the name of the attribute itself (`_initialColor`).

In `ColorMixer`, we get the attribute and pass it to `setColor()`. Since `getInt()` on `AttributeSet` takes a default value, we supply some stock color that will be used if the developer declined to supply an `initialColor` attribute.

Also note that our `ColorMixer` constructor inflates the widget's layout. In particular, it supplies `true` as the third parameter to `inflate()`, meaning that the contents of the layout should be added as children to the `ColorMixer` itself. When the layout is inflated, the `<merge>` element is ignored, and the `<merge>` element's children are added as children to the `ColorMixer`.

Saving the State

Similar to activities, a custom `View` overrides `onSaveInstanceState()` and `onRestoreInstanceState()` to persist data as needed, such as to handle a screen orientation change. The biggest difference is that rather than receive a `Bundle` as a parameter, `onSaveInstanceState()` must return a [Parcelable](#) with its state... including whatever state comes from the parent `View`.

The simplest way to do that is to return a `Bundle`, in which we have filled in our state (the chosen color) and the parent class' state (whatever that may be).

So, for example, here are implementations of `onSaveInstanceState()` and `onRestoreInstanceState()` from `ColorMixer`:

```
@Override
public Parcelable onSaveInstanceState() {
    Bundle state=new Bundle();

    state.putParcelable(SUPERSTATE, super.onSaveInstanceState());
    state.putInt(COLOR, getColor());

    return(state);
}

@Override
public void onRestoreInstanceState(Parcelable ss) {
    Bundle state=(Bundle)ss;

    super.onRestoreInstanceState(state.getParcelable(SUPERSTATE));

    setColor(state.getInt(COLOR));
}
```

(from [Views/ColorMixer/app/src/main/java/com/commonsware/android/colormixer/ColorMixer.java](#))

The Rest of the Functionality

`ColorMixer` defines a callback interface, named `OnColorChangeListener`:

CRAFTING YOUR OWN VIEWS

```
public interface OnColorChangeListener {
    public void onColorChange(int argb);
}
```

(from [Views/ColorMixer/app/src/main/java/com/commonsware/android/colormixer/ColorMixer.java](#))

ColorMixer also provides getters and setters for an OnColorChangeListener object:

```
public OnColorChangeListener getOnColorChangeListener() {
    return(listener);
}

public void setOnColorChangeListener(OnColorChangeListener listener) {
    this.listener=listener;
}
```

(from [Views/ColorMixer/app/src/main/java/com/commonsware/android/colormixer/ColorMixer.java](#))

The rest of the logic is mostly tied up in the SeekBar handler, which will adjust the swatch based on the new color and invoke the OnColorChangeListener object, if there is one:

```
private SeekBar.OnSeekBarChangeListener onMix=new SeekBar.OnSeekBarChangeListener() {
    public void onProgressChanged(SeekBar seekBar, int progress,
        boolean fromUser) {
        int color=getColor();

        swatch.setBackgroundColor(color);

        if (listener!=null) {
            listener.onColorChange(color);
        }
    }

    public void onStartTrackingTouch(SeekBar seekBar) {
        // unused
    }

    public void onStopTrackingTouch(SeekBar seekBar) {
        // unused
    }
};
```

(from [Views/ColorMixer/app/src/main/java/com/commonsware/android/colormixer/ColorMixer.java](#))

Seeing It In Use

The project contains a sample activity, ColorMixerDemo, that shows the use of the ColorMixer widget.

CRAFTING YOUR OWN VIEWS

The layout for that activity, shown below, can be found in `res/layout/main.xml` of the Views/ColorMixer project:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
  xmlns:mixer="http://schemas.android.com/apk/res-auto"
  android:layout_width="match_parent"
  android:layout_height="wrap_content"
  android:orientation="vertical"
>
  <TextView android:id="@+id/color"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
  />
  <com.commonsware.android.colormixer.ColorMixer
    android:id="@+id/mixer"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    mixer:initialColor="#FFA4C639"
  />
</LinearLayout>
```

(from [Views/ColorMixer/app/src/main/res/layout/main.xml](#))

Notice that the root `LinearLayout` element defines two namespaces, the standard `android` namespace, and a separate one named `mixer`. The `mixer` namespace is given a URL of `http://schemas.android.com/apk/res-auto`, which indicates to the Android build system to match up `mixer` attributes with their respective widgets that are supplied via Android library projects.

Our `ColorMixer` widget is in the layout, with a fully-qualified class name (`com.commonsware.android.colormixer.ColorMixer`), since `ColorMixer` is not in the `android.widget` package. Notice that we can treat our custom widget like any other, giving it a width and height and so on.

The one attribute of our `ColorMixer` widget that is unusual is `mixer:initialColor`. `initialColor`, you may recall, was the name of the attribute we declared in `res/values/attrs.xml` and retrieve in Java code, to represent the color to start with. The `mixer` namespace is needed to identify where Android should be pulling the rules for what sort of values an `initialColor` attribute can hold. Since our `<attr>` element indicated that the format of `initialColor` was `color`, Android will expect to see a color value here, rather than a string or dimension.

The `ColorMixerDemo` activity is not very elaborate:

CRAFTING YOUR OWN VIEWS

```
package com.commonware.android.colormixer;

import android.app.Activity;
import android.os.Bundle;
import android.widget.TextView;

public class ColorMixerDemo extends Activity {
    private TextView color=null;

    @Override
    public void onCreate(Bundle state) {
        super.onCreate(state);
        setContentView(R.layout.main);

        color=(TextView)findViewById(R.id.color);

        ColorMixer mixer=(ColorMixer)findViewById(R.id.mixer);

        mixer.setOnColorChangeListener(onColorChange);
    }

    private ColorMixer.OnColorChangeListener onColorChange=
        new ColorMixer.OnColorChangeListener() {
            public void onColorChange(int argb) {
                color.setText(Integer.toHexString(argb));
            }
        };
}
```

(from <Views/ColorMixer/app/src/main/java/com/commonware/android/colormixer/ColorMixerDemo.java>)

It gets access to both the ColorMixer and the TextView in the main layout, then registers an OnColorChangeListener with the ColorMixer. That listener, in turn, puts the value of the color in the TextView, so the user can see the hex value of the color along with the shade itself in the swatch.

ReverseChronometer: Simply a Custom Subclass

Sometimes, what you want to achieve only requires a basic subclass of an existing widget (or container), into which you can pour your business logic.

For example, Android has a Chronometer widget, which is used for denoting elapsed time of some operation. It works well, but it only counts up from zero. It cannot be used to display a countdown instead.

CRAFTING YOUR OWN VIEWS

But, we can roll a `ReverseChronometer` that does, simply by subclassing `TextView`, as seen in the [Views/ReverseChronometer](#) sample project:

```
package com.commonware.android.revchron;

import android.content.Context;
import android.graphics.Color;
import android.os.SystemClock;
import android.util.AttributeSet;
import android.widget.TextView;

public class ReverseChronometer extends TextView implements Runnable {
    long startTime=0L;
    long overallDuration=0L;
    long warningDuration=0L;

    public ReverseChronometer(Context context, AttributeSet attrs) {
        super(context, attrs);

        reset();
    }

    @Override
    public void run() {
        long elapsedSeconds=
            (SystemClock.elapsedRealtime() - startTime) / 1000;

        if (elapsedSeconds < overallDuration) {
            long remainingSeconds=overallDuration - elapsedSeconds;
            long minutes=remainingSeconds / 60;
            long seconds=remainingSeconds - (60 * minutes);

            setText(String.format("%d:%02d", minutes, seconds));

            if (warningDuration > 0 && remainingSeconds < warningDuration) {
                setTextColor(0xFFFF6600); // orange
            }
            else {
                setTextColor(Color.BLACK);
            }

            postDelayed(this, 1000);
        }
        else {
            setText("0:00");
            setTextColor(Color.RED);
        }
    }
}
```

CRAFTING YOUR OWN VIEWS

```
}

public void reset() {
    startTime=SystemClock.elapsedRealtime();
    setText("--:--");
    setTextColor(Color.BLACK);
}

public void stop() {
    removeCallbacks(this);
}

public void setOverallDuration(long overallDuration) {
    this.overallDuration=overallDuration;
}

public void setWarningDuration(long warningDuration) {
    this.warningDuration=warningDuration;
}
}
```

(from [Views/ReverseChronometer/app/src/main/java/com/commonsware/android/revchron/ReverseChronometer.java](#))

ReverseChronometer is designed to show minutes and seconds remaining from some initial time. In the constructor, by means to a call to a `reset()` method, we set the text of the `TextView` to show a generic starting point (“--:--”), set its color to black, and note the current time (`SystemClock.elapsedRealtime()`) in a `startTime` data member.

ReverseChronometer also tracks two durations in seconds, with corresponding setter methods:

- `overallDuration` is how long the countdown should run from beginning to end
- `warningDuration` is how far from the end we should change the color of the `TextView` from black to orange, to hint to the viewer that time is running out

ReverseChronometer implements `Runnable`, and when its `run()` method is called, it determines how many seconds have elapsed since that `startTime` value. Depending on the amount of seconds remaining, we either:

- Just update the text to show the minutes and seconds remaining
- Update the text and set the color to black or orange
- Set the text to “0:00” (time has run out) and set the text color to red

CRAFTING YOUR OWN VIEWS

In either of the first two cases, we also call `postDelayed()` to schedule ourselves to run again in a second, where we can update the `TextView` contents once more. That continues until somebody calls `stop()`.

As with any custom `View`, we can reference this in a layout XML resource, fully-qualifying the class name used as the name of our XML element for the widget. And, since we inherit from `TextView`, we can set any of the attributes that we want on that `TextView`, in terms of styling the text, positioning it within a parent container, etc.:

```
<RelativeLayout xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:tools="http://schemas.android.com/tools"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    tools:context=".MainActivity">

    <com.commonsware.android.revchron.ReverseChronometer
        android:id="@+id/chrono"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:layout_centerInParent="true"
        android:textSize="50sp"
        android:textStyle="bold"/>

</RelativeLayout>
```

(from [Views/ReverseChronometer/app/src/main/res/layout/activity_main.xml](#))

All our activity needs to do is set the durations, then call `run()` and `stop()` at appropriate times, such as when the activity is resumed and paused:

```
package com.commonsware.android.revchron;

import android.app.Activity;
import android.os.Bundle;

public class MainActivity extends Activity {
    private ReverseChronometer chrono=null;

    @Override
    protected void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.activity_main);

        chrono=(ReverseChronometer)findViewById(R.id.chrono);
        chrono.setOverallDuration(90);
        chrono.setWarningDuration(10);
    }
}
```

CRAFTING YOUR OWN VIEWS

```
}  
  
@Override  
public void onResume() {  
    super.onResume();  
  
    chrono.run();  
}  
  
@Override  
public void onPause() {  
    chrono.stop();  
  
    super.onPause();  
}  
}
```

(from [Views/ReverseChronometer/app/src/main/java/com/commonsware/android/revchron/MainActivity.java](#))

The result is much as you would expect: a countdown of the time remaining:

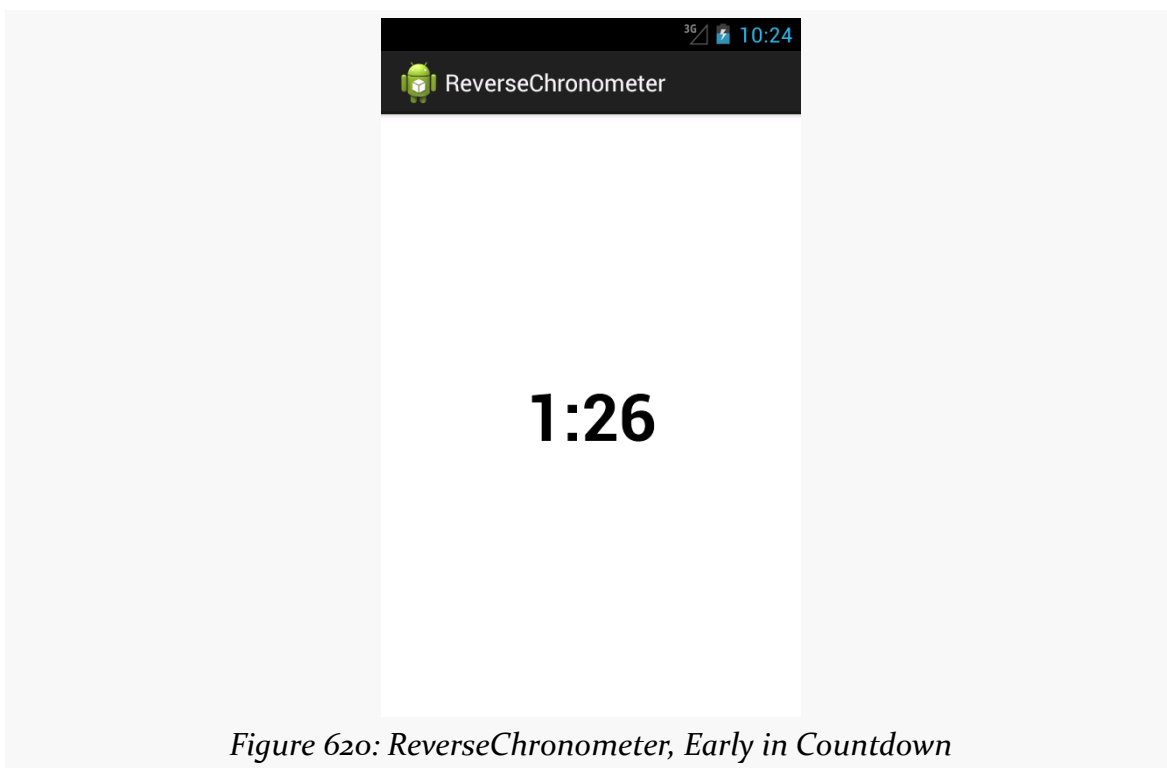

Figure 620: ReverseChronometer, Early in Countdown

...changing to orange when we are within the warning duration:

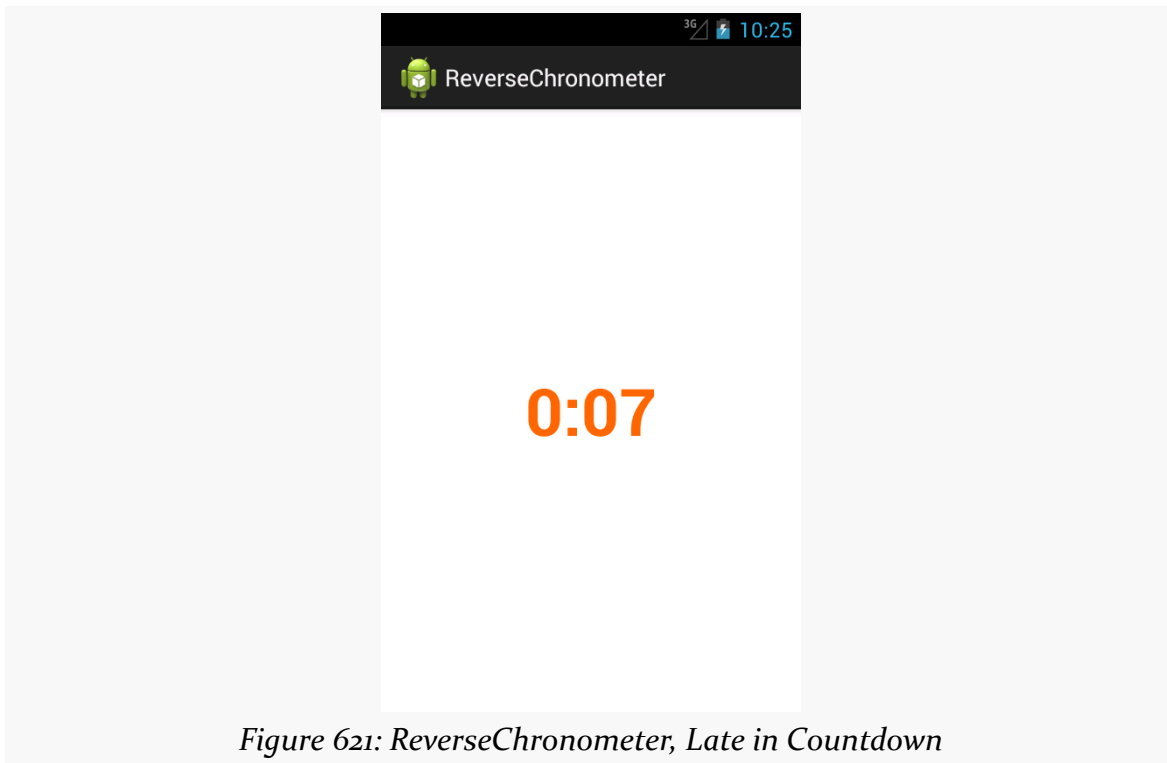

Figure 621: ReverseChronometer, Late in Countdown

...and changing to red when time has run out:

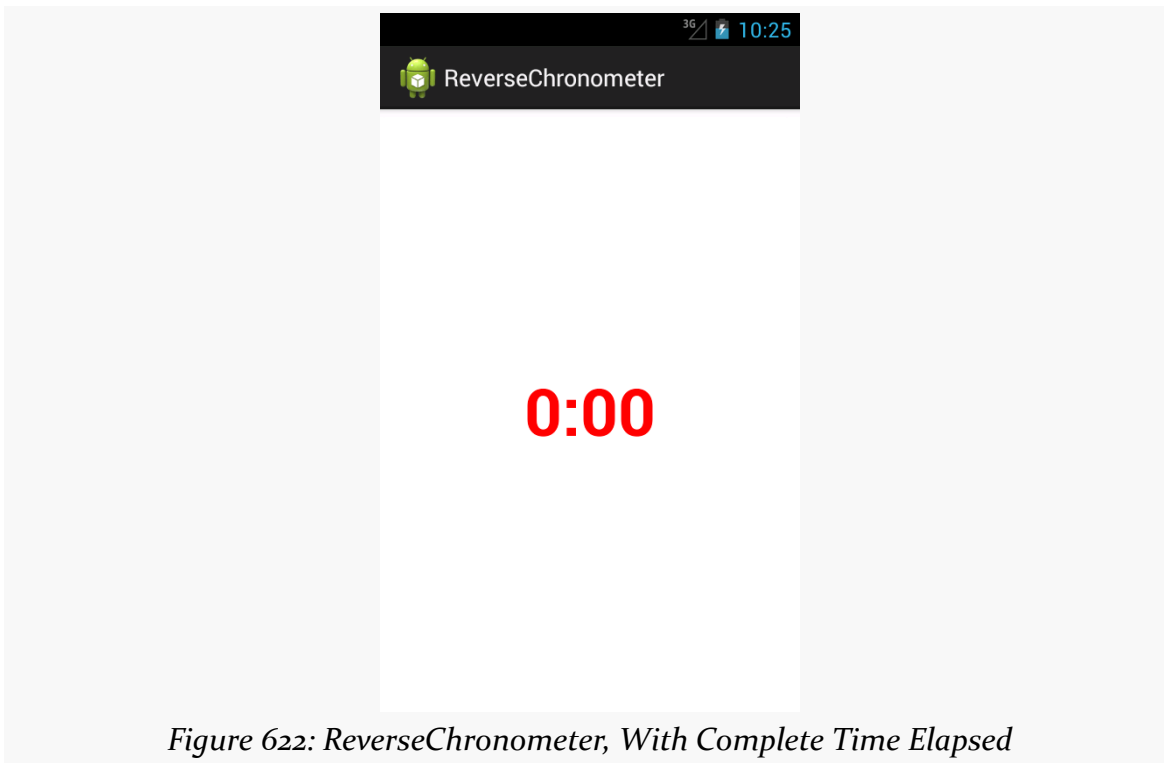

Figure 622: ReverseChronometer, With Complete Time Elapsed

Of course, much more could be done with this widget, if you chose:

- Support other constructors, beyond the two-argument constructor needed for layout inflation
- Support setting durations and colors via custom XML attributes
- Adding listeners for warning and expired events, so other things can be done at those points in time (e.g., play a sound, vibrate the device)

AspectRatioLockedFrameLayout: A Custom Container

You can also craft your own custom container classes, whether inheriting straight from `ViewGroup` to implement your own set of layout rules, or by extending an existing `ViewGroup` to merely augment its functionality.

For example, there may be cases where you want to control the aspect ratio of some set of widgets. This is important when working with preview frames off of the Camera to prevent distortion, for example.

CRAFTING YOUR OWN VIEWS

AspectLockedFrameLayout, therefore, is a custom extension of FrameLayout that ensures that its contents are kept within a particular aspect ratio, reducing the height or width of the contents to keep that aspect ratio.

AspectLockedFrameLayout is published as part of the CWAC-Layouts project, with [its own GitHub repo](#). As with many of the CWAC projects, the reusable code is distributed as a JAR and as an Android library project, with a demo/ sub-project illustrating the use of some of the library's contents.

AspectLockedFrameLayout holds onto two data members:

- A double (aspectRatio) that represents a specific aspect ratio to maintain, initialized to 0.0
- A View (aspectRatioSource) that represents some other widget whose aspect ratio should be matched, initialized to null

AspectLockedFrameLayout has corresponding setters for each:

```
        lockedHeight=(int)(lockedWidth / localRatio + .5);
    }

    // Add the padding of the border.
    lockedWidth+=hPadding;
    lockedHeight+=vPadding;

    // Ask children to follow the new preview dimension.
    super.onMeasure(MeasureSpec.makeMeasureSpec(lockedWidth,
                                                MeasureSpec.EXACTLY),
                   MeasureSpec.makeMeasureSpec(lockedHeight,
                                                MeasureSpec.EXACTLY));
    }
}

/**
 * Supplies a View as a source. The AspectLockedFrameLayout will aim to
 * match the aspect ratio of this View. This is a one-time check; if the
 * View changes its aspect ratio later, the AspectLockedFrameLayout will
 * not attempt to match it.
 *
 * @param v some View
```

The “business logic” of maintaining the aspect ratio comes in onMeasure(). onMeasure() is called on a ViewGroup when it is time for it to determine its actual size, based upon things like the requested height and width and the sizes of its

CRAFTING YOUR OWN VIEWS

children. In our case `onMeasure()` needs to be tweaked to maintain the aspect ratio, assuming that we have an aspect ratio to work with:

```
}

/**
 * {@inheritDoc}
 */
public AspectLockedFrameLayout(Context context, AttributeSet attrs) {
    super(context, attrs);
}

// from com.android.camera.PreviewFrameLayout, with slight
// modifications

/**
 * {@inheritDoc}
 */
@Override
protected void onMeasure(int widthSpec, int heightSpec) {
    double localRatio=aspectRatio;

    if (localRatio == 0.0 && aspectRatioSource != null
        && aspectRatioSource.getHeight() > 0) {
        localRatio=
            (double)aspectRatioSource.getWidth()
                / (double)aspectRatioSource.getHeight();
    }

    if (localRatio == 0.0) {
        super.onMeasure(widthSpec, heightSpec);
    }
    else {
        int lockedWidth=MeasureSpec.getSize(widthSpec);
        int lockedHeight=MeasureSpec.getSize(heightSpec);

        if (lockedWidth == 0 && lockedHeight == 0) {
            throw new IllegalArgumentException(
                "Both width and height cannot be zero -- watch out for
scrollable containers");
        }

        // Get the padding of the border background.
        int hPadding=getPaddingLeft() + getPaddingRight();
        int vPadding=getPaddingTop() + getPaddingBottom();

        // Resize the preview frame with correct aspect ratio.
        lockedWidth-=hPadding;
        lockedHeight-=vPadding;

        if (lockedHeight > 0 && (lockedWidth > lockedHeight * localRatio)) {
            lockedWidth=(int)(lockedHeight * localRatio + .5);
        }
    }
}
```

We start by determining what actually is the desired aspect ratio, held onto in a `localRatio` local variable. That will be `aspectRatio` if we do not have an `aspectRatioSource` that already knows its size, otherwise we will calculate the

aspect ratio from the source. And, if `localRatio` turns out to be `0.0`, indicating that we do not have an aspect ratio to maintain, we just chain to the superclass, so `AspectRatioLockedFrameLayout` will behave just like a normal `FrameLayout`.

If we *do* have an aspect ratio to maintain, we start by determining our requested height and width. `onMeasure()` is passed a pair of “specs” that provides details about our requested size, and we can get the height and width from those by means of the `MeasureSpec` helper class. We remove any horizontal padding — padding is considered to be “outside” the locked area and therefore is ignored in aspect ratio calculations. We then adjust the height or the width, as needed, to maintain the aspect ratio. We add back in the padding, then chain to the superclass with revised height and width “specs” via `MeasureSpec`.

Note that much of this logic was derived from `com.android.camera.PreviewFrameLayout` from the AOSP Camera application, which is used to maintain the aspect ratio of the `SurfaceView` used to display preview frames.

To use an `AspectRatioLockedFrameLayout`, just add it to your layout XML file, with an appropriate child widget/container representing the material that needs to maintain a particular aspect ratio. Since the `AspectRatioLockedFrameLayout` is overriding its natural size, you can use `android:layout_gravity` to control its positioning within some parent widget, such as centering it:

```
<FrameLayout
    android:layout_width="match_parent"
    android:layout_height="match_parent">

    <com.commonware.cwac.layouts.AspectLockedFrameLayout
        android:id="@+id/source"
        android:layout_width="match_parent"
        android:layout_height="match_parent"
        android:layout_gravity="center">

        <!-- children go here -->
    </com.commonware.cwac.layouts.AspectLockedFrameLayout>
</FrameLayout>
```

Mirror and MirroringFrameLayout: Draw It Yourself

Another scenario where aspect ratios matter is when you are presenting information on an external display via `Presentation`, as is covered [elsewhere in this book](#).

Ideally, you fill the external display. And normally this will happen for you automatically, as your `Presentation` content view should fill the available screen space... assuming that the content has the right aspect ratio, or can be suitably stretched.

One scenario where this might be a problem is if you want *the same material* shown on both the main display and on the external display. For example, suppose that you are using `Presentation` to deliver... well... a presentation. The external display is probably some form of video projector, and you will want your slides or other materials shown there. However, it is useful for you to be able to see those same slides and such on the tablet, as typically the projector screen is behind, or to the side of, the presenter. If the presenter has to keep turning around to confirm what is shown on “the big screen”, it can detract from the presentation.

Moreover, you might not only want to *show* the same material, but have it stem *from the same source*, on the tablet, for interactivity reasons. Suppose that you want to display a Web page. You might just pop up a `WebView` in the `Presentation`. But... how do you scroll? The `Presentation` offers no touch interface — projector screens do not magically respond to pinch-to-zoom just because we happen to be projecting something onto them from an Android tablet.

In this case, ideally we would like to *mirror* something. Have the actual widgets shown on the tablet, which can then respond to touch events and the like. At the same time, capture what is shown on the tablet and reproduce it, verbatim, on the `Presentation` for the audience to see. Now everybody can see the same material, and the presenter can manipulate that material.

But now aspect ratios come into play. We want to fill the `Presentation` display space, without black bars or stretching or whatever. That only works if our source material — the widgets and containers to be mirrored — have the same aspect ratio as the `Presentation`'s `Display` itself.

With that in mind, the CWAC Layouts project also contains two classes to solve this problem:

- `MirroringFrameLayout` is an `AspectRatioLockedFrameLayout` that also can mirror its content to...
- `Mirror`, a `View` that takes a `Bitmap` representing the `MirroringFrameLayout` contents and displays it

Technically, `MirroringFrameLayout` works with a `MirrorSink`, an interface that can receive updates to the content to be mirrored when that content changes. `Mirror` implements `MirrorSink`, and you could have other classes implement `MirrorSink` as well if that made sense for your app. The sections that follow focus on `MirroringFrameLayout` working with a `Mirror`, as that is the most likely scenario.

MirroringFrameLayout

`MirroringFrameLayout` extends `AspectRatioLockedFrameLayout`, so that we can lock the aspect ratio of the to-be-mirrored contents to match the aspect ratio of the `Mirror`. The `Mirror` is designed to be projected by the `Presentation`, and so if the `Mirror` fills the `Presentation`'s `Display`, we want our `MirroringFrameLayout` to match the aspect ratio so the entire `Display` can indeed be filled.

Of course, a `ViewGroup` like `FrameLayout` normally just has its children draw to the screen. In our case, we need to capture what is drawn ourselves, to supply to the `Mirror` as needed. This is a bit tricky.

```
package com.commonware.cwac.layouts;

import android.content.Context;
import android.graphics.Bitmap;
import android.graphics.Canvas;
import android.graphics.Rect;
import android.util.AttributeSet;
import android.view.ViewTreeObserver.OnPreDrawListener;
import android.view.ViewTreeObserver.OnScrollChangedListener;

/**
 * A FrameLayout that locks its aspect ratio (courtesy of AspectLockedFrameLayout)
 * and supplies "screenshots" of its contents to an associated MirrorSink,
 * such as a Mirror.
 *
 * Principally, MirroringFrameLayout and Mirror are designed for use with
 * Android's Presentation system. The MirroringFrameLayout would be part of the
 * UI of the activity on the mobile device, allowing for user interaction. The
 * Mirror would be used in the Presentation to show an audience (e.g., via a
 * projector) what is shown inside the MirroringFrameLayout on the mobile
 * device.
 */
public class MirroringFrameLayout extends AspectLockedFrameLayout
    implements OnPreDrawListener, OnScrollChangedListener {
    private MirrorSink mirror=null;
    private Bitmap bmp=null;
    private Canvas bmpBackedCanvas=null;
    private Rect rect=new Rect();

    /**
     * {@inheritDoc}
     */
    public MirroringFrameLayout(Context context) {
```

CRAFTING YOUR OWN VIEWS

```
    this(context, null);
}

/**

    initBitmap(w, h);

    super.onSizeChanged(w, h, oldw, oldh);
}

/**
 * {@inheritDoc}
 */
@Override
public boolean onPreDraw() {
    if (mirror != null) {
        if (bmp == null) {
            requestLayout();
        }
        else {
            invalidate();
        }
    }

    return(true);
}

/**
 * {@inheritDoc}
 */
@Override
public void onScrollChanged() {
    onPreDraw();
}

private void initBitmap(int w, int h) {
    if (mirror != null) {
        if (bmp == null || bmp.getWidth() != w || bmp.getHeight() != h) {
            if (bmp != null) {
                bmp.recycle();
            }

            bmp=Bitmap.createBitmap(w, h, Bitmap.Config.ARGB_8888);
            bmpBackedCanvas=new Canvas(bmp);
        }
    }
}
}
```

Our one-argument constructor uses `this()` to chain to the two-argument constructor. The two-argument constructor calls `setWillNotDraw(false)` indicating to Android that we want this `ViewGroup` to participate in the drawing process like a

regular `View` — normally, certain steps in the drawing process are skipped as being irrelevant to `View` classes that do not draw anything themselves.

We have a `setMirror()` method, where the activity or fragment can supply the `MirrorSink` that is connected to this `MirroringFrameLayout`. In addition to holding onto the `MirrorSink` in a `mirror` data member, we call `setAspectRatioSource()`, inherited from `AspectLockedFrameLayout`, so our contents will match the aspect ratio from that source.

`MirroringFrameLayout` overrides `onAttachedToWindow()` and `onDetachedFromWindow()`. As one might guess, these callbacks are called when views are attached and detached from some window. Usually, that window represents an activity, though it could represent a `Dialog` or a `Presentation`.

In those callbacks, we connect with the `ViewTreeObserver` of the `MirroringFrameLayout`. A `ViewTreeObserver` is a way to find out about events of a view tree, rooted at some `ViewGroup`. In our case, we want to find out when children are going to be drawn (`addOnPreDrawListener()`) and when they are scrolled (`addOnScrollChangeListener()`).

We override `onSizeChanged()`. This is called on any `View` when its size may have changed, either because it is being sized initially when the UI is being set up, or because something else nearby changed size (e.g., its parent) and therefore the size of the `View` itself may now be different. In our case, we use `onSizeChanged()` to set up a `Bitmap` object, sized to match our size, and a `Canvas` object that wraps around that `Bitmap` object. As you will see, we will use this `Canvas` to capture what is being drawn on the screen, for later use by the `Mirror`.

We also override `draw()`. This is, in effect, the “entry point” into the logic that causes a `View` to render itself on the screen, by drawing to a supplied `Canvas` object. Most `View` classes do not override `draw()`, as the real rendering is done in an `onDraw()` method, as we will see with `Mirror` later in this chapter. However, in our case, we have to override `draw()` for one simple reason: we do not want to draw to the `Canvas` supplied by Android to the `draw()` method. We want to draw to our own `Canvas`, backed by that `Bitmap`.

To that end, if we have a `MirrorSink`, we:

- Make sure the `Bitmap` starts off blank by calling `eraseColor()`
- Chain to the superclass, replacing the `Canvas` given to us in `draw()` by our own `Bitmap`-backed `Canvas`

- Calculate a Rect object with our size and position, using `getDrawingRect()`
- Use that Rect and the Bitmap to render the Bitmap to the “real” Canvas supplied to us in `draw()`
- Call `update()` on the `MirrorSink`, to give it the new Bitmap

By rendering our contents to the Bitmap-backed Canvas, instead of the normal one, we capture a copy of the output, in the form of the Bitmap. Since the Bitmap has the same size as the “real” Canvas (courtesy of our `onSizeChanged()` work), when we draw the Bitmap onto the Canvas, we effectively “color in” the same pixels in the same spots as if we had skipped all of this and left the normal `draw()` logic alone. But, since we still hold onto our Bitmap, we can use those same pixels elsewhere... such as in our `Mirror`.

The problem with relying on `draw()` is that it is not always called when there are changes to widgets within the `MirroringFrameLayout`. In particular, `WebView` often does not trigger `draw()` on the `MirroringFrameLayout`. That’s where the pre-draw and scroll-changed events from the `ViewTreeObserver` come into play: they give us more indication that we need to update our Bitmap.

The `onPreDraw()` method is called when a child of this `MirroringFrameLayout` is about to be drawn. If we have our `MirrorSink`, we then either call `requestLayout()` (if we have no bitmap yet) or `invalidate()` (if we do), to trigger Android to go through the draw process for the `MirroringFrameLayout` too, allowing us to update our Bitmap.

The `onScrollChanged()` method is called when a child of this `MirroringFrameLayout` has been scrolled. This delegates to `onPreDraw()`, to run through the same logic to force an update to the Bitmap.

Mirror

`Mirror` extends the base `View` class, and so it is the most “raw” of all the custom widgets and containers shown so far in this chapter. It has an `update()` method, used to connect the `MirroringFrameLayout` from which the `Mirror` can obtain what it is supposed to display:

```
package com.commonware.cwac.layouts;

import android.content.Context;
import android.graphics.Bitmap;
import android.graphics.Canvas;
import android.graphics.Rect;
```

CRAFTING YOUR OWN VIEWS

```
import android.util.AttributeSet;
import android.view.View;

/**
 * A View that implements MirrorSink and renders the supplied bitmaps to its
 * own contents. When connected to a MirroringFrameLayout, Mirror will aim to
 * show the same contents as is in the MirroringFrameLayout, at the same aspect
 * ratio, though possibly at a different size.
 *
 * Principally, MirroringFrameLayout and Mirror are designed for use with
 * Android's Presentation system. The MirroringFrameLayout would be part of the
 * UI of the activity on the mobile device, allowing for user interaction. The
 * Mirror would be used in the Presentation to show an audience (e.g., via a
 * projector) what is shown inside the MirroringFrameLayout on the mobile
 * device.
 */
public class Mirror extends View implements MirrorSink {
    private Rect rect=new Rect();
    private Bitmap bmp=null;

    /**
     * {@inheritDoc}
     */
    public Mirror(Context context) {
        super(context);
    }

    /**
     * {@inheritDoc}
     */
    public Mirror(Context context, AttributeSet attrs) {
        super(context, attrs);
    }

    /**
     * {@inheritDoc}
     */
    public Mirror(Context context, AttributeSet attrs, int defStyle) {
        super(context, attrs, defStyle);
    }

    /**
     * {@inheritDoc}
     */
    @Override
    public void update(Bitmap bmp) {
        this.bmp=bmp;
        invalidate();
    }
}
```

```
}

/**
 * {@inheritDoc}
 */
@Override
protected void onDraw(Canvas canvas) {
    super.onDraw(canvas);

    if (bmp != null) {
        getDrawingRect(rect);

        calcCenter(rect.width(), rect.height(), bmp.getWidth(),
            bmp.getHeight(), rect);
        canvas.drawBitmap(bmp, null, rect, null);
    }
}

// based upon http://stackoverflow.com/a/14679729/115145

static void calcCenter(int vw, int vh, int iw, int ih, Rect out) {
    double scale=
        Math.min((double)vw / (double)iw, (double)vh / (double)ih);

    int h=(int)(scale * ih);
    int w=(int)(scale * iw);
    int x=((vw - w) >> 1);
    int y=((vh - h) >> 1);

    out.set(x, y, x + w, y + h);
}
}
```

The bulk of the “business logic” lies in `onDraw()`, plus a helper `calcCenter()` static method.

`onDraw()` is called on a `View` when it is time for that widget to actually draw its visual representation onto the supplied `Canvas`. Different widgets will use different drawing primitive methods offered by `Canvas`, to draw lines and text and whatnot. In our case, we:

- Calculate a `Rect` object with our size and position, using `getDrawingRect()`
- Get the `Bitmap` object from the `MirroringFrameLayout`, via a call to `getLastBitmap()` (which simply returns the `Bitmap` that the `MirroringFrameLayout` is using)

- Call `calcCenter` to adjust our `Rect` to take into account the fact that our size may be different than the size of the actual `Bitmap`
- Call `drawBitmap()` on our `Canvas`, to render the `Bitmap` into the location specified by the `Rect`, where `drawBitmap()` will automatically down-sample or up-sample the image as needed to fill the necessary space

Usage and Results

Normally, you would use the `Mirror` in a layout for a `Presentation` and the `MirroringFrameLayout` in an activity that controls the `Presentation`. However, it is possible to use both in the same layout file, for light testing. However, please do not put the `Mirror` inside of the `MirroringFrameLayout`, as this is likely to cause a rupture in the space-time continuum, and you really do not want to be responsible for that.

So, in the `SimpleMirrorActivity` from the `demo/` sub-project, we use a layout that has both `Mirror` and `MirroringFrameLayout`, with the latter set to mirror a `WebView`:

```
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:tools="http://schemas.android.com/tools"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:orientation="vertical"
    tools:context=".SimpleMirrorActivity">

    <FrameLayout
        android:layout_width="match_parent"
        android:layout_height="0dp"
        android:layout_weight="1">

        <com.commonware.cwac.layouts.MirroringFrameLayout
            android:id="@+id/source"
            android:layout_width="match_parent"
            android:layout_height="match_parent"
            android:layout_gravity="center">

            <EditText
                android:id="@+id/editor"
                android:layout_width="match_parent"
                android:layout_height="match_parent"
                android:gravity="left|top"
                android:inputType="textMultiLine"/>
        </com.commonware.cwac.layouts.MirroringFrameLayout>
    </FrameLayout>
```

CRAFTING YOUR OWN VIEWS

```
<View
    android:layout_width="match_parent"
    android:layout_height="4dip"
    android:background="#FF00000" />

<com.commonware.cwac.layouts.Mirror
    android:id="@+id/target"
    android:layout_width="match_parent"
    android:layout_height="0dp"
    android:layout_weight="2" />

</LinearLayout>
```

In this case, we set the background of the `FrameLayout` holding our `MirroringFrameLayout` to green, to show how the `MirroringFrameLayout` size is changed to maintain our aspect ratio.

(or, perhaps we just like green)

Besides configuring the to-be-mirrored widgets, all you need to do is call `setMirror()` on the `MirroringFrameLayout` to enable the mirroring logic:

```
package com.commonware.cwac.layouts.demo;

import android.app.Activity;
import android.os.Bundle;
import com.commonware.cwac.layouts.Mirror;
import com.commonware.cwac.layouts.MirroringFrameLayout;

public class SimpleMirrorActivity extends Activity {
    MirroringFrameLayout source=null;

    @Override
    protected void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.simple_mirror);

        source=(MirroringFrameLayout)findViewById(R.id.source);
        Mirror target=(Mirror)findViewById(R.id.target);

        source.setMirror(target);
    }
}
```

CRAFTING YOUR OWN VIEWS

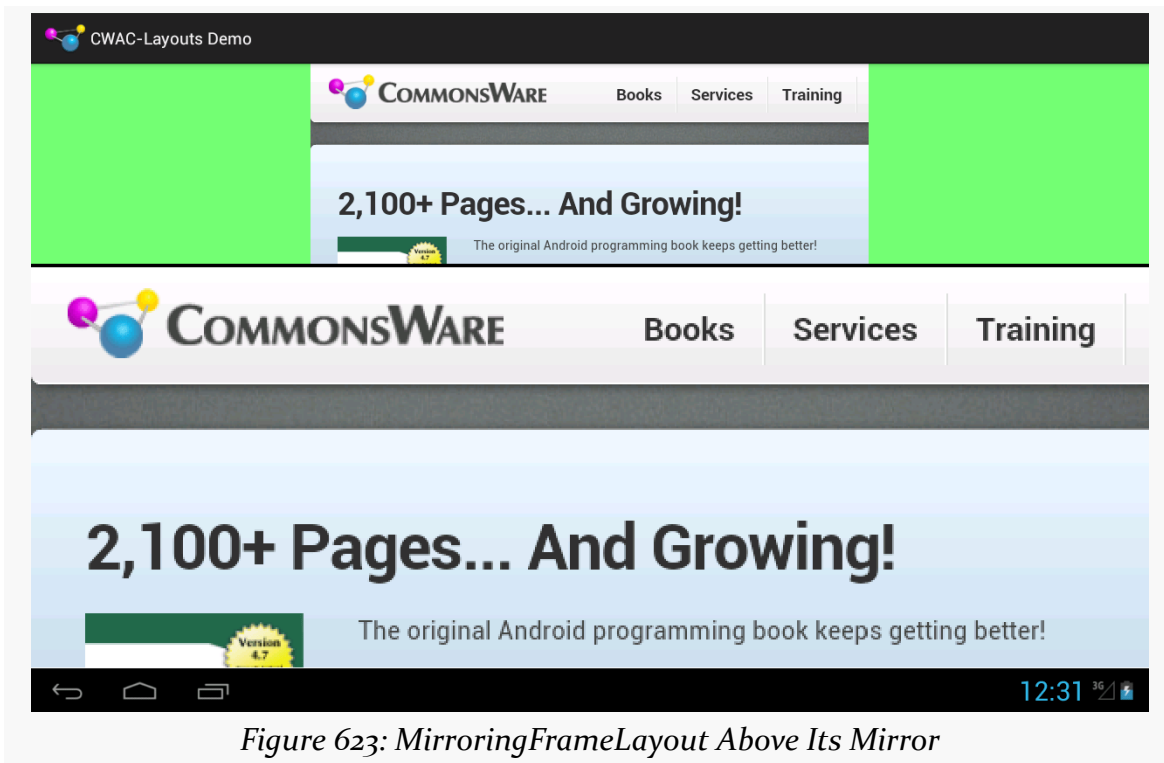

Figure 623: MirroringFrameLayout Above Its Mirror

While the bottom portion is just the `Mirror` and therefore is non-interactive, the top is the real `WebView`, which can be scrolled, with the resulting changes reflected in the `Mirror` in real-time:

Figure 624: *MirroringFrameLayout and Mirror, Showing Scrolled Contents*

Limitations

`MirroringFrameLayout` only works for materials drawn in the Java layer, that therefore can be drawn to the `Bitmap`-backed `Canvas`. Content *not* drawn in the Java layer will not work with `MirroringFrameLayout`, notably anything involving a `SurfaceView`. This not only includes your own `SurfaceView` widgets, but anything else that depends upon `SurfaceView`, such as `VideoView` or the `Maps V2` `MapView` and `MapFragment`.

Also, the re-sampling done by `Mirror` is not especially sophisticated and will cause jagged effects, particularly when up-sampling. Ideally, the `MirroredFrameLayout` will be the same size or larger than the `Mirror`. This may not always be possible, particularly with a `Mirror` shown on a 1080p external display, but the closer you can get will improve the output.

Advanced Preferences

We saw `SharedPreferences` and `PreferenceFragment` [earlier in the book](#). However, we can have more elaborate preference collection options if we wish, such as a full master-detail implementation like the Settings app sports. There are also many other common attributes on the preference XML elements that we might consider taking advantage of, such as allowing us to automatically enable and disable preferences based upon whether some other preference is checked or unchecked.

In this chapter, we will explore some of these additional capabilities in the world of Android preferences.

Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly [the one on `SharedPreferences`](#).

Introducing `PreferenceActivity`

If you have a fairly simple set of preferences to collect from the user, using a single `PreferenceFragment` should be sufficient.

On the far other end of the spectrum, Android's Settings app collects a massive amount of preference values from the user. These are spread across a series of groups of preferences, known as preference headers.

While your app may not need to collect as many preferences as does the Settings app, you may need more than what could be collected easily in a single `PreferenceFragment`. In that case, you can consider adopting the same structure of

headers-and-fragments that the Settings app uses, by means of a PreferenceActivity.

To see this in action, take a look at the [Prefs/FragmentsBC](#) sample project. It is very similar to the original SharedPreferences demo app from [before](#). However, this one arranges to collect a fifth preference value, in a separate PreferenceFragment, and uses PreferenceActivity to allow access to both PreferenceFragment UI structures.

Defining Your Preference Headers

In the master-detail approach offered by PreferenceActivity, the “master” list is a collection of preference headers. Typically, you would define these in another XML resource. In the sample project, that is found in `res/xml/preference_headers.xml`:

```
<preference-headers xmlns:android="http://schemas.android.com/apk/res/android">

  <header
    android:fragment="com.commonware.android.preffragsbc.EditPreferences$First"
    android:summary="@string/header1summary"
    android:title="@string/header1title">
  </header>
  <header
    android:fragment="com.commonware.android.preffragsbc.EditPreferences$Second"
    android:summary="@string/header2summary"
    android:title="@string/header2title">
  </header>

</preference-headers>
```

(from [Prefs/FragmentsBC/app/src/main/res/xml/preference_headers.xml](#))

Here, your root element is `<preference-headers>`, containing a series of `<header>` elements. Each `<header>` contains at least three attributes:

1. `android:fragment`, which identifies the Java class implementing the PreferenceFragment to use for this header, as is described in the next section
2. `android:title`, which is a few words identifying this header to the user

Once again, you may wish to also include `android:summary`, which is a short sentence explaining what the user will find inside of this header.

You can, if you wish, include one or more <extra> child elements inside the <header> element. These values will be put into the “arguments” Bundle that the associated PreferenceFragment can retrieve via getArguments().

Creating Your PreferenceActivity

EditPreferences — which in the original sample app was a regular Activity — is now a PreferenceActivity. It contains little more than the two fragments referenced in the above preference header XML:

```
package com.commonware.android.preffragsbc;

import android.os.Bundle;
import android.preference.PreferenceActivity;
import android.preference.PreferenceFragment;
import java.util.List;

public class EditPreferences extends PreferenceActivity {
    @Override
    public void onBuildHeaders(List<Header> target) {
        loadHeadersFromResource(R.xml.preference_headers, target);
    }

    @Override
    protected boolean isValidFragment(String fragmentName) {
        if (First.class.getName().equals(fragmentName)
            || Second.class.getName().equals(fragmentName)) {
            return(true);
        }

        return(false);
    }

    public static class First extends PreferenceFragment {
        @Override
        public void onCreate(Bundle savedInstanceState) {
            super.onCreate(savedInstanceState);

            addPreferencesFromResource(R.xml.preferences);
        }
    }

    public static class Second extends PreferenceFragment {
        @Override
        public void onCreate(Bundle savedInstanceState) {
            super.onCreate(savedInstanceState);
        }
    }
}
```

ADVANCED PREFERENCES

```
        addPreferencesFromResource(R.xml.preferences2);
    }
}
```

(from [Prefs/FragmentsBC/app/src/main/java/com/commonsware/android/preffragsbc/EditPreferences.java](#))

`onBuildHeaders()` is where we supply the preference headers, via a call to `loadHeadersFromResource()`.

We also need to have an `isValidFragment()` method, that will return `true` if the supplied fragment name is one we should be showing in this `PreferenceActivity`, `false` otherwise. This will only be called on Android 4.4+. However, we need to set up the project build target (e.g., `compileSdkVersion` in Android Studio) to API Level 19 or higher. Failing to have this method will cause your app to crash on Android 4.4+ devices, when the user tries to bring up one of your `PreferenceFragments`.

Each `PreferenceFragment` is then responsible for calling `addPreferencesFromResource()` to populate its contents. In this case, we now have two such resources: `res/xml/preferences.xml` (the original, used by `First`) and `res/xml/preferences2.xml` (used by `Second`).

The Results

On a wide enough screen — like that of a Nexus 9 in landscape — we get a master-detail presentation:

ADVANCED PREFERENCES

Figure 625: PreferenceActivity UI, on a Landscape Nexus 9

Here, we see the first preference fragment already pre-selected, showing its settings. Tapping on the second header will show the other preferences.

On a smaller screen, the master-detail approach means that we see a list of headers first:

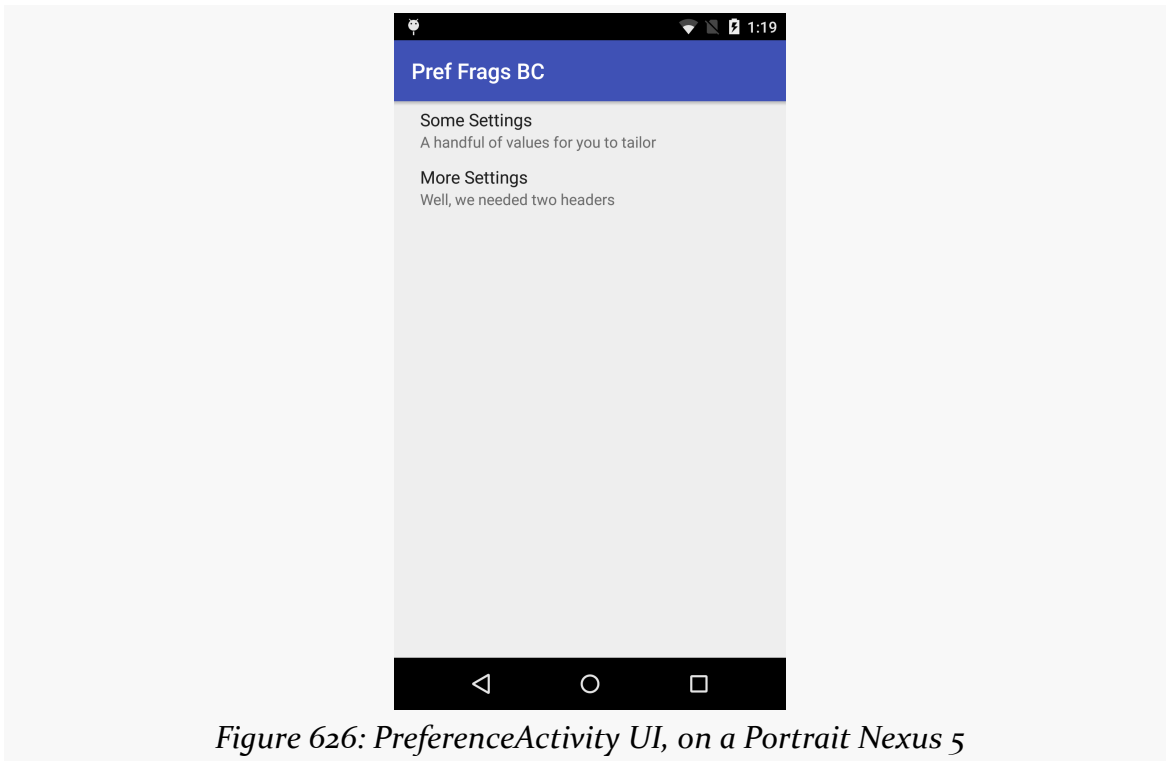

Figure 626: PreferenceActivity UI, on a Portrait Nexus 5

Tapping the headers give us access to the individual fragments.

Intents for Headers or Preferences

If you have the need to collect some preferences that are beyond what the standard preferences can handle, you have some choices.

One is to create a custom Preference. Extending `DialogPreference` to create your own Preference implementation is not especially hard. However, it does constrain you to something that can fit in a dialog.

Another option is to specify an `<intent>` element as a child of a `<header>` element. When the user taps on this header, your specified Intent is used with `startActivity()`, giving you a gateway to your own activity for collecting things that are beyond what the preference UI can handle. For example, you could have the following `<header>`:

```
<header android:icon="@drawable/something"
        android:title="Fancy Stuff"
        android:summary="Click here to transcend your
```

```
plane of existence">  
  <intent android:action="com.commonware.android.MY_CUSTOM_ACTION" />  
</header>
```

Then, so long as you have an activity with an `<intent-filter>` specifying your desired action (`com.commonware.android.MY_CUSTOM_ACTION`), that activity will get control when the user taps on the associated header.

Conditional Headers

The two-tier, headers-and-preferences approach is fine and helps to organize large rosters of preferences. However, it does tend to steer developers in the direction of displaying headers *all of the time*. For many apps, that is rather pointless, because there are too few preferences to collect to warrant having more than one header.

One alternative approach is to use the headers on larger devices, but skip them on smaller devices. That way, the user does not have to tap past a single-item `ListFragment` just to get to the actual preferences to adjust.

This is a wee bit tricky to implement. However, you have two options for how to accomplish it.

(The author would like to thank Richard Le Mesurier, whose question on this topic spurred the development of this section and its samples)

Option #1: Do Not Define the Headers

The basic plan in the first approach is to have smarts in `onBuildHeaders()` to handle this. `onBuildHeaders()` is the callback that Android invokes on our `PreferenceActivity` to let us define the headers to use in the master-detail pattern. If we want to have headers, we would supply them here; if we want to skip the headers, we would instead fall back to the classic (and, admittedly, deprecated) `addPreferencesFromResource()` method to load up some preference XML.

There is an `isMultiPane()` method on `PreferenceActivity`, starting with API Level 11, that will tell you if the activity will render with two fragments (master+detail) or not. In principle, this would be ideal to use. Unfortunately, it does not seem to be designed to be called from `onBuildHeaders()`. Similarly, `addPreferencesFromResource()` does not seem to be callable from `onBuildHeaders()`. Both are due to timing: `onBuildHeaders()` is called in the middle of the `PreferenceActivity onCreate()` processing.

ADVANCED PREFERENCES

So, we have to do some fancy footwork.

By examining [the source code to PreferenceActivity](#), you will see that the logic that drives the single-pane vs. dual-pane UI decision boils down to:

```
onIsHidingHeaders() || !onIsMultiPane()
```

If that expression returns true, we are in single-pane mode; otherwise, we are in dual-pane mode. `onIsHidingHeaders()` will normally return false, while `onIsMultiPane()` will return either true or false based upon screen size.

So, we can leverage this information in a `PreferenceActivity` to conditionally load our headers, as seen in the `EditPreferences` class in the [Prefs/SingleHeader](#) sample project:

```
package com.commonware.android.pref1header;

import android.os.Bundle;
import android.preference.PreferenceActivity;
import java.util.List;

public class EditPreferences extends PreferenceActivity {
    private boolean needResource=false;

    @SuppressWarnings("deprecation")
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        if (needResource) {
            addPreferencesFromResource(R.xml.preferences);
        }
    }

    @Override
    public void onBuildHeaders(List<Header> target) {
        if (onIsHidingHeaders() || !onIsMultiPane()) {
            needResource=true;
        }
        else {
            loadHeadersFromResource(R.xml.preference_headers, target);
        }
    }

    @Override
    protected boolean isValidFragment(String fragmentName) {
```

ADVANCED PREFERENCES

```
return(StockPreferenceFragment.class.getName().equals(fragmentName));
}
}
```

(from [Prefs/SingleHeader/app/src/main/java/com/commonsware/android/prefiheader/EditPreferences.java](#))

Here, if we are in dual-pane mode, `onBuildHeaders()` populates the headers as normal. If, though, we are in single-pane mode, we skip that step and make note that we need to do some more work in `onCreate()`.

Then, in `onCreate()`, if we did not load our headers we use the classic `addPreferencesFromResource()` method.

The net result is that on Android 3.0+ tablets, we get the dual-pane, master-detail look with our one header, but on smaller devices (regardless of version), we roll straight to the preferences themselves.

Note that this sample application uses a single `PreferenceFragment` implementation, named `StockPreferenceFragment`:

```
package com.commonsware.android.pref1header;

import android.os.Bundle;
import android.preference.PreferenceFragment;

public class StockPreferenceFragment extends PreferenceFragment {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        int res=
            getActivity().getResources()
                .getIdentifier(getArguments().getString("resource"),
                    "xml",
                    getActivity().getPackageName());

        addPreferencesFromResource(res);
    }
}
```

(from [Prefs/SingleHeader/app/src/main/java/com/commonsware/android/prefiheader/StockPreferenceFragment.java](#))

`StockPreferenceFragment` does what it is supposed to: call `addPreferencesFromResource()` in `onCreate()` with the resource ID of the

ADVANCED PREFERENCES

preferences to load. However, rather than hard-coding a resource ID, as we normally would, we look it up at runtime.

The `<extra>` elements in our preference header XML supply the name of the preference XML to be loaded:

```
<preference-headers xmlns:android="http://schemas.android.com/apk/res/android">
  <header
    android:fragment="com.commonware.android.pref1header.StockPreferenceFragment"
    android:summary="@string/header1summary"
    android:title="@string/header1title">
    <extra
      android:name="resource"
      android:value="preferences"/>
  </header>
</preference-headers>
```

(from [Prefs/SingleHeader/app/src/main/res/xml/preference_headers.xml](#))

We get that name via the arguments Bundle (`getArguments().getString("resource")`).

To look up a resource ID at runtime, we can use the `Resources` object, available from our activity via a call to `getResources()`. `Resources` has a method, `getIdentifier()`, that will return a resource ID given three pieces of information:

1. The base name of the resource (in our case, the value retrieved from the `<extra>` element)
2. The type of the resource (e.g., "xml")
3. The package holding the resource (in our case, our own package, retrieved from our activity via `getPackageName()`)

Note that `getIdentifier()` uses reflection to find this value, and so there is some overhead in the process. Do not use `getIdentifier()` in a long loop – cache the value instead.

The net is that `StockPreferenceFragment` loads the preference XML described in the `<extra>` element, so we do not need to create separate `PreferenceFragment` implementations per preference header.

Option #2: Go Directly to the Fragment

The advantage of the above approach is that it works with Android’s own logic of whether to display the master-detail fragments or just one at a time. However, that logic — the fact that `onIsHidingHeaders() || !onIsMultiPane()` determines the look of the activity — is not documented, and therefore may change in future Android releases.

Another option is to launch your `PreferenceActivity` in such a way that tells Android to skip showing the headers. This approach is better documented and therefore perhaps more stable. This can also be used in cases where you do want headers sometimes, but at other times you want to route the user to a specific `PreferenceFragment`. The downside is that this technique only works on API Level 11+.

To see how this works, take a look at the [Prefs/SingleHeader2](#) sample project.

Our `EditPreferences` class is the same implementation as in the original sample for this chapter, except that we only load up the single XML resource’s worth of preferences:

```
package com.commonware.android.pref1header;

import android.preference.PreferenceActivity;
import java.util.List;

public class EditPreferences extends PreferenceActivity {
    @Override
    public void onBuildHeaders(List<Header> target) {
        loadHeadersFromResource(R.xml.preference_headers, target);
    }

    @Override
    protected boolean isValidFragment(String fragmentName) {
        return (StockPreferenceFragment.class.getName().equals(fragmentName));
    }
}
```

(from [Prefs/SingleHeader2/app/src/main/java/com/commonware/android/pref1header/EditPreferences.java](#))

However, there is a change in our main activity (`FragmentsDemo`). Before, when the user chose the “Settings” action bar overflow item, we would just call `startActivity()` to bring up `EditPreferences`. Now, we delegate that work to an

ADVANCED PREFERENCES

`editPrefs()` method on `FragmentsDemo`, which will have the smarts to control *how* we bring up the `EditPreferences` activity:

```
private void editPrefs() {
    Intent i=new Intent(this, EditPreferences.class);

    i.putExtra(PreferenceActivity.EXTRA_SHOW_FRAGMENT,
               StockPreferenceFragment.class.getName());

    Bundle b=new Bundle();

    b.putString("resource", "preferences");

    i.putExtra(PreferenceActivity.EXTRA_SHOW_FRAGMENT_ARGUMENTS, b);

    startActivity(i);
}
```

(from [Prefs/SingleHeader2/app/src/main/java/com/commonsware/android/prefiheader/FragmentsDemo.java](https://github.com/commonsware/android/prefiheader/FragmentsDemo.java))

Here, we will add two extras to our Intent:

- `EXTRA_SHOW_FRAGMENT`, set to the fully-qualified class name of the `PreferenceFragment` to be displayed, here obtained by calling `getName()` on the `Class` object for `StockPreferenceFragment`
- `EXTRA_SHOW_FRAGMENT_ARGUMENTS`, set to a `Bundle` containing the same values that would ordinarily be loaded from the `<extra>` elements in the preference header XML resource (in our case, the name of the preference XML resource to load)

Those extras will be automatically handled by `PreferenceActivity` (on API Level 11+) and will have the effect of directly taking the user to our one-and-only fragment, bypassing the headers.

Dependent Preferences

In the Settings app, or in other apps that appear to be using `PreferenceFragment`-based UIs, you may have noticed that there are times when preferences are disabled. They become enabled when you check a `CheckBoxPreference` or toggle on a `SwitchPreference`.

That is handled via the `android:dependency` attribute on the to-be-disabled preferences. The value of `android:dependency` is the key of a `TwoStatePreference`

ADVANCED PREFERENCES

subclass, such as a `CheckBoxPreference` or a `SwitchPreference`. The enabled/disabled state of the preference with the `android:dependency` attribute depends on the checked state of the named dependency.

For example, the [Prefs/Dependency](#) sample project is a clone of [the original SharedPreferences demo app](#) with one slight change: all the preferences other than checkbox are now dependent upon checkbox:

```
<PreferenceScreen xmlns:android="http://schemas.android.com/apk/res/android">

    <CheckBoxPreference
        android:key="checkbox"
        android:summary="@string/pref1summary"
        android:title="@string/pref1title"/>

    <RingtonePreference
        android:dependency="checkbox"
        android:key="ringtone"
        android:showDefault="true"
        android:showSilent="true"
        android:summary="@string/pref2summary"
        android:title="@string/pref2title"/>

    <EditTextPreference
        android:dependency="checkbox"
        android:dialogTitle="@string/dialogtitle"
        android:key="text"
        android:summary="@string/pref3summary"
        android:title="@string/pref3title"/>

    <ListPreference
        android:dependency="checkbox"
        android:dialogTitle="@string/listdialogtitle"
        android:entries="@array/cities"
        android:entryValues="@array/airport_codes"
        android:key="list"
        android:summary="@string/pref4summary"
        android:title="@string/pref4title"/>

</PreferenceScreen>
```

(from [Prefs/Dependency/app/src/main/res/xml/preferences.xml](#))

When you run the project, the dependent preferences are disabled while the checkbox is unchecked:

ADVANCED PREFERENCES

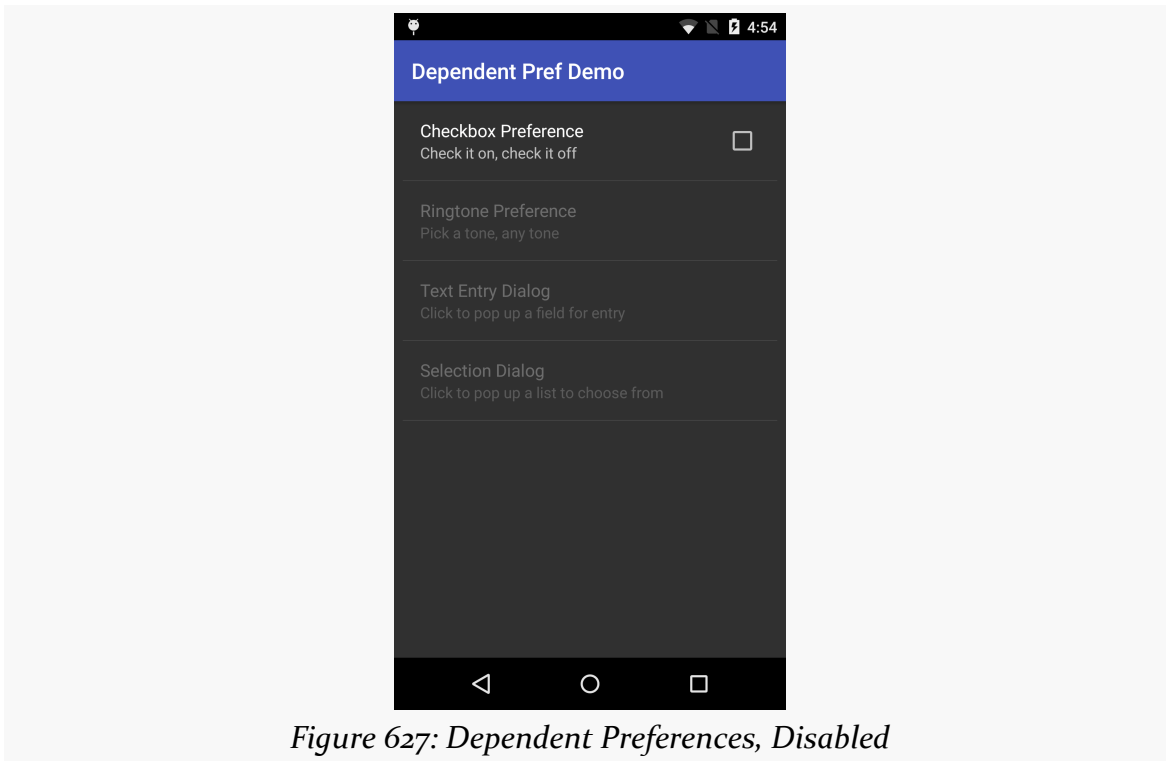

Figure 627: Dependent Preferences, Disabled

...but become enabled once the user checks the checkbox:

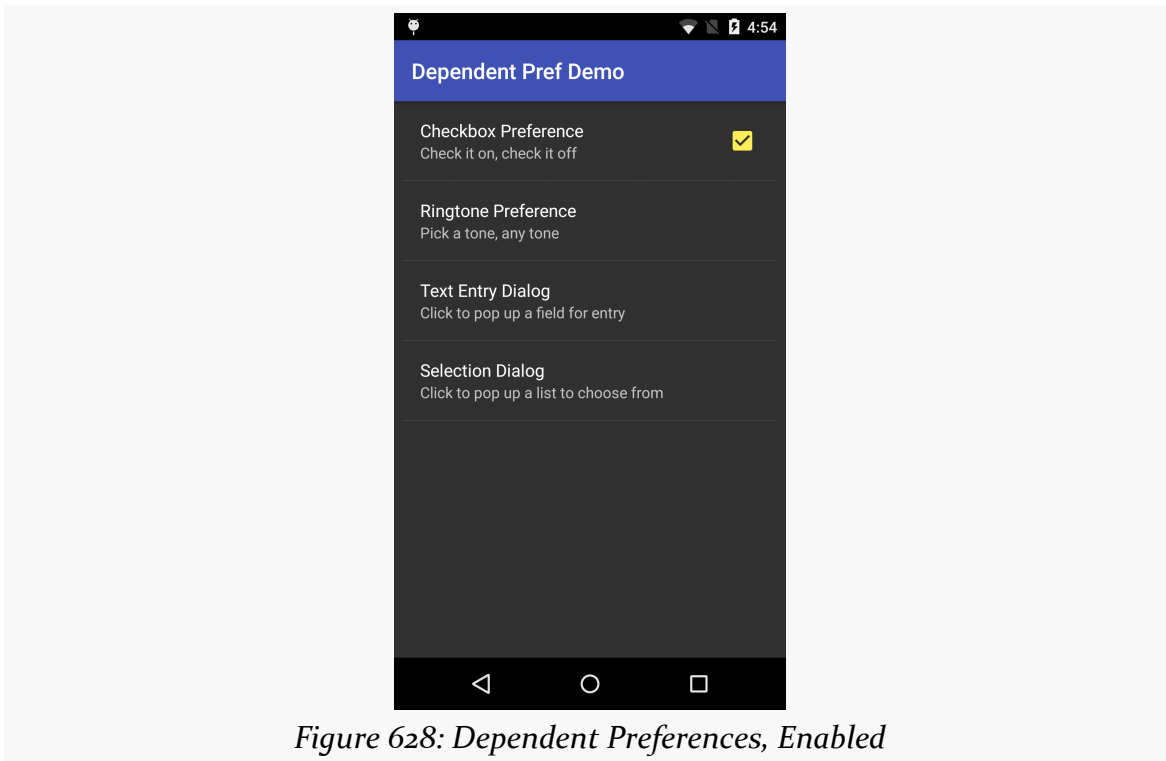

Figure 628: *Dependent Preferences, Enabled*

Nested Screens

Perhaps you have more preferences than you want to collect on a single screen, but you do not feel that a master-detail presentation is the right structure. Or, perhaps you have *lots* of preferences to collect, and even collecting preferences into groups by header is insufficient.

Another possibility is to nest preference screens. One screen holds another. On the outer preference screen, the user has a “preference” entry that simply displays the nested screen, as opposed to directly collecting any preferences.

A `<PreferenceScreen>` element in your preference XML can hold another `<PreferenceScreen>` element. That inner `<PreferenceScreen>` can come in one of two forms:

1. Inside the inner `<PreferenceScreen>` you have more preference XML elements. This means there is only one `PreferenceFragment` for the whole structure (outer `<PreferenceScreen>`, including the inner

ADVANCED PREFERENCES

- <PreferenceScreen>). However, visually, the user will “drill down” from the outer screen into the inner one by tapping on an entry.
2. The inner <PreferenceScreen> has an `android:fragment` attribute, just like a preference header might. This points to a `Fragment` — typically a `PreferenceFragment` — that will be responsible for the “inner” content. This is a bit more complex to set up, as it requires a couple of fragments. However, it gives you greater flexibility. Plus, it is fairly easy to then switch from using preference headers and the master-detail approach to using nested preference screens, or back again, as you are simply reusing the same `PreferenceFragment` implementations in either case.

The [Prefs/NestedScreens](#) sample project takes the master-detail approach shown earlier in this chapter and switches it to having a top-level screen and a nested screen. This is accomplished by adding a <PreferenceScreen> element to `res/xml/preferences.xml`, pointing to our `Second PreferenceFragment`:

```
<PreferenceScreen
    android:fragment="com.commonware.android.preffragsbc.EditPreferences$Second"
    android:key="unused"
    android:title="@string/nested_title"/>
```

(from [Prefs/NestedScreens/app/src/main/res/xml/preferences.xml](#))

Here, the `android:title` (and optional `android:summary`) will be shown on the *outer* screen, as an entry that the user can tap on to get to this inner screen. While in this sample, we are not using `android:key`, in principle you could use this to get at the `PreferenceScreen` itself to manipulate it at runtime (e.g., disable it).

For this style of <PreferenceScreen> to work, the preference XML must be used by a `PreferenceFragment` in a `PreferenceActivity` — you cannot use it with a regular `Activity`. However, just because you use `PreferenceActivity` does not mean that you have to opt into the master-detail structure. We can use the same `onCreate()`, `show-the-PreferenceFragment` approach that we use with a regular `Activity`.

However, there is one big catch: when the user taps on the entry that will launch the inner screen, the Android framework will start *another instance* of our `PreferenceActivity`. It will give us the same `EXTRA_SHOW_FRAGMENT` value as we saw earlier in this chapter. However, `PreferenceActivity` will automatically show that fragment; we do not need to show it ourselves.

But, this means that our `onCreate()` needs to distinguish between the “show the outer screen ourselves” case and the “show the inner screen automatically” case, which we can do by seeing if `EXTRA_SHOW_FRAGMENT` exists:

ADVANCED PREFERENCES

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    if (getIntent().getStringExtra(PreferenceActivity.EXTRA_SHOW_FRAGMENT)==null) {
        if (getFragmentManager().findFragmentById(android.R.id.content)==null) {
            getFragmentManager().beginTransaction()
                .add(android.R.id.content,
                    new First()).commit();
        }
    }
}
```

(from [Prefs/NestedScreens/app/src/main/java/com/commonsware/android/preffragsbc/EditPreferences.java](#))

The result is that we see the outer screen first, containing our entry for the inner screen:

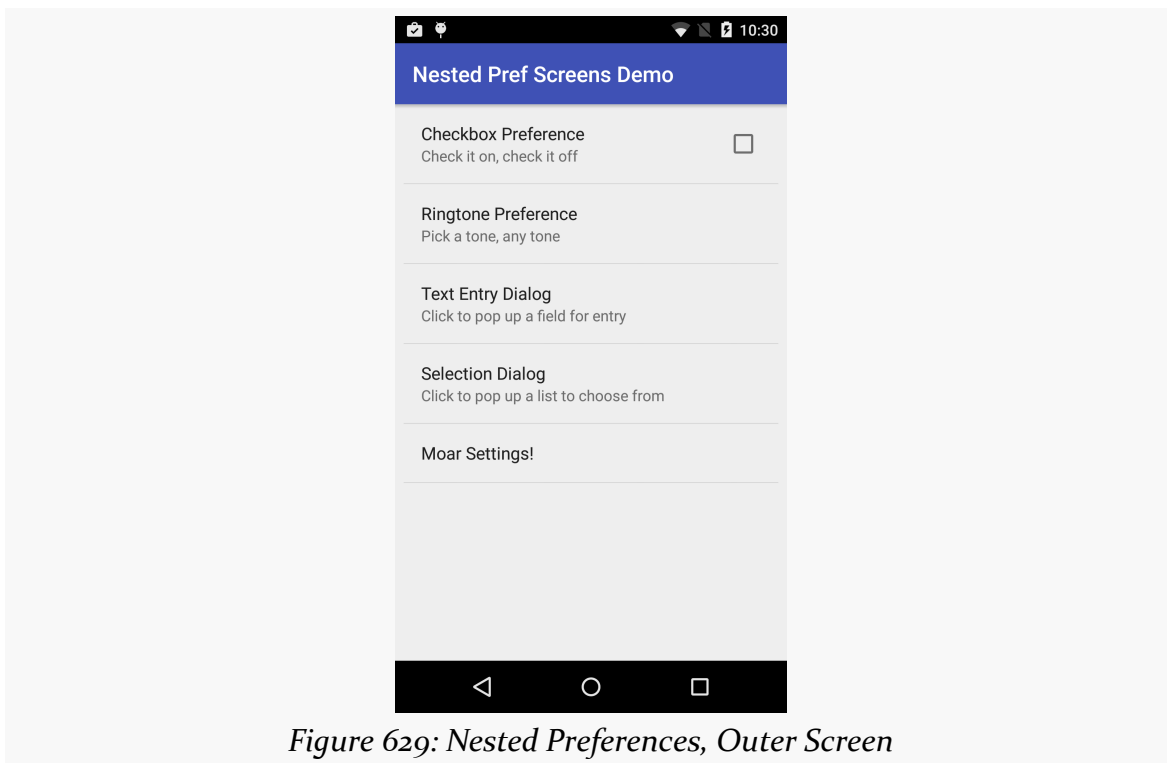

Figure 629: Nested Preferences, Outer Screen

Tapping on that entry brings up the inner, nested, screen:

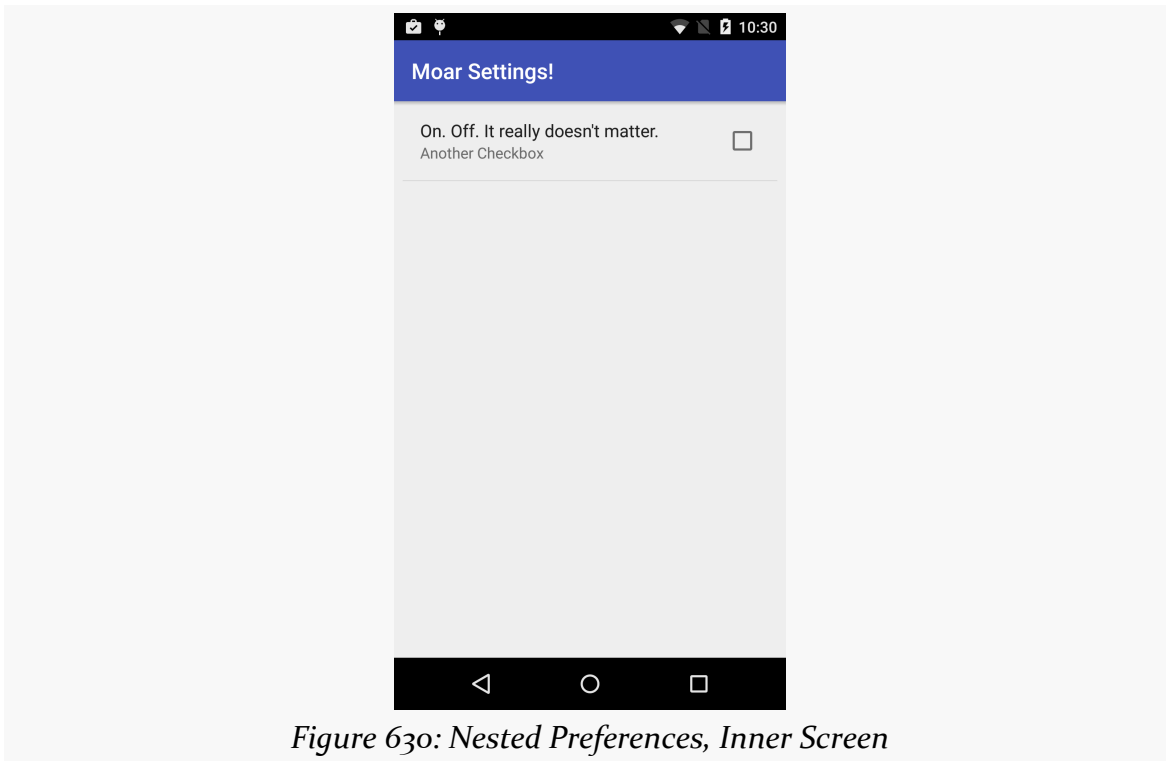

Figure 630: Nested Preferences, Inner Screen

Listening to Preference Changes

Sometimes, you may need to take steps when the user interacts with a preference in your PreferenceFragment-based UI.

A common scenario for this comes with the summary. In some cases, is it handy to have the summary reflect the current value of the preference. While some preferences naturally show their value inline (e.g., a `CheckBoxPreference`), those that extend from `DialogPreference` only show their value when the user taps on the preference to display the dialog. Putting something in the summary that reflects the value can save the user a click.

However, by default, the summary is static, populated by the `android:summary` attribute in your preference XML. If you want it to reflect the current preference value, you not only need to be able to set the summary in Java, but to be able to respond when the user changes the value, so you can update the summary again.

The [Prefs/CustomSubtitle](#) sample project demonstrates how this works. This is yet another clone of [the original SharedPreferences demo app](#). This time, the

ADVANCED PREFERENCES

preference XML is unchanged from the original. However, we have a slightly more elaborate PreferenceFragment implementation:

```
public static class Prefs extends PreferenceFragment
    implements Preference.OnPreferenceChangeListener {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        addPreferencesFromResource(R.xml.preferences);

        Preference pref=findPreference("text");

        updateSummary(pref,
            pref.getSharedPreferences().getString(pref.getKey(), null));
        pref.setOnPreferenceChangeListener(this);
    }

    @Override
    public boolean onPreferenceChange(Preference pref, Object newValue) {
        updateSummary(pref, newValue.toString());

        return(true);
    }

    private void updateSummary(Preference pref, String value) {
        if (value==null || value.length()==0) {
            pref.setSummary(R.string.msg_missing_text);
        }
        else {
            pref.setSummary(value);
        }
    }
}
```

(from [Prefs/CustomSubtitle/app/src/main/java/com/commonsware/android/preffrag/EditPreferences.java](#))

In `onCreate()`, after `addPreferencesFromResource()`, we call `findPreference()` to retrieve the Preference object that manages the snippet of UI for a particular preference. The flow here mimics that of `setContentView()` and `findViewById()`: first you inflate the resource, then you find the Java object corresponding to some XML element out of that resource. `findPreference()` takes the key of the preference that you are looking for; in this case, we are looking for the `EditTextPreference`, whose key is `text`.

ADVANCED PREFERENCES

We then call a private `updateSummary()` method, which takes the Preference and the current value of that preference and updates the summary. To get the current value, `onCreate()` can ask the Preference for its backing `SharedPreferences` (via `getSharedPreferences()`), then retrieve the value using standard getters (e.g., `getString()`). `updateSummary()` then shows the string representation of the current value, or a canned message if there does not appear to be a current value.

We also register the fragment itself as being the `OnPreferenceChangeListener`, and register the fragment with the preference via `setOnPreferenceChangeListener()`. This means that when the user manipulates this preference, we will be called with `onPreferenceChange()`. This is done *before the `SharedPreferences` are updated*. Our options are either to return `true` and have the normal persistence process continue, or return `false` and manage persistence ourselves (e.g., perform some conversion on the raw value before storing it). In our case, we are just using this to call `updateSummary()` again.

If you install the app and run it, you will not have an existing value for the preference, and so the summary shows a stock message:

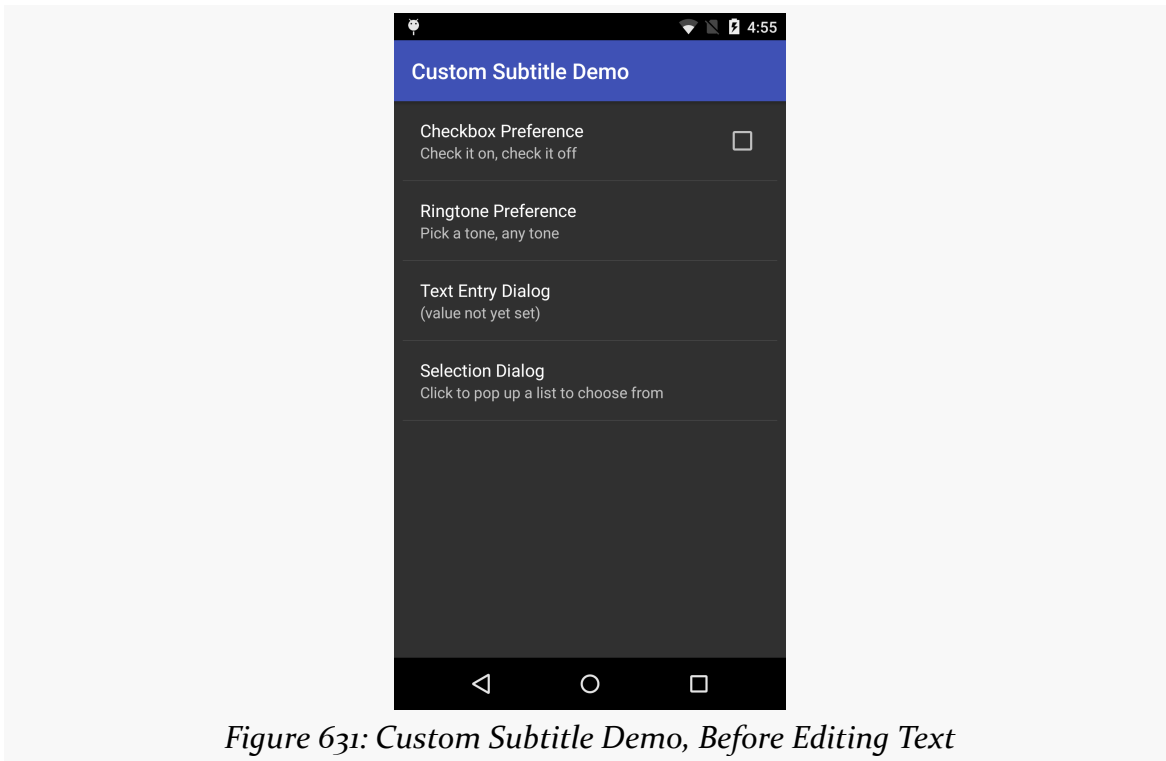

Figure 631: Custom Subtitle Demo, Before Editing Text

ADVANCED PREFERENCES

After you tap on the `EditTextPreference` and fill in some value in the dialog, the summary updates to show what you typed in:

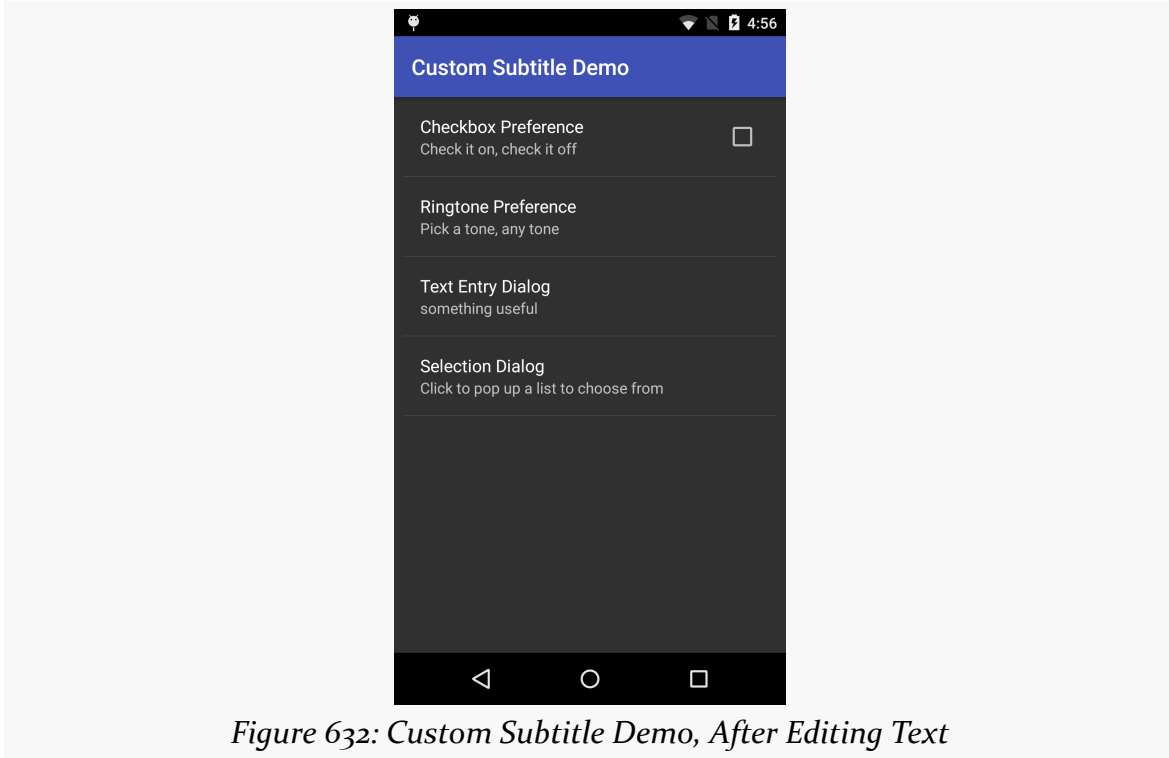

Figure 632: Custom Subtitle Demo, After Editing Text

Defaults, and Defaults

When you use `SharedPreferences` to retrieve a value, you can usually provide a default value along with the key for the value that you want. If there is no preference value for that key, you get the default that you supplied.

A preference in preference XML also has an `android:defaultValue` attribute. This is, roughly speaking, the preference UI counterpart to that second parameter to the `SharedPreferences` getters. If the user interacts with the preference, the `android:defaultValue` value will be presented to the user if there was no preference value stored for that key in the underlying `SharedPreferences`.

To synchronize these, you can call `setDefaultValues()` on the `PreferenceManager` class. Given the resource ID of some preference XML, `PreferenceManager` will find all `android:defaultValue` attributes and then persist those default values to the `SharedPreferences` under their respective keys.

Listening to Preference Value Changes

Sometimes, you will have components that need to know when preference values are changed elsewhere in your app. For example, you may have a Service that is using information from SharedPreferences, and the Service may need to know when those values change.

One approach, used in all the sample apps, is simply to re-read the preference values as needed, rather than caching them in data members or something. After the first time SharedPreferences are accessed, the SharedPreferences themselves are held in heap space, and so accessing them can be fairly cheap. So, the sample apps' launcher activities just re-read the preference values in `onResume()` and update the UI that way.

If, however, that is inappropriate, inconvenient, or otherwise not what you want to do, you can call `registerOnSharedPreferenceChangeListener()` on a SharedPreferences object, supplying an instance of an implementation of the `OnSharedPreferenceChangeListener` interface. That object will be called with `onSharedPreferenceChanged()` every time a preference value changes. You are given the key to the changed value, so you can implement a filter to only pay attention to keys that matter to you. When one of those keys is reported to have changed, you can ask the SharedPreferences for the new value.

Dynamic ListPreference Contents

Many times, the items that the user can choose from in your ListPreference or MultiSelectListPreference are fixed, allowing you to populate them from `<string-array>` resources. However, sometimes, the items (display names and corresponding values) are dynamic, based upon information held elsewhere: database, server, or something at a system level. For those, we need to be able to define the preference in XML, but configure its contents in Java code.

For example, the [Introspection/SAWMonitor](#) sample project is a monitor for new and upgraded apps that ask for the `SYSTEM_ALERT_WINDOW` permission. Such apps have the right to draw over top of other apps, for anything from Facebook "chatheads" to [tapjacking attacks](#).

However, some apps may request this permission that you are perfectly fine with having it. By default, SAWMonitor will point out this permission on each subsequent update, which can get tiresome after a while. Hence, SAWMonitor

ADVANCED PREFERENCES

allows you to add apps to a “whitelist”; those apps will be ignored, even if they request `SYSTEM_ALERT_WINDOW`.

To that end, we have a `settings.xml` resource describing some preferences to collect from the user:

```
<?xml version="1.0" encoding="utf-8"?>
<PreferenceScreen xmlns:android="http://schemas.android.com/apk/res/android">
  <SwitchPreference
    android:key="enabled"
    android:title="@string/msg_enable"
    android:defaultValue="true"/>
  <MultiSelectListPreference
    android:key="whitelist"
    android:title="@string/msg_whitelist" />
</PreferenceScreen>
```

(from [Introspection/SAWMonitor/app/src/main/res/xml/settings.xml](#))

Here we have two preferences: a `SwitchPreference` for whether we should be monitoring for `SYSTEM_ALERT_WINDOW` at all, and a `MultiSelectListPreference` to allow the user to control the whitelist.

In `onCreate()` of our `SettingsFragment`, we load up those preferences into the UI via `addPreferencesFromResource()`, use `findPreference()` to retrieve both of the `Preference` objects, and use `setOnPreferenceChangeListener()` to be notified about changes to the enabled preference:

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    addPreferencesFromResource(R.xml.settings);
    pm=getActivity().getPackageManager();

    SwitchPreference enabled=(SwitchPreference)findPreference("enabled");

    enabled.setOnPreferenceChangeListener(this);

    populateWhitelist((MultiSelectListPreference)findPreference("whitelist"));
}
```

(from [Introspection/SAWMonitor/app/src/main/java/com/commonsware/android/sawmonitor/SettingsFragment.java](#))

The `populateWhitelist()` call is where we fill in the details for the `MultiSelectListPreference`. In our case, the possible values are the apps presently

ADVANCED PREFERENCES

installed that have requested the `SYSTEM_ALERT_WINDOW` permission. So, we use `PackageManager` to find those, then use that information to populate the whitelist preference:

```
void populateWhitelist(MultiSelectListPreference whitelist) {
    List<ApplicationInfo> apps=pm.getInstalledApplications(0);

    Collections.sort(apps,
        new ApplicationInfo.DisplayNameComparator(pm));

    ArrayList<CharSequence> displayNames=
        new ArrayList<CharSequence>();
    ArrayList<String> packageNames=new ArrayList<String>();

    for (ApplicationInfo app : apps) {
        try {
            PackageInfo pkgInfo=
                pm.getPackageInfo(app.packageName,
                    PackageManager.GET_PERMISSIONS);

            if (pkgInfo.requestedPermissions!=null) {
                for (String perm : pkgInfo.requestedPermissions) {
                    if (SYSTEM_ALERT_WINDOW.equals(perm)) {
                        displayNames.add(app.loadLabel(pm));
                        packageNames.add(app.packageName);
                        break;
                    }
                }
            }
        }
        catch (PackageManager.NameNotFoundException e) {
            // should not happen, quietly ignore
        }
    }

    whitelist
        .setEntries(displayNames
            .toArray(new CharSequence[displayNames.size()]));
    whitelist
        .setEntryValues(packageNames
            .toArray(new String[packageNames.size()]));
}
```

(from [Introspection/SAWMonitor/app/src/main/java/com/commonsware/android/sawmonitor/SettingsFragment.java](#))

ADVANCED PREFERENCES

Most of the code is determining which applications have that permission. However, `MultiSelectListPreference` complicates matters, by having two separate setter methods for its contents:

- `setEntries()` sets the display names, what the user will see in the multi-select dialog
- `setEntryValues()` sets the corresponding values, what will be stored in the `SharedPreferences` based upon the user's input

These each take arrays of `CharSequence` implementations, like `String`. Hence, we need two parallel arrays of values, rather than a single `ArrayList` of `Pair` objects or something.

With that in mind, `populateWhitelist()`:

- Gets the list of installed applications from the `PackageManager` (`pm` is a field initialized in `onCreate()`)
- Sorts those by display name, so our results will wind up in alphabetical order
- Creates an `ArrayList` for the display names and a separate one for the package names, which will serve as our entry values
- Iterates over the applications, gets the permissions requested by each app, and if any of those is `SYSTEM_ALERT_WINDOW`, add the display name (`loadLabel()`) and the package name to their respective lists
- Converts each of those `ArrayList` objects into a corresponding Java array, and passes them to their appropriate setters

The resulting `SettingsFragment` has the two preferences:

ADVANCED PREFERENCES

Figure 633: SAWMonitor SettingsFragment

Tapping on the “Whitelist” entry brings up the MultiSelectListPreference:

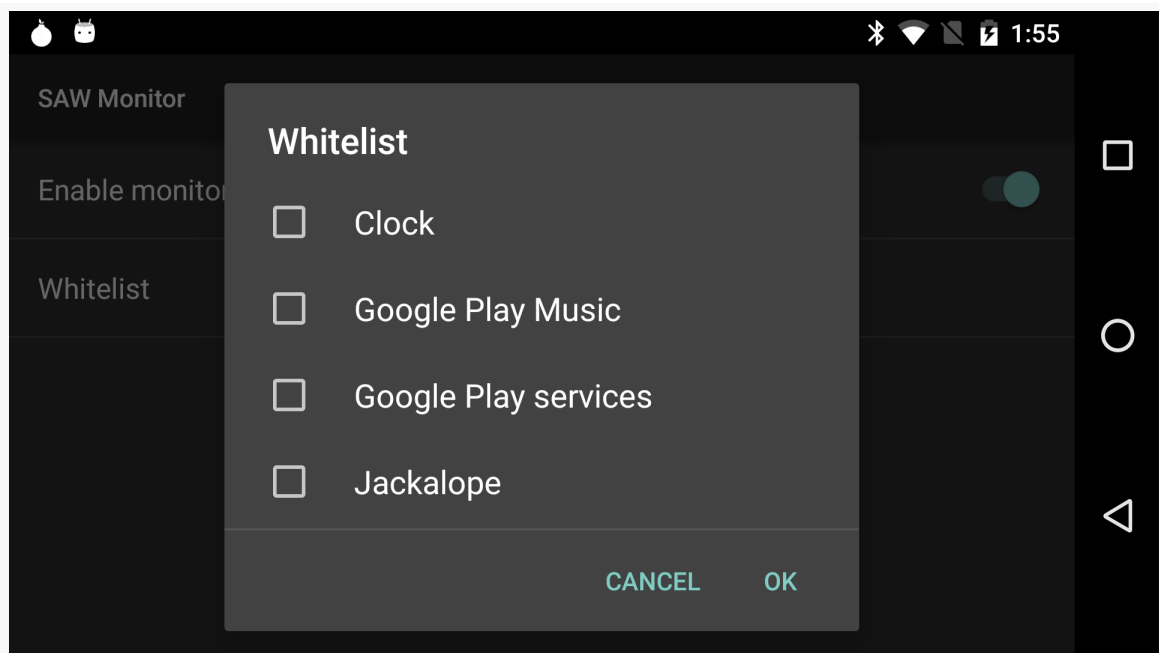

Figure 634: SAWMonitor Whitelist MultiSelectListPreference

If you run the app on your device or emulator, you will wind up with different possible entries in the `MultiSelectListPreference`, as the mix of apps requesting `SYSTEM_ALERT_WINDOW` will be different for different devices and users.

Note that, in addition to this section and the next one, you can learn more about `SAWMonitor` [elsewhere in the book](#).

Dealing with External Changes to Preferences

What happens if you have a `PreferenceFragment` in the foreground, and the preference changes “behind the scenes” by some other component of your app?

For preferences with dialogs — `ListPreference`, `EditTextPreference`, etc. — the pattern seems to be “transaction by dialog”. Whatever the preference value is at the time the dialog appears is what the user sees, and that does not change (and cannot readily *be* changed) if the preference changes while that dialog is on the screen.

However, for inline preferences — `CheckBoxPreference`, `SwitchPreference`, etc. — while the UI will not automatically update based on the external change, you can handle that yourself.

For example, there is another version of `SAWMonitor` known as [Introspection/SAWMonitorTile](#). This sample project is a clone of `SAWMonitor` with one added feature: an optional notification shade tile using a `TileService` on Android 7.0. The tile allows the user to enable and disable the monitoring, just as the user can from the `SwitchPreference`. So... what happens if the `SettingsFragment` is on the screen, the user slides open the notification shade, and taps the tile? By default, the `SettingsFragment` would be oblivious to this, with the result of the `SwitchPreference` being out of sync.

But, we can fix this.

In the `SAWMonitorTile` rendition of `SettingsFragment`, in `onStart()`, we register for preference changes, plus call a `syncEnabledStates()` method. We unregister from preference changes in `onStop()`:

```
@Override
public void onStart() {
    super.onStart();

    prefs=PreferenceManager.getDefaultSharedPreferences(getActivity());
```

ADVANCED PREFERENCES

```
prefs.registerOnSharedPreferenceChangeListener(this);
syncEnabledStates();
}

@Override
public void onStop() {
    super.onStop();

    prefs.unregisterOnSharedPreferenceChangeListener(this);
}
```

(from [Introspection/SAWMonitorTile/app/src/main/java/com/commonsware/android/sawmonitor/SettingsFragment.java](#))

The `onSharedPreferenceChanged()` method on our `SettingsFragment` will be called when any of our preferences changes. If the enabled preference changes, we call `syncEnabledStates()`:

```
@Override
public void onSharedPreferenceChanged(SharedPreferences prefs,
                                     String s) {
    if (PREF_ENABLED.equals(s)) {
        syncEnabledStates();
    }
}
```

(from [Introspection/SAWMonitorTile/app/src/main/java/com/commonsware/android/sawmonitor/SettingsFragment.java](#))

`syncEnabledStates()` simply updates the checked state of enabled based upon the now-current value in `SharedPreferences`:

```
void syncEnabledStates() {
    enabled.setChecked(prefs.getBoolean(PREF_ENABLED, false));
}
```

(from [Introspection/SAWMonitorTile/app/src/main/java/com/commonsware/android/sawmonitor/SettingsFragment.java](#))

This therefore also handles the case where our `SettingsFragment` was displayed, the user navigated elsewhere, one of our preferences changes, and then the user returns to our running `SettingsFragment`. Normally, the `SettingsFragment` might miss that preference change, but with this implementation, the `SettingsFragment` will be kept in sync with the actual preference value.

Preferences in Device Settings App

On Android 7.0+, you can have the Settings app show a “gear” icon on your activity that collects preferences. When the user taps that gear, the Settings app will launch your designated activity:

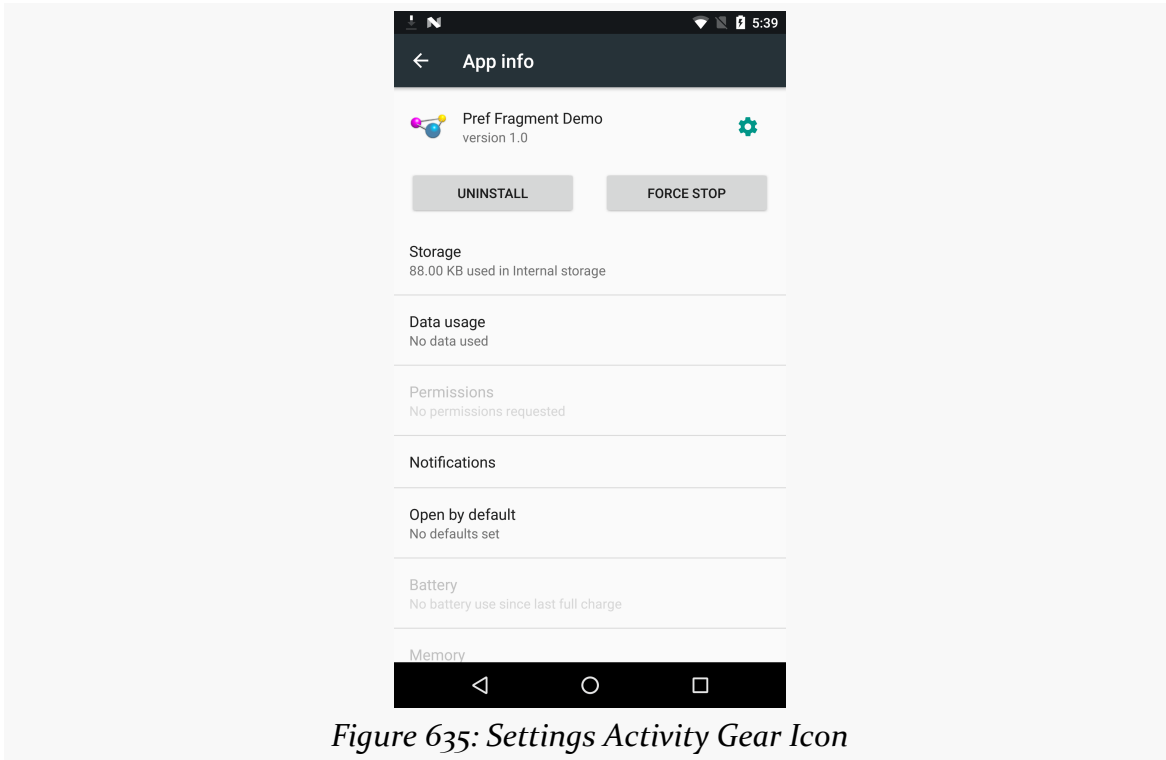

Figure 635: Settings Activity Gear Icon

To offer this, you need to add an `<intent-filter>` for your desired activity, with an `<action>` of `android.intent.action.APPLICATION_PREFERENCES`:

```
<activity
  android:name="EditPreferences"
  android:label="@string/app_name">
  <intent-filter>
    <action android:name="android.intent.action.APPLICATION_PREFERENCES" />
    <category android:name="android.intent.category.DEFAULT" />
  </intent-filter>
</activity>
```

However, by default, there is a cost to this: *any app* can start your settings activity, whenever another app wants to. Your settings activity is exported once you add the

ADVANCED PREFERENCES

<intent-filter>, and it needs to be exported for the Settings app to be able to start the activity.

However, it is fairly likely that this activity was not exported before you added this <intent-filter>. And while you may not mind it if the Settings app starts this activity, or if your own application code starts this activity, you may not want arbitrary other apps to start this activity. A general rule of thumb in modern development is to keep your “attack surface” low. Having an activity be exported for little value is an unnecessary increase in your app’s attack surface.

There is no officially-documented solution for this, though [perhaps they will add one someday](#).

There are two candidate approaches. An [unexpected](#) one works: you can mark the activity as being not exported, via `android:exported="false"`. For some reason, the Settings app can still start up that activity, [perhaps due to some system-level privilege](#). However, other apps will be unable to start the activity. This would result in an <activity> element like this:

```
<activity
  android:name="EditPreferences"
  android:label="@string/app_name"
  android:exported="false">
  <intent-filter>
    <action android:name="android.intent.action.APPLICATION_PREFERENCES" />
    <category android:name="android.intent.category.DEFAULT" />
  </intent-filter>
</activity>
```

Another approach that should work is to use `android:permission` to limit what other apps can start your activity, choosing a permission that the Settings app is sure to have but that most other apps will lack. `WRITE_SECURE_SETTINGS` is one candidate:

```
<activity
  android:name="EditPreferences"
  android:label="@string/app_name"
  android:permission="android.permission.WRITE_SECURE_SETTINGS">
  <intent-filter>
    <action android:name="android.intent.action.APPLICATION_PREFERENCES" />
    <category android:name="android.intent.category.DEFAULT" />
  </intent-filter>
</activity>
```

Now, the only other apps that can start your activity must hold the `WRITE_SECURE_SETTINGS` permission, which ordinary Android SDK apps cannot hold.

Custom Preference Storage

`SharedPreferences` are stored in an app's portion of internal storage as an XML file. This is fine in many cases. However, it is a problem for apps that need to ensure that persisted data is encrypted. While you can create a wrapper around `SharedPreferences` that encrypts the keys and values, that will not work well with things like the preference screen UI system. Basically, anything that does not know about the wrapper would try working with the actual `SharedPreferences` data and be broken by the encryption.

This has always been disappointing, considering that `SharedPreferences` is an interface, and so setting up some sort of decorator approach should have been fairly easy to add.

In Android 8.0+, Google does not do that. |

However, they *do* add in another mechanism: `PreferenceDataStore`.

You can create a `PreferenceDataStore` and associate it with a `PreferenceManager` via `setPreferenceDataStore()`. Then, all `SharedPreferences` loaded from that `PreferenceManager` will not use the normal XML-based persistence. Instead, the `PreferenceDataStore` will be used instead. That interface has getter and setter methods for all of the types supported by `SharedPreferences`, and it is the responsibility of some instance of `PreferenceDataStore` to handle the persistence as you see fit.

This solution is goofy, but it works, after a fashion, as is illustrated in the [Prefs/DataStore](#) sample project.

In that project, we have a `SillyDataStore` implementation of the `PreferenceDataStore` interface. It just stuffs all the data into a `HashMap`:

```
package com.commonware.android.preffrag;

import android.preference.PreferenceDataStore;
import java.util.HashMap;
import java.util.Map;
import java.util.Set;
```

ADVANCED PREFERENCES

```
class SillyDataStore implements PreferenceDataStore {
    static private final SillyDataStore INSTANCE=new SillyDataStore();
    private Map<String, Object> cache=new HashMap<>();

    static SillyDataStore get() {
        return(INSTANCE);
    }

    private SillyDataStore() {
        // just here to prevent accidental creation from outside
    }

    @Override
    public void putString(String key, String value) {
        cache.put(key, value);
    }

    @Override
    public void putStringSet(String key, Set<String> values) {
        cache.put(key, values);
    }

    @Override
    public void putInt(String key, int value) {
        cache.put(key, value);
    }

    @Override
    public void putLong(String key, long value) {
        cache.put(key, value);
    }

    @Override
    public void putFloat(String key, float value) {
        cache.put(key, value);
    }

    @Override
    public void putBoolean(String key, boolean value) {
        cache.put(key, value);
    }

    @SuppressWarnings("Since15")
    @Override
    public String getString(String key, String defValue) {
        return((String)cache.getOrDefault(key, defValue));
    }
}
```

ADVANCED PREFERENCES

```
@SuppressWarnings("Since15")
@Override
public Set<String> getStringSet(String key, Set<String> defValues) {
    return((Set<String>)cache.getOrDefault(key, defValues));
}

@SuppressWarnings("Since15")
@Override
public int getInt(String key, int defValue) {
    return((Integer)cache.getOrDefault(key, defValue));
}

@SuppressWarnings("Since15")
@Override
public long getLong(String key, long defValue) {
    return((Long)cache.getOrDefault(key, defValue));
}

@SuppressWarnings("Since15")
@Override
public float getFloat(String key, float defValue) {
    return((Float)cache.getOrDefault(key, defValue));
}

@SuppressWarnings("Since15")
@Override
public boolean getBoolean(String key, boolean defValue) {
    return((Boolean)cache.getOrDefault(key, defValue));
}
}
```

(from [Prefs/DataStore/app/src/main/java/com/commonsware/android/preffrag/SillyDataStore.java](#))

This implementation is truly silly, as it does no type checking and no persistence. It should be considered the bare minimum implementation of a `PreferenceDataStore`, though one that might be useful, instead of rolling a mock, in unit testing.

(note: the `@SuppressWarnings("Since15")` annotations are because this code uses the `getOrDefault()` method on `HashMap`, which was added in Java 8 and is new to Android 8.0)

There is a singleton instance of `SillyDataStore`. That way we can ensure that the same instance is used wherever we want it.

ADVANCED PREFERENCES

We apply that singleton in the PreferenceFragment subclass:

```
public static class Prefs extends PreferenceFragment {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        if (getPreferenceManager().getPreferenceDataStore()==null) {
            getPreferenceManager().setPreferenceDataStore(SillyDataStore.get());
        }

        addPreferencesFromResource(R.xml.preferences);
    }
}
```

(from [Prefs/DataStore/app/src/main/java/com/commonsware/android/preffrag/EditPreferences.java](#))

Here, we check to see if there is a PreferenceDataStore associated with the PreferenceManager and, if not, we attach the SillyDataStore singleton. This causes the SharedPreferences used by this PreferenceFragment to use the SillyDataStore for storage, instead of the default XML-based persistence.

This works... somewhat. There are some problems.

First, a PreferenceManager is not a system service. Of note, each instance of our PreferenceFragment gets its own fresh PreferenceManager. This is why we need to check for, and set, the PreferenceDataStore on the PreferenceManager for the PreferenceFragment each time.

Second, we have no way of associating a PreferenceDataStore with the default SharedPreferences obtained from PreferenceManager.getDefaultSharedPreferences(). That will always use the standard XML backing store. The initial activity contents are in the form of a PreferenceContentsFragment that reads from the default SharedPreferences in onResume(). Normally, that would cause changes that we make via our PreferenceFragment to show up when the PreferenceContentsFragment is resumed. In this specific sample, that does not happen, as the PreferenceContentsFragment is using the default XML data store, and our data is really in the SillyDataStore.

This illustrates the fatal flaw of this system: you can never really use the SharedPreferences. You cannot create PreferenceManager instances yourself, as it has no public constructors. All of the code that gives you SharedPreferences

ADVANCED PREFERENCES

objects back *other* than through a PreferenceManager has no way of associating a PreferenceDataStore with the SharedPreferences.

Instead of using SharedPreferences... you have to read and write from your PreferenceDataStore itself. This, in turn, loses everything that you normally associate with SharedPreferences, such as atomicity of updates and preference-change listeners.

Worse, since PreferenceDataStore has no API telling you when to persist changes, you would have to do that yourself... somehow.

These can be overcome, with a sufficiently-robust PreferenceDataStore implementation and lots of documentation. However, for casual use, other than perhaps for test mocks, PreferenceDataStore is not a well-engineered solution and probably should be avoided.

Custom Dialogs and Preferences

Android ships with a number of dialog classes for specific circumstances, like `DatePickerDialog` and `ProgressDialog`. Similarly, Android comes with a smattering of Preference classes for your `PreferenceActivity`, to accept text or selections from lists and so on.

However, there is plenty of room for improvement in both areas. As such, you may find the need to create your own custom dialog or preference class. This chapter will show you how that is done.

We start off by looking at creating a [custom `AlertDialog`](#), not by using `AlertDialog.Builder`, but via a custom subclass. Then, we show how to create your [own dialog-style Preference](#), where tapping on the preference pops up a dialog to allow the user to customize the preference value.

Prerequisites

Understanding this chapter requires that you have read [the chapter on dialogs](#), along with [the chapter on the preference system](#). Also, the samples here use the custom `ColorMixer` View described [in another chapter](#).

Your Dialog, Chocolate-Covered

For your own application, the simplest way to create a custom `AlertDialog` is to use `AlertDialog.Builder`, as described [in a previous chapter](#). You do not need to create any special subclass — just call methods on the Builder, then `show()` the resulting dialog.

CUSTOM DIALOGS AND PREFERENCES

However, if you want to create a reusable `AlertDialog`, this may become problematic. For example, where would this code to create the custom `AlertDialog` reside?

So, in some cases, you may wish to extend `AlertDialog` and supply the dialog's contents that way, which is how `TimePickerDialog` and others are implemented. Unfortunately, this technique is not well documented. This section will illustrate how to create such an `AlertDialog` subclass, as determined by looking at how the core Android team did it for their own dialogs.

The sample code is `ColorMixerDialog`, a dialog wrapping around the `ColorMixer` widget shown in a previous chapter. The implementation of `ColorMixerDialog` can be found in the [CWAC-ColorMixer](#) GitHub repository, as it is part of the CommonsWare Android Components.

Using this dialog works much like using `DatePickerDialog` or `TimePickerDialog`. You create an instance of `ColorMixerDialog`, supplying the initial color to show and a listener object to be notified of color changes. Then, call `show()` on the dialog. If the user makes a change and accepts the dialog, your listener will be informed.

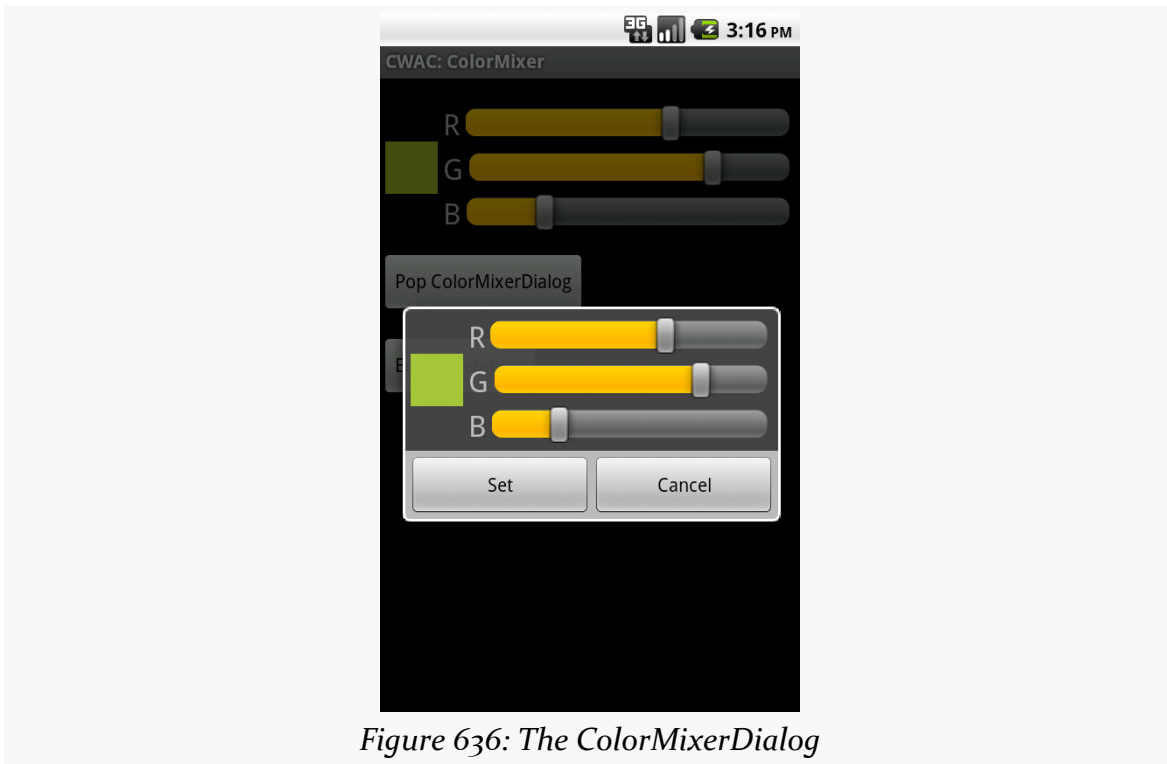

Figure 636: The ColorMixerDialog

Basic AlertDialog Setup

The ColorMixerDialog class is not especially long, since all of the actual color mixing is handled by the ColorMixer widget:

```
package com.commonware.cwac.colormixer;

import android.app.AlertDialog;
import android.content.Context;
import android.content.DialogInterface;
import android.os.Bundle;

public class ColorMixerDialog extends AlertDialog
    implements DialogInterface.OnClickListener {
    static private final String COLOR="c";
    private ColorMixer mixer=null;
    private int initialColor;
    private ColorMixer.OnColorChangeListener onSet=null;

    public ColorMixerDialog(Context ctxt,
        int initialColor,
        ColorMixer.OnColorChangeListener onSet) {

        super(ctxt);

        this.initialColor=initialColor;
        this.onSet=onSet;

        mixer=new ColorMixer(ctxt);
        mixer.setColor(initialColor);

        setView(mixer);
        setButton(ctxt.getText(R.string.cwac_colormixer_set),
            this);
        setButton2(ctxt.getText(R.string.cwac_colormixer_cancel),
            (DialogInterface.OnClickListener)null);
    }

    @Override
    public void onClick(DialogInterface dialog, int which) {
        if (initialColor!=mixer.getColor()) {
            onSet.onColorChange(mixer.getColor());
        }
    }

    @Override
    public Bundle onSaveInstanceState() {
        Bundle state=super.onSaveInstanceState();
```

```
state.putInt(COLOR, mixer.getColor());

return(state);
}

@Override
public void onRestoreInstanceState(Bundle state) {
    super.onRestoreInstanceState(state);

    mixer.setColor(state.getInt(COLOR));
}
}
```

We extend the `AlertDialog` class and implement a constructor of our own design. In this case, we take in three parameters:

1. A `Context` (typically an `Activity`), needed for the superclass
2. The initial color to use for the dialog, such as if the user is editing a color they chose before
3. A `ColorMixer.OnColorChangeListener` object, just like `ColorMixer` uses, to notify the dialog creator when the color is changed

We then create a `ColorMixer` and call `setView()` to make that be the main content of the dialog. We also call `setButton()` and `setButton2()` to specify a “Set” and “Cancel” button for the dialog. The latter just dismisses the dialog, so we need no event handler. The former we route back to the `ColorMixerDialog` itself, which implements the `DialogInterface.OnClickListener` interface.

Handling Color Changes

When the user clicks the “Set” button, we want to notify the application about the color change...if the color actually changed. This is akin to `DatePickerDialog` and `TimePickerDialog` only notifying you of date or times if the user clicks Set and actually changed the values.

The `ColorMixerDialog` tracks the initial color via the `initialColor` data member. In the `onClick()` method — required by `DialogInterface.OnClickListener` — we see if the mixer has a different color than the `initialColor`, and if so, we call the supplied `ColorMixer.OnColorChangeListener` callback object:

```
@Override
public void onClick(DialogInterface dialog, int which) {
```

```
if (initialColor!=mixer.getColor()) {
    onSet.onColorChange(mixer.getColor());
}
}
```

State Management

Dialogs use `onSaveInstanceState()` and `onRestoreInstanceState()`, just like activities do. That way, if the screen is rotated, or if the hosting activity is being evicted from RAM when it is not in the foreground, the dialog can save its state, then get it back later as needed.

The biggest difference with `onSaveInstanceState()` for a dialog is that the `Bundle` of state data is not passed into the method. Rather, you get the `Bundle` by chaining to the superclass, then adding your data to the `Bundle` it returned, before returning it yourself:

```
@Override
public Bundle onSaveInstanceState() {
    Bundle state=super.onSaveInstanceState();

    state.putInt(COLOR, mixer.getColor());

    return(state);
}
```

The `onRestoreInstanceState()` pattern is much closer to the implementation you would find in an Activity, where the `Bundle` with the state data to restore is passed in as a parameter:

```
@Override
public void onRestoreInstanceState(Bundle state) {
    super.onRestoreInstanceState(state);

    mixer.setColor(state.getInt(COLOR));
}
```

Preferring Your Own Preferences, Preferably

The Android Settings application, built using the Preference system, has lots of custom Preference classes. You too can create your own Preference classes, to collect things like dates, numbers, or colors. Once again, though, the process of creating such classes is not well documented. This section reviews one recipe for

making a Preference — specifically, a subclass of `DialogPreference` – based on the implementation of other Preference classes in Android.

The result is `ColorPreference`, a Preference that uses the `ColorMixer` widget. As with the `ColorMixerDialog` from the previous section, the `ColorPreference` is from the CommonsWare Android Components, and its source code can be found in the [CWAC-ColorMixer](#) GitHub repository.

One might think that `ColorPreference`, as a subclass of `DialogPreference`, might use `ColorMixerDialog`. However, that is not the way it works, as you will see.

The Constructor

A Preference is much like a [custom View](#), in that there are a variety of constructors, some taking an `AttributeSet` (for the preference properties), and some taking a default style. In the case of `ColorPreference`, we need to get the string resources to use for the names of the buttons in the dialog box, providing them to `DialogPreference` via `setPositiveButton()` and `setNegativeButton()`.

Here, we just implement the standard two-parameter constructor, since that is the one that is used when this preference is inflated from a preference XML file:

```
public ColorPreference(Context ctxt, AttributeSet attrs) {
    super(ctxt, attrs);

    setPositiveButton(ctxt.getText(R.string.cwac_colormixer_set));
    setNegativeButton(ctxt.getText(R.string.cwac_colormixer_cancel));
}
```

Creating the View

The `DialogPreference` class handles the pop-up dialog that appears when the preference is clicked upon by the user. Subclasses get to provide the View that goes inside the dialog. This is handled a bit reminiscent of a `CursorAdapter`, in that there are two separate methods to be overridden:

- `onCreateDialogView()` works like `newView()` of `CursorAdapter`, returning a View that should go in the dialog
- `onBindDialogView()` works like `bindView()` of `CursorAdapter`, where the custom Preference is supposed to configure the View for the current preference value

In the case of `ColorPreference`, we use a `ColorMixer` for the View:

```
@Override
protected View onCreateDialogView() {
    mixer=new ColorMixer(getContext());

    return(mixer);
}
```

Then, in `onBindDialogView()`, we set the mixer's color to be `lastColor`, a private data member:

```
@Override
protected void onBindDialogView(View v) {
    super.onBindDialogView(v);

    mixer.setColor(lastColor);
}
```

We will see later in this section where `lastColor` comes from – for the moment, take it on faith that it holds the user's chosen color, or a default value.

Dealing with Preference Values

Of course, the whole point behind a Preference is to allow the user to set some value that the application will then use later on. Dealing with values is a bit tricky with `DialogPreference`, but not too bad.

Getting the Default Value

The preference XML format has an `android:defaultValue` attribute, which holds the default value to be used by the preference. Of course, the actual data type of the value will differ widely — an `EditTextPreference` might expect a `String`, while `ColorPreference` needs a color value.

Hence, you need to implement `onGetDefaultValue()`. This is passed a `TypedArray` — similar to how a custom View uses a `TypedArray` for getting at its custom attributes in an XML layout file. It is also passed an index number into the array representing `android:defaultValue`. The custom Preference needs to return an Object representing its interpretation of the default value.

In the case of `ColorPreference`, we simply get an integer out of the `TypedArray`, representing the color value, with an overall default value of `0xFFA4C639` (a.k.a., Android green):

```
@Override
protected Object onGetDefaultValue(TypedArray a, int index) {
    return(a.getInt(index, 0xFFA4C639));
}
```

Setting the Initial Value

When the user clicks on the preference, the `DialogPreference` supplies the last-known preference value to its subclass, or the default value if this preference has not been set by the user to date.

The way this works is that the custom `Preference` needs to override `onSetInitialValue()`. This is passed in a boolean flag (`restoreValue`) indicating whether or not the user set the value of the preference before. It is also passed the `Object` returned by `onGetDefaultValue()`. Typically, a custom `Preference` will look at the flag and choose to either use the default value or load the already-set preference value.

To get the existing value, `Preference` defines a set of type-specific getter methods — `getPersistedInt()`, `getPersistedString()`, etc. So, `ColorPreference` uses `getPersistedInt()` to get the saved color value:

```
@Override
protected void onSetInitialValue(boolean restoreValue, Object defaultValue) {
    lastColor=(restoreValue ? getPersistedInt(lastColor) : (Integer)defaultValue);
}
```

Here, `onSetInitialValue()` stores that value in `lastColor` — which then winds up being used by `onBindDialogView()` to tell the `ColorMixer` what color to show.

Closing the Dialog

When the user closes the dialog, it is time to persist the chosen color from the `ColorMixer`. This is handled by the `onDialogClosed()` callback method on your custom `Preference`:

```
@Override
protected void onDialogClosed(boolean positiveResult) {
    super.onDialogClosed(positiveResult);
}
```

```
if (positiveResult) {
    if (callChangeListener(mixer.getColor())) {
        lastColor=mixer.getColor();
        persistInt(lastColor);
    }
}
}
```

The passed-in boolean indicates if the user accepted or dismissed the dialog, so you can elect to skip saving anything if the user dismissed the dialog. The other `DialogPreference` implementations also call `callChangeListener()`, which is somewhat ill-documented. Assuming both the flag and `callChangeListener()` are true, the Preference should save its value to the persistent store via `persistInt()`, `persistString()`, or `kin`.

Using the Preference

Given all of that, using the custom Preference class in an application is almost anticlimactic. You simply add it to your preference XML, with a fully-qualified class name:

```
<PreferenceScreen
xmlns:android="http://schemas.android.com/apk/res/android">
  <com.commonware.cwac.colormixer.ColorPreference
    android:key="favoriteColor"
    android:defaultValue="0xFFA4C639"
    android:title="Your Favorite Color"
    android:summary="Blue. No yel-- Auuuuuuuugh!" />
</PreferenceScreen>
```

At this point, it behaves no differently than does any other Preference type. Since `ColorPreference` stores the value as an integer, your code would use `getInt()` on the `SharedPreferences` to retrieve the value when needed.

The user sees an ordinary preference entry in the `PreferenceActivity`:

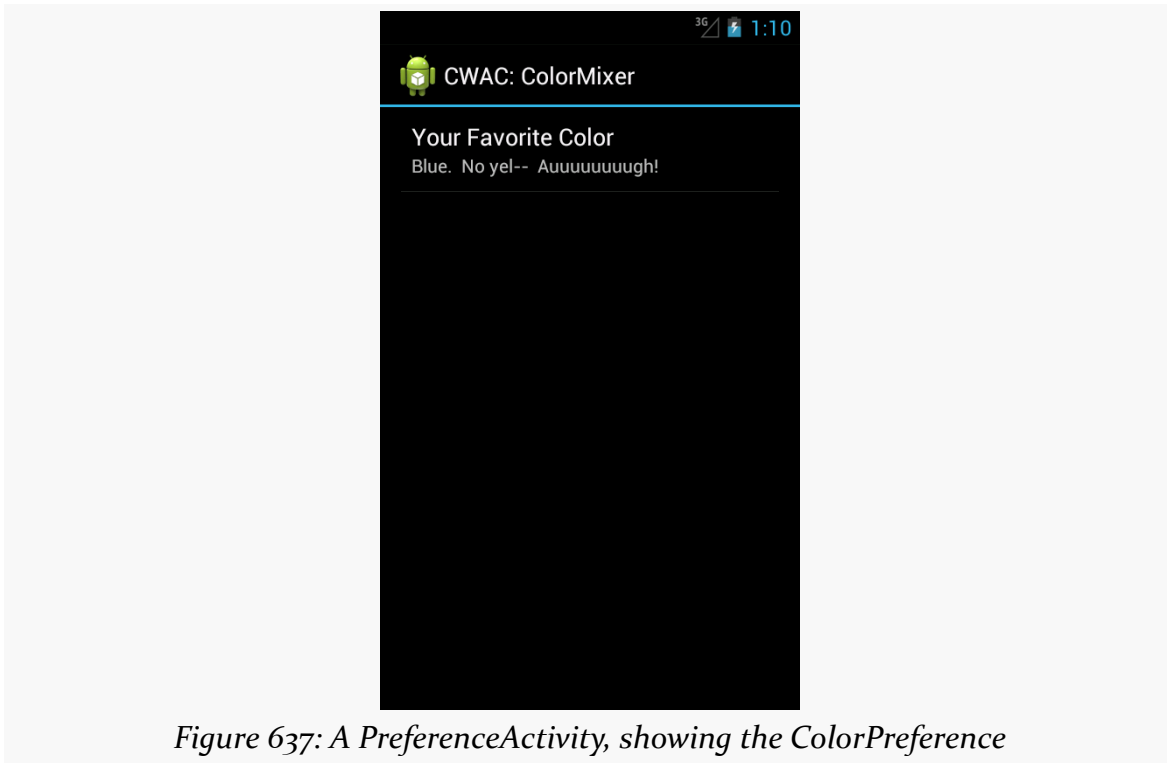

Figure 637: A PreferenceActivity, showing the ColorPreference

When tapped, it brings up the mixer:

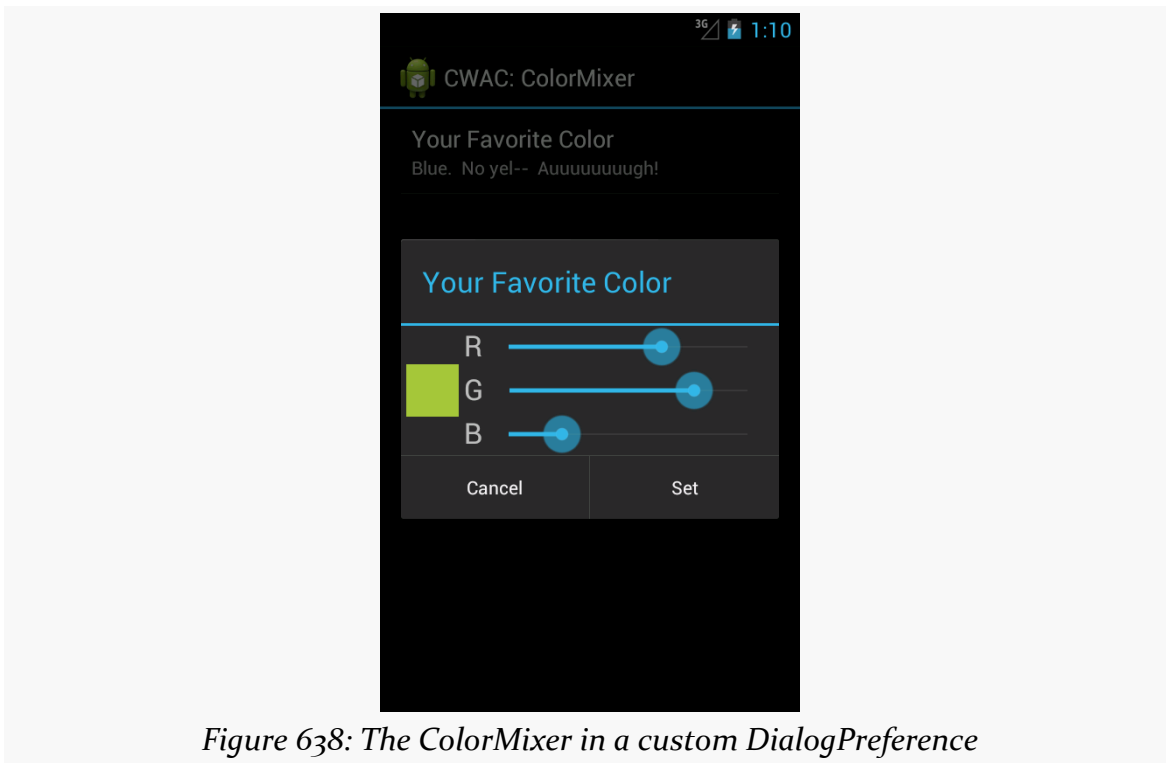

Figure 638: The ColorMixer in a custom DialogPreference

Choosing a color and clicking “Set” persists the color value as a preference.

Progress Indicators

Sometimes, we make the user wait. And wait. And wait some more.

Often, in these cases, it is useful to let the user know that something they requested is something that we are diligently working on. To do this, we can use some form of progress indicator. We saw basic use of a `ProgressBar` in the tutorials earlier in this book — now is the time to take a much closer look at `ProgressBar` and other means of displaying progress.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book. Having read the chapters on [dialogs](#), [custom drawables](#), and [animators](#) is also a good idea.

Progress Bars

The classic way to tell the user that we are doing something for them is to use a `ProgressBar` widget, much as we briefly displayed one in the `EmPubLite` sample app in the tutorials.

However, a `ProgressBar` is much more than a simple spinning image. We can use it to display either indeterminate progress (“we will be done... sometime”) or specific progress (“we are 34% complete”). We can use it either as a circle or as a classic horizontal bar, the latter typically used for specific progress. And, for specific progress, we can actually show two tiers of progress, known as “primary” and “secondary” (e.g., primary for the progress in copying a directory’s worth of files, secondary for the progress on a specific file).

In this section, we will take a look at these different ways of using `ProgressBar`.

Circular vs. Horizontal

As the name suggests, a `ProgressBar` denotes progress. As the name does not suggest, a `ProgressBar` is not a bar, by default — it is a circle. Hence, the following element from an XML layout resource:

```
<ProgressBar
    android:id="@+id/progressCI"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:layout_gravity="center_horizontal"
    android:layout_marginBottom="20dp"
    android:layout_marginTop="20dp"/>
```

(from [Progress/BarSampler/app/src/main/res/layout/activity_main.xml](#))

gives us:

Figure 639: Android 5.1 `ProgressBar`, Default Style

PROGRESS INDICATORS

Figure 640: Android 4.0 ProgressBar, Default Style

However, referencing `style="?android:attr/progressBarStyleHorizontal"` in the element:

```
<ProgressBar
  android:id="@+id/progressHI"
  style="?android:attr/progressBarStyleHorizontal"
  android:layout_width="match_parent"
  android:layout_height="wrap_content"
  android:layout_marginBottom="20dp"
  android:indeterminate="true" />
```

(from [Progress/BarSampler/app/src/main/res/layout/activity_main.xml](#))

gives us a horizontal bar:

Figure 641: Android 5.1 ProgressBar, Horizontal Style

Figure 642: Android 4.0 ProgressBar, Horizontal Style

Note that the look-and-feel of these widgets have changed over the years. On Android 1.x and 2.x, they will look like this:

PROGRESS INDICATORS

Figure 643: Android 2.3.3 ProgressBar, Both Styles

Specific vs. Indeterminate

Typically, you use the circular `ProgressBar` style for indeterminate progress, where the circle simply spins in place to let the user know that work is proceeding and the device (or activity) has not frozen. The horizontal `ProgressBar` style is used to illustrate specific amounts of progress, from 0 to a value you choose.

However, while those patterns are typical, the choice of whether to use indeterminate or some specific amount of progress is independent of the style of the widget.

The `android:indeterminate` attribute controls whether the `ProgressBar` will render an indeterminate look or a specific look. For the latter, calls to `setMax()` (or the `android:max` attribute) will set the upper end of the progress range (the default is 100), and `setProgress()` or `incrementProgressBy()` will set how much progress along that range is illustrated.

Figure 644: Android 5.1 ProgressBar, Horizontal Style, Indeterminate and Specific

Figure 645: Android 4.0 ProgressBar, Horizontal Style, Indeterminate and Specific

Figure 646: Android 2.3.3 ProgressBar, Horizontal Style, Indeterminate and Specific

Primary vs. Secondary

For specific progress, you actually have two independent amounts of progress. `setProgress()`, `incrementProgressBy()`, and `android:progress` control the primary progress, while `setSecondaryProgress()`, `incrementSecondaryProgressBy()`, and `android:secondaryProgress` control the secondary progress. Here, “primary progress” refers to the progress along an entire piece of work (e.g., copying a folder’s worth of files), while “secondary progress” refers the progress along a discrete chunk of the overall work (e.g., copying an individual file).

A `ProgressBar` will render these with different colors, though primary trumps secondary, and so the secondary progress will only be visible when its value exceeds that of the primary progress:

Figure 647: Android 4.0 ProgressBar, Horizontal Style, Primary-Only and Primary-Plus-Secondary

Figure 648: Android 2.3.3 ProgressBar, Horizontal Style, Primary-Only and Primary-Plus-Secondary

ProgressBar and Threads

Normally, you cannot update the UI of a widget from a background thread.

`ProgressBar` is an exception. You *can* safely call `setProgress()` and `incrementProgressBy()` from a background thread to update the primary progress, and you can safely call `setSecondaryProgress()` and `incrementSecondaryProgressBy()` from a background thread to update the secondary progress.

To see this in action, take a look at the [Progress/BarSampler](#) sample project.

This project has a single activity (`MainActivity`), whose layout (`activity_main.xml`) contains four `ProgressBar` widgets, two indeterminate and two for specific progress:

PROGRESS INDICATORS

```
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
  xmlns:tools="http://schemas.android.com/tools"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  android:orientation="vertical">

  <ProgressBar
    android:id="@+id/progressCI"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:layout_gravity="center_horizontal"
    android:layout_marginBottom="20dp"
    android:layout_marginTop="20dp"/>

  <ProgressBar
    android:id="@+id/progressHI"
    style="?android:attr/progressBarStyleHorizontal"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:layout_marginBottom="20dp"
    android:indeterminate="true"/>

  <ProgressBar
    android:id="@+id/progressHS"
    style="?android:attr/progressBarStyleHorizontal"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:layout_marginBottom="20dp"
    android:indeterminate="false"
    android:max="100"/>

  <ProgressBar
    android:id="@+id/progressHS2"
    style="?android:attr/progressBarStyleHorizontal"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:max="100"/>

</LinearLayout>
```

(from [Progress/BarSampler/app/src/main/res/layout/activity_main.xml](#))

The activity gets access to the latter two `ProgressBar` widgets and sets up a `ScheduledThreadPoolExecutor` to get control every second in a background thread, which calls our `run()` method. The `run()` method will increment both `ProgressBar` widgets primary progress by 2 each time, and the secondary progress by 10 (dropping back to the starting point when the secondary progress reaches the

PROGRESS INDICATORS

maximum of 100). When the primary progress gets to 100, we cancel our scheduled work in the ScheduledThreadPoolExecutor:

```
package com.commonware.android.progress;

import android.app.Activity;
import android.os.Bundle;
import android.widget.ProgressBar;
import java.util.concurrent.ScheduledThreadPoolExecutor;
import java.util.concurrent.TimeUnit;

public class MainActivity extends Activity implements Runnable {
    private static final int PERIOD_SECONDS=1;
    private ScheduledThreadPoolExecutor executor=
        new ScheduledThreadPoolExecutor(1);
    private ProgressBar primary=null;
    private ProgressBar secondary=null;

    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.activity_main);

        primary=(ProgressBar)findViewById(R.id.progressHS);
        secondary=(ProgressBar)findViewById(R.id.progressHS2);

        executor.setExecuteExistingDelayedTasksAfterShutdownPolicy(false);
        executor.scheduleAtFixedRate(this, 0, PERIOD_SECONDS,
            TimeUnit.SECONDS);
    }

    @Override
    public void onDestroy() {
        executor.shutdown();

        super.onDestroy();
    }

    @Override
    public void run() {
        if (primary.getProgress() < 100) {
            primary.incrementProgressBy(2);
            secondary.incrementProgressBy(2);

            if (secondary.getSecondaryProgress() == 100) {
                secondary.setSecondaryProgress(10);
            }
        }
    }
}
```

```
    else {
        secondary.incrementSecondaryProgressBy(10);
    }
}
else {
    executor.remove(this);
}
}
}
```

(from [Progress/BarSampler/app/src/main/java/com/commonsware/android/progress/MainActivity.java](#))

The net effect is that you see the progress march across the screen, with the secondary progress going through five passes for the primary progress' single pass through the 0-100 range.

Tailoring Progress Bars

The stock `ProgressBar` look and feel is decent, if perhaps not spectacular. Often times, the stock look is sufficient for your needs. If you wish to have greater control over the look of your `ProgressBar`, the following sections will demonstrate some possibilities.

Changing the Progress Colors

The `ProgressBar` uses different colors for primary and secondary specific progress. By default, those colors are defined by the theme you are using, and the stock themes have firmware-defined colors (e.g., yellows for Android 1.x and 2.x, blues for Android 3.x and higher).

However, you can change the colors by using a [LayerListDrawable](#) and associating it with a `ProgressBar` by means of the `android:progressDrawable` attribute.

The `ProgressBar` background image needs to be a `LayerListDrawable` with three specific layers:

- `android:id="@android:id/background"` for the background color of the bar
- `android:id="@android:id/progress"` for the primary progress
- `android:id="@android:id/secondaryProgress"` for the secondary progress

PROGRESS INDICATORS

Whether those layers are defined as [ShapeDrawable structures](#), or as [nine-patch PNG files](#) is up to you, but they will need the ability to stretch to fit however big your bar winds up being.

To see what this means, let's take a look at the [Progress/Styled](#) sample project. This is a near-clone of the Progress/BarSampler project from earlier, using custom backgrounds for the bars. Here, we will look at the horizontal ProgressBar widgets — in [the next section](#), we will look at how to change the background of a circular indefinite ProgressBar.

For the first horizontal ProgressBar (progressHS), for Android 4.x, we will use a custom style created by the [Android Holo Colors Generator](#), a Web site set up to help us create custom versions of the holographic widget theme.

When you visit this site in Google Chrome (note: other browsers are not supported at this time), you can fill in a name for your theme (e.g., “AppTheme”), the color scheme to use for the theme, and the foundation theme to use (light or dark):

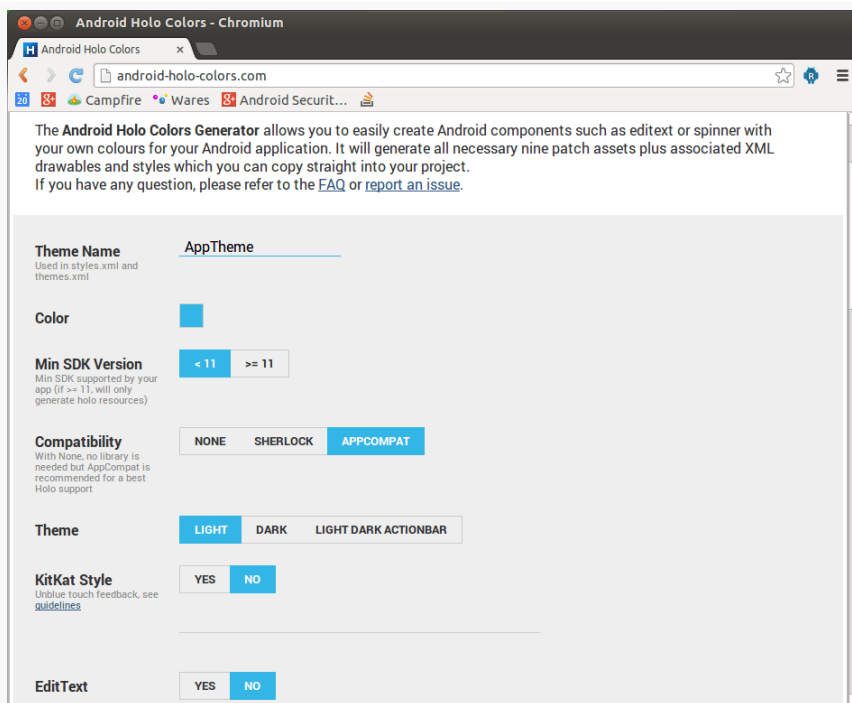

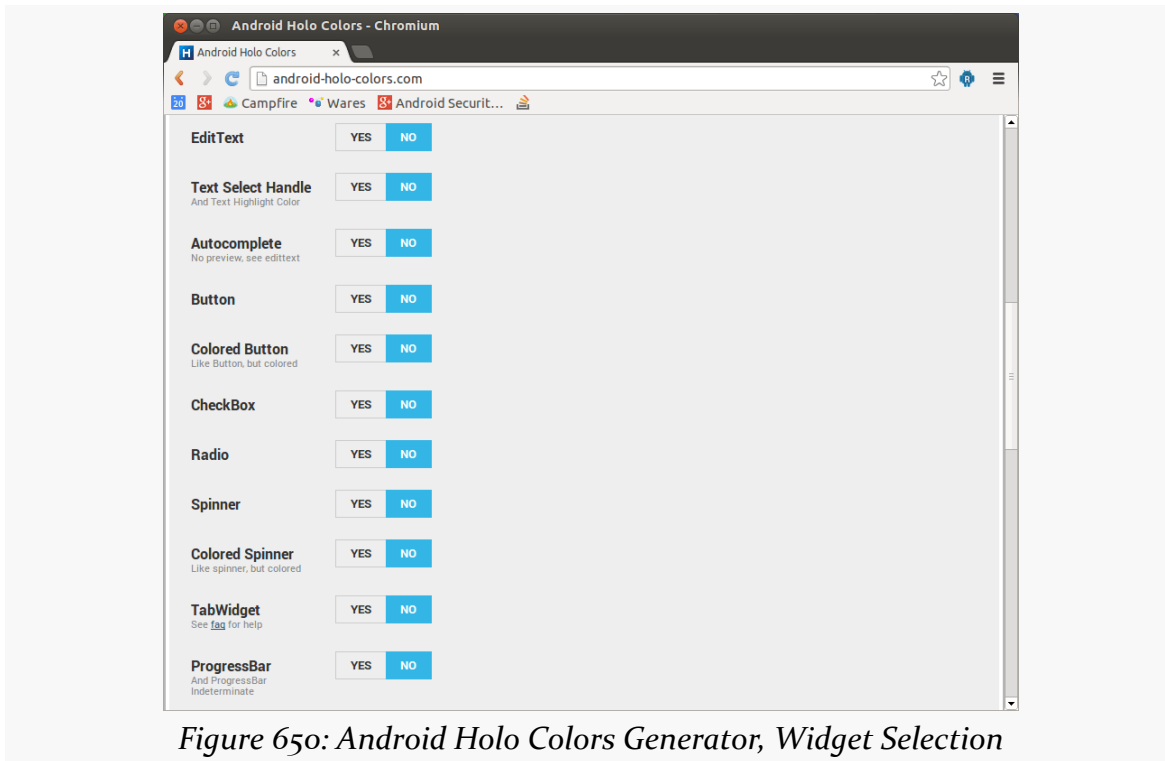

Figure 649: Android Holo Colors Generator, Basic Info

You can then toggle on and off which widgets you intend to use, so the generator will create custom styles for them:

PROGRESS INDICATORS

Then, the generator will create a ZIP file that you can download that contains the generated resources for your custom styles.

The Progress/Styled project contains the files generated by the generator, replacing the original style resources. Note that the generator does not create a .DarkActionBar version of the style resource, so the values-v14 resource directory in the project has one hand-crafted based upon a regular generated style resource.

On Android 5.0+, we will use a theme with the same name, but where we are using tints in the theme to affect the colors of the progress indicators.

Our manifest points to our AppTheme as being how we wish to style widgets in this application:

```
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
    package="com.commonware.android.progress"
    android:versionCode="1"
    android:versionName="1.0">

    <uses-sdk
        android:minSdkVersion="8"
```

PROGRESS INDICATORS

```
    android:targetSdkVersion="15"/>

<application
    android:icon="@drawable/ic_launcher"
    android:label="@string/app_name"
    android:theme="@style/AppTheme">
    <activity
        android:name=".MainActivity"
        android:label="@string/title_activity_main">
        <intent-filter>
            <action android:name="android.intent.action.MAIN"/>

            <category android:name="android.intent.category.LAUNCHER"/>
        </intent-filter>
    </activity>
</application>

</manifest>
```

(from [Progress/Styled/app/src/main/AndroidManifest.xml](#))

That theme, defined in `apptheme_themes.xml`, points to style resources for horizontal `ProgressBar` widgets:

```
<?xml version="1.0" encoding="utf-8"?>

<!-- Generated (in part) with http://android-holo-colors.com -->
<resources xmlns:android="http://schemas.android.com/apk/res/android">

    <style name="AppTheme" parent="android:Theme.Holo.Light.DarkActionBar">

        <item name="android:progressBarStyleHorizontal">@style/ProgressBarAppTheme</item>

    </style>
</resources>
```

(from [Progress/Styled/app/src/main/res/values-v14/apptheme_themes.xml](#))

The `ProgressBarAppTheme` style resource is defined in a separate `apptheme_styles.xml` resource:

```
<?xml version="1.0" encoding="utf-8"?>

<!-- Generated with http://android-holo-colors.com -->
<resources xmlns:android="http://schemas.android.com/apk/res/android">

    <style name="ProgressBarAppTheme" parent="android:Widget.Holo.Light.ProgressBar.Horizontal">
        <item name="android:progressDrawable">@drawable/progress_horizontal_holo_light</item>
        <item name="android:indeterminateDrawable">@drawable/
progress_indeterminate_horizontal_holo_light</item>
    </style>
```

PROGRESS INDICATORS

```
</resources>
```

(from [Progress/Styled/app/src/main/res/values-v11/apptheme_styles.xml](#))

Here, we say that we want the `android:progressDrawable` property to be a `progress_horizontal_holo_light` drawable resource. We also set the `android:indeterminateDrawable` property — used for indeterminate bars — to a `progress_indeterminate_horizontal_holo_light` drawable resource.

Those are defined as XML-based drawables, in the `res/drawable/` directory in the project. The `progress_horizontal_holo_light` resource is defined as:

```
<?xml version="1.0" encoding="utf-8"?>

-->
<layer-list xmlns:android="http://schemas.android.com/apk/res/android">

    <item android:id="@android:id/background"
          android:drawable="@drawable/progress_bg_holo_light" />

    <item android:id="@android:id/secondaryProgress">
        <scale android:scaleWidth="100%"
              android:drawable="@drawable/progress_secondary_holo" />
    </item>

    <item android:id="@android:id/progress">
        <scale android:scaleWidth="100%"
              android:drawable="@drawable/progress_primary_holo" />
    </item>

</layer-list>
```

(from [Progress/Styled/app/src/main/res/drawable/progress_horizontal_holo_light.xml](#))

PROGRESS INDICATORS

The generator creates our `LayerListDrawable` resource with our three layers, each pointing to a nine-patch PNG file (with different versions for different densities) that contains our desired custom color. The `progress` and `secondaryProgress` layers use [ScaleDrawable definitions](#) to ensure that the images are measured against the complete width of the background layer, which in turn will be sized according to the size of the `ProgressBar` itself.

We will take a look at the `progress_indeterminate_horizontal_holo_light` drawable resource in [the next section](#).

Note that you could skip the custom theme and style if you wished, and simply add the `android:progressDrawable` attribute to the `ProgressBar` widget definition in its layout XML resource.

Regardless, the result is that our progress bars have the desired purple color scheme:

Figure 651: Custom ProgressBar Style, Primary and Secondary

Also, you can have your `LayerListDrawable` use `ShapeDrawable` layers, to avoid creating nine-patch PNG files, if you prefer, using a resource like this:

```
<?xml version="1.0" encoding="utf-8"?>
<layer-list xmlns:android="http://schemas.android.com/apk/app/src/main/res/android">
  <item android:id="@android:id/background">
    <shape>
      <stroke android:width="1dip" android:color="#FF333333" />
      <gradient
        android:startColor="#FF9C9E9C"
        android:centerColor="#FF5A5D5A"
        android:centerY="0.71"
        android:endColor="#FF6B716B"
        android:angle="270"
      />
    </shape>
  </item>
  <item android:id="@android:id/secondaryProgress">
    <clip>
      <shape>
        <stroke android:width="1dip" android:color="#FF333333" />
        <gradient
          android:startColor="#4cffffff"

```

PROGRESS INDICATORS

```
        android:centerColor="#4cE7E7"  
        android:centerY="0.71"  
        android:endColor="#4cFFBFF"  
        android:angle="270"  
    />  
    </shape>  
  </clip>  
</item>  
<item android:id="@android:id/progress">  
  <clip>  
    <shape>  
      <stroke android:width="1dip" android:color="#FF333333" />  
      <gradient  
        android:startColor="#FFFFFFF"  
        android:centerColor="#FFE7E7"  
        android:centerY="0.71"  
        android:endColor="#FFFFFFBFF"  
        android:angle="270"  
      />  
    </shape>  
  </clip>  
</item>  
</layer-list>
```

On Android 5.0+, we have it much easier, as `ProgressBar` automatically adopts the accent tint. So we go with a much simpler theme definition:

```
<resources>  
  
  <style name="AppTheme" parent="android:Theme.Material">  
    <item name="android:colorPrimary">@color/primary</item>  
    <item name="android:colorPrimaryDark">@color/primary_dark</item>  
    <item name="android:colorAccent">@color/accent</item>  
  </style>  
  
</resources>
```

(from [Progress/Styled/app/src/main/res/values-v21/styles.xml](#))

This references colors from a separate `colors.xml` resource:

```
<?xml version="1.0" encoding="utf-8"?>  
<resources>  
  <color name="primary">#3f51b5</color>  
  <color name="primary_dark">#1a237e</color>  
  <color name="accent">#ffee58</color>  
</resources>
```

PROGRESS INDICATORS

(from [Progress/Styled/app/src/main/res/values-v21/colors.xml](#))

The result are yellow-tinted progress bars:

Figure 652: Material ProgressBar Style, Primary and Secondary

Changing the Indeterminate Animation

Similarly, for indefinite progress “bars”, changing the progress drawable will let you change the way they look. However, in this case, the drawable also needs to implement the animation itself. You can accomplish this either by using an [AnimationDrawable](#) or by using some other type of drawable wrapped in an animation, such as [a ShapeDrawable wrapped in a <rotate> animation](#).

For example, the Android 4.x custom theme created by the Android Holo Colors Generator assigns the following drawable resource to `android:indeterminateDrawable` in the theme:

```
<?xml version="1.0" encoding="utf-8"?>
<!--
/*
** Copyright 2011, The Android Open Source Project
**
** Licensed under the Apache License, Version 2.0 (the "License");
** you may not use this file except in compliance with the License.
** You may obtain a copy of the License at
**
**     http://www.apache.org/licenses/LICENSE-2.0
**
** Unless required by applicable law or agreed to in writing, software
** distributed under the License is distributed on an "AS IS" BASIS,
** WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
** See the License for the specific language governing permissions and
** limitations under the License.
*/
-->
<animation-list
    xmlns:android="http://schemas.android.com/apk/res/android"
    android:oneshot="false">
    <item android:drawable="@drawable/progressbar_indeterminate_holo1" android:duration="50" />
    <item android:drawable="@drawable/progressbar_indeterminate_holo2" android:duration="50" />
    <item android:drawable="@drawable/progressbar_indeterminate_holo3" android:duration="50" />
    <item android:drawable="@drawable/progressbar_indeterminate_holo4" android:duration="50" />
</animation-list>
```

PROGRESS INDICATORS

```
<item android:drawable="@drawable/progressbar_indeterminate_holo5" android:duration="50" />
<item android:drawable="@drawable/progressbar_indeterminate_holo6" android:duration="50" />
<item android:drawable="@drawable/progressbar_indeterminate_holo7" android:duration="50" />
<item android:drawable="@drawable/progressbar_indeterminate_holo8" android:duration="50" />
</animation-list>
```

(from [Progress/Styled/app/src/main/res/drawable/progress_indeterminate_horizontal_holo_light.xml](#))

Hence, every horizontal indeterminate `ProgressBar` will use that `AnimationDrawable`. The individual images in the animation are PNG files, with different versions for different densities.

Circular `ProgressBar` widgets also need a custom progress drawable, though obviously the image will need to be circular, not a bar. You can certainly use an `AnimationDrawable` for this, or you can use a `ShapeDrawable`, such as the `res/drawable/progress_circular.xml` resource shown below:

```
<?xml version="1.0" encoding="utf-8"?>
<rotate xmlns:android="http://schemas.android.com/apk/res/android"
    android:fromDegrees="0"
    android:pivotX="50%"
    android:pivotY="50%"
    android:toDegrees="360">

    <shape
        android:innerRadiusRatio="3"
        android:shape="ring"
        android:thicknessRatio="8"
        android:useLevel="false">
        <gradient
            android:centerColor="#4c737373"
            android:centerY="0.50"
            android:endColor="#ff9933CC"
            android:startColor="#4c737373"
            android:type="sweep"
            android:useLevel="false"/>
        </shape>
    </rotate>
```

(from [Progress/Styled/app/src/main/res/drawable/progress_circular.xml](#))

Here, we have a ring `ShapeDrawable`, with a certain thickness and radius, filled with a gradient. Half of the fill is actually a solid color (`#4c737373`), as the start and center colors are the same. The other half is a sweep gradient from the starting color to the same purple shade that is used by the other bar styles. This ring is then wrapped in a

PROGRESS INDICATORS

rotate animation. This yields a simple gradient-filled ring, that rotates smoothly to indicate progress:

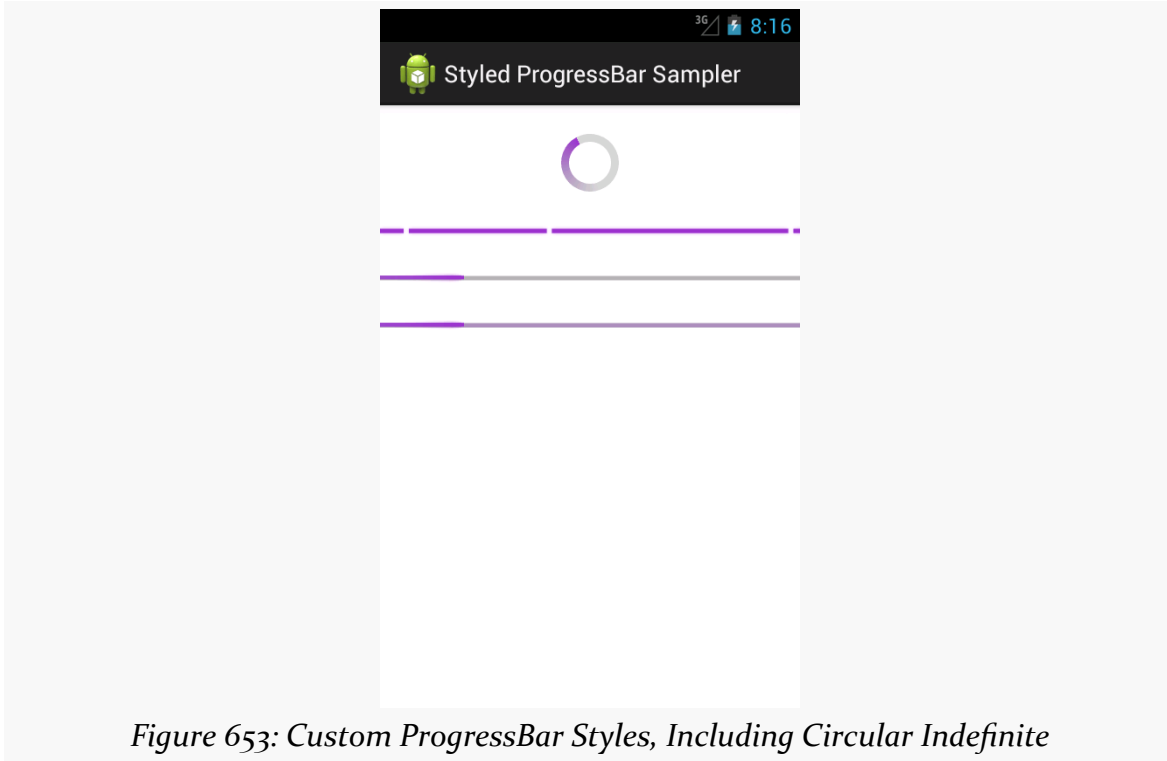

Figure 653: Custom ProgressBar Styles, Including Circular Indefinite

Note that the Android Holo Colors Generator does not generate circular indefinite ProgressBar resources as of the time of this writing.

Once again, Android 5.0+ can leverage `Theme.Material` and get rid of all the extra clutter. Just having an accent color defined will have your indefinite progress bars adopt that same color:

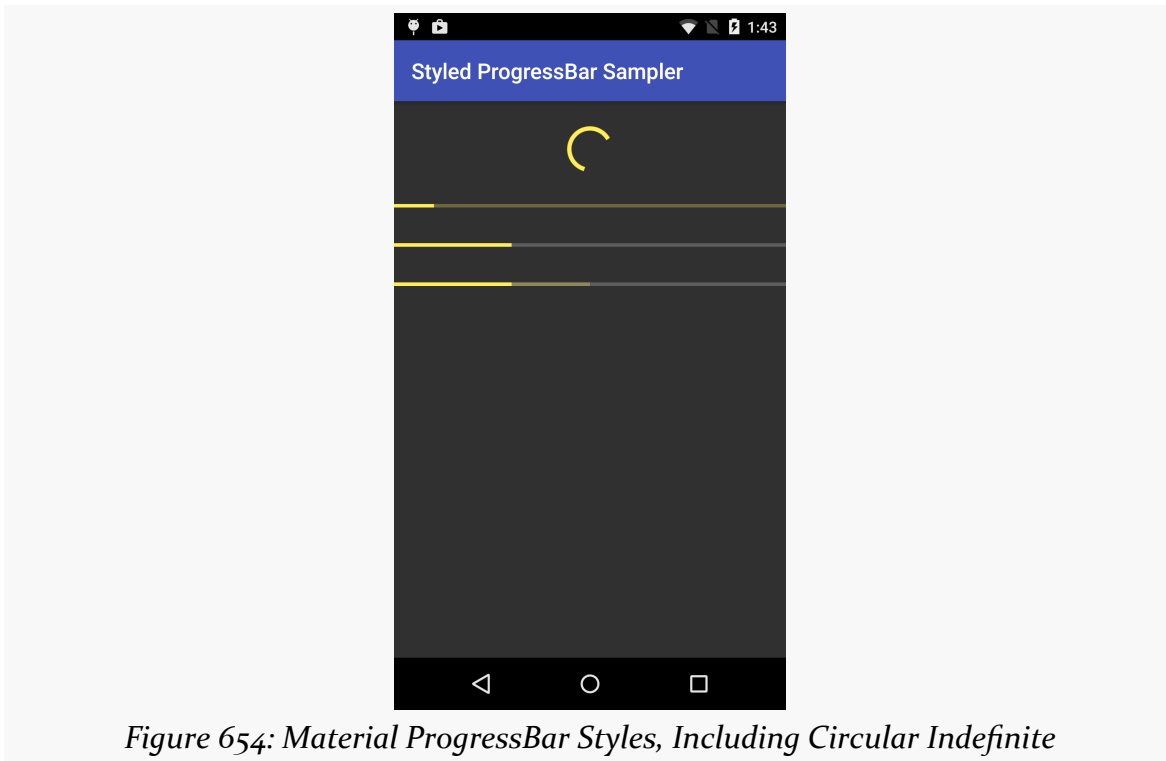

Figure 654: Material ProgressBar Styles, Including Circular Indefinite

Progress Dialogs

One use of a `ProgressBar` is to have it wrapped in a `ProgressDialog`. Like all dialogs, `ProgressDialog` is modal, preventing the user from interacting with an underlying activity while the dialog is displayed. From a UI design standpoint, a `ProgressDialog` is an easy way to temporarily show progress without having to find a spot for a `ProgressBar` widget somewhere in the UI. Also, since usually there are things in the activity that are dependent upon the work being done in the background, having the dialog in place prevents anyone from trying to use things that are not yet ready.

However, modal dialogs are not a great design approach, as they aggressively limit the user's options. `ProgressDialog` is perhaps the worst in this regard, as the user can do nothing except wait. While *part* of your app may not yet be ready, other parts surely are, such as reading the documentation, or adjusting settings, or clicking on your ad banners. Hence, using *anything* else other than `ProgressDialog`, while perhaps a bit more work, will be an improvement in the usability of your app.

PROGRESS INDICATORS

That being said, let us see how to set up a ProgressDialog. The [Progress/Dialog](#) sample project is a near-clone of the [Dialogs/DialogFragment](#) sample project from [the chapter on dialogs](#). The only difference is the `onCreateDialog()` method of our DialogFragment, where we directly create a ProgressDialog instead of using an AlertDialog.Builder to create an AlertDialog as before:

```
@Override
public Dialog onCreateDialog(Bundle savedInstanceState) {
    ProgressDialog dlg=new ProgressDialog(getActivity());

    dlg.setMessage(getActivity().getString(R.string.dlg_title));
    dlg.setIndeterminate(true);
    dlg.setProgressStyle(ProgressDialog.STYLE_SPINNER);

    return(dlg);
}
```

(from [Progress/Dialog/app/src/main/java/com/commonsware/android/progdlg/SampleDialogFragment.java](#))

We create the ProgressDialog via its constructor, set the message explaining what we are waiting for via `setMessage()`, indicate that the ProgressBar should be an indeterminate one via `setIndeterminate()`, and indicate that we want a circular “spinner” ProgressBar rather than a horizontal one by calling `setProgressStyle(ProgressDialog.STYLE_SPINNER)`. There are a variety of other things you could configure on the ProgressDialog if desired, and ProgressDialog inherits from AlertDialog, so some things you could configure on an AlertDialog will also be available on the ProgressDialog.

The result is a dialog that you may have seen from other apps in Android:

Figure 655: ProgressDialog

Title Bar and Action Bar Progress Indicators

Another place to let users know that you are doing something on their behalf is to put a progress indicator in the title bar or action bar of your activity. This avoids your having to put an indeterminate ProgressBar somewhere in your activity's UI. It is also very simple to set up, as we can see in the [Progress/TitleBar](#) sample project.

```
package com.commonware.android.titleprog;

import android.app.Activity;
import android.os.Bundle;
import android.view.Window;

public class MainActivity extends Activity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        getWindow().requestFeature(Window.FEATURE_INDETERMINATE_PROGRESS);
        super.onCreate(savedInstanceState);

        setContentView(R.layout.activity_main);
        setProgressBarIndeterminateVisibility(true);
    }
}
```

PROGRESS INDICATORS

```
}  
}
```

(from [Progress/TitleBar/app/src/main/java/com/commonsware/android/titleprog/MainActivity.java](#))

Up front, as the first thing that you do in your `onCreate()` call, you need to call:

```
getWindow().requestFeature(Window.FEATURE_INDETERMINATE_PROGRESS);
```

This tells Android to reserve space in your title bar or action bar for an indeterminate progress indicator, though the indicator does not appear at this point.

Later on, when you want the indicator to actually appear, call `setProgressBarIndeterminateVisibility(true)` on your activity, and later call `setProgressBarIndeterminateVisibility(false)` to make the indicator go away.

This particular application has `android:targetSdkVersion` set to 11 or higher, but it is not using an action bar backport. Hence, when you run it on an older Android environment, you get a classic title bar with the progress indicator on the right:

Figure 656: Progress Indicator in Title Bar

PROGRESS INDICATORS

When you have an action bar, you get the same basic effect, albeit with a larger indicator to match the larger bar:

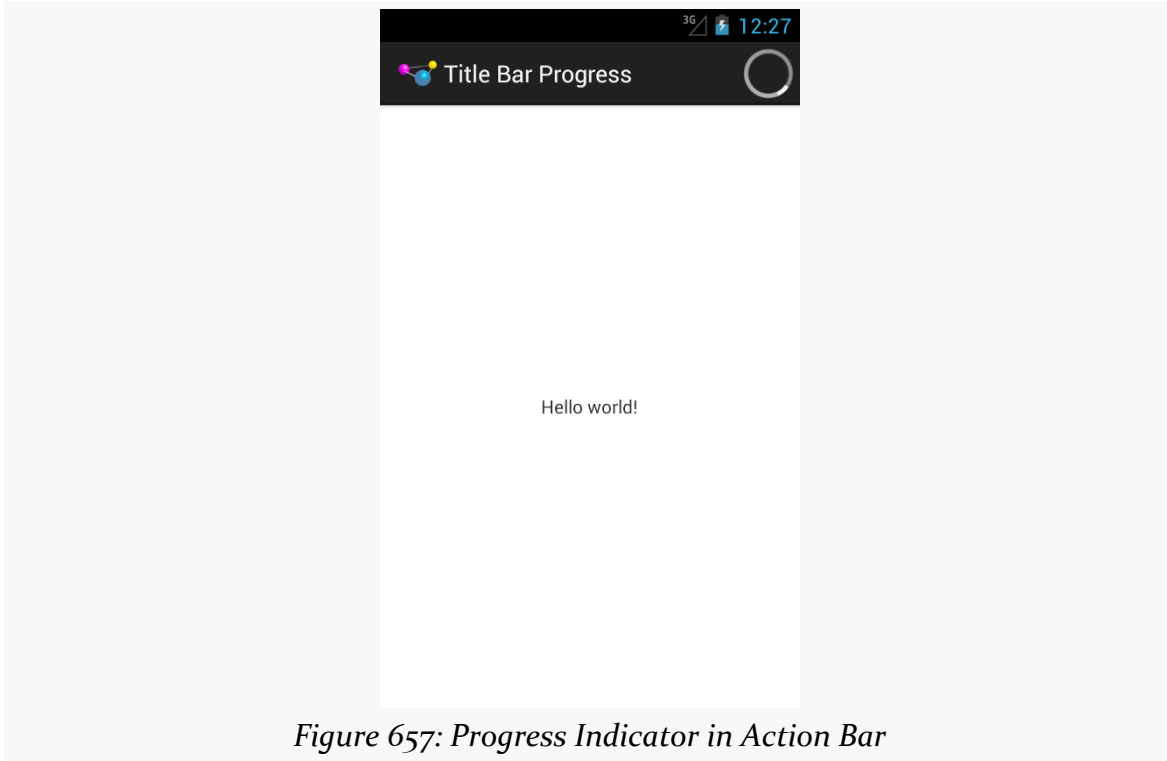

Figure 657: Progress Indicator in Action Bar

Note that this approach is not supported by `Theme.Material` or the `appcompat-v7` action bar backport, which makes it far less commonly used today.

Direct Progress Indication

Sometimes, the best way to let the user know about updates is to simply update the data in place. Rather than have some separate indicator, let the core UI itself convey the work being done.

We saw this in [the chapter on threads](#), where we populated a `ListView` in “real time” as we loaded in data into its adapter. Other variations on this theme include:

- Updating a page count `TextView` to show the number of downloaded pages, while the user is reading earlier pages, perhaps with some sort of style (e.g., italics) or color coding (e.g., red) to indicate data that is being loaded.

PROGRESS INDICATORS

- Simply disabling the buttons, action bar items, and other ways that the user could navigate to a point in your app where you need the data that is being loaded in the background. The key here is to make sure that users understand *why* those items are disabled, and sometimes that is not obvious. Hence, while this step may be necessary, it is often tied in with progress indicators in the title bar or action bar or other means of indicating to the user the *reason* they cannot perform certain operations.

More Fun with Pagers

In earlier chapters, we saw [basic uses of ViewPager](#), along with ways to [show multiple pages at a time on larger screens](#). However, there are other ways to apply ViewPager and integrate it into the rest of your application, some of which we will examine in this chapter.

Prerequisites

This chapter assumes that you have read the core chapters, particularly the one showing [how to use ViewPager](#).

Hosting ViewPager in a Fragment

Classically, the primary restriction on ViewPager was that you could not both have ViewPager be in a fragment *and* have ViewPager host fragments as its pages. You could do one or the other, but not both simultaneously.

As noted [in a previous chapter](#), Android 4.2 supports nested fragments natively, and the latest Android Support package backport also supports nested fragments. With those, you can have ViewPager be in a fragment and host fragments as its pages. However, it requires a minor modification to the way we set up a PagerAdapter, as is illustrated in the [ViewPager/Nested](#) sample project. This is the same project as ViewPager/Indicator, with the twist that the pages are fragments and the ViewPager is inside a fragment.

Our activity now implements the standard add-the-fragment-if-it-does-not-exist pattern that we have seen previously:

MORE FUN WITH PAGERS

```
package com.commonware.android.pagernested;

import android.os.Bundle;
import android.support.v4.app.FragmentActivity;

public class ViewPagerIndicatorActivity extends FragmentActivity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        if (getSupportFragmentManager().findFragmentById(android.R.id.content) == null) {
            getSupportFragmentManager().beginTransaction()
                .add(android.R.id.content,
                    new PagerFragment()).commit();
        }
    }
}
```

(from [ViewPager/Nested/app/src/main/java/com/commonware/android/pagernested/ViewPagerIndicatorActivity.java](#))

This loads a `PagerFragment`, which contains most of the logic from our original activity:

```
package com.commonware.android.pagernested;

import android.os.Bundle;
import android.support.v4.app.Fragment;
import android.support.v4.view.PagerAdapter;
import android.support.v4.view.ViewPager;
import android.view.LayoutInflater;
import android.view.View;
import android.view.ViewGroup;

public class PagerFragment extends Fragment {
    @Override
    public View onCreateView(LayoutInflater inflater,
        ViewGroup container,
        Bundle savedInstanceState) {
        View result=inflater.inflate(R.layout.pager, container, false);
        ViewPager pager=(ViewPager)result.findViewById(R.id.pager);

        pager.setAdapter(buildAdapter());

        return(result);
    }

    private PagerAdapter buildAdapter() {
        return(new SampleAdapter(getActivity(), getChildFragmentManager()));
    }
}
```

MORE FUN WITH PAGERS

(from [ViewPager/Nested/app/src/main/java/com/commonsware/android/pagernested/PagerFragment.java](#))

The biggest difference is that our call to the constructor of `SampleAdapter` no longer uses `getSupportFragmentManager()`. Instead, it uses `getChildFragmentManager()`. This allows `SampleAdapter` to use fragments hosted by `PagerFragment`, rather than ones hosted by the activity as a whole.

No other code changes are required, and from the user's standpoint, there is no visible difference.

Pages and the Action Bar

Fragments that are pages inside a `ViewPager` can participate in the action bar, supplying items to appear as toolbar buttons, in the overflow menu, etc. This is not significantly different than [how any fragment participates in the action bar](#):

- Call `setHasOptionsMenu()` early in the fragment lifecycle (e.g., `onCreateView()`) to state that the fragment wishes to contribute to the action bar contents
- Override `onCreateOptionsMenu()` and `onOptionsItemSelected()`, much as you would with an activity

`ViewPager` and `FragmentManager` will manage the contents of the action bar, based upon the currently-visible page. That page's contributions will appear in the action bar, then will be removed when the user switches to some other page.

To see this in action, take a look at the [ViewPager/ActionBar](#) sample project. This is the same as the `ViewPager/Indicator` project from before, except:

- In `onCreateView()`, for even-numbered page positions (0, 2, etc.), we call `setHasOptionsMenu(true)`:

```
@Override
public View onCreateView(LayoutInflater inflater,
                        ViewGroup container,
                        Bundle savedInstanceState) {
    View result=inflater.inflate(R.layout.editor, container, false);
    EditText editor=(EditText)result.findViewById(R.id.editor);

    position=getArguments().getInt(KEY_POSITION, -1);
    editor.setHint(getTitle(getActivity(), position));
}
```

MORE FUN WITH PAGERS

```
if ((position % 2)==0) {
    setHasOptionsMenu(true);
}

return(result);
}
```

(from [ViewPager/ActionBar/app/src/main/java/com/commonsware/android/pagerbar/EditorFragment.java](#))

- In `onCreateOptionsMenu()`, we inflate a `res/menu/actions.xml` menu resource:

```
@Override
public void onCreateOptionsMenu(Menu menu, MenuInflater inflater) {
    inflater.inflate(R.menu.actions, menu);

    super.onCreateOptionsMenu(menu, inflater);
}
```

(from [ViewPager/ActionBar/app/src/main/java/com/commonsware/android/pagerbar/EditorFragment.java](#))

Normally, we would also implement `onOptionsItemSelected()`, to find out when the action bar item was tapped, though this is skipped in this sample.

The result is that when we have an even-numbered page position — equating to an odd-numbered title and hint — we have items in the action bar:

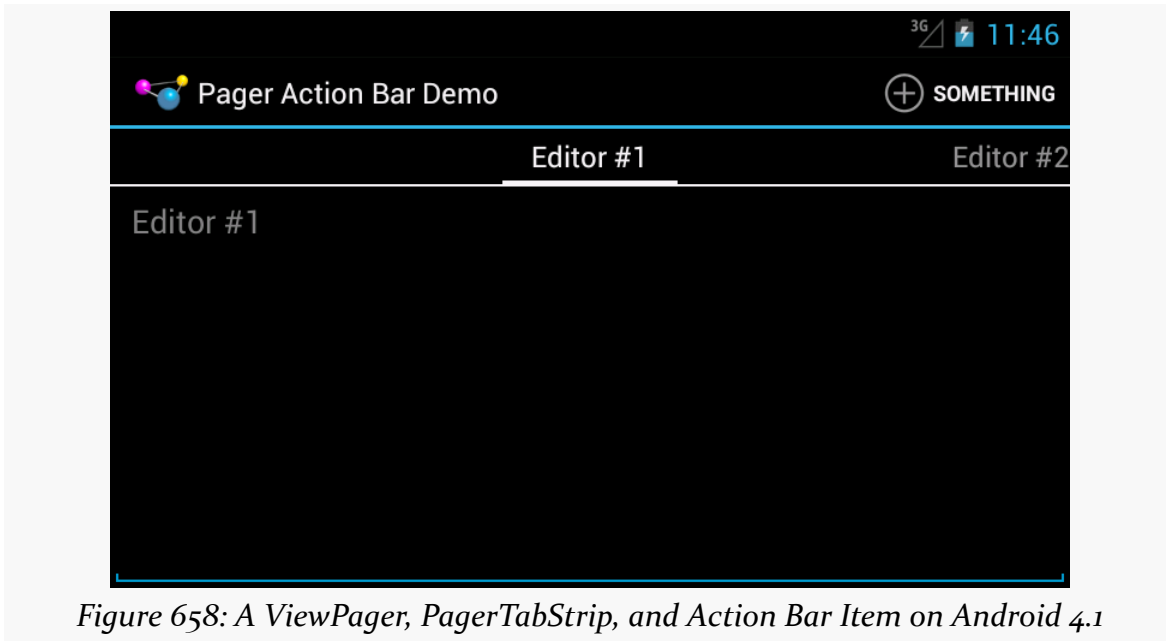

Figure 658: A ViewPager, PagerTabStrip, and Action Bar Item on Android 4.1

...but as soon as we swipe to an odd-numbered page position — equating to an even-numbered title and hint — our action bar item is removed, as that fragment did not call `setHasOptionsMenu(true)`:

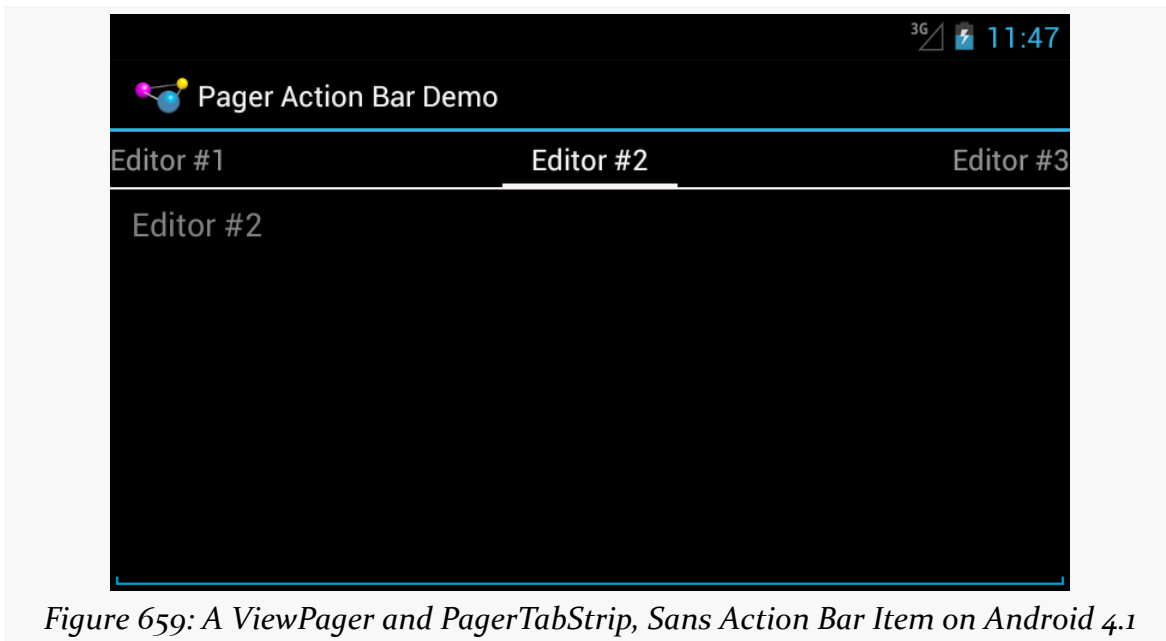

Figure 659: A ViewPager and PagerTabStrip, Sans Action Bar Item on Android 4.1

ViewPagers and Scrollable Contents

There are other things in Android that can be scrolled horizontally, besides a `ViewPager`:

- `HorizontalScrollView`
- `WebView`, for content that is wider than the width of the screen
- the deprecated `Gallery` widget
- maps from many mapping engines, such as Google Maps
- various third-party widgets

The challenge then comes in terms of dealing with horizontal swipe events. The ideal situation is for you to be able to swipe horizontally on the material inside the page, until you hit some edge (e.g., end of the `HorizontalScrollView`), then have swipe events move you to the adjacent page.

You can assist `ViewPager` in handling this scenario by subclassing it and overriding the `canScroll()` method. This will be called on a horizontal swipe, and it is up to you to indicate if the contents can be scrolled (returning `true`) or not (returning `false`). If the built-in logic is insufficient, tailoring `canScroll()` to your particular needs can help.

We will see an example of this later in the book, when [we put some maps into a ViewPager](#).

Columns for Large, Pages for Small

In some cases, you can take better advantage of larger screens by using `ViewPager` more judiciously. In [a previous chapter](#), we explored having `ViewPager` itself display more than one page at a time. A variation on that same theme is to only use a `ViewPager` on screen sizes where you lack sufficient room for everything, and to put those same pages on the screen at the same time when you have room for all of them.

For example, a Twitter client for Android could use the columns-or-pages support for displaying various streams of tweets: your timeline, your @ mentions, hashtags you follow, etc. Each stream is represented by a typical `ListView`, with one row per tweet. On a phone, since screen space is at a premium, those `ListView` widgets are set up in a `ViewPager`, with one list per page. Users can swipe between the lists, or use tabs to navigate the available lists. However, tablets offer more room, so the app

could show three `ListView` widgets side-by-side in landscape mode, so you can take in three sets of content without further interaction with the screen.

The [ViewPager/Columns1](#) sample project will demonstrate how you can accomplish the same basic approach in your own app... with some limitations.

The Layouts

Our main activity layout — cunningly named `main` — has a `ViewPager`-based definition in `res/layout/main.xml`:

```
<?xml version="1.0" encoding="utf-8"?>
<android.support.v4.view.ViewPager android:id="@+id/pager"
  xmlns:android="http://schemas.android.com/apk/res/android"
  android:layout_width="match_parent"
  android:layout_height="match_parent">

  <android.support.v4.view.PagerTabStrip
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:layout_gravity="top" />

</android.support.v4.view.ViewPager>
```

(from [ViewPager/Columns1/app/src/main/res/layout/main.xml](#))

However, in `res/layout-large/`, for 5-inch devices on up, we have a horizontal `LinearLayout` with three `FrameLayout` containers, each representing an equal-sized slot for one of our “pages”:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  android:baselineAligned="false"
  android:orientation="horizontal">

  <FrameLayout
    android:id="@+id/editor1"
    android:layout_width="0dp"
    android:layout_height="match_parent"
    android:layout_weight="1" />

  <FrameLayout
    android:id="@+id/editor2"
```

MORE FUN WITH PAGERS

```
        android:layout_width="0dp"
        android:layout_height="match_parent"
        android:layout_weight="1"/>

<FrameLayout
    android:id="@+id/editor3"
    android:layout_width="0dp"
    android:layout_height="match_parent"
    android:layout_weight="1"/>

</LinearLayout>
```

(from [ViewPager/Columns/app/src/main/res/layout-large/main.xml](#))

Android will automatically inflate the proper layout when we call `setContentView(R.layout.main)`.

The Activity

However, while Android handles the inflation for us, we obviously need to populate the contents a bit differently. In this sample, though, we are relying upon the fact that screen size will not change on the fly. Hence, an instance of our application will either show a `ViewPager` or show the horizontal `LinearLayout`, and not have to switch between those at runtime.

Our `SampleAdapter`, therefore, can remain unchanged, except for reducing the page count to 3:

```
package com.commonware.android.pagercolumns;

import android.app.Fragment;
import android.app.FragmentManager;
import android.content.Context;
import android.support.v13.app.FragmentPagerAdapter;

public class SampleAdapter extends FragmentPagerAdapter {
    Context ctxt=null;

    public SampleAdapter(Context ctxt, FragmentManager mgr) {
        super(mgr);
        this.ctxt=ctxt;
    }

    @Override
    public int getCount() {
        return(3);
    }
}
```

MORE FUN WITH PAGERS

```
}

@Override
public Fragment getItem(int position) {
    return(EditorFragment.newInstance(position));
}

@Override
public String getPageTitle(int position) {
    return(EditorFragment.getTitle(ctxt, position));
}
}
```

(from [ViewPager/Columns/app/src/main/java/com/commonsware/android/pagercolumns/SampleAdapter.java](#))

Our MainActivity will still use the SampleAdapter, and if we have a ViewPager, it will use it the same way as before. However, if we do *not* have a ViewPager, we must be showing three panes of content side by side, in which case we just execute a FragmentTransaction to populate the three FrameLayout containers with the three items created by the SampleAdapter:

```
package com.commonsware.android.pagercolumns;

import android.app.Activity;
import android.os.Bundle;
import android.support.v13.app.FragmentPagerAdapter;
import android.support.v4.view.ViewPager;

public class MainActivity extends Activity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.main);

        ViewPager pager=(ViewPager)findViewById(R.id.pager);

        if (pager==null) {
            if (getFragmentManager().findFragmentById(R.id.editor1)==null) {
                FragmentPagerAdapter adapter=buildAdapter();

                getFragmentManager().beginTransaction()
                    .add(R.id.editor1,
                        adapter.getItem(0))
                    .add(R.id.editor2,
                        adapter.getItem(1))
                    .add(R.id.editor3,
                        adapter.getItem(2)).commit();
            }
        }
    }
}
```

MORE FUN WITH PAGERS

```
    }  
  }  
  else {  
    pager.setAdapter(buildAdapter());  
  }  
}  
  
private FragmentPagerAdapter buildAdapter() {  
  return(new SampleAdapter(this, getFragmentManager()));  
}
```

(from [ViewPager/Columns1/app/src/main/java/com/commonsware/android/pagercolumns/MainActivity.java](#))

Of course, we skip the `FragmentManager` if the fragments already exist, such as due to a screen rotation configuration change.

The Results

On a phone, the `ViewPager`-based layout looks pretty much as it did before:

Figure 66o: A ViewPager. Again.

However, on a tablet, we get our three editors side-by-side:

Figure 661: Same App, Large-Screen Layout with Side-By-Side Editors

The Limitations

The simplified large-screen layout does not contain any indicators above the three editors. This could be added by simple changes to the `res/layout-large/main.xml` layout resource, if desired.

The bigger limitation is that this only works if you want the same look in all configurations *except* screen size, and if the screen size never changes. However, it is eminently possible that you will want to have a different mix than that, such as using the three-column approach only on large-screen *landscape* layouts, using `ViewPager` everywhere else. In that case, our approach breaks down, as we will have different fragments inside the pager and outside the pager, meaning that we will lose our data on a configuration change. Addressing this issue is covered in the next two sections.

Introducing ArrayPagerAdapter

The flexibility of `ViewPager` is governed, to a large extent, by the implementation of its `PagerAdapter`. Inflexible `PagerAdapter` implementations lead to inflexible uses of `ViewPager`.

Notably, the two concrete `PagerAdapter` implementations shipped in the Android Support package — `FragmentPagerAdapter` and `FragmentStatePagerAdapter` — have their limitations when it comes to things like:

- Using fragments created by those adapters in other fashions, such as in the columns-or-pager scenario from the previous section
- Handling dynamically-changing contents, such as adding pages, removing pages, or reordering pages

The `ArrayPagerAdapter` is an attempt to provide a more flexible `PagerAdapter` implementation that still feels a lot like `FragmentPagerAdapter` in terms of its use of fragments. It also bears some resemblance to the `ArrayAdapter` used for `AdapterView` implementations like `ListView`, giving rise to its name.

`ArrayPagerAdapter` is part of [the CWAC-Pager project](#) and is available for use in any Android project compatible with the Apache License 2.0.

We will review the implementation of `ArrayPagerAdapter` [later in this chapter](#). This section reviews how you can use `ArrayPagerAdapter` in your projects.

Adding the Dependency

Android Studio users can use the repositories and dependencies closures outlined on [the CWAC-Pager project home page](#):

```
repositories {
    maven {
        url "https://s3.amazonaws.com/repo.commonware.com"
    }
}

dependencies {
    implementation 'com.commonware.cwac:pager:0.2.+'
```

Choosing the Package

There are two implementations of `ArrayPagerAdapter`. One, in the `com.commonware.cwac.pager` package, is designed for use with native API Level 11 fragments. The other, in the `com.commonware.cwac.pager.v4` package, is designed for use with the Android Support package's backport of fragments. You will need to choose the right `ArrayPagerAdapter` for the type of fragments that you are using.

However, other than choosing suitable versions of classes for `Fragment`, etc., there is no real public API difference between the two. Hence, the documentation that follows is suitable for either implementation of `ArrayPagerAdapter`, so long as you use the one that matches the source of your fragment implementation.

Note that only `ArrayPagerAdapter` lives in the `com.commonware.cwac.pager.v4` package. The classes and interfaces that support `ArrayPagerAdapter`, like `PageDescriptor`, are implemented in `com.commonware.cwac.pager` and used by both implementations of `ArrayPagerAdapter`.

Creating PageDescriptors

You might think that `ArrayPagerAdapter` would take an array of pages, much like `ArrayAdapter` takes an array of models.

That's not how it works.

Instead, `ArrayPagerAdapter` wants an `ArrayList` of `PageDescriptor` objects. `PageDescriptor` is an interface, requiring you to supply implementations of two methods:

- `getTitle()`, which will be the title used for this page, for things like `PagerTabStrip` and the `ViewPagerIndicator` family of indicators
- `getFragmentTag()`, which is a unique tag for this page's fragment

Also, `PageDescriptor` extends [the `Parcelable` interface](#), and so any implementation of `PageDescriptor` must also implement the methods and `CREATOR` required by `Parcelable`.

You are welcome to create your own `PageDescriptor` if you wish. However, there is a built-in implementation, `SimplePageDescriptor`, which probably meets your needs. You just pass the tag and title into the `SimplePageDescriptor` constructor, and it handles everything else, including the `Parcelable` implementation.

Creating and Populating the Adapter

To work with `ArrayPagerAdapter`, you start by creating an `ArrayList` of `PageDescriptor` objects, one for each page that is to be in your pager.

Then, create a subclass of `ArrayPagerAdapter`. `ArrayPagerAdapter` uses Java generics, requiring you to declare the type of fragment the adapter is serving up to the `ViewPager`. So, for example, if you have a `ViewPager` that will have each page be an `EditorFragment`, you would declare your custom `ArrayPagerAdapter` to be:

```
static class SamplePagerAdapter extends ArrayPagerAdapter<EditorFragment>
```

If you will have pages come from a variety of fragments, just use the `Fragment` base class appropriate for your fragment source (e.g., `android.app.Fragment`).

Your custom `ArrayPagerAdapter` subclass will need to override (at minimum) one method: `createFragment()`. This method is responsible for instantiating fragments, as requested. You are passed the `PageDescriptor` for the fragment to be created — you simply create and return that fragment.

Hence, a custom `ArrayPagerAdapter` can be as simple as:

```
static class SamplePagerAdapter extends
    ArrayPagerAdapter<EditorFragment> {
    public SamplePagerAdapter(FragmentManager fragmentManager,
        ArrayList<PageDescriptor> descriptors) {
        super(fragmentManager, descriptors);
    }

    @Override
    protected EditorFragment createFragment(PageDescriptor desc) {
        return(EditorFragment.newInstance(desc.getTitle()));
    }
}
```

Then, you can create an instance of your custom `ArrayPagerAdapter` subclass as needed, supplying the constructor with a suitable `FragmentManager` and your `ArrayList` of `PageDescriptor` objects. Once attached to a `ViewPager`, `ArrayPagerAdapter` behaves much like a `FragmentPagerAdapter` by default.

There is another flavor of the `ArrayPagerAdapter` constructor, one that takes a `RetentionStrategy` as a parameter, as is described [later in this chapter](#).

Modifying the Contents

`ArrayPagerAdapter` offers several methods to allow you to change the contents of the `ViewPager`:

- `add()` takes a `PageDescriptor` and adds a new page at the end of the current roster of pages
- `insert()` takes a `PageDescriptor` and an insertion point and inserts a new page before the current page at that insertion point
- `remove()` takes a position and removes the page at that position
- `move()` takes an old and new position and moves the page from the old position to the new position (effectively combining a `remove()` from the old position and an `insert()` of the same page into the new position)

Other Useful Methods

`getExistingFragment()`, given a position, returns the existing fragment for that position in the `ViewPager`, if that fragment exists. Otherwise, it returns `null`.

`getCurrentFragment()` is like `getExistingFragment()`, but returns the fragment for the currently-viewed page in the `ViewPager`.

Columns for Large *Landscape*, Pages for the Rest

[Earlier in this chapter](#), we saw how you could conditionally use a `ViewPager` in some circumstances, but not others, such as using a `ViewPager` on smaller screens and a set of columns for the “pages” on larger screens. The limitation noted at that time was that you were stuck with one pattern for the lifetime of the activity, meaning that in any configuration change, you had to stick with the `ViewPager` or the columns that you started with.

However, while the columnar approach for larger screens works well in landscape, you may find the columns to be too tall and too skinny in portrait. Hence, a better solution would be to use columns only on larger screens in landscape, and to use the `ViewPager` everywhere else.

This is annoyingly tricky to do, assuming that you want to use the same fragments in each case, so you can arrange to hold onto the contents of their widgets.

Jake Wharton — author of `ViewPagerIndicator` and a seemingly infinite number of other Android open source libraries — raised this issue in [a Google+ post](#). He also posted [a sample solution](#), but one that was limited to only two fragments. Quoting Mr. Wharton:

Due the shenanigans performed by `FragmentPagerAdapter` we're forced to write a custom `PagerAdapter` which handles the instances our selves.

However, while two pages is reasonable, having some flexibility for a few more pages would be useful. So, let's see how we can accomplish the same aims, using `ArrayPagerAdapter`, in the [ViewPager/FlexColumns](#) sample project.

Fragments Inside and Outside the ViewPager

A fragment cannot be in two containers at once. The `ViewPager`, where we have one, is a different container than one of our columns, when we have one.

Hence, if the container is not changing during the operation of our activity — such as using a `ViewPager` in both portrait and landscape on smaller screens — we have no problem. But, if the container *is* changing — such as switching between columns and a `ViewPager` on larger screens — we need to take steps.

One option for those “steps”, of course, is to simply run a separate set of fragments. One set serves as pages of the `ViewPager`; the other serves as the columns. However, then we have to do work to synchronize those on configuration changes, as from the *user's* perspective, the fact that we happen to render things in pages or columns should not cause the user to lose data they entered in one form when switching to the other.

If we want to use the same fragment instances, then we can use normal configuration-change logic, like `onSaveInstanceState()`, to ensure that we hold onto user-entered data during the change. However, we have to arrange to move the fragment from one container to another. This will involve running a `FragmentTransaction` to `remove()` the fragment from the old container and `add()` it to its new container.

Making this more complicated is that the `PagerAdapter` should be handling the `add()` part, when the fragment is being put into a page, as that is how fragment-based `PagerAdapter` implementations like `FragmentPagerAdapter` work.

Adding to the fun is a matter of timing. By default, a `FragmentManager` transaction is committed asynchronously. Attempting to `remove()` a fragment and `add()` the same fragment in the same transaction will fail, because the `add()` will complain that the fragment is already in another container, because the `remove()` will not have happened. Even doing the `remove()` and `add()` in separate normal transactions will not help. Instead, we need to ensure that the `remove()` has completed processing first, before we try to `add()`. To help with this, `FragmentManager` has a `executePendingTransactions()` method we can call, to have it complete its own processing on committed `FragmentManager` transactions synchronously. Committing the `remove()` transaction and calling `executePendingTransactions()` before committing the `add()` transaction works.

The Revised PagerAdapter

With all that in mind, let's look at how this revised sample behaves. The core functionality is the same as with the earlier `pager-or-columns` sample, but now we will only use the columns on -large screen devices in -land orientation, by simply renaming `res/layout-large/` to `res/layout-large-land/`.

Our `PagerAdapter` is still called `SamplePagerAdapter`, but this time it is a `ArrayPagerAdapter` for our `EditorFragment` pages:

```
static class SamplePagerAdapter extends
    ArrayPagerAdapter<EditorFragment> {
    public SamplePagerAdapter(FragmentManager fragmentManager,
        ArrayList<PageDescriptor> descriptors) {
        super(fragmentManager, descriptors);
    }

    @Override
    protected EditorFragment createFragment(PageDescriptor desc) {
        return(createFragment(desc.getTitle()));
    }

    EditorFragment createFragment(String title) {
        return(EditorFragment.newInstance(title));
    }
}
```

(from [ViewPager/FlexColumns/app/src/main/java/com/commonsware/android/pagercolumns/MainActivity.java](#))

The Revised Activity

The `onCreate()` method of the earlier example would see if we had a `ViewPager`, then either populate the columns or populate the `ViewPager` from our `PagerAdapter`. The `onCreate()` method of the new example does the same basic thing, except that it delegates most of the work for actually filling in the columns to a private `populateColumn()` method:

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.main);

    ViewPager pager=(ViewPager)findViewById(R.id.pager);

    if (pager == null) {
        if (getFragmentManager().findFragmentById(R.id.editor1) == null) {
            SamplePagerAdapter adapter=buildAdapter();
            FragmentTransaction ft=
                getFragmentManager().beginTransaction();

            populateColumn(getFragmentManager(), ft, adapter, 0,
                R.id.editor1);
            populateColumn(getFragmentManager(), ft, adapter, 1,
                R.id.editor2);
            populateColumn(getFragmentManager(), ft, adapter, 2,
                R.id.editor3);
            ft.commit();
        }
    }
    else {
        SamplePagerAdapter adapter=buildAdapter();

        pager.setAdapter(adapter);
    }
}
```

(from [ViewPager/FlexColumns/app/src/main/java/com/commonsware/android/pagercolumns/MainActivity.java](#))

The `buildAdapter()` method changes a bit, to create our `ArrayPagerAdapter` subclass using an array of `SimplePageDescriptor` objects:

```
private SamplePagerAdapter buildAdapter() {
    ArrayList<PageDescriptor> pages=new ArrayList<PageDescriptor>();

    for (int i=0; i < 3; i++) {
```

MORE FUN WITH PAGERS

```
pages.add(new SimplePageDescriptor(buildTag(i), buildTitle(i)));
}

return(new SamplePagerAdapter(getFragmentManager(), pages));
}
```

(from [ViewPager/FlexColumns/app/src/main/java/com/commonsware/android/pagercolumns/MainActivity.java](#))

`buildAdapter()`, in turn, uses `buildTag()` and `buildTitle()` methods to retrieve the tag and title to use given a position:

```
private String buildTag(int position) {
    return("editor" + String.valueOf(position));
}

private String buildTitle(int position) {
    return(String.format(getString(R.string.hint), position + 1));
}
```

(from [ViewPager/FlexColumns/app/src/main/java/com/commonsware/android/pagercolumns/MainActivity.java](#))

Finally, our `populateColumn()` method handles the work to fill in one of our columns, if we are in column mode:

```
private void populateColumn(FragmentManager fm,
                           FragmentTransaction ft,
                           SamplePagerAdapter adapter, int position,
                           int slot) {
    EditorFragment f=adapter.getExistingFragment(position);

    if (f == null) {
        f=adapter.createFragment(buildTitle(position));
    }
    else {
        fm.beginTransaction().remove(f).commit();
        fm.executePendingTransactions();
    }

    ft.add(slot, f, buildTag(position));
}
```

(from [ViewPager/FlexColumns/app/src/main/java/com/commonsware/android/pagercolumns/MainActivity.java](#))

First, we ask our `ArrayPagerAdapter` to retrieve for us the existing fragment, if any, for this given column/page, based on its position. This may return `null`, if this is the first time we have run our app, in which case we ask our `ArrayPagerAdapter` to

create the fragment for us (using the same logic that it would when functioning inside of a `ViewPager`, via `createFragment()`).

Otherwise, `getExistingFragment()` should return an existing `EditorFragment` instance, one probably formerly managed by a `ViewPager`. So, we create, commit, and execute a `FragmentTransaction` to `remove()` this fragment from its existing container.

The net is that, in either case, we have an `EditorFragment`, set up for use in this column, that does not have a current container. To add it to our column, we simply call `add()` on the supplied `FragmentTransaction`, which is committed by our activity's `onCreate()` method. However, we use the three-parameter form of `add()`, which allows us not only to put the fragment into a container, but to assign it a tag as well. The tag is how `ArrayPagerAdapter` identifies the various fragments — by using the same tag, this fragment can be picked up by future instances of `ArrayPagerAdapter` in case of a configuration change.

You will notice that while we `remove()` the `EditorFragment` from the `ViewPager` and `add()` it to the column, we are not handling the reverse case, where we would `remove()` the fragment from the column and/or `add()` it to the `ViewPager`. That little bit of logic is supplied to us by `ArrayPagerAdapter`, as we will see when we examine the implementation of `ArrayPagerAdapter` [later in this chapter](#).

The resulting activity works exactly the same as the previous one, except that we use the `ViewPager` in portrait mode on larger-screen devices. Rotating a large-screen device will show our fragments moving between pages and columns, with their contents (whatever you type into the `EditorFragment` instances) being maintained via the built-in `onSaveInstanceState()` support for `EditText` widgets.

Adding, Removing, and Moving Pages

`ArrayPagerAdapter` also supports modifying the roster of pages at runtime: adding, inserting, removing, and moving pages. For example, a Twitter client might:

- Allow users to add pages for new monitored hashtags or search results
- Allow users to reorder the pages, putting more frequently-used ones towards the “front”, for easier access when the app starts from scratch
- Allow users to remove pages they do not use, such as ones they added earlier

To see how this works in practice, we can examine the demo project for the CWAC-Pager library. There are two versions of this demo, [one for the “v4” fragments](#) from the Android Support package, and [one for native API Level 11 fragments](#). Here, we will take a look at the latter project.

Reviewing the Core Functionality

This project is yet another rendition of our bunch-of-EditorFragment-pages sample that we have been examining for various ways of using ViewPager. This one sets up 10 pages at the start. However, it also inflates a menu resource to add four actions to the action bar: add, split, remove, and swap:

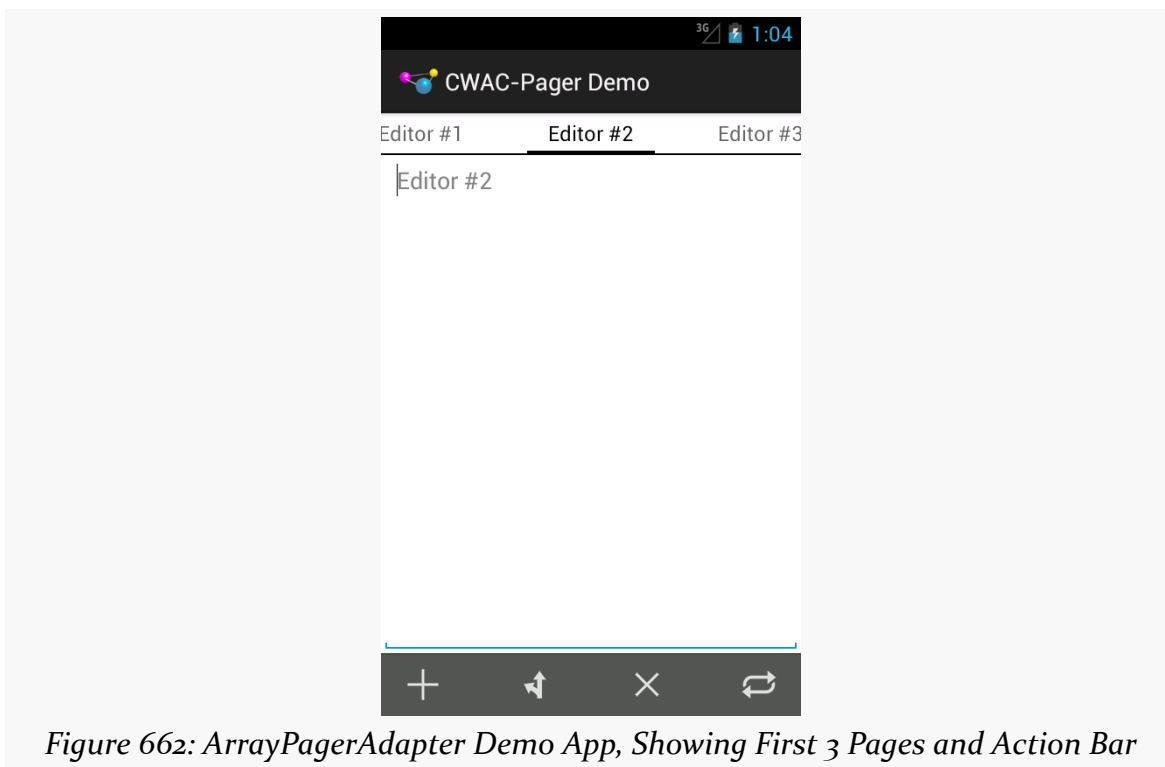

Figure 662: ArrayPagerAdapter Demo App, Showing First 3 Pages and Action Bar

`onOptionsItemSelected()` in our activity routes those four action items to three methods: `add()` (for add and split), `remove()`, and `swap()`.

Add and Split

Tapping the “add” action bar item will add a new page before the current one, with a title and hint based upon the number of existing pages (e.g., tapping “add” with 10 pages will add “Editor #11”):

MORE FUN WITH PAGERS

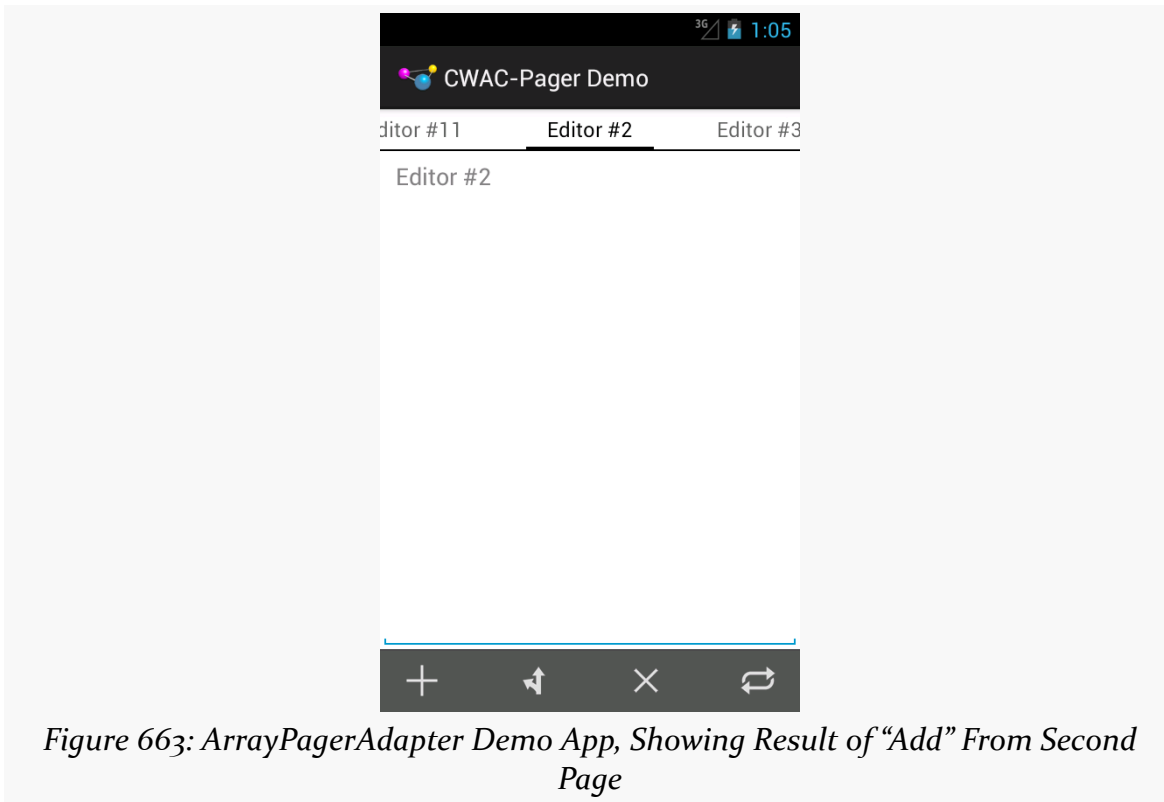

Figure 663: ArrayPagerAdapter Demo App, Showing Result of “Add” From Second Page

Tapping the “split” action bar item will add a new page after the currently-selected one.

Since both of these involve adding pages, this sample consolidates their work into a single `add()` method, taking a boolean parameter to indicate if we are inserting a page before the current one or after:

```
private void add(boolean before) {
    int current=pager.getCurrentItem();
    SimplePageDescriptor desc=
        new SimplePageDescriptor(buildTag(adapter.getCount()),
                                buildTitle(adapter.getCount()));

    if (before) {
        adapter.insert(desc, current);
    }
    else {
        if (current < adapter.getCount() - 1) {
            adapter.insert(desc, current + 1);
        }
        else {
```

```
        adapter.add(desc);
    }
}
```

We call `getCurrentItem()` on the `ViewPager` to determine what the position index is of the currently-selected page. From there, we set up our `SimplePageDescriptor` for the page that we will be adding, giving it a title based upon our hint string resource and a tag based upon the number of pages. We then call `add()` (if we are on the last page and the user clicked on “split”) or `insert()` (for all other scenarios) to inject the new page. The `ArrayPagerAdapter` will be responsible for creating this page, just as it did for all previous pages.

Remove

Tapping “remove” will remove the currently-selected page, so long as we will still have at least one page remaining (just to keep the example simpler, so we do not have to worry about not having a “current page”).

This is handled by the `remove()` method on our activity, which turns around and calls `remove()` on the `ArrayPagerAdapter`:

```
private void remove() {
    if (adapter.getCount() > 1) {
        adapter.remove(pager.getCurrentItem());
    }
}
```

Swap

Tapping “swap” will swap the positions of the current page and the one immediately after it. The exception is if you are on the last page, in which case we will swap the current page with the one immediately before it:

```
private void swap() {
    int current=pager.getCurrentItem();

    if (current < adapter.getCount() - 1) {
        adapter.move(current, current + 1);
    }
    else {
        adapter.move(current, current - 1);
    }
}
```

```
}  
}
```

This is handled by the `swap()` method on our activity, which calls `move()` on the `ArrayPagerAdapter`. `move()` takes the position of the page to be moved and the position it should wind up in after the move, so we call `move(current, current + 1)` to swap the current page with the one after it or `move(current, current - 1)` to swap the current page with the one before it.

Inside ArrayPagerAdapter

`ArrayPagerAdapter` is a relatively large implementation of the `PagerAdapter` interface, and it helps to demonstrate some of the challenges faced when trying to create alternative fragment-based `PagerAdapter` implementations. Hence, this section will dive into portions of the innards of `ArrayPagerAdapter`, to explain how (and, sometimes, why) it does what it does.

Note that `ArrayPagerAdapter` will continue to expand over time, and so the copy in the master branch of the GitHub repo may be newer than the one profiled in this chapter. This chapter covers v0.2.2.

Also note that some of the code in `ArrayPagerAdapter` comes from `FragmentPagerAdapter` — as little of this code was altered as was practical, to help make it easier to integrate changes made to `FragmentPagerAdapter` over time.

Also, to simplify the discussion, this section will demonstrate the `ArrayPagerAdapter` set up for native API Level 11 fragments, in the `com.commonware.cwac.pager` package.

PageDescriptor and PageEntry

`ArrayPagerAdapter` works with two representations of pages: `PageDescriptor` and `PageEntry`.

`PageDescriptor` is a simple interface, supplying the unique tag (`getFragmentTag()`) and indicator title (`getTitle()`) to use for a page:

```
package com.commonware.cwac.pager;  
  
import android.os.Parcelable;
```

MORE FUN WITH PAGERS

```
public interface PageDescriptor extends Parcelable {
    String getFragmentTag();

    String getTitle();
}
```

Developers can use SimplePageDescriptor as an implementation of PageDescriptor in most cases. SimplePageDescriptor just holds onto those two strings, plus handles the implementation of the Parcelable interface:

```
package com.commonsware.cwac.pager;

import android.os.Parcel;
import android.os.Parcelable;

public class SimplePageDescriptor implements PageDescriptor {
    private String tag=null;
    private String title=null;

    public static final Parcelable.Creator<SimplePageDescriptor> CREATOR=
        new Parcelable.Creator<SimplePageDescriptor>() {
            public SimplePageDescriptor createFromParcel(Parcel in) {
                return new SimplePageDescriptor(in);
            }

            public SimplePageDescriptor[] newArray(int size) {
                return new SimplePageDescriptor[size];
            }
        };

    public SimplePageDescriptor(String tag, String title) {
        this.tag=tag;
        this.title=title;
    }

    private SimplePageDescriptor(Parcel in) {
        tag=in.readString();
        title=in.readString();
    }

    @Override
    public int describeContents() {
        return(0);
    }

    @Override
    public void writeToParcel(Parcel out, int flags) {
```

MORE FUN WITH PAGERS

```
    out.writeString(tag);
    out.writeString(title);
}

public String getTitle() {
    return(title);
}

public void setTitle(String title) {
    this.title=title;
}

public String getFragmentTag() {
    return(tag);
}
}
```

However, the actual data model held by `ArrayPagerAdapter` is not the `PageDescriptor`, but rather a `PageEntry`, that holds onto its corresponding `PageDescriptor` *plus* a `Fragment.SavedState` object:

```
    }
};

// public static final RetentionStrategy REMOVE=new
// RetentionStrategy() {
// public void attach(Fragment fragment,
// FragmentTransaction currTransaction) {
// currTransaction.attach(fragment);
// }
//
//
// public void detach(Fragment fragment,
// FragmentTransaction currTransaction) {
// currTransaction.detach(fragment);
// }
// };

private static class PageEntry implements Parcelable {
    private PageDescriptor descriptor=null;
    private Fragment.SavedState state=null;

    public static final Parcelable.Creator<PageEntry> CREATOR=
        new Parcelable.Creator<PageEntry>() {
            public PageEntry createFromParcel(Parcel in) {
                return new PageEntry(in);
            }
        }
}
```

MORE FUN WITH PAGERS

```
    public PageEntry[] newArray(int size) {
        return new PageEntry[size];
    }
};

PageEntry(PageDescriptor descriptor) {
    this.descriptor=descriptor;
}

PageEntry(Parcel in) {
    this.descriptor=in.readParcelable(getClass().getClassLoader());
    this.state=in.readParcelable(getClass().getClassLoader());
}
```

`Fragment.SavedState` is a Parcelable object we can request from a Fragment at any point, representing the saved state of that fragment, as obtained via `onSaveInstanceState()` and related code. At present, that `Fragment.SavedState` is unused, as will be explained in the next section.

RetentionStrategy

`ArrayPagerAdapter` also uses a `RetentionStrategy`, designed to abstract the logic for manipulating the fragments themselves as pages come and go within the `ViewPager`. `RetentionStrategy` is an interface, with methods to `attach()` a fragment to be in the pager and to `detach()` the fragment from the pager:

```
public interface RetentionStrategy {
    void attach(Fragment fragment, FragmentTransaction currTransaction);

    void detach(Fragment fragment, FragmentTransaction currTransaction);
}
```

There is only one stock implementation of this strategy at this time, in the form of a static data member named `KEEP`. This strategy is designed to replicate the behavior of `FragmentManager`, keeping all fragments around once created, and merely `attach()`-ing and `detach()`-ing them from the `FragmentManager` as dictated:

```
public T getCurrentFragment() {
    return(currPrimaryItem);
}

private String getFragmentTag(int position) {
    return(getPageDescriptor(position).getFragmentTag());
}

private void validatePageDescriptor(PageDescriptor desc) {
```

```
for (PageEntry entry : entries) {
    if (desc.getFragmentTag().equals(entry.getDescriptor()
        .getFragmentTag())) {
        throw new IllegalArgumentException(
```

A future implementation of `ArrayPagerAdapter` should include another strategy that behaves more like `FragmentStatePagerAdapter`, removing the fragments entirely and allowing them to be garbage collected, while using `PageEntry` to hold onto their `Fragment`. `SavedState` structures to repopulate them later on if the user swipes back to that page.

Class Declaration and Generics

`ArrayPagerAdapter` uses Java generics to allow developers to state what `Fragment` subclass the pages are. This is for use with convenience methods — `getExistingFragment()` and `getCurrentFragment()` — to help reduce the developer's need to downcast those `Fragment` instances to some subclass. If the pages in the `ViewPager` will all come from a single `Fragment` subclass, the developer would use that class as the `T` in the declaration; otherwise, the developer would just use `Fragment`:

```
abstract public class ArrayPagerAdapter<T extends Fragment> extends
```

Constructors

`ArrayPagerAdapter` offers two constructors. The simpler two-parameter constructor, taking the `FragmentManager` and the desired pages as an `ArrayList` of `PageDescriptor` objects, just chains to the three-parameter constructor. That third parameter is an instance of a `RetentionStrategy`, allowing reusers of `ArrayPagerAdapter` to try their own hand at implementing such a strategy. `null` — the default strategy from the standpoint of the constructors — is replaced with the default `KEEP` strategy, and the `PageDescriptor` objects are wrapped in `PageEntry` objects as the actual data model (an `entries` `ArrayList`):

```
public ArrayPagerAdapter(FragmentManager fragmentManager,
    List<PageDescriptor> descriptors,
    RetentionStrategy retentionStrategy) {
    this.fm=fragmentManager;
    this.entries=new ArrayList<PageEntry>();

    for (PageDescriptor desc : descriptors) {
        validatePageDescriptor(desc);
```

```
entries.add(new PageEntry(desc));
}

this.retentionStrategy=retentionStrategy;

if (this.retentionStrategy == null) {
    this.retentionStrategy=KEEP;
}
```

Core PagerAdapter Methods

All PagerAdapter implementations have some core methods that they must handle. When you create a subclass of FragmentPagerAdapter and FragmentStatePagerAdapter, you only need to worry about getCount() and getPage(). However, if you are creating your own replacement for those fragment-based adapters, there are a few more standard PagerAdapter methods that you will need to override.

getCount()

getCount() is easy: all we need to do is return our desired number of pages. That is based on the number of PageDescriptor objects supplied to our adapter, which we wrapped into PageEntry objects and hold onto in entries:

```
@Override
public int getCount() {
    return(entries.size());
}
```

getPageTitle()

Similarly, getPageTitle() just needs to find the appropriate PageDescriptor and call getTitle() on it, to supply the title for a given page for use by an indicator like PagerTabStrip:

```
@Override
public String getPageTitle(int position) {
    return(getPageDescriptor(position).getTitle());
}
```

instantiateItem() and destroyItem()

The `instantiateItem()` method on `PagerAdapter` is responsible for setting up the user interface for a given page (indicated by position) and adding those widgets to a `ViewGroup` supplied as a parameter. It returns an `Object` that represents a “handle” to the page that `ViewPager` will return to the `PagerAdapter` in future calls, such as to `destroyItem()`.

A `Fragment`-based `PagerAdapter` can use the `fragment` itself as the “handle”, and the `fragment`’s `onCreateView()` as the means of obtaining the UI to pour into the `ViewGroup`.

Hence, the `ArrayPagerAdapter` implementation of `instantiateItem()` does the following:

- First, starts a `FragmentManager`, if there is not one already in progress
- Then, tries to find an existing `Fragment` for this position, using a `getExistingFragment()` helper method (described later in this chapter)
- If an existing `fragment` exists, `instantiateItem()` uses the `RetentionStrategy` to re-attach the UI
- If an existing `fragment` does not exist, `instantiateItem()` calls the abstract `createFragment()` method, to allow the subclass to return the actual `Fragment` object given the `PageDescriptor`, then `add()` that `fragment` to the UI
- If the `fragment` is not already the current page, make sure that its action bar contributions are hidden via `setMenuVisibility()` and `setVisibleHint()`
- Return the `fragment` itself as the “handle”

```
@TargetApi(Build.VERSION_CODES.ICE_CREAM_SANDWICH_MR1)
@Override
public Object instantiateItem(ViewGroup container, int position) {
    if (currTransaction == null) {
        currTransaction=fm.beginTransaction();
    }

    Fragment fragment=getExistingFragment(position);

    if (fragment != null) {
        retentionStrategy.attach(fragment, currTransaction);
    }
    else {
        fragment=createFragment(entries.get(position).getDescriptor());
        currTransaction.add(container.getId(), fragment,
            getFragmentTag(position));
    }
}
```

MORE FUN WITH PAGERS

```
if (fragment != currPrimaryItem) {
    fragment.setMenuVisibility(false);

    if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.ICE_CREAM_SANDWICH_MR1) {
        fragment.setUserVisibleHint(false);
    }
}

return(fragment);
}
```

Conversely, `destroyItem()` is responsible for cleaning up anything from a page that the `PagerAdapter` thinks is no longer needed. The `destroyItem()` method on `ArrayPagerAdapter` starts a transaction if there is none, then delegates the actual work to the `RetentionStrategy`:

```
@TargetApi(Build.VERSION_CODES.HONEYCOMB)
@Override
public void destroyItem(ViewGroup container, int position,
    Object object) {
    if (currTransaction == null) {
        currTransaction=fm.beginTransaction();
    }

    retentionStrategy.detach((Fragment)object, currTransaction);
}
```

startUpdate() and finishUpdate()

The `startUpdate()` method will be called before any calls to `instantiateItem()` or `destroyItem()`, and so, if desired, we can do some initialization work there. In the case of `ArrayPagerAdapter`, all initialization is done lazily, and so `startUpdate()` is not needed. However, since `FragmentPagerAdapter` overrides `startUpdate()` with an empty implementation, we keep that for maximum fidelity with the stock implementation:

```
@Override
public void startUpdate(ViewGroup container) {
}
```

The `finishUpdate()` method will be called after any calls to `instantiateItem()` or `destroyItem()`, where we can do some cleanup work. `ArrayPagerAdapter` creates a `FragmentTransaction` as part of its work in `instantiateItem()` and `destroyItem()`, and so we need to commit that transaction in `finishUpdate()`. Once again, we reproduce the implementation from `FragmentPagerAdapter`, which uses

MORE FUN WITH PAGERS

`commitAllowingStateLoss()` (so we are not concerned with the timing of any state-saving being done at the activity level) and `executePendingTransactions()` (so all of the fragment work is done directly, rather than being posted to the end of the main application thread's work queue):

```
@TargetApi(Build.VERSION_CODES.HONEYCOMB)
@Override
public void finishUpdate(ViewGroup container) {
    if (currTransaction != null) {
        currTransaction.commitAllowingStateLoss();
        currTransaction=null;
        fm.executePendingTransactions();
    }
}
```

setPrimaryItem()

`ViewPager` will call `setPrimaryItem()` on the `PagerAdapter` when a new page is being brought into view, based on gestures or other calls on `ViewPager` itself (e.g., `setCurrentItem()`). Some `PagerAdapter` implementations will have nothing much to do here. `Fragment-based PagerAdapter` implementations, though, need to ensure that the right fragment's action bar items are shown. Hence, `ArrayPagerAdapter` removes the action bar items from the previously-current page and adds the action bar items of the newly-current page:

```
@TargetApi(Build.VERSION_CODES.ICE_CREAM_SANDWICH_MR1)
@SuppressWarnings("unchecked")
@Override
public void setPrimaryItem(ViewGroup container, int position,
    Object object) {
    T fragment=(T)object;

    if (fragment != currPrimaryItem) {
        if (currPrimaryItem != null) {
            currPrimaryItem.setMenuVisibility(false);

            if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.ICE_CREAM_SANDWICH_MR1) {
                currPrimaryItem.setUserVisibleHint(false);
            }
        }

        if (fragment != null) {
            fragment.setMenuVisibility(true);

            if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.ICE_CREAM_SANDWICH_MR1) {
                fragment.setUserVisibleHint(true);
            }
        }

        currPrimaryItem=fragment;
    }
}
```

```
}  
}
```

isViewFromObject()

`isViewFromObject()` helps `ViewPager` keep track of the UI for pages and how it maps back to a page's "handle". In our case, since the "handle" is a `Fragment`, we need to see if the supplied `View` is the `View` from the supplied `Fragment`:

```
@TargetApi(Build.VERSION_CODES.HONEYCOMB)  
@Override  
public boolean isViewFromObject(View view, Object object) {  
    return ((Fragment)object).getView() == view;  
}
```

State Management

Our `PagerAdapter` is called with `saveState()` and `restoreState()` methods, to have us save the state of our data model and restore it, for configuration changes. `saveState()` returns a `Parcelable` which will form part of the state saved by the `ViewPager`, while `restoreState()` is handed back that `Parcelable` (or a copy).

The state of the *fragments* is handled by `FragmentManager`, no different than with any other fragments we might use in an activity. The mere fact that we happen to coordinate those fragments with a `PagerAdapter` does not change this. Hence, the "state" that we are dealing with in `saveState()` and `restoreState()` is solely the state of the `PagerAdapter` data model — in our case, the roster of pages.

To future-proof the implementation a bit, the state is represented as a `Bundle`, into which we can store other `Parcelable` objects. Since `Bundle` knows how to save an `ArrayList` of `Parcelable` objects, we can just call `putParcelableArrayList()` to save our `ArrayList` of `PageEntry` objects, restoring them in `restoreState()` via `getParcelableArrayList()`:

```
@Override  
public Parcelable saveState() {  
    Bundle state=new Bundle();  
  
    state.putParcelableArrayList(KEY_DESCRIPTOR, entries);  
  
    return(state);  
}
```

Content Manipulation and Position Management

Perhaps the trickiest method on `PagerAdapter` that we have to worry about is innocuously named `getItemPosition()`. We are given the `Object` “handle” for a page, and we need to return the position of that page.

However, that’s not really what is going on here.

`getItemPosition()` is used when we call `notifyDataSetChanged()` to indicate a structural change in our data model, such as an added or removed page. `ViewPager` is looking for `getItemPosition()` to tell us the *new* position of pages for this `notifyDataSetChanged()` call. So, as we manipulate our pages, we need to track what is going on with page positions, so `getItemPosition()` can return the correct data.

The actual value returned by `getItemPosition()` is either:

- The actual numerical position of the page, from 0 to `getCount() - 1`, if the page moved to another position (where we return the new position)
- `PagerAdapter.POSITION_UNCHANGED`, if the page has not moved
- `PagerAdapter.POSITION_NONE`, if the page no longer exists (e.g., was removed)

`ArrayPagerAdapter` simply holds a `HashMap` (`positionDelta`), mapping our `Fragment` “handle” to the page to an `Integer` representing any change to the position of that page made by methods like `add()`. When `getItemPosition()` is called, we return the value for that page out of the `HashMap`, or `POSITION_UNCHANGED` if the page does not appear in the `HashMap`, indicating that the page has not been affected:

```
@Override
public int getItemPosition(Object o) {
    Integer result=positionDelta.get(o);

    if (result == null) {
        return(PagerAdapter.POSITION_UNCHANGED);
    }

    return(result);
}
```

The `add()` method needs to add a new page to the data model, given the `PageDescriptor`. We `clear()` our `positionDelta` `HashMap` (as any previous changes

MORE FUN WITH PAGERS

should already have been picked up), `add()` a new `PageEntry` to our data model based on the supplied `PageDescriptor`, then call `notifyDataSetChanged()`:

```
public PageDescriptor getPageDescriptor(int position) {
    return(entries.get(position).getDescriptor());
}

public int getPositionForTag(String tag) {
    for (int i=0;i<entries.size();i++) {
        PageEntry entry=entries.get(i);
```

In this case, we did not need to add an entry to `positionDelta`, as `ViewPager` will use the natural position (based on where it appears in our data model) if we return `POSITION_UNCHANGED`.

The `insert()` method needs to do much the same thing, except rather than adding the new page to the end, we are adding it somewhere in the middle. This requires us to do everything we did in `add()`, plus add entries to the `positionDelta` map to indicate the new positions for every page that appears after the one being inserted:

```
        if (entry.getDescriptor().getFragmentTag().equals(tag)) {
            return(i);
        }
    }

    return(-1);
}

public void add(PageDescriptor desc) {
    validatePageDescriptor(desc);

    positionDelta.clear();
    entries.add(new PageEntry(desc));
    notifyDataSetChanged();
}
```

The `remove()` method needs to get rid of an existing page, given its position. Here, we are not given the “handle”, so we look it up via `getExistingFragment()`, then use that to put `POSITION_NONE` in the `positionDelta` map. We also update `positionDelta` to indicate the new positions for every page that appeared after the one being removed:

```
validatePageDescriptor(desc);
```

MORE FUN WITH PAGERS

```
positionDelta.clear();

for (int i=position; i < entries.size(); i++) {
    Fragment f=getExistingFragment(i);

    if (f != null) {
        positionDelta.put(f, i + 1);
    }
}

entries.add(position, new PageEntry(desc));
notifyDataSetChanged();
}

public void remove(int position) {
    positionDelta.clear();

    Fragment f=getExistingFragment(position);
```

Finally, a `move()` is simply treated as a `remove()` from the old position and an `insert()` of the same page into the new position:

```
if (f != null) {
    positionDelta.put(f, PagerAdapter.POSITION_NONE);
}

for (int i=position + 1; i < entries.size(); i++) {
    f=getExistingFragment(i);

    if (f != null) {
```

Miscellany

One headache with `FragmentPagerAdapter` and `FragmentStatePagerAdapter` is that they like to manage the fragments themselves, making it annoying for you to get at those fragments independently later on. Some developers have resorted to holding onto fragments in their own array, which works, but then you run into problems when it comes to garbage collection with `FragmentStatePagerAdapter`.

`ArrayPagerAdapter` provides two convenience methods to address this:

- `getExistingFragment()` simply returns the fragment for a given position, by finding the tag for that fragment from the `PageDescription`, then looking up the fragment by that tag. This way, if the fragment does not exist due to garbage collection, we can return `null`

MORE FUN WITH PAGERS

- `getCurrentFragment()` returns the `currPrimaryItem` value, indicating the page that we are presently on

```
    }  
}  
  
    entries.remove(position);  
    notifyDataSetChanged();  
}  
  
public void move(int oldPosition, int newPosition) {  
    if (oldPosition != newPosition) {
```

Both are set to return the generic type `T` that the developer uses when creating a subclass of `ArrayPagerAdapter`.

Focus Management and Accessibility

As developers, we are very used to creating apps that are designed to be navigated by touch, with users tapping on widgets and related windows to supply input.

However, not all Android devices have touchscreens, and not all Android users use touchscreens.

Internationalization (i18n) and localization (L10n) give you opportunities to expand your user base to audiences beyond your initial set, based on language. Similarly, you can expand your user base by offering support for non-touchscreen input and output. Long-term, the largest user base of these features may be those with televisions augmented by Android, whether via Android TV, OUYA consoles, or whatever. Short-term, the largest user base of these features may be those for whom touchscreens are rarely a great option, such as the blind. Supporting those with unusual requirements for input and output is called *accessibility* (a11y), and represents a powerful way for you to help your app distinguish itself from competitors.

In this chapter, we will first examine how to better handle focus management, and then segue into examining what else, beyond supporting keyboard-based input, can be done in the area of accessibility.

Prerequisites

Understanding this chapter requires that you have read the core chapters and are familiar with the concept of widgets having focus for user input.

Prepping for Testing

To test focus management, you will need an environment that supports “arrow key” navigation. Here, “arrow key” also includes things like D-pads or trackballs – basically, anything that navigates by key events instead of by touch events.

Examples include:

- The Android emulator, with the `Dpad support hardware` property set to `yes`
- Phones that have actual D-pads, trackballs, arrow keys, or the like
- Television-based Android environments, such as Android TV or the OUYA console
- Devices that have dedicated keyboard accessories, such as the keyboard “slice” available for the ASUS Transformer series of tablets
- A standard Android device accessed via a Bluetooth keyboard, gamepad, or similar sort of pointing device

Hence, even if the emulator will be insufficient for your needs, you should be able to set up a hardware test environment relatively inexpensively. Most modern Android devices support Bluetooth keyboards, and such keyboards frequently can be obtained at low relative cost.

For accessibility beyond merely focus control, you will certainly want to enable TalkBack, via the Accessibility area of the Settings app. This will cause Android to verbally announce what is on the screen, by means of its text-to-speech engine.

On Android 4.0 and higher devices, enabling Talkback will also optionally enable “Explore by Touch”. This allows users to tap on items (e.g., icons in a `GridView`) to have them read aloud via TalkBack, with a double-tap to actually perform what ordinarily would require a single-tap without “Explore by Touch”.

Controlling the Focus

Android tries its best to have intelligent focus management “out of the box”, without developer involvement. Many times, what it offers is sufficient for your needs. Other times, though, the decisions Android makes are inappropriate:

- Trying to navigate in a certain direction (e.g., right) moves focus to a widget that is not logically what should have the focus

- Focus has other side effects, like showing the soft keyboard on an EditText widget, that is not desirable

Hence, if you feel that you need to take more control over how focus management is handled, you have many means of doing so, covered in this section.

Establishing Focus

In order for a widget to get the focus, it has to be focusable.

You might think that the above sentence was just a chance for the author to be witty. It was... a bit. But there are actually two types of “focusable” when it comes to Android apps:

- Is it focusable when somebody is using a pointing device or the keyboard?
- Is it focusable in touch mode?

There are three major patterns for the default state of a widget:

1. Some are initially focusable in both cases (e.g., EditText)
2. Some are focusable in non-touch mode but are not focusable in touch mode (e.g., Button)
3. Some are not focusable in either mode (e.g., TextView)

So, when a Button is not focusable in touch mode, that means that while the button will take the focus when the user navigates to it (e.g., via keys), the button will *not* take the focus when the user simply taps on it.

You can control the focus semantics of a given widget in four ways:

- You can use `android:focusable` and `android:focusableInTouchMode` in a layout
- You can use `setFocusable()` and `setFocusableInTouchMode()` in Java

We will see examples of these shortly.

Requesting (or Abandoning) Focus

By default, the focus will be granted to the first focusable widget in the activity, starting from the upper left. Often times, this is a fine solution.

If you want to have some other widget get the focus (assuming that the widget is focusable, per the section above), you have two choices:

1. Call `requestFocus()` on the widget in question
2. You can give the widget's layout element a child element, named `<requestFocus />`, to stipulate that this widget should be the one to get the focus

Note that this is a child element, not an attribute, as you might ordinarily expect.

For example, let's look at the [Focus/Sampler](#) sample project, which we will use to illustrate various focus-related topics.

Our main activity, creatively named `MainActivity`, loads a layout named `request_focus.xml`, and demonstrates the `<requestFocus />` element:

```
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent">

    <Button
        android:id="@+id/button1"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:text="@string/a_button"/>

    <EditText
        android:id="@+id/editText1"
        android:layout_width="0dp"
        android:layout_height="wrap_content"
        android:layout_weight="1"
        android:contentDescription="@string/first_field"
        android:hint="@string/str_1st_field"
        android:inputType="text"/>

    <EditText
        android:id="@+id/editText2"
        android:layout_width="0dp"
        android:layout_height="wrap_content"
        android:layout_weight="1"
        android:contentDescription="@string/second_field"
        android:hint="@string/str_2nd_field"
        android:inputType="text">

    <requestFocus/>
```

```
</EditText>
</LinearLayout>
```

(from [Focus/Sampler/app/src/main/res/layout/request_focus.xml](#))

Here, we have three widgets in a horizontal `LinearLayout`: a `Button`, and two `EditText` widgets. The second `EditText` widget has the `<requestFocus />` child element, and so it gets the focus when we display our launcher activity:

Figure 664: Focus Sampler, Showing Requested Focus

If we had skipped the `<requestFocus />` element, the focus would have wound up on the first `EditText`... assuming that we are working in touch mode. If the activity had been launched via the pointing device or keyboard, then the `Button` would have the focus, because the `Button` is focusable in non-touch mode by default.

Calling `requestFocus()` from Java code gets a bit trickier. There are a few flavors of the `requestFocus()` method on `View`, of which two will be the most popular:

- An ordinary zero-argument `requestFocus()`
- A one-argument `requestFocus()`, with the argument being the direction in which the focus should theoretically be coming from

FOCUS MANAGEMENT AND ACCESSIBILITY

You might look at the description of the second flavor and decide that the zero-argument `requestFocus()` looks a lot easier. And, sometimes it will work. However, sometimes it will not, as is the case with our second activity, `RequestFocusActivity`.

In this activity, our layout (`focusable_button`) is a bit different:

```
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent">

    <EditText
        android:id="@+id/editText1"
        android:layout_width="0dp"
        android:layout_height="wrap_content"
        android:layout_weight="1"
        android:contentDescription="@string/first_field"
        android:hint="@string/str_1st_field"
        android:inputType="text"/>

    <EditText
        android:id="@+id/editText2"
        android:layout_width="0dp"
        android:layout_height="wrap_content"
        android:layout_weight="1"
        android:contentDescription="@string/second_field"
        android:hint="@string/str_2nd_field"
        android:inputType="text">
    </EditText>

    <Button
        android:id="@+id/button1"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:focusableInTouchMode="true"
        android:text="@string/a_button"/>

</LinearLayout>
```

(from [Focus/Sampler/app/src/main/res/layout/focusable_button.xml](#))

Here, we put the `Button` last instead of first. We have no `<requestFocus />` element anywhere, which would put the default focus on the first `EditText` widget. And, our `Button` has `android:focusableInTouchMode="true"`, so it will be focusable regardless of whether we are in touch mode or not.

FOCUS MANAGEMENT AND ACCESSIBILITY

In `onCreate()` of our activity, we use the one-parameter version of `requestFocus()` to give the Button the focus:

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.focusable_button);
    initActionBar();

    button=findViewById(R.id.button1);
    button.requestFocus(View.FOCUS_RIGHT);
    button.setOnClickListener(this);
}
```

(from [Focus/Sampler/app/src/main/java/com/commonsware/android/focus/RequestFocusActivity.java](#))

If there were only the one `EditText` before the Button, the zero-argument `requestFocus()` works. However, with a widget between the default focus and our Button, the zero-argument `requestFocus()` does not work, but using `requestFocus(View.FOCUS_RIGHT)` does. This tells Android that we want the focus, and it should be as if the user is moving to the right from where the focus currently lies.

All of our activities inherit from a `BaseActivity` that manages our action bar, with an overflow menu to get to the samples and the app icon to get to the original activity.

So, if you run the app and choose “Request Focus” from the overflow menu, you will see:

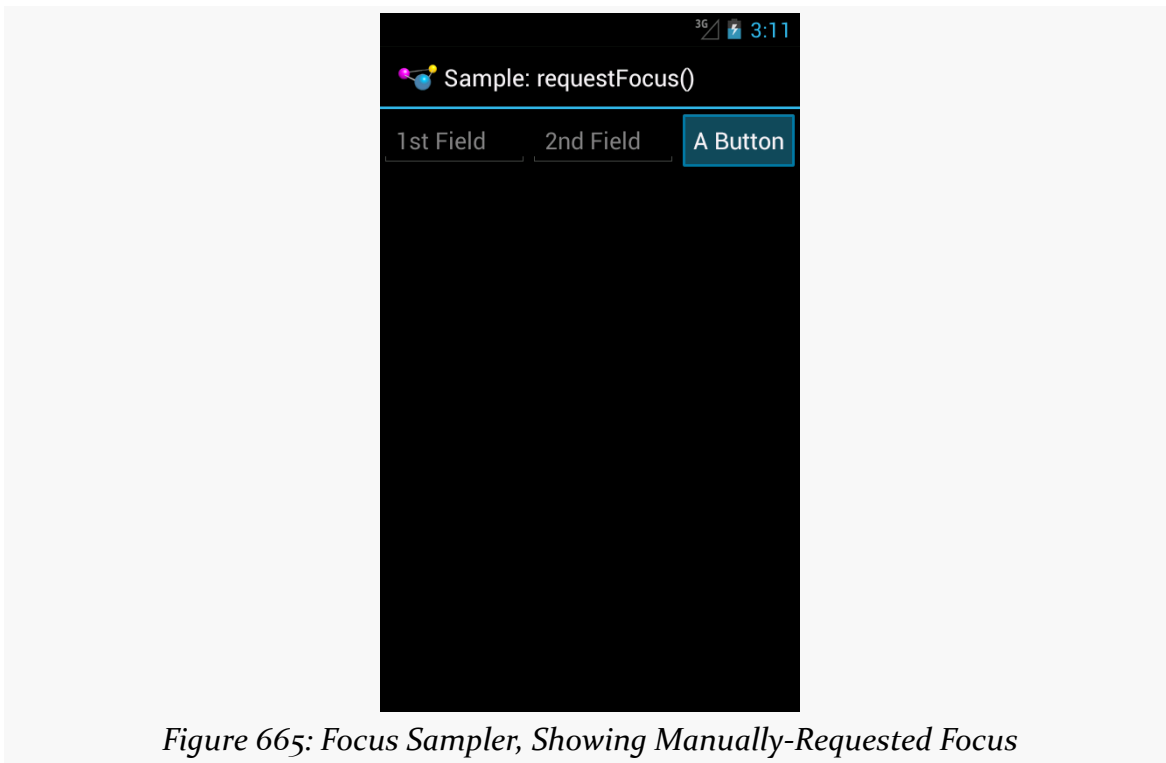

Figure 665: Focus Sampler, Showing Manually-Requested Focus

We also wire up the Button to the activity for click events, and in `onClick()`, we call `clearFocus()` to abandon the focus:

```
@Override
public void onClick(View v) {
    button.clearFocus();
}
```

(from [Focus/Sampler/app/src/main/java/com/commonsware/android/focus/RequestFocusActivity.java](#))

What `clearFocus()` will do is return to the original default focus for this activity, in our case the first `EditText`:

Figure 666: Focus Sampler, After Clearing the Focus

Focus Ordering

Beyond manually placing the focus on a widget (or manually clearing that focus), you can also override the focus order that Android determines automatically. While Android’s decisions usually are OK, they may not be optimal.

A widget can use `android:nextFocus...` attributes in the layout file to indicate the widget that should get control on a focus change in the direction indicated by the ... part. So, `android:nextFocusDown`, applied to Widget A, indicates which widget should receive the focus if, when the focus is on Widget A, the user “moves down” (e.g., presses a DOWN key, presses the down direction on a D-pad). The same logic holds true for the other three directions (`android:nextFocusLeft`, `android:nextFocusRight`, and `android:nextFocusUp`).

For example, the `res/layout/table.xml` resource in the FocusSampler project is based on the `TableLayout` sample from early in this book, with a bit more focus control:

```
<?xml version="1.0" encoding="utf-8"?>
<TableLayout xmlns:android="http://schemas.android.com/apk/res/android"
```

```
android:layout_width="match_parent"
android:layout_height="match_parent"
android:stretchColumns="1">

<TableRow>

    <TextView android:text="@string/url"/>

    <EditText
        android:id="@+id/entry"
        android:layout_span="3"
        android:inputType="text"
        android:nextFocusRight="@+id/ok"/>
</TableRow>

<TableRow>

    <Button
        android:id="@+id/cancel"
        android:layout_column="2"
        android:text="@string/cancel"/>

    <Button
        android:id="@+id/ok"
        android:text="@string/ok"/>
</TableRow>

</TableLayout>
```

(from [Focus/Sampler/app/src/main/res/layout/table.xml](https://github.com/android/samples/blob/master/02-ViewPagerTutorial/app/src/main/res/layout/table.xml))

In the original `TableLayout` sample, by default, pressing either `RIGHT` or `DOWN` while the `EditText` has the focus will move the focus to the “Cancel” button. This certainly works. However, it does mean that there is no single-key means of moving from the `EditText` to the “OK” button, and it would be nice to offer that, so those using the pointing device or keyboard can quickly move to either button.

This is a matter of overriding the default focus-change behavior of the `EditText` widget. In our case, we use `android:nextFocusRight="@+id/ok"` to indicate that the “OK” button should get the focus if the user presses `RIGHT` from the `EditText`. This gives `RIGHT` and `DOWN` different behavior, to reach both buttons.

Scrolling and Focusing Do Not Mix

Let's suppose that you have a UI design with a fixed bar of widgets at the top (e.g., action bar), a `ListView` dominating the activity, and a panel of widgets at the bottom (e.g., a `Toolbar`). This is a common UI pattern on iOS, though it is relatively uncommon on Android nowadays. You used to see it with the so-called “split action bar”, which is now officially deprecated as a pattern:

Figure 667: Split Action Bar

However, this UI pattern does not work well for those using pointing devices or keyboards for navigation. In order to get to the bottom panel of widgets, they will have to scroll through the entire list first, because scrolling trumps focus changes. So while this is easy to navigate via a touchscreen, it is a major problem to navigate for those not using a touchscreen.

Similarly, if the user has scrolled down the list, and now wishes to get to the action bar at the top, the user would have to scroll all the way to the top of the list first.

Workarounds include:

- Overriding focus control such that left and right navigation from the list moves you to the action bar or bottom Toolbar (e.g., left moves you to the action bar, right moves you to the Toolbar)
- In a television setup, having the “action bar” be vertical down the left, and the tools be vertical down the right, so you automatically get the left/right navigation to move between these “zones”
- Eliminating the Toolbar entirely, moving those items instead to the action bar, or perhaps an [action mode](#) (a.k.a., contextual action bar) if the items are only relevant if the user checks one or more items in the list
- Offer a hotkey, separate from navigation, that repositions the focus (e.g.,  to jump to the action bar), if you believe that users will read your documentation to discover this key combination

Accessibility and Focus

People suffering from impaired vision, including the blind, have had to rely heavily on proper keyboard navigation for their use of Android apps, at least prior to Android 4.0 and “Explore by Touch”. These users need focus to be sensible, so that they can find their way through your app, with TalkBack supplying prompts for what has the focus. Having widgets that are unreachable in practice will eliminate features from your app for this audience, simply because they cannot get to them.

“Explore by Touch” provides accessibility assistance without reliance upon proper focus. However:

- “Explore by Touch” is new to Android 4.0, and a few visually-impaired users will be using older devices
- “Explore by Touch” is less reliable than keyboard-based navigation, insofar as users have to remember specific screen locations (and get to them without seeing those locations), rather than simply memorizing certain key combinations
- “Explore by Touch”, by requiring additional taps (e.g., double-tap to tap a Button), may cause some challenges when the UI itself requires additional taps (e.g., a double-tap on a widget to perform an action — is this now a triple-tap in “Explore by Touch” mode?)
- “Explore by Touch” is mostly for the visually impaired, and does not help others that might benefit from key-based navigation (e.g., people with limited motor control)

So, even though “Explore by Touch” will help people use apps that cannot be navigated purely through key events, the better you can support keyboards, the better off your users will be.

Accessibility Beyond Focus

While getting focus management correct goes a long way towards making your application easier to use, it is not the only thing to consider for making your application truly accessible by all possible users. This section covers a number of other things that you should consider as part of your accessibility initiatives.

Content Descriptions

For TalkBack to work, it needs to have something useful to read aloud to the user. By default, for most widgets, all it can say is the type of widget that has the focus (e.g., “a checkbox”). That does not help the TalkBack-reliant user very much.

Please consider adding `android:contentDescription` attributes to most of your widgets, pointing to a string resource that briefly describes the widget (e.g., “the Enabled checkbox”). This will be used in place of the basic type of widget by TalkBack.

Classes that inherit from `TextView` will use the text caption of the widget by default, so your `Button` widgets may not need `android:contentDescription` if their captions will make sense to TalkBack users.

However, with an `EditText`, since the text will be what the user types in, the text is not indicative of the widget itself. Android will first use your `android:hint` value, if available, falling back to `android:contentDescription` if `android:hint` is not supplied.

Also, bear in mind that if the widget changes purpose, you need to change your `android:contentDescription` to match. For example, suppose you have a media player app with an `ImageButton` that you toggle between “play” and “pause” modes by changing its image. When you change the image, you also need to change the `android:contentDescription` as well, lest sighted users think the button will now “pause” while blind users think that the button will now “play”.

Labels

Sometimes, we have `TextView` widgets that serve as on-screen labels for some adjacent other widget, such as an `EditText`. In those cases, you can associate the two by using `android:labelFor` on the `TextView`, supplying the ID of the widget for which the `TextView` is a label. This will help accessibility tools properly announce the widgets, as otherwise those tools do not know that these widgets are related.

Custom Widgets and Accessibility Events

The engine behind TalkBack is an accessibility service. Android ships with some, like TalkBack, and third parties can create other such services.

Stock Android widgets generate relevant accessibility events to feed data into these accessibility services. That is how `android:contentDescription` gets used, for example — on a focus change, stock Android widgets will announce the widget that just received the focus.

If you are creating custom widgets, you may need to raise your own accessibility events. This is particularly true for custom widgets that draw to the Canvas and process raw touch events (rather than custom widgets that merely aggregate existing widgets).

The Android developer documentation provides [instructions for when and how to supply these sorts of events](#).

Announcing Events

Sometimes, your app will change something about its visual state in ways that do not get picked up very well by any traditional accessibility events. For example, you might use `GestureDetector` to handle some defined library of gestures and change state in your app. Those state changes may have visual impacts, but `GestureDetector` will not know what those are and therefore cannot supply any sort of accessibility event about them.

To help with this, API Level 16 added `announceForAccessibility()` as a method on `View`. Just pass it a string and that will be sent out as an “announcement” style of `AccessibilityEvent`. Your code leveraging `GestureDetector`, for example, could use this to explain the results of having applied the gesture.

Font Selection and Size

For users with limited vision, being able to change the font size is a big benefit. Android 4.0 finally allows this, via the Settings app, so users can choose between small, normal, large, and huge font sizes. Any place where text is rendered and is measured in sp will adapt.

The key, of course, is the sp part.

sp is perhaps the most confusing of the available dimension units in Android. px is obvious, and dp (or dip) is understandable once you recognize the impacts of screen density. Similarly, in, mm, and pt are fairly simple, at least once you remember that pt is 1/72nd of an inch.

If the user has the font scale set to “normal”, sp equates to dp, so a dimension of 30sp and 30dp will be the same size. However, values in dp do not change based on font scale; values in sp will increase or decrease in physical size based upon the user’s changes to the font scale.

We can see how this works in the [Accessibility/FontScale](#) sample project.

In our layout (res/layout/activity_main.xml), we have six pieces of text: two each (regular and bold) measured at 30px, 30dp, and 30sp:

```
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
  xmlns:tools="http://schemas.android.com/tools"
  android:id="@+id/LinearLayout1"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  android:orientation="vertical">

  <TextView
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:layout_marginTop="10dp"
    android:text="@string/normal_30px"
    android:textSize="30px"
    tools:context=".MainActivity"/>

  <TextView
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:text="@string/bold_30px"
    android:textSize="30px"
```

FOCUS MANAGEMENT AND ACCESSIBILITY

```
        android:textStyle="bold"
        tools:context=".MainActivity" />

<TextView
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:layout_marginTop="10dp"
    android:text="@string/normal_30dp"
    android:textSize="30dp"
    tools:context=".MainActivity" />

<TextView
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:text="@string/bold_30dp"
    android:textSize="30dp"
    android:textStyle="bold"
    tools:context=".MainActivity" />

<TextView
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:layout_marginTop="10dp"
    android:text="@string/normal_30sp"
    android:textSize="30sp"
    tools:context=".MainActivity" />

<TextView
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:text="@string/bold_30sp"
    android:textSize="30sp"
    android:textStyle="bold"
    tools:context=".MainActivity" />

</LinearLayout>
```

(from [Accessibility/FontScale/app/src/main/res/layout/activity_main.xml](#))

You will be able to see the differences between 30px and 30dp on any Android OS release, simply by running the app on devices with different densities. To see the changes between 30dp and 30sp, you will need to run the app on an Android 4.0+ device or emulator and change the font scale from the Settings app (typically in the Display section).

Here is what the text looks like with a normal font scale:

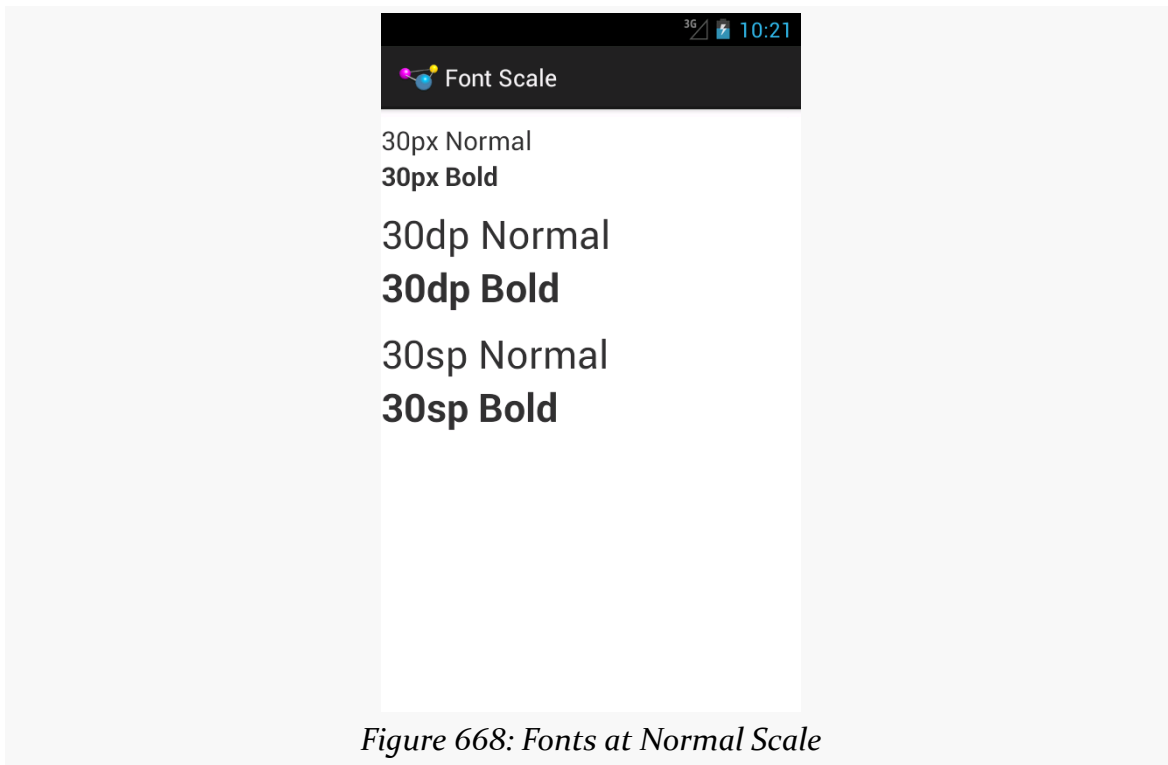

Figure 668: Fonts at Normal Scale

As you can see, 30dp and 30sp are equivalent.

If we raise the font scale to “large”, the 30sp text grows to match:

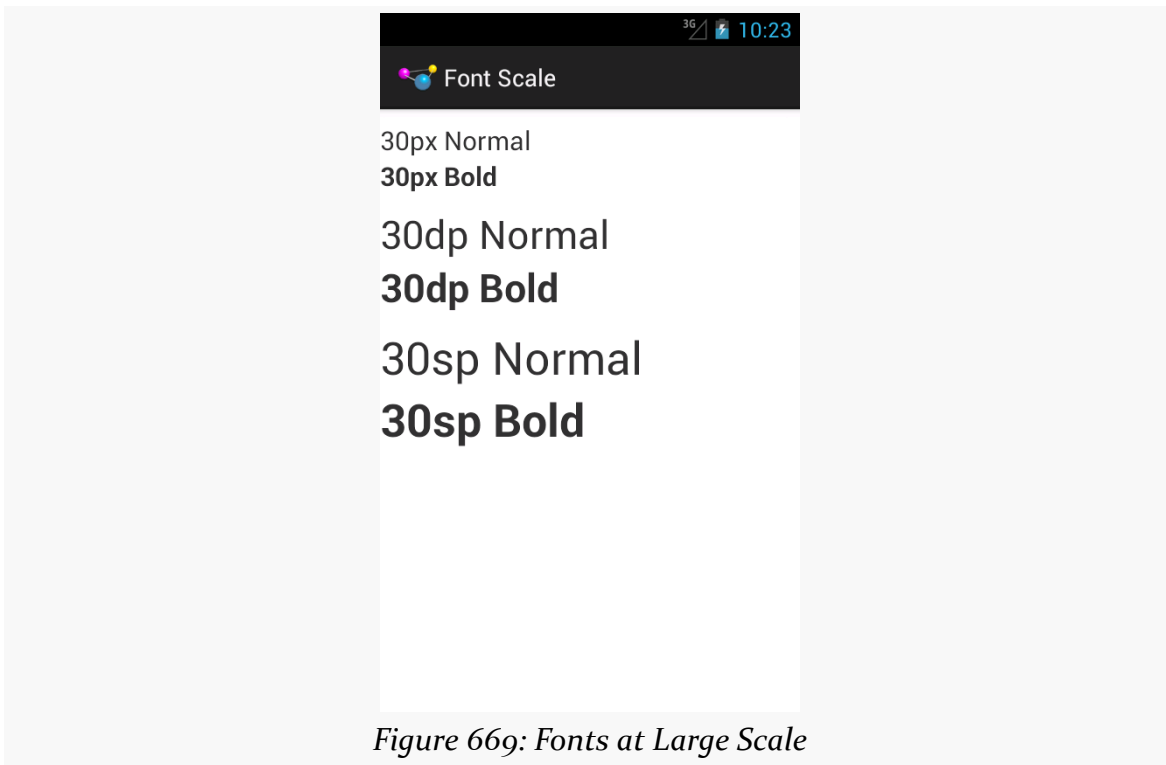

Figure 669: Fonts at Large Scale

Moving to “huge” scale increases the 30sp text size further:

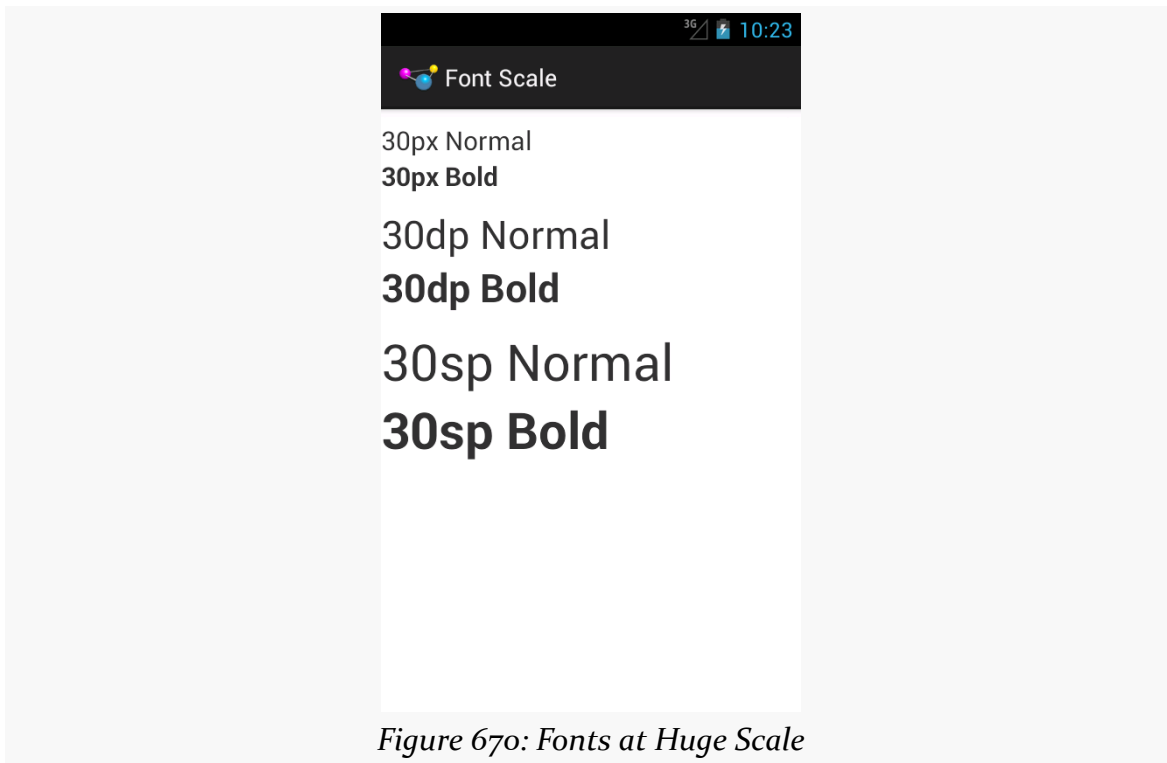

Figure 670: Fonts at Huge Scale

In the other direction, some users may elect to drop their font size to “small”, with a corresponding impact on the 30sp text:

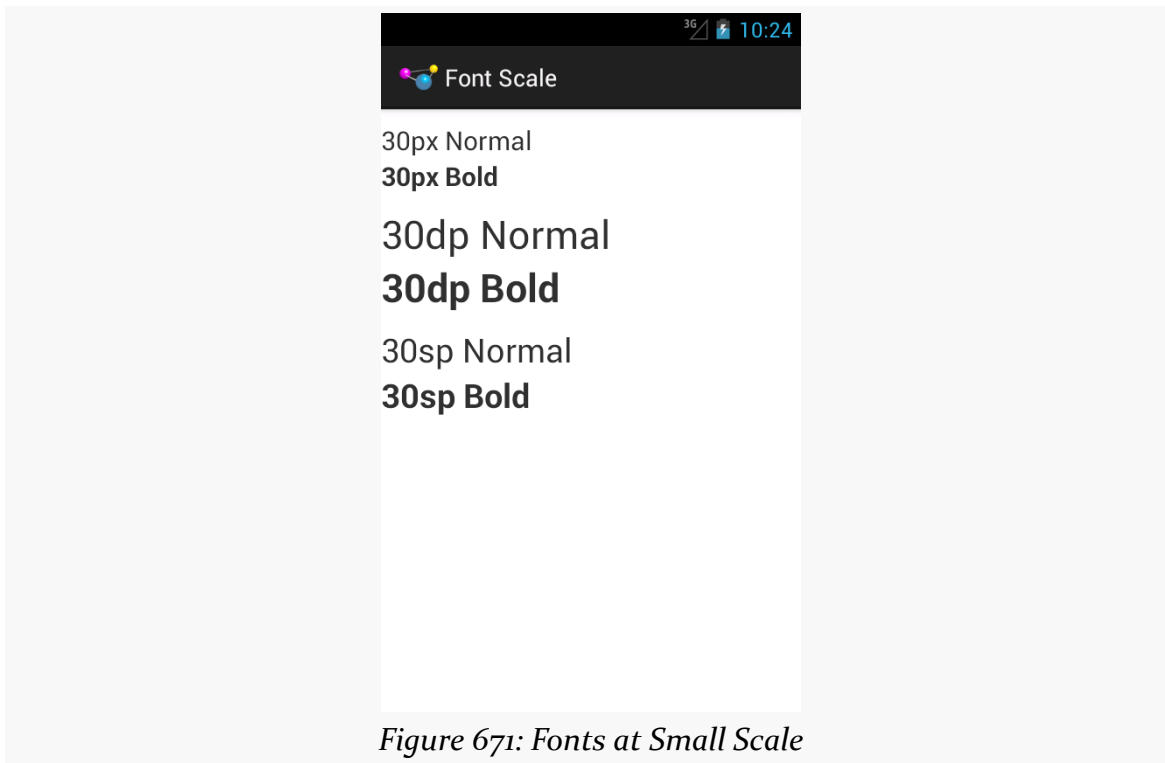

Figure 671: Fonts at Small Scale

As a developer, your initial reaction may be to run away from sp, because you do not control it. However, just as Web developers should deal with changing font scale in Web browsers, Android developers should deal with changing font scale in Android apps. Remember: the user is changing the font scale because the *user* feels that the revised scale is easier for them to use. Blocking such changes in your app, by avoiding sp, will not be met with love and adoration from your user base.

Also, bear in mind that changes to the font scale represent a configuration change. If your app is in memory at the time the user goes into Settings and changes the scale, if the user returns to your app, each activity that comes to the foreground will undergo the configuration change, just as if the user had rotated the screen or put the device into a car dock or something.

Widget Size

Users with ordinary sight already have trouble with tiny widgets, as they are difficult to tap upon.

Users trying to use the Explore by Touch facility added in Android 4.1 have it worse, as they cannot even see (or see well) the tiny target you are expecting them to tap

upon. They need to be able to reliably find your widget based on its relative position on the screen, and their ability to do so will be tied, in part, on widget size.

The [Android design guidelines recommend](#) 7-10mm per side minimum sizes for tappable widgets. In particular, they recommend 48dp per side, which results in a size of about 9mm per side.

You also need to consider how closely packed your widgets are. The closer the tap targets lie, the more likely it is that all users — whether using Explore by Touch or not — will accidentally tap on the wrong thing. Google recommends 8dp or more of margin between widgets. Also note that the key is *margins*, as while increasing padding might visually separate the widgets, the padding is included as part of the widget from the standpoint of touch events. While padding may help users with ordinary sight, margins provide similar help while also being of better benefit to those using Explore by Touch.

Gestures and Taps

If you employ gestures, be careful when employing the same gesture in different spots for different roles, particularly within the same activity.

For example, you might use a horizontal swipe to the right to switch pages in a `ViewPager` in some places and remove items from a `ListView` in others. While there may be visual cues to help explain this to users with ordinary sight, it may be far less obvious what is going on for TalkBack users. This is even more true if you are somehow combining these things (e.g., the `ListView` in question is in a page of the `ViewPager`).

Also, be a bit careful as you “go outside the box” for tap events. You might decide that a double-tap, or a two-finger tap, has special meaning on some widgets. Make sure that this still works when users use Explore by Touch, considering that the first tap will be “consumed” by Explore by Touch to announce the widget being tapped upon.

Enhanced Keyboard Support

All else being equal, users seeking accessibility assistance will tend to use keyboards when available. For users with limited (or no) sight, tactile keyboards are simply easier to use than touchscreens. For users with limited motor control, external devices that interface as keyboards may allow them to use devices that otherwise they could not.

Of course, plenty of users will use keyboards outside of accessibility as well. For example, devices like the ASUS Transformer series form perfectly good “netbook”-style devices when paired with their keyboards.

Hence, consider adding hotkey support, to assist in the navigation of your app. Some hotkeys may be automatically handled (e.g., `Ctrl-C` for copy in an `EditText`). However, in other cases you may wish to add those yourself (e.g., `Ctrl-C` for “copy” with respect to a checklist and its selected rows, in addition to a “copy” action mode item).

API Level 11 adds `KeyEvent` support for methods like `isCtrlPressed()` to detect meta keys used in combination with regular keys.

Audio and Haptics

Of course, another way to make your app more accessible is to provide alternative modes of input and output, beyond the visual.

Audio is popular in this regard:

- Using tones or clicks to reinforce input choices
- Integrating your own text-to-speech to augment TalkBack
- Integrating speech recognition for simple commands

However, bear in mind that deaf users will be unable to hear your audio. You are better served using both auditory and visual output, not just one or the other.

In some cases, haptics can be helpful for input feedback, by using the `Vibrator` system service to power the vibration motor. While most users will be able to feel vibrations, the limitation here is whether the device is capable of vibrating:

- Some tablets lack a vibration motor
- Television-based Android environment may or may not have some sort of vibration output (e.g., remote controls probably will not, but game controllers might)
- Devices not held in one’s hand, such as those in a dock, will make haptics less noticeable

So, audio and vibration can help augment visual input and output, though they should not be considered complete replacements except in rare occurrences.

Color and Color Blindness

[Approximately 8% of men \(and 0.5% of women\)](#) in the world are colorblind, meaning that they cannot distinguish certain close colors:

...It's not that colorblind people (in most cases) are incapable or perceiving "green," instead they merely distinguish fewer shades of green than you do. So where you see three similar shades of green, a colorblind user might only see one shade of green.

(from ["Tips for Designing for Colorblind Users"](#))

Hence, relying solely on colors to distinguish different items, particularly when required for user input, is not a wise move.

Make sure that there is something more to distinguish two pieces of your UI than purely a shift in color, such as:

- Labels or icons
- Textures (e.g., solid vs. striped)
- Borders (e.g., drop shadow)

Accessibility Beyond Impairment

Accessibility is often tied to impaired users: ones with limited (or no) sight, ones with limited (or no) hearing, ones with limited motor control, etc.

In reality, accessibility is for *situations* where users may have limitations. For example, a user who might not normally think of himself as "impaired" has limited sight, hearing, and motor control when those facilities are already in use, such as while driving.

Hence, offering features that help with accessibility can benefit *all* your users, not just ones you think of as "impaired". For example:

- Offer a UI mode with an eye towards use in low-visibility situations that can either be manually invoked (e.g., via a preference) or automatically invoked (e.g., via a car dock)
- Offer voice input (commands) and output (text-to-speech) — iOS's Siri is not just for the blind, after all

FOCUS MANAGEMENT AND ACCESSIBILITY

- Offer hotkeys, not only to help those requiring a keyboard as their primary mode of input (e.g., blind users minimizing touchscreen use), but to help those who opt into using it for input (e.g., using a keyboard with an Android tablet in lieu of a traditional notebook or netbook)

Miscellaneous UI Tricks

While well-written GUI frameworks are better organized than [XKCD's take on home organization](#), there are always a handful of tidbits that do, indeed, get categorized as “miscellaneous”.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book. Having an appreciation for XKCD is welcome, but optional.

Full-Screen and Lights-Out Modes

Full-screen mode, in Android parlance, means removing any system-supplied “bars” from the screen: title bar, action bar, status bar, system bar, navigation bar, etc. You might use this for games, video players, digital book readers, or other places where the time spent in an activity is great enough to warrant removing some of the normal accouterments to free up space for whatever the activity itself is doing.

Lights-out mode, in Android parlance, is where you take the system bar or navigation bar and dim the widgets inside of them, such that the bar is still usable, but is less visually distracting. This is a new concept added in Android 3.0 and has no direct analogue in Android 1.x or 2.x.

Android 1.x/2.x

To have an activity be in full-screen mode, you have two choices:

MISCELLANEOUS UI TRICKS

1. Having the activity use a theme of `Theme.NoTitleBar.Fullscreen` (or some custom theme that inherits from `Theme.NoTitleBar.Fullscreen`)
2. Execute the following statements in `onCreate()` of your activity *before* calling `setContentView()`:

```
requestWindowFeature(Window.FEATURE_NO_TITLE);
getWindow().setFlags(WindowManager.LayoutParams.FLAG_FULLSCREEN,
    WindowManager.LayoutParams.FLAG_FULLSCREEN);
```

The first statement removes the title bar or action bar. The second statement indicates that you want the activity to run in full-screen mode, hiding the status bar.

Android 4.0+

Things got significantly more messy once we started adding in the system bar (and, later, the navigation bar as the replacement for the system bar). Since these bars provide the user access to HOME, BACK, etc., it is usually important for them to be available. Android's behavior, therefore, varies in how you ask for something to happen and what then happens, based upon whether the device is a phone or a tablet.

The [Activities/FullScreen](#) sample project tries to enumerate some of the possibilities. On an Android 4.0 device, we have three `RadioButtons`:

```
<RelativeLayout xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:tools="http://schemas.android.com/tools"
    android:layout_width="match_parent"
    android:layout_height="match_parent">

    <RadioGroup
        android:id="@+id/screenStyle"
        android:layout_width="match_parent"
        android:layout_height="wrap_content">

        <RadioButton
            android:id="@+id/normal"
            android:layout_width="wrap_content"
            android:layout_height="wrap_content"
            android:checked="true"
            android:text="@string/display_normal"/>

        <RadioButton
            android:id="@+id/lowProfile"
            android:layout_width="wrap_content"
```

MISCELLANEOUS UI TRICKS

```
android:layout_height="wrap_content"
android:text="@string/display_low_profile"/>

<RadioButton
    android:id="@+id/hideNav"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:text="@string/display_hide_navigation"/>
</RadioButton>

<Button
    android:id="@+id/button"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:layout_alignParentBottom="true"
    android:text="@string/something_at_the_bottom"/>

</RelativeLayout>
```

(from [Activities/FullScreen/app/src/main/res/layout/main.xml](#))

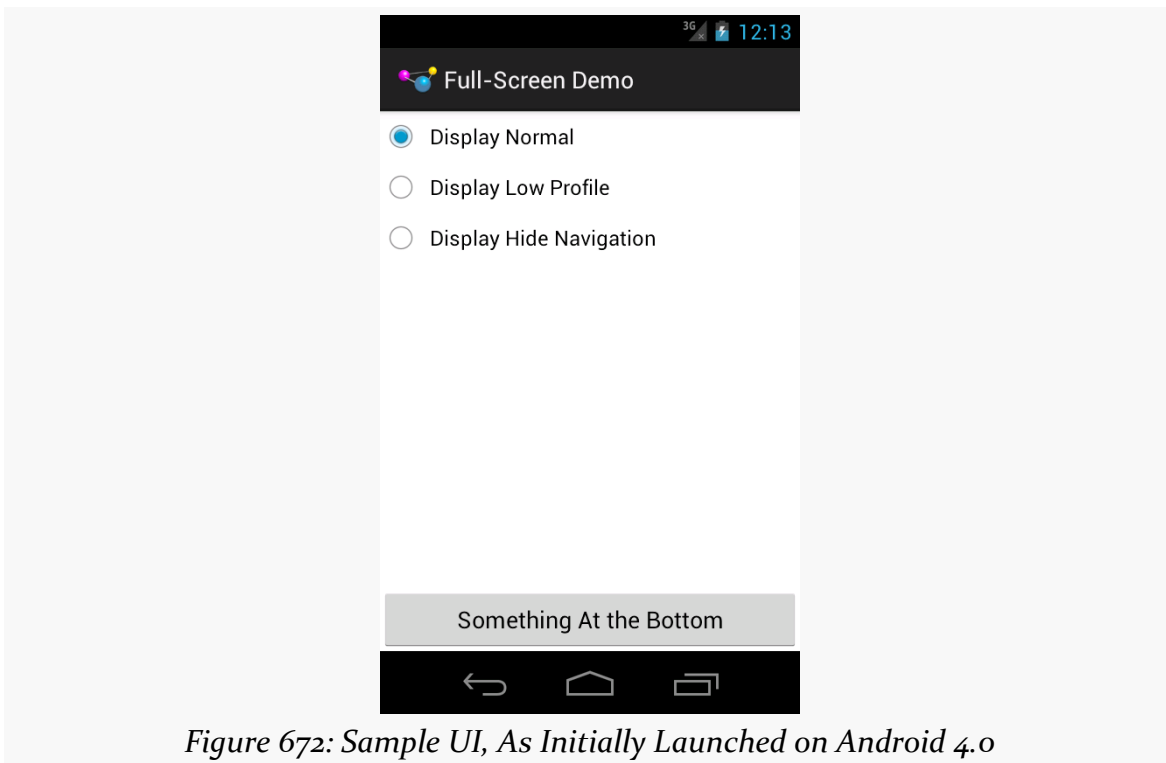

Figure 672: Sample UI, As Initially Launched on Android 4.0

...while on Android 4.1 or higher, we have another two possibilities:

MISCELLANEOUS UI TRICKS

```
<RelativeLayout xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:tools="http://schemas.android.com/tools"
    android:layout_width="match_parent"
    android:layout_height="match_parent">

    <RadioGroup
        android:id="@+id/screenStyle"
        android:layout_width="match_parent"
        android:layout_height="wrap_content">

        <RadioButton
            android:id="@+id/normal"
            android:layout_width="wrap_content"
            android:layout_height="wrap_content"
            android:checked="true"
            android:text="@string/display_normal"/>

        <RadioButton
            android:id="@+id/lowProfile"
            android:layout_width="wrap_content"
            android:layout_height="wrap_content"
            android:text="@string/display_low_profile"/>

        <RadioButton
            android:id="@+id/hideNav"
            android:layout_width="wrap_content"
            android:layout_height="wrap_content"
            android:text="@string/display_hide_navigation"/>

        <RadioButton
            android:id="@+id/hideStatusBar"
            android:layout_width="wrap_content"
            android:layout_height="wrap_content"
            android:text="@string/hide_status_bar"/>

        <RadioButton
            android:id="@+id/fullScreen"
            android:layout_width="wrap_content"
            android:layout_height="wrap_content"
            android:text="@string/display_full_screen"/>
    </RadioGroup>

    <Button
        android:id="@+id/button"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:layout_alignParentBottom="true"
        android:text="@string/something_at_the_bottom"/>
</RelativeLayout>
```

MISCELLANEOUS UI TRICKS

```
</RelativeLayout>
```

(from [Activities/FullScreen/app/src/main/res/layout-v16/main.xml](#))

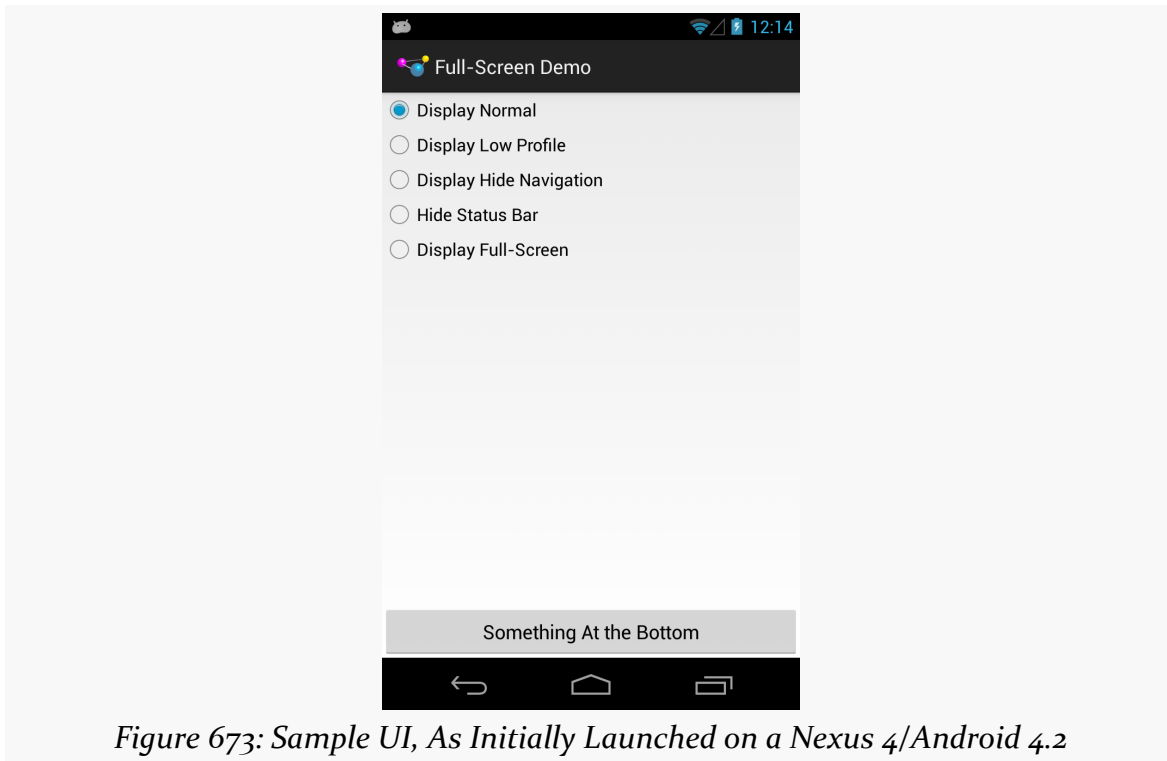

Figure 673: Sample UI, As Initially Launched on a Nexus 4/Android 4.2

Controlling the full-screen and lights-out modes is managed via a call to `setSystemUiVisibility()`, a method on `View`. You pass in a value made up of an OR'd (`|`) set of flags indicating what you want the visibility to be, with the default being normal operation. Hence, in the screenshot above, you see a Nexus 4 in normal mode. Here is the same UI on a Nexus 10 in normal mode:

MISCELLANEOUS UI TRICKS

Lights-out, or low-profile mode, is achieved by calling `setSystemUiVisibility()` with the `View.SYSTEM_UI_FLAG_LOW_PROFILE` flag. This will dim the navigation or system bar, so the bar is there and the buttons are still active, but that they are less visually intrusive:

MISCELLANEOUS UI TRICKS

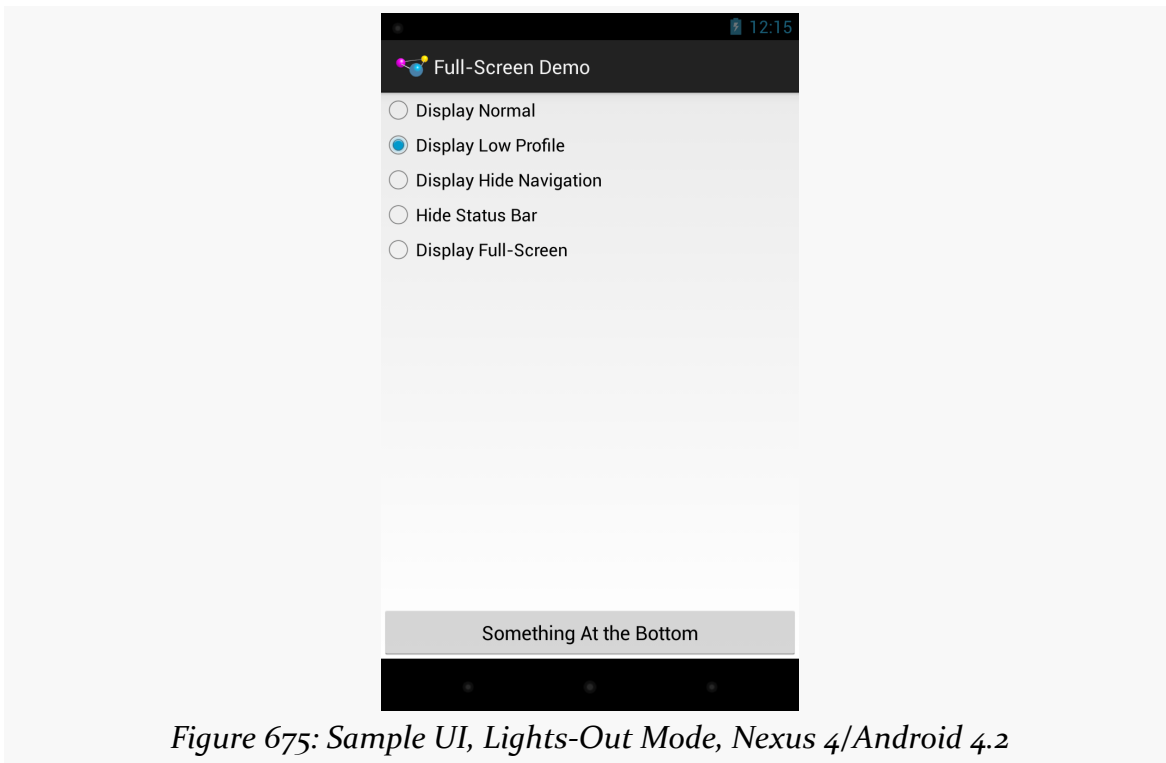

Figure 675: Sample UI, Lights-Out Mode, Nexus 4/Android 4.2

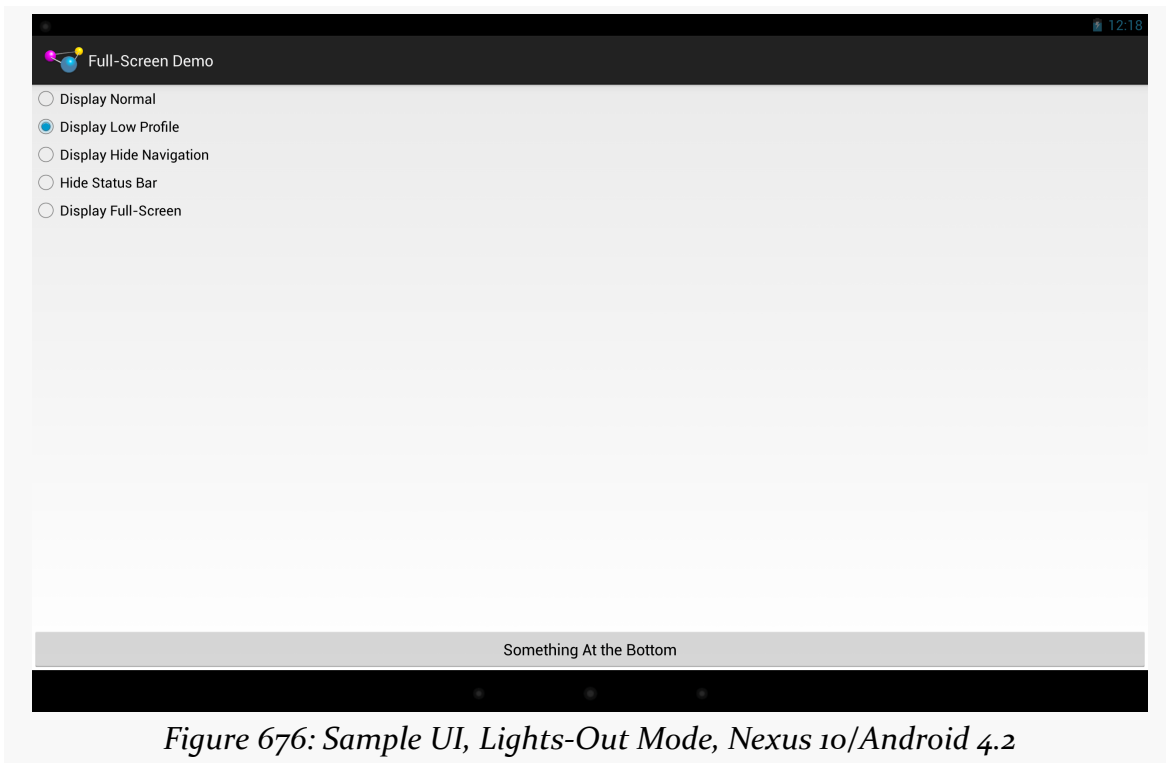

Figure 676: Sample UI, Lights-Out Mode, Nexus 10/Android 4.2

MISCELLANEOUS UI TRICKS

You can temporarily hide the navigation bar (or system bar) by passing `View.SYSTEM_UI_FLAG_HIDE_NAVIGATION` to `setSystemUiVisibility()`. The bar will disappear, until the user touches the UI, in which case the bar reappears:

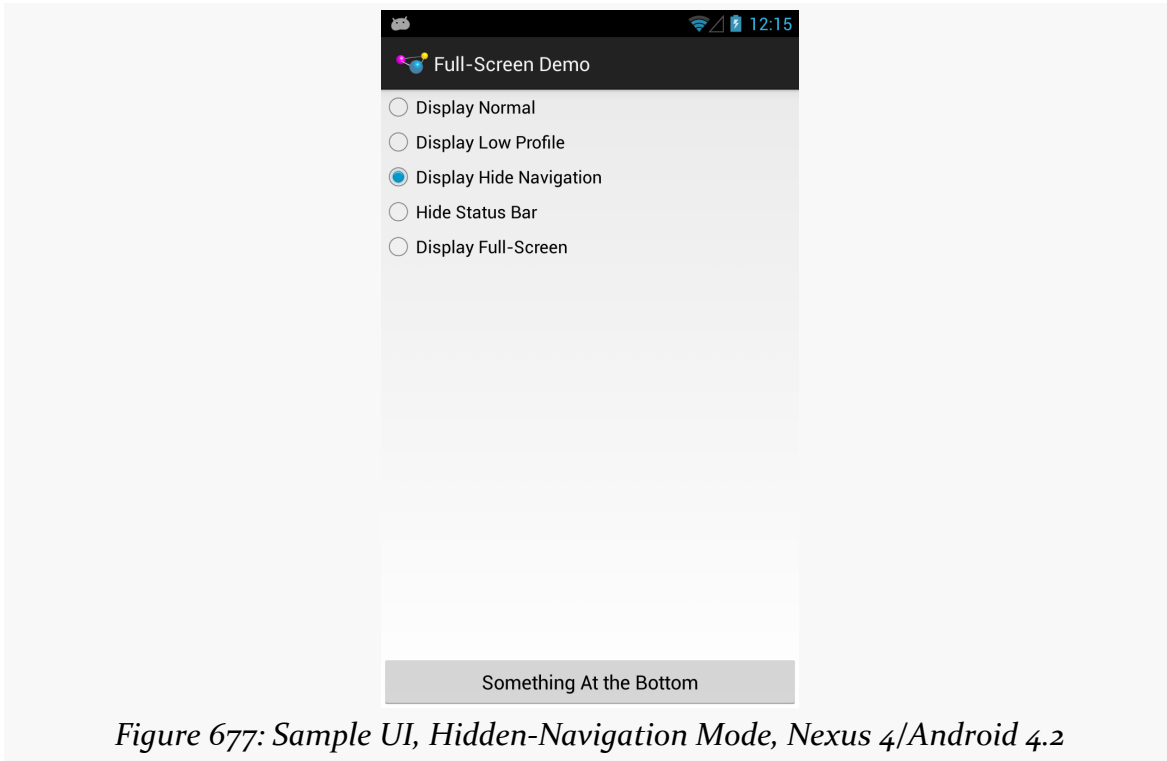

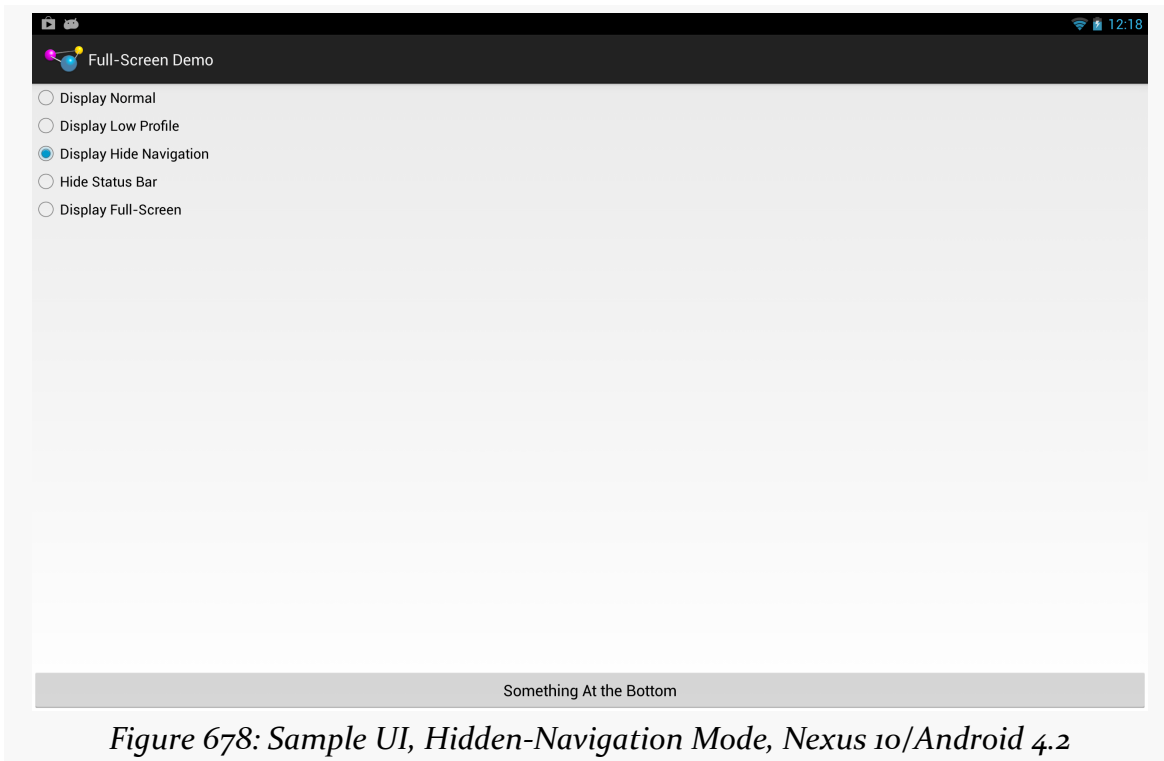

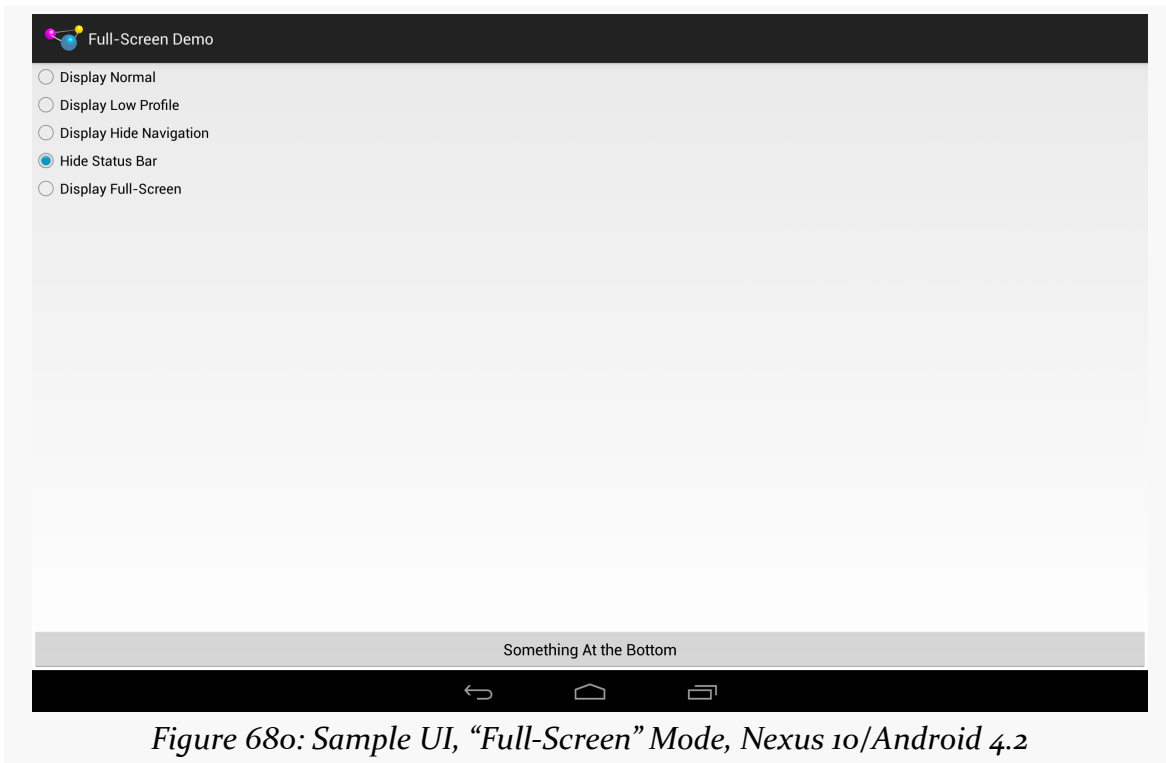

Figure 677: Sample UI, Hidden-Navigation Mode, Nexus 4/Android 4.2

MISCELLANEOUS UI TRICKS

Similarly, you can hide the status bar by passing `View.SYSTEM_UI_FLAG_FULLSCREEN` to `setSystemUiVisibility()`. However, despite this flag's name, it does not affect the navigation or system bar:

MISCELLANEOUS UI TRICKS

MISCELLANEOUS UI TRICKS

Hence, to hide both the status bar and the navigation or system bar, you need to pass both flags (`View.SYSTEM_UI_FLAG_FULLSCREEN` | `View.SYSTEM_UI_FLAG_HIDE_NAVIGATION`):

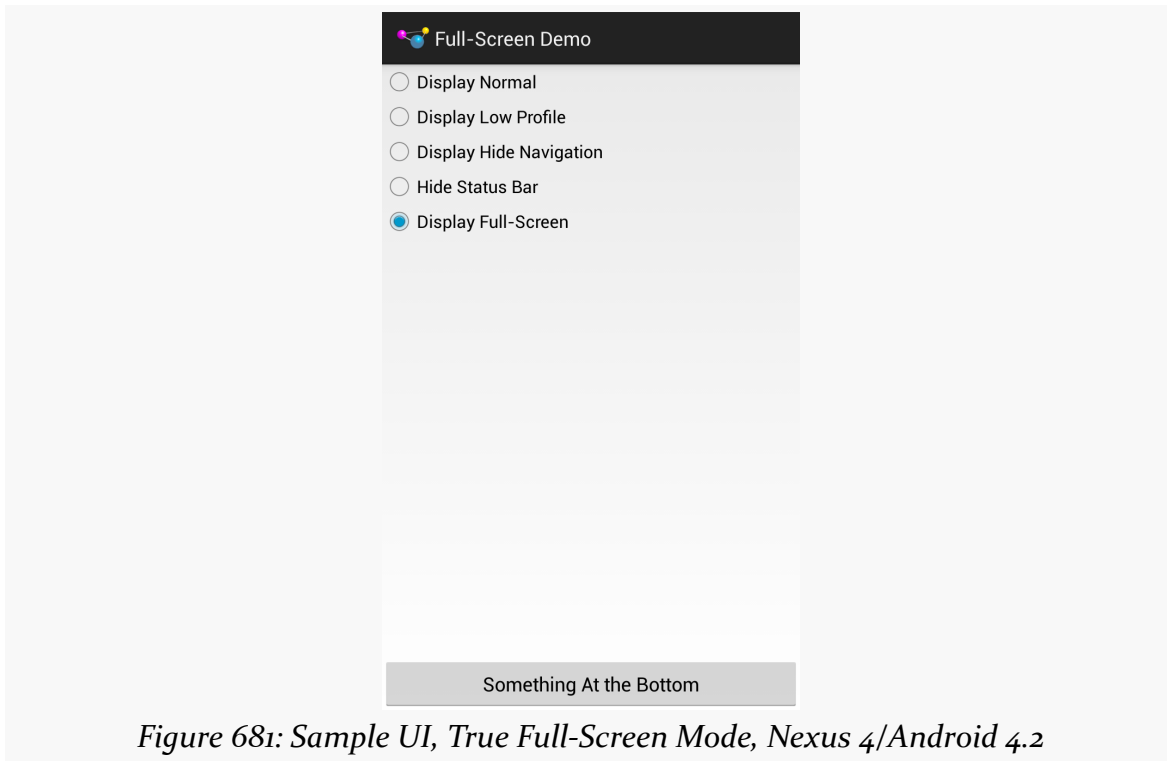

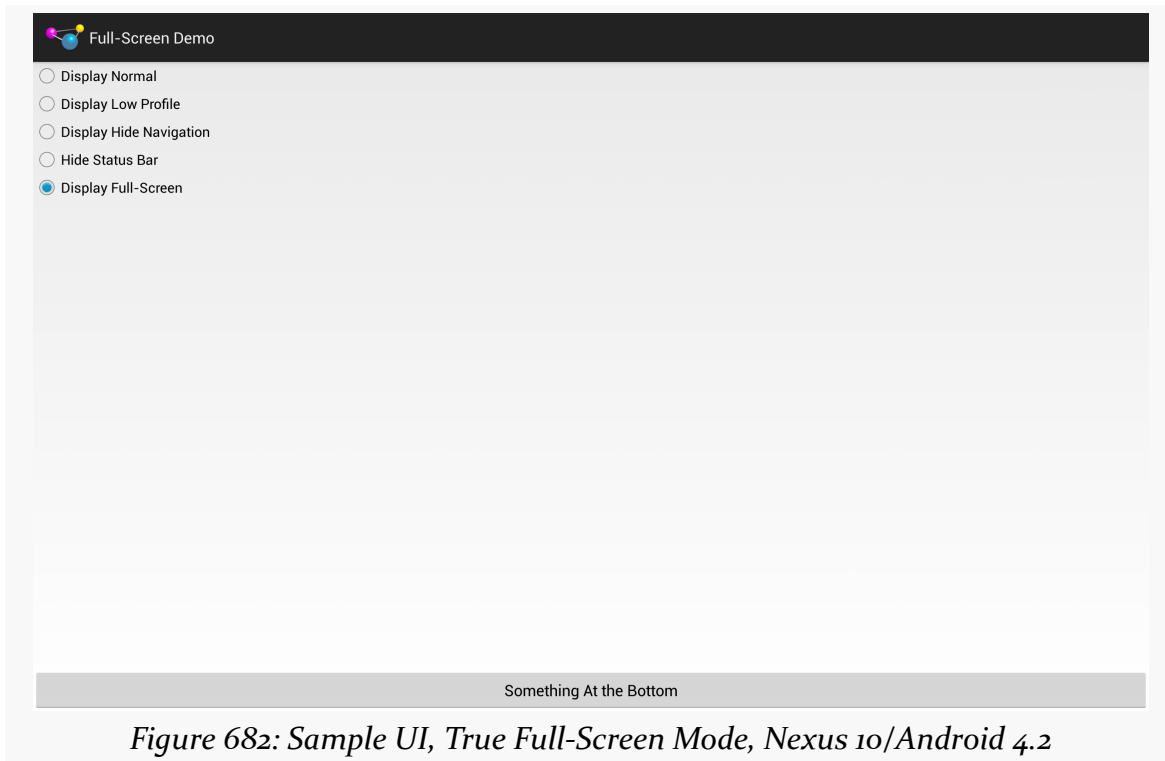

Figure 681: Sample UI, True Full-Screen Mode, Nexus 4/Android 4.2

Note that showing and hiding the `ActionBar` is also possible, via calls to `show()` and `hide()`, respectively.

Offering a Delayed Timeout

Android makes it easy for activities to keep the screen on while the activity is in the foreground, by means of `android:keepScreenOn` and `setKeepScreenOn()`.

However, these are very blunt instruments, and too many developers simply ask to keep the screen on constantly, even when that is not needed and can cause excessive battery drain. That is because it is very easy to *always* keep the screen on.

Say, for example, you are playing a game. Keeping the screen on while the game is being played is probably a good thing, particularly if the game does not require constant interaction with the screen. However, if you press the in-game pause button, the game might keep the screen on while the game is paused. This might lead you to press pause, put down your tablet (expecting it to fall asleep in a normal period of time), and then have the tablet keep going and going and going... until the battery runs dead.

MISCELLANEOUS UI TRICKS

Whether you use `setKeepScreenOn()` or directly use a `WakeLock`, it is useful to think of three tiers of user interaction.

The first tier is when your app is doing its “one big thing”: playing the game, playing the video, displaying the digital book, etc. If you expect that there will be periods of time when the user is actively engaged with your app, but is not interacting with the screen, keep the screen on.

The second tier is when your app is delivering something to the user that *probably* would get used without interaction in the short term, but not indefinitely. For example, a game might reasonably expect that 15 seconds could be too short to have the screen time out, but if the user has not done anything in 5-10 minutes, most likely they are not in front of the game. Similarly, a digital book reader should not try to keep the screen on for an hour without user interaction.

The third tier is when your app is doing anything other than the main content, where normal device behavior should resume. A video player might keep the screen on while the video is playing, but if the video ends, normal behavior should resume. After all, if the person who had been watching the video fell asleep, they will not be in position to press a power button.

The first and third tiers are fairly easy from a programming standpoint. Just `acquire()` and `release()` the `WakeLock`, or toggle `setKeepScreenOn()` between `true` and `false`.

The second tier — where you are willing to have a screen timeout, just not too quickly — requires you to add a bit more smarts to your app. A simple, low-overhead way of addressing this is to have a `postDelayed()` loop, to get a `Runnable` control every 5-10 seconds. Each time the user interacts with your app, update a `lastInteraction` timestamp. The `Runnable` compares `lastInteraction` with the current time, and if it exceeds some threshold, release the `WakeLock` or call `setKeepScreenOn(false)`. When the user interacts again, though, you will need to re-acquire the `WakeLock` or call `setKeepScreenOn(true)`. Basically, you have your own inactivity timing mechanism to control when you are inhibiting normal inactivity behavior or not.

To see the second tier in action, take a look at the [MiscUI/DelayedTimeout](#) sample project.

The UI is a simple button. We want to keep the screen awake while the user is using the button, but let it fall asleep after a period of inactivity that we control. To

MISCELLANEOUS UI TRICKS

accomplish this, we will use a `postDelayed()` loop, to get control every 15 seconds to see if there has been user activity:

```
package com.commonware.android.timeout;

import android.app.Activity;
import android.os.Bundle;
import android.os.SystemClock;
import android.view.View;

public class MainActivity extends Activity implements Runnable {
    private static int TIMEOUT_POLL_PERIOD=15000; // 15 seconds
    private static int TIMEOUT_PERIOD=300000; // 5 minutes
    private View content=null;
    private long lastActivity=SystemClock uptimeMillis();

    @Override
    protected void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.activity_main);

        content=findViewById(android.R.id.content);
        content.setKeepScreenOn(true);
        run();
    }

    @Override
    public void onDestroy() {
        content.removeCallbacks(this);

        super.onDestroy();
    }

    @Override
    public void run() {
        if ((SystemClock uptimeMillis() - lastActivity) > TIMEOUT_PERIOD) {
            content.setKeepScreenOn(false);
        }

        content.postDelayed(this, TIMEOUT_POLL_PERIOD);
    }

    public void onClick(View v) {
        lastActivity=SystemClock uptimeMillis();
    }
}
```

(from [MiscUI/DelayedTimeout/app/src/main/java/com/commonware/android/timeout/MainActivity.java](#))

MISCELLANEOUS UI TRICKS

In `onCreate()`, we call `setKeepScreenOn(true)` to keep the screen on, regardless of what the user's default timeout is. Then, we call the `run()` method from our `Runnable` interface (implemented on the activity itself). `run()` sees if 5 minutes has elapsed since the last bit of user activity (initially set to be the time the activity launches). If 5 minutes has elapsed, we revert to normal screen-timeout behavior with `setKeepScreenOn(false)`. We also schedule ourselves, as a `Runnable`, to get control again in 15 seconds, to see if 5 minutes has elapsed since the last-seen activity. Our button's `onClick()` method simply updates the last-seen timestamp, and `onDestroy()` cleans up our `postDelayed()` loop by calling `removeCallbacks()` to stop invoking our `Runnable`.

The net is that the device's screen will remain on for 5 minutes since the last time the user taps the button, even if the user's default screen timeout is set to shorter than 5 minutes. Yet, at the same time, we do not keep the screen on *forever*, causing unnecessary battery drain.

Note that to test this, you will probably need to unplug your USB cable after installing the app on the device (since many developers have it set up to keep the screen on while plugged in). Also, you will need to set your device's screen timeout to be under 5 minutes, if it is not set that way already.

This is a primitive implementation, missing lots of stuff that you would want in production code (e.g., it never calls `setKeepScreenOn(true)` if we flipped it to `false` but *then* tap the button). And the complexity of determining if the user interacted with the screen will be tied to the complexity of your UI.

That being said, by having a more intelligent use of `WakeLock` and `setKeepScreenOn()`, you can deliver value to the user while not accidentally causing excessive battery drain. Users do not always remember to press the power button, so you need to make sure that just because the user made a mistake, that you do not make it worse.

Event Bus Alternatives

[Earlier in the book](#), we covered the concept of an event bus as a way of communicating between portions of our app, focusing on one event bus implementation: greenrobot's EventBus. Later, in the chapter on broadcast Intent objects, we [briefly covered LocalBroadcastManager](#).

However, those are not the only event buses available for Android, and others may fit your needs better. In this chapter, we will explore these and other event bus implementations, to compare and contrast.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book, particularly the chapters on [basic event bus usage](#), [broadcast Intents](#), [AlarmManager and the scheduled service pattern](#), and [Notifications](#).

A Brief Note About the Sample Apps

The sample apps in this chapter are generally designed to run forever.

It is unlikely that you really want them to run forever, though. Hence, please uninstall each sample after experimenting with it, particularly if you are testing on hardware, such as your personal phone. Your battery will appreciate it.

Standard Intents as Event Bus

You can think of the standard Intent and <intent-filter> system as a three-channel event bus:

EVENT BUS ALTERNATIVES

- One channel is used for starting activities
- One channel is used for starting or binding to services
- One channel is used for more ad-hoc “broadcast” events

The component starting an activity does not need to communicate directly with code for that activity — in fact, often times this is impossible, as they are separate apps running in separate processes. Instead, the component starting an activity sends an event indicating the particular operation to be performed (e.g., view this URL), and Android and the user determine which of candidate consumers is the one to process that event.

However, broadcast Intent objects are a closer analogue to a real “event bus”, in that an event produced by somebody can be consumed by zero, one, or several subscribed consumers, based upon the filtering provided by `<intent-filter>` elements in the manifest or `IntentFilter` objects for use with `registerReceiver()`.

In theory, you could use broadcast Intent objects as the backbone for a fairly flexible event bus within your app. In practice, this is not usually a good idea:

- Each broadcast involves inter-process communication (IPC), even if the event producer and consumer(s) are in the same process. This adds overhead.
- Because broadcasts are intrinsically IPC, you have to take security into account, to ensure only authorized producers can publish events that the consumers pick up.

However, if you specifically need a cross-process event bus, such as between a suite of related apps, using a broadcast Intent is a very likely choice.

LocalBroadcastManager as Event Bus

As was briefly noted [earlier in the book](#), the Android Support package offers a `LocalBroadcastManager`. This is designed to offer an event bus with a feel very similar to classic broadcast Intent objects, but local to your process. Not only does this avoid IPC overhead, but it improves security, as other apps have no means of spying on your internal communications.

`LocalBroadcastManager` is supplied by both the `support-v4` and `support-v13` libraries. Generally speaking, if your `minSdkVersion` is less than 13, you probably should choose `support-v4`.

A Simple LocalBroadcastManager Sample

Let's see LocalBroadcastManager in action via the [Intents/Local](#) sample project.

Here, our LocalActivity sends a command to a NoticeService from onCreate():

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.main);

    notice=(TextView)findViewById(R.id.notice);
    startService(new Intent(this, NoticeService.class));
}
```

(from [Intents/Local/app/src/main/java/com/commonsware/android/localcast/LocalActivity.java](#))

The NoticeService simply delays five seconds, then sends a local broadcast using LocalBroadcastManager:

```
package com.commonsware.android.localcast;

import android.app.IntentService;
import android.content.Intent;
import android.os.SystemClock;
import android.support.v4.content.LocalBroadcastManager;

public class NoticeService extends IntentService {
    public static final String BROADCAST=
        "com.commonsware.android.localcast.NoticeService.BROADCAST";
    private static Intent broadcast=new Intent(BROADCAST);

    public NoticeService() {
        super("NoticeService");
    }

    @Override
    protected void onHandleIntent(Intent intent) {
        SystemClock.sleep(5000);
        LocalBroadcastManager.getInstance(this).sendBroadcast(broadcast);
    }
}
```

(from [Intents/Local/app/src/main/java/com/commonsware/android/localcast/NoticeService.java](#))

EVENT BUS ALTERNATIVES

Specifically, you get at your process' singleton instance of `LocalBroadcastManager` by calling `getInstance()` on the `LocalBroadcastManager` class.

Our `LocalActivity` registers for this local broadcast in `onStart()`, once again using `getInstance()` on `LocalBroadcastManager`:

```
@Override
public void onStart() {
    super.onStart();

    IntentFilter filter=new IntentFilter(NoticeService.BROADCAST);

    LocalBroadcastManager.getInstance(this).registerReceiver(onNotice,
                                                            filter);
}
```

(from [Intents/Local/app/src/main/java/com/commonsware/android/localcast/LocalActivity.java](#))

`LocalActivity` unregisters for this broadcast in `onStop()`:

```
@Override
public void onStop() {
    super.onStop();

    LocalBroadcastManager.getInstance(this).unregisterReceiver(onNotice);
}
```

(from [Intents/Local/app/src/main/java/com/commonsware/android/localcast/LocalActivity.java](#))

The `BroadcastReceiver` simply updates a `TextView` with the current date and time:

```
private BroadcastReceiver onNotice=new BroadcastReceiver() {
    public void onReceive(Context ctxt, Intent i) {
        notice.setText(new Date().toString());
    }
};
```

(from [Intents/Local/app/src/main/java/com/commonsware/android/localcast/LocalActivity.java](#))

If you start up this activity, you will see a “(waiting...)” bit of placeholder text for about five seconds, before having that be replaced by the current date and time.

The `BroadcastReceiver`, the `IntentFilter`, and the `Intent` being broadcast are the same as we would use with full broadcasts. It is merely how we are using them — via `LocalBroadcastManager` – that dictates they are local to our process versus the standard device-wide broadcasts.

A More Elaborate Sample

That sample is not terribly realistic, but it is simple.

A somewhat more realistic sample is the one using `WakefulIntentService` from [earlier in the book](#). However, that app was also fairly unrealistic, at least in terms of its output, as Logcat is not very useful to users. A more typical approach for a background service like this is to notify a foreground `Activity`, if there is one, about work that was accomplished, and otherwise display a `Notification`. We described that pattern in [the chapter on Notifications](#).

In the [EventBus/LocalBroadcastManager](#) sample project, we blend:

- Having a service wake up every so often to do some work
- Arranging to let the user know of background accomplishments via an `Activity` or a `Notification`
- Using `LocalBroadcastManager` to keep the communications in-process

The Activity

The `EventDemoActivity` that is our app's entry point is a bit similar to the one used in the `WakefulIntentService` demo, in that it calls `scheduleAlarms()` on `PollReceiver` to set up the `AlarmManager` schedule:

```
package com.commonware.android.eventbus.lbm;

import android.app.Activity;
import android.os.Bundle;

public class EventDemoActivity extends Activity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        if (getFragmentManager().findFragmentById(android.R.id.content) == null) {
            getFragmentManager().beginTransaction()
                .add(android.R.id.content,
                    new EventLogFragment()).commit();

            PollReceiver.scheduleAlarms(this);
        }
    }
}
```

EVENT BUS ALTERNATIVES

(from [EventBus/LocalBroadcastManager/app/src/main/java/com/commonsware/android/eventbus/lbm/EventDemoActivity.java](#))

However, we also put an `EventLogFragment` on the screen, if it is not already there, via a `FragmentManager`. This is where we will display events coming from the service, while our activity is in the foreground. We will examine `EventLogFragment` and how it participates in the event bus shortly.

The `PollReceiver`

`PollReceiver` is unchanged from its `WakefulIntentService` demo original edition. This `BroadcastReceiver` will be used both for getting control at boot time (to reschedule the alarms, wiped on the reboot) and for sending the work to the `ScheduledService` for processing:

```
package com.commonsware.android.eventbus.lbm;

import android.app.AlarmManager;
import android.app.PendingIntent;
import android.content.BroadcastReceiver;
import android.content.Context;
import android.content.Intent;
import android.os.SystemClock;
import com.commonsware.cwac.wakeful.WakefulIntentService;

public class PollReceiver extends BroadcastReceiver {
    private static final int PERIOD=15000; // 15 seconds
    private static final int INITIAL_DELAY=1000; // 1 second

    @Override
    public void onReceive(Context ctxt, Intent i) {
        if (i.getAction() == null) {
            WakefulIntentService.sendWakefulWork(ctxt, ScheduledService.class);
        }
        else {
            scheduleAlarms(ctxt);
        }
    }

    static void scheduleAlarms(Context ctxt) {
        AlarmManager mgr=
            (AlarmManager)ctxt.getSystemService(Context.ALARM_SERVICE);
        Intent i=new Intent(ctxt, PollReceiver.class);
        PendingIntent pi=PendingIntent.getBroadcast(ctxt, 0, i, 0);

        mgr.setRepeating(AlarmManager.ELAPSED_REALTIME_WAKEUP,
            SystemClock.elapsedRealtime() + INITIAL_DELAY,
```

EVENT BUS ALTERNATIVES

```
        PERIOD, pi);  
    }  
}
```

(from [EventBus/LocalBroadcastManager/app/src/main/java/com/commonsware/android/eventbus/lbm/PollReceiver.java](#))

Note that on Android 5.1 and higher, despite the fact that we are asking for a 15-second polling period, the actual polling period will be one minute, as `AlarmManager` no longer supports sub-minute polling periods.

ScheduledService and Sending Events

Before, our `ScheduledService` just dumped a message to Logcat. This was crude but effective for what that demo required. Now, we want our service to let the UI layer know about some work that was accomplished, or to raise a Notification.

In this case, the “work” is generating a random number.

```
package com.commonsware.android.eventbus.lbm;  
  
import android.app.Notification;  
import android.app.NotificationManager;  
import android.app.PendingIntent;  
import android.content.Intent;  
import android.support.v4.app.NotificationCompat;  
import android.support.v4.content.LocalBroadcastManager;  
import java.util.Calendar;  
import java.util.Random;  
import com.commonsware.cwac.wakeful.WakefulIntentService;  
  
public class ScheduledService extends WakefulIntentService {  
    private static int NOTIFY_ID=1337;  
    private Random rng=new Random();  
  
    public ScheduledService() {  
        super("ScheduledService");  
    }  
  
    @Override  
    protected void doWakefulWork(Intent intent) {  
        Intent event=new Intent(EventLogFragment.ACTION_EVENT);  
        long now=Calendar.getInstance().getTimeInMillis();  
        int random=rng.nextInt();  
  
        event.putExtra(EventLogFragment.EXTRA_RANDOM, random);
```

EVENT BUS ALTERNATIVES

```
event.putExtra(EventLogFragment.EXTRA_TIME, now);

if (!LocalBroadcastManager.getInstance(this).sendBroadcast(event)) {
    NotificationCompat.Builder b=new NotificationCompat.Builder(this);
    Intent ui=new Intent(this, EventDemoActivity.class);

    b.setAutoCancel(true).setDefaults(Notification.DEFAULT_SOUND)
      .setContentTitle(getString(R.string.notif_title))
      .setContentText(Integer.toHexString(random))
      .setSmallIcon(android.R.drawable.stat_notify_more)
      .setTicker(getString(R.string.notif_title))
      .setContentIntent(PendingIntent.getActivity(this, 0, ui, 0));

    NotificationManager mgr=
        (NotificationManager) getSystemService(NOTIFICATION_SERVICE);

    mgr.notify(NOTIFY_ID, b.build());
}
}
```

(from [EventBus/LocalBroadcastManager/app/src/main/java/com/commonsware/android/eventbus/lbm/ScheduledService.java](https://github.com/commonsware/android-eventbus/blob/master/lbm/ScheduledService.java))

LocalBroadcastManager, as we have seen, uses the same Intent and IntentFilter and BroadcastReceiver structures as are used with regular broadcasts, just via a singleton message bus (LocalBroadcastManager.getInstance()) instead of the framework's IPC engine. Hence, we need an Intent that represents the message, so we create one, using an action string published by the EventLogFragment. We also attach two extras to this Intent, using keys published by EventLogFragment: the random number, plus the time of this event.

We then call sendBroadcast() on the singleton LocalBroadcastManager. This returns a boolean value, true indicating that one or more locally-registered receivers were delivered the Intent, false otherwise. Hence, if sendBroadcast() returns true, we can assume that somebody in the UI layer picked up our message and is now responsible for displaying these results to the user.

Conversely, if sendBroadcast() returns false, we must assume that the UI layer did not receive the message, and so the service should inform the user directly, in this case via a Notification, showing the random number as the text in the notification drawer.

EventLogFragment and Receiving Events

EventLogFragment, therefore, is responsible for:

- Registering (and unregistering) to receive the broadcasts to be sent locally by the service
- Doing something with those events to inform the user about the all-important random numbers

In this case, we use a retained ListFragment with a ListView set into transcript mode, meaning that entries are added at the bottom, and older entries scroll off the top, like a chat transcript:

```
package com.commonware.android.eventbus.lbm;

import android.annotation.SuppressLint;
import android.app.ListFragment;
import android.content.BroadcastReceiver;
import android.content.Context;
import android.content.Intent;
import android.content.IntentFilter;
import android.os.Bundle;
import android.support.v4.content.LocalBroadcastManager;
import android.view.View;
import android.view.ViewGroup;
import android.widget.AdapterView;
import android.widget.AdapterView.OnItemClickListener;
import android.widget.AdapterView.OnItemSelectedListener;
import android.widget.ArrayAdapter;
import android.widget.ListView;
import android.widget.TextView;
import java.text.DateFormat;
import java.text.SimpleDateFormat;
import java.util.ArrayList;
import java.util.Date;
import java.util.Locale;

public class EventLogFragment extends ListFragment {
    static final String EXTRA_RANDOM="r";
    static final String EXTRA_TIME="t";
    static final String ACTION_EVENT="e";
    private EventLogAdapter adapter=null;

    @Override
    public void onActivityCreated(Bundle state) {
        super.onActivityCreated(state);

        setRetainInstance(true);
        getListView().setTranscriptMode(ListView.TRANSCRIPT_MODE_NORMAL);
    }
}
```

EVENT BUS ALTERNATIVES

```
    if (adapter == null) {
        adapter=new EventLogAdapter();
    }

    setListAdapter(adapter);
}

@Override
public void onStart() {
    super.onStart();

    IntentFilter filter=new IntentFilter(ACTION_EVENT);

    LocalBroadcastManager.getInstance(getActivity())
        .registerReceiver(onEvent, filter);
}

@Override
public void onStop() {
    LocalBroadcastManager.getInstance(getActivity())
        .unregisterReceiver(onEvent);

    super.onStop();
}

class EventLogAdapter extends ArrayAdapter<Intent> {
    DateFormat fmt=new SimpleDateFormat("HH:mm:ss", Locale.US);

    public EventLogAdapter() {
        super(getActivity(), android.R.layout.simple_list_item_1,
            new ArrayList<Intent>());
    }

    @SuppressWarnings("DefaultLocale")
    @Override
    public View getView(int position, View convertView, ViewGroup parent) {
        TextView row=
            (TextView)super.getView(position, convertView, parent);
        Intent event=getItem(position);
        Date date=new Date(event.getLongExtra(EXTRA_TIME, 0));

        row.setText(String.format("%s = %X", fmt.format(date),
            event.getIntExtra(EXTRA_RANDOM, -1)));

        return(row);
    }
}
```

EVENT BUS ALTERNATIVES

```
private BroadcastReceiver onEvent=new BroadcastReceiver() {  
    @Override  
    public void onReceive(Context context, Intent intent) {  
        adapter.add(intent);  
    }  
};  
}
```

(from [EventBus/LocalBroadcastManager/app/src/main/java/com/commonsware/android/eventbus/lbm/EventLogFragment.java](#))

The ListAdapter for the ListView is an EventLogAdapter, an ArrayAdapter for Intent objects, where in getView() we populate the list rows with the time and random value.

In onStart() and onStop(), we register for (and unregister from) the desired broadcast, pointing to an onEvent BroadcastReceiver that adds the incoming Intent to the EventLogAdapter. That, in turn, updates the ListView.

The result is that while the activity is in the foreground, the events will be displayed to the user directly:

Figure 683: LocalBroadcastManager as Event Bus, Demo Activity

Whereas if events are processed while the activity is not in the foreground, a Notification will be shown with the last results:

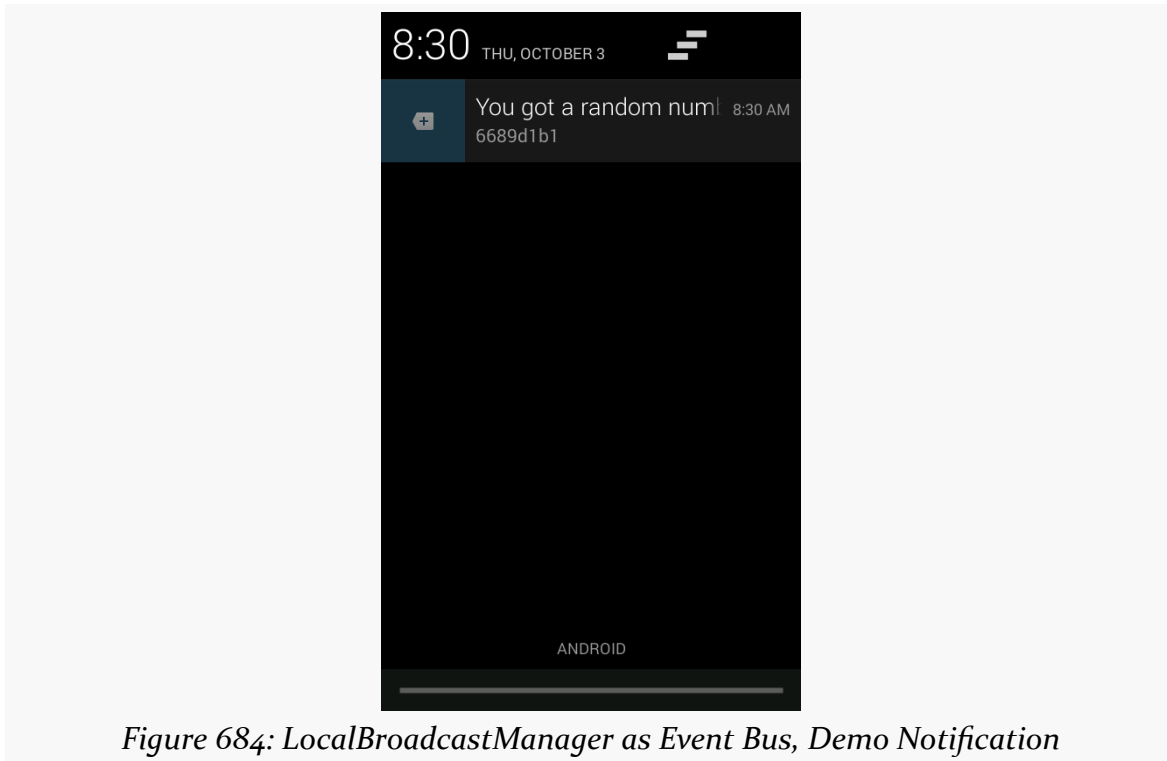

Figure 684: LocalBroadcastManager as Event Bus, Demo Notification

Reference, Not Value

When you send a “real” broadcast Intent, your Intent is converted into a byte array (courtesy of [the Parcelable interface](#)) and transmitted to other processes. This occurs even if the recipient of the Intent is within your own process — that is what makes LocalBroadcastManager faster, as it avoids the inter-process communication.

However, since LocalBroadcastManager does not need to send your Intent between processes, that means it does not turn your Intent into a byte array. Instead, it just passes the Intent along to any registered BroadcastReceiver with a matching IntentFilter. In effect, while “real” broadcasts are pass-by-value, local broadcasts are pass-by-reference.

This can have subtle side effects.

For example, there are a few ways that you can put a collection into an Intent extra, such as `putStringArrayListExtra()`. This takes an `ArrayList` as a parameter. With

a real broadcast, once you send the broadcast, it does not matter what happens to the original `ArrayList` — the rest of the system is working off of a copy. With a local broadcast, though, the `Intent` holds onto the `ArrayList` you supplied via the setter. If you change that `ArrayList` elsewhere (e.g., clear it for reuse), the recipient of the `Intent` will see those changes.

Similarly, if you put a `Parcelable` object in an extra, the `Intent` holds onto the actual object while it is being broadcast locally, whereas a real broadcast would have resulted in a copy. If you change the object while the broadcast is in progress, the recipient of the broadcast will see those changes.

This can be a feature, not a bug, when used properly. But, regardless, it is a non-trivial difference, one that you will need to keep in mind.

Limitations of Local

While `LocalBroadcastManager` is certainly useful, it has some serious limitations.

The biggest is that it is purely local. While traditional broadcasts can either be internal (via `setPackage()`) or device-wide, `LocalBroadcastManager` only handles the local case. Hence, anything that might involve other processes, such as a `PendingIntent`, will not use `LocalBroadcastManager`. For example, you cannot register a receiver through `LocalBroadcastManager`, then use a `getBroadcast()` `PendingIntent` to try to reach that `BroadcastReceiver`. The `PendingIntent` will use the regular broadcast `Intent` mechanism, which the local-only receiver will not respond to.

Similarly, since a manifest-registered `BroadcastReceiver` is spawned via the operating system upon receipt of a matching true broadcast, you cannot use such receivers with `LocalBroadcastManager`. Only a `BroadcastReceiver` registered via `registerReceiver()` on the `LocalBroadcastManager` will use the `LocalBroadcastManager`. For example, you cannot implement the Activity-or-Notification pattern that we will see [later in this book](#) via `LocalBroadcastManager`.

Also, `LocalBroadcastManager` does not offer ordered or sticky broadcasts.

greenrobot's EventBus 3.x

`LocalBroadcastManager` has two major advantages:

EVENT BUS ALTERNATIVES

1. It is part of the Android Support package, and therefore it is part of the officially-supported corner of the Android ecosystem
2. It works like traditional broadcasts, which will make it easier for some developers to “wrap their heads around” it

However, that same dependency on the Intent and IntentFilter structure adds bulk and limits flexibility. Hence, it is not surprising that there are alternative event buses to LocalBroadcastManager.

Java, outside of Android, has had a few event bus implementations. One of the more popular ones in recent years has been the event bus that is part of [Google’s Guava family of libraries](#). However, while a Java event bus perhaps can be used on Android, it may not be *optimal* for Android. Hence, a few projects have started with Guava’s event bus implementation and have extended it to be a bit more Android-aware, or perhaps even Android-centric.

[greenrobot’s EventBus](#) is one such event bus.

NOTE: For the purposes of this chapter, “greenrobot’s EventBus” refers to the library, and “EventBus” refers to the EventBus Java class in that library.

Basic Usage and Sample App

With LocalBroadcastManager, you work with a singleton instance, calling methods like registerReceiver() and sendBroadcast() upon it to subscribe to and raise events, respectively.

With greenrobot’s EventBus, you work with an EventBus instance, calling methods like register() and post() upon it to subscribe to and raise events, respectively. Usually, we use the singleton instance of EventBus that we get by calling getDefault() on the EventBus class, but you are welcome to have different EventBus objects, representing distinct communications channels, if you wish.

Hence, at the core, greenrobot’s EventBus behaves much like LocalBroadcastManager. What differs is in the nature of the events and the subscribers.

With LocalBroadcastManager, events are Intent objects. With greenrobot’s EventBus, an event can be whatever data type you like. Hence, you can create your own . . . Event classes, holding whatever bits of data, in whatever data types suit you — you are not restricted to things that can go in an Intent extra. However, as has

EVENT BUS ALTERNATIVES

been noted on occasion, “[with great power comes great responsibility](#)”, and so you will need to ensure that you use this carefully and do not wind up creating some sort of memory leak as a result. For example, do not pass something from an Activity to a Service via a custom event, where the Service will hold onto that information for a long time, if that “something” holds a reference back to the Activity.

With LocalBroadcastManager, subscribers are BroadcastReceivers, who use an IntentFilter to identify which events they are interested in. With greenrobot’s EventBus, subscribers are any class you want. A special @Subscribe annotation is used to both indicate what sorts of events the subscriber is interested in (based on the parameter to the annotated method) and what method should be invoked when a matching event is raised (the annotated method itself). Hence, not only do you use custom event classes to allow you to carry along custom data, but you use them as a filtering mechanism, much like you would use custom action strings with LocalBroadcastManager.

To see how this works, take a look at the [EventBus/GreenRobot3](#) sample project, which is a clone of the EventBus/LocalBroadcastManager demo, but one where we substitute in greenrobot’s EventBus as a replacement for LocalBroadcastManager. Our activity and PollReceiver are unchanged: they did not directly interact with LocalBroadcastManager and do not need to interact with greenrobot’s EventBus. The changes are isolated in our ScheduledService and EventLogFragment.

NOTE: This sample app uses a 3.x version of greenrobot’s EventBus. This came with a significant API change from the previous 2.x generation. We will examine the 2.x version [later in this chapter](#).

ScheduledService and Sending Events

We will need an EventBus instance, one that serves the same basic role as does the singleton LocalBroadcastManager retrieved by getInstance(). As noted above, you can call getDefault() on EventBus to get a singleton EventBus instance, and this suffices in most cases.

When it comes time for us to send a message, we can call post() on the EventBus, supplying whatever sort of event object that we want:

```
@Override
protected void doWakefulWork(Intent intent) {
    EventBus.getDefault().post(new RandomEvent(rng.nextInt()));
}
```

EVENT BUS ALTERNATIVES

(from [EventBus/GreenRobot3/app/src/main/java/com/commonsware/android/eventbus/greenrobot/ScheduledService.java](#))

Here, we are posting an instance of a RandomEvent:

```
package com.commonsware.android.eventbus.greenrobot;

import java.util.Calendar;
import java.util.Date;

public class RandomEvent {
    Date when=Calendar.getInstance().getTime();
    int value;

    RandomEvent(int value) {
        this.value=value;
    }
}
```

(from [EventBus/GreenRobot3/app/src/main/java/com/commonsware/android/eventbus/greenrobot/RandomEvent.java](#))

EventLogFragment and Receiving Events

Over in our EventLogFragment, rather than register and unregister a BroadcastReceiver in onStart() and onStop(), we register and unregister the fragment itself with the EventBus:

```
@Override
public void onStart() {
    super.onStart();

    EventBus.getDefault().register(this);
}

@Override
public void onStop() {
    EventBus.getDefault().unregister(this);

    super.onStop();
}
```

(from [EventBus/GreenRobot3/app/src/main/java/com/commonsware/android/eventbus/greenrobot/EventLogFragment.java](#))

Now, we can use the @Subscribe annotation to arrange to receive any event we want that is delivered via this EventBus, based on event class. Since we want to receive RandomEvent messages, we merely need to have a public void method, taking a

EVENT BUS ALTERNATIVES

RandomEvent parameter, marked with the @Subscribe annotation, such as onRandomEvent():

```
@Subscribe(threadMode = ThreadMode.MAIN)
public void onRandomEvent(final RandomEvent event) {
    adapter.add(event);
}
```

(from [EventBus/GreenRobot3/app/src/main/java/com/commonsware/android/eventbus/greenrobot/EventLogFragment.java](#))

Note that the method name can be anything we want, as it is the annotation, not the method name, that identifies this as being an event handling method.

Since Java annotations can take key-value pairs for configuration, EventBus 3.x uses that to configure the behavior of @Subscribe. Here, we use @Subscribe(threadMode = ThreadMode.MAIN), to indicate that we want this event to be delivered to this method on the main application thread.

In this method, we can do what we need to with our RandomEvent. In our case, EventLogAdapter has been modified to be an ArrayAdapter of RandomEvent, as opposed to being an ArrayAdapter of Intent as in the earlier sample. What we want to do is append the new RandomEvent to the end of the adapter.

Handling the “Nobody’s Home” Scenario

What is missing, though, is the logic we used in LocalBroadcastManager to determine if somebody received our message, where we raised a Notification if that is not the case.

The solution for this with greenrobot’s EventBus is to have ScheduledService listen for NoSubscriberEvent events. A NoSubscriberEvent is delivered on the bus when an attempt to deliver some other event failed with no subscribers. The NoSubscriberEvent has an originalEvent field that contains the original event that failed to be delivered. If we can get the NoSubscriberEvent, we know the RandomEvent was not handled at the UI layer, and we can raise the Notification.

To do this, not only do we need to register EventLogFragment with the Bus, but we also need to register ScheduledService itself, so it can listen for a NoSubscriberEvent:

```
@Override
public void onCreate() {
```

EVENT BUS ALTERNATIVES

```
super.onCreate();

EventBus.getDefault().register(this);
}
```

(from [EventBus/GreenRobot3/app/src/main/java/com/commonsware/android/eventbus/greenrobot/ScheduledService.java](#))

```
@Override
public void onDestroy() {
    EventBus.getDefault().unregister(this);

    super.onDestroy();
}
```

(from [EventBus/GreenRobot3/app/src/main/java/com/commonsware/android/eventbus/greenrobot/ScheduledService.java](#))

Then, our Notification logic can be moved into some method that has the `@Subscribe` annotation and a `NoSubscriberEvent` parameter:

```
@Subscribe
public void onNoSubscriber(NoSubscriberEvent event) {
    RandomEvent randomEvent=(RandomEvent)event.originalEvent;
    NotificationCompat.Builder b=new NotificationCompat.Builder(this);
    Intent ui=new Intent(this, EventDemoActivity.class);

    b.setAutoCancel(true).setDefaults(Notification.DEFAULT_SOUND)
    .setTitle(getString(R.string.notif_title))
    .setContentText(Integer.toHexString(randomEvent.value))
    .setSmallIcon(android.R.drawable.stat_notify_more)
    .setTicker(getString(R.string.notif_title))
    .setContentIntent(PendingIntent.getActivity(this, 0, ui, 0));

    NotificationManager mgr=
        (NotificationManager) getSystemService(NOTIFICATION_SERVICE);

    mgr.notify(NOTIFY_ID, b.build());
}
```

(from [EventBus/GreenRobot3/app/src/main/java/com/commonsware/android/eventbus/greenrobot/ScheduledService.java](#))

Other Notable Capabilities

In addition to the threading features, greenrobot's EventBus has a few other noteworthy bells and whistles:

- Other thread modes are available, including `ThreadMode.POSTING` (events are delivered on the same thread they are posted from) and

EVENT BUS ALTERNATIVES

ThreadMode.BACKGROUND (events are delivered on a background thread, with EventBus using its own thread if the event was posted from the main application thread).

- `postSticky()` and `registerSticky()` allow you to have sticky events, much like sticky broadcasts with the classic broadcast Intent system.
- Ordered event processing as an option, akin to ordered broadcasts. You accomplish this by assigning a priority to the event handling method (e.g., `@Subscribe(priority = 1)`). If a higher-priority handler wants to consume the event, it can call `cancelEventDelivery()` on the EventBus, passing in the event object.

greenrobot's EventBus 2.x

greenrobot's EventBus came of age with the 2.x version series. However, they made a few changes of note with the new 3.x API. If you are looking at projects using the older library, you will see these changes.

Package Changes

The `org.greenrobot:eventbus` artifact is for the 3.x generation of the library. `de.greenrobot:eventbus` was used previously. So, if you see a project referring to `de.greenrobot:eventbus`, you know that it is using the older library:

```
dependencies {  
    implementation 'de.greenrobot:eventbus:2.4.0'  
    implementation 'com.android.support:support-v13:21.0.3'  
    implementation 'com.commonware.cwac:wakeful:1.0.+'  
}
```

This also affects the Java package used for the classes: 2.x classes were in `de.greenrobot`, while 3.x classes are in `org.greenrobot`.

Magic Method Names

Version 3.x of the greenrobot EventBus API uses the `@Subscribe` annotation. Version 2.x did not. Instead, your event handling method had to be named `onEvent()`, or some variation of it to indicate the thread mode (e.g., `onEventMainThread()`). greenrobot's EventBus would look up the methods matching this naming scheme and use those as event handlers, rather than look up methods using the `@Subscribe` annotation.

Hey, What About Otto?

For a few years, a third major event bus implementation was popular: Square's Otto. Like greenrobot's EventBus, Otto was based off of Guava's EventBus class and was tuned towards Android app development. It shared some characteristics with greenrobot's EventBus, owing to the shared heritage. On the whole, greenrobot's EventBus was a bit more complex to use but offered greater flexibility.

Square has since discontinued work on Otto, so unless you have existing legacy code that uses Otto, you should use some other event bus implementation.

One of the most confusing aspects of Android to deal with is the concept of tasks. Fortunately, the automatic management of tasks is *almost* enough to get by, without you having to do much customization. However, many apps will have needs to tailor how their app interacts with the task system, and understanding what is possible and how to do it is not easy. It is made even more complicated by changes to Android, from both engineering and design perspectives, over the years.

This chapter will attempt to untie the knot of knowledge surrounding Android’s task system, explaining why things are the way they are. However, there will be a few places where the knot turns a bit [Gordian](#), and we will have to settle for more about “how” and less about “why” the task system works as it does.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book.

One sample app makes heavy use of [the PackageManager system service](#) and refers in a few places to the Launcha1ot sample app profiled in that chapter.

First, Some Terminology

It will be useful to establish some common definitions of terms that you will encounter, both in this chapter and in other materials that describe the task system.

Task

So, what exactly *is* a “task”?

The [Android developer documentation](#) describes it as:

A task is a collection of activities that users interact with when performing a certain job. The activities are arranged in a stack (the back stack), in the order in which each activity is opened.

In that sense, a task is reminiscent of a tab in a tabbed browser. As the user navigates, clicking links and submitting forms, the user advances into other Web pages. Those pages could be on the same site as they started or could be on different sites. The browser BACK button is supposed to reverse the navigation, allowing the user to return from whence they came.

Back Stack

The user perceives tasks mostly in the form of pressing the BACK button, using this to return to previous “screens” that they had been on previously.

Sometimes, BACK button processing is handled within a single activity, such as when you put a dynamic fragment onto the “back stack” via `addToBackStack()` on a `FragmentManager`. Or, the activity could override `onBackPressed()` and do special stuff in certain scenarios. Those are part of the user experience of pressing BACK. From the standpoint of the task system, though, internal consumption of the BACK button presses do not affect the task.

At the task level, the “back stack” refers to a chain of activities. This matches the behavior of Web sites, where while pressing the browser BACK button *might* trigger in-page behavior, usually it returns you to the previous page. Similarly, while pressing BACK on an Android device *might* trigger in-activity behavior, usually it triggers a call to `finish()` on the foreground activity and returns control to whatever had preceded it on the back stack.

Recent Tasks

In a tabbed Web browser, if we have several tabs open, we think of all of them as being “running”. Frequently, we do not really even think about the concept, any more than we might think about the state of tabs in an IDE other than the one that

TASKS

we are working in right now. However, if you have ever had some browser tab all of a sudden start playing audio, such as from a reloaded page pulling in an audio-enabled ad banner, you are well aware that tabs are “running”, while you are also “running” to try to figure out what tab is playing the audio so you can get rid of it.

However, that is the behavior on a desktop Web browser. A desktop Web browser is not subject to heap size limitations the way Android apps are. And, historically, mobile devices had less system RAM than did their desktop and notebook counterparts, though that is rapidly changing.

In Android, therefore, developers are used to the notion that their processes may be terminated, while in the background, to free up memory for other processes. This is being done to allow for more apps to deliver more value in less system RAM.

However, from a multitasking standpoint, having apps just up and vanish is awkward. Hence, Android has the notion of “recent tasks”. These are tasks, with their corresponding back stacks, that the user has been in “recently”. How far back “recently” goes depends a bit on the version of Android – there could be as few as eight items. These “recent tasks” may or may not have a currently-running *process* associated with them. However, if the user chooses to return to one of those recent tasks, and there is no process for it, Android will seamlessly fork a fresh process, to be able to not only start up those apps, but return the user to where they were, in terms of UI contents (e.g., saved instance state `Bundle`) and in terms of back stack contents (e.g., where the user goes if the user now presses BACK).

Overview Screen

In a tabbed Web browser, you can navigate between different tabs in some browser-specific way. Some tabs may have the actual “tab” visible around the address bar. Some tabs might only be reachable via some sort of scrolling operation, or via a drop-down list, for people who have lots and lots of tabs open. Regardless, there is some UI means to pick the tab that you want to be viewing in the main browser area.

In Android, the “overview screen” is where the user can view the recent tasks and choose to return to one of them. Many people, including this author, refer to this as the “recent tasks list”, but apparently [the official term is “overview screen”](#).

The way the overview screen has looked and worked has changed over the years.

TASKS

Android 1.x/2.x

In the early days of Android, long-pressing the HOME button would bring up the overview screen, with up to eight recent tasks:

Figure 685: Overview Screen, from Android 2.3.3

And... that was pretty much it.

Android 3.x/4.x

The overall move to the holographic theme for Android brought with us a new icon, for a dedicated way to get to the overview screen:

Figure 686: Overview Screen/Recent Tasks Navigation Bar Icon, from Android 4.3

Devices that offered a navigation bar at the bottom would have this button. Devices that chose to have off-screen affordances for BACK and HOME might have a similar button for the overview screen. For those that neither had a navigation bar nor a dedicated off-screen button for the overview screen, long-pressing HOME would bring up the overview screen.

The overview screen could have more apps (15 or so) before old tasks would be dropped:

TASKS

Figure 687: Overview Screen, from Android 4.3

The overview screen also added more improvements:

- Thumbnails of the top activity in each task's back stack, except for those activities that [used FLAG_SECURE](#) to block this, and except on some emulator images
- Swiping an entry off the list would remove that recent task

Android 5.x

Functionally, the Android 5.x overview screen functions much like its 4.x counterpart, with the ability to see previews of tasks and remove tasks from the screen.

However, there are some differences, starting with the navigation bar icon used to bring up the overview screen:

TASKS

Figure 688: Overview Screen/Recent Tasks Navigation Bar Icon, from Android 5.0

Also, the previews are larger and stacked like cards, more so than being a classically vertically-scrolling list:

Figure 689: Overview Screen, from Android 5.0

More importantly:

- The roster of recent tasks will be restored after a reboot, and

- If there is a limit on how many entries can appear in the list, the author has not run into it yet

Running Tasks

A running task is a task that has running process(es) associated with it. Recent tasks may or may not be running.

And Now, a Bit About Task Killers

In October 2008, the first Android device was publicly released (the T-Mobile G1, a.k.a., HTC Dream).

Around December of 2008, the first task killers appeared on the Android Market (now the Play Store).

While the techniques used in 2008 to kill tasks were removed in later releases, some amount of task management behavior still exists in Android. Having a task killer is useful for understanding how tasks (and their killers) behave on Android. In particular, it is useful to have a way to emulate an app's process being terminated due to low memory conditions... which is exactly what modern task killers do.

So, in this section, we will explore the concept of task killers, including how to implement one, before using this tool to help us explore the overall Android task system.

What Do Task Killers Do?

Despite the name, task killers do not kill tasks.

Rather, task killers terminate background processes. This does not impact the task, insofar as it will still be in the recent tasks roster and will still show up on the overview screen. However, the process for the app associated with the task will shut down.

Task killers can only request to terminate background processes. If your app is in the foreground (i.e., has the foreground activity), you cannot be terminated by a task killer.

TASKS

To terminate background processes, task killers need to hold the `KILL_BACKGROUND_PROCESSES` permission, via a `<uses-permission>` element in their manifests. That enables them to be able to call the `killBackgroundProcesses()` method on `ActivityManager`. Supplied an application ID, `killBackgroundProcesses()` will terminate any background process(es) associated with that application. Normally, there will only be one such process, but if the app in question is using the `android:process` attribute in the manifest to have multiple processes, then all the app's processes will be terminated.

This termination is done using the same internal mechanism that is used by the “out-of-memory killer”, which is responsible for freeing up system RAM due to low memory conditions.

Killing vs. Force-Stopping

For ordinary users, there are a few options for terminating background processes. Using a task killer, or swiping the task off the overview screen on Android 4.0+, will terminate background processes. Both use `killBackgroundProcesses()` (or internal equivalents).

However, users can also go into the Settings app, find the app in the list of installed apps, and click a “Force Stop” button associated with that app. On the surface, this has a similar effect to the above techniques, as the background process is terminated. However, force-stopping the app also unschedules any `AlarmManager` or `JobScheduler` events for that app, plus moves the app back into the “stopped state”, blocking manifest-registered broadcast receivers. Hence, force-stopping an app has a much larger impact than does merely using a task killer.

A few devices have manufacturer-supplied task managers (a.k.a., task killers), where stopping an app from those apps actually does a force stop behind the scenes, rather than `killBackgroundProcesses()`. This is not a good idea, as force-stopping an app has the aforementioned side effects. Fortunately, third-party task killers cannot force-stop apps, barring any security flaws in Android that might make this possible.

Why Use One?

Nowadays, normally, users do not need task killers. Occasionally one can be useful, to stop a background process for a poorly-written app (e.g., one that powers on GPS but fails to let go of GPS when the app moves to the background). On most modern Android devices, swiping the app off the overview screen usually suffices, and so

TASKS

task killers are not nearly as crucial as they were in Android 1.x/2.x, where there was no such built-in background process management solution.

For developers, the problem with swiping an app off the overview screen is that it not only terminates background processes, but it also removes the task entirely. This makes it difficult to see what the behavior is when apps' processes terminate for more conventional reasons (e.g., out-of-memory killer) and how tasks tie into that. While developers have the ability to stop processes through development tools (e.g., the process list in DDMS), that just terminates the process, and it may do so slightly differently than does the out-of-memory killer. Hence, having a task killer around can be useful for experimentation purposes.

And, since getting a task killer on an emulator can be challenging (since emulators do not have access to the Play Store), having the source code for a simple task killer is useful for developers. So, let's look at how to implement a task killer.

A Killer Sample

The [Tasks/Nukesalot](#) sample application implements the Nukesalot app. This is a reworked version of the Launchalot sample from [elsewhere in the book](#). Launchalot lists the launchable activities and lets the user launch those activities by clicking on them in a `ListView`. Nukesalot lists the running applications and allows the user to kill those applications' background processes by clicking on them in a `ListView`.

Finding Killable Apps

First, we need to find apps that are eligible to be killed.

In `onCreate()` of the `MainActivity`, we get our hands on an `ActivityManager` system service. `ActivityManager` is not strictly tied to the UI construct known as activities, but rather to general “activity” of the user with respect to the device.

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.main);

    am=(ActivityManager) getSystemService(ACTIVITY_SERVICE);
}
```

(from [Tasks/Nukesalot/app/src/main/java/com/commonsware/android/nukesalot/Nukesalot.java](#))

TASKS

In `onResume()`, we then call a private `buildAdapter()` method to create an instance of an `AppAdapter` for us:

```
@Override
public void onResume() {
    super.onResume();

    adapter=buildAdapter();
    setListAdapter(adapter);
}
```

(from [Tasks/Nukesalot/app/src/main/java/com/commonsware/android/nukesalot/Nukesalot.java](https://github.com/CommonWare/android-nukesalot/blob/master/tasks/Nukesalot.java))

We do this in `onResume()` so that when our activity returns to the foreground, it shows a fresh list of running apps. This activity lacks the ability to detect new running processes on the fly, something that could be addressed by a manual refresh option (e.g., action bar item). The implementation of this is left as an exercise for the reader.

`buildAdapter()` needs to find out the application ID (a.k.a., package name) of the running applications. It would be easier to list all applications, but there is little point in listing apps that cannot be killed simply because they are not running. The roster of application IDs of the running apps is a `HashSet` named `runningPackages`, initially empty:

```
private AppAdapter buildAdapter() {
    HashSet<String> runningPackages=new HashSet<String>();

    for (ActivityManager.RunningAppProcessInfo proc :
        am.getRunningAppProcesses()) {
        for (String pkg : proc.pkgList) {
            runningPackages.add(pkg);
        }
    }

    PackageManager pm=getPackageManager();
    List<ApplicationInfo> apps=new ArrayList<ApplicationInfo>();

    for (ApplicationInfo app : pm.getInstalledApplications(0)) {
        if (runningPackages.contains(app.packageName)) {
            apps.add(app);
        }
    }

    Collections.sort(apps,
        new ApplicationInfo.DisplayNameComparator(pm));
}
```

TASKS

```
return(new AppAdapter(pm, apps));  
}
```

(from [Tasks/Nukesalot/app/src/main/java/com/commonsware/android/nuke-salot/NukeSalot.java](https://github.com/nuke-salot/nuke-salot/blob/master/app/src/main/java/com/commonsware/android/nuke-salot/NukeSalot.java))

We then iterate over the running application processes, obtained via a call to `getRunningAppProcesses()` on the `ActivityManager`. In theory (though it is unclear how this works in practice), a running app process could hold code from multiple packages. We find out those packages via the `pkgList` in each `RunningAppProcessInfo` object that we get back from `getRunningAppProcesses()`. We then iterate over the strings in `pkgList` and add each to `runningPackages`.

Next, in order to display icons and names for these apps, we really need `ApplicationInfo` objects for each app. Plus, it would be nice if these were in some logical order. So, we get a `PackageManager`, create an `ArrayList` of `ApplicationInfo` objects named `apps`, and iterate over all installed applications (via `getInstalledApplications()` on `PackageManager`). For each app, if its package name (via the `packageName` attribute on the `ApplicationInfo`) is in our `runningPackages`, we add the `ApplicationInfo` to the `ArrayList`. We then sort the `ArrayList` using an `ApplicationInfo.DisplayNameComparator` convenience class provided by the Android SDK, which will sort `ApplicationInfo` arrays based on the display name. We then wrap the `ApplicationInfo` list in an `AppAdapter` and return it.

Displaying Killable Apps

`AppAdapter` itself is an `ArrayAdapter` for `ApplicationInfo` objects, designed to render them in rows containing the app's icon and display name:

```
<?xml version="1.0" encoding="utf-8"?>  
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"  
    android:layout_width="match_parent"  
    android:layout_height="wrap_content"  
    android:orientation="horizontal"  
    >  
    <ImageView android:id="@+id/icon"  
        android:layout_width="48dp"  
        android:layout_height="48dp"  
        android:layout_alignParentLeft="true"  
        android:layout_margin="2dp"  
        android:scaleType="fitCenter"  
        android:layout_gravity="center_vertical"  
    />
```

TASKS

```
<TextView
    android:id="@+id/label"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:textSize="24sp"
    android:layout_margin="2dp"
    android:layout_gravity="center_vertical"
/>
</LinearLayout>
```

(from [Tasks/Nukesalot/app/src/main/res/layout/row.xml](#))

AppAdapter steals a page from CursorAdapter and has `getView()` delegate to `newView()` and `bindView()` methods. `newView()` is called when there is no row to recycle, and it just inflates the row layout. `bindView()` uses `PackageManager` to populate the icon and display name widgets using `loadIcon()` and `loadLabel()` calls:

```
class AppAdapter extends ArrayAdapter<ApplicationInfo> {
    private PackageManager pm=null;

    AppAdapter(PackageManager pm, List<ApplicationInfo> apps) {
        super(Nukesalot.this, R.layout.row, apps);
        this.pm=pm;
    }

    @Override
    public View getView(int position, View convertView,
                       ViewGroup parent) {
        if (convertView==null) {
            convertView=newView(parent);
        }

        bindView(position, convertView);

        return(convertView);
    }

    private View newView(ViewGroup parent) {
        return(getLayoutInflater().inflate(R.layout.row, parent, false));
    }

    private void bindView(int position, View row) {
        TextView label=(TextView)row.findViewById(R.id.label);

        label.setText(getItem(position).loadLabel(pm));
    }
}
```

TASKS

```
ImageView icon=(ImageView)row.findViewById(R.id.icon);

icon.setImageDrawable(getItem(position).loadIcon(pm));
}
}
```

(from [Tasks/Nukesalot/app/src/main/java/com/commonsware/android/nukesalot/Nukesalot.java](#))

`loadIcon()` and `loadLabel()` are methods on `ApplicationInfo` that, given a `PackageManager`, can find the proper resources for those items and retrieve them from the foreign app's package.

The result is a `ListView` filled with running apps... including Nukesalot itself:

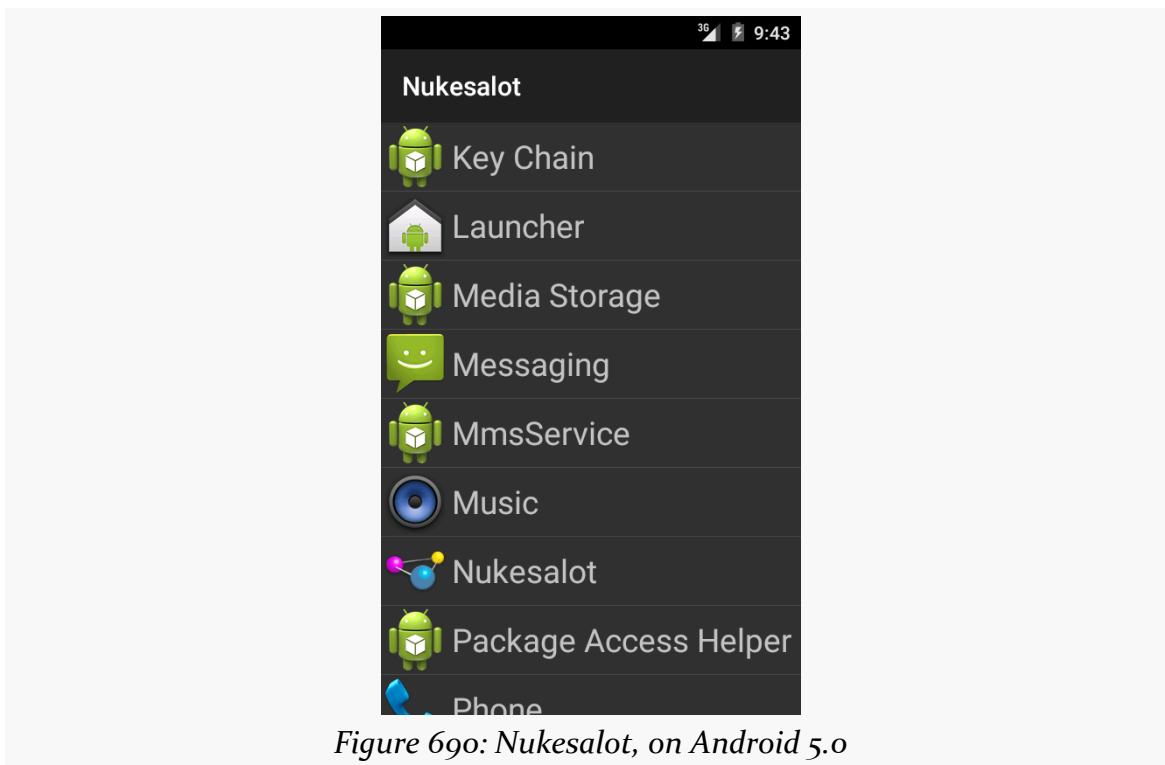

Figure 690: Nukesalot, on Android 5.0

That App Needed Killin'

The idea is that when the user taps on a row in the list, Nukesalot will go and terminate that app's process. So, in `onListItemClick()`, we determine the `ApplicationInfo` of the clicked-upon app, and call `killBackgroundProcesses()` on that app's package name. Then, we refresh the adapter, to show the updated roster of running apps:

TASKS

```
@Override
protected void onListItemClick(ListView l, View v,
                                int position, long id) {
    ApplicationInfo app=adapter.getItem(position);

    am.killBackgroundProcesses(app.packageName);
    adapter=buildAdapter();
    setListAdapter(adapter);
}
```

(from [Tasks/Nukesalot/app/src/main/java/com/commonsware/android/nukesalot/Nukesalot.java](#))

`killBackgroundProcesses()` requires the `KILL_BACKGROUND_PROCESSES` permission, which we have in the manifest:

```
<uses-permission android:name="android.permission.KILL_BACKGROUND_PROCESSES"/>
```

If you tap on a row for some ordinary Android app, other than Nukesalot itself, that process will be terminated. However:

- Nukesalot cannot kill itself, as it is not a background process, but rather is the foreground process. In principle, we could detect this case, `finish()` the activity, and fork a background thread to call `killBackgroundProcesses()` after a short delay to ensure that our process is categorized as a background process. In practice, that seems like an awful lot of work for a book example.
- Some system processes (e.g., “Android System”) simply cannot be killed using `killBackgroundProcesses()`.

More importantly, from the standpoint of this chapter, is that killing a background process using Nukesalot does not disturb the recent-tasks list. Our task still shows up there, even though we terminated the process for it, and that will be useful as we examine the behavior of Android’s task system.

A Canary for the Task’s Coal Mine

In order to see some of the effects of fussing with our tasks, we need an app where we can see when our saved instance state comes and goes. To that end, we have the [Tasks/TaskCanary](#) sample application. It consists of a single activity, with a UI that is merely a full-screen `EditText`. In addition to the automatic saving of the `EditText` contents in the saved instance state `Bundle`, we also keep track of the time we first worked with that `Bundle`, in a data member named `creationTime`, backed by a `STATE_CREATION_TIME` entry in the `Bundle` itself:

TASKS

```
package com.commonware.android.task.canary;

import android.app.Activity;
import android.content.Intent;
import android.os.Bundle;
import android.provider.Settings;
import android.util.Log;
import android.view.Menu;
import android.view.MenuItem;

public class MainActivity extends Activity {
    private static final String STATE_CREATION_TIME="creationTime";
    private long creationTime=-1L;

    @Override
    public void onCreate(Bundle state) {
        super.onCreate(state);
        setContentView(R.layout.activity_main);
    }

    @Override
    protected void onRestoreInstanceState(Bundle savedInstanceState) {
        super.onRestoreInstanceState(savedInstanceState);

        dumpBundleToLog("restore", savedInstanceState);
        creationTime=savedInstanceState.getLong(STATE_CREATION_TIME, -1L);
    }

    @Override
    protected void onSaveInstanceState(Bundle outState) {
        super.onSaveInstanceState(outState);

        outState.putLong(STATE_CREATION_TIME, getCreationTime());
        dumpBundleToLog("save", outState);
    }

    @Override
    public boolean onCreateOptionsMenu(Menu menu) {
        getMenuInflater().inflate(R.menu.actions, menu);

        return(super.onCreateOptionsMenu(menu));
    }

    @Override
    public boolean onOptionsItemSelected(MenuItem item) {
        if (item.getItemId()==R.id.settings) {
            startActivity(new Intent(Settings.ACTION_DATE_SETTINGS));
        }
    }
}
```

TASKS

```
else if (item.getItemId()==R.id.other) {
    startActivity(new Intent(this, OtherActivity.class));
}

return(super.onOptionsItemSelected(item));
}

private long getCreationTime() {
    if (creationTime==-1L) {
        creationTime=System.currentTimeMillis();
    }

    return(creationTime);
}

// inspired by http://stackoverflow.com/a/14948713/115145

private void dumpBundleToLog(String msg, Bundle b) {
    Log.d(getClass().getSimpleName(),
        String.format("Task ID #%d", getTaskId()));

    for (String key: b.keySet()) {
        Log.d(getClass().getSimpleName(),
            String.format("(%s) %s: %s", msg, key, b.get(key)));
    }
}
}
```

(from [Tasks/TaskCanary/app/src/main/java/com/commonsware/android/task/canary/MainActivity.java](#))

Each time we save and restore the instance state, we dump the Bundle to Logcat, so we can see what is in that Bundle. We wind up with lines like:

```
D/MainActivity: (save) android:viewHierarchyState: Bundle[...]
D/MainActivity: (save) creationTime: 1427032894794
D/MainActivity: (restore) android:viewHierarchyState: Bundle[...]
D/MainActivity: (restore) creationTime: 1427032894794
```

(where the ... is a bit long to reproduce in the book and is not essential for the sample)

This way, both in the UI and in the logs, we can confirm that our state is being saved and restored as expected... or perhaps not as expected, in some cases.

You will notice that we have a pair of action bar items. One will bring up a screen from the Settings app, which we will use to see [how this affects our task](#). The other

one will bring up another activity from our app, which we will use to explore [how to start a clean task](#).

The Default User Experience

With all that behind us, let's start talking about tasks, focusing first on what behavior the developer gets “out of the box”, with no task-specific logic in the app. In other words, what is the default user experience for an ordinary Android app?

NOTE: if you wish to reproduce the results described here, you will want to have Nukesalot and the Task Canary installed on your device or emulator.

Starting from the Home Screen

Assume that we are “starting from scratch”. For example, the user has installed your app (or bought a device with your app pre-installed) but has never run your app before. Or, perhaps the overview screen is cleared of all tasks.

If the user taps your home screen launcher icon, not only is a process forked to run your app, but a new task is created, and your app's task will appear in the overview screen.

(see! that wasn't so hard!)

To reproduce this behavior:

- Clear the overview screen of all tasks, by swiping them off the screen. Note that this may take some time on an Android 5.x device that is really being used (versus just being some test device), as there may be a *lot* of tasks to clear.
- Run your app, from the home screen or IDE.

Resuming from the Overview Screen

Eventually, the user wanders away from your app. Then, later on, the user returns to your app, by finding the task associated with your app in the overview screen and tapping upon it.

In the end, you wind up in the same state as before: you have a process for your app, and your task is still in the overview screen. How we get there depends a bit on what

TASKS

happened with your process, in between when you had been in the foreground and when the user taps on your task in the overview screen.

If your app's process was still running, nothing much happens of note, other than you return to the foreground. From a state standpoint, your app would be called with `onSaveInstanceState()` when the user left your app, but you will not be called with `onRestoreInstanceState()`, because your activity was not destroyed yet. Note that this assumes that you did not undergo a configuration change (e.g., user originally was in your app in portrait, then returned to you from the overview screen while the device was in landscape). In the case of a configuration change, your activity would be destroyed and recreated by default, and you *would* be called with `onRestoreInstanceState()`, but that would be due to the configuration change more so than the use of the task and the overview screen.

To reproduce the above behavior, given that your device was in the state after the “Starting from the Home Screen” section above:

- Press HOME to move your app to the background, and notice the “(saved)” entries being reported to Logcat.
- Quickly press RECENTS (or, if you have no such option, long-press HOME) to bring up the overview, and tap on your task there.

However, it is entirely possible that while your task is around that your process is terminated to free up memory for other processes. If the user returns to your app via the overview screen, a fresh process will be forked for your app. This would trigger a call to `onRestoreInstanceState()`, because your old activity no longer exists, because its process no longer exists.

To reproduce the above behavior, given that your device was in the state after the “Starting from the Home Screen” section above:

- Press HOME to move your app to the background, and notice the “(saved)” entries being reported to Logcat.
- Run Nukesalot, find the Task Canary in the list of running apps, and tap upon that entry to terminate its process. You should see its process go away in the list of debuggable processes in DDMS. You could also experiment with just terminating the process directly from DDMS, but Nukesalot may be a bit closer to “natural” device behavior, in terms of how the process is terminated.
- Press RECENTS (or, if you have no such option, long-press HOME) to bring up the overview, and tap on your task there. Note your “(restored)” Logcat

TASKS

entries, which should include the same `creationTime` as you saved, even though it is now in the future.

Note that if you leave a task for an extended period of time — say, 30 minutes or so — the task may be “cleared” when you return to it. This means that you are taken back to whatever the “root” activity of the task is, where by “root” we mean the original activity put into the task.

Starting Another App

Some apps only start up other activities within the same app. However, many apps start up activities from other apps, either directly via `startActivity()` or indirectly (e.g., clicking in links in a `WebView`). For example, the Task Canary app has an item in the action bar overflow that, when clicked, brings up the Settings screen for adjusting date and time settings.

You might think that when the user taps on this overflow item, and Task Canary calls `startActivity()`, that a new task is created. After all, the Settings app is a completely separate app from the Task Canary app.

However, try this:

- Clear the overview screen
- Launch Task Canary
- Choose the Settings action bar overflow item to bring up the date-and-time Settings screen
- Press HOME to bring up the home screen
- Press RECENTS or otherwise bring up the overview screen

You will see one entry in the overview screen, for Task Canary, rather than two. Furthermore, particularly on Android 5.x devices, you will see the Settings screen as the top-most activity within the Task Canary task:

TASKS

Figure 691: The Task Canary Task, on Android 5.1

However, suppose that instead of using `ACTION_DATE_SETTINGS` for the Intent, we used `ACTION_APN_SETTINGS` instead, to allow the user to view mobile access point names and such. You might think, given the above flow, that we would wind up with just one task, as we did with `ACTION_DATE_SETTINGS`. In reality, you will see two tasks, instead of just one:

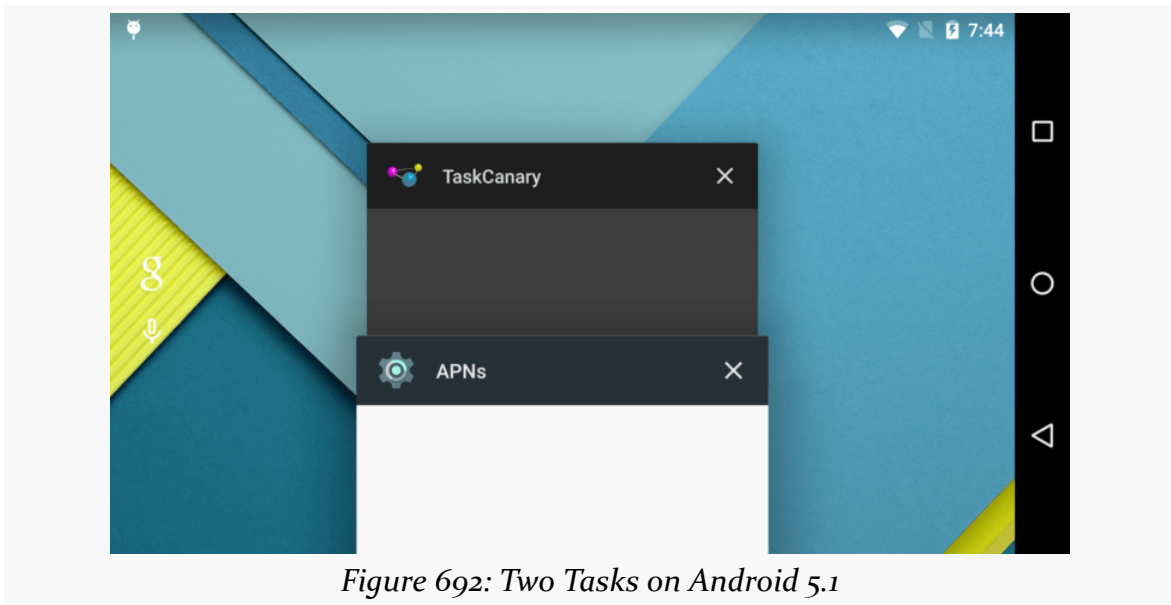

Figure 692: Two Tasks on Android 5.1

This is where things start to get a bit confusing.

Explaining the Default Behavior

With the user experience as background, let's now dive into what is really going on with these operations.

When Tasks are Created

A task is not created just because an activity is started. Otherwise, even individual apps would have lots of tasks, one per activity.

A task is not created just because a task from a different app is started. Otherwise, the two Settings scenarios above would have both resulted in a new task.

Instead, tasks are created when somebody *asks* for a task to be created. That “somebody” could be the author of the app calling `startActivity()` or the author of the activity being started.

There are three major approaches for indicating that a new task should be started: flags on the Intent used with `startActivity()`, task affinity values, and launch modes. We will get into launch modes [later in this chapter](#), as the normally-used launch modes have no impact on tasks. Instead, we will focus on the other two approaches here.

Task-Management Intent Flags

If you want to start an activity, and ensure that the activity starts in a new task, add `Intent.FLAG_ACTIVITY_NEW_TASK` to the flags on the Intent being used with `startActivity()`:

```
startActivity(new Intent(SOME_ACTION_STRING)
    .addFlags(Intent.FLAG_ACTIVITY_NEW_TASK))
```

What will happen, when you call `startActivity()` with `FLAG_ACTIVITY_NEW_TASK`, is that Android will see if there is a task that already has this activity in it. If there is, that task will be brought to the foreground, and the user will see whatever is on the top of that task's stack. Otherwise, if there is no task with this activity in it, Android will create a new task and associate a new instance of the activity with this task.

TASKS

This is what home screen launchers do. When you tap on a home screen launcher icon, if there is a task that has a copy of your home screen activity in it, that task is brought back to the foreground. Otherwise, a new task is started.

If you *also* add `Intent.FLAG_ACTIVITY_MULTIPLE_TASK`, then Android skips the search for existing tasks and unconditionally launches the activity into a new task. This is generally not a good idea, as the user can wind up with many copies of this activity, not know which one is which, and perhaps have difficulty getting back to the right one.

Task Affinities

By default, if Android needs to create a new task as a result of `FLAG_ACTIVITY_NEW_TASK`, it just creates a task. And, if there is no such flag on the `Intent`, Android will put the activity into the task of whoever called `startActivity()`.

If, however, the activity has an `android:taskAffinity` attribute in its `<activity>` element in the manifest, then Android will specifically start this activity in a certain task, identified by the string value of the attribute. Other activities with the same task affinity will also go into this task.

The reason why the two Settings screens behave differently is that the `ACTION_APN_SETTINGS` activity has a certain task affinity value, while `ACTION_DATE_SETTINGS` does not. The task affinity of the `ACTION_APN_SETTINGS` activity is shared by many, though not all, activities within the Settings app. Those activities, when started, will always go into the task identified by the affinity. Hence, when we start `ACTION_DATE_SETTINGS`, it goes in *our* task (because that activity has no affinity and we did not include `FLAG_ACTIVITY_NEW_TASK`), but when we start the `ACTION_APN_SETTINGS` activity, it goes into a Settings-specific task.

Note that you can also have the `android:taskAffinity` value defined on the `<application>` element, to provide a default task affinity for all activities. The overall default is "", or no affinity.

When Tasks are Removed

On Android 3.0 and higher, the user can get rid of a task by swiping the task off of the overview screen.

TASKS

Otherwise, prior to Android 5.0, a task would automatically go away after some amount of user activity, as there were only so many “slots” available for tasks.

On Android 5.0+, though, it is unclear if there is an upper bound to how many tasks can exist. Beyond that, tasks survive a reboot, as information about those tasks is persisted. We will get more into the ramifications of this, and how you can take advantage of it, [later in this chapter](#).

When Tasks (and Processes) are Resumed

A task will be resumed and brought back to the foreground in several situations, including:

- the user manually requests it via the overview screen, by clicking on one of the recent tasks
- if `FLAG_ACTIVITY_NEW_TASK` is added (without `FLAG_ACTIVITY_MULTIPLE_TASK`) to the Intent used to start an activity, and there is a task containing the activity in question
- if the `taskAffinity` for the activity being started ties it to another task
- if the [launch mode](#) for the activity being started ties it to another task

However, just because the task exists does not mean that the process(es) exist for the activities in the task. As needed, Android will fork fresh processes, to be able to load in the app’s code and start the necessary activities. Android will deliver to the newly-created activities the same Intent that was used to create the original incarnation of the activity (via `getIntent()`) and the saved instance state Bundle.

What Happens to Services

In theory, services are immune to task behavior. Tasks can come and go, and services are usually oblivious to this.

A service should be called with `onTaskStopped()` if a task associated with one or more of the app’s activities is removed. The service might use that as a signal that it too should shut itself down.

There appears to be [a quasi-documented android:stopWithTask attribute](#) on the `<service>` element in the manifest. The default is `false`, but if you override it to be `true` on your `<service>`, then `onTaskStopped()` will not be called, and Android will simply destroy your service when the task is removed.

However, as of Android 4.4, there are many reports that services may be destroyed when a task is removed, even without `android:stopWithTask="true"`, though on a slight delay. Developers concerned about this should keep an eye on [this issue](#) and [this issue](#), both for various hacky workarounds and for any signs that this is being permanently addressed.

What's Up with `onDestroy()`?

If the user swipes away the task using the overview screen, `onDestroy()` will be called on all outstanding activities.

If, however, you use Nukesalot to kill the background process, Android does *not* call `onDestroy()` on any outstanding activities. Since other task killers will use the same techniques as does Nukealot, this means that your `onDestroy()` methods will not be called when your process is terminated by those apps as well.

So, removing a *task* is a graceful exit, and Android calls `onDestroy()`, but an explicit termination of your process by another is a not-so-graceful exit, and Android skips `onDestroy()`.

As a result, as previously advised in this book and elsewhere, you cannot count on your `onDestroy()` methods being called, and you need to take this into account in terms of what sorts of code you put in them.

Basic Scenarios for Changing the Behavior

In many cases, the default behavior of tasks is just fine. However, there are many scenarios in which we may want to override the default behavior, routing activities to specific tasks, to have a better flow for the user.

Reusing an Activity

By default, each time you call `startActivity()`, a new instance of the activity is created. Depending upon the user flow, that may not be a bad approach. For example, it may be that the only logical path out of the started activity will be to press BACK and destroy it.

However, there will be plenty of cases where we will not want to keep creating new activity instances. For example, if you elect to have several activities reachable via a [nav drawer](#), you do not want to create fresh instances of activities that the user has

TASKS

already visited via that drawer. Otherwise, they will keep piling up, continuing to consume heap space. Instead, it would be better to try to reuse an existing activity instance, if one is available, creating a fresh one only if needed.

The most flexible approach for accomplishing this involves using a flag on the Intent used to start the activity: `Intent.FLAG_ACTIVITY_REORDER_TO_FRONT`. This tells Android to bring an existing activity matching our Intent to the foreground, if one already exists in our task. If there is no such activity, then go ahead and create a new instance.

The [Tasks/RoundRobin](#) sample application demonstrates this. It consists of two activities (`FirstActivity` and `SecondActivity`), each of whose UI consists of one really big button. Clicking the button should start the other activity, so clicking the button in `FirstActivity` should start an instance of `SecondActivity`. But, we want to reuse activity instances where available, and confirm that indeed we *are* reusing those instances.

`FirstActivity` accomplishes that by adding `FLAG_ACTIVITY_REORDER_TO_FRONT` to the Intent used to start `SecondActivity` when the button is clicked:

```
package com.commonware.android.tasks.roundrobin;

import android.app.Activity;
import android.content.Intent;
import android.os.Bundle;
import android.util.Log;
import android.view.View;

public class FirstActivity extends Activity implements View.OnClickListener {
    @Override
    protected void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        setContentView(R.layout.first);
        findViewById(R.id.button).setOnClickListener(this);

        Log.d(getClass().getSimpleName(),
            String.format("onCreate for %x", hashCode()));
    }

    @Override
    protected void onResume() {
        super.onResume();

        Log.d(getClass().getSimpleName(),
```

TASKS

```
        String.format("onResume for %x", hashCode());
    }

    @Override
    protected void onDestroy() {
        Log.d(getClass().getSimpleName(),
            String.format("onDestroy for %x", hashCode()));

        super.onDestroy();
    }

    @Override
    public void onClick(View view) {
        startActivity(new Intent(this, SecondActivity.class)
            .addFlags(Intent.FLAG_ACTIVITY_REORDER_TO_FRONT));
    }
}
```

(from [Tasks/RoundRobin/app/src/main/java/com/commonsware/android/tasks/roundrobin/FirstActivity.java](https://github.com/commonsware/android-tasks/blob/master/tasks/roundrobin/FirstActivity.java))

SecondActivity has a nearly identical implementation, just routing back to FirstActivity.

If you run the app, the user's perspective is that clicking the button “ping-pongs” the user between the two activities. Looking at Logcat, you will see new instances created the first time the user visits an activity, courtesy of the `Log.d()` call in `onCreate()`. But, if the user returns to an existing instance via the button click, you will see that `onCreate()` is not called, and that the `hashCode()` reported in `onResume()` matches the `hashCode()` of the previously-created instance of this activity:

```
D/FirstActivity: onCreate for b31b9430
D/FirstActivity: onResume for b31b9430
D/SecondActivity: onCreate for b31eb8a8
D/SecondActivity: onResume for b31eb8a8
D/FirstActivity: onResume for b31b9430
D/SecondActivity: onResume for b31eb8a8
```

If you use Nukesalot to terminate the process for RoundRobin, then return to RoundRobin (e.g., via the overview screen), you will see that Android has to create a new instance of whatever activity had been in the foreground, as the old instance went away when the old process did. An instance of the other activity will not be created until the user returns to it, such as via a click of the really big button. In other words, Android lazy-instantiates the activities in the task's back stack, only creating instances when it is absolutely required based upon user navigation.

Note that [launch modes](#) offer another way to control this behavior, having the activity being started indicate that its instance should always be reused. However, this is a specialty case, one that most apps will not require.

Forcing a Clean Task

Let's suppose that you have an app that requires in-app authentication, via some form of login screen. For example, your app's data is held in [SQLCipher for Android](#), and so you need the user to supply a passphrase for the database.

In the beginning, when your app is launched from the home screen, your LAUNCHER activity appears. If that is your login screen, all is good. You collect the passphrase, create your singleton instance of the SQLCipher-enabled SQLiteOpenHelper, and you can access the database.

Eventually, the user presses HOME, and time passes. Android terminates your process to free up system RAM. The user then tries returning to your existing task, such as via the overview screen. Android creates a fresh process for you and takes you to the activity on the top of that task's back stack. But at this point, your singleton SQLiteOpenHelper is gone, and you need to collect a passphrase again.

You might think that this is purely a UI issue. Rather than collecting the passphrase in an activity, you collect it in a fragment, one that your LAUNCHER activity uses directly, and one that other activities can use via a DialogFragment. This way, you can arrange for every activity to be able to complete the re-initialization of your process and give you access to the encrypted database again.

Another approach would be to say that you want to wipe out this task and start over, routing the user back to the LAUNCHER activity for authentication.

There are two main approaches for implementing this: setting Intent flags or using `android:clearTaskOnLaunch` in the manifest.

Starting a Cleared Task Yourself

One way to do that is to have each activity check to see if a new task is needed (e.g., "is the SQLiteOpenHelper singleton null?"). When that situation is detected, you call `startActivity()` for your LAUNCHER activity, with two flags: `FLAG_ACTIVITY_NEW_TASK` and `FLAG_ACTIVITY_CLEAR_TASK`.

TASKS

For example, the [Tasks/Taskсалot](#) sample application is a straight-up clone of Launchalot with only one change of substance: using `FLAG_ACTIVITY_CLEAR_TASK` instead of `FLAG_ACTIVITY_RESET_TASK_IF_NEEDED`:

```
@Override
protected void onItemClick(ListView l, View v,
                           int position, long id) {
    ResolveInfo launchable=adapter.getItem(position);
    ActivityInfo activity=launchable.activityInfo;
    ComponentName name=new ComponentName(activity.applicationInfo.packageName,
                                         activity.name);
    Intent i=new Intent(Intent.ACTION_MAIN);

    i.addCategory(Intent.CATEGORY_LAUNCHER);
    i.setFlags(Intent.FLAG_ACTIVITY_NEW_TASK |
              Intent.FLAG_ACTIVITY_CLEAR_TASK);
    i.setComponent(name);

    startActivity(i);
}
```

(from [Tasks/Taskсалot/app/src/main/java/com/commonsware/android/tasksalot/MainActivity.java](#))

To see this in action:

- Run the TaskCanary sample app and use the overflow to bring up OtherActivity
- Press HOME
- Run Taskсалot
- Click on the “Task Canary” entry in Taskсалot

At this point, you will see the TaskCanary sample app return to the screen. From the logs in Logcat, you will see it is the same task ID as before. Yet, you are seeing the FirstActivity. OtherActivity was removed from the task as part of `FLAG_ACTIVITY_CLEAR_TASK` processing.

This differs from what you see in a home screen, with `FLAG_ACTIVITY_RESET_TASK_IF_NEEDED`. If you run the same test, but rather than use Taskсалot, you tap on the “Task Canary” icon in the home screen launcher, the task will return to the foreground, but you will be taken to OtherActivity. `FLAG_ACTIVITY_CLEAR_TASK` *always* clears the task and makes the activity that you are starting up be the root of the newly-cleared task.

Always Starting a Cleared Task

Perhaps you *always* want to start with a cleared task, whenever the user returns to the task after having left it previously. In other words, you always want to start back at whatever your task's root activity is, which is typically your launcher activity.

To do this, simply have `android:clearTaskOnLaunch="true"` on that launcher activity. Then, for any task where that activity is the root, when the user returns to the task, any other activities in the task are [reparented](#) (if applicable) or dropped.

Note, though, that this does not mean that you get a new *process*. Hence, any singletons you had before may or may not still be there.

So, in the authentication scenario described above, using `android:clearTaskOnLaunch="true"` would take the user back to your initial activity, where you can perform the authentication. However, if you detect that the `SQLiteOpenHelper` still exists, and therefore you do not need the user to log in again, you could switch over to showing your initial content (e.g., run a `FragmentTransaction`).

This is far simpler than having the detect-the-null-singleton-on-each-activity approach. However, the downside is that the user loses context. If they were six activities deep into your app, and they get interrupted by a phone call, when they come back to your app, they are back at the beginning.

Launching an App Into a New Task

A home screen launcher app, when it invokes the user's selected activity, will use code something like this from the `Launchalot` sample:

```
@Override
protected void onItemClick(ListView l, View v,
                            int position, long id) {
    ResolveInfo launchable=adapter.getItem(position);
    ActivityInfo activity=launchable.activityInfo;
    ComponentName name=new ComponentName(activity.applicationInfo.packageName,
                                         activity.name);

    Intent i=new Intent(Intent.ACTION_MAIN);

    i.addCategory(Intent.CATEGORY_LAUNCHER);
    i.setFlags(Intent.FLAG_ACTIVITY_NEW_TASK |
              Intent.FLAG_ACTIVITY_RESET_TASK_IF_NEEDED);
    i.setComponent(name);
}
```

TASKS

```
startActivity(i);  
}
```

(from [Introspection/Launchalot/app/src/main/java/com/commonsware/android/launchalot/Launchalot.java](https://github.com/Introspection/Launchalot/blob/master/app/src/main/java/com/commonsware/android/launchalot/Launchalot.java))

Here, we:

- Create a `ComponentName` identifying the specific activity in the specific app to be started (in this case, based on the `ResolveInfo` that the user chose)
- Create an `Intent` for the `MAIN` action and the `LAUNCHER` category
- Set the `FLAG_ACTIVITY_NEW_TASK` and the `FLAG_ACTIVITY_RESET_TASK_IF_NEEDED` flags in the `Intent`
- Attach the `ComponentName` to the `Intent`, to convert it from an implicit `Intent` into an explicit `Intent`
- Start the activity using the `Intent`

`FLAG_ACTIVITY_NEW_TASK` indicates that we want the activity being started to be the root of a new task. If there is no outstanding task for this app, a new task will be created, a new activity instance will be created, and that activity will be the root of the task. Here, “root” means that if the user presses `BACK` and destroys the activity, the task itself is removed and the user returns to the home screen.

However, despite its name, `FLAG_ACTIVITY_NEW_TASK` does not necessarily create a new task. If there is an existing task for this app containing this activity, that task is brought back to the foreground and is left intact. The activity we request is not created, let alone brought to the foreground.

That is where `FLAG_ACTIVITY_RESET_TASK_IF_NEEDED` comes in. It ensures that the task that is brought to the foreground is showing the requested activity. This may involve [reparenting activities](#) as well.

Another possibility, instead of `FLAG_ACTIVITY_RESET_TASK_IF_NEEDED`, is `FLAG_ACTIVITY_MULTIPLE_TASK`. This *always* starts a fresh task, with a fresh instance of the requested activity in the root of that task. However, this now may mean that the user has multiple tasks for the same app, which may be confusing in some circumstances. However, this also lies at the core of [Android 5.0's documents-as-tasks support](#) and therefore may become more familiar to users over time.

The Invisible Activity

Several sample apps in this book use an “invisible activity”, one with the theme set to `Theme.Translucent.NoTitleBar`. These are useful in cases where something outside your app needs an activity, but you do not really have a UI that you want to display. In the case of the book samples, having a LAUNCHER activity makes it much easier for readers like you to simply run the samples from the IDE.

However, those sample apps usually do not have any other activities. The invisible activity is just there to kick-start something else, such as `AlarmManager` events.

However, if you have a mix of invisible and regular activities in an app, your invisible activities still wind up potentially having a visible impact.

For example, suppose that we have an ordinary Android app, with regular activities. However, we want a home screen shortcut icon to allow the user to start something in the background, such as playing music. While an app widget would allow us to control what happens when the user taps on an icon in that app widget, a home screen shortcut icon *always* launches an activity. So, we make the start-the-music activity invisible via `Theme.Translucent.NoTitleBar`.

If the user taps on that shortcut, and none of our other activities are part of a task, things proceed as expected: the music starts and the user sees nothing (other than perhaps a `Toast` that we show to let the user know that we are responding to their request).

But, if one or more of our activities are in some task, launching the invisible activity *brings the task back to the foreground*. While our invisible activity is still invisible, the user now sees whatever other activity of ours they had last been in. It is possible that this is a feature, and not a bug, for some apps. But, in other cases, we might want the invisible activity to not have this effect.

The solution: task affinity.

Your ordinary activities can use the default task affinity, or have other task affinities as needs dictate. Your invisible activity, though, would have an `android:taskAffinity` value that is distinct from all others, to force it into its own task. That way, when the user taps on the shortcut, the invisible activity routes to its own task. That task will not yet exist, so the invisible activity causes the task to be created. When the invisible activity calls `finish()` to destroy itself after kicking off the background work, the task is now empty and is removed. Since this was a new

task, no existing UI would be brought back to the foreground, and since the task is removed in the end, we are “reset” for the next time the user taps on the shortcut.

Reparenting Tasks

One of the more unusual features of Android’s task system is the ability for activities to be “reparented”, or moved from one task to another. On the surface, this feels a bit odd, as if a Web page on one browser tab might magically show up in a separate browser tab, just via navigation. And, in truth, it is a specialized use case, but one that could conceivably apply to your app.

Suppose that you were writing an SMS client. You have an activity that is your message composer, where the user can type in a text message to send to somebody. You export that activity, with Intent actions like ACTION_SEND and ACTION_SENDTO. A third-party app, using one of those Intent actions, starts up your message composer activity. In the absence of a taskAffinity to stipulate otherwise, by default, your message composer activity will be in the task of the third-party app.

Now, suppose that the user fails to actually send a message, such as by pressing HOME from the third-party app’s task. Some time later, the user taps on your app’s home screen launcher icon. At this point, there are two possibilities as to what happens:

1. You may decide that you want to have the already-running message composer activity appear, to remind the user that they were in the middle of composing a text message and failed to either send it or explicitly BACK out of the activity.
2. You may decide that you do not care, and you are willing to ignore that outstanding message composer activity instance.

The default is option #2. If, instead, you want to offer option #1, that is where task reparenting comes into play.

On your <activity> (or on <application> to set an app-wide default), you can have `android:allowTaskReparenting="true"`. This indicates to Android that the message composing activity, that is on some other app’s task, can move to your app’s task when that task is created.

The trigger for this “reparenting” is the task affinity. If you do not specify a task affinity for an activity, the default affinity is for a task rooted in one of your app’s activities, typically the launcher activity. In some circumstances, when a task for

TASKS

your app is created, Android will search through other tasks to see if there is any activity, in another task, that has an affinity for your task and allows reparenting. If there is a match, that activity is brought into your task.

The “some circumstances” mentioned in the preceding paragraph is something using two Intent flags when calling `startActivity()`:

- `FLAG_ACTIVITY_NEW_TASK`, to create a new task if one is needed, and
- `FLAG_ACTIVITY_RESET_TASK_IF_NEEDED`, to clear out the task if it already has contents *and* reparent any activities in other tasks to this one if appropriate

As it turns out, home screen launchers are supposed to use this pair of flags when they respond to the user tapping on a home screen launcher icon.

The [Tasks/ReparentDemo](#) sample Android Studio project contains a pair of applications as modules that demonstrate this effect, based on David Wasser’s [epic Stack Overflow answer](#).

One module, `app/`, contains an application with two activities, where the second activity (`ReparentableActivity`) has `android:allowTaskReparenting="true"`:

```
<manifest
  xmlns:android="http://schemas.android.com/apk/res/android"
  package="com.commonware.android.tasks.reparent">

  <application
    android:allowBackup="true"
    android:label="@string/app_name"
    android:icon="@drawable/ic_launcher">
    <activity android:name=".MainActivity">
      <intent-filter>
        <action android:name="android.intent.action.MAIN"/>
        <category android:name="android.intent.category.LAUNCHER"/>
      </intent-filter>
    </activity>
    <activity
      android:name=".ReparentableActivity"
      android:allowTaskReparenting="true">
      <intent-filter>
        <action android:name="com.commonware.android.tasks.reparent.WHEEEEE"/>
        <category android:name="android.intent.category.DEFAULT"/>
      </intent-filter>
    </activity>
  </application>
</manifest>
```

TASKS

(from [Tasks/ReparentDemo/app/src/main/AndroidManifest.xml](#))

The two activities just display static messages, indicating which of those two activities you are seeing in the foreground. They also log process and task IDs to Logcat. MainActivity does that in onCreate():

```
package com.commonware.android.tasks.reparent;

import android.app.Activity;
import android.os.Bundle;
import android.util.Log;

public class MainActivity extends Activity {
    @Override
    public void onCreate(Bundle state) {
        super.onCreate(state);
        setContentView(R.layout.main);

        Log.d(getApplicationInfo().loadLabel(getPackageManager()).toString(),
            String.format("Process ID %d, Task ID %d",
                android.os.Process.myPid(), getTaskId()));
    }
}
```

(from [Tasks/ReparentDemo/app/src/main/java/com/commonware/android/tasks/reparent/MainActivity.java](#))

ReparentableActivity logs the same information in onResume():

```
package com.commonware.android.tasks.reparent;

import android.app.Activity;
import android.os.Bundle;
import android.util.Log;

public class ReparentableActivity extends Activity {
    @Override
    public void onCreate(Bundle state) {
        super.onCreate(state);
        setContentView(R.layout.reparent);
    }

    @Override
    public void onResume() {
        super.onResume();

        Log.d(getClass().getSimpleName(),
            String.format("Process ID %d, Task ID %d",
```

TASKS

```
        android.os.Process.myPid(), getTaskId());
    }
}
```

(from [Tasks/ReparentDemo/app/src/main/java/com/commonsware/android/tasks/repair/ReparentableActivity.java](#))

The other module, `app2/`, contains an application with one activity, whose UI consists of one really big button. Clicking that button triggers a `launch()` method that calls `startActivity()` on an Intent identifying the `ReparentableActivity` from the first app:

```
package com.commonsware.android.tasks.reparent.app2;

import android.app.Activity;
import android.content.Intent;
import android.os.Bundle;
import android.util.Log;
import android.view.View;

public class MainActivity extends Activity {
    @Override
    public void onCreate(Bundle state) {
        super.onCreate(state);
        setContentView(R.layout.main);

        Log.d(getApplicationInfo().loadLabel(getPackageManager()).toString(),
            String.format("Process ID %d, Task ID %d",
                android.os.Process.myPid(), getTaskId()));
    }

    public void launch(View v) {
        startActivity(new Intent("com.commonsware.android.tasks.reparent.WHEEEEE"));
    }
}
```

(from [Tasks/ReparentDemo/app2/src/main/java/com/commonsware/android/tasks/repair/app2/MainActivity.java](#))

To see this behavior in action, install both apps. If you run them straight from your IDE, you will want to clear out all relevant tasks, either by swiping them off the recent-tasks list (or by rebooting the device or emulator, if it runs Android 4.4 or lower).

Then, start up the “Reparent Demo Aux” app (from the `app2/` module). Click the button, and you will see the `ReparentableActivity` appear. If you press HOME, bring up the recent-tasks list, and go back to this task, you will see the same `ReparentableActivity`. The task, however, is for “Reparent Demo Aux”.

Now, press HOME, then start up the “Reparent Demo” app (from the `app/` module). Rather than seeing the `MainActivity` from that app, you see the `ReparentableActivity` instance from before. The logs will illustrate that your

TASKS

process ID has not changed, but that the task ID for this activity *has* changed, from the task ID used by the app2/ app to the task ID created for app/. The activity has been reparented.

The use of `FLAG_ACTIVITY_RESET_TASK_IF_NEEDED` may sound a lot like `FLAG_ACTIVITY_CLEAR_TASK`. The “if needed” part comes into play in two cases:

- If a new task is being created, the “reset” work is really the reparenting described above
- If an existing task is being brought back to the foreground, then get rid of resettable activities

Here, by “resettable activities”, we mean:

- Activities launched with the `FLAG_ACTIVITY_CLEAR_WHEN_TASK_RESET` flag
- Any activities that are higher on the back stack than other explicitly resettable activities

So, if our back stack consists of activities A-B-C-D, and C was started with `FLAG_ACTIVITY_CLEAR_WHEN_TASK_RESET`, and we start up one of these activities (say, A) with `FLAG_ACTIVITY_RESET_TASK_IF_NEEDED`, and this existing task is coming back to the foreground, C and D will be cleared from the task. The user ordinarily would be taken to activity D, but instead will be taken to activity B, because C is explicitly resettable and D is higher on the back stack.

The Self-Destructing Activity

Sometimes, you only want an activity around while it is in the foreground and the user can see it. Once the user leaves the app, you no longer want that activity to exist. For example, a bank app showing bank account details might want this behavior, so that highly-sensitive information like this does not hang around. Or, you might want this for certain activities that are memory-intensive, so they release their heap space and reduce the odds of an `OutOfMemoryError`.

You could attempt to manage this yourself, via timely calls to `finish()`, but catching all the cases when `finish()` is needed could get troublesome.

Instead, Android has a pair of options to have no-history activities: activities that automatically finish when the user leaves them:

TASKS

- An activity can decide for itself that it should be removed upon a task switch via the `android:noHistory` attribute on the `<activity>` in the manifest
- You can decide ad-hoc to have activities exhibit this behavior by adding `Intent.FLAG_ACTIVITY_NO_HISTORY` on the `Intent` used to start those activities

You can see these in action in the [Tasks/NoHistory](#) sample application. This is a near-clone of a simple two-activity app that we saw back when we first learned about [how to have multiple activities](#).

There are only two real differences in this version of the sample app.

First, the launcher activity (`MainActivity`) has `android:noHistory="true"` on its `<activity>` element:

```
<activity
  android:name=".MainActivity"
  android:label="@string/app_name"
  android:noHistory="true">
  <intent-filter>
    <action android:name="android.intent.action.MAIN"/>

    <category android:name="android.intent.category.LAUNCHER"/>
  </intent-filter>
</activity>
```

(from [Tasks/NoHistory/app/src/main/AndroidManifest.xml](#))

Second, when that activity goes to start `OtherActivity`, it adds `FLAG_ACTIVITY_NO_HISTORY` to the `Intent` used with `startActivity()`:

```
public void showOther(View v) {
  Intent other=new Intent(this, OtherActivity.class);

  other.putExtra(OtherActivity.EXTRA_MESSAGE,
    getString(R.string.other));
  other.addFlags(Intent.FLAG_ACTIVITY_NO_HISTORY);

  startActivity(other);
}
```

(from [Tasks/NoHistory/app/src/main/java/com/commonsware/android/tasks/nohistory/MainActivity.java](#))

Both of these inherit from the original sample's `LifecycleLoggingActivity`, which just logs messages to Logcat on the major lifecycle methods. If you run the app, click

TASKS

the big button to go from MainActivity to OtherActivity, then switch to some other app (via the overview screen, via the home screen launcher, etc.), you will see that both activities are destroyed, even though we do not press BACK, call finish(), or do anything else ourselves to destroy them.

This has a key side-effect: you cannot combine no-history with startActivityForResult() especially well. If the activity that calls startActivityForResult() has no-history enabled (via the manifest attribute or the Intent flag), it will simply not be called with onActivityResult().

A related attribute is android:finishOnTaskLaunch. If set to true, and if the user leaves the task and returns to it, the activity is destroyed. Whereas android:noHistory removes the activity when the user leaves the *activity*, android:finishOnTaskLaunch only removes the activity when the user leaves the task and returns to it.

The Hidden Task

Perhaps you have a use case where you want your entire task to be hidden from the overview screen.

To do that, you can indicate that the activity that is the root of the task (e.g., your launcher activity) is to be “excluded from recents”. To do that, you can:

- Add android:excludeFromRecents="true" to the appropriate <activity> element in your manifest, or
- Add Intent.FLAG_ACTIVITY_EXCLUDE_FROM_RECENTS to the Intent used to start up the activity and its task

Note that this only matters if the activity in question is the task root (i.e., the one that started the task). Having this setting on other activities higher in the back stack will have no effect on the visibility of the task.

Also, please note that this does not eliminate the task itself. It merely hides it from the overview screen. So, for example, suppose you were to:

- Add android:excludeFromRecents="true" to MainActivity in the TaskCanary sample
- Run the sample app
- Press HOME and note the task ID that shows up in Logcat
- Press RECENTS and note that the task does not show up there

TASKS

- Return to the home screen, find TaskCanary in the launcher, and tap on the launcher icon
- Press HOME again and note the task ID that shows up in Logcat

You will see that those task IDs are the same. So, the task is there, and we can return to that task, but the task is merely suppressed from the listing shown in the overview screen.

Dealing with the Persistent Tasks

As noted previously in this chapter, on Android 5.0+, tasks live forever, insofar as they survive a reboot. That, coupled with a seemingly-infinite roster of recent tasks — compared with rather finite lists in earlier versions of Android — means that your app usually will be brought back from an existing task on Android 5.0+.

However, there are a few key differences.

The State of Your State

For normal process termination, in between device reboots, the `Bundle` that we get in `onSaveInstanceState()` is held onto in RAM by some core OS process. Of course, on a reboot, that process is terminated along with everything else. And a `Bundle` can hold onto objects that, while perhaps `Parcelable`, are not designed to be persisted.

The default behavior is that when your task is brought back to the foreground after a reboot, only the task's root activity is created, and that is the only activity in the task. This effectively mimics the behavior of pre-Android 5.0 versions of Android.

However, if you want to, you can control a bit more how your task behaves on a reboot.

Your `<activity>` element in the manifest can have [a largely-undocumented `android:persistableMode` attribute](#). If you set this to `persistAcrossReboots` on the activity that serves as the root of your task (e.g., your launcher activity), then you will be able to override three additional methods on your `Activity`:

- `onCreate()`
- `onSaveInstanceState()`
- `onRestoreInstanceState()`

TASKS

Right now, you may think that the author of this book is drunk, as we covered those methods already, far earlier in the book.

However, what API Level 21 adds, for `persistAcrossReboots` activities, are flavors of those methods that take two parameters: a `Bundle` (as normal) and a `PersistableBundle`. Values that you store in the latter parameter will be delivered to you when your activity is re-created as part of your task coming back to the foreground, even after a reboot.

Note that all of the above requires that you set your `compileSdkVersion` to 21 or higher.

`PersistableBundle` allows you to save `int`, `long`, `double`, and `String` values, along with arrays of each. On Android 5.1+, you can also save `boolean` and arrays of `boolean` values. Notably, you cannot put a `Parcelable` (or, strangely, a `Serializable`) in a `PersistableBundle`.

If your activity has `persistAcrossReboots` set — as does `MainActivity` in the [Tasks/PersistentCanary](#) sample application — you will be called both with the single-parameter and dual-parameter versions of those methods, in that order. Unless your app has a `minSdkVersion` of 21 or higher, you will probably wind up overriding both versions of each method, where you put stuff in the `Bundle` in the single-parameter method and you put stuff in the `PersistableBundle` in the dual-parameter method. Since versions of Android prior to 5.0 do not know about `PersistableBundle` or methods that take one, only the single-parameter versions of those methods will be called on those devices. If your `minSdkVersion` is 21 or higher, though, you could just override the dual-parameter versions of the methods and work with both `Bundle` and `PersistableBundle` as needed.

Where You Return To

Normally, if your task is in the overview screen, and the user returns to it, the user will be taken to whatever activity was at the top of the back stack.

However, if the device reboots, and the user returns to your task, what happens depends on that semi-documented `persistableMode` value:

- If the value for the root activity of the task is `persistNever`, the task is not persisted across reboots

TASKS

- If the value for the root activity of the task is `persistRootOnly`, the task will be persisted, but only for that root activity; other activities higher on the back stack are discarded
- If the value for the root activity of the task is `persistAcrossReboots`, then not only is the task persisted for the root activity, but other activities on the back stack are also persisted if they too have `persistAcrossReboots` (and were not launched with the `FLAG_CLEAR_TASK_WHEN_RESET` flag)

So, in the case of `PersistentCanary`, even if you use the overflow to bring up the date-and-time Settings screen, since that activity has the default `persistRootOnly` value for `persistableMode`, only the `MainActivity` will be in the task after a reboot.

Documents As Tasks

Tasks used to be relatively app-centric. By and large, each app had its own task, and just one task.

Android 5.0 extended the task system to support the notion of “documents” as tasks. Now, an app may be in several tasks, with different tasks focused on different “documents” or other specific contexts.

The vision is that this would be used by:

- Web browsers, where different browser tabs would be represented as separate tasks
- Editors, where different editing sessions on different content could be represented as separate tasks
- And so on

The benefit to the user is a standard way to switch between these different contexts, by means of the overview screen. The risk is that the overview screen becomes unwieldy, choked with too many entries to sift through.

When You Should Do This

An app should open a new “document” based on some specific explicit “open” operation by the user. So, for example:

- If the user asks to open a new “tab” in a browser, that could start a new document

TASKS

- If the user asks to open a new file into an editor, that *might* start a new document, if you feel that the user understands that there are N other documents out there already opened in this editor
- If the user launches one of your activities from outside of the home screen, such as by clicking on a link in a Web browser, that might start a new document, to keep that work separate from any past work that might be part of other active tasks

Conversely, an app should not open a new document based on pure navigation operations:

- Swiping to a new page in a ViewPager should not open a new document
- Choosing an item in a nav drawer should not open a new document
- Tapping on an action bar item on its own should not open a new document, though it might lead the user down a path to open a new document

Adding a Document

You have a few options for launching an activity as a new document, indicating that it should have a separate entry on the Android 5.0+ overview screen.

android:documentLaunchMode

If you always want this activity to form the basis of a new document, add `android:documentLaunchMode="always"` to the `<activity>` element of your manifest, and you are done. Every time you start up an instance, you will get a new document.

This can be seen in the [Tasks/Docs](#) sample application, which has an `EditorActivity` with the aforementioned attribute:

```
<activity
  android:name=".EditorActivity"
  android:documentLaunchMode="always"
  android:maxRecents="3"
  android:autoRemoveFromRecents="true"/>
```

(from [Tasks/Docs/app/src/main/AndroidManifest.xml](#))

(we will cover those other new attributes shortly)

There are four possible values for `android:documentLaunchMode`:

TASKS

- `always`, as noted, always starts a new document
- `intoExisting`, which looks for an existing document, where the root activity is the same class and the `Intent` is for the same `Uri`, and brings it back to the foreground, or starts a new document if a match cannot be found
- `never` prevents this activity from ever being launched as a new document
- `none`, which is the default, indicates that the activity will only be launched as a new document if `Intent` flags indicate that it should, as will be explained shortly

Since `intoExisting` depends upon `Uri` matches, you only want to use `intoExisting` if you are passing `Uri` values into the activity when starting it. Otherwise, use `always`.

FLAG_ACTIVITY_NEW_DOCUMENT

To conditionally launch an activity as a new document, have its `android:documentLaunchMode` set to `none` (or missing, since that is the default), and add `Intent.FLAG_ACTIVITY_NEW_DOCUMENT` to the `Intent` that is used to start up the activity that would represent a new document. This will have the behavior akin to `intoExisting` for `android:documentLaunchMode`, meaning that Android will search for a matching document and bring it back to the foreground if the match is available.

To replicate `always` functionality, add both `Intent.FLAG_ACTIVITY_NEW_DOCUMENT` and `Intent.FLAG_ACTIVITY_MULTIPLE_TASK` to the `Intent`.

Capping the Number of Documents

By default, you can launch as many documents as you want. However, unless you get rid of the document (as will be described below), or the user gets rid of the document (by swiping it off the overview screen), your roster of documents can keep piling up. Users may get frustrated if their overview screen is flooded by entries for your app.

You can employ an automatic least-recently-used (LRU) algorithm here by adding `android:maxRecents` to the `<activity>` that is the root of the task for the document. This indicates the maximum number of entries there should be in the overview screen for that activity, where Android will remove older tasks to make way for new ones if needed.

So, in the Docs sample, `android:maxRecents="3"` limits the number of `EditorActivity` tasks to 3; if the user tries opening more than this, older ones are quietly removed.

Note that the default value for `android:maxRecents` is 16. Also, there is a cap, ranging from 25 to 50, depending on device RAM — you will be unable to set it higher than this.

Removing and Retaining Documents

Android's default behavior is that the document will exist forever, or until the user swipes it off the overview screen.

It is rather unlikely that this is really the behavior that you or your users will want. Hence, you are going to want to take some steps to ensure that your documents will go away from the overview screen when they are no longer needed.

The simplest solution is to add `android:autoRemoveFromRecents="true"`. This indicates that once the root activity is finished (e.g., the user presses `BACK`), the document is removed. By default, pressing `BACK` does *not* remove the document, so you need to opt into this behavior.

However, that approach assumes that it is fairly easy for the user to get back to the task's root activity and press `BACK`. If you have a complex navigation of activities within the “document”, it may not be easy for the user to trigger document removal this way.

You can also forcibly get rid of the document by calling `finishAndRemoveTask()` yourself on an activity in the task. For example, in a tabbed Web browser, if you have a “close tab” UI element (e.g., action bar item), that could call `finishAndRemoveTask()` to get rid of the “document”.

Other Task-Related Activity Properties

There are other attributes that you can place on your `<activity>` element in the manifest that have impacts on how that activity participates with the task system.

launchMode

Occasionally, particular techniques become much too popular in Android development, courtesy of some blog posts or other resources touting them as “quick hacks” to address certain issues. The `android:launchMode` attribute is one of those. Most Android apps should have no need to change `launchMode` off of its default value of `standard`, or occasionally `singleTop`. Yet, because the Android task system is rather confusing, some developers latch onto other launch modes and use them in places where there are better, more fine-grained solutions.

That being said, let’s explore the launch modes, with the help from the fine people at [Novoda](#). The Novoda developers released [an app on the Play Store](#), and an [accompanying GitHub repo](#) that helps to illustrate the launch modes.

That app has four activities, one for each of the four launch modes:

- `standard`
- `singleTop`
- `singleTask`
- `singleInstance`

The launcher activity is the `standard` activity. Each activity has four buttons, to start up that activity via `startActivity()`, by default with no particular Intent flags (though there’s a legacy options menu that allows you to play with those as well). The color-coded UI for each activity also shows a unique identifier of the activity, the task ID of the task that the activity is in, the lifecycle methods that were invoked on that instance, and a set of stacked bars designed to illustrate what should be on the back stack for that task (using some techniques of dubious reliability, but the sort of thing that should be OK for a demo app like this).

So, when we launch the app, we get a green UI for a `standard` activity:

TASKS

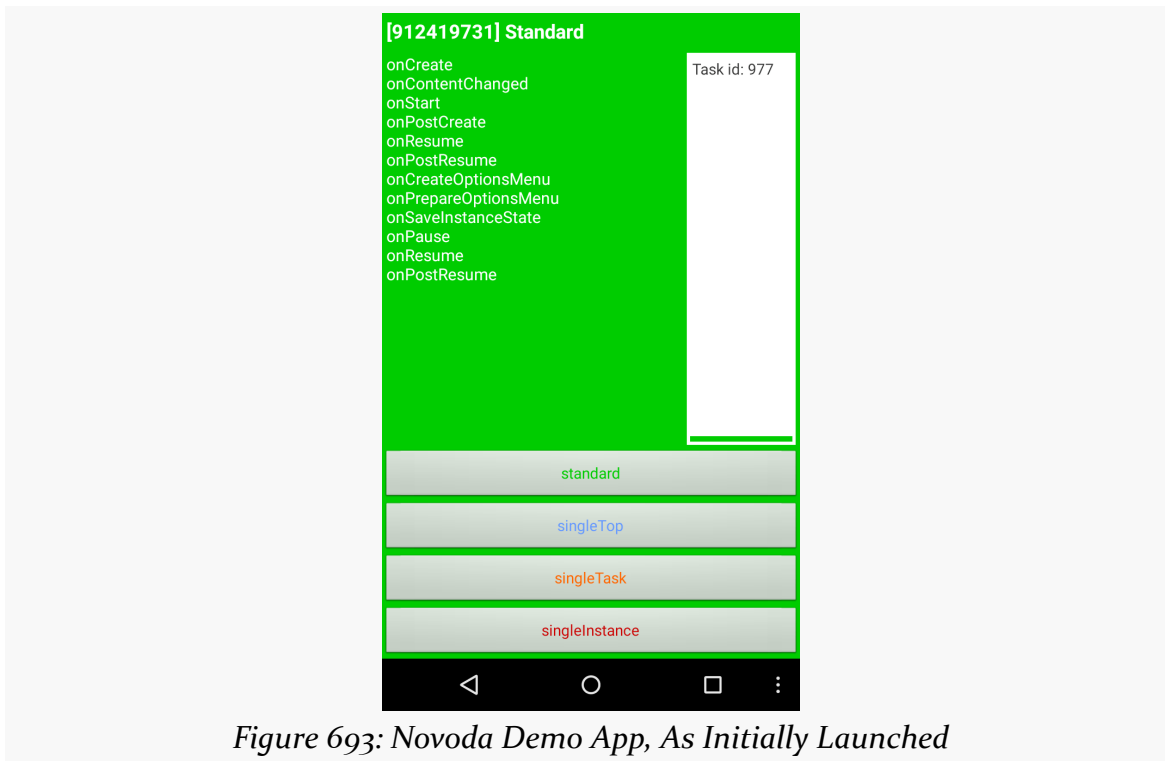

Figure 693: Novoda Demo App, As Initially Launched

singleTop

Using `singleTop` for the `launchMode` has one effect: controlling whether a new instance of the activity is created. Normally, calling `startActivity()` will create a new instance of the activity, unless `Intent` flags dictate otherwise. With `singleTop`, if the activity being started is already at the top of its stack, that existing instance is simply called with `onNewIntent()`. Otherwise, `singleTop` behaves as does `standard`.

So, if we tap the button to launch a `singleTop` method in the Novoda demo app, from our earlier state, we get a blue `singleTop` activity:

TASKS

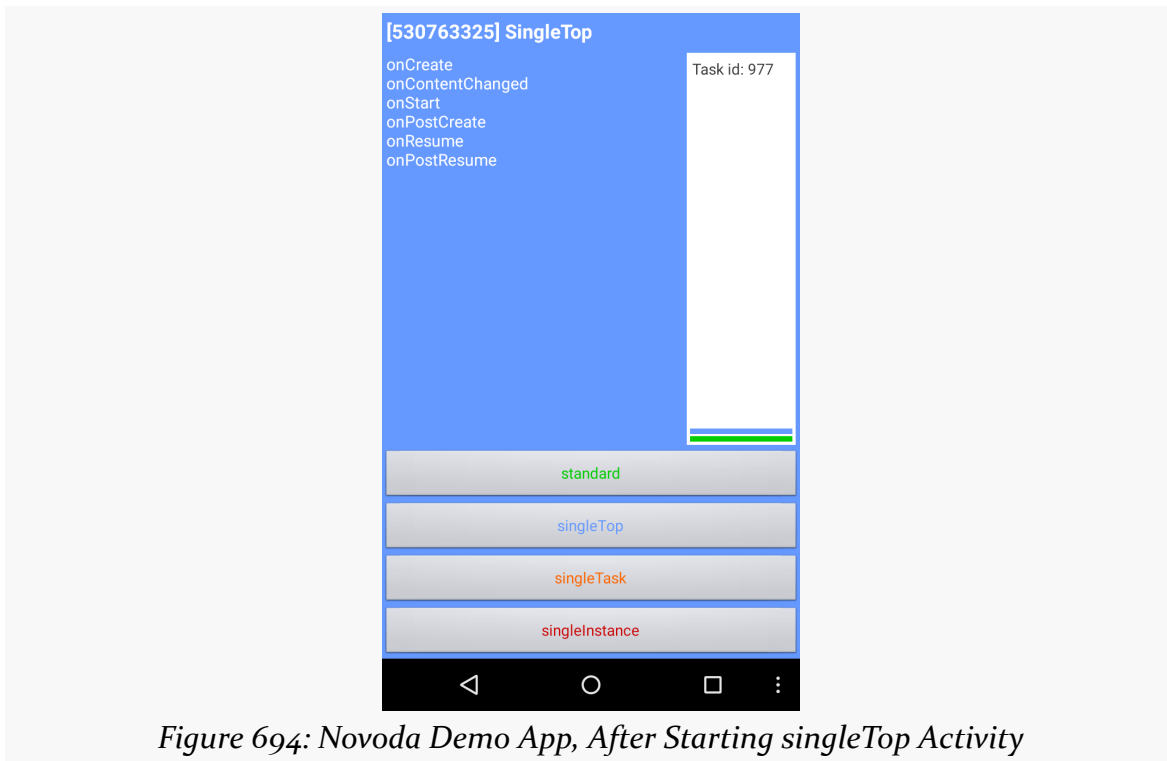

Figure 694: Novoda Demo App, After Starting singleTop Activity

That worked just like standard. But, if we tap the same button again, we do *not* get a new instance of the activity. However, the transcript of lifecycle methods shows that `onNewIntent()` was called:

TASKS

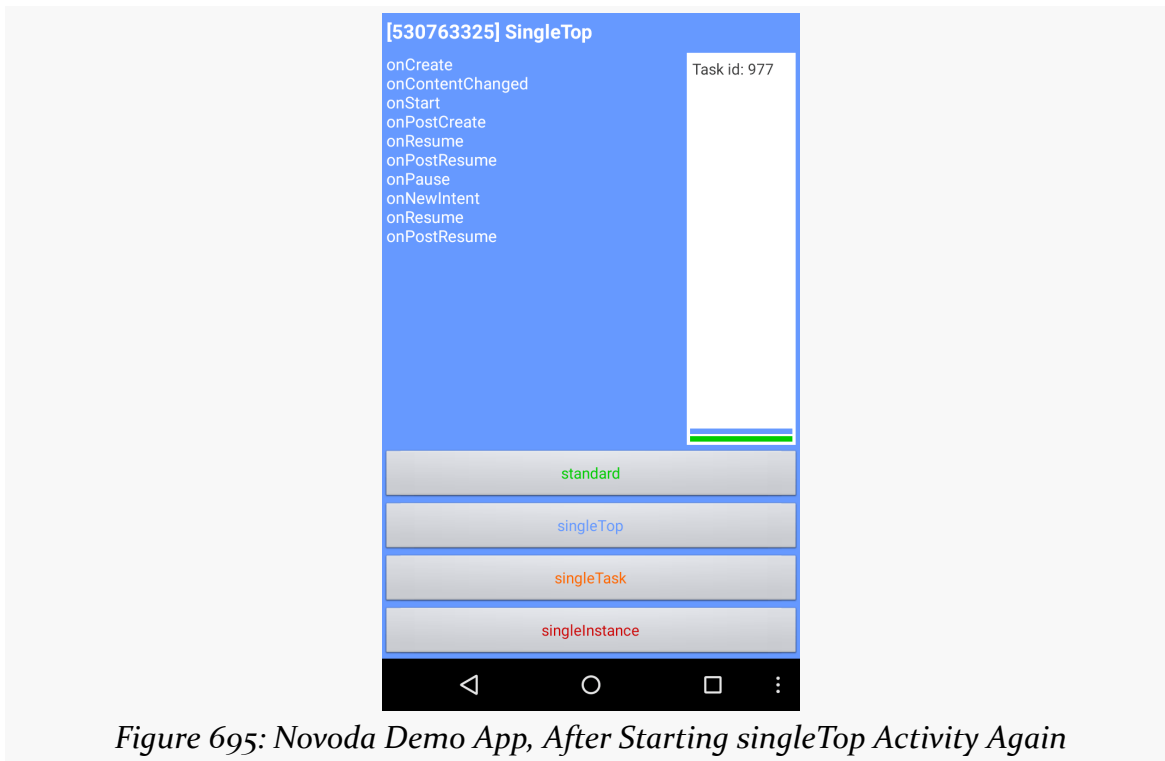

Figure 695: Novoda Demo App, After Starting singleTop Activity Again

Note that you can get a similar result by including `Intent.FLAG_ACTIVITY_SINGLE_TOP` on a `startActivity()` call. Using `launchMode` says you *always* want single-top behavior; using `FLAG_ACTIVITY_SINGLE_TOP` says that *this time* you want single-top behavior.

Pressing BACK returns you to the original green standard activity, with the blue singleTop activity having been destroyed.

singleTask

A `launchMode` of `singleTask` says that this activity must *always* be the root activity of a task.

If the task does not have that activity, a new task is created. So, if we tap the button to launch the `singleTask` activity in the Novoda demo app, we get a new task (ID 978, compared to the previous 977), with an instance of the yellow `singleTask` activity as its root:

TASKS

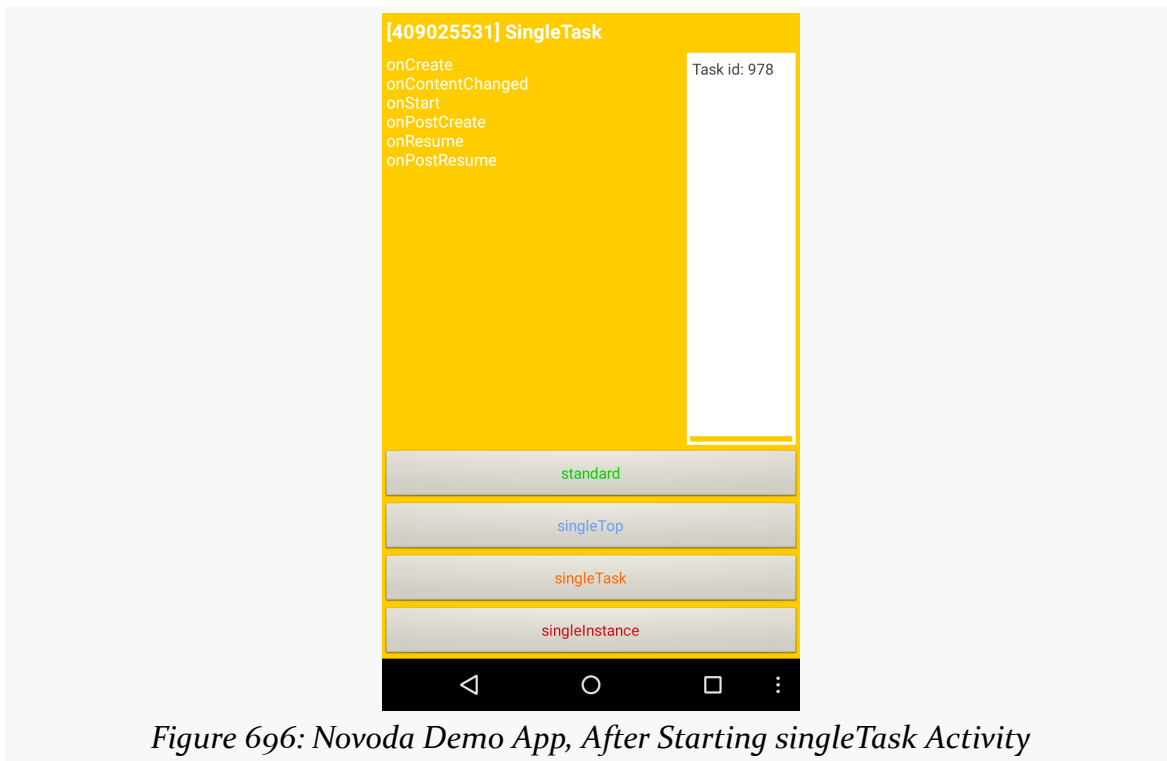

Figure 696: Novoda Demo App, After Starting singleTask Activity

However, if the activity in question is already there as the root of the task, all other activities on the back stack are cleared, and we are taken to the `singleTask` activity again.

So, in the Novoda demo app, if after we start the `singleTask` activity, we tap the button to launch a standard activity or two:

TASKS

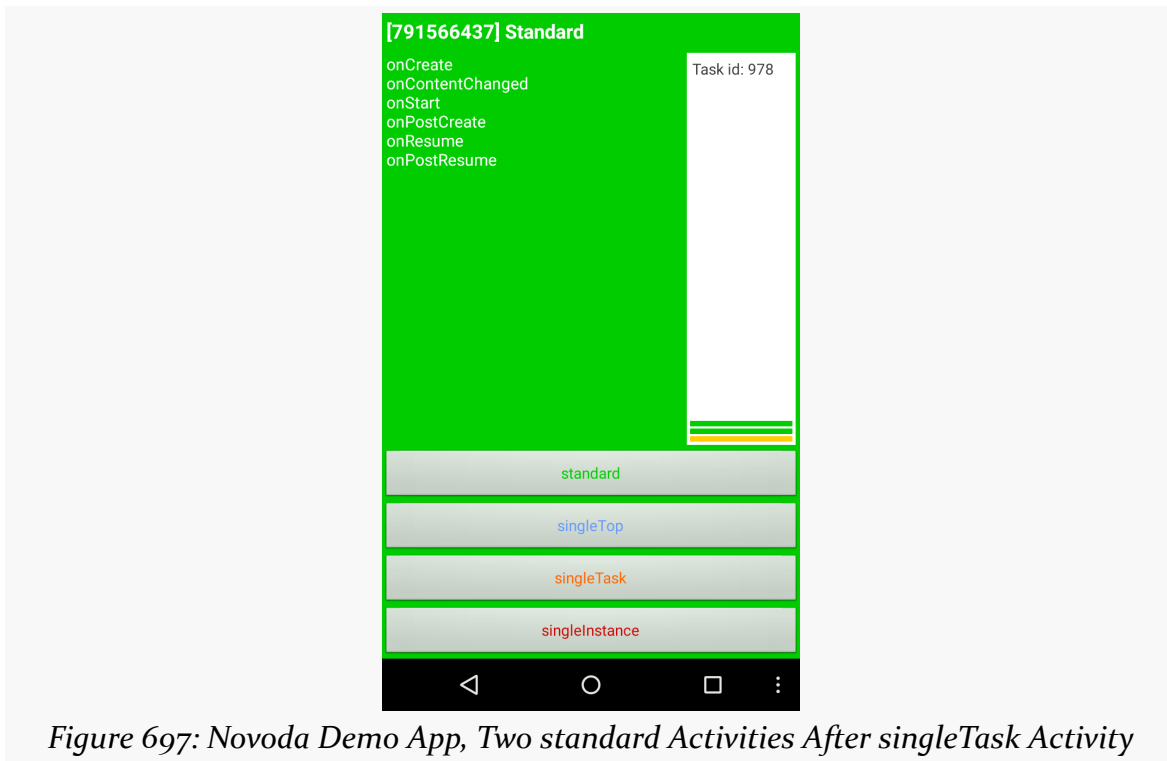

Figure 697: Novoda Demo App, Two standard Activities After singleTask Activity

...then tap the button to launch the `singleTask` activity, we get largely the same screen as before, just with a few more lifecycle methods logged:

TASKS

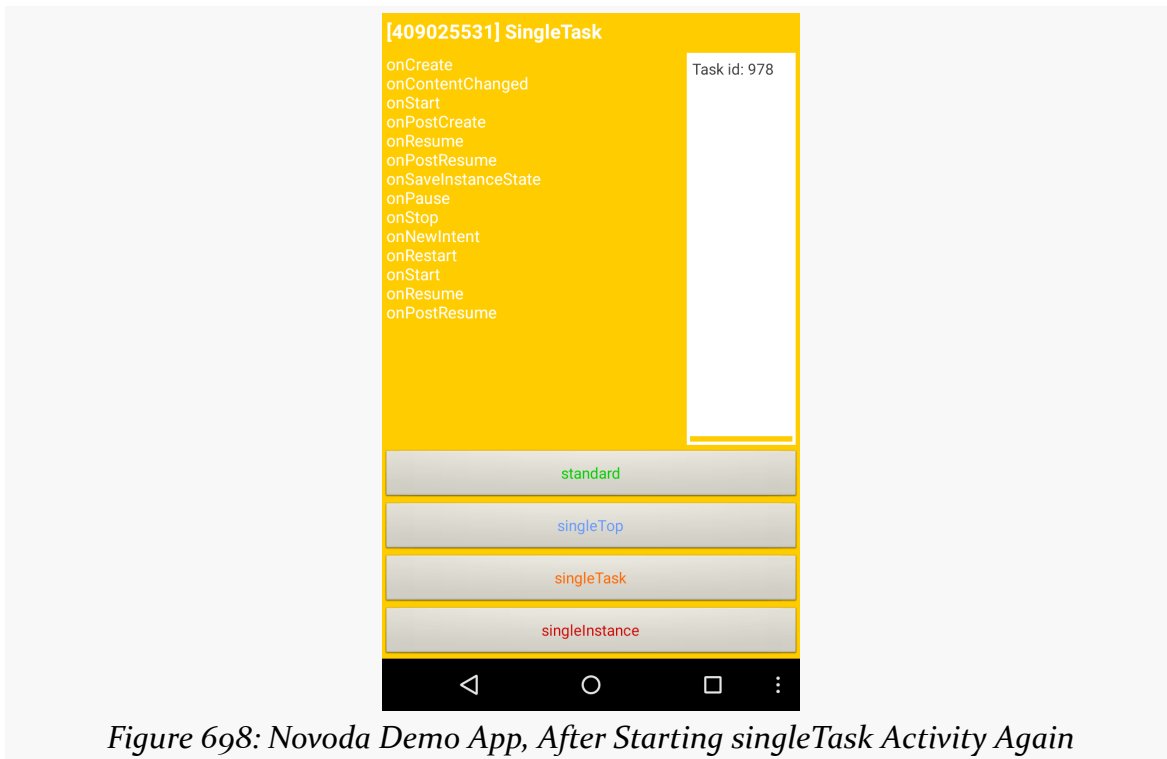

Figure 698: Novoda Demo App, After Starting singleTask Activity Again

It is the same task and the same instance, but with the other activities removed.

singleInstance

`singleInstance` works much like `singleTask`, except that the task will only ever hold this one activity. No other activities will be placed into the task.

So, tapping the button to start a `singleInstance` activity in the Novoda demo app brings up the red `singleInstance` UI:

TASKS

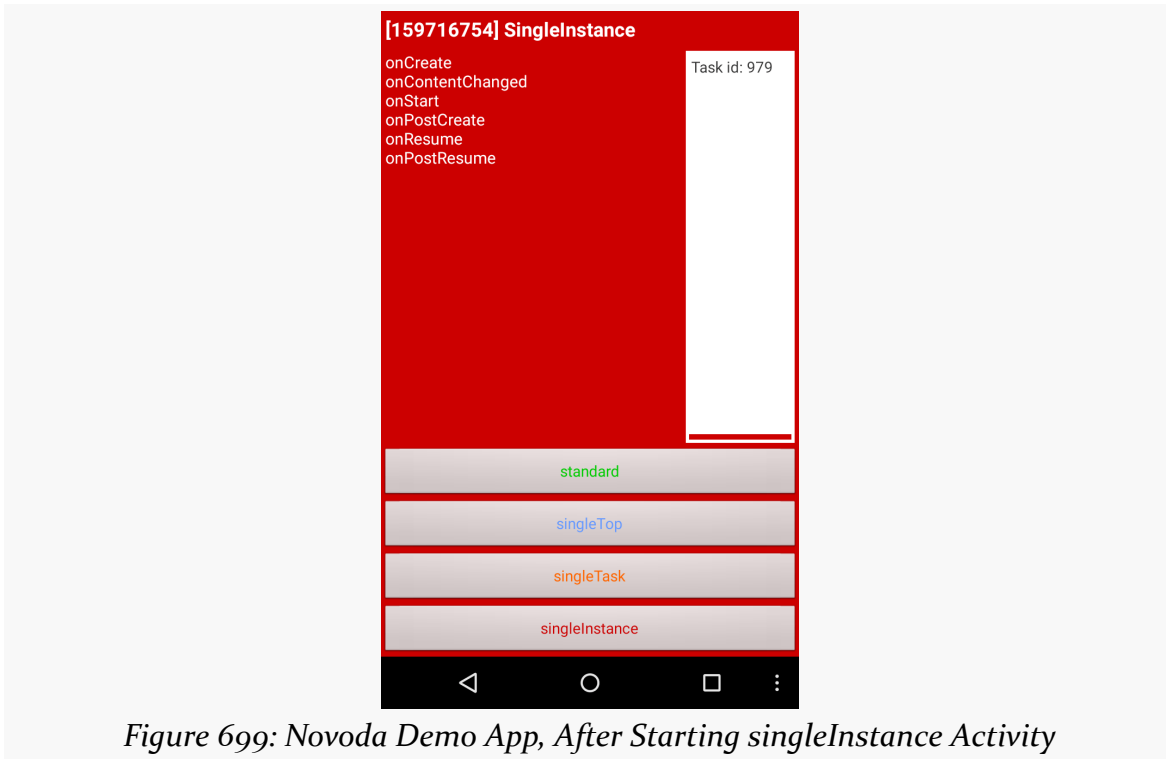

Figure 699: Novoda Demo App, After Starting singleInstance Activity

Tapping the same button again just triggers `onNewIntent()` and other lifecycle methods on the same activity in the same task. If, however, you try tapping on the button for the standard activity, your activity will go to another task. Depending on when and how you try the Novoda demo app, this could be a prior task associated with our app (e.g., one you used for earlier standard tests), or it could be a new task (if you do not have any other ones). This is based on the `taskAffinity` of the activity being started.

In general, `singleTask` and `singleInstance` are for unusual use cases, and ordinary Android apps should have little reason to use them. Google [specifically urges you not to use them](#):

...standard is the default mode and is appropriate for most types of activities. `SingleTop` is also a common and useful launch mode for many types of activities. The other modes — `singleTask` and `singleInstance` — are not appropriate for most applications, since they result in an interaction model that is likely to be unfamiliar to users and is very different from most other applications.

alwaysRetainTaskState

As noted earlier in the chapter, tasks may be cleared by Android if the user has not been in the task for some time (e.g., 30+ minutes). In these cases, the user is taken back to the root activity.

If, however, the root activity has `android:alwaysRetainTaskState="true"` in its manifest entry, then Android will not apply this timeout rule. So long as the task exists, its entire state will be retained and used when the user returns to the task. This is useful for tasks where there is a lot of state that the user might regret losing.

Other Task-Related Activity Methods

There are a handful of other task-related methods and such floating around the Activity class:

finishAffinity()

This calls `finish()` not only on the current activity, but on all activities immediately behind it on the back stack for this task that have the same `taskAffinity` as does the current activity. Much of the time, the activities on the stack will all share an affinity, and therefore this will frequently finish all activities in the task. If the task has a mixed set of affinities (e.g., a mix of explicitly-named affinities and other activities using the default affinity), this method would only wipe out those behind the current with a specific match.

This method is not commonly used.

finishAndRemoveTask()

This calls `finish()` on all activities in the task and removes the task outright.

For example, a “logout” operation might call `finishAndRemoveTask()` to flush the current task, then call `startActivity()` to launch the login activity. That login activity will wind up in a fresh task (since the current one will be removed), and the old activity instances will go away, so the user cannot somehow stumble into them when they are not yet logged in.

getTaskId()

Returns a unique integer that identifies the task the activity resides in.

This method is not commonly used.

isTaskRoot()

`isTaskRoot()` is a method on `Activity`. It will return `true` if this activity instance is at the root of a task, meaning that pressing `BACK` should remove the task and return the user to the home screen.

moveTaskToBack()

This method moves the current task to the background. What comes to the foreground is undocumented but generally seems to be the task for the home screen. Some apps use this to offer a “minimize” or “go to background” option within the app, though this is superfluous, as the task will move to the background naturally as the user navigates their device.

setTaskDescription()

For Android 5.0+, `setTaskDescription()` allows you to associate an `ActivityManager.TaskDescription` instance with your task. Here you can provide values that help drive what the task looks like on the overview screen. Specifically, you can provide the icon, title, and background color to use for the title bar over your thumbnail on the overview screen.

The Assist API (“Now On Tap”)

Android 6.0 introduced the concept of the device “assistant”. The assistant can be triggered by a long-press of the HOME button or via a spoken phrase (if the user has always-on keyphrase detection) enabled. An assistant is a special app that has access to the content of the foreground activity and other visible windows, much like an accessibility service does.

For the vast majority of users of Google Play ecosystem devices running Android 6.0 or higher, the “assistant” is known as Now On Tap. On some devices, such as the Google Pixel series, this assistant is known simply as the “Google Assistant”. This is marketed as an extension of the Google Now UI, where Now On Tap/Google Assistant will take the data from the foreground activity and use that to find other relevant things for the user to do based upon that data.

(for the purposes of this chapter, this Google-supplied assistant will be referred to as “Now On Tap”, to distinguish Google’s assistant from assistants that others might write using these APIs)

For example, suppose the user receives a text message, suggesting dinner at a particular restaurant. The restaurant is merely named — no URL — and so the text messaging client would just display the name of the restaurant as part of the message. If the user invokes Now On Tap, Google will take the contents of this message (and anything else on the screen), and presumably send it to Google’s servers, sending back things like details about the restaurant (e.g., URL to Web site, Google’s scanned reviews of the restaurant, link to Google Maps for driving directions). Google’s search engine technology would scan the data from the app, recognize that the restaurant name appears to be something significant, and give Now On Tap details of what to offer the user.

As with many things from Google, Now On Tap is very compelling and very much a privacy problem. Now On Tap is automatically installed and enabled on Android 6.0 devices — users have to go through some work to disable it. Users and app developers have limited ability to control Now On Tap, in terms of what data it collects and what it does with that data. On the other hand, certain apps (for which there are no privacy considerations) might wish to provide *more* data to Now On Tap, beyond what is visible in widgets, to help provide more context for Now On Tap to help users.

In this chapter, we will explore the Assist API, in terms of:

- what data gets collected
- how apps can add to that data
- how apps can block sensitive information from the assistant
- how to write your own assistant, as a Now On Tap replacement

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book.

What Data Gets Disclosed

Quite a bit of data is made available to Now On Tap or other assistants through the Assist API alone, as will be explored in this section.

Assistants are welcome to use other APIs as well, subject to standard Android permissions and such. So, for example, an app might not show the device’s location, and therefore an assistant could not get the location from the Assist API, but the assistant could use `LocationManager` or the Play Services location API to find out the device’s location.

There is also a risk of pre-installed assistants using undocumented means of getting at data beyond what the normal Android SDK would allow.

All that being said, assistants will get a lot of information about the currently-visible UI, just from what the Assist API provides.

Screenshot

Assistants can get a screenshot of the current screen contents — minus the status bar — when the user activated the assistant (e.g., long-pressed HOME). Developers can [block this](#) for select activities or other windows. Hence, an assistant cannot *assume* that it will get a screenshot, though frequently it will.

Presumably, the “vision” here is to use computer vision and other image recognition techniques on the screenshot to find things of interest. For example, the user might bring up Now On Tap for some activity that is showing a photo of a monument. The activity might not be showing any other details about the monument, such as its name. However, Google’s servers might well recognize what monument it is and therefore give the user links to Wikipedia pages about the monument, a map of where the monument is located, etc.

View Structure

By far the largest dump of data that the assistant gets comes in the form of the view structure. This is represented by a tree of `AssistStructure.ViewNode` objects, one per widget or container within a window. These provide similar information as to what one gets from the accessibility APIs. For most assistants, the key data is the text or content description in the widget. In the case of text, this is available as a `CharSequence` and so may contain additional information (e.g., hyperlinks represented in `URLSpan` objects) beyond the words visible to the user.

Developers can [restrict what widgets and containers are disclosed](#), but that is something developers have to do explicitly. In other words, making data available to assistants is something a developer has to opt out of, not opt into.

Other Data

In addition to the view structure and a largely-undocumented `Bundle`, the other piece of data supplied to the assistant is the `AssistContent`. Here is where an app can provide some additional context about the foreground activity.

Specifically, the app can provide:

- an `Intent` that represents the activity, replacing the `Intent` that was used to start the activity, if there is a better one for long-term use (e.g., the activity

was started via a Notification action and you want to route the user through a different Intent for other scenarios)

- a Uri that points to some Web page of relevance for this activity
- a string of “structured data”, designed to be populated by a snippet of JSON using the schema.org specification, to provide details of the book, song, video, or whatever happens to be in the activity at the moment
- another undocumented Bundle
- an undocumented ClipData

Assistants can use this directly (e.g., offer a link to the Uri supplied in this content) or indirectly (e.g., using the schema.org JSON to find places where the user can purchase related content).

Adding to the Data

You may wish to provide some additional information to Now On Tap or other assistants, such as the Intent or JSON described above. Or, you may just generally want to ensure that your app provides the maximum amount of information to these assistants, without necessarily trying to invent new data to provide.

There are a few options for accomplishing this.

Accessibility

The big one is to ensure that your app provides text or content descriptions for everything visible. This will not only help these assistants, but this will make your app far more accessible to those using TalkBack or other accessibility services.

Mostly, this is a matter of ensuring that your ImageView widgets and other non-textual widgets have a content description, whether set via `android:contentDescription` attributes or by `setContentDescription()` in Java. TextView and its subclasses automatically use their text as the content description; EditText will use the hint if there is no text in the field at the moment.

More advice regarding accessibility can be found in [the chapter on accessibility and focus management](#).

Assist-Specific Data

Beyond that, you can contribute to the `AssistContent` (where the `Intent`, `Uri`, and `JSON` live) and other assist-related information for a given invocation of the assistant by the user.

You have a few options of where to place this logic: in one spot globally, on a per-activity basis, and, for custom views, on a per-view basis.

Globally

You can call `registerOnProvideAssistDataListener()` on the global `Application` object (retrieved by calling `getApplicationContext()` on some other `Context`, like your `Activity`). This takes an `OnProvideAssistDataListener` implementation, which in turn provides an `onProvideAssistData()` implementation, that will be called when the assistant is requested. You are passed the `Activity` of yours that is in the foreground, along with a `Bundle` that you can fill in.

However, the documentation only says that the `Bundle` will go into the `EXTRA_ASSIST_CONTEXT` extra on the `Intent` that invokes the assistant. What that `Bundle` is supposed to contain is undocumented.

Per-Activity

Your primary hooks for customizing the assist data come in the form of two callbacks on your `Activity` subclasses: `onProvideAssistData()` and `onProvideAssistContent()`.

`onProvideAssistData()` is given the same `Bundle` that is given to the `OnProvideAssistDataListener` on a global basis. However, it is unclear what goes in that `Bundle`, and the contents of that `Bundle` do not appear to make it to the assistant, at least through the documented Assist API.

`onProvideAssistContent()`, though, is more relevant.

The [Assist/MoAssist](#) sample project is a clone of [a sample app demonstrating the use of tabs in Android](#). The clone has its `compileSdkVersion` bumped to 23, and it overrides `onProvideAssistData()` and `onProvideAssistContent()`:

```
@Override
public void onProvideAssistData(Bundle data) {
```

THE ASSIST API (“NOW ON TAP”)

```
super.onProvideAssistData(data);

data.putInt("random-value", new SecureRandom().nextInt());
}

@TargetApi(23)
@Override
public void onProvideAssistContent(AssistContent outContent) {
    super.onProvideAssistContent(outContent);

    outContent.setWebUri(Uri.parse("https://commonsware.com"));

    try {
        JSONObject json=new JSONObject()
            .put("@type", "Book")
            .put("author", "https://commonsware.com/mmurphy")
            .put("publisher", "CommonsWare, LLC")
            .put("name", "The Busy Coder's Guide to Android Development");

        outContent.setStructuredData(json.toString());
    }
    catch (JSONException e) {
        Log.e(getClass().getSimpleName(),
            "Um, what happened here?", e);
    }
}
```

(from [Assist/MoAssist/app/src/main/java/com/commonsware/android/assist/mo/MainActivity.java](#))

The `onProvideAssistData()` simply puts a random number into the `Bundle`. That random number does not appear anywhere in [the data collected by an assistant](#).

`onProvideAssistContent()` fills in two items in the `AssistContent`:

- a Web URL of relevance to the activity, in this case the home page of the book’s publisher
- a bit of JSON, following [the published schema.org Book structure](#), with metadata about this book

This information *is* supplied to assistants and can be used by them to do something useful, such as offer links for the user to click on to visit the sites.

Per-View

If you are implementing your own custom views, particularly those that render their own text using low-level Canvas APIs, you may wish to override `onProvideStructure()` and/or `onProvideVirtualStructure()`. These will be called on your widgets to provide the `AssistStructure.ViewNode` details to be passed to the assistant.

However, in all likelihood, you would want to instead work with the accessibility APIs to publish data to be used by accessibility services, such as the text that you are rendering. If you do that, the default implementations of `onProvideStructure()` and `onProvideVirtualStructure()` should suffice.

Removing from the Data

While some developers may embrace Now On Tap, others may specifically want to prevent Now On Tap or other assistants from “spying” on application data. You have a few options for controlling what is provided to assistants; however, all require work and some have side effects. For example, there is nothing in the manifest that you can specify to make your activities opt out of providing assist data.

FLAG_SECURE

The standard approach for making private activities *really* private is to [use FLAG_SECURE](#):

```
public class FlagSecureTestActivity extends Activity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        getWindow().setFlags(LayoutParams.FLAG_SECURE,
            LayoutParams.FLAG_SECURE);

        setContentView(R.layout.main);
    }
}
```

Call `setFlags()` before `setContentView()`, in this case setting `FLAG_SECURE`.

THE ASSIST API (“NOW ON TAP”)

The classic effect of `FLAG_SECURE` is to block screenshots, both user-initiated ones and system-initiated ones (e.g., the screenshots used in the overview/recent-tasks screen on Android 4.0+).

If the user triggers an assistant for a secure activity, the assistant will not get the full view structure (i.e., no widgets and no text) and will not get a screenshot.

Password Fields

An `EditText` that is set up as a password field will have its text blocked from the view structure. The widget will be listed, but its text will be `null`.

Presumably, this relies on the `EditText` using a `PasswordTransformationMethod`, as that is Android’s typical approach for determining whether or not an `EditText` is deemed to be secure. If you have implemented your own `TransformationMethod` (e.g., with a different approach for shrouding the user input), either have it extend `PasswordTransformationMethod` or use other approaches to prevent this field’s contents from being published to assistants.

NoAssistFrameLayout

The apparently-official way to block a widget or container from participating in the assist API is to create a subclass of it and override `dispatchProvideStructure()`. The stock implementation of this triggers the calls to `onProvideStructure()` and `onProvideVirtualStructure()`. Plus, for a `ViewGroup`, it will iterate over the children and call `dispatchProvideStructure()` on each of them.

If you are creating your own custom view, and you want it eliminated from the view structure, just override `dispatchProvideStructure()` and have it do nothing.

Or, you can create a container that is there solely to block the assist data collection. The [Assist/NoAssist](#) sample project does this, in the form of a `NoAssistFrameLayout`:

```
package com.commonware.android.assist.no;

import android.annotation.TargetApi;
import android.content.Context;
import android.os.Build;
import android.util.AttributeSet;
import android.view.ViewStructure;
import android.widget.FrameLayout;
```

THE ASSIST API (“NOW ON TAP”)

```
public class NoAssistFrameLayout extends FrameLayout {
    public NoAssistFrameLayout(Context context) {
        super(context);
    }

    public NoAssistFrameLayout(Context context,
        AttributeSet attrs) {
        super(context, attrs);
    }

    public NoAssistFrameLayout(Context context,
        AttributeSet attrs,
        int defStyleAttr) {
        super(context, attrs, defStyleAttr);
    }

    @TargetApi(Build.VERSION_CODES.LOLLIPOP)
    public NoAssistFrameLayout(Context context,
        AttributeSet attrs,
        int defStyleAttr,
        int defStyleRes) {
        super(context, attrs, defStyleAttr, defStyleRes);
    }

    @Override
    public void dispatchProvideStructure(ViewStructure structure) {
        // no, thanks
    }
}
```

(from [Assist/NoAssist/app/src/main/java/com/commonsware/android/assist/no/NoAssistFrameLayout.java](#))

EditorFragment — responsible for showing a large multi-line EditText for the user to type into — will conditionally use a NoAssistFrameLayout, specifically on the third tab (a ViewPager position of 2):

```
@Override
public View onCreateView(LayoutInflater inflater,
    ViewGroup container,
    Bundle savedInstanceState) {
    int position=getArguments().getInt(KEY_POSITION, -1);
    View result;

    if (position==2) {
        ViewGroup doctorNo=new NoAssistFrameLayout(getActivity());
        inflater.inflate(R.layout.editor, doctorNo);
    }
}
```

THE ASSIST API (“NOW ON TAP”)

```
        result=doctorNo;
    }
    else {
        result=inflater.inflate(R.layout.editor, container, false);
    }

    EditText editor=(EditText)result.findViewById(R.id.editor);

    editor.setHint(getTitle(getActivity(), position));

    if (position==1) {
        editor.
            setTransformationMethod(PasswordTransformationMethod.
                getInstance());
    }

    return(result);
}
```

(from [Assist/NoAssist/app/src/main/java/com/commonsware/android/assist/no/EditorFragment.java](#))

If we are on the third tab, we create a `NoAssistFrameLayout` and inflate our `EditText` into it. Otherwise, we inflate the layout normally.

Note that this sample also applies a `PasswordTransformationMethod` for the second page of the `ViewPager` (a position of 1), to illustrate the null text that will be recorded as a result.

Blocking Assist as a User

It is possible that your reaction to all of this is that you want to opt out of Now On Tap as a user. Or, perhaps you want to provide some instructions to your users on how to opt out of Now On Tap.

Go to `Settings > Apps`. There should be an option for advanced app configuration actions (on Nexus-series devices, this is a gear icon in the action bar). Tap that, then choose “Default Apps” to bring up categories of default apps for various actions:

THE ASSIST API (“NOW ON TAP”)

Figure 700: Android 6.0 Default Apps Screen in Settings

In there, tap on “Assist & voice input”. By default, you should see “Google App” as the chosen option, which means that Now On Tap is active:

THE ASSIST API (“NOW ON TAP”)

Figure 701: Android 6.0 Assist & Voice Input Screen in Settings

Tapping on that entry will bring up a list of available options, including “None”:

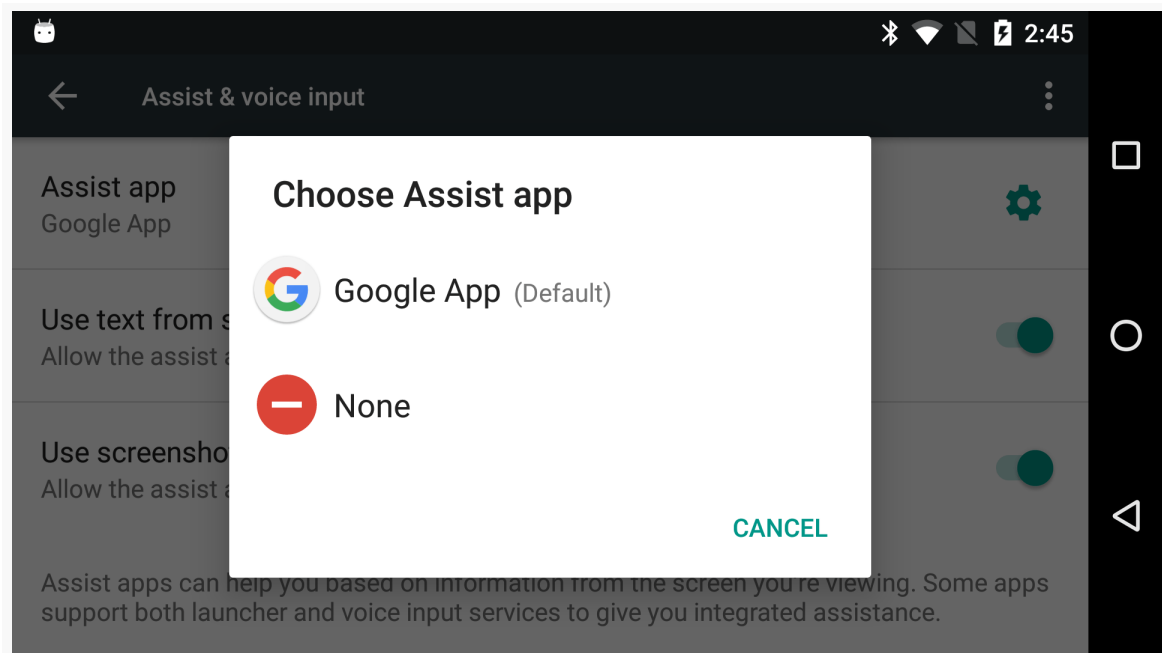

Figure 702: Android 6.0 Assist & Voice Input Options in Settings

Implementing Your Own Assistant

While Now On Tap is pre-installed and pre-activated, and while users can disable Now On Tap, another option for users is to activate some other assistant. Any app that implements the proper pieces of the Assist API will appear in the roster of available assistants for the user to choose from, as described in the previous section. The [Assist/AssistLogger](#) sample project represents one such app.

Primarily, this app is for diagnostic purposes, showing you exactly what your activity is “leaking” to assistants. It was essential in figuring out how the APIs shown in earlier examples in this chapter worked, for instance. However, it also serves as a demonstration of the minimum requirements to implement an assistant in general.

Creating an assistant is technically part of a larger bit of work on handling voice interactions in Android. However, if all you want is an assistant, you can ignore the voice-related bits.

A Stub VoiceInteractionService

Some of what is needed to set up an assistant is some boilerplate.

For example, the entry point for assistants and voice interactions is a custom subclass of `VoiceInteractionService`. If you only are concerned with implementing an assistant, your `VoiceInteractionService` can be empty:

```
package com.commonware.android.assist.logger;

import android.service.voice.VoiceInteractionService;

public class AssistLoggerService extends VoiceInteractionService {
}
```

(from [Assist/AssistLogger/app/src/main/java/com/commonware/android/assist/logger/AssistLoggerService.java](#))

However, it needs to exist, and in particular it needs to have its `<service>` entry in your manifest:

```
<service
    android:name=".AssistLoggerService"
    android:permission="android.permission.BIND_VOICE_INTERACTION">
    <meta-data
        android:name="android.voice_interaction"
        android:resource="@xml/assist_service"/>
```

THE ASSIST API (“NOW ON TAP”)

```
<intent-filter>
  <action android:name="android.service.voice.VoiceInteractionService"/>
</intent-filter>
</service>
```

(from [Assist/AssistLogger/app/src/main/AndroidManifest.xml](#))

The keys to the manifest entry are:

- It needs to have the `android:permission` attribute, limiting it clients that hold the `BIND_VOICE_INTERACTION` permission, which should limit clients to those that are part of the device firmware
- It needs to have the `<intent-filter>` advertising that it supports the `android.service.voice.VoiceInteractionService` action string
- It needs an `android.voice_interaction <meta-data>` element, pointing to an XML resource that further configures the voice interaction/assistant implementation

The sample project has that metadata in `res/xml/assist_service.xml`:

```
<voice-interaction-service
  xmlns:android="http://schemas.android.com/apk/res/android"
  android:recognitionService="com.commonware.android.assist.logger.AssistLoggerService"
  android:sessionService="com.commonware.android.assist.logger.AssistLoggerSessionService"
  android:supportsAssist="true"/>

<!--
  android:settingsActivity="com.android.test.voiceinteraction.SettingsActivity"
-->
```

(from [Assist/AssistLogger/app/src/main/res/xml/assist_service.xml](#))

There are three attributes required on the `<voice-interaction-service>` root element to enable an assistant:

- `android:recognitionService` points back to your `VoiceInteractionService` subclass
- `android:sessionService` points to a subclass of `VoiceInteractionSessionService` (we will examine the project’s implementation shortly)
- `android:supportsAssist` should be `true`

If you want, you can also have an `android:settingsActivity` attribute, shown in this XML as a commented-out snippet at the end of the file. This can point to an activity in your app. If you have this, a gear icon will appear on the “Assist & voice

input” Settings screen that, when tapped, will bring up this activity, to configure the behavior of your assistant. The sample app skips this.

A Trivial VoiceInteractionSessionService

The service pointed to by `android:sessionService` in the metadata needs to be a subclass of `VoiceInteractionSessionService`. The only method that you need to override is `onNewSession()`, where you can return an instance of a `VoiceInteractionSession`:

```
package com.commonware.android.assist.logger;

import android.os.Bundle;
import android.service.voice.VoiceInteractionSession;
import android.service.voice.VoiceInteractionSessionService;

public class AssistLoggerSessionService extends
    VoiceInteractionSessionService {
    @Override
    public VoiceInteractionSession onNewSession(Bundle args) {
        return(new AssistLoggerSession(this));
    }
}
```

(from [Assist/AssistLogger/app/src/main/java/com/commonware/android/assist/logger/AssistLoggerSessionService.java](#))

Here, we return an instance of `AssistLoggerSession`, which is where all of our real business logic resides for our assistant.

Note that this service also should use `android:permission` to limit clients to those that hold the `android.permission.BIND_VOICE_INTERACTION` permission:

```
<service
    android:name=".AssistLoggerSessionService"
    android:permission="android.permission.BIND_VOICE_INTERACTION" />
```

(from [Assist/AssistLogger/app/src/main/AndroidManifest.xml](#))

The VoiceInteractionSession

`VoiceInteractionSession` has a *lot* of methods that you can override, both for voice interactions and for assistant invocations. The sample app overrides the minimum required for an assistant, as its mission simply is to log all of the data received by our assistant to files on external storage, for diagnostic purposes.

THE ASSIST API (“NOW ON TAP”)

NOTE: Running this sample app on hardware that is actually used with private data is stupid beyond words. Any app can then read the files on external storage and see what information is published by whatever apps are in the foreground at the times when you invoke the assistant. Please use this only on test environments.

Basic Setup

Akin to components, a `VoiceInteractionSession` has an `onCreate()` method, called as part of setting up the session. In there, `AssistLoggerSession` sets up an output directory for logging the results, assuming that external storage is available:

```
@Override
public void onCreate() {
    super.onCreate();

    if (Environment.MEDIA_MOUNTED
        .equals(Environment.getExternalStorageState())) {
        String logDirName=
            "assistlogger_"+
                new SimpleDateFormat("yyyyMMdd'-'HHmss").format(new Date());

        logDir=
            new File(getContext().getExternalCacheDir(), logDirName);
        logDir.mkdirs();
    }
}
```

(from [Assist/AssistLogger/app/src/main/java/com/commonsware/android/assist/logger/AssistLoggerSession.java](#))

onHandleScreenshot()

If the user invokes your assistant, you will be called with `onHandleScreenshot()`. Usually, you will be passed a `Bitmap` that contains the screenshot. However, if the foreground activity is using `FLAG_SECURE`, the `Bitmap` that is passed to you will be `null`, so make sure you check it before doing anything with it.

The `AssistLoggerSession` forks a `ScreenshotThread` to save this screenshot in the background:

```
@Override
public void onHandleScreenshot(Bitmap screenshot) {
    super.onHandleScreenshot(screenshot);
}
```

THE ASSIST API (“NOW ON TAP”)

```
if (screenshot!=null) {
    new ScreenshotThread(getContext(), logDir, screenshot).start();
}
}
```

(from [Assist/AssistLogger/app/src/main/java/com/commonsware/android/assist/logger/AssistLoggerSession.java](#))

ScreenshotThread, in turn, just uses `compress()` on `Bitmap` to write the image out as a PNG to the directory that we are using for logging:

```
private static class ScreenshotThread extends Thread {
    private final File logDir;
    private final Bitmap screenshot;
    private final Context ctxt;

    ScreenshotThread(Context ctxt, File logDir, Bitmap screenshot) {
        this.ctxt=ctxt.getApplicationContext();
        this.logDir=logDir;
        this.screenshot=screenshot;
    }

    @Override
    public void run() {
        if (logDir!=null) {
            try {
                File f=new File(logDir, "screenshot.png");
                FileOutputStream fos=new FileOutputStream(f);

                screenshot.compress(Bitmap.CompressFormat.PNG, 100, fos);
                fos.flush();
                fos.getFD().sync();
                fos.close();

                MediaScannerConnection
                    .scanFile(ctxt,
                        new String[] {f.getAbsolutePath()},
                        new String[] {"image/png"}, null);

                Log.d(getClass().getSimpleName(),
                    "screenshot written to: "+f.getAbsolutePath());
            }
            catch (IOException e) {
                Log.e(getClass().getSimpleName(),
                    "Exception writing out screenshot", e);
            }
        }
        else {
            Log.d(getClass().getSimpleName(),
```

THE ASSIST API (“NOW ON TAP”)

```
        String.format("onHandleScreenshot: %dx%d",
            screenshot.getWidth(), screenshot.getHeight());
    }
}
```

(from [Assist/AssistLogger/app/src/main/java/com/commonsware/android/assist/logger/AssistLoggerSession.java](#))

onHandleAssist()

onHandleAssist() is your other main assistant callback. Here is where you get:

- a Bundle of undocumented stuff
- the AssistStructure outlining the contents of the windows, including the view hierarchy
- the AssistContent with the Intent, Web Uri, JSON, and so on

AssistLoggerSession kicks off an AssistDumpThread to record this data in the background:

```
@Override
public void onHandleAssist(Bundle data,
    AssistStructure structure,
    AssistContent content) {
    super.onHandleAssist(data, structure, content);

    new AssistDumpThread(getContext(), logDir, data, structure,
        content).start();
}
```

(from [Assist/AssistLogger/app/src/main/java/com/commonsware/android/assist/logger/AssistLoggerSession.java](#))

AssistDumpThread itself is a *long* class that generates a JSON file containing the information found in the parameters to onHandleAssist():

```
package com.commonsware.android.assist.logger;

import android.app.assist.AssistContent;
import android.app.assist.AssistStructure;
import android.content.Context;
import android.content.Intent;
import android.media.MediaScannerConnection;
import android.os.Bundle;
import android.util.Log;
import org.json.JSONArray;
import org.json.JSONException;
```

THE ASSIST API (“NOW ON TAP”)

```
import org.json.JSONObject;
import java.io.File;
import java.io.FileOutputStream;
import java.io.OutputStreamWriter;
import java.io.PrintWriter;
import java.util.Set;

class AssistDumpThread extends Thread {
    private final File logDir;
    private final Bundle data;
    private final AssistStructure structure;
    private final AssistContent content;
    private final Context ctxt;

    AssistDumpThread(Context ctxt, File logDir, Bundle data,
                    AssistStructure structure,
                    AssistContent content) {
        this.ctxt=ctxt.getApplicationContext();
        this.logDir=logDir;
        this.data=data;
        this.structure=structure;
        this.content=content;
    }

    @Override
    public void run() {
        if (logDir!=null) {
            JSONObject json=new JSONObject();

            try {
                json.put("data", dumpBundle(data, new JSONObject()));
            }
            catch (JSONException e) {
                Log.e(getClass().getSimpleName(),
                    "Exception saving data", e);
            }

            try {
                json.put("content", dumpContent(new JSONObject()));

(from [Assist/AssistLogger/app/src/main/java/com/commonsware/android/assist/logger/AssistDumpThread.java](#))

Making a Real Assistant

AssistLogger is a faithful implementation of an assistant, but it does not really assist the user, except in seeing what sorts of information Google gets via Now On Tap.

If you wanted to make an actual assistant that is a true replacement for Now On Tap, you would also need to implement methods like:

- onCreateContentView(), where you can inflate a layout or otherwise assemble the basic UI to be shown to the user when your assistant is invoked
- onShow(), where you can populate that UI with the details for this particular assist request
- onHide(), called when your UI is no longer visible to the user

...and so on.

Determining the Active Assistant

If you elect to create your own assistant, you might be interested in knowing whether or not your app has been chosen as the user’s assistant. Unfortunately, there is no documented and supported means of doing this.

So, here is the undocumented and unsupported approach that works on Android 6.0.

WARNING: this code may not work on all Android 6.0 devices, let alone on future versions of Android, as it relies a bit on internal implementation that could be changed by device manufacturers or custom ROM authors. Please use this *very carefully* and do not be shocked if it stops working.

Settings.Secure holds the details of the currently-chosen assistant. However, the key under which those details are stored is a hidden entry in Settings.Secure, and so it does not show up in the Android SDK. The key is "voice_interaction_service". The value is the ComponentName of the assistant, serialized (or “flattened”) into a String. So, to get the ComponentName of the assistant, you can use:

```
String assistant=  
    Settings.Secure.getString(getContentResolver(),  
        "voice_interaction_service");
```

THE ASSIST API (“NOW ON TAP”)

```
boolean areWeGood=false;

if (assistant!=null) {
    ComponentName cn=ComponentName.unflattenFromString(assistant);
}
```

cn will then hold the ComponentName.

Leading the User to Make an Assistant Change

If you implement your own assistant, and at the moment you are not the user’s chosen assistant, you might have the need to lead the user over to the spot in the Settings app where they can change this. Once again, this is not explicitly documented.

However, for Android 6.0, `Settings.ACTION_VOICE_INPUT_SETTINGS` contains the action string that opens up the screen where the user can choose their assistant implementation. So, you could call:

```
startActivity(new Intent(Settings.ACTION_VOICE_INPUT_SETTINGS));
```

to lead the user to that screen, plus use a Toast or something to remind the user to tap on the “Assist app” entry to choose the assistant.

However:

- Since `Settings.ACTION_VOICE_INPUT_SETTINGS` is not guaranteed to be on all devices, please wrap the `startActivity()` call in an `ActivityNotFoundException` try/catch block and deal with the missing action accordingly
- There is no guarantee that `Settings.ACTION_VOICE_INPUT_SETTINGS` will lead the user to the correct screen on all Android 6.0+ devices, as the Settings app might be altered by the device manufacturer or custom ROM author

The Autofill API

Many Web browsers, such as Chrome, offer “autofill”. The browser remembers things that you have typed into certain fields, like addresses, and offers to fill those back in when you go to fill in the same form again... or even a different form with similar fields.

Android 8.0 adds autofill capability to Android via the Autofill Framework. Values that users enter into your forms will be remembered and offered again when the user returns to your form, or to other forms that they encounter in other apps on the device. This all happens without any changes to your code... in theory. In practice, you may need some changes to your code.

However, Android itself does not store the form data, nor offer it as suggestions for autofilling in a form. Android is merely serving as a conduit between your app and a third-party autofill service. It is the service that is responsible for determining what could be autofilled in your form and saving prior entries. As with [the Assist API](#), the user can choose an autofill service, and none ship by default with the O Developer Preview. In all likelihood, a Google-branded autofill implementation will be part of the production rollout of Android 8.0, but the user could choose other autofill apps... or perhaps none at all, for privacy reasons.

In this chapter, we will explore the AutoFill API, in terms of:

- what data gets collected
- how apps can block sensitive information from autofill
- how apps can better integrate with autofill

NOTE: O Developer Preview 2 renamed many of the Autofill Framework classes and methods to make the `f` in `Autofill` lowercase. So, for example, `AutoFillService`

became `AutofillService`. Materials written based on O Developer Preview 1 (blog posts, Stack Overflow answers, etc.) will have a capital F instead.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book.

There are commonalities between autofill and [the Assist API](#), and so this chapter will refer back to that one from time to time.

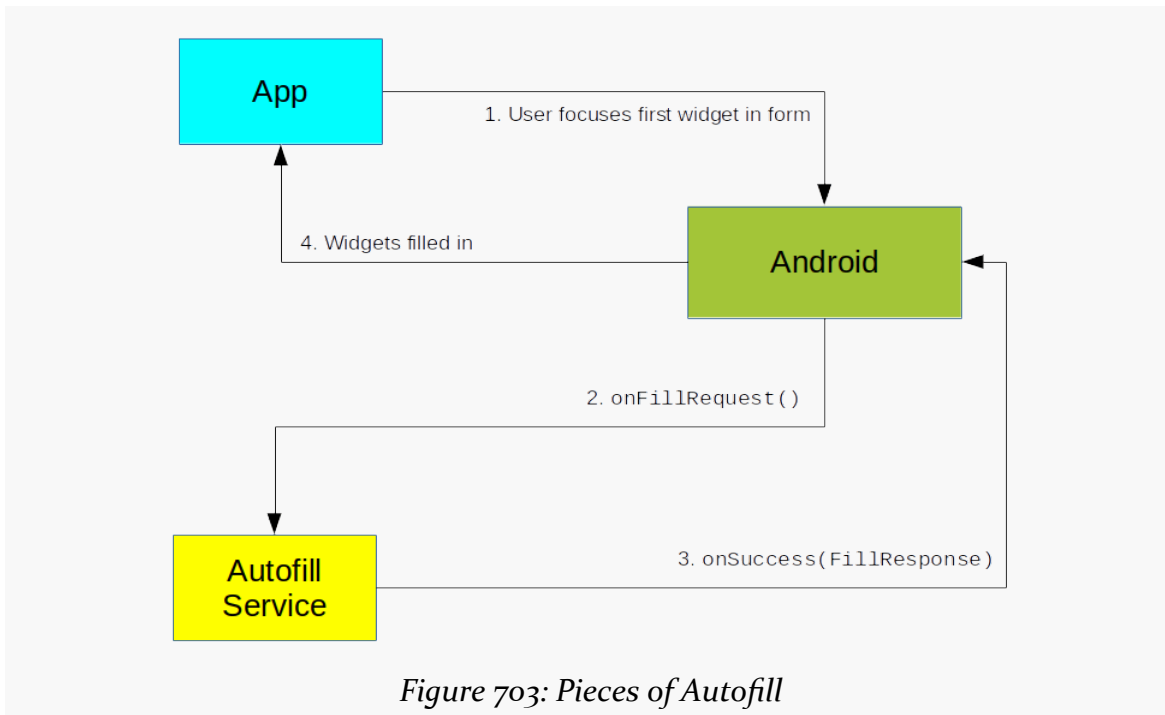

The Pieces of the Puzzle

Android 8.0 provides a framework for apps with a UI to participate in autofill, by denoting roles that some of those widgets have (e.g., “this is the field for the username”). However, Android itself does not save any user input for later use with autofill, nor does Android itself decide what values are candidates for autofill. Instead, Android delegates that work to a separate autofill service. This works akin to how accessibility services and input method editors work:

- Android provides the conduit for apps and pluggable service implementations to communicate
- Android provides a UI in Settings for the user to choose which service implementation(s) to use for a particular role
- App developers provide the actual service implementations

Hence, with autofill, there are three pieces: the app with the UI, Android itself, and the autofill service:

THE AUTOFILL API

Here, `onFillRequest()` and `onSuccess()` are part of the API for autofill service implementations.

The User Experience

Before we get into the implementation, let's see how this looks from the standpoint of the user.

NOTE: These screenshots and explanations are from the O Developer Preview 4. It is possible that this flow will change by the time Android O ships in final form, or even in future developer previews.

While Completing a Form

If an autofill service is activated, and the user visits a screen with a form to be filled in, the user may get a drop-down list from the form, indicating possible “datasets” to use to complete the form:

THE AUTOFILL API

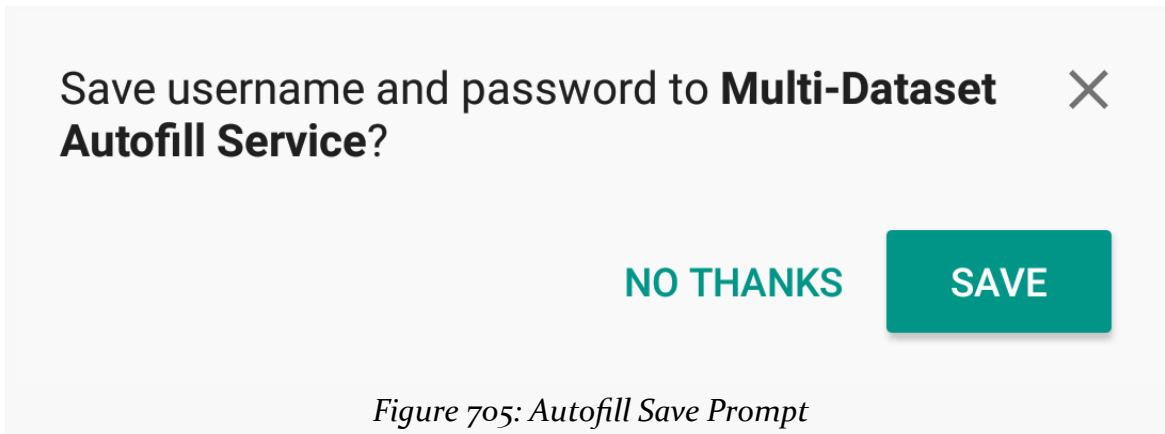

Figure 704: Autofill Datasets for User to Choose From

The actual presentation here (“dataset-2”) comes from the autofill service. It is actually a RemoteViews, not just some text, and so different autofill services will use different formats here.

After Completing a Form

After the user has completed a form, with data not represented in one of those datasets, once the activity containing the form is destroyed, the user gets a “bottom sheet” panel asking if the data should be saved for later autofill use:

This works akin to the pop-up dialog a desktop Web browser might use to ask if certain data should be saved (e.g., authentication credentials) for future visits to that page.

What Data Gets Disclosed

The Assist API discloses [quite a bit of data](#) to the user's chosen assistant app.

The autofill API discloses a bit less. Mostly, it is the view hierarchy, in the form of a `ViewStructure`.

An autofill service gets information about what is in the UI at two points:

1. When it is time to determine if there is anything that could be autofilled-in
2. When it is time to save data for future autofill requests

Here is what an autofill service might see from a small form with username, password, and cc fields (the latter for a credit card number), along with related labels and a “save” button, when it is time to determine if there is anything that could be autofilled-in:

Roughly speaking, you get all the same information that an accessibility service might. Most of this information is likely to be useless to an autofill service, but a few elements, such as `idEntry` (the widget ID) and `text` (the contents of a `TextView` or things inheriting from `TextView`) will be of importance.

Blocking Autofill as a User

The O Developer Preview 3 ships with an “Autofill with Google” autofill service, pre-installed and pre-enabled. Presumably, many devices that ship with Android 8.0 will ship with an autofill service pre-installed, whether that is one from Google, from the device manufacturer, or from another party.

If you, as a user, do not trust the autofill service, you can disable it or switch to a different one via the Settings app. Specifically, Settings > System > Languages & input > Advanced has an “Autofill service” preference:

THE AUTOFILL API

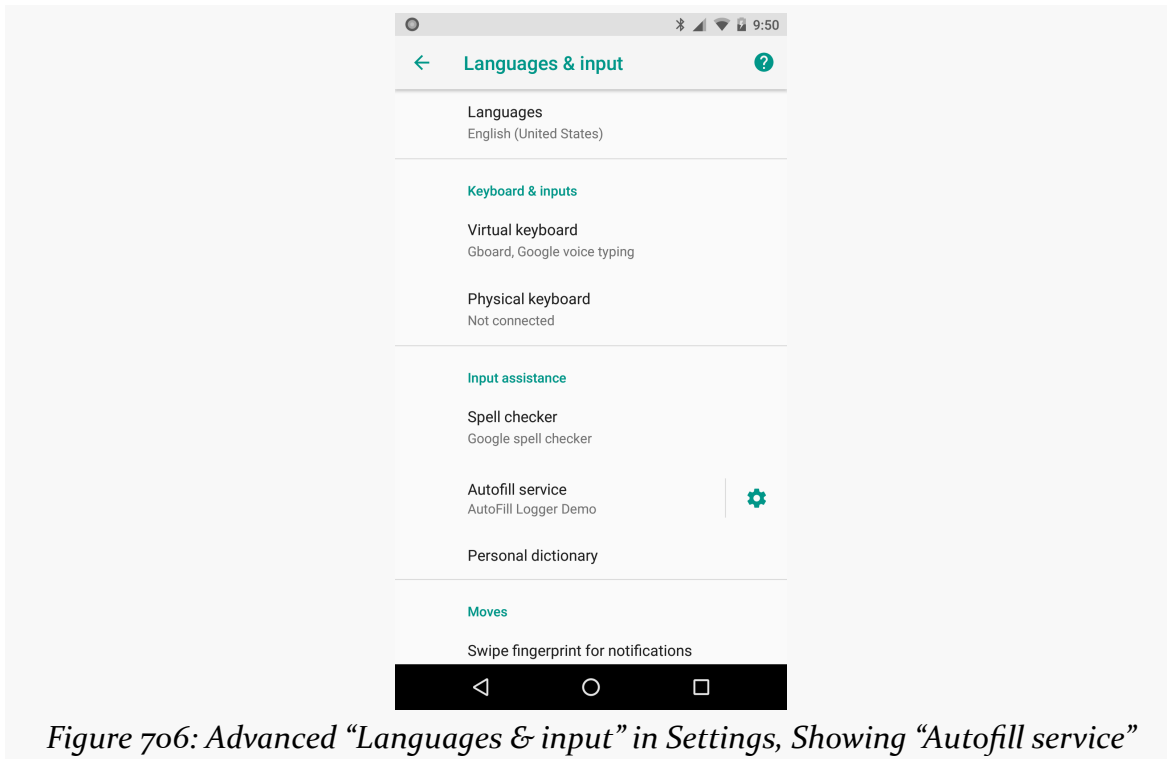

Figure 706: Advanced “Languages & input” in Settings, Showing “Autofill service”

Tapping the gear icon next to the configured autofill service (if there is one) will allow you to configure the service. Tapping the rest of the list row brings up a dialog for you to choose an autofill service from the available candidates, or “None” to opt out of autofill entirely:

THE AUTOFILL API

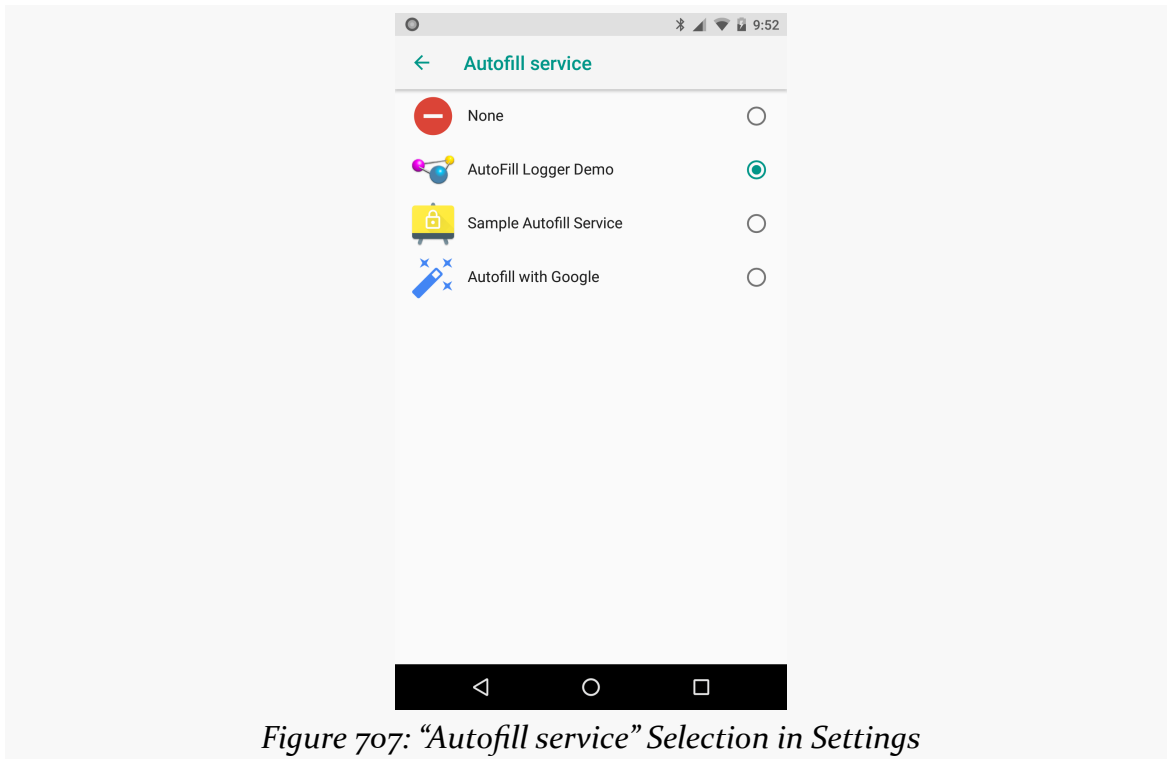

Figure 707: “Autofill service” Selection in Settings

Supporting Autofill with Standard Widgets

The documentation suggests that apps do not need to be modified to work with the Autofill Framework. That is incorrect, at least in general. Layouts do need some modification to work with autofill services, to help those autofill services identify the roles of those widgets and how those roles tie into saved data that could be autofilled-in.

The thing to bear in mind about autofill is that we have three parties to the content negotiation:

- Your app
- The Android Autofill Framework
- The autofill service implementation

This requires some common ground, as otherwise the autofill service will not know what is and is not to be considered candidates for autofill.

Identifying Roles via Hints

The primary thing that you need to do is to identify the roles of various widgets in your form. After all, a field containing a user ID might be called `userid`, `userId`, `uid`, `username`, `user_name`, `login`, or anything else. An autofill service needs to know that your `EditText` with an `android:id` of `@+id/snicklefritz` represents a user ID, for example.

To do this, use `android:autofillHints` in a layout resource, or `setAutofillHints()` from Java. These indicate, for the particular `View` you are configuring what role or role(s) the `View` holds within the world of autofill.

Autofill hint values are strings. Typically, a given widget only needs one hint, and so you can set the hints to that particular string. If, for whatever reason, a widget qualifies for more than one hint, use a comma-delimited list as the value for `android:autofillHints`, or pass multiple strings to `setAutofillHints()` via `varargs`.

The roster of possible hints, by name and Java `View` constant, are:

Value	View Constant
<code>creditCardExpirationDate</code>	<code>AUTOFILL_HINT_CREDIT_CARD_EXPIRATION_DATE</code>
<code>creditCardExpirationDay</code>	<code>AUTOFILL_HINT_CREDIT_CARD_EXPIRATION_DAY</code>
<code>creditCardExpirationMonth</code>	<code>AUTOFILL_HINT_CREDIT_CARD_EXPIRATION_MONTH</code>
<code>creditCardExpirationYear</code>	<code>AUTOFILL_HINT_CREDIT_CARD_EXPIRATION_YEAR</code>
<code>creditCardNumber</code>	<code>AUTOFILL_HINT_CREDIT_CARD_NUMBER</code>
<code>creditCardSecurityCode</code>	<code>AUTOFILL_HINT_CREDIT_CARD_SECURITY_CODE</code>
<code>emailAddress</code>	<code>AUTOFILL_HINT_EMAIL_ADDRESS</code>
<code>name</code>	<code>AUTOFILL_HINT_NAME</code>
<code>password</code>	<code>AUTOFILL_HINT_PASSWORD</code>
<code>phone</code>	<code>AUTOFILL_HINT_PHONE</code>
<code>postalAddress</code>	<code>AUTOFILL_HINT_POSTAL_ADDRESS</code>
<code>postalCode</code>	<code>AUTOFILL_HINT_POSTAL_CODE</code>
<code>username</code>	<code>AUTOFILL_HINT_USERNAME</code>

Here, `name` is for a real name (e.g., “Mark Murphy”), whereas `username` is for something more like a login value (e.g., “commonsguy”).

Since these are strings, and since the Android Autofill Framework (probably) does not care about the specific values, it is theoretically possible for autofill services to document additional hints that they honor (e.g., `birthDate`).

Indicating Importance

Independent from the hint system is `android:importantForAutofill` and the corresponding `setImportantForAutofill()` method. These indicate whether you, as the developer of the UI, think that certain widgets should or should not be considered for autofill purposes. For example, you might have a form that a user might fill out repeatedly and might want autofill capability, but some fields do not fit specific roles governed by the hint system, and so the autofill service might ignore them by default.

The default importance is `auto`, meaning that the autofill service will make its own guess, probably based on whether there is an autofill hint or not. This maps to `IMPORTANT_FOR_AUTOFILL_AUTO` in `setImportantForAutofill()`.

There are four alternatives:

XML Attribute Value	Java Constant	Role
no	<code>IMPORTANT_FOR_AUTOFILL_NO</code>	widget should be ignored from an autofill standpoint
<code>noExcludeDescendants</code>	<code>IMPORTANT_FOR_AUTOFILL_NO_EXCLUDE_DESCENDANTS</code>	widget and all its children should be ignored
yes	<code>IMPORTANT_FOR_AUTOFILL_YES</code>	widget should always be considered for autofill
<code>yesExcludeDescendants</code>	<code>IMPORTANT_FOR_AUTOFILL_YES_EXCLUDE_DESCENDANTS</code>	widget and all its children should be considered

For example:

THE AUTOFILL API

- To block autofill from seeing the value of a sensitive widget, use `android:importantForAutofill="no"` or `setImportantForAutofill(View.IMPORTANT_FOR_AUTOFILL_NO)` on the affected View
- To block autofill for an entire activity, use this in `onCreate()` of the activity:

```
getWindow()  
    .getDecorView()  
    .setImportantForAutofill(View.IMPORTANT_FOR_AUTOFILL_NO_EXCLUDE_DESCENDANTS);
```

Supporting Autofill with Custom Widgets

Other than having identifiable roles via hints, standard widgets are handled automatically via the Autofill Framework. However, the framework has no idea how to handle custom views of your own design, particularly those that use low-level drawing APIs like Canvas to render their contents.

The O Developer Preview documentation has [some instructions](#), for developers of custom views to follow, if and where those views should be participating in autofill.

Dealing with Dynamic Changes

Sometimes, the form content changes significantly on the fly as the user is interacting with it. For example, you might dynamically add some widgets based on user input (e.g., tapping a “+” icon to add a row to a table). Hence, there may be cases when you need to tell the Autofill Framework more explicitly when it should do (or re-do) its work.

There is an `AutofillManager` system service that is your gateway to the Autofill Framework. You can obtain an instance from `getSystemService(AutofillManager.class)` called on a convenient Context, such as your activity.

Then:

- If you need to tell the Autofill Framework to discard any existing autofill logic applied to the current form (e.g., the user did something to reset the form contents), call `cancel()` on the `AutofillManager`
- If you want to ask the Autofill Framework specifically to re-apply the autofill logic for the current form, call `requestAutofill()` on the `AutofillManager`

THE AUTOFILL API

- If you want to do something differently depending upon whether or not autofill is enabled, call `isEnabled()` on the `AutofillManager`
- If you want the Autofill Framework to complete its processing of the current form contents, without waiting for the activity to be destroyed, call `commit()` on the `AutofillManager`

So, for example, if you want to bail out of your activity right away if autofill is enabled — for example, you are concerned that you cannot adequately defend the privacy of your users — you could have the following code snippet in `onCreate()` of the activity:

```
if (getSystemService(android.view.autofill.AutofillManager.class).isEnabled()) {
    Toast.makeText(this, "Ick!", Toast.LENGTH_LONG).show();
    finish();
}
```

(where you would replace the `Toast` with something else to explain the situation to the user)

Or, if you wanted to ensure that the contents of your form were not submitted to the autofill service — again, with privacy in mind — you can `cancel()` the autofill operation in `onBackPressed()`, or perhaps in other lifecycle methods:

```
@Override
public void onBackPressed() {
    getSystemService(android.view.autofill.AutofillManager.class).cancel();

    super.onBackPressed();
}
```

Security Requirements of Autofill Services

Of course, a poorly written autofill provider can leak sensitive data.

That quote is from [a comment](#) on [a security issue](#) regarding a security flaw in Android 8.0's autofill implementation. While those links may not work for you, as the issue is still locked at the time this was written, it contains a long chain of comments about this flaw and how Google expects the Android ecosystem to deal with the flaw.

First, the Flaw

Autofill will fill in widgets that the user cannot see, because:

- The widget is marked as invisible (`android:visibility="invisible"`)
- The widget has no size (width and height of 0dp) or is impossibly tiny (width and height of 1dp)
- The widget has negative margins that cause it to display off-screen
- The widget is behind some other opaque widget (on the Z axis), and so the widget cannot be seen

There may be other similar scenarios. For example some discussion on the issue suggests that autofill will supply data for a widget that does not exist at all in the view hierarchy, but rather is faked by the activity as part of how it populates the `ViewStructure` of information that goes to the autofill service.

Given this flaw, a malicious activity could obtain data that the user does not realize will go to that activity. For example, the activity might have a field for the user to confirm their postal code and have hidden widgets that collect other data, such as the rest of the address, credit card details, usernames/passphrases, etc.

This flaw can be demonstrated using [Google's own sample autofill service](#), though in the future that sample should be updated to show a more secure implementation.

A copy of the flawed autofill service sample, along with a client demonstrating how malicious activities can obtain data covertly from the autofill service, can be found in [this GitHub repo](#). Instructions for reproducing the problem can be found there as well.

Google's Response

Google's engineers on the security issue admit that the flaw exists and that it would be difficult, if not impossible, to defend against malicious activities.

As such, Google is taking the approach of dumping this issue on the laps of the developers of autofill services. That is the context for the quote at the top; Google believes that well-crafted autofill services will resolve this issue. In the issue, Google has stated that their own autofill service implementation that ships pre-installed and pre-enabled on Android 8.0 will be well-crafted.

There are two problems:

1. At present, there is little documentation or sample code on what a well-crafted autofill service looks and works like, so many other developers looking to implement autofill services are left in the dark
2. Their advice will not resolve the problem completely, though it will reduce the scope

What Secure Autofill Services Need To Do

Unfortunately, the documentation for writing autofill services is limited and does not address very well the issue of how to write a secure autofill service.

Instead, Google “work[s] closely with most major autofill providers”, focusing on that instead of documentation, sample code, and public test suites. This approach is difficult to defend, given that there may be entire markets for which Google’s efforts have no impact (e.g., China, if none of the “major autofill providers” distribute their apps there).

So, what is it that Google is expecting autofill service developers to do?

Partition the Dataset

The one bit of advice that Google has published publicly (as of the time this was written) was to partition the dataset. This involves two steps:

1. Cluster the possible requested autofill hints into partitions (e.g., address/phone versus credit card versus username/password)
2. Only hand back the data for one partition at a time, based on what widget has the focus at the time the autofill request is made of the service

So, for example, suppose the form has fields for address, phone number, and the typical batch of credit card details (number, name, expiration date, etc.) A poorly-crafted autofill service provides autofill data for all of that when Android asks for it... despite the fact that this is what the API would appear to expect the autofill service to do. Instead, you need to:

- Identify which widget has the focus
- Determine which partition (address/phone or credit card) that widget belongs to
- Only supply autofill data for that partition on this request

THE AUTOFILL API

Later on, if the user puts the focus on a field that is eligible for autofill but for which you did not provide the data previously, you will get a second chance at the same form, where you repeat the process, only supplying autofill data for the partition associated with the now-focused partition.

See the “Data Partitioning” section in [the AutofillService JavaDocs](#) for complete details.

Only Give Data Back to the App That Supplied It

Another bit of advice: only give data back to the app that supplied it, for anything that you or the user might consider to be sensitive.

On the Web, some autofill works across all domains. Data that you fill into a form on one Web site can be captured by the browser and offered up as candidate responses on other sites, including ones that you have never visited before. If the user fills in an email address for Site A, that email address is available to supply via autofill to Site B.

The equivalent behavior with Android’s autofill would be for the autofill service to have a single pool of data that could be autofilled-in for any app. If the user fills in an email address for App A, that email address is available to supply via autofill to App B.

Google feels that this is fine, so long as the data is not something that the user would consider to be sensitive. In particular, they recommend that usernames and passwords be locked to an individual app and not pooled, which makes perfect sense. For such sensitive content, an autofill service must only provide data back to the specific app that supplied it, via a combination of the `applicationId` (“package”) of the app and the public signing key of that app:

An autofill provider must verify the *package+signature* to prevent phishing - this guarantees that even if a sideloaded app uses another app’s package name and mimics its UI cannot get access to sensitive data associated with it.

At the present time, this “only give data back to the app that supplied it” requirement is undocumented, outside of the aforementioned security issue. According to the developers, it will be documented sometime in the future.

Hint to the User What Data Is Being Autofilled In

The autofill service API has support for the service to require authentication before actually providing the autofill data. In a nutshell, the service creates a `PendingIntent` pointing to the authentication activity associated with the autofill service and includes that `PendingIntent` in its response to an autofill request. If the user elects to proceed, the `PendingIntent` is used to display the authentication activity. If the user successfully authenticates, the user is returned to the activity they had been on previously, but now the secured autofill data should now be available for use.

For anything that is deemed sensitive, Google not only recommends that autofill services use this authentication flow, but that the authentication activity display details of exactly what data will be released. This way, for whatever autofill request triggered the authentication, the user will be informed about all fields that would be filled in... including those that the user cannot see.

This requirement is also undocumented at this time.

What Google's Advice Does Not Solve

There are gaps in Google's advice.

First, there is no real enforcement that any autofill service follow the advice. This might be checked manually for the Play Store:

However, we'll have a manual procedure in place to verify such compliance for apps that want to be listed as an Autofill service option in the "Add Autofill Service" Play Store page that is launched from Settings.

How well this works, and whether any other app distribution channel will implement similar checks, remains to be seen. Similarly, whether any security firms or other independent parties offer some sort of compliance check remains to be seen.

Second, the "only give data back to the app that supplied it" rule will fail for apps for whom the form and the data come from outside the app... such as for Web browsers. There, the app is the *browser*, not the Web site. The autofill service has no obvious means of distinguishing one site from another, or even that there is a concept of "site" that needs to be taken into account.

Third, what the *user* considers to be sensitive data, what *Google* considers to be sensitive data, and what *autofill service developers* consider to be sensitive may differ. For example, the user might be rather concerned about their address being made available. But if the autofill service developers do not consider that to be sensitive data, Google's recommendations may be ignored. In particular, if you implement the partitioning, but do not limit data sharing between apps, a malicious activity can still steal data within a single partition, such as obtaining all the credit card details when just asking visibly for the expiration year.

Fourth, the hint-when-authenticating approach helps, but a malicious activity can defeat simple implementations, by requesting multiple partitions and setting the focus such that an innocuous partition is requested first. For example, the malicious activity's form might have visible fields for email address and postal code, followed by invisible fields for the rest of the address. Putting the email address field first and giving it the focus will cause any authentication to happen for the email partition. If the authentication activity only hints to the user about fields that will be autofilled in from that one partition, the user will only be told about the visible email address field. Authentication should not be required when the user advances to the postal code field, as the user just authenticated, and so the user might not receive the hint about the hidden address fields after the postal code field.

The Data Binding Framework

To quote [Rudyard Kipling](#):

East is East and West is West, and never the twain shall meet

In many programming environments, including classical Android development, one could paraphrase Kipling as “models are models and views are views, and never the twain shall meet, except by means of some controller or presenter or something”. The result is a fair amount of code that populates views with model-supplied data and updates those models as the user alters the data in the views (e.g., types something in an `EditText` widget).

Data binding, in general, refers to frameworks or libraries designed to help simplify some of this data migration, where the definitions of the models and views can be used to automatically “bind” them without as much custom controller- or presenter-style logic.

Interest in data binding spiked in 2015, when Google released the first beta editions of data binding support via Android Studio, the Android Gradle Plugin, and a new data-binding support library.

This chapter explores Google’s data binding support and how to use it to simplify your Android app development.

Prerequisites

This chapter requires that you have read the core chapters of this book. In particular, the sample apps are based off of samples from [the chapter on Internet access](#). Also, some samples use [RecyclerView](#).

The What, Now?

In that chapter on Internet access, we examined a few variations of a sample app that retrieved the latest android questions from Stack Overflow and displayed them in a `ListView`. Our `QuestionsFragment` had an `ItemsAdapter` for populating the `ListView`, complete with a typical `getView()` implementation:

```
setListAdapter(new ItemsAdapter(questions.items));
}

class ItemsAdapter extends ArrayAdapter<Item> {
    ItemsAdapter(List<Item> items) {
        super(getActivity(), R.layout.row, R.id.title, items);
    }

    @Override
    public View getView(int position, View convertView, ViewGroup parent) {
        View row=super.getView(position, convertView, parent);
        Item item=getItem(position);
        ImageView icon=(ImageView)row.findViewById(R.id.icon);

        Picasso.with(getActivity()).load(item.owner.profileImage)
            .fit().centerCrop()
            .placeholder(R.drawable.owner_placeholder)
            .error(R.drawable.owner_error).into(icon);

        TextView title=(TextView)row.findViewById(R.id.title);

        title.setText(Html.fromHtml(getItem(position).title));
    }
}
```

(from [HTTP/Picasso/app/src/main/java/com/commonsware/android/picasso/QuestionsFragment.java](http://Picasso/app/src/main/java/com/commonsware/android/picasso/QuestionsFragment.java))

Some parts of `getView()` are clearly distinct for this application, notably using `Picasso` to download the question asker's avatar and using `Html.fromHtml()` to handle HTML-style entities in the title.

However, the general process used here in `getView()` is fairly rote:

- Get the widget out of the row
- Stuff the data into the widget for the row
- Do the above for each widget needing to be updated as part of binding data to the row (a.k.a., “lather, rinse, repeat”)

Data binding, as a general technique, aims to reduce that rote coding by declaratively telling a framework how to pull data from model objects (e.g., instances of `Item`) and pour that data into widgets (e.g., `ImageView` and `TextView`).

The Basic Steps

With that in mind, let's examine what it takes to convert this sample over to using Google's data binding system.

The code samples shown in this section come from the [DataBinding/Basic](#) sample project.

Setting Up the Toolchain

Data binding only really works well with up-to-date versions of Android Studio (1.3 or higher) and the Android Gradle Plugin (1.5.0 or higher recommended).

The data binding system consists of two pieces: another plugin for Gradle, and a library that gets bundled with our app. However, we do not need to set those up manually. Instead, we simply tell the Android Gradle Plugin that we want data binding, and it adds the requisite plugin and library for us.

All we need is a small `dataBinding` closure, where we set the `enabled` property to `true`:

```
apply plugin: 'com.android.application'

dependencies {
    implementation 'com.squareup.picasso:picasso:2.5.2'
    implementation 'com.squareup.retrofit2:converter-gson:2.1.0'
}

android {
    compileSdkVersion 25
    buildToolsVersion '26.0.2'

    defaultConfig {
        minSdkVersion 15
        targetSdkVersion 25
        versionCode 1
        versionName "1.0"
    }
}
```

THE DATA BINDING FRAMEWORK

```
dataBinding {  
    enabled = true  
}  
}
```

(from [DataBinding/Basic/app/build.gradle](#))

Once you do this, future times that you open this project in Android Studio may result in you getting a “Source folders generated at incorrect location” message:

Figure 708: Data Binding Gradle Sync Message

This is due to [a bug](#) that, in the fullness of time, may get fixed. However, the messages appear to be benign, and they should not cause any problems with your app.

Augmenting the Layout... and the Model

The real fun begins with the layout for our `ListView` row. The original edition of this layout resource was a typical `LinearLayout` with an `ImageView` and `TextView`:

```
<?xml version="1.0" encoding="utf-8"?>  
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"  
    android:layout_width="match_parent"  
    android:layout_height="wrap_content"  
    android:orientation="horizontal">  
  
    <ImageView  
        android:id="@+id/icon"  
        android:layout_width="@dimen/icon"  
        android:layout_height="@dimen/icon"  
        android:layout_gravity="center_vertical"  
        android:contentDescription="@string/icon"  
        android:padding="8dip"/>  
  
    <TextView  
        android:id="@+id/title"  
        android:layout_width="wrap_content"  
        android:layout_height="wrap_content"  
        android:textSize="20sp"
```

THE DATA BINDING FRAMEWORK

```
    android:layout_gravity="left|center_vertical"/>
</LinearLayout>
```

(from [HTTP/Picasso/app/src/main/res/layout/row.xml](http://Picasso/app/src/main/res/layout/row.xml))

We need to make some changes to that in order to leverage data binding:

```
<?xml version="1.0" encoding="utf-8"?>
<layout xmlns:android="http://schemas.android.com/apk/res/android">

    <data>

        <variable
            name="item"
            type="com.commonware.android.databind.basic.Item"/>
    </data>

    <LinearLayout
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:orientation="horizontal">

        <ImageView
            android:id="@+id/icon"
            android:layout_width="@dimen/icon"
            android:layout_height="@dimen/icon"
            android:layout_gravity="center_vertical"
            android:contentDescription="@string/icon"
            android:padding="8dip"/>

        <TextView
            android:id="@+id/title"
            android:layout_width="wrap_content"
            android:layout_height="wrap_content"
            android:layout_gravity="left|center_vertical"
            android:text="@{item.title}"
            android:textSize="20sp"/>

    </LinearLayout>
</layout>
```

(from DataBinding/Basic/app/src/main/res/layout/row.xml)

First, the entire resource file gets wrapped in a `<layout>` element, on which we can place the android namespace declaration.

THE DATA BINDING FRAMEWORK

That `<layout>` element then has two children. The second child is our `LinearLayout`, representing the root `View` or `ViewGroup` for the resource. The first child is a `<data>` element, and that is where we configure how data binding should proceed when this layout resource gets used. Specifically, the `<variable>` element indicates that we want to bind data from an `Item` object into widgets defined in this layout.

Then, if you look at the `TextView`, you will see that it now has an `android:text` attribute that the original layout resource lacked. More importantly, the value for `android:text` is unusual: `@{item.title}`. The `@{}` syntax indicates that rather than interpreting the value as a plain string, or even a reference to a string resource, that the value is really an expression, in a data binding expression language, that should be computed at runtime to get the value to assign to the text of the `TextView`.

In this case, the expression is `item.value`. `item` is the name given to the `Item` object in the `<variable>` element. Any place where we want to pull data from that `Item` object, we can use dot notation to reference things on the `item` expression language variable.

`item.value` means “get the value from the `item`”. At runtime, the data binding library will attempt to get this value either from a public getter method (`getValue()`) or a public field (`value`) on the `Item` class. The original project had a `value` field, but it was not public, so the revised project marks the `Item` fields as public, so we can use them in data binding:

```
package com.commonware.android.databind.basic;

public class Item {
    public String title;
    public Owner owner;
    public String link;

    @Override
    public String toString() {
        return(title);
    }
}
```

(from [DataBinding/Basic/app/src/main/java/com/commonware/android/databind/basic/Item.java](#))

As we will see in this chapter, the expression language used here is much more complex than simply referencing JavaBean-style properties on objects, but for now, this will suffice.

Applying the Binding

The layout configures one side of the binding: pulling data into widgets. We still need to do some work to configure the other side of the binding: supplying the source of that data. In the case of this example, we need to provide the `Item` object for this layout resource.

That is handled via some modifications to the `getView()` method of the `ItemsAdapter` from its original version:

```
@Override
public View getView(int position, View convertView, ViewGroup parent) {
    RowBinding rowBinding=
        DataBindingUtil.getBinding(convertView);

    if (rowBinding==null) {
        rowBinding=
            RowBinding.inflate(getActivity().getLayoutInflater(),
                parent, false);
    }

    Item item=getItem(position);
    ImageView icon=rowBinding.icon;

    rowBinding.setItem(item);

    Picasso.with(getActivity()).load(item.owner.profileImage)
        .fit().centerCrop()
        .placeholder(R.drawable.owner_placeholder)
        .error(R.drawable.owner_error).into(icon);

    return(rowBinding.getRoot());
}
```

(from [DataBinding/Basic/app/src/main/java/com/commonsware/android/databind/basic/QuestionsFragment.java](#))

There are four changes here: we create the binding, provide the model (`Item`) to the binding, retrieve other widgets from the binding, and retrieve the root view of the layout.

Creating the Binding

When we use `<layout>` in a layout resource and set up the layout side of the data binding system, the build system code-generates a Java class associated with that

THE DATA BINDING FRAMEWORK

layout file. The class name is derived from the layout name, where `names_like_this` get converted into `NamesLikeThis` and have `Binding` appended. So, since our layout resource was `row.xml`, we get `RowBinding`. This is code-generated into a databinding Java sub-package of the package name from the manifest. Hence, the fully-qualified import statement for this class is:

```
import com.commonware.android.databind.basic.databinding.RowBinding;
```

This is a subclass of `ViewDataBinding`, supplied by the databinding library that is added to your project by enabling data binding in your `build.gradle` file.

Creating an instance of the binding also inflates the associated layout. Your binding class has a number of factory methods for inflating the layout and creating the binding. These mirror other methods that you have used elsewhere:

- `setContentView()`, taking an `Activity` and the layout resource ID as parameters, inflates the layout, passes the result to `setContentView()` on the `Activity`, and creates the binding
- `inflate()`, with a variety of parameter list options, just inflates the layout using a `LayoutInflater`, and creates the binding

Here, we use the three-parameter flavor of `inflate()`, which takes a `LayoutInflater` (obtained from the hosting activity), the parent container, and `false`. This mirrors the `inflate()` one would use on `LayoutInflater` itself, except that it also gives us our binding.

Of course, this is a `ListView`, and so we have to deal with the possibility that rows get recycled. The `DataBindingUtil` class has a `getBinding()` method that returns the binding for a given root view from the inflated layout — in this case, our `convertView`. So, we try to get the existing binding first, then fall back to inflating a new one if and only if that is necessary. Since `getBinding()` properly handles null values for `convertView`, we do not need to check for null ourselves explicitly.

Pouring the Model into the Binding

The generated binding class will have setters for each `<variable>` in our `<data>` element in the layout. Setter names are generated from the variable names using standard JavaBean conventions, so our `item` variable becomes `setItem()`. When we call `setItem()`, the data binding system will use that `Item` object to populate our `TextView`, applying the binding expression from our `android:text` attribute.

Retrieving Widgets from the Binding

However, we did not do anything related to data binding for the `ImageView` widget in the layout (though we will, later in this chapter). Hence, we still need to manage that manually, getting Picasso to fetch the avatar asynchronously and put it in the `ImageView`.

However, that implies that we *have* the `ImageView`. Normally, we would call `findViewById()` on the inflated layout's root `View` to obtain that.

However, our binding class has code-generated public fields on it for each widget in the layout resource that has an `android:id` value (at least for `@id/...` and `#+id/...` values). Our `ImageView` has an `android:id` value of `#+id/icon`, and so the `RowBinding` class has an `icon` field that holds our `ImageView`. We can simply reference it, rather than doing the `findViewById()` lookup ourselves.

Getting the Actual View

Since `getView()` is supposed to return the inflated layout's root view, we need some way to get that from the binding. Fortunately, `ViewDataBinding` has a `getRoot()` method that our generated class inherits, so we can just call that to get the value to return from `getView()`.

Results

Visually, this app is the same as before (though this version uses `Theme.Material` on compatible devices). Functionally, the app is the same as before. And, from a code complexity standpoint, the app is probably *worse* than before, as we went through a lot of work just to avoid calling `findViewById()` a couple of times and `setText()` once.

Hence, while the data binding system is nice, it really only adds value to larger projects, particularly those with complex layouts. By the end of this chapter, you should have a better sense for when data binding is useful and when it is overkill.

The Extended Layout Resource

As we saw in the preceding example, much of the knowledge that we impart into our app to power the data binding comes in the form of an extended layout resource syntax. The last child of the root `<layout>` element is what our layout resources used

to hold: the `View` or `ViewGroup` at the root of the view hierarchy of this layout. Other children of `<layout>` configure the data binding behavior (and perhaps other features in the future).

With that in mind, let's explore a bit more about what you can do with elements in the `<layout>`.

Imports and Statics

The preceding example lost one feature with respect to the sample app that served as its starting point: handling HTML in titles. While Stack Overflow does not serve HTML tags in question titles, it *does* serve HTML entities in question titles. A question title of "Foo & Bar" would come to us in the JSON as "Foo & Bar". The examples in the chapter on Internet access handle that via `Html.fromHtml()`. However, we do not have that in our data binding.

One way to address this is to add a getter-style method to `Item` that returns the title after passing through `Html.fromHtml()`. For example, we could have a `getInterpretedTitle()` or `getTitleWithEntitiesFixed()` or `getTitleAfterHavingRunItThroughHtmlFromHtml()`. We would then refer to that method in our `android:text` expression (e.g., `@{item.interpretedTitle}`).

However, this blurs the line dividing the responsibilities of model objects and the UI layer. The model itself does not care that the title has HTML entities in it, and some ways of using that model data (e.g., displaying in a `WebView`) might specifically *need* those HTML entities. The fact that we need to convert those HTML entities is a UI responsibility, because the UI chose to use a `TextView`, which does not handle those entities automatically.

A fairly easy way to get our `Html.fromHtml()` logic back in would be to apply it in the layout resource itself. It would be cool if we could have our expression be `@{Html.fromHtml(item.title)}`, for example.

The good news is: that is eminently possible.

However, if you just used that syntax without other changes, the data binding framework would complain that it does not know what `Html` is. In effect, we need to teach the layout resource where to import `Html` from.

THE DATA BINDING FRAMEWORK

To do that, we need to add `<import type="android.text.Html"/>` into the `<data>` element of our layout resource. Now, the generated code will contain that import statement and our references to `Html` will resolve.

You can see that in the [DataBinding/Static](#) sample project. This is a clone of `DataBinding/Basic` with the two changes (expression and `<import>` applied), giving us the following layout resource:

```
<?xml version="1.0" encoding="utf-8"?>
<layout xmlns:android="http://schemas.android.com/apk/res/android">

  <data>

    <import type="android.text.Html"/>

    <variable
      name="item"
      type="com.commonware.android.databind.basic.Item"/>
  </data>

  <LinearLayout
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:orientation="horizontal">

    <ImageView
      android:id="@+id/icon"
      android:layout_width="@dimen/icon"
      android:layout_height="@dimen/icon"
      android:layout_gravity="center_vertical"
      android:contentDescription="@string/icon"
      android:padding="8dip"/>

    <TextView
      android:id="@+id/title"
      android:layout_width="wrap_content"
      android:layout_height="wrap_content"
      android:layout_gravity="left|center_vertical"
      android:text="@{Html.fromHtml(item.title)}"
      android:textSize="20sp"/>

  </LinearLayout>
</layout>
```

(from [DataBinding/Static/app/src/main/res/layout/row.xml](#))

THE DATA BINDING FRAMEWORK

If you run this version of the app, and it so happens that there is a Stack Overflow question with an HTML entity in its title among the recent questions, you will see that entity show up properly in the `ListView`. On the other hand, if you run the previous sample, the HTML entity will show up in HTML source form (e.g., `&` instead of `&`).

The rules for imports here are reminiscent of those of regular Java:

- Do not have conflicting imports (e.g., `android.view.Menu` and `com.myrestaurant.Menu`)
- Do not try to import classes that are automatically imported (e.g., `java.lang.String`)

Variables

As we saw in the preceding samples, you can have `<variable>` elements representing objects that can be referenced by binding expressions.

The type attribute for the `<variable>` element can be:

- a fully-qualified class name, as seen in the `item` variable from the examples
- the name of a class that you added via an `<import>` element
- the name of any class automatically imported into all Java classes (e.g., `Integer`)

So, for example, instead of:

```
<data>
  <variable
    name="item"
    type="com.commonware.android.databind.basic.Item"/>
</data>
```

we could have:

```
<data>
  <import type="com.commonware.android.databind.basic.Item"/>

  <variable
    name="item"
    type="Item"/>
</data>
```

If you have different versions of the same layout in different resource sets for different configurations (e.g., `res/layout/` and `res/layout-land/`), your `<layout>` element needs to be compatible between them. This particularly holds true with respect to variables. If you define a variable `foo` as a `String` in one version of the resource, you cannot define `foo` to be a `Restaurant` in another version of the resource. There is one binding class created for each layout resource, spanning all of the different versions of that resource, and that class cannot have two separate, conflicting definitions for the same variable.

The Binding Expression Language

To a basic approximation, the binding expression language that you can use in layout resources works just like its Java counterpart. If you can include it in a Java expression, you can include it in a binding expression. This not only covers your typical mathematical, logical, and string concatenation operations, but also:

- Casts
- Using parentheses for grouping (e.g., `@{((Location)(restaurant.location)).latitude}`)
- Calling methods, both on objects in the expression and static methods on imported classes
- Accessing fields by name, both on objects and on static classes that you have imported
- Accessing array contents using square-bracket notation, including using other variables as the index (e.g., `@{movie.actor[index].fullName}`)
- Using the ternary operator for inline if-style branching (e.g., `@{movie.isNew ? View.VISIBLE : View.GONE}`)

Stuff You Won't Find in Java

The expression language contains a few conveniences that go beyond what you will see in standard Java.

One of these has already been mentioned: JavaBean-style accessor usage. So, `foo.bar` will try to find a field named `bar` on the `foo` object. If that is not found, `foo.bar` will try to find a `getBar()` method on the `foo` object. This allows the model object to decide whether or not to expose the data via a field or getter method; the binding expression works with either.

THE DATA BINDING FRAMEWORK

If you have a variable that is a `Map`, you can use square-bracket notation to access the map by key, instead of having to call `get()`.

If you try accessing a field or calling a method on `null`, you normally would get a `NullPointerException`. The expression evaluator tries to mitigate that:

- If the field or method is designed to return some primitive, the result of accessing the field or calling the method on `null` returns whatever the default primitive value is (e.g., `int` and `long` values are `0`)
- Otherwise, if the field or method returns some object, the result of accessing the field or calling the method on `null` returns `null`

Another way of working with `null` values is the `??` “null coalescing operator”. In the expression `foo ?? bar`, the result is:

- `foo`, if `foo` is not `null`
- `bar`, if `foo` is `null`

This is useful when you want to replace some optional value with a default when the optional value is `null`. For example, you might use `sub.expirationDate ?? @string/not_yet_subscribed` to either show the expiration date of some subscription, or pull in the value of a string resource to use if there is no expiration date.

That example demonstrates yet another feature of the expression language: references to resources. In general, you reference them just as you would without the data binding system. So, these are equivalent:

- `android:text="@string/foo"`
- `android:text="@{@string/foo}"`

Of course, the power comes in when using those resources in actual expressions, such as using a boolean resource with the ternary operator (e.g., `@{boolean/i_can_haz_foo ? foo : bar}`).

Note that a few resource types use different names in the binding expressions, as the expression evaluator needs to know the data type. So, for example, you normally reference array resources as simply `@array/name`. In binding expressions, you replace `@array` with a different symbol to indicate the type, such as `@stringArray` or `@intArray`.

Caveats

Of course, if all of this were simple, it wouldn't be Android...

Handling String Literals

Numeric literals and `null` can be used in expressions easily enough. String literals get interesting, as the standard Java " quotation system runs afoul of the default XML " quotation system for attribute values. Your options are:

- Use single quotes for the XML attribute, so you can use double quotes for the string literal (e.g., `android:text='@{foo["bar"]}'`)
- Use backticks for the string delimiter instead of double quotes (e.g., `android:text="@{foo[\bar']}"`)
- Use HTML-style `"` entities for the string delimiter (e.g., `android:text="@{foo["bar"]}"`)

Of the three, the latter one is your worst choice, in terms of readability.

Watch Out For Mis-Interpreted Integers

Suppose that you want to have the `android:text` attribute of a `TextView` hold a numeric value, pulled from a variable. You might try using something like `android:text="@{question.score}"`, where `score` is an `int`.

When you try it, you will crash at runtime, with an error indicating that there is no resource with the ID of some hex value, where that hex value *happens* to be your `score`.

That is because `android:text` supports strings *or string resources*. The integer value for `score` will be interpreted as a reference to a string resource, not converted into a string itself.

You then might try `android:text="@{question.score.toString()}"`. That fails to compile, if `score` is an `int`, as Java primitives do not support methods, let alone `toString()`.

The right solution is to use static methods on `Integer` to convert the `int` into a string: `android:text="@{Integer.toString(question.score)}"`

Other Caveats

Because this stuff appears in plain XML, you will need to escape any < or > signs used in the expressions as < and >, respectively, which is aggravating.

You cannot use the new operator to create objects. However, you are welcome to call methods that happen to create new objects. So, in a pinch, create yourself a factory method somewhere to create the object that you were trying to instantiate via new. All things considered, though, the more object instantiation you do in layout binding, the slower that binding can become, particularly for oft-inflated layouts like rows in a rapidly-scrolling list.

You do not have access to this or super, as these would be with reference to the generated binding class itself.

Observables and Updating the Binding

Variables, and the fields or method results that you access on them, can populate View properties, as we have seen so far in this chapter. This is interesting, but it may not “move the needle” for you in terms of adopting data binding. While there may be some minor code maintenance benefit, it hardly seems worth it.

Where data binding really shines, though, is when the variables, and the fields or method results that you access on them, are observable objects (i.e., ones implementing `android.databinding.Observable`). Then, not only do the expressions update your View properties when the layout resources are inflated, **but also when the data changes**. If you have observable models, simply updating those model objects automatically propagates those changes to any live View objects looking at those models.

For example, suppose that you are writing a to-do sort of checklist. The user can tap a `CheckBox` widget to indicate that the particular task is completed, and at that point you want to change the rendering of the task overall in its `RecyclerView` row in addition to updating the model object representing the task. Since the `CheckBox` is part of that same row, bound to the model for the row, handling both the UI updates and the model updates in the same `OnClickListener` may be easy. However, what happens if you do not want to update the rendering until the model change has been saved to the database or the network? Now, some arbitrary number of milliseconds *after* `OnClickListener` returns, you need to update some row of the `RecyclerView`... if there happens to be a row pointing at this model object. After all,

the user might have scrolled, or even left this RecyclerView entirely, in which case the original row should not be changed.

The obvious tradeoff is defining your model objects to use Observable. The less-obvious tradeoff is in reorganizing your code to have *durable model objects*, where operations like Web service calls update those model objects in place, rather than replace those model objects with brand-new instances. The latter approach breaks data binding in general, but it is a much bigger problem when trying to update your UI from those models.

Observable Primitives

The entire model object itself does not have to be Observable. Whatever your binding expressions use, in terms of data, has to be Observable. That could be individual fields, if you are willing to publish those fields as Observable objects, such as by having them be `public final`.

An easy way to make a field be Observable, if the field is a primitive value (e.g., `int`), is to replace the field with the equivalent `Observable... class` (e.g., `ObservableInt`):

```
public final ObservableInt score=new ObservableInt();
```

Your code can use `get()` and `set()` methods on the `Observable... primitive wrappers` to get and set the primitive value itself. Calling `set()` also notifies all registered observers that the data has changed, and the data binding system uses that to find out that it needs to update your UI.

While this may sound a bit clunky, Java developers have used this pattern in other places. A common example are the `Atomic... classes` (e.g., `AtomicInteger`), that make modifying a primitive be guaranteed to be atomic, when that value might be get and set on multiple parallel threads.

ObservableField

For non-primitive values, but where the entire value changes in unison, you can use the generic `ObservableField` approach. In particular, a `String` is not a primitive, yet it is immutable, so changing the value means replacing the old `String` object with a new `String` object. `ObservableField` lets you set up observable strings:

```
public final ObservableField<String> title=  
    new ObservableField<String>();
```

THE DATA BINDING FRAMEWORK

(from [DataBinding/Scored/app/src/main/java/com/commonsware/android/databind/basic/Question.java](#))

This only works when you are replacing the entire object with a new object. So, for example, wrapping a `Location` in an `ObservableField` only works if you change the location by replacing the `Location`, instead of calling `setLatitude()` and `setLongitude()` on the existing `Location`. Replacing the `Location` outright triggers `ObservableField` to tell observers about the change. In contrast, `ObservableField` has no way to know that you called a method on the wrapped object that changes its state in a way that observers need to know about.

ObservableArrayList and ObservableArrayMap

The data binding system ships with two `Observable` classes that are collections.

One, `ObservableArrayList`, is fairly straightforward: it lets you add and remove members of the list, and it informs observers about those changes. Once again, it has no means of knowing if you change the state of a given list member, only if you change the state of the list itself.

The other is `ObservableArrayMap`. Android added the `ArrayMap` class in API Level 19. Functionally, `ArrayMap` works like a `HashMap`, as a collection of values accessed via keys, albeit with some additional APIs for working with the contents by numerical index, as you see with `ArrayList`. The implementation, though, trades off CPU time for memory efficiency. `ObservableArrayMap` adds `Observable` characteristics, such that changes to the contents of the `ArrayMap` are reported to observers.

Custom Observables

You can create your own class implementing the `Observable` interface. Most likely, you would do that by extending `BaseObservable`.

On the one hand, this does not have to be too complicated. For example, here is the implementation of `ObservableBoolean` from the data binding support library:

```
/*

* limitations under the License.
*/
package android.databinding;
import android.os.Parcel;
import android.os.Parcelable;
import java.io.Serializable;
/**
 * An observable class that holds a primitive boolean.
 * <p>
 * Observable field classes may be used instead of creating an Observable object:
 * <pre><code>public class MyDataObject {
 *     public final ObservableBoolean isAdult = new ObservableBoolean();
 * }</code></pre>
 * Fields of this type should be declared final because bindings only detect changes in the
 * field's value, not of the field itself.
 * <p>
 * This class is parcelable and serializable but callbacks are ignored when the object is
 * parcelled / serialized. Unless you add custom callbacks, this will not be an issue because
 * data binding framework always re-registers callbacks when the view is bound.
 */
public class ObservableBoolean extends BaseObservable implements Parcelable, Serializable {
    static final long serialVersionUID = 1L;
    private boolean mValue;
    /**
     * Creates an ObservableBoolean with the given initial value.
     *
     * @param value the initial value for the ObservableBoolean
     */
    public ObservableBoolean(boolean value) {
        mValue = value;
    }
    /**
     * Creates an ObservableBoolean with the initial value of <code>false</code>.
     */
    public ObservableBoolean() {
    }
    /**
     * @return the stored value.
     */
    public boolean get() {
        return mValue;
    }
    /**
     * Set the stored value.
     */
    public void set(boolean value) {
        if (value != mValue) {
            mValue = value;
            notifyChange();
        }
    }
    @Override
    public int describeContents() {
        return 0;
    }
    @Override
    public void writeToParcel(Parcel dest, int flags) {
        dest.writeInt(mValue ? 1 : 0);
    }
}
```

```
}
public static final Parcelable.Creator<ObservableBoolean> CREATOR
    = new Parcelable.Creator<ObservableBoolean>() {
    @Override
    public ObservableBoolean createFromParcel(Parcel source) {
        return new ObservableBoolean(source.readInt() == 1);
    }
    @Override
    public ObservableBoolean[] newArray(int size) {
        return new ObservableBoolean[size];
    }
};
}
```

A lot of that code is dealing with making `ObservableBoolean` [be Parcelable](#). The key, from the standpoint of `BaseObservable`, is the call to `notifyChange()` in the `set()` method. This tells `BaseObservable` to tell all observers that stuff inside this `Observable` changed, and if they are tied to this `Observable`, they should go do something. Usually, “do something” will be to re-evaluate a binding expression and update a property of a `View`, such as updating the text of a `TextView` where a binding expression was used in the `android:text` attribute.

However, creating more complex custom observables is not especially well documented, and so we will explore that more [later in this chapter](#).

An Observable Example

With all that behind us, let’s look at another rendition of the Stack Overflow sample.

There are lots of values that are published for questions via the Stack Exchange API, beyond the ones used so far. One is the score, representing the net of upvotes and downvotes on the question. Of the question properties that we had been using before, only the title has a chance of changing in real time, and that does not happen very often. On the other hand, scores are far more likely to change on the fly.

So, the [DataBinding/Scored](#) sample project starts from the `DataBinding/Static` project and adds in support for the score property. It also makes the title and score `Observable` and adds a refresh action bar item. Tapping that item will update the data for the questions loaded in the app; any changes to titles or scores will be reflected directly, without additional code, by updating the models.

Of course, this sample app was not written with data binding in mind. While the previous two samples added on bits of data binding without significantly changing the app, this time we will have to take a chainsaw to our code to get what we want.

The Limitations of Earlier Examples

The specific problem we have to work around is the nature of our data model.

The previous versions of this sample would request the model objects via Retrofit and then slap them into an adapter to show in the `ListView`. From that point onward, the models were static — no code existed to add new questions, modify existing questions, etc.

However, Retrofit is designed to create new model objects on every call to a Web service interface. So, if we call once to get the latest questions, and then make another call to get updated versions of those questions, we wind up with two separate collections of model objects.

If we were not trying to use data binding, we could take a “caveman” approach: just replace the contents of the adapter with the new model collection. This would work, albeit with some impacts on the user experience (e.g., perhaps scrolling the list back to the top).

However, with data binding, we are effectively tying our *original* data model objects to our views more tightly. This means that when we get a new set of model objects from Retrofit, we cannot use them directly. Instead, we have to use them as a source of data, to be poured into our original model objects. Through the `Observable` mechanism, we can update the original models and not worry about the `ListView` rows, as data binding will take care of that for us. But this does mean that we need to have one “magic” set of model objects that represent the bound data, distinct from any model objects representing updates to that data.

Questions vs. Items

We could address the above problem by giving `Item` the ability to update its state from another `Item`. Our original query to get the most recent questions would create a collection of `Item` objects that would be our “durable” model, the one that we bind our UI to. Later updates that create new `Item` objects would be used solely to update the original durable `Item` objects’ contents, not replace those objects.

But now we run into another problem: the `Observable` requirements of the data binding system may run counter to requirements imposed elsewhere.

In the case of this sample, `Item` is being populated by `Gson`, after Retrofit receives the JSON response from the server. `Gson` does not know anything about

ObservableField, ObservableInt, or any such things. There are two main approaches for dealing with this problem:

1. Use Gson's system of type adapters to try to teach Gson how to take JSON properties and update corresponding ObservableField, ObservableInt, etc. fields in the model. Most likely, this is the right direction for long-term use, though it is conceivable that something about Gson has irreconcilable differences with something about observable elements.
2. Have separate "model" objects. One represents the result of the Web service call (and gets populated by Gson), while the other represents the durable model (and has observable properties).

This revised edition of the sample takes the second approach. There is a new model class, Question, which models a Stack Overflow question. Our data binding will be applied to Question. Item is still there, but it represents the response from the Stack Exchange Web service call.

Keeping Score (and the ID)

Beyond dealing with the duality of Question and Item, we have two more JSON properties from the Web service response that we need to track. One is the score, as mentioned earlier. The other is the question_id, a unique ID for the question. We need this in order to be able to update an existing Question with data from a new Item, when we retrieve updates for our models.

The easy part is getting the new data from Retrofit and Gson. We just need to add two more fields to Item, for the score and question ID:

```
package com.commonware.android.databind.basic;

import com.google.gson.annotations.SerializedName;

public class Item {
    String title;
    Owner owner;
    String link;
    int score;
    @SerializedName("question_id") String id;
}
```

(from [DataBinding/Scored/app/src/main/java/com/commonware/android/databind/basic/Item.java](#))

THE DATA BINDING FRAMEWORK

In the case of the question ID, the JSON property is `question_id`. In Java, we will use `id` instead, using Gson's `@SerializedName` annotation to teach Gson to fill `question_id` properties into the `id` field.

We now also have a `Question` class that will be our observable, durable data model:

```
package com.commonware.android.databind.basic;

import android.databinding.ObservableField;
import android.databinding.ObservableInt;

public class Question {
    public final ObservableField<String> title=
        new ObservableField<String>();
    public final Owner owner;
    public final String link;
    public final ObservableInt score=new ObservableInt();
    public final String id;

    Question(Item item) {
        updateFromItem(item);
        owner=item.owner;
        link=item.link;
        id=item.id;
    }

    void updateFromItem(Item item) {
        title.set(item.title);
        score.set(item.score);
    }
}
```

(from [DataBinding/Scored/app/src/main/java/com/commonware/android/databind/basic/Question.java](#))

It holds the same five values as does `Item`, except that `title` and `score` are now `Observable`, via `ObservableField` and `ObservableInt`, respectively. The `owner`, `link`, and `id` values should be immutable, and we are not binding on them anyway, so keeping them as ordinary fields is fine.

`Question` has a constructor and an `updateFromItem()` method that both copy data from a `Item` into the `Question`. `updateFromItem()` handles the two `Observable` fields, and we will use this when we eventually fetch updates to the question. The constructor calls `updateFromItem()` plus populates the three `final` non-observable fields.

THE DATA BINDING FRAMEWORK

QuestionsFragment now has a more apropos name, as we will have it show the list of Question objects. Among other things, this requires changes to QuestionsAdapter, to work off of Question objects instead of Item objects:

```
class QuestionsAdapter extends ArrayAdapter<Question> {
    QuestionsAdapter(List<Question> items) {
        super(getActivity(), R.layout.row, R.id.title, items);
    }

    @Override
    public View getView(int position, View convertView, ViewGroup parent) {
        RowBinding rowBinding=
            DataBindingUtil.getBinding(convertView);

        if (rowBinding==null) {
            rowBinding=
                RowBinding.inflate(getActivity().getLayoutInflater(),
                    parent, false);
        }

        Question question=getItem(position);
        ImageView icon=rowBinding.icon;

        rowBinding.setQuestion(question);

        Picasso.with(getActivity()).load(question.owner.profileImage)
            .fit().centerCrop()
            .placeholder(R.drawable.owner_placeholder)
            .error(R.drawable.owner_error).into(icon);

        return(rowBinding.getRoot());
    }
}
```

(from [DataBinding/Scored/app/src/main/java/com/commonsware/android/databind/basic/QuestionsFragment.java](#))

Similarly, the <variable> in row.xml needs to be a Question now:

```
<?xml version="1.0" encoding="utf-8"?>
<layout xmlns:android="http://schemas.android.com/apk/res/android">

    <data>

        <import type="android.text.Html"/>

        <variable
            name="question">
```

```
        type="com.commonware.android.databind.basic.Question"/>
</data>

<LinearLayout
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:orientation="horizontal">

    <ImageView
        android:id="@+id/icon"
        android:layout_width="@dimen/icon"
        android:layout_height="@dimen/icon"
        android:layout_gravity="center_vertical"
        android:contentDescription="@string/icon"
        android:padding="8dip"/>

    <TextView
        android:id="@+id/title"
        android:layout_width="0dp"
        android:layout_height="wrap_content"
        android:layout_gravity="left|center_vertical"
        android:layout_weight="1"
        android:text="@{Html.fromHtml(question.title)}"
        android:textSize="20sp"/>

    <TextView
        android:id="@+id/score"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:layout_gravity="center_vertical"
        android:layout_marginLeft="8dp"
        android:layout_marginRight="8dp"
        android:text="@{Integer.toString(question.score)}"
        android:textSize="40sp"
        android:textStyle="bold"/>

</LinearLayout>
</layout>
```

(from [DataBinding/Scored/app/src/main/res/layout/row.xml](#))

You will note that the binding expression for the score TextView is `@{Integer.toString(question.score)}`. That is because the score field on Question is an int, and by default, the data binding system will think that is a reference to a string resource. We have to convert the score into a String to get the results that we want. We will see this more [later in this chapter](#).

Refreshing the Data

Of course, having a QuestionsAdapter that adapts Question object only works if we *have* Question objects.

QuestionsFragment now holds onto two collections of Question objects: an ArrayList in the order that we get them from the Web service API, and a HashMap to find a Question object given its ID:

```
private ArrayList<Question> questions
    =new ArrayList<Question>();
private HashMap<String, Question> questionMap=
    new HashMap<String, Question>();
```

(from [DataBinding/Scored/app/src/main/java/com/commonsware/android/databind/basic/QuestionsFragment.java](#))

We could use a single ArrayMap or SimpleArrayMap instead, as that structure supports both indexed and keyed access. However, we would then have to roll our own BaseAdapter, as ArrayAdapter does not know how to work with ArrayMap or SimpleArrayMap. In this case, with just one group of 25 questions, having the less-efficient approach of two collections is simpler.

Our call to the questions() method on our StackOverflowInterface still returns a collection of Item objects. In onCreateView(), where we call questions(), we arrange to use those Item objects to create the corresponding group of Question objects:

```
@Override
public View onCreateView(LayoutInflater inflater,
                        ViewGroup container,
                        Bundle savedInstanceState) {
    View result=
        super.onCreateView(inflater, container,
            savedInstanceState);

    so.questions("android").enqueue(new Callback<SOQuestions>() {
        @Override
        public void onResponse(Call<SOQuestions> call,
                               Response<SOQuestions> response) {
            for (Item item : response.body().items) {
                Question question=new Question(item);

                questions.add(question);
                questionMap.put(question.id, question);
            }
        }
    });
}
```

THE DATA BINDING FRAMEWORK

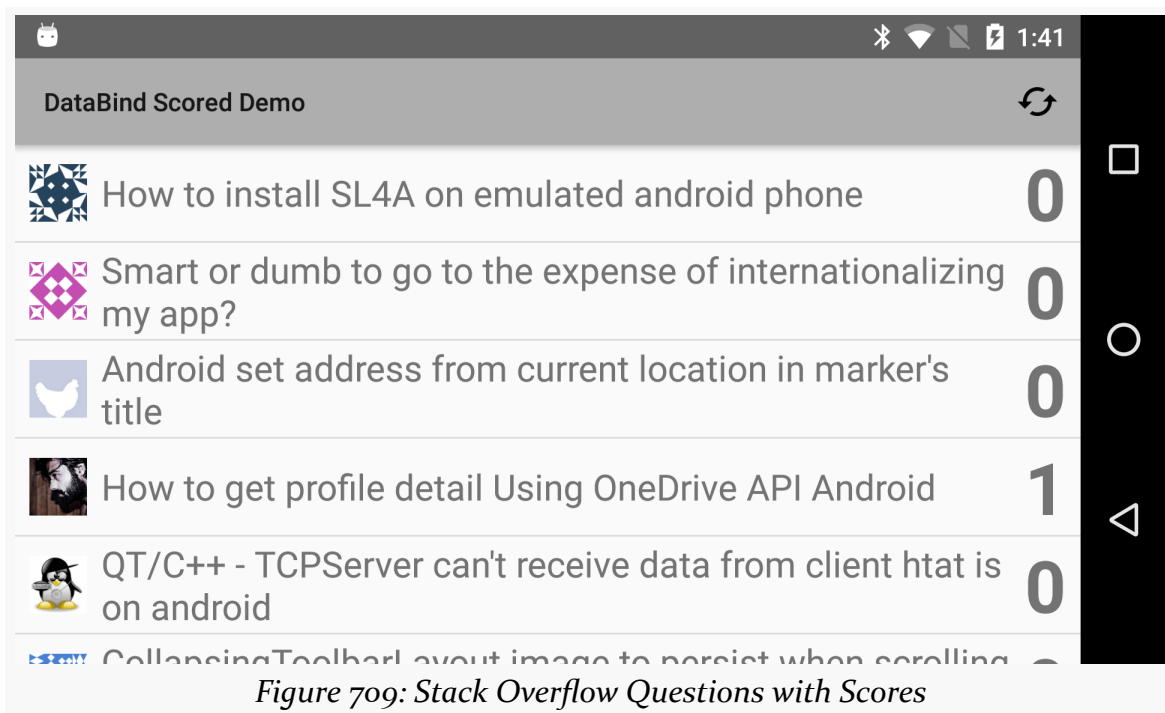

```
        setListAdapter(new QuestionsAdapter(questions));
    }

    @Override
    public void onFailure(Call<SOQuestions> call, Throwable t) {
        onError(t);
    }
});

return(result);
}
```

(from [DataBinding/Scored/app/src/main/java/com/commonsware/android/databind/basic/QuestionsFragment.java](#))

That is sufficient to get our app to run again, showing the scores along with the question titles and asker avatars:

However, we wanted to allow the user to refresh the data for these questions, so we can see a score being updated in real time via the data binding system. That requires a different call to the Stack Exchange API. It is still `/2.1/questions`, but now we have an additional path segment, one that takes a semi-colon-delimited list of question IDs. So, we add a new `@GET` method to `StackOverflowInterface` for this:

THE DATA BINDING FRAMEWORK

```
package com.commonware.android.databind.basic;

import retrofit2.Call;
import retrofit2.http.GET;
import retrofit2.http.Path;
import retrofit2.http.Query;

public interface StackOverflowInterface {
    @GET("/2.1/questions?order=desc&sort=creation&site=stackoverflow")
    Call<SQQuestions> questions(@Query("tagged") String tags);

    @GET("/2.1/questions/{ids}?site=stackoverflow")
    Call<SQQuestions> update(@Path("ids") String tags);
}
```

(from [DataBinding/Scored/app/src/main/java/com/commonware/android/databind/basic/StackOverflowInterface.java](#))

Note the use of `@Path("ids")` on the first parameter, corresponding to the `{ids}` placeholder in the path expressed in the `@GET` annotation. `@Path("ids")` says “the following parameter can be injected as a path segment into the URL”, and `{ids}` indicates specifically where that parameter’s value should go. Note, though, that it is a `String`, not a `String` array or `ArrayList` of strings. That is because we do not have a way to teach Retrofit how to concatenate a collection of strings into a single path segment.

In addition, this sample now has a menu resource directory, with an `actions.xml` resource in it, defining a single “refresh” menu item. The `QuestionsFragment` opts into participating in the action bar and, in `onCreateOptionsMenu()`, applies the actions menu resource. In `onOptionsItemSelected()`, if the user chose our refresh menu item, we call a private `updateQuestions()` method. This method needs to use the new `update()` method on `StackOverflowInterface` to update our collection of questions:

```
private void updateQuestions() {
    ArrayList<String> idList=new ArrayList<String>();

    for (Question question : questions) {
        idList.add(question.id);
    }

    String ids=TextUtils.join(";", idList);

    so.update(ids).enqueue(new Callback<SQQuestions>() {
        @Override
        public void onResponse(Call<SQQuestions> call,
```

```
        Response<SQQuestions> response) {
    for (Item item : response.body().items) {
        Question question=questionMap.get(item.id);

        if (question!=null) {
            question.updateFromItem(item);
        }
    }
}

@Override
public void onFailure(Call<SQQuestions> call, Throwable t) {
    onError(t);
}
});
}
```

(from [DataBinding/Scored/app/src/main/java/com/commonsware/android/databind/basic/QuestionsFragment.java](#))

We collect all of the question IDs, then use `TextUtils.join()` to give us a single String with all the question IDs concatenated with semicolons. That, in turn, is passed to `update()`. For each returned `Item`, we find the corresponding `Question` in the `HashMap` and update it with the new data from the `Item`.

What we do *not* do is touch our UI.

However, if you run the app, choose a good question out of the list of questions, upvote the question, and refresh the list, you will see the new score appear immediately after the refresh. The data binding system handled that for us, without additional manual intervention on our part.

Two-Way Binding

So far, the focus has been on getting data from models into views. That is the most common scenario, as usually a subset of views accept user input, and plenty of user interfaces are read-only.

Plus, the original version of the data binding system only handled populating views from models.

But, in 2016, the data binding system was updated with “two-way binding”, where views can populate models, in addition to having models populate views. While this

THE DATA BINDING FRAMEWORK

feature [is presently undocumented](#), we have some limited information on how to make it work.

The change to the layout resources is very simple: use @= instead of @:
android:checked="@={question.expanded}".

This configures the attribute (the checked state of a `CompoundButton`) with the initial value of the expanded property on a question variable. It also *updates* the property if the user checks or unchecks the `CompoundButton`.

To make this work, you cannot use a simple public field for the property. It needs to either have a setter method (e.g., `setExpanded()`) or be a public `Observable` field.

For example, the [DataBinding/TwoWay](#) sample project is a clone of the `DataBinding/Scored` sample project from earlier in this chapter. However, now the `Question` will track some local state, information not obtained from the Stack Exchange API. Specifically, it will track a boolean value named `expanded`:

```
package com.commonware.android.databind.basic;

import android.databinding.ObservableBoolean;
import android.databinding.ObservableField;
import android.databinding.ObservableInt;

public class Question {
    public final ObservableField<String> title=
        new ObservableField<String>();
    public final Owner owner;
    public final String link;
    public final ObservableInt score=new ObservableInt();
    public final String id;
    public ObservableBoolean expanded=new ObservableBoolean(true);

    Question(Item item) {
        updateFromItem(item);
        owner=item.owner;
        link=item.link;
        id=item.id;
    }

    void updateFromItem(Item item) {
        title.set(item.title);
        score.set(item.score);
    }
}
```

THE DATA BINDING FRAMEWORK

(from [DataBinding/TwoWay/app/src/main/java/com/commonsware/android/databind/basic/Question.java](#))

Our row layout resource now has a Switch widget, bound to the expanded property using the @= syntax shown above:

```
<?xml version="1.0" encoding="utf-8"?>
<layout xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:app="http://schemas.android.com/apk/res-auto">

    <data>

        <import type="android.text.Html" />

        <variable
            name="question"
            type="com.commonsware.android.databind.basic.Question" />

        <variable
            name="controller"
            type="com.commonsware.android.databind.basic.QuestionController" />
    </data>

    <android.support.v7.widget.CardView xmlns:cardview="http://schemas.android.com/apk/res-auto"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:layout_margin="4dp"
        cardview:cardCornerRadius="4dp">

        <LinearLayout
            android:id="@+id/row_content"
            android:layout_width="match_parent"
            android:layout_height="wrap_content"
            android:background="?android:attr/selectableItemBackground"
            android:gravity="center_vertical"
            android:onClick="@{()->controller.showQuestion(question)}"
            android:onTouch="@{(v,event)->controller.onTouch(v,event)}"
            android:orientation="horizontal">

            <Switch
                android:id="@+id/expanded"
                android:layout_width="wrap_content"
                android:layout_height="wrap_content"
                android:checked="@={question.expanded}" />

            <ImageView
                android:id="@+id/icon"
                android:layout_width="@dimen/icon"
                android:layout_height="@dimen/icon"
                android:layout_gravity="center_vertical"
                android:contentDescription="@string/icon"
                android:padding="8dip"
                app:error="@{@drawable/owner_error}"
                app:imageUrl="@{question.owner.profileImage}"
                app:placeholder="@{@drawable/owner_placeholder}" />

            <TextView
                android:id="@+id/title"
                android:layout_width="0dp"
```

THE DATA BINDING FRAMEWORK

```
    android:layout_height="wrap_content"
    android:layout_gravity="left|center_vertical"
    android:layout_weight="1"
    android:text="@{Html.fromHtml(question.title)}"
    android:textSize="20sp" />

<TextView
    android:id="@+id/score"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:layout_gravity="center_vertical"
    android:layout_marginLeft="8dp"
    android:layout_marginRight="8dp"
    android:text="@{Integer.toString(question.score)}"
    android:textSize="40sp"
    android:textStyle="bold" />

</LinearLayout>
</android.support.v7.widget.CardView>
</layout>
```

(from [DataBinding/TwoWay/app/src/main/res/layout/row.xml](#))

If you run the sample project, all of the switches will be checked at the outset, as we are defaulting expanded to true. If you uncheck some of them, and scroll around, you will see that the checked/unchecked state is handled properly, even though rows are being recycled along the way. And we did not have to add any Java code, other than the new property — in particular, neither our `ViewHolder` nor our `Adapter` need to worry about the `Switch`.

Other Features of Note

There are a number of other “bells and whistles” that you can utilize in the data binding system.

Obtaining Views via the Binding Class

The sample apps have been retrieving the `ImageView` widget for the row from the `RowBinding`. Any `View` in the layout file that has an `android:id` value will have a corresponding field in the `...Binding` generated class. So, for cases like the Picasso scenario, where we cannot use data binding to populate the `ImageView` and have to resort to classic bind-it-in-the-adapter logic, we do not have to do the `findViewById()` call ourselves. Instead, we just access the field in the binding class.

Manipulating Variables in the Binding

We have seen using a setter method to bind an object to a layout via the generated binding class. In the sample apps, we have been calling `setItem()` or `setQuestion()` to provide the model object to use in binding expressions. If needed, though, there is also a corresponding getter method (`getItem()`, `getQuestion()`) to retrieve the last-set value.

Views, Setters, and Binding

We have seen the use of `android:text` with a binding expression, to set the text for a `TextView`.

What really is going on is:

- The binding system evaluates the expression. This not only gives us the value to be bound, but also determines the data type of that value (e.g., `String`, `int`).
- The data binding system looks for a setter named `set...()`, where the `...` part is based on the name of the attribute (minus any namespace), where the data type matches the data type of the expression result. So, in the case where the binding expression generates a `String` for an `android:text` attribute, the data binding system will look for `setText(String)` on the widget, in our case a `TextView`. If the binding expression were to return an `int`, instead, the data binding system would look for `setText(int)`. In the case of `TextView`, that exists, and it is expecting the `int` to be a string resource. That is why, in the `Scored` sample app, we needed to convert the `int` to a `String`.

Of course, this is just the simple scenario.

Synthetic Properties

The data binding system maps attribute names to setters. But, what happens if you use an attribute name that does not actually exist?

Like the [honey badger](#), the data binding system don't care.

THE DATA BINDING FRAMEWORK

All the data binding system is doing is using the attribute name to try to find an associated setter method. The fact that the attribute name is not actually part of the `LayoutInflater`-supported XML structure is irrelevant.

This means that you can use *any* attribute that maps to a setter method.

For example, `ViewPager` has no XML attributes of its own, beyond those it inherits from `View` or `ViewGroup`. But, you are welcome to use attributes like `app:currentItem` or `app:pageMargin` in your data binding-enhanced layout resources (where `app` points to a custom namespace of yours). `LayoutInflater` will parse them, but `ViewPager` will ignore them. However, the data binding system will happily let you bind values to them, triggering calls to `setCurrentItem()` and `setPageMargin()`, respectively.

Hence, do not feel that you are limited to only those attributes that are officially supported by `LayoutInflater` and the widgets. If the data binding system can find a setter, you can use it.

However, there is one key limitation with these synthetic properties: the value has to be a binding expression. That is true even if you are not really evaluating much of an expression.

For example, this will not work:

```
<ImageView
  android:id="@+id/icon"
  android:layout_width="@dimen/icon"
  android:layout_height="@dimen/icon"
  android:layout_gravity="center_vertical"
  android:contentDescription="@string/icon"
  android:padding="8dip"
  app:error="@drawable/owner_error"
  app:imageUrl="@{question.owner.profileImage}"
  app:placeholder="@drawable/owner_placeholder"/>
```

Here, we have three synthetic properties, `app:error`, `app:imageUrl`, and `app:placeholder`. Only `app:imageUrl` is using a binding expression, and its use of one makes sense, as we are pulling in data from a variable (`question`). The other two refer to drawables. Ideally, this would work. In practice, it does not work, as the binding system ignores the properties, and then Android complains that the attribute is not recognized.

This, however, works:

```
<ImageView
    android:id="@+id/icon"
    android:layout_width="@dimen/icon"
    android:layout_height="@dimen/icon"
    android:layout_gravity="center_vertical"
    android:contentDescription="@string/icon"
    android:padding="8dip"
    app:error="@{@drawable/owner_error}"
    app:imageUrl="@{question.owner.profileImage}"
    app:placeholder="@{@drawable/owner_placeholder}"/>
```

Now, `app:error` and `app:placeholder` use binding expressions... that happen to just return a drawable resource reference. This works, if one of two things are true:

1. There are setter methods for those properties (e.g., `setError()`) on `ImageView`, which in this case, there isn't, or
2. We use other techniques to tell the data binding system that those attributes get routed elsewhere, as will be seen in the next two sections

Using Different Methods

Of course, finding a setter may be a challenge. Frequently, the attribute name and the setter name follow the described convention (`android:foo` maps to `setFoo()`). Every now and then, though, the attribute name and setter name differ.

For example, `View` has an `android:fadeScrollbars` attribute, used to determine whether or not the scrollbars for a scrollable widget should automatically fade out after a stable period when the widget is not scrolling. However, the associated setter method is not `setFadeScrollbars()`, but instead `setScrollbarFadingEnabled()`. By default, in theory, the data binding system will not find the appropriate setter for `android:fadeScrollbars`.

In practice, the documentation suggests that Google has already fixed up all of the standard attributes from Android framework classes. However, there may still be gaps, particularly in Android Support-supplied classes, let alone third-party widgets.

To overcome the mis-matched attribute/setter pair, you can teach the data binding system how to find the setter for the attribute. To do this, you are supposed to be able to define a class-level `@BindingMethods` annotation, containing one or more `@BindingMethod` annotations, which in turn map an attribute on a type to a setter method name:

```
@BindingMethods({
    @BindingMethod(type = "android.view.View",
        attribute = "android:fadeScrollbars",
        method = "setScrollbarFadingEnabled"),
})
```

BindingAdapters, and the Picasso Scenario

Sometimes, even that is insufficient. Perhaps the setter method takes additional parameters, even though in your case they could be simply hard-coded or pulled from elsewhere in the widget. Perhaps the “setter method” is not really setting a property, but arranging to do some work related to the property.

For example, so far, we have not been able to use data binding with the `ImageView`. While the URL to the image is *related* to the `android:src` attribute, `android:src` does not take a URL, and we want to use Picasso to retrieve the image asynchronously anyway. Hence, we have been stuck with configuring the `ImageView` “the old-fashioned way” in `getView()`, by retrieving the `ImageView` and then telling Picasso how to populate it.

However, the data binding system can handle this too, by defining a custom `@BindingAdapter`.

Let’s take a look at the [DataBinding/Picasso](#) sample project. This starts with the `Scored` sample from before, but now uses the data binding system to update the `ImageView`.

The `ImageView` XML from a little bit ago appears in our revised `row.xml` layout resource:

```
<?xml version="1.0" encoding="utf-8"?>
<layout
    xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:app="http://schemas.android.com/apk/res-auto">

    <data>

        <import type="android.text.Html"/>

        <variable
            name="question"
            type="com.commonware.android.databind.basic.Question"/>
    </data>
```

```
<LinearLayout
  android:layout_width="match_parent"
  android:layout_height="wrap_content"
  android:orientation="horizontal">

  <ImageView
    android:id="@+id/icon"
    android:layout_width="@dimen/icon"
    android:layout_height="@dimen/icon"
    android:layout_gravity="center_vertical"
    android:contentDescription="@string/icon"
    android:padding="8dip"
    app:error="@{@drawable/owner_error}"
    app:imageUrl="@{question.owner.profileImage}"
    app:placeholder="@{@drawable/owner_placeholder}"/>

  <TextView
    android:id="@+id/title"
    android:layout_width="0dp"
    android:layout_height="wrap_content"
    android:layout_gravity="left|center_vertical"
    android:layout_weight="1"
    android:text="@{Html.fromHtml(question.title)}"
    android:textSize="20sp"/>

  <TextView
    android:id="@+id/score"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:layout_gravity="center_vertical"
    android:layout_marginLeft="8dp"
    android:layout_marginRight="8dp"
    android:text="@{Integer.toString(question.score)}"
    android:textSize="40sp"
    android:textStyle="bold"/>

</LinearLayout>
</layout>
```

(from [DataBinding/Picasso/app/src/main/res/layout/row.xml](#))

Here, we have three synthetic properties: attributes that are not really part of `ImageView`, but that we are using with the help of the data binding system.

To make that work, the data binding system has to know what to do with those three values. `ImageView` lacks setters for those, and so in the absence of anything

THE DATA BINDING FRAMEWORK

else, the data binding system will trigger a compilation error, complaining that it does not know what to do with the values we have in the layout.

To make this work, we need a static method somewhere, with the `@BindingAdapter` annotation. In this case, we have it defined on `QuestionsFragment`:

```
@BindingAdapter({"app:imageUrl", "app:placeholder", "app:error"})
public static void bindImageView(ImageView iv,
    String url,
    Drawable placeholder,
    Drawable error) {
    Picasso.with(iv.getContext())
        .load(url)
        .fit()
        .centerCrop()
        .placeholder(placeholder)
        .error(error)
        .into(iv);
}
```

(from [DataBinding/Picasso/app/src/main/java/com/commonsware/android/databind/basic/QuestionsFragment.java](#))

The method name does not matter, so call it whatever will help remind you of its role. It needs to return `void`, and take as parameters:

- the View type that the synthetic properties will appear on (in this case, `ImageView`)
- the values of those properties, in the order that they appear in the list of strings in the `@BindingAdapter` annotation

In our case, `app:placeholder` and `app:error` are resolving to `Drawable` resources, while `app:imageUrl` is resolving to a `String`.

This declaration teaches the data binding framework to call this method any time it finds a View of the designated type (`ImageView`) with the list of synthetic properties, instead of trying to find setter methods for those properties. Since the `<ImageView>` element in our layout file meets those criteria, the `bindImageView()` method will be called.

In that method, it is our job to do whatever it is that we need to do to consume those synthetic property values and apply their results to the supplied View. In this case, we have the snippet of Picasso code formerly found in the `getView()` method. However, before, the values of the drawables (`placeholder` and `error`) were hard-

THE DATA BINDING FRAMEWORK

coded in Java. Now, they are in the layout XML file, which is a bit more flexible, particularly if we are using different layout resources for different configurations.

This means we can junk the last of the manual binding code from `getView()`, leaving behind only the connection from our `ArrayAdapter` to the `RowBinding`:

```
class QuestionsAdapter extends ArrayAdapter<Question> {
    QuestionsAdapter(List<Question> items) {
        super(getActivity(), R.layout.row, R.id.title, items);
    }

    @Override
    public View getView(int position, View convertView, ViewGroup parent) {
        RowBinding rowBinding=
            DataBindingUtil.getBinding(convertView);

        if (rowBinding==null) {
            rowBinding=
                RowBinding.inflate(getActivity().getLayoutInflater(),
                    parent, false);
        }

        rowBinding.setQuestion(getItem(position));

        return(rowBinding.getRoot());
    }
}
```

(from [DataBinding/Picasso/app/src/main/java/com/commonsware/android/databind/basic/QuestionsFragment.java](#))

Note, though, that to make this sample work, we needed to make one other change. `app:imageUrl` refers to the `profileImage` field on the `Owner` class. Formerly, that was package-private, which means that the data binding generated code could not access it. Instead, we had to make it public:

```
package com.commonsware.android.databind.basic;

import com.google.gson.annotations.SerializedName;

public class Owner {
    public @SerializedName("profile_image") String profileImage;
}
```

(from [DataBinding/Picasso/app/src/main/java/com/commonsware/android/databind/basic/Owner.java](#))

THE DATA BINDING FRAMEWORK

As an additional feature, a binding adapter can receive not only the new values for the properties, but the old ones as well (i.e., what had been used for a previous binding). To make that work, you double up all of the parameters, other than the View itself. First come the parameters that will be the old values, then come the parameters that will be the new values. If we wanted to use that in the sample shown in this section, we would have needed seven total parameters:

```
@BindingAdapter({"app:imageUrl", "app:placeholder", "app:error"})
public static void bindImageView(ImageView iv,
    String oldUrl,
    Drawable oldPlaceholder,
    Drawable oldError,
    String newUrl,
    Drawable newPlaceholder,
    Drawable newError) {

    // do good stuff here
}
```

For another example, the chapter on advanced keyboard and mouse support demonstrates [a BindingAdapter to add a focusMode option](#) to layouts, for a more flexible alternative to the <requestFocus/> XML element for controlling the widget that gets the focus.

Two-Way Binding and InverseBindingAdapter

[Two-way binding](#) works well in cases where the way you store the data in the models lines up well with the getters and setters of the associated widget. In the two-way binding example presented earlier, a boolean field in the model works well with the checked property of a CompoundButton like a Switch, as CompoundButton has an isChecked() method returning a boolean and a setChecked() accepting a boolean.

A BindingAdapter allows you to create other mappings between data types and properties, but only for the classic model->view binding. To accomplish the same thing in the reverse direction, you wind up creating an InverseBindingAdapter. As the name suggests, this serves the same basic role as a BindingAdapter, but in the inverse direction, taking data from the widget and preparing it for the model using custom code. Here, the “preparing it for the model” means converting it into a suitable data type for a setter, Observable field, etc. for your model.

This is fairly unusual.

THE DATA BINDING FRAMEWORK

The example used in some places is “what if I want to tie a float to an EditText?”. The `InverseBindingAdapter` would look something like this:

```
@InverseBindingAdapter(attribute = "android:text")
public static float getFloat(EditText et) {
    try {
        return(Float.parseFloat(et.getText().toString()));
    }
    catch (NumberFormatException e) {
        return(0.0f); // because, um, what else can we do?
    }
}
```

The problem is if the user types in something that is not a valid floating-point number, like `snicklefritz`. `parseFloat()` will fail with a `NumberFormatException`. You *should* let the user know that their data entry was invalid. However, two-way data binding does not support this, with a default value (e.g., `0.0f`) being handed to the model instead.

Event Handling

So far, we have focused on binding expressions returning data that populates widgets, specifically by configuring how that widget looks.

But what about configuring how that widget *behaves*?

Whether this is a good idea is up for debate. On the one hand, it reduces the amount of boilerplate Java code necessary to wire up widgets. On the other hand, some might worry about a blurring of the lines separating views from things like controllers or presenters.

A 2016 update to the data binding system made it easier to set up these sorts of connections, though at the present time, this feature [is undocumented](#).

Thinking Back to `android:onClick`

In the beginning, there was `android:onClick`, and it was good.

You could add the `android:onClick` attribute to a view in your layout resource XML, with a value of a method name in the activity that used the layout. That method needed to be public, return void, and take a `View` as a parameter — the same basic method signature as `onClick()` of an `OnClickListener`. When the user clicked the

view, the method named in `android:onClick` would be called, without having to call `setOnClickListener()` in Java with an `OnClickListener` implementation.

Over time, `android:onClick` faded in utility, as other things, such as fragments, started being where we wanted the click events to go. `android:onClick` could *only* call a method on the hosting activity, not a method on an arbitrary other class. No other attributes were created for other event handlers (long-click, touch, etc.), suggesting that this was a one-off experiment that would fade into oblivion.

And it did fade... until 2016, when the data binding system brought back the concept.

Tying Events to Methods Directly

For most events that you will care about with views, you can use a data binding expression to identify a method, on one of your variables, that will be called when the event is raised. Because this ties back to your variables, the method can be on any object that you inject into the binding, not just the activity.

It does make the syntax a bit more verbose. Instead of `android:onClick="doSomething"`, it becomes `android:onClick="@{controller::doSomething}"`, where `controller` is some object that you want to respond to the event (e.g., an MVC-style controller, an MVP-style presenter).

The methods referenced this way must have the same basic signature as the corresponding listener methods, just implemented on a custom class and with a custom name. So, for example, `onLongClick()` of an `OnLongClickListener` needs to return a `boolean`, indicating whether the event is consumed. If you use `android:onClick` to route that event to some custom method, that method must also return a `boolean`. Overall:

- The method must be `public`
- The method must take the same parameters as does the corresponding method on the regular listener class for this event
- The method must have the same return type as does the corresponding method on the regular listener class for this event

Tying Events to Methods via Lambda Expressions

Those restrictions on the methods tied in via data binding expressions can be a pain. In particular, you have no way of passing additional information from bound variables into the method, since those would not be part of the standard event handling method parameters.

However, the data binding system has another option for tying in event handlers: Java 8-style lambda expressions. So, you can have `android:onClick="@{()->controller::doSomething(thing)}`", where `thing` is some variable in your layout resource, or a view (based on its `android:id` value), or the magic name `context` to provide a `Context`. It could also involve expressions using any of those as part of calculations (e.g., concatenating two strings).

You can also blend in parameters that are normally available to the event, such as `android:onClick="@{(v)->controller::doSomething(v, thing)}`".

However, the argument list in the lambda function (the left-hand set of parentheses) either needs to be:

- empty, or
- have one entry for every parameter to the event handling method, even if you do not want all of those objects

For example, the `onCheckedChanged()` method on `OnCheckedChangeListener` for a `CompoundButton` takes two parameters: the `View` whose state changed, and a boolean indicating the new state. You cannot have `android:onCheckedChanged="@{(state)->controller::heyNow(state, thing)}`" or `android:onCheckedChanged="@{(view)->controller::heyNow(view, thing)}`".

Instead, if you want either of those, you need to declare both, then just ignore the one that you do not need, such as `android:onCheckedChanged="@{(v, state)->controller::heyNow(state, thing)}`".

Also, the method that you call still has to be `public` and still has to return the proper return type based on the event (e.g., `void` for `onClick`, `boolean` for `onLongClick()`).

With that in mind, the [DataBinding/RecyclerView](#) sample project demonstrates how this can work, along with how to use the data binding system to populate a `RecyclerView` instead of an `AdapterView`.

Converting to a RecyclerView/CardView UI

First, independent of data binding, we need to migrate the app over to use RecyclerView. Along the way, we can also add in support for CardView, to make the individual elements of the vertically-scrolling list look like cards, complete with rounded corners, drop shadows, and the like.

To that end, we add `recyclerview-v7` and `cardview-v7` to our roster of dependencies in `build.gradle`:

```
dependencies {
    implementation 'org.greenrobot:eventbus:3.0.0'
    implementation 'com.squareup.picasso:picasso:2.5.2'
    implementation 'com.squareup.retrofit2:converter-gson:2.1.0'
    implementation 'com.android.support:recyclerview-v7:25.1.0'
    implementation 'com.android.support:cardview-v7:25.1.0'
    implementation 'com.android.support:support-v4:25.1.0'
```

(from [DataBinding/RecyclerView/app/build.gradle](#))

Our previous samples had used `ListFragment`. We do not have a `RecyclerViewFragment` given to us by the `recyclerview-v7` library. But, we can have our own, copied from one of the RecyclerView sample projects:

```
package com.commonware.android.databind.basic;

import android.app.Fragment;
import android.os.Bundle;
import android.support.v7.widget.RecyclerView;
import android.view.LayoutInflater;
import android.view.View;
import android.view.ViewGroup;

public class RecyclerViewFragment extends Fragment {
    @Override
    public View onCreateView(LayoutInflater inflater, ViewGroup container,
        Bundle savedInstanceState) {
        RecyclerView rv=new RecyclerView(getActivity());

        rv.setHasFixedSize(true);

        return(rv);
    }

    public void setAdapter(RecyclerView.Adapter adapter) {
        getRecyclerView().setAdapter(adapter);
    }
}
```

THE DATA BINDING FRAMEWORK

```
}

public RecyclerView.Adapter getAdapter() {
    return(getRecyclerView().getAdapter());
}

public void setLayoutManager(RecyclerView.LayoutManager mgr) {
    getRecyclerView().setLayoutManager(mgr);
}

public RecyclerView getRecyclerView() {
    return((RecyclerView)getView());
}
}
```

(from [DataBinding/RecyclerView/app/src/main/java/com/commonsware/android/databind/basic/RecyclerViewFragment.java](#))

All this does is manage a RecyclerView on our behalf, including allowing us to manipulate the adapter and the layout manager.

The revised QuestionsFragment now inherits from that RecyclerViewFragment. We configure the RecyclerView in onViewCreated(), mostly just using the code from before, except that we also need to call setLayoutManager() to indicate how we want the items to be laid out — in this case, opting for a vertically-scrolling list:

```
@Override
public void onViewCreated(View view,
    Bundle savedInstanceState) {
    super.onViewCreated(view, savedInstanceState);

    setLayoutManager(new LinearLayoutManager(getActivity()));

    so.questions("android").enqueue(new Callback<SQQuestions>() {
        @Override
        public void onResponse(Call<SQQuestions> call,
            Response<SQQuestions> response) {
            for (Item item : response.body().items) {
                Question question=new Question(item);

                questions.add(question);
                questionMap.put(question.id, question);
            }

            setAdapter(new QuestionsAdapter(questions));
        }

        @Override
```

THE DATA BINDING FRAMEWORK

```
    public void onFailure(Call<SQQuestions> call, Throwable t) {
        onError(t);
    }
});
}
```

(from [DataBinding/RecyclerView/app/src/main/java/com/commonsware/android/databind/basic/QuestionsFragment.java](#))

Our QuestionsAdapter also has to change, to be a RecyclerView.Adapter, instead of an ArrayAdapter:

```
class QuestionsAdapter
    extends RecyclerView.Adapter<QuestionController> {
    private final ArrayList<Question> questions;

    QuestionsAdapter(ArrayList<Question> questions) {
        this.questions=questions;
    }

    @Override
    public QuestionController onCreateViewHolder(ViewGroup parent,
                                                int viewType) {
        RowBinding rowBinding=
            RowBinding.inflate(getActivity().getLayoutInflater(),
                parent, false);

        return(new QuestionController(rowBinding));
    }

    @Override
    public void onBindViewHolder(QuestionController holder,
                                int position) {
        holder.bindModel(getItem(position));
    }

    @Override
    public int getItemCount() {
        return(questions.size());
    }

    Question getItem(int position) {
        return(questions.get(position));
    }
}
```

(from [DataBinding/RecyclerView/app/src/main/java/com/commonsware/android/databind/basic/QuestionsFragment.java](#))

THE DATA BINDING FRAMEWORK

We take in the roster of questions in the constructor and stash that for later use. `getItemCount()` and `getItem()` simply access that roster of questions. Data binding takes place in `onCreateViewHolder()`, where we create the `RowBinding` and use that to set up a `QuestionController`. `QuestionController` is a subclass of `RecyclerView.ViewHolder` and serves as the local controller for the row in our list — we will look at `QuestionController` in greater detail shortly. `onBindViewHolder()` simply tells the `QuestionController` to bind to the supplied `Question` model object.

`RecyclerView.ViewHolder` requires the root `View` for the row be supplied to its constructor. So, in the `QuestionController` constructor, we call `getRoot()` to get that `View` from the `RowBinding` and supply that, along with stashing the `RowBinding` in a field:

```
private final RowBinding rowBinding;

public QuestionController(RowBinding rowBinding) {
    super(rowBinding.getRoot());

    this.rowBinding=rowBinding;
}
```

(from [DataBinding/RecyclerView/app/src/main/java/com/commonsware/android/databind/basic/QuestionController.java](#))

And, in `bindModel()`, we use the `RowBinding` to bind our `Question`, so the binding expressions will pull the title, score, and so forth into our views:

```
void bindModel(Question question) {
    rowBinding.setQuestion(question);
    rowBinding.setController(this);
    rowBinding.executePendingBindings();
}
```

(from [DataBinding/RecyclerView/app/src/main/java/com/commonsware/android/databind/basic/QuestionController.java](#))

In a 2016 Google I/O presentation on data binding, Google engineers recommend that if you use `RecyclerView`, as part of `onBindViewHolder()` processing, that you call `executePendingBindings()` on the binding (e.g., `RowBinding` in the case of this example). This forces the data binding framework to get all of the bindings set up immediately, rather than waiting until the natural time to do it.

In our case, we just tuck that call into the `bindModel()` method of `QuestionController`, shown above.

THE DATA BINDING FRAMEWORK

You will notice that we also call a `setController()` method on the `RowBinding`. This is in support of our event handling binding work, as you will see next.

What About the Event Listeners?

`QuestionController` has two event-related methods. One is `onTouch()`, for handling the ripple effect on Android 5.0+:

```
@Override
public boolean onTouch(View v, MotionEvent event) {
    if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.LOLLIPOP) {
        v
            .findViewById(R.id.row_content)
            .getBackground()
            .setHotspot(event.getX(), event.getY());
    }

    return(false);
}
```

(from [DataBinding/RecyclerView/app/src/main/java/com/commonsware/android/databind/basic/QuestionController.java](#))

The other is `showQuestion()`, which, surprisingly enough, will be called when we want to show the actual question:

```
public void showQuestion(Question question) {
    EventBus.getDefault().post(new QuestionClickedEvent(question));
}
```

(from [DataBinding/RecyclerView/app/src/main/java/com/commonsware/android/databind/basic/QuestionController.java](#))

It contains the `EventBus` logic to tell somebody to go show some specified `Question`.

Those are tied into our app via the data binding framework:

```
<LinearLayout
    android:id="@+id/row_content"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:background="?android:attr/selectableItemBackground"
    android:onClick="@{()->controller.showQuestion(question)}"
    android:onTouch="@{controller::onTouch}"
    android:orientation="horizontal">
```

(from [DataBinding/RecyclerView/app/src/main/res/layout/row.xml](#))

For `android:onClick`, we use the method-reference approach, asking the data binding framework to call `onTouch()` on our controller. For `android:onClick`, we use the lambda expression approach, calling `showQuestion()` on our controller, passing in the question variable, so we have our `Question` to go show.

And that's it. No other changes are needed to tie in these events, either in the `QuestionController` or in the `QuestionsAdapter`.

Type Converters

The result of a binding expression gets cast to the data type expected by the setter, field, or binding adapter that the data binding system identified as being the one to use.

Hopefully, this works.

However, it is possible that you will need to change your binding expression, such as in the case cited earlier in this chapter, where `android:text` can accept an integer, but you wanted that integer to be shown as text, not be a reference to a string resource.

In other cases, there may not be a clear match. Google's documentation cites the case where your binding expression returns the ID of a color resource, but the setter takes a `Drawable`, such as is the case with `setBackground()` on `View`.

One way of addressing this disparity is via a `@BindingMethod`. This teaches the data binding system to use a different method for the setter (e.g., `setBackgroundColors()`). However, this is *always* used for that particular widget class and attribute combination. In the particular case of the `android:background` attribute, there are a variety of possible setters:

- `setBackground(Drawable)`
- `setBackgroundColors(int)` (taking the actual color, not a color resource)
- `setBackgroundDrawable(Drawable)` (as `setBackground(Drawable)` is new to API Level 16)
- `setBackgroundResource(int)`

You may not be in position to use one of these for `android:background` exclusively.

Hence, another approach is to teach the data binding system how to convert data from one type to another, using a `@BindingConversion`-annotated static method:

THE DATA BINDING FRAMEWORK

```
@BindingConversion
public static ColorDrawable colorToDrawable(int color) {
    return new ColorDrawable(color);
}
```

As with binding adapters, the name of the method does not matter. What matters is that it takes an `int` as input and returns a `ColorDrawable`. The data binding system will take this into account and use it if it has a case where the binding expression returned an `int` and it needs a `ColorDrawable...` or a `Drawable`.

Here, though, we start to run into problems with Google's insistence on using `int` values everywhere. This `colorToDrawable()` conversion method takes an `int`. That `int` could be a color. It could be a color resource ID, or a string resource ID, or a layout resource ID, or the score of a Stack Overflow question, or countless other things. The depicted `@BindingConversion`, therefore, may not be especially useful.

Another scenario for `@BindingConversion` is to be able to extract something from deep inside a model without exposing the whole model structure as `public`. For example, the [DataBinding/Conversion](#) sample project uses a `@BindingConversion` to allow an `Owner` to be turned into a `String`, by means of returning the `profileImage` value:

```
@BindingConversion
public static String ownerToString(Owner owner) {
    return(owner.profileImage);
}
```

(from [DataBinding/Conversion/app/src/main/java/com/commonsware/android/databind/basic/QuestionsFragment.java](#))

Once again, the method name does not matter; what matters is that this conversion knows how to handle taking an `Owner` and returning a `String`.

Now, the `app:imageUrl` attribute in the `ImageView` in the layout can refer to `question.owner` instead of `question.owner.profileImage`:

```
<ImageView
    android:id="@+id/icon"
    android:layout_width="@dimen/icon"
    android:layout_height="@dimen/icon"
    android:layout_gravity="center_vertical"
    android:contentDescription="@string/icon"
    android:padding="8dip"
    app:error="@{@drawable/owner_error}"
```

```
app:imageUrl="@{question.owner}"
app:placeholder="@{drawable/owner_placeholder}" />
```

(from [DataBinding/Conversion/app/src/main/res/layout/row.xml](#))

Chained Expressions

The original edition of the data binding system allowed you to create expressions based on variables and static methods. An update to data binding in 2016 added in “chained expressions”, where expressions can refer to attributes of other widgets in the same layout resource. While this feature [is presently undocumented](#), the basics are straightforward enough: just refer to the widgets by ID.

For example, the [DataBinding/Chained](#) sample project is a clone of the [DataBinding/TwoWay](#) sample project from earlier in the chapter. There, we added a Switch widget tied to an expanded property on the Question model objects. The reason for the name “expanded” was in preparation for the [DataBinding/Chained](#) sample, where the visibility of the avatar icon and the score would be toggled based on the Switch status.

The Switch has an `android:id` of `expanded`:

```
<Switch
    android:id="@+id/expanded"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:checked="@={question.expanded}" />
```

(from [DataBinding/Chained/app/src/main/res/layout/row.xml](#))

The `android:visibility` of the icon `ImageView` now is set based on a data binding expression, checking the checked state of the expanded widget, using a ternary operator to convert that into appropriate View values:

```
<ImageView
    android:id="@+id/icon"
    android:layout_width="@dimen/icon"
    android:layout_height="@dimen/icon"
    android:layout_gravity="center_vertical"
    android:contentDescription="@string/icon"
    android:padding="8dip"
    android:visibility="@{expanded.checked ? View.VISIBLE : View.GONE}"
    app:error="@{drawable/owner_error}"
    app:imageUrl="@{question.owner.profileImage}"
    app:placeholder="@{drawable/owner_placeholder}" />
```

THE DATA BINDING FRAMEWORK

(from [DataBinding/Chained/app/src/main/res/layout/row.xml](#))

Note that this requires us to import `View`, to be able to reference `View.VISIBLE` and `View.GONE`:

```
<import type="android.view.View" />
```

(from [DataBinding/Chained/app/src/main/res/layout/row.xml](#))

The score `TextView` could use the exact same expression as was used for the icon `ImageView`. However, in this case, the visibility of score depends upon the visibility of icon:

```
<TextView
    android:id="@+id/score"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:layout_gravity="center_vertical"
    android:layout_marginLeft="8dp"
    android:layout_marginRight="8dp"
    android:text="@{Integer.toString(question.score)}"
    android:textSize="40sp"
    android:textStyle="bold"
    android:visibility="@{icon.visibility}" />
```

(from [DataBinding/Chained/app/src/main/res/layout/row.xml](#))

This way, if the rules for how we derive the visibility change, all we need to do is change icon, leaving score alone.

Now, as the user toggles the `Switch`, the visibility of the icon and the score toggles with it.

Custom Binding Class Names

As noted earlier in this chapter, the binding class name for a layout resource is determined automatically by default. The layout filename is converted into a “Pascal case” rendition, then has `Binding` appended (e.g., `res/layout/foo_bar.xml` becomes `FooBarBinding`). This class goes in the `.databinding` sub-package under the base Java package for your app, as defined in the package attribute in your `<manifest>`.

However, this may result in awkward Java class names. Or, perhaps you want to have the classes be generated in some other Java package, for some reason. You can use

the `class` attribute on the `<data>` element to control the actual Java class name used for the binding class.

This can come in one of three forms:

- `class="Foo"` will name the binding class `Foo` and will place it in the standard `.databinding` sub-package
- `=".Foo"` will name the binding class `Foo`, but will place it in the base package for your app (as defined in the `package` attribute), instead of in the separate `.databinding` sub-package
- `"this.is.fully.qualified.Foo"` will name the binding class `Foo` and place it in the designated Java package

Extended Include Syntax

Android has supported `<include>` as a tag in layout resources since Android 1.0. The tag takes a `layout` attribute, pointing to a layout resource. The contents of the pointed-to layout resource are inserted into the view hierarchy of the original resource. So, if we have:

```
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:orientation="vertical"
    android:layout_width="match_parent"
    android:layout_height="match_parent">

    <include layout="@layout/foo" />

    <!-- other widgets go here -->

</LinearLayout>
```

... then whatever is in the `foo` layout resource will be added to the `LinearLayout`, ahead of any other widgets in that `LinearLayout`.

With the data binding system, you can pass variables from the outer layout to the included one, without having to somehow bind the variable yourself in the included layout from Java code:

```
<layout xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:bind="http://schemas.android.com/apk/res-auto">
    <data>
        <variable name="foo" type="com.thingy.Foo" />
    </data>
```

```
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:orientation="vertical"
    android:layout_width="match_parent"
    android:layout_height="match_parent">

    <include layout="@layout/foo" bind:bar="@{foo}"/>

    <!-- other widgets go here -->

</LinearLayout>
</layout>
```

Here, if the foo layout resource has a variable named bar, it will be populated by evaluating the @{foo} binding expression, so the foo resource can refer to bar in its own binding expressions.

Custom Observables

What you want may not fit any of these patterns. In that case, you are going to have to roll your own Observable implementation. The simplest way to do that is to extend BaseObservable, which handles all of the observer registration logic for you.

There are two types of changes for which you can notify observers:

- Changes to properties, which can be handled by the individual property observers described above, such as ObservableField
- Changes to other intrinsic aspects of the model itself, that cannot be captured in a simple Observable wrapper on some property

For example, you might have a Person class that has birthDate field, of type Date, representing the date on which the person was born. If you wanted to use that date in a binding expression, you could have birthDate be public, or have a getBirthDate() that returned it. If you wanted a binding expression to be updated when the birth date changed (e.g., correcting a typo), you could have birthDate be an ObservableField wrapped around a Date.

However, suppose what you *really* want to use in the binding expression is the person's age. It is easy enough for Person to calculate that, based on the current date and birthDate. However, this would be awkward to publish via an ObservableField, since there should not be an age field — age is a derived value, not a stored value. Instead, you could say that your getAge() method publishes a simple int, and you

will handle notifying observers whenever the age changes, either due to a change in `birthdate`, or if the date changed and it is now the person's birthday.

Bindable Properties

On a `BaseObservable`, you can annotate getter-style methods with `@Bindable`. This tells the data binding framework that those methods represent values that can be bound. Because `BaseObservable` implements `Observable`, the data binding framework can call `addOnPropertyChangedCallback()` to register an `OnPropertyChangedCallback` to find out when `@Bindable` properties are changed.

To make that work, `BaseObservable` supplies a `notifyPropertyChanged()` method. You can call this from the setter method or other place where you are changing the value of the property, to let `BaseObservable` know that the property changed. This, in turn, will let all `OnPropertyChangedCallback` instances know about the change, which will trigger the data binding framework to re-evaluate any binding expressions tied to that property.

Unfortunately, this is broken in the 1.5.1 build of Android Studio and the 1.5.0 edition of the Android Gradle Plugin.

For example, here is a revised version of the `Question` model class that has it use `BaseObservable` and `notifyPropertyChanged()`:

```
package com.commonware.android.databind.basic;

import android.databinding.BaseObservable;
import android.databinding.Bindable;
import com.commonware.android.databind.basic.BR;

public class Question extends BaseObservable {
    private String title;
    private final Owner owner;
    private final String link;
    private int score;
    private final String id;

    Question(Item item) {
        updateFromItem(item);
        owner=item.owner;
        link=item.link;
        id=item.id;
    }
}
```

```
@Bindable
public String getTitle() {
    return(title);
}

@Bindable
public Owner getOwner() {
    return(owner);
}

@Bindable
public String getLink() {
    return(link);
}

@Bindable
public int getScore() {
    return(score);
}

@Bindable
public String getId() {
    return(id);
}

void updateFromItem(Item item) {
    this.title=item.title;
    this.score=item.score;

    notifyPropertyChanged(BR.title);
    notifyPropertyChanged(BR.score);
}
}
```

Here, BR is a generated class. According to the documentation:

The Bindable annotation generates an entry in the BR class file during compilation. The BR class file will be generated in the module package.

Unfortunately, while this is all true, Android Studio does not recognize any of the generated fields, and so while you can import BR, BR.title and BR.score — the int values identifying those properties – are not recognized and result in compile errors.

Notifying About Intrinsic Changes

If the `BaseObservable` itself is what is used in the binding expression, or if you want to use bindable properties and need to work around the BR issue mentioned above, `BaseObservable` also offers `notifyChange()`, indicating that all binding expressions tied to the `BaseObservable` instance should be re-evaluated.

The [DataBinding/Observable](#) sample project is another variation of the sample project that we have been analyzing in this chapter. This one has `Question` extend `BaseObservable`. However, unlike the code snippet above, where we tried using BR and `notifyPropertyChanged()`, here we just settle for `notifyChange()`:

```
package com.commonware.android.databind.basic;

import android.databinding.BaseObservable;
import android.databinding.Bindable;
import android.databinding.ObservableField;
import android.databinding.ObservableInt;
import com.commonware.android.databind.basic.BR;

public class Question extends BaseObservable {
    private String title;
    private final Owner owner;
    private final String link;
    private int score;
    private final String id;

    Question(Item item) {
        updateFromItem(item);
        owner=item.owner;
        link=item.link;
        id=item.id;
    }

    @Bindable
    public String getTitle() {
        return(title);
    }

    @Bindable
    public Owner getOwner() {
        return(owner);
    }

    @Bindable
    public String getLink() {
```

```
        return(link);
    }

    @Bindable
    public int getScore() {
        return(score);
    }

    @Bindable
    public String getId() {
        return(id);
    }

    void updateFromItem(Item item) {
        this.title=item.title;
        this.score=item.score;

        notifyChange();
    }
}
```

(from [DataBinding/Observable/app/src/main/java/com/commonsware/android/databind/basic/Question.java](#))

Even though we are storing title as a simple String and score as a simple int, we can use them in binding expressions, because their getters are @Bindable and we are notifying BaseObservable when their values change.

Thinking Outside the Box

Data binding will usually be used for things like the text of a TextView, or the image shown in an ImageView. However, you are welcome to have other things vary based upon binding expressions. For example, perhaps you want a certain background color or color bar on a row in a list, based upon some category associated with the model objects. You could use data binding to set that color.

Lisa Wray [pointed out](#) another inventive use of data binding: custom fonts.

Historically, using a custom Typeface required Java code. That Java code might be fairly limited, if you only need to update one TextView. Or, that Java code might pull in a library like [Calligraphy](#) to be able to apply arbitrary fonts to arbitrary widgets from within layout files.

The data binding framework can handle that for you, if you create a custom BindingAdapter for some synthetic property (e.g., wray:font). In your layout, you

THE DATA BINDING FRAMEWORK

would have `wray:font` attributes that name the typeface that you want on relevant widgets (e.g., `TextView`):

```
<TextView
  wray:font="@{'MgOpenCosmetica.ttf'}"
  android:layout_width="wrap_content"
  android:layout_height="wrap_content"/>
```

The `BindingAdapter` would retrieve the `Typeface` for that font name, then apply it to the associated widget:

```
@BindingAdapter({"wray:font"})
public static void setFont(TextView tv, String font){
  String assetPath="fonts/" + font;
  Typeface type=Typeface.createFromAsset(tv.getContext().getAssets(), assetPath);

  tv.setTypeface(type);
}
```

This particular implementation has performance issues, as it creates a new `Typeface` object on every binding, which is inefficient. Lisa has [a complete sample app](#) that demonstrates caching the `Typeface` objects to reduce the performance overhead.

It is likely that the Android community will come up with other interesting tricks for simplifying code using fancy data binding adapters, converters, and the like.

Drag and Drop

Desktop applications have long offered drag-and-drop, both within and between applications. Android has supported this for quite some time, but you could only drag and drop within a single activity. As a result, this was not especially popular.

However, starting in Android 7.0, you can drag and drop between applications, so long as their windows are visible in a multi-window environment. Not only does this make drag-and-drop more compelling in general, but in a freeform multi-window environment, users will expect Android apps to behave like their desktop counterparts. Hence, users will expect drag-and-drop capabilities where it makes sense.

In this chapter, we will explore Android’s drag-and-drop facility, including how to perform it between separate applications.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book, as well as the chapter on [the clipboard](#).

One example uses RecyclerView, so reviewing [that chapter](#) is a good idea. Similarly, one sample uses StreamProvider, so you may wish to read [the section on it](#) as well.

The Scope of Drag and Drop

Since the term “drag-and-drop” means different things to different people – including different developers used to different platforms — it will help if we understand exactly what Android’s definition of “drag-and-drop” is.

What Are We Dragging and Dropping?

In Android, the focus is on dragging and dropping content, meaning some information identified by a `Uri` and an associated MIME type. We are using the drag-and-drop process to select some piece of content and inform something else about that content. Specifically, the content that we are dragging and dropping is represented by a `ClipData` object, the same as we could use with the clipboard.

Technically, the `ClipData` does not have to represent content. The clipboard supports plain text `ClipData` items, and nothing is stopping you from using drag and drop for plain text as a result. When dragging and dropping between apps, this may cause some compatibility issues, though the drag-and-drop framework takes steps to help deal with this. Within an app, options like plain text allow you to “cheat” to an extent, allowing drag-and-drop to support anything you want, so long as you can identify the specific “anything you want” by a string ID or key.

From the *user’s* standpoint, the user is dragging some visual representation of this content. That can be whatever bitmap you want, and you will have a few options for specifying what this bitmap is. This bitmap is referred to as the “shadow”.

Where Are We Dragging From?

You will need to provide some UI that triggers a drag-and-drop operation, not only allowing the user to say “let’s drag this somewhere” but also “here is what ‘this’ I want to drag”.

A typical trigger for this is a long-click. So, for example, a long-click on a list row might trigger a drag-and-drop of the content identified by that row.

Usually, the trigger is tied to some view, as drag-and-drop intrinsically is a visual operation. Technically, this is not required, if you can find some other approach that users will understand and appreciate.

Where Are We Dropping To?

You will need to identify possible drop targets, in the form of views. A view can be registered as a potential drop target, then stipulate whether it is a candidate for a *specific* drag-and-drop operation when that operation begins. For example, if you have two lists, and you want the user to drag items between the lists, both are potential drop targets. However, you might elect to say that the user cannot drag

from a list back into that same list, so if the content being dragged originated from the list, that list is not a candidate for that specific drag-and-drop operation.

The Pieces of Drag-and-Drop

As noted above, what we are really dragging and dropping is a `ClipData`, which can represent whatever we want, so long as the recipient of that `ClipData` knows how to work with whatever the provider of that `ClipData` put in it.

However, there are a few other pieces to the drag-and-drop process.

The Drag Shadow

The drag shadow is the visual representation of what the user is dragging and dropping. Programmatically, the shadow is defined as an instance of `View.DragShadowBuilder` (which, despite the name, does *not* implement a builder-style API).

You have two main choices for creating this shadow: use a `View`, or use a `Canvas`.

...From a View

You can create a `View.DragShadowBuilder` via the constructor that takes a `View` as a parameter. This tells `View.DragShadowBuilder` that the drag shadow should be a translucent copy of whatever the `View` is showing at the time we start the drag-and-drop operation.

This is very easy to implement, and it works well if you have a `View` that makes for a likely visual representation of what is being dragged and dropped.

On the other hand, it will not handle all scenarios. Suppose that you want to allow the user to drag from a list. Furthermore, suppose that you want the user to be able to multi-select items in the list and drag the entire selection. Now you no longer have a single `View` that you can use as the basis for the drag shadow.

Also, keep the drag shadow relatively small. It needs to be big enough that the user can see it despite a finger potentially being in the way. However, it also needs to be small enough to make it clear where the user is dropping it. This is another reason why the multi-select list scenario does not work well with creating a `View.DragShadowBuilder` from a `View` — even if you chose the `ListView` or

RecyclerView as being the View from which to create the drag shadow, odds are that the list will be far too large.

...From a Canvas

For cases where using a View as the basis of your drag shadow will not work, you can create your own subclass of `View.DragShadowBuilder` and define the drag shadow however you want.

To do this, you will override two methods. One is `onProvideShadowMetrics()`, where you fill in a pair of `Point` objects. The first represents the size of the drag shadow in pixels. The other represents the point within the drag shadow where the touch point will be — in other words, where is the drag shadow with respect to where the finger is touching the screen.

The other method is `onDragShadow()`, where you are given an appropriately-sized `Canvas` and you can draw whatever you want into that `Canvas` to serve as the drag shadow. For example, you might draw a `Bitmap` in `onDragShadow()` using the dimensions of the `Bitmap` and its center point in `onProvideShadowMetrics()`.

Technically, you can combine the two approaches. You create the `View.DragShadowBuilder` using a `View` but then override one or both of the aforementioned `View.DragShadowBuilder` methods to alter the default behavior a bit. For example, by default, the touch point will be the center of the `View`, but you might want the touch point to be offset towards one corner — you could handle this by overriding `onProvideShadowMetrics()`, chaining to the superclass, then updating the second `Point` object as you see fit.

The Drag Event Listener

To react to drag events in a drop target `View`, you can call `setOnDragListener()`, supplying an implementation of `View.OnDragListener`. This interface has a single method, `onDrag()`, that you will need to implement.

The sample apps in this chapter implement `View.OnDragListener` on the activity that has the drop targets. Typically, you will implement `View.OnDragListener` on whatever object in your UI handles events raised by the widgets (e.g., a controller or presenter).

The Drag Events

`onDrag()` of your `View.OnDragListener` is passed two objects: the `View` that you called `setOnDragListener()` on, and a `DragEvent` representing what is happening with respect to the drag-and-drop process.

The `DragEvent` contains an action `int` value, representing what the state change is in the drag-and-drop operation. Depending on the action, other aspects of the `DragEvent` may be available to you as well.

ACTION_DRAG_STARTED

When the user begins a drag-and-drop operation, and your window is visible (e.g., the user started the drag-and-drop within your own activity), you will receive a `DragEvent` whose action is `ACTION_DRAG_STARTED`.

Your primary job is to return `true` from `onDrag()` if you wish to be considered a drop target for this drag-and-drop operation. Prior to Android 7.0, you might always return `true`, since you are certain to be in control over both the drag and the drop. Starting with Android 7.0, you might conditionally return `true`, if the drag-and-drop operation looks like it might be one that you can handle. Unfortunately, your primary means of determining this is via `getDescription()` on the `DragEvent`, which gives you a `ClipDescription` describing the `ClipData` that is the content. This does not give you much to go on, as we will see in upcoming samples.

If you are a valid drop target, you might also consider adjusting the look and feel of this `View` to indicate to the user that this is a valid drop target. Android does not do anything on its own for this. You might tint the `View`, or add an outline, or something, to help clue the user in that dropping over your `View` might have a positive result.

If you return `true`, you will be notified about the progress of the drag-and-drop event through the other event actions listed below. If you return `false`, you are indicating that this drag-and-drop operation does not concern you, and you will not be given any further `DragEvents` for it.

ACTION_DRAG_ENTERED

You will receive a `DragEvent` with this action once it is possible for the user to drop in your `View`. This will come when the drag shadow enters the bounding box of the `View` (not necessarily only where pixels are drawn for the view).

If you are still interested in this drag-and-drop operation, you should:

- Return `true` from `onDrag()`, and
- Alter the widget's appearance yet again, to reflect the fact that if the user lifts her finger, the content will be dropped into this widget

If precise placement within the widget is important for the drag-and-drop operation (e.g., you wish to highlight some specific cell in a grid), you can call `getX()` and `getY()` on the `DragEvent` to try to determine where the drop point is. Unfortunately, it is not documented whether `getX()` and `getY()` are relative to your widget, the screen, or something else.

ACTION_DRAG_LOCATION

If you return `true` from the `ACTION_DRAG_ENTERED` `DragEvent`, you may receive additional `DragEvents` with `ACTION_DRAG_LOCATION` actions, indicating that the user has moved within the bounding box of your widget. If you are using `getX()` and `getY()` to deal with the highlighting, these values will have changed, and so you will want to update the highlighting to match.

ACTION_DRAG_EXITED

If you return `true` from the `ACTION_DRAG_ENTERED` `DragEvent`, you may receive a `DragEvent` for `ACTION_DRAG_EXITED`. This indicates that the user dragged the item outside of your widget without dropping it. Any state changes to your widget, such as a highlight, that you applied in `ACTION_DRAG_ENTERED` or `ACTION_DRAG_LOCATION` should be reverted. However, the drag-and-drop operation is still proceeding, so any highlight you use for that (e.g., in `ACTION_DRAG_STARTED`) should still be used.

ACTION_DROP

Of course, the fun action is `ACTION_DROP`, which means that the user dropped the content over this widget as the drop target. You can call `getClipData()` to get at the `ClipData` for this content, along with final `getX()` and `getY()` values.

DRAG AND DROP

If you return `true` in `onDrag()`, this indicates that you handled the drop request.

However, you may not be able to handle the drop request. For example, suppose you are looking to have a `Uri` pointing to a video be dropped into your app. All you can determine from the `ClipDescription`, in your `ACTION_DRAG_STARTED` processing, is that the `ClipData` has a `Uri`. So, you have to return `true` from `onDrag()` in your `ACTION_DRAG_STARTED` logic. But, then, in `ACTION_DROP` processing, when you get the real `Uri`, you find out that it has a different MIME type (e.g., `text/html`, instead of `video/*`). You will need to return `false` from `onDrag()` in your `ACTION_DROP` logic. Unfortunately, what happens from this point forward is undocumented.

ACTION_DRAG_ENDED

If you returned `true` from the `ACTION_DRAG_STARTED` `DragEvent`, you should receive a `DragEvent` when the drag-and-drop operation is over, with `ACTION_DRAG_ENDED` as the action. Any state change you made to your widget in `ACTION_DRAG_STARTED` should be reverted here. If it matters to you whether the user did a valid drop or not, call `getResult()` on the `DragEvent` to find out .

Drag-and-Drop, within an Activity

The classic drag-and-drop scenario, prior to Android 7.0, was to drag-and-drop between widgets in a single activity.

The [DragDrop/Simple](#) sample project demonstrates this scenario. It is based on the `RecyclerView/VideoList` sample app from [the chapter on RecyclerView](#).

The Landscape Layout

On smaller screens, we just have the `RecyclerView` as before. However, on larger screens (e.g., 9" tablets in landscape), we put a `VideoView` and an `ImageView` alongside the `RecyclerView`:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:orientation="horizontal">

    <android.support.v7.widget.RecyclerView android:id="@+id/video_list"
        xmlns:android="http://schemas.android.com/apk/res/android"
```

DRAG AND DROP

```
        android:layout_width="0dp"
        android:layout_height="match_parent"
        android:layout_weight="1" />

<LinearLayout
    android:layout_width="0dp"
    android:layout_height="match_parent"
    android:layout_weight="1"
    android:orientation="vertical">

    <FrameLayout
        android:id="@+id/video_frame"
        android:layout_width="match_parent"
        android:layout_height="0dp"
        android:layout_marginBottom="4dp"
        android:layout_weight="1"
        android:padding="4dp">

        <VideoView
            android:id="@+id/player"
            android:layout_width="match_parent"
            android:layout_height="match_parent"
            android:layout_gravity="center" />
    </FrameLayout>

    <FrameLayout
        android:id="@+id/thumbnail_frame"
        android:layout_width="match_parent"
        android:layout_height="0dp"
        android:layout_weight="1"
        android:padding="4dp">

        <ImageView
            android:id="@+id/thumbnail_large"
            android:layout_width="match_parent"
            android:layout_height="match_parent"
            android:scaleType="centerInside" />
    </FrameLayout>
</LinearLayout>
</LinearLayout>
```

(from [DragDrop/Simple/app/src/main/res/layout-w800dp/main.xml](#))

The idea is that the user will be able to drag from the RecyclerView into the other two widgets, which will play the video or show a larger rendition of the thumbnail, respectively.

DRAG AND DROP

The `VideoView` and the `ImageView` are each wrapped in a `FrameLayout`. Mostly, that is to give us a place to render a border around the widgets, indicating that they are drop targets. We have a pair of `<shape>` drawables for this. One is a red dashed line indicating a potential drop target:

```
<?xml version="1.0" encoding="utf-8"?>
<shape xmlns:android="http://schemas.android.com/apk/res/android"
    android:shape="rectangle">
    <stroke
        android:width="2dp"
        android:dashGap="8dp"
        android:dashWidth="8dp"
        android:color="#ff0000" >
    </stroke>
</shape>
```

(from [DragDrop/Simple/app/src/main/res/drawable-nodpi/droppable.xml](#))

The other is a solid green line indicating a “live” drop target, used to indicate that dropping the content here should work:

```
<?xml version="1.0" encoding="utf-8"?>
<shape xmlns:android="http://schemas.android.com/apk/res/android"
    android:shape="rectangle">
    <stroke
        android:width="4dp"
        android:color="#2e7d32" >
    </stroke>
</shape>
```

(from [DragDrop/Simple/app/src/main/res/drawable-nodpi/drop.xml](#))

Registering as Drop Targets

This version of the sample app avoids the `RecyclerViewActivity` used in the `RecyclerView/VideoList` sample app. Instead, `MainActivity` manages all of its widgets directly, including the `RecyclerView`.

In `onCreate()`, after inflating the layout, we attempt to retrieve the `VideoView` and `ImageView`. If we find them, we call `setOnDragListener()`, supplying our `MainActivity` instance itself as the `OnDragListener` implementation:

```
player=(VideoView)findViewById(R.id.player);

if (player!=null) {
```

DRAG AND DROP

```
player.setOnDragListener(this);
}

thumbnailLarge=(ImageView)findViewById(R.id.thumbnail_large);

if (thumbnailLarge!=null) {
    thumbnailLarge.setOnDragListener(this);
}
```

(from [DragDrop/Simple/app/src/main/java/com/commonsware/android/dragdrop/MainActivity.java](#))

We will examine the `onDrag()` method that `OnDragListener` requires shortly.

Starting to Drag

This app supports a long-click on a row in our `RecyclerView` to enter drag-and-drop mode, as we call `setOnLongClickListener()` on the row itself, in `RowController` (our `RecyclerView.ViewHolder` for our list rows):

```
RowController(View row) {
    super(row);

    title=(TextView)row.findViewById(android.R.id.text1);
    thumbnail=(ImageView)row.findViewById(R.id.thumbnail);

    row.setOnClickListener(this);
    row.setOnLongClickListener(this);
}
```

(from [DragDrop/Simple/app/src/main/java/com/commonsware/android/dragdrop/RowController.java](#))

In `onLongClick()`, we:

- Create a `ClipData` based on the `Uri` obtained from `MediaStore` for the video, plus its caption (pulled from the `title TextView`)
- Create a drag shadow, using `View.DragShadowBuilder`, with the `thumbnail ImageView` as the basis
- Call `startDrag()` on the row itself, accessed via the `itemView` field on the `ViewHolder` base class

```
@Override
public boolean onLongClick(View v) {
    ClipData clip=ClipData.newRawUri(title.getText(), videoUri);
    View.DragShadowBuilder shadow=new View.DragShadowBuilder(thumbnail);
```

DRAG AND DROP

```
itemView.startDrag(clip, shadow, Boolean.TRUE, 0);

return(true);
}
```

(from [DragDrop/Simple/app/src/main/java/com/commonsware/android/dragdrop/RowController.java](#))

Besides the `ClipData` and `View.DragShadowBuilder`, `startDrag()` takes two other parameters:

- An arbitrary `Object` referred to as the “local state”, which can provide additional information between the drag source and the drop target, but only when both are in the same window (usually meaning the same activity)
- A set of flags (here unused, so set to 0)

For the local state, we are using `Boolean.TRUE`. That is a fairly arbitrary choice, but it is a good idea to pass a non-null value here, for reasons that we will get into [later in this chapter](#).

Reacting to Drag Events

Our `onDrag()` method in `MainActivity` will handle all of the events related to our registered drop targets:

```
@Override
public boolean onDrag(View v, DragEvent event) {
    boolean result=true;

    switch (event.getAction()) {
        case DragEvent.ACTION_DRAG_STARTED:
            if (event.getLocalState()==null) {
                result=false;
            }
            else {
                applyDropHint(v, R.drawable.droppable);
            }
            break;

        case DragEvent.ACTION_DRAG_ENTERED:
            applyDropHint(v, R.drawable.drop);
            break;

        case DragEvent.ACTION_DRAG_EXITED:
            applyDropHint(v, R.drawable.droppable);
            break;
    }
}
```

DRAG AND DROP

```
case DragEvent.ACTION_DRAG_ENDED:
    applyDropHint(v, -1);
    break;

case DragEvent.ACTION_DROP:
    ClipData.Item clip=event.getClipData().getItemAt(0);
    Uri videoUri=clip.getUri();

    if (v==player) {
        player.setVideoURI(videoUri);
        player.start();
    }
    else {
        Picasso.with(thumbnailLarge.getContext())
            .load(videoUri.toString())
            .fit().centerCrop()
            .placeholder(R.drawable.ic_media_video_poster)
            .into(thumbnailLarge);
    }

    break;
}

return(result);
}
```

(from [DragDrop/Simple/app/src/main/java/com/commonsware/android/dragdrop/MainActivity.java](#))

For most of the actions, we apply (or remove) a drawable from the FrameLayout containers wrapping our VideoView and ImageView widgets, via an `applyDropHint()` utility method:

```
private void applyDropHint(View v, int drawableId) {
    View parent=(View)v.getParent();

    if (drawableId>-1) {
        parent.setBackgroundResource(drawableId);
    }
    else {
        parent.setBackground(null);
    }
}
```

(from [DragDrop/Simple/app/src/main/java/com/commonsware/android/dragdrop/MainActivity.java](#))

DRAG AND DROP

Here, we use -1 as the “ID” of a resource meaning to remove any previous background.

In `onDrag()`, we ignore `ACTION_DRAG_LOCATION` events, as we are not using `getX()` and `getY()` and so do not care if those values change.

However, we do handle two actions a bit differently:

- `ACTION_DRAG_STARTED` examines the local state and rejects any `DragEvent` where that state is null, for reasons that we will get into [later in this chapter](#)
- `ACTION_DROP` retrieves the `ClipData.Item` for the `ClipData` we set as the drag content, retrieves the `Uri` of the video from the `ClipData.Item`, then either plays the video or shows the thumbnail, depending on which widget the user dropped the content into

The Result

If you run the sample app on a large-enough device with a roster of videos, you will get the list of videos on one side, and the empty `VideoView` and `ImageView` on the other side:

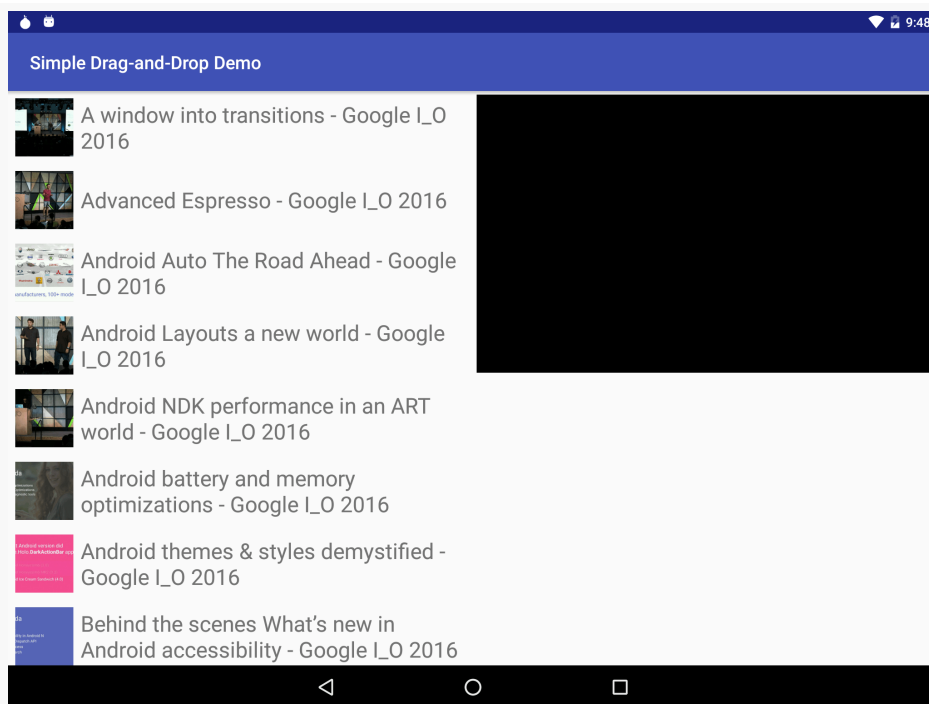

Figure 710: Simple Drag-and-Drop Demo, As Initially Launched

DRAG AND DROP

Once the user long-taps on a list row, a shadow based on the thumbnail appears under the user's finger, and the two drop targets show their red dashed outlines:

If the user drags the drop shadow over one of the drop targets, it gets the `ACTION_DRAG_ENTERED` event and changes its outline to the green solid line:

DRAG AND DROP

Figure 712: Simple Drag-and-Drop Demo, After Drag Enters Drop Target

Finally, if the user drops the item in one of the drop targets, it receives the `ACTION_DROP` event and can actually use the content:

DRAG AND DROP

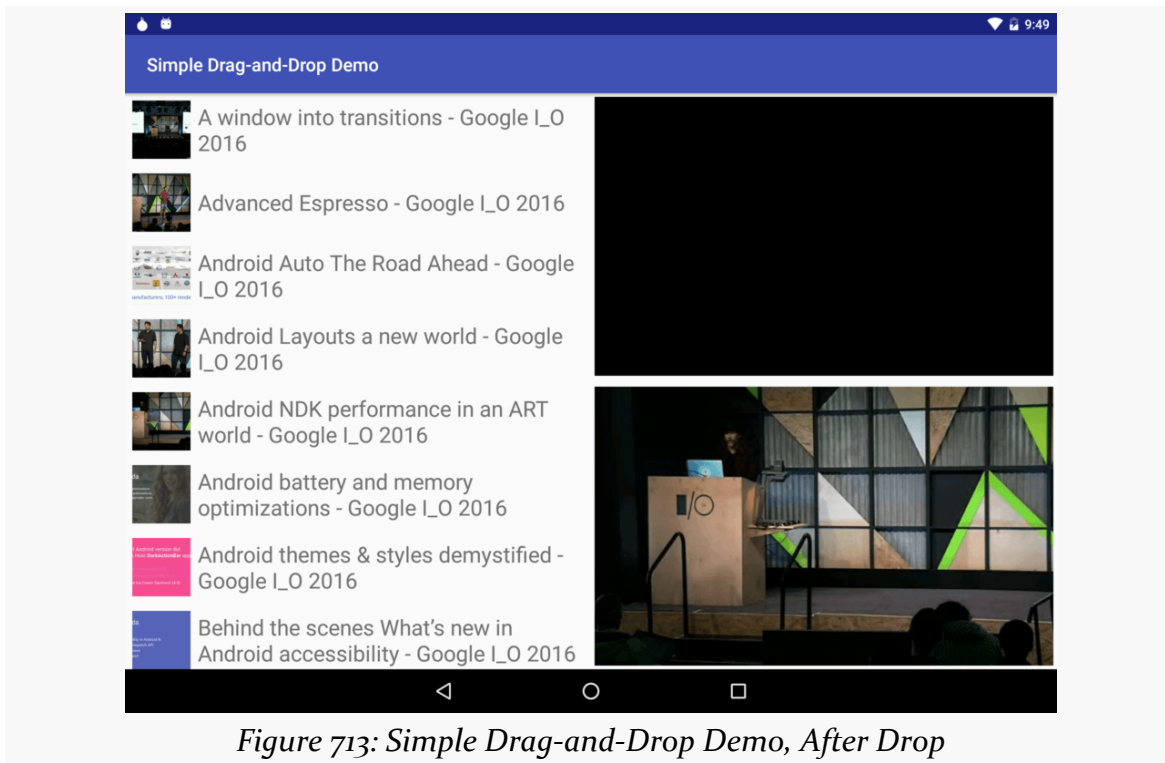

Figure 713: Simple Drag-and-Drop Demo, After Drop

Note that both widgets no longer show an outline, as they each received `ACTION_DROP_ENDED`, where they removed their outlines.

Drag-and-Drop, Between Apps

Android 7.0's multi-window capability ushers in a new era for drag-and-drop, where users drag-and-drop between apps. In theory, very little has to change to support drag-and-drop between apps.

However, there are challenges, the biggest one being permissions. The app with the drop target needs permission to work with whatever content is represented in the drag-and-drop operation. If that content is simply some plain text or something else that can be stuffed into a `ClipData`, permissions are part of drag-and-drop processing, as only the drop target selected by the user gets the `ACTION_DROP` event and can access that `ClipData`.

However, if the `ClipData` contains one or more `Uri` values, the app with the drop target needs access to that underlying content, just as it needs it for the clipboard or any other situation where a `Uri` is passed between apps.

DRAG AND DROP

The [DragDrop/Permissions](#) sample project demonstrates dragging and dropping between apps. This project has two app modules: drag and drop. As you might imagine, drag contains an activity that allows the user to drag something (in this case, an image), while drop contains an activity that accepts an image Uri and displays it.

Because cross-app drag-and-drop requires Android 7.0, both modules are set up with 7.0-compatible build settings in `build.gradle` — we will see the `drag/build.gradle` file shortly.

The Drag App

The drag app has a very simple UI: a single `ImageView`, set to fill the available space:

```
<?xml version="1.0" encoding="utf-8"?>
<ImageView android:id="@+id/asset"
    xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:scaleType="fitCenter" />
```

(from [DragDrop/Permissions/drag/src/main/res/layout/main.xml](#))

The idea is that the user will long-click the `ImageView` to start the drag-and-drop operation. Hence, this is reminiscent of the `DragDrop/Simple` app, just with a single image, rather than one per row in a list.

The Custom Shadow

One problem with using the `ImageView` as the way to start the drag-and-drop operation comes with the drag shadow. In `DragDrop/Simple`, we used the image as the drag shadow. This worked well, because the image was a thumbnail, which usually is a good size for a drag shadow. In the drag app in `DragDrop/Permissions`, though, the `ImageView` is huge, far too large to use as the drag shadow. As a result, we cannot use the `ImageView` directly as before, but instead need to create a custom `View.DragShadowBuilder` subclass, named `ThumbDragShadow`:

```
private class ThumbDragShadow extends View.DragShadowBuilder {
    @Override
    public void onProvideShadowMetrics(Point shadowSize,
        Point shadowTouchPoint) {
        shadowSize.set(iv.getWidth()/8, iv.getHeight()/8);
        shadowTouchPoint.set(shadowSize.x/2, shadowSize.y/2);
    }
}
```

DRAG AND DROP

```
}  
  
@Override  
public void onDrawShadow(Canvas canvas) {  
    iv.draw(canvas);  
}  
}
```

(from [DragDrop/Permissions/drag/src/main/java/com/commonsware/android/dragdrop/MainActivity.java](#))

This is a nested class inside MainActivity, and so it has access to the fields of MainActivity, such as our ImageView, named iv.

In onProvideShadowMetrics(), we set the size of the shadow to be 1/8th of the size of the ImageView. This is a sloppy approach and may wind up with too small of an image on smaller-screen devices. However, it does keep the aspect ratio of the ImageView. In addition, we set the touch point to be in the middle of the image — based on [some Google sample code](#), it appears that this is a reasonable algorithm.

In onDrawShadow(), we need to draw something on the supplied Canvas that represents the drag shadow. In this case, we ask the ImageView to draw itself into that Canvas. This results in a cropped image, as the ImageView is much larger than our Canvas, which is sized based on the Point values we populated in onProvideShadowMetrics(). A better implementation would work with a Bitmap and scale it so the entire image would be seen in the drag shadow; this approach is used here for simplicity.

The StreamProvider

The image itself is stored in assets/. The photo is of [One World Trade Center](#) (a.k.a., “Freedom Tower”) in New York City.

The reason for storing it in assets/ is that not only do we need the image, but we need to provide other apps with access to the image. In this app, we will handle that using StreamProvider, from the author’s CWAC-Provider library, as described in [one of the chapters on the ContentProvider component](#).

To that end, we include the cwac-provider artifact in our drag/build.gradle file:

```
apply plugin: 'com.android.application'  
  
dependencies {  
    compile 'com.android.support:recyclerview-v7:25.3.1'}
```

DRAG AND DROP

```
    compile 'com.squareup.picasso:picasso:2.5.2'
}

android {
    compileSdkVersion 24
    buildToolsVersion '26.0.2'

    defaultConfig {
        applicationId "com.commonware.android.dragdrop.drag"
        minSdkVersion 24
        targetSdkVersion 24
    }

    aaptOptions {
        noCompress 'jpg'
    }
}

repositories {
    maven {
        url "https://s3.amazonaws.com/repo.commonware.com"
    }
}

dependencies {
    compile 'com.commonware.cwac:provider:0.4.0'
}
```

(from [DragDrop/Permissions/drag/build.gradle](#))

Also note that we take steps to ensure that the build tools do not try to compress the JPEG further, by excluding jpg files from aapt compression via `noCompress` in `aaptOptions`

The manifest contains a `<provider>` element for our `StreamProvider`:

```
<provider
    android:name="com.commonware.cwac.provider.StreamProvider"
    android:authorities="${applicationId}.provider"
    android:exported="false"
    android:grantUriPermissions="true">
    <meta-data
        android:name="com.commonware.cwac.provider.STREAM_PROVIDER_PATHS"
        android:resource="@xml/provider"/>
    <meta-data
        android:name="com.commonware.cwac.provider.USE_LEGACY_CURSOR_WRAPPER"
```

DRAG AND DROP

```
        android:value="true" />
    </provider>
```

(from [DragDrop/Permissions/drag/src/main/AndroidManifest.xml](#))

That sets up the authority string to be the application ID with `.provider` appended. It also points `StreamProvider` to some XML metadata in `res/xml/provider.xml`:

```
<?xml version="1.0" encoding="utf-8"?>
<paths>

    <asset name="assets" />

</paths>
```

(from [DragDrop/Permissions/drag/src/main/res/xml/provider.xml](#))

Here, we say that we are willing to serve anything from `assets/`.

The Drag Request

In `onCreate()`, we use `Picasso` to load the image out of `assets/` and display it. However, we also register a `Callback` to find out when that has been completed:

```
@Override
public void onCreate(Bundle state) {
    super.onCreate(state);
    setContentView(R.layout.main);

    iv=(ImageView)findViewById(R.id.asset);

    Picasso.with(this)
        .load("file:///android_asset/FreedomTower-Morning.jpg")
        .fit().centerCrop()
        .into(iv, new Callback() {
            @Override
            public void onSuccess() {
                iv.setOnLongClickListener(MainActivity.this);
            }

            @Override
            public void onError() {
                // TODO
            }
        });
}
```

DRAG AND DROP

(from [DragDrop/Permissions/drag/src/main/java/com/commonsware/android/dragdrop/MainActivity.java](#))

We only call `setOnLongClickListener()` once the image has been loaded successfully, as until then, the user would not know what she is dragging and dropping.

Then, in `onLongClick()`, we start the drag-and-drop operation:

```
@Override
public boolean onLongClick(View view) {
    Uri uri=PROVIDER
        .buildUpon()
        .appendEncodedPath(StreamProvider.getUriPrefix(AUTHORITY))
        .appendEncodedPath("assets/FreedomTower-Morning.jpg")
        .build();

    ClipData clip=ClipData.newRawUri(getString(R.string.msg_photo), uri);
    View.DragShadowBuilder shadow=new ThumbDragShadow();

    iv.startDragAndDrop(clip, shadow, Boolean.TRUE,
        View.DRAG_FLAG_GLOBAL|View.DRAG_FLAG_GLOBAL_URI_READ|
        View.DRAG_FLAG_GLOBAL_PERSISTABLE_URI_PERMISSION);

    return(true);
}
```

(from [DragDrop/Permissions/drag/src/main/java/com/commonsware/android/dragdrop/MainActivity.java](#))

First, we need a `Uri` pointing to our asset. We build such a `Uri` from:

- A static `PROVIDER Uri`, which incorporates our authority string:

```
private static final String AUTHORITY=
    BuildConfig.APPLICATION_ID+".provider";
private static final Uri PROVIDER=
    Uri.parse("content://"+AUTHORITY);
```

(from [DragDrop/Permissions/drag/src/main/java/com/commonsware/android/dragdrop/MainActivity.java](#))

- The unique prefix used for this app by `StreamProvider` (via `getUriPrefix()`)
- The path to our asset

We then build a `ClipData` from that `Uri`, plus a string pulled from a resource. Note that it is unclear where this string is used, though accessibility options is one likely candidate.

DRAG AND DROP

The drag shadow is an instance of the `ThumbDragShadow` shown above.

To start the drag-and-drop operation, we call `startDragAndDrop()`. This is simply a new name for the `startDrag()` method. `startDrag()` is marked as deprecated in Android 7.0, replaced with `startDragAndDrop()`. However, for older, in-app drag-and-drop, feel free to use `startDrag()`, as it is your only option for Android 6.0 and older devices.

This time, we pass in some flags:

- `DRAG_FLAG_GLOBAL` indicates that we want the drag-and-drop operation to work between apps. If we left the flags as 0, the drag-and-drop would be limited only to this app. In this respect, a drag is local by default, with cross-app drag-and-drop being something you have to explicitly opt into.
- `DRAG_FLAG_GLOBAL_URI_READ` indicates that we want the other app to be able to read the content identified by the `Uri` that we are putting into the `ClipData`. Without this, any app receiving the `DragEvent` would be unable to display the image. Note that there is an equivalent `DRAG_FLAG_GLOBAL_URI_WRITE` if you want to offer write access.
- `DRAG_FLAG_GLOBAL_PERSISTABLE_URI_PERMISSION` indicates that we want to grant the recipient app durable rights to the content identified by the `Uri` that we are putting into the `ClipData`. The term “persistable”, and the documentation for this flag, suggests that this access survives reboots. That may be excessive here. We will explore why we are using this flag when we look at the drop app.

The Drop App

The drop app is a version of the drop logic from `DragDrop/Simple`, reduced to just handling the drop in an `ImageView`. However, it does have a few wrinkles, both related to drag-and-drop (permissions) and related to general Android development (configuration change support).

The Layout

The revised layout is simply the `ImageView`, wrapped in the `FrameLayout` for the drop hint drawables:

```
<?xml version="1.0" encoding="utf-8"?>
<FrameLayout android:id="@+id/thumbnail_frame"
  xmlns:android="http://schemas.android.com/apk/res/android"
```

DRAG AND DROP

```
android:layout_width="match_parent"
android:layout_height="match_parent"
android:layout_margin="4dp"
android:padding="4dp">

<ImageView
    android:id="@+id/thumbnail_large"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:scaleType="centerInside" />
</FrameLayout>
```

(from [DragDrop/Permissions/drop/src/main/res/layout/main.xml](#))

In `onCreate()` and `onSaveInstanceState()`, we load that layout, get the `ImageView`, and populate it (via the same `showThumbnail()` as before) if we have a `thumbnailUri` from our saved instance state `Bundle`:

```
@Override
public void onCreate(Bundle state) {
    super.onCreate(state);
    setContentView(R.layout.main);

    image=(ImageView)findViewById(R.id.thumbnail_large);
    image.setOnDragListener(this);

    if (state!=null) {
        imageUri=state.getParcelable(STATE_IMAGE_URI);

        if (imageUri!=null) {
            showThumbnail();
        }
    }
}

@Override
protected void onSaveInstanceState(Bundle outState) {
    super.onSaveInstanceState(outState);

    outState.putParcelable(STATE_IMAGE_URI, imageUri);
}
```

(from [DragDrop/Permissions/drop/src/main/java/com/commonsware/android/dragdrop/MainActivity.java](#))

The Drag Event

The `onDrag()` method is the same as before, except for two events: `ACTION_DRAG_STARTED` and `ACTION_DROP`.

We are expecting to get a `Uri` pointing to an image from the outside app via a drag-and-drop operation. Ideally, we would validate that in `ACTION_DRAG_STARTED`, returning `false` if the content is something else:

```
@Override
public boolean onDrag(View v, DragEvent event) {
    boolean result=true;

    switch (event.getAction()) {
        case DragEvent.ACTION_DRAG_STARTED:
            if (event
                .getClipDescription()
                .hasMimeType(ClipDescription.MIMETYPE_TEXT_URLIST)) {
                applyDropHint(v, R.drawable.droppable);
            }
            else {
                result=false;
            }

            break;

        case DragEvent.ACTION_DRAG_ENTERED:
            applyDropHint(v, R.drawable.drop);
            break;

        case DragEvent.ACTION_DRAG_EXITED:
            applyDropHint(v, R.drawable.droppable);
            break;

        case DragEvent.ACTION_DRAG_ENDED:
            applyDropHint(v, -1);
            break;

        case DragEvent.ACTION_DROP:
            requestDragAndDropPermissions(event);

            ClipData.Item clip=event.getClipData().getItemAt(0);

            imageUri=clip.getUri();
            showThumbnail();
            break;
    }
}
```

DRAG AND DROP

```
}  
  
return(result);  
}
```

(from [DragDrop/Permissions/drop/src/main/java/com/commonsware/android/dragdrop/MainActivity.java](#))

Unfortunately, all we can do is determine that we are getting *some* Uri. The MIME type in our ClipDescription is *not* the MIME type of the content underlying our Uri, but rather will be ClipDescription.MIMETYPE_TEXT_URI_LIST. This is because a ClipData can have several items, each with Uri values. We have no way, given just the ClipDescription to determine if we actually have an image Uri. So, as long as we are getting a Uri value, we assume that the drop might be meaningful and return true.

For ACTION_DROP, we first call requestDragAndDropPermissions(), to grant our app the rights offered to us by whatever app initiated the drag-and-drop operation:

```
case DragEvent.ACTION_DROP:  
    requestDragAndDropPermissions(event);  
  
    ClipData.Item clip=event.getClipData().getItemAt(0);  
  
    imageUri=clip.getUri();  
    showThumbnail();  
    break;
```

(from [DragDrop/Permissions/drop/src/main/java/com/commonsware/android/dragdrop/MainActivity.java](#))

The requestDragAndDropPermissions() method returns a DragAndDropPermissions object. The JavaDocs for this class point out the lifetime of our permissions:

The life cycle of the permissions is bound to the activity used to call requestDragAndDropPermissions(). The permissions are revoked when this activity is destroyed, or when release() is called, whichever occurs first.

However, the user could destroy your activity at any point in time, via a configuration change. As a result, you have three main options here:

1. Make a local copy of the content as soon as you get the Uri, hopefully before your activity gets destroyed via a configuration change
2. Opt out of the automatic destroy-and-recreate cycle for configuration changes for any activity that has drop targets, via android:configChanges in the manifest, and deal with all the problems that technique raises

DRAG AND DROP

3. Ignore the issue and hope that the app that started the drag-and-drop operation included `DRAG_FLAG_GLOBAL_PERSISTABLE_URI_PERMISSION` in its `startDragAndDrop()` call

But, after the `requestDragAndDropPermissions()` call, we grab the first `Uri` out of the `ClipData`, store that in the `imageUri` field, and have `showThumbnail()` display that image via Picasso. A better approach would examine each possible `Uri` in the `ClipItem` for one that represents an image (showing that one), and returning `false` from `onDrag()` if no such `Uri` is found, so the drag-and-drop operation remains active.

The Results

If you run both apps, and have them both visible in a multi-window environment (e.g., split-screen mode on a phone or tablet), you will be able to drag and drop between them:

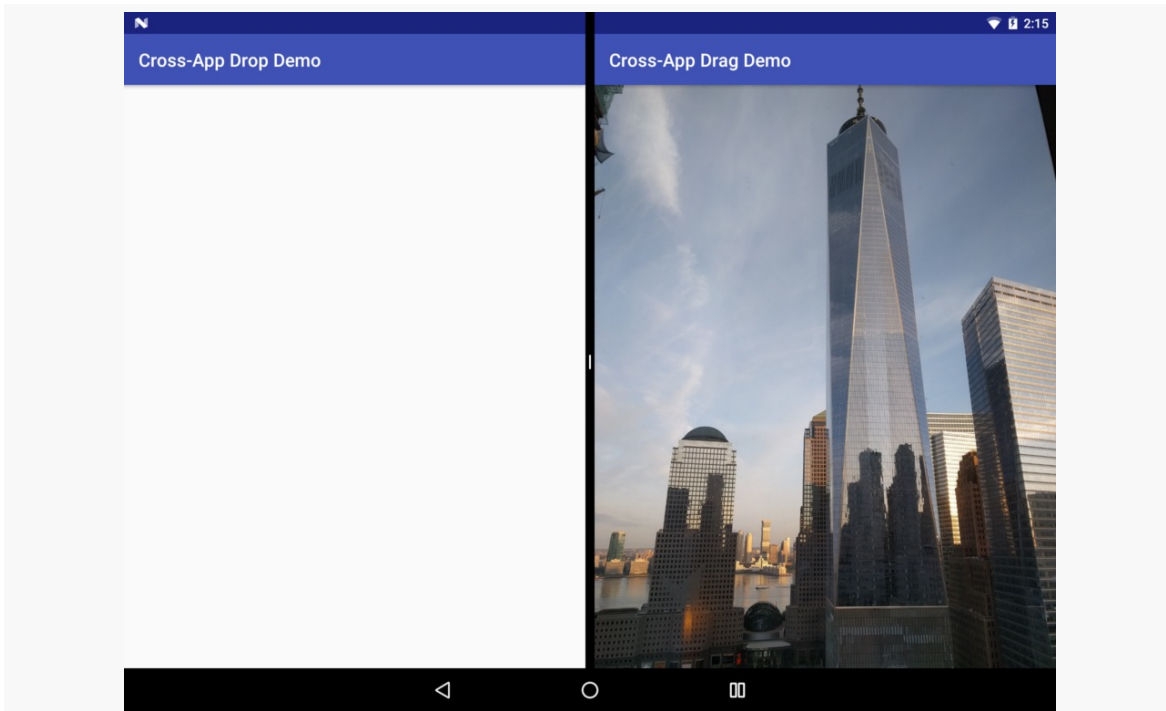

Figure 714: Cross-App Drag-And-Drop, Showing Both Activities As Initially Launched

DRAG AND DROP

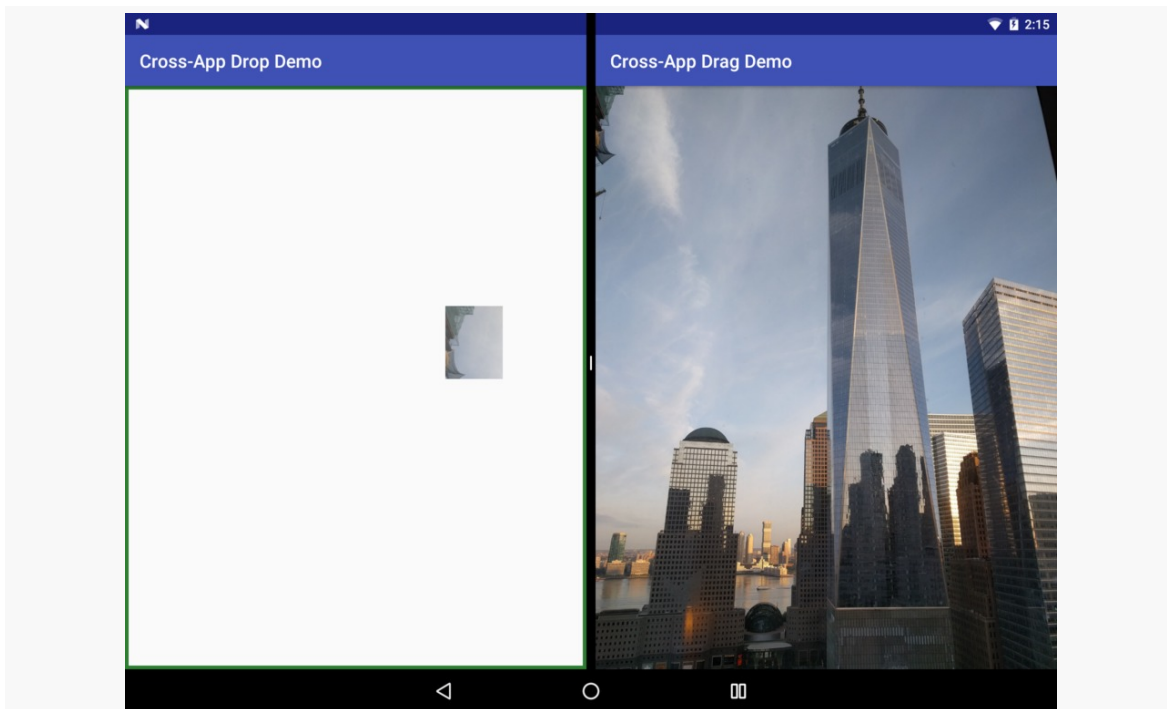

Figure 715: Cross-App Drag-And-Drop, Showing Drag Shadow

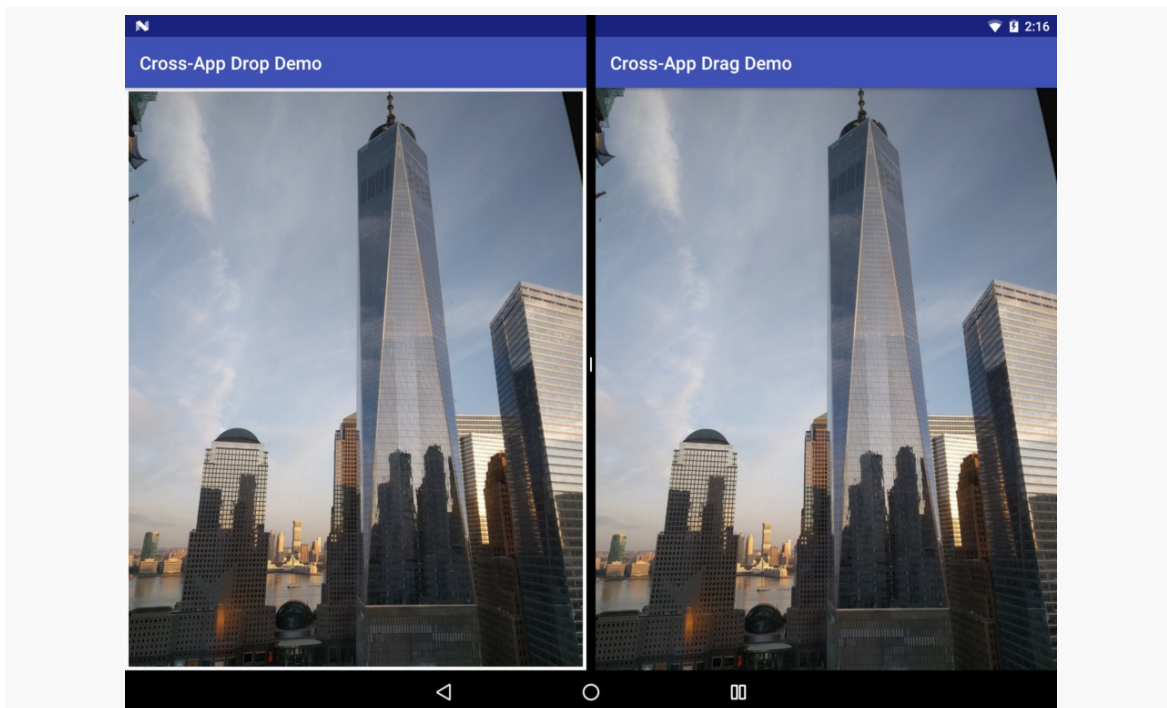

Figure 716: Cross-App Drag-And-Drop, Showing Result of Drag-and-Drop

Detecting Cross-App Drag Events

In the DragDrop/Permissions sample, there is nothing in our `onDrag()` method, or anywhere else, that indicates that we want to allow drag events from third-party apps. **That happens by default, and there is no way to stop it.** Hence, *any* app implementing official drag-and-drop support *has* to support arbitrary apps passing in content. With luck, [this too will get changed](#).

We were given [this recipe](#) for detecting cross-app drag-and-drop:

- Fill in a non-null value for the local state in the call to `startDragAndDrop()`
- Check in `ACTION_DRAG_STARTED` to see if the local state is null, in which case, the drag-and-drop must have started from some other app

However, [this does not work well](#). The local state is local to a *window*, not an app or process. As a result, if your app is visible in more than one window — for example, you used `FLAG_ACTIVITY_LAUNCH_ADJACENT` to start up another activity in another window — then you will lose the local state even for in-app drag-and-drop across these windows.

In the Simple drag-and-drop sample from earlier, we check to see if the local state is null and reject the drag event if it is. There, we are not expecting to have activities in multiple windows, so all drag-and-drop work should be local. Conversely, we do *not* check the local state in the Permissions sample, where we specifically *want* cross-app drag-and-drop.

Intra-App Cross-Window Drag-and-Drop

Drag-and-drop not only works between apps with Android 7.0's multi-window feature — it also works for two windows within the same app.

The [DragDrop/SplitScreen](#) sample project is a clone of the DragDrop/Permissions project. However, both the drag activity (`MainActivity`) and the drop activity (`DropActivity`) are in the same app module (`app/`).

Also, `MainActivity` now has an action bar with a “launch” item that, when tapped, will bring up the `DropActivity` in an adjacent window:

```
@Override
public boolean onOptionsItemSelected(MenuItem item) {
```

DRAG AND DROP

```
if (item.getItemId()==R.id.launch) {
    startActivity(new Intent(this, DropActivity.class)
        .setFlags(Intent.FLAG_ACTIVITY_LAUNCH_ADJACENT |
            Intent.FLAG_ACTIVITY_NEW_TASK |
            Intent.FLAG_ACTIVITY_MULTIPLE_TASK));

    return(true);
}

return(super.onOptionsItemSelected(item));
}
```

(from [DragDrop/SplitScreen/app/src/main/java/com/commonsware/android/dragdrop/MainActivity.java](#))

Launching MainActivity, entering multi-window mode, and launching DropActivity gives you those two activities in separate windows, such as in split-screen mode:

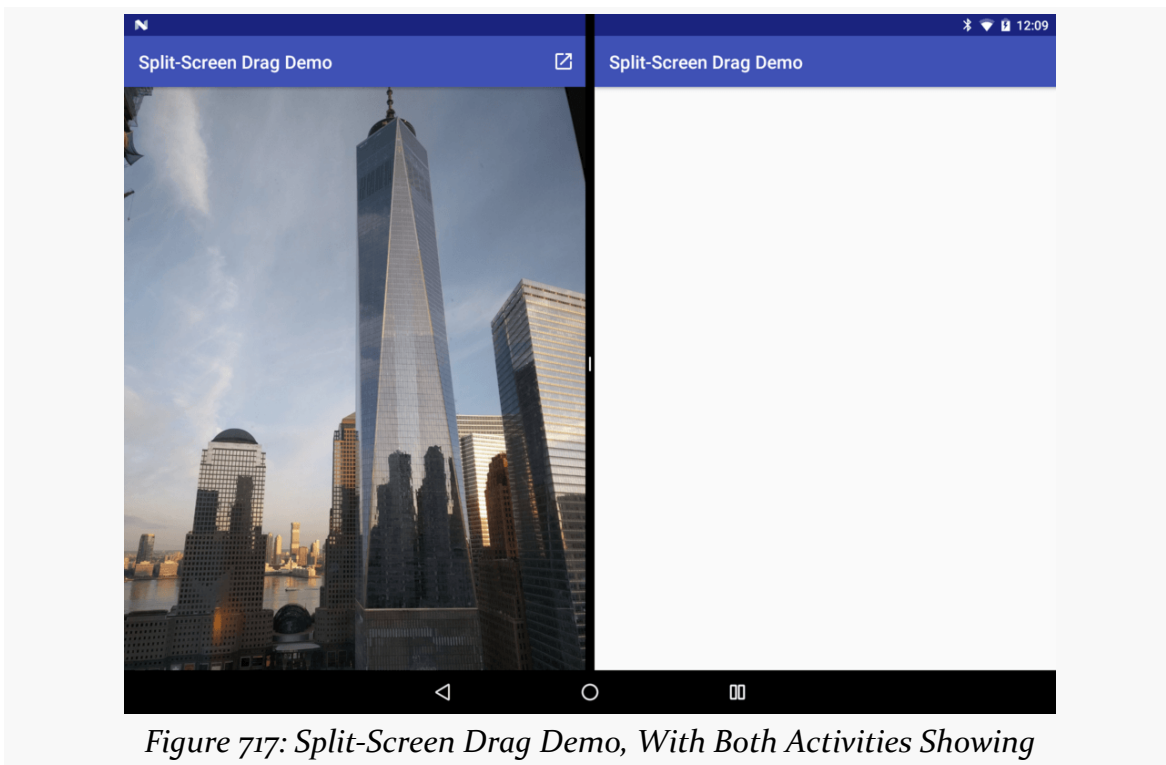

Figure 717: Split-Screen Drag Demo, With Both Activities Showing

And, as in the cross-app scenario, you can drag from one window into the other:

DRAG AND DROP

Figure 718: Split-Screen Drag Demo, Part-Way Through a Drag

Figure 719: Split-Screen Drag Demo, After Drag-and-Drop

However, as was noted above, the local state data is lost in these cross-window drag-and-drop operations, making them indistinguishable from cross-app drag-and-drop operations.

Pondering Legacy Multi-Window

In principle, cross-app drag-and-drop could work with Samsung's [legacy multi-window support](#). However, calling `startDrag()` (the pre-Android 7.0 equivalent of `startDragAndDrop()`) will not grant permissions to the other app to use the content associated with any `Uri`. The only way to make this work would be if the content identified by the `Uri` was readable by all apps, which is not great from a security standpoint.

LG's legacy multi-window support does not seem to support cross-app drag-and-drop.

Also, Chrome OS does not support cross-app drag-and-drop as of the August 2016 round of developer previews.

Dragging and Dropping Simple Stuff

This chapter focuses on drag-and-drop of content, represented by a `Uri`. That is not your only option, just as that is not your only option for putting stuff onto, or removing stuff from, the clipboard.

A `ClipData` object contains one or more `ClipData.Item` objects. These can be of three main forms:

- Text, in the form of a `CharSequence`, including support for any standard Android [spans](#)
- An `Intent`, usually designed for creating some sort of shortcut to be able to launch an activity identified by the `Intent`
- A `Uri`

Outside of specialized cases (e.g., home screens), if you are not using `Uri`, probably you are using text.

If you are implementing a drop target, and all you know how to do is handle text, you can call `coerceToText()` on a `ClipData.Item` object to get the best text representation of whatever it is. For `Uri` values pointing to text content, `coerceToText()` will read in the content and return it. For anything else, you get `backToString()` on the content, more or less.

Multi-Action Drag-and-Drop

The previous section brings up home screens as an example of drag-and-drop. On many Android home screen implementations, if you long-click on an icon in the launcher, you can drag-and-drop that icon into the home screen itself, thereby creating a shortcut. However, in addition to that, many home screens also offer special drop targets tied to specific actions, such as “Uninstall”. If the user drops the icon over the home screen area, a shortcut gets created; if the user drops the icon over a special drop target, the action for that target is performed.

You can do this too.

Mostly, it is a matter of arranging to show those special drop targets only during a drag-and-drop operation, then handling those drops specifically. However, due to the nature of Android’s view hierarchy and the drag-and-drop framework, you need to ensure that you show the special drop target’s view *before* you start the drag-and-drop operation. Otherwise, the special drop target’s view will never receive `ACTION_DRAG_ENTERED` or `ACTION_DROP` events.

We can see how this works in practice in the [DragDrop/Action](#) sample project. This is a clone of the `DragDrop/Simple` app from earlier in this chapter, except that we have added a special “Video Info” drop target.

The Layout

The `-w800dp` layout is mostly as it was in the original app, except that we have added an `info TextView` above the `RecyclerView`:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:orientation="horizontal">

    <LinearLayout
        android:layout_width="0dp"
        android:layout_height="match_parent"
        android:layout_weight="1"
        android:orientation="vertical">

        <TextView
            android:id="@+id/info"
```

DRAG AND DROP

```
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:layout_gravity="center_horizontal"
        android:layout_margin="8dp"
        android:padding="8dp"
        android:text="@string/label_video_info"
        android:textAppearance="?android:textAppearanceLarge"
        android:visibility="gone" />

<android.support.v7.widget.RecyclerView
    android:id="@+id/video_list"
    android:layout_width="match_parent"
    android:layout_height="match_parent" />
</LinearLayout>

<LinearLayout
    android:layout_width="0dp"
    android:layout_height="match_parent"
    android:layout_weight="1"
    android:orientation="vertical">

    <FrameLayout
        android:id="@+id/video_frame"
        android:layout_width="match_parent"
        android:layout_height="0dp"
        android:layout_marginBottom="4dp"
        android:layout_weight="1"
        android:padding="4dp">

        <VideoView
            android:id="@+id/player"
            android:layout_width="match_parent"
            android:layout_height="match_parent"
            android:layout_gravity="center" />
    </FrameLayout>

    <FrameLayout
        android:id="@+id/thumbnail_frame"
        android:layout_width="match_parent"
        android:layout_height="0dp"
        android:layout_weight="1"
        android:padding="4dp">

        <ImageView
            android:id="@+id/thumbnail_large"
            android:layout_width="match_parent"
            android:layout_height="match_parent"
            android:scaleType="centerInside" />
    </FrameLayout>
</LinearLayout>
```

DRAG AND DROP

```
</FrameLayout>
</LinearLayout>
</LinearLayout>
```

(from [DragDrop/Action/app/src/main/res/layout-w800dp/main.xml](#))

However, this `TextView` has a visibility of `gone` at the outset, so it will not show up for users.

Showing and Hiding the Action

`onCreate()` initializes an `info` field with the `TextView`, much as it initializes the fields for the `VideoView` and `ImageView`:

```
player=(VideoView)findViewById(R.id.player);

if (player!=null) {
    player.setOnDragListener(this);
}

thumbnailLarge=(ImageView)findViewById(R.id.thumbnail_large);

if (thumbnailLarge!=null) {
    thumbnailLarge.setOnDragListener(this);
}

info=findViewById(R.id.info);

if (info!=null) {
    info.setOnDragListener(this);
}
```

(from [DragDrop/Action/app/src/main/java/com/commonsware/android/dragdrop/MainActivity.java](#))

However, since `info` is `gone`, the user cannot drag anything over it. We need to arrange to make it visible.

You might try making it visible in `onDrag()`, when we get the `ACTION_DRAG_STARTED` event. After all, this would seem to describe what we want: when the drag begins, show the special drop target as an option for the user. Unfortunately, this does not work: while the user can see the `info` `TextView`, that `TextView` does not get any further `onDrag()` events.

Instead, we are forced to arrange to make the `info` view visible before starting the drag-and-drop operation. As a side effect, that requirement means that we cannot

DRAG AND DROP

use this technique for cross-app drag-and-drop, since we have no idea when some other app starts the drag-and-drop operation.

In fact, it is even a bit awkward to handle in this app, as it is the RowController that initiates the drag-and-drop operation. The RowController knows nothing about the info view, nor should it. Instead, we need to have the RowController let the MainActivity know that a drag-and-drop operation is about to start, so the activity can show the view.

To that end, RowController defines an OnStartDragListener interface. It expects to get such a listener as a constructor parameter, storing it in a field for later use:

```
class RowController extends RecyclerView.ViewHolder
    implements View.OnClickListener, View.OnLongClickListener {
    interface OnStartDragListener {
        void onStartDrag();
    }

    final private TextView title;
    final private ImageView thumbnail;
    private Uri videoUri=null;
    private String videoMimeType=null;
    final private OnStartDragListener listener;

    RowController(View row, OnStartDragListener listener) {
        super(row);

        this.listener=listener;
        title=(TextView)row.findViewById(android.R.id.text1);
        thumbnail=(ImageView)row.findViewById(R.id.thumbnail);

        row.setOnClickListener(this);
        row.setOnLongClickListener(this);
    }
}
```

(from [DragDrop/Action/app/src/main/java/com/commonsware/android/dragdrop/RowController.java](#))

Then, in onLongClick(), if we have a listener, we call onStartDrag() on it, to indicate that we are about to start a drag-and-drop operation:

```
@Override
public boolean onLongClick(View v) {
    if (listener!=null) {
        listener.onStartDrag();
    }
}
```

DRAG AND DROP

```
ClipData clip=ClipData.newRawUri(title.getText(), videoUri);
View.DragShadowBuilder shadow=new View.DragShadowBuilder(thumbnail);

itemView.startDrag(clip, shadow, Boolean.TRUE, 0);

return(true);
}
```

(from [DragDrop/Action/app/src/main/java/com/commonsware/android/dragdrop/RowController.java](#))

The RowController instances are created by the VideoAdapter. Fortunately, VideoAdapter is a nested class inside of MainActivity. So, we implement OnStartDragListener on MainActivity and pass the activity instance to the RowController constructor:

```
@Override
public RowController onCreateViewHolder(ViewGroup parent,
                                       int viewType) {
    return(new RowController(getLayoutInflater()
        .inflate(R.layout.row, parent, false), MainActivity.this));
}
```

(from [DragDrop/Action/app/src/main/java/com/commonsware/android/dragdrop/MainActivity.java](#))

All the onStartDrag() method does is make the info view visible:

```
public void onStartDrag() {
    info.setVisibility(View.VISIBLE);
}
```

(from [DragDrop/Action/app/src/main/java/com/commonsware/android/dragdrop/MainActivity.java](#))

If we make it visible, clearly we need to hide it again at some future point. That would be when the drag-and-drop operation has completed, and it is safe for us to mark info as GONE in our handling of ACTION_DRAG_ENDED in onDrag():

```
case DragEvent.ACTION_DRAG_ENDED:
    applyDropHint(v, -1);
    info.setVisibility(View.GONE);
    break;
```

(from [DragDrop/Action/app/src/main/java/com/commonsware/android/dragdrop/MainActivity.java](#))

Handling Drag Events

We still want to show the drop hint backgrounds, but in this case, we apply them directly to the TextView, rather than going with a wrapping FrameLayout. So, we adjust `applyDropHint()` to only work with the parent of the view if this is not the info view:

```
private void applyDropHint(View v, int drawableId) {
    if (v!=info) {
        v=(View)v.getParent();
    }

    if (drawableId>-1) {
        v.setBackgroundResource(drawableId);
    }
    else {
        v.setBackground(null);
    }
}
```

(from [DragDrop/Action/app/src/main/java/com/commonsware/android/dragdrop/MainActivity.java](#))

And, in `ACTION_DROP` processing, if the user dropped the content over the info view, we simply show a Toast with the text of the Uri:

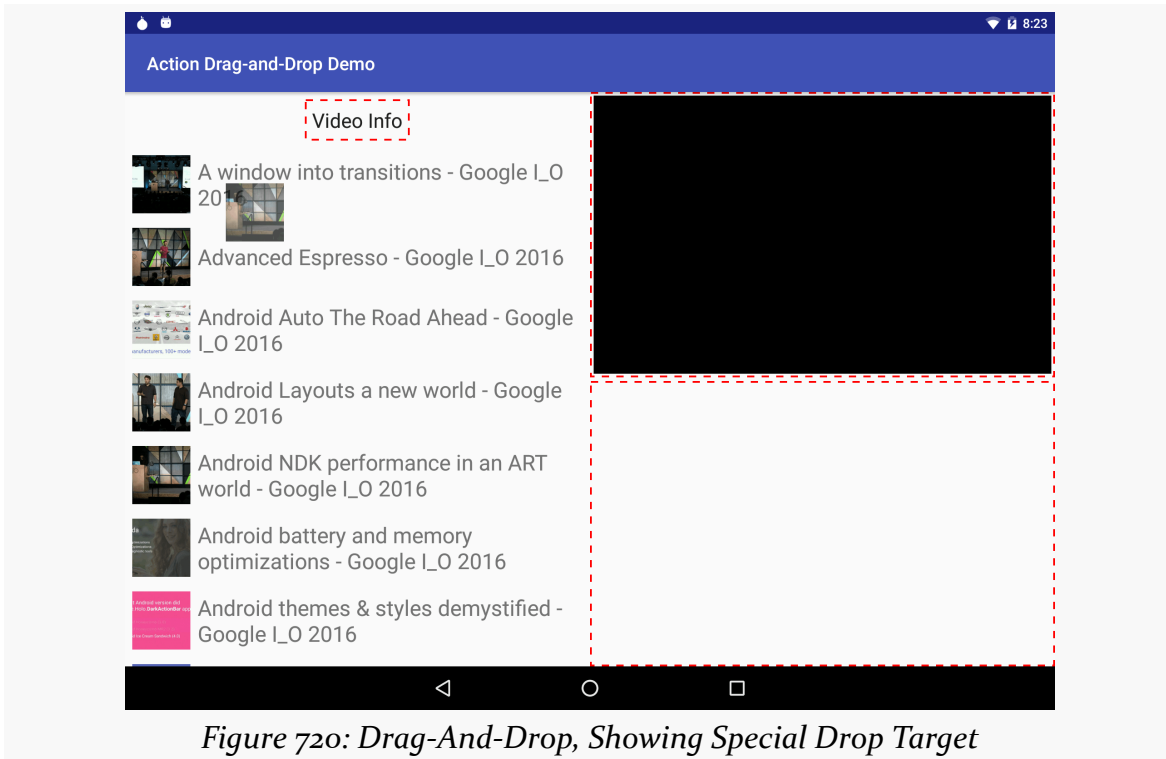

```
case DragEvent.ACTION_DROP:
    ClipData.Item clip=event.getClipData().getItemAt(0);
    Uri videoUri=clip.getUri();

    if (v==player) {
        player.setVideoURI(videoUri);
        player.start();
    }
    else if (v==info) {
        Toast
            .makeText(this, videoUri.toString(), Toast.LENGTH_SHORT)
            .show();
    }
    else {
        Picasso.with(thumbnailLarge.getContext())
            .load(videoUri.toString())
            .fit().centerCrop()
            .placeholder(R.drawable.ic_media_video_poster)
            .into(thumbnailLarge);
    }
}
```

(from [DragDrop/Action/app/src/main/java/com/commonsware/android/dragdrop/MainActivity.java](#))

The Result

Now, when you run the app on a sufficiently-wide screen, and you start a drag-and-drop operation, the “Video Info” TextView appears and serves as a drop target:

Nested Drop Targets

You may have a need for nested drop targets, where you are listening for drag events both on some container and on some view inside of that container. For example, if you are using the drag-and-drop APIs to support reordering items in a `LinearLayout` or `RecyclerView`, there is a good chance that you will need to have listeners both on that container and on existing items in the container (e.g., to animate them out of the way to allow the user to drop in the newly-vacant spot).

Alas, this is an area that has some undocumented behavior changes in Android 7.0, as Dan Lew uncovered in August 2016.

The [DragDrop/Nougat](#) sample project illustrates the old and new behavior, plus some code to get Android 7.0 to behave more like the older versions of Android.

DRAG AND DROP

The behavior change is triggered by nested drop targets, which means we need a nested layout, such as this one:

```
<?xml version="1.0" encoding="utf-8"?>
<FrameLayout android:id="@+id/outer_container"
  xmlns:android="http://schemas.android.com/apk/res/android"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  android:background="@color/outer_normal"
  android:padding="48dp">

  <FrameLayout
    android:id="@+id/inner_container"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:background="@color/inner_normal"
    android:padding="48dp">

    <ImageView
      android:id="@+id/thumbnail_large"
      android:layout_width="match_parent"
      android:layout_height="match_parent"
      android:background="@color/image_normal"
      android:contentDescription="@string/icon"
      android:scaleType="centerInside" />
    </FrameLayout>
  </FrameLayout>
</FrameLayout>
```

(from [DragDrop/Nougat/app/src/main/res/layout/bug.xml](#))

Here, we have a `FrameLayout` holding onto another `FrameLayout`, which holds onto an `ImageView`, each with a different background color:

Figure 721: Garish Background Colors

Further, suppose that we are interested in drag events for all three of these, so we call `setOnDragListener()` for each of them. In the code, we set the background of a drop target to green when we get an `ACTION_DRAG_ENTERED` event for the target, and we revert to the original background in `ACTION_DRAG_EXITED`, `ACTION_DRAG_ENDED`, and `ACTION_DROP`.

The Behavior Prior to Android 7.0

On Android 6.0 and earlier, drag events are inclusive. In other words, if the user has dragged an item into the inner `FrameLayout`, this is *also* considered to be inside the outer `FrameLayout`. From an event standpoint, the outer `FrameLayout` only gets an `ACTION_DRAG_EXITED` event when the dragged item leaves its outer boundaries.

So, as the user drags an item into our nested drop targets, outer targets remain green, even as the item enters inner targets:

DRAG AND DROP

Figure 722: Dragging Over Outer Drop Target on Android 6.0

Figure 723: Dragging Over Inner Drop Target on Android 6.0

Figure 724: Dragging Over ImageView Drop Target on Android 6.0

Android 7.0 Behavior

However, on Android 7.0, drag events are exclusive. If the user drags an item into the inner `FrameLayout`, the item will *exit* the outer `FrameLayout` from a drag-and-drop perspective. So, as the user drags the item towards the inner-most drop target, the user exits the outer drop targets, and we restore the backgrounds along the way:

DRAG AND DROP

Figure 725: Dragging Over Outer Drop Target on Android 7.0

Figure 726: Dragging Over Inner Drop Target on Android 7.0

Figure 727: Dragging Over ImageView Drop Target on Android 7.0

Getting Inclusive on Android 7.0

Which approach is “correct” is somewhat immaterial, as we need consistency across Android OS versions.

The sample app offers one workaround for the discrepancy: a `DropTarget` class that provides inclusive behavior on Android 7.0. Basically, it serves as a composite `OnDragListener`, forwarding `onDrag()` calls to widgets as appropriate. This includes forwarding events to parents of widgets, if those parents are part of the `DropTarget` coverage:

```
package com.commonware.android.dragdrop;

import android.os.Build;
import android.view.DragEvent;
import android.view.View;
import android.view.ViewGroup;
import java.util.ArrayList;

public class DropTarget implements View.OnDragListener {
    private ArrayList<View> views=new ArrayList<>();
```

DRAG AND DROP

```
private View.OnDragListener listener;

public DropTarget on(View... views) {
    for (View v : views) {
        this.views.add(v);
        v.setOnDragListener(this);
    }

    return(this);
}

public void to(View.OnDragListener listener) {
    this.listener=listener;
}

@Override
public boolean onDrag(View view, DragEvent dragEvent) {
    if (Build.VERSION.SDK_INT<Build.VERSION_CODES.N) {
        return(listener.onDrag(view, dragEvent));
    }

    boolean result=listener.onDrag(view, dragEvent);
    ViewParent parent=view.getParent();

    while (parent!=null && parent instanceof View) {
        View parentView=(View)parent;

        if (views.contains(parentView)) {
            listener.onDrag(parentView, dragEvent);
        }

        parent=parentView.getParent();
    }

    return(result);
}
}
```

(from [DragDrop/Nougat/app/src/main/java/com/commonsware/android/dragdrop/DropTarget.java](#))

For each of the views that DropTarget is set to monitor, the DropTarget sets itself up as the OnDragListener. In onDrag(), if we are on a pre-7.0 version of Android, DropTarget just forwards the event along normally. If, however, we are on Android 7.0 or higher, onDrag():

- Calls onDrag() for the listener attached to the DropTarget, using the View originally passed into onDrag(), and holding onto the result boolean

DRAG AND DROP

- Walks the chain of parents, calling `onDrag()` on the listener for each of those that are part of our monitored set of views
- Returns the value from the original (inner-most) `onDrag()` call on the listener

Then, instead of registering the activity as the `OnDragListener` like this:

```
@Override
public void onCreate(Bundle state) {
    super.onCreate(state);

    image=(ImageView)findViewById(R.id.thumbnail_large);
    image.setOnDragListener(this);
    findViewById(R.id.outer_container).setOnDragListener(this);
    findViewById(R.id.inner_container).setOnDragListener(this);
}
```

(from [DragDrop/Nougat/app/src/main/java/com/commonsware/android/dragdrop/BugActivity.java](#))

we can use `DropTarget`:

```
@Override
public void onCreate(Bundle state) {
    super.onCreate(state);

    image=(ImageView)findViewById(R.id.thumbnail_large);

    new DropTarget()
        .on(image,
            findViewById(R.id.outer_container),
            findViewById(R.id.inner_container))
        .to(this);
}
```

(from [DragDrop/Nougat/app/src/main/java/com/commonsware/android/dragdrop/InclusiveActivity.java](#))

The result is more inclusive behavior. In the case of this sample app, it happens to be sufficient to allow Android 7.0 to behave as does Android 6.0 and earlier. More sophisticated drag-and-drop implementations may need a more sophisticated approach than `DropTarget` to achieve a similar workaround.

The State of the Bugs

Both bugs filed by Dan Lew have been marked as “FutureRelease”, with a comment on one indicating that the new exclusive behavior would be restricted to apps with a

`targetSdkVersion` of 24 or higher. It is unclear exactly when this change will be released. And, since many apps will have a `targetSdkVersion` of 24 or higher to avoid warning messages in Android 7.0+ multi-window, the proposed fixes may not help much.

Pondering Standards

Framework-supplied drag-and-drop has not been all that popular to date. As a result, there are no common conventions for how to designate drop targets for the user. Similarly, as of mid-2016, there appears to be no recommendations for this in the Material Design guidelines from Google.

Eventually, the Android development community will start to coalesce around certain patterns, with or without Google's assistance. Experiment now, but watch for conventions to emerge, then adopt those conventions, where they make sense for your app.

Pondering Accessibility

Drag-and-drop is not particularly accessible. Visually-impaired users may have difficulty discerning where one can drag from and where one can drag to. Motor-impaired users may have difficulty doing the gesture to initiate drag-and-drop or in dragging the shadow to the desired location.

As a result, while drag-and-drop is a worthy feature, ensure that it is not the *only* option for performing some action. There should be some other way to do that action, and perhaps more than one other way to do that action, such as:

- Keyboard shortcuts
- Copy-and-paste, perhaps using action modes
- Direct manipulation (e.g., use drag-and-drop on overview screens with lists, plus offer an action bar item or other affordances on detail screens to perform the same action)

Keyboard and Mouse Input

More and more Android users are starting to use external keyboards and mice with their devices. Sometimes, the device is designed for such use, such as [the Jide Remix Mini](#) or all-on-one units like [the HP Slate 21](#). Some people use Android devices designed for use with a TV as quasi-desktops. And, starting in 2016, we have Android available on some Chrome OS devices, most of which rely on keyboard and mouse/trackpad input.

Over time, more and more Android users are going to be expecting Android apps to behave like desktop apps with respect to keyboards and mice. Some of this capability will be built into Android. Some of this capability will need to be handled by apps or libraries.

In this chapter, we will explore various techniques for making your Android app more friendly to keyboards and mice.

Prerequisites

Understanding this chapter requires that you have read the core chapters. Many of the examples use RecyclerView, so you may wish to review [that chapter](#) if you have not used RecyclerView very much. Also, some of the examples are based on drag-and-drop samples covered [elsewhere in the book](#).

Offering Keyboard Shortcuts

One thing that users will expect from desktop-style apps is the ability to use keyboard shortcuts. Basic keyboard navigation comes “for free” for a lot of Android use cases, though in some situations you will need to add in your own keyboard

smarts, such as for [navigating a RecyclerView](#). And some keyboard shortcuts will come automatically, such as `Ctrl-C` and `Ctrl-V` for copy and paste within an `EditText`.

Anything beyond that, though, you would have to provide yourself.

Action Bar Item Shortcuts

The simplest way to add keyboard shortcuts is to use `android:alphabeticShortcut` or `android:numericShortcut` on your `<item>` elements in a `<menu>` resource that you use to populate an action bar. Android will automatically support those in concert with the `Ctrl` key. So, for example, if you had:

```
<?xml version="1.0" encoding="utf-8"?>
<menu xmlns:android="http://schemas.android.com/apk/res/android">
  <item
    android:id="@+id/play_video"
    android:alphabeticShortcut="p"
    android:icon="@drawable/ic_movie_white_24dp"
    android:showAsAction="always"
    android:title="@string/menu_video" />
  <item
    android:id="@+id/show_thumbnail"
    android:alphabeticShortcut="t"
    android:icon="@drawable/ic_insert_photo_white_24dp"
    android:showAsAction="always"
    android:title="@string/menu_thumbnail" />
</menu>
```

(from [KBMouse/HotkeysN/app/src/main/res/menu/actions.xml](#))

then your `onOptionsItemSelected()` method would be called not only if the user taps on the action bar items on-screen, but also if the user pressed `Ctrl-P` or `Ctrl-T` on the keyboard.

As the names suggest, `android:alphabeticShortcut` takes a letter and `android:numericShortcut` takes a number. However, try to avoid overriding existing shortcuts with unrelated logic. For example, you might consider using `android:alphabeticShortcut="v"` for a “play video” action, but that would conflict with the `Ctrl-V` shortcut used for paste. You would be better off going with `android:alphabeticShortcut="p"` to avoid the conflict.

In Android 8.0+, in Java, we can call variations on `setAlphabeticShortcut()`, `setNumericShortcut()`, and `setShortcuts()` that allow us to change the modifier keys from the default. There are equivalent `android:alphabeticModifiers` and `android:numericModifiers` attributes for `<item>` elements in a menu resource, to indicate the modifier keys to be used with alphabetic and numeric shortcuts.

Arbitrary Hotkeys

You may find that the action bar approach is insufficient:

- It may not make sense to have action bar items for the particular operations that you want to offer keyboard shortcuts for
- You may want to support key combinations other than `Ctrl` and a letter or number

You are welcome to make anything be a keyboard shortcut or “hotkey”, by overriding the appropriate `KeyEvent` methods in an `Activity` or `View`.

The [KBMouse/Hotkeys](#) sample project is a clone of the `DragDrop/Simple` sample app from [the chapter on supporting drag-and-drop](#). As with the original app, we show a list of available videos on the device, which the user can play or view a larger thumbnail from the video. However, in addition to drag-and-drop as a way of doing those things, this sample app also supports keyboard shortcuts:

- `Alt-Right` to play the video
- `Ctrl-Right` to view the large thumbnail

However, these keyboard shortcuts imply that the user has chosen a video to play. So, this sample app blends in the keyboard-enabled `RecyclerView` code from [the corresponding section in the RecyclerView chapter](#). So, as the user presses the `Down` and `Up` arrow keys, the chosen row is highlighted. That will be the video that we work with, if the user then goes and presses `Alt-Right` or `Ctrl-Right`.

This means that we need our `play-the-video` and `show-the-large-thumbnail` code to be accessible from multiple entry points, so we pull those out into dedicated `playVideo()` and `showLargeThumbnail()` methods that take the video `Uri` as input:

```
private void playVideo(Uri videoUri) {  
    player.setVideoURI(videoUri);  
}
```

KEYBOARD AND MOUSE INPUT

```
player.start();
}

private void showLargeThumbnail(Uri videoUri) {
    Picasso.with(thumbnailLarge.getContext())
        .load(videoUri.toString())
        .fit().centerCrop()
        .placeholder(R.drawable.ic_media_video_poster)
        .into(thumbnailLarge);
}
```

(from [KBMouse/Hotkeys/app/src/main/java/com/commonsware/android/kbmouse/hotkeys/MainActivity.java](#))

We then use those from the ACTION_DROP processing, for when the user drops the video into either the VideoView (referenced in the player field) or the ImageView:

```
case DragEvent.ACTION_DROP:
    ClipData.Item clip=event.getClipData().getItemAt(0);
    Uri videoUri=clip.getUri();

    if (v==player) {
        playVideo(videoUri);
    }
    else {
        showLargeThumbnail(videoUri);
    }

    break;
```

(from [KBMouse/Hotkeys/app/src/main/java/com/commonsware/android/kbmouse/hotkeys/MainActivity.java](#))

Handling the keyboard shortcuts is relatively straightforward, courtesy of the onKeyDown() callback that we override:

```
@Override
public boolean onKeyDown(int keyCode, KeyEvent event) {
    if (keyCode==KeyEvent.KEYCODE_DPAD_RIGHT && event.getRepeatCount()==0) {
        int position=adapter.getCheckedPosition();

        if (position>=0) {
            Uri videoUri=adapter.getVideoUri(position);

            if (event.isAltPressed()) {
                playVideo(videoUri);
            }
            else if (event.isCtrlPressed()) {
                showLargeThumbnail(videoUri);
            }
        }
    }
}
```

```
    }  
  
    return(true);  
  }  
}  
  
return(super.onKeyDown(keyCode, event));  
}
```

(from [KBMouse/Hotkeys/app/src/main/java/com/commonsware/android/kbmouse/hotkeys/MainActivity.java](#))

We are passed an `int` keycode (`keyCode`) and the full `KeyEvent` for whatever key that the user pressed. If the main key was `Right` (identified as `KEYCODE_DPAD_RIGHT` for historical reasons, and to support D-pad directional navigation options), we find out which row in the `RecyclerView` is checked, if any. If we have a checked row, we find out what the `Uri` is of the video, then call `isAltPressed()` and `isCtrlPressed()` on the `KeyEvent` to find out which modifier key was pressed in conjunction with `Right`, if any. If we have a match, we call the associated `playVideo()` or `showLargeThumbnail()` method.

`onKeyDown()` tends to model user expectations, in that the user expects the event to occur when the key is pressed. However, if the user continues holding down the key, we will get a stream of `onKeyDown()` calls. That is why we also check `getRepeatCount()`, to ignore the repeated keypresses, so we only try playing the video or showing the large thumbnail once if the user holds down `Alt-Right` or `Ctrl-Right`.

Android 7.0 Keyboard Shortcuts Helper

The next challenge is letting the user know what keyboard shortcuts are available. Historically, our primary option would be to hope that the user reads the app's documentation.

(you can stop laughing now)

Android 7.0 recognizes this and provides a system-wide keyboard shortcuts helper. The user can invoke this using one keyboard shortcut that (hopefully) the user will remember: `Meta-/`. On a Windows-centric keyboard, the Meta key is the one with the Windows logo on it.

On pre-N devices, you could offer your own keyboard shortcut mapped to `Alt/` and pop up your own keyboard shortcut dialog. Since `/` is neither a letter or a

KEYBOARD AND MOUSE INPUT

number, and since having a keyboard shortcut action bar item might not make sense, you would do this using the `onKeyDown()` technique profiled in the previous section.

In the [KBMouse/HotkeysN](#) sample project, we will see how to:

- Add our own information to the keyboard shortcuts helper
- Show our own keyboard shortcuts helper on pre-N devices
- Use action bar item alphabetic shortcuts

Mostly, the project is a clone of the hotkey sample shown above, with the `build.gradle` file updated to build for Android 7.0:

```
apply plugin: 'com.android.application'

dependencies {
    implementation 'com.android.support:recyclerview-v7:24.1.1'
    implementation 'com.squareup.picasso:picasso:2.5.2'
}

android {
    compileSdkVersion 24
    buildToolsVersion '26.0.2'

    defaultConfig {
        applicationId "com.commonware.android.kbmouse.hotkeys.n"
        minSdkVersion 23
        targetSdkVersion 24
    }
}
```

(from [KBMouse/HotkeysN/app/build.gradle](#))

We have a menu resource now for our action bar, which happens to be the one shown towards the start of this chapter:

```
<?xml version="1.0" encoding="utf-8"?>
<menu xmlns:android="http://schemas.android.com/apk/res/android">
    <item
        android:id="@+id/play_video"
        android:alphabeticShortcut="p"
        android:icon="@drawable/ic_movie_white_24dp"
        android:showAsAction="always"
        android:title="@string/menu_video" />
    <item
        android:id="@+id/show_thumbnail"
```

KEYBOARD AND MOUSE INPUT

```
    android:alphabeticShortcut="t"
    android:icon="@drawable/ic_insert_photo_white_24dp"
    android:showAsAction="always"
    android:title="@string/menu_thumbnail" />
</menu>
```

(from [KBMouse/HotkeysN/app/src/main/res/menu/actions.xml](#))

We inflate that menu resource in `onCreateOptionsMenu()` using the typical recipe:

```
@Override
public boolean onCreateOptionsMenu(Menu menu) {
    getMenuInflater().inflate(R.menu.actions, menu);

    return(super.onCreateOptionsMenu(menu));
}
```

(from [KBMouse/HotkeysN/app/src/main/java/com/commonsware/android/kbmouse/hotkeys/MainActivity.java](#))

In `onOptionsItemSelected()`, we need to confirm that the user has selected a row in the `RecyclerView` using the keyboard. If that is the case, we can play the video or show the thumbnail, depending upon which action bar item the user used. Otherwise, we show a `Toast` to point out the problem:

```
@Override
public boolean onOptionsItemSelected(MenuItem item) {
    int position=adapter.getCheckedPosition();

    if (item.getItemId()==R.id.play_video) {
        if (position>=0) {
            playVideo(adapter.getVideoUri(position));
        }
        else {
            Toast.makeText(this, R.string.msg_choose,
                Toast.LENGTH_LONG).show();
        }

        return(true);
    }
    else if (item.getItemId()==R.id.show_thumbnail) {
        if (position>=0) {
            showLargeThumbnail(adapter.getVideoUri(position));
        }
        else {
            Toast.makeText(this, R.string.msg_choose,
                Toast.LENGTH_LONG).show();
        }
    }
}
```

KEYBOARD AND MOUSE INPUT

```
        return(true);
    }

    return(super.onOptionsItemSelected(item));
}
```

(from [KBMouse/HotkeysN/app/src/main/java/com/commonsware/android/kbmouse/hotkeys/MainActivity.java](#))

Alternatively, you might elect to disable or hide those action bar items until the user selects a row with the keyboard.

We do not need to do anything special in our code to handle the alphabetic shortcuts — those are applied by Android automatically, routing to the same `onOptionsItemSelected()`. In other words, whether the user chooses the action bar item via a keyboard, mouse, or touchscreen, our same code runs.

The user will find out about those shortcuts through a keyboard shortcuts helper. On Android 7.0 and higher, the system will provide one for us. Note that this helper is implemented as a system-supplied dialog-themed activity. As such, our activity is paused (as we no longer get input) but not stopped (as the helper dialog is not full-screen).

We do not need to do anything special in our code to enable the keyboard shortcuts helper on Android 7.0. However, that helper only knows about our action bar item alphabetic shortcuts, plus system-wide shortcuts. It does not know anything about the `Alt-Right` and `Ctrl-Right` shortcuts that we are handling ourselves. However, we can override `onProvideKeyboardShortcuts()` in our activity to add information to this dialog about our custom shortcuts:

```
@Override
public void onProvideKeyboardShortcuts(
    List<KeyboardShortcutGroup> data, Menu menu, int deviceId) {
    super.onProvideKeyboardShortcuts(data, menu, deviceId);

    List<KeyboardShortcutInfo> shortcuts=new ArrayList<>();
    String caption=getString(R.string.menu_video);

    shortcuts.add(new KeyboardShortcutInfo(caption,
        KeyEvent.KEYCODE_DPAD_RIGHT, KeyEvent.META_ALT_ON));

    caption=getString(R.string.menu_thumbnail);
    shortcuts.add(new KeyboardShortcutInfo(caption,
        KeyEvent.KEYCODE_DPAD_RIGHT, KeyEvent.META_CTRL_ON));
}
```

KEYBOARD AND MOUSE INPUT

```
data.add(new KeyboardShortcutGroup(getString(R.string.msg_custom),
    shortcuts));
}
```

(from [KBMouse/HotkeysN/app/src/main/java/com/commonsware/android/kbmouse/hotkeys/MainActivity.java](https://github.com/CommonWare/android-kbmouse-hotkeys/blob/master/app/src/main/java/com/commonsware/android/kbmouse/hotkeys/MainActivity.java))

This is not especially well documented at this point. What seems to work is:

- Create a new List of KeyboardShortcutInfo objects
- Add one of those for each custom shortcut, via the KeyboardShortcutInfo constructor, where you provide a description, the primary key, and the modifier (e.g., META_ALT_ON) for the shortcut
- Wrap the List of KeyboardShortcutInfo objects in a KeyboardShortcutGroup, with your own caption for the group
- Add that KeyboardShortcutGroup to the passed-in List

This gives us:

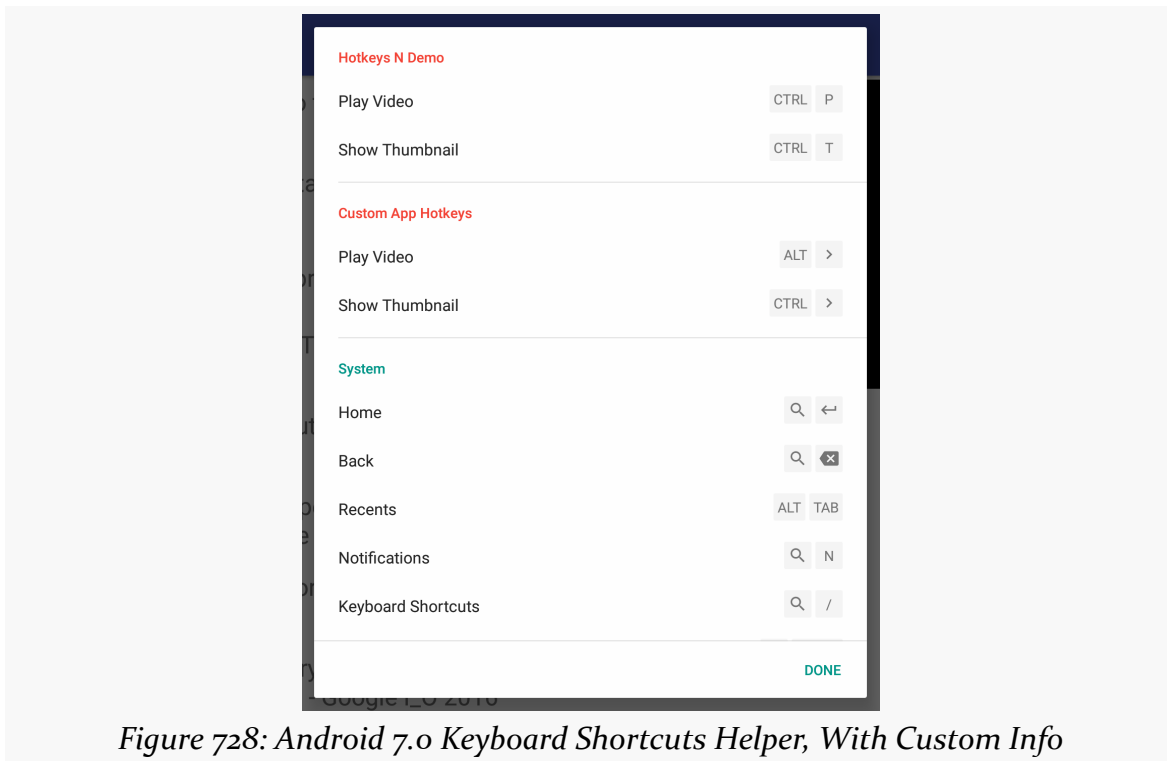

Figure 728: Android 7.0 Keyboard Shortcuts Helper, With Custom Info

The alphabetic shortcuts from the menu appear in a group whose name matches our activity's label. That is followed by our "Custom App Hotkeys" group. Ideally, these two groups would be merged, since both lists are fairly short and both pertain to this

KEYBOARD AND MOUSE INPUT

app. While we might be able to retrieve the existing group from the supplied list of `KeyboardShortcutGroup` objects and modify it, since that is not documented, that is not safe.

This shortcut helper dialog is only available on Android 7.0. For consistency, it might be nice to offer a similar helper on older devices. To do that, we need to find out when the user presses `Meta-/` on those older devices, which we handle in `onKeyDown()`:

```
@Override
public boolean onKeyDown(int keyCode, KeyEvent event) {
    if (event.getRepeatCount()==0) {
        if (keyCode==KeyEvent.KEYCODE_DPAD_RIGHT) {
            int position=adapter.getCheckedPosition();

            if (position>=0) {
                Uri videoUri=adapter.getVideoUri(position);

                if (event.isAltPressed()) {
                    playVideo(videoUri);
                }
                else if (event.isCtrlPressed()) {
                    showLargeThumbnail(videoUri);
                }
            }

            return(true);
        }
    }
    else if (keyCode==KeyEvent.KEYCODE_SLASH &&
            event.isMetaPressed() &&
            Build.VERSION.SDK_INT<Build.VERSION_CODES.N) {
        new ShortcutDialogFragment().show(getFragmentManager(),
            "shortcuts");

        return(true);
    }
}

return(super.onKeyDown(keyCode, event));
}
```

(from [KBMouse/HotkeysN/app/src/main/java/com/commonware/android/kbmouse/hotkeys/MainActivity.java](https://github.com/CommonWare/android-kbmouse-hotkeys/blob/master/src/main/java/com/commonware/android/kbmouse/hotkeys/MainActivity.java))

On those devices, we show a `ShortcutDialogFragment`, which just displays an `AlertDialog` with some simple text about our shortcuts:

KEYBOARD AND MOUSE INPUT

```
package com.commonware.android.kbmouse.hotkeys;

import android.annotation.TargetApi;
import android.app.AlertDialog;
import android.app.Dialog;
import android.app.DialogFragment;
import android.os.Build;
import android.os.Bundle;

@TargetApi(Build.VERSION_CODES.HONEYCOMB)
public class ShortcutDialogFragment extends DialogFragment {
    @Override
    public Dialog onCreateDialog(Bundle savedInstanceState) {
        AlertDialog.Builder builder=new AlertDialog.Builder(getActivity());
        Dialog dlg=builder
            .setTitle(R.string.title_shortcuts)
            .setMessage(R.string.msg_shortcuts)
            .setPositiveButton(android.R.string.ok, null)
            .create();

        return(dlg);
    }
}
```

(from [KBMouse/HotkeysN/app/src/main/java/com/commonware/android/kbmouse/hotkeys/ShortcutDialogFragment.java](https://github.com/CommonWare/KBMouse/blob/master/app/src/main/java/com/commonware/android/kbmouse/hotkeys/ShortcutDialogFragment.java))

Not every device will have a **Meta** key — the Pixel C’s keyboard dock, for example, lacks this key. However, we have no good way of determining if a given hardware keyboard has a **Meta** key. Our options would be:

- To offer keyboard shortcuts help using a different key combination, even if that is non-standard with respect to Android 7.0
- Ignore the problem, not offering keyboard shortcuts help on such devices, until such time as there is an official solution

Custom Copy-and-Paste

Since the alphabetic shortcuts for action bar items are triggered via the **Ctrl** key, one can have action bar items for **Ctrl-C** and **Ctrl-V**, offering custom copy and paste shortcuts for your activity. This is particularly important for accessibility, when your app is reliant upon something else to get content from one point to another. For example, custom copy and paste options could be used as alternatives to [drag and drop](#), including Android 7.0’s cross-app drag-and-drop.

KEYBOARD AND MOUSE INPUT

The [KBMouse/CopyPaste](#) sample project is a clone of [the cross-app drag-and-drop sample](#), with two app modules: drag/ and drop/. This time, though, we are also going to allow the photo to be copied to the clipboard in drag/ and pasted from the clipboard in drop/, as a more accessible alternative. As a side benefit, this will work even on single-window environments, whereas cross-app drag-and-drop assumes that both apps are visible at the same time.

The drag/ app has a menu resource that contains our copy item, with `android:alphabeticShortcut` set to `c`:

```
<?xml version="1.0" encoding="utf-8"?>
<menu xmlns:android="http://schemas.android.com/apk/res/android">
  <item
    android:id="@+id/copy"
    android:alphabeticShortcut="c"
    android:icon="@drawable/ic_content_copy_white_24dp"
    android:showAsAction="ifRoom"
    android:title="@android:string/copy" />
</menu>
```

(from [KBMouse/CopyPaste/drag/src/main/res/menu/actions.xml](#))

We load that resource in `onCreateOptionsMenu()` as normal. In `onOptionsItemSelected()`, we implement the copy by getting the `ClipboardManager` system service and calling `setPrimaryClip()` to populate the clipboard:

```
@Override
public boolean onOptionsItemSelected(MenuItem item) {
    if (item.getItemId()==R.id.copy) {
        getSystemService(ClipboardManager.class)
            .setPrimaryClip(buildClip());
        Toast
            .makeText(this, R.string.msg_copy, Toast.LENGTH_SHORT)
            .show();

        return(true);
    }

    return(super.onOptionsItemSelected(item));
}
```

(from [KBMouse/CopyPaste/drag/src/main/java/com/commonsware/android/dragdrop/MainActivity.java](#))

KEYBOARD AND MOUSE INPUT

Note that we use the API Level 23+ edition of `getSystemService()`, the one that takes the Java class object for the system service as a parameter (instead of a service name) and returns to us the system service already in the proper data type.

What we put on the clipboard is the result of `buildClip()`, which creates a `ClipData` around a `Uri` to the photo that we are publishing from this app:

```
private ClipData buildClip() {
    Uri uri=PROVIDER
        .buildUpon()
        .appendEncodedPath(StreamProvider.getUriPrefix(AUTHORITY))
        .appendEncodedPath("assets/FreedomTower-Morning.jpg")
        .build();

    return(ClipData.newRawUri(getString(R.string.msg_photo), uri));
}
```

(from [KBMouse/CopyPaste/drag/src/main/java/com/commonsware/android/dragdrop/MainActivity.java](#))

We happen to be [using StreamProvider](#) to serve the photo straight from assets, and so we are building up a `Uri` pointing to that asset.

The drop/ app also has a menu resource, this one set up for a paste action tied to

 :

```
<?xml version="1.0" encoding="utf-8"?>
<menu xmlns:android="http://schemas.android.com/apk/res/android">
    <item
        android:id="@+id/paste"
        android:alphabeticShortcut="v"
        android:icon="@drawable/ic_content_paste_white_24dp"
        android:showAsAction="ifRoom"
        android:title="@android:string/paste" />
</menu>
```

(from [KBMouse/CopyPaste/drop/src/main/res/menu/actions.xml](#))

And here, `onOptionsItemSelected()` handles the paste request by getting the `Uri` off the clipboard and using that, in much the same way that we use the `Uri` dropped on our UI:

```
@Override
public boolean onOptionsItemSelected(MenuItem item) {
    if (item.getItemId()==R.id.paste) {
        boolean handled=false;
```

KEYBOARD AND MOUSE INPUT

```
ClipData clip=
    getSystemService(ClipboardManager.class)
        .getPrimaryClip();

if (clip!=null) {
    ClipData.Item clipItem=clip.getItemAt(0);

    if (clipItem!=null) {
        imageUri=clipItem.getUri();

        if (imageUri!=null) {
            showThumbnail();
            handled=true;
        }
    }
}

if (!handled) {
    Toast
        .makeText(this, "Could not paste an image!", Toast.LENGTH_LONG)
        .show();
}

return(handled);
}

return(super.onOptionsItemSelected(item));
}
```

(from [KBMouse/CopyPaste/drop/src/main/java/com/commonsware/android/dragdrop/MainActivity.java](#))

Note that we do not do any MIME type checking to see if the `Uri` points to an image that we can use. We are relying on Picasso to show an error image if it is unable to use the `Uri`, as part of the `showThumbnail()` processing:

```
private void showThumbnail() {
    Picasso.with(this)
        .load(imageUri)
        .fit().centerCrop()
        .placeholder(R.drawable.ic_photo_size_select_actual_black_24dp)
        .error(R.drawable.ic_error_black_24dp)
        .into(image);
}
```

(from [KBMouse/CopyPaste/drop/src/main/java/com/commonsware/android/dragdrop/MainActivity.java](#))

A more sophisticated app might check to see if the MIME type associated with the `Uri` made sense, using either `ContentResolver` or `DocumentFile`. That way, we could offer a custom error message if the user attempted to copy something else.

However, we *do* have crude logic to handle:

- an empty clipboard
- a `ClipData` with no items
- a `ClipData` without a `Uri` (e.g., plain text copied to the clipboard)

Physical Keyboards and Focusing

In [an article complaining about Android's tablet support](#), Ars Technica's Ron Amodeo pointed out an interesting problem for devices with physical keyboards: setting the focus properly when an activity starts up. This can be addressed in a number of ways; this section shows how you can use [a custom `BindingAdapter` and the data binding framework](#) to help manage this problem.

The Problem

Suppose that you have a form that has a mix of widgets in it, including one or more `EditText` widgets. In particular, suppose that one of the `EditText` widgets is near the beginning of the activity's layout.

If you allow that widget to get the focus when the activity starts up, and the device does not have a physical keyboard, the input method editor (IME, a.k.a., "soft keyboard") appears immediately. This can be annoying to users, as perhaps they do not want to type anything into that `EditText`. Depending on the orientation of the phone and other settings, either the IME ties up a bunch of screen space that could be used for other things, or the user cannot see anything other than the full-screen landscape IME.

To save the user having to keep dismissing the IME, you might elect to give some other widget the focus at the outset.

However, for devices *with* a physical keyboard, no IME will appear. And, for users who *do* want to start typing right away, having the focus lie elsewhere is aggravating.

It would be cool if Android offered a `android:requestFocus` attribute that took a few possible values:

KEYBOARD AND MOUSE INPUT

- true, meaning this widget always got the focus (replacing the `<requestFocus/>` child element used for this today)
- false, the default
- ifHardKeyboard, meaning this widget should get the focus for devices with a physical keyboard
- ifNoHardKeyboard, meaning this widget should get the focus for devices without a physical keyboard

Layouts might then use `android:requestFocus` on two widgets, one with `ifHardKeyboard` and one with `ifNoHardKeyboard`, to designate which widget should get the focus in either case.

Alas, this attribute does not exist. However, with a bit of work, and the assistance of [the data binding framework](#), we can implement something fairly close to it, as is demonstrated in the [DataBinding/Focus](#) sample project.

A requestFocus BindingAdapter

To invent new View attributes, like the proposed `requestFocus` attribute, we need a BindingAdapter. The `@BindingAdapter` annotation can be applied to a static method that takes a View (or some subclass, if it only applies to certain view types) and a parameter indicating what sort of attribute value it expects. Then, it is up to the method to actually update the View as needed.

So, the RequestFocusActivity that demonstrates this feature has a `bindRequestFocus() @BindingAdapter` method:

```
@BindingAdapter("app:requestFocus")
public static void bindRequestFocus(View v, String focusMode) {
    Configuration cfg=v.getResources().getConfiguration();
    boolean hasNoKeyboard=
        cfg.keyboard==Configuration.KEYBOARD_NOKEYS;
    boolean keyboardHidden=
        cfg.hardKeyboardHidden==Configuration.HARDKEYBOARDHIDDEN_YES;
    boolean result=false;

    if (TRUE.equals(focusMode)) {
        result=true;
    }
    else if (IF_HARD_KEYBOARD.equals(focusMode)) {
        if (!hasNoKeyboard && !keyboardHidden) {
            result=true;
        }
    }
    else if (IF_NO_HARD_KEYBOARD.equals(focusMode)) {
        if (hasNoKeyboard || keyboardHidden) {
            result=true;
        }
    }
}
```

KEYBOARD AND MOUSE INPUT

```
        if (hasNoKeyboard) v.setFocusableInTouchMode(true);
    }
}
else {
    throw new IllegalArgumentException("Unexpected focusMode value: "+focusMode);
}

if (result) {
    v.setFocusable(true);
    v.requestFocus();
}
}
```

(from [DataBinding/Focus/app/src/main/java/com/commonsware/android/focusbinding/RequestFocusActivity.java](#))

Unfortunately, there is no obvious way to constrain a `BindingAdapter` to some custom enumerated roster of values. So, we have `bindRequestFocus()` accept a `String`, and we throw an `IllegalArgumentException` if the attribute value is not `true`, if the attribute is not one of three recognized values:

```
private static final String TRUE="true";
private static final String IF_HARD_KEYBOARD="ifHardKeyboard";
private static final String IF_NO_HARD_KEYBOARD="ifNoHardKeyboard";
```

(from [DataBinding/Focus/app/src/main/java/com/commonsware/android/focusbinding/RequestFocusActivity.java](#))

(`false` is skipped as a potential value, but you could easily extend this to accept and ignore that value)

The key portion of this method is determining whether or not the user has access to a physical keyboard. This has two components:

1. Does the device have a physical keyboard?
2. Is the physical keyboard presently available?

The latter might be “no” for devices with a sliding keyboard, where the keyboard exists but is not presently exposed.

Using a `Configuration` object, we set up `hasNoKeyboard` and `keyboardHidden` boolean values for those two components. Then, we will call `setFocusable(true)` and `requestFocus()` on the `View` if:

- the attribute value is `true`, or
- the attribute value is `ifHardKeyboard` *and* the device has a physical keyboard *and* the keyboard is not hidden, or
- the attribute value is `ifNoHardKeyboard` *and* either the device lacks a physical keyboard or the physical keyboard is hidden

We also call `setFocusableInTouchMode(true)` if the device has no physical keyboard, to ensure that the widget in question can be focused in touch mode before we try setting its focus.

Using the BindingAdapter

The syntax for our attributes is a bit different than what we aimed for:

- We use the app prefix rather than `android`
- The value has to be a binding expression, otherwise the data binding framework ignores it, so we cannot just use a simple string, but instead have to wrap it in an expression (e.g., `@{"ifNoHardKeyboard"}`)

But, we can use `app:requestFocus` as needed, such as in this layout:

```
<?xml version="1.0" encoding="utf-8"?>
<layout xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:app="http://schemas.android.com/apk/res-auto">

    <LinearLayout
        android:layout_width="match_parent"
        android:layout_height="match_parent">

        <Button
            android:id="@+id/button1"
            android:layout_width="wrap_content"
            android:layout_height="wrap_content"
            android:text="@string/a_button"
            app:requestFocus="@{"ifNoHardKeyboard"}" />

        <EditText
            android:id="@+id/editText1"
            android:layout_width="0dp"
            android:layout_height="wrap_content"
            android:layout_weight="1"
            android:hint="@string/str_1st_field"
            android:inputType="text"
            app:requestFocus="@{"ifHardKeyboard"}" />

        <EditText
            android:id="@+id/editText2"
            android:layout_width="0dp"
            android:layout_height="wrap_content"
            android:layout_weight="1"
            android:hint="@string/str_2nd_field"
```

```
    android:inputType="text" />

</LinearLayout>
</layout>
```

(from [DataBinding/Focus/app/src/main/res/layout/request_focus.xml](#))

Here, if the device has an available physical keyboard, we put the focus on the first `EditText` widget, so that the user can start typing right away. But, if the device lacks an available physical keyboard, we put the focus on the `Button`, to avoid the IME appearing right away.

Offering Mouse Context Menus

One thing that users of mice and trackpads are used to having are context menus, typically displayed as the result of a right-mouse click. More specifically, they are used to a popup menu appearing adjacent to the mouse pointer when they click the right-mouse button.

Android has had its own context menu system since API Level 1. However, it does not look a lot like what desktop users are used to. We can create such a menu ourselves, but it takes a little work, due to bugs and limitations in Android.

Ideally, we would use `PopupMenu`. This does pretty much what the class name implies: displays a popup window containing a menu, driven by a menu resource. However, that popup window will appear to drop down from some anchor `View` that we specify, and there is no way in the public API to adjust its position to be closer to the mouse pointer. Hence, for larger widgets — such as rows in a `ListView` or `RecyclerView` — `PopupMenu` will result in a menu that can appear fairly far away from the mouse pointer, which will be aggravating.

`PopupWindow` and `ListPopupWindow` both allow for fine-grained positioning, which make them better candidates for our purposes. Of the two, `ListPopupWindow` handles the notion of a scrolling list, which may be useful for longer menus. And, we can populate its contents from a simple `ListAdapter`, like an `ArrayAdapter`. The [KBMouse/Context](#) sample project is a clone of the `KBMouse/Hotkeys` sample app that adds in a `ListPopupWindow` for a mouse-driven context menu... but it takes a bit of work.

First, we need to define what goes in the list of the `ListPopupWindow`. A simple solution for that is to use a string-array resource:

KEYBOARD AND MOUSE INPUT

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
  <string-array name="popup">
    <item>@string/menu_video</item>
    <item>@string/menu_thumbnail</item>
  </string-array>
</resources>
```

(from [KBMouse/Context/app/src/main/res/values/arrays.xml](#))

Here, the two items are references to string resources, for internationalization purposes (in theory, at least).

All of our business logic for adding the context menu lies in the `RowController` — just as it handles clicks (to play the video in a standalone player) and long-clicks (to initiate a drag-and-drop), it can now handle context menus.

First, in the `RowController` constructor, we register the `RowController` as handling touch events for the row, via `setOnTouchListener()`:

```
RowController(View row, ChoiceCapableAdapter<?> adapter) {
    super(row);
    this.adapter=adapter;

    title=(TextView)row.findViewById(android.R.id.text1);
    thumbnail=(ImageView)row.findViewById(R.id.thumbnail);

    row.setOnClickListener(this);
    row.setOnLongClickListener(this);
    row.setOnTouchListener(this);
}
```

(from [KBMouse/Context/app/src/main/java/com/commonsware/android/kbmouse/hotkeys/RowController.java](#))

That requires `RowController` to implement the `View.OnTouchListener` interface, and therefore requires `RowController` to override `onTouch()`:

```
@Override
public boolean onTouch(View v, MotionEvent event) {
    if ((event.getButtonState() & MotionEvent.BUTTON_SECONDARY)!=0 &&
        event.getAction()==MotionEvent.ACTION_DOWN) {
        adapter.onChecked(position, true, true);

        String[] items=
            itemView
                .getContext()
```

KEYBOARD AND MOUSE INPUT

```
        .getResources()
        .getStringArray(R.array.popup);
    ArrayAdapter<String> adapter=
        new ArrayAdapter<>(itemView.getContext(),
            android.R.layout.simple_list_item_1,
            items);
    final ListPopupWindow popup=
        new ListPopupWindow(itemView.getContext());

    popup.setAnchorView(itemView);
    popup.setHorizontalOffset((int)event.getX());
    popup.setVerticalOffset((int)event.getY()-itemView.getHeight());
    popup.setAdapter(adapter);
    popup.setWidth(measureContentWidth(itemView.getContext(), adapter));

    popup.setOnItemClickListener(
        new AdapterView.OnItemClickListener() {
            @Override
            public void onItemClick(AdapterView<?> parent, View view,
                int position, long id) {
                if (position==0) {
                    ((MainActivity)itemView.getContext())
                        .playVideo(videoUri);
                }
                else {
                    ((MainActivity)itemView.getContext())
                        .showLargeThumbnail(videoUri);
                }

                popup.dismiss();
            }
        });

    popup.show();

    return(true);
}

return(false);
}
```

(from [KBMouse/Context/app/src/main/java/com/commonsware/android/kbmouse/hotkeys/RowController.java](#))

To determine if a given `MotionEvent` is a trigger for the context menu, we check two things:

1. Is the `BUTTON_SECONDARY` pressed?

2. Is this a “down” event (`ACTION_DOWN`)?

If yes, we tell our `ChoiceCapableAdapter` to check this row, so it is clear to the user what they have right-clicked over.

Then, we load in the string array from the resources and wrap that in a standard `ArrayAdapter`. At that point, we can begin configuring the `ListPopupWindow`.

The constructor for the `ListPopupWindow` takes a `Context`. We grab the `Context` from the `itemView` field of this `ViewHolder`, which represents our row.

We then call five configuration methods to set up the look-and-feel of the `ListPopupWindow`. The first four are fairly straightforward:

- `setAnchorView()` specifies the `View` that this popup is anchored to. In this case, we use the row itself (`itemView`).
- `setHorizontalOffset()` and `setVerticalOffset()` indicate, from the upper-left corner of the anchor view, where to place the upper-left corner of the `ListPopupView`. We want the `ListPopupView` to be adjacent to the mouse pointer, and the `getX()` and `getY()` values of the `MotionEvent` tell us where inside the `itemView` the user clicked. However, the *default* position of the `ListPopupWindow` is to be anchored to the *lower left corner* of the anchor view, not the upper left corner. To adjust the horizontal position, we can simply use `getX()`, since both `getX()` and the default horizontal position of the `ListPopupWindow` are on the left. However, the offset for the vertical position needs to be a negative value, as we want to raise the `ListPopupWindow` to where the mouse pointer is. That value is the difference between the `Y` coordinate of the mouse pointer (`getY()`) and the height of the row (`itemView.getHeight()`).
- `setAdapter()` provides the `ArrayAdapter` to populate the list in the `ListPopupWindow`.

The fifth method — `setWidth()` — is more complex than it should be, due to a bug. Ideally, we would call `setWidth(ListPopupWindow.WRAP_CONTENT)`. According to the documentation, this will set the width of the `ListPopupWindow` to be the width of the content of the adapter. Unfortunately, [this does not work](#). And, since that bug has been outstanding since 2013, it is unlikely that it will ever work.

The workaround — as documented in [Stack Overflow](#) — is to calculate the maximum width of our adapter rows ourselves, then call `setWidth()` with that pixel value. This is isolated in a `measureContentWidth()` method:

KEYBOARD AND MOUSE INPUT

```
// based on http://stackoverflow.com/a/26814964/115145

private int measureContentWidth(Context ctxt, ListAdapter listAdapter) {
    ViewGroup mMeasureParent = null;
    int maxWidth = 0;
    View itemView = null;
    int itemType = 0;

    final ListAdapter adapter = listAdapter;
    final int widthMeasureSpec =
        View.MeasureSpec.makeMeasureSpec(0, View.MeasureSpec.UNSPECIFIED);
    final int heightMeasureSpec =
        View.MeasureSpec.makeMeasureSpec(0, View.MeasureSpec.UNSPECIFIED);
    final int count = adapter.getCount();
    for (int i = 0; i < count; i++) {
        final int positionType = adapter.getItemViewType(i);
        if (positionType != itemType) {
            itemType = positionType;
            itemView = null;
        }

        if (mMeasureParent == null) {
            mMeasureParent = new FrameLayout(ctxt);
        }

        itemView = adapter.getView(i, itemView, mMeasureParent);
        itemView.measure(widthMeasureSpec, heightMeasureSpec);

        final int itemWidth = itemView.getMeasuredWidth();

        if (itemWidth > maxWidth) {
            maxWidth = itemWidth;
        }
    }

    return maxWidth;
}
```

(from [KBMouse/Context/app/src/main/java/com/commonsware/android/kbmouse/hotkeys/RowController.java](#))

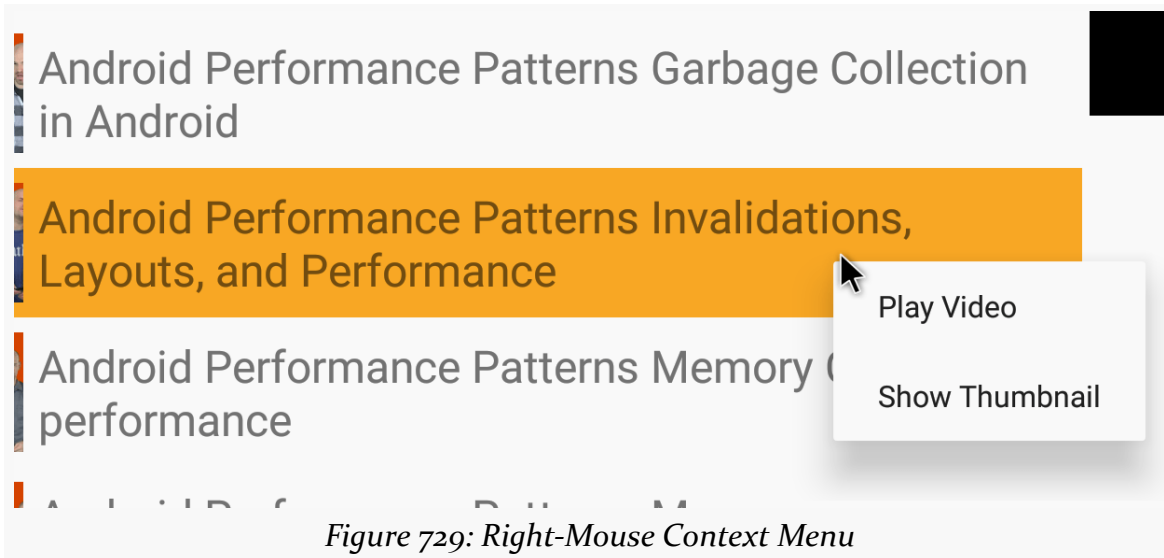

This implementation iterates over the items in the adapter, has the adapter create row views for each row (using a bit of light caching to try to recycle row views in simple adapters), then determines the measured width of those rows. The longest measured width is then used as the result. This works for simple rows and short lists, which is all we really need here anyway.

KEYBOARD AND MOUSE INPUT

Then, we call `setOnItemClickListener()` to register a listener to find out when rows in the list in the `ListPopupWindow` are clicked. This works the same as with a `ListView`. In our case, we look at the passed-in position, and route to the activity's `playVideo()` or `showLargeThumbnail()` methods according to which list item the user clicked upon. We then `dismiss()` the `ListPopupWindow`, so it goes away after the user clicked on one of the list items.

Finally, we can `show()` the `ListPopupWindow`, so it displays its list to the user.

From the user's perspective, right-clicking over one of the videos in the list offers the context menu:

What is missing is the ability for the user to dismiss the context menu. If the user clicks outside the `ListPopupWindow`, it goes away as expected. However, the underlying click event is still processed. So, if the user clicks over the `VideoView` or large thumbnail `ImageView`, everything looks fine. If the user clicks over one of the `RecyclerView` rows... the clicked-upon video starts playing back in a standalone video player, rather than just dismissing the `ListPopupWindow`. This will be addressed in a future edition of this sample app.

Also note that API Level 23 offers `setOnContextClickListener()` on `View`. This works like `setOnClickListener()` and `setOnLongClickListener()`, letting you know via an `OnContextClickListener` that the view was “context-clicked”. However, you do not get details of the touch event, and so you have no good means of positioning the popup to be near where it should go.

Offering Tooltips

Users of desktop operating systems, and even Web apps, are used to having tooltips available on key UI elements (e.g., buttons). In a mouse-driven environment, these usually appear after the mouse has hovered over the UI element for a short while.

Touchscreens can also offer similar contextual help. For example, if the user long-presses on an action bar item's icon, a Toast will appear with the item's title.

So, there are two pieces to the puzzle of offering tooltips:

1. How do you decide when to show a tooltip?
2. What is the UI for the tooltip itself?

As with many things in Android, there are two options, depending on what version of Android you are running on.

Android 7.1 and Older

This section will focus on the first piece — how you decide when to show a tooltip — using a simple Toast for the tooltip UI. There are [many Android libraries for tooltip UIs](#), which you may wish to investigate.

Hover Events

API Level 14 added `setOnHoverListener()` to `View`. This, and the corresponding `OnHoverListener` interface, allow developers to find out when the user is “hovering” over a widget. This can be triggered by a mouse or by some styluses.

The `onHover()` method of your `OnHoverListener` will be called when a change in the state of hovering occurs. You are given the affected `View`, along with the `MotionEvent` that triggered the state change. The `MotionEvent` should have one of three actions:

- `ACTION_HOVER_ENTER`, meaning that the user has begun hovering over the view
- `ACTION_HOVER_MOVE`, meaning that the user was already hovering over the view, but has moved the mouse pointer, so the hover position within the view bounds has changed
- `ACTION_HOVER_EXIT`, meaning that the user is no longer hovering over the view

KEYBOARD AND MOUSE INPUT

The [KBMouse/Tooltip](#) sample project is a clone of the KBMouse/Hotkeys sample app that adds in tooltip support for long-clicks and hovers. MainActivity now implements the OnLongClickListener and OnHoverListener interfaces, so we can register those listeners on our VideoView and large thumbnail ImageView:

```
@Override
public void onCreate(Bundle state) {
    super.onCreate(state);
    setContentView(R.layout.main);

    player=(VideoView)findViewById(R.id.player);

    if (player!=null) {
        player.setOnDragListener(this);
        player.setOnHoverListener(this);
        player.setOnLongClickListener(this);
    }

    thumbnailLarge=(ImageView)findViewById(R.id.thumbnail_large);

    if (thumbnailLarge!=null) {
        thumbnailLarge.setOnDragListener(this);
        thumbnailLarge.setOnHoverListener(this);
        thumbnailLarge.setOnLongClickListener(this);
    }

    setLayoutManager(new LinearLayoutManager(this));
    adapter=new VideoAdapter(getRecyclerView());
    setAdapter(adapter);
    getRecyclerView().requestFocus();

    if (state!=null) {
        isInPermission=
            state.getBoolean(STATE_IN_PERMISSION, false);
    }

    if (hasFilesPermission()) {
        loadVideos();
    }
    else if (!isInPermission) {
        isInPermission=true;

        ActivityCompat.requestPermissions(this,
            new String[] {Manifest.permission.READ_EXTERNAL_STORAGE},
            REQUEST_PERMS);
    }
}
```

KEYBOARD AND MOUSE INPUT

(from [KBMouse/Tooltip/app/src/main/java/com/commonsware/android/kbmouse/hotkeys/MainActivity.java](#))

We will see why we are not registering for events on the RecyclerView [a bit later in this chapter](#).

The `onLongClick()` method for the `OnLongClickListener` forwards the event to a `showTooltip()` method, providing a string resource with the particular message to show:

```
@Override
public boolean onLongClick(View v) {
    if (v==thumbnailLarge) {
        showTooltip(R.string.tooltip_thumbnail);
    }
    else if (v==player) {
        showTooltip(R.string.tooltip_player);
    }
    else {
        return(false);
    }

    return(true);
}
```

(from [KBMouse/Tooltip/app/src/main/java/com/commonsware/android/kbmouse/hotkeys/MainActivity.java](#))

`showTooltip()` shows a Toast... with a slight wrinkle:

```
private void showTooltip(@StringRes int message) {
    if (tooltip!=null) {
        tooltip.cancel();
    }

    tooltip=Toast.makeText(this, message, Toast.LENGTH_LONG);
    tooltip.show();
}
```

(from [KBMouse/Tooltip/app/src/main/java/com/commonsware/android/kbmouse/hotkeys/MainActivity.java](#))

If, while a tooltip Toast is showing, the user long-clicks on a *different* widget, we want to show that tooltip immediately. By default, we would have to wait until the first Toast completed its duration. Toast has a `cancel()` method that does one of three things:

1. If the Toast has not yet been shown, it removes the Toast from the roster of pending Toasts

KEYBOARD AND MOUSE INPUT

2. If the Toast is presently showing, it gets rid of the Toast
3. If the Toast was shown previously, it does nothing, as nothing is needed

So, we hold onto the most-recent tooltip Toast in a field named `tooltip`, and we `cancel()` it before showing the next tooltip.

The `onHover()` method for the `OnHoverListener` forwards the event to a private `onHover()`, where we supply the string resource of the tooltip message:

```
@Override
public boolean onHover(View v, MotionEvent event) {
    if (v==player) {
        onHover(event, R.string.tooltip_player, player);
    }
    else if (v==thumbnailLarge) {
        onHover(event, R.string.tooltip_thumbnail, thumbnailLarge);
    }
    else {
        return(false);
    }

    return(true);
}
```

(from [KBMouse/Tooltip/app/src/main/java/com/commonware/android/kbmouse/hotkeys/MainActivity.java](#))

And that is where things start to get complicated.

Detecting a Long-Enough Hover

The problem is that while we can find out when the user starts and stops hovering over a view, we need additional code to determine when some time has elapsed between those two events. So, for example, if you want to show a tooltip one second after the user begins hovering over a view, you need to:

- Arrange to find out when one second has elapsed after the user starts hovering over the view
- Cancel that work if the user stops hovering over that view, either preventing the tooltip from appearing (if it has not done so yet) or perhaps causing the tooltip to vanish immediately (if it is presently being displayed)

`postDelayed()` provides a nice cheap way of handling this. We can schedule a `Runnable` to be invoked after our one-second delay, and we can use

KEYBOARD AND MOUSE INPUT

`removeCallbacks()` to cancel the `Runnable` if the user stops hovering over that widget.

However, we do not know the exact sequence of hover events. It may be that we are given an `ACTION_HOVER_ENTER` event for a new widget prior to `ACTION_HOVER_EXIT` of the previous widget. Hence, we need to track per-widget state.

In this case, the sample app holds onto a `Runnable` per widget for which we are displaying tooltips, in a `SparseArray` object:

```
private SparseArray<Runnable> hoverTimers=  
    new SparseArray<>();
```

(from [KBMouse/Tooltip/app/src/main/java/com/commonsware/android/kbmouse/hotkeys/MainActivity.java](#))

A `SparseArray` is a data structure that allows `ArrayList`-style indexed access to objects, but it does not assume that the index values are consecutive. Basically, it replaces a `HashMap` of `Integer` objects. The `SparseArray` allows us to use widget IDs as the index values, so as long as each of our tooltip-enabled widgets have unique IDs, we can track their state in the `SparseArray`.

Our private edition of `onHover()` uses this `SparseArray`:

```
private void onHover(MotionEvent event, @StringRes final int message,  
                    final View anchor) {  
    Runnable hover=hoverTimers.get(anchor.getId());  
  
    if (hover==null &&  
        (event.getAction()==MotionEvent.ACTION_HOVER_ENTER ||  
         event.getAction()==MotionEvent.ACTION_HOVER_MOVE)) {  
  
        hover=new Runnable() {  
            @Override  
            public void run() {  
                showTooltip(message);  
            }  
        };  
  
        hoverTimers.put(anchor.getId(), hover);  
        thumbnailLarge.postDelayed(hover, TOOLTIP_DELAY);  
    }  
    else if (hover!=null &&  
             event.getAction()==MotionEvent.ACTION_HOVER_EXIT) {  
        thumbnailLarge.removeCallbacks(hover);  
        hoverTimers.remove(anchor.getId());  
    }  
}
```

KEYBOARD AND MOUSE INPUT

```
}  
}
```

(from [KBMouse/Tooltip/app/src/main/java/com/commonsware/android/kbmouse/hotkeys/MainActivity.java](#))

There are two scenarios that we care about:

1. The user starts hovering over a widget, and we have not yet set up the timer `Runnable`, as it does not exist in the `SparseArray`. So, we create the `Runnable` to show our tooltip (via `showTooltip()`), stuff it in the `SparseArray`, and use `postDelayed()` to trigger the `Runnable` after a second.
2. The user stops hovering over a widget, and we already have the timer `Runnable`. In this case, we call `removeCallbacks()` to ensure that this `Runnable` is not run (if it has not run already), plus remove it from the `SparseArray`.

The net effect is that our `Runnable` will be invoked if one second elapses after the user starts hovering over a widget and the user has not stopped hovering over that same widget.

`showTooltip()` raises a `Toast` to serve as a crude tooltip:

```
private void showTooltip(@StringRes int message) {  
    if (tooltip!=null) {  
        tooltip.cancel();  
    }  
  
    tooltip=Toast.makeText(this, message, Toast.LENGTH_LONG);  
    tooltip.show();  
}
```

(from [KBMouse/Tooltip/app/src/main/java/com/commonsware/android/kbmouse/hotkeys/MainActivity.java](#))

However, it is possible that the user displays one tooltip, then quickly hovers over another widget, and that our one-second delay is shorter than the `Toast` display duration. So, we hold onto each `Toast` that we display, and we `cancel()` it before showing the next one. That way, if one `Toast` is outstanding when we need to show a different `Toast`, we can make the switch immediately, rather than having to wait for the rest of the first `Toast` display duration to elapse before showing the next one.

What We Are Missing

However, the tooltip for the `VideoView` will not display. `VideoView` is an odd widget, consuming a lot of touch events for no really good reason. Most likely, for a sophisticated Android app, you will want to skip `VideoView` and use something else, such as a `MediaPlayer` tied to your own `SurfaceView` or `TextureView`.

This sample app does not attempt to provide tooltips for the rows in the `RecyclerView`. Even though we are set up to show a tooltip for the `RecyclerView` overall, the hover events are for the rows, not the `RecyclerView`, as the `RecyclerView` itself is not visible. If you wanted tooltips here, your choices are:

- Have the tooltip for the whole `RecyclerView`, forwarding hover events from rows up to your tooltip-management logic
- Have tooltips per row, using some different system than our `SparseArray`, as the row widget IDs will all be the same by default

Android 8.0+

Android has had the occasional tooltip-like feature, such as the tooltip that you get on action bar items when long-pressing them. Android 8.0 extends this to all widgets. Simply provide the desired text via `android:tooltipText` or `setTooltipText()`. A tooltip will then appear when either the user long-presses the widget or if the user hovers over the widget. In both cases, though, if the long-press or hover event is consumed by something else, the tooltip is not shown.

The [KBMouse/Tooltip0](#) sample project is a clone of the preceding sample app, where we switch to using the tooltip implementation in Android 8.0+.

Specifically, our large-screen layout has tooltips for the `VideoView` and `ImageView` widgets, using `android:tooltipText`:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:orientation="horizontal">

    <android.support.v7.widget.RecyclerView android:id="@+id/video_list"
        xmlns:android="http://schemas.android.com/apk/res/android"
        android:layout_width="Odp"
        android:layout_height="match_parent"
```

KEYBOARD AND MOUSE INPUT

```
        android:layout_weight="1" />

<LinearLayout
    android:layout_width="0dp"
    android:layout_height="match_parent"
    android:layout_weight="1"
    android:orientation="vertical">

    <FrameLayout
        android:id="@+id/video_frame"
        android:layout_width="match_parent"
        android:layout_height="0dp"
        android:layout_marginBottom="4dp"
        android:layout_weight="1"
        android:padding="4dp">

        <VideoView
            android:id="@+id/player"
            android:layout_width="match_parent"
            android:layout_height="match_parent"
            android:layout_gravity="center"
            android:tooltipText="@string/tooltip_player" />
    </FrameLayout>

    <FrameLayout
        android:id="@+id/thumbnail_frame"
        android:layout_width="match_parent"
        android:layout_height="0dp"
        android:layout_weight="1"
        android:padding="4dp">

        <ImageView
            android:id="@+id/thumbnail_large"
            android:layout_width="match_parent"
            android:layout_height="match_parent"
            android:scaleType="centerInside"
            android:tooltipText="@string/tooltip_thumbnail" />
    </FrameLayout>
</LinearLayout>
</LinearLayout>
```

(from [KBMouse/TooltipO/app/src/main/res/layout-w800dp/main.xml](#))

The result are tooltips reminiscent of those from the original sample:

Figure 730: Tooltip From Long-Press of ImageView

Hovering over either widget, or long-pressing either widget, will bring up the tooltip.

Pointer Capture

On a desktop operating system, the “pointer” refers to the mouse cursor. This feature is normally handled by the operating system. “Pointer capture” refers to when a widget blocks the normal mouse cursor, typically because it is going to use the mouse in some way for which the normal pointer would be inappropriate.

In Android 8.0+, you can call `requestPointerCapture()` and `releasePointerCapture()` to have a widget operate in pointer-capture mode or not.

The vast majority of Android apps should not need this.

Viewing PDFs

The Portable Document Format — better known as PDF — has been around for over two decades, and it is still going strong today. As a result, we often have a need to show PDF files to users, whether those files are:

- Shipped with the app, such as documentation
- Downloaded by the app, such as email attachments for the mail client that you are writing
- Otherwise managed by the app, such as with PDF files held in cloud storage that your app is managing on behalf of the user
- And so on

This is another one of those topics that seems fairly simple on the surface, but can get complicated based on your requirements. In particular, if you want to try to present the PDF to the user *in your app*, as opposed to launching some external PDF viewing app, while you have a few options, they all have their issues.

In this chapter, we will review several ways of displaying a PDF to the user, so you can choose what approach (or approaches) are the best fit for your requirements.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book.

The Criteria

If there are several ways of displaying a PDF, we need some criteria by which to evaluate those options and make our choice. Here are some likely criteria to use, though you may have others that are more specific to your app's requirements.

Where is the PDF?

Most of the PDF-viewing options assume that the PDF is on the device already. However, even within that, there are a few possibilities as to where the PDF might be:

- Internal storage (e.g., `getFilesDir()`) of your app
- External storage (e.g., `getExternalFilesDir()`) associated with your app
- Common locations on external storage, such as the standard Documents directory
- Some `Uri` that you obtained via `ACTION_GET_CONTENT` or `ACTION_OPEN_DOCUMENT`
- An asset or raw resource within your app

And, occasionally, developers get boxed into a corner, with a requirement to show a PDF without downloading the PDF.

Does It Work Offline?

The opposite problem is the offline viewing experience. If the PDF is on the device already, ideally, the PDF-viewing technology can show that PDF without having to have an active Internet connection. After all, many users do not have continuous Internet access.

How Complex is the PDF?

While the PDF file format has been around for years and years, it has expanded over that time. In the beginning, PDF did not offer things like form fields, annotations, and the like. The more feature-rich your PDF is, the more likely it is that some PDF viewers may be incapable of handling all of those features.

This is not restricted to in-app viewing solutions. PDF viewing apps vary in capability, and there will be some that either do not support your desired features

(e.g., allow the user to fill in forms) or only will if the user unlocks the feature through some purchase.

How Stable is the Solution?

Many PDF-viewing apps are continuously updated. If the user happens to choose one that is not, that is the user's fault, not yours.

However, when you build in PDF viewing into your app, now *you* need to ensure that your solution is up to date and likely to stay stable for the duration of your app's use.

How Private is the PDF?

The big one, in terms of the major options for viewing the PDF, is the degree of privacy that is tied to that PDF.

If the document comes from the user — for example, it came in an email attachment to the user's inbox that you are managing — you should assume a modest level of privacy. Do not ship that PDF to other servers without the user's approval. However, if the user wants to view the PDF, you should not be afraid of allowing the user to do so using the user's chosen PDF viewing app.

If the document is more tightly controlled by your app — for example, it came as an attachment to some secure messaging client that you are writing — you may be nervous about granting other apps access to that PDF. After all, you do not necessarily know what those other apps might do with the PDF.

Where things get very messy is when the developers think that *they* “own” the PDF, and therefore are trying to restrict that PDF's access, much as how a DRM solution tries to restrict access to videos. Many PDF-viewing apps offer printing, sharing, and other things that the *user* might want, but that the *developers* do not want. In truth, it is rather likely that the user can get to the PDF anyway, whether the developers like it or not, by various means (e.g., extracting PDFs packaged in the APK using an ordinary ZIP file utility). But, this seems to be the #1 reason why some developers are trying to view PDF files within their own app: treating the user as the enemy.

The Classic Solution: ACTION_VIEW

The quintessential solution — and the one that you should focus on first — is to use `startActivity()` with an `ACTION_VIEW` Intent, where the `Uri` in that Intent points to your PDF file:

```
startActivity(new Intent(Intent.ACTION_VIEW, uriToThePdf));
```

This is quick, easy, and gives the user control over how the PDF is rendered, as they can (usually) choose the PDF viewer to use.

However, this is not a universal solution:

- Android itself does not ship with a PDF viewer app, and therefore some devices will not ship with a PDF viewer app. You wind up with an `ActivityNotFoundException` from your `startActivity()` call, and then you need to guide the user to install a PDF viewer app.
- The user may not be able to install such an app, due to limitations imposed by device owner APIs or because the user is using the device on a secondary user account that lacks app-installation capability.
- For maximum compatibility, you will need to set up a `FileProvider` (or the equivalent) and serve your PDF through it, particularly on Android 7.0+ devices, where the `file` scheme for `Uri` values is banned, in effect.

If you are concerned that the user might choose a PDF viewer app that is malware, or is one that has features that you dislike, you could use `PackageManager` and `queryIntentActivities()` to find all activities that support `ACTION_VIEW` for your PDF file. From there, you can find out the apps associated with those activities, and filter that based on a whitelist (or blacklist) of PDF viewer apps. Then, present your own “chooser”-style UI to allow the user to choose from among the valid options.

The Really Bad Idea: Google Docs

Some developers, though, try desperately to avoid using external PDF viewer apps.

The approach that many of those developers try is the worst available option: have Google Docs render the PDF in a `WebView`, using code reminiscent of:

```
WebView webview=(WebView)findViewById(R.id.webview);
```

VIEWING PDFs

```
webView.getSettings().setJavaScriptEnabled(true);
webView.loadUrl("http://drive.google.com/viewerng/
viewer?embedded=true&url=" + urlToYourPdf);
```

This has many poor characteristics:

- It requires that the PDF be available publicly on the Web, for Google Docs to be able to access it. From a security standpoint, many more attackers can access the PDF online than can on an Android device.
- If the PDF is not already available publicly on the Web, you would need to run a server, or employ some cloud storage or similar service, to host that PDF, adding to your complexity.
- If the PDF needs to be uploaded, now you are consuming lots of extra bandwidth. Not only did you (probably) download the PDF from somewhere, but now you have to re-upload it somewhere, then download whatever bits and bytes the `WebView` winds up using to display it, as served from Google Docs.
- There is no requirement that Google keep this Google Drive view-an-arbitrary-PDF URL working. As soon as they change it, your app breaks. As soon as they discontinue it, this approach has to be replaced anyway.
- This approach requires a live Internet connection. There is no offline option.

Pretty much anything else will be better than this solution.

The Built-In Option: PdfRenderer

Routinely, developers are astonished that Android does not ship with some sort of PDF-viewing app, the way that desktop operating systems do.

The closest thing that Android has to a built-in PDF viewer is `PdfRenderer`. This class was added in API Level 21 (Android 5.0), and it allows you to render pages of a PDF to `Bitmap` objects. In turn, you can then use those `Bitmap` objects to present the pages to the user, by one means or another.

This solution has severe limitations:

- As noted, it requires Android 5.0, leaving out older devices.
- It requires a seekable stream on the content, in the form of a `ParcelFileDescriptor`. The net effect of this is that you can only reliably render something backed by a file. Conversely, you cannot render something

VIEWING PDFs

backed by a pipe. This means that you cannot render assets, raw resources, a PDF that you decrypt into a memory buffer, and so on.

- It chokes on complex PDF files. For example, the author of this book started testing it with [this short research paper](#), only to determine (eventually) that PdfRenderer simply cannot render that PDF. PdfRenderer was added with an eye towards print preview, and so its implementation may be focused on the sorts of PDFs that you can generate for printing, as opposed to arbitrary PDFs.
- It only gives you Bitmap objects. You still have to implement a UI to present those Bitmap objects to the user.

The [PDF/PdfRenderer](#) sample project illustrates the use of PdfRenderer.

The RecyclerView

We need to present pages to the user. In a typical PDF viewer, the user can scroll or swipe to move between pages. One could use a ViewPager for that role. However, large Bitmap objects really should be reused, and ViewPager does not make it easy to reuse objects. A RecyclerView would be a better choice.

The [chapter on advanced RecyclerView uses](#) demonstrates setting up a RecyclerView as a replacement for ViewPager for page-at-a-time presentations. The PdfRenderer sample app uses one of those techniques, [involving SnapHelper](#), for presenting the pages to the user.

Hence, our UI is a RecyclerView with a light gray background:

```
<?xml version="1.0" encoding="utf-8"?>
<android.support.v7.widget.RecyclerView android:id="@+id/pager"
    xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:background="#CCCCCC"
    android:clipToPadding="false" />
```

(from [PDF/PdfRenderer/app/src/main/res/layout/main.xml](#))

In onCreate(), our MainActivity sets up that RecyclerView with a LinearLayoutManager, along with a PagerSnapHelper named snapperCarr:

```
pager.setLayoutManager(new LinearLayoutManager(this,
    LinearLayoutManager.HORIZONTAL, false));
```

VIEWING PDFs

```
snapperCarr.attachToRecyclerView(pager);
```

(from [PDF/PdfRenderer/app/src/main/java/com/commonsware/android/pdfrenderer/MainActivity.java](#))

Eventually, we will tie in a `RecyclerView.Adapter` and `RecyclerView.ViewHolder` classes, named `PageAdapter` and `PageController`. However, there is nothing to render at the outset, as we do not have a PDF to use.

Getting the PDF

Later samples in this chapter happen to use PDF rendering technologies that can work with ordinary streams. In those cases, we can package some PDFs as assets, to provide sample behavior without the user having to rummage around and find a PDF.

Alas, that is not an option with `PdfRenderer`. So, we need to let the user find a PDF on external or removable storage.

To do that, we have an action bar item named “Open” that leads to an `open()` method on `MainActivity`:

```
Intent i=new Intent()
    .setType("application/pdf")
    .setAction(Intent.ACTION_OPEN_DOCUMENT)
    .addCategory(Intent.CATEGORY_OPENABLE);

startActivityForResult(i, REQUEST_OPEN);
}
```

(from [PDF/PdfRenderer/app/src/main/java/com/commonsware/android/pdfrenderer/MainActivity.java](#))

Here, we use [the Storage Access Framework](#), invoking an `ACTION_OPEN_DOCUMENT` Intent, requesting PDF files.

We get control again in `onActivityResult()`:

```
protected void onActivityResult(int requestCode, int resultCode,
                                Intent data) {
    if (resultCode==Activity.RESULT_OK) {
        pickedDocument=data.getData();
        show(pickedDocument);
    }
}
```

VIEWING PDFs

```
}
```

(from [PDF/PdfRenderer/app/src/main/java/com/commonsware/android/pdfrenderer/MainActivity.java](#))

If the user chose a PDF, we stuff its Uri into a pickedDocument field, plus call a private show() method:

```
try {
    adapter=new PageAdapter(getLayoutInflater(),
        getContentResolver().openFileDescriptor(uri, "r"));
    pager.setAdapter(adapter);
}
catch (java.io.IOException e) {
    Log.e("PdfRenderer", getString(R.string.toast_open), e);
    Toast.makeText(this, R.string.toast_open, Toast.LENGTH_LONG).show();
}
}
```

(from [PDF/PdfRenderer/app/src/main/java/com/commonsware/android/pdfrenderer/MainActivity.java](#))

show() creates a PageAdapter, giving it a LayoutInflater and a ParcelFileDescriptor on the Uri, obtained by calling openFileDescriptor() on a ContentResolver. We then attach PageAdapter to our pager-style RecyclerView.

To handle configuration changes, we hold onto pickedDocument in the saved instance state Bundle:

```
protected void onSaveInstanceState(Bundle outState) {
    super.onSaveInstanceState(outState);

    outState.putParcelable(STATE_PICKED, pickedDocument);
}
```

(from [PDF/PdfRenderer/app/src/main/java/com/commonsware/android/pdfrenderer/MainActivity.java](#))

...and restore it in onCreate():

```
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.main);

    pager=(RecyclerView)findViewById(R.id.pager);
    pager.setLayoutManager(new LinearLayoutManager(this,
        LinearLayoutManager.HORIZONTAL, false));
    snapperCarr.attachToRecyclerView(pager);
}
```

VIEWING PDFs

```
if (savedInstanceState!=null) {
    pickedDocument=savedInstanceState.getParcelable(STATE_PICKED);

    if (pickedDocument!=null) {
        show(pickedDocument);
    }
}
}
```

(from [PDF/PdfRenderer/app/src/main/java/com/commonsware/android/pdfrenderer/MainActivity.java](#))

In `onDestroy()`, we call a `close()` method on `PageAdapter` — we will see the role of `close()` shortly:

```
protected void onDestroy() {
    if (adapter!=null) {
        adapter.close();
    }

    super.onDestroy();
}
```

(from [PDF/PdfRenderer/app/src/main/java/com/commonsware/android/pdfrenderer/MainActivity.java](#))

Adding the PdfRenderer

`PageAdapter` is surprisingly short and mostly is focused on implementing the `RecyclerView.Adapter` API:

```
package com.commonsware.android.pdfrenderer;

import android.graphics.pdf.PdfRenderer;
import android.os.ParcelFileDescriptor;
import android.support.v7.widget.RecyclerView;
import android.view.LayoutInflater;
import android.view.ViewGroup;
import java.io.IOException;

class PageAdapter extends RecyclerView.Adapter<PageController> {
    private final LayoutInflater inflater;
    private final PdfRenderer renderer;

    PageAdapter(LayoutInflater inflater, ParcelFileDescriptor pfd)
        throws IOException {
```

VIEWING PDFs

```
    this.inflater=inflater;
    renderer=new PdfRenderer(pfd);
}

@Override
public PageController onCreateViewHolder(ViewGroup parent, int viewType) {
    return(new PageController(inflater.inflate(R.layout.page, parent, false)));
}

@Override
public void onBindViewHolder(PageController holder, int position) {
    PdfRenderer.Page page=renderer.openPage(position);

    holder.setPage(page);
    page.close();
}

@Override
public int getItemCount() {
    return(renderer.getPageCount());
}

void close() {
    renderer.close();
}
}
```

(from [PDF/PdfRenderer/app/src/main/java/com/commonsware/android/pdfrenderer/PageAdapter.java](#))

In the constructor, we create an instance of a PdfRenderer, passing in the ParcelFileDescriptor on our PDF file.

In onCreateViewHolder(), we create an instance of a PageController, passing it an inflated layout representing the page contents — we will examine this in greater detail shortly.

In onBindViewHolder(), we ask the PdfRenderer to give us a PdfRenderer.Page for the page identified by our position, via an openPage() method. We then pass that to the PageController via a setPage() method, before we close() the Page. It is the responsibility of PageController to ensure that it does everything that it needs to do with that page before returning from setPage().

getItemCount() returns the number of pages in the PDF, as determined by getPageCount().

VIEWING PDFs

Finally, `close()` calls `close()` on the `PdfRenderer`, to let it release any resources that it is holding onto, such as that `ParcelFileDescriptor`.

Showing the Pages

The real fun, of course, is in `PageController`, for rendering a page of the PDF into a `Bitmap` to be shown in a page of our pager-style `RecyclerView`.

To allow for pinch-to-zoom functionality, the `PdfRenderer` sample app uses [Dave Morrissey's `SubsamplingScaleImageView`](#):

```
<com.davemorrissey.labs.subscaleview.SubsamplingScaleImageView
    android:id="@+id/page"
    xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:layout_margin="16dp" />
```

(from [PDF/PdfRenderer/app/src/main/res/layout/page.xml](#))

This has a 16dp margin on all four sides, causing each page of the PDF to appear to be floating over the light gray background of the `RecyclerView` itself. Android's `PdfRenderer` does not put any frame around its rendered page, leaving that up to you.

`PageController` grabs the `SubsamplingScaleImageView` in the constructor, then uses `PdfRenderer.Page` and a `Bitmap` to populate it in `setPage()`:

```
package com.commonware.android.pdfrenderer;

import android.graphics.Bitmap;
import android.graphics.pdf.PdfRenderer;
import android.os.Environment;
import android.support.v7.widget.RecyclerView;
import android.view.View;
import android.widget.ImageView;
import com.davemorrissey.labs.subscaleview.ImageSource;
import com.davemorrissey.labs.subscaleview.SubsamplingScaleImageView;
import java.io.File;
import java.io.FileNotFoundException;
import java.io.FileOutputStream;

class PageController extends RecyclerView.ViewHolder {
    private final SubsamplingScaleImageView iv;
    private Bitmap bitmap;
```

VIEWING PDFs

```
PageController(View itemView) {
    super(itemView);

    iv=(SubsamplingScaleImageView)itemView.findViewById(R.id.page);
}

void setPage(PdfRenderer.Page page) {
    if (bitmap==null) {
        int height=2000;
        int width=height * page.getWidth() / page.getHeight();

        bitmap=Bitmap.createBitmap(width, height, Bitmap.Config.ARGB_8888);
    }

    bitmap.eraseColor(0xFFFFFFFF);
    page.render(bitmap, null, null, PdfRenderer.Page.RENDER_MODE_FOR_DISPLAY);
    iv.resetScaleAndCenter();
    iv.setImage(ImageSource.cachedBitmap(bitmap));
}
}
```

(from [PDF/PdfRenderer/app/src/main/java/com/commonsware/android/pdfrenderer/PageController.java](https://github.com/CommunityToolkit/AndroidPdfRenderer/blob/master/AndroidPdfRenderer/src/main/java/com/commonsware/android/pdfrenderer/PageController.java))

In `setPage()`, we lazy-create a `Bitmap`, set to 2000 pixels high and whatever width would be appropriate based on the aspect ratio of the page. This is a simple implementation, suitable for a PDF where all pages have the same aspect ratio. A more sophisticated sample would use some form of object pool for `Bitmap` objects based on aspect ratio.

Note that the `Bitmap` needs to be `ARGB_8888`, exacerbating its memory usage. Attempts to use `RGB_565` — thereby cutting memory usage in half per page — fail with an error from `PdfRenderer`.

Actually rendering the page to the `Bitmap` is performed by the `render()` method on the `Page`. It takes the `Bitmap`, an optional `Rect` indicating a subset of the page to be rendered, an optional `Matrix` to be applied to transform the rendering, and a “render mode” to indicate if this is for use on a screen or (somehow) on a printed page.

However, `render()` does not do anything to the `Bitmap` other than render the page’s contents. In particular, it does not clear the `Bitmap` ahead of time. Since we are reusing the `Bitmap` objects, by default, as those `Bitmap` objects get reused, they would accumulate page contents, which is not what we want. Also, `render()` does not assume any particular background color for pages, if such a color was not specified in the PDF. Instead, it just renders the “ink” on top of the `Bitmap`, with

VIEWING PDFs

everything else left alone. So, we use `eraseColor()` to reset the `Bitmap` to white before we call `render()`, so we clear out any previous page's content, and so we have a solid white background for our pages.

Not only are we reusing the `Bitmap`, but we are reusing the `SubsamplingScaleImageView`. If the user used pinch-to-zoom and panned around a previous page, the `SubsamplingScaleImageView` will retain those settings. So, we call `resetScaleAndCenter()` to switch back to the starting point, then call `setImage()` to hand the `SubsamplingScaleImageView` the page to render. `setImage()` takes an `ImageSource`, and in this case we need to use `cachedBitmap()`, to indicate both that the image is in the form of an existing `Bitmap` and that we are caching the `Bitmap` ourselves (so the `SubsamplingScaleImageView` should not attempt to `recycle()` the `Bitmap`).

The result is a PDF viewer, where we can pick a PDF from the “Open” action bar item, then swipe through the pages:

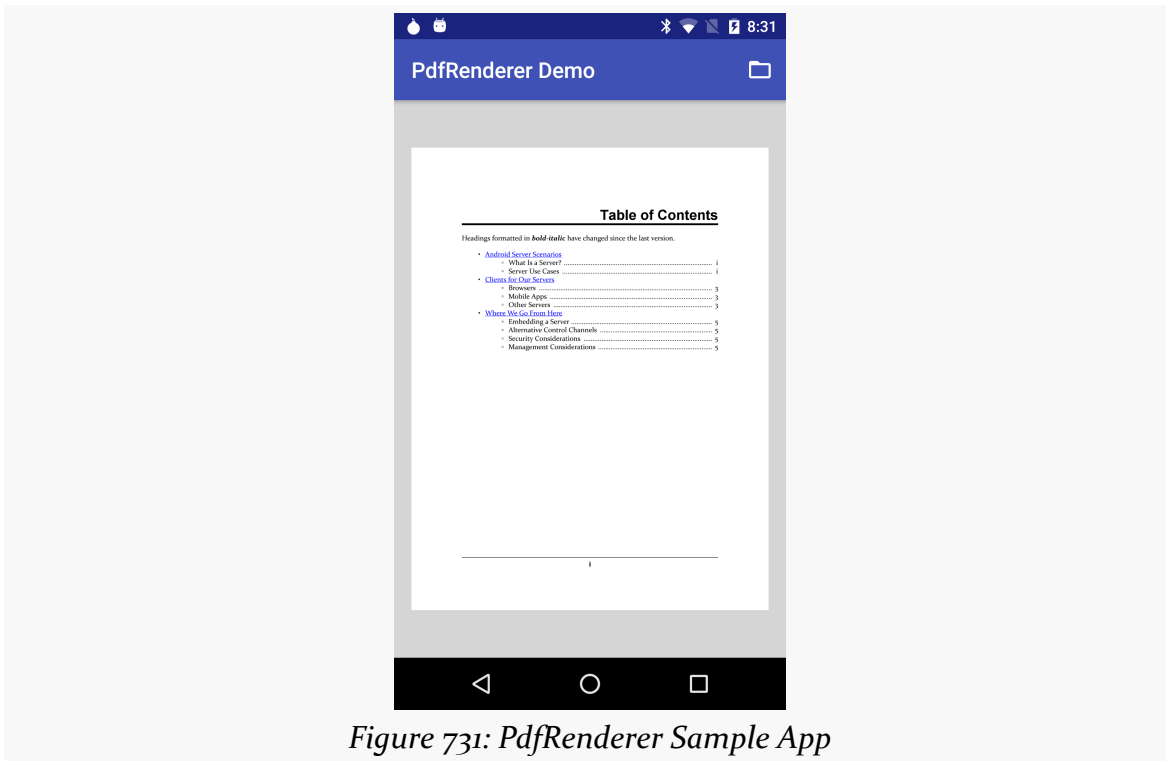

Figure 731: PdfRenderer Sample App

The Thunder Lizard Choice: PDF.js

PdfRenderer has many limitations, none bigger than the fact that it fails to render complex PDFs.

If you have used the Firefox Web browser on your desktop or notebook in the past few years, you may have noticed that its built-in PDF viewer is actually written in JavaScript, in the form of [PDF.js](#). This is designed to handle more complex PDF files, and so it is a more complete solution than is PdfRenderer.

However, PDF.js requires a fairly robust Web rendering engine to work. On Android, that means we are limited to Android 4.4+, when the original WebView was replaced by the “Android System WebView” app’s implementation, which shares more of its guts with Chromium.

The [PDF/PdfJS](#) sample project demonstrates the use of PDF.js.

PDF.js needs a WebView, so we put one in our layout file:

```
<?xml version="1.0" encoding="utf-8"?>
<WebView android:id="@+id/webview"
    xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent" />
```

(from [PDF/PdfJS/app/src/main/res/layout/activity_main.xml](#))

Not surprisingly, it needs JavaScript to be enabled for that WebView. However, we also need to give JavaScript the ability to read from arbitrary URLs when we load the JavaScript itself from a file URL, as our PDF might come from somewhere else (e.g., content scheme for a document opened via ACTION_OPEN_DOCUMENT):

```
wv=(WebView)findViewById(R.id.webview);
wv.getSettings().setJavaScriptEnabled(true);
wv.getSettings().setAllowUniversalAccessFromFileURLs(true);
```

(from [PDF/PdfJS/app/src/main/java/com/commonsware/android/pdfjs/MainActivity.java](#))

PDF.js itself is stored in assets/pdfjs/ in our main source set. This consists of the JavaScript library (build/ directory) and the stock Web-based viewer wrapped around that library (web/ directory). Combined, these two directories represent 4.6MB of material. While some of that could be stripped out or tweaked for mobile

VIEWING PDFs

use, this highlights one of the problems with the PDF.js solution: it is large. Those assets will compress somewhat — expect about 2MB added to your APK file.

This sample app now gives the “Open” action bar item a submenu, where the user can choose from two pre-packaged PDFs as assets (a set of presentation slides and the infamous 1040(A) tax form from the United States Internal Revenue Service) or to pick one from the filesystem:

```
<?xml version="1.0" encoding="utf-8"?>
<menu xmlns:android="http://schemas.android.com/apk/res/android">
  <item
    android:id="@+id/pdfs"
    android:icon="@drawable/ic_folder_open_white_24dp"
    android:showAsAction="always"
    android:title="@string/menu_pdf_files">
    <menu>
      <item android:id="@+id/preso" android:title="@string/menu_presentation"/>
      <item android:id="@+id/taxes" android:title="@string/menu_taxes" />
      <item android:id="@+id/open" android:title="@string/menu_open" />
    </menu>
  </item>
</menu>
```

(from [PDF/PdfJS/app/src/main/res/menu/pdf.xml](#))

In `onOptionsItemSelected()` of `MainActivity`, we route to `loadPdf()` methods for the two assets and the `open()` method for the “Pick” option:

```
@Override
public boolean onOptionsItemSelected(MenuItem item) {
    if (item.getItemId()==R.id.preso) {
        loadPdf("MultiWindowAndYourApp.pdf");
        return(true);
    }
    else if (item.getItemId()==R.id.taxes) {
        loadPdf("f1040a.pdf");
        return(true);
    }
    else if (item.getItemId()==R.id.open) {
        open();
    }
}

return(super.onOptionsItemSelected(item));
}
```

(from [PDF/PdfJS/app/src/main/java/com/commonsware/android/pdfjs/MainActivity.java](#))

VIEWING PDFs

`open()` still uses `ACTION_OPEN_DOCUMENT` to allow the user to pick a PDF file. `onActivityResult()` still saves the `Uri` in the `pickedDocument` field but then calls a `loadPdfUri()` method with the string representation of that `Uri`:

```
@Override
protected void onActivityResult(int requestCode, int resultCode,
                                Intent data) {
    if (resultCode==Activity.RESULT_OK) {
        pickedDocument=data.getData();
        loadPdfUri(pickedDocument.toString());
    }
}
```

(from [PDF/PdfJS/app/src/main/java/com/commonsware/android/pdfjs/MainActivity.java](#))

Similarly, the `loadPdf()` method used by `onOptionsItemSelected()` for the assets stores the chosen asset name in a `chosenAsset` field, then calls `loadPdfUri()` with the proper `file:///android_asset/` URL:

```
private void loadPdf(String name) {
    chosenAsset=name;
    loadPdfUri("file:///android_asset/"+name);
}
```

(from [PDF/PdfJS/app/src/main/java/com/commonsware/android/pdfjs/MainActivity.java](#))

`loadPdfUri()` then uses `loadUrl()` to load up the Web-based PDF viewer in assets, supplying the URL to the PDF in the file query parameter:

```
private void loadPdfUri(String uri) {
    try {
        ww.loadUrl("file:///android_asset/pdfjs/web/viewer.html?file="+
                  URLEncoder.encode(uri, "UTF-8"));
    }
    catch (UnsupportedEncodingException e) {
        e.printStackTrace();
    }
}
```

(from [PDF/PdfJS/app/src/main/java/com/commonsware/android/pdfjs/MainActivity.java](#))

This works “out of the box” for the assets, as both the Web viewer and the PDFs come from file URLs. To get the content scheme to work, you have to add `file://` to `HOSTED_VIEWER_ORIGINS` in `web/viewer.js`, to tell the Web viewer that `file://` is a valid origin for the viewer and that any reachable URL should be tried:

VIEWING PDFs

```
var HOSTED_VIEWER_ORIGINS = [
    'null',
    'http://mozilla.github.io',
    'https://mozilla.github.io',
    'file://'
];
```

(from [PDF/PdfJS/app/src/main/assets/pdfjs/web/viewer.js](#))

We also need to hold onto chosenAsset in our saved instance state:

```
@Override
protected void onSaveInstanceState(Bundle outState) {
    super.onSaveInstanceState(outState);

    outState.putString(STATE_ASSET, chosenAsset);
    outState.putParcelable(STATE_PICKED, pickedDocument);
}
```

(from [PDF/PdfJS/app/src/main/java/com/commonsware/android/pdfjs/MainActivity.java](#))

And we restore the PDF in onCreate():

```
@SuppressWarnings("SetJavaScriptEnabled")
@Override
protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.activity_main);

    ww=(WebView)findViewById(R.id.webview);
    ww.getSettings().setJavaScriptEnabled(true);
    ww.getSettings().setAllowUniversalAccessFromFileURLs(true);

    if (savedInstanceState!=null) {
        chosenAsset=savedInstanceState.getString(STATE_ASSET);

        if (chosenAsset==null) {
            pickedDocument=savedInstanceState.getParcelable(STATE_PICKED);

            if (pickedDocument!=null) {
                loadPdfUri(pickedDocument.toString());
            }
        }
        else {
            loadPdf(chosenAsset);
        }
    }
}
```

VIEWING PDFs

(from <PDF/PdfJS/app/src/main/java/com/commonsware/android/pdfjs/MainActivity.java>)

The result is PDF.js's stock PDF viewer, in our WebView, where the user can scroll vertically to browse all the pages in the PDF:

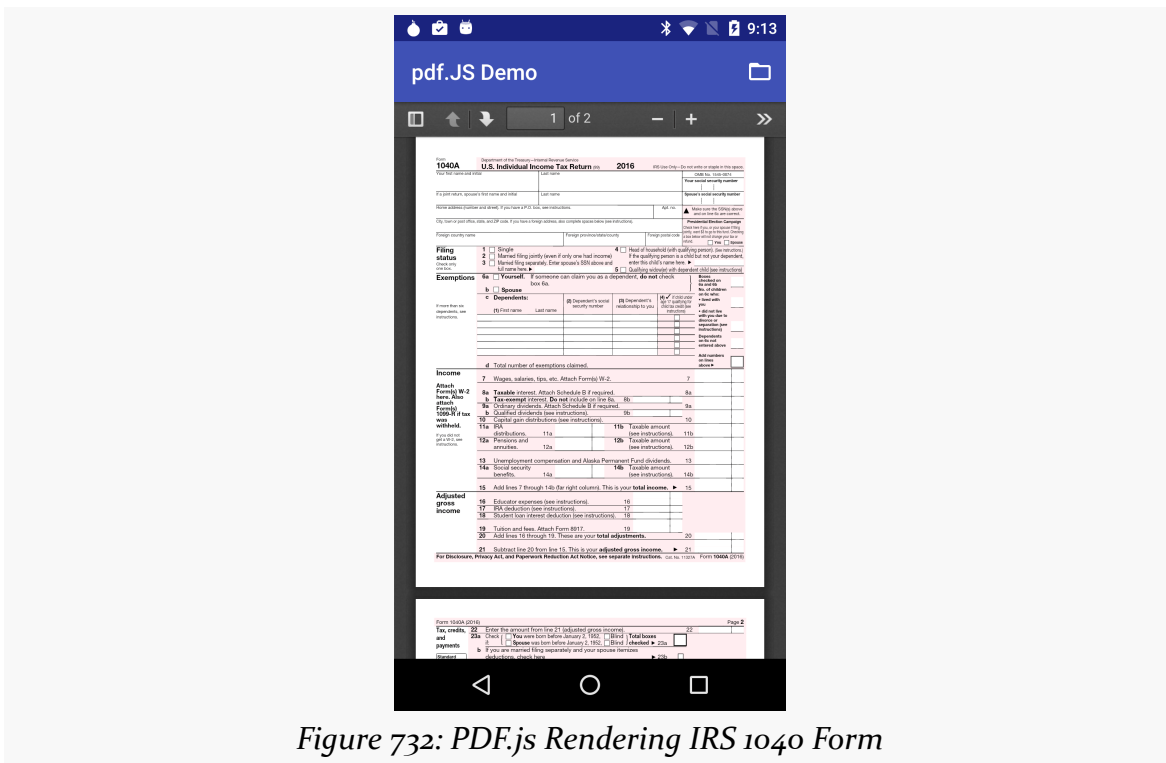

Figure 732: PDF.js Rendering IRS 1040 Form

The Native Approach: Pdfium

The major downside to both PdfRenderer and PDF.js as in-process PDF viewing solutions is the required API level. Both work with Android 5.0+, and PDF.js works with Android 4.4. However, you may have a `minSdkVersion` below 19. One approach would be to use an external PDF viewer for those older devices, but if that were an option, you may be better off using that for *all* Android versions, not just older ones.

Your remaining options involve using some C/C++ code for rendering PDFs.

One popular native code base for PDF rendering is [Pdfium](#), from Google, used in Chromium and Chrome. Roughly speaking, it fills the same role there as PDF.js does with Firefox.

VIEWING PDFs

Bartosz Schiller's [AndroidPdfViewer](#) library wraps Pdfium in a View that handles rendering and standard gestures (e.g., horizontal swipes to move between pages).

On the plus side, Pdfium works well on older Android versions. The author of this book tested it back to Android 4.1 (API Level 16) and had no problems, and the library itself claims to support back to API Level 11.

However, there is a cost: APK size. By default, AndroidPdfViewer gives you NDK binaries that support the major CPU architectures: 32- and 64-bit ARM and x86, plus MIPS. As a result, the native binaries take up 30MB of space in your APK. Dropping support for CPU architectures that are less important to you (e.g., ARM) can help, and you can drop the per-APK cost to ~5MB if you use [ABI splits](#) and ship separate APKs per supported CPU architecture (on distribution channels where that is an option).

The [PDF/Pdfium](#) sample project demonstrates the use of AndroidPdfViewer and Pdfium. It is very similar to the PDF.js sample.

However, we need to pull in the AndroidPdfViewer library:

```
apply plugin: 'com.android.application'

android {
    compileSdkVersion 25
    buildToolsVersion '26.0.2'

    defaultConfig {
        applicationId "com.commonware.android.pdfium"
        minSdkVersion 16
        targetSdkVersion 25
        versionCode 1
        versionName "1.0"
    }
}

dependencies {
    implementation 'com.github.barteksc:android-pdf-viewer:2.3.0'
}
```

(from [PDF/Pdfium/app/build.gradle](#))

Our layout now uses a PDFView widget, instead of a RecyclerView or WebView:

```
<?xml version="1.0" encoding="utf-8"?>
<com.github.barteksc.pdfviewer.PDFView android:id="@+id/viewer"
```

VIEWING PDFs

```
xmlns:android="http://schemas.android.com/apk/res/android"  
android:layout_width="match_parent"  
android:layout_height="match_parent" />
```

(from [PDF/Pdfium/app/src/main/res/layout/activity_main.xml](#))

We also need `open()` to support `ACTION_GET_CONTENT`, since `ACTION_OPEN_DOCUMENT` is not supported prior to API Level 19:

```
private void open() {  
    if (Build.VERSION.SDK_INT < Build.VERSION_CODES.KITKAT) {  
        Intent i=  
            new Intent()  
                .setType("application/pdf")  
                .setAction(Intent.ACTION_GET_CONTENT)  
                .addCategory(Intent.CATEGORY_OPENABLE);  
  
        startActivityForResult(i, REQUEST_GET);  
    }  
    else {  
        Intent i=  
            new Intent()  
                .setType("application/pdf")  
                .setAction(Intent.ACTION_OPEN_DOCUMENT)  
                .addCategory(Intent.CATEGORY_OPENABLE);  
  
        startActivityForResult(i, REQUEST_OPEN);  
    }  
}
```

(from [PDF/Pdfium/app/src/main/java/com/commonsware/android/pdfium/MainActivity.java](#))

Then, instead of `loadPdf()` or `loadPdfUri()` methods, we use a `configureViewer()` method. That method takes a `PDFView.Configurator` object, which we get by calling `fromUri()` on the `PDFView` itself, such as from our `onActivityResult()` method:

```
@Override  
protected void onActivityResult(int requestCode, int resultCode,  
                                Intent data) {  
    if (resultCode == Activity.RESULT_OK) {  
        pickedDocument = data.getData();  
        chosenAsset = null;  
        configureViewer(viewer.fromUri(pickedDocument));  
    }  
}
```

(from [PDF/Pdfium/app/src/main/java/com/commonsware/android/pdfium/MainActivity.java](#))

VIEWING PDFs

configureViewer() then teaches the PDFView how we want to render this document:

```
private void configureViewer(PDFView.Configurator configurator) {
    configurator
        .enableSwipe(true)
        .swipeHorizontal(true)
        .enableDoubletap(true)
        .scrollHandle(new DefaultScrollHandle(this))
        .load();
}
```

(from [PDF/Pdfium/app/src/main/java/com/commonsware/android/pdfium/MainActivity.java](#))

Here, we:

- Enable horizontal swiping to move between pages
- Enable a scroll handle as an alternative for moving between pages
- Enable a double-tap gesture for toggling between a few different zoom levels

The result is similar to the PDF.js result, since Pdfium can handle similarly-complex PDF files:

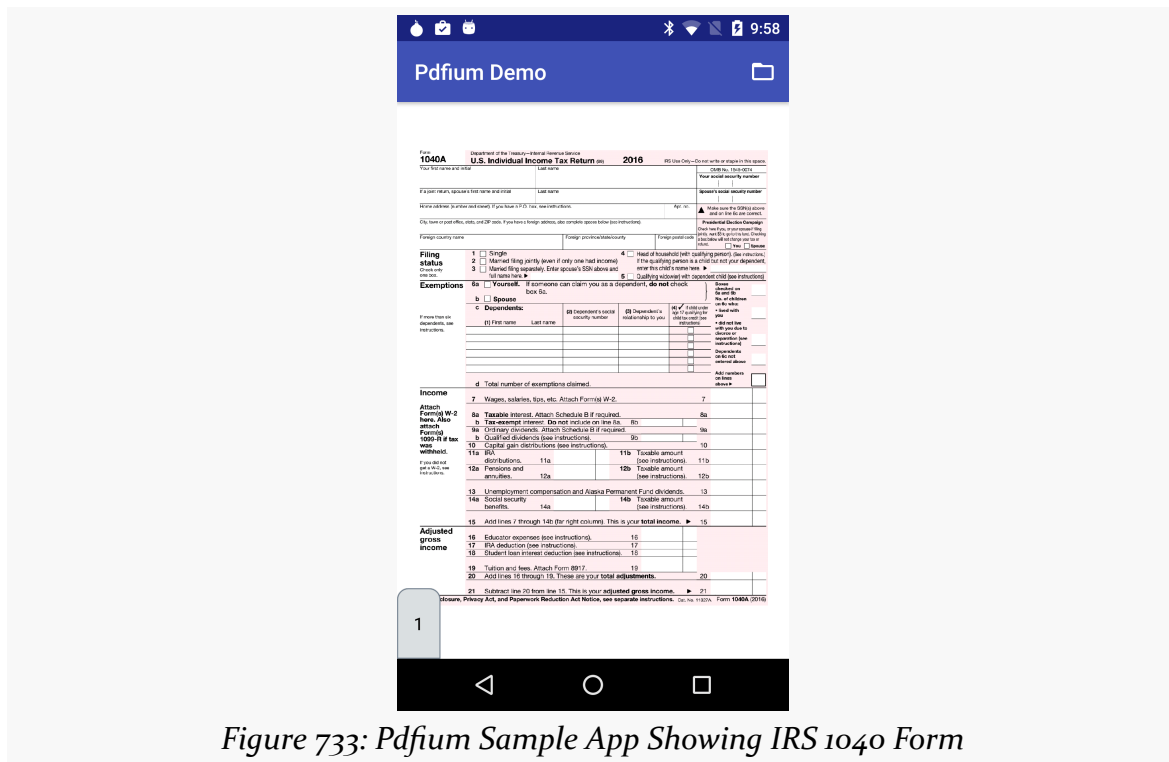

Figure 733: Pdfium Sample App Showing IRS 1040 Form

What To Choose?

So, what do you choose?

Option	Location Flexibility	Offline-Capable	PDF Complexity	Stability	Privacy	APK Size	minSdkVersion
External Viewer	good	good	varies	varies	poor	great	1
Google Docs	poor	poor	good	poor	poor	great	1
PdfRenderer	good	good	poor	good	great	great	21
PDF.js	good	good	good	good	great	meh	19
Pdfium	good	good	good	good	great	poor	11

For most apps, for most situations, using an external PDF viewer is the simplest solution. Use one that already exists, and be in position to suggest one to the user if there is no PDF viewer app available.

If you are certain that you need to keep the PDFs within your own app, and your `minSdkVersion` is 19 or higher, PDF.js offers the best rendering with a modest increase in app size. If, however, you need to support older devices than that, Pdfium will be a solid choice... but be prepared for some distribution complexity as you deal with the ABI splits to keep your APK size down to a reasonable level.

Trail: Home Screen Effects

Home Screen App Widgets

App widgets are live elements that the user can add to her home screen. Android ships with a variety of app widgets, such as a music player, and device manufacturers frequently add more. However, developers can add their own — in this chapter, we will see how this is done.

For the purposes of this book, “app widgets” will refer to these items that go on the home screen. Other uses of the term “widget” will be reserved for the UI widgets, subclasses of `View`, usually found in the `android.widget` Java package.

Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly the chapters on:

- [basic widgets](#)
- [broadcast Intents](#)
- [services](#)

App Widgets and Security

Creating app widgets looks little like creating an activity. That is because the home screen is showing your app widget, whereas your own app shows your own activities. Having a third-party app (a home screen) show a UI from your app has some security ramifications.

Android’s security model is based heavily on Linux user, file, and process security. Each application is (normally) associated with a unique user ID. All of its files are

owned by that user, and its process(es) run as that user. This prevents one application from modifying the files of another or otherwise injecting their own code into another running process. It would be dangerous for the home screen to run arbitrary code itself or somehow allow its UI to be directly manipulated by another process.

The app widget architecture, therefore, is set up to keep the home screen application independent from any code that puts app widgets on that home screen, so bugs in one cannot harm the other.

The Big Picture for a Small App Widget

The way Android pulls off this bit of security is through the use of RemoteViews.

The application component that supplies the UI for an app widget is not an Activity, but rather a BroadcastReceiver (often in tandem with a Service). The BroadcastReceiver, in turn, does not inflate a normal View hierarchy, like an Activity would, but instead inflates a layout into a RemoteViews object.

RemoteViews encapsulates a limited edition of normal widgets, in such a fashion that the RemoteViews can be “easily” transported across process boundaries. You configure the RemoteViews via your BroadcastReceiver and make those RemoteViews available to Android. Android in turn delivers the RemoteViews to the app widget host (usually the home screen), which renders them to the screen itself.

This architectural choice has many impacts:

- You do not have access to the full range of widgets and containers. You can use `FrameLayout`, `LinearLayout`, and `RelativeLayout` for containers, and `AnalogClock`, `Button`, `Chronometer`, `ImageButton`, `ImageView`, `ProgressBar`, and `TextView` for widgets. And, on API Level 11 and higher, you can use some AdapterView-based widgets, like `ListView`, as we will examine [in the next chapter](#). And, as of API Level 16 (Android 4.1), you can use `GridLayout`... but not its backport on earlier devices.
- The only user input you can get is clicks of the `Button` and `ImageButton` widgets. In particular, there is no `EditText` for text input.
- Because the app widgets are rendered in another process, you cannot simply register an `OnClickListener` to get button clicks; rather, you tell RemoteViews a `PendingIntent` to invoke when a given button is clicked.

- You do not hold onto the RemoteViews and reuse them yourself. Rather, you create and send out a brand-new RemoteViews whenever you want to change the contents of the app widget. This, coupled with having to transport the RemoteViews across process boundaries, means that updating the app widget is expensive in terms of CPU time, memory, and battery life, when compared to equivalent UI updates of one of your own activities.
- Because the component handling the updates is a BroadcastReceiver, you have to be quick (lest you take too long and Android consider you to have timed out), you cannot use background threads, and your component itself is lost once the request has been completed. Hence, if your update might take a while, you will probably want to have the BroadcastReceiver start a Service and have the Service do the long-running task and eventual app widget update.

Crafting App Widgets

This will become somewhat easier to understand in the context of some sample code. In the [AppWidget/PairOfDice](#) project, you will find an app widget that displays a roll of a pair of dice. Clicking on the app widget re-rolls, in case you want a better result.

The Manifest

First, we need to register our BroadcastReceiver implementation in our AndroidManifest.xml file, along with a few extra features:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
    package="com.commonware.android.appwidget.dice"
    android:versionCode="1"
    android:versionName="1.0">

    <uses-sdk
        android:minSdkVersion="7"
        android:targetSdkVersion="11"/>

    <supports-screens
        android:largeScreens="true"
        android:normalScreens="true"
        android:smallScreens="false"/>

    <uses-feature
```

HOME SCREEN APP WIDGETS

```
    android:name="android.software.app_widgets"
    android:required="true"/>

<application
    android:allowBackup="false"
    android:icon="@drawable/ic_launcher"
    android:label="@string/app_name">
    <receiver
        android:name=".AppWidget"
        android:icon="@drawable/cw"
        android:label="@string/app_name">
        <intent-filter>
            <action android:name="android.appwidget.action.APPWIDGET_UPDATE"/>
        </intent-filter>

        <meta-data
            android:name="android.appwidget.provider"
            android:resource="@xml/widget_provider"/>
    </receiver>

    <activity
        android:name="PairOfDiceActivity"
        android:theme="@android:style/Theme.Translucent.NoTitleBar">
        <intent-filter>
            <action android:name="android.intent.action.MAIN"/>

            <category android:name="android.intent.category.LAUNCHER"/>
        </intent-filter>
    </activity>
</application>

</manifest>
```

(from [AppWidget/PairOfDice/app/src/main/AndroidManifest.xml](#))

Here, along with a do-nothing activity, we have a `<receiver>`. Of note:

1. Our `<receiver>` has `android:label` and `android:icon` attributes, which are not normally needed on `BroadcastReceiver` declarations. However, in this case, those are used for the entry that goes in the roster of available widgets to add to the home screen. Hence, you will probably want to supply values for both of those, and use appropriate resources in case you want translations for other languages.
2. Our `<receiver>` has an `<intent-filter>` for the `android.appwidget.action.APPWIDGET_UPDATE` action. This means we will get control whenever Android wants us to update the content of our app

widget. There may be other actions we want to monitor — more on this in a [later section](#).

3. Our `<receiver>` also has a `<meta-data>` element, indicating that its `android.appwidget.provider` details can be found in the `res/xml/widget_provider.xml` file. This metadata is described in greater detail shortly.

The uses-feature Element

If the central point of your application is to provide an app widget, you should strongly consider adding a `<uses-feature>` element to advertise this fact to markets like the Play Store:

```
<uses-feature android:name="android.software.app_widgets" android:required="true" />
```

In principle, having this element means that markets should block the installation of your app on devices where there is no app-widget-capable home screen or other known places for supporting app widgets.

If, however, your app has an app widget, but it is an adjunct to other forms of UI (typically a launcher activity), then you may wish to leave off this `<uses-feature>` element, or set it to `android:required="false"`.

The Metadata

Next, we need to define the app widget provider metadata. This has to reside at the location indicated in the manifest — in this case, in `res/xml/widget_provider.xml`:

```
<appwidget-provider xmlns:android="http://schemas.android.com/apk/res/android"
    android:minWidth="144dip"
    android:minHeight="72dip"
    android:updatePeriodMillis="900000"
    android:initialLayout="@layout/widget"
/>
```

(from [AppWidget/PairOfDice/app/src/main/res/xml/widget_provider.xml](#))

Here, we provide a few pieces of information:

1. The minimum width and height of the app widget (`android:minWidth` and `android:minHeight`). These are approximate — the app widget host (e.g., home screen) will tend to convert these values into “cells” based upon the

HOME SCREEN APP WIDGETS

overall layout of the UI where the app widgets will reside. However, they should be no smaller than the minimums cited here. Also, ideally, you use dip instead of px for the dimensions, so the number of cells will remain constant regardless of screen density.

2. The frequency in which Android should request an update of the widget's contents (`android:updatePeriodMillis`). This is expressed in terms of milliseconds, so a value of 3600000 is a 60-minute update cycle. Note that the minimum value for this attribute is 30 minutes — values less than that will be “rounded up” to 30 minutes. Hence our 15-minute (900000 millisecond) request will actually result in an update every 30 minutes.
3. The initial layout to use for the app widget, for the time between when the user requests the app widget and when `onUpdate()` of our `AppWidgetProvider` gets control.

Note that the calculations for determining the number of cells for an app widget varies. The dip dimension value for an N-cell dimension was $(74 * N) - 2$ (e.g., a 2x3 cell app widget would request a width of 146dip and a height of 220dip). The value as of API Level 14 (a.k.a., Ice Cream Sandwich) is now $(70 * N) - 30$ (e.g., a 2x3 cell app widget would request a width of 110dip and a height of 180dip). To have your app widgets maintain a consistent number of cells, you will need two versions of your app widget metadata XML, one in `res/xml-v14/` (with the API Level 14 calculation) and one in `res/xml/` (for prior versions of Android).

The Layout

Eventually, you are going to need a layout that describes what the app widget looks like. You need to stick to the widget and container classes noted above; otherwise, this layout works like any other layout in your project.

For example, here is the layout for the `PairOfDice` app widget:

```
<?xml version="1.0" encoding="utf-8"?>
<RelativeLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/background"
    android:orientation="horizontal"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:background="@drawable/widget_frame"
    >
    <ImageView android:id="@+id/left_die"
        android:layout_centerVertical="true"
        android:layout_alignParentLeft="true"
```

HOME SCREEN APP WIDGETS

```
        android:src="@drawable/die_5"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:layout_marginLeft="7dip"
    />
    <ImageView android:id="@+id/right_die"
        android:layout_centerVertical="true"
        android:layout_alignParentRight="true"
        android:src="@drawable/die_2"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:layout_marginRight="7dip"
    />
</RelativeLayout>
```

(from [AppWidget/PairOfDice/app/src/main/res/layout/widget.xml](#))

All we have is a pair of `ImageView` widgets (one for each die), inside of a `RelativeLayout`. The `RelativeLayout` has a background, specified as a [nine-patch PNG file](#). This allows the `RelativeLayout` to have guaranteed contrast with whatever wallpaper is behind it, so the user can tell the actual app widget bounds.

The BroadcastReceiver

Next, we need a `BroadcastReceiver` that can get control when Android wants us to update our `RemoteViews` for our app widget. To simplify this, Android supplies an `AppWidgetProvider` class we can extend, instead of the normal `BroadcastReceiver`. This simply looks at the received `Intent` and calls out to an appropriate lifecycle method based on the requested action.

The one method that frequently needs to be implemented on the provider is `onUpdate()`. Other lifecycle methods may be of interest and are discussed [later](#) in this chapter.

For example, here is the implementation of the `AppWidgetProvider` for `PairOfDice`:

```
package com.commonware.android.appwidget.dice;

import android.app.PendingIntent;
import android.appwidget.AppWidgetManager;
import android.appwidget.AppWidgetProvider;
import android.content.ComponentName;
import android.content.Context;
import android.content.Intent;
import android.widget.RemoteViews;

public class AppWidget extends AppWidgetProvider {
```

HOME SCREEN APP WIDGETS

```
private static final int[] IMAGES={R.drawable.die_1,R.drawable.die_2,
                                   R.drawable.die_3,R.drawable.die_4,
                                   R.drawable.die_5,R.drawable.die_6};

@Override
public void onUpdate(Context ctxt, AppWidgetManager mgr,
                    int[] appWidgetIds) {
    ComponentName me=new ComponentName(ctxt, AppWidget.class);

    mgr.updateAppWidget(me, buildUpdate(ctxt, appWidgetIds));
}

private RemoteViews buildUpdate(Context ctxt, int[] appWidgetIds) {
    RemoteViews updateViews=new RemoteViews(ctxt.getPackageName(),
                                             R.layout.widget);

    Intent i=new Intent(ctxt, AppWidget.class);

    i.setAction(AppWidgetManager.ACTION_APPWIDGET_UPDATE);
    i.putExtra(AppWidgetManager.EXTRA_APPWIDGET_IDS, appWidgetIds);

    PendingIntent pi=PendingIntent.getBroadcast(ctxt, 0, i,
                                                PendingIntent.FLAG_UPDATE_CURRENT);

    updateViews.setImageViewResource(R.id.left_die,
                                     IMAGES[(int)(Math.random()*6)]);
    updateViews.setOnClickPendingIntent(R.id.left_die, pi);
    updateViews.setImageViewResource(R.id.right_die,
                                     IMAGES[(int)(Math.random()*6)]);
    updateViews.setOnClickPendingIntent(R.id.right_die, pi);
    updateViews.setOnClickPendingIntent(R.id.background, pi);

    return(updateViews);
}
}
```

(from [AppWidget/PairOfDice/app/src/main/java/com/commonsware/android/appwidget/dice/AppWidget.java](#))

To update the RemoteViews for our app widget, we need to build those RemoteViews (delegated to a buildUpdate() helper method) and tell an AppWidgetManager to update the widget via updateAppWidget(). In this case, we use a version of updateAppWidget() that takes a ComponentName as the identifier of the widget to be updated. Note that this means that we will update all instances of this app widget presently in use — the concept of multiple app widget instances is covered in greater detail [later in this chapter](#).

Working with RemoteViews is a bit like trying to tie your shoes while wearing mittens — it may be possible, but it is a bit clumsy. In this case, rather than using methods like findViewById() and then calling methods on individual widgets, we need to call methods on RemoteViews itself, providing the identifier of the widget we wish to modify. This is so our requests for changes can be serialized for transport to the home screen process. It does, however, mean that our view-updating code looks

HOME SCREEN APP WIDGETS

a fair bit different than it would if this were the main View of an activity or row of a ListView.

To create the RemoteViews, we use a constructor that takes our package name and the identifier of our layout. This gives us a RemoteViews that contains all of the widgets we declared in that layout, just as if we inflated the layout using a LayoutInflater. The difference, of course, is that we have a RemoteViews object, not a View, as the result.

We then use methods like:

1. `setImageViewResource()` to set the image for each of our ImageView widgets, in this case a randomly chosen die face (using graphics created from a set of SVG files from the [OpenClipArt site](#))
2. `setOnClickPendingIntent()` to provide a PendingIntent that should get fired off when a die, or the overall app widget background, is clicked

We then supply that RemoteViews to the AppWidgetManager, which pushes the RemoteViews structure to the home screen, which renders our new app widget UI.

The Result

If you compile and install all of this, you will have a new app widget entry available. How you add app widgets to the home screen varies based upon Android version and the home screen implementation, and there are too many possibilities to try to list here.

No matter how you add the Pair of Dice, the app widget will appear on the home screen:

Figure 734: Pair of Dice, In Action

Another and Another

As indicated above, you can have multiple instances of the same app widget outstanding at any one time. For example, one might have multiple picture frames, or multiple “show-me-the-latest-RSS-entry” app widgets, one per feed. You will distinguish between these in your code via the identifier supplied in the relevant `AppWidgetProvider` callbacks (e.g., `onUpdate()`).

If you want to support separate app widget instances, you will need to store your state on a per-app-widget-identifier basis. You will also need to use an appropriate version of `updateAppWidget()` on `AppWidgetManager` when you update the app widgets, one that takes app widget identifiers as the first parameter, so you update the proper app widget instances.

Conversely, there is nothing requiring you to support multiple instances as independent entities. For example, if you add more than one `PairOfDice` app widget to your home screen, nothing blows up – they just show the same roll. That is because `PairOfDice` uses a version of `updateAppWidget()` that does not take any app widget IDs, and therefore updates all app widgets simultaneously.

App Widgets: Their Life and Times

There are three other lifecycle methods that `AppWidgetProvider` offers that you may be interested in:

1. `onEnabled()` will be called when the first widget instance is created for this particular widget provider, so if there is anything you need to do once for all supported widgets, you can implement that logic here
2. `onDeleted()` will be called when a widget instance is removed from the home screen, in case there is any data you need to clean up specific to that instance
3. `onDisabled()` will be called when the last widget instance for this provider is removed from the home screen, so you can clean up anything related to all such widgets

You will need to add appropriate action strings to your `<intent-filter>` for each of these events, such as `ACTION_APPWIDGET_ENABLED` to be notified about enabled events via `onEnabled()`.

Controlling Your (App Widget's) Destiny

As `PairOfDice` illustrates, you are not limited to updating your app widget only based on the timetable specified in your metadata. That timetable is useful if you can get by with a fixed schedule. However, there are cases in which that will not work very well:

1. If you want the user to be able to configure the polling period (the metadata is baked into your APK and therefore cannot be modified at runtime)
2. If you want the app widget to be updated based on external factors, such as a change in location

The recipe shown in `PairOfDice` will let you use `AlarmManager` (described in [another chapter](#)) or proximity alerts or whatever to trigger updates. All you need to do is:

1. Arrange for something to broadcast an `Intent` that will be picked up by the `BroadcastReceiver` you are using for your app widget provider
2. Have the provider process that `Intent` directly or pass it along to a `Service` (such as an `IntentService`)

Also, note that the `updatePeriodMillis` setting not only tells the app widget to update every so often, it will even *wake up the phone* if it is asleep so the widget can perform its update. On the plus side, this means you can easily keep your widgets up to date regardless of the state of the device. On the minus side, this will tend to drain the battery, particularly if the period is too fast. If you want to avoid this wakeup behavior, set `updatePeriodMillis` to 0 and use `AlarmManager` to control the timing and behavior of your widget updates.

Note that if there are multiple instances of your app widget on the user's home screen, they will all update approximately simultaneously if you are using `updatePeriodMillis`. If you elect to set up your own update schedule, you can control which app widgets get updated when, if you choose.

One Size May Not Fit All

It may be that you want to offer multiple app widget sizes to your users. Some might only want a small app widget. Some might really like what you have to offer and want to give you more home screen space to work in.

Android 1.x/2.x

The good news: this is easy to do.

The bad news: it requires you, in effect, to have one app widget per size.

The size of an app widget is determined by the app widget metadata XML file. That XML file is tied to a `<receiver>` element in the manifest representing one app widget. Hence, to have multiple sizes, you need multiple metadata files and multiple `<receiver>` elements.

This also means your app widgets will show up multiple times in the app widget selection list, when the user goes to add an app widget to their home screen. Hence, supporting many sizes will become annoying to the user, if they perceive you are “spamming” the app widget list. Try to keep the number of app widget sizes to a reasonable number (say, one or two sizes).

Android 3.0+

As of API Level 11, it is possible to have a resizable app widget. To do this, you can have an `android:resizeMode` attribute in your widget metadata, with a value of

HOME SCREEN APP WIDGETS

horizontal, vertical, or both (e.g., horizontal|vertical). When the user long-taps on an existing widget, they should see handles to allow the widget to be resized:

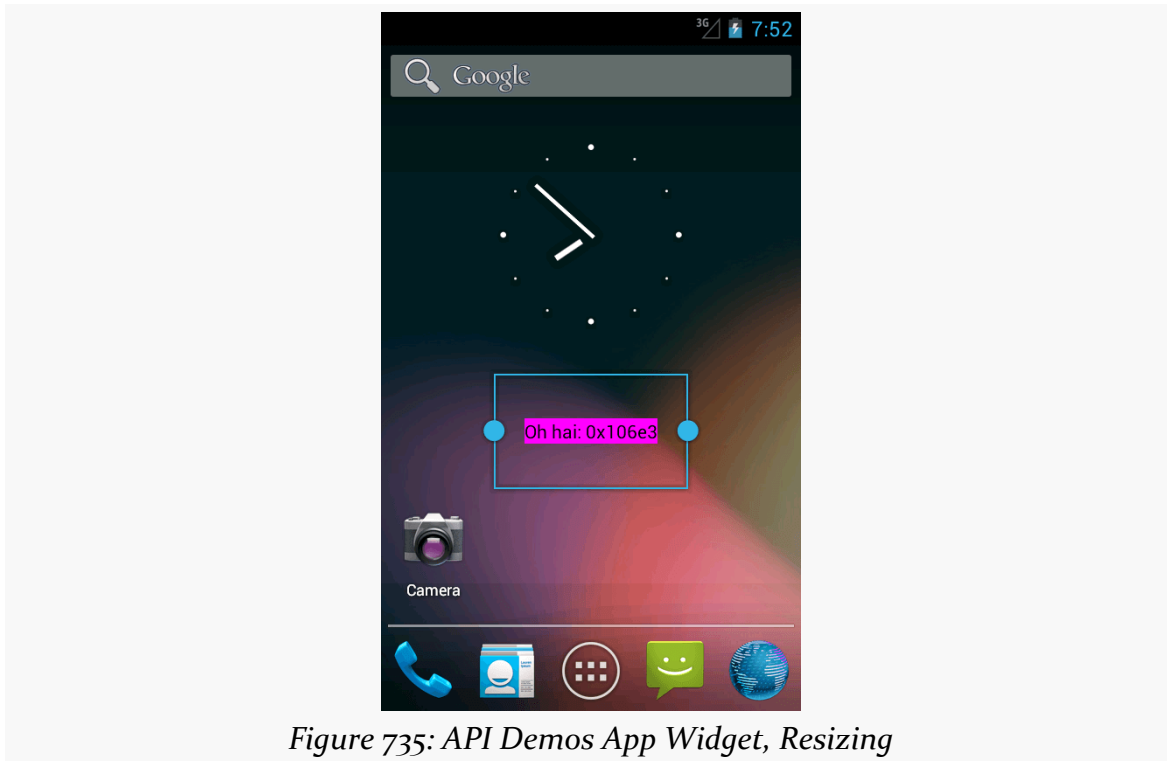

Figure 735: API Demos App Widget, Resizing

You can also have `android:minResizeWidth` and `android:minResizeHeight` attributes, measured in dp, that indicate the approximate smallest size that your app widget can support. These values will be interpreted in terms of “cells”, as with the `android:minWidth` and `android:minHeight` attributes, and so the dp values you supply will not be used precisely.

However, for Android 3.x and 4.0 (API Level 11-15), your code would not be informed about being resized. You had to simply ensure that your layout would intelligently use any extra space automatically. Hence, resizing tended to be used primarily with adapter-driven app widgets, as will be discussed [in the next chapter](#).

Starting with API Level 16, though, you can find out when the user resizes your app widget, so you can perhaps use a different layout for a different size, or otherwise adapt to the available space. Finding out about resize events takes a bit more work, as is illustrated in the [AppWidget/Resize](#) sample project.

HOME SCREEN APP WIDGETS

This app widget project is similar to `PairOfDice`, described earlier in this chapter. However, our layout skips the dice, replacing them with a `TextView` widget in the `RelativeLayout`:

```
<?xml version="1.0" encoding="utf-8"?>
<RelativeLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/background"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:background="@drawable/widget_frame"
    android:orientation="horizontal">

    <TextView
        android:id="@+id/size"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:layout_centerInParent="true"
        android:textAppearance="?android:attr/textAppearanceMedium">

    </TextView>

</RelativeLayout>
```

(from [AppWidget/Resize/app/src/main/res/layout/widget.xml](#))

Our `widget_provider.xml` resource stipulates our desired `android:resizeMode` and minimum resize dimensions:

```
<appwidget-provider xmlns:android="http://schemas.android.com/apk/res/android"
    android:minWidth="180dip"
    android:minHeight="110dip"
    android:minResizeWidth="110dip"
    android:minResizeHeight="40dip"
    android:initialLayout="@layout/widget"
    android:resizeMode="horizontal|vertical"
/>
```

(from [AppWidget/Resize/app/src/main/res/xml/widget_provider.xml](#))

Finding out about app widget resizing is a different event than finding out about app widget updates. Hence, we need to add a new `<action>` element to the `<intent-filter>` of our `<receiver>` in the manifest, indicating that we want `APPWIDGET_OPTIONS_CHANGED` as well as `ACTION_UPDATE`:

```
<application
    android:allowBackup="false"
```

HOME SCREEN APP WIDGETS

```
android:icon="@drawable/ic_launcher"
android:label="@string/app_name">
<receiver
    android:name="AppWidget"
    android:icon="@drawable/ic_launcher"
    android:label="@string/app_name">
    <intent-filter>
        <action android:name="android.appwidget.action.APPWIDGET_UPDATE" />
        <action android:name="android.appwidget.action.APPWIDGET_OPTIONS_CHANGED" />
    </intent-filter>
```

(from [AppWidget/Resize/app/src/main/AndroidManifest.xml](#))

Then, our app widget implementation can override an `onAppWidgetOptionsChanged()` method:

```
@Override
public void onAppWidgetOptionsChanged(Context ctxt,
    AppWidgetManager mgr,
    int appWidgetId,
    Bundle newOptions) {

    RemoteViews updateViews=
        new RemoteViews(ctxt.getPackageName(), R.layout.widget);
    String msg=
        String.format(Locale.getDefault(),
            "[%d-%d] x [%d-%d]",
            newOptions.getInt(AppWidgetManager.OPTION_APPWIDGET_MIN_WIDTH),
            newOptions.getInt(AppWidgetManager.OPTION_APPWIDGET_MAX_WIDTH),
            newOptions.getInt(AppWidgetManager.OPTION_APPWIDGET_MIN_HEIGHT),
            newOptions.getInt(AppWidgetManager.OPTION_APPWIDGET_MAX_HEIGHT));

    updateViews.setTextViewText(R.id.size, msg);

    mgr.updateAppWidget(appWidgetId, updateViews);
}
```

(from [AppWidget/Resize/app/src/main/java/com/commonsware/android/appwidget/resize/AppWidget.java](#))

You will notice that we skip `onUpdate()`. We will be called with `onAppWidgetOptionsChanged()` when the app widget is added and resized. Hence, in the case of this app widget, we can define what the app widget looks like from `onAppWidgetOptionsChanged()`, avoiding `onUpdate()`. That being said, more typical app widgets will wind up implementing both methods, especially if they are supporting lower API levels than 16, where `onAppWidgetOptionsChanged()` will not be called.

Also remember that your process may well be terminated in between calls to app widget lifecycle methods like `onUpdate()` and `onAppWidgetOptionsChanged()`.

HOME SCREEN APP WIDGETS

Hence, if there is data from one method that you want in the other, be sure to persist that data somewhere.

In the `AppWidget` implementation of `onAppWidgetOptionsChanged()`, we can find out about our new app widget size by means of the `Bundle` supplied to our method. What we *cannot* find out is our exact size. Rather, we are provided minimum and maximum dimensions of our app widget via four values in the `Bundle`:

- `AppWidgetManager.OPTION_APPWIDGET_MIN_WIDTH`
- `AppWidgetManager.OPTION_APPWIDGET_MAX_WIDTH`
- `AppWidgetManager.OPTION_APPWIDGET_MIN_HEIGHT`
- `AppWidgetManager.OPTION_APPWIDGET_MAX_HEIGHT`

In our case, we grab these `int` values and pour them into a `String` template, using that to fill in the `TextView` of the app widget's contents.

When our app widget is initially launched, we show our initial size ranges:

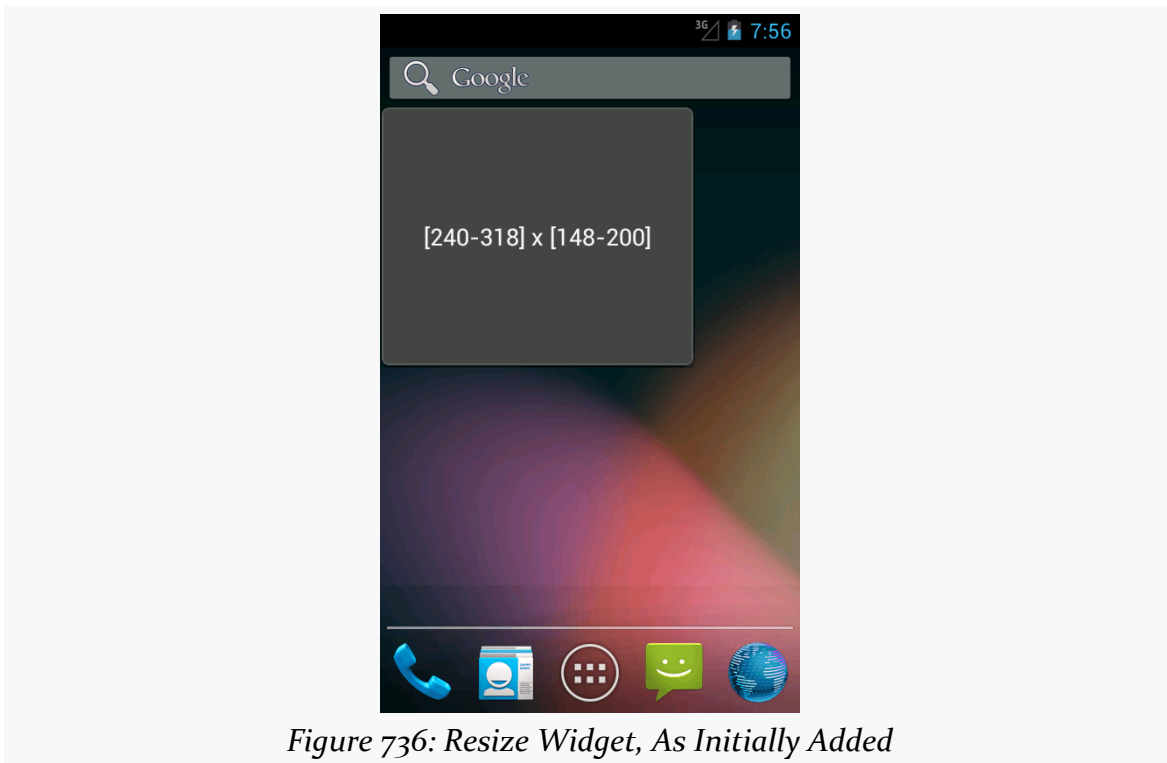

Figure 736: Resize Widget, As Initially Added

When the user resizes our app widget, we show the new size ranges:

HOME SCREEN APP WIDGETS

Figure 737: Resize Widget, During Resize Operation

However, not all home screen implementations will necessarily send the `APPWIDGET_OPTIONS_CHANGED` when an app widget is added to the home screen, only when the user resizes it later. For example, while the emulator's home screen for Android 4.1 broadcasts `APPWIDGET_OPTIONS_CHANGED`, it does not for 4.2 or 4.3. Hence, you may want to also examine the size information in `onUpdate()` as well, so that you react to the initial size as well as any future sizes. One way to do this is to simply iterate over the supplied app widget IDs and invoke your own `onAppWidgetOptionsChanged()` method:

```
// based on http://stackoverflow.com/a/18552461/115145

@Override
public void onUpdate(Context context,
                    AppWidgetManager appWidgetManager,
                    int[] appWidgetIds) {
    super.onUpdate(context, appWidgetManager, appWidgetIds);

    for (int appWidgetId : appWidgetIds) {
        Bundle options=appWidgetManager.getAppWidgetOptions(appWidgetId);

        onAppWidgetOptionsChanged(context, appWidgetManager, appWidgetId,
                                   options);
    }
}
```

```
}  
}
```

(from [AppWidget/Resize/app/src/main/java/com/commonsware/android/appwidget/resize/AppWidget.java](https://github.com/CommonsWare/android-appwidget-resize/blob/master/AppWidget.java))

Lockscreen Widgets

Android's lockscreen (a.k.a., the keyguard) had long been unmodifiable by developers. This led to a number of developers creating so-called "replacement lockscreens", which generally reduce device security, as they can be readily bypassed. However, on Android 4.2 through 4.4, developers can create app widgets that the user can deploy to the lockscreen, helping to eliminate the need for "replacement lockscreens".

However, note that this capability was dropped with Android 5.0. As a result, this particular app widget feature may not be something that you want to worry about. That being said, it *is* available for those versions, and you are welcome to support it for those versions.

Declaring that an app widget supports being on the lockscreen instead of (or in addition to) the home screen is very easy. All you must do is add an `android:widgetCategory` attribute to your app widget metadata resource. That attribute should have a value of either `keyguard` (for the lockscreen), `home_screen`, or both (e.g., `keyguard|home_screen`), depending upon where you want the app widget to be eligible. By default, if this attribute is missing, Android assumes a default value of `home_screen`.

Users cannot resize the lockscreen widgets at this time. However, you still will want to specify an `android:resizeMode` attribute in your app widget metadata, as whether or not you include `vertical` resizing will affect the height of your app widget. Lockscreen widgets without `vertical` will have a fixed small height on tablets, while lockscreen widgets with `vertical` will fill the available height. Lockscreen widgets on phones will always be small (to fit above the PIN/password entry area), and lockscreen widgets on all devices will stretch to fill available space horizontally.

You can also specify a different starting layout to use when your app is added to the lockscreen, as opposed to being added to the home screen. To do this, just add an `android:initialKeyguardLayout` attribute to your app widget metadata, pointing to the lockscreen-specific layout to use.

HOME SCREEN APP WIDGETS

To see this in action, take a look at the [AppWidget/TwoOrThreeDice](#) sample project. This is a revised clone of the `PairOfDice` sample, allowing the dice to be added to the lockscreen, and showing three dice on the lockscreen instead of the two on the home screen.

Our app widget metadata now contains the lockscreen-related attributes: `android:widgetCategory` and `android:initialKeyguardLayout`:

```
<appwidget-provider xmlns:android="http://schemas.android.com/apk/res/android"
    android:minWidth="144dip"
    android:minHeight="72dip"
    android:updatePeriodMillis="900000"
    android:initialLayout="@layout/widget"
    android:initialKeyguardLayout="@layout/lockscreen"
    android:widgetCategory="keyguard|home_screen"
/>
```

(from [AppWidget/TwoOrThreeDice/app/src/main/res/xml/widget_provider.xml](#))

Our lockscreen layout simply adds a third die, `middle_die`:

```
<?xml version="1.0" encoding="utf-8"?>
<RelativeLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/background"
    android:orientation="horizontal"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:background="@drawable/widget_frame"
    >
    <ImageView android:id="@+id/left_die"
        android:layout_centerVertical="true"
        android:layout_alignParentLeft="true"
        android:src="@drawable/die_3"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:layout_marginLeft="7dip"
    />
    <ImageView android:id="@+id/middle_die"
        android:layout_centerInParent="true"
        android:src="@drawable/die_2"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:layout_marginLeft="7dip"
        android:layout_marginRight="7dip"
    />
    <ImageView android:id="@+id/right_die"
```

HOME SCREEN APP WIDGETS

```
        android:layout_centerVertical="true"
        android:layout_alignParentRight="true"
        android:src="@drawable/die_2"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:layout_marginRight="7dip"
    />
</RelativeLayout>
```

(from [AppWidget/TwoOrThreeDice/app/src/main/res/layout/lockscreen.xml](#))

However, by specifying a different layout for the lockscreen widget, we have a problem. We need to know, in our Java code, what layout to use for the RemoteViews and how many dice need to be updated. And, ideally, we would handle this in a backwards-compatible fashion, so our app widget will have its original functionality on older Android devices. Plus, supporting the lockscreen makes it that much more likely that the user will have more than one instance of our app widget (e.g., one on the lockscreen and one on the homescreen), so we should do a better job than `PairOfDice` did about handling multiple app widget instances.

To deal with the latter point, our new `onUpdate()` method iterates over each of the app widget IDs supplied to it and calls a private `updateWidget()` method for each, so we can better support multiple instances:

```
@Override
public void onUpdate(Context ctxt, AppWidgetManager mgr,
                    int[] appWidgetIds) {
    for (int appWidgetId : appWidgetIds) {
        updateWidget(ctxt, mgr, appWidgetId);
    }
}
```

(from [AppWidget/TwoOrThreeDice/app/src/main/java/com/commonsware/android/appwidget/dice/AppWidget.java](#))

The `updateWidget()` method is a bit more complicated than the `PairOfDice` equivalent code:

```
@TargetApi(Build.VERSION_CODES.JELLY_BEAN_MR1)
private void updateWidget(Context ctxt, AppWidgetManager mgr,
                          int appWidgetId) {
    int layout=R.layout.widget;

    if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.JELLY_BEAN_MR1) {
        int category=
            mgr.getAppWidgetOptions(appWidgetId)
                .getInt(AppWidgetManager.OPTION_APPWIDGET_HOST_CATEGORY,
```

HOME SCREEN APP WIDGETS

```
        -1);

    layout=
        (category == AppWidgetProviderInfo.WIDGET_CATEGORY_KEYGUARD)
            ? R.layout.lockscreen : R.layout.widget;
    }

    RemoteViews updateViews=
        new RemoteViews(ctxt.getPackageName(), layout);
    Intent i=new Intent(ctxt, AppWidget.class);

    i.putExtra(AppWidgetManager.EXTRA_APPWIDGET_ID, appWidgetId);

    PendingIntent pi=
        PendingIntent.getBroadcast(ctxt, appWidgetId, i,
            PendingIntent.FLAG_UPDATE_CURRENT);

    updateViews.setImageResource(R.id.left_die,
        IMAGES[(int)(Math.random() * 6)]);
    updateViews.setOnClickPendingIntent(R.id.left_die, pi);
    updateViews.setImageResource(R.id.right_die,
        IMAGES[(int)(Math.random() * 6)]);
    updateViews.setOnClickPendingIntent(R.id.right_die, pi);
    updateViews.setOnClickPendingIntent(R.id.background, pi);

    if (layout == R.layout.lockscreen) {
        updateViews.setImageResource(R.id.middle_die,
            IMAGES[(int)(Math.random() * 6)]);
        updateViews.setOnClickPendingIntent(R.id.middle_die, pi);
    }

    mgr.updateAppWidget(appWidgetId, updateViews);
}
```

(from [AppWidget/TwoOrThreeDice/app/src/main/java/com/commonsware/android/appwidget/dice/AppWidget.java](#))

First, we need to choose which layout we are working with. We assume that we are to use the original `R.layout.widget` resource by default. But, if we are on API Level 17 or higher, we can call `getAppWidgetOptions()` on the `AppWidgetManager`, to get the `Bundle` of options — the same options that we could be delivered in `onAppWidgetOptionsUpdate()` as described [in the previous section](#). One value that will be in this `Bundle` is `AppWidgetManager.OPTION_APPWIDGET_HOST_CATEGORY`, which will be an `int` with a value of `AppWidgetProviderInfo.WIDGET_CATEGORY_KEYGUARD` if our app widget is on the lockscreen. In that case, we switch to using `R.layout.lockscreen`. In addition, we know then we need to update the `middle_die` when we are updating the other dice.

HOME SCREEN APP WIDGETS

There is also a subtle change in our `getBroadcast()` call to `PendingIntent`: we pass in the app widget ID as the second parameter, whereas in `PairOfDice` we passed 0. `PendingIntent` objects are cached in our process, and by default we will get the same `PendingIntent` when we call `getBroadcast()` for the same `Intent`. However, in our case, we may *want* two or more different `PendingIntent` objects for the same `Intent`, with differing extras (`EXTRA_APPWIDGET_ID`). Since extras are not considered when evaluating equivalence of `Intent` objects, just having different extras is insufficient to get different `PendingIntent` objects for those `Intent` objects. The second parameter to `getBroadcast()` (and `getActivity()` and `getService()`) on `PendingIntent` is a unique identifier, to differentiate between two otherwise equivalent `Intent` objects, forcing `PendingIntent` to give us distinct `PendingIntent` objects. This way, we can support two or more app widget instances, each having their own `PendingIntent` objects for their click events.

On an Android 4.2+ lockscreen, you should be able to swipe to one side (e.g., a bezel swipe from left to right), to expose an option to add an app widget:

Figure 738: Lockscreen Add-A-Widget Panel, On a 4.2 Emulator

Tapping the “+” indicator (and, if needed, entering your device PIN or password), brings up an app widget chooser:

HOME SCREEN APP WIDGETS

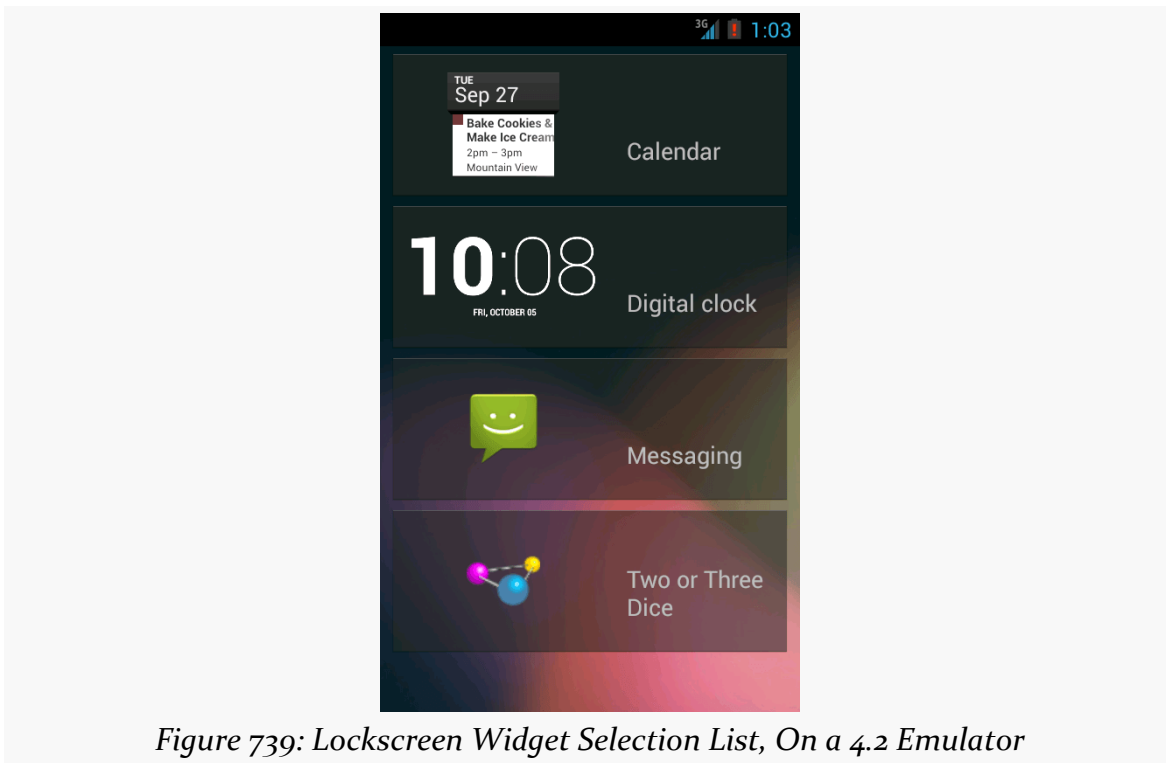

Figure 739: Lockscreen Widget Selection List, On a 4.2 Emulator

Choosing TwoOrThreeDice will then add the app widget to the lockscreen, with three dice, not two:

Figure 740: Lockscreen with TwoOrThreeDice, On a 4.2 Emulator

Preview Images

App widgets can have preview images attached. Preview images are drawable resources representing a preview of what the app widget might look like on the screen. On tablets, this will be used as part of an app widget gallery, replacing the simple context menu presentation you used to see on Android 1.x and 2.x phones:

HOME SCREEN APP WIDGETS

To create the preview image itself, the Android 3.0+ emulator images contain a Widget Preview application that lets you run an app widget in its own container, outside of the home screen:

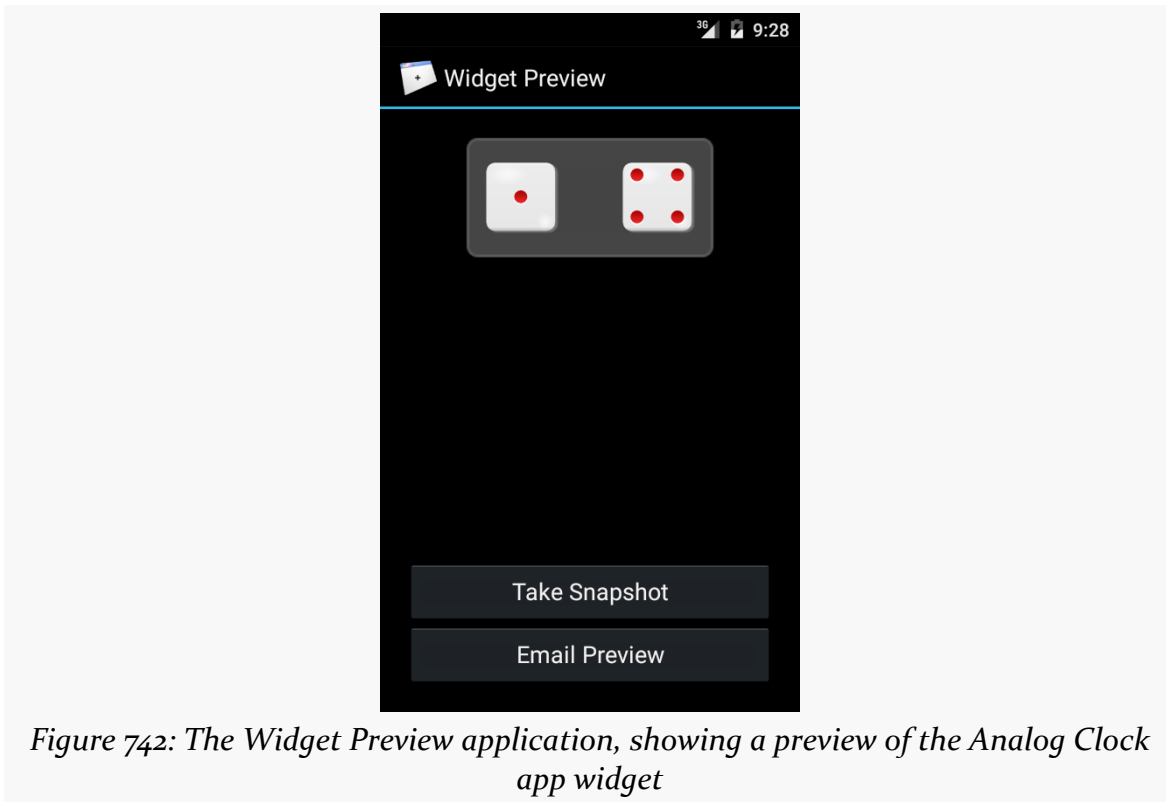

Figure 742: The Widget Preview application, showing a preview of the Analog Clock app widget

From here, you can take a snapshot and save it to external storage, copy it to your project's `res/drawable-nodpi/` directory (indicating that there is no intrinsic density assumed for this image), and reference it in your app widget metadata via an `android:previewImage` attribute. We will see an example of such an attribute in [the chapter on advanced app widgets](#).

Being a Good Host

In addition to creating your own app widgets, it is possible to host app widgets. This is mostly aimed for those creating alternative home screen applications, so they can take advantage of the same app widget framework and all the app widgets being built for it.

This is not very well documented, but it involves the `AppWidgetHost` and `AppWidgetHostView` classes. The latter is a `View` and so should be able to reside in an app widget host's UI like any other ordinary widget.

Adapter-Based App Widgets

API Level 11 introduced a few new capabilities for app widgets, to make them more interactive and more powerful than before. The documentation lags a bit, though, so determining how to use these features takes a bit of exploring. Fortunately for you, the author did some of that exploring on your behalf, to save you some trouble.

Prerequisites

Understanding this chapter requires that you have read [the preceding chapter](#) and all of its prerequisites.

AdapterViews for App Widgets

In addition to the classic widgets available for use in app widgets and RemoteViews, five more were added for API Level 11:

1. GridView
2. ListView
3. StackView
4. ViewFlipper
5. AdapterViewFlipper

Three of these (GridView, ListView, ViewFlipper) are widgets that existed in Android since the outset. StackView was added in API Level 11 to provide a “stack of cards” UI:

Figure 743: The Google Books app widget, showing a StackView

AdapterViewFlipper works like a ViewFlipper, allowing you to toggle between various children with only one visible at a time. However, whereas with ViewFlipper all children are fully-instantiated View objects held by the ViewFlipper parent, AdapterViewFlipper uses the Adapter model, so only a small number of actual View objects are held in memory, no matter how many potential children there are.

With the exception of ViewFlipper, the other four all require the use of an Adapter. This might seem odd, as there is no way to provide an Adapter to a RemoteViews. That is true, but API Level 11 added new ways for Adapter-like communication between the app widget host (e.g., home screen) and your application. We will take an in-depth look at that in [an upcoming section](#).

Building Adapter-Based App Widgets

In an activity, if you put a ListView or GridView into your layout, you will also need to hand it an Adapter, providing the actual row or cell View objects that make up the contents of those selection widgets.

In an app widget, this becomes a bit more complicated. The host of the app widget does not have any Adapter class of yours. Hence, just as we have to send the contents of the app widget's UI via a RemoteViews, we will need to provide the rows or cells via RemoteViews as well. Android, starting with API Level 11, has a RemoteViewsService and RemoteViewsFactory that you can use for this purpose.

Let's take a look, in the form of the [AppWidget/LoremWidget](#) sample project, which will put a `ListView` of 25 Latin words into an app widget.

The AppWidgetProvider

At its core, our `AppWidgetProvider` (named `WidgetProvider`, in a stunning display of creativity) still needs to create and configure a `RemoteViews` object with the app widget UI, then use `updateAppWidget()` to push that `RemoteViews` to the host via the `AppWidgetManager`. However, for an app widget that involves an `AdapterView`, like `ListView`, there are two more key steps:

- You have to tell the `RemoteViews` the identity of a `RemoteViewsService` that will help fill the role that the `Adapter` would in an activity
- You have to provide the `RemoteViews` with a “template” `PendingIntent` to be used when the user taps on a row or cell in the `AdapterView`, to replace the `onListItemClick()` or similar method you might have used in an activity

For example, here is `WidgetProvider` for our Latin-word app widget:

```
package com.commonware.android.appwidget.lorem;

import android.app.PendingIntent;
import android.appwidget.AppWidgetManager;
import android.appwidget.AppWidgetProvider;
import android.content.Context;
import android.content.Intent;
import android.net.Uri;
import android.widget.RemoteViews;

public class WidgetProvider extends AppWidgetProvider {
    public static String EXTRA_WORD=
        "com.commonware.android.appwidget.lorem.WORD";

    @Override
    public void onUpdate(Context ctxt, AppWidgetManager appWidgetManager,
        int[] appWidgetIds) {
        for (int i=0; i<appWidgetIds.length; i++) {
            Intent svcIntent=new Intent(ctxt, WidgetService.class);

            svcIntent.putExtra(AppWidgetManager.EXTRA_APPWIDGET_ID, appWidgetIds[i]);
            svcIntent.setData(Uri.parse(svcIntent.toUri(Intent.URI_INTENT_SCHEME)));

            RemoteViews widget=new RemoteViews(ctxt.getPackageName(),
                R.layout.widget);
```

ADAPTER-BASED APP WIDGETS

```
widget.setRemoteAdapter(R.id.words, svcIntent);

Intent clickIntent=new Intent(ctxt, LoremActivity.class);
PendingIntent clickPI=PendingIntent
    .getActivity(ctxt, 0,
                clickIntent,
                PendingIntent.FLAG_UPDATE_CURRENT);

widget.setPendingIntentTemplate(R.id.words, clickPI);

appWidgetManager.updateAppWidget(appWidgetIds[i], widget);
}

super.onUpdate(ctxt, appWidgetManager, appWidgetIds);
}
}
```

(from [AppWidget/LoremWidget/app/src/main/java/com/commonsware/android/appwidget/lorem/WidgetProvider.java](#))

The call to `setRemoteAdapter()` is where we point the `RemoteViews` to our `RemoteViewsService` for our `AdapterView` widget. The main rules for the `Intent` used to identify the `RemoteViewsService` are:

1. The service must be identified by its data (`Uri`), so even if you create the `Intent` via the `Context-and-Class` constructor, you will need to convert that into a `Uri` via `toUri(Intent.URI_INTENT_SCHEME)` and set that as the `Uri` for the `Intent`. Why? While your application has access to your `RemoteViewsService` Class object, the app widget host will not, and so we need something that will work across process boundaries. You could elect to add your own `<intent-filter>` to the `RemoteViewsService` and use an `Intent` based on that, but that would make your service more publicly visible than you might want.
2. Any extras that you package on the `Intent` — such as the app widget ID in this case — will be on the `Intent` that is delivered to the `RemoteViewsService` when it is invoked by the app widget host.

Note that there are two flavors of `setRemoteAdapter()`. An older deprecated one takes the app widget ID as the first parameter. The current one does not. The current one, though, is only available on API Level 14 and higher.

The call to `setPendingIntentTemplate()` is where we provide a `PendingIntent` that will be used as the template for all row or cell clicks. As we will see in a bit, the

ADAPTER-BASED APP WIDGETS

underlying Intent in the PendingIntent will have more data added to it by our RemoteViewsFactory.

In all other respects, our WidgetProvider is unremarkable compared to other app widgets. It will need to be registered in the manifest as a <receiver>, as with any other app widget.

The RemoteViewsService

Android supplies a RemoteViewsService class that you will need to extend, and this class is the one you must register with the RemoteViews for an AdapterView widget. For example, here is WidgetService (once again, a highly creative name) from the LoremWidget project:

```
package com.commonware.android.appwidget.lorem;

import android.content.Intent;
import android.widget.RemoteViewsService;

public class WidgetService extends RemoteViewsService {
    @Override
    public RemoteViewsFactory onCreateViewFactory(Intent intent) {
        return(new LoremViewsFactory(this.getApplicationContext(),
            intent));
    }
}
```

(from [AppWidget/LoremWidget/app/src/main/java/com/commonware/android/appwidget/lorem/WidgetService.java](#))

As you can see, this service is practically trivial. You have to override one method, onCreateViewFactory(), which will return the RemoteViewsFactory to use for supplying rows or cells for the AdapterView. You are passed in an Intent, the one used in the setRemoteAdapter() call. Hence, if you have more than one AdapterView widget in your app widget, you could elect to have two RemoteViewsService implementations, or one that discriminates between the two widgets via something in the Intent (e.g., custom action string). In our case, we only have one AdapterView, so we create an instance of a LoremViewFactory and return it. Google has suggested using getApplicationContext() here to supply the Context object to RemoteViewsFactory, instead of using the Service as a Context, though it is unclear why this is.

Another thing different about the RemoteViewsService is how it is registered in the manifest:

ADAPTER-BASED APP WIDGETS

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
    package="com.commonware.android.appwidget.lorem"
    android:versionCode="1"
    android:versionName="1.0">

    <uses-sdk
        android:minSdkVersion="14"
        android:targetSdkVersion="19"/>

    <uses-feature
        android:name="android.software.app_widgets"
        android:required="true"/>

    <application
        android:allowBackup="false"
        android:icon="@drawable/ic_launcher"
        android:label="@string/app_name">
        <activity
            android:name="LoremActivity"
            android:label="@string/app_name"
            android:theme="@android:style/Theme.Translucent.NoTitleBar">
            <intent-filter>
                <action android:name="android.intent.action.MAIN"/>

                <category android:name="android.intent.category.LAUNCHER"/>
            </intent-filter>
        </activity>

        <receiver
            android:name="WidgetProvider"
            android:icon="@drawable/ic_launcher"
            android:label="@string/app_name">
            <intent-filter>
                <action android:name="android.appwidget.action.APPWIDGET_UPDATE"/>
            </intent-filter>

            <meta-data
                android:name="android.appwidget.provider"
                android:resource="@xml/widget_provider"/>
        </receiver>

        <service
            android:name="WidgetService"
            android:permission="android.permission.BIND_REMOTEVIEWS"/>
    </application>
</manifest>
```

ADAPTER-BASED APP WIDGETS

(from [AppWidget/LoremWidget/app/src/main/AndroidManifest.xml](#))

Note the use of `android:permission`, specifying that whoever sends an Intent to `WidgetService` must hold the `BIND_REMOTEVIEWS` permission. This can only be held by the operating system. This is a security measure, so arbitrary applications cannot find out about your service and attempt to spoof being the OS and cause you to supply them with `RemoteViews` for the rows, as this might leak private data.

The RemoteViewsFactory

A `RemoteViewsFactory` interface implementation looks and feels a lot like an `Adapter`. In fact, one could imagine that the Android developer community might create `CursorRemoteViewsFactory` and `ArrayRemoteViewsFactory` and such to further simplify writing these classes.

For example, here is `LoremViewsFactory`, the one used by the `LoremWidget` project:

```
package com.commonware.android.appwidget.lorem;

import android.appwidget.AppWidgetManager;
import android.content.Context;
import android.content.Intent;
import android.os.Bundle;
import android.widget.RemoteViews;
import android.widget.RemoteViewsService;

public class LoremViewsFactory implements
    RemoteViewsService.RemoteViewsFactory {
    private static final String[] items= { "lorem", "ipsum", "dolor",
        "sit", "amet", "consectetuer", "adipiscing", "elit", "morbi",
        "vel", "ligula", "vitae", "arcu", "aliquet", "mollis", "etiam",
        "vel", "erat", "placerat", "ante", "porttitor", "sodales",
        "pellentesque", "augue", "purus" };
    private Context ctxt=null;
    private int appWidgetId;

    public LoremViewsFactory(Context ctxt, Intent intent) {
        this.ctxt=ctxt;
        appWidgetId=
            intent.getIntExtra(AppWidgetManager.EXTRA_APPWIDGET_ID,
                AppWidgetManager.INVALID_APPWIDGET_ID);
    }

    @Override
    public void onCreate() {
```

ADAPTER-BASED APP WIDGETS

```
// no-op
}

@Override
public void onDestroy() {
    // no-op
}

@Override
public int getCount() {
    return(items.length);
}

@Override
public RemoteViews getViewAt(int position) {
    RemoteViews row=
        new RemoteViews(ctxt.getPackageName(), R.layout.row);

    row.setTextViewText(android.R.id.text1, items[position]);

    Intent i=new Intent();
    Bundle extras=new Bundle();

    extras.putString(WidgetProvider.EXTRA_WORD, items[position]);
    extras.putInt(AppWidgetManager.EXTRA_APPWIDGET_ID, appWidgetId);
    i.putExtras(extras);
    row.setOnClickFillInIntent(android.R.id.text1, i);

    return(row);
}

@Override
public RemoteViews getLoadingView() {
    return(null);
}

@Override
public int getViewTypeCount() {
    return(1);
}

@Override
public long getItemId(int position) {
    return(position);
}

@Override
public boolean hasStableIds() {
```

ADAPTER-BASED APP WIDGETS

```
    return(true);
}

@Override
public void onDataSetChanged() {
    // no-op
}
}
```

(from [AppWidget/LoremWidget/app/src/main/java/com/commonsware/android/appwidget/lorem/LoremViewsFactory.java](#))

You need to implement a handful of methods that have the same roles in a `RemoteViewsFactory` as they do in an `Adapter`, including:

1. `getCount()`
2. `getViewTypeCount()`
3. `getItemId()`
4. `hasStableIds()`

In addition, you have `onCreate()` and `onDestroy()` methods that you must implement, even if they do nothing, to satisfy the interface.

You will need to implement `getLoadingView()`, which will return a `RemoteViews` to use as a placeholder while the app widget host is getting the real contents for the app widget. If you return `null`, Android will use a default placeholder.

The bulk of your work will go in `getViewAt()`. This serves the same role as `getView()` does for an `Adapter`, in that it returns the row or cell `View` for a given position in your data set. However:

1. You have to return a `RemoteViews`, instead of a `View`, just as you have to use `RemoteViews` for the main content of the app widget in your `AppWidgetProvider`
2. There is no recycling, so you do not get a `View` (or `RemoteViews`) back to somehow repopulate, meaning you will create a new `RemoteViews` every time

The impact of the latter is that you do not want to put large data sets into an app widget, as scrolling may get sluggish, just as you do not want to implement an `Adapter` without recycling unused `View` objects.

In `LoremViewsFactory`, the `getViewAt()` implementation creates a `RemoteViews` for a custom row layout, cribbed from one in the Android SDK:

ADAPTER-BASED APP WIDGETS

```
<?xml version="1.0" encoding="utf-8"?>

-->

<TextView xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@android:id/text1"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:textAppearance="?android:attr/textAppearanceLarge"
    android:gravity="center_vertical"
    android:paddingLeft="6dip"
    android:minHeight="?android:attr/listPreferredItemHeight"
/>
```

(from [AppWidget/LoremWidget/app/src/main/res/layout/row.xml](#))

Then, `getViewAt()` pours in a word from the static `String` array of Latin words into that `RemoteViews` for the `TextView` inside it. It also creates an `Intent` and puts the Latin word in as an `EXTRA_WORD` extra, then provides that `Intent` to `setOnClickFillInIntent()`. In addition, it adds the app widget instance ID as an extra, reusing the framework's own `AppWidgetManager.EXTRA_APPWIDGET_ID` as the key. The contents of the "fill-in" `Intent` are merged into the "template" `PendingIntent` from `setPendingIntentTemplate()`, and the resulting `PendingIntent` is what is invoked when the user taps on an item in the `AdapterView`. The fully-configured `RemoteViews` is then returned.

The Rest of the Story

The app widget metadata needs no changes related to Adapter-based app widget contents. However, `LoremWidget` does add the `android:previewImage` attribute:

```
<appwidget-provider xmlns:android="http://schemas.android.com/apk/res/android"
    android:minWidth="146dip"
```

ADAPTER-BASED APP WIDGETS

```
android:minHeight="146dip"  
android:updatePeriodMillis="0"  
android:initialLayout="@layout/widget"  
android:autoAdvanceViewId="@+id/words"  
android:previewImage="@drawable/preview"  
android:resizeMode="vertical"  
/>
```

(from [AppWidget/LoremWidget/app/src/main/res/xml/widget_provider.xml](#))

This points to the `res/drawable-nodpi/preview.png` file that represents a “widgetshot” of the app widget in isolation, obtained from the Widget Preview application:

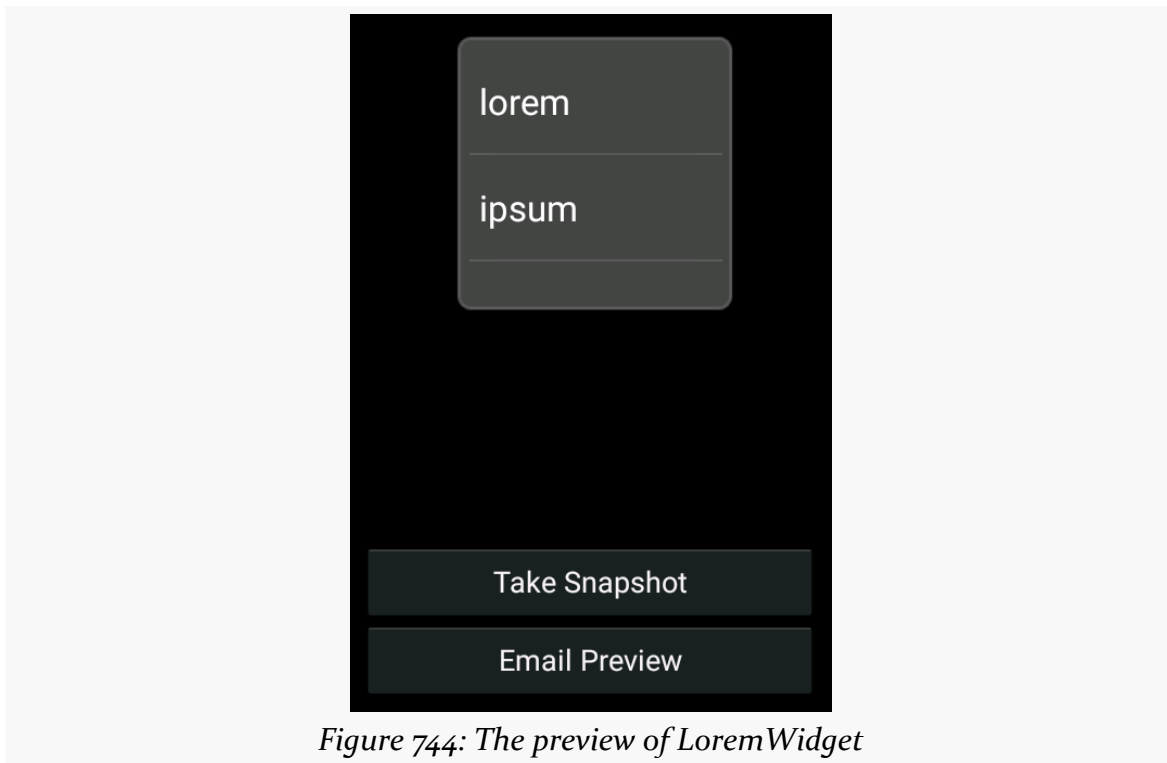

Figure 744: The preview of LoremWidget

Also, the metadata specifies `android:resizeMode="vertical"`. This attribute is new to Android 3.1, and allows the app widget to be resized by the user (in this case, only in the vertical direction, to show more rows). Older versions of Android will ignore this attribute, and the app widget will remain in your requested size. You can use `vertical`, `horizontal`, or both (via the pipe operator) as values for `android:resizeMode`.

ADAPTER-BASED APP WIDGETS

When the user taps on an item in the list, our `PendingIntent` is set to bring up `LoremActivity`. This activity has `android:theme="@android:style/Theme.Translucent.NoTitleBar"` set in the manifest, meaning that [it will not have its own user interface](#). Rather, it will extract our `EXTRA_WORD` — and the app widget ID — out of the `Intent` used to launch the activity and displays it in a `Toast` before finishing:

```
package com.commonware.android.appwidget.lorem;

import android.app.Activity;
import android.appwidget.AppWidgetManager;
import android.os.Bundle;
import android.widget.Toast;

public class LoremActivity extends Activity {
    @Override
    public void onCreate(Bundle state) {
        super.onCreate(state);

        String word=getIntent().getStringExtra(WidgetProvider.EXTRA_WORD);

        if (word == null) {
            word="We did not get a word!";
        }

        Toast.makeText(this,
            String.format("#%d: %s",
                getIntent().getIntExtra(AppWidgetManager.EXTRA_APPWIDGET_ID,
                    AppWidgetManager.INVALID_APPWIDGET_ID),
                word), Toast.LENGTH_LONG).show();

        finish();
    }
}
```

(from [AppWidget/LoremWidget/app/src/main/java/com/commonware/android/appwidget/lorem/LoremActivity.java](#))

The Results

When you compile and install the application, nothing new shows up in the home screen launcher, because we have no activity defined to respond to `ACTION_MAIN` and `CATEGORY_HOME`. This would be unusual for an application distributed through the Play Store, as users often get confused if they install something and then do not know how to start it. However, for the purposes of this example, we should be fine, as readers of programming books never get confused about such things.

However, if you bring up the app widget gallery (e.g., long-tap on the home screen of an Android 6.0 device or emulator), you will see `LoremWidget` there, complete with preview image. You can drag it into one of the home screen panes and position it. When done, the app widget appears as expected:

ADAPTER-BASED APP WIDGETS

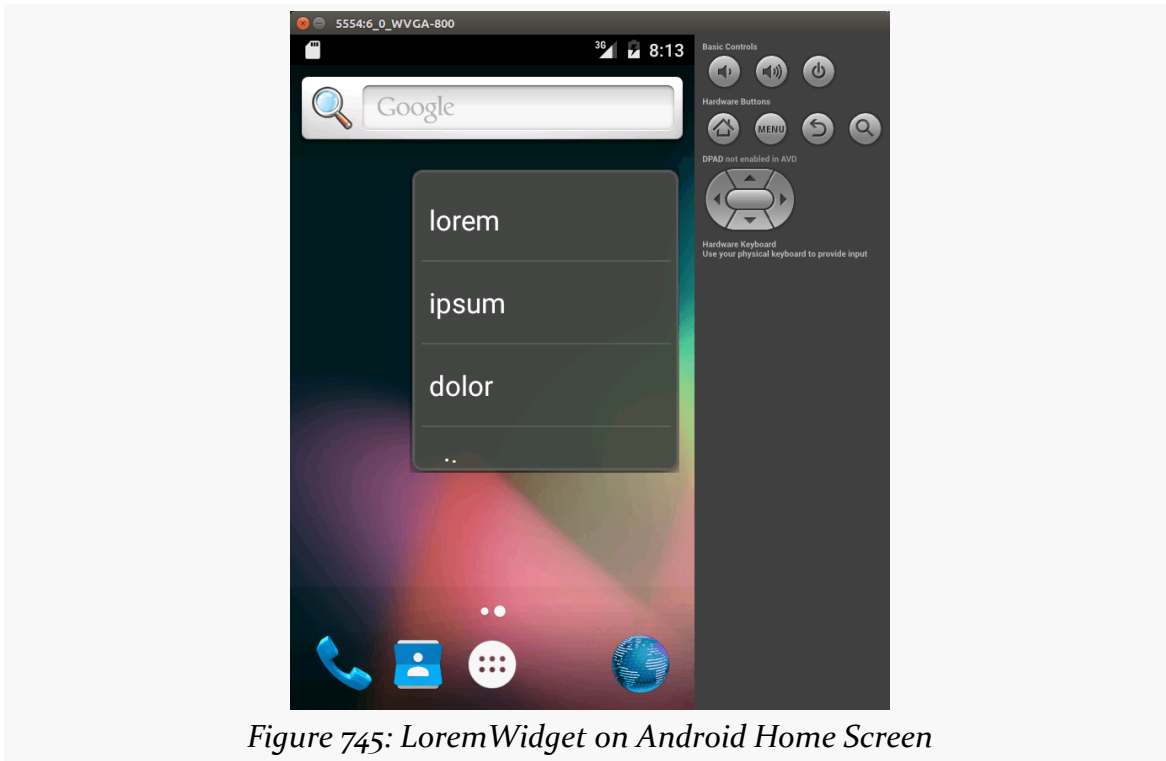

Figure 745: LoremWidget on Android Home Screen

The `ListView` is live and can be scrolled. Tapping an entry brings up the corresponding `Toast`.

If the user long-taps on the app widget, they will be able to reposition it. On Android 3.1 and beyond, when they lift their finger after the long-tap, the app widget will show resize handles on the sides designated by your `android:resizeMode` attribute:

ADAPTER-BASED APP WIDGETS

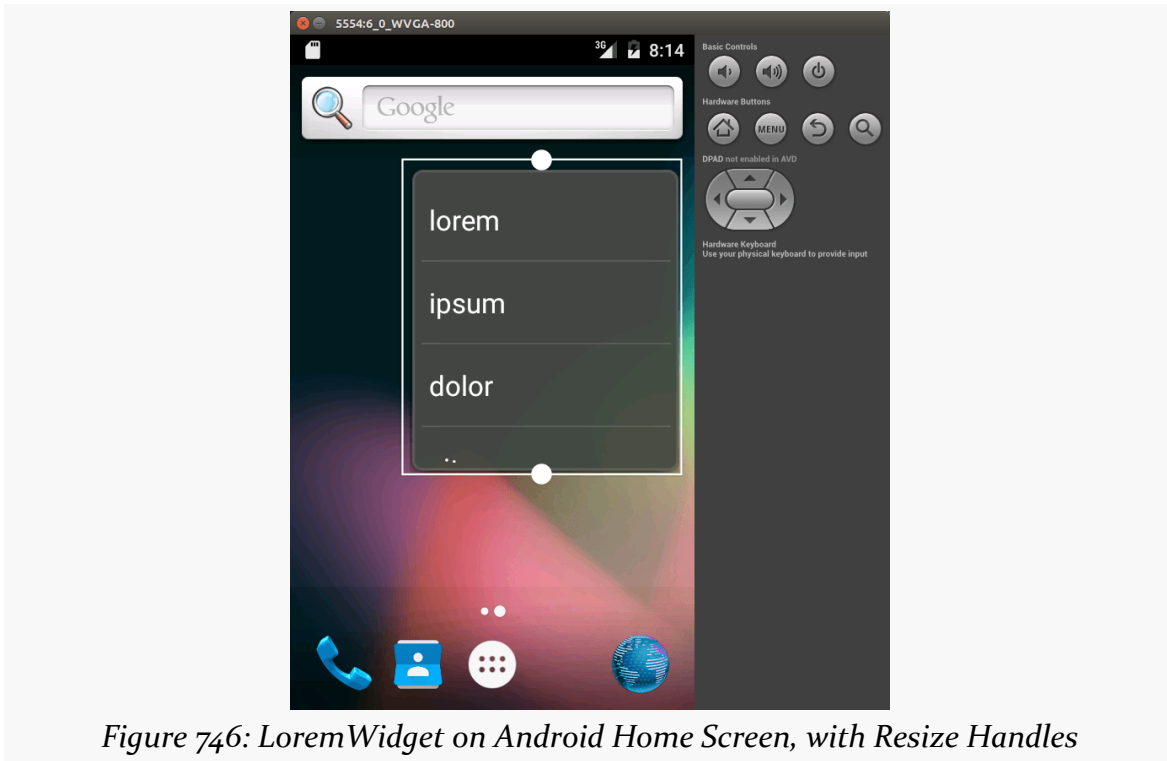

Figure 746: LoremWidget on Android Home Screen, with Resize Handles

The user can then drag those handles to expand or shrink the app widget in the specified dimensions:

Trail: Data Storage and Retrieval

Content Provider Theory

Android publishes data to you via an abstraction known as a “content provider”. Access to contacts and the call log, for example, are given to you via a set of content providers. In a few places, Android expects you to supply a content provider, such as for integrating your own search suggestions with the Android Quick Search Box. And, content providers are one way for you to supply data to third party applications, or to consume information from third party applications. As such, content providers have the potential to be something you would encounter frequently, even if in practice they do not seem used much.

Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly the one on [working with local databases](#).

Using a Content Provider

Any `Uri` in Android that begins with the `content://` scheme represents a resource served up by a content provider. Content providers offer data encapsulation using `Uri` instances as handles – you neither know nor care where the data represented by the `Uri` comes from, so long as it is available to you when needed. The data could be stored in a SQLite database, or in flat files, or retrieved off a device, or be stored on some far-off server accessed over the Internet.

Given a `Uri`, you may be able to perform basic CRUD (create, read, update, delete) operations using a content provider. `Uri` instances can represent either collections or individual pieces of content. Given a collection `Uri`, you may be able to create new pieces of content via insert operations. Given an instance `Uri`, you may be able to

read data represented by the `Uri`, update that data, or delete the instance outright. Or, given a `Uri`, you may be able to open up a handle to what amounts to a file, that you can read and, possibly, write to.

These are all phrased as “may” because the content provider system is a facade. The actual implementation of a content provider dictates what you can and cannot do, and not all content providers will support all capabilities.

Pieces of a Uri

A `Uri` for a `ContentProvider` is made up of two to four components.

A provider `Uri` always has a content scheme. So, when represented as a string, you will see the `Uri` start with `content://`.

After the scheme, where in an `http://` URL you would find a domain name or IP address, a provider `Uri` always has the authority string. This is unique on the device — only one provider will be tied to a given authority string.

What comes after the authority string is up to the provider. It is structured like the path segments of an `http://` URL, but what those path segments mean is up to the provider implementation. The one approximate rule is that a `Uri` pointing to an individual piece of content — such as a row of a table or view in a database — frequently has the `Uri` end in a number, where the number indicates a unique identifier of that content.

Most of the Android APIs expect these to be `Uri` objects, though in common discussion, it is simpler to think of them as strings. The `Uri.parse()` static method creates a `Uri` out of the string representation.

Getting a Handle

So, where do these `Uri` instances come from?

Some `Uri` values are part of the framework. For example, `ContactsContract.Contacts.CONTENT_URI` is a `Uri` pointing at the collection of contacts.

You might also get `Uri` instances handed to you from other sources, such as getting `Uri` handles for contacts via activities responding to `ACTION_PICK` or `ACTION_GET_CONTENT` Intent objects.

You can also hard-wire literal `String` objects (e.g., `"content://contacts/people"`) and convert them into `Uri` instances via `Uri.parse()`. This is not an ideal solution, as the base `Uri` values could conceivably change over time. For example, while you *used* to access contacts via a `Uri` like `content://contacts/people`, that is no longer the case. `ContactsContract.Contacts.CONTENT_URI` is a different value and will give you better results.

The Database-Style API

Of the two flavors of API that a content provider may support, the database-style API is more prevalent. Using a `ContentResolver`, you can perform standard “CRUD” operations (create, read, update, delete) using what looks like a SQL interface.

Makin’ Queries

Given a base `Uri`, you can run a query to return data out of the content provider related to that `Uri`. This has much of the feel of SQL: you specify the “columns” to return, the constraints to determine which “rows” to return, a sort order, etc. The difference is that this request is being made of a content provider, not directly of some database (e.g., SQLite).

You have two main options for running a query:

1. Use the `query()` method on `ContentResolver` from some sort of background thread
2. Use a `CursorLoader`, as is discussed [in an upcoming chapter](#)

The standard `query()` method on `ContentResolver` takes five parameters:

- The base `Uri` of the content provider to query, or the instance `Uri` of a specific object to query
- An array of properties (think “columns”) from that content provider that you want returned by the query
- A constraint statement, functioning like a SQL `WHERE` clause
- An optional set of parameters to bind into the constraint clause, replacing any `?` that appear there
- An optional sort statement, functioning like a SQL `ORDER BY` clause

This method returns a `Cursor` object, which you can use to retrieve the data returned by the query.

CONTENT PROVIDER THEORY

This will hopefully make more sense given an example. This chapter shows some sample bits of code from the [ContentProvider/ConstantsPlus](#) sample project. This is the same basic application as was first shown back in the [chapter on database access](#), but rewritten to pull the database logic into a content provider, which is then used by a retained ListFragment.

As before, in `onViewCreated()`, we kick off a `LoadCursorTask` if we do not already have our `Cursor`, such as via a configuration change:

```
@Override
public void onViewCreated(View view, Bundle savedInstanceState) {
    super.onViewCreated(view, savedInstanceState);

    SimpleCursorAdapter adapter=
        new SimpleCursorAdapter(getActivity(), R.layout.row,
            current, new String[] {
                DatabaseHelper.TITLE,
                DatabaseHelper.VALUE },
            new int[] { R.id.title, R.id.value },
            0);

    setListAdapter(adapter);

    if (current==null) {
        task=new LoadCursorTask(getActivity()).execute();
    }
}
```

(from [ContentProvider/ConstantsPlus/app/src/main/java/com/commonsware/android/constants/ConstantsFragment.java](#))

`LoadCursorTask` inherits from a `BaseTask`. `BaseTask` and its subclasses need a `ContentResolver` to be able to work with our `ContentProvider`. So, `BaseTask` takes a `Context` in its constructor and uses that to retrieve a `ContentResolver`:

```
abstract private class BaseTask<T> extends AsyncTask<T, Void, Cursor> {
    final ContentResolver resolver;

    BaseTask(Context ctxt) {
        super();

        resolver=ctxt.getContentResolver();
    }
}
```

(from [ContentProvider/ConstantsPlus/app/src/main/java/com/commonsware/android/constants/ConstantsFragment.java](#))

CONTENT PROVIDER THEORY

In `doInBackground()`, `LoadCursorTask` calls a `doQuery()` method inherited from `BaseTask`, which in turn uses our `ContentResolver` to query our `ContentProvider`:

```
protected Cursor doQuery() {
    Cursor result=resolver.query(Provider.Constants.CONTENT_URI,
        PROJECTION, null, null, null);

    result.getCount();

    return(result);
}
```

(from [ContentProvider/ConstantsPlus/app/src/main/java/com/commonsware/android/constants/ConstantsFragment.java](#))

In the call to `query()`, we provide:

1. The `Uri` for our provider (`Provider.Constants.CONTENT_URI`), in this case representing the collection of physical constants managed by the provider
2. A list of properties to retrieve
3. Three `null` values, indicating that we do not need a constraint clause (the `Uri` represents the instance we need), nor parameters for the constraint, nor a sort order (we should only get one entry back)

The biggest “magic” here is the list of properties. The lineup of what properties are possible for a given provider should be provided by the documentation (or source code) for the content provider itself. In this case, we define logical values on the `Provider` provider implementation class that represent the various properties (namely, the unique identifier, the display name or title, and the value of the constant), and we refer to them with our `PROJECTION`:

```
private static final String[] PROJECTION=new String[] {
    Provider.Constants._ID, Provider.Constants.TITLE,
    Provider.Constants.VALUE };
```

(from [ContentProvider/ConstantsPlus/app/src/main/java/com/commonsware/android/constants/ConstantsFragment.java](#))

Adapting to the Circumstances

Now that we have a `Cursor` via `query()`, we have access to the query results and can do whatever we want with them. You might, for example, manually extract data from the `Cursor` to populate widgets or other objects.

In our case, we are using the `SimpleCursorAdapter`, set up in `onViewCreated()`, to render our `Cursor`. This means that we need to take the `Cursor` that `doQuery()`

CONTENT PROVIDER THEORY

generates and arrange to hand that to the SimpleCursorAdapter. The `onPostExecute()` method on BaseTask handles this:

```
@Override
public void onPostExecute(Cursor result) {
    ((CursorAdapter)getListAdapter()).changeCursor(result);
    current=result;
    task=null;
}
```

(from [ContentProvider/ConstantsPlus/app/src/main/java/com/commonsware/android/constants/ConstantsFragment.java](#))

Give and Take

Of course, content providers would be astonishingly weak if you couldn't add or remove data from them, and were instead limited to only update what is there. Fortunately, content providers offer these abilities as well.

To insert data into a content provider, you have two options available on the ContentProvider interface (available through `getContentResolver()` to your activity):

- Use `insert()` with a collection `Uri` and a `ContentValues` structure describing the initial set of data to put in the row
- Use `bulkInsert()` with a collection `Uri` and an array of `ContentValues` structures to populate several rows at once

The `insert()` method returns a `Uri` for you to use for future operations on that new object. The `bulkInsert()` method returns the number of created rows; you would need to do a query to get back at the data you just inserted.

For example, if the user chooses our “Add” overflow item, we pop up a dialog to collect a new constant:

```
private void add() {
    LayoutInflater inflater=getActivity().getLayoutInflater();
    View addView=inflater.inflate(R.layout.add_edit, null);
    AlertDialog.Builder builder=new AlertDialog.Builder(getActivity());

    builder.setTitle(R.string.add_title).setView(addView)
        .setPositiveButton(R.string.ok, this)
        .setNegativeButton(R.string.cancel, null).show();
}
```

CONTENT PROVIDER THEORY

(from [ContentProvider/ConstantsPlus/app/src/main/java/com/commonsware/android/constants/ConstantsFragment.java](#))

Then, if the user taps the “OK” button in the dialog, our `onClick()` listener is called, where we collect the entered values from the user, pour them into a `ContentValues` structure, and pass that to an `InsertTask`:

```
@Override
public void onClick(DialogInterface dialog, int which) {
    ContentValues values=new ContentValues(2);
    AlertDialog dlg=(AlertDialog)dialog;
    EditText title=(EditText)dlg.findViewById(R.id.title);
    EditText value=(EditText)dlg.findViewById(R.id.value);

    values.put(DatabaseHelper.TITLE, title.getText().toString());
    values.put(DatabaseHelper.VALUE, value.getText().toString());

    task=new InsertTask(getActivity()).execute(values);
}
```

(from [ContentProvider/ConstantsPlus/app/src/main/java/com/commonsware/android/constants/ConstantsFragment.java](#))

`InsertTask`, in its `doInBackground()` method, calls `insert()` on a `ContentResolver` to insert this row:

```
@Override
protected Cursor doInBackground(ContentValues... values) {
    resolver.insert(Provider.Constants.CONTENT_URI, values[0]);

    return(doQuery());
}
```

(from [ContentProvider/ConstantsPlus/app/src/main/java/com/commonsware/android/constants/ConstantsFragment.java](#))

Notice that we also call `doQuery()` again. That is because our `Cursor` is now out of date, and we need to obtain a fresh `Cursor` with fresh results. And, as with `LoadTask`, `InsertTask` inherits from `BaseTask`, not only providing us with that `doQuery()` method but also the `onPostExecute()` method that puts the `Cursor` into the `SimpleCursorAdapter`.

To delete one or more rows from the content provider, use the `delete()` method on `ContentResolver`. This works akin to a SQL `DELETE` statement and takes three parameters:

- A `Uri` representing the collection (or instance) from which you wish to delete rows

- A constraint statement, functioning like a SQL WHERE clause, to determine which rows should be deleted
- An optional set of parameters to bind into the constraint clause, replacing any ? that appear there

The Streaming API

Sometimes, what you are trying to retrieve does not look like a set of rows and columns, but rather looks like a stream. For example, [the MediaStore provider](#) manages the index of all music, video, and image files available on external storage, and you can use MediaStore to open up a stream to read in the contents of one of those files. Here, working with the Uri and the provider is much like working with a URL and a Web server.

Some content providers, like MediaStore, support both the database-style and streaming APIs — you query to find media that matches your criteria, then can open some file that matches. Other content providers might only support the streaming API.

Working with the Stream

Given a Uri that represents some file managed by the content provider, you can use `openInputStream()` and `openOutputStream()` on a `ContentResolver` to access an `InputStream` or `OutputStream`, respectively. Note, though, that not all content providers may support both modes. For example, a content provider that serves files stored inside the application (e.g., assets in the APK file), you will not be able to get an `OutputStream` to modify the content.

Also note that `openInputStream()` and `openOutputStream()` work with both `file://` and `content://` Uri values — you do not need to manually inspect the Uri and handle files separately if you do not want to.

Retrieving Metadata

You can call `getType()` on a `ContentResolver`, supplying a Uri as a parameter. This will return the MIME type reported by the `ContentProvider` for the data at that Uri. For the streaming API, this will give you results reminiscent of a Web server — some specific MIME type if the provider knows it, otherwise probably some generic MIME type (e.g., `application/octet-stream`).

You can also call `query()` on the `ContentResolver`. Your projection (the list of columns to return) can include:

- `OpenableColumns.SIZE`, which will return the length of the file being streamed to you for that `Uri`, and
- `OpenableColumns.DISPLAY_NAME`, which should be some name for the file that the user might recognize

The DATA Anti-Pattern

However, the authors of `MediaStore` screwed up developer expectations, due to a legacy convention.

The legacy convention was that a `content://Uri` might not be openable directly using something like `openInputStream()`. Instead, it pointed to a database row, retrievable via `query()`, and you would look in the `DATA` column for how to access the actual data. Some providers no doubt continue to use this pattern, as does `MediaStore`. The rules for what the `DATA` column would be were not well documented, but by convention they tended to be a path to a file. The problem is that this runs afoul of Google's current guidance, as there is no guarantee that other apps can access such a file.

Do not blindly assume that if you get a `content://Uri` that it is for the `DATA` pattern. Try to open a stream on the `Uri`, and if that fails, then see if the `DATA` pattern is in play. Or, if you `query()` to get the size and/or display name first, also request the `DATA` column, and if it exists and is not `null`, try that if opening the stream directly does not work.

Building Content Providers

Building a content provider is a very tedious task. There are many requirements of a content provider, in terms of methods to implement and public data members to supply. And, until you try using it, you have no great way of telling if you did any of it correctly (versus, say, building an activity and getting validation errors from the resource compiler).

That being said, building a content provider is of huge importance if your application wishes to make data available to other applications. If your application is keeping its data solely to itself, you may be able to avoid creating a content provider, just accessing the data directly from your activities. But, if you want your data to

possibly be used by others — for example, you are building a feed reader and you want other programs to be able to access the feeds you are downloading and caching — then a content provider is right for you.

First, Some Dissection

The content `Uri` is the linchpin behind accessing data inside a content provider. When using a content provider, all you really need to know is the provider's base `Uri`; from there you can run queries as needed, or construct a `Uri` to a specific instance if you know the instance identifier.

When building a content provider, though, you need to know a bit more about the innards of the content `Uri`.

A content `Uri` has two to four pieces, depending on situation:

1. It always has a scheme (`content://`), indicating it is a content `Uri` instead of a `Uri` to a Web resource (`http://`).
2. It always has an authority, which is the first path segment after the scheme. The authority is a unique string identifying the content provider that handles the content associated with this `Uri`.
3. It may have a data type path, which is the list of path segments after the authority and before the instance identifier (if any). The data type path can be empty, if the content provider only handles one type of content. It can be a single path segment (`foo`) or a chain of path segments (`foo/bar/goo`) as needed to handle whatever data access scenarios the content provider requires.
4. It may have an instance identifier, which is an integer identifying a specific piece of content. A content `Uri` without an instance identifier refers to the collection of content represented by the authority (and, where provided, the data path).

For example, a content `Uri` could be as simple as `content://secrets`, which would refer to the collection of content held by whatever content provider was tied to the `secrets` authority (e.g., `SecretsProvider`). Or, it could be as complex as `content://secrets/card/pin/17`, which would refer to a piece of content (identified as 17) managed by the `secrets` content provider that is of the data type `card/pin`.

Next, Some Typing

Next, you need to come up with some MIME types corresponding with the content your content provider will provide. There are three basic patterns.

For the streaming API, the MIME type that you will use should be the actual MIME type of the stream itself. Perhaps you already know the MIME type (e.g., you got it in an HTTP header when you downloaded the content from a Web server). Perhaps you will use `MimeTypeMap` to try to infer a MIME type based on a file extension. That is up to you, just as it is up to you to ensure that your Web server returns proper MIME types for streams that it serves up.

For the database-style API, even though the MIME type system is not really designed for this sort of thing, we still use MIME types. Each `Uri` will have an associated MIME type, indicating what is represented by that `Uri`. A `Uri` that points to a collection of content (e.g., a database table or view) will use one MIME type structure, while a `Uri` that points to an individual piece of content (e.g., a row in that database table or view) will use a different MIME type structure.

The collection MIME type should be of the form `vnd.X.cursor.dir/Y`, where `X` is the name of your firm, organization, or project, and `Y` is a dot-delimited type name. So, for example, you might use `vnd.tlagency.cursor.dir/sekrits.card.pin` as the MIME type for your collection of secrets.

The instance MIME type, for an individual piece of content, should be of the form `vnd.X.cursor.item/Y`, usually for the same values of `X` and `Y` as you used for the collection MIME type (though that is not strictly required).

Implementing the Database-Style API

Just as an activity and a receiver are both Java classes, so is a content provider. So, the big step in creating a content provider is crafting its Java class, with a base class of `ContentProvider`.

In your subclass of `ContentProvider`, you are responsible for implementing six methods that, when combined, perform the services that a content provider is supposed to offer to activities wishing to create, read, update, or delete content via the database-style API.

Implement onCreate()

As with an activity, the main entry point to a content provider is `onCreate()`. Here, you can do whatever initialization you want. In particular, here is where you should lazy-initialize your data store. For example, if you plan on storing your data in such-and-so directory on external storage, with an XML file serving as a “table of contents”, you should check and see if that directory and XML file are there and, if not, create them so the rest of your content provider knows they are out there and available for use.

Similarly, if you have rewritten your content provider sufficiently to cause the data store to shift structure, you should check to see what structure you have now and adjust it if what you have is out of date.

Implement query()

As one might expect, the `query()` method is where your content provider gets details on a query some activity wants to perform. It is up to you to actually process said query.

The query method gets, as parameters:

1. A `Uri` representing the collection or instance being queried
2. A `String` array representing the list of properties that should be returned
3. A `String` representing what amounts to a SQL `WHERE` clause, constraining which instances should be considered for the query results
4. A `String` array representing values to “pour into” the `WHERE` clause, replacing any `?` found there
5. A `String` representing what amounts to a SQL `ORDER BY` clause

You are responsible for interpreting these parameters however they make sense and returning a `Cursor` that can be used to iterate over and access the data.

As you can imagine, these parameters are aimed towards people using a SQLite database for storage. You are welcome to ignore some of these parameters (e.g., you elect not to try to roll your own SQL `WHERE` clause parser), but you need to document that fact so activities only attempt to query you by instance `Uri` and not by using parameters that you elect to ignore.

Implement insert()

Your `insert()` method will receive a `Uri` representing the collection and a `ContentValues` structure with the initial data for the new instance. You are responsible for creating the new instance, filling in the supplied data, and returning a `Uri` to the new instance.

Implement update()

Your `update()` method gets the `Uri` of the instance or collection to change, a `ContentValues` structure with the new values to apply, a `String` for a SQL `WHERE` clause, and a `String` array with parameters to use to replace `?` found in the `WHERE` clause. Your responsibility is to identify the instance(s) to be modified (based on the `Uri` and `WHERE` clause), then replace those instances' current property values with the ones supplied.

This will be annoying, unless you are using SQLite for storage. Then, you can pretty much pass all the parameters you received to the `update()` call to the database, though the `update()` call will vary slightly depending on whether you are updating one instance or several.

Implement delete()

As with `update()`, `delete()` receives a `Uri` representing the instance or collection to work with and a `WHERE` clause and parameters. If the activity is deleting a single instance, the `Uri` should represent that instance and the `WHERE` clause may be null. But, the activity might be requesting to delete an open-ended set of instances, using the `WHERE` clause to constrain which ones to delete.

As with `update()`, though, this is simple if you are using SQLite for database storage (sense a theme?). You can let it handle the idiosyncrasies of parsing and applying the `WHERE` clause — all you have to do is call `delete()` on the database.

Implement getType()

The last method you need to implement is `getType()`. This takes a `Uri` and returns the MIME type associated with that `Uri`. The `Uri` could be a collection or an instance `Uri`; you need to determine which was provided and return the corresponding MIME type.

Update the Manifest

The glue tying the content provider implementation to the rest of your application resides in your `AndroidManifest.xml` file. Simply add a `<provider>` element as a child of the `<application>` element, such as:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
    package="com.commonware.android.constants"
    android:versionCode="1"
    android:versionName="1.0">

    <supports-screens
        android:anyDensity="true"
        android:largeScreens="true"
        android:normalScreens="true"
        android:smallScreens="true"/>

    <uses-sdk
        android:minSdkVersion="14"
        android:targetSdkVersion="18"/>

    <application
        android:icon="@drawable/ic_launcher"
        android:label="@string/app_name">
        <provider
            android:name=".Provider"
            android:authorities="com.commonware.android.constants.Provider"
            android:exported="false"/>

        <activity
            android:name=".ConstantsBrowser"
            android:label="@string/app_name">
            <intent-filter>
                <action android:name="android.intent.action.MAIN"/>

                <category android:name="android.intent.category.LAUNCHER"/>
            </intent-filter>
        </activity>
    </application>
</manifest>
```

(from [ContentProvider/ConstantsPlus/app/src/main/AndroidManifest.xml](#))

CONTENT PROVIDER THEORY

The `android:name` property is the name of the content provider class, with a leading dot to indicate it is in the stock namespace for this application's classes (just like you use with activities).

The `android:authorities` property should be a semicolon-delimited list of the authority values supported by the content provider. Recall, from earlier in this chapter, that each content `Uri` is made up of a scheme, authority, data type path, and instance identifier. Each authority from each `CONTENT_URI` value should be included in the `android:authorities` list. Now, when Android encounters a content `Uri`, it can sift through the providers registered through manifests to find a matching authority. That tells Android which application and class implements the content provider, and from there Android can bridge between the calling activity and the content provider being called.

Several other attributes relate to security:

- `android:exported` indicates whether third-party apps are able to initiate communications with your provider on their own
- `android:readPermission` and `android:writePermission` allow you to defend your provider with permissions; third-party apps have to have `<uses-permission>` elements for those permissions to be able to work with your provider
- `android:grantUriPermissions` indicates whether you are able to selectively “poke pinholes in the firewall” of your provider security, to say that for specific IPC operations (e.g., starting a third-party activity), that third party has limited access to your provider's content

These will be explored later in this book.

Add Notify-On-Change Support

A feature that your content provider can offer to its clients is notify-on-change support. This means that your content provider will let clients know if the data for a given content `Uri` changes.

For example, suppose you have created a content provider that retrieves RSS and Atom feeds from the Internet based on the user's feed subscriptions (via OPML, perhaps). The content provider offers read-only access to the contents of the feeds, with an eye towards several applications on the phone using those feeds versus everyone implementing their own feed poll-fetch-and-cache system. You have also implemented a service that will get updates to those feeds asynchronously, updating

the underlying data store. Your content provider could alert applications using the feeds that such-and-so feed was updated, so applications using that specific feed can refresh and get the latest data.

On the content provider side, to do this, call `notifyChange()` on your `ContentResolver` instance (available in your content provider via `getContext().getContentResolver()`). This takes two parameters: the `Uri` of the piece of content that changed and the `ContentObserver` that initiated the change. In many cases, the latter will be `null`; a non-`null` value simply means that the observer that initiated the change will not be notified of its own changes.

On the content consumer side, an activity can call `registerContentObserver()` on its `ContentResolver` (via `getContentResolver()`). This ties a `ContentObserver` instance to a supplied `Uri` — the observer will be notified whenever `notifyChange()` is called for that specific `Uri`. When the consumer is done with the `Uri`, `unregisterContentObserver()` releases the connection.

Implementing the Streaming API

If you want to have a `ContentProvider` support streaming data via the streaming API, you will still need to set up the `<provider>` element, choose an authority, and create a subclass of `ContentProvider` as with the database-style API. From there, whether you are adding the streaming API to an existing provider or creating a new one, there is some additional work to be done.

Serving the Stream

If you want consumers of your `ContentProvider` to be able to call `openInputStream()` or `openOutputStream()` on a `Uri`, the most likely approach is to implement the `openFile()` method. The `openFile()` method returns a curious object called a `ParcelFileDescriptor`. Given that, the `ContentResolver` can obtain the `InputStream` or `OutputStream` that was requested. There are various static methods on `ParcelFileDescriptor` to create instances of it, such as an `open()` method that takes a `File` object as the first parameter. Note that this works for both files on external storage and files within your own project's app-local file storage (e.g., `getFilesDir()`).

`openFile()` also gets a `String` parameter that is the “mode” for opening the file. This can be converted into appropriate flags for use with `ParcelFileDescriptor` and its

`open()` method. Mostly, this is for determining whether we are opening the file for read or write operations.

Serving the Metadata

You should implement the `query()` method in your provider as well. If the `Uri` is pointing to one of your streams, you should create a one-row `MatrixCursor` and supply the `OpenableColumns` as the columns. `OpenableColumns` has two values: `DISPLAY_NAME` (for some human-readable name of the stream) and `SIZE` (the length of the stream in bytes). Based on the projection string array passed into `query()`, you can skip columns that the client is not requesting.

You also need to implement `getType()`. For the database-style API, you pretty much invent your own MIME types. For the streaming API, you should be returning MIME types for the `Uri` values that really represent the contents of that `Uri`. In other words, your `getType()` method should behave like you would expect a Web server to do with respect to the `Content-Type` header. If you know the MIME type for certain (e.g., you got it yourself in an HTTP or IMAP operation and saved it), use that. If you do not know the MIME type for certain, you can try the `MimeTypeMap` class, which knows how to map common file extensions to their MIME type counterparts. Worst-case, return `application/octet-stream`.

The Rest of the Requirements

You also have to implement the following abstract methods:

- `onCreate()`
- `insert()`
- `update()`
- `delete()`

If you are not supporting the database-style API, you are welcome to have `insert()`, `update()`, and `delete()` throw some `RuntimeException`, to indicate that those operations are not supported.

Issues with Content Providers

Content providers are not without their issues.

CONTENT PROVIDER THEORY

The biggest complaint seems to be the lack of an `onDestroy()` companion to the `onCreate()` method you can implement. Hence, if you open a database in `onCreate()`, you close it... never. Sometimes, you can alleviate this by initializing things on demand and releasing them immediately, such as opening a database as part of `insert()` and closing it within the same method. This does not always work, however — for example, you cannot close the database you query in `query()`, since the `Cursor` you return would become invalid. Holding onto an open `SQLiteDatabase` is not a problem, as all of your data changes are written to disk as part of committing transactions. So, many `ContentProvider` implementations settle for simply never closing the database.

The fact that `ContentProvider` is effectively a facade means that a consumer of a `ContentProvider` has no idea what to expect. It is up to documentation to explain what `Uri` values can be used, what columns can be returned, what query syntax is supported, and so on. And, the fact that it is a facade means that much of the richness of the `SQLite` interface is lost, such as `GROUP BY`. To top it off, the API supported by `ContentProvider` is rather limited — if what you want to share does not look like a database and does not look like a file, it may be difficult to force it into the `ContentProvider` API.

Another issue is the client's dependence upon the provider itself. If, for whatever reason, the provider's process is terminated while the client has an open `Cursor` on query results, the client's process is also terminated. It is unclear if the same effect occurs when the client has an open stream from a provider through the streaming API, though it seems likely. Now, in theory, the importance of the provider's process should be raised to the highest importance of any of its clients, though this behavior is not documented and may not occur in practice.

This behavior by Android is rather drastic, more drastic than what happens to HTTP clients when the Web server they are connected to crashes. There, the client winds up with some sort of exception and can move on. The moral of this story is: when working with a `ContentProvider`, it behooves you to use the data quickly, particularly if your app is in the background at the time.

Content Provider Implementation Patterns

[The previous chapter](#) focused on the concepts, classes, and methods behind content providers. This chapter more closely examines some implementations of content providers, organized into simple patterns.

Prerequisites

Understanding this chapter requires that you have read [the preceding chapter](#), along with [the chapter on permissions](#).

The Single-Table Database-Backed Content Provider

The simplest database-backed content provider is one that only attempts to expose a single table's worth of data to consumers. The `CallLog` content provider works this way, for example.

Step #1: Create a Provider Class

We start off with a custom subclass of `ContentProvider`, named, cunningly enough, `Provider`. Here we need the database-style API methods: `query()`, `insert()`, `update()`, `delete()`, and `getType()`.

CONTENT PROVIDER IMPLEMENTATION PATTERNS

onCreate()

Here is the onCreate() method for Provider, from the [ContentProvider/ConstantsPlus](#) sample application:

```
@Override
public boolean onCreate() {
    db=new DatabaseHelper(getContext());

    return(true);
}
```

(from [ContentProvider/ConstantsPlus/app/src/main/java/com/commonsware/android/constants/Provider.java](#))

While that does not seem all that special, the “magic” is in the private DatabaseHelper object, a fairly conventional SQLiteOpenHelper implementation:

```
package com.commonsware.android.constants;

import android.content.ContentValues;
import android.content.Context;
import android.database.Cursor;
import android.database.sqlite.SQLiteOpenHelper;
import android.database.sqlite.SQLiteDatabase;
import android.hardware.SensorManager;

class DatabaseHelper extends SQLiteOpenHelper {
    private static final String DATABASE_NAME="constants.db";
    static final String TITLE="title";
    static final String VALUE="value";

    public DatabaseHelper(Context context) {
        super(context, DATABASE_NAME, null, 1);
    }

    @Override
    public void onCreate(SQLiteDatabase db) {
        Cursor c=db.rawQuery("SELECT name FROM sqlite_master WHERE type='table' AND name='constants'", null);

        try {
            if (c.getCount()==0) {
                db.execSQL("CREATE TABLE constants (_id INTEGER PRIMARY KEY AUTOINCREMENT, title TEXT, value REAL);");

                ContentValues cv=new ContentValues();

                cv.put(Provider.Constants.TITLE, "Gravity, Death Star I");
                cv.put(Provider.Constants.VALUE, SensorManager.GRAVITY_DEATH_STAR_I);
                db.insert("constants", Provider.Constants.TITLE, cv);

                cv.put(Provider.Constants.TITLE, "Gravity, Earth");
                cv.put(Provider.Constants.VALUE, SensorManager.GRAVITY_EARTH);
                db.insert("constants", Provider.Constants.TITLE, cv);
            }
        } catch (Exception e) {
            e.printStackTrace();
        }
    }
}
```

CONTENT PROVIDER IMPLEMENTATION PATTERNS

```
        cv.put(Provider.Constants.TITLE, "Gravity, Jupiter");
        cv.put(Provider.Constants.VALUE, SensorManager.GRAVITY_JUPITER);
        db.insert("constants", Provider.Constants.TITLE, cv);

        cv.put(Provider.Constants.TITLE, "Gravity, Mars");
        cv.put(Provider.Constants.VALUE, SensorManager.GRAVITY_MARS);
        db.insert("constants", Provider.Constants.TITLE, cv);

        cv.put(Provider.Constants.TITLE, "Gravity, Mercury");
        cv.put(Provider.Constants.VALUE, SensorManager.GRAVITY_MERCURY);
        db.insert("constants", Provider.Constants.TITLE, cv);

        cv.put(Provider.Constants.TITLE, "Gravity, Moon");
        cv.put(Provider.Constants.VALUE, SensorManager.GRAVITY_MOON);
        db.insert("constants", Provider.Constants.TITLE, cv);

        cv.put(Provider.Constants.TITLE, "Gravity, Neptune");
        cv.put(Provider.Constants.VALUE, SensorManager.GRAVITY_NEPTUNE);
        db.insert("constants", Provider.Constants.TITLE, cv);

        cv.put(Provider.Constants.TITLE, "Gravity, Pluto");
        cv.put(Provider.Constants.VALUE, SensorManager.GRAVITY_PLUTO);
        db.insert("constants", Provider.Constants.TITLE, cv);

        cv.put(Provider.Constants.TITLE, "Gravity, Saturn");
        cv.put(Provider.Constants.VALUE, SensorManager.GRAVITY_SATURN);
        db.insert("constants", Provider.Constants.TITLE, cv);

        cv.put(Provider.Constants.TITLE, "Gravity, Sun");
        cv.put(Provider.Constants.VALUE, SensorManager.GRAVITY_SUN);
        db.insert("constants", Provider.Constants.TITLE, cv);

        cv.put(Provider.Constants.TITLE, "Gravity, The Island");
        cv.put(Provider.Constants.VALUE, SensorManager.GRAVITY_THE_ISLAND);
        db.insert("constants", Provider.Constants.TITLE, cv);

        cv.put(Provider.Constants.TITLE, "Gravity, Uranus");
        cv.put(Provider.Constants.VALUE, SensorManager.GRAVITY_URANUS);
        db.insert("constants", Provider.Constants.TITLE, cv);

        cv.put(Provider.Constants.TITLE, "Gravity, Venus");
        cv.put(Provider.Constants.VALUE, SensorManager.GRAVITY_VENUS);
        db.insert("constants", Provider.Constants.TITLE, cv);
    }
}
finally {
    c.close();
}
}

@Override
public void onUpgrade(SQLiteDatabase db, int oldVersion, int newVersion) {
    android.util.Log.w("Constants", "Upgrading database, which will destroy all old data");
    db.execSQL("DROP TABLE IF EXISTS constants");
    onCreate(db);
}
}
```

(from [ContentProvider/ConstantsPlus/app/src/main/java/com/commonsware/android/constants/DatabaseHelper.java](#))

CONTENT PROVIDER IMPLEMENTATION PATTERNS

Note that we are creating the DatabaseHelper in onCreate() and are never closing it. That is because there is no onDestroy() (or equivalent) method in a ContentProvider. While we might be tempted to open and close the database on every operation, that will not work, as we cannot close the database and still hand back a live Cursor from the database. Hence, we leave it open and assume that SQLite's transactional nature will ensure that our database is not corrupted when Android shuts down the ContentProvider.

query()

For SQLite-backed storage providers like this one, the query() method implementation should be largely boilerplate. Use a SQLiteQueryBuilder to convert the various parameters into a single SQL statement, then use query() on the builder to actually invoke the query and give you a Cursor back. The Cursor is what your query() method then returns.

For example, here is query() from Provider:

```
@Override
public Cursor query(Uri url, String[] projection, String selection,
                   String[] selectionArgs, String sort) {
    SQLiteQueryBuilder qb=new SQLiteQueryBuilder();

    qb.setTables(TABLE);

    String orderBy;

    if (TextUtils.isEmpty(sort)) {
        orderBy=Constants.DEFAULT_SORT_ORDER;
    }
    else {
        orderBy=sort;
    }

    Cursor c=
        qb.query(db.getReadableDatabase(), projection, selection,
                selectionArgs, null, null, orderBy);

    c.setNotificationUri(getContext().getContentResolver(), url);

    return(c);
}
```

(from [ContentProvider/ConstantsPlus/app/src/main/java/com/commonsware/android/constants/Provider.java](#))

CONTENT PROVIDER IMPLEMENTATION PATTERNS

We create a `SQLiteQueryBuilder` and pour the query details into the builder, notably the name of the table that we query against and the sort order (substituting in a default sort if the caller did not request one). When done, we use the `query()` method on the builder to get a `Cursor` for the results. We also tell the resulting `Cursor` what `Uri` was used to create it, for use with the content observer system.

insert()

Since this is a SQLite-backed content provider, once again, the implementation is mostly boilerplate: validate that all required values were supplied by the activity, merge your own notion of default values with the supplied data, and call `insert()` on the database to actually create the instance.

For example, here is `insert()` from `Provider`:

```
@Override
public Uri insert(Uri url, ContentValues initialValues) {
    long rowID=
        db.getWritableDatabase().insert(TABLE, Constants.TITLE,
                                       initialValues);

    if (rowID > 0) {
        Uri uri=
            ContentUris.withAppendedId(Provider.Constants.CONTENT_URI,
                                       rowID);
        getContext().getContentResolver().notifyChange(uri, null);

        return(uri);
    }

    throw new SQLException("Failed to insert row into " + url);
}
```

(from [ContentProvider/ConstantsPlus/app/src/main/java/com/commonsware/android/constants/Provider.java](https://github.com/CommonsWare/android-constants/blob/master/src/main/java/com/commonsware/android/constants/Provider.java))

The pattern is the same as before: use the provider particulars plus the data to be inserted to actually do the insertion.

update()

Here is `update()` from `Provider`:

```
@Override
public int update(Uri url, ContentValues values, String where,
```

CONTENT PROVIDER IMPLEMENTATION PATTERNS

```
        String[] whereArgs) {  
    int count=  
        db.getWritableDatabase()  
            .update(TABLE, values, where, whereArgs);  
  
    getContext().getContentResolver().notifyChange(url, null);  
  
    return(count);  
}
```

(from [ContentProvider/ConstantsPlus/app/src/main/java/com/commonsware/android/constants/Provider.java](#))

In this case, updates are always applied across the entire collection, though we could have a smarter implementation that supported updating a single instance via an instance `Uri`.

delete()

Similarly, here is `delete()` from `Provider`:

```
@Override  
public int delete(Uri url, String where, String[] whereArgs) {  
    int count=db.getWritableDatabase().delete(TABLE, where, whereArgs);  
  
    getContext().getContentResolver().notifyChange(url, null);  
  
    return(count);  
}
```

(from [ContentProvider/ConstantsPlus/app/src/main/java/com/commonsware/android/constants/Provider.java](#))

This is almost a clone of the `update()` implementation described above.

getType()

The last method you need to implement is `getType()`. This takes a `Uri` and returns the MIME type associated with that `Uri`. The `Uri` could be a collection or an instance `Uri`; you need to determine which was provided and return the corresponding MIME type.

For example, here is `getType()` from `Provider`:

```
@Override  
public String getType(Uri url) {  
    if (isCollectionUri(url)) {
```

CONTENT PROVIDER IMPLEMENTATION PATTERNS

```
    return("vnd.android.cursor.dir/constant");
}

    return("vnd.android.cursor.item/constant");
}
```

(from [ContentProvider/ConstantsPlus/app/src/main/java/com/commonsware/android/constants/Provider.java](#))

Step #2: Supply a Uri

You may wish to add a public static member... somewhere, containing the `Uri` for each collection your content provider supports, for use by your own application code. Typically, this is a public static final `Uri` put on the content provider class itself:

```
public static final Uri CONTENT_URI=
    Uri.parse("content://com.commonsware.android.constants.Provider/constants");
```

(from [ContentProvider/ConstantsPlus/app/src/main/java/com/commonsware/android/constants/Provider.java](#))

You may wish to use the same namespace for the content `Uri` that you use for your Java classes, to reduce the chance of collision with others.

Bear in mind that if you intend for third parties to access your content provider, they will not have access to this public static data member, as your class is not in their project. Hence, you will need to publish the string representation of this `Uri` that they can hard-wire into their application.

Step #3: Declare the “Columns”

Remember those “columns” you referenced when you were using a content provider, [in the previous chapter](#)? Well, you may wish to publish public static values for those too for your own content provider.

Specifically, you may want a public static class implementing `BaseColumns` that contains your available column names, such as this example from `Provider`:

```
public static final class Constants implements BaseColumns {
    public static final Uri CONTENT_URI=
        Uri.parse("content://com.commonsware.android.constants.Provider/constants");
    public static final String DEFAULT_SORT_ORDER="title";
    public static final String TITLE="title";
    public static final String VALUE="value";
}
```

(from [ContentProvider/ConstantsPlus/app/src/main/java/com/commonsware/android/constants/Provider.java](#))

CONTENT PROVIDER IMPLEMENTATION PATTERNS

Since we are using SQLite as a data store, the values for the column name constants should be the corresponding column names in the table, so you can just pass the projection (array of columns) to SQLite on a query(), or pass the ContentValues on an insert() or update().

Note that nothing in here stipulates the types of the properties. They could be strings, integers, or whatever. The biggest limitation is what a Cursor can provide access to via its property getters. The fact that there is nothing in code that enforces type safety means you should document the property types well, so people attempting to use your content provider know what they can expect.

Step #4: Update the Manifest

Finally, we need to add the provider to the AndroidManifest.xml file, by adding a <provider> element as a child of the <application> element:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
    package="com.commonware.android.constants"
    android:versionCode="1"
    android:versionName="1.0">

    <supports-screens
        android:anyDensity="true"
        android:largeScreens="true"
        android:normalScreens="true"
        android:smallScreens="true"/>

    <uses-sdk
        android:minSdkVersion="14"
        android:targetSdkVersion="18"/>

    <application
        android:icon="@drawable/ic_launcher"
        android:label="@string/app_name">
        <provider
            android:name=".Provider"
            android:authorities="com.commonware.android.constants.Provider"
            android:exported="false"/>

        <activity
            android:name=".ConstantsBrowser"
            android:label="@string/app_name">
            <intent-filter>
                <action android:name="android.intent.action.MAIN"/>
            </intent-filter>
        </activity>
    </application>
</manifest>
```

```
        <category android:name="android.intent.category.LAUNCHER" />
    </intent-filter>
</activity>
</application>

</manifest>
```

(from [ContentProvider/ConstantsPlus/app/src/main/AndroidManifest.xml](#))

The Local-File Content Provider

Implementing a content provider that supports serving up files based on `Uri` values is similar, and generally simpler, than creating a content provider for the database-style API. In this section, we will examine the [ContentProvider/Files](#) sample project. This project demonstrates a common use of the filesystem-style API: serving files from internal storage to third-party applications (who, by default, cannot read your internally-stored files).

Note that this sample project will only work on devices that have an application capable of viewing PDF files accessed via `content://Uri` values.

The FileProvider Class

Our `ContentProvider` is named `FileProvider`. However, most of the logic is contained in an `AbstractFileProvider` that will be used for a handful of sample apps in this chapter. We will look at both of those classes, focusing first on the `FileProvider`.

`onCreate()`

We have an `onCreate()` method. In many cases, this would not be needed for this sort of provider. After all, there is no database to open. In this case, we use `onCreate()` to copy the file(s) out of assets into the app-local file store. In principle, this would allow our application code to modify these files as the user uses the app (versus the unmodifiable editions in assets/).

```
@Override
public boolean onCreate() {
    File f=new File(getContext().getFilesDir(), "test.pdf");

    if (!f.exists()) {
```

CONTENT PROVIDER IMPLEMENTATION PATTERNS

```
AssetManager assets=getContext().getAssets();

try {
    copy(assets.open("test.pdf"), f);
}
catch (IOException e) {
    Log.e("FileProvider", "Exception copying from assets", e);

    return(false);
}

return(true);
}
```

(from [ContentProvider/Files/app/src/main/java/com/commonsware/android/cp/files/FileProvider.java](#))

This uses a static `copy()` method, inherited from `AbstractFileProvider`, that can copy an `InputStream` from an asset to a local `File`. We will take a peek at this later in this chapter.

openFile()

We need to implement `openFile()`, to return a `ParcelFileDescriptor` corresponding to the supplied `Uri`:

```
@Override
public ParcelFileDescriptor openFile(Uri uri, String mode)
    throws FileNotFoundException {
    File root=getContext().getFilesDir();
    File f=new File(root, uri.getPath()).getAbsolutePath();

    if (!f.getPath().startsWith(root.getPath())) {
        throw new
            SecurityException("Resolved path jumped beyond root");
    }

    if (f.exists()) {
        return(ParcelFileDescriptor.open(f, parseMode(mode)));
    }

    throw new FileNotFoundException(uri.getPath());
}
```

(from [ContentProvider/Files/app/src/main/java/com/commonsware/android/cp/files/FileProvider.java](#))

CONTENT PROVIDER IMPLEMENTATION PATTERNS

We are passed in a *nix-style string mode, which will be a value like r for read access, wt for write access (and truncate the file), etc. In API Level 19+, ParcelFileDescriptor has a convenience method for converting such modes into the equivalent ParcelFileDescriptor flag values. For older devices, you can simply use the parseMode() code that Google added:

```
// following is from ParcelFileDescriptor source code
// Copyright (C) 2006 The Android Open Source Project
// (even though this method was added much after 2006...)

private static int parseMode(String mode) {
    final int modeBits;
    if ("r".equals(mode)) {
        modeBits=ParcelFileDescriptor.MODE_READ_ONLY;
    }
    else if ("w".equals(mode) || "wt".equals(mode)) {
        modeBits=
            ParcelFileDescriptor.MODE_WRITE_ONLY
            | ParcelFileDescriptor.MODE_CREATE
            | ParcelFileDescriptor.MODE_TRUNCATE;
    }
    else if ("wa".equals(mode)) {
        modeBits=
            ParcelFileDescriptor.MODE_WRITE_ONLY
            | ParcelFileDescriptor.MODE_CREATE
            | ParcelFileDescriptor.MODE_APPEND;
    }
    else if ("rw".equals(mode)) {
        modeBits=
            ParcelFileDescriptor.MODE_READ_WRITE
            | ParcelFileDescriptor.MODE_CREATE;
    }
    else if ("rwt".equals(mode)) {
        modeBits=
            ParcelFileDescriptor.MODE_READ_WRITE
            | ParcelFileDescriptor.MODE_CREATE
            | ParcelFileDescriptor.MODE_TRUNCATE;
    }
    else {
        throw new IllegalArgumentException("Bad mode '" + mode + "'");
    }
    return modeBits;
}
```

(from [ContentProvider/Files/app/src/main/java/com/commonsware/android/cp/files/FileProvider.java](#))

CONTENT PROVIDER IMPLEMENTATION PATTERNS

Our `openFile()` method then uses `parseMode()` in the call to the static `open()` method on `ParcelFileDescriptor`, which opens the file (with the desired access mode) and gives us our `ParcelFileDescriptor` back that we can return. If the file is not found, we can throw a `FileNotFoundException` to indicate that.

However, we also check to see that the `File` that we are trying to access is inside `getFilesDir()`, by comparing paths. A `Uri` can have `..` path segments to move up directory levels. Using that with the `File` constructor means that a rogue `Uri` could move outside of our designated root directory (`getFilesDir()`), to perhaps try to access other data on our internal storage (e.g., databases). `getAbsoluteFile()` will net out any path-traversal segments (e.g., `..`). If `getAbsoluteFile()` lies within `getFilesDir()`, we go ahead, otherwise we throw a `SecurityException`.

`getDataLength()`

`AbstractFileProvider` gives us a callback — `getDataLength()` — where we can indicate how big a file is, given its `Uri`. That information will be made available to clients consuming this stream. The default will be to indicate that the file size is unknown... and that usually works. However, if it is easy for you to determine the file size, do so, and it will increase the compatibility of your app with possible consumers.

In this case, determining the size of a local file is easy:

```
@Override
protected long getDataLength(Uri uri) {
    File f=new File(getContext().getFilesDir(), uri.getPath());

    return(f.length());
}
```

(from [ContentProvider/Files/app/src/main/java/com/commonsware/android/cp/files/FileProvider.java](#))

The `AbstractFileProvider` Class

`AbstractFileProvider` is designed to handle a lot of common boilerplate for streaming providers like the one provided in this sample.

`getType()`

Just as our database-style `ContentProvider` needed to implement `getType()` to provide a MIME type given a `Uri`, so too do our streaming providers. The difference

CONTENT PROVIDER IMPLEMENTATION PATTERNS

is that a streaming provider usually wants to use “real” MIME types, values that third-party apps are likely to recognize. For example, a PDF file should use a MIME type of `application/pdf`, as that is what PDF viewing apps will expect.

Android has some convenience code for determining a likely MIME type. You can use `MimeTypeMap` to convert a file extension to a MIME type, or you can use `guessContentTypeFromName()` on `URLConnection` to get a MIME type for a URL. Both use the same underlying database — the difference is mostly a matter of whether you have a bare file extension already or not. So, the default implementation of `getType()` in `AbstractFileProvider` uses `guessContentTypeFromName()`:

```
@Override
public String getType(Uri uri) {
    return(URLConnection.guessContentTypeFromName(uri.toString()));
}
```

(from [ContentProvider/Files/app/src/main/java/com/commonsware/android/cp/files/AbstractFileProvider.java](#))

If you know that *your* MIME type is unlikely to be recognized by Android (e.g., you invented your own), a subclass of `AbstractFileProvider` could handle those cases, chaining to the superclass for other `Uri` values.

insert(), update(), and delete()

`ContentProvider` itself is abstract, requiring us to implement a variety of methods to satisfy the compiler. Three of them — `insert()`, `update()`, and `delete()` — have no role in a pure-streaming `ContentProvider`, so `AbstractFileProvider` has stub implementations:

```
@Override
public Uri insert(Uri uri, ContentValues initialValues) {
    throw new RuntimeException("Operation not supported");
}

@Override
public int update(Uri uri, ContentValues values, String where,
    String[] whereArgs) {
    throw new RuntimeException("Operation not supported");
}

@Override
public int delete(Uri uri, String where, String[] whereArgs) {
    throw new RuntimeException("Operation not supported");
}
```

CONTENT PROVIDER IMPLEMENTATION PATTERNS

(from [ContentProvider/Files/app/src/main/java/com/commonsware/android/cp/files/AbstractFileProvider.java](#))

A `ContentProvider` that supports *both* the database-style and streaming APIs will need real implementations of those methods for the database operations, perhaps throwing an `Exception` for requests to insert, update, or delete a `Uri` that represents a stream.

query() and getFileName()

We also need to implement `query()`. You can get by with having this be a stub similar to `insert()` and `kin`. However, for better compatibility, you should have a more robust `query()` implementation, as it will be used by `ContentResolver` to retrieve two pieces of metadata about a `Uri`:

- What is a valid filename to use to represent this `Uri`, should we need a human-readable name? After all, a `ContentProvider Uri` does not have to represent a human-readable path, and so the last segment of that `Uri` could be a cryptic string of hex digits or something, not a filename.
- What is the length of the data that should be delivered by the stream?

`query()` will be called with a projection that contains either `OpenableColumns.DISPLAY_NAME`, `OpenableColumns.SIZE`, or both. A streaming `ContentProvider` ideally supports returning a `Cursor` with this data. The `AbstractFileProvider` implementation of `query()` handles this for us:

```
abstract class AbstractFileProvider extends ContentProvider {
    private final static String[] OPENABLE_PROJECTION= {
        OpenableColumns.DISPLAY_NAME, OpenableColumns.SIZE };

    @Override
    public Cursor query(Uri uri, String[] projection, String selection,
        String[] selectionArgs, String sortOrder) {
        if (projection == null) {
            projection=OPENABLE_PROJECTION;
        }

        final MatrixCursor cursor=new MatrixCursor(projection, 1);

        MatrixCursor.RowBuilder b=cursor.newRow();

        for (String col : projection) {
            if (OpenableColumns.DISPLAY_NAME.equals(col)) {
                b.add(getFileName(uri));
            }
        }
    }
}
```

CONTENT PROVIDER IMPLEMENTATION PATTERNS

```
    else if (OpenableColumns.SIZE.equals(col)) {
        b.add(getDataLength(uri));
    }
    else { // unknown, so just add null
        b.add(null);
    }
}

return(new LegacyCompatCursorWrapper(cursor));
}
```

(from [ContentProvider/Files/app/src/main/java/com/commonsware/android/cp/files/AbstractFileProvider.java](#))

If the supplied projection is null, we assume that the caller wants the standard `OpenableColumns`; otherwise, we will use the supplied projection.

Our results will be packaged in a `MatrixCursor`. This amounts to a `Cursor` interface on a two-dimensional array, where you build up the rows in that array via a `MatrixCursor.RowBuilder`. In our case, there will only be one such row, for the relevant values for the file to be streamed in support of the requested `Uri`.

We iterate over the columns in the projection, calling out to `getFileName()` and `getDataLength()` methods for `OpenableColumns.DISPLAY_NAME` and `OpenableColumns.SIZE` respectively (and using `null` as the result for anything else). The default implementations of those methods return the last path segment of the `Uri` and `AssetFileDescriptor.UNKNOWN_LENGTH`, respectively:

```
protected String getFileName(Uri uri) {
    return(uri.getLastPathSegment());
}

protected long getDataLength(Uri uri) {
    return(AssetFileDescriptor.UNKNOWN_LENGTH);
}
```

(from [ContentProvider/Files/app/src/main/java/com/commonsware/android/cp/files/AbstractFileProvider.java](#))

Subclasses can override those as needed, as we saw with `getDataLength()` in the concrete `FileProvider` class.

However, `query()` does not return the `MatrixCursor` directly. Instead, it wraps it in a `LegacyCompatCursorWrapper`. This class comes from [the CWAC-Provider project](#), from the author of this book. `LegacyCompatCursorWrapper` is designed to try to improve compatibility with clients that are expecting `query()` results to include a `_DATA` column, the way that `MediaStore` does. Poorly-written clients will crash if this

CONTENT PROVIDER IMPLEMENTATION PATTERNS

column does not exist. LegacyCompatCursorWrapper wraps a Cursor and serves up an empty `_DATA` column for those clients that need one.

copy()

AbstractFileProvider also has a convenience `copy()` static method that copies an `InputStream` to a `File`, used from the `FileProvider.onCreate()` method:

```
static void copy(InputStream in, File dst) throws IOException {
    FileOutputStream out=new FileOutputStream(dst);
    byte[] buf=new byte[1024];
    int len;

    while ((len=in.read(buf)) >= 0) {
        out.write(buf, 0, len);
    }

    in.close();
    out.close();
}
}
```

(from [ContentProvider/Files/app/src/main/java/com/commonsware/android/cp/files/AbstractFileProvider.java](#))

The Manifest

Finally, we need to add the provider to the `AndroidManifest.xml` file, by adding a `<provider>` element as a child of the `<application>` element, as with any other content provider:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
    package="com.commonsware.android.cp.files"
    android:versionCode="1"
    android:versionName="1.0">

    <uses-sdk
        android:minSdkVersion="9"
        android:targetSdkVersion="11"/>

    <supports-screens
        android:largeScreens="true"
        android:normalScreens="true"
        android:smallScreens="true"/>
</manifest>
```

```
<application
  android:icon="@drawable/ic_launcher"
  android:label="@string/app_name">
  <activity
    android:name="FilesCPDemo"
    android:label="@string/app_name"
    android:theme="@android:style/Theme.Translucent.NoTitleBar">
    <intent-filter>
      <action android:name="android.intent.action.MAIN"/>

      <category android:name="android.intent.category.LAUNCHER"/>
    </intent-filter>
  </activity>

  <provider
    android:name=".FileProvider"
    android:authorities="com.commonware.android.cp.files"
    android:exported="true"/>
</application>
</manifest>
```

(from [ContentProvider/Files/app/src/main/AndroidManifest.xml](#))

Note, however, that we have `android:exported="true"` set in our `<provider>` element. This means that this content provider can be accessed from third-party apps or other external processes (e.g., the media framework for playing back videos).

Using this Provider

The activity is fairly trivial, simply creating an `ACTION_VIEW` Intent on our PDF file and starting up an activity for it, then finishing itself:

```
package com.commonware.android.cp.files;

import android.app.Activity;
import android.content.Intent;
import android.net.Uri;
import android.os.Bundle;

public class FilesCPDemo extends Activity {
    @Override
    public void onCreate(Bundle state) {
        super.onCreate(state);
    }
}
```

CONTENT PROVIDER IMPLEMENTATION PATTERNS

```
startActivity(new Intent(Intent.ACTION_VIEW,
                        Uri.parse(FileProvider.CONTENT_URI
                                + "test.pdf")));
finish();
}
```

(from [ContentProvider/Files/app/src/main/java/com/commonsware/android/cp/files/FilesCPDemo.java](#))

Here, we use a `CONTENT_URI` published by `FileProvider` as the basis for identifying the file:

```
public static final Uri CONTENT_URI=
    Uri.parse("content://com.commonsware.android.cp.files/");
```

(from [ContentProvider/Files/app/src/main/java/com/commonsware/android/cp/files/FileProvider.java](#))

The Protected Provider

The problem with the preceding example is that any app on the device, if it knows the right `Uri` to ask for, will be able to access the file. This may be desired, but often times it will not be. Instead, you may want to specifically indicate which apps, at specific points in time, can view the file.

Particularly if your objective is to start a third-party app to work with that file, setting up this sort of security is not that difficult. To see how that works, we will walk through the [ContentProvider/GrantUriPermissions](#) sample project. This is a clone of the `ContentProvider/Files` project with this extra security added on.

The way the defense works is by using [Android's permission system](#). We will mark the `ContentProvider` as being not exported, then selectively grant that access to a specific `Uri` to the app that we want to view our file.

Step #1: Mark the Provider as Not Exported

Putting `android:exported="false"` on the `<provider>` element indicates that no app has the ability to make requests of your `ContentProvider`, except for specific cases where you authorize it:

```
<provider
    android:name="FileProvider"
    android:authorities="com.commonsware.android.cp.files"
    android:exported="false"
```

CONTENT PROVIDER IMPLEMENTATION PATTERNS

```
android:grantUriPermissions="false"  
tools:ignore="ExportedContentProvider">  
<grant-uri-permission android:path="/test.pdf"/>  
</provider>
```

(from [ContentProvider/GrantUriPermissions/app/src/main/AndroidManifest.xml](#))

With no other changes, if we tried to use the app, the third-party PDF viewer would crash when trying to read our PDF file from the Uri.

Step #2: Grant Access to the Uri

To allow third parties to get access only when we specify, we need to make a few more changes.

This `<provider>` element also has `android:grantUriPermissions="false"`. That is the default value for this attribute, shown here purely for illustration purposes. It also has a `<grant-uri-permissions>` child element, listing the local path (within the `ContentProvider`) to our PDF file.

The `<grant-uri-permissions>` element (or elements, plural) allow us to override the permission requirement for certain pieces of content, granting access to that content on a per-request basis. There are three possibilities:

1. If `android:grantUriPermissions` is `true`, then we will be able to grant access to any content within our provider
2. If `android:grantUriPermissions` is `false`, but we have `<grant-uri-permissions>` sub-elements, we can only grant access to the content identified by the Uri paths specified in those sub-elements
3. If `android:grantUriPermissions` is `false`, and we have no `<grant-uri-permissions>` sub-elements (the default case), we cannot grant access to any content within our provider

In this case, we specify that we will only grant access to `/test.pdf`. Since that is the only content in this provider, we could have the same net effect by setting `android:grantUriPermissions` to `true`.

Then, when we create an Intent used to interact with another component, we can include a flag indicating what permission we wish to grant:

```
package com.commonware.android.cp.perms;  
  
import android.app.Activity;
```

CONTENT PROVIDER IMPLEMENTATION PATTERNS

```
import android.content.Intent;
import android.net.Uri;
import android.os.Bundle;

public class FilesCPDemo extends Activity {
    @Override
    public void onCreate(Bundle state) {
        super.onCreate(state);

        Intent i=new Intent(Intent.ACTION_VIEW, Uri.parse(FileProvider.CONTENT_URI + "test.pdf"));

        i.addFlags(Intent.FLAG_GRANT_READ_URI_PERMISSION);
        startActivity(i);
        finish();
    }
}
```

(from [ContentProvider/GrantUriPermissions/app/src/main/java/com/commonsware/android/cp/perms/FilesCPDemo.java](#))

In this revised version of our activity, we add `FLAG_GRANT_READ_URI_PERMISSION` to the Intent used with `startActivity()`. This will grant the activity that responds to our Intent read access to the specific Uri in the Intent, overriding the exported status. That is why, when you run this app on a device, the PDF viewer will still be able to view the file.

There is also `FLAG_GRANT_WRITE_URI_PERMISSION` for granting write access, not needed here, as our provider only supports read access.

While this is most commonly used with `startActivity()` (e.g., allowing a mail program limited access to your attachments provider), this can also be used with `startService()`, `bindService()`, and the various flavors of sending broadcasts (e.g., `sendBroadcast()`).

The Stream Provider

Sometimes, we want a provider that looks like the local-file provider from the preceding section... but we do not have a file. Instead, we have data in some other form, such as a byte array, or a String, or an InputStream. Writing that material to a file may be problematic, or even counterproductive.

For example, imagine an app that stores data on the user's behalf in an encrypted fashion. One such file is a PDF, that the user would like to view. There are PDF viewers that can view files served via `content://Uri` values, as the previous section demonstrated... but that assumes an unencrypted file. While we could decrypt the file, writing the decrypted results to another file, and serve the decrypted data to the PDF viewer, now we have a persistent decrypted version of the data. That opens a

window of time when the data might be accessed by people with nefarious intent, which is something we are trying to avoid by using the encrypted store in the first place. Rather, it would be nice if we could decrypt the data *on the fly* and give that decrypted result to the PDF viewer. Of course, there are security risks intrinsic to that too — after all, we do not know what the PDF viewer might do with the unencrypted data — but it is at least an improvement.

The good news is that Android does support streaming options for `openFile()`-style `ContentProvider` implementations. However, as one might expect, they are not the simplest things to implement.

In this section, we will examine the [ContentProvider/Pipe](#) sample project. This is a near clone of the `ContentProvider/Files` sample from the preceding section. However, rather than simply handing the file to Android to serve as content, we will stream it in ourselves. In principle, as part of this streaming, we could be decrypting it from an encrypted state. Since this sample shares much code with the previous sample, we will focus solely on the changes here.

Note that this sample was inspired by the sample found at <https://github.com/nandeeshwar/Pfd-Create-Pipe>.

The Pipes

Starting with API Level 9, it is possible to create a pipe between two processes, from the Android SDK, via `ParcelFileDescriptor`. In the previous section, we saw how `ParcelFileDescriptor` could be used to open a local file and make that available to other processes — the `createPipe()` method gives us a pipe.

The “pipe” returned by `createPipe()` is a two-element array of `ParcelFileDescriptor` objects. The first element in the array represents the “read” end of the pipe. In our case, that is the end that should be used by a PDF viewer to read in the file contents. The second element of the array represents the “write” end of the pipe, which we will use to supply the file’s contents to the “read” end (and to the PDF viewer by extension).

The Revised `openFile()`

With that in mind, here is our revised `openFile()` method:

```
@Override
public ParcelFileDescriptor openFile(Uri uri, String mode)
```

CONTENT PROVIDER IMPLEMENTATION PATTERNS

```
throws FileNotFoundException {
ParcelFileDescriptor[] pipe=null;

try {
    pipe=ParcelFileDescriptor.createPipe();
    AssetManager assets=getContext().getAssets();

    new TransferThread(assets.open(uri.getLastPathSegment()),
        new AutoCloseOutputStream(pipe[1])).start();
}
catch (IOException e) {
    Log.e(getClass().getSimpleName(), "Exception opening pipe", e);
    throw new FileNotFoundException("Could not open pipe for: "
        + uri.toString());
}

return(pipe[0]);
}
```

(from [ContentProvider/Pipe/app/src/main/java/com/commonsware/android/cp/pipe/PipeProvider.java](#))

We create our pipe via `createPipe()`, then get an `InputStream` on our PDF file stored as an asset — unlike the `ContentProvider/Files` sample, we do not need to copy the asset to a local file now. We then kick off a background thread, implemented in an inner class named `TransferThread`, to actually copy the data from the asset to the write end of the pipe.

Rather than supply `TransferThread` with a `ParcelFileDescriptor` for the write end of the pipe, we supply an `OutputStream`. Specifically, we pass in a `ParcelFileDescriptor.AutoCloseOutputStream`. This is an `OutputStream` that knows to close the `ParcelFileDescriptor` when we close the stream. Otherwise, it behaves like a fairly typical `OutputStream`.

The Transfer

`TransferThread` is a fairly conventional copy-data-from-stream-to-stream implementation:

```
static class TransferThread extends Thread {
    InputStream in;
    OutputStream out;

    TransferThread(InputStream in, OutputStream out) {
        this.in=in;
        this.out=out;
    }
}
```

```
}

@Override
public void run() {
    byte[] buf=new byte[1024];
    int len;

    try {
        while ((len=in.read(buf)) >= 0) {
            out.write(buf, 0, len);
        }

        in.close();
        out.flush();
        out.close();
    }
    catch (IOException e) {
        Log.e(getClass().getSimpleName(),
            "Exception transferring file", e);
    }
}
}
```

(from [ContentProvider/Pipe/app/src/main/java/com/commonsware/android/cp/pipe/PipeProvider.java](#))

Here, we read in data in 1KB blocks from the `InputStream` (our asset) and write the data to our `OutputStream` (obtained from the `ParcelFileDescriptor`).

The Results

Our activity logic has not substantially changed. We still create an `ACTION_VIEW` Intent on the `content://Uri` from our provider, pointing to our `test.pdf` asset. Any PDF viewer capable of handling `content://Uri` values will use a `ContentResolver` to open an `InputStream` for our `Uri`. In the `ContentProvider/Files` sample, that `InputStream` would receive the contents of the file directly from Android. In this new sample, that `InputStream` is reading in bytes off of our pipe, until such time as it has read in all the streamed data and we have closed the `OutputStream`.

Not every possible consumer of a `Uri` will be able to work with our stream, though. For example, `MediaPlayer` expects to be able to move forwards and backwards within the stream, and while that works for file-backed `ParcelFileDescriptors`, it does not work for those representing a pipe. Hence, `MediaPlayer` will crash when trying to use a `Uri` to a pipe-based stream, which is certainly unfortunate.

The author would like to thank Reuben Scratton for his assistance in [tracking down this MediaPlayer limitation](#).

FileProvider

The Android Support package now contains its own implementation of a FileProvider that greatly simplifies serving files from internal or external storage to another app.

Here, we will see Google's FileProvider in action via the [ContentProvider/V4FileProvider](#) sample project. This is a near clone of the ContentProvider/Pipe sample from the preceding section, just leveraging FileProvider to help us serve a file from internal storage.

The Rationale

The [documentation for FileProvider](#) states:

Apps should generally avoid sending raw filesystem paths across process boundaries, since the receiving app may not have the same access as the sender. Instead, apps should send Uri backed by a provider like FileProvider.

This is not just an issue for passing files from internal storage to other apps. On Android 4.2+ tablets, it could even be an issue for external storage, as each user account gets its own portion of external storage. There may be scenarios in which your app (associated with one user) winds up needing to pass the contents of a file on external storage to another app (associated with another user). Regular filesystem paths will not work in this case, as one user account cannot directly access another user account's files, even on external storage.

The Sources of Files

Google's FileProvider offers automatic serving of files from a few root points:

- `getFilesDir()` (i.e., the standard portion of internal storage for your app)
- `getCacheDir()` (i.e., internal storage, but files that the OS can purge if needed to free up disk space)
- `Environment.getExternalStorageDirectory()` (i.e., the root of external storage)

CONTENT PROVIDER IMPLEMENTATION PATTERNS

- `getExternalFilesDir(null)` and `getExternalCacheDir()` (i.e., unique directories on external storage for your app)

For each of these, you will be able to specify a specific subdirectory's worth of files that should be served, if you do not want the entire directory's contents published via `FileProvider`. You will also be able to specify an alias, which serves as the first path segment (after the authority in the `content://Uri`) — `FileProvider` maps that path segment to a specific location of files to serve.

The Manifest Entry

The information about what files to serve comes in the form of an XML resource file. You can name the file whatever you like, but its content needs to be a root `<paths>` element, with a series of children for the different directories you wish to serve. Those directories will be denoted via child elements with specific names:

- `<files-path>` for `getFilesDir()`
- `<cache-path>` for `getCacheDir()`
- `<external-path>` for `Environment.getExternalStorageDirectory()`
- `<external-files-path>` for `getExternalFilesDir(null)`
- `<external-cache-path>` for `getExternalCachePath()`

Note that the latter two require version 24.2.0 or higher of the support library, as they are fairly new.

For example, our sample project has a `res/xml/provider_paths.xml` file with the following contents:

```
<?xml version="1.0" encoding="utf-8"?>
<paths>
  <files-path name="stuff" />
</paths>
```

(from [ContentProvider/V4FileProvider/app/src/main/res/xml/provider_paths.xml](#))

Here, we are saying that we want to serve the contents of `getFilesDir()`, using a virtual root path of `stuff`. With an authority of `com.commonware.android.cp.v4file`, this means that a `Uri` of `content://com.commonware.android.cp.v4file/stuff/test.pdf` would serve up a `test.pdf` file in the `getFilesDir()` directory.

CONTENT PROVIDER IMPLEMENTATION PATTERNS

The optional path attribute of the `<files-path>`, etc. elements indicates a particular subdirectory, relative to the element-specific root, that should be used as the source of files. So, for example, had the `provider_paths.xml` file looked like:

```
<?xml version="1.0" encoding="utf-8"?>
<paths xmlns:android="http://schemas.android.com/apk/res/android">
  <files-path name="stuff" path="help/" />
</paths>
```

...then `content://com.commonware.android.cp.v4file/stuff/test.pdf` would map to `help/test.pdf` inside of `getFilesDir()`.

You then point to this XML resource from a `<meta-data>` element in the `<provider>` element in the manifest, teaching `FileProvider` what to serve. For example, our `<provider>` element in this sample app is:

```
<provider
  android:name="LegacyCompatFileProvider"
  android:authorities="com.commonware.android.cp.v4file"
  android:exported="false"
  android:grantUriPermissions="true">
  <meta-data
    android:name="android.support.FILE_PROVIDER_PATHS"
    android:resource="@xml/provider_paths"/>
</provider>
```

(from [ContentProvider/V4FileProvider/app/src/main/AndroidManifest.xml](#))

Here, our `android:name` points to a `LegacyCompatFileProvider` class that we will examine shortly. We still provide the `android:authorities` value, along with any permission rules that we want. Beyond that, we have a `<meta-data>` element, with an `android:name` of `android.support.FILE_PROVIDER_PATHS`, that points to our XML resource with the path information.

You will also notice that our `android:exported` attribute is set to `false`. As it turns out, `FLAG_GRANT_READ_URI_PERMISSION` trumps the exported status of a provider. If you pass a `Uri` to an activity using `FLAG_GRANT_READ_URI_PERMISSION`, the activity will be able to read the contents of that `Uri`, even if the provider itself is not exported.

The Legacy Compatibility

LegacyCompatFileProvider is a simple subclass of FileProvider, one that overrides query() and wraps its Cursor in a LegacyCompatCursorWrapper to try to improve compatibility with ill-behaved clients:

```
package com.commonware.android.cp.v4file;

import android.database.Cursor;
import android.net.Uri;
import android.support.v4.content.FileProvider;
import com.commonware.cwac.provider.LegacyCompatCursorWrapper;

public class LegacyCompatFileProvider extends FileProvider {
    @Override
    public Cursor query(Uri uri, String[] projection, String selection, String[] selectionArgs, String
sortOrder) {
        return(new LegacyCompatCursorWrapper(super.query(uri, projection, selection, selectionArgs,
sortOrder)));
    }
}
```

(from [ContentProvider/V4FileProvider/app/src/main/java/com/commonware/android/cp/v4file/LegacyCompatFileProvider.java](#))

The Usage

At this point, the provider is ready for use, insofar as we can specify Uri values like content://com.commonware.android.cp.v4file/stuff/test.pdf and get results. Of course, we actually need to have files in our internal storage, and we need to use such a Uri.

Hence, our activity combines the unpack-the-file-from-assets logic from our own providers in earlier samples, plus starts up a PDF viewer on our designated test.pdf file:

```
package com.commonware.android.cp.v4file;

import android.app.Activity;
import android.content.Intent;
import android.content.res.AssetManager;
import android.os.Bundle;
import android.support.v4.content.FileProvider;
import android.util.Log;
import java.io.File;
import java.io.FileOutputStream;
import java.io.IOException;
import java.io.InputStream;
```

CONTENT PROVIDER IMPLEMENTATION PATTERNS

```
public class FilesCPDemo extends Activity {
    private static final String AUTHORITY="com.commonware.android.cp.v4file";

    @Override
    public void onCreate(Bundle state) {
        super.onCreate(state);

        File f=new File(getFilesDir(), "test.pdf");

        if (!f.exists()) {
            AssetManager assets=getAssets();

            try {
                copy(assets.open("test.pdf"), f);
            }
            catch (IOException e) {
                Log.e("FileProvider", "Exception copying from assets", e);
            }
        }

        Intent i=
            new Intent(Intent.ACTION_VIEW,
                FileProvider.getUriForFile(this, AUTHORITY, f));

        i.addFlags(Intent.FLAG_GRANT_READ_URI_PERMISSION);

        startActivity(i);
        finish();
    }

    static private void copy(InputStream in, File dst) throws IOException {
        FileOutputStream out=new FileOutputStream(dst);
        byte[] buf=new byte[1024];
        int len;

        while ((len=in.read(buf)) > 0) {
            out.write(buf, 0, len);
        }

        in.close();
        out.close();
    }
}
```

(from [ContentProvider/V4FileProvider/app/src/main/java/com/commonware/android/cp/v4file/FilesCPDemo.java](#))

FileProvider offers a handy `getUriForFile()` static helper method that will return a `Uri` for a given file, incorporating our specified content provider authority.

The result of running this activity is the same as the other file-serving provider samples from this chapter: a PDF viewer (if one is available) will display the `test.pdf` file.

StreamProvider

`FileProvider` is rather nice: you can serve up typical file-based content without having to roll your own implementation of `ContentProvider` and `openFile()`. However, it only supports a few sources of data.

The author of this book has written `StreamProvider`, a fork of `FileProvider` that adds support for serving content from assets and raw resources. Plus, through subclassing, you can readily serve up content from other sources as well. `StreamProvider` can be found in [the CWAC-Provider project](#).

You can add this library to your Android Studio project much in the same way as you can other CWAC libraries: add the CWAC repository and request the dependency:

```
repositories {
    maven {
        url "https://s3.amazonaws.com/repo.commonsware.com"
    }
}

dependencies {
    implementation 'com.commonsware.cwac.provider:0.5.0'
}
```

Once you have added the CWAC-Provider dependency to your project, you use it much the same as you would use `FileProvider`:

- Define an XML metadata file with a `<paths>` root element, containing one or more elements describing what you want the provider to serve
- Add `com.commonsware.cwac.provider.StreamProvider` as a `<provider>` to your manifest, under your own `android:authority`, with a `<meta-data>` element (with a name of `com.commonsware.cwac.provider.STREAM_PROVIDER_PATHS`), pointing to that XML metadata

```
<provider
    android:name="com.commonsware.cwac.provider.StreamProvider"
```

CONTENT PROVIDER IMPLEMENTATION PATTERNS

```
android:authorities="..."
android:exported="false"
android:grantUriPermissions="true">
<meta-data
  android:name="com.commonware.cwac.provider.STREAM_PROVIDER_PATHS"
  android:resource="@xml/..." />
<meta-data
  android:name="com.commonware.cwac.provider.USE_LEGACY_CURSOR_WRAPPER"
  android:value="true" />
</provider>
```

- Consider adding the `USE_LEGACY_CURSOR_WRAPPER` `<meta-data>` element, shown in the above example, to automatically add in `LegacyCompatCursorWrapper` support, described elsewhere in this chapter
- Use `FLAG_GRANT_READ_URI_PERMISSION` and `FLAG_GRANT_WRITE_URI_PERMISSION` in Intent objects you use to have third parties use the files the `StreamProvider` serves, to allow those apps selective, temporary access to the file

Exporting and Usage Patterns

If your `StreamProvider` is exported, all of your streams will be considered read-only, regardless of any other configuration. Mostly, this mode is here for cases where you need a streaming provider and cannot grant `Uri` permissions (e.g., [implementing a ChooserTargetService](#)).

If your `StreamProvider` is not exported, and it has `android:grantUriPermissions` set, then you can control, on a per-`Uri` basis, which clients get access to your streams. This works identically to how `FileProvider` works. Whether a particular source of streams is read-only or read-write will depend on whether the stream is a file and your metadata configuration.

Wherever possible, elect to not export the provider and use `FLAG_GRANT_READ_URI_PERMISSIONS` or similar techniques to selectively grant access to your content.

Note that the exported-and-read-only rule is on a per-provider basis. If you have some content that needs to be published globally and others that are not:

- Use `StreamProvider` and one `<provider>` element for one set of content, with one authority and `android:exported` setting

- Subclass `StreamProvider` and have a separate `<provider>` element for the other set of content, with a separate authority and `android:exported` setting

Metadata Elements

Google's `FileProvider` supports:

- `<files-path>` for serving files from your app's `getFilesDir()`
- `<external-path>` for serving files from `Environment.getExternalStoragePublicDirectory()`
- `<cache-path>` for serving files from your app's `getCacheDir()`
- `<external-files-path>` for serving files from `getExternalFilesDir()`
- `<external-cache-path>` for serving files from `getExternalCacheDir()`

Each of those take a name attribute, indicating the first path segment of the `Uri` that should identify this particular source of files. For example, a name of `foo` would mean that `content://your.authority.here/foo/...` would look for a `...` file in that particular element's source of files.

Each of those optionally take a `path` attribute, indicating a subdirectory under the element-defined root to use as the source of files, rather than the root itself. So, a `<files-path>` with a `path="stuff"` attribute would serve files from the `stuff/` subdirectory within `getFilesDir()`. Note that `path` can point to a file as well, to limit access to a single file rather than a directory. Note that `path` is required for `<files-path>`, so you do not accidentally serve everything under `getFilesDir()`.

Also, each can optionally take a `readOnly` attribute. If this is set to `true`, then the files will be readable, but not writeable.

`<external-files-path>` also can take an optional `dir` attribute. If missing, the files are served from `getExternalFilesDir()`. If a valid value of `dir` is supplied, that value is passed into `getExternalFilesDir()`. As such, `dir` is limited to be one of the `Environment.DIRECTORY_*` constants:

- `Alarms`
- `DCIM`
- `Documents`
- `Download`
- `Movies`
- `Music`
- `Notifications`

CONTENT PROVIDER IMPLEMENTATION PATTERNS

- Pictures
- Podcasts
- Ringtones

However, you cannot have *both* `<external-files-path>` with no `dir` (indicating that you are serving from `getExternalFilesDir(null)`) *and* one or more `<external-files-path>` elements with `dir` values, as they will conflict.

`StreamProvider` adds support for:

- `<raw-resource>` for serving a particular raw resource, where the path is the name of the raw resource (without file extension)
- `<asset>` for serving files from `assets/`
- `<dir-path>`, for serving files from locations identified by `getDir()`
- `<external-public-path>`, for serving files from locations identified by `Environment.getExternalStoragePublicDirectory()`

Hence, `StreamProvider` is especially useful when you want to package some content — such as a PDF file for online help — that you want to serve from your app. Just drop the file in `assets/` in your project, set up `StreamProvider` to serve up assets, and use an appropriate `Intent` with `startActivity()` to view that file.

In the case of `<dir-path>`, two attributes are required:

- `dir`, which indicates what directory to serve (this is passed into `getDir()`)
- `path`, which serves its normal role, to determine what to serve from the directory identified by `dir`

In the case of `<external-public-path>`, `dir` is required. It needs to be the string value of one of the `Environment.DIRECTORY_*` constants, listed above.

Assets and Gradle

For files you are looking to share from your app's `assets/`, you will need to teach the build system to avoid compressing those files. While annoying, it helps `StreamProvider` be more compatible with various client apps.

To do this, add an `aaptOptions` closure to your `android` closure in your module's `build.gradle` file. For example, you might have:

CONTENT PROVIDER IMPLEMENTATION PATTERNS

```
android {
    compileSdkVersion 25
    buildToolsVersion "25.0.0"

    aaptOptions {
        noCompress 'pdf', 'mp4', 'ogg'
    }
}
```

This would tell Gradle and the build system to not compress files ending in pdf, mp4, and ogg. For your own project, you would choose the file extensions of relevance for the content that you are looking to serve out of assets/.

I Can Haz Uri?

FileProvider has the static `getUriForFile()` convenience method, to build a `Uri` pointing to the FileProvider, given the `File` that you wish to serve.

StreamProvider has a similar `getUriForFile()` method, with three key differences:

1. It only takes the authority string and the `File`; no `Context` is necessary
2. It only works for files, not assets or raw resources
3. Rather than throwing an exception for an unrecognized `File` (the way `FileProvider` does), `StreamProvider` just returns `null`, indicating that the `File` you requested is not one that the `StreamProvider` is configured to serve

So, you can call `StreamProvider.getUriForFile(AUTHORITY, f)`, for some `String` for your `AUTHORITY` and some `File` (here named `f`) to get a `Uri` pointing to that file, for the purposes of using that `Uri` in an `Intent`, etc.

Uri Prefixes

Activities that support `ACTION_SEND` through an appropriate `<intent-filter>` are likely to have a flaw: they probably do not validate the `Uri` being supplied via `EXTRA_STREAM`. The [“surreptitious sharing” attack](#) takes advantage of this, tricking the app into sharing *its own content*. While the researchers who reported this flaw focused on `file:Uri` schemes, `content:is` also vulnerable, if your provider’s `Uri` values are predictable.

To help defeat this attack, `StreamProvider` automatically adds a per-install `UUID` to each `Uri`. So, instead of:

`content://your.authority.here/something/and/a/relative/path.xml`

the `Uri` will be something like:

`content://your.authority.here/9b80af30-4507-4f34-956a-3b47e4a7f27f/
something/and/a/relative/path.xml`

By using a UUID unique for this installation of your app, it makes your `Uri` values dependent upon the device. This makes it more difficult for attackers to hand you a valid `Uri` to your own content to send somewhere that you might not want.

On the flip side, this makes constructing your own `Uri` values a bit more difficult. For files, you can use the `getUriForFile()` method. For assets and raw resources, you can call the static `getUriPrefix()` method to get the prefix that is being used, and add that to your `Uri`, such as by using a `Uri.Builder`:

```
PROVIDER
    .buildUpon()
    .appendPath(StreamProvider.getUriPrefix(AUTHORITY))
    .appendPath(path)
    .build()
```

`getUriPrefix()` takes the authority string of your `StreamProvider` and returns the prefix... or null, if by subclassing `StreamProvider`, you disabled this prefix.

Extending StreamProvider

You are welcome to create subclasses of `StreamProvider`, to extend its capabilities for things that you may want to do in your app. For example, the instrumentation tests for `StreamProvider` demonstrate creating a subclass that supports serving database files, via a custom `<database-path>` element in the metadata.

By and large, you just create a subclass of `StreamProvider` and use it in your `<provider>` element. Of importance are the hooks in `StreamProvider` to allow subclasses to change critical behavior.

Customizing the Uri Prefix

In your subclass, you have three options for changing the Uri prefix used by `StreamProvider`:

- If you want a per-install value, but just not a UUID, override `buildUriPrefix()` and return your own generated `String`
- If you want a fixed prefix, to be used for all installs of this provider, override `getUriPrefix()` and return your constant
- If you do not want a prefix, override `getUriPrefix()` and return `null`

Supporting Other Stream Locations

You may have content located in directories other than what `StreamProvider` supports out of the box, such as the path for SQLite databases. To handle that, you can add support for new XML elements in the `<paths>` element (e.g., `<database-path>` for serving up databases).

To do this, in your `StreamProvider` subclass, override `buildStrategy()` and return a `StreamStrategy` implementation that is configured for your scenario. For files located in unusual spots, `LocalPathStrategy` should work.

In the library's `androidTest/` source set, you will find a `DatabaseProvider` that, at the time of this writing, looks like this:

```
public class DatabaseProvider extends StreamProvider {
    private static final String TAG="database-path";

    @Override
    protected StreamStrategy buildStrategy(Context context,
                                           String tag, String name,
                                           String path, boolean readOnly,
                                           HashMap<String, String> attrs)
        throws IOException {
        if (TAG.equals(tag)) {
            return(new LocalPathStrategy(name,
                context.getDatabasePath(path)));
        }

        return(super.buildStrategy(context, tag, name, path, attrs));
    }
}
```

The parameters to `buildStrategy()` are:

- a `Context`, should you need one (though do not assume it is any particular sort of `Context`)
- the tag we encountered (e.g., `database-path`)
- the value of the `name` attribute, which all of these need to have, as that is how we determine which `StreamStrategy` handles this request
- the value of the `path` attribute, which can be `null`
- a `HashMap` of all attributes, in case you wish to have some custom ones

Either return your own `StreamStrategy` instance based off of this information or chain to the superclass' implementation, so `StreamProvider` can handle the stock tags.

If your provider is intrinsically read-only (i.e., it is impossible to modify the content), you can ignore the `readOnly` flag. If, however, your content could be modified, and you support modification, please honor the `readOnly` flag and block modifications/deletions when that is set to `true`.

Supporting Other Stream Strategies

You may have content located in things that are not files, such as `BLOB` columns in a database. In theory, you can create a custom `StreamStrategy` implementation that handles this. However, this has not been tried much, and so there are likely to be some gaps in the implementation.

That being said, you can examine the built-in strategies (e.g., `AssetStrategy`, `LocalPathStrategy`) and their superclasses (e.g., `AbstractPipeStrategy`) to see how to implement strategies.

Adding Columns to `query()`

You may wish to add other columns in response to a `query()` call, beyond the `OpenableColumns` that `StreamProvider` handles itself and the `_DATA` and `MIME_TYPE` columns added by `LegacyCompatCursorWrapper`.

To do that, override `getValueForQueryColumn()` in your `StreamProvider` subclass. This is supplied the `Uri` of the content and the name of the column requested by the client. You can return an `Object` suitable for stuffing into a `MatrixCursor` to send back – typically, this will be a `String`, `int`, or `long`.

Totally Overhauling Uri Handling

StreamProvider itself holds onto a CompositeStreamStrategy, delegating all operations to it. If you wish to extend CompositeStreamStrategy and do things differently, also override buildCompositeStrategy() on your StreamProvider subclass, to return the instance of the CompositeStreamStrategy that you want the StreamProvider to use.

Overriding Standard Methods

You can override standard ContentProvider methods (e.g., getType()) if needed.

Alternatively, you can override the methods on a StreamStrategy, then use that alternative StreamStrategy implementation in your buildStrategy() method.

Adding Support for insert() and update()

By default, none of the StreamStrategy implementations support insert() or update(). However, your custom StreamStrategy can, whether you are extending one of the stock strategy classes or are implementing your own from scratch.

First, override canInsert() and/or canUpdate(), returning true for those operations you do support. Then, you can override insert() and update(), which have the same method signatures on StreamStrategy as they do on ContentProvider. There, you can do what you wish.

The Loader Framework

One perpetual problem in Android development is getting work to run outside the main application thread. Every millisecond we spend on the main application thread is a millisecond that our UI is frozen and unresponsive. Disk I/O, in particular, is a common source of such slowdowns, particularly since this is one place where the emulator typically out-performs actual devices. While disk operations rarely get to the level of causing an “application not responding” (ANR) dialog to appear, they can make a UI “janky”.

Android 3.0 introduced a new framework to help deal with loading bulk data off of disk, called “loaders”. The hope is that developers can use loaders to move database queries and similar operations into the background and off the main application thread. That being said, loaders themselves have issues, not the least of which is the fact that it is new to Android 3.0 and therefore presents some surmountable challenges for use in older Android devices.

This chapter will outline the programming pattern loaders are designed to solve, how to use loaders (both built-in and third-party ones) in your activities, and how to create your own loaders for scenarios not already covered.

Prerequisites

Understanding this chapter requires that you have read the chapters on:

- [database access](#)
- [content provider theory](#)
- [content provider implementations](#)

Cursors: Issues with Management

Android had the concept of “managed cursors” in Android 1.x/2.x. A managed Cursor was one that an Activity... well... manages. More specifically:

1. When the activity was stopped, the managed Cursor was deactivated, freeing up all of the memory associated with the result set, and thereby reducing the activity’s heap footprint while it was not in the foreground
2. When the activity was restarted, the managed Cursor was requeryed, to bring back the deactivated data, along the way incorporating any changes in that data that may have occurred while the activity was off-screen
3. When the activity was destroyed, the managed Cursor was closed.

This is a delightful set of functionality. Cursor objects obtained from a ContentProvider via `managedQuery()` were automatically managed; a Cursor from `SQLiteDatabase` could be managed by `startManagingCursor()`.

The problem is that the `requery()` operation that was performed when the activity is restarted is executed on the main application thread. As has been noted elsewhere in the book, you *really* do not want to do disk I/O on the main application thread, as it freezes the UI and causes jank. This is particularly true for database I/O, where you may not know in advance exactly how much data you will get back or how long the query will take.

Introducing the Loader Framework

The Loader framework was designed to solve three issues with the old managed Cursor implementation:

- Arranging for a `requery()` (or the equivalent) to be performed on a background thread)
- Arranging for the original query that populated the data in the first place to also be performed on a background thread, which the managed Cursor solution did not address at all
- Supporting loading things other than a Cursor, in case you have data from other sources (e.g., XML files, JSON files, Web service calls) that might be able to take advantage of the same capabilities as you can get from a Cursor via the loaders

There are three major pieces to the Loader framework: LoaderManager, LoaderCallbacks, and the Loader itself.

LoaderManager

LoaderManager is your gateway to the Loader framework. You obtain one by calling `getLoaderManager()` (or `getSupportLoaderManager()`, as is described [later in this chapter](#)). Via the LoaderManager you can initialize a Loader, restart that Loader (e.g., if you have a different query to use for loading the data), etc.

LoaderCallbacks

Much of your interaction with the Loader, though, comes from your LoaderCallbacks object, such as your activity if that is where you elect to implement the LoaderCallbacks interface. Here, you will implement three “lifecycle” methods for consuming a Loader:

1. `onCreateLoader()` is called when your activity requests that a LoaderManager initialize a Loader. Here, you will create the instance of the Loader itself, teaching it whatever it needs to know to go load your data
2. `onLoadFinished()` is called when the Loader has actually loaded the data — you can take those results and pour them into your UI, such as calling `swapCursor()` on a CursorAdapter to supply the fresh Cursor’s worth of data
3. `onLoaderReset()` is called when you should stop using the data supplied to you in the last `onLoadFinished()` call (e.g., the Cursor is going to be closed), so you can arrange to make that happen (e.g., call `swapCursor(null)` on a CursorAdapter)

When you implement the LoaderCallbacks interface, you will need to provide the data type of whatever it is that your Loader is loading (e.g., `LoaderCallbacks<Cursor>`). If you have several loaders returning different data types, you may wish to consider implementing LoaderCallbacks on multiple objects (e.g., instances of anonymous inner classes), so you can take advantage of the type safety offered by Java generics, rather than implementing `LoaderCallbacks<Object>` or something to that effect.

Loader

Then, of course, there is Loader itself.

Consumers of the Loader framework will use some concrete implementation of the abstract Loader class in their LoaderCallbacks onCreateLoader() method. API Level 11 introduced only one concrete implementation: CursorLoader, designed to perform queries on a ContentProvider, and described in [a later section](#).

Choosing an Implementation

Loader and its related classes were introduced in API Level 11 (Android 3.0). If your minSdkVersion is 11 or higher, you can use loaders “naturally” via the standard implementation.

If your minSdkVersion is below 11, the Android Support package offers its own implementation of Loader and the other classes. However, to use it, you will need to work within four constraints:

- You will need to add support-v4 from the Android Support package as a dependency, directly or indirectly. For example, if you are using appcompat-v7, you are already pulling in support-v4.
- You will need to inherit from FragmentActivity, not the OS base Activity class or other refinements (e.g., MapActivity), or from other classes that inherit from FragmentActivity (e.g., AppCompatActivity).
- You will need to import the support.v4 versions of various classes (e.g., android.support.v4.app.LoaderManager instead of android.app.LoaderManager)
- You will need to get your LoaderManager by calling getSupportLoaderManager(), instead of getLoaderManager(), on your FragmentActivity

These limitations are the same ones that you will encounter when using fragments on older devices. Hence, while loaders and fragments are not really related, you may find yourself adopting both of them at the same time, as part of incorporating the Android Support package into your project.

Using CursorLoader

Let’s start off by examining the simplest case: using a CursorLoader to asynchronously populate and update a Cursor retrieved from a ContentProvider. This is illustrated in the [Loaders/ConstantsLoader](#) sample project, which is the same show-the-list-of-gravity-constants sample application that [we examined previously](#), updated to use the Loader framework. Note that this project does not

THE LOADER FRAMEWORK

use the Android Support package and therefore only supports API Level 11 and higher.

In `onCreate()`, rather than executing a `managedQuery()` to retrieve our constants, we ask our `LoaderManager` to initialize a loader, after setting up our `SimpleCursorAdapter` on a null `Cursor`:

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    adapter=new SimpleCursorAdapter(this,
        R.layout.row, null,
        new String[] {Provider.Constants.TITLE,
            Provider.Constants.VALUE},
        new int[] {R.id.title, R.id.value});

    setListAdapter(adapter);
    registerForContextMenu(getListView());
    getLoaderManager().initLoader(0, null, this);
}
```

(from [Loaders/ConstantsLoader/app/src/main/java/com/commonsware/android/loader/ConstantsBrowser.java](#))

Using a null `Cursor` means we will have an empty list at the outset, a problem we will rectify shortly.

The `initLoader()` call on `LoaderManager` (retrieved via `getLoaderManager()`) takes three parameters:

- A locally-unique identifier for this loader
- An optional `Bundle` of data to supply to the loader
- A `LoaderCallbacks` implementation to use for the results from this loader (here set to be the activity itself, as it implements the `LoaderManager.LoaderCallbacks<Cursor>` interface)

The first time you call this for a given identifier, your `onCreateLoader()` method of the `LoaderCallbacks` will be called. Here, you need to initialize the `Loader` to use for this identifier. You are passed the identifier plus the `Bundle` (if any was supplied). In our case, we want to use a `CursorLoader`:

```
public Loader<Cursor> onCreateLoader(int loaderId, Bundle args) {
    return(new CursorLoader(this, Provider.Constants.CONTENT_URI,
```

THE LOADER FRAMEWORK

```
        PROJECTION, null, null, null));  
    }
```

(from [Loaders/ConstantsLoader/app/src/main/java/com/commonsware/android/loader/ConstantsBrowser.java](#))

CursorLoader takes a Context plus all of the parameters you would ordinarily use with `managedQuery()`, such as the content provider Uri. Hence, converting existing code to use CursorLoader means converting your `managedQuery()` call into an invocation of the CursorLoader constructor inside of your `onCreateLoader()` method.

At this point, the CursorLoader will query the content provider, but do so on a background thread, so the main application thread is not tied up. When the Cursor has been retrieved, it is supplied to your `onLoadFinished()` method of your LoaderCallbacks:

```
public void onLoadFinished(Loader<Cursor> loader, Cursor cursor) {  
    adapter.swapCursor(cursor);  
}
```

(from [Loaders/ConstantsLoader/app/src/main/java/com/commonsware/android/loader/ConstantsBrowser.java](#))

Here, we call the new `swapCursor()` available on CursorAdapter, to replace the original null Cursor with the newly-loaded Cursor.

Your `onLoadFinished()` method will also be called whenever the data represented by your Uri changes. That is because the CursorLoader is registering a ContentObserver, so it will find out about data changes and will automatically requery the Cursor and supply you with the updated data.

Eventually, `onLoaderReset()` will be called. You are passed a Cursor object that you were supplied previously in `onLoadFinished()`. You need to make sure that you are no longer using that Cursor at this point — in our case, we swap null back into our CursorAdapter:

```
public void onLoaderReset(Loader<Cursor> loader) {  
    adapter.swapCursor(null);  
}
```

(from [Loaders/ConstantsLoader/app/src/main/java/com/commonsware/android/loader/ConstantsBrowser.java](#))

And that's pretty much it, at least for using CursorLoader. Of course, you need a content provider to make this work, and creating a content provider involves a bit of work.

What Else Is Missing?

The Loader framework does an excellent job of handling queries in the background. What it does not do is help us with anything else that is supposed to be in the background, such as inserts, updates, deletes, or creating/upgrading the database. It is all too easy to put those on the main application thread and therefore possibly encounter issues. Moreover, since the thread(s) used by the Loader framework are an implementation detail, we cannot use those threads ourselves necessarily for the other CRUD operations.

What Happens When...?

Here are some common development scenarios and how the Loader framework addresses them.

... the Data Behind the Loader Changes?

According to [the Loader documentation](#), “They monitor the source of their data and deliver new results when the content changes”.

The documentation is incorrect.

A Loader *can* “monitor the source of their data and deliver new results when the content changes”. There is nothing in the framework that requires this behavior. Moreover, there are some cases where it is clearly a bad idea to do this — imagine a Loader loading data off of the Internet, needing to constantly poll some server to look for changes.

The documentation for a Loader implementation should tell you the rules. Android’s built-in CursorLoader does deliver new results, by means of a behind-the-scenes ContentObserver. However, it is not automatic that a Loader deliver new results, and it may be impractical for a Loader to deliver new results.

... the Configuration Changes?

The managed Cursor system that the Loader framework replaces would automatically requery() any managed Cursor objects when an activity was restarted. This would update the Cursor in place with fresh data after a

configuration change. Of course, it would do that on the main application thread, which was not ideal.

Your Loader objects are retained across the configuration change automatically. Barring bugs in a specific Loader implementation, your Loader should then hand the new activity instance the data that was retrieved on behalf of the old activity instance (e.g., the Cursor).

Hence, you do not have to do anything special for configuration changes.

... the Activity is Destroyed?

Another thing the managed Cursor system gave you was the automatic closing of your Cursor when the activity was destroyed. The Loader framework does this as well, by triggering a reset of the Loader, which obligates the Loader to release any loaded data.

... the Activity is Stopped?

The final major feature of the managed Cursor system was that it would `deactivate()` a managed Cursor when the activity was stopped. This would release all of the heap space held by that Cursor while it was not on the screen. Since the Cursor was refreshed as part of restarting the activity, this usually worked fairly well and would help minimize pressure on the heap.

Alas, this does not appear to be supported by the Loader framework. The Loader is reset when an activity is destroyed, not stopped. Hence, the Loader data will continue to tie up heap space even while the activity is not in the foreground.

For many activities, this should not pose a problem, as the heap space consumed by their Cursor objects is modest. If you have an activity with a massive Cursor, though, you may wish to consider what steps you can take on your own, outside of the Loader framework, to help with this.

Writing a Custom Loader

Perhaps, despite the above issues, and despite the author's assertion that [the Loader framework is a failed abstraction](#), you want to implement a custom Loader.

You have two main choices for doing that:

THE LOADER FRAMEWORK

- If the API that you are using is intrinsically asynchronous, you can extend Loader
- If the API that you are using is synchronous, most likely you should extend AsyncTaskLoader, which manages an AsyncTask for you, giving you a background thread for loading the content

If your API can work either way — synchronously or asynchronously — either option works. In terms of getting the Loader implementation right, you may want to use AsyncTaskLoader, as it will ensure that everything is delivered on the right thread. On the other hand, you may have greater control over the nature of the asynchronous work using the API's native asynchronous capability, such as configuring a thread pool.

The [HTTP/RetroLoader](#) sample project is a clone of the HTTP/Retrofit sample app from [the chapter on Internet access](#). However, this time, the Retrofit work to load the most recent android Stack Overflow questions will be mediated by a QuestionsLoader.

Changing the Retrofit Interface

Retrofit offers both synchronous and asynchronous APIs. For the purposes of this sample, we will use the synchronous API, to see how one might implement an AsyncTaskLoader. That, in turn, requires us to modify StackOverflowInterface, having questions() return the SOQuestions directly, rather than by using a callback:

```
package com.commonware.android.retrofit;

import retrofit.http.GET;
import retrofit.http.Query;

public interface StackOverflowInterface {
    @GET("/2.1/questions?order=desc&sort=creation&site=stackoverflow")
    SOQuestions questions(@Query("tagged") String tags);
}
```

(from [HTTP/RetroLoader/app/src/main/java/com/commonware/android/retrofit/StackOverflowInterface.java](#))

Otherwise, this is unchanged from the original edition of this sample.

Implementing QuestionsLoader

QuestionsLoader is an implementation of AsyncTaskLoader. The documentation for Loader and AsyncTaskLoader leave a lot to be desired. QuestionsLoader is based on “triangulation” between the installed-applications loader included in [the AsyncTaskLoader documentation](#) and [the source code to CursorLoader](#).

Loader uses Java generics. Its declaration requires the type of content being loaded by the Loader. So, QuestionsFragment is a Loader of SOQuestions:

```
public class QuestionsLoader extends AsyncTaskLoader<SOQuestions> {
    final private StackOverflowInterface so;
    private SOQuestions lastResult;

    public QuestionsLoader(Context context) {
        super(context);

        RestAdapter restAdapter=
            new RestAdapter.Builder().setEndpoint("https://api.stackexchange.com")
                .build();

        so=restAdapter.create(StackOverflowInterface.class);
    }

    @Override
    protected void onStartLoading() {
        super.onStartLoading();

        if (lastResult!=null) {
            deliverResult(lastResult);
        }
        else {
            forceLoad();
        }
    }

    @Override
    synchronized public SOQuestions loadInBackground() {
        if (isLoadInBackgroundCanceled()) {
            throw new OperationCanceledException();
        }

        return(so.questions("android"));
    }

    @Override
```

THE LOADER FRAMEWORK

```
public void deliverResult(SOQuestions data) {
    if (isReset()) {
        // actual cleanup, if any
    }

    lastResult=data;

    if (isStarted()) {
        super.deliverResult(data);
    }
}

@Override
protected void onStopLoading() {
    super.onStopLoading();

    cancelLoad();
}

@Override
protected void onReset() {
    super.onReset();

    onStopLoading();
    // plus any actual cleanup
}
}
```

(from [HTTP/RetroLoader/app/src/main/java/com/commonsware/android/retrofit/QuestionsLoader.java](http://retroloader/app/src/main/java/com/commonsware/android/retrofit/QuestionsLoader.java))

The Constructor

A Loader needs to have a constructor that takes a Context as a parameter. So, QuestionsLoader has one, that chains to the superclass constructor, plus sets up the StackOverflowInterface using Retrofit:

```
public QuestionsLoader(Context context) {
    super(context);

    RestAdapter restAdapter=
        new RestAdapter.Builder().setEndpoint("https://api.stackexchange.com")
            .build();

    so=restAdapter.create(StackOverflowInterface.class);
}
```

(from [HTTP/RetroLoader/app/src/main/java/com/commonsware/android/retrofit/QuestionsLoader.java](http://retroloader/app/src/main/java/com/commonsware/android/retrofit/QuestionsLoader.java))

Loading the Questions

The real work for loading the questions comes in `loadInBackground()`. Subclasses of `AsyncTaskLoader` need to implement this to return the content being loaded. As the name suggests, `loadInBackground()` is called on a background thread, so you can take time here.

The key piece of the `loadInBackground()` of `QuestionsFragment` is the call to `questions()` on the `StackOverflowInterface`, to retrieve the desired questions:

```
@Override
synchronized public SOQuestions loadInBackground() {
    if (isLoadInBackgroundCanceled()) {
        throw new OperationCanceledException();
    }

    return(so.questions("android"));
}
```

(from [HTTP/RetroLoader/app/src/main/java/com/commonsware/android/retrofit/QuestionsLoader.java](http://RetroLoader/app/src/main/java/com/commonsware/android/retrofit/QuestionsLoader.java))

However, it is possible that before `loadInBackground()` is called, that something cancels the `AsyncTask` in the `AsyncTaskLoader`. A subclass of `AsyncTaskLoader` needs to check `isLoadInBackgroundCanceled()` in `loadInBackground()`, and throw an `OperationCanceledException` if `isLoadInBackgroundCanceled()` returns true.

Delivering Results

Not only do subclasses of `AsyncTaskLoader` have to load the content, they also have to cache the results of the previous load. So, `QuestionsLoader` has a `lastResult` field, holding onto an `SOQuestions` object.

In `deliverResult()`, we need to do three things:

1. If `isReset()` returns true, indicating that the Loader was reset, we need to clean up anything associated with the previous load results
2. We need to cache the new load results, which are passed into `deliverResult()` as a parameter
3. If the loader is started (`isStarted()` returns true), we need to chain to the superclass implementation of `deliverResult()` to actually deliver the data to the `LoaderCallbacks` implementation:

THE LOADER FRAMEWORK

```
@Override
public void deliverResult(SOQuestions data) {
    if (isReset()) {
        // actual cleanup, if any
    }

    lastResult=data;

    if (isStarted()) {
        super.deliverResult(data);
    }
}
```

(from [HTTP/RetroLoader/app/src/main/java/com/commonsware/android/retrofit/QuestionsLoader.java](http://RetroLoader/app/src/main/java/com/commonsware/android/retrofit/QuestionsLoader.java))

Here, `lastResult` is just a POJO holding onto other POJOs, so there is nothing specific for us to do in case the loader was reset. If our results were a `Cursor`, a `Bitmap`, or other objects with clear “close” or “release” semantics, you might do that work if `onReset()` returned true.

Starting, Stopping, and Resetting

You also need to implement three additional methods.

First is `onStartLoading()`. Here is where we use the cached result, delivering it via `deliverResults()`. If we do not have a cached result, we need to call `forceLoad()` to trigger the `AsyncTask` which, in turn, triggers `loadInBackground()` and the rest of the work to actually retrieve the results:

```
@Override
protected void onStartLoading() {
    super.onStartLoading();

    if (lastResult!=null) {
        deliverResult(lastResult);
    }
    else {
        forceLoad();
    }
}
```

(from [HTTP/RetroLoader/app/src/main/java/com/commonsware/android/retrofit/QuestionsLoader.java](http://RetroLoader/app/src/main/java/com/commonsware/android/retrofit/QuestionsLoader.java))

There is a corresponding `onStopLoading()`, where we need to call `cancelLoad()`, to cancel the `AsyncTask`:

THE LOADER FRAMEWORK

```
@Override
protected void onStopLoading() {
    super.onStopLoading();

    cancelLoad();
}
```

(from [HTTP/RetroLoader/app/src/main/java/com/commonsware/android/retrofit/QuestionsLoader.java](http://RetroLoader/app/src/main/java/com/commonsware/android/retrofit/QuestionsLoader.java))

Finally, there is `onReset()`, where we need to call `onStopLoading()` (as loading should stop if the Loader is reset), plus do any cleanup of our cached results as needed:

```
@Override
protected void onReset() {
    super.onReset();

    onStopLoading();
    // plus any actual cleanup
}
```

(from [HTTP/RetroLoader/app/src/main/java/com/commonsware/android/retrofit/QuestionsLoader.java](http://RetroLoader/app/src/main/java/com/commonsware/android/retrofit/QuestionsLoader.java))

Using QuestionsLoader

You might think that with 70-odd lines of `QuestionsLoader` code that we would have a corresponding savings in `QuestionsFragment`.

Alas, no, though it is a bit shorter.

`QuestionsFragment` now implements `LoaderCallbacks` instead of Retrofit's `Callback` interface:

```
public class QuestionsFragment extends ListFragment implements
    LoaderManager.LoaderCallbacks<SQQuestions> {
```

(from [HTTP/RetroLoader/app/src/main/java/com/commonsware/android/retrofit/QuestionsFragment.java](http://RetroLoader/app/src/main/java/com/commonsware/android/retrofit/QuestionsFragment.java))

In the original `QuestionsFragment`, we fired off the asynchronous Retrofit work in `onCreateView()`, and we processed the results in the `success()` and `failure()` methods.

Now, we just need to call `initLoader()`, in this case from `onViewCreated()`:

THE LOADER FRAMEWORK

```
@Override
public void onViewCreated(View view, Bundle savedInstanceState) {
    super.onViewCreated(view, savedInstanceState);

    getLoaderManager().initLoader(0, null, this);
}
```

(from [HTTP/RetroLoader/app/src/main/java/com/commonsware/android/retrofit/QuestionsFragment.java](http://retroloader.app/src/main/java/com/commonsware/android/retrofit/QuestionsFragment.java))

Then, our LoaderCallbacks methods create the QuestionsLoader and apply the results:

```
@Override
public Loader<SQQuestions> onCreateLoader(int id, Bundle args) {
    return(new QuestionsLoader(getActivity()));
}

@Override
public void onLoadFinished(Loader<SQQuestions> loader,
                           SQQuestions data) {
    setListAdapter(new ItemsAdapter(data.items));
}

@Override
public void onLoaderReset(Loader<SQQuestions> loader) {
    setListAdapter(null);
}
```

(from [HTTP/RetroLoader/app/src/main/java/com/commonsware/android/retrofit/QuestionsFragment.java](http://retroloader.app/src/main/java/com/commonsware/android/retrofit/QuestionsFragment.java))

Considering the Loader Contract

As noted earlier in this chapter, there are three key pieces of the Loader contract: asynchronicity, data retention, and automatic delivery of updates on content changes.

So, how does QuestionsLoader stack up?

- AsyncTaskLoader provides the asynchronous operation for us, so we inherit that
- All loaders are automatically retained by the LoaderManager, so there is nothing specific that we need to do for that
- However, we are unaware of any changes in our content, such as new questions being asked, so we are not delivering updated content to clients of the QuestionsLoader

THE LOADER FRAMEWORK

This is a common gap with loader implementations. Occasionally, we may be in position to find out when the content changes. More often, we are not, or the work to find out about content changes has to be handled by a much larger subsystem, beyond a simple Loader subclass.

For example, if we *really* wanted to have QuestionsLoader automatically deliver a fresh SOQuestions object when new Stack Overflow android questions were asked, we could: use some sort of timing mechanism (e.g., ScheduledExecutorService) to poll the Stack Exchange API every so often. However, then we would need to implement some sort of “diff” algorithm to determine if relevant data changed in the JSON response, so we knew to deliver a fresh SOQuestions to clients. However, our polling period would be somewhat arbitrary. Frequent polling would consume a fair amount of battery and bandwidth as well.

The ContactsContract and CallLog Providers

One of the more popular stores of data on your average Android device is the contact list. Ever since Android 2.0, Android tracks contacts across multiple different “accounts”, or sources of contacts. Some may come from your Google account, while others might come from Exchange or other services.

This chapter will walk you through some of the basics for accessing the contacts on the device. Along the way, we will revisit and expand upon our knowledge of using a ContentProvider.

First, we will review the [contacts APIs](#), past and present. We will then demonstrate how you can connect to the contacts engine to let users [pick and view contacts](#)... all without your application needing to know much of how contacts work. We will then show how you can [query](#) the contacts provider to obtain contacts and some of their details, like email addresses and phone numbers. We wrap by showing how you can invoke a built-in activity to let the user [add a new contact](#), possibly including some data supplied by your application.

In addition, we will take a peek at the CallLog provider, which, as the name suggests, gives you access to a log of calls made on the device.

Prerequisites

Understanding this chapter requires that you have read these chapters in addition to the core chapters:

- [content provider theory](#)

- [content provider implementations](#)
- [the Loader framework](#)

Introducing You to Your Contacts

Android makes contacts available to you via a complex `ContentProvider` framework, so you can access many facets of a contact's data — not just their name, but addresses, phone numbers, groups, etc. Working with the contacts `ContentProvider` set is simple... only if you have an established pattern to work with. Otherwise, it may prove somewhat daunting.

Organizational Structure

The contacts `ContentProvider` framework can be found as the set of `ContactsContract` classes and interfaces in the `android.provider` package. Unfortunately, there is a dizzying array of inner classes to `ContactsContract`.

Contacts can be broken down into two types: raw and aggregate. Raw contacts come from a sync provider or are hand-entered by a user. Aggregate contacts represent the sum of information about an individual culled from various raw contacts. For example, if your Exchange sync provider has a contact with an email address of `jdoe@foo.com`, and your Facebook sync provider has a contact with an email address of `jdoe@foo.com`, Android may recognize that those two raw contacts represent the same person and therefore combine those in the aggregate contact for the user. The classes relating to raw contacts usually have `Raw` somewhere in their name, and these normally would be used only by custom sync providers.

The `ContactsContract.Contacts` and `ContactsContract.Data` classes represent the “entry points” for the `ContentProvider`, allowing you to query and obtain information on a wide range of different pieces of information. What is retrievable from these can be found in the various `ContactsContract.CommonDataKinds` series of classes. We will see examples of these operations later in this chapter.

A Look Back at Android 1.6

Prior to Android 2.0, Android had no contact synchronization built in. As a result, all contacts were in one large pool, whether they were hand-entered by users or were added via third-party applications. The API used for this is the `ContactsContentProvider`.

The Contacts ContentProvider still works, as it is merely deprecated in Android 2.0.1, not removed. In practice, it has one big limitation: it will only report contacts added directly to the device (as opposed to ones synchronized from Microsoft Exchange, Facebook, or other sources). As a result, modern Android apps should **not** be using Contacts in general — use ContactsContract.

Pick a Peck of Pickled People

Back in [the chapter on resource sets and configurations](#), we saw a series of examples of handling [configuration changes](#). Those samples allowed the user to pick a contact and view a contact. There, we focused on the configuration change aspect. Here, let's examine the actual pick and view logic a bit more closely.

Picking a Contact

When the user picks a contact, we call `startActivityForResult()` with an `ACTION_PICK` Intent:

```
public void pickContact(View v) {
    Intent i=
        new Intent(Intent.ACTION_PICK,
            ContactsContract.Contacts.CONTENT_URI);

    startActivityForResult(i, PICK_REQUEST);
}
```

(from [ConfigChange/Fragments/app/src/main/java/com/commonsware/android/rotation/frag/RotationFragment.java](#))

The Intent has `ContactsContract.Contacts.CONTENT_URI` as its `Uri`. Here, `ContactsContract.Contacts.CONTENT_URI` is defined by the Android SDK and points to the contacts “table” inside the ContactsContract “database”, as it were. Whether there is really a database or a table involved is up to the implementation of ContactsContract, of course.

When we call `startActivityForResult()`, Android needs to find an activity to fulfill this request. However, at the outset, all it has is an action string and a `Uri`. There could be all sorts of activities on the device that advertise that they can pick from a collection identified by a `Uri` starting with the content scheme.

To help refine the request, Android asks the ContactsContract ContentProvider what the MIME type is for this `Uri`. Then, Android knows an action string, a MIME type, and a `Uri`. It so happens that the contacts apps that ship on Android have an

activity that has an `<intent-filter>` that indicates that it can handle `ACTION_PICK` of the relevant MIME type from a content `Uri`. And so that is the activity that the user sees.

The `Uri` that we get back in `onActivityResult()` not only points to the contact that the user picked, but also gives us *temporary read access* to that contact's personally identifying information. In effect, it is as if the normal `READ_CONTACTS` permission requirement was suspended, for this one `Uri`, for our app alone. Once our process terminates, we may no longer have the ability to get at details about that contact via its `Uri`, as this read access is temporary.

Viewing a Contact

As it turns out, the sample app does not take advantage of the temporary read access. Instead, when the user clicks the “View” button, the app just brings up an activity to go view that contact:

```
public void viewContact(View v) {
    startActivity(new Intent(Intent.ACTION_VIEW, contact));
}
```

(from [ConfigChange/Fragments/app/src/main/java/com/commonsware/android/rotation/frag/RotationFragment.java](#))

Once again, Android has an action string (`ACTION_VIEW`) and a `Uri` (the one that we got in response to the `ACTION_PICK` request). And, once again, Android asks `ContactsContract` for the MIME type of the data associated with this `Uri`, so that the MIME type can help identify the right activity to handle this request. The contacts app that comes on the device should have an activity that complies, and so we can view the contact.

In truth, the only reason why we as developers can count on these activities existing is because of Google Play Services and the Play Store. The Compatibility Definition Document (CDD) that manufacturers must comply with to get Google's proprietary Android apps requires that the device ship with apps that fulfill all of the `<intent-filter>` elements supported by the apps in the Android Open Source Project (AOSP). Hence, for devices that legitimately have the Play Store on them, there should always be an app that offers activities to allow users to pick and view contacts. However, on devices that do *not* legitimately have the Play Store, those activities might not exist. Manufacturers who avoid Google's proprietary apps *should* still aim to comply with the CDD as much as possible, if they want third-party apps like yours to work successfully on those devices. However, there is no contractual

requirement that they do, and so, as the saying goes, your mileage may vary (YMMV).

Spin Through Your Contacts

The preceding example allows you to work with contacts, yet not actually have any contact data other than a transient `Uri`. All else being equal, it is best to use the contacts system this way, as it means you do not need any extra permissions that might raise privacy issues.

Of course, all else is rarely equal.

Your alternative, therefore, is to execute queries against the contacts `ContentProvider` to get actual contact detail data back, such as names, phone numbers, and email addresses. The [Contacts/Spinners](#) sample application will demonstrate this technique.

Contact Permissions

Since contacts are privileged data, you need certain permissions to work with them. Specifically, you need the `READ_CONTACTS` permission to query and examine the `ContactsContract` content and `WRITE_CONTACTS` to add, modify, or remove contacts from the system. This only holds true if your code will have access to personally-identifying information, which is why the `Pick` sample above — which just has an opaque `Uri` — does not need any permission.

For example, here is the manifest for the `Contacts/Spinners` sample application:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest package="com.commonware.android.contacts.spinners"
  xmlns:android="http://schemas.android.com/apk/res/android"
  android:versionCode="1"
  android:versionName="1.0">

  <uses-permission android:name="android.permission.READ_CONTACTS" />

  <application
    android:icon="@drawable/ic_launcher"
    android:label="@string/app_name"
    android:theme="@style/Theme.Apptheme">
    <activity
      android:name=".ContactSpinners"
```

```
    android:label="@string/app_name">
    <intent-filter>
        <action android:name="android.intent.action.MAIN" />
        <category android:name="android.intent.category.LAUNCHER" />
    </intent-filter>
</activity>
</application>
</manifest>
```

(from [Contacts/Spinners/app/src/main/AndroidManifest.xml](#))

And, since this app has a `targetSdkVersion` of 26, we also need to deal with runtime permissions, as `READ_CONTACTS` has a `protectionLevel` of `dangerous`, so we need to ask the user for permission at runtime. To that end, we use the same `AbstractPermissionActivity` seen elsewhere in the book as the base class for our `ContactSpinners` activity, so we can delegate all of the runtime permission logic to `AbstractPermissionActivity`. The one difference is that this sample originally used a `ListActivity`, so this sample's edition of `AbstractPermissionActivity` inherits from `ListActivity` instead of from `Activity`.

Pre-Joined Data

While the database underlying the `ContactsContract` content provider is private, one can imagine that it has several tables: one for people, one for their phone numbers, one for their email addresses, etc. These are tied together by typical database relations, most likely 1:N, so the phone number and email address tables would have a foreign key pointing back to the table containing information about people.

To simplify accessing all of this through the content provider interface, Android pre-joins queries against some of the tables. For example, you can query for phone numbers and get the contact name and other data along with the number — you do not have to do this join operation yourself.

The UI

The `ContactSpinners` activity has the standard `ListView` along with a `Spinner`:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:orientation="vertical"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
```

THE CONTACTS CONTRACT AND CALL LOG PROVIDERS

```
>
<Spinner android:id="@+id/spinner"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:drawSelectorOnTop="true"
/>
<ListView
    android:id="@android:id/list"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:drawSelectorOnTop="false"
/>
</LinearLayout>
```

(from [Contacts/Spinners/app/src/main/res/layout/main.xml](#))

In `onReady()` of the activity, we load up the Spinner:

```
@Override
public void onReady() {
    setContentView(R.layout.main);

    Spinner spin=(Spinner)findViewById(R.id.spinner);
    spin.setOnItemSelectedListener(this);

    ArrayAdapter<String> aa=new ArrayAdapter<String>(this,
        android.R.layout.simple_spinner_item,
        getResources().getStringArray(R.array.options));

    aa.setDropDownViewResource(
        android.R.layout.simple_spinner_dropdown_item);
    spin.setAdapter(aa);
}
```

(from [Contacts/Spinners/app/src/main/java/com/commonsware/android/contacts/spinners/ContactSpinners.java](#))

In particular, we populate the Spinner based on a `<string-array>` resource from the `res/values/arrays.xml` file:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
    <string-array name="options">
        <item>Contact Names</item>
        <item>Contact Names & Numbers</item>
        <item>Contact Names & Email Addresses</item>
    </string-array>
</resources>
```

(from [Contacts/Spinners/app/src/main/res/values/arrays.xml](#))

Reacting to the Spinner

We set up the activity to be the `OnItemSelectedListener` for the Spinner, which means that we have to implement `onItemSelected()` and `onNothingSelected()`:

```
@Override
public void onItemSelected(AdapterView<?> parent,
                           View v, int position, long id) {
    getLoaderManager().initLoader(position, null, this);
}

@Override
public void onNothingSelected(AdapterView<?> parent) {
    // ignore
}
```

(from [Contacts/Spinners/app/src/main/java/com/commonsware/android/contacts/spinners/ContactSpinners.java](#))

When the user selects something in the Spinner — and for the default selection — we will use the Loader framework and use a `CursorLoader` to query the `ContactsContract` `ContentProvider`. In this case, though, we want three different `Cursor` values, one for each option in the Spinner. That will mean that we need three different `CursorLoader` objects. To identify which loader we are going to initialize, we pass in the position of the Spinner to `initLoader()`, so the `0/1/2` value that we get as the position forms our loader ID.

Loading the Data

In `onCreateLoader()` of our `LoaderCallbacks`, we need to return a `CursorLoader` for whichever loaderId was passed in. What varies is the `Uri` that we want to query and the “projection” of “columns” that we want to get back. So, `onCreateLoader()` uses a `switch` statement to decide what `Uri` and projection to use, then creates a `CursorLoader` based upon that:

```
@Override
public Loader<Cursor> onCreateLoader(int loaderId, Bundle args) {
    String[] projection;
    Uri uri;

    switch (loaderId) {
        case LOADER_NAMES:
            projection=PROJECTION_NAMES;
```

THE CONTACTS CONTRACT AND CALL LOG PROVIDERS

```
        uri=ContactsContract.Contacts.CONTENT_URI;
        break;

    case LOADER_NAMES_NUMBERS:
        projection=PROJECTION_NUMBERS;
        uri=ContactsContract.CommonDataKinds.Phone.CONTENT_URI;
        break;

    default:
        projection=PROJECTION_EMAILS;
        uri=ContactsContract.CommonDataKinds.Email.CONTENT_URI;
        break;
}

return(new CursorLoader(this, uri, projection, null, null,
    ContactsContract.Contacts.DISPLAY_NAME));
}
```

(from [Contacts/Spinners/app/src/main/java/com/commonsware/android/contacts/spinners/ContactSpinners.java](#))

The two case values are just constants tied to the positions from the Spinner, defined as static data members:

```
private static final int LOADER_NAMES=0;
private static final int LOADER_NAMES_NUMBERS=1;
```

(from [Contacts/Spinners/app/src/main/java/com/commonsware/android/contacts/spinners/ContactSpinners.java](#))

Similarly, the three projections are defined as static data members:

```
private static final String[] PROJECTION_NAMES=new String[] {
    ContactsContract.Contacts._ID,
    ContactsContract.Contacts.DISPLAY_NAME,
};
private static final String[] PROJECTION_NUMBERS=new String[] {
    ContactsContract.Contacts._ID,
    ContactsContract.Contacts.DISPLAY_NAME,
    ContactsContract.CommonDataKinds.Phone.NUMBER
};
private static final String[] PROJECTION_EMAILS=new String[] {
    ContactsContract.Contacts._ID,
    ContactsContract.Contacts.DISPLAY_NAME,
    ContactsContract.CommonDataKinds.Email.DATA
};
```

(from [Contacts/Spinners/app/src/main/java/com/commonsware/android/contacts/spinners/ContactSpinners.java](#))

THE CONTACTS CONTRACT AND CALL LOG PROVIDERS

For the “names” Spinner entry, we are going to retrieve the ID and display name of the contact, using the standard `ContactsContract.Contacts.CONTENT_URI` Uri value.

For the “names and phone numbers” Spinner entry, we still want the display name of the contact, but we also want phone numbers. Fortunately, as mentioned earlier, `ContactsContract` denormalizes its data in response to queries, so we can get the display name of the contact even when we are querying the “table” of phone numbers, via `ContactsContract.CommonDataKinds.Phone.CONTENT_URI`. The same basic process holds true for the “names and emails” entry, where we query `ContactsContract.CommonDataKinds.Email.CONTENT_URI`. Note that we will get somewhat redundant information back — if a contact has two phone numbers, we get two rows in our Cursor, both for the same contact, and one per phone number.

We can sort by `DISPLAY_NAME` for all three cases, courtesy of the aforementioned denormalization of the data.

Showing the Results

We also have to implement `onLoadFinished()`, to take in the Cursor that is the result of the query against `ContactsContract` and put the results in the `ListView`. Once again, the rendering will differ a bit based upon whether we are showing just names or names along with other data (e.g., phone numbers). So, we have another switch statement, where we determine what columns we want, what layout ID to use, and what roster of widgets in that layout map to those columns:

```
@Override
public void onLoadFinished(Loader<Cursor> loader, Cursor c) {
    String[] columns;
    int layoutId;
    int[] views;

    switch(loader.getId()) {
        case LOADER_NAMES:
            columns=COLUMNS_NAMES;
            layoutId=android.R.layout.simple_list_item_1;
            views=VIEWS_ONE;
            break;

        case LOADER_NAMES_NUMBERS:
            columns=COLUMNS_NUMBERS;
            layoutId=android.R.layout.simple_list_item_2;
            views=VIEWS_TWO;
```

THE CONTACTS CONTRACT AND CALL LOG PROVIDERS

```
        break;

        default:
            columns=COLUMNS_EMAILS;
            layoutId=android.R.layout.simple_list_item_2;
            views=VIEWS_TWO;
            break;
    }

    setListAdapter(new SimpleCursorAdapter(this, layoutId, c,
                                           columns, views, 0));
}
```

(from [Contacts/Spinners/app/src/main/java/com/commonsware/android/contacts/spinners/ContactSpinners.java](#))

The lists of columns and views are defined as static data members and map positionally (i.e., the first view is for the first column):

```
private static final String[] COLUMNS_NAMES=new String[] {
    ContactsContract.Contacts.DISPLAY_NAME
};
private static final String[] COLUMNS_NUMBERS=new String[] {
    ContactsContract.Contacts.DISPLAY_NAME,
    ContactsContract.CommonDataKinds.Phone.NUMBER
};
private static final String[] COLUMNS_EMAILS=new String[] {
    ContactsContract.Contacts.DISPLAY_NAME,
    ContactsContract.CommonDataKinds.Email.DATA
};
private static final int[] VIEWS_ONE=new int[] {
    android.R.id.text1
};
private static final int[] VIEWS_TWO=new int[] {
    android.R.id.text1,
    android.R.id.text2
};
```

(from [Contacts/Spinners/app/src/main/java/com/commonsware/android/contacts/spinners/ContactSpinners.java](#))

Then, we create a SimpleCursorAdapter wrapped around that information and use that to populate the ListView, thereby showing the contacts and the requested information about those contacts.

Makin' Contacts

Let's now take a peek at the reverse direction: adding contacts to the system. This was never particularly easy and now is... well, different.

First, we need to distinguish between sync providers and other apps. Sync providers are the guts underpinning the accounts system in Android, bridging some existing source of contact data to the Android device. Hence, you can have sync providers for Exchange, Facebook, and so forth. These will need to create raw contacts for newly-added contacts to their backing stores that are being sync'd to the device for the first time. Creating sync providers is outside of the scope of this book for now.

It is possible for other applications to create contacts. These, by definition, will be phone-only contacts, lacking any associated account, no different than if the user added the contact directly. The recommended approach to doing this is to collect the data you want, then spawn an activity to let the user add the contact — this avoids your application needing the `WRITE_CONTACTS` permission and all the privacy/data integrity issues that creates.

To that end, take a look at the [Contacts/Inserter](#) sample project. It defines a simple activity with a two-field UI, with one field apiece for the person's first name and phone number:

```
<?xml version="1.0" encoding="utf-8"?>
<TableLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:orientation="vertical"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:stretchColumns="1"
    >
    <TableRow>
        <TextView
            android:text="First name:"
        />
        <EditText android:id="@+id/name"
        />
    </TableRow>
    <TableRow>
        <TextView
            android:text="Phone:"
        />
        <EditText android:id="@+id/phone"
            android:inputType="phone"
        />
    </TableRow>
</TableLayout>
```

THE CONTACTS CONTRACT AND CALL LOG PROVIDERS

```
    />
  </TableRow>
  <Button android:id="@+id/insert" android:text="Insert!" />
</TableLayout>
```

(from [Contacts/Inserter/app/src/main/res/layout/main.xml](#))

The trivial UI also sports a button to add the contact:

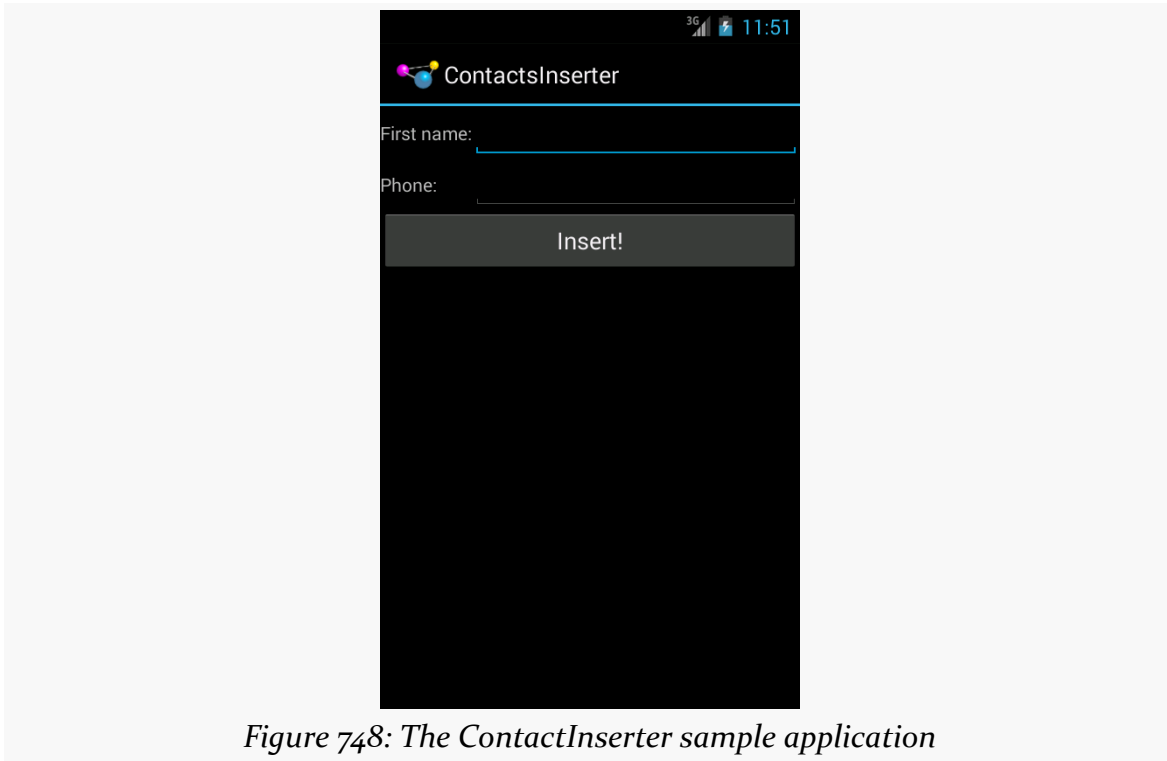

Figure 748: The ContactInserter sample application

When the user clicks the button, the activity gets the data and creates an Intent to be used to launch the add-a-contact activity. This uses the ACTION_INSERT_OR_EDIT action and a couple of extras from the ContactsContract.Insert class:

```
package com.commonware.android.inserter;

import android.app.Activity;
import android.content.Intent;
import android.os.Bundle;
import android.provider.ContactsContract.Contacts;
import android.provider.ContactsContract.Intents.Insert;
import android.view.View;
import android.widget.Button;
import android.widget.EditText;
```

THE CONTACTS CONTRACT AND CALLLOG PROVIDERS

```
public class ContactsInserter extends Activity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.main);

        Button btn=(Button)findViewById(R.id.insert);

        btn.setOnClickListener(onInsert);
    }

    View.OnClickListener onInsert=new View.OnClickListener() {
        public void onClick(View v) {
            EditText fld=(EditText)findViewById(R.id.name);
            String name=fld.getText().toString();

            fld=(EditText)findViewById(R.id.phone);

            String phone=fld.getText().toString();
            Intent i=new Intent(Intent.ACTION_INSERT_OR_EDIT);

            i.setType(Contacts.CONTENT_ITEM_TYPE);
            i.putExtra(Insert.NAME, name);
            i.putExtra(Insert.PHONE, phone);
            startActivity(i);
        }
    };
}
```

(from [Contacts/Inserter/app/src/main/java/com/commonsware/android/inserter/ContactsInserter.java](#))

We also need to set the MIME type on the Intent via `setType()`, to be `CONTENT_ITEM_TYPE`, so Android knows what sort of data we want to actually insert. Then, we call `startActivity()` on the resulting Intent. That brings up an add-or-edit activity:

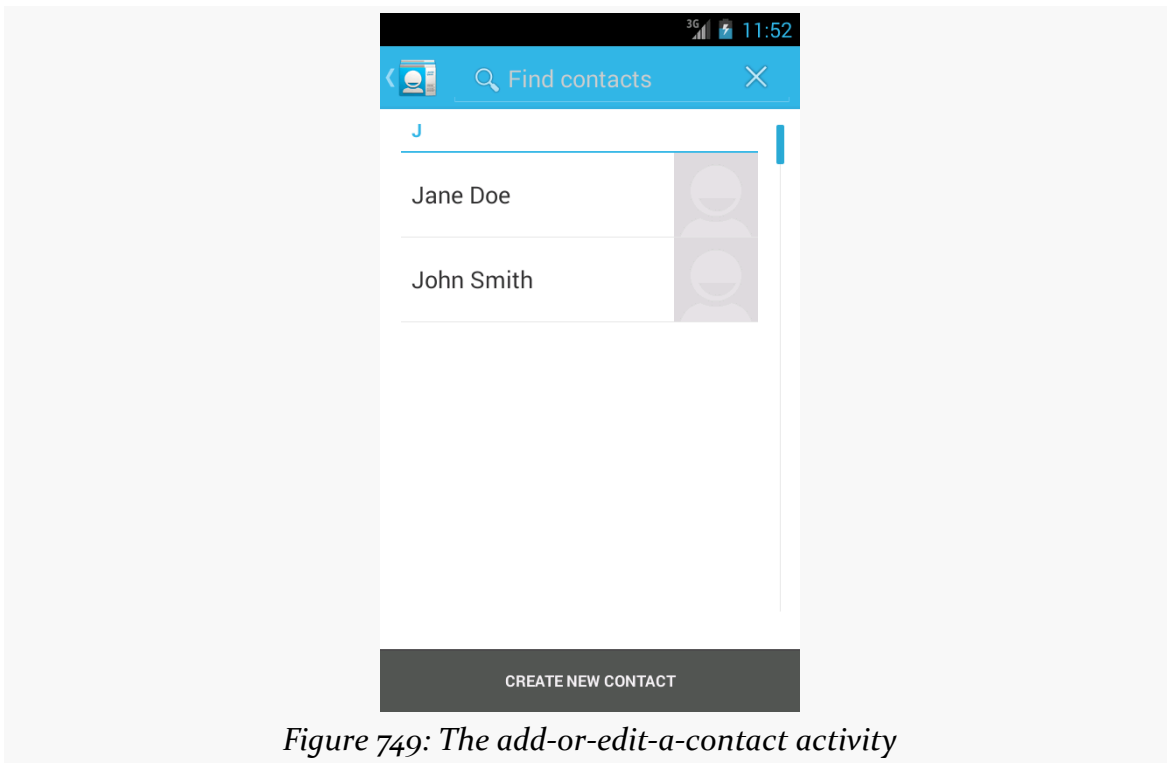

Figure 749: The add-or-edit-a-contact activity

... where if the user chooses “Create new contact”, they are taken to the ordinary add-a-contact activity, with our data pre-filled in:

Figure 750: The edit-contact form, showing the data from the `ContactInserter` activity

Note that the user could choose an existing contact, rather than creating a new contact. If they choose an existing contact, the first name of that contact will be overwritten with the data supplied by the `ContactsInserter` activity, and a new phone number will be added from those `Intent` extras.

Looking at the CallLog

A closely-related `ContentProvider` to `ContactsContract` is `CallLog`. As the name suggests, it contains a log of calls for this device, including things like the date/time of the call, the call duration, and the other party on the call (e.g., a phone number).

If you wish to give the user another look at their calls, independent from the UI available on the device (e.g., `Dialer` app), you might wish to query the `CallLog`, as we do in the [Contacts/CallLog](#) sample application

Pondering Permissions

In the beginning, there was no `READ_CALL_LOG` permission. To read the `CallLog` provider, you needed to hold `READ_CONTACTS`. The reason for the `READ_CONTACTS`

THE CONTACTS CONTRACT AND CALL LOG PROVIDERS

permission is that the `CallLog` denormalizes the data, copying into its own table contact data about the other party, so that the `CallLog` can remain independent of `ContactsContract`.

In API Level 16, though, they added the `READ_CALL_LOG` permission. If your `minSdkVersion` is 16 or higher, you can just request `READ_CALL_LOG`. If your `minSdkVersion` is lower than that, though, you will want to request both permissions, to make sure that you are covered. You might consider using the `android:maxSdkVersion` attribute on the `READ_CONTACTS` `<uses-permission>` element, as you will not need it on newer devices, unless you are also working with `ContactContract`.

Both `READ_CALL_LOG` and `READ_CONTACTS` are dangerous permissions, and therefore if your `targetSdkVersion` is 23 or higher, you need to request those permissions at runtime. Of course, you only need to request the permissions that you need, and so if your `minSdkVersion` is 16 or higher and you are only using `READ_CALL_LOG`, you only need to request `READ_CALL_LOG` at runtime.

Our sample app uses the same `AbstractPermissionActivity` as did the first sample app in this chapter, though this time our `CallLogConsumerActivity` will request `READ_CALL_LOG` instead of `READ_CONTACTS`.

Contents of `CallLog.Calls`

The sample app requests the `READ_CALL_LOG` permission, so it can query the `CallLog`:

```
<uses-permission android:name="android.permission.READ_CALL_LOG" />
```

(from [Contacts/CallLog/app/src/main/AndroidManifest.xml](#))

The app has one Java class, `CallLogConsumerActivity`, which is the launcher activity.

In `onCreate()` — among other bits of work that we will explore shortly — we call `getLoaderManager().initLoader()`, to query the `CallLog` via a `CursorLoader`. The activity itself implements the `LoaderManager.LoaderCallbacks` interface needed by `initLoader()`, and so the activity has the three required `LoaderCallbacks` methods:

```
@Override
public Loader<Cursor> onCreateLoader(int loaderId, Bundle args) {
    return(new CursorLoader(this, CallLog.Calls.CONTENT_URI,
```

THE CONTACTS CONTRACT AND CALLLOG PROVIDERS

```
        PROJECTION, null, null, CallLog.Calls.DATE
            + " DESC"));
    }

    @Override
    public void onLoadFinished(Loader<Cursor> loader, Cursor cursor) {
        adapter.swapCursor(cursor);
    }

    @Override
    public void onLoaderReset(Loader<Cursor> loader) {
        adapter.swapCursor(null);
    }
}
```

(from [Contacts/CallLog/app/src/main/java/com/commonsware/android/calllog/consumer/CallLogConsumerActivity.java](#))

Here, we retrieve the data from the CallLog.Calls “table” via its CONTENT_URI, asking for the “columns” indicated by the PROJECTION:

```
private static final String[] PROJECTION=new String[] {
    CallLog.Calls._ID, CallLog.Calls.NUMBER, CallLog.Calls.DATE };
```

(from [Contacts/CallLog/app/src/main/java/com/commonsware/android/calllog/consumer/CallLogConsumerActivity.java](#))

We sort the data descending by date. It would be nice if the documentation for CallLog included some indication that this approach was endorsed and supported. Based on the CallLog implementation, it should be stable.

The Cursor itself is passed into a SimpleCursorAdapter (named adapter) via swapCursor() calls.

Showing the CallLog

In onReady(), we want to set up that SimpleCursorAdapter for mapping the phone number and date of a call to corresponding TextView widgets in a row layout:

```
@Override
public void onReady() {
    adapter=
        new SimpleCursorAdapter(this, R.layout.row, null, new String[] {
            CallLog.Calls.NUMBER, CallLog.Calls.DATE }, new int[] {
                R.id.number, R.id.date }, 0);

    adapter.setViewBinder(this);
    setListAdapter(adapter);
}
```

THE CONTACTS CONTRACT AND CALL LOG PROVIDERS

```
getLoaderManager().initLoader(0, null, this);
}
```

(from [Contacts/CallLog/app/src/main/java/com/commonsware/android/calllog/consumer/CallLogConsumerActivity.java](#))

Here, we create the `SimpleCursorAdapter` on a null `Cursor` at the outset, to indicate that we do not yet have our data, and we will show the `Cursor` delivered to `onLoadFinished()` at that time.

However we will run into a problem with the date. In the `CallLog` provider, the date is stored as “milliseconds since the Unix epoch”, the same time system used by `System.currentTimeMillis()`. That is a really long number, one that ordinary people will not recognize. If we blindly just convert that into a string and put it in the `TextView`, users will be unable to understand that column.

To get a chance to convert that value into something more useful, the activity implements the `SimpleCursorAdapter.ViewBinder` interface and calls `setViewBinder(this)` on the adapter. A `ViewBinder` will get control every time the `SimpleCursorAdapter` tries binding a value from the `Cursor` to a widget, so we can handle that ourselves where needed.

The `ViewBinder` interface requires a `setViewValue()` method where we do that work:

```
@Override
public boolean setViewValue(View view, Cursor cursor, int columnIndex) {
    if (columnIndex==2) {
        long time=cursor.getLong(columnIndex);
        String formattedTime=DateUtils.formatDateTime(this, time,
            DateUtils.FORMAT_ABBREV_RELATIVE);

        ((TextView)view).setText(formattedTime);

        return(true);
    }

    return(false);
}
```

(from [Contacts/CallLog/app/src/main/java/com/commonsware/android/calllog/consumer/CallLogConsumerActivity.java](#))

If `setViewValue()` returns `false`, that indicates that the `SimpleCursorAdapter` should handle that column normally. Our implementation does that for everything other than column 2, which in our `PROJECTION` is the date. For the date, we get the

THE CONTACTS CONTRACT AND CALL LOG PROVIDERS

long value of the date and use `DateUtils.formatDateTime()` to convert it into a string representation that will be more human-readable. We put that string into the `TextView` and return `true` to indicate that we have handled this widget binding ourselves.

The results is a list of calls by date and phone number.

The CalendarContract Provider

The Android Open Source Project (AOSP) has had a Calendar application from its earliest days. This application originally was designed to sync with Google Calendar, later extended to other sync sources, such as Microsoft's Exchange. However, this application was not part of the Android SDK, so there was no way to access it from your Android application.

At least, no officially documented and supported way.

Many developers poked through the AOSP source code and found that the Calendar application had a `ContentProvider`. Moreover, this `ContentProvider` was exported (by default). So many developers used undocumented and unsupported means for accessing calendar information. This occasionally broke, as Google modified the Calendar app and changed these pseudo-external interfaces.

Android 4.0 added official SDK support for interacting with the Calendar application via its `ContentProvider`. As part of the SDK, these new interfaces should be fairly stable — if nothing else, they should be supported indefinitely, even if new and improved interfaces are added sometime in the future. So, if you want to tie into the user's calendars, you can. Bear in mind, though, that the new `CalendarContract` `ContentProvider` is not identical to the older undocumented providers, so if you are aiming to support pre-4.0 devices, you have some more work to do.

Of course, similar to the `ContactsContract` `ContentProvider`, the `CalendarContract` `ContentProvider` is severely lacking in documentation, and anything not documented is subject to change.

Prerequisites

Understanding this chapter requires that you have read the chapters on:

- [content provider theory](#)
- [content provider implementations](#)

You Can't Be a Faker

While the Android emulator has the `CalendarContract` `ContentProvider`, it will do you little good. While you can define a Google account on the emulator, the emulator lacks any ability to sync content with that account. Hence, you cannot see any events for your calendars in the Calendar app, and you cannot access any calendar data via `CalendarContract`.

You may be able to use an `outlook.com` account, [to sync with an Outlook calendar](#).

Otherwise, in order to test your use of `CalendarContract`, you will need to have hardware that runs Android 4.0 (or higher), with one or more accounts set up that have calendar data.

Do You Have Room on Your Calendar?

As a `ContentProvider`, `CalendarContract` is not significantly different from any other such provider that Android supplies or that you write yourself, in that there are `Uri` values representing collections of data, upon which you can query, insert, update, and delete as needed.

The Collections

The two main collections of data that you are likely to be interested in are `CalendarContract.Calendars` (the collection of all defined calendars) and `CalendarContract.Events` (the collection of all defined events across all calendars). Each of those has a `CONTENT_URI` static data member that you would use with `ContentResolver` or a `CursorLoader` to perform operations on those collections. An entry in `CalendarContract.Events` points back to its corresponding calendar via a `CALENDAR_ID` column that you can query upon; the remaining columns on `CalendarContract.Events` have names apparently designed to match with the

THE CALENDARCONTRACT PROVIDER

[iCalendar specification](#) (e.g., DTSTART and DTEND for the start and end times of the event).

Three other collections may be of interest:

1. `CalendarContract.Instances` has one entry per occurrence of an event, so recurring events get multiple rows
2. `CalendarContract.Attendees` has information about each attendee of an event
3. `CalendarContract.Reminders` has information about each reminder scheduled for an event (e.g., when to remind the user), for those events with associated reminders

Each of those ties back to its associated `CalendarContract.Events` row via an `EVENT_ID` column.

Calendar Permissions

There are two permissions for working with `CalendarContract`: `READ_CALENDAR` and `WRITE_CALENDAR`. As you might expect, querying `CalendarContract` requires the `READ_CALENDAR` permission; modifying `CalendarContract` data requires the `WRITE_CALENDAR` permission.

These permissions have existed since Android's earliest days, even in the SDK, as a side effect of the "meat cleaver" approach the core Android team employed to create the initial SDK. Hence, you can request these permissions in the manifest with any Android build target, without compiler errors. Of course, actually referring to `CalendarContract` will require a build target (i.e., `compileSdkVersion` in Android Studio) of API Level 14 or higher.

Querying for Events

For example, let's populate a `ListView` with the roster of all events the user has across all calendars, using a `CursorLoader`, showing the name of each event, the event's start date, and the event's end date. You can find this in the [Calendar/Query](#) sample project in the book's source code.

Our manifest has the `READ_CALENDARS` permission, as you would expect:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
```

THE CALENDARCONTRACT PROVIDER

```
package="com.commonware.android.cal.query"
android:versionCode="1"
android:versionName="1.0">

<uses-sdk android:minSdkVersion="14"/>

<uses-permission android:name="android.permission.READ_CALENDAR"/>

<application
    android:icon="@drawable/ic_launcher"
    android:label="@string/app_name">
    <activity
        android:name=".CalendarQueryActivity"
        android:label="@string/app_name">
        <intent-filter>
            <action android:name="android.intent.action.MAIN"/>

            <category android:name="android.intent.category.LAUNCHER"/>
        </intent-filter>
    </activity>
</application>

</manifest>
```

(from [Calendar/Query/app/src/main/AndroidManifest.xml](#))

We will use a simple `ListActivity` and so therefore do not need an activity layout. Our row layout (`res/layout/row.xml`) has three `TextView` widgets for the three pieces of data that we want to display:

```
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/linearlayout1"
    android:layout_width="match_parent"
    android:layout_height="wrap_content">

    <TextView
        android:id="@+id/title"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:layout_gravity="center_vertical"
        android:layout_marginLeft="4dip"
        android:layout_marginRight="4dip"
        android:layout_weight="1"
        android:ellipsize="end"
        android:textSize="20sp"/>

    <LinearLayout
```

THE CALENDARCONTRACT PROVIDER

```
android:id="@+id/linearLayout2"
android:layout_width="wrap_content"
android:layout_height="match_parent"
android:layout_marginRight="4dip"
android:orientation="vertical">

<TextView
    android:id="@+id/dtstart"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:layout_gravity="top"
    android:textSize="10sp"/>

<TextView
    android:id="@+id/dtend"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:layout_gravity="bottom"
    android:textSize="10sp"/>
</LinearLayout>
</LinearLayout>
```

(from [Calendar/Query/app/src/main/res/layout/row.xml](#))

In our activity (`CalendarQueryActivity`), in `onCreate()`, we set up a `SimpleCursorAdapter` on a null `Cursor` at the outset and define the activity as being the adapter's `ViewBinder`:

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    adapter=
        new SimpleCursorAdapter(this, R.layout.row, null, ROW_COLUMNS,
                                ROW_IDS);
    adapter.setViewBinder(this);
    setListAdapter(adapter);

    getLoaderManager().initLoader(0, null, this);
}
```

(from [Calendar/Query/app/src/main/java/com/commonsware/android/cal/query/CalendarQueryActivity.java](#))

A `ViewBinder` is a way to tailor how `Cursor` data is poured into row widgets, without subclassing the `SimpleCursorAdapter`. Implementing the `SimpleCursorAdapter.ViewBinder` interface requires us to implement a

THE CALENDARCONTRACT PROVIDER

setViewValue() method, which will be called when the adapter wishes to pour data from one column of a Cursor into one widget. We will examine this method shortly.

The SimpleCursorAdapter will pour data from the ROW_COLUMNS in our Cursor into the ROW_IDS widgets in our row layout:

```
private static final String[] ROW_COLUMNS=  
    new String[] { CalendarContract.Events.TITLE,  
                  CalendarContract.Events.DTSTART,  
                  CalendarContract.Events.DTEND };  
private static final int[] ROW_IDS=  
    new int[] { R.id.title, R.id.dtstart, R.id.dtend };
```

(from [Calendar/Query/app/src/main/java/com/commonsware/android/cal/query/CalendarQueryActivity.java](#))

Our onCreate() also initializes the Loader framework, triggering a call to onCreateLoader(), where we create and return a CursorLoader:

```
public Loader<Cursor> onCreateLoader(int loaderId, Bundle args) {  
    return(new CursorLoader(this, CalendarContract.Events.CONTENT_URI,  
                           PROJECTION, null, null,  
                           CalendarContract.Events.DTSTART));  
}
```

(from [Calendar/Query/app/src/main/java/com/commonsware/android/cal/query/CalendarQueryActivity.java](#))

We query on CalendarContract.Events.CONTENT_URI, asking for a certain set of columns indicated by our PROJECTION static data member:

```
private static final String[] PROJECTION=  
    new String[] { CalendarContract.Events._ID,  
                  CalendarContract.Events.TITLE,  
                  CalendarContract.Events.DTSTART,  
                  CalendarContract.Events.DTEND };
```

(from [Calendar/Query/app/src/main/java/com/commonsware/android/cal/query/CalendarQueryActivity.java](#))

The ROW_COLUMNS we map are a subset of the PROJECTION, skipping the _ID column that SimpleCursorAdapter needs but will not be displayed. Our query is also set up to sort by the start date (CalendarContract.Events.DTSTART).

When the query is complete, we pop it into the adapter in onLoadFinished() and remove it in onLoaderReset():

```
public void onLoadFinished(Loader<Cursor> loader, Cursor cursor) {  
    adapter.swapCursor(cursor);  
}
```

THE CALENDARCONTRACT PROVIDER

```
}  
  
public void onLoaderReset(Loader<Cursor> loader) {  
    adapter.swapCursor(null);  
}
```

(from [Calendar/Query/app/src/main/java/com/commonsware/android/cal/query/CalendarQueryActivity.java](#))

Our `setViewValue()` implementation then converts the DTSTART and DTEND values into formatted strings by way of `DateUtils` and the `formatDateTime()` method:

```
@Override  
public boolean setViewValue(View view, Cursor cursor, int columnIndex) {  
    long time=0;  
    String formattedTime=null;  
  
    switch (columnIndex) {  
        case 2:  
        case 3:  
            time=cursor.getLong(columnIndex);  
            formattedTime=  
                DateUtils.formatDateTime(this, time,  
                                         DateUtils.FORMAT_ABBREV_RELATIVE);  
            ((TextView)view).setText(formattedTime);  
            break;  
  
        default:  
            return(false);  
    }  
  
    return(true);  
}
```

(from [Calendar/Query/app/src/main/java/com/commonsware/android/cal/query/CalendarQueryActivity.java](#))

The `setViewValue()` method should return `true` for any columns it handles and `false` for columns it does not — skipped columns are handled by `SimpleCursorAdapter` itself.

If you run this on a device with available calendar data, you will get a list of those events:

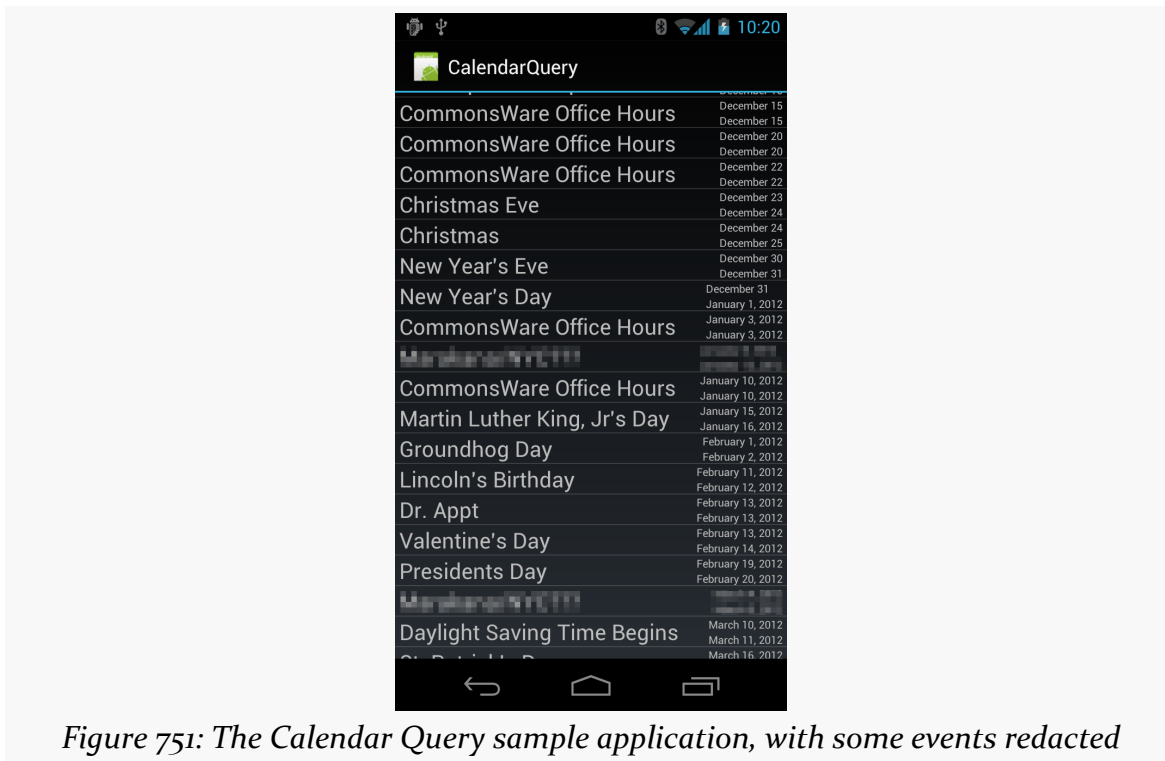

Figure 751: The Calendar Query sample application, with some events redacted

Penciling In an Event

What is rarely documented in the Android SDK is what activities might exist that support the MIME types of a given ContentProvider. In part, that is because device manufacturers have the right to remove or replace many of the built-in applications.

The Calendar application is considered by Google to be a “core” application. Quoting the Android 2.3 version of the [Compatibility Definition Document](#) (CDD):

The Android upstream project defines a number of core applications, such as a phone dialer, calendar, contacts book, music player, and so on. Device implementers MAY replace these applications with alternative versions. However, any such alternative versions MUST honor the same Intent patterns provided by the upstream project. For example, if a device contains an alternative music player, it must still honor the Intent pattern issued by third-party applications to pick a song.

Hence, in theory, so long as the CDD does not change and device manufacturers correctly honor it, those Intent patterns described by the Calendar application’s

THE CALENDARCONTRACT PROVIDER

manifest should be available across Android 4.0 devices. The Calendar application appears to support ACTION_INSERT and ACTION_EDIT for both the collection MIME type (vnd.android.cursor.dir/event) and the instance MIME type (vnd.android.cursor.item/event). Notably, there is no support for ACTION_PICK to pick a calendar or event, the way you can use ACTION_PICK to pick a contact.

The MediaStore Provider

Playing back media is a popular pastime on Android devices, one in which your app may want to participate. The easiest way for you to find out what media is available for you to display, edit, or otherwise work with is via the MediaStore content provider. MediaStore is part of the Android framework and allows you to query for images, audio files, and video files that are indexed on the device.

This chapter will review the general workings of MediaStore, plus work through an example of getting video files — and their thumbnails — from MediaStore.

Prerequisites

Understanding this chapter requires that you have read the chapters on:

- [content provider theory](#)
- [content provider implementations](#)

It is also a pretty good idea to have read the chapters on media recording and playback that might be of relevance, depending on what you intend to do with the MediaStore:

- [Audio Playback](#)
- [Audio Recording](#)
- [Video Playback](#)
- [Using the Camera via 3rd-Party Apps](#)
- [Working Directly with the Camera](#)

You might also wish to consider skimming through [the chapter on files](#) again, as it will be cross-referenced in several places in this chapter.

What Is the MediaStore?

[The documentation for MediaStore](#) describes it this way:

The Media provider contains meta data for all available media on both internal and external storage devices.

This definition... leaves a bit to be desired.

From our standpoint as Android developers, the MediaStore is a ContentProvider, supplied by Android. We can use it much like we use other system-supplied providers, like ContactsContract and CalendarContract. In this case, the primary role of MediaStore is for us to find media, just as the primary role of ContactsContract is for us to find contacts.

The “meta data” reference in the documentation refers to the fact that MediaStore itself does not store the media, even though that’s what the name MediaStore would suggest. MediaMetadataStore would be a more accurate description. We can learn *about* available media — names, durations, etc. — and we can get a Uri from MediaStore pointing to the media, but the media itself lives as a file somewhere else.

Indexed Media

MediaStore has media as a primary focus. Here, “media” refers to:

- Images (typically photos)
- Audio (music, podcasts, etc.)
- Video (whether recorded by the device, downloaded from somewhere, etc.)

MediaStore has intrinsic knowledge of these, particularly for the file formats and codecs that Android supports. As a result, the index maintained by MediaStore will contain some metadata in common for all file types, such as:

- title
- MIME type
- dates (when the file was added, when the file was modified)

...and other metadata that will be unique to one or two of the major types, such as:

- duration for audio and video (but not images)

- height and width for images and video (but not audio)
- geotagging for images and video (but not audio)

Indexed Non-Media

As was mentioned in passing in [the chapter on files](#), Android uses MTP for Android 4.0+ as the USB protocol for sharing files with a desktop or notebook computer.

To power this, Android does not go straight to the filesystem, but rather works with MediaStore. MediaStore maintains an index of *all* files, not just “media”. Whatever shows up in MediaStore is what shows up to the user in their Windows drive letter, macOS mounted volume, etc.

You too can query MediaStore for non-media files. Android will try to maintain a MIME type — probably based on file extensions — and so you can find all indexed PDF files, for example, by querying MediaStore.

MediaStore and “Other” External Storage

In [the chapter on files](#), we covered the difference between internal storage and external storage. Primarily, MediaStore maintains an index of external storage.

However, many Android devices today have multiple locations that could be considered “external storage”. While the vast majority of Android devices have “external storage” as a portion of on-board flash memory, Android device manufacturers are welcome to add other options, such as:

- card slots (typically microSD)
- USB host ports (capable of mounting thumb drives and the like)

From the standpoint of the Android SDK, such secondary storage locations are off-limits, in that there is nothing in the Android SDK to tell us if there are any such locations, where they are located (in terms of File objects to their roots), whether they can be read from, or whether they can be written to. You will find various blog posts and Stack Overflow answers where developers have attempted to catalog all of the possibilities, using a mix of low-level Linux information and manufacturer-based heuristics, but these techniques will be generally unreliable across thousands of device models.

However, many manufacturers who have added such secondary storage options will arrange to have that storage be indexed and be part of MediaStore. So, if the user slides in a microSD card containing audio files, on many devices, when you query MediaStore for available audio files, you will find those on the microSD card in addition to those on “traditional” external storage. From the user’s standpoint, in terms of consuming media, this is sufficient.

How Does My Content Get Indexed?

As was noted back in [the chapter on files](#), if you write files to external storage, you will want to use `MediaScannerConnection` to ensure that those files get indexed. In that chapter, the focus was on ensuring that your files would be visible to attached desktops/notebooks via MTP. However, what *really* happens is that `MediaScannerConnection` updates MediaStore, which in turn drives the MTP-served content.

Even if you fail to index content manually, at some point, Android is likely to pick up the files. For example, Android will scan external storage after a reboot. However, using `MediaScannerConnection` to “tap Android on the shoulder” and have it index your file means that it will show up in MediaStore more quickly. This is very important for multimedia assets — if you downloaded some media, you want that to be indexed as soon as possible, so the user can turn around and consume that media, whether through your app or another one on the user’s device.

How Do I Retrieve Video from the MediaStore?

Video players will need to find out what videos are available on the device, eligible for playback. They may wish to retrieve other details, such as the video title, duration, and so forth. And, of course, they will need something that they can use to actually play back the video itself.

In this section, we will work through the [Media/VideoList](#) sample project. This project has a `VideosFragment` that will show the roster of available videos; tapping on a video in the list will launch the user’s video player to watch that video.

Requesting Permission

Starting on API Level 19 devices, you need to hold the `READ_EXTERNAL_STORAGE` or `WRITE_EXTERNAL_STORAGE` permissions to be able to work with the MediaStore.

THE MEDIASTORE PROVIDER

Hence, the VideoList sample app has the READ_EXTERNAL_STORAGE permission in its manifest, as it has no need to write to external storage:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
    package="com.commonware.android.video.list"
    android:versionCode="1"
    android:versionName="1.0">

    <supports-screens
        android:largeScreens="true"
        android:normalScreens="true"
        android:smallScreens="false"
        android:xlargeScreens="true"/>

    <uses-sdk
        android:minSdkVersion="14"
        android:targetSdkVersion="17"/>

    <uses-permission android:name="android.permission.READ_EXTERNAL_STORAGE" />

    <application
        android:allowBackup="false"
        android:hardwareAccelerated="true"
        android:icon="@drawable/ic_launcher"
        android:label="@string/app_name"
        android:theme="@android:style/Theme.Holo.Light.DarkActionBar">
        <activity
            android:name=".MainActivity"
            android:label="@string/app_name">
            <intent-filter>
                <action android:name="android.intent.action.MAIN"/>

                <category android:name="android.intent.category.LAUNCHER"/>
            </intent-filter>
        </activity>
    </application>
</manifest>
```

(from [Media/VideoList/app/src/main/AndroidManifest.xml](#))

Querying for Video

VideosFragment uses [the Loader framework](#), since MediaStore is a ContentProvider and Loader is a convenient way to asynchronously load content from a

THE MEDIASTORE PROVIDER

ContentProvider.VideosFragment implements the LoaderManager.LoaderCallbacks interface and, in onActivityCreated(), calls getLoaderManager().initLoader() to initialize its Loader.

That triggers a call to onCreateLoader(), where VideosFragment creates a CursorLoader to query the MediaStore for videos:

```
@Override
public Loader<Cursor> onCreateLoader(int arg0, Bundle arg1) {
    return(new CursorLoader(
        getActivity(),
        MediaStore.Video.Media.EXTERNAL_CONTENT_URI,
        null, null, null,
        MediaStore.Video.Media.TITLE));
}
```

(from [Media/VideoList/app/src/main/java/com/commonsware/android/video/list/VideosFragment.java](#))

The Uri for video content from MediaStore is MediaStore.Video.Media.EXTERNAL_CONTENT_URI. Passing in null for the list of columns to return will return all available columns — not the most efficient approach, but it is convenient. The sort order of MediaStore.Video.Media.TITLE has the results sorted by the TITLE column, so the videos are returned alphabetically.

Back up in onCreateView(), we initialized a SimpleCursorAdapter to handle our results, passing in the TITLE and _ID columns into our custom row layout:

```
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:orientation="horizontal"
    android:padding="8dp">

    <ImageView
        android:id="@+id/thumbnail"
        android:layout_width="64dp"
        android:layout_height="64dp"
        android:contentDescription="@string/thumbnail"/>

    <TextView
        android:id="@android:id/text1"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:layout_marginLeft="8dp"
        android:layout_gravity="center_vertical">
```

THE MEDIASTORE PROVIDER

```
        android:textSize="24sp"/>
</LinearLayout>
```

(from [Media/VideoList/app/src/main/res/layout/row.xml](#))

`onViewCreated()` also attaches a custom `ViewBinder`, `ThumbnailBinder`, that we will cover in the next section, before eventually attaching the initially-empty `SimpleCursorAdapter` to the `ListView` of our `ListFragment`:

```
@Override
public void onViewCreated(View view,
                          Bundle savedInstanceState) {
    super.onViewCreated(view, savedInstanceState);

    String[] from=
        { MediaStore.Video.Media.TITLE, MediaStore.Video.Media._ID };
    int[] to= { android.R.id.text1, R.id.thumbnail };
    SimpleCursorAdapter adapter=
        new SimpleCursorAdapter(getActivity(), R.layout.row, null,
                                from, to, 0);

    adapter.setViewBinder(this);
    setListAdapter(adapter);

    getLoaderManager().initLoader(0, null, this);
}
```

(from [Media/VideoList/app/src/main/java/com/commonsware/android/video/list/VideosFragment.java](#))

The rest of our `LoaderManager.LoaderCallbacks` methods are fairly conventional, using `swapCursor()` to load in the results of the query (or `null` if the loader is reset):

```
@Override
public void onLoadFinished(Loader<Cursor> loader, Cursor c) {
    ((CursorAdapter)getListAdapter()).swapCursor(c);
}

@Override
public void onLoaderReset(Loader<Cursor> loader) {
    ((CursorAdapter)getListAdapter()).swapCursor(null);
}
```

(from [Media/VideoList/app/src/main/java/com/commonsware/android/video/list/VideosFragment.java](#))

Showing the Thumbnails

If you have used a video player on Android, most have an activity (or fragment) akin to the one we are implementing in this section. And, most of those will show thumbnail images of the videos in question.

However, retrieving and showing those thumbnails is a bit complicated, because Android may need to *generate* the thumbnail, if there is not already a thumbnail for the video, or if its cache of thumbnails was cleared. Generating a thumbnail takes time, time that we do not want to spend on the main application thread. For that, we will use Picasso, as profiled in [the chapter on Internet access](#).

The thumbnail will need to be displayed using some sort of `ImageView`. Since `SimpleCursorAdapter` cannot populate an `ImageView` directly, we need some other way to fill in the `ImageView`. To handle this, we create an implementation of a `ViewBinder`, named `ThumbnailBinder` — that is what we attached to our `SimpleCursorAdapter` via `setViewBinder()` back in `onActivityCreated()`.

A `ViewBinder` is a way to tailor how `Cursor` data is poured into row widgets, without subclassing the `SimpleCursorAdapter`. Implementing the `SimpleCursorAdapter.ViewBinder` interface requires us to implement a `setViewValue()` method, which will be called when the adapter wishes to pour data from one column of a `Cursor` into one widget:

```
@Override
public boolean setViewValue(View v, Cursor c, int column) {
    if (column == c.getColumnIndex(MediaStore.Video.Media._ID)) {
        Uri video=
            ContentUris.withAppendedId(
                MediaStore.Video.Media.EXTERNAL_CONTENT_URI,
                c.getInt(column));

        Picasso.with(getActivity()).load(video.toString())
            .fit().centerCrop()
            .placeholder(R.drawable.ic_media_video_poster)
            .into((ImageView)v);

        return(true);
    }

    return(false);
}
```

(from [Media/VideoList/app/src/main/java/com/commonsware/android/video/list/VideosFragment.java](#))

THE MEDIASTORE PROVIDER

If our `ViewBinder` is being asked to bind the video ID column (`MediaStore.Video.Media._ID`), we first construct the `Uri` to the video using `ContentUris.withAppendedId()`. Then, we create a UIL-supplied `DisplayImageOptions` object, where we can provide details for how to handle the image load. In this case, we supply a drawable resource to use as a placeholder image while the thumbnail is being loaded. Finally, we tell Picasso to display the image. Picasso recognizes the `Uri` structure for a video from `MediaStore` and uses utility methods like `getThumbnail()` on `MediaStore.Video.Thumbnails` to actually retrieve the thumbnail.

The net result is that when we populate our `ListView` with our `ViewBinder`-enhanced `SimpleCursorAdapter`, the `ListView` rows will initially have the placeholder image, replaced by the actual video thumbnails as they get loaded.

Playing the Selection

`VideosFragment` extends a version of `ContractListFragment`, as was used in the `EU4You` samples [earlier in this book](#). The activity that hosts this fragment is obligated to implement the `VideosFragment.Contract` interface, which in turn requires an `onVideoSelected()` method.

In `onListItemClick()` of `VideosFragment`, the fragment calls `onVideoSelected()` on the `Contract`, supplying:

- the `String` representation of the `Uri` that points to the video itself, pulled from the `MediaStore.Video.Media.DATA` column of the `Cursor` we loaded from the `MediaStore`
- the `MIME` type of that video, pulled from the `MediaStore.Video.Media.MIME_TYPE` column of that same `Cursor`

```
@Override
public void onListItemClick(ListView l, View v, int position, long id) {
    CursorAdapter adapter=(CursorAdapter)getListAdapter();
    Cursor c=(Cursor)adapter.getItem(position);
    int uriColumn=c.getColumnIndex(MediaStore.Video.Media.DATA);
    int mimeTypeColumn=
        c.getColumnIndex(MediaStore.Video.Media.MIME_TYPE);

    getContract().onVideoSelected(c.getString(uriColumn),
        c.getString(mimeTypeColumn));
}
```

(from [Media/VideoList/app/src/main/java/com/commonsware/android/video/list/VideosFragment.java](#))

THE MEDIASTORE PROVIDER

The main activity — surprisingly named MainActivity — loads up a VideosFragment as a static fragment via the res/layout/main.xml resource:

```
<?xml version="1.0" encoding="utf-8"?>
<fragment xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/videos"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:name="com.commonware.android.video.list.VideosFragment"
/>
```

(from [Media/VideoList/app/src/main/res/layout/main.xml](#))

MainActivity implements VideosFragment.Contract and therefore has an onVideoSelected() method. It simply constructs an Intent to view the video and starts an activity with it:

```
package com.commonware.android.video.list;

import android.app.Activity;
import android.content.Intent;
import android.net.Uri;
import android.os.Bundle;
import java.io.File;

public class MainActivity extends Activity implements
    VideosFragment.Contract {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.main);
    }

    @Override
    public void onVideoSelected(String uri, String mimeType) {
        Uri video=Uri.fromFile(new File(uri));
        Intent i=new Intent(Intent.ACTION_VIEW);

        i.setDataAndType(video, mimeType);
        startActivity(i);
    }
}
```

(from [Media/VideoList/app/src/main/java/com/commonware/android/video/list/MainActivity.java](#))

The Results

Running this on a device with videos available should show the list of those videos, complete with title and thumbnail:

Tapping on any entry in the list should bring up a video player on your device, assuming that one or more such players (that are capable of supporting content://Uri values) are installed.

Consuming Documents

Android has long offered the ability for an app to pick some file or stream from another app and consume it. However, the original options were designed around an app loading content from another app. Even though our *code* would be requesting content based on abstractions like MIME types, the *implementation* and user experience would be based on the traditional “pick an app to fulfill this request” chooser.

Google, given its clear interest in cross-cutting storage engines like Google Drive, wanted something better. In Android 4.4, they added the Storage Access Framework (SAF) to provide a better user experience, with only modest changes to client code. With Android’s increasing reliance upon content and document providers for cross-app content sharing, understanding the Storage Access Framework is fairly important for modern app development.

In this chapter, we will examine what it takes to consume documents published via the SAF.

Prerequisites

This chapter assumes that you have read [the chapter on ContentProvider patterns](#) or have equivalent experience with consuming streams published by a ContentProvider.

The Storage Access... What?

Let’s think about photos for a minute.

CONSUMING DOCUMENTS

A person might have photos managed as:

- on-device photos, mediated by an app like a gallery
- photos stored online in a photo-specific service, like Instagram
- photos stored online in a generic file-storage service, like Google Drive or Dropbox

Now, let's suppose that person is in an app that allows the user to pick a photo, such as to attach to an email.

The classic Android solution would be for the user to have to first choose the app to use to find the photo (e.g., Gallery, Instagram, Google Drive, Dropbox), then find the photo using that app. Then, if all goes well, the original app would receive a `Uri` to that photo and be able to make use of it.

However, this flow has three main problems:

1. From the user's standpoint, they need to know where they have the photo before they can go looking for it. Given the prominence of generic file-storage services, the user might not remember where the photo is stored, but might remember enough details about the photo (e.g., timeframe when taken, tags that might have been attached to the photo) to find it... but the user has to sequentially search each possible photo-storing app until the right one is found.
2. From the client app developer's standpoint, too many apps screw up handling the classic `ACTION_PICK` and `ACTION_GET_CONTENT` activities, failing to return a result in all cases. Users then are as likely to blame the client app for the mistake as they are to blame the photo-storing app or Android itself.
3. None of this was designed with online file-sharing services in mind. What happens if an app knows about a possible file, but the file is not available on the device right now, because it has not been downloaded from the online service?

The Storage Access Framework is designed to address these issues. It provides its own "picker" UI to allow users to find a file of interest that matches the MIME type that the client app wants. File providers simply publish details about their available files — including those that may not be on the device but could be retrieved if needed. The picker UI allows for easy browsing and searching across all possible file providers, to streamline the process for the user. And, since Android is the one providing the picker, the picker should more reliably give a result to the client app based upon the user's selection (if any).

The Storage Access Framework Participants

Providers are specialized `ContentProvider` implementations, usually extending `DocumentsProvider`, that can tell Android about the documents that are published by an app. This includes providing any sort of organizational structure (directory tree, tag cloud, etc.)

The **clients** are apps that wish to consume (or create) documents managed by providers. Clients will indicate what sort of document they want, in the form of a MIME type, where applicable.

The **picker** is the system UI that allows the user to pick a document (or documents) from among the documents published by all providers that meet the criteria established by a client requesting access to the document(s).

Picking How to Pick (a Peck of Pickled Pepper Photos)

`ACTION_PICK` would seem to be the Intent action to use to pick something. It works, but it is designed for the case where you know the specific collection of “somethings” you want to pick from. Use this, for example, to pick a contact specifically out of `ContactsContract`.

In cases where you know the MIME type you want, but you do not particularly know or care about the exact source of the file, use `ACTION_GET_CONTENT` on API Level 18 and below for everything.

For MIME types that clearly represent a document, file, or other sort of stream, use `ACTION_OPEN_DOCUMENT` (and the SAF) on API Level 19+. The SAF picker will incorporate both full-fledged SAF-compliant providers’ documents along with apps that only support `ACTION_GET_CONTENT`. However, since `ACTION_OPEN_DOCUMENT` is only available on API Level 19+ devices, if you are supporting older devices, you will need to check `Build.VERSION.SDK_INT` and choose an Intent action accordingly.

For MIME types that represent entries in a database (e.g., a calendar entry), use `ACTION_GET_CONTENT`, even on API Level 19+. Google also recommends using `ACTION_GET_CONTENT` on API Level 19+ “if you want your app to simply read/import data”, though it is unclear why they make this recommendation or why the user experience should differ based upon how the bytes would be used.

Opening a Document

Technically, we do not “open” a document using `ACTION_OPEN_DOCUMENT`. Instead, we are requesting a `Uri` pointing to some document that the user chooses.

To do that, create an `Intent` with:

- `ACTION_OPEN_DOCUMENT` as the action
- `CATEGORY_OPENABLE` as the category
- your desired MIME type

Then, use that `Intent` with `startActivityForResult()`.

For example, the [Documents/Consumer](#) sample application contains a `ConsumerFragment` that adds an “Open” item to the action bar overflow. Clicking on “Open” triggers a call to the `open()` method on the fragment. And, for API Level 19+ devices, that will in turn request to “open” a document:

```
@TargetApi(Build.VERSION_CODES.KITKAT)
private void open() {
    Intent i=new Intent().setType("image/*");

    if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.KITKAT) {
        startActivityForResult(i.setAction(Intent.ACTION_OPEN_DOCUMENT)
            .addCategory(Intent.CATEGORY_OPENABLE),
            REQUEST_OPEN);
    }
    else {
        startActivityForResult(i.setAction(Intent.ACTION_GET_CONTENT)
            .addCategory(Intent.CATEGORY_OPENABLE),
            REQUEST_GET);
    }
}
```

(from [Documents/Consumer/app/src/main/java/com/commonsware/android/documents/consumer/ConsumerFragment.java](#))

This `open()` method also gracefully degrades for older devices, falling back to `ACTION_GET_CONTENT`. In both cases, we are trying to allow the user to pick some image (MIME type of `image/*`). The two `startActivityForResult()` calls use different request IDs (`REQUEST_OPEN` versus `REQUEST_GET`), so that we can distinguish the sort of result that we get in `onActivityResult()`:

```
@Override
public void onActivityResult(int requestCode, int resultCode,
```

CONSUMING DOCUMENTS

```
        Intent resultData) {
    if (resultCode==Activity.RESULT_OK) {
        if (resultData!=null) {
            uri=resultData.getData();

            if (requestCode==REQUEST_OPEN) {
                getLoaderManager().initLoader(0, null, this);
            }
            else {
                logToTranscript(uri.toString());
            }
        }
    }
}
}
```

(from [Documents/Consumer/app/src/main/java/com/commonsware/android/documents/consumer/ConsumerFragment.java](#))

Both ACTION_GET_CONTENT and ACTION_OPEN_DOCUMENT should supply a Uri in the result Intent that points to the document the user chose, if the user actually chose one and we got RESULT_OK as the result code. This sample logs that Uri value to a “transcript” (TextView inside of a ScrollView) to show what we get back.

If the result is from an ACTION_OPEN_DOCUMENT request (REQUEST_OPEN request code), we can try to get some metadata about the document. The provider should support a query on the returned Uri that will give us the display name (OpenableColumns.DISPLAY_NAME) and possibly the size of the file (OpenableColumns.SIZE). So, we use the Loader framework to run this query, with our fragment implementing the LoaderCallbacks:

```
public Loader<Cursor> onCreateLoader(int loaderId, Bundle args) {
    return(new CursorLoader(getActivity(), uri, PROJECTION, null, null, null));
}

public void onLoadFinished(Loader<Cursor> loader, Cursor c) {
    transcript.setText(null);
    logToTranscript(uri.toString());

    if (c!=null && c.moveToFirst()) {
        int displayNameColumn=
            c.getColumnIndex(OpenableColumns.DISPLAY_NAME);

        if (displayNameColumn>=0) {
            logToTranscript("Display name: "
                +c.getString(displayNameColumn));
        }
    }
}
```

CONSUMING DOCUMENTS

```
int sizeColumn=c.getColumnIndex(OpenableColumns.SIZE);

if (sizeColumn<0 || c.isNull(sizeColumn)) {
    logToTranscript("Size not available");
}
else {
    logToTranscript(String.format("Size: %d",
        c.getInt(sizeColumn)));
}
}
else {
    logToTranscript("...no metadata available?");
}
}

public void onLoaderReset(Loader<Cursor> loader) {
    // unused
}
```

(from [Documents/Consumer/app/src/main/java/com/commonsware/android/documents/consumer/ConsumerFragment.java](#))

If we get results back, we try to read out these two values and record them to the transcript as well. Note, though, that:

- There is no guarantee that either column will be in the result set, or that the result set will have any rows
- The size might not be known, particularly if the file is not presently resident on the device (e.g., it is being downloaded now, given that the user chose the file), and so we need to call `isNull()` on the Cursor to see if we actually have a SIZE value before trying to get it as an integer

The user is presented with the system's picker, to choose an image, complete with a navigation drawer to get to various spots within the picker:

CONSUMING DOCUMENTS

Figure 753: Storage Access Framework Picker, Showing Images

When the user taps on an image, the results wind up in our transcript UI:

Figure 754: Uri, Display Name, and Size of Chosen File

Note that the default behavior of `ACTION_OPEN_DOCUMENT` is to let the user choose a single file. If your Intent includes `EXTRA_ALLOW_MULTIPLE`, set to true, then the user can choose multiple documents. Rather than getting their `Uri` values via `getData()` on the result Intent, you will need to call `getClipData()` on the Intent and iterate over the “clipboard entries”.

The `Uri` itself can then be used to get an `InputStream` or `OutputStream` for the contents, using `openInputStream()` and `openOutputStream()` on `ContentResolver`, respectively. Note, though, that you cannot pass the `Uri` to other applications, as they may not have rights to work with that document the way that you do.

Why We Want Things To Be Openable

You will notice that both the `ACTION_OPEN_DOCUMENT` and the `ACTION_GET_CONTENT` Intent objects created in the preceding example have `CATEGORY_OPENABLE` applied to them. This is supposed to guarantee that we can actually consume the content represented by the `Uri` that we get. In particular, we should be able to use a `ContentResolver` and open streams on that content.

If we leave off `CATEGORY_OPENABLE`, it is possible that we will get a `Uri` that we cannot open ourselves.

The difference boils down to what use we intend to put the `Uri` toward:

- If all we plan to do is use that `Uri` for is to wrap it in an `ACTION_VIEW` Intent and start an activity on it, you could skip `CATEGORY_OPENABLE` and perhaps offer more choices to your user
- Otherwise, use `CATEGORY_OPENABLE`

The Rest of the CRUD

`ACTION_OPEN_DOCUMENT` will give you a `Uri` for a document that you can open for reading — the “R” in “CRUD”.

However, the other CRUD operations are also entirely possible.

Create

`ACTION_CREATE_DOCUMENT` will give you a `Uri` for a document that you can open for writing, as it is your document.

To do this, construct an Intent with:

- an action of `ACTION_CREATE_DOCUMENT`
- a category of `CATEGORY_OPENABLE`
- the MIME type of the content you wish to write
- an extra, named `EXTRA_TITLE`, containing your desired filename

Then, invoke `startActivityForResult()` on that Intent, and use the `Uri` supplied in the result Intent delivered to `onActivityResult()`.

We will see an example of `ACTION_CREATE_DOCUMENT` [later in this chapter](#).

Update

The `Uri` returned from an `ACTION_OPEN_DOCUMENT` request may be writable. If it is, you can use `openOutputStream()` on a `ContentResolver` to write to that document. You can determine if a document is writable by examining the `COLUMN_FLAGS` value

returned from a `query()` on the `Uri` — if it includes `FLAG_SUPPORTS_WRITE`, you can write to the document.

We will see an example of modifying a document obtained from the Storage Access Framework [later in this chapter](#).

Delete

Similarly, if the `COLUMN_FLAGS` value includes `FLAG_SUPPORTS_DELETE`, you can delete the document by calling the static `deleteDocument()` method on the `DocumentsContract` class, supplying a `ContentResolver` plus the `Uri` of the document to be deleted.

The DocumentFile Helper

The `support-core-utils` library from the Android Support libraries contains a `DocumentFile` class. This provides a light `File`-like layer atop the low-level API offered through a `ContentResolver` or `DocumentsContract`. Of note, `DocumentFile` offers convenience methods for:

- determining read/write access (`canRead()` and `canWrite()`)
- getting the display name (`getName()`) and length (`length()`) of the document
- getting the MIME type (`getType()`)
- deleting the document (`delete()`)
- and so on

`DocumentFile` can actually work with raw files — just create a `DocumentFile` using the static `fromFile()` method. More often, though, you will create a `DocumentFile` wrapped around the `Uri` that you get from `ACTION_OPEN_DOCUMENT` or `ACTION_CREATE_DOCUMENT`. For that, there is the static `fromSingleUri()` method.

CWAC-Document and DocumentFileCompat

There is one significant problem with `DocumentFile`, though: it only works on document `Uri` values on API Level 19 and higher. However, we can get such `Uri` values on older devices, and we can get `Uri` values from other places than a `DocumentProvider` (e.g., `FileProvider`).

CONSUMING DOCUMENTS

[The CWAC-Document library](#) offers a `DocumentFileCompat` class. This is forked from the official `DocumentFile` but adds support for older devices and non-document `Uri` values. Specifically, for a non-document content `Uri`, you can get:

- the display name, queried via the `OpenableColumns`
- the length, also from the `OpenableColumns`
- the MIME type, from `ContentResolver` and `getType()`

Also, some `DocumentFile` methods whose values can be safely hard-coded for legacy documents, like `isVirtual()` (`false`), `isDirectory()` (`false`), and `isFile()` (`true`) are supported.

`DocumentFileCompat` also offers convenience methods for:

- Accessing streams (`openInputStream()`, `openOutputStream()`)
- Copying the content to something else (`copyTo()`)
- Copying something else into this content (`copyFrom()`, `copyFromAsset()`)

We will see the use of `DocumentFileCompat` in the next couple of sample apps.

Getting Durable Access

By default, you will have the rights to read (and optionally write) to the document represented by the `Uri` until the activity that requested the document via `ACTION_OPEN_DOCUMENT` or `ACTION_CREATE_DOCUMENT` is destroyed.

If you pass the `Uri` to another component — such as a service — you will need to add `FLAG_GRANT_READ_URI_PERMISSION` and/or `FLAG_GRANT_WRITE_URI_PERMISSION` to the `Intent` used to start that component. That extends your access until *that* component is destroyed.

If, however, you need the rights to survive your app restarting, you can call `takePersistableUriPermission()` on a `ContentResolver`, indicating the `Uri` of the document and the permissions (`FLAG_GRANT_READ_URI_PERMISSION` and/or `FLAG_GRANT_WRITE_URI_PERMISSION`) that you want persisted. Those rights will then survive a reboot. However:

- They will not survive the document being deleted, so just because you have a saved `Uri`, do not assume that the `Uri` will still be valid
- Not every storage provider will grant such persistable permissions

CONSUMING DOCUMENTS

- This will only work for `Uri` values that you get from `ACTION_OPEN_DOCUMENT` or `ACTION_CREATE_DOCUMENT`, not ones that you get by other means (e.g., `ACTION_GET_CONTENT`)
- You can revoke those rights by calling `releasePersistableUriPermission()` later on, and there is nothing stopping the storage provider from revoking those permissions itself at some time in the future

In addition, you can call `getPersistedUriPermissions()` to find out what persisted permissions your app has. This returns a `List` of `UriPermission` objects, where each one of those represents a `Uri`, what persisted permissions (read or write) you have, and when the permissions will expire.

If you do not have persistable permissions when you get the `Uri`, your primary recourse is to make a local copy of the content, while you still have temporary access to it. The [Documents/Durable](#) sample application illustrates this. It is based on the `Documents/Consumer` sample app from earlier in this chapter, with a few key changes:

- It provides menu options for opening a document via `ACTION_OPEN_DOCUMENT` or getting content via `ACTION_GET_CONTENT`
- It uses an `IntentService` (`DurablizerService`) to either obtain persistable permissions to the content or to make a local copy, delivering the results asynchronously via an event bus
- It uses `DocumentFileCompat` instead of direct `ContentResolver` queries to get the content metadata

For an event bus, we use greenrobot's `EventBus`, added as a dependency via `build.gradle`, along with the `CWAC-Document` library:

```
apply plugin: 'com.android.application'

android {
    compileSdkVersion 25
    buildToolsVersion '26.0.2'

    defaultConfig {
        minSdkVersion 15
        targetSdkVersion 25
        applicationId "com.commonware.android.documents.durable"
    }
}

repositories {
```

CONSUMING DOCUMENTS

```
maven {
    url "https://s3.amazonaws.com/repo.commonsware.com"
}

dependencies {
    implementation 'org.greenrobot:eventbus:3.0.0'
    implementation 'com.commonsware.cwac:document:0.2.0'
}
```

(from [Documents/Durable/app/build.gradle](#))

MainActivity is the same as in the Documents/Consumer sample app, as is the core UI of ConsumerFragment (ScrollView with a TextView inside). However, ConsumerFragment registers for events in onStart() and unregisters in onStop():

```
@Override
public void onStart() {
    super.onStart();

    EventBus.getDefault().register(this);
}

@Override
public void onStop() {
    EventBus.getDefault().unregister(this);

    super.onStop();
}
```

(from [Documents/Durable/app/src/main/java/com/commonsware/android/documents/consumer/ConsumerFragment.java](#))

The menu resource now has two items, open (for ACTION_OPEN_DOCUMENT) and get (for ACTION_GET_CONTENT):

```
<?xml version="1.0" encoding="utf-8"?>
<menu xmlns:android="http://schemas.android.com/apk/res/android">

    <item
        android:id="@+id/get"
        android:showAsAction="never"
        android:title="@string/get" />
    <item
        android:id="@+id/open"
        android:enabled="false"
        android:showAsAction="never"
        android:title="@string/open" />
</menu>
```

CONSUMING DOCUMENTS

```
</menu>
```

(from [Documents/Durable/app/src/main/res/menu/actions.xml](#))

The open one is disabled (`android:enabled="false"`) at the outset, as `ACTION_OPEN_DOCUMENT` only works on API Level 19+ devices, and the `minSdkVersion` of this sample is 15.

In `onCreateOptionsMenu()`, we conditionally enable the open item, and in `onOptionsItemSelected()`, we route the menu items to `open()` and `get()` methods:

```
@Override
public void onCreateOptionsMenu(Menu menu, MenuInflater inflater) {
    inflater.inflate(R.menu.actions, menu);

    if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.KITKAT) {
        menu.findItem(R.id.open).setEnabled(true);
    }

    super.onCreateOptionsMenu(menu, inflater);
}

@Override
public boolean onOptionsItemSelected(MenuItem item) {
    if (item.getItemId() == R.id.open) {
        open();
    }
    else if (item.getItemId() == R.id.get) {
        get();
    }

    return(super.onOptionsItemSelected(item));
}
```

(from [Documents/Durable/app/src/main/java/com/commonsware/android/documents/consumer/ConsumerFragment.java](#))

Those methods invoke their associated Intent actions, using `*/*` this time for the MIME type:

```
@TargetApi(Build.VERSION_CODES.KITKAT)
private void open() {
    Intent i =
        new Intent()
            .setType("*/*")
            .setAction(Intent.ACTION_OPEN_DOCUMENT)
            .addCategory(Intent.CATEGORY_OPENABLE);
}
```

CONSUMING DOCUMENTS

```
startActivityForResult(i, REQUEST_OPEN);
}

private void get() {
    Intent i=
        new Intent()
            .setType("image/png")
            .setAction(Intent.ACTION_GET_CONTENT)
            .addCategory(Intent.CATEGORY_OPENABLE);

    startActivityForResult(i, REQUEST_GET);
}
```

(from [Documents/Durable/app/src/main/java/com/commonsware/android/documents/consumer/ConsumerFragment.java](#))

However, whereas the Documents/Consumer sample app processed the resulting Uri directly in `onActivityResult()`, now we delegate that work to a `DurablizerService` that is responsible for ensuring that we have durable access to the content:

```
@Override
public void onActivityResult(int requestCode, int resultCode,
                             Intent resultData) {
    if (resultCode==Activity.RESULT_OK) {
        getActivity()
            .startService(new Intent(getActivity(), DurablizerService.class)
                .setData(resultData.getData())
                .addFlags(Intent.FLAG_GRANT_READ_URI_PERMISSION));
    }
}
```

(from [Documents/Durable/app/src/main/java/com/commonsware/android/documents/consumer/ConsumerFragment.java](#))

We pass the Uri via the data facet of the Intent (`setData()`), plus add the `FLAG_GRANT_READ_URI_PERMISSION` flag. This ensures that `DurablizerService` will have access to the content even if `MainActivity` is destroyed before our work is complete.

`onHandleIntent()` in `DurablizerService` has a basic flow:

- Try to obtain persistable permissions
- If that does not work, try to make a local copy
- If either of those work, deliver a `DocumentFile` to the UI layer via a `ContentReadyEvent`

CONSUMING DOCUMENTS

```
@Override
protected void onHandleIntent(Intent intent) {
    Uri document=intent.getData();
    boolean weHaveDurablePermission=obtainDurablePermission(document);

    if (!weHaveDurablePermission) {
        document=makeLocalCopy(document);
    }

    if (weHaveDurablePermission || document!=null) {
        Log.d(getClass().getSimpleName(), document.toString());

        DocumentFileCompat docFile=buildDocFileForUri(document);

        Log.d(getClass().getSimpleName(),
            "Display name: "+docFile.getName());
        Log.d(getClass().getSimpleName(),
            "Size: "+Long.toString(docFile.length()));

        EventBus.getDefault().post(new ContentReadyEvent(docFile));
    }
}
```

(from [Documents/Durable/app/src/main/java/com/commonsware/android/documents/consumer/DurablizerService.java](#))

The job of `obtainDurablePermission()` is to use `takePersistableUriPermission()` on a `ContentResolver` to request read and write access, at least on Android 4.4 or higher. So, we create a perms value that requests both `FLAG_GRANT_READ_URI_PERMISSION` and `FLAG_GRANT_WRITE_URI_PERMISSION`, and pass that to `takePersistableUriPermission()`, along with the document Uri:

```
private boolean obtainDurablePermission(Uri document) {
    boolean weHaveDurablePermission=false;

    if (Build.VERSION.SDK_INT>=Build.VERSION_CODES.KITKAT) {
        int perms=Intent.FLAG_GRANT_READ_URI_PERMISSION
            | Intent.FLAG_GRANT_WRITE_URI_PERMISSION;

        try {
            getContentResolver()
                .takePersistableUriPermission(document, perms);

            for (UriPermission perm :
                getContentResolver().getPersistedUriPermissions()) {
                if (perm.getUri().equals(document)) {
                    weHaveDurablePermission=true;
                }
            }
        }
    }
}
```

CONSUMING DOCUMENTS

```
    }  
  }  
  catch (SecurityException e) {  
    // OK, we were not offered any persistable permissions  
  }  
}  
  
return(weHaveDurablePermission);  
}
```

(from [Documents/Durable/app/src/main/java/com/commonsware/android/documents/consumer/DurablizerService.java](#))

Unfortunately, while `takePersistableUriPermission()` is synchronous, it does not actually tell us if we *have* those permissions. The only way to find out if we have access is to call `getPersistedUriPermissions()`, which returns a roster of `UriPermission` objects listing *every* persisted `Uri` permission held by our app. Then, we have to sift through those, looking for one matching our desired document `Uri`.

`obtainDurablePermission()` then returns a boolean indicating whether or not our request for persistable permissions succeeded.

`makeLocalCopy()` will be called if `obtainDurablePermission()` returns false (e.g., we are on an older Android device or otherwise used `ACTION_GET_CONTENT`). Its job is to make a local copy of the content, so we have indefinite access:

```
private Uri makeLocalCopy(Uri document) {  
    DocumentFileCompat docFile=buildDocFileForUri(document);  
    Uri result=null;  
  
    if (docFile.getName()!=null) {  
        try {  
            String ext=  
                MimeTypeMap.getSingleton().getExtensionFromMimeType(docFile.getType());  
  
            if (ext!=null) {  
                ext="."+ext;  
            }  
  
            File f=File.createTempFile("cw_", ext, getFilesDir());  
  
            docFile.copyTo(f);  
            result=Uri.fromFile(f);  
        }  
        catch (Exception e) {  
            Log.e(getClass().getSimpleName(),  
                "Exception copying content to file", e);  
        }  
    }  
  
    return(result);  
}
```

CONSUMING DOCUMENTS

(from [Documents/Durable/app/src/main/java/com/commonsware/android/documents/consumer/DurablizerService.java](#))

We start off by getting a `DocumentFileCompat` for the document `Uri`, using a `buildDocFileForUri()` helper method:

```
private DocumentFileCompat buildDocFileForUri(Uri document) {
    DocumentFileCompat docFile;

    if (document.getScheme().equals(ContentResolver.SCHEME_CONTENT)) {
        docFile=DocumentFileCompat.fromSingleUri(this, document);
    }
    else {
        docFile=DocumentFileCompat.fromFile(new File(document.getPath()));
    }

    return(docFile);
}
```

(from [Documents/Durable/app/src/main/java/com/commonsware/android/documents/consumer/DurablizerService.java](#))

This handles both likely scenarios:

- We get a `content: Uri`, and so our `DocumentFileCompat` needs to be created using the `fromSingleUri()` factory method
- We get a `file: Uri`, and so our `DocumentFileCompat` needs to be created using the `fromFile()` factory method

Back in `makeLocalCopy()`, we get the file extension associated with the content's MIME type, by way of `MimeTypeMap` and `getExtensionFromMimeType()`. Calling `getType()` on the `DocumentFileCompat` will fail if, for some reason, we have a `content: Uri` but do not have any permission to work with it. For example, had we failed to include `FLAG_GRANT_READ_URI_PERMISSION` on the `Intent` that started `DurablizerService` *and* if the `MainActivity` were destroyed by this point, we would not have any rights to use the content, and `getType()` will fail to get the MIME type for the content.

But, if `getType()` succeeds, we try to get that file extension. That too might fail, returning `null`, if the MIME type is not recognized by `MimeTypeMap`. We can live with a `null` file extension. However, if the file extension is *not* `null`, it will lack the leading `.`, so we add that. Then, we create a unique file in `getFilesDir()`, using that file extension and `createTempFile()` on `File`. From there, we use the convenient `copyTo()` method on `DocumentFileCompat` to copy that content into our temporary file.

CONSUMING DOCUMENTS

The `ContentReadyEvent` simply wraps a `DocumentFileCompat` pointing to our final content: either the original `Uri` (if we obtained durable access to it) or on our local copy:

```
static class ContentReadyEvent {
    final DocumentFileCompat docFile;

    ContentReadyEvent(DocumentFileCompat docFile) {
        this.docFile=docFile;
    }
}
```

(from [Documents/Durable/app/src/main/java/com/commonsware/android/documents/consumer/DurablizerService.java](#))

Back in `ConsumerFragment`, when the `ContentReadyEvent` is received, we log the details to the transcript:

```
@Subscribe(threadMode=ThreadMode.MAIN)
public void onContentReady(DurablizerService.ContentReadyEvent event) {
    logToTranscript(event.docFile.getUri().toString());
    logToTranscript("Display name: "+event.docFile.getName());
    logToTranscript("Size: "+Long.toString(event.docFile.length()));
}
```

(from [Documents/Durable/app/src/main/java/com/commonsware/android/documents/consumer/ConsumerFragment.java](#))

For cases where we are granted persistable permissions, the output will show a content: `Uri`, as we can continue to use the original content:

CONSUMING DOCUMENTS

Figure 755: Durable Document Demo, Showing Document Result

For cases where we were not granted persistable permissions — such as `ACTION_GET_CONTENT` — the output will show a `file: Uri`, representing the local copy of the content:

Figure 756: Durable Document Demo, Showing Content Result

Another Durable Example: Diceware

Dealing with durable documents does not require a service. Services are a good idea when you might need to make a copy of the document (e.g., the `ACTION_GET_CONTENT` scenario) and you do not know how big that document might be. In cases where the document is known to be small, just using background threads is fine, such as via [RxJava](#).

With that in mind, here is another sample app that demonstrates using `ACTION_OPEN_DOCUMENT` and `ACTION_GET_CONTENT` to work with user-provided documents. Unlike most examples in this book, though, this app has some direct usefulness, as it is a passphrase generator, using the diceware approach.

Dice? Where?!?

Simply put, [diceware](#) is a technique for generating a lengthy passphrase that still has a chance of being memorable, by choosing words from a list of common words.

The name “diceware” comes from the canonical way of generating the passphrase: rolling five six-sided dice (the sorts of dice that you see in casinos and board games)

and looking up words in a word list. The more randomly-chosen words in the passphrase, the stronger the passphrase and the more time it would take for it to be cracked by somebody.

Perhaps the most famous such passphrase is [correct horse battery staple](#), though a four-word passphrase is probably a bit short today.

We Want Words!

To use the diceware approach to generate a passphrase, you need a list of words.

A traditional diceware word list contains two columns. The right-hand column is the word, and the left-hand column is the dice roll that corresponds to that word:

4244	liverwurst
4245	lizard
4246	llama
4251	luau
4252	lubricant
4253	lucidity
4254	ludicrous
4255	luggage

[The canonical diceware site](#) has a number of word lists for a variety of languages. Each of those lists has 7,776 words, which equates to 6^5 , or the number of combinations of five rolls of a six-sided die.

However, other word lists also exist. The EFF has [published](#) a few lists, aiming for more commonly-used words and eliminating ones that might cause confusion (e.g., [homophones](#)). They also have some short lists, with only 1,296 (6^4) words, with an emphasis on shorter words. Shorter word lists require more words in the passphrase to get the same level of security (e.g., 8 words from the short lists result in similar security as 6 words from the longer lists).

The [Documents/Diceware](#) sample application packages one of the EFF word lists in the app itself, as an asset, so the app is usable “out of the box” to generate a passphrase. However, it also has action bar items to allow you to use ACTION_OPEN_DOCUMENT or ACTION_GET_CONTENT to use a different word list, if you wanted.

The Results

First, let's take a look at what the app does, before we see how it is built.

When you run the app, you immediately get a `CardView` showing a randomly-generated passphrase, using the word list that is baked into the app:

Figure 757: Diceware App, As Initially Launched

Clicking the refresh action bar item will generate a fresh passphrase, while tapping the “Words” action bar item lets you choose the length of the passphrase (from 4-10 words):

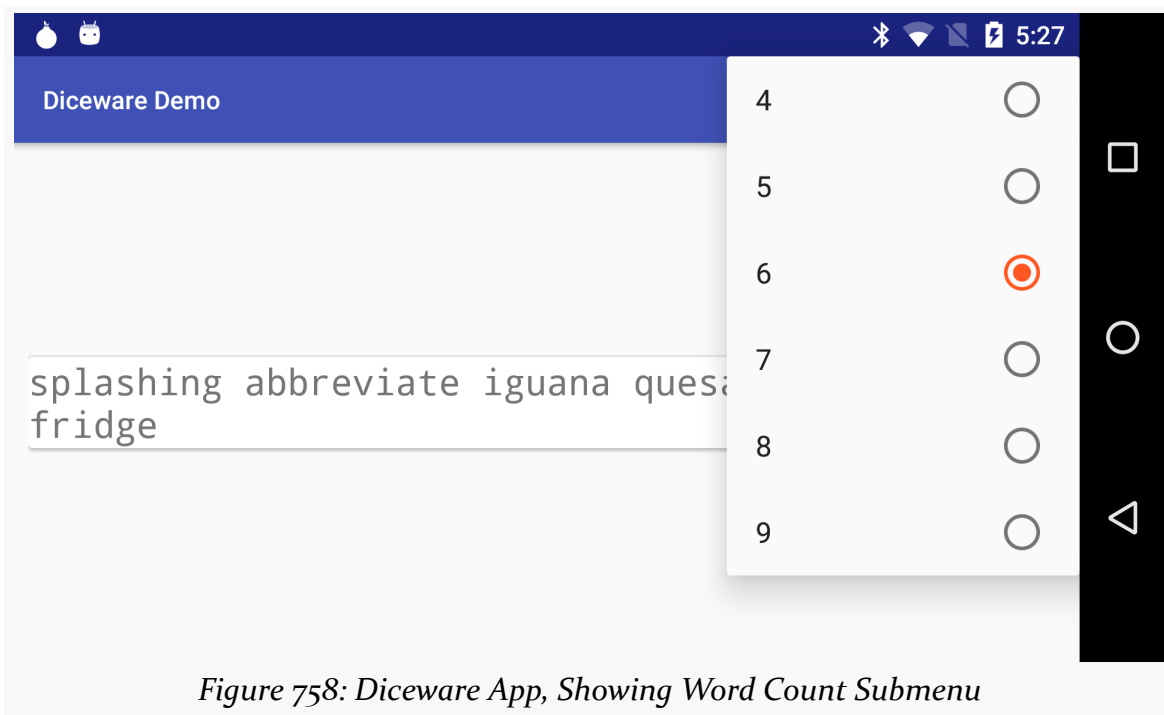

Figure 758: Diceware App, Showing Word Count Submenu

There are three options in the action bar overflow:

- “Get Word File”, which uses `ACTION_GET_CONTENT` to allow you to pick an alternative word list file
- “Open Word File”, which uses `ACTION_OPEN_DOCUMENT` to allow you to do the same
- “Reset”, which switches you back to the built-in word list

How We Got There

The Diceware app consists of a single `PassphraseFragment`, loaded using a `FragmentManager` by the `MainActivity`.

Loading Our Words

`PassphraseFragment` uses two `RxJava Observable` objects:

- One manages loading the list of words and randomly choosing a word from that list (`wordsObservable`)
- The other manages getting durable access to the external word file that you choose to load in (`docObservable`)

CONSUMING DOCUMENTS

When the app first runs, neither of these are set up yet. In `onViewCreated()`, we confirm that we do not have a `docObservable` at the moment — if we did, that would indicate that we are still in the middle of getting durable access to some words. Normally, `docObservable` will be `null` here, and so we call a `loadWords()` method:

```
@Override
public void onViewCreated(View view, Bundle savedInstanceState) {
    super.onViewCreated(view, savedInstanceState);

    passphrase=view.findViewById(R.id.passphrase);

    if (savedInstanceState!=null) {
        wordCount=savedInstanceState.getInt(STATE_WORD_COUNT);
    }

    if (docObservable!=null) {
        docSub();
    }
    else {
        loadWords(false, wordsObservable==null);
    }
}
```

(from [Documents/Diceware/app/src/main/java/com/commonsware/android/diceware/PassphraseFragment.java](#))

(we will cover `docObservable`, `docSub()`, and `wordCount` later)

`loadWords()` takes two boolean parameters:

- The first is “should we forcibly reload our words, even if we already loaded them before?”
- The second is “do we want to generate a new passphrase?”

`PassphraseFragment` is a retained fragment. It is entirely possible that we already have our words loaded from disk, in which case we do not need to load them again (e.g., after the user rotated the screen). So, here we pass `false` for the first parameter.

However, just because the user rotated the screen does not mean that we want to generate a fresh passphrase. We only want to do that if we do not already have a passphrase, or have one being generated right now. If `wordsObservable` exists (is not `null`), then we know that a passphrase has either been displayed or is soon to be displayed, and so we can skip creating a new one. When the app is first launched,

CONSUMING DOCUMENTS

though, wordsObservable is null, and so we tell loadWords() to generate a passphrase.

loadWords() then sets up wordsObservable:

```
private void loadWords(boolean forceReload, boolean regenPassphrase) {
    if (wordsObservable==null || forceReload) {
        final Application app=getActivity().getApplication();

        wordsObservable=Observable
            .defer(() -> (Observable.just(PreferenceManager
                .getDefaultSharedPreferences(app))))
            .subscribeOn(Schedulers.io())
            .map(sharedPreferences -> {
                PassphraseFragment.this.prefs=sharedPreferences;

                return(sharedPreferences.getString(PREF_URI, ""));
            })
            .map(s -> {
                InputStream in;

                if (s.length()==0) {
                    in=app.getAssets().open(ASSET_FILENAME);
                }
                else {
                    in=app.getContentResolver().openInputStream(Uri.parse(s));
                }

                return(readWords(in));
            })
            .cache()
            .observeOn(AndroidSchedulers.mainThread());
    }

    unsubWords();

    if (regenPassphrase) {
        wordsSub=wordsObservable.subscribe(this::rollDemBones, error -> {
            Toast
                .makeText(getActivity(), error.getMessage(), Toast.LENGTH_LONG)
                .show();
            Log.e(getClass().getSimpleName(), "Exception processing request",
                error);
        });
    }
}
```

CONSUMING DOCUMENTS

(from [Documents/Diceware/app/src/main/java/com/commonsware/android/diceware/PassphraseFragment.java](#))

We only need to set up `wordsObservable` if it does not already exist or `forceReload` is true. In either of those cases, we:

- Use `defer()` to set up an `Observable` that starts by loading the default `SharedPreferences` for our app, as that is where we will record the `Uri` of any external word list that we are supposed to be using
- Use `subscribeOn()` to move all this I/O to a background thread
- Use `map()` to extract the `String` preference value, keyed by `PREF_URI`, that is the `Uri` for our external word list, returning the empty string if there is no such `Uri` (note: we cannot return `null` because `RxJava` does not like that)
- Use another `map()` to create an `InputStream` either on that external word list or the one in `assets/`, then read in the words from that stream via `readWords()`
- Use `cache()` to get `RxJava` to hold onto the results of all that work, so long as we have the same `wordsObservable` object
- Use `observeOn()` to arrange to observe the results on the main application thread

`readWords()` simply reads in the lines from the asset or external word list, divides each line on the whitespace between the two columns, and extracts the word from the second column:

```
private static List<String> readWords(InputStream in) throws IOException {
    InputStreamReader isr=new InputStreamReader(in);
    BufferedReader reader=new BufferedReader(isr);
    String line;
    List<String> result=new ArrayList<>();

    while ((line = reader.readLine())!=null) {
        String[] pieces=line.split("\s");

        if (pieces.length==2) {
            result.add(pieces[1]);
        }
    }

    return(result);
}
```

(from [Documents/Diceware/app/src/main/java/com/commonsware/android/diceware/PassphraseFragment.java](#))

CONSUMING DOCUMENTS

`loadWords()` then calls `unsubWords()`. This will `dispose()` any existing subscription to `wordsObservable`:

```
private void unsubWords() {
    if (wordsSub!=null && !wordsSub.isDisposed()) {
        wordsSub.dispose();
    }
}
```

(from [Documents/Diceware/app/src/main/java/com/commonsware/android/diceware/PassphraseFragment.java](#))

Then, if we need a passphrase (`regenPassphrase` is true), we `subscribe()` to the `wordsObservable`, routing the word list to a `rollDemBones()` method, and displaying a `Toast` and logging to `Logcat` in case there is some sort of error (e.g., `IOException` reading in the words).

`rollDemBones()` uses `SecureRandom` to pick `wordCount` words from the list and updates the passphrase `TextView` with those words:

```
private void rollDemBones(List<String> words) {
    StringBuilder buf=new StringBuilder();
    int size=words.size();

    for (int i=0;i<wordCount;i++) {
        if (buf.length()>0) {
            buf.append(' ');
        }

        buf.append(words.get(random.nextInt(size)));
    }

    passphrase.setText(buf.toString());
}
```

(from [Documents/Diceware/app/src/main/java/com/commonsware/android/diceware/PassphraseFragment.java](#))

The net result, after all of that, is that when we first run the app, we create and subscribe to the `wordsObservable`, and after a brief bit of I/O, we show the initial passphrase to the user.

Getting More Words

Handling the `ACTION_GET_CONTENT` and `ACTION_OPEN_DOCUMENT` scenarios is reminiscent of the `Documents/Durable` sample from before.

CONSUMING DOCUMENTS

The two action bar items (“Get Word File”, “Open Word File”) route to `get()` and `open()` methods, each of which call `startActivityForResult()` with the appropriate action string:

```
@TargetApi(Build.VERSION_CODES.KITKAT)
private void open() {
    Intent i=
        new Intent()
            .setType("text/plain")
            .setAction(Intent.ACTION_OPEN_DOCUMENT)
            .addCategory(Intent.CATEGORY_OPENABLE);

    startActivityForResult(i, REQUEST_OPEN);
}

private void get() {
    Intent i=
        new Intent()
            .setType("text/plain")
            .setAction(Intent.ACTION_GET_CONTENT)
            .addCategory(Intent.CATEGORY_OPENABLE);

    startActivityForResult(i, REQUEST_GET);
}
```

(from [Documents/Diceware/app/src/main/java/com/commonsware/android/diceware/PassphraseFragment.java](#))

In `onActivityResult()`, if we received a `RESULT_OK` response, we set up `docObservable`, where we:

- Use `defer()` and `just()` to “observe” the results of calling `createDurableContent()`, supplying it the `Intent` that is the result of the `startActivityForResult()` call
- Use `subscribeOn()` to move that work to a background thread
- Use `cache()` to cache the results for as long as we have `docObservable`
- Use `observeOn()` to observe the results on the main application thread.

`createDurableContent()`, along with `obtainDurablePermissions()`, `makeLocalCopy()`, and `buildDocFileForUri()`, does the same work that the `DurablizerService` did in the `Documents/Durable` sample app:

- Get the persistable `Uri` permissions, if we can have them
- Make a local copy of the content, if we cannot

CONSUMING DOCUMENTS

The biggest differences are that `createDurableContent()` saves the `Uri` of either the opened document (if we got permission) or the local copy in `SharedPreferences`, and it returns a `DocumentFileCompat` representing the external word list:

```
private DocumentFileCompat createDurableContent(Intent result) throws IOException {
    Uri document=result.getData();
    ContentResolver resolver=getActivity().getContentResolver();
    boolean weHaveDurablePermission=obtainDurablePermission(resolver, document);

    if (!weHaveDurablePermission) {
        document=makeLocalCopy(getActivity(), resolver, document);
    }

    if (weHaveDurablePermission || document!=null) {
        prefs
            .edit()
            .putString(PREF_URI, document.toString())
            .commit();

        return(buildDocFileForUri(getActivity(), document));
    }

    throw new IllegalStateException("Could not get durable permission or make copy");
}

private static boolean obtainDurablePermission(ContentResolver resolver,
                                              Uri document) {
    boolean weHaveDurablePermission=false;

    if (Build.VERSION.SDK_INT>=Build.VERSION_CODES.KITKAT) {
        int perms=Intent.FLAG_GRANT_READ_URI_PERMISSION
            | Intent.FLAG_GRANT_WRITE_URI_PERMISSION;

        try {
            resolver.takePersistableUriPermission(document, perms);

            for (UriPermission perm : resolver.getPersistedUriPermissions()) {
                if (perm.getUri().equals(document)) {
                    weHaveDurablePermission=true;
                }
            }
        } catch (SecurityException e) {
            // OK, we were not offered any persistable permissions
        }
    }

    return(weHaveDurablePermission);
}

private static Uri makeLocalCopy(Context ctxt, ContentResolver resolver,
                                Uri document)
    throws IOException {
    DocumentFileCompat docFile=buildDocFileForUri(ctxt, document);
    Uri result=null;

    if (docFile.getName()!=null) {
        String ext=
```

CONSUMING DOCUMENTS

```
MimeTypeMap.getSingleton().getExtensionFromMimeType(docFile.getType());

if (ext!=null) {
    ext="."+ext;
}

File f=File.createTempFile("cw_", ext, ctxt.getFilesDir());

docFile.copyTo(f);
result=Uri.fromFile(f);
}

return(result);
}

private static DocumentFileCompat buildDocFileForUri(Context ctxt, Uri document) {
    DocumentFileCompat docFile;

    if (document.getScheme().equals(ContentResolver.SCHEME_CONTENT)) {
        docFile=DocumentFileCompat.fromSingleUri(ctxt, document);
    }
    else {
        docFile=DocumentFileCompat.fromFile(new File(document.getPath()));
    }

    return(docFile);
}
```

(from [Documents/Diceware/app/src/main/java/com/commonware/android/diceware/PassphraseFragment.java](#))

onActivityResult() then calls docSub():

```
private void docSub() {
    docSub=docObservable.subscribe(documentFile -> {
        docObservable=null;
        loadWords(true, true);
    });
}
```

(from [Documents/Diceware/app/src/main/java/com/commonware/android/diceware/PassphraseFragment.java](#))

Here, we subscribe to docObservable, and when the work is complete, we set docObservable to null (indicating that we are done with it), then call loadWords(true, true) to reload the words from our new source and generate a new passphrase based on those words.

The net result is that tapping either of those action bar items brings up the appropriate system UI to pick a piece of content, after which we start using that content. And, since we are persisting the Uri to that external word list in SharedPreferences, we will continue using that word source for the foreseeable future.

Other Fiddly Bits

That “foreseeable future” may not be all that long. If the user taps the “Reset” action bar overflow item, we `clear()` our `SharedPreferences`, then call `loadWords(true, true)` to read in the asset’s words plus generate a passphrase based that word list:

```
case R.id.reset:
    prefs.edit().clear().apply();
    loadWords(true, true);
    return(true);
```

(from [Documents/Diceware/app/src/main/java/com/commonsware/android/diceware/PassphraseFragment.java](#))

The action bar itself is populated from a menu resource, one that defines a submenu for the possible `wordCount` values:

```
<?xml version="1.0" encoding="utf-8"?>
<menu xmlns:android="http://schemas.android.com/apk/res/android">
  <item
    android:id="@+id/word_count"
    android:showAsAction="ifRoom"
    android:title="@string/menu_words">
    <menu>
      <group android:checkableBehavior="single">
        <item
          android:id="@+id/word_count_4"
          android:title="4" />
        <item
          android:id="@+id/word_count_5"
          android:title="5" />
        <item
          android:id="@+id/word_count_6"
          android:checked="true"
          android:title="6" />
        <item
          android:id="@+id/word_count_7"
          android:title="7" />
        <item
          android:id="@+id/word_count_8"
          android:title="8" />
        <item
          android:id="@+id/word_count_9"
          android:title="9" />
        <item
          android:id="@+id/word_count_10"
          android:title="10" />
      </group>
    </menu>
  </item>
</menu>
```

CONSUMING DOCUMENTS

```
    </group>
  </menu>
</item>
<item
  android:id="@+id/refresh"
  android:icon="@drawable/ic_cached_white_24dp"
  android:showAsAction="ifRoom"
  android:title="@string/menu_refresh" />
<item
  android:id="@+id/get"
  android:showAsAction="never"
  android:title="@string/get" />
<item
  android:id="@+id/open"
  android:enabled="false"
  android:showAsAction="never"
  android:title="@string/open" />
<item
  android:id="@+id/reset"
  android:showAsAction="never"
  android:title="@string/menu_reset" />
</menu>
```

(from [Documents/Diceware/app/src/main/res/menu/actions.xml](#))

We start with the `word_count_6` item checked, and the `wordCount` field is also initialized to 6. If the user taps on any of those submenu items, we update the submenu to check the proper item, figure out the new `wordCount` (by cheating and parsing the menu title as an `Integer`), and if the user changed word count values we generate a fresh passphrase (without re-loading the word list):

```
case R.id.word_count_4:
case R.id.word_count_5:
case R.id.word_count_6:
case R.id.word_count_7:
case R.id.word_count_8:
case R.id.word_count_9:
case R.id.word_count_10:
    item.setChecked(!item.isChecked());

    int temp=Integer.parseInt(item.getTitle().toString());

    if (temp!=wordCount) {
        wordCount=temp;
        loadWords(false, true);
    }
```

CONSUMING DOCUMENTS

```
return(true);
```

(from [Documents/Diceware/app/src/main/java/com/commonware/android/diceware/PassphraseFragment.java](#))

Since that `wordCount` value can change, we save it as part of the saved instance state Bundle in `onSaveInstanceState()`, and we pull that value back out of that Bundle in `onCreateView()`.

However, we are *not* putting the generated passphrase in the saved instance state Bundle ourselves, even though clearly that is being generated at runtime. Here, Diceware takes advantage of a bit of a trick. On the layout resource, the `TextView` that shows the passphrase has `android:freezesText="true"`:

```
<FrameLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:padding="8dp">

    <android.support.v7.widget.CardView
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:layout_gravity="center"
        android:padding="8dp">

        <TextView
            android:id="@+id/passphrase"
            android:layout_width="wrap_content"
            android:layout_height="wrap_content"
            android:freezesText="true"
            android:textSize="20sp"
            android:typeface="monospace" />
    </android.support.v7.widget.CardView>

</FrameLayout>
```

(from [Documents/Diceware/app/src/main/res/layout/activity_main.xml](#))

Ordinarily, the contents of a `TextView` are not part of the saved instance state Bundle, because Android assumes that those values are fixed (e.g., via `android:text` in the layout). In our case, we are generating the passphrase at runtime, and so `android:freezesText="true"` tells Android to hold onto our `TextView` content in the saved instance state Bundle automatically, the way that it does for `EditText`. Hence, with that one attribute, Android will take care of holding onto the passphrase across configuration changes for us.

Extended Example: A Tiny Text Editor

The [Documents/TinyTextEditor](#) sample application offers a more extended look at how the Storage Access Framework can be used in practice. It implements a tab-based text editor, where you use `ACTION_OPEN_DOCUMENT` and `ACTION_CREATE_DOCUMENT` to open existing text files or create new ones. Or, you can use some other app to start an `ACTION_EDIT` Intent on a `file:` or `content:Uri`, and have `TinyTextEditor` open up an editor on that content.

The actual editing is a simple multi-line `EditText` widget, with the results saved on demand, when the activity moves to the background, or when a given tab is closed. As a bonus, on Android 7.0 devices, you can take a tab and launch it into a separate window, for side-by-side editing.

In this sample, we will see how the Storage Access Framework can be used in a somewhat-closer-to-production setting. Along the way, we will explore some advanced `ViewPager` manipulations, supporting multiple windows on Android 7.0 devices, and more.

The Overall Model

Documents are represented as `Uri` values, obtained from the Storage Access Framework. While we retrieve some bits of metadata, like the display name, along with the text of the document, that information is only held in widgets managed by an `EditorFragment`. There is no `TextDocument` model object. For a more sophisticated app, having a clear model layer is usually a good idea.

Where we *do* have a more structured model comes in the form of edit history. The app tracks what documents are open, so the app can re-open those documents when the app's process starts up again the next time. This is not tied strictly to saved instance state, as we want to open the existing files even if the saved instance state is lost (e.g., the user leaves the app for an hour). This is in line with how many other tabbed text editors work for desktop operating systems, such as the [Sublime Text](#) editor that the author is using to write this book.

The `EditHistory` class manages our list of open documents, persisting them to `SharedPreferences`. Since `SharedPreferences` does not support any sort of ordered collection of strings, `EditHistory` maintains a single `String` preference, holding a JSON serialization of an `ArrayList` of `Uri` values.

Opening a Document

From the user’s standpoint, a document is opened either by choosing an “open” action bar item, or by launching the app after having left it previously with open tabs. Technically, we have a third scenario: launching a separate copy of the activity to use in a separate window. While the user may not perceive that as “opening a document”, from a programming standpoint it amounts to the same thing, as our old activities and fragments are for the original window, not the new window.

The Startup Flow

The app’s launcher activity is MainActivity. It uses a ViewPager along with a Material Design-style tab implementation, described [elsewhere in the book](#):

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:app="http://schemas.android.com/apk/res-auto"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:orientation="vertical">

    <io.karim.MaterialTabs
        android:id="@+id/tabs"
        android:layout_width="match_parent"
        android:layout_height="48dp"
        app:mtIndicatorColor="@color/accent"
        app:mtSameWeightTabs="true"/>

    <android.support.v4.view.ViewPager
        android:id="@+id/pager"
        android:layout_width="match_parent"
        android:layout_height="match_parent">
    </android.support.v4.view.ViewPager>
</LinearLayout>
```

(from [Documents/TinyTextEditor/app/src/main/res/layout/main.xml](#))

In onCreate(), mostly we set up the ViewPager and tabs, applying an EditorsAdapter that we will examine shortly:

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.main);
}
```

CONSUMING DOCUMENTS

```
mustRestoreHistory=(savedInstanceState==null &&
    !ACTION_NEW_WINDOW.equals(getIntent().getAction()));

pager=(ViewPager)findViewById(R.id.pager);
adapter=new EditorsAdapter(getFragmentManager());
pager.setAdapter(adapter);

tabs=(MaterialTabs)findViewById(R.id.tabs);
tabs.setViewPager(pager);
}
```

(from [Documents/TinyTextEditor/app/src/main/java/com/commonsware/android/tte/MainActivity.java](#))

The `mustRestoreHistory` value indicates whether, later on in setting up the activity, we need to restore the editor tabs from the last time the user was in the app. There are four main scenarios here:

1. We are launching a fresh activity instance (`savedInstanceState` is `null`) from the home screen launcher (our `Intent` has no `Uri`). In this case, we should restore the tabs from the last time the user was in the app.
2. We underwent a configuration change (`savedInstanceState` is not `null`). In this case, the implementation of `ViewPager` and `FragmentManager` will set up our tabs for us automatically, and so we do not need to do that ourselves.
3. We received a `Uri` in the `Intent` that started the activity, and that `Uri` is for a custom action (`ACTION_NEW_WINDOW`) that we are using. This indicates that we are being started as a separate window, and the `Uri` is the document to be opened in that window. While we will need to open that particular document, we do not need to restore other prior tabs — they are open in the original activity. We will explore the multi-window scenario more [later in this chapter](#).
4. We received a `Uri` in the `Intent` that started the activity, and that `Uri` is for some other action. Presumably, that is `ACTION_EDIT`. In this case, if our activity is being created, we should restore our history *and* open the new document, much the way tabbed editors in desktop operating systems work.

Our `onStart()` and `onStop()` methods mostly hook us up to the greenrobot `EventBus`, which this app uses for communication from background threads to the UI layer:

```
@Override
public void onStart() {
    super.onStart();

    EventBus.getDefault().register(this);
}
```

CONSUMING DOCUMENTS

```
    if (editHistory.initialize(this)) {
        loadEditors();
    }
}

@Override
public void onStop() {
    EventBus.getDefault().unregister(this);

    super.onStop();
}
```

(from [Documents/TinyTextEditor/app/src/main/java/com/commonsware/android/tte/MainActivity.java](#))

We will explore the `editHistory` bit of code [later in this chapter](#). For the moment, take it on faith that `initialize()` returns true if our edit history is already loaded (so we can now open our tabs, if needed), via a `loadEditors()` method.

That `loadEditors()` method, if `mustRestoreHistory` is true, asks the `editHistory` for the `Uri` values that we had opened the last time the user was in the app. We then iterate over that list and call `openEditor()` for each:

```
private void loadEditors() {
    if (mustRestoreHistory) {
        List<Uri> openEditors=editHistory.getOpenEditors();

        for (Uri uri : openEditors) {
            openEditor(uri);
        }

        mustRestoreHistory=false;
    }

    if (getIntent().getData()!=null) {
        openEditor(getIntent().getData());
    }
}
```

(from [Documents/TinyTextEditor/app/src/main/java/com/commonsware/android/tte/MainActivity.java](#))

If, however, `mustRestoreHistory` is false, but we were passed a `Uri` in our Intent, we open an editor on that particular document. That `Uri` would either be for a new window or for an `ACTION_EDIT` request.

The EditorsAdapter

But before we can understand what `openEditor()` does, we need to spend a few moments on `EditorsAdapter`. We associated it with the `ViewPager`, so clearly it is some implementation of `PagerAdapter`. In particular, it is a subclass of `ArrayPagerAdapter`, the author's custom `PagerAdapter` implementation. `EditorsAdapter` coordinates a series of `EditorFragment` instances, one per document being edited:

```
package com.commonware.android.tte;

import android.app.FragmentManager;
import android.net.Uri;
import com.commonware.cwac.pager.ArrayPagerAdapter;
import com.commonware.cwac.pager.PageDescriptor;
import com.commonware.cwac.pager.SimplePageDescriptor;
import java.util.ArrayList;

public class EditorsAdapter extends ArrayPagerAdapter<EditorFragment> {
    public EditorsAdapter(FragmentManager fm) {
        super(fm, new ArrayList<PageDescriptor>());
    }

    @Override
    protected EditorFragment createFragment(PageDescriptor desc) {
        Uri document=Uri.parse(desc.getFragmentTag());

        return(EditorFragment.newInstance(document));
    }

    void addDocument(Uri document) {
        add(new SimplePageDescriptor(document.toString(),
            document.getLastPathSegment()));
    }

    void updateTitle(Uri document, String title) {
        int position=getPositionForDocument(document);

        if (position>=0) {
            SimplePageDescriptor desc=
                (SimplePageDescriptor)getPageDescriptor(position);

            desc.setTitle(title);
        }
    }
}
```

CONSUMING DOCUMENTS

```
void remove(Uri document) {
    int position=getPositionForDocument(document);

    if (position>=0) {
        remove(position);
    }
}

int getPositionForDocument(Uri document) {
    return(getPositionForTag(document.toString()));
}
}
```

(from [Documents/TinyTextEditor/app/src/main/java/com/commonsware/android/tte/EditorsAdapter.java](#))

Full coverage of `ArrayPagerAdapter` can be found [elsewhere in the book](#). Suffice it to say that `ArrayPagerAdapter` works with a `List` of `PageDescriptor` objects, where each of those represents a single page. Those objects hold onto the title for the page (for use by our tabs) and a unique tag (used by `FragmentManager`).

In our case, the tag is the `String` representation of the `Uri`, as that is guaranteed to be unique, since we are only going to allow one open tab per document, where the document is represented by the `Uri`.

Of note for now:

- The `EditorsAdapter` constructor starts off with an empty roster of pages, supplying an empty `ArrayList` to `ArrayPagerAdapter`. We will add (and remove) pages on the fly, based upon the documents to be edited.
- The required `createFragment()` method is given a `PageDescriptor` and needs to create the fragment for that page. Here, we get the tag from the descriptor, convert that back into a `Uri`, and pass that to a `newInstance()` factory method on `EditorFragment`.
- `addDocument()` is responsible for adding a new page to the `ViewPager`, to represent a document to be edited. We chain to the `ArrayPagerAdapter` implementation of `add()`, supplying a `SimplePageDescriptor`, which is a trivial implementation of the `PageDescriptor` interface. We provide the tag (the `String` representation of the document `Uri`) and a temporary title (the last path segment off of the document `Uri`, hoping that perhaps it is some sort of filename).
- `getPositionForDocument()` calls `getPositionForTag()` on `ArrayPagerAdapter`, given the tag generated from the document `Uri`. This

CONSUMING DOCUMENTS

will return -1 if there is no page with this tag, or the 0-based position of the page in the ViewPager if we already have a page.

We will look at the remaining methods on `EditorsAdapter` later in this chapter.

Opening an Editor

With that in mind, the primary job of `openEditor()` is to call that `addDocument()` method on the `EditorsAdapter`, to open up an `EditorFragment` on the associated document:

```
private void openEditor(Uri document) {
    if (ContentResolver.SCHEME_CONTENT.equals(document.getScheme()) ||
        canWriteFiles()) {
        int position=adapter.getPositionForDocument(document);

        if (position!=-1) {
            adapter.addDocument(document);
            pager.setCurrentItem(adapter.getCount()-1);

            if (!editHistory.addOpenEditor(document)) {
                Toast
                    .makeText(this, R.string.msg_save_history,
                        Toast.LENGTH_LONG)
                    .show();
            }
        }
        else {
            pager.setCurrentItem(position);
        }
    }
    else if (ContentResolver.SCHEME_FILE.equals(document.getScheme())) {
        pendingFiles.add(document);
        ActivityCompat.requestPermissions(this, PERMS_FILE,
            REQUEST_PERMS_FILE);
    }
}
```

(from [Documents/TinyTextEditor/app/src/main/java/com/commonsware/android/tte/MainActivity.java](#))

However, this gets complicated.

There are three possibilities for the document:

CONSUMING DOCUMENTS

- It is a content: Uri. Responsibility for getting read/write access to that Uri is in a DocumentStorageService, since that can be done without user intervention.
- It is a file: Uri, but the user has already granted us permission to use WRITE_EXTERNAL_STORAGE, as indicated by the canWriteFiles() method:

```
private boolean canWriteFiles() {  
    return(ContextCompat.checkSelfPermission(this, WRITE_EXTERNAL_STORAGE)==  
        PackageManager.PERMISSION_GRANTED);  
}
```

(from [Documents/TinyTextEditor/app/src/main/java/com/commonsware/android/tte/MainActivity.java](#))

- It is a file: Uri, but we do not have permission to work with external storage yet, such as on the first run of the app.

In the first two cases, we can go ahead and start working on opening the document. In the third case (our scheme is file but canWriteFiles() returned false), we use ActivityCompat.requestPermissions() to try to get permission, adding our document to a pendingFiles list. Our corresponding onRequestPermissionsResult() method confirms that we now have access and, if so, opens the pending files by calling back into openEditor():

```
@Override  
public void onRequestPermissionsResult(int requestCode,  
                                       String[] permissions,  
                                       int[] grantResults) {  
    super.onRequestPermissionsResult(requestCode, permissions,  
                                     grantResults);  
  
    if (REQUEST_PERMS_FILE==requestCode) {  
        if (canWriteFiles()) {  
            for (Uri document : pendingFiles) {  
                openEditor(document);  
            }  
  
            pendingFiles.clear();  
        }  
    }  
}
```

(from [Documents/TinyTextEditor/app/src/main/java/com/commonsware/android/tte/MainActivity.java](#))

If we appear to have the ability to work with the document, we check to see if we already have the document open, by calling getPositionForDocument() on the

CONSUMING DOCUMENTS

EditorsAdapter. If we do have it open already, we just make that position be the current item in the ViewPager. Otherwise, we:

- Call `addDocument()`, as mentioned
- Call `setCurrentItem()` on the ViewPager to move to the newly-added page (which, courtesy of how `add()` works on `ArrayPagerAdapter`, will be added to the end of the list of pages)
- Make sure that this document is part of our edit history, which we will explore more [later in this chapter](#)

Setting Up the Fragment

At this point, we have added a document to the EditorsAdapter, triggering ViewPager and ArrayPagerAdapter to ask EditorsAdapter to create an EditorFragment to represent that page. EditorsAdapter uses a `newInstance()` factory method on EditorFragment, which stuffs the document Uri into the arguments Bundle, so we retain it across configuration changes and such:

```
static EditorFragment newInstance(Uri document) {
    EditorFragment frag=new EditorFragment();
    Bundle args=new Bundle();

    args.putParcelable(KEY_DOCUMENT, document);
    frag.setArguments(args);

    return(frag);
}
```

(from [Documents/TinyTextEditor/app/src/main/java/com/commonsware/android/tte/EditorFragment.java](#))

`onCreate()` makes this a retained fragment (to help optimize the configuration-change scenario) and requests to have an options menu. We also register for the EventBus here, unregistering it on `onDestroy()`:

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    setHasOptionsMenu(true);
    setRetainInstance(true);
    EventBus.getDefault().register(this);
}

@Override
```

CONSUMING DOCUMENTS

```
public void onStop() {
    save();

    super.onStop();
}

@Override
public void onDestroy() {
    EventBus.getDefault().unregister(this);

    super.onDestroy();
}
```

(from [Documents/TinyTextEditor/app/src/main/java/com/commonsware/android/tte/EditorFragment.java](#))

In `onStop()`, though, we call a `save()` method that we will examine later, that saves any user changes to the document, so that we do not lose them (e.g., if our process gets terminated while we are in the background).

Our editor's layout mostly consists of a large `EditText` widget, though we also have a `ProgressBar` to show if it takes a while to load the document:

```
<FrameLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent">

    <EditText
        android:id="@+id/editor"
        android:layout_width="match_parent"
        android:layout_height="match_parent"
        android:gravity="left|top"
        android:inputType="textMultiLine"
        android:visibility="gone" />

    <ProgressBar
        android:id="@+id/progress"
        style="?android:attr/progressBarStyleLarge"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:layout_gravity="center" />

</FrameLayout>
```

(from [Documents/TinyTextEditor/app/src/main/res/layout/editor.xml](#))

In `onCreateView()`, we inflate the layout and grab our widgets:

CONSUMING DOCUMENTS

```
@Override
public View onCreateView(LayoutInflater inflater,
                        ViewGroup container,
                        Bundle savedInstanceState) {
    View result=inflater.inflate(R.layout.editor, container, false);

    editor=(EditText)result.findViewById(R.id.editor);
    progress=result.findViewById(R.id.progress);

    return(result);
}
```

(from [Documents/TinyTextEditor/app/src/main/java/com/commonsware/android/tte/EditorFragment.java](#))

In `onViewCreated()`, if our editor is empty, we assume that we have not yet loaded the document, so we ask a `DocumentStorageService` to `loadDocument()`:

```
@Override
public void onViewCreated(View view,
                        Bundle savedInstanceState) {
    super.onViewCreated(view, savedInstanceState);

    if (editor.getText().length()==0) {
        DocumentStorageService.loadDocument(getActivity(),
            getDocumentUri());
    }
}
```

(from [Documents/TinyTextEditor/app/src/main/java/com/commonsware/android/tte/EditorFragment.java](#))

This will happen asynchronously; in the meantime, the user sees the `ProgressBar` (the `EditText` has `android:visibility="gone"`).

Loading the Content

`DocumentStorageService` is an `IntentService`, one responsible for all I/O related to the Storage Access Framework.

Rather than having clients directly start the service, though, `DocumentStorageService` offers static methods that handle that bit of work, taking relevant parameters, putting them in `Intent` extras, and calling `startService()`. This helps with long-term maintenance: if the rules for `DocumentStorageService` change (e.g., different data types allowed), the static methods can hide those implementation details.

CONSUMING DOCUMENTS

So, `loadDocument()` creates an explicit `Intent` for the service, attaches an action string to identify that we are going to load a document, and puts the `Uri` of the document as the “data” of the `Intent`:

```
public static void loadDocument(Context ctxt, Uri document) {
    Intent i=new Intent(ctxt, DocumentStorageService.class)
        .setAction(Intent.ACTION_OPEN_DOCUMENT)
        .addFlags(Intent.FLAG_GRANT_READ_URI_PERMISSION)
        .setData(document);

    ctxt.startService(i);
}
```

(from [Documents/TinyTextEditor/app/src/main/java/com/commonsware/android/tte/DocumentStorageService.java](#))

`onHandleIntent()` is responsible for unpacking the `Intent` and delegating the real work to a dedicated method. In the case of loading the document, a `load()` method will handle that work:

```
@Override
protected void onHandleIntent(Intent intent) {
    if (Intent.ACTION_OPEN_DOCUMENT.equals(intent.getAction())) {
        load(intent.getData());
    }
    else if (Intent.ACTION_EDIT.equals(intent.getAction())) {
        save(intent.getData(),
            intent.getStringExtra(Intent.EXTRA_TEXT),
            intent.getBooleanExtra(EXTRA_CLOSING, false));
    }
}
```

(from [Documents/TinyTextEditor/app/src/main/java/com/commonsware/android/tte/DocumentStorageService.java](#))

(we will examine the `ACTION_EDIT` path, for saving a document, [later in the chapter](#))

The `load()` method is responsible for doing three main things:

1. Obtaining (or refreshing) our persistable `Uri` permissions, and confirming that we do indeed have access to this document
2. Loading the text of the document itself
3. Obtaining other necessary bits of metadata, such as the display name of the document and whether or not we have write access

This... gets complicated:

CONSUMING DOCUMENTS

```
private void load(Uri document) {
    try {
        boolean weHavePermission=false;
        boolean isContent=
            ContentResolver.SCHEME_CONTENT.equals(document.getScheme());

        if (isContent) {
            int perms=Intent.FLAG_GRANT_READ_URI_PERMISSION
                | Intent.FLAG_GRANT_WRITE_URI_PERMISSION;

            getContentResolver()
                .takePersistableUriPermission(document, perms);

            for (UriPermission perm :
                getContentResolver().getPersistedUriPermissions()) {
                if (perm.getUri().equals(document)) {
                    weHavePermission=true;
                }
            }
        }
        else {
            weHavePermission=true;
        }

        if (weHavePermission) {
            try {
                InputStream is=
                    getContentResolver().openInputStream(document);

                try {
                    String text=slurp(is);
                    DocumentFile docFile;

                    if (isContent) {
                        docFile=DocumentFile.fromSingleUri(this, document);
                    }
                    else {
                        docFile=DocumentFile.fromFile(new File(document.getPath()));
                    }

                    EventBus
                        .getDefault()
                        .post(
                            new DocumentLoadedEvent(document, text,
                                docFile.getName(), docFile.canWrite()));
                }
            }
            finally {
                is.close();
            }
        }
    }
}
```

CONSUMING DOCUMENTS

```
    }
  }
  catch (Exception e) {
    Log.e(getClass().getSimpleName(),
        "Exception loading "+document.toString(), e);
    EventBus
      .getDefault()
      .post(new DocumentLoadErrorEvent(document, e));
  }
}
else {
  Log.e(getClass().getSimpleName(),
      "We failed to get permissions for "+document.toString());
  EventBus
    .getDefault()
    .post(new DocumentPermissionFailureEvent(document));
}
}
catch (SecurityException e) {
  Log.e(getClass().getSimpleName(),
      "Exception getting permissions for "+document.toString(), e);
  EventBus
    .getDefault()
    .post(new DocumentPermissionFailureEvent(document));
}
}
```

(from [Documents/TinyTextEditor/app/src/main/java/com/commonsware/android/tte/DocumentStorageService.java](https://github.com/lorenzobianchi/TinyTextEditor/blob/master/app/src/main/java/com/commonsware/android/tte/DocumentStorageService.java))

We check to see what the scheme is of the document `Uri`. If it is a file, we should already have permission through the runtime permission system from the UI layer, so we can go ahead.

If, however, it is a content `Uri`, we need to take (or refresh) our persistable permissions for that `Uri`. So, we create a perms value that indicates that we want both read and write permissions to the `Uri`, then call `takePersistableUriPermission()` on a `ContentResolver` to request that access. We then check the `getPersistedUriPermissions()` output to see if we actually got our desired permissions.

If we appear to have permission, we then use `openInputStream()` on a `ContentResolver` to read in the text, leveraging a `slurp()` static method to just read in all the text from the `InputStream` and return the result:

```
// based on http://stackoverflow.com/a/309718/115145
```

CONSUMING DOCUMENTS

```
private static String slurp(final InputStream is)
    throws IOException {
    final char[] buffer=new char[8192];
    final StringBuilder out=new StringBuilder();
    final Reader in=new InputStreamReader(is, "UTF-8");
    int rsz=in.read(buffer, 0, buffer.length);

    while (rsz>0) {
        out.append(buffer, 0, rsz);
        rsz=in.read(buffer, 0, buffer.length);
    }

    return(out.toString());
}
```

(from [Documents/TinyTextEditor/app/src/main/java/com/commonsware/android/tte/DocumentStorageService.java](#))

We then create a `DocumentFile` for this document, based on its `Uri`. `DocumentFile`, unfortunately, does not recognize any `Uri` scheme other than `content`. So, we route to `fromFile()` or `fromSingleUri()` based on the scheme.

We use that `DocumentFile` to get the display name (`getName()`) and write access (`canWrite()`), passing those and the text to a `DocumentLoadedEvent` that we publish on the event bus. If we run into some problem, we raise either a `DocumentPermissionFailureEvent` (if the problem appears to be related to permissions) or a `DocumentLoadErrorEvent` (for other sorts of errors).

Hence, the result of `load()` should be an event, of one of those three types, posted on the event bus.

Handling the DocumentLoadedEvent

Our `EditorFragment` handles the `DocumentLoadedEvent`:

```
@Subscribe(threadMode=ThreadMode.MAIN)
public void onDocumentLoaded(DocumentStorageService.DocumentLoadedEvent event) {
    if (event.document.equals(getDocumentUri())) {
        editor.setText(event.text);
        editor.setVisibility(View.VISIBLE);
        progress.setVisibility(View.GONE);
        ((Contract) getActivity())
            .applyDisplayName(getDocumentUri(), event.displayName);
        isLoading=true;
        canWrite=event.canWrite;

        if (!canWrite) {
            editor.setEnabled(false);
        }
    }
}
```

CONSUMING DOCUMENTS

```
}  
}
```

(from [Documents/TinyTextEditor/app/src/main/java/com/commonsware/android/tte/EditorFragment.java](#))

Note that we are using a 3.x generation of greenrobot’s EventBus, and so we use the `@Subscribe` annotation to indicate that we want to receive this event on the main application thread.

Since the events are “generic”, and we may have multiple `EditorFragment` instances on multiple documents, we need to confirm that this event is for this fragment’s particular document, by comparing `Uri` values. If it is a match, we:

- Update the `EditText` with the text
- Toggle the widget visibilities, to show the `EditText` and hide the `ProgressBar`
- Via a `Contract` interface, we ask our hosting activity to update its UI to reflect the document’s actual display name
- Make note that we have loaded the document, setting `isLoading` to `true`
- Make note of whether we can write the document, by updating a `canWrite` field
- If we cannot write to the document, disable the `EditText` to indicate that fact

`MainActivity`, when called with `applyDisplayName()`, tells the `EditorsAdapter` to update the title for a tab, then tells the tabs to reload:

```
@Override  
public void applyDisplayName(Uri document,  
                             String displayName) {  
    adapter.updateTitle(document, displayName);  
    tabs.notifyDataSetChanged();  
}
```

(from [Documents/TinyTextEditor/app/src/main/java/com/commonsware/android/tte/MainActivity.java](#))

`updateTitle()` on `EditorsAdapter` finds the position for the supplied document, gets the `SimplePageDescriptor` for that position, and updates the title in it:

```
void updateTitle(Uri document, String title) {  
    int position=getPositionForDocument(document);  
  
    if (position>=0) {  
        SimplePageDescriptor desc=  
            (SimplePageDescriptor)getPageDescriptor(position);
```

```
desc.setTitle(title);
    }
}
```

(from [Documents/TinyTextEditor/app/src/main/java/com/commonsware/android/tte/EditorsAdapter.java](#))

The Open Action Bar Item

By this time, you may already be tired of opening documents. However, while much of that code will be reusable, the code path specifically was for re-opening any tabs that were open when we last left this activity, or for opening a `Uri` delivered to us by an `ACTION_EDIT` request.

To open a new document, `MainActivity` has an action bar item, named `open`, with a “folder” icon:

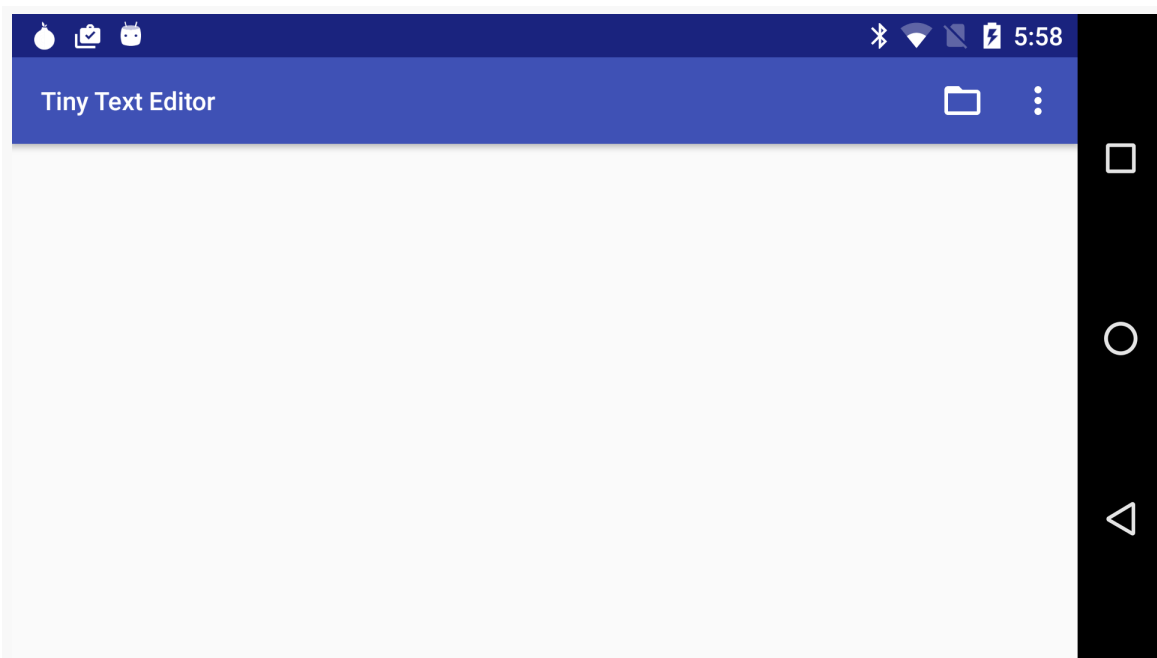

Figure 759: TinyTextEditor, Showing Open Action Bar Item

When the user taps that, our `onOptionsItemSelected()` method will call an `openDocument()` method:

```
private void openDocument(boolean allowMultiple) {
    Intent i=new Intent()
        .setType("text/*")
}
```

CONSUMING DOCUMENTS

```
.setAction(Intent.ACTION_OPEN_DOCUMENT)
.putExtra(Intent.EXTRA_ALLOW_MULTIPLE, allowMultiple)
.addCategory(Intent.CATEGORY_OPENABLE);

startActivityForResult(i, REQUEST_OPEN);
}
```

(from [Documents/TinyTextEditor/app/src/main/java/com/commonsware/android/tte/MainActivity.java](#))

There is also an “Open Multiple” action bar item, tossed into the overflow menu. When tapped, this too calls `openDocument()`, passing in `true` as a parameter, whereas the regular “Open” action bar item triggered an `openDocument()` call with `false`.

That flag gets packaged into the `ACTION_OPEN_DOCUMENT` Intent as the `EXTRA_ALLOW_MULTIPLE` value, to indicate if we want to allow the user to pick multiple files or not. This Intent also requests any text documents (MIME type of `text/*`).

This leads to the Storage Access Framework document picker UI, eventually triggering an `onActivityResult()` call:

```
@Override
protected void onActivityResult(int requestCode,
                                int resultCode, Intent data) {

    switch(requestCode) {
        case REQUEST_OPEN:
            if (resultCode==Activity.RESULT_OK) {
                if (data.getData()==null) {
                    ClipData clip=data.getClipData();

                    for (int i=0;i<clip.getItemCount();i++) {
                        openEditor(clip.getItemAt(i).getUri());
                    }
                }
                else {
                    openEditor(data.getData());
                }
            }
            break;

        case REQUEST_CREATE:
            if (resultCode==Activity.RESULT_OK) {
                openEditor(data.getData());
            }
            break;
    }
}
```

CONSUMING DOCUMENTS

```
}  
}
```

(from [Documents/TinyTextEditor/app/src/main/java/com/commonsware/android/tte/MainActivity.java](#))

For our open-document request, there are two possibilities:

- If `getData()` on the `Intent` is `null`, then we should have received multiple documents, obtained via `getClipData()` and iterating over the individual items
- Otherwise, we received a single document, whose `Uri` is the `getData()` value itself

We call `openEditor()` for the `Uri` value (or values) that we received, going through much of the same code that was shown for loading up the editor initially with past-viewed documents.

From the user's standpoint, they see the requested document in the editor:

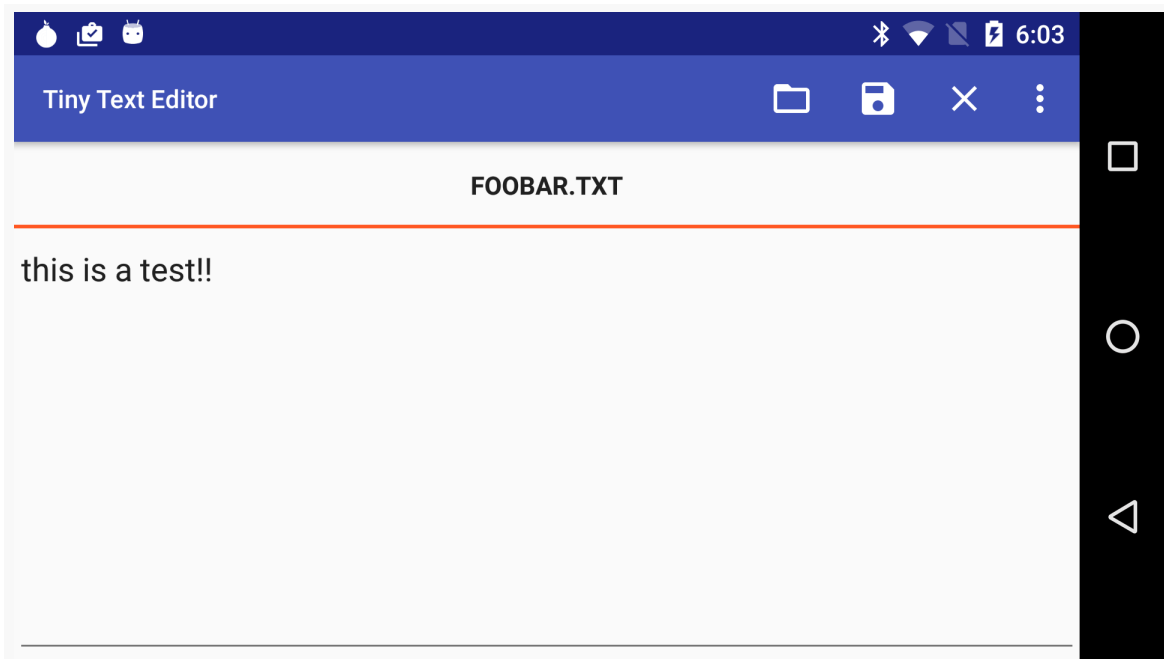

Figure 760: TinyTextEditor, Showing Opened Document

...or more than one, if they so choose:

CONSUMING DOCUMENTS

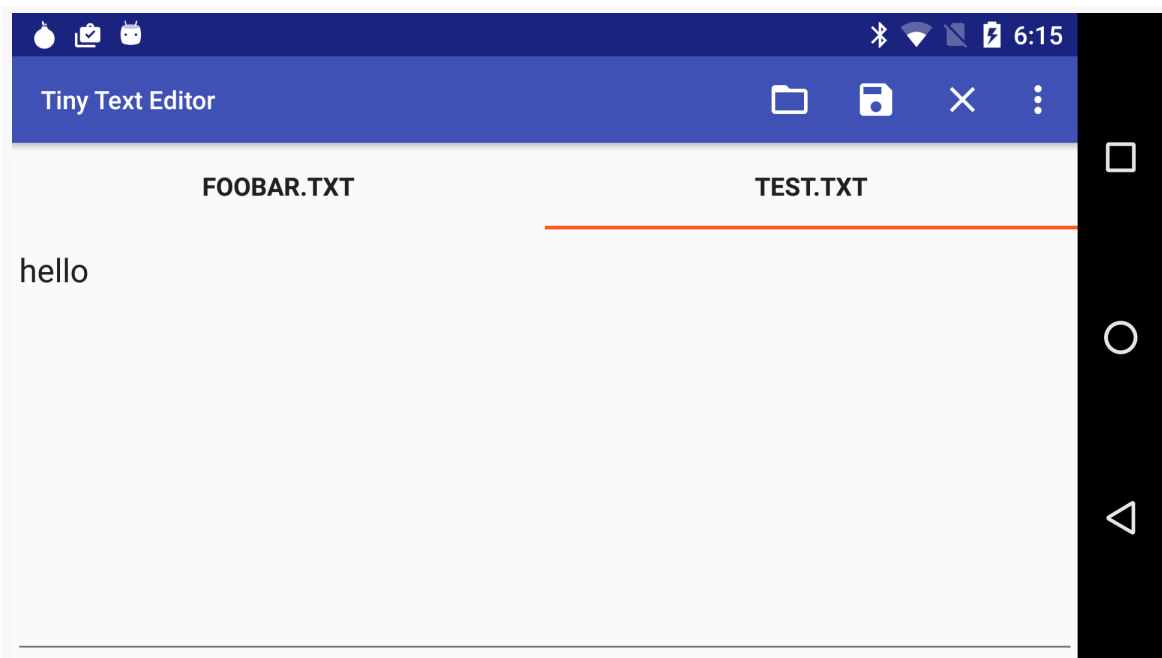

Figure 761: TinyTextEditor, Showing Two Opened Documents

We will explore the `REQUEST_CREATE` portion of `onActivityResult()` in the next section.

Creating a New Document

Given all the above, adding support for creating a new text document is fairly easy.

There is a “Create” action bar item that, when tapped, triggers a `createDocument()` call on our activity:

```
private void createDocument() {
    Intent intent=
        new Intent(Intent.ACTION_CREATE_DOCUMENT)
            .addCategory(Intent.CATEGORY_OPENABLE)
            .setType("text/plain");

    startActivityForResult(intent, REQUEST_CREATE);
}
```

(from [Documents/TinyTextEditor/app/src/main/java/com/commonsware/android/tte/MainActivity.java](#))

This invokes an `ACTION_CREATE_DOCUMENT` activity, asking to create a plain text file.

CONSUMING DOCUMENTS

The user is then presented with a Storage Access Framework activity, where the user can choose a folder and fill in a filename:

Figure 762: Storage Access Framework Create-Document Activity

If the user proceeds to fill in a filename and click “Save”, `onActivityResult()` will give us a `Uri` to the empty document, which we can open in an editor:

```
case REQUEST_CREATE:
    if (resultCode==Activity.RESULT_OK) {
        openEditor(data.getData());
    }
    break;
```

(from [Documents/TinyTextEditor/app/src/main/java/com/commonsware/android/tte/MainActivity.java](#))

Saving a Document

This app uses a typical “low friction” approach to saving changes. While there is a “Save” action bar item to allow the user to manually save, the text is automatically saved when either the `EditorFragment` is stopped (e.g., on a configuration change) or if the user closes the document via a “Close” action bar item. The idea is that while the user *can* manually save changes, the user does not *have to* manually save changes. If you use Android Studio as an IDE, you get the same effect: while there is

CONSUMING DOCUMENTS

a “Save” toolbar icon, it is mostly “for show”, as the IDE automatically saves changes to the files that you are editing, without manual intervention.

Both `onStop()` and `onOptionsItemSelected()` of `EditorFragment` will call a `save()` method on the fragment, though `onOptionsItemSelected()` will only do so if the user tapped the “Save” action bar item. In `save()`, we ask the `DocumentStorageService` to save the document, assuming that the document is loaded and we have write access for it:

```
private void save() {
    if (isLoading && canWrite) {
        editor.setEnabled(false);
        DocumentStorageService.saveDocument(getActivity(),
            getDocumentUri(), editor.getText().toString(),
            isClosing);
    }
}
```

(from [Documents/TinyTextEditor/app/src/main/java/com/commonsware/android/tte/EditorFragment.java](#))

While the document is being saved, we disable the editor, so the user cannot change information on the fly. Most likely that is not needed here, as we get a snapshot of the text via `editor.getText().toString()` and pass that to the service.

The `isClosing` flag passed to `saveDocument()` on `DocumentStorageService` will normally be `false` — we will see when it is true in the next section.

As with `loadDocument()`, `saveDocument()` handles packaging an `Intent` to invoke the `DocumentStorageService` for us:

```
public static void saveDocument(Context ctxt, Uri document,
    String text, boolean isClosing) {
    Intent i=new Intent(ctxt, DocumentStorageService.class)
        .setAction(Intent.ACTION_EDIT)
        .setData(document)
        .addFlags(Intent.FLAG_GRANT_READ_URI_PERMISSION|
            Intent.FLAG_GRANT_WRITE_URI_PERMISSION)
        .putExtra(Intent.EXTRA_TEXT, text)
        .putExtra(EXTRA_CLOSING, isClosing);

    ctxt.startService(i);
}
```

(from [Documents/TinyTextEditor/app/src/main/java/com/commonsware/android/tte/DocumentStorageService.java](#))

CONSUMING DOCUMENTS

Eventually, that triggers a call to `save()` on the service:

```
private void save(Uri document, String text, boolean isClosing) {
    boolean isContent=
        ContentResolver.SCHEME_CONTENT.equals(document.getScheme());

    try {
        OutputStream os=
            getContentResolver().openOutputStream(document, "w");
        OutputStreamWriter osw=new OutputStreamWriter(os);

        try {
            osw.write(text);
            osw.flush();

            if (isClosing && isContent) {
                int perms=Intent.FLAG_GRANT_READ_URI_PERMISSION
                    | Intent.FLAG_GRANT_WRITE_URI_PERMISSION;

                getContentResolver()
                    .releasePersistableUriPermission(document, perms);
            }

            EventBus
                .getDefault()
                .post(new DocumentSavedEvent(document));
        }
        finally {
            osw.close();
        }
    }
    catch (Exception e) {
        Log.e(getClass().getSimpleName(),
            "Exception saving "+document.toString(), e);
        EventBus
            .getDefault()
            .post(new DocumentSaveErrorEvent(document, e));
    }
}
```

(from [Documents/TinyTextEditor/app/src/main/java/com/commonsware/android/tte/DocumentStorageService.java](#))

Mostly, that just writes our text out to an `OutputStream` for the document `Uri`, obtained from a `ContentResolver`. We raise either a `DocumentSavedEvent` or a `DocumentSaveErrorEvent` depending on the success or failure of the operation. We will explore the `isClosing` code path in the next section.

Closing a Document

Visually, closing a document via the “Close” action bar item (looks like an X) closes the document’s tab. Under the covers, we also want to save any lingering changes. Plus, we no longer need our persistable `Uri` permissions, and so it is good form to release those. And, we no longer want this document in our edit history, so if we open the app again in the future, we should not re-open this particular document.

The “Close” action bar item is defined by the activity, leading to a `closeCurrentDocument()` method:

```
private void closeCurrentDocument() {
    EditorFragment frag=adapter.getCurrentFragment();

    frag.markAsClosing();
    closeDocument(frag.getDocumentUri());
}
```

(from [Documents/TinyTextEditor/app/src/main/java/com/commonsware/android/tte/MainActivity.java](#))

Here, we get our current `EditorFragment` from the `EditorsAdapter`, call a `markAsClosing()` method on it (which just sets the `isClosing` flag to true), then call `closeDocument()` with the `Uri` for the document:

```
private void closeDocument(Uri document) {
    if (!editHistory.removeOpenEditor(document)) {
        Toast
            .makeText(this, R.string.msg_save_history,
                Toast.LENGTH_LONG)
            .show();
    }
}
```

(from [Documents/TinyTextEditor/app/src/main/java/com/commonsware/android/tte/MainActivity.java](#))

`closeDocument()` tells the `EditorsAdapter` to remove this page, plus updates the edit history (as will be seen in detail in the next section).

Removing the `EditorFragment` from the `EditorsAdapter` has the effect of destroying that fragment. That triggers an `onStop()` call, which triggers a `save()` call as before. But, this time, we have `isClosing` set to true.

In the service’s `save()` method, having `isClosing` set to true triggers the code that calls `releasePersistableUriPermission()`, where we relinquish our persistable `Uri` permission for the `Uri` for the document. However, we only try that if the `Uri` has a

content scheme — we do not need to do anything to release permissions for a file, and `releasePersistableUriPermission()` crashes if you try using it with a file: `Uri`.

Managing Edit History

The `EditHistory` class is responsible for persisting our roster of open documents, so that we can re-open them when the app is opened again later.

`EditHistory` is a singleton, accessed via the `INSTANCE` static field:

```
public class EditHistory {
    public static final EditHistory INSTANCE=new EditHistory();
    private static final String PREF_OPEN_EDITORS="open";
    private AtomicReference<SharedPreferences> prefsRef=
        new AtomicReference<SharedPreferences>();
```

(from [Documents/TinyTextEditor/app/src/main/java/com/commonsware/android/tte/EditHistory.java](#))

It holds onto a `SharedPreferences` that is being used for storage. However, since disk I/O is needed to load those `SharedPreferences` – which, in turn, requires a background thread — `EditHistory` is using an `AtomicReference` to ensure that we do not wind up in a state where one thread is trying to read a `SharedPreferences` field while another is trying to write it. This may be a bit superfluous — `volatile` may suffice here.

`MainActivity`, in `onStart()` calls `initialize()` on the `EditHistory` instance:

```
public boolean initialize(Context ctxt) {
    if (prefsRef.get()==null) {
        new LoadThread(ctxt).start();

        return(false);
    }

    return(true);
}
```

(from [Documents/TinyTextEditor/app/src/main/java/com/commonsware/android/tte/EditHistory.java](#))

Here, if we do not already have the `SharedPreferences`, we kick off a thread to go load them, and we return a boolean indicating whether or not the `SharedPreferences` are loaded.

CONSUMING DOCUMENTS

The LoadThread just updates the prefsRef field and raises an InitializedEvent once that work is done:

```
private class LoadThread extends Thread {
    private final Context ctxt;

    LoadThread(Context ctxt) {
        this.ctxt=ctxt.getApplicationContext();
    }

    @Override
    public void run() {
        prefsRef.set(PreferenceManager.getDefaultSharedPreferences(ctxt));
        EventBus.getDefault().post(new InitializedEvent());
    }
}
```

(from [Documents/TinyTextEditor/app/src/main/java/com/commonsware/android/tte/EditHistory.java](#))

MainActivity will then call its loadEditors() method at one of two times:

- In onStart(), if initialize() returned true
- In onEditHistoryInitialized(), responding to the InitializedEvent, if initialize() returned false:

```
@Subscribe(threadMode=ThreadMode.MAIN)
public void onEditHistoryInitialized(EditHistory.InitializedEvent event) {
    loadEditors();
}
```

(from [Documents/TinyTextEditor/app/src/main/java/com/commonsware/android/tte/MainActivity.java](#))

loadEditors(), in turn, calls getOpenEditors() on the EditHistory. Rather than use getStringSet(), we instead use getString() on the SharedPreferences and decode it as a JSON array, using JsonReader, an Android SDK class that is to JSON as XmlPullParser is to XML:

```
public List<Uri> getOpenEditors() {
    String editors=prefsRef.get().getString(PREF_OPEN_EDITORS, null);
    ArrayList<Uri> result=new ArrayList<Uri>();

    if (editors!=null) {
        StringReader sr=new StringReader(editors);
        JsonReader json=new JsonReader(sr);

        try {
```

CONSUMING DOCUMENTS

```
    json.beginArray();

    while (json.hasNext()) {
        result.add(Uri.parse(json.nextString()));
    }

    json.endArray();
    json.close();
}
catch (IOException e) {
    Log.e(getClass().getSimpleName(),
        "Exception reading JSON", e);
}
}

return(result);
}
```

(from [Documents/TinyTextEditor/app/src/main/java/com/commonsware/android/tte/EditHistory.java](#))

With `JsonReader`, we are expecting the JSON to be an array of strings, so we read in those strings, parse them into `Uri` objects, and use them in the result.

We then have `addOpenEditor()` and `removeOpenEditor()` methods that manipulate that `ArrayList`:

```
public boolean addOpenEditor(Uri document) {
    List<Uri> current=getOpenEditors();

    if (!current.contains(document)) {
        if (current.size()>9) {
            current.remove(0);
        }

        current.add(document);

        return(saveHistory(current));
    }

    return(true);
}

public boolean removeOpenEditor(Uri document) {
    List<Uri> current=getOpenEditors();

    current.remove(document);
}
```

CONSUMING DOCUMENTS

```
return(saveHistory(current));  
}
```

(from [Documents/TinyTextEditor/app/src/main/java/com/commonsware/android/tte/EditHistory.java](#))

`addOpenEditor()` caps the `ArrayList` length to 9, so we do not open some ridiculous number of tabs when the app is next launched.

Both `addOpenEditor()` and `removeOpenEditor()` call a `saveHistory()` method to persist the revised `ArrayList`:

```
private boolean saveHistory(List<Uri> history) {  
    StringWriter sw=new StringWriter();  
    JsonWriter json=new JsonWriter(sw);  
  
    try {  
        json.beginArray();  
  
        for (Uri uri : history) {  
            json.value(uri.toString());  
        }  
  
        json.endArray();  
        json.close();  
  
        prefsRef  
            .get()  
            .edit()  
            .putString(PREF_OPEN_EDITORS, sw.toString())  
            .apply();  
    }  
    catch (IOException e) {  
        Log.e(getClass().getSimpleName(),  
            "Exception saving JSON", e);  
  
        return(false);  
    }  
  
    return(true);  
}
```

(from [Documents/TinyTextEditor/app/src/main/java/com/commonsware/android/tte/EditHistory.java](#))

`saveHistory()` reverses the work of `getOpenEditors()`: we encode the `ArrayList` into a JSON array of strings, then save that in the `SharedPreferences`.

Managing Multiple Windows

The `EditorFragment` adds a “Launch” option to the action bar (looks like a square with an arrow). When tapped, if the device is in multi-window mode, we want to open this document in a separate window, removing its tab from the current activity. However, “Launch” is only shown if we are running on Android 7.0 *and* are in multi-window mode:

```
@Override
public void onCreateOptionsMenu(Menu menu,
                                MenuInflater inflater) {
    inflater.inflate(R.menu.editor_actions, menu);

    if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.N) {
        launchItem = menu.findItem(R.id.launch);
        launchItem.setVisible(getActivity().isInMultiWindowMode());
    }

    super.onCreateOptionsMenu(menu, inflater);
}
```

(from [Documents/TinyTextEditor/app/src/main/java/com/commonsware/android/tte/EditorFragment.java](#))

The “Launch” option eventually triggers a `launchInNewWindow()` method on the `MainActivity`:

```
@Override
public void launchInNewWindow(Uri document) {
    adapter.remove(document);

    Intent i =
        new Intent(this, MainActivity.class)
            .setAction(ACTION_NEW_WINDOW)
            .setData(document)
            .setFlags(Intent.FLAG_ACTIVITY_LAUNCH_ADJACENT |
                    Intent.FLAG_ACTIVITY_NEW_TASK |
                    Intent.FLAG_ACTIVITY_MULTIPLE_TASK);

    startActivity(i);
}
```

(from [Documents/TinyTextEditor/app/src/main/java/com/commonsware/android/tte/MainActivity.java](#))

Here, we remove our tab and request to open a fresh copy of our `MainActivity`, with the `Uri` of the document put into the `Intent`, with our custom `ACTION_NEW_WINDOW` action, and with `FLAG_ACTIVITY_LAUNCH_ADJACENT` to get a new window. `onCreate()`

CONSUMING DOCUMENTS

of the new `MainActivity` instance will see that it was passed a `Uri` with `ACTION_NEW_WINDOW` and will open that document, instead of trying to open the edit history.

Since the user might toggle multi-window mode while our activity already exists, `EditorFragment` overrides `onMultiWindowModeChanged()` and updates the visibility of the “Launch” action bar item to match:

```
@Override
public void onMultiWindowModeChanged(boolean inMultiWindow) {
    super.onMultiWindowModeChanged(inMultiWindow);

    if (launchItem!=null) {
        launchItem.setVisible(inMultiWindow);
    }
}
```

(from [Documents/TinyTextEditor/app/src/main/java/com/commonsware/android/tte/EditorFragment.java](#))

Here, we implement the one-parameter version of `onMultiWindowModeChanged()`, to be compliant with Android 7.0 and 7.1, despite the fact that it was deprecated in Android 8.0.

ACTION_EDIT and Tasks

We have logic in the app already to handle `ACTION_EDIT`: if the `Intent` used to create our activity has a `Uri`, we open it.

However, what happens if our app is already open, and the user triggers an `ACTION_EDIT` request from another app?

By default, what would happen is that we would open another instance of our activity, separate from the original one. That is not a good user experience for this sort of app, particularly in a single-window environment. Instead, we should pick up the `Intent` in our existing activity instance and just open a new tab.

To implement that, ideally we would add `android:launchMode="singleTop"` to our `<activity>` element in the manifest, along with our `<intent-filter>` for `ACTION_EDIT`. As is covered in [the chapter on tasks](#), `singleTop` will deliver our `Intent` to an existing activity instance... if that instance is on the top of our `BACK` stack. Unfortunately, this breaks the current multi-window support in Android 7.0.

What's Missing

This app is *far* from perfect. After all, it is a tiny text editor, not a full-featured, all-the-bells-and-whistles, hey-let's-go-find-investors sort of text editor.

Of note:

- We always save the text to disk when `save()` gets called... even if there have been no changes to the content
- We wind up making copies of the text a lot, which can be a problem with larger documents due to heap fragmentation
- On a configuration change, we save and reload the text contents, rather than optimizing for that scenario and trying to hold onto the text
- It is possible that there will be some order-of-operations issues when a new window is launched, depending on the timing of `onStop()` of the original `EditorFragment` and when the new fragment in the new activity instance is created

Document Trees

`ACTION_OPEN_DOCUMENT` and `ACTION_CREATE_DOCUMENT` are sufficient for most apps. These roughly correspond to the “file open” and “new file” dialogs that you see in desktop operating systems.

However, there may be cases where you need the equivalent of a “choose folder” dialog, to allow the user to pick a location where you can create (or work with) several documents. For example, suppose that your app offers a report generator, taking data from the database and creating a report with tables and graphs and stuff. Some file formats, like PDF, might have the entire report in a single file — for that, use `ACTION_CREATE_DOCUMENT` to allow the user to choose where to put that report. Other file formats, like HTML, might require several files (e.g., the report body in HTML and embedded graphs in PNG format). For that, you really need a “folder”, into which you can create all of those individual bits of content.

For that, the Storage Access Framework offers document trees... as of Android 5.0 (API Level 21). Android 4.4's edition of the Storage Access Framework lacked this capability.

Getting a Tree

Instead of using `ACTION_OPEN_DOCUMENT`, you can use `ACTION_OPEN_DOCUMENT_TREE`. Once again, you will use `startActivityForResult()` to request access to the tree. In `onActivityResult()`, the result `Intent` has a `Uri` (`getData()`) that represents the tree. You should have full read/write access not only to this tree but to anything inside of it.

Another option, starting with Android 7.0, is “scoped directory access”. Here, you work with `StorageManager` to access the device’s `StorageVolume` list. All devices should have at least one `StorageVolume`, representing what we think of as external storage. Some devices may have more than that, representing mounted removable media. Given a `StorageVolume`, you can call `createAccessIntent()` to get an `Intent` that will ask the user permission for access to some portion of that volume, when called with `startActivityForResult()`. As with `ACTION_OPEN_DOCUMENT_TREE`, you get a `Uri` in `onActivityResult()` that you can then use to work with that tree of files.

Working in the Tree

The simplest approach for then working with the tree is to use the aforementioned `DocumentFile` wrapper. You can create one representing the tree by using the `fromTreeUri()` static method, passing in the `Uri` that you got from the `ACTION_OPEN_DOCUMENT_TREE` request.

From there, you can:

- Call `listFiles()` to get the immediate children of the root of this tree, getting back an array of `DocumentFile` objects representing those children
- Call `isDirectory()` to confirm that you do indeed have a tree (or, call it on a child to see if that child represents a sub-tree)
- For those existing children that are files (`isFile()` returns true), use `getUri()` to get the `Uri` for this child, so you can read its contents using a `ContentResolver` and `openInputStream()`
- Call `createDirectory()` or `createFile()` to add new content as an immediate child of this tree, getting a `DocumentFile` as a result
- For the `createFile()` scenario, call `getUri()` on the `DocumentFile` to get a `Uri` that you can use for writing out the content using `ContentResolver` and `openOutputStream()`
- and so on

Note that you can call `takePersistableUriPermission()` on a `ContentResolver` to try to have durable access to the document tree, just as you can for a `Uri` to an individual document.

Getting a Tree: Example

The [Documents/DocumentTree](#) sample application demonstrates how to use `ACTION_OPEN_DOCUMENT_TREE` and `StorageManager/StorageVolume` to get a `Uri` pointing to a directory that you can work with.

The Objective: a Preference for Storage

The sample app's UI is a `PreferenceFragment`, where we have two preferences: one to pick a document tree via `ACTION_OPEN_DOCUMENT_TREE` and one to pick a `StorageVolume` from among the available volumes. In theory, an app might include one of these for the user to pick an alternative default storage location for files, for example. However, since the `StorageVolume` APIs for choosing a storage volume are new to API Level 24, we will only enable that preference on compatible devices.

In each case, part of the work to get access to these locations involves `startActivityForResult()`, which is unusual for a preference and adds to the sample's complexity.

What the User Sees

When the user first launches the app, the preference subtitles are “no value”, because the user has not chosen anything yet:

CONSUMING DOCUMENTS

Figure 763: DocumentTree Demo, As Initially Launched

If the user taps the “Document Tree Root” preference, the UI for the Storage Access Framework appears, allowing the user to browse for a directory of interest:

CONSUMING DOCUMENTS

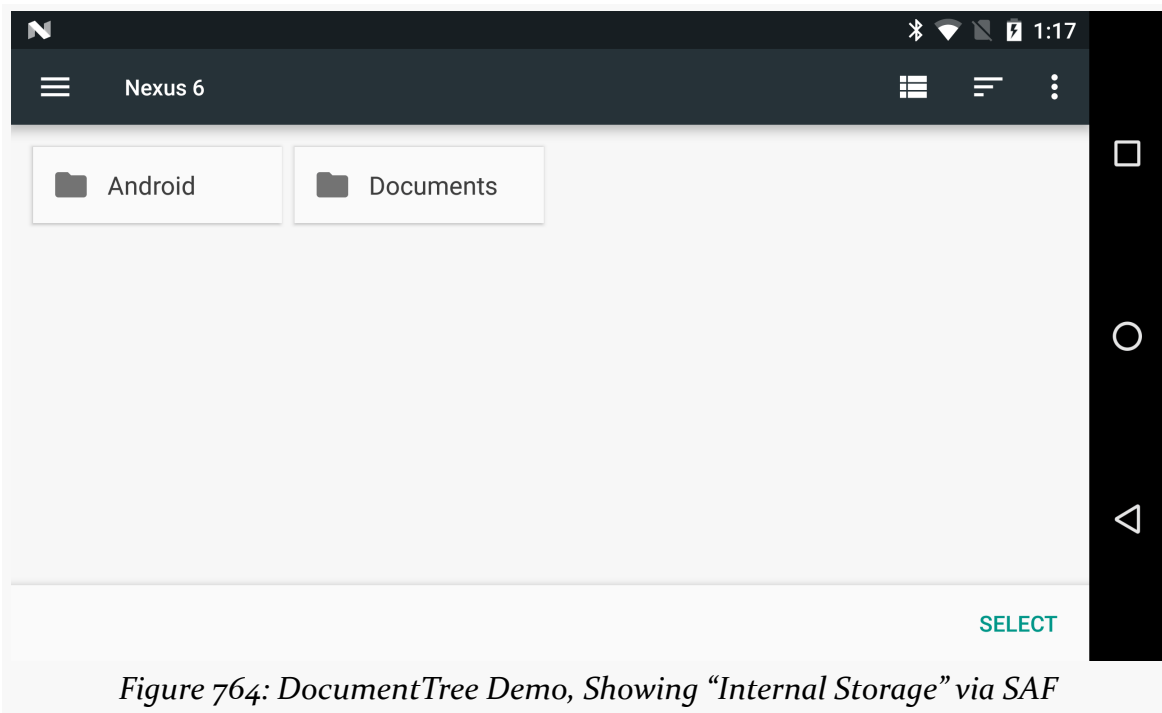

Figure 764: DocumentTree Demo, Showing “Internal Storage” via SAF

If the user chooses a location, the preference is updated with the `Uri` of the selected document tree:

CONSUMING DOCUMENTS

Figure 765: DocumentTree Demo, Showing Selected Document Tree Uri

If the user taps the “Storage Volume” preference, a ListPreference dialog appears, showing the available storage volumes:

CONSUMING DOCUMENTS

Figure 766: DocumentTree Demo, Showing Available Storage Volume(s)

On some devices, there will only be one option (“Internal shared storage”, or what we developer call “external storage”). On other devices, if there is a piece of removable storage mounted, there will be more than one option.

If the user chooses a volume, a permission confirmation dialog may appear, to confirm that the user wants to grant you access to the “Documents” directory inside of that storage volume:

CONSUMING DOCUMENTS

Figure 767: DocumentTree Demo, Requesting Permission

If the user grants permission, once again the preference's subtitle will reflect the Uri of the chosen location:

CONSUMING DOCUMENTS

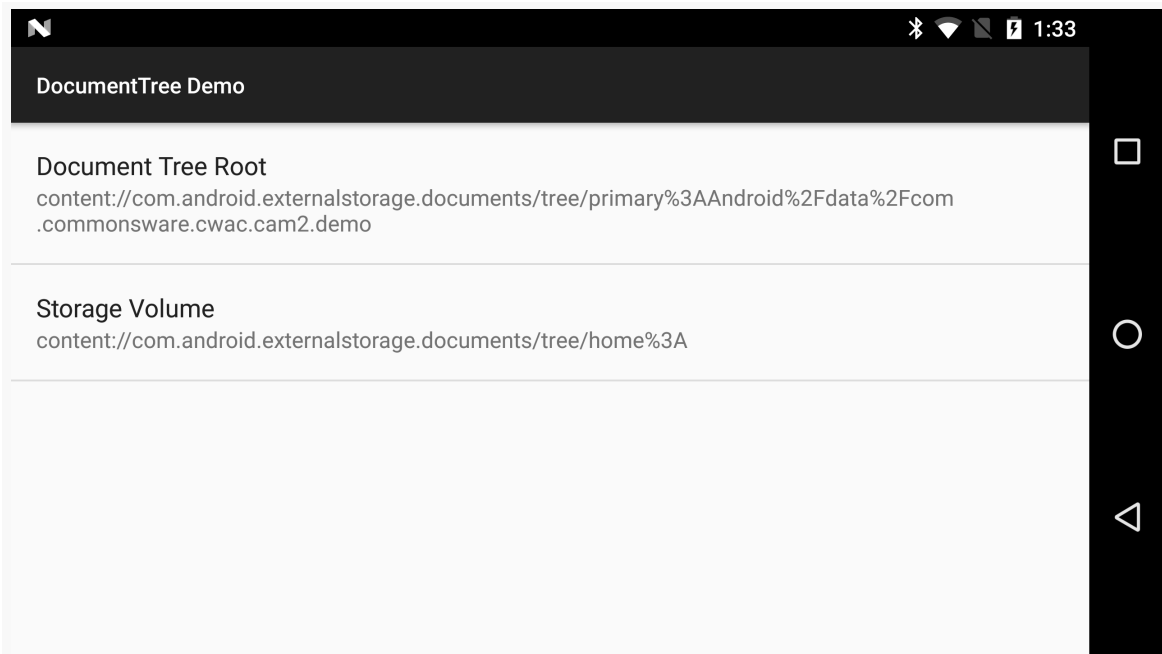

Figure 768: DocumentTree Demo, Showing Selected Storage Volume Directory

On Android 5.0-6.0 devices, the app will run, but the storage volume preference is disabled:

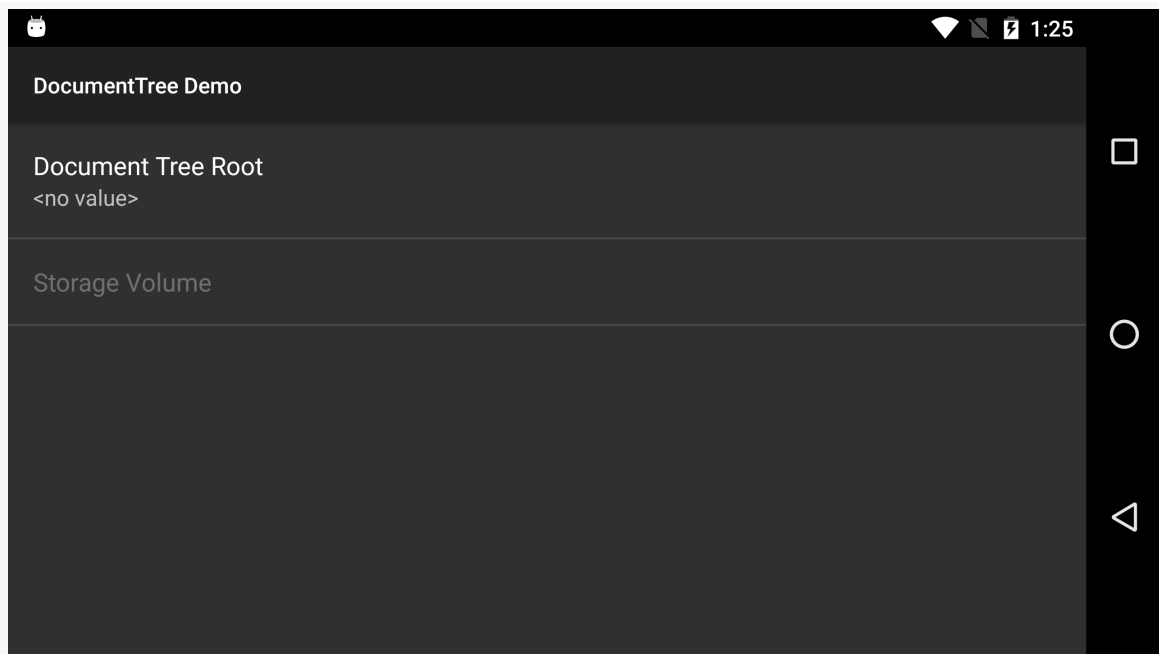

Figure 769: DocumentTree Demo, Running on Android 6.0

The Document Tree

Of the two options, `ACTION_OPEN_DOCUMENT_TREE` is the most straight-forward to implement: call `startActivityForResult()` and get your `Uri` in `onActivityResult()`.

But, since preferences are not set up to handle `startActivityForResult()` or receive data via `onActivityResult()`, we have a little bit of work to do.

The Preference XML

The app has a `res/raw/settings.xml` file containing our preferences:

```
<?xml version="1.0" encoding="utf-8"?>
<PreferenceScreen xmlns:android="http://schemas.android.com/apk/res/android">
  <Preference
    android:key="documentTree"
    android:title="@string/pref_doc_tree" />
  <ListPreference
    android:dialogTitle="@string/dlg_storage_volume"
    android:enabled="@bool/is_nougat"
    android:key="storageVolume"
```

CONSUMING DOCUMENTS

```
    android:title="@string/pref_storage_volume" />
</PreferenceScreen>
```

(from [Documents/DocumentTree/app/src/main/res/xml/settings.xml](#))

The first one is our “Document Tree Root” preference... and it is literally a Preference. This is not used all that frequently, since it cannot actually collect any preference data. In cases like this one, where we really want to handle this more like the user tapped on a generic `ListView` row, it is a reasonable choice.

We will explore the `ListPreference` for the “Storage Volume” option later in this section.

Populating the Preference

The UI is a `PreferenceFragment` subclass named `SettingsFragment`. In `onCreate()`, we call `addPreferencesFromResource()` to inflate that preference XML and populate the fragment:

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    addPreferencesFromResource(R.xml.settings);

    prefDocTree=findPreference(PREF_DOC_TREE);
    prefs=prefDocTree
        .getSharedPreferences();
    prefs.registerOnSharedPreferenceChangeListener(this);
    onSharedPreferenceChanged(prefs, PREF_DOC_TREE);
    docTreeHelper=new DocumentHelper(this,
        prefDocTree);

    prefVolumes=(ListPreference)findPreference(PREF_VOLUMES);

    if (prefVolumes.isEnabled()) {
        populateVolumes();
        onSharedPreferenceChanged(prefs, PREF_STORAGE_URI);
        volumeHelper=
            new VolumeHelper(this, prefVolumes,
                PREF_STORAGE_URI, Environment.DIRECTORY_DOCUMENTS);
    }
}
```

(from [Documents/DocumentTree/app/src/main/java/com/commonsware/android/documenttree/SettingsFragment.java](#))

CONSUMING DOCUMENTS

We then do a few things to set up our “Document Tree Root” preference:

- We call `findPreference()` to get that Preference object, storing it in a `prefDocTree` field.
- We ask the Preference for the SharedPreferences that are being used, holding onto that in a field named `prefs`.
- Register the fragment itself as an `OnSharedPreferenceChangeListener` for the SharedPreferences, then immediately call `onSharedPreferenceChanged()`. That, in turn, fills in the summary of the Preference with the current `Uri`, if we have one:

```
@Override
public void onSharedPreferenceChanged(SharedPreferences prefs,
                                       String key) {
    if (PREF_DOC_TREE.equals(key)) {
        prefDocTree.setSummary(prefs.getString(key, "<no value>"));
    }
    else if (PREF_STORAGE_URI.equals(key)) {
        prefVolumes
            .setSummary(prefs
                .getString(key, "<no value>").replaceAll("%", "%"));
    }
}
```

(from [Documents/DocumentTree/app/src/main/java/com/commonsware/android/documenttree/SettingsFragment.java](#))

- Wrap that Preference in a `DocumentHelper` object, which we will look at shortly.

We will cover the remainder of this code, pertaining to the other preference, later.

Choosing a Tree

We need some common code between the document-root and the storage-volume options:

- Bridging between a Preference and a hosting activity or fragment that can do the `startActivityForResult()` and `onActivityResult()` work
- Calling `takePersistableUriPermission()`
- Updating the SharedPreferences with the `Uri` that we receive

The `TreeUriPreferenceHelper` abstract class, along with its `DocumentHelper` and `VolumeHelper` subclasses, implement this common code.

CONSUMING DOCUMENTS

A `TreeUriPreferenceHelper` subclass' constructor needs to be passed the Preference that we are "helping", along with some implementation of the Host interface:

```
public interface Host {
    void startActivityForHelper(Intent intent,
                               TreeUriPreferenceHelper helper);
}
```

(from [Documents/DocumentTree/app/src/main/java/com/commonsware/android/documenttree/TreeUriPreferenceHelper.java](#))

`DocumentHelper` simply collects those values, passes them to `TreeUriPreferenceHelper`, and registers itself to be called when the user clicks on the Preference:

```
package com.commonsware.android.documenttree;

import android.content.Intent;
import android.preference.Preference;

public class DocumentHelper extends TreeUriPreferenceHelper
    implements Preference.OnPreferenceClickListener {
    public DocumentHelper(Host host, Preference pref) {
        super(host, pref);
        pref.setOnPreferenceClickListener(this);
    }

    @Override
    protected String getUriKey() {
        return (pref.getKey());
    }

    @Override
    public boolean onPreferenceClick(Preference preference) {
        Intent i=new Intent(Intent.ACTION_OPEN_DOCUMENT_TREE);

        host.startActivityForHelper(i, this);

        return(true);
    }
}
```

(from [Documents/DocumentTree/app/src/main/java/com/commonsware/android/documenttree/DocumentHelper.java](#))

`TreeUriPreferenceHelper`, in turn, just holds onto the Host and Preference in host and pref fields, respectively.

CONSUMING DOCUMENTS

When the user clicks on the Preference, the `onPreferenceClick()` method of the `DocumentHelper` is called. There, we create an `ACTION_OPEN_DOCUMENT_TREE` Intent and call `startActivityForHelper()` on the host.

Our Host, in this case, is the `SettingsFragment`, so it has an implementation of `startActivityForHelper()`:

```
@Override
public void startActivityForHelper(Intent intent,
                                  TreeUriPreferenceHelper helper) {
    if (helper==docTreeHelper) {
        startActivityForResult(intent, REQUEST_DOC_TREE);
    }
    else if (helper==volumeHelper) {
        startActivityForResult(intent, REQUEST_STORAGE_VOLUME);
    }
}
```

(from [Documents/DocumentTree/app/src/main/java/com/commonsware/android/documenttree/SettingsFragment.java](#))

It just sees which `TreeUriPreferenceHelper` we are working with, then calls `startActivityForResult()` with an appropriate request code (e.g., `REQUEST_DOC_TREE`).

Eventually, `SettingsFragment` should be called with `onActivityResult()`. If the result is `RESULT_OK`, we forward the result along to the `TreeUriPreferenceHelper`, based on the request code:

```
@Override
public void onActivityResult(int requestCode, int resultCode,
                             Intent data) {
    if (resultCode==Activity.RESULT_OK) {
        if (requestCode==REQUEST_DOC_TREE) {
            docTreeHelper.onActivityResult(data);
        }
        else if (requestCode==REQUEST_STORAGE_VOLUME) {
            volumeHelper.onActivityResult(data);
        }
    }
}
```

(from [Documents/DocumentTree/app/src/main/java/com/commonsware/android/documenttree/SettingsFragment.java](#))

CONSUMING DOCUMENTS

TreeUriPreferenceHelper has the common implementation of `onActivityResult()`, where we call `takePersistableUriPermission()` (asking for read/write access) and put the Uri into the SharedPreferences under some key:

```
public void onActivityResult(Intent data) {
    Uri docTree=data.getData();
    ContentResolver cr=pref.getContext().getContentResolver();
    int perms=Intent.FLAG_GRANT_READ_URI_PERMISSION
        | Intent.FLAG_GRANT_WRITE_URI_PERMISSION;

    cr.takePersistableUriPermission(docTree, perms);

    pref
        .getSharedPreferences()
        .edit()
        .putString(getUriKey(), docTree.toString())
        .apply();
}
```

(from [Documents/DocumentTree/app/src/main/java/com/commonsware/android/documenttree/TreeUriPreferenceHelper.java](#))

In the case of the document-root Preference, that key is the key from the Preference itself (`getKey()`). Saving the value not only persists it, but it also triggers the SettingsFragment to be notified about the new value, causing SettingsFragment to update the Preference summary... which is why we see the Uri show up on the screen right after selecting it.

The Storage Volume

The StorageVolume scenario is a bit more complicated, in that we have to provide the UI for choosing a volume — this is not provided by Android. That, plus some interesting challenges in the StorageVolume implementation, add to our level of effort.

The Preference XML

The `settings.xml` file has a ListPreference that will serve as the UI for selecting a StorageVolume:

```
<ListPreference
    android:dialogTitle="@string/dlg_storage_volume"
    android:enabled="@bool/is_nougat"
    android:key="storageVolume"
```

CONSUMING DOCUMENTS

(from [Documents/DocumentTree/app/src/main/res/xml/settings.xml](#))

Since the roster of possible volumes is dynamic, we cannot provide our `ListPreference` contents via string-array resources, but instead will need to do so from Java code.

Note that this preference is enabled based upon an `is_nougat` bool resource. That is set to `true` for API Level 24+ (in `res/values-v24/bools.xml`), `false` otherwise (in `res/values/bools.xml`).

Populating the Preference

Some of the work from `onCreate()` of `SettingsFragment` is for setting up this `ListPreference`:

```
prefVolumes=(ListPreference)findPreference(PREF_VOLUMES);

if (prefVolumes.isEnabled()) {
    populateVolumes();
    onSharedPreferenceChanged(prefs, PREF_STORAGE_URI);
    volumeHelper=
        new VolumeHelper(this, prefVolumes,
            PREF_STORAGE_URI, Environment.DIRECTORY_DOCUMENTS);
}
```

(from [Documents/DocumentTree/app/src/main/java/com/commonsware/android/documenttree/SettingsFragment.java](#))

We store the `ListPreference` in a `prefVolumes` field, before calling a private `populateVolumes()` method to fill in the list contents. We also trigger updating its summary via a manual call to `onSharedPreferenceChanged()`, plus wrap the `ListPreference` in a `VolumeHelper` that we will explore in detail shortly. And all of this is wrapped in a check to see if the preference is enabled; if it is not, we skip this work, as it is unnecessary.

`populateVolumes()` is responsible for providing the entries and values for the `ListPreference`, based on the available volumes:

```
@TargetApi(Build.VERSION_CODES.N)
private void populateVolumes() {
    StorageManager storage=
        (StorageManager)getActivity()
            .getSystemService(Context.STORAGE_SERVICE);
    List<StorageVolume> volumes=storage.getStorageVolumes();
```

CONSUMING DOCUMENTS

```
Collections.sort(volumes, new Comparator<StorageVolume>() {
    @Override
    public int compare(StorageVolume lhs,
        StorageVolume rhs) {
        return(lhs.getDescription(getActivity())
            .compareTo(rhs.getDescription(getActivity())));
    }
});

String[] displayNames=new String[volumes.size()];
String[] uuids=new String[volumes.size()];

for (int i=0;i<volumes.size();i++) {
    displayNames[i]=volumes.get(i).getDescription(getActivity());
    uuids[i]=volumes.get(i).getUuid();

    if (uuids[i]==null) {
        uuids[i]=STORAGE_FAKE_UUID;
    }
}

prefVolumes.setEntries(displayNames);
prefVolumes.setEntryValues(uuids);
}
```

(from [Documents/DocumentTree/app/src/main/java/com/commonsware/android/documenttree/SettingsFragment.java](#))

We start off by getting a `StorageManager` system service. Here, we are using the newer version of `getSystemService()`, introduced in API Level 21, where we can pass in the Java class of the system service that we want (`StorageManager.class`). This allows Android to return an instance of the actual class, avoiding a cast.

Then, we call `getStorageVolumes()` on the `StorageManager`, to get the roster of available `StorageVolume` objects.

Since those `StorageVolume` objects might arrive in any order, we `sort()` them by their description, which is a human-readable label describing what the volume is. For example, for removable storage, it might be a combination of the manufacturer of the drive or card, plus the stated capacity of the drive or card.

Since `ListPreference` wants two `String` arrays for the entries and values, we set those up, filling them in from the description and UUIDs of the volumes. Each volume is supposed to have a UUID, but that is not guaranteed — in particular, the `StorageVolume` for external storage returns `null` for `getUuid()`. Since `ListPreference` *really* does not like `null` values, we substitute in a non-UUID string

CONSUMING DOCUMENTS

(`STORAGE_FAKE_UUID`, defined to be "fake") to identify it. We then give those two string arrays to the `ListPreference`.

Choosing a Volume

`VolumeHelper`, like `DocumentHelper`, is designed to help bridge between the preference system, the hosting fragment, and the Android APIs for getting a document tree `Uri`.

`VolumeHelper` takes two additional constructor parameters, beyond the `Host` and `Preference`:

- The key for the `SharedPreferences` under which the `Uri` will be stored. The `ListPreference` will store the `UUID` of the storage volume under its key, but once we get the `Uri`, we need to save it to the `SharedPreferences` as well, for later use.
- The directory on the storage volume to use. `createAccessIntent()` accepts any of the standard `Environment` directories — in this case, we are using `DIRECTORY_DOWNLOADS`

The constructor holds onto those additional parameters in fields, then registers itself to respond to when the `ListPreference` value changes, because the user selected a different `StorageVolume` in the list:

```
package com.commonware.android.documenttree;

import android.content.Intent;
import android.os.storage.StorageManager;
import android.os.storage.StorageVolume;
import android.preference.ListPreference;
import android.preference.Preference;
import java.util.List;

public class VolumeHelper extends TreeUriPreferenceHelper
    implements Preference.OnPreferenceChangeListener {
    private final String uriKey;
    private final String dirName;

    public VolumeHelper(Host host, ListPreference pref, String uriKey,
        String dirName) {
        super(host, pref);

        this.uriKey=uriKey;
        this.dirName=dirName;
    }
}
```

CONSUMING DOCUMENTS

```
    pref.setOnPreferenceChangeListener(this);
}

@Override
protected String getUriKey() {
    return(uriKey);
}

@Override
public boolean onPreferenceChange(Preference pref,
                                   Object o) {
    StorageManager storage=
        pref.getContext().getSystemService(StorageManager.class);
    List<StorageVolume> volumes=storage.getStorageVolumes();
    String uuid=o.toString();

    for (StorageVolume volume : volumes) {
        if ((volume.getUuid()==null &&
            uuid.equals(SettingsFragment.STORAGE_FAKE_UUID)) ||
            (uuid.equals(volume.getUuid()))) {
            Intent i=volume.createAccessIntent(dirName);

            host.startActivityForHelper(i, this);
            break;
        }
    }

    return(true);
}
}
```

(from [Documents/DocumentTree/app/src/main/java/com/commonsware/android/documenttree/VolumeHelper.java](#))

When the user eventually does change the selection in the `ListPreference` and `onPreferenceChange()` is called, we get a fresh `StorageManager`. Unfortunately, `StorageManager` does not have any sort of lookup API to get a `StorageVolume` by UUID, so we have to iterate over the currently-available volumes and find a match, taking into account our fake UUID for the null-UUID case.

When we find a match, we call `createAccessIntent()` on the `StorageVolume`, passing in the directory name. That `Intent` is then given to the `Host` via `startActivityForHelper()`. That will trigger the same process as was used for `DocumentHelper`, eventually resulting in the `Uri` being saved to the `SharedPreferences` under the supplied key.

Potential Issues

It is unclear if more than one `StorageVolume` could have a null UUID. If it can, the approach of using a fake value in lieu of null will not work. Of course, if more than one `StorageVolume` could have a null UUID, we will have no means of identifying *which* `StorageVolume` the null UUID refers to, making long-term identification of `StorageVolume` objects difficult.

Scoped Directory Access Bug

The scoped directory access feature — using `StorageVolume` to request access to standard directories — works fairly well on Android 7.0+... with one UX flaw, tied to how the user grants you that access.

The flow of the permission dialogs resembles that of Android 6.0's runtime permissions:

- When you first ask for access, the user can allow or deny
- If the user denied access, and you later ask for access again, the dialog now has a “Don't ask again” checkbox
- If the user checked that checkbox and denied access again, any future attempts you make to request access will be denied immediately, without the user seeing a dialog

One problem is that we have no good way of knowing that the user has previously denied our request, let alone checked the “Don't ask again” checkbox. With Android 6.0's runtime permissions, we have `checkSelfPermission()` and `shouldShowPermissionRequestRationale()` for those things. We have no equivalents for scoped directory access.

However, the bigger problem is that once the user checks “Don't ask again” and denies access, *the user has no further recourse*. With runtime permissions, the user can always go into the Permissions area of an app's page in Settings and manually grant permissions. There is no equivalent of this for the scoped directory access API.

On Android 7.1, the user can use “Clear Data” to reset these dialogs, causing future dialogs to appear again even if “Don't ask again” had been checked. Of course, “Clear Data” has somewhat broader impact than this, and the user might not appreciate wiping out all the app's local data.

Worse, on Android 7.0, not only does “Clear Data” not fix this, but *a full uninstall of the app* does not fix this. Nothing short of a factory reset will allow the app to ask the user for permission and the user have an opportunity again to grant permission.

Admittedly, this is an edge case, but it is one that you should keep in mind if you are using `createAccessIntent()` and the scoped directory access API. Keep an eye on [this issue](#) to try to get some resolution to how the user is supposed to manually revert the “Don’t ask again” status.

Android 8.0 Changes

Android 8.0 introduced some new options for consuming documents and document trees via the Storage Access Framework.

Document Tree Traversal

The `DocumentsContract` client interface to the Storage Access Framework now has a `findDocumentPath()` method. Many developers will think that this means that they can get a filesystem path for a document `Uri` from the Framework.

That is not what this method does.

Instead, `findDocumentPath()` returns a list of document IDs representing the hierarchy of document trees leading to the specific document being requested. In other words, if the document is inside of a `goo` tree, which is inside of a `bar` tree, which is inside of a `foo` tree, and `foo` is the top of a provider’s hierarchy, `findDocumentPath()` would return a `List` of document IDs representing `foo`, `bar`, `goo`, and the requested document.

Presumably, the idea is that this would be used by client UIs to help build a way to traverse the relevant set of document trees for a particular document.

For this to work, the corresponding `DocumentsProvider` needs to implement its own `findDocumentPath()` method.

Web Links for Documents

`DocumentsContract` also has a `createWebLinkIntent()` method, with a corresponding implementation on `DocumentsProvider`. This is very poorly documented, but apparently the idea is that for some cloud document providers,

you can get a URL to the document, given the Storage Access Framework `Uri` for the document. Presumably, this is a publicly-visible document, and the URL could be sent to other parties (e.g., via email) for them to see the document.

Android itself does not ship with a cloud document provider. Google Play devices may ship with Google Drive, and Drive might support this feature.

Document Settings Activity

If you implement [a DocumentsProvider](#), you have the option of including `FLAG_SUPPORTS_SETTINGS` in the details that you return for `queryChildDocuments()`. If you do that, and you have an activity that supports `ACTION_DOCUMENT_SETTINGS`, the user may be presented with an option to visit that activity. The activity should be given the `Uri` of the particular document that the user wishes to manage. A provider might use this for offering management of metadata for the document: tags, access rights, etc.

Providing Documents

The Storage Access Framework gives developers access to `ACTION_OPEN_DOCUMENT` and related Intent actions to perform operations on a document provider.

However, what if you want to *be* a document provider?

To do that, you will need to create a subclass of `DocumentsProvider`, override some abstract methods, and perhaps put up with some really obtuse error messages.

This chapter will help you in setting up your `DocumentsProvider`. With luck, you will escape without encountering errors.

Prerequisites

This chapter assumes that you have read [the preceding chapter on consuming documents](#), along with its prerequisites.

Have Your Content, and Provide it Too

Most apps will not need to implement a document provider. They might not even consume documents, let alone provide them to other apps.

However, if your app has document-style content, and that content is of a MIME type that could reasonably be manipulated by other apps, you should consider implementing a document provider to allow the user to manipulate that content using those other apps.

Historically, developers had two main approaches for content:

PROVIDING DOCUMENTS

1. Store it on internal storage
2. Store it on external storage

The internal storage route would be for content that would not normally be user-accessible, while external storage would be for user-accessible content.

In either of those cases, you will want to consider creating a document provider. In the case of internal storage, the user has no way to get to that content except through your app, and so if your app does not offer some capabilities that other apps do for that content, you limit your user by not having a document provider. In the case of external storage, while users in theory could use a file manager or something to try to get other apps to recognize the content, it will be easier for users if you provide a document provider to proactively publish this content to consuming apps.

However, bear in mind that your app does not have to store its content in either of these places. It could store the content in *somebody else's* document provider, using the mechanisms discussed in [the preceding chapter on consuming documents](#). In this case, you would not need to publish a document provider yourself, as the content is available through the same provider that your code is using.

It may also be the case that while your app is the one directly storing the content on internal or external storage, that content would not reasonably be used by other apps. Perhaps it is in some non-standard format that other apps are unlikely to support. Perhaps the files are not to be used by other apps for security reasons. In these cases, skipping the document provider is reasonable, though not exactly ideal from the user's standpoint. In particular, it restricts them from using those files with apps that can work with any file, such as attaching them to email messages.

So, for example:

- If you are implementing a camera app, and you are not storing the photos in the standard `DIRECTORY_DCIM` location for photos, but you are storing the photos yourself in files consider implementing a document provider so users can get at the photos you are taking. But, if you are implementing a camera app, you might elect to allow the user to indicate some place in somebody else's document provider where you could save the photo on their behalf.
- If you are implementing some sort of network-synced file service (e.g., DropBox, Bittorrent Sync), or some sort of on-device version control system, consider implementing a document provider so users can manipulate the documents that you are managing on their behalf.

Key Provider Concepts

Creating a document provider is significantly more complex than is creating a document consumer. To help make sense of what is required, here are some key terms that you will need to understand.

Roots

A document provider can publish one or more “roots”. Basically, a “root” points to a tree of documents. Many providers will have just one root, but it is entirely possible for your provider to have more than one.

Documents

Documents, in turn, represent what in filesystem terms would be considered files and directories. A document can either have children (e.g., a directory) or it can have content (e.g., a file), but not both.

A root *also* is a document — here, “root” refers to the root of a tree of documents.

Root and Document IDs

Each root has an ID unique to your app to identify that root as being distinct from any other root. This is a string.

Each document — files and directories alike — will have a string document ID to uniquely identify that document within its root. If you have some natural identifier (e.g., a primary key in some table), feel free to use it. Otherwise, you might consider your document ID to be some path to get to the document.

And, since a root is also a document, a root will have both a root ID and a document ID.

These document IDs need to be durable. Clients, or the Storage Access Framework itself, may wind up caching these IDs. Hence, pick something that not only uniquely identifies this document, but will *continue* to uniquely identify the document even after the document has been modified.

Pieces of a Provider

The [Documents/Provider](#) sample application implements a document provider, one that serves documents baked into the app itself in `assets/`. Of course, this is a rather artificial scenario — usually, a document provider will be working with a read/write data store, like internal storage.

The Activity

A document provider app probably needs a real UI. Perhaps that UI is for broader functionality that the app provides on top of serving documents. Perhaps that UI is merely to configure the document store, such as providing account credentials for the online storage service that the document provider exposes on Android.

If nothing else, you will need a do-nothing activity for the user to run, to ensure that your app is moved out of the stopped state.

In the sample app, this is handled by `MainActivity`, which uses `Theme.Translucent.NoDisplay` [to avoid a UI](#) and just shows a `Toast` to indicate that the provider is now activated:

```
package com.commonware.android.documents.provider;

import android.app.Activity;
import android.content.res.AssetManager;
import android.os.Bundle;
import android.util.Log;
import android.widget.Toast;
import java.io.File;
import java.io.FileOutputStream;
import java.io.IOException;
import java.io.InputStream;

public class MainActivity extends Activity {
    protected void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        Toast.makeText(this, R.string.activated, Toast.LENGTH_LONG).show();
        finish();
    }
}
```

(from [Documents/Provider/app/src/main/java/com/commonware/android/documents/provider/MainActivity.java](#))

The API Level Resources

The document provider itself comes courtesy of a subclass of `DocumentsProvider`. However, the `DocumentsProvider` class only exists on API Level 19 and higher — our subclass is useless on older devices. To ensure that our provider is only used on API Level 19 and higher, we should only enable it on API Level 19+ devices.

To that end, in `res/values/bools.xml`, we have a boolean resource named `min19`, set to `false`:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
  <bool name="min19">false</bool>
</resources>
```

(from [Documents/Provider/app/src/main/res/values/bools.xml](#))

In `res/values-v19/bools.xml`, we redefine that boolean resource to be `true`:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
  <bool name="min19">true</bool>
</resources>
```

(from [Documents/Provider/app/src/main/res/values-v19/bools.xml](#))

Hence, when we refer to the `min19` boolean resource, we will get `true` or `false` depending upon whether we are on API Level 19 or not.

The Manifest

Since `DocumentsProvider` is a subclass of `ContentProvider`, we will need a `<provider>` element in the manifest pointing to our subclass of `DocumentsProvider`:

```
<provider
  android:name=".DemoDocumentsProvider"
  android:authorities="com.commonware.android.documents.provider"
  android:enabled="@bool/min19"
  android:exported="true"
  android:grantUriPermissions="true"
  android:permission="android.permission.MANAGE_DOCUMENTS">
  <intent-filter>
    <action android:name="android.content.action.DOCUMENTS_PROVIDER" />
  </intent-filter>
</provider>
```

PROVIDING DOCUMENTS

(from [Documents/Provider/app/src/main/AndroidManifest.xml](#))

That element:

- Uses our `@bool/min19` resource from above to indicate that this component should only be enabled on API Level 19 and higher
- Is exported, but requires that applications looking to talk to our provider hold the `MANAGE_DOCUMENTS` permission, which can only be held by the firmware (or apps signed with the firmware's signing key)
- Sets the `android:grantUriPermissions` attribute to `true`, as that will be used by `DocumentsProvider` to allow third-party apps limited, conditional access to our documents
- Has your standard `android:name` and `android:authorities` attributes, as with any other `<provider>`

In addition, the `<provider>` has a nested `<intent-filter>` element. This may seem odd, as this used to be impossible, and it is not intuitively obvious what it would mean for a `ContentProvider` to have an `IntentFilter`. It also is [not documented as being allowed on <provider>](#), so we have no official explanation of what this means. Most likely, the magic `android.content.action.DOCUMENTS_PROVIDER` filter is being used simply as a marker, to indicate to Android that this particular `<provider>` is part of the Storage Access Framework and implements a `DocumentsProvider`.

The DocumentsProvider

The real business logic of publishing documents comes from your subclass of `DocumentsProvider`. As this class is new to API Level 19, your build target (e.g., `compileSdkVersion` in `build.gradle`) needs to be 19 or higher.

A minimal `DocumentsProvider` implementation will typically need five methods, outlined below.

onCreate()

As with any `ContentProvider`, your `DocumentsProvider` can override `onCreate()` to perform initialization work. Technically, this is not required, but the odds are very good that you will have *something* that you need to initialize.

In the case of our sample `DocumentsProvider` — named `DemoDocumentsProvider` — `onCreate()` simply obtains access to an `AssetManager` instance that can be used for serving documents:

PROVIDING DOCUMENTS

```
private AssetManager assets;

@Override
public boolean onCreate() {
    assets=getContext().getAssets();

    return(true);
}
```

(from [Documents/Provider/app/src/main/java/com/commonsware/android/documents/provider/DemoDocumentsProvider.java](#))

queryRoots()

Your `queryRoots()` method needs to return information about the root(s) that your provider will provide.

However, rather than returning this in the form of some clean object model (e.g., a `List of Document.Root` objects or some such), the return value is a `Cursor`. While in principle this `Cursor` could come from a database, in many cases it will be a `MatrixCursor`, which is a `Cursor` interface over a two-dimensional array representing the rows and columns.

From here, you should return all *presently valid* roots. The “presently valid” part is because a root might exist but not be usable at the present time. For example, suppose that you are writing a `DocumentsProvider` that provides a document interface to an Internet-hosted storage service. In this case, you may need the user to authenticate in order to allow access to those files, such as to pass that authentication data along to the Web service to be able to retrieve directory and file data. If the user is not presently logged in, though, not only can you not talk to the Web service right now, but you do not have the ability to force the user to authenticate right now. Instead, you will have to cull the root(s) governed by those authentication credentials. This may mean that the `Cursor` you return has no rows, as you simply do not have anything that can be published right now.

The `Cursor` that you return will have one row per presently valid root. The columns will be ones defined on the `DocumentsContract.Root` class. Your `queryRoots()` method is passed a `String` array representing the columns requested by the Storage Access Framework. As your app may not support all of those columns, you will need to determine the intersection between the requested columns and the ones you support.

PROVIDING DOCUMENTS

The sample app defines a `SUPPORTED_ROOT_PROJECTION` static data member to list the `DocumentsContract.Root` columns that are supported in general:

```
private static final String[] SUPPORTED_ROOT_PROJECTION=new String[] {
    Root.COLUMN_ROOT_ID, Root.COLUMN_FLAGS, Root.COLUMN_TITLE,
    Root.COLUMN_DOCUMENT_ID, Root.COLUMN_ICON };
```

(from [Documents/Provider/app/src/main/java/com/commonsware/android/documents/provider/DemoDocumentsProvider.java](#))

And the demo provider has a private `netProjection()` utility method that computes the intersection between the requested columns and the supported ones:

```
private static String[] netProjection(String[] requested, String[] supported) {
    if (requested==null) {
        return(supported);
    }

    ArrayList<String> result=new ArrayList<String>();

    for (String request : requested) {
