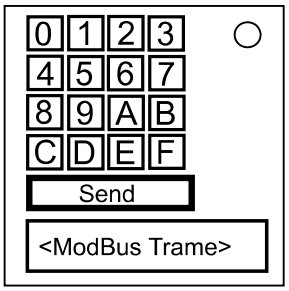
On the Subject of ModBus



"I got this, I'm a professional" was him last word.

The ModBus is a serial communications protocol originally published by Modicon in 1979, for use with it's PLCs (Programmable logic controllers).

A little of History is good, right ?

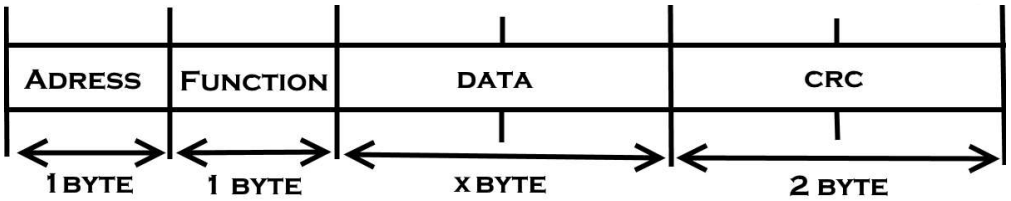
It's now commonly available means of connecting industrial electronic devices...and can be use to make some bomb.
To defuse the module, it's simple, you only need to send the right frame.
Don't send anything before finishing writing the frame.

You just have to follow the instructions. As simple as cooking a turkey !

ModBus Protocol

"READ THIS SECTION ! please."

Like we said before, you need to follow a strict protocol. We are lucky, bomber never use CRC (Cyclic redundancy check, "Error check").
Also, We know, they only use the RTU frame format describe below



Like we said before, we don't need calculate the CRC (lucky you).
PS : Adress here correspond to the slave adress like the adress of the timer.

16 bits word (2 bytes) are send in "Big endian" (Must Signifiant Bit First).
i.e. : You have to send $(42)_{10} = (21)_{HEX}$, you need to send "2" then "1".

Adress

"Where I have to send the defuse code ?"

For fill this, you need to watch the first number (or letter) of the serial code of the bomb.
Convert this (they are all in ASCII) in hexademal number (See Annex ASCII Tab), this is the adress (yay !).

Don't use the decimal numbers !

Function

"Hmm... I guess it's an important section..."

Terrorist (or defuser, or someone else ?) use only 2 function :

1. The function 04, use to read a data word. (and Yes, we will use it)
2. The function 06, use to write a data word.

The choice is simple, look at the last number (or letter) of the serial code.
...Convert it into an decimal number. (they are all in ASCII)
THEN do the modulo 4 of this number(e.g. : 12%4 = 0, 15%4 = 3)

"Simple, right ?"

After that, multiply by 3, and do the modulo 2 of the result
If the result is ...

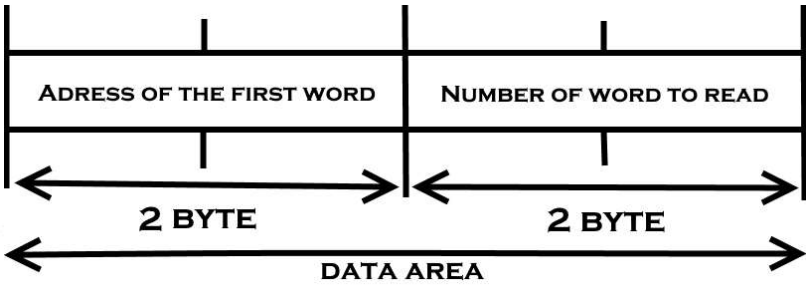
1. ... 0, use the function 04.
2. ... 1, use the function 06.

Function 04

Read a data, defuse the module, be an hero. BOOM dream archieve.

Bomber develop a new kind of protection, you can't defuse the bomb by writing some data word at the right place.
You have to send the right frame, read a useless data but it will defuse automatically the module.

So, How is compose the data area ? (Read the tab below)



You see, It's the last 4 byte to find ! Keep calm and defuse it !

Adress of the word

Firstly, for the adress of the word, multiply the third number by the fourth number.
For letter, convert it in decimal with annex ASCII Tab.
For number, don't change it like above, take the number write (If it's write 5 take 5).
After that, multiply the result by 100.
Then, just take the less significant byte.
i.e. : $(45BA72C)_{HEX}$ -> $(A72C)_{HEX}$

Number of word to read

Hmmm, you should think, "It's useless to say, i will read 210 word", I will respond you, Yes.
BUT, That not work like that, Bomber use this function sneaky, so they don't use the real purpose.
Please find these 2 last bytes (even if they don't correspond to anything).

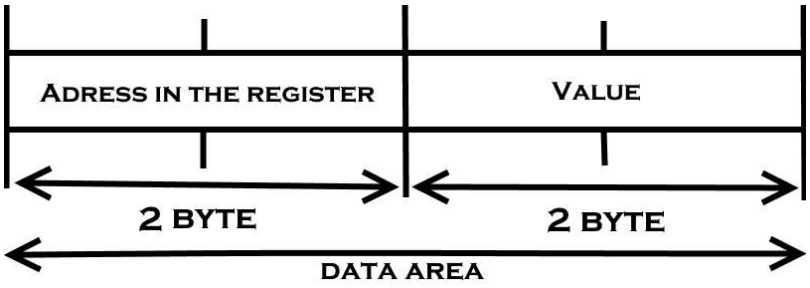
Take the adress of the slave (decimal), multiply by the the number of function (4 or 6) then add the data number (decimal too).
Convert into Hexa the result, simplify like just right before. And you got it !

Send the data and you will be a hero (or not if you failed).

Function 06

Be carefull, the keyboard is stronger than the sword !

You previously determine the slave adress and the function "write".
But now you need to search what you need to write ? and where (in him slave memory)?
See below, how complete the data area when you want to write something.



I believe in you ! You got this !

Adress in the register

I hope you review your binary operation become you will use it ! (It's not a joke).
First step, take the 4th number (or letter, there are all ASCII), convert it with ASCII table (in binary this time).
*When you got the number, complete with some 0 before to convert it into the same number in 16 bits this time. exemple : 101 = 0000 0101 (for 8 bits).
You have to invert this number (NOT Operation), truth table below :

A	NOT A
1	0
0	1

You just have to convert the 16 bits binary number into an decimal number.
Simplify by cut the higher value. i.e. : 265486 -> 5486
Annnnndddd, you got the adress in the register.

Value

The last part is the easiest ! For find the value to enter at this adress, take the first serial number (decimal) soustract the number of function.
Then multiply this result by the 5th serial Number (or lettre), in decimal for sure. Simplify like above.

If you there, you think it's finish, and yes, it's finish !
Now, enter all parameter in the right order, and click on the send button.
YOU DID IT MY BOY !

Annex ASCII table

Dec	Bin	Hex	Char	Dec	Bin	Hex	Char	Dec	Bin	Hex	Char	Dec	Bin	Hex	Char

When you need to convert a letter (or an number in some case), you need to find the letter (or number) into the Char column

Bonus : You got Dec/Bin/Hex/Char Convertion
