1

UNITS, PHYSICAL QUANTITIES AND VECTORS

1.1. **IDENTIFY:** Convert units from mi to km and from km to ft.
SET UP: 1 in. = 2.54 cm, 1 km = 1000 m, 12 in. = 1 ft, 1 mi = 5280 ft.
EXECUTE: **(a)** $1.00 \text{ mi} = (1.00 \text{ mi})\left(\frac{5280 \text{ ft}}{1 \text{ mi}}\right)\left(\frac{12 \text{ in.}}{1 \text{ ft}}\right)\left(\frac{2.54 \text{ cm}}{1 \text{ in.}}\right)\left(\frac{1 \text{ m}}{10^2 \text{ cm}}\right)\left(\frac{1 \text{ km}}{10^3 \text{ m}}\right) = 1.61 \text{ km}$

(b) $1.00 \text{ km} = (1.00 \text{ km})\left(\frac{10^3 \text{ m}}{1 \text{ km}}\right)\left(\frac{10^2 \text{ cm}}{1 \text{ m}}\right)\left(\frac{1 \text{ in.}}{2.54 \text{ cm}}\right)\left(\frac{1 \text{ ft}}{12 \text{ in.}}\right) = 3.28 \times 10^3 \text{ ft}$

EVALUATE: A mile is a greater distance than a kilometer. There are 5280 ft in a mile but only 3280 ft in a km.

1.2. **IDENTIFY:** Convert volume units from L to in.^3.
SET UP: $1 \text{ L} = 1000 \text{ cm}^3$. 1 in. = 2.54 cm
EXECUTE: $0.473 \text{ L} \times \left(\frac{1000 \text{ cm}^3}{1 \text{ L}}\right) \times \left(\frac{1 \text{ in.}}{2.54 \text{ cm}}\right)^3 = 28.9 \text{ in.}^3$.

EVALUATE: 1 in.^3 is greater than 1 cm^3, so the volume in in.^3 is a smaller number than the volume in cm^3, which is 473 cm^3.

1.3. **IDENTIFY:** We know the speed of light in m/s. $t = d/v$. Convert 1.00 ft to m and t from s to ns.
SET UP: The speed of light is $v = 3.00 \times 10^8$ m/s. 1 ft = 0.3048 m. $1 \text{ s} = 10^9$ ns.
EXECUTE: $t = \frac{0.3048 \text{ m}}{3.00 \times 10^8 \text{ m/s}} = 1.02 \times 10^{-9} \text{ s} = 1.02 \text{ ns}$

EVALUATE: In 1.00 s light travels $3.00 \times 10^8 \text{ m} = 3.00 \times 10^5 \text{ km} = 1.86 \times 10^5$ mi.

1.4. **IDENTIFY:** Convert the units from g to kg and from cm^3 to m^3.
SET UP: 1 kg = 1000 g. 1 m = 1000 cm.
EXECUTE: $19.3 \frac{\text{g}}{\text{cm}^3} \times \left(\frac{1 \text{ kg}}{1000 \text{ g}}\right) \times \left(\frac{100 \text{ cm}}{1 \text{ m}}\right)^3 = 1.93 \times 10^4 \frac{\text{kg}}{\text{m}^3}$

EVALUATE: The ratio that converts cm to m is cubed, because we need to convert cm^3 to m^3.

1.5. **IDENTIFY:** Convert volume units from in.^3 to L.
SET UP: $1 \text{ L} = 1000 \text{ cm}^3$. 1 in. = 2.54 cm.
EXECUTE: $(327 \text{ in.}^3) \times (2.54 \text{ cm/in.})^3 \times (1 \text{ L}/1000 \text{ cm}^3) = 5.36 \text{ L}$

EVALUATE: The volume is 5360 cm^3. 1 cm^3 is less than 1 in.^3, so the volume in cm^3 is a larger number than the volume in in.^3.

1.6. **IDENTIFY:** Convert ft^2 to m^2 and then to hectares.
SET UP: 1.00 hectare $= 1.00 \times 10^4 \text{ m}^2$. 1 ft = 0.3048 m.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: The area is $(12.0 \text{ acres})\left(\frac{43{,}600 \text{ ft}^2}{1 \text{ acre}}\right)\left(\frac{0.3048 \text{ m}}{1.00 \text{ ft}}\right)^2\left(\frac{1.00 \text{ hectare}}{1.00\times10^4 \text{ m}^2}\right) = 4.86 \text{ hectares.}$

EVALUATE: Since $1 \text{ ft} = 0.3048 \text{ m}$, $1 \text{ ft}^2 = (0.3048)^2 \text{ m}^2$.

1.7. **IDENTIFY:** Convert seconds to years.

SET UP: 1 billion seconds $= 1\times10^9$ s. 1 day $= 24$ h. 1 h $= 3600$ s.

EXECUTE: $1.00 \text{ billion seconds} = (1.00\times10^9 \text{ s})\left(\frac{1 \text{ h}}{3600 \text{ s}}\right)\left(\frac{1 \text{ day}}{24 \text{ h}}\right)\left(\frac{1 \text{ y}}{365 \text{ days}}\right) = 31.7 \text{ y.}$

EVALUATE: The conversion $1 \text{ y} = 3.156\times10^7$ s assumes $1 \text{ y} = 365.24$ d, which is the average for one extra day every four years, in leap years. The problem says instead to assume a 365-day year.

1.8. **IDENTIFY:** Apply the given conversion factors.

SET UP: 1 furlong $= 0.1250$ mi and 1 fortnight $= 14$ days. 1 day $= 24$ h.

EXECUTE: $(180{,}000 \text{ furlongs/fortnight})\left(\frac{0.125 \text{ mi}}{1 \text{ furlong}}\right)\left(\frac{1 \text{ fortnight}}{14 \text{ days}}\right)\left(\frac{1 \text{ day}}{24 \text{ h}}\right) = 67 \text{ mi/h}$

EVALUATE: A furlong is less than a mile and a fortnight is many hours, so the speed limit in mph is a much smaller number.

1.9. **IDENTIFY:** Convert miles/gallon to km/L.

SET UP: 1 mi $= 1.609$ km. 1 gallon $= 3.788$ L.

EXECUTE: **(a)** $55.0 \text{ miles/gallon} = (55.0 \text{ miles/gallon})\left(\frac{1.609 \text{ km}}{1 \text{ mi}}\right)\left(\frac{1 \text{ gallon}}{3.788 \text{ L}}\right) = 23.4 \text{ km/L.}$

(b) The volume of gas required is $\frac{1500 \text{ km}}{23.4 \text{ km/L}} = 64.1 \text{ L.}$ $\frac{64.1 \text{ L}}{45 \text{ L/tank}} = 1.4 \text{ tanks.}$

EVALUATE: 1 mi/gal $= 0.425$ km/L. A km is very roughly half a mile and there are roughly 4 liters in a gallon, so 1 mi/gal $\sim \frac{2}{4}$ km/L, which is roughly our result.

1.10. **IDENTIFY:** Convert units.

SET UP: Use the unit conversions given in the problem. Also, 100 cm $= 1$ m and 1000 g $= 1$ kg.

EXECUTE: **(a)** $\left(60\frac{\text{mi}}{\text{h}}\right)\left(\frac{1 \text{ h}}{3600 \text{ s}}\right)\left(\frac{5280 \text{ ft}}{1 \text{ mi}}\right) = 88\frac{\text{ft}}{\text{s}}$

(b) $\left(32\frac{\text{ft}}{\text{s}^2}\right)\left(\frac{30.48 \text{ cm}}{1 \text{ ft}}\right)\left(\frac{1 \text{ m}}{100 \text{ cm}}\right) = 9.8\frac{\text{m}}{\text{s}^2}$

(c) $\left(1.0\frac{\text{g}}{\text{cm}^3}\right)\left(\frac{100 \text{ cm}}{1 \text{ m}}\right)^3\left(\frac{1 \text{ kg}}{1000 \text{ g}}\right) = 10^3\frac{\text{kg}}{\text{m}^3}$

EVALUATE: The relations 60 mi/h $= 88$ ft/s and $1 \text{ g/cm}^3 = 10^3 \text{ kg/m}^3$ are exact. The relation $32 \text{ ft/s}^2 = 9.8 \text{ m/s}^2$ is accurate to only two significant figures.

1.11. **IDENTIFY:** We know the density and mass; thus we can find the volume using the relation density = mass/volume = m/V. The radius is then found from the volume equation for a sphere and the result for the volume.

SET UP: Density $= 19.5 \text{ g/cm}^3$ and $m_{\text{critical}} = 60.0$ kg. For a sphere $V = \frac{4}{3}\pi r^3$.

EXECUTE: $V = m_{\text{critical}}/\text{density} = \left(\frac{60.0 \text{ kg}}{19.5 \text{ g/cm}^3}\right)\left(\frac{1000 \text{ g}}{1.0 \text{ kg}}\right) = 3080 \text{ cm}^3.$

$r = \sqrt[3]{\frac{3V}{4\pi}} = \sqrt[3]{\frac{3}{4\pi}(3080 \text{ cm}^3)} = 9.0 \text{ cm.}$

EVALUATE: The density is very large, so the 130-pound sphere is small in size.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

1.12. **IDENTIFY:** Convert units.

SET UP: We know the equalities $1\text{ mg} = 10^{-3}\text{ g}$, $1\ \mu\text{g}\ 10^{-6}\text{ g}$, and $1\text{ kg} = 10^{3}\text{ g}$.

EXECUTE: **(a)** $(410\text{ mg/day})\left(\dfrac{10^{-3}\text{ g}}{1\text{ mg}}\right)\left(\dfrac{1\ \mu\text{g}}{10^{-6}\text{ g}}\right) = 4.10\times10^{5}\ \mu\text{g/day}.$

(b) $(12\text{ mg/kg})(75\text{ kg}) = (900\text{ mg})\left(\dfrac{10^{-3}\text{ g}}{1\text{ mg}}\right) = 0.900\text{ g}.$

(c) The mass of each tablet is $(2.0\text{ mg})\left(\dfrac{10^{-3}\text{ g}}{1\text{ mg}}\right) = 2.0\times10^{-3}\text{ g/day}$. The number of tablets required each day is the number of grams recommended per day divided by the number of grams per tablet:

$\dfrac{0.0030\text{ g/day}}{2.0\times10^{-3}\text{ g/tablet}} = 1.5\text{ tablet/day}$. Take 2 tablets each day.

(d) $(0.000070\text{ g/day})\left(\dfrac{1\text{ mg}}{10^{-3}\text{ g}}\right) = 0.070\text{ mg/day}.$

EVALUATE: Quantities in medicine and nutrition are frequently expressed in a wide variety of units.

1.13. **IDENTIFY:** The percent error is the error divided by the quantity.

SET UP: The distance from Berlin to Paris is given to the nearest 10 km.

EXECUTE: **(a)** $\dfrac{10\text{ m}}{890\times10^{3}\text{ m}} = 1.1\times10^{-3}\%.$

(b) Since the distance was given as 890 km, the total distance should be 890,000 meters. We know the total distance to only three significant figures.

EVALUATE: In this case a very small percentage error has disastrous consequences.

1.14. **IDENTIFY:** When numbers are multiplied or divided, the number of significant figures in the result can be no greater than in the factor with the fewest significant figures. When we add or subtract numbers it is the location of the decimal that matters.

SET UP: 12 mm has two significant figures and 5.98 mm has three significant figures.

EXECUTE: **(a)** $(12\text{ mm})\times(5.98\text{ mm}) = 72\text{ mm}^2$ (two significant figures)

(b) $\dfrac{5.98\text{ mm}}{12\text{ mm}} = 0.50$ (also two significant figures)

(c) 36 mm (to the nearest millimeter)

(d) 6 mm

(e) 2.0 (two significant figures)

EVALUATE: The length of the rectangle is known only to the nearest mm, so the answers in parts **(c)** and (d) are known only to the nearest mm.

1.15. **IDENTIFY:** Use your calculator to display $\pi\times10^{7}$. Compare that number to the number of seconds in a year.

SET UP: $1\text{ yr} = 365.24\text{ days}$, $1\text{ day} = 24\text{ h}$, and $1\text{ h} = 3600\text{ s}$.

EXECUTE: $(365.24\text{ days/1 yr})\left(\dfrac{24\text{ h}}{1\text{ day}}\right)\left(\dfrac{3600\text{ s}}{1\text{ h}}\right) = 3.15567\ldots\times10^{7}\text{ s};\ \pi\times10^{7}\text{ s} = 3.14159\ldots\times10^{7}\text{ s}$

The approximate expression is accurate to two significant figures. The percent error is 0.45%.

EVALUATE: The close agreement is a numerical accident.

1.16. **IDENTIFY:** Estimate the number of people and then use the estimates given in the problem to calculate the number of gallons.

SET UP: Estimate 3×10^{8} people, so 2×10^{8} cars.

EXECUTE: (Number of cars $\times$ miles/car day)/(mi/gal) = gallons/day

$$(2\times10^{8}\text{ cars}\times10000\text{ mi/yr/car}\times1\text{ yr}/365\text{ days})/(20\text{ mi/gal}) = 3\times10^{8}\text{ gal/day}$$

EVALUATE: The number of gallons of gas used each day approximately equals the population of the U.S.

1.17. **IDENTIFY:** Express 200 kg in pounds. Express each of 200 m, 200 cm and 200 mm in inches. Express 200 months in years.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

SET UP: A mass of 1 kg is equivalent to a weight of about 2.2 lbs. 1 in. = 2.54 cm. 1 y = 12 months.

EXECUTE: **(a)** 200 kg is a weight of 440 lb. This is much larger than the typical weight of a man.

(b) $200 \text{ m} = (2.00\times10^4 \text{ cm})\left(\frac{1 \text{ in.}}{2.54 \text{ cm}}\right) = 7.9\times10^3$ inches. This is much greater than the height of a person.

(c) 200 cm = 2.00 m = 79 inches = 6.6 ft. Some people are this tall, but not an ordinary man.

(d) 200 mm = 0.200 m = 7.9 inches. This is much too short.

(e) $200 \text{ months} = (200 \text{ mon})\left(\frac{1 \text{ y}}{12 \text{ mon}}\right) = 17$ y. This is the age of a teenager; a middle-aged man is much older than this.

EVALUATE: None are plausible. When specifying the value of a measured quantity it is essential to give the units in which it is being expressed.

1.18. **IDENTIFY:** The number of kernels can be calculated as $N = V_{\text{bottle}}/V_{\text{kernel}}$.

SET UP: Based on an Internet search, Iowa corn farmers use a sieve having a hole size of 0.3125 in. ≅ 8 mm to remove kernel fragments. Therefore estimate the average kernel length as 10 mm, the width as 6 mm and the depth as 3 mm. We must also apply the conversion factors 1 L = 1000 cm^3 and 1 cm = 10 mm.

EXECUTE: The volume of the kernel is: $V_{\text{kernel}} = (10 \text{ mm})(6 \text{ mm})(3 \text{ mm}) = 180 \text{ mm}^3$. The bottle's volume is: $V_{\text{bottle}} = (2.0 \text{ L})[(1000 \text{ cm}^3)/(1.0 \text{ L})][(10 \text{ mm})^3/(1.0 \text{ cm})^3] = 2.0\times10^6 \text{ mm}^3$. The number of kernels is then $N_{\text{kernels}} = V_{\text{bottle}}/V_{\text{kernels}} \approx (2.0\times10^6 \text{ mm}^3)/(180 \text{ mm}^3) = 11{,}000$ kernels.

EVALUATE: This estimate is highly dependent upon your estimate of the kernel dimensions. And since these dimensions vary amongst the different available types of corn, acceptable answers could range from 6,500 to 20,000.

1.19. **IDENTIFY:** Estimate the number of pages and the number of words per page.

SET UP: Assuming the two-volume edition, there are approximately a thousand pages, and each page has between 500 and a thousand words (counting captions and the smaller print, such as the end-of-chapter exercises and problems).

EXECUTE: An estimate for the number of words is about 10^6.

EVALUATE: We can expect that this estimate is accurate to within a factor of 10.

1.20. **IDENTIFY:** Approximate the number of breaths per minute. Convert minutes to years and cm^3 to m^3 to find the volume in m^3 breathed in a year.

SET UP: Assume 10 breaths/min. $1 \text{ y} = (365 \text{ d})\left(\frac{24 \text{ h}}{1 \text{ d}}\right)\left(\frac{60 \text{ min}}{1 \text{ h}}\right) = 5.3\times10^5$ min. 10^2 cm = 1 m so $10^6 \text{ cm}^3 = 1 \text{ m}^3$. The volume of a sphere is $V = \frac{4}{3}\pi r^3 = \frac{1}{6}\pi d^3$, where r is the radius and d is the diameter. Don't forget to account for four astronauts.

EXECUTE: **(a)** The volume is $(4)(10 \text{ breaths/min})(500\times10^{-6} \text{ m}^3)\left(\frac{5.3\times10^5 \text{ min}}{1 \text{ y}}\right) = 1\times10^4 \text{ m}^3/\text{yr}$.

(b) $d = \left(\frac{6V}{\pi}\right)^{1/3} = \left(\frac{6[1\times10^4 \text{ m}^3]}{\pi}\right)^{1/3} = 27 \text{ m}$

EVALUATE: Our estimate assumes that each cm^3 of air is breathed in only once, where in reality not all the oxygen is absorbed from the air in each breath. Therefore, a somewhat smaller volume would actually be required.

1.21. **IDENTIFY:** Estimate the number of blinks per minute. Convert minutes to years. Estimate the typical lifetime in years.

SET UP: Estimate that we blink 10 times per minute. 1 y = 365 days. 1 day = 24 h, 1 h = 60 min. Use 80 years for the lifetime.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: The number of blinks is $(10 \text{ per min})\left(\frac{60 \text{ min}}{1 \text{ h}}\right)\left(\frac{24 \text{ h}}{1 \text{ day}}\right)\left(\frac{365 \text{ days}}{1 \text{ y}}\right)(80 \text{ y/lifetime}) = 4\times10^8$

EVALUATE: Our estimate of the number of blinks per minute can be off by a factor of two but our calculation is surely accurate to a power of 10.

1.22. **IDENTIFY:** Estimate the number of beats per minute and the duration of a lifetime. The volume of blood pumped during this interval is then the volume per beat multiplied by the total beats.

SET UP: An average middle-aged (40 year-old) adult at rest has a heart rate of roughly 75 beats per minute. To calculate the number of beats in a lifetime, use the current average lifespan of 80 years.

EXECUTE: $N_{\text{beats}} = (75 \text{ beats/min})\left(\frac{60 \text{ min}}{1 \text{ h}}\right)\left(\frac{24 \text{ h}}{1 \text{ day}}\right)\left(\frac{365 \text{ days}}{\text{yr}}\right)\left(\frac{80 \text{ yr}}{\text{lifespan}}\right) = 3\times10^9 \text{ beats/lifespan}$

$V_{\text{blood}} = (50 \text{ cm}^3/\text{beat})\left(\frac{1 \text{ L}}{1000 \text{ cm}^3}\right)\left(\frac{1 \text{ gal}}{3.788 \text{ L}}\right)\left(\frac{3\times10^9 \text{ beats}}{\text{lifespan}}\right) = 4\times10^7 \text{ gal/lifespan}$

EVALUATE: This is a very large volume.

1.23. **IDENTIFY:** Estimation problem

SET UP: Estimate that the pile is $18 \text{ in.}\times18 \text{ in.}\times5 \text{ ft } 8 \text{ in.}$. Use the density of gold to calculate the mass of gold in the pile and from this calculate the dollar value.

EXECUTE: The volume of gold in the pile is $V = 18 \text{ in.}\times18 \text{ in.}\times68 \text{ in.} = 22{,}000 \text{ in.}^3$. Convert to cm^3:

$$V = 22{,}000 \text{ in.}^3(1000 \text{ cm}^3/61.02 \text{ in.}^3) = 3.6\times10^5 \text{ cm}^3.$$

The density of gold is 19.3 g/cm^3, so the mass of this volume of gold is

$$m = (19.3 \text{ g/cm}^3)(3.6\times10^5 \text{ cm}^3) = 7\times10^6 \text{ g}.$$

The monetary value of one gram is \$10, so the gold has a value of $(\$10/\text{gram})(7\times10^6 \text{ grams}) = \$7\times10^7$, or about $\$100\times10^6$ (one hundred million dollars).

EVALUATE: This is quite a large pile of gold, so such a large monetary value is reasonable.

1.24. **IDENTIFY:** Estimate the diameter of a drop and from that calculate the volume of a drop, in m^3. Convert m^3 to L.

SET UP: Estimate the diameter of a drop to be $d = 2$ mm. The volume of a spherical drop is $V = \frac{4}{3}\pi r^3 = \frac{1}{6}\pi d^3$. $10^3 \text{ cm}^3 = 1$ L.

EXECUTE: $V = \frac{1}{6}\pi(0.2 \text{ cm})^3 = 4\times10^{-3} \text{ cm}^3$. The number of drops in 1.0 L is $\frac{1000 \text{ cm}^3}{4\times10^{-3} \text{ cm}^3} = 2\times10^5$

EVALUATE: Since $V \sim d^3$, if our estimate of the diameter of a drop is off by a factor of 2 then our estimate of the number of drops is off by a factor of 8.

1.25. **IDENTIFY:** Estimate the number of students and the average number of pizzas eaten by each student in a school year.

SET UP: Assume a school of a thousand students, each of whom averages ten pizzas a year (perhaps an underestimate)

EXECUTE: They eat a total of 10^4 pizzas.

EVALUATE: The same answer applies to a school of 250 students averaging 40 pizzas a year each.

1.26. **IDENTIFY:** The displacements must be added as vectors and the magnitude of the sum depends on the relative orientation of the two displacements.

SET UP: The sum with the largest magnitude is when the two displacements are parallel and the sum with the smallest magnitude is when the two displacements are antiparallel.

EXECUTE: The orientations of the displacements that give the desired sum are shown in Figure 1.26.

EVALUATE: The orientations of the two displacements can be chosen such that the sum has any value between 0.6 m and 4.2 m.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

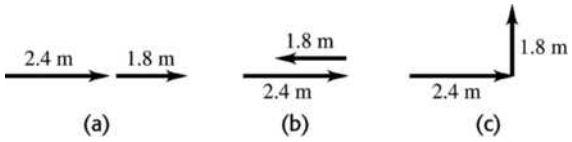

Figure 1.26

1.27. **IDENTIFY:** Draw each subsequent displacement tail to head with the previous displacement. The resultant displacement is the single vector that points from the starting point to the stopping point.

SET UP: Call the three displacements $\vec{A}$, $\vec{B}$, and $\vec{C}$. The resultant displacement $\vec{R}$ is given by $\vec{R} = \vec{A} + \vec{B} + \vec{C}$.

EXECUTE: The vector addition diagram is given in Figure 1.27. Careful measurement gives that $\vec{R}$ is 7.8 km, 38° north of east.

EVALUATE: The magnitude of the resultant displacement, 7.8 km, is less than the sum of the magnitudes of the individual displacements, $2.6\text{ km} + 4.0\text{ km} + 3.1\text{ km}$.

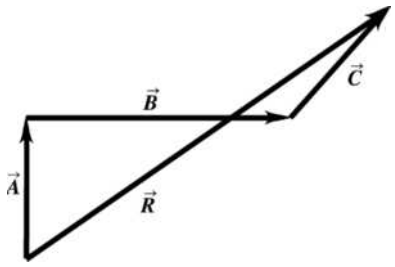

Figure 1.27

1.28. **IDENTIFY:** Draw the vector addition diagram to scale.

SET UP: The two vectors $\vec{A}$ and $\vec{B}$ are specified in the figure that accompanies the problem.

EXECUTE: **(a)** The diagram for $\vec{C} = \vec{A} + \vec{B}$ is given in Figure 1.28a. Measuring the length and angle of $\vec{C}$ gives $C = 9.0$ m and an angle of $\theta = 34°$.

(b) The diagram for $\vec{D} = \vec{A} - \vec{B}$ is given in Figure 1.28b. Measuring the length and angle of $\vec{D}$ gives $D = 22$ m and an angle of $\theta = 250°$.

(c) $-\vec{A} - \vec{B} = -(\vec{A} + \vec{B})$, so $-\vec{A} - \vec{B}$ has a magnitude of 9.0 m (the same as $\vec{A} + \vec{B}$) and an angle with the $+x$ axis of $214°$ (opposite to the direction of $\vec{A} + \vec{B}$).

(d) $\vec{B} - \vec{A} = -(\vec{A} - \vec{B})$, so $\vec{B} - \vec{A}$ has a magnitude of 22 m and an angle with the $+x$ axis of $70°$ (opposite to the direction of $\vec{A} - \vec{B}$).

EVALUATE: The vector $-\vec{A}$ is equal in magnitude and opposite in direction to the vector $\vec{A}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

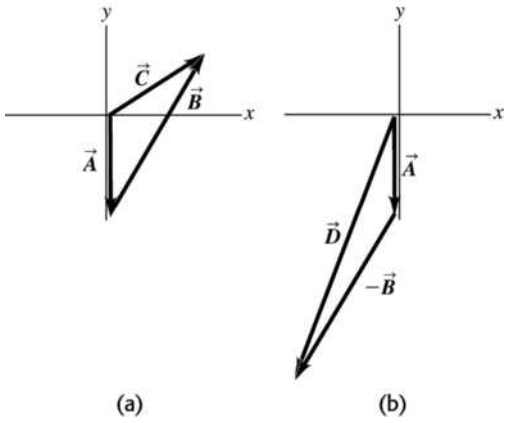

Figure 1.28

1.29. **IDENTIFY:** Since she returns to the starting point, the vector sum of the four displacements must be zero.
SET UP: Call the three given displacements $\vec{A}$, $\vec{B}$, and $\vec{C}$, and call the fourth displacement $\vec{D}$.
$\vec{A}+\vec{B}+\vec{C}+\vec{D}=0$.
EXECUTE: The vector addition diagram is sketched in Figure 1.29. Careful measurement gives that $\vec{D}$ is 144 m, 41° south of west.
EVALUATE: $\vec{D}$ is equal in magnitude and opposite in direction to the sum $\vec{A}+\vec{B}+\vec{C}$.

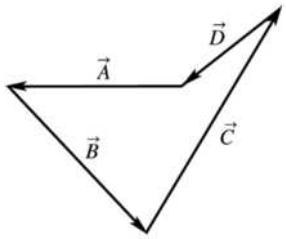

Figure 1.29

1.30. **IDENTIFY:** $\tan\theta=\dfrac{A_y}{A_x}$, for θ measured counterclockwise from the $+x$-axis.
SET UP: A sketch of A_x, A_y and $\vec{A}$ tells us the quadrant in which $\vec{A}$ lies.
EXECUTE:
(a) $\tan\theta=\dfrac{A_y}{A_x}=\dfrac{-1.00\text{ m}}{2.00\text{ m}}=-0.500$. $\theta=\tan^{-1}(-0.500)=360°-26.6°=333°$.
(b) $\tan\theta=\dfrac{A_y}{A_x}=\dfrac{1.00\text{ m}}{2.00\text{ m}}=0.500$. $\theta=\tan^{-1}(0.500)=26.6°$.
(c) $\tan\theta=\dfrac{A_y}{A_x}=\dfrac{1.00\text{ m}}{-2.00\text{ m}}=-0.500$. $\theta=\tan^{-1}(-0.500)=180°-26.6°=153°$.
(d) $\tan\theta=\dfrac{A_y}{A_x}=\dfrac{-1.00\text{ m}}{-2.00\text{ m}}=0.500$. $\theta=\tan^{-1}(0.500)=180°+26.6°=207°$
EVALUATE: The angles 26.6° and 207° have the same tangent. Our sketch tells us which is the correct value of θ.

1.31. **IDENTIFY:** For each vector $\vec{V}$, use that $V_x=V\cos\theta$ and $V_y=V\sin\theta$, when θ is the angle $\vec{V}$ makes with the $+x$ axis, measured counterclockwise from the axis.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

SET UP: For $\vec{A}$, $\theta = 270.0°$. For $\vec{B}$, $\theta = 60.0°$. For $\vec{C}$, $\theta = 205.0°$. For $\vec{D}$, $\theta = 143.0°$.

EXECUTE: $A_x = 0$, $A_y = -8.00$ m. $B_x = 7.50$ m, $B_y = 13.0$ m. $C_x = -10.9$ m, $C_y = -5.07$ m. $D_x = -7.99$ m, $D_y = 6.02$ m.

EVALUATE: The signs of the components correspond to the quadrant in which the vector lies.

1.32. **IDENTIFY:** Given the direction and one component of a vector, find the other component and the magnitude.

SET UP: Use the tangent of the given angle and the definition of vector magnitude.

EXECUTE: **(a)** $\tan 34.0° = \dfrac{|A_x|}{|A_y|}$

$$|A_y| = \frac{|A_x|}{\tan 34.0°} = \frac{16.0 \text{ m}}{\tan 34.0°} = 23.72 \text{ m}$$

$A_y = -23.7$ m.

(b) $A = \sqrt{A_x^2 + A_y^2} = 28.6$ m.

EVALUATE: The magnitude is greater than either of the components.

1.33. **IDENTIFY:** Given the direction and one component of a vector, find the other component and the magnitude.

SET UP: Use the tangent of the given angle and the definition of vector magnitude.

EXECUTE: **(a)** $\tan 32.0° = \dfrac{|A_x|}{|A_y|}$

$|A_x| = (13.0 \text{ m})\tan 32.0° = 8.12$ m. $A_x = -8.12$ m.

(b) $A = \sqrt{A_x^2 + A_y^2} = 15.3$ m.

EVALUATE: The magnitude is greater than either of the components.

1.34. **IDENTIFY:** Find the vector sum of the three given displacements.

SET UP: Use coordinates for which $+x$ is east and $+y$ is north. The driver's vector displacements are: $\vec{A} = 2.6$ km, 0° of north; $\vec{B} = 4.0$ km, 0° of east; $\vec{C} = 3.1$ km, 45° north of east.

EXECUTE: $R_x = A_x + B_x + C_x = 0 + 4.0 \text{ km} + (3.1 \text{ km})\cos(45°) = 6.2$ km; $R_y = A_y + B_y + C_y = 2.6 \text{ km} + 0 + (3.1 \text{ km})(\sin 45°) = 4.8$ km; $R = \sqrt{R_x^2 + R_y^2} = 7.8$ km; $\theta = \tan^{-1}[(4.8 \text{ km})/(6.2 \text{ km})] = 38°$; $\vec{R} = 7.8$ km, 38° north of east. This result is confirmed by the sketch in Figure 1.34.

EVALUATE: Both R_x and R_y are positive and $\vec{R}$ is in the first quadrant.

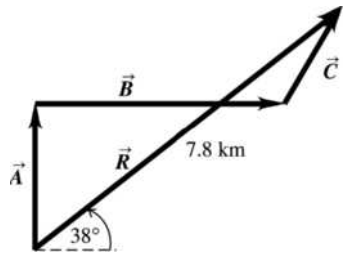

Figure 1.34

1.35. **IDENTIFY:** If $\vec{C} = \vec{A} + \vec{B}$, then $C_x = A_x + B_x$ and $C_y = A_y + B_y$. Use C_x and C_y to find the magnitude and direction of $\vec{C}$.

SET UP: From Figure E1.28 in the textbook, $A_x = 0$, $A_y = -8.00$ m and $B_x = +B\sin 30.0° = 7.50$ m, $B_y = +B\cos 30.0° = 13.0$ m.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: **(a)** $\vec{C} = \vec{A} + \vec{B}$ so $C_x = A_x + B_x = 7.50$ m and $C_y = A_y + B_y = +5.00$ m. $C = 9.01$ m.

$\tan\theta = \dfrac{C_y}{C_x} = \dfrac{5.00 \text{ m}}{7.50 \text{ m}}$ and $\theta = 33.7°$.

(b) $\vec{B} + \vec{A} = \vec{A} + \vec{B}$, so $\vec{B} + \vec{A}$ has magnitude 9.01 m and direction specified by $33.7°$.

(c) $\vec{D} = \vec{A} - \vec{B}$ so $D_x = A_x - B_x = -7.50$ m and $D_y = A_y - B_y = -21.0$ m. $D = 22.3$ m.

$\tan\phi = \dfrac{D_y}{D_x} = \dfrac{-21.0 \text{ m}}{-7.50 \text{ m}}$ and $\phi = 70.3°$. $\vec{D}$ is in the 3rd quadrant and the angle θ counterclockwise from the $+x$ axis is $180° + 70.3° = 250.3°$.

(d) $\vec{B} - \vec{A} = -(\vec{A} - \vec{B})$, so $\vec{B} - \vec{A}$ has magnitude 22.3 m and direction specified by $\theta = 70.3°$.

EVALUATE: These results agree with those calculated from a scale drawing in Problem 1.28.

1.36. **IDENTIFY:** Use Equations (1.7) and (1.8) to calculate the magnitude and direction of each of the given vectors.

SET UP: A sketch of A_x, A_y and $\vec{A}$ tells us the quadrant in which $\vec{A}$ lies.

EXECUTE: **(a)** $\sqrt{(-8.60 \text{ cm})^2 + (5.20 \text{ cm})^2} = 10.0$ cm, $\arctan\left(\dfrac{5.20}{-8.60}\right) = 148.8°$ (which is $180° - 31.2°$).

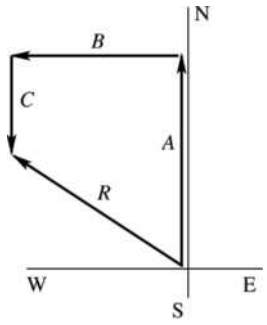
(b) $\sqrt{(-9.7 \text{ m})^2 + (-2.45 \text{ m})^2} = 10.0$ m, $\arctan\left(\dfrac{-2.45}{-9.7}\right) = 14° + 180° = 194°$.

(c) $\sqrt{(7.75 \text{ km})^2 + (-2.70 \text{ km})^2} = 8.21$ km, $\arctan\left(\dfrac{-2.7}{7.75}\right) = 340.8°$ (which is $360° - 19.2°$).

EVALUATE: In each case the angle is measured counterclockwise from the $+x$ axis. Our results for θ agree with our sketches.

1.37. **IDENTIFY:** Vector addition problem. We are given the magnitude and direction of three vectors and are asked to find their sum.

SET UP:



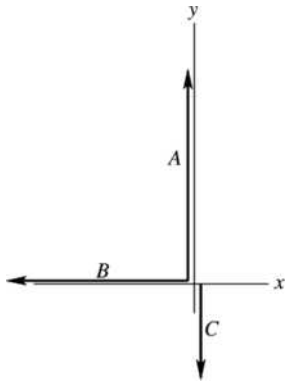
$A = 3.25$ km
$B = 2.90$ km
$C = 1.50$ km

Figure 1.37a

Select a coordinate system where $+x$ is east and $+y$ is north. Let $\vec{A}$, $\vec{B}$ and $\vec{C}$ be the three displacements of the professor. Then the resultant displacement $\vec{R}$ is given by $\vec{R} = \vec{A} + \vec{B} + \vec{C}$. By the method of components, $R_x = A_x + B_x + C_x$ and $R_y = A_y + B_y + C_y$. Find the x and y components of each vector; add them to find the components of the resultant. Then the magnitude and direction of the resultant can be found from its x and y components that we have calculated. As always it is essential to draw a sketch.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE:



$A_x = 0,\ A_y = +3.25$ km

$B_x = -2.90$ km, $B_y = 0$

$C_x = 0,\ C_y = -1.50$ km

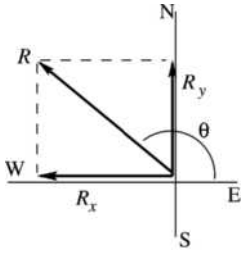
$R_x = A_x + B_x + C_x$

$R_x = 0 - 2.90 \text{ km} + 0 = -2.90 \text{ km}$

$R_y = A_y + B_y + C_y$

$R_y = 3.25 \text{ km} + 0 - 1.50 \text{ km} = 1.75 \text{ km}$

Figure 1.37b



$R = \sqrt{R_x^2 + R_y^2} = \sqrt{(-2.90 \text{ km})^2 + (1.75 \text{ km})^2}$

$R = 3.39$ km

$\tan\theta = \dfrac{R_y}{R_x} = \dfrac{1.75 \text{ km}}{-2.90 \text{ km}} = -0.603$

$\theta = 148.9°$

Figure 1.37c

The angle θ measured counterclockwise from the $+x$-axis. In terms of compass directions, the resultant displacement is $31.1°$ N of W.

EVALUATE: $R_x < 0$ and $R_y > 0$, so $\vec{R}$ is in 2nd quadrant. This agrees with the vector addition diagram.

1.38. **IDENTIFY:** We know the vector sum and want to find the magnitude of the vectors. Use the method of components.

SET UP: The two vectors $\vec{A}$ and $\vec{B}$ and their resultant $\vec{C}$ are shown in Figure 1.38. Let $+y$ be in the direction of the resultant. $A = B$.

EXECUTE: $C_y = A_y + B_y$. $372 \text{ N} = 2A\cos 43.0°$ and $A = 254$ N.

EVALUATE: The sum of the magnitudes of the two forces exceeds the magnitude of the resultant force because only a component of each force is upward.

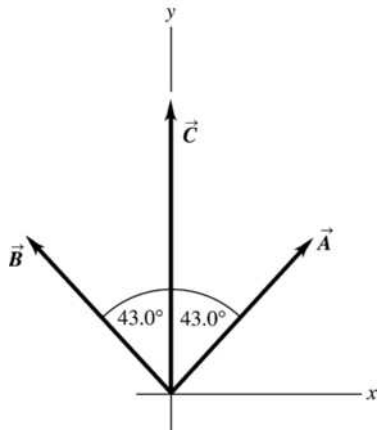


Figure 1.38

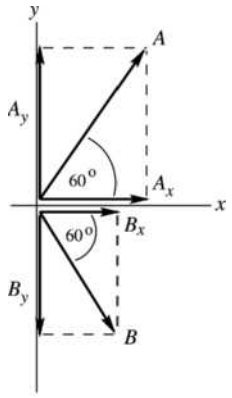
© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

1.39. **IDENTIFY:** Vector addition problem. $\vec{A} - \vec{B} = \vec{A} + (-\vec{B})$.

SET UP: Find the x- and y-components of $\vec{A}$ and $\vec{B}$. Then the x- and y-components of the vector sum are calculated from the x- and y-components of $\vec{A}$ and $\vec{B}$.

EXECUTE:



$A_x = A\cos(60.0°)$

$A_x = (2.80\text{ cm})\cos(60.0°) = +1.40\text{ cm}$

$A_y = A\sin(60.0°)$

$A_y = (2.80\text{ cm})\sin(60.0°) = +2.425\text{ cm}$

$B_x = B\cos(-60.0°)$

$B_x = (1.90\text{ cm})\cos(-60.0°) = +0.95\text{ cm}$

$B_y = B\sin(-60.0°)$

$B_y = (1.90\text{ cm})\sin(-60.0°) = -1.645\text{ cm}$

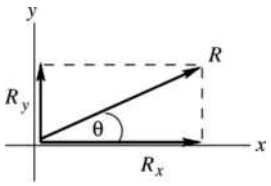
Note that the signs of the components correspond to the directions of the component vectors.

Figure 1.39a

(a) Now let $\vec{R} = \vec{A} + \vec{B}$.

$R_x = A_x + B_x = +1.40\text{ cm} + 0.95\text{ cm} = +2.35\text{ cm}.$

$R_y = A_y + B_y = +2.425\text{ cm} - 1.645\text{ cm} = +0.78\text{ cm}.$



$R = \sqrt{R_x^2 + R_y^2} = \sqrt{(2.35\text{ cm})^2 + (0.78\text{ cm})^2}$

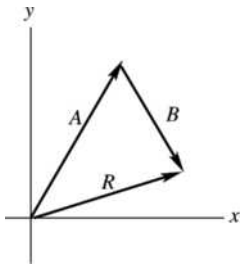
$R = 2.48\text{ cm}$

$\tan\theta = \dfrac{R_y}{R_x} = \dfrac{+0.78\text{ cm}}{+2.35\text{ cm}} = +0.3319$

$\theta = 18.4°$

Figure 1.39b

EVALUATE: The vector addition diagram for $\vec{R} = \vec{A} + \vec{B}$ is



$\vec{R}$ is in the 1st quadrant, with $|R_y| < |R_x|$, in agreement with our calculation.

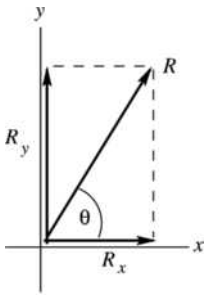
Figure 1.39c

(b) EXECUTE: Now let $\vec{R} = \vec{A} - \vec{B}$.

$R_x = A_x - B_x = +1.40\text{ cm} - 0.95\text{ cm} = +0.45\text{ cm}.$

$R_y = A_y - B_y = +2.425\text{ cm} + 1.645\text{ cm} = +4.070\text{ cm}.$

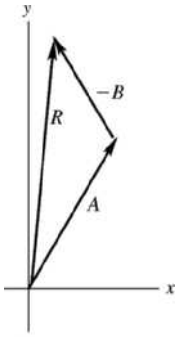
© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.



$$R = \sqrt{R_x^2 + R_y^2} = \sqrt{(0.45\text{ cm})^2 + (4.070\text{ cm})^2}$$
$$R = 4.09\text{ cm}$$
$$\tan\theta = \frac{R_y}{R_x} = \frac{4.070\text{ cm}}{0.45\text{ cm}} = +9.044$$
$$\theta = 83.7°$$

Figure 1.39d

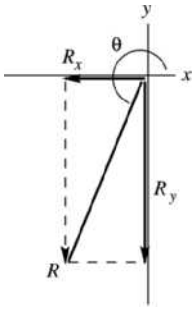
EVALUATE: The vector addition diagram for $\vec{\boldsymbol{R}} = \vec{\boldsymbol{A}} + (-\vec{\boldsymbol{B}})$ is



$\vec{\boldsymbol{R}}$ is in the 1st quadrant, with $|R_x| < |R_y|$, in agreement with our calculation.

Figure 1.39e

(c) EXECUTE:



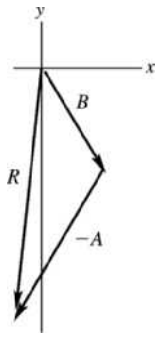
$\vec{\boldsymbol{B}} - \vec{\boldsymbol{A}} = -(\vec{\boldsymbol{A}} - \vec{\boldsymbol{B}})$

$\vec{\boldsymbol{B}} - \vec{\boldsymbol{A}}$ and $\vec{\boldsymbol{A}} - \vec{\boldsymbol{B}}$ are equal in magnitude and opposite in direction.

$R = 4.09$ cm and $\theta = 83.7° + 180° = 264°$

Figure 1.39f

EVALUATE: The vector addition diagram for $\vec{\boldsymbol{R}} = \vec{\boldsymbol{B}} + (-\vec{\boldsymbol{A}})$ is



$\vec{\boldsymbol{R}}$ is in the 3rd quadrant, with $|R_x| < |R_y|$, in agreement with our calculation.

Figure 1.39g

1.40. **IDENTIFY:** The general expression for a vector written in terms of components and unit vectors is $\vec{A} = A_x\hat{i} + A_y\hat{j}$.

SET UP: $5.0\vec{B} = 5.0(4\hat{i} - 6\hat{j}) = 20\vec{i} - 30\vec{j}$

EXECUTE: **(a)** $A_x = 5.0,\ A_y = -6.3$ **(b)** $A_x = 11.2,\ A_y = -9.91$ **(c)** $A_x = -15.0,\ A_y = 22.4$ **(d)** $A_x = 20,\ A_y = -30$

EVALUATE: The components are signed scalars.

1.41. **IDENTIFY:** Find the components of each vector and then use Eq. (1.14).

SET UP: $A_x = 0,\ A_y = -8.00$ m. $B_x = 7.50$ m, $B_y = 13.0$ m. $C_x = -10.9$ m, $C_y = -5.07$ m. $D_x = -7.99$ m, $D_y = 6.02$ m.

EXECUTE: $\vec{A} = (-8.00\text{ m})\hat{j}$; $\vec{B} = (7.50\text{ m})\hat{i} + (13.0\text{ m})\hat{j}$; $\vec{C} = (-10.9\text{ m})\hat{i} + (-5.07\text{ m})\hat{j}$; $\vec{D} = (-7.99\text{ m})\hat{i} + (6.02\text{ m})\hat{j}$.

EVALUATE: All these vectors lie in the *xy*-plane and have no *z*-component.

1.42. **IDENTIFY:** Find A and B. Find the vector difference using components.

SET UP: Deduce the *x*- and *y*-components and use Eq. (1.8).

EXECUTE: **(a)** $\vec{A} = 4.00\hat{i} + 7.00\hat{j}$; $A_x = +4.00$; $A_y = +7.00$.

$A = \sqrt{A_x^2 + A_y^2} = \sqrt{(4.00)^2 + (7.00)^2} = 8.06$. $\vec{B} = 5.00\hat{i} - 2.00\hat{j}$; $B_x = +5.00$; $B_y = -2.00$;

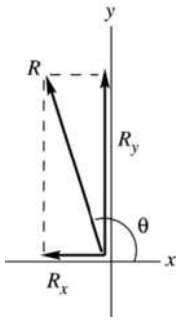
$B = \sqrt{B_x^2 + B_y^2} = \sqrt{(5.00)^2 + (-2.00)^2} = 5.39$.

EVALUATE: Note that the magnitudes of $\vec{A}$ and $\vec{B}$ are each larger than either of their components.

EXECUTE: **(b)** $\vec{A} - \vec{B} = 4.00\hat{i} + 7.00\hat{j} - (5.00\hat{i} - 2.00\hat{j}) = (4.00 - 5.00)\hat{i} + (7.00 + 2.00)\hat{j}$.

$\vec{A} - \vec{B} = -1.00\hat{i} + 9.00\hat{j}$

(c) Let $\vec{R} = \vec{A} - \vec{B} = -1.00\hat{i} + 9.00\hat{j}$. Then $R_x = -1.00,\ R_y = 9.00$.



$$R = \sqrt{R_x^2 + R_y^2}$$

$$R = \sqrt{(-1.00)^2 + (9.00)^2} = 9.06.$$

$$\tan\theta = \frac{R_y}{R_x} = \frac{9.00}{-1.00} = -9.00$$

$$\theta = -83.6° + 180° = 96.3°.$$

Figure 1.42

EVALUATE: $R_x < 0$ and $R_y > 0$, so $\vec{R}$ is in the 2nd quadrant.

1.43. **IDENTIFY:** Use trig to find the components of each vector. Use Eq. (1.11) to find the components of the vector sum. Eq. (1.14) expresses a vector in terms of its components.

SET UP: Use the coordinates in the figure that accompanies the problem.

EXECUTE: **(a)** $\vec{A} = (3.60\text{ m})\cos 70.0°\hat{i} + (3.60\text{ m})\sin 70.0°\hat{j} = (1.23\text{ m})\hat{i} + (3.38\text{ m})\hat{j}$

$\vec{B} = -(2.40\text{ m})\cos 30.0°\hat{i} - (2.40\text{ m})\sin 30.0°\hat{j} = (-2.08\text{ m})\hat{i} + (-1.20\text{ m})\hat{j}$

(b) $\vec{C} = (3.00)\vec{A} - (4.00)\vec{B} = (3.00)(1.23\text{ m})\hat{i} + (3.00)(3.38\text{ m})\hat{j} - (4.00)(-2.08\text{ m})\hat{i} - (4.00)(-1.20\text{ m})\hat{j}$

$= (12.01\text{ m})\hat{i} + (14.94)\hat{j}$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(c) From Equations (1.7) and (1.8),

$C = \sqrt{(12.01\text{ m})^2 + (14.94\text{ m})^2} = 19.17\text{ m}$, $\arctan\left(\dfrac{14.94\text{ m}}{12.01\text{ m}}\right) = 51.2°$

EVALUATE: C_x and C_y are both positive, so θ is in the first quadrant.

1.44. **IDENTIFY:** A unit vector has magnitude equal to 1.

SET UP: The magnitude of a vector is given in terms of its components by Eq. (1.12).

EXECUTE: **(a)** $|\hat{\boldsymbol{i}} + \hat{\boldsymbol{j}} + \hat{\boldsymbol{k}}| = \sqrt{1^2 + 1^2 + 1^2} = \sqrt{3} \neq 1$ so it is not a unit vector.

(b) $|\vec{\boldsymbol{A}}| = \sqrt{A_x^2 + A_y^2 + A_z^2}$. If any component is greater than $+1$ or less than -1, $|\vec{\boldsymbol{A}}| > 1$, so it cannot be a unit vector. $\vec{\boldsymbol{A}}$ can have negative components since the minus sign goes away when the component is squared.

(c) $|\vec{\boldsymbol{A}}| = 1$ gives $\sqrt{a^2(3.0)^2 + a^2(4.0)^2} = 1$ and $\sqrt{a^2}\sqrt{25} = 1$. $a = \pm\dfrac{1}{5.0} = \pm 0.20$.

EVALUATE: The magnitude of a vector is greater than the magnitude of any of its components.

1.45. **IDENTIFY:** $\vec{\boldsymbol{A}} \cdot \vec{\boldsymbol{B}} = AB\cos\phi$

SET UP: For $\vec{\boldsymbol{A}}$ and $\vec{\boldsymbol{B}}$, $\phi = 150.0°$. For $\vec{\boldsymbol{B}}$ and $\vec{\boldsymbol{C}}$, $\phi = 145.0°$. For $\vec{\boldsymbol{A}}$ and $\vec{\boldsymbol{C}}$, $\phi = 65.0°$.

EXECUTE: **(a)** $\vec{\boldsymbol{A}} \cdot \vec{\boldsymbol{B}} = (8.00\text{ m})(15.0\text{ m})\cos 150.0° = -104\text{ m}^2$

(b) $\vec{\boldsymbol{B}} \cdot \vec{\boldsymbol{C}} = (15.0\text{ m})(12.0\text{ m})\cos 145.0° = -148\text{ m}^2$

(c) $\vec{\boldsymbol{A}} \cdot \vec{\boldsymbol{C}} = (8.00\text{ m})(12.0\text{ m})\cos 65.0° = 40.6\text{ m}^2$

EVALUATE: When $\phi < 90°$ the scalar product is positive and when $\phi > 90°$ the scalar product is negative.

1.46. **IDENTIFY:** Target variables are $\vec{\boldsymbol{A}} \cdot \vec{\boldsymbol{B}}$ and the angle ϕ between the two vectors.

SET UP: We are given $\vec{\boldsymbol{A}}$ and $\vec{\boldsymbol{B}}$ in unit vector form and can take the scalar product using Eq. (1.19). The angle ϕ can then be found from Eq. (1.18).

EXECUTE: **(a)** $\vec{\boldsymbol{A}} = 4.00\hat{\boldsymbol{i}} + 7.00\hat{\boldsymbol{j}}$, $\vec{\boldsymbol{B}} = 5.00\hat{\boldsymbol{i}} - 2.00\hat{\boldsymbol{j}}$; $A = 8.06$, $B = 5.39$.

$\vec{\boldsymbol{A}} \cdot \vec{\boldsymbol{B}} = (4.00\hat{\boldsymbol{i}} + 7.00\hat{\boldsymbol{j}}) \cdot (5.00\hat{\boldsymbol{i}} - 2.00\hat{\boldsymbol{j}}) = (4.00)(5.00) + (7.00)(-2.00) = 20.0 - 14.0 = +6.00$.

(b) $\cos\phi = \dfrac{\vec{\boldsymbol{A}} \cdot \vec{\boldsymbol{B}}}{AB} = \dfrac{6.00}{(8.06)(5.39)} = 0.1382$; $\phi = 82.1°$.

EVALUATE: The component of $\vec{\boldsymbol{B}}$ along $\vec{\boldsymbol{A}}$ is in the same direction as $\vec{\boldsymbol{A}}$, so the scalar product is positive and the angle ϕ is less than $90°$.

1.47. **IDENTIFY:** For all of these pairs of vectors, the angle is found from combining Eqs. (1.18) and (1.21), to give the angle ϕ as $\phi = \arccos\left(\dfrac{\vec{\boldsymbol{A}} \cdot \vec{\boldsymbol{B}}}{AB}\right) = \arccos\left(\dfrac{A_x B_x + A_y B_y}{AB}\right)$.

SET UP: Eq. (1.14) shows how to obtain the components for a vector written in terms of unit vectors.

EXECUTE: **(a)** $\vec{\boldsymbol{A}} \cdot \vec{\boldsymbol{B}} = -22$, $A = \sqrt{40}$, $B = \sqrt{13}$, and so $\phi = \arccos\left(\dfrac{-22}{\sqrt{40}\sqrt{13}}\right) = 165°$.

(b) $\vec{\boldsymbol{A}} \cdot \vec{\boldsymbol{B}} = 60$, $A = \sqrt{34}$, $B = \sqrt{136}$, $\phi = \arccos\left(\dfrac{60}{\sqrt{34}\sqrt{136}}\right) = 28°$.

(c) $\vec{\boldsymbol{A}} \cdot \vec{\boldsymbol{B}} = 0$ and $\phi = 90°$.

EVALUATE: If $\vec{\boldsymbol{A}} \cdot \vec{\boldsymbol{B}} > 0$, $0 \leq \phi < 90°$. If $\vec{\boldsymbol{A}} \cdot \vec{\boldsymbol{B}} < 0$, $90° < \phi \leq 180°$. If $\vec{\boldsymbol{A}} \cdot \vec{\boldsymbol{B}} = 0$, $\phi = 90°$ and the two vectors are perpendicular.

1.48. **IDENTIFY:** Target variable is the vector $\vec{\boldsymbol{A}} \times \vec{\boldsymbol{B}}$ expressed in terms of unit vectors.

SET UP: We are given $\vec{\boldsymbol{A}}$ and $\vec{\boldsymbol{B}}$ in unit vector form and can take the vector product using Eq. (1.24).

EXECUTE: $\vec{\boldsymbol{A}} = 4.00\hat{\boldsymbol{i}} + 7.00\hat{\boldsymbol{j}}$, $\vec{\boldsymbol{B}} = 5.00\hat{\boldsymbol{i}} - 2.00\hat{\boldsymbol{j}}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$\vec{A}\times\vec{B}=(4.00\hat{i}+7.00\hat{j})\times(5.00\hat{i}-2.00\hat{j})=20.0\hat{i}\times\hat{i}-8.00\hat{i}\times\hat{j}+35.0\hat{j}\times\hat{i}-14.0\hat{j}\times\hat{j}$. But $\hat{i}\times\hat{i}=\hat{j}\times\hat{j}=0$ and $\hat{i}\times\hat{j}=\hat{k}$, $\hat{j}\times\hat{i}=-\hat{k}$, so $\vec{A}\times\vec{B}=-8.00\hat{k}+35.0(-\hat{k})=-43.0\hat{k}$. The magnitude of $\vec{A}\times\vec{B}$ is 43.0.

EVALUATE: Sketch the vectors $\vec{A}$ and $\vec{B}$ in a coordinate system where the xy-plane is in the plane of the paper and the z-axis is directed out toward you. By the right-hand rule $\vec{A}\times\vec{B}$ is directed into the plane of the paper, in the $-z$-direction. This agrees with the above calculation that used unit vectors.

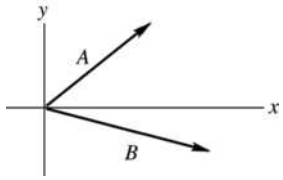


Figure 1.48

1.49. **IDENTIFY:** $\vec{A}\times\vec{D}$ has magnitude $AD\sin\phi$. Its direction is given by the right-hand rule.
SET UP: $\phi=180°-53°=127°$

EXECUTE: **(a)** $|\vec{A}\times\vec{D}|=(8.00\text{ m})(10.0\text{ m})\sin 127°=63.9\text{ m}^2$. The right-hand rule says $\vec{A}\times\vec{D}$ is in the $-z$-direction (into the page).

(b) $\vec{D}\times\vec{A}$ has the same magnitude as $\vec{A}\times\vec{D}$ and is in the opposite direction.

EVALUATE: The component of $\vec{D}$ perpendicular to $\vec{A}$ is $D_\perp=D\sin 53.0°=7.99$ m.
$|\vec{A}\times\vec{D}|=AD_\perp=63.9\text{ m}^2$, which agrees with our previous result.

1.50. **IDENTIFY:** The right-hand rule gives the direction and Eq. (1.22) gives the magnitude.
SET UP: $\phi=120.0°$.

EXECUTE: **(a)** The direction of $\vec{A}\times\vec{B}$ is into the page (the $-z$-direction). The magnitude of the vector product is $AB\sin\phi=(2.80\text{ cm})(1.90\text{ cm})\sin 120°=4.61\text{ cm}^2$.

(b) Rather than repeat the calculations, Eq. (1.23) may be used to see that $\vec{B}\times\vec{A}$ has magnitude $4.61\,\text{cm}^2$ and is in the $+z$-direction (out of the page).

EVALUATE: For part (a) we could use Eq. (1.27) and note that the only non-vanishing component is
$C_z=A_xB_y-A_yB_x=(2.80\text{ cm})\cos 60.0°(-1.90\text{ cm})\sin 60°$
$-(2.80\text{ cm})\sin 60.0°(1.90\text{ cm})\cos 60.0°=-4.61\text{ cm}^2$.
This gives the same result.

1.51. **IDENTIFY:** Apply Eqs. (1.18) and (1.22).
SET UP: The angle between the vectors is $20°+90°+30°=140°$.

EXECUTE: **(a)** Eq. (1.18) gives $\vec{A}\cdot\vec{B}=(3.60\text{ m})(2.40\text{ m})\cos 140°=-6.62\text{ m}^2$.

(b) From Eq. (1.22), the magnitude of the cross product is $(3.60\text{ m})(2.40\text{ m})\sin 140°=5.55\text{ m}^2$ and the direction, from the right-hand rule, is out of the page (the $+z$-direction).

EVALUATE: We could also use Eqs. (1.21) and (1.27), with the components of $\vec{A}$ and $\vec{B}$.

1.52. **IDENTIFY:** Use Eq. (1.27) for the components of the vector product.
SET UP: Use coordinates with the $+x$-axis to the right, $+y$-axis toward the top of the page, and $+z$-axis out of the page. $A_x=0$, $A_y=0$ and $A_z=-3.50$ cm. The page is 20 cm by 35 cm, so $B_x=-20$ cm and $B_y=35$ cm.

EXECUTE: $(\vec{A}\times\vec{B})_x=122\text{ cm}^2$, $(\vec{A}\times\vec{B})_y=70\text{ cm}^2$, $(\vec{A}\times\vec{B})_z=0$.

EVALUATE: From the components we calculated the magnitude of the vector product is 141 cm^2.
$B=40.3$ cm and $\phi=90°$, so $AB\sin\phi=141\text{ cm}^2$, which agrees.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

1.53. **IDENTIFY:** $\vec{A}$ and $\vec{B}$ are given in unit vector form. Find A, B and the vector difference $\vec{A}-\vec{B}$.

SET UP: $\vec{A}=-2.00\vec{i}+3.00\vec{j}+4.00\vec{k}$, $\vec{B}=3.00\vec{i}+1.00\vec{j}-3.00\vec{k}$

Use Eq. (1.8) to find the magnitudes of the vectors.

EXECUTE: **(a)** $A=\sqrt{A_x^2+A_y^2+A_z^2}=\sqrt{(-2.00)^2+(3.00)^2+(4.00)^2}=5.38$

$B=\sqrt{B_x^2+B_y^2+B_z^2}=\sqrt{(3.00)^2+(1.00)^2+(-3.00)^2}=4.36$

(b) $\vec{A}-\vec{B}=(-2.00\hat{i}+3.00\hat{j}+4.00\hat{k})-(3.00\hat{i}+1.00\hat{j}-3.00\hat{k})$

$\vec{A}-\vec{B}=(-2.00-3.00)\hat{i}+(3.00-1.00)\hat{j}+(4.00-(-3.00))\hat{k}=-5.00\hat{i}+2.00\hat{j}+7.00\hat{k}$.

(c) Let $\vec{C}=\vec{A}-\vec{B}$, so $C_x=-5.00$, $C_y=+2.00$, $C_z=+7.00$

$$C=\sqrt{C_x^2+C_y^2+C_z^2}=\sqrt{(-5.00)^2+(2.00)^2+(7.00)^2}=8.83$$

$\vec{B}-\vec{A}=-(\vec{A}-\vec{B})$, so $\vec{A}-\vec{B}$ and $\vec{B}-\vec{A}$ have the same magnitude but opposite directions.

EVALUATE: A, B and C are each larger than any of their components.

1.54. **IDENTIFY:** Area is length times width. Do unit conversions.

SET UP: 1 mi = 5280 ft. 1 ft^3 = 7.477 gal.

EXECUTE: **(a)** The area of one acre is $\frac{1}{8}\text{ mi}\times\frac{1}{80}\text{ mi}=\frac{1}{640}\text{ mi}^2$, so there are 640 acres to a square mile.

(b) $(1\text{ acre})\times\left(\dfrac{1\text{ mi}^2}{640\text{ acre}}\right)\times\left(\dfrac{5280\text{ ft}}{1\text{ mi}}\right)^2=43{,}560\text{ ft}^2$

(all of the above conversions are exact).

(c) $(1\text{ acre-foot})=(43{,}560\text{ ft}^3)\times\left(\dfrac{7.477\text{ gal}}{1\text{ ft}^3}\right)=3.26\times10^5\text{ gal}$, which is rounded to three significant figures.

EVALUATE: An acre is much larger than a square foot but less than a square mile. A volume of 1 acre-foot is much larger than a gallon.

1.55. **IDENTIFY:** The density relates mass and volume. Use the given mass and density to find the volume and from this the radius.

SET UP: The earth has mass $m_E=5.97\times10^{24}$ kg and radius $r_E=6.38\times10^6$ m. The volume of a sphere is $V=\frac{4}{3}\pi r^3$. $\rho=1.76\text{ g/cm}^3=1760\text{ km/m}^3$.

EXECUTE: **(a)** The planet has mass $m=5.5m_E=3.28\times10^{25}$ kg. $V=\dfrac{m}{\rho}=\dfrac{3.28\times10^{25}\text{ kg}}{1760\text{ kg/m}^3}=1.86\times10^{22}\text{ m}^3$.

$$r=\left(\frac{3V}{4\pi}\right)^{1/3}=\left(\frac{3[1.86\times10^{22}\text{ m}^3]}{4\pi}\right)^{1/3}=1.64\times10^7\text{ m}=1.64\times10^4\text{ km}$$

(b) $r=2.57r_E$

EVALUATE: Volume V is proportional to mass and radius r is proportional to $V^{1/3}$, so r is proportional to $m^{1/3}$. If the planet and earth had the same density its radius would be $(5.5)^{1/3}r_E=1.8r_E$. The radius of the planet is greater than this, so its density must be less than that of the earth.

1.56. **IDENTIFY** and **SET UP:** Unit conversion.

EXECUTE: **(a)** $f=1.420\times10^9$ cycles/s, so $\dfrac{1}{1.420\times10^9}\text{ s}=7.04\times10^{-10}\text{ s}$ for one cycle.

(b) $\dfrac{3600\text{ s/h}}{7.04\times10^{-10}\text{ s/cycle}}=5.11\times10^{12}\text{ cycles/h}$

(c) Calculate the number of seconds in 4600 million years $=4.6\times10^9$ y and divide by the time for 1 cycle:

$$\frac{(4.6\times10^9\text{ y})(3.156\times10^7\text{ s/y})}{7.04\times10^{-10}\text{ s/cycle}}=2.1\times10^{26}\text{ cycles}$$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(d) The clock is off by 1 s in $100{,}000 \text{ y} = 1\times10^5$ y, so in 4.60×10^9 y it is off by

$$(1\text{ s})\left(\frac{4.60\times10^9}{1\times10^5}\right) = 4.6\times10^4 \text{ s (about 13 h).}$$

EVALUATE: In each case the units in the calculation combine algebraically to give the correct units for the answer.

1.57. **IDENTIFY:** Using the density of the oxygen and volume of a breath, we want the mass of oxygen (the target variable in part (a)) breathed in per day and the dimensions of the tank in which it is stored.

SET UP: The mass is the density times the volume. Estimate 12 breaths per minute. We know 1 day = 24 h, 1 h = 60 min and 1000 L = 1 m^3. The volume of a cube having faces of length l is $V = l^3$.

EXECUTE: **(a)** $(12 \text{ breaths/min})\left(\frac{60 \text{ min}}{1 \text{ h}}\right)\left(\frac{24 \text{ h}}{1 \text{ day}}\right) = 17{,}280$ breaths/day. The volume of air breathed in one day is $(\frac{1}{2}$ L/breath$)(17{,}280 \text{ breaths/day}) = 8640 \text{ L} = 8.64 \text{ m}^3$. The mass of air breathed in one day is the density of air times the volume of air breathed: $m = (1.29 \text{ kg/m}^3)(8.64 \text{ m}^3) = 11.1$ kg. As 20% of this quantity is oxygen, the mass of oxygen breathed in 1 day is $(0.20)(11.1 \text{ kg}) = 2.2 \text{ kg} = 2200$ g.

(b) $V = 8.64 \text{ m}^3$ and $V = l^3$, so $l = V^{1/3} = 2.1$ m.

EVALUATE: A person could not survive one day in a closed tank of this size because the exhaled air is breathed back into the tank and thus reduces the percent of oxygen in the air in the tank. That is, a person cannot extract all of the oxygen from the air in an enclosed space.

1.58. **IDENTIFY:** Use the extreme values in the piece's length and width to find the uncertainty in the area.

SET UP: The length could be as large as 7.61 cm and the width could be as large as 1.91 cm.

EXECUTE: The area is $14.44 \pm 0.095 \text{ cm}^2$. The fractional uncertainty in the area is $\frac{0.095 \text{ cm}^2}{14.44 \text{ cm}^2} = 0.66\%$, and the fractional uncertainties in the length and width are $\frac{0.01 \text{ cm}}{7.61 \text{ cm}} = 0.13\%$ and $\frac{0.01 \text{ cm}}{1.9 \text{ cm}} = 0.53\%$. The sum of these fractional uncertainties is $0.13\% + 0.53\% = 0.66\%$, in agreement with the fractional uncertainty in the area.

EVALUATE: The fractional uncertainty in a product of numbers is greater than the fractional uncertainty in any of the individual numbers.

1.59. **IDENTIFY:** Calculate the average volume and diameter and the uncertainty in these quantities.

SET UP: Using the extreme values of the input data gives us the largest and smallest values of the target variables and from these we get the uncertainty.

EXECUTE: **(a)** The volume of a disk of diameter d and thickness t is $V = \pi(d/2)^2 t$.

The average volume is $V = \pi(8.50 \text{ cm}/2)^2(0.50 \text{ cm}) = 2.837 \text{ cm}^3$. But t is given to only two significant figures so the answer should be expressed to two significant figures: $V = 2.8 \text{ cm}^3$.

We can find the uncertainty in the volume as follows. The volume could be as large as $V = \pi(8.52 \text{ cm}/2)^2(0.055 \text{ cm}) = 3.1 \text{ cm}^3$, which is 0.3 cm^3 larger than the average value. The volume could be as small as $V = \pi(8.48 \text{ cm}/2)^2(0.045 \text{ cm}) = 2.5 \text{ cm}^3$, which is 0.3 cm^3 smaller than the average value. The uncertainty is $\pm 0.3 \text{ cm}^3$, and we express the volume as $V = 2.8 \pm 0.3 \text{ cm}^3$.

(b) The ratio of the average diameter to the average thickness is $8.50 \text{ cm}/0.050 \text{ cm} = 170$. By taking the largest possible value of the diameter and the smallest possible thickness we get the largest possible value for this ratio: $8.52 \text{ cm}/0.045 \text{ cm} = 190$. The smallest possible value of the ratio is $8.48/0.055 = 150$. Thus the uncertainty is ± 20 and we write the ratio as 170 ± 20.

EVALUATE: The thickness is uncertain by 10% and the percentage uncertainty in the diameter is much less, so the percentage uncertainty in the volume and in the ratio should be about 10%.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

1.60. **IDENTIFY:** Estimate the volume of each object. The mass m is the density times the volume.

SET UP: The volume of a sphere of radius r is $V = \frac{4}{3}\pi r^3$. The volume of a cylinder of radius r and length l is $V = \pi r^2 l$. The density of water is $1000\ \text{kg/m}^3$.

EXECUTE: **(a)** Estimate the volume as that of a sphere of diameter 10 cm: $V = 5.2\times10^{-4}\ \text{m}^3$.
$m = (0.98)(1000\ \text{kg/m}^3)(5.2\times10^{-4}\ \text{m}^3) = 0.5\ \text{kg}$.

(b) Approximate as a sphere of radius $r = 0.25\mu\text{m}$ (probably an overestimate): $V = 6.5\times10^{-20}\ \text{m}^3$.
$m = (0.98)(1000\ \text{kg/m}^3)(6.5\times10^{-20}\ \text{m}^3) = 6\times10^{-17}\ \text{kg} = 6\times10^{-14}\ \text{g}$.

(c) Estimate the volume as that of a cylinder of length 1 cm and radius 3 mm: $V = \pi r^2 l = 2.8\times10^{-7}\ \text{m}^3$.
$m = (0.98)(1000\ \text{kg/m}^3)(2.8\times10^{-7}\ \text{m}^3) = 3\times10^{-4}\ \text{kg} = 0.3\ \text{g}$.

EVALUATE: The mass is directly proportional to the volume.

1.61. **IDENTIFY:** The number of atoms is your mass divided by the mass of one atom.

SET UP: Assume a 70-kg person and that the human body is mostly water. Use Appendix D to find the mass of one H_2O molecule: $18.015\ \text{u}\times1.661\times10^{-27}\ \text{kg/u} = 2.992\times10^{-26}\ \text{kg/molecule}$.

EXECUTE: $(70\ \text{kg})/(2.992\times10^{-26}\ \text{kg/molecule}) = 2.34\times10^{27}$ molecules. Each H_2O molecule has 3 atoms, so there are about 6×10^{27} atoms.

EVALUATE: Assuming carbon to be the most common atom gives 3×10^{27} molecules, which is a result of the same order of magnitude.

1.62. **IDENTIFY:** The number of bills is the distance to the moon divided by the thickness of one bill.

SET UP: Estimate the thickness of a dollar bill by measuring a short stack, say ten, and dividing the measurement by the total number of bills. I obtain a thickness of roughly 1 mm. From Appendix F, the distance from the earth to the moon is 3.8×10^8 m.

EXECUTE: $N_{\text{bills}} = \left(\dfrac{3.8\times10^8\ \text{m}}{0.1\ \text{mm/bill}}\right)\left(\dfrac{10^3\ \text{mm}}{1\ \text{m}}\right) = 3.8\times10^{12}\ \text{bills} \approx 4\times10^{12}\ \text{bills}$

EVALUATE: This answer represents 4 trillion dollars! The cost of a single space shuttle mission in 2005 is significantly less—roughly 1 billion dollars.

1.63. **IDENTIFY:** The cost would equal the number of dollar bills required; the surface area of the U.S. divided by the surface area of a single dollar bill.

SET UP: By drawing a rectangle on a map of the U.S., the approximate area is 2600 mi by 1300 mi or $3{,}380{,}000\ \text{mi}^2$. This estimate is within 10 percent of the actual area, $3{,}794{,}083\ \text{mi}^2$. The population is roughly 3.0×10^8 while the area of a dollar bill, as measured with a ruler, is approximately $6\frac{1}{8}$ in. by $2\frac{5}{8}$ in.

EXECUTE: $A_{\text{U.S.}} = (3{,}380{,}000\ \text{mi}^2)[(5280\ \text{ft})/(1\ \text{mi})]^2[(12\ \text{in.})/(1\ \text{ft})]^2 = 1.4\times10^{16}\ \text{in.}^2$
$A_{\text{bill}} = (6.125\ \text{in.})(2.625\ \text{in.}) = 16.1\ \text{in.}^2$
Total cost $= N_{\text{bills}} = A_{\text{U.S.}}/A_{\text{bill}} = (1.4\times10^{16}\ \text{in.}^2)/(16.1\ \text{in.}^2/\text{bill}) = 9\times10^{14}\ \text{bills}$
Cost per person $= (9\times10^{14}\ \text{dollars})/(3.0\times10^8\ \text{persons}) = 3\times10^6\ \text{dollars/person}$

EVALUATE: The actual cost would be somewhat larger, because the land isn't flat.

1.64. **IDENTIFY:** Estimate the volume of sand in all the beaches on the earth. The diameter of a grain of sand determines its volume. From the volume of one grain and the total volume of sand we can calculate the number of grains.

SET UP: The volume of a sphere of diameter d is $V = \frac{1}{6}\pi d^3$. Consulting an atlas, we estimate that the continents have about 1.45×10^5 km of coastline. Add another 25% of this for rivers and lakes, giving 1.82×10^5 km of coastline. Assume that a beach extends 50 m beyond the water and that the sand is 2 m deep. $1\ \text{billion} = 1\times10^9$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: **(a)** The volume of sand is $(1.82\times10^{8}\text{ m})(50\text{ m})(2\text{ m}) = 2\times10^{10}\text{ m}^3$. The volume of a grain is $V = \frac{1}{6}\pi(0.2\times10^{-3}\text{ m})^3 = 4\times10^{-12}\text{ m}^3$. The number of grains is $\dfrac{2\times10^{10}\text{ m}^3}{4\times10^{-12}\text{ m}^3} = 5\times10^{21}$. The number of grains of sand is about 10^{22}.

(b) The number of stars is $(100\times10^{9})(100\times10^{9}) = 10^{22}$. The two estimates result in comparable numbers for these two quantities.

EVALUATE: Both numbers are crude estimates but are probably accurate to a few powers of 10.

1.65. **IDENTIFY:** We know the magnitude and direction of the sum of the two vector pulls and the direction of one pull. We also know that one pull has twice the magnitude of the other. There are two unknowns, the magnitude of the smaller pull and its direction. $A_x + B_x = C_x$ and $A_y + B_y = C_y$ give two equations for these two unknowns.

SET UP: Let the smaller pull be $\vec{A}$ and the larger pull be $\vec{B}$. $B = 2A$. $\vec{C} = \vec{A} + \vec{B}$ has magnitude 460.0 N and is northward. Let $+x$ be east and $+y$ be north. $B_x = -B\sin 25.0°$ and $B_y = B\cos 25.0°$. $C_x = 0$, $C_y = 460.0$ N. $\vec{A}$ must have an eastward component to cancel the westward component of $\vec{B}$. There are then two possibilities, as sketched in Figures 1.65 a and b. $\vec{A}$ can have a northward component or $\vec{A}$ can have a southward component.

EXECUTE: In either Figure 1.65 a or b, $A_x + B_x = C_x$ and $B = 2A$ gives $(2A)\sin 25.0° = A\sin\phi$ and $\phi = 57.7°$. In Figure 1.65a, $A_y + B_y = C_y$ gives $2A\cos 25.0° + A\cos 57.7° = 460.0$ N and $A = 196$ N. In Figure 1.65b, $2A\cos 25.0° - A\cos 57.7° = 460.0$ N and $A = 360$ N. One solution is for the smaller pull to be $57.7°$ east of north. In this case, the smaller pull is 196 N and the larger pull is 392 N. The other solution is for the smaller pull to be $57.7°$ east of south. In this case the smaller pull is 360 N and the larger pull is 720 N.

EVALUATE: For the first solution, with $\vec{A}$ east of north, each worker has to exert less force to produce the given resultant force and this is the sensible direction for the worker to pull.

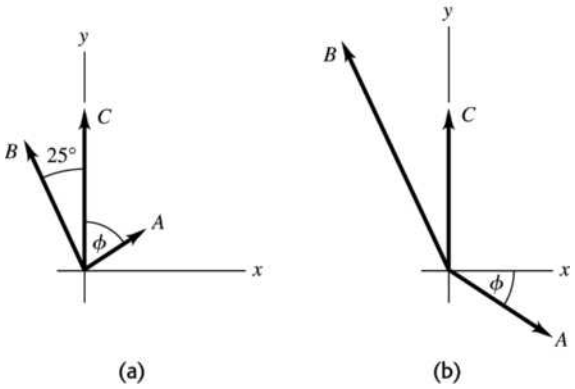

Figure 1.65

1.66. **IDENTIFY:** Let $\vec{D}$ be the fourth force. Find $\vec{D}$ such that $\vec{A} + \vec{B} + \vec{C} + \vec{D} = 0$, so $\vec{D} = -(\vec{A} + \vec{B} + \vec{C})$.

SET UP: Use components and solve for the components D_x and D_y of $\vec{D}$.

EXECUTE: $A_x = +A\cos 30.0° = +86.6\text{ N}$, $A_y = +A\sin 30.0° = +50.00\text{ N}$.

$B_x = -B\sin 30.0° = -40.00\text{ N}$, $B_y = +B\cos 30.0° = +69.28\text{ N}$.

$C_x = -C\cos 53.0° = -24.07\text{ N}$, $C_y = -C\sin 53.0° = -31.90\text{ N}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

Then $D_x = -22.53$ N, $D_y = -87.34$ N and $D = \sqrt{D_x^2 + D_y^2} = 90.2$ N. $\tan\alpha = |D_y/D_x| = 87.34/22.53$. $\alpha = 75.54°$. $\phi = 180° + \alpha = 256°$, counterclockwise from the $+x$-axis.

EVALUATE: As shown in Figure 1.66, since D_x and D_y are both negative, $\vec{D}$ must lie in the third quadrant.

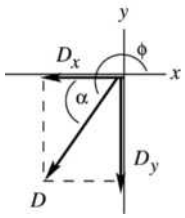

Figure 1.66

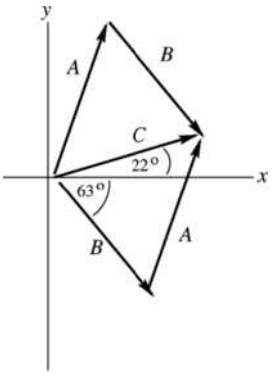
1.67. **IDENTIFY:** $\vec{A} + \vec{B} = \vec{C}$ (or $\vec{B} + \vec{A} = \vec{C}$). The target variable is vector $\vec{A}$.

SET UP: Use components and Eq. (1.10) to solve for the components of $\vec{A}$. Find the magnitude and direction of $\vec{A}$ from its components.

EXECUTE: **(a)**



$C_x = A_x + B_x$, so $A_x = C_x - B_x$

$C_y = A_y + B_y$, so $A_y = C_y - B_y$

$C_x = C\cos 22.0° = (6.40 \text{ cm})\cos 22.0°$

$C_x = +5.934$ cm

$C_y = C\sin 22.0° = (6.40 \text{ cm})\sin 22.0°$

$C_y = +2.397$ cm

$B_x = B\cos(360° - 63.0°) = (6.40 \text{ cm})\cos 297.0°$

$B_x = +2.906$ cm

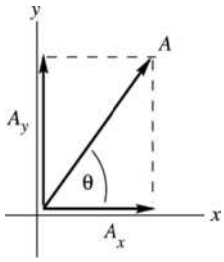
$B_y = B\sin 297.0° = (6.40 \text{ cm})\sin 297.0°$

$B_y = -5.702$ cm

Figure 1.67a

(b) $A_x = C_x - B_x = +5.934 \text{ cm} - 2.906 \text{ cm} = +3.03 \text{ cm}$

$A_y = C_y - B_y = +2.397 \text{ cm} - (-5.702) \text{ cm} = +8.10 \text{ cm}$



$A = \sqrt{A_x^2 + A_y^2}$

$A = \sqrt{(3.03 \text{ cm})^2 + (8.10 \text{ cm})^2} = 8.65$ cm

$\tan\theta = \dfrac{A_y}{A_x} = \dfrac{8.10 \text{ cm}}{3.03 \text{ cm}} = 2.67$

$\theta = 69.5°$

Figure 1.67b

EVALUATE: The $\vec{A}$ we calculated agrees qualitatively with vector $\vec{A}$ in the vector addition diagram in part (a).

1.68. **IDENTIFY:** Find the vector sum of the two displacements.

SET UP: Call the two displacements $\vec{A}$ and $\vec{B}$, where $A = 170$ km and $B = 230$ km. $\vec{A} + \vec{B} = \vec{R}$. $\vec{A}$ and $\vec{B}$ are as shown in Figure 1.68.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: $R_x = A_x + B_x = (170 \text{ km})\sin 68° + (230 \text{ km})\cos 48° = 311.5 \text{ km}.$

$R_y = A_y + B_y = (170 \text{ km})\cos 68° - (230 \text{ km})\sin 48° = -107.2 \text{ km}.$

$R = \sqrt{R_x^2 + R_y^2} = \sqrt{(311.5 \text{ km})^2 + (-107.2 \text{ km})^2} = 330 \text{ km}.$ $\tan\theta_R = \left|\frac{R_y}{R_x}\right| = \frac{107.2 \text{ km}}{311.5 \text{ km}} = 0.344.$

$\theta_R = 19°$ south of east.

EVALUATE: Our calculation using components agrees with $\vec{\boldsymbol{R}}$ shown in the vector addition diagram, Figure 1.68.

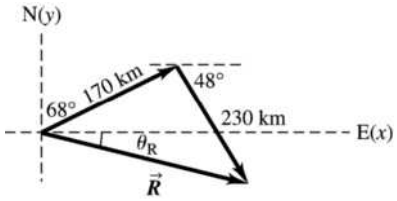


Figure 1.68

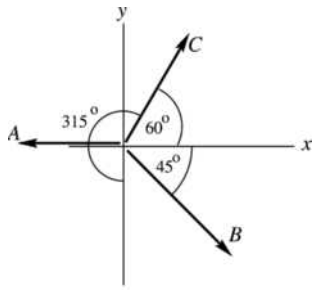
1.69. **IDENTIFY:** Vector addition. Target variable is the 4th displacement.

SET UP: Use a coordinate system where east is in the $+x$-direction and north is in the $+y$-direction. Let $\vec{\boldsymbol{A}}$, $\vec{\boldsymbol{B}}$, and $\vec{\boldsymbol{C}}$ be the three displacements that are given and let $\vec{\boldsymbol{D}}$ be the fourth unmeasured displacement. Then the resultant displacement is $\vec{\boldsymbol{R}} = \vec{\boldsymbol{A}} + \vec{\boldsymbol{B}} + \vec{\boldsymbol{C}} + \vec{\boldsymbol{D}}$. And since she ends up back where she started, $\vec{\boldsymbol{R}} = 0$.

$0 = \vec{\boldsymbol{A}} + \vec{\boldsymbol{B}} + \vec{\boldsymbol{C}} + \vec{\boldsymbol{D}}$, so $\vec{\boldsymbol{D}} = -(\vec{\boldsymbol{A}} + \vec{\boldsymbol{B}} + \vec{\boldsymbol{C}})$

$D_x = -(A_x + B_x + C_x)$ and $D_y = -(A_y + B_y + C_y)$

EXECUTE:



$A_x = -180 \text{ m}, \quad A_y = 0$

$B_x = B\cos 315° = (210 \text{ m})\cos 315° = +148.5 \text{ m}$

$B_y = B\sin 315° = (210 \text{ m})\sin 315° = -148.5 \text{ m}$

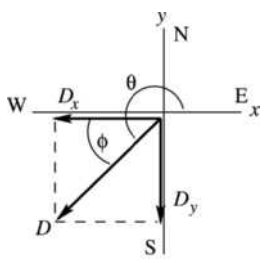
$C_x = C\cos 60° = (280 \text{ m})\cos 60° = +140 \text{ m}$

$C_y = C\sin 60° = (280 \text{ m})\sin 60° = +242.5 \text{ m}$

Figure 1.69a

$D_x = -(A_x + B_x + C_x) = -(-180 \text{ m} + 148.5 \text{ m} + 140 \text{ m}) = -108.5 \text{ m}$

$D_y = -(A_y + B_y + C_y) = -(0 - 148.5 \text{ m} + 242.5 \text{ m}) = -94.0 \text{ m}$



$D = \sqrt{D_x^2 + D_y^2}$

$D = \sqrt{(-108.5 \text{ m})^2 + (-94.0 \text{ m})^2} = 144 \text{ m}$

$\tan\theta = \frac{D_y}{D_x} = \frac{-94.0 \text{ m}}{-108.5 \text{ m}} = 0.8664$

$\theta = 180° + 40.9° = 220.9°$

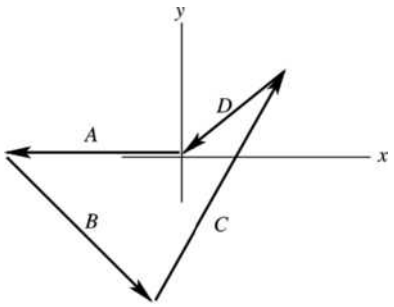
($\vec{\boldsymbol{D}}$ is in the third quadrant since both D_x and D_y are negative.)

Figure 1.69b

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

The direction of $\vec{D}$ can also be specified in terms of $\phi = \theta - 180° = 40.9°$; $\vec{D}$ is $41°$ south of west.

EVALUATE: The vector addition diagram, approximately to scale, is



Vector $\vec{D}$ in this diagram agrees qualitatively with our calculation using components.

Figure 1.69c

1.70. **IDENTIFY:** Add the vectors using the method of components.

SET UP: $A_x = 0$, $A_y = -8.00$ m. $B_x = 7.50$ m, $B_y = 13.0$ m. $C_x = -10.9$ m, $C_y = -5.07$ m.

EXECUTE: **(a)** $R_x = A_x + B_x + C_x = -3.4$ m. $R_y = A_y + B_y + C_y = -0.07$ m. $R = 3.4$ m. $\tan\theta = \dfrac{-0.07 \text{ m}}{-3.4 \text{ m}}$.

$\theta = 1.2°$ below the $-x$-axis.

(b) $S_x = C_x - A_x - B_x = -18.4$ m. $S_y = C_y - A_y - B_y = -10.1$ m. $S = 21.0$ m. $\tan\theta = \dfrac{S_y}{S_x} = \dfrac{-10.1 \text{ m}}{-18.4 \text{ m}}$.

$\theta = 28.8°$ below the $-x$-axis.

EVALUATE: The magnitude and direction we calculated for $\vec{R}$ and $\vec{S}$ agree with our vector diagrams.

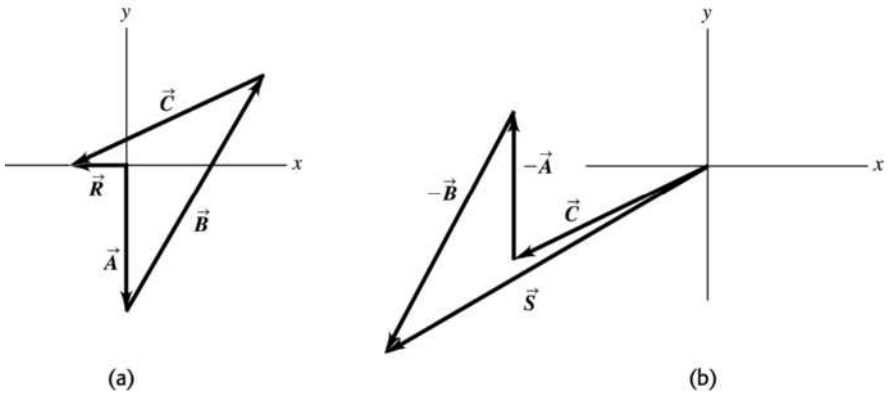


Figure 1.70

1.71. **IDENTIFY:** Find the vector sum of the two forces.

SET UP: Use components to add the two forces. Take the $+x$-direction to be forward and the $+y$-direction to be upward.

EXECUTE: The second force has components $F_{2x} = F_2 \cos 32.4° = 433$ N and $F_{2y} = F_2 \sin 32.4° = 275$ N.

The first force has components $F_{1x} = 480$ N and $F_{1y} = 0$. $F_x = F_{1x} + F_{2x} = 913$ N and

$F_y = F_{1y} + F_{2y} = 275$ N. The resultant force is 954 N in the direction 16.8° above the forward direction.

EVALUATE: Since the two forces are not in the same direction the magnitude of their vector sum is less than the sum of their magnitudes.

1.72. **IDENTIFY:** Solve for one of the vectors in the vector sum. Use components.

SET UP: Use coordinates for which $+x$ is east and $+y$ is north. The vector displacements are:

$\vec{A} = 2.00$ km, 0°of east; $\vec{B} = 3.50$ m, 45° south of east; and $\vec{R} = 5.80$ m, 0° east

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: $C_x = R_x - A_x - B_x = 5.80\text{ km} - (2.00\text{ km}) - (3.50\text{ km})(\cos 45°) = 1.33\text{ km}$; $C_y = R_y - A_y - B_y$ $= 0\text{ km} - 0\text{ km} - (-3.50\text{ km})(\sin 45°) = 2.47\text{ km}$; $C = \sqrt{(1.33\text{ km})^2 + (2.47\text{ km})^2} = 2.81\text{ km}$; $\theta = \tan^{-1}[(2.47\text{ km})/(1.33\text{ km})] = 61.7°$ north of east. The vector addition diagram in Figure 1.72 shows good qualitative agreement with these values.

EVALUATE: The third leg lies in the first quadrant since its x and y components are both positive.

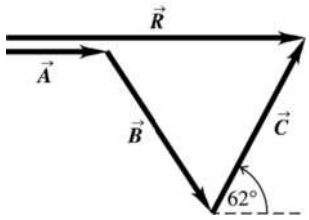

Figure 1.72

1.73. **IDENTIFY:** We know the resultant of two forces of known equal magnitudes and want to find that magnitude (the target variable).

SET UP: Use coordinates having a horizontal $+x$ axis and an upward $+y$ axis. Then $A_x + B_x = R_x$ and $R_x = 5.60$ N.

SOLVE: $A_x + B_x = R_x$ and $A\cos 32° + B\sin 32° = R_x$. Since $A = B$,

$2A\cos 32° = R_x$, so $A = \dfrac{R_x}{(2)(\cos 32°)} = 3.30$ N.

EVALUATE: The magnitude of the x component of each pull is 2.80 N, so the magnitude of each pull (3.30 N) is greater than its x component, as it should be.

1.74. **IDENTIFY:** The four displacements return her to her starting point, so $\vec{D} = -(\vec{A} + \vec{B} + \vec{C})$, where $\vec{A}$, $\vec{B}$ and $\vec{C}$ are in the three given displacements and $\vec{D}$ is the displacement for her return.

START UP: Let $+x$ be east and $+y$ be north.

EXECUTE: **(a)** $D_x = -[(147\text{ km})\sin 85° + (106\text{ km})\sin 167° + (166\text{ km})\sin 235°] = -34.3\text{ km}$.

$D_y = -[(147\text{ km})\cos 85° + (106\text{ km})\cos 167° + (166\text{ km})\cos 235°] = +185.7\text{ km}$.

$D = \sqrt{(-34.3\text{ km})^2 + (185.7\text{ km})^2} = 189\text{ km}$.

(b) The direction relative to north is $\phi = \arctan\left(\dfrac{34.3\text{ km}}{185.7\text{ km}}\right) = 10.5°$. Since $D_x < 0$ and $D_y > 0$, the direction of $\vec{D}$ is $10.5°$ west of north.

EVALUATE: The four displacements add to zero.

1.75. **IDENTIFY:** The sum of the vector forces on the beam sum to zero, so their x components and their y components sum to zero. Solve for the components of $\vec{F}$.

SET UP: The forces on the beam are sketched in Figure 1.75a. Choose coordinates as shown in the sketch. The 100-N pull makes an angle of $30.0° + 40.0° = 70.0°$ with the horizontal. $\vec{F}$ and the 100-N pull have been replaced by their x and y components.

EXECUTE: **(a)** The sum of the x-components is equal to zero gives $F_x + (100\text{ N})\cos 70.0° = 0$ and $F_x = -34.2$ N. The sum of the y-components is equal to zero gives $F_y + (100\text{ N})\sin 70.0° - 124\text{ N} = 0$ and $F_y = +30.0$ N. $\vec{F}$ and its components are sketched in Figure 1.75b. $F = \sqrt{F_x^2 + F_y^2} = 45.5$ N.

$\tan\phi = \dfrac{|F_y|}{|F_x|} = \dfrac{30.0\text{ N}}{34.2\text{ N}}$ and $\phi = 41.3°$. $\vec{F}$ is directed at $41.3°$ above the $-x$-axis in Figure 1.75a.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) The vector addition diagram is given in Figure 1.75c. $\vec{F}$ determined from the diagram agrees with $\vec{F}$ calculated in part (a) using components.

EVALUATE: The vertical component of the 100 N pull is less than the 124 N weight so $\vec{F}$ must have an upward component if all three forces balance.

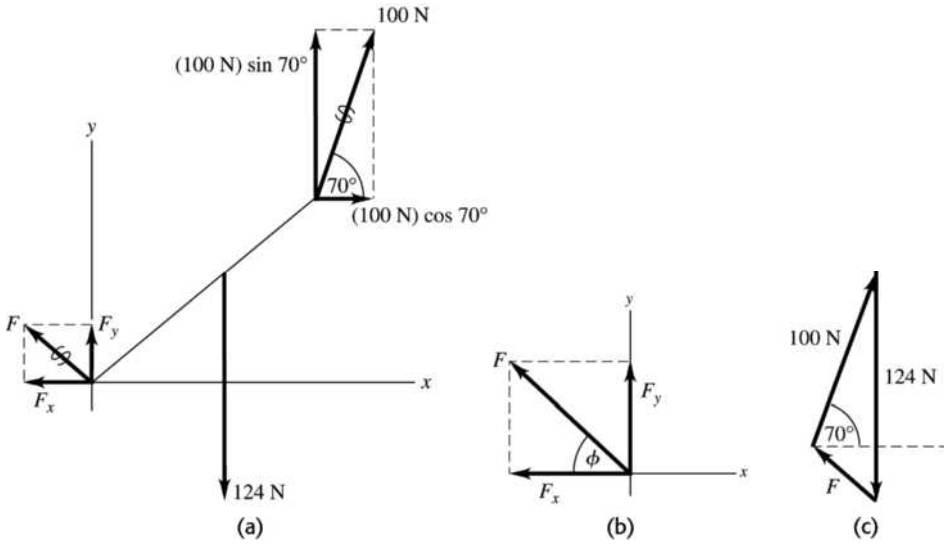

Figure 1.75

1.76. **IDENTIFY:** Let the three given displacements be $\vec{A}$, $\vec{B}$ and $\vec{C}$, where $A = 40$ steps, $B = 80$ steps and $C = 50$ steps. $\vec{R} = \vec{A} + \vec{B} + \vec{C}$. The displacement $\vec{C}$ that will return him to his hut is $-\vec{R}$.

SET UP: Let the east direction be the $+x$-direction and the north direction be the $+y$-direction.

EXECUTE: **(a)** The three displacements and their resultant are sketched in Figure 1.76.

(b) $R_x = (40)\cos 45° - (80)\cos 60° = -11.7$ and $R_y = (40)\sin 45° + (80)\sin 60° - 50 = 47.6$.

The magnitude and direction of the resultant are $\sqrt{(-11.7)^2 + (47.6)^2} = 49$, $\arctan\left(\dfrac{47.6}{11.7}\right) = 76°$, north of west. We know that $\vec{R}$ is in the second quadrant because $R_x < 0$, $R_y > 0$. To return to the hut, the explorer must take 49 steps in a direction $76°$ south of east, which is $14°$ east of south.

EVALUATE: It is useful to show R_x, R_y and $\vec{R}$ on a sketch, so we can specify what angle we are computing.

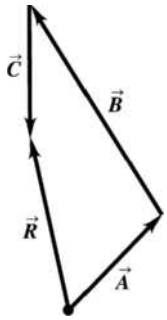

Figure 1.76

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

1.77. **IDENTIFY** and **SET UP:** The vector $\vec{A}$ that connects points (x_1, y_1) and (x_2, y_2) has components $A_x = x_2 - x_1$ and $A_y = y_2 - y_1$.

EXECUTE: **(a)** Angle of first line is $\theta = \tan^{-1}\left(\frac{200-20}{210-10}\right) = 42°$. Angle of second line is $42° + 30° = 72°$.

Therefore $X = 10 + 250\cos 72° = 87$, $Y = 20 + 250\sin 72° = 258$ for a final point of (87,258).

(b) The computer screen now looks something like Figure 1.77. The length of the bottom line is $\sqrt{(210-87)^2 + (200-258)^2} = 136$ and its direction is $\tan^{-1}\left(\frac{258-200}{210-87}\right) = 25°$ below straight left.

EVALUATE: Figure 1.77 is a vector addition diagram. The vector first line plus the vector arrow gives the vector for the second line.

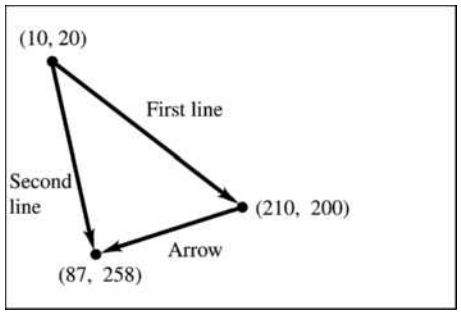

Figure 1.77

1.78. **IDENTIFY:** Vector addition. One vector and the sum are given; find the second vector (magnitude and direction).

SET UP: Let $+x$ be east and $+y$ be north. Let $\vec{A}$ be the displacement 285 km at $40.0°$ north of west and let $\vec{B}$ be the unknown displacement.

$\vec{A} + \vec{B} = \vec{R}$ where $\vec{R} = 115$ km, east

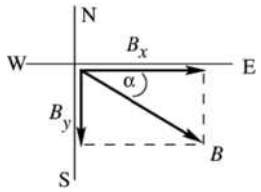
$\vec{B} = \vec{R} - \vec{A}$

$B_x = R_x - A_x$, $B_y = R_y - A_y$

EXECUTE: $A_x = -A\cos 40.0° = -218.3$ km, $A_y = +A\sin 40.0° = +183.2$ km

$R_x = 115$ km, $R_y = 0$

Then $B_x = 333.3$ km, $B_y = -183.2$ km. $B = \sqrt{B_x^2 + B_y^2} = 380$ km;



$\tan\alpha = |B_y/B_x| = (183.2 \text{ km})/(333.3 \text{ km})$

$\alpha = 28.8°$, south of east

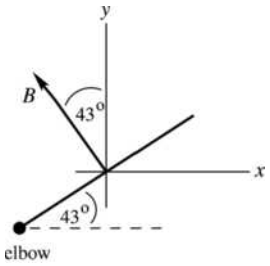
Figure 1.78

EVALUATE: The southward component of $\vec{B}$ cancels the northward component of $\vec{A}$. The eastward component of $\vec{B}$ must be 115 km larger than the magnitude of the westward component of $\vec{A}$.

1.79. **IDENTIFY:** Vector addition. One force and the vector sum are given; find the second force.

SET UP: Use components. Let $+y$ be upward.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.



$\vec{\boldsymbol{B}}$ is the force the biceps exerts.

Figure 1.79a

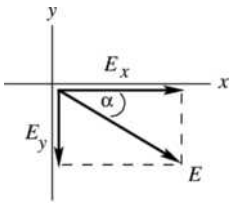
$\vec{\boldsymbol{E}}$ is the force the elbow exerts. $\vec{\boldsymbol{E}} + \vec{\boldsymbol{B}} = \vec{\boldsymbol{R}}$, where $R = 132.5$ N and is upward.

$E_x = R_x - B_x$, $E_y = R_y - B_y$

EXECUTE: $B_x = -B\sin 43° = -158.2$ N, $B_y = +B\cos 43° = +169.7$ N, $R_x = 0$, $R_y = +132.5$ N

Then $E_x = +158.2$ N, $E_y = -37.2$ N.

$E = \sqrt{E_x^2 + E_y^2} = 160$ N;



$\tan\alpha = |E_y/E_x| = 37.2/158.2$

$\alpha = 13°$, below horizontal

Figure 1.79b

EVALUATE: The x-component of $\vec{\boldsymbol{E}}$ cancels the x-component of $\vec{\boldsymbol{B}}$. The resultant upward force is less than the upward component of $\vec{\boldsymbol{B}}$, so E_y must be downward.

1.80. **IDENTIFY:** Find the vector sum of the four displacements.

SET UP: Take the beginning of the journey as the origin, with north being the y-direction, east the x-direction, and the z-axis vertical. The first displacement is then $(-30\text{ m})\hat{\boldsymbol{k}}$, the second is $(-15\text{ m})\hat{\boldsymbol{j}}$, the third is $(200\text{ m})\hat{\boldsymbol{i}}$, and the fourth is $(100\text{ m})\hat{\boldsymbol{j}}$.

EXECUTE: **(a)** Adding the four displacements gives

$(-30\text{ m})\hat{\boldsymbol{k}} + (-15\text{ m})\hat{\boldsymbol{j}} + (200\text{ m})\hat{\boldsymbol{i}} + (100\text{ m})\hat{\boldsymbol{j}} = (200\text{ m})\hat{\boldsymbol{i}} + (85\text{ m})\hat{\boldsymbol{j}} - (30\text{ m})\hat{\boldsymbol{k}}$.

(b) The total distance traveled is the sum of the distances of the individual segments:

$30\text{ m} + 15\text{ m} + 200\text{ m} + 100\text{ m} = 345$ m. The magnitude of the total displacement is:

$$D = \sqrt{D_x^2 + D_y^2 + D_z^2} = \sqrt{(200\text{ m})^2 + (85\text{ m})^2 + (-30\text{ m})^2} = 219\text{ m}.$$

EVALUATE: The magnitude of the displacement is much less than the distance traveled along the path.

1.81. **IDENTIFY:** The sum of the force displacements must be zero. Use components.

SET UP: Call the displacements $\vec{\boldsymbol{A}}$, $\vec{\boldsymbol{B}}$, $\vec{\boldsymbol{C}}$ and $\vec{\boldsymbol{D}}$, where $\vec{\boldsymbol{D}}$ is the final unknown displacement for the return from the treasure to the oak tree. Vectors $\vec{\boldsymbol{A}}$, $\vec{\boldsymbol{B}}$, and $\vec{\boldsymbol{C}}$ are sketched in Figure 1.81a.

$\vec{\boldsymbol{A}} + \vec{\boldsymbol{B}} + \vec{\boldsymbol{C}} + \vec{\boldsymbol{D}} = 0$ says $A_x + B_x + C_x + D_x = 0$ and $A_y + B_y + C_y + D_y = 0$. $A = 825$ m, $B = 1250$ m, and $C = 1000$ m. Let $+x$ be eastward and $+y$ be north.

EXECUTE: **(a)** $A_x + B_x + C_x + D_x = 0$ gives

$D_x = -(A_x + B_x + C_x) = -(0 - [1250\text{ m}]\sin 30.0° + [1000\text{ m}]\cos 40.0°) = -141$ m. $A_y + B_y + C_y + D_y = 0$

gives $D_y = -(A_y + B_y + C_y) = -(-825\text{ m} + [1250\text{ m}]\cos 30.0° + [1000\text{ m}]\sin 40.0°) = -900$ m. The fourth

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

displacement $\vec{D}$ and its components are sketched in Figure 1.81b. $D = \sqrt{D_x^2 + D_y^2} = 911$ m.

$\tan\phi = \dfrac{|D_x|}{|D_y|} = \dfrac{141 \text{ m}}{900 \text{ m}}$ and $\phi = 8.9°$. You should head $8.9°$ west of south and must walk 911 m.

(b) The vector diagram is sketched in Figure 1.81c. The final displacement $\vec{D}$ from this diagram agrees with the vector $\vec{D}$ calculated in part **(a)** using components.

EVALUATE: Note that $\vec{D}$ is the negative of the sum of $\vec{A}$, $\vec{B}$, and $\vec{C}$.

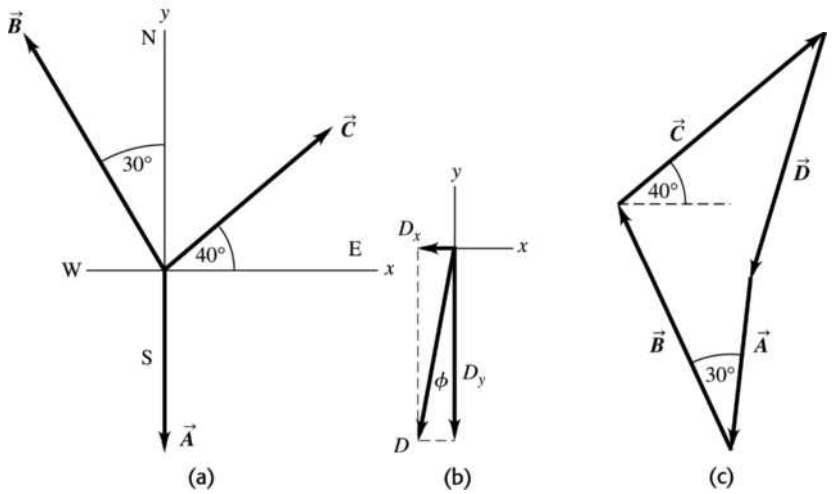


Figure 1.81

1.82. **IDENTIFY:** The displacements are vectors in which we know the magnitude of the resultant and want to find the magnitude of one of the other vectors.

SET UP: Calling $\vec{A}$ the vector from you to the first post, $\vec{B}$ the vector from you to the second post, and $\vec{C}$ the vector from the first to the second post, we have $\vec{A} + \vec{C} + \vec{B}$. Solving using components and the magnitude of $\vec{C}$ gives $A_x + C_x = B_x$ and $A_y + C_y = B_y$.

EXECUTE: $B_x = 0$, $A_x = 41.53$ m and $C_x = B_x - A_x = -41.53$ m.

$C = 80.0$ m, so $C_y = \pm\sqrt{C^2 - C_x^2} = \pm 68.38$ m.

The post is 37.1 m from you.

EVALUATE: $B_y = -37.1$ m (negative) since post is south of you (in the negative y direction).

1.83. **IDENTIFY:** We are given the resultant of three vectors, two of which we know, and want to find the magnitude and direction of the third vector.

SET UP: Calling $\vec{C}$ the unknown vector and $\vec{A}$ and $\vec{B}$ the known vectors, we have $\vec{A} + \vec{B} + \vec{C} = \vec{R}$. The components are $A_x + B_x + C_x = R_x$ and $A_y + B_y + C_y = R_y$.

EXECUTE: The components of the known vectors are $A_x = 12.0$ m, $A_y = 0$,

$B_x = -B\sin 50.0° = -21.45$ m, $B_y = B\cos 50.0° = +18.00$ m, $R_x = 0$, and $R_y = -10.0$ m. Therefore the components of $\vec{C}$ are $C_x = R_x - A_x - B_x = 0 - 12.0 \text{ m} - (-21.45 \text{ m}) = 9.45$ m and

$C_y = R_y - A_y - B_y = -10.0 \text{ m} - 0 - 18.0 \text{ m} = -28.0$ m.

Using these components to find the magnitude and direction of $\vec{C}$ gives $C = 29.6$ m and $\tan\theta = \dfrac{9.45}{28.0}$ and $\theta = 18.6°$ east of south

EVALUATE: A graphical sketch shows that this answer is reasonable.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

1.84. **IDENTIFY:** The displacements are vectors in which we know the magnitude of the resultant and want to find the magnitude of one of the other vectors.

SET UP: Calling $\vec{A}$ the vector of Ricardo's displacement from the tree, $\vec{B}$ the vector of Jane's displacement from the tree, and $\vec{C}$ the vector from Ricardo to Jane, we have $\vec{A}+\vec{C}=\vec{B}$. Solving using components we have $A_x + C_x = B_x$ and $A_y + C_y = B_y$.

EXECUTE: **(a)** The components of $\vec{A}$ and $\vec{B}$ are $A_x = -(26.0\text{ m})\sin 60.0° = -22.52\text{ m}$,

$A_y = (26.0\text{ m})\cos 60.0° = +13.0\text{ m}$, $B_x = -(16.0\text{ m})\cos 30.0° = -13.86\text{ m}$,

$B_y = -(16.0\text{ m})\sin 30.0° = -8.00\text{ m}$, $C_x = B_x - A_x = -13.86\text{ m} - (-22.52\text{ m}) = +8.66\text{ m}$,

$C_y = B_y - A_y = -8.00\text{ m} - (13.0\text{ m}) = -21.0\text{ m}$

Finding the magnitude from the components gives $C = 22.7$ m.

(b) Finding the direction from the components gives $\tan\theta = \dfrac{8.66}{21.0}$ and $\theta = 22.4°$, east of south.

EVALUATE: A graphical sketch confirms that this answer is reasonable.

1.85. **IDENTIFY:** Think of the displacements of the three people as vectors. We know two of them and want to find their resultant.

SET UP: Calling $\vec{A}$ the vector from John to Paul, $\vec{B}$ the vector from Paul to George, and $\vec{C}$ the vector from John to George, we have $\vec{A}+\vec{B}=\vec{C}$, which gives $A_x + B_x = C_x$ and $A_y + B_y = C_y$.

EXECUTE: The known components are $A_x = -14.0$ m, $A_y = 0$, $B_x = B\cos 37° = 28.75$ m, and $B_y = -B\sin 37° = -21.67$ m. Therefore $C_x = -14.0\text{ m} + 28.75\text{ m} = 14.75\text{ m}$, $C_y = 0 - 21.67\text{ m} = -21.67\text{ m}$.

These components give $C = 26.2$ m and $\tan\theta = \dfrac{14.75}{21.67}$, which gives $\theta = 34.2°$ east of south.

EVALUATE: A graphical sketch confirms that this answer is reasonable.

1.86. **IDENTIFY:** If the vector from your tent to Joe's is $\vec{A}$ and from your tent to Karl's is $\vec{B}$, then the vector from Joe's tent to Karl's is $\vec{B}-\vec{A}$.

SET UP: Take your tent's position as the origin. Let $+x$ be east and $+y$ be north.

EXECUTE: The position vector for Joe's tent is

$([21.0\text{ m}]\cos 23°)\hat{i} - ([21.0\text{ m}]\sin 23°)\hat{j} = (19.33\text{ m})\hat{i} - (8.205\text{ m})\hat{j}$.

The position vector for Karl's tent is $([32.0\text{ m}]\cos 37°)\hat{i} + ([32.0\text{ m}]\sin 37°)\hat{j} = (25.56\text{ m})\hat{i} + (19.26\text{ m})\hat{j}$.

The difference between the two positions is

$(19.33\text{ m} - 25.56\text{ m})\hat{i} + (-8.205\text{ m} - 19.25\text{ m})\hat{j} = -(6.23\text{ m})\hat{i} - (27.46\text{ m})\hat{j}$. The magnitude of this vector is the distance between the two tents: $D = \sqrt{(-6.23\text{ m})^2 + (-27.46\text{ m})^2} = 28.2$ m

EVALUATE: If both tents were due east of yours, the distance between them would be $32.0\text{ m} - 21.0\text{ m} = 11.0$ m. If Joe's was due north of yours and Karl's was due south of yours, then the distance between them would be $32.0\text{ m} + 21.0\text{ m} = 53.0$ m. The actual distance between them lies between these limiting values.

1.87. **IDENTIFY:** We know the scalar product and the magnitude of the vector product of two vectors and want to know the angle between them.

SET UP: The scalar product is $\vec{A}\cdot\vec{B} = AB\cos\theta$ and the vector product is $\left|\vec{A}\times\vec{B}\right| = AB\sin\theta$.

EXECUTE: $\vec{A}\cdot\vec{B} = AB\cos\theta = -6.00$ and $\left|\vec{A}\times\vec{B}\right| = AB\sin\theta = +9.00$. Taking the ratio gives $\tan\theta = \dfrac{9.00}{-6.00}$, so $\theta = 124°$.

EVALUATE: Since the scalar product is negative, the angle must be between 90° and 180°.

1.88. **IDENTIFY:** Calculate the scalar product and use Eq. (1.18) to determine ϕ.

SET UP: The unit vectors are perpendicular to each other.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: The direction vectors each have magnitude $\sqrt{3}$, and their scalar product is $(1)(1)+(1)(-1)+(1)(-1)=-1$, so from Eq. (1.18) the angle between the bonds is

$$\arccos\left(\frac{-1}{\sqrt{3}\sqrt{3}}\right)=\arccos\left(-\frac{1}{3}\right)=109°.$$

EVALUATE: The angle between the two vectors in the bond directions is greater than $90°$.

1.89. **IDENTIFY:** We know the magnitude of two vectors and their scalar product and want to find the magnitude of their vector product.

SET UP: The scalar product is $\vec{A}\cdot\vec{B}=AB\cos\theta$ and the vector product is $\left|\vec{A}\times\vec{B}\right|=AB\sin\theta$.

EXECUTE: $\vec{A}\cdot\vec{B}=AB\cos\theta=90.0\ \text{m}^2$, which gives $\cos\theta=\dfrac{90.0\ \text{m}^2}{AB}=\dfrac{90.0\ \text{m}^2}{(12.0\ \text{m})(16.0\ \text{m})}=0.4688$, so $\theta=62.05°$. Therefore $\left|\vec{A}\times\vec{B}\right|=AB\sin\theta=(12.0\ \text{m})(16.0\ \text{m})\sin 62.05°=170\ \text{m}^2$.

EVALUATE: The magnitude of the vector product is greater than the scalar product because the angle between the vectors is greater than 45º.

1.90. **IDENTIFY:** Let $\vec{C}=\vec{A}+\vec{B}$ and calculate the scalar product $\vec{C}\cdot\vec{C}$.

SET UP: For any vector $\vec{V}$, $\vec{V}\cdot\vec{V}=V^2$. $\vec{A}\cdot\vec{B}=AB\cos\phi$.

EXECUTE: **(a)** Use the linearity of the dot product to show that the square of the magnitude of the sum $\vec{A}+\vec{B}$ is

$$(\vec{A}+\vec{B})\cdot(\vec{A}+\vec{B})=\vec{A}\cdot\vec{A}+\vec{A}\cdot\vec{B}+\vec{B}\cdot\vec{A}+\vec{B}\cdot\vec{B}=\vec{A}\cdot\vec{A}+\vec{B}\cdot\vec{B}+2\vec{A}\cdot\vec{B}=A^2+B^2+2\vec{A}\cdot\vec{B}$$
$$=A^2+B^2+2AB\cos\phi$$

(b) Using the result of part (a), with $A=B$, the condition is that $A^2=A^2+A^2+2A^2\cos\phi$, which solves for $1=2+2\cos\phi$, $\cos\phi=-\frac{1}{2}$, and $\phi=120°$.

EVALUATE: The expression $C^2=A^2+B^2+2AB\cos\phi$ is called the law of cosines.

1.91. **IDENTIFY:** Find the angle between specified pairs of vectors.

SET UP: Use $\cos\phi=\dfrac{\vec{A}\cdot\vec{B}}{AB}$

EXECUTE: **(a)** $\vec{A}=\hat{k}$ (along line *ab*)

$\vec{B}=\hat{i}+\hat{j}+\hat{k}$ (along line *ad*)

$A=1,\ B=\sqrt{1^2+1^2+1^2}=\sqrt{3}$

$\vec{A}\cdot\vec{B}=\hat{k}\cdot(\hat{i}+\hat{j}+\hat{k})=1$

So $\cos\phi=\dfrac{\vec{A}\cdot\vec{B}}{AB}=1/\sqrt{3};\ \phi=54.7°$

(b) $\vec{A}=\hat{i}+\hat{j}+\hat{k}$ (along line *ad*)

$\vec{B}=\hat{j}+\hat{k}$ (along line *ac*)

$A=\sqrt{1^2+1^2+1^2}=\sqrt{3};\ \ B=\sqrt{1^2+1^2}=\sqrt{2}$

$\vec{A}\cdot\vec{B}=(\hat{i}+\hat{j}+\hat{k})\cdot(\hat{i}+\hat{j})=1+1=2$

So $\cos\phi=\dfrac{\vec{A}\cdot\vec{B}}{AB}=\dfrac{2}{\sqrt{3}\sqrt{2}}=\dfrac{2}{\sqrt{6}};\ \ \phi=35.3°$

EVALUATE: Each angle is computed to be less than $90°$, in agreement with what is deduced from Figure P1.91 in the textbook.

1.92. **IDENTIFY:** We know the magnitude of two vectors and the magnitude of their vector product, and we want to find the possible values of their scalar product.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

SET UP: The vector product is $\left|\vec{A}\times\vec{B}\right| = AB\sin\theta$ and the scalar product is $\vec{A}\cdot\vec{B} = AB\cos\theta$.

EXECUTE: $\left|\vec{A}\times\vec{B}\right| = AB\sin\theta = 12.0\ \text{m}^2$, so $\sin\theta = \dfrac{12.0\ \text{m}^2}{(6.00\ \text{m})(3.00\ \text{m})} = 0.6667$, which gives two possible values: $\theta = 41.81°$ or $\theta = 138.19°$. Therefore the two possible values of the scalar product are $\vec{A}\cdot\vec{B} = AB\cos\theta = 13.4\ \text{m}^2$ or $-13.4\ \text{m}^2$.

EVALUATE: The two possibilities have equal magnitude but opposite sign because the two possible angles are supplementary to each other. The sines of these angles are the same but the cosines differ by a factor of -1. See Figure 1.92.

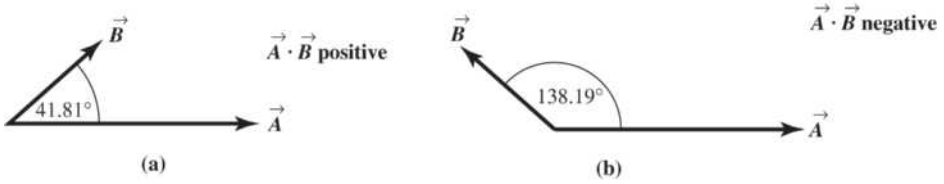

Figure 1.92

1.93. **IDENTIFY:** We know the scalar product of two vectors, both their directions, and the magnitude of one of them, and we want to find the magnitude of the other vector.

SET UP: $\vec{A}\cdot\vec{B} = AB\cos\theta$. Since we know the direction of each vector, we can find the angle between them.

EXECUTE: The angle between the vectors is $\theta = 79.0°$. Since $\vec{A}\cdot\vec{B} = AB\cos\theta$, we have

$$B = \frac{\vec{A}\cdot\vec{B}}{A\cos\theta} = \frac{48.0\ \text{m}^2}{(9.00\ \text{m})\cos 79.0°} = 28.0\ \text{m}.$$

EVALUATE: Vector $\vec{B}$ has the same units as vector $\vec{A}$.

1.94. **IDENTIFY:** The cross product $\vec{A}\times\vec{B}$ is perpendicular to both $\vec{A}$ and $\vec{B}$.

SET UP: Use Eq. (1.27) to calculate the components of $\vec{A}\times\vec{B}$.

EXECUTE: The cross product is

$(-13.00)\hat{i} + (6.00)\hat{j} + (-11.00)\hat{k} = 13\left[-(1.00)\hat{i} + \left(\dfrac{6.00}{13.00}\right)\hat{j} - \dfrac{11.00}{13.00}\hat{k}\right]$. The magnitude of the vector in square brackets is $\sqrt{1.93}$, and so a unit vector in this direction is

$$\left[\frac{-(1.00)\hat{i} + (6.00/13.00)\hat{j} - (11.00/13.00)\hat{k}}{\sqrt{1.93}}\right].$$

The negative of this vector,

$$\left[\frac{(1.00)\hat{i} - (6.00/13.00)\hat{j} + (11.00/13.00)\hat{k}}{\sqrt{1.93}}\right],$$

is also a unit vector perpendicular to $\vec{A}$ and $\vec{B}$.

EVALUATE: Any two vectors that are not parallel or antiparallel form a plane and a vector perpendicular to both vectors is perpendicular to this plane.

1.95. **IDENTIFY** and **SET UP:** The target variables are the components of $\vec{C}$. We are given $\vec{A}$ and $\vec{B}$. We also know $\vec{A}\cdot\vec{C}$ and $\vec{B}\cdot\vec{C}$, and this gives us two equations in the two unknowns C_x and C_y.

EXECUTE: $\vec{A}$ and $\vec{C}$ are perpendicular, so $\vec{A}\cdot\vec{C} = 0$. $A_xC_x + A_yC_y = 0$, which gives $5.0C_x - 6.5C_y = 0$.

$\vec{B}\cdot\vec{C} = 15.0$, so $-3.5C_x + 7.0C_y = 15.0$

We have two equations in two unknowns C_x and C_y. Solving gives $C_x = 8.0$ and $C_y = 6.1$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: We can check that our result does give us a vector $\vec{C}$ that satisfies the two equations $\vec{A}\cdot\vec{C}=0$ and $\vec{B}\cdot\vec{C}=15.0$.

1.96. **IDENTIFY:** Calculate the magnitude of the vector product and then use Eq. (1.22).
SET UP: The magnitude of a vector is related to its components by Eq. (1.12).

EXECUTE: $|\vec{A}\times\vec{B}|=AB\sin\theta$. $\sin\theta=\dfrac{|\vec{A}\times\vec{B}|}{AB}=\dfrac{\sqrt{(-5.00)^2+(2.00)^2}}{(3.00)(3.00)}=0.5984$ and

$\theta=\sin^{-1}(0.5984)=36.8°$.

EVALUATE: We haven't found $\vec{A}$ and $\vec{B}$, just the angle between them.

1.97. **(a) IDENTIFY:** Prove that $\vec{A}\cdot(\vec{B}\times\vec{C})=(\vec{A}\times\vec{B})\cdot\vec{C}$.
SET UP: Express the scalar and vector products in terms of components.
EXECUTE:

$$\vec{A}\cdot(\vec{B}\times\vec{C})=A_x(\vec{B}\times\vec{C})_x+A_y(\vec{B}\times\vec{C})_y+A_z(\vec{B}\times\vec{C})_z$$

$$\vec{A}\cdot(\vec{B}\times\vec{C})=A_x(B_yC_z-B_zC_y)+A_y(B_zC_x-B_xC_z)+A_z(B_xC_y-B_yC_x)$$

$$(\vec{A}\times\vec{B})\cdot\vec{C}=(\vec{A}\times\vec{B})_xC_x+(\vec{A}\times\vec{B})_yC_y+(\vec{A}\times\vec{B})_zC_z$$

$$(\vec{A}\times\vec{B})\cdot\vec{C}=(A_yB_z-A_zB_y)C_x+(A_zB_x-A_xB_z)C_y+(A_xB_y-A_yB_x)C_z$$

Comparison of the expressions for $\vec{A}\cdot(\vec{B}\times\vec{C})$ and $(\vec{A}\times\vec{B})\cdot\vec{C}$ shows they contain the same terms, so $\vec{A}\cdot(\vec{B}\times\vec{C})=(\vec{A}\times\vec{B})\cdot\vec{C}$.

(b) IDENTIFY: Calculate $(\vec{A}\times\vec{B})\cdot\vec{C}$, given the magnitude and direction of $\vec{A}$, $\vec{B}$ and $\vec{C}$.

SET UP: Use Eq. (1.22) to find the magnitude and direction of $\vec{A}\times\vec{B}$. Then we know the components of $\vec{A}\times\vec{B}$ and of $\vec{C}$ and can use an expression like Eq. (1.21) to find the scalar product in terms of components.
EXECUTE: $A=5.00;\ \theta_A=26.0°;\ B=4.00,\ \theta_B=63.0°$

$|\vec{A}\times\vec{B}|=AB\sin\phi$.

The angle ϕ between $\vec{A}$ and $\vec{B}$ is equal to $\phi=\theta_B-\theta_A=63.0°-26.0°=37.0°$. So

$|\vec{A}\times\vec{B}|=(5.00)(4.00)\sin 37.0°=12.04$, and by the right hand-rule $\vec{A}\times\vec{B}$ is in the $+z$-direction. Thus

$(\vec{A}\times\vec{B})\cdot\vec{C}=(12.04)(6.00)=72.2$

EVALUATE: $\vec{A}\times\vec{B}$ is a vector, so taking its scalar product with $\vec{C}$ is a legitimate vector operation. $(\vec{A}\times\vec{B})\cdot\vec{C}$ is a scalar product between two vectors so the result is a scalar.

1.98. **IDENTIFY:** Use the maximum and minimum values of the dimensions to find the maximum and minimum areas and volumes.
SET UP: For a rectangle of width W and length L the area is LW. For a rectangular solid with dimensions L, W and H the volume is LWH.
EXECUTE: **(a)** The maximum and minimum areas are $(L+l)(W+w)=LW+lW+Lw$, $(L-l)(W-w)=LW-lW-Lw$, where the common terms wl have been omitted. The area and its uncertainty are then $WL\pm(lW+Lw)$, so the uncertainty in the area is $a=lW+Lw$.

(b) The fractional uncertainty in the area is $\dfrac{a}{A}=\dfrac{lW+Wl}{WL}=\dfrac{l}{L}+\dfrac{w}{W}$, the sum of the fractional uncertainties in the length and width.
(c) The similar calculation to find the uncertainty v in the volume will involve neglecting the terms lwH, lWh and Lwh as well as lwh; the uncertainty in the volume is $v=lWH+LwH+LWh$, and the fractional

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

uncertainty in the volume is $\frac{v}{V}=\frac{lWH+LwH+LWh}{LWH}=\frac{l}{L}+\frac{w}{W}+\frac{h}{H}$, the sum of the fractional uncertainties in the length, width and height.

EVALUATE: The calculation assumes the uncertainties are small, so that terms involving products of two or more uncertainties can be neglected.

1.99. **IDENTIFY:** Add the vector displacements of the receiver and then find the vector from the quarterback to the receiver.

SET UP: Add the x-components and the y-components.

EXECUTE: The receiver's position is

$[(+1.0+9.0-6.0+12.0)\text{yd}]\hat{\boldsymbol{i}}+[(-5.0+11.0+4.0+18.0)\text{yd}]\hat{\boldsymbol{j}}=(16.0\text{ yd})\hat{\boldsymbol{i}}+(28.0\text{ yd})\hat{\boldsymbol{j}}$.

The vector from the quarterback to the receiver is the receiver's position minus the quarterback's position, or $(16.0\text{ yd})\hat{\boldsymbol{i}}+(35.0\text{ yd})\hat{\boldsymbol{j}}$, a vector with magnitude $\sqrt{(16.0\text{ yd})^2+(35.0\text{ yd})^2}=38.5\text{ yd}$. The angle is $\arctan\left(\frac{16.0}{35.0}\right)=24.6°$ to the right of downfield.

EVALUATE: The vector from the quarterback to receiver has positive x-component and positive y-component.

1.100. **IDENTIFY:** Use the x and y coordinates for each object to find the vector from one object to the other; the distance between two objects is the magnitude of this vector. Use the scalar product to find the angle between two vectors.

SET UP: If object A has coordinates (x_A, y_A) and object B has coordinates (x_B, y_B), the vector $\vec{\boldsymbol{r}}_{AB}$ from A to B has x-component x_B-x_A and y-component y_B-y_A.

EXECUTE: **(a)** The diagram is sketched in Figure 1.100.

(b) (i) In AU, $\sqrt{(0.3182)^2+(0.9329)^2}=0.9857$.

(ii) In AU, $\sqrt{(1.3087)^2+(-0.4423)^2+(-0.0414)^2}=1.3820$.

(iii) In AU $\sqrt{(0.3182-1.3087)^2+(0.9329-(-0.4423))^2+(0.0414)^2}=1.695$.

(c) The angle between the directions from the Earth to the Sun and to Mars is obtained from the dot product. Combining Eqs. (1.18) and (1.21),

$$\phi=\arccos\left(\frac{(-0.3182)(1.3087-0.3182)+(-0.9329)(-0.4423-0.9329)+(0)}{(0.9857)(1.695)}\right)=54.6°.$$

(d) Mars could not have been visible at midnight, because the Sun-Mars angle is less than $90°$.

EVALUATE: Our calculations correctly give that Mars is farther from the Sun than the earth is. Note that on this date Mars was farther from the earth than it is from the Sun.

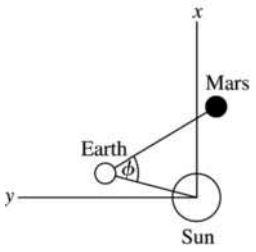

Figure 1.100

1.101. **IDENTIFY:** Draw the vector addition diagram for the position vectors.

SET UP: Use coordinates in which the Sun to Merak line lies along the x-axis. Let $\vec{\boldsymbol{A}}$ be the position vector of Alkaid relative to the Sun, $\vec{\boldsymbol{M}}$ is the position vector of Merak relative to the Sun, and $\vec{\boldsymbol{R}}$ is the position vector for Alkaid relative to Merak. $A=138$ ly and $M=77$ ly.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: The relative positions are shown in Figure 1.101. $\vec{M}+\vec{R}=\vec{A}$. $A_x = M_x + R_x$ so $R_x = A_x - M_x = (138 \text{ ly})\cos 25.6° - 77 \text{ ly} = 47.5 \text{ ly}$. $R_y = A_y - M_y = (138 \text{ ly})\sin 25.6° - 0 = 59.6 \text{ ly}$. $R = 76.2$ ly is the distance between Alkaid and Merak.

(b) The angle is angle ϕ in Figure 1.101. $\cos\theta = \dfrac{R_x}{R} = \dfrac{47.5 \text{ ly}}{76.2 \text{ ly}}$ and $\theta = 51.4°$. Then $\phi = 180° - \theta = 129°$.

EVALUATE: The concepts of vector addition and components make these calculations very simple.

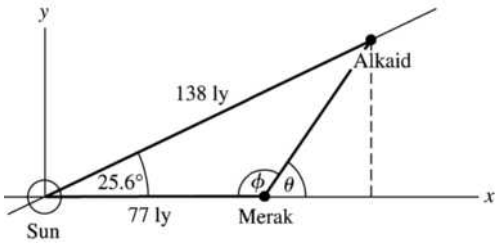

Figure 1.101

1.102. **IDENTIFY:** Define $\vec{S} = A\hat{i} + B\hat{j} + C\hat{k}$. Show that $\vec{r}\cdot\vec{S} = 0$ if $Ax + By + Cz = 0$.

SET UP: Use Eq. (1.21) to calculate the scalar product.

EXECUTE: $\vec{r}\cdot\vec{S} = (x\hat{i} + y\hat{j} + z\hat{k})\cdot(A\hat{i} + B\hat{j} + C\hat{k}) = Ax + By + Cz$

If the points satisfy $Ax + By + Cz = 0$, then $\vec{r}\cdot\vec{S} = 0$ and all points $\vec{r}$ are perpendicular to $\vec{S}$. The vector and plane are sketched in Figure 1.102.

EVALUATE: If two vectors are perpendicular their scalar product is zero.

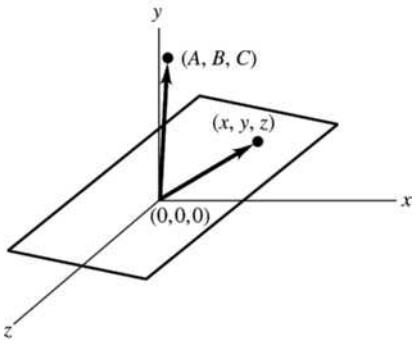

Figure 1.102

2

MOTION ALONG A STRAIGHT LINE

2.1. **IDENTIFY:** $\Delta x = v_{\text{av-}x}\Delta t$

SET UP: We know the average velocity is 6.25 m/s.

EXECUTE: $\Delta x = v_{\text{av-}x}\Delta t = 25.0$ m

EVALUATE: In round numbers, 6 m/s × 4 s = 24 m ≈ 25 m, so the answer is reasonable.

2.2. **IDENTIFY:** $v_{\text{av-}x} = \dfrac{\Delta x}{\Delta t}$

SET UP: 13.5 days $= 1.166\times10^6$ s. At the release point, $x = +5.150\times10^6$ m.

EXECUTE: **(a)** $v_{\text{av-}x} = \dfrac{x_2 - x_1}{\Delta t} = \dfrac{5.150\times10^6 \text{ m}}{1.166\times10^6 \text{ s}} = -4.42$ m/s

(b) For the round trip, $x_2 = x_1$ and $\Delta x = 0$. The average velocity is zero.

EVALUATE: The average velocity for the trip from the nest to the release point is positive.

2.3. **IDENTIFY:** Target variable is the time Δt it takes to make the trip in heavy traffic. Use Eq. (2.2) that relates the average velocity to the displacement and average time.

SET UP: $v_{\text{av-}x} = \dfrac{\Delta x}{\Delta t}$ so $\Delta x = v_{\text{av-}x}\Delta t$ and $\Delta t = \dfrac{\Delta x}{v_{\text{av-}x}}$.

EXECUTE: Use the information given for normal driving conditions to calculate the distance between the two cities:

$$\Delta x = v_{\text{av-}x}\Delta t = (105 \text{ km/h})(1 \text{ h}/60 \text{ min})(140 \text{ min}) = 245 \text{ km}.$$

Now use $v_{\text{av-}x}$ for heavy traffic to calculate Δt; Δx is the same as before:

$$\Delta t = \frac{\Delta x}{v_{\text{av-}x}} = \frac{245 \text{ km}}{70 \text{ km/h}} = 3.50 \text{ h} = 3 \text{ h and } 30 \text{ min}.$$

The trip takes an additional 1 hour and 10 minutes.

EVALUATE: The time is inversely proportional to the average speed, so the time in traffic is $(105/70)(140 \text{ min}) = 210$ min.

2.4. **IDENTIFY:** The average velocity is $v_{\text{av-}x} = \dfrac{\Delta x}{\Delta t}$. Use the average speed for each segment to find the time traveled in that segment. The average speed is the distance traveled by the time.

SET UP: The post is 80 m west of the pillar. The total distance traveled is 200 m + 280 m = 480 m.

EXECUTE: **(a)** The eastward run takes time $\dfrac{200 \text{ m}}{5.0 \text{ m/s}} = 40.0$ s and the westward run takes $\dfrac{280 \text{ m}}{4.0 \text{ m/s}} = 70.0$ s.

The average speed for the entire trip is $\dfrac{480 \text{ m}}{110.0 \text{ s}} = 4.4$ m/s.

(b) $v_{\text{av-}x} = \dfrac{\Delta x}{\Delta t} = \dfrac{-80 \text{ m}}{110.0 \text{ s}} = -0.73$ m/s. The average velocity is directed westward.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: The displacement is much less than the distance traveled and the magnitude of the average velocity is much less than the average speed. The average speed for the entire trip has a value that lies between the average speed for the two segments.

2.5. **IDENTIFY:** Given two displacements, we want the average velocity and the average speed.

SET UP: The average velocity is $v_{\text{av-}x} = \dfrac{\Delta x}{\Delta t}$ and the average speed is just the total distance walked divided by the total time to walk this distance.

EXECUTE: **(a)** Let $+x$ be east. $\Delta x = 60.0\text{ m} - 40.0\text{ m} = 20.0\text{ m}$ and $\Delta t = 28.0\text{ s} + 36.0\text{ s} = 64.0\text{ s}$. So $v_{\text{av-}x} = \dfrac{\Delta x}{\Delta t} = \dfrac{20.0\text{ m}}{64.0\text{ s}} = 0.312\text{ m/s}$.

(b) $\text{average speed} = \dfrac{60.0\text{ m} + 40.0\text{ m}}{64.0\text{ s}} = 1.56\text{ m/s}$

EVALUATE: The average speed is much greater than the average velocity because the total distance walked is much greater than the magnitude of the displacement vector.

2.6. **IDENTIFY:** The average velocity is $v_{\text{av-}x} = \dfrac{\Delta x}{\Delta t}$. Use $x(t)$ to find x for each t.

SET UP: $x(0) = 0$, $x(2.00\text{ s}) = 5.60\text{ m}$, and $x(4.00\text{ s}) = 20.8\text{ m}$

EXECUTE: **(a)** $v_{\text{av-}x} = \dfrac{5.60\text{ m} - 0}{2.00\text{ s}} = +2.80\text{ m/s}$

(b) $v_{\text{av-}x} = \dfrac{20.8\text{ m} - 0}{4.00\text{ s}} = +5.20\text{ m/s}$

(c) $v_{\text{av-}x} = \dfrac{20.8\text{ m} - 5.60\text{ m}}{2.00\text{ s}} = +7.60\text{ m/s}$

EVALUATE: The average velocity depends on the time interval being considered.

2.7. **(a) IDENTIFY:** Calculate the average velocity using Eq. (2.2).

SET UP: $v_{\text{av-}x} = \dfrac{\Delta x}{\Delta t}$ so use $x(t)$ to find the displacement Δx for this time interval.

EXECUTE: $t = 0$: $x = 0$

$t = 10.0\text{ s}$: $x = (2.40\text{ m/s}^2)(10.0\text{ s})^2 - (0.120\text{ m/s}^3)(10.0\text{ s})^3 = 240\text{ m} - 120\text{ m} = 120\text{ m}$.

Then $v_{\text{av-}x} = \dfrac{\Delta x}{\Delta t} = \dfrac{120\text{ m}}{10.0\text{ s}} = 12.0\text{ m/s}$.

(b) IDENTIFY: Use Eq. (2.3) to calculate $v_x(t)$ and evaluate this expression at each specified t.

SET UP: $v_x = \dfrac{dx}{dt} = 2bt - 3ct^2$.

EXECUTE: (i) $t = 0$: $v_x = 0$

(ii) $t = 5.0\text{ s}$: $v_x = 2(2.40\text{ m/s}^2)(5.0\text{ s}) - 3(0.120\text{ m/s}^3)(5.0\text{ s})^2 = 24.0\text{ m/s} - 9.0\text{ m/s} = 15.0\text{ m/s}$.

(iii) $t = 10.0\text{ s}$: $v_x = 2(2.40\text{ m/s}^2)(10.0\text{ s}) - 3(0.120\text{ m/s}^3)(10.0\text{ s})^2 = 48.0\text{ m/s} - 36.0\text{ m/s} = 12.0\text{ m/s}$.

(c) IDENTIFY: Find the value of t when $v_x(t)$ from part (b) is zero.

SET UP: $v_x = 2bt - 3ct^2$

$v_x = 0$ at $t = 0$.

$v_x = 0$ next when $2bt - 3ct^2 = 0$

EXECUTE: $2b = 3ct$ so $t = \dfrac{2b}{3c} = \dfrac{2(2.40\text{ m/s}^2)}{3(0.120\text{ m/s}^3)} = 13.3\text{ s}$

EVALUATE: $v_x(t)$ for this motion says the car starts from rest, speeds up, and then slows down again.

2.8. **IDENTIFY:** We know the position $x(t)$ of the bird as a function of time and want to find its instantaneous velocity at a particular time.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

SET UP: The instantaneous velocity is $v_x(t) = \dfrac{dx}{dt} = \dfrac{d(28.0\text{ m} + (12.4\text{ m/s})t - (0.0450\text{ m/s}^3)t^3)}{dt}$.

EXECUTE: $v_x(t) = \dfrac{dx}{dt} = 12.4\text{ m/s} - (0.135\text{ m/s}^3)t^2$. Evaluating this at $t = 8.0$ s gives $v_x = 3.76$ m/s.

EVALUATE: The acceleration is not constant in this case.

2.9. **IDENTIFY:** The average velocity is given by $v_{\text{av-}x} = \dfrac{\Delta x}{\Delta t}$. We can find the displacement Δt for each constant velocity time interval. The average speed is the distance traveled divided by the time.

SET UP: For $t = 0$ to $t = 2.0$ s, $v_x = 2.0$ m/s. For $t = 2.0$ s to $t = 3.0$ s, $v_x = 3.0$ m/s. In part (b), $v_x = -3.0$ m/s for $t = 2.0$ s to $t = 3.0$ s. When the velocity is constant, $\Delta x = v_x \Delta t$.

EXECUTE: **(a)** For $t = 0$ to $t = 2.0$ s, $\Delta x = (2.0\text{ m/s})(2.0\text{ s}) = 4.0$ m. For $t = 2.0$ s to $t = 3.0$ s, $\Delta x = (3.0\text{ m/s})(1.0\text{ s}) = 3.0$ m. For the first 3.0 s, $\Delta x = 4.0\text{ m} + 3.0\text{ m} = 7.0$ m. The distance traveled is also 7.0 m. The average velocity is $v_{\text{av-}x} = \dfrac{\Delta x}{\Delta t} = \dfrac{7.0\text{ m}}{3.0\text{ s}} = 2.33$ m/s. The average speed is also 2.33 m/s.

(b) For $t = 2.0$ s to 3.0 s, $\Delta x = (-3.0\text{ m/s})(1.0\text{ s}) = -3.0$ m. For the first 3.0 s, $\Delta x = 4.0\text{ m} + (-3.0\text{ m}) = +1.0$ m. The dog runs 4.0 m in the $+x$-direction and then 3.0 m in the $-x$-direction, so the distance traveled is still 7.0 m. $v_{\text{av-}x} = \dfrac{\Delta x}{\Delta t} = \dfrac{1.0\text{ m}}{3.0\text{ s}} = 0.33$ m/s. The average speed is $\dfrac{7.00\text{ m}}{3.00\text{ s}} = 2.33$ m/s.

EVALUATE: When the motion is always in the same direction, the displacement and the distance traveled are equal and the average velocity has the same magnitude as the average speed. When the motion changes direction during the time interval, those quantities are different.

2.10. **IDENTIFY** and **SET UP:** The instantaneous velocity is the slope of the tangent to the x versus t graph.

EXECUTE: **(a)** The velocity is zero where the graph is horizontal; point IV.

(b) The velocity is constant and positive where the graph is a straight line with positive slope; point I.

(c) The velocity is constant and negative where the graph is a straight line with negative slope; point V.

(d) The slope is positive and increasing at point II.

(e) The slope is positive and decreasing at point III.

EVALUATE: The sign of the velocity indicates its direction.

2.11. **IDENTIFY:** Find the instantaneous velocity of a car using a graph of its position as a function of time.

SET UP: The instantaneous velocity at any point is the slope of the x versus t graph at that point. Estimate the slope from the graph.

EXECUTE: A: $v_x = 6.7$ m/s; B: $v_x = 6.7$ m/s; C: $v_x = 0$; D: $v_x = -40.0$ m/s; E: $v_x = -40.0$ m/s; F: $v_x = -40.0$ m/s; G: $v_x = 0$.

EVALUATE: The sign of v_x shows the direction the car is moving. v_x is constant when x versus t is a straight line.

2.12. **IDENTIFY:** $a_{\text{av-}x} = \dfrac{\Delta v_x}{\Delta t}$. $a_x(t)$ is the slope of the v_x versus t graph.

SET UP: 60 km/h = 16.7 m/s

EXECUTE: **(a)** (i) $a_{\text{av-}x} = \dfrac{16.7\text{ m/s} - 0}{10\text{ s}} = 1.7\text{ m/s}^2$. (ii) $a_{\text{av-}x} = \dfrac{0 - 16.7\text{ m/s}}{10\text{ s}} = -1.7\text{ m/s}^2$.

(iii) $\Delta v_x = 0$ and $a_{\text{av-}x} = 0$. (iv) $\Delta v_x = 0$ and $a_{\text{av-}x} = 0$.

(b) At $t = 20$ s, v_x is constant and $a_x = 0$. At $t = 35$ s, the graph of v_x versus t is a straight line and $a_x = a_{\text{av-}x} = -1.7\text{ m/s}^2$.

EVALUATE: When $a_{\text{av-}x}$ and v_x have the same sign the speed is increasing. When they have opposite sign the speed is decreasing.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

2.13. **IDENTIFY:** The average acceleration for a time interval Δt is given by $a_{\text{av-}x} = \dfrac{\Delta v_x}{\Delta t}$.

SET UP: Assume the car is moving in the $+x$ direction. 1 mi/h = 0.447 m/s, so 60 mi/h = 26.82 m/s, 200 mi/h = 89.40 m/s and 253 mi/h = 113.1 m/s.

EXECUTE: **(a)** The graph of v_x versus t is sketched in Figure 2.13. The graph is not a straight line, so the acceleration is not constant.

(b) (i) $a_{\text{av-}x} = \dfrac{26.82 \text{ m/s} - 0}{2.1 \text{ s}} = 12.8 \text{ m/s}^2$ (ii) $a_{\text{av-}x} = \dfrac{89.40 \text{ m/s} - 26.82 \text{ m/s}}{20.0 \text{ s} - 2.1 \text{ s}} = 3.50 \text{ m/s}^2$

(iii) $a_{\text{av-}x} = \dfrac{113.1 \text{ m/s} - 89.40 \text{ m/s}}{53 \text{ s} - 20.0 \text{ s}} = 0.718 \text{ m/s}^2$. The slope of the graph of v_x versus t decreases as t increases. This is consistent with an average acceleration that decreases in magnitude during each successive time interval.

EVALUATE: The average acceleration depends on the chosen time interval. For the interval between 0 and 53 s, $a_{\text{av-}x} = \dfrac{113.1 \text{ m/s} - 0}{53 \text{ s}} = 2.13 \text{ m/s}^2$.

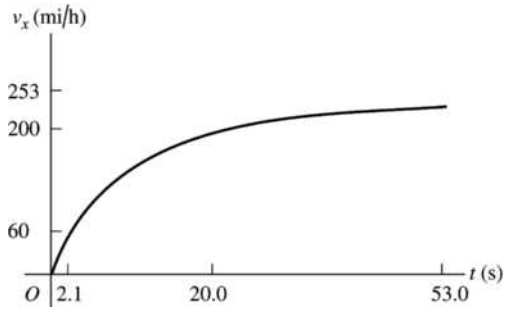

Figure 2.13

2.14. **IDENTIFY:** We know the velocity $v(t)$ of the car as a function of time and want to find its acceleration at the instant that its velocity is 16.0 m/s.

SET UP: $a_x(t) = \dfrac{dv_x}{dt} = \dfrac{d((0.860 \text{ m/s}^3)t^2)}{dt}$.

EXECUTE: $a_x(t) = \dfrac{dv_x}{dt} = (1.72 \text{ m/s}^3)t$. When $v_x = 16.0$ m/s, $t = 4.313$ s. At this time, $a_x = 7.42 \text{ m/s}^2$.

EVALUATE: The acceleration of this car is not constant.

2.15. **IDENTIFY** and **SET UP:** Use $v_x = \dfrac{dx}{dt}$ and $a_x = \dfrac{dv_x}{dt}$ to calculate $v_x(t)$ and $a_x(t)$.

EXECUTE: $v_x = \dfrac{dx}{dt} = 2.00 \text{ cm/s} - (0.125 \text{ cm/s}^2)t$

$a_x = \dfrac{dv_x}{dt} = -0.125 \text{ cm/s}^2$

(a) At $t = 0$, $x = 50.0$ cm, $v_x = 2.00$ cm/s, $a_x = -0.125 \text{ cm/s}^2$.

(b) Set $v_x = 0$ and solve for t: $t = 16.0$ s.

(c) Set $x = 50.0$ cm and solve for t. This gives $t = 0$ and $t = 32.0$ s. The turtle returns to the starting point after 32.0 s.

(d) The turtle is 10.0 cm from starting point when $x = 60.0$ cm or $x = 40.0$ cm.

Set $x = 60.0$ cm and solve for t: $t = 6.20$ s and $t = 25.8$ s.

At $t = 6.20$ s, $v_x = +1.23$ cm/s.

At $t = 25.8$ s, $v_x = -1.23$ cm/s.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

Set $x = 40.0$ cm and solve for t: $t = 36.4$ s (other root to the quadratic equation is negative and hence nonphysical).

At $t = 36.4$ s, $v_x = -2.55$ cm/s.

(e) The graphs are sketched in Figure 2.15.

Figure 2.15

EVALUATE: The acceleration is constant and negative. v_x is linear in time. It is initially positive, decreases to zero, and then becomes negative with increasing magnitude. The turtle initially moves farther away from the origin but then stops and moves in the $-x$-direction.

2.16. **IDENTIFY:** Use Eq. (2.4), with $\Delta t = 10$ s in all cases.

SET UP: v_x is negative if the motion is to the left.

EXECUTE: **(a)** $((5.0 \text{ m/s}) - (15.0 \text{ m/s}))/(10 \text{ s}) = -1.0 \text{ m/s}^2$

(b) $((-15.0 \text{ m/s}) - (-5.0 \text{ m/s}))/(10 \text{ s}) = -1.0 \text{ m/s}^2$

(c) $((-15.0 \text{ m/s}) - (+15.0 \text{ m/s}))/(10 \text{ s}) = -3.0 \text{ m/s}^2$

EVALUATE: In all cases, the negative acceleration indicates an acceleration to the left.

2.17. **IDENTIFY:** The average acceleration is $a_{\text{av-}x} = \dfrac{\Delta v_x}{\Delta t}$. Use $v_x(t)$ to find v_x at each t. The instantaneous acceleration is $a_x = \dfrac{dv_x}{dt}$.

SET UP: $v_x(0) = 3.00$ m/s and $v_x(5.00 \text{ s}) = 5.50$ m/s.

EXECUTE: **(a)** $a_{\text{av-}x} = \dfrac{\Delta v_x}{\Delta t} = \dfrac{5.50 \text{ m/s} - 3.00 \text{ m/s}}{5.00 \text{ s}} = 0.500 \text{ m/s}^2$

(b) $a_x = \dfrac{dv_x}{dt} = (0.100 \text{ m/s}^3)(2t) = (0.200 \text{ m/s}^3)t$. At $t = 0$, $a_x = 0$. At $t = 5.00$ s, $a_x = 1.00 \text{ m/s}^2$.

(c) Graphs of $v_x(t)$ and $a_x(t)$ are given in Figure 2.17.

EVALUATE: $a_x(t)$ is the slope of $v_x(t)$ and increases as t increases. The average acceleration for $t = 0$ to $t = 5.00$ s equals the instantaneous acceleration at the midpoint of the time interval, $t = 2.50$ s, since $a_x(t)$ is a linear function of t.

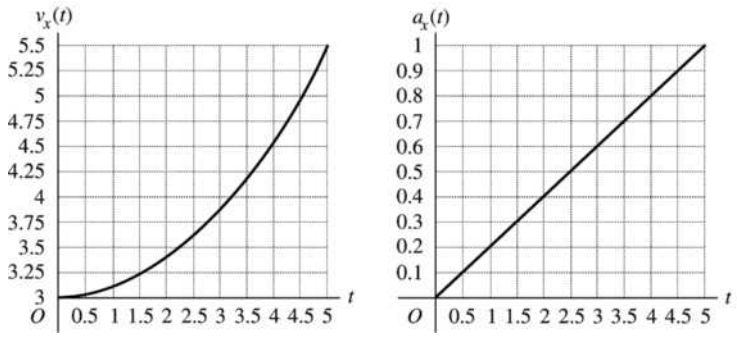

Figure 2.17

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

2.18. **IDENTIFY:** $v_x(t) = \dfrac{dx}{dt}$ and $a_x(t) = \dfrac{dv_x}{dt}$

SET UP: $\dfrac{d}{dt}(t^n) = nt^{n-1}$ for $n \geq 1$.

EXECUTE: **(a)** $v_x(t) = (9.60\ \text{m/s}^2)t - (0.600\ \text{m/s}^6)t^5$ and $a_x(t) = 9.60\ \text{m/s}^2 - (3.00\ \text{m/s}^6)t^4$. Setting $v_x = 0$ gives $t = 0$ and $t = 2.00$ s. At $t = 0$, $x = 2.17$ m and $a_x = 9.60\ \text{m/s}^2$. At $t = 2.00$ s, $x = 15.0$ m and $a_x = -38.4\ \text{m/s}^2$.

(b) The graphs are given in Figure 2.18.

EVALUATE: For the entire time interval from $t = 0$ to $t = 2.00$ s, the velocity v_x is positive and x increases. While a_x is also positive the speed increases and while a_x is negative the speed decreases.

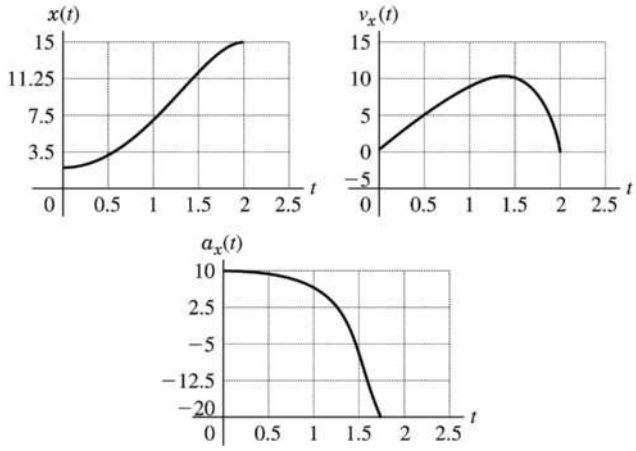

Figure 2.18

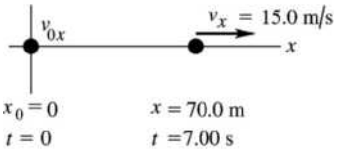
2.19. **IDENTIFY:** Use the constant acceleration equations to find v_{0x} and a_x.

(a) SET UP: The situation is sketched in Figure 2.19.



$x - x_0 = 70.0$ m
$t = 7.00$ s
$v_x = 15.0$ m/s
$v_{0x} = ?$

Figure 2.19

EXECUTE: Use $x - x_0 = \left(\dfrac{v_{0x} + v_x}{2}\right)t$, so $v_{0x} = \dfrac{2(x - x_0)}{t} - v_x = \dfrac{2(70.0\ \text{m})}{7.00\ \text{s}} - 15.0\ \text{m/s} = 5.0\ \text{m/s}.$

(b) Use $v_x = v_{0x} + a_x t$, so $a_x = \dfrac{v_x - v_{0x}}{t} = \dfrac{15.0\ \text{m/s} - 5.0\ \text{m/s}}{7.00\ \text{s}} = 1.43\ \text{m/s}^2.$

EVALUATE: The average velocity is $(70.0\ \text{m})/(7.00\ \text{s}) = 10.0$ m/s. The final velocity is larger than this, so the antelope must be speeding up during the time interval; $v_{0x} < v_x$ and $a_x > 0$.

2.20. **IDENTIFY:** In (a) find the time to reach the speed of sound with an acceleration of $5g$, and in (b) find his speed at the end of 5.0 s if he has an acceleration of $5g$.

SET UP: Let $+x$ be in his direction of motion and assume constant acceleration of $5g$ so the standard kinematics equations apply so $v_x = v_{0x} + a_x t$. **(a)** $v_x = 3(331\ \text{m/s}) = 993$ m/s, $v_{0x} = 0$, and $a_x = 5g = 49.0\ \text{m/s}^2$. **(b)** $t = 5.0$ s

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: **(a)** $v_x = v_{0x} + a_x t$ and $t = \dfrac{v_x - v_{0x}}{a_x} = \dfrac{993 \text{ m/s} - 0}{49.0 \text{ m/s}^2} = 20.3 \text{ s}$. Yes, the time required is larger than 5.0 s.

(b) $v_x = v_{0x} + a_x t = 0 + (49.0 \text{ m/s}^2)(5.0 \text{ s}) = 245 \text{ m/s}$.

EVALUATE: In 5 s he can only reach about 2/3 the speed of sound without blacking out.

2.21. **IDENTIFY:** For constant acceleration, Eqs. (2.8), (2.12), (2.13) and (2.14) apply.

SET UP: Assume the ball starts from rest and moves in the $+x$-direction.

EXECUTE: **(a)** $x - x_0 = 1.50$ m, $v_x = 45.0$ m/s and $v_{0x} = 0$. $v_x^2 = v_{0x}^2 + 2a_x(x - x_0)$ gives

$$a_x = \frac{v_x^2 - v_{0x}^2}{2(x - x_0)} = \frac{(45.0 \text{ m/s})^2}{2(1.50 \text{ m})} = 675 \text{ m/s}^2.$$

(b) $x - x_0 = \left(\dfrac{v_{0x} + v_x}{2}\right) t$ gives $t = \dfrac{2(x - x_0)}{v_{0x} + v_x} = \dfrac{2(1.50 \text{ m})}{45.0 \text{ m/s}} = 0.0667 \text{ s}$

EVALUATE: We could also use $v_x = v_{0x} + a_x t$ to find $t = \dfrac{v_x}{a_x} = \dfrac{45.0 \text{ m/s}}{675 \text{ m/s}^2} = 0.0667 \text{ s}$ which agrees with our previous result. The acceleration of the ball is very large.

2.22. **IDENTIFY:** For constant acceleration, Eqs. (2.8), (2.12), (2.13) and (2.14) apply.

SET UP: Assume the ball moves in the $+x$ direction.

EXECUTE: **(a)** $v_x = 73.14$ m/s, $v_{0x} = 0$ and $t = 30.0$ ms. $v_x = v_{0x} + a_x t$ gives

$$a_x = \frac{v_x - v_{0x}}{t} = \frac{73.14 \text{ m/s} - 0}{30.0 \times 10^{-3} \text{ s}} = 2440 \text{ m/s}^2.$$

(b) $x - x_0 = \left(\dfrac{v_{0x} + v_x}{2}\right) t = \left(\dfrac{0 + 73.14 \text{ m/s}}{2}\right)(30.0 \times 10^{-3} \text{ s}) = 1.10 \text{ m}$

EVALUATE: We could also use $x - x_0 = v_{0x} t + \frac{1}{2} a_x t^2$ to calculate $x - x_0$:

$x - x_0 = \frac{1}{2}(2440 \text{ m/s}^2)(30.0 \times 10^{-3} \text{ s})^2 = 1.10 \text{ m}$, which agrees with our previous result. The acceleration of the ball is very large.

2.23. **IDENTIFY:** Assume that the acceleration is constant and apply the constant acceleration kinematic equations. Set $|a_x|$ equal to its maximum allowed value.

SET UP: Let $+x$ be the direction of the initial velocity of the car. $a_x = -250 \text{ m/s}^2$. 105 km/h = 29.17 m/s.

EXECUTE: $v_{0x} = +29.17$ m/s. $v_x = 0$. $v_x^2 = v_{0x}^2 + 2a_x(x - x_0)$ gives

$$x - x_0 = \frac{v_x^2 - v_{0x}^2}{2a_x} = \frac{0 - (29.17 \text{ m/s})^2}{2(-250 \text{ m/s}^2)} = 1.70 \text{ m}.$$

EVALUATE: The car frame stops over a shorter distance and has a larger magnitude of acceleration. Part of your 1.70 m stopping distance is the stopping distance of the car and part is how far you move relative to the car while stopping.

2.24. **IDENTIFY:** In (a) we want the time to reach Mach 4 with an acceleration of 4*g*, and in (b) we want to know how far he can travel if he maintains this acceleration during this time.

SET UP: Let $+x$ be the direction the jet travels and take $x_0 = 0$. With constant acceleration, the equations $v_x = v_{0x} + a_x t$ and $x = x_0 + v_{0x} t + \frac{1}{2} a_x t^2$ both apply. $a_x = 4g = 39.2 \text{ m/s}^2$, $v_x = 4(331 \text{ m/s}) = 1324 \text{ m/s}$, and $v_{0x} = 0$.

EXECUTE: **(a)** Solving $v_x = v_{0x} + a_x t$ for t gives $t = \dfrac{v_x - v_{0x}}{a_x} = \dfrac{1324 \text{ m/s} - 0}{39.2 \text{ m/s}^2} = 33.8 \text{ s}$.

(b) $x = x_0 + v_{0x} t + \frac{1}{2} a_x t^2 = \frac{1}{2}(39.2 \text{ m/s}^2)(33.8 \text{ s})^2 = 2.24 \times 10^4 \text{ m} = 22.4 \text{ km}$.

EVALUATE: The answer in (a) is about ½ min, so if he wanted to reach Mach 4 any sooner than that, he would be in danger of blacking out.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

2.25. **IDENTIFY:** If a person comes to a stop in 36 ms while slowing down with an acceleration of 60*g*, how far does he travel during this time?

SET UP: Let $+x$ be the direction the person travels. $v_x = 0$ (he stops), a_x is negative since it is opposite to the direction of the motion, and $t = 36 \text{ ms} = 3.6 \times 10^{-2} \text{ s}$. The equations $v_x = v_{0x} + a_x t$ and $x = x_0 + v_{0x}t + \frac{1}{2}a_x t^2$ both apply since the acceleration is constant.

EXECUTE: Solving $v_x = v_{0x} + a_x t$ for v_{0x} gives $v_{0x} = -a_x t$. Then $x = x_0 + v_{0x}t + \frac{1}{2}a_x t^2$ gives $x = -\frac{1}{2}a_x t^2 = -\frac{1}{2}(-588 \text{ m/s}^2)(3.6 \times 10^{-2} \text{ s})^2 = 38 \text{ cm}$.

EVALUATE: Notice that we were not given the initial speed, but we could find it:

$$v_{0x} = -a_x t = -(-588 \text{ m/s}^2)(36 \times 10^{-3} \text{ s}) = 21 \text{ m/s} = 47 \text{ mph}.$$

2.26. **IDENTIFY:** In (a) the hip pad must reduce the person's speed from 2.0 m/s to 1.3 m/s over a distance of 2.0 cm, and we want the acceleration over this distance, assuming constant acceleration. In (b) we want to find out how the acceleration in (a) lasts.

SET UP: Let $+y$ be downward. $v_{0y} = 2.0 \text{ m/s}$, $v_y = 1.3 \text{ m/s}$, and $y - y_0 = 0.020 \text{ m}$. The equations $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ and $y - y_0 = \left(\frac{v_{0y} + v_y}{2}\right)t$ apply for constant acceleration.

EXECUTE: **(a)** Solving $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ for a_y gives

$$a_y = \frac{v_y^2 - v_{0y}^2}{2(y - y_0)} = \frac{(1.3 \text{ m/s})^2 - (2.0 \text{ m/s})^2}{2(0.020 \text{ m})} = -58 \text{ m/s}^2 = -5.9g.$$

(b) $y - y_0 = \left(\frac{v_{0y} + v_y}{2}\right)t$ gives $t = \frac{2(y - y_0)}{v_{0y} + v_y} = \frac{2(0.020 \text{ m})}{2.0 \text{ m/s} + 1.3 \text{ m/s}} = 12 \text{ ms}$.

EVALUATE: The acceleration is very large, but it only lasts for 12 ms so it produces a small velocity change.

2.27. **IDENTIFY:** We know the initial and final velocities of the object, and the distance over which the velocity change occurs. From this we want to find the magnitude and duration of the acceleration of the object.

SET UP: The constant-acceleration kinematics formulas apply. $v_x^2 = v_{0x}^2 + 2a_x(x - x_0)$, where $v_{0x} = 0$, $v_x = 5.0 \times 10^3 \text{ m/s}$, and $x - x_0 = 4.0 \text{ m}$.

EXECUTE: **(a)** $v_x^2 = v_{0x}^2 + 2a_x(x - x_0)$ gives $a_x = \frac{v_x^2 - v_{0x}^2}{2(x - x_0)} = \frac{(5.0 \times 10^3 \text{ m/s})^2}{2(4.0 \text{ m})} = 3.1 \times 10^6 \text{ m/s}^2 = 3.2 \times 10^5 \, g$.

(b) $v_x = v_{0x} + a_x t$ gives $t = \frac{v_x - v_{0x}}{a_x} = \frac{5.0 \times 10^3 \text{ m/s}}{3.1 \times 10^6 \text{ m/s}^2} = 1.6 \text{ ms}$.

EVALUATE: **(c)** The calculated *a* is less than 450,000 *g* so the acceleration required doesn't rule out this hypothesis.

2.28. **IDENTIFY:** Apply constant acceleration equations to the motion of the car.

SET UP: Let $+x$ be the direction the car is moving.

EXECUTE: **(a)** From Eq. (2.13), with $v_{0x} = 0$, $a_x = \frac{v_x^2}{2(x - x_0)} = \frac{(20 \text{ m/s})^2}{2(120 \text{ m})} = 1.67 \text{ m/s}^2$.

(b) Using Eq. (2.14), $t = 2(x - x_0)/v_x = 2(120 \text{ m})/(20 \text{ m/s}) = 12 \text{ s}$.

(c) $(12 \text{ s})(20 \text{ m/s}) = 240 \text{ m}$.

EVALUATE: The average velocity of the car is half the constant speed of the traffic, so the traffic travels twice as far.

2.29. **IDENTIFY:** The average acceleration is $a_{\text{av-}x} = \frac{\Delta v_x}{\Delta t}$. For constant acceleration, Eqs. (2.8), (2.12), (2.13) and (2.14) apply.

SET UP: Assume the shuttle travels in the $+x$ direction. $161 \text{ km/h} = 44.72 \text{ m/s}$ and $1610 \text{ km/h} = 447.2 \text{ m/s}$. $1.00 \text{ min} = 60.0 \text{ s}$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: **(a)** (i) $a_{\text{av-}x} = \dfrac{\Delta v_x}{\Delta t} = \dfrac{44.72 \text{ m/s} - 0}{8.00 \text{ s}} = 5.59 \text{ m/s}^2$

(ii) $a_{\text{av-}x} = \dfrac{447.2 \text{ m/s} - 44.72 \text{ m/s}}{60.0 \text{ s} - 8.00 \text{ s}} = 7.74 \text{ m/s}^2$

(b) (i) $t = 8.00$ s, $v_{0x} = 0$, and $v_x = 44.72$ m/s. $x - x_0 = \left(\dfrac{v_{0x} + v_x}{2}\right)t = \left(\dfrac{0 + 44.72 \text{ m/s}}{2}\right)(8.00 \text{ s}) = 179 \text{ m}.$

(ii) $\Delta t = 60.0 \text{ s} - 8.00 \text{ s} = 52.0$ s, $v_{0x} = 44.72$ m/s, and $v_x = 447.2$ m/s.

$x - x_0 = \left(\dfrac{v_{0x} + v_x}{2}\right)t = \left(\dfrac{44.72 \text{ m/s} + 447.2 \text{ m/s}}{2}\right)(52.0 \text{ s}) = 1.28 \times 10^4 \text{ m}.$

EVALUATE: When the acceleration is constant the instantaneous acceleration throughout the time interval equals the average acceleration for that time interval. We could have calculated the distance in part (a) as $x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2 = \frac{1}{2}(5.59 \text{ m/s}^2)(8.00 \text{ s})^2 = 179 \text{ m},$ which agrees with our previous calculation.

2.30. **IDENTIFY:** The acceleration a_x is the slope of the graph of v_x versus t.

SET UP: The signs of v_x and of a_x indicate their directions.

EXECUTE: **(a)** Reading from the graph, at $t = 4.0$ s, $v_x = 2.7$ cm/s, to the right and at $t = 7.0$ s, $v_x = 1.3$ cm/s, to the left.

(b) v_x versus t is a straight line with slope $-\dfrac{8.0 \text{ cm/s}}{6.0 \text{ s}} = -1.3 \text{ cm/s}^2$. The acceleration is constant and equal to 1.3 cm/s^2, to the left. It has this value at all times.

(c) Since the acceleration is constant, $x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2$. For $t = 0$ to 4.5 s,

$x - x_0 = (8.0 \text{ cm/s})(4.5 \text{ s}) + \frac{1}{2}(-1.3 \text{ cm/s}^2)(4.5 \text{ s})^2 = 22.8 \text{ cm}.$ For $t = 0$ to 7.5 s,

$x - x_0 = (8.0 \text{ cm/s})(7.5 \text{ s}) + \frac{1}{2}(-1.3 \text{ cm/s}^2)(7.5 \text{ s})^2 = 23.4 \text{ cm}$

(d) The graphs of a_x and x versus t are given in Figure 2.30.

EVALUATE: In part (c) we could have instead used $x - x_0 = \left(\dfrac{v_{0x} + v_x}{2}\right)t.$

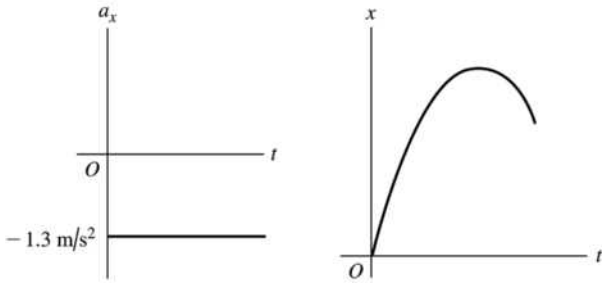


Figure 2.30

2.31. **(a) IDENTIFY** and **SET UP:** The acceleration a_x at time t is the slope of the tangent to the v_x versus t curve at time t.

EXECUTE: At $t = 3$ s, the v_x versus t curve is a horizontal straight line, with zero slope. Thus $a_x = 0$.

At $t = 7$ s, the v_x versus t curve is a straight-line segment with slope $\dfrac{45 \text{ m/s} - 20 \text{ m/s}}{9 \text{ s} - 5 \text{ s}} = 6.3 \text{ m/s}^2$.

Thus $a_x = 6.3 \text{ m/s}^2$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

At $t = 11$ s the curve is again a straight-line segment, now with slope $\frac{-0 - 45 \text{ m/s}}{13 \text{ s} - 9 \text{ s}} = -11.2 \text{ m/s}^2$.

Thus $a_x = -11.2 \text{ m/s}^2$.

EVALUATE: $a_x = 0$ when v_x is constant, $a_x > 0$ when v_x is positive and the speed is increasing, and $a_x < 0$ when v_x is positive and the speed is decreasing.

(b) IDENTIFY: Calculate the displacement during the specified time interval.

SET UP: We can use the constant acceleration equations only for time intervals during which the acceleration is constant. If necessary, break the motion up into constant acceleration segments and apply the constant acceleration equations for each segment. For the time interval $t = 0$ to $t = 5$ s the acceleration is constant and equal to zero. For the time interval $t = 5$ s to $t = 9$ s the acceleration is constant and equal to 6.25 m/s^2. For the interval $t = 9$ s to $t = 13$ s the acceleration is constant and equal to -11.2 m/s^2.

EXECUTE: During the first 5 seconds the acceleration is constant, so the constant acceleration kinematic formulas can be used.

$v_{0x} = 20 \text{ m/s}$ $a_x = 0$ $t = 5$ s $x - x_0 = ?$

$x - x_0 = v_{0x}t$ ($a_x = 0$ so no $\frac{1}{2}a_x t^2$ term)

$x - x_0 = (20 \text{ m/s})(5 \text{ s}) = 100 \text{ m}$; this is the distance the officer travels in the first 5 seconds.

During the interval $t = 5$ s to 9 s the acceleration is again constant. The constant acceleration formulas can be applied to this 4-second interval. It is convenient to restart our clock so the interval starts at time $t = 0$ and ends at time $t = 4$ s. (Note that the acceleration is *not* constant over the entire $t = 0$ to $t = 9$ s interval.)

$v_{0x} = 20 \text{ m/s}$ $a_x = 6.25 \text{ m/s}^2$ $t = 4$ s $x_0 = 100 \text{ m}$ $x - x_0 = ?$

$x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2$

$x - x_0 = (20 \text{ m/s})(4 \text{ s}) + \frac{1}{2}(6.25 \text{ m/s}^2)(4 \text{ s})^2 = 80 \text{ m} + 50 \text{ m} = 130 \text{ m}.$

Thus $x - x_0 + 130 \text{ m} = 100 \text{ m} + 130 \text{ m} = 230 \text{ m}.$

At $t = 9$ s the officer is at $x = 230$ m, so she has traveled 230 m in the first 9 seconds.

During the interval $t = 9$ s to $t = 13$ s the acceleration is again constant. The constant acceleration formulas can be applied for this 4-second interval but *not* for the whole $t = 0$ to $t = 13$ s interval. To use the equations restart our clock so this interval begins at time $t = 0$ and ends at time $t = 4$ s.

$v_{0x} = 45 \text{ m/s}$ (at the start of this time interval)

$a_x = -11.2 \text{ m/s}^2$ $t = 4$ s $x_0 = 230 \text{ m}$ $x - x_0 = ?$

$x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2$

$x - x_0 = (45 \text{ m/s})(4 \text{ s}) + \frac{1}{2}(-11.2 \text{ m/s}^2)(4 \text{ s})^2 = 180 \text{ m} - 89.6 \text{ m} = 90.4 \text{ m}.$

Thus $x = x_0 + 90.4 \text{ m} = 230 \text{ m} + 90.4 \text{ m} = 320 \text{ m}.$

At $t = 13$ s the officer is at $x = 320$ m, so she has traveled 320 m in the first 13 seconds.

EVALUATE: The velocity v_x is always positive so the displacement is always positive and displacement and distance traveled are the same. The average velocity for time interval Δt is $v_{\text{av-}x} = \Delta x/\Delta t$. For $t = 0$ to 5 s, $v_{\text{av-}x} = 20$ m/s. For $t = 0$ to 9 s, $v_{\text{av-}x} = 26$ m/s. For $t = 0$ to 13 s, $v_{\text{av-}x} = 25$ m/s. These results are consistent with Figure 2.37 in the textbook.

2.32. **IDENTIFY:** $v_x(t)$ is the slope of the x versus t graph. Car B moves with constant speed and zero acceleration. Car A moves with positive acceleration; assume the acceleration is constant.

SET UP: For car B, v_x is positive and $a_x = 0$. For car A, a_x is positive and v_x increases with t.

EXECUTE: **(a)** The motion diagrams for the cars are given in Figure 2.32a.

(b) The two cars have the same position at times when their x-t graphs cross. The figure in the problem shows this occurs at approximately $t = 1$ s and $t = 3$ s.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(c) The graphs of v_x versus t for each car are sketched in Figure 2.32b.

(d) The cars have the same velocity when their x-t graphs have the same slope. This occurs at approximately $t = 2$ s.

(e) Car A passes car B when x_A moves above x_B in the x-t graph. This happens at $t = 3$ s.

(f) Car B passes car A when x_B moves above x_A in the x-t graph. This happens at $t = 1$ s.

EVALUATE: When $a_x = 0$, the graph of v_x versus t is a horizontal line. When a_x is positive, the graph of v_x versus t is a straight line with positive slope.

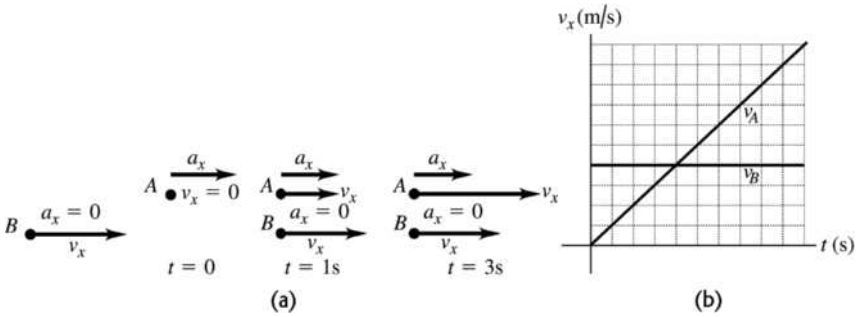

Figure 2.32a-b

2.33. **IDENTIFY:** For constant acceleration, Eqs. (2.8), (2.12), (2.13) and (2.14) apply.

SET UP: Take $+y$ to be downward, so the motion is in the $+y$ direction. 19,300 km/h = 5361 m/s, 1600 km/h = 444.4 m/s, and 321 km/h = 89.2 m/s. 4.0 min = 240 s.

EXECUTE: **(a)** Stage A: $t = 240$ s, $v_{0y} = 5361$ m/s, $v_y = 444.4$ m/s. $v_y = v_{0y} + a_y t$ gives

$$a_y = \frac{v_y - v_{0y}}{t} = \frac{444.4 \text{ m/s} - 5361 \text{ m/s}}{240 \text{ s}} = -20.5 \text{ m/s}^2.$$

Stage B: $t = 94$ s, $v_{0y} = 444.4$ m/s, $v_y = 89.2$ m/s. $v_y = v_{0y} + a_y t$ gives

$$a_y = \frac{v_y - v_{0y}}{t} = \frac{89.2 \text{ m/s} - 444.4 \text{ m/s}}{94 \text{ s}} = -3.8 \text{ m/s}^2.$$

Stage C: $y - y_0 = 75$ m, $v_{0y} = 89.2$ m/s, $v_y = 0$. $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ gives

$a_y = \dfrac{v_y^2 - v_{0y}^2}{2(y - y_0)} = \dfrac{0 - (89.2 \text{ m/s})^2}{2(75 \text{ m})} = -53.0 \text{ m/s}^2$. In each case the negative sign means that the acceleration is upward.

(b) Stage A: $y - y_0 = \left(\dfrac{v_{0y} + v_y}{2}\right)t = \left(\dfrac{5361 \text{ m/s} + 444.4 \text{ m/s}}{2}\right)(240 \text{ s}) = 697 \text{ km}.$

Stage B: $y - y_0 = \left(\dfrac{444.4 \text{ m/s} + 89.2 \text{ m/s}}{2}\right)(94 \text{ s}) = 25 \text{ km}.$

Stage C: The problem states that $y - y_0 = 75$ m $= 0.075$ km.

The total distance traveled during all three stages is 697 km + 25 km + 0.075 km = 722 km.

EVALUATE: The upward acceleration produced by friction in stage A is calculated to be greater than the upward acceleration due to the parachute in stage B. The effects of air resistance increase with increasing speed and in reality the acceleration was probably not constant during stages A and B.

2.34. **IDENTIFY:** Apply the constant acceleration equations to the motion of each vehicle. The truck passes the car when they are at the same x at the same $t > 0$.

SET UP: The truck has $a_x = 0$. The car has $v_{0x} = 0$. Let $+x$ be in the direction of motion of the vehicles. Both vehicles start at $x_0 = 0$. The car has $a_C = 3.20 \text{ m/s}^2$. The truck has $v_x = 20.0$ m/s.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: **(a)** $x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2$ gives $x_T = v_{0T}t$ and $x_C = \frac{1}{2}a_C t^2$. Setting $x_T = x_C$ gives $t = 0$ and $v_{0T} = \frac{1}{2}a_C t$, so $t = \dfrac{2v_{0T}}{a_C} = \dfrac{2(20.0 \text{ m/s})}{3.20 \text{ m/s}^2} = 12.5 \text{ s}$. At this t, $x_T = (20.0 \text{ m/s})(12.5 \text{ s}) = 250 \text{ m}$ and $x = \frac{1}{2}(3.20 \text{ m/s}^2)(12.5 \text{ s})^2 = 250 \text{ m}$. The car and truck have each traveled 250 m.

(b) At $t = 12.5$ s, the car has $v_x = v_{0x} + a_x t = (3.20 \text{ m/s}^2)(12.5 \text{ s}) = 40 \text{ m/s}$.

(c) $x_T = v_{0T}t$ and $x_C = \frac{1}{2}a_C t^2$. The x-t graph of the motion for each vehicle is sketched in Figure 2.34a.

(d) $v_T = v_{0T}$. $v_C = a_C t$. The v_x-t graph for each vehicle is sketched in Figure 2.34b.

EVALUATE: When the car overtakes the truck its speed is twice that of the truck.

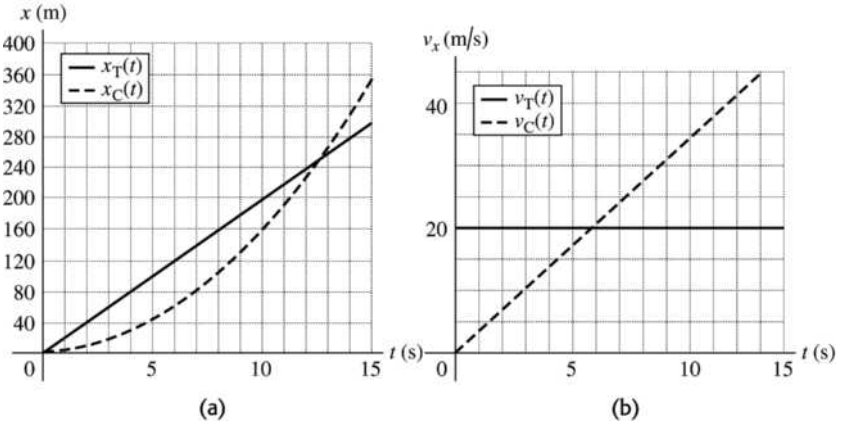

Figure 2.34a-b

2.35. **IDENTIFY:** Apply the constant acceleration equations to the motion of the flea. After the flea leaves the ground, $a_y = g$, downward. Take the origin at the ground and the positive direction to be upward.

(a) SET UP: At the maximum height $v_y = 0$.

$v_y = 0 \quad y - y_0 = 0.440 \text{ m} \quad a_y = -9.80 \text{ m/s}^2 \quad v_{0y} = ?$

$v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$

EXECUTE: $v_{0y} = \sqrt{-2a_y(y - y_0)} = \sqrt{-2(-9.80 \text{ m/s}^2)(0.440 \text{ m})} = 2.94 \text{ m/s}$

(b) SET UP: When the flea has returned to the ground $y - y_0 = 0$.

$y - y_0 = 0 \quad v_{0y} = +2.94 \text{ m/s} \quad a_y = -9.80 \text{ m/s}^2 \quad t = ?$

$y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$

EXECUTE: With $y - y_0 = 0$ this gives $t = -\dfrac{2v_{0y}}{a_y} = -\dfrac{2(2.94 \text{ m/s})}{-9.80 \text{ m/s}^2} = 0.600 \text{ s}$.

EVALUATE: We can use $v_y = v_{0y} + a_y t$ to show that with $v_{0y} = 2.94$ m/s, $v_y = 0$ after 0.300 s.

2.36. **IDENTIFY:** The rock has a constant downward acceleration of 9.80 m/s^2. We know its initial velocity and position and its final position.

SET UP: We can use the kinematics formulas for constant acceleration.

EXECUTE: **(a)** $y - y_0 = -30$ m, $v_{0y} = 18.0$ m/s, $a_y = -9.8$ m/s^2. The kinematics formulas give $v_y = -\sqrt{v_{0y}^2 + 2a_y(y - y_0)} = -\sqrt{(18.0 \text{ m/s})^2 + 2(-9.8 \text{ m/s}^2)(-30 \text{ m})} = -30.2 \text{ m/s}$, so the speed is 30.2 m/s.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) $v_y = v_{0y} + a_y t$ and $t = \dfrac{v_y - v_{0y}}{a_y} = \dfrac{-30.3 \text{ m/s} - 18.0 \text{ m/s}}{-9.8 \text{ m/s}^2} = 4.92 \text{ s}.$

EVALUATE: The vertical velocity in part (a) is negative because the rock is moving downward, but the speed is always positive. The 4.92 s is the total time in the air.

2.37. **IDENTIFY:** The pin has a constant downward acceleration of 9.80 m/s^2 and returns to its initial position.

SET UP: We can use the kinematics formulas for constant acceleration.

EXECUTE: The kinematics formulas give $y - y_0 = v_{0y}t + \dfrac{1}{2}a_y t^2$. We know that $y - y_0 = 0$, so

$$t = -\frac{2v_{0y}}{a_y} = -\frac{2(8.20 \text{ m/s})}{-9.80 \text{ m/s}^2} = +1.67 \text{ s}.$$

EVALUATE: It takes the pin half this time to reach its highest point and the remainder of the time to return.

2.38. **IDENTIFY:** The putty has a constant downward acceleration of 9.80 m/s^2. We know the initial velocity of the putty and the distance it travels.

SET UP: We can use the kinematics formulas for constant acceleration.

EXECUTE: **(a)** $v_{0y} = 9.50$ m/s and $y - y_0 = 3.60$ m, which gives

$$v_y = \sqrt{v_{0y}^2 + 2a_y(y - y_0)} = -\sqrt{(9.50 \text{ m/s})^2 + 2(-9.80 \text{ m/s}^2)(3.60 \text{ m})} = 4.44 \text{ m/s}$$

(b) $t = \dfrac{v_y - v_{0y}}{a_y} = \dfrac{4.44 \text{ m/s} - 9.50 \text{ m/s}}{-9.8 \text{ m/s}^2} = 0.517 \text{ s}$

EVALUATE: The putty is stopped by the ceiling, not by gravity.

2.39. **IDENTIFY:** A ball on Mars that is hit directly upward returns to the same level in 8.5 s with a constant downward acceleration of 0.379g. How high did it go and how fast was it initially traveling upward?

SET UP: Take $+y$ upward. $v_y = 0$ at the maximum height. $a_y = -0.379g = -3.71 \text{ m/s}^2$. The constant-acceleration formulas $v_y = v_{0y} + a_y t$ and $y = y_0 + v_{0y}t + \frac{1}{2}a_y t^2$ both apply.

EXECUTE: Consider the motion from the maximum height back to the initial level. For this motion $v_{0y} = 0$ and $t = 4.25$ s. $y = y_0 + v_{0y}t + \frac{1}{2}a_y t^2 = \frac{1}{2}(-3.71 \text{ m/s}^2)(4.25 \text{ s})^2 = -33.5$ m. The ball went 33.5 m above its original position.

(b) Consider the motion from just after it was hit to the maximum height. For this motion $v_y = 0$ and $t = 4.25$ s. $v_y = v_{0y} + a_y t$ gives $v_{0y} = -a_y t = -(-3.71 \text{ m/s}^2)(4.25 \text{ s}) = 15.8$ m/s.

(c) The graphs are sketched in Figure 2.39.

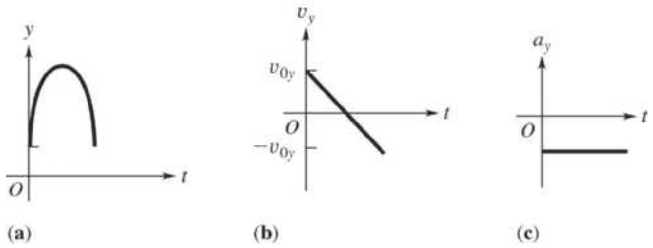

Figure 2.39

EVALUATE: The answers can be checked several ways. For example, $v_y = 0$, $v_{0y} = 15.8$ m/s, and $a_y = -3.7 \text{ m/s}^2$ in $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ gives $y - y_0 = \dfrac{v_y^2 - v_{0y}^2}{2a_y} = \dfrac{0 - (15.8 \text{ m/s})^2}{2(-3.71 \text{ m/s}^2)} = 33.6$ m, which agrees with the height calculated in (a).

2.40. **IDENTIFY:** Apply constant acceleration equations to the motion of the lander.

SET UP: Let $+y$ be positive. Since the lander is in free-fall, $a_y = +1.6 \text{ m/s}^2$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: $v_{0y} = 0.8$ m/s, $y - y_0 = 5.0$ m, $a_y = +1.6$ m/s^2 in $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ gives

$v_y = \sqrt{v_{0y}^2 + 2a_y(y - y_0)} = \sqrt{(0.8 \text{ m/s})^2 + 2(1.6 \text{ m/s}^2)(5.0 \text{ m})} = 4.1$ m/s.

EVALUATE: The same descent on earth would result in a final speed of 9.9 m/s, since the acceleration due to gravity on earth is much larger than on the moon.

2.41. **IDENTIFY:** Apply constant acceleration equations to the motion of the meterstick. The time the meterstick falls is your reaction time.

SET UP: Let $+y$ be downward. The meter stick has $v_{0y} = 0$ and $a_y = 9.80$ m/s^2. Let d be the distance the meterstick falls.

EXECUTE: **(a)** $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$ gives $d = (4.90 \text{ m/s}^2)t^2$ and $t = \sqrt{\dfrac{d}{4.90 \text{ m/s}^2}}$.

(b) $t = \sqrt{\dfrac{0.176 \text{ m}}{4.90 \text{ m/s}^2}} = 0.190$ s

EVALUATE: The reaction time is proportional to the square of the distance the stick falls.

2.42. **IDENTIFY:** Apply constant acceleration equations to the vertical motion of the brick.

SET UP: Let $+y$ be downward. $a_y = 9.80$ m/s^2

EXECUTE: **(a)** $v_{0y} = 0, t = 2.50$ s, $a_y = 9.80$ m/s^2. $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2 = \frac{1}{2}(9.80 \text{ m/s}^2)(2.50 \text{ s})^2 = 30.6$ m.

The building is 30.6 m tall.

(b) $v_y = v_{0y} + a_y t = 0 + (9.80 \text{ m/s}^2)(2.50 \text{ s}) = 24.5$ m/s

(c) The graphs of a_y, v_y and y versus t are given in Figure 2.42. Take $y = 0$ at the ground.

EVALUATE: We could use either $y - y_0 = \left(\dfrac{v_{0y} + v_y}{2}\right)t$ or $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ to check our results.

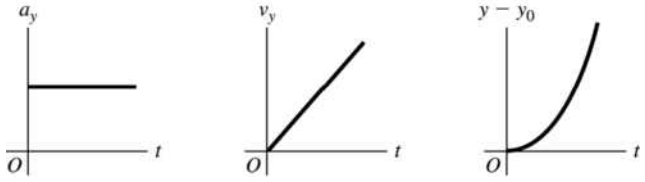

Figure 2.42

2.43. **IDENTIFY:** When the only force is gravity the acceleration is 9.80 m/s^2, downward. There are two intervals of constant acceleration and the constant acceleration equations apply during each of these intervals.

SET UP: Let $+y$ be upward. Let $y = 0$ at the launch pad. The final velocity for the first phase of the motion is the initial velocity for the free-fall phase.

EXECUTE: **(a)** Find the velocity when the engines cut off. $y - y_0 = 525$ m, $a_y = +2.25$ m/s^2, $v_{0y} = 0$.

$v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ gives $v_y = \sqrt{2(2.25 \text{ m/s}^2)(525 \text{ m})} = 48.6$ m/s.

Now consider the motion from engine cut-off to maximum height: $y_0 = 525$ m, $v_{0y} = +48.6$ m/s, $v_y = 0$ (at the maximum height), $a_y = -9.80$ m/s^2. $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ gives

$y - y_0 = \dfrac{v_y^2 - v_{0y}^2}{2a_y} = \dfrac{0 - (48.6 \text{ m/s})^2}{2(-9.80 \text{ m/s}^2)} = 121$ m and $y = 121 \text{ m} + 525 \text{ m} = 646$ m.

(b) Consider the motion from engine failure until just before the rocket strikes the ground:

$y - y_0 = -525$ m, $a_y = -9.80$ m/s^2, $v_{0y} = +48.6$ m/s. $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ gives

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$v_y = -\sqrt{(48.6\text{ m/s})^2 + 2(-9.80\text{ m/s}^2)(-525\text{ m})} = -112\text{ m/s}$. Then $v_y = v_{0y} + a_y t$ gives

$$t = \frac{v_y - v_{0y}}{a_y} = \frac{-112\text{ m/s} - 48.6\text{ m/s}}{-9.80\text{ m/s}^2} = 16.4\text{ s}.$$

(c) Find the time from blast-off until engine failure: $y - y_0 = 525$ m, $v_{0y} = 0$, $a_y = +2.25\text{ m/s}^2$.

$y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$ gives $t = \sqrt{\frac{2(y - y_0)}{a_y}} = \sqrt{\frac{2(525\text{ m})}{2.25\text{ m/s}^2}} = 21.6$ s. The rocket strikes the launch pad $21.6\text{ s} + 16.4\text{ s} = 38.0$ s after blast-off. The acceleration a_y is $+2.25\text{ m/s}^2$ from $t = 0$ to $t = 21.6$ s. It is -9.80 m/s^2 from $t = 21.6$ s to 38.0 s. $v_y = v_{0y} + a_y t$ applies during each constant acceleration segment, so the graph of v_y versus t is a straight line with positive slope of 2.25 m/s^2 during the blast-off phase and with negative slope of -9.80 m/s^2 after engine failure. During each phase $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$. The sign of a_y determines the curvature of $y(t)$. At $t = 38.0$ s the rocket has returned to $y = 0$. The graphs are sketched in Figure 2.43.

EVALUATE: In part (b) we could have found the time from $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$, finding v_y first allows us to avoid solving for t from a quadratic equation.

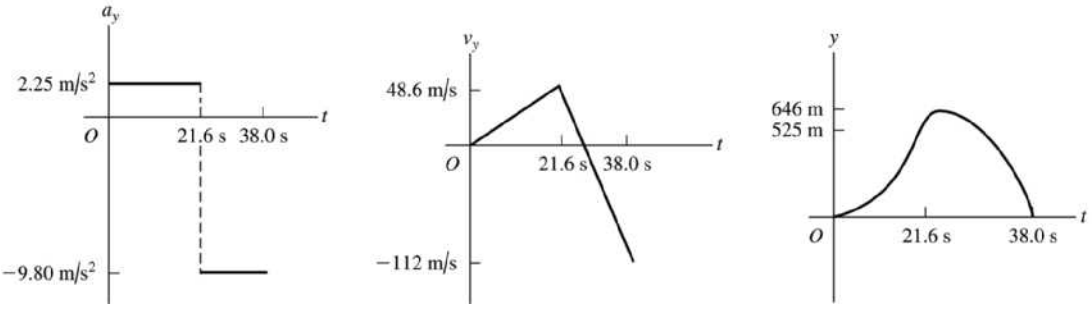

Figure 2.43

2.44. **IDENTIFY:** Apply constant acceleration equations to the vertical motion of the sandbag.

SET UP: Take $+y$ upward. $a_y = -9.80\text{ m/s}^2$. The initial velocity of the sandbag equals the velocity of the balloon, so $v_{0y} = +5.00$ m/s. When the balloon reaches the ground, $y - y_0 = -40.0$ m. At its maximum height the sandbag has $v_y = 0$.

EXECUTE: **(a)** $t = 0.250$ s: $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2 = (5.00\text{ m/s})(0.250\text{ s}) + \frac{1}{2}(-9.80\text{ m/s}^2)(0.250\text{ s})^2 = 0.94$ m. The sandbag is 40.9 m above the ground. $v_y = v_{0y} + a_y t = +5.00\text{ m/s} + (-9.80\text{ m/s}^2)(0.250\text{ s}) = 2.55$ m/s.

$t = 1.00$ s: $y - y_0 = (5.00\text{ m/s})(1.00\text{ s}) + \frac{1}{2}(-9.80\text{ m/s}^2)(1.00\text{ s})^2 = 0.10$ m. The sandbag is 40.1 m above the ground. $v_y = v_{0y} + a_y t = +5.00\text{ m/s} + (-9.80\text{ m/s}^2)(1.00\text{ s}) = -4.80$ m/s.

(b) $y - y_0 = -40.0$ m, $v_{0y} = 5.00$ m/s, $a_y = -9.80\text{ m/s}^2$. $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$ gives

$-40.0\text{ m} = (5.00\text{ m/s})t - (4.90\text{ m/s}^2)t^2$. $(4.90\text{ m/s}^2)t^2 - (5.00\text{ m/s})t - 40.0\text{ m} = 0$ and

$$t = \frac{1}{9.80}\left(5.00 \pm \sqrt{(-5.00)^2 - 4(4.90)(-40.0)}\right)\text{s} = (0.51 \pm 2.90)\text{ s}.$$

t must be positive, so $t = 3.41$ s.

(c) $v_y = v_{0y} + a_y t = +5.00\text{ m/s} + (-9.80\text{ m/s}^2)(3.41\text{ s}) = -28.4$ m/s

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(d) $v_{0y} = 5.00$ m/s, $a_y = -9.80$ m/s^2, $v_y = 0$. $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ gives

$$y - y_0 = \frac{v_y^2 - v_{0y}^2}{2a_y} = \frac{0 - (5.00 \text{ m/s})^2}{2(-9.80 \text{ m/s}^2)} = 1.28 \text{ m}.$$ The maximum height is 41.3 m above the ground.

(e) The graphs of a_y, v_y, and y versus t are given in Figure 2.44. Take $y = 0$ at the ground.

EVALUATE: The sandbag initially travels upward with decreasing velocity and then moves downward with increasing speed.

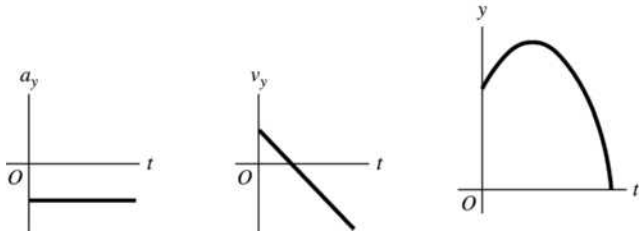

Figure 2.44

2.45. **IDENTIFY:** Use the constant acceleration equations to calculate a_x and $x - x_0$.

(a) SET UP: $v_x = 224$ m/s, $v_{0x} = 0$, $t = 0.900$ s, $a_x = ?$

$v_x = v_{0x} + a_x t$

EXECUTE: $a_x = \dfrac{v_x - v_{0x}}{t} = \dfrac{224 \text{ m/s} - 0}{0.900 \text{ s}} = 249 \text{ m/s}^2$

(b) $a_x/g = (249 \text{ m/s}^2)/(9.80 \text{ m/s}^2) = 25.4$

(c) $x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2 = 0 + \frac{1}{2}(249 \text{ m/s}^2)(0.900 \text{ s})^2 = 101 \text{ m}$

(d) SET UP: Calculate the acceleration, assuming it is constant:
$t = 1.40$ s, $v_{0x} = 283$ m/s, $v_x = 0$ (stops), $a_x = ?$

$v_x = v_{0x} + a_x t$

EXECUTE: $a_x = \dfrac{v_x - v_{0x}}{t} = \dfrac{0 - 283 \text{ m/s}}{1.40 \text{ s}} = -202 \text{ m/s}^2$

$a_x/g = (-202 \text{ m/s}^2)/(9.80 \text{ m/s}^2) = -20.6$; $a_x = -20.6g$

If the acceleration while the sled is stopping is constant then the magnitude of the acceleration is only 20.6*g*. But if the acceleration is not constant it is certainly possible that at some point the instantaneous acceleration could be as large as 40*g*.

EVALUATE: It is reasonable that for this motion the acceleration is much larger than *g*.

2.46. **IDENTIFY:** Since air resistance is ignored, the egg is in free-fall and has a constant downward acceleration of magnitude 9.80 m/s^2. Apply the constant acceleration equations to the motion of the egg.

SET UP: Take $+y$ to be upward. At the maximum height, $v_y = 0$.

EXECUTE: **(a)** $y - y_0 = -30.0$ m, $t = 5.00$ s, $a_y = -9.80$ m/s^2. $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$ gives

$$v_{0y} = \frac{y - y_0}{t} - \tfrac{1}{2}a_y t = \frac{-30.0 \text{ m}}{5.00 \text{ s}} - \tfrac{1}{2}(-9.80 \text{ m/s}^2)(5.00 \text{ s}) = +18.5 \text{ m/s}.$$

(b) $v_{0y} = +18.5$ m/s, $v_y = 0$ (at the maximum height), $a_y = -9.80$ m/s^2. $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ gives

$$y - y_0 = \frac{v_y^2 - v_{0y}^2}{2a_y} = \frac{0 - (18.5 \text{ m/s})^2}{2(-9.80 \text{ m/s}^2)} = 17.5 \text{ m}.$$

(c) At the maximum height $v_y = 0$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(d) The acceleration is constant and equal to $9.80\ \text{m/s}^2$, downward, at all points in the motion, including at the maximum height.
(e) The graphs are sketched in Figure 2.46.

EVALUATE: The time for the egg to reach its maximum height is $t = \dfrac{v_y - v_{0y}}{a_y} = \dfrac{-18.5\ \text{m/s}}{-9.8\ \text{m/s}^2} = 1.89\ \text{s}$. The egg has returned to the level of the cornice after 3.78 s and after 5.00 s it has traveled downward from the cornice for 1.22 s.

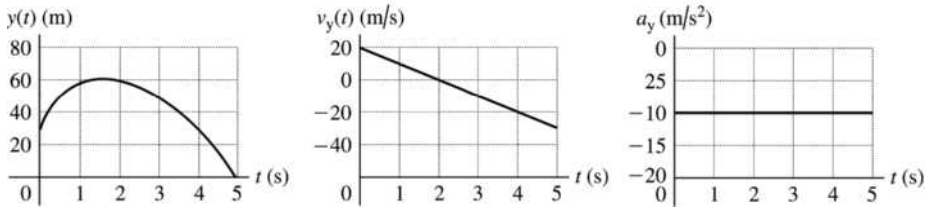

Figure 2.46

2.47. **IDENTIFY:** We can avoid solving for the common height by considering the relation between height, time of fall and acceleration due to gravity and setting up a ratio involving time of fall and acceleration due to gravity.
SET UP: Let g_{En} be the acceleration due to gravity on Enceladus and let g be this quantity on earth. Let h be the common height from which the object is dropped. Let $+y$ be downward, so $y - y_0 = h$. $v_{0y} = 0$

EXECUTE: $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$ gives $h = \frac{1}{2}gt_{\text{E}}^2$ and $h = \frac{1}{2}g_{\text{En}}t_{\text{En}}^2$. Combining these two equations gives

$$gt_{\text{E}}^2 = g_{\text{En}}t_{\text{En}}^2 \text{ and } g_{\text{En}} = g\left(\frac{t_{\text{E}}}{t_{\text{En}}}\right)^2 = (9.80\ \text{m/s}^2)\left(\frac{1.75\ \text{s}}{18.6\ \text{s}}\right)^2 = 0.0868\ \text{m/s}^2.$$

EVALUATE: The acceleration due to gravity is inversely proportional to the square of the time of fall.

2.48. **IDENTIFY:** Since air resistance is ignored, the boulder is in free-fall and has a constant downward acceleration of magnitude $9.80\ \text{m/s}^2$. Apply the constant acceleration equations to the motion of the boulder.
SET UP: Take $+y$ to be upward.

EXECUTE: **(a)** $v_{0y} = +40.0\ \text{m/s}$, $v_y = +20.0\ \text{m/s}$, $a_y = -9.80\ \text{m/s}^2$. $v_y = v_{0y} + a_y t$ gives

$$t = \frac{v_y - v_{0y}}{a_y} = \frac{20.0\ \text{m/s} - 40.0\ \text{m/s}}{-9.80\ \text{m/s}^2} = +2.04\ \text{s}.$$

(b) $v_y = -20.0\ \text{m/s}$. $t = \dfrac{v_y - v_{0y}}{a_y} = \dfrac{-20.0\ \text{m/s} - 40.0\ \text{m/s}}{-9.80\ \text{m/s}^2} = +6.12\ \text{s}$.

(c) $y - y_0 = 0$, $v_{0y} = +40.0\ \text{m/s}$, $a_y = -9.80\ \text{m/s}^2$. $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$ gives $t = 0$ and

$$t = -\frac{2v_{0y}}{a_y} = -\frac{2(40.0\ \text{m/s})}{-9.80\ \text{m/s}^2} = +8.16\ \text{s}.$$

(d) $v_y = 0$, $v_{0y} = +40.0\ \text{m/s}$, $a_y = -9.80\ \text{m/s}^2$. $v_y = v_{0y} + a_y t$ gives $t = \dfrac{v_y - v_{0y}}{a_y} = \dfrac{0 - 40.0\ \text{m/s}}{-9.80\ \text{m/s}^2} = 4.08\ \text{s}$.

(e) The acceleration is $9.80\ \text{m/s}^2$, downward, at all points in the motion.
(f) The graphs are sketched in Figure 2.48.
EVALUATE: $v_y = 0$ at the maximum height. The time to reach the maximum height is half the total time in the air, so the answer in part (d) is half the answer in part (c). Also note that $2.04\ \text{s} < 4.08\ \text{s} < 6.12\ \text{s}$. The boulder is going upward until it reaches its maximum height and after the maximum height it is traveling downward.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

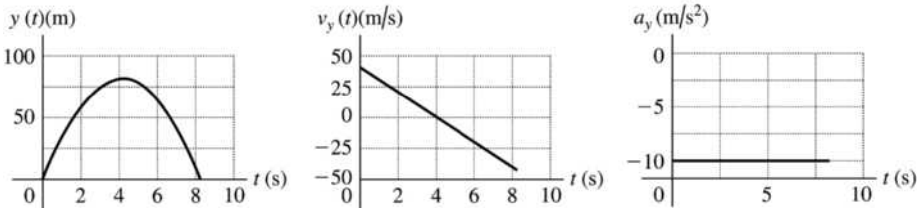

Figure 2.48

2.49. **IDENTIFY:** Two stones are thrown up with different speeds. (a) Knowing how soon the faster one returns to the ground, how long it will take the slow one to return? (b) Knowing how high the slower stone went, how high did the faster stone go?

SET UP: Use subscripts f and s to refer to the faster and slower stones, respectively. Take $+y$ to be upward and $y_0 = 0$ for both stones. $v_{0\mathrm{f}} = 3v_{0\mathrm{s}}$. When a stone reaches the ground, $y = 0$. The constant-acceleration formulas $y = y_0 + v_{0y}t + \frac{1}{2}a_y t^2$ and $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ both apply.

EXECUTE: **(a)** $y = y_0 + v_{0y}t + \frac{1}{2}a_y t^2$ gives $a_y = -\dfrac{2v_{0y}}{t}$. Since both stones have the same a_y, $\dfrac{v_{0\mathrm{f}}}{t_\mathrm{f}} = \dfrac{v_{0\mathrm{s}}}{t_\mathrm{s}}$ and $t_\mathrm{s} = t_\mathrm{f}\left(\dfrac{v_{0\mathrm{s}}}{v_{0\mathrm{f}}}\right) = \left(\frac{1}{3}\right)(10\text{ s}) = 3.3\text{ s}$.

(b) Since $v_y = 0$ at the maximum height, then $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ gives $a_y = -\dfrac{v_{0y}^2}{2y}$. Since both have the same a_y, $\dfrac{v_{0\mathrm{f}}^2}{y_\mathrm{f}} = \dfrac{v_{0\mathrm{s}}^2}{y_\mathrm{s}}$ and $y_\mathrm{f} = y_\mathrm{s}\left(\dfrac{v_{0\mathrm{f}}}{v_{0\mathrm{s}}}\right)^2 = 9H$.

EVALUATE: The faster stone reaches a greater height so it travels a greater distance than the slower stone and takes more time to return to the ground.

2.50. **IDENTIFY:** We start with the more general formulas and use them to derive the formulas for constant acceleration.

SET UP: The general formulas are $v_x = v_{0x} + \int_0^t a_x dt$ and $x = x_0 + \int_0^t v_x dt$.

EXECUTE: For constant acceleration, these formulas give $v_x = v_{0x} + \int_0^t a_x dt = v_{0x} + a_x\int_0^t dt = v_{0x} + a_x t$ and

$$x = x_0 + \int_0^t v_x dt = x_0 + \int_0^t (v_{0x} + a_x t)dt = x_0 + v_{0x}\int_0^t dt + a_x\int_0^t t dt = x_0 + v_{0x}t + \frac{1}{2}a_x t^2.$$

EVALUATE: The general formulas give the expected results for constant acceleration.

2.51. **IDENTIFY:** The acceleration is not constant, but we know how it varies with time. We can use the definitions of instantaneous velocity and position to find the rocket's position and speed.

SET UP: The basic definitions of velocity and position are $v_y(t) = \int_0^t a_y dt$ and $y - y_0 = \int_0^t v_y dt$.

EXECUTE: **(a)** $v_y(t) = \int_0^t a_y dt = \int_0^t (2.80\text{ m/s}^3)t dt = (1.40\text{ m/s}^3)t^2$

$y - y_0 = \int_0^t v_y dt = \int_0^t (1.40\text{ m/s}^3)t^2 dt = (0.4667\text{ m/s}^3)t^3$. For $t = 10.0$ s, $y - y_0 = 467$ m.

(b) $y - y_0 = 325$ m so $(0.4667\text{ m/s}^3)t^3 = 325$ m and $t = 8.864$ s. At this time

$v_y = (1.40\text{ m/s}^3)(8.864\text{ s})^2 = 110$ m/s.

EVALUATE: The time in part (b) is less than 10.0 s, so the given formulas are valid.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

2.52. **IDENTIFY:** The acceleration is not constant so the constant acceleration equations cannot be used. Instead, use Eqs. (2.17) and (2.18). Use the values of v_x and of x at $t = 1.0$ s to evaluate v_{0x} and x_0.

SET UP: $\int t^n dt = \dfrac{1}{n+1} t^{n+1}$, for $n \geq 0$.

EXECUTE: **(a)** $v_x = v_{0x} + \int_0^t \alpha t dt = v_{0x} + \frac{1}{2}\alpha t^2 = v_{0x} + (0.60 \text{ m/s}^3)t^2$. $v_x = 5.0$ m/s when $t = 1.0$ s gives $v_{0x} = 4.4$ m/s. Then, at $t = 2.0$ s, $v_x = 4.4 \text{ m/s} + (0.60 \text{ m/s}^3)(2.0 \text{ s})^2 = 6.8$ m/s.

(b) $x = x_0 + \int_0^t (v_{0x} + \frac{1}{2}\alpha t^2) dt = x_0 + v_{0x}t + \frac{1}{6}\alpha t^3$. $x = 6.0$ m at $t = 1.0$ s gives $x_0 = 1.4$ m. Then, at $t = 2.0$ s, $x = 1.4 \text{ m} + (4.4 \text{ m/s})(2.0 \text{ s}) + \frac{1}{6}(1.2 \text{ m/s}^3)(2.0 \text{ s})^3 = 11.8$ m.

(c) $x(t) = 1.4 \text{ m} + (4.4 \text{ m/s})t + (0.20 \text{ m/s}^3)t^3$. $v_x(t) = 4.4 \text{ m/s} + (0.60 \text{ m/s}^3)t^2$. $a_x(t) = (1.20 \text{m/s}^3)t$. The graphs are sketched in Figure 2.52.

EVALUATE: We can verify that $a_x = \dfrac{dv_x}{dt}$ and $v_x = \dfrac{dx}{dt}$.

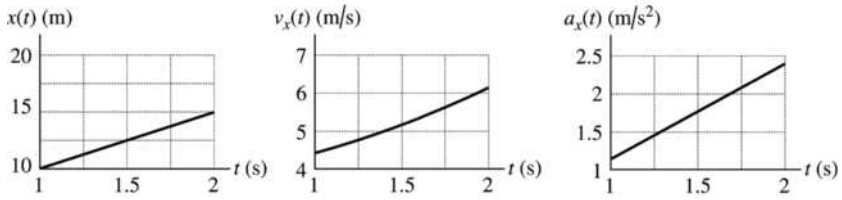

Figure 2.52

$a_x = At - Bt^2$ with $A = 1.50 \text{ m/s}^3$ and $B = 0.120 \text{ m/s}^4$

2.53. **(a) IDENTIFY:** Integrate $a_x(t)$ to find $v_x(t)$ and then integrate $v_x(t)$ to find $x(t)$.

SET UP: $v_x = v_{0x} + \int_0^t a_x \, dt$

EXECUTE: $v_x = v_{0x} + \int_0^t (At - Bt^2)\, dt = v_{0x} + \frac{1}{2}At^2 - \frac{1}{3}Bt^3$

At rest at $t = 0$ says that $v_{0x} = 0$, so

$v_x = \frac{1}{2}At^2 - \frac{1}{3}Bt^3 = \frac{1}{2}(1.50 \text{ m/s}^3)t^2 - \frac{1}{3}(0.120 \text{ m/s}^4)t^3$

$v_x = (0.75 \text{ m/s}^3)t^2 - (0.040 \text{ m/s}^4)t^3$

SET UP: $x - x_0 + \int_0^t v_x \, dt$

EXECUTE: $x = x_0 + \int_0^t (\frac{1}{2}At^2 - \frac{1}{3}Bt^3)\, dt = x_0 + \frac{1}{6}At^3 - \frac{1}{12}Bt^4$

At the origin at $t = 0$ says that $x_0 = 0$, so

$x = \frac{1}{6}At^3 - \frac{1}{12}Bt^4 = \frac{1}{6}(1.50 \text{ m/s}^3)t^3 - \frac{1}{12}(0.120 \text{ m/s}^4)t^4$

$x = (0.25 \text{ m/s}^3)t^3 - (0.010 \text{ m/s}^4)t^4$

EVALUATE: We can check our results by using them to verify that $v_x(t) = \dfrac{dx}{dt}$ and $a_x(t) = \dfrac{dv_x}{dt}$.

(b) IDENTIFY and **SET UP:** At time t, when v_x is a maximum, $\dfrac{dv_x}{dt} = 0$. (Since $a_x = \dfrac{dv_x}{dt}$, the maximum velocity is when $a_x = 0$. For earlier times a_x is positive so v_x is still increasing. For later times a_x is negative and v_x is decreasing.)

EXECUTE: $a_x = \dfrac{dv_x}{dt} = 0$ so $At - Bt^2 = 0$

One root is $t = 0,$ but at this time $v_x = 0$ and not a maximum.

The other root is $t = \dfrac{A}{B} = \dfrac{1.50 \text{ m/s}^3}{0.120 \text{ m/s}^4} = 12.5 \text{ s}$

At this time $v_x = (0.75 \text{ m/s}^3)t^2 - (0.040 \text{ m/s}^4)t^3$ gives

$v_x = (0.75 \text{ m/s}^3)(12.5 \text{ s})^2 - (0.040 \text{ m/s}^4)(12.5 \text{ s})^3 = 117.2 \text{ m/s} - 78.1 \text{ m/s} = 39.1 \text{ m/s}.$

EVALUATE: For $t < 12.5$ s, $a_x > 0$ and v_x is increasing. For $t > 12.5$ s, $a_x < 0$ and v_x is decreasing.

2.54. **IDENTIFY:** $a(t)$ is the slope of the v versus t graph and the distance traveled is the area under the v versus t graph.

SET UP: The v versus t graph can be approximated by the graph sketched in Figure 2.54.

EXECUTE: **(a)** Slope $= a = 0$ for $t \geq 1.3$ ms.

(b)

$h_{\max} = \text{Area under } v\text{-}t \text{ graph} \approx A_{\text{Triangle}} + A_{\text{Rectangle}} \approx \dfrac{1}{2}(1.3 \text{ ms})(133 \text{ cm/s}) + (2.5 \text{ ms} - 1.3 \text{ ms})(133 \text{ cm/s}) \approx 0.25 \text{ cm}$

(c) $a = \text{slope of } v\text{-}t \text{ graph. } a(0.5 \text{ ms}) \approx a(1.0 \text{ ms}) \approx \dfrac{133 \text{ cm/s}}{1.3 \text{ ms}} = 1.0 \times 10^5 \text{ cm/s}^2.$

$a(1.5 \text{ ms}) = 0$ because the slope is zero.

(d) $h = \text{area under } v\text{-}t \text{ graph. } h(0.5 \text{ ms}) \approx A_{\text{Triangle}} = \dfrac{1}{2}(0.5 \text{ ms})(33 \text{ cm/s}) = 8.3 \times 10^{-3} \text{ cm}.$

$h(1.0 \text{ ms}) \approx A_{\text{Triangle}} = \dfrac{1}{2}(1.0 \text{ ms})(100 \text{ cm/s}) = 5.0 \times 10^{-2} \text{ cm}.$

$h(1.5 \text{ ms}) \approx A_{\text{Triangle}} + A_{\text{Rectangle}} = \dfrac{1}{2}(1.3 \text{ ms})(133 \text{ cm/s}) + (0.2 \text{ ms})1.33 \text{ cm/s} = 0.11 \text{ cm}$

EVALUATE: The acceleration is constant until $t = 1.3$ ms, and then it is zero. $g = 980 \text{ cm/s}^2$. The acceleration during the first 1.3 ms is much larger than this and gravity can be neglected for the portion of the jump that we are considering.

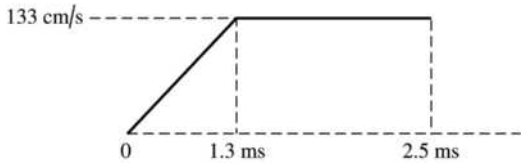

Figure 2.54

2.55. **IDENTIFY:** The sprinter's acceleration is constant for the first 2.0 s but zero after that, so it is not constant over the entire race. We need to break up the race into segments.

SET UP: When the acceleration is constant, the formula $x - x_0 = \left(\dfrac{v_{0x} + v_x}{2}\right)t$ applies. The average velocity is $v_{\text{av-}x} = \dfrac{\Delta x}{\Delta t}.$

EXECUTE: **(a)** $x - x_0 = \left(\dfrac{v_{0x} + v_x}{2}\right)t = \left(\dfrac{0 + 10.0 \text{ m/s}}{2}\right)(2.0 \text{ s}) = 10.0 \text{ m}.$

(b) (i) 40.0 m at 10.0 m/s so time at constant speed is 4.0 s. The total time is 6.0 s, so

$v_{\text{av-}x} = \dfrac{\Delta x}{\Delta t} = \dfrac{50.0 \text{ m}}{6.0 \text{ s}} = 8.33 \text{ m/s}.$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(ii) He runs 90.0 m at 10.0 m/s so the time at constant speed is 9.0 s. The total time is 11.0 s, so $v_{\text{av-}x} = \dfrac{100 \text{ m}}{11.0 \text{ s}} = 9.09 \text{ m/s}$.

(iii) He runs 190 m at 10.0 m/s so time at constant speed is 19.0 s. His total time is 21.0 s, so $v_{\text{av-}x} = \dfrac{200 \text{ m}}{21.0 \text{ s}} = 9.52 \text{ m/s}$.

EVALUATE: His average velocity keeps increasing because he is running more and more of the race at his top speed.

2.56. **IDENTIFY:** The average speed is the total distance traveled divided by the total time. The elapsed time is the distance traveled divided by the average speed.

SET UP: The total distance traveled is 20 mi. With an average speed of 8 mi/h for 10 mi, the time for that first 10 miles is $\dfrac{10 \text{ mi}}{8 \text{ mi/h}} = 1.25 \text{ h}$.

EXECUTE: **(a)** An average speed of 4 mi/h for 20 mi gives a total time of $\dfrac{20 \text{ mi}}{4 \text{ mi/h}} = 5.0 \text{ h}$. The second 10 mi must be covered in $5.0 \text{ h} - 1.25 \text{ h} = 3.75 \text{ h}$. This corresponds to an average speed of $\dfrac{10 \text{ mi}}{3.75 \text{ h}} = 2.7 \text{ mi/h}$.

(b) An average speed of 12 mi/h for 20 mi gives a total time of $\dfrac{20 \text{ mi}}{12 \text{ mi/h}} = 1.67 \text{ h}$. The second 10 mi must be covered in $1.67 \text{ h} - 1.25 \text{ h} = 0.42 \text{ h}$. This corresponds to an average speed of $\dfrac{10 \text{ mi}}{0.42 \text{ h}} = 24 \text{ mi/h}$.

(c) An average speed of 16 mi/h for 20 mi gives a total time of $\dfrac{20 \text{ mi}}{16 \text{ mi/h}} = 1.25 \text{ h}$. But 1.25 h was already spent during the first 10 miles and the second 10 miles would have to be covered in zero time. This is not possible and an average speed of 16 mi/h for the 20-mile ride is not possible.

EVALUATE: The average speed for the total trip is not the average of the average speeds for each 10-mile segment. The rider spends a different amount of time traveling at each of the two average speeds.

2.57. **IDENTIFY:** $v_x(t) = \dfrac{dx}{dt}$ and $a_x = \dfrac{dv_x}{dt}$.

SET UP: $\dfrac{d}{dt}(t^n) = nt^{n-1}$, for $n \geq 1$.

EXECUTE: **(a)** $v_x(t) = (9.00 \text{ m/s}^3)t^2 - (20.0 \text{ m/s}^2)t + 9.00 \text{ m/s}$. $a_x(t) = (18.0 \text{ m/s}^3)t - 20.0 \text{ m/s}^2$. The graphs are sketched in Figure 2.57.

(b) The particle is instantaneously at rest when $v_x(t) = 0$. $v_{0x} = 0$ and the quadratic formula gives $t = \dfrac{1}{18.0}\left(20.0 \pm \sqrt{(20.0)^2 - 4(9.00)(9.00)}\right) \text{ s} = 1.11 \text{ s} \pm 0.48 \text{ s}$. $t = 0.627 \text{ s}$ and $t = 1.59 \text{ s}$. These results agree with the v_x-t graphs in part (a).

(c) For $t = 0.627 \text{ s}$, $a_x = (18.0 \text{ m/s}^3)(0.627 \text{ s}) - 20.0 \text{ m/s}^2 = -8.7 \text{ m/s}^2$. For $t = 1.59 \text{ s}$, $a_x = +8.6 \text{ m/s}^2$. At $t = 0.627 \text{ s}$ the slope of the v_x-t graph is negative and at $t = 1.59 \text{ s}$ it is positive, so the same answer is deduced from the $v_x(t)$ graph as from the expression for $a_x(t)$.

(d) $v_x(t)$ is instantaneously not changing when $a_x = 0$. This occurs at $t = \dfrac{20.0 \text{ m/s}^2}{18.0 \text{ m/s}^3} = 1.11 \text{ s}$.

(e) When the particle is at its greatest distance from the origin, $v_x = 0$ and $a_x < 0$ (so the particle is starting to move back toward the origin). This is the case for $t = 0.627 \text{ s}$, which agrees with the x-t graph in part (a). At $t = 0.627 \text{ s}$, $x = 2.45 \text{ m}$.

(f) The particle's speed is changing at its greatest rate when a_x has its maximum magnitude. The a_x-t graph in part (a) shows this occurs at $t = 0$ and at $t = 2.00 \text{ s}$. Since v_x is always positive in this time interval, the particle is speeding up at its greatest rate when a_x is positive, and this is for $t = 2.00 \text{ s}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

The particle is slowing down at its greatest rate when a_x is negative and this is for $t = 0$.

EVALUATE: Since $a_x(t)$ is linear in t, $v_x(t)$ is a parabola and is symmetric around the point where $|v_x(t)|$ has its minimum value ($t = 1.11$ s). For this reason, the answer to part (d) is midway between the two times in part (c).

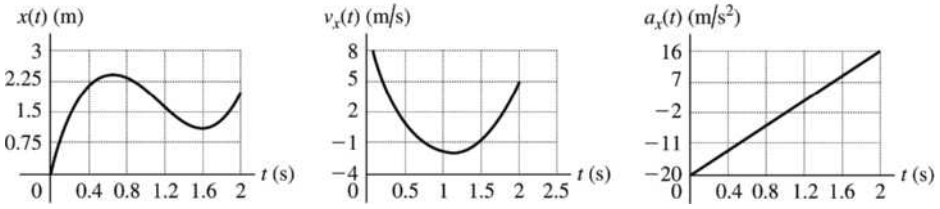

Figure 2.57

2.58. **IDENTIFY:** We know the vertical position of the lander as a function of time and want to use this to find its velocity initially and just before it hits the lunar surface.

SET UP: By definition, $v_y(t) = \dfrac{dy}{dt}$, so we can find v_y as a function of time and then evaluate it for the desired cases.

EXECUTE: **(a)** $v_y(t) = \dfrac{dy}{dt} = -c + 2dt$. At $t = 0$, $v_y(t) = -c = -60.0$ m/s. The initial velocity is 60.0 m/s downward.

(b) $y(t) = 0$ says $b - ct + dt^2 = 0$. The quadratic formula says $t = 28.57$ s ± 7.38 s. It reaches the surface at $t = 21.19$ s. At this time, $v_y = -60.0$ m/s $+ 2(1.05$ m/s$^2)(21.19$ s$) = -15.5$ m/s.

EVALUATE: The given formula for $y(t)$ is of the form $y = y_0 + v_{0y}t + \frac{1}{2}at^2$. For part (a), $v_{0y} = -c = -60$m/s.

2.59. **IDENTIFY:** In time t_S the S-waves travel a distance $d = v_S t_S$ and in time t_P the P-waves travel a distance $d = v_P t_P$.

SET UP: $t_S = t_P + 33$ s

EXECUTE: $\dfrac{d}{v_S} = \dfrac{d}{v_P} + 33$ s. $d\left(\dfrac{1}{3.5 \text{ km/s}} - \dfrac{1}{6.5 \text{ km/s}}\right) = 33$ s and $d = 250$ km.

EVALUATE: The times of travel for each wave are $t_S = 71$ s and $t_P = 38$ s.

2.60. **IDENTIFY:** The average velocity is $v_{\text{av-}x} = \dfrac{\Delta x}{\Delta t}$. The average speed is the distance traveled divided by the elapsed time.

SET UP: Let $+x$ be in the direction of the first leg of the race. For the round trip, $\Delta x = 0$ and the total distance traveled is 50.0 m. For each leg of the race both the magnitude of the displacement and the distance traveled are 25.0 m.

EXECUTE: **(a)** $|v_{\text{av-}x}| = \left|\dfrac{\Delta x}{\Delta t}\right| = \dfrac{25.0 \text{ m}}{20.0 \text{ s}} = 1.25$ m/s. This is the same as the average speed for this leg of the race.

(b) $|v_{\text{av-}x}| = \left|\dfrac{\Delta x}{\Delta t}\right| = \dfrac{25.0 \text{ m}}{15.0 \text{ s}} = 1.67$ m/s. This is the same as the average speed for this leg of the race.

(c) $\Delta x = 0$ so $v_{\text{av-}x} = 0$.

(d) The average speed is $\dfrac{50.0 \text{ m}}{35.0 \text{ s}} = 1.43$ m/s.

EVALUATE: Note that the average speed for the round trip is not equal to the arithmetic average of the average speeds for each leg.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

2.61. **IDENTIFY:** The average velocity is $v_{\text{av-}x} = \dfrac{\Delta x}{\Delta t}$.

SET UP: Let $+x$ be upward.

EXECUTE: **(a)** $v_{\text{av-}x} = \dfrac{1000 \text{ m} - 63 \text{ m}}{4.75 \text{ s}} = 197 \text{ m/s}$

(b) $v_{\text{av-}x} = \dfrac{1000 \text{ m} - 0}{5.90 \text{ s}} = 169 \text{ m/s}$

EVALUATE: For the first 1.15 s of the flight, $v_{\text{av-}x} = \dfrac{63 \text{ m} - 0}{1.15 \text{ s}} = 54.8 \text{ m/s}$. When the velocity isn't constant the average velocity depends on the time interval chosen. In this motion the velocity is increasing.

2.62. **(a) IDENTIFY** and **SET UP:** The change in speed is the area under the a_x versus t curve between vertical lines at $t = 2.5$ s and $t = 7.5$ s.

EXECUTE: This area is $\frac{1}{2}(4.00 \text{ cm/s}^2 + 8.00 \text{ cm/s}^2)(7.5 \text{ s} - 2.5 \text{ s}) = 30.0 \text{ cm/s}$

This acceleration is positive so the change in velocity is positive.

(b) Slope of v_x versus t is positive and increasing with t. The graph is sketched in Figure 2.62.

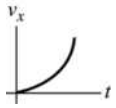

Figure 2.62

EVALUATE: The calculation in part (a) is equivalent to $\Delta v_x = (a_{\text{av-}x})\Delta t$. Since a_x is linear in t, $a_{\text{av-}x} = (a_{0x} + a_x)/2$. Thus $a_{\text{av-}x} = \frac{1}{2}(4.00 \text{ cm/s}^2 + 8.00 \text{ cm/s}^2)$ for the time interval $t = 2.5$ s to $t = 7.5$ s.

2.63. **IDENTIFY:** Use information about displacement and time to calculate average speed and average velocity. Take the origin to be at Seward and the positive direction to be west.

(a) SET UP: $\text{average speed} = \dfrac{\text{distance traveled}}{\text{time}}$

EXECUTE: The distance traveled (different from the net displacement $(x - x_0)$) is $76 \text{ km} + 34 \text{ km} = 110 \text{ km}$.

Find the total elapsed time by using $v_{\text{av-}x} = \dfrac{\Delta x}{\Delta t} = \dfrac{x - x_0}{t}$ to find t for each leg of the journey.

Seward to Auora: $t = \dfrac{x - x_0}{v_{\text{av-}x}} = \dfrac{76 \text{ km}}{88 \text{ km/h}} = 0.8636 \text{ h}$

Auora to York: $t = \dfrac{x - x_0}{v_{\text{av-}x}} = \dfrac{-34 \text{ km}}{-72 \text{ km/h}} = 0.4722 \text{ h}$

Total $t = 0.8636 \text{ h} + 0.4722 \text{ h} = 1.336 \text{ h}$.

Then $\text{average speed} = \dfrac{110 \text{ km}}{1.336 \text{ h}} = 82 \text{ km/h}$.

(b) SET UP: $v_{\text{av-}x} = \dfrac{\Delta x}{\Delta t}$, where Δx is the displacement, not the total distance traveled.

For the whole trip he ends up $76 \text{ km} - 34 \text{ km} = 42 \text{ km}$ west of his starting point. $v_{\text{av-}x} = \dfrac{42 \text{ km}}{1.336 \text{ h}} = 31 \text{ km/h}$.

EVALUATE: The motion is not uniformly in the same direction so the displacement is less than the distance traveled and the magnitude of the average velocity is less than the average speed.

2.64. **IDENTIFY:** Use constant acceleration equations to find $x - x_0$ for each segment of the motion.

SET UP: Let $+x$ be the direction the train is traveling.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: $t = 0$ to 14.0 s: $x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2 = \frac{1}{2}(1.60\ \text{m/s}^2)(14.0\ \text{s})^2 = 157\ \text{m}$.

At $t = 14.0$ s, the speed is $v_x = v_{0x} + a_x t = (1.60\ \text{m/s}^2)(14.0\ \text{s}) = 22.4\ \text{m/s}$. In the next 70.0 s, $a_x = 0$ and $x - x_0 = v_{0x}t = (22.4\ \text{m/s})(70.0\ \text{s}) = 1568\ \text{m}$.

For the interval during which the train is slowing down, $v_{0x} = 22.4$ m/s, $a_x = -3.50\ \text{m/s}^2$ and $v_x = 0$.

$v_x^2 = v_{0x}^2 + 2a_x(x - x_0)$ gives $x - x_0 = \dfrac{v_x^2 - v_{0x}^2}{2a_x} = \dfrac{0 - (22.4\ \text{m/s})^2}{2(-3.50\ \text{m/s}^2)} = 72\ \text{m}$.

The total distance traveled is $157\ \text{m} + 1568\ \text{m} + 72\ \text{m} = 1800\ \text{m}$.

EVALUATE: The acceleration is not constant for the entire motion but it does consist of constant acceleration segments and we can use constant acceleration equations for each segment.

2.65. **(a) IDENTIFY:** Calculate the average acceleration using $a_{\text{av-}x} = \dfrac{\Delta v_x}{\Delta t} = \dfrac{v_x - v_{0x}}{t}$. Use the information about the time and total distance to find his maximum speed.

SET UP: $v_{0x} = 0$ since the runner starts from rest.

$t = 4.0$ s, but we need to calculate v_x, the speed of the runner at the end of the acceleration period.

EXECUTE: For the last $9.1\ \text{s} - 4.0\ \text{s} = 5.1\ \text{s}$ the acceleration is zero and the runner travels a distance of $d_1 = (5.1\ \text{s})v_x$ (obtained using $x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2$).

During the acceleration phase of 4.0 s, where the velocity goes from 0 to v_x, the runner travels a distance

$$d_2 = \left(\frac{v_{0x} + v_x}{2}\right)t = \frac{v_x}{2}(4.0\ \text{s}) = (2.0\ \text{s})v_x$$

The total distance traveled is 100 m, so $d_1 + d_2 = 100$ m. This gives $(5.1\ \text{s})v_x + (2.0\ \text{s})v_x = 100$ m.

$v_x = \dfrac{100\ \text{m}}{7.1\ \text{s}} = 14.08$ m/s.

Now we can calculate $a_{\text{av-}x}$: $a_{\text{av-}x} = \dfrac{v_x - v_{0x}}{t} = \dfrac{14.08\ \text{m/s} - 0}{4.0\ \text{s}} = 3.5\ \text{m/s}^2$.

(b) For this time interval the velocity is constant, so $a_{\text{av-}x} = 0$.

EVALUATE: Now that we have v_x we can calculate $d_1 = (5.1\ \text{s})(14.08\ \text{m/s}) = 71.8\ \text{m}$ and $d_2 = (2.0\ \text{s})(14.08\ \text{m/s}) = 28.2\ \text{m}$. So, $d_1 + d_2 = 100$ m, which checks.

(c) IDENTIFY and **SET UP:** $a_{\text{av-}x} = \dfrac{v_x - v_{0x}}{t}$, where now the time interval is the full 9.1 s of the race.

We have calculated the final speed to be 14.08 m/s, so

$$a_{\text{av-}x} = \frac{14.08\ \text{m/s}}{9.1\ \text{s}} = 1.5\ \text{m/s}^2.$$

EVALUATE: The acceleration is zero for the last 5.1 s, so it makes sense for the answer in part **(c)** to be less than half the answer in part (a).

(d) The runner spends different times moving with the average accelerations of parts (a) and (b).

2.66. **IDENTIFY:** Apply the constant acceleration equations to the motion of the sled. The average velocity for a time interval Δt is $v_{\text{av-}x} = \dfrac{\Delta x}{\Delta t}$.

SET UP: Let $+x$ be parallel to the incline and directed down the incline. The problem doesn't state how much time it takes the sled to go from the top to 14.4 m from the top.

EXECUTE: **(a)** 14.4 m to 25.6 m: $v_{\text{av-}x} = \dfrac{25.6\ \text{m} - 14.4\ \text{m}}{2.00\ \text{s}} = 5.60$ m/s. 25.6 to 40.0 m:

$v_{\text{av-}x} = \dfrac{40.0\ \text{m} - 25.6\ \text{m}}{2.00\ \text{s}} = 7.20$ m/s. 40.0 m to 57.6 m: $v_{\text{av-}x} = \dfrac{57.6\ \text{m} - 40.0\ \text{m}}{2.00\ \text{s}} = 8.80$ m/s.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) For each segment we know $x - x_0$ and t but we don't know v_{0x} or v_x. Let $x_1 = 14.4$ m and $x_2 = 25.6$ m. For this interval $\left(\frac{v_1 + v_2}{2}\right) = \frac{x_2 - x_1}{t}$ and $at = v_2 - v_1$. Solving for v_2 gives $v_2 = \frac{1}{2}at + \frac{x_2 - x_1}{t}$. Let $x_2 = 25.6$ m and $x_3 = 40.0$ m. For this second interval, $\left(\frac{v_2 + v_3}{2}\right) = \frac{x_3 - x_2}{t}$ and $at = v_3 - v_2$. Solving for v_2 gives $v_2 = -\frac{1}{2}at + \frac{x_3 - x_2}{t}$. Setting these two expressions for v_2 equal to each other and solving for a gives $a = \frac{1}{t^2}[(x_3 - x_2) - (x_2 - x_1)] = \frac{1}{(2.00\text{ s})^2}[(40.0\text{ m} - 25.6\text{ m}) - (25.6\text{ m} - 14.4\text{ m})] = 0.80\text{ m/s}^2$.

Note that this expression for a says $a = \frac{v_{\text{av-23}} - v_{\text{av-12}}}{t}$, where $v_{\text{av-12}}$ and $v_{\text{av-23}}$ are the average speeds for successive 2.00 s intervals.

(c) For the motion from $x = 14.4$ m to $x = 25.6$ m, $x - x_0 = 11.2$ m, $a_x = 0.80\text{ m/s}^2$ and $t = 2.00$ s.

$x - x_0 = v_{0x}t + \frac{1}{2}a_xt^2$ gives $v_{0x} = \frac{x - x_0}{t} - \frac{1}{2}a_xt = \frac{11.2\text{ m}}{2.00\text{ s}} - \frac{1}{2}(0.80\text{ m/s}^2)(2.00\text{ s}) = 4.80\text{ m/s}$.

(d) For the motion from $x = 0$ to $x = 14.4$ m, $x - x_0 = 14.4$ m, $v_{0x} = 0$, and $v_x = 4.8$ m/s.

$x - x_0 = \left(\frac{v_{0x} + v_x}{2}\right)t$ gives $t = \frac{2(x - x_0)}{v_{0x} + v_x} = \frac{2(14.4\text{ m})}{4.8\text{ m/s}} = 6.0\text{ s}$.

(e) For this 1.00 s time interval, $t = 1.00$ s, $v_{0x} = 4.8$ m/s, $a_x = 0.80\text{ m/s}^2$.

$x - x_0 = v_{0x}t + \frac{1}{2}a_xt^2 = (4.8\text{ m/s})(1.00\text{ s}) + \frac{1}{2}(0.80\text{ m/s}^2)(1.00\text{ s})^2 = 5.2\text{ m}$.

EVALUATE: With $x = 0$ at the top of the hill, $x(t) = v_{0x}t + \frac{1}{2}a_xt^2 = (0.40\text{ m/s}^2)t^2$. We can verify that $t = 6.0$ s gives $x = 14.4$ m, $t = 8.0$ s gives 25.6 m, $t = 10.0$ s gives 40.0 m, and $t = 12.0$ s gives 57.6 m.

2.67. **IDENTIFY:** When the graph of v_x versus t is a straight line the acceleration is constant, so this motion consists of two constant acceleration segments and the constant acceleration equations can be used for each segment. Since v_x is always positive the motion is always in the $+x$ direction and the total distance moved equals the magnitude of the displacement. The acceleration a_x is the slope of the v_x versus t graph.

SET UP: For the $t = 0$ to $t = 10.0$ s segment, $v_{0x} = 4.00$ m/s and $v_x = 12.0$ m/s. For the $t = 10.0$ s to 12.0 s segment, $v_{0x} = 12.0$ m/s and $v_x = 0$.

EXECUTE: **(a)** For $t = 0$ to $t = 10.0$ s, $x - x_0 = \left(\frac{v_{0x} + v_x}{2}\right)t = \left(\frac{4.00\text{ m/s} + 12.0\text{ m/s}}{2}\right)(10.0\text{ s}) = 80.0\text{ m}$.

For $t = 10.0$ s to $t = 12.0$ s, $x - x_0 = \left(\frac{12.0\text{ m/s} + 0}{2}\right)(2.00\text{ s}) = 12.0\text{ m}$. The total distance traveled is 92.0 m.

(b) $x - x_0 = 80.0\text{ m} + 12.0\text{ m} = 92.0\text{ m}$

(c) For $t = 0$ to 10.0 s, $a_x = \frac{12.0\text{ m/s} - 4.00\text{ m/s}}{10.0\text{ s}} = 0.800\text{ m/s}^2$. For $t = 10.0$ s to 12.0 s, $a_x = \frac{0 - 12.0\text{ m/s}}{2.00\text{ s}} = -6.00\text{ m/s}^2$. The graph of a_x versus t is given in Figure 2.67.

EVALUATE: When v_x and a_x are both positive, the speed increases. When v_x is positive and a_x is negative, the speed decreases.

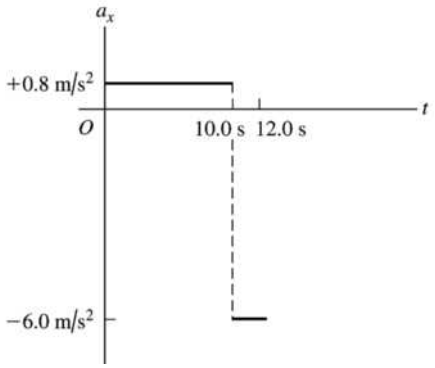

Figure 2.67

2.68. **IDENTIFY:** When the graph of v_x versus t is a straight line the acceleration is constant, so this motion consists of two constant acceleration segments and the constant acceleration equations can be used for each segment. For $t = 0$ to 5.0 s, v_x is positive and the ball moves in the $+x$ direction. For $t = 5.0$ s to 20.0 s, v_x is negative and the ball moves in the $-x$ direction. The acceleration a_x is the slope of the v_x versus t graph.

SET UP: For the $t = 0$ to $t = 5.0$ s segment, $v_{0x} = 0$ and $v_x = 30.0$ m/s. For the $t = 5.0$ s to $t = 20.0$ s segment, $v_{0x} = -20.0$ m/s and $v_x = 0$.

EXECUTE: **(a)** For $t = 0$ to 5.0 s, $x - x_0 = \left(\frac{v_{0x} + v_x}{2}\right)t = \left(\frac{0 + 30.0 \text{ m/s}}{2}\right)(5.0 \text{ m/s}) = 75.0$ m. The ball travels a distance of 75.0 m. For $t = 5.0$ s to 20.0 s, $x - x_0 = \left(\frac{-20.0 \text{ m/s} + 0}{2}\right)(15.0 \text{ m/s}) = -150.0$ m. The total distance traveled is $75.0 \text{ m} + 150.0 \text{ m} = 225.0$ m.

(b) The total displacement is $x - x_0 = 75.0 \text{ m} + (-150.0 \text{ m}) = -75.0$ m. The ball ends up 75.0 m in the negative x-direction from where it started.

(c) For $t = 0$ to 5.0 s, $a_x = \frac{30.0 \text{ m/s} - 0}{5.0 \text{ s}} = 6.00 \text{ m/s}^2$. For $t = 5.0$ s to 20.0 s, $a_x = \frac{0 - (-20.0 \text{ m/s})}{15.0 \text{ s}} = +1.33 \text{ m/s}^2$. The graph of a_x versus t is given in Figure 2.68.

(d) The ball is in contact with the floor for a small but nonzero period of time and the direction of the velocity doesn't change instantaneously. So, no, the actual graph of $v_x(t)$ is not really vertical at 5.00 s.

EVALUATE: For $t = 0$ to 5.0 s, both v_x and a_x are positive and the speed increases. For $t = 5.0$ s to 20.0 s, v_x is negative and a_x is positive and the speed decreases. Since the direction of motion is not the same throughout, the displacement is not equal to the distance traveled.

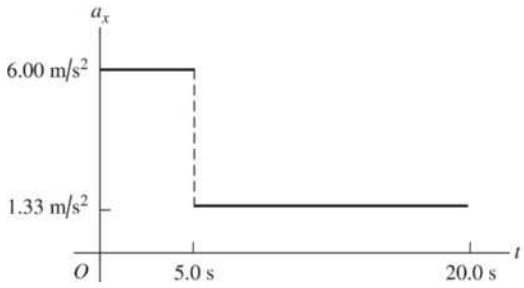

Figure 2.68

2.69. **IDENTIFY** and **SET UP:** Apply constant acceleration equations.
Find the velocity at the start of the second 5.0 s; this is the velocity at the end of the first 5.0 s. Then find $x - x_0$ for the first 5.0 s.

EXECUTE: For the first 5.0 s of the motion, $v_{0x} = 0,\ t = 5.0$ s.

$v_x = v_{0x} + a_x t$ gives $v_x = a_x(5.0\text{ s})$.

This is the initial speed for the second 5.0 s of the motion. For the second 5.0 s:

$v_{0x} = a_x(5.0\text{ s}),\ t = 5.0\text{ s},\ x - x_0 = 150\text{ m}$.

$x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2$ gives $150\text{ m} = (25\text{ s}^2)a_x + (12.5\text{ s}^2)a_x$ and $a_x = 4.0\text{ m/s}^2$

Use this a_x and consider the first 5.0 s of the motion:

$x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2 = 0 + \frac{1}{2}(4.0\text{ m/s}^2)(5.0\text{ s})^2 = 50.0\text{ m}$.

EVALUATE: The ball is speeding up so it travels farther in the second 5.0 s interval than in the first. In fact, $x - x_0$ is proportional to t^2 since it starts from rest. If it goes 50.0 m in 5.0 s, in twice the time (10.0 s) it should go four times as far. In 10.0 s we calculated it went $50\text{ m} + 150\text{ m} = 200$ m, which is four times 50 m.

2.70. **IDENTIFY:** Apply $x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2$ to the motion of each train. A collision means the front of the passenger train is at the same location as the caboose of the freight train at some common time.

SET UP: Let P be the passenger train and F be the freight train. For the front of the passenger train $x_0 = 0$ and for the caboose of the freight train $x_0 = 200$ m. For the freight train $v_F = 15.0$ m/s and $a_F = 0$. For the passenger train $v_P = 25.0$ m/s and $a_P = -0.100\text{ m/s}^2$.

EXECUTE: **(a)** $x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2$ for each object gives $x_P = v_P t + \frac{1}{2}a_P t^2$ and $x_F = 200\text{ m} + v_F t$. Setting $x_P = x_F$ gives $v_P t + \frac{1}{2}a_P t^2 = 200\text{ m} + v_F t$. $(0.0500\text{ m/s}^2)t^2 - (10.0\text{ m/s})t + 200\text{ m} = 0$. The quadratic formula gives $t = \dfrac{1}{0.100}\left(+10.0 \pm \sqrt{(10.0)^2 - 4(0.0500)(200)}\right)\text{ s} = (100 \pm 77.5)\text{ s}$. The collision occurs at $t = 100\text{ s} - 77.5\text{ s} = 22.5$ s. The equations that specify a collision have a physical solution (real, positive t), so a collision does occur.

(b) $x_P = (25.0\text{ m/s})(22.5\text{ s}) + \frac{1}{2}(-0.100\text{ m/s}^2)(22.5\text{ s})^2 = 537$ m. The passenger train moves 537 m before the collision. The freight train moves $(15.0\text{ m/s})(22.5\text{ s}) = 337$ m.

(c) The graphs of x_F and x_P versus t are sketched in Figure 2.70.

EVALUATE: The second root for the equation for t, $t = 177.5$ s is the time the trains would meet again if they were on parallel tracks and continued their motion after the first meeting.

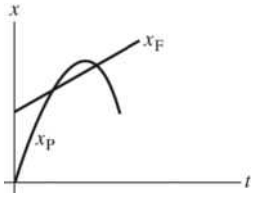

Figure 2.70

2.71. **IDENTIFY:** Apply constant acceleration equations to the motion of the two objects, you and the cockroach. You catch up with the roach when both objects are at the same place at the same time. Let T be the time when you catch up with the cockroach.

SET UP: Take $x = 0$ to be at the $t = 0$ location of the roach and positive x to be in the direction of motion of the two objects.

roach:

$v_{0x} = 1.50\text{ m/s},\ a_x = 0,\ x_0 = 0,\ x = 1.20\text{ m},\ t = T$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

you:
$v_{0x} = 0.80$ m/s, $x_0 = -0.90$ m, $x = 1.20$ m, $t = T$, $a_x = ?$

Apply $x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2$ to both objects:

EXECUTE: roach: $1.20\text{ m} = (1.50\text{ m/s})T$, so $T = 0.800$ s.

you: $1.20\text{ m} - (-0.90\text{ m}) = (0.80\text{ m/s})T + \frac{1}{2}a_x T^2$

$2.10\text{ m} = (0.80\text{ m/s})(0.800\text{ s}) + \frac{1}{2}a_x(0.800\text{ s})^2$

$2.10\text{ m} = 0.64\text{ m} + (0.320\text{ s}^2)a_x$

$a_x = 4.6\text{ m/s}^2$.

EVALUATE: Your final velocity is $v_x = v_{0x} + a_x t = 4.48$ m/s. Then $x - x_0 = \left(\frac{v_{0x} + v_x}{2}\right)t = 2.10$ m, which checks. You have to accelerate to a speed greater than that of the roach so you will travel the extra 0.90 m you are initially behind.

2.72. **IDENTIFY:** The insect has constant speed 15 m/s during the time it takes the cars to come together.
SET UP: Each car has moved 100 m when they hit.

EXECUTE: The time until the cars hit is $\frac{100\text{ m}}{10\text{ m/s}} = 10$ s. During this time the grasshopper travels a distance of $(15\text{ m/s})(10\text{ s}) = 150$ m.

EVALUATE: The grasshopper ends up 100 m from where it started, so the magnitude of his final displacement is 100 m. This is less than the total distance he travels since he spends part of the time moving in the opposite direction.

2.73. **IDENTIFY:** Apply constant acceleration equations to each object.
Take the origin of coordinates to be at the initial position of the truck, as shown in Figure 2.73a.
Let d be the distance that the auto initially is behind the truck, so $x_0(\text{auto}) = -d$ and $x_0(\text{truck}) = 0$. Let T be the time it takes the auto to catch the truck. Thus at time T the truck has undergone a displacement $x - x_0 = 40.0$ m, so is at $x = x_0 + 40.0\text{ m} = 40.0$ m. The auto has caught the truck so at time T is also at $x = 40.0$ m.

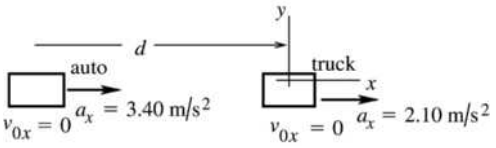

Figure 2.73a

(a) SET UP: Use the motion of the truck to calculate T:
$x - x_0 = 40.0$ m, $v_{0x} = 0$ (starts from rest), $a_x = 2.10\text{ m/s}^2$, $t = T$

$x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2$

Since $v_{0x} = 0$, this gives $t = \sqrt{\frac{2(x - x_0)}{a_x}}$

EXECUTE: $T = \sqrt{\frac{2(40.0\text{ m})}{2.10\text{ m/s}^2}} = 6.17$ s

(b) SET UP: Use the motion of the auto to calculate d:
$x - x_0 = 40.0\text{ m} + d$, $v_{0x} = 0$, $a_x = 3.40\text{ m/s}^2$, $t = 6.17$ s

$x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: $d + 40.0 \text{ m} = \frac{1}{2}(3.40 \text{ m/s}^2)(6.17 \text{ s})^2$

$d = 64.8 \text{ m} - 40.0 \text{ m} = 24.8 \text{ m}$

(c) auto: $v_x = v_{0x} + a_x t = 0 + (3.40 \text{ m/s}^2)(6.17 \text{ s}) = 21.0 \text{ m/s}$

truck: $v_x = v_{0x} + a_x t = 0 + (2.10 \text{ m/s}^2)(6.17 \text{ s}) = 13.0 \text{ m/s}$

(d) The graph is sketched in Figure 2.73b.

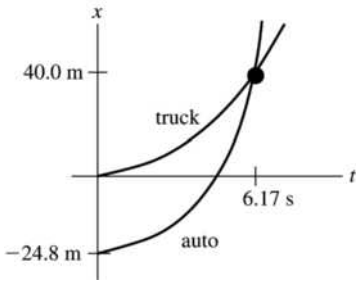

Figure 2.73b

EVALUATE: In part (c) we found that the auto was traveling faster than the truck when they came abreast. The graph in part (d) agrees with this: at the intersection of the two curves the slope of the *x*-*t* curve for the auto is greater than that of the truck. The auto must have an average velocity greater than that of the truck since it must travel farther in the same time interval.

2.74. **IDENTIFY:** Apply the constant acceleration equations to the motion of each car. The collision occurs when the cars are at the same place at the same time.

SET UP: Let $+x$ be to the right. Let $x = 0$ at the initial location of car 1, so $x_{01} = 0$ and $x_{02} = D$. The cars collide when $x_1 = x_2$. $v_{0x1} = 0$, $a_{x1} = a_x$, $v_{0x2} = -v_0$ and $a_{x2} = 0$.

EXECUTE: **(a)** $x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2$ gives $x_1 = \frac{1}{2}a_x t^2$ and $x_2 = D - v_0 t$. $x_1 = x_2$ gives $\frac{1}{2}a_x t^2 = D - v_0 t$. $\frac{1}{2}a_x t^2 + v_0 t - D = 0$. The quadratic formula gives $t = \frac{1}{a_x}\left(-v_0 \pm \sqrt{v_0^2 + 2a_x D}\right)$. Only the positive root is physical, so $t = \frac{1}{a_x}\left(-v_0 + \sqrt{v_0^2 + 2a_x D}\right)$.

(b) $v_1 = a_x t = \sqrt{v_0^2 + 2a_x D} - v_0$

(c) The *x*-*t* and v_x-*t* graphs for the two cars are sketched in Figure 2.74.

EVALUATE: In the limit that $a_x = 0$, $D - v_0 t = 0$ and $t = D/v_0$, the time it takes car 2 to travel distance *D*. In the limit that $v_0 = 0$, $t = \sqrt{\frac{2D}{a_x}}$, the time it takes car 1 to travel distance *D*.

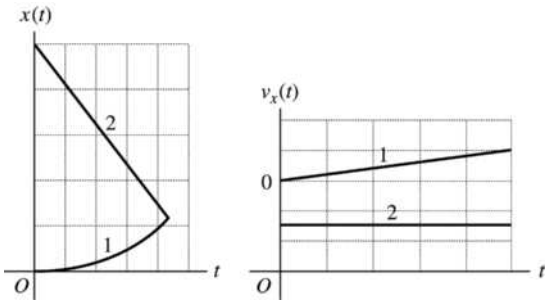

Figure 2.74

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

2.75. **IDENTIFY:** The average speed is the distance traveled divided by the time. The average velocity is $v_{\text{av-}x} = \dfrac{\Delta x}{\Delta t}$.

SET UP: The distance the ball travels is half the circumference of a circle of diameter 50.0 cm so is $\frac{1}{2}\pi d = \frac{1}{2}\pi(50.0 \text{ cm}) = 78.5 \text{ cm}$. Let $+x$ be horizontally from the starting point toward the ending point, so Δx equals the diameter of the bowl.

EXECUTE: **(a)** The average speed is $\dfrac{\frac{1}{2}\pi d}{t} = \dfrac{78.5 \text{ cm}}{10.0 \text{ s}} = 7.85 \text{ cm/s}$.

(b) The average velocity is $v_{\text{av-}x} = \dfrac{\Delta x}{\Delta t} = \dfrac{50.0 \text{ cm}}{10.0 \text{ s}} = 5.00 \text{ cm/s}$.

EVALUATE: The average speed is greater than the magnitude of the average velocity, since the distance traveled is greater than the magnitude of the displacement.

2.76. **IDENTIFY:** The acceleration is not constant so the constant acceleration equations cannot be used. Instead, use $a_x(t) = \dfrac{dv_x}{dt}$ and $x = x_0 + \int_0^t v_x(t)dt$.

SET UP: $\int t^n dt = \dfrac{1}{n+1}t^{n+1}$ for $n \geq 0$.

EXECUTE: **(a)** $x(t) = x_0 + \int_0^t [\alpha - \beta t^2]dt = x_0 + \alpha t - \frac{1}{3}\beta t^3$. $x = 0$ at $t = 0$ gives $x_0 = 0$ and

$x(t) = \alpha t - \frac{1}{3}\beta t^3 = (4.00 \text{ m/s})t - (0.667 \text{ m/s}^3)t^3$. $a_x(t) = \dfrac{dv_x}{dt} = -2\beta t = -(4.00 \text{ m/s}^3)t$.

(b) The maximum positive x is when $v_x = 0$ and $a_x < 0$. $v_x = 0$ gives $\alpha - \beta t^2 = 0$ and

$t = \sqrt{\dfrac{\alpha}{\beta}} = \sqrt{\dfrac{4.00 \text{ m/s}}{2.00 \text{ m/s}^3}} = 1.41 \text{ s}$. At this t, a_x is negative. For $t = 1.41$ s,

$x = (4.00 \text{ m/s})(1.41 \text{ s}) - (0.667 \text{ m/s}^3)(1.41 \text{ s})^3 = 3.77 \text{ m}$.

EVALUATE: After $t = 1.41$ s the object starts to move in the $-x$ direction and goes to $x = -\infty$ as $t \to \infty$.

2.77. **IDENTIFY:** Apply constant acceleration equations to each vehicle.

SET UP: **(a)** It is very convenient to work in coordinates attached to the truck.
Note that these coordinates move at constant velocity relative to the earth. In these coordinates the truck is at rest, and the initial velocity of the car is $v_{0x} = 0$. Also, the car's acceleration in these coordinates is the same as in coordinates fixed to the earth.

EXECUTE: First, let's calculate how far the car must travel relative to the truck: The situation is sketched in Figure 2.77.

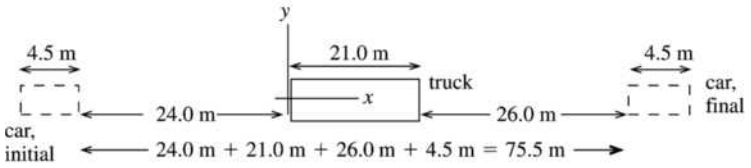

Figure 2.77

The car goes from $x_0 = -24.0$ m to $x = 51.5$ m. So $x - x_0 = 75.5$ m for the car.

Calculate the time it takes the car to travel this distance:

$a_x = 0.600 \text{ m/s}^2$, $v_{0x} = 0$, $x - x_0 = 75.5 \text{ m}$, $t = ?$

$x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2$

$t = \sqrt{\dfrac{2(x - x_0)}{a_x}} = \sqrt{\dfrac{2(75.5 \text{ m})}{0.600 \text{ m/s}^2}} = 15.86 \text{ s}$

It takes the car 15.9 s to pass the truck.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) Need how far the car travels relative to the earth, so go now to coordinates fixed to the earth. In these coordinates $v_{0x} = 20.0$ m/s for the car. Take the origin to be at the initial position of the car.

$v_{0x} = 20.0$ m/s, $a_x = 0.600$ m/s^2, $t = 15.86$ s, $x - x_0 = ?$

$x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2 = (20.0 \text{ m/s})(15.86 \text{ s}) + \frac{1}{2}(0.600 \text{ m/s}^2)(15.86 \text{ s})^2$

$x - x_0 = 317.2 \text{ m} + 75.5 \text{ m} = 393 \text{ m}.$

(c) In coordinates fixed to the earth:

$v_x = v_{0x} + a_x t = 20.0 \text{ m/s} + (0.600 \text{ m/s}^2)(15.86 \text{ s}) = 29.5 \text{ m/s}$

EVALUATE: In 15.86 s the truck travels $x - x_0 = (20.0 \text{ m/s})(15.86 \text{ s}) = 317.2$ m. The car travels $392.7 \text{ m} - 317.2 \text{ m} = 75 \text{ m}$ farther than the truck, which checks with part (a). In coordinates attached to the truck, for the car $v_{0x} = 0$, $v_x = 9.5$ m/s and in 15.86 s the car travels $x - x_0 = \left(\frac{v_{0x} + v_x}{2}\right)t = 75$ m, which checks with part (a).

2.78. **IDENTIFY:** Use a velocity-time graph to find the acceleration of a stone. Then use that information to find how long it takes the stone to fall through a known distance and how fast you would have to throw it upward to reach a given height and the time to reach that height.

SET UP: Take $+y$ to be downward. The acceleration is the slope of the v_y versus t graph.

EXECUTE: **(a)** Since v_y is downward, it is positive and equal to the speed v. The v versus t graph has slope $a_y = \dfrac{30.0 \text{ m/s}}{2.0 \text{ s}} = 15 \text{ m/s}^2$. The formulas $y = y_0 + v_{0y}t + \frac{1}{2}a_y t^2$, $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$, and $v_y = v_y + a_y t$ apply.

(b) $v_{0y} = 0$ and let $y_0 = 0$. $y = y_0 + v_{0y}t + \frac{1}{2}a_y t^2$ gives $t = \sqrt{\dfrac{2y}{a_y}} = \sqrt{\dfrac{2(3.5 \text{ m})}{15 \text{ m/s}^2}} = 0.68$ s.

$v_y = v_{0y} + a_y t = (15 \text{ m/s}^2)(0.68 \text{ s}) = 10.2 \text{ m/s}.$

(c) At the maximum height, $v_y = 0$. Let $y_0 = 0$. $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ gives

$v_{0y} = \sqrt{-2a_y(y - y_0)} = \sqrt{-2(-15 \text{ m/s}^2)(18.0 \text{ m})} = 23 \text{ m/s}$. $v_y = v_y + a_y t$ gives

$t = \dfrac{v_y - v_{0y}}{a_y} = \dfrac{0 - 23 \text{ m/s}}{-15 \text{ m/s}^2} = 1.5 \text{ s}.$

EVALUATE: The acceleration is 9.80 m/s^2, downward, throughout the motion. The velocity initially is upward, decreases to zero because of the downward acceleration and then is downward and increasing in magnitude because of the downward acceleration.

2.79. $a(t) = \alpha + \beta t$, with $\alpha = -2.00 \text{ m/s}^2$ and $\beta = 3.00 \text{ m/s}^3$

(a) IDENTIFY and **SET UP:** Integrate $a_x(t)$ to find $v_x(t)$ and then integrate $v_x(t)$ to find $x(t)$.

EXECUTE: $v_x = v_{0x} + \int_0^t a_x \, dt = v_{0x} + \int_0^t (\alpha + \beta t) \, dt = v_{0x} + \alpha t + \frac{1}{2}\beta t^2$

$x = x_0 + \int_0^t v_x \, dt = x_0 + \int_0^t (v_{0x} + \alpha t + \frac{1}{2}\beta t^2) \, dt = x_0 + v_{0x}t + \frac{1}{2}\alpha t^2 + \frac{1}{6}\beta t^3$

At $t = 0$, $x = x_0$.

To have $x = x_0$ at $t_1 = 4.00$ s requires that $v_{0x}t_1 + \frac{1}{2}\alpha t_1^2 + \frac{1}{6}\beta t_1^3 = 0$.

Thus $v_{0x} = -\frac{1}{6}\beta t_1^2 - \frac{1}{2}\alpha t_1 = -\frac{1}{6}(3.00 \text{ m/s}^3)(4.00 \text{ s})^2 - \frac{1}{2}(-2.00 \text{ m/s}^2)(4.00 \text{ s}) = -4.00 \text{ m/s}.$

(b) With v_{0x} as calculated in part (a) and $t = 4.00$ s,

$v_x = v_{0x} + \alpha t + \frac{1}{2}\beta t^2 = -4.00 \text{ s} + (-2.00 \text{ m/s}^2)(4.00 \text{ s}) + \frac{1}{2}(3.00 \text{ m/s}^3)(4.00 \text{ s})^2 = +12.0 \text{ m/s}.$

EVALUATE: $a_x = 0$ at $t = 0.67$ s. For $t > 0.67$ s, $a_x > 0$. At $t = 0$, the particle is moving in the $-x$-direction and is speeding up. After $t = 0.67$ s, when the acceleration is positive, the object slows down and then starts to move in the $+x$-direction with increasing speed.

2.80. **IDENTIFY:** Find the distance the professor walks during the time t it takes the egg to fall to the height of his head.

SET UP: Let $+y$ be downward. The egg has $v_{0y} = 0$ and $a_y = 9.80 \text{ m/s}^2$. At the height of the professor's head, the egg has $y - y_0 = 44.2$ m.

EXECUTE: $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$ gives $t = \sqrt{\dfrac{2(y-y_0)}{a_y}} = \sqrt{\dfrac{2(44.2 \text{ m})}{9.80 \text{ m/s}^2}} = 3.00$ s. The professor walks a distance $x - x_0 = v_{0x}t = (1.20 \text{ m/s})(3.00 \text{ s}) = 3.60$ m. Release the egg when your professor is 3.60 m from the point directly below you.

EVALUATE: Just before the egg lands its speed is $(9.80 \text{ m/s}^2)(3.00\text{s}) = 29.4$ m/s. It is traveling much faster than the professor.

2.81. **IDENTIFY:** Use the constant acceleration equations to establish a relationship between maximum height and acceleration due to gravity and between time in the air and acceleration due to gravity.

SET UP: Let $+y$ be upward. At the maximum height, $v_y = 0$. When the rock returns to the surface, $y - y_0 = 0$.

EXECUTE: **(a)** $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ gives $a_y H = -\frac{1}{2}v_{0y}^2$, which is constant, so $a_E H_E = a_M H_M$.

$$H_M = H_E\left(\frac{a_E}{a_M}\right) = H\left(\frac{9.80 \text{ m/s}^2}{3.71 \text{ m/s}^2}\right) = 2.64H.$$

(b) $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$ with $y - y_0 = 0$ gives $a_y t = -2v_{0y}$, which is constant, so $a_E T_E = a_M T_M$.

$$T_M = T_E\left[\frac{a_E}{a_M}\right] = 2.64T.$$

EVALUATE: On Mars, where the acceleration due to gravity is smaller, the rocks reach a greater height and are in the air for a longer time.

2.82. **IDENTIFY:** Calculate the time it takes her to run to the table and return. This is the time in the air for the thrown ball. The thrown ball is in free-fall after it is thrown. Assume air resistance can be neglected.

SET UP: For the thrown ball, let $+y$ be upward. $a_y = -9.80 \text{ m/s}^2$. $y - y_0 = 0$ when the ball returns to its original position.

EXECUTE: **(a)** It takes her $\dfrac{5.50 \text{ m}}{2.50 \text{ m/s}} = 2.20$ s to reach the table and an equal time to return. For the ball, $y - y_0 = 0$, $t = 4.40$ s and $a_y = -9.80 \text{ m/s}^2$. $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$ gives

$v_{0y} = -\frac{1}{2}a_y t = -\frac{1}{2}(-9.80 \text{ m/s}^2)(4.40 \text{ s}) = 21.6$ m/s.

(b) Find $y - y_0$ when $t = 2.20$ s.

$y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2 = (21.6 \text{ m/s})(2.20 \text{ s}) + \frac{1}{2}(-9.80 \text{ m/s}^2)(2.20 \text{ s})^2 = 23.8$ m

EVALUATE: It takes the ball the same amount of time to reach its maximum height as to return from its maximum height, so when she is at the table the ball is at its maximum height. Note that this large maximum height requires that the act either be done outdoors, or in a building with a very high ceiling.

2.83. **(a) IDENTIFY:** Use constant acceleration equations, with $a_y = g$, downward, to calculate the speed of the diver when she reaches the water.

SET UP: Take the origin of coordinates to be at the platform, and take the $+y$-direction to be downward.

$y - y_0 = +21.3$ m, $a_y = +9.80 \text{ m/s}^2$, $v_{0y} = 0$ (since diver just steps off), $v_y = ?$

$v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: $v_y = +\sqrt{2a_y(y-y_0)} = +\sqrt{2(9.80\text{ m/s}^2)(21.3\text{ m})} = +20.4\text{ m/s}$.

We know that v_y is positive because the diver is traveling downward when she reaches the water.

The announcer has exaggerated the speed of the diver.

EVALUATE: We could also use $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$ to find $t = 2.085$ s. The diver gains 9.80 m/s of speed each second, so has $v_y = (9.80\text{ m/s}^2)(2.085\text{ s}) = 20.4\text{ m/s}$ when she reaches the water, which checks.

(b) IDENTIFY: Calculate the initial upward velocity needed to give the diver a speed of 25.0 m/s when she reaches the water. Use the same coordinates as in part (a).

SET UP: $v_{0y} = ?,\ v_y = +25.0\text{ m/s},\ a_y = +9.80\text{ m/s}^2,\ y - y_0 = +21.3\text{ m}$

$v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$

EXECUTE: $v_{0y} = -\sqrt{v_y^2 - 2a_y(y-y_0)} = -\sqrt{(25.0\text{ m/s})^2 - 2(9.80\text{ m/s}^2)(21.3\text{ m})} = -14.4\text{ m/s}$

(v_{0y} is negative since the direction of the initial velocity is upward.)

EVALUATE: One way to decide if this speed is reasonable is to calculate the maximum height above the platform it would produce:

$v_{0y} = -14.4\text{ m/s},\ v_y = 0$ (at maximum height), $a_y = +9.80\text{ m/s}^2,\ y - y_0 = ?$

$v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$

$$y - y_0 = \frac{v_y^2 - v_{0y}^2}{2a_y} = \frac{0 - (-14.4\text{ s})^2}{2(+9.80\text{ m/s})} = -10.6\text{ m}$$

This is not physically attainable; a vertical leap of 10.6 m upward is not possible.

2.84. **IDENTIFY:** The flowerpot is in free-fall. Apply the constant acceleration equations. Use the motion past the window to find the speed of the flowerpot as it reaches the top of the window. Then consider the motion from the windowsill to the top of the window.

SET UP: Let $+y$ be downward. Throughout the motion $a_y = +9.80\text{ m/s}^2$.

EXECUTE: Motion past the window: $y - y_0 = 1.90\text{ m},\ t = 0.420\text{ s},\ a_y = +9.80\text{ m/s}^2$. $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$ gives $v_{0y} = \dfrac{y - y_0}{t} - \frac{1}{2}a_y t = \dfrac{1.90\text{ m}}{0.420\text{ s}} - \frac{1}{2}(9.80\text{ m/s}^2)(0.420\text{ s}) = 2.466\text{ m/s}$. This is the velocity of the flowerpot when it is at the top of the window.

Motion from the windowsill to the top of the window: $v_{0y} = 0,\ v_y = 2.466\text{ m/s},\ a_y = +9.80\text{ m/s}^2$.

$v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ gives $y - y_0 = \dfrac{v_y^2 - v_{0y}^2}{2a_y} = \dfrac{(2.466\text{ m/s})^2 - 0}{2(9.80\text{ m/s}^2)} = 0.310\text{ m}$. The top of the window is 0.310 m below the windowsill.

EVALUATE: It takes the flowerpot $t = \dfrac{v_y - v_{0y}}{a_y} = \dfrac{2.466\text{ m/s}}{9.80\text{ m/s}^2} = 0.252\text{ s}$ to fall from the sill to the top of the window. Our result says that from the windowsill the pot falls $0.310\text{ m} + 1.90\text{ m} = 2.21\text{ m}$ in $0.252\text{ s} + 0.420\text{ s} = 0.672\text{ s}$. $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2 = \frac{1}{2}(9.80\text{ m/s}^2)(0.672\text{ s})^2 = 2.21\text{ m}$, which checks.

2.85. **(a) IDENTIFY:** Consider the motion from when he applies the acceleration to when the shot leaves his hand.

SET UP: Take positive y to be upward. $v_{0y} = 0,\ v_y = ?,\ a_y = 35.0\text{ m/s}^2,\ y - y_0 = 0.640\text{ m}$,

$v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$

EXECUTE: $v_y = \sqrt{2a_y(y-y_0)} = \sqrt{2(35.0\text{ m/s}^2)(0.640\text{ m})} = 6.69\text{ m/s}$

(b) IDENTIFY: Consider the motion of the shot from the point where he releases it to its maximum height, where $v = 0$. Take $y = 0$ at the ground.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

SET UP: $y_0 = 2.20$ m, $y = ?$, $a_y = -9.80$ m/s^2 (free fall), $v_{0y} = 6.69$ m/s (from part (a), $v_y = 0$ at maximum height), $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$

EXECUTE: $y - y_0 = \dfrac{v_y^2 - v_{0y}^2}{2a_y} = \dfrac{0 - (6.69 \text{ m/s})^2}{2(-9.80 \text{ m/s}^2)} = 2.29$ m, $y = 2.20 \text{ m} + 2.29 \text{ m} = 4.49$ m.

(c) IDENTIFY: Consider the motion of the shot from the point where he releases it to when it returns to the height of his head. Take $y = 0$ at the ground.

SET UP: $y_0 = 2.20$ m, $y = 1.83$ m, $a_y = -9.80$ m/s^2, $v_{0y} = +6.69$ m/s, $t = ?$ $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$

EXECUTE: $1.83 \text{ m} - 2.20 \text{ m} = (6.69 \text{ m/s})t + \frac{1}{2}(-9.80 \text{ m/s}^2)t^2 = (6.69 \text{ m/s})t - (4.90 \text{ m/s}^2)t^2$,

$4.90t^2 - 6.69t - 0.37 = 0$, with t in seconds. Use the quadratic formula to solve for t:

$t = \dfrac{1}{9.80}\left(6.69 \pm \sqrt{(6.69)^2 - 4(4.90)(-0.37)}\right) = 0.6830 \pm 0.7362$. Since t must be positive,

$t = 0.6830 \text{ s} + 0.7362 \text{ s} = 1.42$ s.

EVALUATE: Calculate the time to the maximum height: $v_y = v_{0y} + a_y t$, so $t = (v_y - v_{0y})/a_y =$ $-(6.69 \text{ m/s})/(-9.80 \text{ m/s}^2) = 0.68$ s. It also takes 0.68 s to return to 2.2 m above the ground, for a total time of 1.36 s. His head is a little lower than 2.20 m, so it is reasonable for the shot to reach the level of his head a little later than 1.36 s after being thrown; the answer of 1.42 s in part (c) makes sense.

2.86. **IDENTIFY:** The motion of the rocket can be broken into 3 stages, each of which has constant acceleration, so in each stage we can use the standard kinematics formulas for constant acceleration. But the acceleration is not the same throughout all 3 stages.

SET UP: The formulas $y - y_0 = \left(\dfrac{v_{0y} + v_y}{2}\right)t$, $y - y_0 = v_{0y}t + \dfrac{1}{2}a_y t^2$, and $v_y = v_{0y} + a_y t$ apply.

EXECUTE: **(a)** Let $+y$ be upward. At $t = 25.0$ s, $y - y_0 = 1094$ m and $v_y = 87.5$ m/s. During the next 10.0 s the rocket travels upward an additional distance $y - y_0 = \left(\dfrac{v_{0y} + v_y}{2}\right)t = \left(\dfrac{87.5 \text{ m/s} + 132.5 \text{ m/s}}{2}\right)(10.0 \text{ s}) = 1100$ m.

The height above the launch pad when the second stage quits therefore is $1094 \text{ m} + 1100 \text{ m} = 2194$ m.

For the free-fall motion after the second stage quits: $y - y_0 = \dfrac{v_y^2 - v_{0y}^2}{2a_y} = \dfrac{0 - (132.5 \text{ m/s})^2}{2(-9.8 \text{ m/s}^2)} = 896$ m.

The maximum height above the launch pad that the rocket reaches is $2194 \text{ m} + 896 \text{ m} = 3090$ m.

(b) $y - y_0 = v_{0y}t + \dfrac{1}{2}a_y t^2$ gives $-2194 \text{ m} = (132.5 \text{ m/s})t - (4.9 \text{ m/s}^2)t^2$. From the quadratic formula the positive root is $t = 38.6$ s.

(c) $v_y = v_{0y} + a_y t = 132.5 \text{ m/s} + (-9.8 \text{ m/s}^2)(38.6 \text{ s}) = -246$ m/s. The rocket's speed will be 246 m/s just before it hits the ground.

EVALUATE: We cannot solve this problem in a single step because the acceleration, while constant in each stage, is not constant over the entire motion. The standard kinematics equations apply to each stage but not to the motion as a whole.

2.87. **IDENTIFY** and **SET UP:** Let $+y$ be upward. Each ball moves with constant acceleration $a_y = -9.80$ m/s^2. In parts (c) and (d) require that the two balls be at the same height at the same time.

EXECUTE: **(a)** At ceiling, $v_y = 0$, $y - y_0 = 3.0$ m, $a_y = -9.80$ m/s^2. Solve for v_{0y}.

$v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ gives $v_{0y} = 7.7$ m/s.

(b) $v_y = v_{0y} + a_y t$ with the information from part (a) gives $t = 0.78$ s.

(c) Let the first ball travel downward a distance d in time t. It starts from its maximum height, so $v_{0y} = 0$.

$y - y_0 = v_{0y}t = \frac{1}{2}a_y t^2$ gives $d = (4.9 \text{ m/s}^2)t^2$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

The second ball has $v_{0y} = \frac{2}{3}(7.7 \text{ m/s}) = 5.1 \text{ m/s}$. In time t it must travel upward $3.0 \text{ m} - d$ to be at the same place as the first ball.

$y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$ gives $3.0 \text{ m} - d = (5.1 \text{ m/s})t - (4.9 \text{ m/s}^2)t^2$.

We have two equations in two unknowns, d and t. Solving gives $t = 0.59$ s and $d = 1.7$ m.

(d) $3.0 \text{ m} - d = 1.3$ m

EVALUATE: In 0.59 s the first ball falls $d = (4.9 \text{ m/s}^2)(0.59 \text{ s})^2 = 1.7$ m, so is at the same height as the second ball.

2.88. **IDENTIFY:** The teacher is in free-fall and falls with constant acceleration 9.80 m/s^2, downward. The sound from her shout travels at constant speed. The sound travels from the top of the cliff, reflects from the ground and then travels upward to her present location. If the height of the cliff is h and she falls a distance y in 3.0 s, the sound must travel a distance $h + (h - y)$ in 3.0 s.

SET UP: Let $+y$ be downward, so for the teacher $a_y = 9.80 \text{ m/s}^2$ and $v_{0y} = 0$. Let $y = 0$ at the top of the cliff.

EXECUTE: **(a)** For the teacher, $y = \frac{1}{2}(9.80 \text{ m/s}^2)(3.0 \text{ s})^2 = 44.1$ m. For the sound, $h + (h - y) = v_s t$.

$h = \frac{1}{2}(v_s t + y) = \frac{1}{2}([340 \text{ m/s}][3.0 \text{ s}] + 44.1 \text{ m}) = 532$ m, which rounds to 530 m.

(b) $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ gives $v_y = \sqrt{2a_y(y - y_0)} = \sqrt{2(9.80 \text{ m/s}^2)(532 \text{ m})} = 102$ m/s.

EVALUATE: She is in the air for $t = \dfrac{v_y - v_{0y}}{a_y} = \dfrac{102 \text{ m/s}}{9.80 \text{ m/s}^2} = 10.4$ s and strikes the ground at high speed.

2.89. **IDENTIFY:** The helicopter has two segments of motion with constant acceleration: upward acceleration for 10.0 s and then free-fall until it returns to the ground. Powers has three segments of motion with constant acceleration: upward acceleration for 10.0 s, free-fall for 7.0 s and then downward acceleration of 2.0 m/s^2.

SET UP: Let $+y$ be upward. Let $y = 0$ at the ground.

EXECUTE: **(a)** When the engine shuts off both objects have upward velocity

$v_y = v_{0y} + a_y t = (5.0 \text{ m/s}^2)(10.0 \text{ s}) = 50.0$ m/s and are at $y = v_{0y}t + \frac{1}{2}a_y t^2 = \frac{1}{2}(5.0 \text{ m/s}^2)(10.0 \text{ s})^2 = 250$ m.

For the helicopter, $v_y = 0$ (at the maximum height), $v_{0y} = +50.0$ m/s, $y_0 = 250$ m, and $a_y = -9.80 \text{ m/s}^2$.

$v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ gives $y = \dfrac{v_y^2 - v_{0y}^2}{2a_y} + y_0 = \dfrac{0 - (50.0 \text{ m/s})^2}{2(-9.80 \text{ m/s}^2)} + 250 \text{ m} = 378$ m, which rounds to 380 m.

(b) The time for the helicopter to crash from the height of 250 m where the engines shut off can be found using $v_{0y} = +50.0$ m/s, $a_y = -9.80 \text{ m/s}^2$, and $y - y_0 = -250$ m. $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$ gives

$-250 \text{ m} = (50.0 \text{ m/s})t - (4.90 \text{ m/s}^2)t^2$. $(4.90 \text{ m/s}^2)t^2 - (50.0 \text{ m/s})t - 250 \text{ m} = 0$. The quadratic formula gives

$t = \dfrac{1}{9.80}\left(50.0 \pm \sqrt{(50.0)^2 + 4(4.90)(250)}\right)$ s. Only the positive solution is physical, so $t = 13.9$ s. Powers therefore has free-fall for 7.0 s and then downward acceleration of 2.0 m/s^2 for $13.9 \text{ s} - 7.0 \text{ s} = 6.9$ s. After 7.0 s of free-fall he is at $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2 = 250 \text{ m} + (50.0 \text{ m/s})(7.0 \text{ s}) + \frac{1}{2}(-9.80 \text{ m/s}^2)(7.0 \text{ s})^2 = 360$ m and has velocity $v_x = v_{0x} + a_x t = 50.0 \text{ m/s} + (-9.80 \text{ m/s}^2)(7.0 \text{ s}) = -18.6$ m/s. After the next 6.9 s he is at $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2 = 360 \text{ m} + (-18.6 \text{ m/s})(6.9 \text{ s}) + \frac{1}{2}(-2.00 \text{ m/s}^2)(6.9 \text{ s})^2 = 184$ m. Powers is 184 m above the ground when the helicopter crashes.

EVALUATE: When Powers steps out of the helicopter he retains the initial velocity he had in the helicopter but his acceleration changes abruptly from 5.0 m/s^2 upward to 9.80 m/s^2 downward. Without the jet pack he would have crashed into the ground at the same time as the helicopter. The jet pack slows his descent so he is above the ground when the helicopter crashes.

2.90. **IDENTIFY:** Apply constant acceleration equations to the motion of the rock. Sound travels at constant speed.

SET UP: Let t_{fall} be the time for the rock to fall to the ground and let t_s be the time it takes the sound to travel from the impact point back to you. $t_{\text{fall}} + t_s = 10.0$ s. Both the rock and sound travel a distance d that is equal to the height of the cliff. Take $+y$ downward for the motion of the rock. The rock has $v_{0y} = 0$ and $a_y = 9.80 \text{ m/s}^2$.

EXECUTE: **(a)** For the rock, $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$ gives $t_{\text{fall}} = \sqrt{\dfrac{2d}{9.80 \text{ m/s}^2}}$.

For the sound, $t_s = \dfrac{d}{330 \text{ m/s}}$. Let $\alpha^2 = d$. $0.00303\alpha^2 + 0.4518\alpha - 10.0 = 0$. $\alpha = 19.6$ and $d = 384$ m.

(b) You would have calculated $d = \frac{1}{2}(9.80 \text{ m/s}^2)(10.0 \text{ s})^2 = 490$ m. You would have overestimated the height of the cliff. It actually takes the rock less time than 10.0 s to fall to the ground.

EVALUATE: Once we know d we can calculate that $t_{\text{fall}} = 8.8$ s and $t_s = 1.2$ s. The time for the sound of impact to travel back to you is 12% of the total time and cannot be neglected. The rock has speed 86 m/s just before it strikes the ground.

2.91. **(a) IDENTIFY:** Let $+y$ be upward. The can has constant acceleration $a_y = -g$. The initial upward velocity of the can equals the upward velocity of the scaffolding; first find this speed.

SET UP: $y - y_0 = -15.0$ m, $t = 3.25$ s, $a_y = -9.80 \text{ m/s}^2$, $v_{0y} = ?$

EXECUTE: $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$ gives $v_{0y} = 11.31$ m/s

Use this v_{0y} in $v_y = v_{0y} + a_y t$ to solve for v_y: $v_y = -20.5$ m/s

(b) IDENTIFY: Find the maximum height of the can, above the point where it falls from the scaffolding:

SET UP: $v_y = 0$, $v_{0y} = +11.31$ m/s, $a_y = -9.80 \text{ m/s}^2$, $y - y_0 = ?$

EXECUTE: $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ gives $y - y_0 = 6.53$ m

The can will pass the location of the other painter. Yes, he gets a chance.

EVALUATE: Relative to the ground the can is initially traveling upward, so it moves upward before stopping momentarily and starting to fall back down.

2.92. **IDENTIFY:** Both objects are in free-fall. Apply the constant acceleration equations to the motion of each person.

SET UP: Let $+y$ be downward, so $a_y = +9.80 \text{ m/s}^2$ for each object.

EXECUTE: **(a)** Find the time it takes the student to reach the ground: $y - y_0 = 180$ m, $v_{0y} = 0$, $a_y = 9.80 \text{ m/s}^2$. $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$ gives $t = \sqrt{\dfrac{2(y - y_0)}{a_y}} = \sqrt{\dfrac{2(180 \text{ m})}{9.80 \text{ m/s}^2}} = 6.06$ s. Superman must reach the ground in $6.06 \text{ s} - 5.00 \text{ s} = 1.06$ s: $t = 1.06$ s, $y - y_0 = 180$ m, $a_y = +9.80 \text{ m/s}^2$. $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$ gives $v_{0y} = \dfrac{y - y_0}{t} - \frac{1}{2}a_y t = \dfrac{180 \text{ m}}{1.06 \text{ s}} - \frac{1}{2}(9.80 \text{ m/s}^2)(1.06 \text{ s}) = 165$ m/s. Superman must have initial speed $v_0 = 165$ m/s.

(b) The graphs of y-t for Superman and for the student are sketched in Figure 2.92.

(c) The minimum height of the building is the height for which the student reaches the ground in 5.00 s, before Superman jumps. $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2 = \frac{1}{2}(9.80 \text{ m/s}^2)(5.00 \text{ s})^2 = 122$ m. The skyscraper must be at least 122 m high.

EVALUATE: 165 m/s = 369 mi/h, so only Superman could jump downward with this initial speed.

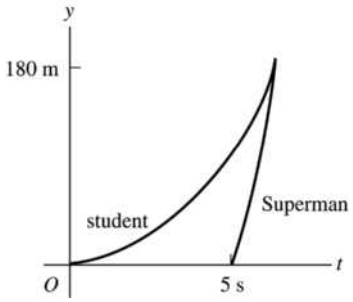

Figure 2.92

2.93. **IDENTIFY:** Apply constant acceleration equations to the motion of the rocket and to the motion of the canister after it is released. Find the time it takes the canister to reach the ground after it is released and find the height of the rocket after this time has elapsed. The canister travels up to its maximum height and then returns to the ground.

SET UP: Let $+y$ be upward. At the instant that the canister is released, it has the same velocity as the rocket. After it is released, the canister has $a_y = -9.80\ \text{m/s}^2$. At its maximum height the canister has $v_y = 0$.

EXECUTE: **(a)** Find the speed of the rocket when the canister is released: $v_{0y} = 0,\ a_y = 3.30\ \text{m/s}^2$, $y - y_0 = 235\ \text{m}$. $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ gives $v_y = \sqrt{2a_y(y - y_0)} = \sqrt{2(3.30\ \text{m/s}^2)(235\ \text{m})} = 39.4\ \text{m/s}$.

For the motion of the canister after it is released, $v_{0y} = +39.4\ \text{m/s},\ a_y = -9.80\ \text{m/s}^2,\ y - y_0 = -235\ \text{m}$. $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$ gives $-235\ \text{m} = (39.4\ \text{m/s})t - (4.90\ \text{m/s}^2)t^2$. The quadratic formula gives $t = 12.0\ \text{s}$ as the positive solution. Then for the motion of the rocket during this 12.0 s,
$y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2 = 235\ \text{m} + (39.4\ \text{m/s})(12.0\ \text{s}) + \frac{1}{2}(3.30\ \text{m/s}^2)(12.0\ \text{s})^2 = 945\ \text{m}$.

(b) Find the maximum height of the canister above its release point: $v_{0y} = +39.4\ \text{m/s},\ v_y = 0$, $a_y = -9.80\ \text{m/s}^2$. $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ gives $y - y_0 = \dfrac{v_y^2 - v_{0y}^2}{2a_y} = \dfrac{0 - (39.4\ \text{m/s})^2}{2(-9.80\ \text{m/s}^2)} = 79.2\ \text{m}$. After its release the canister travels upward 79.2 m to its maximum height and then back down $79.2\ \text{m} + 235\ \text{m}$ to the ground. The total distance it travels is 393 m.

EVALUATE: The speed of the rocket at the instant that the canister returns to the launch pad is $v_y = v_{0y} + a_y t = 39.4\ \text{m/s} + (3.30\ \text{m/s}^2)(12.0\ \text{s}) = 79.0\ \text{m/s}$. We can calculate its height at this instant by $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ with $v_{0y} = 0$ and $v_y = 79.0\ \text{m/s}$. $y - y_0 = \dfrac{v_y^2 - v_{0y}^2}{2a_y} = \dfrac{(79.0\ \text{m/s})^2}{2(3.30\ \text{m/s}^2)} = 946\ \text{m}$, which agrees with our previous calculation.

2.94. **IDENTIFY:** Both objects are in free-fall and move with constant acceleration $9.80\ \text{m/s}^2$, downward. The two balls collide when they are at the same height at the same time.

SET UP: Let $+y$ be upward, so $a_y = -9.80\ \text{m/s}^2$ for each ball. Let $y = 0$ at the ground. Let ball A be the one thrown straight up and ball B be the one dropped from rest at height H. $y_{0A} = 0,\ y_{0B} = H$.

EXECUTE: **(a)** $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$ applied to each ball gives $y_A = v_0 t - \frac{1}{2}gt^2$ and $y_B = H - \frac{1}{2}gt^2$. $y_A = y_B$ gives $v_0 t - \frac{1}{2}gt^2 = H - \frac{1}{2}gt^2$ and $t = \dfrac{H}{v_0}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) For ball A at its highest point, $v_{yA} = 0$ and $v_y = v_{0y} + a_y t$ gives $t = \dfrac{v_0}{g}$. Setting this equal to the time in part (a) gives $\dfrac{H}{v_0} = \dfrac{v_0}{g}$ and $H = \dfrac{v_0^2}{g}$.

EVALUATE: In part (a), using $t = \dfrac{H}{v_0}$ in the expressions for y_A and y_B gives $y_A = y_B = H\left(1 - \dfrac{gH}{2v_0^2}\right)$. H must be less than $\dfrac{2v_0^2}{g}$ in order for the balls to collide before ball A returns to the ground. This is because it takes ball A time $t = \dfrac{2v_0}{g}$ to return to the ground and ball B falls a distance $\frac{1}{2}gt^2 = \dfrac{2v_0^2}{g}$ during this time. When $H = \dfrac{2v_0^2}{g}$ the two balls collide just as ball A reaches the ground and for H greater than this ball A reaches the ground before they collide.

2.95. **IDENTIFY** and **SET UP:** Use $v_x = dx/dt$ and $a_x = dv_x/dt$ to calculate $v_x(t)$ and $a_x(t)$ for each car. Use these equations to answer the questions about the motion.

EXECUTE: $x_A = \alpha t + \beta t^2,\ v_{Ax} = \dfrac{dx_A}{dt} = \alpha + 2\beta t,\ a_{Ax} = \dfrac{dv_{Ax}}{dt} = 2\beta$

$x_B = \gamma t^2 - \delta t^3,\ v_{Bx} = \dfrac{dx_B}{dt} = 2\gamma t - 3\delta t^2,\ a_{Bx} = \dfrac{dv_{Bx}}{dt} - 2\gamma - 6\delta t$

(a) IDENTIFY and **SET UP:** The car that initially moves ahead is the one that has the larger v_{0x}.

EXECUTE: At $t = 0,\ v_{Ax} = \alpha$ and $v_{Bx} = 0$. So initially car A moves ahead.

(b) IDENTIFY and **SET UP:** Cars at the same point implies $x_A = x_B$.

$\alpha t + \beta t^2 = \gamma t^2 - \delta t^3$

EXECUTE: One solution is $t = 0,$ which says that they start from the same point. To find the other solutions, divide by t: $\alpha + \beta t = \gamma t - \delta t^2$

$\delta t^2 + (\beta - \gamma)t + \alpha = 0$

$t = \dfrac{1}{2\delta}\left(-(\beta-\gamma) \pm \sqrt{(\beta-\gamma)^2 - 4\delta\alpha}\right) = \dfrac{1}{0.40}\left(+1.60 \pm \sqrt{(1.60)^2 - 4(0.20)(2.60)}\right) = 4.00\ \text{s} \pm 1.73\ \text{s}$

So $x_A = x_B$ for $t = 0,\ t = 2.27$ s and $t = 5.73$ s.

EVALUATE: Car A has constant, positive a_x. Its v_x is positive and increasing. Car B has $v_{0x} = 0$ and a_x that is initially positive but then becomes negative. Car B initially moves in the $+x$-direction but then slows down and finally reverses direction. At $t = 2.27$ s car B has overtaken car A and then passes it. At $t = 5.73$ s, car B is moving in the $-x$-direction as it passes car A again.

(c) IDENTIFY: The distance from A to B is $x_B - x_A$. The rate of change of this distance is $\dfrac{d(x_B - x_A)}{dt}$. If this distance is not changing, $\dfrac{d(x_B - x_A)}{dt} = 0$. But this says $v_{Bx} - v_{Ax} = 0$. (The distance between A and B is neither decreasing nor increasing at the instant when they have the same velocity.)

SET UP: $v_{Ax} = v_{Bx}$ requires $\alpha + 2\beta t = 2\gamma t - 3\delta t^2$

EXECUTE: $3\delta t^2 + 2(\beta - \gamma)t + \alpha = 0$

$t = \dfrac{1}{6\delta}\left(-2(\beta-\gamma) \pm \sqrt{4(\beta-\gamma)^2 - 12\delta\alpha}\right) = \dfrac{1}{1.20}\left(3.20 \pm \sqrt{4(-1.60)^2 - 12(0.20)(2.60)}\right)$

$t = 2.667\ \text{s} \pm 1.667\ s,$ so $v_{Ax} = v_{Bx}$ for $t = 1.00$ s and $t = 4.33$ s.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: At $t = 1.00$ s, $v_{Ax} = v_{Bx} = 5.00$ m/s. At $t = 4.33$ s, $v_{Ax} = v_{Bx} = 13.0$ m/s. Now car B is slowing down while A continues to speed up, so their velocities aren't ever equal again.

(d) IDENTIFY and **SET UP:** $a_{Ax} = a_{Bx}$ requires $2\beta = 2\gamma - 6\delta t$

EXECUTE: $t = \dfrac{\gamma - \beta}{3\delta} = \dfrac{2.80 \text{ m/s}^2 - 1.20 \text{ m/s}^2}{3(0.20 \text{ m/s}^3)} = 2.67 \text{ s}.$

EVALUATE: At $t = 0$, $a_{Bx} > a_{Ax}$, but a_{Bx} is decreasing while a_{Ax} is constant. They are equal at $t = 2.67$ s but for all times after that $a_{Bx} < a_{Ax}$.

2.96. **IDENTIFY:** Apply $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$ to the motion from the maximum height, where $v_{0y} = 0$. The time spent above $y_{\max}/2$ on the way down equals the time spent above $y_{\max}/2$ on the way up.

SET UP: Let $+y$ be downward. $a_y = g$. $y - y_0 = y_{\max}/2$ when he is a distance $y_{\max}/2$ above the floor.

EXECUTE: The time from the maximum height to $y_{\max}/2$ above the floor is given by $y_{\max}/2 = \frac{1}{2}gt_1^2$. The time from the maximum height to the floor is given by $y_{\max} = \frac{1}{2}gt_{\text{tot}}^2$ and the time from a height of $y_{\max}/2$ to the floor is $t_2 = t_{tot} - t_1$.

$$\frac{2t_1}{t_2} = \frac{\sqrt{y_{\max}/2}}{\sqrt{y_{\max}} - \sqrt{y_{\max}/2}} = \frac{1}{\sqrt{2} - 1} = 4.8.$$

EVALUATE: The person spends over twice as long above $y_{\max}/2$ as below $y_{\max}/2$. His average speed is less above $y_{\max}/2$ than it is when he is below this height.

2.97. **IDENTIFY:** Apply constant acceleration equations to the motion of the two objects, the student and the bus.

SET UP: For convenience, let the student's (constant) speed be v_0 and the bus's initial position be x_0. Note that these quantities are for separate objects, the student and the bus. The initial position of the student is taken to be zero, and the initial velocity of the bus is taken to be zero. The positions of the student x_1 and the bus x_2 as functions of time are then $x_1 = v_0 t$ and $x_2 = x_0 + (1/2)at^2$.

EXECUTE: **(a)** Setting $x_1 = x_2$ and solving for the times t gives $t = \dfrac{1}{a}\left(v_0 \pm \sqrt{v_0^2 - 2ax_0}\right)$.

$$t = \frac{1}{(0.170 \text{ m/s}^2)}\left((5.0 \text{ m/s}) \pm \sqrt{(5.0 \text{ m/s})^2 - 2(0.170 \text{ m/s}^2)(40.0 \text{ m})}\right) = 9.55 \text{ s and } 49.3 \text{ s}.$$

The student will be likely to hop on the bus the first time she passes it (see part (d) for a discussion of the later time). During this time, the student has run a distance $v_0 t = (5 \text{ m/s})(9.55 \text{ s}) = 47.8$ m.

(b) The speed of the bus is $(0.170 \text{ m/s}^2)(9.55 \text{ s}) = 1.62$ m/s.

(c) The results can be verified by noting that the x lines for the student and the bus intersect at two points, as shown in Figure 2.97a.

(d) At the later time, the student has passed the bus, maintaining her constant speed, but the accelerating bus then catches up to her. At this later time the bus's velocity is $(0.170 \text{ m/s}^2)(49.3 \text{ s}) = 8.38$ m/s.

(e) No; $v_0^2 < 2ax_0$, and the roots of the quadratic are imaginary. When the student runs at 3.5 m/s, Figure 2.97b shows that the two lines do *not* intersect:

(f) For the student to catch the bus, $v_0^2 > 2ax_0$. And so the minimum speed is $\sqrt{2(0.170 \text{ m/s}^2)(40 \text{ m/s})} = 3.688$ m/s. She would be running for a time $\dfrac{3.69 \text{ m/s}}{0.170 \text{ m/s}^2} = 21.7$ s, and covers a distance $(3.688 \text{ m/s})(21.7 \text{ s}) = 80.0$ m.

However, when the student runs at 3.688 m/s, the lines intersect at *one* point, at $x = 80$ m, as shown in Figure 2.97c.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: The graph in part (c) shows that the student is traveling faster than the bus the first time they meet but at the second time they meet the bus is traveling faster.

$t_2 = t_{\text{tot}} - t_1$

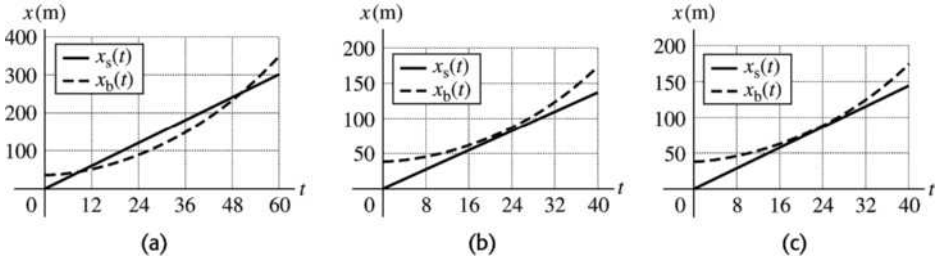

Figure 2.97

2.98. **IDENTIFY:** Apply constant acceleration equations to the motion of the boulder.

SET UP: Let $+y$ be downward, so $a_y = +g$.

EXECUTE: **(a)** Let the height be h and denote the 1.30-s interval as Δt; the simultaneous equations $h = \frac{1}{2}gt^2$, $\frac{2}{3}h = \frac{1}{2}g(t-\Delta t)^2$ can be solved for t. Eliminating h and taking the square root, $\frac{t}{t-\Delta t} = \sqrt{\frac{3}{2}}$, and $t = \frac{\Delta t}{1-\sqrt{2/3}}$, and substitution into $h = \frac{1}{2}gt^2$ gives $h = 246$ m.

(b) The above method assumed that $t > 0$ when the square root was taken. The negative root (with $\Delta t = 0$) gives an answer of 2.51 m, clearly not a "cliff." This would correspond to an object that was initially near the bottom of this "cliff" being thrown upward and taking 1.30 s to rise to the top and fall to the bottom. Although physically possible, the conditions of the problem preclude this answer.

EVALUATE: For the first two-thirds of the distance, $y - y_0 = 164$ m, $v_{0y} = 0$, and $a_y = 9.80\ \text{m/s}^2$. $v_y = \sqrt{2a_y(y-y_0)} = 56.7$ m/s. Then for the last third of the distance, $y - y_0 = 82.0$ m, $v_{0y} = 56.7$ m/s and $a_y = 9.80\ \text{m/s}^2$. $y - y_0 = v_{0y}t + \frac{1}{2}a_yt^2$ gives $(4.90\ \text{m/s}^2)t^2 + (56.7\ \text{m/s})t - 82.0\ \text{m} = 0$.

$t = \frac{1}{9.8}\left(-56.7 + \sqrt{(56.7)^2 + 4(4.9)(82.0)}\right)\ \text{s} = 1.30\ \text{s}$, as required.

2.99. **IDENTIFY:** Apply constant acceleration equations to both objects.

SET UP: Let $+y$ be upward, so each ball has $a_y = -g$. For the purpose of doing all four parts with the least repetition of algebra, quantities will be denoted symbolically. That is, let $y_1 = h + v_0t - \frac{1}{2}gt^2$, $y_2 = h - \frac{1}{2}g(t-t_0)^2$. In this case, $t_0 = 1.00$ s.

EXECUTE: **(a)** Setting $y_1 = y_2 = 0$, expanding the binomial $(t-t_0)^2$ and eliminating the common term $\frac{1}{2}gt^2$ yields $v_0t = gt_0t - \frac{1}{2}gt_0^2$. Solving for t: $t = \frac{\frac{1}{2}gt_0^2}{gt_0 - v_0} = \frac{t_0}{2}\left(\frac{1}{1 - v_0/(gt_0)}\right)$.

Substitution of this into the expression for y_1 and setting $y_1 = 0$ and solving for h as a function of v_0 yields, after some algebra, $h = \frac{1}{2}gt_0^2\frac{\left(\frac{1}{2}gt_0 - v_0\right)^2}{(gt_0 - v_0)^2}$. Using the given value $t_0 = 1.00$ s and $g = 9.80\ \text{m/s}^2$,

$h = 20.0\ \text{m} = (4.9\ \text{m})\left(\frac{4.9\ \text{m/s} - v_0}{9.8\ \text{m/s} - v_0}\right)^2$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

This has two solutions, one of which is unphysical (the first ball is still going up when the second is released; see part (c)). The physical solution involves taking the negative square root before solving for v_0, and yields 8.2 m/s. The graph of y versus t for each ball is given in Figure 2.99.

(b) The above expression gives for (i), 0.411 m and for (ii) 1.15 km.

(c) As v_0 approaches 9.8 m/s, the height h becomes infinite, corresponding to a relative velocity at the time the second ball is thrown that approaches zero. If $v_0 > 9.8$ m/s, the first ball can never catch the second ball.

(d) As v_0 approaches 4.9 m/s, the height approaches zero. This corresponds to the first ball being closer and closer (on its way down) to the top of the roof when the second ball is released. If $v_0 < 4.9$ m/s, the first ball will already have passed the roof on the way down before the second ball is released, and the second ball can never catch up.

EVALUATE: Note that the values of v_0 in parts (a) and (b) are all greater than v_{min} and less than v_{max}.

3

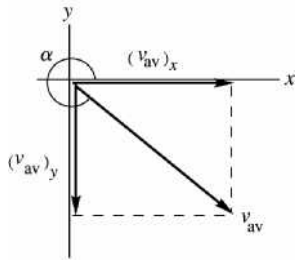
MOTION IN TWO OR THREE DIMENSIONS

3.1. **IDENTIFY** and **SET UP:** Use Eq. (3.2), in component form.

EXECUTE: **(a)** $(v_{\text{av}})_x = \dfrac{\Delta x}{\Delta t} = \dfrac{x_2 - x_1}{t_2 - t_1} = \dfrac{5.3\text{ m} - 1.1\text{ m}}{3.0\text{ s} - 0} = 1.4\text{ m/s}$

$(v_{\text{av}})_y = \dfrac{\Delta y}{\Delta t} = \dfrac{y_2 - y_1}{t_2 - t_1} = \dfrac{-0.5\text{ m} - 3.4\text{ m}}{3.0\text{ s} - 0} = -1.3\text{ m/s}$

(b)



$\tan\alpha = \dfrac{(v_{\text{av}})_y}{(v_{\text{av}})_x} = \dfrac{-1.3\text{ m/s}}{1.4\text{ m/s}} = -0.9286$

$\alpha = 360° - 42.9° = 317°$

$v_{\text{av}} = \sqrt{(v_{\text{av}})_x^2 + (v_{\text{av}})_y^2}$

$v_{\text{av}} = \sqrt{(1.4\text{ m/s})^2 + (-1.3\text{ m/s})^2} = 1.9\text{ m/s}$

Figure 3.1

EVALUATE: Our calculation gives that $\vec{v}_{\text{av}}$ is in the 4th quadrant. This corresponds to increasing x and decreasing y.

3.2. **IDENTIFY:** Use Eq. (3.2), written in component form. The distance from the origin is the magnitude of $\vec{r}$.

SET UP: At time t_1, $x_1 = y_1 = 0$.

EXECUTE: **(a)** $x = (v_{\text{av-}x})\Delta t = (-3.8\text{ m/s})(12.0\text{ s}) = -45.6\text{ m}$ and $y = (v_{\text{av-}y})\Delta t = (4.9\text{ m/s})(12.0\text{ s}) = 58.8\text{ m}$.

(b) $r = \sqrt{x^2 + y^2} = \sqrt{(-45.6\text{ m})^2 + (58.8\text{ m})^2} = 74.4\text{ m}$.

EVALUATE: $\Delta\vec{r}$ is in the direction of $\vec{v}_{\text{av}}$. Therefore, Δx is negative since $v_{\text{av-}x}$ is negative and Δy is positive since $v_{\text{av-}y}$ is positive.

3.3. **(a) IDENTIFY** and **SET UP:** From $\vec{r}$ we can calculate x and y for any t.
Then use Eq. (3.2), in component form.

EXECUTE: $\vec{r} = [4.0\text{ cm} + (2.5\text{ cm/s}^2)t^2]\hat{\boldsymbol{i}} + (5.0\text{ cm/s})t\hat{\boldsymbol{j}}$

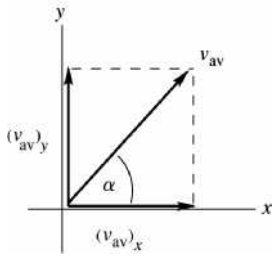
At $t = 0$, $\vec{r} = (4.0\text{ cm})\,\hat{\boldsymbol{i}}$.

At $t = 2.0$ s, $\vec{r} = (14.0\text{ cm})\,\hat{\boldsymbol{i}} + (10.0\text{ cm})\,\hat{\boldsymbol{j}}$.

$(v_{\text{av}})_x = \dfrac{\Delta x}{\Delta t} = \dfrac{10.0\text{ cm}}{2.0\text{ s}} = 5.0\text{ cm/s}.$

$(v_{\text{av}})_y = \dfrac{\Delta y}{\Delta t} = \dfrac{10.0\text{ cm}}{2.0\text{ s}} = 5.0\text{ cm/s}.$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.



$$v_{av} = \sqrt{(v_{av})_x^2 + (v_{av})_y^2} = 7.1 \text{ cm/s}$$

$$\tan\alpha = \frac{(v_{av})_y}{(v_{av})_x} = 1.00$$

$\theta = 45°$.

Figure 3.3a

EVALUATE: Both x and y increase, so $\vec{v}_{av}$ is in the 1st quadrant.

(b) IDENTIFY and **SET UP:** Calculate $\vec{r}$ by taking the time derivative of $\vec{r}(t)$.

EXECUTE: $\vec{v} = \dfrac{d\vec{r}}{dt} = ([5.0 \text{ cm/s}^2]t)\hat{i} + (5.0 \text{ cm/s})\hat{j}$

$t = 0$: $v_x = 0$, $v_y = 5.0$ cm/s; $v = 5.0$ cm/s and $\theta = 90°$

$t = 1.0$ s: $v_x = 5.0$ cm/s, $v_y = 5.0$ cm/s; $v = 7.1$ cm/s and $\theta = 45°$

$t = 2.0$ s: $v_x = 10.0$ cm/s, $v_y = 5.0$ cm/s; $v = 11$ cm/s and $\theta = 27°$

(c) The trajectory is a graph of y versus x.

$x = 4.0 \text{ cm} + (2.5 \text{ cm/s}^2)\,t^2$, $y = (5.0 \text{ cm/s})t$

For values of t between 0 and 2.0 s, calculate x and y and plot y versus x.

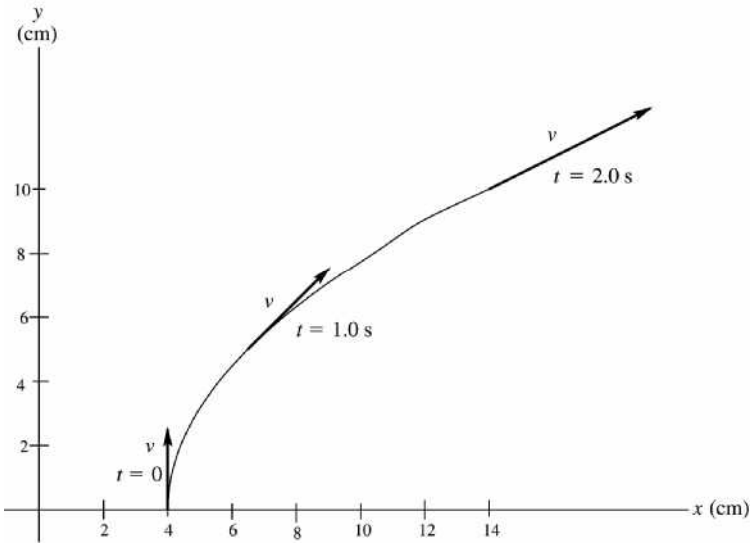


Figure 3.3b

EVALUATE: The sketch shows that the instantaneous velocity at any t is tangent to the trajectory.

3.4. **IDENTIFY:** Given the position vector of a squirrel, find its velocity components in general, and at a specific time find its velocity components and the magnitude and direction of its position vector and velocity.

SET UP: $v_x = dx/dt$ and $v_y = dy/dt$; the magnitude of a vector is $A = \sqrt{(A_x^2 + A_y^2)}$.

EXECUTE: **(a)** Taking the derivatives gives $v_x(t) = 0.280 \text{ m/s} + (0.0720 \text{ m/s}^2)t$ and $v_y(t) = (0.0570 \text{ m/s}^3)t^2$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) Evaluating the position vector at $t = 5.00$ s gives $x = 2.30$ m and $y = 2.375$ m, which gives $r = 3.31$ m.

(c) At $t = 5.00$ s, $v_x = +0.64$ m/s, $v_y = 1.425$ m/s, which gives $v = 1.56$ m/s and $\tan\theta = \dfrac{1.425}{0.64}$ so the direction is $\theta = 65.8^{\circ}$ (counterclockwise from +x-axis)

EVALUATE: The acceleration is not constant, so we cannot use the standard kinematics formulas.

3.5. **IDENTIFY** and **SET UP:** Use Eq. (3.8) in component form to calculate $(a_{\text{av}})_x$ and $(a_{\text{av}})_y$.

EXECUTE: **(a)** The velocity vectors at $t_1 = 0$ and $t_2 = 30.0$ s are shown in Figure 3.5a.

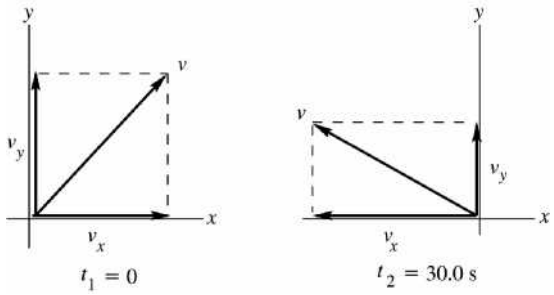

Figure 3.5a

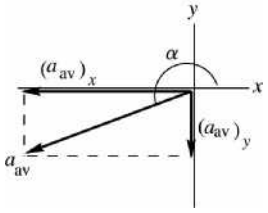
(b) $(a_{\text{av}})_x = \dfrac{\Delta v_x}{\Delta t} = \dfrac{v_{2x} - v_{1x}}{t_2 - t_1} = \dfrac{-170 \text{ m/s} - 90 \text{ m/s}}{30.0 \text{ s}} = -8.67 \text{ m/s}^2$

$(a_{\text{av}})_y = \dfrac{\Delta v_y}{\Delta t} = \dfrac{v_{2y} - v_{1y}}{t_2 - t_1} = \dfrac{40 \text{ m/s} - 110 \text{ m/s}}{30.0 \text{ s}} = -2.33 \text{ m/s}^2$

(c)



$a = \sqrt{(a_{\text{av}})_x^2 + (a_{\text{av}})_y^2} = 8.98 \text{ m/s}^2$

$\tan\alpha = \dfrac{(a_{\text{av}})_y}{(a_{\text{av}})_x} = \dfrac{-2.33 \text{ m/s}^2}{-8.67 \text{ m/s}^2} = 0.269$

$\alpha = 15^{\circ} + 180^{\circ} = 195^{\circ}$

Figure 3.5b

EVALUATE: The changes in v_x and v_y are both in the negative x or y direction, so both components of $\vec{a}_{\text{av}}$ are in the 3rd quadrant.

3.6. **IDENTIFY:** Use Eq. (3.8), written in component form.

SET UP: $a_x = (0.45\text{m/s}^2)\cos 31.0^{\circ} = 0.39\text{m/s}^2$, $a_y = (0.45\text{m/s}^2)\sin 31.0^{\circ} = 0.23\text{m/s}^2$

EXECUTE: **(a)** $a_{\text{av-}x} = \dfrac{\Delta v_x}{\Delta t}$ and $v_x = 2.6 \text{ m/s} + (0.39 \text{ m/s}^2)(10.0 \text{ s}) = 6.5 \text{ m/s}$. $a_{\text{av-}y} = \dfrac{\Delta v_y}{\Delta t}$ and $v_y = -1.8 \text{ m/s} + (0.23 \text{ m/s}^2)(10.0 \text{ s}) = 0.52 \text{ m/s}$.

(b) $v = \sqrt{(6.5\text{m/s})^2 + (0.52\text{m/s})^2} = 6.52\text{m/s}$, at an angle of $\arctan\left(\dfrac{0.52}{6.5}\right) = 4.6^{\circ}$ above the horizontal.

(c) The velocity vectors $\vec{v}_1$ and $\vec{v}_2$ are sketched in Figure 3.6. The two velocity vectors differ in magnitude and direction.

EVALUATE: $\vec{v}_1$ is at an angle of 35° below the +x-axis and has magnitude $v_1 = 3.2$ m/s, so $v_2 > v_1$ and the direction of $\vec{v}_2$ is rotated counterclockwise from the direction of $\vec{v}_1$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

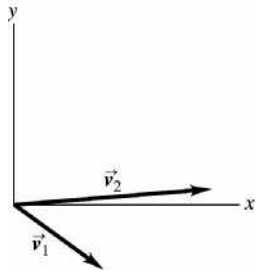


Figure 3.6

3.7. **IDENTIFY** and **SET UP:** Use Eqs. (3.4) and (3.12) to find v_x, v_y, a_x, and a_y as functions of time. The magnitude and direction of $\vec{r}$ and $\vec{a}$ can be found once we know their components.
EXECUTE: **(a)** Calculate x and y for t values in the range 0 to 2.0 s and plot y versus x. The results are given in Figure 3.7a.

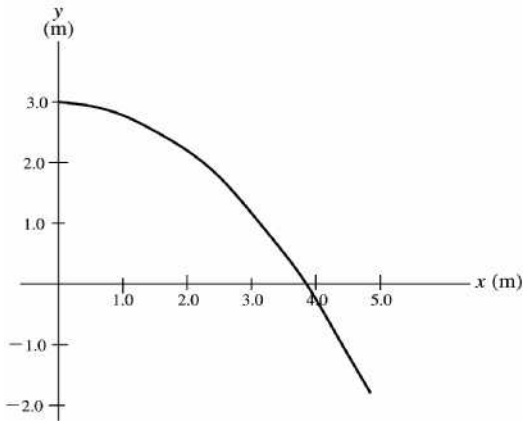

Figure 3.7a

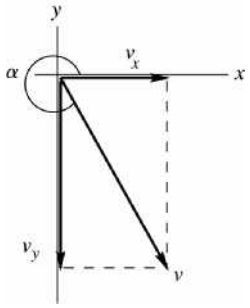
(b) $v_x = \dfrac{dx}{dt} = \alpha \quad v_y = \dfrac{dy}{dt} = -2\beta t$

$a_y = \dfrac{dv_x}{dt} = 0 \quad a_y = \dfrac{dv_y}{dt} = -2\beta$

Thus $\vec{\boldsymbol{v}} = \alpha\hat{\boldsymbol{i}} - 2\beta t\hat{\boldsymbol{j}} \quad \vec{\boldsymbol{a}} = -2\beta\hat{\boldsymbol{j}}$

(c) velocity: At $t = 2.0$ s, $v_x = 2.4$ m/s, $v_y = -2(1.2 \text{ m/s}^2)(2.0 \text{ s}) = -4.8$ m/s



$v = \sqrt{v_x^2 + v_y^2} = 5.4 \text{ m/s}$

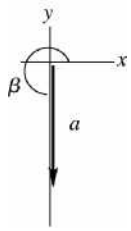
$\tan\alpha = \dfrac{v_y}{v_x} = \dfrac{-4.8 \text{ m/s}}{2.4 \text{ m/s}} = -2.00$

$\alpha = -63.4° + 360° = 297°$

Figure 3.7b

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

acceleration**:** At $t = 2.0$ s, $a_x = 0$, $a_y = -2\,(1.2\ \text{m/s}^2) = -2.4\ \text{m/s}^2$

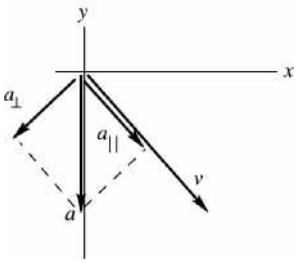


$$a = \sqrt{a_x^2 + a_y^2} = 2.4\ \text{m/s}^2$$

$$\tan\beta = \frac{a_y}{a_x} = \frac{-2.4\ \text{m/s}^2}{0} = -\infty$$

$$\beta = 270°$$

Figure 3.7c



EVALUATE: **(d)** $\vec{a}$ has a component $a_{\parallel}$ in the same direction as $\vec{v}$, so we know that v is increasing (the bird is speeding up.) $\vec{a}$ also has a component $a_{\perp}$ perpendicular to $\vec{v}$, so that the direction of $\vec{v}$ is changing; the bird is turning toward the $-y$-direction (toward the right)

Figure 3.7d

$\vec{v}$ is always tangent to the path; $\vec{v}$ at $t = 2.0$ s shown in part (c) is tangent to the path at this t, conforming to this general rule. $\vec{a}$ is constant and in the $-y$-direction; the direction of $\vec{v}$ is turning toward the $-y$-direction.

3.8. **IDENTIFY:** Use the velocity components of a car (given as a function of time) to find the acceleration of the car as a function of time and to find the magnitude and direction of the car's velocity and acceleration at a specific time.

SET UP: $a_x = dv_x/dt$ and $a_y = dv_y/dt$; the magnitude of a vector is $A = \sqrt{(A_x^2 + A_y^2)}$.

EXECUTE: **(a)** Taking the derivatives gives $a_x(t) = (-0.0360\ \text{m/s}^3)t$ and $a_y(t) = 0.550\ \text{m/s}^2$.

(b) Evaluating the velocity components at $t = 8.00$ s gives $v_x = 3.848$ m/s and $v_y = 6.40$ m/s, which gives $v = 7.47$ m/s. The direction is $\tan\theta = \dfrac{6.40}{3.848}$ so $\theta = 59.0^{\text{o}}$ (counterclockwise from $+x$-axis).

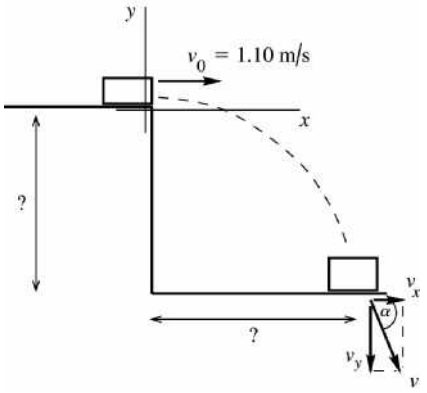
(c) Evaluating the acceleration components at $t = 8.00$ s gives $a_x = -0.288\ \text{m/s}^2$ and $a_y = 0.550\ \text{m/s}^2$, which gives $a = 0.621\ \text{m/s}^2$. The angle with the $+y$ axis is given by $\tan\theta = \dfrac{0.288}{0.550}$, so $\theta = 27.6^{\text{o}}$. The direction is therefore 118^{o} counterclockwise from $+x$-axis.

EVALUATE: The acceleration is not constant, so we cannot use the standard kinematics formulas.

3.9. **IDENTIFY:** The book moves in projectile motion once it leaves the table top. Its initial velocity is horizontal.

SET UP: Take the positive y-direction to be upward. Take the origin of coordinates at the initial position of the book, at the point where it leaves the table top.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.



x-component:
$a_x = 0,\ v_{0x} = 1.10$ m/s,
$t = 0.350$ s
y-component:
$a_y = -9.80$ m/s^2,
$v_{0y} = 0$,
$t = 0.350$ s

Figure 3.9a

Use constant acceleration equations for the x and y components of the motion, with $a_x = 0$ and $a_y = -g$.

EXECUTE: (a) $y - y_0 = ?$

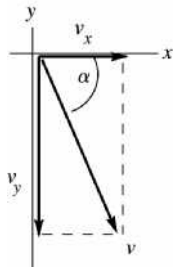
$y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2 = 0 + \frac{1}{2}(-9.80 \text{ m/s}^2)(0.350 \text{ s})^2 = -0.600$ m. The table top is 0.600 m above the floor.

(b) $x - x_0 = ?$

$x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2 = (1.10 \text{ m/s})(0.350 \text{ s}) + 0 = 0.385$ m.

(c) $v_x = v_{0x} + a_x t = 1.10$ m/s (The x-component of the velocity is constant, since $a_x = 0$.)

$v_y = v_{0y} + a_y t = 0 + (-9.80 \text{ m/s}^2)(0.350 \text{ s}) = -3.43$ m/s



$v = \sqrt{v_x^2 + v_y^2} = 3.60$ m/s

$\tan\alpha = \dfrac{v_y}{v_x} = \dfrac{-3.43 \text{ m/s}}{1.10 \text{ m/s}} = -3.118$

$\alpha = -72.2°$

Direction of $\vec{v}$ is 72.2° below the horizontal

Figure 3.9b

(d) The graphs are given in Figure 3.9c.

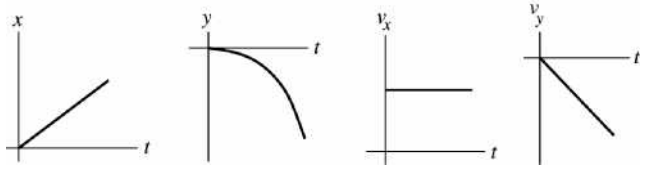


Figure 3.9c

EVALUATE: In the x-direction, $a_x = 0$ and v_x is constant. In the y-direction, $a_y = -9.80$ m/s^2 and v_y is downward and increasing in magnitude since a_y and v_y are in the same directions. The x and y motions occur independently, connected only by the time. The time it takes the book to fall 0.600 m is the time it travels horizontally.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

3.10. **IDENTIFY:** The person moves in projectile motion. She must travel 1.75 m horizontally during the time she falls 9.00 m vertically.

SET UP: Take $+y$ downward. $a_x = 0,\ a_y = +9.80\ \text{m/s}^2.\ v_{0x} = v_0,\ v_{0y} = 0.$

EXECUTE: Time to fall 9.00 m: $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$ gives $t = \sqrt{\dfrac{2(y-y_0)}{a_y}} = \sqrt{\dfrac{2(9.00\ \text{m})}{9.80\ \text{m/s}^2}} = 1.36\ \text{s}.$

Speed needed to travel 1.75 m horizontally during this time: $x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2$ gives

$$v_0 = v_{0x} = \frac{x - x_0}{t} = \frac{1.75\ \text{m}}{1.36\ \text{s}} = 1.29\ \text{m/s}.$$

EVALUATE: If she increases her initial speed she still takes 1.36 s to reach the level of the ledge, but has traveled horizontally farther than 1.75 m.

3.11. **IDENTIFY:** Each object moves in projectile motion.

SET UP: Take $+y$ to be downward. For each cricket, $a_x = 0$ and $a_y = +9.80\ \text{m/s}^2$. For Chirpy, $v_{0x} = v_{0y} = 0$. For Milada, $v_{0x} = 0.950\ \text{m/s},\ v_{0y} = 0.$

EXECUTE: Milada's horizontal component of velocity has no effect on her vertical motion. She also reaches the ground in 3.50 s. $x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2 = (0.950\ \text{m/s})(3.50\ \text{s}) = 3.32\ \text{m}$

EVALUATE: The x and y components of motion are totally separate and are connected only by the fact that the time is the same for both.

3.12. **IDENTIFY:** The football moves in projectile motion.

SET UP: Let $+y$ be upward. $a_x = 0,\ a_y = -g.$ At the highest point in the trajectory, $v_y = 0.$

EXECUTE: **(a)** $v_y = v_{0y} + a_y t.$ The time t is $\dfrac{v_{0y}}{g} = \dfrac{12.0\text{m/s}}{9.80\text{m/s}^2} = 1.224\ \text{s},$ which we round to 1.22 s.

(b) Different constant acceleration equations give different expressions but the same numerical result:

$$\tfrac{1}{2}gt^2 = \tfrac{1}{2}v_{y0}t = \frac{v_{0y}^2}{2g} = 7.35\ \text{m}.$$

(c) Regardless of how the algebra is done, the time will be twice that found in part (a), which is 2(1.224 s) = 2.45 s.

(d) $a_x = 0,$ so $x - x_0 = v_{0x}t = (20.0\ \text{m/s})(2.45\ \text{s}) = 49.0\ \text{m}.$

(e) The graphs are sketched in Figure 3.12.

EVALUATE: When the football returns to its original level, $v_x = 20.0\ \text{m/s}$ and $v_y = -12.0\ \text{m/s}.$

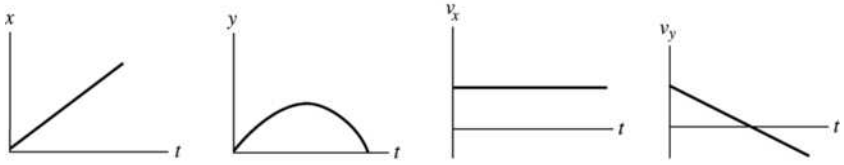

Figure 3.12

3.13. **IDENTIFY:** The car moves in projectile motion. The car travels $21.3\ \text{m} - 1.80\ \text{m} = 19.5\ \text{m}$ downward during the time it travels 61.0 m horizontally.

SET UP: Take $+y$ to be downward. $a_x = 0,\ a_y = +9.80\ \text{m/s}^2.\ v_{0x} = v_0,\ v_{0y} = 0.$

EXECUTE: **(a)** Use the vertical motion to find the time in the air:

$y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$ gives $t = \sqrt{\dfrac{2(y-y_0)}{a_y}} = \sqrt{\dfrac{2(19.5\ \text{m})}{9.80\ \text{m/s}^2}} = 1.995\ \text{s}$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

Then $x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2$ gives $v_0 = v_{0x} = \dfrac{x - x_0}{t} = \dfrac{61.0\text{ m}}{1.995\text{ s}} = 30.6\text{ m/s}$.

(b) $v_x = 30.6\text{ m/s}$ since $a_x = 0$. $v_y = v_{0y} + a_y t = -19.6\text{ m/s}$. $v = \sqrt{v_x^2 + v_y^2} = 36.3\text{ m/s}$.

EVALUATE: We calculate the final velocity by calculating its x and y components.

3.14. **IDENTIFY:** Knowing the maximum reached by the froghopper and its angle of takeoff, we want to find its takeoff speed and the horizontal distance it travels while in the air.

SET UP: Use coordinates with the origin at the ground and $+y$ upward. $a_x = 0$, $a_y = -9.80\text{ m/s}^2$. At the maximum height $v_y = 0$. The constant-acceleration formulas $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ and $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$ apply.

EXECUTE: **(a)** $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ gives

$v_y = \sqrt{-2a_y(y - y_0)} = \sqrt{-2(-9.80\text{ m/s}^2)(0.587\text{ m})} = 3.39\text{ m/s}$. $v_{0y} = v_0 \sin\theta_0$ so

$v_0 = \dfrac{v_{0y}}{\sin\theta_0} = \dfrac{3.39\text{ m/s}}{\sin 58.0°} = 4.00\text{ m/s}$.

(b) Use the vertical motion to find the time in the air. When the froghopper has returned to the ground, $y - y_0 = 0$. $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$ gives $t = -\dfrac{2v_{0y}}{a_y} = -\dfrac{2(3.39\text{ m/s})}{-9.80\text{ m/s}^2} = 0.692\text{ s}$.

Then $x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2 = (v_0 \cos\theta_0)t = (4.00\text{ m/s})(\cos 58.0°)(0.692\text{ s}) = 1.47\text{ m}$.

EVALUATE: $v_y = 0$ when $t = -\dfrac{v_{0y}}{a_y} = -\dfrac{3.39\text{ m/s}}{-9.80\text{ m/s}^2} = 0.346\text{ s}$. The total time in the air is twice this.

3.15. **IDENTIFY:** The ball moves with projectile motion with an initial velocity that is horizontal and has magnitude v_0. The height h of the table and v_0 are the same; the acceleration due to gravity changes from $g_E = 9.80\text{ m/s}^2$ on earth to g_X on planet X.

SET UP: Let $+x$ be horizontal and in the direction of the initial velocity of the marble and let $+y$ be upward. $v_{0x} = v_0$, $v_{0y} = 0$, $a_x = 0$, $a_y = -g$, where g is either g_E or g_X.

EXECUTE: Use the vertical motion to find the time in the air: $y - y_0 = -h$. $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$ gives $t = \sqrt{\dfrac{2h}{g}}$. Then $x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2$ gives $x - x_0 = v_{0x}t = v_0\sqrt{\dfrac{2h}{g}}$. $x - x_0 = D$ on earth and $2.76D$ on Planet X. $(x - x_0)\sqrt{g} = v_0\sqrt{2h}$, which is constant, so $D\sqrt{g_E} = 2.76D\sqrt{g_X}$.

$g_X = \dfrac{g_E}{(2.76)^2} = 0.131 g_E = 1.28\text{ m/s}^2$.

EVALUATE: On Planet X the acceleration due to gravity is less, it takes the ball longer to reach the floor and it travels farther horizontally.

3.16. **IDENTIFY:** The shell moves in projectile motion.

SET UP: Let $+x$ be horizontal, along the direction of the shell's motion, and let $+y$ be upward. $a_x = 0$, $a_y = -9.80\text{ m/s}^2$.

EXECUTE: **(a)** $v_{0x} = v_0 \cos\alpha_0 = (50.0\text{ m/s})\cos 60.0° = 25.0\text{ m/s}$,

$v_{0y} = v_0 \sin\alpha_0 = (50.0\text{ m/s})\sin 60.0° = 43.3\text{ m/s}$.

(b) At the maximum height $v_y = 0$. $v_y = v_{0y} + a_y t$ gives $t = \dfrac{v_y - v_{0y}}{a_y} = \dfrac{0 - 43.3\text{ m/s}}{-9.80\text{ m/s}^2} = 4.42\text{ s}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(c) $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ gives $y - y_0 = \dfrac{v_y^2 - v_{0y}^2}{2a_y} = \dfrac{0 - (43.3 \text{ m/s})^2}{2(-9.80 \text{ m/s}^2)} = 95.7 \text{ m}.$

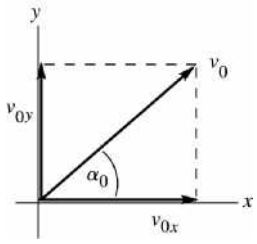
(d) The total time in the air is twice the time to the maximum height, so
$x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2 = (25.0 \text{ m/s})(8.84 \text{ s}) = 221 \text{ m}.$

(e) At the maximum height, $v_x = v_{0x} = 40.0$ m/s and $v_y = 0$. At all points in the motion, $a_x = 0$ and $a_y = -9.80 \text{ m/s}^2$.

EVALUATE: The equation for the horizontal range R derived in the text is $R = \dfrac{v_0^2 \sin 2\alpha_0}{g}$. This gives

$R = \dfrac{(50.0 \text{ m/s})^2 \sin(120.0°)}{9.80 \text{ m/s}^2} = 221 \text{ m},$ which agrees with our result in part (d).

3.17. **IDENTIFY:** The baseball moves in projectile motion. In part (c) first calculate the components of the velocity at this point and then get the resultant velocity from its components.
SET UP: First find the x- and y-components of the initial velocity. Use coordinates where the $+y$-direction is upward, the $+x$-direction is to the right and the origin is at the point where the baseball leaves the bat.



$v_{0x} = v_0 \cos\alpha_0 = (30.0 \text{ m/s}) \cos 36.9° = 24.0 \text{ m/s}$
$v_{0y} = v_0 \sin\alpha_0 = (30.0 \text{ m/s}) \sin 36.9° = 18.0 \text{ m/s}$

Figure 3.17a

Use constant acceleration equations for the x and y motions, with $a_x = 0$ and $a_y = -g$.

EXECUTE: **(a)** y-component (vertical motion):

$y - y_0 = +10.0 \text{ m/s}, \quad v_{0y} = 18.0 \text{ m/s}, \quad a_y = -9.80 \text{ m/s}^2, \quad t = ?$

$y - y_0 = v_{0y} + \frac{1}{2}a_y t^2$

$10.0 \text{ m} = (18.0 \text{ m/s})t - (4.90 \text{ m/s}^2)t^2$

$(4.90 \text{ m/s}^2)t^2 - (18.0 \text{ m/s})t + 10.0 \text{ m} = 0$

Apply the quadratic formula: $t = \frac{1}{9.80}\left[18.0 \pm \sqrt{(-18.0)^2 - 4\,(4.90)(10.0)}\right] \text{ s} = (1.837 \pm 1.154) \text{ s}$

The ball is at a height of 10.0 above the point where it left the bat at $t_1 = 0.683$ s and at $t_2 = 2.99$ s. At the earlier time the ball passes through a height of 10.0 m as its way up and at the later time it passes through 10.0 m on its way down.

(b) $v_x = v_{0x} = +24.0$ m/s, at all times since $a_x = 0$.

$v_y = v_{0y} + a_y t$

$t_1 = 0.683$ s: $v_y = +18.0 \text{ m/s} + (-9.80 \text{ m/s}^2)(0.683 \text{ s}) = +11.3 \text{ m/s}.$ (v_y is positive means that the ball is traveling upward at this point.

$t_2 = 2.99$ s: $v_y = +18.0 \text{ m/s} + (-9.80 \text{ m/s}^2)(2.99 \text{ s}) = -11.3 \text{ m/s}.$ (v_y is negative means that the ball is traveling downward at this point.)

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(c) $v_x = v_{0x} = 24.0$ m/s

Solve for v_y:

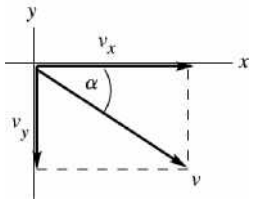
$v_y = ?,\ \ y - y_0 = 0$ (when ball returns to height where motion started),

$a_y = -9.80\ \text{m/s}^2,\ \ v_{0y} = +18.0$ m/s

$v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$

$v_y = -v_{0y} = -18.0$ m/s (negative, since the baseball must be traveling downward at this point)

Now solve for the magnitude and direction of $\vec{v}$.



$$v = \sqrt{v_x^2 + v_y^2}$$

$$v = \sqrt{(24.0\ \text{m/s})^2 + (-18.0\ \text{m/s})^2} = 30.0\ \text{m/s}$$

$$\tan\alpha = \frac{v_y}{v_x} = \frac{-18.0\ \text{m/s}}{24.0\ \text{m/s}}$$

$\alpha = -36.9°,\ \ 36.9°$ below the horizontal

Figure 3.17b

The velocity of the ball when it returns to the level where it left the bat has magnitude 30.0 m/s and is directed at an angle of $36.9°$ below the horizontal.

EVALUATE: The discussion in parts (a) and (b) explains the significance of two values of t for which $y - y_0 = +10.0$ m. When the ball returns to its initial height, our results give that its speed is the same as its initial speed and the angle of its velocity below the horizontal is equal to the angle of its initial velocity above the horizontal; both of these are general results.

3.18. **IDENTIFY:** The shot moves in projectile motion.

SET UP: Let $+y$ be upward.

EXECUTE: **(a)** If air resistance is to be ignored, the components of acceleration are 0 horizontally and $-g = -9.80\ \text{m/s}^2$ vertically downward.

(b) The x-component of velocity is constant at $v_x = (12.0\ \text{m/s})\cos 51.0° = 7.55$ m/s. The y-component is $v_{0y} = (12.0\ \text{m/s})\sin 51.0° = 9.32$ m/s at release and

$v_y = v_{0y} - gt = (9.32\ \text{m/s}) - (9.80\ \text{m/s})(2.08\ \text{s}) = -11.06$ m/s when the shot hits.

(c) $x - x_0 = v_{0x}t = (7.55\ \text{m/s})(2.08\ \text{s}) = 15.7$ m.

(d) The initial and final heights are not the same.

(e) With $y = 0$ and v_{0y} as found above, Eq. (3.18) gives $y_0 = 1.81$m.

(f) The graphs are sketched in Figure 3.18.

EVALUATE: When the shot returns to its initial height, $v_y = -9.32$ m/s. The shot continues to accelerate downward as it travels downward 1.81 m to the ground and the magnitude of v_y at the ground is larger than 9.32 m/s.

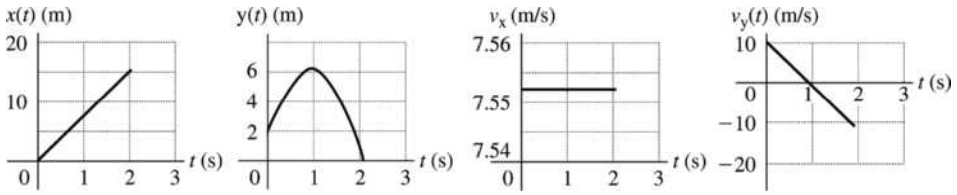


Figure 3.18

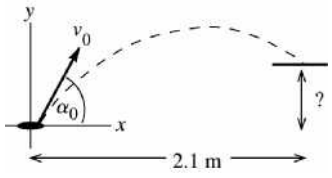
3.19. **IDENTIFY:** Take the origin of coordinates at the point where the quarter leaves your hand and take positive y to be upward. The quarter moves in projectile motion, with $a_x = 0$, and $a_y = -g$. It travels vertically for the time it takes it to travel horizontally 2.1 m.



$v_{0x} = v_0 \cos\alpha_0 = (6.4 \text{ m/s}) \cos 60°$

$v_{0x} = 3.20 \text{ m/s}$

$v_{0y} = v_0 \sin\alpha_0 = (6.4 \text{ m/s}) \sin 60°$

$v_{0y} = 5.54 \text{ m/s}$

Figure 3.19

(a) SET UP: Use the horizontal (x-component) of motion to solve for t, the time the quarter travels through the air:

$t = ?,\ x - x_0 = 2.1 \text{ m},\ v_{0x} = 3.2 \text{ m/s},\ a_x = 0$

$x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2 = v_{0x}t,$ since $a_x = 0$

EXECUTE: $t = \dfrac{x - x_0}{v_{0x}} = \dfrac{2.1 \text{ m}}{3.2 \text{ m/s}} = 0.656 \text{ s}$

SET UP: Now find the vertical displacement of the quarter after this time:

$y - y_0 = ?,\ a_y = -9.80 \text{ m/s}^2,\ v_{0y} = +5.54 \text{ m/s},\ t = 0.656 \text{ s}$

$y - y_0 + v_{0y}t + \frac{1}{2}a_y t^2$

EXECUTE: $y - y_0 = (5.54 \text{ m/s})(0.656 \text{ s}) + \frac{1}{2}(-9.80 \text{ m/s}^2)(0.656 \text{ s})^2 = 3.63 \text{ m} - 2.11 \text{ m} = 1.5 \text{ m}.$

(b) SET UP: $v_y = ?,\ t = 0.656 \text{ s},\ a_y = -9.80 \text{ m/s}^2,\ v_{0y} = +5.54 \text{ m/s}\ \ v_y = v_{0y} + a_y t$

EXECUTE: $v_y = 5.54 \text{ m/s} + (-9.80 \text{ m/s}^2)(0.656 \text{ s}) = -0.89 \text{ m/s}.$

EVALUATE: The minus sign for v_y indicates that the y-component of $\vec{v}$ is downward. At this point the quarter has passed through the highest point in its path and is on its way down. The horizontal range if it returned to its original height (it doesn't!) would be 3.6 m. It reaches its maximum height after traveling horizontally 1.8 m, so at $x - x_0 = 2.1$ m it is on its way down.

3.20. **IDENTIFY:** Use the analysis of Example 3.10.

SET UP: From Example 3.10, $t = \dfrac{d}{v_0 \cos\alpha_0}$ and $y_{\text{dart}} = (v_0 \sin\alpha_0)t - \frac{1}{2}gt^2$.

EXECUTE: Substituting for t in terms of d in the expression for y_{dart} gives

$$y_{\text{dart}} = d\left(\tan\alpha_0 - \frac{gd}{2v_0^2 \cos^2\alpha_0}\right).$$

Using the given values for d and α_0 to express this as a function of v_0,

$$y = (3.00 \text{ m})\left(0.90 - \frac{26.62 \text{ m}^2/\text{s}^2}{v_0^2}\right).$$

(a) $v_0 = 12.0$ m/s gives $y = 2.14$ m.

(b) $v_0 = 8.0$ m/s gives $y = 1.45$ m.

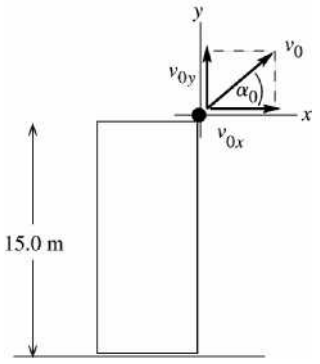
(c) $v_0 = 4.0$ m/s gives $y = -2.29$ m. In this case, the dart was fired with so slow a speed that it hit the ground before traveling the 3-meter horizontal distance.

EVALUATE: For (a) and (b) the trajectory of the dart has the shape shown in Figure 3.26 in the textbook. For (c) the dart moves in a parabola and returns to the ground before it reaches the x-coordinate of the monkey.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

3.21. **IDENTIFY:** Take the origin of coordinates at the roof and let the $+y$-direction be upward. The rock moves in projectile motion, with $a_x = 0$ and $a_y = -g$. Apply constant acceleration equations for the x and y components of the motion.

SET UP:



$v_{0x} = v_0 \cos\alpha_0 = 25.2$ m/s
$v_{0y} = v_0 \sin\alpha_0 = 16.3$ m/s

Figure 3.21a

(a) At the maximum height $v_y = 0$.

$a_y = -9.80\ \text{m/s}^2$, $v_y = 0$, $v_{0y} = +16.3$ m/s, $y - y_0 = ?$

$v_y^2 = v_{0y}^2 + 2a_y\,(y - y_0)$

EXECUTE: $y - y_0 = \dfrac{v_y^2 - v_{0y}^2}{2a_y} = \dfrac{0 - (16.3\ \text{m/s})^2}{2(-9.80\ \text{m/s}^2)} = +13.6\ \text{m}$

(b) SET UP: Find the velocity by solving for its x and y components.

$v_x = v_{0x} = 25.2$ m/s (since $a_x = 0$)

$v_y = ?$, $a_y = -9.80\ \text{m/s}^2$, $y - y_0 = -15.0$ m (negative because at the ground the rock is below its initial position), $v_{0y} = 16.3$ m/s

$v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$

$v_y = -\sqrt{v_{0y}^2 + 2a_y(y - y_0)}$ (v_y is negative because at the ground the rock is traveling downward.)

EXECUTE: $v_y = -\sqrt{(16.3\ \text{m/s})^2 + 2(-9.80\ \text{m/s}^2)(-15.0\ \text{m})} = -23.7$ m/s

Then $v = \sqrt{v_x^2 + v_y^2} = \sqrt{(25.2\ \text{m/s})^2 + (-23.7\ \text{m/s})^2} = 34.6$ m/s.

(c) SET UP: Use the vertical motion (y-component) to find the time the rock is in the air:

$t = ?$, $v_y = -23.7$ m/s (from part (b)), $a_y = -9.80\ \text{m/s}^2$, $v_{0y} = +16.3$ m/s

EXECUTE: $t = \dfrac{v_y - v_{0y}}{a_y} = \dfrac{-23.7\ \text{m/s} - 16.3\ \text{m/s}}{-9.80\ \text{m/s}^2} = +4.08$ s

SET UP: Can use this t to calculate the horizontal range:

$t = 4.08$ s, $v_{0x} = 25.2$ m/s, $a_x = 0$, $x - x_0 = ?$

EXECUTE: $x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2 = (25.2\ \text{m/s})(4.08\ \text{s}) + 0 = 103$ m

(d) Graphs of x versus t, y versus t, v_x versus t and v_y versus t:

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

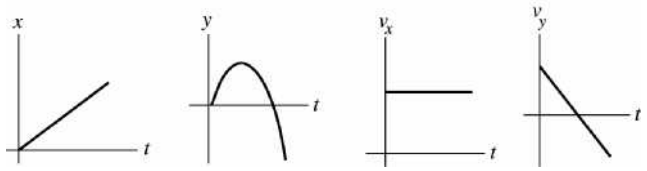


Figure 3.21b

EVALUATE: The time it takes the rock to travel vertically to the ground is the time it has to travel horizontally. With $v_{0y} = +16.3$ m/s the time it takes the rock to return to the level of the roof ($y = 0$) is $t = 2v_{0y}/g = 3.33$ s. The time in the air is greater than this because the rock travels an additional 15.0 m to the ground.

3.22. **IDENTIFY:** Consider the horizontal and vertical components of the projectile motion. The water travels 45.0 m horizontally in 3.00 s.

SET UP: Let $+y$ be upward. $a_x = 0$, $a_y = -9.80$ m/s^2. $v_{0x} = v_0 \cos\theta_0$, $v_{0y} = v_0 \sin\theta_0$.

EXECUTE: **(a)** $x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2$ gives $x - x_0 = v_0(\cos\theta_0)t$ and $\cos\theta_0 = \dfrac{45.0\text{ m}}{(25.0\text{ m/s})(3.00\text{ s})} = 0.600$;

$\theta_0 = 53.1°$

(b) At the highest point $v_x = v_{0x} = (25.0\text{ m/s})\cos 53.1° = 15.0$ m/s, $v_y = 0$ and $v = \sqrt{v_x^2 + v_y^2} = 15.0$ m/s. At all points in the motion, $a = 9.80$ m/s^2 downward.

(c) Find $y - y_0$ when $t = 3.00$ s:

$y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2 = (25.0\text{ m/s})(\sin 53.1°)(3.00\text{ s}) + \frac{1}{2}(-9.80\text{ m/s}^2)(3.00\text{ s})^2 = 15.9$ m

$v_x = v_{0x} = 15.0$ m/s, $v_y = v_{0y} + a_y t = (25.0\text{ m/s})(\sin 53.1°) - (9.80\text{m/s}^2)(3.00\text{ s}) = -9.41$ m/s, and

$v = \sqrt{v_x^2 + v_y^2} = \sqrt{(15.0\text{ m/s})^2 + (-9.41\text{ m/s})^2} = 17.7$ m/s

EVALUATE: The acceleration is the same at all points of the motion. It takes the water $t = -\dfrac{v_{0y}}{a_y} = -\dfrac{20.0\text{ m/s}}{-9.80\text{ m/s}^2} = 2.04$ s to reach its maximum height. When the water reaches the building it has passed its maximum height and its vertical component of velocity is downward.

3.23. **IDENTIFY** and **SET UP:** The stone moves in projectile motion. Its initial velocity is the same as that of the balloon. Use constant acceleration equations for the x and y components of its motion. Take $+y$ to be downward.

EXECUTE: **(a)** Use the vertical motion of the rock to find the initial height.

$t = 6.00$ s, $v_{0y} = +20.0$ m/s, $a_y = +9.80$ m/s^2, $y - y_0 = ?$

$y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$ gives $y - y_0 = 296$ m

(b) In 6.00 s the balloon travels downward a distance $y - y_0 = (20.0\text{ m/s})(6.00\text{ s}) = 120$ m. So, its height above ground when the rock hits is $296\text{ m} - 120\text{ m} = 176$ m.

(c) The horizontal distance the rock travels in 6.00 s is 90.0 m. The vertical component of the distance between the rock and the basket is 176 m, so the rock is $\sqrt{(176\text{ m})^2 + (90\text{ m})^2} = 198$ m from the basket when it hits the ground.

(d) (i) The basket has no horizontal velocity, so the rock has horizontal velocity 15.0 m/s relative to the basket. Just before the rock hits the ground, its vertical component of velocity is $v_y = v_{0y} + a_y t = 20.0\text{ m/s} + (9.80\text{ m/s}^2)(6.00\text{ s}) = 78.8$ m/s, downward, relative to the ground. The basket is moving downward at 20.0 m/s, so relative to the basket the rock has a downward component of velocity 58.8 m/s.

(ii) horizontal: 15.0 m/s; vertical: 78.8 m/s

EVALUATE: The rock has a constant horizontal velocity and accelerates downward

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

3.24. **IDENTIFY:** We want to find the acceleration of the inner ear of a dancer, knowing the rate at which she spins.

SET UP: $R = 0.070$ m. For 3.0 rev/s, the period T (time for one revolution) is $T = \dfrac{1.0 \text{ s}}{3.0 \text{ rev}} = 0.333$ s. The speed is $v = d/T = (2\pi R)/T$, and $a_{\text{rad}} = v^2/R$.

EXECUTE: $a_{\text{rad}} = \dfrac{v^2}{R} = \dfrac{(2\pi R/T)^2}{R} = \dfrac{4\pi^2 R}{T^2} = \dfrac{4\pi^2(0.070 \text{ m})}{(0.333 \text{ s})^2} = 25 \text{ m/s}^2 = 2.5g.$

EVALUATE: The acceleration is large and the force on the fluid must be 2.5 times its weight.

3.25. **IDENTIFY:** Apply Eq. (3.30).

SET UP: $T = 24$ h.

EXECUTE: **(a)** $a_{\text{rad}} = \dfrac{4\pi^2(6.38\times10^6 \text{ m})}{((24 \text{ h})(3600 \text{ s/h}))^2} = 0.034 \text{ m/s}^2 = 3.4\times10^{-3} g.$

(b) Solving Eq. (3.30) for the period T with $a_{\text{rad}} = g$, $T = \sqrt{\dfrac{4\pi^2(6.38\times10^6 \text{m})}{9.80 \text{ m/s}^2}} = 5070 \text{ s} = 1.4 \text{ h}.$

EVALUATE: a_{rad} is proportional to $1/T^2$, so to increase a_{rad} by a factor of $\dfrac{1}{3.4\times10^{-3}} = 294$ requires that T be multiplied by a factor of $\dfrac{1}{\sqrt{294}}$. $\dfrac{24 \text{ h}}{\sqrt{294}} = 1.4$ h.

3.26. **IDENTIFY:** Each blade tip moves in a circle of radius $R = 3.40$ m and therefore has radial acceleration $a_{\text{rad}} = v^2/R$.

SET UP: 550 rev/min = 9.17 rev/s, corresponding to a period of $T = \dfrac{1}{9.17 \text{ rev/s}} = 0.109$ s.

EXECUTE: **(a)** $v = \dfrac{2\pi R}{T} = 196$ m/s.

(b) $a_{\text{rad}} = \dfrac{v^2}{R} = 1.13\times10^4 \text{ m/s}^2 = 1.15\times10^3 g.$

EVALUATE: $a_{\text{rad}} = \dfrac{4\pi^2 R}{T^2}$ gives the same results for a_{rad} as in part (b).

3.27. **IDENTIFY:** For the curved lowest part of the dive, the pilot's motion is approximately circular. We know the pilot's acceleration and the radius of curvature, and from this we want to find the pilot's speed.

SET UP: $a_{\text{rad}} = 5.5g = 53.9 \text{ m/s}^2$. 1 mph = 0.4470 m/s. $a_{\text{rad}} = \dfrac{v^2}{R}$.

EXECUTE: $a_{\text{rad}} = \dfrac{v^2}{R}$, so $v = \sqrt{Ra_{\text{rad}}} = \sqrt{(350 \text{ m})(53.9 \text{ m/s}^2)} = 140 \text{ m/s} = 310 \text{ mph}.$

EVALUATE: This speed is reasonable for the type of plane flown by a test pilot.

3.28. **IDENTIFY:** Each planet moves in a circular orbit and therefore has acceleration $a_{\text{rad}} = v^2/R$.

SET UP: The radius of the earth's orbit is $r = 1.50\times10^{11}$ m and its orbital period is $T = 365 \text{ days} = 3.16\times10^7$ s. For Mercury, $r = 5.79\times10^{10}$ m and $T = 88.0 \text{ days} = 7.60\times10^6$ s.

EXECUTE: **(a)** $v = \dfrac{2\pi r}{T} = 2.98\times10^4$ m/s

(b) $a_{\text{rad}} = \dfrac{v^2}{r} = 5.91\times10^{-3} \text{ m/s}^2.$

(c) $v = 4.79\times10^4$ m/s, and $a_{\text{rad}} = 3.96\times10^{-2} \text{ m/s}^2.$

EVALUATE: Mercury has a larger orbital velocity and a larger radial acceleration than earth.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

3.29. **IDENTIFY:** Uniform circular motion.

SET UP: Since the magnitude of $\vec{v}$ is constant, $v_{\tan} = \dfrac{d|\vec{v}|}{dt} = 0$ and the resultant acceleration is equal to the radial component. At each point in the motion the radial component of the acceleration is directed in toward the center of the circular path and its magnitude is given by v^2/R.

EXECUTE: **(a)** $a_{\text{rad}} = \dfrac{v^2}{R} = \dfrac{(7.00 \text{ m/s})^2}{14.0 \text{ m}} = 3.50 \text{ m/s}^2,$ upward.

(b) The radial acceleration has the same magnitude as in part (a), but now the direction toward the center of the circle is downward. The acceleration at this point in the motion is $3.50 \text{ m/s}^2,$ downward.

(c) SET UP: The time to make one rotation is the period T, and the speed v is the distance for one revolution divided by T.

EXECUTE: $v = \dfrac{2\pi R}{T}$ so $T = \dfrac{2\pi R}{v} = \dfrac{2\pi (14.0 \text{ m})}{7.00 \text{ m/s}} = 12.6 \text{ s}$

EVALUATE: The radial acceleration is constant in magnitude since v is constant and is at every point in the motion directed toward the center of the circular path. The acceleration is perpendicular to $\vec{v}$ and is nonzero because the direction of $\vec{v}$ changes.

3.30. **IDENTIFY:** Each part of his body moves in uniform circular motion, with $a_{\text{rad}} = \dfrac{v^2}{R}$. The speed in rev/s is $1/T,$ where T is the period in seconds (time for 1 revolution). The speed v increases with R along the length of his body but all of him rotates with the same period T.

SET UP: For his head $R = 8.84 \text{ m}$ and for his feet $R = 6.84 \text{ m}$.

EXECUTE: **(a)** $v = \sqrt{Ra_{\text{rad}}} = \sqrt{(8.84 \text{ m})(12.5)(9.80 \text{ m/s}^2)} = 32.9 \text{ m/s}$

(b) Use $a_{\text{rad}} = \dfrac{4\pi^2 R}{T^2}$. Since his head has $a_{\text{rad}} = 12.5g$ and $R = 8.84 \text{ m},$

$T = 2\pi\sqrt{\dfrac{R}{a_{\text{rad}}}} = 2\pi\sqrt{\dfrac{8.84\text{m}}{12.5(9.80\text{m/s}^2)}} = 1.688\text{s}.$ Then his feet have $a_{\text{rad}} = \dfrac{R}{T^2} = \dfrac{4\pi^2(6.84\text{m})}{(1.688\text{s})^2} = 94.8\text{m/s}^2 = 9.67 \text{ g}.$

The difference between the acceleration of his head and his feet is $12.5g - 9.67g = 2.83g = 27.7 \text{ m/s}^2.$

(c) $\dfrac{1}{T} = \dfrac{1}{1.69 \text{ s}} = 0.592 \text{ rev/s} = 35.5 \text{ rpm}$

EVALUATE: His feet have speed $v = \sqrt{Ra_{\text{rad}}} = \sqrt{(6.84 \text{ m})(94.8 \text{ m/s}^2)} = 25.5 \text{ m/s}$

3.31. **IDENTIFY:** Relative velocity problem. The time to walk the length of the moving sidewalk is the length divided by the velocity of the woman relative to the ground.

SET UP: Let W stand for the woman, G for the ground and S for the sidewalk. Take the positive direction to be the direction in which the sidewalk is moving.

The velocities are $v_{\text{W/G}}$ (woman relative to the ground), $v_{\text{W/S}}$ (woman relative to the sidewalk), and $v_{\text{S/G}}$ (sidewalk relative to the ground).

Eq. (3.33) becomes $v_{\text{W/G}} = v_{\text{W/S}} + v_{\text{S/G}}$.

The time to reach the other end is given by $t = \dfrac{\text{distance traveled relative to ground}}{v_{\text{W/G}}}$

EXECUTE: **(a)** $v_{\text{S/G}} = 1.0 \text{ m/s}$

$v_{\text{W/S}} = +1.5 \text{ m/s}$

$v_{\text{W/G}} = v_{\text{W/S}} + v_{\text{S/G}} = 1.5 \text{ m/s} + 1.0 \text{ m/s} = 2.5 \text{ m/s}.$

$t = \dfrac{35.0 \text{ m}}{v_{\text{W/G}}} = \dfrac{35.0 \text{ m}}{2.5 \text{ m/s}} = 14 \text{ s}.$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) $v_{S/G} = 1.0$ m/s

$v_{W/S} = -1.5$ m/s

$v_{W/G} = v_{W/S} + v_{S/G} = -1.5$ m/s $+ 1.0$ m/s $= -0.5$ m/s. (Since $v_{W/G}$ now is negative, she must get on the moving sidewalk at the opposite end from in part (a).)

$$t = \frac{-35.0 \text{ m}}{v_{W/G}} = \frac{-35.0 \text{ m}}{-0.5 \text{ m/s}} = 70 \text{ s.}$$

EVALUATE: Her speed relative to the ground is much greater in part (a) when she walks with the motion of the sidewalk.

3.32. **IDENTIFY:** The relative velocities are $\vec{v}_{S/F}$, the velocity of the scooter relative to the flatcar, $\vec{v}_{S/G}$, the scooter relative to the ground and $\vec{v}_{F/G}$, the flatcar relative to the ground. $\vec{v}_{S/G} = \vec{v}_{S/F} + \vec{v}_{F/G}$. Carry out the vector addition by drawing a vector addition diagram.

SET UP: $\vec{v}_{S/F} = \vec{v}_{S/G} - \vec{v}_{F/G}$. $\vec{v}_{F/G}$ is to the right, so $-\vec{v}_{F/G}$ is to the left.

EXECUTE: In each case the vector addition diagram gives

(a) 5.0 m/s to the right

(b) 16.0 m/s to the left

(c) 13.0 m/s to the left.

EVALUATE: The scooter has the largest speed relative to the ground when it is moving to the right relative to the flatcar, since in that case the two velocities $\vec{v}_{S/F}$ and $\vec{v}_{F/G}$ are in the same direction and their magnitudes add.

3.33. **IDENTIFY:** Apply the relative velocity relation.

SET UP: The relative velocities are $\vec{v}_{C/E}$, the canoe relative to the earth, $\vec{v}_{R/E}$, the velocity of the river relative to the earth and $\vec{v}_{C/R}$, the velocity of the canoe relative to the river.

EXECUTE: $\vec{v}_{C/E} = \vec{v}_{C/R} + \vec{v}_{R/E}$ and therefore $\vec{v}_{C/R} = \vec{v}_{C/E} - \vec{v}_{R/E}$. The velocity components of $\vec{v}_{C/R}$ are -0.50 m/s $+ (0.40$ m/s$)/\sqrt{2}$, east and $(0.40$ m/s$)/\sqrt{2}$, south, for a velocity relative to the river of 0.36 m/s, at $52.5°$ south of west.

EVALUATE: The velocity of the canoe relative to the river has a smaller magnitude than the velocity of the canoe relative to the earth.

3.34. **IDENTIFY:** Calculate the rower's speed relative to the shore for each segment of the round trip.

SET UP: The boat's speed relative to the shore is 6.8 km/h downstream and 1.2 km/h upstream.

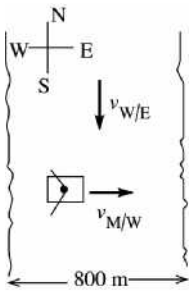
EXECUTE: The walker moves a total distance of 3.0 km at a speed of 4.0 km/h, and takes a time of three fourths of an hour (45.0 min).

The total time the rower takes is $\dfrac{1.5 \text{ km}}{6.8 \text{ km/h}} + \dfrac{1.5 \text{ km}}{1.2 \text{ km/h}} = 1.47 \text{ h} = 88.2 \text{ min.}$

EVALUATE: It takes the rower longer, even though for half the distance his speed is greater than 4.0 km/h. The rower spends more time at the slower speed.

3.35. **IDENTIFY:** Relative velocity problem in two dimensions. His motion relative to the earth (time displacement) depends on his velocity relative to the earth so we must solve for this velocity.

(a) SET UP: View the motion from above.



The velocity vectors in the problem are:

$\vec{v}_{M/E}$, the velocity of the man relative to the earth

$\vec{v}_{W/E}$, the velocity of the water relative to the earth

$\vec{v}_{M/W}$, the velocity of the man relative to the water

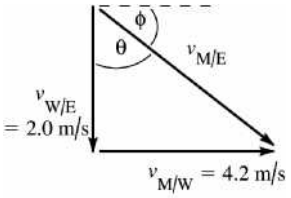
The rule for adding these velocities is

$\vec{v}_{M/E} = \vec{v}_{M/W} + \vec{v}_{W/E}$

Figure 3.35a

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

The problem tells us that $\vec{v}_{W/E}$ has magnitude 2.0 m/s and direction due south. It also tells us that $\vec{v}_{M/W}$ has magnitude 4.2 m/s and direction due east. The vector addition diagram is then as shown in Figure 3.35b.



This diagram shows the vector addition $\vec{v}_{M/E} = \vec{v}_{M/W} + \vec{v}_{W/E}$ and also has $\vec{v}_{M/W}$ and $\vec{v}_{W/E}$ in their specified directions. Note that the vector diagram forms a right triangle.

Figure 3.35b

The Pythagorean theorem applied to the vector addition diagram gives $v_{M/E}^2 = v_{M/W}^2 + v_{W/E}^2$.

EXECUTE: $v_{M/E} = \sqrt{v_{M/W}^2 + v_{W/E}^2} = \sqrt{(4.2\text{ m/s})^2 + (2.0\text{ m/s})^2} = 4.7\text{ m/s};\ \tan\theta = \dfrac{v_{M/W}}{v_{W/E}} = \dfrac{4.2\text{ m/s}}{2.0\text{ m/s}} = 2.10;$ $\theta = 65°;$ or $\phi = 90° - \theta = 25°.$ The velocity of the man relative to the earth has magnitude 4.7 m/s and direction 25° S of E.

(b) This requires careful thought. To cross the river the man must travel 800 m due east relative to the earth. The man's velocity relative to the earth is $\vec{v}_{M/E}$. But, from the vector addition diagram the eastward component of $v_{M/E}$ equals $v_{M/W} = 4.2$ m/s.

Thus $t = \dfrac{x - x_0}{v_x} = \dfrac{800\text{ m}}{4.2\text{ m/s}} = 190\text{ s}.$

(c) The southward component of $\vec{v}_{M/E}$ equals $v_{W/E} = 2.0$ m/s. Therefore, in the 190 s it takes him to cross the river, the distance south the man travels relative to the earth is

$$y - y_0 = v_y t = (2.0\text{ m/s})(190\text{ s}) = 380\text{ m}.$$

EVALUATE: If there were no current he would cross in the same time, (800 m)/(4.2 m/s) = 190 s. The current carries him downstream but doesn't affect his motion in the perpendicular direction, from bank to bank.

3.36. **IDENTIFY:** Use the relation that relates the relative velocities.

SET UP: The relative velocities are the water relative to the earth, $\vec{v}_{W/E}$, the boat relative to the water, $\vec{v}_{B/W}$, and the boat relative to the earth, $\vec{v}_{B/E}$. $\vec{v}_{B/E}$ is due east, $\vec{v}_{W/E}$ is due south and has magnitude 2.0 m/s. $v_{B/W} = 4.2$ m/s. $\vec{v}_{B/E} = \vec{v}_{B/W} + \vec{v}_{W/E}$. The velocity addition diagram is given in Figure 3.36.

EXECUTE: **(a)** Find the direction of $\vec{v}_{B/W}$. $\sin\theta = \dfrac{v_{W/E}}{v_{B/W}} = \dfrac{2.0\text{ m/s}}{4.2\text{ m/s}}.$ $\theta = 28.4°,$ north of east.

(b) $v_{B/E} = \sqrt{v_{B/W}^2 - v_{W/E}^2} = \sqrt{(4.2\text{ m/s})^2 - (2.0\text{ m/s})^2} = 3.7\text{ m/s}$

(c) $t = \dfrac{800\text{ m}}{v_{B/E}} = \dfrac{800\text{ m}}{3.7\text{ m/s}} = 216\text{ s}.$

EVALUATE: It takes longer to cross the river in this problem than it did in Problem 3.35. In the direction straight across the river (east) the component of his velocity relative to the earth is lass than 4.2 m/s.

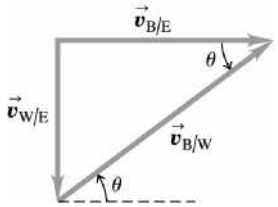


Figure 3.36

3.37. **IDENTIFY:** Relative velocity problem in two dimensions.

(a) SET UP: $\vec{v}_{P/A}$ is the velocity of the plane relative to the air. The problem states that $\vec{v}_{P/A}$ has magnitude 35 m/s and direction south.

$\vec{v}_{A/E}$ is the velocity of the air relative to the earth. The problem states that $\vec{v}_{A/E}$ is to the southwest (45° S of W) and has magnitude 10 m/s.

The relative velocity equation is $\vec{v}_{P/E} = \vec{v}_{P/A} + \vec{v}_{A/E}$.

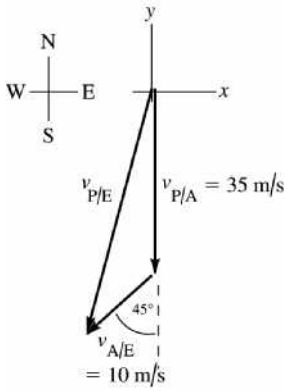

Figure 3.37a

EXECUTE: **(b)** $(v_{P/A})_x = 0, \ (v_{P/A})_y = -35$ m/s

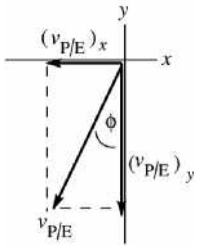
$(v_{A/E})_x = -(10 \text{ m/s})\cos 45° = -7.07$ m/s,

$(v_{A/E})_y = -(10 \text{ m/s})\sin 45° = -7.07$ m/s

$(v_{P/E})_x = (v_{P/A})_x + (v_{A/E})_x = 0 - 7.07 \text{ m/s} = -7.1 \text{ m/s}$

$(v_{P/E})_y = (v_{P/A})_y + (v_{A/E})_y = -35 \text{ m/s} - 7.07 \text{ m/s} = -42 \text{ m/s}$

(c)



$$v_{P/E} = \sqrt{(v_{P/E})_x^2 + (v_{P/E})_y^2}$$

$$v_{P/E} = \sqrt{(-7.1 \text{ m/s})^2 + (-42 \text{ m/s})^2} = 43 \text{ m/s}$$

$$\tan\phi = \frac{(v_{P/E})_x}{(v_{P/E})_y} = \frac{-7.1}{-42} = 0.169$$

$\phi = 9.6°$; (9.6° west of south)

Figure 3.37b

EVALUATE: The relative velocity addition diagram does not form a right triangle so the vector addition must be done using components. The wind adds both southward and westward components to the velocity of the plane relative to the ground.

3.38. **IDENTIFY:** Use the relation that relates the relative velocities.

SET UP: The relative velocities are the velocity of the plane relative to the ground, $\vec{v}_{P/G}$, the velocity of the plane relative to the air, $\vec{v}_{P/A}$, and the velocity of the air relative to the ground, $\vec{v}_{A/G}$. $\vec{v}_{P/G}$ must due west and $\vec{v}_{A/G}$ must be south. $v_{A/G} = 80$ km/h and $v_{P/A} = 320$ km/h. $\vec{v}_{P/G} = \vec{v}_{P/A} + \vec{v}_{A/G}$. The relative velocity addition diagram is given in Figure 3.38.

EXECUTE: **(a)** $\sin\theta = \dfrac{v_{A/G}}{v_{P/A}} = \dfrac{80 \text{ km/h}}{320 \text{ km/h}}$ and $\theta = 14°$, north of west.

(b) $v_{P/G} = \sqrt{v_{P/A}^2 - v_{A/G}^2} = \sqrt{(320 \text{ km/h})^2 - (80.0 \text{ km/h})^2} = 310$ km/h.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: To travel due west the velocity of the plane relative to the air must have a westward component and also a component that is northward, opposite to the wind direction.

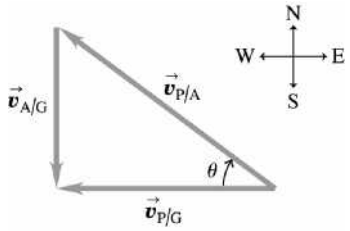


Figure 3.38

3.39. **IDENTIFY:** The resultant velocity, relative to the ground, is directly southward. This velocity is the sum of the velocity of the bird relative to the air and the velocity of the air relative to the ground.

SET UP: $v_{B/A} = 100$ km/h. $\vec{v}_{A/G} = 40$ km/h, east. $\vec{v}_{B/G} = \vec{v}_{B/A} + \vec{v}_{A/G}$.

EXECUTE: We want $\vec{v}_{B/G}$ to be due south. The relative velocity addition diagram is shown in Figure 3.39.

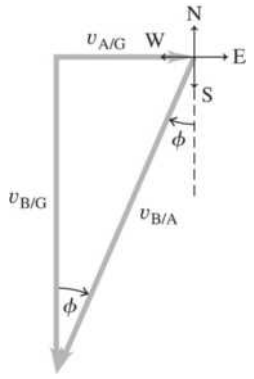

Figure 3.39

(a) $\sin\phi = \dfrac{v_{A/G}}{v_{B/A}} = \dfrac{40 \text{ km/h}}{100 \text{ km/h}}$, $\phi = 24°$, west of south.

(b) $v_{B/G} = \sqrt{{v_{B/A}}^2 - {v_{A/G}}^2} = 91.7$ km/h. $t = \dfrac{d}{v_{B/G}} = \dfrac{500 \text{ km}}{91.7 \text{ km/h}} = 5.5$ h.

EVALUATE: The speed of the bird relative to the ground is less than its speed relative to the air. Part of its velocity relative to the air is directed to oppose the effect of the wind.

3.40. **IDENTIFY:** As the runner runs around the track, his speed stays the same but the direction of his velocity changes so he has acceleration.

SET UP: $(v_x)_{av} = \dfrac{\Delta x}{\Delta t}$, $(a_x)_{av} = \dfrac{\Delta v_x}{\Delta t}$ (and likewise for the y components). The coordinates of each point are: A, $(-50 \text{ m}, 0)$; B, $(0, +50 \text{ m})$; C, $(+50 \text{ m}, 0)$; D, $(0, -50 \text{ m})$. At each point the velocity is tangent to the circular path, as shown in Figure 3.40. The components (v_x, v_y) of the velocity at each point are: A, $(0, +6.0 \text{ m/s})$; B, $(+6.0 \text{ m/s}, 0)$; C, $(0, -6.0 \text{ m/s})$; D, $(-6.0 \text{ m/s}, 0)$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

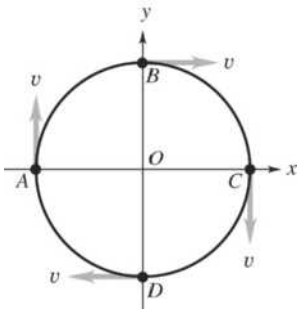

Figure 3.40

EXECUTE: **(a)** A to B: The time for one full lap is $t = \dfrac{2\pi r}{v} = \dfrac{2\pi(50\text{ m})}{6.0\text{ m/s}} = 52.4\text{ s}$. A to B is one-quarter lap and takes $\frac{1}{4}(52.4\text{ s}) = 13.1\text{ s}$. $(v_x)_{\text{av}} = \dfrac{\Delta x}{\Delta t} = \dfrac{0-(-50\text{ m})}{13.1\text{ s}} = 3.8\text{ m/s}$; $(v_y)_{\text{av}} = \dfrac{\Delta y}{\Delta t} = \dfrac{+50\text{ m}-0}{13.1\text{ s}} = 3.8\text{ m/s}$.

$(a_x)_{\text{av}} = \dfrac{\Delta v_x}{\Delta t} = \dfrac{6.0\text{ m/s}-0}{13.1\text{ s}} = 0.46\text{ m/s}^2$; $(a_y)_{\text{av}} = \dfrac{\Delta v_y}{\Delta t} = \dfrac{0-6.0\text{ m/s}}{13.1\text{ s}} = -0.46\text{ m/s}^2$

(b) A to C: $t = \frac{1}{2}(52.4\text{ s}) = 26.2\text{ s}$. $(v_x)_{\text{av}} = \dfrac{\Delta x}{\Delta t} = \dfrac{+50\text{ m}-(-50\text{ m})}{26.2\text{ s}} = 3.8\text{ m/s}$; $(v_y)_{\text{av}} = \dfrac{\Delta y}{\Delta t} = 0$.

$(a_x)_{\text{av}} = \dfrac{\Delta v_x}{\Delta t} = 0$; $(a_y)_{\text{av}} = \dfrac{\Delta v_y}{\Delta t} = \dfrac{-6.0\text{ m/s}-6.0\text{ m/s}}{26.2\text{ s}} = -0.46\text{ m/s}^2$.

(c) C to D: $t = \frac{1}{4}(52.4\text{ s}) = 13.1\text{ s}$. $(v_x)_{\text{av}} = \dfrac{\Delta x}{\Delta t} = \dfrac{0-50\text{ m}}{13.1\text{ s}} = -3.8\text{ m/s}$;

$(v_y)_{\text{av}} = \dfrac{\Delta y}{\Delta t} = \dfrac{-50\text{ m}-0}{13.1\text{ s}} = -3.8\text{ m/s}$. $(a_x)_{\text{av}} = \dfrac{\Delta v_x}{\Delta t} = \dfrac{-6.0\text{ m/s}-0}{13.1\text{ s}} = -0.46\text{ m/s}^2$;

$(a_y)_{\text{av}} = \dfrac{\Delta v_y}{\Delta t} = \dfrac{0-(-6.0\text{ m/s})}{13.1\text{ s}} = 0.46\text{ m/s}^2$.

(d) A to A: $\Delta x = \Delta y = 0$ so $(v_x)_{\text{av}} = (v_y)_{\text{av}} = 0$, and $\Delta v_x = \Delta v_y = 0$ so $(a_x)_{\text{av}} = (a_y)_{\text{av}} = 0$.

(e) For A to B: $v_{\text{av}} = \sqrt{(v_x)_{\text{av}}^2 + (v_y)_{\text{av}}^2} = \sqrt{(3.8\text{ m/s})^2 + (3.8\text{ m/s})^2} = 5.4\text{ m/s}$. The speed is constant so the average speed is 6.0 m/s. The average speed is larger than the magnitude of the average velocity because the distance traveled is larger than the magnitude of the displacement.

(f) Velocity is a vector, with both magnitude and direction. The magnitude of the velocity is constant but its direction is changing.

EVALUATE: For this motion the acceleration describes the rate of change of the direction of the velocity, not the rate of change of the speed.

3.41. **IDENTIFY:** $\vec{\boldsymbol{v}} = \dfrac{d\vec{\boldsymbol{r}}}{dt}$ and $\vec{\boldsymbol{a}} = \dfrac{d\vec{\boldsymbol{v}}}{dt}$

SET UP: $\dfrac{d}{dt}(t^n) = nt^{n-1}$. At $t = 1.00\text{ s}$, $a_x = 4.00\text{ m/s}^2$ and $a_y = 3.00\text{ m/s}^2$. At $t = 0$, $x = 0$ and $y = 50.0\text{ m}$.

EXECUTE: **(a)** $v_x = \dfrac{dx}{dt} = 2Bt$. $a_x = \dfrac{dv_x}{dt} = 2B$, which is independent of t. $a_x = 4.00\text{ m/s}^2$ gives $B = 2.00\text{ m/s}^2$. $v_y = \dfrac{dy}{dt} = 3Dt^2$. $a_y = \dfrac{dv_y}{dt} = 6Dt$. $a_y = 3.00\text{ m/s}^2$ gives $D = 0.500\text{ m/s}^3$. $x = 0$ at $t = 0$ gives $A = 0$. $y = 50.0\text{ m}$ at $t = 0$ gives $C = 50.0\text{ m}$.

(b) At $t = 0$, $v_x = 0$ and $v_y = 0$, so $\vec{\boldsymbol{v}} = 0$. At $t = 0$, $a_x = 2B = 4.00\text{ m/s}^2$ and $a_y = 0$, so $\vec{\boldsymbol{a}} = (4.00\text{ m/s}^2)\hat{\boldsymbol{i}}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(c) At $t = 10.0$ s, $v_x = 2\,(2.00\ \text{m/s}^2)(10.0\ \text{s}) = 40.0$ m/s and $v_y = 3(0.500\ \text{m/s}^3)(10.0\ \text{s})^2 = 150$ m/s.

$v = \sqrt{v_x^2 + v_y^2} = 155$ m/s.

(d) $x = (2.00\ \text{m/s}^2)(10.0\ \text{s})^2 = 200$ m, $y = 50.0\ \text{m} + (0.500\ \text{m/s}^3)(10.0\ \text{s})^3 = 550$ m.

$\vec{r} = (200\ \text{m})\hat{i} + (550\ \text{m})\hat{j}$.

EVALUATE: The velocity and acceleration vectors as functions of time are $\vec{v}(t) = (2Bt)\hat{i} + (3Dt^2)\hat{j}$ and $\vec{a}(t) = (2B)\hat{i} + (6Dt)\hat{j}$. The acceleration is not constant.

3.42. **IDENTIFY:** Use Eqs. (2.17) and (2.18).

SET UP: At the maximum height $v_y = 0$.

EXECUTE: **(a)** $v_x = v_{0x} + \frac{\alpha}{3}t^3$, $v_y = v_{0y} + \beta t - \frac{\gamma}{2}t^2$, and $x = v_{0x}t + \frac{\alpha}{12}t^4$, $y = v_{0y}t + \frac{\beta}{2}t^2 - \frac{\gamma}{6}t^3$.

(b) Setting $v_y = 0$ yields a quadratic in t, $0 = v_{0y} + \beta t - \frac{\gamma}{2}t^2$, which has as the positive solution

$t = \frac{1}{\gamma}\left[\beta + \sqrt{\beta^2 + 2v_{0y}\gamma}\right] = 13.59$ s. Using this time in the expression for $y(t)$ gives a maximum height of 341 m.

(c) The path of the rocket is sketched in Figure 3.42.

(d) $y = 0$ gives $0 = v_{0y}t + \frac{\beta}{2}t^2 - \frac{\gamma}{6}t^3$ and $\frac{\gamma}{6}t^2 - \frac{\beta}{2}t - v_{0y} = 0$. The positive solution is $t = 20.73$ s. For this t, $x = 3.85 \times 10^4$ m.

EVALUATE: The graph in part (c) shows the path is not symmetric about the highest point and the time to return to the ground is less than twice the time to the maximum height.

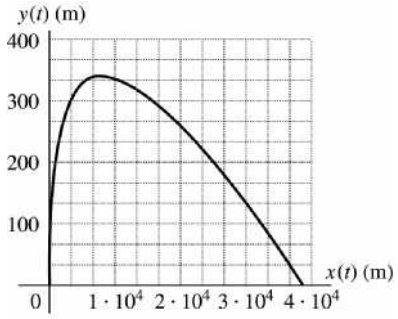

Figure 3.42

3.43. **IDENTIFY:** $\vec{v} = d\vec{r}/dt$. This vector will make a 45° angle with both axes when its x- and y-components are equal.

SET UP: $\frac{d(t^n)}{dt} = nt^{n-1}$.

EXECUTE: $\vec{v} = 2bt\hat{i} + 3ct^2\hat{j}$. $v_x = v_y$ gives $t = 2b/3c$.

EVALUATE: Both components of $\vec{v}$ change with t.

3.44. **IDENTIFY:** Use the position vector of a dragonfly to determine information about its velocity vector and acceleration vector.

SET UP: Use the definitions $v_x = dx/dt$, $v_y = dy/dt$, $a_x = dv_x/dt$, and $a_y = dv_y/dt$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: **(a)** Taking derivatives of the position vector gives the components of the velocity vector: $v_x(t) = (0.180 \text{ m/s}^2)t$, $v_y(t) = (-0.0450 \text{ m/s}^3)t^2$. Use these components and the given direction:

$\tan 30.0^\circ = \dfrac{(0.0450 \text{ m/s}^2)t^2}{(0.180 \text{ m/s}^2)t}$, which gives $t = 2.31$ s.

(b) Taking derivatives of the velocity components gives the acceleration components: $a_x = 0.180 \text{ m/s}^2$, $a_y(t) = -(0.0900 \text{ m/s}^3)t$. At $t = 2.31$ s, $a_x = 0.180 \text{ m/s}^2$ and $a_y = -0.208 \text{ m/s}^2$, giving $a = 0.275 \text{ m/s}^2$. The direction is $\tan\theta = \dfrac{0.208}{0.180}$, so $\theta = 49.1^\circ$ clockwise from $+x$-axis.

EVALUATE: The acceleration is not constant, so we cannot use the standard kinematics formulas.

3.45. **IDENTIFY:** Given the velocity components of a plane, when will its velocity be perpendicular to its acceleration?

SET UP: By definition, $a_x = dv_x/dt$, and $a_y = dv_y/dt$. When two vectors are perpendicular, their scalar product is zero.

EXECUTE: Taking the time derivative of the velocity vector gives $\vec{\boldsymbol{a}}(t) = (1.20 \text{ m/s}^2)\hat{\boldsymbol{i}} + (-2.00 \text{ m/s}^2)\hat{\boldsymbol{j}}$. When the velocity and acceleration are perpendicular to each other, $\vec{\boldsymbol{v}} \cdot \vec{\boldsymbol{a}} = (1.20 \text{ m/s}^2)^2 t + (12.0 \text{ m/s} - (2.00 \text{ m/s}^2)t)(-2.00 \text{ m/s}^2) = 0$. Solving for t gives $(5.44 \text{ m}^2/\text{s}^4)t = 24.0 \text{ m}^2/\text{s}^3$, so $t = 4.41$ s.

EVALUATE: There is only one instant at which the velocity and acceleration are perpendicular, so it is not a general rule.

3.46. **IDENTIFY:** $\vec{\boldsymbol{r}} = \vec{\boldsymbol{r}}_0 + \int_0^t \vec{\boldsymbol{v}}(t)dt$ and $\boldsymbol{a} = \dfrac{d\vec{\boldsymbol{v}}}{dt}$.

SET UP: At $t = 0$, $x_0 = 0$ and $y_0 = 0$.

EXECUTE: **(a)** Integrating, $\vec{\boldsymbol{r}} = \left(\alpha t - \dfrac{\beta}{3}t^3\right)\hat{\boldsymbol{i}} + \left(\dfrac{\gamma}{2}t^2\right)\hat{\boldsymbol{j}}$. Differentiating, $\vec{\boldsymbol{a}} = (-2\beta t)\hat{\boldsymbol{i}} + \gamma\hat{\boldsymbol{j}}$.

(b) The positive time at which $x = 0$ is given by $t^2 = 3\alpha/\beta$. At this time, the y-coordinate is

$$y = \frac{\gamma}{2}t^2 = \frac{3\alpha\gamma}{2\beta} = \frac{3(2.4 \text{ m/s})(4.0 \text{ m/s}^2)}{2(1.6 \text{ m/s}^3)} = 9.0 \text{ m}.$$

EVALUATE: The acceleration is not constant.

3.47. **IDENTIFY:** Once the rocket leaves the incline it moves in projectile motion. The acceleration along the incline determines the initial velocity and initial position for the projectile motion.

SET UP: For motion along the incline let $+x$ be directed up the incline. $v_x^2 = v_{0x}^2 + 2a_x(x - x_0)$ gives $v_x = \sqrt{2(1.25 \text{ m/s}^2)(200 \text{ m})} = 22.36$ m/s. When the projectile motion begins the rocket has $v_0 = 22.36$ m/s at 35.0° above the horizontal and is at a vertical height of $(200.0 \text{ m})\sin 35.0^\circ = 114.7$ m. For the projectile motion let $+x$ be horizontal to the right and let $+y$ be upward. Let $y = 0$ at the ground. Then $y_0 = 114.7$ m, $v_{0x} = v_0\cos 35.0^\circ = 18.32$ m/s, $v_{0y} = v_0\sin 35.0^\circ = 12.83$ m/s, $a_x = 0$, $a_y = -9.80 \text{ m/s}^2$. Let $x = 0$ at point A, so $x_0 = (200.0 \text{ m})\cos 35.0^\circ = 163.8$ m.

EXECUTE: **(a)** At the maximum height $v_y = 0$. $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ gives

$y - y_0 = \dfrac{v_y^2 - v_{0y}^2}{2a_y} = \dfrac{0 - (12.83 \text{ m/s})^2}{2(-9.80 \text{ m/s}^2)} = 8.40$ m and $y = 114.7 \text{ m} + 8.40 \text{ m} = 123$ m. The maximum height above ground is 123 m.

(b) The time in the air can be calculated from the vertical component of the projectile motion: $y - y_0 = -114.7$ m, $v_{0y} = 12.83$ m/s, $a_y = -9.80 \text{ m/s}^2$. $y - y_0 = v_{0y}t + \frac{1}{2}a_yt^2$ gives $(4.90 \text{ m/s}^2)t^2 - (12.83 \text{ m/s})t - 114.7$ m. The quadratic formula gives

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$t = \dfrac{1}{9.80}\left(12.83 \pm \sqrt{(12.83)^2 + 4(4.90)(114.7)}\right)$ s. The positive root is $t = 6.32$ s. Then $x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2 = (18.32 \text{ m/s})(6.32 \text{ s}) = 115.8 \text{ m}$ and $x = 163.8 \text{ m} + 115.8 \text{ m} = 280 \text{ m}$. The horizontal range of the rocket is 280 m.

EVALUATE: The expressions for h and R derived in Example 3.8 do not apply here. They are only for a projectile fired on level ground.

3.48. **IDENTIFY:** The person moves in projectile motion. Use the results in Example 3.8 to determine how T, h and D depend on g and set up a ratio.

SET UP: From Example 3.8, the time in the air is $t = \dfrac{2v_0 \sin\alpha_0}{g}$, the maximum height is $h = \dfrac{v_0^2 \sin^2\alpha_0}{2g}$ and the horizontal range (called D in the problem) is $D = \dfrac{v_0^2 \sin 2\alpha_0}{g}$. The person has the same v_0 and α_0 on Mars as on the earth.

EXECUTE: $tg = 2v_0 \sin\alpha_0$, which is constant, so $t_E g_E = t_M g_M$. $t_M = \left(\dfrac{g_E}{g_M}\right)t_E = \left(\dfrac{g_E}{0.379 g_E}\right)t_E = 2.64 t_E$.

$hg = \dfrac{v_0^2 \sin^2\alpha_0}{2}$, which is constant, so $h_E g_E = h_M g_M$. $h_M = \left(\dfrac{g_E}{g_M}\right)h_E = 2.64 h_E$. $Dg = v_0^2 \sin 2\alpha_0$, which is constant, so $D_E g_E = D_M g_M$. $D_M = \left(\dfrac{g_E}{g_M}\right)D_E = 2.64 D_E$.

EVALUATE: All three quantities are proportional to $1/g$ so all increase by the same factor of $g_E / g_M = 2.64$.

3.49. **IDENTIFY:** The range for a projectile that lands at the same height from which it was launched is $R = \dfrac{v_0^2 \sin 2\alpha}{g}$.

SET UP: The maximum range is for $\alpha = 45°$.

EXECUTE: Assuming $\alpha = 45°$, and $R = 50$ m, $v_0 = \sqrt{gR} = 22$ m/s.

EVALUATE: We have assumed that debris was launched at all angles, including the angle of $45°$ that gives maximum range.

3.50. **IDENTIFY:** The velocity has a horizontal tangential component and a vertical component. The vertical component of acceleration is zero and the horizontal component is $a_{rad} = \dfrac{v_x^2}{R}$.

SET UP: Let $+y$ be upward and $+x$ be in the direction of the tangential velocity at the instant we are considering.

EXECUTE: **(a)** The bird's tangential velocity can be found from $v_x = \dfrac{\text{circumference}}{\text{time of rotation}} = \dfrac{2\pi(6.00 \text{ m})}{5.00 \text{ s}} = 7.54 \text{ m/s}$.

Thus its velocity consists of the components $v_x = 7.54$ m/s and $v_y = 3.00$ m/s. The speed relative to the ground is then $v = \sqrt{v_x^2 + v_y^2} = 8.11$ m/s.

(b) The bird's speed is constant, so its acceleration is strictly centripetal—entirely in the horizontal direction, toward the center of its spiral path—and has magnitude $a_{rad} = \dfrac{v_x^2}{r} = \dfrac{(7.54 \text{ m/s})^2}{6.00 \text{ m}} = 9.48 \text{ m/s}^2$.

(c) Using the vertical and horizontal velocity components $\theta = \tan^{-1}\dfrac{3.00 \text{ m/s}}{7.54 \text{ m/s}} = 21.7°$.

EVALUATE: The angle between the bird's velocity and the horizontal remains constant as the bird rises.

3.51. **IDENTIFY:** Take $+y$ to be downward. Both objects have the same vertical motion, with v_{0y} and $a_y = +g$. Use constant acceleration equations for the x and y components of the motion.

SET UP: Use the vertical motion to find the time in the air:
$v_{0y} = 0,\ a_y = 9.80\ \text{m/s}^2,\ y - y_0 = 25\ \text{m},\ t = ?$.

EXECUTE: $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$ gives $t = 2.259$ s.

During this time the dart must travel 90 m, so the horizontal component of its velocity must be
$v_{0x} = \dfrac{x - x_0}{t} = \dfrac{70\ \text{m}}{2.25\ \text{s}} = 31\ \text{m/s}$.

EVALUATE: Both objects hit the ground at the same time. The dart hits the monkey for any muzzle velocity greater than 31 m/s.

3.52. **IDENTIFY:** The person moves in projectile motion. Her vertical motion determines her time in the air.

SET UP: Take $+y$ upward. $v_{0x} = 15.0$ m/s, $v_{0y} = +10.0$ m/s, $a_x = 0$, $a_y = -9.80\ \text{m/s}^2$.

EXECUTE: **(a)** Use the vertical motion to find the time in the air: $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$ with $y - y_0 = -30.0$ m gives $-30.0\ \text{m} = (10.0\ \text{m/s})t - (4.90\ \text{m/s}^2)t^2$. The quadratic formula gives $t = \dfrac{1}{2(4.9)}\left(+10.0 \pm \sqrt{(-10.0)^2 - 4(4.9)(-30)}\right)$ s. The positive solution is $t = 3.70$ s. During this time she travels a horizontal distance $x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2 = (15.0\ \text{m/s})(3.70\ \text{s}) = 55.5$ m. She will land 55.5 m south of the point where she drops from the helicopter and this is where the mats should have been placed.

(b) The x-t, y-t, v_x -t and v_y -t graphs are sketched in Figure 3.52.

EVALUATE: If she had dropped from rest at a height of 30.0 m it would have taken her $t = \sqrt{\dfrac{2(30.0\ \text{m})}{9.80\ \text{m/s}^2}} = 2.47$ s. She is in the air longer than this because she has an initial vertical component of velocity that is upward.

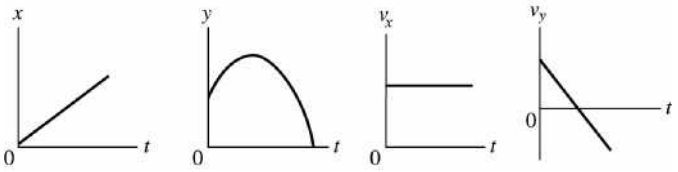

Figure 3.52

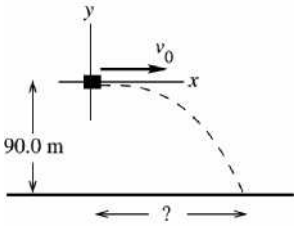
3.53. **IDENTIFY:** The cannister moves in projectile motion. Its initial velocity is horizontal. Apply constant acceleration equations for the x and y components of motion.

SET UP:



Take the origin of coordinates at the point where the canister is released. Take $+y$ to be upward. The initial velocity of the canister is the velocity of the plane, 64.0 m/s in the $+x$-direction.

Figure 3.53

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

Use the vertical motion to find the time of fall:

$t = ?,\ v_{0y} = 0,\ a_y = -9.80\ \text{m/s}^2,\ y - y_0 = -90.0\ \text{m}$ (When the canister reaches the ground it is 90.0 m below the origin.)

$$y - y_0 = v_{0y}t + \tfrac{1}{2}a_y t^2$$

EXECUTE: Since $v_{0y} = 0,\ t = \sqrt{\dfrac{2(y - y_0)}{a_y}} = \sqrt{\dfrac{2(-90.0\ \text{m})}{-9.80\ \text{m/s}^2}} = 4.286\ \text{s}.$

SET UP: Then use the horizontal component of the motion to calculate how far the canister falls in this time:

$x - x_0 = ?,\ a_x - 0,\ v_{0x} = 64.0\ \text{m/s}$

EXECUTE: $x - x_0 = v_0 t + \tfrac{1}{2}at^2 = (64.0\ \text{m/s})(4.286\ \text{s}) + 0 = 274\ \text{m}.$

EVALUATE: The time it takes the cannister to fall 90.0 m, starting from rest, is the time it travels horizontally at constant speed.

3.54. **IDENTIFY:** The shell moves as a projectile. To just clear the top of the cliff, the shell must have $y - y_0 = 25.0$ m when it has $x - x_0 = 60.0$ m.

SET UP: Let $+y$ be upward. $a_x = 0,\ a_y = -g.\ v_{0x} = v_0 \cos 43°,\ v_{0y} = v_0 \sin 43°.$

EXECUTE: **(a)** horizontal motion: $x - x_0 = v_{0x}t$ so $t = \dfrac{60.0\ \text{m}}{(v_0 \cos 43°)}$.

vertical motion: $y - y_0 = v_{0y}t + \tfrac{1}{2}a_y t^2$ gives $25.0\text{m} = (v_0 \sin 43.0°)\,t + \tfrac{1}{2}(-9.80\text{m/s}^2)\,t^2$.

Solving these two simultaneous equations for v_0 and t gives $v_0 = 32.6$ m/s and $t = 2.51$ s.

(b) v_y when shell reaches cliff:

$$v_y = v_{0y} + a_y t = (32.6\ \text{m/s}) \sin 43.0° - (9.80\ \text{m/s}^2)(2.51\ \text{s}) = -2.4\ \text{m/s}$$

The shell is traveling downward when it reaches the cliff, so it lands right at the edge of the cliff.

EVALUATE: The shell reaches its maximum height at $t = -\dfrac{v_{0y}}{a_y} = 2.27$ s, which confirms that at $t = 2.51$ s it has passed its maximum height and is on its way down when it strikes the edge of the cliff.

3.55. **IDENTIFY:** The suitcase moves in projectile motion. The initial velocity of the suitcase equals the velocity of the airplane.

SET UP: Take $+y$ to be upward. $a_x = 0,\ a_y = -g.$

EXECUTE: Use the vertical motion to find the time it takes the suitcase to reach the ground:

$v_{0y} = v_0 \sin 23°,\ a_y = -9.80\ \text{m/s}^2, y - y_0 = -114\ \text{m}, t = ?\ \ y - y_0 = v_{0y}t + \tfrac{1}{2}a_y t^2$ gives $t = 9.60$ s.

The distance the suitcase travels horizontally is $x - x_0 = v_{0x} = (v_0 \cos 23.0°)t = 795$ m.

EVALUATE: An object released from rest at a height of 114 m strikes the ground at $t = \sqrt{\dfrac{2(y - y_0)}{-g}} = 4.82$ s. The suitcase is in the air much longer than this since it initially has an upward component of velocity.

3.56. **IDENTIFY:** The equipment moves in projectile motion. The distance D is the horizontal range of the equipment plus the distance the ship moves while the equipment is in the air.

SET UP: For the motion of the equipment take $+x$ to be to the right and $+y$ to be upward. Then $a_x = 0$, $a_y = -9.80\ \text{m/s}^2,\ v_{0x} = v_0 \cos\alpha_0 = 7.50$ m/s and $v_{0y} = v_0 \sin\alpha_0 = 13.0$ m/s. When the equipment lands in the front of the ship, $y - y_0 = -8.75$ m.

EXECUTE: Use the vertical motion of the equipment to find its time in the air: $y - y_0 = v_{0y}t + \tfrac{1}{2}a_y t^2$ gives $t = \dfrac{1}{9.80}\left(13.0 \pm \sqrt{(-13.0)^2 + 4(4.90)(8.75)}\right)$ s. The positive root is $t = 3.21$ s. The horizontal range of the

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

equipment is $x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2 = (7.50 \text{ m/s})(3.21 \text{ s}) = 24.1 \text{ m}$. In 3.21 s the ship moves a horizontal distance $(0.450 \text{ m/s})(3.21 \text{ s}) = 1.44 \text{ m}$, so $D = 24.1 \text{ m} + 1.44 \text{ m} = 25.5 \text{ m}$.

EVALUATE: The equation $R = \dfrac{v_0^2 \sin 2\alpha_0}{g}$ from Example 3.8 can't be used because the starting and ending points of the projectile motion are at different heights.

3.57. **IDENTIFY:** Find the horizontal distance a rocket moves if it has a non-constant horizontal acceleration but a constant vertical acceleration of *g* downward.

SET UP: The vertical motion is *g* downward, so we can use the constant acceleration formulas for that component of the motion. We must use integration for the horizontal motion because the acceleration is not constant. Solving for *t* in the kinematics formula for *y* gives $t = \sqrt{\dfrac{2(y - y_0)}{a_y}}$. In the horizontal direction we must use $v_x(t) = v_{0x} + \int_0^t a_x(t')dt'$ and $x - x_0 = \int_0^t v_x(t')dt'$.

EXECUTE: Use vertical motion to find *t*. $t = \sqrt{\dfrac{2(y - y_0)}{a_y}} = \sqrt{\dfrac{2(30.0 \text{ m})}{9.80 \text{ m/s}^2}} = 2.474 \text{ s}$.

In the horizontal direction we have

$v_x(t) = v_{0x} + \int_0^t a_x(t')dt' = v_{0x} + (0.800 \text{ m/s}^3)t^2 = 12.0 \text{ m/s} + (0.800 \text{ m/s}^2)t^2$. Integrating $v_x(t)$ gives

$x - x_0 = (12.0 \text{ m/s})t + (0.2667 \text{ m/s}^3)t^3$. At $t = 2.474$ s, $x - x_0 = 29.69 \text{ m} + 4.04 \text{ m} = 33.7 \text{ m}$.

EVALUATE: The vertical part of the motion is familiar projectile motion, but the horizontal part is not.

3.58. **IDENTIFY:** While the hay falls 150 m with an initial upward velocity and with a downward acceleration of *g*, it must travel a horizontal distance (the target variable) with constant horizontal velocity.

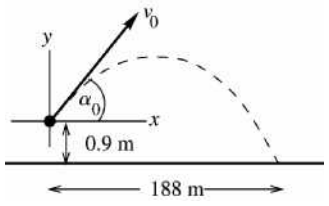
SET UP: Use coordinates with $+y$ upward and $+x$ horizontal. The bale has initial velocity components $v_{0x} = v_0 \cos\alpha_0 = (75 \text{ m/s})\cos 55° = 43.0 \text{ m/s}$ and $v_{0y} = v_0 \sin\alpha_0 = (75 \text{ m/s})\sin 55° = 61.4 \text{ m/s}$. $y_0 = 150$ m and $y = 0$. The equation $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$ applies to the vertical motion and a similar equation to the horizontal motion.

EXECUTE: Use the vertical motion to find *t*: $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$ gives

$-150 \text{ m} = (61.4 \text{ m/s})t - (4.90 \text{ m/s}^2)t^2$. The quadratic formula gives $t = 6.27 \pm 8.36$ s. The physical value is the positive one, and $t = 14.6$ s. Then $x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2 = (43.0 \text{ m/s})(14.6 \text{ s}) = 630 \text{ m}$.

EVALUATE: If the airplane maintains constant velocity after it releases the bales, it will also travel horizontally 630 m during the time it takes the bales to fall to the ground, so the airplane will be directly over the impact spot when the bales land.

3.59. **IDENTIFY:** Projectile motion problem.



Take the origin of coordinates at the point where the ball leaves the bat, and take +*y* to be upward.

$v_{0x} = v_0 \cos\alpha_0$

$v_{0y} = v_0 \sin\alpha_0$,

but we don't know v_0.

Figure 3.59

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

Write down the equation for the horizontal displacement when the ball hits the ground and the corresponding equation for the vertical displacement. The time t is the same for both components, so this will give us two equations in two unknowns (v_0 and t).

(a) SET UP: y-component:

$a_y = -9.80\ \text{m/s}^2,\ \ y - y_0 = -0.9\ \text{m},\ \ v_{0y} = v_0 \sin 45°$

$y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$

EXECUTE: $-0.9\ \text{m} = (v_0 \sin 45°)t + \frac{1}{2}(-9.80\ \text{m/s}^2)t^2$

SET UP: x-component:

$a_x = 0,\ \ x - x_0 = 188\ \text{m},\ \ v_{0x} = v_0 \cos 45°$

$x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2$

EXECUTE: $t = \dfrac{x - x_0}{v_{0x}} = \dfrac{188\ \text{m}}{v_0 \cos 45°}$

Put the expression for t from the x-component motion into the y-component equation and solve for v_0. (Note that $\sin 45° = \cos 45°$.)

$$-0.9\ \text{m} = (v_0 \sin 45°)\left(\frac{188\ \text{m}}{v_0 \cos 45°}\right) - (4.90\ \text{m/s}^2)\left(\frac{188\ \text{m}}{v_0 \cos 45°}\right)^2$$

$$4.90\ \text{m/s}^2\left(\frac{188\ \text{m}}{v_0 \cos 45°}\right)^2 = 188\ \text{m} + 0.9\ \text{m} = 188.9\ \text{m}$$

$$\left(\frac{v_0 \cos 45°}{188\ \text{m}}\right)^2 = \frac{4.90\ \text{m/s}^2}{188.9\ \text{m}},\ \ v_0 = \left(\frac{188\ \text{m}}{\cos 45°}\right)\sqrt{\frac{4.90\ \text{m/s}^2}{188.9\ \text{m}}} = 42.8\ \text{m/s}$$

(b) Use the horizontal motion to find the time it takes the ball to reach the fence:

SET UP: x-component:

$x - x_0 = 116\ \text{m},\ \ a_x = 0,\ \ v_{0x} = v_0 \cos 45° = (42.8\ \text{m/s}) \cos 45° = 30.3\ \text{m/s},\ \ t = ?$

$x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2$

EXECUTE: $t = \dfrac{x - x_0}{v_{0x}} = \dfrac{116\ \text{m}}{30.3\ \text{m/s}} = 3.83\ \text{s}$

SET UP: Find the vertical displacement of the ball at this t:

y-component:

$y - y_0 = ?,\ \ a_y = -9.80\ \text{m/s}^2,\ \ v_{0y} = v_0 \sin 45° = 30.3\ \text{m/s},\ \ t = 3.83\ \text{s}$

$y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$

EXECUTE: $y - y_0 = (30.3\ \text{s})(3.83\ \text{s}) + \frac{1}{2}(-9.80\ \text{m/s}^2)(3.83\ \text{s})^2$

$y - y_0 = 116.0\ \text{m} - 71.9\ \text{m} = +44.1\ \text{m}$, above the point where the ball was hit. The height of the ball above the ground is $44.1\ \text{m} + 0.90\ \text{m} = 45.0\ \text{m}$. It's height then above the top of the fence is $45.0\ \text{m} - 3.0\ \text{m} = 42.0\ \text{m}$.

EVALUATE: With $v_0 = 42.8\ \text{m/s}$, $v_{0y} = 30.3\ \text{m/s}$ and it takes the ball 6.18 s to return to the height where it was hit and only slightly longer to reach a point 0.9 m below this height. $t = (188\ \text{m})/(v_0 \cos 45°)$ gives $t = 6.21\ \text{s}$, which agrees with this estimate. The ball reaches its maximum height approximately $(188\ \text{m})/2 = 94\ \text{m}$ from home plate, so at the fence the ball is not far past its maximum height of 47.6 m, so a height of 45.0 m at the fence is reasonable.

3.60. **IDENTIFY:** The water moves in projectile motion.

SET UP: Let $x_0 = y_0 = 0$ and take $+y$ to be positive. $a_x = 0,\ \ a_y = -g$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: The equations of motions are $y=(v_0 \sin\alpha)t-\frac{1}{2}gt^2$ and $x=(v_0\cos\alpha)t$. When the water goes in the tank for the *minimum* velocity, $y=2D$ and $x=6D$. When the water goes in the tank for the *maximum* velocity, $y=2D$ and $x=7D$. In both cases, $\sin\alpha=\cos\alpha=\sqrt{2}/2$.

To reach the *minimum* distance: $6D=\frac{\sqrt{2}}{2}v_0t$, and $2D=\frac{\sqrt{2}}{2}v_0t-\frac{1}{2}gt^2$. Solving the first equation for t gives $t=\frac{6D\sqrt{2}}{v_0}$. Substituting this into the second equation gives $2D=6D-\frac{1}{2}g\left(\frac{6D\sqrt{2}}{v_0}\right)^2$. Solving this for v_0 gives $v_0=3\sqrt{gD}$.

To reach the *maximum* distance: $7D=\frac{\sqrt{2}}{2}v_0t$, and $2D=\frac{\sqrt{2}}{2}v_0t-\frac{1}{2}gt^2$. Solving the first equation for t gives $t=\frac{7D\sqrt{2}}{v_0}$. Substituting this into the second equation gives $2D=7D-\frac{1}{2}g\left(\frac{7D\sqrt{2}}{v_0}\right)^2$. Solving this for v_0 gives $v_0=\sqrt{49gD/5}=3.13\sqrt{gD}$, which, as expected, is larger than the previous result.

EVALUATE: A launch speed of $v_0=\sqrt{6}\sqrt{gD}=2.45\sqrt{gD}$ is required for a horizontal range of $6D$. The minimum speed required is greater than this, because the water must be at a height of at least $2D$ when it reaches the front of the tank.

3.61. **IDENTIFY:** The equations for h and R from Example 3.8 can be used.

SET UP: $h=\frac{v_0^2\sin^2\alpha_0}{2g}$ and $R=\frac{v_0^2\sin 2\alpha_0}{g}$. If the projectile is launched straight up, $\alpha_0=90°$.

EXECUTE: **(a)** $h=\frac{v_0^2}{2g}$ and $v_0=\sqrt{2gh}$.

(b) Calculate α_0 that gives a maximum height of h when $v_0=2\sqrt{2gh}$. $h=\frac{8gh\sin^2\alpha_0}{2g}=4h\sin^2\alpha_0$.

$\sin\alpha_0=\frac{1}{2}$ and $\alpha_0=30.0°$.

(c) $R=\frac{(2\sqrt{2gh})^2\sin 60.0°}{g}=6.93h$.

EVALUATE: $\frac{v_0^2}{g}=\frac{2h}{\sin^2\alpha_0}$ so $R=\frac{2h\sin(2\alpha_0)}{\sin^2\alpha_0}$. For a given α_0, R increases when h increases. For $\alpha_0=90°$, $R=0$ and for $\alpha_0=0°$, $h=0$ and $R=0$. For $\alpha_0=45°$, $R=4h$.

3.62. **IDENTIFY:** To clear the bar the ball must have a height of 10.0 ft when it has a horizontal displacement of 36.0 ft. The ball moves as a projectile. When v_0 is very large, the ball reaches the goal posts in a very short time and the acceleration due to gravity causes negligible downward displacement.

SET UP: 36.0 ft = 10.97 m; 10.0 ft = 3.048 m. Let $+x$ be to the right and $+y$ be upward, so $a_x=0$, $a_y=-g$, $v_{0x}=v_0\cos\alpha_0$ and $v_{0y}=v_0\sin\alpha_0$.

EXECUTE: **(a)** The ball cannot be aimed lower than directly at the bar. $\tan\alpha_0=\frac{10.0\text{ ft}}{36.0\text{ ft}}$ and $\alpha_0=15.5°$.

(b) $x-x_0=v_{0x}t+\frac{1}{2}a_xt^2$ gives $t=\frac{x-x_0}{v_{0x}}=\frac{x-x_0}{v_0\cos\alpha_0}$. Then $y-y_0=v_{0y}t+\frac{1}{2}a_yt^2$ gives

$$y-y_0=(v_0\sin\alpha_0)\left(\frac{x-x_0}{v_0\cos\alpha_0}\right)-\frac{1}{2}g\frac{(x-x_0)^2}{v_0^2\cos^2\alpha_0}=(x-x_0)\tan\alpha_0-\frac{1}{2}g\frac{(x-x_0)^2}{v_0^2\cos^2\alpha_0}.$$

$$v_0=\frac{(x-x_0)}{\cos\alpha_0}\sqrt{\frac{g}{2[(x-x_0)\tan\alpha_0-(y-y_0)]}}=\frac{10.97\text{ m}}{\cos 45.0°}\sqrt{\frac{9.80\text{ m/s}^2}{2[10.97\text{ m}-3.048\text{ m}]}}=12.2\text{ m/s}$$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: With the v_0 in part (b) the horizontal range of the ball is $R = \dfrac{v_0^2 \sin 2\alpha_0}{g} = 15.2 \text{ m} = 49.9 \text{ ft}$. The ball reaches the highest point in its trajectory when $x - x_0 = R/2$, so when it reaches the goal posts it is on its way down.

3.63. **IDENTIFY:** From the figure in the text, we can read off the maximum height and maximum horizontal distance reached by the grasshopper. Knowing its acceleration is *g* downward, we can find its initial speed and the height of the cliff (the target variables).

SET UP: Use coordinates with the origin at the ground and $+y$ upward. $a_x = 0$, $a_y = -9.80 \text{ m/s}^2$. The constant-acceleration kinematics formulas $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ and $x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2$ apply.

EXECUTE: **(a)** $v_y = 0$ when $y - y_0 = 0.0674$ m. $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ gives

$v_{0y} = \sqrt{-2a_y(y - y_0)} = \sqrt{-2(-9.80 \text{ m/s}^2)(0.0674 \text{ m})} = 1.15 \text{ m/s}$. $v_{0y} = v_0 \sin\alpha_0$ so

$v_0 = \dfrac{v_{0y}}{\sin\alpha_0} = \dfrac{1.15 \text{ m/s}}{\sin 50.0^\circ} = 1.50 \text{ m/s}$.

(b) Use the horizontal motion to find the time in the air. The grasshopper travels horizontally $x - x_0 = 1.06$ m. $x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2$ gives $t = \dfrac{x - x_0}{v_{0x}} = \dfrac{x - x_0}{v_0 \cos 50.0^\circ} = 1.10$ s. Find the vertical displacement of the grasshopper at $t = 1.10$ s:

$y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2 = (1.15 \text{ m/s})(1.10 \text{ s}) + \frac{1}{2}(-9.80 \text{ m/s}^2)(1.10 \text{ s})^2 = -4.66$ m. The height of the cliff is 4.66 m.

EVALUATE: The grasshopper's maximum height (6.74 cm) is physically reasonable, so its takeoff speed of 1.50 m/s must also be reasonable. Note that the equation $R = \dfrac{v_0^2 \sin 2\alpha_0}{g}$ does *not* apply here since the launch point is not at the same level as the landing point.

3.64. **IDENTIFY:** We know the initial height, the angle of projection, the horizontal range, and the acceleration (*g* downward) of the object and want to find its initial speed.

SET UP: Use coordinates with the origin at the ground and $+y$ upward. The shot put has $y_0 = 2.00$ m, $v_{0x} = v_0 \cos\alpha_0$, $v_{0y} = v_0 \sin\alpha_0$, $a_x = 0$ and $a_y = -9.80 \text{ m/s}^2$. The constant-acceleration kinematics formula $x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2$ applies. Also 1 mph = 0.4470 m/s.

EXECUTE: $x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2$ gives $23.11 \text{ m} = (v_0 \cos 40.0^\circ)\, t$ and $v_0 t = 30.17$ m.

$y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$ gives $0 = 2.00 \text{ m} + (v_0 \sin 40.0^\circ)\, t - (4.90 \text{ m/s}^2)\, t^2$. Use $v_0 t = 30.17$ m and solve for *t*. This gives $t = 2.09$ s. Then $v_0 = \dfrac{30.17 \text{ m}}{2.09 \text{ s}} = 14.4 \text{ m/s} = 32.2 \text{ mph}$.

EVALUATE: At a speed of about 32 mph, the object leaves the athlete's hand with a speed around half of freeway speed for a car. Also, since the initial and final heights are not the same, the equation $R = \dfrac{v_0^2 \sin 2\alpha_0}{g}$ does not apply.

3.65. **IDENTIFY:** The snowball moves in projectile motion. In part (a) the vertical motion determines the time in the air. In part (c), find the height of the snowball above the ground after it has traveled horizontally 4.0 m.

SET UP: Let +*y* be downward. $a_x = 0$, $a_y = +9.80 \text{ m/s}^2$. $v_{0x} = v_0 \cos\theta_0 = 5.36$ m/s, $v_{0y} = v_0 \sin\theta_0 = 4.50$ m/s.

EXECUTE: **(a)** Use the vertical motion to find the time in the air: $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$ with $y - y_0 = 14.0$ m gives $14.0 \text{ m} = (4.50 \text{ m/s})\, t + (4.9 \text{ m/s}^2)\, t^2$. The quadratic formula gives

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$t = \dfrac{1}{2(4.9)}\left(-4.50 \pm \sqrt{(4.50)^2 - 4\,(4.9)(-14.0)}\right)$ s. The positive root is $t = 1.29$ s. Then

$x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2 = (5.36 \text{ m/s})(1.29 \text{ s}) = 6.91$ m.

(b) The *x*-*t*, *y*-*t*, v_x-t and v_y-t graphs are sketched in Figure 3.65.

(c) $x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2$ gives $t = \dfrac{x - x_0}{v_{0x}} = \dfrac{4.0 \text{ m}}{5.36 \text{ m/s}} = 0.746$ s. In this time the snowball travels downward a distance $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2 = 6.08$ m and is therefore $14.0 \text{ m} - 6.08 \text{ m} = 7.9$ m above the ground. The snowball passes well above the man and doesn't hit him.

EVALUATE: If the snowball had been released from rest at a height of 14.0 m it would have reached the ground in $t = \sqrt{\dfrac{2(14.0 \text{ m})}{9.80 \text{ m/s}^2}} = 1.69$ s. The snowball reaches the ground in a shorter time than this because of its initial downward component of velocity.

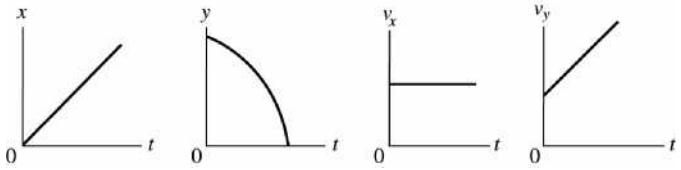


Figure 3.65

3.66. **IDENTIFY:** Mary Belle moves in projectile motion.

SET UP: Let $+y$ be upward. $a_x = 0$, $a_y = -g$.

EXECUTE: **(a)** Eq. (3.27) with $x = 8.2$ m, $y = 6.1$ m and $\alpha_0 = 53°$ gives $v_0 = 13.8$ m/s.

(b) When she reached Joe Bob, $t = \dfrac{8.2 \text{ m}}{v_0 \cos 53°} = 0.9874$ s. $v_x = v_{0x} = 8.31$ m/s and

$v_y = v_{0y} + a_y t = +1.34$ m/s. $v = 8.4$ m/s, at an angle of $9.16°$.

(c) The graph of $v_x(t)$ is a horizontal line. The other graphs are sketched in Figure 3.66.

(d) Use Eq. (3.27), which becomes $y = (1.327)\,x - (0.071115 \text{ m}^{-1})\,x^2$. Setting $y = -8.6$ m gives $x = 23.8$ m as the positive solution.

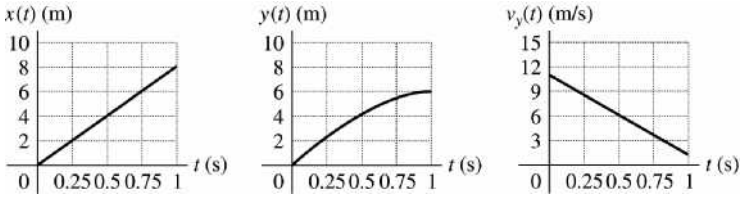

Figure 3.66

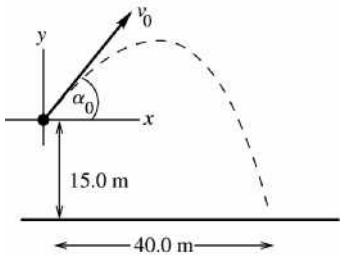
3.67. **(a) IDENTIFY:** Projectile motion.



Take the origin of coordinates at the top of the ramp and take $+y$ to be upward.

The problem specifies that the object is displaced 40.0 m to the right when it is 15.0 m below the origin.

Figure 3.67

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

We don't know *t*, the time in the air, and we don't know v_0. Write down the equations for the horizontal and vertical displacements. Combine these two equations to eliminate one unknown.

SET UP: *y*-component:

$y - y_0 = -15.0 \text{ m}, \ a_y = -9.80 \text{ m/s}^2, \ v_{0y} = v_0 \sin 53.0°$

$y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$

EXECUTE: $-15.0 \text{ m} = (v_0 \sin 53.0°)\, t - (4.90 \text{ m/s}^2)\, t^2$

SET UP: *x*-component:

$x - x_0 = 40.0 \text{ m}, \ a_x = 0, \ v_{0x} = v_0 \cos 53.0°$

$x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2$

EXECUTE: $40.0 \text{ m} = (v_0 t)\cos 53.0°$

The second equation says $v_0 t = \dfrac{40.0 \text{ m}}{\cos 53.0°} = 66.47 \text{ m}.$

Use this to replace $v_0 t$ in the first equation:

$-15.0 \text{ m} = (66.47 \text{ m}) \sin 53° - (4.90 \text{ m/s}^2)\, t^2$

$t = \sqrt{\dfrac{(66.46 \text{ m}) \sin 53° + 15.0 \text{ m}}{4.90 \text{ m/s}^2}} = \sqrt{\dfrac{68.08 \text{ m}}{4.90 \text{ m/s}^2}} = 3.727 \text{ s}.$

Now that we have *t* we can use the *x*-component equation to solve for v_0:

$v_0 = \dfrac{40.0 \text{ m}}{t \cos 53.0°} = \dfrac{40.0 \text{ m}}{(3.727 \text{ s}) \cos 53.0°} = 17.8 \text{ m/s}.$

EVALUATE: Using these values of v_0 and *t* in the $y = y_0 = v_{0y} + \frac{1}{2}a_y t^2$ equation verifies that $y - y_0 = -15.0 \text{ m}.$

(b) IDENTIFY: $v_0 = (17.8 \text{ m/s})/2 = 8.9 \text{ m/s}$

This is less than the speed required to make it to the other side, so he lands in the river.

Use the vertical motion to find the time it takes him to reach the water:

SET UP: $y - y_0 = -100 \text{ m}; \ v_{0y} = +v_0 \sin 53.0° = 7.11 \text{ m/s}; \ a_y = -9.80 \text{ m/s}^2$

$y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$ gives $-100 = 7.11t - 4.90t^2$

EXECUTE: $4.90t^2 - 7.11t - 100 = 0$ and $t = \frac{1}{9.80}\left(7.11 \pm \sqrt{(7.11)^2 - 4\,(4.90)(-100)}\right)$

$t = 0.726 \text{ s} \pm 4.57 \text{ s}$ so $t = 5.30 \text{ s}.$

The horizontal distance he travels in this time is

$$x - x_0 = v_{0x}t = (v_0 \cos 53.0°)\, t = (5.36 \text{ m/s})(5.30 \text{ s}) = 28.4 \text{ m}.$$

He lands in the river a horizontal distance of 28.4 m from his launch point.

EVALUATE: He has half the minimum speed and makes it only about halfway across.

3.68. **IDENTIFY:** The rock moves in projectile motion.

SET UP: Let $+y$ be upward. $a_x = 0, \ a_y = -g$. Eqs. (3.22) and (3.23) give v_x and v_y.

EXECUTE: Combining Eqs. 3.25, 3.22 and 3.23 gives

$v^2 = v_0^2 \cos^2 \alpha_0 + (v_0 \sin \alpha_0 - gt)^2 = v_0^2\,(\sin^2 \alpha_0 + \cos^2 \alpha_0) - 2v_0 \sin \alpha_0 gt + (gt)^2.$

$v^2 = v_0^2 - 2g\left(v_0 \sin \alpha_0 t - \dfrac{1}{2}gt^2\right) = v_0^2 - 2gy,$ where Eq. (3.21) has been used to eliminate *t* in favor of *y*. For the case of a rock thrown from the roof of a building of height *h*, the speed at the ground is found by substituting $y = -h$ into the above expression, yielding $v = \sqrt{v_0^2 + 2gh},$ which is independent of α_0.

EVALUATE: This result, as will be seen in the chapter dealing with conservation of energy (Chapter 7), is valid for any *y*, positive, negative or zero, as long as $v_0^2 - 2gy > 0.$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

3.69. **IDENTIFY** and **SET UP:** Take $+y$ to be upward. The rocket moves with projectile motion, with $v_{0y} = +40.0$ m/s and $v_{0x} = 30.0$ m/s relative to the ground. The vertical motion of the rocket is unaffected by its horizontal velocity.

EXECUTE: **(a)** $v_y = 0$ (at maximum height), $v_{0y} = +40.0$ m/s, $a_y = -9.80$ m/s^2, $y - y_0 = ?$

$v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ gives $y - y_0 = 81.6$ m

(b) Both the cart and the rocket have the same constant horizontal velocity, so both travel the same horizontal distance while the rocket is in the air and the rocket lands in the cart.

(c) Use the vertical motion of the rocket to find the time it is in the air.

$v_{0y} = 40$ m/s, $a_y = -9.80$ m/s^2, $v_y = -40$ m/s, $t = ?$

$v_y = v_{0y} + a_y t$ gives $t = 8.164$ s

Then $x - x_0 = v_{0x}t = (30.0 \text{ m/s})(8.164 \text{ s}) = 245$ m.

(d) Relative to the ground the rocket has initial velocity components $v_{0x} = 30.0$ m/s and $v_{0y} = 40.0$ m/s, so it is traveling at $53.1°$ above the horizontal.

(e) (i)

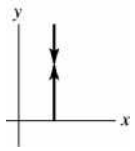


Figure 3.69a

Relative to the cart, the rocket travels straight up and then straight down.

(ii)

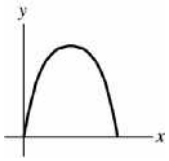

Figure 3.69b

Relative to the ground the rocket travels in a parabola.

EVALUATE: Both the cart and rocket have the same constant horizontal velocity. The rocket lands in the cart.

3.70. **IDENTIFY:** The ball moves in projectile motion.

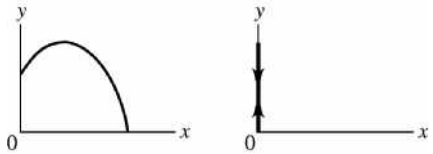
SET UP: The woman and ball travel for the same time and must travel the same horizontal distance, so for the ball $v_{0x} = 6.00$ m/s.

EXECUTE: **(a)** $v_{0x} = v_0 \cos\theta_0$. $\cos\theta_0 = \dfrac{v_{0x}}{v_0} = \dfrac{6.00 \text{ m/s}}{20.0 \text{ m/s}}$ and $\theta_0 = 72.5°$. The ball is in the air for 5.55s and she runs a distance of $(6.00 \text{ m/s})(5.55 \text{ s}) = 33.3$ m.

(b) Relative to the ground the ball moves in a parabola. The ball and the runner have the same horizontal component of velocity, so relative to the runner the ball has only vertical motion. The trajectories as seen by each observer are sketched in Figure 3.70.

EVALUATE: The ball could be thrown with a different speed, so long as the angle at which it was thrown was adjusted to keep $v_{0x} = 6.00$ m/s.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.



Viewed by person at rest on ground

Viewed by the runner

Figure 3.70

3.71. **IDENTIFY:** The boulder moves in projectile motion.

SET UP: Take $+y$ downward. $v_{0x} = v_0$, $a_x = 0$, $a_x = 0$, $a_y = +9.80\ \text{m/s}^2$.

EXECUTE: **(a)** Use the vertical motion to find the time for the boulder to reach the level of the lake: $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$ with $y - y_0 = +20\ \text{m}$ gives $t = \sqrt{\dfrac{2(y-y_0)}{a_y}} = \sqrt{\dfrac{2(20\ \text{m})}{9.80\ \text{m/s}^2}} = 2.02\ \text{s}$. The rock must travel horizontally 100 m during this time. $x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2$ gives $v_0 = v_{0x} = \dfrac{x - x_0}{t} = \dfrac{100\ \text{m}}{2.02\ \text{s}} = 49.5\ \text{m/s}$

(b) In going from the edge of the cliff to the plain, the boulder travels downward a distance of $y - y_0 = 45\ \text{m}$. $t = \sqrt{\dfrac{2(y-y_0)}{a_y}} = \sqrt{\dfrac{2(45\ \text{m})}{9.80\ \text{m/s}^2}} = 3.03\ \text{s}$ and $x - x_0 = v_{0x}t = (49.5\ \text{m/s})(3.03\ \text{s}) = 150\ \text{m}$.

The rock lands $150\ \text{m} - 100\ \text{m} = 50\ \text{m}$ beyond the foot of the dam.

EVALUATE: The boulder passes over the dam 2.02 s after it leaves the cliff and then travels an additional 1.01 s before landing on the plain. If the boulder has an initial speed that is less than 49 m/s, then it lands in the lake.

3.72. **IDENTIFY:** The bagels move in projectile motion. Find Henrietta's location when the bagels reach the ground, and require the bagels to have this horizontal range.

SET UP: Let $+y$ be downward and let $x_0 = y_0 = 0$. $a_x = 0$, $a_y = +g$. When the bagels reach the ground, $y = 38.0\ \text{m}$.

EXECUTE: **(a)** When she catches the bagels, Henrietta has been jogging for 9.00 s plus the time for the bagels to fall 38.0 m from rest. Get the time to fall: $y = \dfrac{1}{2}gt^2$, $38.0\ \text{m} = \dfrac{1}{2}(9.80\ \text{m/s}^2)\,t^2$ and $t = 2.78\ \text{s}$.

So, she has been jogging for $9.00\ \text{s} + 2.78\ \text{s} = 11.78\ \text{s}$. During this time she has gone $x = vt = (3.05\ \text{m/s})(11.78\ \text{s}) = 35.9\ \text{m}$. Bruce must throw the bagels so they travel 35.9 m horizontally in 2.78 s. This gives $x = vt$. $35.9\ \text{m} = v\,(2.78\ \text{s})$ and $v = 12.9\ \text{m/s}$.

(b) 35.9 m from the building.

EVALUATE: If $v > 12.9\ \text{m/s}$ the bagels land in front of her and if $v < 12.9\ \text{m/s}$ they land behind her. There is a range of velocities greater than 12.9 m/s for which she would catch the bagels in the air, at some height above the sidewalk.

3.73. **IDENTIFY:** The shell moves in projectile motion. To find the horizontal distance between the tanks we must find the horizontal velocity of one tank relative to the other. Take $+y$ to be upward.

(a) SET UP: The vertical motion of the shell is unaffected by the horizontal motion of the tank. Use the vertical motion of the shell to find the time the shell is in the air:

$v_{0y} = v_0 \sin\alpha = 43.4\ \text{m/s}$, $a_y = -9.80\ \text{m/s}^2$, $y - y_0 = 0$ (returns to initial height), $t = ?$

EXECUTE: $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$ gives $t = 8.86\ \text{s}$

SET UP: Consider the motion of one tank relative to the other.

EXECUTE: Relative to tank #1 the shell has a constant horizontal velocity $v_0 \cos\alpha = 246.2\ \text{m/s}$. Relative to the ground the horizontal velocity component is $246.2\ \text{m/s} + 15.0\ \text{m/s} = 261.2\ \text{m/s}$. Relative to tank #2 the shell has horizontal velocity component $261.2\ \text{m/s} - 35.0\ \text{m/s} = 226.2\ \text{m/s}$. The distance between the tanks when the shell was fired is the $(226.2\ \text{m/s})(8.86\ \text{s}) = 2000\ \text{m}$ that the shell travels relative to tank #2 during the 8.86 s that the shell is in the air.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) The tanks are initially 2000 m apart. In 8.86 s tank #1 travels 133 m and tank #2 travels 310 m, in the same direction. Therefore, their separation increases by $310\text{ m} - 133\text{ m} = 177\text{ m}$. So, the separation becomes 2180 m (rounding to 3 significant figures).

EVALUATE: The retreating tank has greater speed than the approaching tank, so they move farther apart while the shell is in the air. We can also calculate the separation in part (b) as the relative speed of the tanks times the time the shell is in the air: $(35.0\text{ m/s} - 15.0\text{ m/s})(8.86\text{ s}) = 177\text{ m}$.

3.74. **IDENTIFY:** The object moves with constant acceleration in both the horizontal and vertical directions.

SET UP: Let $+y$ be downward and let $+x$ be the direction in which the firecracker is thrown.

EXECUTE: The firecracker's falling time can be found from the vertical motion: $t = \sqrt{\dfrac{2h}{g}}$.

The firecracker's horizontal position at any time t (taking the student's position as $x = 0$) is $x = vt - \frac{1}{2}at^2$. $x = 0$ when cracker hits the ground, so $t = 2v/a$. Combining this with the expression for the falling time gives $\dfrac{2v}{a} = \sqrt{\dfrac{2h}{g}}$ and $h = \dfrac{2v^2 g}{a^2}$.

EVALUATE: When h is smaller, the time in the air is smaller and either v must be smaller or a must be larger.

3.75. **IDENTIFY:** The original firecracker moves as a projectile. At its maximum height its velocity is horizontal. The velocity $\vec{v}_{A/G}$ of fragment A relative to the ground is related to the velocity $\vec{v}_{F/G}$ of the original firecracker relative to the ground and the velocity $\vec{v}_{A/F}$ of the fragment relative to the original firecracker by $\vec{v}_{A/G} = \vec{v}_{A/F} + \vec{v}_{F/G}$. Fragment B obeys a similar equation.

SET UP: Let $+x$ be along the direction of the horizontal motion of the firecracker before it explodes and let $+y$ be upward. Fragment A moves at $53.0°$ above the $+x$ direction and fragment B moves at $53.0°$ below the $+x$ direction. Before it explodes the firecracker has $a_x = 0$ and $a_y = -9.80\text{ m/s}^2$.

EXECUTE: The horizontal component of the firecracker's velocity relative to the ground is constant (since $a_x = 0$), so $v_{F/G-x} = (25.0\text{ m/s})\cos 30.0° = 21.65\text{ m/s}$. At the time of the explosion, $v_{F/G-y} = 0$. For fragment A, $v_{A/F-x} = (20.0\text{ m/s})\cos 53.0° = 12.0\text{ m/s}$ and $v_{A/F-y} = (20.0\text{ m/s})\sin 53.0° = 16.0\text{ m/s}$.

$v_{A/G-x} = v_{A/F-x} + v_{F/G-x} = 12.0\text{ m/s} + 21.65\text{ m/s} = 33.7\text{ m/s}$. $v_{A/G-y} = v_{A/F-y} + v_{F/G-y} = 16.0\text{ m/s}$.

$\tan\alpha_0 = \dfrac{v_{A/G-y}}{v_{A/G-x}} = \dfrac{16.0\text{ m/s}}{33.7\text{ m/s}}$ and $\alpha_0 = 25.4°$. The calculation for fragment B is the same, except $v_{A/F-y} = -16.0\text{ m/s}$. The fragments move at $25.4°$ above and $25.4°$ below the horizontal.

EVALUATE: As the initial velocity of the firecracker increases the angle with the horizontal for the fragments, as measured from the ground, decreases.

3.76. **IDENTIFY:** The velocity $\vec{v}_{R/G}$ of the rocket relative to the ground is related to the velocity $\vec{v}_{S/G}$ of the secondary rocket relative to the ground and the velocity $\vec{v}_{S/R}$ of the secondary rocket relative to the rocket by $\vec{v}_{S/G} = \vec{v}_{S/R} + \vec{v}_{R/G}$.

SET UP: Let $+y$ be upward and let $y = 0$ at the ground. Let $+x$ be in the direction of the horizontal component of the secondary rocket's motion. After it is launched the secondary rocket has $a_x = 0$ and $a_y = -9.80\text{ m/s}^2$, relative to the ground.

EXECUTE: **(a)** (i) $v_{S/R\text{-}x} = (12.0\text{ m/s})\cos 53.0° = 7.22\text{ m/s}$ and $v_{S/R\text{-}y} = (12.0\text{ m/s})\sin 53.0° = 9.58\text{ m/s}$.

(ii) $v_{R/G\text{-}x} = 0$ and $v_{R/G\text{-}y} = 8.50\text{ m/s}$. $v_{S/G\text{-}x} = v_{S/R\text{-}x} + v_{R/G\text{-}x} = 7.22\text{ m/s}$ and

$v_{S/G\text{-}y} = v_{S/R\text{-}y} + v_{R/G\text{-}y} = 9.58\text{ m/s} + 8.50\text{ m/s} = 18.1\text{ m/s}$.

(b) $v_{S/G} = \sqrt{(v_{S/G\text{-}x})^2 + (v_{S/G\text{-}y})^2} = 19.5\text{ m/s}$. $\tan\alpha_0 = \dfrac{v_{S/G\text{-}y}}{v_{S/G\text{-}x}} = \dfrac{18.1\text{ m/s}}{7.22\text{ m/s}}$ and $\alpha_0 = 68.3°$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(c) Relative to the ground the secondary rocket has $y_0 = 145$ m, $v_{0y} = +18.1$ m/s, $a_y = -9.80$ m/s^2 and $v_y = 0$ (at the maximum height). $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ gives

$$y - y_0 = \frac{v_y^2 - v_{0y}^2}{2a_y} = \frac{0 - (18.1 \text{ m/s})^2}{2(-9.80 \text{ m/s}^2)} = 16.7 \text{ m}. \quad y = 145 \text{ m} + 16.7 \text{ m} = 162 \text{ m}.$$

EVALUATE: The secondary rocket reaches its maximum height in time $t = \frac{v_y - v_{0y}}{a_y} = \frac{-18.1 \text{ m/s}}{-9.80 \text{ m/s}^2} = 1.85$ s after it is launched. At this time the primary rocket has height $145 \text{ m} + (8.50 \text{ m/s})(1.85 \text{ s}) = 161$ m, so is at nearly the same height as the secondary rocket. The secondary rocket first moves upward from the primary rocket but then loses vertical velocity due to the acceleration of gravity.

3.77. **IDENTIFY:** The grenade moves in projectile motion. 110 km/h = 30.6 m/s. The horizontal range R of the grenade must be 15.8 m plus the distance d that the enemy's car travels while the grenade is in the air.

SET UP: For the grenade take $+y$ upward, so $a_x = 0$, $a_y = -g$. Let v_0 be the magnitude of the velocity of the grenade relative to the hero. $v_{0x} = v_0 \cos 45°$, $v_{0y} = v_0 \sin 45°$. 90 km/h = 25 m/s; The enemy's car is traveling away from the hero's car with a relative velocity of $v_{\text{rel}} = 30.6 \text{ m/s} - 25 \text{ m/s} = 5.6$ m/s.

EXECUTE: $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$ with $y - y_0 = 0$ gives $t = -\frac{2v_{0y}}{a_y} = \frac{2v_0 \sin 45°}{g}$. $d = v_{\text{rel}}t = \frac{\sqrt{2}v_0 v_{\text{rel}}}{g}$.

$R = v_{0x}t = v_0(\cos 45°)\,t = \frac{2v_0^2 \sin 45° \cos 45°}{g} = \frac{v_0^2}{g}$. $R = d + 15.8$ m gives that $\frac{v_0^2}{g} = \frac{\sqrt{2}v_{\text{rel}}}{g}v_0 + 15.8$ m.

$v_0^2 - \sqrt{2}v_{\text{rel}}v_0 - (15.8 \text{ m})\,g = 0$. $v_0^2 - 7.92v_0 - 154.8 = 0$. The quadratic formula gives $v_0 = 17.0$ m/s = 61.2 km/h. The grenade has velocity of magnitude 61.2 km/h relative to the hero. Relative to the hero the velocity of the grenade has components $v_{0x} = v_0 \cos 45° = 43.3$ km/h and $v_{0y} = v_0 \sin 45° = 43.3$ km/h. Relative to the earth the velocity of the grenade has components $v_{Ex} = 43.3 \text{ km/h} + 90 \text{ km/h} = 133.3$ km/h and $v_{Ey} = 43.3$ km/h. The magnitude of the velocity relative to the earth is $v_E = \sqrt{v_{Ex}^2 + v_{Ey}^2} = 140$ km/h.

EVALUATE: The time the grenade is in the air is $t = \frac{2v_0 \sin 45°}{g} = \frac{2(17.0 \text{ m/s}) \sin 45°}{9.80 \text{ m/s}^2} = 2.45$ s. During this time the grenade travels a horizontal distance $x - x_0 = (133.3 \text{ km/h})(2.45 \text{ s})(1 \text{ h}/3600 \text{ s}) = 90.7$ m, relative to the earth, and the enemy's car travels a horizontal distance $x - x_0 = (110 \text{ km/h})(2.45 \text{ s})(1 \text{ h}/3600 \text{ s}) = 74.9$ m, relative to the earth. The grenade has traveled 15.8 m farther.

3.78. **IDENTIFY:** All velocities are constant, so the distance traveled is $d = v_{B/E}t$, where $v_{B/E}$ is the magnitude of the velocity of the boat relative to the earth. The relative velocities $\vec{v}_{B/E}$, $\vec{v}_{B/W}$ (boat relative to the water) and $\vec{v}_{W/E}$ (water relative to the earth) are related by $\vec{v}_{B/E} = \vec{v}_{B/W} + \vec{v}_{W/E}$.

SET UP: Let $+x$ be east and let $+y$ be north. $v_{W/E-x} = +30.0$ m/min and $v_{W/E-y} = 0$. $v_{B/W} = 100.0$ m/min. The direction of $\vec{v}_{B/W}$ is the direction in which the boat is pointed or aimed.

EXECUTE: **(a)** $v_{B/W-y} = +100.0$ m/min and $v_{B/W-x} = 0$. $v_{B/E-x} = v_{B/W-x} + v_{W/E-x} = 30.0$ m/min and $v_{B/E-y} = v_{B/W-y} + v_{W/E-y} = 100.0$ m/min. The time to cross the river is $t = \frac{y - y_0}{v_{B/E-y}} = \frac{400.0 \text{ m}}{100.0 \text{ m/min}} = 4.00$ min. $x - x_0 = (30.0 \text{ m/min})(4.00 \text{ min}) = 120.0$ m. You will land 120.0 m east of point B, which is 45.0 m east of point C. The distance you will have traveled is $\sqrt{(400.0 \text{ m})^2 + (120.0 \text{ m})^2} = 418$ m.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) $\vec{v}_{B/W}$ is directed at angle ϕ east of north, where $\tan\phi = \dfrac{75.0\text{ m}}{400.0\text{ m}}$ and $\phi = 10.6°$.

$v_{B/W-x} = (100.0\text{ m/min})\sin 10.6° = 18.4\text{ m/min}$ and $v_{B/W-y} = (100.0\text{ m/min})\cos 10.6° = 98.3\text{ m/min}$.

$v_{B/E-x} = v_{B/W-x} + v_{W/E-x} = 18.4\text{ m/min} + 30.0\text{ m/min} = 48.4\text{ m/min}$.

$v_{B/E-y} = v_{B/W-y} + v_{W/E-y} = 98.3\text{ m/min}$. $t = \dfrac{y - y_0}{v_{B/E-y}} = \dfrac{400.0\text{ m}}{98.3\text{ m/min}} = 4.07\text{ min}$.

$x - x_0 = (48.4\text{ m/min})(4.07\text{ min}) = 197\text{ m}$. You will land 197 m downstream from B, so 122 m downstream from C.

(c) (i) If you reach point C, then $\vec{v}_{B/E}$ is directed at $10.6°$ east of north, which is $79.4°$ north of east. We don't know the magnitude of $\vec{v}_{B/E}$ and the direction of $\vec{v}_{B/W}$. In part (a) we found that if we aim the boat due north we will land east of C, so to land at C we must aim the boat west of north. Let $\vec{v}_{B/W}$ be at an angle ϕ of north of west. The relative velocity addition diagram is sketched in Figure 3.78. The law of sines says $\dfrac{\sin\theta}{v_{W/E}} = \dfrac{\sin 79.4°}{v_{B/W}}$. $\sin\theta = \left(\dfrac{30.0\text{ m/min}}{100.0\text{ m/min}}\right)\sin 79.4°$ and $\theta = 17.15°$. Then $\phi = 180° - 79.4° - 17.15° = 83.5°$. The boat will head $83.5°$ north of west, so $6.5°$ west of north.

$v_{B/E-x} = v_{B/W-x} + v_{W/E-x} = -(100.0\text{ m/min})\cos 83.5° + 30.0\text{ m/min} = 18.7\text{ m/min}$.

$v_{B/E-y} = v_{B/W-y} + v_{W/E-y} = (100.0\text{ m/min})\sin 83.5° = 99.4\text{ m/min}$. Note that these two components do give the direction of $\vec{v}_{B/E}$ to be $79.4°$ north of east, as required. (ii) The time to cross the river is $t = \dfrac{y - y_0}{v_{B/E-y}} = \dfrac{400.0\text{ m}}{99.4\text{ m/min}} = 4.02\text{ min}$. (iii) You travel from A to C, a distance of $\sqrt{(400.0\text{ m})^2 + (75.0\text{ m})^2} = 407\text{ m}$. (iv) $v_{B/E} = \sqrt{(v_{B/E-x})^2 + (v_{B/E-y})^2} = 101\text{ m/min}$. Note that $v_{B/E}t = 406\text{ m}$, the distance traveled (apart from a small difference due to rounding).

EVALUATE: You cross the river in the shortest time when you head toward point B, as in part (a), even though you travel farther than in part (c).

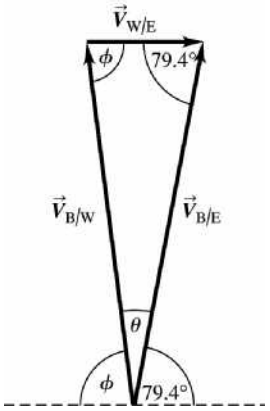


Figure 3.78

3.79. **IDENTIFY:** $v_x = dx/dt$, $v_y = dy/dt$, $a_x = dv_x/dt$ and $a_y = dv_y/dt$.

SET UP: $\dfrac{d(\sin\omega t)}{dt} = \omega\cos(\omega t)$ and $\dfrac{d(\cos\omega t)}{dt} = -\omega\sin(\omega t)$.

EXECUTE: **(a)** The path is sketched in Figure 3.79.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) To find the velocity components, take the derivative of x and y with respect to time: $v_x = R\omega(1-\cos\omega t)$, and $v_y = R\omega\sin\omega t$. To find the acceleration components, take the derivative of v_x and v_y with respect to time: $a_x = R\omega^2\sin\omega t$, and $a_y = R\omega^2\cos\omega t$.

(c) The particle is at rest $(v_y = v_x = 0)$ every period, namely at $t = 0, 2\pi/\omega, 4\pi/\omega, \ldots$. At that time, $x = 0, 2\pi R, 4\pi R, \ldots$; and $y = 0$. The acceleration is $a = R\omega^2$ in the $+y$-direction.

(d) No, since $a = \left[(R\omega^2\sin\omega t)^2 + (R\omega^2\cos\omega t)^2\right]^{1/2} = R\omega^2$. The magnitude of the acceleration is the same as for uniform circular motion.

EVALUATE: The velocity is tangent to the path. v_x is always positive; v_y changes sign during the motion.

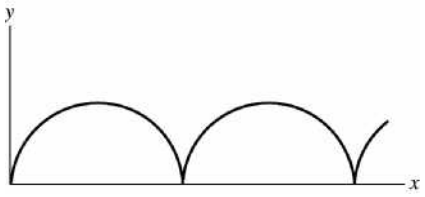

Figure 3.79

3.80. **IDENTIFY:** At the highest point in the trajectory the velocity of the projectile relative to the earth is horizontal. The velocity $\vec{v}_{P/E}$ of the projectile relative to the earth, the velocity $\vec{v}_{F/P}$ of a fragment relative to the projectile, and the velocity $\vec{v}_{F/E}$ of a fragment relative to the earth are related by $\vec{v}_{F/E} = \vec{v}_{F/P} + \vec{v}_{P/E}$.

SET UP: Let $+x$ be along the horizontal component of the projectile motion. Let the speed of each fragment relative to the projectile be v. Call the fragments 1 and 2, where fragment 1 travels in the $+x$ direction and fragment 2 is in the $-x$-direction, and let the speeds just after the explosion of the two fragments relative to the earth be v_1 and v_2. Let v_p be the speed of the projectile just before the explosion.

EXECUTE: $v_{F/E-x} = v_{F/P-x} + v_{P/E-x}$ gives $v_1 = v_p + v$ and $-v_2 = v_p - v$. Both fragments start from the same height with zero vertical component of velocity relative to the earth, so they both fall for the same time t, and this is also the same time as it took for the projectile to travel a horizontal distance D, so $v_p t = D$. Since fragment 2 lands at A it travels a horizontal distance D as it falls and $v_2 t = D$.

$-v_2 = +v_p - v$ gives $v = v_p + v_2$ and $vt = v_p t + v_2 t = 2D$. Then $v_1 t = v_p t + vt = 3D$. This fragment lands a horizontal distance $3D$ from the point of explosion and hence $4D$ from A.

EVALUATE: Fragment 1, that is ejected in the direction of the motion of the projectile travels with greater speed relative to the earth than the fragment that travels in the opposite direction.

3.81. **IDENTIFY:** Relative velocity problem. The plane's motion relative to the earth is determined by its velocity relative to the earth.

SET UP: Select a coordinate system where $+y$ is north and $+x$ is east.

The velocity vectors in the problem are:

$\vec{v}_{P/E}$, the velocity of the plane relative to the earth.

$\vec{v}_{P/A}$, the velocity of the plane relative to the air (the magnitude $v_{P/A}$ is the airspeed of the plane and the direction of $\vec{v}_{P/A}$ is the compass course set by the pilot).

$\vec{v}_{A/E}$, the velocity of the air relative to the earth (the wind velocity).

The rule for combining relative velocities gives $\vec{v}_{P/E} = \vec{v}_{P/A} + \vec{v}_{A/E}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(a) We are given the following information about the relative velocities:
$\vec{v}_{P/A}$ has magnitude 220 km/h and its direction is west. In our coordinates it has components
$(v_{P/A})_x = -220$ km/h and $(v_{P/A})_y = 0$.
From the displacement of the plane relative to the earth after 0.500 h, we find that $\vec{v}_{P/E}$ has components in our coordinate system of

$$(v_{P/E})_x = -\frac{120 \text{ km}}{0.500 \text{ h}} = -240 \text{ km/h (west)}$$

$$(v_{P/E})_y = -\frac{20 \text{ km}}{0.500 \text{ h}} = -40 \text{ km/h (south)}$$

With this information the diagram corresponding to the velocity addition equation is shown in Figure 3.81a.

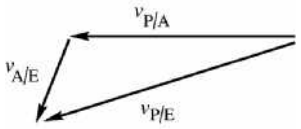

Figure 3.81a

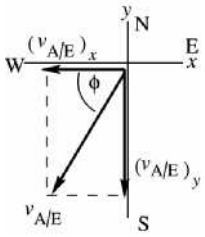
We are asked to find $\vec{v}_{A/E}$, so solve for this vector:
$\vec{v}_{P/E} = \vec{v}_{P/A} + \vec{v}_{A/E}$ gives $\vec{v}_{A/E} = \vec{v}_{P/E} - \vec{v}_{P/A}$.
EXECUTE: The x-component of this equation gives
$(v_{A/E})_x = (v_{P/E})_x - (v_{P/A})_x = -240 \text{ km/h} - (-220 \text{ km/h}) = -20 \text{ km/h}$.
The y-component of this equation gives
$(v_{A/E})_y = (v_{P/E})_y - (v_{P/A})_y = -40$ km/h.
Now that we have the components of $\vec{v}_{A/E}$ we can find its magnitude and direction.



$$v_{A/E} = \sqrt{(v_{A/E})_x^2 + (v_{A/E})_y^2}$$

$$v_{A/E} = \sqrt{(-20 \text{ km/h})^2 + (-40 \text{ km/h})^2} = 44.7 \text{ km/h}$$

$$\tan\phi = \frac{40 \text{ km/h}}{20 \text{ km/h}} = 2.00; \quad \phi = 63.4°$$

The direction of the wind velocity is 63.4° S of W, or 26.6° W of S.

Figure 3.81b

EVALUATE: The plane heads west. It goes farther west than it would without wind and also travels south, so the wind velocity has components west and south.
(b) SET UP: The rule for combining the relative velocities is still $\vec{v}_{P/E} = \vec{v}_{P/A} + \vec{v}_{A/E}$, but some of these velocities have different values than in part **(a)**.
$\vec{v}_{P/A}$ has magnitude 220 km/h but its direction is to be found.
$\vec{v}_{A/E}$ has magnitude 40 km/h and its direction is due south.
The direction of $\vec{v}_{P/E}$ is west; its magnitude is not given.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

The vector diagram for $\vec{v}_{P/E} = \vec{v}_{P/A} + \vec{v}_{A/E}$ and the specified directions for the vectors is shown in Figure 3.81c.

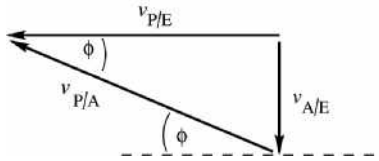


Figure 3.81c

The vector addition diagram forms a right triangle.

EXECUTE: $\sin\phi = \dfrac{v_{A/E}}{v_{P/A}} = \dfrac{40 \text{ km/h}}{220 \text{ km/h}} = 0.1818; \quad \phi = 10.5°.$

The pilot should set her course $10.5°$ north of west.

EVALUATE: The velocity of the plane relative to the air must have a northward component to counteract the wind and a westward component in order to travel west.

3.82. **IDENTIFY:** Use the relation that relates the relative velocities.

SET UP: The relative velocities are the raindrop relative to the earth, $\vec{v}_{R/E}$, the raindrop relative to the train, $\vec{v}_{R/T}$, and the train relative to the earth, $\vec{v}_{T/E}$. $\vec{v}_{R/E} = \vec{v}_{R/T} + \vec{v}_{T/E}$. $\vec{v}_{T/E}$ is due east and has magnitude 12.0 m/s. $\vec{v}_{R/T}$ is $30.0°$ west of vertical. $\vec{v}_{R/E}$ is vertical. The relative velocity addition diagram is given in Figure 3.82.

EXECUTE: **(a)** $\vec{v}_{R/E}$ is vertical and has zero horizontal component. The horizontal component of $\vec{v}_{R/T}$ is $-\vec{v}_{T/E}$, so is 12.0 m/s westward.

(b) $v_{R/E} = \dfrac{v_{T/E}}{\tan 30.0°} = \dfrac{12.0 \text{ m/s}}{\tan 30.0°} = 20.8 \text{ m/s}.$ $v_{R/T} = \dfrac{v_{T/E}}{\sin 30.0°} = \dfrac{12.0 \text{ m/s}}{\sin 30.0°} = 24.0 \text{ m/s}.$

EVALUATE: The speed of the raindrop relative to the train is greater than its speed relative to the earth, because of the motion of the train.

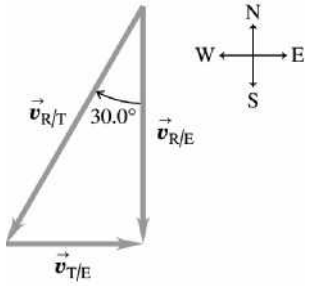

Figure 3.82

3.83. **IDENTIFY:** Relative velocity problem.

SET UP: The three relative velocities are:

$\vec{v}_{J/G}$, Juan relative to the ground. This velocity is due north and has magnitude $\vec{v}_{J/G} = 8.00$ m/s.

$\vec{v}_{B/G}$, the ball relative to the ground. This vector is $37.0°$ east of north and has magnitude $v_{B/G} = 12.00$ m/s.

$\vec{v}_{B/J}$, the ball relative to Juan. We are asked to find the magnitude and direction of this vector.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

The relative velocity addition equation is $\vec{v}_{B/G} = \vec{v}_{B/J} + \vec{v}_{J/G}$, so $\vec{v}_{B/J} = \vec{v}_{B/G} - \vec{v}_{J/G}$.

The relative velocity addition diagram does not form a right triangle so we must do the vector addition using components.

Take $+y$ to be north and $+x$ to be east.

EXECUTE: $v_{B/Jx} = +v_{B/G}\sin 37.0° = 7.222$ m/s

$v_{B/Jy} = +v_{B/G}\cos 37.0° - v_{J/G} = 1.584$ m/s

These two components give $v_{B/J} = 7.39$ m/s at $12.4°$ north of east.

EVALUATE: Since Juan is running due north, the ball's eastward component of velocity relative to him is the same as its eastward component relative to the earth. The northward component of velocity for Juan and the ball are in the same direction, so the component for the ball relative to Juan is the difference in their components of velocity relative to the ground.

3.84. **IDENTIFY:** Both the bolt and the elevator move vertically with constant acceleration.

SET UP: Let $+y$ be upward and let $y = 0$ at the initial position of the floor of the elevator, so y_0 for the bolt is 3.00 m.

EXECUTE: **(a)** The position of the bolt is $3.00\text{ m} + (2.50\text{ m/s})\,t - (1/2)(9.80\text{ m/s}^2)\,t^2$ and the position of the floor is (2.50 m/s)t. Equating the two, $3.00\text{ m} = (4.90\text{ m/s}^2)\,t^2$. Therefore, $t = 0.782$ s.

(b) The velocity of the bolt is $2.50\text{ m/s} - (9.80\text{ m/s}^2)(0.782\text{ s}) = -5.17$ m/s relative to earth, therefore, relative to an observer in the elevator $v = -5.17\text{ m/s} - 2.50\text{ m/s} = -7.67$ m/s.

(c) As calculated in part (b), the speed relative to earth is 5.17 m/s.

(d) Relative to earth, the distance the bolt traveled is

$(2.50\text{ m/s})\,t - (1/2)(9.80\text{ m/s}^2)\,t^2 = (2.50\text{ m/s})(0.782\text{ s}) - (4.90\text{ m/s}^2)(0.782\text{ s})^2 = -1.04$ m.

EVALUATE: As viewed by an observer in the elevator, the bolt has $v_{0y} = 0$ and $a_y = -9.80\text{ m/s}^2$, so in 0.782 s it falls $-\frac{1}{2}(9.80\text{ m/s}^2)(0.782\text{ s})^2 = -3.00$ m.

3.85. **IDENTIFY:** In an earth frame the elevator accelerates upward at 4.00 m/s^2 and the bolt accelerates downward at 9.80 m/s^2. Relative to the elevator the bolt has a downward acceleration of $4.00\text{ m/s}^2 + 9.80\text{ m/s}^2 = 13.80\text{ m/s}^2$. In either frame, that of the earth or that of the elevator, the bolt has constant acceleration and the constant acceleration equations can be used.

SET UP: Let $+y$ be upward. The bolt travels 3.00 m downward relative to the elevator.

EXECUTE: **(a)** In the frame of the elevator, $v_{0y} = 0$, $y - y_0 = -3.00$ m, $a_y = -13.8\text{ m/s}^2$.

$y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$ gives $t = \sqrt{\dfrac{2(y - y_0)}{a_y}} = \sqrt{\dfrac{2(-3.00\text{ m})}{-13.8\text{ m/s}^2}} = 0.659$ s.

(b) $v_y = v_{0y} + a_y t$. $v_{0y} = 0$ and $t = 0.659$ s. (i) $a_y = -13.8\text{ m/s}^2$ and $v_y = -9.09$ m/s. The bolt has speed 9.09 m/s when it reaches the floor of the elevator. (ii) $a_y = -9.80\text{ m/s}^2$ and $v_y = -6.46$ m/s. In this frame the bolt has speed 6.46 m/s when it reaches the floor of the elevator.

(c) $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$. $v_{0y} = 0$ and $t = 0.659$ s. (i) $a_y = -13.8\text{ m/s}^2$ and $y - y_0 = \frac{1}{2}(-13.8\text{ m/s}^2)(0.659\text{ s})^2 = -3.00$ m. The bolt falls 3.00 m, which is correctly the distance between the floor and roof of the elevator. (ii) $a_y = -9.80\text{ m/s}^2$ and $y - y_0 = \frac{1}{2}(-9.80\text{ m/s}^2)(0.659\text{ s})^2 = -2.13$ m. The bolt falls 2.13 m.

EVALUATE: In the earth's frame the bolt falls 2.13 m and the elevator rises $\frac{1}{2}(4.00\text{ m/s}^2)(0.659\text{ s})^2 = 0.87$ m during the time that the bolt travels from the ceiling to the floor of the elevator.

3.86. **IDENTIFY:** We need to use relative velocities.
SET UP: If B is moving relative to M and M is moving relative to E, the velocity of B relative to E is $\vec{v}_{B/E} = \vec{v}_{B/M} + \vec{v}_{M/E}$.
EXECUTE: Let $+x$ be east and $+y$ be north. We have $v_{B/M,x} = 2.50$ m/s, $v_{B/M,y} = -4.33$ m/s, $v_{M/E,x} = 0$, and $v_{M/E,y} = 6.00$ m/s. Therefore $v_{B/E,x} = v_{B/M,x} + v_{M/E,x} = 2.50$ m/s and $v_{B/E,y} = v_{B/M,y} + v_{M/E,y} = -4.33$ m/s $+ 6.00$ m/s $= +1.67$ m/s. The magnitude is $v_{B/E} = \sqrt{(2.50 \text{ m/s})^2 + (1.67 \text{ m/s})^2} = 3.01$ m/s, and the direction is $\tan\theta = \dfrac{1.67}{2.50}$, which gives $\theta = 33.7^{\circ}$ north of east.
EVALUATE: Since Mia is moving, the velocity of the ball relative to her is different from its velocity relative to the ground or relative to Alice.

3.87. **IDENTIFY:** The arrow moves in projectile motion.
SET UP: Use coordinates for which the axes are horizontal and vertical. Let θ be the angle of the slope and let ϕ be the angle of projection relative to the sloping ground.
EXECUTE: The horizontal distance x in terms of the angles is

$$\tan\theta = \tan(\theta+\phi) - \left(\frac{gx}{2v_0^2}\right)\frac{1}{\cos^2(\theta+\phi)}.$$

Denote the dimensionless quantity $gx/2v_0^2$ by β; in this case

$$\beta = \frac{(9.80 \text{ m/s}^2)(60.0 \text{ m})\cos 30.0^{\circ}}{2\,(32.0 \text{ m/s})^2} = 0.2486.$$

The above relation can then be written, on multiplying both sides by the product $\cos\theta\cos(\theta+\phi)$,

$$\sin\theta\cos(\theta+\phi) = \sin(\theta+\phi)\cos\theta - \frac{\beta\cos\theta}{\cos(\theta+\phi)},$$

and so $\sin(\theta+\phi)\cos\theta - \cos(\theta+\phi)\sin\theta = \dfrac{\beta\cos\theta}{\cos(\theta+\phi)}$. The term on the left is $\sin((\theta+\phi)-\theta) = \sin\phi$, so the result of this combination is $\sin\phi\cos(\theta+\phi) = \beta\cos\theta$.
Although this can be done numerically (by iteration, trial-and-error, or other methods), the expansion $\sin a\cos b = \frac{1}{2}(\sin(a+b) + \sin(a-b))$ allows the angle ϕ to be isolated; specifically, then

$$\frac{1}{2}(\sin(2\phi+\theta) + \sin(-\theta)) = \beta\cos\theta, \text{ with the net result that } \sin(2\phi+\theta) = 2\beta\cos\theta + \sin\theta.$$

(a) For $\theta = 30^{\circ}$, and β as found above, $\phi = 19.3^{\circ}$ and the angle above the horizontal is $\theta + \phi = 49.3^{\circ}$. For level ground, using $\beta = 0.2871$, gives $\phi = 17.5^{\circ}$.
(b) For $\theta = -30^{\circ}$, the same β as with $\theta = 30^{\circ}$ may be used $(\cos 30^{\circ} = \cos(-30^{\circ}))$, giving $\phi = 13.0^{\circ}$ and $\phi + \theta = -17.0^{\circ}$.
EVALUATE: For $\theta = 0$ the result becomes $\sin(2\phi) = 2\beta = gx/v_0^2$. This is equivalent to the expression $R = \dfrac{v_0^2\sin(2\alpha_0)}{g}$ derived in Example 3.8.

3.88. **IDENTIFY:** Write an expression for the square of the distance (D^2) from the origin to the particle, expressed as a function of time. Then take the derivative of D^2 with respect to t, and solve for the value of t when this derivative is zero. If the discriminant is zero or negative, the distance D will never decrease.
SET UP: $D^2 = x^2 + y^2$, with $x(t)$ and $y(t)$ given by Eqs. (3.20) and (3.21).
EXECUTE: Following this process, $\sin^{-1}\sqrt{8/9} = 70.5^{\circ}$.
EVALUATE: We know that if the object is thrown straight up it moves away from P and then returns, so we are not surprised that the projectile angle must be less than some maximum value for the distance to always increase with time.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

3.89. **IDENTIFY:** Apply the relative velocity relation.

SET UP: Let $v_{C/W}$ be the speed of the canoe relative to water and $v_{W/G}$ be the speed of the water relative to the ground.

EXECUTE: **(a)** Taking all units to be in km and h, we have three equations. We know that heading upstream $v_{C/W} - v_{W/G} = 2$. We know that heading downstream for a time t, $(v_{C/W} + v_{W/G})t = 5$. We also know that for the bottle $v_{W/G}(t+1) = 3$. Solving these three equations for $v_{W/G} = x$, $v_{C/W} = 2 + x$, therefore $(2 + x + x)t = 5$ or $(2 + 2x)t = 5$. Also $t = 3/x - 1$, so $(2 + 2x)\left(\frac{3}{x} - 1\right) = 5$ or $2x^2 + x - 6 = 0$.

The positive solution is $x = v_{W/G} = 1.5$ km/h.

(b) $v_{C/W} = 2$ km/h $+ v_{W/G} = 3.5$ km/h.

EVALUATE: When they head upstream, their speed relative to the ground is 3.5 km/h $-$ 1.5 km/h $=$ 2.0 km/h. When they head downstream, their speed relative to the ground is 3.5 km/h $+$ 1.5 km/h $=$ 5.0 km/h. The bottle is moving downstream at 1.5 km/s relative to the earth, so they are able to overtake it.

3.90. **IDENTIFY:** The rocket has two periods of constant acceleration motion.

SET UP: Let $+y$ be upward. During the free-fall phase, $a_x = 0$ and $a_y = -g$. After the engines turn on, $a_x = (3.00g)\cos 30.0°$ and $a_y = (3.00g)\sin 30.0°$. Let t be the total time since the rocket was dropped and let T be the time the rocket falls before the engine starts.

EXECUTE: (i) The diagram is given in Figure 3.90 a.

(ii) The x-position of the plane is $(236 \text{ m/s})t$ and the x-position of the rocket is $(236 \text{ m/s})t + (1/2)(3.00)(9.80 \text{ m/s}^2)\cos 30°(t - T)^2$. The graphs of these two equations are sketched in Figure 3.90 b.

(iii) If we take $y = 0$ to be the altitude of the airliner, then $y(t) = -1/2gT^2 - gT(t - T) + 1/2(3.00)(9.80 \text{ m/s}^2)(\sin 30°)(t - T)^2$ for the rocket. The airliner has constant y. The graphs are sketched in Figure 3.90b.

In each of the Figures 3.90a–c, the rocket is dropped at $t = 0$ and the time T when the motor is turned on is indicated.

By setting $y = 0$ for the rocket, we can solve for t in terms of T: $0 = -(4.90 \text{ m/s}^2)T^2 - (9.80 \text{ m/s}^2)T(t - T) + (7.35 \text{ m/s}^2)(t - T)^2$. Using the quadratic formula for the variable $x = t - T$ we find $x = t - T = \dfrac{(9.80 \text{ m/s}^2)T + \sqrt{(9.80 \text{ m/s}^2 T)^2 + (4)(7.35 \text{ m/s}^2)(4.9)T^2}}{2(7.35 \text{ m/s}^2)}$, or $t = 2.72\,T$. Now, using the condition that $x_{\text{rocket}} - x_{\text{plane}} = 1000$ m, we find $(236 \text{ m/s})t + (12.7 \text{ m/s}^2)(t - T)^2 - (236 \text{ m/s})t = 1000$ m, or $(1.72T)^2 = 78.6 \text{ s}^2$. Therefore $T = 5.15$ s.

EVALUATE: During the free-fall phase the rocket and airliner have the same x coordinate but the rocket moves downward from the airliner. After the engines fire, the rocket starts to move upward and its horizontal component of velocity starts to exceed that of the airliner.

4

NEWTON'S LAWS OF MOTION

4.1. **IDENTIFY:** Consider the vector sum in each case.

SET UP: Call the two forces $\vec{F}_1$ and $\vec{F}_2$. Let $\vec{F}_1$ be to the right. In each case select the direction of $\vec{F}_2$ such that $\vec{F} = \vec{F}_1 + \vec{F}_2$ has the desired magnitude.

EXECUTE: **(a)** For the magnitude of the sum to be the sum of the magnitudes, the forces must be parallel, and the angle between them is zero. The two vectors and their sum are sketched in Figure 4.1a.

(b) The forces form the sides of a right isosceles triangle, and the angle between them is $90°$. The two vectors and their sum are sketched in Figure 4.1b.

(c) For the sum to have zero magnitude, the forces must be antiparallel, and the angle between them is $180°$. The two vectors are sketched in Figure 4.1c.

EVALUATE: The maximum magnitude of the sum of the two vectors is $2F$, as in part (a).

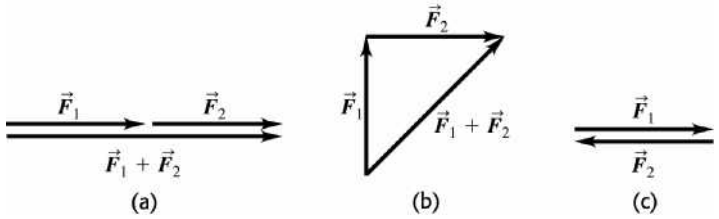

Figure 4.1

4.2. **IDENTIFY:** We know the magnitudes and directions of three vectors and want to use them to find their components, and then to use the components to find the magnitude and direction of the resultant vector.

SET UP: Let $F_1 = 985$ N, $F_2 = 788$ N, and $F_3 = 411$ N. The angles θ that each force makes with the $+x$ axis are $\theta_1 = 31°$, $\theta_2 = 122°$, and $\theta_3 = 233°$. The components of a force vector are $F_x = F\cos\theta$ and $F_y = F\sin\theta$, and $R = \sqrt{R_x^2 + R_y^2}$ and $\tan\theta = \dfrac{R_y}{R_x}$.

EXECUTE: **(a)** $F_{1x} = F_1\cos\theta_1 = 844$ N, $F_{1y} = F_1\sin\theta_1 = 507$ N, $F_{2x} = F_2\cos\theta_2 = -418$ N, $F_{2y} = F_2\sin\theta_2 = 668$ N, $F_{3x} = F_3\cos\theta_3 = -247$ N, and $F_{3y} = F_3\sin\theta_3 = -328$ N.

(b) $R_x = F_{1x} + F_{2x} + F_{3x} = 179$ N; $R_y = F_{1y} + F_{2y} + F_{3y} = 847$ N. $R = \sqrt{R_x^2 + R_y^2} = 886$ N; $\tan\theta = \dfrac{R_y}{R_x}$ so $\theta = 78.1°$. $\vec{R}$ and its components are shown in Figure 4.2.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

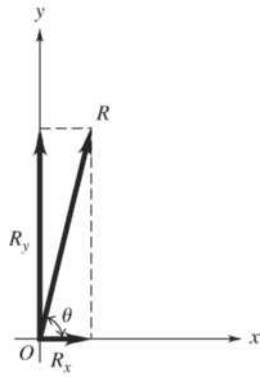

Figure 4.2

EVALUATE: A graphical sketch of the vector sum should agree with the results found in (b). Adding the forces as vectors gives a very different result from adding their magnitudes.

4.3. **IDENTIFY:** We know the resultant of two vectors of equal magnitude and want to find their magnitudes. They make the same angle with the vertical.

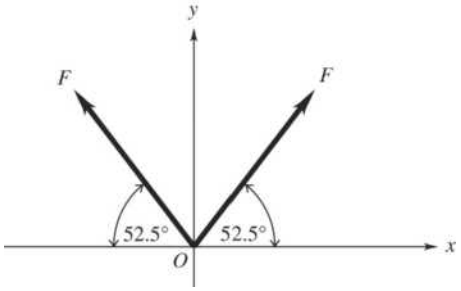

Figure 4.3

SET UP: Take $+y$ to be upward, so $\sum F_y = 5.00$ N. The strap on each side of the jaw exerts a force F directed at an angle of 52.5° above the horizontal, as shown in Figure 4.3.

EXECUTE: $\sum F_y = 2F\sin 52.5° = 5.00$ N, so $F = 3.15$ N.

EVALUATE: The resultant force has magnitude 5.00 N which is *not* the same as the sum of the magnitudes of the two vectors, which would be 6.30 N.

4.4. **IDENTIFY:** $F_x = F\cos\theta$, $F_y = F\sin\theta$.

SET UP: Let $+x$ be parallel to the ramp and directed up the ramp. Let $+y$ be perpendicular to the ramp and directed away from it. Then $\theta = 30.0°$.

EXECUTE: **(a)** $F = \dfrac{F_x}{\cos\theta} = \dfrac{60.0\text{ N}}{\cos 30°} = 69.3$ N.

(b) $F_y = F\sin\theta = F_x\tan\theta = 34.6$ N.

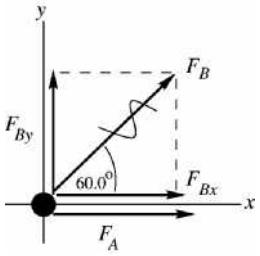
EVALUATE: We can verify that $F_x^2 + F_y^2 = F^2$. The signs of F_x and F_y show their direction.

4.5. **IDENTIFY:** Vector addition.

SET UP: Use a coordinate system where the $+x$-axis is in the direction of $\vec{F}_A$, the force applied by dog A. The forces are sketched in Figure 4.5.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE:



$F_{Ax} = +270 \text{ N}, \quad F_{Ay} = 0$

$F_{Bx} = F_B \cos 60.0° = (300 \text{ N}) \cos 60.0° = +150 \text{ N}$

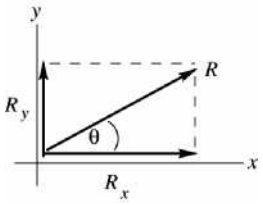
$F_{By} = F_B \sin 60.0° = (300 \text{ N}) \sin 60.0° = +260 \text{ N}$

Figure 4.5a

$\vec{R} = \vec{F}_A + \vec{F}_B$

$R_x = F_{Ax} + F_{Bx} = +270 \text{ N} + 150 \text{ N} = +420 \text{ N}$

$R_y = F_{Ay} + F_{By} = 0 + 260 \text{ N} = +260 \text{ N}$



$R = \sqrt{R_x^2 + R_y^2}$

$R = \sqrt{(420 \text{ N})^2 + (260 \text{ N})^2} = 494 \text{ N}$

$\tan\theta = \dfrac{R_y}{R_x} = 0.619$

$\theta = 31.8°$

Figure 4.5b

EVALUATE: The forces must be added as vectors. The magnitude of the resultant force is less than the sum of the magnitudes of the two forces and depends on the angle between the two forces.

4.6. **IDENTIFY:** Add the two forces using components.

SET UP: $F_x = F\cos\theta$, $F_y = F\sin\theta$, where θ is the angle $\vec{F}$ makes with the $+x$ axis.

EXECUTE: **(a)** $F_{1x} + F_{2x} = (9.00 \text{ N})\cos 120° + (6.00 \text{ N})\cos(233.1°) = -8.10 \text{ N}$

$F_{1y} + F_{2y} = (9.00 \text{ N})\sin 120° + (6.00 \text{ N})\sin(233.1°) = +3.00 \text{ N}.$

(b) $R = \sqrt{R_x^2 + R_y^2} = \sqrt{(8.10 \text{ N})^2 + (3.00 \text{ N})^2} = 8.64 \text{ N}.$

EVALUATE: Since $F_x < 0$ and $F_y > 0$, $\vec{F}$ is in the second quadrant.

4.7. **IDENTIFY:** Friction is the only horizontal force acting on the skater, so it must be the one causing the acceleration. Newton's second law applies.

SET UP: Take $+x$ to be the direction in which the skater is moving initially. The final velocity is $v_x = 0$, since the skater comes to rest. First use the kinematics formula $v_x = v_{0x} + a_x t$ to find the acceleration, then apply $\sum F_x = 5.00 \text{ N}$ to the skater.

EXECUTE: $v_x = v_{0x} + a_x t$ so $a_x = \dfrac{v_x - v_{0x}}{t} = \dfrac{0 - 2.40 \text{ m/s}}{3.52 \text{ s}} = -0.682 \text{ m/s}^2$. The only horizontal force on the skater is the friction force, so $f_x = ma_x = (68.5 \text{ kg})(-0.682 \text{ m/s}^2) = -46.7 \text{ N}$. The force is 46.7 N, directed opposite to the motion of the skater.

EVALUATE: Although other forces are acting on the skater (gravity and the upward force of the ice), they are vertical and therefore do not affect the horizontal motion.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

4.8. **IDENTIFY:** The elevator and everything in it are accelerating upward, so we apply Newton's second law in the vertical direction.

SET UP: Your mass is $m = w/g = 63.8$ kg. Both you and the package have the same acceleration as the elevator. Take $+y$ to be upward, in the direction of the acceleration of the elevator, and apply $\sum F_y = ma_y$.

EXECUTE: **(a)** Your free-body diagram is shown in Figure 4.8a, where n is the scale reading. $\sum F_y = ma_y$ gives $n - w = ma$. Solving for n gives $n = w + ma = 625 \text{ N} + (63.8 \text{ kg})(2.50 \text{ m/s}^2) = 784 \text{ N}$.

(b) The free-body diagram for the package is given in Figure 4.8b. $\sum F_y = ma_y$ gives $T - w = ma$, so $T = w + ma = (3.85 \text{ kg})(9.80 \text{ m/s}^2 + 2.50 \text{ m/s}^2) = 47.4 \text{ N}$.

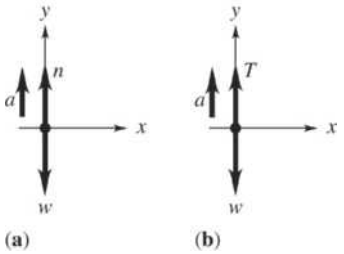


Figure 4.8

EVALUATE: The objects accelerate upward so for each of them the upward force is greater than the downward force.

4.9. **IDENTIFY:** Apply $\sum \vec{F} = m\vec{a}$ to the box.

SET UP: Let $+x$ be the direction of the force and acceleration. $\sum F_x = 48.0$ N.

EXECUTE: $\sum F_x = ma_x$ gives $m = \dfrac{\Sigma F_x}{a_x} = \dfrac{48.0 \text{ N}}{3.00 \text{ m/s}^2} = 16.0 \text{ kg}$.

EVALUATE: The vertical forces sum to zero and there is no motion in that direction.

4.10. **IDENTIFY:** Use the information about the motion to find the acceleration and then use $\sum F_x = ma_x$ to calculate m.

SET UP: Let $+x$ be the direction of the force. $\sum F_x = 80.0$ N.

EXECUTE: **(a)** $x - x_0 = 11.0$ m, $t = 5.00$ s, $v_{0x} = 0$. $x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2$ gives

$a_x = \dfrac{2(x - x_0)}{t^2} = \dfrac{2(11.0 \text{ m})}{(5.00 \text{ s})^2} = 0.880 \text{ m/s}^2$. $m = \dfrac{\Sigma F_x}{a_x} = \dfrac{80.0 \text{ N}}{0.880 \text{ m/s}^2} = 90.9 \text{ kg}$.

(b) $a_x = 0$ and v_x is constant. After the first 5.0 s, $v_x = v_{0x} + a_x t = (0.880 \text{ m/s}^2)(5.00 \text{ s}) = 4.40$ m/s.

$x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2 = (4.40 \text{ m/s})(5.00 \text{ s}) = 22.0$ m.

EVALUATE: The mass determines the amount of acceleration produced by a given force. The block moves farther in the second 5.00 s than in the first 5.00 s.

4.11. **IDENTIFY** and **SET UP:** Use Newton's second law in component form (Eq. 4.8) to calculate the acceleration produced by the force. Use constant acceleration equations to calculate the effect of the acceleration on the motion.

EXECUTE: **(a)** During this time interval the acceleration is constant and equal to

$$a_x = \frac{F_x}{m} = \frac{0.250 \text{ N}}{0.160 \text{ kg}} = 1.562 \text{ m/s}^2$$

We can use the constant acceleration kinematic equations from Chapter 2.

$x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2 = 0 + \frac{1}{2}(1.562 \text{ m/s}^2)(2.00 \text{ s})^2$,

so the puck is at $x = 3.12$ m.

$v_x = v_{0x} + a_x t = 0 + (1.562 \text{ m/s}^2)(2.00 \text{ s}) = 3.12$ m/s.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) In the time interval from $t = 2.00$ s to 5.00 s the force has been removed so the acceleration is zero. The speed stays constant at $v_x = 3.12$ m/s. The distance the puck travels is $x - x_0 = v_{0x}t = (3.12 \text{ m/s})(5.00 \text{ s} - 2.00 \text{ s}) = 9.36$ m. At the end of the interval it is at $x = x_0 + 9.36 \text{ m} = 12.5$ m.

In the time interval from $t = 5.00$ s to 7.00 s the acceleration is again $a_x = 1.562 \text{ m/s}^2$. At the start of this interval $v_{0x} = 3.12$ m/s and $x_0 = 12.5$ m.

$x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2 = (3.12 \text{ m/s})(2.00 \text{ s}) + \frac{1}{2}(1.562 \text{ m/s}^2)(2.00 \text{ s})^2$.

$x - x_0 = 6.24 \text{ m} + 3.12 \text{ m} = 9.36$ m.

Therefore, at $t = 7.00$ s the puck is at $x = x_0 + 9.36 \text{ m} = 12.5 \text{ m} + 9.36 \text{ m} = 21.9$ m.

$$v_x = v_{0x} + a_x t \approx 3.12 \text{ m/s} + (1.562 \text{ m/s}^2)(2.00 \text{ s}) = 6.24 \text{ m/s}$$

EVALUATE: The acceleration says the puck gains 1.56 m/s of velocity for every second the force acts. The force acts a total of 4.00 s so the final velocity is $(1.56 \text{ m/s})(4.0 \text{ s}) = 6.24$ m/s.

4.12. **IDENTIFY:** Apply $\sum \vec{F} = m\vec{a}$. Then use a constant acceleration equation to relate the kinematic quantities.
SET UP: Let $+x$ be in the direction of the force.

EXECUTE: **(a)** $a_x = F_x / m = (140 \text{ N})/(32.5 \text{ kg}) = 4.31 \text{ m/s}^2$.

(b) $x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2$. With $v_{0x} = 0$, $x = \frac{1}{2}at^2 = 215$ m.

(c) $v_x = v_{0x} + a_x t$. With $v_{0x} = 0$, $v_x = a_x t = 2x/t = 43.0$ m/s.

EVALUATE: The acceleration connects the motion to the forces.

4.13. **IDENTIFY:** The force and acceleration are related by Newton's second law.
SET UP: $\sum F_x = ma_x$, where $\sum F_x$ is the net force. $m = 4.50$ kg.

EXECUTE: **(a)** The maximum net force occurs when the acceleration has its maximum value.
$\sum F_x = ma_x = (4.50 \text{ kg})(10.0 \text{ m/s}^2) = 45.0$ N. This maximum force occurs between 2.0 s and 4.0 s.
(b) The net force is constant when the acceleration is constant. This is between 2.0 s and 4.0 s.
(c) The net force is zero when the acceleration is zero. This is the case at $t = 0$ and $t = 6.0$ s.

EVALUATE: A graph of $\sum F_x$ versus *t* would have the same shape as the graph of a_x versus *t*.

4.14. **IDENTIFY:** The force and acceleration are related by Newton's second law. $a_x = \dfrac{dv_x}{dt}$, so a_x is the slope of the graph of v_x versus *t*.

SET UP: The graph of v_x versus *t* consists of straight-line segments. For $t = 0$ to $t = 2.00$ s, $a_x = 4.00 \text{ m/s}^2$. For $t = 2.00$ s to 6.00 s, $a_x = 0$. For $t = 6.00$ s to 10.0 s, $a_x = 1.00 \text{ m/s}^2$.
$\sum F_x = ma_x$, with $m = 2.75$ kg. $\sum F_x$ is the net force.

EXECUTE: **(a)** The maximum net force occurs when the acceleration has its maximum value.
$\sum F_x = ma_x = (2.75 \text{ kg})(4.00 \text{ m/s}^2) = 11.0$ N. This maximum occurs in the interval $t = 0$ to $t = 2.00$ s.
(b) The net force is zero when the acceleration is zero. This is between 2.00 s and 6.00 s.
(c) Between 6.00 s and 10.0 s, $a_x = 1.00 \text{ m/s}^2$, so $\sum F_x = (2.75 \text{ kg})(1.00 \text{ m/s}^2) = 2.75$ N.

EVALUATE: The net force is largest when the velocity is changing most rapidly.

4.15. **IDENTIFY:** The net force and the acceleration are related by Newton's second law. When the rocket is near the surface of the earth the forces on it are the upward force $\vec{F}$ exerted on it because of the burning fuel and the downward force $\vec{F}_{\text{grav}}$ of gravity. $F_{\text{grav}} = mg$.

SET UP: Let $+y$ be upward. The weight of the rocket is $F_{\text{grav}} = (8.00 \text{ kg})(9.80 \text{ m/s}^2) = 78.4$ N.

EXECUTE: **(a)** At $t = 0$, $F = A = 100.0$ N. At $t = 2.00$ s, $F = A + (4.00 \text{ s}^2)B = 150.0$ N and

$$B = \frac{150.0 \text{ N} - 100.0 \text{ N}}{4.00 \text{ s}^2} = 12.5 \text{ N/s}^2.$$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) (i) At $t = 0$, $F = A = 100.0$ N. The net force is $\sum F_y = F - F_{\text{grav}} = 100.0\text{ N} - 78.4\text{ N} = 21.6$ N.

$a_y = \dfrac{\sum F_y}{m} = \dfrac{21.6\text{ N}}{8.00\text{ kg}} = 2.70\text{ m/s}^2$. (ii) At $t = 3.00$ s, $F = A + B(3.00\text{ s})^2 = 212.5$ N.

$\sum F_y = 212.5\text{ N} - 78.4\text{ N} = 134.1$ N. $a_y = \dfrac{\sum F_y}{m} = \dfrac{134.1\text{ N}}{8.00\text{ kg}} = 16.8\text{ m/s}^2$.

(c) Now $F_{\text{grav}} = 0$ and $\sum F_y = F = 212.5$ N. $a_y = \dfrac{212.5\text{ N}}{8.00\text{ kg}} = 26.6\text{ m/s}^2$.

EVALUATE: The acceleration increases as F increases.

4.16. **IDENTIFY:** Use constant acceleration equations to calculate a_x and t. Then use $\sum \vec{F} = m\vec{a}$ to calculate the net force.

SET UP: Let $+x$ be in the direction of motion of the electron.

EXECUTE: **(a)** $v_{0x} = 0$, $(x - x_0) = 1.80\times10^{-2}$ m, $v_x = 3.00\times10^6$ m/s. $v_x^2 = v_{0x}^2 + 2a_x(x - x_0)$ gives

$$a_x = \frac{v_x^2 - v_{0x}^2}{2(x - x_0)} = \frac{(3.00\times10^6\text{ m/s})^2 - 0}{2(1.80\times10^{-2}\text{ m})} = 2.50\times10^{14}\text{ m/s}^2$$

(b) $v_x = v_{0x} + a_x t$ gives $t = \dfrac{v_x - v_{0x}}{a_x} = \dfrac{3.00\times10^6\text{ m/s} - 0}{2.50\times10^{14}\text{ m/s}^2} = 1.2\times10^{-8}$ s

(c) $\sum F_x = ma_x = (9.11\times10^{-31}\text{ kg})(2.50\times10^{14}\text{ m/s}^2) = 2.28\times10^{-16}$ N.

EVALUATE: The acceleration is in the direction of motion since the speed is increasing, and the net force is in the direction of the acceleration.

4.17. **IDENTIFY** and **SET UP:** $F = ma$. We must use $w = mg$ to find the mass of the boulder.

EXECUTE: $m = \dfrac{w}{g} = \dfrac{2400\text{ N}}{9.80\text{ m/s}^2} = 244.9$ kg

Then $F = ma = (244.9\text{ kg})(12.0\text{ m/s}^2) = 2940$ N.

EVALUATE: We must use mass in Newton's second law. Mass and weight are proportional.

4.18. **IDENTIFY:** Find weight from mass and vice versa.

SET UP: Equivalencies we'll need are: $1\,\mu\text{g} = 10^{-6}\text{ g} = 10^{-9}$ kg, $1\text{ mg} = 10^{-3}\text{ g} = 10^{-6}$ kg, $1\text{ N} = 0.2248$ lb, and $g = 9.80\text{ m/s}^2 = 32.2\text{ ft/s}^2$.

EXECUTE: **(a)** $m = 210\,\mu\text{g} = 2.10\times10^{-7}$ kg. $w = mg = (2.10\times10^{-7}\text{ kg})(9.80\text{ m/s}^2) = 2.06\times10^{-6}$ N.

(b) $m = 12.3\text{ mg} = 1.23\times10^{-5}$ kg. $w = mg = (1.23\times10^{-5}\text{ kg})(9.80\text{ m/s}^2) = 1.21\times10^{-4}$ N.

(c) $(45\text{ N})\left(\dfrac{0.2248\text{ lb}}{1\text{ N}}\right) = 10.1$ lb. $m = \dfrac{w}{g} = \dfrac{45\text{ N}}{9.80\text{ m/s}^2} = 4.6$ kg.

EVALUATE: We are not converting mass to weight (or vice versa) since they are different types of quantities. We are finding what a given mass will weigh and how much mass a given weight contains.

4.19. **IDENTIFY** and **SET UP:** $w = mg$. The mass of the watermelon is constant, independent of its location. Its weight differs on earth and Jupiter's moon. Use the information about the watermelon's weight on earth to calculate its mass:

EXECUTE: **(a)** $w = mg$ gives that $m = \dfrac{w}{g} = \dfrac{44.0\text{ N}}{9.80\text{ m/s}^2} = 4.49$ kg.

(b) On Jupiter's moon, $m = 4.49$ kg, the same as on earth. Thus the weight on Jupiter's moon is $w = mg = (4.49\text{ kg})(1.81\text{ m/s}^2) = 8.13$ N.

EVALUATE: The weight of the watermelon is less on Io, since g is smaller there.

4.20. **IDENTIFY:** Weight and mass are related by $w = mg$. The mass is constant but g and w depend on location.

SET UP: On earth, $g = 9.80\text{ m/s}^2$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: **(a)** $\frac{w}{g} = m$, which is constant, so $\frac{w_E}{g_E} = \frac{w_A}{g_A}$. $w_E = 17.5$ N, $g_E = 9.80$ m/s^2, and $w_A = 3.24$ N.

$$g_A = \left(\frac{w_A}{w_E}\right) g_E = \left(\frac{3.24 \text{ N}}{17.5 \text{ N}}\right)(9.80 \text{ m/s}^2) = 1.81 \text{ m/s}^2.$$

(b) $$m = \frac{w_E}{g_E} = \frac{17.5 \text{ N}}{9.80 \text{ m/s}^2} = 1.79 \text{ kg}.$$

EVALUATE: The weight at a location and the acceleration due to gravity at that location are directly proportional.

4.21. **IDENTIFY:** Apply $\sum F_x = ma_x$ to find the resultant horizontal force.

SET UP: Let the acceleration be in the $+x$ direction.

EXECUTE: $\sum F_x = ma_x = (55 \text{ kg})(15 \text{ m/s}^2) = 825$ N. The force is exerted by the blocks. The blocks push on the sprinter because the sprinter pushes on the blocks.

EVALUATE: The force the blocks exert on the sprinter has the same magnitude as the force the sprinter exerts on the blocks. The harder the sprinter pushes, the greater the force on her.

4.22. **IDENTIFY:** Newton's third law problem.

SET UP: The car exerts a force on the truck and the truck exerts a force on the car.

EXECUTE: The force and the reaction force are always exactly the same in magnitude, so the force that the truck exerts on the car is 1200 N, by Newton's third law.

EVALUATE: Even though the truck is much larger and more massive than the car, it cannot exert a larger force on the car than the car exerts on it.

4.23. **IDENTIFY:** The system is accelerating so we use Newton's second law.

SET UP: The acceleration of the entire system is due to the 100-N force, but the acceleration of box B is due to the force that box A exerts on it. $\sum F = ma$ applies to the two-box system and to each box individually.

EXECUTE: For the two-box system: $a_x = \frac{100 \text{ N}}{25 \text{ kg}} = 4.0 \text{ m/s}^2$. Then for box B, where F_A is the force exerted on B by A, $F_A = m_B a = (5.0 \text{ kg})(4.0 \text{ m/s}^2) = 20$ N.

EVALUATE: The force on B is less than the force on A.

4.24. **IDENTIFY:** The reaction forces in Newton's third law are always between a pair of objects. In Newton's second law all the forces act on a single object.

SET UP: Let $+y$ be downward. $m = w/g$.

EXECUTE: The reaction to the upward normal force on the passenger is the downward normal force, also of magnitude 620 N, that the passenger exerts on the floor. The reaction to the passenger's weight is the gravitational force that the passenger exerts on the earth, upward and also of magnitude 650 N. $\frac{\sum F_y}{m} = a_y$ gives $a_y = \frac{650 \text{ N} - 620 \text{ N}}{(650 \text{ N})/(9.80 \text{ m/s}^2)} = 0.452 \text{ m/s}^2$. The passenger's acceleration is 0.452 m/s^2, downward.

EVALUATE: There is a net downward force on the passenger and the passenger has a downward acceleration.

4.25. **IDENTIFY:** Apply Newton's second law to the earth.

SET UP: The force of gravity that the earth exerts on her is her weight, $w = mg = (45 \text{ kg})(9.8 \text{ m/s}^2) = 441$ N. By Newton's third law, she exerts an equal and opposite force on the earth.

Apply $\sum \vec{F} = m\vec{a}$ to the earth, with $\left|\sum \vec{F}\right| = w = 441$ N, but must use the mass of the earth for m.

EXECUTE: $a = \frac{w}{m} = \frac{441 \text{ N}}{6.0 \times 10^{24} \text{ kg}} = 7.4 \times 10^{-23} \text{ m/s}^2$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: This is *much* smaller than her acceleration of $9.8\ \text{m/s}^2$. The force she exerts on the earth equals in magnitude the force the earth exerts on her, but the acceleration the force produces depends on the mass of the object and her mass is *much* less than the mass of the earth.

4.26. **IDENTIFY** and **SET UP:** The only force on the ball is the gravity force, $\vec{F}_{\text{grav}}$. This force is mg, downward and is independent of the motion of the object.

EXECUTE: The free-body diagram is sketched in Figure 4.26. The free-body diagram is the same in all cases.

EVALUATE: Some forces, such as friction, depend on the motion of the object but the gravity force does not.

Figure 4.26

4.27. **IDENTIFY:** Identify the forces on each object.

SET UP: In each case the forces are the noncontact force of gravity (the weight) and the forces applied by objects that are in contact with each crate. Each crate touches the floor and the other crate, and some object applies $\vec{F}$ to crate A.

EXECUTE: **(a)** The free-body diagrams for each crate are given in Figure 4.27.

F_{AB} (the force on m_A due to m_B) and F_{BA} (the force on m_B due to m_A) form an action-reaction pair.

(b) Since there is no horizontal force opposing F, any value of F, no matter how small, will cause the crates to accelerate to the right. The weight of the two crates acts at a right angle to the horizontal, and is in any case balanced by the upward force of the surface on them.

EVALUATE: Crate B is accelerated by F_{BA} and crate A is accelerated by the net force $F - F_{AB}$. The greater the total weight of the two crates, the greater their total mass and the smaller will be their acceleration.

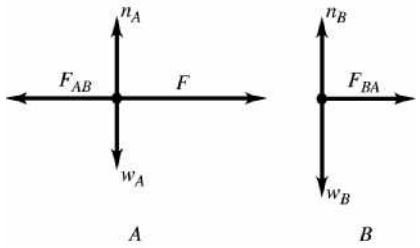

Figure 4.27

4.28. **IDENTIFY:** The surface of block B can exert both a friction force and a normal force on block A. The friction force is directed so as to oppose relative motion between blocks B and A. Gravity exerts a downward force w on block A.

SET UP: The pull is a force on B not on A.

EXECUTE: **(a)** If the table is frictionless there is a net horizontal force on the combined object of the two blocks, and block B accelerates in the direction of the pull. The friction force that B exerts on A is to the right, to try to prevent A from slipping relative to B as B accelerates to the right. The free-body diagram is sketched in Figure 4.28a. f is the friction force that B exerts on A and n is the normal force that B exerts on A.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) The pull and the friction force exerted on *B* by the table cancel and the net force on the system of two blocks is zero. The blocks move with the same constant speed and *B* exerts no friction force on *A*. The free-body diagram is sketched in Figure 4.28b.

EVALUATE: If in part (b) the pull force is decreased, block *B* will slow down, with an acceleration directed to the left. In this case the friction force on *A* would be to the left, to prevent relative motion between the two blocks by giving *A* an acceleration equal to that of *B*.

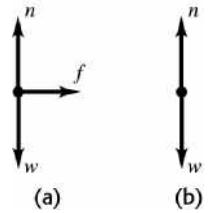

Figure 4.28

4.29. **IDENTIFY:** Since the observer in the train sees the ball hang motionless, the ball must have the same acceleration as the train car. By Newton's second law, there must be a net force on the ball in the same direction as its acceleration.

SET UP: The forces on the ball are gravity, which is *w*, downward, and the tension $\vec{T}$ in the string, which is directed along the string.

EXECUTE: **(a)** The acceleration of the train is zero, so the acceleration of the ball is zero. There is no net horizontal force on the ball and the string must hang vertically. The free-body diagram is sketched in Figure 4.29a.

(b) The train has a constant acceleration directed east so the ball must have a constant eastward acceleration. There must be a net horizontal force on the ball, directed to the east. This net force must come from an eastward component of $\vec{T}$ and the ball hangs with the string displaced west of vertical. The free-body diagram is sketched in Figure 4.29b.

EVALUATE: When the motion of an object is described in an inertial frame, there must be a net force in the direction of the acceleration.

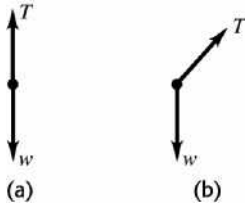

Figure 4.29

4.30. **IDENTIFY:** Use a constant acceleration equation to find the stopping time and acceleration. Then use $\sum \vec{F} = m\vec{a}$ to calculate the force.

SET UP: Let $+x$ be in the direction the bullet is traveling. $\vec{F}$ is the force the wood exerts on the bullet.

EXECUTE: **(a)** $v_{0x} = 350$ m/s, $v_x = 0$ and $(x - x_0) = 0.130$ m. $(x - x_0) = \left(\frac{v_{0x} + v_x}{2}\right)t$ gives

$$t = \frac{2(x - x_0)}{v_{0x} + v_x} = \frac{2(0.130 \text{ m})}{350 \text{ m/s}} = 7.43 \times 10^{-4} \text{ s}.$$

(b) $v_x^2 = v_{0x}^2 + 2a_x(x - x_0)$ gives $a_x = \frac{v_x^2 - v_{0x}^2}{2(x - x_0)} = \frac{0 - (350 \text{ m/s})^2}{2(0.130 \text{ m})} = -4.71 \times 10^5 \text{ m/s}^2$

$\sum F_x = ma_x$ gives $-F = ma_x$ and $F = -ma_x = -(1.80 \times 10^{-3} \text{ kg})(-4.71 \times 10^5 \text{ m/s}^2) = 848$ N.

EVALUATE: The acceleration and net force are opposite to the direction of motion of the bullet.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

4.31. **IDENTIFY:** Identify the forces on the chair. The floor exerts a normal force and a friction force.
SET UP: Let $+y$ be upward and let $+x$ be in the direction of the motion of the chair.
EXECUTE: **(a)** The free-body diagram for the chair is given in Figure 4.31.
(b) For the chair, $a_y = 0$ so $\sum F_y = ma_y$ gives $n - mg - F\sin 37° = 0$ and $n = 142$ N.
EVALUATE: n is larger than the weight because $\vec{F}$ has a downward component.

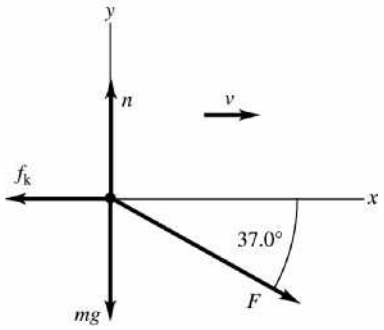

Figure 4.31

4.32. **IDENTIFY:** Identify the forces on the skier and apply $\sum \vec{F} = m\vec{a}$. Constant speed means $a = 0$.
SET UP: Use coordinates that are parallel and perpendicular to the slope.
EXECUTE: **(a)** The free-body diagram for the skier is given in Figure 4.32.
(b) $\sum F_x = ma_x$ with $a_x = 0$ gives $T = mg\sin\theta = (65.0\text{ kg})(9.80\text{ m/s}^2)\sin 26.0° = 279$ N.
EVALUATE: T is less than the weight of the skier. It is equal to the component of the weight that is parallel to the incline.

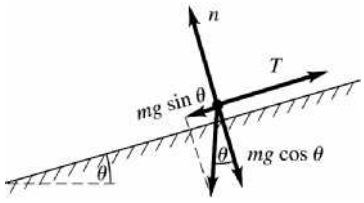

Figure 4.32

4.33. **IDENTIFY:** Apply Newton's second law to the bucket and constant-acceleration kinematics.
SET UP: The minimum time to raise the bucket will be when the tension in the cord is a maximum since this will produce the greatest acceleration of the bucket.
EXECUTE: Apply Newton's second law to the bucket: $T - mg = ma$. For the maximum acceleration, the tension is greatest, so $a = \dfrac{T - mg}{m} = \dfrac{75.0\text{ N} - (4.80\text{ kg})(9.8\text{ m/s}^2)}{4.80\text{ kg}} = 5.825\text{ m/s}^2$.

The kinematics equation for $y(t)$ gives $t = \sqrt{\dfrac{2(y - y_0)}{a_y}} = \sqrt{\dfrac{2(12.0\text{ m})}{5.825\text{ m/s}^2}} = 2.03$ s.

EVALUATE: A shorter time would require a greater acceleration and hence a stronger pull, which would break the cord.

4.34. **IDENTIFY:** Identify the forces for each object. Action-reaction pairs of forces act between two objects.
SET UP: Friction is parallel to the surfaces and is directly opposite to the relative motion between the surfaces.
EXECUTE: The free-body diagram for the box is given in Figure 4.34a. The free-body diagram for the truck is given in Figure 4.34b. The box's friction force on the truck bed and the truck bed's friction force on the box form an action-reaction pair. There would also be some small air-resistance force action to the left, presumably negligible at this speed.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: The friction force on the box, exerted by the bed of the truck, is in the direction of the truck's acceleration. This friction force can't be large enough to give the box the same acceleration that the truck has and the truck acquires a greater speed than the box.

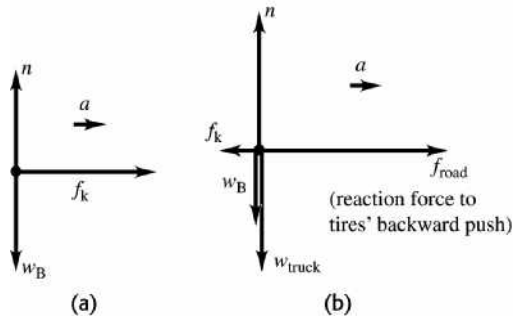

Figure 4.34

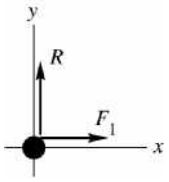
4.35. **IDENTIFY:** Vector addition problem. Write the vector addition equation in component form. We know one vector and its resultant and are asked to solve for the other vector.

SET UP: Use coordinates with the $+x$-axis along $\vec{F}_1$ and the $+y$-axis along $\vec{R}$, as shown in Figure 4.35a.



$F_{1x} = +1300 \text{ N}, \quad F_{1y} = 0$

$R_x = 0, \; R_y = +1300 \text{ N}$

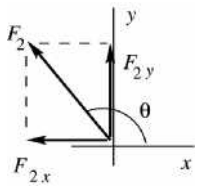
Figure 4.35a

$\vec{F}_1 + \vec{F}_2 = \vec{R}$, so $\vec{F}_2 = \vec{R} - \vec{F}_1$

EXECUTE: $F_{2x} = R_x - F_{1x} = 0 - 1300 \text{ N} = -1300 \text{ N}$

$F_{2y} = R_y - F_{1y} = +1300 \text{ N} - 0 = +1300 \text{ N}$

The components of $\vec{F}_2$ are sketched in Figure 4.35b.



$F_2 = \sqrt{F_{2x}^2 + F_{2y}^2} = \sqrt{(-1300 \text{ N})^2 + (1300 \text{ N})^2}$

$F = 1840 \text{ N}$

$\tan\theta = \dfrac{F_{2y}}{F_{2x}} = \dfrac{+1300 \text{ N}}{-1300 \text{ N}} = -1.00$

$\theta = 135°$

Figure 4.35b

The magnitude of $\vec{F}_2$ is 1840 N and its direction is 135° counterclockwise from the direction of $\vec{F}_1$.

EVALUATE: $\vec{F}_2$ has a negative x-component to cancel $\vec{F}_1$ and a y-component to equal $\vec{R}$.

4.36. **IDENTIFY:** Use the motion of the ball to calculate g, the acceleration of gravity on the planet. Then $w = mg$.

SET UP: Let $+y$ be downward and take $y_0 = 0$. $v_{0y} = 0$ since the ball is released from rest.

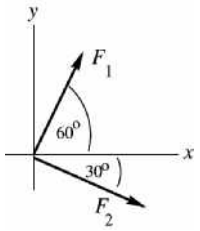
© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: Get g on X: $y = \frac{1}{2}gt^2$ gives $10.0\text{ m} = \frac{1}{2}g(2.2\text{ s})^2$. $g = 4.13\text{ m/s}^2$ and then

$w_X = mg_X = (0.100\text{ kg})(4.13\text{ m/s}^2) = 0.41\text{ N}$.

EVALUATE: g on Planet X is smaller than on earth and the object weighs less than it would on earth.

4.37. **IDENTIFY:** If the box moves in the $+x$-direction it must have $a_y = 0$, so $\sum F_y = 0$.



The smallest force the child can exert and still produce such motion is a force that makes the y-components of all three forces sum to zero, but that doesn't have any x-component.

Figure 4.37

SET UP: $\vec{F}_1$ and $\vec{F}_2$ are sketched in Figure 4.37. Let $\vec{F}_3$ be the force exerted by the child.

$\sum F_y = ma_y$ implies $F_{1y} + F_{2y} + F_{3y} = 0$, so $F_{3y} = -(F_{1y} + F_{2y})$.

EXECUTE: $F_{1y} = +F_1 \sin 60° = (100\text{ N})\sin 60° = 86.6\text{ N}$

$F_{2y} = +F_2 \sin(-30°) = -F_2 \sin 30° = -(140\text{ N})\sin 30° = -70.0\text{ N}$

Then $F_{3y} = -(F_{1y} + F_{2y}) = -(86.6\text{ N} - 70.0\text{ N}) = -16.6\text{ N}$; $F_{3x} = 0$

The smallest force the child can exert has magnitude 17 N and is directed at 90° clockwise from the $+x$-axis shown in the figure.

(b) IDENTIFY and SET UP: Apply $\sum F_x = ma_x$. We know the forces and a_x so can solve for m. The force exerted by the child is in the $-y$-direction and has no x-component.

EXECUTE: $F_{1x} = F_1 \cos 60° = 50\text{ N}$

$F_{2x} = F_2 \cos 30° = 121.2\text{ N}$

$\sum F_x = F_{1x} + F_{2x} = 50\text{ N} + 121.2\text{ N} = 171.2\text{ N}$

$$m = \frac{\sum F_x}{a_x} = \frac{171.2\text{ N}}{2.00\text{ m/s}^2} = 85.6\text{ kg}$$

Then $w = mg = 840\text{ N}$.

EVALUATE: In part (b) we don't need to consider the y-component of Newton's second law. $a_y = 0$ so the mass doesn't appear in the $\sum F_y = ma_y$ equation.

4.38. **IDENTIFY:** Use $\sum \vec{F} = m\vec{a}$ to calculate the acceleration of the tanker and then use constant acceleration kinematic equations.

SET UP: Let $+x$ be the direction the tanker is moving initially. Then $a_x = -F/m$.

EXECUTE: $v_x^2 = v_{0x}^2 + 2a_x(x - x_0)$ says that if the reef weren't there the ship would stop in a distance of

$$x - x_0 = -\frac{v_{0x}^2}{2a_x} = \frac{v_0^2}{2(F/m)} = \frac{mv_0^2}{2F} = \frac{(3.6\times10^7\text{ kg})(1.5\text{ m/s})^2}{2(8.0\times10^4\text{ N})} = 506\text{ m},$$

so the ship would hit the reef. The speed when the tanker hits the reef is found from $v_x^2 = v_{0x}^2 + 2a_x(x - x_0)$, so it is

$$v = \sqrt{v_0^2 - (2Fx/m)} = \sqrt{(1.5\text{ m/s})^2 - \frac{2(8.0\times10^4\text{ N})(500\text{ m})}{(3.6\times10^7\text{ kg})}} = 0.17\text{ m/s},$$

and the oil should be safe.

EVALUATE: The force and acceleration are directed opposite to the initial motion of the tanker and the speed decreases.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

4.39. **IDENTIFY:** We can apply constant acceleration equations to relate the kinematic variables and we can use Newton's second law to relate the forces and acceleration.

(a) SET UP: First use the information given about the height of the jump to calculate the speed he has at the instant his feet leave the ground. Use a coordinate system with the $+y$-axis upward and the origin at the position when his feet leave the ground.

$v_y = 0$ (at the maximum height), $v_{0y} = ?$, $a_y = -9.80 \text{ m/s}^2$, $y - y_0 = +1.2 \text{ m}$

$v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$

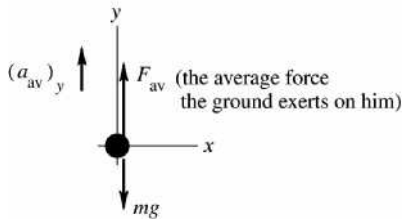
EXECUTE: $v_{0y} = \sqrt{-2a_y(y - y_0)} = \sqrt{-2(-9.80 \text{ m/s}^2)(1.2 \text{ m})} = 4.85 \text{ m/s}$

(b) SET UP: Now consider the acceleration phase, from when he starts to jump until when his feet leave the ground. Use a coordinate system where the $+y$-axis is upward and the origin is at his position when he starts his jump.

EXECUTE: Calculate the average acceleration:

$$(a_{\text{av}})_y = \frac{v_y - v_{0y}}{t} = \frac{4.85 \text{ m/s} - 0}{0.300 \text{ s}} = 16.2 \text{ m/s}^2$$

(c) SET UP: Finally, find the average upward force that the ground must exert on him to produce this average upward acceleration. (Don't forget about the downward force of gravity.) The forces are sketched in Figure 4.39.



EXECUTE:

$m = w/g = \dfrac{890 \text{ N}}{9.80 \text{ m/s}^2} = 90.8 \text{ kg}$

$\sum F_y = ma_y$

$F_{\text{av}} - mg = m(a_{\text{av}})_y$

$F_{\text{av}} = m(g + (a_{\text{av}})_y)$

$F_{\text{av}} = 90.8 \text{ kg}(9.80 \text{ m/s}^2 + 16.2 \text{ m/s}^2)$

$F_{\text{av}} = 2360 \text{ N}$

Figure 4.39

This is the average force exerted on him by the ground. But by Newton's third law, the average force he exerts on the ground is equal and opposite, so is 2360 N, downward. The net force on him is equal to ma, so $F_{\text{net}} = ma = (90.8 \text{ kg})(16.2 \text{ m/s}^2) = 1470 \text{ N}$ upward.

EVALUATE: In order for him to accelerate upward, the ground must exert an upward force greater than his weight.

4.40. **IDENTIFY:** Use constant acceleration equations to calculate the acceleration a_x that would be required. Then use $\sum F_x = ma_x$ to find the necessary force.

SET UP: Let $+x$ be the direction of the initial motion of the auto.

EXECUTE: $v_x^2 = v_{0x}^2 + 2a_x(x - x_0)$ with $v_x = 0$ gives $a_x = -\dfrac{v_{0x}^2}{2(x - x_0)}$. The force F is directed opposite to the motion and $a_x = -\dfrac{F}{m}$. Equating these two expressions for a_x gives

$$F = m\frac{v_{0x}^2}{2(x - x_0)} = (850 \text{ kg})\frac{(12.5 \text{ m/s})^2}{2(1.8 \times 10^{-2} \text{ m})} = 3.7 \times 10^6 \text{ N}.$$

EVALUATE: A very large force is required to stop such a massive object in such a short distance.

4.41. **IDENTIFY:** Using constant-acceleration kinematics, we can find the acceleration of the ball. Then we can apply Newton's second law to find the force causing that acceleration.

SET UP: Use coordinates where $+x$ is in the direction the ball is thrown. $v_x^2 = v_{0x}^2 + 2a_x(x - x_0)$ and $\sum F_x = ma_x$.

EXECUTE: **(a)** Solve for a_x: $x - x_0 = 1.0$ m, $v_{0x} = 0$, $v_x = 46$ m/s. $v_x^2 = v_{0x}^2 + 2a_x(x - x_0)$ gives

$$a_x = \frac{v_x^2 - v_{0x}^2}{2(x - x)} = \frac{(46 \text{ m/s})^2 - 0}{2(1.0 \text{ m})} = 1058 \text{ m/s}^2.$$

The free-body diagram for the ball during the pitch is shown in Figure 4.41a. The force $\vec{F}$ is applied to the ball by the pitcher's hand. $\sum F_x = ma_x$ gives $F = (0.145 \text{ kg})(1058 \text{ m/s}^2) = 153$ N.

(b) The free-body diagram after the ball leaves the hand is given in Figure 4.41b. The only force on the ball is the downward force of gravity.

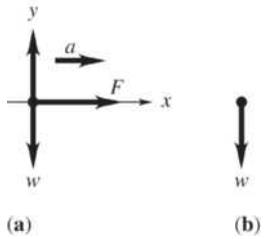

Figure 4.41

EVALUATE: The force is much greater than the weight of the ball because it gives it an acceleration much greater than g.

4.42. **IDENTIFY:** Kinematics will give us the ball's acceleration, and Newton's second law will give us the horizontal force acting on it.

SET UP: Use coordinates with $+x$ horizontal and in the direction of the motion of the ball and with $+y$ upward. $\sum F_x = ma_x$ and for constant acceleration, $v_x = v_{0x} + a_x t$.

SOLVE: **(a)** $v_{0x} = 0$, $v_x = 73.14$ m/s, $t = 3.00 \times 10^{-2}$ s. $v_x = v_{0x} + a_x t$ gives

$$a_x = \frac{v_x - v_{0x}}{t} = \frac{73.14 \text{ m/s} - 0}{3.00 \times 10^{-2} \text{ s}} = 2.44 \times 10^3 \text{ m/s}^2. \quad \sum F_x = ma_x \text{ gives}$$

$$F = ma_x = (57 \times 10^{-3} \text{ kg})(2.44 \times 10^3 \text{ m/s}^2) = 140 \text{ N}.$$

(b) The free-body diagram while the ball is in contact with the racket is given in Figure 4.42a. $\vec{F}$ is the force exerted on the ball by the racket. After the ball leaves the racket, $\vec{F}$ ceases to act, as shown in Figure 4.42b.

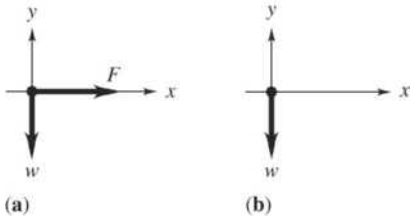

Figure 4.42

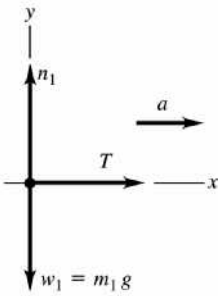
© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: The force is around 30 lb, which is quite large for a light-weight object like a tennis ball, but is reasonable because it acts for only 30 ms yet during that time gives the ball an acceleration of about 250*g*.

4.43. **IDENTIFY:** Use Newton's second law to relate the acceleration and forces for each crate.

(a) SET UP: Since the crates are connected by a rope, they both have the same acceleration, 2.50 m/s^2.

(b) The forces on the 4.00 kg crate are shown in Figure 4.43a.



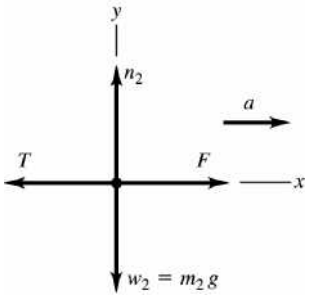
EXECUTE:

$\sum F_x = ma_x$

$T = m_1 a = (4.00 \text{ kg})(2.50 \text{ m/s}^2) = 10.0 \text{ N}.$

Figure 4.43a

(c) SET UP: Forces on the 6.00 kg crate are shown in Figure 4.43b.



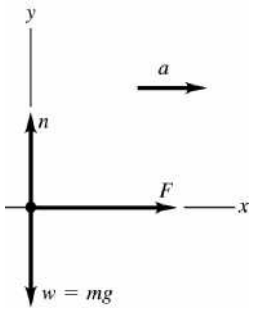
The crate accelerates to the right, so the net force is to the right. *F* must be larger than *T*.

Figure 4.43b

(d) EXECUTE: $\sum F_x = ma_x$ gives $F - T = m_2 a$

$$F = T + m_2 a = 10.0 \text{ N} + (6.00 \text{ kg})(2.50 \text{ m/s}^2) = 10.0 \text{ N} + 15.0 \text{ N} = 25.0 \text{ N}$$

EVALUATE: We can also consider the two crates and the rope connecting them as a single object of mass $m = m_1 + m_2 = 10.0$ kg. The free-body diagram is sketched in Figure 4.43c.



$\sum F_x = ma_x$

$F = ma = (10.0 \text{ kg})(2.50 \text{ m/s}^2) = 25.0 \text{ N}$

This agrees with our answer in part (d).

Figure 4.43c

4.44. **IDENTIFY:** Apply Newton's second and third laws.
SET UP: Action-reaction forces act between a pair of objects. In the second law all the forces act on the same object.
EXECUTE: **(a)** The force the astronaut exerts on the cable and the force that the cable exerts on the astronaut are an action-reaction pair, so the cable exerts a force of 80.0 N on the astronaut.
(b) The cable is under tension.
(c) $a = \dfrac{F}{m} = \dfrac{80.0 \text{ N}}{105.0\ kg} = 0.762 \text{ m/s}^2$.
(d) There is no net force on the massless cable, so the force that the spacecraft exerts on the cable must be 80.0 N (this is *not* an action-reaction pair). Thus, the force that the cable exerts on the spacecraft must be 80.0 N.
(e) $a = \dfrac{F}{m} = \dfrac{80.0 \text{ N}}{9.05\times10^4 \text{ kg}} = 8.84\times10^{-4} \text{ m/s}^2$.
EVALUATE: Since the cable is massless the net force on it is zero and the tension is the same at each end.

4.45. **IDENTIFY** and **SET UP:** Take derivatives of $x(t)$ to find v_x and a_x. Use Newton's second law to relate the acceleration to the net force on the object.
EXECUTE:
(a) $x = (9.0\times10^3 \text{ m/s}^2)t^2 - (8.0\times10^4 \text{m/s}^3)t^3$
$x = 0$ at $t = 0$
When $t = 0.025$ s, $x = (9.0\times10^3 \text{ m/s}^2)(0.025 \text{ s})^2 - (8.0\times10^4 \text{ m/s}^3)(0.025 \text{ s})^3 = 4.4$ m.
The length of the barrel must be 4.4 m.
(b) $v_x = \dfrac{dx}{dt} = (18.0\times10^3 \text{ m/s}^2)t - (24.0\times10^4 \text{ m/s}^3)t^2$
At $t = 0$, $v_x = 0$ (object starts from rest).
At $t = 0.025$ s, when the object reaches the end of the barrel,
$v_x = (18.0\times10^3 \text{ m/s}^2)(0.025 \text{ s}) - (24.0\times10^4 \text{ m/s}^3)(0.025 \text{ s})^2 = 300$ m/s
(c) $\sum F_x = ma_x$, so must find a_x.
$a_x = \dfrac{dv_x}{dt} = 18.0\times10^3 \text{ m/s}^2 - (48.0\times10^4 \text{ m/s}^3)t$
(i) At $t = 0$, $a_x = 18.0\times10^3 \text{ m/s}^2$ and $\sum F_x = (1.50 \text{ kg})(18.0\times10^3 \text{ m/s}^2) = 2.7\times10^4$ N.
(ii) At $t = 0.025$ s, $a_x = 18\times10^3 \text{ m/s}^2 - (48.0\times10^4 \text{ m/s}^3)(0.025 \text{ s}) = 6.0\times10^3 \text{ m/s}^2$ and
$\sum F_x = (1.50 \text{ kg})(6.0\times10^3 \text{ m/s}^2) = 9.0\times10^3$ N.
EVALUATE: The acceleration and net force decrease as the object moves along the barrel.

4.46. **IDENTIFY:** Apply $\sum \vec{F} = m\vec{a}$ and solve for the mass m of the spacecraft.
SET UP: $w = mg$. Let $+y$ be upward.
EXECUTE: **(a)** The velocity of the spacecraft is downward. When it is slowing down, the acceleration is upward. When it is speeding up, the acceleration is downward.
(b) In each case the net force is in the direction of the acceleration. Speeding up: $w > F$ and the net force is downward. Slowing down: $w < F$ and the net force is upward.
(c) Denote the y-component of the acceleration when the thrust is F_1 by a_1 and the y-component of the acceleration when the thrust is F_2 by a_1. $a_1 = +1.20 \text{ m/s}^2$ and $a_2 = -0.80 \text{ m/s}^2$. The forces and accelerations are then related by $F_1 - w = ma_1$, $F_2 - w = ma_2$. Dividing the first of these by the second to eliminate the mass gives $\dfrac{F_1 - w}{F_2 - w} = \dfrac{a_1}{a_2}$, and solving for the weight w gives
$w = \dfrac{a_1F_2 - a_2F_1}{a_1 - a_2}$. Substituting the given numbers, with $+y$ upward, gives

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$w = \frac{(1.20\ \text{m/s}^2)(10.0\times10^3\ \text{N}) - (-0.80\ \text{m/s}^2)(25.0\times10^3\ \text{N})}{1.20\ \text{m/s}^2 - (-0.80\ \text{m/s}^2)} = 16.0\times10^3\ \text{N}.$$

EVALUATE: The acceleration due to gravity at the surface of Mercury did not need to be found.

4.47. **IDENTIFY:** The ship and instrument have the same acceleration. The forces and acceleration are related by Newton's second law. We can use a constant acceleration equation to calculate the acceleration from the information given about the motion.

SET UP: Let $+y$ be upward. The forces on the instrument are the upward tension $\vec{T}$ exerted by the wire and the downward force $\vec{w}$ of gravity. $w = mg = (6.50\ \text{kg})(9.80\ \text{m/s}^2) = 63.7\ \text{N}$

EXECUTE: **(a)** The free-body diagram is sketched in Figure 4.47. The acceleration is upward, so $T > w$.

(b) $y - y_0 = 276\ \text{m}$, $t = 15.0\ \text{s}$, $v_{0y} = 0$. $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$ gives $a_y = \dfrac{2(y-y_0)}{t^2} = \dfrac{2(276\ \text{m})}{(15.0\ \text{s})^2} = 2.45\ \text{m/s}^2$.

$\sum F_y = ma_y$ gives $T - w = ma$ and $T = w + ma = 63.7\ \text{N} + (6.50\ \text{kg})(2.45\ \text{m/s}^2) = 79.6\ \text{N}$.

EVALUATE: There must be a net force in the direction of the acceleration.

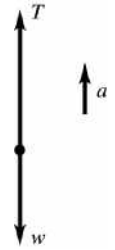

Figure 4.47

4.48. If the rocket is moving downward and its speed is decreasing, its acceleration is upward, just as in Problem 4.47. The solution is identical to that of Problem 4.47.

4.49. **IDENTIFY:** Using kinematics we can find the acceleration of the froghopper and then apply Newton's second law to find the force on it from the ground.

SET UP: Take $+y$ to be upward. $\sum F_y = ma_y$ and for constant acceleration, $v_y = v_{0y} + a_y t$.

EXECUTE: **(a)** The free-body diagram for the froghopper while it is still pushing against the ground is given in Figure 4.49.

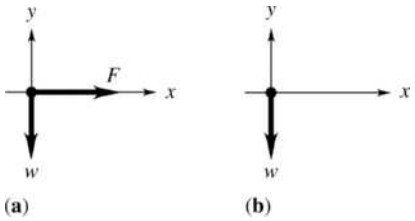

Figure 4.49

(b) $v_{0y} = 0$, $v_y = 4.0\ \text{m/s}$, $t = 1.0\times10^{-3}\ \text{s}$. $v_y = v_{0y} + a_y t$ gives

$a_y = \dfrac{v_y - v_{0y}}{t} = \dfrac{4.0\ \text{m/s} - 0}{1.0\times10^{-3}\ \text{s}} = 4.0\times10^3\ \text{m/s}^2$. $\sum F_y = ma_y$ gives $n - w = ma$, so

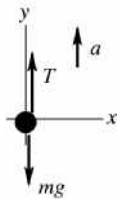
$n = w + ma = m(g + a) = (12.3\times10^{-6}\ \text{kg})(9.8\ \text{m/s}^2 + 4.0\times10^3\ \text{m/s}^2) = 0.049\ \text{N}$.

(c) $\dfrac{F}{w} = \dfrac{0.049\ \text{N}}{(12.3\times10^{-6}\ \text{kg})(9.8\ \text{m/s}^2)} = 410$; $F = 410w$.

EVALUATE: Because the force from the ground is huge compared to the weight of the froghopper, it produces an acceleration of around $400g$!

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

4.50. **IDENTIFY:** Apply $\sum \vec{F} = m\vec{a}$ to the elevator to relate the forces on it to the acceleration.
(a) SET UP: The free-body diagram for the elevator is sketched in Figure 4.50.



The net force is $T - mg$ (upward).

Figure 4.50

Take the $+y$-direction to be upward since that is the direction of the acceleration. The maximum upward acceleration is obtained from the maximum possible tension in the cables.
EXECUTE: $\sum F_y = ma_y$ gives $T - mg = ma$

$$a = \frac{T - mg}{m} = \frac{28{,}000 \text{ N} - (2200 \text{ kg})(9.80 \text{ m/s}^2)}{2200 \text{ kg}} = 2.93 \text{ m/s}^2.$$

(b) What changes is the weight mg of the elevator.

$$a = \frac{T - mg}{m} = \frac{28{,}000 \text{ N} - (2200 \text{ kg})(1.62 \text{ m/s}^2)}{2200 \text{ kg}} = 11.1 \text{ m/s}^2.$$

EVALUATE: The cables can give the elevator a greater acceleration on the moon since the downward force of gravity is less there and the same T then gives a greater net force.

4.51. **IDENTIFY:** He is in free-fall until he contacts the ground. Use the constant acceleration equations and apply $\sum \vec{F} = m\vec{a}$.
SET UP: Take $+y$ downward. While he is in the air, before he touches the ground, his acceleration is $a_y = 9.80 \text{ m/s}^2$.

EXECUTE: **(a)** $v_{0y} = 0$, $y - y_0 = 3.10$ m, and $a_y = 9.80 \text{ m/s}^2$. $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ gives

$$v_y = \sqrt{2a_y(y - y_0)} = \sqrt{2(9.80 \text{ m/s}^2)(3.10 \text{ m})} = 7.79 \text{ m/s}$$

(b) $v_{0y} = 7.79$ m/s, $v_y = 0$, $y - y_0 = 0.60$ m. $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ gives

$$a_y = \frac{v_y^2 - v_{0y}^2}{2(y - y_0)} = \frac{0 - (7.79 \text{ m/s})^2}{2(0.60 \text{ m})} = -50.6 \text{ m/s}^2.$$ The acceleration is upward.

(c) The free-body diagram is given in Fig. 4.51. $\vec{F}$ is the force the ground exerts on him.
$\sum F_y = ma_y$ gives $mg - F = -ma$. $F = m(g + a) = (75.0 \text{ kg})(9.80 \text{ m/s}^2 + 50.6 \text{ m/s}^2) = 4.53 \times 10^3$ N, upward.

$$\frac{F}{w} = \frac{4.53 \times 10^3 \text{ N}}{(75.0 \text{ kg})(9.80 \text{ m/s}^2)} \text{ so, } F = 6.16w = 6.16mg.$$

By Newton's third law, the force his feet exert on the ground is $-\vec{F}$.
EVALUATE: The force the ground exerts on him is about six times his weight.

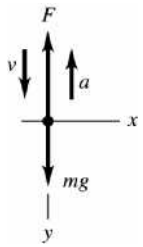


Figure 4.51

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

4.52. **IDENTIFY:** Apply $\sum \vec{F} = m\vec{a}$ to the hammer head. Use a constant acceleration equation to relate the motion to the acceleration.
SET UP: Let $+y$ be upward.
EXECUTE: **(a)** The free-body diagram for the hammer head is sketched in Figure 4.52.
(b) The acceleration of the hammer head is given by $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ with $v_y = 0$, $v_{0y} = -3.2$ m/s^2 and $y - y_0 = -0.0045$ m. $a_y = v_{0y}^2/2(y - y_0) = (3.2 \text{ m/s})^2/2(0.0045 \text{ cm}) = 1.138 \times 10^3$ m/s^2. The mass of the hammer head is its weight divided by g, $(4.9 \text{ N})/(9.80 \text{ m/s}^2) = 0.50$ kg, and so the net force on the hammer head is $(0.50 \text{ kg})(1.138 \times 10^3 \text{ m/s}^2) = 570$ N. This is the sum of the forces on the hammer head: the upward force that the nail exerts, the downward weight and the downward 15-N force. The force that the nail exerts is then 590 N, and this must be the magnitude of the force that the hammer head exerts on the nail.
(c) The distance the nail moves is 0.12 m, so the acceleration will be 4267 m/s^2, and the net force on the hammer head will be 2133 N. The magnitude of the force that the nail exerts on the hammer head, and hence the magnitude of the force that the hammer head exerts on the nail, is 2153 N, or about 2200 N.
EVALUATE: For the shorter stopping distance the acceleration has a larger magnitude and the force between the nail and hammer head is larger.

Figure 4.52

4.53. **IDENTIFY:** Apply $\sum \vec{F} = m\vec{a}$ to some portion of the cable.
SET UP: The free-body diagrams for the whole cable, the top half of the cable and the bottom half are sketched in Figure 4.53. The cable is at rest, so in each diagram the net force is zero.
EXECUTE: **(a)** The net force on a point of the cable at the top is zero; the tension in the cable must be equal to the weight w.
(b) The net force on the cable must be zero; the difference between the tensions at the top and bottom must be equal to the weight w, and with the result of part (a), there is no tension at the bottom.
(c) The net force on the bottom half of the cable must be zero, and so the tension in the cable at the middle must be half the weight, $w/2$. Equivalently, the net force on the upper half of the cable must be zero. From part (a) the tension at the top is w, the weight of the top half is $w/2$ and so the tension in the cable at the middle must be $w - w/2 = w/2$.
(d) A graph of T vs. distance will be a negatively sloped line.
EVALUATE: The tension decreases linearly from a value of w at the top to zero at the bottom of the cable.

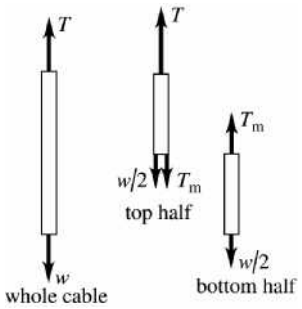

Figure 4.53

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

4.54. **IDENTIFY:** Note that in this problem the mass of the rope is given, and that it is not negligible compared to the other masses. Apply $\sum \vec{F} = m\vec{a}$ to each object to relate the forces to the acceleration.
(a) SET UP: The free-body diagrams for each block and for the rope are given in Figure 4.54a.

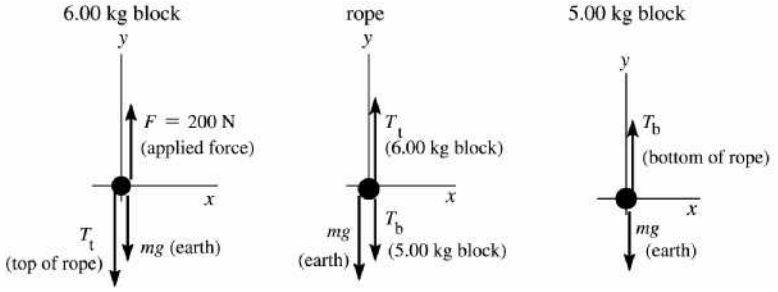

Figure 4.54a

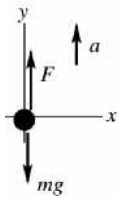
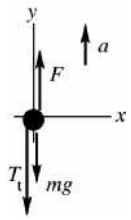
T_t is the tension at the top of the rope and T_b is the tension at the bottom of the rope.
EXECUTE: **(b)** Treat the rope and the two blocks together as a single object, with mass $m = 6.00\text{ kg} + 4.00\text{ kg} + 5.00\text{ kg} = 15.0\text{ kg}$. Take $+y$ upward, since the acceleration is upward. The free-body diagram is given in Figure 4.54b.



$$\sum F_y = ma_y$$
$$F - mg = ma$$
$$a = \frac{F - mg}{m}$$
$$a = \frac{200\text{ N} - (15.0\text{ kg})(9.80\text{ m/s}^2)}{15.0\text{ kg}} = 3.53\text{ m/s}^2$$

Figure 4.54b

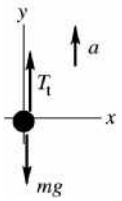
(c) Consider the forces on the top block $(m = 6.00\text{ kg})$, since the tension at the top of the rope (T_t) will be one of these forces.



$$\sum F_y = ma_y$$
$$F - mg - T_t = ma$$
$$T_t = F - m(g + a)$$
$$T = 200\text{ N} - (6.00\text{ kg})(9.80\text{ m/s}^2 + 3.53\text{ m/s}^2) = 120\text{ N}$$

Figure 4.54c

Alternatively, can consider the forces on the combined object rope plus bottom block $(m = 9.00\text{ kg})$:

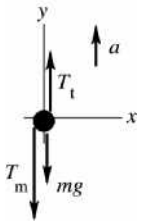


$$\sum F_y = ma_y$$
$$T_t - mg = ma$$
$$T_t = m(g + a) = 9.00\text{ kg}(9.80\text{ m/s}^2 + 3.53\text{ m/s}^2) = 120\text{ N},$$
which checks

Figure 4.54d

(d) One way to do this is to consider the forces on the top half of the rope $(m = 2.00\text{ kg})$. Let T_m be the tension at the midpoint of the rope.

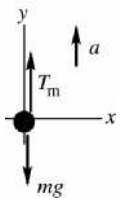
© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.



$$\sum F_y = ma_y$$
$$T_t - T_m - mg = ma$$
$$T_m = T_t - m(g+a) = 120\text{ N} - 2.00\text{ kg}(9.80\text{ m/s}^2 + 3.53\text{ m/s}^2) = 93.3\text{ N}$$

Figure 4.54e

To check this answer we can alternatively consider the forces on the bottom half of the rope plus the lower block taken together as a combined object $(m = 2.00\text{ kg} + 5.00\text{ kg} = 7.00\text{ kg})$:



$$\sum F_y = ma_y$$
$$T_m - mg = ma$$
$$T_m = m(g+a) = 7.00\text{ kg}(9.80\text{ m/s}^2 + 3.53\text{ m/s}^2) = 93.3\text{ N},$$
which checks

Figure 4.54f

EVALUATE: The tension in the rope is not constant but increases from the bottom of the rope to the top. The tension at the top of the rope must accelerate the rope as well the 5.00-kg block. The tension at the top of the rope is less than F; there must be a net upward force on the 6.00-kg block.

4.55. **IDENTIFY:** Apply $\sum \vec{F} = m\vec{a}$ to the barbell and to the athlete. Use the motion of the barbell to calculate its acceleration.

SET UP: Let $+y$ be upward.

EXECUTE: **(a)** The free-body diagrams for the baseball and for the athlete are sketched in Figure 4.55.

(b) The athlete's weight is $mg = (90.0\text{ kg})(9.80\text{ m/s}^2) = 882\text{ N}$. The upward acceleration of the barbell is found from $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$. $a_y = \dfrac{2(y-y_0)}{t^2} = \dfrac{2(0.600\text{ m})}{(1.6\text{ s})^2} = 0.469\text{ m/s}^2$. The force needed to lift the barbell is given by $F_{\text{lift}} - w_{\text{barbell}} = ma_y$. The barbell's mass is $(490\text{ N})/(9.80\text{ m/s}^2) = 50.0\text{ kg}$, so

$F_{\text{lift}} = w_{\text{barbell}} + ma = 490\text{ N} + (50.0\text{ kg})(0.469\text{ m/s}^2) = 490\text{ N} + 23\text{ N} = 513\text{ N}.$

The athlete is not accelerating, so $F_{\text{floor}} - F_{\text{lift}} - w_{\text{athlete}} = 0$. $F_{\text{floor}} = F_{\text{lift}} + w_{\text{athlete}} = 513\text{ N} + 882\text{ N} = 1395\text{ N}$.

EVALUATE: Since the athlete pushes upward on the barbell with a force greater than its weight, the barbell pushes down on him and the normal force on the athlete is greater than the total weight, 1372 N, of the athlete plus barbell.

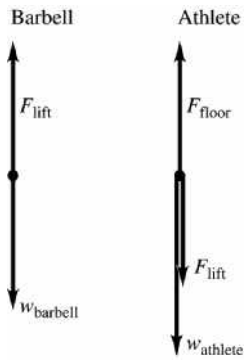


Figure 4.55

4.56. **IDENTIFY:** Apply $\sum \vec{F} = m\vec{a}$ to the balloon and its passengers and cargo, both before and after objects are dropped overboard.

SET UP: When the acceleration is downward take $+y$ to be downward and when the acceleration is upward take $+y$ to be upward.

EXECUTE: **(a)** The free-body diagram for the descending balloon is given in Figure 4.56.

L is the lift force.

(b) $\sum F_y = ma_y$ gives $Mg - L = M(\text{g}/3)$ and $L = 2Mg/3$.

(c) Now $+y$ is upward, so $L - mg = m(\text{g}/2)$, where m is the mass remaining.

$L = 2Mg/3$, so $m = 4M/9$. Mass $5M/9$ must be dropped overboard.

EVALUATE: In part (b) the lift force is greater than the total weight and in part (c) the lift force is less than the total weight.

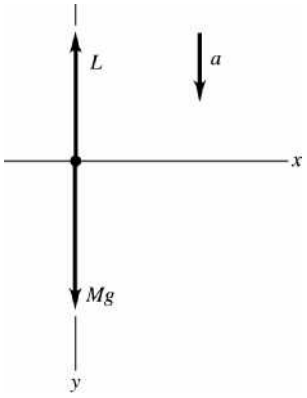

Figure 4.56

4.57. **IDENTIFY:** The system is accelerating, so we apply Newton's second law to each box and can use the constant acceleration kinematics for formulas to find the acceleration.

SET UP: First use the constant acceleration kinematics for formulas to find the acceleration of the system. Then apply $\sum F = ma$ to each box.

EXECUTE: **(a)** The kinematics formula for $y(t)$ gives

$a_y = \dfrac{2(y - y_0)}{t^2} = \dfrac{2(12.0\text{ m})}{(4.0\text{ s})^2} = 1.5\text{ m/s}^2$. For box B, $mg - T = ma$ and

$m = \dfrac{T}{g - a} = \dfrac{36.0\text{ N}}{9.8\text{ m/s}^2 - 1.5\text{ m/s}^2} = 4.34\text{ kg}.$

(b) For box A, $T + mg - F = ma$ and $m = \dfrac{F - T}{g - a} = \dfrac{80.0\text{ N} - 36.0\text{ N}}{9.8\text{ m/s}^2 - 1.5\text{ m/s}^2} = 5.30\text{ kg}.$

EVALUATE: The boxes have the same acceleration but experience different forces because they have different masses.

4.58. **IDENTIFY:** Calculate $\vec{a}$ from $\vec{a} = d^2\vec{r}/dt^2$. Then $\vec{F}_{\text{net}} = m\vec{a}$.

SET UP: $w = mg$

EXECUTE: Differentiating twice, the acceleration of the helicopter as a function of time is $\vec{a} = (0.120\text{ m/s}^3)t\hat{i} - (0.12\text{ m/s}^2)\hat{k}$ and at $t = 5.0\text{s}$, the acceleration is $\vec{a} = (0.60\text{ m/s}^2)\hat{i} - (0.12\text{ m/s}^2)\hat{k}$.

The force is then

$$\vec{F} = m\vec{a} = \frac{w}{g}\vec{a} = \frac{(2.75\times10^5\text{ N})}{(9.80\text{ m/s}^2)}\left[(0.60\text{ m/s}^2)\hat{i} - (0.12\text{ m/s}^2)\hat{k}\right] = (1.7\times10^4\text{ N})\hat{i} - (3.4\times10^3\text{ N})\hat{k}$$

EVALUATE: The force and acceleration are in the same direction. They are both time dependent.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

4.59. **IDENTIFY:** $F_x = ma_x$ and $a_x = \dfrac{d^2x}{dt^2}$.

SET UP: $\dfrac{d}{dt}(t^n) = nt^{n-1}$

EXECUTE: The velocity as a function of time is $v_x(t) = A - 3Bt^2$ and the acceleration as a function of time is $a_x(t) = -6Bt$, and so the force as a function of time is $F_x(t) = ma(t) = -6mBt$.

EVALUATE: Since the acceleration is along the *x*-axis, the force is along the *x*-axis.

4.60. **IDENTIFY:** $\vec{a} = \vec{F}/m$. $\vec{v} = \vec{v}_0 + \int_0^t \vec{a}\, dt$.

SET UP: $v_0 = 0$ since the object is initially at rest.

EXECUTE: $\vec{v}(t) = \dfrac{1}{m}\int_0^t \vec{F}\, dt = \dfrac{1}{m}\left(k_1 t\hat{\boldsymbol{i}} + \dfrac{k_2}{4}t^4\hat{\boldsymbol{j}}\right)$.

EVALUATE: $\vec{F}$ has both *x* and *y* components, so $\vec{v}$ develops *x* and *y* components.

4.61. **IDENTIFY:** The rocket accelerates due to a variable force, so we apply Newton's second law. But the acceleration will not be constant because the force is not constant.

SET UP: We can use $a_x = F_x/m$ to find the acceleration, but must integrate to find the velocity and then the distance the rocket travels.

EXECUTE: Using $a_x = F_x/m$ gives $a_x(t) = \dfrac{(16.8\text{ N/s})t}{45.0\text{ kg}} = (0.3733\text{ m/s}^3)t$. Now integrate the acceleration to get the velocity, and then integrate the velocity to get the distance moved.

$v_x(t) = v_0 + \int_0^t a_x(t')dt' = (0.1867\text{ m/s}^3)t^2$ and $x - x_0 = \int_0^t v(t')dt' = (0.06222\text{ m/s}^3)t^3$. At $t = 5.00$ s, $x - x_0 = 7.78$ m.

EVALUATE: The distance moved during the next 5.0 s would be considerably greater because the acceleration is increase with time.

4.62. **IDENTIFY:** $x = \int_0^t v_x dt$ and $v_x = \int_0^t a_x dt$, and similar equations apply to the *y*-component.

SET UP: In this situation, the *x*-component of force depends explicitly on the *y*-component of position. As the *y*-component of force is given as an explicit function of time, v_y and *y* can be found as functions of time and used in the expression for $a_x(t)$.

EXECUTE: $a_y = (k_3/m)t$, so $v_y = (k_3/2m)t^2$ and $y = (k_3/6m)t^3$, where the initial conditions $v_{0y} = 0, y_0 = 0$ have been used. Then, the expressions for a_x, v_x and *x* are obtained as functions of time:

$a_x = \dfrac{k_1}{m} + \dfrac{k_2 k_3}{6m^2}t^3$, $v_x = \dfrac{k_1}{m}t + \dfrac{k_2 k_3}{24m^2}t^4$ and $x = \dfrac{k_1}{2m}t^2 + \dfrac{k_2 k_3}{120m^2}t^5$.

In vector form, $\vec{r} = \left(\dfrac{k_1}{2m}t^2 + \dfrac{k_2 k_3}{120m^2}t^5\right)\hat{\boldsymbol{i}} + \left(\dfrac{k_3}{6m}t^3\right)\hat{\boldsymbol{j}}$ and $\vec{v} = \left(\dfrac{k_1}{m}t + \dfrac{k_2 k_3}{24m^2}t^4\right)\hat{\boldsymbol{i}} + \left(\dfrac{k_3}{2m}t^2\right)\hat{\boldsymbol{j}}$.

EVALUATE: a_x depends on time because it depends on *y*, and *y* is a function of time.

5

APPLYING NEWTON'S LAWS

5.1. **IDENTIFY:** $a = 0$ for each object. Apply $\Sigma F_y = ma_y$ to each weight and to the pulley.

SET UP: Take $+y$ upward. The pulley has negligible mass. Let T_r be the tension in the rope and let T_c be the tension in the chain.

EXECUTE: **(a)** The free-body diagram for each weight is the same and is given in Figure 5.1a. $\Sigma F_y = ma_y$ gives $T_r = w = 25.0$ N.

(b) The free-body diagram for the pulley is given in Figure 5.1b. $T_c = 2T_r = 50.0$ N.

EVALUATE: The tension is the same at all points along the rope.

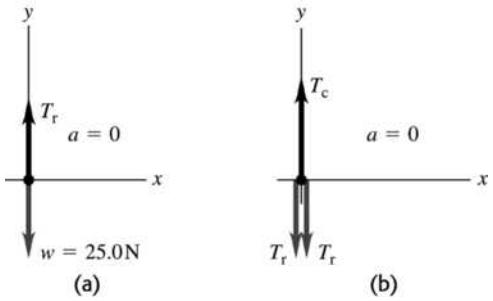

Figure 5.1a, b

5.2. **IDENTIFY:** Apply $\Sigma \vec{F} = m\vec{a}$ to each weight.

SET UP: Two forces act on each mass: w down and $T(= w)$ up.

EXECUTE: In all cases, each string is supporting a weight w against gravity, and the tension in each string is w.

EVALUATE: The tension is the same in all three cases.

5.3. **IDENTIFY:** Both objects are at rest and $a = 0$. Apply Newton's first law to the appropriate object. The maximum tension T_{max} is at the top of the chain and the minimum tension is at the bottom of the chain.

SET UP: Let $+y$ be upward. For the maximum tension take the object to be the chain plus the ball. For the minimum tension take the object to be the ball. For the tension T three-fourths of the way up from the bottom of the chain, take the chain below this point plus the ball to be the object. The free-body diagrams in each of these three cases are sketched in Figures 5.3a, 5.3b and 5.3c. $m_{b+c} = 75.0 \text{ kg} + 26.0 \text{ kg} = 101.0 \text{ kg}$.

$m_b = 75.0$ kg. m is the mass of three-fourths of the chain: $m = \frac{3}{4}(26.0 \text{ kg}) = 19.5 \text{ kg}$.

EXECUTE: **(a)** From Figure 5.3a, $\Sigma F_y = 0$ gives $T_{max} - m_{b+c}g = 0$ and

$T_{max} = (101.0 \text{ kg})(9.80 \text{ m/s}^2) = 990$ N. From Figure 5.3b, $\Sigma F_y = 0$ gives $T_{min} - m_b g = 0$ and

$T_{min} = (75.0 \text{ kg})(9.80 \text{ m/s}^2) = 735$ N.

(b) From Figure 5.3c, $\Sigma F_y = 0$ gives $T - (m + m_b)g = 0$ and $T = (19.5 \text{ kg} + 75.0 \text{ kg})(9.80 \text{ m/s}^2) = 926$ N.

EVALUATE: The tension in the chain increases linearly from the bottom to the top of the chain.

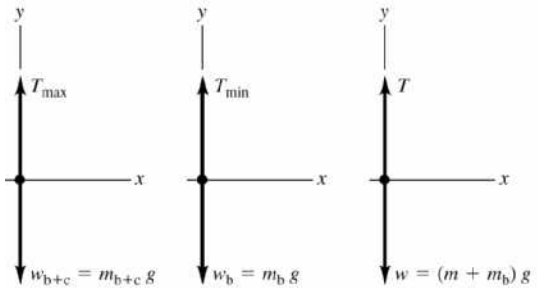

Figure 5.3a–c

5.4. **IDENTIFY:** For the maximum tension, the patient is just ready to slide so static friction is at its maximum and the forces on him add to zero.

SET UP: **(a)** The free-body diagram for the person is given in Figure 5.4a. F is magnitude of the traction force along the spinal column and $w = mg$ is the person's weight. At maximum static friction, $f_s = \mu_s n$.

(b) The free-body diagram for the collar where the cables are attached is given in Figure 5.4b. The tension in each cable has been resolved into its x and y components.

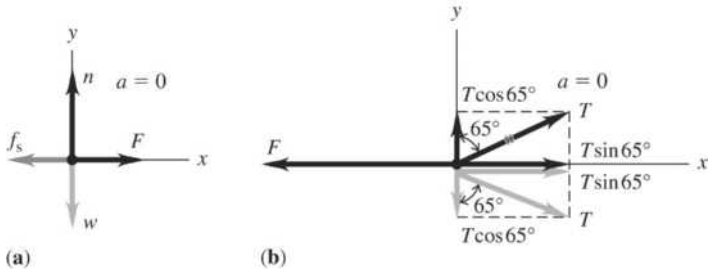

Figure 5.4

EXECUTE: **(a)** $n = w$ and $F = f_s = \mu_s n = 0.75w = 0.75(9.80\ \text{m/s}^2)(78.5\ \text{kg}) = 577\ \text{N}$.

(b) $2T\sin 65° - F = 0$ so $T = \dfrac{F}{2\sin 65°} = \dfrac{0.75w}{2\sin 65°} = 0.41w = (0.41)(9.80\ \text{m/s}^2)(78.5\ \text{kg}) = 315\ \text{N}$.

EVALUATE: The two tensions add up to 630 N, which is more than the traction force, because the cables do not pull directly along the spinal column.

5.5. **IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$ to the frame.

SET UP: Let w be the weight of the frame. Since the two wires make the same angle with the vertical, the tension is the same in each wire. $T = 0.75w$.

EXECUTE: The vertical component of the force due to the tension in each wire must be half of the weight, and this in turn is the tension multiplied by the cosine of the angle each wire makes with the vertical.

$\dfrac{w}{2} = \dfrac{3w}{4}\cos\theta$ and $\theta = \arccos\frac{2}{3} = 48°$.

EVALUATE: If $\theta = 0°$, $T = w/2$ and $T \to \infty$ as $\theta \to 90°$. Therefore, there must be an angle where $T = 3w/4$.

5.6. **IDENTIFY:** Apply Newton's first law to the wrecking ball. Each cable exerts a force on the ball, directed along the cable.

SET UP: The force diagram for the wrecking ball is sketched in Figure 5.6.

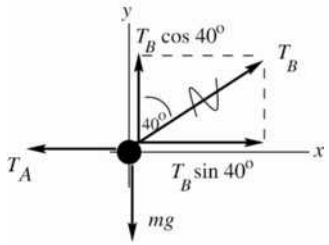

Figure 5.6

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: **(a)** $\Sigma F_y = ma_y$

$T_B \cos 40° - mg = 0$

$T_B = \dfrac{mg}{\cos 40°} = \dfrac{(4090 \text{ kg})(9.80 \text{ m/s}^2)}{\cos 40°} = 5.23 \times 10^4 \text{ N}$

(b) $\Sigma F_x = ma_x$

$T_B \sin 40° - T_A = 0$

$T_A = T_B \sin 40° = 3.36 \times 10^4 \text{ N}$

EVALUATE: If the angle 40° is replaced by 0° (cable B is vertical), then $T_B = mg$ and $T_A = 0$.

5.7. **IDENTIFY:** Apply $\Sigma \vec{F} = m\vec{a}$ to the object and to the knot where the cords are joined.

SET UP: Let $+y$ be upward and $+x$ be to the right.

EXECUTE: **(a)** $T_C = w$, $T_A \sin 30° + T_B \sin 45° = T_C = w$, and $T_A \cos 30° - T_B \cos 45° = 0$. Since $\sin 45° = \cos 45°$, adding the last two equations gives $T_A(\cos 30° + \sin 30°) = w$, and so

$T_A = \dfrac{w}{1.366} = 0.732w$. Then, $T_B = T_A \dfrac{\cos 30°}{\cos 45°} = 0.897w$.

(b) Similar to part (a), $T_C = w$, $-T_A \cos 60° + T_B \sin 45° = w$, and $T_A \sin 60° - T_B \cos 45° = 0$.

Adding these two equations, $T_A = \dfrac{w}{(\sin 60° - \cos 60°)} = 2.73w$, and $T_B = T_A \dfrac{\sin 60°}{\cos 45°} = 3.35w$.

EVALUATE: In part (a), $T_A + T_B > w$ since only the vertical components of T_A and T_B hold the object against gravity. In part (b), since T_A has a downward component T_B is greater than w.

5.8. **IDENTIFY:** Apply Newton's first law to the car.

SET UP: Use x and y coordinates that are parallel and perpendicular to the ramp.

EXECUTE: **(a)** The free-body diagram for the car is given in Figure 5.8. The vertical weight w and the tension T in the cable have each been replaced by their x and y components.

(b) $\Sigma F_x = 0$ gives $T \cos 31.0° - w \sin 25.0° = 0$ and

$T = w \dfrac{\sin 25.0°}{\cos 31.0°} = (1130 \text{ kg})(9.80 \text{ m/s}^2) \dfrac{\sin 25.0°}{\cos 31.0°} = 5460 \text{ N}.$

(c) $\Sigma F_y = 0$ gives $n + T \sin 31.0° - w \cos 25.0° = 0$ and

$n = w \cos 25.0° - T \sin 31.0° = (1130 \text{ kg})(9.80 \text{ m/s}^2) \cos 25.0° - (5460 \text{ N}) \sin 31.0° = 7220 \text{ N}$

EVALUATE: We could also use coordinates that are horizontal and vertical and would obtain the same values of n and T.

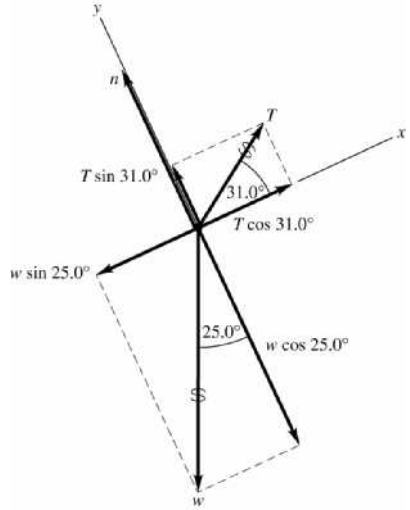

Figure 5.8

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

5.9. **IDENTIFY:** Since the velocity is constant, apply Newton's first law to the piano. The push applied by the man must oppose the component of gravity down the incline.

SET UP: The free-body diagrams for the two cases are shown in Figures 5.9a and b. $\vec{F}$ is the force applied by the man. Use the coordinates shown in the figure.

EXECUTE: **(a)** $\Sigma F_x = 0$ gives $F - w\sin 11.0° = 0$ and $F = (180 \text{ kg})(9.80 \text{ m/s}^2)\sin 11.0° = 337 \text{ N}$.

(b) $\Sigma F_y = 0$ gives $n\cos 11.0° - w = 0$ and $n = \dfrac{w}{\cos 11.0°}$. $\Sigma F_x = 0$ gives $F - n\sin 11.0° = 0$ and

$F = \left(\dfrac{w}{\cos 11.0°}\right)\sin 11.0° = w\tan 11.0° = 343 \text{ N}$.

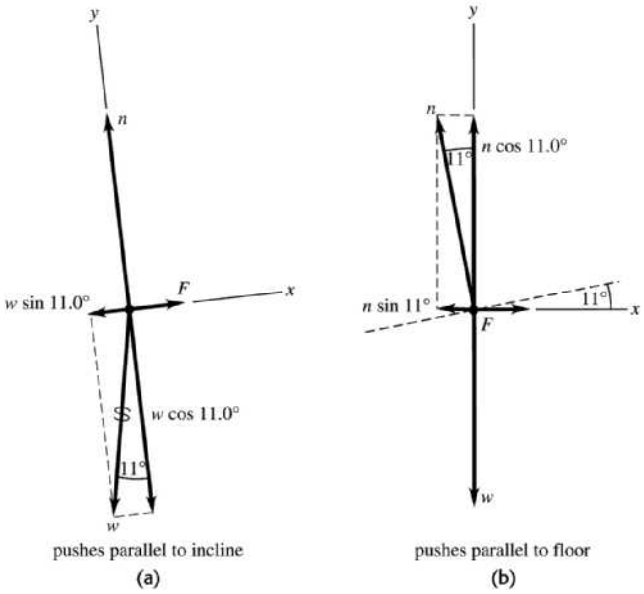

Figure 5.9a, b

5.10. **IDENTIFY:** Apply Newton's first law to the hanging weight and to each knot. The tension force at each end of a string is the same.

(a) Let the tensions in the three strings be T, T', and T'', as shown in Figure 5.10a.

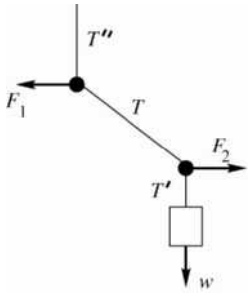

Figure 5.10a

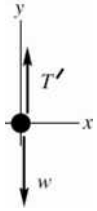
SET UP: The free-body diagram for the block is given in Figure 5.10b.



EXECUTE:

$\Sigma F_y = 0$

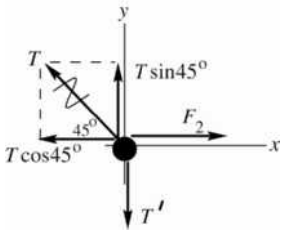
$T' - w = 0$

$T' = w = 60.0 \text{ N}$

Figure 5.10b

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

SET UP: The free-body diagram for the lower knot is given in Figure 5.10c.



EXECUTE:

$$\Sigma F_y = 0$$

$$T\sin 45° - T' = 0$$

$$T = \frac{T'}{\sin 45°} = \frac{60.0\text{ N}}{\sin 45°} = 84.9\text{ N}$$

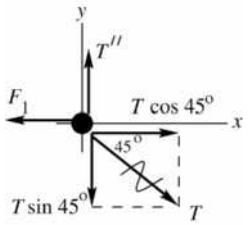
Figure 5.10c

(b) Apply $\Sigma F_x = 0$ to the force diagram for the lower knot:

$$\Sigma F_x = 0$$

$$F_2 = T\cos 45° = (84.9\text{ N})\cos 45° = 60.0\text{ N}$$

SET UP: The free-body diagram for the upper knot is given in Figure 5.10d.



EXECUTE:

$$\Sigma F_x = 0$$

$$T\cos 45° - F_1 = 0$$

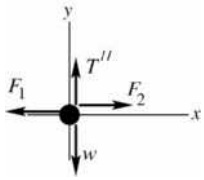
$$F_1 = (84.9\text{ N})\cos 45°$$

$$F_1 = 60.0\text{ N}$$

Figure 5.10d

Note that $F_1 = F_2$.

EVALUATE: Applying $\Sigma F_y = 0$ to the upper knot gives $T'' = T\sin 45° = 60.0\text{ N} = w$. If we treat the whole system as a single object, the force diagram is given in Figure 5.10e.



$\Sigma F_x = 0$ gives $F_2 = F_1$, which checks

$\Sigma F_y = 0$ gives $T'' = w$, which checks

Figure 5.10e

5.11. **IDENTIFY:** We apply Newton's second law to the rocket and the astronaut in the rocket. A constant force means we have constant acceleration, so we can use the standard kinematics equations.

SET UP: The free-body diagrams for the rocket (weight w_r) and astronaut (weight w) are given in Figures 5.11a and 5.11b. F_T is the thrust and n is the normal force the rocket exerts on the astronaut. The speed of sound is 331 m/s. We use $\Sigma F_y = ma_y$ and $v = v_0 + at$.

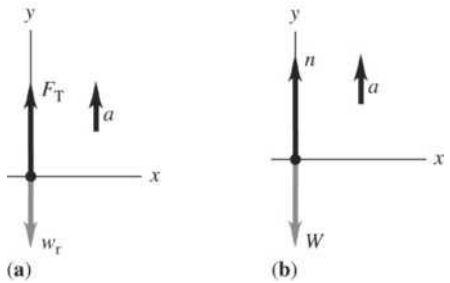


Figure 5.11

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: **(a)** Apply $\Sigma F_y = ma_y$ to the rocket: $F_T - w_r = ma$. $a = 4g$ and $w_r = mg$, so

$F = m(5g) = (2.25\times10^6 \text{ kg})(5)(9.80 \text{ m/s}^2) = 1.10\times10^8 \text{ N}$.

(b) Apply $\Sigma F_y = ma_y$ to the astronaut: $n - w = ma$. $a = 4g$ and $m = \dfrac{w}{g}$, so $n = w + \left(\dfrac{w}{g}\right)(4g) = 5w$.

(c) $v_0 = 0$, $v = 331$ m/s and $a = 4g = 39.2 \text{ m/s}^2$. $v = v_0 + at$ gives $t = \dfrac{v - v_0}{a} = \dfrac{331 \text{ m/s}}{39.2 \text{ m/s}^2} = 8.4$ s.

EVALUATE: The 8.4 s is probably an unrealistically short time to reach the speed of sound because you would not want your astronauts at the brink of blackout during a launch.

5.12. **IDENTIFY:** Apply Newton's second law to the rocket plus its contents and to the power supply. Both the rocket and the power supply have the same acceleration.

SET UP: The free-body diagrams for the rocket and for the power supply are given in Figures 5.12a and b. Since the highest altitude of the rocket is 120 m, it is near to the surface of the earth and there is a downward gravity force on each object. Let $+y$ be upward, since that is the direction of the acceleration.

The power supply has mass $m_{ps} = (15.5 \text{ N})/(9.80 \text{ m/s}^2) = 1.58$ kg.

EXECUTE: **(a)** $\Sigma F_y = ma_y$ applied to the rocket gives $F - m_r g = m_r a$.

$a = \dfrac{F - m_r g}{m_r} = \dfrac{1720 \text{ N} - (125 \text{ kg})(9.80 \text{ m/s}^2)}{125 \text{ kg}} = 3.96 \text{ m/s}^2$.

(b) $\Sigma F_y = ma_y$ applied to the power supply gives $n - m_{ps} g = m_{ps} a$.

$n = m_{ps}(g + a) = (1.58 \text{ kg})(9.80 \text{ m/s}^2 + 3.96 \text{ m/s}^2) = 21.7$ N.

EVALUATE: The acceleration is constant while the thrust is constant and the normal force is constant while the acceleration is constant. The altitude of 120 m is not used in the calculation.

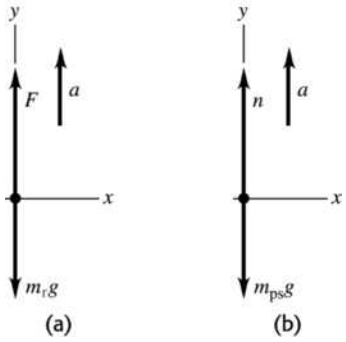

Figure 5.12

5.13. **IDENTIFY:** Use the kinematic information to find the acceleration of the capsule and the stopping time. Use Newton's second law to find the force F that the ground exerted on the capsule during the crash.

SET UP: Let $+y$ be upward. 311 km/h = 86.4 m/s. The free-body diagram for the capsule is given in Figure 5.13.

EXECUTE: $y - y_0 = -0.810$ m, $v_{0y} = -86.4$ m/s, $v_y = 0$. $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ gives

$a_y = \dfrac{v_y^2 - v_{0y}^2}{2(y - y_0)} = \dfrac{0 - (-86.4 \text{ m/s})^2}{2(-0.810) \text{ m}} = 4610 \text{ m/s}^2 = 470g$.

(b) $\Sigma F_y = ma_y$ applied to the capsule gives $F - mg = ma$ and

$F = m(g + a) = (210 \text{ kg})(9.80 \text{ m/s}^2 + 4610 \text{ m/s}^2) = 9.70\times10^5 \text{ N} = 471w$.

(c) $y - y_0 = \left(\dfrac{v_{0y} + v_y}{2}\right)t$ gives $t = \dfrac{2(y - y_0)}{v_{0y} + v_y} = \dfrac{2(-0.810 \text{ m})}{-86.4 \text{ m/s} + 0} = 0.0187$ s

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: The upward force exerted by the ground is much larger than the weight of the capsule and stops the capsule in a short amount of time. After the capsule has come to rest, the ground still exerts a force mg on the capsule, but the large 9.70×10^5 N force is exerted only for 0.0187 s.

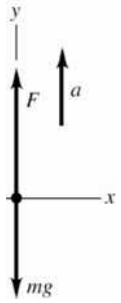

Figure 5.13

5.14. **IDENTIFY:** Apply Newton's second law to the three sleds taken together as a composite object and to each individual sled. All three sleds have the same horizontal acceleration a.
SET UP: The free-body diagram for the three sleds taken as a composite object is given in Figure 5.14a and for each individual sled in Figure 5.14b–d. Let $+x$ be to the right, in the direction of the acceleration. $m_{\text{tot}} = 60.0$ kg.
EXECUTE: **(a)** $\Sigma F_x = ma_x$ for the three sleds as a composite object gives $P = m_{\text{tot}}a$ and $a = \dfrac{P}{m_{\text{tot}}} = \dfrac{125\text{ N}}{60.0\text{ kg}} = 2.08\text{ m/s}^2$.
(b) $\Sigma F_x = ma_x$ applied to the 10.0 kg sled gives $P - T_A = m_{10}a$ and $T_A = P - m_{10}a = 125\text{ N} - (10.0\text{ kg})(2.08\text{ m/s}^2) = 104\text{ N}$. $\Sigma F_x = ma_x$ applied to the 30.0 kg sled gives $T_B = m_{30}a = (30.0\text{ kg})(2.08\text{ m/s}^2) = 62.4\text{ N}$.
EVALUATE: If we apply $\Sigma F_x = ma_x$ to the 20.0 kg sled and calculate a from T_A and T_B found in part (b), we get $T_A - T_B = m_{20}a$. $a = \dfrac{T_A - T_B}{m_{20}} = \dfrac{104\text{ N} - 62.4\text{ N}}{20.0\text{ kg}} = 2.08\text{ m/s}^2$, which agrees with the value we calculated in part (a).

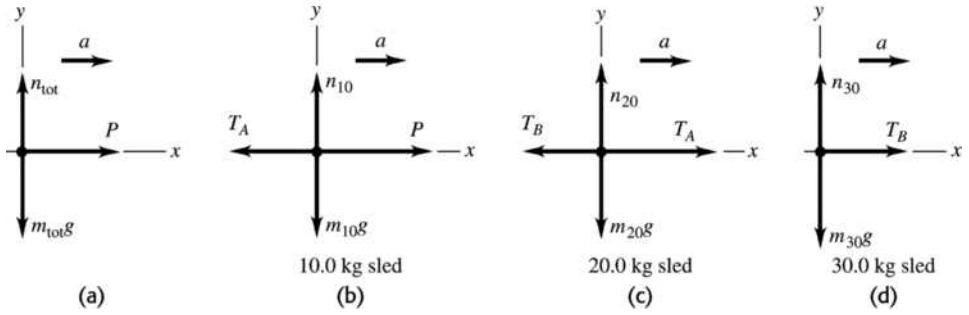

Figure 5.14

5.15. **IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$ to the load of bricks and to the counterweight. The tension is the same at each end of the rope. The rope pulls up with the same force (T) on the bricks and on the counterweight. The counterweight accelerates downward and the bricks accelerate upward; these accelerations have the same magnitude.
(a) SET UP: The free-body diagrams for the bricks and counterweight are given in Figure 5.15.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

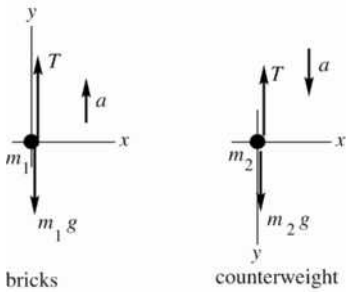

Figure 5.15

(b) EXECUTE: Apply $\Sigma F_y = ma_y$ to each object. The acceleration magnitude is the same for the two objects. For the bricks take $+y$ to be upward since $\vec{a}$ for the bricks is upward. For the counterweight take $+y$ to be downward since $\vec{a}$ is downward.

bricks: $\Sigma F_y = ma_y$

$T - m_1 g = m_1 a$

counterweight: $\Sigma F_y = ma_y$

$m_2 g - T = m_2 a$

Add these two equations to eliminate T:

$$(m_2 - m_1)g = (m_1 + m_2)a$$

$$a = \left(\frac{m_2 - m_1}{m_1 + m_2}\right)g = \left(\frac{28.0\text{ kg} - 15.0\text{ kg}}{15.0\text{ kg} + 28.0\text{ kg}}\right)(9.80\text{ m/s}^2) = 2.96\text{ m/s}^2$$

(c) $T - m_1 g = m_1 a$ gives $T = m_1(a + g) = (15.0\text{ kg})(2.96\text{ m/s}^2 + 9.80\text{ m/s}^2) = 191\text{ N}$

As a check, calculate T using the other equation.

$m_2 g - T = m_2 a$ gives $T = m_2(g - a) = 28.0\text{ kg}(9.80\text{ m/s}^2 - 2.96\text{ m/s}^2) = 191\text{ N}$, which checks.

EVALUATE: The tension is 1.30 times the weight of the bricks; this causes the bricks to accelerate upward. The tension is 0.696 times the weight of the counterweight; this causes the counterweight to accelerate downward. If $m_1 = m_2$, $a = 0$ and $T = m_1 g = m_2 g$. In this special case the objects don't move. If $m_1 = 0$, $a = g$ and $T = 0$; in this special case the counterweight is in free fall. Our general result is correct in these two special cases.

5.16. **IDENTIFY:** In part (a) use the kinematic information and the constant acceleration equations to calculate the acceleration of the ice. Then apply $\Sigma\vec{F} = m\vec{a}$. In part (b) use $\Sigma\vec{F} = m\vec{a}$ to find the acceleration and use this in the constant acceleration equations to find the final speed.

SET UP: Figures 5.16a and b give the free-body diagrams for the ice both with and without friction. Let $+x$ be directed down the ramp, so $+y$ is perpendicular to the ramp surface. Let ϕ be the angle between the ramp and the horizontal. The gravity force has been replaced by its x and y components.

EXECUTE: **(a)** $x - x_0 = 1.50$ m, $v_{0x} = 0$. $v_x = 2.50$ m/s. $v_x^2 = v_{0x}^2 + 2a_x(x - x_0)$ gives

$a_x = \dfrac{v_x^2 - v_{0x}^2}{2(x - x_0)} = \dfrac{(2.50\text{ m/s})^2 - 0}{2(1.50\text{ m})} = 2.08\text{ m/s}^2$. $\Sigma F_x = ma_x$ gives $mg\sin\phi = ma$ and $\sin\phi = \dfrac{a}{g} = \dfrac{2.08\text{ m/s}^2}{9.80\text{ m/s}^2}$.

$\phi = 12.3°$.

(b) $\Sigma F_x = ma_x$ gives $mg\sin\phi - f = ma$ and

$$a = \frac{mg\sin\phi - f}{m} = \frac{(8.00\text{ kg})(9.80\text{ m/s}^2)\sin 12.3° - 10.0\text{ N}}{8.00\text{ kg}} = 0.838\text{ m/s}^2.$$

Then $x - x_0 = 1.50$ m, $v_{0x} = 0$. $a_x = 0.838\text{ m/s}^2$ and $v_x^2 = v_{0x}^2 + 2a_x(x - x_0)$ gives

$$v_x = \sqrt{2a_x(x - x_0)} = \sqrt{2(0.838\text{ m/s}^2)(1.50\text{ m})} = 1.59\text{ m/s}$$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: With friction present the speed at the bottom of the ramp is less.

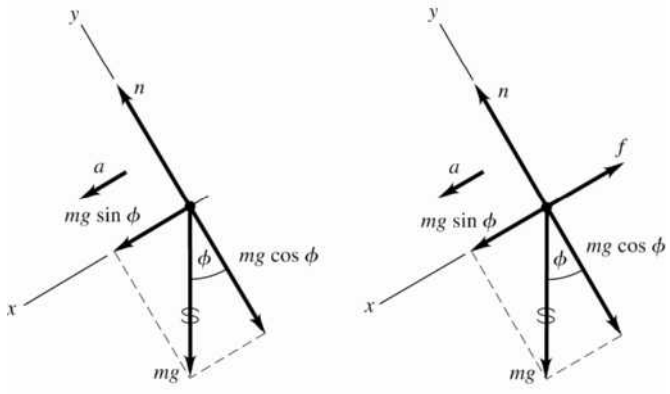

Figure 5.16a, b

5.17. **IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$ to each block. Each block has the same magnitude of acceleration a.

SET UP: Assume the pulley is to the right of the 4.00 kg block. There is no friction force on the 4.00 kg block; the only force on it is the tension in the rope. The 4.00 kg block therefore accelerates to the right and the suspended block accelerates downward. Let $+x$ be to the right for the 4.00 kg block, so for it $a_x = a$, and let $+y$ be downward for the suspended block, so for it $a_y = a$.

EXECUTE: **(a)** The free-body diagrams for each block are given in Figures 5.17a and b.

(b) $\Sigma F_x = ma_x$ applied to the 4.00 kg block gives $T = (4.00 \text{ kg})a$ and $a = \dfrac{T}{4.00 \text{ kg}} = \dfrac{10.0 \text{ N}}{4.00 \text{ kg}} = 2.50 \text{ m/s}^2$.

(c) $\Sigma F_y = ma_y$ applied to the suspended block gives $mg - T = ma$ and

$$m = \frac{T}{g - a} = \frac{10.0 \text{ N}}{9.80 \text{ m/s}^2 - 2.50 \text{ m/s}^2} = 1.37 \text{ kg}.$$

(d) The weight of the hanging block is $mg = (1.37 \text{ kg})(9.80 \text{ m/s}^2) = 13.4$ N. This is greater than the tension in the rope; $T = 0.75mg$.

EVALUATE: Since the hanging block accelerates downward, the net force on this block must be downward and the weight of the hanging block must be greater than the tension in the rope. Note that the blocks accelerate no matter how small m is. It is not necessary to have $m > 4.00$ kg, and in fact in this problem m is less than 4.00 kg.

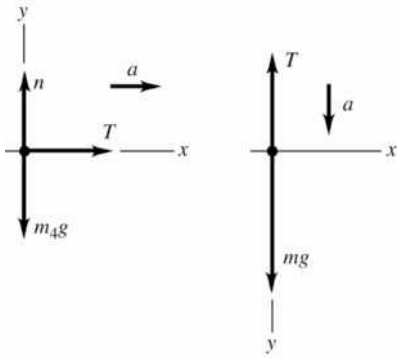

Figure 5.17a, b

5.18. **IDENTIFY:** **(a)** Consider both gliders together as a single object, apply $\Sigma\vec{F} = m\vec{a}$, and solve for a. Use a in a constant acceleration equation to find the required runway length.
(b) Apply $\Sigma\vec{F} = m\vec{a}$ to the second glider and solve for the tension T_g in the towrope that connects the two gliders.
SET UP: In part (a), set the tension T_t in the towrope between the plane and the first glider equal to its maximum value, $T_t = 12{,}000$ N.
EXECUTE: **(a)** The free-body diagram for both gliders as a single object of mass $2m = 1400$ kg is given in Figure 5.18a. $\Sigma F_x = ma_x$ gives $T_t - 2f = (2m)a$ and $a = \dfrac{T_t - 2f}{2m} = \dfrac{12{,}000\text{ N} - 5000\text{ N}}{1400\text{ kg}} = 5.00\text{ m/s}^2$. Then

$a_x = 5.00\text{ m/s}^2$, $v_{0x} = 0$ and $v_x = 40$ m/s in $v_x^2 = v_{0x}^2 + 2a_x(x - x_0)$ gives $(x - x_0) = \dfrac{v_x^2 - v_{0x}^2}{2a_x} = 160$ m.

(b) The free-body diagram for the second glider is given in Figure 5.18b.
$\Sigma F_x = ma_x$ gives $T_g - f = ma$ and $T = f + ma = 2500\text{ N} + (700\text{ kg})(5.00\text{ m/s}^2) = 6000$ N.
EVALUATE: We can verify that $\Sigma F_x = ma_x$ is also satisfied for the first glider.

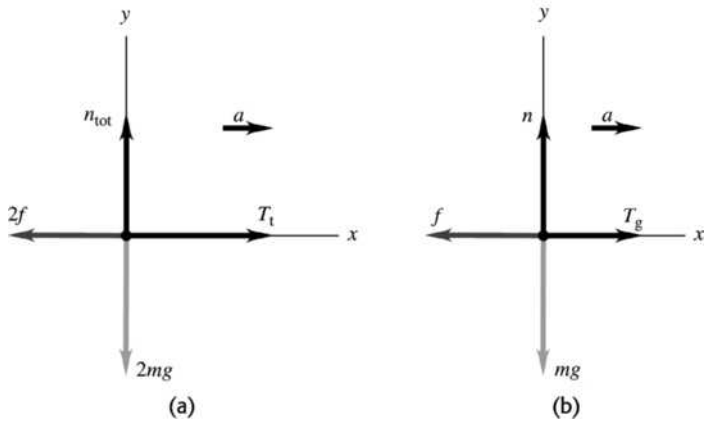

Figure 5.18

5.19. **IDENTIFY:** The maximum tension in the chain is at the top of the chain. Apply $\Sigma\vec{F} = m\vec{a}$ to the composite object of chain and boulder. Use the constant acceleration kinematic equations to relate the acceleration to the time.
SET UP: Let $+y$ be upward. The free-body diagram for the composite object is given in Figure 5.19.
$T = 2.50w_{chain}$. $m_{tot} = m_{chain} + m_{boulder} = 1325$ kg.
EXECUTE: **(a)** $\Sigma F_y = ma_y$ gives $T - m_{tot}g = m_{tot}a$.

$$a = \frac{T - m_{tot}g}{m_{tot}} = \frac{2.50m_{chain}g - m_{tot}g}{m_{tot}} = \left(\frac{2.50m_{chain}}{m_{tot}} - 1\right)g$$

$$a = \left(\frac{2.50[575\text{ kg}]}{1325\text{ kg}} - 1\right)(9.80\text{ m/s}^2) = 0.832\text{ m/s}^2$$

(b) Assume the acceleration has its maximum value: $a_y = 0.832\text{ m/s}^2$, $y - y_0 = 125$ m and $v_{0y} = 0$.

$$y - y_0 = v_{0y}t + \tfrac{1}{2}a_yt^2 \text{ gives } t = \sqrt{\frac{2(y - y_0)}{a_y}} = \sqrt{\frac{2(125\text{ m})}{0.832\text{ m/s}^2}} = 17.3\text{ s}$$

EVALUATE: The tension in the chain is $T = 1.41\times10^4$ N and the total weight is 1.30×10^4 N. The upward force exceeds the downward force and the acceleration is upward.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

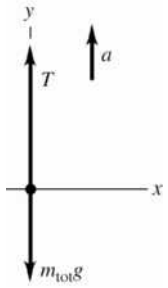

Figure 5.19

5.20. **IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$ to the composite object of elevator plus student ($m_{tot} = 850$ kg) and also to the student ($w = 550$ N). The elevator and the student have the same acceleration.

SET UP: Let $+y$ be upward. The free-body diagrams for the composite object and for the student are given in Figures 5.20a and b. T is the tension in the cable and n is the scale reading, the normal force the scale exerts on the student. The mass of the student is $m = w/g = 56.1$ kg.

EXECUTE: **(a)** $\Sigma F_y = ma_y$ applied to the student gives $n - mg = ma_y$.

$a_y = \dfrac{n - mg}{m} = \dfrac{450\text{ N} - 550\text{ N}}{56.1\text{ kg}} = -1.78\text{ m/s}^2$. The elevator has a downward acceleration of 1.78 m/s^2.

(b) $a_y = \dfrac{670\text{ N} - 550\text{ N}}{56.1\text{ kg}} = 2.14\text{ m/s}^2$.

(c) $n = 0$ means $a_y = -g$. The student should worry; the elevator is in free fall.

(d) $\Sigma F_y = ma_y$ applied to the composite object gives $T - m_{tot}g = m_{tot}a$. $T = m_{tot}(a_y + g)$. In part (a), $T = (850\text{ kg})(-1.78\text{ m/s}^2 + 9.80\text{ m/s}^2) = 6820$ N. In part (c), $a_y = -g$ and $T = 0$.

EVALUATE: In part (b), $T = (850\text{ kg})(2.14\text{ m/s}^2 + 9.80\text{ m/s}^2) = 10{,}150$ N. The weight of the composite object is 8330 N. When the acceleration is upward the tension is greater than the weight and when the acceleration is downward the tension is less than the weight.

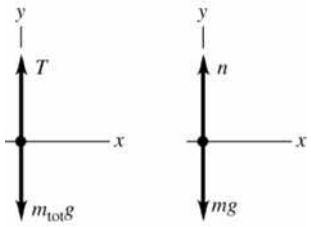

Figure 5.20a, b

5.21. **IDENTIFY:** While the person is in contact with the ground, he is accelerating upward and experiences two forces: gravity downward and the upward force of the ground. Once he is in the air, only gravity acts on him so he accelerates downward. Newton's second law applies during the jump (and at all other times).

SET UP: Take $+y$ to be upward. After he leaves the ground the person travels upward 60 cm and his acceleration is $g = 9.80\text{ m/s}^2$, downward. His weight is w so his mass is w/g. $\Sigma F_y = ma_y$ and $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ apply to the jumper.

EXECUTE: **(a)** $v_y = 0$ (at the maximum height), $y - y_0 = 0.60$ m, $a_y = -9.80\text{ m/s}^2$.

$v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ gives $v_{0y} = \sqrt{-2a_y(y - y_0)} = \sqrt{-2(-9.80\text{ m/s}^2)(0.60\text{ m})} = 3.4$ m/s.

(b) The free-body diagram for the person while he is pushing up against the ground is given in Figure 5.21.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(c) For the jump, $v_{0y} = 0$, $v_y = 3.4$ m/s (from part (a)), and $y - y_0 = 0.50$ m.

$v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ gives $a_y = \dfrac{v_y^2 - v_{0y}^2}{2(y - y_0)} = \dfrac{(3.4 \text{ m/s})^2 - 0}{2(0.50 \text{ m})} = 11.6 \text{ m/s}^2$. $\Sigma F_y = ma_y$ gives $n - w = ma$.

$n = w + ma = w\left(1 + \dfrac{a}{g}\right) = 2.2w.$

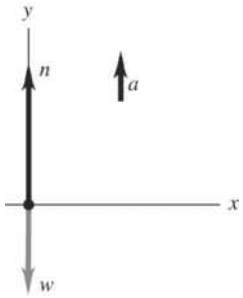

Figure 5.21

EVALUATE: To accelerate the person upward during the jump, the upward force from the ground must exceed the downward pull of gravity. The ground pushes up on him because he pushes down on the ground.

5.22. **IDENTIFY:** Acceleration and velocity are related by $a_y = \dfrac{dv_y}{dt}$. Apply $\Sigma\vec{F} = m\vec{a}$ to the rocket.

SET UP: Let $+y$ be upward. The free-body diagram for the rocket is sketched in Figure 5.22. $\vec{F}$ is the thrust force.

EXECUTE: **(a)** $v_y = At + Bt^2$. $a_y = A + 2Bt$. At $t = 0$, $a_y = 1.50 \text{ m/s}^2$ so $A = 1.50 \text{ m/s}^2$. Then

$v_y = 2.00$ m/s at $t = 1.00$ s gives $2.00 \text{ m/s} = (1.50 \text{ m/s}^2)(1.00 \text{ s}) + B(1.00 \text{ s})^2$ and $B = 0.50 \text{ m/s}^3$.

(b) At $t = 4.00$ s, $a_y = 1.50 \text{ m/s}^2 + 2(0.50 \text{ m/s}^3)(4.00 \text{ s}) = 5.50 \text{ m/s}^2$.

(c) $\Sigma F_y = ma_y$ applied to the rocket gives $T - mg = ma$ and

$T = m(a + g) = (2540 \text{ kg})(9.80 \text{ m/s}^2 + 5.50 \text{ m/s}^2) = 3.89 \times 10^4$ N. $T = 1.56w$.

(d) When $a = 1.50 \text{ m/s}^2$, $T = (2540 \text{ kg})(9.80 \text{ m/s}^2 + 1.50 \text{ m/s}^2) = 2.87 \times 10^4$ N

EVALUATE: During the time interval when $v(t) = At + Bt^2$ applies the magnitude of the acceleration is increasing, and the thrust is increasing.

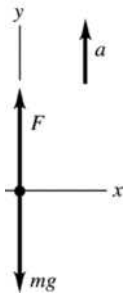

Figure 5.22

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

5.23. **IDENTIFY:** We know the external forces on the box and want to find the distance it moves and its speed. The force is not constant, so the acceleration will not be constant, so we cannot use the standard constant-acceleration kinematics formulas. But Newton's second law will apply.

SET UP: First use Newton's second law to find the acceleration as a function of time: $a_x(t) = \frac{F_x}{m}$. Then integrate the acceleration to find the velocity as a function of time, and next integrate the velocity to find the position as a function of time.

EXECUTE: Let $+x$ be to the right. $a_x(t) = \frac{F_x}{m} = \frac{(-6.00\ \text{N/s}^2)t^2}{2.00\ \text{kg}} = -(3.00\ \text{m/s}^4)t^2$. Integrate the acceleration to find the velocity as a function of time: $v_x(t) = -(1.00\ \text{m/s}^4)t^3 + 9.00\ \text{m/s}$. Next integrate the velocity to find the position as a function of time: $x(t) = -(0.250\ \text{m/s}^4)t^4 + (9.00\ \text{m/s})t$. Now use the given values of time.

(a) $v_x = 0$ when $(1.00\ \text{m/s}^4)t^3 = 9.00\ \text{m/s}$. This gives $t = 2.08$ s. At $t = 2.08$ s,

$x = (9.00\ \text{m/s})(2.08\ \text{s}) - (0.250\ \text{m/s}^4)(2.08\ \text{s})^4 = 18.72\ \text{m} - 4.68\ \text{m} = 14.0\ \text{m}$.

(b) At $t = 3.00$ s, $v_x(t) = -(1.00\ \text{m/s}^4)(3.00\ \text{s})^3 + 9.00\ \text{m/s} = -18.0\ \text{m/s}$, so the speed is 18.0 m/s.

EVALUATE: The box starts out moving to the right. But because the acceleration is to the left, it reverses direction and v_x is negative in part (b).

5.24. **IDENTIFY:** We know the position of the crate as a function of time, so we can differentiate to find its acceleration. Then we can apply Newton's second law to find the upward force.

SET UP: $v_y(t) = dy/dt$, $a_y(t) = dv_y/dt$, and $\Sigma F_y = ma_y$.

EXECUTE: Let $+y$ be upward. $dy/dt = v_y(t) = 2.80\ \text{m/s} + (1.83\ \text{m/s}^3)t^2$ and

$dv_y/dt = a_y(t) = (3.66\ \text{m/s}^3)t$. At $t = 4.00$ s, $a_y = 14.64\ \text{m/s}^2$. Newton's second law in the y direction gives $F - mg = ma$. Solving for F gives $F = 49\ \text{N} + (5.00\ \text{kg})(14.64\ \text{m/s}^2) = 122\ \text{N}$.

EVALUATE: The force is greater than the weight since it is accelerating the crate upwards.

5.25. **IDENTIFY:** At the maximum tilt angle, the patient is just ready to slide down, so static friction is at its maximum and the forces on the patient balance.

SET UP: Take $+x$ to be down the incline. At the maximum angle $f_s = \mu_s n$ and $\Sigma F_x = ma_x = 0$.

EXECUTE: The free-body diagram for the patient is given in Figure 5.25. $\Sigma F_y = ma_y$ gives $n = mg\cos\theta$.

$\Sigma F_x = 0$ gives $mg\sin\theta - \mu_s n = 0$. $mg\sin\theta - \mu_s mg\cos\theta = 0$. $\tan\theta = \mu_s$ so $\theta = 50°$.

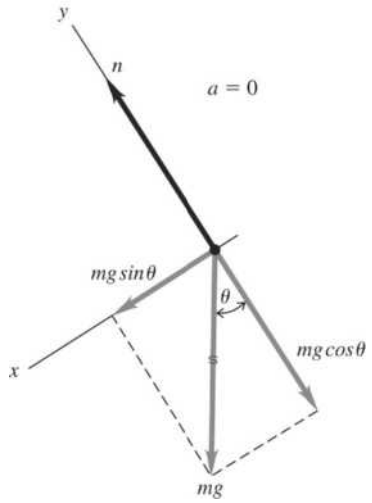

Figure 5.25

EVALUATE: A larger angle of tilt would cause more blood to flow to the brain, but it would also cause the patient to slide down the bed.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

5.26. **IDENTIFY:** $f_s \le \mu_s n$ and $f_k = \mu_k n$. The normal force n is determined by applying $\Sigma \vec{F} = m\vec{a}$ to the block. Normally, $\mu_k \le \mu_s$. f_s is only as large as it needs to be to prevent relative motion between the two surfaces.

SET UP: Since the table is horizontal, with only the block present $n = 135$ N. With the brick on the block, $n = 270$ N.

EXECUTE: **(a)** The friction is static for $P = 0$ to $P = 75.0$ N. The friction is kinetic for $P > 75.0$ N.

(b) The maximum value of f_s is $\mu_s n$. From the graph the maximum f_s is $f_s = 75.0$ N, so $\mu_s = \dfrac{\max f_s}{n} = \dfrac{75.0 \text{ N}}{135 \text{ N}} = 0.556$. $f_k = \mu_k n$. From the graph, $f_k = 50.0$ N and $\mu_k = \dfrac{f_k}{n} = \dfrac{50.0 \text{ N}}{135 \text{ N}} = 0.370$.

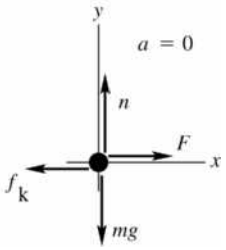
(c) When the block is moving the friction is kinetic and has the constant value $f_k = \mu_k n$, independent of P. This is why the graph is horizontal for $P > 75.0$ N. When the block is at rest, $f_s = P$ since this prevents relative motion. This is why the graph for $P < 75.0$ N has slope $+1$.

(d) max f_s and f_k would double. The values of f on the vertical axis would double but the shape of the graph would be unchanged.

EVALUATE: The coefficients of friction are independent of the normal force.

5.27. **(a) IDENTIFY:** Constant speed implies $a = 0$. Apply Newton's first law to the box. The friction force is directed opposite to the motion of the box.

SET UP: Consider the free-body diagram for the box, given in Figure 5.27a. Let $\vec{F}$ be the horizontal force applied by the worker. The friction is kinetic friction since the box is sliding along the surface.



EXECUTE:

$\Sigma F_y = ma_y$

$n - mg = 0$

$n = mg$

so $f_k = \mu_k n = \mu_k mg$

Figure 5.27a

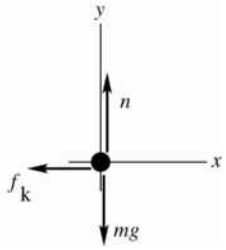
$\Sigma F_x = ma_x$

$F - f_k = 0$

$F = f_k = \mu_k mg = (0.20)(11.2 \text{ kg})(9.80 \text{ m/s}^2) = 22 \text{ N}$

(b) IDENTIFY: Now the only horizontal force on the box is the kinetic friction force. Apply Newton's second law to the box to calculate its acceleration. Once we have the acceleration, we can find the distance using a constant acceleration equation. The friction force is $f_k = \mu_k mg$, just as in part (a).

SET UP: The free-body diagram is sketched in Figure 5.27b.



EXECUTE:

$\Sigma F_x = ma_x$

$-f_k = ma_x$

$-\mu_k mg = ma_x$

$a_x = -\mu_k g = -(0.20)(9.80 \text{ m/s}^2) = -1.96 \text{ m/s}^2$

Figure 5.27b

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

Use the constant acceleration equations to find the distance the box travels:

$v_x = 0,\ \ v_{0x} = 3.50 \text{ m/s},\ \ a_x = -1.96 \text{ m/s}^2,\ \ x - x_0 = ?$

$v_x^2 = v_{0x}^2 + 2a_x(x - x_0)$

$$x - x_0 = \frac{v_x^2 - v_{0x}^2}{2a_x} = \frac{0 - (3.50 \text{ m/s})^2}{2(-1.96 \text{ m/s}^2)} = 3.1 \text{ m}$$

EVALUATE: The normal force is the component of force exerted by a surface perpendicular to the surface. Its magnitude is determined by $\Sigma\vec{F} = m\vec{a}$. In this case n and mg are the only vertical forces and $a_y = 0,$ so $n = mg$. Also note that f_k and n are proportional in magnitude but perpendicular in direction.

5.28. **IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$ to the box.

SET UP: Since the only vertical forces are n and w, the normal force on the box equals its weight. Static friction is as large as it needs to be to prevent relative motion between the box and the surface, up to its maximum possible value of $f_s^{\max} = \mu_s n$. If the box is sliding then the friction force is $f_k = \mu_k n$.

EXECUTE: **(a)** If there is no applied force, no friction force is needed to keep the box at rest.

(b) $f_s^{\max} = \mu_s n = (0.40)(40.0 \text{ N}) = 16.0 \text{ N}$. If a horizontal force of 6.0 N is applied to the box, then $f_s = 6.0 \text{ N}$ in the opposite direction.

(c) The monkey must apply a force equal to $f_s^{\max},$ 16.0 N.

(d) Once the box has started moving, a force equal to $f_k = \mu_k n = 8.0 \text{ N}$ is required to keep it moving at constant velocity.

(e) $f_k = 8.0 \text{ N}.\ \ a = (18.0 \text{ N} - 8.0 \text{ N})/(40.0 \text{ N}/9.80 \text{ m/s}^2) = 2.45 \text{ m/s}^2$

EVALUATE: $\mu_k < \mu_s$ and less force must be applied to the box to maintain its motion than to start it moving.

5.29. **IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$ to the crate. $f_s \le \mu_s n$ and $f_k = \mu_k n$.

SET UP: Let $+y$ be upward and let $+x$ be in the direction of the push. Since the floor is horizontal and the push is horizontal, the normal force equals the weight of the crate: $n = mg = 441 \text{ N}$. The force it takes to start the crate moving equals max f_s and the force required to keep it moving equals f_k.

EXECUTE: **(a)** $\max f_s = 313 \text{ N},$ so $\mu_s = \dfrac{313 \text{ N}}{441 \text{ N}} = 0.710.$ $f_k = 208 \text{ N},$ so $\mu_k = \dfrac{208 \text{ N}}{441 \text{ N}} = 0.472.$

(b) The friction is kinetic. $\Sigma F_x = ma_x$ gives $F - f_k = ma$ and

$F = f_k + ma = 208 \text{ N} + (45.0 \text{ kg})(1.10 \text{ m/s}^2) = 258 \text{ N}.$

(c) (i) The normal force now is $mg = 72.9 \text{ N}$. To cause it to move,

$F = \max f_s = \mu_s n = (0.710)(72.9 \text{ N}) = 51.8 \text{ N}.$

(ii) $F = f_k + ma$ and $a = \dfrac{F - f_k}{m} = \dfrac{258 \text{ N} - (0.472)(72.9 \text{ N})}{45.0 \text{ kg}} = 4.97 \text{ m/s}^2$

EVALUATE: The kinetic friction force is independent of the speed of the object. On the moon, the mass of the crate is the same as on earth, but the weight and normal force are less.

5.30. **IDENTIFY:** Newton's second law applies to the rocks on the hill. When they are moving, kinetic friction acts on them, but when they are at rest, static friction acts.

SET UP: Use coordinates with axes parallel and perpendicular to the incline, with $+x$ in the direction of the acceleration. $\Sigma F_x = ma_x$ and $\Sigma F_y = ma_y = 0.$

EXECUTE: With the rock sliding up the hill, the friction force is down the hill. The free-body diagram is given in Figure 5.30a.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

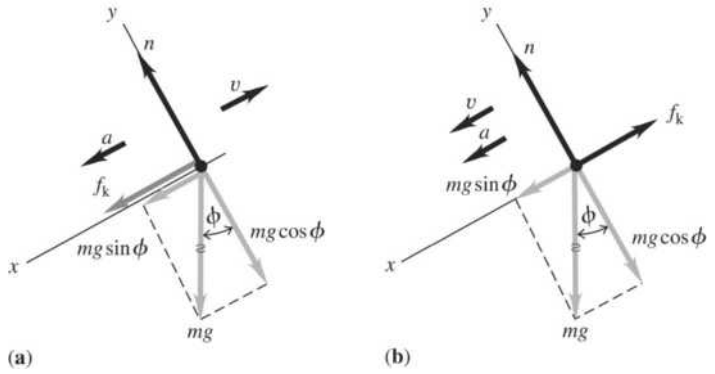


Figure 5.30

$\Sigma F_y = ma_y = 0$ gives $n = mg\cos\phi$ and $f_k = \mu_k n = \mu_k mg\cos\phi$. $\Sigma F_x = ma_x$ gives $mg\sin\phi + \mu_k mg\cos\phi = ma$.

$a = g(\sin\phi + \mu_k\cos\phi) = (9.80\ \text{m/s}^2)[\sin 36° + (0.45)\cos 36°]$. $a = 9.33\ \text{m/s}^2$, down the incline.

(b) The component of gravity down the incline is $mg\sin\phi = 0.588mg$. The maximum possible static friction force is $f_s = \mu_s n = \mu_s mg\cos\phi = 0.526mg$. f_s can't be as large as $mg\sin\phi$ and the rock slides back down. As the rock slides down, f_k is up the incline. The free-body diagram is given in Figure 5.30b.

$\Sigma F_y = ma_y = 0$ gives $n = mg\cos\phi$ and $f_k = \mu_k n = \mu_k mg\cos\phi$. $\Sigma F_x = ma_x$ gives

$mg\sin\phi - \mu_k mg\cos\phi = ma$, so $a = g(\sin\phi - \mu_k\cos\phi) = 2.19\ \text{m/s}^2$, down the incline.

EVALUATE: The acceleration down the incline in (a) is greater than that in (b) because in (a) the static friction and gravity are both acting down the incline, whereas in (b) friction is up the incline, opposing gravity which still acts down the incline.

5.31. **IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$ to the composite object consisting of the two boxes and to the top box. The friction the ramp exerts on the lower box is kinetic friction. The upper box doesn't slip relative to the lower box, so the friction between the two boxes is static. Since the speed is constant the acceleration is zero.

SET UP: Let $+x$ be up the incline. The free-body diagrams for the composite object and for the upper box are given in Figures 5.31a and b. The slope angle ϕ of the ramp is given by $\tan\phi = \dfrac{2.50\ \text{m}}{4.75\ \text{m}}$, so $\phi = 27.76°$. Since the boxes move down the ramp, the kinetic friction force exerted on the lower box by the ramp is directed up the incline. To prevent slipping relative to the lower box the static friction force on the upper box is directed up the incline. $m_{\text{tot}} = 32.0\ \text{kg} + 48.0\ \text{kg} = 80.0\ \text{kg}$.

EXECUTE: **(a)** $\Sigma F_y = ma_y$ applied to the composite object gives $n_{\text{tot}} = m_{\text{tot}}g\cos\phi$ and $f_k = \mu_k m_{\text{tot}}g\cos\phi$. $\Sigma F_x = ma_x$ gives $f_k + T - m_{\text{tot}}g\sin\phi = 0$ and

$T = (\sin\phi - \mu_k\cos\phi)m_{\text{tot}}g = (\sin 27.76° - [0.444]\cos 27.76°)(80.0\ \text{kg})(9.80\ \text{m/s}^2) = 57.1\ \text{N}$.

The person must apply a force of 57.1 N, directed up the ramp.

(b) $\Sigma F_x = ma_x$ applied to the upper box gives $f_s = mg\sin\phi = (32.0\ \text{kg})(9.80\ \text{m/s}^2)\sin 27.76° = 146\ \text{N}$, directed up the ramp.

EVALUATE: For each object the net force is zero.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

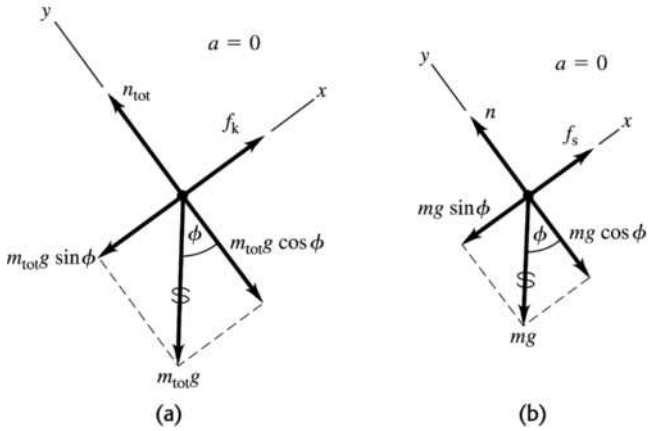

Figure 5.31

5.32. **IDENTIFY:** For the shortest time, the acceleration is a maximum, so the toolbox is just ready to slide relative to the bed of the truck. The box is at rest relative to the truck, but it is accelerating relative to the ground because the truck is accelerating. Therefore Newton's second law will be useful.
SET UP: If the truck accelerates to the right the static friction force on the box is to the right, to try to prevent the box from sliding relative to the truck. The free-body diagram for the box is given in Figure 5.32. The maximum acceleration of the box occurs when f_s has its maximum value, so $f_s = \mu_s n$. If the box doesn't slide, its acceleration equals the acceleration of the truck. The constant-acceleration equation $v_x = v_{0x} + a_x t$ applies.

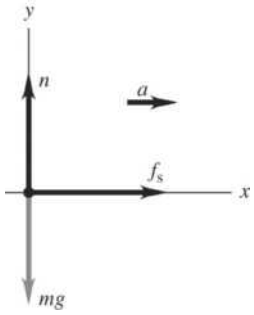

Figure 5.32

EXECUTE: $n = mg$. $\Sigma F_x = ma_x$ gives $f_s = ma$ so $\mu_s mg = ma$ and $a = \mu_s g = 6.37\ \text{m/s}^2$. $v_{0x} = 0$, $v_x = 30.0$ m/s. $v_x = v_{0x} + a_x t$ gives $t = \dfrac{v_x - v_{0x}}{a_x} = \dfrac{30.0\ \text{m/s} - 0}{6.37\ \text{m/s}^2} = 4.71\ \text{s}$

EVALUATE: If the truck has a smaller acceleration it is still true that $f_s = ma$, but now $f_s < \mu_s n$.

5.33. **IDENTIFY:** Use $\Sigma\vec{F} = m\vec{a}$ to find the acceleration that can be given to the car by the kinetic friction force. Then use a constant acceleration equation.
SET UP: Take $+x$ in the direction the car is moving.
EXECUTE: **(a)** The free-body diagram for the car is shown in Figure 5.33. $\Sigma F_y = ma_y$ gives $n = mg$. $\Sigma F_x = ma_x$ gives $-\mu_k n = ma_x$. $-\mu_k mg = ma_x$ and $a_x = -\mu_k g$. Then $v_x = 0$ and $v_x^2 = v_{0x}^2 + 2a_x(x - x_0)$ gives $(x - x_0) = -\dfrac{v_{0x}^2}{2a_x} = +\dfrac{v_{0x}^2}{2\mu_k g} = \dfrac{(28.7\ \text{m/s})^2}{2(0.80)(9.80\ \text{m/s}^2)} = 52.5\ \text{m}$.

(b) $v_{0x} = \sqrt{2\mu_k g(x - x_0)} = \sqrt{2(0.25)(9.80\ \text{m/s}^2)52.5\ \text{m}} = 16.0\ \text{m/s}$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: For constant stopping distance $\frac{v_{0x}^2}{\mu_k}$ is constant and v_{0x} is proportional to $\sqrt{\mu_k}$. The answer to part (b) can be calculated as $(28.7 \text{ m/s})\sqrt{0.25/0.80} = 16.0 \text{ m/s}$.

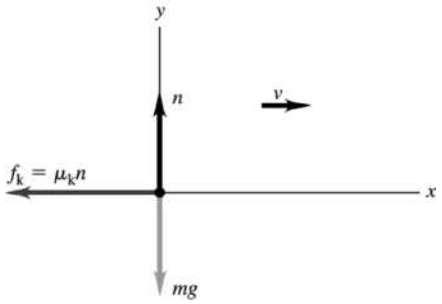

Figure 5.33

5.34. **IDENTIFY:** Constant speed means zero acceleration for each block. If the block is moving, the friction force the tabletop exerts on it is kinetic friction. Apply $\Sigma\vec{F} = m\vec{a}$ to each block.

SET UP: The free-body diagrams and choice of coordinates for each block are given by Figure 5.34. $m_A = 4.59$ kg and $m_B = 2.55$ kg.

EXECUTE: **(a)** $\Sigma F_y = ma_y$ with $a_y = 0$ applied to block B gives $m_B g - T = 0$ and $T = 25.0$ N. $\Sigma F_x = ma_x$ with $a_x = 0$ applied to block A gives $T - f_k = 0$ and $f_k = 25.0$ N. $n_A = m_A g = 45.0$ N and $\mu_k = \frac{f_k}{n_A} = \frac{25.0 \text{ N}}{45.0 \text{ N}} = 0.556$.

(b) Now let A be block A plus the cat, so $m_A = 9.18$ kg. $n_A = 90.0$ N and $f_k = \mu_k n = (0.556)(90.0 \text{ N}) = 50.0$ N. $\sum F_x = ma_x$ for A gives $T - f_k = m_A a_x$. $\sum Fy = ma_y$ for block B gives $m_B g - T = m_B a_y$. a_x for A equals a_y for B, so adding the two equations gives $m_B g - f_k = (m_A + m_B)a_y$ and $a_y = \frac{m_B g - f_k}{m_A + m_B} = \frac{25.0 \text{ N} - 50.0 \text{ N}}{9.18 \text{ kg} + 2.55 \text{ kg}} = -2.13 \text{ m/s}^2$. The acceleration is upward and block B slows down.

EVALUATE: The equation $m_B g - f_k = (m_A + m_B)a_y$ has a simple interpretation. If both blocks are considered together then there are two external forces: $m_B g$ that acts to move the system one way and f_k that acts oppositely. The net force of $m_B g - f_k$ must accelerate a total mass of $m_A + m_B$.

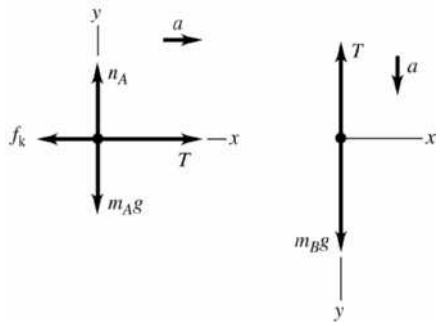

Figure 5.34

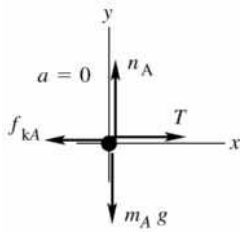
5.35. **IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$ to each crate. The rope exerts force T to the right on crate A and force T to the left on crate B. The target variables are the forces T and F. Constant v implies $a = 0$.

SET UP: The free-body diagram for A is sketched in Figure 5.35a

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.



EXECUTE:

$\Sigma F_y = ma_y$

$n_A - m_A g = 0$

$n_A = m_A g$

$f_{kA} = \mu_k n_A = \mu_k m_A g$

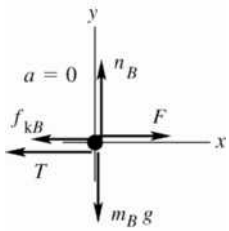
Figure 5.35a

$\Sigma F_x = ma_x$

$T - f_{kA} = 0$

$T = \mu_k m_A g$

SET UP: The free-body diagram for *B* is sketched in Figure 5.35b.



EXECUTE:

$\Sigma F_y = ma_y$

$n_B - m_B g = 0$

$n_B = m_B g$

$f_{kB} = \mu_k n_B = \mu_k m_B g$

Figure 5.35b

$\Sigma F_x = ma_x$

$F - T - f_{kB} = 0$

$F = T + \mu_k m_B g$

Use the first equation to replace T in the second:

$F = \mu_k m_A g + \mu_k m_B g.$

(a) $F = \mu_k (m_A + m_B) g$

(b) $T = \mu_k m_A g$

EVALUATE: We can also consider both crates together as a single object of mass $(m_A + m_B)$. $\Sigma F_x = ma_x$ for this combined object gives $F = f_k = \mu_k (m_A + m_B) g,$ in agreement with our answer in part (a).

5.36. **IDENTIFY:** Apply $\Sigma \vec{F} = m\vec{a}$ to the box. When the box is ready to slip the static friction force has its maximum possible value, $f_s = \mu_s n.$

SET UP: Use coordinates parallel and perpendicular to the ramp.

EXECUTE: **(a)** The normal force will be $w\cos\alpha$ and the component of the gravitational force along the ramp is $w\sin\alpha.$ The box begins to slip when $w\sin\alpha > \mu_s w\cos\alpha,$ or $\tan\alpha > \mu_s = 0.35,$ so slipping occurs at $\alpha = \arctan(0.35) = 19.3°.$

(b) When moving, the friction force along the ramp is $\mu_k w\cos\alpha,$ the component of the gravitational force along the ramp is $w\sin\alpha,$ so the acceleration is

$$(w\sin\alpha - w\mu_k\cos\alpha)/m = g(\sin\alpha - \mu_k\cos\alpha) = 0.92 \text{ m/s}^2.$$

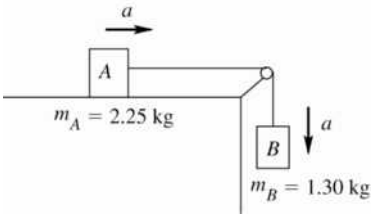
(c) Since $v_{0x} = 0,$ $2ax = v^2,$ so $v = (2ax)^{1/2},$ or $v = [(2)(0.92\text{m/s}^2)(5\text{ m})]^{1/2} = 3$ m/s.

EVALUATE: When the box starts to move, friction changes from static to kinetic and the friction force becomes smaller.

5.37. **IDENTIFY:** Apply $\Sigma \vec{F} = m\vec{a}$ to each block. The target variables are the tension T in the cord and the acceleration a of the blocks. Then a can be used in a constant acceleration equation to find the speed of each block. The magnitude of the acceleration is the same for both blocks.

SET UP: The system is sketched in Figure 5.37a.

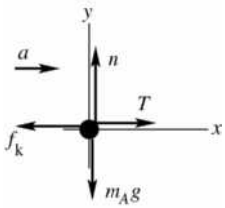
© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.



For each block take a positive coordinate direction to be the direction of the block's acceleration.

Figure 5.37a

block on the table: The free-body is sketched in Figure 5.37b.



EXECUTE:

$\Sigma F_y = ma_y$

$n - m_A g = 0$

$n = m_A g$

$f_k = \mu_k n = \mu_k m_A g$

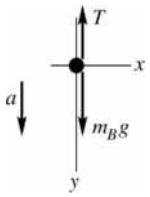
Figure 5.37b

$\Sigma F_x = ma_x$

$T - f_k = m_A a$

$T - \mu_k m_A g = m_A a$

SET UP: hanging block: The free-body is sketched in Figure 5.37c.



EXECUTE:

$\Sigma F_y = ma_y$

$m_B g - T = m_B a$

$T = m_B g - m_B a$

Figure 5.37c

(a) Use the second equation in the first

$$m_B g - m_B a - \mu_k m_A g = m_A a$$

$$(m_A + m_B)a = (m_B - \mu_k m_A)g$$

$$a = \frac{(m_B - \mu_k m_A)g}{m_A + m_B} = \frac{(1.30\text{ kg} - (0.45)(2.25\text{ kg}))(9.80\text{ m/s}^2)}{2.25\text{ kg} + 1.30\text{ kg}} = 0.7937\text{ m/s}^2$$

SET UP: Now use the constant acceleration equations to find the final speed. Note that the blocks have the same speeds. $x - x_0 = 0.0300$ m, $a_x = 0.7937$ m/s^2, $v_{0x} = 0$, $v_x = ?$

$v_x^2 = v_{0x}^2 + 2a_x(x - x_0)$

EXECUTE: $v_x = \sqrt{2a_x(x - x_0)} = \sqrt{2(0.7937\text{ m/s}^2)(0.0300\text{ m})} = 0.218\text{ m/s} = 21.8\text{ cm/s}.$

(b) $T = m_B g - m_B a = m_B(g - a) = 1.30\text{ kg}(9.80\text{ m/s}^2 - 0.7937\text{ m/s}^2) = 11.7\text{ N}$

Or, to check, $T - \mu_k m_A g = m_A a$.

$T = m_A(a + \mu_k g) = 2.25\text{ kg}(0.7937\text{ m/s}^2 + (0.45)(9.80\text{ m/s}^2)) = 11.7\text{ N},$ which checks.

EVALUATE: The force T exerted by the cord has the same value for each block. $T < m_B g$ since the hanging block accelerates downward. Also, $f_k = \mu_k m_A g = 9.92$ N. $T > f_k$ and the block on the table accelerates in the direction of T.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

5.38. **IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$ to the box.

SET UP: Let $+y$ be upward and $+x$ be horizontal, in the direction of the acceleration. Constant speed means $a = 0$.

EXECUTE: **(a)** There is no net force in the vertical direction, so $n + F\sin\theta - w = 0$, or $n = w - F\sin\theta = mg - F\sin\theta$. The friction force is $f_k = \mu_k n = \mu_k(mg - F\sin\theta)$. The net horizontal force is $F\cos\theta - f_k = F\cos\theta - \mu_k(mg - F\sin\theta)$, and so at constant speed,

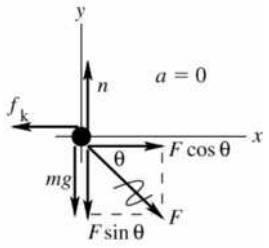
$$F = \frac{\mu_k mg}{\cos\theta + \mu_k \sin\theta}$$

(b) Using the given values, $F = \dfrac{(0.35)(90\text{ kg})(9.80\text{m/s}^2)}{(\cos 25° + (0.35)\sin 25°)} = 290$ N.

EVALUATE: If $\theta = 0°$, $F = \mu_k mg$.

5.39. **(a) IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$ to the crate. Constant v implies $a = 0$. Crate moving says that the friction is kinetic friction. The target variable is the magnitude of the force applied by the woman.

SET UP: The free-body diagram for the crate is sketched in Figure 5.39.



EXECUTE:

$\Sigma F_y = ma_y$

$n - mg - F\sin\theta = 0$

$n = mg + F\sin\theta$

$f_k = \mu_k n = \mu_k mg + \mu_k F\sin\theta$

Figure 5.39

$\Sigma F_x = ma_x$

$F\cos\theta - f_k = 0$

$F\cos\theta - \mu_k mg - \mu_k F\sin\theta = 0$

$F(\cos\theta - \mu_k\sin\theta) = \mu_k mg$

$$F = \frac{\mu_k mg}{\cos\theta - \mu_k\sin\theta}$$

(b) IDENTIFY and **SET UP:** "start the crate moving" means the same force diagram as in part (a), except that μ_k is replaced by μ_s. Thus $F = \dfrac{\mu_s mg}{\cos\theta - \mu_s\sin\theta}$.

EXECUTE: $F \to \infty$ if $\cos\theta - \mu_s\sin\theta = 0$. This gives $\mu_s = \dfrac{\cos\theta}{\sin\theta} = \dfrac{1}{\tan\theta}$.

EVALUATE: $\vec{F}$ has a downward component so $n > mg$. If $\theta = 0$ (woman pushes horizontally), $n = mg$ and $F = f_k = \mu_k mg$.

5.40. **IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$ to the ball. At the terminal speed, $f = mg$.

SET UP: The fluid resistance is directed opposite to the velocity of the object. At half the terminal speed, the magnitude of the frictional force is one-fourth the weight.

EXECUTE: **(a)** If the ball is moving up, the frictional force is down, so the magnitude of the net force is $(5/4)w$ and the acceleration is $(5/4)g$, down.

(b) While moving down, the frictional force is up, and the magnitude of the net force is $(3/4)w$ and the acceleration is $(3/4)g$, down.

EVALUATE: The frictional force is less than mg in each case and in each case the net force is downward and the acceleration is downward.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

5.41. **IDENTIFY** and **SET UP:** Apply Eq. (5.13).

EXECUTE: **(a)** Solving for D in terms of v_t, $D = \dfrac{mg}{v_t^2} = \dfrac{(80\text{ kg})(9.80\text{ m/s}^2)}{(42\text{ m/s})^2} = 0.44\text{ kg/m}$.

(b) $v_t = \sqrt{\dfrac{mg}{D}} = \sqrt{\dfrac{(45\text{ kg})(9.80\text{ m/s}^2)}{(0.25\text{ kg/m})}} = 42\text{ m/s}$.

EVALUATE: "Terminal speed depends on the mass of the falling object."

5.42. **IDENTIFY:** The acceleration of the car at the top and bottom is toward the center of the circle, and Newton's second law applies to it.

SET UP: Two forces are acting on the car, gravity and the normal force. At point B (the top), both forces are toward the center of the circle, so Newton's second law gives $mg + n_B = ma$. At point A (the bottom), gravity is downward but the normal force is upward, so $n_A - mg = ma$.

EXECUTE: Solving the equation at B for the acceleration gives $a = \dfrac{mg + n_B}{m} = \dfrac{(0.800\text{ kg})(9.8\text{ m/s}^2) + 6.00\text{ N}}{0.800\text{ kg}} = 17.3\text{ m/s}^2$. Solving the equation at A for the normal force gives $n_A = m(g + a) = (0.800\text{ kg})(9.8\text{ m/s}^2 + 17.3\text{ m/s}^2) = 21.7\text{ N}$.

EVALUATE: The normal force at the bottom is greater than at the top because it must balance the weight in addition to accelerate the car toward the center of its track.

5.43. **IDENTIFY:** Apply $\Sigma\vec{\boldsymbol{F}} = m\vec{\boldsymbol{a}}$ to one of the masses. The mass moves in a circular path, so has acceleration $a_{\text{rad}} = \dfrac{v^2}{R}$, directed toward the center of the path.

SET UP: In each case, $R = 0.200$ m. In part (a), let $+x$ be toward the center of the circle, so $a_x = a_{\text{rad}}$. In part (b) let $+y$ be toward the center of the circle, so $a_y = a_{\text{rad}}$. $+y$ is downward when the mass is at the top of the circle and $+y$ is upward when the mass is at the bottom of the circle. Since a_{rad} has its greatest possible value, $\vec{\boldsymbol{F}}$ is in the direction of $\vec{\boldsymbol{a}}_{\text{rad}}$ at both positions.

EXECUTE: **(a)** $\Sigma F_x = ma_x$ gives $F = ma_{\text{rad}} = m\dfrac{v^2}{R}$. $F = 75.0$ N and $v = \sqrt{\dfrac{FR}{m}} = \sqrt{\dfrac{(75.0\text{ N})(0.200\text{ m})}{1.15\text{ kg}}} = 3.61\text{ m/s}$.

(b) The free-body diagrams for a mass at the top of the path and at the bottom of the path are given in Figure 5.43. At the top, $\Sigma F_y = ma_y$ gives $F = ma_{\text{rad}} - mg$ and at the bottom it gives $F = mg + ma_{\text{rad}}$. For a given rotation rate and hence value of a_{rad}, the value of F required is larger at the bottom of the path.

(c) $F = mg + ma_{\text{rad}}$ so $\dfrac{v^2}{R} = \dfrac{F}{m} - g$ and

$$v = \sqrt{R\left(\frac{F}{m} - g\right)} = \sqrt{(0.200\text{ m})\left(\frac{75.0\text{ N}}{1.15\text{ kg}} - 9.80\text{ m/s}^2\right)} = 3.33\text{ m/s}$$

EVALUATE: The maximum speed is less for the vertical circle. At the bottom of the vertical path $\vec{\boldsymbol{F}}$ and the weight are in opposite directions so F must exceed ma_{rad} by an amount equal to mg. At the top of the vertical path F and mg are in the same direction and together provide the required net force, so F must be larger at the bottom.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

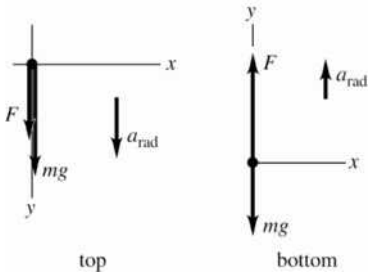


Figure 5.43

5.44. **IDENTIFY:** Since the car travels in an arc of a circle, it has acceleration $a_{rad} = v^2/R$, directed toward the center of the arc. The only horizontal force on the car is the static friction force exerted by the roadway. To calculate the minimum coefficient of friction that is required, set the static friction force equal to its maximum value, $f_s = \mu_s n$. Friction is static friction because the car is not sliding in the radial direction.

SET UP: The free-body diagram for the car is given in Figure 5.44. The diagram assumes the center of the curve is to the left of the car.

EXECUTE: **(a)** $\Sigma F_y = ma_y$ gives $n = mg$. $\Sigma F_x = ma_x$ gives $\mu_s n = m\dfrac{v^2}{R}$. $\mu_s mg = m\dfrac{v^2}{R}$ and

$$\mu_s = \frac{v^2}{gR} = \frac{(25.0 \text{ m/s})^2}{(9.80 \text{ m/s}^2)(220 \text{ m})} = 0.290$$

(b) $\dfrac{v^2}{\mu_s} = Rg = \text{constant}$, so $\dfrac{v_1^2}{\mu_{s1}} = \dfrac{v_2^2}{\mu_{s2}}$. $v_2 = v_1\sqrt{\dfrac{\mu_{s2}}{\mu_{s1}}} = (25.0 \text{ m/s})\sqrt{\dfrac{\mu_{s1}/3}{\mu_{s1}}} = 14.4 \text{ m/s}.$

EVALUATE: A smaller coefficient of friction means a smaller maximum friction force, a smaller possible acceleration and therefore a smaller speed.

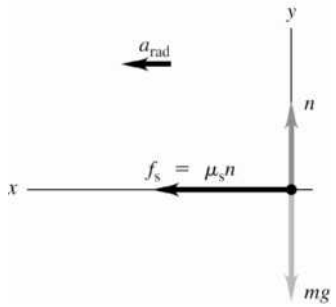

Figure 5.44

5.45. **IDENTIFY:** We can use the analysis done in Example 5.22. As in that example, we assume friction is negligible.

SET UP: From Example 5.22, the banking angle β is given by $\tan\beta = \dfrac{v^2}{gR}$. Also, $n = mg/\cos\beta$.

65.0 mi/h = 29.1 m/s.

EXECUTE: **(a)** $\tan\beta = \dfrac{(29.1 \text{ m/s})^2}{(9.80 \text{ m/s}^2)(225 \text{ m})}$ and $\beta = 21.0°$. The expression for $\tan\beta$ does not involve the mass of the vehicle, so the truck and car should travel at the same speed.

(b) For the car, $n_{car} = \dfrac{(1125 \text{ kg})(9.80 \text{ m/s}^2)}{\cos 21.0°} = 1.18\times10^4$ N and $n_{truck} = 2n_{car} = 2.36\times10^4$ N, since $m_{truck} = 2m_{car}$.

EVALUATE: The vertical component of the normal force must equal the weight of the vehicle, so the normal force is proportional to *m*.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

5.46. **IDENTIFY:** The acceleration of the person is $a_{\text{rad}} = v^2/R$, directed horizontally to the left in the figure in the problem. The time for one revolution is the period $T = \dfrac{2\pi R}{v}$. Apply $\Sigma\vec{F} = m\vec{a}$ to the person.

SET UP: The person moves in a circle of radius $R = 3.00\text{ m} + (5.00\text{ m})\sin 30.0° = 5.50\text{ m}$. The free-body diagram is given in Figure 5.46. $\vec{F}$ is the force applied to the seat by the rod.

EXECUTE: **(a)** $\Sigma F_y = ma_y$ gives $F\cos 30.0° = mg$ and $F = \dfrac{mg}{\cos 30.0°}$. $\Sigma F_x = ma_x$ gives $F\sin 30.0° = m\dfrac{v^2}{R}$. Combining these two equations gives $v = \sqrt{Rg\tan\theta} = \sqrt{(5.50\text{ m})(9.80\text{ m/s}^2)\tan 30.0°} = 5.58\text{ m/s}$. Then the period is $T = \dfrac{2\pi R}{v} = \dfrac{2\pi(5.50\text{ m})}{5.58\text{ m/s}} = 6.19\text{ s}$.

(b) The net force is proportional to m so in $\Sigma\vec{F} = m\vec{a}$ the mass divides out and the angle for a given rate of rotation is independent of the mass of the passengers.

EVALUATE: The person moves in a horizontal circle so the acceleration is horizontal. The net inward force required for circular motion is produced by a component of the force exerted on the seat by the rod.

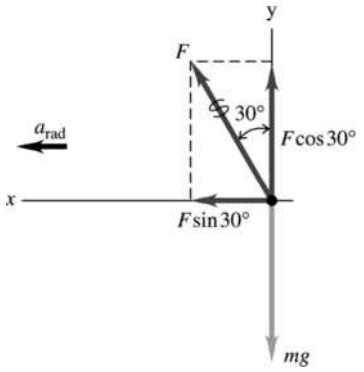

Figure 5.46

5.47. **IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$ to the composite object of the person plus seat. This object moves in a horizontal circle and has acceleration a_{rad}, directed toward the center of the circle.

SET UP: The free-body diagram for the composite object is given in Figure 5.47. Let $+x$ be to the right, in the direction of $\vec{a}_{\text{rad}}$. Let $+y$ be upward. The radius of the circular path is $R = 7.50$ m. The total mass is $(255\text{ N} + 825\text{ N})/(9.80\text{ m/s}^2) = 110.2\text{ kg}$. Since the rotation rate is $32.0\text{ rev/min} = 0.5333\text{ rev/s}$, the period T is $\dfrac{1}{0.5333\text{ rev/s}} = 1.875\text{ s}$.

EXECUTE: $\Sigma F_y = ma_y$ gives $T_A\cos 40.0° - mg = 0$ and $T_A = \dfrac{mg}{\cos 40.0°} = \dfrac{255\text{ N} + 825\text{ N}}{\cos 40.0°} = 1410\text{ N}$.

$\Sigma F_x = ma_x$ gives $T_A\sin 40.0° + T_B = ma_{\text{rad}}$ and

$$T_B = m\frac{4\pi^2 R}{T^2} - T_A\sin 40.0° = (110.2\text{ kg})\frac{4\pi^2(7.50\text{ m})}{(1.875\text{ s})^2} - (1410\text{ N})\sin 40.0° = 8370\text{ N}$$

The tension in the horizontal cable is 8370 N and the tension in the other cable is 1410 N.

EVALUATE: The weight of the composite object is 1080 N. The tension in cable A is larger than this since its vertical component must equal the weight. $ma_{\text{rad}} = 9280$ N. The tension in cable B is less than this because part of the required inward force comes from a component of the tension in cable A.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

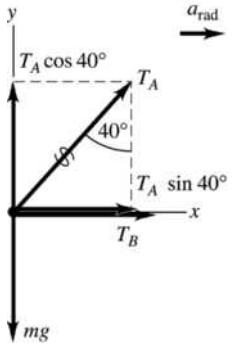

Figure 5.47

5.48. **IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$ to the button. The button moves in a circle, so it has acceleration a_{rad}.

SET UP: The situation is equivalent to that of Example 5.21.

EXECUTE: **(a)** $\mu_s = \dfrac{v^2}{Rg}$. Expressing v in terms of the period T, $v = \dfrac{2\pi R}{T}$ so $\mu_s = \dfrac{4\pi^2 R}{T^2 g}$. A platform speed of 40.0 rev/min corresponds to a period of 1.50 s, so $\mu_s = \dfrac{4\pi^2(0.150\text{ m})}{(1.50\text{ s})^2(9.80\text{ m/s}^2)} = 0.269$.

(b) For the same coefficient of static friction, the maximum radius is proportional to the square of the period (longer periods mean slower speeds, so the button may be moved farther out) and so is inversely proportional to the square of the speed. Thus, at the higher speed, the maximum radius is

$(0.150\text{ m})\left(\dfrac{40.0}{60.0}\right)^2 = 0.067\text{ m}$.

EVALUATE: $a_{rad} = \dfrac{4\pi^2 R}{T^2}$. The maximum radial acceleration that friction can give is $\mu_s mg$. At the faster rotation rate T is smaller so R must be smaller to keep a_{rad} the same.

5.49. **IDENTIFY:** The acceleration due to circular motion is $a_{rad} = \dfrac{4\pi^2 R}{T^2}$.

SET UP: $R = 400$ m. $1/T$ is the number of revolutions per second.

EXECUTE: **(a)** Setting $a_{rad} = g$ and solving for the period T gives

$$T = 2\pi\sqrt{\frac{R}{g}} = 2\pi\sqrt{\frac{400\text{ m}}{9.80\text{ m/s}^2}} = 40.1\text{ s},$$

so the number of revolutions per minute is $(60\text{ s/min})/(40.1\text{ s}) = 1.5$ rev/min.

(b) The lower acceleration corresponds to a longer period, and hence a lower rotation rate, by a factor of the square root of the ratio of the accelerations, $T' = (1.5\text{ rev/min}) \times \sqrt{3.70/9.8} = 0.92$ rev/min.

EVALUATE: In part (a) the tangential speed of a point at the rim is given by $a_{rad} = \dfrac{v^2}{R}$, so $v = \sqrt{Ra_{rad}} = \sqrt{Rg} = 62.6$ m/s; the space station is rotating rapidly.

5.50. **IDENTIFY:** $T = \dfrac{2\pi R}{v}$. The apparent weight of a person is the normal force exerted on him by the seat he is sitting on. His acceleration is $a_{rad} = v^2/R$, directed toward the center of the circle.

SET UP: The period is $T = 60.0$ s. The passenger has mass $m = w/g = 90.0$ kg.

EXECUTE: **(a)** $v = \dfrac{2\pi R}{T} = \dfrac{2\pi(50.0\text{ m})}{60.0\text{ s}} = 5.24$ m/s. Note that $a_{rad} = \dfrac{v^2}{R} = \dfrac{(5.24\text{ m/s})^2}{50.0\text{ m}} = 0.549\text{ m/s}^2$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) The free-body diagram for the person at the top of his path is given in Figure 5.50a. The acceleration is downward, so take $+y$ downward. $\Sigma F_y = ma_y$ gives $mg - n = ma_{\text{rad}}$.

$n = m(g - a_{\text{rad}}) = (90.0 \text{ kg})(9.80 \text{ m/s}^2 - 0.549 \text{ m/s}^2) = 833 \text{ N}.$

The free-body diagram for the person at the bottom of his path is given in Figure 5.50b. The acceleration is upward, so take $+y$ upward. $\Sigma F_y = ma_y$ gives $n - mg = ma_{\text{rad}}$ and $n = m(g + a_{\text{rad}}) = 931 \text{ N}$.

(c) Apparent weight $= 0$ means $n = 0$ and $mg = ma_{\text{rad}}$. $g = \dfrac{v^2}{R}$ and $v = \sqrt{gR} = 22.1$ m/s. The time for one revolution would be $T = \dfrac{2\pi R}{v} = \dfrac{2\pi(50.0 \text{ m})}{22.1 \text{ m/s}} = 14.2$ s. Note that $a_{\text{rad}} = g$.

(d) $n = m(g + a_{\text{rad}}) = 2mg = 2(882 \text{ N}) = 1760 \text{ N}$, twice his true weight.

EVALUATE: At the top of his path his apparent weight is less than his true weight and at the bottom of his path his apparent weight is greater than his true weight.

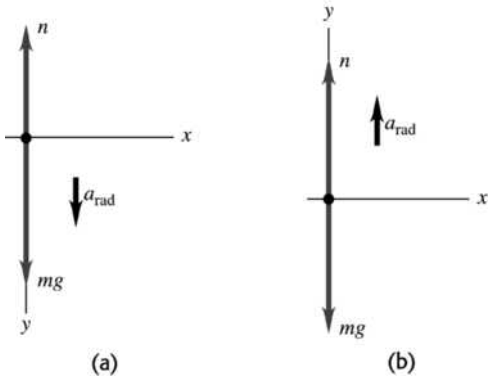

Figure 5.50a, b

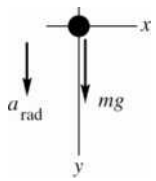
5.51. **IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$ to the motion of the pilot. The pilot moves in a vertical circle. The apparent weight is the normal force exerted on him. At each point $\vec{a}_{\text{rad}}$ is directed toward the center of the circular path.

(a) SET UP: "the pilot feels weightless" means that the vertical normal force n exerted on the pilot by the chair on which the pilot sits is zero. The force diagram for the pilot at the top of the path is given in Figure 5.51a.



EXECUTE:

$\Sigma F_y = ma_y$

$mg = ma_{\text{rad}}$

$g = \dfrac{v^2}{R}$

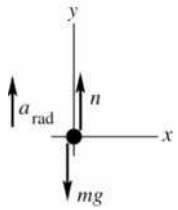
Figure 5.51a

Thus $v = \sqrt{gR} = \sqrt{(9.80 \text{ m/s}^2)(150 \text{ m})} = 38.34$ m/s

$$v = (38.34 \text{ m/s})\left(\frac{1 \text{ km}}{10^3 \text{ m}}\right)\left(\frac{3600 \text{ s}}{1 \text{ h}}\right) = 138 \text{ km/h}$$

(b) Set Up: The force diagram for the pilot at the bottom of the path is given in Figure 5.51b. Note that the vertical normal force exerted on the pilot by the chair on which the pilot sits is now upward.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.



EXECUTE:

$\Sigma F_y = ma_y$

$n - mg = m\dfrac{v^2}{R}$

$n = mg + m\dfrac{v^2}{R}$

This normal force is the pilot's apparent weight.

Figure 5.51b

$w = 700$ N, so $m = \dfrac{w}{g} = 71.43$ kg

$v = (280 \text{ km/h})\left(\dfrac{1 \text{ h}}{3600 \text{ s}}\right)\left(\dfrac{10^3 \text{ m}}{1 \text{ km}}\right) = 77.78$ m/s

Thus $n = 700 \text{ N} + 71.43 \text{ kg}\dfrac{(77.78 \text{ m/s})^2}{150 \text{ m}} = 3580$ N.

EVALUATE: In part (b), $n > mg$ since the acceleration is upward. The pilot feels he is much heavier than when at rest. The speed is not constant, but it is still true that $a_{\text{rad}} = v^2/R$ at each point of the motion.

5.52. **IDENTIFY:** $a_{\text{rad}} = v^2/R$, directed toward the center of the circular path. At the bottom of the dive, $\vec{a}_{\text{rad}}$ is upward. The apparent weight of the pilot is the normal force exerted on her by the seat on which she is sitting.

SET UP: The free-body diagram for the pilot is given in Figure 5.52.

EXECUTE: **(a)** $a_{\text{rad}} = \dfrac{v^2}{R}$ gives $R = \dfrac{v^2}{a_{\text{rad}}} = \dfrac{(95.0 \text{ m/s})^2}{4.00(9.80 \text{ m/s}^2)} = 230$ m.

(b) $\Sigma F_y = ma_y$ gives $n - mg = ma_{\text{rad}}$.

$n = m(g + a_{\text{rad}}) = m(g + 4.00g) = 5.00mg = (5.00)(50.0 \text{ kg})(9.80 \text{ m/s}^2) = 2450$ N

EVALUATE: Her apparent weight is five times her true weight, the force of gravity the earth exerts on her.

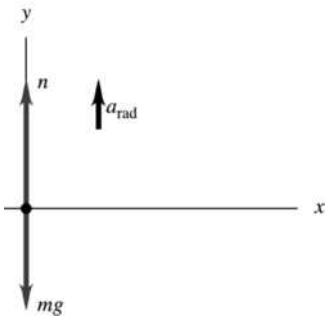


Figure 5.52

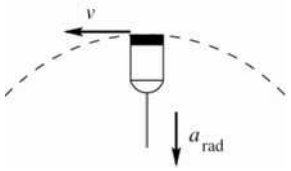
5.53. **IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$ to the water. The water moves in a vertical circle. The target variable is the speed v; we will calculate a_{rad} and then get v from $a_{\text{rad}} = v^2/R$.

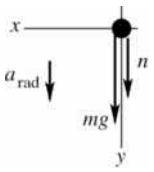
SET UP: Consider the free-body diagram for the water when the pail is at the top of its circular path, as shown in Figures 5.53a and b.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.



The radial acceleration is in toward the center of the circle so at this point is downward. *n* is the downward normal force exerted on the water by the bottom of the pail.

Figure 5.53a



EXECUTE:
$\Sigma F_y = ma_y$

$n + mg = m\dfrac{v^2}{R}$

Figure 5.53b

At the minimum speed the water is just ready to lose contact with the bottom of the pail, so at this speed, $n \to 0$. (Note that the force *n* cannot be upward.)

With $n \to 0$ the equation becomes $mg = m\dfrac{v^2}{R}$. $v = \sqrt{gR} = \sqrt{(9.80\ \text{m/s}^2)(0.600\ \text{m})} = 2.42$ m/s.

EVALUATE: At the minimum speed $a_{rad} = g$. If *v* is less than this minimum speed, gravity pulls the water (and bucket) out of the circular path.

5.54. **IDENTIFY:** The ball has acceleration $a_{rad} = v^2/R$, directed toward the center of the circular path. When the ball is at the bottom of the swing, its acceleration is upward.

SET UP: Take $+y$ upward, in the direction of the acceleration. The bowling ball has mass $m = w/g = 7.27$ kg.

EXECUTE: **(a)** $a_{rad} = \dfrac{v^2}{R} = \dfrac{(4.20\ \text{m/s})^2}{3.80\ \text{m}} = 4.64$ m/s, upward.

(b) The free-body diagram is given in Figure 5.54. $\Sigma F_y = ma_y$ gives $T - mg = ma_{rad}$.

$T = m(g + a_{rad}) = (7.27\ \text{kg})(9.80\ \text{m/s}^2 + 4.64\ \text{m/s}^2) = 105$ N

EVALUATE: The acceleration is upward, so the net force is upward and the tension is greater than the weight.

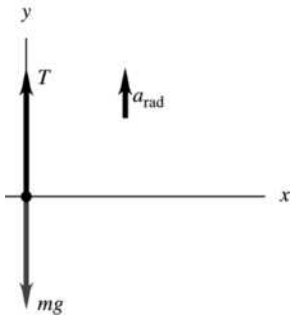


Figure 5.54

5.55. **IDENTIFY:** Since the arm is swinging in a circle, objects in it are accelerated toward the center of the circle, and Newton's second law applies to them.

SET UP: $R = 0.700$ m. A 45° angle is $\frac{1}{8}$ of a full rotation, so in $\frac{1}{2}$ s a hand travels through a distance of $\frac{1}{8}(2\pi R)$. In (c) use coordinates where $+y$ is upward, in the direction of $\vec{a}_{rad}$ at the bottom of the swing.

The acceleration is $a_{rad} = \dfrac{v^2}{R}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: **(a)** $v = \frac{1}{8}\left(\frac{2\pi R}{0.50\text{ s}}\right) = 1.10\text{ m/s}$ and $a_{\text{rad}} = \frac{v^2}{R} = \frac{(1.10\text{ m/s})^2}{0.700\text{ m}} = 1.73\text{ m/s}^2$.

(b) The free-body diagram is shown in Figure 5.55. F is the force exerted by the blood vessel.

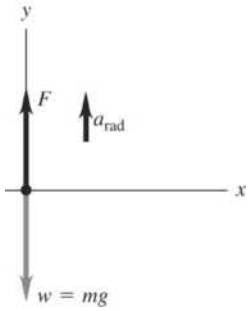

Figure 5.55

(c) $\Sigma F_y = ma_y$ gives $F - w = ma_{\text{rad}}$ and

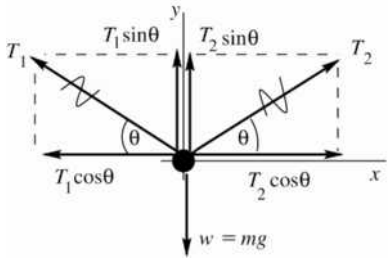
$F = m(g + a_{\text{rad}}) = (1.00\times10^{-3}\text{ kg})(9.80\text{ m/s}^2 + 1.73\text{ m/s}^2) = 1.15\times10^{-2}\text{ N}$, upward.

(d) When the arm hangs vertically and is at rest, $a_{\text{rad}} = 0$ so $F = w = mg = 9.8\times10^{-3}\text{ N}$.

EVALUATE: The acceleration of the hand is only about 20% of g, so the increase in the force on the blood drop when the arm swings is about 20%.

5.56. **IDENTIFY:** Apply Newton's first law to the person. Each half of the rope exerts a force on him, directed along the rope and equal to the tension T in the rope.

SET UP: **(a)** The force diagram for the person is given in Figure 5.56.



T_1 and T_2 are the tensions in each half of the rope.

Figure 5.56

EXECUTE: $\Sigma F_x = 0$

$T_2\cos\theta - T_1\cos\theta = 0$

This says that $T_1 = T_2 = T$ (The tension is the same on both sides of the person.)

$\Sigma F_y = 0$

$T_1\sin\theta + T_2\sin\theta - mg = 0$

But $T_1 = T_2 = T$, so $2T\sin\theta = mg$

$$T = \frac{mg}{2\sin\theta} = \frac{(90.0\text{ kg})(9.80\text{ m/s}^2)}{2\sin10.0^\circ} = 2540\text{ N}$$

(b) The relation $2T\sin\theta = mg$ still applies but now we are given that $T = 2.50\times10^4$ N (the breaking strength) and are asked to find θ.

$$\sin\theta = \frac{mg}{2T} = \frac{(90.0\text{ kg})(9.80\text{ m/s}^2)}{2(2.50\times10^4\text{ N})} = 0.01764,\quad \theta = 1.01^\circ.$$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: $T = mg/(2\sin\theta)$ says that $T = mg/2$ when $\theta = 90°$ (rope is vertical).
$T \to \infty$ when $\theta \to 0$ since the upward component of the tension becomes a smaller fraction of the tension.

5.57. **IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$ to the knot.
SET UP: $a = 0$. Use coordinates with axes that are horizontal and vertical.
EXECUTE: **(a)** The free-body diagram for the knot is sketched in Figure 5.57.
T_1 is more vertical so supports more of the weight and is larger. You can also see this from $\Sigma F_x = ma_x$:
$T_2\cos 40° - T_1\cos 60° = 0$. $T_2\cos 40° - T_1\cos 60° = 0$.
(b) T_1 is larger so set $T_1 = 5000$ N. Then $T_2 = T_1/1.532 = 3263.5$ N. $\Sigma F_y = ma_y$ gives
$T_1\sin 60° + T_2\sin 40° = w$ and $w = 6400$ N.
EVALUATE: The sum of the vertical components of the two tensions equals the weight of the suspended object. The sum of the tensions is greater than the weight.

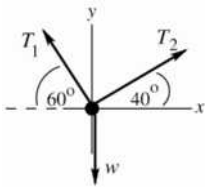


Figure 5.57

5.58. **IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$ to each object. Constant speed means $a = 0$.
SET UP: The free-body diagrams are sketched in Figure 5.58. T_1 is the tension in the lower chain, T_2 is the tension in the upper chain and $T = F$ is the tension in the rope.
EXECUTE: The tension in the lower chain balances the weight and so is equal to w. The lower pulley must have no net force on it, so twice the tension in the rope must be equal to w and the tension in the rope, which equals F, is $w/2$. Then, the downward force on the upper pulley due to the rope is also w, and so the upper chain exerts a force w on the upper pulley, and the tension in the upper chain is also w.
EVALUATE: The pulley combination allows the worker to lift a weight w by applying a force of only $w/2$.

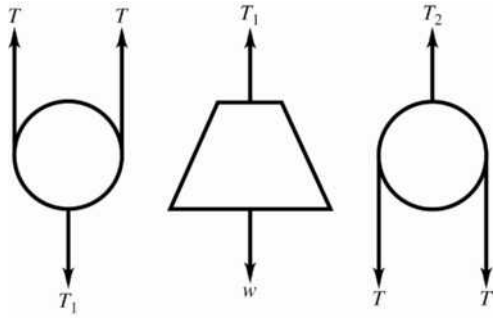

Figure 5.58

5.59. **IDENTIFY:** Apply Newton's first law to the ball. The force of the wall on the ball and the force of the ball on the wall are related by Newton's third law.
SET UP: The forces on the ball are its weight, the tension in the wire, and the normal force applied by the wall.
To calculate the angle ϕ that the wire makes with the wall, use Figure 5.59a. $\sin\phi = \dfrac{16.0\text{ cm}}{46.0\text{ cm}}$ and $\phi = 20.35°$
EXECUTE: **(a)** The free-body diagram is shown in Figure 5.59b. Use the x and y coordinates shown in the figure. $\Sigma F_y = 0$ gives $T\cos\phi - w = 0$ and $T = \dfrac{w}{\cos\phi} = \dfrac{(45.0\text{ kg})(9.80\text{ m/s}^2)}{\cos 20.35°} = 470$ N

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) $\Sigma F_x = 0$ gives $T\sin\phi - n = 0$. $n = (470\text{ N})\sin 20.35° = 163\text{ N}$. By Newton's third law, the force the ball exerts on the wall is 163 N, directed to the right.

EVALUATE: $n = \left(\dfrac{w}{\cos\phi}\right)\sin\phi = w\tan\phi$. As the angle ϕ decreases (by increasing the length of the wire), T decreases and n decreases.

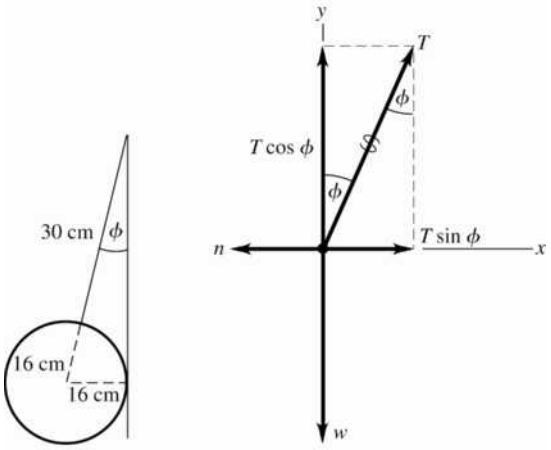

Figure 5.59a, b

5.60. **IDENTIFY:** Apply Newton's first law to the ball. Treat the ball as a particle.

SET UP: The forces on the ball are gravity, the tension in the wire and the normal force exerted by the surface. The normal force is perpendicular to the surface of the ramp. Use x and y axes that are horizontal and vertical.

EXECUTE: **(a)** The free-body diagram for the ball is given in Figure 5.60. The normal force has been replaced by its x and y components.

(b) $\Sigma F_y = 0$ gives $n\cos 35.0° - w = 0$ and $n = \dfrac{mg}{\cos 35.0°} = 1.22mg$.

(c) $\Sigma F_x = 0$ gives $T - n\sin 35.0° = 0$ and $T = (1.22mg)\sin 35.0° = 0.700mg$.

EVALUATE: Note that the normal force is greater than the weight, and increases without limit as the angle of the ramp increases toward 90°. The tension in the wire is $w\tan\phi$, where ϕ is the angle of the ramp and T also increases without limit as $\phi \to 90°$.

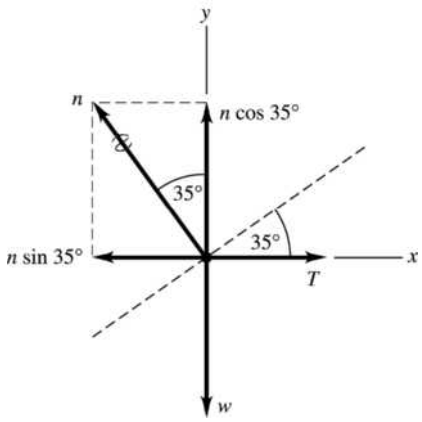

Figure 5.60

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

5.61. **IDENTIFY:** Kinematics will give us the acceleration of the person, and Newton's second law will give us the force (the target variable) that his arms exert on the rest of his body.

SET UP: Let the person's weight be W, so $W = 680$ N. Assume constant acceleration during the speeding up motion and assume that the body moves upward 15 cm in 0.50 s while speeding up. The constant-acceleration kinematics formula $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$ and $\Sigma F_y = ma_y$ apply. The free-body diagram for the person is given in Figure 5.61. F is the force exerted on him by his arms.

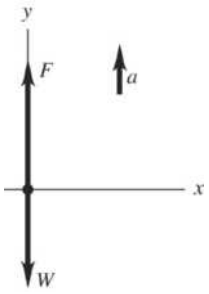

Figure 5.61

EXECUTE: $v_{0y} = 0$, $y - y_0 = 0.15$ m, $t = 0.50$ s. $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$ gives

$a_y = \dfrac{2(y - y_0)}{t^2} = \dfrac{2(0.15 \text{ m})}{(0.50 \text{ s})^2} = 1.2 \text{ m/s}^2$. $\Sigma F_y = ma_y$ gives $F - W = ma$. $m = \dfrac{W}{g}$, so

$F = W\left(1 + \dfrac{a}{g}\right) = 1.12W = 762$ N.

EVALUATE: The force is greater than his weight, which it must be if he is to accelerate upward.

5.62. **IDENTIFY:** The person is first in free fall and then slows down uniformly. Newton's second law and the constant-acceleration kinematics formulas apply while she is falling and also while she is slowing down.

SET UP: Take $+y$ downward. (a) Assume the hip is in free fall. (b) The free-body diagram for the person is given in Figure 5.62. It is assumed that the whole mass of the person has the same acceleration as her hip. The formulas $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$, $v_y = v_{0y} + a_y t$, and $\Sigma F_y = ma_y$ apply to the person.

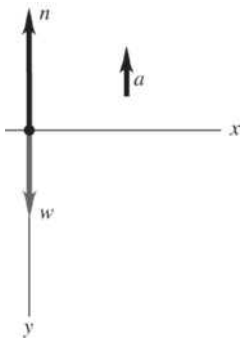

Figure 5.62

EXECUTE: **(a)** $v_{0y} = 0$, $y - y_0 = 1.0$ m, $a_y = +9.80 \text{ m/s}^2$. $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ gives

$v_y = \sqrt{2a_y(y - y_0)} = \sqrt{2(9.80 \text{ m/s}^2)(1.0 \text{ m})} = 4.4$ m/s.

(b) $v_{0y} = 4.4$ m/s, $y - y_0 = 0.020$ m, $v_y = 1.3$ m/s. $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ gives

$a_y = \dfrac{v_y^2 - v_{0y}^2}{2(y - y_0)} = \dfrac{(1.3 \text{ m/s})^2 - (4.4 \text{ m/s})^2}{2(0.020 \text{ m})} = -440 \text{ m/s}^2$. The acceleration is 440 m/s^2, upward.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$\Sigma F_y = ma_y$ gives $w - n = -ma$ and $n = w + ma = m(a+g) = (55\text{ kg})(440\text{ m/s}^2 + 9.80\text{ m/s}^2) = 25{,}000\text{ N}$.

(c) $v_y = v_{0y} + a_y t$ gives $t = \dfrac{v_y - v_{0y}}{a_y} = \dfrac{1.3\text{ m/s} - 4.4\text{ m/s}}{-440\text{ m/s}^2} = 7.0\text{ ms}$.

EVALUATE: When the velocity change occurs over a small distance the acceleration is large.

5.63. **IDENTIFY:** We know the forces on the box and want to find information about its position and velocity. Newton's second law will give us the box's acceleration.

SET UP: $a_y(t) = \dfrac{\Sigma F_y}{m}$. We can integrate the acceleration to find the velocity and the velocity to find the position. At an altitude of several hundred meters, the acceleration due to gravity is essentially the same as it is at the earth's surface.

EXECUTE: Let $+y$ be upward. Newton's second law gives $T - mg = ma_y$, so $a_y(t) = (12.0\text{ m/s}^3)t - 9.8\text{ m/s}^2$. Integrating the acceleration gives $v_y(t) = (6.00\text{ m/s}^3)t^2 - (9.8\text{ m/s}^2)t$.

(a) (i) At $t = 1.00$ s, $v_y = -3.80$ m/s. (ii) At $t = 3.00$ s, $v_y = 24.6$ m/s.

(b) Integrating the velocity gives $y - y_0 = (2.00\text{ m/s}^3)t^3 - (4.9\text{ m/s}^2)t^2$. $v_y = 0$ at $t = 1.63$ s. At $t = 1.63$ s, $y - y_0 = 8.71\text{ m} - 13.07\text{ m} = -4.36$ m.

(c) Setting $y - y_0 = 0$ and solving for t gives $t = 2.45$ s.

EVALUATE: The box accelerates and initially moves downward until the tension exceeds the weight of the box. Once the tension exceeds the weight, the box will begin to accelerate upward and will eventually move upward, as we saw in part (b).

5.64. **IDENTIFY:** We can use the standard kinematics formulas because the force (and hence the acceleration) is constant, and we can use Newton's second law to find the force needed to cause that acceleration. Kinetic friction, not static friction, is acting.

SET UP: From kinematics, we have $x - x_0 = v_{0x}t + \dfrac{1}{2}a_x t^2$ and $\Sigma F_x = ma_x$ applies. Forces perpendicular to the ramp balance. The force of kinetic friction is $f_k = \mu_k mg\cos\theta$.

EXECUTE: Call $+x$ upward along the surface of the ramp. Kinematics gives $a_x = \dfrac{2(x - x_0)}{t^2} = \dfrac{2(8.00\text{ m})}{(4.00\text{ s})^2} = 1.00\text{ m/s}^2$. $\Sigma F_x = ma_x$ gives $F - mg\sin\theta - \mu_k mg\cos\theta = ma_x$. Solving for F gives $F = m(a_x + g\sin\theta + \mu_k mg\cos\theta) = (5.00\text{ kg})(1.00\text{ m/s}^2 + 4.9\text{ m/s}^2 + 3.395\text{ m/s}^2) = 46.5\text{ N}$.

EVALUTE: As long as the box is moving, only kinetic friction, not static friction, acts on it. The force can be less than the weight of the box because only part of the box's weight acts down the ramp.

5.65. **IDENTIFY:** The system of boxes is accelerating, so we apply Newton's second law to each box. The friction is kinetic friction. We can use the known acceleration to find the tension and the mass of the second box.

SET UP: The force of friction is $f_k = \mu_k n$, $\Sigma F_x = ma_x$ applies to each box, and the forces perpendicular to the surface balance.

EXECUTE: **(a)** Call the $+x$ axis along the surface. For the 5 kg block, the vertical forces balance, so $n + F\sin 53.1° - mg = 0$, which gives $n = 49.0\text{ N} - 31.99\text{ N} = 17.01$ N. The force of kinetic friction is $f_k = \mu_k n = 5.104$ N. Applying Newton's second law along the surface gives $F\cos 53.1° - T - f_k = ma$. Solving for T gives $T = F\cos 53.1° - f_k - ma = 24.02\text{ N} - 5.10\text{ N} - 7.50\text{ N} = 11.4$ N.

(b) For the second box, $T - f_k = ma$. $T - \mu_k mg = ma$. Solving for m gives

$$m = \frac{T}{\mu_k g + a} = \frac{11.42\text{ N}}{(0.3)(9.8\text{ m/s}^2) + 1.5\text{ m/s}^2} = 2.57\text{ kg}.$$

EVALUATE: The normal force for box B is less than its weight due to the upward pull, but the normal force for box A is equal to its weight because the rope pulls horizontally on A.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

5.66. **IDENTIFY:** The horizontal force has a component up the ramp and a component perpendicular to the surface of the ramp. The upward component causes the upward acceleration and the perpendicular component affects the normal force on the box. Newton's second law applies. The forces perpendicular to the surface balance.
SET UP: Balance forces perpendicular to the ramp: $n - mg\cos\theta - F\sin\theta = 0$. Apply Newton's second law parallel to the ramp surface: $F\cos\theta - f_k - mg\sin\theta = ma$.

EXECUTE: Using the above equations gives $n = mg\cos\theta + F\sin\theta$. The force of friction is $f_k = \mu_k n$, so $f_k = \mu_k (mg\cos\theta + F\sin\theta)$. $F\cos\theta - \mu_k mg\cos\theta - \mu_k F\sin\theta - mg\sin\theta = ma$. Solving for F gives $F = \dfrac{m(a + \mu_k g\cos\theta + g\sin\theta)}{\cos\theta - \mu_k \sin\theta}$. Putting in the numbers, we get

$$F = \frac{(6.00\text{ kg})[4.20\text{ m/s}^2 + (0.30)(9.80\text{ m/s}^2)\cos 37.0^\circ + (9.80\text{ m/s}^2)\sin 37.0^\circ]}{\cos 37.0^\circ - (0.30)\sin 37.0^\circ} = 121\text{ N}$$

EVALUATE: Even though the push is horizontal, it can cause a vertical acceleration because it causes the normal force to have a vertical component greater than the vertical component of the box's weight.

5.67. **IDENTIFY:** Both blocks have the same constant acceleration. Kinematics will give us the acceleration, Newton's laws will give us the mass of block A, and kinetic friction is acting.
SET UP: Newton's second law applies to each block. The standard kinematics formulas can be used because the acceleration is constant. The normal force on A is mg, so the force of friction on it is $f_k = \mu_k mg$.

EXECUTE: The initial velocity is zero, so kinematics gives $a_y = \dfrac{2(y - y_0)}{t^2} = \dfrac{2(5.00\text{ m})}{(3.00\text{ s})^2} = 1.111\text{ m/s}^2$.

For block B, Newton's second law gives $m_B g - T = m_B a$, so $T = m_B(g - a) = (6.00\text{ kg})(9.8\text{ m/s}^2 - 1.111\text{ m/s}^2) = 52.13\text{ N}$. For block A, $n = mg$, so $f_k = \mu_k mg$. Using this in Newton's second law gives $T - f_k = ma$, so $T - \mu_k mg = ma$. Solving for m gives

$$m = \frac{T}{a + \mu_k g} = \frac{52.13\text{ N}}{1.111\text{ m/s}^2 + (0.40)(9.80\text{ m/s}^2)} = 10.4\text{ kg}.$$

EVALUATE: Instead of breaking it up into two parts, we could think of the blocks as a two-mass system. In that case, Newton's second law would give $m_B g - f_k = (m_A + m_B)a$. Substituting for f_k makes this $m_B g - \mu_k m_A g = (m_A + m_B)a$, which gives the same result.

5.68. **IDENTIFY:** This is a system having constant acceleration, so we can use the standard kinematics formulas as well as Newton's second law to find the unknown mass m_2.
SET UP: Newton's second law applies to each block. The standard kinematics formulas can be used to find the acceleration because the acceleration is constant. The normal force on m_1 is $m_1 g\cos\alpha$, so the force of friction on it is $f_k = \mu_k m_1 g\cos\alpha$.

EXECUTE: Standard kinematics gives the acceleration of the system to be $a_y = \dfrac{2(y - y_0)}{t^2} = \dfrac{2(12.0\text{ m})}{(3.00\text{ s})^2} = 2.667\text{ m/s}^2$. For m_1, $n = m_1 g\cos\alpha = 117.7\text{ N}$, so the friction force on m_1 is $f_k = (0.40)(117.7\text{ N}) = 47.08\text{ N}$. Applying Newton's second law to m_1 gives $T - f_k - m_1 g\sin\alpha = m_1 a$, where T is the tension in the cord. Solving for T gives $T = f_k + m_1 g\sin\alpha + m_1 a = 47.08\text{ N} + 156.7\text{ N} + 53.34\text{ N} = 257.1\text{ N}$. Newton's second law for m_2 gives $m_2 g - T = m_2 a$, so $m_2 = \dfrac{T}{g - a} = \dfrac{257.1\text{ N}}{9.8\text{ m/s}^2 - 2.667\text{ m/s}^2} = 36.0\text{ kg}$.

EVALUATE: This problem is similar to Problem 5.67, except for the sloped surface. As in that problem, we could treat these blocks as a two-block system. Newton's second law would then give $m_2 g - m_1 g\sin\alpha - \mu_k m_1 g\cos\alpha = (m_1 + m_2)a$, which gives the same result as above.

5.69. **IDENTIFY:** $f = \mu_r n$. Apply $\Sigma\vec{F} = m\vec{a}$ to the tire.
SET UP: $n = mg$ and $f = ma$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

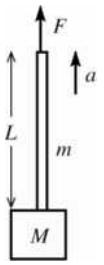
EXECUTE: $a_x = \dfrac{v^2 - v_0^2}{L}$, where L is the distance covered before the wheel's speed is reduced to half its original speed and $v = v_0/2$. $\mu_r = \dfrac{a}{g} = \dfrac{v_0^2 - v^2}{2Lg} = \dfrac{v_0^2 - \frac{1}{4}v_0^2}{2Lg} = \dfrac{3}{8}\dfrac{v_0^2}{Lg}$.

Low pressure, $L = 18.1$ m and $\dfrac{3}{8}\dfrac{(3.50 \text{ m/s})^2}{(18.1 \text{ m})(9.80 \text{ m/s}^2)} = 0.0259$.

High pressure, $L = 92.9$ m and $\dfrac{3}{8}\dfrac{(3.50 \text{ m/s})^2}{(92.9 \text{ m})(9.80 \text{ m/s}^2)} = 0.00505$.

EVALUATE: μ_r is inversely proportional to the distance L, so $\dfrac{\mu_{r1}}{\mu_{r2}} = \dfrac{L_2}{L_1}$.

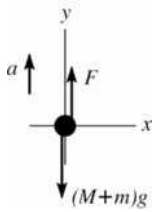
5.70. **IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$ to the combined rope plus block to find a. Then apply $\Sigma\vec{F} = m\vec{a}$ to a section of the rope of length x. First note the limiting values of the tension. The system is sketched in Figure 5.70a.



At the top of the rope $T = F$
At the bottom of the rope $T = M(g + a)$

Figure 5.70a

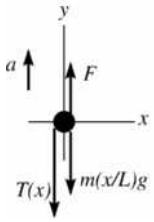
SET UP: Consider the rope and block as one combined object, in order to calculate the acceleration: The free-body diagram is sketched in Figure 5.70b.



EXECUTE:
$\Sigma F_y = ma_y$
$F - (M + m)g = (M + m)a$
$a = \dfrac{F}{M + m} - g$

Figure 5.70b

SET UP: Now consider the forces on a section of the rope that extends a distance $x < L$ below the top. The tension at the bottom of this section is $T(x)$ and the mass of this section is $m(x/L)$. The free-body diagram is sketched in Figure 5.70c.



EXECUTE:
$\Sigma F_y = ma_y$
$F - T(x) - m(x/L)g = m(x/L)a$
$T(x) = F - m(x/L)g - m(x/L)a$

Figure 5.70c

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

Using our expression for a and simplifying gives

$$T(x) = F\left(1 - \frac{mx}{L(M+m)}\right)$$

EVALUATE: Important to check this result for the limiting cases:
$x = 0$: The expression gives the correct value of $T = F$.
$x = L$: The expression gives $T = F(M/(M+m))$. This should equal $T = M(g+a)$, and when we use the expression for a we see that it does.

5.71. **IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$ to each block.

SET UP: Constant speed means $a = 0$. When the blocks are moving, the friction force is f_k and when they are at rest, the friction force is f_s.

EXECUTE: **(a)** The tension in the cord must be $m_2 g$ in order that the hanging block move at constant speed. This tension must overcome friction and the component of the gravitational force along the incline, so $m_2 g = (m_1 g \sin\alpha + \mu_k m_1 g \cos\alpha)$ and $m_2 = m_1(\sin\alpha + \mu_k \cos\alpha)$.

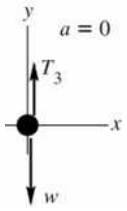
(b) In this case, the friction force acts in the same direction as the tension on the block of mass m_1, so $m_2 g = (m_1 g \sin\alpha - \mu_k m_1 g \cos\alpha)$, or $m_2 = m_1(\sin\alpha - \mu_k \cos\alpha)$.

(c) Similar to the analysis of parts (a) and (b), the largest m_2 could be is $m_1(\sin\alpha + \mu_s \cos\alpha)$ and the smallest m_2 could be is $m_1(\sin\alpha - \mu_s \cos\alpha)$.

EVALUATE: In parts (a) and (b) the friction force changes direction when the direction of the motion of m_1 changes. In part (c), for the largest m_2 the static friction force on m_1 is directed down the incline and for the smallest m_2 the static friction force on m_1 is directed up the incline.

5.72. **IDENTIFY:** The system is in equilibrium. Apply Newton's first law to block A, to the hanging weight and to the knot where the cords meet. Target variables are the two forces.

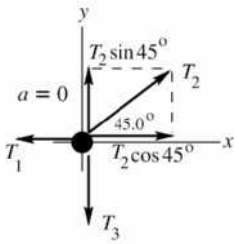
(a) SET UP: The free-body diagram for the hanging block is given in Figure 5.72a.



EXECUTE:
$\Sigma F_y = ma_y$
$T_3 - w = 0$
$T_3 = 12.0\ \text{N}$

Figure 5.72a

SET UP: The free-body diagram for the knot is given in Figure 5.72b.



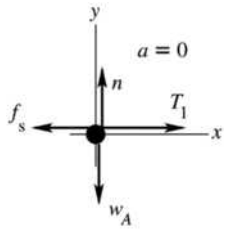
EXECUTE:
$\Sigma F_y = ma_y$
$T_2 \sin 45.0° - T_3 = 0$
$T_2 = \dfrac{T_3}{\sin 45.0°} = \dfrac{12.0\ \text{N}}{\sin 45.0°}$
$T_2 = 17.0\ \text{N}$

Figure 5.72b

$\Sigma F_x = ma_x$
$T_2 \cos 45.0° - T_1 = 0$
$T_1 = T_2 \cos 45.0° = 12.0\ \text{N}$

SET UP: The free-body diagram for block A is given in Figure 5.72c.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.



EXECUTE:
$\Sigma F_x = ma_x$
$T_1 - f_s = 0$
$f_s = T_1 = 12.0$ N

Figure 5.72c

EVALUATE: Also can apply $\Sigma F_y = ma_y$ to this block:

$$n - w_A = 0$$

$$n = w_A = 60.0 \text{ N}$$

Then $\mu_s n = (0.25)(60.0 \text{ N}) = 15.0$ N; this is the maximum possible value for the static friction force. We see that $f_s < \mu_s n$; for this value of w the static friction force can hold the blocks in place.

(b) SET UP: We have all the same free-body diagrams and force equations as in part (a) but now the static friction force has its largest possible value, $f_s = \mu_s n = 15.0$ N. Then $T_1 = f_s = 15.0$ N.

EXECUTE: From the equations for the forces on the knot

$T_2 \cos 45.0° - T_1 = 0$ implies $T_2 = T_1 / \cos 45.0° = \dfrac{15.0 \text{ N}}{\cos 45.0°} = 21.2$ N

$T_2 \sin 45.0° - T_3 = 0$ implies $T_3 = T_2 \sin 45.0° = (21.2 \text{ N}) \sin 45.0° = 15.0$ N

And finally $T_3 - w = 0$ implies $w = T_3 = 15.0$ N.

EVALUATE: Compared to part (a), the friction is larger in part (b) by a factor of $(15.0/12.0)$ and w is larger by this same ratio.

5.73. **IDENTIFY:** Apply $\Sigma \vec{F} = m\vec{a}$ to each block. Use Newton's third law to relate forces on A and on B.

SET UP: Constant speed means $a = 0$.

EXECUTE: **(a)** Treat A and B as a single object of weight $w = w_A + w_B = 6.00$ N. The free-body diagram for this combined object is given in Figure 5.73a. $\Sigma F_y = ma_y$ gives $n = w = 6.00$ N. $f_k = \mu_k n = 1.80$ N. $\Sigma F_x = ma_x$ gives $F = f_k = 1.80$ N.

(b) The free-body force diagrams for blocks A and B are given in Figure 5.73b. n and f_k are the normal and friction forces applied to block B by the tabletop and are the same as in part (a). f_{kB} is the friction force that A applies to B. It is to the right because the force from A opposes the motion of B. n_B is the downward force that A exerts on B. f_{kA} is the friction force that B applies to A. It is to the left because block B wants A to move with it. n_A is the normal force that block B exerts on A. By Newton's third law, $f_{kB} = f_{kA}$ and these forces are in opposite directions. Also, $n_A = n_B$ and these forces are in opposite directions.

$\Sigma F_y = ma_y$ for block A gives $n_A = w_A = 2.40$ N, so $n_B = 2.40$ N.

$f_{kA} = \mu_k n_A = (0.300)(2.40 \text{ N}) = 0.720$ N, and $f_{kB} = 0.720$ N.

$\Sigma F_x = ma_x$ for block A gives $T = f_{kA} = 0.720$ N.

$\Sigma F_x = ma_x$ for block B gives $F = f_{kB} + f_k = 0.720 \text{ N} + 1.80 \text{ N} = 2.52$ N.

EVALUATE: In part (a) block A is at rest with respect to B and it has zero acceleration. There is no horizontal force on A besides friction, and the friction force on A is zero. A larger force F is needed in part (b), because of the friction force between the two blocks.

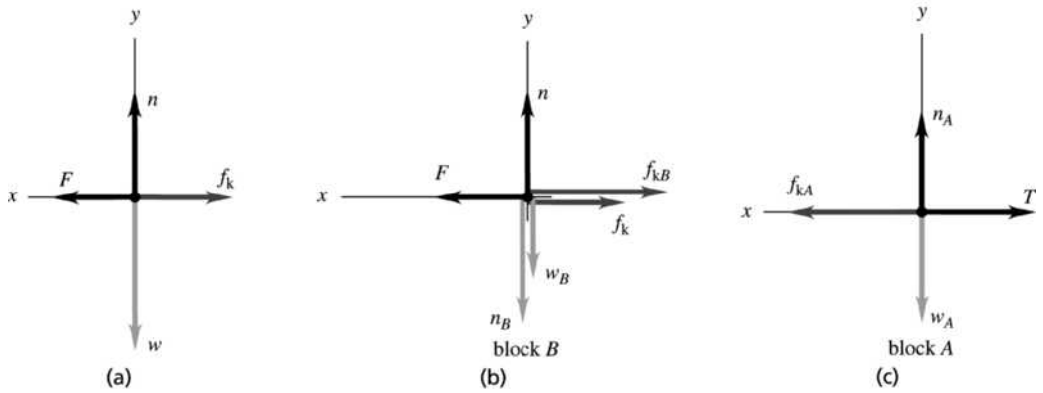

Figure 5.73a–c

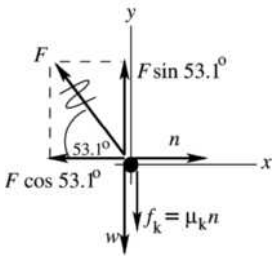
5.74. **IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$ to the brush. Constant speed means $a = 0$. Target variables are two of the forces on the brush.

SET UP: Note that the normal force exerted by the wall is horizontal, since it is perpendicular to the wall. The kinetic friction force exerted by the wall is parallel to the wall and opposes the motion, so it is vertically downward. The free-body diagram is given in Figure 5.74.



EXECUTE:

$\Sigma F_x = ma_x$

$n - F\cos 53.1° = 0$

$n = F\cos 53.1°$

$f_k = \mu_k n = \mu_k F\cos 53.1°$

Figure 5.74

$\Sigma F_y = ma_y$: $F\sin 53.1° - w - f_k = 0$. $F\sin 53.1° - w - \mu_k F\cos 53.1° = 0$. $F(\sin 53.1° - \mu_k \cos 53.1°) = w$.

$$F = \frac{w}{\sin 53.1° - \mu_k \cos 53.1°}.$$

(a) $$F = \frac{w}{\sin 53.1° - \mu_k \cos 53.1°} = \frac{15\text{ N}}{\sin 53.1° - (0.150)\cos 53.1°} = 21.1\text{ N}$$

(b) $n = F\cos 53.1° = (21.1\text{ N})\cos 53.1° = 12.7\text{ N}$

EVALUATE: In the absence of friction $w = F\sin 53.1°$, which agrees with our expression.

5.75. **IDENTIFY:** The net force at any time is $F_{net} = ma$.

SET UP: At $t = 0$, $a = 62g$. The maximum acceleration is 140g at $t = 1.2$ ms.

EXECUTE: **(a)** $F_{net} = ma = 62mg = 62(210\times10^{-9}\text{ kg})(9.80\text{ m/s}^2) = 1.3\times10^{-4}$ N. This force is 62 times the flea's weight.

(b) $F_{net} = 140mg = 2.9\times10^{-4}$ N, at $t = 1.2$ ms.

(c) Since the initial speed is zero, the maximum speed is the area under the $a_x - t$ graph. This gives 1.2 m/s.

EVALUATE: a is much larger than g and the net external force is much larger than the flea's weight.

5.76. **IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$ to the instrument and calculate the acceleration. Then use constant acceleration equations to describe the motion.

SET UP: The free-body diagram for the instrument is given in Figure 5.76. The instrument has mass $m = w/g = 1.531$ kg.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: **(a)** Adding the forces on the instrument, we have $\Sigma F_y = ma_y$, which gives $T - mg = ma$ and $a = \dfrac{T - mg}{m} = 19.6 \text{ m/s}^2$. $v_{0y} = 0, v_y = 330 \text{ m/s}, a_y = 19.6 \text{ m/s}^2, t = ?$ Then $v_y = v_{0y} + a_y t$ gives $t = 16.8$ s.

Consider forces on the rocket; rocket has the same a_y. Let F be the thrust of the rocket engines.

$F - mg = ma$ and $F = m(g + a) = (25{,}000 \text{ kg})(9.80 \text{ m/s}^2 + 19.6 \text{ m/s}^2) = 7.35 \times 10^5 \text{ N}$.

(b) $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$ gives $y - y_0 = 2770$ m.

EVALUATE: The rocket and instrument have the same acceleration. The tension in the wire is over twice the weight of the instrument and the upward acceleration is greater than g.

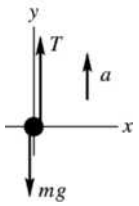


Figure 5.76

5.77. **IDENTIFY:** $a = dv/dt$. Apply $\Sigma\vec{F} = m\vec{a}$ to yourself.

SET UP: The reading of the scale is equal to the normal force the scale applies to you.

EXECUTE: The elevator's acceleration is $a = \dfrac{dv(t)}{dt} = 3.0 \text{ m/s}^2 + 2(0.20 \text{ m/s}^3)t = 3.0 \text{ m/s}^2 + (0.40 \text{ m/s}^3)t$.

At $t = 4.0$ s, $a = 3.0 \text{ m/s}^2 + (0.40 \text{ m/s}^3)(4.0 \text{ s}) = 4.6 \text{ m/s}^2$. From Newton's second law, the net force on you is $F_{\text{net}} = F_{\text{scale}} - w = ma$ and $F_{\text{scale}} = w + ma = (64 \text{ kg})(9.8 \text{ m/s}^2) + (64 \text{ kg})(4.6 \text{ m/s}^2) = 920$ N.

EVALUATE: a increases with time, so the scale reading is increasing.

5.78. **IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$ to the passenger to find the maximum allowed acceleration. Then use a constant acceleration equation to find the maximum speed.

SET UP: The free-body diagram for the passenger is given in Figure 5.78.

EXECUTE: $\Sigma F_y = ma_y$ gives $n - mg = ma$. $n = 1.6mg$, so $a = 0.60g = 5.88 \text{ m/s}^2$.

$y - y_0 = 3.0$ m, $a_y = 5.88 \text{ m/s}^2, v_{0y} = 0$ so $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ gives $v_y = 5.9$ m/s.

EVALUATE: A larger final speed would require a larger value of a_y, which would mean a larger normal force on the person.

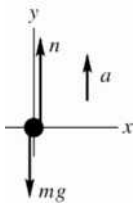

Figure 5.78

5.79. **IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$ to the package. Calculate a and then use a constant acceleration equation to describe the motion.

SET UP: Let $+x$ be directed up the ramp.

EXECUTE: **(a)** $F_{\text{net}} = -mg\sin 37° - f_k = -mg\sin 37° - \mu_k mg\cos 37° = ma$ and

$$a = -(9.8 \text{ m/s}^2)(0.602 + (0.30)(0.799)) = -8.25 \text{ m/s}^2$$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

Since we know the length of the slope, we can use $v_x^2 = v_{0x}^2 + 2a_x(x - x_0)$ with $x_0 = 0$ and $v_x = 0$ at the top. $v_0^2 = -2ax = -2(-8.25\ \text{m/s}^2)(8.0\ \text{m}) = 132\ \text{m}^2/\text{s}^2$ and $v_0 = \sqrt{132\ \text{m}^2/\text{s}^2} = 11.5\ \text{m/s}$

(b) For the trip back down the slope, gravity and the friction force operate in opposite directions to each other. $F_{\text{net}} = -mg\sin 37° + \mu_k mg\cos 37° = ma$ and

$a = g(-\sin 37° + 0.30\ \cos 37°) = (9.8\ \text{m/s}^2)((-0.602) + (0.30)(0.799)) = -3.55\ \text{m/s}^2$.

Now we have $v_0 = 0, x_0 = -8.0\ \text{m}, x = 0$ and

$v^2 = v_0^2 + 2a(x - x_0) = 0 + 2(-3.55\ \text{m/s}^2)(-8.0\ \text{m}) = 56.8\ \text{m}^2/\text{s}^2$, so $v = \sqrt{56.8\ \text{m}^2/\text{s}^2} = 7.54\ \text{m/s}$.

EVALUATE: In both cases, moving up the incline and moving down the incline, the acceleration is directed down the incline. The magnitude of a is greater when the package is going up the incline, because $mg\sin 37°$ and f_k are in the same direction whereas when the package is going down these two forces are in opposite directions.

5.80. **IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$ to the hammer. Since the hammer is at rest relative to the bus, its acceleration equals that of the bus.

SET UP: The free-body diagram for the hammer is given in Figure 5.80.

EXECUTE: $\Sigma F_y = ma_y$ gives $T\sin 67° - mg = 0$ so $T\sin 67° = mg$. $\Sigma F_x = ma_x$ gives $T\cos 67° = ma$.

Divide the second equation by the first: $\dfrac{a}{g} = \dfrac{1}{\tan 67°}$ and $a = 4.2\ \text{m/s}^2$.

EVALUATE: When the acceleration increases, the angle between the rope and the ceiling of the bus decreases, and the angle the rope makes with the vertical increases.

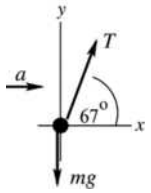

Figure 5.80

5.81. **IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$ to the washer and to the crate. Since the washer is at rest relative to the crate, these two objects have the same acceleration.

SET UP: The free-body diagram for the washer is given in Figure 5.81.

EXECUTE: It's interesting to look at the string's angle measured from the perpendicular to the top of the crate. This angle is $\theta_{\text{string}} = 90° - $ angle measured from the top of the crate. The free-body diagram for the washer then leads to the following equations, using Newton's second law and taking the upslope direction as positive:

$$-m_w g\sin\theta_{\text{slope}} + T\sin\theta_{\text{string}} = m_w a \text{ and } T\sin\theta_{\text{string}} = m_w(a + g\ \sin\theta_{\text{slope}})$$

$$-m_w g\cos\theta_{\text{slope}} + T\cos\theta_{\text{string}} = 0 \text{ and } T\cos\theta_{\text{string}} = m_w g\cos\theta_{\text{slope}}$$

Dividing the two equations: $\tan\theta_{\text{string}} = \dfrac{a + g\sin\theta_{\text{slope}}}{g\cos\theta_{\text{slope}}}$

For the crate, the component of the weight along the slope is $-m_c g\ \sin\theta_{\text{slope}}$ and the normal force is $m_c g\cos\theta_{\text{slope}}$. Using Newton's second law again: $-m_c g\sin\theta_{\text{slope}} + \mu_k m_c g\cos\theta_{\text{slope}} = m_c a$.

$\mu_k = \dfrac{a + g\sin\theta_{\text{slope}}}{g\cos\theta_{\text{slope}}}$. This leads to the interesting observation that the string will hang at an angle whose tangent is equal to the coefficient of kinetic friction:

$$\mu_k = \tan\theta_{\text{string}} = \tan(90° - 68°) = \tan 22° = 0.40.$$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: In the limit that $\mu_k \to 0$, $\theta_{string} \to 0$ and the string is perpendicular to the top of the crate. As μ_k increases, θ_{string} increases.

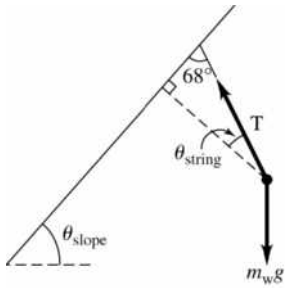

Figure 5.81

5.82. **IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$ to yourself and calculate a. Then use constant acceleration equations to describe the motion.
SET UP: The free-body diagram is given in Figure 5.82.
EXECUTE: **(a)** $\Sigma F_y = ma_y$ gives $n = mg\cos\alpha$. $\Sigma F_x = ma_x$ gives $mg\sin\alpha - f_k = ma$. Combining these two equations, we have $a = g(\sin\alpha - \mu_k\cos\alpha) = -3.094\ \text{m/s}^2$. Find your stopping distance: $v_x = 0, a_x = -3.094\ \text{m/s}^2, v_{0x} = 20\ \text{m/s}$. $v_x^2 = v_{0x}^2 + 2a_x(x - x_0)$ gives $x - x_0 = 64.6\ \text{m}$, which is greater than 40 m. You don't stop before you reach the hole, so you fall into it.
(b) $a_x = -3.094\ \text{m/s}^2$, $x - x_0 = 40\ \text{m}$, $v_x = 0$. $v_x^2 = v_{0x}^2 + 2a_x(x - x_0)$ gives $v_{0x} = 16\ \text{m/s}$.
EVALUATE: Your stopping distance is proportional to the square of your initial speed, so your initial speed is proportional to the square root of your stopping distance. To stop in 40 m instead of 64.6 m your initial speed must be $(20\ \text{m/s})\sqrt{\dfrac{40\ \text{m}}{64.6\ \text{m}}} = 16\ \text{m/s}$.

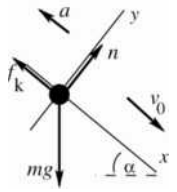

Figure 5.82

5.83. **IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$ to each block and to the rope. The key idea in solving this problem is to recognize that if the system is accelerating, the tension that block A exerts on the rope is different from the tension that block B exerts on the rope. (Otherwise the net force on the rope would be zero, and the rope couldn't accelerate.)
SET UP: Take a positive coordinate direction for each object to be in the direction of the acceleration of that object. All three objects have the same magnitude of acceleration.
EXECUTE: The second law equations for the three different parts of the system are:
Block A (The only horizontal forces on A are tension to the right, and friction to the left): $-\mu_k m_A g + T_A = m_A a$.
Block B (The only vertical forces on B are gravity down, and tension up): $m_B g - T_B = m_B a$.
Rope (The forces on the rope along the direction of its motion are the tensions at either end and the weight of the portion of the rope that hangs vertically): $m_{rope}\left(\dfrac{d}{L}\right)g + T_B - T_A = m_{rope}a$.

To solve for a and eliminate the tensions, add the left-hand sides and right-hand sides of the three equations: $-\mu_k m_A g + m_B g + m_{rope}\left(\dfrac{d}{L}\right)g = (m_A + m_B + m_{rope})a$, or $a = g\dfrac{m_B + m_{rope}(d/L) - \mu_k m_A}{(m_A + m_B + m_{rope})}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(a) When $\mu_k = 0, a = g\dfrac{m_B + m_{\text{rope}}(d/L)}{(m_A + m_B + m_{\text{rope}})}$. As the system moves, d will increase, approaching L as a limit, and thus the acceleration will approach a maximum value of $a = g\dfrac{m_B + m_{\text{rope}}}{(m_A + m_B + m_{\text{rope}})}$.

(b) For the blocks to just begin moving, $a > 0$, so solve $0 = [m_B + m_{\text{rope}}(d/L) - \mu_s m_A]$ for d. Note that we must use static friction to find d for when the block will *begin* to move. Solving for d,

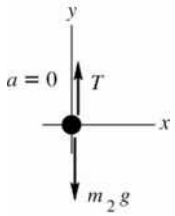
$d = \dfrac{L}{m_{\text{rope}}}(\mu_s m_A - m_B)$ or $d = \dfrac{1.0\text{ m}}{0.160\text{ kg}}(0.25(2\text{ kg}) - 0.4\text{ kg}) = 0.63\text{ m}.$

(c) When $m_{\text{rope}} = 0.04\text{ kg}$, $d = \dfrac{1.0\text{ m}}{0.04\text{ kg}}(0.25(2\text{ kg}) - 0.4\text{ kg}) = 2.50\text{ m}.$ This is not a physically possible situation since $d > L$. The blocks won't move, no matter what portion of the rope hangs over the edge.

EVALUATE: For the blocks to move when released, the weight of B plus the weight of the rope that hangs vertically must be greater than the maximum static friction force on A, which is $\mu_s n = 4.9$ N.

5.84. **IDENTIFY:** Apply Newton's first law to the rope. Let m_1 be the mass of that part of the rope that is on the table, and let m_2 be the mass of that part of the rope that is hanging over the edge. ($m_1 + m_2 = m$, the total mass of the rope). Since the mass of the rope is not being neglected, the tension in the rope varies along the length of the rope. Let T be the tension in the rope at that point that is at the edge of the table.

SET UP: The free-body diagram for the hanging section of the rope is given in Figure 5.84a



EXECUTE:

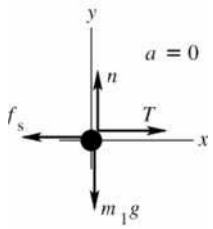
$\Sigma F_y = ma_y$

$T - m_2 g = 0$

$T = m_2 g$

Figure 5.84a

SET UP: The free-body diagram for that part of the rope that is on the table is given in Figure 5.84b.



EXECUTE:

$\Sigma F_y = ma_y$

$n - m_1 g = 0$

$n = m_1 g$

Figure 5.84b

When the maximum amount of rope hangs over the edge the static friction has its maximum value:

$f_s = \mu_s n = \mu_s m_1 g$

$\Sigma F_x = ma_x$

$T - f_s = 0$

$T = \mu_s m_1 g$

Use the first equation to replace T:

$m_2 g = \mu_s m_1 g$

$m_2 = \mu_s m_1$

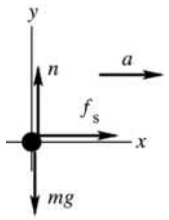
© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

The fraction that hangs over is $\frac{m_2}{m} = \frac{\mu_s m_1}{m_1 + \mu_s m_1} = \frac{\mu_s}{1 + \mu_s}$.

EVALUATE: As $\mu_s \to 0$, the fraction goes to zero and as $\mu_s \to \infty$, the fraction goes to unity.

5.85. **IDENTIFY:** First calculate the maximum acceleration that the static friction force can give to the case. Apply $\Sigma\vec{F} = m\vec{a}$ to the case.

(a) SET UP: The static friction force is to the right in Figure 5.85a (northward) since it tries to make the case move with the truck. The maximum value it can have is $f_s = \mu_s N$.



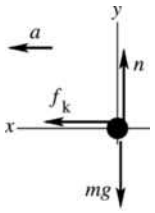
EXECUTE:
$\Sigma F_y = ma_y$
$n - mg = 0$
$n = mg$
$f_s = \mu_s n = \mu_s mg$

Figure 5.85a

$\Sigma F_x = ma_x$. $f_s = ma$. $\mu_s mg = ma$. $a = \mu_s g = (0.30)(9.80 \text{ m/s}^2) = 2.94 \text{ m/s}^2$. The truck's acceleration is less than this so the case doesn't slip relative to the truck; the case's acceleration is $a = 2.20 \text{ m/s}^2$ (northward). Then $f_s = ma = (40.0 \text{ kg})(2.20 \text{ m/s}^2) = 88.0 \text{ N}$, northward.

(b) IDENTIFY: Now the acceleration of the truck is greater than the acceleration that static friction can give the case. Therefore, the case slips relative to the truck and the friction is kinetic friction. The friction force still tries to keep the case moving with the truck, so the acceleration of the case and the friction force are both southward. The free-body diagram is sketched in Figure 5.85b.

SET UP:



EXECUTE:
$\Sigma F_y = ma_y$
$n - mg = 0$
$n = mg$
$f_k = \mu_k mg = (0.20)(40.0 \text{ kg})(9.80 \text{ m/s}^2)$
$f_k = 78 \text{ N}$, southward

Figure 5.85b

EVALUATE: $f_k = ma$ implies $a = \frac{f_k}{m} = \frac{78 \text{ N}}{40.0 \text{ kg}} = 2.0 \text{ m/s}^2$. The magnitude of the acceleration of the case is less than that of the truck and the case slides toward the front of the truck. In both parts (a) and (b) the friction is in the direction of the motion and accelerates the case. Friction opposes *relative* motion between two surfaces in contact.

5.86. **IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$ to the car to calculate its acceleration. Then use a constant acceleration equation to find the initial speed.

SET UP: Let $+x$ be in the direction of the car's initial velocity. The friction force f_k is then in the $-x$-direction. 192 ft = 58.52 m.

EXECUTE: $n = mg$ and $f_k = \mu_k mg$. $\Sigma F_x = ma_x$ gives $-\mu_k mg = ma_x$ and $a_x = -\mu_k g = -(0.750)(9.80 \text{ m/s}^2) = -7.35 \text{ m/s}^2$. $v_x = 0$ (stops), $x - x_0 = 58.52$ m. $v_x^2 = v_{0x}^2 + 2a_x(x - x_0)$ gives $v_{0x} = \sqrt{-2a_x(x - x_0)} = \sqrt{-2(-7.35 \text{ m/s}^2)(58.52 \text{ m})} = 29.3 \text{ m/s} = 65.5 \text{ mi/h}$. He was guilty.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: $x - x_0 = \dfrac{v_x^2 - v_{0x}^2}{2a_x} = -\dfrac{v_{0x}^2}{2a_x}$. If his initial speed had been 45 mi/h he would have stopped in $\left(\dfrac{45 \text{ mi/h}}{65.5 \text{ mi/h}}\right)^2 (192 \text{ ft}) = 91 \text{ ft}$.

5.87. **IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$ to the point where the three wires join and also to one of the balls. By symmetry the tension in each of the 35.0 cm wires is the same.

SET UP: The geometry of the situation is sketched in Figure 5.87a. The angle ϕ that each wire makes with the vertical is given by $\sin\phi = \dfrac{12.5 \text{ cm}}{47.5 \text{ cm}}$ and $\phi = 15.26°$. Let T_A be the tension in the vertical wire and let T_B be the tension in each of the other two wires. Neglect the weight of the wires. The free-body diagram for the left-hand ball is given in Figure 5.87b and for the point where the wires join in Figure 5.87c. n is the force one ball exerts on the other.

EXECUTE: **(a)** $\Sigma F_y = ma_y$ applied to the ball gives $T_B \cos\phi - mg = 0$.

$T_B = \dfrac{mg}{\cos\phi} = \dfrac{(15.0 \text{ kg})(9.80 \text{ m/s}^2)}{\cos 15.26°} = 152 \text{ N}$. Then $\Sigma F_y = ma_y$ applied in Figure 5.87c gives $T_A - 2T_B \cos\phi = 0$ and $T_A = 2(152 \text{ N})\cos\phi = 294 \text{ N}$.

(b) $\Sigma F_x = ma_x$ applied to the ball gives $n - T_B \sin\phi = 0$ and $n = (152 \text{ N})\sin 15.26° = 40.0 \text{ N}$.

EVALUATE: T_A equals the total weight of the two balls.

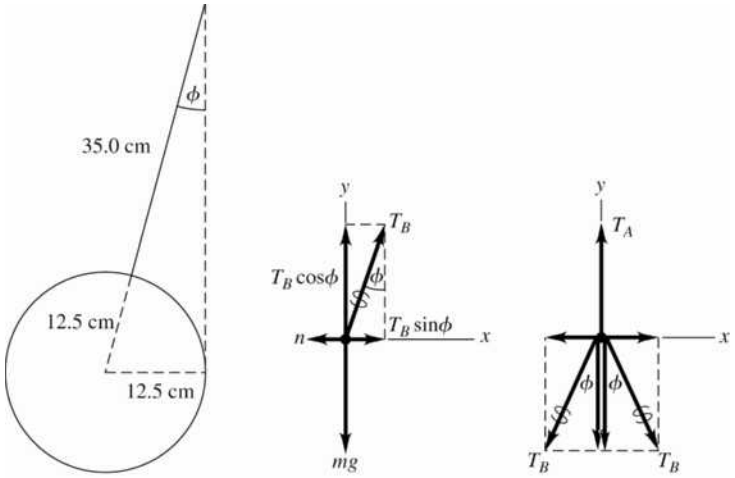


Figure 5.87a–c

5.88. **IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$ to the box. Compare the acceleration of the box to the acceleration of the truck and use constant acceleration equations to describe the motion.

SET UP: Both objects have acceleration in the same direction; take this to be the $+x$-direction.

EXECUTE: If the box were to remain at rest relative to the truck, the friction force would need to cause an acceleration of 2.20 m/s^2; however, the maximum acceleration possible due to static friction is $(0.19)(9.80 \text{ m/s}^2) = 1.86 \text{ m/s}^2$, and so the box will move relative to the truck; the acceleration of the box would be $\mu_k g = (0.15)(9.80 \text{ m/s}^2) = 1.47 \text{ m/s}^2$. The difference between the distance the truck moves and the distance the box moves (i.e., the distance the box moves relative to the truck) will be 1.80 m after a time

$$t = \sqrt{\frac{2\Delta x}{a_{\text{truck}} - a_{\text{box}}}} = \sqrt{\frac{2(1.80 \text{ m})}{(2.20 \text{ m/s}^2 - 1.47 \text{ m/s}^2)}} = 2.221 \text{ s}.$$

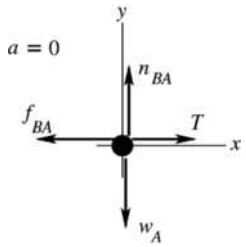
© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

In this time, the truck moves $\frac{1}{2}a_{\text{truck}}t^2 = \frac{1}{2}(2.20\text{m/s}^2)(2.221\text{ s})^2 = 5.43\text{ m}$.

EVALUATE: To prevent the box from sliding off the truck the coefficient of static friction would have to be $\mu_s = (2.20\text{ m/s}^2)/g = 0.224$.

5.89. **IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$ to each block. Forces between the blocks are related by Newton's third law. The target variable is the force F. Block B is pulled to the left at constant speed, so block A moves to the right at constant speed and $a = 0$ for each block.

SET UP: The free-body diagram for block A is given in Figure 5.89a. n_{BA} is the normal force that B exerts on A. $f_{BA} = \mu_k n_{BA}$ is the kinetic friction force that B exerts on A. Block A moves to the right relative to B, and f_{BA} opposes this motion, so f_{BA} is to the left. Note also that F acts just on B, not on A.



EXECUTE:
$\Sigma F_y = ma_y$
$n_{BA} - w_A = 0$
$n_{BA} = 1.90\text{ N}$
$f_{BA} = \mu_k n_{BA} = (0.30)(1.90\text{ N}) = 0.57\text{ N}$

Figure 5.89a

$\Sigma F_x = ma_x$. $T - f_{BA} = 0$. $T = f_{BA} = 0.57$ N.

SET UP: The free-body diagram for block B is given in Figure 5.89b.

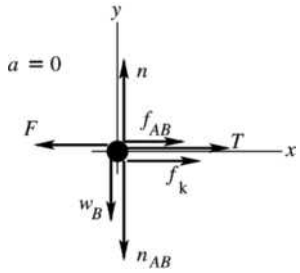


Figure 5.89b

EXECUTE: n_{AB} is the normal force that block A exerts on block B. By Newton's third law n_{AB} and n_{BA} are equal in magnitude and opposite in direction, so $n_{AB} = 1.90$ N. f_{AB} is the kinetic friction force that A exerts on B. Block B moves to the left relative to A and f_{AB} opposes this motion, so f_{AB} is to the right. $f_{AB} = \mu_k n_{AB} = (0.30)(1.90\text{ N}) = 0.42$ N. n and f_k are the normal and friction force exerted by the floor on block B; $f_k = \mu_k n$. Note that block B moves to the left relative to the floor and f_k opposes this motion, so f_k is to the right.

$\Sigma F_y = ma_y$: $n - w_B - n_{AB} = 0$. $n = w_B + n_{AB} = 4.20\text{ N} + 1.90\text{ N} = 6.10$ N. Then
$f_k = \mu_k n = (0.30)(6.10\text{ N}) = 1.83$ N. $\Sigma F_x = ma_x$: $f_{AB} + T + f_k - F = 0$.
$F = T + f_{AB} + f_k = 0.57\text{ N} + 0.57\text{ N} + 1.83\text{ N} = 3.0$ N.

EVALUATE: Note that f_{AB} and f_{BA} are a third law action-reaction pair, so they must be equal in magnitude and opposite in direction and this is indeed what our calculation gives.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

5.90. **IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$ to the person to find the acceleration the PAPS unit produces. Apply constant acceleration equations to her free fall motion and to her motion after the PAPS fires.
SET UP: We take the upward direction as positive.
EXECUTE: The explorer's vertical acceleration is $-3.7\ \text{m/s}^2$ for the first 20 s. Thus at the end of that time her vertical velocity will be $v_y = a_y t = (-3.7\ \text{m/s}^2)(20\ \text{s}) = -74\ \text{m/s}$. She will have fallen a distance $d = v_{\text{av}}t = \left(\frac{-74\ \text{m/s}}{2}\right)(20\ \text{s}) = -740\ \text{m}$ and will thus be $1200\ \text{m} - 740\ \text{m} = 460\ \text{m}$ above the surface. Her vertical velocity must reach zero as she touches the ground; therefore, taking the ignition point of the PAPS as

$y_0 = 0,\ v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ gives $a_y = \frac{v_y^2 - v_{0y}^2}{2(y - y_0)} = \frac{0 - (-74\ \text{m/s})}{-460\ \text{m}} = 5.95\ \text{m/s}^2$, which is the vertical acceleration that must be provided by the PAPS. The time it takes to reach the ground is given by

$$t = \frac{v_y - v_{0y}}{a_y} = \frac{0 - (-74\ \text{m/s})}{5.95\ \text{m/s}^2} = 12.4\ \text{s}$$

Using Newton's second law for the vertical direction $F_{\text{PAPSv}} - mg = ma$. This gives

$$F_{\text{PAPSv}} = m(a + g) = (150\ \text{kg})(5.95 + 3.7)\ \text{m/s}^2 = 1450\ \text{N},$$

which is the vertical component of the PAPS force. The vehicle must also be brought to a stop horizontally in 12.4 seconds; the acceleration needed to do this is

$$a_y = \frac{v_y - v_{0y}}{t} = \frac{0 - 33\ \text{m/s}}{12.4\ \text{s}} = 2.66\ \text{m/s}^2$$

and the force needed is $F_{\text{PAPSh}} = ma = (150\ \text{kg})(2.66\ \text{m/s}^2) = 400\ \text{N}$, since there are no other horizontal forces.
EVALUATE: The acceleration produced by the PAPS must bring to zero both her horizontal and vertical components of velocity.

5.91. **IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$ to each block. Parts (a) and (b) will be done together.

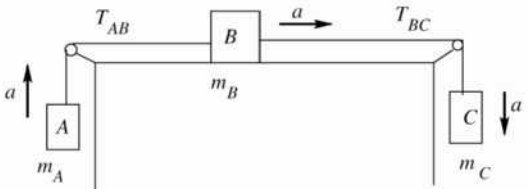

Figure 5.91a

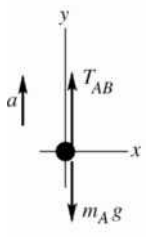
Note that each block has the same magnitude of acceleration, but in different directions. For each block let the direction of $\vec{a}$ be a positive coordinate direction.
SET UP: The free-body diagram for block A is given in Figure 5.91b.

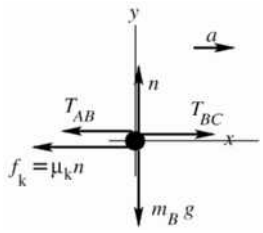


EXECUTE:
$\Sigma F_y = ma_y$
$T_{AB} - m_A g = m_A a$
$T_{AB} = m_A(a + g)$
$T_{AB} = 4.00\ \text{kg}(2.00\ \text{m/s}^2 + 9.80\ \text{m/s}^2) = 47.2\ \text{N}$

Figure 5.91b

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

SET UP: The free-body diagram for block *B* is given in Figure 5.91c.



EXECUTE:

$\Sigma F_y = ma_y$

$n - m_B g = 0$

$n = m_B g$

Figure 5.91c

$f_k = \mu_k n = \mu_k m_B g = (0.25)(12.0 \text{ kg})(9.80 \text{ m/s}^2) = 29.4 \text{ N}$

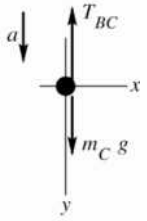
$\Sigma F_x = ma_x$

$T_{BC} - T_{AB} - f_k = m_B a$

$T_{BC} = T_{AB} + f_k + m_B a = 47.2 \text{ N} + 29.4 \text{ N} + (12.0 \text{ kg})(2.00 \text{ m/s}^2)$

$T_{BC} = 100.6 \text{ N}$

SET UP: The free-body diagram for block *C* is sketched in Figure 5.91d.



EXECUTE:

$\Sigma F_y = ma_y$

$m_C g - T_{BC} = m_C a$

$m_C (g - a) = T_{BC}$

$$m_C = \frac{T_{BC}}{g - a} = \frac{100.6 \text{ N}}{9.80 \text{ m/s}^2 - 2.00 \text{ m/s}^2} = 12.9 \text{ kg}$$

Figure 5.91d

EVALUATE: If all three blocks are considered together as a single object and $\Sigma\vec{F} = m\vec{a}$ is applied to this combined object, $m_C g - m_A g - \mu_k m_B g = (m_A + m_B + m_C)a$. Using the values for μ_k, m_A and m_B given in the problem and the mass m_C we calculated, this equation gives $a = 2.00 \text{ m/s}^2$, which checks.

5.92. **IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$ to each block. They have the same magnitude of acceleration, *a*.

SET UP: Consider positive accelerations to be to the right (up and to the right for the left-hand block, down and to the right for the right-hand block).

EXECUTE: **(a)** The forces along the inclines and the accelerations are related by $T - (100 \text{ kg})g \sin 30.0° = (100 \text{ kg})a$ and $(50 \text{ kg})g \sin 53.1° - T = (50 \text{ kg})a$, where *T* is the tension in the cord and *a* the mutual magnitude of acceleration. Adding these relations, $(50 \text{ kg} \sin 53.1° - 100 \text{ kg} \sin 30.0°)g = (50 \text{ kg} + 100 \text{ kg})a$, or $a = -0.067g$. Since *a* comes out negative, the blocks will slide to the left; the 100-kg block will slide down. Of course, if coordinates had been chosen so that positive accelerations were to the left, *a* would be $+0.067g$.

(b) $a = 0.067(9.80 \text{ m/s}^2) = 0.658 \text{ m/s}^2$.

(c) Substituting the value of *a* (including the proper sign, depending on choice of coordinates) into either of the above relations involving *T* yields 424 N.

EVALUATE: For part (a) we could have compared $mg \sin\theta$ for each block to determine which direction the system would move.

5.93. **IDENTIFY:** Let the tensions in the ropes be T_1 and T_2.

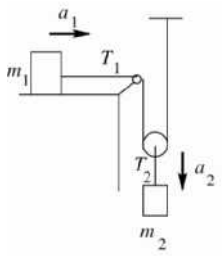

Figure 5.93a

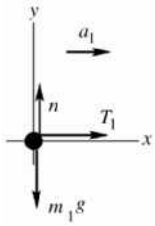
Consider the forces on each block. In each case take a positive coordinate direction in the direction of the acceleration of that block.

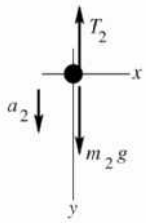
SET UP: The free-body diagram for m_1 is given in Figure 5.93b.



EXECUTE:
$\Sigma F_x = ma_x$
$T_1 = m_1 a_1$

Figure 5.93b

SET UP: The free-body diagram for m_2 is given in Figure 5.93c.

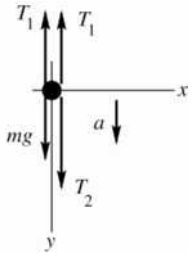


EXECUTE:
$\Sigma F_y = ma_y$
$m_2 g - T_2 = m_2 a_2$

Figure 5.93c

This gives us two equations, but there are four unknowns (T_1, T_2, a_1 and a_2) so two more equations are required.

SET UP: The free-body diagram for the moveable pulley (mass *m*) is given in Figure 5.93d.



EXECUTE:
$\Sigma F_y = ma_y$
$mg + T_2 - 2T_1 = ma$

Figure 5.93d

But our pulleys have negligible mass, so $mg = ma = 0$ and $T_2 = 2T_1$. Combine these three equations to eliminate T_1 and T_2: $m_2 g - T_2 = m_2 a_2$ gives $m_2 g - 2T_1 = m_2 a_2$. And then with $T_1 = m_1 a_1$ we have $m_2 g - 2m_1 a_1 = m_2 a_2$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

SET UP: There are still two unknowns, a_1 and a_2. But the accelerations a_1 and a_2 are related. In any time interval, if m_1 moves to the right a distance d, then in the same time m_2 moves downward a distance $d/2$. One of the constant acceleration kinematic equations says $x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2$, so if m_2 moves half the distance it must have half the acceleration of m_1: $a_2 = a_1/2$, or $a_1 = 2a_2$.

EXECUTE: This is the additional equation we need. Use it in the previous equation and get

$m_2 g - 2m_1(2a_2) = m_2 a_2$.

$a_2(4m_1 + m_2) = m_2 g$

$$a_2 = \frac{m_2 g}{4m_1 + m_2} \text{ and } a_1 = 2a_2 = \frac{2m_2 g}{4m_1 + m_2}.$$

EVALUATE: If $m_2 \to 0$ or $m_1 \to \infty$, $a_1 = a_2 = 0$. If $m_2 >> m_1$, $a_2 = g$ and $a_1 = 2g$.

5.94. **IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$ to block B, to block A and B as a composite object and to block C. If A and B slide together all three blocks have the same magnitude of acceleration.

SET UP: If A and B don't slip, the friction between them is static. The free-body diagrams for block B, for blocks A and B, and for C are given in Figures 5.94a–c. Block C accelerates downward and A and B accelerate to the right. In each case take a positive coordinate direction to be in the direction of the acceleration. Since block A moves to the right, the friction force f_s on block B is to the right, to prevent relative motion between the two blocks. When C has its largest mass, f_s has its largest value: $f_s = \mu_s n$.

EXECUTE: $\Sigma F_x = ma_x$ applied to the block B gives $f_s = m_B a$. $n = m_B g$ and $f_s = \mu_s m_B g$. $\mu_s m_B g = m_B a$ and $a = \mu_s g$. $\Sigma F_x = ma_x$ applied to blocks $A + B$ gives $T = m_{AB}a = m_{AB}\mu_s g$. $\Sigma F_y = ma_y$ applied to block C gives

$m_C g - T = m_C a$. $m_C g - m_{AB}\mu_s g = m_C \mu_s g$. $m_C = \frac{m_{AB}\mu_s}{1 - \mu_s} = (5.00 \text{ kg} + 8.00 \text{ kg})\left(\frac{0.750}{1 - 0.750}\right) = 39.0 \text{ kg}.$

EVALUATE: With no friction from the tabletop, the system accelerates no matter how small the mass of C is. If m_C is less than 39.0 kg, the friction force that A exerts on B is less than $\mu_s n$. If m_C is greater than 39.0 kg, blocks C and A have a larger acceleration than friction can give to block B, and A accelerates out from under B.

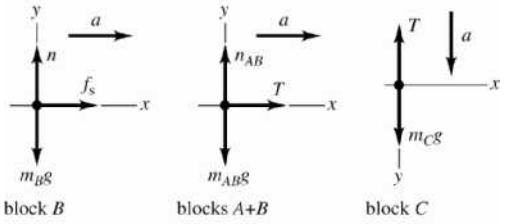


Figure 5.94

5.95. **IDENTIFY:** Apply the method of Exercise 5.15 to calculate the acceleration of each object. Then apply constant acceleration equations to the motion of the 2.00 kg object.

SET UP: After the 5.00 kg object reaches the floor, the 2.00 kg object is in free fall, with downward acceleration g.

EXECUTE: The 2.00-kg object will accelerate upward at $g\frac{5.00 \text{ kg} - 2.00 \text{ kg}}{5.00 \text{ kg} + 2.00 \text{ kg}} = 3g/7$, and the 5.00-kg object will accelerate downward at $3g/7$. Let the initial height above the ground be h_0. When the large object hits the ground, the small object will be at a height $2h_0$, and moving upward with a speed given by $v_0^2 = 2ah_0 = 6gh_0/7$. The small object will continue to rise a distance $v_0^2/2g = 3h_0/7$, and so the maximum height reached will be $2h_0 + 3h_0/7 = 17h_0/7 = 1.46$ m above the floor , which is 0.860 m above its initial height.

EVALUATE: The small object is 1.20 m above the floor when the large object strikes the floor, and it rises an additional 0.26 m after that.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

5.96. **IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$ to the box.

SET UP: The box has an upward acceleration of $a = 1.90 \text{ m/s}^2$.

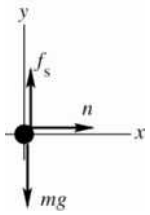
EXECUTE: The floor exerts an upward force n on the box, obtained from $n - mg = ma$, or $n = m(a + g)$. The friction force that needs to be balanced is

$$\mu_k n = \mu_k m(a + g) = (0.32)(28.0 \text{ kg})(1.90 \text{ m/s}^2 + 9.80 \text{ m/s}^2) = 105 \text{ N}.$$

EVALUATE: If the elevator wasn't accelerating the normal force would be $n = mg$ and the friction force that would have to be overcome would be 87.8 N. The upward acceleration increases the normal force and that increases the friction force.

5.97. **IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$ to the block. The cart and the block have the same acceleration. The normal force exerted by the cart on the block is perpendicular to the front of the cart, so is horizontal and to the right. The friction force on the block is directed so as to hold the block up against the downward pull of gravity. We want to calculate the minimum a required, so take static friction to have its maximum value, $f_s = \mu_s n$.

SET UP: The free-body diagram for the block is given in Figure 5.97.



EXECUTE:

$\Sigma F_x = ma_x$

$n = ma$

$f_s = \mu_s n = \mu_s ma$

Figure 5.97

$\Sigma F_y = ma_y$

$f_s - mg = 0$

$\mu_s ma = mg$

$a = g/\mu_s$

EVALUATE: An observer on the cart sees the block pinned there, with no reason for a horizontal force on it because the block is at rest relative to the cart. Therefore, such an observer concludes that $n = 0$ and thus $f_s = 0$, and he doesn't understand what holds the block up against the downward force of gravity. The reason for this difficulty is that $\Sigma\vec{F} = m\vec{a}$ does not apply in a coordinate frame attached to the cart. This reference frame is accelerated, and hence not inertial. The smaller μ_s is, the larger a must be to keep the block pinned against the front of the cart.

5.98. **IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$ to each block.

SET UP: Use coordinates where $+x$ is directed down the incline.

EXECUTE: **(a)** Since the larger block (the trailing block) has the larger coefficient of friction, it will need to be pulled down the plane; i.e., the larger block will not move faster than the smaller block, and the blocks will have the same acceleration. For the smaller block, $(4.00 \text{ kg})g(\sin 30° - (0.25)\cos 30°) - T = (4.00 \text{ kg})a$, or $11.11\,N - T = (4.00 \text{ kg})a$, and similarly for the larger, $15.44 \text{ N} + T = (8.00 \text{ kg})a$. Adding these two relations, $26.55 \text{ N} = (12.00 \text{ kg})a$, $a = 2.21 \text{ m/s}^2$.

(b) Substitution into either of the above relations gives $T = 2.27$ N.

(c) The string will be slack. The 4.00-kg block will have $a = 2.78 \text{ m/s}^2$ and the 8.00-kg block will have $a = 1.93 \text{ m/s}^2$, until the 4.00-kg block overtakes the 8.00-kg block and collides with it.

EVALUATE: If the string is cut the acceleration of each block will be independent of the mass of that block and will depend only on the slope angle and the coefficient of kinetic friction. The 8.00-kg block would have a smaller acceleration even though it has a larger mass, since it has a larger μ_k.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

5.99. **IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$ to the block and to the plank.

SET UP: Both objects have $a = 0$.

EXECUTE: Let n_B be the normal force between the plank and the block and n_A be the normal force between the block and the incline. Then, $n_B = w\cos\theta$ and $n_A = n_B + 3w\cos\theta = 4w\cos\theta$. The net frictional force on the block is $\mu_k(n_A + n_B) = \mu_k 5w\cos\theta$. To move at constant speed, this must balance the component of the block's weight along the incline, so $3w\sin\theta = \mu_k 5w\cos\theta$, and $\mu_k = \frac{3}{5}\tan\theta = \frac{3}{5}\tan 37° = 0.452$.

EVALUATE: In the absence of the plank the block slides down at constant speed when the slope angle and coefficient of friction are related by $\tan\theta = \mu_k$. For $\theta = 36.9°$, $\mu_k = 0.75$. A smaller μ_k is needed when the plank is present because the plank provides an additional friction force.

5.100. **IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$ to the ball, to m_1 and to m_2.

SET UP: The free-body diagrams for the ball, m_1 and m_2 are given in Figures 5.100a–c. All three objects have the same magnitude of acceleration. In each case take the direction of $\vec{a}$ to be a positive coordinate direction.

EXECUTE: **(a)** $\Sigma F_y = ma_y$ applied to the ball gives $T\cos\theta = mg$. $\Sigma F_x = ma_x$ applied to the ball gives $T\sin\theta = ma$. Combining these two equations to eliminate T gives $\tan\theta = a/g$.

(b) $\Sigma F_x = ma_x$ applied to m_2 gives $T = m_2 a$. $\Sigma F_y = ma_y$ applied to m_1 gives $m_1 g - T = m_1 a$. Combining these two equations gives $a = \left(\frac{m_1}{m_1 + m_2}\right)g$. Then $\tan\theta = \frac{m_1}{m_1 + m_2} = \frac{250\text{ kg}}{1500\text{ kg}}$ and $\theta = 9.46°$.

(c) As m_1 becomes much larger than m_2, $a \to g$ and $\tan\theta \to 1$, so $\theta \to 45°$.

EVALUATE: The device requires that the ball is at rest relative to the platform; any motion swinging back and forth must be damped out. When $m_1 << m_2$ the system still accelerates, but with small a and $\theta \to 0°$.

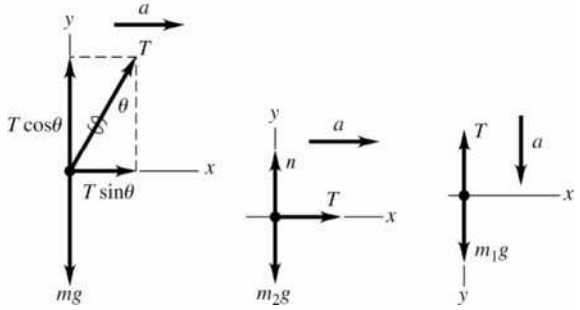


Figure 5.100a–c

5.101. **IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$ to the automobile.

SET UP: The "correct" banking angle is for zero friction and is given by $\tan\beta = \frac{v_0^2}{gR}$, as derived in Example 5.22. Use coordinates that are vertical and horizontal, since the acceleration is horizontal.

EXECUTE: For speeds larger than v_0, a frictional force is needed to keep the car from skidding. In this case, the inward force will consist of a part due to the normal force n and the friction force f; $n\sin\beta + f\cos\beta = ma_{rad}$. The normal and friction forces both have vertical components; since there is no vertical acceleration, $n\cos\beta - f\sin\beta = mg$. Using $f = \mu_s n$ and $a_{rad} = \frac{v^2}{R} = \frac{(1.5v_0)^2}{R} = 2.25\,g\tan\beta$, these two relations become $n\sin\beta + \mu_s n\cos\beta = 2.25\,mg\tan\beta$ and $n\cos\beta - \mu_s n\sin\beta = mg$. Dividing to

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

cancel n gives $\dfrac{\sin\beta+\mu_s\cos\beta}{\cos\beta-\mu_s\sin\beta}=2.25\tan\beta$. Solving for μ_s and simplifying yields $\mu_s=\dfrac{1.25\sin\beta\cos\beta}{1+1.25\sin^2\beta}$.

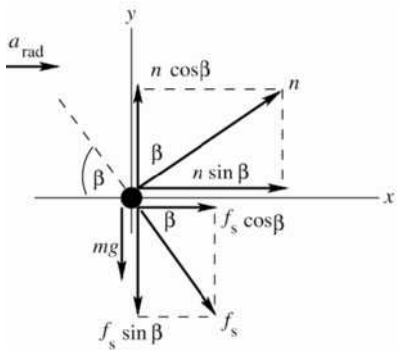
Using $\beta=\arctan\left(\dfrac{(20\text{ m/s})^2}{(9.80\text{ m/s}^2)(120\text{ m})}\right)=18.79°$ gives $\mu_s=0.34$.

EVALUATE: If μ_s is insufficient, the car skids away from the center of curvature of the roadway, so the friction is inward.

5.102. **IDENTIFY:** Apply $\Sigma\vec{F}=m\vec{a}$ to the car. The car moves in the arc of a horizontal circle, so $\vec{a}=\vec{a}_{\text{rad}}$, directed toward the center of curvature of the roadway. The target variable is the speed of the car. a_{rad} will be calculated from the forces and then v will be calculated from $a_{\text{rad}}=v^2/R$.

(a) To keep the car from sliding up the banking the static friction force is directed down the incline. At maximum speed the static friction force has its maximum value $f_s=\mu_s n$.

SET UP: The free-body diagram for the car is sketched in Figure 5.102a.



EXECUTE:

$\Sigma F_y=ma_y$

$n\cos\beta-f_s\sin\beta-mg=0$

But $f_s=\mu_s n$, so

$n\cos\beta-\mu_s n\sin\beta-mg=0$

$n=\dfrac{mg}{\cos\beta-\mu_s\sin\beta}$

Figure 5.102a

$\Sigma F_x=ma_x$

$n\sin\beta+\mu_s n\cos\beta=ma_{\text{rad}}$

$n(\sin\beta+\mu_s\cos\beta)=ma_{\text{rad}}$

Use the ΣF_y equation to replace n:

$\left(\dfrac{mg}{\cos\beta-\mu_s\sin\beta}\right)(\sin\beta+\mu_s\cos\beta)=ma_{\text{rad}}$

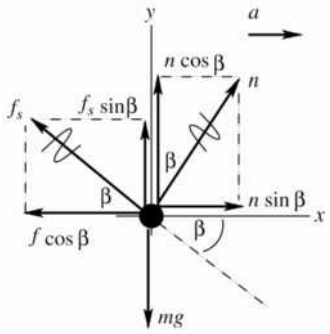
$a_{\text{rad}}=\left(\dfrac{\sin\beta+\mu_s\cos\beta}{\cos\beta-\mu_s\sin\beta}\right)g=\left(\dfrac{\sin 25°+(0.30)\cos 25°}{\cos 25°-(0.30)\sin 25°}\right)(9.80\text{ m/s}^2)=8.73\text{ m/s}^2$

$a_{\text{rad}}=v^2/R$ implies $v=\sqrt{a_{\text{rad}}R}=\sqrt{(8.73\text{ m/s}^2)(50\text{ m})}=21\text{ m/s}$.

(b) IDENTIFY: To keep the car from sliding *down* the banking the static friction force is directed up the incline. At the minimum speed the static friction force has its maximum value $f_s=\mu_s n$.

SET UP: The free-body diagram for the car is sketched in Figure 5.102b.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.



The free-body diagram is identical to that in part (a) except that now the components of f_s have opposite directions. The force equations are all the same except for the opposite sign for terms containing μ_s.

Figure 5.102b

EXECUTE: $a_{\text{rad}} = \left(\dfrac{\sin\beta - \mu_s\cos\beta}{\cos\beta + \mu_s\sin\beta}\right)g = \left(\dfrac{\sin 25° - (0.30)\cos 25°}{\cos 25° + (0.30)\sin 25°}\right)(9.80\ \text{m/s}^2) = 1.43\ \text{m/s}^2$

$v = \sqrt{a_{\text{rad}}R} = \sqrt{(1.43\ \text{m/s}^2)(50\ \text{m})} = 8.5\ \text{m/s}.$

EVALUATE: For v between these maximum and minimum values, the car is held on the road at a constant height by a static friction force that is less than $\mu_s n$. When $\mu_s \to 0$, $a_{\text{rad}} = g\tan\beta$. Our analysis agrees with the result of Example 5.22 in this special case.

5.103. **IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$ to each block.

SET UP: For block B use coordinates parallel and perpendicular to the incline. Since they are connected by ropes, blocks A and B also move with constant speed.

EXECUTE: **(a)** The free-body diagrams are sketched in Figure 5.103.

(b) The blocks move with constant speed, so there is no net force on block A; the tension in the rope connecting A and B must be equal to the frictional force on block A, $T_1 = (0.35)(25.0\ \text{N}) = 8.8\ \text{N}$.

(**c**) The weight of block C will be the tension in the rope connecting B and C; this is found by considering the forces on block B. The components of force along the ramp are the tension in the first rope (8.8 N, from part (b)), the component of the weight along the ramp, the friction on block B and the tension in the second rope. Thus, the weight of block C is

$$w_C = 8.8\ \text{N} + w_B(\sin 36.9° + \mu_k\cos 36.9°) = 8.8\ \text{N} + (25.0\ \text{N})(\sin 36.9° + (0.35)\cos 36.9°) = 30.8\ \text{N}$$

The intermediate calculation of the first tension may be avoided to obtain the answer in terms of the common weight w of blocks A and B, $w_C = w(\mu_k + (\sin\theta + \mu_k\cos\theta))$, giving the same result.

(d) Applying Newton's second law to the remaining masses (B and C) gives:

$$a = g(w_C - \mu_k w_B\cos\theta - w_B\sin\theta)/(w_B + w_C) = 1.54\ \text{m/s}^2.$$

EVALUATE: Before the rope between A and B is cut the net external force on the system is zero. When the rope is cut the friction force on A is removed from the system and there is a net force on the system of blocks B and C.

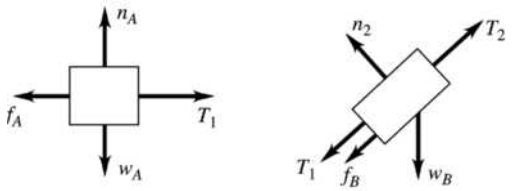


Figure 5.103

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

5.104. **IDENTIFY:** The analysis of this problem is the same as that of Example 5.20.

SET UP: From Example 5.20, $\tan\beta = \dfrac{a_{\text{rad}}}{g} = \dfrac{v^2}{Rg}$.

EXECUTE: Solving for v in terms of β and R,

$v = \sqrt{gR\tan\beta} = \sqrt{(9.80\ \text{m/s}^2)(50.0\ \text{m})\tan 30.0^\circ} = 16.8\ \text{m/s}$, about 60.6 km/h.

EVALUATE: The greater the speed of the bus the larger will be the angle β, so T will have a larger horizontal, inward component.

5.105. **IDENTIFY** and **SET UP:** The monkey and bananas have the same mass and the tension in the rope has the same upward value at the bananas and at the monkey. Therefore, the monkey and bananas will have the same net force and hence the same acceleration, in both magnitude and direction.

EXECUTE: **(a)** For the monkey to move up, $T > mg$. The bananas also move up.

(b) The bananas and monkey move with the same acceleration and the distance between them remains constant.

(c) Both the monkey and bananas are in free fall. They have the same initial velocity and as they fall the distance between them doesn't change.

(d) The bananas will slow down at the same rate as the monkey. If the monkey comes to a stop, so will the bananas.

EVALUATE: None of these actions bring the monkey any closer to the bananas.

5.106. **IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$, with $f = kv$.

SET UP: Follow the analysis that leads to Eq. (5.10), except now the initial speed is $v_{0y} = 3mg/k = 3v_t$ rather than zero.

EXECUTE: The separated equation of motion has a lower limit of $3v_t$ instead of 0; specifically,

$$\int_{3v_t}^{v} \frac{dv}{v - v_t} = \ln\frac{v_t - v}{-2v_t} = \ln\left(\frac{v}{2v_t} - \frac{1}{2}\right) = -\frac{k}{m}t, \text{ or } v = 2v_t\left[\frac{1}{2} + e^{-(k/m)t}\right].$$

EVALUATE: As $t \to \infty$ the speed approaches v_t. The speed is always greater than v_t and this limit is approached from above.

5.107. **IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$ to the rock.

SET UP: Equations 5.9 through 5.13 apply, but with a_0 rather than g as the initial acceleration.

EXECUTE: **(a)** The rock is released from rest, and so there is initially no resistive force and $a_0 = (18.0\ \text{N})/(3.00\ \text{kg}) = 6.00\ \text{m/s}^2$.

(b) $(18.0\ \text{N} - (2.20\ \text{N}\cdot\text{s/m})\ (3.00\ \text{m/s}))/(3.00\ \text{kg}) = 3.80\ \text{m/s}^2$.

(c) The net force must be 1.80 N, so $kv = 16.2\ \text{N}$ and $v = (16.2\ \text{N})/(2.20\ \text{N}\cdot\text{s/m}) = 7.36\ \text{m/s}$.

(d) When the net force is equal to zero, and hence the acceleration is zero, $kv_t = 18.0\ \text{N}$ and $v_t = (18.0\ \text{N})/(2.20\ \text{N}\cdot\text{s/m}) = 8.18\ \text{m/s}$.

(e) From Eq. (5.12),

$$y = (8.18\ \text{m/s})\left[(2.00\ \text{s}) - \frac{3.00\ \text{kg}}{2.20\ \text{N}\cdot\text{s/m}}\left(1 - e^{-((2.20\ \text{N}\cdot\text{s/m})/(3.00\ \text{kg}))(2.00\ \text{s})}\right)\right] = +7.78\ \text{m}.$$

From Eq. (5.10), $v = (8.18\ \text{m/s})\left[1 - e^{-((2.20\ \text{N}\cdot\text{s/m})/(3.00\ \text{kg}))(2.00\ \text{s})}\right] = 6.29\ \text{m/s}$.

From Eq. (5.11), but with a_0 instead of g, $a = (6.00\ \text{m/s}^2)e^{-((2.20\ \text{N}\cdot\text{s/m})/(3.00\ \text{kg}))(2.00\ \text{s})} = 1.38\ \text{m/s}^2$.

(f) $1 - \dfrac{v}{v_t} = 0.1 = e^{-(k/m)t}$ and $t = \dfrac{m}{k}\ln(10) = 3.14\ \text{s}$.

EVALUATE: The acceleration decreases with time until it becomes zero when $v = v_t$. The speed increases with time and approaches v_t as $t \to \infty$.

5.108. **IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$ to the rock. $a = \dfrac{dv}{dt}$ and $v = \dfrac{dx}{dt}$ yield differential equations that can be integrated to give $v(t)$ and $x(t)$.

SET UP: The retarding force of the surface is the only horizontal force acting.

EXECUTE: **(a)** Thus $a = \dfrac{F_{\text{net}}}{m} = \dfrac{F_{\text{R}}}{m} = \dfrac{-kv^{1/2}}{m} = \dfrac{dv}{dt}$ and $\dfrac{dv}{v^{1/2}} = -\dfrac{k}{m}dt$. Integrating gives $\displaystyle\int_{v_0}^{v}\frac{dv}{v^{1/2}} = -\frac{k}{m}\int_0^t dt$ and $2v^{1/2}\Big|_{v_0}^{v} = -\dfrac{kt}{m}$. This gives $v = v_0 - \dfrac{v_0^{1/2}kt}{m} + \dfrac{k^2t^2}{4m^2}$.

For the rock's position: $\dfrac{dx}{dt} = v_0 - \dfrac{v_0^{1/2}kt}{m} + \dfrac{k^2t^2}{4m^2}$ and $dx = v_0dt - \dfrac{v_0^{1/2}ktdt}{m} + \dfrac{k^2t^2dt}{4m^2}$.

Integrating gives $x = v_0t - \dfrac{v_0^{1/2}kt^2}{2m} + \dfrac{k^2t^3}{12m^2}$.

(b) $v = 0 = v_0 - \dfrac{v_0^{1/2}kt}{m} + \dfrac{k^2t^2}{2m^2}$. This is a quadratic equation in t; from the quadratic formula we can find the single solution $t = \dfrac{2mv_0^{1/2}}{k}$.

(c) Substituting the expression for t into the equation for x:

$$x = v_0\cdot\frac{2mv_0^{1/2}}{k} - \frac{v_0^{1/2}k}{2m}\cdot\frac{4m^2v_0}{k^2} + \frac{k^2}{12m^2}\cdot\frac{8m^3v_0^{3/2}}{k^3} = \frac{2mv_0^{3/2}}{3k}$$

EVALUATE: The magnitude of the average acceleration is $a_{\text{av}} = \left|\dfrac{\Delta v}{\Delta t}\right| = \dfrac{v_0}{(2mv_0^{1/2}/k)} = \dfrac{1}{2}\dfrac{kv_0^{1/2}}{m}$. The average force is $F_{\text{av}} = ma_{\text{av}} = \frac{1}{2}kv_0^{1/2}$, which is $\frac{1}{2}$ times the initial value of the force.

5.109. **IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$ to the car.

SET UP: The forces on the car are the air drag force $f_{\text{D}} = Dv^2$ and the rolling friction force $\mu_{\text{r}}mg$. Take the velocity to be in the $+x$-direction. The forces are opposite in direction to the velocity.

EXECUTE: **(a)** $\Sigma F_x = ma_x$ gives $-Dv^2 - \mu_{\text{r}}mg = ma$. We can write this equation twice, once with $v = 32$ m/s and $a = -0.42$ m/s^2 and once with $v = 24$ m/s and $a = -0.30$ m/s^2. Solving these two simultaneous equations in the unknowns D and μ_{r} gives $\mu_{\text{r}} = 0.015$ and $D = 0.36$ N $\cdot$ s^2/m^2.

(b) $n = mg\cos\beta$ and the component of gravity parallel to the incline is $mg\sin\beta$, where $\beta = 2.2°$. For constant speed, $mg\sin 2.2° - \mu_{\text{r}}mg\cos 2.2° - Dv^2 = 0$. Solving for v gives $v = 29$ m/s.

(c) For angle β, $mg\sin\beta - \mu_{\text{r}}mg\cos\beta - Dv^2 = 0$ and $v = \sqrt{\dfrac{mg(\sin\beta - \mu_{\text{r}}\cos\beta)}{D}}$. The terminal speed for a falling object is derived from $Dv_{\text{t}}^2 - mg = 0$, so $v_{\text{t}} = \sqrt{mg/D}$. $v/v_{\text{t}} = \sqrt{\sin\beta - \mu_{\text{r}}\cos\beta}$. And since $\mu_{\text{r}} = 0.015$, $v/v_{\text{t}} = \sqrt{\sin\beta - (0.015)\cos\beta}$.

EVALUATE: In part (c), $v \to v_{\text{t}}$ as $\beta \to 90°$, since in that limit the incline becomes vertical.

5.110. **IDENTIFY:** The block has acceleration $a_{\text{rad}} = v^2/r$, directed to the left in the figure in the problem. Apply $\Sigma\vec{F} = m\vec{a}$ to the block.

SET UP: The block moves in a horizontal circle of radius $r = \sqrt{(1.25\text{ m})^2 - (1.00\text{ m})^2} = 0.75$ m. Each string makes an angle θ with the vertical. $\cos\theta = \dfrac{1.00\text{ m}}{1.25\text{ m}}$, so $\theta = 36.9°$. The free-body diagram for the block is given in Figure 5.110. Let $+x$ be to the left and let $+y$ be upward.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: **(a)** $\Sigma F_y = ma_y$ gives $T_u \cos\theta - T_l \cos\theta - mg = 0$.

$T_l = T_u - \dfrac{mg}{\cos\theta} = 80.0 \text{ N} - \dfrac{(4.00 \text{ kg})(9.80 \text{ m/s}^2)}{\cos 36.9°} = 31.0 \text{ N}.$

(b) $\Sigma F_x = ma_x$ gives $(T_u + T_l)\sin\theta = m\dfrac{v^2}{r}$.

$v = \sqrt{\dfrac{r(T_u + T_l)\sin\theta}{m}} = \sqrt{\dfrac{(0.75 \text{ m})(80.0 \text{ N} + 31.0 \text{ N})\sin 36.9°}{4.00 \text{ kg}}} = 3.53 \text{ m/s}.$ The number of revolutions per second is $\dfrac{v}{2\pi r} = \dfrac{3.53 \text{ m/s}}{2\pi(0.75 \text{ m})} = 0.749 \text{ rev/s} = 44.9 \text{ rev/min}.$

(c) If $T_l \to 0$, $T_u \cos\theta = mg$ and $T_u = \dfrac{mg}{\cos\theta} = \dfrac{(4.00 \text{ kg})(9.80 \text{ m/s}^2)}{\cos 36.9°} = 49.0 \text{ N}$. $T_u \sin\theta = m\dfrac{v^2}{r}$.

$v = \sqrt{\dfrac{rT_u \sin\theta}{m}} = \sqrt{\dfrac{(0.75 \text{ m})(49.0 \text{ N})\sin 36.9°}{4.00 \text{ kg}}} = 2.35 \text{ m/s}.$ The number of revolutions per minute is

$(44.9 \text{ rev/min})\left(\dfrac{2.35 \text{ m/s}}{3.53 \text{ m/s}}\right) = 29.9 \text{ rev/min}.$

EVALUATE: The tension in the upper string must be greater than the tension in the lower string so that together they produce an upward component of force that balances the weight of the block.

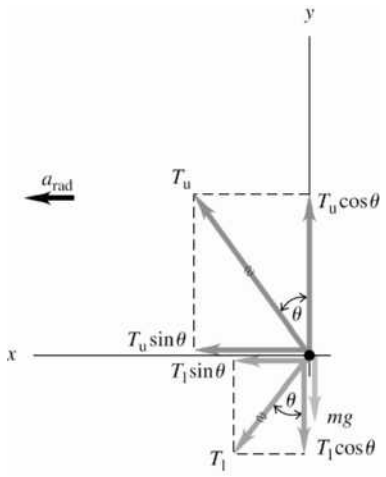

Figure 5.110

5.111. **IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$ to the falling object.

SET UP: Follow the steps that lead to Eq. (5.10), except now $v_{0y} = v_0$ and is not zero.

EXECUTE: **(a)** Newton's second law gives $m\dfrac{dv_y}{dt} = mg - kv_y$, where $\dfrac{mg}{k} = v_t$. $\displaystyle\int_{v_0}^{v_y} \frac{dv_y}{v_y - v_t} = -\frac{k}{m}\int_0^t dt$. This is the same expression used in the derivation of Eq. (5.10), except the lower limit in the velocity integral is the initial speed v_0 instead of zero. Evaluating the integrals and rearranging gives $v_y = v_0 e^{-kt/m} + v_t(1 - e^{-kt/m})$. Note that at $t = 0$ this expression says $v_y = v_0$ and at $t \to \infty$ it says $v_y \to v_t$.

(b) The downward gravity force is larger than the upward fluid resistance force so the acceleration is downward, until the fluid resistance force equals gravity when the terminal speed is reached. The object speeds up until $v_y = v_t$. Take $+y$ to be downward. The graph is sketched in Figure 5.111a.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(c) The upward resistance force is larger than the downward gravity force so the acceleration is upward and the object slows down, until the fluid resistance force equals gravity when the terminal speed is reached. Take $+y$ to be downward. The graph is sketched in Figure 5.111b.

(d) When $v_0 = v_t$ the acceleration at $t = 0$ is zero and remains zero; the velocity is constant and equal to the terminal velocity.

EVALUATE: In all cases the speed becomes v_t as $t \to \infty$.

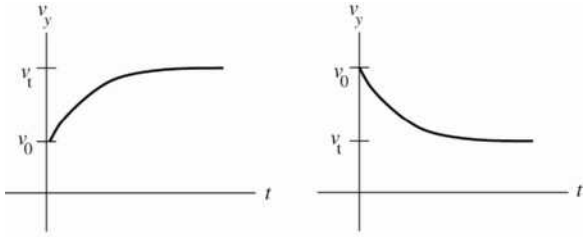

Figure 5.111a, b

5.112. **IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$ to the rock.

SET UP: At the maximum height, $v_y = 0$. Let $+y$ be upward. Suppress the y subscripts on v and a.

EXECUTE: **(a)** To find the maximum height and time to the top without fluid resistance:

$v^2 = v_0^2 + 2a(y - y_0)$ and $y - y_0 = \dfrac{v^2 - v_0^2}{2a} = \dfrac{0 - (6.0\text{ m/s})^2}{2(-9.8\text{ m/s}^2)} = 1.84\text{ m}$. $t = \dfrac{v - v_0}{a} = \dfrac{0 - 6.0\text{ m/s}}{-9.8\text{ m/s}^2} = 0.61\text{ s}$.

(**b)** Starting from Newton's second law for this situation $m\dfrac{dv}{dt} = mg - kv$. We rearrange and integrate, taking downward as positive as in the text and noting that the velocity at the top of the rock's flight is zero. The initial velocity is upward, so $v_0 = -6.0$ m/s. $\displaystyle\int_{v_0}^{0} \frac{dv}{v - v_t} = -\frac{k}{m}t$.

$$\ln(v - v_t)\Big|_{v_0}^{0} = \ln\frac{-v_t}{v_0 - v_t} = \ln\frac{-2.0\text{ m/s}}{-6.0\text{ m/s} - 2.0\text{ m/s}} = \ln(0.25) = -1.386$$

From Eq. (5.9), $m/k = v_t/g = (2.0\text{ m/s}^2)/(9.8\text{ m/s}^2) = 0.204$ s, and

$t = -\dfrac{m}{k}(-1.386) = (0.204\text{ s})(1.386) = 0.283$ s to the top.

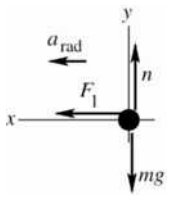
Integrating the expression for $v_y = dy/dt$ in part (a) of Problem 5.111 gives $y = \dfrac{m}{k}e^{-kt/m}(v_t - v_0) + v_t t$.

At $t = 0.283$ s, $y = 0.974$ m. At $t = 0$, $y = 1.63$ m. Therefore, $y - y_0 = -0.66$ m. since $+y$ is downward, this says that the rock rises to a maximum height of 0.66 m above its initial position.

EVALUATE: With fluid resistance present the maximum height is much less and the time to reach it is less.

5.113. **(a) IDENTIFY:** Use the information given about Jena to find the time t for one revolution of the merry-go-round. Her acceleration is a_{rad}, directed in toward the axis. Let $\vec{F}_1$ be the horizontal force that keeps her from sliding off. Let her speed be v_1 and let R_1 be her distance from the axis. Apply $\Sigma\vec{F} = m\vec{a}$ to Jena, who moves in uniform circular motion.

SET UP: The free-body diagram for Jena is sketched in Figure 5.113a



EXECUTE:

$\Sigma F_x = ma_x$

$F_1 = ma_{rad}$

$F_1 = m\dfrac{v_1^2}{R_1}$, $v_1 = \sqrt{\dfrac{R_1 F_1}{m}} = 1.90$ m/s

Figure 5.113a

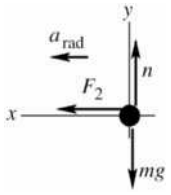
© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

The time for one revolution is $t = \dfrac{2\pi R_1}{v_1} = 2\pi R_1\sqrt{\dfrac{m}{R_1F_1}}$. Jackie goes around once in the same time but her speed (v_2) and the radius of her circular path (R_2) are different.

$$v_2 = \frac{2\pi R_2}{t} = 2\pi R_2\left(\frac{1}{2\pi R_1}\right)\sqrt{\frac{R_1F_1}{m}} = \frac{R_2}{R_1}\sqrt{\frac{R_1F_1}{m}}.$$

IDENTIFY: Now apply $\Sigma\vec{F} = m\vec{a}$ to Jackie. She also moves in uniform circular motion.

SET UP: The free-body diagram for Jackie is sketched in Figure 5.113b.



EXECUTE:
$\Sigma F_x = ma_x$
$F_2 = ma_{\text{rad}}$

Figure 5.113b

$$F_2 = m\frac{v_2^2}{R_2} = \left(\frac{m}{R_2}\right)\left(\frac{R_2^2}{R_1^2}\right)\left(\frac{R_1F_1}{m}\right) = \left(\frac{R_2}{R_1}\right)F_1 = \left(\frac{3.60\text{ m}}{1.80\text{ m}}\right)(60.0\text{ N}) = 120.0\text{ N}$$

(b) $F_2 = m\dfrac{v_2^2}{R_2}$, so $v_2 = \sqrt{\dfrac{F_2R_2}{m}} = \sqrt{\dfrac{(120.0\text{ N})(3.60\text{ m})}{30.0\text{ kg}}} = 3.79\text{ m/s}$

EVALUATE: Both girls rotate together so have the same period *T*. By Eq. (5.16), a_{rad} is larger for Jackie so the force on her is larger. Eq. (5.15) says $R_1/v_1 = R_2/v_2$ so $v_2 = v_1(R_2/R_1)$; this agrees with our result in (a).

5.114. **IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$ to the person and to the cart.

SET UP: The apparent weight, w_{app} is the same as the upward force on the person exerted by the car seat.

EXECUTE: (a) The apparent weight is the actual weight of the person minus the centripetal force needed to keep him moving in his circular path:

$$w_{\text{app}} = mg - \frac{mv^2}{R} = (70\text{ kg})\left[(9.8\text{ m/s}^2) - \frac{(12\text{ m/s})^2}{40\text{ m}}\right] = 434\text{ N}.$$

(b) The cart will lose contact with the surface when its apparent weight is zero; i.e., when the road no longer has to exert any upward force on it: $mg - \dfrac{mv^2}{R} = 0$. $v = \sqrt{Rg} = \sqrt{(40\text{ m})\ (9.8\text{ m/s}^2)} = 19.8\text{ m/s}$. The answer doesn't depend on the cart's mass, because the centripetal force needed to hold it on the road is proportional to its mass and so to its weight, which provides the centripetal force in this situation.

EVALUATE: At the speed calculated in part (b), the downward force needed for circular motion is provided by gravity. For speeds greater than this, more downward force is needed and there is no source for it and the cart leaves the circular path. For speeds less than this, less downward force than gravity is needed, so the roadway must exert an upward vertical force.

5.115. **IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$ to the person. The person moves in a horizontal circle so his acceleration is $a_{\text{rad}} = v^2/R$, directed toward the center of the circle. The target variable is the coefficient of static friction between the person and the surface of the cylinder.

$$v = (0.60\text{ rev/s})\left(\frac{2\pi R}{1\text{ rev}}\right) = (0.60\text{ rev/s})\left(\frac{2\pi(2.5\text{ m})}{1\text{ rev}}\right) = 9.425\text{ m/s}$$

(a) SET UP: The problem situation is sketched in Figure 5.115a.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

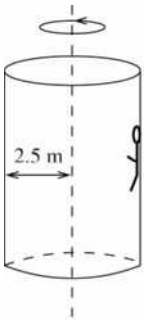


Figure 5.115a

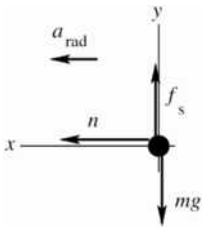


The free-body diagram for the person is sketched in Figure 5.115b.
The person is held up against gravity by the static friction force exerted on him by the wall.
The acceleration of the person is a_{rad}, directed in toward the axis of rotation.

Figure 5.115b

(b) EXECUTE: To calculate the minimum μ_s required, take f_s to have its maximum value, $f_s = \mu_s n$.

$\Sigma F_y = ma_y$

$f_s - mg = 0$

$\mu_s n = mg$

$\Sigma F_x = ma_x$

$n = mv^2/R$

Combine these two equations to eliminate n:

$\mu_s mv^2/R = mg$

$$\mu_s = \frac{Rg}{v^2} = \frac{(2.5\text{ m})(9.80\text{ m/s}^2)}{(9.425\text{ m/s})^2} = 0.28$$

(c) EVALUATE: No, the mass of the person divided out of the equation for μ_s. Also, the smaller μ_s is, the larger v must be to keep the person from sliding down. For smaller μ_s the cylinder must rotate faster to make n large enough.

5.116. **IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$ to the passenger. The passenger has acceleration a_{rad}, directed inward toward the center of the circular path.

SET UP: The passenger's velocity is $v = 2\pi R/t = 8.80$ m/s. The vertical component of the seat's force must balance the passenger's weight and the horizontal component must provide the centripetal force.

EXECUTE: **(a)** $F_{seat}\sin\theta = mg = 833$ N and $F_{seat}\cos\theta = \dfrac{mv^2}{R} = 188$ N. Therefore

$\tan\theta = (833\text{ N})/(188\text{ N}) = 4.43$; $\theta = 77.3°$ above the horizontal. The magnitude of the net force exerted by the seat (note that this is not the net force on the passenger) is

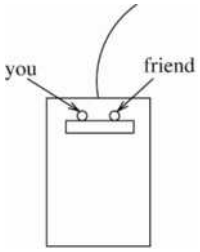
$$F_{seat} = \sqrt{(833\text{ N})^2 + (188\text{ N})^2} = 854\text{ N}$$

(b) The magnitude of the force is the same, but the horizontal component is reversed.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: At the highest point in the motion, $F_{\text{seat}} = mg - m\dfrac{v^2}{R} = 645$ N. At the lowest point in the motion, $F_{\text{seat}} = mg + m\dfrac{v^2}{R} = 1021$ N. The result in parts (a) and (b) lies between these extreme values.

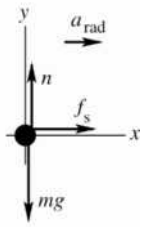
5.117. **IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$ to your friend. Your friend moves in the arc of a circle as the car turns.
(a) Turn to the right. The situation is sketched in Figure 5.117a.



As viewed in an inertial frame, in the absence of sufficient friction your friend doesn't make the turn completely and you move to the right toward your friend.

Figure 5.117a

(b) The maximum radius of the turn is the one that makes a_{rad} just equal to the maximum acceleration that static friction can give to your friend, and for this situation f_s has its maximum value $f_s = \mu_s n$.
SET UP: The free-body diagram for your friend, as viewed by someone standing behind the car, is sketched in Figure 5.117b.



EXECUTE:
$\Sigma F_y = ma_y$
$n - mg = 0$
$n = mg$

Figure 5.117b

$\Sigma F_x = ma_x$
$f_s = ma_{\text{rad}}$
$\mu_s n = mv^2/R$
$\mu_s mg = mv^2/R$
$R = \dfrac{v^2}{\mu_s g} = \dfrac{(20\text{ m/s})^2}{(0.35)(9.80\text{ m/s}^2)} = 120\text{ m}$

EVALUATE: The larger μ_s is, the smaller the radius R must be.

5.118. **IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$ to the combined object of motorcycle plus rider.
SET UP: The object has acceleration $a_{\text{rad}} = v^2/r$, directed toward the center of the circular path.
EXECUTE: **(a)** For the tires not to lose contact, there must be a downward force on the tires. Thus, the (downward) acceleration at the top of the sphere must exceed mg, so $m\dfrac{v^2}{R} > mg$, and
$v > \sqrt{gR} = \sqrt{(9.80\text{ m/s}^2)\ (13.0\text{ m})} = 11.3\text{ m/s}.$

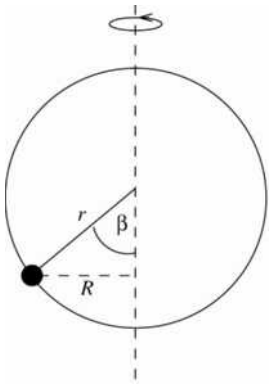
© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) The (upward) acceleration will then be $4g$, so the upward normal force must be $5mg = 5(110\text{ kg})(9.80\text{ m/s}^2) = 5390\text{ N}$.

EVALUATE: At any nonzero speed the normal force at the bottom of the path exceeds the weight of the object.

5.119. **IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$ to the circular motion of the bead. Also use Eq. (5.16) to relate a_{rad} to the period of rotation T.

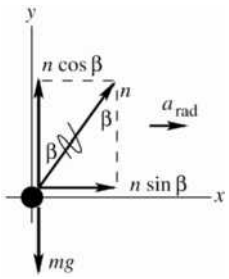
SET UP: The bead and hoop are sketched in Figure 5.119a.



The bead moves in a circle of radius $R = r\sin\beta$. The normal force exerted on the bead by the hoop is radially inward.

Figure 5.119a

The free-body diagram for the bead is sketched in Figure 5.119b.



EXECUTE:

$\Sigma F_y = ma_y$

$n\cos\beta - mg = 0$

$n = mg/\cos\beta$

$\Sigma F_x = ma_x$

$n\sin\beta = ma_{\text{rad}}$

Figure 5.119b

Combine these two equations to eliminate n:

$$\left(\frac{mg}{\cos\beta}\right)\sin\beta = ma_{\text{rad}}$$

$$\frac{\sin\beta}{\cos\beta} = \frac{a_{\text{rad}}}{g}$$

$a_{\text{rad}} = v^2/R$ and $v = 2\pi R/T$, so $a_{\text{rad}} = 4\pi^2 R/T^2$, where T is the time for one revolution.

$R = r\sin\beta$, so $a_{\text{rad}} = \dfrac{4\pi^2 r\sin\beta}{T^2}$

Use this in the above equation: $\dfrac{\sin\beta}{\cos\beta} = \dfrac{4\pi^2 r\sin\beta}{T^2 g}$

This equation is satisfied by $\sin\beta = 0$, so $\beta = 0$, or by

$\dfrac{1}{\cos\beta} = \dfrac{4\pi^2 r}{T^2 g}$, which gives $\cos\beta = \dfrac{T^2 g}{4\pi^2 r}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(a) 4.00 rev/s implies $T = (1/4.00)\ \text{s} = 0.250\ \text{s}$

Then $\cos\beta = \dfrac{(0.250\ \text{s})^2(9.80\ \text{m/s}^2)}{4\pi^2(0.100\ \text{m})}$ and $\beta = 81.1°$.

(b) This would mean $\beta = 90°$. But $\cos 90° = 0$, so this requires $T \to 0$. So β approaches $90°$ as the hoop rotates very fast, but $\beta = 90°$ is not possible.

(c) 1.00 rev/s implies $T = 1.00\ \text{s}$

The $\cos\beta = \dfrac{T^2 g}{4\pi^2 r}$ equation then says $\cos\beta = \dfrac{(1.00\ \text{s})^2(9.80\ \text{m/s}^2)}{4\pi^2(0.100\ \text{m})} = 2.48,$ which is not possible. The only way to have the $\Sigma\vec{F} = m\vec{a}$ equations satisfied is for $\sin\beta = 0$. This means $\beta = 0;$ the bead sits at the bottom of the hoop.

EVALUATE: $\beta \to 90°$ as $T \to 0$ (hoop moves faster). The largest value T can have is given by $T^2 g/(4\pi^2 r) = 1$ so $T = 2\pi\sqrt{r/g} = 0.635$ s. This corresponds to a rotation rate of $(1/0.635)$ rev/s $= 1.58$ rev/s. For a rotation rate less than 1.58 rev/s, $\beta = 0$ is the only solution and the bead sits at the bottom of the hoop. Part (c) is an example of this.

5.120. **IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$ to the car. It has acceleration $\vec{a}_{\text{rad}},$ directed toward the center of the circular path.

SET UP: The analysis is the same as in Example 5.23.

EXECUTE: **(a)** $F_A = m\left(g + \dfrac{v^2}{R}\right) = (1.60\ \text{kg})\left(9.80\ \text{m/s}^2 + \dfrac{(12.0\ \text{m/s})^2}{5.00\ \text{m}}\right) = 61.8\ \text{N}.$

(b) $F_B = m\left(g - \dfrac{v^2}{R}\right) = (1.60\ \text{kg})\left(9.80\ \text{m/s}^2 - \dfrac{(12.0\ \text{m/s})^2}{5.00\ \text{m}}\right) = -30.4\ \text{N}.,$ where the minus sign indicates that the track pushes down on the car. The magnitude of this force is 30.4 N.

EVALUATE: $|F_A| > |F_B|$. $|F_A| - 2mg = |F_B|$.

5.121. **IDENTIFY:** Use the results of Problem 5.38.

SET UP: $f(x)$ is a minimum when $\dfrac{df}{dx} = 0$ and $\dfrac{d^2 f}{dx^2} > 0.$

EXECUTE: **(a)** $F = \mu_{\text{k}} w/(\cos\theta + \mu_{\text{k}}\sin\theta)$

(b) The graph of F versus θ is given in Figure 5.121.

(c) F is minimized at $\tan\theta = \mu_{\text{k}}$. For $\mu_{\text{k}} = 0.25,$ $\theta = 14.0°$.

EVALUATE: Small θ means F is more nearly in the direction of the motion. But $\theta \to 90°$ means F is directed to reduce the normal force and thereby reduce friction. The optimum value of θ is somewhere in between and depends on μ_{k}.

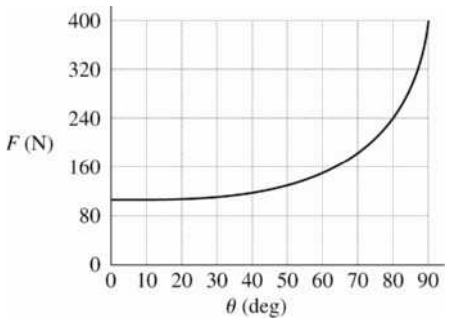


Figure 5.121

5.122. **IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$ to the block and to the wedge.

SET UP: For both parts, take the *x*-direction to be horizontal and positive to the right, and the *y*-direction to be vertical and positive upward. The normal force between the block and the wedge is *n*; the normal force between the wedge and the horizontal surface will not enter, as the wedge is presumed to have zero vertical acceleration. The horizontal acceleration of the wedge is *A*, and the components of acceleration of the block are a_x and a_y.

EXECUTE: **(a)** The equations of motion are then $MA = -n\sin\alpha$, $ma_x = n\sin\alpha$ and $ma_y = n\cos\alpha - mg$. Note that the normal force gives the wedge a negative acceleration; the wedge is expected to move to the left. These are three equations in four unknowns, A, a_x, a_y and n. Solution is possible with the imposition of the relation between A, a_x and a_y. An observer on the wedge is not in an inertial frame, and should not apply Newton's laws, but the kinematic relation between the components of acceleration are not so restricted. To such an observer, the vertical acceleration of the block is a_y, but the horizontal acceleration of the block is $a_x - A$. To this observer, the block descends at an angle α, so the relation needed is $\dfrac{a_y}{a_x - A} = -\tan\alpha$. At this point, algebra is unavoidable. A possible approach is to eliminate a_x by noting that $a_x = -\dfrac{M}{m}A$, using this in the kinematic constraint to eliminate a_y and then eliminating *n*. The results are:

$$A = \frac{-gm}{(M+m)\tan\alpha + (M/\tan\alpha)}$$

$$a_x = \frac{gM}{(M+m)\tan\alpha + (M/\tan\alpha)}$$

$$a_y = \frac{-g(M+m)\tan\alpha}{(M+m)\tan\alpha + (M/\tan\alpha)}$$

(b) When $M >> m$, $A \to 0$, as expected (the large block won't move). Also, $a_x \to \dfrac{g}{\tan\alpha + (1/\tan\alpha)} = g\dfrac{\tan\alpha}{\tan^2\alpha + 1} = g\sin\alpha\cos\alpha$ which is the acceleration of the block ($g\sin\alpha$ in this case), with the factor of $\cos\alpha$ giving the horizontal component. Similarly, $a_y \to -g\sin^2\alpha$.

(c) The trajectory is a straight line with slope $-\left(\dfrac{M+m}{M}\right)\tan\alpha$.

EVALUATE: If $m >> M$, our general results give $a_x = 0$ and $a_y = -g$. The massive block accelerates straight downward, as if it were in free fall.

5.123. **IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$ to the block and to the wedge.

SET UP: From Problem 5.122, $ma_x = n\sin\alpha$ and $ma_y = n\cos\alpha - mg$ for the block. $a_y = 0$ gives $a_x = g\tan\alpha$.

EXECUTE: If the block is not to move vertically, both the block and the wedge have this horizontal acceleration and the applied force must be $F = (M+m)a = (M+m)g\tan\alpha$.

EVALUATE: $F \to 0$ as $\alpha \to 0$ and $F \to \infty$ as $\alpha \to 90°$.

5.124. **IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$ to the ball. At the terminal speed, $a = 0$.

SET UP: For convenience, take the positive direction to be down, so that for the baseball released from rest, the acceleration and velocity will be positive, and the speed of the baseball is the same as its positive component of velocity. Then the resisting force, directed against the velocity, is upward and hence negative.

EXECUTE: **(a)** The free-body diagram for the falling ball is sketched in Figure 5.124.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) Newton's second law is then $ma = mg - Dv^2$. Initially, when $v = 0$, the acceleration is g, and the speed increases. As the speed increases, the resistive force increases and hence the acceleration decreases. This continues as the speed approaches the terminal speed.

(c) At terminal velocity, $a = 0$, so $v_t = \sqrt{\frac{mg}{D}}$ in agreement with Eq. (5.13).

(d) The equation of motion may be rewritten as $\frac{dv}{dt} = \frac{g}{v_t^2}(v_t^2 - v^2)$. This is a separable equation and may be expressed as $\int \frac{dv}{v_t^2 - v^2} = \frac{g}{v_t^2}\int dt$ or $\frac{1}{v_t}\operatorname{arctanh}\left(\frac{v}{v_t}\right) = \frac{gt}{v_t^2}$. $v = v_t \tanh(gt/v_t)$.

EVALUATE: $\tanh x = \frac{e^x - e^{-x}}{e^x + e^{-x}}$. At $t \to 0$, $\tanh(gt/v_t) \to 0$ and $v \to 0$. At $t \to \infty$, $\tanh(gt/v_t) \to 1$ and $v = v_t$.

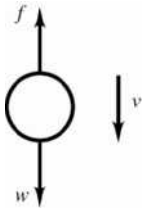

Figure 5.24

5.125. **IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$ to each of the three masses and to the pulley B.

SET UP: Take all accelerations to be positive downward. The equations of motion are straightforward, but the kinematic relations between the accelerations, and the resultant algebra, are not immediately obvious. If the acceleration of pulley B is a_B, then $a_B = -a_3$, and a_B is the average of the accelerations of masses 1 and 2, or $a_1 + a_2 = 2a_B = -2a_3$.

EXECUTE: **(a)** There can be no net force on the massless pulley B, so $T_C = 2T_A$. The five equations to be solved are then $m_1 g - T_A = m_1 a_1$, $m_2 g - T_A = m_2 a_2$, $m_3 g - T_C = m_3 a_3$, $a_1 + a_2 + 2a_3 = 0$ and $2T_A - T_C = 0$. These are five equations in five unknowns, and may be solved by standard means.

The accelerations a_1 and a_2 may be eliminated by using $2a_3 = -(a_1 + a_2) = -(2g - T_A((1/m_1) + (1/m_2)))$.

The tension T_A may be eliminated by using $T_A = (1/2)T_C = (1/2)m_3(g - a_3)$.

Combining and solving for a_3 gives $a_3 = g\frac{-4m_1m_2 + m_2m_3 + m_1m_3}{4m_1m_2 + m_2m_3 + m_1m_3}$.

(b) The acceleration of the pulley B has the same magnitude as a_3 and is in the opposite direction.

(c) $a_1 = g - \frac{T_A}{m_1} = g - \frac{T_C}{2m_1} = g - \frac{m_3}{2m_1}(g - a_3)$. Substituting the above expression for a_3 gives $a_1 = g\frac{4m_1m_2 - 3m_2m_3 + m_1m_3}{4m_1m_2 + m_2m_3 + m_1m_3}$.

(d) A similar analysis (or, interchanging the labels 1 and 2) gives $a_2 = g\frac{4m_1m_2 - 3m_1m_3 + m_2m_3}{4m_1m_2 + m_2m_3 + m_1m_3}$.

(e), **(f)** Once the accelerations are known, the tensions may be found by substitution into the appropriate equation of motion, giving $T_A = g\frac{4m_1m_2m_3}{4m_1m_2 + m_2m_3 + m_1m_3}$, $T_C = g\frac{8m_1m_2m_3}{4m_1m_2 + m_2m_3 + m_1m_3}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(g) If $m_1 = m_2 = m$ and $m_3 = 2m$, all of the accelerations are zero, $T_C = 2mg$ and $T_A = mg$. All masses and pulleys are in equilibrium, and the tensions are equal to the weights they support, which is what is expected.

EVALUATE: It is useful to consider special cases. For example, when $m_1 = m_2 >> m_3$ our general result gives $a_1 = a_2 = +g$ and $a_3 = g$.

5.126. **IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$ to each block. The tension in the string is the same at both ends. If $T < w$ for a block, that block remains at rest.

SET UP: In all cases, the tension in the string will be half of F.

EXECUTE: **(a)** $F/2 = 62$ N, which is insufficient to raise either block; $a_1 = a_2 = 0$.

(b) $F/2 = 147$ N. The larger block (of weight 196 N) will not move, so $a_1 = 0$, but the smaller block, of weight 98 N, has a net upward force of 49 N applied to it, and so will accelerate upward with

$$a_2 = \frac{49 \text{ N}}{10.0 \text{ kg}} = 4.9 \text{ m/s}^2.$$

(c) $F/2 = 212$ N, so the net upward force on block A is 16 N and that on block B is 114 N, so

$$a_1 = \frac{16 \text{ N}}{20.0 \text{ kg}} = 0.8 \text{ m/s}^2 \text{ and } a_2 = \frac{114 \text{ N}}{10.0 \text{ kg}} = 11.4 \text{ m/s}^2.$$

EVALUATE: The two blocks need not have accelerations with the same magnitudes.

5.127. **IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$ to the ball at each position.

SET UP: When the ball is at rest, $a = 0$. When the ball is swinging in an arc it has acceleration component $a_{\text{rad}} = \frac{v^2}{R}$, directed inward.

EXECUTE: Before the horizontal string is cut, the ball is in equilibrium, and the vertical component of the tension force must balance the weight, so $T_A \cos\beta = w$ or $T_A = w/\cos\beta$. At point B, the ball is not in equilibrium; its speed is instantaneously 0, so there is no radial acceleration, and the tension force must balance the radial component of the weight, so $T_B = w\cos\beta$ and the ratio $(T_B/T_A) = \cos^2\beta$.

EVALUATE: At point B the net force on the ball is not zero; the ball has a tangential acceleration.

6

WORK AND KINETIC ENERGY

6.1. **IDENTIFY** and **SET UP:** For parts (a) through (d), identify the appropriate value of ϕ and use the relation $W = F_{\text{P}}s = (F\cos\phi)s$. In part (e), apply the relation $W_{\text{net}} = W_{\text{student}} + W_{\text{grav}} + W_n + W_f$.

EXECUTE: **(a)** Since you are applying a horizontal force, $\phi = 0°$. Thus,

$W_{\text{student}} = (2.40\text{ N})(\cos 0°)(1.50\text{ m}) = 3.60\text{ J}$

(b) The friction force acts in the horizontal direction, opposite to the motion, so $\phi = 180°$.

$W_f = (F_f\cos\phi)s = (0.600\text{ N})(\cos 180°)(1.50\text{ m}) = -0.900\text{ J}$.

(c) Since the normal force acts upward and perpendicular to the tabletop, $\phi = 90°$.

$W_n = (n\cos\phi)s = (ns)(\cos 90°) = 0.0\text{ J}$

(d) Since gravity acts downward and perpendicular to the tabletop, $\phi = 270°$.

$W_{\text{grav}} = (mg\cos\phi)s = (mgs)(\cos 270°) = 0.0\text{ J}$.

(e) $W_{\text{net}} = W_{\text{student}} + W_{\text{grav}} + W_n + W_f = 3.60\text{ J} + 0.0\text{ J} + 0.0\text{ J} - 0.900\text{ J} = 2.70\text{ J}$.

EVALUATE: Whenever a force acts perpendicular to the direction of motion, its contribution to the net work is zero.

6.2. **IDENTIFY:** In each case the forces are constant and the displacement is along a straight line, so $W = Fs\cos\phi$.

SET UP: In part **(a)**, when the cable pulls horizontally $\phi = 0°$ and when it pulls at $35.0°$ above the horizontal $\phi = 35.0°$. In part **(b)**, if the cable pulls horizontally $\phi = 180°$. If the cable pulls on the car at $35.0°$ above the horizontal it pulls on the truck at $35.0°$ below the horizontal and ϕ 145.0°. For the gravity force $\phi = 90°$, since the force is vertical and the displacement is horizontal.

EXECUTE: **(a)** When the cable is horizontal, $W = (850\text{ N})(5.00\times10^3\text{ m})\cos 0° = 4.26\times10^6\text{ J}$. When the cable is $35.0°$ above the horizontal, $W = (850\text{ N})(5.00\times10^3\text{ m})\cos 35.0° = 3.48\times10^6\text{ J}$.

(b) $\cos 180° = -\cos 0°$ and $\cos 145.0° = -\cos 35.0°$, so the answers are $-4.25\times10^6\text{ J}$ and $-3.48\times10^6\text{ J}$.

(c) Since $\cos\phi = \cos 90° = 0$, $W = 0$ in both cases.

EVALUATE: If the car and truck are taken together as the system, the tension in the cable does no net work.

6.3. **IDENTIFY:** Each force can be used in the relation $W = F_{\|}s = (F\cos\phi)s$ for parts (b) through (d). For part (e), apply the net work relation as $W_{\text{net}} = W_{\text{worker}} + W_{\text{grav}} + W_n + W_f$.

SET UP: In order to move the crate at constant velocity, the worker must apply a force that equals the force of friction, $F_{\text{worker}} = f_{\text{k}} = \mu_{\text{k}}n$.

EXECUTE: **(a)** The magnitude of the force the worker must apply is:

$$F_{\text{worker}} = f_{\text{k}} = \mu_{\text{k}}n = \mu_{\text{k}}mg = (0.25)(30.0\text{ kg})(9.80\text{ m/s}^2) = 74\text{ N}$$

(b) Since the force applied by the worker is horizontal and in the direction of the displacement, $\phi = 0°$ and the work is:

$$W_{\text{worker}} = (F_{\text{worker}}\cos\phi)s = [(74\text{ N})(\cos 0°)](4.5\text{ m}) = +333\text{ J}$$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(c) Friction acts in the direction opposite of motion, thus $\phi = 180°$ and the work of friction is:

$$W_f = (f_k \cos\phi)s = [(74\text{ N})(\cos 180°)](4.5\text{ m}) = -333\text{ J}$$

(d) Both gravity and the normal force act perpendicular to the direction of displacement. Thus, neither force does any work on the crate and $W_{grav} = W_n = 0.0$ J.

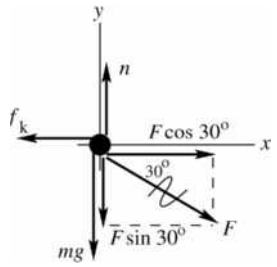
(e) Substituting into the net work relation, the net work done on the crate is:

$$W_{net} = W_{worker} + W_{grav} + W_n + W_f = +333\text{ J} + 0.0\text{ J} + 0.0\text{ J} - 333\text{ J} = 0.0\text{ J}$$

EVALUATE: The net work done on the crate is zero because the two contributing forces, F_{worker} and F_f, are equal in magnitude and opposite in direction.

6.4. **IDENTIFY:** The forces are constant so Eq. (6.2) can be used to calculate the work. Constant speed implies $a = 0$. We must use $\Sigma\vec{F} = m\vec{a}$ applied to the crate to find the forces acting on it.

(a) SET UP: The free-body diagram for the crate is given in Figure 6.4.



EXECUTE: $\Sigma F_y = ma_y$

$n - mg - F\sin 30° = 0$

$n = mg + F\sin 30°$

$f_k = \mu_k n = \mu_k mg + F\mu_k \sin 30°$

Figure 6.4

$\Sigma F_x = ma_x$

$F\cos 30° - f_k = 0$

$F\cos 30° - \mu_k mg - \mu_k \sin 30° F = 0$

$$F = \frac{\mu_k mg}{\cos 30° - \mu_k \sin 30°} = \frac{0.25(30.0\text{ kg})(9.80\text{ m/s}^2)}{\cos 30° - (0.25)\sin 30°} = 99.2\text{ N}$$

(b) $W_F = (F\cos\phi)s = (99.2\text{ N})(\cos 30°)(4.5\text{ m}) = 387\text{ J}$

($F\cos 30°$ is the horizontal component of $\vec{F}$; the work done by $\vec{F}$ is the displacement times the component of $\vec{F}$ in the direction of the displacement.)

(c) We have an expression for f_k from part (a):

$$f_k = \mu_k(mg + F\sin 30°) = (0.250)[(30.0\text{ kg})(9.80\text{ m/s}^2) + (99.2\text{ N})(\sin 30°)] = 85.9\text{ N}$$

$\phi = 180°$ since f_k is opposite to the displacement. Thus $W_f = (f_k\cos\phi)s = (85.9\text{ N})(\cos 180°)(4.5\text{ m}) = -387\text{ J}$

(d) The normal force is perpendicular to the displacement so $\phi = 90°$ and $W_n = 0$. The gravity force (the weight) is perpendicular to the displacement so $\phi = 90°$ and $W_w = 0$.

(e) $W_{tot} = W_F + W_f + W_n + W_w = +387\text{ J} + (-387\text{ J}) = 0$

EVALUATE: Forces with a component in the direction of the displacement do positive work, forces opposite to the displacement do negative work and forces perpendicular to the displacement do zero work. The total work, obtained as the sum of the work done by each force, equals the work done by the net force. In this problem, $F_{net} = 0$ since $a = 0$ and $W_{tot} = 0$, which agrees with the sum calculated in part (e).

6.5. **IDENTIFY:** The gravity force is constant and the displacement is along a straight line, so $W = Fs\cos\phi$.

SET UP: The displacement is upward along the ladder and the gravity force is downward, so $\phi = 180.0° - 30.0° = 150.0°$. $w = mg = 735$ N.

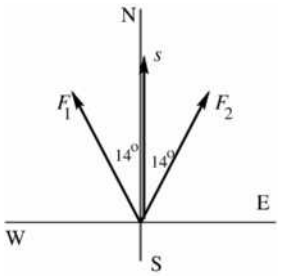
EXECUTE: **(a)** $W = (735\text{ N})(2.75\text{ m})\cos 150.0° = -1750$ J.

(b) No, the gravity force is independent of the motion of the painter.

EVALUATE: Gravity is downward and the vertical component of the displacement is upward, so the gravity force does negative work.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

6.6. **IDENTIFY** and **SET UP:** $W_F = (F\cos\phi)s$, since the forces are constant. We can calculate the total work by summing the work done by each force. The forces are sketched in Figure 6.6.



EXECUTE: $W_1 = F_1 s\cos\phi_1$

$W_1 = (1.80\times10^6\ \text{N})(0.75\times10^3\ \text{m})\cos14°$

$W_1 = 1.31\times10^9\ \text{J}$

$W_2 = F_2 s\cos\phi_2 = W_1$

Figure 6.6

$W_{\text{tot}} = W_1 + W_2 = 2(1.31\times10^9\ \text{J}) = 2.62\times10^9\ \text{J}$

EVALUATE: Only the component $F\cos\phi$ of force in the direction of the displacement does work. These components are in the direction of $\vec{s}$ so the forces do positive work.

6.7. **IDENTIFY:** All forces are constant and each block moves in a straight line, so $W = Fs\cos\phi$. The only direction the system can move at constant speed is for the 12.0 N block to descend and the 20.0 N block to move to the right.

SET UP: Since the 12.0 N block moves at constant speed, $a = 0$ for it and the tension T in the string is $T = 12.0$ N. Since the 20.0 N block moves to the right at constant speed the friction force f_k on it is to the left and $f_k = T = 12.0$ N.

EXECUTE: **(a)** (i) $\phi = 0°$ and $W = (12.0\ \text{N})(0.750\ \text{m})\cos0° = 9.00$ J. (ii) $\phi = 180°$ and $W = (12.0\ \text{N})(0.750\ \text{m})\cos180° = -9.00$ J.

(b) (i) $\phi = 90°$ and $W = 0$. (ii) $\phi = 0°$ and $W = (12.0\ \text{N})(0.750\ \text{m})\cos0° = 9.00$ J. (iii) $\phi = 180°$ and $W = (12.0\ \text{N})(0.750\ \text{m})\cos180° = -9.00$ J. (iv) $\phi = 90°$ and $W = 0$.

(c) $W_{\text{tot}} = 0$ for each block.

EVALUATE: For each block there are two forces that do work, and for each block the two forces do work of equal magnitude and opposite sign. When the force and displacement are in opposite directions, the work done is negative.

6.8. **IDENTIFY:** Apply Eq. (6.5).

SET UP: $\hat{\boldsymbol{i}}\cdot\hat{\boldsymbol{i}} = \hat{\boldsymbol{j}}\cdot\hat{\boldsymbol{j}} = 1$ and $\hat{\boldsymbol{i}}\cdot\hat{\boldsymbol{j}} = \hat{\boldsymbol{j}}\cdot\hat{\boldsymbol{i}} = 0$

EXECUTE: The work you do is $\vec{\boldsymbol{F}}\cdot\vec{\boldsymbol{s}} = ((30\ \text{N})\hat{\boldsymbol{i}} - (40\ \text{N})\hat{\boldsymbol{j}})\cdot((-9.0\ \text{m})\hat{\boldsymbol{i}} - (3.0\ \text{m})\hat{\boldsymbol{j}})$

$\vec{\boldsymbol{F}}\cdot\vec{\boldsymbol{s}} = (30\ \text{N})(-9.0\ \text{m}) + (-40\ \text{N})(-3.0\ \text{m}) = -270\ \text{N}\cdot\text{m} + 120\ \text{N}\cdot\text{m} = -150$ J.

EVALUATE: The x-component of $\vec{\boldsymbol{F}}$ does negative work and the y-component of $\vec{\boldsymbol{F}}$ does positive work. The total work done by $\vec{\boldsymbol{F}}$ is the sum of the work done by each of its components.

6.9. **IDENTIFY:** Apply Eq. (6.2) or (6.3).

SET UP: The gravity force is in the $-y$-direction, so $\vec{\boldsymbol{F}}_{mg}\cdot\vec{\boldsymbol{s}} = -mg(y_2 - y_1)$

EXECUTE: **(a)** (i) Tension force is always perpendicular to the displacement and does no work.
(ii) Work done by gravity is $-mg(y_2 - y_1)$. When $y_1 = y_2$, $W_{mg} = 0$.

(b) (i) Tension does no work. (ii) Let l be the length of the string. $W_{mg} = -mg(y_2 - y_1) = -mg(2l) = -25.1$ J

EVALUATE: In part (b) the displacement is upward and the gravity force is downward, so the gravity force does negative work.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

6.10. **IDENTIFY** and **SET UP:** Use $W = F_p s = (F\cos\phi)s$ to calculate the work done in each of parts (a) through (c). In part (d), the net work consists of the contributions due to all three forces, or $w_{net} = w_{grav} + w_n + w_f$.

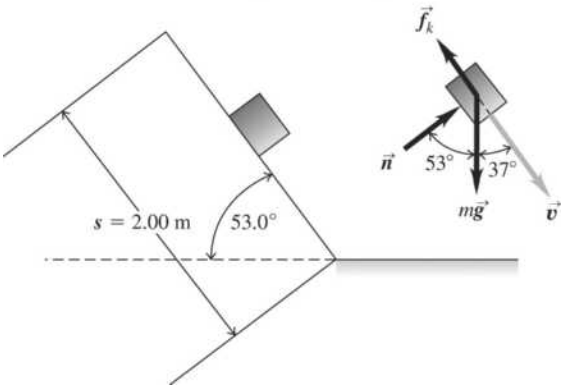


Figure 6.10

EXECUTE: **(a)** As the package slides, work is done by the frictional force which acts at $\phi = 180°$ to the displacement. The normal force is $mg\cos 53.0°$. Thus for $\mu_k = 0.40$,

$W_f = F_p s = (f_k\cos\phi)s = (\mu_k n\cos\phi)s = [\mu_k(mg\cos 53.0°)](\cos 180°)s.$

$W_f = (0.40)[(8.00\text{ kg})(9.80\text{ m/s}^2)(\cos 53.0°)](\cos 180°)(2.00\text{ m}) = -38\text{ J}.$

(b) Work is done by the component of the gravitational force parallel to the displacement. $\phi = 90° - 53° = 37°$ and the work of gravity is

$W_{grav} = (mg\cos\phi)s = [(8.00\text{ kg})(9.80\text{ m/s}^2)(\cos 37.0°)](2.00\text{ m}) = +125\text{ J}.$

(c) $W_n = 0$ since the normal force is perpendicular to the displacement.

(d) The net work done on the package is $W_{net} = W_{grav} + W_n + W_f = 125\text{ J} + 0.0\text{ J} - 38\text{ J} = 87\text{ J}.$

EVALUATE: The net work is positive because gravity does more positive work than the magnitude of the negative work done by friction.

6.11. **IDENTIFY:** Since the speed is constant, the acceleration and the net force on the monitor are zero.
SET UP: Use the fact that the net force on the monitor is zero to develop expressions for the friction force, f_k, and the normal force, n. Then use $W = F_P s = (F\cos\phi)s$ to calculate W.

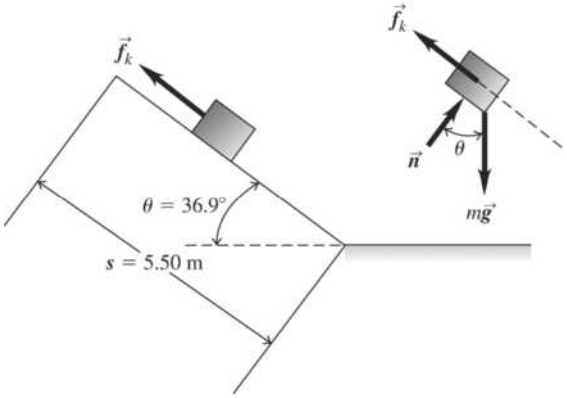

Figure 6.11

EXECUTE: **(a)** Summing forces along the incline, $\Sigma F = ma = 0 = f_k - mg\sin\theta$, giving $f_k = mg\cos\theta$, directed up the incline. Substituting gives $W_f = (f_k\cos\phi)s = [(mg\sin\theta)\cos\phi]s$.

$W_f = [(10.0\text{ kg})(9.80\text{ m/s}^2)(\sin 36.9°)](\cos 0°)(5.50\text{ m}) = +324\text{ J}.$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) The gravity force is downward and the displacement is directed up the incline so $\phi = 126.9°$.

$W_{\text{grav}} = (10.0 \text{ kg})(9.80 \text{ m/s}^2)(\cos 126.9°)(5.50 \text{ m}) = -324 \text{ J}$.

(c) The normal force, n, is perpendicular to the displacement and thus does zero work.

EVALUATE: Friction does positive work and gravity does negative work. The net work done is zero.

6.12. **IDENTIFY:** We want to find the work done by a known force acting through a known displacement.

SET UP: $W = \vec{F} \cdot \vec{s} = F_x s_x + F_y s_y$. We know the components of $\vec{F}$ but need to find the components of the displacement $\vec{s}$.

EXECUTE: Using the magnitude and direction of $\vec{s}$, its components are

$x = (48.0 \text{ m})\cos 240.0^{\text{o}} = -24.0 \text{ m}$ and $y = (48.0 \text{ m})\sin 240.0^{\text{o}} = -41.57 \text{ m}$. Therefore,

$\vec{s} = (-24.0 \text{ m})\hat{\boldsymbol{i}} + (-41.57 \text{ m})\hat{\boldsymbol{j}}$. The definition of work gives

$W = \vec{F} \cdot \vec{s} = (-68.0 \text{ N})(-24.0 \text{ m}) + (36.0 \text{ N})(-41.57 \text{ m}) = +1632 \text{ J} - 1497 \text{ J} = +135 \text{ J}$

EVALUATE: The mass of the car is not needed since it is the given force that is doing the work.

6.13. **IDENTIFY:** Find the kinetic energy of the cheetah knowing its mass and speed.

SET UP: Use $K = \frac{1}{2}mv^2$ to relate v and K.

EXECUTE: **(a)** $K = \frac{1}{2}mv^2 = \frac{1}{2}(70 \text{ kg})(32 \text{ m/s})^2 = 3.6 \times 10^4 \text{ J}$.

(b) K is proportional to v^2, so K increases by a factor of 4 when v doubles.

EVALUATE: A running person, even with a mass of 70 kg, would have only 1/100 of the cheetah's kinetic energy since a person's top speed is only about 1/10 that of the cheetah.

6.14. **IDENTIFY:** The book changes its speed and hence its kinetic energy, so work must have been done on it.

SET UP: Use the work-kinetic energy theorem $W_{\text{net}} = K_{\text{f}} - K_{\text{i}}$, with $K = \frac{1}{2}mv^2$. In part (a) use K_{i} and K_{f} to calculate W. In parts (b) and (c) use K_{i} and W to calculate K_{f}.

EXECUTE: **(a)** Substituting the notation $\text{i} = A$ and $\text{f} = B$,

$W_{\text{net}} = K_B - K_A = \frac{1}{2}(1.50 \text{ kg})[(1.25 \text{ m/s})^2 - (3.21 \text{ m/s})^2] = -6.56 \text{ J}$.

(b) Noting $\text{i} = B$ and $\text{f} = C$, $K_C = K_B + W_{\text{net}} = \frac{1}{2}(1.50 \text{ kg})(1.25 \text{ m/s})^2 - 0.750 \text{ J} = +0.422 \text{ J}$. $K_C = \frac{1}{2}mv_C^2$ so $v_C = \sqrt{2K_C/m} = 0.750 \text{ m/s}$.

(c) Similarly, $K_C = \frac{1}{2}(1.50 \text{ kg})(1.25 \text{ m/s})^2 + 0.750 \text{ J} = 1.922 \text{ J}$ and $v_C = 1.60 \text{ m/s}$.

EVALUATE: Negative W_{net} corresponds to a decrease in kinetic energy (slowing down) and positive W_{net} corresponds to an increase in kinetic energy (speeding up).

6.15. **IDENTIFY:** $K = \frac{1}{2}mv^2$. Since the meteor comes to rest the energy it delivers to the ground equals its original kinetic energy.

SET UP: $v = 12 \text{ km/s} = 1.2 \times 10^4 \text{ m/s}$. A 1.0 megaton bomb releases $4.184 \times 10^{15} \text{ J}$ of energy.

EXECUTE: **(a)** $K = \frac{1}{2}(1.4 \times 10^8 \text{ kg})(1.2 \times 10^4 \text{ m/s})^2 = 1.0 \times 10^{16} \text{ J}$.

(b) $\dfrac{1.0 \times 10^{16} \text{ J}}{4.184 \times 10^{15} \text{ J}} = 2.4$. The energy is equivalent to 2.4 one-megaton bombs.

EVALUATE: Part of the energy transferred to the ground lifts soil and rocks into the air and creates a large crater.

6.16. **IDENTIFY:** Use the equations for free-fall to find the speed of the weight when it reaches the ground and use the formula for kinetic energy.

SET UP: Kinetic energy is $K = \frac{1}{2}mv^2$. The mass of an electron is 9.11×10^{-31} kg. In part (b) take $+y$ downward, so $a_y = +9.80 \text{ m/s}^2$ and $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: **(a)** $K = \frac{1}{2}(9.11\times10^{-31}\text{ kg})(2.19\times10^{6}\text{ m/s})^2 = 2.18\times10^{-18}\text{ J}$.

(b) $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ gives $v_y = \sqrt{2(9.80\text{ m/s}^2)(1\cdot\text{m})} = 4.43\text{ m/s}$. $K = \frac{1}{2}(1.0\text{ kg})(4.43\text{ m/s})^2 = 9.8\text{ J}$.

(c) Solving $K = \frac{1}{2}mv^2$ for v gives $v = \sqrt{\frac{2K}{m}} = \sqrt{\frac{2(100\text{ J})}{30\text{ kg}}} = 2.6\text{ m/s}$. Yes, this is reasonable.

EVALUATE: A running speed of 6 m/s corresponds to running a 100-m dash in about 17 s, so 2.6 m/s is reasonable for a running child.

6.17. **IDENTIFY:** Newton's second law applies to the system of blocks, as well as the work-energy theorem.

SET UP: Newton's second law is $\Sigma F_x = ma_x$ and the work-energy theorem is $W_{\text{tot}} = \Delta K = K_{\text{f}} - K_{\text{i}}$.

EXECUTE: **(a)** For the hanging block, Newton's second law gives $12.0\text{ N} - T = (1.224\text{ kg})a$ and for the block on the table $T = (2.041\text{ kg})a$. $12.0\text{ N} = (3.265\text{ kg})a$. This gives $a = 3.675\text{ m/s}^2$ and $T = 7.50\text{ N}$.

(b) (i) $W_T = T(1.20\text{ m}) = (7.50\text{ N})(1.20\text{ m}) = +9.00\text{ J}$.

(ii) $W_{mg} = mg(1.20\text{ m}) = (12.0\text{ N})(1.20\text{ m}) = 14.4\text{ J}$. $W_T = -T(1.20\text{ m}) = -9.00\text{ J}$. $W_{\text{tot}} = 5.40\text{ J}$.

(c) For the system of two blocks, $W_{\text{tot}} = +9.00\text{ J} + 5.40\text{ J} = 14.4\text{ J}$. This equals the work done by gravity on the 12.0 N block. The total work done by T is zero.

(d) $W_{\text{tot}} = \Delta K = K_{\text{f}} - K_{\text{i}}$. Since $K_{\text{i}} = 0$, $K_{\text{f}} = \frac{1}{2}(2.041\text{ kg})v^2 + \frac{1}{2}(1.224\text{ kg})v^2$.

Therefore $14.4\text{ J} = \left[\frac{1}{2}(2.041\text{ kg}) + \frac{1}{2}(1.224\text{ kg})\right]v^2$ gives $v = 2.97\text{ m/s}$.

EVALUATE: As a check, we could find the velocity in part (d) using the standard kinematics formulas since the acceleration is constant: $v^2 = 0 + 2ax = 2(3.675\text{ m/s}^2)(1.20\text{ m})$ gives the same answer as in (d).

6.18. **IDENTIFY:** Only gravity does work on the watermelon, so $W_{\text{tot}} = W_{\text{grav}}$. $W_{\text{tot}} = \Delta K$ and $K = \frac{1}{2}mv^2$.

SET UP: Since the watermelon is dropped from rest, $K_1 = 0$.

EXECUTE: **(a)** $W_{\text{grav}} = mgs = (4.80\text{ kg})(9.80\text{ m/s}^2)(25.0\text{ m}) = 1180\text{ J}$

(b) $W_{\text{tot}} = K_2 - K_1$ so $K_2 = 1180\text{ J}$. $v = \sqrt{\frac{2K_2}{m}} = \sqrt{\frac{2(1180\text{ J})}{4.80\text{ kg}}} = 22.2\text{ m/s}$.

(c) The work done by gravity would be the same. Air resistance would do negative work and W_{tot} would be less than W_{grav}. The answer in (a) would be unchanged and both answers in (b) would decrease.

EVALUATE: The gravity force is downward and the displacement is downward, so gravity does positive work.

6.19. **IDENTIFY:** $W_{\text{tot}} = K_2 - K_1$. In each case calculate W_{tot} from what we know about the force and the displacement.

SET UP: The gravity force is mg, downward. The friction force is $f_{\text{k}} = \mu_{\text{k}}n = \mu_{\text{k}}mg$ and is directed opposite to the displacement. The mass of the object isn't given, so we expect that it will divide out in the calculation.

EXECUTE: **(a)** $K_1 = 0$. $W_{\text{tot}} = W_{\text{grav}} = mgs$. $mgs = \frac{1}{2}mv_2^2$ and

$v_2 = \sqrt{2gs} = \sqrt{2(9.80\text{ m/s}^2)(95.0\text{ m})} = 43.2\text{ m/s}$.

(b) $K_2 = 0$ (at the maximum height). $W_{\text{tot}} = W_{\text{grav}} = -mgs$. $-mgs = -\frac{1}{2}mv_1^2$ and

$v_1 = \sqrt{2gs} = \sqrt{2(9.80\text{ m/s}^2)(525\text{ m})} = 101\text{ m/s}$.

(c) $K_1 = \frac{1}{2}mv_1^2$. $K_2 = 0$. $W_{\text{tot}} = W_f = -\mu_{\text{k}}mgs$. $-\mu_{\text{k}}mgs = -\frac{1}{2}mv_1^2$.

$s = \frac{v_1^2}{2\mu_{\text{k}}g} = \frac{(5.00\text{ m/s})^2}{2(0.220)(9.80\text{ m/s}^2)} = 5.80\text{ m}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(d) $K_1 = \frac{1}{2}mv_1^2$. $K_2 = \frac{1}{2}mv_2^2$. $W_{\text{tot}} = W_f = -\mu_k mgs$. $K_2 = W_{\text{tot}} + K_1$. $\frac{1}{2}mv_2^2 = -\mu_k mgs + \frac{1}{2}mv_1^2$.

$v_2 = \sqrt{v_1^2 - 2\mu_k gs} = \sqrt{(5.00 \text{ m/s})^2 - 2(0.220)(9.80 \text{ m/s}^2)(2.90 \text{ m})} = 3.53 \text{ m/s}$.

(e) $K_1 = \frac{1}{2}mv_1^2$. $K_2 = 0$. $W_{\text{grav}} = -mgy_2$, where y_2 is the vertical height. $-mgy_2 = -\frac{1}{2}mv_1^2$ and

$$y_2 = \frac{v_1^2}{2g} = \frac{(12.0 \text{ m/s})^2}{2(9.80 \text{ m/s}^2)} = 7.35 \text{ m}.$$

EVALUATE: In parts (c) and (d), friction does negative work and the kinetic energy is reduced. In part (a), gravity does positive work and the speed increases. In parts (b) and (e), gravity does negative work and the speed decreases. The vertical height in part (e) is independent of the slope angle of the hill.

6.20. **IDENTIFY:** From the work-energy relation, $W = W_{\text{grav}} = \Delta K_{\text{rock}}$.

SET UP: As the rock rises, the gravitational force, $F = mg$, does work on the rock. Since this force acts in the direction opposite to the motion and displacement, *s*, the work is negative. Let *h* be the vertical distance the rock travels.

EXECUTE: **(a)** Applying $W_{\text{grav}} = K_2 - K_1$ we obtain $-mgh = \frac{1}{2}mv_2^2 - \frac{1}{2}mv_1^2$. Dividing by *m* and solving for v_1, $v_1 = \sqrt{v_2^2 + 2gh}$. Substituting $h = 15.0$ m and $v_2 = 25.0$ m/s,

$$v_1 = \sqrt{(25.0 \text{ m/s})^2 + 2(9.80 \text{ m/s}^2)(15.0 \text{ m})} = 30.3 \text{ m/s}$$

(b) Solve the same work-energy relation for *h*. At the maximum height $v_2 = 0$.

$-mgh = \frac{1}{2}mv_2^2 - \frac{1}{2}mv_1^2$ and $h = \frac{v_1^2 - v_2^2}{2g} = \frac{(30.3 \text{ m/s})^2 - (0.0 \text{ m/s})^2}{2(9.80 \text{ m/s}^2)} = 46.8 \text{ m}$.

EVALUATE: Note that the weight of 20 N was never used in the calculations because both gravitational potential and kinetic energy are proportional to mass, *m*. Thus any object, that attains 25.0 m/s at a height of 15.0 m, must have an initial velocity of 30.3 m/s. As the rock moves upward gravity does negative work and this reduces the kinetic energy of the rock.

6.21. **IDENTIFY** and **SET UP:** Apply Eq. (6.6) to the box. Let point 1 be at the bottom of the incline and let point 2 be at the skier. Work is done by gravity and by friction. Solve for K_1 and from that obtain the required initial speed.

EXECUTE: $W_{\text{tot}} = K_2 - K_1$

$K_1 = \frac{1}{2}mv_0^2$, $K_2 = 0$

Work is done by gravity and friction, so $W_{\text{tot}} = W_{mg} + W_f$.

$W_{mg} = -mg(y_2 - y_1) = -mgh$

$W_f = -fs$. The normal force is $n = mg\cos\alpha$ and $s = h/\sin\alpha$, where *s* is the distance the box travels along the incline.

$W_f = -(\mu_k mg\cos\alpha)(h/\sin\alpha) = -\mu_k mgh/\tan\alpha$

Substituting these expressions into the work-energy theorem gives

$-mgh - \mu_k mgh/\tan\alpha = -\frac{1}{2}mv_0^2$.

Solving for v_0 then gives $v_0 = \sqrt{2gh(1 + \mu_k/\tan\alpha)}$.

EVALUATE: The result is independent of the mass of the box. As $\alpha \to 90°$, $h = s$ and $v_0 = \sqrt{2gh}$, the same as throwing the box straight up into the air. For $\alpha = 90°$ the normal force is zero so there is no friction.

6.22. **IDENTIFY:** Apply $W = Fs\cos\phi$ and $W_{\text{tot}} = \Delta K$.

SET UP: Parallel to incline: force component $W_{\parallel} = mg\sin\alpha$, down incline; displacement $s = h/\sin\alpha$, down incline. Perpendicular to the incline: $s = 0$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: **(a)** $W_{\parallel} = (mg\sin\alpha)(h/\sin\alpha) = mgh$. $W_{\parallel} = 0$, since there is no displacement in this direction. $W_{mg} = W_{\parallel} + W_{\perp} = mgh$, same as falling height h.

(b) $W_{\text{tot}} = K_2 - K_1$ gives $mgh = \frac{1}{2}mv^2$ and $v = \sqrt{2gh}$, same as if had been dropped from height h. The work done by gravity depends only on the vertical displacement of the object. When the slope angle is small, there is a small force component in the direction of the displacement but a large displacement in this direction. When the slope angle is large, the force component in the direction of the displacement along the incline is larger but the displacement in this direction is smaller.

(c) $h = 15.0$ m, so $v = \sqrt{2gh} = 17.1$ s.

EVALUATE: The acceleration and time of travel are different for an object sliding down an incline and an object in free-fall, but the final velocity is the same in these two cases.

6.23. **IDENTIFY:** Apply $W = Fs\cos\phi$ and $W_{\text{tot}} = \Delta K$.

SET UP: $\phi = 0°$

EXECUTE: From Eqs. (6.1), (6.5) and (6.6), and solving for F,

$$F = \frac{\Delta K}{s} = \frac{\frac{1}{2}m(v_2^2 - v_1^2)}{s} = \frac{\frac{1}{2}(8.00\text{ kg})((6.00\text{ m/s})^2 - (4.00\text{ m/s})^2)}{(2.50\text{ m})} = 32.0\text{ N}.$$

EVALUATE: The force is in the direction of the displacement, so the force does positive work and the kinetic energy of the object increases.

6.24. **IDENTIFY** and **SET UP:** Use Eq. (6.6) to calculate the work done by the foot on the ball. Then use Eq. (6.2) to find the distance over which this force acts.

EXECUTE: $W_{\text{tot}} = K_2 - K_1$

$K_1 = \frac{1}{2}mv_1^2 = \frac{1}{2}(0.420\text{ kg})(2.00\text{ m/s})^2 = 0.84\text{ J}$

$K_2 = \frac{1}{2}mv_2^2 = \frac{1}{2}(0.420\text{ kg})(6.00\text{ m/s})^2 = 7.56\text{ J}$

$W_{\text{tot}} = K_2 - K_1 = 7.56\text{ J} - 0.84\text{ J} = 6.72\text{ J}$

The 40.0 N force is the only force doing work on the ball, so it must do 6.72 J of work. $W_F = (F\cos\phi)s$ gives that

$$s = \frac{W}{F\cos\phi} = \frac{6.72\text{ J}}{(40.0\text{ N})(\cos 0)} = 0.168\text{ m}$$

EVALUATE: The force is in the direction of the motion so positive work is done and this is consistent with an increase in kinetic energy.

6.25. **IDENTIFY:** Apply $W_{\text{tot}} = \Delta K$.

SET UP: $v_1 = 0$, $v_2 = v$. $f_k = \mu_k mg$ and f_k does negative work. The force $F = 36.0$ N is in the direction of the motion and does positive work.

EXECUTE: **(a)** If there is no work done by friction, the final kinetic energy is the work done by the applied force, and solving for the speed,

$$v = \sqrt{\frac{2W}{m}} = \sqrt{\frac{2Fs}{m}} = \sqrt{\frac{2(36.0\text{ N})(1.20\text{ m})}{(4.30\text{ kg})}} = 4.48\text{ m/s}.$$

(b) The net work is $Fs - f_k s = (F - \mu_k mg)s$, so

$$v = \sqrt{\frac{2(F - \mu_k mg)s}{m}} = \sqrt{\frac{2(36.0\text{ N} - (0.30)(4.30\text{ kg})(9.80\text{ m/s}^2)(1.20\text{ m})}{(4.30\text{ kg})}} = 3.61\text{ m/s}$$

EVALUATE: The total work done is larger in the absence of friction and the final speed is larger in that case.

6.26. **IDENTIFY:** Apply $W = Fs\cos\phi$ and $W_{\text{tot}} = \Delta K$.

SET UP: The gravity force has magnitude mg and is directed downward.

EXECUTE: **(a)** On the way up, gravity is opposed to the direction of motion, and so

$W = -mgs = -(0.145\text{ kg})(9.80\text{ m/s}^2)(20.0\text{ m}) = -28.4\text{ J}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) $v_2 = \sqrt{v_1^2 + 2\dfrac{W}{m}} = \sqrt{(25.0\text{ m/s})^2 + \dfrac{2(-28.4\text{ J})}{(0.145\text{ kg})}} = 15.3\text{ m/s}.$

(c) No; in the absence of air resistance, the ball will have the same speed on the way down as on the way up. On the way down, gravity will have done both negative and positive work on the ball, but the net work at this height will be the same.

EVALUATE: As the baseball moves upward, gravity does negative work and the speed of the baseball decreases.

6.27. **(a) IDENTIFY** and **SET UP:** Use Eq. (6.2) to find the work done by the positive force. Then use Eq. (6.6) to find the final kinetic energy, and then $K_2 = \frac{1}{2}mv_2^2$ gives the final speed.

EXECUTE: $W_{\text{tot}} = K_2 - K_1$, so $K_2 = W_{\text{tot}} + K_1$

$K_1 = \frac{1}{2}mv_1^2 = \frac{1}{2}(7.00\text{ kg})(4.00\text{ m/s})^2 = 56.0\text{ J}$

The only force that does work on the wagon is the 10.0 N force. This force is in the direction of the displacement so $\phi = 0°$ and the force does positive work:

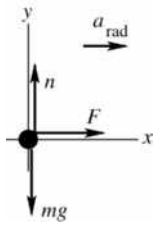
$$W_F = (F\cos\phi)s = (10.0\text{ N})(\cos 0)(3.0\text{ m}) = 30.0\text{ J}$$

Then $K_2 = W_{\text{tot}} + K_1 = 30.0\text{ J} + 56.0\text{ J} = 86.0\text{ J}.$

$$K_2 = \tfrac{1}{2}mv_2^2;\ v_2 = \sqrt{\frac{2K_2}{m}} = \sqrt{\frac{2(86.0\text{ J})}{7.00\text{ kg}}} = 4.96\text{ m/s}$$

(b) IDENTIFY: Apply $\Sigma\vec{F} = m\vec{a}$ to the wagon to calculate a. Then use a constant acceleration equation to calculate the final speed. The free-body diagram is given in Figure 6.27.

SET UP:



EXECUTE: $\Sigma F_x = ma_x$

$F = ma_x$

$a_x = \dfrac{F}{m} = \dfrac{10.0\text{ N}}{7.00\text{ kg}} = 1.43\text{ m/s}^2$

Figure 6.27

$v_{2x}^2 = v_{1x}^2 + 2a_2(x - x_0)$

$v_{2x} = \sqrt{v_{1x}^2 + 2a_x(x - x_0)} = \sqrt{(4.00\text{ m/s})^2 + 2(1.43\text{ m/s}^2)(3.0\text{ m})} = 4.96\text{ m/s}$

EVALUATE: This agrees with the result calculated in part (a). The force in the direction of the motion does positive work and the kinetic energy and speed increase. In part (b), the equivalent statement is that the force produces an acceleration in the direction of the velocity and this causes the magnitude of the velocity to increase.

6.28. **IDENTIFY:** Apply $W_{\text{tot}} = K_2 - K_1$.

SET UP: $K_1 = 0$. The normal force does no work. The work W done by gravity is $W = mgh$, where $h = L\sin\theta$ is the vertical distance the block has dropped when it has traveled a distance L down the incline and θ is the angle the plane makes with the horizontal.

EXECUTE: The work-energy theorem gives $v = \sqrt{\dfrac{2K}{m}} = \sqrt{\dfrac{2W}{m}} = \sqrt{2gh} = \sqrt{2gL\sin\theta}$. Using the given numbers, $v = \sqrt{2(9.80\text{ m/s}^2)(0.75\text{ m})\sin 36.9°} = 2.97\text{ m/s}.$

EVALUATE: The final speed of the block is the same as if it had been dropped from a height h.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

6.29. **IDENTIFY:** $W_{\text{tot}} = K_2 - K_1$. Only friction does work.

SET UP: $W_{\text{tot}} = W_{f_k} = -\mu_k mgs$. $K_2 = 0$ (car stops). $K_1 = \frac{1}{2}mv_0^2$.

EXECUTE: **(a)** $W_{\text{tot}} = K_2 - K_1$ gives $-\mu_k mgs = -\frac{1}{2}mv_0^2$. $s = \dfrac{v_0^2}{2\mu_k g}$.

(b) (i) $\mu_{kb} = 2\mu_{ka}$. $s\mu_k = \dfrac{v_0^2}{2g} = \text{constant}$ so $s_a\mu_{ka} = s_b\mu_{kb}$. $s_b = \left(\dfrac{\mu_{ka}}{\mu_{kb}}\right)s_a = s_a/2$. The minimum stopping distance would be halved. (ii) $v_{0b} = 2v_{0a}$. $\dfrac{s}{v_0^2} = \dfrac{1}{2\mu_k g} = \text{constant}$, so $\dfrac{s_a}{v_{0a}^2} = \dfrac{s_b}{v_{0b}^2}$. $s_b = s_a\left(\dfrac{v_{0b}}{v_{0a}}\right)^2 = 4s_a$. The stopping distance would become 4 times as great. (iii) $v_{0b} = 2v_{0a}$, $\mu_{kb} = 2\mu_{ka}$. $\dfrac{s\mu_k}{v_0^2} = \dfrac{1}{2g} = \text{constant}$, so $\dfrac{s_a\mu_{ka}}{v_{0a}^2} = \dfrac{s_b\mu_{kb}}{v_{0b}^2}$. $s_b = s_a\left(\dfrac{\mu_{ka}}{\mu_{kb}}\right)\left(\dfrac{v_{0b}}{v_{0a}}\right)^2 = s_a\left(\dfrac{1}{2}\right)(2)^2 = 2s_a$. The stopping distance would double.

EVALUATE: The stopping distance is directly proportional to the square of the initial speed and indirectly proportional to the coefficient of kinetic friction.

6.30. **IDENTIFY:** We know (or can calculate) the change in the kinetic energy of the crate and want to find the work needed to cause this change, so the work-energy theorem applies.

SET UP: $W_{\text{tot}} = \Delta K = K_f - K_i = \frac{1}{2}mv_f^2 - \frac{1}{2}mv_i^2$.

EXECUTE: $W_{\text{tot}} = K_f - K_i = \frac{1}{2}(30.0 \text{ kg})(5.62 \text{ m/s})^2 - \frac{1}{2}(30.0 \text{ kg})(3.90 \text{ m/s})^2$.

$W_{\text{tot}} = 473.8 \text{ J} - 228.2 \text{ J} = 246 \text{ J}$.

EVALUATE: Kinetic energy is a scalar and does not depend on direction, so only the initial and final speeds are relevant.

6.31. **IDENTIFY:** The elastic aortal material behaves like a spring, so we can apply Hooke's law to it.

SET UP: $|F_{\text{spr}}| = F$, where F is the pull on the strip or the force the strip exerts, and $F = kx$.

EXECUTE: **(a)** Solving $F = kx$ for k gives $k = \dfrac{F}{x} = \dfrac{1.50 \text{ N}}{0.0375 \text{ m}} = 40.0 \text{ N/m}$.

(b) $F = kx = (40.0 \text{ N/m})(0.0114 \text{ m}) = 0.456 \text{ N}$.

EVALUATE: It takes 0.40 N to stretch this material by 1.0 cm, so it is not as stiff as many laboratory springs.

6.32. **IDENTIFY:** The work that must be done to move the end of a spring from x_1 to x_2 is $W = \frac{1}{2}kx_2^2 - \frac{1}{2}kx_1^2$.

The force required to hold the end of the spring at displacement x is $F_x = kx$.

SET UP: When the spring is at its unstretched length, $x = 0$. When the spring is stretched, $x > 0$, and when the spring is compressed, $x < 0$.

EXECUTE: **(a)** $x_1 = 0$ and $W = \frac{1}{2}kx_2^2$. $k = \dfrac{2W}{x_2^2} = \dfrac{2(12.0 \text{ J})}{(0.0300 \text{ m})^2} = 2.67\times10^4 \text{ N/m}$.

(b) $F_x = kx = (2.67\times10^4 \text{ N/m})(0.0300 \text{ m}) = 801 \text{ N}$.

(c) $x_1 = 0$, $x_2 = -0.0400$ m. $W = \frac{1}{2}(2.67\times10^4 \text{ N/m})(-0.0400 \text{ m})^2 = 21.4 \text{ J}$.

$F_x = kx = (2.67\times10^4 \text{ N/m})(0.0400 \text{ m}) = 1070 \text{ N}$.

EVALUATE: When a spring, initially unstretched, is either compressed or stretched, positive work is done by the force that moves the end of the spring.

6.33. **IDENTIFY:** The springs obey Hook's law and balance the downward force of gravity.

SET UP: Use coordinates with $+y$ upward. Label the masses 1, 2, and 3 and call the amounts the springs are stretched x_1, x_2, and x_3. Each spring force is kx.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: **(a)** The three free-body diagrams are shown in Figure 6.33.

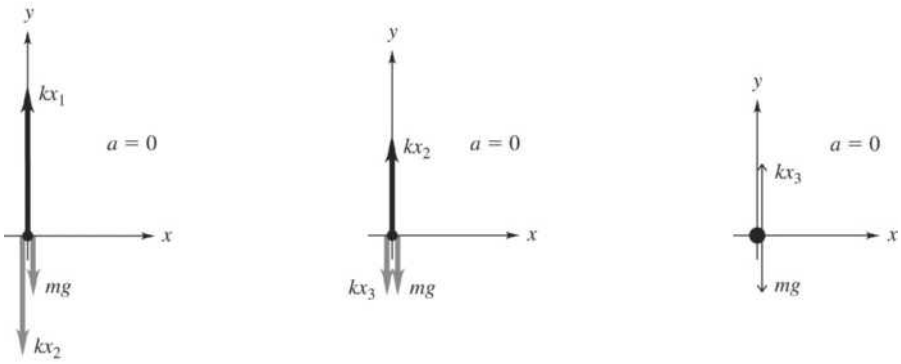


Figure 6.33

(b) Balancing forces on each of the masses and using $F = kx$ gives $kx_3 = mg$ so

$x_3 = \dfrac{mg}{k} = \dfrac{(6.40\text{ kg})(9.80\text{ m/s}^2)}{7.80\times10^3\text{ N/m}} = 0.800\text{ cm.}$ $kx_2 = mg + kx_3 = 2mg$ so $x_2 = 2\left(\dfrac{mg}{k}\right) = 1.60\text{ cm.}$

$kx_1 = mg + kx_2 = 3mg$ so $x_3 = 3\left(\dfrac{mg}{k}\right) = 2.40\text{ cm.}$ The lengths of the springs, starting from the top one, are 14.4 cm, 13.6 cm and 12.8 cm.

EVALUATE: The top spring stretches most because it supports the most weight, while the bottom spring stretches least because it supports the least weight.

6.34. **IDENTIFY:** The magnitude of the work can be found by finding the area under the graph.

SET UP: The area under each triangle is 1/2 base×height. $F_x > 0$, so the work done is positive when x increases during the displacement.

EXECUTE: **(a)** $1/2\ (8\text{ m})(10\text{ N}) = 40\text{ J}$.

(b) $1/2\ (4\text{ m})(10\text{ N}) = 20\text{ J}$.

(c) $1/2\ (12\text{ m})(10\text{ N}) = 60\text{ J}$.

EVALUATE: The sum of the answers to parts (a) and (b) equals the answer to part (c).

6.35. **IDENTIFY:** Use the work-energy theorem and the results of Problem 6.30.

SET UP: For $x = 0$ to $x = 8.0$ m, $W_{\text{tot}} = 40$ J. For $x = 0$ to $x = 12.0$ m, $W_{\text{tot}} = 60$ J.

EXECUTE: **(a)** $v = \sqrt{\dfrac{(2)(40\text{ J})}{10\text{ kg}}} = 2.83\text{ m/s}$

(b) $v = \sqrt{\dfrac{(2)(60\text{ J})}{10\text{ kg}}} = 3.46\text{ m/s.}$

EVALUATE: $\vec{F}$ is always in the $+x$-direction. For this motion $\vec{F}$ does positive work and the speed continually increases during the motion.

6.36. **IDENTIFY:** The force of the spring is the same on each box, but they have different accelerations because their masses are different. Hooke's law gives the spring force.

SET UP: The free-body diagrams for the boxes are shown in Figure 6.36. Label the boxes A and B, with $m_A = 2.0$ kg and $m_B = 3.0$ kg. $F = kx$ is the spring force and is the same for each box. We apply $\Sigma F = ma$ to each box.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

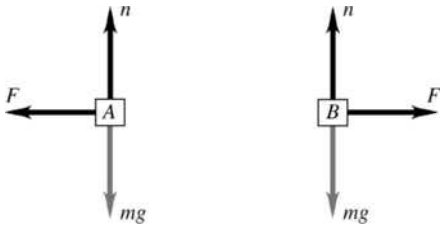

Figure 6.36

EXECUTE: $F = k|x| = (250 \text{ N/m})(0.060 \text{ m}) = 15.0 \text{ N}$. $a_A = \dfrac{F}{m_A} = \dfrac{15.0 \text{ N}}{2.0 \text{ kg}} = 7.5 \text{ m/s}^2$;

$a_B = \dfrac{F}{m_B} = \dfrac{15.0 \text{ N}}{3.0 \text{ kg}} = 5.0 \text{ m/s}^2$. The accelerations are in opposite directions.

EVALUATE: The same magnitude of force is exerted on each object, but the acceleration that is produced by this force is larger for the object of smaller mass.

6.37. **IDENTIFY:** Apply Eq. (6.6) to the box.

SET UP: Let point 1 be just before the box reaches the end of the spring and let point 2 be where the spring has maximum compression and the box has momentarily come to rest.

EXECUTE: $W_{\text{tot}} = K_2 - K_1$

$K_1 = \frac{1}{2}mv_0^2$, $K_2 = 0$

Work is done by the spring force. $W_{\text{tot}} = -\frac{1}{2}kx_2^2$, where x_2 is the amount the spring is compressed.

$-\frac{1}{2}kx_2^2 = -\frac{1}{2}mv_0^2$ and $x_2 = v_0\sqrt{m/k} = (3.0 \text{ m/s})\sqrt{(6.0 \text{ kg})/(7500 \text{ N/m})} = 8.5 \text{ cm}$

EVALUATE: The compression of the spring increases when either v_0 or m increases and decreases when k increases (stiffer spring).

6.38. **IDENTIFY:** The force applied to the springs is $F_x = kx$. The work done on a spring to move its end from x_1 to x_2 is $W = \frac{1}{2}kx_2^2 - \frac{1}{2}kx_1^2$. Use the information that is given to calculate k.

SET UP: When the springs are compressed 0.200 m from their uncompressed length, $x_1 = 0$ and $x_2 = -0.200$ m. When the platform is moved 0.200 m farther, x_2 becomes -0.400 m.

EXECUTE: **(a)** $k = \dfrac{2W}{x_2^2 - x_1^2} = \dfrac{2(80.0 \text{ J})}{(0.200 \text{ m})^2 - 0} = 4000 \text{ N/m}$. $F_x = kx = (4000 \text{ N/m})(-0.200 \text{ m}) = -800 \text{ N}$.

The magnitude of force that is required is 800 N.

(b) To compress the springs from $x_1 = 0$ to $x_2 = -0.400$ m, the work required is

$W = \frac{1}{2}kx_2^2 - \frac{1}{2}kx_1^2 = \frac{1}{2}(4000 \text{ N/m})(-0.400 \text{ m})^2 = 320 \text{ J}$. The additional work required is

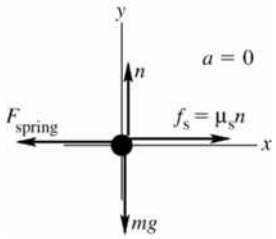
$320 \text{ J} - 80 \text{ J} = 240 \text{ J}$. For $x = -0.400$ m, $F_x = kx = -1600$ N. The magnitude of force required is 1600 N.

EVALUATE: More work is required to move the end of the spring from $x = -0.200$ m to $x = -0.400$ m than to move it from $x = 0$ to $x = -0.200$ m, even though the displacement of the platform is the same in each case. The magnitude of the force increases as the compression of the spring increases.

6.39. **IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$ to calculate the μ_s required for the static friction force to equal the spring force.

SET UP: **(a)** The free-body diagram for the glider is given in Figure 6.39.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.



EXECUTE: $\Sigma F_y = ma_y$

$n - mg = 0$

$n = mg$

$f_s = \mu_s mg$

Figure 6.39

$\Sigma F_x = ma_x$

$f_s - F_{spring} = 0$

$\mu_s mg - kd = 0$

$$\mu_s = \frac{kd}{mg} = \frac{(20.0 \text{ N/m})(0.086 \text{ m})}{(0.100 \text{ kg})(9.80 \text{ m/s}^2)} = 1.76$$

(b) IDENTIFY and **SET UP:** Apply $\Sigma\vec{F} = m\vec{a}$ to find the maximum amount the spring can be compressed and still have the spring force balanced by friction. Then use $W_{tot} = K_2 - K_1$ to find the initial speed that results in this compression of the spring when the glider stops.

EXECUTE: $\mu_s mg = kd$

$$d = \frac{\mu_s mg}{k} = \frac{(0.60)(0.100 \text{ kg})(9.80 \text{ m/s}^2)}{20.0 \text{ N/m}} = 0.0294 \text{ m}$$

Now apply the work-energy theorem to the motion of the glider:

$W_{tot} = K_2 - K_1$

$K_1 = \frac{1}{2}mv_1^2$, $K_2 = 0$ (instantaneously stops)

$W_{tot} = W_{spring} + W_{fric} = -\frac{1}{2}kd^2 - \mu_k mgd$ (as in Example 6.8)

$W_{tot} = -\frac{1}{2}(20.0 \text{ N/m})(0.0294 \text{ m})^2 - 0.47(0.100 \text{ kg})(9.80 \text{ m/s}^2)(0.0294 \text{ m}) = -0.02218 \text{ J}$

Then $W_{tot} = K_2 - K_1$ gives $-0.02218 \text{ J} = -\frac{1}{2}mv_1^2$.

$$v_1 = \sqrt{\frac{2(0.02218 \text{ J})}{0.100 \text{ kg}}} = 0.67 \text{ m/s}$$

EVALUATE: In Example 6.8 an initial speed of 1.50 m/s compresses the spring 0.086 m and in part (a) of this problem we found that the glider doesn't stay at rest. In part (b) we found that a smaller displacement of 0.0294 m when the glider stops is required if it is to stay at rest. And we calculate a smaller initial speed (0.67 m/s) to produce this smaller displacement.

6.40. **IDENTIFY:** For the spring, $W = \frac{1}{2}kx_1^2 - \frac{1}{2}kx_2^2$. Apply $W_{tot} = K_2 - K_1$.

SET UP: $x_1 = -0.025$ m and $x_2 = 0$.

EXECUTE: **(a)** $W = \frac{1}{2}kx_1^2 = \frac{1}{2}(200 \text{ N/m})(-0.025 \text{ m})^2 = 0.060 \text{ J}$.

(b) The work-energy theorem gives $v_2 = \sqrt{\frac{2W}{m}} = \sqrt{\frac{2(0.062 \text{ J})}{(4.0 \text{ kg})}} = 0.18 \text{ m/s}$.

EVALUATE: The block moves in the direction of the spring force, the spring does positive work and the kinetic energy of the block increases.

6.41. **IDENTIFY** and **SET UP:** The magnitude of the work done by F_x equals the area under the F_x versus x curve. The work is positive when F_x and the displacement are in the same direction; it is negative when they are in opposite directions.

EXECUTE: **(a)** F_x is positive and the displacement Δx is positive, so $W > 0$.

$W = \frac{1}{2}(2.0 \text{ N})(2.0 \text{ m}) + (2.0 \text{ N})(1.0 \text{ m}) = +4.0 \text{ J}$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) During this displacement $F_x = 0$, so $W = 0$.

(c) F_x is negative, Δx is positive, so $W < 0$. $W = -\frac{1}{2}(1.0\text{ N})(2.0\text{ m}) = -1.0\text{ J}$

(d) The work is the sum of the answers to parts (a), (b), and (c), so $W = 4.0\text{ J} + 0 - 1.0\text{ J} = +3.0\text{ J}$.

(e) The work done for $x = 7.0$ m to $x = 3.0$ m is $+1.0$ J. This work is positive since the displacement and the force are both in the $-x$-direction. The magnitude of the work done for $x = 3.0$ m to $x = 2.0$ m is 2.0 J, the area under F_x versus x. This work is negative since the displacement is in the $-x$-direction and the force is in the $+x$-direction. Thus $W = +1.0\text{ J} - 2.0\text{ J} = -1.0\text{ J}$.

EVALUATE: The work done when the car moves from $x = 2.0$ m to $x = 0$ is $-\frac{1}{2}(2.0\text{ N})(2.0\text{ m}) = -2.0$ J. Adding this to the work for $x = 7.0$ m to $x = 2.0$ m gives a total of $W = -3.0$ J for $x = 7.0$ m to $x = 0$. The work for $x = 7.0$ m to $x = 0$ is the negative of the work for $x = 0$ to $x = 7.0$ m.

6.42. **IDENTIFY:** Apply $W_{\text{tot}} = K_2 - K_1$.

SET UP: $K_1 = 0$. From Exercise 6.41, the work for $x = 0$ to $x = 3.0$ m is 4.0 J. W for $x = 0$ to $x = 4.0$ m is also 4.0 J. For $x = 0$ to $x = 7.0$ m, $W = 3.0$ J.

EXECUTE: **(a)** $K = 4.0$ J, so $v = \sqrt{2K/m} = \sqrt{2(4.0\text{ J})/(2.0\text{ kg})} = 2.00$ m/s.

(b) No work is done between $x = 3.0$ m and $x = 4.0$ m, so the speed is the same, 2.00 m/s.

(c) $K = 3.0$ J, so $v = \sqrt{2K/m} = \sqrt{2(3.0\text{ J})/(2.0\text{ kg})} = 1.73$ m/s.

EVALUATE: In each case the work done by F is positive and the car gains kinetic energy.

6.43. **IDENTIFY** and **SET UP:** Apply Eq. (6.6). Let point 1 be where the sled is released and point 2 be at $x = 0$ for part (a) and at $x = -0.200$ m for part (b). Use Eq. (6.10) for the work done by the spring and calculate K_2. Then $K_2 = \frac{1}{2}mv_2^2$ gives v_2.

EXECUTE: **(a)** $W_{\text{tot}} = K_2 - K_1$ so $K_2 = K_1 + W_{\text{tot}}$

$K_1 = 0$ (released with no initial velocity), $K_2 = \frac{1}{2}mv_2^2$

The only force doing work is the spring force. Eq. (6.10) gives the work done *on* the spring to move its end from x_1 to x_2. The force the spring exerts on an object attached to it is $F = -kx$, so the work the spring does is

$W_{\text{spr}} = -\left(\frac{1}{2}kx_2^2 - \frac{1}{2}kx_1^2\right) = \frac{1}{2}kx_1^2 - \frac{1}{2}kx_2^2$. Here $x_1 = -0.375$ m and $x_2 = 0$. Thus

$W_{\text{spr}} = \frac{1}{2}(4000\text{ N/m})(-0.375\text{ m})^2 - 0 = 281\text{ J}$.

$K_2 = K_1 + W_{\text{tot}} = 0 + 281\text{ J} = 281\text{ J}$

Then $K_2 = \frac{1}{2}mv_2^2$ implies $v_2 = \sqrt{\dfrac{2K_2}{m}} = \sqrt{\dfrac{2(281\text{ J})}{70.0\text{ kg}}} = 2.83$ m/s.

(b) $K_2 = K_1 + W_{\text{tot}}$

$K_1 = 0$

$W_{\text{tot}} = W_{\text{spr}} = \frac{1}{2}kx_1^2 - \frac{1}{2}kx_2^2$. Now $x_2 = 0.200$ m, so

$W_{\text{spr}} = \frac{1}{2}(4000\text{ N/m})(-0.375\text{ m})^2 - \frac{1}{2}(4000\text{ N/m})(-0.200\text{ m})^2 = 281\text{ J} - 80\text{ J} = 201\text{ J}$

Thus $K_2 = 0 + 201\text{ J} = 201\text{ J}$ and $K_2 = \frac{1}{2}mv_2^2$ gives $v_2 = \sqrt{\dfrac{2K_2}{m}} = \sqrt{\dfrac{2(201\text{ J})}{70.0\text{ kg}}} = 2.40$ m/s.

EVALUATE: The spring does positive work and the sled gains speed as it returns to $x = 0$. More work is done during the larger displacement in part (a), so the speed there is larger than in part (b).

6.44. **IDENTIFY:** $F_x = kx$

SET UP: When the spring is in equilibrium, the same force is applied to both ends of any segment of the spring.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

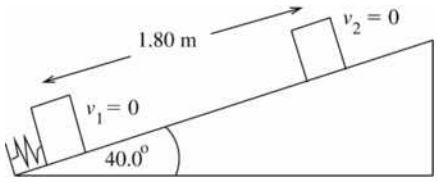
EXECUTE: **(a)** When a force F is applied to each end of the original spring, the end of the spring is displaced a distance x. Each half of the spring elongates a distance x_h, where $x_h = x/2$. Since F is also the force applied to each half of the spring, $F = kx$ and $F = k_h x_h$. $kx = k_h x_h$ and $k_h = k\left(\frac{x}{x_h}\right) = 2k$.

(b) The same reasoning as in part (a) gives $k_{seg} = 3k$, where k_{seg} is the force constant of each segment.

EVALUATE: For half of the spring the same force produces less displacement than for the original spring. Since $k = F/x$, smaller x for the same F means larger k.

6.45. **IDENTIFY** and **SET UP:** Apply Eq. (6.6) to the glider. Work is done by the spring and by gravity. Take point 1 to be where the glider is released. In part (a) point 2 is where the glider has traveled 1.80 m and $K_2 = 0$. There are two points shown in Figure 6.45a. In part (b) point 2 is where the glider has traveled 0.80 m.

EXECUTE: (a) $W_{tot} = K_2 - K_1 = 0$. Solve for x_1, the amount the spring is initially compressed.



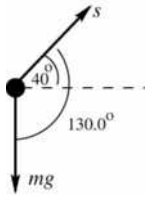
$W_{tot} = W_{spr} + W_w = 0$

So $W_{spr} = -W_w$

(The spring does positive work on the glider since the spring force is directed up the incline, the same as the direction of the displacement.)

Figure 6.45a

The directions of the displacement and of the gravity force are shown in Figure 6.45b.



$W_w = (w\cos\phi)s = (mg\cos 130.0°)s$

$W_w = (0.0900\text{ kg})(9.80\text{ m/s}^2)(\cos 130.0°)(1.80\text{ m}) = -1.020\text{ J}$

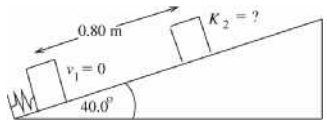
(The component of w parallel to the incline is directed down the incline, opposite to the displacement, so gravity does negative work.)

Figure 6.45b

$W_{spr} = -W_w = +1.020\text{ J}$

$W_{spr} = \frac{1}{2}kx_1^2$ so $x_1 = \sqrt{\frac{2W_{spr}}{k}} = \sqrt{\frac{2(1.020\text{ J})}{640\text{ N/m}}} = 0.0565\text{ m}$

(b) The spring was compressed only 0.0565 m so at this point in the motion the glider is no longer in contact with the spring. Points 1 and 2 are shown in Figure 6.45c.



$W_{tot} = K_2 - K_1$

$K_2 = K_1 + W_{tot}$

$K_1 = 0$

Figure 6.45c

$W_{tot} = W_{spr} + W_w$

From part (a), $W_{spr} = 1.020\text{ J}$ and

$W_w = (mg\cos 130.0°)s = (0.0900\text{ kg})(9.80\text{ m/s}^2)(\cos 130.0°)(0.80\text{ m}) = -0.454\text{ J}$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

Then $K_2 = W_{\text{spr}} + W_w = +1.020\text{ J} - 0.454\text{ J} = +0.57\text{ J}$.

EVALUATE: The kinetic energy in part (b) is positive, as it must be. In part (a), $x_2 = 0$ since the spring force is no longer applied past this point. In computing the work done by gravity we use the full 0.80 m the glider moves.

6.46. **IDENTIFY:** Apply $W_{\text{tot}} = K_2 - K_1$ to the brick. Work is done by the spring force and by gravity.

SET UP: At the maximum height, $v = 0$. Gravity does negative work, $W_{\text{grav}} = -mgh$. The work done by the spring is $\frac{1}{2}kd^2$, where d is the distance the spring is compressed initially.

EXECUTE: The initial and final kinetic energies of the brick are both zero, so the net work done on the brick by the spring and gravity is zero, so $(1/2)kd^2 - mgh = 0$, or

$d = \sqrt{2mgh/k} = \sqrt{2(1.80\text{ kg})(9.80\text{ m/s}^2)(3.6\text{ m})/(450\text{ N/m})} = 0.53\text{ m}$. The spring will provide an upward force while the spring and the brick are in contact. When this force goes to zero, the spring is at its uncompressed length. But when the spring reaches its uncompressed length the brick has an upward velocity and leaves the spring.

EVALUATE: Gravity does negative work because the gravity force is downward and the brick moves upward. The spring force does positive work on the brick because the spring force is upward and the brick moves upward.

6.47. **IDENTIFY:** The force does work on the box, which gives it kinetic energy, so the work-energy theorem applies. The force is variable so we must integrate to calculate the work it does on the box.

SET UP: $W_{\text{tot}} = \Delta K = K_{\text{f}} - K_{\text{i}} = \frac{1}{2}mv_{\text{f}}^2 - \frac{1}{2}mv_{\text{i}}^2$ and $W_{\text{tot}} = \int_{x_1}^{x_2} F(x)dx$.

EXECUTE: $W_{\text{tot}} = \int_{x_1}^{x_2} F(x)dx = \int_0^{14.0\text{m}} [18.0\text{ N} - (0.530\text{ N/m})x]dx$

$W_{\text{tot}} = (18.0\text{ N})(14.0\text{ m}) - (0.265\text{ N/m})(14.0\text{ m})^2 = 252.0\text{ J} - 51.94\text{ J} = 200.1\text{ J}$. The initial kinetic energy is zero, so $W_{\text{tot}} = \Delta K = K_{\text{f}} - K_{\text{i}} = \frac{1}{2}mv_{\text{f}}^2$. Solving for v_{f} gives $v_{\text{f}} = \sqrt{\dfrac{2W_{\text{tot}}}{m}} = \sqrt{\dfrac{2(200.1\text{ J})}{6.00\text{ kg}}} = 8.17\text{ m/s}$.

EVALUATE: We could not readily do this problem by integrating the acceleration over time because we know the force as a function of x, not of t. The work-energy theorem provides a much simpler method.

6.48. **IDENTIFY:** The force acts through a distance over time, so it does work on the crate and hence supplies power to it. The force exerted by the worker is variable but the acceleration of the cart is constant.

SET UP: Use $P = Fv$ to find the power, and we can use $v = v_0 + at$ to find the instantaneous velocity.

EXECUTE: First find the instantaneous force and velocity: $F = (5.40\text{ N/s})(5.00\text{ s}) = 27.0\text{ N}$ and $v = v_0 + at = (2.80\text{ m/s}^2)(5.00\text{ s}) = 14.0\text{ m/s}$. Now find the power: $P = (27.0\text{ N})(14.0\text{ m/s}) = 378\text{ W}$.

EVALUATE: The instantaneous power will increase as the worker pushes harder and harder.

6.49. **IDENTIFY:** Apply the relation between energy and power.

SET UP: Use $P = \dfrac{W}{\Delta t}$ to solve for W, the energy the bulb uses. Then set this value equal to $\frac{1}{2}mv^2$ and solve for the speed.

EXECUTE: $W = P\Delta t = (100\text{ W})(3600\text{ s}) = 3.6\times10^5\text{ J}$

$K = 3.6\times10^5\text{ J}$ so $v = \sqrt{\dfrac{2K}{m}} = \sqrt{\dfrac{2(3.6\times10^5\text{ J})}{70\text{ kg}}} = 100\text{ m/s}$

EVALUATE: Olympic runners achieve speeds up to approximately 10 m/s, or roughly one-tenth the result calculated.

6.50. **IDENTIFY:** Knowing the rate at which energy is consumed, we want to find out the total energy used.

SET UP: Find the elapsed time Δt in each case by dividing the distance by the speed, $\Delta t = d/v$. Then calculate the energy as $W = P\Delta t$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: *Running:* $\Delta t = (5.0 \text{ km})/(10 \text{ km/h}) = 0.50 \text{ h} = 1.8\times10^3 \text{ s}$. The energy used is

$W = (700 \text{ W})(1.8\times10^3 \text{ s}) = 1.3\times10^6 \text{ J}$.

Walking: $\Delta t = \dfrac{5.0 \text{ km}}{3.0 \text{ km/h}}\left(\dfrac{3600 \text{ s}}{\text{h}}\right) = 6.0\times10^3 \text{ s}$. The energy used is

$W = (290 \text{ W})(6.0\times10^3 \text{ s}) = 1.7\times10^6 \text{ J}$.

EVALUATE: The less intense exercise lasts longer and therefore burns up more energy than the intense exercise.

6.51. **IDENTIFY:** $P_{\text{av}} = \dfrac{\Delta W}{\Delta t}$. ΔW is the energy released.

SET UP: ΔW is to be the same. $1 \text{ y} = 3.156\times10^7$ s.

EXECUTE: $P_{\text{av}}\Delta t = \Delta W = \text{constant}$, so $P_{\text{av-sun}}\Delta t_{\text{sun}} = P_{\text{av-m}}\Delta t_{\text{m}}$.

$$P_{\text{av-m}} = P_{\text{av-sun}}\left(\frac{\Delta t_{\text{sun}}}{\Delta t_{\text{m}}}\right) = \left(\frac{[2.5\times10^5 \text{ y}][3.156\times10^7 \text{ s/y}]}{0.20 \text{ s}}\right) = 3.9\times10^{13}\,P.$$

EVALUATE: Since the power output of the magnetar is so much larger than that of our sun, the mechanism by which it radiates energy must be quite different.

6.52. **IDENTIFY:** The thermal energy is produced as a result of the force of friction, $F = \mu_{\text{k}} mg$. The average thermal power is thus the average rate of work done by friction or $P = F_{\|}v_{\text{av}}$.

SET UP: $v_{\text{av}} = \dfrac{v_2 + v_1}{2} = \left(\dfrac{8.00 \text{ m/s} + 0}{2}\right) = 4.00 \text{ m/s}$

EXECUTE: $P = Fv_{\text{av}} = [(0.200)(20.0 \text{ kg})(9.80 \text{ m/s}^2)](4.00 \text{ m/s}) = 157 \text{ W}$

EVALUATE: The power could also be determined as the rate of change of kinetic energy, $\Delta K/t$, where the time is calculated from $v_{\text{f}} = v_{\text{i}} + at$ and a is calculated from a force balance, $\Sigma F = ma = \mu_{\text{k}} mg$.

6.53. **IDENTIFY:** Use the relation $P = F_{\|}v$ to relate the given force and velocity to the total power developed.

SET UP: $1 \text{ hp} = 746 \text{ W}$

EXECUTE: The total power is $P = F_{\|}v = (165 \text{ N})(9.00 \text{ m/s}) = 1.49\times10^3$ W. Each rider therefore contributes $P_{\text{each rider}} = (1.49\times10^3 \text{ W})/2 = 745 \text{ W} \approx 1 \text{ hp}$.

EVALUATE: The result of one horsepower is very large; a rider could not sustain this output for long periods of time.

6.54. **IDENTIFY** and **SET UP:** Calculate the power used to make the plane climb against gravity. Consider the vertical motion since gravity is vertical.

EXECUTE: The rate at which work is being done against gravity is

$P = Fv = mgv = (700 \text{ kg})(9.80 \text{ m/s}^2)(2.5 \text{ m/s}) = 17.15 \text{ kW}$.

This is the part of the engine power that is being used to make the airplane climb. The fraction this is of the total is $17.15 \text{ kW}/75 \text{ kW} = 0.23$.

EVALUATE: The power we calculate for making the airplane climb is considerably less than the power output of the engine.

6.55. **IDENTIFY:** $P_{\text{av}} = \dfrac{\Delta W}{\Delta t}$. The work you do in lifting mass m a height h is mgh.

SET UP: $1 \text{ hp} = 746 \text{ W}$

EXECUTE: **(a)** The number per minute would be the average power divided by the work (mgh) required to lift one box, $\dfrac{(0.50 \text{ hp})(746 \text{ W/hp})}{(30 \text{ kg})(9.80 \text{ m/s}^2)(0.90 \text{ m})} = 1.41/\text{s}$, or $84.6/\text{min}$.

(b) Similarly, $\dfrac{(100 \text{ W})}{(30 \text{ kg})(9.80 \text{ m/s}^2)(0.90 \text{ m})} = 0.378/\text{s}$, or $22.7/\text{min}$.

EVALUATE: A 30-kg crate weighs about 66 lbs. It is not possible for a person to perform work at this rate.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

6.56. **IDENTIFY** and **SET UP:** Use Eq. (6.15) to relate the power provided and the amount of work done against gravity in 16.0 s. The work done against gravity depends on the total weight which depends on the number of passengers.

EXECUTE: Find the total mass that can be lifted:

$P_{\text{av}} = \dfrac{\Delta W}{\Delta t} = \dfrac{mgh}{t}$, so $m = \dfrac{P_{\text{av}}t}{gh}$

$P_{\text{av}} = (40 \text{ hp})\left(\dfrac{746 \text{ W}}{1 \text{ hp}}\right) = 2.984\times10^4 \text{ W}$

$m = \dfrac{P_{\text{av}}t}{gh} = \dfrac{(2.984\times10^4 \text{ W})(16.0 \text{ s})}{(9.80 \text{ m/s}^2)(20.0 \text{ m})} = 2.436\times10^3 \text{ kg}$

This is the total mass of elevator plus passengers. The mass of the passengers is

$2.436\times10^3 \text{ kg} - 600 \text{ kg} = 1.836\times10^3 \text{ kg}$. The number of passengers is $\dfrac{1.836\times10^3 \text{ kg}}{65.0 \text{ kg}} = 28.2$.

28 passengers can ride.

EVALUATE: Typical elevator capacities are about half this, in order to have a margin of safety.

6.57. **IDENTIFY:** To lift the skiers, the rope must do positive work to counteract the negative work developed by the component of the gravitational force acting on the total number of skiers, $F_{\text{rope}} = Nmg\sin\alpha$.

SET UP: $P = F_{\|}v = F_{\text{rope}}v$

EXECUTE: $P_{\text{rope}} = F_{\text{rope}}v = [+Nmg(\cos\phi)]v$.

$P_{\text{rope}} = [(50 \text{ riders})(70.0 \text{ kg})(9.80 \text{ m/s}^2)(\cos 75.0)]\left[(12.0 \text{ km/h})\left(\dfrac{1 \text{ m/s}}{3.60 \text{ km/h}}\right)\right]$.

$P_{\text{rope}} = 2.96\times10^4 \text{ W} = 29.6 \text{ kW}$.

EVALUATE: Some additional power would be needed to give the riders kinetic energy as they are accelerated from rest.

6.58. **IDENTIFY:** Apply $P = F_{\|}v$. $F_{\|}$ is the force F of water resistance.

SET UP: 1 hp = 746 W. 1 km/h = 0.228 m/s

EXECUTE: $F = \dfrac{(0.70)P}{v} = \dfrac{(0.70)(280{,}000 \text{ hp})(746 \text{ W/hp})}{(65 \text{ km/h})((0.278 \text{ m/s})/(1 \text{ km/h}))} = 8.1\times10^6 \text{ N}$.

EVALUATE: The power required depends on speed, because of the factor of v in $P = F_{\|}v$ and also because the resistive force increases with speed.

6.59. **IDENTIFY:** Relate power, work and time.

SET UP: Work done in each stroke is $W = Fs$ and $P_{\text{av}} = W/t$.

EXECUTE: 100 strokes per second means $P_{\text{av}} = 100Fs/t$ with $t = 1.00$ s, $F = 2mg$ and $s = 0.010$ m.

$P_{\text{av}} = 0.20$ W.

EVALUATE: For a 70-kg person to apply a force of twice his weight through a distance of 0.50 m for 100 times per second, the average power output would be 7.0×10^4 W. This power output is very far beyond the capability of a person.

6.60. **IDENTIFY:** The force has only an x-component and the motion is along the x-direction, so $W = \int_{x_1}^{x_2} F_x dx$.

SET UP: $x_1 = 0$ and $x_2 = 6.9$ m.

EXECUTE: The work you do with your changing force is

$W = \int_{x_1}^{x_2} F(x)dx = \int_{x_1}^{x_2} (-20.0 \text{ N})dx - \int_{x_1}^{x_2} (3.0 \text{ N/m})xdx = (-20.0 \text{ N})x\,|_{x_1}^{x_2} - (3.0 \text{ N/m})(x^2/2)\,|_{x_1}^{x_2}$

$W = -138 \text{ N}\cdot\text{m} - 71.4 \text{ N}\cdot\text{m} = -209 \text{ J}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: The work is negative because the cow continues to move forward (in the $+x$-direction) as you vainly attempt to push her backward.

6.61. **IDENTIFY:** For mass dm located a distance x from the axis and moving with speed v, the kinetic energy is $K = \frac{1}{2}(dm)v^2$. Follow the procedure specified in the hint.

SET UP: The bar and an infinitesimal mass element along the bar are sketched in Figure 6.61. Let $M =$ total mass and $T =$ time for one revolution. $v = \dfrac{2\pi x}{T}$.

EXECUTE: $K = \int \frac{1}{2}(dm)v^2$. $dm = \dfrac{M}{L}dx$, so

$$K = \int_0^L \frac{1}{2}\left(\frac{M}{L}dx\right)\left(\frac{2\pi x}{T}\right)^2 = \frac{1}{2}\left(\frac{M}{L}\right)\left(\frac{4\pi^2}{T^2}\right)\int_0^L x^2 dx = \frac{1}{2}\left(\frac{M}{L}\right)\left(\frac{4\pi^2}{T^2}\right)\left(\frac{L^3}{3}\right) = \frac{2}{3}\pi^2 ML^2/T^2$$

There are 5 revolutions in 3 seconds, so $T = 3/5 \text{ s} = 0.60 \text{ s}$

$$K = \frac{2}{3}\pi^2(12.0 \text{ kg})(2.00 \text{ m})^2/(0.60 \text{ s})^2 = 877 \text{ J}.$$

EVALUATE: If a point mass 12.0 kg is 2.00 m from the axis and rotates at the same rate as the bar, $v = \dfrac{2\pi(2.00 \text{ m})}{0.60 \text{ s}} = 20.9 \text{ m/s}$ and $K = \frac{1}{2}mv^2 = \frac{1}{2}(12 \text{ kg})(20.9 \text{ m/s})^2 = 2.62\times10^3$ J. K for the bar is smaller by a factor of 0.33. The speed of a segment of the bar decreases toward the axis.

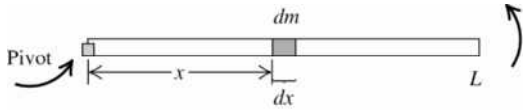


Figure 6.61

6.62. **IDENTIFY:** Density is mass per unit volume, $\rho = m/V$, so we can calculate the mass of the asteroid. $K = \frac{1}{2}mv^2$. Since the asteroid comes to rest, the kinetic energy it delivers equals its initial kinetic energy.

SET UP: The volume of a sphere is related to its diameter by $V = \dfrac{1}{6}\pi d^3$.

EXECUTE: **(a)** $V = \dfrac{\pi}{6}(320 \text{ m})^3 = 1.72\times10^7 \text{ m}^3$. $m = \rho V = (2600 \text{ kg/m}^3)(1.72\times10^7 \text{ m}^3) = 4.47\times10^{10}$ kg.

$K = \frac{1}{2}mv^2 = \frac{1}{2}(4.47\times10^{10} \text{ kg})(12.6\times10^3 \text{ m/s})^2 = 3.55\times10^{18}$ J.

(b) The yield of a Castle/Bravo device is $(15)(4.184\times10^{15} \text{ J}) = 6.28\times10^{16}$ J. $\dfrac{3.55\times10^{18} \text{ J}}{6.28\times10^{16} \text{ J}} = 56.5$ devices.

EVALUATE: If such an asteroid were to hit the earth the effect would be catastrophic.

6.63. **IDENTIFY** and **SET UP:** Since the forces are constant, Eq. (6.2) can be used to calculate the work done by each force. The forces on the suitcase are shown in Figure 6.63a.

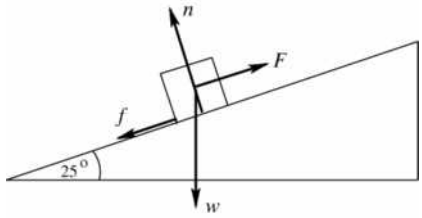

Figure 6.63a

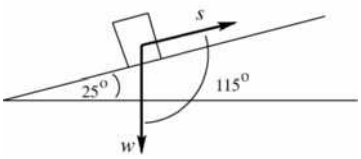
In part (f), Eq. (6.6) is used to relate the total work to the initial and final kinetic energy.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: **(a)** $W_F = (F\cos\phi)s$

Both $\vec{F}$ and $\vec{s}$ are parallel to the incline and in the same direction, so $\phi = 90°$ and $W_F = Fs = (140\text{ N})(3.80\text{ m}) = 532\text{ J}$.

(b) The directions of the displacement and of the gravity force are shown in Figure 6.63b.



$W_w = (w\cos\phi)s$

$\phi = 115°$, so

$W_w = (196\text{ N})(\cos 115°)(3.80\text{ m})$

$W_w = -315\text{ J}$

Figure 6.63b

Alternatively, the component of w parallel to the incline is $w\sin 25°$. This component is down the incline so its angle with $\vec{s}$ is $\phi = 180°$. $W_{w\sin 25°} = (196\text{ N}\sin 25°)(\cos 180°)(3.80\text{ m}) = -315\text{ J}$. The other component of w, $w\cos 25°$, is perpendicular to $\vec{s}$ and hence does no work. Thus $W_w = W_{w\sin 25°} = -315\text{ J}$, which agrees with the above.

(c) The normal force is perpendicular to the displacement $(\phi = 90°)$, so $W_n = 0$.

(d) $n = w\cos 25°$ so $f_k = \mu_k n = \mu_k w\cos 25° = (0.30)(196\text{ N})\cos 25° = 53.3\text{ N}$

$W_f = (f_k\cos\phi)x = (53.3\text{ N})(\cos 180°)(3.80\text{ m}) = -202\text{ J}$

(e) $W_{tot} = W_F + W_w + W_n + W_f = +532\text{ J} - 315\text{ J} + 0 - 202\text{ J} = 15\text{ J}$

(f) $W_{tot} = K_2 - K_1$, $K_1 = 0$, so $K_2 = W_{tot}$

$\frac{1}{2}mv_2^2 = W_{tot}$ so $v_2 = \sqrt{\frac{2W_{tot}}{m}} = \sqrt{\frac{2(15\text{ J})}{20.0\text{ kg}}} = 1.2\text{ m/s}$

EVALUATE: The total work done is positive and the kinetic energy of the suitcase increases as it moves up the incline.

6.64. **IDENTIFY:** The work he does to lift his body a distance h is $W = mgh$. The work per unit mass is $(W/m) = gh$.

SET UP: The quantity gh has units of N/kg.

EXECUTE: **(a)** The man does work, $(9.8\text{ N/kg})(0.4\text{ m}) = 3.92\text{ J/kg}$.

(b) $(3.92\text{ J/kg})/(70\text{ J/kg})\times 100 = 5.6\%$.

(c) The child does work $(9.8\text{ N/kg})(0.2\text{ m}) = 1.96\text{ J/kg}$. $(1.96\text{ J/kg})/(70\text{ J/kg})\times 100 = 2.8\%$.

(d) If both the man and the child can do work at the rate of 70 J/kg, and if the child only needs to use 1.96 J/kg instead of 3.92 J/kg, the child should be able to do more chin-ups.

EVALUATE: Since the child has arms half the length of his father's arms, the child must lift his body only 0.20 m to do a chin-up.

6.65. **IDENTIFY:** Four forces act on the crate: the 290-N push, gravity, friction, and the normal force due to the surface of the ramp. The total work is the sum of the work due to all four of these forces. The acceleration is constant because the forces are constant.

SET UP: The work is $W = Fs\cos\phi$. We can use the standard kinematics formulas because the acceleration is constant. The work-energy theorem, $W_{tot} = \Delta K$, applies.

EXECUTE: **(a)** First calculate the work done by each of the four forces. The normal force does no work because it is perpendicular to the displacement. The other work is

$W_F = (F\cos 34.0°)(15.0\text{ m}) = (290\text{ N})(\cos 34.0°)(15.0\text{ m}) = 3606\text{ J}$,

$W_{mg} = -mg(15.0\text{ m})(\sin 34.0°) = -(20.0\text{ kg})(9.8\text{ m/s}^2)(15.0\text{ m})(\sin 34.0°) = -1644\text{ J}$ and

$W_f = -f(15.0\text{ m}) = -(65.0\text{ N})(15.0\text{ m}) = -975\text{ J}$. The total work is

$W_{tot} = 3606\text{ J} - 1644\text{ J} - 975\text{ J} = 987\text{ J}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) First find the final velocity: $W_{\text{tot}} = \Delta K$ so $v_{\text{f}} = \sqrt{\dfrac{2(987\text{ J})}{20.0\text{ kg}}} = 9.935$ m/s.

Constant acceleration gives $x - x_0 = \left(\dfrac{v_{0x} + v_x}{2}\right)t$ so

$$t = \frac{2(x - x_0)}{v_{0x} + v_x} = \frac{2(15.0\text{ m})}{0 + (9.935\text{ m/s})} = 3.02\text{ s}.$$

EVALUATE: Work is a scalar, so we can algebraically add the work done by each of the forces.

6.66. **IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$ to each block to find the tension in the string. Each force is constant and $W = Fs\cos\phi$.

SET UP: The free-body diagram for each block is given in Figure 6.66. $m_A = \dfrac{20.0\text{ N}}{g} = 2.04$ kg and $m_B = \dfrac{12.0\text{ N}}{g} = 1.22$ kg.

EXECUTE: $T - f_{\text{k}} = m_A a$. $w_B - T = m_B a$. $w_B - f_{\text{k}} = (m_A + m_B)a$.

(a) $f_{\text{k}} = 0$. $a = \left(\dfrac{w_B}{m_A + m_B}\right)$ and $T = w_B\left(\dfrac{m_A}{m_A + m_B}\right) = w_B\left(\dfrac{w_A}{w_A + w_B}\right) = 7.50$ N.

20.0 N block: $W_{\text{tot}} = Ts = (7.50\text{ N})(0.750\text{ m}) = 5.62$ J.

12.0 N block: $W_{\text{tot}} = (w_B - T)s = (12.0\text{ N} - 7.50\text{ N})(0.750\text{ m}) = 3.38$ J.

(b) $f_{\text{k}} = \mu_{\text{k}} w_A = 6.50$ N. $a = \dfrac{w_B - \mu_{\text{k}} w_A}{m_A + m_B}$.

$$T = f_{\text{k}} + (w_B - \mu_{\text{k}} w_A)\left(\frac{m_A}{m_A + m_B}\right) = \mu_{\text{k}} w_A + (w_B - \mu_{\text{k}} w_A)\left(\frac{w_A}{w_A + w_B}\right).$$

$T = 6.50\text{ N} + (5.50\text{ N})(0.625) = 9.94$ N.

20.0 N block: $W_{\text{tot}} = (T - f_{\text{k}})s = (9.94\text{ N} - 6.50\text{ N})(0.750\text{ m}) = 2.58$ J.

12.0 N block: $W_{\text{tot}} = (w_B - T)s = (12.0\text{ N} - 9.94\text{ N})(0.750\text{ m}) = 1.54$ J.

EVALUATE: Since the two blocks move with equal speeds, for each block $W_{\text{tot}} = K_2 - K_1$ is proportional to the mass (or weight) of that block. With friction the gain in kinetic energy is less, so the total work on each block is less.

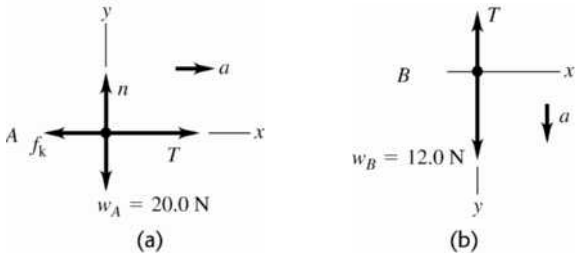


Figure 6.66

6.67. **IDENTIFY:** $K = \frac{1}{2}mv^2$. Find the speed of the shuttle relative to the earth and relative to the satellite.

SET UP: Velocity is distance divided by time. For one orbit the shuttle travels a distance $2\pi R$.

EXECUTE: **(a)** $\dfrac{1}{2}mv^2 = \dfrac{1}{2}m\left(\dfrac{2\pi R}{T}\right)^2 = \dfrac{1}{2}(86{,}400\text{ kg})\left(\dfrac{2\pi(6.66\times10^6\text{ m})}{(90.1\text{ min})(60\text{ s/min})}\right)^2 = 2.59\times10^{12}$ J.

(b) $(1/2)\,mv^2 = (1/2)(86{,}400\text{ kg})((1.00\text{ m})/(3.00\text{ s}))^2 = 4.80\times10^3$ J.

EVALUATE: The kinetic energy of an object depends on the reference frame in which it is measured.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

6.68. **IDENTIFY:** $W = Fs\cos\phi$ and $W_{\text{tot}} = K_2 - K_1$.

SET UP: $f_k = \mu_k n$. The normal force is $n = mg\cos\theta$, with $\theta = 24.0°$. The component of the weight parallel to the incline is $mg\sin\theta$.

EXECUTE: **(a)** $\phi = 180°$ and

$W_f = -f_k s = -(\mu_k mg\cos\theta)s = -(0.31)(5.00\text{ kg})(9.80\text{ m/s}^2)(\cos 24.0°)(1.50\text{ m}) = -20.8\text{ J}.$

(b) $(5.00\text{ kg})(9.80\text{ m/s}^2)(\sin 24.0°)(1.50\text{ m}) = 29.9\text{ J}.$

(c) The normal force does no work.

(d) $W_{\text{tot}} = 29.9\text{ J} - 20.8\text{ J} = +9.1\text{ J}.$

(e) $K_2 = K_1 + W_{\text{tot}} = (1/2)(5.00\text{ kg})(2.2\text{ m/s})^2 + 9.1\text{ J} = 21.2\text{ J},$ and so $v_2 = \sqrt{2(21.2\text{ J})/(5.00\text{ kg})} = 2.9\text{ m/s}.$

EVALUATE: Friction does negative work and gravity does positive work. The net work is positive and the kinetic energy of the object increases.

6.69. **IDENTIFY:** The initial kinetic energy of the head is absorbed by the neck bones during a sudden stop. Newton's second law applies to the passengers as well as to their heads.

SET UP: In part (a), the initial kinetic energy of the head is absorbed by the neck bones, so $\frac{1}{2}mv_{\text{max}}^2 = 8.0$ J. For part (b), assume constant acceleration and use $v_f = v_i + at$ with $v_i = 0,$ to calculate a; then apply $F_{\text{net}} = ma$ to find the net accelerating force.

Solve: (a) $v_{\text{max}} = \sqrt{\dfrac{2(8.0\text{ J})}{5.0\text{ kg}}} = 1.8\text{ m/s} = 4.0\text{ mph}.$

(b) $a = \dfrac{v_f - v_i}{t} = \dfrac{1.8\text{ m/s} - 0}{10.0\times10^{-3}\text{ s}} = 180\text{ m/s}^2 \approx 18g,$ and $F_{\text{net}} = ma = (5.0\text{ kg})(180\text{ m/s}^2) = 900\text{ N}.$

EVALUATE: The acceleration is very large, but if it lasts for only 10 ms it does not do much damage.

6.70. **IDENTIFY:** The force does work on the object, which changes its kinetic energy, so the work-energy theorem applies. The force is variable so we must integrate to calculate the work it does on the object.

SET UP: $W_{\text{tot}} = \Delta K = K_f - K_i = \frac{1}{2}mv_f^2 - \frac{1}{2}mv_i^2$ and $W_{\text{tot}} = \int_{x_1}^{x_2} F(x)dx.$

EXECUTE: $W_{\text{tot}} = \int_{x_i}^{x_2} F(x)dx = \int_0^{5.00\text{ m}} [-12.0\text{ N} + (0.300\text{ N/m}^2)x^2]dx.$

$W_{\text{tot}} = -(12.0\text{ N})(5.00\text{ m}) + (0.100\text{ N/m}^2)(5.00\text{ m})^3 = -60.0\text{ J} + 12.5\text{ J} = -47.5\text{ J}.$

$W_{\text{tot}} = \frac{1}{2}mv_f^2 - \frac{1}{2}mv_i^2 = -47.5\text{ J},$ so the final velocity is

$v_f = \sqrt{v_i^2 - \dfrac{2(47.5\text{ J})}{m}} = \sqrt{(6.00\text{ m/s})^2 - \dfrac{2(47.5\text{ J})}{5.00\text{ kg}}} = 4.12\text{ m/s}.$

EVALUATE: We could not readily do this problem by integrating the acceleration over time because we know the force as a function of x, not of t. The work-energy theorem provides a much simpler method.

6.71. **IDENTIFY:** Apply Eq. (6.7).

SET UP: $\int \dfrac{dx}{x^2} = -\dfrac{1}{x}.$

EXECUTE: **(a)** $W = \int_{x_1}^{x_2} F_x dx = -k\int_{x_1}^{x_2} \dfrac{dx}{x^2} = -k\left[-\dfrac{1}{x}\right]_{x_1}^{x_2} = k\left(\dfrac{1}{x_2} - \dfrac{1}{x_1}\right).$ The force is given to be attractive, so $F_x < 0$, and k must be positive. If $x_2 > x_1,$ $\dfrac{1}{x_2} < \dfrac{1}{x_1}$, and $W < 0.$

(b) Taking "slowly" to be constant speed, the net force on the object is zero. The force applied by the hand is opposite F_x, and the work done is negative of that found in part (a), or $k\left(\dfrac{1}{x_1} - \dfrac{1}{x_2}\right)$, which is positive if $x_2 > x_1.$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(c) The answers have the same magnitude but opposite signs; this is to be expected, in that the net work done is zero.

EVALUATE: Your force is directed away from the origin, so when the object moves away from the origin your force does positive work.

6.72. **IDENTIFY:** Apply Eq. (6.6) to the motion of the asteroid.

SET UP: Let point 1 be at a great distance and let point 2 be at the surface of the earth. Assume $K_1 = 0$. From the information given about the gravitational force its magnitude as a function of distance r from the center of the earth must be $F = mg(R_E/r)^2$. This force is directed in the $-\hat{\boldsymbol{r}}$ direction since it is a "pull." F is not constant so Eq. (6.7) must be used to calculate the work it does.

EXECUTE: $W = -\int_1^2 F\, ds = -\int_\infty^{R_E} \left(\frac{mgR_E^2}{r^2}\right) dr = -mgR_E^2(-(1/r)\big|_\infty^{R_E}) = mgR_E$

$W_{tot} = K_2 - K_1,\ K_1 = 0$

This gives $K_2 = mgR_E = 1.25\times10^{12}$ J

$K_2 = \frac{1}{2}mv_2^2$ so $v_2 = \sqrt{2K_2/m} = 11{,}000$ m/s

EVALUATE: Note that $v_2 = \sqrt{2gR_E}$; the impact speed is independent of the mass of the asteroid.

6.73. **IDENTIFY:** Calculate the work done by friction and apply $W_{tot} = K_2 - K_1$. Since the friction force is not constant, use Eq. (6.7) to calculate the work.

SET UP: Let x be the distance past P. Since μ_k increases linearly with x, $\mu_k = 0.100 + Ax$. When $x = 12.5$ m, $\mu_k = 0.600$, so $A = 0.500/(12.5\text{ m}) = 0.0400/\text{m}$.

EXECUTE: **(a)** $W_{tot} = \Delta K = K_2 - K_1$ gives $-\int \mu_k mg\,dx = 0 - \frac{1}{2}mv_1^2$. Using the above expression for μ_k,

$g\int_0^{x_2}(0.100 + Ax)dx = \frac{1}{2}v_1^2$ and $g\left[(0.100)x_2 + A\frac{x_2^2}{2}\right] = \frac{1}{2}v_1^2$.

$(9.80\text{ m/s}^2)\left[(0.100)x_2 + (0.0400/\text{m})\frac{x_2^2}{2}\right] = \frac{1}{2}(4.50\text{ m/s})^2$. Solving for x_2 gives $x_2 = 5.11$ m.

(b) $\mu_k = 0.100 + (0.0400/\text{m})(5.11\text{ m}) = 0.304$

(c) $W_{tot} = K_2 - K_1$ gives $-\mu_k mgx_2 = 0 - \frac{1}{2}mv_1^2$. $x_2 = \frac{v_1^2}{2\mu_k g} = \frac{(4.50\text{ m/s})^2}{2(0.100)(9.80\text{ m/s}^2)} = 10.3$ m.

EVALUATE: The box goes farther when the friction coefficient doesn't increase.

6.74. **IDENTIFY:** Use Eq. (6.7) to calculate W.

SET UP: $x_1 = 0$. In part (a), $x_2 = 0.050$ m. In part (b), $x_2 = -0.050$ m.

EXECUTE: **(a)** $W = \int_0^{x_2} F dx = \int_0^{x_2}(kx - bx^2 + cx^3)\,dx = \frac{k}{2}x_2^2 - \frac{b}{3}x_2^3 + \frac{c}{4}x_2^4$.

$W = (50.0\text{ N/m})\,x_2^2 - (233\text{ N/m}^2)\,x_2^3 + (3000\text{ N/m}^3)\,x_2^4$. When $x_2 = 0.050$ m, $W = 0.12$ J.

(b) When $x_2 = -0.050$ m, $W = 0.17$ J.

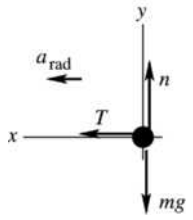
(c) It's easier to stretch the spring; the quadratic $-bx^2$ term is always in the $-x$-direction, and so the needed force, and hence the needed work, will be less when $x_2 > 0$.

EVALUATE: When $x = 0.050$ m, $F_x = 4.75$ N. When $x = -0.050$ m, $F_x = -8.25$ N.

6.75. **IDENTIFY** and **SET UP:** Use $\Sigma\vec{\boldsymbol{F}} = m\vec{\boldsymbol{a}}$ to find the tension force T. The block moves in uniform circular motion and $\vec{\boldsymbol{a}} = \vec{\boldsymbol{a}}_{rad}$.

(a) The free-body diagram for the block is given in Figure 6.75.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.



EXECUTE: $\Sigma F_x = ma_x$

$$T = m\frac{v^2}{R}$$

$$T = (0.0900\text{ kg})\frac{(0.70\text{ m/s})^2}{0.40\text{ m}} = 0.11\text{ N}.$$

Figure 6.75

(b) $T = m\dfrac{v^2}{R} = (0.0900\text{ kg})\dfrac{(2.80\text{ m/s})^2}{0.10\text{ m}} = 7.1\text{ N}.$

(c) SET UP: The tension changes as the distance of the block from the hole changes. We could use $W = \int_{x_1}^{x_2} F_x\,dx$ to calculate the work. But a much simpler approach is to use $W_{\text{tot}} = K_2 - K_1$.

EXECUTE: The only force doing work on the block is the tension in the cord, so $W_{\text{tot}} = W_T$.

$K_1 = \frac{1}{2}mv_1^2 = \frac{1}{2}(0.0900\text{ kg})(0.70\text{ m/s})^2 = 0.0221\text{ J}$, $K_2 = \frac{1}{2}mv_2^2 = \frac{1}{2}(0.0900\text{ kg})(2.80\text{ m/s})^2 = 0.353\text{ J}$, so $W_{\text{tot}} = K_2 - K_1 = 0.353\text{ J} - 0.0221\text{ J} = 0.33\text{ J}$. This is the amount of work done by the person who pulled the cord.

EVALUATE: The block moves inward, in the direction of the tension, so T does positive work and the kinetic energy increases.

6.76. **IDENTIFY:** Use Eq. (6.7) to find the work done by F. Then apply $W_{\text{tot}} = K_2 - K_1$.

SET UP: $\int \dfrac{dx}{x^2} = -\dfrac{1}{x}$.

EXECUTE: $W = \int_{x_1}^{x_2} \dfrac{\alpha}{x^2}\,dx = \alpha\left(\dfrac{1}{x_1} - \dfrac{1}{x_2}\right)$.

$W = (2.12\times10^{-26}\text{ N}\cdot\text{m}^2)((0.200\text{ m}^{-1}) - (1.25\times10^{9}\text{ m}^{-1})) = -2.65\times10^{-17}\text{ J}$.

Note that x_1 is so large compared to x_2 that the term $1/x_1$ is negligible. Then, using Eq. (6.13) and solving for v_2,

$$v_2 = \sqrt{v_1^2 + \frac{2W}{m}} = \sqrt{(3.00\times10^5\text{ m/s})^2 + \frac{2(-2.65\times10^{-17}\text{ J})}{(1.67\times10^{-27}\text{ kg})}} = 2.41\times10^5\text{ m/s}.$$

(b) With $K_2 = 0, W = -K_1$. Using $W = -\dfrac{\alpha}{x_2}$,

$$x_2 = \frac{\alpha}{K_1} = \frac{2\alpha}{mv_1^2} = \frac{2(2.12\times10^{-26}\text{ N}\cdot\text{m}^2)}{(1.67\times10^{-27}\text{ kg})(3.00\times10^5\text{ m/s})^2} = 2.82\times10^{-10}\text{ m}.$$

(c) The repulsive force has done no net work, so the kinetic energy and hence the speed of the proton have their original values, and the speed is 3.00×10^5 m/s.

EVALUATE: As the proton moves toward the uranium nucleus the repulsive force does negative work and the kinetic energy of the proton decreases. As the proton moves away from the uranium nucleus the repulsive force does positive work and the kinetic energy of the proton increases.

6.77. **IDENTIFY** and **SET UP:** Use $v_x = dx/dt$ and $a_x = dv_x/dt$. Use $\Sigma\vec{F} = m\vec{a}$ to calculate $\vec{F}$ from $\vec{a}$.

EXECUTE: **(a)** $x(t) = \alpha t^2 + \beta t^3$, $v_x(t) = \dfrac{dx}{dt} = 2\alpha t + 3\beta t^2$. At $t = 4.00$ s:

$v_x = 2(0.200\text{ m/s}^2)(4.00\text{ s}) + 3(0.0200\text{ m/s}^3)(4.00\text{ s})^2 = 2.56\text{ m/s}.$

(b) $a_x(t) = \dfrac{dv_x}{dt} = 2\alpha + 6\beta t$, so $F_x = ma_x = m(2\alpha + 6\beta t)$. At $t = 4.00$ s:

$$F_x = (4.00\text{ kg})[2(0.200\text{ m/s}^2) + 6(0.0200\text{ m/s}^3)(4.00\text{ s})] = 3.52\text{ N}.$$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(c) IDENTIFY and **SET UP:** Use Eq. (6.6) to calculate the work.

EXECUTE: $W_{\text{tot}} = K_2 - K_1$. At $t_1 = 0$, $v_1 = 0$ so $K_1 = 0$. $W_{\text{tot}} = W_F$.

$K_2 = \frac{1}{2}mv_2^2 = \frac{1}{2}(4.00 \text{ kg})(2.56 \text{ m/s})^2 = 13.1 \text{ J}$. Then $W_{\text{tot}} = K_2 - K_1$ gives that $W_F = 13.1$ J.

EVALUATE: Since v increases with t, the kinetic energy increases and the work done is positive. We can also calculate W_F directly from Eq. (6.7), by writing dx as $v_x\,dt$ and performing the integral.

6.78. **IDENTIFY** and **SET UP:** Use Eq. (6.6). You do positive work and gravity does negative work. Let point 1 be at the base of the bridge and point 2 be at the top of the bridge.

EXECUTE: **(a)** $W_{\text{tot}} = K_2 - K_1$

$K_1 = \frac{1}{2}mv_1^2 = \frac{1}{2}(80.0 \text{ kg})(5.00 \text{ m/s})^2 = 1000 \text{ J}$

$K_2 = \frac{1}{2}mv_2^2 = \frac{1}{2}(80.0 \text{ kg})(1.50 \text{ m/s})^2 = 90 \text{ J}$

$W_{\text{tot}} = 90 \text{ J} - 1000 \text{ J} = -910 \text{ J}$

(b) Neglecting friction, work is done by you (with the force you apply to the pedals) and by gravity: $W_{\text{tot}} = W_{\text{you}} + W_{\text{gravity}}$. The gravity force is $w = mg = (80.0 \text{ kg})(9.80 \text{ m/s}^2) = 784 \text{ N}$, downward. The displacement is 5.20 m, upward. Thus $\phi = 180°$ and

$$W_{\text{gravity}} = (F\cos\phi)s = (784 \text{ N})(5.20 \text{ m})\cos 180° = -4077 \text{ J}$$

Then $W_{\text{tot}} = W_{\text{you}} + W_{\text{gravity}}$ gives

$$W_{\text{you}} = W_{\text{tot}} - W_{\text{gravity}} = -910 \text{ J} - (-4077 \text{ J}) = +3170 \text{ J}$$

EVALUATE: The total work done is negative and you lose kinetic energy.

6.79. **IDENTIFY:** The negative work done by the spring equals the change in kinetic energy of the car.

SET UP: The work done by a spring when it is compressed a distance x from equilibrium is $-\frac{1}{2}kx^2$.

$K_2 = 0$.

EXECUTE: $-\frac{1}{2}kx^2 = K_2 - K_1$ gives $\frac{1}{2}kx^2 = \frac{1}{2}mv_1^2$ and

$k = (mv_1^2)/x^2 = [(1200 \text{ kg})(0.65 \text{ m/s})^2]/(0.090 \text{ m})^2 = 6.3\times10^4 \text{ N/m}$.

EVALUATE: When the spring is compressed, the spring force is directed opposite to the displacement of the object and the work done by the spring is negative.

6.80. **IDENTIFY:** Apply $W_{\text{tot}} = K_2 - K_1$.

SET UP: Let x_0 be the initial distance the spring is compressed. The work done by the spring is $\frac{1}{2}kx_0^2 - \frac{1}{2}kx^2$, where x is the final distance the spring is compressed.

EXECUTE: **(a)** Equating the work done by the spring to the gain in kinetic energy, $\frac{1}{2}kx_0^2 = \frac{1}{2}mv^2$, so

$$v = \sqrt{\frac{k}{m}}x_0 = \sqrt{\frac{400 \text{ N/m}}{0.0300 \text{ kg}}}(0.060 \text{ m}) = 6.93 \text{ m/s}.$$

(b) W_{tot} must now include friction, so $\frac{1}{2}mv^2 = W_{\text{tot}} = \frac{1}{2}kx_0^2 - fx_0$, where f is the magnitude of the friction force. Then,

$$v = \sqrt{\frac{k}{m}x_0^2 - \frac{2f}{m}x_0} = \sqrt{\frac{400 \text{ N/m}}{0.0300 \text{ kg}}(0.060 \text{ m})^2 - \frac{2(6.00 \text{ N})}{(0.0300 \text{ kg})}(0.060 \text{ m})} = 4.90 \text{ m/s}.$$

(c) The greatest speed occurs when the acceleration (and the net force) are zero. Let x be the amount the spring is still compressed, so the distance the ball has moved is $x_0 - x$. $kx = f$, $x = \frac{f}{k} = \frac{6.00 \text{ N}}{400 \text{ N/m}} = 0.0150 \text{ m}$.

The ball is 0.0150 m from the end of the barrel, or 0.0450 m from its initial position.

To find the speed, the net work is $W_{\text{tot}} = \frac{1}{2}k(x_0^2 - x^2) - f(x_0 - x)$, so the maximum speed is

$$v_{\text{max}} = \sqrt{\frac{k}{m}(x_0^2 - x^2) - \frac{2f}{m}(x_0 - x)}.$$

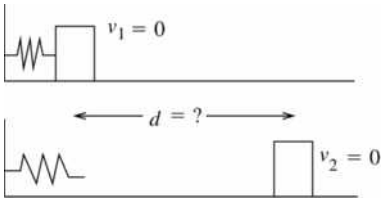
© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$v_{\max} = \sqrt{\frac{400 \text{ N/m}}{(0.0300 \text{ kg})}((0.060 \text{ m})^2 - (0.0150 \text{ m})^2) - \frac{2(6.00 \text{ N})}{(0.0300 \text{ kg})}(0.060 \text{ m} - 0.0150 \text{ m})} = 5.20 \text{ m/s}$$

EVALUATE: The maximum speed with friction present (part (c)) is larger than the result of part (b) but smaller than the result of part (a).

6.81. **IDENTIFY** and **SET UP:** Use Eq. (6.6). Work is done by the spring and by gravity. Let point 1 be where the textbook is released and point 2 be where it stops sliding. $x_2 = 0$ since at point 2 the spring is neither stretched nor compressed. The situation is sketched in Figure 6.81.

EXECUTE:



$W_{\text{tot}} = K_2 - K_1$
$K_1 = 0, \quad K_2 = 0$
$W_{\text{tot}} = W_{\text{fric}} + W_{\text{spr}}$

Figure 6.81

$W_{\text{spr}} = \frac{1}{2}kx_1^2$, where $x_1 = 0.250$ m (Spring force is in direction of motion of block so it does positive work.)

$W_{\text{fric}} = -\mu_k mgd$

Then $W_{\text{tot}} = K_2 - K_1$ gives $\frac{1}{2}kx_1^2 - \mu_k mgd = 0$

$$d = \frac{kx_1^2}{2\mu_k mg} = \frac{(250 \text{ N/m})(0.250 \text{ m})^2}{2(0.30)(2.50 \text{ kg})(9.80 \text{ m/s}^2)} = 1.1 \text{ m, measured from the point where the block was released.}$$

EVALUATE: The positive work done by the spring equals the magnitude of the negative work done by friction. The total work done during the motion between points 1 and 2 is zero and the textbook starts and ends with zero kinetic energy.

6.82. **IDENTIFY:** Apply $W_{\text{tot}} = K_2 - K_1$ to the cat.

SET UP: Let point 1 be at the bottom of the ramp and point 2 be at the top of the ramp.

EXECUTE: The work done by gravity is $W_g = -mgL\sin\theta$ (negative since the cat is moving up), and the work done by the applied force is FL, where F is the magnitude of the applied force. The total work is

$$W_{\text{tot}} = (100 \text{ N})(2.00 \text{ m}) - (7.00 \text{ kg})(9.80 \text{ m/s}^2)(2.00 \text{ m})\sin 30° = 131.4 \text{ J}.$$

The cat's initial kinetic energy is $\frac{1}{2}mv_1^2 = \frac{1}{2}(7.00 \text{ kg})(2.40 \text{ m/s})^2 = 20.2$ J, and

$$v_2 = \sqrt{\frac{2(K_1 + W)}{m}} = \sqrt{\frac{2(20.2 \text{ J} + 131.4 \text{ J})}{(7.00 \text{ kg})}} = 6.58 \text{ m/s}.$$

EVALUATE: The net work done on the cat is positive and the cat gains speed. Without your push, $W_{\text{tot}} = W_{\text{grav}} = -68.6$ J and the cat wouldn't have enough initial kinetic energy to reach the top of the ramp.

6.83. **IDENTIFY:** Apply $W_{\text{tot}} = K_2 - K_1$ to the vehicle.

SET UP: Call the bumper compression x and the initial speed v_0. The work done by the spring is $-\frac{1}{2}kx^2$ and $K_2 = 0$.

EXECUTE: **(a)** The necessary relations are $\frac{1}{2}kx^2 = \frac{1}{2}mv_0^2$, $kx < 5mg$. Combining to eliminate k and then x, the two inequalities are $x > \frac{v^2}{5g}$ and $k < 25\frac{mg^2}{v^2}$. Using the given numerical values,

$$x > \frac{(20.0 \text{ m/s})^2}{5(9.80 \text{ m/s}^2)} = 8.16 \text{ m} \text{ and } k < 25\frac{(1700 \text{ kg})(9.80 \text{ m/s}^2)^2}{(20.0 \text{ m/s})^2} = 1.02 \times 10^4 \text{ N/m}.$$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) A distance of 8 m is not commonly available as space in which to stop a car. Also, the car stops only momentarily and then returns to its original speed when the spring returns to its original length.

EVALUATE: If k were doubled, to 2.04×10^4 N/m, then $x = 5.77$ m. The stopping distance is reduced by a factor of $1/\sqrt{2}$, but the maximum acceleration would then be $kx/m = 69.2$ m/s^2, which is $7.07g$.

6.84. **IDENTIFY:** Apply $W_{\text{tot}} = K_2 - K_1$. $W = Fs\cos\phi$.

SET UP: The students do positive work, and the force that they exert makes an angle of $30.0°$ with the direction of motion. Gravity does negative work, and is at an angle of $120.0°$ with the chair's motion.

EXECUTE: The total work done is

$W_{\text{tot}} = ((600\text{ N})\cos30.0° + (85.0\text{ kg})(9.80\text{ m/s}^2)\cos120.0°)(2.50\text{ m}) = 257.8\text{ J}$, and so the speed at the top of the ramp is $v_2 = \sqrt{v_1^2 + \dfrac{2W_{\text{tot}}}{m}} = \sqrt{(2.00\text{ m/s})^2 + \dfrac{2(257.8\text{ J})}{(85.0\text{ kg})}} = 3.17\text{ m/s}.$

EVALUATE: The component of gravity down the incline is $mg\sin30° = 417$ N and the component of the push up the incline is $(600\text{ N})\cos30° = 520$ N. The force component up the incline is greater than the force component down the incline; the net work done is positive and the speed increases.

6.85. **IDENTIFY:** Apply $W_{\text{tot}} = K_2 - K_1$ to the blocks.

SET UP: If X is the distance the spring is compressed, the work done by the spring is $-\frac{1}{2}kX^2$. At maximum compression, the spring (and hence the block) is not moving, so the block has no kinetic energy and $x_2 = 0$.

EXECUTE: **(a)** The work done *by* the block is equal to its initial kinetic energy, and the maximum compression is found from $\frac{1}{2}kX^2 = \frac{1}{2}mv_0^2$ and $X = \sqrt{\dfrac{m}{k}}v_0 = \sqrt{\dfrac{5.00\text{ kg}}{500\text{ N/m}}}(6.00\text{ m/s}) = 0.600\text{ m}.$

(b) Solving for v_0 in terms of a known X, $v_0 = \sqrt{\dfrac{k}{m}}X = \sqrt{\dfrac{500\text{ N/m}}{5.00\text{ kg}}}(0.150\text{ m}) = 1.50\text{ m/s}.$

EVALUATE: The negative work done by the spring removes the kinetic energy of the block.

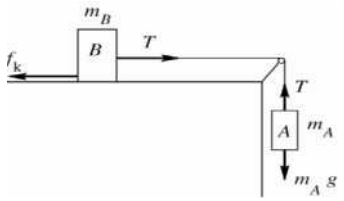
6.86. **IDENTIFY:** Apply $W_{\text{tot}} = K_2 - K_1$ to the system of the two blocks. The total work done is the sum of that done by gravity (on the hanging block) and that done by friction (on the block on the table).

SET UP: Let h be the distance the 6.00 kg block descends. The work done by gravity is (6.00 kg)gh and the work done by friction is $-\mu_{\text{k}}(8.00\text{ kg})gh$.

EXECUTE: $W_{\text{tot}} = (6.00\text{ kg} - (0.25)(8.00\text{ kg}))(9.80\text{ m/s}^2)(1.50\text{ m}) = 58.8\text{ J}$. This work increases the kinetic energy of both blocks: $W_{\text{tot}} = \dfrac{1}{2}(m_1 + m_2)v^2$, so $v = \sqrt{\dfrac{2(58.8\text{ J})}{(14.00\text{ kg})}} = 2.90\text{ m/s}.$

EVALUATE: Since the two blocks are connected by the rope, they move the same distance h and have the same speed v.

6.87. **IDENTIFY** and **SET UP:** Apply $W_{\text{tot}} = K_2 - K_1$ to the system consisting of both blocks. Since they are connected by the cord, both blocks have the same speed at every point in the motion. Also, when the 6.00-kg block has moved downward 1.50 m, the 8.00-kg block has moved 1.50 m to the right. The target variable, μ_{k}, will be a factor in the work done by friction. The forces on each block are shown in Figure 6.87.



EXECUTE:

$K_1 = \frac{1}{2}m_Av_1^2 + \frac{1}{2}m_Bv_1^2 = \frac{1}{2}(m_A + m_B)v_1^2$

$K_2 = 0$

Figure 6.87

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

The tension T in the rope does positive work on block B and the same magnitude of negative work on block A, so T does no net work on the system. Gravity does work $W_{mg} = m_A gd$ on block A, where $d = 2.00$ m. (Block B moves horizontally, so no work is done on it by gravity.) Friction does work $W_{\text{fric}} = -\mu_k m_B gd$ on block B. Thus $W_{\text{tot}} = W_{mg} + W_{\text{fric}} = m_A gd - \mu_k m_B gd$. Then $W_{\text{tot}} = K_2 - K_1$ gives $m_A gd - \mu_k m_B gd = -\frac{1}{2}(m_A + m_B)v_1^2$ and

$$\mu_k = \frac{m_A}{m_B} + \frac{\frac{1}{2}(m_A + m_B)v_1^2}{m_B gd} = \frac{6.00 \text{ kg}}{8.00 \text{ kg}} + \frac{(6.00 \text{ kg} + 8.00 \text{ kg})\,(0.900 \text{ m/s})^2}{2(8.00 \text{ kg})\,(9.80 \text{ m/s}^2)\,(2.00 \text{ m})} = 0.786$$

EVALUATE: The weight of block A does positive work and the friction force on block B does negative work, so the net work is positive and the kinetic energy of the blocks increases as block A descends. Note that K_1 includes the kinetic energy of both blocks. We could have applied the work-energy theorem to block A alone, but then W_{tot} includes the work done on block A by the tension force.

6.88. **IDENTIFY:** Apply $W_{\text{tot}} = K_2 - K_1$. The work done by the force from the bow is the area under the graph of F_x versus the draw length.

SET UP: One possible way of estimating the work is to approximate the F versus x curve as a parabola which goes to zero at $x = 0$ and $x = x_0$, and has a maximum of F_0 at $x = x_0/2$, so that $F(x) = (4F_0/x_0^2)\,x\,(x_0 - x)$. This may seem like a crude approximation to the figure, but it has the advantage of being easy to integrate.

EXECUTE: $\int_0^{x_0} F dx = \frac{4F_0}{x_0^2}\int_0^{x_0}(x_0 x - x^2)\,dx = \frac{4F_0}{x_0^2}\left(x_0\frac{x_0^2}{2} - \frac{x_0^3}{3}\right) = \frac{2}{3}F_0 x_0$. With $F_0 = 200$ N and $x_0 = 0.75$ m, $W = 100$ J. The speed of the arrow is then $\sqrt{\frac{2W}{m}} = \sqrt{\frac{2(100 \text{ J})}{(0.025\ kg)}} = 89$ m/s.

EVALUATE: We could alternatively represent the area as that of a rectangle 180 N by 0.55 m. This gives $W = 99$ J, in close agreement with our more elaborate estimate.

6.89. **IDENTIFY:** Apply Eq. (6.6) to the skater.

SET UP: Let point 1 be just before she reaches the rough patch and let point 2 be where she exits from the patch. Work is done by friction. We don't know the skater's mass so can't calculate either friction or the initial kinetic energy. Leave her mass m as a variable and expect that it will divide out of the final equation.

EXECUTE: $f_k = 0.25mg$ so $W_f = W_{\text{tot}} = -(0.25mg)s$, where s is the length of the rough patch.

$W_{\text{tot}} = K_2 - K_1$

$K_1 = \frac{1}{2}mv_0^2$, $K_2 = \frac{1}{2}mv_2^2 = \frac{1}{2}m(0.55v_0)^2 = 0.3025\left(\frac{1}{2}mv_0^2\right)$

The work-energy relation gives $-(0.25mg)s = (0.3025 - 1)\frac{1}{2}mv_0^2$

The mass divides out, and solving gives $s = 1.3$ m.

EVALUATE: Friction does negative work and this reduces her kinetic energy.

6.90. **IDENTIFY:** $P_{\text{av}} = F_{\|}v_{\text{av}}$. Use $F = ma$ to calculate the force.

SET UP: $v_{\text{av}} = \frac{0 + 6.00 \text{ m/s}}{2} = 3.00$ m/s

EXECUTE: Your friend's average acceleration is $a = \frac{v - v_0}{t} = \frac{6.00 \text{ m/s}}{3.00 \text{ s}} = 2.00 \text{ m/s}^2$. Since there are no other horizontal forces acting, the force you exert on her is given by

$F_{\text{net}} = ma = (65.0 \text{ kg})(2.00 \text{ m/s}^2) = 130$ N. $P_{\text{av}} = (130 \text{ N})(3.00 \text{ m/s}) = 390$ W.

EVALUATE: We could also use the work-energy theorem:

$W = K_2 - K_1 = \frac{1}{2}(65.0 \text{ kg})(6.00 \text{ m/s})^2 = 1170$ J.

$P_{\text{av}} = \frac{W}{t} = \frac{1170 \text{ J}}{3.00 \text{ s}} = 390$ W, the same as obtained by our other approach.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

6.91. **IDENTIFY:** To lift a mass m a height h requires work $W = mgh$. To accelerate mass m from rest to speed v requires $W = K_2 - K_1 = \frac{1}{2}mv^2$. $P_{\text{av}} = \dfrac{\Delta W}{\Delta t}$.

SET UP: $t = 60$ s

EXECUTE: **(a)** $(800 \text{ kg})(9.80 \text{ m/s}^2)(14.0 \text{ m}) = 1.10\times10^5$ J

(b) $(1/2)(800 \text{ kg})(18.0 \text{ m/s}^2) = 1.30\times10^5$ J.

(c) $\dfrac{1.10\times10^5 \text{ J} + 1.30\times10^5 \text{ J}}{60 \text{ s}} = 3.99 \text{ kW}.$

EVALUATE: Approximately the same amount of work is required to lift the water against gravity as to accelerate it to its final speed.

6.92. **IDENTIFY** and **SET UP:** $W = Pt$

EXECUTE: **(a)** The hummingbird produces energy at a rate of 0.7 J/s to 1.75 J/s. At 10 beats/s, the bird must expend between 0.07 J/beat and 0.175 J/beat.

(b) The steady output of the athlete is $(500 \text{ W})/(70 \text{ kg}) = 7$ W/kg, which is below the 10 W/kg necessary to stay aloft. Though the athlete can expend $1400 \text{ W}/70 \text{ kg} = 20$ W/kg for short periods of time, no human-powered aircraft could stay aloft for very long.

EVALUATE: Movies of early attempts at human-powered flight bear out our results.

6.93. **IDENTIFY** and **SET UP:** Energy is $P_{\text{av}}t$. The total energy expended in one day is the sum of the energy expended in each type of activity.

EXECUTE: $1 \text{ day} = 8.64\times10^4$ s

Let t_{walk} be the time she spends walking and t_{other} be the time she spends in other activities;

$t_{\text{other}} = 8.64\times10^4 \text{ s} - t_{\text{walk}}$.

The energy expended in each activity is the power output times the time, so

$E = Pt = (280 \text{ W})t_{\text{walk}} + (100 \text{ W})t_{\text{other}} = 1.1\times10^7$ J

$(280 \text{ W})t_{\text{walk}} + (100 \text{ W})(8.64\times10^4 \text{ s} - t_{\text{walk}}) = 1.1\times10^7$ J

$(180 \text{ W})t_{\text{walk}} = 2.36\times10^6$ J

$t_{\text{walk}} = 1.31\times10^4 \text{ s} = 218 \text{ min} = 3.6 \text{ h}.$

EVALUATE: Her average power for one day is $(1.1\times10^7 \text{ J})/([24][3600 \text{ s}]) = 127$ W. This is much closer to her 100 W rate than to her 280 W rate, so most of her day is spent at the 100 W rate.

6.94. **IDENTIFY** and **SET UP:** Use Eq. (6.15). The work done on the water by gravity is mgh, where $h = 170$ m. Solve for the mass m of water for 1.00 s and then calculate the volume of water that has this mass.

EXECUTE: The power output is $P_{\text{av}} = 2000 \text{ MW} = 2.00\times10^9$ W. $P_{\text{av}} = \dfrac{\Delta W}{\Delta t}$ and 92% of the work done on the water by gravity is converted to electrical power output, so in 1.00 s the amount of work done on the water by gravity is

$W = \dfrac{P_{\text{av}}\Delta t}{0.92} = \dfrac{(2.00\times10^9 \text{ W})(1.00 \text{ s})}{0.92} = 2.174\times10^9$ J

$W = mgh$, so the mass of water flowing over the dam in 1.00 s must be

$m = \dfrac{W}{gh} = \dfrac{2.174\times10^9 \text{ J}}{(9.80 \text{ m/s}^2)(170 \text{ m})} = 1.30\times10^6 \text{ kg}$

$\text{density} = \dfrac{m}{V}$ so $V = \dfrac{m}{\text{density}} = \dfrac{1.30\times10^6 \text{ kg}}{1.00\times10^3 \text{ kg/m}^3} = 1.30\times10^3 \text{ m}^3.$

EVALUATE: The dam is 1270 m long, so this volume corresponds to about a m^3 flowing over each 1 m length of the dam, a reasonable amount.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

6.95. **IDENTIFY** and **SET UP:** For part (a) calculate m from the volume of blood pumped by the heart in one day. For part (b) use W calculated in part (a) in Eq. (6.15).

EXECUTE: (a) $W = mgh$, as in Example 6.10. We need the mass of blood lifted; we are given the volume

$$V = (7500 \text{ L})\left(\frac{1\times10^{-3} \text{ m}^3}{1 \text{ L}}\right) = 7.50 \text{ m}^3.$$

$m = \text{density} \times \text{volume} = (1.05\times10^3 \text{ kg/m}^3)(7.50 \text{ m}^3) = 7.875\times10^3 \text{ kg}$

Then $W = mgh = (7.875\times10^3 \text{ kg})(9.80 \text{ m/s}^2)(1.63 \text{ m}) = 1.26\times10^5 \text{ J}.$

(b) $P_{\text{av}} = \dfrac{\Delta W}{\Delta t} = \dfrac{1.26\times10^5 \text{ J}}{(24 \text{ h})(3600 \text{ s/h})} = 1.46 \text{ W}.$

EVALUATE: Compared to light bulbs or common electrical devices, the power output of the heart is rather small.

6.96. **IDENTIFY:** $P = F_{\|}v = Mav$. To overcome gravity on a slope that is at an angle α above the horizontal, $P = (Mg\sin\alpha)v$.

SET UP: $1 \text{ MW} = 10^6 \text{ W}$. $1 \text{ kN} = 10^3 \text{ N}$. When α is small, $\tan\alpha \approx \sin\alpha$.

EXECUTE: **(a)** The number of cars is the total power available divided by the power needed per car,

$\dfrac{13.4\times10^6 \text{ W}}{(2.8\times10^3 \text{ N})(27 \text{ m/s})} = 177$, rounding down to the nearest integer.

(b) To accelerate a total mass M at an acceleration a and speed v, the extra power needed is Mav. To climb a hill of angle α, the extra power needed is $(Mg\sin\alpha)v$. This will be nearly the same if $a \sim g\sin\alpha$; if $g\sin\alpha \sim g\tan\alpha \sim 0.10 \text{ m/s}^2$, the power is about the same as that needed to accelerate at 0.10 m/s^2.

(c) $P = (Mg\sin\alpha)v$, where M is the total mass of the diesel units.

$P = (1.10\times10^6 \text{ kg})(9.80 \text{ m/s}^2)(0.010)(27 \text{ m/s}) = 2.9 \text{ MW}.$

(d) The power available to the cars is 13.4 MW, minus the 2.9 MW needed to maintain the speed of the diesel units on the incline. The total number of cars is then

$\dfrac{13.4\times10^6 \text{ W} - 2.9\times10^6 \text{ W}}{(2.8\times10^3 \text{ N} + (8.2\times10^4 \text{ kg})(9.80 \text{ m/s}^2)(0.010))(27 \text{ m/s})} = 36,$ rounding to the nearest integer.

EVALUATE: For a single car, $Mg\sin\alpha = (8.2\times10^4 \text{ kg})(9.80 \text{ m/s}^2)(0.010) = 8.0\times10^3 \text{ N}$, which is over twice the 2.8 kN required to pull the car at 27 m/s on level tracks. Even a slope as gradual as 1.0% greatly increases the power requirements, or for constant power greatly decreases the number of cars that can be pulled.

6.97. **IDENTIFY:** $P = F_{\|}v$. The force required to give mass m an acceleration a is $F = ma$. For an incline at an angle α above the horizontal, the component of mg down the incline is $mg\sin\alpha$.

SET UP: For small α, $\sin\alpha \approx \tan\alpha$.

EXECUTE: **(a)** $P_0 = Fv = (53\times10^3 \text{ N})(45 \text{ m/s}) = 2.4 \text{ MW}.$

(b) $P_1 = mav = (9.1\times10^5 \text{ kg})(1.5 \text{ m/s}^2)(45 \text{ m/s}) = 61 \text{ MW}.$

(c) Approximating $\sin\alpha$, by $\tan\alpha$, and using the component of gravity down the incline as $mg\sin\alpha$,

$P_2 = (mg\sin\alpha)v = (9.1\times10^5 \text{ kg})(9.80 \text{ m/s}^2)(0.015)(45 \text{ m/s}) = 6.0 \text{ MW}.$

EVALUATE: From Problem 6.96, we would expect that a 0.15 m/s^2 acceleration and a 1.5% slope would require the same power. We found that a 1.5 m/s^2 acceleration requires ten times more power than a 1.5% slope, which is consistent.

6.98. **IDENTIFY:** $W = \int_{x_1}^{x_2} F_x dx$, and F_x depends on both x and y.

SET UP: In each case, use the value of y that applies to the specified path. $\int x dx = \frac{1}{2}x^2$. $\int x^2 dx = \frac{1}{3}x^3$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: **(a)** Along this path, y is constant, with the value $y = 3.00$ m.

$$W = \alpha y \int_{x_1}^{x_2} x\,dx = (2.50 \text{ N/m}^2)(3.00 \text{ m})\frac{(2.00 \text{ m})^2}{2} = 15.0 \text{ J, since } x_1 = 0 \text{ and } x_2 = 2.00 \text{ m.}$$

(b) Since the force has no y-component, no work is done moving in the y-direction.

(c) Along this path, y varies with position along the path, given by $y = 1.5x$, so $F_x = \alpha(1.5x)x = 1.5\alpha x^2$, and

$$W = \int_{x_1}^{x_2} F\,dx = 1.5\alpha \int_{x_1}^{x_2} x^2\,dx = 1.5(2.50 \text{ N/m}^2)\frac{(2.00 \text{ m})^3}{3} = 10.0 \text{ J.}$$

EVALUATE: The force depends on the position of the object along its path.

6.99. **IDENTIFY** and **SET UP:** Use Eq. (6.18) to relate the forces to the power required. The air resistance force is $F_{\text{air}} = \frac{1}{2}CA\rho v^2$, where C is the drag coefficient.

EXECUTE: **(a)** $P = F_{\text{tot}}v$, with $F_{\text{tot}} = F_{\text{roll}} + F_{\text{air}}$

$F_{\text{air}} = \frac{1}{2}CA\rho v^2 = \frac{1}{2}(1.0)(0.463 \text{ m}^3)(1.2 \text{ kg/m}^3)(12.0 \text{ m/s})^2 = 40.0 \text{ N}$

$F_{\text{roll}} = \mu_{\text{r}} n = \mu_{\text{r}} w = (0.0045)(490 \text{ N} + 118 \text{ N}) = 2.74 \text{ N}$

$P = (F_{\text{roll}} + F_{\text{air}})\,v = (2.74 \text{ N} + 40.0 \text{ N})(12.0 \text{ s}) = 513 \text{ W}$

(b) $F_{\text{air}} = \frac{1}{2}CA\rho v^2 = \frac{1}{2}(0.88)(0.366 \text{ m}^3)(1.2 \text{ kg/m}^3)(12.0 \text{ m/s})^2 = 27.8 \text{ N}$

$F_{\text{roll}} = \mu_{\text{r}} n = \mu_{\text{r}} w = (0.0030)(490 \text{ N} + 88 \text{ N}) = 1.73 \text{ N}$

$P = (F_{\text{roll}} + F_{\text{air}})v = (1.73 \text{ N} + 27.8 \text{ N})(12.0 \text{ s}) = 354 \text{ W}$

(c) $F_{\text{air}} = \frac{1}{2}CA\rho v^2 = \frac{1}{2}(0.88)(0.366 \text{ m}^3)(1.2 \text{ kg/m}^3)(6.0 \text{ m/s})^2 = 6.96 \text{ N}$

$F_{\text{roll}} = \mu_{\text{r}} n = 1.73 \text{ N}$ (unchanged)

$P = (F_{\text{roll}} + F_{\text{air}})v = (1.73 \text{ N} + 6.96 \text{ N})(6.0 \text{ m/s}) = 52.1 \text{ W}$

EVALUATE: Since F_{air} is proportional to v^2 and $P = Fv$, reducing the speed greatly reduces the power required.

6.100. **IDENTIFY:** $P = F_{\|}v$

SET UP: 1 m/s = 3.6 km/h

EXECUTE: **(a)** $F = \dfrac{P}{v} = \dfrac{28.0\times10^3 \text{ W}}{(60.0 \text{ km/h})((1 \text{ m/s})/(3.6 \text{ km/h}))} = 1.68\times10^3 \text{ N.}$

(b) The speed is lowered by a factor of one-half, and the resisting force is lowered by a factor of $(0.65 + 0.35/4)$, and so the power at the lower speed is $(28.0 \text{ kW})(0.50)(0.65 + 0.35/4) = 10.3 \text{ kW} = 13.8 \text{ hp.}$

(c) Similarly, at the higher speed, $(28.0 \text{ kW})(2.0)(0.65 + 0.35\times4) = 114.8 \text{ kW} = 154 \text{ hp.}$

EVALUATE: At low speeds rolling friction dominates the power requirement but at high speeds air resistance dominates.

6.101. **IDENTIFY** and **SET UP:** Use Eq. (6.18) to relate F and P. In part (a), F is the retarding force. In parts (b) and (c), F includes gravity.

EXECUTE: **(a)** $P = Fv$, so $F = P/v$.

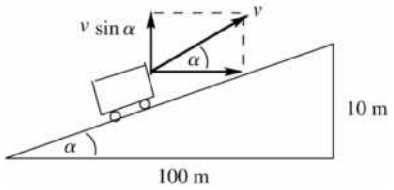
$$P = (8.00 \text{ hp})\left(\frac{746 \text{ W}}{1 \text{ hp}}\right) = 5968 \text{ W}$$

$$v = (60.0 \text{ km/h})\left(\frac{1000 \text{ m}}{1 \text{ km}}\right)\left(\frac{1 \text{ h}}{3600 \text{ s}}\right) = 16.67 \text{ m/s}$$

$$F = \frac{P}{v} = \frac{5968 \text{ W}}{16.67 \text{ m/s}} = 358 \text{ N.}$$

(b) The power required is the 8.00 hp of part (a) plus the power P_g required to lift the car against gravity. The situation is sketched in Figure 6.101.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.



$$\tan\alpha = \frac{10\text{ m}}{100\text{ m}} = 0.10$$
$$\alpha = 5.71°$$

Figure 6.101

The vertical component of the velocity of the car is $v\sin\alpha = (16.67\text{ m/s})\sin 5.71° = 1.658\text{ m/s}$.

Then $P_g = F(v\sin a) = mgv\sin\alpha = (1800\text{ kg})(9.80\text{ m/s}^2)(1.658\text{ m/s}) = 2.92\times10^4\text{ W}$

$$P_g = 2.92\times10^4\text{ W}\left(\frac{1\text{ hp}}{746\text{ W}}\right) = 39.1\text{ hp}$$

The total power required is $8.00\text{ hp} + 39.1\text{ hp} = 47.1\text{ hp}$.

(c) The power required from the engine is *reduced* by the rate at which gravity does positive work. The road incline angle α is given by $\tan\alpha = 0.0100$, so $\alpha = 0.5729°$.

$P_g = mg(v\sin\alpha) = (1800\text{ kg})\,(9.80\text{ m/s}^2)(16.67\text{ m/s})\sin 0.5729° = 2.94\times10^3\text{ W} = 3.94\text{ hp}$.

The power required from the engine is then $8.00\text{ hp} - 3.94\text{ hp} = 4.06\text{ hp}$.

(d) No power is needed from the engine if gravity does work at the rate of $P_g = 8.00\text{ hp} = 5968\text{ W}$.

$$P_g = mgv\sin\alpha,\ \text{so}\ \sin\alpha = \frac{P_g}{mgv} = \frac{5968\text{ W}}{(1800\text{ kg})(9.80\text{ m/s}^2)(16.67\text{ m/s})} = 0.02030$$

$\alpha = 1.163°$ and $\tan\alpha = 0.0203$, a 2.03% grade.

EVALUATE: More power is required when the car goes uphill and less when it goes downhill. In part (d), at this angle the component of gravity down the incline is $mg\sin\alpha = 358\text{ N}$ and this force cancels the retarding force and no force from the engine is required. The retarding force depends on the speed so it is the same in parts (a), (b) and (c).

6.102. **IDENTIFY:** Apply $W_{\text{tot}} = K_2 - K_1$ to relate the initial speed v_0 to the distance x along the plank that the box moves before coming to rest.

SET UP: The component of weight down the incline is $mg\sin\alpha$, the normal force is $mg\cos\alpha$ and the friction force is $f = \mu mg\cos\alpha$.

EXECUTE: $\Delta K = 0 - \frac{1}{2}mv_0^2$ and $W = \int_0^x(-mg\sin\alpha - \mu mg\cos\alpha)dx$. Then,

$$W = 2mg\int_0^x(\sin\alpha + Ax\cos\alpha)dx,\ W = -mg\left[\sin\alpha x + \frac{Ax^2}{2}\cos\alpha\right].$$

Set $W = \Delta K$: $-\frac{1}{2}mv_0^2 = -mg\left[\sin\alpha x + \frac{Ax^2}{2}\cos\alpha\right]$. To eliminate x, note that the box comes to a rest when the force of static friction balances the component of the weight directed down the plane. So, $mg\sin\alpha = Ax\,mg\cos\alpha$. Solve this for x and substitute into the previous equation: $x = \frac{\sin\alpha}{A\cos\alpha}$. Then,

$\frac{1}{2}v_0^2 = +g\left[\sin\alpha\frac{\sin\alpha}{A\cos\alpha} + \frac{1}{2}A\left(\frac{\sin\alpha}{A\cos\alpha}\right)^2\cos\alpha\right]$, and upon canceling factors and collecting terms,

$v_0^2 = \frac{3g\sin^2\alpha}{A\cos\alpha}$. The box will remain stationary whenever $v_0^2 = \frac{3g\sin^2\alpha}{A\cos\alpha}$.

EVALUATE: If v_0 is too small the box stops at a point where the friction force is too small to hold the box in place. $\sin\alpha$ increases and $\cos\alpha$ decreases as α increases, so the v_0 required increases as α increases.

6.103. **IDENTIFY:** In part (a) follow the steps outlined in the problem. For parts (b), (c) and (d) apply the work-energy theorem.

SET UP: $\int x^2 dx = \frac{1}{3}x^3$

EXECUTE: **(a)** Denote the position of a piece of the spring by l; $l = 0$ is the fixed point and $l = L$ is the moving end of the spring. Then the velocity of the point corresponding to l, denoted u, is $u(l) = v(l/L)$ (when the spring is moving, l will be a function of time, and so u is an implicit function of time). The mass of a piece of length dl is $dm = (M/L)dl$, and so $dK = \frac{1}{2}(dm)u^2 = \frac{1}{2}\frac{Mv^2}{L^3}l^2 dl$, and $K = \int dK = \frac{Mv^2}{2L^3}\int_0^L l^2 dl = \frac{Mv^2}{6}$.

(b) $\frac{1}{2}kx^2 = \frac{1}{2}mv^2$, so $v = \sqrt{(k/m)x} = \sqrt{(3200\text{ N/m})/(0.053\text{ kg})}\,(2.50\times10^{-2}\text{ m}) = 6.1\text{ m/s}$.

(c) With the mass of the spring included, the work that the spring does goes into the kinetic energies of both the ball and the spring, so $\frac{1}{2}kx^2 = \frac{1}{2}mv^2 + \frac{1}{6}Mv^2$. Solving for v,

$$v = \sqrt{\frac{k}{m + M/3}}\,x = \sqrt{\frac{(3200\text{ N/m})}{(0.053\text{ kg}) + (0.243\text{ kg})/3}}(2.50\times10^{-2}\text{m}) = 3.9\text{ m/s}.$$

(d) Algebraically, $\frac{1}{2}mv^2 = \frac{(1/2)kx^2}{(1 + M/3m)} = 0.40\text{ J}$ and $\frac{1}{6}Mv^2 = \frac{(1/2)kx^2}{(1 + 3m/M)} = 0.60\text{ J}$.

EVALUATE: For this ball and spring, $\frac{K_{\text{ball}}}{K_{\text{spring}}} = \frac{3m}{M} = 3\left(\frac{0.053\text{ kg}}{0.243\text{ kg}}\right) = 0.65$. The percentage of the final kinetic energy that ends up with each object depends on the ratio of the masses of the two objects. As expected, when the mass of the spring is a small fraction of the mass of the ball, the fraction of the kinetic energy that ends up in the spring is small.

6.104. **IDENTIFY:** In both cases, a given amount of fuel represents a given amount of work W_0 that the engine does in moving the plane forward against the resisting force. Write W_0 in terms of the range R and speed v and in terms of the time of flight T and v.

SET UP: In both cases assume v is constant, so $W_0 = RF$ and $R = vT$.

EXECUTE: In terms of the range R and the constant speed v, $W_0 = RF = R\left(\alpha v^2 + \frac{\beta}{v^2}\right)$.

In terms of the time of flight $T, R = vt$, so $W_0 = vTF = T\left(\alpha v^3 + \frac{\beta}{v}\right)$.

(a) Rather than solve for R as a function of v, differentiate the first of these relations with respect to v, setting $\frac{dW_0}{dv} = 0$ to obtain $\frac{dR}{dv}F + R\frac{dF}{dv} = 0$. For the maximum range, $\frac{dR}{dv} = 0$, so $\frac{dF}{dv} = 0$. Performing the differentiation, $\frac{dF}{dv} = 2\alpha v - 2\beta/v^3 = 0$, which is solved for

$$v = \left(\frac{\beta}{\alpha}\right)^{1/4} = \left(\frac{3.5\times10^5\text{ N}\cdot\text{m}^2/\text{s}^2}{0.30\text{ N}\cdot\text{s}^2/\text{m}^2}\right)^{1/4} = 32.9\text{ m/s} = 118\text{ km/h}.$$

(b) Similarly, the maximum time is found by setting $\frac{d}{dv}(Fv) = 0$; performing the differentiation,

$3\alpha v^2 - \beta/v^2 = 0$. $v = \left(\frac{\beta}{3\alpha}\right)^{1/4} = \left(\frac{3.5\times10^5\text{ N}\cdot\text{m}^2/\text{s}^2}{3(0.30\text{ N}\cdot\text{s}^2/\text{m}^2)}\right)^{1/4} = 25\text{ m/s} = 90\text{ km/h}$.

EVALUATE: When $v = (\beta/\alpha)^{1/4}$, F_{air} has its minimum value $F_{\text{air}} = 2\sqrt{\alpha\beta}$. For this v, $R_1 = (0.50)\frac{W_0}{\sqrt{\alpha\beta}}$ and $T_1 = (0.50)\alpha^{-1/4}\beta^{-3/4}$. When $v = (\beta/3\alpha)^{1/4}$, $F_{\text{air}} = 2.3\sqrt{\alpha\beta}$. For this v, $R_2 = (0.43)\frac{W_0}{\sqrt{\alpha\beta}}$ and $T_2 = (0.57)\alpha^{-1/4}\beta^{-3/4}$. $R_1 > R_2$ and $T_2 > T_1$, as they should be.

7

POTENTIAL ENERGY AND ENERGY CONSERVATION

7.1. **IDENTIFY:** $U_{\text{grav}} = mgy$ so $\Delta U_{\text{grav}} = mg(y_2 - y_1)$

SET UP: $+y$ is upward.

EXECUTE: **(a)** $\Delta U = (75 \text{ kg})(9.80 \text{ m/s}^2)(2400 \text{ m} - 1500 \text{ m}) = +6.6\times10^5 \text{ J}$

(b) $\Delta U = (75 \text{ kg})(9.80 \text{ m/s}^2)(1350 \text{ m} - 2400 \text{ m}) = -7.7\times10^5 \text{ J}$

EVALUATE: U_{grav} increases when the altitude of the object increases.

7.2. **IDENTIFY:** The change in height of a jumper causes a change in their potential energy.

SET UP: Use $\Delta U_{\text{grav}} = mg(y_{\text{f}} - y_{\text{i}})$.

EXECUTE: $\Delta U_{\text{grav}} = (72 \text{ kg})(9.80 \text{ m/s}^2)(0.60 \text{ m}) = 420 \text{ J}$.

EVALUATE: This gravitational potential energy comes from elastic potential energy stored in the jumper's tensed muscles.

7.3. **IDENTIFY:** Use the free-body diagram for the bag and Newton's first law to find the force the worker applies. Since the bag starts and ends at rest, $K_2 - K_1 = 0$ and $W_{\text{tot}} = 0$.

SET UP: A sketch showing the initial and final positions of the bag is given in Figure 7.3a. $\sin\phi = \dfrac{2.0 \text{ m}}{3.5 \text{ m}}$ and $\phi = 34.85°$. The free-body diagram is given in Figure 7.3b. $\vec{F}$ is the horizontal force applied by the worker. In the calculation of U_{grav} take $+y$ upward and $y = 0$ at the initial position of the bag.

EXECUTE: **(a)** $\Sigma F_y = 0$ gives $T\cos\phi = mg$ and $\Sigma F_x = 0$ gives $F = T\sin\phi$. Combining these equations to eliminate T gives $F = mg\tan\phi = (120 \text{ kg})(9.80 \text{ m/s}^2)\tan 34.85° = 820 \text{ N}$.

(b) (i) The tension in the rope is radial and the displacement is tangential so there is no component of T in the direction of the displacement during the motion and the tension in the rope does no work.

(ii) $W_{\text{tot}} = 0$ so $W_{\text{worker}} = -W_{\text{grav}} = U_{\text{grav},2} - U_{\text{grav},1} = mg(y_2 - y_1) = (120 \text{ kg})(9.80 \text{ m/s}^2)(0.6277 \text{ m}) = 740 \text{ J}$.

EVALUATE: The force applied by the worker varies during the motion of the bag and it would be difficult to calculate W_{worker} directly.

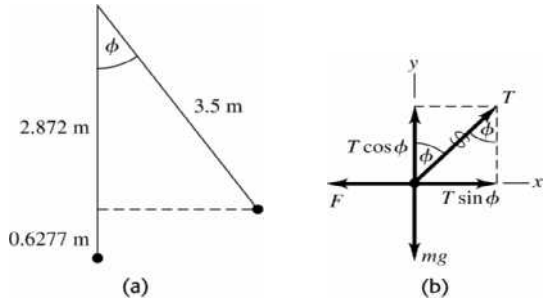

Figure 7.3

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

7.4. **IDENTIFY:** The energy from the food goes into the increased gravitational potential energy of the hiker. We must convert food calories to joules.

SET UP: The change in gravitational potential energy is $\Delta U_{\text{grav}} = mg\ (y_{\text{f}} - y_{\text{i}})$, while the increase in kinetic energy is negligible. Set the food energy, expressed in joules, equal to the mechanical energy developed.

EXECUTE: **(a)** The food energy equals $mg(y_{\text{f}} - y_{\text{i}})$, so

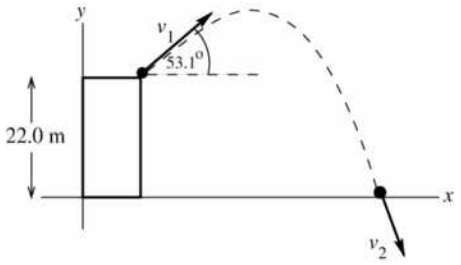
$$y_{\text{f}} - y_{\text{i}} = \frac{(140 \text{ food calories})(4186 \text{ J/1 food calorie})}{(65 \text{ kg})(9.80 \text{ m/s}^2)} = 920 \text{ m}.$$

(b) The mechanical energy would be 20% of the results of part (a), so $\Delta y = (0.20)(920 \text{ m}) = 180 \text{ m}$.

EVALUATE: Since only 20% of the food calories go into mechanical energy, the hiker needs much less of climb to turn off the calories in the bar.

7.5. **IDENTIFY** and **SET UP:** Use energy methods. Points 1 and 2 are shown in Figure 7.5.

(a) $K_1 + U_1 + W_{\text{other}} = K_2 + U_2$. Solve for K_2 and then use $K_2 = \frac{1}{2}mv_2^2$ to obtain v_2.



$W_{\text{other}} = 0$ (The only force on the ball while it is in the air is gravity.)
$K_1 = \frac{1}{2}mv_1^2;\ K_2 = \frac{1}{2}mv_2^2$
$U_1 = mgy_1,\ y_1 = 22.0$ m
$U_2 = mgy_2 = 0,$ since $y_2 = 0$ for our choice of coordinates.

Figure 7.5

EXECUTE: $\frac{1}{2}mv_1^2 + mgy_1 = \frac{1}{2}mv_2^2$

$$v_2 = \sqrt{v_1^2 + 2gy_1} = \sqrt{(12.0 \text{ m/s})^2 + 2(9.80 \text{ m/s}^2)(22.0 \text{ m})} = 24.0 \text{ m/s}$$

EVALUATE: The projection angle of $53.1°$ doesn't enter into the calculation. The kinetic energy depends only on the magnitude of the velocity; it is independent of the direction of the velocity.

(b) Nothing changes in the calculation. The expression derived in part (a) for v_2 is independent of the angle, so $v_2 = 24.0$ m/s, the same as in part (a).

(c) The ball travels a shorter distance in part (b), so in that case air resistance will have less effect.

7.6. **IDENTIFY:** The normal force does no work, so only gravity does work and Eq. (7.4) applies.

SET UP: $K_1 = 0$. The crate's initial point is at a vertical height of $d\sin\alpha$ above the bottom of the ramp.

EXECUTE: **(a)** $y_2 = 0,\ y_1 = d\sin\alpha.\ K_1 + U_{\text{grav},1} = K_2 + U_{\text{grav},2}$ gives $U_{\text{grav},1} = K_2.\ mgd\sin\alpha = \frac{1}{2}mv_2^2$ and $v_2 = \sqrt{2gd\sin\alpha}$.

(b) $y_1 = 0,\ y_2 = -d\sin\alpha.\ K_1 + U_{\text{grav},1} = K_2 + U_{\text{grav},2}$ gives $0 = K_2 + U_{\text{grav},2}.\ 0 = \frac{1}{2}mv_2^2 + (-mgd\sin\alpha)$ and $v_2 = \sqrt{2gd\sin\alpha}$, the same as in part (a).

(c) The normal force is perpendicular to the displacement and does no work.

EVALUATE: When we use $U_{\text{grav}} = mgy$ we can take any point as $y = 0$ but we must take $+y$ to be upward.

7.7. **IDENTIFY:** The take-off kinetic energy of the flea goes into gravitational potential energy.

SET UP: Use $K_{\text{f}} + U_{\text{f}} = K_{\text{i}} + U_{\text{i}}$. Let $y_{\text{i}} = 0$ and $y_{\text{f}} = h$ and note that $U_{\text{i}} = 0$ while $K_{\text{f}} = 0$ at the maximum height. Consequently, conservation of energy becomes $mgh = \frac{1}{2}mv_{\text{i}}^2$.

EXECUTE: **(a)** $v_{\text{i}} = \sqrt{2gh} = \sqrt{2(9.80 \text{ m/s}^2)(0.20 \text{ m})} = 2.0$ m/s.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) $K_{\rm i} = mgh = (0.50\times10^{-6}\ {\rm kg})(9.80\ {\rm m/s^2})(0.20\ {\rm m}) = 9.8\times10^{-7}\ {\rm J}$. The kinetic energy per kilogram is

$$\frac{K_{\rm i}}{m} = \frac{9.8\times10^{-7}\ {\rm J}}{0.50\times10^{-6}\ {\rm kg}} = 2.0\ {\rm J/kg}.$$

(c) The human can jump to a height of $h_{\rm h} = h_{\rm f}\left(\frac{l_{\rm h}}{l_{\rm f}}\right) = (0.20\ {\rm m})\left(\frac{2.0\ {\rm m}}{2.0\times10^{-3}\ {\rm m}}\right) = 200\ {\rm m}$. To attain this height, he would require a takeoff speed of: $v_{\rm i} = \sqrt{2gh} = \sqrt{2(9.80\ {\rm m/s^2})(200\ {\rm m})} = 63\ {\rm m/s}$.

(d) The human's kinetic energy per kilogram is $\frac{K_{\rm i}}{m} = gh = (9.80\ {\rm m/s^2})(0.60\ {\rm m}) = 5.9\ {\rm J/kg}$.

(e) EVALUATE: The flea stores the energy in its tensed legs.

7.8. **IDENTIFY** and **SET UP:** Apply Eq. (7.7) and consider how each term depends on the mass.

EXECUTE: The speed is v and the kinetic energy is $4K$. The work done by friction is proportional to the normal force, and hence to the mass, and so each term in Eq. (7.7) is proportional to the total mass of the crate, and the speed at the bottom is the same for any mass. The kinetic energy is proportional to the mass, and for the same speed but four times the mass, the kinetic energy is quadrupled.

EVALUATE: The same result is obtained if we apply $\Sigma\vec{F} = m\vec{a}$ to the motion. Each force is proportional to m and m divides out, so a is independent of m.

7.9. **IDENTIFY:** $W_{\rm tot} = K_B - K_A$. The forces on the rock are gravity, the normal force and friction.

SET UP: Let $y = 0$ at point B and let $+y$ be upward. $y_A = R = 0.50$ m. The work done by friction is negative; $W_f = -0.22$ J. $K_A = 0$. The free-body diagram for the rock at point B is given in Figure 7.9. The acceleration of the rock at this point is $a_{\rm rad} = v^2/R$, upward.

EXECUTE: **(a)** (i) The normal force is perpendicular to the displacement and does zero work.

(ii) $W_{\rm grav} = U_{{\rm grav},A} - U_{{\rm grav},B} = mgy_A = (0.20\ {\rm kg})(9.80\ {\rm m/s^2})(0.50\ {\rm m}) = 0.98\ {\rm J}$.

(b) $W_{\rm tot} = W_n + W_f + W_{\rm grav} = 0 + (-0.22\ {\rm J}) + 0.98\ {\rm J} = 0.76\ {\rm J}$. $W_{\rm tot} = K_B - K_A$ gives $\frac{1}{2}mv_B^2 = W_{\rm tot}$.

$$v_B = \sqrt{\frac{2W_{\rm tot}}{m}} = \sqrt{\frac{2(0.76\ {\rm J})}{0.20\ {\rm kg}}} = 2.8\ {\rm m/s}.$$

(c) Gravity is constant and equal to mg. n is not constant; it is zero at A and not zero at B. Therefore, $f_{\rm k} = \mu_{\rm k} n$ is also not constant.

(d) $\Sigma F_y = ma_y$ applied to Figure 7.9 gives $n - mg = ma_{\rm rad}$.

$$n = m\left(g + \frac{v^2}{R}\right) = (0.20\ {\rm kg})\left(9.80\ {\rm m/s^2} + \frac{[2.8\ {\rm m/s}]^2}{0.50\ {\rm m}}\right) = 5.1\ {\rm N}.$$

EVALUATE: In the absence of friction, the speed of the rock at point B would be $\sqrt{2gR} = 3.1$ m/s. As the rock slides through point B, the normal force is greater than the weight $mg = 2.0$ N of the rock.

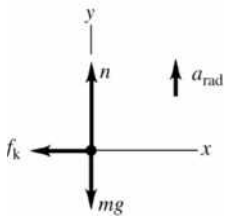


Figure 7.9

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

7.10. **IDENTIFY:** The potential energy is transformed into kinetic energy which is then imparted to the bone.
SET UP: The initial gravitational potential energy must be absorbed by the leg bones. $U_i = mgh$.

EXECUTE: **(a)** $mgh = 2(200\text{ J})$, so $h = \dfrac{400\text{ J}}{(60\text{ kg})(9.80\text{ m/s}^2)} = 0.68\text{ m} = 68\text{ cm}$.

(b) EVALUATE: They flex when they land and their joints and muscles absorb most of the energy.
(c) EVALUATE: Their bones are more fragile so can absorb less energy without breaking and their muscles and joints are weaker and less flexible and therefore less able to absorb energy.

7.11. **IDENTIFY:** Apply Eq. (7.7) to the motion of the car.
SET UP: Take $y = 0$ at point A. Let point 1 be A and point 2 be B.

$$K_1 + U_1 + W_{\text{other}} = K_2 + U_2$$

EXECUTE: $U_1 = 0$, $U_2 = mg(2R) = 28{,}224\text{ J}$, $W_{\text{other}} = W_f$

$K_1 = \frac{1}{2}mv_1^2 = 37{,}500\text{ J}$, $K_2 = \frac{1}{2}mv_2^2 = 3840\text{ J}$

The work-energy relation then gives $W_f = K_2 + U_2 - K_1 = -5400\text{ J}$.

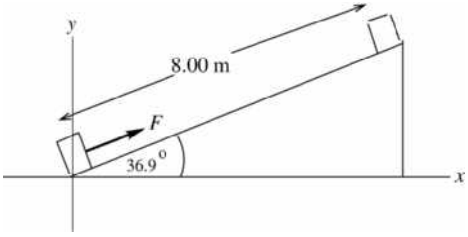
EVALUATE: Friction does negative work. The final mechanical energy $(K_2 + U_2 = 32{,}064\text{ J})$ is less than the initial mechanical energy $(K_1 + U_1 = 37{,}500\text{ J})$ because of the energy removed by friction work.

7.12. **IDENTIFY:** Only gravity does work, so apply Eq. (7.5).
SET UP: $v_1 = 0$, so $\frac{1}{2}mv_2^2 = mg(y_1 - y_2)$.

EXECUTE: Tarzan is lower than his original height by a distance $y_1 - y_2 = l(\cos 30° - \cos 45°)$ so his speed is $v = \sqrt{2gl(\cos 30° - \cos 45°)} = 7.9\text{ m/s}$, a bit quick for conversation.

EVALUATE: The result is independent of Tarzan's mass.

7.13.

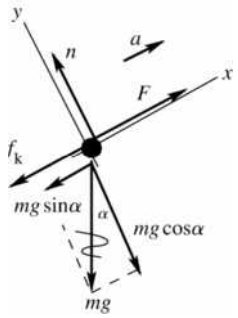


$y_1 = 0$
$y_2 = (8.00\text{ m})\sin 36.9°$
$y_2 = 4.80\text{ m}$

Figure 7.13a

(a) IDENTIFY and **SET UP:** $\vec{F}$ is constant so Eq. (6.2) can be used. The situation is sketched in Figure 7.13a.
EXECUTE: $W_F = (F\cos\phi)s = (110\text{ N})(\cos 0°)(8.00\text{ m}) = 880\text{ J}$

EVALUATE: $\vec{F}$ is in the direction of the displacement and does positive work.
(b) IDENTIFY and **SET UP**: Calculate W using Eq. (6.2) but first must calculate the friction force. Use the free-body diagram for the oven sketched in Figure 7.13b to calculate the normal force n; then the friction force can be calculated from $f_k = \mu_k n$. For this calculation use coordinates parallel and perpendicular to the incline.



EXECUTE: $\Sigma F_y = ma_y$
$n - mg\cos 36.9° = 0$
$n = mg\cos 36.9°$
$f_k = \mu_k n = \mu_k mg\cos 36.9°$
$f_k = (0.25)(10.0\text{ kg})(9.80\text{ m/s}^2)\cos 36.9° = 19.6\text{ N}$

Figure 7.13b

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$W_f = (f_k \cos\phi)s = (19.6\text{ N})(\cos 180°)(8.00\text{ m}) = -157\text{ J}$

EVALUATE: Friction does negative work.

(c) IDENTIFY and **SET UP:** $U = mgy$; take $y = 0$ at the bottom of the ramp.

EXECUTE: $\Delta U = U_2 - U_1 = mg(y_2 - y_1) = (10.0\text{ kg})(9.80\text{ m/s}^2)(4.80\text{ m} - 0) = 470\text{ J}$

EVALUATE: The object moves upward and U increases.

(d) IDENTIFY and **SET UP:** Use Eq. (7.7). Solve for ΔK.

EXECUTE: $K_1 + U_1 + W_{\text{other}} = K_2 + U_2$

$\Delta K = K_2 - K_1 = U_1 - U_2 + W_{\text{other}}$

$\Delta K = W_{\text{other}} - \Delta U$

$W_{\text{other}} = W_F + W_f = 880\text{ J} - 157\text{ J} = 723\text{ J}$

$\Delta U = 470\text{ J}$

Thus $\Delta K = 723\text{ J} - 470\text{ J} = 253\text{ J}$.

EVALUATE: W_{other} is positive. Some of W_{other} goes to increasing U and the rest goes to increasing K.

(e) IDENTIFY: Apply $\Sigma\vec{F} = m\vec{a}$ to the oven. Solve for $\vec{a}$ and then use a constant acceleration equation to calculate v_2.

SET UP: We can use the free-body diagram that is in part (b):

$\Sigma F_x = ma_x$

$F - f_k - mg\sin 36.9° = ma$

EXECUTE: $a = \dfrac{F - f_k - mg\sin 36.9°}{m} = \dfrac{110\text{ N} - 19.6\text{ N} - (10\text{ kg})(9.80\text{ m/s}^2)\sin 36.9°}{10.0\text{ kg}} = 3.16\text{ m/s}^2$

SET UP: $v_{1x} = 0,\ a_x = 3.16\text{ m/s}^2,\ x - x_0 = 8.00\text{ m},\ v_{2x} = ?$

$v_{2x}^2 = v_{1x}^2 + 2a_x(x - x_0)$

EXECUTE: $v_{2x} = \sqrt{2a_x(x - x_0)} = \sqrt{2(3.16\text{ m/s}^2)(8.00\text{ m})} = 7.11\text{ m/s}$

Then $\Delta K = K_2 - K_1 = \frac{1}{2}mv_2^2 = \frac{1}{2}(10.0\text{ kg})(7.11\text{ m/s})^2 = 253\text{ J}$.

EVALUATE: This agrees with the result calculated in part (d) using energy methods.

7.14. **IDENTIFY:** Use the information given in the problem with $F = kx$ to find k. Then $U_{\text{el}} = \frac{1}{2}kx^2$.

SET UP: x is the amount the spring is stretched. When the weight is hung from the spring, $F = mg$.

EXECUTE: $k = \dfrac{F}{x} = \dfrac{mg}{x} = \dfrac{(3.15\text{ kg})(9.80\text{ m/s}^2)}{0.1340\text{ m} - 0.1200\text{ m}} = 2205\text{ N/m}.$

$x = \pm\sqrt{\dfrac{2U_{\text{el}}}{k}} = \pm\sqrt{\dfrac{2(10.0\text{ J})}{2205\text{ N/m}}} = \pm 0.0952\text{ m} = \pm 9.52\text{ cm}.$ The spring could be either stretched 9.52 cm or compressed 9.52 cm. If it were stretched, the total length of the spring would be $12.00\text{ cm} + 9.52\text{ cm} = 21.52\text{ cm}$. If it were compressed, the total length of the spring would be $12.00\text{ cm} - 9.52\text{ cm} = 2.48\text{ cm}$.

EVALUATE: To stretch or compress the spring 9.52 cm requires a force $F = kx = 210\text{ N}$.

7.15. **IDENTIFY:** Apply $U_{\text{el}} = \frac{1}{2}kx^2$.

SET UP: $kx = F$, so $U = \frac{1}{2}Fx$, where F is the magnitude of force required to stretch or compress the spring a distance x.

EXECUTE: **(a)** $(1/2)(800\text{ N})(0.200\text{ m}) = 80.0\text{ J}$.

(b) The potential energy is proportional to the square of the compression or extension;

$(80.0\text{ J})\ (0.050\text{ m}/0.200\text{ m})^2 = 5.0\text{ J}$.

EVALUATE: We could have calculated $k = \dfrac{F}{x} = \dfrac{800\text{ N}}{0.200\text{ m}} = 4000\text{ N/m}$ and then used $U_{\text{el}} = \frac{1}{2}kx^2$ directly.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

7.16. **IDENTIFY:** We treat the tendon like a spring and apply Hooke's law to it. Knowing the force stretching the tendon and how much it stretched, we can find its force constant.

SET UP: Use $F_{\text{on tendon}} = kx$. In part (a), $F_{\text{on tendon}}$ equals mg, the weight of the object suspended from it. In part(b), also apply $U_{\text{el}} = \frac{1}{2}kx^2$ to calculate the stored energy.

EXECUTE: **(a)** $k = \dfrac{F_{\text{on tendon}}}{x} = \dfrac{(0.250\text{ kg})(9.80\text{ m/s}^2)}{0.0123\text{ m}} = 199\text{ N/m}.$

(b) $x = \dfrac{F_{\text{on tendon}}}{k} = \dfrac{138\text{ N}}{199\text{ N/m}} = 0.693\text{m} = 69.3\text{ cm};\ U_{\text{el}} = \frac{1}{2}(199\text{ N/m})(0.693\text{ m})^2 = 47.8\text{ J}.$

EVALUATE: The 250 g object has a weight of 2.45 N. The 138 N force is much larger than this and stretches the tendon a much greater distance.

7.17. **IDENTIFY:** Apply $U_{\text{el}} = \frac{1}{2}kx^2$.

SET UP: $U_0 = \frac{1}{2}kx_0^2$. x is the distance the spring is stretched or compressed.

EXECUTE: **(a)** (i) $x = 2x_0$ gives $U_{\text{el}} = \frac{1}{2}k(2x_0)^2 = 4(\frac{1}{2}kx_0^2) = 4U_0$. (ii) $x = x_0/2$ gives $U_{\text{el}} = \frac{1}{2}k(x_0/2)^2 = \frac{1}{4}(\frac{1}{2}kx_0^2) = U_0/4$.

(b) (i) $U = 2U_0$ gives $\frac{1}{2}kx^2 = 2(\frac{1}{2}kx_0^2)$ and $x = x_0\sqrt{2}$. (ii) $U = U_0/2$ gives $\frac{1}{2}kx^2 = \frac{1}{2}(\frac{1}{2}kx_0^2)$ and $x = x_0/\sqrt{2}$.

EVALUATE: U is proportional to x^2 and x is proportional to $\sqrt{U}$.

7.18. **IDENTIFY:** Apply Eq. (7.13).

SET UP: Initially and at the highest point, $v = 0$, so $K_1 = K_2 = 0$. $W_{\text{other}} = 0$.

EXECUTE: **(a)** In going from rest in the slingshot's pocket to rest at the maximum height, the potential energy stored in the rubber band is converted to gravitational potential energy;
$U = mgy = (10\times10^{-3}\text{ kg})(9.80\text{ m/s}^2)\ (22.0\text{ m}) = 2.16\text{ J}.$

(b) Because gravitational potential energy is proportional to mass, the larger pebble rises only 8.8 m.

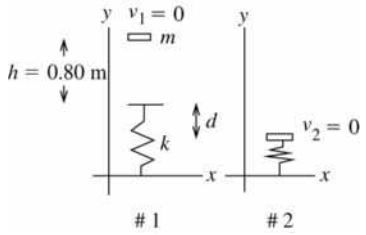
(c) The lack of air resistance and no deformation of the rubber band are two possible assumptions.

EVALUATE: The potential energy stored in the rubber band depends on k for the rubber band and the maximum distance it is stretched.

7.19. **IDENTIFY** and **SET UP:** Use energy methods. There are changes in both elastic and gravitational potential energy; elastic; $U = \frac{1}{2}kx^2$, gravitational: $U = mgy$.

EXECUTE: **(a)** $U = \frac{1}{2}kx^2$ so $x = \sqrt{\dfrac{2U}{k}} = \sqrt{\dfrac{2(3.20\text{ J})}{1600\text{ N/m}}} = 0.0632\text{ m} = 6.32\text{ cm}$

(b) Points 1 and 2 in the motion are sketched in Figure 7.19.



$K_1 + U_1 + W_{\text{other}} = K_2 + U_2$
$W_{\text{other}} = 0$ (Only work is that done by gravity and spring force)
$K_1 = 0,\ K_2 = 0$
$y = 0$ at final position of book
$U_1 = mg(h + d),\ U_2 = \frac{1}{2}kd^2$

Figure 7.19

$0 + mg(h + d) + 0 = \frac{1}{2}kd^2$

The original gravitational potential energy of the system is converted into potential energy of the compressed spring.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$\frac{1}{2}kd^2 - mgd - mgh = 0$

$$d = \frac{1}{k}\left(mg \pm \sqrt{(mg)^2 + 4\left(\frac{1}{2}k\right)(mgh)} \right)$$

d must be positive, so $d = \frac{1}{k}\left(mg + \sqrt{(mg)^2 + 2kmgh} \right)$

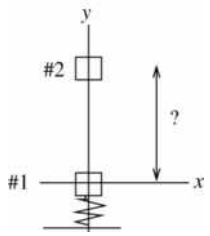
$$d = \frac{1}{1600 \text{ N/m}}(1.20 \text{ kg})(9.80 \text{ m/s}^2) + \sqrt{((1.20 \text{ kg})(9.80 \text{ m/s}^2))^2 + 2(1600 \text{ N/m})(1.20 \text{ kg})(9.80 \text{ m/s}^2)(0.80 \text{ m})}$$

$d = 0.0074 \text{ m} + 0.1087 \text{ m} = 0.12 \text{ m} = 12 \text{ cm}$

EVALUATE: It was important to recognize that the total displacement was $h + d$; gravity continues to do work as the book moves against the spring. Also note that with the spring compressed 0.12 m it exerts an upward force (192 N) greater than the weight of the book (11.8 N). The book will be accelerated upward from this position.

7.20. **IDENTIFY:** Use energy methods. There are changes in both elastic and gravitational potential energy.

SET UP: $K_1 + U_1 + W_{\text{other}} = K_2 + U_2$. Points 1 and 2 in the motion are sketched in Figure 7.20.



The spring force and gravity are the only forces doing work on the cheese, so $W_{\text{other}} = 0$ and $U = U_{\text{grav}} + U_{\text{el}}$.

Figure 7.20

EXECUTE: Cheese released from rest implies $K_1 = 0$.

At the maximum height $v_2 = 0$ so $K_2 = 0$. $U_1 = U_{1,\text{el}} + U_{1,\text{grav}}$

$y_1 = 0$ implies $U_{1,\text{grav}} = 0$

$U_{1,\text{el}} = \frac{1}{2}kx_1^2 = \frac{1}{2}(1800 \text{ N/m})(0.15 \text{ m})^2 = 20.25 \text{ J}$

(Here x_1 refers to the amount the spring is stretched or compressed when the cheese is at position 1; it is *not* the x-coordinate of the cheese in the coordinate system shown in the sketch.)

$U_2 = U_{2,\text{el}} + U_{2,\text{grav}}$ $U_{2,\text{grav}} = mgy_2$, where y_2 is the height we are solving for. $U_{2,\text{el}} = 0$ since now the spring is no longer compressed. Putting all this into $K_1 + U_1 + W_{\text{other}} = K_2 + U_2$ gives $U_{1,\text{el}} = U_{2,\text{grav}}$

$$y_2 = \frac{20.25 \text{ J}}{mg} = \frac{20.25 \text{ J}}{(1.20 \text{ kg})(9.80 \text{ m/s}^2)} = 1.72 \text{ m}$$

EVALUATE: The description in terms of energy is very simple; the elastic potential energy originally stored in the spring is converted into gravitational potential energy of the system.

7.21. **IDENTIFY:** Apply Eq. (7.13).

SET UP: $W_{\text{other}} = 0$. As in Example 7.7, $K_1 = 0$ and $U_1 = 0.0250$ J.

EXECUTE: For $v_2 = 0.20$ m/s, $K_2 = 0.0040$ J. $U_2 = 0.0210 \text{ J} = \frac{1}{2}kx^2$, and $x = \pm\sqrt{\frac{2(0.0210\text{J})}{5.00\text{N/m}}} = \pm 0.092\text{m}$.

The glider has this speed when the spring is stretched 0.092 m or compressed 0.092 m.

EVALUATE: Example 7.7 showed that $v_x = 0.30$ m/s when $x = 0.0800$ m. As x increases, v_x decreases, so our result of $v_x = 0.20$ m/s at $x = 0.092$ m is consistent with the result in the example.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

7.22. **IDENTIFY** and **SET UP:** Use energy methods. The elastic potential energy changes. In part (a) solve for K_2 and from this obtain v_2. In part (b) solve for U_1 and from this obtain x_1.

(a) $K_1 + U_1 + W_{\text{other}=} K_2 + U_2$

point 1: the glider is at its initial position, where $x_1 = 0.100$ m and $v_1 = 0$

point 2: the glider is at $x = 0$

EXECUTE: $K_1 = 0$ (released from rest), $K_2 = \frac{1}{2}mv_2^2$

$U_1 = \frac{1}{2}kx_1^2$, $U_2 = 0$, $W_{\text{other}} = 0$ (only the spring force does work)

Thus $\frac{1}{2}kx_1^2 = \frac{1}{2}mv_2^2$. (The initial potential energy of the stretched spring is converted entirely into kinetic energy of the glider.)

$$v_2 = x_1\sqrt{\frac{k}{m}} = (0.100\text{ m})\sqrt{\frac{5.00\text{ n/m}}{0.200\text{ kg}}} = 0.500\text{ m/s}$$

(b) The maximum speed occurs at $x = 0$, so the same equation applies.

$$\tfrac{1}{2}kx_1^2 = \tfrac{1}{2}mv_2^2$$

$$x_1 = v_2\sqrt{\frac{m}{k}} = 2.50\text{ m/s}\sqrt{\frac{0.200\text{kg}}{5.00\text{N/m}}} = 0.500\text{ m}$$

EVALUATE: Elastic potential energy is converted into kinetic energy. A larger x_1 gives a larger v_2.

7.23. **IDENTIFY:** Only the spring does work and Eq. (7.11) applies. $a = \frac{F}{m} = \frac{-kx}{m}$, where F is the force the spring exerts on the mass.

SET UP: Let point 1 be the initial position of the mass against the compressed spring, so $K_1 = 0$ and $U_1 = 11.5$ J. Let point 2 be where the mass leaves the spring, so $U_{\text{el},2} = 0$.

EXECUTE: **(a)** $K_1 + U_{\text{el},1} = K_2 + U_{\text{el},2}$ gives $U_{\text{el},1} = K_2$. $\frac{1}{2}mv_2^2 = U_{\text{el},1}$ and

$$v_2 = \sqrt{\frac{2U_{\text{el},1}}{m}} = \sqrt{\frac{2(11.5\text{ J})}{2.50\text{ kg}}} = 3.03\text{ m/s}.$$

K is largest when U_{el} is least and this is when the mass leaves the spring. The mass achieves its maximum speed of 3.03 m/s as it leaves the spring and then slides along the surface with constant speed.

(b) The acceleration is greatest when the force on the mass is the greatest, and this is when the spring has its maximum compression. $U_{\text{el}} = \frac{1}{2}kx^2$ so $x = -\sqrt{\frac{2U_{\text{el}}}{k}} = 2\sqrt{\frac{2(11.5\text{ J})}{2500\text{ N/m}}} = -0.0959$ m. The minus sign indicates compression. $F = -kx = ma_x$ and $a_x = -\frac{kx}{m} = -\frac{(2500\text{ N/m})(-0.0959\text{ m})}{2.50\text{ kg}} = 95.9\text{ m/s}^2$.

EVALUATE: If the end of the spring is displaced to the left when the spring is compressed, then a_x in part (b) is to the right, and vice versa.

7.24. **(a) IDENTIFY** and **SET UP:** Use energy methods. Both elastic and gravitational potential energy changes. Work is done by friction.

Choose point 1 as in Example 7.9 and let that be the origin, so $y_1 = 0$. Let point 2 be 1.00 m below point 1, so $y_2 = -1.00$ m.

EXECUTE: $K_1 + U_1 + W_{\text{other}} = K_2 + U_2$

$K_1 = \frac{1}{2}mv_1^2 = \frac{1}{2}(2000\text{ kg})(25\text{ m/s})^2 = 625{,}000\text{ J}$, $U_1 = 0$

$W_{\text{other}} = -f|y_2| = -(17{,}000\text{ N})(1.00\text{ m}) = -17{,}000\text{ J}$

$K_2 = \frac{1}{2}mg_2^2$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$U_2 = U_{2,\text{grav}} + U_{2,\text{el}} = mgy_2 + \frac{1}{2}ky_2^2$

$U_2 = (2000\text{ kg})(9.80\text{ m/s}^2)(-1.00\text{ m}) + \frac{1}{2}(1.41\times10^5\text{ N/m})(1.00\text{ m})^2$

$U_2 = -19{,}600\text{ J} + 70{,}500\text{ J} = +50{,}900\text{ J}$

Thus $625{,}000\text{ J} - 17{,}000\text{ J} = \frac{1}{2}mv_2^2 + 50{,}900\text{ J}$

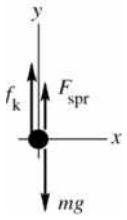
$\frac{1}{2}mv_2^2 = 557{,}100\text{ J}$

$v_2 = \sqrt{\dfrac{2(557{,}100\text{ J})}{2000\text{ kg}}} = 23.6\text{ m/s}$

EVALUATE: The elevator stops after descending 3.00 m. After descending 1.00 m it is still moving but has slowed down.

(b) IDENTIFY: Apply $\Sigma\vec{F} = m\vec{a}$ to the elevator. We know the forces and can solve for $\vec{a}$.

SET UP: The free-body diagram for the elevator is given in Figure 7.24.



EXECUTE: $F_{\text{spr}} = kd$, where d is the distance the spring is compressed

$\Sigma F_y = ma_y$

$f_k + F_{\text{spr}} - mg = ma$

$f_k + kd - mg = ma$

Figure 7.24

$$a = \frac{f_k + kd - mg}{m} = \frac{17{,}000\text{ N} + (1.41\times10^5\text{ N/m})(1.00\text{ m}) - (2000\text{ kg})(9.80\text{ m/s}^2)}{2000\text{ kg}} = 69.2\text{ m/s}^2$$

We calculate that a is positive, so the acceleration is upward.

EVALUATE: The velocity is downward and the acceleration is upward, so the elevator is slowing down at this point. Note that $a = 7.1g$; this is unacceptably high for an elevator.

7.25. **IDENTIFY:** Apply Eq. (7.13) and $F = ma$.

SET UP: $W_{\text{other}} = 0$. There is no change in U_{grav}. $K_1 = 0$, $U_2 = 0$.

EXECUTE: $\frac{1}{2}kx^2 = \frac{1}{2}mv_x^2$. The relations for m, v_x, k and x are $kx^2 = mv_x^2$ and $kx = 5mg$.

Dividing the first equation by the second gives $x = \dfrac{v_x^2}{5g}$, and substituting this into the second gives

$k = 25\dfrac{mg^2}{v_x^2}$.

(a) $k = 25\dfrac{(1160\text{ kg})(9.80\text{ m/s}^2)^2}{(2.50\text{ m/s})^2} = 4.46\times10^5\text{ N/m}$

(b) $x = \dfrac{(2.50\text{ m/s})^2}{5(9.80\text{ m/s}^2)} = 0.128\text{ m}$

EVALUATE: Our results for k and x do give the required values for a_x and v_x:

$$a_x = \frac{kx}{m} = \frac{(4.46\times10^5\text{ N/m})(0.128\text{ m})}{1160\text{ kg}} = 49.2\text{ m/s}^2 = 5.0g \text{ and } v_x = x\sqrt{\frac{k}{m}} = 2.5\text{ m/s}.$$

7.26. **IDENTIFY:** The spring force is conservative but the force of friction is nonconservative. Energy is conserved during the process. Initially all the energy is stored in the spring, but part of this goes to kinetic energy, part remains as elastic potential energy, and the rest does work against friction.

SET UP: Energy conservation: $K_1 + U_1 + W_{\text{other}} = K_2 + U_2$, the elastic energy in the spring is $U = \frac{1}{2}kx^2$, and the work done by friction is $W_f = -f_k s = -\mu_k mgs$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: The initial and final elastic potential energies are $U_1 = \frac{1}{2}kx_1^2 = \frac{1}{2}(840 \text{ N/m})(0.0300 \text{ m})^2 = 0.378 \text{ J}$ and $U_2 = \frac{1}{2}kx_2^2 = \frac{1}{2}(840 \text{ N/m})(0.0100 \text{ m})^2 = 0.0420 \text{ J}$. The initial and final kinetic energies are $K_1 = 0$ and $K_2 = \frac{1}{2}mv_2^2$. The work done by friction is $W_{\text{other}} = W_{f_k} = -f_k s = -\mu_k mgs = -(0.40)(2.50 \text{ kg})(9.8 \text{ m/s}^2)(0.0200 \text{ m}) = -0.196 \text{ J}$. Energy conservation gives $K_2 = \frac{1}{2}mv_2^2 = K_1 + U_1 + W_{\text{other}} - U_2 = 0.378 \text{ J} + (-0.196 \text{ J}) - 0.0420 \text{ J} = 0.140 \text{ J}$. Solving for v_2 gives $v_2 = \sqrt{\frac{2K_2}{m}} = \sqrt{\frac{2(0.140 \text{ J})}{2.50 \text{ kg}}} = 0.335 \text{ m/s}$.

EVALUATE: Mechanical energy is not conserved due to friction.

7.27. **IDENTIFY:** Apply $W_{f_k} = f_k s\cos\phi$. $f_k = \mu_k n$.

SET UP: For a circular trip the distance traveled is $d = 2\pi r$. At each point in the motion the friction force and the displacement are in opposite directions and $\phi = 180°$. Therefore, $W_{f_k} = -f_k d = -f_k(2\pi r)$. $n = mg$ so $f_k = \mu_k mg$.

EXECUTE: **(a)** $W_{f_k} = -\mu_k mg2\pi r = -(0.250)(10.0 \text{ kg})(9.80 \text{ m/s}^2)(2\pi)(2.00 \text{ m}) = -308 \text{ J}$.

(b) The distance along the path doubles so the work done doubles and becomes -616 J.

(c) The work done for a round trip displacement is not zero and friction is a nonconservative force.

EVALUATE: The direction of the friction force depends on the direction of motion of the object and that is why friction is a nonconservative force.

7.28. **IDENTIFY:** $W_{\text{grav}} = mg\cos\phi$.

SET UP: When he moves upward, $\phi = 180°$ and when he moves downward, $\phi = 0°$. When he moves parallel to the ground, $\phi = 90°$.

EXECUTE: (a) $W_{\text{grav}} = (75 \text{ kg})(9.80 \text{ m/s}^2)(7.0 \text{ m})\cos 180° = -5100 \text{ J}$.

(b) $W_{\text{grav}} = (75 \text{ kg})(9.80 \text{ m/s}^2)(7.0 \text{ m})\cos 0° = +5100 \text{ J}$.

(c) $\phi = 90°$ in each case and $W_{\text{grav}} = 0$ in each case.

(d) The total work done on him by gravity during the round trip is $-5100 \text{ J} + 5100 \text{ J} = 0$.

(e) Gravity is a conservative force since the total work done for a round trip is zero.

EVALUATE: The gravity force is independent of the position and motion of the object. When the object moves upward gravity does negative work and when the object moves downward gravity does positive work.

7.29. **IDENTIFY:** Since the force is constant, use $W = Fs\cos\phi$.

SET UP: For both displacements, the direction of the friction force is opposite to the displacement and $\phi = 180°$.

EXECUTE: **(a)** When the book moves to the left, the friction force is to the right, and the work is $-(1.2 \text{ N})(3.0 \text{ m}) = -3.6 \text{ J}$.

(b) The friction force is now to the left, and the work is again -3.6 J.

(c) -7.2 J.

(d) The net work done by friction for the round trip is not zero, and friction is not a conservative force.

EVALUATE: The direction of the friction force depends on the motion of the object. For the gravity force, which is conservative, the force does not depend on the motion of the object.

7.30. **IDENTIFY** and **SET UP:** The force is not constant so we must use Eq. (6.14) to calculate W. The properties of work done by a conservative force are described in Section 7.3.

$$W = \int_1^2 \vec{F}\cdot d\vec{l}, \quad \vec{F} = -\alpha x^2\hat{i}$$

EXECUTE: **(a)** $d\vec{l} = dy\hat{j}$ (x is constant; the displacement is in the $+y$-direction)

$\vec{F}\cdot d\vec{l} = 0$ (since $\hat{i}\cdot\hat{j} = 0$) and thus $W = 0$.

(b) $d\vec{l} = dx\hat{i}$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$\vec{F} \cdot d\vec{l} = (-\alpha x^2 \hat{i}) \cdot (dx\hat{i}) = -\alpha x^2\, dx$

$$W = \int_{x_1}^{x_2} (-\alpha x^2)\, dx = -\tfrac{1}{3} a x^3 \,|_{x_1}^{x_2} = -\tfrac{1}{3}\alpha\,(x_2^3 - x_1^3) = -\frac{12 \text{ N/m}^2}{3}\,((0.300 \text{ m})^3 - (0.10 \text{ m})^3) = -0.10 \text{ J}$$

(c) $d\vec{l} = dx\hat{i}$ as in part (b), but now $x_1 = 0.30$ m and $x_2 = 0.10$ m

$$W = -\tfrac{1}{3}\alpha(x_2^3 - x_1^3) = +0.10 \text{ J}$$

(d) EVALUATE: The total work for the displacement along the x-axis from 0.10 m to 0.30 m and then back to 0.10 m is the sum of the results of parts (b) and (c), which is zero. The total work is zero when the starting and ending points are the same, so the force is conservative.

EXECUTE: $W_{x_1 \to x_2} = -\tfrac{1}{3}\alpha(x_2^3 - x_1^3) = \tfrac{1}{3}\alpha x_1^3 - \tfrac{1}{3}\alpha x_2^3$

The definition of the potential energy function is $W_{x_1 \to x_2} = U_1 - U_2$. Comparison of the two expressions for W gives $U = \tfrac{1}{3}\alpha x^3$. This does correspond to $U = 0$ when $x = 0$.

EVALUATE: In part **(a)** the work done is zero because the force and displacement are perpendicular. In part **(b)** the force is directed opposite to the displacement and the work done is negative. In part **(c)** the force and displacement are in the same direction and the work done is positive.

7.31. **IDENTIFY** and **SET UP:** The friction force is constant during each displacement and Eq. (6.2) can be used to calculate work, but the direction of the friction force can be different for different displacements.

$f = \mu_k mg = (0.25)(1.5 \text{ kg})(9.80 \text{ m/s}^2) = 3.675$ N; direction of $\vec{f}$ is opposite to the motion.

EXECUTE: **(a)** The path of the book is sketched in Figure 7.31a.

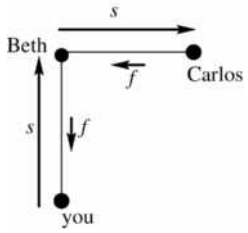


Figure 7.31a

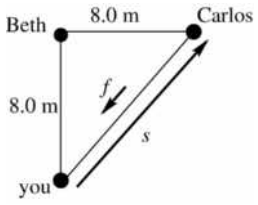
For the motion from you to Beth the friction force is directed opposite to the displacement $\vec{s}$ and $W_1 = -fs = -(3.675 \text{ N})(8.0 \text{ m}) = -29.4$ J.

For the motion from Beth to Carlos the friction force is again directed opposite to the displacement and $W_2 = -29.4$ J.

$$W_{\text{tot}} = W_1 + W_2 = -29.4 \text{ J} - 29.4 \text{ J} = -59 \text{ J}$$

(b) The path of the book is sketched in Figure 7.31b.



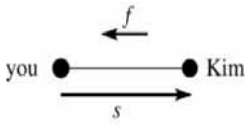
$s = \sqrt{2(8.0 \text{ m})^2} = 11.3$ m

Figure 7.31b

$\vec{f}$ is opposite to $\vec{s}$, so $W = -fs = -(3.675 \text{ N})(11.3 \text{ m}) = -42$ J

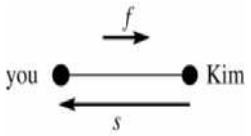
© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(c)



For the motion from you to Kim (Figure 7.31c)
$W = -fs$
$W = -(3.675\ \text{N})(8.0\ \text{m}) = -29.4\ \text{J}$

Figure 7.31c



For the motion from Kim to you (Figure 7.31d)
$W = -fs = -29.4\ \text{J}$

Figure 7.31d

The total work for the round trip is $-29.4\ \text{J} - 29.4\ \text{J} = -59\ \text{J}$.

(d) EVALUATE: Parts (a) and (b) show that for two different paths between you and Carlos, the work done by friction is different. Part (c) shows that when the starting and ending points are the same, the total work is not zero. Both these results show that the friction force is nonconservative.

7.32. **IDENTIFY:** Some of the initial gravitational potential energy is converted to kinetic energy, but some of it is lost due to work by the nonconservative friction force.

SET UP: The energy of the box at the edge of the roof is given by: $E_{\text{mech, f}} = E_{\text{mech, i}} - f_{\text{k}}s$. Setting $y_{\text{f}} = 0$ at this point, $y_{\text{i}} = (4.25\ \text{m})\sin 36° = 2.50\ \text{m}$. Furthermore, by substituting $K_{\text{i}} = 0$ and $K_{\text{f}} = \frac{1}{2}mv_{\text{f}}^2$ into the conservation equation, $\frac{1}{2}mv_{\text{f}}^2 = mgy_{\text{i}} - f_{\text{k}}s$ or $v_{\text{f}} = \sqrt{2gy_{\text{i}} - 2f_{\text{k}}sg/w} = \sqrt{2g(y_{\text{i}} - f_{\text{k}}s/w)}$.

EXECUTE: $v_{\text{f}} = \sqrt{2(9.80\ \text{m/s}^2)\left[(2.50\ \text{m}) - (22.0\ \text{N})(4.25\ \text{m})/(85.0\ \text{N})\right]} = 5.24\ \text{m/s}$.

EVALUATE: Friction does negative work and removes mechanical energy from the system. In the absence of friction the final speed of the toolbox would be 7.00 m/s.

7.33. **IDENTIFY:** Some of the mechanical energy of the skier is converted to internal energy by the nonconservative force of friction on the rough patch.

SET UP: For part (a) use $E_{\text{mech},f} = E_{\text{mech, i}} - f_{\text{k}}s$ where $f_{\text{k}} = \mu_{\text{k}}mg$. Let $y_{\text{f}} = 0$ at the bottom of the hill; then $y_{\text{i}} = 2.50\ \text{m}$ along the rough patch. The energy equation is thus $\frac{1}{2}mv_{\text{f}}^2 = \frac{1}{2}mv_{\text{i}}^2 + mgy_{\text{i}} - \mu_{\text{k}}mgs$. Solving for her final speed gives $v_{\text{f}} = \sqrt{v_{\text{i}}^2 + 2gy_{\text{i}} - 2\mu_{\text{k}}gs}$. For part (b), the internal energy is calculated as the negative of the work done by friction: $-W_f = +f_{\text{k}}s = +\mu_{\text{k}}mgs$.

EXECUTE: **(a)** $v_{\text{f}} = \sqrt{(6.50\ \text{m/s})^2 + 2(9.80\ \text{m/s}^2)(2.50\ \text{m}) - 2(0.300)(9.80\ \text{m/s}^2)(3.50\ \text{m})} = 8.41\ \text{m/s}$.

(b) Internal energy $= \mu_{\text{k}}mgs = (0.300)(62.0\ \text{kg})(9.80\ \text{m/s}^2)(3.50\ \text{m}) = 638\ \text{J}$.

EVALUATE: Without friction the skier would be moving faster at the bottom of the hill than at the top, but in this case she is moving *slower* because friction converted some of her initial kinetic energy into internal energy.

7.34. **IDENTIFY** and **SET UP:** Use Eq. (7.17) to calculate the force from $U(x)$. Use coordinates where the origin is at one atom. The other atom then has coordinate x.

EXECUTE:

$$F_x = -\frac{dU}{dx} = -\frac{d}{dx}\left(-\frac{C_6}{x^6}\right) = +C_6\frac{d}{dx}\left(\frac{1}{x^6}\right) = -\frac{6C_6}{x^7}$$

The minus sign mean that F_x is directed in the $-x$-direction, toward the origin. The force has magnitude $6C_6/x^7$ and is attractive.

EVALUATE: U depends only on x so $\vec{F}$ is along the x-axis; it has no y or z components.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

7.35. **IDENTIFY:** Apply Eq. (7.16).
SET UP: The sign of F_x indicates its direction.
EXECUTE: $F_x = -\dfrac{dU}{dx} = -4\alpha x^3 = -(4.8\ \text{J/m}^4)x^3$. $F_x(-0.800\ \text{m}) = -(4.8\ \text{J/m}^4)(-0.80\ \text{m})^3 = 2.46\ \text{N}$. The force is in the $+x$-direction.
EVALUATE: $F_x > 0$ when $x < 0$ and $F_x < 0$ when $x > 0$, so the force is always directed towards the origin.

7.36. **IDENTIFY:** Apply Eq. (7.18).
SET UP: $\dfrac{d}{dx}\left(\dfrac{1}{x^2}\right) = -\dfrac{2}{x^3}$ and $\dfrac{d}{dy}\left(\dfrac{1}{y^2}\right) = -\dfrac{2}{y^3}$.
EXECUTE: $\vec{F} = -\dfrac{\partial U}{\partial x}\hat{\boldsymbol{i}} - \dfrac{\partial U}{\partial y}\hat{\boldsymbol{j}}$ since U has no z-dependence. $\dfrac{\partial U}{\partial x} = \dfrac{-2\alpha}{x^3}$ and $\dfrac{\partial U}{\partial y} = \dfrac{-2\alpha}{y^3}$, so

$$\vec{F} = -\alpha\left(\frac{-2}{x^3}\hat{\boldsymbol{i}} + \frac{-2}{y^3}\hat{\boldsymbol{j}}\right) = 2\alpha\left(\frac{\vec{\boldsymbol{i}}}{x^3} + \frac{\vec{\boldsymbol{j}}}{y^3}\right).$$

EVALUATE: F_x and x have the same sign and F_y and y have the same sign. When $x > 0$, F_x is in the $+x$-direction, and so forth.

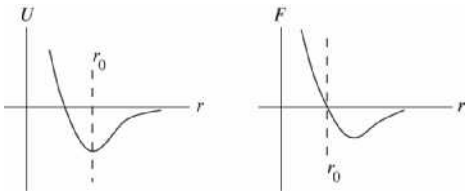
7.37. **IDENTIFY:** From the potential energy function of the block, we can find the force on it, and from the force we can use Newton's second law to find its acceleration.
SET UP: The force components are $F_x = -\dfrac{\partial U}{\partial x}$ and $F_y = -\dfrac{\partial U}{\partial y}$. The acceleration components are $a_x = F_x/m$ and $a_y = F_y/m$. The magnitude of the acceleration is $a = \sqrt{a_x^2 + a_y^2}$ and we can find its angle with the $+x$ axis using $\tan\theta = a_y/a_x$.
EXECUTE: $F_x = -\dfrac{\partial U}{\partial x} = -(11.6\ \text{J/m}^2)x$ and $F_y = -\dfrac{\partial U}{\partial y} = (10.8\ \text{J/m}^3)y^2$. At the point ($x = 0.300$ m, $y = 0.600$ m), $F_x = -(11.6\ \text{J/m}^2)(0.300\ \text{m}) = -3.48\ \text{N}$ and $F_y = (10.8\ \text{J/m}^3)(0.600\ \text{m})^2 = 3.89\ \text{N}$. Therefore $a_x = \dfrac{F_x}{m} = -87.0\ \text{m/s}^2$ and $a_y = \dfrac{F_y}{m} = 97.2\ \text{m/s}^2$, giving $a = \sqrt{a_x^2 + a_y^2} = 130\ \text{m/s}^2$ and $\tan\theta = \dfrac{97.2}{87.0}$, so $\theta = 48.2°$. The direction is 132^o counterclockwise from the $+x$-axis.
EVALUATE: The force is not constant, so the acceleration will not be the same at other points.

7.38. **IDENTIFY:** Apply Eq. (7.16).
SET UP: $\dfrac{dU}{dx}$ is the slope of the U versus x graph.
EXECUTE: **(a)** Considering only forces in the x-direction, $F_x = -\dfrac{dU}{dx}$ and so the force is zero when the slope of the U *vs* x graph is zero, at points b and d.
(b) Point b is at a potential minimum; to move it away from b would require an input of energy, so this point is stable.
(c) Moving away from point d involves a decrease of potential energy, hence an increase in kinetic energy, and the marble tends to move further away, and so d is an unstable point.
EVALUATE: At point b, F_x is negative when the marble is displaced slightly to the right and F_x is positive when the marble is displaced slightly to the left, the force is a restoring force, and the equilibrium is stable. At point d, a small displacement in either direction produces a force directed away from d and the equilibrium is unstable.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

7.39. **IDENTIFY** and **SET UP:** Use Eq. (7.17) to calculate the force from U. At equilibrium $F = 0$.

(a) EXECUTE: The graphs are sketched in Figure 7.39.



$$U = \frac{a}{r^{12}} - \frac{b}{r^6}$$

$$F = -\frac{dU}{dr} = +\frac{12a}{r^{13}} - \frac{6b}{r^7}$$

Figure 7.39

(b) At equilibrium $F = 0$, so $\dfrac{dU}{dr} = 0$

$$F = 0 \text{ implies } \frac{+12a}{r^{13}} - \frac{6b}{r^7} = 0$$

$6br^6 = 12a$; solution is the equilibrium distance $r_0 = (2a/b)^{1/6}$

U is a minimum at this r; the equilibrium is stable.

(c) At $r = (2a/b)^{1/6}$, $U = a/r^{12} - b/r^6 = a(b/2a)^2 - b(b/2a) = -b^2/4a$.

At $r \to \infty$, $U = 0$. The energy that must be added is $-\Delta U = b^2/4a$.

(d) $r_0 = (2a/b)^{1/6} = 1.13\times10^{-10}$ m gives that

$2a/b = 2.082\times10^{-60}$ m^6 and $b/4a = 2.402\times10^{59}$ m^{-6}

$b^2/4a = b(b/4a) = 1.54\times10^{-18}$ J

$b(2.402\times10^{59}\ \text{m}^{-6}) = 1.54\times10^{-18}$ J and $b = 6.41\times10^{-78}$ J $\cdot$ m^6.

Then $2a/b = 2.082\times10^{-60}$ m^6 gives $a = (b/2)(2.082\times10^{-60}\ \text{m}^6) =$

$\frac{1}{2}(6.41\times10^{-78}\ \text{J}\cdot\text{m}^6)\ (2.082\times10^{-60}\ \text{m}^6) = 6.67\times10^{-138}$ J $\cdot$ m^{12}

EVALUATE: As the graphs in part (a) show, $F(r)$ is the slope of $U(r)$ at each r. $U(r)$ has a minimum where $F = 0$.

7.40. **IDENTIFY:** For the system of two blocks, only gravity does work. Apply Eq. (7.5).

SET UP: Call the blocks A and B, where A is the more massive one. $v_{A1} = v_{B1} = 0$. Let $y = 0$ for each block to be at the initial height of that block, so $y_{A1} = y_{B1} = 0$. $y_{A2} = -1.20$ m and $y_{B2} = +1.20$ m. $v_{A2} = v_{B2} = v_2 = 3.00$ m/s.

EXECUTE: Eq. (7.5) gives $0 = \frac{1}{2}(m_A + m_B)v_2^2 + g(1.20\ \text{m})(m_B - m_A)\cdot m_A + m_B = 15.0$ kg $\cdot$

$\frac{1}{2}(15.0\ \text{kg})(3.00\ \text{m/s})^2 + (9.80\ \text{m/s}^2)(1.20\ \text{m})(15.0\ \text{kg} - 2m_A)$. Solving for m_A gives $m_A = 10.4$ kg.

And then $m_B = 4.6$ kg.

EVALUATE: The final kinetic energy of the two blocks is 68 J. The potential energy of block A decreases by 122 J. The potential energy of block B increases by 54 J. The total decrease in potential energy is 122 J – 54 J = 68 J, and this equals the increase in kinetic energy of the system.

7.41. **IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$ to the bag and to the box. Apply Eq. (7.7) to the motion of the system of the box and bucket after the bag is removed.

SET UP: Let $y = 0$ at the final height of the bucket, so $y_1 = 2.00$ m and $y_2 = 0$. $K_1 = 0$. The box and the bucket move with the same speed v, so $K_2 = \frac{1}{2}(m_{\text{box}} + m_{\text{bucket}})v^2$. $W_{\text{other}} = -f_k d$, with $d = 2.00$ m and $f_k = \mu_k m_{\text{box}} g$. Before the bag is removed, the maximum possible friction force the roof can exert on the box is $(0.700)(80.0\ \text{kg} + 50.0\ \text{kg})(9.80\ \text{m/s}^2) = 892$ N. This is larger than the weight of the bucket (637 N), so before the bag is removed the system is at rest.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: **(a)** The friction force on the bag of gravel is zero, since there is no other horizontal force on the bag for friction to oppose. The static friction force on the box equals the weight of the bucket, 637 N.

(b) Eq. (7.7) gives $m_{\text{bucket}}gy_1 - f_k d = \frac{1}{2}m_{\text{tot}}v^2$, with $m_{\text{tot}} = 145.0$ kg. $v = \sqrt{\frac{2}{m_{\text{tot}}}(m_{\text{bucket}}gy_1 - \mu_k m_{\text{box}}gd)}$.

$$v = \sqrt{\frac{2}{145.0 \text{ kg}}[(65.0 \text{ kg})(9.80 \text{ m/s}^2)(2.00 \text{ m}) - (0.400)(80.0 \text{ kg})(9.80 \text{ m/s}^2)(2.00 \text{ m})]}.$$

$v = 2.99$ m/s.

EVALUATE: If we apply $\Sigma\vec{F} = m\vec{a}$ to the box and to the bucket we can calculate their common acceleration a. Then a constant acceleration equation applied to either object gives $v = 2.99$ m/s, in agreement with our result obtained using energy methods.

7.42. **IDENTIFY:** Apply Eq. (7.14).

SET UP: Only the spring force and gravity do work, so $W_{\text{other}} = 0$. Let $y = 0$ at the horizontal surface.

EXECUTE: **(a)** Equating the potential energy stored in the spring to the block's kinetic energy,

$\frac{1}{2}kx^2 = \frac{1}{2}mv^2$, or $v = \sqrt{\frac{k}{m}}x = \sqrt{\frac{400 \text{ N/m}}{2.00 \text{ kg}}}(0.220 \text{ m}) = 3.11$ m/s.

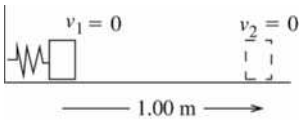
(b) Using energy methods directly, the initial potential energy of the spring equals the final gravitational potential energy, $\frac{1}{2}kx^2 = mgL\sin\theta$, or $L = \frac{\frac{1}{2}kx^2}{mg\sin\theta} = \frac{\frac{1}{2}(400 \text{ N/m})(0.220 \text{ m})^2}{(2.00 \text{ kg})(9.80 \text{ m/s}^2)\sin 37.0^\circ} = 0.821$ m.

EVALUATE: The total energy of the system is constant. Initially it is all elastic potential energy stored in the spring, then it is all kinetic energy and finally it is all gravitational potential energy.

7.43. **IDENTIFY:** Use the work-energy theorem, Eq. (7.7). The target variable μ_k will be a factor in the work done by friction.

SET UP: Let point 1 be where the block is released and let point 2 be where the block stops, as shown in Figure 7.43.

$K_1 + U_1 + W_{\text{other}} = K_2 + U_2$



Work is done on the block by the spring and by friction, so $W_{\text{other}} = W_f$ and $U = U_{\text{el}}$.

Figure 7.43

EXECUTE: $K_1 = K_2 = 0$

$U_1 = U_{1,\text{el}} = \frac{1}{2}kx_1^2 = \frac{1}{2}(100 \text{ N/m})(0.200 \text{ m})^2 = 2.00$ J

$U_2 = U_{2,\text{el}} = 0$, since after the block leaves the spring has given up all its stored energy

$W_{\text{other}} = W_f = (f_k\cos\phi)s = \mu_k mg(\cos\phi)s = -\mu_k mgs$, since $\phi = 180^\circ$ (The friction force is directed opposite to the displacement and does negative work.)

Putting all this into $K_1 + U_1 + W_{\text{other}} = K_2 + U_2$ gives

$U_{1,\text{el}} + W_f = 0$

$\mu_k mgs = U_{1,\text{el}}$

$$\mu_k = \frac{U_{1,\text{el}}}{mgs} = \frac{2.00 \text{ J}}{(0.50 \text{ kg})(9.80 \text{ m/s}^2)(1.00 \text{ m})} = 0.41.$$

EVALUATE: $U_{1,\text{el}} + W_f = 0$ says that the potential energy originally stored in the spring is taken out of the system by the negative work done by friction.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

7.44. **IDENTIFY:** Apply Eq. (7.14). Calculate f_k from the fact that the crate slides a distance $x = 5.60$ m before coming to rest. Then apply Eq. (7.14) again, with $x = 2.00$ m.

SET UP: $U_1 = U_{el} = 360$ J. $U_2 = 0$. $K_1 = 0$. $W_{other} = -f_k x$.

EXECUTE: Work done by friction against the crate brings it to a halt: $U_1 = -W_{other}$.

$f_k x =$ potential energy of compressed spring, and $f_k = \dfrac{360 \text{ J}}{5.60 \text{ m}} = 64.29$ N.

The friction force working over a 2.00-m distance does work equal to $-f_k x = -(64.29 \text{ N})(2.00 \text{ m}) = -128.6$ J. The kinetic energy of the crate at this point is thus $360 \text{ J} - 128.6 \text{ J} = 231.4 \text{ J}$, and its speed is found from $mv^2/2 = 231.4$ J, so $v = \sqrt{\dfrac{2(231.4 \text{ J})}{50.0 \text{ kg}}} = 3.04$ m/s.

EVALUATE: The energy of the compressed spring goes partly into kinetic energy of the crate and is partly removed by the negative work done by friction. After the crate leaves the spring the crate slows down as friction does negative work on it.

7.45. **IDENTIFY:** The mechanical energy of the roller coaster is conserved since there is no friction with the track. We must also apply Newton's second law for the circular motion.

SET UP: For part (a), apply conservation of energy to the motion from point A to point B: $K_B + U_{grav,B} = K_A + U_{grav,A}$ with $K_A = 0$. Defining $y_B = 0$ and $y_A = 13.0$ m, conservation of energy becomes $\frac{1}{2}mv_B{}^2 = mgy_A$ or $v_B = \sqrt{2gy_A}$. In part (b), the free-body diagram for the roller coaster car at point B is shown in Figure 7.45. $\Sigma F_y = ma_y$ gives $mg + n = ma_{rad}$, where $a_{rad} = v^2/r$. Solving for the normal force gives $n = m\left(\dfrac{v^2}{r} - g\right)$.

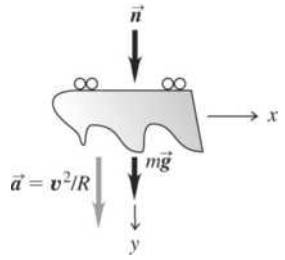


Figure 7.45

EXECUTE: **(a)** $v_B = \sqrt{2(9.80 \text{ m/s}^2)(13.0 \text{ m})} = 16.0$ m/s.

(b) $n = (350 \text{ kg})\left[\dfrac{(16.0 \text{ m/s})^2}{6.0 \text{ m}} - 9.80 \text{ m/s}^2\right] = 1.15 \times 10^4$ N.

EVALUATE: The normal force n is the force that the tracks exert on the roller coaster car. The car exerts a force of equal magnitude and opposite direction on the tracks.

7.46. **IDENTIFY:** Apply Eq. (7.14) to relate h and v_B. Apply $\Sigma\vec{F} = m\vec{a}$ at point B to find the minimum speed required at B for the car not to fall off the track.

SET UP: At B, $a = v_B^2/R$, downward. The minimum speed is when $n \to 0$ and $mg = mv_B^2/R$. The minimum speed required is $v_B = \sqrt{gR}$. $K_1 = 0$ and $W_{other} = 0$.

EXECUTE: **(a)** Eq. (7.14) applied to points A and B gives $U_A - U_B = \frac{1}{2}mv_B^2$. The speed at the top must be at least $\sqrt{gR}$. Thus, $mg(h - 2R) > \dfrac{1}{2}mgR$, or $h > \dfrac{5}{2}R$.

(b) Apply Eq. (7.14) to points A and C. $U_A - U_C = (2.50)Rmg = K_C$, so

$$v_C = \sqrt{(5.00)gR} = \sqrt{(5.00)(9.80 \text{ m/s}^2)(20.0 \text{ m})} = 31.3 \text{ m/s}.$$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

The radial acceleration is $a_{\text{rad}} = \dfrac{v_C^2}{R} = 49.0 \text{ m/s}^2$. The tangential direction is down, the normal force at point C is horizontal, there is no friction, so the only downward force is gravity, and $a_{\tan} = g = 9.80 \text{ m/s}^2$.

EVALUATE: If $h > \frac{5}{2}R$, then the downward acceleration at B due to the circular motion is greater than g and the track must exert a downward normal force n. n increases as h increases and hence v_B increases.

7.47. **(a) IDENTIFY:** Use work-energy relation to find the kinetic energy of the wood as it enters the rough bottom.

SET UP: Let point 1 be where the piece of wood is released and point 2 be just before it enters the rough bottom. Let $y = 0$ be at point 2.

EXECUTE: $U_1 = K_2$ gives $K_2 = mgy_1 = 78.4$ J.

IDENTIFY: Now apply work-energy relation to the motion along the rough bottom.

SET UP: Let point 1 be where it enters the rough bottom and point 2 be where it stops.

$$K_1 + U_1 + W_{\text{other}} = K_2 + U_2$$

EXECUTE: $W_{\text{other}} = W_f = -\mu_k mgs$, $K_2 = U_1 = U_2 = 0$; $K_1 = 78.4$ J

$78.4 \text{ J} - \mu_k mgs = 0$; solving for s gives $s = 20.0$ m.

The wood stops after traveling 20.0 m along the rough bottom.

(b) Friction does -78.4 J of work.

EVALUATE: The piece of wood stops before it makes one trip across the rough bottom. The final mechanical energy is zero. The negative friction work takes away all the mechanical energy initially in the system.

7.48. **IDENTIFY:** Apply Eq. (7.14) to the rock. $W_{\text{other}} = W_{f_k}$.

SET UP: Let $y = 0$ at the foot of the hill, so $U_1 = 0$ and $U_2 = mgh$, where h is the vertical height of the rock above the foot of the hill when it stops.

EXECUTE: **(a)** At the maximum height, $K_2 = 0$. Eq. (7.14) gives $K_{\text{Bottom}} + W_{f_k} = U_{\text{Top}}$.

$\dfrac{1}{2}mv_0^2 - \mu_k mg\cos\theta\, d = mgh$. $d = h/\sin\theta$, so $\dfrac{1}{2}v_0^2 - \mu_k g\cos\theta\dfrac{h}{\sin\theta} = gh$.

$\dfrac{1}{2}(15 \text{ m/s})^2 - (0.20)(9.8 \text{ m/s}^2)\dfrac{\cos 40^\circ}{\sin 40^\circ}h = (9.8 \text{ m/s}^2)h$ and $h = 9.3$ m.

(b) Compare maximum static friction force to the weight component down the plane.

$f_s = \mu_s mg\cos\theta = (0.75)(28 \text{ kg})(9.8 \text{ m/s}^2)\cos 40^\circ = 158$ N.

$mg\sin\theta = (28 \text{ kg})(9.8 \text{ m/s}^2)(\sin 40^\circ) = 176 \text{ N} > f_s$, so the rock will slide down.

(c) Use same procedure as in part (a), with $h = 9.3$ m and v_B being the speed at the bottom of the hill.

$U_{\text{Top}} + W_{f_k} = K_B$. $mgh - \mu_k mg\cos\theta\dfrac{h}{\sin\theta} = \dfrac{1}{2}mv_B^2$ and

$v_B = \sqrt{2gh - 2\mu_k gh\cos\theta/\sin\theta} = 11.8$ m/s.

EVALUATE: For the round trip up the hill and back down, there is negative work done by friction and the speed of the rock when it returns to the bottom of the hill is less than the speed it had when it started up the hill.

7.49. **IDENTIFY:** Apply Eq. (7.7) to the motion of the stone.

SET UP: $K_1 + U_1 + W_{\text{other}} = K_2 + U_2$

Let point 1 be point A and point 2 be point B. Take $y = 0$ at point B.

EXECUTE: $mgy_1 + \frac{1}{2}mv_1^2 = \frac{1}{2}mv_2^2$, with $h = 20.0$ m and $v_1 = 10.0$ m/s

$v_2 = \sqrt{v_1^2 + 2gh} = 22.2$ m/s

EVALUATE: The loss of gravitational potential energy equals the gain of kinetic energy.

(b) IDENTIFY: Apply Eq. (7.8) to the motion of the stone from point B to where it comes to rest against the spring.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

SET UP: Use $K_1 + U_1 + W_{other} = K_2 + U_2$, with point 1 at B and point 2 where the spring has its maximum compression x.

EXECUTE: $U_1 = U_2 = K_2 = 0$; $K_1 = \frac{1}{2}mv_1^2$ with $v_1 = 22.2$ m/s

$W_{other} = W_f + W_{el} = -\mu_k mgs - \frac{1}{2}kx^2$, with $s = 100\text{ m} + x$

The work-energy relation gives $K_1 + W_{other} = 0$.

$\frac{1}{2}mv_1^2 - \mu_k mgs - \frac{1}{2}kx^2 = 0$

Putting in the numerical values gives $x^2 + 29.4x - 750 = 0$. The positive root to this equation is $x = 16.4$ m.

EVALUATE: Part of the initial mechanical (kinetic) energy is removed by friction work and the rest goes into the potential energy stored in the spring.

(c) IDENTIFY and **SET UP:** Consider the forces.

EXECUTE: When the spring is compressed $x = 16.4$ m the force it exerts on the stone is $F_{el} = kx = 32.8$ N. The maximum possible static friction force is

$\max f_s = \mu_s mg = (0.80)(15.0\text{ kg})(9.80\text{ m/s}^2) = 118$ N.

EVALUATE: The spring force is less than the maximum possible static friction force so the stone remains at rest.

7.50. **IDENTIFY:** Once the block leaves the top of the hill it moves in projectile motion. Use Eq. (7.14) to relate the speed v_B at the bottom of the hill to the speed v_{Top} at the top and the 70 m height of the hill.

SET UP: For the projectile motion, take $+y$ to be downward. $a_x = 0$, $a_y = g$. $v_{0x} = v_{Top}$, $v_{0y} = 0$. For the motion up the hill only gravity does work. Take $y = 0$ at the base of the hill.

EXECUTE: First get speed at the top of the hill for the block to clear the pit. $y = \frac{1}{2}gt^2$.

$20\text{ m} = \frac{1}{2}(9.8\text{ m/s}^2)t^2$. $t = 2.0$ s. Then $v_{Top}t = 40$ m gives $v_{Top} = \frac{40\text{ m}}{2.0\text{ s}} = 20$ m/s.

Energy conservation applied to the motion up the hill: $K_{Bottom} = U_{Top} + K_{Top}$ gives

$\frac{1}{2}mv_B^2 = mgh + \frac{1}{2}mv_{Top}^2$. $v_B = \sqrt{v_{Top}^2 + 2gh} = \sqrt{(20\text{ m/s})^2 + 2(9.8\text{ m/s}^2)(70\text{ m})} = 42$ m/s.

EVALUATE: The result does not depend on the mass of the block.

7.51. **IDENTIFY:** Apply $K_1 + U_1 + W_{other} = K_2 + U_2$ to the motion of the person.

SET UP: Point 1 is where he steps off the platform and point 2 is where he is stopped by the cord. Let $y = 0$ at point 2. $y_1 = 41.0$ m. $W_{other} = -\frac{1}{2}kx^2$, where $x = 11.0$ m is the amount the cord is stretched at point 2. The cord does negative work.

EXECUTE: $K_1 = K_2 = U_2 = 0$, so $mgy_1 - \frac{1}{2}kx^2 = 0$ and $k = 631$ N/m.

Now apply $F = kx$ to the test pulls:

$F = kx$ so $x = F/k = 0.602$ m.

EVALUATE: All his initial gravitational potential energy is taken away by the negative work done by the force exerted by the cord, and this amount of energy is stored as elastic potential energy in the stretched cord.

7.52. **IDENTIFY:** Apply Eq. (7.14) to the motion of the skier from the gate to the bottom of the ramp.

SET UP: $W_{other} = -4000$ J. Let $y = 0$ at the bottom of the ramp.

EXECUTE: For the skier to be moving at no more than 30.0 m/s, his kinetic energy at the bottom of the ramp can be no bigger than $\frac{mv^2}{2} = \frac{(85.0\text{ kg})(30.0\text{ m/s})^2}{2} = 38{,}250$ J. Friction does -4000 J of work on him during his run, which means his combined U and K at the top of the ramp must be no more than $38{,}250\text{ J} + 4000\text{ J} = 42{,}250$ J. His K at the top is $\frac{mv^2}{2} = \frac{(85.0\text{ kg})(2.0\text{ m/s})^2}{2} = 170$ J. His U at the top

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

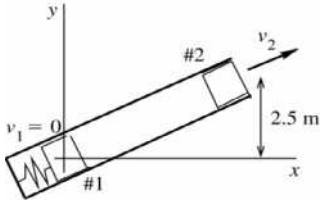
should thus be no more than $42,250\text{ J} - 170\text{ J} = 42,080\text{ J}$, which gives a height above the bottom of the ramp of $h = \dfrac{42,080\text{ J}}{mg} = \dfrac{42,080\text{ J}}{(85.0\text{ kg})(9.80\text{ m/s}^2)} = 50.5\text{ m}$.

EVALUATE: In the absence of air resistance, for this h his speed at the bottom of the ramp would be 31.5 m/s. The work done by air resistance is small compared to the kinetic and potential energies that enter into the calculation.

7.53. **IDENTIFY:** Use the work-energy theorem, Eq. (7.7). Solve for K_2 and then for v_2.

SET UP: Let point 1 be at his initial position against the compressed spring and let point 2 be at the end of the barrel, as shown in Figure 7.53. Use $F = kx$ to find the amount the spring is initially compressed by the 4400 N force.

$K_1 + U_1 + W_{\text{other}} = K_2 + U_2$



Take $y = 0$ at his initial position.

EXECUTE: $K_1 = 0,\ K_2 = \frac{1}{2}mv_2^2$

$W_{\text{other}} = W_{\text{fric}} = -fs$

$W_{\text{other}} = -(40\text{ N})(4.0\text{ m}) = -160\text{ J}$

Figure 7.53

$U_{1,\text{grav}} = 0,\ U_{1,\text{el}} = \frac{1}{2}kd^2$, where d is the distance the spring is initially compressed.

$F = kd$ so $d = \dfrac{F}{k} = \dfrac{4400\text{ N}}{1100\text{ N/m}} = 4.00\text{ m}$

and $U_{1,\text{el}} = \frac{1}{2}(1100\text{ N/m})(4.00\text{ m})^2 = 8800\text{ J}$

$U_{2,\text{grav}} = mgy_2 = (60\text{ kg})(9.80\text{ m/s}^2)(2.5\text{ m}) = 1470\text{ J},\ U_{2,\text{el}} = 0$

Then $K_1 + U_1 + W_{\text{other}} = K_2 + U_2$ gives

$8800\text{ J} - 160\text{ J} = \frac{1}{2}mv_2^2 + 1470\text{ J}$

$\frac{1}{2}mv_2^2 = 7170\text{ J}$ and $v_2 = \sqrt{\dfrac{2(7170\text{ J})}{60\text{ kg}}} = 15.5\text{ m/s}$

EVALUATE: Some of the potential energy stored in the compressed spring is taken away by the work done by friction. The rest goes partly into gravitational potential energy and partly into kinetic energy.

7.54. **IDENTIFY:** To be at equilibrium at the bottom, with the spring compressed a distance x_0, the spring force must balance the component of the weight down the ramp plus the largest value of the static friction, or $kx_0 = w\sin\theta + f$. Apply Eq. (7.14) to the motion down the ramp.

SET UP: $K_2 = 0,\ K_1 = \frac{1}{2}mv^2$, where v is the speed at the top of the ramp. Let $U_2 = 0$, so $U_1 = wL\sin\theta$, where L is the total length traveled down the ramp.

EXECUTE: Eq. (7.14) gives $\dfrac{1}{2}kx_0^2 = (w\sin\theta - f)L + \dfrac{1}{2}mv^2$. With the given parameters, $\frac{1}{2}kx_0^2 = 248\text{ J}$ and $kx_0 = 1.10\times10^3\text{ N}$. Solving for k gives $k = 2440\text{ N/m}$.

EVALUATE: $x_0 = 0.451\text{ m}$. $w\sin\theta = 551\text{ N}$. The decrease in gravitational potential energy is only slightly larger than the amount of mechanical energy removed by the negative work done by friction. $\frac{1}{2}mv^2 = 243\text{ J}$. The energy stored in the spring is only slightly larger than the initial kinetic energy of the crate at the top of the ramp.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

7.55. **IDENTIFY:** Apply Eq. (7.7) to the system consisting of the two buckets. If we ignore the inertia of the pulley we ignore the kinetic energy it has.

SET UP: $K_1 + U_1 + W_{\text{other}} = K_2 + U_2$. Points 1 and 2 in the motion are sketched in Figure 7.55.

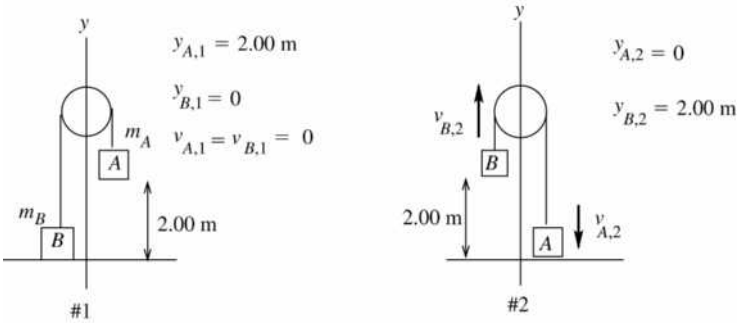


Figure 7.55

The tension force does positive work on the 4.0 kg bucket and an equal amount of negative work on the 12.0 kg bucket, so the net work done by the tension is zero.

Work is done on the system only by gravity, so $W_{\text{other}} = 0$ and $U = U_{\text{grav}}$

EXECUTE: $K_1 = 0$

$K_2 = \frac{1}{2}m_A v_{A,2}^2 + \frac{1}{2}m_B v_{B,2}^2$ But since the two buckets are connected by a rope they move together and have the same speed: $v_{A,2} = v_{B,2} = v_2$.

Thus $K_2 = \frac{1}{2}(m_A + m_B)v_2^2 = (8.00 \text{ kg})v_2^2$.

$U_1 = m_A g y_{A,1} = (12.0 \text{ kg})(9.80 \text{ m/s}^2)(2.00 \text{ m}) = 235.2 \text{ J}$.

$U_2 = m_B g y_{B,2} = (4.0 \text{ kg})(9.80 \text{ m/s}^2)(2.00 \text{ m}) = 78.4 \text{ J}$.

Putting all this into $K_1 + U_1 + W_{\text{other}} = K_2 + U_2$ gives

$U_1 = K_2 + U_2$

$235.2 \text{ J} = (8.00 \text{ kg})v_2^2 + 78.4 \text{ J}$

$$v_2 = \sqrt{\frac{235.2 \text{ J} - 78.4 \text{ J}}{8.00 \text{ kg}}} = 4.4 \text{ m/s}$$

EVALUATE: The gravitational potential energy decreases and the kinetic energy increases by the same amount. We could apply Eq. (7.7) to one bucket, but then we would have to include in W_{other} the work done on the bucket by the tension T.

7.56. **IDENTIFY:** Apply $K_1 + U_1 + W_{\text{other}} = K_2 + U_2$ to the motion of the rocket from the starting point to the base of the ramp. W_{other} is the work done by the thrust and by friction.

SET UP: Let point 1 be at the starting point and let point 2 be at the base of the ramp. $v_1 = 0$, $v_2 = 50.0$ m/s. Let $y = 0$ at the base and take $+y$ upward. Then $y_2 = 0$ and $y_1 = d\sin 53°$, where d is the distance along the ramp from the base to the starting point. Friction does negative work.

EXECUTE: $K_1 = 0$, $U_2 = 0$. $U_1 + W_{\text{other}} = K_2$. $W_{\text{other}} = (2000 \text{ N})d - (500 \text{ N})d = (1500 \text{ N})d$.

$mgd\sin 53° + (1500 \text{ N})d = \frac{1}{2}mv_2^2$.

$$d = \frac{mv_2^2}{2[mg\sin 53° + 1500 \text{ N}]} = \frac{(1500 \text{ kg})(50.0 \text{ m/s})^2}{2[(1500 \text{ kg})(9.80 \text{ m/s}^2)\sin 53° + 1500 \text{ N}]} = 142 \text{ m}.$$

EVALUATE: The initial height is $y_1 = (142 \text{ m})\sin 53° = 113$ m. An object free-falling from this distance attains a speed $v = \sqrt{2gy_1} = 47.1$ m/s. The rocket attains a greater speed than this because the forward thrust is greater than the friction force.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

7.57. **IDENTIFY:** Apply $K_1 + U_1 + W_{\text{other}} = K_2 + U_2$

SET UP: $U_1 = U_2 = K_2 = 0$. $W_{\text{other}} = W_f = -\mu_k mgs$, with $s = 280 \text{ ft} = 85.3 \text{ m}$

EXECUTE: **(a)** The work-energy expression gives $\frac{1}{2}mv_1^2 - \mu_k mgs = 0$.

$v_1 = \sqrt{2\mu_k gs} = 22.4 \text{ m/s} = 50 \text{ mph}$; the driver was speeding.

(b) 15 mph over speed limit so \$150 ticket.

EVALUATE: The negative work done by friction removes the kinetic energy of the object.

7.58. **IDENTIFY:** Conservation of energy says the decrease in potential energy equals the gain in kinetic energy.

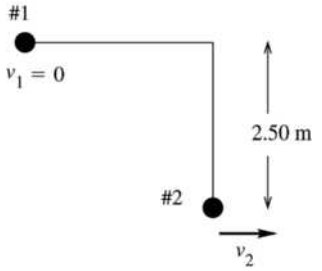
SET UP: Since the two animals are equidistant from the axis, they each have the same speed v.

EXECUTE: One mass rises while the other falls, so the net loss of potential energy is $(0.500 \text{ kg} - 0.200 \text{ kg})(9.80 \text{ m/s}^2)(0.400 \text{ m}) = 1.176 \text{ J}$. This is the sum of the kinetic energies of the animals and is equal to $\frac{1}{2}m_{\text{tot}}v^2$, and $v = \sqrt{\dfrac{2(1.176 \text{ J})}{(0.700 \text{ kg})}} = 1.83 \text{ m/s}$.

EVALUATE: The mouse gains both gravitational potential energy and kinetic energy. The rat's gain in kinetic energy is less than its decrease of potential energy, and the energy difference is transferred to the mouse.

7.59. **(a) IDENTIFY** and **SET UP:** Apply Eq. (7.7) to the motion of the potato. Let point 1 be where the potato is released and point 2 be at the lowest point in its motion, as shown in Figure 7.59a.

$K_1 + U_1 + W_{\text{other}} = K_2 + U_2$



$y_1 = 2.50 \text{ m}$

$y_2 = 0$

The tension in the string is at all points in the motion perpendicular to the displacement, so $W_r = 0$

The only force that does work on the potato is gravity, so $W_{\text{other}} = 0$.

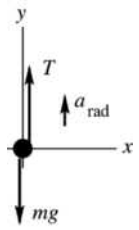
Figure 7.59a

EXECUTE: $K_1 = 0$, $K_2 = \frac{1}{2}mv_2^2$, $U_1 = mgy_1$, $U_2 = 0$. Thus $U_1 = K_2$. $mgy_1 = \frac{1}{2}mv_2^2$, which gives $v_2 = \sqrt{2gy_1} = \sqrt{2(9.80 \text{ m/s}^2)(2.50 \text{ m})} = 7.00 \text{ m/s}$.

EVALUATE: The speed v_2 is the same as if the potato fell through 2.50 m.

(b) IDENTIFY: Apply $\Sigma\vec{F} = m\vec{a}$ to the potato. The potato moves in an arc of a circle so its acceleration is $\vec{a}_{\text{rad}}$, where $a_{\text{rad}} = v^2/R$ and is directed toward the center of the circle. Solve for one of the forces, the tension T in the string.

SET UP: The free-body diagram for the potato as it swings through its lowest point is given in Figure 7.59b.



The acceleration $\vec{a}_{\text{rad}}$ is directed in toward the center of the circular path, so at this point it is upward.

Figure 7.59b

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: $\Sigma F_y = ma_y$ gives $T - mg = ma_{\text{rad}}$. Solving for T gives $T = m(g + a_{\text{rad}}) = m\left(g + \dfrac{v_2^2}{R}\right)$, where the radius R for the circular motion is the length L of the string. It is instructive to use the algebraic expression for v_2 from part (a) rather than just putting in the numerical value: $v_2 = \sqrt{2gy_1} = \sqrt{2gL}$, so $v_2^2 = 2gL$. Then $T = m\left(g + \dfrac{v_2^2}{L}\right) = m\left(g + \dfrac{2gL}{L}\right) = 3mg$. The tension at this point is three times the weight of the potato, so $T = 3mg = 3(0.300 \text{ kg})(9.80 \text{ m/s}^2) = 8.82 \text{ N}$.

EVALUATE: The tension is greater than the weight; the acceleration is upward so the net force must be upward.

7.60. **IDENTIFY:** Eq. (7.14) says $W_{\text{other}} = K_2 + U_2 - (K_1 + U_1)$. W_{other} is the work done on the baseball by the force exerted by the air.

SET UP: $U = mgy$. $K = \frac{1}{2}mv^2$, where $v^2 = v_x^2 + v_y^2$.

EXECUTE: **(a)** The change in total energy is the work done by the air,

$$W_{\text{other}} = (K_2 + U_2) - (K_1 + U_1) = m\left(\frac{1}{2}(v_2^2 - v_1^2) + gy_2\right).$$

$W_{\text{other}} = (0.145 \text{ kg})((1/2[(18.6 \text{ m/s})^2 - (30.0 \text{ m/s})^2 - (40.0 \text{ m/s})^2] + (9.80 \text{ m/s}^2)(53.6 \text{ m}))$.

$W_{\text{other}} = -80.0 \text{ J}$.

(b) Similarly, $W_{\text{other}} = (K_3 + U_3) - (K_2 + U_2)$.

$W_{\text{other}} = (0.145 \text{ kg})((1/2)[(11.9 \text{ m/s})^2 + (-28.7 \text{ m/s})^2 - (18.6 \text{ m/s})^2] - (9.80 \text{ m/s}^2)(53.6 \text{ m}))$.

$W_{\text{other}} = -31.3 \text{ J}$.

(c) The ball is moving slower on the way down, and does not go as far (in the x-direction), and so the work done by the air is smaller in magnitude.

EVALUATE: The initial kinetic energy of the baseball is $\frac{1}{2}(0.145 \text{ kg})(50.0 \text{ m/s})^2 = 181 \text{ J}$. For the total motion from the ground, up to the maximum height, and back down the total work done by the air is 111 J. The ball returns to the ground with $181 \text{ J} - 111 \text{ J} = 70 \text{ J}$ of kinetic energy and a speed of 31 m/s, less than its initial speed of 50 m/s.

7.61. **IDENTIFY** and **SET UP:** There are two situations to compare: stepping off a platform and sliding down a pole. Apply the work-energy theorem to each.

(a) EXECUTE: Speed at ground if steps off platform at height h:

$K_1 + U_1 + W_{\text{other}} = K_2 + U_2$

$mgh = \frac{1}{2}mv_2^2$, so $v_2^2 = 2gh$

Motion from top to bottom of pole: (take $y = 0$ at bottom)

$K_1 + U_1 + W_{\text{other}} = K_2 + U_2$

$mgd - fd = \frac{1}{2}mv_2^2$

Use $v_2^2 = 2gh$ and get $mgd - fd = mgh$

$fd = mg(d - h)$

$f = mg(d - h)/d = mg(1 - h/d)$

EVALUATE: For $h = d$ this gives $f = 0$ as it should (friction has no effect).

For $h = 0$, $v_2 = 0$ (no motion). The equation for f gives $f = mg$ in this special case. When $f = mg$ the forces on him cancel and he doesn't accelerate down the pole, which agrees with $v_2 = 0$.

(b) EXECUTE: $f = mg(1 - h/d) = (75 \text{ kg})(9.80 \text{ m/s}^2)(1 - 1.0 \text{ m}/2.5 \text{ m}) = 441 \text{ N}$.

(c) Take $y = 0$ at bottom of pole, so $y_1 = d$ and $y_2 = y$.

$K_1 + U_1 + W_{\text{other}} = K_2 + U_2$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$0 + mgd - f(d-y) = \frac{1}{2}mv^2 + mgy$

$\frac{1}{2}mv^2 = mg(d-y) - f(d-y)$

Using $f = mg(1-h/d)$ gives $\frac{1}{2}mv^2 = mg(d-y) - mg(1-h/d)(d-y)$

$\frac{1}{2}mv^2 = mg(h/d)(d-y)$ and $v = \sqrt{2gh(1-y/d)}$

EVALUATE: This gives the correct results for $y = 0$ and for $y = d$.

7.62. **IDENTIFY:** Apply Eq. (7.14) to each stage of the motion.

SET UP: Let $y = 0$ at the bottom of the slope. In part (a), W_{other} is the work done by friction. In part (b), W_{other} is the work done by friction and the air resistance force. In part (c), W_{other} is the work done by the force exerted by the snowdrift.

EXECUTE: **(a)** The skier's kinetic energy at the bottom can be found from the potential energy at the top minus the work done by friction, $K_1 = mgh - W_f = (60.0\text{ kg})(9.8\text{ N/kg})(65.0\text{ m}) - 10{,}500\text{ J}$, or

$K_1 = 38{,}200\text{ J} - 10{,}500\text{ J} = 27{,}720\text{ J}$. Then $v_1 = \sqrt{\frac{2K_1}{m}} = \sqrt{\frac{2(27{,}720\text{ J})}{60\text{ kg}}} = 30.4\text{ m/s}$.

(b) $K_2 = K_1 - (W_f + W_{\text{air}}) = 27{,}720\text{ J} - (\mu_k mgd + f_{\text{air}}d)$.

$K_2 = 27{,}720\text{ J} - [(0.2)(588\text{ N})(82\text{ m}) + (160\text{ N})(82\text{ m})]$ or $K_2 = 27{,}720\text{ J} - 22{,}763\text{ J} = 4957\text{ J}$. Then,

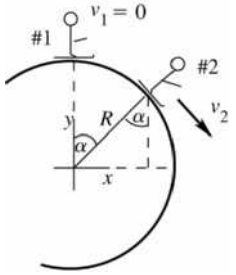
$v_2 = \sqrt{\frac{2K}{m}} = \sqrt{\frac{2(4957\text{ J})}{60\text{ kg}}} = 12.9\text{ m/s}$

(c) Use the Work-Energy Theorem to find the force. $W = \Delta K$, $F = K/d = (4957\text{ J})/(2.5\text{ m}) = 2000\text{ N}$.

EVALUATE: In each case, W_{other} is negative and removes mechanical energy from the system.

7.63. **IDENTIFY** and **SET UP:** First apply $\Sigma\vec{F} = m\vec{a}$ to the skier.

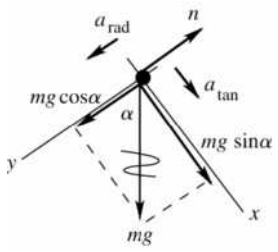
Find the angle α where the normal force becomes zero, in terms of the speed v_2 at this point. Then apply the work-energy theorem to the motion of the skier to obtain another equation that relates v_2 and α. Solve these two equations for α.



Let point 2 be where the skier loses contact with the snowball, as sketched in Figure 7.63a
Loses contact implies $n \to 0$.
$y_1 = R$, $y_2 = R\cos\alpha$

Figure 7.63a

First, analyze the forces on the skier when she is at point 2. The free-body diagram is given in Figure 7.63b. For this use coordinates that are in the tangential and radial directions. The skier moves in an arc of a circle, so her acceleration is $a_{\text{rad}} = v^2/R$, directed in towards the center of the snowball.



EXECUTE: $\Sigma F_y = ma_y$

$mg\cos\alpha - n = mv_2^2/R$

But $n = 0$ so $mg\cos\alpha = mv_2^2/R$

$v_2^2 = Rg\cos\alpha$

Figure 7.63b

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

Now use conservation of energy to get another equation relating v_2 to α:

$K_1 + U_1 + W_{\text{other}} = K_2 + U_2$

The only force that does work on the skier is gravity, so $W_{\text{other}} = 0$.

$K_1 = 0, \quad K_2 = \frac{1}{2}mv_2^2$

$U_1 = mgy_1 = mgR, \quad U_2 = mgy_2 = mgR\cos\alpha$

Then $mgR = \frac{1}{2}mv_2^2 + mgR\cos\alpha$

$v_2^2 = 2gR(1-\cos\alpha)$

Combine this with the $\Sigma F_y = ma_y$ equation:

$Rg\cos\alpha = 2gR(1-\cos\alpha)$

$\cos\alpha = 2 - 2\cos\alpha$

$3\cos\alpha = 2$ so $\cos\alpha = 2/3$ and $\alpha = 48.2°$

EVALUATE: She speeds up and her a_{rad} increases as she loses gravitational potential energy. She loses contact when she is going so fast that the radially inward component of her weight isn't large enough to keep her in the circular path. Note that α where she loses contact does not depend on her mass or on the radius of the snowball.

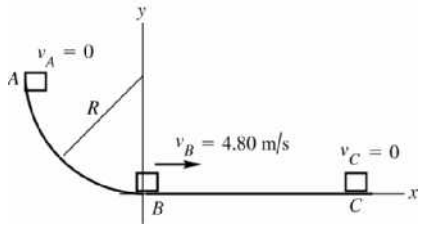
7.64. **IDENTIFY:** Initially the ball has all kinetic energy, but at its highest point it has kinetic energy and potential energy. Since it is thrown upward at an angle, its kinetic energy is *not* zero at its highest point.

SET UP: Apply conservation of energy: $K_f + U_f = K_i + U_i$. Let $y_i = 0$, so $y_f = h$, the maximum height. At this maximum height, $v_{f,y} = 0$ and $v_{f,x} = v_{i,x}$, so $v_f = v_{i,x} = (15 \text{ m/s})(\cos 60.0°) = 7.5 \text{ m/s}$. Substituting into conservation of energy equation gives $\frac{1}{2}mv_i^2 = mgh + \frac{1}{2}m(7.5 \text{ m/s})^2$.

EXECUTE: Solve for h: $h = \dfrac{v_i^2 - (7.5 \text{ m/s})^2}{2g} = \dfrac{(15 \text{ m/s})^2 - (7.5 \text{ m/s})^2}{2(9.80 \text{ m/s}^2)} = 8.6 \text{ m}.$

EVALUATE: If the ball were thrown straight up, its maximum height would be 11.5 m, since all of its kinetic energy would be converted to potential energy. But in this case it reaches a lower height because it still retains some kinetic energy at its highest point.

7.65. **IDENTIFY** and **SET UP:**



$y_A = R$

$y_B = y_C = 0$

Figure 7.65

(a) Apply conservation of energy to the motion from B to C:

$K_B + U_B + W_{\text{other}} = K_C + U_C$. The motion is described in Figure 7.65.

EXECUTE: The only force that does work on the package during this part of the motion is friction, so

$W_{\text{other}} = W_f = f_k(\cos\phi)s = \mu_k mg(\cos 180°)s = -\mu_k mgs$

$K_B = \frac{1}{2}mv_B^2, \quad K_C = 0$

$U_B = 0, \quad U_C = 0$

Thus $K_B + W_f = 0$

$\frac{1}{2}mv_B^2 - \mu_k mgs = 0$

$\mu_k = \dfrac{\mu_B^2}{2gs} = \dfrac{(4.80 \text{ m/s})^2}{2(9.80 \text{ m/s}^2)(3.00 \text{ m})} = 0.392$

EVALUATE: The negative friction work takes away all the kinetic energy.

(b) IDENTIFY and **SET UP:** Apply conservation of energy to the motion from A to B:

$$K_A + U_A + W_{\text{other}} = K_B + U_B$$

EXECUTE: Work is done by gravity and by friction, so $W_{\text{other}} = W_f$.

$K_A = 0,\ K_B = \frac{1}{2}mv_B^2 = \frac{1}{2}(0.200\ \text{kg})(4.80\ \text{m/s})^2 = 2.304\ \text{J}$

$U_A = mgy_A = mgR = (0.200\ \text{kg})(9.80\ \text{m/s}^2)(1.60\ \text{m}) = 3.136\ \text{J},\ U_B = 0$

Thus $U_A + W_f = K_B$

$W_f = K_B - U_A = 2.304\ \text{J} - 3.136\ \text{J} = -0.83\ \text{J}$

EVALUATE: W_f is negative as expected; the friction force does negative work since it is directed opposite to the displacement.

7.66. **IDENTIFY:** Apply Eq. (7.14) to the initial and final positions of the truck.

SET UP: Let $y = 0$ at the lowest point of the path of the truck. W_{other} is the work done by friction. $f_r = \mu_r n = \mu_r mg\cos\beta$.

EXECUTE: Denote the distance the truck moves up the ramp by x. $K_1 = \frac{1}{2}mv_0^2,\ U_1 = mgL\sin\alpha,\ K_2 = 0,$ $U_2 = mgx\sin\beta$ and $W_{\text{other}} = -\mu_r mgx\cos\beta$. From $W_{\text{other}} = (K_2 + U_2) - (K_1 + U_1)$, and solving for x,

$$x = \frac{K_1 + mgL\sin\alpha}{mg(\sin\beta + \mu_r\cos\beta)} = \frac{(v_0^2/2g) + L\sin\alpha}{\sin\beta + \mu_r\cos\beta}.$$

EVALUATE: x increases when v_0 increases and decreases when μ_r increases.

7.67. $F_x = -\alpha x - \beta x^2,\ \alpha = 60.0\ \text{N/m}$ and $\beta = 18.0\ \text{N/m}^2$

(a) IDENTIFY: Use Eq. (6.7) to calculate W and then use $W = -\Delta U$ to identify the potential energy function $U(x)$.

SET UP: $W_{F_x} = U_1 - U_2 = \int_{x_1}^{x_2} F_x(x)\,dx$

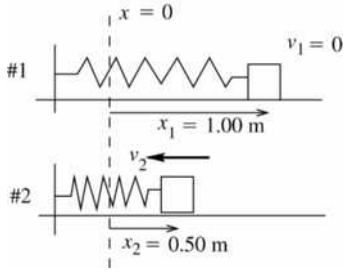
Let $x_1 = 0$ and $U_1 = 0$. Let x_2 be some arbitrary point x, so $U_2 = U(x)$.

EXECUTE: $U(x) = -\int_0^x F_x(x)\,dx = -\int_0^x (-\alpha x - \beta x^2)\,dx = \int_0^x (\alpha x + \beta x^2)\,dx = \frac{1}{2}\alpha x^2 + \frac{1}{3}\beta x^3.$

EVALUATE: If $\beta = 0$, the spring does obey Hooke's law, with $k = \alpha$, and our result reduces to $\frac{1}{2}kx^2$.

(b) IDENTIFY: Apply Eq. (7.15) to the motion of the object.

SET UP: The system at points 1 and 2 is sketched in Figure 7.67.



$K_1 + U_1 + W_{\text{other}} = K_2 + U_2$

The only force that does work on the object is the spring force, so $W_{\text{other}} = 0$.

Figure 7.67

EXECUTE: $K_1 = 0,\ K_2 = \frac{1}{2}mv_2^2$

$U_1 = U(x_1) = \frac{1}{2}\alpha x_1^2 + \frac{1}{3}\beta x_1^3 = \frac{1}{2}(60.0\ \text{N/m})(1.00\ \text{m})^2 + \frac{1}{3}(18.0\ \text{N/m}^2)(1.00\ \text{m})^3 = 36.0\ \text{J}$

$U_2 = U(x_2) = \frac{1}{2}\alpha x_2^2 + \frac{1}{3}\beta x_2^3 = \frac{1}{2}(60.0\ \text{N/m})(0.500\ \text{m})^2 + \frac{1}{3}(18.0\ \text{N/m}^2)(0.500\ \text{m})^3 = 8.25\ \text{J}$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

Thus $36.0\text{ J} = \frac{1}{2}mv_2^2 + 8.25\text{ J}$

$$v_2 = \sqrt{\frac{2(36.0\text{ J} - 8.25\text{ J})}{0.900\text{ kg}}} = 7.85\text{ m/s}$$

EVALUATE: The elastic potential energy stored in the spring decreases and the kinetic energy of the object increases.

7.68. **IDENTIFY:** Mechanical energy is conserved on the hill, which gives us the speed of the sled at the top. After it leaves the cliff, we must use projectile motion.

SET UP: Use conservation of energy to find the speed of the sled at the edge of the cliff. Let $y_\text{i} = 0$ so $y_\text{f} = h = 11.0\text{ m}$. $K_\text{f} + U_\text{f} = K_\text{i} + U_\text{i}$ gives $\frac{1}{2}mv_\text{f}{}^2 + mgh = \frac{1}{2}mv_\text{i}{}^2$ or $v_\text{f} = \sqrt{v_\text{i}{}^2 - 2gh}$. Then analyze the projectile motion of the sled: use the vertical component of motion to find the time t that the sled is in the air; then use the horizontal component of the motion with $a_x = 0$ to find the horizontal displacement.

EXECUTE: $v_\text{f} = \sqrt{(22.5\text{ m/s})^2 - 2(9.80\text{ m/s}^2)(11.0\text{ m})} = 17.1\text{ m/s}$. $y_\text{f} = v_{\text{i},y}t + \frac{1}{2}a_y t^2$ gives

$$t = \sqrt{\frac{2y_\text{f}}{a_y}} = \sqrt{\frac{2(-11.0\text{ m})}{-9.80\text{ m/s}^2}} = 1.50\text{ s}.$$ $x_\text{f} = v_{\text{i},x}t + \frac{1}{2}a_x t^2$ gives $x_\text{f} = v_{\text{i},x}t = (17.1\text{ m/s})(1.50\text{ s}) = 25.6\text{ m}$.

EVALUATE: Conservation of energy can be used to find the speed of the sled at any point of the motion but does not specify how far the sled travels while it is in the air.

7.69. **IDENTIFY:** Apply Eq. (7.14) to the motion of the block.

SET UP: Let $y = 0$ at the floor. Let point 1 be the initial position of the block against the compressed spring and let point 2 be just before the block strikes the floor.

EXECUTE: With $U_2 = 0, K_1 = 0,\ K_2 = U_1$. $\frac{1}{2}mv_2^2 = \frac{1}{2}kx^2 + mgh$. Solving for v_2,

$$v_2 = \sqrt{\frac{kx^2}{m} + 2gh} = \sqrt{\frac{(1900\text{ N/m})(0.045\text{ m})^2}{(0.150\text{ kg})} + 2(9.80\text{ m/s}^2)(1.20\text{ m})} = 7.01\text{ m/s}.$$

EVALUATE: The potential energy stored in the spring and the initial gravitational potential energy all go into the final kinetic energy of the block.

7.70. **IDENTIFY:** Apply Eq. (7.14). U is the total elastic potential energy of the two springs.

SET UP: Call the two points in the motion where Eq. (7.14) is applied A and B to avoid confusion with springs 1 and 2, that have force constants k_1 and k_2. At any point in the motion the distance one spring is stretched equals the distance the other spring is compressed. Let $+x$ be to the right. Let point A be the initial position of the block, where it is released from rest, so $x_{1A} = +0.150$ m and $x_{2A} = -0.150$ m.

EXECUTE: **(a)** With no friction, $W_\text{other} = 0$. $K_A = 0$ and $U_A = K_B + U_B$. The maximum speed is when $U_B = 0$ and this is at $x_{1B} = x_{2B} = 0$, when both springs are at their natural length.

$\frac{1}{2}k_1x_{1A}^2 + \frac{1}{2}k_2x_{2A}^2 = \frac{1}{2}mv_B^2$. $x_{1A}^2 = x_{2A}^2 = (0.150\text{ m})^2$, so

$$v_B = \sqrt{\frac{k_1 + k_2}{m}}(0.150\text{ m}) = \sqrt{\frac{2500\text{ N/m} + 2000\text{ N/m}}{3.00\text{ kg}}}(0.150\text{ m}) = 6.00\text{ m/s}.$$

(b) At maximum compression of spring 1, spring 2 has its maximum extension and $v_B = 0$. Therefore, at this point $U_A = U_B$. The distance spring 1 is compressed equals the distance spring 2 is stretched, and vice versa: $x_{1A} = -x_{2A}$ and $x_{1B} = -x_{2B}$. Then $U_A = U_B$ gives $\frac{1}{2}(k_1 + k_2)x_{1A}^2 = \frac{1}{2}(k_1 + k_2)x_{1B}^2$ and $x_{1B} = -x_{1A} = -0.150$ m. The maximum compression of spring 1 is 15.0 cm.

EVALUATE: When friction is not present mechanical energy is conserved and is continually transformed between kinetic energy of the block and potential energy in the springs. If friction is present, its work removes mechanical energy from the system.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

7.71. **IDENTIFY:** Apply conservation of energy to relate x and h. Apply $\Sigma\vec{F} = m\vec{a}$ to relate a and x.
SET UP: The first condition, that the maximum height above the release point is h, is expressed as $\frac{1}{2}kx^2 = mgh$. The magnitude of the acceleration is largest when the spring is compressed to a distance x; at this point the net upward force is $kx - mg = ma$, so the second condition is expressed as $x = (m/k)(g + a)$.
EXECUTE: **(a)** Substituting the second expression into the first gives

$$\frac{1}{2}k\left(\frac{m}{k}\right)^2 (g+a)^2 = mgh, \text{ or } k = \frac{m(g+a)^2}{2gh}.$$

(b) Substituting this into the expression for x gives $x = \dfrac{2gh}{g+a}$.

EVALUATE: When $a \to 0$, our results become $k = \dfrac{mg}{2h}$ and $x = 2h$. The initial spring force is $kx = mg$ and the net upward force approaches zero. But $\frac{1}{2}kx^2 = mgh$ and sufficient potential energy is stored in the spring to move the mass to height h.

7.72. **IDENTIFY:** At equilibrium the upward spring force equals the weight mg of the object. Apply conservation of energy to the motion of the fish.
SET UP: The distance that the mass descends equals the distance the spring is stretched. $K_1 = K_2 = 0$, so $U_1(\text{gravitational}) = U_2(\text{spring})$
EXECUTE: Following the hint, the force constant k is found from $mg = kd$, or $k = mg/d$. When the fish falls from rest, its gravitational potential energy decreases by mgy; this becomes the potential energy of the spring, which is $\frac{1}{2}ky^2 = \frac{1}{2}(mg/d)y^2$. Equating these, $\dfrac{1}{2}\dfrac{mg}{d}y^2 = mgy$, or $y = 2d$.

EVALUATE: At its lowest point the fish is not in equilibrium. The upward spring force at this point is $ky = 2kd$, and this is equal to twice the weight. At this point the net force is mg, upward, and the fish has an upward acceleration equal to g.

7.73. **IDENTIFY:** Only conservative forces (gravity and the spring) act on the fish, so its mechanical energy is conserved.
SET UP: Energy conservation tells us $K_1 + U_1 + W_{\text{other}} = K_2 + U_2$, where $W_{\text{other}} = 0$. $U_g = mgy$, $K = \frac{1}{2}mv^2$, and $U_{spring} = \frac{1}{2}ky^2$.
EXECUTE: **(a)** $K_1 + U_1 + W_{\text{other}} = K_2 + U_2$. Let y be the distance the fish has descended, so $y = 0.0500$ m. $K_1 = 0$, $W_{\text{other}} = 0$, $U_1 = mgy$, $K_2 = \dfrac{1}{2}mv_2^2$, and $U_2 = \dfrac{1}{2}ky^2$. Solving for K_2 gives

$$K_2 = U_1 - U_2 = mgy - \frac{1}{2}ky^2 = (3.00\text{ kg})(9.8\text{ m/s}^2)(0.0500\text{ m}) - \frac{1}{2}(900\text{ N/m})(0.0500\text{ m})^2$$

$K_2 = 1.47\text{ J} - 1.125\text{ J} = 0.345\text{ J}$. Solving for v_2 gives $v_2 = \sqrt{\dfrac{2K_2}{m}} = \sqrt{\dfrac{2(0.345\text{ J})}{3.00\text{ kg}}} = 0.480$ m/s.

(b) The maximum speed is when K_2 is maximum, which is when $dK_2/dy = 0$. Using $K_2 = mgy - \dfrac{1}{2}ky^2$ gives $\dfrac{dK_2}{dy} = mg - ky = 0$. Solving for y gives $y = \dfrac{mg}{k} = \dfrac{(3.00\text{ kg})(9.8\text{ m/s}^2)}{900\text{ N/m}} = 0.03267$ m. At this y,

$$K_2 = (3.00\text{ kg})(9.8\text{ m/s}^2)(0.03267\text{ m}) - \frac{1}{2}(900\text{ N/m})(0.03267\text{ m})^2.$$

$K_2 = 0.9604\text{ J} - 0.4803\text{ J} = 0.4801\text{ J}$, so $v_2 = \sqrt{\dfrac{2K_2}{m}} = 0.566$ m/s.

EVALUATE: The speed in part (b) is greater than the speed in part (a), as it should be since it is the maximum speed.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

7.74. **IDENTIFY:** The spring obeys Hooke's law. Gravity and the spring provide the vertical forces on the brick. The mechanical energy of the system is conserved.

SET UP: Use $K_f + U_f = K_i + U_i$. In part (a), setting $y_f = 0$, we have $y_i = x$, the amount the spring will stretch. Also, since $K_i = K_f = 0$, $\frac{1}{2}kx^2 = mgx$. In part (b), $y_i = h + x$, where $h = 1.0$ m.

EXECUTE: **(a)** $x = \dfrac{2mg}{k} = \dfrac{2(3.0 \text{ kg})(9.80 \text{ m/s}^2)}{1500 \text{ N/m}} = 0.039 \text{ m} = 3.9 \text{ cm}$.

(b) $\frac{1}{2}kx^2 = mg(h + x)$, $kx^2 - 2mgx - 2mgh = 0$ and $x = \dfrac{mg}{k}\left(1 \pm \sqrt{1 + \dfrac{2hk}{mg}}\right)$. Since x must be positive, we have $x = \dfrac{mg}{k}\left(1 + \sqrt{1 + \dfrac{2hk}{mg}}\right) = \dfrac{(3.0 \text{ kg})(9.80 \text{ m/s}^2)}{1500 \text{ N/m}}\left(1 + \sqrt{1 + \dfrac{2(1.0 \text{ m})(1500 \text{ N/m})}{3.0 \text{ kg}(9.80 \text{ m/s}^2)}}\right) = 0.22 \text{ m} = 22 \text{ cm}$

EVALUATE: In part (b) there is additional initial energy (from gravity), so the spring is stretched more.

7.75. **(a) IDENTIFY** and **SET UP:** Apply $K_A + U_A + W_{other} = K_B + U_B$ to the motion from A to B.

EXECUTE: $K_A = 0$, $K_B = \frac{1}{2}mv_B^2$

$U_A = 0$, $U_B = U_{el,B} = \frac{1}{2}kx_B^2$, where $x_B = 0.25$ m

$W_{other} = W_F = Fx_B$

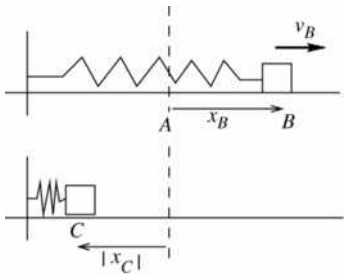
Thus $Fx_B = \frac{1}{2}mv_B^2 + \frac{1}{2}kx_B^2$. (The work done by F goes partly to the potential energy of the stretched spring and partly to the kinetic energy of the block.)

$Fx_B = (20.0 \text{ N})(0.25 \text{ m}) = 5.0 \text{ J}$ and $\frac{1}{2}kx_B^2 = \frac{1}{2}(40.0 \text{ N/m})(0.25 \text{ m})^2 = 1.25 \text{ J}$

Thus $5.0 \text{ J} = \frac{1}{2}mv_B^2 + 1.25 \text{ J}$ and $v_B = \sqrt{\dfrac{2(3.75 \text{ J})}{0.500 \text{ kg}}} = 3.87 \text{ m/s}$

(b) IDENTIFY: Apply Eq. (7.15) to the motion of the block. Let point C be where the block is closest to the wall. When the block is at point C the spring is compressed an amount $|x_C|$, so the block is $0.60 \text{ m} - |x_C|$ from the wall, and the distance between B and C is $x_B + |x_C|$.

SET UP: The motion from A to B to C is described in Figure 7.75.



$K_B + U_B + W_{other} = K_C + U_C$

EXECUTE: $W_{other} = 0$

$K_B = \frac{1}{2}mv_B^2 = 5.0 \text{ J} - 1.25 \text{ J} = 3.75 \text{ J}$ (from part (a))

$U_B = \frac{1}{2}kx_B^2 = 1.25 \text{ J}$

$K_C = 0$ (instantaneously at rest at point closest to wall)

$U_C = \frac{1}{2}k|x_C|^2$

Figure 7.75

Thus $3.75 \text{ J} + 1.25 \text{ J} = \frac{1}{2}k|x_C|^2$

$|x_C| = \sqrt{\dfrac{2(5.0 \text{ J})}{40.0 \text{ N/m}}} = 0.50 \text{ m}$

The distance of the block from the wall is $0.60 \text{ m} - 0.50 \text{ m} = 0.10 \text{ m}$.

EVALUATE: The work $(20.0 \text{ N})(0.25 \text{ m}) = 5.0 \text{ J}$ done by F puts 5.0 J of mechanical energy into the system. No mechanical energy is taken away by friction, so the total energy at points B and C is 5.0 J.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

7.76. **IDENTIFY:** Apply Eq. (7.14) to the motion of the student.

SET UP: Let $x_0 = 0.18$ m, $x_1 = 0.71$ m. The spring constants (assumed identical) are then known in terms of the unknown weight w, $4kx_0 = w$. Let $y = 0$ at the initial position of the student.

EXECUTE: **(a)** The speed of the brother at a given height h above the point of maximum compression is then found from $\frac{1}{2}(4k)x_1^2 = \frac{1}{2}\left(\frac{w}{g}\right)v^2 + mgh$, or $v^2 = \frac{(4k)g}{w}x_1^2 - 2gh = g\left(\frac{x_1^2}{x_0} - 2h\right)$. Therefore,

$v = \sqrt{(9.80\ \text{m/s}^2)((0.71\ \text{m})^2/(0.18\ \text{m}) - 2(0.90\ \text{m}))} = 3.13$ m/s, or 3.1 m/s to two figures.

(b) Setting $v = 0$ and solving for h, $h = \frac{2kx_1^2}{mg} = \frac{x_1^2}{2x_0} = 1.40$ m, or 1.4 m to two figures.

(c) No; the distance x_0 will be different, and the ratio $\frac{x_1^2}{x_0} = \frac{(x_0 + 0.53\ \text{m})^2}{x_0} = x_0\left(1 + \frac{0.53\ \text{m}}{x_0}\right)^2$ will be different. Note that on a planet with lower g, x_0 will be smaller and h will be larger.

EVALUATE: We are able to solve the problem without knowing either the mass of the student or the force constant of the spring.

7.77. **IDENTIFY:** We can apply Newton's second law to the block. The only forces acting on the block are gravity downward and the normal force from the track pointing toward the center of the circle. The mechanical energy of the block is conserved since only gravity does work on it. The normal force does no work since it is perpendicular to the displacement of the block. The target variable is the normal force at the top of the track.

SET UP: For circular motion $\Sigma F = m\frac{v^2}{R}$. Energy conservation tells us that $K_A + U_A + W_{\text{other}} = K_B + U_B$, where $W_{\text{other}} = 0$. $U_g = mgy$ and $K = \frac{1}{2}mv^2$.

EXECUTE: Let point A be at the bottom of the path and point B be at the top of the path. At the bottom of the path, $n_A - mg = m\frac{v^2}{R}$ (from Newton's second law).

$v_A = \sqrt{\frac{R}{m}(n_A - mg)} = \sqrt{\frac{0.800\ \text{m}}{0.0500\ \text{kg}}(3.40\ \text{N} - 0.49\ \text{N})} = 6.82$ m/s. Use energy conservation to find the speed at point B. $K_A + U_A + W_{\text{other}} = K_B + U_B$, giving $\frac{1}{2}mv_A^2 = \frac{1}{2}mv_B^2 + mg(2R)$. Solving for v_B gives $v_B = \sqrt{v_A^2 - 4Rg} = \sqrt{(6.82\ \text{m/s})^2 - 4(0.800\ \text{M})(9.8\ \text{m/s}^2)} = 3.89$ m/s. Then at point B, Newton's second law gives $n_B + mg = m\frac{v_B^2}{R}$. Solving for n_B gives

$n_B = m\frac{v_B^2}{R} - mg = (0.0500\ \text{kg})\left(\frac{(3.89\ \text{m/s})^2}{0.800\ \text{m}} - 9.8\ \text{m/s}^2\right) = 0.456$ N.

EVALUATE: The normal force at the top is considerably less than it is at the bottom for two reasons: the block is moving slower at the top and the downward force of gravity at the top aids the normal force in keeping the block moving in a circle.

7.78. **IDENTIFY:** Applying Newton's second law, we can use the known normal forces to find the speeds of the block at the top and bottom of the circle. We can then use energy conservation to find the work done by friction, which is the target variable.

SET UP: For circular motion $\Sigma F = m\frac{v^2}{R}$. Energy conservation tells us that $K_A + U_A + W_{\text{other}} = K_B + U_B$, where W_{other} is the work done by friction. $U_g = mgy$ and $K = \frac{1}{2}mv^2$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: Use the given values for the normal force to find the block's speed at points A and B. At point A, Newton's second law gives $n_A - mg = m\dfrac{v_A^2}{R}$. So

$v_A = \sqrt{\dfrac{R}{m}(n_A - mg)} = \sqrt{\dfrac{0.500\text{ m}}{0.0400\text{ kg}}(3.95\text{ N} - 0.392\text{ N})} = 6.669$ m/s. Similarly at point B, $n_B + mg = m\dfrac{v_B^2}{R}$.

Solving for v_B gives $v_B = \sqrt{\dfrac{R}{m}(n_B + mg)} = \sqrt{\dfrac{0.500\text{ m}}{0.0400\text{ kg}}(0.680\text{ N} + 0.392\text{ N})} = 3.660$ m/s. Now apply the work-energy theorem to find the work done by friction. $K_A + U_A + W_{\text{other}} = K_B + U_B$.

$W_{\text{other}} = K_B + U_B - K_A$.

$W_{\text{other}} = \dfrac{1}{2}(0.40\text{ kg})(3.66\text{ m/s})^2 + (0.04\text{ kg})(9.8\text{ m/s}^2)(1.0\text{ m}) - \dfrac{1}{2}(0.04\text{ kg})(6.669\text{ m/s})^2$.

$W_{\text{other}} = 0.2679\text{ J} + 0.392\text{ J} - 0.8895\text{ J} = -0.230\text{ J}$.

EVALUATE: The work done by friction is negative, as it should be. This work is equal to the loss of mechanical energy between the top and bottom of the circle.

7.79. **IDENTIFY:** $U = mgh$. Use $h = 150$ m for all the water that passes through the dam.

SET UP: $m = \rho V$ and $V = A\Delta h$ is the volume of water in a height Δh of water in the lake.

EXECUTE: **(a)** Stored energy $= mgh = (\rho V)gh = \rho A(1\text{ m})gh$.

stored energy $= (1000\text{ kg/m}^3)(3.0\times10^6\text{ m}^2)(1\text{ m})(9.8\text{ m/s}^2)(150\text{ m}) = 4.4\times10^{12}$ J.

(b) 90% of the stored energy is converted to electrical energy, so $(0.90)(mgh) = 1000$ kWh.

$(0.90)\rho Vgh = 1000$ kWh. $V = \dfrac{(1000\text{ kWh})((3600\text{ s})/(1\text{ h}))}{(0.90)(1000\text{ kg/m}^3)(150\text{ m})(9.8\text{ m/s}^2)} = 2.7\times10^3\text{ m}^3$.

Change in level of the lake: $A\Delta h = V_{\text{water}}$. $\Delta h = \dfrac{V}{A} = \dfrac{2.7\times10^3\text{ m}^3}{3.0\times10^6\text{ m}^2} = 9.0\times10^{-4}\text{ m}$.

EVALUATE: Δh is much less than 150 m, so using $h = 150$ m for all the water that passed through the dam was a very good approximation.

7.80. **IDENTIFY** and **SET UP:** The potential energy of a horizontal layer of thickness dy, area A, and height y is $dU = (dm)gy$. Let ρ be the density of water.

EXECUTE: $dm = \rho\, dV = \rho A\, dy$, so $dU = \rho Agy\, dy$.

The total potential energy U is

$U = \int_0^h dU = \rho Ag\int_0^h y\, dy = \frac{1}{2}\rho Agh^2$.

$A = 3.0\times10^6$ m^2 and $h = 150$ m, so $U = 3.3\times10^{14}$ J $= 9.2\times10^7$ kWh

EVALUATE: The volume is Ah and the mass of water is $\rho V = \rho Ah$. The average depth is $h_{\text{av}} = h/2$, so $U = mgh_{\text{av}}$.

7.81. **IDENTIFY:** Apply Eq. (7.15) to the motion of the block.

SET UP: The motion from A to B is described in Figure 7.81.

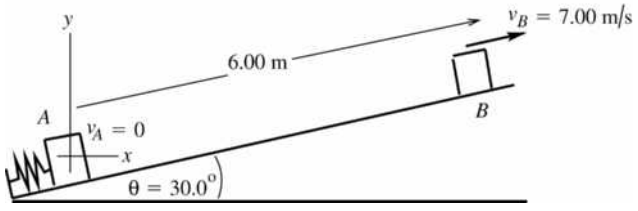


Figure 7.81

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

The normal force is $n = mg\cos\theta$, so $f_k = \mu_k n = \mu_k mg\cos\theta$.

$y_A = 0;\ \ y_B = (6.00\text{ m})\sin 30.0° = 3.00\text{ m}$

$K_A + U_A + W_{other} = K_B + U_B$

EXECUTE: Work is done by gravity, by the spring force, and by friction, so $W_{other} = W_f$ and

$U = U_{el} + U_{grav}$

$K_A = 0,\ \ K_B = \frac{1}{2}mv_B^2 = \frac{1}{2}(1.50\text{ kg})(7.00\text{ m/s})^2 = 36.75\text{ J}$

$U_A = U_{el,A} + U_{grav,A} = U_{el,A}$, since $U_{grav,A} = 0$

$U_B = U_{el,B} + U_{grav,B} = 0 + mgy_B = (1.50\text{ kg})(9.80\text{ m/s}^2)(3.00\text{ m}) = 44.1\text{ J}$

$W_{other} = W_f = (f_k\cos\phi)s = \mu_k mg\cos\theta(\cos 180°)s = -\mu_k mg\cos\theta s$

$W_{other} = -(0.50)(1.50\text{ kg})(9.80\text{ m/s}^2)(\cos 30.0°)(6.00\text{ m}) = -38.19\text{ J}$

Thus $U_{el,A} - 38.19\text{ J} = 36.75\text{ J} + 44.10\text{ J}$

$U_{el,A} = 38.19\text{ J} + 36.75\text{ J} + 44.10\text{ J} = 119\text{ J}$

EVALUATE: U_{el} must always be positive. Part of the energy initially stored in the spring was taken away by friction work; the rest went partly into kinetic energy and partly into an increase in gravitational potential energy.

7.82. **IDENTIFY:** Only gravity does work, so apply Eq. (7.4). Use $\Sigma\vec{F} = m\vec{a}$ to calculate the tension.

SET UP: Let $y = 0$ at the bottom of the arc. Let point 1 be when the string makes a $45°$ angle with the vertical and point 2 be where the string is vertical. The rock moves in an arc of a circle, so it has radial acceleration $a_{rad} = v^2/r$

EXECUTE: **(a)** At the top of the swing, when the kinetic energy is zero, the potential energy (with respect to the bottom of the circular arc) is $mgl(1-\cos\theta)$, where l is the length of the string and θ is the angle the string makes with the vertical. At the bottom of the swing, this potential energy has become kinetic energy, so $mgl(1-\cos\theta) = \frac{1}{2}mv^2$, or $v = \sqrt{2gl(1-\cos\theta)} = \sqrt{2(9.80\text{ m/s}^2)(0.80\text{ m})(1-\cos 45°)} = 2.1\text{ m/s}$.

(b) At $45°$ from the vertical, the speed is zero, and there is no radial acceleration; the tension is equal to the radial component of the weight, or $mg\cos\theta = (0.12\text{ kg})(9.80\text{ m/s}^2)\cos 45° = 0.83\text{ N}$.

(c) At the bottom of the circle, the tension is the sum of the weight and the mass times the radial acceleration,

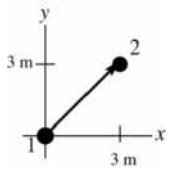
$$mg + mv_2^2/l = mg(1 + 2(1-\cos 45°)) = 1.9\text{ N}$$

EVALUATE: When the string passes through the vertical, the tension is greater than the weight because the acceleration is upward.

7.83. $\vec{F} = -\alpha xy^2\hat{j},\ \ \alpha = 2.50\text{ N/m}^3$

IDENTIFY: $\vec{F}$ is not constant so use Eq. (6.14) to calculate W. $\vec{F}$ must be evaluated along the path.

(a) SET UP: The path is sketched in Figure 7.83a.



$d\vec{l} = dx\hat{i} + dy\hat{j}$

$\vec{F}\cdot d\vec{l} = -\alpha xy^2\,dy$

On the path, $x = y$ so $\vec{F}\cdot d\vec{l} = -\alpha y^3\,dy$

Figure 7.83a

EXECUTE: $W = \int_1^2 \vec{F}\cdot d\vec{l} = \int_{y_1}^{y_2}(-\alpha y^3)\,dy = -(\alpha/4)\left(y^4\Big|_{y_1}^{y_2}\right) = -(\alpha/4)(y_2^4 - y_1^4)$

$y_1 = 0,\ \ y_2 = 3.00\text{ m}$, so $W = -\frac{1}{4}(2.50\text{ N/m}^3)(3.00\text{ m})^4 = -50.6\text{ J}$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) SET UP: The path is sketched in Figure 7.83b.

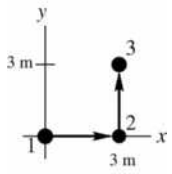


Figure 7.83b

For the displacement from point 1 to point 2, $d\vec{\boldsymbol{l}} = dx\hat{\boldsymbol{i}}$, so $\vec{\boldsymbol{F}} \cdot d\vec{\boldsymbol{l}} = 0$ and $W = 0$. (The force is perpendicular to the displacement at each point along the path, so $W = 0$.)

For the displacement from point 2 to point 3, $d\vec{\boldsymbol{l}} = dy\hat{\boldsymbol{j}}$, so $\vec{\boldsymbol{F}} \cdot d\vec{\boldsymbol{l}} = -\alpha xy^2\, dy$. On this path, $x = 3.00$ m, so

$$\vec{\boldsymbol{F}} \cdot d\vec{\boldsymbol{l}} = -(2.50 \text{ N/m}^3)(3.00 \text{ m})y^2\, dy = -(7.50 \text{ N/m}^2)y^2\, dy.$$

EXECUTE: $W = \int_2^3 \vec{\boldsymbol{F}} \cdot d\vec{\boldsymbol{l}} = -(7.50 \text{ N/m}^2)\int_{y_2}^{y_3} y^2\, dy = -(7.50 \text{ N/m}^2)\frac{1}{3}(y_3^3 - y_2^3)$

$W = -(7.50 \text{ N/m}^2)\left(\frac{1}{3}\right)(3.00 \text{ m})^3 = -67.5 \text{ J}$

(c) EVALUATE: For these two paths between the same starting and ending points the work is different, so the force is nonconservative.

7.84. **IDENTIFY:** Calculate the work W done by this force. If the force is conservative, the work is path independent.

SET UP: $W = \int_{P_1}^{P_2} \vec{\boldsymbol{F}} \cdot d\vec{\boldsymbol{l}}$.

EXECUTE: **(a)** $W = \int_{P_1}^{P_2} F_y dy = C\int_{P_1}^{P_2} y^2 dy$. W doesn't depend on x, so it is the same for all paths between P_1 and P_2. The force is conservative.

(b) $W = \int_{P_1}^{P_2} F_x dx = C\int_{P_1}^{P_2} y^2 dx$. W will be different for paths between points P_1 and P_2 for which y has different values. For example, if y has the constant value y_0 along the path, then $W = Cy_0(x_2 - x_1)$. W depends on the value of y_0. The force is not conservative.

EVALUATE: $\vec{\boldsymbol{F}} = Cy^2\hat{\boldsymbol{j}}$ has the potential energy function $U(y) = -\dfrac{Cy^3}{3}$. We cannot find a potential energy function for $\vec{\boldsymbol{F}} = Cy^2\hat{\boldsymbol{i}}$.

7.85. **IDENTIFY:** Use $W = \int_{P_1}^{P_2} \vec{\boldsymbol{F}} \cdot d\vec{\boldsymbol{l}}$ to calculate W for each segment of the path.

SET UP: $\vec{\boldsymbol{F}} \cdot d\vec{\boldsymbol{l}} = F_x dx = \alpha xy\, dx$

EXECUTE: **(a)** The path is sketched in Figure 7.85.

(b) (1): $x = 0$ along this leg, so $\vec{\boldsymbol{F}} = 0$ and $W = 0$. (2): Along this leg, $y = 1.50$ m, so $\vec{\boldsymbol{F}} \cdot d\vec{\boldsymbol{l}} = (3.00 \text{ N/m})x dx$, and $W = (1.50 \text{ N/m})((1.50 \text{ m})^2 - 0) = 3.38$ J (3) $\vec{\boldsymbol{F}} \cdot d\vec{\boldsymbol{l}} = 0$, so $W = 0$ (4) $y = 0$, so $\vec{\boldsymbol{F}} = 0$ and $W = 0$. The work done in moving around the closed path is 3.38 J.

(c) The work done in moving around a closed path is not zero, and the force is not conservative.

EVALUATE: There is no potential energy function for this force.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

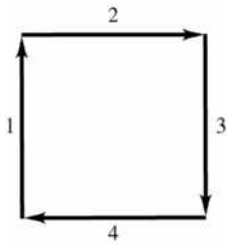

Figure 7.85

7.86. **IDENTIFY:** Use Eq. (7.16) to relate F_x and $U(x)$. The equilibrium is stable where $U(x)$ is a local minimum and the equilibrium is unstable where $U(x)$ is a local maximum.

SET UP: dU/dx is the slope of the graph of U versus x. $K = E - U$, so K is a maximum when U is a minimum. The maximum x is where $E = U$.

EXECUTE: **(a)** The slope of the U *vs.* x curve is negative at point A, so F_x is positive (Eq. (7.16)).

(b) The slope of the curve at point B is positive, so the force is negative.

(c) The kinetic energy is a maximum when the potential energy is a minimum, and that figures to be at around 0.75 m.

(d) The curve at point C looks pretty close to flat, so the force is zero.

(e) The object had zero kinetic energy at point A, and in order to reach a point with more potential energy than $U(A)$, the kinetic energy would need to be negative. Kinetic energy is never negative, so the object can never be at any point where the potential energy is larger than $U(A)$. On the graph, that looks to be at about 2.2 m.

(f) The point of minimum potential (found in part (c)) is a stable point, as is the relative minimum near 1.9 m.

(g) The only potential maximum, and hence the only point of unstable equilibrium, is at point C.

EVALUATE: If E is less than U at point C, the particle is trapped in one or the other of the potential "wells" and cannot move from one allowed region of x to the other.

7.87. **IDENTIFY:** $K = E - U$ determines $v(x)$.

SET UP: v is a maximum when U is a minimum and v is a minimum when U is a maximum. $F_x = -dU/dx$. The extreme values of x are where $E = U(x)$.

EXECUTE: **(a)** Eliminating β in favor of α and $x_0 (\beta = \alpha/x_0)$,

$$U(x) = \frac{\alpha}{x^2} - \frac{\beta}{x} = \frac{\alpha}{x_0^2}\frac{x_0^2}{x^2} - \frac{\alpha}{x_0 x} = \frac{\alpha}{x_0^2}\left[\left(\frac{x_0}{x}\right)^2 - \left(\frac{x_0}{x}\right)\right].$$

$U(x_0) = \left(\frac{\alpha}{x_0^2}\right)(1-1) = 0$. $U(x)$ is positive for $x < x_0$ and negative for $x > x_0$ (α and β must be taken as positive). The graph of $U(x)$ is sketched in Figure 7.87a.

(b) $v(x) = \sqrt{-\frac{2}{m}U} = \sqrt{\left(\frac{2\alpha}{mx_0^2}\right)\left(\left(\frac{x_0}{x}\right) - \left(\frac{x_0}{x}\right)^2\right)}$. The proton moves in the positive x-direction, speeding up until it reaches a maximum speed (see part (c)), and then slows down, although it never stops. The minus sign in the square root in the expression for $v(x)$ indicates that the particle will be found only in the region where $U < 0$, that is, $x > x_0$. The graph of $v(x)$ is sketched in Figure 7.87b.

(c) The maximum speed corresponds to the maximum kinetic energy, and hence the minimum potential energy. This minimum occurs when $\frac{dU}{dx} = 0$, or $\frac{dU}{dx} = \frac{\alpha}{x_0} 3\left[-2\left(\frac{x_0}{x}\right)^3 + \left(\frac{x_0}{x}\right)^2\right] = 0$,

which has the solution $x = 2x_0$. $U(2x_0) = -\frac{\alpha}{4x_0^2}$, so $v = \sqrt{\frac{\alpha}{2mx_0^2}}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(d) The maximum speed occurs at a point where $\frac{dU}{dx} = 0,$ and from Eq. (7.15), the force at this point is zero.

(e) $x_1 = 3x_0,$ and $U(3x_0) = -\frac{2\alpha}{9x_0^2}.$

$$v(x) = \sqrt{\frac{2}{m}(U(x_1) - U(x))} = \sqrt{\frac{2}{m}\left[\left(\frac{-2}{9}\frac{\alpha}{x_0^2}\right) - \frac{\alpha}{x_0^2}\left(\left(\frac{x_0}{x}\right)^2 - \frac{x_0}{x}\right)\right]} = \sqrt{\frac{2\alpha}{mx_0^2}\left(\left(\frac{x_0}{x}\right) - \left(\frac{x_0}{x}\right)^2 - \frac{2}{9}\right)}.$$

The particle is confined to the region where $U(x) < U(x_1).$ The maximum speed still occurs at $x = 2x_0,$ but now the particle will oscillate between x_1 and some minimum value (see part (f)).

(f) Note that $U(x) - U(x_1)$ can be written as

$$\frac{\alpha}{x_0^2}\left[\left(\frac{x_0}{x}\right)^2 - \left(\frac{x_0}{x}\right) + \left(\frac{2}{9}\right)\right] = \frac{\alpha}{x_0^2}\left[\left(\frac{x_0}{x}\right) - \frac{1}{3}\right]\left[\left(\frac{x_0}{x}\right) - \frac{2}{3}\right],$$

which is zero (and hence the kinetic energy is zero) at $x = 3x_0 = x_1$ and $x = \frac{3}{2}x_0.$ Thus, when the particle is released from $x_0,$ it goes on to infinity, and doesn't reach any maximum distance. When released from $x_1,$ it oscillates between $\frac{3}{2}x_0$ and $3x_0.$

EVALUATE: In each case the proton is released from rest and $E = U(x_i),$ where x_i is the point where it is released. When $x_i = x_0$ the total energy is zero. When $x_i = x_1$ the total energy is negative. $U(x) \to 0$ as $x \to \infty,$ so for this case the proton can't reach $x \to \infty$ and the maximum x it can have is limited.

8

MOMENTUM, IMPULSE, AND COLLISIONS

8.1. **IDENTIFY** and **SET UP:** $p = mv$. $K = \frac{1}{2}mv^2$.

EXECUTE: (a) $p = (10{,}000 \text{ kg})(12.0 \text{ m/s}) = 1.20\times10^5 \text{ kg}\cdot\text{m/s}$

(b) (i) $v = \dfrac{p}{m} = \dfrac{1.20\times10^5 \text{ kg}\cdot\text{m/s}}{2000 \text{ kg}} = 60.0 \text{ m/s}$. (ii) $\frac{1}{2}m_\text{T}v_\text{T}^2 = \frac{1}{2}m_\text{SUV}v_\text{SUV}^2$, so

$$v_\text{SUV} = \sqrt{\frac{m_\text{T}}{m_\text{SUV}}}v_\text{T} = \sqrt{\frac{10{,}000 \text{ kg}}{2000 \text{ kg}}}(12.0 \text{ m/s}) = 26.8 \text{ m/s}$$

EVALUATE: The SUV must have less speed to have the same kinetic energy as the truck than to have the same momentum as the truck.

8.2. **IDENTIFY:** Each momentum component is the mass times the corresponding velocity component.
SET UP: Let $+x$ be along the horizontal motion of the shotput. Let $+y$ be vertically upward.
$v_x = v\cos\theta$, $v_y = v\sin\theta$.

EXECUTE: The horizontal component of the initial momentum is

$$p_x = mv_x = mv\cos\theta = (7.30 \text{ kg})(15.0 \text{ m/s})\cos 40.0° = 83.9 \text{ kg}\cdot\text{m/s}.$$

The vertical component of the initial momentum is

$$p_y = mv_y = mv\sin\theta = (7.30 \text{ kg})(15.0 \text{ m/s})\sin 40.0° = 70.4 \text{ kg}\cdot\text{m/s}.$$

EVALUATE: The initial momentum is directed at $40.0°$ above the horizontal.

8.3. **IDENTIFY** and **SET UP:** $p = mv$. $K = \frac{1}{2}mv^2$.

EXECUTE: **(a)** $v = \dfrac{p}{m}$ and $K = \frac{1}{2}m\left(\dfrac{p}{m}\right)^2 = \dfrac{p^2}{2m}$.

(b) $K_\text{c} = K_\text{b}$ and the result from part (a) gives $\dfrac{p_\text{c}^2}{2m_\text{c}} = \dfrac{p_\text{b}^2}{2m_\text{b}}$. $p_\text{b} = \sqrt{\dfrac{m_\text{b}}{m_\text{c}}}p_\text{c} = \sqrt{\dfrac{0.145 \text{ kg}}{0.040 \text{ kg}}}p_\text{c} = 1.90p_\text{c}$. The baseball has the greater magnitude of momentum. $p_\text{c}/p_\text{b} = 0.526$.

(c) $p^2 = 2mK$ so $p_\text{m} = p_\text{w}$ gives $2m_\text{m}K_\text{m} = 2m_\text{w}K_\text{w}$. $w = mg$, so $w_\text{m}K_\text{m} = w_\text{w}K_\text{w}$.

$$K_\text{w} = \left(\frac{w_\text{m}}{w_\text{w}}\right)K_\text{m} = \left(\frac{700 \text{ N}}{450 \text{ N}}\right)K_\text{m} = 1.56K_\text{m}.$$

The woman has greater kinetic energy. $K_\text{m}/K_\text{w} = 0.641$.

EVALUATE: For equal kinetic energy, the more massive object has the greater momentum. For equal momenta, the less massive object has the greater kinetic energy.

8.4. **IDENTIFY:** For each object $\vec{p} = m\vec{v}$ and the net momentum of the system is $\vec{P} = \vec{p}_A + \vec{p}_B$. The momentum vectors are added by adding components. The magnitude and direction of the net momentum is calculated from its x and y components.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

SET UP: Let object A be the pickup and object B be the sedan. $v_{Ax} = -14.0$ m/s, $v_{Ay} = 0$. $v_{Bx} = 0$, $v_{By} = +23.0$ m/s.

EXECUTE: **(a)** $P_x = p_{Ax} + p_{Bx} = m_A v_{Ax} + m_B v_{Bx} = (2500 \text{ kg})(-14.0 \text{ m/s}) + 0 = -3.50\times10^4 \text{ kg}\cdot\text{m/s}$

$$P_y = p_{Ay} + p_{By} = m_A v_{Ay} + m_B v_{By} = (1500 \text{ kg})(+23.0 \text{ m/s}) = +3.45\times10^4 \text{ kg}\cdot\text{m/s}$$

(b) $P = \sqrt{P_x^2 + P_y^2} = 4.91\times10^4 \text{ kg}\cdot\text{m/s}$. From Figure 8.4, $\tan\theta = \left|\dfrac{P_x}{P_y}\right| = \dfrac{3.50\times10^4 \text{ kg}\cdot\text{m/s}}{3.45\times10^4 \text{ kg}\cdot\text{m/s}}$ and $\theta = 45.4°$.

The net momentum has magnitude $4.91\times10^4 \text{ kg}\cdot\text{m/s}$ and is directed at $45.4°$ west of north.

EVALUATE: The momenta of the two objects must be added as vectors. The momentum of one object is west and the other is north. The momenta of the two objects are nearly equal in magnitude, so the net momentum is directed approximately midway between west and north.

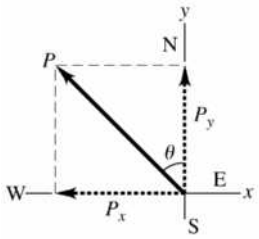

Figure 8.4

8.5. **IDENTIFY:** For each object, $\vec{p} = m\vec{v}$ and $K = \frac{1}{2}mv^2$. The total momentum is the vector sum of the momenta of each object. The total kinetic energy is the scalar sum of the kinetic energies of each object.

SET UP: Let object A be the 110 kg lineman and object B the 125 kg lineman. Let $+x$ be to the right, so $v_{Ax} = +2.75$ m/s and $v_{Bx} = -2.60$ m/s.

EXECUTE: **(a)** $P_x = m_A v_{Ax} + m_B v_{Bx} = (110 \text{ kg})(2.75 \text{ m/s}) + (125 \text{ kg})(-2.60 \text{ m/s}) = -22.5 \text{ kg}\cdot\text{m/s}$. The net momentum has magnitude $22.5 \text{ kg}\cdot\text{m/s}$ and is directed to the left.

(b) $K = \frac{1}{2}m_A v_A^2 + \frac{1}{2}m_B v_B^2 = \frac{1}{2}(110 \text{ kg})(2.75 \text{ m/s})^2 + \frac{1}{2}(125 \text{ kg})(2.60 \text{ m/s})^2 = 838 \text{ J}$

EVALUATE: The kinetic energy of an object is a scalar and is never negative. It depends only on the magnitude of the velocity of the object, not on its direction. The momentum of an object is a vector and has both magnitude and direction. When two objects are in motion, their total kinetic energy is greater than the kinetic energy of either one. But if they are moving in opposite directions, the net momentum of the system has a smaller magnitude than the magnitude of the momentum of either object.

8.6. **IDENTIFY:** We know the contact time of the ball with the racket, the change in velocity of the ball, and the mass of the ball. From this information we can use the fact that the impulse is equal to the change in momentum to find the force exerted on the ball by the racket.

SET UP: $J_x = \Delta p_x$ and $J_x = F_x \Delta t$. In part (a), take the $+x$ direction to be along the final direction of motion of the ball. The initial speed of the ball is zero. In part (b), take the $+x$ direction to be in the direction the ball is traveling before it is hit by the opponent's racket.

EXECUTE: **(a)** $J_x = mv_{2x} - mv_{1x} = (57\times10^{-3}\text{kg})(73.14 \text{ m/s} - 0) = 4.2 \text{ kg}\cdot\text{m/s}$. Using $J_x = F_x \Delta t$ gives

$$F_x = \frac{J_x}{\Delta t} = \frac{4.2 \text{ kg}\cdot\text{m/s}}{30.0\times10^{-3}\text{s}} = 140 \text{ N}.$$

(b) $J_x = mv_{2x} - mv_{1x} = (57\times10^{-3}\text{kg})(-55 \text{ m/s} - 73.14 \text{ m/s}) = -7.3 \text{ kg}\cdot\text{m/s}$.

$$F_x = \frac{J_x}{\Delta t} = \frac{-7.3 \text{ kg}\cdot\text{m/s}}{30.0\times10^{-3}\text{s}} = -240 \text{ N}.$$

EVALUATE: The signs of J_x and F_x show their direction. 140 N = 31 lb. This very attainable force has a large effect on the light ball. 140 N is 250 times the weight of the ball.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

8.7. **IDENTIFY:** The average force on an object and the object's change in momentum are related by Eq. 8.9. The weight of the ball is $w = mg$.

SET UP: Let $+x$ be in the direction of the final velocity of the ball, so $v_{1x} = 0$ and $v_{2x} = 25.0$ m/s.

EXECUTE: $(F_{\text{av}})_x(t_2 - t_1) = mv_{2x} - mv_{1x}$ gives $(F_{\text{av}})_x = \dfrac{mv_{2x} - mv_{1x}}{t_2 - t_1} = \dfrac{(0.0450 \text{ kg})(25.0 \text{ m/s})}{2.00\times10^{-3} \text{ s}} = 562 \text{ N}.$

$w = (0.0450 \text{ kg})(9.80 \text{ m/s}^2) = 0.441 \text{ N}.$ The force exerted by the club is much greater than the weight of the ball, so the effect of the weight of the ball during the time of contact is not significant.

EVALUATE: Forces exerted during collisions typically are very large but act for a short time.

8.8. **IDENTIFY:** The change in momentum, the impulse and the average force are related by Eq. 8.9.

SET UP: Let the direction in which the batted ball is traveling be the $+x$ direction, so $v_{1x} = -45.0$ m/s and $v_{2x} = 55.0$ m/s.

EXECUTE: **(a)** $\Delta p_x = p_{2x} - p_{1x} = m(v_{2x} - v_{1x}) = (0.145 \text{ kg})(55.0 \text{ m/s} - [-45.0 \text{ m/s}]) = 14.5 \text{ kg}\cdot\text{m/s}.$

$J_x = \Delta p_x$, so $J_x = 14.5 \text{ kg}\cdot\text{m/s}$. Both the change in momentum and the impulse have magnitude $14.5 \text{ kg}\cdot\text{m/s}$.

(b) $(F_{\text{av}})_x = \dfrac{J_x}{\Delta t} = \dfrac{14.5 \text{ kg}\cdot\text{m/s}}{2.00\times10^{-3} \text{ s}} = 7250 \text{ N}.$

EVALUATE: The force is in the direction of the momentum change.

8.9. **IDENTIFY:** Use Eq. 8.9. We know the initial momentum and the impulse so can solve for the final momentum and then the final velocity.

SET UP: Take the *x*-axis to be toward the right, so $v_{1x} = +3.00$ m/s. Use Eq. 8.5 to calculate the impulse, since the force is constant.

EXECUTE: **(a)** $J_x = p_{2x} - p_{1x}$

$$J_x = F_x(t_2 - t_1) = (+25.0 \text{ N})(0.050 \text{ s}) = +1.25 \text{ kg}\cdot\text{m/s}$$

Thus $p_{2x} = J_x + p_{1x} = +1.25 \text{ kg}\cdot\text{m/s} + (0.160 \text{ kg})(+3.00 \text{ m/s}) = +1.73 \text{ kg}\cdot\text{m/s}$

$$v_{2x} = \frac{p_{2x}}{m} = \frac{1.73 \text{ kg}\cdot\text{m/s}}{0.160 \text{ kg}} = +10.8 \text{ m/s} \ (\text{to the right})$$

(b) $J_x = F_x(t_2 - t_1) = (-12.0 \text{ N})(0.050 \text{ s}) = -0.600 \text{ kg}\cdot\text{m/s}$ (negative since force is to left)

$$p_{2x} = J_x + p_{1x} = -0.600 \text{ kg}\cdot\text{m/s} + (0.160 \text{ kg})(+3.00 \text{ m/s}) = -0.120 \text{ kg}\cdot\text{m/s}$$

$$v_{2x} = \frac{p_{2x}}{m} = \frac{-0.120 \text{ kg}\cdot\text{m/s}}{0.160 \text{ kg}} = -0.75 \text{ m/s (to the left)}$$

EVALUATE: In part (a) the impulse and initial momentum are in the same direction and v_x increases. In part (b) the impulse and initial momentum are in opposite directions and the velocity decreases.

8.10. **IDENTIFY:** The impulse, change in momentum and change in velocity are related by Eq. 8.9.

SET UP: $F_y = 26{,}700$ N and $F_x = 0$. The force is constant, so $(F_{\text{av}})_y = F_y$.

EXECUTE: **(a)** $J_y = F_y\Delta t = (26{,}700 \text{ N})(3.90 \text{ s}) = 1.04\times10^5 \text{ N}\cdot\text{s}.$

(b) $\Delta p_y = J_y = 1.04\times10^5 \text{ kg}\cdot\text{m/s}.$

(c) $\Delta p_y = m\Delta v_y$. $\Delta v_y = \dfrac{\Delta p_y}{m} = \dfrac{1.04\times10^5 \text{ kg}\cdot\text{m/s}}{95{,}000 \text{ kg}} = 1.09 \text{ m/s}.$

(d) The initial velocity of the shuttle isn't known. The change in kinetic energy is $\Delta K = K_2 - K_1 = \frac{1}{2}m(v_2^2 - v_1^2)$. It depends on the initial and final speeds and isn't determined solely by the change in speed.

EVALUATE: The force in the $+y$ direction produces an increase of the velocity in the $+y$ direction.

8.11. **IDENTIFY:** The force is not constant so $\vec{\boldsymbol{J}} = \int_{t_1}^{t_2} \vec{\boldsymbol{F}}dt$. The impulse is related to the change in velocity by Eq. 8.9.

SET UP: Only the *x* component of the force is nonzero, so $J_x = \int_{t_1}^{t_2} F_x dt$ is the only nonzero component of $\vec{\boldsymbol{J}}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$J_x = m(v_{2x} - v_{1x}).\ \ t_1 = 2.00\text{ s},\ \ t_2 = 3.50\text{ s}.$$

EXECUTE: **(a)** $A = \dfrac{F_x}{t^2} = \dfrac{781.25\text{ N}}{(1.25\text{ s})^2} = 500\text{ N/s}^2.$

(b) $J_x = \int_{t_1}^{t_2} At^2\,dt = \frac{1}{3}A(t_2^3 - t_1^3) = \frac{1}{3}(500\text{ N/s}^2)([3.50\text{ s}]^3 - [2.00\text{ s}]^3) = 5.81\times10^3\text{ N}\cdot\text{s}.$

(c) $\Delta v_x = v_{2x} - v_{1x} = \dfrac{J_x}{m} = \dfrac{5.81\times10^3\text{ N}\cdot\text{s}}{2150\text{ kg}} = 2.70\text{ m/s}.$ The x component of the velocity of the rocket increases by 2.70 m/s.

EVALUATE: The change in velocity is in the same direction as the impulse, which in turn is in the direction of the net force. In this problem the net force equals the force applied by the engine, since that is the only force on the rocket.

8.12. **IDENTIFY:** Apply Eq. 8.9 to relate the change in momentum to the components of the average force on it.

SET UP: Let $+x$ be to the right and $+y$ be upward.

EXECUTE: $J_x = \Delta p_x = mv_{2x} - mv_{1x} = (0.145\text{ kg})(-[65.0\text{ m/s}]\cos 30° - 50.0\text{ m/s}) = -15.4\text{ kg}\cdot\text{m/s}.$

$$J_y = \Delta p_y = mv_{2y} - mv_{1y} = (0.145\text{ kg})([65.0\text{ m/s}]\sin 30° - 0) = 4.71\text{ kg}\cdot\text{m/s}$$

The horizontal component is $15.4\text{ kg}\cdot\text{m/s},$ to the left and the vertical component is $4.71\text{ kg}\cdot\text{m/s},$ upward.

$F_{\text{av-}x} = \dfrac{J_x}{\Delta t} = \dfrac{-15.4\text{ kg}\cdot\text{m/s}}{1.75\times10^{-3}\text{ s}} = -8800\text{ N}.$ $F_{\text{av-}y} = \dfrac{J_y}{\Delta t} = \dfrac{4.71\text{ kg}\cdot\text{m/s}}{1.75\times10^{-3}\text{ s}} = 2690\text{ N}.$

The horizontal component is 8800 N, to the left, and the vertical component is 2690 N, upward.

EVALUATE: The ball gains momentum to the left and upward and the force components are in these directions.

8.13. **IDENTIFY:** The force is constant during the 1.0 ms interval that it acts, so $\vec{\boldsymbol{J}} = \vec{\boldsymbol{F}}\Delta t.$ $\vec{\boldsymbol{J}} = \vec{\boldsymbol{p}}_2 - \vec{\boldsymbol{p}}_1 = m(\vec{\boldsymbol{v}}_2 - \vec{\boldsymbol{v}}_1).$

SET UP: Let $+x$ be to the right, so $v_{1x} = +5.00$ m/s. Only the x component of $\vec{\boldsymbol{J}}$ is nonzero, and $J_x = m(v_{2x} - v_{1x}).$

EXECUTE: **(a)** The magnitude of the impulse is $J = F\Delta t = (2.50\times10^3\text{ N})(1.00\times10^{-3}\text{ s}) = 2.50\text{ N}\cdot\text{s}.$ The direction of the impulse is the direction of the force.

(b) (i) $v_{2x} = \dfrac{J_x}{m} + v_{1x}.$ $J_x = +2.50\text{ N}\cdot\text{s}.$ $v_{2x} = \dfrac{+2.50\text{ N}\cdot\text{s}}{2.00\text{ kg}} + 5.00\text{ m/s} = 6.25\text{ m/s}.$ The stone's velocity has magnitude 6.25 m/s and is directed to the right. (ii) Now $J_x = -2.50\text{ N}\cdot\text{s}$ and $v_{2x} = \dfrac{-2.50\text{ N}\cdot\text{s}}{2.00\text{ kg}} + 5.00\text{ m/s} = 3.75\text{ m/s}.$ The stone's velocity has magnitude 3.75 m/s and is directed to the right.

EVALUATE: When the force and initial velocity are in the same direction the speed increases and when they are in opposite directions the speed decreases.

8.14. **IDENTIFY:** The force imparts an impulse to the forehead, which changes the momentum of the skater.

SET UP: $J_x = \Delta p_x$ and $J_x = F_x\Delta t.$ With $A = 1.5\times10^{-4}\text{m}^2,$ the maximum force without breaking the bone is $(1.5\times10^{-4}\text{ m}^2)(1.03\times10^8\text{ N/m}^2) = 1.5\times10^4\text{ N}.$ Set the magnitude of the average force F_{av} during the collision equal to this value. Use coordinates where $+x$ is in his initial direction of motion. F_x is opposite to this direction, so $F_x = -1.5\times10^4\text{ N}.$

EXECUTE: $J_x = F_x\,\Delta t = (-1.5\times10^4\text{ N})(10.0\times10^{-3}\text{ s}) = -150.0\text{ N}\cdot\text{s}.$ $J_x = mx_{2x} - mx_{1x}$ and $v_{2x} = 0.$ $v_{1x} = -\dfrac{J_x}{m} = -\dfrac{-150\text{ N}\cdot\text{s}}{70\text{ kg}} = 2.1\text{ m/s}.$

EVALUATE: This speed is about the same as a jog. However, in most cases the skater would not be completely stopped, so in that case a greater speed would not result in injury.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

8.15. **IDENTIFY:** The player imparts an impulse to the ball which gives it momentum, causing it to go upward.
SET UP: Take $+y$ to be upward. Use the motion of the ball after it leaves the racket to find its speed just after it is hit. After it leaves the racket $a_y = -g$. At the maximum height $v_y = 0$. Use $J_y = \Delta p_y$ and the kinematics equation $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ for constant acceleration.

EXECUTE: $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ gives $v_{0y} = \sqrt{-2a_y(y - y_0)} = \sqrt{-2(-9.80\ \text{m/s}^2)(5.50\ \text{m})} = 10.4$ m/s.
For the interaction with the racket $v_{1y} = 0$ and $v_{2y} = 10.4$ m/s.

$J_y = mv_{2y} - mv_{1y} = (57\times10^{-3}\ \text{kg})(10.4\ \text{m/s} - 0) = 0.593\ \text{kg}\cdot\text{m/s}$.

EVALUATE: We could have found the initial velocity using energy conservation instead of free-fall kinematics.

8.16. **IDENTIFY:** We know the force acting on a box as a function of time and its initial momentum and want to find its momentum at a later time. The target variable is the final momentum.

SET UP: Use $\int_{t_1}^{t_2} \vec{\boldsymbol{F}}(t)dt = \vec{\boldsymbol{p}}_2 - \vec{\boldsymbol{p}}_1$ to find $\vec{\boldsymbol{p}}_2$ since we know $\vec{\boldsymbol{p}}_1$ and $\vec{\boldsymbol{F}}(t)$.

EXECUTE: $\vec{\boldsymbol{p}}_1 = (-3.00\ \text{kg}\cdot\text{m/s})\hat{\boldsymbol{i}} + (4.00\ \text{kg}\cdot\text{m/s})\hat{\boldsymbol{j}}$ at $t_1 = 0$, and $t_2 = 2.00$ s. Work with the components of the force and momentum. $\int_{t_1}^{t_2} F_x(t)dt = (0.280\ \text{N/s})\int_{t_1}^{t_2} t\,dt = (0.140\ \text{N/s})t_2^2 = 0.560\ \text{N}\cdot\text{s}$

$p_{2x} = p_{1x} + 0.560\ \text{N}\cdot\text{s} = -3.00\ \text{kg}\cdot\text{m/s} + 0.560\ \text{N}\cdot\text{s} = -2.44\ \text{kg}\cdot\text{m/s}$.

$\int_{t_1}^{t_2} F_y(t)dt = (-0.450\ \text{N/s}^2)\int_{t_1}^{t_2} t^2dt = (-0.150\ \text{N/s}^2)t_2^3 = -1.20\ \text{N}\cdot\text{s}$.

$p_{2y} = p_{1y} + (-1.20\ \text{N}\cdot\text{s}) = 4.00\ \text{kg}\cdot\text{m/s} + (-1.20\ \text{N}\cdot\text{s}) = +2.80\ \text{kg}\cdot\text{m/s}$. So

$\vec{\boldsymbol{p}}_2 = (-2.44\ \text{kg}\cdot\text{m/s})\hat{\boldsymbol{i}} + (2.80\ \text{kg}\cdot\text{m/s})\hat{\boldsymbol{j}}$

EVALUATE: Since the given force has *x* and *y* components, it changes both components of the box's momentum.

8.17. **IDENTIFY:** Since the rifle is loosely held there is no net external force on the system consisting of the rifle, bullet and propellant gases and the momentum of this system is conserved. Before the rifle is fired everything in the system is at rest and the initial momentum of the system is zero.
SET UP: Let $+x$ be in the direction of the bullet's motion. The bullet has speed $601\ \text{m/s} - 1.85\ \text{m/s} = 599\ \text{m/s}$ relative to the earth. $P_{2x} = p_{\text{r}x} + p_{\text{b}x} + p_{\text{g}x}$, the momenta of the rifle, bullet and gases. $v_{\text{r}x} = -1.85$ m/s and $v_{\text{b}x} = +599$ m/s.

EXECUTE: $P_{2x} = P_{1x} = 0$. $p_{\text{r}x} + p_{\text{b}x} + p_{\text{g}x} = 0$.

$p_{\text{g}x} = -p_{\text{r}x} - p_{\text{b}x} = -(2.80\ \text{kg})(-1.85\ \text{m/s}) - (0.00720\ \text{kg})(599\ \text{m/s})$ and

$p_{\text{g}x} = +5.18\ \text{kg}\cdot\text{m/s} - 4.31\ \text{kg}\cdot\text{m/s} = 0.87\ \text{kg}\cdot\text{m/s}$. The propellant gases have momentum $0.87\ \text{kg}\cdot\text{m/s}$, in the same direction as the bullet is traveling.

EVALUATE: The magnitude of the momentum of the recoiling rifle equals the magnitude of the momentum of the bullet plus that of the gases as both exit the muzzle.

8.18. **IDENTIFY:** Apply conservation of momentum to the system of the astronaut and tool.
SET UP: Let *A* be the astronaut and *B* be the tool. Let $+x$ be the direction in which she throws the tool, so $v_{B2x} = +3.20$ m/s. Assume she is initially at rest, so $v_{A1x} = v_{B1x} = 0$. Solve for v_{A2x}.

EXECUTE: $P_{1x} = P_{2x}$. $P_{1x} = m_A v_{A1x} + m_B v_{B1x} = 0$. $P_{2x} = m_A v_{A2x} + m_B v_{B2x} = 0$ and

$v_{A2x} = -\dfrac{m_B v_{A2x}}{m_A} = -\dfrac{(2.25\ \text{kg})(3.20\ \text{m/s})}{68.5\ \text{kg}} = -0.105$ m/s. Her speed is 0.105 m/s and she moves opposite to the direction in which she throws the tool.

EVALUATE: Her mass is much larger than that of the tool, so to have the same magnitude of momentum as the tool her speed is much less.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

8.19. **IDENTIFY:** Since drag effects are neglected there is no net external force on the system of squid plus expelled water and the total momentum of the system is conserved. Since the squid is initially at rest, with the water in its cavity, the initial momentum of the system is zero. For each object, $K = \frac{1}{2}mv^2$.

SET UP: Let A be the squid and B be the water it expels, so $m_A = 6.50\text{ kg} - 1.75\text{ kg} = 4.75\text{ kg}$. Let $+x$ be the direction in which the water is expelled. $v_{A2x} = -2.50$ m/s. Solve for v_{B2x}.

EXECUTE: **(a)** $P_{1x} = 0$. $P_{2x} = P_{1x}$, so $0 = m_A v_{A2x} + m_B v_{B2x}$.

$$v_{B2x} = -\frac{m_A v_{A2x}}{m_B} = -\frac{(4.75\text{ kg})(-2.50\text{ m/s})}{1.75\text{ kg}} = +6.79\text{ m/s}.$$

(b) $K_2 = K_{A2} + K_{B2} = \frac{1}{2}m_A v_{A2}^2 + \frac{1}{2}m_B v_{B2}^2 = \frac{1}{2}(4.75\text{ kg})(2.50\text{ m/s})^2 + \frac{1}{2}(1.75\text{ kg})(6.79\text{ m/s})^2 = 55.2\text{ J}$. The initial kinetic energy is zero, so the kinetic energy produced is $K_2 = 55.2$ J.

EVALUATE: The two objects end up with momenta that are equal in magnitude and opposite in direction, so the total momentum of the system remains zero. The kinetic energy is created by the work done by the squid as it expels the water.

8.20. **IDENTIFY:** Apply conservation of momentum to the system of you and the ball. In part (a) both objects have the same final velocity.

SET UP: Let $+x$ be in the direction the ball is traveling initially. $m_A = 0.400$ kg (ball). $m_B = 70.0$ kg (you).

EXECUTE: **(a)** $P_{1x} = P_{2x}$ gives $(0.400\text{ kg})(10.0\text{ m/s}) = (0.400\text{ kg} + 70.0\text{ kg})v_2$ and $v_2 = 0.0568$ m/s.

(b) $P_{1x} = P_{2x}$ gives $(0.400\text{ kg})(10.0\text{ m/s}) = (0.400\text{ kg})(-8.00\text{ m/s}) + (70.0\text{ kg})v_{B2}$ and $v_{B2} = 0.103$ m/s.

EVALUATE: When the ball bounces off it has a greater change in momentum and you acquire a greater final speed.

8.21. **IDENTIFY:** Apply conservation of momentum to the system of the two pucks.

SET UP: Let $+x$ be to the right.

EXECUTE: **(a)** $P_{1x} = P_{2x}$ says $(0.250\text{ kg})v_{A1} = (0.250\text{ kg})(-0.120\text{ m/s}) + (0.350\text{ kg})(0.650\text{ m/s})$ and $v_{A1} = 0.790$ m/s.

(b) $K_1 = \frac{1}{2}(0.250\text{ kg})(0.790\text{ m/s})^2 = 0.0780\text{ J}$.

$K_2 = \frac{1}{2}(0.250\text{ kg})(0.120\text{ m/s})^2 + \frac{1}{2}(0.350\text{ kg})(0.650\text{ m/s})^2 = 0.0757\text{ J}$ and $\Delta K = K_2 - K_1 = -0.0023\text{ J}$.

EVALUATE: The total momentum of the system is conserved but the total kinetic energy decreases.

8.22. **IDENTIFY:** Since road friction is neglected, there is no net external force on the system of the two cars and the total momentum of the system is conserved. For each object, $K = \frac{1}{2}mv^2$.

SET UP: Let A be the 1750 kg car and B be the 1450 kg car. Let $+x$ be to the right, so $v_{A1x} = +1.50$ m/s, $v_{B1x} = -1.10$ m/s, and $v_{A2x} = +0.250$ m/s. Solve for v_{B2x}.

EXECUTE: **(a)** $P_{1x} = P_{2x}$. $m_A v_{A1x} + m_B v_{B1x} = m_A v_{A2x} + m_B v_{B2x}$. $v_{B2x} = \dfrac{m_A v_{A1x} + m_B v_{B1x} - m_A v_{A2x}}{m_B}$.

$$v_{B2x} = \frac{(1750\text{ kg})(1.50\text{ m/s}) + (1450\text{ kg})(-1.10\text{ m/s}) - (1750\text{ kg})(0.250\text{ m/s})}{1450\text{ kg}} = 0.409\text{ m/s}.$$

After the collision the lighter car is moving to the right with a speed of 0.409 m/s.

(b) $K_1 = \frac{1}{2}m_A v_{A1}^2 + \frac{1}{2}m_B v_{B1}^2 = \frac{1}{2}(1750\text{ kg})(1.50\text{ m/s})^2 + \frac{1}{2}(1450\text{ kg})(1.10\text{ m/s})^2 = 2846\text{ J}$.

$$K_2 = \frac{1}{2}m_A v_{A2}^2 + \frac{1}{2}m_B v_{B2}^2 = \frac{1}{2}(1750\text{ kg})(0.250\text{ m/s})^2 + \frac{1}{2}(1450\text{ kg})(0.409\text{ m/s})^2 = 176\text{ J}.$$

The change in kinetic energy is $\Delta K = K_2 - K_1 = 176\text{ J} - 2846\text{ J} = -2670\text{ J}$.

EVALUATE: The total momentum of the system is constant because there is no net external force during the collision. The kinetic energy of the system decreases because of negative work done by the forces the cars exert on each other during the collision.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

8.23. **IDENTIFY:** The momentum and the mechanical energy of the system are both conserved. The mechanical energy consists of the kinetic energy of the masses and the elastic potential energy of the spring. The potential energy stored in the spring is transformed into the kinetic energy of the two masses.
SET UP: Let the system be the two masses and the spring. The system is sketched in Figure 8.23, in its initial and final situations. Use coordinates where $+x$ is to the right. Call the masses A and B.

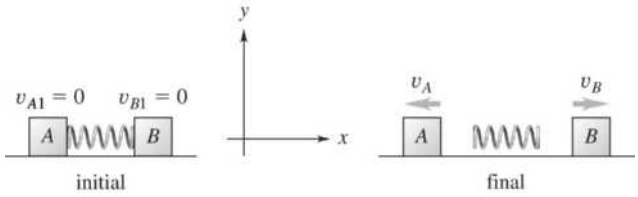

Figure 8.23

EXECUTE: $P_{1x} = P_{2x}$ so $0 = (1.50 \text{ kg})(-v_A) + (1.50 \text{ kg})(v_B)$ and, since the masses are equal, $v_A = v_B$. Energy conservation says the potential energy originally stored in the spring is all converted into kinetic energy of the masses, so $\frac{1}{2}kx_1^2 = \frac{1}{2}mv_A^2 + \frac{1}{2}mv_B^2$. Since $v_A = v_B$, this equation gives

$$v_A = x_1\sqrt{\frac{k}{2m}} = (0.200 \text{ m})\sqrt{\frac{175 \text{ N/m}}{2(1.50 \text{ kg})}} = 1.53 \text{ m/s}.$$

EVALUATE: If the objects have different masses they will end up with different speeds. The lighter one will have the greater speed, since they end up with equal magnitudes of momentum.

8.24. **IDENTIFY:** In part (a) no horizontal force implies P_x is constant. In part (b) use the energy expression, Eq. 7.14, to find the potential energy initially in the spring.
SET UP: Initially both blocks are at rest.

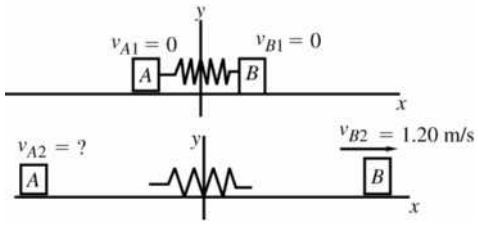

Figure 8.24

EXECUTE: **(a)** $m_A v_{A1x} + m_B v_{B1x} = m_A v_{A2x} + m_B v_{B2x}$

$$0 = m_A v_{A2x} + m_B v_{B2x}$$

$$v_{A2x} = -\left(\frac{m_B}{m_A}\right)v_{B2x} = -\left(\frac{3.00 \text{ kg}}{1.00 \text{ kg}}\right)(+1.20 \text{ m/s}) = -3.60 \text{ m/s}$$

Block A has a final speed of 3.60 m/s, and moves off in the opposite direction to B.
(b) Use energy conservation: $K_1 + U_1 + W_{\text{other}} = K_2 + U_2$.
Only the spring force does work so $W_{\text{other}} = 0$ and $U = U_{\text{el}}$.
$K_1 = 0$ (the blocks initially are at rest)
$U_2 = 0$ (no potential energy is left in the spring)

$$K_2 = \tfrac{1}{2}m_A v_{A2}^2 + \tfrac{1}{2}m_B v_{B2}^2 = \tfrac{1}{2}(1.00 \text{ kg})(3.60 \text{ m/s})^2 + \tfrac{1}{2}(3.00 \text{ kg})(1.20 \text{ m/s})^2 = 8.64 \text{ J}$$

$U_1 = U_{1,\text{el}}$ the potential energy stored in the compressed spring.
Thus $U_{1,\text{el}} = K_2 = 8.64$ J

EVALUATE: The blocks have equal and opposite momenta as they move apart, since the total momentum is zero. The kinetic energy of each block is positive and doesn't depend on the direction of the block's velocity, just on its magnitude.

8.25. **IDENTIFY:** Since friction at the pond surface is neglected, there is no net external horizontal force and the horizontal component of the momentum of the system of hunter plus bullet is conserved. Both objects are initially at rest, so the initial momentum of the system is zero. Gravity and the normal force exerted by the ice together produce a net vertical force while the rifle is firing, so the vertical component of momentum is not conserved.

SET UP: Let object A be the hunter and object B be the bullet. Let $+x$ be the direction of the horizontal component of velocity of the bullet. Solve for v_{A2x}.

EXECUTE: **(a)** $v_{B2x} = +965$ m/s. $P_{1x} = P_{2x} = 0$. $0 = m_A v_{A2x} + m_B v_{B2x}$ and

$$v_{A2x} = -\frac{m_B}{m_A} v_{B2x} = -\left(\frac{4.20\times10^{-3}\text{ kg}}{72.5\text{ kg}}\right)(965\text{ m/s}) = -0.0559\text{ m/s}.$$

(b) $v_{B2x} = v_{B2}\cos\theta = (965\text{ m/s})\cos 56.0° = 540$ m/s. $v_{A2x} = -\left(\frac{4.20\times10^{-3}\text{ kg}}{72.5\text{ kg}}\right)(540\text{ m/s}) = -0.0313$ m/s.

EVALUATE: The mass of the bullet is much less than the mass of the hunter, so the final mass of the hunter plus gun is still 72.5 kg, to three significant figures. Since the hunter has much larger mass, his final speed is much less than the speed of the bullet.

8.26. **IDENTIFY:** Assume the nucleus is initially at rest. $K = \frac{1}{2}mv^2$.

SET UP: Let $+x$ be to the right. $v_{A2x} = -v_A$ and $v_{B2x} = +v_B$.

EXECUTE: **(a)** $P_{2x} = P_{1x} = 0$ gives $m_A v_{A2x} + m_B v_{B2x} = 0$. $v_B = \left(\frac{m_A}{m_B}\right) v_A$.

(b) $\frac{K_A}{K_B} = \frac{\frac{1}{2}m_A v_A^2}{\frac{1}{2}m_B v_B^2} = \frac{m_A v_A^2}{m_B (m_A v_A/m_B)^2} = \frac{m_B}{m_A}$.

EVALUATE: The lighter fragment has the greater kinetic energy.

8.27. **IDENTIFY:** Each horizontal component of momentum is conserved. $K = \frac{1}{2}mv^2$.

SET UP: Let $+x$ be the direction of Rebecca's initial velocity and let the $+y$ axis make an angle of $36.9°$ with respect to the direction of her final velocity. $v_{D1x} = v_{D1y} = 0$. $v_{R1x} = 13.0$ m/s; $v_{R1y} = 0$. $v_{R2x} = (8.00\text{ m/s})\cos 53.1° = 4.80$ m/s; $v_{R2y} = (8.00\text{ m/s})\sin 53.1° = 6.40$ m/s. Solve for v_{D2x} and v_{D2y}.

EXECUTE: **(a)** $P_{1x} = P_{2x}$ gives $m_R v_{R1x} = m_R v_{R2x} + m_D v_{D2x}$.

$$v_{D2x} = \frac{m_R (v_{R1x} - v_{R2x})}{m_D} = \frac{(45.0\text{ kg})(13.0\text{ m/s} - 4.80\text{ m/s})}{65.0\text{ kg}} = 5.68\text{ m/s}.$$

$P_{1y} = P_{2y}$ gives $0 = m_R v_{R2y} + m_D v_{D2y}$. $v_{D2y} = -\frac{m_R}{m_D} v_{R2y} = -\left(\frac{45.0\text{ kg}}{65.0\text{ kg}}\right)(6.40\text{ m/s}) = -4.43$ m/s.

The directions of $\vec{v}_{R1}$, $\vec{v}_{R2}$ and $\vec{v}_{D2}$ are sketched in Figure 8.27. $\tan\theta = \left|\frac{v_{D2y}}{v_{D2x}}\right| = \frac{4.43\text{ m/s}}{5.68\text{ m/s}}$ and $\theta = 38.0°$. $v_D = \sqrt{v_{D2x}^2 + v_{D2y}^2} = 7.20$ m/s.

(b) $K_1 = \frac{1}{2}m_R v_{R1}^2 = \frac{1}{2}(45.0\text{ kg})(13.0\text{ m/s})^2 = 3.80\times10^3$ J.

$K_2 = \frac{1}{2}m_R v_{R2}^2 + \frac{1}{2}m_D v_{D2}^2 = \frac{1}{2}(45.0\text{ kg})(8.00\text{ m/s})^2 + \frac{1}{2}(65.0\text{ kg})(7.20\text{ m/s})^2 = 3.12\times10^3$ J.

$\Delta K = K_2 - K_1 = -680$ J.

EVALUATE: Each component of momentum is separately conserved. The kinetic energy of the system decreases.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

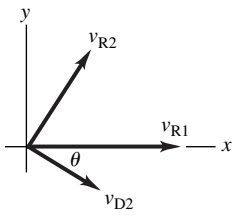

Figure 8.27

8.28. **IDENTIFY** and **SET UP:** Let the $+x$-direction be horizontal, along the direction the rock is thrown. There is no net horizontal force, so P_x is constant. Let object A be you and object B be the rock.

EXECUTE: $0 = -m_A v_A + m_B v_B \cos 35.0°$

$$v_A = \frac{m_B v_B \cos 35.0°}{m_A} = 2.11 \text{ m/s}$$

EVALUATE: P_y is not conserved because there is a net external force in the vertical direction; as you throw the rock the normal force exerted on you by the ice is larger than the total weight of the system.

8.29. **IDENTIFY:** The horizontal component of the momentum of the system of the rain and freight car is conserved.

SET UP: Let $+x$ be the direction the car is moving initially. Before it lands in the car the rain has no momentum along the x-axis.

EXECUTE: **(a)** $P_{1x} = P_{2x}$ gives $(24{,}000 \text{ kg})(4.00 \text{ m/s}) = (27{,}000 \text{ kg})v_{2x}$ and $v_{2x} = 3.56$ m/s.

(b) After it lands in the car the water must gain horizontal momentum, so the car loses horizontal momentum.

EVALUATE: The vertical component of the momentum is not conserved, because of the vertical external force exerted by the track on the train.

8.30. **IDENTIFY:** There is no net external force on the system of astronaut plus canister, so the momentum of the system is conserved.

SET UP: Let object A be the astronaut and object B be the canister. Assume the astronaut is initially at rest. After the collision she must be moving in the same direction as the canister. Let $+x$ be the direction in which the canister is traveling initially, so $v_{A1x} = 0$, $v_{A2x} = +2.40$ m/s, $v_{B1x} = +3.50$ m/s, and $v_{B2x} = +1.20$ m/s. Solve for m_B.

EXECUTE: $P_{1x} = P_{2x}$. $m_A v_{A1x} + m_B v_{B1x} = m_A v_{A2x} + m_B v_{B2x}$.

$$m_B = \frac{m_A(v_{A2x} - v_{A1x})}{v_{B1x} - v_{B2x}} = \frac{(78.4 \text{ kg})(2.40 \text{ m/s} - 0)}{3.50 \text{ m/s} - 1.20 \text{ m/s}} = 81.8 \text{ kg}.$$

EVALUATE: She must exert a force on the canister in the $-x$-direction to reduce its velocity component in the $+x$-direction. By Newton's third law, the canister exerts a force on her that is in the $+x$-direction and she gains velocity in that direction.

8.31. **IDENTIFY:** The x and y components of the momentum of the system of the two asteroids are separately conserved.

SET UP: The before and after diagrams are given in Figure 8.31 and the choice of coordinates is indicated. Each asteroid has mass m.

EXECUTE: **(a)** $P_{1x} = P_{2x}$ gives $mv_{A1} = mv_{A2}\cos 30.0° + mv_{B2}\cos 45.0°$. $40.0 \text{ m/s} = 0.866v_{A2} + 0.707v_{B2}$ and $0.707v_{B2} = 40.0 \text{ m/s} - 0.866v_{A2}$.

$P_{2y} = P_{2y}$ gives $0 = mv_{A2}\sin 30.0° - mv_{B2}\sin 45.0°$ and $0.500v_{A2} = 0.707v_{B2}$.

Combining these two equations gives $0.500v_{A2} = 40.0 \text{ m/s} - 0.866v_{A2}$ and $v_{A2} = 29.3$ m/s. Then

$$v_{B2} = \left(\frac{0.500}{0.707}\right)(29.3 \text{ m/s}) = 20.7 \text{ m/s}.$$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) $K_1 = \frac{1}{2}mv_{A1}^2$. $K_2 = \frac{1}{2}mv_{A2}^2 + \frac{1}{2}mv_{B2}^2$. $\frac{K_2}{K_1} = \frac{v_{A2}^2 + v_{B2}^2}{v_{A1}^2} = \frac{(29.3 \text{ m/s})^2 + (20.7 \text{ m/s})^2}{(40.0 \text{ m/s})^2} = 0.804.$

$$\frac{\Delta K}{K_1} = \frac{K_2 - K_1}{K_1} = \frac{K_2}{K_1} - 1 = -0.196.$$

19.6% of the original kinetic energy is dissipated during the collision.

EVALUATE: We could use any directions we wish for the x and y coordinate directions, but the particular choice we have made is especially convenient.

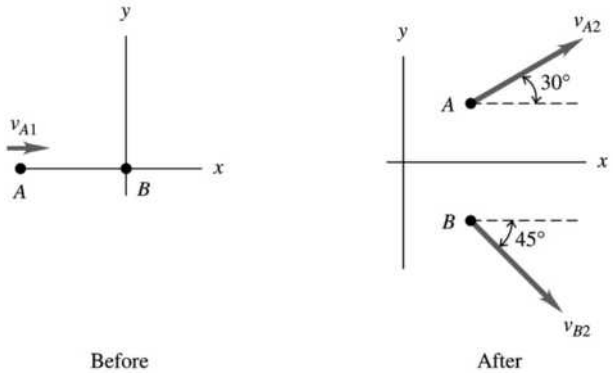

Figure 8.31

8.32. **IDENTIFY:** There is no net external force on the system of the two skaters and the momentum of the system is conserved.

SET UP: Let object A be the skater with mass 70.0 kg and object B be the skater with mass 65.0 kg. Let $+x$ be to the right, so $v_{A1x} = +2.00$ m/s and $v_{B1x} = -2.50$ m/s. After the collision the two objects are combined and move with velocity $\vec{v}_2$. Solve for v_{2x}.

EXECUTE: $P_{1x} = P_{2x}$. $m_A v_{A1x} + m_B v_{B1x} = (m_A + m_B)v_{2x}$.

$$v_{2x} = \frac{m_A v_{A1x} + m_B v_{B1x}}{m_A + m_B} = \frac{(70.0 \text{ kg})(2.00 \text{ m/s}) + (65.0 \text{ kg})(-2.50 \text{ m/s})}{70.0 \text{ kg} + 65.0 \text{ kg}} = -0.167 \text{ m/s}.$$

The two skaters move to the left at 0.167 m/s.

EVALUATE: There is a large decrease in kinetic energy.

8.33. **IDENTIFY:** Since drag effects are neglected there is no net external force on the system of two fish and the momentum of the system is conserved. The mechanical energy equals the kinetic energy, which is $K = \frac{1}{2}mv^2$ for each object.

SET UP: Let object A be the 15.0 kg fish and B be the 4.50 kg fish. Let $+x$ be the direction the large fish is moving initially, so $v_{A1x} = 1.10$ m/s and $v_{B1x} = 0$. After the collision the two objects are combined and move with velocity $\vec{v}_2$. Solve for v_{2x}.

EXECUTE: **(a)** $P_{1x} = P_{2x}$. $m_A v_{A1x} + m_B v_{B1x} = (m_A + m_B)v_{2x}$.

$$v_{2x} = \frac{m_A v_{A1x} + m_B v_{B1x}}{m_A + m_B} = \frac{(15.0 \text{ kg})(1.10 \text{ m/s}) + 0}{15.0 \text{ kg} + 4.50 \text{ kg}} = 0.846 \text{ m/s}.$$

(b) $K_1 = \frac{1}{2}m_A v_{A1}^2 + \frac{1}{2}m_B v_{B1}^2 = \frac{1}{2}(15.0 \text{ kg})(1.10 \text{ m/s})^2 = 9.08$ J.

$K_2 = \frac{1}{2}(m_A + m_B)v_2^2 = \frac{1}{2}(19.5 \text{ kg})(0.846 \text{ m/s})^2 = 6.98$ J.

$\Delta K = K_2 - K_1 = -2.10$ J . 2.10 J of mechanical energy is dissipated.

EVALUATE: The total kinetic energy always decreases in a collision where the two objects become combined.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

8.34. **IDENTIFY:** There is no net external force on the system of the two otters and the momentum of the system is conserved. The mechanical energy equals the kinetic energy, which is $K = \frac{1}{2}mv^2$ for each object.

SET UP: Let A be the 7.50 kg otter and B be the 5.75 kg otter. After the collision their combined velocity is $\vec{v}_2$. Let $+x$ be to the right, so $v_{A1x} = -5.00$ m/s and $v_{B1x} = +6.00$ m/s. Solve for v_{2x}.

EXECUTE: **(a)** $P_{1x} = P_{2x}$. $m_A v_{A1x} + m_B v_{B1x} = (m_A + m_B)v_{2x}$.

$$v_{2x} = \frac{m_A v_{A1x} + m_B v_{B1x}}{m_A + m_B} = \frac{(7.50 \text{ kg})(-5.00 \text{ m/s}) + (5.75 \text{ kg})(+6.00 \text{ m/s})}{7.50 \text{ kg} + 5.75 \text{ kg}} = -0.226 \text{ m/s}.$$

(b) $K_1 = \frac{1}{2}m_A v_{A1}^2 + \frac{1}{2}m_B v_{B1}^2 = \frac{1}{2}(7.50 \text{ kg})(5.00 \text{ m/s})^2 + \frac{1}{2}(5.75 \text{ kg})(6.00 \text{ m/s})^2 = 197.2 \text{ J}.$

$K_2 = \frac{1}{2}(m_A + m_B)v_2^2 = \frac{1}{2}(13.25 \text{ kg})(0.226 \text{ m/s})^2 = 0.338 \text{ J}.$

$\Delta K = K_2 - K_1 = -197$ J. 197 J of mechanical energy is dissipated.

EVALUATE: The total kinetic energy always decreases in a collision where the two objects become combined.

8.35. **IDENTIFY:** Treat the comet and probe as an isolated system for which momentum is conserved.

SET UP: In part (a) let object A be the probe and object B be the comet. Let $-x$ be the direction the probe is traveling just before the collision. After the collision the combined object moves with speed v_2. The change in velocity is $\Delta v = v_{2x} - v_{B1x}$. In part (a) the impact speed of 37,000 km/h is the speed of the probe relative to the comet just before impact: $v_{A1x} - v_{B1x} = -37{,}000$ km/h. In part (b) let object A be the comet and object B be the earth. Let $-x$ be the direction the comet is traveling just before the collision. The impact speed is 40,000 km/h, so $v_{A1x} - v_{B1x} = -40{,}000$ km/h.

EXECUTE: **(a)** $P_{1x} = P_{2x}$. $v_{2x} = \dfrac{m_A v_{A1x} + m_B v_{B1x}}{m_A + m_B}$.

$$\Delta v = v_{2x} - v_{B1x} = \left(\frac{m_A}{m_A + m_B}\right)v_{A1x} + \left(\frac{m_B - m_A - m_B}{m_A + m_B}\right)v_{B1x} = \left(\frac{m_A}{m_A + m_B}\right)(v_{A1x} - v_{B1x}).$$

$$\Delta v = \left(\frac{372 \text{ kg}}{372 \text{ kg} + 0.10\times10^{14} \text{ kg}}\right)(-37{,}000 \text{ km/h}) = -1.4\times10^{-6} \text{ km/h}.$$

The speed of the comet decreased by 1.4×10^{-6} km/h. This change is not noticeable.

(b) $\Delta v = \left(\dfrac{0.10\times10^{14} \text{ kg}}{0.10\times10^{14} \text{ kg} + 5.97\times10^{24} \text{ kg}}\right)(-40{,}000 \text{ km/h}) = -6.7\times10^{-8}$ km/h. The speed of the earth would change by 6.7×10^{-8} km/h. This change is not noticeable.

EVALUATE: $v_{A1x} - v_{B1x}$ is the velocity of the projectile (probe or comet) relative to the target (comet or earth). The expression for Δv can be derived directly by applying momentum conservation in coordinates in which the target is initially at rest.

8.36. **IDENTIFY:** The forces the two vehicles exert on each other during the collision are much larger than the horizontal forces exerted by the road, and it is a good approximation to assume momentum conservation.

SET UP: Let $+x$ be eastward. After the collision two vehicles move with a common velocity $\vec{v}_2$.

EXECUTE: **(a)** $P_{1x} = P_{2x}$ gives $m_{SC}v_{SCx} + m_T v_{Tx} = (m_{SC} + m_T)v_{2x}$.

$$v_{2x} = \frac{m_{SC}v_{SCx} + m_T v_{Tx}}{m_{SC} + m_T} = \frac{(1050 \text{ kg})(-15.0 \text{ m/s}) + (6320 \text{ kg})(+10.0 \text{ m/s})}{1050 \text{ kg} + 6320 \text{ kg}} = 6.44 \text{ m/s}.$$

The final velocity is 6.44 m/s, eastward.

(b) $P_{1x} = P_{2x} = 0$ gives $m_{SC}v_{SCx} + m_T v_{Tx} = 0$. $v_{Tx} = -\left(\dfrac{m_{SC}}{m_T}\right)v_{SCx} = -\left(\dfrac{1050 \text{ kg}}{6320 \text{ kg}}\right)(-15.0 \text{ m/s}) = 2.50 \text{ m/s}.$

The truck would need to have initial speed 2.50 m/s.

(c) part (a): $\Delta K = \frac{1}{2}(7370 \text{ kg})(6.44 \text{ m/s})^2 - \frac{1}{2}(1050 \text{ kg})(15.0 \text{ m/s})^2 - \frac{1}{2}(6320 \text{ kg})(10.0 \text{ m/s})^2 = -2.81\times10^5$ J

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

part (b): $\Delta K = 0 - \frac{1}{2}(1050 \text{ kg})(15.0 \text{ m/s})^2 - \frac{1}{2}(6320 \text{ kg})(2.50 \text{ m/s})^2 = -1.38\times10^5$ J. The change in kinetic energy has the greater magnitude in part (a).

EVALUATE: In part (a) the eastward momentum of the truck has a greater magnitude than the westward momentum of the car and the wreckage moves eastward after the collision. In part (b) the two vehicles have equal magnitudes of momentum, the total momentum of the system is zero and the wreckage is at rest after the collision.

8.37. **IDENTIFY:** The forces the two players exert on each other during the collision are much larger than the horizontal forces exerted by the slippery ground and it is a good approximation to assume momentum conservation. Each component of momentum is separately conserved.

SET UP: Let $+x$ be east and $+y$ be north. After the collision the two players have velocity $\vec{v}_2$. Let the linebacker be object A and the halfback be object B, so $v_{A1x} = 0$, $v_{A1y} = 8.8$ m/s, $v_{B1x} = 7.2$ m/s and $v_{B1y} = 0$. Solve for v_{2x} and v_{2y}.

EXECUTE: $P_{1x} = P_{2x}$ gives $m_A v_{A1x} + m_B v_{B1x} = (m_A + m_B)v_{2x}$.

$$v_{2x} = \frac{m_A v_{A1x} + m_B v_{B1x}}{m_A + m_B} = \frac{(85 \text{ kg})(7.2 \text{ m/s})}{110 \text{ kg} + 85 \text{ kg}} = 3.14 \text{ m/s}.$$

$P_{1y} = P_{2y}$ gives $m_A v_{A1y} + m_B v_{B1y} = (m_A + m_B)v_{2y}$.

$$v_{2y} = \frac{m_A v_{A1y} + m_B v_{B1y}}{m_A + m_B} = \frac{(110 \text{ kg})(8.8 \text{ m/s})}{110 \text{ kg} + 85 \text{ kg}} = 4.96 \text{ m/s}.$$

$v = \sqrt{v_{2x}^2 + v_{2y}^2} = 5.9$ m/s.

$$\tan\theta = \frac{v_{2y}}{v_{2x}} = \frac{4.96 \text{ m/s}}{3.14 \text{ m/s}} \text{ and } \theta = 58°.$$

The players move with a speed of 5.9 m/s and in a direction $58°$ north of east.

EVALUATE: Each component of momentum is separately conserved.

8.38. **IDENTIFY:** The momentum is conserved during the collision. Since the motions involved are in two dimensions, we must consider the components separately.

SET UP: Use coordinates where $+x$ is east and $+y$ is south. The system of two cars before and after the collision is sketched in Figure 8.38. Neglect friction from the road during the collision. The enmeshed cars have a total mass of $2000 \text{ kg} + 1500 \text{ kg} = 3500 \text{ kg}$. Momentum conservation tells us that $P_{1x} = P_{2x}$ and $P_{1y} = P_{2y}$.

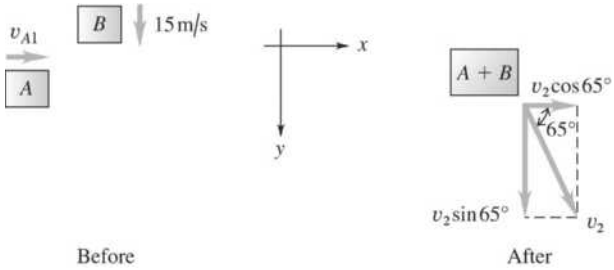

Figure 8.38

EXECUTE: There are no external horizontal forces during the collision, so $P_{1x} = P_{2x}$ and $P_{1y} = P_{2y}$.

(a) $P_{1x} = P_{2x}$ gives $(1500 \text{ kg})(15 \text{ m/s}) = (3500 \text{ kg})v_2\sin 65°$ and $v_2 = 7.1$ m/s.

(b) $P_{1y} = P_{2y}$ gives $(2000 \text{ kg})v_{A1} = (3500 \text{ kg})v_2\cos 65°$. And then using $v_2 = 7.1$ m/s, we have $v_{A1} = 5.2$ m/s.

EVALUATE: Momentum is a vector so we must treat each component separately.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

8.39. **IDENTIFY:** Neglect external forces during the collision. Then the momentum of the system of the two cars is conserved.

SET UP: $m_S = 1200$ kg, $m_L = 3000$ kg. The small car has velocity v_S and the large car has velocity v_L.

EXECUTE: **(a)** The total momentum of the system is conserved, so the momentum lost by one car equals the momentum gained by the other car. They have the same magnitude of change in momentum. Since $\vec{p} = m\vec{v}$ and $\Delta\vec{p}$ is the same, the car with the smaller mass has a greater change in velocity.

(b) $m_S \Delta v_S = m_L \Delta v_L$ and $\Delta v_S = \left(\frac{m_L}{m_S}\right)\Delta v_L = \left(\frac{3000 \text{ kg}}{1200 \text{ kg}}\right)\Delta v = 2.50\Delta v$.

(c) The acceleration of the small car is greater, since it has a greater change in velocity during the collision. The large acceleration means a large force on the occupants of the small car and they would sustain greater injuries.

EVALUATE: Each car exerts the same magnitude of force on the other car but the force on the compact has a greater effect on its velocity since its mass is less.

8.40. **IDENTIFY:** The collision forces are large so gravity can be neglected during the collision. Therefore, the horizontal and vertical components of the momentum of the system of the two birds are conserved.

SET UP: The system before and after the collision is sketched in Figure 8.40. Use the coordinates shown.

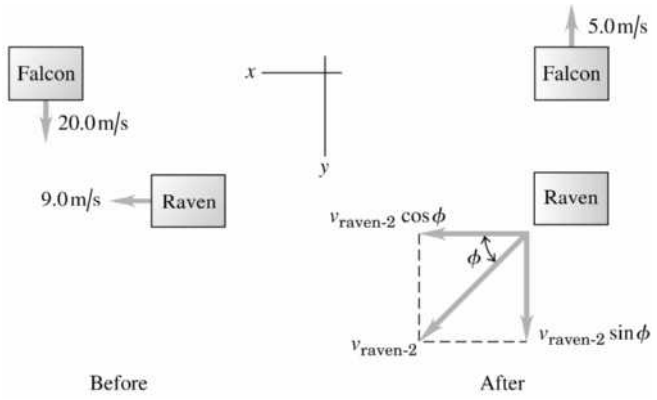

Figure 8.40

EXECUTE: **(a)** There is no external force on the system so $P_{1x} = P_{2x}$ and $P_{1y} = P_{2y}$.

$P_{1x} = P_{2x}$ gives $(1.5 \text{ kg})(9.0 \text{ m/s}) = (1.5 \text{ kg})v_{\text{raven-2}} \cos\phi$ and $v_{\text{raven-2}} \cos\phi = 9.0$ m/s.

$P_{1y} = P_{2y}$ gives $(0.600 \text{ kg})(20.0 \text{ m/s}) = (0.600 \text{ kg})(-5.0 \text{ m/s}) + (1.5 \text{ kg})v_{\text{raven-2}} \sin\phi$ and

$v_{\text{raven-2}} \sin\phi = 10.0$ m/s.

Combining these two equations gives $\tan\phi = \frac{10.0 \text{ m/s}}{9.0 \text{ m/s}}$ and $\phi = 48°$.

(b) $v_{\text{raven-2}} = 13.5$ m/s

EVALUATE: Due to its large initial speed the lighter falcon was able to produce a large change in the raven's direction of motion.

8.41. **IDENTIFY:** Since friction forces from the road are ignored, the x and y components of momentum are conserved.

SET UP: Let object A be the subcompact and object B be the truck. After the collision the two objects move together with velocity $\vec{v}_2$. Use the x and y coordinates given in the problem. $v_{A1y} = v_{B1x} = 0$.

$v_{2x} = (16.0 \text{ m/s})\sin 24.0° = 6.5$ m/s; $v_{2y} = (16.0 \text{ m/s})\cos 24.0° = 14.6$ m/s.

EXECUTE: $P_{1x} = P_{2x}$ gives $m_A v_{A1x} = (m_A + m_B)v_{2x}$.

$$v_{A1x} = \left(\frac{m_A + m_B}{m_A}\right)v_{2x} = \left(\frac{950 \text{ kg} + 1900 \text{ kg}}{950 \text{ kg}}\right)(6.5 \text{ m/s}) = 19.5 \text{ m/s}.$$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$P_{1y} = P_{2y}$ gives $m_A v_{B1y} = (m_A + m_B) v_{2y}$.

$$v_{B1y} = \left(\frac{m_A + m_B}{m_A} \right) v_{2y} = \left(\frac{950 \text{ kg} + 1900 \text{ kg}}{1900 \text{ kg}} \right) (14.6 \text{ m/s}) = 21.9 \text{ m/s}.$$

Before the collision the subcompact car has speed 19.5 m/s and the truck has speed 21.9 m/s.

EVALUATE: Each component of momentum is independently conserved.

8.42. **IDENTIFY:** Apply conservation of momentum to the collision. Apply conservation of energy to the motion of the block after the collision.

SET UP: Conservation of momentum applied to the collision between the bullet and the block: Let object A be the bullet and object B be the block. Let v_A be the speed of the bullet before the collision and let V be the speed of the block with the bullet inside just after the collision.

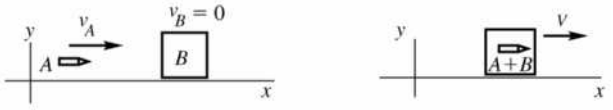

Figure 8.42a

P_x is constant gives $m_A v_A = (m_A + m_B) V$.

Conservation of energy applied to the motion of the block after the collision:

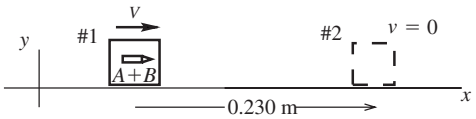

Figure 8.42b

$K_1 + U_1 + W_{\text{other}} = K_2 + U_2$

EXECUTE: Work is done by friction so $W_{\text{other}} = W_f = (f_k \cos\phi) s = -f_k s = -\mu_k mgs$

$U_1 = U_2 = 0$ (no work done by gravity)

$K_1 = \frac{1}{2} mV^2$; $K_2 = 0$ (block has come to rest)

Thus $\frac{1}{2} mV^2 - \mu_k mgs = 0$

$V = \sqrt{2\mu_k gs} = \sqrt{2(0.20)(9.80 \text{ m/s}^2)(0.230 \text{ m})} = 0.9495 \text{ m/s}$

Use this in the conservation of momentum equation

$$v_A = \left(\frac{m_A + m_B}{m_A} \right) V = \left(\frac{5.00 \times 10^{-3} \text{ kg} + 1.20 \text{ kg}}{5.00 \times 10^{-3} \text{ kg}} \right) (0.9495 \text{ m/s}) = 229 \text{ m/s}$$

EVALUATE: When we apply conservation of momentum to the collision we are ignoring the impulse of the friction force exerted by the surface during the collision. This is reasonable since this force is much smaller than the forces the bullet and block exert on each other during the collision. This force does work as the block moves after the collision, and takes away all the kinetic energy.

8.43. **IDENTIFY:** Apply conservation of momentum to the collision and conservation of energy to the motion after the collision. After the collision the kinetic energy of the combined object is converted to gravitational potential energy.

SET UP: Immediately after the collision the combined object has speed V. Let h be the vertical height through which the pendulum rises.

EXECUTE: **(a)** Conservation of momentum applied to the collision gives

$(12.0 \times 10^{-3} \text{ kg})(380 \text{ m/s}) = (6.00 \text{ kg} + 12.0 \times 10^{-3} \text{ kg}) V$ and $V = 0.758 \text{ m/s}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

Conservation of energy applied to the motion after the collision gives $\frac{1}{2}m_{\text{tot}}V^2 = m_{\text{tot}}gh$ and

$$h = \frac{V^2}{2g} = \frac{(0.758 \text{ m/s})^2}{2(9.80 \text{ m/s}^2)} = 0.0293 \text{ m} = 2.93 \text{ cm}.$$

(b) $K = \frac{1}{2}m_{\text{b}}v_{\text{b}}^2 = \frac{1}{2}(12.0\times10^{-3} \text{ kg})(380 \text{ m/s})^2 = 866 \text{ J}.$

(c) $K = \frac{1}{2}m_{\text{tot}}V^2 = \frac{1}{2}(6.00 \text{ kg} + 12.0\times10^{-3} \text{ kg})(0.758 \text{ m/s})^2 = 1.73 \text{ J}.$

EVALUATE: Most of the initial kinetic energy of the bullet is dissipated in the collision.

8.44. **IDENTIFY:** During the collision, momentum is conserved. After the collision, mechanical energy is conserved.

SET UP: The collision occurs over a short time interval and the block moves very little during the collision, so the spring force during the collision can be neglected. Use coordinates where $+x$ is to the right. During the collision, momentum conservation gives $P_{1x} = P_{2x}$. After the collision, $\frac{1}{2}mv^2 = \frac{1}{2}kx^2$.

EXECUTE: *Collision*: There is no external horizontal force during the collision and $P_{1x} = P_{2x}$, so $(3.00 \text{ kg})(8.00 \text{ m/s}) = (15.0 \text{ kg})v_{\text{block, 2}} - (3.00 \text{ kg})(2.00 \text{ m/s})$ and $v_{\text{block, 2}} = 2.00 \text{ m/s}$.

Motion after the collision: When the spring has been compressed the maximum amount, all the initial kinetic energy of the block has been converted into potential energy $\frac{1}{2}kx^2$ that is stored in the compressed spring. Conservation of energy gives $\frac{1}{2}(15.0 \text{ kg})(2.00 \text{ m/s})^2 = \frac{1}{2}(500.0 \text{ kg})x^2$, so $x = 0.346 \text{ m}$.

EVALUATE: We cannot say that the momentum was converted to potential energy, because momentum and energy are different types of quantities.

8.45. **IDENTIFY:** The missile gives momentum to the ornament causing it to swing in a circular arc and thereby be accelerated toward the center of the circle.

SET UP: After the collision the ornament moves in an arc of a circle and has acceleration $a_{\text{rad}} = \frac{v^2}{r}$.

During the collision, momentum is conserved, so $P_{1x} = P_{2x}$. The free-body diagram for the ornament plus missile is given in Figure 8.45. Take $+y$ to be upward, since that is the direction of the acceleration. Take the $+x$ direction to be the initial direction of motion of the missile.

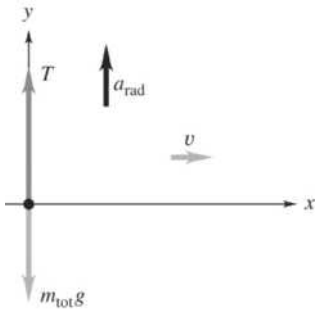

Figure 8.45

EXECUTE: Apply conservation of momentum to the collision. Using $P_{1x} = P_{2x}$, we get $(3.00 \text{ kg})(12.0 \text{ m/s}) = (8.00 \text{ kg})V$, which gives $V = 4.50 \text{ m/s}$, the speed of the ornament immediately after the collision. Then $\Sigma F_y = ma_y$ gives $T - m_{\text{tot}}g = m_{\text{tot}}\frac{v^2}{r}$. Solving for T gives

$$T = m_{\text{tot}}\left(g + \frac{v^2}{r}\right) = (8.00 \text{ kg})\left(9.80 \text{ m/s}^2 + \frac{(4.50 \text{ m/s})^2}{1.50 \text{ m}}\right) = 186 \text{ N}.$$

EVALUATE: We cannot use energy conservation during the collision because it is an inelastic collision (the objects stick together).

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

8.46. **IDENTIFY:** No net external horizontal force so P_x is conserved. Elastic collision so $K_1 = K_2$ and can use Eq. 8.27.
SET UP:

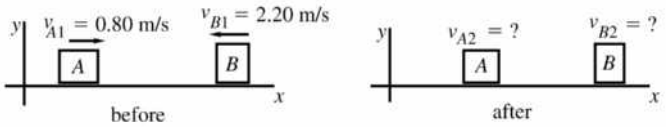

Figure 8.46

EXECUTE: From conservation of x-component of momentum:

$$m_A v_{A1x} + m_B v_{B1x} = m_A v_{A2x} + m_B v_{B2x}$$

$$m_A v_{A1} - m_B v_{B1} = m_A v_{A2x} + m_B v_{B2x}$$

$$(0.150\text{ kg})(0.80\text{ m/s}) - (0.300\text{ kg})(2.20\text{ m/s}) = (0.150\text{ kg})v_{A2x} + (0.300\text{ kg})v_{B2x}$$

$$-3.60\text{ m/s} = v_{A2x} + 2v_{B2x}$$

From the relative velocity equation for an elastic collision Eq. 8.27:

$$v_{B2x} - v_{A2x} = -(v_{B1x} - v_{A1x}) = -(-2.20\text{ m/s} - 0.80\text{ m/s}) = +3.00\text{ m/s}$$

$$3.00\text{ m/s} = -v_{A2x} + v_{B2x}$$

Adding the two equations gives $-0.60\text{ m/s} = 3v_{B2x}$ and $v_{B2x} = -0.20$ m/s. Then $v_{A2x} = v_{B2x} - 3.00\text{ m/s} = -3.20$ m/s.

The 0.150 kg glider (A) is moving to the left at 3.20 m/s and the 0.300 kg glider (B) is moving to the left at 0.20 m/s.

EVALUATE: We can use our v_{A2x} and v_{B2x} to show that P_x is constant and $K_1 = K_2$

8.47. **IDENTIFY:** When the spring is compressed the maximum amount the two blocks aren't moving relative to each other and have the same velocity $\vec{V}$ relative to the surface. Apply conservation of momentum to find V and conservation of energy to find the energy stored in the spring. Since the collision is elastic, Eqs. 8.24 and 8.25 give the final velocity of each block after the collision.
SET UP: Let $+x$ be the direction of the initial motion of A.
EXECUTE: **(a)** Momentum conservation gives $(2.00\text{ kg})(2.00\text{ m/s}) = (12.0\text{ kg})V$ and $V = 0.333$ m/s.
Both blocks are moving at 0.333 m/s, in the direction of the initial motion of block A. Conservation of energy says the initial kinetic energy of A equals the total kinetic energy at maximum compression plus the potential energy U_b stored in the bumpers: $\frac{1}{2}(2.00\text{ kg})(2.00\text{ m/s})^2 = U_b + \frac{1}{2}(12.0\text{ kg})(0.333\text{ m/s})^2$ and $U_b = 3.33$ J.

(b) $v_{A2x} = \left(\dfrac{m_A - m_B}{m_A + m_B}\right)v_{A1x} = \left(\dfrac{2.00\text{ kg} - 10.0\text{ kg}}{12.0\text{ kg}}\right)(2.00\text{ m/s}) = -1.33\text{ m/s}$. Block A is moving in the $-x$ direction at 1.33 m/s.

$v_{B2x} = \left(\dfrac{2m_A}{m_A + m_B}\right)v_{A1x} = \dfrac{2(2.00\text{ kg})}{12.0\text{ kg}}(2.00\text{ m/s}) = +0.667\text{ m/s}$. Block B is moving in the $+x$ direction at 0.667 m/s.

EVALUATE: When the spring is compressed the maximum amount the system must still be moving in order to conserve momentum.

8.48. **IDENTIFY:** Since the collision is elastic, both momentum conservation and Eq. 8.27 apply.
SET UP: Let object A be the 30.0 g marble and let object B be the 10.0 g marble. Let $+x$ be to the right.
EXECUTE: **(a)** Conservation of momentum gives
$(0.0300\text{ kg})(0.200\text{ m/s}) + (0.0100\text{ kg})(-0.400\text{ m/s}) = (0.0300\text{ kg})v_{A2x} + (0.0100\text{ kg})v_{B2x}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$3v_{A2x} + v_{B2x} = 0.200$ m/s. Eq. 8.27 says $v_{B2x} - v_{A2x} = -(-0.400 \text{ m/s} - 0.200 \text{ m/s}) = +0.600$ m/s. Solving this pair of equations gives $v_{A2x} = -0.100$ m/s and $v_{B2x} = +0.500$ m/s. The 30.0 g marble is moving to the left at 0.100 m/s and the 10.0 g marble is moving to the right at 0.500 m/s.

(b) For marble A, $\Delta P_{Ax} = m_A v_{A2x} - m_A v_{A1x} = (0.0300 \text{ kg})(-0.100 \text{ m/s} - 0.200 \text{ m/s}) = -0.00900 \text{ kg} \cdot \text{m/s}$.

For marble B, $\Delta P_{Bx} = m_B v_{B2x} - m_B v_{B1x} = (0.0100 \text{ kg})(0.500 \text{ m/s} - [-0.400 \text{ m/s}]) = +0.00900 \text{ kg} \cdot \text{m/s}$.

The changes in momentum have the same magnitude and opposite sign.

(c) For marble A, $\Delta K_A = \frac{1}{2} m_A v_{A2}^2 - \frac{1}{2} m_A v_{A1}^2 = \frac{1}{2}(0.0300 \text{ kg})([0.100 \text{ m/s}]^2 - [0.200 \text{ m/s}]^2) = -4.5 \times 10^{-4}$ J.

For marble B, $\Delta K_B = \frac{1}{2} m_B v_{B2}^2 - \frac{1}{2} m_B v_{B1}^2 = \frac{1}{2}(0.0100 \text{ kg})([0.500 \text{ m/s}]^2 - [0.400 \text{ m/s}]^2) = +4.5 \times 10^{-4}$ J.

The changes in kinetic energy have the same magnitude and opposite sign.

EVALUATE: The results of parts **(b)** and **(c)** show that momentum and kinetic energy are conserved in the collision.

8.49. **IDENTIFY:** Eqs. 8.24 and 8.25 apply, with object A being the neutron.

SET UP: Let $+x$ be the direction of the initial momentum of the neutron. The mass of a neutron is $m_n = 1.0$ u.

EXECUTE: **(a)** $v_{A2x} = \left(\dfrac{m_A - m_B}{m_A + m_B}\right) v_{A1x} = \dfrac{1.0 \text{ u} - 2.0 \text{ u}}{1.0 \text{ u} + 2.0 \text{ u}} v_{A1x} = -v_{A1x}/3.0$. The speed of the neutron after the collision is one-third its initial speed.

(b) $K_2 = \frac{1}{2} m_n v_n^2 = \frac{1}{2} m_n (v_{A1}/3.0)^2 = \dfrac{1}{9.0} K_1$.

(c) After n collisions, $v_{A2} = \left(\dfrac{1}{3.0}\right)^n v_{A1} \cdot \left(\dfrac{1}{3.0}\right)^n = \dfrac{1}{59{,}000}$, so $3.0^n = 59{,}000$. $n \log 3.0 = \log 59{,}000$ and $n = 10$.

EVALUATE: Since the collision is elastic, in each collision the kinetic energy lost by the neutron equals the kinetic energy gained by the deuteron.

8.50. **IDENTIFY:** Elastic collision. Solve for mass and speed of target nucleus.

SET UP: **(a)** Let A be the proton and B be the target nucleus. The collision is elastic, all velocities lie along a line, and B is at rest before the collision. Hence the results of Eqs. 8.24 and 8.25 apply.

EXECUTE: Eq. 8.24: $m_B(v_x + v_{Ax}) = m_A(v_x - v_{Ax})$, where v_x is the velocity component of A before the collision and v_{Ax} is the velocity component of A after the collision. Here, $v_x = 1.50 \times 10^7$ m/s (take direction of incident beam to be positive) and $v_{Ax} = -1.20 \times 10^7$ m/s (negative since traveling in direction opposite to incident beam).

$$m_B = m_A\left(\frac{v_x - v_{Ax}}{v_x + v_{Ax}}\right) = m\left(\frac{1.50 \times 10^7 \text{ m/s} + 1.20 \times 10^7 \text{ m/s}}{1.50 \times 10^7 \text{ m/s} - 1.20 \times 10^7 \text{ m/s}}\right) = m\left(\frac{2.70}{0.30}\right) = 9.00m.$$

(b) Eq. 8.25: $v_{Bx} = \left(\dfrac{2m_A}{m_A + m_B}\right) v = \left(\dfrac{2m}{m + 9.00m}\right)(1.50 \times 10^7 \text{ m/s}) = 3.00 \times 10^6$ m/s.

EVALUATE: Can use our calculated v_{Bx} and m_B to show that P_x is constant and that $K_1 = K_2$.

8.51. **IDENTIFY:** Apply Eq. 8.28.

SET UP: $m_A = 0.300$ kg, $m_B = 0.400$ kg, $m_C = 0.200$ kg.

EXECUTE: $x_{cm} = \dfrac{m_A x_A + m_B x_B + m_C x_C}{m_A + m_B + m_C}$.

$$x_{cm} = \frac{(0.300 \text{ kg})(0.200 \text{ m}) + (0.400 \text{ kg})(0.100 \text{ m}) + (0.200 \text{ kg})(-0.300 \text{ m})}{0.300 \text{ kg} + 0.400 \text{ kg} + 0.200 \text{ kg}} = 0.0444 \text{ m}.$$

$$y_{cm} = \frac{m_A y_A + m_B y_B + m_C y_C}{m_A + m_B + m_C}.$$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$y_{\text{cm}} = \frac{(0.300\text{ kg})(0.300\text{ m}) + (0.400\text{ kg})(-0.400\text{ m}) + (0.200\text{ kg})(0.600\text{ m})}{0.300\text{ kg} + 0.400\text{ kg} + 0.200\text{ kg}} = 0.0556\text{ m}.$$

EVALUATE: There is mass at both positive and negative x and at positive and negative y and therefore the center of mass is close to the origin.

8.52. **IDENTIFY:** Calculate x_{cm}.

SET UP: Apply Eq. 8.28 with the sun as mass 1 and Jupiter as mass 2. Take the origin at the sun and let Jupiter lie on the positive x-axis.

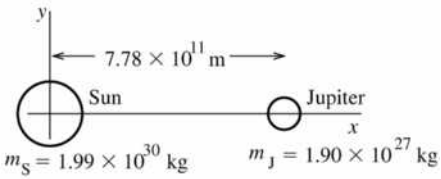

Figure 8.52

$$x_{\text{cm}} = \frac{m_1 x_1 + m_2 x_2}{m_1 + m_2}$$

EXECUTE: $x_1 = 0$ and $x_2 = 7.78\times10^{11}$ m

$$x_{\text{cm}} = \frac{(1.90\times10^{27}\text{ kg})(7.78\times10^{11}\text{ m})}{1.99\times10^{30}\text{ kg} + 1.90\times10^{27}\text{ kg}} = 7.42\times10^{8}\text{ m}$$

The center of mass is 7.42×10^8 m from the center of the sun and is on the line connecting the centers of the sun and Jupiter. The sun's radius is 6.96×10^8 m so the center of mass lies just outside the sun.

EVALUATE: The mass of the sun is much greater than the mass of Jupiter so the center of mass is much closer to the sun. For each object we have considered all the mass as being at the center of mass (geometrical center) of the object.

8.53. **IDENTIFY:** The location of the center of mass is given by Eq. 8.48. The mass can be expressed in terms of the diameter. Each object can be replaced by a point mass at its center.

SET UP: Use coordinates with the origin at the center of Pluto and the $+x$ direction toward Charon, so $x_{\text{P}} = 0$, $x_{\text{C}} = 19{,}700$ km. $m = \rho V = \rho\frac{4}{3}\pi r^3 = \frac{1}{6}\rho\pi d^3$.

EXECUTE: $x_{\text{cm}} = \dfrac{m_{\text{P}}x_{\text{P}} + m_{\text{C}}x_{\text{C}}}{m_{\text{P}} + m_{\text{C}}} = \left(\dfrac{m_{\text{C}}}{m_{\text{P}} + m_{\text{C}}}\right)x_{\text{C}} = \left(\dfrac{\frac{1}{6}\rho\pi d_{\text{C}}^3}{\frac{1}{6}\rho\pi d_{\text{P}}^3 + \frac{1}{6}\rho\pi d_{\text{C}}^3}\right)x_{\text{C}} = \left(\dfrac{d_{\text{C}}^3}{d_{\text{P}}^3 + d_{\text{C}}^3}\right)x_{\text{C}}.$

$$x_{\text{cm}} = \left(\frac{[1250\text{ km}]^3}{[2370\text{ km}]^3 + [1250\text{ km}]^3}\right)(19{,}700\text{ km}) = 2.52\times10^3\text{ km}.$$

The center of mass of the system is 2.52×10^3 km from the center of Pluto.

EVALUATE: The center of mass is closer to Pluto because Pluto has more mass than Charon.

8.54. **IDENTIFY:** Apply Eqs. 8.28, 8.30 and 8.32. There is only one component of position and velocity.

SET UP: $m_A = 1200$ kg, $m_B = 1800$ kg. $M = m_A + m_B = 3000$ kg. Let $+x$ be to the right and let the origin be at the center of mass of the station wagon.

EXECUTE: **(a)** $x_{\text{cm}} = \dfrac{m_A x_A + m_B x_B}{m_A + m_B} = \dfrac{0 + (1800\text{ kg})(40.0\text{ m})}{1200\text{ kg} + 1800\text{ kg}} = 24.0\text{ m}.$

The center of mass is between the two cars, 24.0 m to the right of the station wagon and 16.0 m behind the lead car.

(b) $P_x = m_A v_{A,x} + m_B v_{B,x} = (1200\text{ kg})(12.0\text{ m/s}) + (1800\text{ kg})(20.0\text{ m/s}) = 5.04\times10^4\text{ kg}\cdot\text{m/s}.$

(c) $v_{\text{cm},x} = \dfrac{m_A v_{A,x} + m_B v_{B,x}}{m_A + m_B} = \dfrac{(1200\text{ kg})(12.0\text{ m/s}) + (1800\text{ kg})(20.0\text{ m/s})}{1200\text{ kg} + 1800\text{ kg}} = 16.8\text{ m/s}.$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(d) $P_x = Mv_{\text{cm}-x} = (3000 \text{ kg})(16.8 \text{ m/s}) = 5.04\times10^4 \text{ kg}\cdot\text{m/s}$, the same as in part (b).

EVALUATE: The total momentum can be calculated either as the vector sum of the momenta of the individual objects in the system, or as the total mass of the system times the velocity of the center of mass.

8.55. **IDENTIFY:** Use Eq. 8.28 to find the x and y coordinates of the center of mass of the machine part for each configuration of the part. In calculating the center of mass of the machine part, each uniform bar can be represented by a point mass at its geometrical center.

SET UP: Use coordinates with the axis at the hinge and the $+x$ and $+y$ axes along the horizontal and vertical bars in the figure in the problem. Let (x_i, y_i) and (x_f, y_f) be the coordinates of the bar before and after the vertical bar is pivoted. Let object 1 be the horizontal bar, object 2 be the vertical bar and 3 be the ball.

EXECUTE: $x_\text{i} = \dfrac{m_1x_1 + m_2x_2 + m_3x_3}{m_1 + m_2 + m_3} = \dfrac{(4.00 \text{ kg})(0.750 \text{ m}) + 0 + 0}{4.00 \text{ kg} + 3.00 \text{ kg} + 2.00 \text{ kg}} = 0.333 \text{ m}.$

$$y_\text{i} = \frac{m_1y_1 + m_2y_2 + m_3y_3}{m_1 + m_2 + m_3} = \frac{0 + (3.00 \text{ kg})(0.900 \text{ m}) + (2.00 \text{ kg})(1.80 \text{ m})}{9.00 \text{ kg}} = 0.700 \text{ m}.$$

$$x_\text{f} = \frac{(4.00 \text{ kg})(0.750 \text{ m}) + (3.00 \text{ kg})(-0.900 \text{ m}) + (2.00 \text{ kg})(-1.80 \text{ m})}{9.00 \text{ kg}} = -0.366 \text{ m}.$$

$y_\text{f} = 0$. $x_\text{f} - x_\text{i} = -0.700$ m and $y_\text{f} - y_\text{i} = -0.700$ m. The center of mass moves 0.700 m to the right and 0.700 m upward.

EVALUATE: The vertical bar moves upward and to the right so it is sensible for the center of mass of the machine part to move in these directions.

8.56. **IDENTIFY:** Use Eq. 8.28.

SET UP: The target variable is m_1.

EXECUTE: $x_\text{cm} = 2.0$ m, $y_\text{cm} = 0$

$$x_\text{cm} = \frac{m_1x_1 + m_2x_2}{m_1 + m_2} = \frac{m_1(0) + (0.10 \text{ kg})(8.0 \text{ m})}{m_1 + (0.10 \text{ kg})} = \frac{0.80 \text{ kg}\cdot\text{m}}{m_1 + 0.10 \text{ kg}}.$$

$$x_\text{cm} = 2.0 \text{ m gives } 2.0 \text{ m} = \frac{0.80 \text{ kg}\cdot\text{m}}{m_1 + 0.10 \text{ kg}}.$$

$$m_1 + 0.10 \text{ kg} = \frac{0.80 \text{ kg}\cdot\text{m}}{2.0 \text{ m}} = 0.40 \text{ kg}.$$

$$m_1 = 0.30 \text{ kg}.$$

EVALUATE: The cm is closer to m_1 so its mass is larger then m_2.

(b) IDENTIFY: Use Eq. 8.32 to calculate $\vec{\boldsymbol{P}}$.

SET UP: $\vec{\boldsymbol{v}}_\text{cm}$ (5.0 m/s) $\hat{\boldsymbol{i}}$.

$$\vec{\boldsymbol{P}} = M\vec{\boldsymbol{v}}_\text{cm} = (0.10 \text{ kg} + 0.30 \text{ kg})(5.0 \text{ m/s})\,\hat{\boldsymbol{i}} = (2.0 \text{ kg}\cdot\text{m/s})\hat{\boldsymbol{i}}.$$

(c) IDENTIFY: Use Eq. 8.31.

SET UP: $\vec{\boldsymbol{v}}_\text{cm} = \dfrac{m_1\vec{\boldsymbol{v}}_1 + m_2\vec{\boldsymbol{v}}_2}{m_1 + m_2}$. The target variable is $\vec{\boldsymbol{v}}_1$. Particle 2 at rest says $v_2 = 0$.

EXECUTE: $\vec{\boldsymbol{v}}_1 = \left(\dfrac{m_1 + m_2}{m_1}\right)\vec{\boldsymbol{v}}_\text{cm} = \left(\dfrac{0.30 \text{ kg} + 0.10 \text{ kg}}{0.30 \text{ kg}}\right)(5.00 \text{ m/s})\hat{\boldsymbol{i}} = (6.7 \text{ m/s})\hat{\boldsymbol{i}}.$

EVALUATE: Using the result of part (c) we can calculate $\vec{\boldsymbol{p}}_1$ and $\vec{\boldsymbol{p}}_2$ and show that $\vec{\boldsymbol{P}}$ as calculated in part (b) does equal $\vec{\boldsymbol{p}}_1 + \vec{\boldsymbol{p}}_2$.

8.57. **IDENTIFY:** There is no net external force on the system of James, Ramon and the rope and the momentum of the system is conserved and the velocity of its center of mass is constant. Initially there is no motion, and the velocity of the center of mass remains zero after Ramon has started to move.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

SET UP: Let $+x$ be in the direction of Ramon's motion. Ramon has mass $m_R = 60.0$ kg and James has mass $m_J = 90.0$ kg.

EXECUTE: $v_{cm\text{-}x} = \dfrac{m_R v_{Rx} + m_J v_{Jx}}{m_R + m_J} = 0.$

$$v_{Jx} = -\left(\frac{m_R}{m_J}\right) v_{Rx} = -\left(\frac{60.0 \text{ kg}}{90.0 \text{ kg}}\right)(0.700 \text{ m/s}) = -0.47 \text{ m/s}.$$ James' speed is 0.47 m/s.

EVALUATE: As they move, the two men have momenta that are equal in magnitude and opposite in direction, and the total momentum of the system is zero. Also, Example 8.14 shows that Ramon moves farther than James in the same time interval. This is consistent with Ramon having a greater speed.

8.58. **(a) IDENTIFY** and **SET UP:** Apply Eq. 8.28 and solve for m_1 and m_2.

EXECUTE: $y_{cm} = \dfrac{m_1 y_1 + m_2 y_2}{m_1 + m_2}$

$$m_1 + m_2 = \frac{m_1 y_1 + m_2 y_2}{y_{cm}} = \frac{m_1(0) + (0.50 \text{ kg})(6.0 \text{ m})}{2.4 \text{ m}} = 1.25 \text{ kg}$$ and $m_1 = 0.75$ kg.

EVALUATE: y_{cm} is closer to m_1 since $m_1 > m_2$.

(b) IDENTIFY and **SET UP:** Apply $\vec{a} = d\vec{v}/dt$ for the cm motion.

EXECUTE: $\vec{a}_{cm} = \dfrac{d\vec{v}_{cm}}{dt} = (1.5 \text{ m/s}^3)t\hat{i}.$

(c) IDENTIFY and **SET UP:** Apply Eq. 8.34.

EXECUTE: $\sum \vec{F}_{ext} = M\vec{a}_{cm} = (1.25 \text{ kg})(1.5 \text{ m/s}^3)t\hat{i}.$

At $t = 3.0$ s, $\sum \vec{F}_{ext} = (1.25 \text{ kg})(1.5 \text{ m/s}^3)(3.0 \text{ s})\hat{i} = (5.6 \text{ N})\hat{i}.$

EVALUATE: $v_{cm\text{-}x}$ is positive and increasing so $a_{cm\text{-}x}$ is positive and $\vec{F}_{ext}$ is in the $+x$-direction. There is no motion and no force component in the y-direction.

8.59. **IDENTIFY:** Apply $\sum \vec{F} = \dfrac{d\vec{P}}{dt}$ to the airplane.

SET UP: $\dfrac{d}{dt}(t^n) = nt^{n-1}$. $1 \text{ N} = 1 \text{ kg} \cdot \text{m/s}^2$

EXECUTE: $\dfrac{d\vec{P}}{dt} = [-(1.50 \text{ kg} \cdot \text{m/s}^3)t]\,\vec{i} + (0.25 \text{ kg} \cdot \text{m/s}^2)\,\vec{j}$. $F_x = -(1.50 \text{ N/s})t$, $F_y = 0.25$ N, $F_z = 0$.

EVALUATE: There is no momentum or change in momentum in the z direction and there is no force component in this direction.

8.60. **IDENTIFY:** Raising your leg changes the location of its center of mass and hence the location of your body's center of mass.

SET UP: The leg in each position is sketched in Figures 8.60a and 8.60b. Use the coordinates shown. The mass of each part of the leg may be taken as concentrated at the center of that part. The location of the x coordinate of the center of mass of two particles is $x_{cm} = \dfrac{m_1 x_1 + m_2 x_2}{m_1 + m_2}$. and likewise for the y coordinate.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

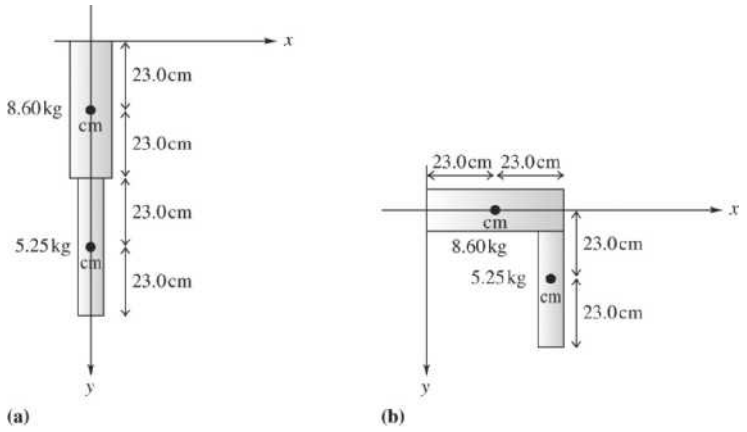

Figure 8.60

EXECUTE: **(a)** $x_{cm} = 0,\ y_{cm} = \dfrac{(23.0\text{ cm})(8.60\text{ kg}) + (69.0\text{ cm})(5.25\text{ kg})}{8.60\text{ kg} + 5.25\text{ kg}} = 40.4\text{ cm}$. The center of mass of the leg is 40.4 cm below the hip.

(b) $x_{cm} = \dfrac{(23.0\text{ cm})(8.60\text{ kg}) + (46.0\text{ cm})(5.25\text{ kg})}{8.60\text{ kg} + 5.25\text{ kg}} = 31.7\text{ cm}$ and $y_{cm} = \dfrac{0 + (23.0\text{ cm})(5.25\text{ kg})}{8.60\text{ kg} + 5.25\text{ kg}} = 8.7\text{ cm}$.

The center of mass is a vertical distance of 8.7 cm below the hip and a horizontal distance of 31.7 cm from the hip.

EVALUATE: Since the body is not a rigid object, the location of its center of mass is not fixed.

8.61. **IDENTIFY:** $a = -\dfrac{v_{ex}}{m}\dfrac{dm}{dt}$. Assume that dm/dt is constant over the 5.0 s interval, since m doesn't change much during that interval. The thrust is $F = -v_{ex}\dfrac{dm}{dt}$.

SET UP: Take m to have the constant value $110\text{ kg} + 70\text{ kg} = 180\text{ kg}$. dm/dt is negative since the mass of the MMU decreases as gas is ejected.

EXECUTE: **(a)** $\dfrac{dm}{dt} = -\dfrac{m}{v_{ex}}a = -\left(\dfrac{180\text{ kg}}{490\text{ m/s}}\right)(0.029\text{ m/s}^2) = -0.0106\text{ kg/s}$. In 5.0 s the mass that is ejected is $(0.0106\text{ kg/s})(5.0\text{ s}) = 0.053\text{ kg}$.

(b) $F = -v_{ex}\dfrac{dm}{dt} = -(490\text{ m/s})(-0.0106\text{ kg/s}) = 5.19\text{ N}$.

EVALUATE: The mass change in the 5.0 s is a very small fraction of the total mass m, so it is accurate to take m to be constant.

8.62. **IDENTIFY:** Use Eq. 8.38, applied to a finite time interval.

SET UP: $v_{ex} = 1600\text{ m/s}$

EXECUTE: **(a)** $F = -v_{ex}\dfrac{\Delta m}{\Delta t} = -(1600\text{ m/s})\dfrac{-0.0500\text{ kg}}{1.00\text{ s}} = +80.0\text{ N}$.

(b) The absence of atmosphere would not prevent the rocket from operating. The rocket could be steered by ejecting the gas in a direction with a component perpendicular to the rocket's velocity and braked by ejecting it in a direction parallel (as opposed to antiparallel) to the rocket's velocity.

EVALUATE: The thrust depends on the speed of the ejected gas relative to the rocket and on the mass of gas ejected per second.

8.63. **IDENTIFY** and **SET UP:** $(F_{av})\Delta t = J$ relates the impulse J to the average thrust F_{av}. Eq. 8.38 applied to a finite time interval gives $F_{av} = -v_{ex}\dfrac{\Delta m}{\Delta t}$. $v - v_0 = v_{ex}\ln\left(\dfrac{m_0}{m}\right)$. The remaining mass m after 1.70 s is 0.0133 kg.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: **(a)** $F_{\text{av}} = \dfrac{J}{\Delta t} = \dfrac{10.0 \text{ N}\cdot\text{s}}{1.70 \text{ s}} = 5.88 \text{ N}$. $F_{\text{av}}/F_{\text{max}} = 0.442$.

(b) $v_{\text{ex}} = -\dfrac{F_{\text{av}}\Delta t}{-0.0125 \text{ kg}} = 800 \text{ m/s}$.

(c) $v_0 = 0$ and $v = v_{\text{ex}} \ln\left(\dfrac{m_0}{m}\right) = (800 \text{ m/s}) \ln\left(\dfrac{0.0258 \text{ kg}}{0.0133 \text{ kg}}\right) = 530 \text{ m/s}$.

EVALUATE: The acceleration of the rocket is not constant. It increases as the mass remaining decreases.

8.64. **IDENTIFY** and **SET UP:** Use Eq. 8.40: $v - v_0 = v_{\text{ex}} \ln(m_0/m)$.

$v_0 = 0$ ("fired from rest"), so $v/v_{\text{ex}} = \ln(m_0/m)$.

Thus $m_0/m = e^{v/v_{\text{ex}}}$, or $m/m_0 = e^{-v/v_{\text{ex}}}$.

If v is the final speed then m is the mass left when all the fuel has been expended; m/m_0 is the fraction of the initial mass that is not fuel.

(a) EXECUTE: $v = 1.00\times10^{-3}c = 3.00\times10^{5}$ m/s gives

$$m/m_0 = e^{-(3.00\times10^5 \text{ m/s})/(2000 \text{ m/s})} = 7.2\times10^{-66}.$$

EVALUATE: This is clearly not feasible, for so little of the initial mass to not be fuel.

(b) EXECUTE: $v = 3000$ m/s gives $m/m_0 = e^{-(3000 \text{ m/s})/(2000 \text{ m/s})} = 0.223$.

EVALUATE: 22.3% of the total initial mass not fuel, so 77.7% is fuel; this is possible.

8.65. **IDENTIFY:** $v - v_0 = v_{\text{ex}} \ln\left(\dfrac{m_0}{m}\right)$.

SET UP: $v_0 = 0$.

EXECUTE: $\ln\left(\dfrac{m_0}{m}\right) = \dfrac{v}{v_{\text{ex}}} = \dfrac{8.00\times10^3 \text{ m/s}}{2100 \text{ m/s}} = 3.81$ and $\dfrac{m_0}{m} = e^{3.81} = 45.2$.

EVALUATE: Note that the final speed of the rocket is greater than the relative speed of the exhaust gas.

8.66. **IDENTIFY:** The westward force changes the westward momentum of the girl and gives her an acceleration in the westward direction. Since it changes her speed, it does work on her.

SET UP: We use $\int_{t_1}^{t_2} \vec{\boldsymbol{F}}(t)dt = \vec{\boldsymbol{p}}_2 - \vec{\boldsymbol{p}}_1$ to find the time for her final momentum to reach $60.0 \text{ kg}\cdot\text{m/s}$ in the westward direction, the work-energy theorem, $W_{\text{tot}} = K_2 - K_1$, to find the work done on her, and $F_x = ma_x$ to find her acceleration.

EXECUTE: **(a)** Let $+x$ be toward the east. $p_{1x} = +90.0 \text{ kg}\cdot\text{m/s}$ and $F_x(t) = -(8.20 \text{ N/s})t$. We want t_2 and have $t_1 = 0$. So $p_{2x} = p_{1x} + \int_{t_1}^{t_2} F_x(t)dt = +90.0 \text{ kg}\cdot\text{m/s} - (8.20 \text{ N/s})\int_0^{t_2} t dt = 90.0 \text{ kg}\cdot\text{m/s} - (4.10 \text{ N/s})t_2^2$. We know that $p_{2x} = -60.0 \text{ kg}\cdot\text{m/s}$, so $-60.0 \text{ kg}\cdot\text{m/s} = 90.0 \text{ kg}\cdot\text{m/s} - (4.10 \text{ N/s})t_2^2$, which gives $t_2 = 6.05$ s.

(b) $W_{\text{tot}} = K_2 - K_1$ and $K = \dfrac{p^2}{2m}$. $K_1 = \dfrac{p_{1x}^2}{2m} = \dfrac{(90.0 \text{ kg}\cdot\text{m/s})^2}{2(40.0 \text{ kg})} = 101.2 \text{ J}$ and

$K_2 = \dfrac{p_{2x}^2}{2m} = \dfrac{(60.0 \text{ kg}\cdot\text{m/s})^2}{2(40.0 \text{ kg})} = 45.0 \text{ J}$. $W_{\text{tot}} = K_2 - K_1 = 45.0 \text{ J} - 101.2 \text{ J} = -56.2 \text{ J}$.

(c) At $t = 6.05$ s, $F = (8.20 \text{ N/s})(6.05 \text{ s}) = 49.61 \text{ N}$, so $a = \dfrac{F}{m} = 1.24 \text{ m/s}^2$.

EVALUATE: The girl is initially moving eastward and the force on her is westward, so it reverses her momentum and does negative work on her which decreases her kinetic energy.

8.67. **IDENTIFY:** Use the heights to find v_{1y} and v_{2y}, the velocity of the ball just before and just after it strikes the slab. Then apply $J_y = F_y\Delta t = \Delta p_y$.

SET UP: Let $+y$ be downward.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: **(a)** $\frac{1}{2}mv^2 = mgh$ so $v = \pm\sqrt{2gh}$.

$v_{1y} = +\sqrt{2(9.80\ \text{m/s}^2)(2.00\ \text{m})} = 6.26\ \text{m/s}$. $v_{2y} = -\sqrt{2(9.80\ \text{m/s}^2)(1.60\ \text{m})} = -5.60\ \text{m/s}$.

$$J_y = \Delta p_y = m(v_{2y} - v_{1y}) = (40.0\times10^{-3}\ \text{kg})(-5.60\ \text{m/s} - 6.26\ \text{m/s}) = -0.474\ \text{kg}\cdot\text{m/s}.$$

The impulse is $0.474\ \text{kg}\cdot\text{m/s}$, upward.

(b) $F_y = \frac{J_y}{\Delta t} = \frac{-0.474\ \text{kg}\cdot\text{m/s}}{2.00\times10^{-3}\ \text{s}} = -237\ \text{N}$. The average force on the ball is 237 N, upward.

EVALUATE: The upward force on the ball changes the direction of its momentum.

8.68. **IDENTIFY:** Momentum is conserved in the explosion. At the highest point the velocity of the boulder is zero. Since one fragment moves horizontally the other fragment also moves horizontally. Use projectile motion to relate the initial horizontal velocity of each fragment to its horizontal displacement.

SET UP: Use coordinates where $+x$ is north. Since both fragments start at the same height with zero vertical component of velocity, the time in the air, t, is the same for both. Call the fragments A and B, with A being the one that lands to the north. Therefore, $m_B = 3m_A$.

EXECUTE: Apply $P_{1x} = P_{2x}$ to the collision: $0 = m_A v_{Ax} + m_B v_{Bx}$. $v_{Bx} = -\frac{m_A}{m_B}v_{Ax} = -v_{Ax}/3$. Apply projectile motion to the motion after the collision: $x - x_0 = v_{0x}t$. Since t is the same, $\frac{(x-x_0)_A}{v_{Ax}} = \frac{(x-x_0)_B}{v_{Bx}}$ and $(x-x_0)_B = \left(\frac{v_{Bx}}{v_{Ax}}\right)(x-x_0)_A = \left(\frac{-v_{Ax}/3}{v_{Ax}}\right)(x-x_0)_A = -(318\ \text{m})/3 = -106\ \text{m}$. The other fragment lands 106 m directly south of the point of explosion.

EVALUATE: The fragment that has three times the mass travels one-third as far.

8.69. **IDENTIFY:** The impulse, force and change in velocity are related by Eq. 8.9.

SET UP: $m = w/g = 0.0571$ kg. Since the force is constant, $\vec{F} = \vec{F}_{\text{av}}$.

EXECUTE: **(a)** $J_x = F_x\Delta t = (-380\ \text{N})(3.00\times10^{-3}\ \text{s}) = -1.14\ \text{N}\cdot\text{s}$.

$J_y = F_y\Delta t = (110\ \text{N})(3.00\times10^{-3}\ \text{s}) = 0.330\ \text{N}\cdot\text{s}$.

(b) $v_{2x} = \frac{J_x}{m} + v_{1x} = \frac{-1.14\ \text{N}\cdot\text{s}}{0.0571\ \text{kg}} + 20.0\ \text{m/s} = 0.04\ \text{m/s}$.

$v_{2y} = \frac{J_y}{m} + v_{1y} = \frac{0.330\ \text{N}\cdot\text{s}}{0.0571\ \text{kg}} + (-4.0\ \text{m/s}) = +1.8\ \text{m/s}$.

EVALUATE: The change in velocity $\Delta\vec{v}$ is in the same direction as the force, so $\Delta\vec{v}$ has a negative x component and a positive y component.

8.70. **IDENTIFY:** The total momentum of the system is conserved and is equal to zero, since the pucks are released from rest.

SET UP: Each puck has the same mass m. Let $+x$ be east and $+y$ be north. Let object A be the puck that moves west. All three pucks have the same speed v.

EXECUTE: $P_{1x} = P_{2x}$ gives $0 = -mv + mv_{Bx} + mv_{Cx}$ and $v = v_{Bx} + v_{Cx}$. $P_{1y} = P_{2y}$ gives $0 = mv_{By} + mv_{Cy}$ and $v_{By} = -v_{Cy}$. Since $v_B = v_C$ and the y components are equal in magnitude, the x components must also be equal: $v_{Bx} = v_{Cx}$ and $v = v_{Bx} + v_{Cx}$ says $v_{Bx} = v_{Cx} = v/2$. If v_{By} is positive then v_{Cy} is negative. The angle θ that puck B makes with the x axis is given by $\cos\theta = \frac{v/2}{v}$ and $\theta = 60°$. One puck moves in a direction $60°$ north of east and the other puck moves in a direction $60°$ south of east.

EVALUATE: Each component of momentum is separately conserved.

8.71. **IDENTIFY:** $P_x = p_{Ax} + p_{Bx}$ and $P_y = p_{Ay} + p_{By}$.

SET UP: Let object A be the convertible and object B be the SUV. Let $+x$ be west and $+y$ be south, $p_{Ax} = 0$ and $p_{By} = 0$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: $P_x = (7200 \text{ kg} \cdot \text{m/s})\sin 60.0° = 6235 \text{ kg} \cdot \text{m/s}$, so $p_{Bx} = 6235 \text{ kg} \cdot \text{m/s}$ and $v_{Bx} = \dfrac{6235 \text{ kg} \cdot \text{m/s}}{2000 \text{ kg}} = 3.12 \text{ m/s}$. $P_y = (7200 \text{ kg} \cdot \text{m/s})\cos 60.0° = 3600 \text{ kg} \cdot \text{m/s}$, so $p_{Bx} = 3600 \text{ kg} \cdot \text{m/s}$ and $v_{Ay} = \dfrac{3600 \text{ kg} \cdot \text{m/s}}{1500 \text{ kg}} = 2.40 \text{ m/s}$. The convertible has speed 2.40 m/s and the SUV has speed 3.12 m/s.

EVALUATE: Each component of the total momentum arises from a single vehicle.

8.72. **IDENTIFY:** Use a coordinate system attached to the ground. Take the x-axis to be east (along the tracks) and the y-axis to be north (parallel to the ground and perpendicular to the tracks). Then P_x is conserved and P_y is *not* conserved, due to the sideways force exerted by the tracks, the force that keeps the handcar on the tracks.

(a) SET UP: Let A be the 25.0 kg mass and B be the car (mass 175 kg). After the mass is thrown sideways relative to the car it still has the same eastward component of velocity, 5.00 m/s as it had before it was thrown.

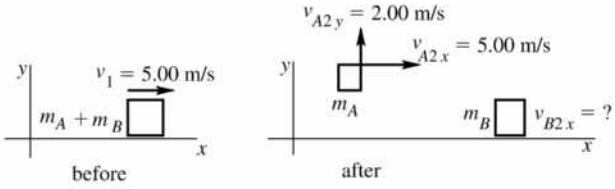

Figure 8.72a

P_x is conserved so $(m_A + m_B)v_1 = m_A v_{A2x} + m_B v_{B2x}$

EXECUTE: $(200 \text{ kg})(5.00 \text{ m/s}) = (25.0 \text{ kg})(5.00 \text{ m/s}) + (175 \text{ kg})v_{B2x}$.

$$v_{B2x} = \frac{1000 \text{ kg} \cdot \text{m/s} - 125 \text{ kg} \cdot \text{m/s}}{175 \text{ kg}} = 5.00 \text{ m/s}.$$

The final velocity of the car is 5.00 m/s, east (unchanged).

EVALUATE: The thrower exerts a force on the mass in the y-direction and by Newton's third law the mass exerts an equal and opposite force in the $-y$-direction on the thrower and car.

(b) SET UP: We are applying $P_x = \text{constant}$ in coordinates attached to the ground, so we need the final velocity of A relative to the ground. Use the relative velocity addition equation. Then use $P_x = \text{constant}$ to find the final velocity of the car.

EXECUTE: $\vec{v}_{A/E} = \vec{v}_{A/B} + \vec{v}_{B/E}$

$v_{B/E} = +5.00$ m/s

$v_{A/B} = -5.00$ m/s (minus since the mass is moving west relative to the car). This gives $v_{A/E} = 0$; the mass is at rest relative to the earth after it is thrown backwards from the car.

As in part (a) $(m_A + m_B)v_1 = m_A v_{A2x} + m_B v_{B2x}$.

Now $v_{A2x} = 0$, so $(m_A + m_B)v_1 = m_B v_{B2x}$.

$$v_{B2x} = \left(\frac{m_A + m_B}{m_B}\right)v_1 = \left(\frac{200 \text{ kg}}{175 \text{ kg}}\right)(5.00 \text{ m/s}) = 5.71 \text{ m/s}.$$

The final velocity of the car is 5.71 m/s, east.

EVALUATE: The thrower exerts a force in the $-x$-direction so the mass exerts a force on him in the $+x$-direction and he and the car speed up.

(c) SET UP: Let A be the 25.0 kg mass and B be the car (mass $m_B = 200$ kg).

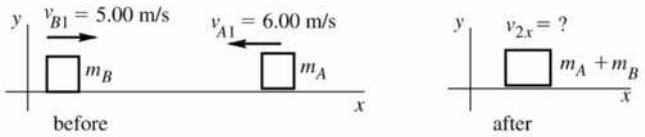

Figure 8.72b

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

P_x is conserved so $m_A v_{A1x} + m_B v_{B1x} = (m_A + m_B) v_{2x}$.

EXECUTE: $-m_A v_{A1} + m_B v_{B1} = (m_A + m_B) v_{2x}$.

$$v_{2x} = \frac{m_B v_{B1} - m_A v_{A1}}{m_A + m_B} = \frac{(200 \text{ kg})(5.00 \text{ m/s}) - (25.0 \text{ kg})(6.00 \text{ m/s})}{200 \text{ kg} + 25.0 \text{ kg}} = 3.78 \text{ m/s}.$$

The final velocity of the car is 3.78 m/s, east.

EVALUATE: The mass has negative p_x so reduces the total P_x of the system and the car slows down.

8.73. **IDENTIFY:** The x and y components of the momentum of the system are conserved.

SET UP: After the collision the combined object with mass $m_{\text{tot}} = 0.100$ kg moves with velocity $\vec{v}_2$. Solve for v_{Cx} and v_{Cy}.

EXECUTE: **(a)** $P_{1x} = P_{2x}$ gives $m_A v_{Ax} + m_B v_{Bx} + m_C v_{Cx} = m_{\text{tot}} v_{2x}$.

$$v_{Cx} = -\frac{m_A v_{Ax} + m_B v_{Bx} - m_{\text{tot}} v_{2x}}{m_C}$$

$$v_{Cx} = -\frac{(0.020 \text{ kg})(-1.50 \text{ m/s}) + (0.030 \text{ kg})(-0.50 \text{ m/s})\cos 60° - (0.100 \text{ kg})(0.50 \text{ m/s})}{0.050 \text{ kg}}.$$

$$v_{Cx} = 1.75 \text{ m/s}.$$

$P_{1y} = P_{2y}$ gives $m_A v_{Ay} + m_B v_{By} + m_C v_{Cy} = m_{\text{tot}} v_{2y}$.

$$v_{Cy} = -\frac{m_A v_{Ay} + m_B v_{By} - m_{tot} v_{2y}}{m_C} = -\frac{(0.030 \text{ kg})(-0.50 \text{ m/s})\sin 60°}{0.050 \text{ kg}} = +0.260 \text{ m/s}.$$

(b) $v_C = \sqrt{v_{Cx}^2 + v_{Cy}^2} = 1.77$ m/s. $\Delta K = K_2 - K_1$.

$\Delta K = \frac{1}{2}(0.100 \text{ kg})(0.50 \text{ m/s})^2 - [\frac{1}{2}(0.020 \text{ kg})(1.50 \text{ m/s})^2 + \frac{1}{2}(0.030 \text{ kg})(0.50 \text{ m/s})^2 + \frac{1}{2}(0.050 \text{ kg})(1.77 \text{ m/s})^2]$

$\Delta K = -0.092$ J.

EVALUATE: Since there is no horizontal external force the vector momentum of the system is conserved. The forces the spheres exert on each other do negative work during the collision and this reduces the kinetic energy of the system.

8.74. **IDENTIFY:** Each component of horizontal momentum is conserved.

SET UP: Let $+x$ be east and $+y$ be north. $v_{S1y} = v_{A1x} = 0$. $v_{S2x} = (6.00 \text{ m/s})\cos 37.0° = 4.79$ m/s, $v_{S2y} = (6.00 \text{ m/s})\sin 37.0° = 3.61$ m/s, $v_{A2x} = (9.00 \text{ m/s})\cos 23.0° = 8.28$ m/s and $v_{A2y} = -(9.00 \text{ m/s})\sin 23.0° = -3.52$ m/s.

EXECUTE: $P_{1x} = P_{2x}$ gives $m_S v_{S1x} = m_S v_{S2x} + m_A v_{A2x}$.

$$v_{S1x} = \frac{m_S v_{S2x} + m_A v_{A2x}}{m_S} = \frac{(80.0 \text{ kg})(4.79 \text{ m/s}) + (50.0 \text{ kg})(8.28 \text{ m/s})}{80.0 \text{ kg}} = 9.97 \text{ m/s}.$$

Sam's speed before the collision was 9.97 m/s.

$P_{1y} = P_{2y}$ gives $m_A v_{A1y} = m_S v_{S2y} + m_A v_{A2y}$.

$$v_{A1y} = \frac{m_S v_{S2y} + m_A v_{A2y}}{m_S} = \frac{(80.0 \text{ kg})(3.61 \text{ m/s}) + (50.0 \text{ kg})(-3.52 \text{ m/s})}{50.0 \text{ kg}} = 2.26 \text{ m/s}.$$

Abigail's speed before the collision was 2.26 m/s.

(b) $\Delta K = \frac{1}{2}(80.0 \text{ kg})(6.00 \text{ m/s})^2 + \frac{1}{2}(50.0 \text{ kg})(9.00 \text{ m/s})^2 - \frac{1}{2}(80.0 \text{ kg})(9.97 \text{ m/s})^2 - \frac{1}{2}(50.0 \text{ kg})(2.26 \text{ m/s})^2$.

$\Delta K = -639$ J.

EVALUATE: The total momentum is conserved because there is no net external horizontal force. The kinetic energy decreases because the forces between the objects do negative work during the collision.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

8.75. **IDENTIFY:** Apply conservation of momentum to the nucleus and its fragments. The initial momentum is zero. The ^{214}Po nucleus has mass $214(1.67\times10^{-27}\text{ kg}) = 3.57\times10^{-25}\text{ kg}$, where $1.67\times10^{-27}\text{ kg}$ is the mass of a nucleon (proton or neutron). $K = \frac{1}{2}mv^2$.

SET UP: Let $+x$ be the direction in which the alpha particle is emitted. The nucleus that is left after the decay has mass $m_n = 3.75\times10^{-25}\text{ kg} - m_\alpha = 3.57\times10^{-25}\text{ kg} - 6.65\times10^{-27}\text{ kg} = 3.50\times10^{-25}\text{ kg}$.

EXECUTE: $P_{2x} = P_{1x} = 0$ gives $m_\alpha v_\alpha + m_n v_n = 0$. $v_n = \dfrac{m_\alpha}{m_n} v_\alpha$.

$v_\alpha = \sqrt{\dfrac{2K_\alpha}{m_\alpha}} = \sqrt{\dfrac{2(1.23\times10^{-12}\text{ J})}{6.65\times10^{-27}\text{ kg}}} = 1.92\times10^7\text{ m/s}$. $v_n = \left(\dfrac{6.65\times10^{-27}\text{ kg}}{3.50\times10^{-25}\text{ kg}}\right)(1.92\times10^7\text{ m/s}) = 3.65\times10^5\text{ m/s}$.

EVALUATE: The recoil velocity of the more massive nucleus is much less than the speed of the emitted alpha particle.

8.76. **IDENTIFY:** Kinetic energy is $K = \frac{1}{2}mv^2$ and the magnitude of the momentum is $p = mv$. The force and the time t it acts are related to the change in momentum whereas the force and distance d it acts are related to the change in kinetic energy.

SET UP: Assume the net forces are constant and let the forces and the motion be along the x axis. The impulse-momentum theorem then says $Ft = \Delta p$ and the work-energy theorem says $Fd = \Delta K$.

EXECUTE: **(a)** $K_N = \frac{1}{2}(840\text{ kg})(9.0\text{ m/s})^2 = 3.40\times10^4$ J. $K_P = \frac{1}{2}(1620\text{ kg})(5.0\text{ m/s})^2 = 2.02\times10^4$ J. The Nash has the greater kinetic energy and $\dfrac{K_N}{K_P} = 1.68$.

(b) $p_N = (840\text{ kg})(9.0\text{ m/s}) = 7.56\times10^3\text{ kg}\cdot\text{m/s}$. $p_P = (1620\text{ kg})(5.0\text{ m/s}) = 8.10\times10^3\text{ kg}\cdot\text{m/s}$. The Packard has the greater magnitude of momentum and $\dfrac{p_N}{p_P} = 0.933$.

(c) Since the cars stop, the magnitude of the change in momentum equals the initial momentum. Since $p_P > p_N$, $F_P > F_N$ and $\dfrac{F_N}{F_P} = \dfrac{p_N}{p_P} = 0.933$.

(d) Since the cars stop, the magnitude of the change in kinetic energy equals the initial kinetic energy. Since $K_N > K_P$, $F_N > F_P$ and $\dfrac{F_N}{F_P} = \dfrac{K_N}{K_P} = 1.68$.

EVALUATE: If the stopping forces were the same, the Packard would have a larger stopping time but would travel a shorter distance while stopping. This is consistent with it having a smaller initial speed.

8.77. **IDENTIFY:** Momentum is conserved during the collision, and the wood (with the clay attached) is in free fall as it falls since only gravity acts on it.

SET UP: Apply conservation of momentum to the collision to find the velocity V of the combined object just after the collision. After the collision, the wood's downward acceleration is g and it has no horizontal acceleration, so we can use the standard kinematics equations: $y - y_0 = v_{0y}t + \dfrac{1}{2}a_y t^2$ and $x - x_0 = v_{0x}t + \dfrac{1}{2}a_x t^2$.

EXECUTE: Momentum conservation gives $(0.500\text{ kg})(24.0\text{ m/s}) = (8.50\text{ kg})V$, so $V = 1.412$ m/s. Consider the projectile motion after the collision: $a_y = +9.8\text{ m/s}^2$, $v_{0y} = 0$, $y - y_0 = +2.20$ m, and t is unknown.

$y - y_0 = v_{0y}t + \dfrac{1}{2}a_y t^2$ gives $t = \sqrt{\dfrac{2(y - y_0)}{a_y}} = \sqrt{\dfrac{2(2.20\text{ m})}{9.8\text{ m/s}^2}} = 0.6701$ s. The horizontal acceleration is zero so $x - x_0 = v_{0x}t + \dfrac{1}{2}a_x t^2 = (1.412\text{ m/s})(0.6701\text{ s}) = 0.946$ m.

EVALUATE: The momentum is *not* conserved after the collision because an external force (gravity) acts on the system. Mechanical energy is *not* conserved during the collision because the clay and block stick together, making it an inelastic collision.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

8.78. **IDENTIFY:** An inelastic collision (the objects stick together) occurs during which momentum is conserved, followed by a swing during which mechanical energy is conserved. The target variable is the initial speed of the bullet.

SET UP: Newton's second law, $\Sigma\vec{F} = m\vec{a}$, will relate the tension in the cord to the speed of the block during the swing. Mechanical energy is conserved after the collision, and momentum is conserved during the collision.

EXECUTE: First find the speed v of the block, at a height of 0.800 m. The mass of the combined object is 0.812 kg. $\cos\theta = \dfrac{0.8\text{ m}}{1.6\text{ m}} = 0.50$ so $\theta = 60.0^\circ$ is the angle the cord makes with the vertical. At this position, Newton's second law gives $T - mg\cos\theta = m\dfrac{v^2}{R}$, where we have taken force components toward the center of the circle. Solving for v gives $v = \sqrt{\dfrac{R}{m}(T - mg\cos\theta)} = \sqrt{\dfrac{1.6\text{ m}}{0.812\text{ kg}}(4.80\text{ N} - 3.979\text{ N})} = 1.272$ m/s. Now apply conservation of energy to find the velocity V of the combined object just after the collision: $\frac{1}{2}mV^2 = mgh + \frac{1}{2}mv^2$. Solving for V gives

$V = \sqrt{2gh + v^2} = \sqrt{2(9.8\text{ m/s}^2)(0.8\text{ m}) + (1.272\text{ m/s})^2} = 4.159$ m/s. Now apply conservation of momentum to the collision: $(0.012\text{ kg})v_0 = (0.812\text{ kg})(4.159\text{ m/s})$, which gives $v_0 = 281$ m/s.

EVALUATE: We cannot solve this problem in a single step because different conservation laws apply to the collision and the swing.

8.79. **IDENTIFY:** During the collision, momentum is conserved, but after the collision mechanical energy is conserved. We cannot solve this problem in a single step because the collision and the motion after the collision involve different conservation laws.

SET UP: Use coordinates where $+x$ is to the right and $+y$ is upward. Momentum is conserved during the collision, so $P_{1x} = P_{2x}$. Energy is conserved after the collision, so $K_1 = U_2$, where $K = \frac{1}{2}mv^2$ and $U = mgh$.

EXECUTE: *Collision*: There is no external horizontal force during the collision so $P_{1x} = P_{2x}$. This gives $(5.00\text{ kg})(12.0\text{ m/s}) = (10.0\text{ kg})v_2$ and $v_2 = 6.0$ m/s.

Motion after the collision: Only gravity does work and the initial kinetic energy of the combined chunks is converted entirely to gravitational potential energy when the chunk reaches its maximum height h above the valley floor. Conservation of energy gives $\frac{1}{2}m_{\text{tot}}v^2 = m_{\text{tot}}gh$ and $h = \dfrac{v^2}{2g} = \dfrac{(6.0\text{ m/s})^2}{2(9.8\text{ m/s}^2)} = 1.8$ m.

EVALUATE: After the collision the energy of the system is $\frac{1}{2}m_{\text{tot}}v^2 = \frac{1}{2}(10.0\text{ kg})(6.0\text{ m/s})^2 = 180$ J when it is all kinetic energy and the energy is $m_{\text{tot}}gh = (10.0\text{ kg})(9.8\text{ m/s}^2)(1.8\text{ m}) = 180$ J when it is all gravitational potential energy. Mechanical energy is conserved during the motion after the collision. But before the collision the total energy of the system is $\frac{1}{2}(5.0\text{ kg})(12.0\text{ m/s})^2 = 360$ J; 50% of the mechanical energy is dissipated during the inelastic collision of the two chunks.

8.80. **IDENTIFY:** During the inelastic collision, momentum is conserved but not mechanical energy. After the collision, momentum is not conserved and the kinetic energy of the cars is dissipated by nonconservative friction.

SET UP: Treat the collision and motion after the collision as separate events. Apply conservation of momentum to the collision and conservation of energy to the motion after the collision. The friction force on the combined cars is $\mu_k(m_A + m_B)g$.

EXECUTE: *Motion after the collision*: The kinetic energy of the combined cars immediately after the collision is taken away by the negative work done by friction: $\frac{1}{2}(m_A + m_B)V^2 = \mu_k(m_A + m_B)gd$, where $d = 7.15$ m. This gives $V = \sqrt{2\mu_k gd} = 9.54$ m/s.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

Collision: Momentum conservation gives $m_A v_A = (m_A + m_B)V$, which gives

$$v_A = \left(\frac{m_A + m_B}{m_A}\right)V = \left(\frac{1500\text{ kg} + 1900\text{ kg}}{1500\text{ kg}}\right)(9.54\text{ m/s}) = 21.6\text{ m/s}.$$

(b) $v_A = 21.6$ m/s = 48 mph, which is 13 mph greater than the speed limit.

EVALUATE: We cannot solve this problem in a single step because the collision and the motion after the collision involve different principles (momentum conservation and energy conservation).

8.81. **IDENTIFY:** During the inelastic collision, momentum is conserved (in two dimensions), but after the collision we must use energy principles.

SET UP: The friction force is $\mu_k m_{tot} g$. Use energy considerations to find the velocity of the combined object immediately after the collision. Apply conservation of momentum to the collision. Use coordinates where $+x$ is west and $+y$ is south. For momentum conservation, we have $P_{1x} = P_{2x}$ and $P_{1y} = P_{2y}$.

EXECUTE: *Motion after collision*: The negative work done by friction takes away all the kinetic energy that the combined object has just after the collision. Calling ϕ the angle south of west at which the enmeshed cars slid, we have $\tan\phi = \dfrac{6.43\text{ m}}{5.39\text{ m}}$ and $\phi = 50.0°$. The wreckage slides 8.39 m in a direction $50.0°$ south of west. Energy conservation gives $\frac{1}{2}m_{tot}V^2 = \mu_k m_{tot} g d$, so $V = \sqrt{2\mu_k g d} = \sqrt{2(0.75)(9.80\text{ m/s}^2)(8.39\text{ m})} = 11.1$ m/s. The velocity components are $V_x = V\cos\phi = 7.13$ m/s; $V_y = V\sin\phi = 8.50$ m/s.

Collision: $P_{1x} = P_{2x}$ gives $(2200\text{ kg})v_{SUV} = (1500\text{ kg} + 2200\text{ kg})V_x$ and $v_{SUV} = 12$ m/s. $P_{1y} = P_{2y}$ gives $(1500\text{ kg})v_{sedan} = (1500\text{ kg} + 2200\text{ kg})V_y$ and $v_{sedan} = 21$ m/s.

EVALUATE: We cannot solve this problem in a single step because the collision and the motion after the collision involve different principles (momentum conservation and energy conservation).

8.82. **IDENTIFY:** Find k for the spring from the forces when the frame hangs at rest, use constant acceleration equations to find the speed of the putty just before it strikes the frame, apply conservation of momentum to the collision between the putty and the frame and then apply conservation of energy to the motion of the frame after the collision.

SET UP: Use the free-body diagram in Figure 8.82a for the frame when it hangs at rest on the end of the spring to find the force constant k of the spring. Let s be the amount the spring is stretched.

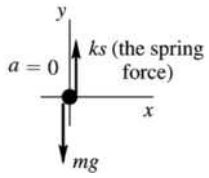

Figure 8.82a

EXECUTE: $\Sigma F_y = ma_y$ gives $-mg + ks = 0$. $k = \dfrac{mg}{s} = \dfrac{(0.150\text{ kg})(9.80\text{ m/s}^2)}{0.070\text{ m}} = 21.0$ N/m.

SET UP: Next find the speed of the putty when it reaches the frame. The putty falls with acceleration $a = g$, downward (see Figure 8.82b).

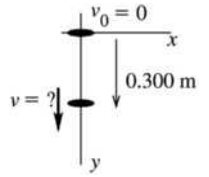

Figure 8.82b

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$v_0 = 0$, $y - y_0 = 0.300$ m, $a = +9.80$ m/s^2, and we want to find v. The constant-acceleration $v^2 = v_0^2 + 2a(y - y_0)$ applies to this motion.

EXECUTE: $v = \sqrt{2a(y - y_0)} = \sqrt{2(9.80 \text{ m/s}^2)(0.300 \text{ m})} = 2.425$ m/s.

SET UP: Apply conservation of momentum to the collision between the putty (A) and the frame (B). See Figure 8.82c.

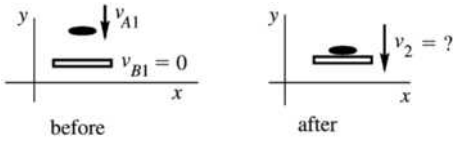

Figure 8.82c

P_y is conserved, so $-m_A v_{A1} = -(m_A + m_B)v_2$.

EXECUTE: $v_2 = \left(\dfrac{m_A}{m_A + m_B}\right)v_{A1} = \left(\dfrac{0.200 \text{ kg}}{0.350 \text{ kg}}\right)(2.425 \text{ m/s}) = 1.386$ m/s.

SET UP: Apply conservation of energy to the motion of the frame on the end of the spring after the collision. Let point 1 be just after the putty strikes and point 2 be when the frame has its maximum downward displacement. Let d be the amount the frame moves downward (see Figure 8.82d).

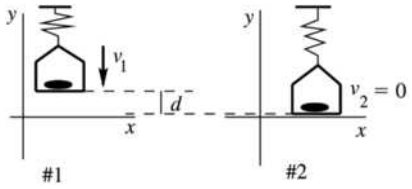

Figure 8.82d

When the frame is at position 1 the spring is stretched a distance $x_1 = 0.070$ m. When the frame is at position 2 the spring is stretched a distance $x_2 = 0.070 \text{ m} + d$. Use coordinates with the y-direction upward and $y = 0$ at the lowest point reached by the frame, so that $y_1 = d$ and $y_2 = 0$. Work is done on the frame by gravity and by the spring force, so $W_{\text{other}} = 0$, and $U = U_{\text{el}} + U_{\text{gravity}}$.

EXECUTE: $K_1 + U_1 + W_{\text{other}} = K_2 + U_2$. $W_{\text{other}} = 0$.

$K_1 = \frac{1}{2}mv_1^2 = \frac{1}{2}(0.350 \text{ kg})(1.386 \text{ m/s})^2 = 0.3362$ J.

$U_1 = U_{1,\text{el}} + U_{1,\text{grav}} = \frac{1}{2}kx_1^2 + mgy_1 = \frac{1}{2}(21.0 \text{ N/m})(0.070 \text{ m})^2 + (0.350 \text{ kg})(9.80 \text{ m/s}^2)d$.

$U_1 = 0.05145 \text{ J} + (3.43 \text{ N})d$. $U_2 = U_{2,\text{el}} + U_{2,\text{grav}} = \frac{1}{2}kx_2^2 + mgy_2 = \frac{1}{2}(21.0 \text{ N/m})(0.070 \text{ m} + d)^2$.

$U_2 = 0.05145 \text{ J} + (1.47 \text{ N})d + (10.5 \text{ N/m})d^2$. Thus

$0.3362 \text{ J} + 0.05145 \text{ J} + (3.43 \text{ N})d = 0.05145 \text{ J} + (1.47 \text{ N})d + (10.5 \text{ N/m})d^2$.

$(10.5 \text{ N/m})d^2 - (1.96 \text{ N})d - 0.3362 \text{ J} = 0$.

$d = \dfrac{1.96 \pm \sqrt{(1.96)^2 - 4(10.5)(-0.3362)}}{21.0}$ m $= 0.09333 \text{ m} \pm 0.2018$ m. The solution we want is a positive (downward) distance, so $d = 0.09333 \text{ m} + 0.2018 \text{ m} = 0.295$ m.

EVALUATE: The collision is inelastic and mechanical energy is lost. Thus the decrease in gravitational potential energy is *not* equal to the increase in potential energy stored in the spring.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

8.83. **IDENTIFY:** Apply conservation of momentum to the collision and conservation of energy to the motion after the collision.

SET UP: Let $+x$ be to the right. The total mass is $m = m_{\text{bullet}} + m_{\text{block}} = 1.00$ kg. The spring has force constant $k = \dfrac{|F|}{|x|} = \dfrac{0.750 \text{ N}}{0.250\times10^{-2} \text{ m}} = 300$ N/m. Let V be the velocity of the block just after impact.

EXECUTE: **(a)** Conservation of energy for the motion after the collision gives $K_1 = U_{\text{el}2}$. $\frac{1}{2}mV^2 = \frac{1}{2}kx^2$ and

$$V = x\sqrt{\frac{k}{m}} = (0.150 \text{ m})\sqrt{\frac{300 \text{ N/m}}{1.00 \text{ kg}}} = 2.60 \text{ m/s}.$$

(b) Conservation of momentum applied to the collision gives $m_{\text{bullet}}v_1 = mV$.

$$v_1 = \frac{mV}{m_{\text{bullet}}} = \frac{(1.00 \text{ kg})(2.60 \text{ m/s})}{8.00\times10^{-3} \text{ kg}} = 325 \text{ m/s}.$$

EVALUATE: The initial kinetic energy of the bullet is 422 J. The energy stored in the spring at maximum compression is 3.38 J. Most of the initial mechanical energy of the bullet is dissipated in the collision.

8.84. **IDENTIFY:** The horizontal components of momentum of the system of bullet plus stone are conserved. The collision is elastic if $K_1 = K_2$.

SET UP: Let A be the bullet and B be the stone.

(a)

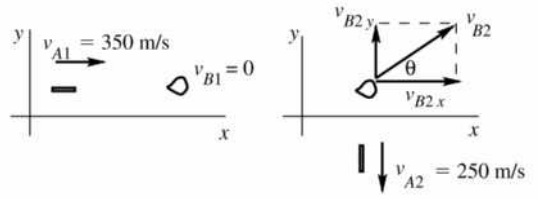

Figure 8.84

EXECUTE: P_x is conserved so $m_Av_{A1x} + m_Bv_{B1x} = m_Av_{A2x} + m_Bv_{B2x}$.

$m_Av_{A1} = m_Bv_{B2x}$.

$$v_{B2x} = \left(\frac{m_A}{m_B}\right)v_{A1} = \left(\frac{6.00\times10^{-3} \text{ kg}}{0.100 \text{ kg}}\right)(350 \text{ m/s}) = 21.0 \text{ m/s}$$

P_y is conserved so $m_Av_{A1y} + m_Bv_{B1y} = m_Av_{A2y} + m_Bv_{B2y}$.

$0 = -m_Av_{A2} + m_Bv_{B2y}$.

$$v_{B2y} = \left(\frac{m_A}{m_B}\right)v_{A2} = \left(\frac{6.00\times10^{-3} \text{ kg}}{0.100 \text{ kg}}\right)(250 \text{ m/s}) = 15.0 \text{ m/s}.$$

$$v_{B2} = \sqrt{v_{B2x}^2 + v_{B2y}^2} = \sqrt{(21.0 \text{ m/s})^2 + (15.0 \text{ m/s})^2} = 25.8 \text{ m/s}.$$

$\tan\theta = \dfrac{v_{B2y}}{v_{B2x}} = \dfrac{15.0 \text{ m/s}}{21.0 \text{ m/s}} = 0.7143$; $\theta = 35.5°$ (defined in the sketch).

(b) To answer this question compare K_1 and K_2 for the system:

$$K_1 = \tfrac{1}{2}m_Av_{A1}^2 + \tfrac{1}{2}m_Bv_{B1}^2 = \tfrac{1}{2}(6.00\times10^{-3} \text{ kg})(350 \text{ m/s})^2 = 368 \text{ J}.$$

$$K_2 = \tfrac{1}{2}m_Av_{A2}^2 + \tfrac{1}{2}m_Bv_{B2}^2 = \tfrac{1}{2}(6.00\times10^{-3} \text{ kg})(250 \text{ m/s})^2 + \tfrac{1}{2}(0.100 \text{ kg})(25.8 \text{ m/s})^2 = 221 \text{ J}.$$

$$\Delta K = K_2 - K_1 = 221 \text{ J} - 368 \text{ J} = -147 \text{ J}.$$

EVALUATE: The kinetic energy of the system decreases by 147 J as a result of the collision; the collision is *not* elastic. Momentum is conserved because $\Sigma \boldsymbol{F}_{\text{ext},x} = 0$ and $\Sigma \boldsymbol{F}_{\text{ext},y} = 0$. But there are internal forces between the bullet and the stone. These forces do negative work that reduces K.

8.85. **IDENTIFY:** Apply conservation of momentum to the collision between the two people. Apply conservation of energy to the motion of the stuntman before the collision and to the entwined people after the collision.

SET UP: For the motion of the stuntman, $y_1 - y_2 = 5.0$ m. Let v_S be the magnitude of his horizontal velocity just before the collision. Let V be the speed of the entwined people just after the collision. Let d be the distance they slide along the floor.

EXECUTE: **(a)** Motion before the collision: $K_1 + U_1 = K_2 + U_2$. $K_1 = 0$ and $\frac{1}{2}mv_S^2 = mg(y_1 - y_2)$.

$$v_S = \sqrt{2g(y_1 - y_2)} = \sqrt{2(9.80 \text{ m/s}^2)(5.0 \text{ m})} = 9.90 \text{ m/s}.$$

Collision: $m_S v_S = m_{tot} V$. $V = \frac{m_S}{m_{tot}} v_S = \left(\frac{80.0 \text{ kg}}{150.0 \text{ kg}}\right)(9.90 \text{ m/s}) = 5.28 \text{ m/s}.$

(b) Motion after the collision: $K_1 + U_1 + W_{other} = K_2 + U_2$ gives $\frac{1}{2}m_{tot}V^2 - \mu_k m_{tot} g d = 0$.

$$d = \frac{V^2}{2\mu_k g} = \frac{(5.28 \text{ m/s})^2}{2(0.250)(9.80 \text{ m/s}^2)} = 5.7 \text{ m}.$$

EVALUATE: Mechanical energy is dissipated in the inelastic collision, so the kinetic energy just after the collision is less than the initial potential energy of the stuntman.

8.86. **IDENTIFY:** Apply conservation of energy to the motion before and after the collision and apply conservation of momentum to the collision.

SET UP: Let v be the speed of the mass released at the rim just before it strikes the second mass. Let each object have mass m.

EXECUTE: Conservation of energy says $\frac{1}{2}mv^2 = mgR$; $v = \sqrt{2gR}$.

SET UP: This is speed v_1 for the collision. Let v_2 be the speed of the combined object just after the collision.

EXECUTE: Conservation of momentum applied to the collision gives $mv_1 = 2mv_2$ so $v_2 = v_1/2 = \sqrt{gR/2}$.

SET UP: Apply conservation of energy to the motion of the combined object after the collision. Let y_3 be the final height above the bottom of the bowl.

EXECUTE: $\frac{1}{2}(2m)v_2^2 = (2m)gy_3$.

$$y_3 = \frac{v_2^2}{2g} = \frac{1}{2g}\left(\frac{gR}{2}\right) = R/4.$$

EVALUATE: Mechanical energy is lost in the collision, so the final gravitational potential energy is less than the initial gravitational potential energy.

8.87. **IDENTIFY:** Eqs. 8.24 and 8.25 give the outcome of the elastic collision. Apply conservation of energy to the motion of the block after the collision.

SET UP: Object B is the block, initially at rest. If L is the length of the wire and θ is the angle it makes with the vertical, the height of the block is $y = L(1 - \cos\theta)$. Initially, $y_1 = 0$.

EXECUTE: Eq. 8.25 gives $v_B = \left(\frac{2m_A}{m_A + m_B}\right)v_A = \left(\frac{2M}{M + 3M}\right)(4.00 \text{ m/s}) = 2.00 \text{ m/s}.$

Conservation of energy gives $\frac{1}{2}m_B v_B^2 = m_B gL(1 - \cos\theta)$.

$$\cos\theta = 1 - \frac{v_B^2}{2gL} = 1 - \frac{(2.00 \text{ m/s})^2}{2(9.80 \text{ m/s}^2)(0.500 \text{ m})} = 0.5918, \text{ which gives } \theta = 53.7°.$$

EVALUATE: Only a portion of the initial kinetic energy of the ball is transferred to the block in the collision.

8.88. **IDENTIFY:** Apply conservation of energy to the motion before and after the collision. Apply conservation of momentum to the collision.

SET UP: First consider the motion after the collision. The combined object has mass $m_{tot} = 25.0$ kg. Apply $\Sigma\vec{F} = m\vec{a}$ to the object at the top of the circular loop, where the object has speed v_3. The acceleration is $a_{rad} = v_3^2/R$, downward.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: $T + mg = m\dfrac{v_3^2}{R}$.

The minimum speed v_3 for the object not to fall out of the circle is given by setting $T = 0$. This gives $v_3 = \sqrt{Rg}$, where $R = 3.50$ m.

SET UP: Next, use conservation of energy with point 2 at the bottom of the loop and point 3 at the top of the loop. Take $y = 0$ at point 2. Only gravity does work, so $K_2 + U_2 = K_3 + U_3$

EXECUTE: $\frac{1}{2}m_{\text{tot}}v_2^2 = \frac{1}{2}m_{\text{tot}}v_3^2 + m_{\text{tot}}g(2R)$.

Use $v_3 = \sqrt{Rg}$ and solve for v_2: $v_2 = \sqrt{5gR} = 13.1$ m/s.

SET UP: Now apply conservation of momentum to the collision between the dart and the sphere. Let v_1 be the speed of the dart before the collision.

EXECUTE: $(5.00\text{ kg})v_1 = (25.0\text{ kg})(13.1\text{ m/s})$.

$v_1 = 65.5$ m/s.

EVALUATE: The collision is inelastic and mechanical energy is removed from the system by the negative work done by the forces between the dart and the sphere.

8.89. **IDENTIFY:** Use Eq. 8.25 to find the speed of the hanging ball just after the collision. Apply $\Sigma\vec{\boldsymbol{F}} = m\vec{\boldsymbol{a}}$ to find the tension in the wire. After the collision the hanging ball moves in an arc of a circle with radius $R = 1.35$ m and acceleration $a_{\text{rad}} = v^2/R$.

SET UP: Let A be the 2.00 kg ball and B be the 8.00 kg ball. For applying $\Sigma\vec{\boldsymbol{F}} = m\vec{\boldsymbol{a}}$ to the hanging ball, let $+y$ be upward, since $\vec{\boldsymbol{a}}_{\text{rad}}$ is upward. The free-body force diagram for the 8.00 kg ball is given in Figure 8.89.

EXECUTE: $v_{B2x} = \left(\dfrac{2m_A}{m_A + m_B}\right)v_{A1x} = \left(\dfrac{2[2.00\text{kg}]}{2.00\text{ kg} + 8.00\text{ kg}}\right)(5.00\text{ m/s}) = 2.00\text{ m/s}$. Just after the collision the 8.00 kg ball has speed $v = 2.00$ m/s. Using the free-body diagram, $\Sigma F_y = ma_y$ gives $T - mg = ma_{\text{rad}}$.

$$T = m\left(g + \frac{v^2}{R}\right) = (8.00\text{ kg})\left(9.80\text{ m/s}^2 + \frac{[2.00\text{ m/s}]^2}{1.35\text{ m}}\right) = 102\text{ N}.$$

EVALUATE: The tension before the collision is the weight of the ball, 78.4 N. Just after the collision, when the ball has started to move, the tension is greater than this.

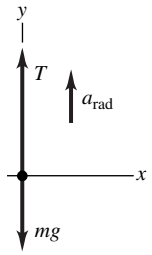

Figure 8.89

8.90. **IDENTIFY:** The momentum during the explosion is conserved, but kinetic energy is created from the energy released by the exploding fuel or powder.

SET UP: Call the fragments A and B, with $m_A = 2.0$ kg and $m_B = 5.0$ kg. After the explosion fragment A moves in the $+x$-direction with speed v_A and fragment B moves in the $-x$-direction with speed v_B. Momentum conservation gives $P_1 = P_2$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

SOLVE: From momentum conservation, we have $P_{1x} = P_{2x}$, so $0 = m_A v_A + m_B(-v_B)$, which gives $v_A = \left(\frac{m_B}{m_A}\right)v_B = \left(\frac{5.0\text{ kg}}{2.0\text{ kg}}\right)v_B = 2.5v_B$. The ratio of the kinetic energies is

$\frac{K_A}{K_B} = \frac{\frac{1}{2}m_A{v_A}^2}{\frac{1}{2}m_B{v_B}^2} = \frac{\frac{1}{2}(2.0\text{ kg})(2.5v_B)^2}{\frac{1}{2}(5.0\text{ kg}){v_B}^2} = \frac{12.5}{5.0} = 2.5$. Since $K_A = 100$ J, we have $K_B = 250$ J.

EVALUATE: In an explosion the lighter fragment receives more of the liberated energy, but both fragments receive the same amount of momentum.

8.91. **IDENTIFY:** Apply conservation of momentum to the collision between the bullet and the block and apply conservation of energy to the motion of the block after the collision.

(a) SET UP: For the collision between the bullet and the block, let object A be the bullet and object B be the block. Apply momentum conservation to find the speed v_{B2} of the block just after the collision (see Figure 8.91a).

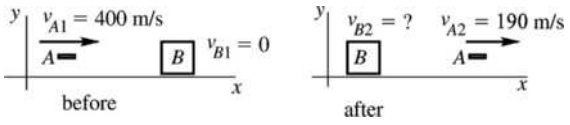

Figure 8.91a

EXECUTE: P_x is conserved so $m_A v_{A1x} + m_B v_{B1x} = m_A v_{A2x} + m_B v_{B2x}$. $m_A v_{A1} = m_A v_{A2} + m_B v_{B2x}$.

$v_{B2x} = \frac{m_A(v_{A1} - v_{A2})}{m_B} = \frac{4.00\times10^{-3}\text{ kg}(400\text{ m/s} - 190\text{ m/s})}{0.800\text{ kg}} = 1.05\text{ m/s}.$

SET UP: For the motion of the block after the collision, let point 1 in the motion be just after the collision, where the block has the speed 1.05 m/s calculated above, and let point 2 be where the block has come to rest (see Figure 8.91b).

$K_1 + U_1 + W_{\text{other}} = K_2 + U_2$.

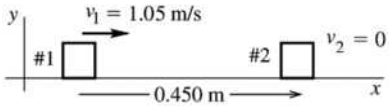

Figure 8.91b

EXECUTE: Work is done on the block by friction, so $W_{\text{other}} = W_f$.

$W_{\text{other}} = W_f = (f_k\cos\phi)s = -f_k s = -\mu_k mgs$, where $s = 0.450$ m. $U_1 = 0$, $U_2 = 0$, $K_1 = \frac{1}{2}mv_1^2$, $K_2 = 0$ (the block has come to rest). Thus $\frac{1}{2}mv_1^2 - \mu_k mgs = 0$. Therefore $\mu_k = \frac{v_1^2}{2gs} = \frac{(1.05\text{ m/s})^2}{2(9.80\text{ m/s}^2)(0.450\text{ m})} = 0.125.$

(b) For the bullet, $K_1 = \frac{1}{2}mv_1^2 = \frac{1}{2}(4.00\times10^{-3}\text{ kg})(400\text{ m/s})^2 = 320$ J and

$K_2 = \frac{1}{2}mv_2^2 = \frac{1}{2}(4.00\times10^{-3}\text{ kg})(190\text{ m/s})^2 = 72.2$ J. $\Delta K = K_2 - K_1 = 72.2\text{ J} - 320\text{ J} = -248$ J. The kinetic energy of the bullet decreases by 248 J.

(c) Immediately after the collision the speed of the block is 1.05 m/s, so its kinetic energy is $K = \frac{1}{2}mv^2 = \frac{1}{2}(0.800\text{ kg})(1.05\text{ m/s})^2 = 0.441$ J.

EVALUATE: The collision is highly inelastic. The bullet loses 248 J of kinetic energy but only 0.441 J is gained by the block. But momentum is conserved in the collision. All the momentum lost by the bullet is gained by the block.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

8.92. **IDENTIFY:** Apply conservation of momentum to the collision and conservation of energy to the motion of the block after the collision.

SET UP: Let $+x$ be to the right. Let the bullet be A and the block be B. Let V be the velocity of the block just after the collision.

EXECUTE: *Motion of block after the collision*: $K_1 = U_{\text{grav}2}$. $\frac{1}{2}m_B V^2 = m_B gh$.

$$V = \sqrt{2gh} = \sqrt{2(9.80\ \text{m/s}^2)(0.38\times10^{-2}\ \text{m})} = 0.273\ \text{m/s}.$$

Collision: $v_{B2} = 0.273$ m/s. $P_{1x} = P_{2x}$ gives $m_A v_{A1} = m_A v_{A2} + m_B v_{B2}$.

$$v_{A2} = \frac{m_A v_{A1} - m_B v_{B2}}{m_A} = \frac{(5.00\times10^{-3}\ \text{kg})(450\ \text{m/s}) - (1.00\ \text{kg})(0.273\ \text{m/s})}{5.00\times10^{-3}\ \text{kg}} = 395\ \text{m/s}.$$

EVALUATE: We assume the block moves very little during the time it takes the bullet to pass through it.

8.93. **IDENTIFY:** Eqs. 8.24 and 8.25 give the outcome of the elastic collision. The value of M where the kinetic energy loss K_{loss} of the neutron is a maximum satisfies $dK_{\text{loss}}/dM = 0$.

SET UP: Let object A be the neutron and object B be the nucleus. Let the initial speed of the neutron be v_{A1}. All motion is along the x-axis. $K_0 = \frac{1}{2}mv_{A1}^2$.

EXECUTE: **(a)** $v_{A2} = \dfrac{m-M}{m+M}v_{A1}$.

$$K_{\text{loss}} = \tfrac{1}{2}mv_{A1}^2 - \tfrac{1}{2}mv_{A2}^2 = \tfrac{1}{2}m\left(1 - \left[\frac{m-M}{m+M}\right]^2\right)v_{A1}^2 = \frac{2m^2M}{(M+m)^2}v_{A1}^2 = \frac{4K_0mM}{(M+m)^2},$$ as was to be shown.

(b) $\dfrac{dK_{\text{loss}}}{dM} = 4K_0m\left[\dfrac{1}{(M+m)^2} - \dfrac{2M}{(M+m)^3}\right] = 0$. $\dfrac{2M}{M+m} = 1$ and $M = m$. The incident neutron loses the most kinetic energy when the target has the same mass as the neutron.

(c) When $m_A = m_B$, Eq. 8.24 says $v_{A2} = 0$. The final speed of the neutron is zero and the neutron loses all of its kinetic energy.

EVALUATE: When $M >> m$, $v_{A2x} \approx -v_{A1x}$ and the neutron rebounds with speed almost equal to its initial speed. In this case very little kinetic energy is lost; $K_{\text{loss}} = 4K_0m/M$, which is very small.

8.94. **IDENTIFY:** Eqs. 8.24 and 8.25 give the outcome of the elastic collision.

SET UP: Let all the motion be along the x axis. $v_{A1x} = v_0$.

EXECUTE: **(a)** $v_{A2x} = \left(\dfrac{m_A - m_B}{m_A + m_B}\right)v_0$ and $v_{B2x} = \left(\dfrac{2m_A}{m_A + m_B}\right)v_0$. $K_1 = \frac{1}{2}m_A v_0^2$.

$$K_{A2} = \tfrac{1}{2}m_A v_{A2x}^2 = \tfrac{1}{2}m_A\left(\frac{m_A - m_B}{m_A + m_B}\right)^2 v_0^2 = \left(\frac{m_A - m_B}{m_A + m_B}\right)^2 K_1 \text{ and } \frac{K_{A2}}{K_1} = \left(\frac{m_A - m_B}{m_A + m_B}\right)^2.$$

$$K_{B2} = \tfrac{1}{2}m_B v_{B2x}^2 = \tfrac{1}{2}m_B\left(\frac{2m_A}{m_A + m_B}\right)^2 v_0^2 = \frac{4m_Am_B}{(m_A + m_B)^2}K_1 \text{ and } \frac{K_{B2}}{K_1} = \frac{4m_Am_B}{(m_A + m_B)^2}.$$

(b) (i) For $m_A = m_B$, $\dfrac{K_{A2}}{K_1} = 0$ and $\dfrac{K_{B2}}{K_1} = 1$. (ii) For $m_A = 5m_B$, $\dfrac{K_{A2}}{K_1} = \dfrac{4}{9}$ and $\dfrac{K_{B2}}{K_1} = \dfrac{5}{9}$.

(c) Equal sharing of the kinetic energy means $\dfrac{K_{A2}}{K_1} = \dfrac{K_{B2}}{K_1} = \dfrac{1}{2}$. $\left(\dfrac{m_A - m_B}{m_A + m_B}\right)^2 = \dfrac{1}{2}$.

$2m_A^2 + 2m_B^2 - 4m_Am_B = m_A^2 + 2m_Am_B + m_B^2$. $m_A^2 - 6m_Am_B + m_B^2 = 0$. The quadratic formula gives $\dfrac{m_A}{m_B} = 5.83$ or $\dfrac{m_A}{m_B} = 0.172$. We can also verify that these values give $\dfrac{K_{B2}}{K_1} = \dfrac{1}{2}$.

EVALUATE: When $m_A << m_B$ or when $m_A >> m_B$, object A retains almost all of the original kinetic energy.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

8.95. **IDENTIFY:** Apply conservation of energy to the motion of the package before the collision and apply conservation of the horizontal component of momentum to the collision.

(a) SET UP: Apply conservation of energy to the motion of the package from point 1 as it leaves the chute to point 2 just before it lands in the cart. Take $y = 0$ at point 2, so $y_1 = 4.00$ m. Only gravity does work, so

$$K_1 + U_1 = K_2 + U_2.$$

EXECUTE: $\frac{1}{2}mv_1^2 + mgy_1 = \frac{1}{2}mv_2^2.$

$v_2 = \sqrt{v_1^2 + 2gy_1} = 9.35$ m/s.

(b) SET UP: In the collision between the package and the cart, momentum is conserved in the horizontal direction. (But not in the vertical direction, due to the vertical force the floor exerts on the cart.) Take $+x$ to be to the right. Let A be the package and B be the cart.

EXECUTE: P_x is constant gives $m_A v_{A1x} + m_B v_{B1x} = (m_A + m_B)v_{2x}.$

$v_{B1x} = -5.00$ m/s.

$v_{A1x} = (3.00 \text{ m/s})\cos 37.0°$. (The horizontal velocity of the package is constant during its free fall.)

Solving for v_{2x} gives $v_{2x} = -3.29$ m/s. The cart is moving to the left at 3.29 m/s after the package lands in it.

EVALUATE: The cart is slowed by its collision with the package, whose horizontal component of momentum is in the opposite direction to the motion of the cart.

8.96. **IDENTIFY:** Eqs. 8.24, 8.25 and 8.27 give the outcome of the elastic collision.

SET UP: The blue puck is object A and the red puck is object B. Let $+x$ be the direction of the initial motion of A. $v_{A1x} = 0.200$ m/s, $v_{A2x} = 0.050$ m/s and $v_{B1x} = 0$

EXECUTE: **(a)** Eq. 8.27 gives $v_{B2x} = v_{A2x} - v_{B1x} + v_{A1x} = 0.250$ m/s.

(b) Eq. 8.25 gives $m_B = m_A\left(2\frac{v_{A1x}}{v_{B2x}} - 1\right) = (0.0400 \text{ kg})\left(2\left[\frac{0.200 \text{ m/s}}{0.250 \text{ m/s}}\right] - 1\right) = 0.024$ kg.

EVALUATE: We can verify that our results give $K_1 = K_2$ and $P_{1x} = P_{2x}$, as required in an elastic collision.

8.97. **IDENTIFY:** Apply conservation of momentum to the system consisting of Jack, Jill and the crate. The speed of Jack or Jill relative to the ground will be different from 4.00 m/s.

SET UP: Use an inertial coordinate system attached to the ground. Let $+x$ be the direction in which the people jump. Let Jack be object A, Jill be B and the crate be C.

EXECUTE: **(a)** If the final speed of the crate is v, $v_{C2x} = -v$, and $v_{A2x} = v_{B2x} = 4.00 \text{ m/s} - v$. $P_{2x} = P_{1x}$ gives $m_A v_{A2x} + m_B v_{Bx2} + m_C v_{Cx2} = 0.$

$(75.0 \text{ kg})(4.00 \text{ m/s} - v) + (45.0 \text{ kg})(4.00 \text{ m/s} - v) + (15.0 \text{ kg})(-v) = 0$ and

$$v = \frac{(75.0 \text{ kg} + 45.0 \text{ kg})(4.00 \text{ m/s})}{75.0 \text{ kg} + 45.0 \text{ kg} + 15.0 \text{ kg}} = 3.56 \text{ m/s}.$$

(b) Let v' be the speed of the crate after Jack jumps. Apply momentum conservation to Jack jumping:

$(75.0 \text{ kg})(4.00 \text{ m/s} - v') + (60.0 \text{ kg})(-v') = 0$ and $v' = \frac{(75.0 \text{ kg})(4.00 \text{ m/s})}{135.0 \text{ kg}} = 2.22$ m/s. Then apply momentum conservation to Jill jumping, with v being the final speed of the crate: $P_{1x} = P_{2x}$ gives $(60.0 \text{ kg})(-v') = (45.0 \text{ kg})(4.00 \text{ m/s} - v) + (15.0 \text{ kg})(-v).$

$$v = \frac{(45.0 \text{ kg})(4.00 \text{ m/s}) + (60.0 \text{ kg})(2.22 \text{ m/s})}{60.0 \text{ kg}} = 5.22 \text{ m/s}.$$

(c) Repeat the calculation in (b), but now with Jill jumping first.

Jill jumps: $(45.0 \text{ kg})(4.00 \text{ m/s} - v') + (90.0 \text{ kg})(-v') = 0$ and $v' = 1.33$ m/s.

Jack jumps: $(90.0 \text{ kg})(-v') = (75.0 \text{ kg})(4.00 \text{ m/s} - v) + (15.0 \text{ kg})(-v).$

$$v = \frac{(75.0 \text{ kg})(4.00 \text{ m/s}) + (90.0 \text{ kg})(1.33 \text{ m/s})}{90.0 \text{ kg}} = 4.66 \text{ m/s}.$$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: The final speed of the crate is greater when Jack jumps first, then Jill. In this case Jack leaves with a speed of 1.78 m/s relative to the ground, whereas when they both jump simultaneously Jack and Jill each leave with a speed of only 0.44 m/s relative to the ground.

8.98. **IDENTIFY:** Eq. 8.27 describes the elastic collision, with x replaced by y. Speed and height are related by conservation of energy.

SET UP: Let $+y$ be upward. Let A be the large ball and B be the small ball, so $v_{B1y} = -v$ and $v_{A1y} = +v$. If the large ball has much greater mass than the small ball its speed is changed very little in the collision and $v_{A2y} = +v$.

EXECUTE: **(a)** $v_{B2y} - v_{A2y} = -(v_{B1y} - v_{A1y})$ gives $v_{B2y} = +v_{A2y} - v_{B1y} + v_{A1y} = v - (-v) + v = +3v$. The small ball moves upward with speed $3v$ after the collision.

(b) Let h_1 be the height the small ball fell before the collision. Conservation of energy applied to the motion from the release point to the floor gives $U_1 = K_2$ and $mgh_1 = \frac{1}{2}mv^2$. $h_1 = \dfrac{v^2}{2g}$. Conservation of energy applied to the motion of the small ball from immediately after the collision to its maximum height h_2 (rebound distance) gives $K_1 = U_2$ and $\frac{1}{2}m(3v)^2 = mgh_2$. $h_2 = \dfrac{9v^2}{2g} = 9h_1$. The ball's rebound distance is nine times the distance it fell.

EVALUATE: The mechanical energy gained by the small ball comes from the energy of the large ball. But since the large ball's mass is much larger it can give up this energy with very little decrease in speed.

8.99. **IDENTIFY** and **SET UP:**

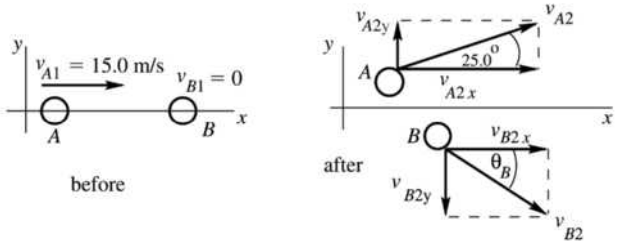

Figure 8.99

P_x and P_y are conserved in the collision since there is no external horizontal force.

The collision is elastic, so $25.0° + \theta_B = 90°$, so that $\theta_B = 65.0°$. (A and B move off in perpendicular directions.)

EXECUTE: P_x is conserved so $m_A v_{A1x} + m_B v_{B1x} = m_A v_{A2x} + m_B v_{B2x}$.

But $m_A = m_B$ so $v_{A1} = v_{A2}\cos 25.0° + v_{B2}\cos 65.0°$.

P_y is conserved so $m_A v_{A1y} + m_B v_{B1y} = m_A v_{A2y} + m_B v_{B2y}$.

$0 = v_{A2y} + v_{B2y}$.

$0 = v_{A2}\sin 25.0° - v_{B2}\sin 65.0°$.

$v_{B2} = (\sin 25.0°/\sin 65.0°)v_{A2}$.

This result in the first equation gives $v_{A1} = v_{A2}\cos 25.0° + \left(\dfrac{\sin 25.0°\cos 65.0°}{\sin 65.0°}\right)v_{A2}$.

$v_{A1} = 1.103 v_{A2}$.

$v_{A2} = v_{A1}/1.103 = (15.0 \text{ m/s})/1.103 = 13.6 \text{ m/s}$.

And then $v_{B2} = (\sin 25.0°/\sin 65.0°)(13.6 \text{ m/s}) = 6.34 \text{ m/s}$.

EVALUATE: We can use our numerical results to show that $K_1 = K_2$ and that $P_{1x} = P_{2x}$ and $P_{1y} = P_{2y}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

8.100. **IDENTIFY:** Momentum is conserved in the explosion. The total kinetic energy of the two fragments is Q.
SET UP: Let the final speed of the two fragments be v_A and v_B. They must move in opposite directions after the explosion.
EXECUTE: **(a)** Since the initial momentum of the system is zero, conservation of momentum says

$m_A v_A = m_B v_B$ and $v_B = \left(\frac{m_A}{m_B}\right) v_A$. $K_A + K_B = Q$ gives $\frac{1}{2} m_A v_A^2 + \frac{1}{2} m_B \left(\frac{m_A}{m_B}\right)^2 v_A^2 = Q$. $\frac{1}{2} m_A v_A^2 \left(1 + \frac{m_A}{m_B}\right) = Q$.

$$K_A = \frac{Q}{1 + m_A/m_B} = \left(\frac{m_B}{m_A + m_B}\right) Q. \quad K_B = Q - K_A = Q\left(1 - \frac{m_B}{m_A + m_B}\right) = \left(\frac{m_A}{m_A + m_B}\right) Q.$$

(b) If $m_B = 4m_A$, then $K_A = \frac{4}{5} Q$ and $K_B = \frac{1}{5} Q$. The lighter fragment gets 80% of the energy that is released.

EVALUATE: If $m_A = m_B$ the fragments share the energy equally. In the limit that $m_B >> m_A$, the lighter fragment gets almost all of the released energy.

8.101. **IDENTIFY:** Apply conservation of momentum to the system of the neutron and its decay products.
SET UP: Let the proton be moving in the $+x$ direction with speed v_p after the decay. The initial momentum of the neutron is zero, so to conserve momentum the electron must be moving in the $-x$ direction after the decay. Let the speed of the electron be v_e.

EXECUTE: $P_{1x} = P_{2x}$ gives $0 = m_\text{p} v_\text{p} - m_\text{e} v_\text{e}$ and $v_\text{e} = \left(\frac{m_\text{p}}{m_\text{e}}\right) v_\text{p}$. The total kinetic energy after the decay is

$$K_\text{tot} = \tfrac{1}{2} m_\text{e} v_\text{e}^2 + \tfrac{1}{2} m_\text{p} v_\text{p}^2 = \tfrac{1}{2} m_\text{e} \left(\frac{m_\text{p}}{m_\text{e}}\right)^2 v_\text{p}^2 + \tfrac{1}{2} m_\text{p} v_\text{p}^2 = \tfrac{1}{2} m_\text{p} v_\text{p}^2 \left(1 + \frac{m_\text{p}}{m_\text{e}}\right).$$

Thus, $\frac{K_\text{p}}{K_\text{tot}} = \frac{1}{1 + m_\text{p}/m_\text{e}} = \frac{1}{1 + 1836} = 5.44 \times 10^{-4} = 0.0544\%$.

EVALUATE: Most of the released energy goes to the electron, since it is much lighter than the proton.

8.102. **IDENTIFY:** Momentum is conserved in the decay. The results of Problem 8.100 give the kinetic energy of each fragment.
SET UP: Let A be the alpha particle and let B be the radium nucleus, so $m_A/m_B = 0.0176$. $Q = 6.54 \times 10^{-13}$ J.

EXECUTE: $K_A = \frac{Q}{1 + m_A/m_B} = \frac{6.54 \times 10^{-13} \text{ J}}{1 + 0.0176} = 6.43 \times 10^{-13}$ J and $K_B = 0.11 \times 10^{-13}$ J.

EVALUATE: The lighter particle receives most of the released energy.

8.103. **IDENTIFY:** The momentum of the system is conserved.
SET UP: Let $+x$ be to the right. $P_{1x} = 0$. p_ex, p_nx and p_anx are the momenta of the electron, polonium nucleus and antineutrino, respectively.
EXECUTE: $P_{1x} = P_{2x}$ gives $p_\text{ex} + p_\text{nx} + p_\text{anx} = 0$. $p_\text{anx} = -(p_\text{ex} + p_\text{nx})$.

$p_\text{anx} = -(5.60 \times 10^{-22} \text{ kg} \cdot \text{m/s} + [3.50 \times 10^{-25} \text{ kg}][-1.14 \times 10^3 \text{ m/s}]) = -1.61 \times 10^{-22} \text{ kg} \cdot \text{m/s}$.

The antineutrino has momentum to the left with magnitude 1.61×10^{-22} kg · m/s.

EVALUATE: The antineutrino interacts very weakly with matter and most easily shows its presence by the momentum it carries away.

8.104. **IDENTIFY:** Since there is no friction, the horizontal component of momentum of the system of Jonathan, Jane and the sleigh is conserved.
SET UP: Let $+x$ be to the right. $w_A = 800$ N, $w_B = 600$ N and $w_C = 1000$ N.
EXECUTE: $P_{1x} = P_{2x}$ gives $0 = m_A v_{A2x} + m_B v_{B2x} + m_C v_{C2x}$.

$$v_{C2x} = -\frac{m_A v_{A2x} + m_B v_{B2x}}{m_C} = -\frac{w_A v_{A2x} + w_B v_{B2x}}{w_C}.$$

$$v_{C2x} = -\frac{(800 \text{ N})(-[5.00 \text{ m/s}]\cos 30.0°) + (600 \text{ N})(+[7.00 \text{ m/s}]\cos 36.9°)}{1000 \text{ N}} = 0.105 \text{ m/s}.$$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

The sleigh's velocity is 0.105 m/s, to the right.

EVALUATE: The vertical component of the momentum of the system consisting of the two people and the sleigh is not conserved, because of the net force exerted on the sleigh by the ice while they jump.

8.105. **IDENTIFY:** No net external force acts on the Burt-Ernie-log system, so the center of mass of the system does not move.

SET UP: $x_{\text{cm}} = \dfrac{m_1x_1 + m_2x_2 + m_3x_3}{m_1 + m_2 + m_3}$.

EXECUTE: Use coordinates where the origin is at Burt's end of the log and where $+x$ is toward Ernie, which makes $x_1 = 0$ for Burt initially. The initial coordinate of the center of mass is $x_{\text{cm},1} = \dfrac{(20.0\text{ kg})(1.5\text{ m}) + (40.0\text{ kg})(3.0\text{ m})}{90.0\text{ kg}}$. Let d be the distance the log moves toward Ernie's original position. The final location of the center of mass is $x_{\text{cm},2} = \dfrac{(30.0\text{ kg})d + (1.5\text{ kg} + d)(20.0\text{ kg}) + (40.0\text{ kg})d}{90.0\text{ kg}}$.

The center of mass does not move, so $x_{\text{cm},1} = x_{\text{cm},2}$, which gives $(20.0\text{ kg})(1.5\text{ m}) + (40.0\text{ kg})(3.0\text{ m}) = (30.0\text{ kg})d + (20.0\text{ kg})(1.5\text{ m} + d) + (40.0\text{ kg})d$. Solving for d gives $d = 1.33$ m.

EVALUATE: Burt, Ernie and the log all move, but the center of mass of the system does not move.

8.106. **IDENTIFY:** There is no net horizontal external force so v_{cm} is constant.

SET UP: Let $+x$ be to the right, with the origin at the initial position of the left-hand end of the canoe. $m_{\text{A}} = 45.0$ kg, $m_B = 60.0$ kg. The center of mass of the canoe is at its center.

EXECUTE: Initially, $v_{\text{cm}} = 0$, so the center of mass doesn't move. Initially, $x_{\text{cm1}} = \dfrac{m_Ax_{A1} + m_Bx_{B1}}{m_A + m_B}$. After she walks, $x_{\text{cm2}} = \dfrac{m_Ax_{A2} + m_Bx_{B2}}{m_A + m_B}$. $x_{\text{cm1}} = x_{\text{cm2}}$ gives $m_Ax_{A1} + m_Bx_{B1} = m_Ax_{A2} + m_Bx_{B2}$. She walks to a point 1.00 m from the right-hand end of the canoe, so she is 1.50 m to the right of the center of mass of the canoe and $x_{A2} = x_{B2} + 1.50$ m.

$$(45.0\text{ kg})(1.00\text{ m}) + (60.0\text{ kg})(2.50\text{ m}) = (45.0\text{ kg})(x_{B2} + 1.50\text{ m}) + (60.0\text{ kg})x_{B2}.$$

$(105.0\text{ kg})x_{B2} = 127.5\text{ kg}\cdot\text{m}$ and $x_{B2} = 1.21$ m. $x_{B2} - x_{B1} = 1.21\text{ m} - 2.50\text{ m} = -1.29$ m. The canoe moves 1.29 m to the left.

EVALUATE: When the woman walks to the right, the canoe moves to the left. The woman walks 3.00 m to the right relative to the canoe and the canoe moves 1.29 m to the left, so she moves $3.00\text{ m} - 1.29\text{ m} = 1.71$ m to the right relative to the water. Note that this distance is $(60.0\text{ kg}/45.0\text{ kg})(1.29\text{ m})$.

8.107. **IDENTIFY:** Take as the system you and the slab. There is no horizontal force, so horizontal momentum is conserved. By Eq. 8.32, since $\vec{\boldsymbol{P}}$ is constant, $\vec{\boldsymbol{v}}_{\text{cm}}$ is constant (for a system of constant mass). Use coordinates fixed to the ice, with the direction you walk as the x-direction. $\vec{\boldsymbol{v}}_{\text{cm}}$ is constant and initially $\vec{\boldsymbol{v}}_{\text{cm}} = 0$.

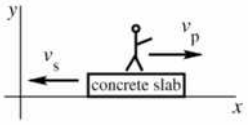

Figure 8.107

$$\vec{\boldsymbol{v}}_{\text{cm}} = \frac{m_{\text{p}}\vec{\boldsymbol{v}}_{\text{p}} + m_{\text{s}}\vec{\boldsymbol{v}}_{\text{s}}}{m_{\text{p}} + m_{\text{s}}} = 0.$$

$$m_{\text{p}}\vec{\boldsymbol{v}}_{\text{p}} + m_{\text{s}}\vec{\boldsymbol{v}}_{\text{s}} = 0.$$

$$m_{\text{p}}v_{\text{p}x} + m_{\text{s}}v_{\text{s}x} = 0.$$

$$v_{\text{s}x} = -(m_{\text{p}}/m_{\text{s}})v_{\text{p}x} = -(m_{\text{p}}/5m_{\text{p}})2.00\text{ m/s} = -0.400\text{ m/s}.$$

The slab moves at 0.400 m/s, in the direction opposite to the direction you are walking.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: The initial momentum of the system is zero. You gain momentum in the $+x$-direction so the slab gains momentum in the $-x$-direction. The slab exerts a force on you in the $+x$-direction so you exert a force on the slab in the $-x$-direction.

8.108. **IDENTIFY:** Conservation of x and y components of momentum applies to the collision. At the highest point of the trajectory the vertical component of the velocity of the projectile is zero.

SET UP: Let $+y$ be upward and $+x$ be horizontal and to the right. Let the two fragments be A and B, each with mass m. For the projectile before the explosion and the fragments after the explosion. $a_x = 0$, $a_y = -9.80 \text{ m/s}^2$.

EXECUTE: **(a)** $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ with $v_y = 0$ gives that the maximum height of the projectile is $h = -\dfrac{v_{0y}^2}{2a_y} = -\dfrac{([80.0 \text{ m/s}]\sin 60.0°)^2}{2(-9.80 \text{ m/s}^2)} = 244.9 \text{ m}$. Just before the explosion the projectile is moving to the right with horizontal velocity $v_x = v_{0x} = v_0 \cos 60.0° = 40.0$ m/s. After the explosion $v_{Ax} = 0$ since fragment A falls vertically. Conservation of momentum applied to the explosion gives $(2m)(40.0 \text{ m/s}) = mv_{Bx}$ and $v_{Bx} = 80.0$ m/s. Fragment B has zero initial vertical velocity so $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$ gives a time of fall of $t = \sqrt{-\dfrac{2h}{a_y}} = \sqrt{-\dfrac{2(244.9 \text{ m})}{-9.80 \text{ m/s}^2}} = 7.07$ s. During this time the fragment travels horizontally a distance $(80.0 \text{ m/s})(7.07 \text{ s}) = 566$ m. It also took the projectile 7.07 s to travel from launch to maximum height and during this time it travels a horizontal distance of $([80.0 \text{ m/s}]\cos 60.0°)(7.07 \text{ s}) = 283$ m. The second fragment lands $283 \text{ m} + 566 \text{ m} = 849$ m from the firing point.

(b) For the explosion, $K_1 = \frac{1}{2}(20.0 \text{ kg})(40.0 \text{ m/s})^2 = 1.60 \times 10^4$ J. $K_2 = \frac{1}{2}(10.0 \text{ kg})(80.0 \text{ m/s})^2 = 3.20 \times 10^4$ J. The energy released in the explosion is 1.60×10^4 J.

EVALUATE: The kinetic energy of the projectile just after it is launched is 6.40×10^4 J. We can calculate the speed of each fragment just before it strikes the ground and verify that the total kinetic energy of the fragments just before they strike the ground is $6.40 \times 10^4 \text{ J} + 1.60 \times 10^4 \text{ J} = 8.00 \times 10^4$ J. Fragment A has speed 69.3 m/s just before it strikes the ground, and hence has kinetic energy 2.40×10^4 J. Fragment B has speed $\sqrt{(80.0 \text{ m/s})^2 + (69.3 \text{ m/s})^2} = 105.8$ m/s just before it strikes the ground, and hence has kinetic energy 5.60×10^4 J. Also, the center of mass of the system has the same horizontal range $R = \dfrac{v_0^2}{g}\sin(2\alpha_0) = 565$ m that the projectile would have had if no explosion had occurred. One fragment lands at $R/2$ so the other, equal mass fragment lands at a distance $3R/2$ from the launch point.

8.109. **IDENTIFY:** The rocket moves in projectile motion before the explosion and its fragments move in projectile motion after the explosion. Apply conservation of energy and conservation of momentum to the explosion.

(a) SET UP: Apply conservation of energy to the explosion. Just before the explosion the rocket is at its maximum height and has zero kinetic energy. Let A be the piece with mass 1.40 kg and B be the piece with mass 0.28 kg. Let v_A and v_B be the speeds of the two pieces immediately after the collision.

EXECUTE: $\frac{1}{2}m_A v_A^2 + \frac{1}{2}m_B v_B^2 = 860$ J

SET UP: Since the two fragments reach the ground at the same time, their velocities just after the explosion must be horizontal. The initial momentum of the rocket before the explosion is zero, so after the explosion the pieces must be moving in opposite horizontal directions and have equal magnitude of momentum: $m_A v_A = m_B v_B$.

EXECUTE: Use this to eliminate v_A in the first equation and solve for v_B:

$$\tfrac{1}{2}m_B v_B^2(1 + m_B/m_A) = 860 \text{ J} \text{ and } v_B = 71.6 \text{ m/s}.$$

Then $v_A = (m_B/m_A)v_B = 14.3$ m/s.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) SET UP: Use the vertical motion from the maximum height to the ground to find the time it takes the pieces to fall to the ground after the explosion. Take $+y$ downward.

$$v_{0y} = 0,\ \ a_y = +9.80\ \text{m/s}^2,\ \ y - y_0 = 80.0\ \text{m},\ \ t = ?$$

EXECUTE: $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$ gives $t = 4.04$ s.

During this time the horizontal distance each piece moves is $x_A = v_A t = 57.8$ m and $x_B = v_B t = 289.1$ m. They move in opposite directions, so they are $x_A + x_B = 347$ m apart when they land.

EVALUATE: Fragment A has more mass so it is moving slower right after the collision, and it travels horizontally a smaller distance as it falls to the ground.

8.110. **IDENTIFY:** Apply conservation of momentum to the explosion. At the highest point of its trajectory the shell is moving horizontally. If one fragment received some upward momentum in the explosion, the other fragment would have had to receive a downward component. Since they each hit the ground at the same time, each must have zero vertical velocity immediately after the explosion.

SET UP: Let $+x$ be horizontal, along the initial direction of motion of the projectile and let $+y$ be upward. At its maximum height the projectile has $v_x = v_0 \cos 55.0° = 86.0$ m/s. Let the heavier fragment be A and the lighter fragment be B. $m_A = 9.00$ kg and $m_B = 3.00$ kg.

EXECUTE: Since fragment A returns to the launch point, immediately after the explosion it has $v_{Ax} = -86.0$ m/s. Conservation of momentum applied to the explosion gives $(12.0\ \text{kg})(86.0\ \text{m/s}) = (9.00\ \text{kg})(-86.0\ \text{m/s}) + (3.00\ \text{kg})v_{Bx}$ and $v_{Bx} = 602$ m/s. The horizontal range of the projectile, if no explosion occurred, would be $R = \dfrac{v_0^2}{g}\sin(2\alpha_0) = 2157$ m. The horizontal distance each fragment travels is proportional to its initial speed and the heavier fragment travels a horizontal distance $R/2 = 1078$ m after the explosion, so the lighter fragment travels a horizontal distance $\left(\dfrac{602\ \text{m}}{86\ \text{m}}\right)(1078\ \text{m}) = 7546$ m from the point of explosion and $1078\ \text{m} + 7546\ \text{m} = 8624$ m from the launch point. The energy released in the explosion is

$K_2 - K_1 = \frac{1}{2}(9.00\ \text{kg})(86.0\ \text{m/s})^2 + \frac{1}{2}(3.00\ \text{kg})(602\ \text{m/s})^2 - \frac{1}{2}(12.0\ \text{kg})(86.0\ \text{m/s})^2 = 5.33\times10^5$ J.

EVALUATE: The center of mass of the system has the same horizontal range $R = 2157$ m as if the explosion didn't occur. This gives $(12.0\ \text{kg})(2157\ \text{m}) = (9.00\ \text{kg})(0) + (3.00\ \text{kg})d$ and $d = 8630$ m, where d is the distance from the launch point to where the lighter fragment lands. This agrees with our calculation.

8.111. **IDENTIFY:** Apply conservation of energy to the motion of the wagon before the collision. After the collision the combined object moves with constant speed on the level ground. In the collision the horizontal component of momentum is conserved.

SET UP: Let the wagon be object A and treat the two people together as object B. Let $+x$ be horizontal and to the right. Let V be the speed of the combined object after the collision.

EXECUTE: **(a)** The speed v_{A1} of the wagon just before the collision is given by conservation of energy applied to the motion of the wagon prior to the collision. $U_1 = K_2$ says $m_A g([50\ \text{m}][\sin 6.0°]) = \frac{1}{2}m_A v_{A1}^2$. $v_{A1} = 10.12$ m/s. $P_{1x} = P_{2x}$ for the collision says $m_A v_{A1} = (m_A + m_B)V$ and $V = \left(\dfrac{300\ \text{kg}}{300\ \text{kg} + 75.0\ \text{kg} + 60.0\ \text{kg}}\right)(10.12\ \text{m/s}) = 6.98$ m/s. In 5.0 s the wagon travels $(6.98\ \text{m/s})(5.0\ \text{s}) = 34.9$ m, and the people will have time to jump out of the wagon before it reaches the edge of the cliff.

(b) For the wagon, $K_1 = \frac{1}{2}(300\ \text{kg})(10.12\ \text{m/s})^2 = 1.54\times10^4$ J. Assume that the two heroes drop from a small height, so their kinetic energy just before the wagon can be neglected compared to K_1 of the wagon. $K_2 = \frac{1}{2}(435\ \text{kg})(6.98\ \text{m/s})^2 = 1.06\times10^4$ J. The kinetic energy of the system decreases by $K_1 - K_2 = 4.8\times10^3$ J.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: The wagon slows down when the two heroes drop into it. The mass that is moving horizontally increases, so the speed decreases to maintain the same horizontal momentum. In the collision the vertical momentum is not conserved, because of the net external force due to the ground.

8.112. **IDENTIFY:** Gravity gives a downward external force of magnitude mg. The impulse of this force equals the change in momentum of the rocket.

SET UP: Let $+y$ be upward. Consider an infinitesimal time interval dt. In Example 8.15, $v_{ex} = 2400$ m/s and $\dfrac{dm}{dt} = -\dfrac{m_0}{120\text{ s}}$. In Example 8.16, $m = m_0/4$ after $t = 90$ s.

EXECUTE: **(a)** The impulse-momentum theorem gives $-mg\,dt = (m + dm)(v + dv) + (dm)(v - v_{ex}) - mv$.

This simplifies to $-mg\,dt = m\,dv + v_{ex}\,dm$ and $m\dfrac{dv}{dt} = -v_{ex}\dfrac{dm}{dt} - mg$.

(b) $a = \dfrac{dv}{dt} = -\dfrac{v_{ex}}{m}\dfrac{dm}{dt} - g$.

(c) At $t = 0$, $a = -\dfrac{v_{ex}}{m_0}\dfrac{dm}{dt} - g = -(2400\text{ m/s})\left(-\dfrac{1}{120\text{ s}}\right) - 9.80\text{ m/s}^2 = 10.2\text{ m/s}^2$.

(d) $dv = -\dfrac{v_{ex}}{m}dm - g\,dt$. Integrating gives $v - v_0 = +v_{ex}\ln\dfrac{m_0}{m} - gt$. $v_0 = 0$ and

$v = +(2400\text{ m/s})\ln 4 - (9.80\text{ m/s}^2)(90\text{ s}) = 2445$ m/s.

EVALUATE: Both the initial acceleration in Example 8.15 and the final speed of the rocket in Example 8.16 are reduced by the presence of gravity.

8.113. **IDENTIFY** and **SET UP:** Apply Eq. 8.40 to the single-stage rocket and to each stage of the two-stage rocket.

(a) EXECUTE: $v - v_0 = v_{ex}\ln(m_0/m)$; $v_0 = 0$ so $v = v_{ex}\ln(m_0/m)$

The total initial mass of the rocket is $m_0 = 12{,}000\text{ kg} + 1000\text{ kg} = 13{,}000$ kg. Of this, $9000\text{ kg} + 700\text{ kg} = 9700$ kg is fuel, so the mass m left after all the fuel is burned is $13{,}000\text{ kg} - 9700\text{ kg} = 3300$ kg.

$$v = v_{ex}\ln(13{,}000\text{ kg}/3300\text{ kg}) = 1.37v_{ex}.$$

(b) First stage: $v = v_{ex}\ln(m_0/m)$

$m_0 = 13{,}000$ kg

The first stage has 9000 kg of fuel, so the mass left after the first stage fuel has burned is $13{,}000\text{ kg} - 9000\text{ kg} = 4000$ kg.

$$v = v_{ex}\ln(13{,}000\text{ kg}/4000\text{ kg}) = 1.18v_{ex}.$$

(c) Second stage: $m_0 = 1000$ kg, $m = 1000\text{ kg} - 700\text{ kg} = 300$ kg.

$$v = v_0 + v_{ex}\ln(m_0/m) = 1.18v_{ex} + v_{ex}\ln(1000\text{ kg}/300\text{ kg}) = 2.38v_{ex}.$$

(d) $v = 7.00$ km/s

$$v_{ex} = v/2.38 = (7.00\text{ km/s})/2.38 = 2.94\text{ km/s}.$$

EVALUATE: The two-stage rocket achieves a greater final speed because it jettisons the left-over mass of the first stage before the second-state fires and this reduces the final m and increases m_0/m.

8.114. **IDENTIFY:** From our analysis of motion with constant acceleration, if $v = at$ and a is constant, then $x - x_0 = v_0t + \frac{1}{2}at^2$.

SET UP: Take $v_0 = 0$, $x_0 = 0$ and let $+x$ downward.

EXECUTE: **(a)** $\dfrac{dv}{dt} = a$, $v = at$ and $x = \frac{1}{2}at^2$. Substituting into $xg = x\dfrac{dv}{dt} + v^2$ gives $\frac{1}{2}at^2g = \frac{1}{2}at^2a + a^2t^2 = \frac{3}{2}a^2t^2$. The nonzero solution is $a = g/3$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) $x = \frac{1}{2}at^2 = \frac{1}{6}gt^2 = \frac{1}{6}(9.80\ \text{m/s}^2)(3.00\ \text{s})^2 = 14.7\ \text{m}.$

(c) $m = kx = (2.00\ \text{g/m})(14.7\ \text{m}) = 29.4\ \text{g}.$

EVALUATE: The acceleration is less than g because the small water droplets are initially at rest, before they adhere to the falling drop. The small droplets are suspended by buoyant forces that we ignore for the raindrops.

8.115. **IDENTIFY** and **SET UP:** $dm = \rho dV$. $dV = Adx$. Since the thin rod lies along the x axis, $y_{\text{cm}} = 0$. The mass of the rod is given by $M = \int dm$.

EXECUTE: **(a)** $x_{\text{cm}} = \frac{1}{M}\int_0^L x dm = \frac{\rho}{M}A\int_0^L x dx = \frac{\rho A}{M}\frac{L^2}{2}$. The volume of the rod is AL and $M = \rho AL$.

$x_{\text{cm}} = \frac{\rho AL^2}{2\rho AL} = \frac{L}{2}$. The center of mass of the uniform rod is at its geometrical center, midway between its ends.

(b) $x_{\text{cm}} = \frac{1}{M}\int_0^L x dm = \frac{1}{M}\int_0^L x\rho A dx = \frac{A\alpha}{M}\int_0^L x^2 dx = \frac{A\alpha L^3}{3M}$. $M = \int dm = \int_0^L \rho A dx = \alpha A\int_0^L x dx = \frac{\alpha AL^2}{2}$.

Therefore, $x_{\text{cm}} = \left(\frac{A\alpha L^3}{3}\right)\left(\frac{2}{\alpha AL^2}\right) = \frac{2L}{3}$.

EVALUATE: When the density increases with x, the center of mass is to the right of the center of the rod.

8.116. **IDENTIFY:** $x_{\text{cm}} = \frac{1}{M}\int x dm$ and $y_{\text{cm}} = \frac{1}{M}\int y dm$. At the upper surface of the plate, $y^2 + x^2 = a^2$.

SET UP: To find x_{cm}, divide the plate into thin strips parallel to the y-axis, as shown in Figure 8.116a. To find y_{cm}, divide the plate into thin strips parallel to the x-axis as shown in Figure 8.116b. The plate has volume one-half that of a circular disk, so $V = \frac{1}{2}\pi a^2 t$ and $M = \frac{1}{2}\rho\pi a^2 t$.

EXECUTE: In Figure 8.116a each strip has length $y = \sqrt{a^2 - x^2}$. $x_{\text{cm}} = \frac{1}{M}\int x dm$, where

$dm = \rho t y dx = \rho t\sqrt{a^2 - x^2}\,dx$. $x_{\text{cm}} = \frac{\rho t}{M}\int_{-a}^{a} x\sqrt{a^2 - x^2}\,dx = 0$, since the integrand is an odd function of x.

$x_{\text{cm}} = 0$ because of symmetry. In Figure 8.116b each strip has length $2x = 2\sqrt{a^2 - y^2}$. $y_{\text{cm}} = \frac{1}{M}\int y dm$,

where $dm = 2\rho t x dy = 2\rho t\sqrt{a^2 - y^2}\,dy$. $y_{\text{cm}} = \frac{2\rho t}{M}\int_{-a}^{a} y\sqrt{a^2 - y^2}\,dy$. The integral can be evaluated using

$u = a^2 - y^2$, $du = -2y dy$. This substitution gives

$$y_{\text{cm}} = \frac{2\rho t}{M}\left(-\frac{1}{2}\right)\int_{a^2}^{0} u^{1/2} du = \frac{2\rho t a^3}{3M} = \left(\frac{2\rho t a^3}{3}\right)\left(\frac{2}{\rho\pi a^2 t}\right) = \frac{4a}{3\pi}.$$

EVALUATE: $\frac{4}{3\pi} = 0.424$. y_{cm} is less than $a/2$, as expected, since the plate becomes wider as y decreases.

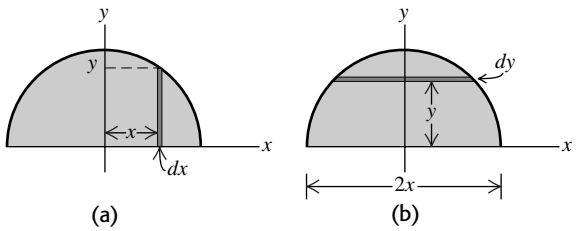

Figure 8.116

9

ROTATION OF RIGID BODIES

9.1. **IDENTIFY:** $s = r\theta$, with θ in radians.

SET UP: π rad $= 180°$.

EXECUTE: **(a)** $\theta = \dfrac{s}{r} = \dfrac{1.50 \text{ m}}{2.50 \text{ m}} = 0.600 \text{ rad} = 34.4°$

(b) $r = \dfrac{s}{\theta} = \dfrac{14.0 \text{ cm}}{(128°)(\pi \text{ rad}/180°)} = 6.27 \text{ cm}$

(c) $s = r\theta = (1.50 \text{ m})(0.700 \text{ rad}) = 1.05 \text{ m}$

EVALUATE: An angle is the ratio of two lengths and is dimensionless. But, when $s = r\theta$ is used, θ must be in radians. Or, if $\theta = s/r$ is used to calculate θ, the calculation gives θ in radians.

9.2. **IDENTIFY:** $\theta - \theta_0 = \omega t$, since the angular velocity is constant.

SET UP: 1 rpm $= (2\pi/60)$ rad/s.

EXECUTE: **(a)** $\omega = (1900)(2\pi \text{ rad}/60 \text{ s}) = 199 \text{ rad/s}$

(b) $35° = (35°)(\pi/180°) = 0.611$ rad. $t = \dfrac{\theta - \theta_0}{\omega} = \dfrac{0.611 \text{ rad}}{199 \text{ rad/s}} = 3.1 \times 10^{-3}$ s

EVALUATE: In $t = \dfrac{\theta - \theta_0}{\omega}$ we must use the same angular measure (radians, degrees or revolutions) for both $\theta - \theta_0$ and ω.

9.3. **IDENTIFY** $\alpha_z(t) = \dfrac{d\omega_z}{dt}$. Writing Eq. (2.16) in terms of angular quantities gives $\theta - \theta_0 = \int_{t_1}^{t_2} \omega_z dt$.

SET UP: $\dfrac{d}{dt}t^n = nt^{n-1}$ and $\int t^n dt = \dfrac{1}{n+1}t^{n+1}$

EXECUTE: **(a)** A must have units of rad/s and B must have units of rad/s^3.

(b) $\alpha_z(t) = 2Bt = (3.00 \text{ rad/s}^3)t$. (i) For $t = 0$, $\alpha_z = 0$. (ii) For $t = 5.00$ s, $\alpha_z = 15.0$ rad/s^2.

(c) $\theta_2 - \theta_1 = \int_{t_1}^{t_2}(A + Bt^2)dt = A(t_2 - t_1) + \frac{1}{3}B(t_2^3 - t_1^3)$. For $t_1 = 0$ and $t_2 = 2.00$ s,

$\theta_2 - \theta_1 = (2.75 \text{ rad/s})(2.00 \text{ s}) + \frac{1}{3}(1.50 \text{ rad/s}^3)(2.00 \text{ s})^3 = 9.50$ rad.

EVALUATE: Both α_z and ω_z are positive and the angular speed is increasing.

9.4. **IDENTIFY:** $\alpha_z = d\omega_z/dt$. $\alpha_{\text{av-}z} = \dfrac{\Delta\omega_z}{\Delta t}$.

SET UP: $\dfrac{d}{dt}(t^2) = 2t$

EXECUTE: **(a)** $\alpha_z(t) = \dfrac{d\omega_z}{dt} = -2\beta t = (-1.60 \text{ rad/s}^3)t$.

(b) $\alpha_z(3.0 \text{ s}) = (-1.60 \text{ rad/s}^3)(3.0 \text{ s}) = -4.80 \text{ rad/s}^2$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$\alpha_{\text{av-}z} = \frac{\omega_z(3.0\text{ s}) - \omega_z(0)}{3.0\text{ s}} = \frac{-2.20\text{ rad/s} - 5.00\text{ rad/s}}{3.0\text{ s}} = -2.40\text{ rad/s}^2,$$

which is half as large (in magnitude) as the acceleration at $t = 3.0$ s.

EVALUATE: $\alpha_z(t)$ increases linearly with time, so $\alpha_{\text{av-}z} = \dfrac{\alpha_z(0) + \alpha_z(3.0\text{ s})}{2}$. $\alpha_z(0) = 0$.

9.5. **IDENTIFY** and **SET UP:** Use Eq. (9.3) to calculate the angular velocity and Eq. (9.2) to calculate the average angular velocity for the specified time interval.

EXECUTE: $\theta = \gamma t + \beta t^3$; $\gamma = 0.400$ rad/s, $\beta = 0.0120$ rad/s^3

(a) $\omega_z = \dfrac{d\theta}{dt} = \gamma + 3\beta t^2$

(b) At $t = 0$, $\omega_z = \gamma = 0.400$ rad/s

(c) At $t = 5.00$ s, $\omega_z = 0.400\text{ rad/s} + 3(0.0120\text{ rad/s}^3)(5.00\text{ s})^2 = 1.30$ rad/s

$$\omega_{\text{av-}z} = \frac{\Delta\theta}{\Delta t} = \frac{\theta_2 - \theta_1}{t_2 - t_1}$$

For $t_1 = 0$, $\theta_1 = 0$.

For $t_2 = 5.00$ s, $\theta_2 = (0.400\text{ rad/s})(5.00\text{ s}) + (0.012\text{ rad/s}^3)(5.00\text{ s})^3 = 3.50$ rad

So $\omega_{\text{av-}z} = \dfrac{3.50\text{ rad} - 0}{5.00\text{ s} - 0} = 0.700$ rad/s.

EVALUATE: The average of the instantaneous angular velocities at the beginning and end of the time interval is $\frac{1}{2}(0.400\text{ rad/s} + 1.30\text{ rad/s}) = 0.850$ rad/s. This is larger than $\omega_{\text{av-}z}$, because $\omega_z(t)$ is increasing faster than linearly.

9.6. **IDENTIFY:** $\omega_z(t) = \dfrac{d\theta}{dt}$. $\alpha_z(t) = \dfrac{d\omega_z}{dt}$. $\omega_{\text{av}-z} = \dfrac{\Delta\theta}{\Delta t}$.

SET UP: $\omega_z = (250\text{ rad/s}) - (40.0\text{ rad/s}^2)t - (4.50\text{ rad/s}^3)t^2$. $\alpha_z = -(40.0\text{ rad/s}^2) - (9.00\text{ rad/s}^3)t$.

EXECUTE: **(a)** Setting $\omega_z = 0$ results in a quadratic in t. The only positive root is $t = 4.23$ s.

(b) At $t = 4.23$ s, $\alpha_z = -78.1$ rad/s^2.

(c) At $t = 4.23$ s, $\theta = 586$ rad $= 93.3$ rev.

(d) At $t = 0$, $\omega_z = 250$ rad/s.

(e) $\omega_{\text{av-}z} = \dfrac{586\text{ rad}}{4.23\text{ s}} = 138$ rad/s.

EVALUATE: Between $t = 0$ and $t = 4.23$ s, ω_z decreases from 250 rad/s to zero. ω_z is not linear in t, so $\omega_{\text{av-}z}$ is not midway between the values of ω_z at the beginning and end of the interval.

9.7. **IDENTIFY:** $\omega_z(t) = \dfrac{d\theta}{dt}$. $\alpha_z(t) = \dfrac{d\omega_z}{dt}$. Use the values of θ and ω_z at $t = 0$ and α_z at 1.50 s to calculate a, b, and c.

SET UP: $\dfrac{d}{dt}t^n = nt^{n-1}$

EXECUTE: **(a)** $\omega_z(t) = b - 3ct^2$. $\alpha_z(t) = -6ct$. At $t = 0$, $\theta = a = \pi/4$ rad and $\omega_z = b = 2.00$ rad/s. At $t = 1.50$ s, $\alpha_z = -6c(1.50\text{ s}) = 1.25$ rad/s^2 and $c = -0.139$ rad/s^3.

(b) $\theta = \pi/4$ rad and $\alpha_z = 0$ at $t = 0$.

(c) $\alpha_z = 3.50$ rad/s^2 at $t = -\dfrac{\alpha_z}{6c} = -\dfrac{3.50\text{ rad/s}^2}{6(-0.139\text{ rad/s}^3)} = 4.20$ s. At $t = 4.20$ s,

$\theta = \dfrac{\pi}{4}\text{ rad} + (2.00\text{ rad/s})(4.20\text{ s}) - (-0.139\text{ rad/s}^3)(4.20\text{ s})^3 = 19.5$ rad.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$\omega_z = 2.00 \text{ rad/s} - 3(-0.139 \text{ rad/s}^3)(4.20 \text{ s})^2 = 9.36 \text{ rad/s}.$

EVALUATE: θ, ω_z and α_z all increase as t increases.

9.8. **IDENTIFY:** $\alpha_z = \dfrac{d\omega_z}{dt}$. $\theta - \theta_0 = \omega_{\text{av-}z}t$. When ω_z is linear in t, $\omega_{\text{av-}z}$ for the time interval t_1 to t_2 is $\omega_{\text{av-}z} = \dfrac{\omega_{z1} + \omega_{z2}}{t_2 - t_1}$.

SET UP: From the information given, $\omega_z(t) = -6.00 \text{ rad/s} + (2.00 \text{ rad/s}^2)t$.

EXECUTE: **(a)** The angular acceleration is positive, since the angular velocity increases steadily from a negative value to a positive value.

(b) It takes 3.00 seconds for the wheel to stop ($\omega_z = 0$). During this time its speed is decreasing. For the next 4.00 s its speed is increasing from 0 rad/s to + 8.00 rad/s.

(c) The average angular velocity is $\dfrac{-6.00 \text{ rad/s} + 8.00 \text{ rad/s}}{2} = 1.00 \text{ rad/s}$. $\theta - \theta_0 = \omega_{\text{av-}z}t$ then leads to displacement of 7.00 rad after 7.00 s.

EVALUATE: When α_z and ω_z have the same sign, the angular speed is increasing; this is the case for $t = 3.00$ s to $t = 7.00$ s. When α_z and ω_z have opposite signs, the angular speed is decreasing; this is the case between $t = 0$ and $t = 3.00$ s.

9.9. **IDENTIFY:** Apply the constant angular acceleration equations.

SET UP: Let the direction the wheel is rotating be positive.

EXECUTE: **(a)** $\omega_z = \omega_{0z} + \alpha_z t = 1.50 \text{ rad/s} + (0.300 \text{ rad/s}^2)(2.50 \text{ s}) = 2.25 \text{ rad/s}.$

(b) $\theta - \theta_0 = \omega_{0z}t + \frac{1}{2}\alpha_z t^2 = (1.50 \text{ rad/s})(2.50 \text{ s}) + \frac{1}{2}(0.300 \text{ rad/s}^2)(2.50 \text{ s})^2 = 4.69 \text{ rad}.$

EVALUATE: $\theta - \theta_0 = \left(\dfrac{\omega_{0z} + \omega_z}{2}\right)t = \left(\dfrac{1.50 \text{ rad/s} + 2.25 \text{ rad/s}}{2}\right)(2.50 \text{ s}) = 4.69 \text{ rad},$ the same as calculated with another equation in part (b).

9.10. **IDENTIFY:** Apply the constant angular acceleration equations to the motion of the fan.

(a) SET UP: $\omega_{0z} = (500 \text{ rev/min})(1 \text{ min}/60 \text{ s}) = 8.333 \text{ rev/s}$, $\omega_z = (200 \text{ rev/min})(1 \text{ min}/60 \text{ s}) = 3.333 \text{ rev/s}$, $t = 4.00$ s, $\alpha_z = ?$

$\omega_z = \omega_{0z} + \alpha_z t$

EXECUTE: $\alpha_z = \dfrac{\omega_z - \omega_{0z}}{t} = \dfrac{3.333 \text{ rev/s} - 8.333 \text{ rev/s}}{4.00 \text{ s}} = -1.25 \text{ rev/s}^2$

$\theta - \theta_0 = ?$

$\theta - \theta_0 = \omega_{0z}t + \frac{1}{2}\alpha_z t^2 = (8.333 \text{ rev/s})(4.00 \text{ s}) + \frac{1}{2}(-1.25 \text{ rev/s}^2)(4.00 \text{ s})^2 = 23.3 \text{ rev}$

(b) SET UP: $\omega_z = 0$ (comes to rest); $\omega_{0z} = 3.333 \text{ rev/s}$; $\alpha_z = -1.25 \text{ rev/s}^2$; $t = ?$

$\omega_z = \omega_{0z} + \alpha_z t$

EXECUTE: $t = \dfrac{\omega_z - \omega_{0z}}{\alpha_z} = \dfrac{0 - 3.333 \text{ rev/s}}{-1.25 \text{ rev/s}^2} = 2.67 \text{ s}$

EVALUATE: The angular acceleration is negative because the angular velocity is decreasing. The average angular velocity during the 4.00 s time interval is 350 rev/min and $\theta - \theta_0 = \omega_{\text{av-}z}t$ gives $\theta - \theta_0 = 23.3$ rev, which checks.

9.11. **IDENTIFY:** Apply the constant angular acceleration equations to the motion. The target variables are t and $\theta - \theta_0$.

SET UP: **(a)** $\alpha_z = 1.50 \text{ rad/s}^2$; $\omega_{0z} = 0$ (starts from rest); $\omega_z = 36.0 \text{ rad/s}$; $t = ?$

$\omega_z = \omega_{0z} + \alpha_z t$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: $t = \dfrac{\omega_z - \omega_{0z}}{\alpha_z} = \dfrac{36.0 \text{ rad/s} - 0}{1.50 \text{ rad/s}^2} = 24.0 \text{ s}$

(b) $\theta - \theta_0 = ?$

$\theta - \theta_0 = \omega_{0z}t + \frac{1}{2}\alpha_z t^2 = 0 + \frac{1}{2}(1.50 \text{ rad/s}^2)(24.0 \text{ s})^2 = 432 \text{ rad}$

$\theta - \theta_0 = 432 \text{ rad}(1 \text{ rev}/2\pi \text{ rad}) = 68.8 \text{ rev}$

EVALUATE: We could use $\theta - \theta_0 = \frac{1}{2}(\omega_z + \omega_{0z})t$ to calculate $\theta - \theta_0 = \frac{1}{2}(0 + 36.0 \text{ rad/s})(24.0 \text{ s}) = 432 \text{ rad}$, which checks.

9.12. **IDENTIFY:** In part (b) apply the equation derived in part (a).

SET UP: Let the direction the propeller is rotating be positive.

EXECUTE: **(a)** Solving Eq. (9.7) for t gives $t = \dfrac{\omega_z - \omega_{0z}}{\alpha_z}$. Rewriting Eq. (9.11) as $\theta - \theta_0 = t(\omega_{0z} + \frac{1}{2}\alpha_z t)$ and substituting for t gives

$$\theta - \theta_0 = \left(\frac{\omega_z - \omega_{0z}}{\alpha_z}\right)\left(\omega_{0z} + \frac{1}{2}(\omega_z - \omega_{0z})\right) = \frac{1}{\alpha_z}(\omega_z - \omega_{0z})\left(\frac{\omega_z + \omega_{0z}}{2}\right) = \frac{1}{2\alpha_z}(\omega_z^2 - \omega_{0z}^2),$$

which when rearranged gives Eq. (9.12).

(b) $\alpha_z = \frac{1}{2}\left(\dfrac{1}{\theta - \theta_0}\right)\left(\omega_z^2 - \omega_{0z}^2\right) = \frac{1}{2}\left(\dfrac{1}{7.00 \text{ rad}}\right)\left((16.0 \text{ rad/s})^2 - (12.0 \text{ rad/s})^2\right) = 8.00 \text{ rad/s}^2$

EVALUATE: We could also use $\theta - \theta_0 = \left(\dfrac{\omega_{0z} + \omega_z}{2}\right)t$ to calculate $t = 0.500$ s. Then $\omega_z = \omega_{0z} + \alpha_z t$ gives $\alpha_z = 8.00 \text{ rad/s}^2$, which agrees with our results in part (b).

9.13. **IDENTIFY:** Use a constant angular acceleration equation and solve for ω_{0z}.

SET UP: Let the direction of rotation of the flywheel be positive.

EXECUTE: $\theta - \theta_0 = \omega_{0z}t + \frac{1}{2}\alpha_z t^2$ gives $\omega_{0z} = \dfrac{\theta - \theta_0}{t} - \frac{1}{2}a_z\, t = \dfrac{60.0 \text{ rad}}{4.00 \text{ s}} - \frac{1}{2}(2.25 \text{ rad/s}^2)(4.00 \text{ s}) = 10.5 \text{ rad/s}.$

EVALUATE: At the end of the 4.00 s interval, $\omega_z = \omega_{0z} + \alpha_z t = 19.5 \text{ rad/s}$.

$\theta - \theta_0 = \left(\dfrac{\omega_{0z} + \omega_z}{2}\right)t = \left(\dfrac{10.5 \text{ rad/s} + 19.5 \text{ rad/s}}{2}\right)(4.00 \text{ s}) = 60.0 \text{ rad}$, which checks.

9.14. **IDENTIFY:** Apply the constant angular acceleration equations.

SET UP: Let the direction of the rotation of the blade be positive. $\omega_{0z} = 0$.

EXECUTE: $\omega_z = \omega_{0z} + \alpha_z t$ gives $\alpha_z = \dfrac{\omega_z - \omega_{0z}}{t} = \dfrac{140 \text{ rad/s} - 0}{6.00 \text{ s}} = 23.3 \text{ rad/s}^2.$

$(\theta - \theta_0) = \left(\dfrac{\omega_{0z} + \omega_z}{2}\right)t = \left(\dfrac{0 + 140 \text{ rad/s}}{2}\right)(6.00 \text{ s}) = 420 \text{ rad}$

EVALUATE: We could also use $\theta - \theta_0 = \omega_{0z}t + \frac{1}{2}\alpha_z t^2$. This equation gives

$\theta - \theta_0 = \frac{1}{2}(23.3 \text{ rad/s}^2)(6.00 \text{ s})^2 = 419 \text{ rad}$, in agreement with the result obtained above.

9.15. **IDENTIFY:** Apply constant angular acceleration equations.

SET UP: Let the direction the flywheel is rotating be positive.

$\theta - \theta_0 = 200$ rev, $\omega_{0z} = 500$ rev/min $= 8.333$ rev/s, $t = 30.0$ s.

EXECUTE: **(a)** $\theta - \theta_0 = \left(\dfrac{\omega_{0z} + \omega_z}{2}\right)t$ gives $\omega_z = 5.00 \text{ rev/s} = 300 \text{ rpm}$

(b) Use the information in part (a) to find α_z: $\omega_z = \omega_{0z} + \alpha_z t$ gives $\alpha_z = -0.1111 \text{ rev/s}^2$. Then $\omega_z = 0$, $\alpha_z = -0.1111 \text{ rev/s}^2$, $\omega_{0z} = 8.333 \text{ rev/s}$ in $\omega_z = \omega_{0z} + \alpha_z t$ gives $t = 75.0$ s and $\theta - \theta_0 = \left(\dfrac{\omega_{0z} + \omega_z}{2}\right)t$ gives $\theta - \theta_0 = 312$ rev.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: The mass and diameter of the flywheel are not used in the calculation.

9.16. **IDENTIFY:** Apply the constant angular acceleration equations separately to the time intervals 0 to 2.00 s and 2.00 s until the wheel stops.

(a) SET UP: Consider the motion from $t = 0$ to $t = 2.00$ s:

$\theta - \theta_0 = ?;\ \omega_{0z} = 24.0$ rad/s; $\alpha_z = 30.0$ rad/s^2; $t = 2.00$ s

EXECUTE: $\theta - \theta_0 = \omega_{0z}t + \frac{1}{2}\alpha_z t^2 = (24.0 \text{ rad/s})(2.00 \text{ s}) + \frac{1}{2}(30.0 \text{ rad/s}^2)(2.00 \text{ s})^2$

$\theta - \theta_0 = 48.0 \text{ rad} + 60.0 \text{ rad} = 108 \text{ rad}$

Total angular displacement from $t = 0$ until stops: 108 rad + 432 rad = 540 rad

Note: At $t = 2.00$ s, $\omega_z = \omega_{0z} + \alpha_z t = 24.0 \text{ rad/s} + (30.0 \text{ rad/s}^2)(2.00 \text{ s}) = 84.0$ rad/s; angular speed when breaker trips.

(b) SET UP: Consider the motion from when the circuit breaker trips until the wheel stops. For this calculation let $t = 0$ when the breaker trips.

$t = ?;\ \theta - \theta_0 = 432$ rad; $\omega_z = 0$; $\omega_{0z} = 84.0$ rad/s (from part (a))

$$\theta - \theta_0 = \left(\frac{\omega_{0z} + \omega_z}{2}\right)t$$

EXECUTE: $$t = \frac{2(\theta - \theta_0)}{\omega_{0z} + \omega_z} = \frac{2(432 \text{ rad})}{84.0 \text{ rad/s} + 0} = 10.3 \text{ s}$$

The wheel stops 10.3 s after the breaker trips so $2.00 \text{ s} + 10.3 \text{ s} = 12.3$ s from the beginning.

(c) SET UP: $\alpha_z = ?$; consider the same motion as in part (b):

$\omega_z = \omega_{0z} + \alpha_z t$

EXECUTE: $$\alpha_z = \frac{\omega_z - \omega_{0z}}{t} = \frac{0 - 84.0 \text{ rad/s}}{10.3 \text{ s}} = -8.16 \text{ rad/s}^2$$

EVALUATE: The angular acceleration is positive while the wheel is speeding up and negative while it is slowing down. We could also use $\omega_z^2 = \omega_{0z}^2 + 2\alpha_z(\theta - \theta_0)$ to calculate

$$\alpha_z = \frac{\omega_z^2 - \omega_{0z}^2}{2(\theta - \theta_0)} = \frac{0 - (84.0 \text{ rad/s})^2}{2(432 \text{ rad})} = -8.16 \text{ rad/s}^2$$ for the acceleration after the breaker trips.

9.17. **IDENTIFY:** Apply Eq. (9.12) to relate ω_z to $\theta - \theta_0$.

SET UP: Establish a proportionality.

EXECUTE: From Eq. (9.12), with $\omega_{0z} = 0$, the number of revolutions is proportional to the square of the initial angular velocity, so tripling the initial angular velocity increases the number of revolutions by 9, to 9.00 rev.

EVALUATE: We don't have enough information to calculate α_z; all we need to know is that it is constant.

9.18. **IDENTIFY:** The linear distance the elevator travels, its speed and the magnitude of its acceleration are equal to the tangential displacement, speed and acceleration of a point on the rim of the disk. $s = r\theta$, $v = r\omega$ and $a = r\alpha$. In these equations the angular quantities must be in radians.

SET UP: 1 rev $= 2\pi$ rad. 1 rpm $= 0.1047$ rad/s. π rad $= 180°$. For the disk, $r = 1.25$ m.

EXECUTE: **(a)** $v = 0.250$ m/s so $$\omega = \frac{v}{r} = \frac{0.250 \text{ m/s}}{1.25 \text{ m}} = 0.200 \text{ rad/s} = 1.91 \text{ rpm}.$$

(b) $a = \frac{1}{8}g = 1.225$ m/s^2. $$\alpha = \frac{a}{r} = \frac{1.225 \text{ m/s}^2}{1.25 \text{ m}} = 0.980 \text{ rad/s}^2.$$

(c) $s = 3.25$ m. $$\theta = \frac{s}{r} = \frac{3.25 \text{ m}}{1.25 \text{ m}} = 2.60 \text{ rad} = 149°.$$

EVALUATE: When we use $s = r\theta$, $v = r\omega$ and $a_{\tan} = r\alpha$ to solve for θ, ω and α, the results are in rad, rad/s and rad/s^2.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

9.19. **IDENTIFY:** When the angular speed is constant, $\omega = \theta/t$. $v_{\tan} = r\omega$, $a_{\tan} = r\alpha$ and $a_{\text{rad}} = r\omega^2$. In these equations radians must be used for the angular quantities.

SET UP: The radius of the earth is $R_E = 6.38\times10^6$ m and the earth rotates once in 1 day = 86,400 s. The orbit radius of the earth is 1.50×10^{11} m and the earth completes one orbit in 1 y = 3.156×10^7 s. When ω is constant, $\omega = \theta/t$.

EXECUTE: **(a)** $\theta = 1 \text{ rev} = 2\pi \text{ rad}$ in $t = 3.156\times10^7$ s. $\omega = \dfrac{2\pi \text{ rad}}{3.156\times10^7 \text{ s}} = 1.99\times10^{-7}$ rad/s.

(b) $\theta = 1 \text{ rev} = 2\pi \text{ rad}$ in $t = 86{,}400$ s. $\omega = \dfrac{2\pi \text{ rad}}{86{,}400 \text{ s}} = 7.27\times10^{-5}$ rad/s

(c) $v = r\omega = (1.50\times10^{11} \text{ m})(1.99\times10^{-7} \text{ rad/s}) = 2.98\times10^4$ m/s.

(d) $v = r\omega = (6.38\times10^6 \text{ m})(7.27\times10^{-5} \text{ rad/s}) = 464$ m/s.

(e) $a_{\text{rad}} = r\omega^2 = (6.38\times10^6 \text{ m})(7.27\times10^{-5} \text{ rad/s})^2 = 0.0337 \text{ m/s}^2$. $a_{\tan} = r\alpha = 0$. $\alpha = 0$ since the angular velocity is constant.

EVALUATE: The tangential speeds associated with these motions are large even though the angular speeds are very small, because the radius for the circular path in each case is quite large.

9.20. **IDENTIFY:** Linear and angular velocities are related by $v = r\omega$. Use $\omega_z = \omega_{0z} + \alpha_z t$ to calculate α_z.

SET UP: $\omega = v/r$ gives ω in rad/s.

EXECUTE: **(a)** $\dfrac{1.25 \text{ m/s}}{25.0\times10^{-3} \text{ m}} = 50.0$ rad/s, $\dfrac{1.25 \text{ m/s}}{58.0\times10^{-3} \text{ m}} = 21.6$ rad/s.

(b) $(1.25 \text{ m/s})(74.0 \text{ min})(60 \text{ s/min}) = 5.55$ km.

(c) $\alpha_z = \dfrac{21.55 \text{ rad/s} - 50.0 \text{ rad/s}}{(74.0 \text{ min})(60 \text{ s/min})} = -6.41\times10^{-3} \text{ rad/s}^2$.

EVALUATE: The width of the tracks is very small, so the total track length on the disc is huge.

9.21. **IDENTIFY:** Use constant acceleration equations to calculate the angular velocity at the end of two revolutions. $v = r\omega$.

SET UP: 2 rev = 4π rad. $r = 0.200$ m.

EXECUTE: **(a)** $\omega_z^2 = \omega_{0z}^2 + 2\alpha_z(\theta - \theta_0)$. $\omega_z = \sqrt{2\alpha_z(\theta - \theta_0)} = \sqrt{2(3.00 \text{ rad/s}^2)(4\pi \text{ rad})} = 8.68$ rad/s.

$a_{\text{rad}} = r\omega^2 = (0.200 \text{ m})(8.68 \text{ rad/s})^2 = 15.1 \text{ m/s}^2$.

(b) $v = r\omega = (0.200 \text{ m})(8.68 \text{ rad/s}) = 1.74$ m/s. $a_{\text{rad}} = \dfrac{v^2}{r} = \dfrac{(1.74 \text{ m/s})^2}{0.200 \text{ m}} = 15.1 \text{ m/s}^2$.

EVALUATE: $r\omega^2$ and v^2/r are completely equivalent expressions for a_{rad}.

9.22. **IDENTIFY:** $v = r\omega$ and $a_{\tan} = r\alpha$.

SET UP: The linear acceleration of the bucket equals $a_{\tan}$ for a point on the rim of the axle.

EXECUTE: **(a)** $v = R\omega$. $2.00 \text{ cm/s} = R\left(\dfrac{7.5 \text{ rev}}{\text{min}}\right)\left(\dfrac{1 \text{ min}}{60 \text{ s}}\right)\left(\dfrac{2\pi \text{ rad}}{1 \text{ rev}}\right)$ gives $R = 2.55$ cm.

$D = 2R = 5.09$ cm.

(b) $a_{\tan} = R\alpha$. $\alpha = \dfrac{a_{\tan}}{R} = \dfrac{0.400 \text{ m/s}^2}{0.0255 \text{ m}} = 15.7 \text{ rad/s}^2$.

EVALUATE: In $v = R\omega$ and $a_{\tan} = R\alpha$, ω and α must be in radians.

9.23. **IDENTIFY** and **SET UP:** Use constant acceleration equations to find ω and α after each displacement. Then use Eqs. (9.14) and (9.15) to find the components of the linear acceleration.

EXECUTE: **(a)** <u>at the start</u> $t = 0$

flywheel starts from rest so $\omega = \omega_{0z} = 0$

$a_{\tan} = r\alpha = (0.300 \text{ m})(0.600 \text{ rad/s}^2) = 0.180 \text{ m/s}^2$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$a_{\text{rad}} = r\omega^2 = 0$

$a = \sqrt{a_{\text{rad}}^2 + a_{\text{tan}}^2} = 0.180 \text{ m/s}^2$

(b) $\theta - \theta_0 = 60°$

$a_{\text{tan}} = r\alpha = 0.180 \text{ m/s}^2$

Calculate ω:

$\theta - \theta_0 = 60°(\pi \text{ rad}/180°) = 1.047 \text{ rad}$; $\omega_{0z} = 0$; $\alpha_z = 0.600 \text{ rad/s}^2$; $\omega_z = ?$

$\omega_z^2 = \omega_{0z}^2 + 2\alpha_z(\theta - \theta_0)$

$\omega_z = \sqrt{2\alpha_z(\theta - \theta_0)} = \sqrt{2(0.600 \text{ rad/s}^2)(1.047 \text{ rad})} = 1.121 \text{ rad/s}$ and $\omega = \omega_z$.

Then $a_{\text{rad}} = r\omega^2 = (0.300 \text{ m})(1.121 \text{ rad/s})^2 = 0.377 \text{ m/s}^2$.

$a = \sqrt{a_{\text{rad}}^2 + a_{\text{tan}}^2} = \sqrt{(0.377 \text{ m/s}^2)^2 + (0.180 \text{ m/s}^2)^2} = 0.418 \text{ m/s}^2$

(c) $\theta - \theta_0 = 120°$

$a_{\text{tan}} = r\alpha = 0.180 \text{ m/s}^2$

Calculate ω:

$\theta - \theta_0 = 120°(\pi \text{ rad}/180°) = 2.094 \text{ rad}$; $\omega_{0z} = 0$; $\alpha_z = 0.600 \text{ rad/s}^2$; $\omega_z = ?$

$\omega_z^2 = \omega_{0z}^2 + 2\alpha_z(\theta - \theta_0)$

$\omega_z = \sqrt{2\alpha_z(\theta - \theta_0)} = \sqrt{2(0.600 \text{ rad/s}^2)(2.094 \text{ rad})} = 1.585 \text{ rad/s}$ and $\omega = \omega_z$.

Then $a_{\text{rad}} = r\omega^2 = (0.300 \text{ m})(1.585 \text{ rad/s})^2 = 0.754 \text{ m/s}^2$.

$a = \sqrt{a_{\text{rad}}^2 + a_{\text{tan}}^2} = \sqrt{(0.754 \text{ m/s}^2)^2 + (0.180 \text{ m/s}^2)^2} = 0.775 \text{ m/s}^2$.

EVALUATE: α is constant so α_{tan} is constant. ω increases so a_{rad} increases.

9.24. **IDENTIFY:** Apply constant angular acceleration equations. $v = r\omega$. A point on the rim has both tangential and radial components of acceleration.

SET UP: $a_{\text{tan}} = r\alpha$ and $a_{\text{rad}} = r\omega^2$.

EXECUTE: **(a)** $\omega_z = \omega_{0z} + \alpha_z t = 0.250 \text{ rev/s} + (0.900 \text{ rev/s}^2)(0.200 \text{ s}) = 0.430 \text{ rev/s}$

(Note that since ω_{0z} and α_z are given in terms of revolutions, it's not necessary to convert to radians).

(b) $\omega_{\text{av-}z}\Delta t = (0.340 \text{ rev/s})(0.2 \text{ s}) = 0.068 \text{ rev}$.

(c) Here, the conversion to radians must be made to use Eq. (9.13), and

$$v = r\omega = \left(\frac{0.750 \text{ m}}{2}\right)(0.430 \text{ rev/s})(2\pi \text{ rad/rev}) = 1.01 \text{ m/s}.$$

(d) Combining Eqs. (9.14) and (9.15),

$a = \sqrt{a_{\text{rad}}^2 + a_{\text{tan}}^2} = \sqrt{(\omega^2 r)^2 + (\alpha r)^2}$.

$a = \sqrt{\left[((0.430 \text{ rev/s})(2\pi \text{ rad/rev}))^2(0.375 \text{ m})\right]^2 + \left[(0.900 \text{ rev/s}^2)(2\pi \text{ rad/rev})(0.375 \text{ m})\right]^2}$.

$a = 3.46 \text{ m/s}^2$.

EVALUATE: If the angular acceleration is constant, a_{tan} is constant but a_{rad} increases as ω increases.

9.25. **IDENTIFY:** Use Eq. (9.15) and solve for r.

SET UP: $a_{\text{rad}} = r\omega^2$ so $r = a_{\text{rad}}/\omega^2$, where ω must be in rad/s

EXECUTE: $a_{\text{rad}} = 3000g = 3000(9.80 \text{ m/s}^2) = 29{,}400 \text{ m/s}^2$

$$\omega = (5000 \text{ rev/min})\left(\frac{1 \text{ min}}{60 \text{ s}}\right)\left(\frac{2\pi \text{ rad}}{1 \text{ rev}}\right) = 523.6 \text{ rad/s}$$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

Then $r = \dfrac{a_{\text{rad}}}{\omega^2} = \dfrac{29{,}400 \text{ m/s}^2}{(523.6 \text{ rad/s})^2} = 0.107 \text{ m}.$

EVALUATE: The diameter is then 0.214 m, which is larger than 0.127 m, so the claim is *not* realistic.

9.26. **IDENTIFY:** In part (b) apply the result derived in part (a).

SET UP: $a_{\text{rad}} = r\omega^2$ and $v = r\omega$, combine to eliminate r.

EXECUTE: **(a)** $a_{\text{rad}} = \omega^2 r = \omega^2 \left(\dfrac{v}{\omega}\right) = \omega v.$

(b) From the result of part (a), $\omega = \dfrac{a_{\text{rad}}}{v} = \dfrac{0.500 \text{ m/s}^2}{2.00 \text{ m/s}} = 0.250 \text{ rad/s}.$

EVALUATE: $a_{\text{rad}} = r\omega^2$ and $v = r\omega$ both require that ω be in rad/s, so in $a_{\text{rad}} = \omega v$, ω is in rad/s.

9.27. **IDENTIFY:** $v = r\omega$ and $a_{\text{rad}} = r\omega^2 = v^2/r$.

SET UP: 2π rad $= 1$ rev, so π rad/s $= 30$ rev/min.

EXECUTE: **(a)** $\omega r = (1250 \text{ rev/min})\left(\dfrac{\pi \text{ rad/s}}{30 \text{ rev/min}}\right)\left(\dfrac{12.7\times10^{-3} \text{m}}{2}\right) = 0.831 \text{ m/s}.$

(b) $\dfrac{v^2}{r} = \dfrac{(0.831 \text{ m/s})^2}{(12.7\times10^{-3} \text{ m})/2} = 109 \text{ m/s}^2.$

EVALUATE: In $v = r\omega$, ω must be in rad/s.

9.28. **IDENTIFY:** $a_{\text{tan}} = r\alpha$, $v = r\omega$ and $a_{\text{rad}} = v^2/r$. $\theta - \theta_0 = \omega_{\text{av-}z} t$.

SET UP: When α_z is constant, $\omega_{\text{av-}z} = \dfrac{\omega_{0z} + \omega_z}{2}$. Let the direction the wheel is rotating be positive.

EXECUTE: **(a)** $\alpha = \dfrac{a_{\text{tan}}}{r} = \dfrac{-10.0 \text{ m/s}^2}{0.200 \text{ m}} = -50.0 \text{ rad/s}^2$

(b) At $t = 3.00$ s, $v = 50.0$ m/s and $\omega = \dfrac{v}{r} = \dfrac{50.0 \text{ m/s}}{0.200 \text{ m}} = 250 \text{ rad/s}$ and at $t = 0$,

$v = 50.0 \text{ m/s} + (-10.0 \text{ m/s}^2)(0 - 3.00 \text{ s}) = 80.0 \text{ m/s}, \quad \omega = 400 \text{ rad/s}.$

(c) $\omega_{\text{av-}z} t = (325 \text{ rad/s})(3.00 \text{ s}) = 975 \text{ rad} = 155 \text{ rev}.$

(d) $v = \sqrt{a_{\text{rad}} r} = \sqrt{(9.80 \text{ m/s}^2)(0.200 \text{ m})} = 1.40 \text{ m/s}.$ This speed will be reached at time

$\dfrac{50.0 \text{ m/s} - 1.40 \text{ m/s}}{10.0 \text{ m/s}^2} = 4.86 \text{ s}$ after $t = 3.00$ s, or at $t = 7.86$ s. (There are many equivalent ways to do this calculation.)

EVALUATE: At $t = 0$, $a_{\text{rad}} = r\omega^2 = 3.20\times10^4$ m/s^2. At $t = 3.00$ s, $a_{\text{rad}} = 1.25\times10^4$ m/s^2. For $a_{\text{rad}} = g$ the wheel must be rotating more slowly than at 3.00 s so it occurs some time after 3.00 s.

9.29. **IDENTIFY** and **SET UP:** Use Eq. (9.15) to relate ω to a_{rad} and $\sum \vec{F} = m\vec{a}$ to relate a_{rad} to F_{rad}. Use Eq. (9.13) to relate ω and v, where v is the tangential speed.

EXECUTE: **(a)** $a_{\text{rad}} = r\omega^2$ and $F_{\text{rad}} = ma_{\text{rad}} = mr\omega^2$

$\dfrac{F_{\text{rad},2}}{F_{\text{rad},1}} = \left(\dfrac{\omega_2}{\omega_1}\right)^2 = \left(\dfrac{640 \text{ rev/min}}{423 \text{ rev/min}}\right)^2 = 2.29$

(b) $v = r\omega$

$\dfrac{v_2}{v_1} = \dfrac{\omega_2}{\omega_1} = \dfrac{640 \text{ rev/min}}{423 \text{ rev/min}} = 1.51$

(c) $v = r\omega$

$\omega = (640 \text{ rev/min})\left(\dfrac{1 \text{ min}}{60 \text{ s}}\right)\left(\dfrac{2\pi \text{ rad}}{1 \text{ rev}}\right) = 67.0 \text{ rad/s}$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

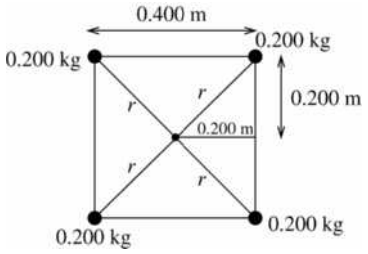
Then $v = r\omega = (0.235\text{ m})(67.0\text{ rad/s}) = 15.7\text{ m/s}$.

$a_{\text{rad}} = r\omega^2 = (0.235\text{ m})(67.0\text{ rad/s})^2 = 1060\text{ m/s}^2$

$\dfrac{a_{\text{rad}}}{g} = \dfrac{1060\text{ m/s}^2}{9.80\text{ m/s}^2} = 108;\quad a = 108g$

EVALUATE: In parts (a) and (b), since a ratio is used the units cancel and there is no need to convert ω to rad/s. In part (c), v and a_{rad} are calculated from ω, and ω must be in rad/s.

9.30. **IDENTIFY** and **SET UP:** Use Eq. (9.16). Treat the spheres as point masses and ignore I of the light rods.
EXECUTE: The object is shown in Figure 9.30a.
(a)



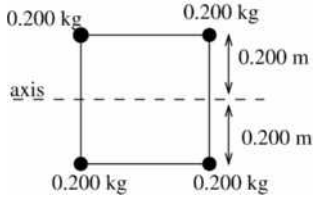
$r = \sqrt{(0.200\text{ m})^2 + (0.200\text{ m})^2} = 0.2828\text{ m}$

$I = \sum m_i r_i^2 = 4(0.200\text{ kg})(0.2828\text{ m})^2$

$I = 0.0640\text{ kg}\cdot\text{m}^2$

Figure 9.30a

(b) The object is shown in Figure 9.30b.



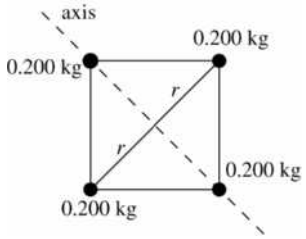
$r = 0.200\text{ m}$

$I = \sum m_i r_i^2 = 4(0.200\text{ kg})(0.200\text{ m})^2$

$I = 0.0320\text{ kg}\cdot\text{m}^2$

Figure 9.30b

(c) The object is shown in Figure 9.30c.



$r = 0.2828\text{ m}$

$I = \sum m_i r_i^2 = 2(0.200\text{ kg})(0.2828\text{ m})^2$

$I = 0.0320\text{ kg}\cdot\text{m}^2$

Figure 9.30c

EVALUATE: In general I depends on the axis and our answer for part (a) is larger than for parts (b) and (c). It just happens that I is the same in parts (b) and (c).

9.31. **IDENTIFY:** Use Table 9.2. The correct expression to use in each case depends on the shape of the object and the location of the axis.
SET UP: In each case express the mass in kg and the length in m, so the moment of inertia will be in $\text{kg}\cdot\text{m}^2$.

EXECUTE: **(a)** (i) $I = \frac{1}{3}ML^2 = \frac{1}{3}(2.50\text{ kg})(0.750\text{ m})^2 = 0.469\text{ kg}\cdot\text{m}^2$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(ii) $I = \frac{1}{12}ML^2 = \frac{1}{4}(0.469\ \text{kg}\cdot\text{m}^2) = 0.117\ \text{kg}\cdot\text{m}^2$. (iii) For a very thin rod, all of the mass is at the axis and $I = 0$.

(b) (i) $I = \frac{2}{5}MR^2 = \frac{2}{5}(3.00\ \text{kg})(0.190\ \text{m})^2 = 0.0433\ \text{kg}\cdot\text{m}^2$.

(ii) $I = \frac{2}{3}MR^2 = \frac{5}{3}(0.0433\ \text{kg}\cdot\text{m}^2) = 0.0722\ \text{kg}\cdot\text{m}^2$.

(c) (i) $I = MR^2 = (8.00\ \text{kg})(0.0600\ \text{m})^2 = 0.0288\ \text{kg}\cdot\text{m}^2$.

(ii) $I = \frac{1}{2}MR^2 = \frac{1}{2}(8.00\ \text{kg})(0.0600\ \text{m})^2 = 0.0144\ \text{kg}\cdot\text{m}^2$.

EVALUATE: I depends on how the mass of the object is distributed relative to the axis.

9.32. **IDENTIFY:** Treat each block as a point mass, so for each block $I = mr^2$, where r is the distance of the block from the axis. The total I for the object is the sum of the I for each of its pieces.

SET UP: In part (a) two blocks are a distance $L/2$ from the axis and the third block is on the axis. In part (b) two blocks are a distance $L/4$ from the axis and one is a distance $3L/4$ from the axis.

EXECUTE: **(a)** $I = 2m(L/2)^2 = \frac{1}{2}mL^2$.

(b) $I = 2m(L/4)^2 + m(3L/4)^2 = \dfrac{1}{16}mL^2(2+9) = \dfrac{11}{16}mL^2$.

EVALUATE: For the same object I is in general different for different axes.

9.33. **IDENTIFY:** I for the object is the sum of the values of I for each part.

SET UP: For the bar, for an axis perpendicular to the bar, use the appropriate expression from Table 9.2. For a point mass, $I = mr^2$, where r is the distance of the mass from the axis.

EXECUTE: **(a)** $I = I_{\text{bar}} + I_{\text{balls}} = \dfrac{1}{12}M_{\text{bar}}L^2 + 2m_{\text{balls}}\left(\dfrac{L}{2}\right)^2$.

$$I = \frac{1}{12}(4.00\ \text{kg})(2.00\ \text{m})^2 + 2(0.500\ \text{kg})(1.00\ \text{m})^2 = 2.33\ \text{kg}\cdot\text{m}^2$$

(b) $I = \dfrac{1}{3}m_{\text{bar}}L^2 + m_{\text{ball}}L^2 = \dfrac{1}{3}(4.00\ \text{kg})(2.00\ \text{m})^2 + (0.500\ \text{kg})(2.00\ \text{m})^2 = 7.33\ \text{kg}\cdot\text{m}^2$

(c) $I = 0$ because all masses are on the axis.

(d) All the mass is a distance $d = 0.500$ m from the axis and

$I = m_{\text{bar}}d^2 + 2m_{\text{ball}}d^2 = M_{\text{Total}}d^2 = (5.00\ \text{kg})(0.500\ \text{m})^2 = 1.25\ \text{kg}\cdot\text{m}^2$.

EVALUATE: I for an object depends on the location and direction of the axis.

9.34. **IDENTIFY:** Compare this object to a uniform disk of radius R and mass $2M$.

SET UP: With an axis perpendicular to the round face of the object at its center, I for a uniform disk is the same as for a solid cylinder.

EXECUTE: **(a)** The total I for a disk of mass $2M$ and radius R, $I = \frac{1}{2}(2M)R^2 = MR^2$. Each half of the disk has the same I, so for the half-disk, $I = \frac{1}{2}MR^2$.

(b) The same mass M is distributed the same way as a function of distance from the axis.

(c) The same method as in part (a) says that I for a quarter-disk of radius R and mass M is half that of a half-disk of radius R and mass $2M$, so $I = \frac{1}{2}(\frac{1}{2}[2M]R^2) = \frac{1}{2}MR^2$.

EVALUATE: I depends on how the mass of the object is distributed relative to the axis, and this is the same for any segment of a disk.

9.35. **IDENTIFY** and **SET UP:** $I = \sum m_i r_i^2$ implies $I = I_{\text{rim}} + I_{\text{spokes}}$

EXECUTE: $I_{\text{rim}} = MR^2 = (1.40\ \text{kg})(0.300\ \text{m})^2 = 0.126\ \text{kg}\cdot\text{m}^2$

Each spoke can be treated as a slender rod with the axis through one end, so

$I_{\text{spokes}} = 8\left(\frac{1}{3}ML^2\right) = \frac{8}{3}(0.280\ \text{kg})(0.300\ \text{m})^2 = 0.0672\ \text{kg}\cdot\text{m}^2$

$I = I_{\text{rim}} + I_{\text{spokes}} = 0.126\ \text{kg}\cdot\text{m}^2 + 0.0672\ \text{kg}\cdot\text{m}^2 = 0.193\ \text{kg}\cdot\text{m}^2$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: Our result is smaller than $m_{\text{tot}}R^2 = (3.64\text{ kg})(0.300\text{ m})^2 = 0.328\text{ kg}\cdot\text{m}^2$, since the mass of each spoke is distributed between $r = 0$ and $r = R$.

9.36. **IDENTIFY:** $K = \frac{1}{2}I\omega^2$. Use Table 9.2b to calculate I.

SET UP: $I = \frac{1}{12}ML^2$. 1 rpm = 0.1047 rad/s

EXECUTE: **(a)** $I = \frac{1}{12}(117\text{ kg})(2.08\text{ m})^2 = 42.2\text{ kg}\cdot\text{m}^2$. $\omega = (2400\text{ rev/min})\left(\dfrac{0.1047\text{ rad/s}}{1\text{ rev/min}}\right) = 251\text{ rad/s}$.

$K = \frac{1}{2}I\omega^2 = \frac{1}{2}(42.2\text{ kg}\cdot\text{m}^2)(251\text{ rad/s})^2 = 1.33\times10^6\text{ J}$.

(b) $K_1 = \frac{1}{12}M_1L_1^2\omega_1^2$, $K_2 = \frac{1}{12}M_2L_2^2\omega_2^2$. $L_1 = L_2$ and $K_1 = K_2$, so $M_1\omega_1^2 = M_2\omega_2^2$.

$$\omega_2 = \omega_1\sqrt{\frac{M_1}{M_2}} = (2400\text{ rpm})\sqrt{\frac{M_1}{0.750M_1}} = 2770\text{ rpm}$$

EVALUATE: The rotational kinetic energy is proportional to the square of the angular speed and directly proportional to the mass of the object.

9.37. **IDENTIFY:** I for the compound disk is the sum of I of the solid disk and of the ring.

SET UP: For the solid disk, $I = \frac{1}{2}m_{\text{d}}r_{\text{d}}^2$. For the ring, $I_{\text{r}} = \frac{1}{2}m_{\text{r}}(r_1^2 + r_2^2)$, where $r_1 = 50.0$ cm, $r_2 = 70.0$ cm. The mass of the disk and ring is their area times their area density.

EXECUTE: $I = I_{\text{d}} + I_{\text{r}}$.

Disk: $m_{\text{d}} = (3.00\text{ g/cm}^2)\pi r_{\text{d}}^2 = 23.56\text{ kg}$. $I_{\text{d}} = \dfrac{1}{2}m_{\text{d}}r_{\text{d}}^2 = 2.945\text{ kg}\cdot\text{m}^2$.

Ring: $m_{\text{r}} = (2.00\text{ g/cm}^2)\pi(r_2^2 - r_1^2) = 15.08\text{ kg}$. $I_{\text{r}} = \dfrac{1}{2}m_{\text{r}}(r_1^2 + r_2^2) = 5.580\text{ kg}\cdot\text{m}^2$.

$I = I_{\text{d}} + I_{\text{r}} = 8.52\text{ kg}\cdot\text{m}^2$.

EVALUATE: Even though $m_{\text{r}} < m_{\text{d}}$, $I_{\text{r}} > I_{\text{d}}$ since the mass of the ring is farther from the axis.

9.38. **IDENTIFY:** We can use angular kinematics (for constant angular acceleration) to find the angular velocity of the wheel. Then knowing its kinetic energy, we can find its moment of inertia, which is the target variable.

SET UP: $\theta - \theta_0 = \left(\dfrac{\omega_{0z} + \omega_z}{2}\right)t$ and $K = \dfrac{1}{2}I\omega^2$.

EXECUTE: Converting the angle to radians gives $\theta - \theta_0 = (8.20\text{ rev})(2\pi\text{ rad/1 rev}) = 51.52\text{ rad}$.

$\theta - \theta_0 = \left(\dfrac{\omega_{0z} + \omega_z}{2}\right)t$ gives $\omega_z = \dfrac{2(\theta - \theta_0)}{t} = \dfrac{2(51.52\text{ rad})}{12.0\text{ s}} = 8.587\text{ rad/s}$. Solving $K = \dfrac{1}{2}I\omega^2$ for I gives

$$I = \frac{2K}{\omega^2} = \frac{2(36.0\text{ J})}{(8.587\text{ rad/s})^2} = 0.976\text{ kg}\cdot\text{m}^2.$$

EVALUATE: The angular velocity must be in radians to use the formula $K = \dfrac{1}{2}I\omega^2$.

9.39. **IDENTIFY:** Knowing the kinetic energy, mass and radius of the sphere, we can find its angular velocity. From this we can find the tangential velocity (the target variable) of a point on the rim.

SET UP: $K = \frac{1}{2}I\omega^2$ and $I = \frac{2}{5}MR^2$ for a solid uniform sphere. The tagential velocity is $v = r\omega$.

EXECUTE: $I = \frac{2}{5}MR^2 = \frac{2}{5}(28.0\text{ kg})(0.380\text{ m})^2 = 1.617\text{ kg}\cdot\text{m}^2$. $K = \frac{1}{2}I\omega^2$ so

$$\omega = \sqrt{\frac{2K}{I}} = \sqrt{\frac{2(176\text{ J})}{1.617\text{ kg}\cdot\text{m}^2}} = 14.75\text{ rad/s}.$$

$v = r\omega = (0.380\text{ m})(14.75\text{ rad/s}) = 5.61\text{ m/s}$.

EVALUATE: This is the speed of a point on the surface of the sphere that is farthest from the axis of rotation (the "equator" of the sphere). Points off the "equator" would have smaller tangential velocity but the same angular velocity.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

9.40. **IDENTIFY:** Knowing the angular acceleration of the sphere, we can use angular kinematics (with constant angular acceleration) to find its angular velocity. Then using its mass and radius, we can find its kinetic energy, the target variable.

SET UP: $\omega_z^2 = \omega_{0z}^2 + 2\alpha_z(\theta - \theta_0)$, $K = \frac{1}{2}I\omega^2$, and $I = \frac{2}{3}MR^2$ for a uniform hollow spherical shell.

EXECUTE: $I = \frac{2}{3}MR^2 = \frac{2}{3}(8.20\text{ kg})(0.220\text{ m})^2 = 0.2646\text{ kg}\cdot\text{m}^2$. Converting the angle to radians gives $\theta - \theta_0 = (6.00\text{ rev})(2\pi\text{ rad/1 rev}) = 37.70\text{ rad}$. The angular velocity is $\omega_z^2 = \omega_{0z}^2 + 2\alpha_z(\theta - \theta_0)$, which gives $\omega_z = \sqrt{2\alpha_z(\theta - \theta_0)} = \sqrt{2(0.890\text{ rad/s}^2)(37.70\text{ rad})} = 8.192\text{ rad/s}$.

$K = \frac{1}{2}(0.2646\text{ kg}\cdot\text{m}^2)(8.192\text{ rad/s})^2 = 8.88\text{ J}$.

EVALUATE: The angular velocity must be in radians to use the formula $K = \frac{1}{2}I\omega^2$.

9.41. **IDENTIFY:** $K = \frac{1}{2}I\omega^2$. Use Table 9.2 to calculate I.

SET UP: $I = \frac{2}{5}MR^2$. For the moon, $M = 7.35\times10^{22}$ kg and $R = 1.74\times10^6$ m. The moon moves through 1 rev $= 2\pi$ rad in 27.3 d. 1 d $= 8.64\times10^4$ s.

EXECUTE: **(a)** $I = \frac{2}{5}(7.35\times10^{22}\text{ kg})(1.74\times10^6\text{ m})^2 = 8.90\times10^{34}\text{ kg}\cdot\text{m}^2$.

$$\omega = \frac{2\pi\text{ rad}}{(27.3\text{ d})(8.64\times10^4\text{ s/d})} = 2.66\times10^{-6}\text{ rad/s}.$$

$K = \frac{1}{2}I\omega^2 = \frac{1}{2}(8.90\times10^{34}\text{ kg}\cdot\text{m}^2)(2.66\times10^{-6}\text{ rad/s})^2 = 3.15\times10^{23}\text{ J}$.

(b) $\dfrac{3.15\times10^{23}\text{ J}}{5(4.0\times10^{20}\text{ J})} = 158$ years. Considering the expense involved in tapping the moon's rotational energy, this does not seem like a worthwhile scheme for only 158 years worth of energy.

EVALUATE: The moon has a very large amount of kinetic energy due to its motion. The earth has even more, but changing the rotation rate of the earth would change the length of a day.

9.42. **IDENTIFY:** $K = \frac{1}{2}I\omega^2$. Use Table 9.2 to relate I to the mass M of the disk.

SET UP: 45.0 rpm = 4.71 rad/s. For a uniform solid disk, $I = \frac{1}{2}MR^2$.

EXECUTE: **(a)** $I = \dfrac{2K}{\omega^2} = \dfrac{2(0.250\text{ J})}{(4.71\text{ rad/s})^2} = 0.0225\text{ kg}\cdot\text{m}^2$.

(b) $I = \frac{1}{2}MR^2$ and $M = \dfrac{2I}{R^2} = \dfrac{2(0.0225\text{ kg}\cdot\text{m}^2)}{(0.300\text{ m})^2} = 0.500\text{ kg}$.

EVALUATE: No matter what the shape is, the rotational kinetic energy is proportional to the mass of the object.

9.43. **IDENTIFY:** $K = \frac{1}{2}I\omega^2$, with ω in rad/s. Solve for I.

SET UP: 1 rev/min $= (2\pi/60)$ rad/s. $\Delta K = -500$ J

EXECUTE: $\omega_1 = 650$ rev/min $= 68.1$ rad/s. $\omega_f = 520$ rev/min $= 54.5$ rad/s. $\Delta K = K_f - K_i = \frac{1}{2}I(\omega_f^2 - \omega_i^2)$ and $I = \dfrac{2(\Delta K)}{\omega_f^2 - \omega_i^2} = \dfrac{2(-500\text{ J})}{(54.5\text{ rad/s})^2 - (68.1\text{ rad/s})^2} = 0.600\text{ kg}\cdot\text{m}^2$.

EVALUATE: In $K = \frac{1}{2}I\omega^2$, ω must be in rad/s.

9.44. **IDENTIFY:** The work done on the cylinder equals its gain in kinetic energy.

SET UP: The work done on the cylinder is PL, where L is the length of the rope. $K_1 = 0$. $K_2 = \frac{1}{2}I\omega^2$.

$I = mr^2 = \left(\dfrac{w}{g}\right)r^2$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: $PL = \frac{1}{2}\frac{w}{g}v^2$, or $P = \frac{1}{2}\frac{w}{g}\frac{v^2}{L} = \frac{(40.0\text{ N})(6.00\text{ m/s})^2}{2(9.80\text{ m/s}^2)(5.00\text{ m})} = 14.7\text{ N}$.

EVALUATE: The linear speed v of the end of the rope equals the tangential speed of a point on the rim of the cylinder. When K is expressed in terms of v, the radius r of the cylinder doesn't appear.

9.45. **IDENTIFY** and **SET UP:** Combine Eqs. (9.17) and (9.15) to solve for K. Use Table 9.2 to get I.

EXECUTE: $K = \frac{1}{2}I\omega^2$

$a_{\text{rad}} = R\omega^2$, so $\omega = \sqrt{a_{\text{rad}}/R} = \sqrt{(3500\text{ m/s}^2)/1.20\text{ m}} = 54.0\text{ rad/s}$

For a disk, $I = \frac{1}{2}MR^2 = \frac{1}{2}(70.0\text{ kg})(1.20\text{ m})^2 = 50.4\text{ kg}\cdot\text{m}^2$

Thus $K = \frac{1}{2}I\omega^2 = \frac{1}{2}(50.4\text{ kg}\cdot\text{m}^2)(54.0\text{ rad/s})^2 = 7.35\times10^4\text{ J}$

EVALUATE: The limit on a_{rad} limits ω which in turn limits K.

9.46. **IDENTIFY:** Repeat the calculation in Example 9.8, but with a different expression for I.

SET UP: For the solid cylinder in Example 9.8, $I = \frac{1}{2}MR^2$. For the thin-walled, hollow cylinder, $I = MR^2$.

EXECUTE: **(a)** With $I = MR^2$, the expression for v is $v = \sqrt{\frac{2gh}{1+M/m}}$.

(b) This expression is smaller than that for the solid cylinder; more of the cylinder's mass is concentrated at its edge, so for a given speed, the kinetic energy of the cylinder is larger. A larger fraction of the potential energy is converted to the kinetic energy of the cylinder, and so less is available for the falling mass.

EVALUATE: When M is much larger than m, v is very small. When M is much less than m, v becomes $v = \sqrt{2gh}$, the same as for a mass that falls freely from a height h.

9.47. **IDENTIFY:** Apply conservation of energy to the system of stone plus pulley. $v = r\omega$ relates the motion of the stone to the rotation of the pulley.

SET UP: For a uniform solid disk, $I = \frac{1}{2}MR^2$. Let point 1 be when the stone is at its initial position and point 2 be when it has descended the desired distance. Let $+y$ be upward and take $y = 0$ at the initial position of the stone, so $y_1 = 0$ and $y_2 = -h$, where h is the distance the stone descends.

EXECUTE: **(a)** $K_{\text{p}} = \frac{1}{2}I_{\text{p}}\omega^2$. $I_{\text{p}} = \frac{1}{2}M_{\text{p}}R^2 = \frac{1}{2}(2.50\text{ kg})(0.200\text{ m})^2 = 0.0500\text{ kg}\cdot\text{m}^2$.

$\omega = \sqrt{\frac{2K_{\text{p}}}{I_{\text{p}}}} = \sqrt{\frac{2(4.50\text{ J})}{0.0500\text{ kg}\cdot\text{m}^2}} = 13.4\text{ rad/s}$. The stone has speed $v = R\omega = (0.200\text{ m})(13.4\text{ rad/s}) = 2.68\text{ m/s}$.

The stone has kinetic energy $K_{\text{s}} = \frac{1}{2}mv^2 = \frac{1}{2}(1.50\text{ kg})(2.68\text{ m/s})^2 = 5.39\text{ J}$. $K_1 + U_1 = K_2 + U_2$ gives

$0 = K_2 + U_2$. $0 = 4.50\text{ J} + 5.39\text{ J} + mg(-h)$. $h = \frac{9.89\text{ J}}{(1.50\text{ kg})(9.80\text{ m/s}^2)} = 0.673\text{ m}$.

(b) $K_{\text{tot}} = K_{\text{p}} + K_{\text{s}} = 9.89\text{ J}$. $\frac{K_{\text{p}}}{K_{\text{tot}}} = \frac{4.50\text{ J}}{9.89\text{ J}} = 45.5\%$.

EVALUATE: The gravitational potential energy of the pulley doesn't change as it rotates. The tension in the wire does positive work on the pulley and negative work of the same magnitude on the stone, so no net work on the system.

9.48. **IDENTIFY:** $K_{\text{p}} = \frac{1}{2}I\omega^2$ for the pulley and $K_{\text{b}} = \frac{1}{2}mv^2$ for the bucket. The speed of the bucket and the rotational speed of the pulley are related by $v = R\omega$.

SET UP: $K_{\text{p}} = \frac{1}{2}K_{\text{b}}$

EXECUTE: $\frac{1}{2}I\omega^2 = \frac{1}{2}(\frac{1}{2}mv^2) = \frac{1}{4}mR^2\omega^2$. $I = \frac{1}{2}mR^2$.

EVALUATE: The result is independent of the rotational speed of the pulley and the linear speed of the mass.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

9.49. **IDENTIFY:** With constant acceleration, we can use kinematics to find the speed of the falling object. Then we can apply the work-energy expression to the entire system and find the moment of inertia of the wheel. Finally, using its radius we can find its mass, the target variable.

SET UP: With constant acceleration, $y - y_0 = \left(\frac{v_{0y} + v_y}{2}\right)t$. The angular velocity of the wheel is related to the linear velocity of the falling mass by $\omega_z = \frac{v_y}{R}$. The work-energy theorem is $K_1 + U_1 + W_{\text{other}} = K_2 + U_2$, and the moment of inertia of a uniform disk is $I = \frac{1}{2}MR^2$.

EXECUTE: Find v_y, the velocity of the block after it has descended 3.00 m. $y - y_0 = \left(\frac{v_{0y} + v_y}{2}\right)t$ gives $v_y = \frac{2(y - y_0)}{t} = \frac{2(3.00\text{ m})}{2.00\text{ s}} = 3.00$ m/s. For the wheel, $\omega_z = \frac{v_y}{R} = \frac{3.00\text{ m/s}}{0.280\text{ m}} = 10.71$ rad/s. Apply the work-energy expression: $K_1 + U_1 + W_{\text{other}} = K_2 + U_2$, giving $mg(3.00\text{ m}) = \frac{1}{2}mv^2 + \frac{1}{2}I\omega^2$. Solving for I gives $I = \frac{2}{\omega^2}\left[mg(3.00\text{ m}) - \frac{1}{2}mv^2\right]$.

$I = \frac{2}{(10.71\text{ rad/s})^2}\left[(4.20\text{ kg})(9.8\text{ m/s}^2)(3.00\text{ m}) - \frac{1}{2}(4.20\text{ kg})(3.00\text{ m/s})^2\right]$. $I = 1.824\text{ kg}\cdot\text{m}^2$. For a solid disk, $I = \frac{1}{2}MR^2$ gives $M = \frac{2I}{R^2} = \frac{2(1.824\text{ kg}\cdot\text{m}^2)}{(0.280\text{ m})^2} = 46.5$ kg.

EVALUATE: The gravitational potential of the falling object is converted into the kinetic energy of that object and the rotational kinetic energy of the wheel.

9.50. **IDENTIFY:** The work the person does is the negative of the work done by gravity. $W_{\text{grav}} = U_{\text{grav},1} - U_{\text{grav},2}$. $U_{\text{grav}} = Mgy_{\text{cm}}$.

SET UP: The center of mass of the ladder is at its center, 1.00 m from each end. $y_{\text{cm},1} = (1.00\text{ m})\sin 53.0° = 0.799$ m. $y_{\text{cm},2} = 1.00$ m.

EXECUTE: $W_{\text{grav}} = (9.00\text{ kg})(9.80\text{ m/s}^2)(0.799\text{ m} - 1.00\text{ m}) = -17.7$ J. The work done by the person is 17.7 J.

EVALUATE: The gravity force is downward and the center of mass of the ladder moves upward, so gravity does negative work. The person pushes upward and does positive work.

9.51. **IDENTIFY:** The general expression for I is Eq. (9.16). $K = \frac{1}{2}I\omega^2$.

SET UP: R will be multiplied by f.

EXECUTE: **(a)** In the expression of Eq. (9.16), each term will have the mass multiplied by f^3 and the distance multiplied by f, and so the moment of inertia is multiplied by $f^3(f)^2 = f^5$.

(b) $(2.5\text{ J})(48)^5 = 6.37\times10^8$ J.

EVALUATE: Mass and volume are proportional to each other so both scale by the same factor.

9.52. **IDENTIFY:** $U = Mgy_{\text{cm}}$. $\Delta U = U_2 - U_1$.

SET UP: Half the rope has mass 1.50 kg and length 12.0 m. Let $y = 0$ at the top of the cliff and take $+y$ to be upward. The center of mass of the hanging section of rope is at its center and $y_{\text{cm},2} = -6.00$ m.

EXECUTE: $\Delta U = U_2 - U_1 = mg(y_{\text{cm},2} - y_{\text{cm},1}) = (1.50\text{ kg})(9.80\text{ m/s}^2)(-6.00\text{ m} - 0) = -88.2$ J.

EVALUATE: The potential energy of the rope decreases when part of the rope moves downward.

9.53. **IDENTIFY:** Use Eq. (9.19) to relate I for the wood sphere about the desired axis to I for an axis along a diameter.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

SET UP: For a thin-walled hollow sphere, axis along a diameter, $I = \frac{2}{3}MR^2$.

For a solid sphere with mass M and radius R, $I_{cm} = \frac{2}{5}MR^2$, for an axis along a diameter.

EXECUTE: Find d such that $I_P = I_{cm} + Md^2$ with $I_P = \frac{2}{3}MR^2$:

$\frac{2}{3}MR^2 = \frac{2}{5}MR^2 + Md^2$

The factors of M divide out and the equation becomes $(\frac{2}{3} - \frac{2}{5})R^2 = d^2$

$d = \sqrt{(10-6)/15}R = 2R/\sqrt{15} = 0.516R.$

The axis is parallel to a diameter and is $0.516R$ from the center.

EVALUATE: $I_{cm}(\text{lead}) > I_{cm}(\text{wood})$ even though M and R are the same since for a hollow sphere all the mass is a distance R from the axis. Eq. (9.19) says $I_P > I_{cm}$, so there must be a d where $I_P(\text{wood}) = I_{cm}(\text{lead})$.

9.54. **IDENTIFY:** Apply Eq. (9.19), the parallel-axis theorem.

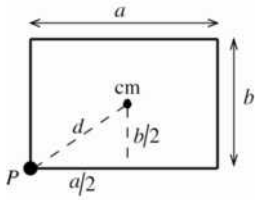
SET UP: The center of mass of the hoop is at its geometrical center.

EXECUTE: In Eq. (9.19), $I_{cm} = MR^2$ and $d = R^2$, so $I_P = 2MR^2$.

EVALUATE: I is larger for an axis at the edge than for an axis at the center. Some mass is closer than distance R from the axis but some is also farther away. Since I for each piece of the hoop is proportional to the square of the distance from the axis, the increase in distance has a larger effect.

9.55. **IDENTIFY** and **SET UP:** Use Eq. (9.19). The cm of the sheet is at its geometrical center. The object is sketched in Figure 9.55.

EXECUTE: $I_P = I_{cm} + Md^2$.



From part (c) of Table 9.2, $I_{cm} = \frac{1}{12}M(a^2 + b^2)$.

The distance d of P from the cm is $d = \sqrt{(a/2)^2 + (b/2)^2}$.

Figure 9.55

Thus $I_P = I_{cm} + Md^2 = \frac{1}{12}M(a^2+b^2) + M(\frac{1}{4}a^2 + \frac{1}{4}b^2) = (\frac{1}{12} + \frac{1}{4})M(a^2+b^2) = \frac{1}{3}M(a^2+b^2)$

EVALUATE: $I_P = 4I_{cm}$. For an axis through P mass is farther from the axis.

9.56. **IDENTIFY:** Consider the plate as made of slender rods placed side-by-side.

SET UP: The expression in Table 9.2(a) gives I for a rod and an axis through the center of the rod.

EXECUTE: **(a)** I is the same as for a rod with length a: $I = \frac{1}{12}Ma^2$.

(b) I is the same as for a rod with length b: $I = \frac{1}{12}Mb^2$.

EVALUATE: I is smaller when the axis is through the center of the plate than when it is along one edge.

9.57. **IDENTIFY:** Use the equations in Table 9.2. I for the rod is the sum of I for each segment. The parallel-axis theorem says $I_p = I_{cm} + Md^2$.

SET UP: The bent rod and axes a and b are shown in Figure 9.57. Each segment has length $L/2$ and mass $M/2$.

EXECUTE: **(a)** For each segment the moment of inertia is for a rod with mass $M/2$, length $L/2$ and the axis through one end. For one segment, $I_s = \frac{1}{3}\left(\frac{M}{2}\right)\left(\frac{L}{2}\right)^2 = \frac{1}{24}ML^2$. For the rod, $I_a = 2I_s = \frac{1}{12}ML^2$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) The center of mass of each segment is at the center of the segment, a distance of $L/4$ from each end. For each segment, $I_{\text{cm}} = \frac{1}{12}\left(\frac{M}{2}\right)\left(\frac{L}{2}\right)^2 = \frac{1}{96}ML^2$. Axis *b* is a distance $L/4$ from the cm of each segment, so for each segment the parallel axis theorem gives *I* for axis *b* to be $I_{\text{s}} = \frac{1}{96}ML^2 + \frac{M}{2}\left(\frac{L}{4}\right)^2 = \frac{1}{24}ML^2$ and $I_{\text{b}} = 2I_{\text{s}} = \frac{1}{12}ML^2$.

EVALUATE: *I* for these two axes are the same.

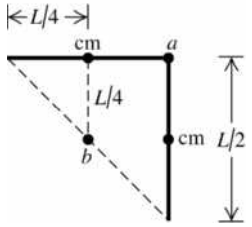


Figure 9.57

9.58. **IDENTIFY:** Eq. (9.20), $I = \int r^2\, dm$

SET UP:

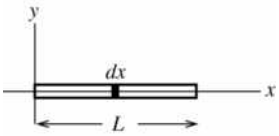

Figure 9.58

Take the *x*-axis to lie along the rod, with the origin at the left end. Consider a thin slice at coordinate *x* and width *dx*, as shown in Figure 9.58. The mass per unit length for this rod is M/L, so the mass of this slice is $dm = (M/L)\, dx$.

EXECUTE: $I = \int_0^L x^2 (M/L)\, dx = (M/L)\int_0^L x^2\, dx = (M/L)(L^3/3) = \frac{1}{3}ML^2$

EVALUATE: This result agrees with Table 9.2.

9.59. **IDENTIFY:** Apply Eq. (9.20).

SET UP: $dm = \rho dV = \rho(2\pi rL\, dr)$, where *L* is the thickness of the disk. $M = \pi L\rho R^2$.

EXECUTE: The analysis is identical to that of Example 9.10, with the lower limit in the integral being zero and the upper limit being *R*. The result is $I = \frac{1}{2}MR^2$.

EVALUATE: Our result agrees with Table 9.2(f).

9.60. **IDENTIFY:** Apply Eq. (9.20).

SET UP: For this case, $dm = \gamma\, dx$.

EXECUTE: **(a)** $M = \int dm = \int_0^L \gamma x\, dx = \gamma\frac{x^2}{2}\Big|_0^L = \frac{\gamma L^2}{2}$

(b) $I = \int_0^L x^2(\gamma x)dx = \gamma\frac{x^4}{4}\Big|_0^L = \frac{\gamma L^4}{4} = \frac{M}{2}L^2$. This is larger than the moment of inertia of a uniform rod of the same mass and length, since the mass density is greater farther away from the axis than nearer the axis.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(c) $I=\int_0^L (L-x)^2\gamma x\,dx=\gamma\int_0^L (L^2x-2Lx^2+x^3)dx=\gamma\left(L^2\frac{x^2}{2}-2L\frac{x^3}{3}+\frac{x^4}{4}\right)\Big|_0^L=\gamma\frac{L^4}{12}=\frac{M}{6}L^2$.

This is a third of the result of part (b), reflecting the fact that more of the mass is concentrated at the right end.

EVALUATE: For a uniform rod with an axis at one end, $I=\frac{1}{3}ML^2$. The result in (b) is larger than this and the result in (c) is smaller than this.

9.61. **IDENTIFY:** We know the angular acceleration as a function of time and want to find the angular velocity and the angle the flywheel has turned through at a later time.

SET UP: $\omega_z(t)=\omega_{0z}+\int_0^t\alpha_z(t')dt'$ and $\theta-\theta_0=\int_0^t\omega_z(t')dt'$.

EXECUTE: **(a)** Integrating the angular acceleration gives the angular velocity:

$\omega_z(t)=\omega_{0z}+\int_0^t\alpha_z(t')dt'=\int_0^t[(8.60\text{ rad/s}^2)-(2.30\text{ rad/s}^3)t']dt'=(8.60\text{ rad/s}^2)t-(1.15\text{ rad/s}^3)t^2$

At $t=5.00$ s, $\omega_z=(8.60\text{ rad/s}^2)(5.00\text{ s})-(1.15\text{ rad/s}^3)(5.00\text{ s})^2=14.2$ rad/s.

(b) Integrating the angular velocity gives the angle:

$\theta-\theta_0=\int_0^t\omega_z(t')dt'=(4.30\text{ rad/s}^2)t^2-(0.3833\text{ rad/s}^3)t^3$. At $t=5.00$ s,

$\theta-\theta_0=107.5\text{ rad}-47.9\text{ rad}=59.6\text{ rad}$.

EVALUATE: With non-constant angular acceleration, we cannot use the standard angular kinematics formulas, but must use integration instead.

9.62. **IDENTIFY:** Using the equation for the angle as a function of time, we can find the angular acceleration of the disk at a given time and use this to find the linear acceleration of a point on the rim (the target variable).

SET UP: We can use the definitions of the angular velocity and the angular acceleration: $\omega_z(t)=\frac{d\theta}{dt}$ and $\alpha_z(t)=\frac{d\omega_z}{dt}$. The acceleration components are $a_{\text{rad}}=R\omega^2$ and $a_{\tan}=R\alpha$, and the magnitude of the acceleration is $a=\sqrt{a_{\text{rad}}^2+a_{\tan}^2}$.

SET UP: $\omega_z(t)=\frac{d\theta}{dt}=1.10\text{ rad/s}+(17.2\text{ rad/s}^2)t$. $\alpha_z(t)=\frac{d\omega_z}{dt}=17.2\text{ rad/s}^2$ (constant).

$\theta=0.100\text{ rev}=0.6283\text{ rad}$ gives $8.60t^2+1.10t-0.6283=0$, so $t=-0.064\pm0.2778$ s. Since t must be positive, $t=0.2138$ s. At this t, $\omega_z(t)=4.777$ rad/s and $\alpha_z(t)=17.2\text{ rad/s}^2$. For a point on the rim, $a_{\text{rad}}=R\omega^2=9.129\text{ m/s}^2$ and $a_{\tan}=R\alpha=6.88\text{ m/s}^2$, so $a=\sqrt{a_{\text{rad}}^2+a_{\tan}^2}=11.4\text{ m/s}^2$.

EVALUATE: Since the angular acceleration is constant, we could use the constant acceleration formulas as a check. For example, $\frac{1}{2}\alpha_z=8.60\text{ rad/s}^2$ gives $\alpha_z=17.2\text{ rad/s}^2$.

9.63. **IDENTIFY:** The target variable is the horizontal distance the piece travels before hitting the floor. Using the angular acceleration of the blade, we can find its angular velocity when the piece breaks off. This will give us the linear horizontal speed of the piece. It is then in free fall, so we can use the linear kinematics equations.

SET UP: $\omega_z^2=\omega_{0z}^2+2\alpha_z(\theta-\theta_0)$ for the blade, and $v=r\omega$ is the horizontal velocity of the piece.

$y-y_0=v_{0y}t+\frac{1}{2}a_yt^2$ for the falling piece.

EXECUTE: Find the initial horizontal velocity of the piece just after it breaks off.

$\theta-\theta_0=(155\text{ rev})(2\pi\text{ rad/1 rev})=973.9$ rad.

$\alpha_z=(3.00\text{ rev/s}^2)(2\pi\text{ rad/1 rev})=18.85\text{ rad/s}^2$. $\omega_z^2=\omega_{0z}^2+2\alpha_z(\theta-\theta_0)$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$\omega_z = \sqrt{2\alpha_z(\theta-\theta_0)} = \sqrt{2(18.85\text{ rad/s}^2)(973.9\text{ rad})} = 191.6$ rad/s. The horizontal velocity of the piece is $v = r\omega = (0.120\text{ m})(191.6\text{ rad/s}) = 23.0$ m/s. Now consider the projectile motion of the piece. Take +y downward and use the vertical motion to find t. Solving $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$ for t gives

$t = \sqrt{\frac{2(y-y_0)}{a_y}} = \sqrt{\frac{2(0.820\text{ m})}{9.8\text{ m/s}^2}} = 0.4091$ s. Then $x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2 = (23.0\text{ m/s})(0.4091\text{ s}) = 9.41$ m.

EVALUATE: Once the piece is free of the blade, the only force acting on it is gravity so its acceleration is g downward.

9.64. **IDENTIFY** and **SET UP:** Use Eqs. (9.3) and (9.5). As long as $\alpha_z > 0$, ω_z increases. At the t when $\alpha_z = 0$, ω_z is at its maximum positive value and then starts to decrease when α_z becomes negative.

$\theta(t) = \gamma t^2 - \beta t^3$; $\gamma = 3.20\text{ rad/s}^2$, $\beta = 0.500\text{ rad/s}^3$

EXECUTE: **(a)** $\omega_z(t) = \frac{d\theta}{dt} = \frac{d(\gamma t^2 - \beta t^3)}{dt} = 2\gamma t - 3\beta t^2$

(b) $\alpha_z(t) = \frac{d\omega_z}{dt} = \frac{d(2\gamma t - 3\beta t^2)}{dt} = 2\gamma - 6\beta t$

(c) The maximum angular velocity occurs when $\alpha_z = 0$.

$2\gamma - 6\beta t = 0$ implies $t = \frac{2\gamma}{6\beta} = \frac{\gamma}{3\beta} = \frac{3.20\text{ rad/s}^2}{3(0.500\text{ rad/s}^3)} = 2.133$ s

At this t, $\omega_z = 2\gamma t - 3\beta t^2 = 2(3.20\text{ rad/s}^2)(2.133\text{ s}) - 3(0.500\text{ rad/s}^3)(2.133\text{ s})^2 = 6.83$ rad/s

The maximum positive angular velocity is 6.83 rad/s and it occurs at 2.13 s.

EVALUATE: For large t both ω_z and α_z are negative and ω_z increases in magnitude. In fact, $\omega_z \to -\infty$ at $t \to \infty$. So the answer in (c) is not the largest angular speed, just the largest positive angular velocity.

9.65. **IDENTIFY:** The angular acceleration α of the disk is related to the linear acceleration a of the ball by $a = R\alpha$. Since the acceleration is not constant, use $\omega_z - \omega_{0z} = \int_0^t \alpha_z dt$ and $\theta - \theta_0 = \int_0^t \omega_z dt$ to relate θ, ω_z, α_z and t for the disk. $\omega_{0z} = 0$.

SET UP: $\int t^n dt = \frac{1}{n+1}t^{n+1}$. In $a = R\alpha$, α is in rad/s^2.

EXECUTE: **(a)** $A = \frac{a}{t} = \frac{1.80\text{ m/s}^2}{3.00\text{ s}} = 0.600\text{ m/s}^3$

(b) $\alpha = \frac{a}{R} = \frac{(0.600\text{ m/s}^3)t}{0.250\text{ m}} = (2.40\text{ rad/s}^3)t$

(c) $\omega_z = \int_0^t (2.40\text{ rad/s}^3)t dt = (1.20\text{ rad/s}^3)t^2$. $\omega_z = 15.0$ rad/s for $t = \sqrt{\frac{15.0\text{ rad/s}}{1.20\text{ rad/s}^3}} = 3.54$ s.

(d) $\theta - \theta_0 = \int_0^t \omega_z dt = \int_0^t (1.20\text{ rad/s}^3)t^2 dt = (0.400\text{ rad/s}^3)t^3$. For $t = 3.54$ s, $\theta - \theta_0 = 17.7$ rad.

EVALUATE: If the disk had turned at a constant angular velocity of 15.0 rad/s for 3.54 s it would have turned through an angle of 53.1 rad in 3.54 s. It actually turns through less than half this because the angular velocity is increasing in time and is less than 15.0 rad/s at all but the end of the interval.

9.66. **IDENTIFY** and **SET UP:** The translational kinetic energy is $K = \frac{1}{2}mv^2$ and the kinetic energy of the rotating flywheel is $K = \frac{1}{2}I\omega^2$. Use the scale speed to calculate the actual speed v. From that calculate K for the car and then solve for ω that gives this K for the flywheel.

EXECUTE: **(a)** $\frac{v_{\text{toy}}}{v_{\text{scale}}} = \frac{L_{\text{toy}}}{L_{\text{real}}}$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$v_{\text{toy}} = v_{\text{scale}}\left(\frac{L_{\text{toy}}}{L_{\text{real}}}\right) = (700 \text{ km/h})\left(\frac{0.150 \text{ m}}{3.0 \text{ m}}\right) = 35.0 \text{ km/h}$$

$$v_{\text{toy}} = (35.0 \text{ km/h})(1000 \text{ m/1 km})(1 \text{ h}/3600 \text{ s}) = 9.72 \text{ m/s}$$

(b) $K = \frac{1}{2}mv^2 = \frac{1}{2}(0.180 \text{ kg})(9.72 \text{ m/s})^2 = 8.50 \text{ J}$

(c) $K = \frac{1}{2}I\omega^2$ gives that $\omega = \sqrt{\frac{2K}{I}} = \sqrt{\frac{2(8.50 \text{ J})}{4.00\times10^{-5} \text{ kg}\cdot\text{m}^2}} = 652 \text{ rad/s}$

EVALUATE: $K = \frac{1}{2}I\omega^2$ gives ω in rad/s. 652 rad/s = 6200 rev/min so the rotation rate of the flywheel is very large.

9.67. **IDENTIFY:** $a_{\text{tan}} = r\alpha$, $a_{\text{rad}} = r\omega^2$. Apply the constant acceleration equations and $\sum \vec{F} = m\vec{a}$.

SET UP: a_{tan} and a_{rad} are perpendicular components of $\vec{a}$, so $a = \sqrt{a_{\text{rad}}^2 + a_{\text{tan}}^2}$.

EXECUTE: **(a)** $\alpha = \frac{a_{\text{tan}}}{r} = \frac{2.00 \text{ m/s}^2}{60.0 \text{ m}} = 0.0333 \text{ rad/s}^2$.

(b) $\alpha t = (0.0333 \text{ rad/s}^2)(6.00 \text{ s}) = 0.200 \text{ rad/s}$.

(c) $a_{\text{rad}} = \omega^2 r = (0.200 \text{ rad/s})^2(60.0 \text{ m}) = 2.40 \text{ m/s}^2$.

(d) The sketch is given in Figure 9.67.

(e) $a = \sqrt{a_{\text{rad}}^2 + a_{\text{tan}}^2} = \sqrt{(2.40 \text{ m/s}^2)^2 + (2.00 \text{ m/s}^2)^2} = 3.12 \text{ m/s}^2$, and the magnitude of the force is $F = ma = (1240 \text{ kg})(3.12 \text{ m/s}^2) = 3.87 \text{ kN}$.

(f) $\arctan\left(\frac{a_{\text{rad}}}{a_{\text{tan}}}\right) = \arctan\left(\frac{2.40}{2.00}\right) = 50.2°$.

EVALUATE: a_{tan} is constant and a_{rad} increases as ω increases. At $t = 0$, $\vec{a}$ is parallel to $\vec{v}$. As t increases, $\vec{a}$ moves toward the radial direction and the angle between $\vec{a}$ and $\vec{v}$ increases toward 90°.

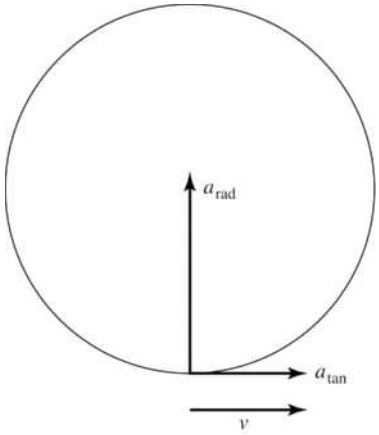

Figure 9.67

9.68. **IDENTIFY:** Apply conservation of energy to the system of drum plus falling mass, and compare the results for earth and for Mars.

SET UP: $K_{\text{drum}} = \frac{1}{2}I\omega^2$. $K_{\text{mass}} = \frac{1}{2}mv^2$. $v = R\omega$ so if K_{drum} is the same, ω is the same and v is the same on both planets. Therefore, K_{mass} is the same. Let $y = 0$ at the initial height of the mass and take $+y$ upward. Configuration 1 is when the mass is at its initial position and 2 is when the mass has descended 5.00 m, so $y_1 = 0$ and $y_2 = -h$, where h is the height the mass descends.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: **(a)** $K_1 + U_1 = K_2 + U_2$ gives $0 = K_{\text{drum}} + K_{\text{mass}} - mgh$. $K_{\text{drum}} + K_{\text{mass}}$ are the same on both planets, so $mg_{\text{E}}h_{\text{E}} = mg_{\text{M}}h_{\text{M}}$. $h_{\text{M}} = h_{\text{E}}\left(\dfrac{g_{\text{E}}}{g_{\text{M}}}\right) = (5.00\text{ m})\left(\dfrac{9.80\text{ m/s}^2}{3.71\text{ m/s}^2}\right) = 13.2\text{ m}.$

(b) $mg_{\text{M}}h_{\text{M}} = K_{\text{drum}} + K_{\text{mass}}$. $\frac{1}{2}mv^2 = mg_{\text{M}}h_{\text{M}} - K_{\text{drum}}$ and

$$v = \sqrt{2g_{\text{M}}h_{\text{M}} - \frac{2K_{\text{drum}}}{m}} = \sqrt{2(3.71\text{ m/s}^2)(13.2\text{ m}) - \frac{2(250.0\text{ J})}{15.0\text{ kg}}} = 8.04\text{ m/s}$$

EVALUATE: We did the calculations without knowing the moment of inertia I of the drum, or the mass and radius of the drum.

9.69. **IDENTIFY** and **SET UP:** All points on the belt move with the same speed. Since the belt doesn't slip, the speed of the belt is the same as the speed of a point on the rim of the shaft and on the rim of the wheel, and these speeds are related to the angular speed of each circular object by $v = r\omega$.

EXECUTE:

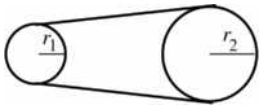

Figure 9.69

(a) $v_1 = r_1\omega_1$

$\omega_1 = (60.0\text{ rev/s})(2\pi\text{ rad/1 rev}) = 377\text{ rad/s}$

$v_1 = r_1\omega_1 = (0.45\times10^{-2}\text{ m})(377\text{ rad/s}) = 1.70\text{ m/s}$

(b) $v_1 = v_2$

$r_1\omega_1 = r_2\omega_2$

$\omega_2 = (r_1/r_2)\omega_1 = (0.45\text{ cm}/1.80\text{ cm})(377\text{ rad/s}) = 94.2\text{ rad/s}$

EVALUATE: The wheel has a larger radius than the shaft so turns slower to have the same tangential speed for points on the rim.

9.70. **IDENTIFY:** The speed of all points on the belt is the same, so $r_1\omega_1 = r_2\omega_2$ applies to the two pulleys.

SET UP: The second pulley, with half the diameter of the first, must have twice the angular velocity, and this is the angular velocity of the saw blade. π rad/s = 30 rev/min.

EXECUTE: **(a)** $v_2 = (2(3450\text{ rev/min}))\left(\dfrac{\pi}{30}\dfrac{\text{rad/s}}{\text{rev/min}}\right)\left(\dfrac{0.208\text{ m}}{2}\right) = 75.1\text{ m/s}.$

(b) $a_{\text{rad}} = \omega^2 r = \left(2(3450\text{ rev/min})\left(\dfrac{\pi}{30}\dfrac{\text{rad/s}}{\text{rev/min}}\right)\right)^2\left(\dfrac{0.208\text{ m}}{2}\right) = 5.43\times10^4\text{ m/s}^2,$

so the force holding sawdust on the blade would have to be about 5500 times as strong as gravity.

EVALUATE: In $v = r\omega$ and $a_{\text{rad}} = r\omega^2$, ω must be in rad/s.

9.71. **IDENTIFY:** Apply $v = r\omega$.

SET UP: Points on the chain all move at the same speed, so $r_{\text{r}}\omega_{\text{r}} = r_{\text{f}}\omega_{\text{f}}$.

EXECUTE: The angular velocity of the rear wheel is $\omega_{\text{r}} = \dfrac{v_{\text{r}}}{r} = \dfrac{5.00\text{ m/s}}{0.330\text{ m}} = 15.15\text{ rad/s}.$

The angular velocity of the front wheel is $\omega_{\text{f}} = 0.600\text{ rev/s} = 3.77\text{ rad/s}$. $r_{\text{r}} = r_{\text{f}}(\omega_{\text{f}}/\omega_{\text{r}}) = 2.99\text{ cm}.$

EVALUATE: The rear sprocket and wheel have the same angular velocity and the front sprocket and wheel have the same angular velocity. $r\omega$ is the same for both, so the rear sprocket has a smaller radius since it has a larger angular velocity. The speed of a point on the chain is $v = r_{\text{r}}\omega_{\text{r}} = (2.99\times10^{-2}\text{ m})(15.15\text{ rad/s}) =$ 0.453 m/s. The linear speed of the bicycle is 5.00 m/s.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

9.72. **IDENTIFY:** Use the constant angular acceleration equations, applied to the first revolution and to the first two revolutions.

SET UP: Let the direction the disk is rotating be positive. 1 rev $= 2\pi$ rad. Let t be the time for the first revolution. The time for the first two revolutions is $t + 0.750$ s.

EXECUTE: **(a)** $\theta - \theta_0 = \omega_{0z}t + \frac{1}{2}\alpha_z t^2$ applied to the first revolution and then to the first two revolutions gives $2\pi \text{ rad} = \frac{1}{2}\alpha_z t^2$ and $4\pi \text{ rad} = \frac{1}{2}\alpha_z (t + 0.750 \text{ s})^2$. Eliminating α_z between these equations gives

$4\pi \text{ rad} = \dfrac{2\pi \text{ rad}}{t^2}(t + 0.750 \text{ s})^2$. $2t^2 = (t + 0.750 \text{ s})^2$. $\sqrt{2}t = \pm(t + 0.750 \text{ s})$. The positive root is

$$t = \frac{0.750 \text{ s}}{\sqrt{2} - 1} = 1.81 \text{ s}.$$

(b) $2\pi \text{ rad} = \frac{1}{2}\alpha_z t^2$ and $t = 1.81$ s gives $\alpha_z = 3.84 \text{ rad/s}^2$

EVALUATE: At the start of the second revolution, $\omega_{0z} = (3.84 \text{ rad/s}^2)(1.81 \text{ s}) = 6.95 \text{ rad/s}$. The distance the disk rotates in the next 0.750 s is $\theta - \theta_0 = \omega_{0z}t + \frac{1}{2}\alpha_z t^2 = (6.95 \text{ rad/s})(0.750 \text{ s}) + \frac{1}{2}(3.84 \text{ rad/s}^2)(0.750 \text{ s})^2 = 6.29 \text{ rad}$, which is two revolutions.

9.73. **IDENTIFY** and **SET UP:** Use Eq. (9.15) to relate a_{rad} to ω and then use a constant acceleration equation to replace ω.

EXECUTE: **(a)** $a_{\text{rad}} = r\omega^2$, $a_{\text{rad},1} = r\omega_1^2$, $a_{\text{rad},2} = r\omega_2^2$. $\Delta a_{\text{rad}} = a_{\text{rad},2} - a_{\text{rad},1} = r(\omega_2^2 - \omega_1^2)$. One of the constant acceleration equations can be written $\omega_{2z}^2 = \omega_{1z}^2 + 2\alpha(\theta_2 - \theta_1)$, or $\omega_{2z}^2 - \omega_{1z}^2 = 2\alpha_z(\theta_2 - \theta_1)$. Thus $\Delta a_{\text{rad}} = r2\alpha_z(\theta_2 - \theta_1) = 2r\alpha_z(\theta_2 - \theta_1)$, as was to be shown.

(b) $\alpha_z = \dfrac{\Delta a_{\text{rad}}}{2r(\theta_2 - \theta_1)} = \dfrac{85.0 \text{ m/s}^2 - 25.0 \text{ m/s}^2}{2(0.250 \text{ m})(20.0 \text{ rad})} = 6.00 \text{ rad/s}^2$. Then

$a_{\text{tan}} = r\alpha = (0.250 \text{ m})(6.00 \text{ rad/s}^2) = 1.50 \text{ m/s}^2$.

EVALUATE: ω^2 is proportional to α_z and $(\theta - \theta_0)$ so a_{rad} is also proportional to these quantities. a_{rad} increases while r stays fixed, ω_z increases, and α_z is positive.

IDENTIFY and **SET UP:** Use Eq. (9.17) to relate K and ω and then use a constant acceleration equation to replace ω.

EXECUTE: **(c)** $K = \frac{1}{2}I\omega^2$; $K_2 = \frac{1}{2}I\omega_2^2$, $K_1 = \frac{1}{2}I\omega_1^2$

$\Delta K = K_2 - K_1 = \frac{1}{2}I(\omega_2^2 - \omega_1^2) = \frac{1}{2}I(2\alpha_z(\theta_2 - \theta_1)) = I\alpha_z(\theta_2 - \theta_1)$, as was to be shown.

(d) $I = \dfrac{\Delta K}{\alpha_z(\theta_2 - \theta_1)} = \dfrac{45.0 \text{ J} - 20.0 \text{ J}}{(6.00 \text{ rad/s}^2)(20.0 \text{ rad})} = 0.208 \text{ kg} \cdot \text{m}^2$.

EVALUATE: α_z is positive, ω increases and K increases.

9.74. **IDENTIFY:** $I = I_{\text{wood}} + I_{\text{lead}}$. $m = \rho V$, where ρ is the volume density and $m = \sigma A$, where σ is the area density.

SET UP: For a solid sphere, $I = \frac{2}{5}mR^2$. For the hollow sphere (foil), $I = \frac{2}{3}mR^2$. For a sphere, $V = \frac{4}{3}\pi R^3$ and $A = 4\pi R^2$. $m_{\text{w}} = \rho_{\text{w}}V_{\text{w}} = \rho_{\text{w}}\dfrac{4}{3}\pi R^3$. $m_{\text{L}} = \sigma_{\text{L}}A_{\text{L}} = \sigma_{\text{L}}4\pi R^2$.

EXECUTE: $I = \dfrac{2}{5}m_{\text{w}}R^2 + \dfrac{2}{3}m_{\text{L}}R^2 = \dfrac{2}{5}\left(\rho_{\text{w}}\dfrac{4}{3}\pi R^3\right)R^2 + \dfrac{2}{3}(\sigma_{\text{L}}4\pi R^2)R^2 = \dfrac{8}{3}\pi R^4\left(\dfrac{\rho_{\text{w}}R}{5} + \sigma_{\text{L}}\right)$.

$$I = \frac{8\pi}{3}(0.30 \text{ m})^4\left[\frac{(800 \text{ kg/m}^3)(0.30 \text{ m})}{5} + 20 \text{ kg/m}^2\right] = 4.61 \text{ kg} \cdot \text{m}^2.$$

EVALUATE: $m_{\text{W}} = 90.5$ kg and $I_{\text{W}} = 3.26 \text{ kg} \cdot \text{m}^2$. $m_{\text{L}} = 22.6$ kg and $I_{\text{L}} = 1.36 \text{ kg} \cdot \text{m}^2$. Even though the foil is only 20% of the total mass, its contribution to I is about 30% of the total.

9.75. **IDENTIFY:** $K = \frac{1}{2}I\omega^2$. $a_{\text{rad}} = r\omega^2$. $m = \rho V$.

SET UP: For a disk with the axis at the center, $I = \frac{1}{2}mR^2$. $V = t\pi R^2$, where $t = 0.100$ m is the thickness of the flywheel. $\rho = 7800 \text{ kg/m}^3$ is the density of the iron.

EXECUTE: **(a)** $\omega = 90.0 \text{ rpm} = 9.425 \text{ rad/s}$. $I = \dfrac{2K}{\omega^2} = \dfrac{2(10.0\times10^6 \text{ J})}{(9.425 \text{ rad/s})^2} = 2.252\times10^5 \text{ kg}\cdot\text{m}^2$.

$m = \rho V = \rho\pi R^2 t$. $I = \dfrac{1}{2}mR^2 = \dfrac{1}{2}\rho\pi t R^4$. This gives $R = \left(2I/\rho\pi t\right)^{1/4} = 3.68$ m and the diameter is 7.36 m.

(b) $a_{\text{rad}} = R\omega^2 = 327 \text{ m/s}^2$

EVALUATE: In $K = \frac{1}{2}I\omega^2$, ω must be in rad/s. a_{rad} is about $33g$; the flywheel material must have large cohesive strength to prevent the flywheel from flying apart.

9.76. **IDENTIFY:** $K = \frac{1}{2}I\omega^2$. To have the same K for any ω the two parts must have the same I. Use Table 9.2 for I.

SET UP: For a solid sphere, $I_{\text{solid}} = \frac{2}{5}M_{\text{solid}}R^2$. For a hollow sphere, $I_{\text{hollow}} = \frac{2}{3}M_{\text{hollow}}R^2$.

EXECUTE: $I_{\text{solid}} = I_{\text{hollow}}$ gives $\frac{2}{5}M_{\text{solid}}R^2 = \frac{2}{3}M_{\text{hollow}}R^2$ and $M_{\text{hollow}} = \frac{3}{5}M_{\text{solid}} = \frac{3}{5}M$.

EVALUATE: The hollow sphere has less mass since all its mass is distributed farther from the rotation axis.

9.77. **IDENTIFY:** $K = \frac{1}{2}I\omega^2$. $\omega = \dfrac{2\pi \text{ rad}}{T}$, where T is the period of the motion. For the earth's orbital motion it can be treated as a point mass and $I = MR^2$.

SET UP: The earth's rotational period is $24 \text{ h} = 86{,}164$ s. Its orbital period is $1 \text{ yr} = 3.156\times10^7$ s. $M = 5.97\times10^{24}$ kg. $R = 6.38\times10^6$ m.

EXECUTE: **(a)** $K = \dfrac{2\pi^2 I}{T^2} = \dfrac{2\pi^2(0.3308)(5.97\times10^{24} \text{ kg})(6.38\times10^6 \text{ m})^2}{(86.164 \text{ s})^2} = 2.14\times10^{29}$ J.

(b) $K = \dfrac{1}{2}M\left(\dfrac{2\pi R}{T}\right)^2 = \dfrac{2\pi^2(5.97\times10^{24} \text{ kg})(1.50\times10^{11} \text{ m})^2}{(3.156\times10^7 \text{ s})^2} = 2.66\times10^{33}$ J.

(c) Since the earth's moment of inertia is less than that of a uniform sphere, more of the earth's mass must be concentrated near its center.

EVALUATE: These kinetic energies are very large, because the mass of the earth is very large.

9.78. **IDENTIFY:** Using energy considerations, the system gains as kinetic energy the lost potential energy, mgR.

SET UP: The kinetic energy is $K = \dfrac{1}{2}I\omega^2 + \dfrac{1}{2}mv^2$, with $I = \frac{1}{2}mR^2$ for the disk. $v = R\omega$.

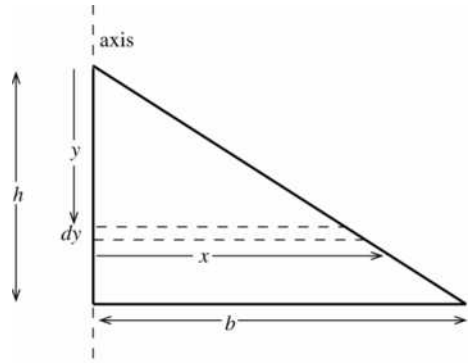
EXECUTE: $K = \dfrac{1}{2}I\omega^2 + \dfrac{1}{2}m(\omega R)^2 = \dfrac{1}{2}(I + mR^2)\omega^2$. Using $I = \frac{1}{2}mR^2$ and solving for ω, $\omega^2 = \dfrac{4}{3}\dfrac{g}{R}$ and $\omega = \sqrt{\dfrac{4}{3}\dfrac{g}{R}}$.

EVALUATE: The small object has speed $v = \sqrt{\dfrac{2}{3}}\sqrt{2gR}$. If it was not attached to the disk and was dropped from a height h, it would attain a speed $\sqrt{2gR}$. Being attached to the disk reduces its final speed by a factor of $\sqrt{\dfrac{2}{3}}$.

9.79. **IDENTIFY:** Use Eq. (9.20) to calculate I. Then use $K = \frac{1}{2}I\omega^2$ to calculate K.

(a) SET UP: The object is sketched in Figure 9.79.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.



Consider a small strip of width *dy* and a distance *y* below the top of the triangle. The length of the strip is $x = (y/h)b$.

Figure 9.79

EXECUTE: The strip has area $x\,dy$ and the area of the sign is $\frac{1}{2}bh$, so the mass of the strip is

$$dm = M\left(\frac{x\,dy}{\frac{1}{2}bh}\right) = M\left(\frac{yb}{h}\right)\left(\frac{2\,dy}{bh}\right) = \left(\frac{2M}{h^2}\right)y\,dy$$

$$dI = \tfrac{1}{3}(dm)x^2 = \left(\frac{2Mb^2}{3h^4}\right)y^3\,dy$$

$$I = \int_0^h dI = \frac{2Mb^2}{3h^4}\int_0^h y^3\,dy = \frac{2Mb^2}{3h^4}\left(\frac{1}{4}y^4\Big|_0^h\right) = \frac{1}{6}Mb^2$$

(b) $I = \frac{1}{6}Mb^2 = 2.304\ \text{kg}\cdot\text{m}^2$

$\omega = 2.00\ \text{rev/s} = 4.00\pi\ \text{rad/s}$

$K = \frac{1}{2}I\omega^2 = 182\ \text{J}$

EVALUATE: From Table (9.2), if the sign were rectangular, with length *b*, then $I = \frac{1}{3}Mb^2$. Our result is one-half this, since mass is closer to the axis for the triangular than for the rectangular shape.

9.80. **IDENTIFY:** Apply conservation of energy to the system.

SET UP: For the falling mass $K = \frac{1}{2}mv^2$. For the wheel $K = \frac{1}{2}I\omega^2$.

EXECUTE: **(a)** The kinetic energy of the falling mass after 2.00 m is $K = \frac{1}{2}mv^2 = \frac{1}{2}(8.00\ \text{kg})(5.00\ \text{m/s})^2 =$ 100 J. The change in its potential energy while falling is $mgh = (8.00\ \text{kg})(9.8\ \text{m/s}^2)(2.00\ \text{m}) = 156.8$ J. The wheel must have the "missing" 56.8 J in the form of rotational kinetic energy. Since its outer rim is moving at the same speed as the falling mass, 5.00 m/s , $v = r\omega$ gives $\omega = \frac{v}{r} = \frac{5.00\ \text{m/s}}{0.370\ \text{m}} = 13.51$ rad/s.

$K = \frac{1}{2}I\omega^2$; therefore $I = \frac{2K}{\omega^2} = \frac{2(56.8\ \text{J})}{(13.51\ \text{rad/s})^2} = 0.622\ \text{kg}\cdot\text{m}^2$.

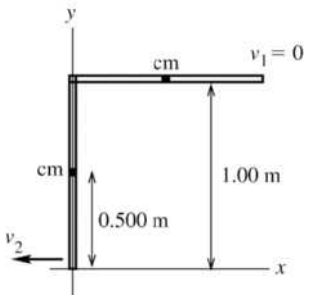
(b) The wheel's mass is $(280\ \text{N})/(9.8\ \text{m/s}^2) = 28.6$ kg. The wheel with the largest possible moment of inertia would have all this mass concentrated in its rim. Its moment of inertia would be $I = MR^2 = (28.6\ \text{kg})(0.370\ \text{m})^2 = 3.92\ \text{kg}\cdot\text{m}^2$. The boss's wheel is physically impossible.

EVALUATE: If the mass falls from rest in free fall its speed after it has descended 2.00 m is $v = \sqrt{2g(2.00\ \text{m})} = 6.26$ m/s. Its actual speed is less because some of the energy of the system is in the form of rotational kinetic energy of the wheel.

9.81. **IDENTIFY:** Use conservation of energy. The stick rotates about a fixed axis so $K = \frac{1}{2}I\omega^2$. Once we have ω use $v = r\omega$ to calculate *v* for the end of the stick.

SET UP: The object is sketched in Figure 9.81.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.



Take the origin of coordinates at the lowest point reached by the stick and take the positive *y*-direction to be upward.

Figure 9.81

EXECUTE: **(a)** Use Eq.(9.18): $U = Mgy_{\text{cm}}$. $\Delta U = U_2 - U_1 = Mg(y_{\text{cm2}} - y_{\text{cm1}})$. The center of mass of the meter stick is at its geometrical center, so $y_{\text{cm1}} = 1.00$ m and $y_{\text{cm2}} = 0.50$ m. Then

$\Delta U = (0.180 \text{ kg})(9.80 \text{ m/s}^2)(0.50 \text{ m} - 1.00 \text{ m}) = -0.882$ J.

(b) Use conservation of energy: $K_1 + U_1 + W_{\text{other}} = K_2 + U_2$. Gravity is the only force that does work on the meter stick, so $W_{\text{other}} = 0$. $K_1 = 0$. Thus $K_2 = U_1 - U_2 = -\Delta U$, where ΔU was calculated in part (a). $K_2 = \frac{1}{2}I\omega_2^2$ so $\frac{1}{2}I\omega_2^2 = -\Delta U$ and $\omega_2 = \sqrt{2(-\Delta U)/I}$. For stick pivoted about one end, $I = \frac{1}{3}ML^2$ where $L = 1.00$ m, so $\omega_2 = \sqrt{\dfrac{6(-\Delta U)}{ML^2}} = \sqrt{\dfrac{6(0.882 \text{ J})}{(0.180 \text{ kg})(1.00 \text{ m})^2}} = 5.42$ rad/s.

(c) $v = r\omega = (1.00 \text{ m})(5.42 \text{ rad/s}) = 5.42$ m/s.

(d) For a particle in free fall, with $+y$ upward, $v_{0y} = 0$; $y - y_0 = -1.00$ m; $a_y = -9.80$ m/s^2; and $v_y = ?$ Solving the equation $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ for v_y gives

$v_y = -\sqrt{2a_y(y - y_0)} = -\sqrt{2(-9.80 \text{ m/s}^2)(-1.00 \text{ m})} = -4.43$ m/s.

EVALUATE: The magnitude of the answer in part (c) is larger. $U_{1,\text{grav}}$ is the same for the stick as for a particle falling from a height of 1.00 m. For the stick $K = \frac{1}{2}I\omega_2^2 = \frac{1}{2}(\frac{1}{3}ML^2)(v/L)^2 = \frac{1}{6}Mv^2$. For the stick and for the particle, K_2 is the same but the same *K* gives a larger *v* for the end of the stick than for the particle. The reason is that all the other points along the stick are moving slower than the end opposite the axis.

9.82. **IDENTIFY:** Apply conservation of energy to the system of cylinder and rope.

SET UP: Taking the zero of gravitational potential energy to be at the axle, the initial potential energy is zero (the rope is wrapped in a circle with center on the axle).When the rope has unwound, its center of mass is a distance πR below the axle, since the length of the rope is $2\pi R$ and half this distance is the position of the center of the mass. Initially, every part of the rope is moving with speed $\omega_0 R$, and when the rope has unwound, and the cylinder has angular speed ω, the speed of the rope is ωR (the upper end of the rope has the same tangential speed at the edge of the cylinder). $I = (1/2)MR^2$ for a uniform cylinder.

EXECUTE: $K_1 = K_2 + U_2$. $\left(\dfrac{M}{4} + \dfrac{m}{2}\right)R^2\omega_0^2 = \left(\dfrac{M}{4} + \dfrac{m}{2}\right)R^2\omega^2 - mg\pi R$. Solving for ω gives

$\omega = \sqrt{\omega_0^2 + \dfrac{(4\pi mg/R)}{(M + 2m)}}$, and the speed of any part of the rope is $v = \omega R$.

EVALUATE: When $m \to 0$, $\omega \to \omega_0$, When $m >> M$, $\omega = \sqrt{\omega_0^2 + \dfrac{2\pi g}{R}}$ and $v = \sqrt{v_0^2 + 2\pi gR}$. This is the final speed when an object with initial speed v_0 descends a distance πR.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

9.83. **IDENTIFY:** Apply conservation of energy to the system consisting of blocks A and B and the pulley.
SET UP: The system at points 1 and 2 of its motion is sketched in Figure 9.83.

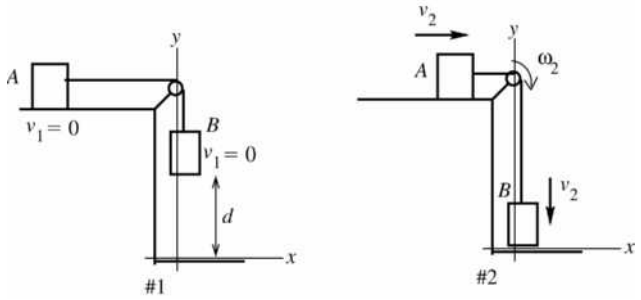


Figure 9.83

Use the work-energy relation $K_1 + U_1 + W_{\text{other}} = K_2 + U_2$. Use coordinates where $+y$ is upward and where the origin is at the position of block B after it has descended. The tension in the rope does positive work on block A and negative work of the same magnitude on block B, so the net work done by the tension in the rope is zero. Both blocks have the same speed.
EXECUTE: Gravity does work on block B and kinetic friction does work on block A. Therefore $W_{\text{other}} = W_f = -\mu_k m_A g d$.

$K_1 = 0$ (system is released from rest)

$U_1 = m_B g y_{B1} = m_B g d;\ \ U_2 = m_B g y_{B2} = 0$

$K_2 = \frac{1}{2} m_A v_2^2 + \frac{1}{2} m_B v_2^2 + \frac{1}{2} I \omega_2^2$.

But $v(\text{blocks}) = R\omega(\text{pulley})$, so $\omega_2 = v_2/R$ and

$K_2 = \frac{1}{2}(m_A + m_B) v_2^2 + \frac{1}{2} I (v_2/R)^2 = \frac{1}{2}(m_A + m_B + I/R^2) v_2^2$

Putting all this into the work-energy relation gives

$m_B g d - \mu_k m_A g d = \frac{1}{2}(m_A + m_B + I/R^2) v_2^2$

$(m_A + m_B + I/R^2) v_2^2 = 2 g d (m_B - \mu_k m_A)$

$$v_2 = \sqrt{\frac{2gd(m_B - \mu_k m_A)}{m_A + m_B + I/R^2}}$$

EVALUATE: If $m_B >> m_A$ and I/R^2, then $v_2 = \sqrt{2gd}$; block B falls freely. If I is very large, v_2 is very small. Must have $m_B > \mu_k m_A$ for motion, so the weight of B will be larger than the friction force on A.
I/R^2 has units of mass and is in a sense the "effective mass" of the pulley.

9.84. **IDENTIFY:** Apply conservation of energy to the system of two blocks and the pulley.
SET UP: Let the potential energy of each block be zero at its initial position. The kinetic energy of the system is the sum of the kinetic energies of each object. $v = R\omega$, where v is the common speed of the blocks and ω is the angular velocity of the pulley.
EXECUTE: The amount of gravitational potential energy which has become kinetic energy is $K = (4.00\ \text{kg} - 2.00\ \text{kg})(9.80\ \text{m/s}^2)(5.00\ \text{m}) = 98.0\ \text{J}$. In terms of the common speed v of the blocks, the kinetic energy of the system is $K = \frac{1}{2}(m_1 + m_2) v^2 + \frac{1}{2} I \left(\frac{v}{R}\right)^2$.

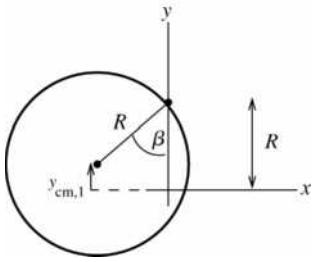
© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$K = v^2\frac{1}{2}\left(4.00\text{ kg} + 2.00\text{ kg} + \frac{(0.560\text{ kg}\cdot\text{m}^2)}{(0.160\text{ m})^2}\right) = v^2(13.94\text{ kg})$. Solving for v gives

$v = \sqrt{\frac{98.0\text{ J}}{13.94\text{ kg}}} = 2.65\text{ m/s}.$

EVALUATE: If the pulley is massless, $98.0\text{ J} = \frac{1}{2}(4.00\text{ kg} + 2.00\text{ kg})v^2$ and $v = 5.72$ m/s. The moment of inertia of the pulley reduces the final speed of the blocks.

9.85. **IDENTIFY** and **SET UP:** Apply conservation of energy to the motion of the hoop. Use Eq. (9.18) to calculate U_{grav}. Use $K = \frac{1}{2}I\omega^2$ for the kinetic energy of the hoop. Solve for ω. The center of mass of the hoop is at its geometrical center.



Take the origin to be at the original location of the center of the hoop, before it is rotated to one side, as shown in Figure 9.85.

Figure 9.85

$y_{\text{cm1}} = R - R\cos\beta = R(1-\cos\beta)$

$y_{\text{cm2}} = 0$ (at equilibrium position hoop is at original position)

EXECUTE: $K_1 + U_1 + W_{\text{other}} = K_2 + U_2$

$W_{\text{other}} = 0$ (only gravity does work)

$K_1 = 0$ (released from rest), $K_2 = \frac{1}{2}I\omega_2^2$

For a hoop, $I_{\text{cm}} = MR^2$, so $I = Md^2 + MR^2$ with $d = R$ and $I = 2MR^2$, for an axis at the edge. Thus $K_2 = \frac{1}{2}(2MR^2)\omega_2^2 = MR^2\omega_2^2$.

$U_1 = Mgy_{\text{cm1}} = MgR(1-\cos\beta)$, $U_2 = mgy_{\text{cm2}} = 0$

Thus $K_1 + U_1 + W_{\text{other}} = K_2 + U_2$ gives

$MgR(1-\cos\beta) = MR^2\omega_2^2$ and $\omega_2 = \sqrt{g(1-\cos\beta)/R}$

EVALUATE: If $\beta = 0$, then $\omega_2 = 0$. As β increases, ω_2 increases.

9.86. **IDENTIFY:** $K = \frac{1}{2}I\omega^2$, with ω in rad/s. $P = \dfrac{\text{energy}}{t}$

SET UP: For a solid cylinder, $I = \frac{1}{2}MR^2$. 1 rev/min = $(2\pi/60)$ rad/s

EXECUTE: **(a)** $\omega = 3000$ rev/min $= 314$ rad/s. $I = \frac{1}{2}(1000\text{ kg})(0.900\text{ m})^2 = 405\text{ kg}\cdot\text{m}^2$

$K = \frac{1}{2}(405\text{ kg}\cdot\text{m}^2)(314\text{ rad/s})^2 = 2.00\times10^7$ J.

(b) $t = \dfrac{K}{P} = \dfrac{2.00\times10^7\text{ J}}{1.86\times10^4\text{ W}} = 1.08\times10^3\text{ s} = 17.9\text{ min}.$

EVALUATE: In $K = \frac{1}{2}I\omega^2$, we must use ω in rad/s.

9.87. **IDENTIFY:** $I = I_1 + I_2$. Apply conservation of energy to the system. The calculation is similar to Example 9.8.

SET UP: $\omega = \dfrac{v}{R_1}$ for part (b) and $\omega = \dfrac{v}{R_2}$ for part (c).

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: **(a)** $I=\frac{1}{2}M_1R_1^2+\frac{1}{2}M_2R_2^2=\frac{1}{2}((0.80\text{ kg})(2.50\times10^{-2}\text{ m})^2+(1.60\text{ kg})(5.00\times10^{-2}\text{ m})^2)$

$I=2.25\times10^{-3}\text{ kg}\cdot\text{m}^2$.

(b) The method of Example 9.8 yields $v=\sqrt{\frac{2gh}{1+(I/mR_1^2)}}$.

$$v=\sqrt{\frac{2(9.80\text{ m/s}^2)(2.00\text{ m})}{(1+((2.25\times10^{-3}\text{ kg}\cdot\text{m}^2)/(1.50\text{ kg})(0.025\text{ m})^2))}}=3.40\text{ m/s}.$$

(c) The same calculation, with R_2 instead of R_1 gives $v=4.95$ m/s.

EVALUATE: The final speed of the block is greater when the string is wrapped around the larger disk. $v=R\omega$, so when $R=R_2$ the factor that relates v to ω is larger. For $R=R_2$ a larger fraction of the total kinetic energy resides with the block. The total kinetic energy is the same in both cases (equal to mgh), so when $R=R_2$ the kinetic energy and speed of the block are greater.

9.88. **IDENTIFY:** The potential energy of the falling block is transformed into kinetic energy of the block and kinetic energy of the turning wheel, but some of it is lost to the work by friction. Energy conservation applies, with the target variable being the angular velocity of the wheel when the block has fallen a given distance.

SET UP: $K_1+U_1+W_{\text{other}}=K_2+U_2$, where $K=\frac{1}{2}mv^2$, $U=mgh$, and W_{other} is the work done by friction.

EXECUTE: Energy conservation gives $mgh+(-6.00\text{ J})=\frac{1}{2}mv^2+\frac{1}{2}I\omega^2$. $v=R\omega$, so $\frac{1}{2}mv^2=\frac{1}{2}mR^2\omega^2$

and $mgh+(-6.00\text{ J})=\frac{1}{2}(mR^2+I)\omega^2$. Solving for ω gives

$$\omega=\sqrt{\frac{2[mgh+(-6.00\text{ J})]}{mR^2+I}}=\sqrt{\frac{2[(0.340\text{ kg})(9.8\text{ m/s}^2)(3.00\text{ m})-6.00\text{ J}]}{(0.340\text{ kg})(0.180\text{ m})^2+0.480\text{ kg}\cdot\text{m}^2}}=4.03\text{ rad/s}.$$

EVALUATE: Friction does negative work because it opposes the turning of the wheel.

9.89. **IDENTIFY:** Apply conservation of energy to relate the height of the mass to the kinetic energy of the cylinder.

SET UP: First use $K(\text{cylinder})=480$ J to find ω for the cylinder and v for the mass.

EXECUTE: $I=\frac{1}{2}MR^2=\frac{1}{2}(10.0\text{ kg})(0.150\text{ m})^2=0.1125\text{ kg}\cdot\text{m}^2$. $K=\frac{1}{2}I\omega^2$ so $\omega=\sqrt{2K/I}=92.38$ rad/s.

$v=R\omega=13.86$ m/s.

SET UP: Use conservation of energy $K_1+U_1=K_2+U_2$ to solve for the distance the mass descends. Take $y=0$ at lowest point of the mass, so $y_2=0$ and $y_1=h$, the distance the mass descends.

EXECUTE: $K_1=U_2=0$ so $U_1=K_2$. $mgh=\frac{1}{2}mv^2+\frac{1}{2}I\omega^2$, where $m=12.0$ kg. For the cylinder,

$I=\frac{1}{2}MR^2$ and $\omega=v/R$, so $\frac{1}{2}I\omega^2=\frac{1}{4}Mv^2$. Solving $mgh=\frac{1}{2}mv^2+\frac{1}{4}Mv^2$ for h gives

$$h=\frac{v^2}{2g}\left(1+\frac{M}{2m}\right)=13.9\text{ m}.$$

EVALUATE: For the cylinder $K_{\text{cyl}}=\frac{1}{2}I\omega^2=\frac{1}{2}(\frac{1}{2}MR^2)(v/R)^2=\frac{1}{4}Mv^2$. $K_{\text{mass}}=\frac{1}{2}mv^2$, so

$K_{\text{mass}}=(2m/M)K_{\text{cyl}}=[2(12.0\text{ kg})/10.0\text{ kg}](480\text{ J})=1150$ J. The mass has 1150 J of kinetic energy when the cylinder has 480 J of kinetic energy and at this point the system has total energy 1630 J since $U_2=0$. Initially the total energy of the system is $U_1=mgy_1=mgh=1630$ J, so the total energy is shown to be conserved.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

9.90. **IDENTIFY:** Energy conservation: Loss of U of box equals gain in K of system. Both the cylinder and pulley have kinetic energy of the form $K = \frac{1}{2}I\omega^2$.

$m_{\text{box}}gh = \frac{1}{2}m_{\text{box}}v_{\text{box}}^2 + \frac{1}{2}I_{\text{pulley}}\omega_{\text{pulley}}^2 + \frac{1}{2}I_{\text{cylinder}}\omega_{\text{cylinder}}^2$.

SET UP: $\omega_{\text{pulley}} = \frac{v_{\text{box}}}{r_{\text{p}}}$ and $\omega_{\text{cylinder}} = \frac{v_{\text{box}}}{r_{\text{cylinder}}}$.

Let B = box, P = pulley and C = cylinder.

EXECUTE: $m_{\text{B}}gh = \frac{1}{2}m_{\text{B}}v_{\text{B}}^2 + \frac{1}{2}\left(\frac{1}{2}m_{\text{P}}r_{\text{P}}^2\right)\left(\frac{v_{\text{B}}}{r_{\text{P}}}\right)^2 + \frac{1}{2}\left(\frac{1}{2}m_{\text{C}}r_{\text{C}}^2\right)\left(\frac{v_{\text{B}}}{r_{\text{C}}}\right)^2$.

$m_{\text{B}}gh = \frac{1}{2}m_{\text{B}}v_{\text{B}}^2 + \frac{1}{4}m_{\text{P}}v_{\text{B}}^2 + \frac{1}{4}m_{\text{C}}v_{\text{B}}^2$ and

$$v_{\text{B}} = \sqrt{\frac{m_{\text{B}}gh}{\frac{1}{2}m_{\text{B}} + \frac{1}{4}m_{\text{P}} + \frac{1}{4}m_{\text{C}}}} = \sqrt{\frac{(3.00\text{ kg})(9.80\text{ m/s}^2)(2.50\text{ m})}{1.50\text{ kg} + \frac{1}{4}(7.00\text{ kg})}} = 4.76\text{ m/s}.$$

EVALUATE: If the box was disconnected from the rope and dropped from rest, after falling 2.50 m its speed would be $v = \sqrt{2g(2.50\text{ m})} = 7.00$ m/s. Since in the problem some of the energy of the system goes into kinetic energy of the cylinder and of the pulley, the final speed of the box is less than this.

9.91. **IDENTIFY:** $I = I_{\text{disk}} - I_{\text{hole}}$, where I_{hole} is I for the piece punched from the disk. Apply the parallel-axis theorem to calculate the required moments of inertia.

SET UP: For a uniform disk, $I = \frac{1}{2}MR^2$.

EXECUTE: **(a)** The initial moment of inertia is $I_0 = \frac{1}{2}MR^2$. The piece punched has a mass of $\frac{M}{16}$ and a moment of inertia with respect to the axis of the original disk of

$$\frac{M}{16}\left[\frac{1}{2}\left(\frac{R}{4}\right)^2 + \left(\frac{R}{2}\right)^2\right] = \frac{9}{512}MR^2.$$

The moment of inertia of the remaining piece is then $I = \frac{1}{2}MR^2 - \frac{9}{512}MR^2 = \frac{247}{512}MR^2$.

(b) $I = \frac{1}{2}MR^2 + M(R/2)^2 - \frac{1}{2}(M/16)(R/4)^2 = \frac{383}{512}MR^2$.

EVALUATE: For a solid disk and an axis at a distance $R/2$ from the disk's center, the parallel-axis theorem gives $I = \frac{1}{2}MR^2 = \frac{3}{4}MR^2 = \frac{384}{512}MR^2$. For both choices of axes the presence of the hole reduces I, but the effect of the hole is greater in part (a), when it is farther from the axis.

9.92. **IDENTIFY:** We know (or can calculate) the masses and geometric measurements of the various parts of the body. We can model them as familiar objects, such as uniform spheres, rods, and cylinders, and calculate their moments of inertia and kinetic energies.

SET UP: My total mass is $m = 90$ kg. I model my head as a uniform sphere of radius 8 cm. I model my trunk and legs as a uniform solid cylinder of radius 12 cm. I model my arms as slender rods of length 60 cm. $\omega = 72$ rev/min $= 7.5$ rad/s. For a solid uniform sphere, $I = 2/5\ MR^2$, for a solid cylinder, $I = \frac{1}{2}MR^2$, and for a rod rotated about one end $I = 1/3\ ML^2$.

EXECUTE: **(a)** Using the formulas indicated above, we have $I_{\text{tot}} = I_{\text{head}} + I_{\text{trunk+legs}} + I_{\text{arms}}$, which gives $I_{\text{tot}} = \frac{2}{5}(0.070m)(0.080\text{ m})^2 + \frac{1}{2}(0.80m)(0.12\text{ m})^2 + 2\left(\frac{1}{3}\right)(0.13m)(0.60\text{ m})^2 = 3.3\text{ kg}\cdot\text{m}^2$ where we have used $m = 90$ kg.

(b) $K_{\text{rot}} = \frac{1}{2}I\omega^2 = \frac{1}{2}(3.3\text{ kg}\cdot\text{m}^2)(7.5\text{ rad/s})^2 = 93$ J.

EVALUATE: According to these estimates about 85% of the total I is due to the outstretched arms. If the initial translational kinetic energy $\frac{1}{2}mv^2$ of the skater is converted to this rotational kinetic energy as he goes into a spin, his initial speed must be 1.4 m/s.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

9.93. **IDENTIFY:** The total kinetic energy of a walker is the sum of his translational kinetic energy plus the rotational kinetic of his arms and legs. We can model these parts of the body as uniform bars.

SET UP: For a uniform bar pivoted about one end, $I = \frac{1}{3}mL^2$. $v = 5.0$ km/h $= 1.4$ m/s.

$K_{\text{tran}} = \frac{1}{2}mv^2$ and $K_{\text{rot}} = \frac{1}{2}I\omega^2$.

EXECUTE: **(a)** $60° = \left(\frac{1}{3}\right)$ rad. The average angular speed of each arm and leg is $\frac{\frac{1}{3}\text{ rad}}{1\text{ s}} = 1.05$ rad/s.

(b) Adding the moments of inertia gives

$I = \frac{1}{3}m_{\text{arm}}L_{\text{arm}}{}^2 + \frac{1}{3}m_{\text{leg}}L_{\text{leg}}{}^2 = \frac{1}{3}[(0.13)(75\text{ kg})(0.70\text{ m})^2 + (0.37)(75\text{ kg})(0.90\text{ m})^2]$. $I = 9.08\text{ kg}\cdot\text{m}^2$.

$K_{\text{rot}} = \frac{1}{2}I\omega^2 = \frac{1}{2}(9.08\text{ kg}\cdot\text{m}^2)(1.05\text{ rad/s})^2 = 5.0$ J.

(c) $K_{\text{tran}} = \frac{1}{2}mv^2 = \frac{1}{2}(75\text{ kg})(1.4\text{ m/s})^2 = 73.5$ J and $K_{\text{tot}} = K_{\text{tran}} + K_{\text{rot}} = 78.5$ J.

(d) $\frac{K_{\text{rot}}}{K_{\text{tran}}} = \frac{5.0\text{ J}}{78.5\text{ J}} = 6.4\%$.

EVALUATE: If you swing your arms more vigorously more of your energy input goes into the kinetic energy of walking and it is more effective exercise. Carrying weights in our hands would also be effective.

9.94. **IDENTIFY:** The total kinetic energy of a runner is the sum of his translational kinetic energy plus the rotational kinetic of his arms and legs. We can model these parts of the body as uniform bars.

SET UP: Now $v = 12$ km/h $= 3.33$ m/s. $I_{\text{tot}} = 9.08\text{ kg}\cdot\text{m}^2$ as in Problem 9.93.

EXECUTE: **(a)** $\omega_{\text{av}} = \frac{1/3\text{ rad}}{0.5\text{ s}} = 2.1$ rad/s.

(b) $K_{\text{rot}} = \frac{1}{2}I\omega^2 = \frac{1}{2}(9.08\text{ kg}\cdot\text{m}^2)(2.1\text{ rad/s})^2 = 20$ J.

(c) $K_{\text{tran}} = \frac{1}{2}mv^2 = \frac{1}{2}(75\text{ kg})(3.33\text{ m/s})^2 = 416$ J. Therefore

$K_{\text{tot}} = K_{\text{tran}} + K_{\text{rot}} = 416\text{ J} + 20\text{ J} = 436\text{ J}$.

(d) $\frac{K_{\text{rot}}}{K_{\text{tot}}} = \frac{20\text{ J}}{436\text{ J}} = 4.6\%$.

9.95. **IDENTIFY:** Follow the instructions in the problem to derive the perpendicular-axis theorem. Then apply that result in part (b).

SET UP: $I = \sum_i m_i r_i^2$. The moment of inertia for the washer and an axis perpendicular to the plane of the washer at its center is $\frac{1}{2}M(R_1^2 + R_2^2)$. In part (b), I for an axis perpendicular to the plane of the square at its center is $\frac{1}{12}M\left(L^2 + L^2\right) = \frac{1}{6}ML^2$.

EXECUTE: **(a)** With respect to O, $r_i^2 = x_i^2 + y_i^2$, and so

$I_O = \sum_i m_i r_i^2 = \sum_i m_i(x_i^2 + y_i^2) = \sum_i m_i x_i^2 + \sum_i m_i y_i^2 = I_x + I_y$.

(b) Two perpendicular axes, both perpendicular to the washer's axis, will have the same moment of inertia about those axes, and the perpendicular-axis theorem predicts that they will sum to the moment of inertia about the washer axis, which is $I = \frac{1}{2}M(R_1^2 + R_2^2)$, and so $I_x = I_y = \frac{1}{4}M(R_1^2 + R_2^2)$.

(c) $I_0 = \frac{1}{6}mL^2$. Since $I_0 = I_x + I_y$, and $I_x = I_y$, both I_x and I_y must be $\frac{1}{12}mL^2$.

EVALUATE: The result in part (c) says that I is the same for an axis that bisects opposite sides of the square as for an axis along the diagonal of the square, even though the distribution of mass relative to the two axes is quite different in these two cases.

9.96. **IDENTIFY:** Apply the parallel-axis theorem to each side of the square.

SET UP: Each side has length a and mass $M/4$, and the moment of inertia of each side about an axis perpendicular to the side and through its center is $\frac{1}{12}\left(\frac{1}{4}Ma^2\right) = \frac{1}{48}Ma^2$.

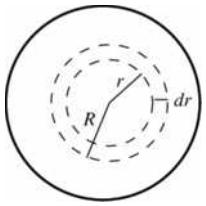
© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: The moment of inertia of each side about the axis through the center of the square is, from the perpendicular axis theorem, $\frac{Ma^2}{48}+\frac{M}{4}\left(\frac{a}{2}\right)^2=\frac{Ma^2}{12}$. The total moment of inertia is the sum of the contributions from the four sides, or $4\times\frac{Ma^2}{12}=\frac{Ma^2}{3}$.

EVALUATE: If all the mass of a side were at its center, a distance $a/2$ from the axis, we would have $I=4\left(\frac{M}{4}\right)\left(\frac{a}{2}\right)^2=\frac{1}{4}Ma^2$. If all the mass was divided equally among the four corners of the square, a distance $a/\sqrt{2}$ from the axis, we would have $I=4\left(\frac{M}{4}\right)\left(\frac{a}{\sqrt{2}}\right)^2=\frac{1}{2}Ma^2$. The actual I is between these two values.

9.97. **IDENTIFY:** Use Eq. (9.20) to calculate I.

(a) SET UP: Let L be the length of the cylinder. Divide the cylinder into thin cylindrical shells of inner radius r and outer radius $r+dr$. An end view is shown in Figure 9.97



$\rho=\alpha r$

The mass of the thin cylindrical shell is

$dm=\rho\,dV=\rho(2\pi r\,dr)L=2\pi\alpha Lr^2\,dr$

Figure 9.97

EXECUTE: $I=\int r^2\,dm=2\pi\alpha L\int_0^R r^4\,dr=2\pi\alpha L\left(\frac{1}{5}R^5\right)=\frac{2}{5}\pi\alpha LR^5$

Relate M to α: $M=\int dm=2\pi\alpha L\int_0^R r^2\,dr=2\alpha\pi L\left(\frac{1}{3}R^3\right)=\frac{2}{3}\pi\alpha LR^3$, so $\pi\alpha LR^3=3M/2$.

Using this in the above result for I gives $I=\frac{2}{5}(3M/2)R^2=\frac{3}{5}MR^2$.

(b) EVALUATE: For a cylinder of uniform density $I=\frac{1}{2}MR^2$. The answer in (a) is larger than this. Since the density increases with distance from the axis the cylinder in (a) has more mass farther from the axis than for a cylinder of uniform density.

9.98. **IDENTIFY:** Write K in terms of the period T and take derivatives of both sides of this equation to relate dK/dt to dT/dt.

SET UP: $\omega=\frac{2\pi}{T}$ and $K=\frac{1}{2}I\omega^2$. The speed of light is $c=3.00\times10^8$ m/s.

EXECUTE: **(a)** $K=\frac{2\pi^2I}{T^2}$. $\frac{dK}{dt}=-\frac{4\pi^2I}{T^3}\frac{dT}{dt}$. The rate of energy loss is $\frac{4\pi^2I}{T^3}\frac{dT}{dt}$. Solving for the moment of inertia I in terms of the power P,

$$I=\frac{PT^3}{4\pi^2}\frac{1}{dT/dt}=\frac{(5\times10^{31}\text{ W})(0.0331\text{ s})^3}{4\pi^2}\frac{1\text{ s}}{4.22\times10^{-13}\text{ s}}=1.09\times10^{38}\text{ kg}\cdot\text{m}^2$$

(b) $R=\sqrt{\frac{5I}{2M}}=\sqrt{\frac{5(1.08\times10^{38}\text{ kg}\cdot\text{m}^2)}{2(1.4)(1.99\times10^{30}\text{ kg})}}=9.9\times10^3$ m, about 10 km.

(c) $v=\frac{2\pi R}{T}=\frac{2\pi(9.9\times10^3\text{ m})}{(0.0331\text{ s})}=1.9\times10^6\text{ m/s}=6.3\times10^{-3}c$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(d) $\rho = \dfrac{M}{V} = \dfrac{M}{(4\pi/3)R^3} = 6.9\times10^{17}\ \text{kg/m}^3$, which is much higher than the density of ordinary rock by 14 orders of magnitude, and is comparable to nuclear mass densities.

EVALUATE: I is huge because M is huge. A small rate of change in the period corresponds to a large release of energy.

9.99. **IDENTIFY:** The density depends on the distance from the center of the sphere, so it is a function of r. We need to integrate to find the mass and the moment of inertia.

SET UP: $M = \int dm = \int \rho dV$ and $I = \int dI$.

EXECUTE: **(a)** Divide the sphere into thin spherical shells of radius r and thickness dr. The volume of each shell is $dV = 4\pi r^2 dr$. $\rho(r) = a - br$, with $a = 3.00\times10^3\ \text{kg/m}^3$ and $b = 9.00\times10^3\ \text{kg/m}^4$. Integrating gives $M = \int dm = \int \rho dV = \int_0^R (a-br)4\pi r^2 dr = \dfrac{4}{3}\pi R^3\left(a - \dfrac{3}{4}bR\right)$.

$$M = \frac{4}{3}\pi(0.200)^3\left(3.00\times10^3\ \text{kg/m}^3 - \frac{3}{4}(9.00\times10^3\ \text{kg/m}^4)(0.200\ \text{m})\right) = 55.3\ \text{kg}.$$

(b) The moment of inertia of each thin spherical shell is

$$dI = \frac{2}{3}r^2 dm = \frac{2}{3}r^2\rho dV = \frac{2}{3}r^2(a-br)4\pi r^2 dr = \frac{8\pi}{3}r^4(a-br)dr.$$

$$I = \int_0^R dI = \frac{8\pi}{3}\int_0^R r^4(a-br)dr = \frac{8\pi}{15}R^5\left(a - \frac{5b}{6}R\right).$$

$$I = \frac{8\pi}{15}(0.200\ \text{m})^5\left(3.00\times10^3\ \text{kg/m}^3 - \frac{5}{6}(9.00\times10^3\ \text{kg/m}^4)(0.200\ \text{m})\right) = 0.804\ \text{kg}\cdot\text{m}^2.$$

EVALUATE: We cannot use the formulas $M = \rho V$ and $I = \dfrac{1}{2}MR^2$ because this sphere is not uniform throughout. Its density increases toward the surface. For a uniform sphere with density $3.00\times10^3\ \text{kg/m}^3$, the mass is $\dfrac{4}{3}\pi R^3\rho = 100.5\ \text{kg}$. The mass of the sphere in this problem is less than this. For a uniform sphere with mass 55.3 kg and $R = 0.200$ m, $I = \dfrac{2}{5}MR^2 = 0.885\ \text{kg}\cdot\text{m}^2$. The moment of inertia for the sphere in this problem is less than this, since the density decreases with distance from the center of the sphere.

9.100. **IDENTIFY:** Apply Eq. (9.20).

SET UP: Let z be the coordinate along the vertical axis. $r(z) = \dfrac{zR}{h}$. $dm = \pi\rho\dfrac{R^2z^2}{h^2}$ and $dI = \dfrac{\pi\rho}{2}\dfrac{R^4}{h^4}z^4\,dz$.

EXECUTE: $I = \int dI = \dfrac{\pi\rho}{2}\dfrac{R^4}{h^4}\int_0^h z^4\,dz = \dfrac{\pi\rho}{10}\dfrac{R^4}{h^4}\left[z^5\right]_0^h = \dfrac{1}{10}\pi\rho R^4 h$. The volume of a right circular cone is $V = \frac{1}{3}\pi R^2 h$, the mass is $\frac{1}{3}\pi\rho R^2 h$ and so $I = \dfrac{3}{10}\left(\dfrac{\pi\rho R^2 h}{3}\right)R^2 = \dfrac{3}{10}MR^2$.

EVALUATE: For a uniform cylinder of radius R and for an axis through its center, $I = \frac{1}{2}MR^2$. I for the cone is less, as expected, since the cone is constructed from a series of parallel discs whose radii decrease from R to zero along the vertical axis of the cone.

9.101. **IDENTIFY:** Follow the steps outlined in the problem.

SET UP: $\omega_z = d\theta/dt$. $\alpha_z = d^2\omega_z/dt^2$.

EXECUTE: **(a)** $ds = r\,d\theta = r_0 d\theta + \beta\theta\,d\theta$ so $s(\theta) = r_0\theta + \dfrac{\beta}{2}\theta^2$. θ must be in radians.

(b) Setting $s = vt = r_0\theta + \dfrac{\beta}{2}\theta^2$ gives a quadratic in θ. The positive solution is

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$\theta(t) = \dfrac{1}{\beta}\left[\sqrt{r_0{}^2 + 2\beta v t} - r_0\right]$.

(The negative solution would be going backwards, to values of r smaller than r_0.)

(c) Differentiating, $\omega_z(t) = \dfrac{d\theta}{dt} = \dfrac{v}{\sqrt{r_0^2 + 2\beta v t}}$, $\alpha_z = \dfrac{d\omega_z}{dt} = -\dfrac{\beta v^2}{(r_0^2 + 2\beta v t)^{3/2}}$. The angular acceleration α_z is not constant.

(d) $r_0 = 25.0$ mm. θ must be measured in radians, so $\beta = (1.55\mu\text{m/rev})(1\text{ rev}/2\pi\text{ rad}) = 0.247\mu\text{m/rad}$. Using $\theta(t)$ from part (b), the total angle turned in 74.0 min = 4440 s is

$$\theta = \frac{1}{2.47\times10^{-7}\text{ m/rad}}\left(\sqrt{2(2.47\times10^{-7}\text{ m/rad})(1.25\text{ m/s})(4440\text{ s}) + (25.0\times10^{-3}\text{ m})^2} - 25.0\times10^{-3}\text{ m}\right)$$

$\theta = 1.337\times10^5$ rad, which is 2.13×10^4 rev.

(e) The graphs are sketched in Figure 9.101.

EVALUATE: ω_z must decrease as r increases, to keep $v = r\omega$ constant. For ω_z to decrease in time, α_z must be negative.

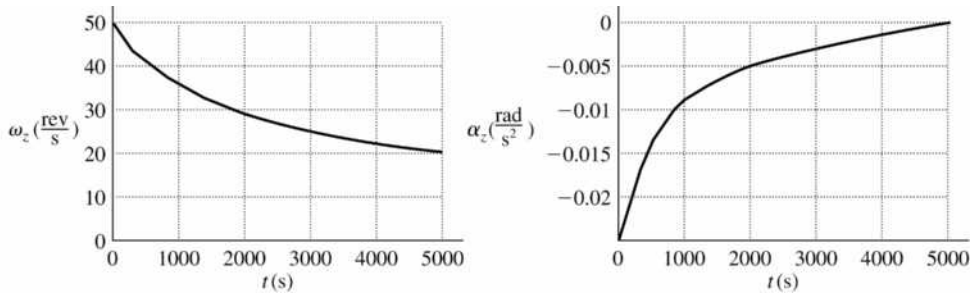


Figure 9.101

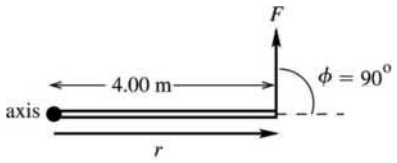
10

DYNAMICS OF ROTATIONAL MOTION

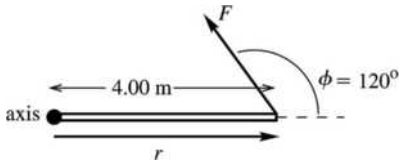
10.1. **IDENTIFY:** Use Eq. (10.2) to calculate the magnitude of the torque and use the right-hand rule illustrated in Figure 10.4 in the textbook to calculate the torque direction.
(a) SET UP: Consider Figure 10.1a.



EXECUTE: $\tau = Fl$
$l = r\sin\phi = (4.00\text{ m})\sin 90°$
$l = 4.00\text{ m}$
$\tau = (10.0\text{ N})(4.00\text{ m}) = 40.0\text{ N}\cdot\text{m}$

Figure 10.1a

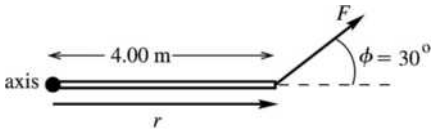
This force tends to produce a counterclockwise rotation about the axis; by the right-hand rule the vector $\vec{\tau}$ is directed out of the plane of the figure.
(b) SET UP: Consider Figure 10.1b.



EXECUTE: $\tau = Fl$
$l = r\sin\phi = (4.00\text{ m})\sin 120°$
$l = 3.464\text{ m}$
$\tau = (10.0\text{ N})(3.464\text{ m}) = 34.6\text{ N}\cdot\text{m}$

Figure 10.1b

This force tends to produce a counterclockwise rotation about the axis; by the right-hand rule the vector $\vec{\tau}$ is directed out of the plane of the figure.
(c) SET UP: Consider Figure 10.1c.



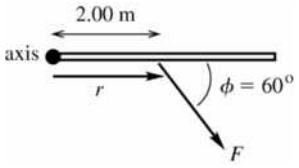
EXECUTE: $\tau = Fl$
$l = r\sin\phi = (4.00\text{ m})\sin 30°$
$l = 2.00\text{ m}$
$\tau = (10.0\text{ N})(2.00\text{ m}) = 20.0\text{ N}\cdot\text{m}$

Figure 10.1c

This force tends to produce a counterclockwise rotation about the axis; by the right-hand rule the vector $\vec{\tau}$ is directed out of the plane of the figure.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(d) SET UP: Consider Figure 10.1d.

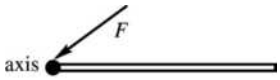


EXECUTE: $\tau = Fl$
$l = r\sin\phi = (2.00\text{ m})\sin 60^\circ = 1.732\text{ m}$
$\tau = (10.0\text{ N})(1.732\text{ m}) = 17.3\text{ N}\cdot\text{m}$

Figure 10.1d

This force tends to produce a clockwise rotation about the axis; by the right-hand rule the vector $\vec{\tau}$ is directed into the plane of the figure.

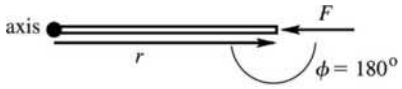
(e) SET UP: Consider Figure 10.1e.



EXECUTE: $\tau = Fl$
$r = 0$ so $l = 0$ and $\tau = 0$

Figure 10.1e

(f) SET UP: Consider Figure 10.1f.



EXECUTE: $\tau = Fl$
$l = r\sin\phi$, $\phi = 180^\circ$,
so $l = 0$ and $\tau = 0$

Figure 10.1f

EVALUATE: The torque is zero in parts (e) and (f) because the moment arm is zero; the line of action of the force passes through the axis.

10.2. **IDENTIFY:** $\tau = Fl$ with $l = r\sin\phi$. Add the two torques to calculate the net torque.

SET UP: Let counterclockwise torques be positive.

EXECUTE: $\tau_1 = -F_1 l_1 = -(8.00\text{ N})(5.00\text{ m}) = -40.0\text{ N}\cdot\text{m}$.

$\tau_2 = +F_2 l_2 = (12.0\text{ N})(2.00\text{ m})\sin 30.0^\circ = +12.0\text{ N}\cdot\text{m}$. $\sum\tau = \tau_1 + \tau_2 = -28.0\text{ N}\cdot\text{m}$. The net torque is $28.0\text{ N}\cdot\text{m}$, clockwise.

EVALUATE: Even though $F_1 < F_2$, the magnitude of τ_1 is greater than the magnitude of τ_2, because F_1 has a larger moment arm.

10.3. **IDENTIFY** and **SET UP:** Use Eq. (10.2) to calculate the magnitude of each torque and use the right-hand rule (Figure 10.4 in the textbook) to determine the direction. Consider Figure 10.3.

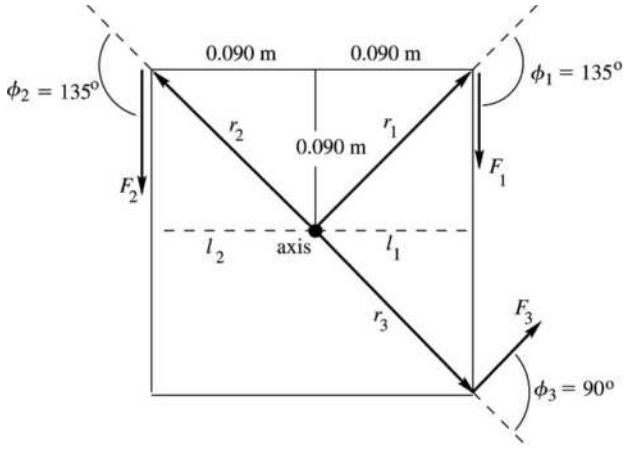


Figure 10.3

Let counterclockwise be the positive sense of rotation.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: $r_1 = r_2 = r_3 = \sqrt{(0.090\text{ m})^2 + (0.090\text{ m})^2} = 0.1273\text{ m}$

$\tau_1 = -F_1 l_1$

$l_1 = r_1 \sin\phi_1 = (0.1273\text{ m})\sin 135° = 0.0900\text{ m}$

$\tau_1 = -(18.0\text{ N})(0.0900\text{ m}) = -1.62\text{ N}\cdot\text{m}$

$\vec{\tau}_1$ is directed into paper

$\tau_2 = +F_2 l_2$

$l_2 = r_2 \sin\phi_2 = (0.1273)\sin 135° = 0.0900\text{ m}$

$\tau_2 = +(26.0\text{ N})(0.0900\text{ m}) = +2.34\text{ N}\cdot\text{m}$

$\vec{\tau}_2$ is directed out of paper

$\tau_3 = +F_3 l_3$

$l_3 = r_3 \sin\phi_3 = (0.1273\text{ m})\sin 90° = 0.1273\text{ m}$

$\tau_3 = +(14.0\text{ N})(0.1273\text{ m}) = +1.78\text{ N}\cdot\text{m}$

$\vec{\tau}_3$ is directed out of paper

$\sum\tau = \tau_1 + \tau_2 + \tau_3 = -1.62\text{ N}\cdot\text{m} + 2.34\text{ N}\cdot\text{m} + 1.78\text{ N}\cdot\text{m} = 2.50\text{ N}\cdot\text{m}$

EVALUATE: The net torque is positive, which means it tends to produce a counterclockwise rotation; the vector torque is directed out of the plane of the paper. In summing the torques it is important to include $+$ or $-$ signs to show direction.

10.4. **IDENTIFY:** Use $\tau = Fl = rF\sin\phi$ to calculate the magnitude of each torque and use the right-hand rule to determine the direction of each torque. Add the torques to find the net torque.

SET UP: Let counterclockwise torques be positive. For the 11.9 N force (F_1), $r = 0$. For the 14.6 N force (F_2), $r = 0.350$ m and $\phi = 40.0°$. For the 8.50 N force (F_3), $r = 0.350$ m and $\phi = 90.0°$.

EXECUTE: $\tau_1 = 0$. $\tau_2 = -(14.6\text{ N})(0.350\text{ m})\sin 40.0° = -3.285\text{ N}\cdot\text{m}$.

$\tau_3 = +(8.50\text{ N})(0.350\text{ m})\sin 90.0° = +2.975\text{ N}\cdot\text{m}$. $\sum\tau = -3.285\text{ N}\cdot\text{m} + 2.975\text{ N}\cdot\text{m} = -0.31\text{ N}\cdot\text{m}$. The net torque is $0.31\text{ N}\cdot\text{m}$ and is clockwise.

EVALUATE: If we treat the torques as vectors, $\vec{\boldsymbol{\tau}}_2$ is into the page and $\vec{\boldsymbol{\tau}}_3$ is out of the page.

10.5. **IDENTIFY** and **SET UP:** Calculate the torque using Eq. (10.3) and also determine the direction of the torque using the right-hand rule.

(a) $\vec{\boldsymbol{r}} = (-0.450\text{ m})\hat{\boldsymbol{i}} + (0.150\text{ m})\hat{\boldsymbol{j}}$; $\vec{\boldsymbol{F}} = (-5.00\text{ N})\hat{\boldsymbol{i}} + (4.00\text{ N})\hat{\boldsymbol{j}}$. The sketch is given in Figure 10.5.

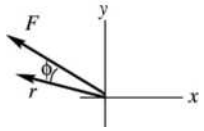

Figure 10.5

EXECUTE: **(b)** When the fingers of your right hand curl from the direction of $\vec{\boldsymbol{r}}$ into the direction of $\vec{\boldsymbol{F}}$ (through the smaller of the two angles, angle ϕ) your thumb points into the page (the direction of $\vec{\boldsymbol{\tau}}$, the $-z$-direction).

(c) $\vec{\boldsymbol{\tau}} = \vec{\boldsymbol{r}} \times \vec{\boldsymbol{F}} = [(-0.450\text{ m})\hat{\boldsymbol{i}} + (0.150\text{ m})\hat{\boldsymbol{j}}] \times [(-5.00\text{ N})\hat{\boldsymbol{i}} + (4.00\text{ N})\hat{\boldsymbol{j}}]$

$\vec{\boldsymbol{\tau}} = +(2.25\text{ N}\cdot\text{m})\hat{\boldsymbol{i}}\times\hat{\boldsymbol{i}} - (1.80\text{ N}\cdot\text{m})\hat{\boldsymbol{i}}\times\hat{\boldsymbol{j}} - (0.750\text{ N}\cdot\text{m})\hat{\boldsymbol{j}}\times\hat{\boldsymbol{i}} + (0.600\text{ N}\cdot\text{m})\hat{\boldsymbol{j}}\times\hat{\boldsymbol{j}}$

$\hat{\boldsymbol{i}}\times\hat{\boldsymbol{i}} = \hat{\boldsymbol{j}}\times\hat{\boldsymbol{j}} = 0$

$\hat{\boldsymbol{i}}\times\hat{\boldsymbol{j}} = \hat{\boldsymbol{k}}$, $\hat{\boldsymbol{j}}\times\hat{\boldsymbol{i}} = -\hat{\boldsymbol{k}}$

Thus $\vec{\boldsymbol{\tau}} = -(1.80\text{ N}\cdot\text{m})\hat{\boldsymbol{k}} - (0.750\text{ N}\cdot\text{m})(-\hat{\boldsymbol{k}}) = (-1.05\text{ N}\cdot\text{m})\hat{\boldsymbol{k}}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: The calculation gives that $\vec{\tau}$ is in the $-z$-direction. This agrees with what we got from the right-hand rule.

10.6. **IDENTIFY:** Knowing the force on a bar and the point where it acts, we want to find the position vector for the point where the force acts and the torque the force exerts on the bar.

SET UP: The position vector is $\vec{r} = x\hat{i} + y\hat{j}$ and the torque is $\vec{\tau} = \vec{r} \times \vec{F}$.

EXECUTE: **(a)** Using $x = 3.00$ m and $y = 4.00$ m, we have $\vec{r} = (3.00)\hat{i} + (4.00)\hat{j}$.

(b) $\vec{\tau} = \vec{r} \times \vec{F} = [(3.00 \text{ m})\hat{i} + (4.00 \text{ m})\hat{j}] \times [(7.00 \text{ N})\hat{i} + (-3.00 \text{ N})\hat{j}]$.

$\vec{\tau} = (-9.00 \text{ N} \cdot \text{m})\hat{k} + (-28.0 \text{ N} \cdot \text{m})(-\hat{k}) = (-37.0 \text{ N} \cdot \text{m})\hat{k}$. The torque has magnitude $37.0 \text{ N} \cdot \text{m}$ and is in the $-z$-direction.

EVALUATE: Applying the right-hand rule for the vector product to $\vec{r} \times \vec{F}$ shows that the torque must be in the $-z$-direction because it is perpendicular to both $\vec{r}$ and $\vec{F}$, which are both in the x-y plane.

10.7. **IDENTIFY:** The total torque is the sum of the torques due to all the forces.

SET UP: The torque due to a force is the product of the force times its moment arm: $\tau = Fl$. Let counterclockwise torques be positive.

EXECUTE: **(a)** $\tau_A = +(50 \text{ N})(0.20 \text{ m})\sin 60° = +8.7 \text{ N} \cdot \text{m}$, counterclockwise. $\tau_B = 0$.

$\tau_C = -(50 \text{ N})(0.20 \text{ m})\sin 30° = -5.0 \text{ N} \cdot \text{m}$, clockwise. $\tau_D = -(50 \text{ N})(0.20 \text{ m})\sin 90° = -10.0 \text{ N} \cdot \text{m}$, clockwise.

(b) $\sum \tau = \tau_A + \tau_B + \tau_C + \tau_D = -6.3 \text{ N} \cdot \text{m}$, clockwise.

EVALUATE: In the above solution, we used the force component perpendicular to the 20-cm line. We could also have constructed the component of the 20-cm line perpendicular to each force, but that would have been a bit more intricate.

10.8. **IDENTIFY:** Use $\tau = Fl = rF\sin\phi$ for the magnitude of the torque and the right-hand rule for the direction.

SET UP: In part (a), $r = 0.250$ m and $\phi = 37°$.

EXECUTE: **(a)** $\tau = (17.0 \text{ N})(0.250 \text{ m})\sin 37° = 2.56 \text{ N} \cdot \text{m}$. The torque is counterclockwise.

(b) The torque is maximum when $\phi = 90°$ and the force is perpendicular to the wrench. This maximum torque is $(17.0 \text{ N})(0.250 \text{ m}) = 4.25 \text{ N} \cdot \text{m}$.

EVALUATE: If the force is directed along the handle then the torque is zero. The torque increases as the angle between the force and the handle increases.

10.9. **IDENTIFY:** Apply $\sum \tau_z = I\alpha_z$.

SET UP: $\omega_{0z} = 0$. $\omega_z = (400 \text{ rev/min})\left(\dfrac{2\pi \text{ rad/rev}}{60 \text{ s/min}}\right) = 41.9 \text{ rad/s}$

EXECUTE: $\tau_z = I\alpha_z = I\dfrac{\omega_z - \omega_{0z}}{t} = (2.50 \text{ kg} \cdot \text{m}^2)\dfrac{41.9 \text{ rad/s}}{8.00 \text{ s}} = 13.1 \text{ N} \cdot \text{m}$.

EVALUATE: In $\tau_z = I\alpha_z$, α_z must be in rad/s^2.

10.10. **IDENTIFY:** The constant force produces a torque which gives a constant angular acceleration to the disk and a linear acceleration to points on the disk.

SET UP: $\sum \tau_z = I\alpha_z$ applies to the disk, $\omega_z^2 = \omega_{0z}^2 + 2\alpha_z(\theta - \theta_0)$ because the angular acceleration is constant. The acceleration components of the rim are $a_{\text{tan}} = r\alpha$ and $a_{\text{rad}} = r\omega^2$, and the magnitude of the acceleration is $a = \sqrt{a_{\text{tan}}^2 + a_{\text{rad}}^2}$.

EXECUTE: **(a)** $\sum \tau_z = I\alpha_z$ gives $Fr = I\alpha_z$. For a uniform disk,

$I = \dfrac{1}{2}MR^2 = \dfrac{1}{2}(40.0 \text{ kg})(0.200 \text{ m})^2 = 0.800 \text{ kg} \cdot \text{m}^2$. $\alpha_z = \dfrac{Fr}{I} = \dfrac{(30.0 \text{ N})(0.200 \text{ m})}{0.800 \text{ kg} \cdot \text{m}^2} = 7.50 \text{ rad/s}^2$.

$\theta - \theta_0 = 0.200 \text{ rev} = 1.257 \text{ rad}$. $\omega_{0z} = 0$, so $\omega_z^2 = \omega_{0z}^2 + 2\alpha_z(\theta - \theta_0)$ gives

$\omega_z = \sqrt{2(7.50 \text{ rad/s}^2)(1.257 \text{ rad})} = 4.342 \text{ rad/s}$. $v = r\omega = (0.200 \text{ m})(4.342 \text{ rad/s}) = 0.868 \text{ m/s}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) $a_{\tan} = r\alpha = (0.200 \text{ m})(7.50 \text{ rad/s}^2) = 1.50 \text{ m/s}^2$. $a_{\text{rad}} = r\omega^2 = (0.200 \text{ m})(4.342 \text{ rad/s})^2 = 3.771 \text{ m/s}^2$. $a = \sqrt{a_{\tan}^2 + a_{\text{rad}}^2} = 4.06 \text{ m/s}^2$.

EVALUATE: The net acceleration is neither toward the center nor tangent to the disk.

10.11. **IDENTIFY:** Use $\sum \tau_z = I\alpha_z$ to calculate α. Use a constant angular acceleration kinematic equation to relate α_z, ω_z and t.

SET UP: For a solid uniform sphere and an axis through its center, $I = \frac{2}{5}MR^2$. Let the direction the sphere is spinning be the positive sense of rotation. The moment arm for the friction force is $l = 0.0150$ m and the torque due to this force is negative.

EXECUTE: **(a)** $\alpha_z = \dfrac{\tau_z}{I} = \dfrac{-(0.0200 \text{ N})(0.0150 \text{ m})}{\frac{2}{5}(0.225 \text{ kg})(0.0150 \text{ m})^2} = -14.8 \text{ rad/s}^2$

(b) $\omega_z - \omega_{0z} = -22.5$ rad/s. $\omega_z = \omega_{0z} + \alpha_z t$ gives $t = \dfrac{\omega_z - \omega_{0z}}{\alpha_z} = \dfrac{-22.5 \text{ rad/s}}{-14.8 \text{ rad/s}^2} = 1.52$ s.

EVALUATE: The fact that α_z is negative means its direction is opposite to the direction of spin. The negative α_z causes ω_z to decrease.

10.12. **IDENTIFY:** Apply $\sum \tau_z = I\alpha_z$ to the wheel. The acceleration a of a point on the cord and the angular acceleration α of the wheel are related by $a = R\alpha$.

SET UP: Let the direction of rotation of the wheel be positive. The wheel has the shape of a disk and $I = \frac{1}{2}MR^2$. The free-body diagram for the wheel is sketched in Figure 10.12a for a horizontal pull and in Figure 10.12b for a vertical pull. P is the pull on the cord and F is the force exerted on the wheel by the axle.

EXECUTE: **(a)** $\alpha_z = \dfrac{\tau_z}{I} = \dfrac{(40.0 \text{ N})(0.250 \text{ m})}{\frac{1}{2}(9.20 \text{ kg})(0.250 \text{ m})^2} = 34.8 \text{ rad/s}^2$.

$a = R\alpha = (0.250 \text{ m})(34.8 \text{ rad/s}^2) = 8.70 \text{ m/s}^2$.

(b) $F_x = -P$, $F_y = Mg$. $F = \sqrt{P^2 + (Mg)^2} = \sqrt{(40.0 \text{ N})^2 + ([9.20 \text{ kg}][9.80 \text{ m/s}^2])^2} = 98.6$ N.

$\tan\phi = \dfrac{|F_y|}{|F_x|} = \dfrac{Mg}{P} = \dfrac{(9.20 \text{ kg})(9.80 \text{ m/s}^2)}{40.0 \text{ N}}$ and $\phi = 66.1°$. The force exerted by the axle has magnitude 98.6 N and is directed at $66.1°$ above the horizontal, away from the direction of the pull on the cord.

(c) The pull exerts the same torque as in part (a), so the answers to part (a) don't change. In part (b), $F + P = Mg$ and $F = Mg - P = (9.20 \text{ kg})(9.80 \text{ m/s}^2) - 40.0 \text{ N} = 50.2$ N. The force exerted by the axle has magnitude 50.2 N and is upward.

EVALUATE: The weight of the wheel and the force exerted by the axle produce no torque because they act at the axle.

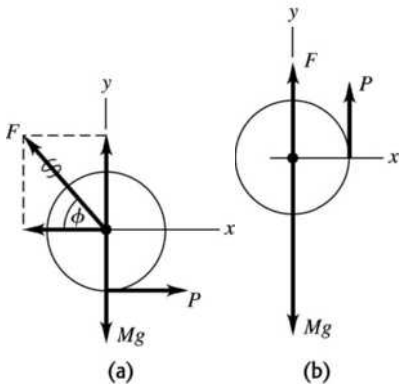

Figure 10.12

10.13. **IDENTIFY:** Apply $\sum \vec{F} = m\vec{a}$ to each book and apply $\sum \tau_z = I\alpha_z$ to the pulley. Use a constant acceleration equation to find the common acceleration of the books.

SET UP: $m_1 = 2.00$ kg, $m_2 = 3.00$ kg. Let T_1 be the tension in the part of the cord attached to m_1 and T_2 be the tension in the part of the cord attached to m_2. Let the $+x$-direction be in the direction of the acceleration of each book. $a = R\alpha$.

EXECUTE: **(a)** $x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2$ gives $a_x = \dfrac{2(x - x_0)}{t^2} = \dfrac{2(1.20 \text{ m})}{(0.800 \text{ s})^2} = 3.75 \text{ m/s}^2$. $a_1 = 3.75 \text{ m/s}^2$ so $T_1 = m_1 a_1 = 7.50$ N and $T_2 = m_2(g - a_1) = 18.2$ N.

(b) The torque on the pulley is $(T_2 - T_1)R = 0.803 \text{ N} \cdot \text{m}$, and the angular acceleration is $\alpha = a_1/R = 50 \text{ rad/s}^2$, so $I = \tau/\alpha = 0.016 \text{ kg} \cdot \text{m}^2$.

EVALUATE: The tensions in the two parts of the cord must be different, so there will be a net torque on the pulley.

10.14. **IDENTIFY:** Apply $\sum \vec{F} = m\vec{a}$ to the stone and $\sum \tau_z = I\alpha_z$ to the pulley. Use a constant acceleration equation to find a for the stone.

SET UP: For the motion of the stone take $+y$ to be downward. The pulley has $I = \frac{1}{2}MR^2$. $a = R\alpha$.

EXECUTE: **(a)** $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$ gives $12.6 \text{ m} = \frac{1}{2}a_y(3.00 \text{ s})^2$ and $a_y = 2.80 \text{ m/s}^2$.

Then $\sum F_y = ma_y$ applied to the stone gives $mg - T = ma$.

$\sum \tau_z = I\alpha_z$ applied to the pulley gives $TR = \frac{1}{2}MR^2\alpha = \frac{1}{2}MR^2(a/R)$. $T = \frac{1}{2}Ma$.

Combining these two equations to eliminate T gives

$$m = \frac{M}{2}\left(\frac{a}{g - a}\right) = \left(\frac{10.0 \text{ kg}}{2}\right)\left(\frac{2.80 \text{ m/s}^2}{9.80 \text{ m/s}^2 - 2.80 \text{ m/s}^2}\right) = 2.00 \text{ kg}.$$

(b) $T = \dfrac{1}{2}Ma = \dfrac{1}{2}(10.0 \text{ kg})(2.80 \text{ m/s}^2) = 14.0$ N

EVALUATE: The tension in the wire is less than the weight $mg = 19.6$ N of the stone, because the stone has a downward acceleration.

10.15. **IDENTIFY:** The constant force produces a torque which gives a constant angular acceleration to the wheel.

SET UP: $\omega_z = \omega_{0z} + \alpha_z t$ because the angular acceleration is constant, and $\sum \tau_z = I\alpha_z$ applies to the wheel.

EXECUTE: $\omega_{0z} = 0$ and $\omega_z = 12.0 \text{ rev/s} = 75.40 \text{ rad/s}$. $\omega_z = \omega_{0z} + \alpha_z t$, so

$\alpha_z = \dfrac{\omega_z - \omega_{0z}}{t} = \dfrac{75.40 \text{ rad/s}}{2.00 \text{ s}} = 37.70 \text{ rad/s}^2$. $\sum \tau_z = I\alpha_z$ gives

$I = \dfrac{Fr}{\alpha_z} = \dfrac{(80.0 \text{ N})(0.120 \text{ m})}{37.70 \text{ rad/s}^2} = 0.255 \text{ kg} \cdot \text{m}^2$.

EVALUATE: The units of the answer are the proper ones for moment of inertia.

10.16. **IDENTIFY:** Apply $\sum F_y = ma_y$ to the bucket, with $+y$ downward. Apply $\sum \tau_z = I\alpha_z$ to the cylinder, with the direction the cylinder rotates positive.

SET UP: The free-body diagram for the bucket is given in Figure 10.16a and the free-body diagram for the cylinder is given in Figure 10.16b. $I = \frac{1}{2}MR^2$. $a(\text{bucket}) = R\alpha(\text{cylinder})$

EXECUTE: **(a)** For the bucket, $mg - T = ma$. For the cylinder, $\sum \tau_z = I\alpha_z$ gives $TR = \frac{1}{2}MR^2\alpha$. $\alpha = a/R$ then gives $T = \frac{1}{2}Ma$. Combining these two equations gives $mg - \frac{1}{2}Ma = ma$ and

$$a = \frac{mg}{m + M/2} = \left(\frac{15.0 \text{ kg}}{15.0 \text{ kg} + 6.0 \text{ kg}}\right)(9.80 \text{ m/s}^2) = 7.00 \text{ m/s}^2.$$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$T = m(g - a) = (15.0 \text{ kg})(9.80 \text{ m/s}^2 - 7.00 \text{ m/s}^2) = 42.0 \text{ N}.$

(b) $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ gives $v_y = \sqrt{2(7.00 \text{ m/s}^2)(10.0 \text{ m})} = 11.8 \text{ m/s}.$

(c) $a_y = 7.00 \text{ m/s}^2$, $v_{0y} = 0$, $y - y_0 = 10.0 \text{ m}$. $y - y_0 = v_{0y}t + \frac{1}{2}\alpha_y t^2$ gives

$$t = \sqrt{\frac{2(y - y_0)}{a_y}} = \sqrt{\frac{2(10.0 \text{ m})}{7.00 \text{ m/s}^2}} = 1.69 \text{ s}$$

(d) $\sum F_y = ma_y$ applied to the cylinder gives $n - T - Mg = 0$ and

$n = T + mg = 42.0 \text{ N} + (12.0 \text{ kg})(9.80 \text{ m/s}^2) = 160 \text{ N}.$

EVALUATE: The tension in the rope is less than the weight of the bucket, because the bucket has a downward acceleration. If the rope were cut, so the bucket would be in free fall, the bucket would strike the water in $t = \sqrt{\frac{2(10.0 \text{ m})}{9.80 \text{ m/s}^2}} = 1.43 \text{ s}$ and would have a final speed of 14.0 m/s. The presence of the cylinder slows the fall of the bucket.

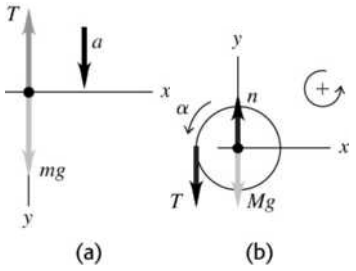

Figure 10.16

10.17. **IDENTIFY:** Apply $\sum \vec{F} = m\vec{a}$ to each box and $\sum \tau_z = I\alpha_z$ to the pulley. The magnitude a of the acceleration of each box is related to the magnitude of the angular acceleration α of the pulley by $a = R\alpha$.

SET UP: The free-body diagrams for each object are shown in Figure 10.17a–c. For the pulley, $R = 0.250 \text{ m}$ and $I = \frac{1}{2}MR^2$. T_1 and T_2 are the tensions in the wire on either side of the pulley. $m_1 = 12.0 \text{ kg}$, $m_2 = 5.00 \text{ kg}$ and $M = 2.00 \text{ kg}$. $\vec{F}$ is the force that the axle exerts on the pulley. For the pulley, let clockwise rotation be positive.

EXECUTE: **(a)** $\sum F_x = ma_x$ for the 12.0 kg box gives $T_1 = m_1 a$. $\sum F_y = ma_y$ for the 5.00 kg weight gives $m_2 g - T_2 = m_2 a$. $\sum \tau_z = I\alpha_z$ for the pulley gives $(T_2 - T_1)R = \left(\frac{1}{2}MR^2\right)\alpha$. $a = R\alpha$ and $T_2 - T_1 = \frac{1}{2}Ma$.

Adding these three equations gives $m_2 g = (m_1 + m_2 + \frac{1}{2}M)a$ and

$a = \left(\frac{m_2}{m_1 + m_2 + \frac{1}{2}M}\right)g = \left(\frac{5.00 \text{ kg}}{12.0 \text{ kg} + 5.00 \text{ kg} + 1.00 \text{ kg}}\right)(9.80 \text{ m/s}^2) = 2.72 \text{ m/s}^2$. Then

$T_1 = m_1 a = (12.0 \text{ kg})(2.72 \text{ m/s}^2) = 32.6 \text{ N}$. $m_2 g - T_2 = m_2 a$ gives

$T_2 = m_2(g - a) = (5.00 \text{ kg})(9.80 \text{ m/s}^2 - 2.72 \text{ m/s}^2) = 35.4 \text{ N}$. The tension to the left of the pulley is 32.6 N and below the pulley it is 35.4 N.

(b) $a = 2.72 \text{ m/s}^2$

(c) For the pulley, $\sum F_x = ma_x$ gives $F_x = T_1 = 32.6 \text{ N}$ and $\sum F_y = ma_y$ gives

$F_y = Mg + T_2 = (2.00 \text{ kg})(9.80 \text{ m/s}^2) + 35.4 \text{ N} = 55.0 \text{ N}.$

EVALUATE: The equation $m_2 g = (m_1 + m_2 + \frac{1}{2}M)a$ says that the external force $m_2 g$ must accelerate all three objects.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

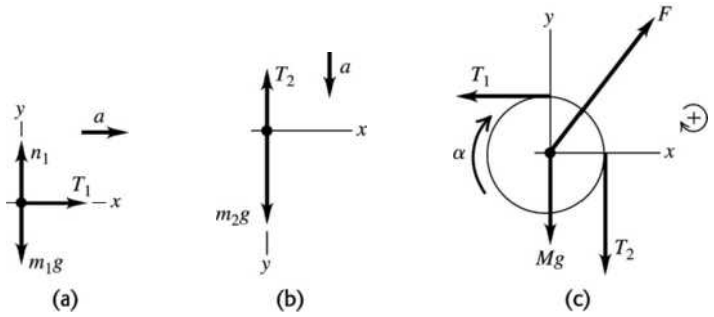

Figure 10.17

10.18. **IDENTIFY:** The tumbler has kinetic energy due to the linear motion of his center of mass plus kinetic energy due to his rotational motion about his center of mass.

SET UP: $v_{cm} = R\omega$. $\omega = 0.50$ rev/s $= 3.14$ rad/s. $I = \frac{1}{2}MR^2$ with $R = 0.50$ m. $K_{cm} = \frac{1}{2}Mv_{cm}^2$ and $K_{rot} = \frac{1}{2}I_{cm}\omega^2$.

EXECUTE: **(a)** $K_{tot} = K_{cm} + K_{rot}$ with $K_{cm} = \frac{1}{2}Mv_{cm}^2$ and $K_{rot} = \frac{1}{2}I_{cm}\omega^2$.

$y_{cm} = R\omega = (0.50 \text{ m})(3.14 \text{ rad/s}) = 1.57$ m/s. $K_{cm} = \frac{1}{2}(75 \text{ kg})(1.57 \text{ m/s})^2 = 92.4$ J.

$K_{rot} = \frac{1}{2}I_{cm}\omega^2 = \frac{1}{4}MR^2\omega^2 = \frac{1}{4}Mv_{cm}^2 = 46.2$ J. $K_{tot} = 92.4 \text{ J} + 46.2 \text{ J} = 140$ J.

(b) $\dfrac{K_{rot}}{K_{tot}} = \dfrac{46.2 \text{ J}}{140 \text{ J}} = 33\%$.

EVALUATE: The kinetic energy due to the gymnast's rolling motion makes a substantial contribution (33%) to his total kinetic energy.

10.19. **IDENTIFY:** Since there is rolling without slipping, $v_{cm} = R\omega$. The kinetic energy is given by Eq. (10.8). The velocities of points on the rim of the hoop are as described in Figure 10.13 in Chapter 10.

SET UP: $\omega = 3.00$ rad/s and $R = 0.600$ m. For a hoop rotating about an axis at its center, $I = MR^2$.

EXECUTE: **(a)** $v_{cm} = R\omega = (0.600 \text{ m})(3.00 \text{ rad/s}) = 1.80$ m/s.

(b) $K = \frac{1}{2}Mv_{cm}^2 + \frac{1}{2}I\omega^2 = \frac{1}{2}Mv_{cm}^2 + \frac{1}{2}(MR^2)(v_{cm}/R^2) = Mv_{cm}^2 = (2.20 \text{ kg})(1.80 \text{ m/s})^2 = 7.13$ J

(c) (i) $v = 2v_{cm} = 3.60$ m/s. $\vec{v}$ is to the right. (ii) $v = 0$

(iii) $v = \sqrt{v_{cm}^2 + v_{tan}^2} = \sqrt{v_{cm}^2 + (R\omega)^2} = \sqrt{2}v_{cm} = 2.55$ m/s. $\vec{v}$ at this point is at $45°$ below the horizontal.

(d) To someone moving to the right at $v = v_{cm}$, the hoop appears to rotate about a stationary axis at its center. (i) $v = R\omega = 1.80$ m/s, to the right. (ii) $v = 1.80$ m/s, to the left. (iii) $v = 1.80$ m/s, downward.

EVALUATE: For the special case of a hoop, the total kinetic energy is equally divided between the motion of the center of mass and the rotation about the axis through the center of mass. In the rest frame of the ground, different points on the hoop have different speed.

10.20. **IDENTIFY:** Only gravity does work, so $W_{other} = 0$ and conservation of energy gives $K_1 + U_1 = K_2 + U_2$. $K_2 = \frac{1}{2}Mv_{cm}^2 + \frac{1}{2}I_{cm}\omega^2$.

SET UP: Let $y_2 = 0$, so $U_2 = 0$ and $y_1 = 0.750$ m. The hoop is released from rest so $K_1 = 0$. $v_{cm} = R\omega$. For a hoop with an axis at its center, $I_{cm} = MR^2$.

EXECUTE: **(a)** Conservation of energy gives $U_1 = K_2$. $K_2 = \frac{1}{2}MR^2\omega^2 + \frac{1}{2}(MR^2)\omega^2 = MR^2\omega^2$, so

$MR^2\omega^2 = Mgy_1$. $\omega = \dfrac{\sqrt{gy_1}}{R} = \dfrac{\sqrt{(9.80 \text{ m/s}^2)(0.750 \text{ m})}}{0.0800 \text{ m}} = 33.9$ rad/s.

(b) $v = R\omega = (0.0800 \text{ m})(33.9 \text{ rad/s}) = 2.71$ m/s

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: An object released from rest and falling in free fall for 0.750 m attains a speed of $\sqrt{2g(0.750\text{ m})} = 3.83$ m/s. The final speed of the hoop is less than this because some of its energy is in kinetic energy of rotation. Or, equivalently, the upward tension causes the magnitude of the net force of the hoop to be less than its weight.

10.21. **IDENTIFY:** Apply Eq. (10.8).

SET UP: For an object that is rolling without slipping, $v_{cm} = R\omega$.

EXECUTE: The fraction of the total kinetic energy that is rotational is

$$\frac{(1/2)I_{cm}\omega^2}{(1/2)Mv_{cm}^2 + (1/2)I_{cm}\omega^2} = \frac{1}{1 + (M/I_{cm})v_{cm}^2/\omega^2} = \frac{1}{1 + (MR^2/I_{cm})}$$

(a) $I_{cm} = (1/2)MR^2$, so the above ratio is 1/3.

(b) $I_{cm} = (2/5)MR^2$ so the above ratio is 2/7.

(c) $I_{cm} = (2/3)MR^2$ so the ratio is 2/5.

(d) $I_{cm} = (5/8)MR^2$ so the ratio is 5/13.

EVALUATE: The moment of inertia of each object takes the form $I = \beta MR^2$. The ratio of rotational kinetic energy to total kinetic energy can be written as $\frac{1}{1+1/\beta} = \frac{\beta}{1+\beta}$. The ratio increases as β increases.

10.22. **IDENTIFY:** Apply $\sum \vec{F} = m\vec{a}$ to the translational motion of the center of mass and $\sum \tau_z = I\alpha_z$ to the rotation about the center of mass.

SET UP: Let $+x$ be down the incline and let the shell be turning in the positive direction. The free-body diagram for the shell is given in Figure 10.22. From Table 9.2, $I_{cm} = \frac{2}{3}mR^2$.

EXECUTE: **(a)** $\sum F_x = ma_x$ gives $mg\sin\beta - f = ma_{cm}$. $\sum \tau_z = I\alpha_z$ gives $fR = \left(\frac{2}{3}mR^2\right)\alpha$. With $\alpha = a_{cm}/R$ this becomes $f = \frac{2}{3}ma_{cm}$. Combining the equations gives $mg\sin\beta - \frac{2}{3}ma_{cm} = ma_{cm}$ and $a_{cm} = \frac{3g\sin\beta}{5} = \frac{3(9.80\text{ m/s}^2)(\sin 38.0°)}{5} = 3.62\text{ m/s}^2$. $f = \frac{2}{3}ma_{cm} = \frac{2}{3}(2.00\text{ kg})(3.62\text{ m/s}^2) = 4.83$ N. The friction is static since there is no slipping at the point of contact. $n = mg\cos\beta = 15.45$ N.

$$\mu_s = \frac{f}{n} = \frac{4.83\text{ N}}{15.45\text{ N}} = 0.313.$$

(b) The acceleration is independent of m and doesn't change. The friction force is proportional to m so will double; $f = 9.66$ N. The normal force will also double, so the minimum μ_s required for no slipping wouldn't change.

EVALUATE: If there is no friction and the object slides without rolling, the acceleration is $g\sin\beta$. Friction and rolling without slipping reduce a to 0.60 times this value.

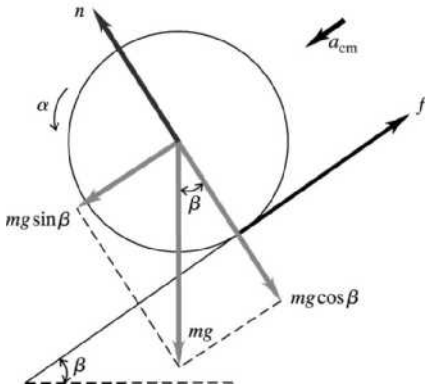

Figure 10.22

10.23. **IDENTIFY:** Apply $\sum \vec{F}_{\text{ext}} = m\vec{a}_{\text{cm}}$ and $\sum \tau_z = I_{\text{cm}}\alpha_z$ to the motion of the ball.

(a) SET UP: The free-body diagram is given in Figure 10.23a.

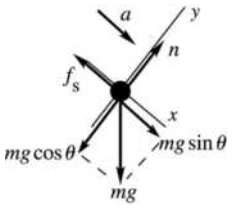

Figure 10.23a

EXECUTE: $\sum F_y = ma_y$

$n = mg\cos\theta$ and $f_s = \mu_s mg\cos\theta$

$\sum F_x = ma_x$

$mg\sin\theta - \mu_s mg\cos\theta = ma$

$g(\sin\theta - \mu_s\cos\theta) = a$ (eq. 1)

SET UP: Consider Figure 10.23b.

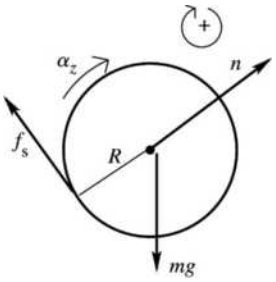

Figure 10.23b

n and *mg* act at the center of the ball and provide no torque.

EXECUTE: $\sum \tau = \tau_f = \mu_s mg\cos\theta R;\ I = \frac{2}{5}mR^2$

$\sum \tau_z = I_{\text{cm}}\alpha_z$ gives $\mu_s\, mg\cos\theta R = \frac{2}{5}mR^2\alpha$

No slipping means $\alpha = a/R,$ so $\mu_s g\cos\theta = \frac{2}{5}a$ (eq.2)

We have two equations in the two unknowns *a* and μ_s. Solving gives $a = \frac{5}{7}g\sin\theta$ and

$\mu_s = \frac{2}{7}\tan\theta = \frac{2}{7}\tan 65.0° = 0.613.$

(b) Repeat the calculation of part (a), but now $I = \frac{2}{3}mR^2.$ $a = \frac{3}{5}g\sin\theta$ and

$\mu_s = \frac{2}{5}\tan\theta = \frac{2}{5}\tan 65.0° = 0.858$

The value of μ_s calculated in part (a) is not large enough to prevent slipping for the hollow ball.

(c) EVALUATE: There is no slipping at the point of contact. More friction is required for a hollow ball since for a given *m* and *R* it has a larger *I* and more torque is needed to provide the same α. Note that the required μ_s is independent of the mass or radius of the ball and only depends on how that mass is distributed.

10.24. **IDENTIFY:** Apply conservation of energy to the motion of the marble.

SET UP: $K = \frac{1}{2}mv^2 + \frac{1}{2}I\omega^2,$ with $I = \frac{2}{5}MR^2.$ $v_{\text{cm}} = R\omega$ for no slipping.

Let $y = 0$ at the bottom of the bowl. The marble at its initial and final locations is sketched in Figure 10.24.

EXECUTE: **(a)** Motion from the release point to the bottom of the bowl: $mgh = \frac{1}{2}mv^2 + \frac{1}{2}I\omega^2.$

$mgh = \frac{1}{2}mv^2 + \frac{1}{2}\left(\frac{2}{5}mR^2\right)\left(\frac{v}{R}\right)^2$ and $v = \sqrt{\frac{10}{7}gh}.$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

Motion along the smooth side: The rotational kinetic energy does not change, since there is no friction torque on the marble, $\frac{1}{2}mv^2 + K_{\text{rot}} = mgh' + K_{\text{rot}}$. $h' = \frac{v^2}{2g} = \frac{\frac{10}{7}gh}{2g} = \frac{5}{7}h$

(b) $mgh = mgh'$ so $h' = h$.

EVALUATE: **(c)** With friction on both halves, all the initial potential energy gets converted back to potential energy. Without friction on the right half some of the energy is still in rotational kinetic energy when the marble is at its maximum height.

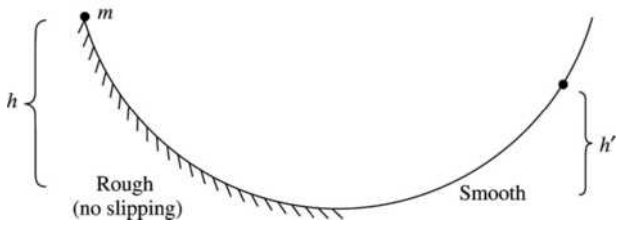

Figure 10.24

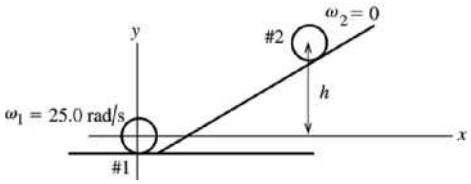
10.25. **IDENTIFY:** Apply conservation of energy to the motion of the wheel.

SET UP: The wheel at points 1 and 2 of its motion is shown in Figure 10.25.



Take $y = 0$ at the center of the wheel when it is at the bottom of the hill.

Figure 10.25

The wheel has both translational and rotational motion so its kinetic energy is $K = \frac{1}{2}I_{\text{cm}}\omega^2 + \frac{1}{2}Mv_{\text{cm}}^2$.

EXECUTE: $K_1 + U_1 + W_{\text{other}} = K_2 + U_2$

$W_{\text{other}} = W_{\text{fric}} = -3500$ J (the friction work is negative)

$K_1 = \frac{1}{2}I\omega_1^2 + \frac{1}{2}Mv_1^2$; $v = R\omega$ and $I = 0.800MR^2$ so

$K_1 = \frac{1}{2}(0.800)MR^2\omega_1^2 + \frac{1}{2}MR^2\omega_1^2 = 0.900MR^2\omega_1^2$

$K_2 = 0$, $U_1 = 0$, $U_2 = Mgh$

Thus $0.900MR^2\omega_1^2 + W_{\text{fric}} = Mgh$

$M = w/g = 392 \text{ N}/(9.80 \text{ m/s}^2) = 40.0 \text{ kg}$

$$h = \frac{0.900MR^2\omega_1^2 + W_{\text{fric}}}{Mg}$$

$$h = \frac{(0.900)(40.0 \text{ kg})(0.600 \text{ m})^2(25.0 \text{ rad/s})^2 - 3500 \text{ J}}{(40.0 \text{ kg})(9.80 \text{ m/s}^2)} = 11.7 \text{ m}$$

EVALUATE: Friction does negative work and reduces h.

10.26. **IDENTIFY:** Apply $\sum\tau_z = I\alpha_z$ and $\sum\vec{F} = m\vec{a}$ to the motion of the bowling ball.

SET UP: $a_{\text{cm}} = R\alpha$. $f_s = \mu_s n$. Let $+x$ be directed down the incline.

EXECUTE: **(a)** The free-body diagram is sketched in Figure 10.26.

The angular speed of the ball must decrease, and so the torque is provided by a friction force that acts up the hill.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) The friction force results in an angular acceleration, given by $I\alpha = fR$. $\sum \vec{F} = m\vec{a}$ applied to the motion of the center of mass gives $mg\sin\beta - f = ma_{\text{cm}}$, and the acceleration and angular acceleration are related by $a_{\text{cm}} = R\alpha$.

Combining, $mg\sin\beta = ma_{\text{cm}}\left(1 + \dfrac{I}{mR^2}\right) = ma_{\text{cm}}(7/5)$. $a_{\text{cm}} = (5/7)g\sin\beta$.

(c) From either of the above relations between f and a_{cm}, $f = \dfrac{2}{5}ma_{\text{cm}} = \dfrac{2}{7}mg\sin\beta \le \mu_{\text{s}}n = \mu_{\text{s}}mg\cos\beta$.

$\mu_{\text{s}} \ge (2/7)\tan\beta$.

EVALUATE: If $\mu_{\text{s}} = 0$, $a_{\text{cm}} = mg\sin\beta$. a_{cm} is less when friction is present. The ball rolls farther uphill when friction is present, because the friction removes the rotational kinetic energy and converts it to gravitational potential energy. In the absence of friction the ball retains the rotational kinetic energy that is has initially.

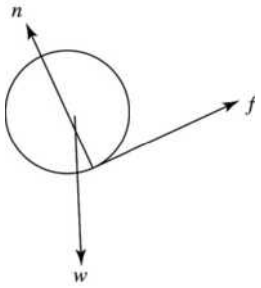


Figure 10.26

10.27. **IDENTIFY:** As the cylinder falls, its potential energy is transformed into both translational and rotational kinetic energy. Its mechanical energy is conserved.

SET UP: The hollow cylinder has $I = \frac{1}{2}m(R_a^2 + R_b^2)$, where $R_a = 0.200$ m and $R_b = 0.350$ m. Use coordinates where $+y$ is upward and $y = 0$ at the initial position of the cylinder. Then $y_1 = 0$ and $y_2 = -d$, where d is the distance it has fallen. $v_{\text{cm}} = R\omega$. $K_{\text{cm}} = \frac{1}{2}Mv_{\text{cm}}^2$ and $K_{\text{rot}} = \frac{1}{2}I_{\text{cm}}\omega^2$.

EXECUTE: **(a)** Conservation of energy gives $K_1 + U_1 = K_2 + U_2$. $K_1 = 0$, $U_1 = 0$. $0 = U_2 + K_2$ and $0 = -mgd + \frac{1}{2}mv_{\text{cm}}^2 + \frac{1}{2}I_{\text{cm}}\omega^2$. $\frac{1}{2}I\omega^2 = \frac{1}{2}\left(\frac{1}{2}m[R_a^2 + R_b^2]\right)(v_{\text{cm}}/R_b)^2 = \frac{1}{4}m[1 + (R_a/R_b)^2]v_{\text{cm}}^2$, so

$\frac{1}{2}\left(1 + \frac{1}{2}[1 + (R_a/R_b)^2]\right)v_{\text{cm}}^2 = gd$ and $d = \dfrac{\left(1 + \frac{1}{2}[1 + (R_a/R_b)^2]\right)v_{\text{cm}}^2}{2g} = \dfrac{(1 + 0.663)(6.66\text{ m/s})^2}{2(9.80\text{ m/s}^2)} = 3.76$ m.

(b) $K_2 = \frac{1}{2}mv_{\text{cm}}^2$ since there is no rotation. So $mgd = \frac{1}{2}mv_{\text{cm}}^2$ which gives

$v_{\text{cm}} = \sqrt{2gd} = \sqrt{2(9.80\text{ m/s}^2)(3.76\text{ m})} = 8.58$ m/s.

(c) In part (a) the cylinder has rotational as well as translational kinetic energy and therefore less translational speed at a given kinetic energy. The kinetic energy comes from a decrease in gravitational potential energy and that is the same, so in (a) the translational speed is less.

EVALUATE: If part (a) were repeated for a solid cylinder, $R_a = 0$ and $d = 3.39$ m. For a thin-walled hollow cylinder, $R_a = R_b$ and $d = 4.52$ cm. Note that all of these answers are independent of the mass m of the cylinder.

10.28. **IDENTIFY:** At the top of the hill the wheel has translational and rotational kinetic energy plus gravitational potential energy. The potential energy is transformed into additional kinetic energy as the wheel rolls down the hill.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

SET UP: The wheel has $I = MR^2$, with $M = 2.25$ kg and $R = 0.425$ m. Rolling without slipping means $v_{cm} = R\omega$ for the wheel. Initially the wheel has $v_{cm,1} = 11.0$ m/s. Use coordinates where $+y$ is upward and $y = 0$ at the bottom of the hill, so $y_1 = 75.0$ m and $y_2 = 0$. The total kinetic energy of the wheel is $K = \frac{1}{2}mv_{cm}^2 + \frac{1}{2}I_{cm}\omega^2$ and its potential energy is $U = mgh$.

EXECUTE: **(a)** Conservation of energy gives $K_1 + U_1 = K_2 + U_2$.

$K = \frac{1}{2}mv_{cm}^2 + \frac{1}{2}I_{cm}\omega^2 = \frac{1}{2}mv_{cm}^2 + \frac{1}{2}(mR^2)\left(\frac{v_{cm}}{R}\right)^2 = mv_{cm}^2$. Therefore $K_1 = mv_{cm,1}^2$ and $K_2 = mv_{cm,2}^2$.

$U_1 = mgy_1$, $U_2 = mgy_2 = 0$, so $mgy_1 + mv_{cm,1}^2 = mv_{cm,2}^2$. Solving for $v_{cm,2}$ gives

$v_{cm,2} = \sqrt{v_{cm,1}^2 + gy_1} = \sqrt{(11.0 \text{ m/s})^2 + (9.80 \text{ m/s}^2)(75.0 \text{ m})} = 29.3$ m/s.

(b) From (b) we have $K_2 = mv_{cm,2}^2 = (2.25 \text{ kg})(29.3 \text{ m/s})^2 = 1.93 \times 10^3$ J.

EVALUATE: Because of the shape of the wheel (thin-walled cylinder), the kinetic energy is shared equally between the translational and rotational forms. This is *not* true for other shapes, such as solid disks or spheres.

10.29. **IDENTIFY:** As the ball rolls up the hill, its kinetic energy (translational and rotational) is transformed into gravitational potential energy. Since there is no slipping, its mechanical energy is conserved.

SET UP: The ball has moment of inertia $I_{cm} = \frac{2}{3}mR^2$. Rolling without slipping means $v_{cm} = R\omega$. Use coordinates where $+y$ is upward and $y = 0$ at the bottom of the hill, so $y_1 = 0$ and $y_2 = h = 5.00$ m. The ball's kinetic energy is $K = \frac{1}{2}mv_{cm}^2 + \frac{1}{2}I_{cm}\omega^2$ and its potential energy is $U = mgh$.

EXECUTE: **(a)** Conservation of energy gives $K_1 + U_1 = K_2 + U_2$. $U_1 = 0$, $K_2 = 0$ (the ball stops).

Therefore $K_1 = U_2$ and $\frac{1}{2}mv_{cm}^2 + \frac{1}{2}I_{cm}\omega^2 = mgh$. $\frac{1}{2}I_{cm}\omega^2 = \frac{1}{2}\left(\frac{2}{3}mR^2\right)\left(\frac{v_{cm}}{R}\right)^2 = \frac{1}{3}mv_{cm}^2$ so

$\frac{5}{6}mv_{cm}^2 = mgh$. Therefore $v_{cm} = \sqrt{\frac{6gh}{5}} = \sqrt{\frac{6(9.80 \text{ m/s}^2)(5.00 \text{ m})}{5}} = 7.67$ m/s and

$\omega = \frac{v_{cm}}{R} = \frac{7.67 \text{ m/s}}{0.113 \text{ m}} = 67.9$ rad/s.

(b) $K_{rot} = \frac{1}{2}I\omega^2 = \frac{1}{3}mv_{cm}^2 = \frac{1}{3}(0.426 \text{ kg})(7.67 \text{ m/s})^2 = 8.35$ J.

EVALUATE: Its translational kinetic energy at the base of the hill is $\frac{1}{2}mv_{cm}^2 = \frac{3}{2}K_{rot} = 12.52$ J. Its total kinetic energy is 20.9 J, which equals its final potential energy:

$mgh = (0.426 \text{ kg})(9.80 \text{ m/s}^2)(5.00 \text{ m}) = 20.9$ J.

10.30. **IDENTIFY:** Apply $P = \tau\omega$ and $W = \tau\Delta\theta$.

SET UP: P must be in watts, $\Delta\theta$ must be in radians, and ω must be in rad/s. 1 rev $= 2\pi$ rad. 1 hp $= 746$ W. π rad/s $= 30$ rev/min.

EXECUTE: **(a)** $\tau = \frac{P}{\omega} = \frac{(175 \text{ hp})(746 \text{ W/hp})}{(2400 \text{ rev/min})\left(\frac{\pi}{30}\frac{\text{rad/s}}{\text{rev/min}}\right)} = 519 \text{ N} \cdot \text{m}$.

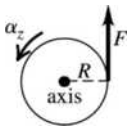
(b) $W = \tau\Delta\theta = (519 \text{ N} \cdot \text{m})(2\pi \text{ rad}) = 3260$ J

EVALUATE: $\omega = 40$ rev/s, so the time for one revolution is 0.025 s. $P = 1.306 \times 10^5$ W, so in one revolution, $W = Pt = 3260$ J, which agrees with our result.

10.31. **(a) IDENTIFY:** Use Eq. (10.7) to find α_z and then use a constant angular acceleration equation to find ω_z.

SET UP: The free-body diagram is given in Figure 10.31.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.



EXECUTE: Apply $\sum\tau_z = I\alpha_z$ to find the angular acceleration:

$FR = I\alpha_z$

$$\alpha_z = \frac{FR}{I} = \frac{(18.0\text{ N})(2.40\text{ m})}{2100\text{ kg}\cdot\text{m}^2} = 0.02057\text{ rad/s}^2$$

Figure 10.31

SET UP: Use the constant α_z kinematic equations to find ω_z.

$\omega_z = ?$; ω_{0z} (initially at rest); $\alpha_z = 0.02057\text{ rad/s}^2$; $t = 15.0\text{ s}$

EXECUTE: $\omega_z = \omega_{0z} + \alpha_z t = 0 + (0.02057\text{ rad/s}^2)(15.0\text{ s}) = 0.309\text{ rad/s}$

(b) IDENTIFY and **SET UP:** Calculate the work from Eq. (10.21), using a constant angular acceleration equation to calculate $\theta - \theta_0$, or use the work-energy theorem. We will do it both ways.

EXECUTE: (1) $W = \tau_z\Delta\theta$ (Eq. (10.21))

$\Delta\theta = \theta - \theta_0 = \omega_{0z}t + \frac{1}{2}\alpha_z t^2 = 0 + \frac{1}{2}(0.02057\text{ rad/s}^2)(15.0\text{ s})^2 = 2.314\text{ rad}$

$\tau_z = FR = (18.0\text{ N})(2.40\text{ m}) = 43.2\text{ N}\cdot\text{m}$

Then $W = \tau_z\Delta\theta = (43.2\text{ N}\cdot\text{m})(2.314\text{ rad}) = 100\text{ J}$.

or

(2) $W_{\text{tot}} = K_2 - K_1$ (the work-energy relation from Chapter 6)

$W_{\text{tot}} = W$, the work done by the child

$K_1 = 0$; $K_2 = \frac{1}{2}I\omega^2 = \frac{1}{2}(2100\text{ kg}\cdot\text{m}^2)(0.309\text{ rad/s})^2 = 100\text{ J}$

Thus $W = 100\text{ J}$, the same as before.

EVALUATE: Either method yields the same result for W.

(c) IDENTIFY and **SET UP:** Use Eq. (6.15) to calculate P_{av}.

EXECUTE: $P_{\text{av}} = \dfrac{\Delta W}{\Delta t} = \dfrac{100\text{ J}}{15.0\text{ s}} = 6.67\text{ W}$

EVALUATE: Work is in joules, power is in watts.

10.32. **IDENTIFY:** The power output of the motor is related to the torque it produces and to its angular velocity by $P = \tau_z\omega_z$, where ω_z must be in rad/s.

SET UP: The work output of the motor in 60.0 s is $\frac{2}{3}(9.00\text{ kJ}) = 6.00\text{ kJ}$, so $P = \dfrac{6.00\text{ kJ}}{60.0\text{ s}} = 100\text{ W}$.

$\omega_z = 2500\text{ rev/min} = 262\text{ rad/s}$.

EXECUTE: $\tau_z = \dfrac{P}{\omega_z} = \dfrac{100\text{ W}}{262\text{ rad/s}} = 0.382\text{ N}\cdot\text{m}$

EVALUATE: For a constant power output, the torque developed decreases when the rotation speed of the motor increases.

10.33. **IDENTIFY:** Apply $\sum\tau_z = I\alpha_z$ and constant angular acceleration equations to the motion of the wheel.

SET UP: 1 rev $= 2\pi$ rad. π rad/s $= 30$ rev/min.

EXECUTE: **(a)** $\tau_z = I\alpha_z = I\dfrac{\omega_z - \omega_{0z}}{t}$.

$$\tau_z = \frac{\left((1/2)(1.50\text{ kg})(0.100\text{ m})^2\right)(1200\text{ rev/min})\left(\dfrac{\pi}{30}\dfrac{\text{rad/s}}{\text{rev/min}}\right)}{2.5\text{ s}} = 0.377\text{ N}\cdot\text{m}$$

(b) $\omega_{\text{av}}\Delta t = \dfrac{(600\text{ rev/min})(2.5\text{ s})}{60\text{ s/min}} = 25.0\text{ rev} = 157\text{ rad}.$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(c) $W = \tau\Delta\theta = (0.377\ \text{N}\cdot\text{m})(157\ \text{rad}) = 59.2\ \text{J}$.

(d) $K = \frac{1}{2}I\omega^2 = \frac{1}{2}\left((1/2)(1.5\ \text{kg})(0.100\ \text{m})^2\right)\left((1200\ \text{rev/min})\left(\frac{\pi}{30}\frac{\text{rad/s}}{\text{rev/min}}\right)\right)^2 = 59.2\ \text{J}$.

the same as in part (c).

EVALUATE: The agreement between the results of parts (c) and (d) illustrates the work-energy theorem.

10.34. **IDENTIFY:** Apply $\Sigma\tau_z = I\alpha_z$ to the motion of the propeller and then use constant acceleration equations to analyze the motion. $W = \tau\Delta\theta$.

SET UP: $I = \frac{1}{12}mL^2 = \frac{1}{12}(117\ \text{kg})(2.08\ \text{m})^2 = 42.2\ \text{kg}\cdot\text{m}^2$.

EXECUTE: **(a)** $\alpha = \frac{\tau}{I} = \frac{1950\ \text{N}\cdot\text{m}}{42.2\ \text{kg}\cdot\text{m}^2} = 46.2\ \text{rad/s}^2$.

(b) $\omega_z^2 = \omega_{0z}^2 + 2\alpha_z(\theta - \theta_0)$ gives $\omega = \sqrt{2\alpha\theta} = \sqrt{2(46.2\ \text{rad/s}^2)(5.0\ \text{rev})(2\pi\ \text{rad/rev})} = 53.9\ \text{rad/s}$.

(c) $W = \tau\theta = (1950\ \text{N}\cdot\text{m})(5.00\ \text{rev})(2\pi\ \text{rad/rev}) = 6.13\times10^4\ \text{J}$.

(d) $t = \frac{\omega_z - \omega_{0z}}{\alpha_z} = \frac{53.9\ \text{rad/s}}{46.2\ \text{rad/s}^2} = 1.17\ \text{s}$. $P_{\text{av}} = \frac{W}{\Delta t} = \frac{6.13\times10^4\ \text{J}}{1.17\ \text{s}} = 52.5\ \text{kW}$.

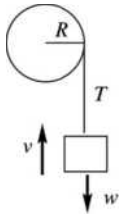
EVALUATE: $P = \tau\omega$. τ is constant and ω is linear in t, so P_{av} is half the instantaneous power at the end of the 5.00 revolutions. We could also calculate W from $W = \Delta K = \frac{1}{2}I\omega^2 = \frac{1}{2}(42.2\ \text{kg}\cdot\text{m}^2)(53.9\ \text{rad/s})^2 = 6.13\times10^4\ \text{J}$.

10.35. **(a) IDENTIFY** and **SET UP:** Use Eq. (10.23) and solve for τ_z. $P = \tau_z\omega_z$, where ω_z must be in rad/s

EXECUTE: $\omega_z = (4000\ \text{rev/min})(2\pi\ \text{rad/1 rev})(1\ \text{min/60 s}) = 418.9\ \text{rad/s}$

$$\tau_z = \frac{P}{\omega_z} = \frac{1.50\times10^5\ \text{W}}{418.9\ \text{rad/s}} = 358\ \text{N}\cdot\text{m}$$

(b) IDENTIFY and **SET UP:** Apply $\Sigma\vec{F} = m\vec{a}$ to the drum. Find the tension T in the rope using τ_z from part (a). The system is sketched in Figure 10.35.



EXECUTE: v constant implies $a = 0$
and $T = w$
$\tau_z = TR$ implies
$T = \tau_z/R = 358\ \text{N}\cdot\text{m}/0.200\ \text{m} = 1790\ \text{N}$
Thus a weight $w = 1790\ \text{N}$ can be lifted.

Figure 10.35

(c) IDENTIFY and **SET UP:** Use $v = R\omega$.

EXECUTE: The drum has $\omega = 418.9\ \text{rad/s}$, so $v = (0.200\ \text{m})(418.9\ \text{rad/s}) = 83.8\ \text{m/s}$.

EVALUATE: The rate at which T is doing work on the drum is $P = Tv = (1790\ \text{N})(83.8\ \text{m/s}) = 150\ \text{kW}$. This agrees with the work output of the motor.

10.36. **IDENTIFY:** $L = I\omega$ and $I = I_{\text{disk}} + I_{\text{woman}}$.

SET UP: $\omega = 0.50\ \text{rev/s} = 3.14\ \text{rad/s}$. $I_{\text{disk}} = \frac{1}{2}m_{\text{disk}}R^2$ and $I_{\text{woman}} = m_{\text{woman}}R^2$.

EXECUTE: $I = (55\ \text{kg} + 50.0\ \text{kg})(4.0\ \text{m})^2 = 1680\ \text{kg}\cdot\text{m}^2$.

$L = (1680\ \text{kg}\cdot\text{m}^2)(3.14\ \text{rad/s}) = 5.28\times10^3\ \text{kg}\cdot\text{m}^2/\text{s}$

EVALUATE: The disk and the woman have similar values of I, even though the disk has twice the mass.

10.37. **(a) IDENTIFY:** Use $L = mvr\sin\phi$ (Eq. (10.25)):

SET UP: Consider Figure 10.37.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

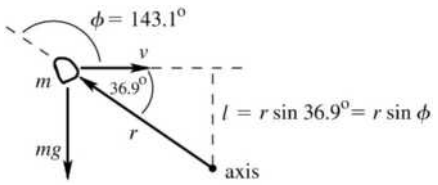


Figure 10.37

EXECUTE: $L = mvr\sin\phi =$
(2.00 kg)(12.0 m/s)(8.00 m)sin143.1°
$L = 115 \text{ kg} \cdot \text{m}^2/\text{s}$

To find the direction of $\vec{L}$ apply the right-hand rule by turning $\vec{r}$ into the direction of $\vec{v}$ by pushing on it with the fingers of your right hand. Your thumb points into the page, in the direction of $\vec{L}$.

(b) IDENTIFY and **SET UP:** By Eq. (10.26) the rate of change of the angular momentum of the rock equals the torque of the net force acting on it.

EXECUTE: $\tau = mg(8.00 \text{ m})\cos 36.9° = 125 \text{ kg} \cdot \text{m}^2/\text{s}^2$

To find the direction of $\vec{\tau}$ and hence of $d\vec{L}/dt$, apply the right-hand rule by turning $\vec{r}$ into the direction of the gravity force by pushing on it with the fingers of your right hand. Your thumb points out of the page, in the direction of $d\vec{L}/dt$.

EVALUATE: $\vec{L}$ and $d\vec{L}/dt$ are in opposite directions, so L is decreasing. The gravity force is accelerating the rock downward, toward the axis. Its horizontal velocity is constant but the distance l is decreasing and hence L is decreasing.

10.38. IDENTIFY: $L_z = I\omega_z$

SET UP: For a particle of mass m moving in a circular path at a distance r from the axis, $I = mr^2$ and $v = r\omega$. For a uniform sphere of mass M and radius R and an axis through its center, $I = \frac{2}{5}MR^2$. The earth has mass $m_E = 5.97\times10^{24}$ kg, radius $R_E = 6.38\times10^6$ m and orbit radius $r = 1.50\times10^{11}$ m. The earth completes one rotation on its axis in $24 \text{ h} = 86{,}400$ s and one orbit in $1 \text{ y} = 3.156\times10^7$ s.

EXECUTE: **(a)** $L_z = I\omega_z = mr^2\omega_z = (5.97\times10^{24} \text{ kg})(1.50\times10^{11} \text{ m})^2\left(\dfrac{2\pi \text{ rad}}{3.156\times10^7 \text{ s}}\right) = 2.67\times10^{40} \text{ kg} \cdot \text{m}^2/\text{s}.$

The radius of the earth is much less than its orbit radius, so it is very reasonable to model it as a particle for this calculation.

(b) $L_z = I\omega_z = (\frac{2}{5}MR^2)\omega = \frac{2}{5}(5.97\times10^{24} \text{ kg})(6.38\times10^6 \text{ m})^2\left(\dfrac{2\pi \text{ rad}}{86{,}400 \text{ s}}\right) = 7.07\times10^{33} \text{ kg} \cdot \text{m}^2/\text{s}$

EVALUATE: The angular momentum associated with each of these motions is very large.

10.39. IDENTIFY and **SET UP:** Use $L = I\omega$.

EXECUTE: The second hand makes 1 revolution in 1 minute, so
$\omega = (1.00 \text{ rev/min})(2\pi \text{ rad/1 rev})(1 \text{ min}/60 \text{ s}) = 0.1047 \text{ rad/s}.$

For a slender rod, with the axis about one end,
$I = \frac{1}{3}ML^2 = \frac{1}{3}(6.00\times10^{-3} \text{ kg})(0.150 \text{ m})^2 = 4.50\times10^{-5} \text{ kg} \cdot \text{m}^2.$

Then $L = I\omega = (4.50\times10^{-5} \text{ kg} \cdot \text{m}^2)(0.1047 \text{ rad/s}) = 4.71\times10^{-6} \text{ kg} \cdot \text{m}^2/\text{s}.$

EVALUATE: $\vec{L}$ is clockwise.

10.40. IDENTIFY: $\omega_z = d\theta/dt$. $L_z = I\omega_z$ and $\tau_z = dL_z/dt$.

SET UP: For a hollow, thin-walled sphere rolling about an axis through its center, $I = \frac{2}{3}MR^2$.
$R = 0.240$ m.

EXECUTE: **(a)** $A = 1.50 \text{ rad/s}^2$ and $B = 1.10 \text{ rad/s}^4$, so that $\theta(t)$ will have units of radians.

(b) (i) $\omega_z = \dfrac{d\theta}{dt} = 2At + 4Bt^3$. At $t = 3.00$ s,

$\omega_z = 2(1.50 \text{ rad/s}^2)(3.00 \text{ s}) + 4(1.10 \text{ rad/s}^4)(3.00 \text{ s})^3 = 128 \text{ rad/s}.$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$L_z = (\frac{2}{3}MR^2)\omega_z = \frac{2}{3}(12.0\text{ kg})(0.240\text{ m})^2(128\text{ rad/s}) = 59.0\text{ kg}\cdot\text{m}^2/\text{s}.$

(ii) $\tau_z = \dfrac{dL_z}{dt} = I\dfrac{d\omega_z}{dt} = I(2A + 12Bt^2)$ and

$\tau_z = \frac{2}{3}(12.0\text{ kg})(0.240\text{ m})^2(2[1.50\text{ rad/s}^2] + 12[1.10\text{ rad/s}^4][3.00\text{ s}]^2) = 56.1\text{ N}\cdot\text{m}.$

EVALUATE: The angular speed of rotation is increasing. This increase is due to an acceleration α_z that is produced by the torque on the sphere. When I is constant, as it is here, $\tau_z = dL_z/dt = Id\omega_z/dt = I\alpha_z$ and Eqs. (10.29) and (10.7) are identical.

10.41. **IDENTIFY:** Apply conservation of angular momentum.

SET UP: For a uniform sphere and an axis through its center, $I = \frac{2}{5}MR^2$.

EXECUTE: The moment of inertia is proportional to the square of the radius, and so the angular velocity will be proportional to the inverse of the square of the radius, and the final angular velocity is

$$\omega_2 = \omega_1\left(\frac{R_1}{R_2}\right)^2 = \left(\frac{2\pi\text{ rad}}{(30\text{ d})(86{,}400\text{ s/d})}\right)\left(\frac{7.0\times10^5\text{ km}}{16\text{ km}}\right)^2 = 4.6\times10^3\text{ rad/s}.$$

EVALUATE: $K = \frac{1}{2}I\omega^2 = \frac{1}{2}L\omega$. L is constant and ω increases by a large factor, so there is a large increase in the rotational kinetic energy of the star. This energy comes from potential energy associated with the gravity force within the star.

10.42. **IDENTIFY** and **SET UP:** $\vec{L}$ is conserved if there is no net external torque.

Use conservation of angular momentum to find ω at the new radius and use $K = \frac{1}{2}I\omega^2$ to find the change in kinetic energy, which is equal to the work done on the block.

EXECUTE: **(a)** Yes, angular momentum is conserved. The moment arm for the tension in the cord is zero so this force exerts no torque and there is no net torque on the block.

(b) $L_1 = L_2$ so $I_1\omega_1 = I_2\omega_2$. Block treated as a point mass, so $I = mr^2$, where r is the distance of the block from the hole.

$mr_1^2\omega_1 = mr_2^2\omega_2$

$$\omega_2 = \left(\frac{r_1}{r_2}\right)^2\omega_1 = \left(\frac{0.300\text{ m}}{0.150\text{ m}}\right)^2(1.75\text{ rad/s}) = 7.00\text{ rad/s}$$

(c) $K_1 = \frac{1}{2}I_1\omega_1^2 = \frac{1}{2}mr_1^2\omega_1^2 = \frac{1}{2}mv_1^2$

$v_1 = r_1\omega_1 = (0.300\text{ m})(1.75\text{ rad/s}) = 0.525\text{ m/s}$

$K_1 = \frac{1}{2}mv_1^2 = \frac{1}{2}(0.0250\text{ kg})(0.525\text{ m/s})^2 = 0.00345\text{ J}$

$K_2 = \frac{1}{2}mv_2^2$

$v_2 = r_2\omega_2 = (0.150\text{ m})(7.00\text{ rad/s}) = 1.05\text{ m/s}$

$K_2 = \frac{1}{2}mv_2^2 = \frac{1}{2}(0.0250\text{ kg})(1.05\text{ m/s})^2 = 0.01378\text{ J}$

$\Delta K = K_2 - K_1 = 0.01378\text{ J} - 0.00345\text{ J} = 0.0103\text{ J}$

(d) $W_{\text{tot}} = \Delta K$

But $W_{\text{tot}} = W$, the work done by the tension in the cord, so $W = 0.0103$ J.

EVALUATE: Smaller r means smaller I. $L = I\omega$ is constant so ω increases and K increases. The work done by the tension is positive since it is directed inward and the block moves inward, toward the hole.

10.43. **IDENTIFY:** Apply conservation of angular momentum to the motion of the skater.

SET UP: For a thin-walled hollow cylinder $I = mR^2$. For a slender rod rotating about an axis through its center, $I = \frac{1}{12}ml^2$.

EXECUTE: $L_{\text{i}} = L_{\text{f}}$ so $I_{\text{i}}\omega_{\text{i}} = I_{\text{f}}\omega_{\text{f}}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$I_i = 0.40\ \text{kg}\cdot\text{m}^2 + \frac{1}{12}(8.0\ \text{kg})(1.8\ \text{m})^2 = 2.56\ \text{kg}\cdot\text{m}^2$. $I_f = 0.40\ \text{kg}\cdot\text{m}^2 + (8.0\ \text{kg})(0.25\ \text{m})^2 = 0.90\ \text{kg}\cdot\text{m}^2$.

$$\omega_f = \left(\frac{I_i}{I_f}\right)\omega_i = \left(\frac{2.56\ \text{kg}\cdot\text{m}^2}{0.90\ \text{kg}\cdot\text{m}^2}\right)(0.40\ \text{rev/s}) = 1.14\ \text{rev/s}.$$

EVALUATE: $K = \frac{1}{2}I\omega^2 = \frac{1}{2}L\omega$. ω increases and L is constant, so K increases. The increase in kinetic energy comes from the work done by the skater when he pulls in his hands.

10.44. **IDENTIFY** and **SET UP:** Apply conservation of angular momentum to the diver.

SET UP: The number of revolutions she makes in a certain time is proportional to her angular velocity. The ratio of her untucked to tucked angular velocity is $(3.6\ \text{kg}\cdot\text{m}^2)/(18\ \text{kg}\cdot\text{m}^2)$.

EXECUTE: If she had tucked, she would have made $(2\ \text{rev})(3.6\ \text{kg}\cdot\text{m}^2)/(18\ \text{kg}\cdot\text{m}^2) = 0.40\ \text{rev}$ in the last 1.0 s, so she would have made $(0.40\ \text{rev})(1.5/1.0) = 0.60\ \text{rev}$ in the total 1.5 s.

EVALUATE: Untucked she rotates slower and completes fewer revolutions.

10.45. **IDENTIFY** and **SET UP:** There is no net external torque about the rotation axis so the angular momentum $L = I\omega$ is conserved.

EXECUTE: **(a)** $L_1 = L_2$ gives $I_1\omega_1 = I_2\omega_2$, so $\omega_2 = (I_1/I_2)\omega_1$

$I_1 = I_{tt} = \frac{1}{2}MR^2 = \frac{1}{2}(120\ \text{kg})(2.00\ \text{m})^2 = 240\ \text{kg}\cdot\text{m}^2$

$I_2 = I_{tt} + I_p = 240\ \text{kg}\cdot\text{m}^2 + mR^2 = 240\ \text{kg}\cdot\text{m}^2 + (70\ \text{kg})(2.00\ \text{m})^2 = 520\ \text{kg}\cdot\text{m}^2$

$\omega_2 = (I_1/I_2)\omega_1 = (240\ \text{kg}\cdot\text{m}^2/520\ \text{kg}\cdot\text{m}^2)(3.00\ \text{rad/s}) = 1.38\ \text{rad/s}$

(b) $K_1 = \frac{1}{2}I_1\omega_1^2 = \frac{1}{2}(240\ \text{kg}\cdot\text{m}^2)(3.00\ \text{rad/s})^2 = 1080\ \text{J}$

$K_2 = \frac{1}{2}I_2\omega_2^2 = \frac{1}{2}(520\ \text{kg}\cdot\text{m}^2)(1.38\ \text{rad/s})^2 = 495\ \text{J}$

EVALUATE: The kinetic energy decreases because of the negative work done on the turntable and the parachutist by the friction force between these two objects.

The angular speed decreases because I increases when the parachutist is added to the system.

10.46. **IDENTIFY:** Apply conservation of angular momentum to the collision.

SET UP: Let the width of the door be l. The initial angular momentum of the mud is $mv(l/2)$, since it strikes the door at its center. For the axis at the hinge, $I_{door} = \frac{1}{3}Ml^2$ and $I_{mud} = m(l/2)^2$.

EXECUTE: $$\omega = \frac{L}{I} = \frac{mv(l/2)}{(1/3)Ml^2 + m(l/2)^2}.$$

$$\omega = \frac{(0.500\ \text{kg})(12.0\ \text{m/s})(0.500\ \text{m})}{(1/3)(40.0\ \text{kg})(1.00\ \text{m})^2 + (0.500\ \text{kg})(0.500\ \text{m})^2} = 0.223\ \text{rad/s}.$$

Ignoring the mass of the mud in the denominator of the above expression gives $\omega = 0.225$ rad/s, so the mass of the mud in the moment of inertia does affect the third significant figure.

EVALUATE: Angular momentum is conserved but there is a large decrease in the kinetic energy of the system.

10.47. **(a) IDENTIFY** and **SET UP:** Apply conservation of angular momentum $\vec{L}$, with the axis at the nail. Let object A be the bug and object B be the bar. Initially, all objects are at rest and $L_1 = 0$. Just after the bug jumps, it has angular momentum in one direction of rotation and the bar is rotating with angular velocity ω_B in the opposite direction.

EXECUTE: $L_2 = m_A v_A r - I_B\omega_B$ where $r = 1.00$ m and $I_B = \frac{1}{3}m_B r^2$

$L_1 = L_2$ gives $m_A v_A r = \frac{1}{3}m_B r^2\omega_B$

$$\omega_B = \frac{3m_A v_A}{m_B r} = 0.120\ \text{rad/s}$$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) $K_1 = 0;\ K_2 = \frac{1}{2}m_A v_A^2 + \frac{1}{2}I_B\omega_B^2 =$

$\frac{1}{2}(0.0100\text{ kg})(0.200\text{ m/s})^2 + \frac{1}{2}\left(\frac{1}{3}[0.0500\text{ kg}][1.00\text{ m}]^2\right)(0.120\text{ rad/s})^2 = 3.2\times10^{-4}$ J.

(c) The increase in kinetic energy comes from work done by the bug when it pushes against the bar in order to jump.

EVALUATE: There is no external torque applied to the system and the total angular momentum of the system is constant. There are internal forces, forces the bug and bar exert on each other. The forces exert torques and change the angular momentum of the bug and the bar, but these changes are equal in magnitude and opposite in direction. These internal forces do positive work on the two objects and the kinetic energy of each object and of the system increases.

10.48. **IDENTIFY:** Apply conservation of angular momentum to the system of earth plus asteroid.

SET UP: Take the axis to be the earth's rotation axis. The asteroid may be treated as a point mass and it has zero angular momentum before the collision, since it is headed toward the center of the earth. For the earth, $L_z = I\omega_z$ and $I = \frac{2}{5}MR^2$, where M is the mass of the earth and R is its radius. The length of a day is $T = \dfrac{2\pi\text{ rad}}{\omega}$, where ω is the earth's angular rotation rate.

EXECUTE: Conservation of angular momentum applied to the collision between the earth and asteroid gives $\frac{2}{5}MR^2\omega_1 = (mR^2 + \frac{2}{5}MR^2)\omega_2$ and $m = \frac{2}{5}M\left(\dfrac{\omega_1 - \omega_2}{\omega_2}\right)$. $T_2 = 1.250T_1$ gives $\dfrac{1}{\omega_2} = \dfrac{1.250}{\omega_1}$ and

$\omega_1 = 1.250\omega_2$. $\dfrac{\omega_1 - \omega_2}{\omega_2} = 0.250$. $m = \frac{2}{5}(0.250)M = 0.100M$.

EVALUATE: If the asteroid hit the surface of the earth tangentially it could have some angular momentum with respect to the earth's rotation axis, and could either speed up or slow down the earth's rotation rate.

10.49. **IDENTIFY:** Apply conservation of angular momentum to the collision.

SET UP: The system before and after the collision is sketched in Figure 10.49. Let counterclockwise rotation be positive. The bar has $I = \frac{1}{3}m_2L^2$.

EXECUTE: **(a)** Conservation of angular momentum: $m_1v_0d = -m_1vd + \frac{1}{3}m_2L^2\omega$.

$$(3.00\text{ kg})(10.0\text{ m/s})(1.50\text{ m}) = -(3.00\text{ kg})(6.00\text{ m/s})(1.50\text{ m}) + \frac{1}{3}\left(\frac{90.0\text{ N}}{9.80\text{ m/s}^2}\right)(2.00\text{ m})^2\omega$$

$\omega = 5.88$ rad/s.

(b) There are no unbalanced torques about the pivot, so angular momentum is conserved. But the pivot exerts an unbalanced horizontal external force on the system, so the linear momentum is not conserved.

EVALUATE: Kinetic energy is not conserved in the collision.

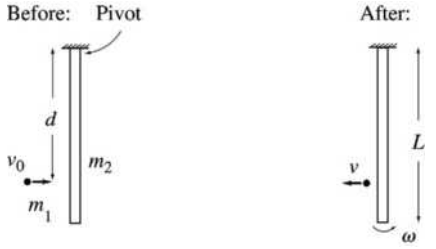

Figure 10.49

10.50. **IDENTIFY:** As the bug moves outward, it increases the moment of inertia of the rod-bug system. The angular momentum of this system is conserved because no unbalanced external torques act on it.

SET UP: The moment of inertia of the rod is $I = \dfrac{1}{3}ML^2$, and conservation of angular momentum gives $I_1\omega_1 = I_2\omega_2$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: **(a)** $I = \frac{1}{3}ML^2$ gives $M = \frac{3I}{L^2} = \frac{3(3.00\times10^{-3}\ \text{kg}\cdot\text{m}^2)}{(0.500\ \text{m})^2} = 0.0360\ \text{kg}.$

(b) $L_1 = L_2$, so $I_1\omega_1 = I_2\omega_2$. $\omega_2 = \frac{v}{r} = \frac{0.160\ \text{m/s}}{0.500\ \text{m}} = 0.320\ \text{rad/s}$, so

$(3.00\times10^{-3}\ \text{kg}\cdot\text{m}^2)(0.400\ \text{rad/s}) = (3.00\times10^{-3}\ \text{kg}\cdot\text{m}^2 + m_{\text{bug}}(0.500\ \text{m})^2)(0.320\ \text{rad/s}).$

$$m_{\text{bug}} = \frac{(3.00\times10^{-3}\ \text{kg}\cdot\text{m}^2)(0.400\ \text{rad/s} - 0.320\ \text{rad/s})}{(0.320\ \text{rad/s})(0.500\ \text{m})^2} = 3.00\times10^{-3}\ \text{kg}.$$

EVALUATE: This is a 3.00 mg bug, which is not unreasonable.

10.51. **IDENTIFY:** If we take the raven and the gate as a system, the torque about the pivot is zero, so the angular momentum of the system about the pivot is conserved.

SET UP: The system before and after the collision is sketched in Figure 10.51. The gate has $I = \frac{1}{3}ML^2$. Take counterclockwise torques to be positive.

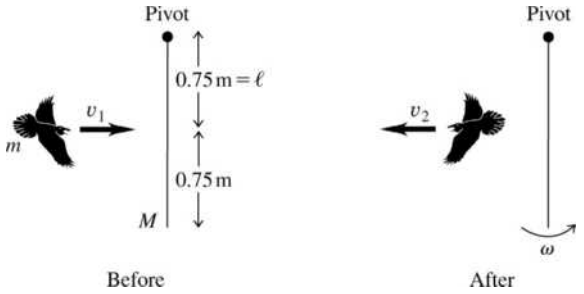

Figure 10.51

EXECUTE: **(a)** The gravity forces exert no torque at the moment of collision and angular momentum is conserved. $L_1 = L_2$. $mv_1l = -mv_2l + I_{\text{gate}}\omega$ with $l = L/2$.

$$\omega = \frac{m(v_1 + v_2)l}{\frac{1}{3}ML^2} = \frac{3m(v_1 + v_2)}{2ML} = \frac{3(1.1\ \text{kg})(5.0\ \text{m/s} + 2.0\ \text{m/s})}{2(4.5\ \text{kg})(1.5\ \text{m})} = 1.71\ \text{rad/s}.$$

(b) Linear momentum is not conserved; there is an external force exerted by the pivot. But the force on the pivot has zero torque. There is no external torque and angular momentum is conserved.

EVALUATE: $K_1 = \frac{1}{2}(1.1\ \text{kg})(5.0\ \text{m/s})^2 = 13.8\ \text{J}.$

$K_2 = \frac{1}{2}(1.1\ \text{kg})(2.0\ \text{m/s})^2 + \frac{1}{2}(\frac{1}{3}[4.5\ \text{kg}][1.5\ \text{m/s}]^2)(1.71\ \text{rad/s})^2 = 7.1\ \text{J}.$ This is an inelastic collision and $K_2 < K_1$.

10.52. **IDENTIFY:** The angular momentum of Sedna is conserved as it moves in its orbit.

SET UP: The angular momentum of Sedna is $L = mvl$.

EXECUTE: **(a)** $L = mvl$ so $v_1l_1 = v_2l_2$. When $v_1 = 4.64$ km/s, $l_1 = 76$ AU.

$$v_2 = v_1\left(\frac{l_1}{l_2}\right) = (4.64\ \text{km/s})\left(\frac{76\ \text{AU}}{942\ \text{AU}}\right) = 0.374\ \text{km/s}.$$

(b) Since vl is constant the maximum speed is at the minimum distance and the minimum speed is at the maximum distance.

(c) $$\frac{K_1}{K_2} = \frac{\frac{1}{2}mv_1^2}{\frac{1}{2}mv_2^2} = \left(\frac{v_1}{v_2}\right)^2 = \left(\frac{l_2}{l_1}\right)^2 = \left(\frac{942\ \text{AU}}{76\ \text{AU}}\right)^2 = 154.$$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: Since the units of l cancel in the ratios there is no need to convert from AU to m. The gravity force of the sun does work on Sedna as it moves toward or away from the sun and this changes the kinetic energy during the orbit. But this force exerts no torque, so the angular momentum of Sedna is constant.

10.53. **IDENTIFY:** The precession angular velocity is $\Omega = \dfrac{wr}{I\omega}$, where ω is in rad/s. Also apply $\sum \vec{F} = m\vec{a}$ to the gyroscope.

SET UP: The total mass of the gyroscope is $m_r + m_f = 0.140\ \text{kg} + 0.0250\ \text{kg} = 0.165\ \text{kg}$.

$\Omega = \dfrac{2\pi\ \text{rad}}{T} = \dfrac{2\pi\ \text{rad}}{2.20\ \text{s}} = 2.856\ \text{rad/s}.$

EXECUTE: **(a)** $F_p = w_{\text{tot}} = (0.165\ \text{kg})(9.80\ \text{m/s}^2) = 1.62\ \text{N}$

(b) $\omega = \dfrac{wr}{I\Omega} = \dfrac{(0.165\ \text{kg})(9.80\ \text{m/s}^2)(0.0400\ \text{m})}{(1.20\times10^{-4}\ \text{kg}\cdot\text{m}^2)(2.856\ \text{rad/s})} = 189\ \text{rad/s} = 1.80\times10^3\ \text{rev/min}$

(c) If the figure in the problem is viewed from above, $\vec{\tau}$ is in the direction of the precession and $\vec{L}$ is along the axis of the rotor, away from the pivot.

EVALUATE: There is no vertical component of acceleration associated with the motion, so the force from the pivot equals the weight of the gyroscope. The larger ω is, the slower the rate of precession.

10.54. **IDENTIFY:** The precession angular speed is related to the acceleration due to gravity by Eq. (10.33), with $w = mg$.

SET UP: $\Omega_E = 0.50$ rad/s, $g_E = g$ and $g_M = 0.165g$. For the gyroscope, m, r, I, and ω are the same on the moon as on the earth.

EXECUTE: $\Omega = \dfrac{mgr}{I\omega}$. $\dfrac{\Omega}{g} = \dfrac{mr}{I\omega} = \text{constant}$, so $\dfrac{\Omega_E}{g_E} = \dfrac{\Omega_M}{g_M}$.

$\Omega_M = \Omega_E\left(\dfrac{g_M}{g_E}\right) = 0.165\Omega_E = (0.165)(0.50\ \text{rad/s}) = 0.0825\ \text{rad/s}.$

EVALUATE: In the limit that $g \to 0$ the precession rate $\to 0$.

10.55. **IDENTIFY** and **SET UP:** Apply Eq. (10.33).

EXECUTE: **(a)** halved

(b) doubled (assuming that the added weight is distributed in such a way that r and I are not changed)

(c) halved (assuming that w and r are not changed)

(d) doubled

(e) unchanged.

EVALUATE: Ω is directly proportional to w and r and is inversely proportional to I and ω.

10.56. **IDENTIFY:** An external torque will cause precession of the telescope.

SET UP: $I = MR^2$, with $R = 2.5\times10^{-2}$ m. 1.0×10^{-6} degree $= 1.745\times10^{-8}$ rad.

$\omega = 19{,}200$ rpm $= 2.01\times10^3$ rad/s. $t = 5.0$ h $= 1.8\times10^4$ s.

EXECUTE: $\Omega = \dfrac{\Delta\phi}{\Delta t} = \dfrac{1.745\times10^{-8}\ \text{rad}}{1.8\times10^4\ \text{s}} = 9.694\times10^{-13}\ \text{rad/s}.$ $\Omega = \dfrac{\tau}{I\omega}$ so $\tau = \Omega I\omega = \Omega MR^2\omega$. Putting in the numbers gives $\tau = (9.694\times10^{-13}\ \text{rad/s})(2.0\ \text{kg})(2.5\times10^{-2}\ \text{m})^2\,(2.01\times10^3\ \text{rad/s}) = 2.4\times10^{-12}\ \text{N}\cdot\text{m}.$

EVALUATE: The external torque must be very small for this degree of stability.

10.57. **IDENTIFY:** Apply $\sum\tau_z = I\alpha_z$ and constant acceleration equations to the motion of the grindstone.

SET UP: Let the direction of rotation of the grindstone be positive. The friction force is $f = \mu_k n$ and produces torque fR. $\omega = (120\text{rev/min})\left(\dfrac{2\pi\ \text{rad}}{1\ \text{rev}}\right)\left(\dfrac{1\ \text{min}}{60\ \text{s}}\right) = 4\pi\ \text{rad/s}.$ $I = \frac{1}{2}MR^2 = 1.69\ \text{kg}\cdot\text{m}^2.$

EXECUTE: **(a)** The net torque must be

$$\tau = I\alpha = I\frac{\omega_z - \omega_{0z}}{t} = (1.69\ \text{kg}\cdot\text{m}^2)\frac{4\pi\ \text{rad/s}}{9.00\ \text{s}} = 2.36\ \text{N}\cdot\text{m}.$$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

This torque must be the sum of the applied force FR and the opposing frictional torques τ_f at the axle and $fR = \mu_k nR$ due to the knife. $F = \frac{1}{R}(\tau + \tau_f + \mu_k nR)$.

$F = \frac{1}{0.500\text{ m}}((2.36\text{ N}\cdot\text{m}) + (6.50\text{ N}\cdot\text{m}) + (0.60)(160\text{ N})(0.260\text{ m})) = 67.6\text{ N}$.

(b) To maintain a constant angular velocity, the net torque τ is zero, and the force F' is

$F' = \frac{1}{0.500\text{ m}}(6.50\text{ N}\cdot\text{m} + 24.96\text{ N}\cdot\text{m}) = 62.9\text{ N}$.

(c) The time t needed to come to a stop is found by taking the magnitudes in Eq. (10.29), with $\tau = \tau_f$ constant; $t = \frac{L}{\tau_f} = \frac{\omega I}{\tau_f} = \frac{(4\pi\text{ rad/s})(1.69\text{ kg}\cdot\text{m}^2)}{6.50\text{ N}\cdot\text{m}} = 3.27\text{ s}$.

EVALUATE: The time for a given change in ω is proportional to α, which is in turn proportional to the net torque, so the time in part (c) can also be found as $t = (9.00\text{ s})\frac{2.36\text{ N}\cdot\text{m}}{6.50\text{ N}\cdot\text{m}}$.

10.58. **IDENTIFY:** Apply $\sum\tau_z = I\alpha_z$ and use the constant acceleration equations to relate α to the motion.

SET UP: Let the direction the wheel is rotating be positive. 100 rev/min = 10.47 rad/s

EXECUTE: **(a)** $\omega_z = \omega_{0z} + \alpha_z t$ gives $\alpha_z = \frac{\omega_z - \omega_{0z}}{t} = \frac{10.47\text{ rad/s} - 0}{2.00\text{ s}} = 5.235\text{ rad/s}^2$.

$I = \frac{\sum\tau_z}{\alpha_z} = \frac{7.00\text{ N}\cdot\text{m}}{5.235\text{ rad/s}^2} = 1.34\text{ kg}\cdot\text{m}^2$.

(b) $\omega_{0z} = 10.47$ rad/s, $\omega_z = 0$, $t = 125$ s. $\omega_z = \omega_{0z} + \alpha_z t$ gives

$\alpha_z = \frac{\omega_z - \omega_{0z}}{t} = \frac{0 - 10.47\text{ rad/s}}{125\text{ s}} = -0.0838\text{ rad/s}^2$. Applying $\sum\tau_z = I\alpha_z$ gives

$\sum\tau_z = I\alpha_z = (1.34\text{ kg}\cdot\text{m}^2)(-0.0838\text{ rad/s}^2) = -0.112\text{ N}\cdot\text{m}$.

(c) $\theta = \left(\frac{\omega_{0z} + \omega_z}{2}\right)t = \left(\frac{10.47\text{ rad/s} + 0}{2}\right)(125\text{ s}) = 654\text{ rad} = 104\text{ rev}$.

EVALUATE: The applied net torque $(7.00\text{ N}\cdot\text{m})$ is much larger than the magnitude of the friction torque $(0.112\text{ N}\cdot\text{m})$, so the time of 2.00 s that it takes the wheel to reach an angular speed of 100 rev/min is much less than the 125 s it takes the wheel to be brought to rest by friction.

10.59. **IDENTIFY:** Use the kinematic information to solve for the angular acceleration of the grindstone. Assume that the grindstone is rotating counterclockwise and let that be the positive sense of rotation. Then apply Eq. (10.7) to calculate the friction force and use $f_k = \mu_k n$ to calculate μ_k.

SET UP: $\omega_{0z} = 850\text{ rev/min}(2\pi\text{ rad/1 rev})(1\text{ min/60 s}) = 89.0\text{ rad/s}$

$t = 7.50$ s; $\omega_z = 0$ (comes to rest); $\alpha_z = ?$

EXECUTE: $\omega_z = \omega_{0z} + \alpha_z t$

$\alpha_z = \frac{0 - 89.0\text{ rad/s}}{7.50\text{ s}} = -11.9\text{ rad/s}^2$

SET UP: Apply $\sum\tau_z = I\alpha_z$ to the grindstone. The free-body diagram is given in Figure 10.59.

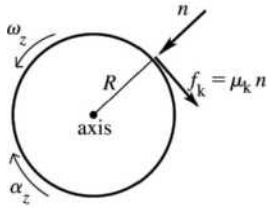

Figure 10.59

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

The normal force has zero moment arm for rotation about an axis at the center of the grindstone, and therefore zero torque. The only torque on the grindstone is that due to the friction force f_k exerted by the ax; for this force the moment arm is $l = R$ and the torque is negative.

EXECUTE: $\sum \tau_z = -f_k R = -\mu_k n R$

$I = \frac{1}{2}MR^2$ (solid disk, axis through center)

Thus $\sum \tau_z = I\alpha_z$ gives $-\mu_k nR = (\frac{1}{2}MR^2)\alpha_z$

$$\mu_k = -\frac{MR\alpha_z}{2n} = -\frac{(50.0 \text{ kg})(0.260 \text{ m})(-11.9 \text{ rad/s}^2)}{2(160 \text{ N})} = 0.483$$

EVALUATE: The friction torque is clockwise and slows down the counterclockwise rotation of the grindstone.

10.60. **IDENTIFY:** Use a constant acceleration equation to calculate α_z and then apply $\sum \tau_z = I\alpha_z$.

SET UP: $I = \frac{2}{3}MR^2 + 2mR^2$, where $M = 8.40$ kg, $m = 2.00$ kg, so $I = 0.600 \text{ kg} \cdot \text{m}^2$.

$\omega_{0z} = 75.0$ rpm $= 7.854$ rad/s; $\omega_z = 50.0$ rpm $= 5.236$ rad/s; $t = 30.0$ s.

EXECUTE: $\omega_z = \omega_{0_z} + \alpha_z t$ gives $\alpha_z = -0.08726 \text{ rad/s}^2$. $\tau_z = I\alpha_z = -0.0524 \text{ N} \cdot \text{m}$

EVALUATE: The torque is negative because its direction is opposite to the direction of rotation, which must be the case for the speed to decrease.

10.61. **IDENTIFY:** Use a constant angular acceleration equation to calculate α_z and then apply $\sum \tau_z = I\alpha_z$ to the motion of the cylinder. $f_k = \mu_k n$.

SET UP: $I = \frac{1}{2}mR^2 = \frac{1}{2}(8.25 \text{ kg})(0.0750 \text{ m})^2 = 0.02320 \text{ kg} \cdot \text{m}^2$. Let the direction the cylinder is rotating be positive. $\omega_{0z} = 220$ rpm $= 23.04$ rad/s; $\omega_z = 0$; $\theta - \theta_0 = 5.25$ rev $= 33.0$ rad.

EXECUTE: $\omega_z^2 = \omega_{0z}^2 + 2\alpha_z(\theta - \theta_0)$ gives $\alpha_z = -8.046 \text{ rad/s}^2$. $\sum \tau_z = \tau_f = -f_k R = -\mu_k nR$. Then $\sum \tau_z = I\alpha_z$ gives $-\mu_k nR = I\alpha_z$ and $n = -\dfrac{I\alpha_z}{\mu_k R} = 7.47$ N.

EVALUATE: The friction torque is directed opposite to the direction of rotation and therefore produces an angular acceleration that slows the rotation.

10.62. **IDENTIFY:** The kinetic energy of the disk is $K = \frac{1}{2}Mv_{cm}^2 + \frac{1}{2}I\omega^2$. As it falls its gravitational potential energy decreases and its kinetic energy increases. The only work done on the disk is the work done by gravity, so $K_1 + U_1 = K_2 + U_2$.

SET UP: $I_{cm} = \frac{1}{2}M(R_2^2 + R_1^2)$, where $R_1 = 0.300$ m and $R_2 = 0.500$ m. $v_{cm} = R_2\omega$. Take $y_1 = 0$, so $y_2 = -2.20$ m.

EXECUTE: $K_1 + U_1 = K_2 + U_2$. $K_1 = 0$, $U_1 = 0$. $K_2 = -U_2$. $\frac{1}{2}Mv_{cm}^2 + \frac{1}{2}I_{cm}\omega^2 = -Mgy_2$.

$\frac{1}{2}I_{cm}\omega^2 = \frac{1}{4}M(1 + [R_1/R_2]^2)v_{cm}^2 = 0.340Mv_{cm}^2$. Then $0.840Mv_{cm}^2 = -Mgy_2$ and

$$v_{cm} = \sqrt{\frac{-gy_2}{0.840}} = \sqrt{\frac{-(9.80 \text{ m/s}^2)(-2.20 \text{ m})}{0.840}} = 5.07 \text{ m/s}.$$

EVALUATE: A point mass in free fall acquires a speed of 6.57 m/s after falling 2.20 m. The disk has a value of v_{cm} that is less than this, because some of the original gravitational potential energy has been converted to rotational kinetic energy.

10.63. **IDENTIFY:** Use $\sum \tau_z = I\alpha_z$ to find the angular acceleration just after the ball falls off and use conservation of energy to find the angular velocity of the bar as it swings through the vertical position.

SET UP: The axis of rotation is at the axle. For this axis the bar has $I = \frac{1}{12}m_{bar}L^2$, where $m_{bar} = 3.80$ kg and $L = 0.800$ m. Energy conservation gives $K_1 + U_1 = K_2 + U_2$. The gravitational potential energy of the bar doesn't change. Let $y_1 = 0$, so $y_2 = -L/2$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: **(a)** $\tau_z = m_{\text{ball}}g(L/2)$ and $I = I_{\text{ball}} + I_{\text{bar}} = \frac{1}{12}m_{\text{bar}}L^2 + m_{\text{ball}}(L/2)^2$. $\sum\tau_z = I\alpha_z$ gives

$$\alpha_z = \frac{m_{\text{ball}}g(L/2)}{\frac{1}{12}m_{\text{bar}}L^2 + m_{\text{ball}}(L/2)^2} = \frac{2g}{L}\left(\frac{m_{\text{ball}}}{m_{\text{ball}} + m_{\text{bar}}/3}\right) \text{ and}$$

$$\alpha_z = \frac{2(9.80\ \text{m/s}^2)}{0.800\ \text{m}}\left(\frac{2.50\ \text{kg}}{2.50\ \text{kg} + [3.80\ \text{kg}]/3}\right) = 16.3\ \text{rad/s}^2.$$

(b) As the bar rotates, the moment arm for the weight of the ball decreases and the angular acceleration of the bar decreases.

(c) $K_1 + U_1 = K_2 + U_2$. $0 = K_2 + U_2$. $\frac{1}{2}(I_{\text{bar}} + I_{\text{ball}})\omega^2 = -m_{\text{ball}}g(-L/2)$.

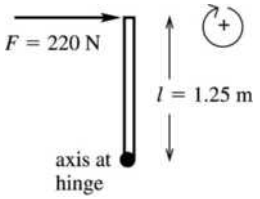
$$\omega = \sqrt{\frac{m_{\text{ball}}gL}{m_{\text{ball}}L^2/4 + m_{\text{bar}}L^2/12}} = \sqrt{\frac{g}{L}\left(\frac{4m_{\text{ball}}}{m_{\text{ball}} + m_{\text{bar}}/3}\right)} = \sqrt{\frac{9.80\ \text{m/s}^2}{0.800\ \text{m}}\left(\frac{4[2.50\ \text{kg}]}{2.50\ \text{kg} + [3.80\ \text{kg}]/3}\right)}$$

$\omega = 5.70$ rad/s.

EVALUATE: As the bar swings through the vertical, the linear speed of the ball that is still attached to the bar is $v = (0.400\ \text{m})(5.70\ \text{rad/s}) = 2.28$ m/s. A point mass in free-fall acquires a speed of 2.80 m/s after falling 0.400 m; the ball on the bar acquires a speed less than this.

10.64. **IDENTIFY:** Use $\sum\tau_z = I\alpha_z$ to find α_z, and then use the constant α_z kinematic equations to solve for t.

SET UP: The door is sketched in Figure 10.64.



EXECUTE:
$\sum\tau_z = Fl = (220\ \text{N})(1.25\ \text{m}) = 275\ \text{N}\cdot\text{m}$

From Table 9.2(d), $I = \frac{1}{3}Ml^2$

$I = \frac{1}{3}(750\ \text{N}/9.80\ \text{m/s}^2)(1.25\ \text{m})^2 =$

$39.9\ \text{kg}\cdot\text{m}^2$

Figure 10.64

$\sum\tau_z = I\alpha_z$ so $\alpha_z = \frac{\sum\tau_z}{I} = \frac{275\ \text{N}\cdot\text{m}}{39.9\ \text{kg}\cdot\text{m}^2} = 6.89\ \text{rad/s}^2$

SET UP: $\alpha_z = 6.89\ \text{rad/s}^2$; $\theta - \theta_0 = 90°(\pi\ \text{rad}/180°) = \pi/2$ rad; $\omega_{0z} = 0$ (door initially at rest); $t = ?$

$\theta - \theta_0 = \omega_{0z}t + \frac{1}{2}\alpha_z t^2$

EXECUTE: $t = \sqrt{\frac{2(\theta - \theta_0)}{\alpha_z}} - \sqrt{\frac{2(\pi/2\ \text{rad})}{6.89\ \text{rad/s}^2}} = 0.675$ s

EVALUATE: The forces and the motion are connected through the angular acceleration.

10.65. **IDENTIFY:** Calculate W using the procedure specified in the problem. In part (c) apply the work-energy theorem. In part (d), $a_{\text{tan}} = R\alpha$ and $\sum\tau_z = I\alpha_z$. $a_{\text{rad}} = R\omega^2$.

SET UP: Let θ be the angle the disk has turned through. The moment arm for F is $R\cos\theta$.

EXECUTE: **(a)** The torque is $\tau = FR\cos\theta$.

$$W = \int_0^{\pi/2} FR\cos\theta\, d\theta = FR.$$

(b) In Eq. (6.14), dl is the horizontal distance the point moves, and so $W = F\int dl = FR$, the same as part (a).

(c) From $K_2 = W = (MR^2/4)\omega^2$, $\omega = \sqrt{4F/MR}$.

(d) The torque, and hence the angular acceleration, is greatest when $\theta = 0$,
at which point $\alpha = (\tau/I) = 2F/MR$, and so the maximum tangential acceleration is $2F/M$.

(e) Using the value for ω found in part (c), $a_{\text{rad}} = \omega^2 R = 4F/M$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist.
No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: $a_{\tan} = \alpha R$ is maximum initially, when the moment arm for F is a maximum, and it is zero after the disk has rotated one-quarter of a revolution. a_{rad} is zero initially and is a maximum at the end of the motion, after the disk has rotated one-quarter of a revolution.

10.66. **IDENTIFY:** Apply $\sum \tau_z = I\alpha_z$, where τ_z is due to the gravity force on the object.

SET UP: $I = I_{\text{rod}} + I_{\text{clay}}$. $I_{\text{rod}} = \frac{1}{3}ML^2$. In part (b), $I_{\text{clay}} = ML^2$. In part (c), $I_{\text{clay}} = 0$.

EXECUTE: **(a)** A distance $L/4$ from the end with the clay.

(b) In this case $I = (4/3)ML^2$ and the gravitational torque is $(3L/4)(2Mg)\sin\theta = (3MgL/2)\sin\theta$, so $\alpha = (9g/8L)\sin\theta$.

(c) In this case $I = (1/3)ML^2$ and the gravitational torque is $(L/4)(2Mg)\sin\theta = (MgL/2)\sin\theta$, so $\alpha = (3g/2L)\sin\theta$.

This is greater than in part (b).

(d) The greater the angular acceleration of the upper end of the cue, the faster you would have to react to overcome deviations from the vertical.

EVALUATE: In part (b), I is 4 times larger than in part (c) and τ is 3 times larger. $\alpha = \tau/I$, so the net effect is that α is smaller in (b) than in (c).

10.67. **IDENTIFY:** Blocks A and B have linear acceleration and therefore obey the linear form of Newton's second law $\sum F_y = ma_y$. The wheel C has angular acceleration, so it obeys the rotational form of Newton's second law $\sum \tau_z = I\alpha_z$.

SET UP: A accelerates downward, B accelerates upward and the wheel turns clockwise. Apply $\sum F_y = ma_y$ to blocks A and B. Let $+y$ be downward for A and $+y$ be upward for B. Apply $\sum \tau_z = I\alpha_z$ to the wheel, with the clockwise sense of rotation positive. Each block has the same magnitude of acceleration, a, and $a = R\alpha$. Call the T_A the tension in the cord between C and A and T_B the tension between C and B.

EXECUTE: For A, $\sum F_y = ma_y$ gives $m_Ag - T_A = m_Aa$. For B, $\sum F_y = ma_y$ gives $T_B - m_Bg = m_Ba$. For the wheel, $\sum \tau_z = I\alpha_z$ gives $T_AR - T_BR = I\alpha = I(a/R)w$ and $T_A - T_B = \left(\frac{I}{R^2}\right)a$. Adding these three equations gives $(m_A - m_B)g = \left(m_A + m_B + \frac{I}{R^2}\right)a$. Solving for a, we have

$$a = \left(\frac{m_A - m_B}{m_A + m_B + I/R^2}\right)g = \left(\frac{4.00\text{ kg} - 2.00\text{ kg}}{4.00\text{ kg} + 2.00\text{ kg} + (0.300\text{ kg}\cdot\text{m}^2)/(0.120\text{ m})^2}\right)(9.80\text{ m/s}^2) = 0.730\text{ m/s}^2.$$

$$\alpha = \frac{a}{R} = \frac{0.730\text{ m/s}^2}{0.120\text{ m}} = 6.08\text{ rad/s}^2.$$

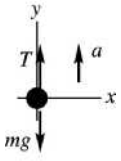
$$T_A = m_A(g - a) = (4.00\text{ kg})(9.80\text{ m/s}^2 - 0.730\text{ m/s}^2) = 36.3\text{ N}.$$

$$T_B = m_B(g + a) = (2.00\text{ kg})(9.80\text{ m/s}^2 + 0.730\text{ m/s}^2) = 21.1\text{ N}.$$

EVALUATE: The tensions must be different in order to produce a torque that accelerates the wheel when the blocks accelerate.

10.68. **IDENTIFY:** Apply $\sum \vec{F} = m\vec{a}$ to the crate and $\sum \tau_z = I\alpha_z$ to the cylinder. The motions are connected by $a(\text{crate}) = R\alpha(\text{cylinder})$.

SET UP: The force diagram for the crate is given in Figure 10.68a.



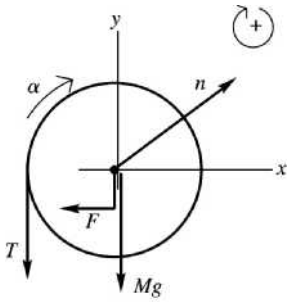
EXECUTE: Applying $\sum F_y = ma_y$ gives $T - mg = ma$. Solving for T gives

$$T = m(g + a) = (50\text{ kg})(9.80\text{ m/s}^2 + 1.40\text{ m/s}^2) = 560\text{ N}.$$

Figure 10.68a

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

SET UP: The force diagram for the cylinder is given in Figure 10.68b.



EXECUTE: $\sum \tau_z = I\alpha_z$ gives $Fl - TR = I\alpha_z$, where $l = 0.12$ m and $R = 0.25$ m. $a = R\alpha$ so $\alpha_z = a/R$. Therefore $Fl = TR + Ia/R$.

Figure 10.68b

$$F = T\left(\frac{R}{l}\right) + \frac{Ia}{Rl} = (560\text{ N})\left(\frac{0.25\text{ m}}{0.12\text{ m}}\right) + \frac{(2.9\text{ kg}\cdot\text{m}^2)(1.40\text{ m/s}^2)}{(0.25\text{ m})(0.12\text{ m})} = 1300\text{ N}.$$

EVALUATE: The tension in the rope is greater than the weight of the crate since the crate accelerates upward. If F were applied to the rim of the cylinder ($l = 0.25$ m), it would have the value $F = 625$ N. This is greater than T because it must accelerate the cylinder as well as the crate. And F is larger than this because it is applied closer to the axis than R so has a smaller moment arm and must be larger to give the same torque.

10.69. **IDENTIFY:** Apply $\sum \vec{F}_{\text{ext}} = m\vec{a}_{\text{cm}}$ and $\sum \tau_z = I_{\text{cm}}\alpha_z$ to the roll.

SET UP: At the point of contact, the wall exerts a friction force f directed downward and a normal force n directed to the right. This is a situation where the net force on the roll is zero, but the net torque is *not* zero.

EXECUTE: **(a)** Balancing vertical forces, $F_{\text{rod}}\cos\theta = f + w + F$, and balancing horizontal forces $F_{\text{rod}}\sin\theta = n$. With $f = \mu_{\text{k}}n$, these equations become $F_{\text{rod}}\cos\theta = \mu_{\text{k}}n + F + w$, $F_{\text{rod}}\sin\theta = n$. Eliminating n and solving for F_{rod} gives $F_{\text{rod}} = \dfrac{w + F}{\cos\theta - \mu_{\text{k}}\sin\theta} = \dfrac{(16.0\text{ kg})(9.80\text{ m/s}^2) + (60.0\text{ N})}{\cos 30° - (0.25)\sin 30°} = 293\text{ N}.$

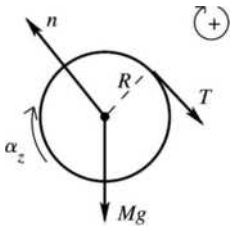
(b) With respect to the center of the roll, the rod and the normal force exert zero torque. The magnitude of the net torque is $(F - f)R$, and $f = \mu_{\text{k}}n$ may be found by insertion of the value found for F_{rod} into either of the above relations; i.e., $f = \mu_{\text{k}}F_{\text{rod}}\sin\theta = 36.57$ N. Then,

$$\alpha = \frac{\tau}{I} = \frac{(60.0\text{ N} - 36.57\text{ N})(18.0\times10^{-2}\text{ m})}{(0.260\text{ kg}\cdot\text{m}^2)} = 16.2\text{ rad/s}^2.$$

EVALUATE: If the applied force F is increased, F_{rod} increases and this causes n and f to increase. The angle θ changes as the amount of paper unrolls and this affects α for a given F.

10.70. **IDENTIFY:** Apply $\sum \tau_z = I\alpha_z$ to the flywheel and $\sum \vec{F} = m\vec{a}$ to the block. The target variables are the tension in the string and the acceleration of the block.

(a) SET UP: Apply $\sum \tau_z = I\alpha_z$ to the rotation of the flywheel about the axis. The free-body diagram for the flywheel is given in Figure 10.70a.

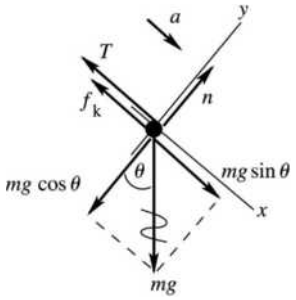


EXECUTE: The forces n and Mg act at the axis so have zero torque.
$\sum \tau_z = TR$
$TR = I\alpha_z$

Figure 10.70a

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

SET UP: Apply $\sum \vec{F} = m\vec{a}$ to the translational motion of the block. The free-body diagram for the block is given in Figure 10.70b.



EXECUTE: $\Sigma F_y = ma_y$

$n - mg\cos 36.9° = 0$

$n = mg\cos 36.9°$

$f_k = \mu_k n = \mu_k mg\cos 36.9°$

Figure 10.70b

$\sum F_x = ma_x$

$mg\sin 36.9° - T - \mu_k mg\cos 36.9° = ma$

$mg(\sin 36.9° - \mu_k \cos 36.9°) - T = ma$

But we also know that $a_{\text{block}} = R\alpha_{\text{wheel}}$, so $\alpha = a/R$. Using this in the $\sum \tau_z = I\alpha_z$ equation gives $TR = Ia/R$ and $T = (I/R^2)a$. Use this to replace T in the $\sum F_x = ma_x$ equation:

$mg(\sin 36.9° - \mu_k \cos 36.9°) - (I/R^2)a = ma$

$$a = \frac{mg(\sin 36.9° - \mu_k \cos 36.9°)}{m + I/R^2}$$

$$a = \frac{(5.00\text{ kg})(9.80\text{ m/s}^2)(\sin 36.9° - (0.25)\cos 36.9°)}{5.00\text{ kg} + 0.500\text{ kg}\cdot\text{m}^2/(0.200\text{ m})^2} = 1.12\text{ m/s}^2$$

(b) $T = \dfrac{0.500\text{ kg}\cdot\text{m}^2}{(0.200\text{ m})^2}(1.12\text{ m/s}^2) = 14.0\text{ N}$

EVALUATE: If the string is cut the block will slide down the incline with $a = g\sin 36.9° - \mu_k g\cos 36.9° = 3.92\text{ m/s}^2$. The actual acceleration is less than this because $mg\sin 36.9°$ must also accelerate the flywheel. $mg\sin 36.9° - f_k = 19.6$ N. T is less than this; there must be more force on the block directed down the incline than up the incline since the block accelerates down the incline.

10.71. **IDENTIFY:** Apply $\sum \vec{F} = m\vec{a}$ to the block and $\sum \tau_z = I\alpha_z$ to the combined disks.

SET UP: For a disk, $I_{\text{disk}} = \frac{1}{2}MR^2$, so I for the disk combination is $I = 2.25\times 10^{-3}\text{ kg}\cdot\text{m}^2$.

EXECUTE: For a tension T in the string, $mg - T = ma$ and $TR = I\alpha = I\dfrac{a}{R}$.

Eliminating T and solving for a gives $a = g\dfrac{m}{m + I/R^2} = \dfrac{g}{1 + I/mR^2}$, where m is the mass of the hanging block and R is the radius of the disk to which the string is attached.

(a) With $m = 1.50$ kg and $R = 2.50\times 10^{-2}$ m, $a = 2.88\text{ m/s}^2$.

(b) With $m = 1.50$ kg and $R = 5.00\times 10^{-2}$ m, $a = 6.13\text{ m/s}^2$.

The acceleration is larger in case (b); with the string attached to the larger disk, the tension in the string is capable of applying a larger torque.

EVALUATE: $\omega = v/R$, where v is the speed of the block and ω is the angular speed of the disks. When R is larger, in part (b), a smaller fraction of the kinetic energy resides with the disks. The block gains more speed as it falls a certain distance and therefore has a larger acceleration.

10.72. **IDENTIFY:** Apply both $\sum \vec{F} = m\vec{a}$ and $\sum \tau_z = I\alpha_z$ to the motion of the roller. Rolling without slipping means $a_{cm} = R\alpha$. Target variables are a_{cm} and f.

SET UP: The free-body diagram for the roller is given in Figure 10.72.

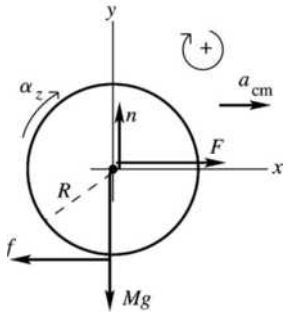

Figure 10.72

EXECUTE: Apply $\sum \vec{F} = m\vec{a}$ to the translational motion of the center of mass:

$\sum F_x = ma_x$

$F - f = Ma_{cm}$

Apply $\sum \tau_z = I\alpha_z$ to the rotation about the center of mass:

$\sum \tau_z = fR$

thin-walled hollow cylinder: $I = MR^2$

Then $\sum \tau_z = I\alpha_z$ implies $fR = MR^2\alpha$.

But $\alpha_{cm} = R\alpha$, so $f = Ma_{cm}$.

Using this in the $\sum F_x = ma_x$ equation gives $F - Ma_{cm} = Ma_{cm}$.

$a_{cm} = F/2M$, and then $f = Ma_{cm} = M(F/2M) = F/2$.

EVALUATE: If the surface were frictionless the object would slide without rolling and the acceleration would be $a_{cm} = F/M$. The acceleration is less when the object rolls.

10.73. **IDENTIFY:** Apply $\sum \vec{F} = m\vec{a}$ to each object and apply $\sum \tau_z = I\alpha_z$ to the pulley.

SET UP: Call the 75.0 N weight A and the 125 N weight B. Let T_A and T_B be the tensions in the cord to the left and to the right of the pulley. For the pulley, $I = \frac{1}{2}MR^2$, where $Mg = 80.0$ N and $R = 0.300$ m.

The 125 N weight accelerates downward with acceleration a, the 75.0 N weight accelerates upward with acceleration a and the pulley rotates clockwise with angular acceleration α, where $a = R\alpha$.

EXECUTE: $\sum \vec{F} = m\vec{a}$ applied to the 75.0 N weight gives $T_A - w_A = m_A a$. $\sum \vec{F} = m\vec{a}$ applied to the 125.0 N weight gives $w_B - T_B = m_B a$. $\sum \tau_z = I\alpha_z$ applied to the pulley gives $(T_B - T_A)R = (\frac{1}{2}MR^2)\alpha_z$ and $T_B - T_A = \frac{1}{2}Ma$. Combining these three equations gives $w_B - w_A = (m_A + m_B + M/2)a$ and

$$a = \left(\frac{w_B - w_A}{w_A + w_B + w_{\text{pulley}}/2}\right)g = \left(\frac{125\text{ N} - 75.0\text{ N}}{75.0\text{ N} + 125\text{ N} + 40.0\text{ N}}\right)g = 0.2083g.$$

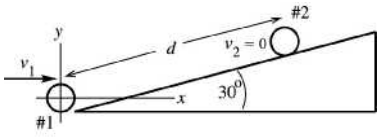
$T_A = w_A(1 + a/g) = 1.2083w_A = 90.62$ N. $T_B = w_B(1 - a/g) = 0.792w_B = 98.96$ N. $\sum \vec{F} = m\vec{a}$ applied to the pulley gives that the force F applied by the hook to the pulley is $F = T_A + T_B + w_{\text{pulley}} = 270$ N. The force the ceiling applies to the hook is 270 N.

EVALUATE: The force the hook exerts on the pulley is less than the total weight of the system, since the net effect of the motion of the system is a downward acceleration of mass.

10.74. **IDENTIFY:** This problem can be done either with conservation of energy or with $\sum \vec{F}_{\text{ext}} = m\vec{a}$. We will do it both ways.

(a) SET UP: (1) *Conservation of energy:* $K_1 + U_1 + W_{\text{other}} = K_2 + U_2$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.



Take position 1 to be the location of the disk at the base of the ramp and 2 to be where the disk momentarily stops before rolling back down, as shown in Figure 10.74a.

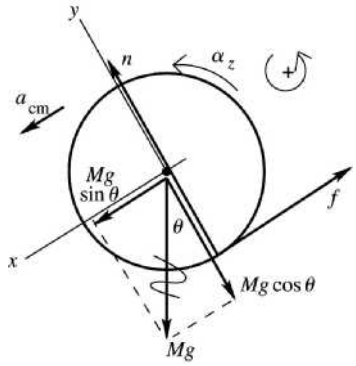
Figure 10.74a

Take the origin of coordinates at the center of the disk at position 1 and take $+y$ to be upward. Then $y_1 = 0$ and $y_2 = d\sin 30°,$ where d is the distance that the disk rolls up the ramp. "Rolls without slipping" and neglect rolling friction says $W_f = 0;$ only gravity does work on the disk, so $W_{\text{other}} = 0.$

EXECUTE: $U_1 = Mgy_1 = 0.$ $K_1 = \frac{1}{2}Mv_1^2 + \frac{1}{2}I_{\text{cm}}\omega_1^2$ (Eq. 10.8). But $\omega_1 = v_1/R$ and $I_{\text{cm}} = \frac{1}{2}MR^2,$ so $\frac{1}{2}I_{\text{cm}}\omega_1^2 = \frac{1}{2}(\frac{1}{2}MR^2)(v_1/R)^2 = \frac{1}{4}Mv_1^2.$ Thus $K_1 = \frac{1}{2}Mv_1^2 + \frac{1}{4}Mv_1^2 = \frac{3}{4}Mv_1^2.$ $U_2 = Mgy_2 = Mgd\sin 30°.$ $K_2 = 0$ (disk is at rest at point 2). Thus $\frac{3}{4}Mv_1^2 = Mgd\sin 30°,$ which gives

$$d = \frac{3v_1^2}{4g\sin 30°} = \frac{3(3.60\text{ m/s})^2}{4(9.80\text{ m/s}^2)\sin 30°} = 1.98\text{ m}.$$

SET UP: (2) *Force and acceleration:* The free-body diagram is given in Figure 10.74b.



EXECUTE: Apply $\sum F_x = ma_x$ to the translational motion of the center of mass:

$Mg\sin\theta - f = Ma_{\text{cm}}$

Apply $\sum\tau_z = I\alpha_z$ to the rotation about the center of mass:

$fR = (\frac{1}{2}MR^2)\alpha_z$

$f = \frac{1}{2}MR\alpha_z$

Figure 10.74b

But $a_{\text{cm}} = R\alpha$ in this equation gives $f = \frac{1}{2}Ma_{\text{cm}}.$ Use this in the $\sum F_x = ma_x$ equation to eliminate f:

$Mg\sin\theta - \frac{1}{2}Ma_{\text{cm}} = Ma_{\text{cm}}.$ M divides out and $\frac{3}{2}a_{\text{cm}} = g\sin\theta.$

$a_{\text{cm}} = \frac{2}{3}g\sin\theta = \frac{2}{3}(9.80\text{ m/s}^2)\sin 30° = 3.267\text{ m/s}^2.$

SET UP: Apply the constant acceleration equations to the motion of the center of mass. Note that in our coordinates the positive x-direction is down the incline. $v_{0x} = -3.60$ m/s (directed up the incline); $a_x = +3.267\text{ m/s}^2;$ $v_x = 0$ (momentarily comes to rest); and $x - x_0 = ?.$ We use the kinematics equation $v_x^2 = v_{0x}^2 + 2a_x(x - x_0)$ to solve for $x - x_0.$

EXECUTE: $$x - x_0 = -\frac{v_{0x}^2}{2a_x} = -\frac{(-3.60\text{ m/s})^2}{2(3.267\text{ m/s}^2)} = -1.98\text{ m}.$$

(b) EVALUATE: The results from the two methods agree; the disk rolls 1.98 m up the ramp before it stops. The mass M enters both in the linear inertia and in the gravity force so divides out. The mass M and radius R enter in both the rotational inertia and the gravitational torque so divide out.

10.75. **IDENTIFY:** Apply $\sum\vec{F}_{\text{ext}} = m\vec{a}_{\text{cm}}$ to the motion of the center of mass and apply $\sum\tau_z = I_{\text{cm}}\alpha_z$ to the rotation about the center of mass.

SET UP: $I = 2\left(\frac{1}{2}mR^2\right) = mR^2.$ The moment arm for T is b.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: The tension is related to the acceleration of the yo-yo by $(2m)g - T = (2m)a,$ and to the angular acceleration by $Tb = I\alpha = I\dfrac{a}{b}.$ Dividing the second equation by b and adding to the first to eliminate T yields $a = g\dfrac{2m}{(2m + I/b^2)} = g\dfrac{2}{2 + (R/b)^2},$ $\alpha = g\dfrac{2}{2b + R^2/b}.$ The tension is found by substitution into either of the two equations:

$$T = (2m)(g - a) = (2mg)\left(1 - \frac{2}{2 + (R/b)^2}\right) = 2mg\frac{(R/b)^2}{2 + (R/b)^2} = \frac{2mg}{(2(b/R)^2 + 1)}.$$

EVALUATE: $a \to 0$ when $b \to 0$. As $b \to R,$ $a \to 2g/3.$

10.76. **IDENTIFY:** Apply conservation of energy to the motion of the shell, to find its linear speed v at points A and B. Apply $\sum \vec{F} = m\vec{a}$ to the circular motion of the shell in the circular part of the track to find the normal force exerted by the track at each point. Since $r << R$ the shell can be treated as a point mass moving in a circle of radius R when applying $\sum \vec{F} = m\vec{a}.$ But as the shell rolls along the track, it has both translational and rotational kinetic energy.

SET UP: $K_1 + U_1 = K_2 + U_2.$ Let 1 be at the starting point and take $y = 0$ to be at the bottom of the track, so $y_1 = h_0.$ $K = \frac{1}{2}mv^2 + \frac{1}{2}I\omega^2.$ $I = \frac{2}{3}mr^2$ and $\omega = v/r,$ so $K = \frac{5}{6}mv^2.$ During the circular motion, $a_{\text{rad}} = v^2/R.$

EXECUTE: **(a)** $\sum \vec{F} = m\vec{a}$ at point A gives $n + mg = m\dfrac{v^2}{R}.$ The minimum speed for the shell not to fall off the track is when $n \to 0$ and $v^2 = gR.$ Let point 2 be A, so $y_2 = 2R$ and $v_2^2 = gR.$ Then $K_1 + U_1 = K_2 + U_2$ gives $mgh_0 = 2mgR + \frac{5}{6}m(gR).$ $h_0 = \left(2 + \frac{5}{6}\right)R = \frac{17}{6}R.$

(b) Let point 2 be B, so $y_2 = R.$ Then $K_1 + U_1 = K_2 + U_2$ gives $mgh_0 = mgR + \frac{5}{6}mv_2^2.$ With $h = \frac{17}{6}R$ this gives $v^2 = \frac{11}{5}gR.$ Then $\sum \vec{F} = m\vec{a}$ at B gives $n = m\dfrac{v^2}{R} = \frac{11}{5}mg.$

(c) Now $K = \frac{1}{2}mv^2$ instead of $\frac{5}{6}mv^2.$ The shell would be moving faster at A than with friction and would still make the complete loop.

(d) In part (c): $mgh_0 = mg(2R) + \frac{1}{2}mv^2.$ $h_0 = \frac{17}{6}R$ gives $v^2 = \frac{5}{3}gR.$ $\sum \vec{F} = m\vec{a}$ at point A gives $mg + n = m\dfrac{v^2}{R}$ and $n = m\left(\dfrac{v^2}{R} - g\right) = \frac{2}{3}mg.$ In part (a), $n = 0,$ since at this point gravity alone supplies the net downward force that is required for the circular motion.

EVALUATE: The normal force at A is greater when friction is absent because the speed of the shell at A is greater when friction is absent than when there is rolling without slipping.

10.77. **IDENTIFY:** Apply $\sum \tau_z = I\alpha_z$ to the cylinder or hoop. Find a for the free end of the cable and apply constant acceleration equations.

SET UP: a_{tan} for a point on the rim equals a for the free end of the cable, and $a_{\text{tan}} = R\alpha.$

EXECUTE: **(a)** $\sum \tau_z = I\alpha_z$ and $a_{\text{tan}} = R\alpha$ gives $FR = \dfrac{1}{2}MR^2\alpha = \dfrac{1}{2}MR^2\left(\dfrac{a_{\text{tan}}}{R}\right).$

$a_{\text{tan}} = \dfrac{2F}{M} = \dfrac{200\text{ N}}{4.00\text{ kg}} = 50\text{ m/s}^2.$ Distance the cable moves: $x - x_0 = v_{0x}t + \frac{1}{2}a_xt^2$

gives $50\text{ m} = \dfrac{1}{2}(50\text{ m/s}^2)t^2$ and $t = 1.41\text{ s}.$ $v_x = v_{0x} + a_xt = 0 + (50\text{ m/s}^2)(1.41\text{ s}) = 70.5\text{ m/s}.$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) For a hoop, $I = MR^2$, which is twice as large as before, so α and $a_{\tan}$ would be half as large. Therefore the time would be longer by a factor of $\sqrt{2}$. For the speed, $v_x^2 = v_{0x}^2 + 2a_x x$, in which x is the same, so v_x would be half as large since a_x is smaller.

EVALUATE: The acceleration a that is produced depends on the mass of the object but is independent of its radius. But a depends on how the mass is distributed and is different for a hoop versus a cylinder.

10.78. **IDENTIFY:** Apply $\sum \vec{F}_{\text{ext}} = m\vec{a}_{\text{cm}}$ to the motion of the center of mass and $\sum \tau_z = I_{\text{cm}}\alpha_z$ to the rotation about the center of mass.

SET UP: For a hoop, $I = MR^2$. For a solid disk, $I = \frac{1}{2}MR^2$.

EXECUTE: **(a)** Because there is no vertical motion, the tension is just the weight of the hoop: $T = Mg = (0.180 \text{ kg})(9.8 \text{ N/kg}) = 1.76 \text{ N}$.

(b) Use $\tau = I\alpha$ to find α. The torque is RT, so $\alpha = RT/I = RT/MR^2 = T/MR = Mg/MR$, so $\alpha = g/R = (9.8 \text{ m/s}^2)/(0.08 \text{ m}) = 122.5 \text{ rad/s}^2$.

(c) $a = R\alpha = 9.8 \text{ m/s}^2$

(d) T would be unchanged because the mass M is the same; α and a would be twice as great because I is now $\frac{1}{2}MR^2$.

EVALUATE: $a_{\tan}$ for a point on the rim of the hoop or disk equals a for the free end of the string. Since I is smaller for the disk, the same value of T produces a greater angular acceleration.

10.79. **IDENTIFY:** As it rolls down the rough slope, the basketball gains rotational kinetic energy as well as translational kinetic energy. But as it moves up the smooth slope, its rotational kinetic energy does not change since there is no friction.

SET UP: $I_{\text{cm}} = \frac{2}{3}mR^2$. When it rolls without slipping, $v_{\text{cm}} = R\omega$. When there is no friction the angular speed of rotation is constant. Take $+y$ upward and let $y = 0$ in the valley.

EXECUTE: **(a)** Find the speed v_{cm} in the level valley: $K_1 + U_1 = K_2 + U_2$. $y_1 = H_0$, $y_2 = 0$. $K_1 = 0$, $U_2 = 0$. Therefore, $U_1 = K_2$. $mgH_0 = \frac{1}{2}mv_{\text{cm}}^2 + \frac{1}{2}I_{\text{cm}}\omega^2$. $\frac{1}{2}I_{\text{cm}}\omega^2 = \frac{1}{2}\left(\frac{2}{3}mR^2\right)\left(\frac{v_{\text{cm}}}{R}\right)^2 = \frac{1}{3}mv_{\text{cm}}^2$, so $mgH_0 = \frac{5}{6}mv_{\text{cm}}^2$ and $v_{\text{cm}}^2 = \dfrac{6gH_0}{5}$. Find the height H it goes up the other side. Its rotational kinetic energy stays constant as it rolls on the frictionless surface. $\frac{1}{2}mv_{\text{cm}}^2 + \frac{1}{2}I_{\text{cm}}\omega^2 = \frac{1}{2}I_{\text{cm}}\omega^2 + mgH$.

$$H = \frac{v_{\text{cm}}^2}{2g} = \frac{3}{5}H_0.$$

(b) Some of the initial potential energy has been converted into rotational kinetic energy so there is less potential energy at the second height H than at the first height H_0.

EVALUATE: Mechanical energy is conserved throughout this motion. But the initial gravitational potential energy on the rough slope is not all transformed into potential energy on the smooth slope because some of that energy remains as rotational kinetic energy at the highest point on the smooth slope.

10.80. **IDENTIFY:** Use projectile motion to find the speed v the marble needs at the edge of the pit to make it to the level ground on the other side. Apply conservation of energy to the motion down the hill in order to relate the initial height to the speed v at the edge of the pit. $W_{\text{other}} = 0$ so conservation of energy gives $K_1 + U_1 = K_2 + U_2$.

SET UP: In the projectile motion the marble must travel 36 m horizontally while falling vertically 20 m. Let $+y$ be downward. For the motion down the hill, let $y_2 = 0$ so $U_2 = 0$ and $y_1 = h$. $K_1 = 0$. Rolling without slipping means $v = R\omega$. $K = \frac{1}{2}I_{\text{cm}}\omega^2 + \frac{1}{2}mv^2 = \frac{1}{2}\left(\frac{2}{5}mR^2\right)\omega^2 + \frac{1}{2}mv^2 = \frac{7}{10}mv^2$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: **(a)** Projectile motion: $v_{0y} = 0$. $a_y = 9.80 \text{ m/s}^2$. $y - y_0 = 20 \text{ m}$. $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$ gives $t = \sqrt{\dfrac{2(y - y_0)}{a_y}} = 2.02 \text{ s}$. Then $x - x_0 = v_{0x}t$ gives $v = v_{0x} = \dfrac{x - x_0}{t} = \dfrac{36 \text{ m}}{2.02 \text{ s}} = 17.8 \text{ m/s}$.

Motion down the hill: $U_1 = K_2$. $mgh = \frac{7}{10}mv^2$. $h = \dfrac{7v^2}{10g} = \dfrac{7(17.8 \text{ m/s})^2}{10(9.80 \text{ m/s}^2)} = 22.6 \text{ m}$.

(b) $\frac{1}{2}I\omega^2 = \frac{1}{5}mv^2$, independent of R. I is proportional to R^2 but ω^2 is proportional to $1/R^2$ for a given translational speed v.

(c) The object still needs $v = 17.8 \text{ m/s}$ at the bottom of the hill in order to clear the pit. But now $K_2 = \frac{1}{2}mv^2$ and $h = \dfrac{v^2}{2g} = 16.2 \text{ m}$.

EVALUATE: The answer to part (a) also does not depend on the mass of the marble. But, it does depend on how the mass is distributed within the object. The answer would be different if the object were a hollow spherical shell. In part (c) less height is needed to give the object the same translational speed because in (c) none of the energy goes into rotational motion.

10.81. **IDENTIFY:** Apply conservation of energy to the motion of the boulder.

SET UP: $K = \frac{1}{2}mv^2 + \frac{1}{2}I\omega^2$ and $v = R\omega$ when there is rolling without slipping. $I = \frac{2}{5}mR^2$.

EXECUTE: Break into two parts, the rough and smooth sections.

Rough: $mgh_1 = \frac{1}{2}mv^2 + \frac{1}{2}I\omega^2$. $mgh_1 = \dfrac{1}{2}mv^2 + \dfrac{1}{2}\left(\dfrac{2}{5}mR^2\right)\left(\dfrac{v}{R}\right)^2$. $v^2 = \dfrac{10}{7}gh_1$.

Smooth: Rotational kinetic energy does not change. $mgh_2 + \dfrac{1}{2}mv^2 + K_{\text{rot}} = \dfrac{1}{2}mv_{\text{Bottom}}^2 + K_{\text{rot}}$.

$gh_2 + \dfrac{1}{2}\left(\dfrac{10}{7}gh_1\right) = \dfrac{1}{2}v_{\text{Bottom}}^2$. $v_{\text{Bottom}} = \sqrt{\dfrac{10}{7}gh_1 + 2gh_2} = \sqrt{\dfrac{10}{7}(9.80 \text{ m/s}^2)(25 \text{ m}) + 2(9.80 \text{ m/s}^2)(25 \text{ m})} = 29.0 \text{ m/s}$.

EVALUATE: If all the hill was rough enough to cause rolling without slipping, $v_{\text{Bottom}} = \sqrt{\dfrac{10}{7}g(50 \text{ m})} = 26.5 \text{ m/s}$. A smaller fraction of the initial gravitational potential energy goes into translational kinetic energy of the center of mass than if part of the hill is smooth. If the entire hill is smooth and the boulder slides without slipping, $v_{\text{Bottom}} = \sqrt{2g(50 \text{ m})} = 31.3 \text{ m/s}$. In this case all the initial gravitational potential energy goes into the kinetic energy of the translational motion.

10.82. **IDENTIFY:** Apply conservation of energy to the motion of the ball as it rolls up the hill. After the ball leaves the edge of the cliff it moves in projectile motion and constant acceleration equations can be used.

(a) SET UP: Use conservation of energy to find the speed v_2 of the ball just before it leaves the top of the cliff. Let point 1 be at the bottom of the hill and point 2 be at the top of the hill. Take $y = 0$ at the bottom of the hill, so $y_1 = 0$ and $y_2 = 28.0 \text{ m}$.

EXECUTE: $K_1 + U_1 = K_2 + U_2$

$\frac{1}{2}mv_1^2 + \frac{1}{2}I\omega_1^2 = mgy_2 + \frac{1}{2}mv_2^2 + \frac{1}{2}I\omega_2^2$

Rolling without slipping means $\omega = v/r$ and $\frac{1}{2}I\omega^2 = \frac{1}{2}\left(\frac{2}{5}mr^2\right)(v/r)^2 = \frac{1}{5}mv^2$.

$\frac{7}{10}mv_1^2 = mgy_2 + \frac{7}{10}mv_2^2$

$v_2 = \sqrt{v_1^2 - \frac{10}{7}gy_2} = 15.26 \text{ m/s}$

SET UP: Consider the projectile motion of the ball, from just after it leaves the top of the cliff until just before it lands. Take $+y$ to be downward. Use the vertical motion to find the time in the air:

$v_{0y} = 0$, $a_y = 9.80 \text{ m/s}^2$, $y - y_0 = 28.0 \text{ m}$, $t = ?$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$ gives $t = 2.39$ s

During this time the ball travels horizontally

$x - x_0 = v_{0x}t = (15.26 \text{ m/s})(2.39 \text{ s}) = 36.5$ m.

Just before it lands, $v_y = v_{0y} + a_y t = 23.4$ m/s and $v_x = v_{0x} = 15.3$ m/s

$v = \sqrt{v_x^2 + v_y^2} = 28.0$ m/s

(b) EVALUATE: At the bottom of the hill, $\omega = v/r = (25.0 \text{ m/s})/r$. The rotation rate doesn't change while the ball is in the air, after it leaves the top of the cliff, so just before it lands $\omega = (15.3 \text{ m/s})/r$. The total kinetic energy is the same at the bottom of the hill and just before it lands, but just before it lands less of this energy is rotational kinetic energy, so the translational kinetic energy is greater.

10.83. **IDENTIFY:** Apply conservation of energy to the motion of the wheel. $K = \frac{1}{2}mv^2 + \frac{1}{2}I\omega^2$.

SET UP: No slipping means that $\omega = v/R$. Uniform density means $m_r = \lambda 2\pi R$ and $m_s = \lambda R$, where m_r is the mass of the rim and m_s is the mass of each spoke. For the wheel, $I = I_{\text{rim}} + I_{\text{spokes}}$. For each spoke, $I = \frac{1}{3}m_s R^2$.

EXECUTE: **(a)** $mgh = \frac{1}{2}mv^2 + \frac{1}{2}I\omega^2$. $I = I_{\text{rim}} + I_{\text{spokes}} = m_r R^2 + 6\left(\frac{1}{3}m_s R^2\right)$

Also, $m = m_r + m_s = 2\pi R\lambda + 6R\lambda = 2R\lambda(\pi + 3)$. Substituting into the conservation of energy equation gives $2R\lambda(\pi+3)gh = \frac{1}{2}(2R\lambda)(\pi+3)(R\omega)^2 + \frac{1}{2}\left[2\pi R\lambda R^2 + 6\left(\frac{1}{3}\lambda R R^2\right)\right]\omega^2$.

$$\omega = \sqrt{\frac{(\pi+3)gh}{R^2(\pi+2)}} = \sqrt{\frac{(\pi+3)(9.80 \text{ m/s}^2)(58.0 \text{ m})}{(0.210 \text{ m})^2(\pi+2)}} = 124 \text{ rad/s}$$ and $v = R\omega = 26.0$ m/s

(b) Doubling the density would have no effect because it does not appear in the answer. ω is inversely proportional to R so doubling the diameter would double the radius which would reduce ω by half, but $v = R\omega$ would be unchanged.

EVALUATE: Changing the masses of the rim and spokes by different amounts would alter the speed v at the bottom of the hill.

10.84. **IDENTIFY:** Apply the work-energy theorem to the motion of the basketball. $K = \frac{1}{2}mv^2 + \frac{1}{2}I\omega^2$ and $v = R\omega$.

SET UP: For a thin-walled, hollow sphere $I = \frac{2}{3}mR^2$.

EXECUTE: For rolling without slipping, the kinetic energy is $(1/2)(m + I/R^2)v^2 = (5/6)mv^2$; initially, this is 32.0 J and at the return to the bottom it is 8.0 J. Friction has done -24.0 J of work, -12.0 J each going up and down. The potential energy at the highest point was 20.0 J, so the height above the ground was $\dfrac{20.0 \text{ J}}{(0.600 \text{ kg})(9.80 \text{ m/s}^2)} = 3.40$ m.

EVALUATE: All of the kinetic energy of the basketball, translational and rotational, has been removed at the point where the basketball is at its maximum height up the ramp.

10.85. **IDENTIFY:** Apply conservation of energy to the motion of the ball. Once the ball leaves the track the ball moves in projectile motion.

SET UP: The ball has $I = \frac{2}{5}mR^2$; the silver dollar has $I = \frac{1}{2}mR^2$. For the projectile motion take $+y$ downward, so $a_x = 0$ and $a_y = +g$.

EXECUTE: **(a)** The kinetic energy of the ball when it leaves the track (when it is still rolling without slipping) is $(7/10)mv^2$ and this must be the work done by gravity, $W = mgh$, so $v = \sqrt{10gh/7}$.

The ball is in the air for a time $t = \sqrt{2y/g}$, so $x = vt = \sqrt{20hy/7}$.

(b) The answer does not depend on g, so the result should be the same on the moon.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(c) The presence of rolling friction would decrease the distance.

(d) For the dollar coin, modeled as a uniform disc, $K = (3/4)mv^2$, and so $x = \sqrt{8hy/3}$.

EVALUATE: The sphere travels a little farther horizontally, because its moment of inertia is a smaller fraction of MR^2 than for the disk. The result is independent of the mass and radius of the object but it does depend on how that mass is distributed within the object.

10.86. **IDENTIFY:** Apply $\sum \tau_z = I\alpha_z$ to the drawbridge and calculate α_z. For part (c) use conservation of energy.

SET UP: The free-body diagram for the drawbridge is given in Figure 10.86. For an axis at the lower end, $I = \frac{1}{3}ml^2$.

EXECUTE: **(a)** $\sum \tau_z = I\alpha_z$ gives $mg(4.00\text{ m})(\cos 60.0°) = \frac{1}{3}ml^2\alpha_z$ and

$$\alpha_z = \frac{3g(4.00\text{ m})(\cos 60.0°)}{(8.00\text{ m})^2} = 0.919\text{ rad/s}^2.$$

(b) α_z depends on the angle the bridge makes with the horizontal. α_z is not constant during the motion and $\omega_z = \omega_{0z} + \alpha_z t$ cannot be used.

(c) Use conservation of energy. Take $y = 0$ at the lower end of the drawbridge, so $y_1 = (4.00\text{ m})(\sin 60.0°)$ and $y_2 = 0$. $K_2 + U_2 = K_1 + U_1 + W_{\text{other}}$ gives $U_1 = K_2$, $mgy_1 = \frac{1}{2}I\omega^2$. $mgy_1 = \frac{1}{2}\left(\frac{1}{3}ml^2\right)\omega^2$ and

$$\omega = \frac{\sqrt{6gy_1}}{l} = \frac{\sqrt{6(9.80\text{ m/s}^2)(4.00\text{ m})(\sin 60.0°)}}{8.00\text{ m}} = 1.78\text{ rad/s}.$$

EVALUATE: If we incorrectly assume that α_z is constant and has the value calculated in part (a), then $\omega_z^2 = \omega_{0z}^2 + 2\alpha_z(\theta - \theta_0)$ gives $\omega = 1.39$ rad/s. The angular acceleration increases as the bridge rotates and the actual angular velocity is larger than this.

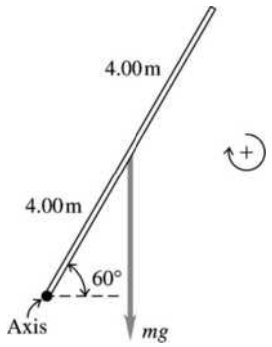


Figure 10.86

10.87. **IDENTIFY:** Use conservation of energy to relate the speed of the block to the distance it has descended. Then use a constant acceleration equation to relate these quantities to the acceleration.

SET UP: For the cylinder, $I = \frac{1}{2}M(2R)^2$, and for the pulley, $I = \frac{1}{2}MR^2$.

EXECUTE: Doing this problem using kinematics involves four unknowns (six, counting the two angular accelerations), while using energy considerations simplifies the calculations greatly. If the block and the cylinder both have speed v, the pulley has angular velocity v/R and the cylinder has angular velocity $v/2R$, the total kinetic energy is

$$K = \frac{1}{2}\left[Mv^2 + \frac{M(2R)^2}{2}(v/2R)^2 + \frac{MR^2}{2}(v/R)^2 + Mv^2\right] = \frac{3}{2}Mv^2.$$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

This kinetic energy must be the work done by gravity; if the hanging mass descends a distance y, $K = Mgy$, or $v^2 = (2/3)gy$. For constant acceleration, $v^2 = 2ay$, and comparison of the two expressions gives $a = g/3$.

EVALUATE: If the pulley were massless and the cylinder slid without rolling, $Mg = 2Ma$ and $a = g/2$. The rotation of the objects reduces the acceleration of the block.

10.88. **IDENTIFY:** The rings and the rod exert forces on each other, but there is no net force or torque on the system, and so the angular momentum will be constant.

SET UP: For the rod, $I = \frac{1}{12}ML^2$. For each ring, $I = mr^2$, where r is their distance from the axis.

EXECUTE: **(a)** As the rings slide toward the ends, the moment of inertia changes, and the final angular velocity is given by $\omega_2 = \omega_1 \dfrac{I_1}{I_2} = \omega_1 \left[\dfrac{\frac{1}{12}ML^2 + 2mr_1^2}{\frac{1}{12}ML^2 + 2mr_2^2} \right] = \omega_1 \dfrac{5.00\times10^{-4}\ \text{kg}\cdot\text{m}^2}{2.00\times10^{-3}\ \text{kg}\cdot\text{m}^2} = \dfrac{\omega_1}{4}$, so $\omega_2 = 7.5$ rev/min.

(b) The forces and torques that the rings and the rod exert on each other will vanish, but the common angular velocity will be the same, 7.5 rev/min.

EVALUATE: Note that conversion from rev/min to rad/s was not necessary. The angular velocity of the rod decreases as the rings move away from the rotation axis.

10.89. **IDENTIFY:** Apply conservation of energy to the motion of the first ball before the collision and to the motion of the second ball after the collision. Apply conservation of angular momentum to the collision between the first ball and the bar.

SET UP: The speed of the ball just before it hits the bar is $v = \sqrt{2gy} = 15.34$ m/s. Use conservation of angular momentum to find the angular velocity ω of the bar just after the collision. Take the axis at the center of the bar.

EXECUTE: $L_1 = mvr = (5.00\ \text{kg})(15.34\ \text{m/s})(2.00\ \text{m}) = 153.4\ \text{kg}\cdot\text{m}^2$

Immediately after the collision the bar and both balls are rotating together.

$L_2 = I_{\text{tot}}\omega$

$I_{\text{tot}} = \frac{1}{12}Ml^2 + 2mr^2 = \frac{1}{12}(8.00\ \text{kg})(4.00\ \text{m})^2 + 2(5.00\ \text{kg})(2.00\ \text{m})^2 = 50.67\ \text{kg}\cdot\text{m}^2$

$L_2 = L_1 = 153.4\ \text{kg}\cdot\text{m}^2$

$\omega = L_2/I_{\text{tot}} = 3.027$ rad/s

Just after the collision the second ball has linear speed $v = r\omega = (2.00\ \text{m})(3.027\ \text{rad/s}) = 6.055$ m/s and is moving upward. $\frac{1}{2}mv^2 = mgy$ gives $y = 1.87$ m for the height the second ball goes.

EVALUATE: Mechanical energy is lost in the inelastic collision and some of the final energy is in the rotation of the bar with the first ball stuck to it. As a result, the second ball does not reach the height from which the first ball was dropped.

10.90. **IDENTIFY:** As Jane grabs the helpless Tarzan from the jaws of the hippo, the angular momentum of the Jane-Vine-Tarzan system is conserved about the point at which the vine swings. Before and after that, mechanical energy is conserved.

SET UP: Take $+y$ upward and $y = 0$ at the ground. The center of mass of the vine is 4.00 m from either end. Treat the motion in three parts: (i) Jane swinging to where the vine is vertical. Apply conservation of energy. (ii) The inelastic collision between Jane and Tarzan. Apply conservation of angular momentum. (iii) The motion of the combined object after the collision. Apply conservation of energy. The vine has $I = \frac{1}{3}m_{\text{vine}}l^2$ and Jane has $I = m_{\text{Jane}}l^2$, so the system of Jane plus vine has $I_{\text{tot}} = \left(\frac{1}{3}m_{\text{vine}} + m_{\text{Jane}}\right)l^2$.

Angular momentum is $L = I\omega$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

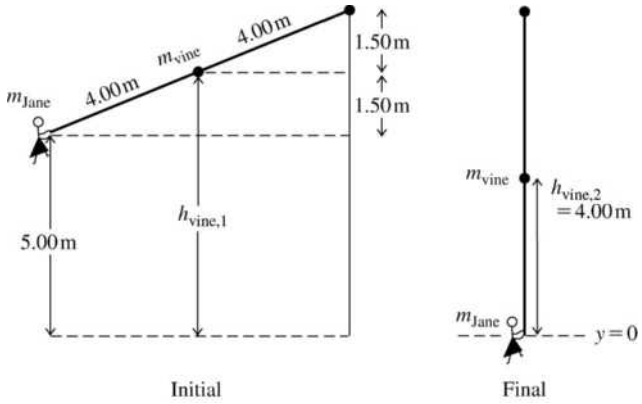

Figure 10.90a

EXECUTE: (a) The initial and final positions of Jane and the vine for the first stage of the motion are sketched in Figure 10.90a. The initial height of the center of the vine is $h_{\text{vine, 1}} = 6.50$ m and its final height is $h_{\text{vine, 2}} = 4.00$ m. Conservation of energy gives $U_1 + K_1 = U_2 + K_2$. $K_1 = 0$ so

$$m_{\text{Jane}}g(5.00\text{ m}) + m_{\text{vine}}g(6.50\text{ m}) = m_{\text{vine}}g(4.00\text{ m}) + \tfrac{1}{2}I_{\text{tot}}\omega^2.\ \omega = \sqrt{\frac{2[m_{\text{Jane}}(5.00\text{ m}) + m_{\text{vine}}(2.50\text{ m})]g}{\left(\tfrac{1}{3}m_{\text{vine}} + m_{\text{Jane}}\right)l^2}},$$

which gives $\omega = \sqrt{\dfrac{2[(60.0\text{ kg})(5.00\text{ m}) + (30.0\text{ kg})(2.50\text{ m})](9.80\text{ m/s}^2)}{\left[\tfrac{1}{3}(30.0\text{ kg}) + 60.0\text{ kg}\right](8.00\text{ m})^2}} = 1.28\text{ rad/s}.$

(b) Conservation of angular momentum applied to the collision gives $L_1 = L_2$, so $I_1\omega_1 = I_2\omega_2$.

$\omega_1 = 1.28$ rad/s.

$I_1 = \left[\tfrac{1}{3}(30.0\text{ kg}) + 60.0\text{ kg}\right](8.00\text{ m})^2 = 4.48 \times 10^3\text{ kg}\cdot\text{m}^2.$

$I_2 = I_1 + m_{\text{Tarzan}}l^2 = 4.48 \times 10^3\text{ kg}\cdot\text{m}^2 + (72.0\text{ kg})(8.00\text{ m})^2 = 9.09 \times 10^3\text{ kg}\cdot\text{m}^2.$

$$\omega_2 = \left(\frac{I_1}{I_2}\right)\omega_1 = \left(\frac{4.48 \times 10^3\text{ kg}\cdot\text{m}^2}{9.09 \times 10^3\text{ kg}\cdot\text{m}^2}\right)(1.28\text{ rad/s}) = 0.631\text{ rad/s}.$$

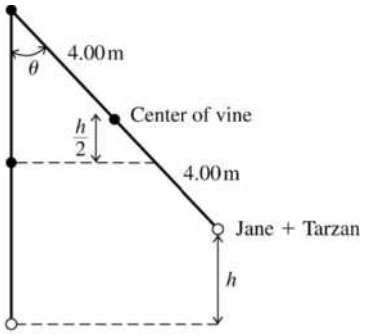

Figure 10.90b

(c) The final position of Tarzan and Jane, when they have swung to their maximum height, is shown in Figure 10.90b. If Tarzan and Jane rise to a height h, then the center of the vine rises to a height $h/2$. Conservation of energy gives $\tfrac{1}{2}I\omega^2 = (m_{\text{Jane}} + m_{\text{Tarzan}})gh + m_{\text{vine}}gh/2$, where $I = 9.09 \times 10^3\text{ kg}\cdot\text{m}^2$ and $\omega = 0.631$ rad/s, from part (b).

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

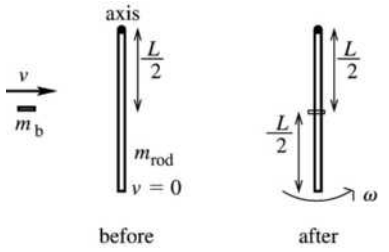
$$h=\frac{I\omega^2}{2(m_{\text{Jane}}+m_{\text{Tarzan}}+0.5m_{\text{vine}})g}=\frac{(9.09\times10^3\ \text{kg}\cdot\text{m}^2)(0.631\ \text{rad/s})^2}{2(60.0\ \text{kg}+72.0\ \text{kg}+15.0\ \text{kg})(9.80\ \text{m/s}^2)}=1.26\ \text{m}.$$

EVALUATE: Mechanical energy is lost in the inelastic collision.

10.91. **IDENTIFY:** Apply conservation of angular momentum to the collision. Linear momentum is not conserved because of the force applied to the rod at the axis. But since this external force acts at the axis, it produces no torque and angular momentum is conserved.

SET UP: The system before and after the collision is sketched in Figure 10.91.

EXECUTE: **(a)** $m_{\text{b}}=\frac{1}{4}m_{\text{rod}}$



EXECUTE: $L_1=m_{\text{b}}vr=\frac{1}{4}m_{\text{rod}}v(L/2)$

$L_1=\frac{1}{8}m_{\text{rod}}vL$

$L_2=(I_{\text{rod}}+I_{\text{b}})\omega$

$I_{\text{rod}}=\frac{1}{3}m_{\text{rod}}L^2$

$I_{\text{b}}=m_{\text{b}}r^2=\frac{1}{4}m_{\text{rod}}(L/2)^2$

$I_{\text{b}}=\frac{1}{16}m_{\text{rod}}L^2$

Figure 10.91

Thus $L_1=L_2$ gives $\frac{1}{8}m_{\text{rod}}vL=\left(\frac{1}{3}m_{\text{rod}}L^2+\frac{1}{16}m_{\text{rod}}L^2\right)\omega$

$\frac{1}{8}v=\frac{19}{48}L\omega$

$\omega=\frac{6}{19}v/L$

(b) $K_1=\frac{1}{2}mv^2=\frac{1}{8}m_{\text{rod}}v^2$

$K_2=\frac{1}{2}I\omega^2=\frac{1}{2}(I_{\text{rod}}+I_{\text{b}})\omega^2=\frac{1}{2}\left(\frac{1}{3}m_{\text{rod}}L^2+\frac{1}{16}m_{\text{rod}}L^2\right)(6v/19L)^2$

$K_2=\frac{1}{2}\left(\frac{19}{48}\right)\left(\frac{6}{19}\right)^2m_{\text{rod}}v^2=\frac{3}{152}m_{\text{rod}}v^2$

Then $\frac{K_2}{K_1}=\frac{\frac{3}{152}m_{\text{rod}}v^2}{\frac{1}{8}m_{\text{rod}}v^2}=3/19.$

EVALUATE: The collision is inelastic and $K_2<K_1$.

10.92. **IDENTIFY:** Apply Eq. (10.29).

SET UP: The door has $I=\frac{1}{3}ml^2$. The torque applied by the force is rF_{av}, where $r=l/2$.

EXECUTE: $\Sigma\tau_{\text{av}}=rF_{\text{av,}}$ and $\Delta L=rF_{\text{av}}\Delta t=rJ$. The angular velocity ω is then

$\omega=\frac{\Delta L}{I}=\frac{rF_{\text{av}}\Delta t}{I}=\frac{(l/2)F_{\text{av}}\Delta t}{\frac{1}{3}ml^2}=\frac{3}{2}\frac{F_{\text{av}}\Delta t}{ml}$, where l is the width of the door. Substitution of the given numeral values gives $\omega=0.514$ rad/s.

EVALUATE: The final angular velocity of the door is proportional to both the magnitude of the average force and also to the time it acts.

10.93. **(a) IDENTIFY:** Apply conservation of angular momentum to the collision between the bullet and the board:

SET UP: The system before and after the collision is sketched in Figure 10.93a.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

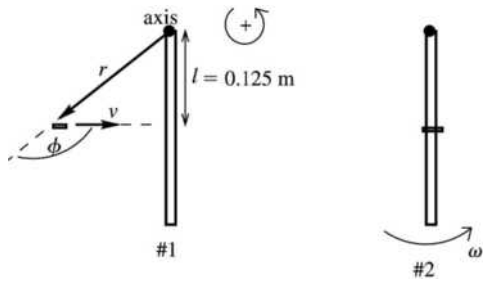


Figure 10.93a

EXECUTE: $L_1 = L_2$

$L_1 = mvr\sin\phi = mvl = (1.90\times10^{-3}\text{ kg})(360\text{ m/s})(0.125\text{ m}) = 0.0855\text{ kg}\cdot\text{m}^2/\text{s}$

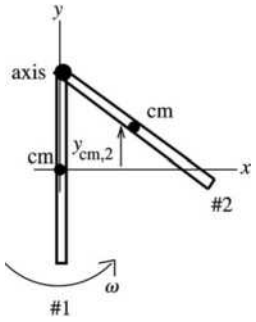
$L_2 = I_2\omega_2$

$I_2 = I_{\text{board}} + I_{\text{bullet}} = \frac{1}{3}ML^2 + mr^2$

$I_2 = \frac{1}{3}(0.750\text{ kg})(0.250\text{ m})^2 + (1.90\times10^{-3}\text{ kg})(0.125\text{ m})^2 = 0.01565\text{ kg}\cdot\text{m}^2$

Then $L_1 = L_2$ gives that $\omega_2 = \dfrac{L_1}{I_2} = \dfrac{0.0855\text{ kg}\cdot\text{m}^2/\text{s}}{0.1565\text{ kg}\cdot\text{m}^2} = 5.46\text{ rad/s}$

(b) IDENTIFY: Apply conservation of energy to the motion of the board after the collision.
SET UP: The position of the board at points 1 and 2 in its motion is shown in Figure 10.93b. Take the origin of coordinates at the center of the board and $+y$ to be upward, so $y_{\text{cm},1} = 0$ and $y_{\text{cm},2} = h$, the height being asked for.



$K_1 + U_1 + W_{\text{other}} = K_2 + U_2$

EXECUTE: Only gravity does work, so $W_{\text{other}} = 0$.

$K_1 = \frac{1}{2}I\omega^2$

$U_1 = mgy_{\text{cm},1} = 0$

$K_2 = 0$

$U_2 = mgy_{\text{cm},2} = mgh$

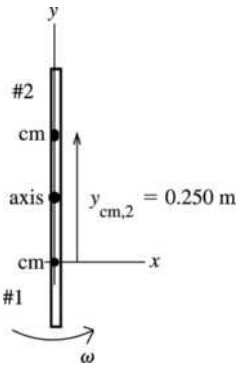
Figure 10.93b

Thus $\frac{1}{2}I\omega^2 = mgh$.

$h = \dfrac{I\omega^2}{2mg} = \dfrac{(0.01565\text{ kg}\cdot\text{m}^2)(5.46\text{ rad/s})^2}{2(0.750\text{ kg} + 1.90\times10^{-3}\text{ kg})(9.80\text{ m/s}^2)} = 0.0317\text{ m} = 3.17\text{ cm}$

(c) IDENTIFY and **SET UP:** The position of the board at points 1 and 2 in its motion is shown in Figure 10.93c.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.



Apply conservation of energy as in part (b), except now we want $y_{cm,2} = h = 0.250$ m. Solve for the ω after the collision that is required for this to happen.

Figure 10.93c

EXECUTE: $\frac{1}{2}I\omega^2 = mgh$

$$\omega = \sqrt{\frac{2mgh}{I}} = \sqrt{\frac{2(0.750\text{ kg} + 1.90\times10^{-3}\text{ kg})(9.80\text{ m/s}^2)(0.250\text{ m})}{0.01565\text{ kg}\cdot\text{m}^2}}$$

$\omega = 15.34$ rad/s

Now go back to the equation that results from applying conservation of angular momentum to the collision and solve for the initial speed of the bullet. $L_1 = L_2$ implies $m_{\text{bullet}}vl = I_2\omega_2$

$$v = \frac{I_2\omega_2}{m_{\text{bullet}}l} = \frac{(0.01565\text{ kg}\cdot\text{m}^2)(15.34\text{ rad/s})}{(1.90\times10^{-3}\text{ kg})(0.125\text{ m})} = 1010\text{ m/s}$$

EVALUATE: We have divided the motion into two separate events: the collision and the motion after the collision. Angular momentum is conserved in the collision because the collision happens quickly. The board doesn't move much until after the collision is over, so there is no gravity torque about the axis. The collision is inelastic and mechanical energy is lost in the collision. Angular momentum of the system is not conserved during this motion, due to the external gravity torque. Our answer to parts (b) and (c) say that a bullet speed of 360 m/s causes the board to swing up only a little and a speed of 1010 m/s causes it to swing all the way over.

10.94. **IDENTIFY:** Angular momentum is conserved, so $I_0\omega_0 = I_2\omega_2$.

SET UP: For constant mass the moment of inertia is proportional to the square of the radius.

EXECUTE: $R_0^2\omega_0 = R_2^2\omega_2$, or $R_0^2\omega_0 = (R_0 + \Delta R)^2(\omega_0 + \Delta\omega) = R_0^2\omega_0 + 2R_0\Delta R\omega_0 + R_0^2\Delta\omega$, where the terms in $\Delta R\Delta\omega$ and $(\Delta\omega)^2$ have been omitted. Canceling the $R_0^2\omega_0$ term gives

$$\Delta R = -\frac{R_0}{2}\frac{\Delta\omega}{\omega_0} = -1.1\text{ cm}.$$

EVALUATE: $\Delta R/R_0$ and $\Delta\omega/\omega_0$ are each very small so the neglect of terms containing $\Delta R\Delta\omega$ or $(\Delta\omega)^2$ is an accurate simplifying approximation.

10.95. **IDENTIFY:** Apply conservation of angular momentum to the collision between the bird and the bar and apply conservation of energy to the motion of the bar after the collision.

SET UP: For conservation of angular momentum take the axis at the hinge. For this axis the initial angular momentum of the bird is $m_{\text{bird}}(0.500\text{ m})v$, where $m_{\text{bird}} = 0.500$ kg and $v = 2.25$ m/s. For this axis the moment of inertia is $I = \frac{1}{3}m_{\text{bar}}L^2 = \frac{1}{3}(1.50\text{ kg})(0.750\text{ m})^2 = 0.281\text{ kg}\cdot\text{m}^2$. For conservation of energy, the gravitational potential energy of the bar is $U = m_{\text{bar}}gy_{\text{cm}}$, where y_{cm} is the height of the center of the bar. Take $y_{\text{cm},1} = 0$, so $y_{\text{cm},2} = -0.375$ m.

EXECUTE: **(a)** $L_1 = L_2$ gives $m_{\text{bird}}(0.500\text{ m})v = (\frac{1}{3}m_{\text{bar}}L^2)\omega$.

$$\omega = \frac{3m_{\text{bird}}(0.500\text{ m})v}{m_{\text{bar}}L^2} = \frac{3(0.500\text{ kg})(0.500\text{ m})(2.25\text{ m/s})}{(1.50\text{ kg})(0.750\text{ m})^2} = 2.00\text{ rad/s}.$$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) $U_1 + K_1 = U_2 + K_2$ applied to the motion of the bar after the collision gives

$\frac{1}{2}I\omega_1^2 = m_{\text{bar}}g(-0.375\text{ m}) + \frac{1}{2}I\omega_2^2$. $\omega_2 = \sqrt{\omega_1^2 + \frac{2}{I}m_{\text{bar}}g(0.375\text{ m})}$.

$$\omega_2 = \sqrt{(2.00\text{ rad/s})^2 + \frac{2}{0.281\text{ kg}\cdot\text{m}^2}(1.50\text{ kg})(9.80\text{ m/s}^2)(0.375\text{ m})} = 6.58\text{ rad/s}$$

EVALUATE: Mechanical energy is not conserved in the collision. The kinetic energy of the bar just after the collision is less than the kinetic energy of the bird just before the collision.

10.96. **IDENTIFY:** Angular momentum is conserved, since the tension in the string is in the radial direction and therefore produces no torque. Apply $\sum\vec{F} = m\vec{a}$ to the block, with $a = a_{\text{rad}} = v^2/r$.

SET UP: The block's angular momentum with respect to the hole is $L = mvr$.

EXECUTE: The tension is related to the block's mass and speed, and the radius of the circle, by $T = m\frac{v^2}{r}$.

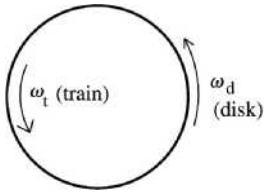
$T = mv^2\frac{1}{r} = \frac{m^2v^2}{m}\frac{r^2}{r^3} = \frac{(mvr)^2}{mr^3} = \frac{L^2}{mr^3}$. The radius at which the string breaks is

$r^3 = \frac{L^2}{mT_{\text{max}}} = \frac{(mv_1r_1)^2}{mT_{\text{max}}} = \frac{((0.250\text{ kg})(4.00\text{ m/s})(0.800\text{ m}))^2}{(0.250\text{ kg})(30.0\text{ N})}$, from which $r = 0.440$ m.

EVALUATE: Just before the string breaks the speed of the rock is $(4.00\text{ m/s})\left(\frac{0.800\text{ m}}{0.440\text{ m}}\right) = 7.27$ m/s. We can verify that $v = 7.27$ m/s and $r = 0.440$ m do give $T = 30.0$ N.

10.97. **IDENTIFY** and **SET UP:** Apply conservation of angular momentum to the system consisting of the disk and train.

SET UP: $L_1 = L_2$, counterclockwise positive. The motion is sketched in Figure 10.97.



$L_1 = 0$ (before you switch on the train's engine; both the train and the platform are at rest)
$L_2 = L_{\text{train}} + L_{\text{disk}}$

Figure 10.97

EXECUTE: The train is $\frac{1}{2}(0.95\text{ m}) = 0.475$ m from the axis of rotation, so for it

$I_t = m_tR_t^2 = (1.20\text{ kg})(0.475\text{ m})^2 = 0.2708\text{ kg}\cdot\text{m}^2$

$\omega_{\text{rel}} = v_{\text{rel}}/R_t = (0.600\text{ m/s})/0.475\text{ m} = 1.263$ rad/s

This is the angular velocity of the train relative to the disk. Relative to the earth $\omega_t = \omega_{\text{rel}} + \omega_d$.

Thus $L_{\text{train}} = I_t\omega_t = I_t(\omega_{\text{rel}} + \omega_d)$.

$L_2 = L_1$ says $L_{\text{disk}} = -L_{\text{train}}$

$L_{\text{disk}} = I_d\omega_d$, where $I_d = \frac{1}{2}m_dR_d^2$

$\frac{1}{2}m_dR_d^2\omega_d = -I_t(\omega_{\text{rel}} + \omega_d)$

$$\omega_d = -\frac{I_t\omega_{\text{rel}}}{\frac{1}{2}m_dR_d^2 + I_t} = -\frac{(0.2708\text{ kg}\cdot\text{m}^2)(1.263\text{ rad/s})}{\frac{1}{2}(7.00\text{ kg})(0.500\text{ m})^2 + 0.2708\text{ kg}\cdot\text{m}^2} = -0.30\text{ rad/s}.$$

EVALUATE: The minus sign tells us that the disk is rotating clockwise relative to the earth. The disk and train rotate in opposite directions, since the total angular momentum of the system must remain zero. Note that we applied $L_1 = L_2$ in an inertial frame attached to the earth.

10.98. **IDENTIFY:** Apply conservation of momentum to the system of the runner and turntable.

SET UP: Let the positive sense of rotation be the direction the turntable is rotating initially.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: The initial angular momentum is $I\omega_1 - mRv_1$, with the minus sign indicating that runner's motion is opposite the motion of the part of the turntable under his feet. The final angular momentum is $\omega_2(I + mR^2)$, so $\omega_2 = \dfrac{I\omega_1 - mRv_1}{I + mR^2}$.

$$\omega_2 = \frac{(80\ \text{kg}\cdot\text{m}^2)(0.200\ \text{rad/s}) - (55.0\ \text{kg})(3.00\ \text{m})(2.8\ \text{m/s})}{(80\ \text{kg}\cdot\text{m}^2) + (55.0\ \text{kg})(3.00\ \text{m})^2} = -0.776\ \text{rad/s}.$$

EVALUATE: The minus sign indicates that the turntable has reversed its direction of motion. This happened because the man had the larger magnitude of angular momentum initially.

10.99. **IDENTIFY:** Follow the method outlined in the hint.

SET UP: $J = m\Delta v_{\text{cm}}$. $\Delta L = J(x - x_{\text{cm}})$.

EXECUTE: The velocity of the center of mass will change by $\Delta v_{\text{cm}} = J/m$ and the angular velocity will change by $\Delta\omega = \dfrac{J(x - x_{\text{cm}})}{I}$. The change in velocity of the end of the bat will then be $\Delta v_{\text{end}} = \Delta v_{\text{cm}} - \Delta\omega x_{\text{cm}} = \dfrac{J}{m} - \dfrac{J(x - x_{\text{cm}})x_{\text{cm}}}{I}$. Setting $\Delta v_{\text{end}} = 0$ allows cancellation of J and gives $I = (x - x_{\text{cm}})x_{\text{cm}}m$, which when solved for x is $x = \dfrac{I}{x_{\text{cm}}m} + x_{\text{cm}} = \dfrac{(5.30\times10^{-2}\ \text{kg}\cdot\text{m}^2)}{(0.600\ \text{m})(0.800\ \text{kg})} + (0.600\ \text{m}) = 0.710\ \text{m}$.

EVALUATE: The center of percussion is farther from the handle than the center of mass.

10.100. **IDENTIFY:** Apply conservation of energy to the motion of the ball.

SET UP: In relating $\frac{1}{2}mv_{\text{cm}}^2$ and $\frac{1}{2}I\omega^2$, instead of $v_{\text{cm}} = R\omega$ use the relation derived in part (a). $I = \frac{2}{5}mR^2$.

EXECUTE: **(a)** Consider the sketch in Figure 10.100.

The distance from the center of the ball to the midpoint of the line joining the points where the ball is in contact with the rails is $\sqrt{R^2 - (d/2)^2}$, so $v_{\text{cm}} = \omega\sqrt{R^2 - d^2/4}$. When $d = 0$, this reduces to $v_{\text{cm}} = \omega R$, the same as rolling on a flat surface. When $d = 2R$, the rolling radius approaches zero, and $v_{\text{cm}} \to 0$ for any ω.

(b) $K = \dfrac{1}{2}mv^2 + \dfrac{1}{2}I\omega^2 = \dfrac{1}{2}\left[mv_{\text{cm}}^2 + (2/5)mR^2\left(\dfrac{v_{\text{cm}}}{\sqrt{R^2 - (d^2/4)}}\right)^2\right] = \dfrac{mv_{\text{cm}}^2}{10}\left[5 + \dfrac{2}{(1 - d^2/4R^2)}\right]$

Setting this equal to mgh and solving for v_{cm} gives the desired result.

(c) The denominator in the square root in the expression for v_{cm} is larger than for the case $d = 0$, so v_{cm} is smaller. For a given speed, ω is larger than in the $d = 0$ case, so a larger fraction of the kinetic energy is rotational, and the translational kinetic energy, and hence v_{cm}, is smaller.

(d) Setting the expression in part (b) equal to 0.95 of that of the $d = 0$ case and solving for the ratio d/R gives $d/R = 1.05$. Setting the ratio equal to 0.995 gives $d/R = 0.37$.

EVALUATE: If we set $d = 0$ in the expression in part (b), $v_{\text{cm}} = \sqrt{\dfrac{10gh}{7}}$, the same as for a sphere rolling down a ramp. When $d \to 2R$, the expression gives $v_{\text{cm}} = 0$, as it should.

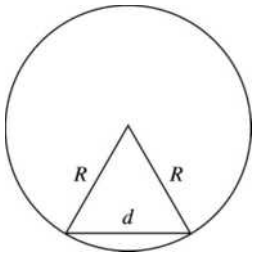


Figure 10.100

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

10.101. **IDENTIFY:** Apply $\sum \vec{F}_{\text{ext}} = m\vec{a}_{\text{cm}}$ and $\sum \tau_z = I_{\text{cm}}\alpha_z$ to the motion of the cylinder. Use constant acceleration equations to relate a_x to the distance the object travels. Use the work-energy theorem to find the work done by friction.

SET UP: The cylinder has $I_{\text{cm}} = \frac{1}{2}MR^2$.

EXECUTE: **(a)** The free-body diagram is sketched in Figure 10.101. The friction force is $f = \mu_k n = \mu_k Mg$, so $a = \mu_k g$. The magnitude of the angular acceleration is $\frac{fR}{I} = \frac{\mu_k MgR}{(1/2)MR^2} = \frac{2\mu_k g}{R}$.

(b) Setting $v = at = \omega R = (\omega_0 - \alpha t)R$ and solving for t gives $t = \frac{R\omega_0}{a + R\alpha} = \frac{R\omega_0}{\mu_k g + 2\mu_k g} = \frac{R\omega_0}{3\mu_k g}$,

and $d = \frac{1}{2}at^2 = \frac{1}{2}(\mu_k g)\left(\frac{R\omega_0}{3\mu_k g}\right)^2 = \frac{R^2\omega_0^2}{18\mu_k g}$.

(c) The final kinetic energy is $(3/4)Mv^2 = (3/4)M(at)^2$, so the change in kinetic energy is

$$\Delta K = \frac{3}{4}M\left(\mu_k g\frac{R\omega_0}{3\mu_k g}\right)^2 - \frac{1}{4}MR^2\omega_0^2 = -\frac{1}{6}MR^2\omega_0^2.$$

EVALUATE: The fraction of the initial kinetic energy that is removed by friction work is $\frac{\frac{1}{6}MR\omega_0^2}{\frac{1}{4}MR\omega_0^2} = \frac{2}{3}$.

This fraction is independent of the initial angular speed ω_0.

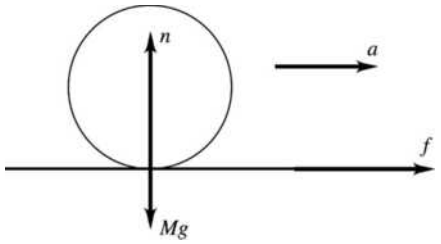

Figure 10.101

10.102. **IDENTIFY:** The vertical forces must sum to zero. Apply Eq. (10.33).

SET UP: Denote the upward forces that the hands exert as F_L and F_R. $\tau = (F_L - F_R)r$, where $r = 0.200$ m.

EXECUTE: The conditions that F_L and F_R must satisfy are $F_L + F_R = w$ and $F_L - F_R = \Omega\frac{I\omega}{r}$, where the second equation is $\tau = \Omega L$, divided by r. These two equations can be solved for the forces by first adding and then subtracting, yielding $F_L = \frac{1}{2}\left(w + \Omega\frac{I\omega}{r}\right)$ and $F_R = \frac{1}{2}\left(w - \Omega\frac{I\omega}{r}\right)$. Using the values

$w = mg = (8.00\text{ kg})(9.80\text{ m/s}^2) = 78.4$ N and

$\frac{I\omega}{r} = \frac{(8.00\text{ kg})(0.325\text{ m})^2(5.00\text{ rev/s}\times 2\pi\text{ rad/rev})}{(0.200\text{ m})} = 132.7\text{ kg}\cdot\text{m/s}$ gives

$F_L = 39.2\text{ N} + \Omega(66.4\text{ N}\cdot\text{s})$, $F_R = 39.2\text{ N} - \Omega(66.4\text{ N}\cdot\text{s})$.

(a) $\Omega = 0$, $F_L = F_R = 39.2$ N.

(b) $\Omega = 0.05$ rev/s $= 0.314$ rad/s, $F_L = 60.0$ N, $F_R = 18.4$ N.

(c) $\Omega = 0.3$ rev/s $= 1.89$ rad/s, $F_L = 165$ N, $F_R = -86.2$ N, with the minus sign indicating a downward force.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(d) $F_R = 0$ gives $\Omega = \dfrac{39.2\ \text{N}}{66.4\ \text{N}\cdot\text{s}} = 0.590$ rad/s, which is 0.0940 rev/s.

EVALUATE: The larger the precession rate Ω, the greater the torque on the wheel and the greater the difference between the forces exerted by the two hands.

10.103. **IDENTIFY:** The answer to part (a) can be taken from the solution to Problem 10.96. The work-energy theorem says $W = \Delta K$.

SET UP: Problem 10.96 uses conservation of angular momentum to show that $r_1 v_1 = r_2 v_2$.

EXECUTE: **(a)** $T = mv_1^2 r_1^2 / r^3$.

(b) $\vec{\boldsymbol{T}}$ and $d\vec{\boldsymbol{r}}$ are always antiparallel. $\vec{\boldsymbol{T}} \cdot d\vec{\boldsymbol{r}} = -T\,dr$.

$$W = -\int_{r_1}^{r_2} T\,dr = mv_1^2 r_1^2 \int_{r_2}^{r_1} \frac{dr}{r^3} = \frac{mv_1^2}{2} r_1^2 \left[\frac{1}{r_2^2} - \frac{1}{r_1^2}\right].$$

(c) $v_2 = v_1(r_1/r_2)$, so $\Delta K = \dfrac{1}{2} m(v_2^2 - v_1^2) = \dfrac{mv_1^2}{2}[(r_1/r_2)^2 - 1]$, which is the same as the work found in part (b).

EVALUATE: The work done by T is positive, since $\vec{\boldsymbol{T}}$ is toward the hole in the surface and the block moves toward the hole. Positive work means the kinetic energy of the object increases.

11

EQUILIBRIUM AND ELASTICITY

11.1. **IDENTIFY:** Use Eq. (11.3) to calculate x_{cm}. The center of gravity of the bar is at its center and it can be treated as a point mass at that point.

SET UP: Use coordinates with the origin at the left end of the bar and the $+x$ axis along the bar. $m_1 = 0.120$ kg, $m_2 = 0.055$ kg, $m_3 = 0.110$ kg.

EXECUTE: $x_{cm} = \dfrac{m_1x_1 + m_2x_2 + m_3x_3}{m_1 + m_2 + m_3} = \dfrac{(0.120 \text{ kg})(0.250 \text{ m}) + 0 + (0.110 \text{ kg})(0.500 \text{ m})}{0.120 \text{ kg} + 0.055 \text{ kg} + 0.110 \text{ kg}} = 0.298 \text{ m}$. The fulcrum should be placed 29.8 cm to the right of the left-hand end.

EVALUATE: The mass at the right-hand end is greater than the mass at the left-hand end. So the center of gravity is to the right of the center of the bar.

11.2. **IDENTIFY:** Use Eq. (11.3) to calculate x_{cm} of the composite object.

SET UP: Use coordinates where the origin is at the original center of gravity of the object and $+x$ is to the right. With the 1.50 g mass added, $x_{cm} = -2.20$ cm, $m_1 = 5.00$ g and $m_2 = 1.50$ g. $x_1 = 0$.

EXECUTE: $x_{cm} = \dfrac{m_2x_2}{m_1 + m_2}$. $x_2 = \left(\dfrac{m_1 + m_2}{m_2}\right)x_{cm} = \left(\dfrac{5.00 \text{ g} + 1.50 \text{ g}}{1.50 \text{ g}}\right)(-2.20 \text{ cm}) = -9.53 \text{ cm}$.

The additional mass should be attached 9.53 cm to the left of the original center of gravity.

EVALUATE: The new center of gravity is somewhere between the added mass and the original center of gravity.

11.3. **IDENTIFY:** Treat the rod and clamp as point masses. The center of gravity of the rod is at its midpoint, and we know the location of the center of gravity of the rod-clamp system.

SET UP: $x_{cm} = \dfrac{m_1x_1 + m_2x_2}{m_1 + m_2}$.

EXECUTE: $1.20 \text{ m} = \dfrac{(1.80 \text{ kg})(1.00 \text{ m}) + (2.40 \text{ kg})x_2}{1.80 \text{ kg} + 2.40 \text{ kg}}$.

$$x_2 = \frac{(1.20 \text{ m})(1.80 \text{ kg} + 2.40 \text{ kg}) - (1.80 \text{ kg})(1.00 \text{ m})}{2.40 \text{ kg}} = 1.35 \text{ m}$$

EVALUATE: The clamp is to the right of the center of gravity of the system, so the center of gravity of the system lies between that of the rod and the clamp, which is reasonable.

11.4. **IDENTIFY:** Apply the first and second conditions for equilibrium to the trap door.

SET UP: For $\sum \tau_z = 0$ take the axis at the hinge. Then the torque due to the applied force must balance the torque due to the weight of the door.

EXECUTE: **(a)** The force is applied at the center of gravity, so the applied force must have the same magnitude as the weight of the door, or 300 N. In this case the hinge exerts no force.

(b) With respect to the hinges, the moment arm of the applied force is twice the distance to the center of mass, so the force has half the magnitude of the weight, or 150 N.

The hinges supply an upward force of $300 \text{ N} - 150 \text{ N} = 150$ N.

EVALUATE: Less force must be applied when it is applied farther from the hinges.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

11.5. **IDENTIFY:** Apply $\sum \tau_z = 0$ to the ladder.

SET UP: Take the axis to be at point A. The free-body diagram for the ladder is given in Figure 11.5. The torque due to F must balance the torque due to the weight of the ladder.

EXECUTE: $F(8.0\text{ m})\sin 40° = (2800\text{ N})(10.0\text{ m})$, so $F = 5.45$ kN.

EVALUATE: The force required is greater than the weight of the ladder, because the moment arm for F is less than the moment arm for w.

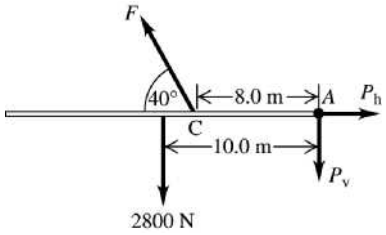

Figure 11.5

11.6. **IDENTIFY:** Apply the first and second conditions of equilibrium to the board.

SET UP: The free-body diagram for the board is given in Figure 11.6. Since the board is uniform its center of gravity is 1.50 m from each end. Apply $\sum F_y = 0$, with $+y$ upward. Apply $\sum \tau_z = 0$ with the axis at the end where the first person applies a force and with counterclockwise torques positive.

EXECUTE: $\sum F_y = 0$ gives $F_1 + F_2 - w = 0$ and $F_2 = w - F_1 = 160\text{ N} - 60\text{ N} = 100\text{ N}$. $\sum \tau_z = 0$ gives $F_2 x - w(1.50\text{ m}) = 0$ and $x = \left(\frac{w}{F_2}\right)(1.50\text{ m}) = \left(\frac{160\text{ N}}{100\text{ N}}\right)(1.50\text{ m}) = 2.40\text{ m}$. The other person lifts with a force of 100 N at a point 2.40 m from the end where the other person lifts.

EVALUATE: By considering the axis at the center of gravity we can see that a larger force is applied by the person who pushes closer to the center of gravity.

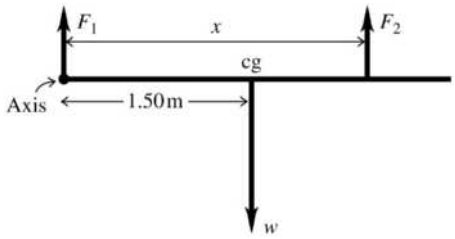

Figure 11.6

11.7. **IDENTIFY:** Apply $\sum F_y = 0$ and $\sum \tau_z = 0$ to the board.

SET UP: Let $+y$ be upward. Let x be the distance of the center of gravity of the motor from the end of the board where the 400 N force is applied.

EXECUTE: **(a)** If the board is taken to be massless, the weight of the motor is the sum of the applied forces, 1000 N. The motor is a distance $\frac{(2.00\text{ m})(600\text{ N})}{(1000\text{ N})} = 1.20\text{ m}$ from the end where the 400 N force is applied, and so is 0.800 m from the end where the 600 N force is applied.

(b) The weight of the motor is $400\text{ N} + 600\text{ N} - 200\text{ N} = 800\text{ N}$. Applying $\sum \tau_z = 0$ with the axis at the end of the board where the 400 N acts gives $(600\text{ N})(2.00\text{ m}) = (200\text{ N})(1.00\text{ m}) + (800\text{ N})x$ and $x = 1.25$ m. The center of gravity of the motor is 0.75 m from the end of the board where the 600 N force is applied.

EVALUATE: The motor is closest to the end of the board where the larger force is applied.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

11.8. **IDENTIFY:** Apply the first and second conditions of equilibrium to the shelf.
SET UP: The free-body diagram for the shelf is given in Figure 11.8. Take the axis at the left-hand end of the shelf and let counterclockwise torque be positive. The center of gravity of the uniform shelf is at its center.
EXECUTE: **(a)** $\sum \tau_z = 0$ gives $-w_t(0.200\text{ m}) - w_s(0.300\text{ m}) + T_2(0.400\text{ m}) = 0.$

$$T_2 = \frac{(25.0\text{ N})(0.200\text{ m}) + (50.0\text{ N})(0.300\text{ m})}{0.400\text{ m}} = 50.0\text{ N}$$

$\sum F_y = 0$ gives $T_1 + T_2 - w_t - w_s = 0$ and $T_1 = 25.0$ N. The tension in the left-hand wire is 25.0 N and the tension in the right-hand wire is 50.0 N.
EVALUATE: We can verify that $\sum \tau_z = 0$ is zero for any axis, for example for an axis at the right-hand end of the shelf.

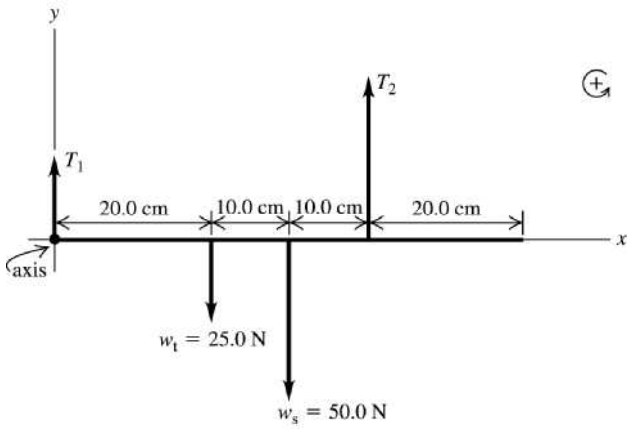

Figure 11.8

11.9. **IDENTIFY:** Apply the conditions for equilibrium to the bar. Set each tension equal to its maximum value.
SET UP: Let cable A be at the left-hand end. Take the axis to be at the left-hand end of the bar and x be the distance of the weight w from this end. The free-body diagram for the bar is given in Figure 11.9.
EXECUTE: **(a)** $\sum F_y = 0$ gives $T_A + T_B - w - w_{\text{bar}} = 0$ and

$w = T_A + T_B - w_{\text{bar}} = 500.0\text{ N} + 400.0\text{ N} - 350.0\text{ N} = 550\text{ N}.$

(b) $\sum \tau_z = 0$ gives $T_B(1.50\text{ m}) - wx - w_{\text{bar}}(0.750\text{ m}) = 0.$

$x = \dfrac{T_B(1.50\text{ m}) - w_{\text{bar}}(0.750\text{ m})}{w} = \dfrac{(400.0\text{ N})(1.50\text{ m}) - (350\text{ N})(0.750\text{ m})}{550\text{ N}} = 0.614\text{ m}.$ The weight should be placed 0.614 m from the left-hand end of the bar (cable A).
EVALUATE: If the weight is moved to the left, T_A exceeds 500.0 N and if it is moved to the right T_B exceeds 400.0 N.

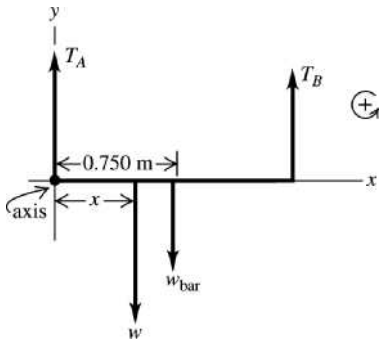

Figure 11.9

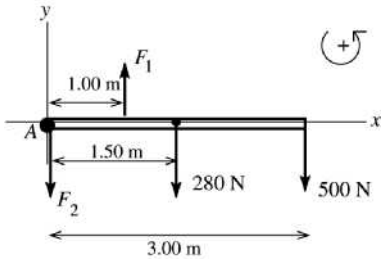
11.10. **IDENTIFY:** Apply the first and second conditions for equilibrium to the ladder.
SET UP: Let n_2 be the upward normal force exerted by the ground and let n_1 be the horizontal normal force exerted by the wall. The maximum possible static friction force that can be exerted by the ground is $\mu_s n_2$.
EXECUTE: **(a)** Since the wall is frictionless, the only vertical forces are the weights of the man and the ladder, and the normal force n_2. For the vertical forces to balance, $n_2 = w_l + w_m = 160\text{ N} + 740\text{ N} = 900\text{ N}$, and the maximum frictional force is $\mu_s n_2 = (0.40)(900\text{N}) = 360\text{N}$.
(b) Note that the ladder makes contact with the wall at a height of 4.0 m above the ground. Balancing torques about the point of contact with the ground,
$(4.0\text{ m})n_1 = (1.5\text{ m})(160\text{ N}) + (1.0\text{ m})(3/5)(740\text{ N}) = 684\text{ N}\cdot\text{m}$, so $n_1 = 171.0\text{ N}$. This horizontal force must be balanced by the friction force, which must then be 170 N to two figures.
(c) Setting the friction force, and hence n_1, equal to the maximum of 360 N and solving for the distance x along the ladder, $(4.0\text{ m})(360\text{ N}) = (1.50\text{ m})(160\text{ N}) + x(3/5)(740\text{ N})$, so $x = 2.7\text{ m}$.
EVALUATE: The normal force exerted by the ground doesn't change as the man climbs up the ladder. But the normal force exerted by the wall and the friction force exerted by the ground both increase as he moves up the ladder.

11.11. **IDENTIFY:** The system of the person and diving board is at rest so the two conditions of equilibrium apply.
(a) SET UP: The free-body diagram for the diving board is given in Figure 11.11. Take the origin of coordinates at the left-hand end of the board (point *A*).



$\vec{F}_1$ is the force applied at the support point and $\vec{F}_2$ is the force at the end that is held down.

Figure 11.11

EXECUTE: $\sum\tau_A = 0$ gives $+F_1(1.0\text{ m}) - (500\text{ N})(3.00\text{ m}) - (280\text{ N})(1.50\text{ m}) = 0$

$$F_1 = \frac{(500\text{ N})(3.00\text{ m}) + (280\text{ N})(1.50\text{ m})}{1.00\text{ m}} = 1920\text{ N}$$

(b) $\sum F_y = ma_y$

$F_1 - F_2 - 280\text{ N} - 500\text{ N} = 0$

$F_2 = F_1 - 280\text{ N} - 500\text{ N} = 1920\text{ N} - 280\text{ N} - 500\text{ N} = 1140\text{ N}$

EVALUATE: We can check our answers by calculating the net torque about some point and checking that $\sum\tau_z = 0$ for that point also. Net torque about the right-hand end of the board:
$(1140\text{ N})(3.00\text{ m}) + (280\text{ N})(1.50\text{ m}) - (1920\text{ N})(2.00\text{ m}) = 3420\text{ N}\cdot\text{m} + 420\text{ N}\cdot\text{m} - 3840\text{ N}\cdot\text{m} = 0$, which checks.

11.12. **IDENTIFY:** Apply the first and second conditions of equilibrium to the beam.
SET UP: The boy exerts a downward force on the beam that is equal to his weight.
EXECUTE: **(a)** The graphs are given in Figure 11.12.
(b) $x = 6.25\text{ m}$ when $F_A = 0$, which is 1.25 m beyond point *B*.
(c) Take torques about the right end. When the beam is just balanced, $F_A = 0$, so $F_B = 900\text{ N}$.
The distance that point *B* must be from the right end is then $\dfrac{(300\text{ N})(4.50\text{ m})}{(900\text{ N})} = 1.50\text{ m}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: When the beam is on the verge of tipping it starts to lift off the support A and the normal force F_A exerted by the support goes to zero.

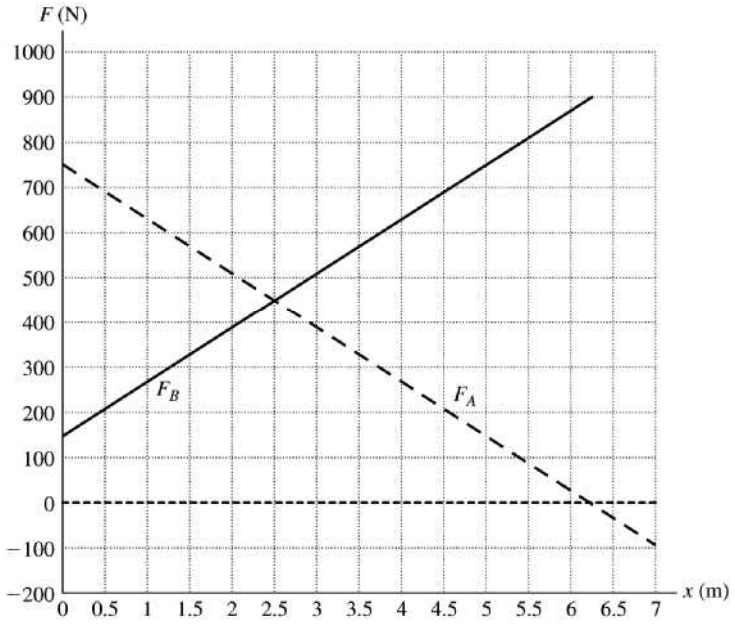


Figure 11.12

11.13. **IDENTIFY:** Apply the first and second conditions of equilibrium to the strut.

(a) SET UP: The free-body diagram for the strut is given in Figure 11.13a. Take the origin of coordinates at the hinge (point A) and $+y$ upward. Let F_{h} and F_{v} be the horizontal and vertical components of the force $\vec{F}$ exerted on the strut by the pivot. The tension in the vertical cable is the weight w of the suspended object. The weight w of the strut can be taken to act at the center of the strut. Let L be the length of the strut.

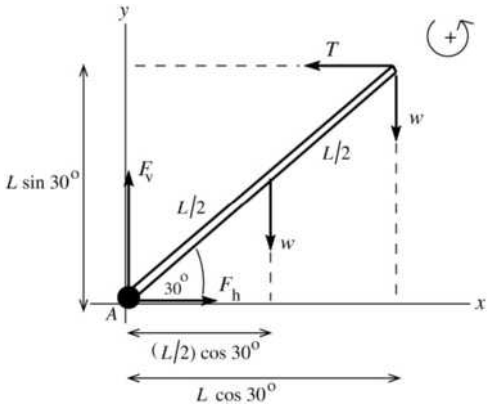

Figure 11.13a

EXECUTE:

$\sum F_y = ma_y$

$F_{\text{v}} - w - w = 0$

$F_{\text{v}} = 2w$

Sum torques about point A. The pivot force has zero moment arm for this axis and so doesn't enter into the torque equation.

$\tau_A = 0$

$TL\sin 30.0° - w((L/2)\cos 30.0°) - w(L\cos 30.0°) = 0$

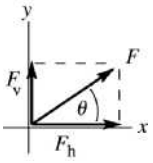
$T\sin 30.0° - (3w/2)\cos 30.0° = 0$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$T = \frac{3w\cos 30.0°}{2\sin 30.0°} = 2.60w$$

Then $\sum F_x = ma_x$ implies $T - F_h = 0$ and $F_h = 2.60w$.

We now have the components of $\vec{F}$ so can find its magnitude and direction (Figure 11.13b).



$$F = \sqrt{F_h^2 + F_v^2}$$

$$F = \sqrt{(2.60w)^2 + (2.00w)^2}$$

$$F = 3.28w$$

$$\tan\theta = \frac{F_v}{F_h} = \frac{2.00w}{2.60w}$$

$$\theta = 37.6°$$

Figure 11.13b

(b) SET UP: The free-body diagram for the strut is given in Figure 11.13c.

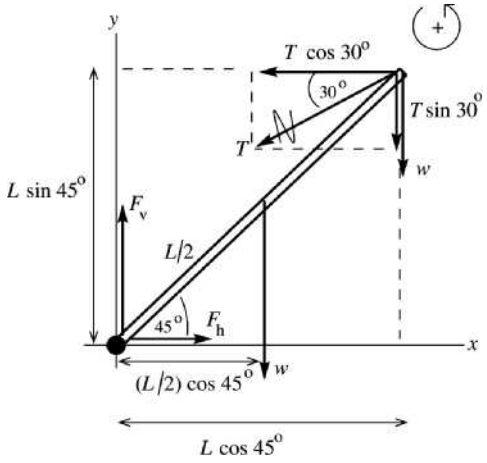


Figure 11.13c

The tension T has been replaced by its x and y components. The torque due to T equals the sum of the torques of its components, and the latter are easier to calculate.

EXECUTE: $\sum \tau_A = 0 + (T\cos 30.0°)(L\sin 45.0°) - (T\sin 30.0°)(L\cos 45.0°) - w((L/2)\cos 45.0°) - w(L\cos 45.0°) = 0$

The length L divides out of the equation. The equation can also be simplified by noting that $\sin 45.0° = \cos 45.0°$.

Then $T(\cos 30.0° - \sin 30.0°) = 3w/2$.

$$T = \frac{3w}{2(\cos 30.0° - \sin 30.0°)} = 4.10w$$

$$\sum F_x = ma_x$$

$$F_h - T\cos 30.0° = 0$$

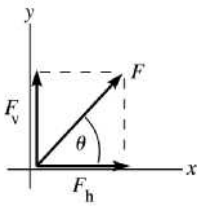
$$F_h = T\cos 30.0° = (4.10w)(\cos 30.0°) = 3.55w$$

$$\sum F_y = ma_y$$

$$F_v - w - w - T\sin 30.0° = 0$$

$$F_v = 2w + (4.10w)\sin 30.0° = 4.05w$$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.



From Figure 11.13d,

$$F = \sqrt{F_h^2 + F_v^2}$$

$$F = \sqrt{(3.55w)^2 + (4.05w)^2} = 5.39w$$

$$\tan\theta = \frac{F_v}{F_h} = \frac{4.05w}{3.55w}$$

$$\theta = 48.8°$$

Figure 11.13d

EVALUATE: In each case the force exerted by the pivot does not act along the strut. Consider the net torque about the upper end of the strut. If the pivot force acted along the strut, it would have zero torque about this point. The two forces acting at this point also have zero torque and there would be one nonzero torque, due to the weight of the strut. The net torque about this point would then not be zero, violating the second condition of equilibrium.

11.14. **IDENTIFY:** Apply the first and second conditions of equilibrium to the beam.

SET UP: The free-body diagram for the beam is given in Figure 11.14. H_v and H_h are the vertical and horizontal components of the force exerted on the beam at the wall (by the hinge). Since the beam is uniform, its center of gravity is 2.00 m from each end. The angle θ has $\cos\theta = 0.800$ and $\sin\theta = 0.600$. The tension T has been replaced by its x and y components.

EXECUTE: **(a)** H_v, H_h and $T_x = T\cos\theta$ all produce zero torque. $\sum\tau_z = 0$ gives

$$-w(2.00\text{ m}) - w_{load}(4.00\text{ m}) + T\sin\theta(4.00\text{ m}) = 0 \text{ and } T = \frac{(150\text{ N})(2.00\text{ m}) + (300\text{ N})(4.00\text{ m})}{(4.00\text{ m})(0.600)} = 625\text{ N}.$$

(b) $\sum F_x = 0$ gives $H_h - T\cos\theta = 0$ and $H_h = (625\text{ N})(0.800) = 500\text{ N}$. $\sum F_y = 0$ gives

$$H_v - w - w_{load} + T\sin\theta = 0 \text{ and } H_v = w + w_{load} - T\sin\theta = 150\text{ N} + 300\text{ N} - (625\text{ N})(0.600) = 75\text{ N}.$$

EVALUATE: For an axis at the right-hand end of the beam, only w and H_v produce torque. The torque due to w is counterclockwise so the torque due to H_v must be clockwise. To produce a clockwise torque, H_v must be upward, in agreement with our result from $\sum F_y = 0$.

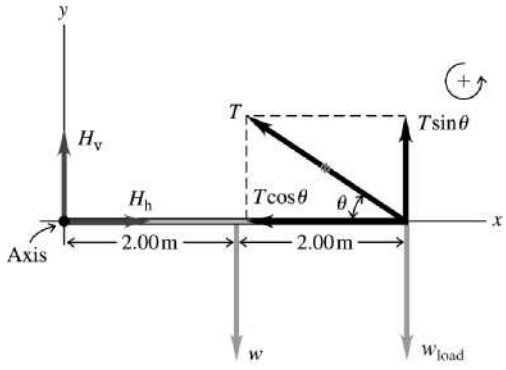


Figure 11.14

11.15. **IDENTIFY:** The athlete is in equilibrium, so the forces and torques on him must balance. The target variables are the forces on his hands and feet due to the floor.

SET UP: The free-body diagram is given in Figure 11.15. F_f is the force on each foot and F_h is the force on each hand. Use coordinates as shown. Take the pivot at his feet and let counterclockwise torques be positive. $\sum\tau_z = 0$ and $\sum F_y = 0$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

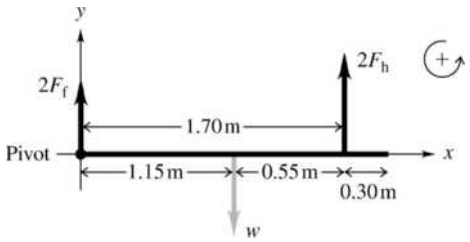

Figure 11.15

EXECUTE: $\sum\tau_z = 0$ gives $(2F_h)(1.70\text{ m}) - w(1.15\text{ m}) = 0$. Solving for F_h gives

$F_h = w\dfrac{1.15\text{ m}}{2(1.70\text{ m})} = 0.338w = 272\text{ N}$. Applying $\sum F_y = 0$, we get $2F_f + 2F_h - w = 0$ which gives

$F_f = \frac{1}{2}w - F_h = 402\text{ N} - 272\text{ N} = 130\text{ N}$.

EVALUATE: His center of mass is closer to his hands than to his feet, so his hands exert a greater force.

11.16. **IDENTIFY:** Apply the conditions of equilibrium to the wheelbarrow plus its contents. The upward force applied by the person is 650 N.

SET UP: The free-body diagram for the wheelbarrow is given in Figure 11.16. $F = 650$ N, $w_{wb} = 80.0$ N and w is the weight of the load placed in the wheelbarrow.

EXECUTE: **(a)** $\sum\tau_z = 0$ with the axis at the center of gravity gives $n(0.50\text{ m}) - F(0.90\text{ m}) = 0$ and

$n = F\left(\dfrac{0.90\text{ m}}{0.50\text{ m}}\right) = 1170\text{ N}$. $\sum F_y = 0$ gives $F + n - w_{wb} - w = 0$ and

$w = F + n - w_{wb} = 650\text{ N} + 1170\text{ N} - 80.0\text{ N} = 1740\text{ N}$.

(b) The extra force is applied by the ground pushing up on the wheel.

EVALUATE: You can verify that $\sum\tau_z = 0$ for any axis, for example for an axis where the wheel contacts the ground.

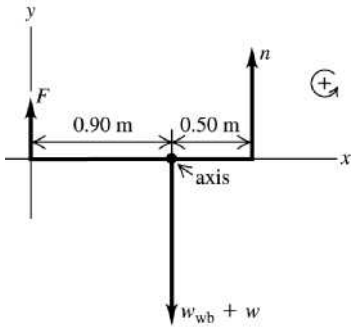

Figure 11.6

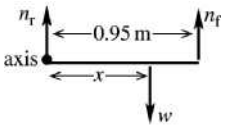
11.17. **IDENTIFY:** Apply the first and second conditions of equilibrium to Clea.

SET UP: Consider the forces on Clea. The free-body diagram is given in Figure 11.17



EXECUTE:

$n_r = 89$ N, $n_f = 157$ N

$n_r + n_f = w$ so $w = 246$ N

Figure 11.17

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$\sum \tau_z = 0$, axis at rear feet

Let x be the distance from the rear feet to the center of gravity.

$n_f(0.95\text{ m}) - xw = 0$

$x = 0.606$ m from rear feet so 0.34 m from front feet.

EVALUATE: The normal force at her front feet is greater than at her rear feet, so her center of gravity is closer to her front feet.

11.18. **IDENTIFY:** Apply the conditions for equilibrium to the crane.

SET UP: The free-body diagram for the crane is sketched in Figure 11.18. F_h and F_v are the components of the force exerted by the axle. $\vec{T}$ pulls to the left so F_h is to the right. $\vec{T}$ also pulls downward and the two weights are downward, so F_v is upward.

EXECUTE: **(a)** $\sum \tau_z = 0$ gives $T([13\text{ m}]\sin 25°) - w_c([7.0\text{ m}]\cos 55°) - w_b([16.0\text{ m}]\cos 55°) = 0$.

$$T = \frac{(11{,}000\text{ N})([16.0\text{ m}]\cos 55°) + (15{,}000\text{ N})([7.0\text{ m}]\cos 55°)}{(13.0\text{ m})\sin 25°} = 2.93\times 10^4\text{ N}.$$

(b) $\sum F_x = 0$ gives $F_h - T\cos 30° = 0$ and $F_h = 2.54\times 10^4$ N.

$\sum F_y = 0$ gives $F_v - T\sin 30° - w_c - w_b = 0$ and $F_v = 4.06\times 10^4$ N.

EVALUATE: $\tan\theta = \dfrac{F_v}{F_h} = \dfrac{4.06\times 10^4\text{ N}}{2.54\times 10^4\text{ N}}$ and $\theta = 58°$. The force exerted by the axle is not directed along the crane.

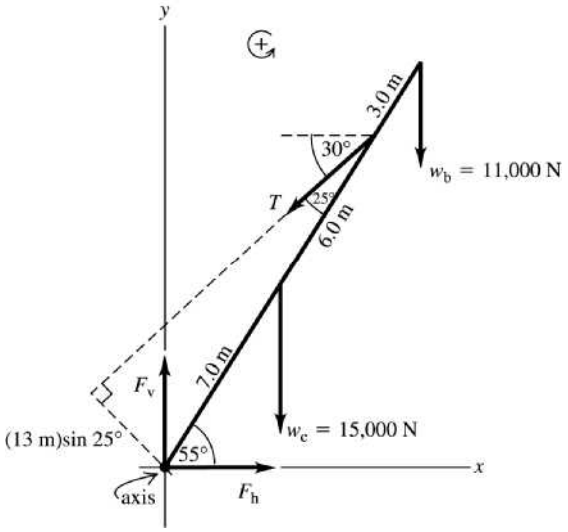


Figure 11.18

11.19. **IDENTIFY:** Apply the first and second conditions of equilibrium to the rod.

SET UP: The force diagram for the rod is given in Figure 11.19.

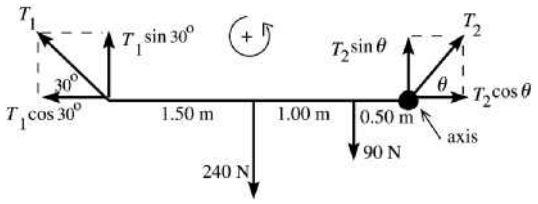

Figure 11.19

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: $\sum \tau_z = 0$, axis at right end of rod, counterclockwise torque is positive

$(240 \text{ N})(1.50 \text{ m}) + (90 \text{ N})(0.50 \text{ m}) - (T_1 \sin 30.0°)(3.00 \text{ m}) = 0$

$$T_1 = \frac{360 \text{ N} \cdot \text{m} + 45 \text{ N} \cdot \text{m}}{1.50 \text{ m}} = 270 \text{ N}$$

$\sum F_x = ma_x$

$T_2 \cos\theta - T_1 \cos 30° = 0$ and $T_2 \cos\theta = 234$ N

$\sum F_y = ma_y$

$T_1 \sin 30° + T_2 \sin\theta - 240 \text{ N} - 90 \text{ N} = 0$

$T_2 \sin\theta = 330 \text{ N} - (270 \text{ N}) \sin 30° = 195 \text{ N}$

Then $\dfrac{T_2 \sin\theta}{T_2 \cos\theta} = \dfrac{195 \text{ N}}{234 \text{ N}}$ gives $\tan\theta = 0.8333$ and $\theta = 40°$

And $T_2 = \dfrac{195 \text{ N}}{\sin 40°} = 303$ N.

EVALUATE: The monkey is closer to the right rope than to the left one, so the tension is larger in the right rope. The horizontal components of the tensions must be equal in magnitude and opposite in direction. Since $T_2 > T_1$, the rope on the right must be at a greater angle above the horizontal to have the same horizontal component as the tension in the other rope.

11.20. **IDENTIFY:** Apply the first and second conditions for equilibrium to the beam.

SET UP: The free-body diagram for the beam is given in Figure 11.20.

EXECUTE: The cable is given as perpendicular to the beam, so the tension is found by taking torques about the pivot point; $T(3.00 \text{ m}) = (1.00 \text{ kN})(2.00 \text{ m})\cos 25.0° + (5.00 \text{ kN})(4.50 \text{ m})\cos 25.0°$, and $T = 7.40$ kN. The vertical component of the force exerted on the beam by the pivot is the net weight minus the upward component of T, $6.00 \text{ kN} - T\cos 25.0° = -0.71$ kN. The vertical component is downward. The horizontal force is $T \sin 25.0° = 3.13$ kN.

EVALUATE: The vertical component of the tension is nearly the same magnitude as the total weight of the object and the vertical component of the force exerted by the pivot is much less than its horizontal component.

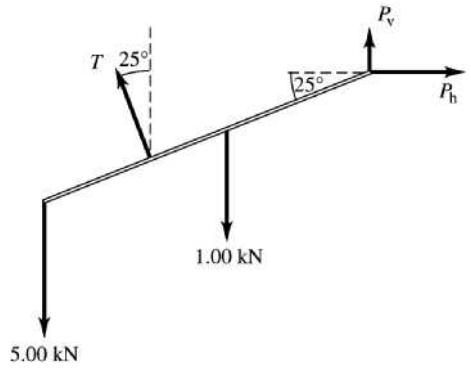

Figure 11.20

11.21. **(a) IDENTIFY** and **SET UP:** Use Eq. (10.3) to calculate the torque (magnitude and direction) for each force and add the torques as vectors. See Figure 11.21a.

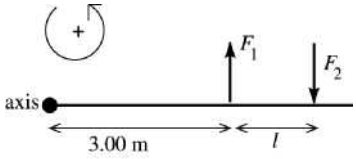

Figure 11.21a

EXECUTE:

$\tau_1 = F_1 l_1 = +(8.00 \text{ N})(3.00 \text{ m})$

$\tau_1 = +24.0 \text{ N} \cdot \text{m}$

$\tau_2 = -F_2 l_2 = -(8.00 \text{ N})(l + 3.00 \text{ m})$

$\tau_2 = -24.0 \text{ N} \cdot \text{m} - (8.00 \text{ N})l$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$\sum\tau_z = \tau_1 + \tau_2 = +24.0\ \text{N}\cdot\text{m} - 24.0\ \text{N}\cdot\text{m} - (8.00\ \text{N})l = -(8.00\ \text{N})l$

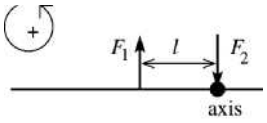
Want l that makes $\sum\tau_z = -6.40\ \text{N}\cdot\text{m}$ (net torque must be clockwise)

$-(8.00\ \text{N})l = -6.40\ \text{N}\cdot\text{m}$

$l = (6.40\ \text{N}\cdot\text{m})/8.00\ \text{N} = 0.800\ \text{m}$

(b) $|\tau_2| > |\tau_1|$ since F_2 has a larger moment arm; the net torque is clockwise.

(c) See Figure 11.21b.



$\tau_1 = -F_1 l_1 = -(8.00\ \text{N})l$

$\tau_2 = 0$ since $\vec{F}_2$ is at the axis

Figure 11.21b

$\sum\tau_z = -6.40\ \text{N}\cdot\text{m}$ gives $-(8.00\ \text{N})l = -6.40\ \text{N}\cdot\text{m}$

$l = 0.800$ m, same as in part (a).

EVALUATE: The force couple gives the same magnitude of torque for the pivot at any point.

11.22. **IDENTIFY:** The person is in equilibrium, so the torques on him must balance. The target variable is the force exerted by the deltoid muscle.

SET UP: The free-body diagram for the arm is given in Figure 11.22. Take the pivot at the shoulder joint and let counterclockwise torques be positive. Use coordinates as shown. Let F be the force exerted by the deltoid muscle. There are also the weight of the arm and forces at the shoulder joint, but none of these forces produce any torque when the arm is in this position. The forces F and T have been replaced by their x and y components. $\sum\tau_z = 0$.

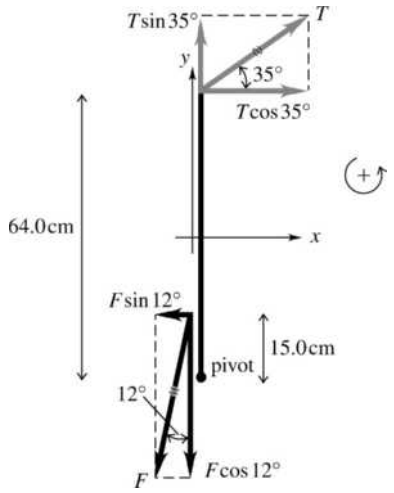


Figure 11.22

EXECUTE: $\sum\tau_z = 0$ gives $(F\sin 12.0°)(15.0\ \text{cm}) - (T\cos 35°)(64.0\ \text{cm}) = 0$.

$$F = \frac{(36.0\ \text{N})(\cos 35°)(64.0\ \text{cm})}{(\sin 12.0°)(15.0\ \text{cm})} = 605\ \text{N}.$$

EVALUATE: The force exerted by the deltoid muscle is much larger than the tension in the cable because the deltoid muscle makes a small angle (only 12.0°) with the humerus.

11.23. **IDENTIFY:** The student's head is at rest, so the torques on it must balance. The target variable is the tension in her neck muscles.

SET UP: Let the pivot be at point P and let counterclockwise torques be positive. $\sum\tau_z = 0$.

EXECUTE: **(a)** The free-body diagram is given in Figure 11.23.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

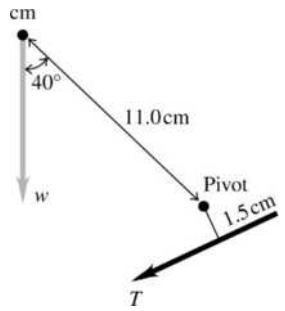

Figure 11.23

(b) $\sum \tau_z = 0$ gives $w(11.0\text{ cm})(\sin 40.0°) - T(1.50\text{ cm}) = 0.$

$$T = \frac{(4.50\text{ kg})(9.80\text{ m/s}^2)(11.0\text{ cm})\sin 40.0°}{1.50\text{ cm}} = 208\text{ N}.$$

EVALUATE: Her head weighs about 45 N but the tension in her neck muscles must be much larger because the tension has a small moment arm.

11.24. **IDENTIFY:** $Y = \dfrac{l_0 F_\perp}{A\Delta l}$

SET UP: $A = 50.0\text{ cm}^2 = 50.0\times10^{-4}\text{ m}^2.$

EXECUTE: relaxed: $Y = \dfrac{(0.200\text{ m})(25.0\text{ N})}{(50.0\times10^{-4}\text{ m}^2)(3.0\times10^{-2}\text{ m})} = 3.33\times10^4\text{ Pa}$

maximum tension: $Y = \dfrac{(0.200\text{ m})(500\text{ N})}{(50.0\times10^{-4}\text{ m}^2)(3.0\times10^{-2}\text{ m})} = 6.67\times10^5\text{ Pa}$

EVALUATE: The muscle tissue is much more difficult to stretch when it is under maximum tension.

11.25. **IDENTIFY** and **SET UP:** Apply Eq. (11.10) and solve for A and then use $A = \pi r^2$ to get the radius and $d = 2r$ to calculate the diameter.

EXECUTE: $Y = \dfrac{l_0 F_\perp}{A\Delta l}$ so $A = \dfrac{l_0 F_\perp}{Y\Delta l}$ (A is the cross-section area of the wire)

For steel, $Y = 2.0\times10^{11}$ Pa (Table 11.1)

Thus $A = \dfrac{(2.00\text{ m})(400\text{ N})}{(2.0\times10^{11}\text{ Pa})(0.25\times10^{-2}\text{ m})} = 1.6\times10^{-6}\text{ m}^2.$

$A = \pi r^2$, so $r = \sqrt{A/\pi} = \sqrt{1.6\times10^{-6}\text{ m}^2/\pi} = 7.1\times10^{-4}\text{ m}$

$d = 2r = 1.4\times10^{-3}\text{ m} = 1.4\text{ mm}$

EVALUATE: Steel wire of this diameter doesn't stretch much; $\Delta l/l_0 = 0.12\%$.

11.26. **IDENTIFY:** Apply Eq. (11.10).

SET UP: From Table 11.1, for steel, $Y = 2.0\times10^{11}$ Pa and for copper, $Y = 1.1\times10^{11}$ Pa.

$A = \pi(d^2/4) = 1.77\times10^{-4}\text{ m}^2$. $F_\perp = 4000$ N for each rod.

EXECUTE: **(a)** The strain is $\dfrac{\Delta l}{l_0} = \dfrac{F}{YA}$. For steel $\dfrac{\Delta l}{l_0} = \dfrac{(4000\text{ N})}{(2.0\times10^{11}\text{ Pa})(1.77\times10^{-4}\text{ m}^2)} = 1.1\times10^{-4}.$

Similarly, the strain for copper is 2.1×10^{-4}.

(b) Steel: $(1.1\times10^{-4})(0.750\text{ m}) = 8.3\times10^{-5}$ m. Copper: $(2.1\times10^{-4})(0.750\text{ m}) = 1.6\times10^{-4}$ m.

EVALUATE: Copper has a smaller Y and therefore a greater elongation.

11.27. **IDENTIFY:** $Y = \dfrac{l_0 F_\perp}{A\Delta l}$

SET UP: $A = 0.50\text{ cm}^2 = 0.50\times10^{-4}\text{ m}^2$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: $Y = \dfrac{(4.00\text{ m})(5000\text{ N})}{(0.50\times10^{-4}\text{ m}^2)(0.20\times10^{-2}\text{ m})} = 2.0\times10^{11}\text{ Pa}$

EVALUATE: Our result is the same as that given for steel in Table 11.1.

11.28. **IDENTIFY:** $Y = \dfrac{l_0 F_\perp}{A\Delta l}$

SET UP: $A = \pi r^2 = \pi(3.5\times10^{-3}\text{ m})^2 = 3.85\times10^{-5}\text{ m}^2$. The force applied to the end of the rope is the weight of the climber: $F_\perp = (65.0\text{ kg})(9.80\text{ m/s}^2) = 637\text{ N}$.

EXECUTE: $Y = \dfrac{(45.0\text{ m})(637\text{ N})}{(3.85\times10^{-5}\text{ m}^2)(1.10\text{ m})} = 6.77\times10^{8}\text{ Pa}$

EVALUATE: Our result is a lot smaller than the values given in Table 11.1. An object made of rope material is much easier to stretch than if the object were made of metal.

11.29. **IDENTIFY:** Use the first condition of equilibrium to calculate the tensions T_1 and T_2 in the wires (Figure 11.29a). Then use Eq. (11.10) to calculate the strain and elongation of each wire.

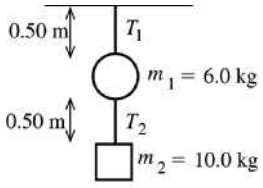

Figure 11.29a

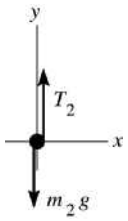
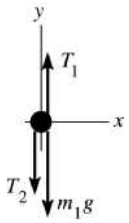
SET UP: The free-body diagram for m_2 is given in Figure 11.27b.



EXECUTE:
$\sum F_y = ma_y$
$T_2 - m_2 g = 0$
$T_2 = 98.0\text{ N}$

Figure 11.29b

SET UP: The free-body-diagram for m_1 is given in Figure 11.29c.



EXECUTE:
$\sum F_y = ma_y$
$T_1 - T_2 - m_1 g = 0$
$T_1 = T_2 + m_1 g$
$T_1 = 98.0\text{ N} + 58.8\text{ N} = 157\text{ N}$

Figure 11.29c

(a) $Y = \dfrac{\text{stress}}{\text{strain}}$ so $\text{strain} = \dfrac{\text{stress}}{Y} = \dfrac{F_\perp}{AY}$

upper wire: $\text{strain} = \dfrac{T_1}{AY} = \dfrac{157\text{ N}}{(2.5\times10^{-7}\text{ m}^2)(2.0\times10^{11}\text{ Pa})} = 3.1\times10^{-3}$

lower wire: $\text{strain} = \dfrac{T_2}{AY} = \dfrac{98\text{ N}}{(2.5\times10^{-7}\text{ m}^2)(2.0\times10^{11}\text{ Pa})} = 2.0\times10^{-3}$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) strain $= \Delta l/l_0$ so $\Delta l = l_0(\text{strain})$

upper wire: $\Delta l = (0.50\text{ m})(3.1\times10^{-3}) = 1.6\times10^{-3}\text{ m} = 1.6\text{ mm}$

lower wire: $\Delta l = (0.50\text{ m})(2.0\times10^{-3}) = 1.0\times10^{-3}\text{ m} = 1.0\text{ mm}$

EVALUATE: The tension is greater in the upper wire because it must support both objects. The wires have the same length and diameter, so the one with the greater tension has the greater strain and elongation.

11.30. **IDENTIFY:** Apply Eqs. (11.8), (11.9) and (11.10).

SET UP: The cross-sectional area of the post is $A = \pi r^2 = \pi(0.125\text{ m})^2 = 0.0491\text{ m}^2$. The force applied to the end of the post is $F_\perp = (8000\text{ kg})(9.80\text{ m/s}^2) = 7.84\times10^4$ N. The Young's modulus of steel is $Y = 2.0\times10^{11}$ Pa.

EXECUTE: **(a)** $\text{stress} = \dfrac{F_\perp}{A} = -\dfrac{7.84\times10^4\text{ N}}{0.0491\text{ m}^2} = -1.60\times10^6\text{ Pa}$. The minus sign indicates that the stress is compressive.

(b) $\text{strain} = \dfrac{\text{stress}}{Y} = -\dfrac{1.60\times10^6\text{ Pa}}{2.0\times10^{11}\text{ Pa}} = -8.0\times10^{-6}$. The minus sign indicates that the length decreases.

(c) $\Delta l = l_0(\text{strain}) = (2.50\text{ m})(-8.0\times10^{-6}) = -2.0\times10^{-5}\text{ m}$

EVALUATE: The fractional change in length of the post is very small.

11.31. **IDENTIFY:** The amount of compression depends on the bulk modulus of the bone.

SET UP: $\dfrac{\Delta V}{V_0} = -\dfrac{\Delta p}{B}$ and $1\text{ atm} = 1.01\times10^5\text{ Pa}$.

EXECUTE: **(a)** $\Delta p = -B\dfrac{\Delta V}{V_0} = -(15\times10^9\text{ Pa})(-0.0010) = 1.5\times10^7\text{ Pa} = 150\text{ atm}$.

(b) The depth for a pressure increase of 1.5×10^7 Pa is 1.5 km.

EVALUATE: An extremely large pressure increase is needed for just a 0.10% bone compression, so pressure changes do not appreciably affect the bones. Unprotected dives do not approach a depth of 1.5 km, so bone compression is not a concern for divers.

11.32. **IDENTIFY:** Apply Eq. (11.13).

SET UP: $\Delta V = -\dfrac{V_0\Delta p}{B}$. Δp is positive when the pressure increases.

EXECUTE: **(a)** The volume would increase slightly.
(b) The volume change would be twice as great.
(c) The volume change is inversely proportional to the bulk modulus for a given pressure change, so the volume change of the lead ingot would be four times that of the gold.

EVALUATE: For lead, $B = 4.1\times10^{10}$ Pa, so $\Delta p/B$ is very small and the fractional change in volume is very small.

11.33. **IDENTIFY:** Vigorous downhill hiking produces a shear force on the knee cartilage which could deform the cartilage. The target variable is the angle of deformation of the cartilage.

SET UP: $S = \dfrac{F_\parallel}{A\phi}$, where $\phi = x/h$. $F_\parallel = F\sin12°$. ϕ is in radians. $F = 8mg$, with $m = 10$ kg. $1\text{ rad} = 180°$.

EXECUTE: $\phi = \dfrac{F_\parallel}{AS} = \dfrac{8mg\sin12°}{(10\times10^{-4}\text{ m}^2)(12\times10^6\text{ Pa})} = 0.1494\text{ rad} = 8.6°$.

EVALUATE: The shear modulus of cartilage is much less than the values for metals given in Table 11.1 in the text.

11.34. **IDENTIFY:** Apply Eq. (11.13). Density $= m/V$.

SET UP: At the surface the pressure is 1.0×10^5 Pa, so $\Delta p = 1.16\times10^8$ Pa. $V_0 = 1.00\text{ m}^3$. At the surface 1.00 m^3 of water has mass 1.03×10^3 kg.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: **(a)** $B = -\dfrac{(\Delta p)V_0}{\Delta V}$ gives $\Delta V = -\dfrac{(\Delta p)V_0}{B} = -\dfrac{(1.16\times10^8\ \text{Pa})(1.00\ \text{m}^3)}{2.2\times10^9\ \text{Pa}} = -0.0527\ \text{m}^3$

(b) At this depth 1.03×10^3 kg of seawater has volume $V_0 + \Delta V = 0.9473\ \text{m}^3$. The density is

$\dfrac{1.03\times10^3\ \text{kg}}{0.9473\ \text{m}^3} = 1.09\times10^3\ \text{kg/m}^3$.

EVALUATE: The density is increased because the volume is compressed due to the increased pressure.

11.35. **IDENTIFY** and **SET UP:** Use Eqs. (11.13) and (11.14) to calculate B and k.

EXECUTE: $B = -\dfrac{\Delta p}{\Delta V/V_0} = -\dfrac{(3.6\times10^6\ \text{Pa})(600\ \text{cm}^3)}{(-0.45\ \text{cm}^3)} = +4.8\times10^9\ \text{Pa}$

$k = 1/B = 1/4.8\times10^9\ \text{Pa} = 2.1\times10^{-10}\ \text{Pa}^{-1}$

EVALUATE: k is the same as for glycerine (Table 11.2).

11.36. **IDENTIFY:** Apply Eq. (11.17).

SET UP: $F_\parallel = 9.0\times10^5$ N. $A = (0.100\ \text{m})(0.500\times10^{-2}\ \text{m})$. $h = 0.100$ m. From Table 11.1, $S = 7.5\times10^{10}$ Pa for steel.

EXECUTE: **(a)** Shear strain $= \dfrac{F_\parallel}{AS} = \dfrac{(9\times10^5\ \text{N})}{[(0.100\ \text{m})(0.500\times10^{-2}\text{m})][7.5\times10^{10}\ \text{Pa}]} = 2.4\times10^{-2}$.

(b) Using Eq. (11.16), $x = (\text{Shear strain})\cdot h = (0.024)(0.100\ \text{m}) = 2.4\times10^{-3}\text{m}$.

EVALUATE: This very large force produces a small displacement; $x/h = 2.4\%$.

11.37. **IDENTIFY:** The forces on the cube must balance. The deformation x is related to the force by $S = \dfrac{F_\parallel}{A}\dfrac{h}{x}$.

$F_\parallel = F$ since F is applied parallel to the upper face.

SET UP: $A = (0.0600\ \text{m})^2$ and $h = 0.0600$ m. Table 11.1 gives $S = 4.4\times10^{10}$ Pa for copper and 0.6×10^{10} Pa for lead.

EXECUTE: **(a)** Since the horizontal forces balance, the glue exerts a force F in the opposite direction.

(b) $F = \dfrac{AxS}{h} = \dfrac{(0.0600\ \text{m})^2(0.250\times10^{-3}\ \text{m})(4.4\times10^{10}\ \text{Pa})}{0.0600\ \text{m}} = 6.6\times10^5\ \text{N}$

(c) $x = \dfrac{Fh}{AS} = \dfrac{(6.6\times10^5\ \text{N})(0.0600\ \text{m})}{(0.0600\ \text{m})^2(0.6\times10^{10}\ \text{Pa})} = 1.8\ \text{mm}$

EVALUATE: Lead has a smaller S than copper, so the lead cube has a greater deformation than the copper cube.

11.38. **IDENTIFY:** The force components parallel to the face of the cube produce a shear which can deform the cube.

SET UP: $S = \dfrac{F_\parallel}{A\phi}$, where $\phi = x/h$. $F_\parallel$ is the component of the force tangent to the surface, so $F_\parallel = (1375\ \text{N})\cos 8.50° = 1360$ N. ϕ must be in radians, $\phi = 1.24° = 0.0216$ rad.

EXECUTE: $S = \dfrac{1360\ \text{N}}{(0.0925\ \text{m})^2(0.0216\ \text{rad})} = 7.36\times10^6\ \text{Pa}$.

EVALUATE: The shear modulus of this material is much less than the values for metals given in Table 11.1 in the text.

11.39. **IDENTIFY** and **SET UP:** Use Eq. (11.8).

EXECUTE: Tensile stress $= \dfrac{F_\perp}{A} = \dfrac{F_\perp}{\pi r^2} = \dfrac{90.8\ \text{N}}{\pi(0.92\times10^{-3}\ \text{m})^2} = 3.41\times10^7\ \text{Pa}$

EVALUATE: A modest force produces a very large stress because the cross-sectional area is small.

11.40. **IDENTIFY:** The proportional limit and breaking stress are values of the stress, $F_\perp/A$. Use Eq. (11.10) to calculate Δl.

SET UP: For steel, $Y = 20\times10^{10}$ Pa. $F_\perp = w$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: **(a)** $w = (1.6\times10^{-3})(20\times10^{10}\ \text{Pa})(5\times10^{-6}\ \text{m}^2) = 1.60\times10^{3}\ \text{N}$.

(b) $\Delta l = \left(\frac{F_\perp}{A}\right)\frac{l_0}{Y} = (1.6\times10^{-3})(4.0\ \text{m}) = 6.4\ \text{mm}$

(c) $(6.5\times10^{-3})(20\times10^{10}\ \text{Pa})(5\times10^{-6}\ \text{m}^2) = 6.5\times10^{3}\ \text{N}$.

EVALUATE: At the proportional limit, the fractional change in the length of the wire is 0.16%.

11.41. **IDENTIFY:** The elastic limit is a value of the stress, $F_\perp/A$. Apply $\sum \vec{F} = m\vec{a}$ to the elevator in order to find the tension in the cable.

SET UP: $\frac{F_\perp}{A} = \frac{1}{3}(2.40\times10^{8}\ \text{Pa}) = 0.80\times10^{8}\ \text{Pa}$. The free-body diagram for the elevator is given in Figure 11.41. $F_\perp$ is the tension in the cable.

EXECUTE: $F_\perp = A(0.80\times10^{8}\ \text{Pa}) = (3.00\times10^{-4}\ \text{m}^2)(0.80\times10^{8}\ \text{Pa}) = 2.40\times10^{4}\ \text{N}$. $\sum F_y = ma_y$ applied to the elevator gives $F_\perp - mg = ma$ and $a = \frac{F_\perp}{m} - g = \frac{2.40\times10^{4}\ \text{N}}{1200\ \text{kg}} - 9.80\ \text{m/s}^2 = 10.2\ \text{m/s}^2$

EVALUATE: The tension in the cable is about twice the weight of the elevator.

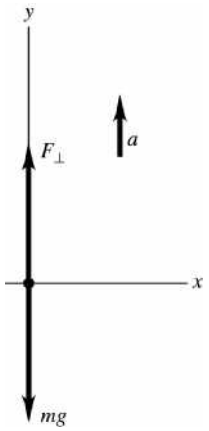


Figure 11.41

11.42. **IDENTIFY:** The breaking stress of the wire is the value of $F_\perp/A$ at which the wire breaks.

SET UP: From Table 11.3, the breaking stress of brass is 4.7×10^{8} Pa. The area A of the wire is related to its diameter by $A = \pi d^2/4$.

EXECUTE: $A = \frac{350\ \text{N}}{4.7\times10^{8}\ \text{Pa}} = 7.45\times10^{-7}\ \text{m}^2$, so $d = \sqrt{4A/\pi} = 0.97\ \text{mm}$.

EVALUATE: The maximum force a wire can withstand without breaking is proportional to the square of its diameter.

11.43. **IDENTIFY:** The center of gravity of the combined object must be at the fulcrum. Use Eq. (11.3) to calculate x_{cm}.

SET UP: The center of gravity of the sand is at the middle of the box. Use coordinates with the origin at the fulcrum and $+x$ to the right. Let $m_1 = 25.0$ kg, so $x_1 = 0.500$ m. Let $m_2 = m_{\text{sand}}$, so $x_2 = -0.625$ m. $x_{\text{cm}} = 0$.

EXECUTE: $x_{\text{cm}} = \frac{m_1x_1 + m_2x_2}{m_1 + m_2} = 0$ and $m_2 = -m_1\frac{x_1}{x_2} = -(25.0\ \text{kg})\left(\frac{0.500\ \text{m}}{-0.625\ \text{m}}\right) = 20.0\ \text{kg}$.

EVALUATE: The mass of sand required is less than the mass of the plank since the center of the box is farther from the fulcrum than the center of gravity of the plank is.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

11.44. **IDENTIFY:** Apply the first and second conditions of equilibrium to the door.

SET UP: The free-body diagram for the door is given in Figure 11.44. Let $\vec{H}_1$ and $\vec{H}_2$ be the forces exerted by the upper and lower hinges. Take the origin of coordinates at the bottom hinge (point A) and $+y$ upward.

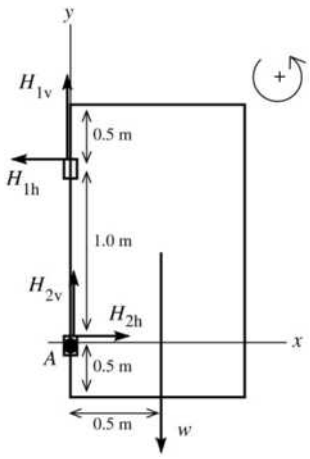

Figure 11.44

EXECUTE:
We are given that
$H_{1v} = H_{2v} = w/2 = 140$ N.
$\sum F_x = ma_x$
$H_{2h} - H_{1h} = 0$
$H_{1h} = H_{2h}$
The horizontal components of the hinge forces are equal in magnitude and opposite in direction.

Sum torques about point A. H_{1v}, H_{2v} and H_{2h} all have zero moment arm and hence zero torque about an axis at this point. Thus $\sum \tau_A = 0$ gives $H_{1h}(1.00\text{ m}) - w(0.50\text{ m}) = 0$

$$H_{1h} = w\left(\frac{0.50\text{ m}}{1.00\text{ m}}\right) = \tfrac{1}{2}(280\text{ N}) = 140\text{ N}.$$

The horizontal component of each hinge force is 140 N.

EVALUATE: The horizontal components of the force exerted by each hinge are the only horizontal forces so must be equal in magnitude and opposite in direction. With an axis at A, the torque due to the horizontal force exerted by the upper hinge must be counterclockwise to oppose the clockwise torque exerted by the weight of the door. So, the horizontal force exerted by the upper hinge must be to the left. You can also verify that the net torque is also zero if the axis is at the upper hinge.

11.45. **IDENTIFY:** Apply the conditions of equilibrium to the climber. For the minimum coefficient of friction the static friction force has the value $f_s = \mu_s n$.

SET UP: The free-body diagram for the climber is given in Figure 11.45. f_s and n are the vertical and horizontal components of the force exerted by the cliff face on the climber. The moment arm for the force T is $(1.4\text{ m})\cos 10°$.

EXECUTE: **(a)** $\sum \tau_z = 0$ gives $T(1.4\text{ m})\cos 10° - w(1.1\text{ m})\cos 35.0° = 0$.

$$T = \frac{(1.1\text{ m})\cos 35.0°}{(1.4\text{ m})\cos 10°}(82.0\text{ kg})(9.80\text{ m/s}^2) = 525\text{ N}$$

(b) $\sum F_x = 0$ gives $n = T\sin 25.0° = 222$ N. $\sum F_y = 0$ gives $f_s + T\cos 25° - w = 0$ and

$f_s = (82.0\text{ kg})(9.80\text{ m/s}^2) - (525\text{ N})\cos 25° = 328$ N.

(c) $\mu_s = \dfrac{f_s}{n} = \dfrac{328\text{ N}}{222\text{ N}} = 1.48$

EVALUATE: To achieve this large value of μ_s the climber must wear special rough-soled shoes.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

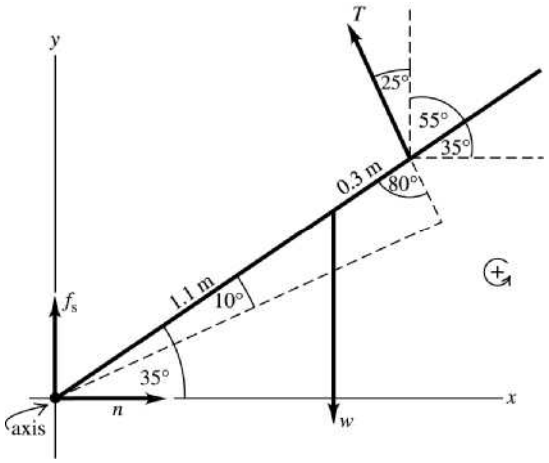

Figure 11.45

11.46. **IDENTIFY:** Apply $\sum \tau_z = 0$ to the bridge.

SET UP: Let the axis of rotation be at the left end of the bridge and let counterclockwise torques be positive.

EXECUTE: If Lancelot were at the end of the bridge, the tension in the cable would be (from taking torques about the hinge of the bridge) obtained from

$T(12.0\text{ m}) = (600\text{ kg})(9.80\text{ m/s}^2)(12.0\text{ m}) + (200\text{ kg})(9.80\text{ m/s}^2)(6.0\text{ m}),$ so $T = 6860\text{ N}.$

This exceeds the maximum tension that the cable can have, so Lancelot is going into the drink. To find the distance x Lancelot can ride, replace the 12.0 m multiplying Lancelot's weight by x and the tension T by $T_{\max} = 5.80\times10^3\text{ N}$ and solve for x;

$$x = \frac{(5.80\times10^3\text{ N})(12.0\text{ m}) - (200\text{ kg})(9.80\text{ m/s}^2)(6.0\text{ m})}{(600\text{ kg})(9.80\text{ m/s}^2)} = 9.84\text{ m}.$$

EVALUATE: Before Lancelot goes onto the bridge, the tension in the supporting cable is

$T = \dfrac{(6.0\text{ m})(200\text{ kg})(9.80\text{ m/s}^2)}{12.0\text{ m}} = 980\text{ N},$ well below the breaking strength of the cable. As he moves along the bridge, the increase in tension is proportional to x, the distance he has moved along the bridge.

11.47. **IDENTIFY:** For the airplane to remain in level flight, both $\sum F_y = 0$ and $\sum \tau_z = 0.$

SET UP: The free-body diagram for the airplane is given in Figure 11.47. Let $+y$ be upward.

EXECUTE: $-F_{\text{tail}} - W + F_{\text{wing}} = 0.$ Taking the counterclockwise direction as positive, and taking torques about the point where the tail force acts, $-(3.66\text{ m})(6700\text{ N}) + (3.36\text{ m})F_{\text{wing}} = 0.$ This gives

$F_{\text{wing}} = 7300\text{ N(up)}$ and $F_{\text{tail}} = 7300\text{ N} - 6700\text{ N} = 600\text{ N(down)}.$

EVALUATE: We assumed that the wing force was upward and the tail force was downward. When we solved for these forces we obtained positive values for them, which confirms that they do have these directions. Note that the rear stabilizer provides a *downward* force. It does not hold up the tail of the aircraft, but serves to counter the torque produced by the wing. Thus balance, along with weight, is a crucial factor in airplane loading.

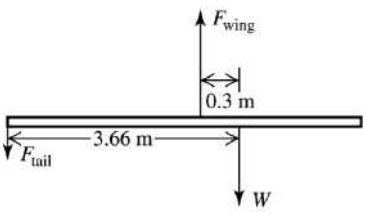

Figure 11.47

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

11.48. **IDENTIFY:** Apply the first and second conditions of equilibrium to the truck.

SET UP: The weight on the front wheels is n_f, the normal force exerted by the ground on the front wheels. The weight on the rear wheels is n_r, the normal force exerted by the ground on the rear wheels. When the front wheels come off the ground, $n_f \to 0$. The free-body diagram for the truck without the box is given in Figure 11.48a and with the box in Figure 11.48b. The center of gravity of the truck, without the box, is a distance x from the rear wheels.

EXECUTE: $\sum F_y = 0$ in Figure 11.48a gives $w = n_r + n_f = 8820\text{ N} + 10{,}780\text{ N} = 19{,}600\text{ N}$.

$\sum \tau_z = 0$ in Figure 11.48a, with the axis at the rear wheels and counterclockwise torques positive, gives

$$n_f(3.00\text{ m}) - wx = 0 \text{ and } x = \frac{n_f(3.00\text{ m})}{w} = \left(\frac{10{,}780\text{ N}}{19{,}600\text{ N}}\right)(3.00\text{ m}) = 1.65\text{ m}.$$

(a) $\sum \tau_z = 0$ in Figure 11.48b, with the axis at the rear wheels and counterclockwise torques positive, gives $w_{box}(1.00\text{ m}) + n_f(3.00\text{ m}) - w(1.65\text{ m}) = 0$.

$$n_f = \frac{-(3600\text{ N})(1.00\text{ m}) + (19{,}600\text{ N})(1.65\text{ m})}{3.00\text{ m}} = 9580\text{ N}$$

$\sum F_y = 0$ gives $n_r + n_f = w_{box} + w$ and $n_r = 3600\text{ N} + 19{,}600\text{ N} - 9580\text{ N} = 13{,}620\text{ N}$. There is 9580 N on the front wheels and 13,620 N on the rear wheels.

(b) $n_f \to 0$. $\sum \tau_z = 0$ gives $w_{box}(1.00\text{ m}) - w(1.65\text{ m}) = 0$ and $w_{box} = 1.65w = 3.23\times10^4$ N.

EVALUATE: Placing the box on the tailgate in part (b) reduces the normal force exerted at the front wheels.

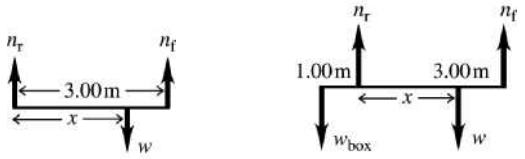

Figure 11.48a, b

11.49. **IDENTIFY:** In each case, to achieve balance the center of gravity of the system must be at the fulcrum. Use Eq. (11.3) to locate x_{cm}, with m_i replaced by w_i.

SET UP: Let the origin be at the left-hand end of the rod and take the $+x$ axis to lie along the rod. Let $w_1 = 255$ N (the rod) so $x_1 = 1.00$ m, let $w_2 = 225$ N so $x_2 = 2.00$ m and let $w_3 = W$. In part (a) $x_3 = 0.500$ m and in part (b) $x_3 = 0.750$ m.

EXECUTE: **(a)** $x_{cm} = 1.25$ m. $x_{cm} = \dfrac{w_1x_1 + w_2x_2 + w_3x_3}{w_1 + w_2 + w_3}$ gives $w_3 = \dfrac{(w_1 + w_2)x_{cm} - w_1x_1 - w_2x_2}{x_3 - x_{cm}}$ and

$$W = \frac{(480\text{ N})(1.25\text{ m}) - (255\text{ N})(1.00\text{ m}) - (225\text{ N})(2.00\text{ m})}{0.500\text{ m} - 1.25\text{ m}} = 140\text{ N}.$$

(b) Now $w_3 = W = 140$ N and $x_3 = 0.750$ m.

$$x_{cm} = \frac{(255\text{ N})(1.00\text{ m}) + (225\text{ N})(2.00\text{ m}) + (140\text{ N})(0.750\text{ m})}{255\text{ N} + 225\text{ N} + 140\text{ N}} = 1.31\text{ m}.$$ W must be moved 1.31 m − 1.25 m = 6 cm to the right.

EVALUATE: Moving W to the right means x_{cm} for the system moves to the right.

11.50. **IDENTIFY:** The beam is at rest, so the forces and torques on it must balance.

SET UP: The weight of the beam acts 4.0 m from each end. Take the pivot at the hinge and let counterclockwise torques be positive. Represent the force exerted by the hinge by its horizontal and vertical components, H_h and H_v. $\sum F_x = 0$, $\sum F_y = 0$ and $\sum \tau_z = 0$.

EXECUTE: **(a)** The free-body diagram for the beam is given in Figure 11.50a.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

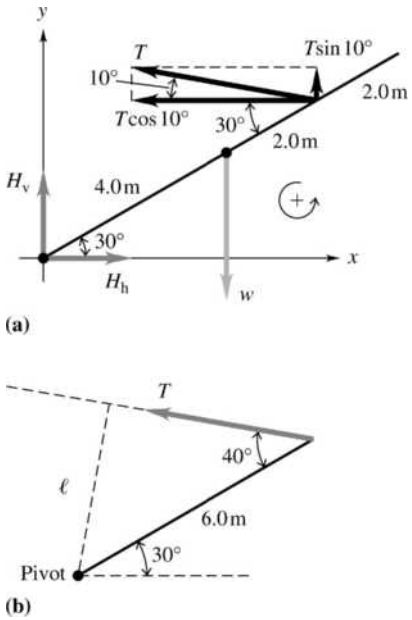

Figure 11.50

(b) The moment arm for T is sketched in Figure 11.50b and is equal to $(6.0\text{ m})\sin 40.0°$. $\sum \tau_z = 0$ gives $T(6.0\text{ m})(\sin 40.0°) - w(4.0\text{ m})(\cos 30.0°) = 0$. $T = \dfrac{(1500\text{ kg})(9.80\text{ m/s}^2)(4.0\text{ m})(\cos 30.0°)}{(6.0\text{ m})(\sin 40.0°)} = 1.32\times 10^4\text{ N}$.

(c) $\sum F_x = 0$ gives $H_h - T\cos 10.0° = 0$ and $H_h = T\cos 10.0° = 1.30\times 10^4$ N. $\sum F_y = 0$ gives $H_v + T\sin 10.0° - w = 0$ and $H_v = w - T\sin 10.0° = (1500\text{ kg})(9.80\text{ m/s}^2) - 2.29\times 10^3\text{ N} = 1.24\times 10^4$ N. $H = \sqrt{H_h^2 + H_v^2} = 1.80\times 10^4$ N. This is the force the hinge exerts on the beam. By Newton's third law, the force the beam exerts on the wall has the same magnitude, so is 1.80×10^4 N.

EVALUATE: The tension is less than the weight of the beam because it has a larger moment arm than the weight force has.

11.51. **IDENTIFY:** Apply the conditions of equilibrium to the horizontal beam. Since the two wires are symmetrically placed on either side of the middle of the sign, their tensions are equal and are each equal to $T_w = mg/2 = 137$ N.

SET UP: The free-body diagram for the beam is given in Figure 11.51. F_v and F_h are the horizontal and vertical forces exerted by the hinge on the sign. Since the cable is 2.00 m long and the beam is 1.50 m long, $\cos\theta = \dfrac{1.50\text{ m}}{2.00\text{ m}}$ and $\theta = 41.4°$. The tension T_c in the cable has been replaced by its horizontal and vertical components.

EXECUTE: **(a)** $\sum \tau_z = 0$ gives $T_c(\sin 41.4°)(1.50\text{ m}) - w_{beam}(0.750\text{ m}) - T_w(1.50\text{ m}) - T_w(0.60\text{ m}) = 0$.

$T_c = \dfrac{(12.0\text{ kg})(9.80\text{ m/s}^2)(0.750\text{ m}) + (137\text{ N})(1.50\text{ m} + 0.60\text{ m})}{(1.50\text{ m})(\sin 41.4°)} = 379\text{ N}$.

(b) $\sum F_y = 0$ gives $F_v + T_c\sin 41.4° - w_{beam} - 2T_w = 0$ and $F_v = 2T_w + w_{beam} - T_c\sin 41.4° = 2(137\text{ N}) + (12.0\text{ kg})(9.80\text{ m/s}^2) - (379\text{ N})(\sin 41.4°) = 141\text{ N}$. The hinge must be able to supply a vertical force of 141 N.

EVALUATE: The force from the two wires could be replaced by the weight of the sign acting at a point 0.60 m to the left of the right-hand edge of the sign.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

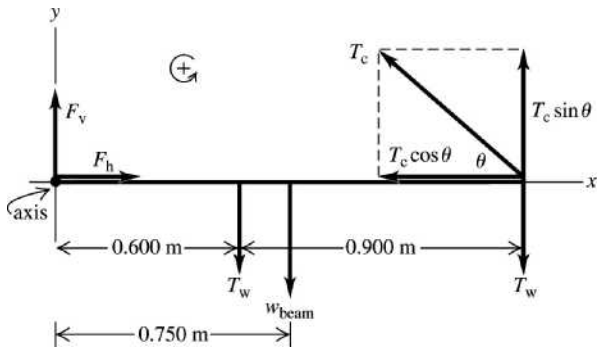

Figure 11.51

11.52. **IDENTIFY:** Apply $\sum \tau_z = 0$ to the hammer.

SET UP: Take the axis of rotation to be at point A.

EXECUTE: The force $\vec{F}_1$ is directed along the length of the nail, and so has a moment arm of $(0.080\text{ m})\sin 60°$. The moment arm of $\vec{F}_2$ is 0.300 m, so

$$F_2 = F_1 \frac{(0.0800\text{ m})\sin 60°}{(0.300\text{ m})} = (400\text{ N})(0.231) = 92.4\text{ N}.$$

EVALUATE: The force F_2 that must be applied to the hammer handle is much less than the force that the hammer applies to the nail, because of the large difference in the lengths of the moment arms.

11.53. **IDENTIFY:** Apply the first and second conditions of equilibrium to the bar.

SET UP: The free-body diagram for the bar is given in Figure 11.53. n is the normal force exerted on the bar by the surface. There is no friction force at this surface. H_h and H_v are the components of the force exerted on the bar by the hinge. The components of the force of the bar on the hinge will be equal in magnitude and opposite in direction.

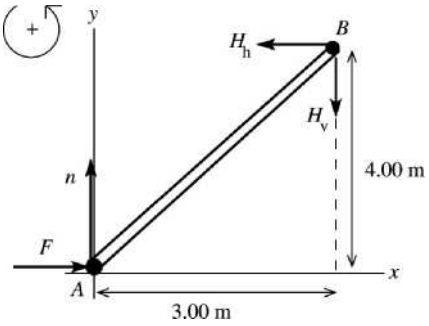

Figure 11.53

EXECUTE:

$\sum F_x = ma_x$

$F = H_h = 160\text{ N}$

$\sum F_y = ma_y$

$n - H_v = 0$

$H_v = n$, but we don't know either of these forces.

$\sum \tau_B = 0$ gives $F(4.00\text{ m}) - n(3.00\text{ m}) = 0.$

$n = (4.00\text{ m}/3.00\text{ m})F = \frac{4}{3}(160\text{ N}) = 213\text{ N}$ and then $H_v = 213\text{ N}.$

Force of bar on hinge:
horizontal component 160 N, to right
vertical component 213 N, upward

EVALUATE: $H_h/H_v = 160/213 = 0.750 = 3.00/4.00$, so the force the hinge exerts on the bar is directed along the bar. $\vec{n}$ and $\vec{F}$ have zero torque about point A, so the line of action of the hinge force $\vec{H}$ must pass through this point also if the net torque is to be zero.

11.54. **IDENTIFY:** Apply $\sum \tau_z = 0$ to the piece of art.

SET UP: The free-body diagram for the piece of art is given in Figure 11.54.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: $\sum \tau_z = 0$ gives $T_B(1.25\text{ m}) - w(1.02\text{ m}) = 0$. $T_B = (426\text{ N})\left(\dfrac{1.02\text{ m}}{1.25\text{ m}}\right) = 348\text{ N}$.

$\sum F_y = 0$ gives $T_A + T_B - w = 0$ and $T_A = w - T_B = 426\text{ N} - 348\text{ N} = 78\text{ N}$.

EVALUATE: If we consider the sum of torques about the center of gravity of the piece of art, T_A has a larger moment arm than T_B, and this is why $T_A < T_B$.

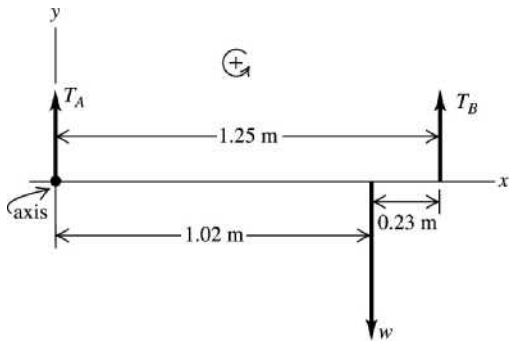

Figure 11.54

11.55. **IDENTIFY:** We want to locate the center of mass of the leg-cast system. We can treat each segment of the leg and cast as a point-mass located at its center of mass.

SET UP: The force diagram for the leg is given in Figure 11.55. The weight of each piece acts at the center of mass of that piece. The mass of the upper leg is $m_{\text{ul}} = (0.215)(37\text{ kg}) = 7.955\text{ kg}$. The mass of the lower leg is $m_{\text{ll}} = (0.140)(37\text{ kg}) = 5.18\text{ kg}$. Use the coordinates shown, with the origin at the hip and the x-axis along the leg, and use $x_{\text{cm}} = \dfrac{x_{\text{ul}}m_{\text{ul}} + x_{\text{ll}}m_{\text{ll}} + x_{\text{cast}}m_{\text{cast}}}{m_{\text{ul}} + m_{\text{ll}} + m_{\text{cast}}}$.

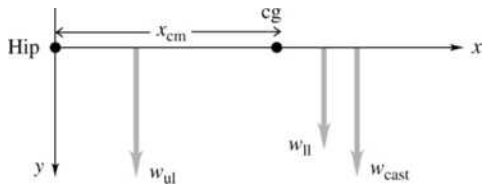

Figure 11.55

EXECUTE: Using $x_{\text{cm}} = \dfrac{x_{\text{ul}}m_{\text{ul}} + x_{\text{ll}}m_{\text{ll}} + x_{\text{cast}}m_{\text{cast}}}{m_{\text{ul}} + m_{\text{ll}} + m_{\text{cast}}}$, we have

$$x_{\text{cm}} = \frac{(18.0\text{ cm})(7.955\text{ kg}) + (69.0\text{ cm})(5.18\text{ kg}) + (78.0\text{ cm})(5.50\text{ kg})}{7.955\text{ kg} + 5.18\text{ kg} + 5.50\text{ kg}} = 49.9\text{ cm}$$

EVALUATE: The strap is attached to the left of the center of mass of the cast, but it is still supported by the rigid cast since the cast extends beyond its center of mass.

11.56. **IDENTIFY:** Apply the first and second conditions for equilibrium to the bridge.

SET UP: Find torques about the hinge. Use L as the length of the bridge and w_{T} and w_{B} for the weights of the truck and the raised section of the bridge. Take $+y$ to be upward and $+x$ to be to the right.

EXECUTE: **(a)** $TL\sin 70° = w_{\text{T}}(\frac{3}{4}L)\cos 30° + w_{\text{B}}(\frac{1}{2}L)\cos 30°$, so

$$T = \frac{(\frac{3}{4}m_{\text{T}} + \frac{1}{2}m_{\text{B}})(9.80\text{ m/s}^2)\cos 30°}{\sin 70°} = 2.84\times 10^5\text{ N}.$$

(b) Horizontal: $T\cos(70° - 30°) = 2.18\times 10^5\text{ N}$ (to the right).

Vertical: $w_{\text{T}} + w_{\text{B}} - T\sin 40° = 2.88\times 10^5\text{ N}$ (upward).

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: If ϕ is the angle of the hinge force above the horizontal,

$\tan\phi = \dfrac{2.88\times10^5 \text{ N}}{2.18\times10^5 \text{ N}}$ and $\phi = 52.9°$. The hinge force is not directed along the bridge.

11.57. **IDENTIFY:** The leg is not rotating, so the external torques on it must balance.

SET UP: The free-body diagram for the leg is given in Figure 11.57. Take the pivot at the hip joint and let counterclockwise torque be positive. There are also forces on the leg exerted by the hip joint but these forces produce no torque and aren't shown. $\sum\tau_z = 0$ for no rotation.

EXECUTE: **(a)** $\sum\tau_z = 0$ gives $T(10 \text{ cm})(\sin\theta) - w(44 \text{ cm})(\cos\theta) = 0$.

$T = \dfrac{4.4w\cos\theta}{\sin\theta} = \dfrac{4.4w}{\tan\theta}$ and for $\theta = 60°$, $T = \dfrac{4.4(15 \text{ kg})(9.80 \text{ m/s}^2)}{\tan 60°} = 370 \text{ N}$.

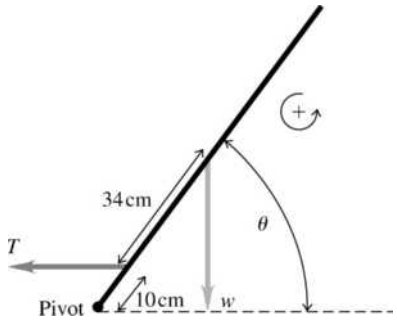

Figure 11.57

(b) For $\theta = 5°$, $T = 7400$ N. The tension is much greater when he just starts to raise his leg off the ground.

(c) $T \to \infty$ as $\theta \to 0$. The person could not raise his leg. If the leg is horizontal so θ is zero, the moment arm for T is zero and T produces no torque to rotate the leg against the torque due to its weight.

EVALUATE: Most of the exercise benefit of leg-raises occurs when the person just starts to raise his legs off the ground.

11.58. **IDENTIFY:** Apply the first and second conditions of equilibrium to the ladder.

SET UP: Take torques about the pivot. Let $+y$ be upward.

EXECUTE: **(a)** The force F_V that the ground exerts on the ladder is given to be vertical, so $\sum\tau_z = 0$ gives $F_V(6.0 \text{ m})\sin\theta = (250 \text{ N})(4.0 \text{ m})\sin\theta + (750 \text{ N})(1.50 \text{ m})\sin\theta$, so $F_V = 354$ N.

(b) There are no other horizontal forces on the ladder, so the horizontal pivot force is zero. The vertical force that the pivot exerts on the ladder must be (750 N) + (250 N) − (354 N) = 646 N, up, so the ladder exerts a downward force of 646 N on the pivot.

(c) The results in parts (a) and (b) are independent of θ.

EVALUATE: All the forces on the ladder are vertical, so all the moment arms are vertical and are proportional to $\sin\theta$. Therefore, $\sin\theta$ divides out of the torque equations and the results are independent of θ.

11.59. **IDENTIFY:** Apply the first and second conditions for equilibrium to the strut.

SET UP: Denote the length of the strut by L.

EXECUTE: **(a)** $V = mg + w$ and $H = T$. To find the tension, take torques about the pivot point.

$T\left(\dfrac{2}{3}L\right)\sin\theta = w\left(\dfrac{2}{3}L\right)\cos\theta + mg\left(\dfrac{L}{6}\right)\cos\theta$ and $T = \left(w + \dfrac{mg}{4}\right)\cot\theta$.

(b) Solving the above for w, and using the maximum tension for T,

$w = T\ \tan\theta - \dfrac{mg}{4} = (700 \text{ N})\tan 55.0° - (7.50 \text{ kg})(9.80 \text{ m/s}^2) = 926 \text{ N}$.

(c) Solving the expression obtained in part (a) for $\tan\theta$ and letting

$w \to 0$, $\tan\theta = \dfrac{mg}{4T} = 0.105$, so $\theta = 6.00°$.

EVALUATE: As the strut becomes closer to the horizontal, the moment arm for the horizontal tension force approaches zero and the tension approaches infinity.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

11.60. **IDENTIFY:** Apply the first and second conditions of equilibrium to each rod.
SET UP: Apply $\sum F_y = 0$ with $+y$ upward and apply $\sum \tau_z = 0$ with the pivot at the point of suspension for each rod.
EXECUTE: **(a)** The free-body diagram for each rod is given in Figure 11.60.
(b) $\sum \tau_z = 0$ for the lower rod: $(6.0\text{ N})(4.0\text{ cm}) = w_A(8.0\text{ cm})$ and $w_A = 3.0\text{ N}$.
$\sum F_y = 0$ for the lower rod: $S_3 = 6.0\text{ N} + w_A = 9.0\text{ N}$
$\sum \tau_z = 0$ for the middle rod: $w_B(3.0\text{ cm}) = (5.0\text{ cm})S_3$ and $w_B = \left(\frac{5.0}{3.0}\right)(9.0\text{ N}) = 15.0\text{ N}$.
$\sum F_y = 0$ for the middle rod: $S_2 = 9.0\text{ N} + S_3 = 24.0\text{ N}$
$\sum \tau_z = 0$ for the upper rod: $S_2(2.0\text{ cm}) = w_C(6.0\text{ cm})$ and $w_C = \left(\frac{2.0}{6.0}\right)(24.0\text{ N}) = 8.0\text{ N}$.
$\sum F_y = 0$ for the upper rod: $S_1 = S_2 + w_C = 32.0\text{ N}$.
In summary, $w_A = 3.0\text{ N}$, $w_B = 15.0\text{ N}$, $w_C = 8.0\text{ N}$. $S_1 = 32.0\text{ N}$, $S_2 = 24.0\text{ N}$, $S_3 = 9.0\text{ N}$.
(c) The center of gravity of the entire mobile must lie along a vertical line that passes through the point where S_1 is located.
EVALUATE: For the mobile as a whole the vertical forces must balance, so $S_1 = w_A + w_B + w_C + 6.0\text{ N}$.

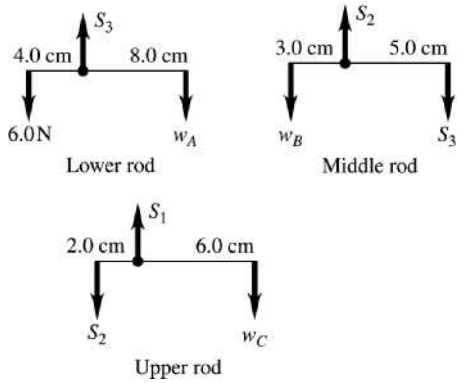

Figure 11.60

11.61. **IDENTIFY:** Apply $\sum \tau_z = 0$ to the beam.
SET UP: The free-body diagram for the beam is given in Figure 11.61.
EXECUTE: $\sum \tau_z = 0$, axis at hinge, gives $T(6.0\text{ m})(\sin 40°) - w(3.75\text{ m})(\cos 30°) = 0$ and $T = 4900\text{ N}$.
EVALUATE: The tension in the cable is less than the weight of the beam. $T\sin 40°$ is the component of T that is perpendicular to the beam.

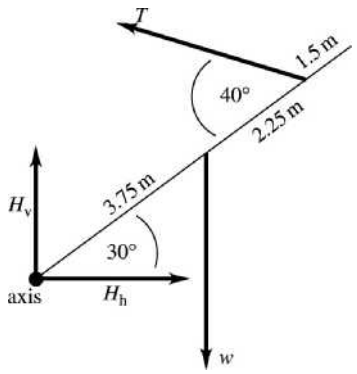

Figure 11.61

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

11.62. **IDENTIFY:** Apply the first and second conditions of equilibrium to the drawbridge.

SET UP: The free-body diagram for the drawbridge is given in Figure 11.62. H_v and H_h are the components of the force the hinge exerts on the bridge. In part (c), apply $\sum \tau_z = I\alpha$ to the rotating bridge and in part (d) apply energy conservation to the bridge.

EXECUTE: **(a)** $\sum \tau_z = 0$ with the axis at the hinge gives $-w(7.0\text{ m})(\cos 37°) + T(3.5\text{ m})(\sin 37°) = 0$ and $T = 2w\dfrac{\cos 37°}{\sin 37°} = 2\dfrac{(45{,}000\text{ N})}{\tan 37°} = 1.19\times 10^5$ N.

(b) $\sum F_x = 0$ gives $H_h = T = 1.19\times 10^5$ N. $\sum F_y = 0$ gives $H_v = w = 4.50\times 10^4$ N.

$H = \sqrt{H_h^2 + H_v^2} = 1.27\times 10^5$ N. $\tan\theta = \dfrac{H_v}{H_h}$ and $\theta = 20.7°$. The hinge force has magnitude 1.27×10^5 N and is directed at 20.7° above the horizontal.

(c) We can treat the bridge as a uniform bar rotating around one end, so $I = 1/3\, mL^2$. $\sum \tau_z = I\alpha_z$ gives $mg(L/2)\cos 37° = 1/3\, mL^2\alpha$. Solving for α gives $\alpha = \dfrac{3g\cos 37°}{2L} = \dfrac{3(9.80\text{ m/s}^2)\cos 37°}{2(14.0\text{ m})} = 0.839\text{ rad/s}^2$.

(d) Energy conservation gives $U_1 = K_2$, giving $mgh = 1/2\ I\omega^2 = (1/2)(1/3\ mL^2)\omega^2$. Trigonometry gives $h = L/2\sin 37°$. Canceling m, the energy conservation equation gives $g(L/2)\sin 37° = (1/6)L^2\omega^2$. Solving for ω gives $\omega = \sqrt{\dfrac{3g\sin 37°}{L}} = \sqrt{\dfrac{3(9.80\text{ m/s}^2)\sin 37°}{14.0\text{ m}}} = 1.12\text{ rad/s}$.

EVALUATE: The hinge force is not directed along the bridge. If it were, it would have zero torque for an axis at the center of gravity of the bridge and for that axis the tension in the cable would produce a single, unbalanced torque.

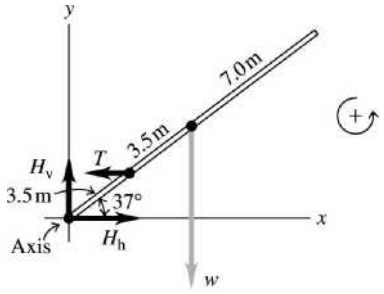

Figure 11.62

11.63. **IDENTIFY:** The amount the tendon stretches depends on Young's modulus for the tendon material. The foot is in rotational equilibrium, so the torques on it balance.

SET UP: $Y = \dfrac{F_T/A}{\Delta l/l_0}$. The foot is in rotational equilibrium, so $\sum \tau_z = 0$.

EXECUTE: **(a)** The free-body diagram for the foot is given in Figure 11.63. T is the tension in the tendon and A is the force exerted on the foot by the ankle. $n = (75\text{ kg})g$, the weight of the person.

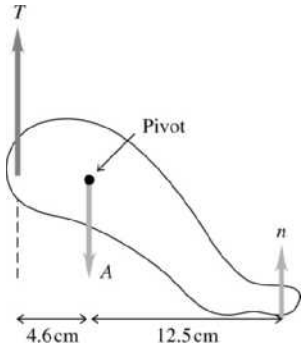

Figure 11.63

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) Apply $\sum \tau_z = 0,$ letting counterclockwise torques be positive and with the pivot at the ankle:

$T(4.6\text{ cm}) - n(12.5\text{ cm}) = 0.\ T = \left(\dfrac{12.5\text{ cm}}{4.6\text{ cm}}\right)(75\text{ kg})(9.80\text{ m/s}^2) = 2000\text{ N},$ which is 2.72 times his weight.

(c) The foot pulls downward on the tendon with a force of 2000 N.

$$\Delta l = \left(\frac{F_{\mathrm{T}}}{YA}\right) l_0 = \frac{2000\text{ N}}{(1470\times 10^6\text{ Pa})(78\times 10^{-6}\text{ m}^2)}(25\text{ cm}) = 4.4\text{ mm}.$$

EVALUATE: The tension is quite large, but the Achilles tendon stretches about 4.4 mm, which is only about 1/6 of an inch, so it must be a strong tendon.

11.64. **IDENTIFY:** Apply $\sum \tau_z = 0$ to the beam.

SET UP: The center of mass of the beam is 1.0 m from the suspension point.

EXECUTE: **(a)** Taking torques about the suspension point,
$w(4.00\text{ m})\sin 30° + (140.0\text{ N})(1.00\text{ m})\sin 30° = (100\text{ N})(2.00\text{ m})\sin 30°.$

The common factor of $\sin 30°$ divides out, from which $w = 15.0$ N.

(b) In this case, a common factor of $\sin 45°$ would be factored out, and the result would be the same.

EVALUATE: All the forces are vertical, so the moments are all horizontal and all contain the factor $\sin\theta$, where θ is the angle the beam makes with the horizontal.

11.65. **IDENTIFY:** Apply $\sum \tau_z = 0$ to the flagpole.

SET UP: The free-body diagram for the flagpole is given in Figure 11.65. Let clockwise torques be positive. θ is the angle the cable makes with the horizontal pole.

EXECUTE: **(a)** Taking torques about the hinged end of the pole
$(200\text{ N})(2.50\text{ m}) + (600\text{ N})(5.00\text{ m}) - T_y(5.00\text{ m}) = 0.\ T_y = 700$ N. The x-component of the tension is then

$T_x = \sqrt{(1000\text{ N})^2 - (700\text{ N})^2} = 714$ N. $\tan\theta = \dfrac{h}{5.00\text{ m}} = \dfrac{T_y}{T_x}.$ The height above the pole that the wire must be attached is $(5.00\text{ m})\dfrac{700}{714} = 4.90$ m.

(b) The y-component of the tension remains 700 N. Now $\tan\theta = \dfrac{4.40\text{ m}}{5.00\text{ m}}$ and $\theta = 41.35°,$ so

$T = \dfrac{T_y}{\sin\theta} = \dfrac{700\text{ N}}{\sin 41.35°} = 1060\text{ N},$ an increase of 60 N.

EVALUATE: As the wire is fastened closer to the hinged end of the pole, the moment arm for T decreases and T must increase to produce the same torque about that end.

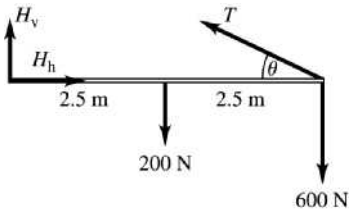

Figure 11.65

11.66. **IDENTIFY:** Apply $\sum \vec{F} = 0$ to each object, including the point where D, C and B are joined. Apply $\sum \tau_z = 0$ to the rod.

SET UP: To find T_C and $T_D,$ use a coordinate system with axes parallel to the cords.

EXECUTE: A and B are straightforward, the tensions being the weights suspended:
$T_A = (0.0360\text{ kg})(9.80\text{ m/s}^2) = 0.353$ N and $T_B = (0.0240\text{ kg} + 0.0360\text{ kg})(9.80\text{ m/s}^2) = 0.588$ N. Applying $\sum F_x = 0$ and $\sum F_y = 0$ to the point where the cords are joined, $T_C = T_B\cos 36.9° = 0.470$ N and $T_D = T_B\cos 53.1° = 0.353$ N. To find $T_E,$ take torques about the point where string F is attached.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$T_E(1.00\text{ m}) = T_D \sin 36.9°(0.800\text{ m}) + T_C \sin 53.1°(0.200\text{ m}) + (0.120\text{ kg})(9.80\text{ m/s}^2)(0.500\text{ m})$ and $T_E = 0.833$ N.

T_F may be found similarly, or from the fact that $T_E + T_F$ must be the total weight of the ornament. $(0.180\text{kg})(9.80\text{m/s}^2) = 1.76$ N, from which $T_F = 0.931$ N.

EVALUATE: The vertical line through the spheres is closer to F than to E, so we expect $T_F > T_E$, and this is indeed the case.

11.67. **IDENTIFY:** The torques must balance since the person is not rotating.

SET UP: Figure 11.67a shows the distances and angles. $\theta + \phi = 90°$. $\theta = 56.3°$ and $\phi = 33.7°$. The distances x_1 and x_2 are $x_1 = (90\text{ cm})\cos\theta = 50.0$ cm and $x_2 = (135\text{ cm})\cos\phi = 112$ cm. The free-body diagram for the person is given in Figure 11.67b. $w_l = 277$ N is the weight of his feet and legs, and $w_t = 473$ N is the weight of his trunk. n_f and f_f are the total normal and friction forces exerted on his feet and n_h and f_h are those forces on his hands. The free-body diagram for his legs is given in Figure 11.67c. F is the force exerted on his legs by his hip joints. For balance, $\sum \tau_z = 0$.

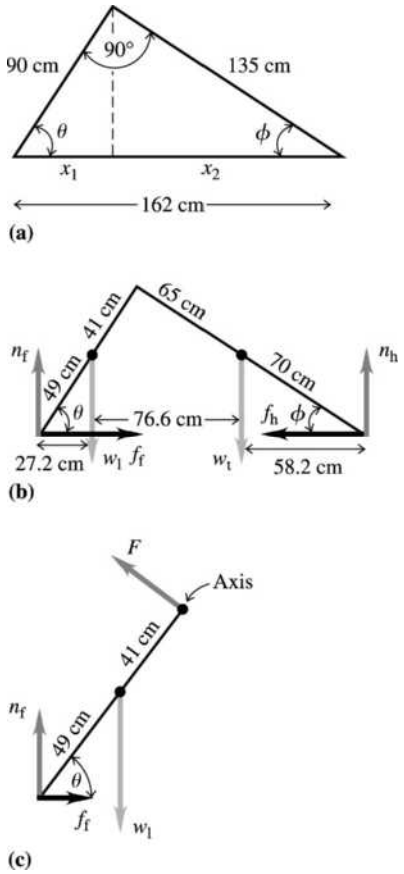

Figure 11.67

EXECUTE: **(a)** Consider the force diagram of Figure 11.67b. $\sum \tau_z = 0$ with the pivot at his feet and counterclockwise torques positive gives $n_h(162\text{ cm}) - (277\text{ N})(27.2\text{ cm}) - (473\text{ N})(103.8\text{ cm}) = 0$.

$n_h = 350$ N, so there is a normal force of 175 N at each hand. $n_f + n_h - w_l - w_t = 0$ so $n_f = w_l + w_t - n_h = 750\text{ N} - 350\text{ N} = 400$ N, so there is a normal force of 200 N at each foot.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) Consider the force diagram of Figure 11.67c. $\sum \tau_z = 0$ with the pivot at his hips and counterclockwise torques positive gives $f_f(74.9\text{ cm}) + w_l(22.8\text{ cm}) - n_f(50.0\text{ cm}) = 0$.

$f_f = \dfrac{(400\text{ N})(50.0\text{ cm}) - (277\text{ N})(22.8\text{ cm})}{74.9\text{ cm}} = 182.7\text{ N}$. There is a friction force of 91 N at each foot.

$\sum F_x = 0$ in Figure 11.67b gives $f_h = f_f$, so there is a friction force of 91 N at each hand.

EVALUATE: In this position the normal forces at his feet and at his hands don't differ very much.

11.68. **IDENTIFY:** Apply Eq. (11.10) and the relation $\Delta w/w_0 = -\sigma \Delta l/l_0$ that is given in the problem.

SET UP: The steel rod in Example 11.5 has $\Delta l/l_0 = 9.0\times10^{-4}$. For nickel, $Y = 2.1\times10^{11}$ Pa. The width w_0 is $w_0 = \sqrt{4A/\pi}$.

EXECUTE: **(a)** $\Delta w = -\sigma\,(\Delta l/l)w_0 = -(0.23)(9.0\times10^{-4})\sqrt{4(0.30\times10^{-4}\text{ m}^2)/\pi} = -1.3\ \mu\text{m}$.

(b) $F_\perp = AY\dfrac{\Delta l}{l} = AY\dfrac{1}{\sigma}\dfrac{\Delta w}{w}$ and $F_\perp = \dfrac{(2.1\times10^{11}\text{ Pa})\,(\pi\,(2.0\times10^{-2}\text{ m})^2)}{0.42}\dfrac{0.10\times10^{-3}\text{ m}}{2.0\times10^{-2}\text{ m}} = 3.1\times10^{6}\text{ N}$.

EVALUATE: For nickel and steel, $\sigma < 1$ and the fractional change in width is less than the fractional change in length.

11.69. **IDENTIFY:** Apply the equilibrium conditions to the crate. When the crate is on the verge of tipping it touches the floor only at its lower left-hand corner and the normal force acts at this point. The minimum coefficient of static friction is given by the equation $f_s = \mu_s n$.

SET UP: The free-body diagram for the crate when it is ready to tip is given in Figure 11.69.

EXECUTE: **(a)** $\sum \tau_z = 0$ gives $P(1.50\text{ m})\sin 53.0° - w(1.10\text{ m}) = 0$.

$P = w\left(\dfrac{1.10\text{ m}}{[1.50\text{ m}][\sin 53.0°]}\right) = 1.15\times10^{3}\text{ N}$

(b) $\sum F_y = 0$ gives $n - w - P\cos 53.0° = 0$.

$n = w + P\cos 53.0° = 1250\text{ N} + (1.15\times10^{3}\text{ N})\cos 53° = 1.94\times10^{3}\text{ N}$

(c) $\sum F_y = 0$ gives $f_s = P\sin 53.0° = (1.15\times10^{3}\text{ N})\sin 53.0° = 918\text{ N}$.

(d) $\mu_s = \dfrac{f_s}{n} = \dfrac{918\text{ N}}{1.94\times10^{3}\text{ N}} = 0.473$

EVALUATE: The normal force is greater than the weight because P has a downward component.

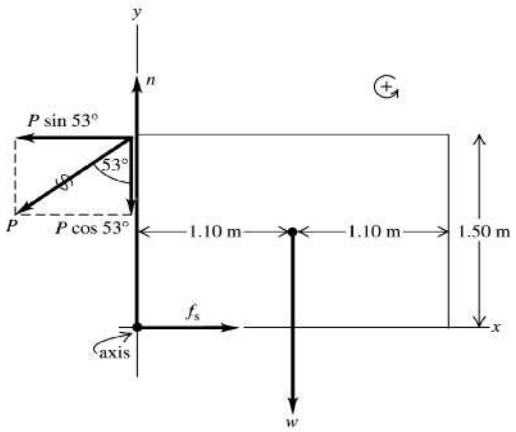

Figure 11.69

11.70. **IDENTIFY:** Apply $\sum \tau_z = 0$ to the meterstick.

SET UP: The wall exerts an upward static friction force f and a horizontal normal force n on the stick. Denote the length of the stick by l. $f = \mu_s n$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: **(a)** Taking torques about the right end of the stick, the friction force is half the weight of the stick, $f = w/2$. Taking torques about the point where the cord is attached to the wall (the tension in the cord and the friction force exert no torque about this point), and noting that the moment arm of the normal force is $l\tan\theta$, $n\tan\theta = w/2$. Then, $(f/n) = \tan\theta < 0.40$, so $\theta < \arctan(0.40) = 22°$.

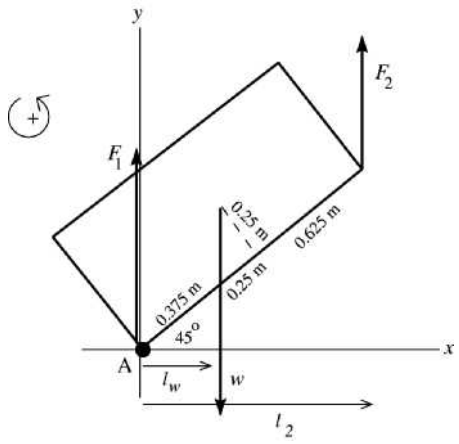
(b) Taking torques as in part (a), $fl = w\frac{l}{2} + w(l-x)$ and $nl\ \tan\ \theta = w\frac{l}{2} + wx$. In terms of the coefficient of friction μ_s, $\mu_s > \frac{f}{n} = \frac{l/2+(l-x)}{l/2+x}\tan\theta = \frac{3l-2x}{l+2x}\tan\theta$. Solving for x, $x > \frac{l}{2}\frac{3\tan\theta-\mu_s}{\mu_s+\tan\theta} = 30.2$ cm.

(c) In the above expression, setting $x = 10$ cm and $l = 100$ cm and solving for μ_s gives

$$\mu_s > \frac{(3-20/l)\tan\theta}{1+20/l} = 0.625.$$

EVALUATE: For $\theta = 15°$ and without the block suspended from the stick, a value of $\mu_s \geq 0.268$ is required to prevent slipping. Hanging the block from the stick increases the value of μ_s that is required.

11.71. **IDENTIFY:** Apply the first and second conditions of equilibrium to the crate.
SET UP: The free-body diagram for the crate is given in Figure 11.71.



$l_w = (0.375\text{ m})\cos 45°$
$l_2 = (1.25\text{ m})\cos 45°$
Let $\vec{F}_1$ and $\vec{F}_2$ be the vertical forces exerted by you and your friend. Take the origin at the lower left-hand corner of the crate (point A).

Figure 11.71

EXECUTE: $\sum F_y = ma_y$ gives $F_1 + F_2 - w = 0$

$F_1 + F_2 = w = (200\text{ kg})(9.80\text{ m/s}^2) = 1960$ N

$\sum \tau_A = 0$ gives $F_2 l_2 - w l_w = 0$

$$F_2 = w\left(\frac{l_w}{l_2}\right) = 1960\text{ N}\left(\frac{0.375\text{ m}\cos 45°}{1.25\text{ m}\cos 45°}\right) = 590\text{ N}$$

Then $F_1 = w - F_2 = 1960\text{ N} - 590\text{ N} = 1370$ N.

EVALUATE: The person below (you) applies a force of 1370 N. The person above (your friend) applies a force of 590 N. It is better to be the person above. As the sketch shows, the moment arm for $\vec{F}_1$ is less than for $\vec{F}_2$, so must have $F_1 > F_2$ to compensate.

11.72. **IDENTIFY:** Apply the first and second conditions for equilibrium to the forearm.
SET UP: The free-body diagram is given in Figure 11.72a, and when holding the weight in Figure 11.72b. Let $+y$ be upward.

EXECUTE: **(a)** $\sum \tau_{\text{Elbow}} = 0$ gives $F_B(3.80\text{ cm}) = (15.0\text{ N})(15.0\text{ cm})$ and $F_B = 59.2$ N.

(b) $\sum \tau_{\text{Elbow}} = 0$ gives $F_B(3.80\text{ cm}) = (15.0\text{ N})(15.0\text{ cm}) + (80.0\text{ N})(33.0\text{ cm})$ and $F_B = 754$ N. The biceps force has a short lever arm, so it must be large to balance the torques.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(c) $\sum F_y = 0$ gives $-F_E + F_B - 15.0\text{ N} - 80.0\text{ N} = 0$ and $F_E = 754\text{N} - 15.0\text{ N} - 80.0\text{ N} = 659\text{ N}$.

EVALUATE: **(d)** The biceps muscle acts perpendicular to the forearm, so its lever arm stays the same, but those of the other two forces decrease as the arm is raised. Therefore the tension in the biceps muscle *decreases*.

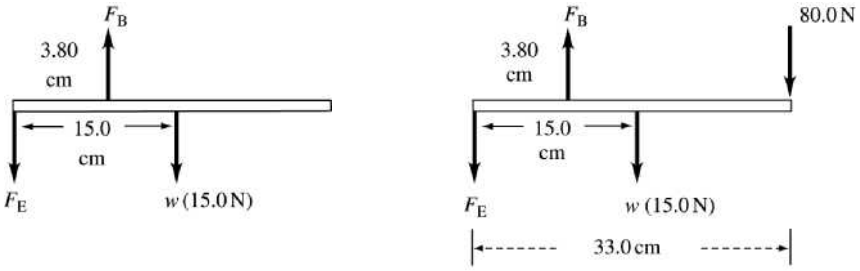


Figure 11.72a, b

11.73. **IDENTIFY:** Apply $\sum \tau_z = 0$ to the forearm.

SET UP: The free-body diagram for the forearm is given in Figure 11.10 in the textbook.

EXECUTE: **(a)** $\sum \tau_z = 0$, axis at elbow gives $wL - (T\ \sin\theta)D = 0$. $\sin\theta = \dfrac{h}{\sqrt{h^2 + D^2}}$ so $w = T\dfrac{hD}{L\sqrt{h^2 + D^2}}$.

$w_{\max} = T_{\max}\dfrac{hD}{L\sqrt{h^2 + D^2}}$.

(b) $\dfrac{dw_{\max}}{dD} = \dfrac{T_{\max}h}{L\sqrt{h^2 + D^2}}\left(1 - \dfrac{D^2}{h^2 + D^2}\right)$; the derivative is positive.

EVALUATE: **(c)** The result of part (b) shows that $w_{\max}$ increases when D increases, since the derivative is positive. $w_{\max}$ is larger for a chimp since D is larger.

11.74. **IDENTIFY:** Apply the first and second conditions for equilibrium to the table.

SET UP: Label the legs as shown in Figure 11.74a. Legs A and C are 3.6 m apart. Let the weight be placed closest to legs C and D. By symmetry, $A = B$ and $C = D$. Redraw the table as viewed from the AC side. The free-body diagram in this view is given in Figure 11.74b.

EXECUTE: $\sum \tau_z$ (about right end) $= 0$ gives $2A(3.6\text{ m}) = (90.0\text{ N})(1.8\text{ m}) + (1500\text{ N})(0.50\text{ m})$ and $A = 130\text{ N} = B$. $\sum F_y = 0$ gives $A + B + C + D = 1590\text{ N}$. Using $A = B = 130\text{ N}$ and $C = D$ gives $C = D = 670\text{ N}$. By Newton's third law of motion, the forces A, B, C and D on the table are the same magnitude as the forces the table exerts on the floor.

EVALUATE: As expected, the legs closest to the 1500 N weight exert a greater force on the floor.

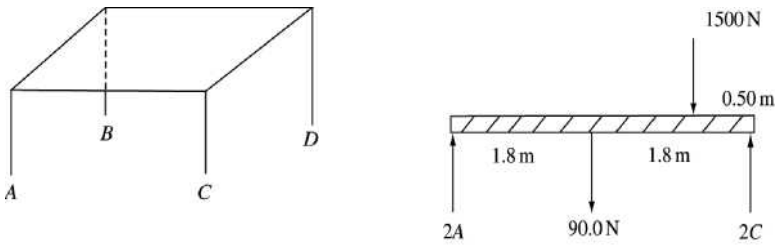

Figure 11.74a, b

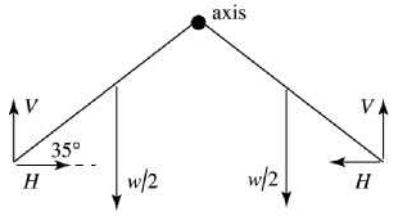
11.75. **IDENTIFY:** Apply $\sum \tau_z = 0$ first to the roof and then to one wall.

(a) SET UP: Consider the forces on the roof; see Figure 11.75a.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.



V and H are the vertical and horizontal forces each wall exerts on the roof.
$w = 20{,}000$ N is the total weight of the roof.
$2V = w$ so $V = w/2$

Figure 11.75a

Apply $\sum \tau_z = 0$ to one half of the roof, with the axis along the line where the two halves join. Let each half have length L.

EXECUTE: $(w/2)(L/2)(\cos 35.0°) + HL\sin 35.0° - VL\cos 35° = 0$

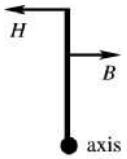
L divides out, and use $V = w/2$

$H\sin 35.0° = \frac{1}{4}w\cos 35.0°$

$$H = \frac{w}{4\tan 35.0°} = 7140 \text{ N}$$

EVALUATE: By Newton's third law, the roof exerts a horizontal, outward force on the wall. For torque about an axis at the lower end of the wall, at the ground, this force has a larger moment arm and hence larger torque the taller the walls.

(b) SET UP: The force diagram for one wall is given in Figure 11.75b.



Consider the torques on this wall.

Figure 11.75b

H is the horizontal force exerted by the roof, as considered in part (a). B is the horizontal force exerted by the buttress. Now the angle is $40°$, so $H = \frac{w}{4\tan 40°} = 5959$ N.

EXECUTE: $\sum \tau_z = 0$, axis at the ground

$H(40 \text{ m}) - B(30 \text{ m}) = 0$ and $B = 7900$ N.

EVALUATE: The horizontal force exerted by the roof is larger as the roof becomes more horizontal, since for torques applied to the roof the moment arm for H decreases. The force B required from the buttress is less the higher up on the wall this force is applied.

11.76. **IDENTIFY:** Apply $\sum \tau_z = 0$ to the wheel.

SET UP: Take torques about the upper corner of the curb.

EXECUTE: The force $\vec{F}$ acts at a perpendicular distance $R - h$ and the weight acts at a perpendicular distance $\sqrt{R^2 - (R-h)^2} = \sqrt{2Rh - h^2}$. Setting the torques equal for the minimum necessary force,

$$F = mg\frac{\sqrt{2Rh - h^2}}{R - h}.$$

(b) The torque due to gravity is the same, but the force $\vec{F}$ acts at a perpendicular distance $2R - h$, so the minimum force is $(mg)\sqrt{2Rh - h^2}/(2R - h)$.

EVALUATE: **(c)** Less force is required when the force is applied at the top of the wheel, since in this case $\vec{F}$ has a larger moment arm.

11.77. **IDENTIFY:** Apply the first and second conditions of equilibrium to the gate.

SET UP: The free-body diagram for the gate is given in Figure 11.77.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

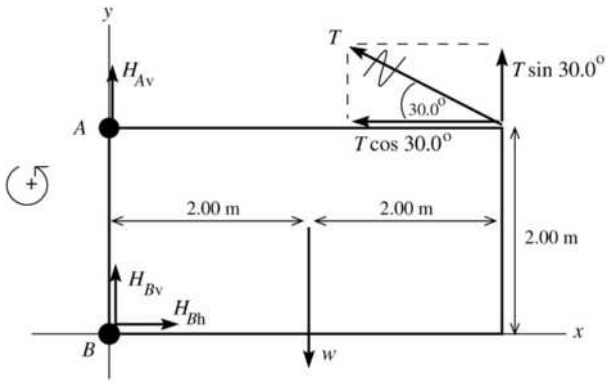


Figure 11.77

Use coordinates with the origin at B. Let $\vec{\boldsymbol{H}}_A$ and $\vec{\boldsymbol{H}}_B$ be the forces exerted by the hinges at A and B. The problem states that $\vec{\boldsymbol{H}}_A$ has no horizontal component. Replace the tension $\vec{\boldsymbol{T}}$ by its horizontal and vertical components.

EXECUTE: **(a)** $\sum \tau_B = 0$ gives $+(T\sin 30.0°)(4.00\text{ m}) + (T\cos 30.0°)(2.00\text{ m}) - w(2.00\text{ m}) = 0$

$T(2\sin 30.0° + \cos 30.0°) = w$

$$T = \frac{w}{2\sin 30.0° + \cos 30.0°} = \frac{500\text{ N}}{2\sin 30.0° + \cos 30.0°} = 268\text{ N}$$

(b) $\sum F_x = ma_x$ says $H_{Bh} - T\cos 30.0° = 0$

$H_{Bh} = T\cos 30.0° = (268\text{ N})\cos 30.0° = 232\text{ N}$

(c) $\sum F_y = ma_y$ says $H_{Av} + H_{Bv} + T\sin 30.0° - w = 0$

$H_{Av} + H_{Bv} = w - T\sin 30.0° = 500\text{ N} - (268\text{ N})\sin 30.0° = 366\text{ N}$

EVALUATE: T has a horizontal component to the left so H_{Bh} must be to the right, as these are the only two horizontal forces. Note that we cannot determine H_{Av} and H_{Bv} separately, only their sum.

11.78. **IDENTIFY:** Use Eq. (11.3) to locate the x-coordinate of the center of gravity of the block combinations.

SET UP: The center of mass and the center of gravity are the same point. For two identical blocks, the center of gravity is midway between the center of the two blocks.

EXECUTE: **(a)** The center of gravity of the top block can be as far out as the edge of the lower block. The center of gravity of this combination is then $3L/4$ to the left of the right edge of the upper block, so the overhang is $3L/4$.

(b) Take the two-block combination from part (a), and place it on top of the third block such that the overhang of $3L/4$ is from the right edge of the third block; that is, the center of gravity of the first two blocks is above the right edge of the third block. The center of mass of the three-block combination, measured from the right end of the bottom block, is $-L/6$ and so the largest possible overhang is $(3L/4) + (L/6) = 11L/12$. Similarly, placing this three-block combination with its center of gravity over the right edge of the fourth block allows an extra overhang of $L/8$, for a total of $25L/24$.

(c) As the result of part (b) shows, with only four blocks, the overhang can be larger than the length of a single block.

EVALUATE: The sequence of maximum overhangs is $\frac{18L}{24}, \frac{22L}{24}, \frac{25L}{24}, \ldots$. The increase of overhang when one more block is added is decreasing.

11.79. **IDENTIFY:** Apply the first and second conditions of equilibrium, first to both marbles considered as a composite object and then to the bottom marble.

(a) SET UP: The forces on each marble are shown in Figure 11.79.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

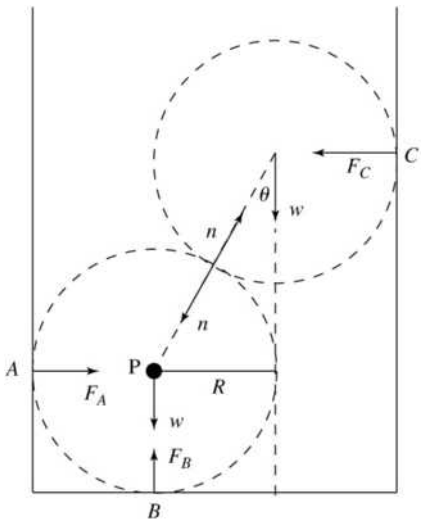

Figure 11.79

EXECUTE:

$F_B = 2w = 1.47$ N

$\sin\theta = R/2R$ so $\theta = 30°$

$\sum \tau_z = 0$, axis at P

$F_C(2R\cos\theta) - wR = 0$

$$F_C = \frac{mg}{2\cos 30°} = 0.424 \text{ N}$$

$F_A = F_C = 0.424$ N

(b) Consider the forces on the bottom marble. The horizontal forces must sum to zero, so $F_A = n\sin\theta$.

$$n = \frac{F_A}{\sin 30°} = 0.848 \text{ N}$$

Could use instead that the vertical forces sum to zero

$F_B - mg - n\cos\theta = 0$

$$n = \frac{F_B - mg}{\cos 30°} = 0.848 \text{ N, which checks.}$$

EVALUATE: If we consider each marble separately, the line of action of every force passes through the center of the marble so there is clearly no torque about that point for each marble. We can use the results we obtained to show that $\sum F_x = 0$ and $\sum F_y = 0$ for the top marble.

11.80. **IDENTIFY:** Apply $\sum \tau_z = 0$ to the right-hand beam.

SET UP: Use the hinge as the axis of rotation and take counterclockwise rotation as positive. If F_{wire} is the tension in each wire and $w = 200$ N is the weight of each beam, $2F_{\text{wire}} - 2w = 0$ and $F_{\text{wire}} = w$. Let L be the length of each beam.

EXECUTE: **(a)** $\sum \tau_z = 0$ gives $F_{\text{wire}} L\sin\frac{\theta}{2} - F_{\text{c}}\frac{L}{2}\cos\frac{\theta}{2} - w\frac{L}{2}\sin\frac{\theta}{2} = 0$, where θ is the angle between the beams and F_{c} is the force exerted by the cross bar. The length drops out, and all other quantities except F_{c} are known, so $F_{\text{c}} = \dfrac{F_{\text{wire}}\sin(\theta/2)) - \frac{1}{2}w\sin(\theta/2)}{\frac{1}{2}\cos(\theta/2)} = (2F_{\text{wire}} - w)\tan\dfrac{\theta}{2}$. Therefore $F = (260 \text{ N})\tan\dfrac{53°}{2} = 130$ N.

(b) The crossbar is under compression, as can be seen by imagining the behavior of the two beams if the crossbar were removed. It is the crossbar that holds them apart.

(c) The upward pull of the wire on each beam is balanced by the downward pull of gravity, due to the symmetry of the arrangement. The hinge therefore exerts no vertical force. It must, however, balance the outward push of the crossbar. The hinge exerts a force 130 N horizontally to the left for the right-hand beam and 130 N to the right for the left-hand beam. Again, it's instructive to visualize what the beams would do if the hinge were removed.

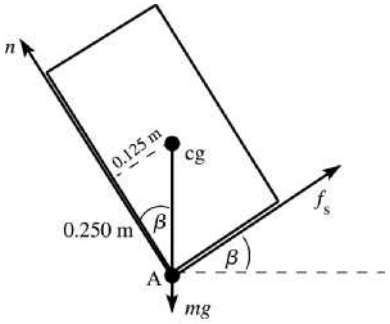
EVALUATE: The force exerted on each beam increases as θ increases and exceeds the weight of the beam for $\theta \geq 90°$.

11.81. **IDENTIFY:** Apply the first and second conditions of equilibrium to the bale.

(a) SET UP: Find the angle where the bale starts to tip. When it starts to tip only the lower left-hand corner of the bale makes contact with the conveyor belt. Therefore the line of action of the normal force n passes through the left-hand edge of the bale. Consider $\Sigma\tau_z = 0$ with point A at the lower left-hand corner.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

Then $\tau_n = 0$ and $\tau_f = 0,$ so it must be that $\tau_{mg} = 0$ also. This means that the line of action of the gravity must pass through point A. Thus the free-body diagram must be as shown in Figure 11.81a.

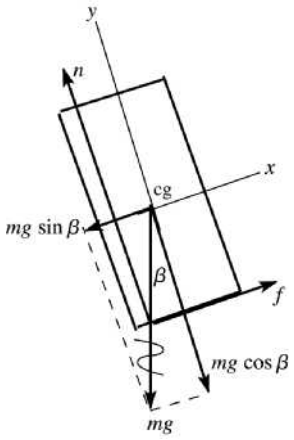


EXECUTE: $\tan\beta = \dfrac{0.125\text{ m}}{0.250\text{ m}}$

$\beta = 27°,$ angle where tips

Figure 11.81a

SET UP: At the angle where the bale is ready to slip down the incline f_s has its maximum possible value, $f_s = \mu_s n.$ The free-body diagram for the bale, with the origin of coordinates at the cg is given in Figure 11.81b.



EXECUTE:

$\sum F_y = ma_y$

$n - mg\cos\beta = 0$

$n = mg\cos\beta$

$f_s = \mu_s mg\cos\beta$

(f_s has maximum value when bale ready to slip)

$\sum F_x = ma_x$

$f_s - mg\sin\beta = 0$

$\mu_s mg\cos\beta - mg\sin\beta = 0$

$\tan\beta = \mu_s$

$\mu_s = 0.60$ gives that $\beta = 31°$

Figure 11.81b

$\beta = 27°$ to tip; $\beta = 31°$ to slip, so tips first

(b) The magnitude of the friction force didn't enter into the calculation of the tipping angle; still tips at $\beta = 27°.$ For $\mu_s = 0.40$ slips at $\beta = \arctan(0.40) = 22°.$

Now the bale will start to slide down the incline before it tips.

EVALUATE: With a smaller μ_s the slope angle β where the bale slips is smaller.

11.82. **IDENTIFY:** Apply the equilibrium conditions to the pole. The horizontal component of the tension in the wire is 22.0 N.

SET UP: The free-body diagram for the pole is given in Figure 11.82. The tension in the cord equals the weight $W.$ F_v and F_h are the components of the force exerted by the hinge. If either of these forces is actually in the opposite direction to what we have assumed, we will get a negative value when we solve for it.

EXECUTE: **(a)** $T\sin 37.0° = 22.0$ N so $T = 36.6$ N. $\sum \tau_z = 0$ gives $(T\sin 37.0°)(1.75\text{ m}) - W(1.35\text{ m}) = 0.$

$$W = \frac{(22.0\text{ N})(1.75\text{ m})}{1.35\text{ m}} = 28.5\text{ N}.$$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) $\sum F_y = 0$ gives $F_{\rm v} - T\cos 37.0° - w = 0$ and $F_{\rm v} = (36.6\text{ N})\cos 37.0° + 55.0\text{ N} = 84.2\text{ N}$. $\sum F_x = 0$ gives $W - T\sin 37.0° - F_{\rm h} = 0$ and $F_{\rm h} = 28.5\text{ N} - 22.0\text{ N} = 6.5\text{ N}$. The magnitude of the hinge force is $F = \sqrt{F_{\rm h}^2 + F_{\rm v}^2} = 84.5\text{ N}$.

EVALUATE: If we consider torques about an axis at the top of the pole, we see that $F_{\rm h}$ must be to the left in order for its torque to oppose the torque produced by the force W.

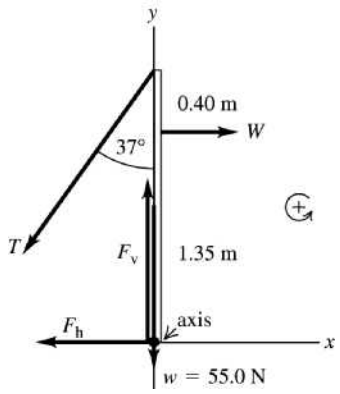


Figure 11.82

11.83. **IDENTIFY:** Apply the first and second conditions of equilibrium to the door.

(a) SET UP: The free-body diagram for the door is given in Figure 11.83.

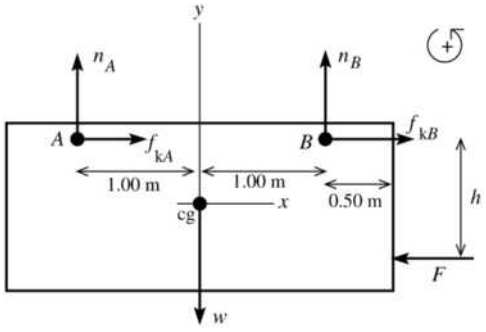

Figure 11.83

Take the origin of coordinates at the center of the door (at the cg). Let n_A, f_{kA}, n_B and f_{kB} be the normal and friction forces exerted on the door at each wheel.

EXECUTE: $\sum F_y = ma_y$

$n_A + n_B - w = 0$

$n_A + n_B = w = 950\text{ N}$

$\sum F_x = ma_x$

$f_{kA} + f_{kB} - F = 0$

$F = f_{kA} + f_{kB}$

$f_{kA} = \mu_{\rm k} n_A$, $f_{kB} = \mu_{\rm k} n_B$, so $F = \mu_{\rm k}(n_A + n_B) = \mu_{\rm k} w = (0.52)(950\text{ N}) = 494\text{ N}$

$\sum \tau_B = 0$

n_B, f_{kA} and f_{kB} all have zero moment arms and hence zero torque about this point.

Thus $+w(1.00\text{ m}) - n_A(2.00\text{ m}) - F(h) = 0$

$$n_A = \frac{w(1.00\text{ m}) - F(h)}{2.00\text{ m}} = \frac{(950\text{ N})(1.00\text{ m}) - (494\text{ N})(1.60\text{ m})}{2.00\text{ m}} = 80\text{ N}$$

And then $n_B = 950\text{ N} - n_A = 950\text{ N} - 80\text{ N} = 870\text{ N}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) SET UP: If h is too large the torque of F will cause wheel A to leave the track. When wheel A just starts to lift off the track n_A and f_{kA} both go to zero.

EXECUTE: The equations in part (a) still apply.

$n_A + n_B - w = 0$ gives $n_B = w = 950$ N

Then $f_{kB} = \mu_k n_B = 0.52(950\text{ N}) = 494$ N

$F = f_{kA} + f_{kB} = 494$ N

$+w(1.00\text{ m}) - n_A(2.00\text{ m}) - F(h) = 0$

$$h = \frac{w(1.00\text{ m})}{F} = \frac{(950\text{ N})(1.00\text{ m})}{494\text{ N}} = 1.92\text{ m}$$

EVALUATE: The result in part (b) is larger than the value of h in part (a). Increasing h increases the clockwise torque about B due to F and therefore decreases the clockwise torque that n_A must apply.

11.84. **IDENTIFY:** Apply the first and second conditions for equilibrium to the boom.

SET UP: Take the rotation axis at the left end of the boom.

EXECUTE: **(a)** The magnitude of the torque exerted by the cable must equal the magnitude of the torque due to the weight of the boom. The torque exerted by the cable about the left end is $TL\sin\theta$.

For any angle θ, $\sin(180° - \theta) = \sin\theta$, so the tension T will be the same for either angle. The horizontal component of the force that the pivot exerts on the boom will be $T\cos\theta$ or $T\cos(180° - \theta) = -T\cos\theta$.

(b) From the result of part (a), T is proportional to $\dfrac{1}{\sin\theta}$ and this becomes infinite as $\theta \to 0$ or $\theta \to 180°$.

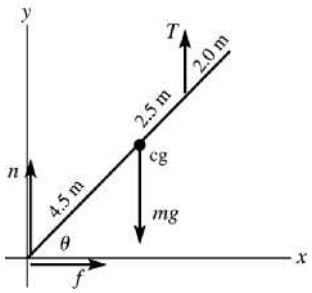
(c) The tension is a minimum when $\sin\theta$ is a maximum, or $\theta = 90°$, a vertical cable.

(d) There are no other horizontal forces, so for the boom to be in equilibrium, the pivot exerts zero horizontal force on the boom.

EVALUATE: As the cable approaches the horizontal direction, its moment arm for the axis at the pivot approaches zero, so T must go to infinity in order for the torque due to the cable to continue to equal the gravity torque.

11.85. **IDENTIFY:** Apply the first and second conditions of equilibrium to the pole.

(a) SET UP: The free-body diagram for the pole is given in Figure 11.85.



n and f are the vertical and horizontal components of the force the ground exerts on the pole.

$\sum F_x = ma_x$

$f = 0$

The force exerted by the ground has no horizontal component.

Figure 11.85

EXECUTE: $\sum \tau_A = 0$

$+T(7.0\text{ m})\cos\theta - mg(4.5\text{ m})\cos\theta = 0$

$T = mg(4.5\text{ m}/7.0\text{ m}) = (4.5/7.0)(5700\text{ N}) = 3700$ N

$\sum F_y = 0$

$n + T - mg = 0$

$n = mg - T = 5700\text{ N} - 3700\text{ N} = 2000$ N

The force exerted by the ground is vertical (upward) and has magnitude 2000 N.

EVALUATE: We can verify that $\sum \tau_z = 0$ for an axis at the cg of the pole. $T > n$ since T acts at a point closer to the cg and therefore has a smaller moment arm for this axis than n does.

(b) In the $\sum \tau_A = 0$ equation the angle θ divided out. All forces on the pole are vertical and their moment arms are all proportional to $\cos\theta$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

11.86. **IDENTIFY:** Apply $\sum \tau_z = 0$ to the slab.

SET UP: The free-body diagram is given in Figure 11.86a. $\tan\beta = \dfrac{3.75\text{ m}}{1.75\text{ m}}$ so $\beta = 65.0°$. $20.0° + \beta + \alpha = 90°$ so $\alpha = 5.0°$. The distance from the axis to the center of the block is $\sqrt{\left(\dfrac{3.75\text{ m}}{2}\right)^2 + \left(\dfrac{1.75\text{ m}}{2}\right)^2} = 2.07\text{ m}$.

EXECUTE: **(a)** $w(2.07\text{ m})\sin 5.0° - T(3.75\text{ m})\sin 52.0° = 0$. $T = 0.061w$. Each worker must exert a force of $0.012w$, where w is the weight of the slab.

(b) As θ increases, the moment arm for w decreases and the moment arm for T increases, so the worker needs to exert less force.

(c) $T \to 0$ when w passes through the support point. This situation is sketched in Figure 11.86b. $\tan\theta = \dfrac{(1.75\text{ m})/2}{(3.75\text{ m})/2}$ and $\theta = 25.0°$. If θ exceeds this value the gravity torque causes the slab to tip over.

EVALUATE: The moment arm for T is much greater than the moment arm for w, so the force the workers apply is much less than the weight of the slab.

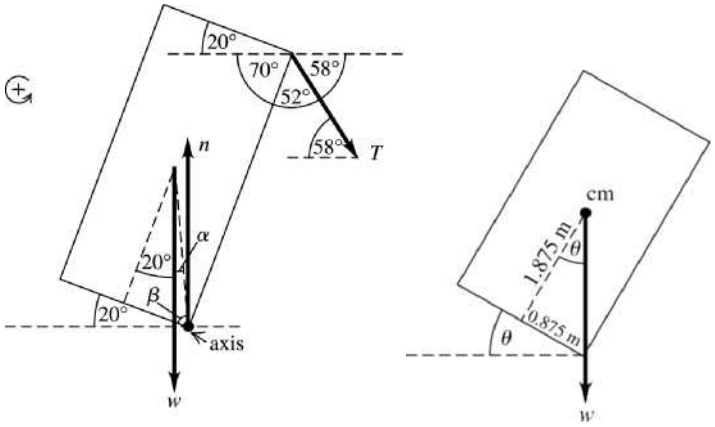


Figure 11.86 a, b

11.87. **IDENTIFY** and **SET UP:** $Y = F_\perp l_0/A\,\Delta l$ (Eq. 11.10 holds since the problem states that the stress is proportional to the strain.) Thus $\Delta l = F_\perp l_0/AY$. Use proportionality to see how changing the wire properties affects Δl.

EXECUTE: **(a)** Change l_0 but $F_\perp$ (same floodlamp), A (same diameter wire), and Y (same material) all stay the same.

$\dfrac{\Delta l}{l_0} = \dfrac{F_\perp}{AY} = \text{constant}$, so $\dfrac{\Delta l_1}{l_{01}} = \dfrac{\Delta l_2}{l_{02}}$

$\Delta l_2 = \Delta l_1(l_{02}/l_{01}) = 2\Delta l_1 = 2(0.18\text{ mm}) = 0.36\text{ mm}$

(b) $A = \pi(d/2)^2 = \frac{1}{4}\pi d^2$, so $\Delta l = \dfrac{F_\perp l_0}{\frac{1}{4}\pi d^2 Y}$

$F_\perp$, l_0, Y all stay the same, so $\Delta l(d^2) = F_\perp l_0/(\frac{1}{4}\pi Y) = \text{constant}$

$\Delta l_1(d_1^2) = \Delta l_2(d_2^2)$

$\Delta l_2 = \Delta l_1(d_1/d_2)^2 = (0.18\text{ mm})(1/2)^2 = 0.045\text{ mm}$

(c) $F_\perp$, l_0, A all stay the same so $\Delta l Y = F_\perp l_0/A = \text{constant}$

$\Delta l_1 Y_1 = \Delta l_2 Y_2$

$\Delta l_2 = \Delta l_1(Y_1/Y_2) = (0.18\text{ mm})(20\times10^{10}\text{ Pa}/11\times10^{10}\text{ Pa}) = 0.33\text{ mm}$

EVALUATE: Greater l means greater Δl, greater diameter means less Δl, and smaller Y means greater Δl.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

11.88. **IDENTIFY:** For a spring, $F = kx$. $Y = \dfrac{F_\perp l_0}{A\Delta l}$.

SET UP: $F_\perp = F = W$ and $\Delta l = x$. For copper, $Y = 11\times10^{10}$ Pa.

EXECUTE: **(a)** $F = \left(\dfrac{YA}{l_0}\right)\Delta l = \left(\dfrac{YA}{l_0}\right)x$. This in the form of $F = kx$, with $k = \dfrac{YA}{l_0}$.

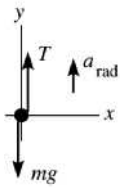
(b) $k = \dfrac{YA}{l_0} = \dfrac{(11\times10^{10}\text{ Pa})\pi(6.455\times10^{-4}\text{ m})^2}{0.750\text{ m}} = 1.9\times10^5\text{ N/m}$

(c) $W = kx = (1.9\times10^5\text{ N/m})(1.25\times10^{-3}\text{ m}) = 240\text{ N}$

EVALUATE: For the wire the force constant is very large, much larger than for a typical spring.

11.89. **IDENTIFY:** Apply Newton's second law to the mass to find the tension in the wire. Then apply Eq. (11.10) to the wire to find the elongation this tensile force produces.

(a) SET UP: Calculate the tension in the wire as the mass passes through the lowest point. The free-body diagram for the mass is given in Figure 11.89a.



The mass moves in an arc of a circle with radius $R = 0.50$ m. It has acceleration $\vec{a}_{\text{rad}}$ directed in toward the center of the circle, so at this point $\vec{a}_{\text{rad}}$ is upward.

Figure 11.89 a

EXECUTE: $\sum F_y = ma_y$

$T - mg = mR\omega^2$ so that $T = m(g + R\omega^2)$.

But ω must be in rad/s:

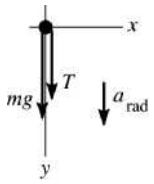
$\omega = (120\text{ rev/min})(2\pi\text{ rad/1 rev})(1\text{ min/60 s}) = 12.57\text{ rad/s}$.

Then $T = (12.0\text{ kg})(9.80\text{ m/s}^2 + (0.50\text{ m})(12.57\text{ rad/s})^2) = 1066\text{ N}$.

Now calculate the elongation Δl of the wire that this tensile force produces:

$Y = \dfrac{F_\perp l_0}{A\Delta l}$ so $\Delta l = \dfrac{F_\perp l_0}{YA} = \dfrac{(1066\text{ N})(0.50\text{ m})}{(7.0\times10^{10}\text{ Pa})(0.014\times10^{-4}\text{ m}^2)} = 0.54\text{ cm}$.

(b) SET UP: The acceleration $\vec{a}_{\text{rad}}$ is directed in toward the center of the circular path, and at this point in the motion this direction is downward. The free-body diagram is given in Figure 11.89b.



EXECUTE:

$\sum F_y = ma_y$

$mg + T = mR\omega^2$

$T = m(R\omega^2 - g)$

Figure 11.89 b

$T = (12.0\text{ kg})((0.50\text{ m})(12.57\text{ rad/s})^2 - 9.80\text{ m/s}^2) = 830\text{ N}$

$\Delta l = \dfrac{F_\perp l_0}{YA} = \dfrac{(830\text{ N})(0.50\text{ m})}{(7.0\times10^{10}\text{ Pa})(0.014\times10^{-4}\text{ m}^2)} = 0.42\text{ cm}$.

EVALUATE: At the lowest point T and w are in opposite directions and at the highest point they are in the same direction, so T is greater at the lowest point and the elongation is greatest there. The elongation is at most 1% of the length.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

11.90. **IDENTIFY:** $F_\perp = \left(\frac{YA}{l_0}\right)\Delta l$ so the slope of the graph in part (a) depends on Young's modulus.

SET UP: $F_\perp$ is the total load, 20 N plus the added load.

EXECUTE: **(a)** The graph is given in Figure 11.90.

(b) The slope is $\frac{60\text{ N}}{(3.32-3.02)\times10^{-2}\text{ m}} = 2.0\times10^4\text{ N/m}$.

$$Y = \left(\frac{l_0}{\pi r^2}\right)(2.0\times10^4\text{ N/m}) = \left(\frac{3.50\text{ m}}{\pi[0.35\times10^{-3}\text{ m}]^2}\right)(2.0\times10^4\text{ N/m}) = 1.8\times10^{11}\text{ Pa}$$

(c) The stress is $F_\perp/A$. The total load at the proportional limit is $60\text{ N} + 20\text{ N} = 80\text{ N}$.

$$\text{stress} = \frac{80\text{ N}}{\pi(0.35\times10^{-3}\text{ m})^2} = 2.1\times10^8\text{ Pa}$$

EVALUATE: The value of Y we calculated is close to the value for iron, nickel and steel in Table 11.1.

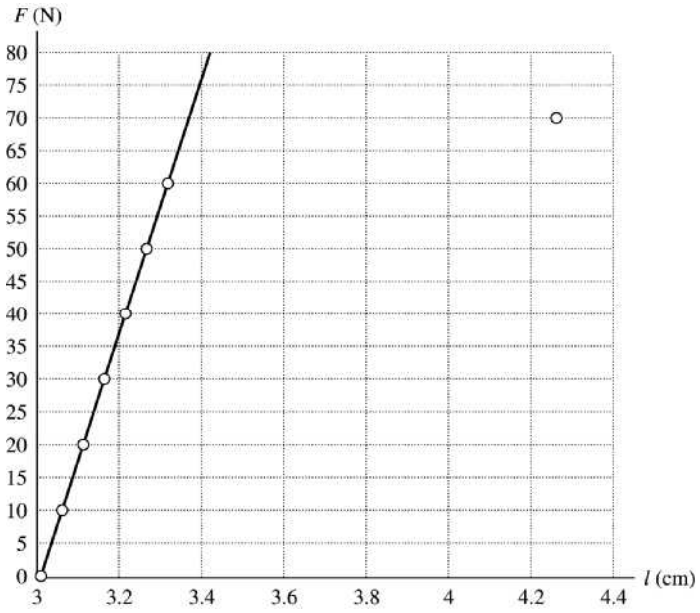


Figure 11.90

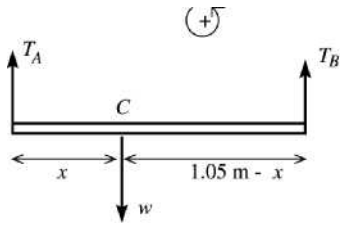
11.91. **IDENTIFY:** Use the second condition of equilibrium to relate the tension in the two wires to the distance w is from the left end. Use Eqs. (11.8) and (11.10) to relate the tension in each wire to its stress and strain.

(a) SET UP: stress $= F_\perp/A$, so equal stress implies T/A same for each wire.

$T_A/2.00\text{ mm}^2 = T_B/4.00\text{ mm}^2$ so $T_B = 2.00T_A$

The question is where along the rod to hang the weight in order to produce this relation between the tensions in the two wires. Let the weight be suspended at point C, a distance x to the right of wire A. The free-body diagram for the rod is given in Figure 11.91.



EXECUTE:

$\sum \tau_C = 0$

$+T_B(1.05\text{ m} - x) - T_A x = 0$

Figure 11.91

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

But $T_B = 2.00T_A$ so $2.00T_A(1.05\text{ m} - x) - T_A x = 0$

$2.10\text{ m} - 2.00x = x$ and $x = 2.10\text{ m}/3.00 = 0.70\text{ m}$ (measured from A).

(b) SET UP: $Y = \text{stress/strain}$ gives that $\text{strain} = \text{stress}/Y = F_\perp/AY$.

EXECUTE: Equal strain thus implies

$$\frac{T_A}{(2.00\text{ mm}^2)(1.80\times10^{11}\text{ Pa})} = \frac{T_B}{(4.00\text{ mm}^2)(1.20\times10^{11}\text{ Pa})}$$

$$T_B = \left(\frac{4.00}{2.00}\right)\left(\frac{1.20}{1.80}\right)T_A = 1.333T_A.$$

The $\sum\tau_C = 0$ equation still gives $T_B(1.05\text{ m} - x) - T_A x = 0$.

But now $T_B = 1.333T_A$ so $(1.333T_A)(1.05\text{ m} - x) - T_A x = 0$.

$1.40\text{ m} = 2.33x$ and $x = 1.40\text{ m}/2.33 = 0.60\text{ m}$ (measured from A).

EVALUATE: Wire B has twice the diameter so it takes twice the tension to produce the same stress. For equal stress the moment arm for T_B (0.35 m) is half that for T_A (0.70 m), since the torques must be equal. The smaller Y for B partially compensates for the larger area in determining the strain and for equal strain the moment arms are closer to being equal.

11.92. **IDENTIFY:** Apply Eq. (11.10) and calculate Δl.

SET UP: When the ride is at rest the tension $F_\perp$ in the rod is the weight 1900 N of the car and occupants. When the ride is operating, the tension $F_\perp$ in the rod is obtained by applying $\sum\vec{F} = m\vec{a}$ to a car and its occupants. The free-body diagram is shown in Figure 11.92. The car travels in a circle of radius $r = l\sin\theta$, where l is the length of the rod and θ is the angle the rod makes with the vertical. For steel, $Y = 2.0\times10^{11}$ Pa. $\omega = 8.00$ rev/min $= 0.838$ rad/s.

EXECUTE: **(a)** $\Delta l = \dfrac{l_0 F_\perp}{YA} = \dfrac{(15.0\text{ m})(1900\text{ N})}{(2.0\times10^{11}\text{ Pa})(8.00\times10^{-4}\text{ m}^2)} = 1.78\times10^{-4}\text{ m} = 0.18\text{ mm}$

(b) $\sum F_x = ma_x$ gives $F_\perp\sin\theta = mr\omega^2 = ml\sin\theta\omega^2$ and

$$F_\perp = ml\omega^2 = \left(\frac{1900\text{ N}}{9.80\text{ m/s}^2}\right)(15.0\text{ m})(0.838\text{ rad/s})^2 = 2.04\times10^3\text{ N}.$$

$$\Delta l = \left(\frac{2.04\times10^3\text{ N}}{1900\text{ N}}\right)(0.18\text{ mm}) = 0.19\text{ mm}$$

EVALUATE: $\sum F_y = ma_y$ gives $F_\perp\cos\theta = mg$ and $\cos\theta = mg/F_\perp$. As ω increases $F_\perp$ increases and $\cos\theta$ becomes small. Smaller $\cos\theta$ means θ increases, so the rods move toward the horizontal as ω increases.

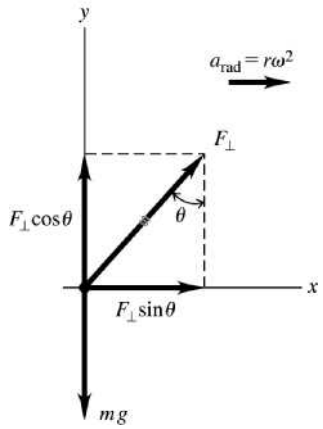


Figure 11.92

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

11.93. **IDENTIFY** and **SET UP:** The tension is the same at all points along the composite rod. Apply Eqs. (11.8) and (11.10) to relate the elongations, stresses and strains for each rod in the compound.

EXECUTE: Each piece of the composite rod is subjected to a tensile force of 4.00×10^4 N.

(a) $Y=\dfrac{F_\perp l_0}{A\Delta l}$ so $\Delta l=\dfrac{F_\perp l_0}{YA}$

$\Delta l_\text{b}=\Delta l_\text{n}$ gives that $\dfrac{F_\perp l_{0,\text{b}}}{Y_\text{b}A_\text{b}}=\dfrac{F_\perp l_{0,\text{n}}}{Y_\text{n}A_\text{n}}$ (b for brass and n for nickel); $l_{0,\text{n}}=L$

But the $F_\perp$ is the same for both, so

$$l_{0,\text{n}}=\frac{Y_\text{n}}{Y_\text{b}}\frac{A_\text{n}}{A_\text{b}}l_{0,\text{b}}$$

$$L=\left(\frac{21\times10^{10}\text{ Pa}}{9.0\times10^{10}\text{ Pa}}\right)\left(\frac{1.00\text{ cm}^2}{2.00\text{ cm}^2}\right)(1.40\text{ m})=1.63\text{ m}$$

(b) stress $=F_\perp/A=T/A$

brass: stress $=T/A=(4.00\times10^4\text{ N})/(2.00\times10^{-4}\text{ m}^2)=2.00\times10^8$ Pa

nickel: stress $=T/A=(4.00\times10^4\text{ N})/(1.00\times10^{-4}\text{ m}^2)=4.00\times10^8$ Pa

(c) $Y=$ stress/strain and strain $=$ stress/Y

brass: strain $=(2.00\times10^8\text{ Pa})/(9.0\times10^{10}\text{ Pa})=2.22\times10^{-3}$

nickel: strain $=(4.00\times10^8\text{ Pa})/(21\times10^{10}\text{ Pa})=1.90\times10^{-3}$

EVALUATE: Larger Y means less Δl and smaller A means greater Δl, so the two effects largely cancel and the lengths don't differ greatly. Equal Δl and nearly equal l means the strains are nearly the same. But equal tensions and A differing by a factor of 2 means the stresses differ by a factor of 2.

11.94. **IDENTIFY:** Apply $\dfrac{F_\perp}{A}=Y\left(\dfrac{\Delta l}{l_0}\right)$. The height from which he jumps determines his speed at the ground. The acceleration as he stops depends on the force exerted on his legs by the ground.

SET UP: In considering his motion take $+y$ downward. Assume constant acceleration as he is stopped by the floor.

EXECUTE: **(a)** $F_\perp=YA\left(\dfrac{\Delta l}{l_0}\right)=(3.0\times10^{-4}\text{ m}^2)(14\times10^9\text{ Pa})(0.010)=4.2\times10^4$ N

(b) As he is stopped by the ground, the net force on him is $F_\text{net}=F_\perp-mg$, where $F_\perp$ is the force exerted on him by the ground. From part (a), $F_\perp=2(4.2\times10^4\text{ N})=8.4\times10^4$ N and

$F=8.4\times10^4\text{ N}-(70\text{ kg})(9.80\text{ m/s}^2)=8.33\times10^4$ N. $F_\text{net}=ma$ gives $a=1.19\times10^3\text{ m/s}^2$.

$a_y=-1.19\times10^3\text{ m/s}^2$ since the acceleration is upward. $v_y=v_{0y}+a_yt$ gives

$v_{0y}=-a_yt=(-1.19\times10^3\text{ m/s}^2)(0.030\text{ s})=35.7$ m/s. His speed at the ground therefore is $v=35.7$ m/s.

This speed is related to his initial height h above the floor by $\frac{1}{2}mv^2=mgh$ and

$$h=\frac{v^2}{2g}=\frac{(35.7\text{ m/s})^2}{2(9.80\text{ m/s}^2)}=65\text{ m}.$$

EVALUATE: Our estimate is based solely on compressive stress; other injuries are likely at a much lower height.

11.95. **IDENTIFY:** Apply Eq. (11.13) and calculate ΔV.

SET UP: The pressure increase is w/A, where w is the weight of the bricks and A is the area πr^2 of the piston.

EXECUTE: $\Delta p=\dfrac{(1420\text{ kg})(9.80\text{ m/s}^2)}{\pi(0.150\text{ m})^2}=1.97\times10^5$ Pa

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$\Delta p = -B\dfrac{\Delta V}{V_0}$ gives $\Delta V = -\dfrac{(\Delta p)V_0}{B} = -\dfrac{(1.97\times10^5\text{ Pa})(250\text{ L})}{9.09\times10^8\text{ Pa}} = -0.0542\text{ L}$

EVALUATE: The fractional change in volume is only 0.022%, so this attempt is not worth the effort.

11.96. **IDENTIFY:** Apply the equilibrium conditions to the ladder combination and also to each ladder.

SET UP: The geometry of the 3-4-5 right triangle simplifies some of the intermediate algebra. Denote the forces on the ends of the ladders by F_L and F_R (left and right). The contact forces at the ground will be vertical, since the floor is assumed to be frictionless.

EXECUTE: **(a)** Taking torques about the right end, $F_L(5.00\text{ m}) = (480\text{ N})(3.40\text{ m}) + (360\text{ N})(0.90\text{ m})$, so $F_L = 391\text{ N}$. F_R may be found in a similar manner, or from $F_R = 840\text{ N} - F_L = 449\text{ N}$.

(b) The tension in the rope may be found by finding the torque on each ladder, using the point A as the origin. The lever arm of the rope is 1.50 m. For the left ladder, $T(1.50\text{ m}) = F_L(3.20\text{ m}) - (480\text{ N})(1.60\text{ m})$, so $T = 322.1\text{ N}$ (322 N to three figures). As a check, using the torques on the right ladder, $T(1.50\text{ m}) = F_R(1.80\text{ m}) - (360\text{ N})(0.90\text{ m})$ gives the same result.

(c) The horizontal component of the force at A must be equal to the tension found in part (b). The vertical force must be equal in magnitude to the difference between the weight of each ladder and the force on the bottom of each ladder, $480\text{ N} - 391\text{ N} = 449\text{ N} - 360\text{ N} = 89\text{ N}$. The magnitude of the force at A is then $\sqrt{(322.1\text{ N})^2 + (89\text{ N})^2} = 334\text{ N}$.

(d) The easiest way to do this is to see that the added load will be distributed at the floor in such a way that $F_L' = F_L + (0.36)(800\text{ N}) = 679\text{ N}$, and $F_R' = F_R + (0.64)(800\text{ N}) = 961\text{ N}$. Using these forces in the form for the tension found in part (b) gives

$$T = \frac{F'_L(3.20\text{ m}) - (480\text{ N})(1.60\text{ m})}{(1.50\text{ m})} = \frac{F'_R(1.80\text{ m}) - (360\text{ N})(0.90\text{ m})}{(1.50\text{ m})} = 937\text{ N}.$$

EVALUATE: The presence of the painter increases the tension in the rope, even though his weight is vertical and the tension force is horizontal.

11.97. **IDENTIFY:** Apply the first and second conditions for equilibrium to the bookcase.

SET UP: When the bookcase is on the verge of tipping, it contacts the floor only at its lower left-hand edge and the normal force acts at this point. When the bookcase is on the verge of slipping, the static friction force has its largest possible value, $\mu_s n$.

EXECUTE: **(a)** Taking torques about the left edge of the left leg, the bookcase would tip when $F = \dfrac{(1500\text{ N})(0.90\text{ m})}{(1.80\text{ m})} = 750\text{ N}$ and would slip when $F = (\mu_s)(1500\text{ N}) = 600\text{ N}$, so the bookcase slides before tipping.

(b) If F is vertical, there will be no net horizontal force and the bookcase could not slide. Again taking torques about the left edge of the left leg, the force necessary to tip the case is $\dfrac{(1500\text{ N})(0.90\text{ m})}{(0.10\text{ m})} = 13.5\text{ kN}$.

(c) To slide, the friction force is $f = \mu_s(w + F\cos\theta)$, and setting this equal to $F\sin\theta$ and solving for F gives $F = \dfrac{\mu_s w}{\sin\theta - \mu_s\cos\theta}$ (to slide). To tip, the condition is that the normal force exerted by the right leg is zero, and taking torques about the left edge of the left leg, $F\sin\theta(1.80\text{ m}) + F\cos\theta(0.10\text{ m}) = w(0.90\text{ m})$, and solving for F gives $F = \dfrac{w}{(1/9)\cos\theta + 2\sin\theta}$ (to tip).

Setting the two expressions equal to each other gives $\mu_s((1/9)\cos\theta + 2\sin\theta) = \sin\theta - \mu_s\cos\theta$ and solving for θ gives $\theta = \arctan\left(\dfrac{(10/9)\mu_s}{(1-2\mu_s)}\right) = 66°$.

EVALUATE: The result in (c) depends not only on the numerical value of μ_s but also on the width and height of the bookcase.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

11.98. **IDENTIFY:** Apply $\sum \tau_z = 0$ to the post, for various choices of the location of the rotation axis.

SET UP: When the post is on the verge of slipping, f_s has its largest possible value, $f_s = \mu_s n$.

EXECUTE: **(a)** Taking torques about the point where the rope is fastened to the ground, the lever arm of the applied force is $h/2$ and the lever arm of both the weight and the normal force is $h\tan\theta$, and so

$$F\frac{h}{2} = (n-w)h\tan\theta.$$

Taking torques about the upper point (where the rope is attached to the post), $fh = F\frac{h}{2}$. Using $f \le \mu_s n$ and solving for F, $F \le 2w\left(\frac{1}{\mu_s} - \frac{1}{\tan\theta}\right)^{-1} = 2(400\text{ N})\left(\frac{1}{0.30} - \frac{1}{\tan 36.9°}\right)^{-1} = 400\text{ N}.$

(b) The above relations between F, n and f become $F\frac{3}{5}h = (n-w)h\tan\theta, f = \frac{2}{5}F$, and eliminating f and n and solving for F gives $F \le w\left(\frac{2/5}{\mu_s} - \frac{3/5}{\tan\theta}\right)^{-1}$, and substitution of numerical values gives 750 N to two figures.

(c) If the force is applied a distance y above the ground, the above relations become $Fy = (n-w)h\tan\theta$, $F(h-y) = fh$, which become, on eliminating n and f, $w \ge F\left[\frac{(1-y/h)}{\mu_s} - \frac{(y/h)}{\tan\theta}\right]$.

As the term in square brackets approaches zero, the necessary force becomes unboundedly large. The limiting value of y is found by setting the term in square brackets equal to zero. Solving for y gives

$$\frac{y}{h} = \frac{\tan\theta}{\mu_s + \tan\theta} = \frac{\tan 36.9°}{0.30 + \tan 36.9°} = 0.71.$$

EVALUATE: For the post to slip, for an axis at the top of the post the torque due to F must balance the torque due to the friction force. As the point of application of F approaches the top of the post, its moment arm for this axis approaches zero.

11.99. **IDENTIFY:** Apply $\sum \tau_z = 0$ to the girder.

SET UP: Assume that the center of gravity of the loaded girder is at $L/2$, and that the cable is attached a distance x to the right of the pivot. The sine of the angle between the lever arm and the cable is then $h/\sqrt{h^2 + ((L/2)-x)^2}$.

EXECUTE: The tension is obtained from balancing torques about the pivot;

$T\left[\frac{hx}{\sqrt{h^2 + ((L/2)-x)^2}}\right] = wL/2$, where w is the total load. The minimum tension will occur when the term in square brackets is a maximum; differentiating and setting the derivative equal to zero gives a maximum, and hence a minimum tension, at $x_{\min} = (h^2/L) + (L/2)$. However, if $x_{\min} > L$, which occurs if $h > L/\sqrt{2}$, the cable must be attached at L, the farthest point to the right.

EVALUATE: Note that $x_{\min}$ is greater than $L/2$ but approaches $L/2$ as $h \to 0$. The tension is a minimum when the cable is attached somewhere on the right-hand half of the girder.

11.100. **IDENTIFY:** Write $\Delta(pV)$ or $\Delta(pV^\gamma)$ in terms of Δp and ΔV and use the fact that pV or pV^γ is constant.

SET UP: B is given by Eq. (11.13).

EXECUTE: **(a)** For constant temperature $(\Delta T = 0)$, $\Delta(pV) = (\Delta p)V + p(\Delta V) = 0$ and $B = -\frac{(\Delta p)V}{(\Delta V)} = p$

(b) In this situation, $(\Delta p)V^\gamma + \gamma p(\Delta V)\,V^{\gamma-1} = 0$, $(\Delta p) + \gamma p\frac{\Delta V}{V} = 0$, and $B = -\frac{(\Delta p)V}{\Delta V} = \gamma p$.

EVALUATE: We will see later that $\gamma > 1$, so B is larger in part (b).

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

11.101. **IDENTIFY:** Apply Eq. (11.10) to calculate Δl.

SET UP: For steel, $Y = 2.0\times10^{11}$ Pa .

EXECUTE: **(a)** From Eq. (11.10), $\Delta l = \dfrac{(4.50\text{ kg})(9.80\text{ m/s}^2)(1.50\text{ m})}{(20\times10^{10}\text{ Pa})(5.00\times10^{-7}\text{m}^2)} = 6.62\times10^{-4}$ m, or 0.66 mm to two figures.

(b) $(4.50\text{ kg})(9.80\text{ m/s}^2)(0.0500\times10^{-2}\text{ m}) = 0.022$ J.

(c) The magnitude F will vary with distance; the average force is $YA(0.0250\text{ cm}/l_0) = 16.7$ N, and so the work done by the applied force is $(16.7\text{ N})(0.0500\times10^{-2}\text{ m}) = 8.35\times10^{-3}$ J.

(d) The average force the wire exerts is $(4.50\text{ kg})g + 16.7\text{ N} = 60.8$ N. The work done is negative, and equal to $-(60.8\text{ N})(0.0500\times10^{-2}\text{ m}) = -3.04\times10^{-2}$ J.

(e) Eq. (11.10) is in the form of Hooke's law, with $k = \dfrac{YA}{l_0}$. $U_{\text{el}} = \frac{1}{2}kx^2$, so $\Delta U_{\text{el}} = \frac{1}{2}k(x_2^2 - x_1^2)$.

$x_1 = 6.62\times10^{-4}$ m and $x_2 = 0.500\times10^{-3}\text{ m} + x_1 = 11.62\times10^{-4}$ m. The change in elastic potential energy is $\dfrac{(20\times10^{10}\text{ Pa})(5.00\times10^{-7}\text{ m}^2)}{2(1.50\text{ m})}((11.62\times10^{-4}\text{ m})^2 - (6.62\times10^{-4}\text{ m})^2) = 3.04\times10^{-2}$ J, the negative of the result of part (d).

EVALUATE: The tensile force in the wire is conservative and obeys the relation $W = -\Delta U$.

12

FLUID MECHANICS

12.1. **IDENTIFY:** Use Eq. (12.1) to calculate the mass and then use $w = mg$ to calculate the weight.

SET UP: $\rho = m/V$ so $m = \rho V$ From Table 12.1, $\rho = 7.8\times10^3$ kg/m^3.

EXECUTE: For a cylinder of length L and radius R,
$V = (\pi R^2)L = \pi(0.01425\text{ m})^2(0.858\text{ m}) = 5.474\times10^{-4}$ m^3.

Then $m = \rho V = (7.8\times10^3\text{ kg/m}^3)(5.474\times10^{-4}\text{ m}^3) = 4.27$ kg, and

$w = mg = (4.27\text{ kg})(9.80\text{ m/s}^2) = 41.8$ N (about 9.4 lbs). A cart is not needed.

EVALUATE: The rod is less than 1m long and less than 3 cm in diameter, so a weight of around 10 lbs seems reasonable.

12.2. **IDENTIFY:** The volume of the remaining object is the volume of a cube minus the volume of a cylinder, and it is this object for which we know the mass. The target variables are the density of the metal of the cube and the original weight of the cube.

SET UP: The volume of a cube with side length L is L^3, the volume of a cylinder of radius r and length L is $\pi r^2 L$, and density is $\rho = m/V$.

EXECUTE: **(a)** The volume of the metal left after the hole is drilled is the volume of the solid cube minus the volume of the cylindrical hole:
$V = L^3 - \pi r^2 L = (5.0\text{ cm})^3 - \pi(1.0\text{ cm})^2(5.0\text{ cm}) = 109\text{ cm}^3 = 1.09\times10^{-4}\text{ m}^3$. The cube with the hole has mass $m = \dfrac{w}{g} = \dfrac{7.50\text{ N}}{9.80\text{ m/s}^2} = 0.765$ kg and density $\rho = \dfrac{m}{V} = \dfrac{0.765\text{ kg}}{1.09\times10^{-4}\text{ m}^3} = 7.02\times10^3\text{ kg/m}^3$.

(b) The solid cube has volume $V = L^3 = 125\text{ cm}^3 = 1.25\times10^{-4}\text{ m}^3$ and mass
$m = \rho V = (7.02\times10^3\text{ kg/m}^3)(1.25\times10^{-4}\text{ m}^3) = 0.878$ kg. The original weight of the cube was
$w = mg = 8.60$ N.

EVALUATE: As Table 12.1 shows, the density of this metal is close to that of iron or steel, so it is reasonable.

12.3. **IDENTIFY:** $\rho = m/V$

SET UP: The density of gold is 19.3×10^3 kg/m^3.

EXECUTE: $V = (5.0\times10^{-3}\text{ m})(15.0\times10^{-3}\text{ m})(30.0\times10^{-3}\text{ m}) = 2.25\times10^{-6}$ m^3.

$\rho = \dfrac{m}{V} = \dfrac{0.0158\text{ kg}}{2.25\times10^{-6}\text{ m}^3} = 7.02\times10^3$ kg/m^3. The metal is not pure gold.

EVALUATE: The average density is only 36% that of gold, so at most 36% of the mass is gold.

12.4. **IDENTIFY:** Find the mass of gold that has a value of $\$1.00\times10^6$. Then use the density of gold to find the volume of this mass of gold.

SET UP: For gold, $\rho = 19.3\times10^3$ kg/m^3. The volume V of a cube is related to the length L of one side by $V = L^3$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: $m = (\$1.00\times10^6)\left(\frac{1 \text{ troy ounce}}{\$426.60}\right)\left(\frac{31.1035\times10^{-3} \text{ kg}}{1 \text{ troy ounce}}\right) = 72.9 \text{ kg}$. $\rho = \frac{m}{V}$ so

$V = \frac{m}{\rho} = \frac{72.9 \text{ kg}}{19.3\times10^3 \text{ kg/m}^3} = 3.78\times10^{-3} \text{ m}^3$. $L = V^{1/3} = 0.156 \text{ m} = 15.6 \text{ cm}$.

EVALUATE: The cube of gold would weigh about 160 lbs.

12.5. **IDENTIFY:** Apply $\rho = m/V$ to relate the densities and volumes for the two spheres.

SET UP: For a sphere, $V = \frac{4}{3}\pi r^3$. For lead, $\rho_l = 11.3\times10^3 \text{ kg/m}^3$ and for aluminum, $\rho_a = 2.7\times10^3 \text{ kg/m}^3$.

EXECUTE: $m = \rho V = \frac{4}{3}\pi r^3\rho$. Same mass means $r_a^3\rho_a = r_l^3\rho_l$. $\frac{r_a}{r_l} = \left(\frac{\rho_l}{\rho_a}\right)^{1/3} = \left(\frac{11.3\times10^3}{2.7\times10^3}\right)^{1/3} = 1.6$.

EVALUATE: The aluminum sphere is larger, since its density is less.

12.6. **IDENTIFY:** Average density is $\rho = m/V$.

SET UP: For a sphere, $V = \frac{4}{3}\pi R^3$. The sun has mass $M_{sun} = 1.99\times10^{30} \text{ kg}$ and radius $6.96\times10^8 \text{ m}$.

EXECUTE: **(a)** $\rho = \frac{M_{sun}}{V_{sun}} = \frac{1.99\times10^{30} \text{ kg}}{\frac{4}{3}\pi(6.96\times10^8 \text{ m})^3} = \frac{1.99\times10^{30} \text{ kg}}{1.412\times10^{27} \text{ m}^3} = 1.409\times10^3 \text{ kg/m}^3$

(b) $\rho = \frac{1.99\times10^{30} \text{ kg}}{\frac{4}{3}\pi(2.00\times10^4 \text{ m})^3} = \frac{1.99\times10^{30} \text{ kg}}{3.351\times10^{13} \text{ m}^3} = 5.94\times10^{16} \text{ kg/m}^3$

EVALUATE: For comparison, the average density of the earth is $5.5\times10^3 \text{kg/m}^3$. A neutron star is extremely dense.

12.7. **IDENTIFY:** $w = mg$ and $m = \rho V$. Find the volume V of the pipe.

SET UP: For a hollow cylinder with inner radius R_1, outer radius R_2, and length L the volume is $V = \pi(R_2^2 - R_1^2)L$. $R_1 = 1.25\times10^{-2} \text{ m}$ and $R_2 = 1.75\times10^{-2} \text{ m}$.

EXECUTE: $V = \pi([0.0175 \text{ m}]^2 - [0.0125 \text{ m}]^2)(1.50 \text{ m}) = 7.07\times10^{-4} \text{ m}^3$.

$m = \rho V = (8.9\times10^3 \text{ kg/m}^3)(7.07\times10^{-4} \text{ m}^3) = 6.29 \text{ kg}$. $w = mg = 61.6 \text{ N}$.

EVALUATE: The pipe weights about 14 pounds.

12.8. **IDENTIFY:** The gauge pressure $p - p_0$ at depth h is $p - p_0 = \rho gh$.

SET UP: Ocean water is seawater and has a density of $1.03\times10^3 \text{ kg/m}^3$.

EXECUTE: $p - p_0 = (1.03\times10^3 \text{ kg/m}^3)(9.80 \text{ m/s}^2)(3200 \text{ m}) = 3.23\times10^7 \text{ Pa}$.

$p - p_0 = (3.23\times10^7 \text{ Pa})\left(\frac{1 \text{ atm}}{1.013\times10^5 \text{ Pa}}\right) = 319 \text{ atm}$.

EVALUATE: The gauge pressure is about 320 times the atmospheric pressure at the surface.

12.9. **IDENTIFY:** The gauge pressure $p - p_0$ at depth h is $p - p_0 = \rho gh$.

SET UP: Freshwater has density $1.00\times10^3 \text{ kg/m}^3$ and seawater has density $1.03\times10^3 \text{ kg/m}^3$.

EXECUTE: **(a)** $p - p_0 = (1.00\times10^3 \text{ kg/m}^3)(3.71 \text{ m/s}^2)(500 \text{ m}) = 1.86\times10^6 \text{ Pa}$.

(b) $h = \frac{p - p_0}{\rho g} = \frac{1.86\times10^6 \text{ Pa}}{(1.03\times10^3 \text{ kg/m}^3)(9.80 \text{ m/s}^2)} = 184 \text{ m}$

EVALUATE: The pressure at a given depth is greater on earth because a cylinder of water of that height weighs more on earth than on Mars.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

12.10. **IDENTIFY:** The difference in pressure at points with heights y_1 and y_2 is $p - p_0 = \rho g(y_1 - y_2)$. The outward force $F_\perp$ is related to the surface area A by $F_\perp = pA$.

SET UP: For blood, $\rho = 1.06\times10^3$ kg/m^3. $y_1 - y_2 = 1.65$ m. The surface area of the segment is πDL, where $D = 1.50\times10^{-3}$ m and $L = 2.00\times10^{-2}$ m.

EXECUTE: **(a)** $p_1 - p_2 = (1.06\times10^3 \text{ kg/m}^3)(9.80 \text{ m/s}^2)(1.65 \text{ m}) = 1.71\times10^4$ Pa.

(b) The additional force due to this pressure difference is $\Delta F_\perp = (p_1 - p_2)A$.

$A = \pi DL = \pi(1.50\times10^{-3} \text{ m})(2.00\times10^{-2} \text{ m}) = 9.42\times10^{-5}$ m^2.

$\Delta F_\perp = (1.71\times10^4 \text{ Pa})(9.42\times10^{-5} \text{ m}^2) = 1.61$ N.

EVALUATE: The pressure difference is about $\frac{1}{6}$ atm.

12.11. **IDENTIFY:** Apply $p = p_0 + \rho gh$.

SET UP: Gauge pressure is $p - p_{\text{air}}$.

EXECUTE: The pressure difference between the top and bottom of the tube must be at least 5980 Pa in order to force fluid into the vein: $\rho gh = 5980$ Pa and

$$h = \frac{5980 \text{ Pa}}{\rho h} = \frac{5980 \text{ N/m}^2}{(1050 \text{ kg/m}^3)(9.80 \text{ m/s}^2)} = 0.581 \text{ m}.$$

EVALUATE: The bag of fluid is typically hung from a vertical pole to achieve this height above the patient's arm.

12.12. **IDENTIFY:** $p_0 = p_{\text{surface}} + \rho gh$ where p_{surface} is the pressure at the surface of a liquid and p_0 is the pressure at a depth h below the surface.

SET UP: The density of water is 1.00×10^3 kg/m^3.

EXECUTE: **(a)** For the oil layer, $p_{\text{surface}} = p_{\text{atm}}$ and p_0 is the pressure at the oil-water interface.

$p_0 - p_{\text{atm}} = p_{\text{gauge}} = \rho gh = (600 \text{ kg/m}^3)(9.80 \text{ m/s}^2)(0.120 \text{ m}) = 706$ Pa

(b) For the water layer, $p_{\text{surface}} = 706$ Pa + p_{atm}.

$p_0 - p_{\text{atm}} = p_{\text{gauge}} = 706 \text{ Pa} + \rho gh = 706 \text{ Pa} + (1.00\times10^3 \text{ kg/m}^3)(9.80 \text{ m/s}^2)(0.250 \text{ m}) = 3.16\times10^3$ Pa

EVALUATE: The gauge pressure at the bottom of the barrel is due to the combined effects of the oil layer and water layer. The pressure at the bottom of the oil layer is the pressure at the top of the water layer.

12.13. **IDENTIFY:** There will be a difference in blood pressure between your head and feet due to the depth of the blood.

SET UP: The added pressure is equal to ρgh.

EXECUTE: **(a)** $\rho gh = (1060 \text{ kg/m}^3)(9.80 \text{ m/s}^2)(1.85 \text{ m}) = 1.92\times10^4$ Pa.

(b) This additional pressure causes additional outward force on the walls of the blood vessels in your brain.

EVALUATE: The pressure difference is about 1/5 atm, so it would be noticeable.

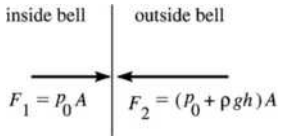
12.14. **IDENTIFY** and **SET UP:** Use Eq. (12.8) to calculate the gauge pressure at this depth. Use Eq. (12.3) to calculate the force the inside and outside pressures exert on the window, and combine the forces as vectors to find the net force.

EXECUTE: **(a)** gauge pressure $= p - p_0 = \rho gh$ From Table 12.1 the density of seawater is 1.03×10^3 kg/m^3, so

$$p - p_0 = \rho gh = (1.03\times10^3 \text{ kg/m}^3)(9.80 \text{ m/s}^2)(250 \text{ m}) = 2.52\times10^6 \text{ Pa}$$

(b) The force on each side of the window is $F = pA$. Inside the pressure is p_0 and outside in the water the pressure is $p = p_0 + \rho gh$. The forces are shown in Figure 12.14.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.



The net force is

$$F_2 - F_1 = (p_0 + \rho gh)A - p_0 A = (\rho gh)A$$

$$F_2 - F_1 = (2.52\times10^6 \text{ Pa})\pi(0.150 \text{ m})^2$$

$$F_2 - F_1 = 1.78\times10^5 \text{ N}$$

Figure 12.14

EVALUATE: The pressure at this depth is very large, over 20 times normal air pressure, and the net force on the window is huge. Diving bells used at such depths must be constructed to withstand these large forces.

12.15. **IDENTIFY:** The external pressure on the eardrum increases with depth in the ocean. This increased pressure could damage the eardrum.

SET UP: The density of seawater is 1.03×10^3 kg/m^3. The area of the eardrum is $A = \pi r^2$, with $r = 4.1$ mm. The pressure increase with depth is $\Delta p = \rho gh$ and $F = pA$.

EXECUTE: $\Delta F = (\Delta p)A = \rho ghA$. Solving for h gives

$$h = \frac{\Delta F}{\rho gA} = \frac{1.5 \text{ N}}{(1.03\times10^3 \text{ kg/m}^3)(9.80 \text{ m/s}^2)\pi(4.1\times10^{-3} \text{ m})^2} = 2.8 \text{ m}.$$

EVALUATE: 2.8 m is less than 10 ft, so it is probably a good idea to wear ear plugs if you scuba dive.

12.16. **IDENTIFY** and **SET UP:** Use Eq. (12.6) to calculate the pressure at the specified depths in the open tube. The pressure is the same at all points the same distance from the bottom of the tubes, so the pressure calculated in part (b) is the pressure in the tank. Gauge pressure is the difference between the absolute pressure and air pressure.

EXECUTE: $p_a = 980$ millibar $= 9.80\times10^4$ Pa

(a) Apply $p = p_0 + \rho gh$ to the right-hand tube. The top of this tube is open to the air so $p_0 = p_a$. The density of the liquid (mercury) is 13.6×10^3 kg/m^3.

Thus $p = 9.80\times10^4$ Pa $+ (13.6\times10^3 \text{ kg/m}^3)(9.80 \text{ m/s}^2)(0.0700 \text{ m}) = 1.07\times10^5$ Pa.

(b) $p = p_0 + \rho gh = 9.80\times10^4$ Pa $+ (13.6\times10^3 \text{ kg/m}^3)(9.80 \text{ m/s}^2)(0.0400 \text{ m}) = 1.03\times10^5$ Pa.

(c) Since $y_2 - y_1 = 4.00$ cm the pressure at the mercury surface in the left-hand end tube equals that calculated in part (b). Thus the absolute pressure of gas in the tank is 1.03×10^5 Pa.

(d) $p - p_0 = \rho gh = (13.6\times10^3 \text{ kg/m}^3)(9.80 \text{ m/s}^2)(0.0400 \text{ m}) = 5.33\times10^3$ Pa.

EVALUATE: If Eq. (12.8) is evaluated with the density of mercury and $p - p_a = 1$ atm $= 1.01\times10^5$ Pa, then $h = 76$cm. The mercury columns here are much shorter than 76 cm, so the gauge pressures are much less than 1.0×10^5 Pa.

12.17. **IDENTIFY:** Apply $p = p_0 + \rho gh$.

SET UP: For water, $\rho = 1.00\times10^3$ kg/m^3.

EXECUTE: $p - p_{air} = \rho gh = (1.00\times10^3 \text{ kg/m}^3)(9.80 \text{ m/s}^2)(6.1 \text{ m}) = 6.0\times10^4$ Pa.

EVALUATE: The pressure difference increases linearly with depth.

12.18. **IDENTIFY** and **SET UP:** Apply Eq. (12.6) to the water and mercury columns. The pressure at the bottom of the water column is the pressure at the top of the mercury column.

EXECUTE: With just the mercury, the gauge pressure at the bottom of the cylinder is $p = p_0 + \rho_m g h_m$. With the water to a depth h_w, the gauge pressure at the bottom of the cylinder is $p = p_0 + \rho_m g h_m + \rho_w g h_w$. If this is to be double the first value, then $\rho_w g h_w = \rho_m g h_m$.

$$h_w = h_m(\rho_m/\rho_w) = (0.0500 \text{ m})(13.6\times10^3/1.00\times10^3) = 0.680 \text{ m}$$

The volume of water is $V = hA = (0.680 \text{ m})(12.0\times10^{-4} \text{ m}^2) = 8.16\times10^{-4} \text{ m}^3 = 816 \text{ cm}^3$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: The density of mercury is 13.6 times the density of water and $(13.6)(5\text{ cm}) = 68\text{ cm}$, so the pressure increase from the top to the bottom of a 68-cm tall column of water is the same as the pressure increase from top to bottom for a 5-cm tall column of mercury.

12.19. **IDENTIFY:** $p = p_0 + \rho gh$. $F = pA$.

SET UP: For seawater, $\rho = 1.03\times10^3\text{ kg/m}^3$

EXECUTE: The force F that must be applied is the difference between the upward force of the water and the downward forces of the air and the weight of the hatch. The difference between the pressure inside and out is the gauge pressure, so

$$F = (\rho gh)\,A - w = (1.03\times10^3\text{ kg/m}^3)(9.80\text{ m/s}^2)(30\text{ m})(0.75\text{ m}^2) - 300\text{ N} = 2.27\times10^5\text{ N}.$$

EVALUATE: The force due to the gauge pressure of the water is much larger than the weight of the hatch and would be impossible for the crew to apply it just by pushing.

12.20. **IDENTIFY:** Apply $p = p_0 + \rho gh$, where p_0 is the pressure at the surface of the fluid. Gauge pressure is $p - p_{\text{air}}$.

SET UP: For water, $\rho = 1.00\times10^3\text{ kg/m}^3$.

EXECUTE: **(a)** The pressure difference between the surface of the water and the bottom is due to the weight of the water and is still 2500 Pa after the pressure increase above the surface. But the surface pressure increase is also transmitted to the fluid, making the total difference from atmospheric pressure $2500\text{ Pa} + 1500\text{ Pa} = 4000\text{ Pa}$.

(b) Initially, the pressure due to the water alone is $2500\text{ Pa} = \rho gh$. Thus

$h = \dfrac{2500\text{ N/m}^2}{(1000\text{ kg/m}^3)(9.80\text{ m/s}^2)} = 0.255\text{ m}$. To keep the bottom gauge pressure at 2500 Pa after the 1500 Pa increase at the surface, the pressure due to the water's weight must be reduced to 1000 Pa:

$h = \dfrac{1000\text{ N/m}^2}{(1000\text{ kg/m}^3)(9.80\text{ m/s}^2)} = 0.102\text{ m}$. Thus the water must be lowered by

$0.255\text{ m} - 0.102\text{ m} = 0.153\text{ m}$.

EVALUATE: Note that ρgh, with $h = 0.153\text{ m}$, is 1500 Pa.

12.21. **IDENTIFY:** The gauge pressure at the top of the oil column must produce a force on the disk that is equal to its weight.

SET UP: The area of the bottom of the disk is $A = \pi r^2 = \pi(0.150\text{ m})^2 = 0.0707\text{ m}^2$.

EXECUTE: **(a)** $p - p_0 = \dfrac{w}{A} = \dfrac{45.0\text{ N}}{0.0707\text{ m}^2} = 636\text{ Pa}$.

(b) The increase in pressure produces a force on the disk equal to the increase in weight. By Pascal's law the increase in pressure is transmitted to all points in the oil.

(i) $\Delta p = \dfrac{83.0\text{ N}}{0.0707\text{ m}^2} = 1170\text{ Pa}$. (ii) 1170 Pa

EVALUATE: The absolute pressure at the top of the oil produces an upward force on the disk but this force is partially balanced by the force due to the air pressure at the top of the disk.

12.22. **IDENTIFY:** The force on an area A due to pressure p is $F_\perp = pA$. Use $p - p_0 = \rho gh$ to find the pressure inside the tank, at the bottom.

SET UP: $1\text{ atm} = 1.013\times10^5\text{ Pa}$. For benzene, $\rho = 0.90\times10^3\text{ kg/m}^3$. The area of the bottom of the tank is $\pi D^2/4$, where $D = 1.72\text{ m}$. The area of the vertical walls of the tank is πDL, where $L = 11.50\text{ m}$.

EXECUTE: **(a)** At the bottom of the tank,

$p = p_0 + \rho gh = 92(1.013\times10^5\text{ Pa}) + (0.90\times10^3\text{ kg/m}^3)(0.894)(9.80\text{ m/s}^2)(11.50\text{ m})$.

$p = 9.32\times10^6\text{ Pa} + 9.07\times10^4\text{ Pa} = 9.41\times10^6\text{ Pa}$. $F_\perp = pA = (9.41\times10^6\text{ Pa})\pi(1.72\text{ m})^2/4 = 2.19\times10^7\text{ N}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) At the outside surface of the bottom of the tank, the air pressure is
$p = (92)(1.013\times10^5 \text{ Pa}) = 9.32\times10^6 \text{ Pa}$. $F_\perp = pA = (9.32\times10^6 \text{ Pa})\pi(1.72 \text{ m})^2/4 = 2.17\times10^7 \text{ N}$.

(c) $F_\perp = pA = 92(1.013\times10^5 \text{ Pa})\pi(1.72 \text{ m})(11.5 \text{ m}) = 5.79\times10^8 \text{ N}$

EVALUATE: Most of the force in part (a) is due to the 92 atm of air pressure above the surface of the benzene and the net force on the bottom of the tank is much less than the inward and outward forces.

12.23. **IDENTIFY:** $F_2 = \dfrac{A_2}{A_1}F_1$. F_2 must equal the weight $w = mg$ of the car.

SET UP: $A = \pi D^2/4$. D_1 is the diameter of the vessel at the piston where F_1 is applied and D_2 of the diameter at the car.

EXECUTE: $mg = \dfrac{\pi D_2^2/4}{\pi D_1^2/4}F_1$. $\dfrac{D_2}{D_1} = \sqrt{\dfrac{mg}{F_1}} = \sqrt{\dfrac{(1520 \text{ kg})(9.80 \text{ m/s}^2)}{125 \text{ N}}} = 10.9$

EVALUATE: The diameter is smaller where the force is smaller, so the pressure will be the same at both pistons.

12.24. **IDENTIFY:** Apply $\Sigma F_y = ma_y$ to the piston, with $+y$ upward. $F = pA$.

SET UP: $1 \text{ atm} = 1.013\times10^5 \text{ Pa}$. The force diagram for the piston is given in Figure 12.24. p is the absolute pressure of the hydraulic fluid.

EXECUTE: $pA - w - p_{\text{atm}}A = 0$ and

$$p - p_{\text{atm}} = p_{\text{gauge}} = \frac{w}{A} = \frac{mg}{\pi r^2} = \frac{(1200 \text{ kg})(9.80 \text{ m/s}^2)}{\pi(0.15 \text{ m})^2} = 1.7\times10^5 \text{ Pa} = 1.7 \text{ atm}$$

EVALUATE: The larger the diameter of the piston, the smaller the gauge pressure required to lift the car.

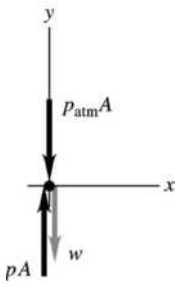


Figure 12.24

12.25. **IDENTIFY:** By Archimedes's principle, the additional buoyant force will be equal to the additional weight (the man).

SET UP: $V = \dfrac{m}{\rho}$ where $dA = V$ and d is the additional distance the buoy will sink.

EXECUTE: With man on buoy must displace additional 70.0 kg of water.

$V = \dfrac{m}{\rho} = \dfrac{70.0 \text{ kg}}{1030 \text{ kg/m}^3} = 0.06796 \text{ m}^3$. $dA = V$ so $d = \dfrac{V}{A} = \dfrac{0.06796 \text{ m}^3}{\pi(0.450 \text{ m})^2} = 0.107 \text{ m}$.

EVALUATE: We do not need to use the mass of the buoy because it is already floating and hence in balance.

12.26. **IDENTIFY:** Apply Newton's second law to the woman plus slab. The buoyancy force exerted by the water is upward and given by $B = \rho_{\text{water}}V_{\text{displ}}g$, where V_{displ} is the volume of water displaced.

SET UP: The floating object is the slab of ice plus the woman; the buoyant force must support both. The volume of water displaced equals the volume V_{ice} of the ice. The free-body diagram is given in Figure 12.26.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

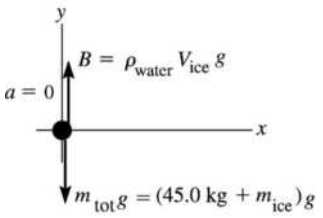

Figure 12.26

EXECUTE: $\Sigma F_y = ma_y$

$B - m_{\text{tot}} g = 0$

$\rho_{\text{water}} V_{\text{ice}} g = (45.0 \text{ kg} + m_{\text{ice}}) g$

But $\rho = m/V$ so $m_{\text{ice}} = \rho_{\text{ice}} V_{\text{ice}}$

$$V_{\text{ice}} = \frac{45.0 \text{ kg}}{\rho_{\text{water}} - \rho_{\text{ice}}} = \frac{45.0 \text{ kg}}{1000 \text{ kg/m}^3 - 920 \text{ kg/m}^3} = 0.562 \text{ m}^3.$$

EVALUATE: The mass of ice is $m_{\text{ice}} = \rho_{\text{ice}} V_{\text{ice}} = 517$ kg.

12.27. **IDENTIFY:** Apply $\Sigma F_y = ma_y$ to the sample, with $+y$ upward. $B = \rho_{\text{water}} V_{\text{obj}} g$.

SET UP: $w = mg = 17.50$ N and $m = 1.79$ kg.

EXECUTE: $T + B - mg = 0$. $B = mg - T = 17.50 \text{ N} - 11.20 \text{ N} = 6.30$ N.

$$V_{\text{obj}} = \frac{B}{\rho_{\text{water}} g} = \frac{6.30 \text{ N}}{(1.00 \times 10^3 \text{ kg/m}^3)(9.80 \text{ m/s}^2)} = 6.43 \times 10^{-4} \text{ m}^3.$$

$$\rho = \frac{m}{V} = \frac{1.79 \text{ kg}}{6.43 \times 10^{-4} \text{ m}^3} = 2.78 \times 10^3 \text{ kg/m}^3.$$

EVALUATE: The density of the sample is greater than that of water and it doesn't float.

12.28. **IDENTIFY:** The upward buoyant force B exerted by the liquid equals the weight of the fluid displaced by the object. Since the object floats the buoyant force equals its weight.

SET UP: Glycerin has density $\rho_{\text{gly}} = 1.26 \times 10^3$ kg/m^3 and seawater has density $\rho_{\text{sw}} = 1.03 \times 10^3$ kg/m^3. Let V_{obj} be the volume of the apparatus. $g_{\text{E}} = 9.80$ m/s^2; $g_{\text{C}} = 4.15$ m/s^2. Let V_{sub} be the volume submerged on Caasi.

EXECUTE: On earth $B = \rho_{\text{sw}}(0.250 V_{\text{obj}}) g_{\text{E}} = mg_{\text{E}}$. $m = (0.250)\rho_{\text{sw}} V_{\text{obj}}$. On Caasi, $B = \rho_{\text{gly}} V_{\text{sub}} g_{\text{C}} = mg_{\text{C}}$. $m = \rho_{\text{gyl}} V_{\text{sub}}$. The two expressions for m must be equal, so

$$(0.250) V_{\text{obj}} \rho_{\text{sw}} = \rho_{\text{gly}} V_{\text{sub}} \text{ and } V_{\text{sub}} = \left(\frac{0.250 \rho_{\text{sw}}}{\rho_{\text{gly}}} \right) V_{\text{obj}} = \left(\frac{[0.250][1.03 \times 10^3 \text{ kg/m}^3]}{1.26 \times 10^3 \text{ kg/m}^3} \right) V_{\text{obj}} = 0.204 V_{\text{obj}}.$$

20.4% of the volume will be submerged on Caasi.

EVALUATE: Less volume is submerged in glycerin since the density of glycerin is greater than the density of seawater. The value of g on each planet cancels out and has no effect on the answer. The value of g changes the weight of the apparatus and the buoyant force by the same factor.

12.29. **IDENTIFY:** For a floating object, the weight of the object equals the upward buoyancy force, B, exerted by the fluid.

SET UP: $B = \rho_{\text{fluid}} V_{\text{submerged}} g$. The weight of the object can be written as $w = \rho_{\text{object}} V_{\text{object}} g$. For seawater, $\rho = 1.03 \times 10^3$ kg/m^3.

EXECUTE: **(a)** The displaced fluid has less volume than the object but must weigh the same, so $\rho < \rho_{\text{fluid}}$.

(b) If the ship does not leak, much of the water will be displaced by air or cargo, and the average density of the floating ship is less than that of water.

(c) Let the portion submerged have volume V, and the total volume be V_0. Then $\rho V_0 = \rho_{\text{fluid}} V$, so $\frac{V}{V_0} = \frac{\rho}{\rho_{\text{fluid}}}$. The fraction above the fluid surface is then $1 - \frac{\rho}{\rho_{\text{fluid}}}$. If $\rho \to 0$, the entire object floats, and if $\rho \to \rho_{\text{fluid}}$, none of the object is above the surface.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(d) Using the result of part (c), $1-\dfrac{\rho}{\rho_{\text{fluid}}}=1-\dfrac{(0.042\text{ kg})/([5.0][4.0][3.0]\times10^{-6}\text{m}^3)}{1030\text{kg/m}^3}=0.32=32\%.$

EVALUATE: For a given object, the fraction of the object above the surface increases when the density of the fluid in which it floats increases.

12.30. **IDENTIFY:** $B=\rho_{\text{water}}V_{\text{obj}}g$. The net force on the sphere is zero.

SET UP: The density of water is 1.00×10^3 kg/m^3.

EXECUTE: **(a)** $B=(1000\text{ kg/m}^3)(0.650\text{ m}^3)(9.80\text{ m/s}^2)=6.37\times10^3\text{ N}$

(b) $B=T+mg$ and $m=\dfrac{B-T}{g}=\dfrac{6.37\times10^3\text{ N}-900\text{ N}}{9.80\text{ m/s}^2}=558\text{ kg}.$

(c) Now $B=\rho_{\text{water}}V_{\text{sub}}g,$ where V_{sub} is the volume of the sphere that is submerged. $B=mg$.

$\rho_{\text{water}}V_{\text{sub}}g=mg$ and $V_{\text{sub}}=\dfrac{m}{\rho_{\text{water}}}=\dfrac{558\text{ kg}}{1000\text{ kg/m}^3}=0.558\text{ m}^3.$ $\dfrac{V_{\text{sub}}}{V_{\text{obj}}}=\dfrac{0.558\text{ m}^3}{0.650\text{ m}^3}=0.858=85.8\%.$

EVALUATE: The average density of the sphere is $\rho_{\text{sph}}=\dfrac{m}{V}=\dfrac{558\text{ kg}}{0.650\text{ m}^3}=858\text{ kg/m}^3.$ $\rho_{\text{sph}}<\rho_{\text{water}},$ and that is why it floats with 85.8% of its volume submerged.

12.31. **IDENTIFY** and **SET UP:** Use Eq. (12.8) to calculate the gauge pressure at the two depths.

(a) The distances are shown in Figure 12.31a.

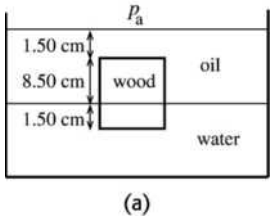

Figure 12.31a

EXECUTE: $p-p_0=\rho gh$

The upper face is 1.50 cm below the top of the oil, so

$p-p_0=(790\text{ kg/m}^3)(9.80\text{ m/s}^2)(0.0150\text{ m})$

$p-p_0=116\text{ Pa}$

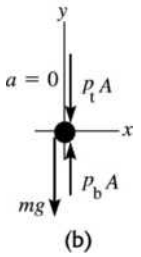
(b) The pressure at the interface is $p_{\text{interface}}=p_{\text{a}}+\rho_{\text{oil}}g(0.100\text{ m}).$ The lower face of the block is 1.50 cm below the interface, so the pressure there is $p=p_{\text{interface}}+\rho_{\text{water}}g(0.0150\text{ m}).$ Combining these two equations gives

$p-p_{\text{a}}=\rho_{\text{oil}}g(0.100\text{ m})+\rho_{\text{water}}g(0.0150\text{ m})$

$p-p_{\text{a}}=[(790\text{ kg/m}^3)(0.100\text{ m})+(1000\text{ kg/m}^3)(0.0150\text{ m})](9.80\text{ m/s}^2)$

$p-p_{\text{a}}=921\text{ Pa}$

(c) **IDENTIFY** and **SET UP:** Consider the forces on the block. The area of each face of the block is $A=(0.100\text{ m})^2=0.0100\text{ m}^2.$ Let the absolute pressure at the top face be p_{t} and the pressure at the bottom face be $p_{\text{b}}.$ In Eq. (12.3) use these pressures to calculate the force exerted by the fluids at the top and bottom of the block. The free-body diagram for the block is given in Figure 12.31b.



EXECUTE: $\Sigma F_y=ma_y$

$p_{\text{b}}A-p_{\text{t}}A-mg=0$

$(p_{\text{b}}-p_{\text{t}})A=mg$

Figure 12.31b

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

Note that $(p_b - p_t) = (p_b - p_a) - (p_t - p_a) = 921\text{ Pa} - 116\text{ Pa} = 805\text{ Pa}$; the difference in absolute pressures equals the difference in gauge pressures.

$$m = \frac{(p_b - p_t)A}{g} = \frac{(805\text{ Pa})(0.0100\text{ m}^2)}{9.80\text{ m/s}^2} = 0.821\text{ kg}.$$

And then $\rho = m/V = 0.821\text{ kg}/(0.100\text{ m})^3 = 821\text{ kg/m}^3$.

EVALUATE: We can calculate the buoyant force as $B = (\rho_{oil}V_{oil} + \rho_{water}V_{water})g$ where $V_{oil} = (0.0100\text{ m}^2)(0.0850\text{ m}) = 8.50\times10^{-4}\text{ m}^3$ is the volume of oil displaced by the block and $V_{water} = (0.0100\text{ m}^2)(0.0150\text{ m}) = 1.50\times10^{-4}\text{ m}^3$ is the volume of water displaced by the block. This gives $B = (0.821\text{ kg})g$. The mass of water displaced equals the mass of the block.

12.32. **IDENTIFY:** The sum of the vertical forces on the ingot is zero. $\rho = m/V$. The buoyant force is $B = \rho_{water}V_{obj}g$.

SET UP: The density of aluminum is $2.7\times10^3\text{ kg/m}^3$. The density of water is $1.00\times10^3\text{ kg/m}^3$.

EXECUTE: **(a)** $T = mg = 89\text{ N}$ so $m = 9.08\text{ kg}$. $V = \dfrac{m}{\rho} = \dfrac{9.08\text{ kg}}{2.7\times10^3\text{ kg/m}^3} = 3.36\times10^{-3}\text{ m}^3 = 3.4\text{ L}$.

(b) When the ingot is totally immersed in the water while suspended, $T + B - mg = 0$.

$B = \rho_{water}V_{obj}g = (1.00\times10^3\text{ kg/m}^3)(3.36\times10^{-3}\text{ m}^3)(9.80\text{ m/s}^2) = 32.9\text{ N}$.

$T = mg - B = 89\text{ N} - 32.9\text{ N} = 56\text{ N}$.

EVALUATE: The buoyant force is equal to the difference between the apparent weight when the object is submerged in the fluid and the actual gravity force on the object.

12.33. **IDENTIFY:** The vertical forces on the rock sum to zero. The buoyant force equals the weight of liquid displaced by the rock. $V = \frac{4}{3}\pi R^3$.

SET UP: The density of water is $1.00\times10^3\text{ kg/m}^3$.

EXECUTE: The rock displaces a volume of water whose weight is $39.2\text{ N} - 28.4\text{ N} = 10.8\text{ N}$. The mass of this much water is thus $10.8\text{ N}/(9.80\text{ m/s}^2) = 1.102\text{ kg}$ and its volume, equal to the rock's volume, is $\dfrac{1.102\text{ kg}}{1.00\times10^3\text{ kg/m}^3} = 1.102\times10^{-3}\text{ m}^3$. The weight of unknown liquid displaced is $39.2\text{ N} - 18.6\text{ N} = 20.6\text{ N}$, and its mass is $20.6\text{ N}/(9.80\text{ m/s}^2) = 2.102\text{ kg}$. The liquid's density is thus $2.102\text{ kg}/(1.102\times10^{-3}\text{ m}^3) = 1.91\times10^3\text{ kg/m}^3$.

EVALUATE: The density of the unknown liquid is roughly twice the density of water.

12.34. **IDENTIFY:** The volume flow rate is Av.

SET UP: $Av = 0.750\text{ m}^3/\text{s}$. $A = \pi D^2/4$.

EXECUTE: **(a)** $v\pi D^2/4 = 0.750\text{ m}^3/\text{s}$. $v = \dfrac{4(0.750\text{ m}^3/\text{s})}{\pi(4.50\times10^{-2}\text{ m})^2} = 472\text{ m/s}$.

(b) vD^2 must be constant, so $v_1D_1^2 = v_2D_2^2$. $v_2 = v_1\left(\dfrac{D_1}{D_2}\right)^2 = (472\text{ m/s})\left(\dfrac{D_1}{3D_1}\right)^2 = 52.4\text{ m/s}$.

EVALUATE: The larger the hole, the smaller the speed of the fluid as it exits.

12.35. **IDENTIFY:** Apply the equation of continuity, $v_1A_1 = v_2A_2$.

SET UP: $A = \pi r^2$

EXECUTE: $v_2 = v_1(A_1/A_2)$. $A_1 = \pi(0.80\text{ cm})^2$, $A_2 = 20\pi(0.10\text{ cm})^2$. $v_2 = (3.0\text{ m/s})\dfrac{\pi(0.80)^2}{20\pi(0.10)^2} = 9.6\text{ m/s}$.

EVALUATE: The total area of the shower head openings is less than the cross-sectional area of the pipe, and the speed of the water in the shower head opening is greater than its speed in the pipe.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

12.36. **IDENTIFY:** $v_1A_1 = v_2A_2$. The volume flow rate is vA.

SET UP: 1.00 h = 3600 s.

EXECUTE: **(a)** $v_2 = v_1\left(\frac{A_1}{A_2}\right) = (3.50 \text{ m/s})\left(\frac{0.070 \text{ m}^2}{0.105 \text{ m}^2}\right) = 2.33 \text{ m/s}$

(b) $v_2 = v_1\left(\frac{A_1}{A_2}\right) = (3.50 \text{ m/s})\left(\frac{0.070 \text{ m}^2}{0.047 \text{ m}^2}\right) = 5.21 \text{ m/s}$

(c) $V = v_1A_1t = (3.50 \text{ m/s})(0.070 \text{ m}^2)(3600 \text{ s}) = 882 \text{ m}^3$.

EVALUATE: The equation of continuity says the volume flow rate is the same at all points in the pipe.

12.37. **IDENTIFY** and **SET UP:** Apply Eq. (12.10). In part (a) the target variable is V. In part (b) solve for A and then from that get the radius of the pipe.

EXECUTE: **(a)** $vA = 1.20 \text{ m}^3/\text{s}$

$$v = \frac{1.20 \text{ m}^3/\text{s}}{A} = \frac{1.20 \text{ m}^3/\text{s}}{\pi r^2} = \frac{1.20 \text{ m}^3/\text{s}}{\pi(0.150 \text{ m})^2} = 17.0 \text{ m/s}$$

(b) $vA = 1.20 \text{ m}^3/\text{s}$

$v\pi r^2 = 1.20 \text{ m}^3/\text{s}$

$$r = \sqrt{\frac{1.20 \text{ m}^3/\text{s}}{v\pi}} = \sqrt{\frac{1.20 \text{ m}^3/\text{s}}{(3.80 \text{ m/s})\pi}} = 0.317 \text{ m}$$

EVALUATE: The speed is greater where the area and radius are smaller.

12.38. **IDENTIFY:** Narrowing the width of the pipe will increase the speed of flow of the fluid.

SET UP: The continuity equation is $A_1v_1 = A_2v_2$. $A = \frac{1}{2}\pi d^2$, where d is the pipe diameter.

EXECUTE: The continuity equation gives $\frac{1}{2}\pi d_1^2 v_1 = \frac{1}{2}\pi d_2^2 v_2$, so

$$v_2 = \left(\frac{d_1}{d_2}\right)^2 v_1 = \left(\frac{2.50 \text{ in.}}{1.00 \text{ in.}}\right)^2 (6.00 \text{ cm/s}) = 37.5 \text{ cm/s}$$

EVALUATE: To achieve the same volume flow rate the water flows faster in the smaller diameter pipe. Note that the pipe diameters entered in a ratio so there was no need to convert units.

12.39. **IDENTIFY:** A change in the speed of the water indicates that the cross-sectional area of the canal must have changed.

SET UP: The continuity equation is $A_1v_1 = A_2v_2$.

EXECUTE: If h is the depth of the canal, then $(18.5 \text{ m})(3.75 \text{ m})(2.50 \text{ cm/s}) = (16.5 \text{ m})h(11.0 \text{ cm/s})$ so $h = 0.956 \text{ m}$, the depth of the canal at the second point.

EVALUATE: The speed of the water has increased, so the cross-sectional area must have decreased, which is consistent with our result for h.

12.40. **IDENTIFY:** A change in the speed of the blood indicates that there is a difference in the cross-sectional area of the artery. Bernoulli's equation applies to the fluid.

SET UP: Bernoulli's equation is $p_1 + \rho g y_1 + \frac{1}{2}\rho v_1^2 = p_2 + \rho g y_2 + \frac{1}{2}\rho v_2^2$. The two points are close together so we can neglect $\rho g(y_1 - y_2)$. $\rho = 1.06 \times 10^3 \text{ kg/m}^3$. The continuity equation is $A_1v_1 = A_2v_2$.

EXECUTE: Solve $p_1 - p_2 + \frac{1}{2}\rho v_1^2 = \frac{1}{2}\rho v_2^2$ for v_2:

$$v_2 = \sqrt{\frac{2(p_1 - p_2)}{\rho} + v_1^2} = \sqrt{\frac{2(1.20 \times 10^4 \text{ Pa} - 1.15 \times 10^4 \text{ Pa})}{1.06 \times 10^3 \text{ kg/m}^3} + (0.300 \text{ m/s})^2}.$$ $v_2 = 1.0 \text{ m/s} = 100 \text{ cm/s}$. The continuity equation gives $\frac{A_2}{A_1} = \frac{v_1}{v_2} = \frac{30 \text{ cm/s}}{100 \text{ cm/s}} = 0.30$. $A_2 = 0.30A_1$, so 70% of the artery is blocked.

EVALUATE: A 70% blockage reduces the blood speed from 100 cm/s to 30 cm/s, which should easily be detectable.

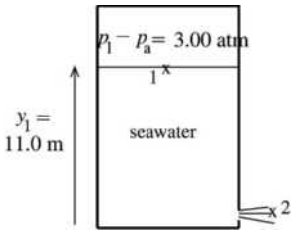
12.41. **IDENTIFY** and **SET UP:**



Apply Bernoulli's equation with points 1 and 2 chosen as shown in Figure 12.41. Let $y = 0$ at the bottom of the tank so $y_1 = 11.0$ m and $y_2 = 0$. The target variable is v_2.

Figure 12.41

$p_1 + \rho g y_1 + \frac{1}{2}\rho v_1^2 = p_2 + \rho g y_2 + \frac{1}{2}\rho v_2^2$

$A_1 v_1 = A_2 v_2$, so $v_1 = (A_2/A_1)v_2$. But the cross-sectional area of the tank (A_1) is much larger than the cross-sectional area of the hole (A_2), so $v_1 << v_2$ and the $\frac{1}{2}\rho v_1^2$ term can be neglected.

EXECUTE: This gives $\frac{1}{2}\rho v_2^2 = (p_1 - p_2) + \rho g y_1$.

Use $p_2 = p_a$ and solve for v_2:

$$v_2 = \sqrt{2(p_1 - p_a)/\rho + 2gy_1} = \sqrt{\frac{2(3.039\times10^5 \text{ Pa})}{1030 \text{ kg/m}^3} + 2(9.80 \text{ m/s}^2)(11.0 \text{ m})}$$

$v_2 = 28.4$ m/s

EVALUATE: If the pressure at the top surface of the water were air pressure, then Toricelli's theorem (Example: 12.8) gives $v_2 = \sqrt{2g(y_1 - y_2)} = 14.7$ m/s. The actual afflux speed is much larger than this due to the excess pressure at the top of the tank.

12.42. **IDENTIFY:** Toricelli's theorem says the speed of efflux is $v = \sqrt{2gh}$, where *h* is the distance of the small hole below the surface of the water in the tank. The volume flow rate is *vA*.

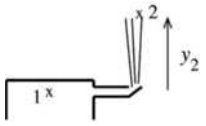
SET UP: $A = \pi D^2/4$, with $D = 6.00\times10^{-3}$ m.

EXECUTE: **(a)** $v = \sqrt{2(9.80 \text{ m/s}^2)(14.0 \text{ m})} = 16.6$ m/s

(b) $vA = (16.6 \text{ m/s})\pi(6.00\times10^{-3} \text{ m})^2/4 = 4.69\times10^{-4}$ m^3/s. A volume of 4.69×10^{-4} m^3 $= 0.469$ L is discharged each second.

EVALUATE: We have assumed that the diameter of the hole is much less than the diameter of the tank.

12.43. **IDENTIFY** and **SET UP:**



Apply Bernoulli's equation to points 1 and 2 as shown in Figure 12.43. Point 1 is in the mains and point 2 is at the maximum height reached by the stream, so $v_2 = 0$.

Figure 12.43

Solve for p_1 and then convert this absolute pressure to gauge pressure.

EXECUTE: $p_1 + \rho g y_1 + \frac{1}{2}\rho v_1^2 = p_2 + \rho g y_2 + \frac{1}{2}\rho v_2^2$

Let $y_1 = 0$, $y_2 = 15.0$ m. The mains have large diameter, so $v_1 \approx 0$.

Thus $p_1 = p_2 + \rho g y_2$.

But $p_2 = p_a$, so $p_1 - p_a = \rho g y_2 = (1000 \text{ kg/m}^3)(9.80 \text{ m/s}^2)(15.0 \text{ m}) = 1.47\times10^5$ Pa.

EVALUATE: This is the gauge pressure at the bottom of a column of water 15.0 m high.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

12.44. **IDENTIFY:** Apply Bernoulli's equation to the two points.
SET UP: The continuity equation says $v_1A_1 = v_2A_2$. In Eq. (12.17) either absolute or gauge pressures can be used at both points.
EXECUTE: Using $v_2 = \frac{1}{4}v_1$,

$$p_2 = p_1 + \frac{1}{2}\rho(v_1^2 - v_2^2) + \rho g(y_1 - y_2) = p_1 + \rho\left[\left(\frac{15}{32}\right)v_1^2 + g(y_1 - y_2)\right]$$

$$p_2 = 5.00\times10^4 \text{ Pa} + (1.00\times10^3 \text{ kg/m}^3)\left(\frac{15}{32}(3.00 \text{ m/s})^2 + (9.80 \text{ m/s}^2)(11.0 \text{ m})\right) = 1.62\times10^5 \text{ Pa}.$$

EVALUATE: The decrease in speed and the decrease in height at point 2 both cause the pressure at point 2 to be greater than the pressure at point 1.

12.45. **IDENTIFY:** Apply Bernoulli's equation to the two points.
SET UP: $y_1 = y_2$. $v_1A_1 = v_2A_2$. $A_2 = 2A_1$.

EXECUTE: $p_1 + \rho g y_1 + \frac{1}{2}\rho v_1^2 = p_2 + \rho g y_2 + \frac{1}{2}\rho v_2^2$. $v_2 = v_1\left(\frac{A_1}{A_2}\right) = (2.50 \text{ m/s})\left(\frac{A_1}{2A_1}\right) = 1.25 \text{ m/s}.$

$$p_2 = p_1 + \tfrac{1}{2}\rho(v_1^2 - v_2^2) = 1.80\times10^4 \text{ Pa} + \tfrac{1}{2}(1000 \text{ kg/m}^3)([2.50 \text{ m/s}]^2 - [1.25 \text{ m/s}]^2) = 2.03\times10^4 \text{ Pa}$$

EVALUATE: The gauge pressure is higher at the second point because the water speed is less there.

12.46. **IDENTIFY:** $\rho = m/V$. Apply the equation of continuity and Bernoulli's equation to points 1 and 2.
SET UP: The density of water is 1 kg/L.

EXECUTE: **(a)** $\frac{(220)(0.355 \text{ kg})}{60.0 \text{ s}} = 1.30 \text{ kg/s}.$

(b) The density of the liquid is $\frac{0.355 \text{ kg}}{0.355\times10^{-3} \text{ m}^3} = 1000 \text{ kg/m}^3,$ and so the volume flow rate is

$\frac{1.30 \text{ kg/s}}{1000 \text{ kg/m}^3} = 1.30\times10^{-3} \text{ m}^3/\text{s} = 1.30 \text{ L/s}.$ This result may also be obtained from

$\frac{(220)(0.355 \text{ L})}{60.0 \text{ s}} = 1.30 \text{ L/s}.$

(c) $v_1 = \frac{1.30\times10^{-3} \text{ m}^3/\text{s}}{2.00\times10^{-4}\text{m}^2} = 6.50 \text{ m/s}.$ $v_2 = v_1/4 = 1.63 \text{ m/s}.$

(d) $p_1 = p_2 + \frac{1}{2}\rho(v_2^2 - v_1^2) + \rho g(y_2 - y_1).$

$p_1 = 152 \text{ kPa} + (1000 \text{ kg/m}^3)\left(\frac{1}{2}[(1.63 \text{ m/s})^2 - (6.50 \text{ m/s})^2] + (9.80 \text{ m/s}^2)(-1.35 \text{ m})\right).$ $p_1 = 119 \text{ kPa}.$

EVALUATE: The increase in height and the increase in fluid speed at point 1 both cause the pressure at point 1 to be less than the pressure at point 2.

12.47. **IDENTIFY** and **SET UP:** Let point 1 be where $r_1 = 4.00$ cm and point 2 be where $r_2 = 2.00$ cm. The volume flow rate vA has the value $7200 \text{ cm}^3/\text{s}$ at all points in the pipe. Apply Eq. (12.10) to find the fluid speed at points 1 and 2 and then use Bernoulli's equation for these two points to find p_2.

EXECUTE: $v_1A_1 = v_1\pi r_1^2 = 7200 \text{ cm}^3,$ so $v_1 = 1.43$ m/s

$v_2A_2 = v_2\pi r_2^2 = 7200 \text{ cm}^3/\text{s},$ so $v_2 = 5.73$ m/s

$p_1 + \rho g y_1 + \frac{1}{2}\rho v_1^2 = p_2 + \rho g y_2 + \frac{1}{2}\rho v_2^2$

$y_1 = y_2$ and $p_1 = 2.40\times10^5$ Pa, so $p_2 = p_1 + \frac{1}{2}\rho(v_1^2 - v_2^2) = 2.25\times10^5$ Pa

EVALUATE: Where the area decreases the speed increases and the pressure decreases.

12.48. **IDENTIFY:** Since a pressure difference is needed to keep the fluid flowing, there must be viscosity in the fluid.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

SET UP: From Section 12.6, the pressure difference Δp over a length L of cylindrical pipe of radius R is proportional to L/R^4. In this problem, the length L is the same in both cases, so $R^4\,\Delta p$ must be constant. The target variable is the pressure difference.

EXECUTE: Since $R^4\,\Delta p$ is constant, we have $\Delta p_1 R_1^4 = \Delta p_2 R_2^4$.

$$\Delta p_2 = \Delta p_1\left(\frac{R_1}{R_2}\right)^4 = (6.00\times10^4\ \text{Pa})\left(\frac{0.21\ \text{m}}{0.0700\ \text{m}}\right)^4 = 4.86\times10^6\ \text{Pa}.$$

EVALUATE: The pipe is narrower, so the pressure difference must be greater.

12.49. **IDENTIFY:** Increasing the cross-sectional area of the artery will increase the amount of blood that flows through it per second.

SET UP: The flow rate, $\dfrac{\Delta V}{\Delta t}$, is related to the radius R or diameter D of the artery by Poiseuille's law: $\dfrac{\Delta V}{\Delta t} = \dfrac{\pi R^4}{8\eta}\left(\dfrac{p_1 - p_2}{L}\right) = \dfrac{\pi D^4}{128\eta}\left(\dfrac{p_1 - p_2}{L}\right)$. Assume the pressure gradient $(p_1 - p_2)/L$ in the artery remains the same.

EXECUTE: $(\Delta V/\Delta t)/D^4 = \dfrac{\pi}{128\eta}\left(\dfrac{p_1 - p_2}{L}\right) = \text{constant}$, so $(\Delta V/\Delta t)_{\text{old}}/{D_{\text{old}}}^4 = (\Delta V/\Delta t)_{\text{new}}/{D_{\text{new}}}^4$.

$(\Delta V/\Delta t)_{\text{new}} = 2(\Delta V/\Delta t)_{\text{old}}$ and $D_{\text{old}} = D$. This gives $D_{\text{new}} = D_{\text{old}}\left[\dfrac{(\Delta V/\Delta t)_{\text{new}}}{(\Delta V/\Delta t)_{\text{old}}}\right]^{1/4} = 2^{1/4}D = 1.19D.$

EVALUATE: Since the flow rate is proportional to D^4, a 19% increase in D doubles the flow rate.

12.50. **IDENTIFY:** Apply $p = p_0 + \rho g h$ and $\Delta V = -\dfrac{(\Delta p)V_0}{B}$, where B is the bulk modulus.

SET UP: Seawater has density $\rho = 1.03\times10^3\ \text{kg/m}^3$. The bulk modulus of water is $B = 2.2\times10^9\ \text{Pa}$. $p_{\text{air}} = 1.01\times10^5\ \text{Pa}$.

EXECUTE:

(a) $p_0 = p_{\text{air}} + \rho g h = 1.01\times10^5\ \text{Pa} + (1.03\times10^3\ \text{kg/m}^3)(9.80\ \text{m/s}^2)(10.92\times10^3\ \text{m}) = 1.10\times10^8\ \text{Pa}$

(b) At the surface $1.00\ \text{m}^3$ of seawater has mass $1.03\times10^3\ \text{kg}$. At a depth of 10.92 km the change in volume is $\Delta V = -\dfrac{(\Delta p)V_0}{B} = -\dfrac{(1.10\times10^8\ \text{Pa})(1.00\ \text{m}^3)}{2.2\times10^9\ \text{Pa}} = -0.050\ \text{m}^3$. The volume of this mass of water at this depth therefore is $V = V_0 + \Delta V = 0.950\ \text{m}^3$. $\rho = \dfrac{m}{V} = \dfrac{1.03\times10^3\ \text{kg}}{0.950\ \text{m}^3} = 1.08\times10^3\ \text{kg/m}^3$. The density is 5% larger than at the surface.

EVALUATE: For water B is small and a very large increase in pressure corresponds to a small fractional change in volume.

12.51. **IDENTIFY:** $F = pA$, where A is the cross-sectional area presented by a hemisphere. The force F_{bb} that the body builder must apply must equal in magnitude the net force on each hemisphere due to the air inside and outside the sphere.

SET UP: $A = \pi\frac{D^2}{4}$.

EXECUTE: **(a)** $F_{\text{bb}} = (p_0 - p)\pi\frac{D^2}{4}$.

(b) The force on each hemisphere due to the atmosphere is $\pi(5.00\times10^{-2}\ \text{m})^2(1.013\times10^5\ \text{Pa/atm})(0.975\ \text{atm}) = 776\ \text{N}$. The bodybuilder must exert this force on each hemisphere to pull them apart.

EVALUATE: The force is about 170 lbs, feasible only for a very strong person. The force required is proportional to the square of the diameter of the hemispheres.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

12.52. **IDENTIFY:** As the fish inflates its swim bladder, it changes its volume and hence the volume of water it displaces. This in turn changes the buoyant force on it, by Archimedes's principle.

SET UP: The buoyant force exerted by the water is $F_B = \rho_w g V_{fish}$. When the fish is fully submerged the buoyant force on it must equal its weight.

EXECUTE: **(a)** The average density of the fish is very close to the density of water.

(b) Before inflation, $F_B = w = (2.75 \text{ kg})(9.80 \text{ m/s}^2) = 27.0 \text{ N}$. When the volume increases by a factor of 1.10, the buoyant force also increases by a factor of 1.10 and becomes $(1.10)(27.0 \text{ N}) = 29.7 \text{ N}$.

(c) The water exerts an upward force 29.7 N and gravity exerts a downward force of 27.0 N so there is a net upward force of 2.7 N; the fish moves upward.

EVALUATE: Normally the buoyant force on the fish is equal to its weight, but if the fish inflates itself, the buoyant force increases and the fish rises.

12.53. **IDENTIFY:** In part (a), the force is the weight of the water. In part (b), the pressure due to the water at a depth h is $\rho g h$. $F = pA$ and $m = \rho V$.

SET UP: The density of water is $1.00 \times 10^3 \text{ kg/m}^3$.

EXECUTE: **(a)** The weight of the water is

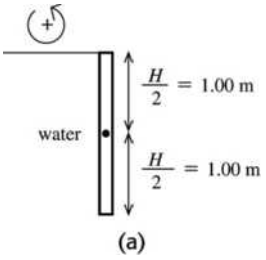
$\rho g V = (1.00 \times 10^3 \text{ kg/m}^3)(9.80 \text{ m/s}^2)((5.00 \text{ m})(4.0 \text{ m})(3.0 \text{ m})) = 5.9 \times 10^5 \text{ N}$.

(b) Integration gives the expected result that the force is what it would be if the pressure were uniform and equal to the pressure at the midpoint. If d is the depth of the pool and A is the area of one end of the pool, then $F = \rho g A \frac{d}{2} = (1.00 \times 10^3 \text{kg/m}^3)(9.80 \text{ m/s}^2)((4.0 \text{ m})(3.0 \text{ m}))(1.50 \text{ m}) = 1.76 \times 10^5 \text{ N}$.

EVALUATE: The answer to part (a) can be obtained as $F = pA$, where $p = \rho g d$ is the gauge pressure at the bottom of the pool and $A = (5.0 \text{ m})(4.0 \text{ m})$ is the area of the bottom of the pool.

12.54. **IDENTIFY:** Use Eq. (12.8) to find the gauge pressure versus depth, use Eq. (12.3) to relate the pressure to the force on a strip of the gate, calculate the torque as force times moment arm, and follow the procedure outlined in the hint to calculate the total torque.

SET UP: The gate is sketched in Figure 12.54a.



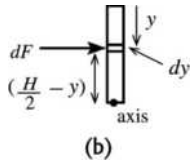
Let τ_u be the torque due to the net force of the water on the upper half of the gate, and τ_l be the torque due to the force on the lower half.

Figure 12.54a

With the indicated sign convention, τ_l is positive and τ_u is negative, so the net torque about the hinge is $\tau = \tau_l - \tau_u$. Let H be the height of the gate.

Upper-half of gate:

Calculate the torque due to the force on a narrow strip of height dy located a distance y below the top of the gate, as shown in Figure 12.54b. Then integrate to get the total torque.



The net force on the strip is $dF = p(y)\,dA$, where $p(y) = \rho g y$ is the pressure at this depth and $dA = W\,dy$ with $W = 4.00$ m.

$dF = \rho g y W\,dy$

Figure 12.54b

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

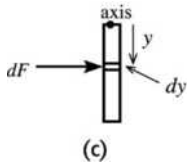
The moment arm is $(H/2 - y)$, so $d\tau = \rho g W (H/2 - y) y\, dy$.

$$\tau_u = \int_0^{H/2} d\tau = \rho g W \int_0^{H/2} (H/2 - y) y\, dy = \rho g W ((H/4) y^2 - y^3/3)\Big|_0^{H/2}$$

$$\tau_u = \rho g W (H^3/16 - H^3/24) = \rho g W (H^3/48)$$

$$\tau_u = (1000 \text{ kg/m}^3)(9.80 \text{ m/s}^2)(4.00 \text{ m})(2.00 \text{ m})^3/48 = 6.533 \times 10^3 \text{ N} \cdot \text{m}$$

Lower-half of gate:



Consider the narrow strip shown in Figure 12.54c. The depth of the strip is $(H/2 + y)$ so the force dF is $dF = p(y)\, dA = \rho g (H/2 + y) W\, dy$.

Figure 12.54c

The moment arm is y, so $d\tau = \rho g W (H/2 + y) y\, dy$.

$$\tau_l = \int_0^{H/2} d\tau = \rho g W \int_0^{H/2} (H/2 + y) y\, dy = \rho g W ((H/4) y^2 + y^3/3)\Big|_0^{H/2}$$

$$\tau_l = \rho g W (H^3/16 + H^3/24) = \rho g W (5H^3/48)$$

$$\tau_l = (1000 \text{ kg/m}^3)(9.80 \text{ m/s}^2)(4.00 \text{ m})5(2.00 \text{ m})^3/48 = 3.267 \times 10^4 \text{ N} \cdot \text{m}$$

Then $\tau = \tau_l - \tau_u = 3.267 \times 10^4 \text{ N} \cdot \text{m} - 6.533 \times 10^3 \text{ N} \cdot \text{m} = 2.61 \times 10^4 \text{ N} \cdot \text{m}$.

EVALUATE: The forces and torques on the upper and lower halves of the gate are in opposite directions so find the net value by subtracting the magnitudes. The torque on the lower half is larger than the torque on the upper half since pressure increases with depth.

12.55. **IDENTIFY:** Compute the force and the torque on a thin, horizontal strip at a depth h and integrate to find the total force and torque.

SET UP: The strip has an area $dA = (dh)L$, where dh is the height of the strip and L is its length. $A = HL$. The height of the strip about the bottom of the dam is $H - h$.

EXECUTE: **(a)** $dF = pdA = \rho g h L dh$. $F = \int_0^H dF = \rho g L \int_0^H h dh = \rho g L H^2/2 = \rho g A H/2$.

(b) The torque about the bottom on a strip of vertical thickness dh is $d\tau = dF(H - h) = \rho g L h (H - h) dh$, and integrating from $h = 0$ to $h = H$ gives $\tau = \rho g L H^3/6 = \rho g A H^2/6$.

(c) The force depends on the width and on the square of the depth, and the torque about the bottom depends on the width and the cube of the depth; the surface area of the lake does not affect either result (for a given width).

EVALUATE: The force is equal to the average pressure, at depth $H/2$, times the area A of the vertical side of the dam that faces the lake. But the torque is not equal to $F(H/2)$, where $H/2$ is the moment arm for a force acting at the center of the dam.

12.56. **IDENTIFY:** The buoyant force B equals the weight of the air displaced by the balloon.

SET UP: $B = \rho_{air} V g$. Let g_M be the value of g for Mars. For a sphere $V = \frac{4}{3}\pi R^3$. The surface area of a sphere is given by $A = 4\pi R^2$. The mass of the balloon is $(5.00 \times 10^{-3} \text{ kg/m}^2)(4\pi R^2)$.

EXECUTE: **(a)** $B = mg_M$. $\rho_{air} V g_M = mg_M$. $\rho_{air} \frac{4}{3}\pi R^3 = (5.00 \times 10^{-3} \text{ kg/m}^2)(4\pi R^2)$.

$$R = \frac{3(5.00 \times 10^{-3} \text{ kg/m}^2)}{\rho_{air}} = 0.974 \text{ m}. \quad m = (5.00 \times 10^{-3} \text{ kg/m}^2)(4\pi R^2) = 0.0596 \text{ kg}.$$

(b) $F_{net} = B - mg = ma$. $B = \rho_{air} V g = \rho_{air} \frac{4}{3}\pi R^3 g = (1.20 \text{ kg/m}^3)\left(\frac{4\pi}{3}\right)(0.974 \text{ m})^3(9.80 \text{ m/s}^2) = 45.5 \text{ N}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$a = \frac{B - mg}{m} = \frac{45.5\text{ N} - (0.0596\text{ kg})(9.80\text{ m/s}^2)}{0.0596\text{ m}} = 754\text{ m/s}^2,\text{ upward.}$$

(c) $B = m_{\text{tot}}g$. $\rho_{\text{air}}Vg = (m_{\text{balloon}} + m_{\text{load}})g$. $m_{\text{load}} = \rho_{\text{air}}\frac{4}{3}\pi R^3 - (5.00\times10^{-3}\text{ kg/m}^2)4\pi R^2$.

$$m_{\text{load}} = (0.0154\text{ kg/m}^3)\left(\frac{4\pi}{3}\right)(5[0.974\text{ m}])^3 - (5.00\times10^{-3}\text{ kg/m}^2)(4\pi)(5[0.974\text{ m}])^2$$

$$m_{\text{load}} = 7.45\text{ kg} - 1.49\text{ kg} = 5.96\text{ kg}$$

EVALUATE: The buoyant force is proportional to R^3 and the mass of the balloon is proportional to R^2, so the load that can be carried increases when the radius of the balloon increases. We calculated the mass of the load. To find the weight of the load we would need to know the value of g for Mars.

12.57. **IDENTIFY:** The buoyant force on an object in a liquid is equal to the weight of the liquid it displaces.

SET UP: $V = \frac{m}{\rho}$.

EXECUTE: When it is floating, the ice displaces an amount of glycerin equal to its weight. From Table 12.1, the density of glycerin is 1260 kg/m^3. The volume of this amount of glycerin is $V = \frac{m}{\rho} = \frac{0.180\text{ kg}}{1260\text{ kg/m}^3} = 1.429\times10^{-4}\text{ m}^3$. The ice cube produces 0.180 kg of water. The volume of this mass of water is $V = \frac{m}{\rho} = \frac{0.180\text{ kg}}{1000\text{ kg/m}^3} = 1.80\times10^{-4}\text{ m}^3$. The volume of water from the melted ice is greater than the volume of glycerin displaced by the floating cube and the level of liquid in the cylinder rises. The distance the level rises is $\frac{1.80\times10^{-4}\text{ m}^3 - 1.429\times10^{-4}\text{ m}^3}{\pi(0.0350\text{ m})^2} = 9.64\times10^{-3}\text{ m} = 0.964\text{ cm}$.

EVALUATE: The melted ice has the same mass as the solid ice, but a different density.

12.58. **IDENTIFY:** The pressure must be the same at the bottom of the tube. Therefore since the liquids have different densities, they must have difference heights.

SET UP: After the barrier is removed the top of the water moves downward a distance x and the top of the oil moves up a distance x, as shown in Figure 12.58. After the heights have changed, the gauge pressure at the bottom of each of the tubes is the same. The gauge pressure p at a depth h is $p - p_{\text{atm}} = \rho gh$.

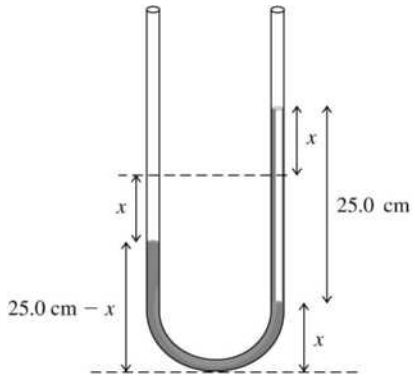


Figure 12.58

EXECUTE: The gauge pressure at the bottom of arm A of the tube is $p - p_{\text{atm}} = \rho_{\text{w}}g(25.0\text{ cm} - x)$. The gauge pressure at the bottom of arm B of the tube is $p - p_{\text{atm}} = \rho_{\text{oil}}g(25.0\text{ cm}) + \rho_{\text{w}}gx$. The gauge pressures must be equal, so $\rho_{\text{w}}g(25.0\text{ cm} - x) = \rho_{\text{oil}}g(25.0\text{ cm}) + \rho_{\text{w}}gx$. Dividing out g and using $\rho_{\text{oil}} = 0.80\rho_{\text{w}}$, we have $\rho_{\text{w}}(25.0\text{ cm} - x) = 0.80\rho_{\text{w}}(25.0\text{ cm}) + \rho_{\text{w}}x$. ρ_{w} divides out and leaves

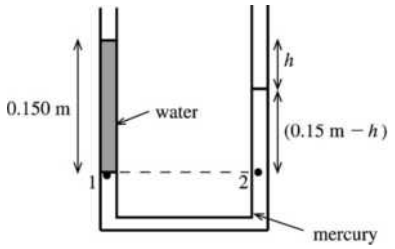
© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$25.0\text{ cm} - x = 20.0\text{ cm} + x$, so $x = 2.5$ cm. The height of fluid in arm A is $25.0\text{ cm} - x = 22.5$ cm and the height in arm B is $25.0\text{ cm} + x = 27.5$ cm.

(b) (i) If the densities were the same there would be no reason for a difference in height and the height would be 25.0 cm on each side. (ii) The pressure exerted by the column of oil would be very small and the water would divide equally on both sides. The height in arm A would be 12.5 cm and the height in arm B would be $25.0\text{ cm} + 12.5\text{ cm} = 37.5$ cm.

EVALUATE: The less dense fluid rises to a higher height, which is physically reasonable.

12.59. **(a) IDENTIFY** and **SET UP:**



Apply $p = p_0 + \rho gh$ to the water in the left-hand arm of the tube. See Figure 12.59.

Figure 12.59

EXECUTE: $p_0 = p_a$, so the gauge pressure at the interface (point 1) is

$p - p_a = \rho gh = (1000\text{ kg/m}^3)(9.80\text{ m/s}^2)(0.150\text{ m}) = 1470\text{ Pa}.$

(b) IDENTIFY and **SET UP:** The pressure at point 1 equals the pressure at point 2. Apply Eq. (12.6) to the right-hand arm of the tube and solve for h.

EXECUTE: $p_1 = p_a + \rho_w g(0.150\text{ m})$ and $p_2 = p_a + \rho_{Hg} g(0.150\text{ m} - h)$

$p_1 = p_2$ implies $\rho_w g(0.150\text{ m}) = \rho_{Hg} g(0.150\text{ m} - h)$

$$0.150\text{ m} - h = \frac{\rho_w(0.150\text{ m})}{\rho_{Hg}} = \frac{(1000\text{ kg/m}^3)(0.150\text{ m})}{13.6\times10^3\text{ kg/m}^3} = 0.011\text{ m}$$

$h = 0.150\text{ m} - 0.011\text{ m} = 0.139\text{ m} = 13.9\text{ cm}$

EVALUATE: The height of mercury above the bottom level of the water is 1.1 cm. This height of mercury produces the same gauge pressure as a height of 15.0 cm of water.

12.60. **IDENTIFY:** Follow the procedure outlined in the hint. $F = pA$.

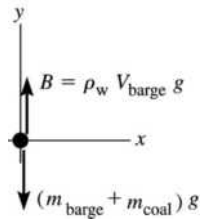
SET UP: The circular ring has area $dA = (2\pi R)dy$. The pressure due to the molasses at depth y is ρgy.

EXECUTE: $F = \int_0^h (\rho gy)(2\pi R)dy = \rho g\pi Rh^2$ where R and h are the radius and height of the tank. Using the given numerical values gives $F = 2.11\times10^8$ N.

EVALUATE: The net outward force is the area of the wall of the tank, $A = 2\pi Rh$, times the average pressure, the pressure $\rho gh/2$ at depth $h/2$.

12.61. **IDENTIFY:** Apply Newton's second law to the barge plus its contents. Apply Archimedes's principle to express the buoyancy force B in terms of the volume of the barge.

SET UP: The free-body diagram for the barge plus coal is given in Figure 12.61.



EXECUTE: $\sum F_y = ma_y$

$B - (m_{barge} + m_{coal})g = 0$

$\rho_w V_{barge} g = (m_{barge} + m_{coal})g$

$m_{coal} = \rho_w V_{barge} - m_{barge}$

Figure 12.61

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$V_{\text{barge}} = (22\text{ m})(12\text{ m})(40\text{ m}) = 1.056\times10^4\text{ m}^3$

The mass of the barge is $m_{\text{barge}} = \rho_s V_s$, where s refers to steel.

From Table 12.1, $\rho_s = 7800\text{ kg/m}^3$. The volume V_s is 0.040 m times the total area of the five pieces of steel that make up the barge

$$V_s = (0.040\text{ m})[2(22\text{ m})(12\text{ m}) + 2(40\text{ m})(12\text{ m}) + (22\text{ m})(40\text{ m})] = 94.7\text{ m}^3.$$

Therefore, $m_{\text{barge}} = \rho_s V_s = (7800\text{ kg/m}^3)(94.7\text{ m}^3) = 7.39\times10^5\text{ kg}$.

Then $m_{\text{coal}} = \rho_w V_{\text{barge}} - m_{\text{barge}} = (1000\text{ kg/m}^3)(1.056\times10^4\text{ m}^3) - 7.39\times10^5\text{ kg} = 9.8\times10^6\text{ kg}$.

The volume of this mass of coal is $V_{\text{coal}} = m_{\text{coal}}/\rho_{\text{coal}} = 9.8\times10^6\text{ kg}/1500\text{ kg/m}^3 = 6500\text{ m}^3$; this is less than V_{barge} so it will fit into the barge.

EVALUATE: The buoyancy force *B* must support both the weight of the coal and also the weight of the barge. The weight of the coal is about 13 times the weight of the barge. The buoyancy force increases when more of the barge is submerged, so when it holds the maximum mass of coal the barge is fully submerged.

12.62. **IDENTIFY:** The buoyant force on the balloon must equal the total weight of the balloon fabric, the basket and its contents and the gas inside the balloon. $m_{\text{gas}} = \rho_{\text{gas}} V$. $B = \rho_{\text{air}} V g$.

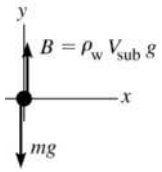
SET UP: The total weight, exclusive of the gas inside the balloon, is $900\text{ N} + 1700\text{ N} + 3200\text{ N} = 5800\text{ N}$.

EXECUTE: $5800\text{ N} + \rho_{\text{gas}} V g = \rho_{\text{air}} V g$ and $\rho_{\text{gas}} = 1.23\text{ kg/m}^3 - \dfrac{(5800\text{ N})}{(9.80\text{ m/s}^2)(2200\text{ m}^3)} = 0.96\text{ kg/m}^3$.

EVALUATE: The volume of a given mass of gas increases when the gas is heated, and the density of the gas therefore decreases.

12.63. **IDENTIFY:** Apply Newton's second law to the car. The buoyancy force is given by Archimedes's principle.

(a) SET UP: The free-body diagram for the floating car is given in Figure 12.63. (V_{sub} is the volume that is submerged.)



EXECUTE: $\sum F_y = ma_y$

$B - mg = 0$

$\rho_w V_{\text{sub}} g - mg = 0$

Figure 12.63

$V_{\text{sub}} = m/\rho_w = (900\text{ kg})/(1000\text{ kg/m}^3) = 0.900\text{ m}^3$

$V_{\text{sub}}/V_{\text{obj}} = (0.900\text{ m}^3)/(3.0\text{ m}^3) = 0.30 = 30\%$

EVALUATE: The average density of the car is $(900\text{ kg})/(3.0\text{ m}^3) = 300\text{ kg/m}^3$. $\rho_{\text{car}}/\rho_{\text{water}} = 0.30$; this equals $V_{\text{sub}}/V_{\text{obj}}$.

(b) SET UP: When the car starts to sink it is fully submerged and the buoyant force is equal to the weight of the car plus the water that is inside it.

EXECUTE: When the car is fully submerged $V_{\text{sub}} = V$, the volume of the car, and

$B = \rho_{\text{water}} V g = (1000\text{ kg/m}^3)(3.0\text{ m}^3)(9.80\text{ m/s}^2) = 2.94\times10^4\text{ N}$.

The weight of the car is $mg = (900\text{ kg})(9.80\text{ m/s}^2) = 8820\text{ N}$.

Thus the weight of the water in the car when it sinks is the buoyant force minus the weight of the car itself:

$m_{\text{water}} = (2.94\times10^4\text{ N} - 8820\text{ N})/(9.80\text{ m/s}^2) = 2.10\times10^3\text{ kg}$

And $V_{\text{water}} = m_{\text{water}}/\rho_{\text{water}} = (2.10\times10^3\text{ kg})/(1000\text{ kg/m}^3) = 2.10\text{ m}^3$

The fraction this is of the total interior volume is $(2.10\text{ m}^3)/(3.00\text{ m}^3) = 0.70 = 70\%$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: The average density of the car plus the water inside it is $(900\text{ kg} + 2100\text{ kg})/(3.0\text{ m}^3) = 1000\text{ kg/m}^3$, so $\rho_{\text{car}} = \rho_{\text{water}}$ when the car starts to sink.

12.64. **IDENTIFY:** For a floating object, the buoyant force equals the weight of the object. $B = \rho_{\text{fluid}} V_{\text{submerged}} g$.

SET UP: Water has density $\rho = 1.00\text{ g/cm}^3$.

EXECUTE: **(a)** The volume displaced must be that which has the same weight and mass as the ice, $\dfrac{9.70\text{ gm}}{1.00\text{ gm/cm}^3} = 9.70\text{ cm}^3$.

(b) No; when melted, the cube produces the same volume of water as was displaced by the floating cube, and the water level does not change.

(c) $\dfrac{9.70\text{ gm}}{1.05\text{ gm/cm}^3} = 9.24\text{ cm}^3$

(d) The melted water takes up more volume than the salt water displaced, and so 0.46 cm^3 flows over.

EVALUATE: The volume of water from the melted cube is less than the volume of the ice cube, but the cube floats with only part of its volume submerged.

12.65. **IDENTIFY:** For a floating object the buoyant force equals the weight of the object. The buoyant force when the wood sinks is $B = \rho_{\text{water}} V_{\text{tot}} g$, where V_{tot} is the volume of the wood plus the volume of the lead. $\rho = m/V$.

SET UP: The density of lead is $11.3\times10^3\text{ kg/m}^3$.

EXECUTE: $V_{\text{wood}} = (0.600\text{ m})(0.250\text{ m})(0.080\text{ m}) = 0.0120\text{ m}^3$.

$m_{\text{wood}} = \rho_{\text{wood}} V_{\text{wood}} = (700\text{ kg/m}^3)(0.0120\text{ m}^3) = 8.40\text{ kg}$.

$B = (m_{\text{wood}} + m_{\text{lead}})g$. Using $B = \rho_{\text{water}} V_{\text{tot}} g$ and $V_{\text{tot}} = V_{\text{wood}} + V_{\text{lead}}$ gives

$\rho_{\text{water}}(V_{\text{wood}} + V_{\text{lead}})g = (m_{\text{wood}} + m_{\text{lead}})g$. $m_{\text{lead}} = \rho_{\text{lead}} V_{\text{lead}}$ then gives

$\rho_{\text{water}} V_{\text{wood}} + \rho_{\text{water}} V_{\text{lead}} = m_{\text{wood}} + \rho_{\text{lead}} V_{\text{lead}}$.

$$V_{\text{lead}} = \frac{\rho_{\text{water}} V_{\text{wood}} - m_{\text{wood}}}{\rho_{\text{lead}} - \rho_{\text{water}}} = \frac{(1000\text{ kg/m}^3)(0.0120\text{ m}^3) - 8.40\text{ kg}}{11.3\times10^3\text{ kg/m}^3 - 1000\text{ kg/m}^3} = 3.50\times10^{-4}\text{ m}^3.$$

$m_{\text{lead}} = \rho_{\text{lead}} V_{\text{lead}} = 3.95\text{ kg}$.

EVALUATE: The volume of the lead is only 2.9% of the volume of the wood. If the contribution of the volume of the lead to F_{B} is neglected, the calculation is simplified: $\rho_{\text{water}} V_{\text{wood}} g = (m_{\text{wood}} + m_{\text{lead}})g$ and $m_{\text{lead}} = 3.6\text{ kg}$. The result of this calculation is in error by about 9%.

12.66. **IDENTIFY:** The fraction f of the volume that floats above the fluid is $f = 1 - \dfrac{\rho}{\rho_{\text{fluid}}}$, where ρ is the average density of the hydrometer (see Problem 12.29). This gives $\rho_{\text{fluid}} = \rho\dfrac{1}{1-f}$.

SET UP: The volume above the surface is hA, where h is the height of the stem above the surface and $A = 0.400\text{ cm}^2$.

EXECUTE: If two fluids are observed to have floating fraction f_1 and f_2, $\rho_2 = \rho_1\dfrac{1-f_1}{1-f_2}$. Using

$f_1 = \dfrac{(8.00\text{ cm})(0.400\text{ cm}^2)}{(13.2\text{ cm}^3)} = 0.242$, $f_2 = \dfrac{(3.20\text{ cm})(0.400\text{ cm}^2)}{(13.2\text{ cm}^3)} = 0.097$ gives

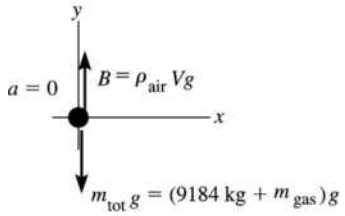
$\rho_{\text{alcohol}} = (0.839)\rho_{\text{water}} = 839\text{ kg/m}^3$.

EVALUATE: $\rho_{\text{alcohol}} < \rho_{\text{water}}$. When ρ_{fluid} increases, the fraction f of the object's volume that is above the surface increases.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

12.67. **(a) IDENTIFY:** Apply Newton's second law to the airship. The buoyancy force is given by Archimedes's principle; the fluid that exerts this force is the air.

SET UP: The free-body diagram for the dirigible is given in Figure 12.67. The lift corresponds to a mass $m_{\text{lift}} = (90\times10^3 \text{ N})/(9.80 \text{ m/s}^2) = 9.184\times10^3$ kg. The mass m_{tot} is 9.184×10^3 kg plus the mass m_{gas} of the gas that fills the dirigible. B is the buoyant force exerted by the air.



EXECUTE: $\sum F_y = ma_y$

$B - m_{\text{tot}}g = 0$

$\rho_{\text{air}}Vg = (9.184\times10^3 \text{ kg} + m_{\text{gas}})g$

Figure 12.67

Write m_{gas} in terms of V: $m_{\text{gas}} = \rho_{\text{gas}}V$ and let g divide out; the equation becomes

$\rho_{\text{air}}V = 9.184\times10^3 \text{ kg} + \rho_{\text{gas}}V$.

$$V = \frac{9.184\times10^3 \text{ kg}}{1.20 \text{ kg/m}^3 - 0.0899 \text{ kg/m}^3} = 8.27\times10^3 \text{ m}^3$$

EVALUATE: The density of the airship is less than the density of air and the airship is totally submerged in the air, so the buoyancy force exceeds the weight of the airship.

(b) SET UP: Let m_{lift} be the mass that could be lifted.

EXECUTE: From part (a), $m_{\text{lift}} = (\rho_{\text{air}} - \rho_{\text{gas}})V = (1.20 \text{ kg/m}^3 - 0.166 \text{ kg/m}^3)(8.27\times10^3 \text{ m}^3) = 8550$ kg.

The lift force is $m_{\text{lift}} = (8550 \text{ kg})(9.80 \text{ m/s}^2) = 83.8$ kN.

EVALUATE: The density of helium is less than that of air but greater than that of hydrogen. Helium provides lift, but less lift than hydrogen. Hydrogen is not used because it is highly explosive in air.

12.68. **IDENTIFY:** The buoyant force on the boat is equal to the weight of the water it displaces, by Archimedes's principle.

SET UP: $F_{\text{B}} = \rho_{\text{fluid}}gV_{\text{sub}}$, where V_{sub} is the volume of the object that is below the fluid's surface.

EXECUTE: **(a)** The boat floats, so the buoyant force on it equals the weight of the object: $F_{\text{B}} = mg$. Using Archimedes's principle gives $\rho_{\text{w}}gV = mg$ and $V = \dfrac{m}{\rho_{\text{w}}} = \dfrac{5750 \text{ kg}}{1.00\times10^3 \text{ kg/m}^3} = 5.75 \text{ m}^3$.

(b) $F_{\text{B}} = mg$ and $\rho_{\text{w}}gV_{\text{sub}} = mg$. $V_{\text{sub}} = 0.80V = 4.60 \text{ m}^3$, so the mass of the floating object is $m = \rho_{\text{w}}V_{\text{sub}} = (1.00\times10^3 \text{ kg/m}^3)(4.60 \text{ m}^3) = 4600$ kg. He must throw out $5750 \text{ kg} - 4600 \text{ kg} = 1150$ kg.

EVALUATE: He must throw out 20% of the boat's mass.

12.69. **IDENTIFY:** Bernoulli's principle will give us the speed with which the acid leaves the hole in the tank, and two-dimensional projectile motion will give us how far the acid travels horizontally after it leaves the tank.

SET UP: Apply Bernoulli's principle, $p_1 + \rho gy_1 + \frac{1}{2}\rho v_1^2 = p_2 + \rho gy_2 + \frac{1}{2}\rho v_2^2$, with point 1 at the surface of the acid in the tank and point 2 in the stream as it emerges from the hole. $p_1 = p_2 = p_{\text{air}}$. Since the hole is small the level in the tank drops slowly and $v_1 \approx 0$. After a drop of acid exits the hole the only force on it is gravity and it moves in projectile motion. For the projectile motion take $+y$ downward, so $a_x = 0$ and $a_y = +9.80 \text{ m/s}^2$.

EXECUTE: Bernoulli's equation with $p_1 = p_2$ and $v_1 = 0$ gives

$v_2 = \sqrt{2g(y_1 - y_2)} = \sqrt{2(9.80 \text{ m/s}^2)(0.75 \text{ m})} = 3.83$ m/s. Now apply projectile motion. Use the vertical

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

motion to find the time in the air. Combining $v_{0y} = 0$, $a_y = +9.80\ \text{m/s}^2$, $y - y_0 = 1.4$ m.

$y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$ gives $t = \sqrt{\dfrac{2(y - y_0)}{a_y}} = \sqrt{\dfrac{2(1.4\ \text{m})}{9.80\ \text{m/s}^2}} = 0.535$ s. The horizontal distance a drop travels in this time is $x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2 = (3.83\ \text{m/s})(0.535\ \text{s}) = 2.05$ m.

EVALUATE: If the depth of acid in the tank is increased, then the velocity of the stream as it emerges from the hole increases and the horizontal range of the stream increases.

12.70. **IDENTIFY:** After the water leaves the hose the only force on it is gravity. Use conservation of energy to relate the initial speed to the height the water reaches. The volume flow rate is Av.

SET UP: $A = \pi D^2/4$

EXECUTE: **(a)** $\frac{1}{2}mv^2 = mgh$ gives $v = \sqrt{2gh} = \sqrt{2(9.80\ \text{m/s}^2)(28.0\ \text{m})} = 23.4$ m/s.

$(\pi D^2/4)v = 0.500\ \text{m}^3/\text{s}$. $D = \sqrt{\dfrac{4(0.500\ \text{m}^3/\text{s})}{\pi v}} = \sqrt{\dfrac{4(0.500\ \text{m}^3/\text{s})}{\pi(23.4\ \text{m/s})}} = 0.165\ \text{m} = 16.5\ \text{cm}$.

(b) $D^2 v$ is constant so if D is twice as great, then v is decreased by a factor of 4. h is proportional to v^2, so h is decreased by a factor of 16. $h = \dfrac{28.0\ \text{m}}{16} = 1.75$ m.

EVALUATE: The larger the diameter of the nozzle the smaller the speed with which the water leaves the hose and the smaller the maximum height.

12.71. **IDENTIFY:** Find the horizontal range x as a function of the height y of the hole above the base of the cylinder. Then find the value of y for which x is a maximum. Once the water leaves the hole it moves in projectile motion.

SET UP: Apply Bernoulli's equation to points 1 and 2, where point 1 is at the surface of the water and point 2 is in the stream as the water leaves the hole. Since the hole is small the volume flow rate out the hole is small and $v_1 \approx 0$. $y_1 - y_2 = H - y$ and $p_1 = p_2 = \rho_{\text{air}}$. For the projectile motion, take $+y$ to be upward; $a_x = 0$ and $a_y = -9.80\ \text{m/s}^2$.

EXECUTE: **(a)** $p_1 + \rho g y_1 + \dfrac{1}{2}\rho v_1^2 = p_2 + \rho g y_2 + \dfrac{1}{2}\rho v_2^2$ gives $v_2 = \sqrt{2g(H - y)}$. In the projectile motion, $v_{0y} = 0$ and $y - y_0 = -y$, so $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$ gives $t = \sqrt{\dfrac{2y}{g}}$. The horizontal range is $x = v_{0x}t = v_2 t = 2\sqrt{y(H - y)}$. The y that gives maximum x satisfies $\dfrac{dx}{dy} = 0$. $(Hy - y^2)^{-1/2}(H - 2y) = 0$ and $y = H/2$.

(b) $x = 2\sqrt{y(H - y)} = 2\sqrt{(H/2)(H - H/2)} = H$.

EVALUATE: A smaller y gives a larger v_2, but a smaller time in the air after the water leaves the hole.

12.72. **IDENTIFY:** As water flows from the tank, the water level changes. This affects the speed with which the water flows out of the tank and the pressure at the bottom of the tank.

SET UP: Bernoulli's equation, $p_1 + \rho g y_1 + \dfrac{1}{2}\rho v_1^2 = p_2 + \rho g y_2 + \dfrac{1}{2}\rho v_2^2$, and the continuity equation, $A_1 v_1 = A_2 v_2$, both apply.

EXECUTE: **(a)** Let point 1 be at the surface of the water in the tank and let point 2 be in the stream of water that is emerging from the tank. $p_1 + \rho g y_1 + \dfrac{1}{2}\rho v_1^2 = p_2 + \rho g y_2 + \dfrac{1}{2}\rho v_2^2$. $v_1 = \dfrac{\pi d_2^2}{\pi d_1^2} v_2$, with $d_2 = 0.0200$ m and $d_1 = 2.00$ m. $v_1 << v_2$ so the $\dfrac{1}{2}\rho v_1^2$ term can be neglected. $v_2 = \sqrt{\dfrac{2p_0}{\rho} + 2gh}$, where $h = y_1 - y_2$ and $p_0 = p_1 - p_2 = 5.00 \times 10^3$ Pa. Initially $h = h_0 = 0.800$ m and when the tank has drained

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$h = 0$. At $t = 0$, $v_2 = \sqrt{\dfrac{2(5.00\times10^3\ \text{Pa})}{1000\ \text{kg/m}^3} + 2(9.8\ \text{m/s}^2)(0.800\ \text{m})} = \sqrt{10 + 15.68}\ \text{m/s} = 5.07\ \text{m/s}$. If the tank is open to the air, $p_0 = 0$ and $v_2 = 3.96$ m/s. The ratio is 1.28.

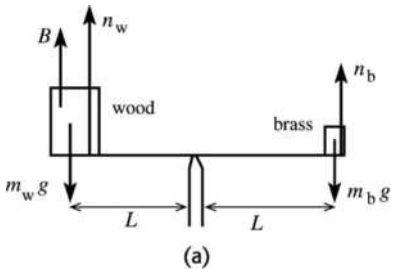
(b) $v_1 = -\dfrac{dh}{dt} = \dfrac{A_2}{A_1}v_2 = \left(\dfrac{d_2}{d_1}\right)^2\sqrt{\dfrac{2p_0}{\rho} + 2gh} = \left(\dfrac{d_2}{d_1}\right)^2\sqrt{2g}\sqrt{\dfrac{p_0}{g\rho} + h}$. Separating variables gives $\dfrac{dh}{\sqrt{\dfrac{p_0}{g\rho} + h}} = -\left(\dfrac{d_2}{d_1}\right)^2\sqrt{2g}\,dt$. We now must integrate $\displaystyle\int_{h_0}^{0}\frac{dh'}{\sqrt{\dfrac{p_0}{g\rho} + h'}} = -\left(\frac{d_2}{d_1}\right)^2\sqrt{2g}\int_0^t dt'$. To do the left-hand side integral, make the substitution $u = \dfrac{p_0}{g\rho} + h'$, which makes $du = dh'$. The integral is then of the form $\displaystyle\int\frac{du}{u^{1/2}}$, which can be readily integrated using $\displaystyle\int u^n\,du = \frac{u^{n+1}}{n+1}$. The result is $2\left(\sqrt{\dfrac{p_0}{g\rho}} - \sqrt{\dfrac{p_0}{g\rho} + h_0}\right) = -\left(\dfrac{d_2}{d_1}\right)^2\sqrt{2g}\,t$. Solving for t gives $t = \left(\dfrac{d_1}{d_2}\right)^2\sqrt{\dfrac{2}{g}}\left(\sqrt{\dfrac{p_0}{g\rho} + h_0} - \sqrt{\dfrac{p_0}{g\rho}}\right)$. Since $\dfrac{p_0}{g\rho} = \dfrac{5.00\times10^3\ \text{Pa}}{(9.8\ \text{m/s}^2)(1000\ \text{kg/m}^3)} = 0.5102\ \text{m}$, we get

$t = \left(\dfrac{2.00}{0.0200}\right)^2\sqrt{\dfrac{2}{9.8\ \text{m/s}^2}}\left(\sqrt{0.5102\ \text{m} + 0.800\ \text{m}} - \sqrt{0.5102\ \text{m}}\right) = 1.944\times10^3\ \text{s} = 32.4\ \text{min}$. When $p_0 = 0$, $t = \left(\dfrac{2.00}{0.0200}\right)^2\sqrt{\dfrac{2}{9.8\ \text{m/s}^2}}\left(\sqrt{0.800\ \text{m}}\right) = 4.04\times10^3\ \text{s} = 67.3\ \text{min}$. The ratio is 2.08.

EVALUATE: Both ratios are greater than one because a surface pressure greater than atmospheric pressure causes the water to drain with a greater speed and in a shorter time than if the surface were open to the atmosphere with a pressure of one atmosphere.

12.73. **IDENTIFY:** Apply the second condition of equilibrium to the balance arm and apply the first condition of equilibrium to the block and to the brass mass. The buoyancy force on the wood is given by Archimedes's principle and the buoyancy force on the brass mass is ignored.

SET UP: The objects and forces are sketched in Figure 12.73a.

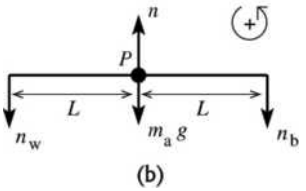


The buoyant force on the brass is neglected, but we include the buoyant force B on the block of wood. n_w and n_b are the normal forces exerted by the balance arm on which the objects sit.

Figure 12.73a

The free-body diagram for the balance arm is given in Figure 12.73b.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.



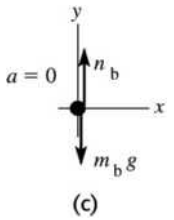
EXECUTE: $\tau_P = 0$

$n_w L - n_b L = 0$

$n_w = n_b$

Figure 12.73b

SET UP: The free-body diagram for the brass mass is given in Figure 12.73c.



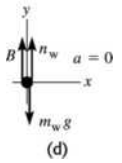
EXECUTE: $\sum F_y = ma_y$

$n_b - m_b g = 0$

$n_b = m_b g$

Figure 12.73c

The free-body diagram for the block of wood is given in Figure 12.73d.



$\sum F_y = ma_y$

$n_w + B - m_w g = 0$

$n_w = m_w g - B$

Figure 12.73d

But $n_b = n_w$ implies $m_b g = m_w g - B$.

And $B = \rho_{air} V_w g = \rho_{air}(m_w/\rho_w)g$, so $m_b g = m_w g - \rho_{air}(m_w/\rho_w)g$.

$$m_w = \frac{m_b}{1-\rho_{air}/\rho_w} = \frac{0.115\ \text{kg}}{1-((1.20\ \text{kg/m}^3)/(150\ \text{kg/m}^3))} = 0.116\ \text{kg}.$$

EVALUATE: The mass of the wood is greater than the mass of the brass; the wood is partially supported by the buoyancy force exerted by the air. The buoyancy in air of the brass can be neglected because the density of brass is much more than the density of air; the buoyancy force exerted on the brass by the air is much less than the weight of the brass. The density of the balsa wood is much less than the density of the brass, so the buoyancy force on the balsa wood is not such a small fraction of its weight.

12.74. **IDENTIFY:** $B = \rho V_A g$. Apply Newton's second law to the beaker, liquid and block as a combined object and also to the block as a single object.

SET UP: Take $+y$ upward. Let F_D and F_E be the forces corresponding to the scale reading.

EXECUTE: Forces on the combined object: $F_D + F_E - (w_A + w_B + w_C) = 0$. $w_A = F_D + F_E - w_B - w_C$.

D and E read mass rather than weight, so write the equation as $m_A = m_D + m_E - m_B - m_C$. $m_D = F_D/g$ is the reading in kg of scale D; a similar statement applies to m_E.

$m_A = 3.50\ \text{kg} + 7.50\ \text{kg} - 1.00\ \text{kg} - 1.80\ \text{kg} = 8.20\ \text{kg}$.

Forces on A: $B + F_D - w_A = 0$. $\rho V_A g + F_D - m_A g = 0$. $\rho V_A + m_D = m_A$.

$$\rho = \frac{m_A - m_D}{V_A} = \frac{8.20\ \text{kg} - 3.50\ \text{kg}}{3.80\times10^{-3}\ \text{m}^3} = 1.24\times10^3\ \text{kg/m}^3$$

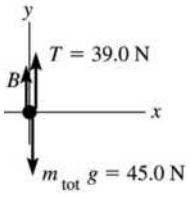
(b) D reads the mass of A: 8.20 kg. E reads the total mass of B and C: 2.80 kg.

EVALUATE: The sum of the readings of the two scales remains the same.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

12.75. **IDENTIFY:** Apply Newton's second law to the ingot. Use the expression for the buoyancy force given by Archimedes's principle to solve for the volume of the ingot. Then use the facts that the total mass is the mass of the gold plus the mass of the aluminum and that the volume of the ingot is the volume of the gold plus the volume of the aluminum.

SET UP: The free-body diagram for the piece of alloy is given in Figure 12.75.



EXECUTE: $\sum F_y = ma_y$

$B + T - m_{\text{tot}}g = 0$

$B = m_{\text{tot}}g - T$

$B = 45.0\text{ N} - 39.0\text{ N} = 6.0\text{ N}$

Figure 12.75

Also, $m_{\text{tot}}g = 45.0\text{ N}$ so $m_{\text{tot}} = 45.0\text{ N}/(9.80\text{ m/s}^2) = 4.59\text{ kg}$.

We can use the known value of the buoyant force to calculate the volume of the object:

$B = \rho_{\text{w}}V_{\text{obj}}g = 6.0\text{ N}$

$$V_{\text{obj}} = \frac{6.0\text{ N}}{\rho_{\text{w}}g} = \frac{6.0\text{ N}}{(1000\text{ kg/m}^3)(9.80\text{ m/s}^2)} = 6.122\times10^{-4}\text{ m}^3$$

We know two things:

(1) The mass m_{g} of the gold plus the mass m_{a} of the aluminum must add to m_{tot}: $m_{\text{g}} + m_{\text{a}} = m_{\text{tot}}$

We write this in terms of the volumes V_{g} and V_{a} of the gold and aluminum: $\rho_{\text{g}}V_{\text{g}} + \rho_{\text{a}}V_{\text{a}} = m_{\text{tot}}$

(2) The volumes V_{a} and V_{g} must add to give V_{obj}: $V_{\text{a}} + V_{\text{g}} = V_{\text{obj}}$ so that $V_{\text{a}} = V_{\text{obj}} - V_{\text{g}}$

Use this in the equation in (1) to eliminate V_{a}: $\rho_{\text{g}}V_{\text{g}} + \rho_{\text{a}}(V_{\text{obj}} - V_{\text{g}}) = m_{\text{tot}}$

$$V_{\text{g}} = \frac{m_{\text{tot}} - \rho_{\text{a}}V_{\text{obj}}}{\rho_{\text{g}} - \rho_{\text{a}}} = \frac{4.59\text{ kg} - (2.7\times10^3\text{ kg/m}^3)(6.122\times10^{-4}\text{ m}^3)}{19.3\times10^3\text{ kg/m}^3 - 2.7\times10^3\text{ kg/m}^3} = 1.769\times10^{-4}\text{ m}^3.$$

Then $m_{\text{g}} = \rho_{\text{g}}V_{\text{g}} = (19.3\times10^3\text{ kg/m}^3)(1.769\times10^{-4}\text{ m}^3) = 3.41\text{ kg}$ and the weight of gold is $w_{\text{g}} = m_{\text{g}}g = 33.4\text{ N}$.

EVALUATE: The gold is 29% of the volume but 74% of the mass, since the density of gold is much greater than the density of aluminum.

12.76. **IDENTIFY:** Apply $\sum F_y = ma_y$ to the ball, with $+y$ upward. The buoyant force is given by Archimedes's principle.

SET UP: The ball's volume is $V = \frac{4}{3}\pi r^3 = \frac{4}{3}\pi(12.0\text{ cm})^3 = 7238\text{ cm}^3$. As it floats, it displaces a weight of water equal to its weight.

EXECUTE: **(a)** By pushing the ball under water, you displace an additional amount of water equal to 76.0% of the ball's volume or $(0.760)(7238\text{ cm}^3) = 5501\text{ cm}^3$. This much water has a mass of $5501\ g = 5.501\text{ kg}$ and weighs $(5.501\text{ kg})(9.80\text{ m/s}^2) = 53.9\text{ N}$, which is how hard you'll have to push to submerge the ball.

(b) The upward force on the ball in excess of its own weight was found in part (a): 53.9 N. The ball's mass is equal to the mass of water displaced when the ball is floating:

$$(0.240)(7238\text{ cm}^3)(1.00\text{ g/cm}^3) = 1737\text{ g} = 1.737\text{ kg},$$

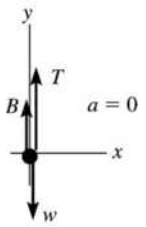
and its acceleration upon release is thus $a = \frac{F_{\text{net}}}{m} = \frac{53.9\text{ N}}{1.737\text{ kg}} = 31.0\text{ m/s}^2$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: When the ball is totally immersed the upward buoyant force on it is much larger than its weight.

12.77. **(a) IDENTIFY:** Apply Newton's second law to the crown. The buoyancy force is given by Archimedes's principle. The target variable is the ratio ρ_c/ρ_w (c = crown, w = water).

SET UP: The free-body diagram for the crown is given in Figure 12.77.



EXECUTE: $\sum F_y = ma_y$

$T + B - w = 0$

$T = fw$

$B = \rho_w V_c g$, where ρ_w = density of water, V_c = volume of crown

Figure 12.77

Then $fw + \rho_w V_c g - w = 0.$

$(1-f)w = \rho_w V_c g$

Use $w = \rho_c V_c g$, where ρ_c = density of crown.

$(1-f)\rho_c V_c g = \rho_w V_c g$

$\dfrac{\rho_c}{\rho_w} = \dfrac{1}{1-f}$, as was to be shown.

$f \to 0$ gives $\rho_c/\rho_w = 1$ and $T = 0$. These values are consistent. If the density of the crown equals the density of the water, the crown just floats, fully submerged, and the tension should be zero.

When $f \to 1$, $\rho_c >> \rho_w$ and $T = w$. If $\rho_c >> \rho_w$ then B is negligible relative to the weight w of the crown and T should equal w.

(b) "apparent weight" equals T in the rope when the crown is immersed in water. $T = fw$, so need to compute f.

$\rho_c = 19.3\times10^3$ kg/m^3; $\rho_w = 1.00\times10^3$ kg/m^3

$\dfrac{\rho_c}{\rho_w} = \dfrac{1}{1-f}$ gives $\dfrac{19.3\times10^3 \text{ kg/m}^3}{1.00\times10^3 \text{ kg/m}^3} = \dfrac{1}{1-f}$

$19.3 = 1/(1-f)$ and $f = 0.9482$

Then $T = fw = (0.9482)(12.9 \text{ N}) = 12.2 \text{ N}.$

(c) Now the density of the crown is very nearly the density of lead;

$\rho_c = 11.3\times10^3$ kg/m^3.

$\dfrac{\rho_c}{\rho_w} = \dfrac{1}{1-f}$ gives $\dfrac{11.3\times10^3 \text{ kg/m}^3}{1.00\times10^3 \text{ kg/m}^3} = \dfrac{1}{1-f}$

$11.3 = 1/(1-f)$ and $f = 0.9115$

Then $T = fw = (0.9115)(12.9 \text{ N}) = 11.8 \text{ N}.$

EVALUATE: In part (c) the average density of the crown is less than in part (b), so the volume is greater. B is greater and T is less. These measurements can be used to determine if the crown is solid gold, without damaging the crown.

12.78. **IDENTIFY:** Problem 12.77 says $\dfrac{\rho_{object}}{\rho_{fluid}} = \dfrac{1}{1-f}$, where the apparent weight of the object when it is totally immersed in the fluid is fw.

SET UP: For the object in water, $f_{water} = w_{water}/w$ and for the object in the unknown fluid, $f_{fluid} = w_{fluid}/w$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: **(a)** $\frac{\rho_{\text{steel}}}{\rho_{\text{fluid}}} = \frac{w}{w - w_{\text{fluid}}}$, $\frac{\rho_{\text{steel}}}{\rho_{\text{water}}} = \frac{w}{w - w_{\text{water}}}$. Dividing the second of these by the first gives $\frac{\rho_{\text{fluid}}}{\rho_{\text{water}}} = \frac{w - w_{\text{fluid}}}{w - w_{\text{water}}}$.

(b) When w_{fluid} is greater than w_{water}, the term on the right in the above expression is less than one, indicating that the fluid is less dense than water, and this is consistent with the buoyant force when suspended in liquid being less than that when suspended in water. If the density of the fluid is the same as that of water $w_{\text{fluid}} = w_{\text{water}}$, as expected. Similarly, if w_{fluid} is less than w_{water}, the term on the right in the above expression is greater than one, indicating that the fluid is more dense than water.

(c) Writing the result of part (a) as $\frac{\rho_{\text{fluid}}}{\rho_{\text{water}}} = \frac{1 - f_{\text{fluid}}}{1 - f_{\text{water}}}$, and solving for f_{fluid},

$$f_{\text{fluid}} = 1 - \frac{\rho_{\text{fluid}}}{\rho_{\text{water}}}(1 - f_{\text{water}}) = 1 - (1.220)(0.128) = 0.844 = 84.4\%.$$

EVALUATE: Formic acid has density greater than the density of water. When the object is immersed in formic acid the buoyant force is greater and the apparent weight is less than when the object is immersed in water.

12.79. **IDENTIFY** and **SET UP:** Use Archimedes's principle for B.

(a) $B = \rho_{\text{water}} V_{\text{tot}} g$, where V_{tot} is the total volume of the object.

$V_{\text{tot}} = V_{\text{m}} + V_0$, where V_{m} is the volume of the metal.

EXECUTE: $V_{\text{m}} = w/g\rho_{\text{m}}$ so $V_{\text{tot}} = w/g\rho_{\text{m}} + V_0$

This gives $B = \rho_{\text{water}} g(w/g\rho_{\text{m}} + V_0)$.

Solving for V_0 gives $V_0 = B/(\rho_{\text{water}} g) - w/(\rho_{\text{m}} g)$, as was to be shown.

(b) The expression derived in part (a) gives

$$V_0 = \frac{20\text{ N}}{(1000\text{ kg/m}^3)(9.80\text{ m/s}^2)} - \frac{156\text{ N}}{(8.9\times10^3\text{ kg/m}^3)(9.80\text{ m/s}^2)} = 2.52\times10^{-4}\text{ m}^3$$

$$V_{\text{tot}} = \frac{B}{\rho_{\text{water}} g} = \frac{20\text{ N}}{(1000\text{ kg/m}^3)(9.80\text{ m/s}^2)} = 2.04\times10^{-3}\text{ m}^3 \text{ and}$$

$V_0/V_{\text{tot}} = (2.52\times10^{-4}\text{ m}^3)/(2.04\times10^{-3}\text{ m}^3) = 0.124.$

EVALUATE: When $V_0 \to 0$, the object is solid and $V_{\text{obj}} = V_{\text{m}} = w/(\rho_{\text{m}} g)$. For $V_0 = 0$, the result in part (a) gives $B = (w/\rho_{\text{m}})\rho_{\text{water}} = V_{\text{m}}\rho_{\text{water}} g = V_{\text{obj}}\rho_{\text{water}} g$, which agrees with Archimedes's principle. As V_0 increases with the weight kept fixed, the total volume of the object increases and there is an increase in B.

12.80. **IDENTIFY:** For a floating object the buoyant force equals the weight of the object. Archimedes's principle says the buoyant force equals the weight of fluid displaced by the object. $m = \rho V$.

SET UP: Let d be the depth of the oil layer, h the depth that the cube is submerged in the water and L be the length of a side of the cube.

EXECUTE: **(a)** Setting the buoyant force equal to the weight and canceling the common factors of g and the cross-sectional area, $(1000)h + (750)d = (550)L$. d, h and L are related by $d + h + 0.35L = L$, so $h = 0.65L - d$. Substitution into the first relation gives $d = L\frac{(0.65)(1000) - (550)}{(1000) - (750)} = \frac{2L}{5.00} = 0.040\text{ m}$.

(b) The gauge pressure at the lower face must be sufficient to support the block (the oil exerts only sideways forces directly on the block), and $p = \rho_{\text{wood}} gL = (550\text{ kg/m}^3)(9.80\text{ m/s}^2)(0.100\text{ m}) = 539\text{ Pa}$.

EVALUATE: As a check, the gauge pressure, found from the depths and densities of the fluids, is $[(0.040\text{ m})(750\text{ kg/m}^3) + (0.025\text{ m})(1000\text{ kg/m}^3)](9.80\text{ m/s}^2) = 539\text{ Pa}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

12.81. **IDENTIFY** and **SET UP:** Apply the first condition of equilibrium to the barge plus the anchor. Use Archimedes's principle to relate the weight of the boat and anchor to the amount of water displaced. In both cases the total buoyant force must equal the weight of the barge plus the weight of the anchor. Thus the total amount of water displaced must be the same when the anchor is in the boat as when it is over the side. When the anchor is in the water the barge displaces less water, less by the amount the anchor displaces. Thus the barge rises in the water.

EXECUTE: The volume of the anchor is $V_{\text{anchor}} = m/\rho = (35.0 \text{ kg})/(7860 \text{ kg/m}^3) = 4.453\times10^{-3} \text{ m}^3$. The barge rises in the water a vertical distance h given by $hA = 4.453\times10^{-3} \text{ m}^3$, where A is the area of the bottom of the barge. $h = (4.453\times10^{-3} \text{ m}^3)/(8.00 \text{ m}^2) = 5.57\times10^{-4} \text{ m}$.

EVALUATE: The barge rises a very small amount. The buoyancy force on the barge plus the buoyancy force on the anchor must equal the weight of the barge plus the weight of the anchor. When the anchor is in the water, the buoyancy force on it is less than its weight (the anchor doesn't float on its own), so part of the buoyancy force on the barge is used to help support the anchor. If the rope is cut, the buoyancy force on the barge must equal only the weight of the barge and the barge rises still farther.

12.82. **IDENTIFY:** Apply $\sum F_y = ma_y$ to the barrel, with $+y$ upward. The buoyant force on the barrel is given by Archimedes's principle.

SET UP: $\rho_{\text{av}} = m_{\text{tot}}/V$. An object floats in a fluid if its average density is less than the density of the fluid. The density of seawater is 1030 kg/m^3.

EXECUTE: **(a)** The average density of a filled barrel is

$\dfrac{m_{\text{oil}} + m_{\text{steel}}}{V} = \rho_{\text{oil}} + \dfrac{m_{\text{steel}}}{V} = 750 \text{ kg/m}^3 + \dfrac{15.0 \text{ kg}}{0.120 \text{ m}^3} = 875 \text{ kg/m}^3$, which is less than the density of seawater, so the barrel floats.

(b) The fraction above the surface (see Problem 12.29) is

$$1 - \frac{\rho_{\text{av}}}{\rho_{\text{water}}} = 1 - \frac{875 \text{ kg/m}^3}{1030 \text{ kg/m}^3} = 0.150 = 15.0\%.$$

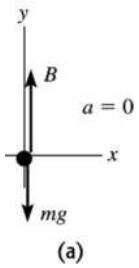
(c) The average density is $910 \text{ kg/m}^3 + \dfrac{32.0 \text{ kg}}{0.120 \text{ m}^3} = 1172 \text{ kg/m}^3$, which means the barrel sinks. In order to lift it, a tension

$T = w_{\text{tot}} - B = (1177 \text{ kg/m}^3)(0.120 \text{ m}^3)(9.80 \text{ m/s}^2) - (1030 \text{ kg/m}^3)(0.120 \text{ m}^3)(9.80 \text{ m/s}^2) = 173 \text{ N}$ is required.

EVALUATE: When the barrel floats, the buoyant force B equals its weight, w. In part (c) the buoyant force is less than the weight and $T = w - B$.

12.83. **IDENTIFY:** Apply Newton's second law to the block. In part (a), use Archimedes's principle for the buoyancy force. In part (b), use Eq. (12.6) to find the pressure at the lower face of the block and then use Eq. (12.3) to calculate the force the fluid exerts.

(a) SET UP: The free-body diagram for the block is given in Figure 12.83a.



EXECUTE: $\sum F_y = ma_y$

$B - mg = 0$

$\rho_{\text{L}} V_{\text{sub}} g = \rho_{\text{B}} V_{\text{obj}} g$

Figure 12.83a

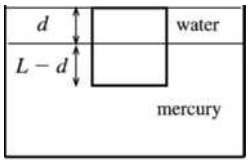
© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

The fraction of the volume that is submerged is $V_{\text{sub}}/V_{\text{obj}} = \rho_{\text{B}}/\rho_{\text{L}}$.

Thus the fraction that is *above* the surface is $V_{\text{above}}/V_{\text{obj}} = 1 - \rho_{\text{B}}/\rho_{\text{L}}$.

EVALUATE: If $\rho_{\text{B}} = \rho_{\text{L}}$ the block is totally submerged as it floats.

(b) SET UP: Let the water layer have depth *d*, as shown in Figure 12.83b.



(b)

EXECUTE: $p = p_0 + \rho_{\text{w}} g d + \rho_{\text{L}} g(L - d)$

Applying $\sum F_y = ma_y$ to the block gives

$(p - p_0)A - mg = 0.$

Figure 12.83b

$[\rho_{\text{w}} g d + \rho_{\text{L}} g(L - d)]A = \rho_{\text{B}} LAg$

A and g divide out and $\rho_{\text{w}} d + \rho_{\text{L}}(L - d) = \rho_{\text{B}} L$

$d(\rho_{\text{w}} - \rho_{\text{L}}) = (\rho_{\text{B}} - \rho_{\text{L}})L$

$$d = \left(\frac{\rho_{\text{L}} - \rho_{\text{B}}}{\rho_{\text{L}} - \rho_{\text{w}}}\right)L$$

(c) $$d = \left(\frac{13.6\times10^3\ \text{kg/m}^3 - 7.8\times10^3\ \text{kg/m}^3}{13.6\times10^3\ \text{kg/m}^3 - 1000\ \text{kg/m}^3}\right)(0.100\ \text{m}) = 0.0460\ \text{m} = 4.60\ \text{cm}$$

EVALUATE: In the expression derived in part (b), if $\rho_{\text{B}} = \rho_{\text{L}}$ the block floats in the liquid totally submerged and no water needs to be added. If $\rho_{\text{L}} \to \rho_{\text{w}}$ the block continues to float with a fraction $1 - \rho_{\text{B}}/\rho_{\text{w}}$ above the water as water is added, and the water never reaches the top of the block $(d \to \infty)$.

12.84. **IDENTIFY:** For the floating tanker, the buoyant force equals its total weight. The buoyant force is given by Archimedes's principle.

SET UP: When the metal is in the tanker, it displaces its weight of water and after it has been pushed overboard it displaces its volume of water.

EXECUTE: **(a)** The change in height Δy is related to the displaced volume ΔV by $\Delta y = \dfrac{\Delta V}{A}$, where A is the surface area of the water in the lock. ΔV is the volume of water that has the same weight as the metal, so $\Delta y = \dfrac{\Delta V}{A} = \dfrac{w/(\rho_{\text{water}} g)}{A} = \dfrac{w}{\rho_{\text{water}} gA} = \dfrac{(2.50\times10^6\ \text{N})}{(1.00\times10^3\ \text{kg/m}^3)(9.80\ \text{m/s}^2)[(60.0\ \text{m})(20.0\ \text{m})]} = 0.213\ \text{m}.$

(b) In this case, ΔV is the volume of the metal; in the above expression, ρ_{water} is replaced by $\rho_{\text{metal}} = 9.00\rho_{\text{water}}$, which gives $\Delta y' = \dfrac{\Delta y}{9}$, and $\Delta y - \Delta y' = \dfrac{8}{9}\Delta y = 0.189\ \text{m}$; the water level falls this amount.

EVALUATE: The density of the metal is greater than the density of water, so the volume of water that has the same weight as the steel is greater than the volume of water that has the same volume as the steel.

12.85. **IDENTIFY:** Consider the fluid in the horizontal part of the tube. This fluid, with mass ρAl, is subject to a net force due to the pressure difference between the ends of the tube.

SET UP: The difference between the gauge pressures at the bottoms of the ends of the tubes is $\rho g(y_{\text{L}} - y_{\text{R}})$.

EXECUTE: The net force on the horizontal part of the fluid is $\rho g(y_{\text{L}} - y_{\text{R}})A = \rho Ala$, or, $(y_{\text{L}} - y_{\text{R}}) = \dfrac{a}{g}l.$

(b) Again consider the fluid in the horizontal part of the tube. As in part (a), the fluid is accelerating; the center of mass has a radial acceleration of magnitude $a_{\text{rad}} = \omega^2 l/2$, and so the difference in heights

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

between the columns is $(\omega^2 l/2)(l/g) = \omega^2 l^2/2g$. An equivalent way to do part (b) is to break the fluid in the horizontal part of the tube into elements of thickness *dr*; the pressure difference between the sides of this piece is $dp = \rho(\omega^2 r)dr$ and integrating from $r = 0$ to $r = l$ gives $\Delta p = \rho\omega^2 l^2/2$, the same result.

EVALUATE: **(c)** The pressure at the bottom of each arm is proportional to ρ and the mass of fluid in the horizontal portion of the tube is proportional to ρ, so ρ divides out and the results are independent of the density of the fluid. The pressure at the bottom of a vertical arm is independent of the cross-sectional area of the arm. Newton's second law could be applied to a cross-sectional of fluid smaller than that of the tubes. Therefore, the results are independent and of the size and shape of all parts of the tube.

12.86. **IDENTIFY:** Apply $\sum \vec{F} = m\vec{a}$ to a small fluid element located a distance *r* from the axis.

SET UP: For rotational motion, $a = \omega^2 r$.

EXECUTE: **(a)** The change in pressure with respect to the vertical distance supplies the force necessary to keep a fluid element in vertical equilibrium (opposing the weight). For the rotating fluid, the change in pressure with respect to radius supplies the force necessary to keep a fluid element accelerating toward the axis; specifically, $dp = \dfrac{\partial p}{\partial r}dr = \rho a\, dr$, and using $a = \omega^2 r$ gives $\dfrac{\partial p}{\partial r} = \rho\omega^2 r$.

(b) Let the pressure at $y = 0, r = 0$ be p_a (atmospheric pressure); integrating the expression for $\dfrac{\partial p}{\partial r}$ from part (a) gives $p(r, y = 0) = p_a + \dfrac{\rho\omega^2}{2}r^2$.

(c) In Eq. (12.5), $p_2 = p_a$, $p = p_1 = p(r, y = 0)$ as found in part (b), $y_1 = 0$ and $y_2 = h(r)$, the height of the liquid above the $y = 0$ plane. Using the result of part (b) gives $h(r) = \omega^2 r^2/2g$.

EVALUATE: The curvature of the surface increases as the speed of rotation increases.

12.87. **IDENTIFY:** Follow the procedure specified in part (a) and integrate this result for part (b).

SET UP: A rotating particle a distance r' from the rotation axis has inward acceleration $\omega^2 r'$.

EXECUTE: **(a)** The net inward force is $(p + dp)A - pA = Adp$, and the mass of the fluid element is $\rho A dr'$. Using Newton's second law, with the inward radial acceleration of $\omega^2 r'$, gives $dp = \rho\omega^2 r' dr'$.

(b) Integrating the above expression, $\int_{p_0}^{p} dp = \int_{r_0}^{r} \rho\omega^2 r' dr'$ and $p - p_0 = \left(\dfrac{\rho\omega^2}{2}\right)(r^2 - r_0^2)$, which is the desired result.

(c) The net force on the object must be the same as that on a fluid element of the same shape. Such a fluid element is accelerating inward with an acceleration of magnitude $\omega^2 R_{cm}$, and so the force on the object is $\rho V \omega^2 R_{cm}$.

(d) If $\rho R_{cm} > \rho_{ob} R_{cm\,ob}$, the inward force is greater than that needed to keep the object moving in a circle with radius $R_{cm\,ob}$ at angular frequency ω, and the object moves inward. If $\rho R_{cm} < \rho_{ob} R_{cm\,ob}$, the net force is insufficient to keep the object in the circular motion at that radius, and the object moves outward.

(e) Objects with lower densities will tend to move toward the center, and objects with higher densities will tend to move away from the center.

EVALUATE: The pressure in the fluid increases as the distance *r* from the rotation axis increases.

12.88. **IDENTIFY:** Follow the procedure specified in the problem.

SET UP: Let increasing *x* correspond to moving toward the back of the car.

EXECUTE: **(a)** The mass of air in the volume element is $\rho dV = \rho A dx$, and the net force on the element in the forward direction is $(p + dp)A - pA = Adp$. From Newton's second law, $Adp = (\rho A dx)a$, from which $dp = \rho a dx$.

(b) With ρ given to be constant, and with $p = p_0$ at $x = 0$, $p = p_0 + \rho a x$.

(c) Using $\rho = 1.2$ kg/m^3 in the result of part (b) gives

$(1.2\text{ kg/m}^3)(5.0\text{ m/s}^2)(2.5\text{ m}) = 15.0\text{ Pa} = 15\times10^{-5}\, p_{atm}$, so the fractional pressure difference is negligible.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(d) Following the argument in Section 12.3, the force on the balloon must be the same as the force on the same volume of air; this force is the product of the mass ρV and the acceleration, or ρVa.

(e) The acceleration of the balloon is the force found in part (d) divided by the mass $\rho_{\text{bal}}V$, or $(\rho/\rho_{\text{bal}})a$. The acceleration relative to the car is the difference between this acceleration and the car's acceleration, $a_{\text{rel}} = [(\rho/\rho_{\text{bal}}) - 1]a$.

(f) For a balloon filled with air, $(\rho/\rho_{\text{bal}}) < 1$ (air balloons tend to sink in still air), and so the quantity in square brackets in the result of part (e) is negative; the balloon moves to the back of the car. For a helium balloon, the quantity in square brackets is positive, and the balloon moves to the front of the car.

EVALUATE: The pressure in the air inside the car increases with distance from the windshield toward the rear of the car. This pressure increase is proportional to the acceleration of the car.

12.89. **IDENTIFY:** After leaving the tank, the water is in free fall, with $a_x = 0$ and $a_y = +g$.

SET UP: From Example 12.8, the speed of efflux is $\sqrt{2gh}$.

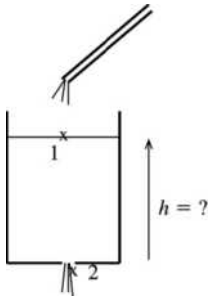
EXECUTE: **(a)** The time it takes any portion of the water to reach the ground is $t = \sqrt{\dfrac{2(H-h)}{g}}$, in which time the water travels a horizontal distance $R = vt = 2\sqrt{h(H-h)}$.

(b) Note that if $h' = H - h$, $h'(H - h') = (H - h)h$, and so $h' = H - h$ gives the same range. A hole $H - h$ below the water surface is a distance h above the bottom of the tank.

EVALUATE: For the special case of $h = H/2$, $h = h'$ and the two points coincide. For the upper hole the speed of efflux is less but the time in the air during the free fall is greater.

12.90. **IDENTIFY:** Use Bernoulli's equation to find the velocity with which the water flows out the hole.

SET UP: The water level in the vessel will rise until the volume flow rate into the vessel, 2.40×10^{-4} m^3/s, equals the volume flow rate out the hole in the bottom.



Let points 1 and 2 be chosen as in Figure 12.90.

Figure 12.90

EXECUTE: Bernoulli's equation: $p_1 + \rho g y_1 + \frac{1}{2}\rho v_1^2 = p_2 + \rho g y_2 + \frac{1}{2}\rho v_2^2$

Volume flow rate out of hole equals volume flow rate from tube gives that $v_2 A_2 = 2.40\times10^{-4}$ m^3/s and

$$v_2 = \frac{2.40\times10^{-4}\ \text{m}^3/\text{s}}{1.50\times10^{-4}\ \text{m}^2} = 1.60\ \text{m/s}$$

$A_1 \gg A_2$ and $v_1A_1 = v_2A_2$ says that $\frac{1}{2}\rho v_1^2 \ll \frac{1}{2}\rho v_2^2$; neglect the $\frac{1}{2}\rho v_1^2$ term.

Measure y from the bottom of the bucket, so $y_2 = 0$ and $y_1 = h$.

$p_1 = p_2 = p_a$ (air pressure)

Then $p_a + \rho gh = p_a + \frac{1}{2}\rho v_2^2$ and $h = v_2^2/2g = (1.60\ \text{m/s})^2/2(9.80\ \text{m/s}^2) = 0.131\ \text{m} = 13.1\ \text{cm}$

EVALUATE: The greater the flow rate into the bucket, the larger v_2 will be at equilibrium and the higher the water will rise in the bucket.

12.91. **IDENTIFY:** Apply Bernoulli's equation and the equation of continuity.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

SET UP: Example 12.8 says the speed of efflux is $\sqrt{2gh}$, where h is the distance of the hole below the surface of the fluid.

EXECUTE: **(a)** $v_3A_3 = \sqrt{2g(y_1 - y_3)}A_3 = \sqrt{2(9.80\ \text{m/s}^2)(8.00\ \text{m})}(0.0160\ \text{m}^2) = 0.200\ \text{m}^3/\text{s}$.

(b) Since p_3 is atmospheric pressure, the gauge pressure at point 2 is

$$p_2 = \frac{1}{2}\rho(v_3^2 - v_2^2) = \frac{1}{2}\rho v_3^2\left(1 - \left(\frac{A_3}{A_2}\right)^2\right) = \frac{8}{9}\rho g(y_1 - y_3),$$ using the expression for v_3 found above.

Substitution of numerical values gives $p_2 = 6.97\times10^4$ Pa.

EVALUATE: We could also calculate p_2 by applying Bernoulli's equation to points 1 and 2.

12.92. **IDENTIFY:** Apply Bernoulli's equation to the air in the hurricane.

SET UP: For a particle a distance r from the axis, the angular momentum is $L = mvr$.

EXECUTE: **(a)** Using the constancy of angular momentum, the product of the radius and speed is constant, so the speed at the rim is about $(200\ \text{km/h})\left(\frac{30}{350}\right) = 17\ \text{km/h}$.

(b) The pressure is lower at the eye, by an amount

$$\Delta p = \frac{1}{2}(1.2\ \text{kg/m}^3)((200\ \text{km/h})^2 - (17\ \text{km/h})^2)\left(\frac{1\ \text{m/s}}{3.6\ \text{km/h}}\right)^2 = 1.8\times10^3\ \text{Pa}.$$

(c) $\frac{v^2}{2g} = 160\ \text{m}$.

(d) The pressure difference at higher altitudes is even greater.

EVALUATE: According to Bernoulli's equation, the pressure decreases when the fluid velocity increases.

12.93. **IDENTIFY:** Apply Bernoulli's equation and the equation of continuity.

SET UP: Example 12.8 shows that the speed of efflux at point D is $\sqrt{2gh_1}$.

EXECUTE: Applying the equation of continuity to points at C and D gives that the fluid speed is $\sqrt{8gh_1}$ at C. Applying Bernoulli's equation to points A and C gives that the gauge pressure at C is $\rho gh_1 - 4\rho gh_1 = -3\rho gh_1$, and this is the gauge pressure at the surface of the fluid at E. The height of the fluid in the column is $h_2 = 3h_1$.

EVALUATE: The gauge pressure at C is less than the gauge pressure ρgh_1 at the bottom of tank A because of the speed of the fluid at C.

12.94. **IDENTIFY:** Apply Bernoulli's equation to points 1 and 2. Apply $p = p_0 + \rho gh$ to both arms of the U-shaped tube in order to calculate h.

SET UP: The discharge rate is $v_1A_1 = v_2A_2$. The density of mercury is $\rho_\text{m} = 13.6\times10^3\ \text{kg/m}^3$ and the density of water is $\rho_\text{w} = 1.00\times10^3\ \text{kg/m}^3$. Let point 1 be where $A_1 = 40.0\times10^{-4}\ \text{m}^2$ and point 2 is where $A_2 = 10.0\times10^{-4}\ \text{m}^2$. $y_1 = y_2$.

EXECUTE: **(a)** $v_1 = \dfrac{6.00\times10^{-3}\ \text{m}^3/\text{s}}{40.0\times10^{-4}\ \text{m}^2} = 1.50\ \text{m/s}$. $v_2 = \dfrac{6.00\times10^{-3}\ \text{m}^3/\text{s}}{10.0\times10^{-4}\ \text{m}^2} = 6.00\ \text{m/s}$

(b) $p_1 + \rho gy_1 + \frac{1}{2}\rho v_1^2 = p_2 + \rho gy_2 + \frac{1}{2}\rho v_2^2$.

$p_1 - p_2 = \frac{1}{2}\rho(v_2^2 - v_1^2) = \frac{1}{2}(1000\ \text{kg/m}^3)([6.00\ \text{m/s}]^2 - [1.50\ \text{m/s}]^2) = 1.69\times10^4$ Pa

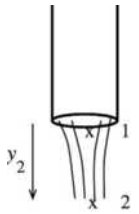
(c) $p_1 + \rho_\text{w}gh = p_2 + \rho_\text{m}gh$ and

$$h = \frac{p_1 - p_2}{(\rho_\text{m} - \rho_\text{w})g} = \frac{1.69\times10^4\ \text{Pa}}{(13.6\times10^3\ \text{kg/m}^3 - 1.00\times10^3\ \text{kg/m}^3)(9.80\ \text{m/s}^2)} = 0.137\ \text{m} = 13.7\ \text{cm}.$$

EVALUATE: The pressure in the fluid decreases when the speed of the fluid increases.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

12.95. **(a) IDENTIFY:** Apply constant acceleration equations to the falling liquid to find its speed as a function of the distance below the outlet. Then apply Eq. (12.10) to relate the speed to the radius of the stream.
SET UP:



Let point 1 be at the end of the pipe and let point 2 be in the stream of liquid at a distance y_2 below the end of the tube, as shown in Figure 12.95.

Figure 12.95

Consider the free fall of the liquid. Take $+y$ to be downward.

Free fall implies $a_y = g$. v_y is positive, so replace it by the speed v.

EXECUTE: $v_2^2 = v_1^2 + 2a(y - y_0)$ gives $v_2^2 = v_1^2 + 2gy_2$ and $v_2 = \sqrt{v_1^2 + 2gy_2}$.

Equation of continuity says $v_1 A_1 = v_2 A_2$

And since $A = \pi r^2$ this becomes $v_1 \pi r_1^2 = v_2 \pi r_2^2$ and $v_2 = v_1 (r_1/r_2)^2$.

Use this in the above to eliminate v_2: $v_1 (r_1^2/r_2^2) = \sqrt{v_1^2 + 2gy_2}$

$r_2 = r_1 \sqrt{v_1}/(v_1^2 + 2gy_2)^{1/4}$

To correspond to the notation in the problem, let $v_1 = v_0$ and $r_1 = r_0$, since point 1 is where the liquid first leaves the pipe, and let r_2 be r and y_2 be y. The equation we have derived then becomes

$r = r_0 \sqrt{v_0}/(v_0^2 + 2gy)^{1/4}$

(b) $v_0 = 1.20$ m/s

We want the value of y that gives $r = \frac{1}{2} r_0$, or $r_0 = 2r$.

The result obtained in part (a) says $r^4 (v_0^2 + 2gy) = r_0^4 v_0^2$.

Solving for y gives $y = \dfrac{[(r_0/r)^4 - 1]v_0^2}{2g} = \dfrac{(16-1)(1.20 \text{ m/s})^2}{2(9.80 \text{ m/s}^2)} = 1.10 \text{ m}.$

EVALUATE: The equation derived in part (a) says that r decreases with distance below the end of the pipe.

12.96. **IDENTIFY:** Apply $\sum F_y = ma_y$ to the rock.

SET UP: In the accelerated frame, all of the quantities that depend on g (weights, buoyant forces, gauge pressures and hence tensions) may be replaced by $g' = g + a$, with the positive direction taken upward.

EXECUTE: **(a)** The volume V of the rock is

$$V = \frac{B}{\rho_{\text{water}} g} = \frac{w - T}{\rho_{\text{water}} g} = \frac{((3.00 \text{ kg})(9.80 \text{ m/s}^2) - 21.0 \text{ N})}{(1.00 \times 10^3 \text{ kg/m}^3)(9.80 \text{ m/s}^2)} = 8.57 \times 10^{-4} \text{ m}^3.$$

(b) The tension is $T = mg' - B' = (m - \rho V)g' = T_0 \dfrac{g'}{g}$, where $T_0 = 21.0$N. $g' = g + a$. For $a = 2.50$ m/s^2,

$T = (21.0 \text{ N}) \dfrac{9.80 + 2.50}{9.80} = 26.4 \text{ N}.$

(c) For $a = -2.50$ m/s^2, $T = (21.0 \text{ N}) \dfrac{9.80 - 2.50}{9.80} = 15.6 \text{ N}.$

(d) If $a = -g$, $g' = 0$ and $T = 0$.

EVALUATE: The acceleration of the water alters the buoyant force it exerts.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

12.97. **IDENTIFY:** The sum of the vertical forces on the object must be zero.

SET UP: The depth of the bottom of the styrofoam is not given; let this depth be h_0. Denote the length of the piece of foam by L and the length of the two sides by l. The volume of the object is $\frac{1}{2}l^2L$.

EXECUTE: **(a)** The tension in the cord plus the weight must be equal to the buoyant force, so $T = Vg(\rho_{\text{water}} - \rho_{\text{foam}}) = \frac{1}{2}(0.20\text{ m})^2(0.50\text{ m})(9.80\text{ m/s}^2)(1000\text{ kg/m}^3 - 180\text{ kg/m}^3) = 80.4\text{ N}$.

(b) The pressure force on the bottom of the foam is $(p_0 + \rho g h_0)L\left(\sqrt{2}l\right)$ and is directed up. The pressure on each side is not constant; the force can be found by integrating, or using the results of Problem 12.53 or Problem 12.55. Although these problems found forces on vertical surfaces, the result that the force is the product of the average pressure and the area is valid. The average pressure is $p_0 + \rho g(h_0 - (l/(2\sqrt{2})))$, and the force on one side has magnitude $(p_0 + \rho g(h_0 - l/(2\sqrt{2})))Ll$ and is directed perpendicular to the side, at an angle of $45.0°$ from the vertical. The force on the other side has the same magnitude, but has a horizontal component that is opposite that of the other side. The horizontal component of the net buoyant force is zero, and the vertical component is

$B = (p_0 + \rho g h_0)Ll\sqrt{2} - 2(\cos 45.0°)(p_0 + \rho g(h_0 - l/(2\sqrt{2})))Ll = \rho g\dfrac{Ll^2}{2}$, the weight of the water displaced.

EVALUATE: The density of the object is less than the density of water, so if the cord were cut the object would float. When the object is fully submerged, the upward buoyant force is greater than its weight and the cord must pull downward on the object to hold it beneath the surface.

12.98. **IDENTIFY:** Apply Bernoulli's equation to the fluid in the siphon.

SET UP: Example 12.8 shows that the efflux speed from a small hole a distance h below the surface of fluid in a large open tank is $\sqrt{2gh}$.

EXECUTE: **(a)** The fact that the water first moves upward before leaving the siphon does not change the efflux speed, $\sqrt{2gh}$.

(b) Water will not flow if the absolute (not gauge) pressure would be negative. The hose is open to the atmosphere at the bottom, so the pressure at the top of the siphon is $p_a - \rho g(H + h)$, where the assumption that the cross-sectional area is constant has been used to equate the speed of the liquid at the top and bottom. Setting $p = 0$ and solving for H gives $H = (p_a/\rho g) - h$.

EVALUATE: The analysis shows that $H + h < \dfrac{p_a}{\rho g}$, so there is also a limitation on $H + h$. For water and normal atmospheric pressure, $\dfrac{p_a}{\rho g} = 10.3\text{ m}$.

13

GRAVITATION

13.1. **IDENTIFY** and **SET UP:** Use the law of gravitation, Eq. (13.1), to determine F_g.

EXECUTE: $F_{\text{S on M}} = G\dfrac{m_S m_M}{r_{SM}^2}$ (S = sun, M = moon); $F_{\text{E on M}} = G\dfrac{m_E m_M}{r_{EM}^2}$ (E = earth)

$$\frac{F_{\text{S on M}}}{F_{\text{E on M}}} = \left(G\frac{m_S m_M}{r_{SM}^2}\right)\left(\frac{r_{EM}^2}{Gm_E m_M}\right) = \frac{m_S}{m_E}\left(\frac{r_{EM}}{r_{SM}}\right)^2$$

r_{EM}, the radius of the moon's orbit around the earth is given in Appendix F as 3.84×10^8 m. The moon is much closer to the earth than it is to the sun, so take the distance r_{SM} of the moon from the sun to be r_{SE}, the radius of the earth's orbit around the sun.

$$\frac{F_{\text{S on M}}}{F_{\text{E on M}}} = \left(\frac{1.99\times10^{30}\text{ kg}}{5.98\times10^{24}\text{ kg}}\right)\left(\frac{3.84\times10^{8}\text{ m}}{1.50\times10^{11}\text{ m}}\right)^2 = 2.18.$$

EVALUATE: The force exerted by the sun is larger than the force exerted by the earth. The moon's motion is a combination of orbiting the sun and orbiting the earth.

13.2. **IDENTIFY:** The gravity force between spherically symmetric spheres is $F_g = \dfrac{Gm_1m_2}{r^2}$, where r is the separation between their centers.

SET UP: $G = 6.67\times10^{-11}\text{ N}\cdot\text{m}^2/\text{kg}^2$. The moment arm for the torque due to each force is 0.150 m.

EXECUTE: **(a)** For each pair of spheres, $F_g = \dfrac{(6.67\times10^{-11}\text{ N}\cdot\text{m}^2/\text{kg}^2)(1.10\text{ kg})(25.0\text{ kg})}{(0.120\text{ m})^2} = 1.27\times10^{-7}\text{ N}.$

From Figure 13.4 in the textbook we see that the forces for each pair are in opposite directions, so $F_{net} = 0$.

(b) The net torque is $\tau_{net} = 2F_g l = 2(1.27\times10^{-7}\text{ N})(0.150\text{ m}) = 3.81\times10^{-8}\text{ N}\cdot\text{m}$.

(c) The torque is very small and the apparatus must be very sensitive. The torque could be increased by increasing the mass of the spheres or by decreasing their separation.

EVALUATE: The quartz fiber must twist through a measurable angle when a small torque is applied to it.

13.3. **IDENTIFY:** The gravitational attraction of the astronauts on each other causes them to accelerate toward each other, so Newton's second law of motion applies to their motion.

SET UP: The net force on each astronaut is the gravity force exerted by the other astronaut. Call the astronauts A and B, where $m_A = 65$ kg and $m_B = 72$ kg. $F_{grav} = Gm_1m_2/r^2$ and $\Sigma F = ma$.

EXECUTE: **(a)** The free-body diagram for astronaut A is given in Figure 13.3a and for astronaut B in Figure 13.3b.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

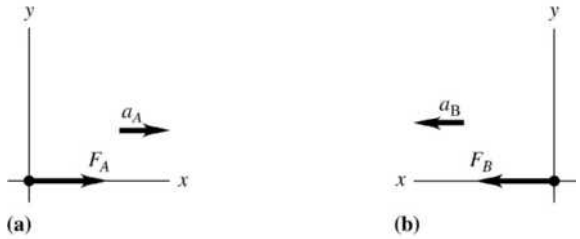

Figure 13.3

$\Sigma F_x = ma_x$ for A gives $F_A = m_A a_A$ and $a_A = \dfrac{F_A}{m_A}$. And for B, $a_B = \dfrac{F_B}{m_B}$.

$$F_A = F_B = G\frac{m_A m_B}{r^2} = (6.673\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)\frac{(65\ \text{kg})(72\ \text{kg})}{(20.0\ \text{m})^2} = 7.807\times10^{-10}\ \text{N}$$ so

$$a_A = \frac{7.807\times10^{-10}\ \text{N}}{65\ \text{kg}} = 1.2\times10^{-11}\ \text{m/s}^2 \text{ and } a_B = \frac{7.807\times10^{-10}\ \text{N}}{72\ \text{kg}} = 1.1\times10^{-11}\ \text{m/s}^2.$$

(b) Using constant-acceleration kinematics, we have $x = x_0 + v_{0x}t + \frac{1}{2}a_x t^2$, which gives $x_A = \frac{1}{2}a_A t^2$ and $x_B = \frac{1}{2}a_B t^2$. $x_A + x_B = 20.0$ m, so $20.0\ \text{m} = \frac{1}{2}(a_A + a_B)t^2$ and

$$t = \sqrt{\frac{2(20.0\ \text{m})}{1.2\times10^{-11}\ \text{m/s}^2 + 1.1\times10^{-11}\ \text{m/s}^2}} = 1.32\times10^6\ \text{s} = 15\ \text{days}.$$

(c) Their accelerations would increase as they moved closer and the gravitational attraction between them increased.

EVALUATE: Even though the gravitational attraction of the astronauts is much weaker than ordinary forces on earth, if it were the only force acting on the astronauts, it would produce noticeable effects.

13.4. **IDENTIFY:** Apply Eq. (13.2), generalized to any pair of spherically symmetric objects.

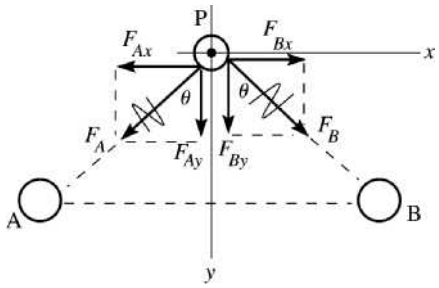
SET UP: The separation of the centers of the spheres is $2R$.

EXECUTE: The magnitude of the gravitational attraction is $GM^2/(2R)^2 = GM^2/4R^2$.

EVALUATE: Eq. (13.2) applies to any pair of spherically symmetric objects; one of the objects doesn't have to be the earth.

13.5. **IDENTIFY:** Use Eq. (13.1) to find the force exerted by each large sphere. Add these forces as vectors to get the net force and then use Newton's 2nd law to calculate the acceleration.

SET UP: The forces are shown in Figure 13.5.



$\sin\theta = 0.80$
$\cos\theta = 0.60$
Take the origin of coordinate at point P.

Figure 13.5

EXECUTE: $F_A = G\dfrac{m_A m}{r^2} = G\dfrac{(0.26\ \text{kg})(0.010\ \text{kg})}{(0.100\ \text{m})^2} = 1.735\times10^{-11}\ \text{N}$

$$F_B = G\frac{m_B m}{r^2} = 1.735\times10^{-11}\ \text{N}$$

$$F_{Ax} = -F_A\sin\theta = -(1.735\times10^{-11}\ \text{N})(0.80) = -1.39\times10^{-11}\ \text{N}$$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$F_{Ay} = +F_A \cos\theta = +(1.735\times10^{-11}\ \text{N})(0.60) = +1.04\times10^{-11}\ \text{N}$

$F_{Bx} = +F_B \sin\theta = +1.39\times10^{-11}\ \text{N}$

$F_{By} = +F_B \cos\theta = +1.04\times10^{-11}\ \text{N}$

$\Sigma F_x = ma_x$ gives $F_{Ax} + F_{Bx} = ma_x$

$0 = ma_x$ so $a_x = 0$

$\Sigma F_y = ma_y$ gives $F_{Ay} + F_{By} = ma_y$

$2(1.04\times10^{-11}\ \text{N}) = (0.010\ \text{kg})a_y$

$a_y = 2.1\times10^{-9}\ \text{m/s}^2$, directed downward midway between A and B

EVALUATE: For ordinary size objects the gravitational force is very small, so the initial acceleration is very small. By symmetry there is no x-component of net force and the y-component is in the direction of the two large spheres, since they attract the small sphere.

13.6. **IDENTIFY:** The net force on A is the vector sum of the force due to B and the force due to C. In part (a), the two forces are in the same direction, but in (b) they are in opposite directions.

SET UP: Use coordinates where $+x$ is to the right. Each gravitational force is attractive, so is toward the mass exerting it. Treat the masses as uniform spheres, so the gravitational force is the same as for point masses with the same center-to-center distances. The free-body diagrams for (a) and (b) are given in Figures 13.6a and 13.6b. The gravitational force is $F_{\text{grav}} = Gm_1m_2/r^2$.

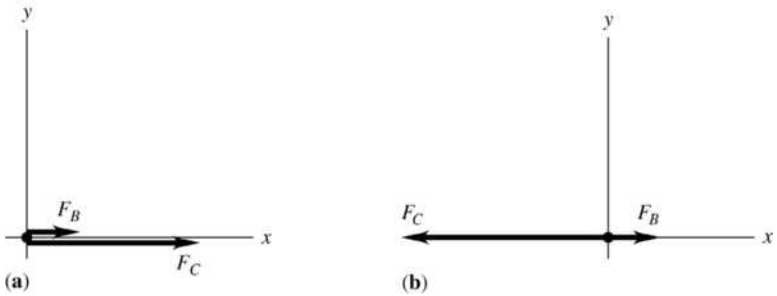


Figure 13.6

EXECUTE: **(a)** Calling F_B the force due to mass B and likewise for C, we have

$F_B = G\dfrac{m_Am_B}{r_{AB}^2} = (6.673\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)\dfrac{(2.00\ \text{kg})^2}{(0.50\ \text{m})^2} = 1.069\times10^{-9}\ \text{N}$ and

$F_C = G\dfrac{m_Am_C}{r_{AC}^2} = (6.673\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)\dfrac{(2.00\ \text{kg})^2}{(0.10\ \text{m})^2} = 2.669\times10^{-8}\ \text{N}$. The net force is

$F_{\text{net},x} = F_{Bx} + F_{Cx} = 1.069\times10^{-9}\ \text{N} + 2.669\times10^{-8}\ \text{N} = 2.8\times10^{-8}\ \text{N}$ to the right.

(b) Following the same procedure as in (a), we have

$F_B = G\dfrac{m_Am_B}{r_{AB}^2} = (6.673\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)\dfrac{(2.00\ \text{kg})^2}{(0.40\ \text{m})^2} = 1.668\times10^{-9}\ \text{N}$

$F_C = G\dfrac{m_Am_C}{r_{AC}^2} = (6.673\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)\dfrac{(2.00\ \text{kg})^2}{(0.10\ \text{m})^2} = 2.669\times10^{-8}\ \text{N}$

$F_{\text{net},x} = F_{Bx} + F_{Cx} = 1.668\times10^{-9}\ \text{N} - 2.669\times10^{-8}\ \text{N} = -2.5\times10^{-8}\ \text{N}$

The net force on A is $2.5\times10^{-8}\ \text{N}$, to the left.

EVALUATE: As with any force, the gravitational force is a vector and must be treated like all other vectors. The formula $F_{\text{grav}} = Gm_1m_2/r^2$ only gives the magnitude of this force.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

13.7. **IDENTIFY:** The force exerted by the moon is the gravitational force, $F_g = \dfrac{Gm_M m}{r^2}$. The force exerted on the person by the earth is $w = mg$.

SET UP: The mass of the moon is $m_M = 7.35\times10^{22}$ kg. $G = 6.67\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2$.

EXECUTE: **(a)** $F_{moon} = F_g = (6.67\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)\dfrac{(7.35\times10^{22}\ \text{kg})(70\ \text{kg})}{(3.78\times10^{8}\ \text{m})^2} = 2.4\times10^{-3}$ N.

(b) $F_{earth} = w = (70\ \text{kg})(9.80\ \text{m/s}^2) = 690$ N. $F_{moon}/F_{earth} = 3.5\times10^{-6}$.

EVALUATE: The force exerted by the earth is much greater than the force exerted by the moon. The mass of the moon is less than the mass of the earth and the center of the earth is much closer to the person than is the center of the moon.

13.8. **IDENTIFY:** Use Eq. (13.2) to find the force each point mass exerts on the particle, find the net force, and use Newton's second law to calculate the acceleration.

SET UP: Each force is attractive. The particle (mass m) is a distance $r_1 = 0.200$ m from $m_1 = 8.00$ kg and therefore a distance $r_2 = 0.300$ m from $m_2 = 15.0$ kg. Let $+x$ be toward the 15.0 kg mass.

EXECUTE: $F_1 = \dfrac{Gm_1 m}{r_1^2} = (6.67\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)\dfrac{(8.00\ \text{kg})m}{(0.200\ \text{m})^2} = (1.334\times10^{-8}\ \text{N/kg})m$, in the $-x$-direction. $F_2 = \dfrac{Gm_2 m}{r_2^2} = (6.67\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)\dfrac{(15.0\ \text{kg})m}{(0.300\ \text{m})^2} = (1.112\times10^{-8}\ \text{N/kg})m$, in the $+x$-direction. The net force is

$F_x = F_{1x} + F_{2x} = (-1.334\times10^{-8}\ \text{N/kg} + 1.112\times10^{-8}\ \text{N/kg})m = (-2.2\times10^{-9}\ \text{N/kg})m$.

$a_x = \dfrac{F_x}{m} = -2.2\times10^{-9}\ \text{m/s}^2$. The acceleration is $2.2\times10^{-9}\ \text{m/s}^2$, toward the 8.00 kg mass.

EVALUATE: The smaller mass exerts the greater force, because the particle is closer to the smaller mass.

13.9. **IDENTIFY:** Use Eq. (13.2) to calculate the gravitational force each particle exerts on the third mass. The equilibrium is stable when for a displacement from equilibrium the net force is directed toward the equilibrium position and it is unstable when the net force is directed away from the equilibrium position.

SET UP: For the net force to be zero, the two forces on M must be in opposite directions. This is the case only when M is on the line connecting the two particles and between them. The free-body diagram for M is given in Figure 13.9. $m_1 = 3m$ and $m_2 = m$. If M is a distance x from m_1, it is a distance $1.00\ \text{m} - x$ from m_2.

EXECUTE: **(a)** $F_x = F_{1x} + F_{2x} = -G\dfrac{3mM}{x^2} + G\dfrac{mM}{(1.00\ \text{m} - x)^2} = 0.3\ (1.00\ \text{m} - x)^2 = x^2$.

$1.00\ \text{m} - x = \pm x/\sqrt{3}$. Since M is between the two particles, x must be less than 1.00 m and $x = \dfrac{1.00\ \text{m}}{1 + 1/\sqrt{3}} = 0.634$ m. M must be placed at a point that is 0.634 m from the particle of mass $3m$ and 0.366 m from the particle of mass m.

(b) (i) If M is displaced slightly to the right in Figure 13.9, the attractive force from m is larger than the force from $3m$ and the net force is to the right. If M is displaced slightly to the left in Figure 13.9, the attractive force from $3m$ is larger than the force from m and the net force is to the left. In each case the net force is away from equilibrium and the equilibrium is unstable.

(ii) If M is displaced a very small distance along the y axis in Figure 13.9, the net force is directed opposite to the direction of the displacement and therefore the equilibrium is stable.

EVALUATE: The point where the net force on M is zero is closer to the smaller mass.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

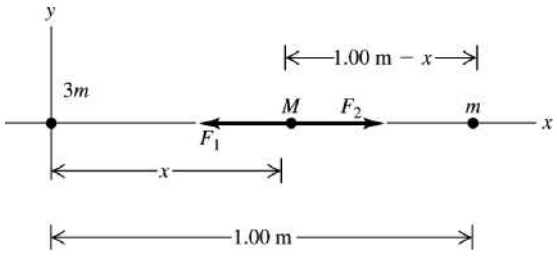

Figure 13.9

13.10. **IDENTIFY:** The force $\vec{F}_1$ exerted by m on M and the force $\vec{F}_2$ exerted by $2m$ on M are each given by Eq. (13.2) and the net force is the vector sum of these two forces.

SET UP: Each force is attractive. The forces on M in each region are sketched in Figure 13.10a. Let M be at coordinate x on the x-axis.

EXECUTE: **(a)** For the net force to be zero, $\vec{F}_1$ and $\vec{F}_2$ must be in opposite directions and this is the case only for $0 < x < L$. $\vec{F}_1 + \vec{F}_2 = 0$ then requires $F_1 = F_2$. $\dfrac{GmM}{x^2} = \dfrac{G(2m)M}{(L-x)^2}$. $2x^2 = (L-x)^2$ and $L - x = \pm\sqrt{2}x$. x must be less than L, so $x = \dfrac{L}{1+\sqrt{2}} = 0.414L$.

(b) For $x < 0$, $F_x > 0$. $F_x \to 0$ as $x \to -\infty$ and $F_x \to +\infty$ as $x \to 0$. For $x > L$, $F_x < 0$. $F_x \to 0$ as $x \to \infty$ and $F_x \to -\infty$ as $x \to L$. For $0 < x < 0.414L$, $F_x < 0$ and F_x increases from $-\infty$ to 0 as x goes from 0 to $0.414L$. For $0.414L < x < L$, $F_x > 0$ and F_x increases from 0 to $+\infty$ as x goes from $0.414L$ to L. The graph of F_x versus x is sketched in Figure 13.10b.

EVALUATE: Any real object is not exactly a point so it is not possible to have both m and M exactly at $x = 0$ or $2m$ and M both exactly at $x = L$. But the magnitude of the gravitational force between two objects approaches infinity as the objects get very close together.

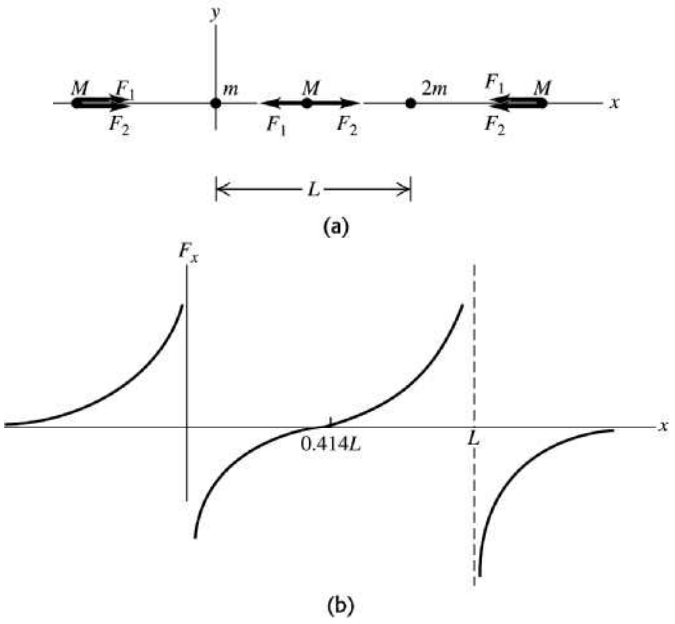

Figure 13.10

13.11. **IDENTIFY:** $F_g = G\dfrac{mm_E}{r^2}$, so $a_g = G\dfrac{m_E}{r^2}$, where r is the distance of the object from the center of the earth.

SET UP: $r = h + R_E$, where h is the distance of the object above the surface of the earth and $R_E = 6.38\times10^6$ m is the radius of the earth.

EXECUTE: To decrease the acceleration due to gravity by one-tenth, the distance from the center of the earth must be increased by a factor of $\sqrt{10}$, and so the distance above the surface of the earth is $(\sqrt{10}-1)R_E = 1.38\times10^7$ m.

EVALUATE: This height is about twice the radius of the earth.

13.12. **IDENTIFY:** Apply Eq. (13.4) to the earth and to Venus. $w = mg$.

SET UP: $g = \dfrac{Gm_E}{R_E^2} = 9.80$ m/s^2. $m_V = 0.815m_E$ and $R_V = 0.949R_E$. $w_E = mg_E = 75.0$ N.

EXECUTE: **(a)** $g_V = \dfrac{Gm_V}{R_V^2} = \dfrac{G(0.815m_E)}{(0.949R_E)^2} = 0.905\dfrac{Gm_E}{R_E^2} = 0.905g_E$.

(b) $w_V = mg_V = 0.905mg_E = (0.905)(75.0\text{ N}) = 67.9$ N.

EVALUATE: The mass of the rock is independent of its location but its weight equals the gravitational force on it and that depends on its location.

13.13. **(a) IDENTIFY** and **SET UP:** Apply Eq. (13.4) to the earth and to Titania. The acceleration due to gravity at the surface of Titania is given by $g_T = Gm_T/R_T^2$, where m_T is its mass and R_T is its radius.

For the earth, $g_E = Gm_E/R_E^2$.

EXECUTE: For Titania, $m_T = m_E/1700$ and $R_T = R_E/8$, so

$$g_T = \frac{Gm_T}{R_T^2} = \frac{G(m_E/1700)}{(R_E/8)^2} = \left(\frac{64}{1700}\right)\frac{Gm_E}{R_E^2} = 0.0377g_E.$$

Since $g_E = 9.80$ m/s^2, $g_T = (0.0377)(9.80\text{ m/s}^2) = 0.37$ m/s^2.

EVALUATE: g on Titania is much smaller than on earth. The smaller mass reduces g and is a greater effect than the smaller radius, which increases g.

(b) IDENTIFY and **SET UP:** Use density = mass/volume. Assume Titania is a sphere.

EXECUTE: From Section 13.2 we know that the average density of the earth is 5500 kg/m^3. For Titania

$$\rho_T = \frac{m_T}{\frac{4}{3}\pi R_T^3} = \frac{m_E/1700}{\frac{4}{3}\pi(R_E/8)^3} = \frac{512}{1700}\rho_E = \frac{512}{1700}(5500\text{ kg/m}^3) = 1700\text{ kg/m}^3.$$

EVALUATE: The average density of Titania is about a factor of 3 smaller than for earth. We can write Eq. (13.4) for Titania as $g_T = \frac{4}{3}\pi GR_T\rho_T$. $g_T < g_E$ both because $\rho_T < \rho_E$ and $R_T < R_E$.

13.14. **IDENTIFY:** Apply Eq. (13.4) to Rhea.

SET UP: $\rho = m/V$. The volume of a sphere is $V = \frac{4}{3}\pi R^3$.

EXECUTE: $M = \dfrac{gR^2}{G} = 2.44\times10^{21}$ kg and $\rho = \dfrac{M}{(4\pi/3)R^3} = 1.30\times10^3$ kg/m^3.

EVALUATE: The average density of Rhea is about one-fourth that of the earth.

13.15. **IDENTIFY:** Apply Eq. (13.2) to the astronaut.

SET UP: $m_E = 5.97\times10^{24}$ kg and $R_E = 6.38\times10^6$ m.

EXECUTE: $F_g = G\dfrac{mm_E}{r^2}$. $r = 600\times10^3\text{ m} + R_E$ so $F_g = 610$ N. At the surface of the earth, $w = mg = 735$ N. The gravity force is not zero in orbit. The satellite and the astronaut have the same acceleration so the astronaut's apparent weight is zero.

EVALUATE: In Eq. (13.2), r is the distance of the object from the center of the earth.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

13.16. **IDENTIFY:** The gravity of Io limits the height to which volcanic material will rise. The acceleration due to gravity at the surface of Io depends on its mass and radius.

SET UP: The radius of Io is $R = 1.815\times10^6$ m. Use coordinates where $+y$ is upward. At the maximum height, $v_{0y} = 0$, $a_y = -g_{\text{Io}}$, which is assumed to be constant. Therefore the constant-acceleration kinematics formulas apply. The acceleration due to gravity at Io's surface is given by $g_{\text{Io}} = Gm/R^2$.

SOLVE: At the surface of Io, $g_{\text{Io}} = \dfrac{Gm}{R^2} = \dfrac{(6.673\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)(8.94\times10^{22}\ \text{kg})}{(1.815\times10^6\ \text{m})^2} = 1.81\ \text{m/s}^2$. For constant acceleration (assumed), the equation $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ applies, so $v_{0y} = \sqrt{-2a_y(y - y_0)} = \sqrt{-2(-1.81\ \text{m/s}^2)(5.00\times10^5\ \text{m})} = 1.345\times10^3$ m/s. Now solve for $y - y_0$ when $v_{0y} = 1.345\times10^3$ m/s and $a_y = -9.80\ \text{m/s}^2$. The equation $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ gives

$$y - y_0 = \frac{v_y^2 - v_{0y}^2}{2a_y} = \frac{-(1.345\times10^3\ \text{m/s})^2}{2(-9.80\ \text{m/s}^2)} = 92\ \text{km}.$$

EVALUATE: Even though the mass of Io is around 100 times smaller than that of the earth, the acceleration due to gravity at its surface is only about 1/6 of that of the earth because Io's radius is much smaller than earth's radius.

13.17. **IDENTIFY:** The escape speed, from the results of Example 13.5, is $\sqrt{2GM/R}$.

SET UP: For Mars, $M = 6.42\times10^{23}$ kg and $R = 3.40\times10^6$ m. For Jupiter, $M = 1.90\times10^{27}$ kg and $R = 6.91\times10^7$ m.

EXECUTE: **(a)** $v = \sqrt{2(6.673\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)(6.42\times10^{23}\ \text{kg})/(3.40\times10^6\ \text{m})} = 5.02\times10^3$ m/s.

(b) $v = \sqrt{2(6.673\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2(1.90\times10^{27}\ \text{kg})/(6.91\times10^7\ \text{m})} = 6.06\times10^4$ m/s.

(c) Both the kinetic energy and the gravitational potential energy are proportional to the mass of the spacecraft.

EVALUATE: Example 13.5 calculates the escape speed for earth to be 1.12×10^4 m/s. This is larger than our result for Mars and less than our result for Jupiter.

13.18. **IDENTIFY:** The kinetic energy is $K = \frac{1}{2}mv^2$ and the potential energy is $U = -\dfrac{GMm}{r}$.

SET UP: The mass of the earth is $M_{\text{E}} = 5.97\times10^{24}$ kg.

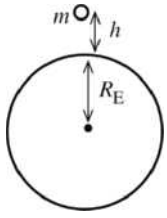
EXECUTE: **(a)** $K = \frac{1}{2}(629\ \text{kg})(3.33\times10^3\ \text{m/s})^2 = 3.49\times10^9$ J

(b) $U = -\dfrac{GM_{\text{E}}m}{r} = -\dfrac{(6.673\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)(5.97\times10^{24}\ \text{kg})(629\ \text{kg})}{2.87\times10^9\ \text{m}} = -8.73\times10^7$ J.

EVALUATE: The total energy $K + U$ is positive.

13.19. **IDENTIFY:** Apply Newton's second law to the motion of the satellite and obtain an equation that relates the orbital speed v to the orbital radius r.

SET UP: The distances are shown in Figure 13.19a.



The radius of the orbit is $r = h + R_{\text{E}}$.

$r = 7.80\times10^5\ \text{m} + 6.38\times10^6\ \text{m} = 7.16\times10^6$ m.

Figure 13.19a

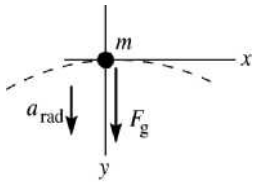
The free-body diagram for the satellite is given in Figure 13.19b.



(a) EXECUTE: $\Sigma F_y = ma_y$

$F_{\text{g}} = ma_{\text{rad}}$

$$G\frac{mm_E}{r^2} = m\frac{v^2}{r}$$

Figure 13.19b

$$v = \sqrt{\frac{Gm_{\text{E}}}{r}} = \sqrt{\frac{(6.673\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)(5.97\times10^{24}\ \text{kg})}{7.16\times10^{6}\ \text{m}}} = 7.46\times10^{3}\ \text{m/s}$$

(b) $T = \dfrac{2\pi r}{v} = \dfrac{2\pi(7.16\times10^{6}\ \text{m})}{7.46\times10^{3}\ \text{m/s}} = 6030\ \text{s} = 1.68\ \text{h}.$

EVALUATE: Note that $r = h + R_{\text{E}}$ is the radius of the orbit, measured from the center of the earth. For this satellite r is greater than for the satellite in Example 13.6, so its orbital speed is less.

13.20. **IDENTIFY:** The time to complete one orbit is the period T, given by Eq. (13.12). The speed v of the satellite is given by $v = \dfrac{2\pi r}{T}$.

SET UP: If h is the height of the orbit above the earth's surface, the radius of the orbit is $r = h + R_{\text{E}}$.

$R_{\text{E}} = 6.38\times10^{6}$ m and $m_{\text{E}} = 5.97\times10^{24}$ kg.

EXECUTE: **(a)** $T = \dfrac{2\pi r^{3/2}}{\sqrt{Gm_{\text{E}}}} = \dfrac{2\pi(7.05\times10^{5}\ \text{m} + 6.38\times10^{6}\ \text{m})^{3/2}}{\sqrt{(6.67\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)(5.97\times10^{24}\ \text{kg})}} = 5.94\times10^{3}\ \text{s} = 99.0\ \text{min}$

(b) $v = \dfrac{2\pi(7.05\times10^{5}\ \text{m} + 6.38\times10^{6}\ \text{m})}{5.94\times10^{3}\ \text{s}} = 7.49\times10^{3}\ \text{m/s} = 7.49\ \text{km/s}$

EVALUATE: The satellite in Example 13.6 is at a lower altitude and therefore has a smaller orbit radius than the satellite in this problem. Therefore, the satellite in this problem has a larger period and a smaller orbital speed. But a large percentage change in h corresponds to a small percentage change in r and the values of T and v for the two satellites do not differ very much.

13.21. **IDENTIFY:** We know orbital data (speed and orbital radius) for one satellite and want to use it to find the orbital speed of another satellite having a known orbital radius. Newton's second law and the law of universal gravitation apply to both satellites.

SET UP: For circular motion, $F_{\text{net}} = ma = mv^2/r$, which in this case is $G\dfrac{mm_{\text{p}}}{r^2} = m\dfrac{v^2}{r}$.

EXECUTE: Using $G\dfrac{mm_{\text{p}}}{r^2} = m\dfrac{v^2}{r}$, we get $Gm_{\text{p}} = rv^2 = \text{constant}$. $r_1v_1^2 = r_2v_2^2$.

$$v_2 = v_1\sqrt{\frac{r_1}{r_2}} = (4800\ \text{m/s})\sqrt{\frac{5.00\times10^{7}\ \text{m}}{3.00\times10^{7}\ \text{m}}} = 6200\ \text{m/s}.$$

EVALUATE: The more distant satellite moves slower than the closer satellite, which is reasonable since the planet's gravity decreases with distance. The masses of the satellites do not affect their orbits.

13.22. **IDENTIFY:** We can calculate the orbital period T from the number of revolutions per day. Then the period and the orbit radius are related by Eq. (13.12).

SET UP: $m_{\text{E}} = 5.97\times10^{24}$ kg and $R_{\text{E}} = 6.38\times10^{6}$ m. The height h of the orbit above the surface of the earth is related to the orbit radius r by $r = h + R_{\text{E}}$. $1\ \text{day} = 8.64\times10^{4}$ s.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: The satellite moves 15.65 revolutions in 8.64×10^4 s, so the time for 1.00 revolution is $T=\dfrac{8.64\times10^4\text{ s}}{15.65}=5.52\times10^3\text{ s}$. $T=\dfrac{2\pi r^{3/2}}{\sqrt{Gm_E}}$ gives

$$r=\left(\frac{Gm_ET^2}{4\pi^2}\right)^{1/3}=\left(\frac{[6.67\times10^{-11}\text{ N}\cdot\text{m}^2/\text{kg}^2][5.97\times10^{24}\text{ kg}][5.52\times10^3\text{ s}]^2}{4\pi^2}\right)^{1/3}.$$

$r=6.75\times10^6$ m and $h=r-R_E=3.7\times10^5\text{ m}=370\text{ km}$.

EVALUATE: The period of this satellite is slightly larger than the period for the satellite in Example 13.6 and the altitude of this satellite is therefore somewhat greater.

13.23. **IDENTIFY:** Apply $\Sigma\vec{F}=m\vec{a}$ to the motion of the baseball. $v=\dfrac{2\pi r}{T}$.

SET UP: $r_D=6\times10^3$ m.

EXECUTE: **(a)** $F_g=ma_{rad}$ gives $G\dfrac{m_Dm}{r_D^2}=m\dfrac{v^2}{r_D}$.

$$v=\sqrt{\frac{Gm_D}{r_D}}=\sqrt{\frac{(6.673\times10^{-11}\text{ N}\cdot\text{m}^2/\text{kg}^2)(2.0\times10^{15}\text{ kg})}{6\times10^3\text{ m}}}=4.7\text{ m/s}$$

4.7 m/s = 11 mph, which is easy to achieve.

(b) $T=\dfrac{2\pi r}{v}=\dfrac{2\pi(6\times10^3\text{ m})}{4.7\text{ m/s}}=8020\text{ s}=134\text{ min}=2.23\text{ h}$. The game would last a long time.

EVALUATE: The speed v is relative to the center of Deimos. The baseball would already have some speed before we throw it, because of the rotational motion of Deimos.

13.24. **IDENTIFY:** $T=\dfrac{2\pi r}{v}$ and $F_g=ma_{rad}$.

SET UP: The sun has mass $m_S=1.99\times10^{30}$ kg. The radius of Mercury's orbit is 5.79×10^{10} m, so the radius of Vulcan's orbit is 3.86×10^{10} m.

EXECUTE: $F_g=ma_{rad}$ gives $G\dfrac{m_Sm}{r^2}=m\dfrac{v^2}{r}$ and $v^2=\dfrac{Gm_S}{r}$.

$$T=2\pi r\sqrt{\frac{r}{Gm_S}}=\frac{2\pi r^{3/2}}{\sqrt{Gm_S}}=\frac{2\pi(3.86\times10^{10}\text{ m})^{3/2}}{\sqrt{(6.673\times10^{-11}\text{ N}\cdot\text{m}^2/\text{kg}^2)(1.99\times10^{30}\text{ kg})}}=4.13\times10^6\text{ s}=47.8\text{ days}$$

EVALUATE: The orbital period of Mercury is 88.0 d, so we could calculate T for Vulcan as $T=(88.0\text{ d})(2/3)^{3/2}=47.9$ days.

13.25. **IDENTIFY:** The orbital speed is given by $v=\sqrt{Gm/r}$, where m is the mass of the star. The orbital period is given by $T=\dfrac{2\pi r}{v}$.

SET UP: The sun has mass $m_S=1.99\times10^{30}$ kg. The orbit radius of the earth is 1.50×10^{11} m.

EXECUTE: **(a)** $v=\sqrt{Gm/r}$.

$$v=\sqrt{(6.673\times10^{-11}\text{ N}\cdot\text{m}^2/\text{kg}^2)(0.85\times1.99\times10^{30}\text{ kg})/((1.50\times10^{11}\text{ m})(0.11))}=8.27\times10^4\text{ m/s}.$$

(b) $2\pi r/v=1.25\times10^6\text{ s}=14.5$ days (about two weeks).

EVALUATE: The orbital period is less than the 88-day orbital period of Mercury; this planet is orbiting very close to its star, compared to the orbital radius of Mercury.

13.26. **IDENTIFY:** The period of each satellite is given by Eq. (13.12). Set up a ratio involving T and r.

SET UP: $T=\dfrac{2\pi r^{3/2}}{\sqrt{Gm_p}}$ gives $\dfrac{T}{r^{3/2}}=\dfrac{2\pi}{\sqrt{Gm_p}}=\text{constant}$, so $\dfrac{T_1}{r_1^{3/2}}=\dfrac{T_2}{r_2^{3/2}}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: $T_2 = T_1\left(\frac{r_2}{r_1}\right)^{3/2} = (6.39 \text{ days})\left(\frac{48{,}000 \text{ km}}{19{,}600 \text{ km}}\right)^{3/2} = 24.5 \text{ days}$. For the other satellite,

$T_2 = (6.39 \text{ days})\left(\frac{64{,}000 \text{ km}}{19{,}600 \text{ km}}\right)^{3/2} = 37.7 \text{ days}$.

EVALUATE: T increases when r increases.

13.27. **IDENTIFY:** In part (b) apply the results from part (a).

SET UP: For Pluto, $e = 0.248$ and $a = 5.92\times10^{12}$ m. For Neptune, $e = 0.010$ and $a = 4.50\times10^{12}$ m. The orbital period for Pluto is $T = 247.9$ y.

EXECUTE: **(a)** The result follows directly from Figure 13.18 in the textbook.

(b) The closest distance for Pluto is $(1-0.248)(5.92\times10^{12} \text{ m}) = 4.45\times10^{12}$ m. The greatest distance for Neptune is $(1+0.010)(4.50\times10^{12} \text{ m}) = 4.55\times10^{12}$ m.

(c) The time is the orbital period of Pluto, $T = 248$ y.

EVALUATE: Pluto's closest distance calculated in part (a) is $0.10\times10^{12} \text{ m} = 1.0\times10^{8}$ km, so Pluto is about 100 million km closer to the sun than Neptune, as is stated in the problem. The eccentricity of Neptune's orbit is small, so its distance from the sun is approximately constant.

13.28. **IDENTIFY:** $T = \frac{2\pi r^{3/2}}{\sqrt{Gm_{\text{star}}}}$, where m_{star} is the mass of the star. $v = \frac{2\pi r}{T}$.

SET UP: 3.09 days $= 2.67\times10^5$ s. The orbit radius of Mercury is 5.79×10^{10} m. The mass of our sun is 1.99×10^{30} kg.

EXECUTE: **(a)** $T = 2.67\times10^5$ s. $r = (5.79\times10^{10} \text{ m})/9 = 6.43\times10^9$ m. $T = \frac{2\pi r^{3/2}}{\sqrt{Gm_{\text{star}}}}$ gives

$m_{\text{star}} = \frac{4\pi^2 r^3}{T^2 G} = \frac{4\pi^2(6.43\times10^9 \text{ m})^3}{(2.67\times10^5 \text{ s})^2(6.67\times10^{-11} \text{ N}\cdot\text{m}^2/\text{kg}^2)} = 2.21\times10^{30} \text{ kg}$. $\frac{m_{\text{star}}}{m_{\text{sun}}} = 1.11$, so

$m_{\text{star}} = 1.11 m_{\text{sun}}$.

(b) $v = \frac{2\pi r}{T} = \frac{2\pi(6.43\times10^9 \text{ m})}{2.67\times10^5 \text{ s}} = 1.51\times10^5 \text{ m/s} = 151 \text{ km/s}$

EVALUATE: The orbital period of Mercury is 88.0 d. The period for this planet is much less primarily because the orbit radius is much less and also because the mass of the star is greater than the mass of our sun.

13.29. **IDENTIFY:** Knowing the orbital radius and orbital period of a satellite, we can calculate the mass of the object about which it is revolving.

SET UP: The radius of the orbit is $r = 10.5\times10^9$ m and its period is $T = 6.3$ days $= 5.443\times10^5$ s. The mass of the sun is $m_{\text{S}} = 1.99\times10^{30}$ kg. The orbital period is given by $T = \frac{2\pi r^{3/2}}{\sqrt{Gm_{\text{HD}}}}$.

EXECUTE: Solving $T = \frac{2\pi r^{3/2}}{\sqrt{Gm_{\text{HD}}}}$ for the mass of the star gives

$m_{\text{HD}} = \frac{4\pi^2 r^3}{T^2 G} = \frac{4\pi^2(10.5\times10^9 \text{ m})^3}{(5.443\times10^5 \text{ s})^2(6.673\times10^{-11} \text{ N}\cdot\text{m}^2/\text{kg}^2)} = 2.3\times10^{30} \text{ kg}$, which is $m_{\text{HD}} = 1.2 m_{\text{S}}$.

EVALUATE: The mass of the star is only 20% greater than that of our sun, yet the orbital period of the planet is much shorter than that of the earth, so the planet must be much closer to the star than the earth is.

13.30. **IDENTIFY:** Section 13.6 states that for a point mass outside a spherical shell the gravitational force is the same as if all the mass of the shell were concentrated at its center. It also states that for a point inside a spherical shell the force is zero.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

SET UP: For $r = 5.01$ m the point mass is outside the shell and for $r = 4.99$ m and $r = 2.72$ m the point mass is inside the shell.

EXECUTE: **(a)** (i) $F_g = \dfrac{Gm_1m_2}{r^2} = (6.67\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)\dfrac{(1000.0\ \text{kg})(2.00\ \text{kg})}{(5.01\ \text{m})^2} = 5.31\times10^{-9}\ \text{N}.$

(ii) $F_g = 0$. (iii) $F_g = 0$.

(b) For $r < 5.00$ m the force is zero and for $r > 5.00$ m the force is proportional to $1/r^2$. The graph of F_g versus r is sketched in Figure 13.30.

EVALUATE: Inside the shell the gravitational potential energy is constant and the force on a point mass inside the shell is zero.

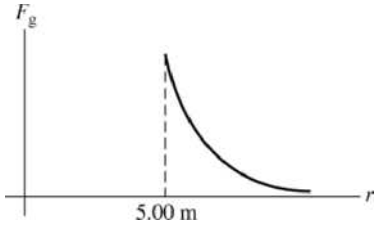


Figure 13.30

13.31. **IDENTIFY:** Section 13.6 states that for a point mass outside a uniform sphere the gravitational force is the same as if all the mass of the sphere were concentrated at its center. It also states that for a point mass a distance r from the center of a uniform sphere, where r is less than the radius of the sphere, the gravitational force on the point mass is the same as though we removed all the mass at points farther than r from the center and concentrated all the remaining mass at the center.

SET UP: The density of the sphere is $\rho = \dfrac{M}{\frac{4}{3}\pi R^3}$, where M is the mass of the sphere and R is its radius.

The mass inside a volume of radius $r < R$ is $M_r = \rho V_r = \left(\dfrac{M}{\frac{4}{3}\pi R^3}\right)\left(\frac{4}{3}\pi r^3\right) = M\left(\dfrac{r}{R}\right)^3$. $r = 5.01$ m is outside the sphere and $r = 2.50$ m is inside the sphere.

EXECUTE: **(a)** (i) $F_g = \dfrac{GMm}{r^2} = (6.67\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)\dfrac{(1000.0\ \text{kg})(2.00\ \text{kg})}{(5.01\ \text{m})^2} = 5.31\times10^{-9}\ \text{N}.$

(ii) $F_g = \dfrac{GM'm}{r^2}$. $M' = M\left(\dfrac{r}{R}\right)^3 = (1000.0\ \text{kg})\left(\dfrac{2.50\ \text{m}}{5.00\ \text{m}}\right)^3 = 125\ \text{kg}.$

$$F_g = (6.67\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)\frac{(125\ \text{kg})(2.00\ \text{kg})}{(2.50\ \text{m})^2} = 2.67\times10^{-9}\ \text{N}.$$

(b) $F_g = \dfrac{GM(r/R)^3m}{r^2} = \left(\dfrac{GMm}{R^3}\right)r$ for $r < R$ and $F_g = \dfrac{GMm}{r^2}$ for $r > R$. The graph of F_g versus r is sketched in Figure 13.31.

EVALUATE: At points outside the sphere the force on a point mass is the same as for a shell of the same mass and radius. For $r < R$ the force is different in the two cases of uniform sphere versus hollow shell.

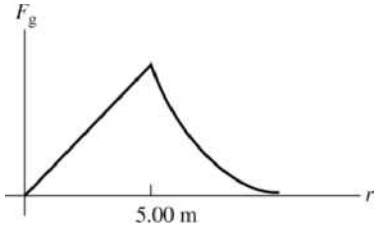

Figure 13.31

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

13.32. **IDENTIFY:** The gravitational potential energy of a pair of point masses is $U = -G\frac{m_1 m_2}{r}$. Divide the rod into infinitesimal pieces and integrate to find U.

SET UP: Divide the rod into differential masses dm at position l, measured from the right end of the rod. $dm = dl(M/L)$.

EXECUTE: **(a)** $U = -\frac{Gm\ dm}{l+x} = -\frac{GmM}{L}\frac{dl}{l+x}$.

Integrating, $U - \frac{GmM}{L}\int_0^L \frac{dl}{l+x} = -\frac{GmM}{L}\ln\left(1+\frac{L}{x}\right)$. For $x \gg L$, the natural logarithm is $\sim(L/x)$, and $U \to -GmM/x$.

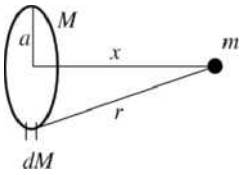
(b) The x-component of the gravitational force on the sphere is

$F_x = -\frac{\partial U}{\partial x} = \frac{GmM}{L}\frac{(-L/x^2)}{(1+(L/x))} = -\frac{GmM}{(x^2+Lx)}$, with the minus sign indicating an attractive force. As $x \gg L$, the denominator in the above expression approaches x^2, and $F_x \to -GmM/x^2$, as expected.

EVALUATE: When x is much larger than L the rod can be treated as a point mass, and our results for U and F_x do reduce to the correct expression when $x \gg L$.

13.33. **IDENTIFY:** Find the potential due to a small segment of the ring and integrate over the entire ring to find the total U.

(a) SET UP:



Divide the ring up into small segments dM, as indicated in Figure 13.33.

Figure 13.33

EXECUTE: The gravitational potential energy of dM and m is $dU = -GmdM/r$.

The total gravitational potential energy of the ring and particle is $U = \int dU = -Gm\int dM/r$.

But $r = \sqrt{x^2+a^2}$ is the same for all segments of the ring, so

$U = -\frac{Gm}{r}\int dM = -\frac{GmM}{r} = -\frac{GmM}{\sqrt{x^2+a^2}}$.

(b) EVALUATE: When $x \gg a$, $\sqrt{x^2+a^2} \to \sqrt{x^2} = x$ and $U = -GmM/x$. This is the gravitational potential energy of two point masses separated by a distance x. This is the expected result.

(c) IDENTIFY and **SET UP:** Use $F_x = -dU/dx$ with $U(x)$ from part (a) to calculate F_x.

EXECUTE: $F_x = -\frac{dU}{dx} = -\frac{d}{dx}\left(-\frac{GmM}{\sqrt{x^2+a^2}}\right)$

$F_x = +GmM\frac{d}{dx}(x^2+a^2)^{-1/2} = GmM\left(-\frac{1}{2}(2x)(x^2+a^2)^{-3/2}\right)$

$F_x = -GmMx/(x^2+a^2)^{3/2}$; the minus sign means the force is attractive.

EVALUATE: **(d)** For $x \gg a$, $(x^2+a^2)^{3/2} \to (x^2)^{3/2} = x^3$

Then $F_x = -GmMx/x^3 = -GmM/x^2$. This is the force between two point masses separated by a distance x and is the expected result.

(e) For $x = 0$, $U = -GMm/a$. Each small segment of the ring is the same distance from the center and the potential is the same as that due to a point charge of mass M located at a distance a.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

For $x = 0$, $F_x = 0$. When the particle is at the center of the ring, symmetrically placed segments of the ring exert equal and opposite forces and the total force exerted by the ring is zero.

13.34. **IDENTIFY:** At the north pole, Sneezy has no circular motion and therefore no acceleration. But at the equator he has acceleration toward the center of the earth due to the earth's rotation.

SET UP: The earth has mass $m_E = 5.97\times10^{24}$ kg, radius $R_E = 6.38\times10^6$ m and rotational period $T = 24$ hr $= 8.64\times10^4$ s. Use coordinates for which the $+y$ direction is toward the center of the earth. The free-body diagram for Sneezy at the equator is given in Figure 13.34. The radial acceleration due to Sneezy's circular motion at the equator is $a_{rad} = \dfrac{4\pi^2 R}{T^2}$, and Newton's second law applies to Sneezy.

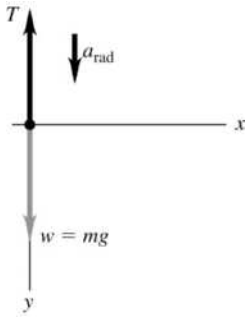


Figure 13.34

EXECUTE: At the north pole Sneezy has $a = 0$ and $T = w = 475.0$ N (the gravitational force exerted by the earth). Sneezy has mass $w/g = 48.47$ kg. At the equator Sneezy is traveling in a circular path and has radial acceleration $a_{rad} = \dfrac{4\pi^2 R}{T^2} = \dfrac{4\pi^2(6.38\times10^6 \text{ m})}{(8.64\times10^4 \text{ s})^2} = 0.0337 \text{ m/s}^2$. Newton's second law $\Sigma F_y = ma_y$ gives $w - T = ma_{rad}$. Solving for T gives

$T = w - ma_{rad} = m(g - a_{rad}) = (48.47 \text{ kg})(9.80 \text{ m/s}^2 - 0.0337 \text{ m/s}^2) = 473.4$ N.

EVALUATE: At the equator Sneezy has an inward acceleration and the outward tension is less than the true weight, since there is a net inward force.

13.35. **IDENTIFY** and **SET UP:** At the north pole, $F_g = w_0 = mg_0$, where g_0 is given by Eq. (13.4) applied to Neptune. At the equator, the apparent weight is given by Eq. (13.28). The orbital speed v is obtained from the rotational period using Eq. (13.12).

EXECUTE: **(a)** $g_0 = Gm/R^2 = (6.673\times10^{-11} \text{ N}\cdot\text{m}^2/\text{kg}^2)(1.0\times10^{26} \text{ kg})/(2.5\times10^7 \text{ m})^2 = 10.7 \text{ m/s}^2$. This agrees with the value of g given in the problem.

$F = w_0 = mg_0 = (5.0 \text{ kg})(10.7 \text{ m/s}^2) = 53$ N; this is the true weight of the object.

(b) From Eq. (13.28), $w = w_0 - mv^2/R$

$T = \dfrac{2\pi r}{v}$ gives $v = \dfrac{2\pi r}{T} = \dfrac{2\pi(2.5\times10^7 \text{ m})}{(16 \text{ h})(3600 \text{ s/1 h})} = 2.727\times10^3$ m/s

$v^2/R = (2.727\times10^3 \text{ m/s})^2/2.5\times10^7 \text{ m} = 0.297 \text{ m/s}^2$

Then $w = 53 \text{ N} - (5.0 \text{ kg})(0.297 \text{ m/s}^2) = 52$ N.

EVALUATE: The apparent weight is less than the true weight. This effect is larger on Neptune than on earth.

13.36. **IDENTIFY:** The radius of a black hole and its mass are related by $R_S = \dfrac{2GM}{c^2}$.

SET UP: $R_S = 0.50\times10^{-15}$ m, $G = 6.67\times10^{-11} \text{ N}\cdot\text{m}^2/\text{kg}^2$ and $c = 3.00\times10^8$ m/s.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: $M = \dfrac{c^2 R_S}{2G} = \dfrac{(3.00\times10^8 \text{ m/s})^2(0.50\times10^{-15} \text{ m})}{2(6.67\times10^{-11} \text{ N}\cdot\text{m}^2/\text{kg}^2)} = 3.4\times10^{11} \text{ kg}$

EVALUATE: The average density of the black hole would be

$\rho = \dfrac{M}{\frac{4}{3}\pi R_S^3} = \dfrac{3.4\times10^{11} \text{ kg}}{\frac{4}{3}\pi(0.50\times10^{-15} \text{ m})^3} = 6.49\times10^{56} \text{ kg/m}^3$. We can combine $\rho = \dfrac{M}{\frac{4}{3}\pi R_S^3}$ and $R_S = \dfrac{2GM}{c^2}$ to give $\rho = \dfrac{3c^6}{32\pi G^3 M^2}$. The average density of a black hole increases when its mass decreases. The average density of this mini black hole is much greater than the average density of the much more massive black hole in Example 13.11.

13.37. **IDENTIFY:** The orbital speed for an object a distance r from an object of mass M is $v = \sqrt{\dfrac{GM}{r}}$. The mass M of a black hole and its Schwarzschild radius R_S are related by Eq. (13.30).

SET UP: $c = 3.00\times10^8$ m/s. 1 ly $= 9.461\times10^{15}$ m.

EXECUTE: **(a)**

$M = \dfrac{rv^2}{G} = \dfrac{(7.5 \text{ ly})(9.461\times10^{15} \text{ m/ly})(200\times10^3 \text{ m/s})^2}{(6.673\times10^{-11} \text{ N}\cdot\text{m}^2/\text{kg}^2)} = 4.3\times10^{37} \text{ kg} = 2.1\times10^7 \text{ M}_S.$

(b) No, the object has a mass very much greater than 50 solar masses.

(c) $R_S = \dfrac{2GM}{c^2} = \dfrac{2v^2 r}{c^2} = 6.32\times10^{10}$ m, which does fit.

EVALUATE: The Schwarzschild radius of a black hole is approximately the same as the radius of Mercury's orbit around the sun.

13.38. **IDENTIFY:** Apply Eq. (13.1) to calculate the gravitational force. For a black hole, the mass M and Schwarzschild radius R_S are related by Eq. (13.30).

SET UP: The speed of light is $c = 3.00\times10^8$ m/s.

EXECUTE: **(a)** $\dfrac{GMm}{r^2} = \dfrac{(R_S c^2/2)m}{r^2} = \dfrac{mc^2 R_S}{2r^2}$.

(b) $\dfrac{(5.00 \text{ kg})(3.00\times10^8 \text{ m/s})^2(1.4\times10^{-2} \text{ m})}{2(3.00\times10^6 \text{ m})^2} = 350 \text{ N}.$

(c) Solving Eq. (13.30) for M, $M = \dfrac{R_S c^2}{2G} = \dfrac{(14.00\times10^{-3} \text{ m})\,(3.00\times10^8 \text{ m/s})^2}{2(6.673\times10^{-11} \text{ N}\cdot\text{m}^2/\text{kg}^2)} = 9.44\times10^{24} \text{ kg}.$

EVALUATE: The mass of the black hole is about twice the mass of the earth.

13.39. **IDENTIFY:** The clumps orbit the black hole. Their speed, orbit radius and orbital period are related by $v = \dfrac{2\pi r}{T}$. Their orbit radius and period are related to the mass M of the black hole by $T = \dfrac{2\pi r^{3/2}}{\sqrt{GM}}$. The radius of the black hole's event horizon is related to the mass of the black hole by $R_S = \dfrac{2GM}{c^2}$.

SET UP: $v = 3.00\times10^7$ m/s. $T = 27 \text{ h} = 9.72\times10^4$ s. $c = 3.00\times10^8$ m/s.

EXECUTE: **(a)** $r = \dfrac{vT}{2\pi} = \dfrac{(3.00\times10^7 \text{ m/s})(9.72\times10^4 \text{ s})}{2\pi} = 4.64\times10^{11} \text{ m}.$

(b) $T = \dfrac{2\pi r^{3/2}}{\sqrt{GM}}$ gives $M = \dfrac{4\pi^2 r^3}{GT^2} = \dfrac{4\pi^2(4.64\times10^{11} \text{ m})^3}{(6.67\times10^{-11} \text{ N}\cdot\text{m}^2/\text{kg}^2)(9.72\times10^4 \text{ s})^2} = 6.26\times10^{36} \text{ kg}.$

$= 3.15\times10^6 M_S$, where M_S is the mass of our sun

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(c) $R_S = \dfrac{2GM}{c^2} = \dfrac{2(6.67\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)(6.26\times10^{36}\ \text{kg})}{(3.00\times10^8\ \text{m/s})^2} = 9.28\times10^9\ \text{m}$

EVALUATE: The black hole has a mass that is about 3×10^6 solar masses.

13.40. **IDENTIFY:** Apply Eq. (13.1) to calculate the magnitude of each gravitational force. Each force is attractive.

SET UP: The forces on one of the masses are sketched in Figure 13.40. The figure shows that the vector sum of the three forces is toward the center of the square.

EXECUTE: $F_{\text{onA}} = 2F_B\cos 45° + F_D = 2\dfrac{Gm_Am_B\cos 45°}{r_{AB}^2} + \dfrac{Gm_Am_D}{r_{AD}^2}$.

$$F_{\text{onA}} = \frac{2(6.67\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)(800\ \text{kg})^2\cos45°}{(0.10\ \text{m})^2} + \frac{(6.67\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)(800\ \text{kg})^2}{2(0.10\ \text{m})^2} = 8.2\times10^{-3}\ \text{N}$$

toward the center of the square.

EVALUATE: We have assumed each mass can be treated as a uniform sphere. Each mass must have an unusually large density in order to have mass 800 kg and still fit into a square of side length 10.0 cm.

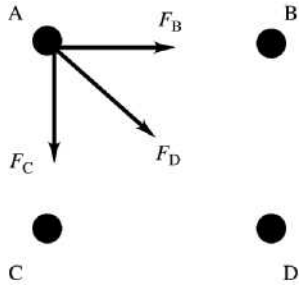

Figure 13.40

13.41. **IDENTIFY:** $g_n = G\dfrac{m_n}{R_n^2}$, where the subscript n refers to the neutron star. $w = mg$.

SET UP: $R_n = 10.0\times10^3$ m. $m_n = 1.99\times10^{30}$ kg. Your mass is $m = \dfrac{w}{g} = \dfrac{675\ \text{N}}{9.80\ \text{m/s}^2} = 68.9\ \text{kg}$.

EXECUTE: $g_n = (6.673\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)\dfrac{1.99\times10^{30}\ \text{kg}}{(10.0\times10^3\ \text{m})^2} = 1.33\times10^{12}\ \text{m/s}^2$

Your weight on the neutron star would be $w_n = mg_n = (68.9\ \text{kg})(1.33\times10^{12}\ \text{m/s}^2) = 9.16\times10^{13}$ N.

EVALUATE: Since R_n is much less than the radius of the sun, the gravitational force exerted by the neutron star on an object at its surface is immense.

13.42. **IDENTIFY:** Use Eq. (13.4) to calculate g for Europa. The acceleration of a particle moving in a circular path is $a_{\text{rad}} = r\omega^2$.

SET UP: In $a_{\text{rad}} = r\omega^2$, ω must be in rad/s. For Europa, $R = 1.569\times10^6$ m.

EXECUTE: $g = \dfrac{Gm}{R^2} = \dfrac{(6.67\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)(4.8\times10^{22}\ \text{kg})}{(1.569\times10^6\ \text{m})^2} = 1.30\ \text{m/s}^2$. $g = a_{\text{rad}}$ gives

$$\omega = \sqrt{\frac{g}{r}} = \sqrt{\frac{1.30\ \text{m/s}^2}{4.25\ \text{m}}} = (0.553\ \text{rad/s})\left(\frac{60\ \text{s}}{1\ \text{min}}\right)\left(\frac{1\ \text{rev}}{2\pi\ \text{rad}}\right) = 5.28\ \text{rpm}.$$

EVALUATE: The radius of Europa is about one-fourth that of the earth and its mass is about one-hundredth that of earth, so g on Europa is much less than g on earth. The lander would have some spatial extent so different points on it would be different distances from the rotation axis and a_{rad} would have different values. For the ω we calculated, $a_{\text{rad}} = g$ at a point that is precisely 4.25 m from the rotation axis.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

13.43. **IDENTIFY:** Use Eq. (13.1) to find each gravitational force. Each force is attractive. In part (b) apply conservation of energy.

SET UP: For a pair of masses m_1 and m_2 with separation r, $U = -G\dfrac{m_1 m_2}{r}$.

EXECUTE: **(a)** From symmetry, the net gravitational force will be in the direction $45°$ from the x-axis (bisecting the x and y axes), with magnitude

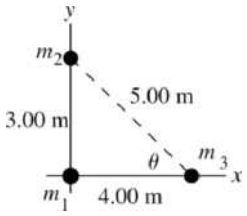
$$F = (6.673\times10^{-11}\,\text{N}\cdot\text{m}^2/\text{kg}^2)(0.0150\text{ kg})\left[\frac{(2.0\text{ kg})}{(2(0.50\text{ m})^2)} + 2\frac{(1.0\text{ kg})}{(0.50\text{ m})^2}\sin 45°\right] = 9.67\times10^{-12}\text{ N}$$

(b) The initial displacement is so large that the initial potential energy may be taken to be zero. From the work-energy theorem, $\dfrac{1}{2}mv^2 = Gm\left[\dfrac{(2.0\text{ kg})}{\sqrt{2}\ (0.50\text{ m})} + 2\dfrac{(1.0\text{ kg})}{(0.50\text{ m})}\right]$. Canceling the factor of m and solving for v, and using the numerical values gives $v = 3.02\times10^{-5}$ m/s.

EVALUATE: The result in part (b) is independent of the mass of the particle. It would take the particle a long time to reach point P.

13.44. **IDENTIFY:** Use Eq. (13.1) to calculate each gravitational force and add the forces as vectors.

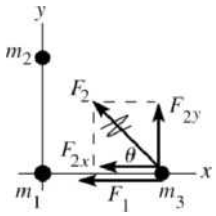
(a) SET UP: The locations of the masses are sketched in Figure 13.44a.



Section 13.6 proves that any two spherically symmetric masses interact as though they were point masses with all the mass concentrated at their centers.

Figure 13.44a

The force diagram for m_3 is given in Figure 13.44b.



$\cos\theta = 0.800$
$\sin\theta = 0.600$

Figure 13.44b

EXECUTE: $F_1 = G\dfrac{m_1 m_3}{r_{13}^2} = \dfrac{(6.673\times10^{-11}\text{ N}\cdot\text{m}^2/\text{kg}^2)(60.0\text{ kg})(0.500\text{ kg})}{(4.00\text{ m})^2} = 1.251\times10^{-10}\text{ N}$

$F_2 = G\dfrac{m_2 m_3}{r_{23}^2} = \dfrac{(6.673\times10^{-11}\text{ N}\cdot\text{m}^2/\text{kg}^2)(80.0\text{ kg})(0.500\text{ kg})}{(5.00\text{ m})^2} = 1.068\times10^{-10}\text{ N}$

$F_{1x} = -1.251\times10^{-10}\text{ N},\quad F_{1y} = 0$

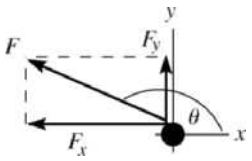
$F_{2x} = -F_2\cos\theta = -(1.068\times10^{-10}\text{ N})(0.800) = -8.544\times10^{-11}\text{ N}$

$F_{2y} = +F_2\sin\theta = +(1.068\times10^{-10}\text{ N})(0.600) = +6.408\times10^{-11}\text{ N}$

$F_x = F_{1x} + F_{2x} = -1.251\times10^{-10}\text{ N} - 8.544\times10^{-11}\text{ N} = -2.105\times10^{-10}\text{ N}$

$F_y = F_{1y} + F_{2y} = 0 + 6.408\times10^{-11}\text{ N} = +6.408\times10^{-11}\text{ N}$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.



F and its components are sketched in Figure 13.44c.

$$F = \sqrt{F_x^2 + F_y^2}$$

$$F = \sqrt{(-2.105\times10^{-10}\ \text{N})^2 + (+6.408\times10^{-11}\ \text{N})^2}$$

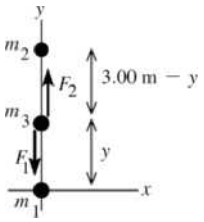
$$F = 2.20\times10^{-10}\ \text{N}$$

$$\tan\theta = \frac{F_y}{F_x} = \frac{+6.408\times10^{-11}\ \text{N}}{-2.105\times10^{-10}\ \text{N}};\quad \theta = 163°$$

Figure 13.44c

EVALUATE: Both spheres attract the third sphere and the net force is in the second quadrant.

(b) SET UP: For the net force to be zero the forces from the two spheres must be equal in magnitude and opposite in direction. For the forces on it to be opposite in direction the third sphere must be on the y-axis and between the other two spheres. The forces on the third sphere are shown in Figure 13.44d.



EXECUTE: $F_{\text{net}} = 0$ if $F_1 = F_2$

$$G\frac{m_1 m_3}{y^2} = G\frac{m_2 m_3}{(3.00\ \text{m} - y)^2}$$

$$\frac{60.0}{y^2} = \frac{80.0}{(3.00\ \text{m} - y)^2}$$

Figure 13.44d

$$\sqrt{80.0}\,y = \sqrt{60.0}(3.00\ \text{m} - y)$$

$$(\sqrt{80.0} + \sqrt{60.0})\,y = (3.00\ \text{m})\sqrt{60.0} \quad \text{and} \quad y = 1.39\ \text{m}$$

Thus the sphere would have to be placed at the point $x = 0,\ y = 1.39$ m.

EVALUATE: For the forces to have the same magnitude the third sphere must be closer to the sphere that has smaller mass.

13.45. **IDENTIFY:** The mass and radius of the moon determine the acceleration due to gravity at its surface. This in turn determines the normal force on the hip, which then determines the kinetic friction force while walking.

SET UP: $m_{\text{M}} = 7.35\times10^{22}$ kg, $R_{\text{M}} = 1.74\times10^{6}$ m. The mass supported by the hip is $(0.65)(65\ \text{kg}) + 43\ \text{kg} = 85.25\ \text{kg}$. The acceleration due to gravity on the moon is $g_{\text{M}} = \dfrac{Gm_{\text{M}}}{{R_{\text{M}}}^2}$ and $f_{\text{k}} = \mu_{\text{k}} n$.

EXECUTE: **(a)** The acceleration due to gravity on the moon is

$$g_{\text{M}} = \frac{Gm_{\text{M}}}{{R_{\text{M}}}^2} = \frac{(6.673\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)(7.35\times10^{22}\ \text{kg})}{(1.74\times10^{6}\ \text{m})^2} = 1.62\ \text{m/s}^2.$$

(b) $n = (85.25\ \text{kg})g_{\text{M}} = 138$ N and $f_{\text{k}} = \mu_{\text{k}} n = (0.0050)(138\ \text{N}) = 0.69$ N.

(c) $n = (85.25\ \text{kg})g_{\text{E}} = 835$ N and $f_{\text{k}} = \mu_{\text{k}} n = 4.2$ N.

EVALUATE: Walking on the moon should produce much less wear on the hip joints than on the earth.

13.46. **IDENTIFY:** The gravitational pulls of Titan and Saturn on the *Huygens* probe should be in opposite directions and of equal magnitudes to cancel.

SET UP: The mass of Saturn is $m_{\text{S}} = 5.68\times10^{26}$ kg. When the probe is a distance d from the center of Titan it is a distance $1.22\times10^{9}\ \text{m} - d$ from the center of Saturn. The magnitude of the gravitational force is given by $F_{\text{grav}} = GmM/r^2$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: Equal gravity forces means the two gravitational pulls on the probe must balance, so $G\frac{mm_T}{d^2} = G\frac{mm_S}{(1.22\times10^9\text{ m}-d)^2}$. Simplifying, this becomes $d = \sqrt{\frac{m_T}{m_S}}(1.22\times10^9\text{ m}-d)$. Using the masses from the text and solving for d we get $d = \sqrt{\frac{1.35\times10^{23}\text{ kg}}{5.68\times10^{26}\text{ kg}}}(1.22\times10^9\text{ m}-d) = (0.0154)(1.22\times10^9\text{ m}-d)$, so $d = 1.85\times10^7\text{ m} = 1.85\times10^4\text{ km}$.

EVALUATE: For the forces to balance, the probe must be much closer to Titan than to Saturn since Titan's mass is much smaller than that of Saturn.

13.47. **IDENTIFY:** Knowing the density and radius of Toro, we can calculate its mass and then the acceleration due to gravity at its surface. We can then use orbital mechanics to determine its orbital speed knowing the radius of its orbit.

SET UP: Density is $\rho = m/V$, and the volume of a sphere is $\frac{4}{3}\pi R^3$. Use the assumption that the density of Toro is the same as that of earth to calculate the mass of Toro. Then $g_T = G\frac{m_T}{R_T{}^2}$. Apply $\Sigma\vec{F} = m\vec{a}$ to the object to find its speed when it is in a circular orbit around Toro.

EXECUTE: **(a)** Toro and the earth are assumed to have the same densities, so $\frac{m_E}{\frac{4}{3}\pi R_E{}^3} = \frac{m_T}{\frac{4}{3}\pi R_T{}^3}$ gives

$$m_T = m_E\left(\frac{R_T}{R_E}\right)^3 = (5.97\times10^{24}\text{ kg})\left(\frac{5.0\times10^3\text{ m}}{6.38\times10^6\text{ m}}\right)^3 = 2.9\times10^{15}\text{ kg}.$$

$$g_T = G\frac{m_T}{R_T{}^2} = \frac{(6.673\times10^{-11}\text{ N}\cdot\text{m}^2/\text{kg}^2)(2.9\times10^{15}\text{ kg})}{(5.0\times10^3\text{ m})^2} = 7.7\times10^{-3}\text{ m/s}^2.$$

(b) The force of gravity on the object is mg_T. In a circular orbit just above the surface of Toro, its acceleration is $\frac{v^2}{R_T}$. Then $\Sigma\vec{F} = m\vec{a}$ gives $mg_T = m\frac{v^2}{R_T}$ and

$$v = \sqrt{g_T R_T} = \sqrt{(7.7\times10^{-3}\text{ m/s}^2)(5.0\times10^3\text{ m})} = 6.2\text{ m/s}.$$

EVALUATE: A speed of 6.2 m/s corresponds to running 100 m in 16.1 s, which is barely possible for the average person, but a well-conditioned athlete might do it.

13.48. **IDENTIFY:** The gravity force for each pair of objects is given by Eq. (13.1). The work done is $W = -\Delta U$.

SET UP: The simplest way to approach this problem is to find the force between the spacecraft and the center of mass of the earth-moon system, which is 4.67×10^6 m from the center of the earth. The distance from the spacecraft to the center of mass of the earth-moon system is 3.82×10^8 m (Figure 13.48).

$m_E = 5.97\times10^{24}$ kg, $m_M = 7.35\times10^{22}$ kg.

EXECUTE: **(a)** Using the Law of Gravitation, the force on the spacecraft is 3.4 N, an angle of $0.61°$ from the earth-spacecraft line.

(b) $U = -G\frac{m_A m_B}{r}$. $U_2 = 0$ and $r_1 = 3.84\times10^8$ m for the spacecraft and the earth, and the spacecraft and the moon.

$$W = U_2 - U_1 = +\frac{GMm}{r_1} = +\frac{(6.673\times10^{-11}\text{ N}\cdot\text{m}^2/\text{kg}^2)(5.97\times10^{24}\text{ kg}+7.35\times10^{22}\text{ kg})(1250\text{ kg})}{3.84\times10^8\text{ m}}.$$

$W = 1.31\times10^9$ J.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

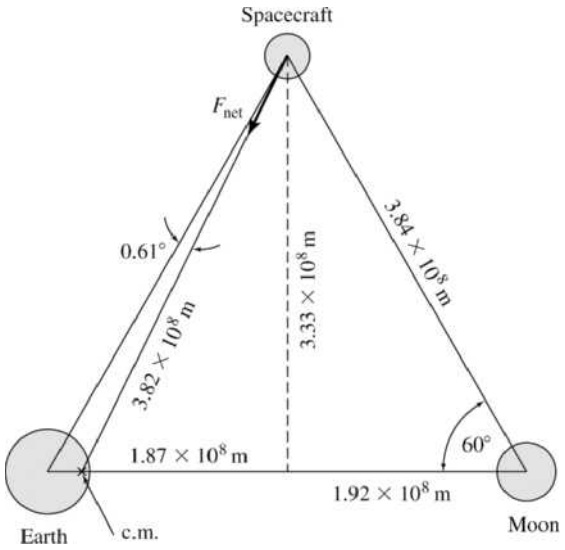


Figure 13.48

EVALUATE: The work done by the attractive gravity forces is negative. The work you do is positive.

13.49. **IDENTIFY:** Apply conservation of energy and conservation of linear momentum to the motion of the two spheres.

SET UP: Denote the 50.0-kg sphere by a subscript 1 and the 100-kg sphere by a subscript 2.

EXECUTE: **(a)** Linear momentum is conserved because we are ignoring all other forces, that is, the net external force on the system is zero. Hence, $m_1v_1 = m_2v_2$.

(b) (i) From the work-energy theorem in the form $K_i + U_i = K_f + U_f$, with the initial kinetic energy $K_i = 0$ and $U = -G\dfrac{m_1m_2}{r}$, $Gm_1m_2\left[\dfrac{1}{r_f} - \dfrac{1}{r_i}\right] = \dfrac{1}{2}(m_1v_1^2 + m_2v_2^2)$. Using the conservation of momentum relation $m_1v_1 = m_2v_2$ to eliminate v_2 in favor of v_1 and simplifying yields $v_1^2 = \dfrac{2Gm_2^2}{m_1 + m_2}\left[\dfrac{1}{r_f} - \dfrac{1}{r_i}\right]$, with a similar expression for v_2. Substitution of numerical values gives $v_1 = 1.49\times10^{-5}$ m/s, $v_2 = 7.46\times10^{-6}$ m/s.

(ii) The magnitude of the relative velocity is the sum of the speeds, 2.24×10^{-5} m/s.

(c) The distance the centers of the spheres travel (x_1 and x_2) is proportional to their acceleration, and $\dfrac{x_1}{x_2} = \dfrac{a_1}{a_2} = \dfrac{m_2}{m_1}$, or $x_1 = 2x_2$. When the spheres finally make contact, their centers will be a distance of $2r$ apart, or $x_1 + x_2 + 2r = 40$ m, or $2x_2 + x_2 + 2r = 40$ m. Thus, $x_2 = 40/3\text{ m} - 2r/3$, and $x_1 = 80/3\text{ m} - 4r/3$. The point of contact of the surfaces is $80/3\text{ m} - r/3 = 26.6$ m from the initial position of the center of the 50.0-kg sphere.

EVALUATE: The result $x_1/x_2 = 2$ can also be obtained from the conservation of momentum result that $\dfrac{v_1}{v_2} = \dfrac{m_2}{m_1}$, at every point in the motion.

13.50. **IDENTIFY:** The information about Europa allows us to evaluate g at the surface of Europa. Since there is no atmosphere, $p_0 = 0$ at the surface. The pressure at depth h is $p = \rho gh$. The inward force on the window is $F_\perp = pA$.

SET UP: $g = \dfrac{Gm}{R^2}$, where $G = 6.67\times10^{-11}\text{ N}\cdot\text{m}^2/\text{kg}^2$. $R = 1.569\times10^6$ m. Assume the ocean water has density $\rho = 1.00\times10^3\text{ kg/m}^3$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: $g = \dfrac{(6.67\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)(4.8\times10^{22}\ \text{kg})}{(1.569\times10^{6}\ \text{m})^2} = 1.30\ \text{m/s}^2$. The maximum pressure at the window is $p = \dfrac{9750\ \text{N}}{(0.250\ \text{m})^2} = 1.56\times10^{5}\ \text{Pa}$. $p = \rho g h$ so $h = \dfrac{1.56\times10^{5}\ \text{Pa}}{(1.00\times10^{3}\ \text{kg/m}^3)(1.30\ \text{m/s}^2)} = 120\ \text{m}$.

EVALUATE: 9750 N is the inward force exerted by the surrounding water. This will also be the net force on the window if the pressure inside the submarine is essentially zero.

13.51. **IDENTIFY** and **SET UP:** **(a)** To stay above the same point on the surface of the earth the orbital period of the satellite must equal the orbital period of the earth:

$T = 1\ \text{d}(24\ \text{h/1 d})(3600\ \text{s/1 h}) = 8.64\times10^{4}\ \text{s}$

Eq. (13.14) gives the relation between the orbit radius and the period:

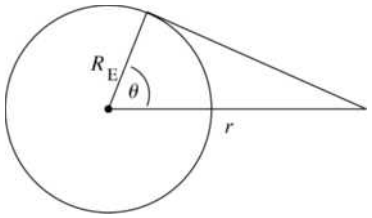
EXECUTE: $T = \dfrac{2\pi r^{3/2}}{\sqrt{Gm_{\text{E}}}}$ and $T^2 = \dfrac{4\pi^2 r^3}{Gm_{\text{E}}}$

$$r = \left(\frac{T^2 G m_{\text{E}}}{4\pi^2}\right)^{1/3} = \left(\frac{(8.64\times10^{4}\ \text{s})^2(6.673\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)(5.97\times10^{24}\ \text{kg})}{4\pi^2}\right)^{1/3} = 4.23\times10^{7}\ \text{m}$$

This is the radius of the orbit; it is related to the height h above the earth's surface and the radius R_{E} of the earth by $r = h + R_{\text{E}}$. Thus $h = r - R_{\text{E}} = 4.23\times10^{7}\ \text{m} - 6.38\times10^{6}\ \text{m} = 3.59\times10^{7}\ \text{m}$.

EVALUATE: The orbital speed of the geosynchronous satellite is $2\pi r/T = 3080$ m/s. The altitude is much larger and the speed is much less than for the satellite in Example 13.6.

(b) Consider Figure 13.51.



$$\cos\theta = \frac{R_{\text{E}}}{r} = \frac{6.38\times10^{6}\ \text{m}}{4.23\times10^{7}\ \text{m}}$$
$$\theta = 81.3^\circ$$

Figure 13.51

A line from the satellite is tangent to a point on the earth that is at an angle of 81.3° above the equator. The sketch shows that points at higher latitudes are blocked by the earth from viewing the satellite.

13.52. **IDENTIFY:** Apply Eq. (13.12) to relate the orbital period T and M_{P}, the planet's mass, and then use Eq. (13.2) applied to the planet to calculate the astronaut's weight.

SET UP: The radius of the orbit of the lander is $5.75\times10^{5}\ \text{m} + 4.80\times10^{6}\ \text{m}$.

EXECUTE: From Eq. (13.14), $T^2 = \dfrac{4\pi^2 r^3}{GM_{\text{P}}}$ and

$$M_{\text{P}} = \frac{4\pi^2 r^3}{GT^2} = \frac{4\pi^2(5.75\times10^{5}\ \text{m} + 4.80\times10^{6}\ \text{m})^3}{(6.673\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)(5.8\times10^{3}\ \text{s})^2} = 2.731\times10^{24}\ \text{kg},$$

or about half the earth's mass. Now we can find the astronaut's weight on the surface from Eq. (13.2). (The landing on the north pole removes any need to account for centripetal acceleration.)

$$w = \frac{GM_{\text{p}}m_{\text{a}}}{r_{\text{p}}^2} = \frac{(6.673\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)(2.731\times10^{24}\ \text{kg})(85.6\ \text{kg})}{(4.80\times10^{6}\ \text{m})^2} = 677\ \text{N}.$$

EVALUATE: At the surface of the earth the weight of the astronaut would be 839 N.

13.53. **IDENTIFY:** From Example 13.5, the escape speed is $v = \sqrt{\dfrac{2GM}{R}}$. Use $\rho = M/V$ to write this expression in terms of ρ.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

SET UP: For a sphere $V = \frac{4}{3}\pi R^3$.

EXECUTE: In terms of the density ρ, the ratio M/R is $(4\pi/3)\rho R^2$, and so the escape speed is $v = \sqrt{(8\pi/3)(6.673\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)(2500\ \text{kg/m}^3)(150\times10^3\ \text{m})^2} = 177$ m/s.

EVALUATE: This is much less than the escape speed for the earth, 11,200 m/s.

13.54. **IDENTIFY:** From Example 13.5, the escape speed is $v = \sqrt{\frac{2GM}{R}}$. Use $\rho = M/V$ to write this expression in terms of ρ. On earth, the height h you can jump is related to your jump speed by $v = \sqrt{2gh}$. For part (b), apply Eq. (13.4) to Europa.

SET UP: For a sphere $V = \frac{4}{3}\pi R^3$

EXECUTE: **(a)** $\rho = M/\left(\frac{4}{3}\pi R^3\right)$, so the escape speed can be written as $v = \sqrt{\frac{8\pi G\rho R^2}{3}}$. Equating the two expressions for v and squaring gives $2gh = \frac{8\pi}{3}\rho G R^2$, or $R^2 = \frac{3}{4\pi}\frac{gh}{\rho G}$, where $g = 9.80$ m/s^2 is for the surface of the earth, not the asteroid. Estimate $h = 1$ m (variable for different people, of course), $R = 3.7$ km.

(b) For Europa, $g = \frac{GM}{R^2} = \frac{4\pi\rho RG}{3}$.

$$\rho = \frac{3g}{4\pi RG} = \frac{3(1.33\ \text{m/s}^2)}{4\pi(1.57\times10^6\ \text{m})(6.673\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)} = 3.03\times10^3\ \text{kg/m}^3.$$

EVALUATE: The earth has average density 5500 kg/m^3. The average density of Europa is about half that of the earth but a little larger than the average density of most asteroids.

13.55. **IDENTIFY** and **SET UP:** The observed period allows you to calculate the angular velocity of the satellite relative to you. You know your angular velocity as you rotate with the earth, so you can find the angular velocity of the satellite in a space-fixed reference frame. $v = r\omega$ gives the orbital speed of the satellite and Newton's second law relates this to the orbit radius of the satellite.

EXECUTE: **(a)** The satellite is revolving west to east, in the same direction the earth is rotating. If the angular speed of the satellite is ω_s and the angular speed of the earth is ω_E, the angular speed ω_{rel} of the satellite relative to you is $\omega_{rel} = \omega_s - \omega_E$.

$\omega_{rel} = (1\ \text{rev})/(12\ \text{h}) = \left(\frac{1}{12}\right)$ rev/h

$\omega_E = \left(\frac{1}{24}\right)$ rev/h

$\omega_s = \omega_{rel} + \omega_E = \left(\frac{1}{8}\right)$ rev/h $= 2.18\times10^{-4}$ rad/s

$\Sigma\vec{F} = m\vec{a}$ says $G\frac{mm_E}{r^2} = m\frac{v^2}{r}$

$v^2 = \frac{Gm_E}{r}$ and with $v = r\omega$ this gives $r^3 = \frac{Gm_E}{\omega^2}$; $r = 2.03\times10^7$ m

This is the radius of the satellite's orbit. Its height h above the surface of the earth is $h = r - R_E = 1.39\times10^7$ m.

(b) Now the satellite is revolving opposite to the rotation of the earth. If west to east is positive, then

$\omega_{rel} = \left(-\frac{1}{12}\right)$ rev/h

$\omega_s = \omega_{rel} + \omega_E = \left(-\frac{1}{24}\right)$ rev/h $= -7.27\times10^{-5}$ rad/s

$r^3 = \frac{Gm_E}{\omega^2}$ gives $r = 4.22\times10^7$ m and $h = 3.59\times10^7$ m

EVALUATE: In part (a) the satellite is revolving faster than the earth's rotation and in part (b) it is revolving slower. Slower v and ω means larger orbit radius r.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

13.56. **IDENTIFY:** Apply the law of gravitation to the astronaut at the north pole to calculate the mass of planet. Then apply $\Sigma\vec{F} = m\vec{a}$ to the astronaut, with $a_{\text{rad}} = \dfrac{4\pi^2 R}{T^2}$, toward the center of the planet, to calculate the period T. Apply Eq. (13.12) to the satellite in order to calculate its orbital period.

SET UP: Get radius of X: $\frac{1}{4}(2\pi R) = 18{,}850$ km and $R = 1.20\times10^7$ m. Astronaut mass:

$$m = \frac{w}{g} = \frac{943 \text{ N}}{9.80 \text{ m/s}^2} = 96.2 \text{ kg}.$$

EXECUTE: $\dfrac{GmM_{\text{X}}}{R^2} = w$, where $w = 915.0$ N.

$$M_{\text{X}} = \frac{mg_{\text{x}}R^2}{Gm} = \frac{(915 \text{ N})(1.20\times10^7 \text{ m})^2}{(6.67\times10^{-11} \text{ N}\cdot\text{m}^2/\text{kg}^2)(96.2 \text{ kg})} = 2.05\times10^{25} \text{ kg}$$

Apply Newton's second law to astronaut on a scale at the equator of X. $F_{\text{grav}} - F_{\text{scale}} = ma_{\text{rad}}$, so

$F_{\text{grav}} - F_{\text{scale}} = \dfrac{4\pi^2 mR}{T^2}$. $915.0 \text{ N} - 850.0 \text{ N} = \dfrac{4\pi^2(96.2 \text{ kg})(1.20\times10^7 \text{ m})}{T^2}$ and

$$T = 2.65\times10^4 \text{s}\left(\frac{1 \text{ h}}{3600 \text{ s}}\right) = 7.36 \text{ h}.$$

(b) For the satellite, $T = \sqrt{\dfrac{4\pi^2 r^3}{Gm_{\text{X}}}} = \sqrt{\dfrac{4\pi^2(1.20\times10^7 \text{ m} + 2.0\times10^6 \text{ m})^3}{(6.67\times10^{-11} \text{ N}\cdot\text{m}^2/\text{kg}^2)(2.05\times10^{25} \text{ kg})}} = 8.90\times10^3 \text{ s} = 2.47$ hours.

EVALUATE: The acceleration of gravity at the surface of the planet is $g_{\text{X}} = \dfrac{915.0 \text{ N}}{96.2 \text{ kg}} = 9.51 \text{ m/s}^2$, similar to the value on earth. The radius of the planet is about twice that of earth. The planet rotates more rapidly than earth and the length of a day is about one-third what it is on earth.

13.57. **IDENTIFY:** Use $g = \dfrac{Gm_{\text{E}}}{R_{\text{E}}^2}$ and follow the procedure specified in the problem.

SET UP: $R_{\text{E}} = 6.38\times10^6$ m

EXECUTE: The fractional error is $1 - \dfrac{mgh}{Gmm_{\text{E}}(1/R_{\text{E}} - 1/(R_{\text{E}} + h))} = 1 - \dfrac{g}{Gm_{\text{E}}}(R_{\text{E}} + h)(R_{\text{E}})$.

Using Eq. (13.4) for g the fractional difference is $1 - (R_{\text{E}} + h)/R_{\text{E}} = -h/R_{\text{E}}$, so if the fractional difference is -1%, $h = (0.01)R_{\text{E}} = 6.4\times10^4$ m.

EVALUATE: For $h = 1$ km, the fractional error is only 0.016%. Eq. (7.2) is very accurate for the motion of objects near the earth's surface.

13.58. **IDENTIFY:** Use the measurements of the motion of the rock to calculate g_{M}, the value of g on Mongo. Then use this to calculate the mass of Mongo. For the ship, $F_{\text{g}} = ma_{\text{rad}}$ and $T = \dfrac{2\pi r}{v}$.

SET UP: Take $+y$ upward. When the stone returns to the ground its velocity is 12.0 m/s, downward.

$g_{\text{M}} = G\dfrac{m_{\text{M}}}{R_{\text{M}}^2}$. The radius of Mongo is $R_{\text{M}} = \dfrac{c}{2\pi} = \dfrac{2.00\times10^8 \text{ m}}{2\pi} = 3.18\times10^7$ m. The ship moves in an orbit of radius $r = 3.18\times10^7 \text{ m} + 3.00\times10^7 \text{ m} = 6.18\times10^7$ m.

EXECUTE: **(a)** $v_{0y} = +12.0$ m/s, $v_y = -12.0$ m/s, $a_y = -g_{\text{M}}$ and $t = 6.00$ s. $v_y = v_{0y} + a_y t$ gives

$-g_{\text{M}} = \dfrac{v_y - v_{0y}}{t} = \dfrac{-12.0 \text{ m/s} - 12.0 \text{ m/s}}{6.00 \text{ s}}$ and $g_{\text{M}} = 4.00 \text{ m/s}^2$.

$$m_{\text{M}} = \frac{g_{\text{M}}R_{\text{M}}^2}{G} = \frac{(4.00 \text{ m/s}^2)(3.18\times10^7 \text{ m})^2}{6.673\times10^{-11} \text{ N}\cdot\text{m}^2/\text{kg}^2} = 6.06\times10^{25} \text{ kg}$$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) $F_g = ma_{rad}$ gives $G\frac{m_M m}{r^2} = m\frac{v^2}{r}$ and $v^2 = \frac{Gm_M}{r}$.

$$T = \frac{2\pi r}{v} = 2\pi r\sqrt{\frac{r}{Gm_M}} = \frac{2\pi r^{3/2}}{\sqrt{Gm_M}} = \frac{2\pi(6.18\times10^7\ \text{m})^{3/2}}{\sqrt{(6.673\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)(6.06\times10^{25}\ \text{kg})}}$$

$T = 4.80\times10^4\ \text{s} = 13.3\ \text{h}$

EVALUATE: $R_M = 5.0R_E$ and $m_M = 10.2m_E$, so $g_M = \frac{10.2}{(5.0)^2}g_E = 0.408g_E$, which agrees with the value calculated in part (a).

13.59. **IDENTIFY:** The free-fall time of the rock will give us the acceleration due to gravity at the surface of the planet. Applying Newton's second law and the law of universal gravitation will give us the mass of the planet since we know its radius.

SET UP: For constant acceleration, $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$. At the surface of the planet, Newton's second law gives $m_{rock}g = \frac{Gm_{rock}m_p}{R_p^2}$.

EXECUTE: First find $a_y = g$. $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$. $a_y = \frac{2(y-y_0)}{t^2} = \frac{2(1.90\ \text{m})}{(0.480\ \text{s})^2} = 16.49\ \text{m/s}^2 = g$.

$g = 16.49\ \text{m/s}^2$. $m_p = \frac{gR_p^2}{G} = \frac{(16.49\ \text{m/s})(8.60\times10^7\ \text{m})^2}{6.674\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2} = 1.83\times10^{27}\ \text{kg}$.

EVALUATE: The planet's mass is over 100 times that of the earth, which is reasonable since it is larger (in size) than the earth yet has a greater acceleration due to gravity at its surface.

13.60. **IDENTIFY:** Apply Eq. (13.9) to the particle-earth and particle-moon systems.

SET UP: When the particle is a distance r from the center of the earth, it is a distance $R_{EM} - r$ from the center of the moon.

EXECUTE: **(a)** The total gravitational potential energy in this model is $U = -Gm\left[\frac{m_E}{r} + \frac{m_M}{R_{EM}-r}\right]$.

(b) The point where the net gravitational force vanishes is $r = \frac{R_{EM}}{1+\sqrt{m_M/m_E}} = 3.46\times10^8\ \text{m}$. Using this value for r in the expression in part (a) and the work-energy theorem, including the initial potential energy of $-Gm(m_E/R_E + m_M/(R_{EM} - R_E))$ gives 11.1 km/s.

(c) The final distance from the earth is the Earth-moon distance minus the radius of the moon, or $3.823\times10^8\ \text{m}$. From the work-energy theorem, the rocket impacts the moon with a speed of 2.9 km/s.

EVALUATE: The spacecraft has a greater gravitational potential energy at the surface of the moon than at the surface of the earth, so it reaches the surface of the moon with a speed that is less than its launch speed on earth.

13.61. **IDENTIFY** and **SET UP:** Use Eq. (13.2) to calculate the gravity force at each location. For the top of Mount Everest write $r = h + R_E$ and use the fact that $h \ll R_E$ to obtain an expression for the difference in the two forces.

EXECUTE: At Sacramento, the gravity force on you is $F_1 = G\frac{mm_E}{R_E^2}$.

At the top of Mount Everest, a height of $h = 8800\ \text{m}$ above sea level, the gravity force on you is

$$F_2 = G\frac{mm_E}{(R_E+h)^2} = G\frac{mm_E}{R_E^2(1+h/R_E)^2}$$

$(1+h/R_E)^{-2} \approx 1 - \frac{2h}{R_E}$, $F_2 = F_1\left(1 - \frac{2h}{R_E}\right)$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$\frac{F_1 - F_2}{F_1} = \frac{2h}{R_E} = 0.28\%$$

EVALUATE: The change in the gravitational force is very small, so for objects near the surface of the earth it is a good approximation to treat it as a constant.

13.62. **IDENTIFY:** The 0.100 kg sphere has gravitational potential energy due to the other two spheres. Its mechanical energy is conserved.

SET UP: From energy conservation, $K_1 + U_1 = K_2 + U_2$, where $K = \frac{1}{2}mv^2$, and $U = -Gm_1m_2/r$.

EXECUTE: Using $K_1 + U_1 = K_2 + U_2$, we have $K_1 = 0$, $m_A = 5.00$ kg, $m_B = 10.0$ kg and $m = 0.100$ kg.

$$U_1 = -\frac{Gmm_A}{r_{A1}} - \frac{Gmm_B}{r_{B1}} = -(6.674\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)(0.100\ \text{kg})\left(\frac{5.00\ \text{kg}}{0.400\ \text{m}} + \frac{10.0\ \text{kg}}{0.600\ \text{m}}\right)$$

$$U_1 = -1.9466\times10^{-10}\ \text{J}.$$

$$U_2 = -\frac{Gmm_A}{r_{A2}} - \frac{Gmm_B}{r_{B2}} = -(6.674\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)(0.100\ \text{kg})\left(\frac{5.00\ \text{kg}}{0.800\ \text{m}} + \frac{10.0\ \text{kg}}{0.200\ \text{m}}\right)$$

$U_2 = -3.7541\times10^{-10}$ J. $K_2 = U_1 - U_2 = -1.9466\times10^{-10}\ \text{J} - (-3.7541\times10^{-10}\ \text{J}) = 1.8075\times10^{-10}$ J.

$$\frac{1}{2}mv^2 = K_2 \text{ and } v = \sqrt{\frac{2K_2}{m}} = \sqrt{\frac{2(1.8075\times10^{-10}\ \text{J})}{0.100\ \text{kg}}} = 6.01\times10^{-5}\ \text{m/s}.$$

EVALUATE: The kinetic energy gained by the sphere is equal to the loss in its potential energy.

13.63. **IDENTIFY** and **SET UP:** First use the radius of the orbit to find the initial orbital speed, from Eq. (13.10) applied to the moon.

EXECUTE: $v = \sqrt{Gm/r}$ and $r = R_M + h = 1.74\times10^6\ \text{m} + 50.0\times10^3\ \text{m} = 1.79\times10^6\ \text{m}$

Thus $v = \sqrt{\dfrac{(6.673\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)(7.35\times10^{22}\ \text{kg})}{1.79\times10^6\ \text{m}}} = 1.655\times10^3\ \text{m/s}$

After the speed decreases by 20.0 m/s it becomes $1.655\times10^3\ \text{m/s} - 20.0\ \text{m/s} = 1.635\times10^3$ m/s.

IDENTIFY and **SET UP:** Use conservation of energy to find the speed when the spacecraft reaches the lunar surface.

$K_1 + U_1 + W_{other} = K_2 + U_2$

Gravity is the only force that does work so $W_{other} = 0$ and $K_2 = K_1 + U_1 - U_2$

EXECUTE: $U_1 = -Gm_m m/r$; $U_2 = -Gm_m m/R_m$

$\frac{1}{2}mv_2^2 = \frac{1}{2}mv_1^2 + Gmm_m(1/R_m - 1/r)$

And the mass m divides out to give $v_2 = \sqrt{v_1^2 + 2Gm_m(1/R_m - 1/r)}$

$v_2 = 1.682\times10^3$ m/s(1 km/1000 m)(3600 s/1 h) = 6060 km/h

EVALUATE: After the thruster fires the spacecraft is moving too slowly to be in a stable orbit; the gravitational force is larger than what is needed to maintain a circular orbit. The spacecraft gains energy as it is accelerated toward the surface.

13.64. **IDENTIFY:** In part (a) use the expression for the escape speed that is derived in Example 13.5. In part (b) apply conservation of energy.

SET UP: $R = 4.5\times10^3$ m. In part (b) let point 1 be at the surface of the comet.

EXECUTE: **(a)** The escape speed is $v = \sqrt{\dfrac{2GM}{R}}$ so

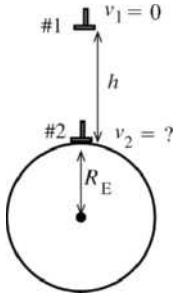
$$M = \frac{Rv^2}{2G} = \frac{(4.5\times10^3\ \text{m})(1.0\ \text{m/s})^2}{2(6.67\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)} = 3.37\times10^{13}\ \text{kg}.$$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) (i) $K_1 = \frac{1}{2}mv_1^2$. $K_2 = 0.100K_1$. $U_1 = -\frac{GMm}{R}$; $U_2 = -\frac{GMm}{r}$. $K_1 + U_1 = K_2 + U_2$ gives $\frac{1}{2}mv_1^2 - \frac{GMm}{R} = (0.100)(\frac{1}{2}mv_1^2) - \frac{GMm}{r}$. Solving for r gives $\frac{1}{r} = \frac{1}{R} - \frac{0.450v_1^2}{GM} = \frac{1}{4.5\times10^3\text{ m}} - \frac{0.450(1.0\text{ m/s})^2}{(6.67\times10^{-11}\text{ N}\cdot\text{m}^2/\text{kg}^2)(3.37\times10^{13}\text{ kg})}$ and $r = 45$ km. (ii) The debris never loses all of its initial kinetic energy, but $K_2 \to 0$ as $r \to \infty$. The farther the debris are from the comet's center, the smaller is their kinetic energy.

EVALUATE: The debris will have lost 90.0% of their initial kinetic energy when they are at a distance from the comet's center of about ten times the radius of the comet.

13.65. **IDENTIFY** and **SET UP:** Apply conservation of energy. Must use Eq. (13.9) for the gravitational potential energy since h is not small compared to R_E.



As indicated in Figure 13.65, take point 1 to be where the hammer is released and point 2 to be just above the surface of the earth, so $r_1 = R_E + h$ and $r_2 = R_E$.

Figure 13.65

EXECUTE: $K_1 + U_1 + W_{other} = K_2 + U_2$

Only gravity does work, so $W_{other} = 0$.

$K_1 = 0$, $K_2 = \frac{1}{2}mv_2^2$

$U_1 = -G\frac{mm_E}{r_1} = -\frac{Gmm_E}{h + R_E}$, $U_2 = -G\frac{mm_E}{r_2} = -\frac{Gmm_E}{R_E}$

Thus, $-G\frac{mm_E}{h + R_E} = \frac{1}{2}mv_2^2 - G\frac{mm_E}{R_E}$

$v_2^2 = 2Gm_E\left(\frac{1}{R_E} - \frac{1}{R_E + h}\right) = \frac{2Gm_E}{R_E(R_E + h)}(R_E + h - R_E) = \frac{2Gm_Eh}{R_E(R_E + h)}$

$v_2 = \sqrt{\frac{2Gm_Eh}{R_E(R_E + h)}}$

EVALUATE: If $h \to \infty$, $v_2 \to \sqrt{2Gm_E/R_E}$, which equals the escape speed. In this limit this event is the reverse of an object being projected upward from the surface with the escape speed. If $h \ll R_E$, then $v_2 = \sqrt{2Gm_Eh/R_E^2} = \sqrt{2gh}$, the same result if Eq. (7.2) used for U.

13.66. **IDENTIFY:** In orbit the total mechanical energy of the satellite is $E = -\frac{Gm_Em}{2R_E}$. $U = -G\frac{m_Em}{r}$.

$W = E_2 - E_1$.

SET UP: $U \to 0$ as $r \to \infty$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: **(a)** The energy the satellite has as it sits on the surface of the Earth is $E_1 = \dfrac{-GmM_E}{R_E}$. The energy it has when it is in orbit at a radius $R \approx R_E$ is $E_2 = \dfrac{-GmM_E}{2R_E}$. The work needed to put it in orbit is the difference between these: $W = E_2 - E_1 = \dfrac{GmM_E}{2R_E}$.

(b) The total energy of the satellite far away from the earth is zero, so the additional work needed is $0 - \left(\dfrac{-GmM_E}{2R_E}\right) = \dfrac{GmM_E}{2R_E}$.

EVALUATE: **(c)** The work needed to put the satellite into orbit was the same as the work needed to put the satellite from orbit to the edge of the universe.

13.67. **IDENTIFY:** At the escape speed, $E = K + U = 0$.

SET UP: At the surface of the earth the satellite is a distance $R_E = 6.38\times10^6$ m from the center of the earth and a distance $R_{ES} = 1.50\times10^{11}$ m from the sun. The orbital speed of the earth is $\dfrac{2\pi R_{ES}}{T}$, where $T = 3.156\times10^7$ s is the orbital period. The speed of a point on the surface of the earth at an angle ϕ from the equator is $v = \dfrac{2\pi R_E \cos\phi}{T}$, where $T = 86{,}400$ s is the rotational period of the earth.

EXECUTE: **(a)** The escape speed will be $v = \sqrt{2G\left[\dfrac{m_E}{R_E} + \dfrac{m_S}{R_{ES}}\right]} = 4.35\times10^4$ m/s. Making the simplifying assumption that the direction of launch is the direction of the earth's motion in its orbit, the speed relative to the center of the earth is $v - \dfrac{2\pi R_{ES}}{T} = 4.35\times10^4 \text{ m/s} - \dfrac{2\pi(1.50\times10^{11}\text{ m})}{(3.156\times10^7\text{ s})} = 1.37\times10^4$ m/s.

(b) The rotational speed at Cape Canaveral is $\dfrac{2\pi(6.38\times10^6\text{ m})\cos 28.5°}{86{,}400\text{ s}} = 4.09\times10^2$ m/s, so the speed relative to the surface of the earth is 1.33×10^4 m/s.

(c) In French Guiana, the rotational speed is 4.63×10^2 m/s, so the speed relative to the surface of the earth is 1.32×10^4 m/s.

EVALUATE: The orbital speed of the earth is a large fraction of the escape speed, but the rotational speed of a point on the surface of the earth is much less.

13.68. **IDENTIFY:** From the discussion of Section 13.6, the force on a point mass at a distance *r* from the center of a spherically symmetric mass distribution is the same as though we removed all the mass at points farther than *r* from the center and concentrated all the remaining mass at the center.

SET UP: The mass *M* of a hollow sphere of density ρ, inner radius R_1 and outer radius R_2 is $M = \rho\frac{4}{3}\pi(R_2^3 - R_1^3)$. From Figure 13.9 in the textbook, the inner core has outer radius 1.2×10^6 m, inner radius zero and density 1.3×10^4 kg/m^3. The outer core has inner radius 1.2×10^6 m, outer radius 3.6×10^6 m and density 1.1×10^4 kg/m^3. The total mass of the earth is $m_E = 5.97\times10^{24}$ kg and its radius is $R_E = 6.38\times10^6$ m.

EXECUTE: **(a)** $F_g = G\dfrac{m_E m}{R_E^2} = mg = (10.0\text{ kg})(9.80\text{ m/s}^2) = 98.0$ N.

(b) The mass of the inner core is $m_{inner} = \rho_{inner}\frac{4}{3}\pi(R_2^3 - R_1^3) = (1.3\times10^4\text{ kg/m}^3)\frac{4}{3}\pi(1.2\times10^6\text{ m})^3 = 9.4\times10^{22}$ kg. The mass of the outer core is $m_{outer} = (1.1\times10^4\text{ kg/m}^3)\frac{4}{3}\pi([3.6\times10^6\text{ m}]^3 - [1.2\times10^6\text{ m}]^3) = 2.1\times10^{24}$ kg. Only the inner and outer cores contribute to the force.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$F_g = (6.67\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)\frac{(9.4\times10^{22}\ \text{kg}+2.1\times10^{24}\ \text{kg})(10.0\ \text{kg})}{(3.6\times10^{6}\ \text{m})^2} = 110\ \text{N}.$$

(c) Only the inner core contributes to the force and

$$F_g = (6.67\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)\frac{(9.4\times10^{22}\ \text{kg})(10.0\ \text{kg})}{(1.2\times10^{6}\ \text{m})^2} = 44\ \text{N}.$$

(d) At $r = 0,\ F_g = 0.$

EVALUATE: In this model the earth is spherically symmetric but not uniform, so the result of Example 13.10 doesn't apply. In particular, the force at the surface of the outer core is greater than the force at the surface of the earth.

13.69. **IDENTIFY:** Eq. (13.12) relates orbital period and orbital radius for a circular orbit.

SET UP: The mass of the sun is $M = 1.99\times10^{30}$ kg.

EXECUTE: **(a)** The period of the asteroid is $T = \dfrac{2\pi a^{3/2}}{\sqrt{GM}}$. Inserting (i) 3×10^{11} m for a gives 2.84 y and (ii) 5×10^{11} m gives a period of 6.11 y.

(b) If the period is 5.93 y, then $a = 4.90\times10^{11}$m.

(c) This happens because $0.4 = 2/5,$ another ratio of integers. So once every 5 orbits of the asteroid and 2 orbits of Jupiter, the asteroid is at its perijove distance. Solving when $T = 4.74\ y,\ a = 4.22\times10^{11}$ m.

EVALUATE: The orbit radius for Jupiter is 7.78×10^{11} m and for Mars it is 2.28×10^{11} m. The asteroid belt lies between Mars and Jupiter. The mass of Jupiter is about 3000 times that of Mars, so the effect of Jupiter on the asteroids is much larger.

13.70. **IDENTIFY:** Apply the work-energy relation in the form $W = \Delta E,$ where $E = K + U.$ The speed v is related to the orbit radius by Eq. (13.10).

SET UP: $m_E = 5.97\times10^{24}$ kg

EXECUTE: **(a)** In moving to a lower orbit by whatever means, gravity does positive work, and so the speed does increase.

(b) $v = (Gm_E)^{1/2}r^{-1/2},$ so $\Delta v = (Gm_E)^{1/2}\left(-\dfrac{-\Delta r}{2}\right)r^{-3/2} = \left(\dfrac{\Delta r}{2}\right)\sqrt{\dfrac{Gm_E}{r^3}}.$ Note that a positive Δr is given as a decrease in radius. Similarly, the kinetic energy is $K = (1/2)mv^2 = (1/2)Gm_Em/r,$ and so

$\Delta K = (1/2)(Gm_Em/r^2)\Delta r$ and $\Delta U = -(Gm_Em/r^2)\Delta r.$

$W = \Delta U + \Delta K = -(Gm_Em/2r^2)\,\Delta r$

(c) $v = \sqrt{Gm_E/r} = 7.72\times10^{3}$ m/s, $\Delta v = (\Delta r/2)\sqrt{Gm_E/r^3} = 28.9$ m/s, $E = -Gm_Em/2r = -8.95\times10^{10}$ J (from Eq. (13.15)), $\Delta K = (Gm_Em/2r^2)(\Delta r) = 6.70\times10^{8}$ J, $\Delta U = -2\Delta K = -1.34\times10^{9}$ J, and $W = -\Delta K = -6.70\times10^{8}$ J.

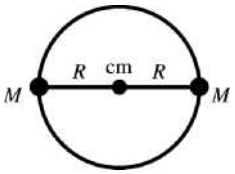
(d) As the term "burns up" suggests, the energy is converted to heat or is dissipated in the collisions of the debris with the ground.

EVALUATE: When r decreases, K increases and U decreases (becomes more negative).

13.71. **IDENTIFY:** Use Eq. (13.2) to calculate F_g. Apply Newton's second law to circular motion of each star to find the orbital speed and period. Apply the conservation of energy expression, Eq. (7.13), to calculate the energy input (work) required to separate the two stars to infinity.

(a) SET UP: The cm is midway between the two stars since they have equal masses. Let R be the orbit radius for each star, as sketched in Figure 13.71.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.



The two stars are separated by a distance $2R$, so $F_g = GM^2/(2R)^2 = GM^2/4R^2$

Figure 13.71

(b) EXECUTE: $F_g = ma_{rad}$

$GM^2/4R^2 = M(v^2/R)$ so $v = \sqrt{GM/4R}$

And $T = 2\pi R/v = 2\pi R\sqrt{4R/GM} = 4\pi\sqrt{R^3/GM}$

(c) SET UP: Apply $K_1 + U_1 + W_{other} = K_2 + U_2$ to the system of the two stars. Separate to infinity implies $K_2 = 0$ and $U_2 = 0$.

EXECUTE: $K_1 = \frac{1}{2}Mv^2 + \frac{1}{2}Mv^2 = 2\left(\frac{1}{2}M\right)(GM/4R) = GM^2/4R$

$U_1 = -GM^2/2R$

Thus the energy required is $W_{other} = -(K_1 + U_1) = -(GM^2/4R - GM^2/2R) = GM^2/4R$.

EVALUATE: The closer the stars are and the greater their mass, the larger their orbital speed, the shorter their orbital period and the greater the energy required to separate them.

13.72. **IDENTIFY:** In the center of mass coordinate system, $r_{cm} = 0$. Apply $\vec{F} = m\vec{a}$ to each star, where F is the gravitational force of one star on the other and $a = a_{rad} = \dfrac{4\pi^2 R}{T^2}$.

SET UP: $v = \dfrac{2\pi R}{T}$ allows R to be calculated from v and T.

EXECUTE: **(a)** The radii R_1 and R_2 are measured with respect to the center of mass, and so $M_1R_1 = M_2R_2$, and $R_1/R_2 = M_2/M_1$.

(b) The forces on each star are equal in magnitude, so the product of the mass and the radial accelerations are equal: $\dfrac{4\pi^2 M_1R_1}{T_1^2} = \dfrac{4\pi^2 M_2R_2}{T_2^2}$. From the result of part (a), the numerators of these expressions are equal, and so the denominators are equal, and the periods are the same. To find the period in the symmetric form desired, there are many possible routes. An elegant method, using a bit of hindsight, is to use the above expressions to relate the periods to the force $F_g = \dfrac{GM_1M_2}{(R_1 + R_2)^2}$, so that equivalent expressions for the period are $M_2T^2 = \dfrac{4\pi^2 R_1(R_1 + R_2)^2}{G}$ and $M_1T^2 = \dfrac{4\pi^2 R_2(R_1 + R_2)^2}{G}$. Adding the expressions gives

$(M_1 + M_2)T^2 = \dfrac{4\pi^2(R_1 + R_2)^3}{G}$ or $T = \dfrac{2\pi(R_1 + R_2)^{3/2}}{\sqrt{G(M_1 + M_2)}}$.

(c) First we must find the radii of each orbit given the speed and period data. In a circular orbit, $v = \dfrac{2\pi R}{T}$, or $R = \dfrac{vT}{2\pi}$. Thus $R_\alpha = \dfrac{(36\times10^3 \text{ m/s})(137 \text{ d})(86{,}400 \text{ s/d})}{2\pi} = 6.78\times10^{10}$ m and

$R_\beta = \dfrac{(12\times10^3 \text{ m/s})(137 \text{ d})(86{,}400 \text{ s/d})}{2\pi} = 2.26\times10^{10}$ m. Now find the sum of the masses.

$(M_\alpha + M_\beta) = \dfrac{4\pi^2(R_\alpha + R_\beta)^3}{T^2G}$. Inserting the values of T and the radii gives

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$(M_\alpha + M_\beta) = \dfrac{4\pi^2(6.78\times10^{10}\text{ m} + 2.26\times10^{10}\text{ m})^3}{[(137\text{ d})(86{,}400\text{ s/d})]^2(6.673\times10^{-11}\text{ N}\cdot\text{m}^2/\text{kg}^2)} = 3.12\times10^{30}$ kg. Since

$M_\beta = M_\alpha R_\alpha/R_\beta = 3M_\alpha$, $4M_\alpha = 3.12\times10^{30}$ kg, or $M_\alpha = 7.80\times10^{29}$ kg, and $M_\beta = 2.34\times10^{30}$ kg.

(d) Let α refer to the star and β refer to the black hole. Use the relationships derived in parts (a) and (b):

$R_\beta = (M_\alpha/M_\beta)R_\alpha = (0.67/3.8)R_\alpha = (0.176)R_\alpha$, $R_\alpha + R_\beta = \sqrt[3]{\dfrac{(M_\alpha + M_\beta)T^2G}{4\pi^2}}$. For Monocerotis,

inserting the values for M and T gives $R_\alpha = 1.9\times10^9$ m, $v_\alpha = 4.4\times10^2$ km/s and for the black hole

$R_\beta = 34\times10^8$ m, $v_\beta = 77$ km/s.

EVALUATE: Since T is the same, v is smaller when R is smaller.

13.73. **IDENTIFY** and **SET UP:** Use conservation of energy, $K_1 + U_1 + W_{\text{other}} = K_2 + U_2$. The gravity force exerted by the sun is the only force that does work on the comet, so $W_{\text{other}} = 0$.

EXECUTE: $K_1 = \frac{1}{2}mv_1^2$, $v_1 = 2.0\times10^4$ m/s

$U_1 = -Gm_Sm/r_1$, $r_1 = 2.5\times10^{11}$ m

$K_2 = \frac{1}{2}mv_2^2$

$U_2 = -Gm_Sm/r_2$, $r_2 = 5.0\times10^{10}$ m

$\frac{1}{2}mv_1^2 - Gm_Sm/r_1 = \frac{1}{2}mv_2^2 - Gm_Sm/r_2$

$v_2^2 = v_1^2 + 2Gm_S\left(\dfrac{1}{r_2} - \dfrac{1}{r_1}\right) = v_1^2 + 2Gm_S\left(\dfrac{r_1 - r_2}{r_1r_2}\right)$

$v_2 = 6.8\times10^4$ m/s

EVALUATE: The comet has greater speed when it is closer to the sun.

13.74. **IDENTIFY** and **SET UP:** Apply Eq. (12.6) and solve for g.
Then use Eq. (13.4) to relate g to the mass of the planet.

EXECUTE: $p - p_0 = \rho gd$.

This expression gives that $g = (p - p_0)/\rho d = (p - p_0)V/md$.

But also $g = Gm_p/R^2$. (Eq. (13.4) applied to the planet rather than to earth.)

Equating these two expressions for g gives $Gm_p/R^2 = (p - p_0)V/md$ and $m_p = (p - p_0)VR^2/Gmd$.

EVALUATE: The greater p is at a given depth, the greater g is for the planet and greater g means greater m_p.

13.75. **IDENTIFY:** Follow the procedure outlined in part (b). For a spherically symmetric object, with total mass m and radius r, at points on the surface of the object, $g(r) = Gm/r^2$.

SET UP: The earth has mass $m_E = 5.97\times10^{24}$ kg. If $g(r)$ is a maximum at $r = r_{\max}$, then $\dfrac{dg}{dr} = 0$ for $r = r_{\max}$.

EXECUTE: **(a)** At $r = 0$, the model predicts $\rho = A = 12{,}700$ kg/m^3 and at $r = R$, the model predicts $\rho = A - BR = 12{,}700\text{ kg/m}^3 - (1.50\times10^{-3}\text{ kg/m}^4)(6.37\times10^6\text{ m}) = 3.15\times10^3$ kg/m^3.

(b) and **(c)** $M = \int dm = 4\pi\int_0^R [A - Br]r^2dr = 4\pi\left[\dfrac{AR^3}{3} - \dfrac{BR^4}{4}\right] = \left(\dfrac{4\pi R^3}{3}\right)\left[A - \dfrac{3BR}{4}\right]$.

$M = \left(\dfrac{4\pi(6.37\times10^6\text{ m})^3}{3}\right)\left[12{,}700\text{ kg/m}^3 - \dfrac{3(1.50\times10^{-3}\text{ kg/m}^4)(6.37\times10^6\text{ m})}{4}\right] = 5.99\times10^{24}$ kg

which is within 0.36% of the earth's mass.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(d) If $m(r)$ is used to denote the mass contained in a sphere of radius r, then $g = Gm(r)/r^2$. Using the same integration as that in part (b), with an upper limit of r instead of R gives the result.

(e) $g = 0$ at $r = 0$, and g at $r = R$ is

$g = Gm(R)/R^2 = (6.673\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)(5.99\times10^{24}\ \text{kg})/(6.37\times10^{6}\ \text{m})^2 = 9.85\ \text{m/s}^2.$

(f) $\dfrac{dg}{dr} = \left(\dfrac{4\pi G}{3}\right)\dfrac{d}{dr}\left[Ar - \dfrac{3Br^2}{4}\right] = \left(\dfrac{4\pi G}{3}\right)\left[A - \dfrac{3Br}{2}\right]$. Setting this equal to zero gives

$r = 2A/3B = 5.64\times10^{6}\ \text{m},$ and at this radius $g = \left(\dfrac{4\pi G}{3}\right)\left(\dfrac{2A}{3B}\right)\left[A - \left(\dfrac{3}{4}\right)B\left(\dfrac{2A}{3B}\right)\right] = \dfrac{4\pi GA^2}{9B}.$

$$g = \frac{4\pi(6.673\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)(12{,}700\ \text{kg/m}^3)^2}{9(1.50\times10^{-3}\ \text{kg/m}^4)} = 10.02\ \text{m/s}^2.$$

EVALUATE: If the earth were a uniform sphere of density ρ, then $g(r) = \dfrac{\rho V(r)}{r^2} = \left(\dfrac{4\pi\rho G}{3}\right)r,$ the same as setting $B = 0$ and $A = \rho$ in $g(r)$ in part (d). If r_{max} is the value of r in part (f) where $g(r)$ is a maximum, then $r_{\text{max}}/R = 0.885$. For a uniform sphere, $g(r)$ is maximum at the surface.

13.76. **IDENTIFY:** Follow the procedure outlined in part (a).

SET UP: The earth has mass $M = 5.97\times10^{24}$ kg and radius $R = 6.38\times10^{6}$ m. Let $g_S = 9.80\ \text{m/s}^2$.

EXECUTE: **(a)** Eq. (12.4), with the radius r instead of height y, becomes $dp = -\rho g(r)\,dr = -\rho g_S(r/R)dr$. This form shows that the pressure decreases with increasing radius. Integrating, with $p = 0$ at $r = R$,

$$p = -\frac{\rho g_S}{R}\int_R^r r\,dr = \frac{\rho g_S}{R}\int_r^R r\,dr = \frac{\rho g_S}{2R}(R^2 - r^2).$$

(b) Using the above expression with $r = 0$ and $\rho = \dfrac{M}{V} = \dfrac{3M}{4\pi R^3}$,

$$p(0) = \frac{3(5.97\times10^{24}\ \text{kg})(9.80\ \text{m/s}^2)}{8\pi(6.38\times10^{6}\ \text{m})^2} = 1.71\times10^{11}\ \text{Pa}.$$

(c) While the same order of magnitude, this is not in very good agreement with the estimated value. In more realistic density models (see Problem 13.75), the concentration of mass at lower radii leads to a higher pressure.

EVALUATE: In this model, the pressure at the center of the earth is about 10^6 times what it is at the surface.

13.77. **(a) IDENTIFY** and **SET UP:** Use Eq. (13.17), applied to the satellites orbiting the earth rather than the sun.

EXECUTE: Find the value of a for the elliptical orbit:

$2a = r_a + r_p = R_E + h_a + R_E + h_p,$ where h_a and h_p are the heights at apogee and perigee, respectively.

$a = R_E + (h_a + h_p)/2$

$a = 6.38\times10^{6}\ \text{m} + (400\times10^{3}\ \text{m} + 4000\times10^{3}\ \text{m})/2 = 8.58\times10^{6}\ \text{m}$

$$T = \frac{2\pi a^{3/2}}{\sqrt{GM_E}} = \frac{2\pi(8.58\times10^{6}\ \text{m})^{3/2}}{\sqrt{(6.673\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)(5.97\times10^{24}\ \text{kg})}} = 7.91\times10^{3}\ \text{s}$$

(b) Conservation of angular momentum gives $r_a v_a = r_p v_p$

$$\frac{v_p}{v_a} = \frac{r_a}{r_p} = \frac{6.38\times10^{6}\ \text{m} + 4.00\times10^{6}\ \text{m}}{6.38\times10^{6}\ \text{m} + 4.00\times10^{5}\ \text{m}} = 1.53$$

(c) Conservation of energy applied to apogee and perigee gives $K_a + U_a = K_p + U_p$

$\frac{1}{2}mv_a^2 - Gm_E m/r_a = \frac{1}{2}mv_P^2 - Gm_E m/r_p$

$v_p^2 - v_a^2 = 2Gm_E(1/r_p - 1/r_a) = 2Gm_E(r_a - r_p)/r_a r_p$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

But $v_p = 1.532v_a$, so $1.347v_a^2 = 2Gm_E(r_a - r_p)/r_a r_p$

$v_a = 5.51\times10^3$ m/s, $v_p = 8.43\times10^3$ m/s

(d) Need v so that $E = 0$, where $E = K + U$.

at perigee: $\frac{1}{2}mv_p^2 - Gm_Em/r_p = 0$

$v_p = \sqrt{2Gm_E/r_p} = \sqrt{2(6.673\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)(5.97\times10^{24}\ \text{kg})/6.78\times10^6\ \text{m}} = 1.084\times10^4$ m/s

This means an increase of 1.084×10^4 m/s $- 8.43\times10^3$ m/s $= 2.41\times10^3$ m/s.

at apogee:

$v_a = \sqrt{2Gm_E/r_a} = \sqrt{2(6.673\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)(5.97\times10^{24}\ \text{kg})/1.038\times10^7\ \text{m}} = 8.761\times10^3$ m/s

This means an increase of 8.761×10^3 m/s $- 5.51\times10^3$ m/s $= 3.25\times10^3$ m/s.

EVALUATE: Perigee is more efficient. At this point r is smaller so v is larger and the satellite has more kinetic energy and more total energy.

13.78. **IDENTIFY:** $g = \dfrac{GM}{R^2}$, where M and R are the mass and radius of the planet.

SET UP: Let m_U and R_U be the mass and radius of Uranus and let g_U be the acceleration due to gravity at its poles. The orbit radius of Miranda is $r = h + R_U$, where $h = 1.04\times10^8$ m is the altitude of Miranda above the surface of Uranus.

EXECUTE: **(a)** From the value of g at the poles,

$$m_U = \frac{g_U R_U^2}{G} = \frac{(11.1\ \text{m/s}^2)(2.556\times10^7\ \text{m})^2}{(6.673\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)} = 1.09\times10^{26}\ \text{kg}.$$

(b) $Gm_U/r^2 = g_U(R_U/r)^2 = 0.432$ m/s^2.

(c) $Gm_M/R_M^2 = 0.080$ m/s^2.

EVALUATE: **(d)** No. Both the object and Miranda are in orbit together around Uranus, due to the gravitational force of Uranus. The object has additional force toward Miranda.

13.79. **IDENTIFY** and **SET UP:** Apply conservation of energy (Eq. (7.13)) and solve for W_{other}. Only $r = h + R_E$ is given, so use Eq. (13.10) to relate r and v.

EXECUTE: $K_1 + U_1 + W_{other} = K_2 + U_2$

$U_1 = -Gm_Mm/r_1$, where m_M is the mass of Mars and $r_1 = R_M + h$, where R_M is the radius of Mars and $h = 2000\times10^3$ m.

$$U_1 = -(6.673\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)\frac{(6.42\times10^{23}\ \text{kg})(5000\ \text{kg})}{3.40\times10^6\ \text{m} + 2000\times10^3\ \text{m}} = -3.9667\times10^{10}\ \text{J}$$

$U_2 = -Gm_Mm/r_2$, where r_2 is the new orbit radius.

$$U_2 = -(6.673\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)\frac{(6.42\times10^{23}\ \text{kg})(5000\ \text{kg})}{3.40\times10^6\ \text{m} + 4000\times10^3\ \text{m}} = -2.8950\times10^{10}\ \text{J}$$

For a circular orbit $v = \sqrt{Gm_M/r}$ (Eq. (13.10)), with the mass of Mars rather than the mass of the earth).

Using this gives $K = \frac{1}{2}mv^2 = \frac{1}{2}m(Gm_M/r) = \frac{1}{2}Gm_Mm/r$, so $K = -\frac{1}{2}U$.

$K_1 = -\frac{1}{2}U_1 = +1.9833\times10^{10}$ J and $K_2 = -\frac{1}{2}U_2 = +1.4475\times10^{10}$ J

Then $K_1 + U_1 + W_{other} = K_2 + U_2$ gives

$W_{other} = (K_2 - K_1) + (U_2 - U) = (1.4475\times10^{10}\ \text{J} - 1.9833\times10^{10}\ \text{J}) + (+3.9667\times10^{10}\ \text{J} - 2.8950\times10^{10}\ \text{J})$

$W_{other} = -5.3580\times10^9\ \text{J} + 1.0717\times10^{10}\ \text{J} = 5.36\times10^9\ \text{J}.$

EVALUATE: When the orbit radius increases the kinetic energy decreases and the gravitational potential energy increases. $K = -U/2$ so $E = K + U = -U/2$ and the total energy also increases (becomes less negative). Positive work must be done to increase the total energy of the satellite.

13.80. **IDENTIFY** and **SET UP:** Use Eq. (13.17) to calculate a. $T = 30{,}000 \text{ y}(3.156\times10^7 \text{ s/1 y}) = 9.468\times10^{11}$ s

EXECUTE: Eq. (13.17): $T = \dfrac{2\pi a^{3/2}}{\sqrt{Gm_S}}$, $T^2 = \dfrac{4\pi^2 a^3}{Gm_S}$

$$a = \left(\frac{Gm_S T^2}{4\pi^2}\right)^{1/3} = 1.4\times10^{14} \text{ m}.$$

EVALUATE: The average orbit radius of Pluto is 5.9×10^{12} m (Appendix F); the semi-major axis for this comet is larger by a factor of 24.

4.3 light years = 4.3 light years$(9.461\times10^{15}$ m/1 light year$) = 4.1\times10^{16}$ m

The distance of Alpha Centauri is larger by a factor of 300.

The orbit of the comet extends well past Pluto but is well within the distance to Alpha Centauri.

13.81. **IDENTIFY:** Integrate $dm = \rho dV$ to find the mass of the planet. Outside the planet, the planet behaves like a point mass, so at the surface $g = GM/R^2$.

SET UP: A thin spherical shell with thickness dr has volume $dV = 4\pi r^2 dr$. The earth has radius $R_E = 6.38\times10^6$ m.

EXECUTE: Get $M: M = \int dm = \int \rho dV = \int \rho 4\pi r^2 dr$. The density is $\rho = \rho_0 - br$, where

$\rho_0 = 15.0\times10^3$ kg/m^3 at the center and at the surface, $\rho_S = 2.0\times10^3$ kg/m^3, so $b = \dfrac{\rho_0 - \rho_s}{R}$.

$$M = \int_0^R (\rho_0 - br)\, 4\pi r^2 dr = \frac{4\pi}{3}\rho_0 R^3 - \pi b R^4 = \frac{4}{3}\pi R^3\rho_0 - \pi R^4\left(\frac{\rho_0 - \rho_S}{R}\right) = \pi R^3\left(\frac{1}{3}\rho_0 + \rho_s\right)$$ and

$M = 5.71\times10^{24}$ kg. Then $g = \dfrac{GM}{R^2} = \dfrac{G\pi R^3\left(\frac{1}{3}\rho_0 + \rho_s\right)}{R^2} = \pi RG\left(\frac{1}{3}\rho_0 + \rho_s\right)$.

$$g = \pi(6.38\times10^6 \text{m})(6.67\times10^{-11} \text{ N}\cdot\text{m}^2/\text{kg}^2)\left(\frac{15.0\times10^3 \text{ kg/m}^3}{3} + 2.0\times10^3 \text{ kg/m}^3\right).$$

$g = 9.36$ m/s^2.

EVALUATE: The average density of the planet is

$\rho_{av} = \dfrac{M}{V} = \dfrac{M}{\frac{4}{3}\pi R^3} = \dfrac{3(5.71\times10^{24} \text{ kg})}{4\pi(6.38\times10^6 \text{ m})^3} = 5.25\times10^3$ kg/m^3. Note that this is not $(\rho_0 + \rho_S)/2$.

13.82. **IDENTIFY** and **SET UP:** Use Eq. (13.1) to calculate the force between the point mass and a small segment of the semicircle.

EXECUTE: The radius of the semicircle is $R = L/\pi$.

Divide the semicircle up into small segments of length $R\,d\theta$, as shown in Figure 13.82.

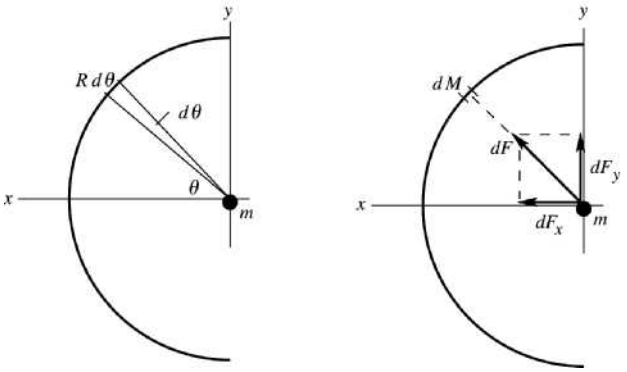

Figure 13.82

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$dM = (M/L)R\,d\theta = (M/\pi)\,d\theta$

$d\vec{\boldsymbol{F}}$ is the gravity force on m exerted by dM

$\int dF_y = 0;$ the y-components from the upper half of the semicircle cancel the y-components from the lower half.

The x-components are all in the $+x$-direction and all add.

$$dF = G\frac{m\,dM}{R^2}$$

$$dF_x = G\frac{m\,dM}{R^2}\cos\theta = \frac{Gm\pi M}{L^2}\cos\theta\,d\theta$$

$$F_x = \int_{-\pi/2}^{\pi/2} dF_x = \frac{Gm\pi M}{L^2}\int_{-\pi/2}^{\pi/2}\cos\theta\,d\theta = \frac{Gm\pi M}{L^2}(2)$$

$$F = \frac{2\pi GmM}{L^2}$$

EVALUATE: If the semicircle were replaced by a point mass M at $x = R$, the gravity force would be $GmM/R^2 = \pi^2 GmM/L^2$. This is $\pi/2$ times larger than the force exerted by the semicirclar wire. For the semicircle it is the x-components that add, and the sum is less than if the force magnitudes were added.

13.83. **IDENTIFY:** The direct calculation of the force that the sphere exerts on the ring is slightly more involved than the calculation of the force that the ring exerts on the sphere. These forces are equal in magnitude but opposite in direction, so it will suffice to do the latter calculation. By symmetry, the force on the sphere will be along the axis of the ring in Figure E13.33 in the textbook, toward the ring.

SET UP: Divide the ring into infinitesimal elements with mass dM.

EXECUTE: Each mass element dM of the ring exerts a force of magnitude $\dfrac{(Gm)dM}{a^2 + x^2}$ on the sphere, and the x-component of this force is $\dfrac{GmdM}{a^2 + x^2}\dfrac{x}{\sqrt{a^2 + x^2}} = \dfrac{GmdMx}{(a^2 + x^2)^{3/2}}$.

Therefore, the force on the sphere is $GmMx/(a^2 + x^2)^{3/2}$, in the $-x$-direction. The sphere attracts the ring with a force of the same magnitude.

EVALUATE: As $x \gg a$ the denominator approaches x^3 and $F \to \dfrac{GMm}{x^2}$, as expected.

13.84. **IDENTIFY:** Use Eq. (13.1) for the force between a small segment of the rod and the particle. Integrate over the length of the rod to find the total force.

SET UP: Use a coordinate system with the origin at the left-hand end of the rod and the x'-axis along the rod, as shown in Figure 13.84. Divide the rod into small segments of length dx'. (Use x' for the coordinate so not to confuse with the distance x from the end of the rod to the particle.)

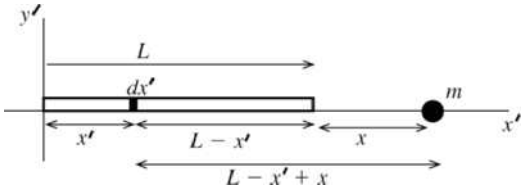

Figure 13.84

EXECUTE: The mass of each segment is $dM = dx'(M/L)$. Each segment is a distance $L - x' + x$ from mass m, so the force on the particle due to a segment is $dF = \dfrac{Gm\,dM}{(L - x' + x)^2} = \dfrac{GMm}{L}\dfrac{dx'}{(L - x' + x)^2}$.

$$F = \int_L^0 dF = \frac{GMm}{L}\int_L^0 \frac{dx'}{(L - x' + x)^2} = \frac{GMm}{L}\left(-\frac{1}{L - x' + x}\Big|_L^0\right)$$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$F = \frac{GMm}{L}\left(\frac{1}{x} - \frac{1}{L+x}\right) = \frac{GMm}{L}\frac{(L+x-x)}{x(L+x)} = \frac{GMm}{x(L+x)}$$

EVALUATE: For $x \gg L$ this result becomes $F = GMm/x^2$, the same as for a pair of point masses.

13.85. **IDENTIFY:** Compare F_E to Hooke's law.

SET UP: The earth has mass $m_E = 5.97\times10^{24}$ kg and radius $R_E = 6.38\times10^6$ m.

EXECUTE: **(a)** For $F_x = -kx$, $U = \frac{1}{2}kx^2$. The force here is in the same form, so by analogy $U(r) = \frac{Gm_E m}{2R_E^3}r^2$. This is also given by the integral of F_g from 0 to r with respect to distance.

(b) From part (a), the initial gravitational potential energy is $\frac{Gm_E m}{2R_E}$. Equating initial potential energy and final kinetic energy (initial kinetic energy and final potential energy are both zero) gives $v^2 = \frac{Gm_E}{R_E}$, so $v = 7.90\times10^3$ m/s.

EVALUATE: When $r = 0$, $U(r) = 0$, as specified in the problem.

13.86. **IDENTIFY:** In Eqs. (13.12) and (13.16) replace T by $T + \Delta T$ and r by $r + \Delta r$. Use the expression in the hint to simplify the resulting equations.

SET UP: The earth has $m_E = 5.97\times10^{24}$ kg and $R = 6.38\times10^6$ m. $r = h + R_E$, where h is the altitude above the surface of the earth.

EXECUTE: **(a)** $T = \frac{2\pi r^{3/2}}{\sqrt{GM_E}}$ therefore

$$T + \Delta T = \frac{2\pi}{\sqrt{GM_E}}(r+\Delta r)^{3/2} = \frac{2\pi r^{3/2}}{\sqrt{GM_E}}\left(1+\frac{\Delta r}{r}\right)^{3/2} \approx \frac{2\pi r^{3/2}}{\sqrt{GM_E}}\left(1+\frac{3\Delta r}{2r}\right) = T + \frac{3\pi r^{1/2}\Delta r}{\sqrt{GM_E}}.$$

Since $v = \sqrt{\frac{GM_E}{r}}$, $\Delta T = \frac{3\pi\,\Delta r}{v}$. $v = \sqrt{GM_E}\,r^{-1/2}$, and therefore

$$v - \Delta v = \sqrt{GM_E}\,(r+\Delta r)^{-1/2} = \sqrt{GM_E}\,r^{-1/2}\left(1+\frac{\Delta r}{r}\right)^{-1/2} \text{ and } v \approx \sqrt{GM_E}\,r^{-1/2}\left(1-\frac{\Delta r}{2r}\right) = v - \frac{\sqrt{GM_E}}{2r^{3/2}}\Delta r.$$

Since $T = \frac{2\pi r^{3/2}}{\sqrt{GM_E}}$, $\Delta v = \frac{\pi\Delta r}{T}$.

(b) Starting with $T = \frac{2\pi r^{3/2}}{\sqrt{GM}}$ (Eq. (13.12), $T = 2\pi r/v$, and $v = \sqrt{\frac{GM}{r}}$ (Eq. (13.10)), find the velocity and period of the initial orbit: $v = \sqrt{\frac{(6.673\times10^{-11}\text{N}\cdot\text{m}^2/\text{kg}^2)(5.97\times10^{24}\text{kg})}{6.776\times10^6\text{m}}} = 7.672\times10^3$ m/s, and $T = 2\pi r/v = 5549$ s $= 92.5$ min. We then can use the two derived equations to approximate ΔT and Δv:

$\Delta T = \frac{3\pi\Delta r}{v} = \frac{3\pi(100\text{ m})}{7.672\times10^3\text{ m/s}} = 0.1228$ s and $\Delta v = \frac{\pi\Delta r}{T} = \frac{\pi(100\text{ m})}{(5549\text{ s})} = 0.05662$ m/s. Before the cable breaks, the shuttle will have traveled a distance d, $d = \sqrt{(125\text{ m}^2) - (100\text{ m}^2)} = 75$ m.

$t = (75\text{ m})/(0.05662\text{ m/s}) = 1324.7\text{ s} = 22$ min. It will take 22 minutes for the cable to break.

(c) The ISS is moving faster than the space shuttle, so the total angle it covers in an orbit must be 2π radians more than the angle that the space shuttle covers before they are once again in line. Mathematically, $\frac{vt}{r} - \frac{(v-\Delta v)t}{(r+\Delta r)} = 2\pi$. Using the binomial theorem and neglecting terms of order

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$\Delta v\Delta r$, $\frac{vt}{r}-\frac{(v-\Delta v)t}{r}(1+\frac{\Delta r}{r})^{-1}\approx t\left(\frac{\Delta v}{r}+\frac{v\Delta r}{r^2}\right)=2\pi$. Therefore, $t=\frac{2\pi r}{\left(\Delta v+\frac{v\Delta r}{r}\right)}=\frac{v_T}{\frac{\pi\,\Delta r}{T}+\frac{v\Delta r}{r}}$. Since

$2\pi r=vT$ and $\Delta r=\frac{v\Delta T}{3\pi}$, $t=\frac{vT}{\frac{\pi}{t}\left(\frac{v\Delta T}{3\pi}\right)+\frac{2\pi}{T}\left(\frac{v\Delta T}{3\pi}\right)}=\frac{T^2}{\Delta T}$, as was to be shown.

$t=\frac{T^2}{\Delta T}=\frac{(5549\text{ s})^2}{(0.1228\text{ s})}=2.5\times10^8\text{ s}=2900\text{ d}=7.9\text{ y}$. It is highly doubtful the shuttle crew would survive the congressional hearings if they miss!

EVALUATE: When the orbit radius increases, the orbital period increases and the orbital speed decreases.

13.87. **IDENTIFY:** Apply Eq. (13.19) to the transfer orbit.

SET UP: The orbit radius for earth is $r_E=1.50\times10^{11}$ m and for Mars it is $r_M=2.28\times10^{11}$ m. From Figure 13.18 in the textbook, $a=\frac{1}{2}(r_E+r_M)$.

EXECUTE: **(a)** To get from the circular orbit of the earth to the transfer orbit, the spacecraft's energy must increase, and the rockets are fired in the direction opposite that of the motion, that is, in the direction that increases the speed. Once at the orbit of Mars, the energy needs to be increased again, and so the rockets need to be fired in the direction opposite that of the motion. From Figure 13.18 in the textbook, the semimajor axis of the transfer orbit is the arithmetic average of the orbit radii of the earth and Mars, and so from Eq. (13.13), the energy of the spacecraft while in the transfer orbit is intermediate between the energies of the circular orbits. Returning from Mars to the earth, the procedure is reversed, and the rockets are fired against the direction of motion.

(b) The time will be half the period as given in Eq. (13.17), with the semimajor axis equal to $a=\frac{1}{2}(r_E+r_M)=1.89\times10^{11}$ m so

$t=\frac{T}{2}=\frac{\pi\,(1.89\times10^{11}\text{ m})^{3/2}}{\sqrt{(6.673\times10^{-11}\text{ N}\cdot\text{m}^2/\text{kg}^2)(1.99\times10^{30}\text{ kg})}}=2.24\times10^7\text{ s}=259\text{ days}$, which is more than $8\frac{1}{2}$ months.

(c) During this time, Mars will pass through an angle of $(360°)\frac{(2.24\times10^7\text{ s})}{(687\text{ d})(86{,}400\text{ s/d})}=135.9°$, and the spacecraft passes through an angle of $180°$, so the angle between the earth-sun line and the Mars-sun line must be $44.1°$.

EVALUATE: The period T for the transfer orbit is 526 days, the average of the orbital periods for earth and Mars.

13.88. **IDENTIFY:** Apply $\Sigma\vec{F}=m\vec{a}$ to each ear.

SET UP: Denote the orbit radius as r and the distance from this radius to either ear as δ. Each ear, of mass m, can be modeled as subject to two forces, the gravitational force from the black hole and the tension force (actually the force from the body tissues), denoted by F.

EXECUTE: The force equation for either ear is $\frac{GMm}{(r+\delta)^2}-F=m\omega^2(r+\delta)$, where δ can be of either sign.

Replace the product $m\omega^2$ with the value for $\delta=0$, $m\omega^2=GMm/r^3$, and solve for F:

$$F=(GMm)\left[\frac{r+\delta}{r^3}-\frac{1}{(r+\delta)^2}\right]=\frac{GMm}{r^3}\left[r+\delta-r(1+(\delta/r)^{-2}\right].$$

Using the binomial theorem to expand the term in square brackets in powers of δ/r,

$$F\approx\frac{GMm}{r^3}[r+\delta-r(1-2(\delta/r))]=\frac{GMm}{r^3}(3\delta)=2.1\text{ kN}.$$

This tension is much larger than that which could be sustained by human tissue, and the astronaut is in trouble.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) The center of gravity is not the center of mass. The gravity force on the two ears is not the same.

EVALUATE: The tension between her ears is proportional to their separation.

13.89. **IDENTIFY:** As suggested in the problem, divide the disk into rings of radius r and thickness dr.

SET UP: Each ring has an area $dA = 2\pi r\,dr$ and mass $dM = \dfrac{M}{\pi a^2}dA = \dfrac{2M}{a^2}r\,dr$.

EXECUTE: The magnitude of the force that this small ring exerts on the mass m is then $(Gm\,dM)(x/(r^2 + x^2)^{3/2})$. The contribution dF to the force is $dF = \dfrac{2GMmx}{a^2}\dfrac{rdr}{(x^2 + r^2)^{3/2}}$.

The total force F is then the integral over the range of r;

$$F = \int dF = \frac{2GMmx}{a^2}\int_0^a \frac{r}{(x^2 + r^2)^{3/2}}dr.$$

The integral (either by looking in a table or making the substitution $u = r^2 + a^2$) is

$$\int_0^a \frac{r}{(x^2 + r^2)^{3/2}}dr = \left[\frac{1}{x} - \frac{1}{\sqrt{a^2 + x^2}}\right] = \frac{1}{x}\left[1 - \frac{x}{\sqrt{a^2 + x^2}}\right].$$

Substitution yields the result $F = \dfrac{2GMm}{a^2}\left[1 - \dfrac{x}{\sqrt{a^2 + x^2}}\right]$. The force on m is directed toward the center of the ring. The second term in brackets can be written as

$$\frac{1}{\sqrt{1 + (a/x)^2}} = (1 + (a/x)^2)^{-1/2} \approx 1 - \frac{1}{2}\left(\frac{a}{x}\right)^2$$

if $x \gg a$, where the binomial expansion has been used. Substitution of this into the above form gives $F \approx \dfrac{GMm}{x^2}$, as it should.

EVALUATE: As $x \to 0$, the force approaches a constant.

13.90. **IDENTIFY:** Divide the rod into infinitesimal segments. Calculate the force each segment exerts on m and integrate over the rod to find the total force.

SET UP: From symmetry, the component of the gravitational force parallel to the rod is zero. To find the perpendicular component, divide the rod into segments of length dx and mass $dm = dx\dfrac{M}{2L}$, positioned at a distance x from the center of the rod.

EXECUTE: The magnitude of the gravitational force from each segment is $dF = \dfrac{Gm\,dM}{x^2 + a^2} = \dfrac{GmM}{2L}\dfrac{dx}{x^2 + a^2}$. The component of dF perpendicular to the rod is $dF\dfrac{a}{\sqrt{x^2 + a^2}}$ and so the net gravitational force is $F = \int_{-L}^{L} dF = \dfrac{GmMa}{2L}\int_{-L}^{L}\dfrac{dx}{(x^2 + a^2)^{3/2}}$.

The integral can be found in a table, or found by making the substitution $x = a\tan\theta$. Then, $dx = a\sec^2\theta\,d\theta, (x^2 + a^2) = a^2\sec^2\theta$, and so

$$\int \frac{dx}{(x^2 + a^2)^{3/2}} = \int \frac{a\sec^2\theta\,d\theta}{a^3\sec^3\theta} = \frac{1}{a^2}\int \cos\theta\,d\theta = \frac{1}{a^2}\sin\theta = \frac{x}{a^2\sqrt{x^2 + a^2}},$$

and the definite integral is $F = \dfrac{GmM}{a\sqrt{a^2 + L^2}}$.

EVALUATE: When $a \gg L$, the term in the square root approaches a^2 and $F \to \dfrac{GmM}{a^2}$, as expected.

14

PERIODIC MOTION

14.1. **IDENTIFY:** We want to relate the characteristics of various waves, such as the period, frequency and angular frequency.

SET UP: The frequency f in Hz is the number of cycles per second. The angular frequency ω is $\omega = 2\pi f$ and has units of radians per second. The period T is the time for one cycle of the wave and has units of seconds. The period and frequency are related by $T = \frac{1}{f}$.

EXECUTE: **(a)** $T = \frac{1}{f} = \frac{1}{466\ \text{Hz}} = 2.15\times10^{-3}\ \text{s}$.

$\omega = 2\pi f = 2\pi(466\ \text{Hz}) = 2.93\times10^{3}\ \text{rad/s}$.

(b) $f = \frac{1}{T} = \frac{1}{50.0\times10^{-6}\ \text{s}} = 2.00\times10^{4}\ \text{Hz}$. $\omega = 2\pi f = 1.26\times10^{5}\ \text{rad/s}$.

(c) $f = \frac{\omega}{2\pi}$ so f ranges from $\frac{2.7\times10^{15}\ \text{rad/s}}{2\pi\ \text{rad}} = 4.3\times10^{14}\ \text{Hz}$ to

$\frac{4.7\times10^{15}\ \text{rad/s}}{2\pi\ \text{rad}} = 7.5\times10^{14}\ \text{Hz}$. $T = \frac{1}{f}$ so T ranges from

$\frac{1}{7.5\times10^{14}\ \text{Hz}} = 1.3\times10^{-15}\text{s}$ to $\frac{1}{4.3\times10^{14}\ \text{Hz}} = 2.3\times10^{-15}\text{s}$.

(d) $T = \frac{1}{f} = \frac{1}{5.0\times10^{6}\ \text{Hz}} = 2.0\times10^{-7}\text{s}$ and $\omega = 2\pi f = 2\pi(5.0\times10^{6}\ \text{Hz}) = 3.1\times10^{7}\ \text{rad/s}$.

EVALUATE: Visible light has much higher frequency than either sounds we can hear or ultrasound. Ultrasound is sound with frequencies higher than what the ear can hear. Large f corresponds to small T.

14.2. **IDENTIFY** and **SET UP:** The amplitude is the maximum displacement from equilibrium. In one period the object goes from $x = +A$ to $x = -A$ and returns.

EXECUTE: **(a)** $A = 0.120$ m

(b) $0.800\ \text{s} = T/2$ so the period is 1.60 s

(c) $f = \frac{1}{T} = 0.625\ \text{Hz}$

EVALUATE: Whenever the object is released from rest, its initial displacement equals the amplitude of its SHM.

14.3. **IDENTIFY:** The period is the time for one vibration and $\omega = \frac{2\pi}{T}$.

SET UP: The units of angular frequency are rad/s.

EXECUTE: The period is $\frac{0.50\ \text{s}}{440} = 1.14\times10^{-3}$ s and the angular frequency is $\omega = \frac{2\pi}{T} = 5.53\times10^{3}\ \text{rad/s}$.

EVALUATE: There are 880 vibrations in 1.0 s, so $f = 880$ Hz. This is equal to $1/T$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

14.4. **IDENTIFY:** The period is the time for one cycle and the amplitude is the maximum displacement from equilibrium. Both these values can be read from the graph.
SET UP: The maximum x is 10.0 cm. The time for one cycle is 16.0 s.

EXECUTE: **(a)** $T = 16.0$ s so $f = \dfrac{1}{T} = 0.0625$ Hz.

(b) $A = 10.0$ cm.
(c) $T = 16.0$ s
(d) $\omega = 2\pi f = 0.393$ rad/s

EVALUATE: After one cycle the motion repeats.

14.5. **IDENTIFY:** This displacement is $\frac{1}{4}$ of a period.

SET UP: $T = 1/f = 0.200$ s.

EXECUTE: $t = 0.0500$ s

EVALUATE: The time is the same for $x = A$ to $x = 0$, for $x = 0$ to $x = -A$, for $x = -A$ to $x = 0$ and for $x = 0$ to $x = A$.

14.6. **IDENTIFY:** Apply Eq. (14.12).
SET UP: The period will be twice the interval between the times at which the glider is at the equilibrium position.

EXECUTE: $k = \omega^2 m = \left(\dfrac{2\pi}{T}\right)^2 m = \left(\dfrac{2\pi}{2(2.60\text{ s})}\right)^2 (0.200\text{ kg}) = 0.292$ N/m.

EVALUATE: $1\text{ N} = 1\text{ kg}\cdot\text{m/s}^2$, so $1\text{ N/m} = 1\text{ kg/s}^2$.

14.7. **IDENTIFY** and **SET UP:** Use Eq. (14.1) to calculate T, Eq. (14.2) to calculate ω and Eq. (14.10) for m.
EXECUTE: **(a)** $T = 1/f = 1/6.00\text{ Hz} = 0.167$ s

(b) $\omega = 2\pi f = 2\pi(6.00\text{ Hz}) = 37.7$ rad/s

(c) $\omega = \sqrt{k/m}$ implies $m = k/\omega^2 = (120\text{ N/m})/(37.7\text{ rad/s})^2 = 0.0844$ kg

EVALUATE: We can verify that k/ω^2 has units of mass.

14.8. **IDENTIFY:** The mass and frequency are related by $f = \dfrac{1}{2\pi}\sqrt{\dfrac{k}{m}}$.

SET UP: $f\sqrt{m} = \dfrac{\sqrt{k}}{2\pi} =$ constant, so $f_1\sqrt{m_1} = f_2\sqrt{m_2}$.

EXECUTE: **(a)** $m_1 = 0.750$ kg, $f_1 = 1.33$ Hz and $m_2 = 0.750\text{ kg} + 0.220\text{ kg} = 0.970$ kg.

$f_2 = f_1\sqrt{\dfrac{m_1}{m_2}} = (1.33\text{ Hz})\sqrt{\dfrac{0.750\text{ kg}}{0.970\text{ kg}}} = 1.17$ Hz.

(b) $m_2 = 0.750\text{ kg} - 0.220\text{ kg} = 0.530$ kg. $f_2 = (1.33\text{ Hz})\sqrt{\dfrac{0.750\text{ kg}}{0.530\text{ kg}}} = 1.58$ Hz

EVALUATE: When the mass increases the frequency decreases and when the mass decreases the frequency increases.

14.9. **IDENTIFY:** For SHM the motion is sinusoidal.
SET UP: $x(t) = A\cos(\omega t)$.

EXECUTE: $x(t) = A\cos(\omega t)$, where $A = 0.320$ m and $\omega = \dfrac{2\pi}{T} = \dfrac{2\pi}{0.900\text{ s}} = 6.981$ rad/s.

(a) $x = 0.320$ m at $t_1 = 0$. Let t_2 be the instant when $x = 0.160$ m. Then we have

$0.160\text{ m} = (0.320\text{ m})\cos(\omega t_2)$. $\cos(\omega t_2) = 0.500$. $\omega t_2 = 1.047$ rad. $t_2 = \dfrac{1.047\text{ rad}}{6.981\text{ rad/s}} = 0.150$ s. It takes $t_2 - t_1 = 0.150$ s.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) Let t_3 be when $x = 0$. Then we have $\cos(\omega t_3) = 0$ and $\omega t_3 = 1.571$ rad. $t_3 = \dfrac{1.571 \text{ rad}}{6.981 \text{ rad/s}} = 0.225$ s. It takes $t_3 - t_2 = 0.225 \text{ s} - 0.150 \text{ s} = 0.0750$ s.

EVALUATE: Note that it takes twice as long to go from $x = 0.320$ m to $x = 0.160$ m than to go from $x = 0.160$ m to $x = 0$, even though the two distances are the same, because the speeds are different over the two distances.

14.10. **IDENTIFY:** For SHM the restoring force is directly proportional to the displacement and the system obeys Newton's second law.

SET UP: $F_x = ma_x$ and $f = \dfrac{1}{2\pi}\sqrt{\dfrac{k}{m}}$.

EXECUTE: $F_x = ma_x$ gives $a_x = -\dfrac{kx}{m}$, so $\dfrac{k}{m} = -\dfrac{a_x}{x} = -\dfrac{-5.30 \text{ m/s}^2}{0.280 \text{ m}} = 18.93 \text{ s}^{-2}$.

$f = \dfrac{1}{2\pi}\sqrt{\dfrac{k}{m}} = \dfrac{1}{2\pi}\sqrt{18.93 \text{ s}^{-2}} = 0.692$ Hz

EVALUATE: The period is around 1.5 s, so this is a rather slow vibration.

14.11. **IDENTIFY:** Use Eq. (14.19) to calculate A. The initial position and velocity of the block determine ϕ. $x(t)$ is given by Eq. (14.13).

SET UP: $\cos\theta$ is zero when $\theta = \pm\pi/2$ and $\sin(\pi/2) = 1$.

EXECUTE: **(a)** From Eq. (14.19), $A = \left|\dfrac{v_0}{\omega}\right| = \left|\dfrac{v_0}{\sqrt{k/m}}\right| = 0.98$ m.

(b) Since $x(0) = 0$, Eq. (14.14) requires $\phi = \pm\frac{\pi}{2}$. Since the block is initially moving to the left, $v_{0x} < 0$ and Eq. (14.7) requires that $\sin\phi > 0$, so $\phi = +\frac{\pi}{2}$.

(c) $\cos(\omega t + (\pi/2)) = -\sin\omega t$, so $x = (-0.98 \text{ m})\sin((12.2 \text{ rad/s})t)$.

EVALUATE: The $x(t)$ result in part (c) does give $x = 0$ at $t = 0$ and $x < 0$ for t slightly greater than zero.

14.12. **IDENTIFY** and **SET UP:** We are given k, m, x_0, and v_0. Use Eqs. (14.19), (14.18) and (14.13).

EXECUTE: **(a)** Eq. (14.19): $A = \sqrt{x_0^2 + v_{0x}^2/\omega^2} = \sqrt{x_0^2 + mv_{0x}^2/k}$

$A = \sqrt{(0.200 \text{ m})^2 + (2.00 \text{ kg})(-4.00 \text{ m/s})^2/(300 \text{ N/m})} = 0.383$ m

(b) Eq. (14.18): $\phi = \arctan(-v_{0x}/\omega x_0)$

$\omega = \sqrt{k/m} = \sqrt{(300 \text{ N/m})/2.00 \text{ kg}} = 12.25$ rad/s

$\phi = \arctan\left(-\dfrac{(-4.00 \text{ m/s})}{(12.25 \text{ rad/s})(0.200 \text{ m})}\right) = \arctan(+1.633) = 58.5°$ (or 1.02 rad)

(c) $x = A\cos(\omega t + \phi)$ gives $x = (0.383 \text{ m})\cos([12.2\text{rad/s}]t + 1.02 \text{ rad})$

EVALUATE: At $t = 0$ the block is displaced 0.200 m from equilibrium but is moving, so $A > 0.200$ m. According to Eq. (14.15), a phase angle ϕ in the range $0 < \phi < 90°$ gives $v_{0x} < 0$.

14.13. **IDENTIFY:** For SHM, $a_x = -\omega^2 x = -(2\pi f)^2 x$. Apply Eqs. (14.13), (14.15) and (14.16), with A and ϕ from Eqs. (14.18) and (14.19).

SET UP: $x = 1.1$ cm, $v_{0x} = -15$ cm/s. $\omega = 2\pi f$, with $f = 2.5$ Hz.

EXECUTE: **(a)** $a_x = -(2\pi(2.5 \text{ Hz}))^2(1.1\times10^{-2} \text{ m}) = -2.71 \text{ m/s}^2$.

(b) From Eq. (14.19) the amplitude is 1.46 cm, and from Eq. (14.18) the phase angle is 0.715 rad. The angular frequency is $2\pi f = 15.7$ rad/s, so $x = (1.46 \text{ cm})\cos((15.7 \text{ rad/s})t + 0.715 \text{ rad})$,

$v_x = (-22.9 \text{ cm/s})\sin((15.7 \text{ rad/s})t + 0.715 \text{ rad})$ and $a_x = (-359 \text{ cm/s}^2)\cos((15.7 \text{ rad/s})t + 0.715 \text{ rad})$.

EVALUATE: We can verify that our equations for x, v_x and a_x give the specified values at $t = 0$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

14.14. **IDENTIFY:** The motion is SHM, and in each case the motion described is one-half of a complete cycle.

SET UP: For SHM, $x = A\cos(\omega t)$ and $\omega = \dfrac{2\pi}{T}$.

EXECUTE: **(a)** The time is half a period. The period is independent of the amplitude, so it still takes 2.70 s.

(b) $x = 0.090$ m at time t_1. $T = 5.40$ s and $\omega = \dfrac{2\pi}{T} = 1.164$ rad/s. $x_1 = A\cos(\omega t_1)$. $\cos(\omega t_1) = 0.500$. $\omega t_1 = 1.047$ rad and $t_1 = 0.8997$ s. $x = -0.090$ m at time t_2. $\cos(\omega t_2) = -0.500$ m. $\omega t_2 = 2.094$ rad and $t_2 = 1.800$ s. The elapsed time is $t_2 - t_1 = 1.800\text{ s} - 0.8997\text{ s} = 0.900$ s.

EVALUATE: It takes less time to travel from ±0.090 m in (b) than it originally did because the block has larger speed at ± 0.090 m with the increased amplitude.

14.15. **IDENTIFY:** Apply $T = 2\pi\sqrt{\dfrac{m}{k}}$. Use the information about the empty chair to calculate *k*.

SET UP: When $m = 42.5$ kg, $T = 1.30$ s.

EXECUTE: Empty chair: $T = 2\pi\sqrt{\dfrac{m}{k}}$. gives $k = \dfrac{4\pi^2 m}{T^2} = \dfrac{4\pi^2(42.5\text{ kg})}{(1.30\text{ s})^2} = 993$ N/m

With person in chair: $T = 2\pi\sqrt{\dfrac{m}{k}}$ gives $m = \dfrac{T^2 k}{4\pi^2} = \dfrac{(2.54\text{ s})^2(993\text{ N/m})}{4\pi^2} = 162$ kg and $m_{\text{person}} = 162\text{ kg} - 42.5\text{ kg} = 120$ kg.

EVALUATE: For the same spring, when the mass increases, the period increases.

14.16. **IDENTIFY** and **SET UP:** Use Eq. (14.12) for *T* and Eq. (14.4) to relate a_x and *k*.

EXECUTE: $T = 2\pi\sqrt{\dfrac{m}{k}}$, $m = 0.400$ kg

Use $a_x = -2.70\text{ m/s}^2$ to calculate *k*: $-kx = ma_x$ gives

$k = -\dfrac{ma_x}{x} = -\dfrac{(0.400\text{ kg})(-2.70\text{ m/s}^2)}{0.300\text{ m}} = +3.60$ N/m $T = 2\pi\sqrt{\dfrac{m}{k}} = 2.09$ s

EVALUATE: a_x is negative when *x* is positive. ma_x/x has units of N/m and $\sqrt{m/k}$ has units of s.

14.17. **IDENTIFY:** $T = 2\pi\sqrt{\dfrac{m}{k}}$. $a_x = -\dfrac{k}{m}x$ so $a_{\max} = \dfrac{k}{m}A$. $F = -kx$.

SET UP: a_x is proportional to *x* so a_x goes through one cycle when the displacement goes through one cycle. From the graph, one cycle of a_x extends from $t = 0.10$ s to $t = 0.30$ s, so the period is $T = 0.20$ s. $k = 2.50$ N/cm = 250 N/m. From the graph the maximum acceleration is 12.0 m/s^2.

EXECUTE: **(a)** $T = 2\pi\sqrt{\dfrac{m}{k}}$ gives $m = k\left(\dfrac{T}{2\pi}\right)^2 = (250\text{ N/m})\left(\dfrac{0.20\text{ s}}{2\pi}\right)^2 = 0.253$ kg

(b) $A = \dfrac{ma_{\max}}{k} = \dfrac{(0.253\text{ kg})(12.0\text{ m/s}^2)}{250\text{ N/m}} = 0.0121\text{ m} = 1.21\text{ cm}$

(c) $F_{\max} = kA = (250\text{ N/m})(0.0121\text{ m}) = 3.03$ N

EVALUATE: We can also calculate the maximum force from the maximum acceleration: $F_{\max} = ma_{\max} = (0.253\text{ kg})(12.0\text{ m/s}^2) = 3.04$ N, which agrees with our previous results.

14.18. **IDENTIFY:** The general expression for $v_x(t)$ is $v_x(t) = -\omega A\sin(\omega t + \phi)$. We can determine ω and *A* by comparing the equation in the problem to the general form.

SET UP: $\omega = 4.71$ rad/s. $\omega A = 3.60$ cm/s = 0.0360 m/s.

EXECUTE: **(a)** $T = \dfrac{2\pi}{\omega} = \dfrac{2\pi\text{ rad}}{4.71\text{ rad/s}} = 1.33$ s

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) $A = \dfrac{0.0360 \text{ m/s}}{\omega} = \dfrac{0.0360 \text{ m/s}}{4.71 \text{ rad/s}} = 7.64\times10^{-3} \text{ m} = 7.64 \text{ mm}$

(c) $a_{\max} = \omega^2 A = (4.71 \text{ rad/s})^2(7.64\times10^{-3} \text{ m}) = 0.169 \text{ m/s}^2$

(d) $\omega = \sqrt{\dfrac{k}{m}}$ so $k = m\omega^2 = (0.500 \text{ kg})(4.71 \text{ rad/s})^2 = 11.1 \text{ N/m}.$

EVALUATE: The overall positive sign in the expression for $v_x(t)$ and the factor of $-\pi/2$ both are related to the phase factor ϕ in the general expression.

14.19. **IDENTIFY:** Compare the specific $x(t)$ given in the problem to the general form of Eq. (14.13).

SET UP: $A = 7.40$ cm, $\omega = 4.16$ rad/s, and $\phi = -2.42$ rad.

EXECUTE: **(a)** $T = \dfrac{2\pi}{\omega} = \dfrac{2\pi}{4.16 \text{ rad/s}} = 1.51 \text{ s}.$

(b) $\omega = \sqrt{\dfrac{k}{m}}$ so $k = m\omega^2 = (1.50 \text{ kg})(4.16 \text{ rad/s})^2 = 26.0 \text{ N/m}$

(c) $v_{\max} = \omega A = (4.16 \text{ rad/s})(7.40 \text{ cm}) = 30.8 \text{ cm/s}$

(d) $F_x = -kx$ so $F_{\max} = kA = (26.0 \text{ N/m})(0.0740 \text{ m}) = 1.92 \text{ N}.$

(e) $x(t)$ evaluated at $t = 1.00$ s gives $x = -0.0125$ m. $v_x = -\omega A\sin(\omega t + \phi) = 30.4$ cm/s.

$a_x = -kx/m = -\omega^2 x = +0.216 \text{ m/s}^2.$

(f) $F_x = -kx = -(26.0 \text{ N/m})(-0.0125 \text{ m}) = +0.325 \text{ N}$

EVALUATE: The maximum speed occurs when $x = 0$ and the maximum force is when $x = \pm A$.

14.20. **IDENTIFY:** The frequency of vibration of a spring depends on the mass attached to the spring. Differences in frequency are due to differences in mass, so by measuring the frequencies we can determine the mass of the virus, which is the target variable.

SET UP: The frequency of vibration is $f = \dfrac{1}{2\pi}\sqrt{\dfrac{k}{m}}.$

Solve: **(a)** The frequency without the virus is $f_{\text{s}} = \dfrac{1}{2\pi}\sqrt{\dfrac{k}{m_{\text{s}}}},$ and the frequency with the virus is

$f_{\text{s+v}} = \dfrac{1}{2\pi}\sqrt{\dfrac{k}{m_{\text{s}} + m_{\text{v}}}}.$ $\dfrac{f_{\text{s+v}}}{f_{\text{s}}} = \left(\dfrac{1}{2\pi}\sqrt{\dfrac{k}{m_{\text{s}} + m_{\text{v}}}}\right)\left(2\pi\sqrt{\dfrac{m_{\text{s}}}{k}}\right) = \sqrt{\dfrac{m_{\text{s}}}{m_{\text{s}} + m_{\text{v}}}} = \dfrac{1}{\sqrt{1 + m_{\text{v}}/m_{\text{s}}}}.$

(b) $\left(\dfrac{f_{\text{s+v}}}{f_{\text{s}}}\right)^2 = \dfrac{1}{1 + m_{\text{v}}/m_{\text{s}}}.$ Solving for m_{v} gives

$m_{\text{v}} = m_{\text{s}}\left(\left[\dfrac{f_{\text{s}}}{f_{\text{s+v}}}\right]^2 - 1\right) = (2.10\times10^{-16} \text{ g})\left(\left[\dfrac{2.00\times10^{15} \text{ Hz}}{2.87\times10^{14} \text{ Hz}}\right]^2 - 1\right) = 9.99\times10^{-15} \text{ g}, \text{ or}$

$m_{\text{v}} = 9.99$ femtograms.

EVALUATE: When the mass increases, the frequency of oscillation increases.

14.21. **IDENTIFY** and **SET UP:** Use Eqs. (14.13), (14.15) and (14.16).

EXECUTE: $f = 440$ Hz, $A = 3.0$ mm, $\phi = 0$

(a) $x = A\cos(\omega t + \phi)$

$\omega = 2\pi f = 2\pi(440 \text{ Hz}) = 2.76\times10^3 \text{ rad/s}$

$x = (3.0\times10^{-3} \text{ m})\cos((2.76\times10^3 \text{ rad/s})t)$

(b) $v_x = -\omega A\sin(\omega t + \phi)$

$v_{\max} = \omega A = (2.76\times10^3 \text{ rad/s})(3.0\times10^{-3} \text{ m}) = 8.3 \text{ m/s}$ (maximum magnitude of velocity)

$a_x = -\omega^2 A\cos(\omega t + \phi)$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$a_{max} = \omega^2 A = (2.76\times10^3 \text{ rad/s})^2(3.0\times10^{-3} \text{ m}) = 2.3\times10^4 \text{ m/s}^2$ (maximum magnitude of acceleration)

(c) $a_x = -\omega^2 A\cos\omega t$

$da_x/dt = +\omega^3 A\sin\omega t = [2\pi(440 \text{ Hz})]^3 (3.0\times10^{-3} \text{ m})\sin([2.76\times10^3 \text{ rad/s}]t) =$

$(6.3\times10^7 \text{ m/s}^3)\sin([2.76\times10^3 \text{rad/s}]t)$

Maximum magnitude of the jerk is $\omega^3 A = 6.3\times10^7 \text{ m/s}^3$

EVALUATE: The period of the motion is small, so the maximum acceleration and jerk are large.

14.22. **IDENTIFY:** The mechanical energy of the system is conserved. The maximum acceleration occurs at the maximum displacement and the motion is SHM.

SET UP: Energy conservation gives $\frac{1}{2}mv_{max}^2 = \frac{1}{2}kA^2$, $T = 2\pi\sqrt{\frac{m}{k}}$, and $a_{max} = \frac{kA}{m}$.

EXECUTE: **(a)** From the graph, we read off T = 16.0 s and A = 10.0 cm = 0.100 m. $\frac{1}{2}mv_{max}^2 = \frac{1}{2}kA^2$ gives $v_{max} = A\sqrt{\frac{k}{m}}$. $T = 2\pi\sqrt{\frac{m}{k}}$, so $\sqrt{\frac{k}{m}} = \frac{2\pi}{T}$. Therefore $v_{max} = A\left(\frac{2\pi}{T}\right) = (0.100 \text{ m})\left(\frac{2\pi}{16.0 \text{ s}}\right) = 0.0393 \text{ m/s}$.

(b) $a_{max} = \frac{kA}{m} = \left(\frac{2\pi}{T}\right)^2 A = \left(\frac{2\pi}{16.0 \text{ s}}\right)^2 (0.100 \text{ m}) = 0.0154 \text{ m/s}^2$

EVALUATE: The acceleration is much less than g.

14.23. **IDENTIFY:** The mechanical energy of the system is conserved. The maximum acceleration occurs at the maximum displacement and the motion is SHM.

SET UP: Energy conservation gives $\frac{1}{2}mv_{max}^2 = \frac{1}{2}kA^2$ and $a_{max} = \frac{kA}{m}$.

EXECUTE: $A = 0.120$ m. $\frac{1}{2}mv_{max}^2 = \frac{1}{2}kA^2$ gives $\frac{k}{m} = \left(\frac{v_{max}}{A}\right)^2 = \left(\frac{3.90 \text{ m/s}}{0.120 \text{ m}}\right)^2 = 1056 \text{ s}^{-2}$.

$a_{max} = \frac{kA}{m} = (1056 \text{ s}^{-2})(0.120 \text{ m}) = 127 \text{ m/s}^2$

EVALUATE: The acceleration is much greater than g.

14.24. **IDENTIFY:** The mechanical energy of the system is conserved, Newton's second law applies and the motion is SHM.

SET UP: Energy conservation gives $\frac{1}{2}mv_x^2 + \frac{1}{2}kx^2 = \frac{1}{2}kA^2$, $F_x = ma_x$, $F_x = -kx$, and the period is $T = 2\pi\sqrt{\frac{m}{k}}$.

EXECUTE: Solving $\frac{1}{2}mv_x^2 + \frac{1}{2}kx^2 = \frac{1}{2}kA^2$ for v_x gives $v_x = \sqrt{\frac{k}{m}}\sqrt{A^2 - x^2}$. $T = 2\pi\sqrt{\frac{m}{k}}$, so $\sqrt{\frac{k}{m}} = \frac{2\pi}{T} = \frac{2\pi}{3.20 \text{ s}} = 1.963 \text{ s}^{-1}$. $v_x = (1.963 \text{ s}^{-1})\sqrt{(0.250 \text{ m})^2 - (0.160 \text{ m})^2} = 0.377 \text{ m/s}$.

$a_x = -\frac{kx}{m} = -(1.963 \text{ s}^{-1})^2 (0.160 \text{ m}) = -0.617 \text{ m/s}^2$.

EVALUATE: The block is on the positive side of the equilibrium position $(x = 0)$ and is moving in the positive direction but is accelerating in the negative direction, so it must be slowing down.

14.25. **IDENTIFY:** $v_{max} = \omega A = 2\pi fA$. $K_{max} = \frac{1}{2}mv_{max}^2$

SET UP: The fly has the same speed as the tip of the tuning fork.

EXECUTE: **(a)** $v_{max} = 2\pi fA = 2\pi(392 \text{ Hz})(0.600\times10^{-3} \text{ m}) = 1.48 \text{ m/s}$

(b) $K_{max} = \frac{1}{2}mv_{max}^2 = \frac{1}{2}(0.0270\times10^{-3} \text{ kg})(1.48 \text{ m/s})^2 = 2.96\times10^{-5} \text{ J}$

EVALUATE: v_{max} is directly proportional to the frequency and to the amplitude of the motion.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

14.26. **IDENTIFY** and **SET UP:** Use Eq. (14.21) to relate K and U. U depends on x and K depends on v_x.

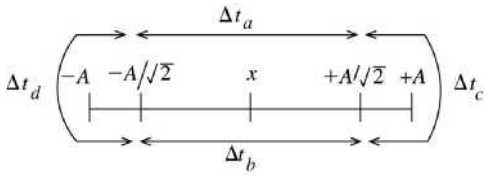
EXECUTE: **(a)** $U + K = E$, so $U = K$ says that $2U = E$

$2\left(\frac{1}{2}kx^2\right) = \frac{1}{2}kA^2$ and $x = \pm A/\sqrt{2}$; magnitude is $A/\sqrt{2}$

But $U = K$ also implies that $2K = E$

$2\left(\frac{1}{2}mv_x^2\right) = \frac{1}{2}kA^2$ and $v_x = \pm\sqrt{k/m}\,A/\sqrt{2} = \pm\omega A/\sqrt{2}$; magnitude is $\omega A/\sqrt{2}$.

(b) In one cycle x goes from A to 0 to $-A$ to 0 to $+A$. Thus $x = +A\sqrt{2}$ twice and $x = -A/\sqrt{2}$ twice in each cycle. Therefore, $U = K$ four times each cycle. The time between $U = K$ occurrences is the time Δt_a for $x_1 = +A/\sqrt{2}$ to $x_2 = -A\sqrt{2}$, time Δt_b for $x_1 = -A/\sqrt{2}$ to $x_2 = +A/\sqrt{2}$, time Δt_c for $x_1 = +A/\sqrt{2}$ to $x_2 = +A\sqrt{2}$, or the time Δt_d for $x_1 = -A/\sqrt{2}$ to $x_2 = -A/\sqrt{2}$, as shown in Figure 14.26.



$\Delta t_a = \Delta t_b$

$\Delta t_c = \Delta t_d$

Figure 14.26

Calculation of Δt_a:

Specify x in $x = A\cos\omega t$ (choose $\phi = 0$ so $x = A$ at $t = 0$) and solve for t.

$x_1 = +A/\sqrt{2}$ implies $A/\sqrt{2} = A\cos(\omega t_1)$

$\cos\omega t_1 = 1/\sqrt{2}$ so $\omega t_1 = \arccos(1/\sqrt{2}) = \pi/4$ rad

$t_1 = \pi/4\omega$

$x_2 = -A/\sqrt{2}$ implies $-A/\sqrt{2} = A\cos(\omega t_2)$

$\cos\omega t_2 = -1/\sqrt{2}$ so $\omega t_1 = 3\pi/4$ rad

$t_2 = 3\pi/4\omega$

$\Delta t_a = t_2 - t_1 = 3\pi/4\omega - \pi/4\omega = \pi/2\omega$ (Note that this is $T/4$, one fourth period.)

Calculation of Δt_d:

$x_1 = -A/\sqrt{2}$ implies $t_1 = 3\pi/4\omega$

$x_2 = -A/\sqrt{2}$, t_2 is the *next* time after t_1 that gives $\cos\omega t_2 = -1/\sqrt{2}$

Thus $\omega t_2 = \omega t_1 + \pi/2 = 5\pi/4$ and $t_2 = 5\pi/4\omega$

$\Delta t_d = t_2 - t_1 = 5\pi/4\omega - 3\pi/4\omega = \pi/2\omega$, so is the same as Δt_a.

Therfore the occurrences of $K = U$ are equally spaced in time, with a time interval between them of $\pi/2\omega$.

EVALUATE: This is one-fourth T, as it must be if there are 4 equally spaced occurrences each period.

(c) EXECUTE: $x = A/2$ and $U + K = E$

$K = E - U = \frac{1}{2}kA^2 - \frac{1}{2}kx^2 = \frac{1}{2}kA^2 - \frac{1}{2}k(A/2)^2 = \frac{1}{2}kA^2 - \frac{1}{8}kA^2 = 3kA^2/8$

Then $\frac{K}{E} = \frac{3kA^2/8}{\frac{1}{2}kA^2} = \frac{3}{4}$ and $\frac{U}{E} = \frac{\frac{1}{8}kA^2}{\frac{1}{2}kA^2} = \frac{1}{4}$

EVALUATE: At $x = 0$ all the energy is kinetic and at $x = \pm A$ all the energy is potiential. But $K = U$ does not occur at $x = \pm A/2$, since U is not linear in x.

14.27. **IDENTIFY:** Velocity and position are related by $E=\frac{1}{2}kA^2=\frac{1}{2}mv_x^2+\frac{1}{2}kx^2$. Acceleration and position are related by $-kx=ma_x$.

SET UP: The maximum speed is at $x=0$ and the maximum magnitude of acceleration is at $x=\pm A$.

EXECUTE: **(a)** For $x=0$, $\frac{1}{2}mv_{\max}^2=\frac{1}{2}kA^2$ and $v_{\max}=A\sqrt{\frac{k}{m}}=(0.040\text{ m})\sqrt{\frac{450\text{ N/m}}{0.500\text{ kg}}}=1.20\text{ m/s}$

(b) $v_x=\pm\sqrt{\frac{k}{m}}\sqrt{A^2-x^2}=\pm\sqrt{\frac{450\text{ N/m}}{0.500\text{ kg}}}\sqrt{(0.040\text{ m})^2-(0.015\text{ m})^2}=\pm 1.11\text{ m/s}.$

The speed is $v=1.11$ m/s.

(c) For $x=\pm A$, $a_{\max}=\frac{k}{m}A=\left(\frac{450\text{ N/m}}{0.500\text{ kg}}\right)(0.040\text{ m})=36\text{ m/s}^2$

(d) $a_x=-\frac{kx}{m}=-\frac{(450\text{ N/m})(-0.015\text{ m})}{0.500\text{ kg}}=+13.5\text{ m/s}^2$

(e) $E=\frac{1}{2}kA^2=\frac{1}{2}(450\text{ N/m})(0.040\text{ m})^2=0.360\text{ J}$

EVALUATE: The speed and acceleration at $x=-0.015$ m are less than their maximum values.

14.28. **IDENTIFY** and **SET UP:** a_x is related to x by Eq. (14.4) and v_x is related to x by Eq. (14.21). a_x is a maximum when $x=\pm A$ and v_x is a maximum when $x=0$. t is related to x by Eq. (14.13).

EXECUTE: **(a)** $-kx=ma_x$ so $a_x=-(k/m)x$ (Eq.14.4). But the maximum $|x|$ is A, so

$a_{\max}=(k/m)A=\omega^2A.$

$f=0.850$ Hz implies $\omega=\sqrt{k/m}=2\pi f=2\pi(0.850\text{ Hz})=5.34$ rad/s.

$a_{\max}=\omega^2A=(5.34\text{ rad/s})^2(0.180\text{ m})=5.13\text{ m/s}^2.$

$\frac{1}{2}mv_x^2+\frac{1}{2}kx^2=\frac{1}{2}kA^2$

$v_x=v_{\max}$ when $x=0$ so $\frac{1}{2}mv_{\max}^2=\frac{1}{2}kA^2$

$v_{\max}=\sqrt{k/m}A=\omega A=(5.34\text{ rad/s})(0.180\text{ m})=0.961\text{ m/s}$

(b) $a_x=-(k/m)x=-\omega^2x=-(5.34\text{ rad/s})^2(0.090\text{ m})=-2.57\text{ m/s}^2$

$\frac{1}{2}mv_x^2+\frac{1}{2}kx^2=\frac{1}{2}kA^2$ says that $v_x=\pm\sqrt{k/m}\sqrt{A^2-x^2}=\pm\omega\sqrt{A^2-x^2}$

$v_x=\pm(5.34\text{ rad/s})\sqrt{(0.180\text{ m})^2-(0.090\text{ m})^2}=\pm 0.832\text{ m/s}$

The speed is 0.832 m/s.

(c) $x=A\cos(\omega t+\phi)$

Let $\phi=-\pi/2$ so that $x=0$ at $t=0$.

Then $x=A\cos(\omega t-\pi/2)=A\sin(\omega t)$ [Using the trig identity $\cos(a-\pi/2)=\sin a$]

Find the time t that gives $x=0.120$ m.

$0.120\text{ m}=(0.180\text{ m})\sin(\omega t)$

$\sin\omega t=0.6667$

$t=\arcsin(0.6667)/\omega=0.7297\text{ rad}/(5.34\text{ rad/s})=0.137\text{ s}$

EVALUATE: It takes one-fourth of a period for the object to go from $x=0$ to $x=A=0.180$ m. So the time we have calculated should be less than $T/4$. $T=1/f=1/0.850\text{ Hz}=1.18$ s, $T/4=0.295$ s, and the time we calculated is less than this. Note that the a_x and v_x we calculated in part (b) are smaller in magnitude than the maximum values we calculated in part (b).

(d) The conservation of energy equation relates v and x and $F=ma$ relates a and x. So the speed and acceleration can be found by energy methods but the time cannot.

Specifying x uniquely determines a_x but determines only the magnitude of v_x; at a given x the object could be moving either in the $+x$ or $-x$ direction.

14.29. **IDENTIFY:** Use the results of Example 14.5 and also that $E = \frac{1}{2}kA^2$.

SET UP: In the example, $A_2 = A_1\sqrt{\frac{M}{M+m}}$ and now we want $A_2 = \frac{1}{2}A_1$. Therefore, $\frac{1}{2} = \sqrt{\frac{M}{M+m}}$, or $m = 3M$. For the energy, $E_2 = \frac{1}{2}kA_2^2$, but since $A_2 = \frac{1}{2}A_1$, $E_2 = \frac{1}{4}E_1$, and $\frac{3}{4}E_1$ is lost to heat.

EXECUTE: The putty and the moving block undergo a totally inelastic collision and the mechanical energy of the system decreases.

14.30. **IDENTIFY** and **SET UP:** Use Eq. (14.21). $x = \pm A\omega$ when $v_x = 0$ and $v_x = \pm v_{\max}$ when $x = 0$.

EXECUTE: **(a)** $E = \frac{1}{2}mv^2 + \frac{1}{2}kx^2$

$E = \frac{1}{2}(0.150\text{ kg})(0.300\text{ m/s})^2 + \frac{1}{2}(300\text{ N/m})(0.012\text{ m})^2 = 0.0284\text{ J}$

(b) $E = \frac{1}{2}kA^2$ so $A = \sqrt{2E/k} = \sqrt{2(0.0284\text{ J})/300\text{ N/m}} = 0.014\text{ m}$

(c) $E = \frac{1}{2}mv_{\max}^2$ so $v_{\max} = \sqrt{2E/m} = \sqrt{2(0.0284\text{ J})/0.150\text{ kg}} = 0.615\text{ m/s}$

EVALUATE: The total energy E is constant but is transferred between kinetic and potential energy during the motion.

14.31. **IDENTIFY:** Conservation of energy says $\frac{1}{2}mv^2 + \frac{1}{2}kx^2 = \frac{1}{2}kA^2$ and Newton's second law says $-kx = ma_x$.

SET UP: Let $+x$ be to the right. Let the mass of the object be m.

EXECUTE: $k = -\frac{ma_x}{x} = -m\left(\frac{-8.40\text{ m/s}^2}{0.600\text{ m}}\right) = (14.0\text{ s}^{-2})m.$

$A = \sqrt{x^2 + (m/k)v^2} = \sqrt{(0.600\text{ m})^2 + \left(\frac{m}{[14.0\text{ s}^{-2}]m}\right)(2.20\text{ m/s})^2} = 0.840\text{ m}$. The object will therefore travel $0.840\text{ m} - 0.600\text{ m} = 0.240\text{ m}$ to the right before stopping at its maximum amplitude.

EVALUATE: The acceleration is not constant and we cannot use the constant acceleration kinematic equations.

14.32. **IDENTIFY:** When the box has its maximum speed all of the energy of the system is in the form of kinetic energy. When the stone is removed the oscillating mass is decreased and the speed of the remaining mass is unchanged. The period is given by $T = 2\pi\sqrt{\frac{m}{k}}$.

SET UP: The maximum speed is $v_{\max} = \omega A = \sqrt{\frac{k}{m}}A$. With the stone in the box $m = 8.64\text{ kg}$ and $A = 0.0750\text{ m}$.

EXECUTE: **(a)** $T = 2\pi\sqrt{\frac{m}{k}} = 2\pi\sqrt{\frac{5.20\text{ kg}}{375\text{ N/m}}} = 0.740\text{ s}$

(b) Just before the stone is removed, the speed is $v_{\max} = \sqrt{\frac{375\text{ N/m}}{8.64\text{ kg}}}(0.0750\text{ m}) = 0.494\text{ m/s}$. The speed of the box isn't altered by removing the stone but the mass on the spring decreases to 5.20 kg. The new amplitude is $A = \sqrt{\frac{m}{k}}v_{\max} = \sqrt{\frac{5.20\text{ kg}}{375\text{ N/m}}}(0.494\text{ m/s}) = 0.0582\text{ m}$. The new amplitude can also be calculated as $\sqrt{\frac{5.20\text{ kg}}{8.64\text{ kg}}}(0.0750\text{ m}) = 0.0582\text{ m}$.

(c) $T = 2\pi\sqrt{\frac{m}{k}}$. The force constant remains the same. m decreases, so T decreases.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: After the stone is removed, the energy left in the system is $\frac{1}{2}m_{\text{box}}v_{\text{max}}^2 = \frac{1}{2}(5.20\text{ kg})(0.494\text{ m/s})^2 = 0.6345\text{ J}$. This then is the energy stored in the spring at its maximum extension or compression and $\frac{1}{2}kA^2 = 0.6345\text{ J}$. This gives the new amplitude to be 0.0582 m, in agreement with our previous calculation.

14.33. **IDENTIFY:** The mechanical energy (the sum of the kinetic energy and potential energy) is conserved.

SET UP: $K + U = E$, with $E = \frac{1}{2}kA^2$ and $U = \frac{1}{2}kx^2$

EXECUTE: $U = K$ says $2U = E$. This gives $2(\frac{1}{2}kx^2) = \frac{1}{2}kA^2$, so $x = A/\sqrt{2}$.

EVALUATE: When $x = A/2$ the kinetic energy is three times the elastic potential energy.

14.34. **IDENTIFY:** The velocity is a sinusoidal function. From the graph we can read off the period and use it to calculate the other quantities.

SET UP: The period is the time for 1 cycle; after time T the motion repeats. The graph shows that $T = 1.60$ s and $v_{\text{max}} = 20.0$ cm/s. Mechanical energy is conserved, so $\frac{1}{2}mv_x^2 + \frac{1}{2}kx^2 = \frac{1}{2}kA^2$, and Newton's second law applies to the mass.

EXECUTE: **(a)** $T = 1.60$ s (from the graph).

(b) $f = \dfrac{1}{T} = 0.625$ Hz.

(c) $\omega = 2\pi f = 3.93$ rad/s.

(d) $v_x = v_{\text{max}}$ when $x = 0$ so $\frac{1}{2}kA^2 = \frac{1}{2}mv_{\text{max}}^2$. $A = v_{\text{max}}\sqrt{\dfrac{m}{k}}$. $f = \dfrac{1}{2\pi}\sqrt{\dfrac{k}{m}}$ so $A = v_{\text{max}}/(2\pi f)$. From the graph in the problem, $v_{\text{max}} = 0.20$ m/s, so $A = \dfrac{0.20\text{ m/s}}{2\pi(0.625\text{ Hz})} = 0.051\text{ m} = 5.1\text{ cm}$. The mass is at $x = \pm A$ when $v_x = 0$, and this occurs at $t = 0.4$ s, 1.2 s, and 1.8 s.

(e) Newton's second law gives $-kx = ma_x$, so

$a_{\text{max}} = \dfrac{kA}{m} = (2\pi f)^2 A = (4\pi^2)(0.625\text{ Hz})^2(0.051\text{ m}) = 0.79\text{ m/s}^2 = 79\text{ cm/s}^2$. The acceleration is maximum when $x = \pm A$ and this occurs at the times given in (d).

(f) $T = 2\pi\sqrt{\dfrac{m}{k}}$ so $m = k\left(\dfrac{T}{2\pi}\right)^2 = (75\text{ N/m})\left(\dfrac{1.60\text{ s}}{2\pi}\right)^2 = 4.9\text{ kg}$.

EVALUATE: The speed is maximum at $x = 0$, when $a_x = 0$. The magnitude of the acceleration is maximum at $x = \pm A$, where $v_x = 0$.

14.35. **IDENTIFY:** Work in an inertial frame moving with the vehicle after the engines have shut off. The acceleration before engine shut-off determines the amount the spring is initially stretched. The initial speed of the ball relative to the vehicle is zero.

SET UP: Before the engine shut-off the ball has acceleration $a = 5.00\text{ m/s}^2$.

EXECUTE: **(a)** $F_x = -kx = ma_x$ gives $A = \dfrac{ma}{k} = \dfrac{(3.50\text{ kg})(5.00\text{ m/s}^2)}{225\text{ N/m}} = 0.0778\text{ m}$. This is the amplitude of the subsequent motion.

(b) $f = \dfrac{1}{2\pi}\sqrt{\dfrac{k}{m}} = \dfrac{1}{2\pi}\sqrt{\dfrac{225\text{ N/m}}{3.50\text{ kg}}} = 1.28\text{ Hz}$

(c) Energy conservation gives $\frac{1}{2}kA^2 = \frac{1}{2}mv_{\text{max}}^2$ and $v_{\text{max}} = \sqrt{\dfrac{k}{m}}A = \sqrt{\dfrac{225\text{ N/m}}{3.50\text{ kg}}}(0.0778\text{ m}) = 0.624\text{ m/s}$.

EVALUATE: During the simple harmonic motion of the ball its maximum acceleration, when $x = \pm A$, continues to have magnitude 5.00 m/s^2.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

14.36. **IDENTIFY:** Use the amount the spring is stretched by the weight of the fish to calculate the force constant k of the spring. $T = 2\pi\sqrt{m/k}$. $v_{max} = \omega A = 2\pi fA$.

SET UP: When the fish hangs at rest the upward spring force $|F_x| = kx$ equals the weight mg of the fish. $f = 1/T$. The amplitude of the SHM is 0.0500 m.

EXECUTE: **(a)** $mg = kx$ so $k = \dfrac{mg}{x} = \dfrac{(65.0\text{ kg})(9.80\text{ m/s}^2)}{0.120\text{ m}} = 5.31\times10^3\text{ N/m}$.

(b) $T = 2\pi\sqrt{\dfrac{m}{k}} = 2\pi\sqrt{\dfrac{65.0\text{ kg}}{5.31\times10^3\text{ N/m}}} = 0.695\text{ s}$.

(c) $v_{max} = 2\pi fA = \dfrac{2\pi A}{T} = \dfrac{2\pi(0.0500\text{ m})}{0.695\text{ s}} = 0.452\text{ m/s}$

EVALUATE: Note that T depends only on m and k and is independent of the distance the fish is pulled down. But v_{max} does depend on this distance.

14.37. **IDENTIFY:** Initially part of the energy is kinetic energy and part is potential energy in the stretched spring. When $x = \pm A$ all the energy is potential energy and when the glider has its maximum speed all the energy is kinetic energy. The total energy of the system remains constant during the motion.

SET UP: Initially $v_x = \pm 0.815$ m/s and $x = \pm 0.0300$ m.

EXECUTE: **(a)** Initially the energy of the system is
$E = \frac{1}{2}mv^2 + \frac{1}{2}kx^2 = \frac{1}{2}(0.175\text{ kg})(0.815\text{ m/s})^2 + \frac{1}{2}(155\text{ N/m})(0.0300\text{ m})^2 = 0.128\text{ J}$. $\frac{1}{2}kA^2 = E$ and

$A = \sqrt{\dfrac{2E}{k}} = \sqrt{\dfrac{2(0.128\text{ J})}{155\text{ N/m}}} = 0.0406\text{ m} = 4.06\text{ cm}$.

(b) $\frac{1}{2}mv_{max}^2 = E$ and $v_{max} = \sqrt{\dfrac{2E}{m}} = \sqrt{\dfrac{2(0.128\text{ J})}{0.175\text{ kg}}} = 1.21\text{ m/s}$.

(c) $\omega = \sqrt{\dfrac{k}{m}} = \sqrt{\dfrac{155\text{ N/m}}{0.175\text{ kg}}} = 29.8\text{ rad/s}$

EVALUATE: The amplitude and the maximum speed depend on the total energy of the system but the angular frequency is independent of the amount of energy in the system and just depends on the force constant of the spring and the mass of the object.

14.38. **IDENTIFY:** $K = \frac{1}{2}mv^2$, $U_{grav} = mgy$ and $U_{el} = \frac{1}{2}kx^2$.

SET UP: At the lowest point of the motion, the spring is stretched an amount $2A$.

EXECUTE: **(a)** At the top of the motion, the spring is unstretched and so has no potential energy, the cat is not moving and so has no kinetic energy, and the gravitational potential energy relative to the bottom is $2mgA = 2(4.00\text{ kg})(9.80\text{ m/s}^2)(0.050\text{ m}) = 3.92$ J. This is the total energy, and is the same total for each part.

(b) $U_{grav} = 0, K = 0,$ so $U_{spring} = 3.92$ J.

(c) At equilibrium the spring is stretched half as much as it was for part (a), and so
$U_{spring} = \frac{1}{4}(3.92\text{ J}) = 0.98$ J, $U_{grav} = \frac{1}{2}(3.92\text{ J}) = 1.96$ J, and so $K = 0.98$ J.

EVALUATE: During the motion, work done by the forces transfers energy among the forms kinetic energy, gravitational potential energy and elastic potential energy.

14.39. **IDENTIFY:** The location of the equilibrium position, the position where the downward gravity force is balanced by the upward spring force, changes when the mass of the suspended object changes.

SET UP: At the equilibrium position, the spring is stretched a distance d. The amplitude is the maximum distance of the object from the equilibrium position.

EXECUTE: **(a)** The force of the glue on the lower ball is the upward force that accelerates that ball upward. The upward acceleration of the two balls is greatest when they have the greatest downward displacement, so this is when the force of the glue must be greatest.

(b) With both balls, the distance d_1 that the spring is stretched at equilibrium is given by
$kd_1 = (1.50\text{ kg} + 2.00\text{ kg})g$ and $d_1 = 20.8$ cm. At the lowest point the spring is stretched

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$20.8\text{ cm} + 15.0\text{ cm} = 35.8\text{ cm}$. After the 1.50 kg ball falls off the distance d_2 that the spring is stretched at equilibrium is given by $kd_2 = (2.00\text{ kg})g$ and $d_2 = 11.9\text{ cm}$. The new amplitude is $35.8\text{ cm} - 11.9\text{ cm} = 23.9\text{ cm}$. The new frequency is $f = \frac{1}{2\pi}\sqrt{\frac{k}{m}} = \frac{1}{2\pi}\sqrt{\frac{165\text{ N/m}}{2.00\text{ kg}}} = 1.45\text{ Hz}$.

EVALUATE: The potential energy stored in the spring doesn't change when the lower ball comes loose.

14.40. **IDENTIFY:** The torsion constant κ is defined by $\tau_z = -\kappa\theta$. $f = \frac{1}{2\pi}\sqrt{\frac{\kappa}{I}}$ and $T = 1/f$. $\theta(t) = \Theta\cos(\omega t + \phi)$.

SET UP: For the disk, $I = \frac{1}{2}MR^2$. $\tau_z = -FR$. At $t = 0$, $\theta = \Theta = 3.34° = 0.0583\text{ rad}$, so $\phi = 0$.

EXECUTE: **(a)** $\kappa = -\frac{\tau_z}{\theta} = -\frac{-FR}{0.0583\text{ rad}} = +\frac{(4.23\text{ N})(0.120\text{ m})}{0.0583\text{ rad}} = 8.71\text{ N}\cdot\text{m/rad}$

(b) $f = \frac{1}{2\pi}\sqrt{\frac{\kappa}{I}} = \frac{1}{2\pi}\sqrt{\frac{2\kappa}{MR^2}} = \frac{1}{2\pi}\sqrt{\frac{2(8.71\text{ N}\cdot\text{m/rad})}{(6.50\text{ kg})(0.120\text{ m})^2}} = 2.17\text{ Hz}$. $T = 1/f = 0.461\text{ s}$.

(c) $\omega = 2\pi f = 13.6\text{ rad/s}$. $\theta(t) = (3.34°)\cos([13.6\text{ rad/s}]t)$.

EVALUATE: The frequency and period are independent of the initial angular displacement, so long as this displacement is small.

14.41. **IDENTIFY** and **SET UP:** The number of ticks per second tells us the period and therefore the frequency. We can use a formula from Table 9.2 to calculate *I*. Then Eq. (14.24) allows us to calculate the torsion constant κ.

EXECUTE: Ticks four times each second implies 0.25 s per tick. Each tick is half a period, so $T = 0.50\text{ s}$ and $f = 1/T = 1/0.50\text{ s} = 2.00\text{ Hz}$.

(a) Thin rim implies $I = MR^2$ (from Table 9.2). $I = (0.900\times10^{-3}\text{ kg})(0.55\times10^{-2}\text{ m})^2 = 2.7\times10^{-8}\text{ kg}\cdot\text{m}^2$

(b) $T = 2\pi\sqrt{I/\kappa}$ so $\kappa = I(2\pi/T)^2 = (2.7\times10^{-8}\text{ kg}\cdot\text{m}^2)(2\pi/0.50\text{ s})^2 = 4.3\times10^{-6}\text{ N}\cdot\text{m/rad}$

EVALUATE: Both *I* and κ are small numbers.

14.42. **IDENTIFY:** Eq. (14.24) and $T = 1/f$ says $T = 2\pi\sqrt{\frac{I}{\kappa}}$.

SET UP: $I = \frac{1}{2}mR^2$.

EXECUTE: Solving Eq. (14.24) for κ in terms of the period,

$\kappa = \left(\frac{2\pi}{T}\right)^2 I = \left(\frac{2\pi}{1.00\text{ s}}\right)^2((1/2)(2.00\times10^{-3}\text{ kg})(2.20\times10^{-2}\text{ m})^2) = 1.91\times10^{-5}\text{ N}\cdot\text{m/rad}$.

EVALUATE: The longer the period, the smaller the torsion constant.

14.43. **IDENTIFY:** $f = \frac{1}{2\pi}\sqrt{\frac{\kappa}{I}}$.

SET UP: $f = 125/(265\text{ s})$, the number of oscillations per second.

EXECUTE: $I = \frac{\kappa}{(2\pi f)^2} = \frac{0.450\text{ N}\cdot\text{m/rad}}{(2\pi(125)/(265\text{ s}))^2} = 0.0512\text{ kg}\cdot\text{m}^2$.

EVALUATE: For a larger *I*, *f* is smaller.

14.44. **IDENTIFY:** $\theta(t)$ is given by $\theta(t) = \Theta\cos(\omega t + \phi)$. Evaluate the derivatives specified in the problem.

SET UP: $d(\cos\omega t)/dt = -\omega\sin\omega t$. $d(\sin\omega t)/dt = \omega\cos\omega t$. $\sin^2\theta + \cos^2\theta = 1$

In this problem, $\varphi = 0$.

EXECUTE: **(a)** $\frac{d\theta}{dt} = -\omega\Theta\sin(\omega t)$ and $\alpha = \frac{d^2\theta}{dt^2} = -\omega^2\Theta\cos(\omega t)$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) When the angular displacement is Θ, $\Theta = \Theta\cos(\omega t)$. This occurs at $t = 0$, so $\omega = 0$. $\alpha = -\omega^2\Theta$.

When the angular displacement is $\Theta/2$, $\frac{\Theta}{2} = \Theta\cos(\omega t)$, or $\frac{1}{2} = \cos(\omega t)$. $\frac{d\theta}{dt} = \frac{-\omega\Theta\sqrt{3}}{2}$ since $\sin(\omega t) = \frac{\sqrt{3}}{2}$. $\alpha = \frac{-\omega^2\Theta}{2}$, since $\cos(\omega t) = 1/2$.

EVALUATE: $\cos(\omega t) = \frac{1}{2}$ when $\omega t = \pi/3$ rad $= 60°$. At this t, $\cos(\omega t)$ is decreasing and θ is decreasing, as required. There are other, larger values of ωt for which $\theta = \Theta/2$, but θ is increasing.

14.45. **IDENTIFY:** $T = 2\pi\sqrt{L/g}$ is the time for one complete swing.

SET UP: The motion from the maximum displacement on either side of the vertical to the vertical position is one-fourth of a complete swing.

EXECUTE: **(a)** To the given precision, the small-angle approximation is valid. The highest speed is at the bottom of the arc, which occurs after a quarter period, $\frac{T}{4} = \frac{\pi}{2}\sqrt{\frac{L}{g}} = 0.25$ s.

(b) The same as calculated in (a), 0.25 s. The period is independent of amplitude.

EVALUATE: For small amplitudes of swing, the period depends on L and g.

14.46. **IDENTIFY:** Since the rope is long compared to the height of a person, the system can be modeled as a simple pendulum. Since the amplitude is small, the period of the motion is $T = 2\pi\sqrt{\frac{L}{g}}$.

SET UP: From his initial position to his lowest point is one-fourth of a cycle. He returns to this lowest point in time $T/2$ from when he was previously there.

EXECUTE: **(a)** $T = 2\pi\sqrt{\frac{6.50\text{ m}}{9.80\text{ m/s}^2}} = 5.12$ s. $t = T/4 = 1.28$ s.

(b) $t = 3T/4 = 3.84$ s.

EVALUATE: The period is independent of his mass.

14.47. **IDENTIFY:** Since the cord is much longer than the height of the object, the system can be modeled as a simple pendulum. We will assume the amplitude of swing is small, so that $T = 2\pi\sqrt{\frac{L}{g}}$.

SET UP: The number of swings per second is the frequency $f = \frac{1}{T} = \frac{1}{2\pi}\sqrt{\frac{g}{L}}$.

EXECUTE: $f = \frac{1}{2\pi}\sqrt{\frac{9.80\text{ m/s}^2}{1.50\text{ m}}} = 0.407$ swings per second.

EVALUATE: The period and frequency are both independent of the mass of the object.

14.48. **IDENTIFY:** Use Eq. (14.34) to relate the period to g.

SET UP: Let the period on earth be $T_E = 2\pi\sqrt{L/g_E}$, where $g_E = 9.80$ m/s^2, the value on earth.

Let the period on Mars be $T_M = 2\pi\sqrt{L/g_M}$, where $g_M = 3.71$ m/s^2, the value on Mars.

We can eliminate L, which we don't know, by taking a ratio:

EXECUTE: $\frac{T_M}{T_E} = 2\pi\sqrt{\frac{L}{g_M}}\frac{1}{2\pi}\sqrt{\frac{g_E}{L}} = \sqrt{\frac{g_E}{g_M}}$.

$T_M = T_E\sqrt{\frac{g_E}{g_M}} = (1.60\text{ s})\sqrt{\frac{9.80\text{ m/s}^2}{3.71\text{ m/s}^2}} = 2.60$ s.

EVALUATE: Gravity is weaker on Mars so the period of the pendulum is longer there.

14.49. **IDENTIFY:** Apply $T = 2\pi\sqrt{L/g}$

SET UP: The period of the pendulum is $T = (136\text{ s})/100 = 1.36$ s.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: $g = \dfrac{4\pi^2 L}{T^2} = \dfrac{4\pi^2(0.500\text{ m})}{(1.36\text{ s})^2} = 10.7\text{ m/s}^2$.

EVALUATE: The same pendulum on earth, where g is smaller, would have a larger period.

14.50. **IDENTIFY:** $a_{\text{tan}} = L\alpha$, $a_{\text{rad}} = L\omega^2$ and $a = \sqrt{a_{\text{tan}}^2 + a_{\text{rad}}^2}$. Apply conservation of energy to calculate the speed in part(c).

SET UP: Just after the sphere is released, $\omega = 0$ and $a_{\text{rad}} = 0$. When the rod is vertical, $a_{\text{tan}} = 0$.

EXECUTE: **(a)** The forces and acceleration are shown in Figure 14.50a. $a_{\text{rad}} = 0$ and $a = a_{\text{tan}} = g\sin\theta$.

(b) The forces and acceleration are shown in Figure 14.50b.

(c) The forces and acceleration are shown in Figure 14.50c. $U_{\text{i}} = K_{\text{f}}$ gives $mgL(1-\cos\Theta) = \frac{1}{2}mv^2$ and $v = \sqrt{2gL(1-\cos\Theta)}$.

EVALUATE: As the rod moves toward the vertical, v increases, a_{rad} increases and a_{tan} decreases.

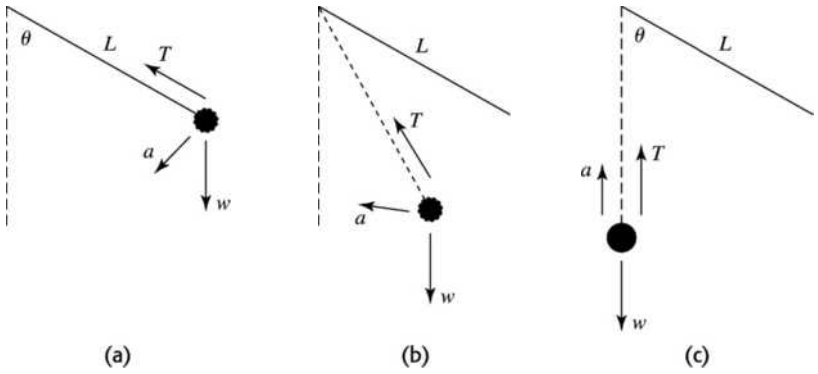

Figure 14.50

14.51. **IDENTIFY:** If a small amplitude is assumed, $T = 2\pi\sqrt{\dfrac{L}{g}}$.

SET UP: The fourth term in Eq. (14.35) would be $\dfrac{1^2\cdot 3^2\cdot 5^2}{2^2\cdot 4^2\cdot 6^2}\sin^6\dfrac{\Theta}{2}$.

EXECUTE: **(a)** $T = 2\pi\sqrt{\dfrac{2.00\text{ m}}{9.80\text{ m/s}^2}} = 2.84\text{ s}$

(b) $T = (2.84\text{ s})\left(1 + \dfrac{1}{4}\sin^2 15.0° + \dfrac{9}{64}\sin^4 15.0° + \dfrac{225}{2304}\sin^6 15.0°\right) = 2.89\text{ s}$

(c) Eq. (14.35) is more accurate. Eq. (14.34) is in error by $\dfrac{2.84\text{ s} - 2.89\text{ s}}{2.89\text{ s}} = -2\%$,

EVALUATE: As Figure 14.22 in Section 14.5 shows, the approximation $F_\theta = -mg\theta$ is larger in magnitude than the true value as θ increases. Eq. (14.34) therefore overestimates the restoring force and this results in a value of T that is smaller than the actual value.

14.52. **IDENTIFY:** $T = 2\pi\sqrt{I/mgd}$

SET UP: From the parallel axis theorem, the moment of inertia of the hoop about the nail is $I = MR^2 + MR^2 = 2MR^2$. $d = R$.

EXECUTE: Solving for R, $R = gT^2/8\pi^2 = 0.496$ m.

EVALUATE: A simple pendulum of length $L = R$ has period $T = 2\pi\sqrt{R/g}$. The hoop has a period that is larger by a factor of $\sqrt{2}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

14.53. **IDENTIFY:** $T = 2\pi\sqrt{I/mgd}$.

SET UP: $d = 0.200$ m. $T = (120\text{ s})/100$.

EXECUTE: $I = mgd\left(\dfrac{T}{2\pi}\right)^2 = (1.80\text{ kg})(9.80\text{ m/s}^2)(0.200\text{ m})\left(\dfrac{120\text{ s}/100}{2\pi}\right)^2 = 0.129\text{ kg.m}^2$.

EVALUATE: If the rod were uniform, its center of gravity would be at its geometrical center and it would have length $l = 0.400$ m. For a uniform rod with an axis at one end, $I = \frac{1}{3}ml^2 = 0.096\text{ kg}\cdot\text{m}^2$. The value of I for the actual rod is about 34% larger than this value.

14.54. **IDENTIFY:** Apply Eq. (14.39) to calculate I and conservation of energy to calculate the maximum angular speed, $\Omega_{\max}$.

SET UP: $d = 0.250$ m. In part (b), $y_i = d(1-\cos\Theta)$, with $\Theta = 0.400$ rad and $y_f = 0$.

EXECUTE: **(a)** Solving Eq. (14.39) for I,

$$I = \left(\frac{T}{2\pi}\right)^2 mgd = \left(\frac{0.940\text{ s}}{2\pi}\right)^2 (1.80\text{ kg})(9.80\text{ m/s}^2)(0.250\text{ m}) = 0.0987\text{ kg}\cdot\text{m}^2.$$

(b) The small-angleapproximation will not give three-figure accuracy for $\Theta = 0.400$ rad. From energy considerations, $mgd(1-\cos\Theta) = \dfrac{1}{2}I\Omega_{\max}^2$. Expressing $\Omega_{\max}$ in terms of the period of small-angle oscillations, this becomes

$$\Omega_{\max} = \sqrt{2\left(\frac{2\pi}{T}\right)^2(1-\cos\Theta)} = \sqrt{2\left(\frac{2\pi}{0.940\text{ s}}\right)^2(1-\cos(0.400\text{ rad}))} = 2.66\text{ rad/s}.$$

EVALUATE: The time for the motion in part (b) is $t = T/4$, so $\Omega_{av} = \Delta\theta/\Delta t = (0.400\text{ rad})/(0.235\text{ s}) = 1.70$ rad/s. Ω increases during the motion and the final Ω is larger than the average Ω.

14.55. **IDENTIFY:** Pendulum A can be treated as a simple pendulum. Pendulum B is a physical pendulum.

SET UP: For pendulum B the distance d from the axis to the center of gravity is $3L/4$. $I = \dfrac{1}{3}(m/2)L^2$ for a bar of mass $m/2$ and the axis at one end. For a small ball of mass $m/2$ at a distance L from the axis, $I_{\text{ball}} = (m/2)L^2$.

EXECUTE: Pendulum A: $T_A = 2\pi\sqrt{\dfrac{L}{g}}$.

Pendulum B: $I = I_{\text{bar}} + I_{\text{ball}} = \dfrac{1}{3}(m/2)L^2 + (m/2)L^2 = \dfrac{2}{3}mL^2$.

$T_B = 2\pi\sqrt{\dfrac{I}{mgd}} = 2\pi\sqrt{\dfrac{\frac{2}{3}mL^2}{mg(3L/4)}} = 2\pi\sqrt{\dfrac{L}{g}}\sqrt{\dfrac{2}{3}\cdot\dfrac{4}{3}} = \sqrt{\dfrac{8}{9}}\left(2\pi\sqrt{\dfrac{L}{g}}\right) = 0.943T_A$. The period is longer for pendulum A.

EVALUATE: Example 14.9 shows that for the bar alone, $T = \sqrt{\dfrac{2}{3}}T_A = 0.816T_A$. Adding the ball of equal mass to the end of the rod increases the period compared to that for the rod alone.

14.56. **IDENTIFY:** The ornament is a physical pendulum: $T = 2\pi\sqrt{I/mgd}$ (Eq.14.39). T is the target variable.

SET UP: $I = 5MR^2/3$, the moment of inertia about an axis at the edge of the sphere. d is the distance from the axis to the center of gravity, which is at the center of the sphere, so $d = R$.

EXECUTE: $T = 2\pi\sqrt{5/3}\sqrt{R/g} = 2\pi\sqrt{5/3}\sqrt{0.050\text{ m}/(9.80\text{m/s}^2)} = 0.58$ s.

EVALUATE: A simple pendulum of length $R = 0.050$ m has period 0.45 s; the period of the physical pendulum is longer.

14.57. **IDENTIFY:** Pendulum A can be treated as a simple pendulum. Pendulum B is a physical pendulum. Use the parallel-axis theorem to find the moment of inertia of the ball in B for an axis at the top of the string.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

SET UP: For pendulum B the center of gravity is at the center of the ball, so $d = L$. For a solid sphere with an axis through its center, $I_{\text{cm}} = \frac{2}{5}MR^2$. $R = L/2$ and $I_{\text{cm}} = \frac{1}{10}ML^2$.

EXECUTE: Pendulum A: $T_A = 2\pi\sqrt{\dfrac{L}{g}}$.

Pendulum B: The parallel-axis theorem says $I = I_{\text{cm}} + ML^2 = \frac{11}{10}ML^2$.

$T = 2\pi\sqrt{\dfrac{I}{mgd}} = 2\pi\sqrt{\dfrac{11ML^2}{10MgL}} = \sqrt{\dfrac{11}{10}}\left(2\pi\sqrt{\dfrac{L}{g}}\right) = \sqrt{\dfrac{11}{10}}T_A = 1.05T_A$. It takes pendulum B longer to complete a swing.

EVALUATE: The center of the ball is the same distance from the top of the string for both pendulums, but the mass is distributed differently and I is larger for pendulum B, even though the masses are the same.

14.58. **IDENTIFY:** The amplitude of swing decreases, indicating that potential energy has been lost.

SET UP: As shown in Figure 14.58, the height h above the lowest point of the swing is $h = L - L\cos\theta = L(1 - \cos\theta)$. The energy lost is the difference in the maximum potential energy.

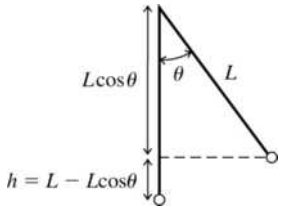

Figure 14.58

EXECUTE: **(a)** At the maximum angle of swing, $K = 0$ and $E = mgh$.

$E_1 = mgL(1 - \cos\theta_1) = (2.50\text{ kg})(9.80\text{ m/s}^2)(1.45\text{ m})(1 - \cos 11°) = 0.653\text{ J}$.

$E_2 = mgL(1 - \cos\theta_2) = (2.50\text{ kg})(9.80\text{ m/s}^2)(1.45\text{ m})(1 - \cos 4.5°) = 0.110\text{ J}$. The mechanical energy lost is $E_1 - E_2 = 0.543\text{ J}$.

(b) The mechanical energy has been converted to other forms by air resistance and by dissipative forces within the rope.

EVALUATE: After a while the rock will come to rest and then all its initial mechanical energy will have been "lost" because it will have been converted to other forms of energy by nonconservative forces.

14.59. **IDENTIFY** and **SET UP:** Use Eq. (14.43) to calculate ω', and then $f' = \omega'/2\pi$.

(a) EXECUTE: $\omega' = \sqrt{(k/m) - (b^2/4m^2)} = \sqrt{\dfrac{2.50\text{ N/m}}{0.300\text{ kg}} - \dfrac{(0.900\text{ kg/s})^2}{4(0.300\text{ kg})^2}} = 2.47\text{ rad/s}$

$f' = \omega'/2\pi = (2.47\text{ rad/s})/2\pi = 0.393\text{ Hz}$

(b) IDENTIFY and **SET UP:** The condition for critical damping is $b = 2\sqrt{km}$ (Eq.14.44).

EXECUTE: $b = 2\sqrt{(2.50\text{ N/m})(0.300\text{ kg})} = 1.73\text{ kg/s}$

EVALUATE: The value of b in part (a) is less than the critical damping value found in part (b). With no damping, the frequency is $f = 0.459\text{ Hz}$; the damping reduces the oscillation frequency.

14.60. **IDENTIFY:** From Eq. (14.42) $A_2 = A_1 \exp\left(-\dfrac{b}{2m}t\right)$.

SET UP: $\ln(e^{-x}) = -x$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: $b = \dfrac{2m}{t}\ln\left(\dfrac{A_1}{A_2}\right) = \dfrac{2(0.050\text{ kg})}{(5.00\text{ s})}\ln\left(\dfrac{0.300\text{ m}}{0.100\text{ m}}\right) = 0.0220\text{ kg/s}.$

EVALUATE: As a check, note that the oscillation frequency is the same as the undamped frequency to $4.8\times10^{-3}\%$, so Eq. (14.42) is valid.

14.61. **IDENTIFY:** $x(t)$ is given by Eq. (14.42). $v_x = dx/dt$ and $a_x = dv_x/dt$.

SET UP: $d(\cos\omega' t)/dt = -\omega'\sin\omega' t$. $d(\sin\omega' t)/dt = \omega'\cos\omega' t$. $d(e^{-\alpha t})/dt = -\alpha e^{-\alpha t}$.

EXECUTE: **(a)** With $\phi = 0$, $x(0) = A$.

(b) $v_x = \dfrac{dx}{dt} = Ae^{(b/2m)t}\left[-\dfrac{b}{2m}\cos\omega' t - \omega'\sin\omega' t\right]$, and at $t = 0$, $v_x = -Ab/2m$; the graph of x versus t near $t = 0$ slopes down.

(c) $a_x = \dfrac{dv_x}{dt} = Ae^{-(b/2m)t}\left[\left(\dfrac{b^2}{4m^2} - \omega'^2\right)\cos\omega' t + \dfrac{\omega' b}{2m}\sin\omega' t\right]$, and at $t = 0$,

$a_x = A\left(\dfrac{b^2}{4m^2} - \omega'^2\right) = A\left(\dfrac{b^2}{2m^2} - \dfrac{k}{m}\right)$. (Note that this is $(-bv_0 - kx_0)/m$.) This will be negative if $b < \sqrt{2km}$, zero if $b = \sqrt{2km}$ and positive if $b > \sqrt{2km}$. The graph in the three cases will be curved down, not curved, or curved up, respectively.

EVALUATE: $a_x(0) = 0$ corresponds to the situation of critical damping.

14.62. **IDENTIFY:** The graph shows that the amplitude of vibration is decreasing, so the system must be losing mechanical energy.

SET UP: The mechanical energy is $E = \frac{1}{2}mv_x^2 + \frac{1}{2}kx^2$.

EXECUTE: **(a)** When $|x|$ is a maximum and the tangent to the curve is horizontal the speed of the mass is zero. This occurs at $t = 0$, $t = 1.0$ s, $t = 2.0$ s, $t = 3.0$ s and $t = 4.0$ s.

(b) At $t = 0$, $v_x = 0$ and $x = 7.0$ cm so $E_0 = \frac{1}{2}kx^2 = \frac{1}{2}(225\text{ N/m})(0.070\text{ m})^2 = 0.55$ J.

(c) At $t = 1.0$ s, $v_x = 0$ and $x = -6.0$ cm so $E_1 = \frac{1}{2}kx^2 = \frac{1}{2}(225\text{ N/m})(-0.060\text{ m})^2 = 0.405$ J.

At $t = 4.0$ s, $v_x = 0$ and $x = 3.0$ cm so $E_4 = \frac{1}{2}kx^2 = \frac{1}{2}(225\text{ N/m})(0.030\text{ m})^2 = 0.101$ J. The mechanical energy "lost" is $E_1 - E_4 = 0.30$ J. The mechanical energy lost was converted to other forms of energy by nonconservative forces, such as friction, air resistance and other dissipative forces.

EVALUATE: After a while the mass will come to rest and then all its initial mechanical energy will have been "lost" because it will have been converted to other forms of energy by nonconservative forces.

14.63. **IDENTIFY** and **SET UP:** Apply Eq. (14.46): $A = \dfrac{F_{\max}}{\sqrt{\left(k - m\omega_d^2\right)^2 + b^2\omega_d^2}}$

EXECUTE: **(a)** Consider the special case where $k - m\omega_d^2 = 0$, so $A = F_{\max}/b\omega_d$ and $b = F_{\max}/A\omega_d$. Units of $\dfrac{F_{\max}}{A\omega_d}$ are $\dfrac{\text{kg}\cdot\text{m/s}^2}{(\text{m})(\text{s}^{-1})} = \text{kg/s}$. For units consistency the units of b must be kg/s.

(b) Units of $\sqrt{km}$: $[(\text{N/m})\text{kg}]^{1/2} = (\text{N kg/m})^{1/2} = [(\text{kg}\cdot\text{m/s}^2)(\text{kg})/\text{m}]^{1/2} = (\text{kg}^2/\text{s}^2)^{1/2} = \text{kg/s}$, the same as the units for b.

(c) For $\omega_d = \sqrt{k/m}$ (at resonance) $A = (F_{\max}/b)\sqrt{m/k}$.

(i) $b = 0.2\sqrt{km}$

$A = F_{\max}\sqrt{\dfrac{m}{k}}\dfrac{1}{0.2\sqrt{km}} = \dfrac{F_{\max}}{0.2k} = 5.0\dfrac{F_{\max}}{k}$.

(ii) $b = 0.4\sqrt{km}$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$A = F_{\max}\sqrt{\frac{m}{k}}\frac{1}{0.4\sqrt{km}} = \frac{F_{\max}}{0.4k} = 2.5\frac{F_{\max}}{k}.$$

EVALUATE: Both these results agree with what is shown in Figure 14.28 in the textbook. As b increases the maximum amplitude decreases.

14.64. **IDENTIFY:** Apply Eq. (14.46).

SET UP: $\omega_d = \sqrt{k/m}$ corresponds to resonance, and in this case Eq. (14.46) reduces to $A = F_{\max}/b\omega_d$.

EXECUTE: **(a)** $A_1/3$

(b) $2A_1$

EVALUATE: Note that the resonance frequency is independent of the value of b. (See Figure 14.28 in the textbook).

14.65. **IDENTIFY** and **SET UP:** Calculate x using Eq. (14.13). Use T to calculate ω and x_0 to calculate ϕ.

EXECUTE: $x = 0$ at $t = 0$ implies that $\phi = \pm\pi/2$ rad

Thus $x = A\cos(\omega t \pm \pi/2)$.

$T = 2\pi/\omega$ so $\omega = 2\pi/T = 2\pi/1.20\text{ s} = 5.236$ rad/s

$x = (0.600\text{ m})\cos([5.236\text{ rad/s}][0.480\text{ s}] \pm \pi/2) = \mp 0.353$ m.

The distance of the object from the equilibrium position is 0.353 m.

EVALUATE: The problem doesn't specify whether the object is moving in the $+x$ or $-x$-direction at $t = 0$.

14.66. **IDENTIFY:** Apply $x(t) = A\cos(\omega t + \phi)$

SET UP: $x = A$ at $t = 0$, so $\phi = 0$. $A = 6.00$ cm. $\omega = \dfrac{2\pi}{T} = \dfrac{2\pi}{0.300\text{ s}} = 20.9$ rad/s, so

$x(t) = (6.00\text{ cm})\cos)([20.9\text{ rad/s}]t)$.

EXECUTE: $t = 0$ at $x = 6.00$ cm. $x = -1.50$ cm when $-1.50\text{ cm} = (6.00\text{ cm})\cos((20.9\text{ rad/s})t)$.

$$t = \left(\frac{1}{20.9\text{ rad/s}}\right)\arccos\left(\frac{1.50\text{ cm}}{6.00\text{ cm}}\right) = 0.0872\text{ s}.$$ It takes 0.0872 s.

EVALUATE: It takes $t = T/4 = 0.075$ s to go from $x = 6.00$ cm to $x = 0$ and 0.150 s to go from $x = +6.00$ cm to $x = -6.00$ cm. Our result is between these values, as it should be.

14.67. **IDENTIFY:** $ma_x = -kx$ so $a_{\max} = \dfrac{k}{m}A = \omega^2 A$ is the magnitude of the acceleration when $x = \pm A$.

$v_{\max} = \sqrt{\dfrac{k}{m}}A = \omega A$. $P = \dfrac{W}{t} = \dfrac{\Delta K}{t}$.

SET UP: $A = 0.0500$ m. $\omega = 4500$ rpm $= 471.24$ rad/s.

EXECUTE: **(a)** $a_{\max} = \omega^2 A = (471.24\text{ rad/s})^2(0.0500\text{ m}) = 1.11\times10^4$ m/s^2.

(b) $F_{\max} = ma_{\max} = (0.450\text{ kg})(1.11\times10^4\text{ m/s}^2) = 5.00\times10^3$ N.

(c) $v_{\max} = \omega A = (471.24\text{ rad/s})(0.0500\text{ m}) = 23.6$ m/s.

$K_{\max} = \frac{1}{2}mv_{\max}^2 = \frac{1}{2}(0.450\text{ kg})(23.6\text{ m/s})^2 = 125$ J.

(d) $P = \dfrac{K_{\max}}{t}$ and $t = \dfrac{T}{4} = \dfrac{2\pi}{4\omega} = \dfrac{\pi}{2\omega}$, so

$$P = \frac{K_{\max}}{t} = \frac{K_{\max}}{\pi/2\omega} = \frac{2\omega K_{\max}}{\pi} = \frac{2(471.24\text{ rad/s})(125\text{ J})}{\pi} = 3.75\times10^4\text{ W}.$$

(e) $a_{\max}$ is proportional to ω^2, so $F_{\max}$ increases by a factor of 4500/7000, to 1.21×10^4 N. $v_{\max}$ is proportional to ω, so $v_{\max}$ increases by a factor of 4500/7000, to 36.7 m/s, and $K_{\max}$ increases by a factor of $(7000/4500)^2$, to 302 J. In part (d), t decreases by a factor of 4500/7000 and K increases by a factor of $(7000/4500)^2$, so $P_{\max}$ increases by a factor of $(7000/4500)^3$ and becomes 1.41×10^5 W.

EVALUATE: For a given amplitude, the maximum acceleration and maximum velocity increase when the frequency of the motion increases and the period decreases.

14.68. **IDENTIFY:** $T = 2\pi\sqrt{\dfrac{m}{k}}$. The period changes when the mass changes.

SET UP: M is the mass of the empty car and the mass of the loaded car is $M = 250$ kg.

EXECUTE: The period of the empty car is $T_{\rm E} = 2\pi\sqrt{\dfrac{M}{k}}$. The period of the loaded car is

$$T_{\rm L} = 2\pi\sqrt{\frac{M + 250\ \text{kg}}{k}}.\quad k = \frac{(250\ \text{kg})(9.80\ \text{m/s}^2)}{4.00\times10^{-2}\ \text{m}} = 6.125\times10^4\ \text{N/m}$$

$$M = \left(\frac{T_{\rm L}}{2\pi}\right)^2 k - 250\ \text{kg} = \left(\frac{1.92\ \text{s}}{2\pi}\right)^2 (6.125\times10^4\ \text{N/m}) - 250\ \text{kg} = 5.469\times10^3\ \text{kg}.$$

$$T_{\rm E} = 2\pi\sqrt{\frac{5.469\times10^3\ \text{kg}}{6.125\times10^4\ \text{N/m}}} = 1.88\ \text{s}.$$

EVALUATE: When the mass decreases, the period decreases.

14.69. **IDENTIFY** and **SET UP:** Use Eqs. (14.12), (14.21) and (14.22) to relate the various quantities to the amplitude.

EXECUTE: **(a)** $T = 2\pi\sqrt{m/k}$; independent of A so period doesn't change

$f = 1/T$; doesn't change

$\omega = 2\pi f$; doesn't change

(b) $E = \frac{1}{2}kA^2$ when $x = \pm A$. When A is halved E decreases by a factor of 4; $E_2 = E_1/4$.

(c) $v_{\max} = \omega A = 2\pi fA$

$v_{\max,1} = 2\pi fA_1$, $v_{\max,2} = 2\pi fA_2$ (f doesn't change)

Since $A_2 = \frac{1}{2}A_1, v_{\max,2} = 2\pi f\left(\frac{1}{2}A_1\right) = \frac{1}{2}2\pi fA_1 = \frac{1}{2}v_{\max,1}$; $v_{\max}$ is one-half as great

(d) $v_x = \pm\sqrt{k/m}\sqrt{A^2 - x^2}$

$x = \pm A_1/4$ gives $v_x = \pm\sqrt{k/m}\sqrt{A^2 - A_1^2/16}$

With the original amplitude $v_{1x} = \pm\sqrt{k/m}\sqrt{A_1^2 - A_1^2/16} = \pm\sqrt{15/16}(\sqrt{k/m})A_1$

With the reduced amplitude $v_{2x} = \pm\sqrt{k/m}\sqrt{A_2^2 - A_1^2/16} = \pm\sqrt{k/m}\sqrt{(A_1/2)^2 - A_1^2/16} = \pm\sqrt{3/16}(\sqrt{k/m})A_1$

$v_{1x}/v_{2x} = \sqrt{15/3} = \sqrt{5}$, so $v_2 = v_1/\sqrt{5}$; the speed at this x is $1/\sqrt{5}$ times as great.

(e) $U = \frac{1}{2}kx^2$; same x so same U.

$K = \frac{1}{2}mv_x^2$; $K_1 = \frac{1}{2}mv_{1x}^2$

$K_2 = \frac{1}{2}mv_{2x}^2 = \frac{1}{2}m(v_{1x}/\sqrt{5})^2 = \frac{1}{5}(\frac{1}{2}mv_{1x}^2) = K_1/5$; 1/5 times as great.

EVALUATE: Reducing A reduces the total energy but doesn't affect the period and the frequency.

14.70. **(a) IDENTIFY** and **SET UP:** Combine Eqs. (14.12) and (14.21) to relate v_x and x to T.

EXECUTE: $T = 2\pi\sqrt{m/k}$

We are given information about v_x at a particular x. The expression relating these two quantities comes from conservation of energy: $\frac{1}{2}mv_x^2 + \frac{1}{2}kx^2 = \frac{1}{2}kA^2$

We can solve this equation for $\sqrt{m/k}$, and then use that result to calculate T. $mv_x^2 = k(A^2 - x^2)$ gives

$$\sqrt{\frac{m}{k}} = \frac{\sqrt{A^2 - x^2}}{v_x} = \frac{\sqrt{(0.100\ \text{m})^2 - (0.060\ \text{m})^2}}{0.400\ \text{m/s}} = 0.200\ \text{s}.$$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

Then $T = 2\pi\sqrt{m/k} = 2\pi(0.200\text{ s}) = 1.26\text{ s}$.

(b) IDENTIFY and **SET UP:** We are asked to relate x and v_x, so use conservation of energy equation:

$\frac{1}{2}mv_x^2 + \frac{1}{2}kx^2 = \frac{1}{2}kA^2$

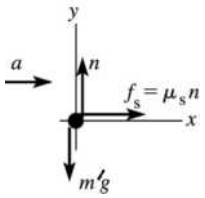
$kx^2 = kA^2 - mv_x^2$

$x = \sqrt{A^2 - (m/k)v_x^2} = \sqrt{(0.100\text{ m})^2 - (0.200\text{ s})^2(0.160\text{ m/s})^2} = 0.0947\text{ m}.$

EVALUATE: Smaller $|v_x|$ means larger x.

(c) IDENTIFY: If the slice doesn't slip, the maximum acceleration of the plate (Eq.14.4) equals the maximum acceleration of the slice, which is determined by applying Newton's second law to the slice.

SET UP: For the plate, $-kx = ma_x$ and $a_x = -(k/m)x$. The maximum $|x|$ is A, so $a_{\max} = (k/m)A$. If the carrot slice doesn't slip then the static friction force must be able to give it this much acceleration. The free-body diagram for the carrot slice (mass m') is given in Figure 14.70.



EXECUTE: $\sum F_y = ma_y$

$n - m'g = 0$

$n = m'g$

Figure 14.70

$\sum F_x = ma_x$

$\mu_s n = m'a$

$\mu_s m'g = m'a$ and $a = \mu_s g$

But we require that $a = a_{\max} = (k/m)A = \mu_s g$ and $\mu_s = \frac{k}{m}\frac{A}{g} = \left(\frac{1}{0.200\text{ s}}\right)^2\left(\frac{0.100\text{ m}}{9.80\text{ m/s}^2}\right) = 0.255.$

EVALUATE: We can write this as $\mu_s = \omega^2 A/g$. More friction is required if the frequency or the amplitude is increased.

14.71. IDENTIFY: The largest downward acceleration the ball can have is g whereas the downward acceleration of the tray depends on the spring force. When the downward acceleration of the tray is greater than g, then the ball leaves the tray. $y(t) = A\cos(\omega t + \phi)$.

SET UP: The downward force exerted by the spring is $F = kd$, where d is the distance of the object above the equilibrium point. The downward acceleration of the tray has magnitude $\frac{F}{m} = \frac{kd}{m}$, where m is the total mass of the ball and tray. $x = A$ at $t = 0$, so the phase angle ϕ is zero and $+x$ is downward.

EXECUTE: (a) $\frac{kd}{m} = g$ gives $d = \frac{mg}{k} = \frac{(1.775\text{ kg})(9.80\text{ m/s}^2)}{185\text{ N/m}} = 9.40\text{ cm}$. This point is 9.40 cm above the equilibrium point so is $9.40\text{ cm} + 15.0\text{ cm} = 24.4\text{ cm}$ above point A.

(b) $\omega = \sqrt{\frac{k}{m}} = \sqrt{\frac{185\text{ N/m}}{1.775\text{ kg}}} = 10.2\text{ rad/s}$. The point in (a) is above the equilibrium point so $x = -9.40\text{ cm}$.

$x = A\cos(\omega t)$ gives $\omega t = \arccos\left(\frac{x}{A}\right) = \arccos\left(\frac{-9.40\text{ cm}}{15.0\text{ cm}}\right) = 2.25\text{ rad}$. $t = \frac{2.25\text{ rad}}{10.2\text{ rad/s}} = 0.221\text{ s}.$

(c) $\frac{1}{2}kx^2 + \frac{1}{2}mv^2 = \frac{1}{2}kA^2$ gives $v = \sqrt{\frac{k}{m}(A^2 - x^2)} = \sqrt{\frac{185\text{ N/m}}{1.775\text{ kg}}([0.150\text{ m}]^2 - [-0.0940\text{ m}]^2)} = 1.19\text{ m/s}.$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: The period is $T = 2\pi\sqrt{\frac{m}{k}} = 0.615$ s. To go from the lowest point to the highest point takes time $T/2 = 0.308$ s. The time in (b) is less than this, as it should be.

14.72. **IDENTIFY:** In SHM, $a_{\max} = \frac{k}{m_{\text{tot}}}A$. Apply $\sum \vec{F} = m\vec{a}$ to the top block.

SET UP: The maximum acceleration of the lower block can't exceed the maximum acceleration that can be given to the other block by the friction force.

EXECUTE: For block m, the maximum friction force is $f_s = \mu_s n = \mu_s mg$. $\sum F_x = ma_x$ gives $\mu_s mg = ma$ and $a = \mu_s g$. Then treat both blocks together and consider their simple harmonic motion.

$a_{\max} = \left(\frac{k}{M+m}\right)A$. Set $a_{\max} = a$ and solve for A: $\mu_s g = \left(\frac{k}{M+m}\right)A$ and $A = \frac{\mu_s g(M+m)}{k}$.

EVALUATE: If A is larger than this the spring gives the block with mass M a larger acceleration than friction can give the other block, and the first block accelerates out from underneath the other block.

14.73. **IDENTIFY:** Apply conservation of linear momentum to the collision and conservation of energy to the motion after the collision. $f = \frac{1}{2\pi}\sqrt{\frac{k}{m}}$ and $T = \frac{1}{f}$.

SET UP: The object returns to the equilibrium position in time $T/2$.

EXECUTE: **(a)** Momentum conservation during the collision: $mv_0 = (2m)V$.

$V = \frac{1}{2}v_0 = \frac{1}{2}(2.00 \text{ m/s}) = 1.00 \text{ m/s}$.

Energy conservation after the collision: $\frac{1}{2}MV^2 = \frac{1}{2}kx^2$.

$x = \sqrt{\frac{MV^2}{k}} = \sqrt{\frac{(20.0 \text{ kg})(1.00 \text{ m/s})^2}{110.0 \text{ N/m}}} = 0.426$ m (amplitude)

$\omega = 2\pi f = \sqrt{k/M}$. $f = \frac{1}{2\pi}\sqrt{k/M} = \frac{1}{2\pi}\sqrt{\frac{110.0 \text{ N/m}}{20.0 \text{ kg}}} = 0.373$ Hz. $T = \frac{1}{f} = \frac{1}{0.373 \text{ Hz}} = 2.68$ s.

(b) It takes 1/2 period to first return: $\frac{1}{2}(2.68 \text{ s}) = 1.34$ s.

EVALUATE: The total mechanical energy of the system determines the amplitude. The frequency and period depend only on the force constant of the spring and the mass that is attached to the spring.

14.74. **IDENTIFY:** The upward acceleration of the rocket produces an effective downward acceleration for objects in its frame of reference that is equal to $g' = a + g$.

SET UP: The amplitude is the maximum displacement from equilibrium and is unaffected by the motion of the rocket. The period is affected and is given by $T = 2\pi\sqrt{\frac{L}{g'}}$.

EXECUTE: The amplitude is $8.50°$. $T = 2\pi\sqrt{\frac{1.10 \text{ m}}{4.00 \text{ m/s}^2 + 9.80 \text{ m/s}^2}} = 1.77$ s.

EVALUATE: For a pendulum of the same length and with its point of support at rest relative to the earth, $T = 2\pi\sqrt{\frac{L}{g}} = 2.11$ s. The upward acceleration decreases the period of the pendulum. If the rocket were instead accelerating downward, the period would be greater than 2.11 s.

14.75. **IDENTIFY** and **SET UP:** The bounce frequency is given by Eq. (14.11) and the pendulum frequency by Eq. (14.33). Use the relation between these two frequencies that is specified in the problem to calculate the equilibrium length L of the spring, when the apple hangs at rest on the end of the spring.

EXECUTE: vertical SHM: $f_b = \frac{1}{2\pi}\sqrt{\frac{k}{m}}$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

pendulum motion (small amplitude): $f_p = \dfrac{1}{2\pi}\sqrt{\dfrac{g}{L}}$

The problem specifies that $f_p = \frac{1}{2} f_b$.

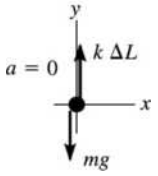
$$\frac{1}{2\pi}\sqrt{\frac{g}{L}} = \frac{1}{2}\frac{1}{2\pi}\sqrt{\frac{k}{m}}$$

$g/L = k/4m$ so $L = 4gm/k = 4w/k = 4(1.00\text{ N})/1.50\text{ N/m} = 2.67\text{ m}$

EVALUATE: This is the *stretched* length of the spring, its length when the apple is hanging from it. (Note: Small angle of swing means v is small as the apple passes through the lowest point, so a_{rad} is small and the component of mg perpendicular to the spring is small. Thus the amount the spring is stretched changes very little as the apple swings back and forth.)

IDENTIFY: Use Newton's second law to calculate the distance the spring is stretched from its unstretched length when the apple hangs from it.

SET UP: The free-body diagram for the apple hanging at rest on the end of the spring is given in Figure14.75.



EXECUTE: $\sum F_y = ma_y$

$k\Delta L - mg = 0$

$\Delta L = mg/k = w/k =$

$1.00\text{ N}/1.50\text{ N/m} = 0.667\text{ m}$

Figure 14.75

Thus the unstretched length of the spring is $2.67\text{ m} - 0.67\text{ m} = 2.00\text{ m}$.

EVALUATE: The spring shortens to its unstretched length when the apple is removed.

14.76. **IDENTIFY:** The vertical forces on the floating object must sum to zero. The buoyant force B applied to the object by the liquid is given by Archimedes's principle. The motion is SHM if the net force on the object is of the form $F_y = -ky$ and then $T = 2\pi\sqrt{m/k}$.

SET UP: Take $+y$ to be downward.

EXECUTE: **(a)** $V_{submerged} = LA$, where L is the vertical distance from the surface of the liquid to the bottom of the object. Archimedes' principle states $\rho gLA = Mg$, so $L = \dfrac{M}{\rho A}$.

(b) The buoyant force is $\rho gA(L + y) = Mg + F$, where y is the additional distance the object moves downward. Using the result of part (a) and solving for y gives $y = \dfrac{F}{\rho gA}$.

(c) The net force is $F_{net} = Mg - \rho gA(L + y) = -\rho gAy$. $k = \rho gA$, and the period of oscillation is

$$T = 2\pi\sqrt{\frac{M}{k}} = 2\pi\sqrt{\frac{M}{\rho gA}}.$$

EVALUATE: The force F determines the amplitude of the motion but the period does not depend on how much force was applied.

14.77. **IDENTIFY:** Apply the results of Problem 14.76.

SET UP: The additional force F applied to the buoy is the weight $w = mg$ of the man.

EXECUTE: **(a)** $y = \dfrac{w}{\rho gA} = \dfrac{mg}{\rho gA} = \dfrac{m}{\rho A} = \dfrac{(70.0\text{ kg})}{(1.03\times10^3\text{ kg/m}^3)\pi(0.450\text{ m})^2} = 0.107\text{ m}.$

(b) Note that in part (c) of Problem 14.76, M is the mass of the buoy, not the mass of the man, and A is the cross-section area of the buoy, not the amplitude. The period is then

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$T = 2\pi\sqrt{\frac{(950\text{ kg})}{(1.03\times10^3\text{ kg/m}^3)(9.80\text{ m/s}^2)\pi(0.450\text{ m})^2}} = 2.42\text{ s}$$

EVALUATE: The period is independent of the mass of the man.

14.78. **IDENTIFY:** Tarzan on the swinging vine (with or without the chimp) is a simple pendulum.

SET UP: Tarzan first comes to rest after beginning his swing at the end of one-half of a cycle, so the period is $T = 8.0$ s. Apply conservation of linear momentum to find the speed and kinetic energy of the system just after Tarzan has grabbed the chimp. The figure in the solution to Problem 14.58 shows that the height h above the lowest point of the swing is $h = L(1-\cos\theta)$. The period of a simple pendulum is $T = 2\pi\sqrt{\frac{L}{g}}$.

EXECUTE: **(a)** $T = 2\pi\sqrt{\frac{L}{g}}$ so $L = g\left(\frac{T}{2\pi}\right)^2 = (9.80\text{ m/s}^2)\left(\frac{8.0\text{ s}}{2\pi}\right)^2 = 15.9$ m.

(b) $f = \frac{1}{T} = \frac{1}{8.0\text{ s}} = 0.125$ Hz. The amplitude is 12°.

(c) Apply conservation of energy to find Tarzan's speed just before he grabs the chimp: $U_1 = K_2$.

$mgL(1-\cos\theta) = \frac{1}{2}mv^2$. $v = \sqrt{2gL(1-\cos\theta)} = \sqrt{2(9.80\text{ m/s}^2)(15.9\text{ m})(1-\cos12°)} = 2.61$ m/s. Apply conservation of momentum to the inelastic collision between Tarzan and the chimp: $(65\text{ kg})(2.61\text{ m/s}) = (65\text{ kg} + 35\text{ kg})V$ gives $V = 1.70$ m/s. Apply conservation of energy to find the maximum angle of swing after the collision: $\frac{1}{2}m_{\text{tot}}V^2 = m_{\text{tot}}gL(1-\cos\theta)$ Solving for θ gives

$1-\cos\theta = \frac{V^2}{2gL} = \frac{(1.70\text{ m/s})^2}{2(9.80\text{ m/s}^2)(15.9\text{ m})} = 0.00927$ so $\theta = 7.8°$. $f = \frac{1}{2\pi}\sqrt{\frac{g}{L}}$. The length doesn't change so f remains 0.125 Hz. f doesn't depend on the mass or on the amplitude of swing.

EVALUATE: Since the amplitude of swing is fairly small, we can use the small-angle approximation for which the period is independent of the amplitude. If the angle of swing were a bit larger, this approximation would not be valid.

14.79. **IDENTIFY:** The object oscillates as a physical pendulum, so $f = \frac{1}{2\pi}\sqrt{\frac{m_{\text{object}}gd}{I}}$. Use the parallel-axis theorem, $I = I_{\text{cm}} + Md^2$, to find the moment of inertia of each stick about an axis at the hook.

SET UP: The center of mass of the square object is at its geometrical center, so its distance from the hook is $L\cos45° = L/\sqrt{2}$. The center of mass of each stick is at its geometrical center. For each stick, $I_{\text{cm}} = \frac{1}{12}mL^2$.

EXECUTE: The parallel-axis theorem gives I for each stick for an axis at the center of the square to be $\frac{1}{12}mL^2 + m(L/2)^2 = \frac{1}{3}mL^2$ and the total I for this axis is $\frac{4}{3}mL^2$. For the entire object and an axis at the hook, applying the parallel-axis theorem again to the object of mass $4m$ gives $I = \frac{4}{3}mL^2 + 4m(L/\sqrt{2})^2 = \frac{10}{3}mL^2$.

$$f = \frac{1}{2\pi}\sqrt{\frac{m_{\text{object}}gd}{I}} = \frac{1}{2\pi}\sqrt{\frac{4m_{\text{object}}gL/\sqrt{2}}{\frac{10}{3}m_{\text{object}}L^2}} = \sqrt{\frac{6}{5\sqrt{2}}}\left(\frac{1}{2\pi}\sqrt{\frac{g}{L}}\right) = 0.921\left(\frac{1}{2\pi}\sqrt{\frac{g}{L}}\right).$$

EVALUATE: Just as for a simple pendulum, the frequency is independent of the mass. A simple pendulum of length L has frequency $f = \frac{1}{2\pi}\sqrt{\frac{g}{L}}$ and this object has a frequency that is slightly less than this.

14.80. **IDENTIFY:** Conservation of energy says $K + U = E$.

SET UP: $U = \frac{1}{2}kx^2$ and $E = U_{\text{max}} = \frac{1}{2}kA^2$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: **(a)** The graph is given in Figure 14.80. The following answers are found algebraically, to be used as a check on the graphical method.

(b) $A=\sqrt{\dfrac{2E}{k}}=\sqrt{\dfrac{2(0.200\text{ J})}{(10.0\text{ N/m})}}=0.200\text{ m}.$

(c) $\dfrac{E}{4}=0.050\text{ J}.$

(d) $U=\dfrac{1}{2}E.\ \ x=\dfrac{A}{\sqrt{2}}=0.141\text{ m}.$

(e) From Eq. (14.18), using $v_0=\sqrt{\dfrac{2K_0}{m}}$ and $x_0=-\sqrt{\dfrac{2U_0}{k}},\ \ -\dfrac{v_0}{\omega x_0}=\dfrac{\sqrt{(2K_0/m)}}{\sqrt{(k/m)}\sqrt{(2U_0/k)}}=\sqrt{\dfrac{K_0}{U_0}}=\sqrt{0.429}$

and $\phi=\arctan(\sqrt{0.429})=3.72$ rad.

EVALUATE: The dependence of U on x is not linear and $U=\frac{1}{2}U_{\max}$ does not occur at $x=\frac{1}{2}x_{\max}$.

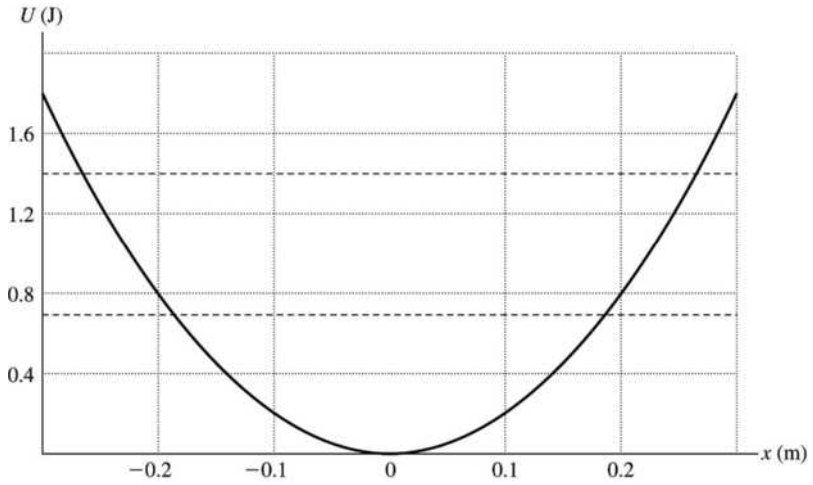


Figure 14.80

14.81. **IDENTIFY:** $T=2\pi\sqrt{\dfrac{m}{k}}$ so the period changes because the mass changes.

SET UP: $\dfrac{dm}{dt}=-2.00\times10^{-3}$ kg/s. The rate of change of the period is $\dfrac{dT}{dt}$.

EXECUTE: **(a)** When the bucket is half full, $m=7.00$ kg. $T=2\pi\sqrt{\dfrac{7.00\text{ kg}}{125\text{ N/m}}}=1.49$ s.

(b) $\dfrac{dT}{dt}=\dfrac{2\pi}{\sqrt{k}}\dfrac{d}{dt}(m^{1/2})=\dfrac{2\pi}{\sqrt{k}}\tfrac{1}{2}m^{-1/2}\dfrac{dm}{dt}=\dfrac{\pi}{\sqrt{mk}}\dfrac{dm}{dt}.$

$\dfrac{dT}{dt}=\dfrac{\pi}{\sqrt{(7.00\text{ kg})(125\text{ N/m})}}(-2.00\times10^{-3}\text{ kg/s})=-2.12\times10^{-4}$ s per s. $\dfrac{dT}{dt}$. is negative; the period is getting shorter.

(c) The shortest period is when all the water has leaked out and $m=2.00$ kg. Then $T=0.795$ s.

EVALUATE: The rate at which the period changes is not constant but instead increases in time, even though the rate at which the water flows out is constant.

14.82. **IDENTIFY:** Use $F_x=-kx$ to determine k for the wire. Then $f=\dfrac{1}{2\pi}\sqrt{\dfrac{k}{m}}$.

SET UP: $F=mg$ moves the end of the wire a distance Δl.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: The force constant for this wire is $k = \dfrac{mg}{\Delta l}$, so

$$f = \frac{1}{2\pi}\sqrt{\frac{k}{m}} = \frac{1}{2\pi}\sqrt{\frac{g}{\Delta l}} = \frac{1}{2\pi}\sqrt{\frac{9.80\text{m/s}^2}{2.00\times10^{-3}\text{m}}} = 11.1 \text{ Hz}.$$

EVALUATE: The frequency is independent of the additional distance the ball is pulled downward, so long as that distance is small.

14.83. **IDENTIFY** and **SET UP:** Measure x from the equilibrium position of the object, where the gravity and spring forces balance. Let $+x$ be downward.

(a) Use conservation of energy (Eq.14.21) to relate v_x and x. Use Eq. (14.21) to relate T to k/m.

EXECUTE: $\frac{1}{2}mv_x^2 + \frac{1}{2}kx^2 = \frac{1}{2}kA^2$

For $x = 0, \frac{1}{2}mv_x^2 = \frac{1}{2}kA^2$ and $v = A\sqrt{k/m}$, just as for horizontal SHM. We can use the period to calculate $\sqrt{k/m}$: $T = 2\pi\sqrt{m/k}$ implies $\sqrt{k/m} = 2\pi/T$. Thus $v = 2\pi A/T = 2\pi(0.100 \text{ m})/4.20 \text{ s} = 0.150 \text{ m/s}$.

(b) IDENTIFY and **SET UP:** Use Eq. (14.4) to relate a_x and x.

EXECUTE: $ma_x = -kx$ so $a_x = -(k/m)x$

+x-direction is downward, so here $x = -0.050$ m

$a_x = -(2\pi/T)^2(-0.050 \text{ m}) = +(2\pi/4.20 \text{ s})^2(0.050 \text{ m}) = 0.112 \text{ m/s}^2$ (positive, so direction is downward)

(c) IDENTIFY and **SET UP:** Use Eq. (14.13) to relate x and t. The time asked for is twice the time it takes to go from $x = 0$ to $x = +0.050$ m.

EXECUTE: $x(t) = A\cos(\omega t + \phi)$

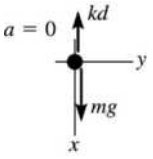
Let $\phi = -\pi/2$, so $x = 0$ at $t = 0$. Then $x = A\cos(\omega t - \pi/2) = A\sin\omega t = A\sin(2\pi t/T)$. Find the time t that gives $x = +0.050$ m: $0.050 \text{ m} = (0.100 \text{ m})\sin(2\pi t/T)$

$2\pi t/T = \arcsin(0.50) = \pi/6$ and $t = T/12 = 4.20 \text{ s}/12 = 0.350 \text{ s}$

The time asked for in the problem is twice this, 0.700 s.

(d) IDENTIFY: The problem is asking for the distance d that the spring stretches when the object hangs at rest from it. Apply Newton's second law to the object.

SET UP: The free-body diagram for the object is given in Figure 14.83.



EXECUTE: $\sum F_x = ma_x$

$mg - kd = 0$

$d = (m/k)g$

Figure 14.83

But $\sqrt{k/m} = 2\pi/T$ (part (a)) and $m/k = (T/2\pi)^2$

$$d = \left(\frac{T}{2\pi}\right)^2 g = \left(\frac{4.20 \text{ s}}{2\pi}\right)^2 (9.80 \text{ m/s}^2) = 4.38 \text{ m}.$$

EVALUATE: When the displacement is upward (part (b)), the acceleration is downward. The mass of the partridge is never entered into the calculation. We used just the ratio k/m, that is determined from T.

14.84. **IDENTIFY:** $x(t) = A\cos(\omega t + \phi)$, $v_x = -A\omega\sin(\omega t + \phi)$ and $a_x = -\omega^2 x$. $\omega = 2\pi/T$.

SET UP: $x = A$ when $t = 0$ gives $\phi = 0$.

EXECUTE: $x = (0.240 \text{ m})\cos\left(\dfrac{2\pi t}{1.50 \text{ s}}\right)$. $v_x = -\left(\dfrac{2\pi(0.240 \text{ m})}{(1.50 \text{ s})}\right)\sin\left(\dfrac{2\pi t}{1.50 \text{ s}}\right) = -(1.00530 \text{ m/s})\sin\left(\dfrac{2\pi t}{1.50 \text{ s}}\right)$.

$$a_x = -\left(\frac{2\pi}{1.50 \text{ s}}\right)^2 (0.240 \text{ m})\cos\left(\frac{2\pi t}{1.50 \text{ s}}\right) = -(4.2110 \text{ m/s}^2)\cos\left(\frac{2\pi t}{1.50 \text{ s}}\right).$$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(a) Substitution gives $x = -0.120$ m, or using $t = \frac{T}{3}$ gives $x = A\cos 120° = \frac{-A}{2}$.

(b) Substitution gives $ma_x = +(0.0200\text{ kg})(2.106\text{ m/s}^2) = 4.21\times10^{-2}$ N, in the $+x$-direction.

(c) $t = \frac{T}{2\pi}\arccos\left(\frac{-3A/4}{A}\right) = 0.577$ s.

(d) Using the time found in part (c), $v = 0.665$ m/s.

EVALUATE: We could also calculate the speed in part (d) from the conservation of energy expression, Eq. (14.22).

14.85. **IDENTIFY:** Apply conservation of linear momentum to the collision between the steak and the pan. Then apply conservation of energy to the motion after the collision to find the amplitude of the subsequent SHM. Use Eq. (14.12) to calculate the period.

(a) SET UP: First find the speed of the steak just before it strikes the pan. Use a coordinate system with $+y$ downward.

$v_{0y} = 0$ (released from the rest); $y - y_0 = 0.40$ m; $a_y = +9.80$ m/s^2; $v_y = ?$

$v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$

EXECUTE: $v_y = +\sqrt{2a_y(y - y_0)} = +\sqrt{2(9.80\text{ m/s}^2)(0.40\text{ m})} = +2.80$ m/s

SET UP: Apply conservation of momentum to the collision between the steak and the pan. After the collision the steak and the pan are moving together with common velocity v_2. Let A be the steak and B be the pan. The system before and after the collision is shown in Figure 14.85.

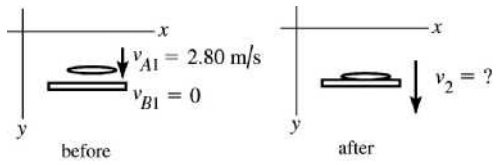


Figure 14.85

EXECUTE: P_y conserved: $m_Av_{A1y} + m_Bv_{B1y} = (m_A + m_B)v_{2y}$

$m_Av_{A1} = (m_A + m_B)v_2$

$v_2 = \left(\frac{m_A}{m_A + m_B}\right)v_{A1} = \left(\frac{2.2\text{ kg}}{2.2\text{ kg} + 0.20\text{ kg}}\right)(2.80\text{ m/s}) = 2.57\text{ m/s}$

(b) SET UP: Conservation of energy applied to the SHM gives: $\frac{1}{2}mv_0^2 + \frac{1}{2}kx_0^2 = \frac{1}{2}kA^2$ where v_0 and x_0 are the initial speed and displacement of the object and where the displacement is measured from the equilibrium position of the object.

EXECUTE: The weight of the steak will stretch the spring an additional distance d given by $kd = mg$ so $d = \frac{mg}{k} = \frac{(2.2\text{ kg})(9.80\text{ m/s}^2)}{400\text{ N/m}} = 0.0539$ m. So just after the steak hits the pan, before the pan has had time to move, the steak plus pan is 0.0539 m above the equilibrium position of the combined object. Thus $x_0 = 0.0539$ m. From part (a) $v_0 = 2.57$ m/s, the speed of the combined object just after the collision. Then $\frac{1}{2}mv_0^2 + \frac{1}{2}kx_0^2 = \frac{1}{2}kA^2$ gives

$$A = \sqrt{\frac{mv_0^2 + kx_0^2}{k}} = \sqrt{\frac{2.4\text{ kg}(2.57\text{ m/s})^2 + (400\text{ N/m})(0.0539\text{ m})^2}{400\text{ N/m}}} = 0.21\text{ m}$$

(c) $T = 2\pi\sqrt{m/k} = 2\pi\sqrt{\frac{2.4\text{ kg}}{400\text{ N/m}}} = 0.49$ s

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: The amplitude is less than the initial height of the steak above the pan because mechanical energy is lost in the inelastic collision.

14.86. **IDENTIFY:** $f = \dfrac{1}{2\pi}\sqrt{\dfrac{k}{m}}$. Use energy considerations to find the new amplitude.

SET UP: $f = 0.600$ Hz, $m = 400$ kg; $f = \frac{1}{2\pi}\sqrt{\dfrac{k}{m}}$ gives $k = 5685$ N/m. This is the effective force constant of the two springs.

(a) After the gravel sack falls off, the remaining mass attached to the springs is 225 kg. The force constant of the springs is unaffected, so $f = 0.800$ Hz. To find the new amplitude use energy considerations to find the distance downward that the beam travels after the gravel falls off. Before the sack falls off, the amount x_0 that the spring is stretched at equilibrium is given by $mg - kx_0$, so $x_0 = mg/k = (400 \text{ kg})(9.80 \text{ m/s}^2)/(5685 \text{ N/m}) = 0.6895$ m. The maximum upward displacement of the beam is $A = 0.400$ m above this point, so at this point the spring is stretched 0.2895 m. With the new mass, the mass 225 kg of the beam alone, at equilibrium the spring is stretched $mg/k = (225 \text{ kg})(9.80 \text{ m/s}^2)/(5685 \text{ N/m}) = 0.3879$ m. The new amplitude is therefore $0.3879 \text{ m} - 0.2895 \text{ m} = 0.098$ m. The beam moves 0.098 m above and below the new equilibrium position. Energy calculations show that $v = 0$ when the beam is 0.098 m above and below the equilibrium point.

(b) The remaining mass and the spring constant is the same in part (a), so the new frequency is again 0.800 Hz. The sack falls off when the spring is stretched 0.6895 m. And the speed of the beam at this point is $v = A\sqrt{k/m} = \sqrt{(5685 \text{ N/m})/(400 \text{ kg})} = 1.508$ m/s. Take $y = 0$ at this point. The total energy of the beam at this point, just after the sack falls off, is $E = K + U_{\text{el}} + U_{\text{grav}} = \frac{1}{2}(225 \text{ kg})(1.508 \text{ m/s})^2 + \frac{1}{2}(5685 \text{ N/m})(0.6895 \text{ m})^2 + 0 = 1608$ J. Let this be point 1. Let point 2 be where the beam has moved upward a distance d and where $v = 0$. $E_2 = \frac{1}{2}k(0.6895 \text{ m} - d)^2 + mgd$. $E_1 = E_2$ gives $d = 0.7275$ m. At this end point of motion the spring is compressed $0.7275 \text{ m} - 0.6895 \text{ m} = 0.0380$ m. At the new equilibrium position the spring is stretched 0.3879 m, so the new amplitude is $0.3879 \text{ m} + 0.0380 \text{ m} = 0.426$ m. Energy calculations show that v is also zero when the beam is 0.426 m below the equilibrium position.

EVALUATE: The new frequency is independent of the point in the motion at which the bag falls off. The new amplitude is smaller than the original amplitude when the sack falls off at the maximum upward displacement of the beam. The new amplitude is larger than the original amplitude when the sack falls off when the beam has maximum speed.

14.87. **IDENTIFY** and **SET UP:** Use Eq. (14.12) to calculate g and use Eq. (14.4) applied to Newtonia to relate g to the mass of the planet.

EXECUTE: The pendulum swings through $\frac{1}{2}$ cycle in 1.42 s, so $T = 2.84$ s. $L = 1.85$ m. Use T to find g:

$T = 2\pi\sqrt{L/g}$ so $g = L(2\pi/T)^2 = 9.055 \text{ m/s}^2$

Use g to find the mass M_{p} of Newtonia: $g = GM_{\text{p}}/R_{\text{p}}^2$

$2\pi R_{\text{p}} = 5.14 \times 10^7$ m, so $R_{\text{p}} = 8.18 \times 10^6$ m

$$m_{\text{p}} = \frac{gR_{\text{p}}^2}{G} = 9.08 \times 10^{24} \text{ kg}$$

EVALUATE: g is similar to that at the surface of the earth. The radius of Newtonia is a little less than earth's radius and its mass is a little more.

14.88. **IDENTIFY**: $F_x = -kx$ allows us to calculate k. $T = 2\pi\sqrt{m/k}$. $x(t) = A\cos(\omega t + \phi)$. $F_{\text{net}} = -kx$.

SET UP: Let $\phi = \pi/2$ so $x(t) = A\sin(\omega t)$. At $t = 0$, $x = 0$ and the object is moving downward. When the object is below the equilibrium position, F_{spring} is upward.

EXECUTE: **(a)** Solving Eq. (14.12) for m, and using $k = \dfrac{F}{\Delta l}$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$m = \left(\frac{T}{2\pi}\right)^2 \frac{F}{\Delta l} = \left(\frac{1.00\text{ s}}{2\pi}\right)^2 \frac{40.0\text{ N}}{0.250\text{ m}} = 4.05\text{ kg}.$$

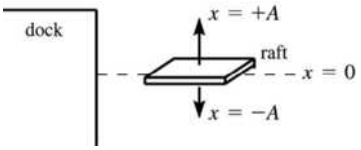
(b) $t = (0.35)T$, and so $x = -A\sin[2\pi(0.35)] = -0.0405$ m. Since $t > T/4$, the mass has already passed the lowest point of its motion, and is on the way up.

(c) Taking upward forces to be positive, $F_{\text{spring}} - mg = -kx$, where x is the displacement from equilibrium, so $F_{\text{spring}} = -(160\text{ N/m})(-0.030\text{ m}) + (4.05\text{ kg})(9.80\text{ m/s}^2) = 44.5$ N.

EVALUATE: When the object is below the equilibrium position the net force is upward and the upward spring force is larger in magnitude than the downward weight of the object.

14.89. **IDENTIFY**: Use Eq. (14.13) to relate x and t. $T = 3.5$ s.

SET UP: The motion of the raft is sketched in Figure 14.89.



Let the raft be at $x = +A$ when $t = 0$.
Then $\phi = 0$ and $x(t) = A\cos\omega t$.

Figure 14.89

EXECUTE: Calculate the time it takes the raft to move from $x = +A = +0.200$ m to $x = A - 0.100\text{ m} = 0.100$ m.

Write the equation for $x(t)$ in terms of T rather than ω. $\omega = 2\pi/T$ gives that $x(t) = A\cos(2\pi t/T)$

$x = A$ at $t = 0$

$x = 0.100$ m implies $0.100\text{ m} = (0.200\text{ m})\cos(2\pi t/T)$

$\cos(2\pi t/T) = 0.500$ so $2\pi t/T = \arccos(0.500) = 1.047$ rad

$t = (T/2\pi)(1.047\text{ rad}) = (3.5\text{ s}/2\pi)(1.047\text{ rad}) = 0.583$ s

This is the time for the raft to move down from $x = 0.200$ m to $x = 0.100$ m. But people can also get off while the raft is moving up from $x = 0.100$ m to $x = 0.200$ m, so during each period of the motion the time the people have to get off is $2t = 2(0.583\text{ s}) = 1.17$ s.

EVALUATE: The time to go from $x = 0$ to $x = A$ and return is $T/2 = 1.75$ s. The time to go from $x = A/2$ to A and return is less than this.

14.90. **IDENTIFY**: $T = 2\pi/\omega$. $F_r(r) = -kr$ to determine k.

SET UP: Example 13.10 derives $F_r(r) = -\dfrac{GM_{\text{E}}m}{R_{\text{E}}^3}r$.

EXECUTE: $a_r = F_r/m$ is in the form of Eq. (14.8), with x replaced by r, so the motion is simple harmonic. $k = \dfrac{GM_{\text{E}}m}{R_{\text{E}}^3}$. $\omega^2 = \dfrac{k}{m} = \dfrac{GM_{\text{E}}}{R_{\text{E}}^3} = \dfrac{g}{R_{\text{E}}}$. The period is then

$$T = \frac{2\pi}{\omega} = 2\pi\sqrt{\frac{R_{\text{E}}}{g}} = 2\pi\sqrt{\frac{6.38\times10^6\text{ m}}{9.80\text{ m/s}^2}} = 5070\text{ s, or } 84.5\text{ min.}$$

EVALUATE: The period is independent of the mass of the object but does depend on R_{E}, which is also the amplitude of the motion.

14.91. **IDENTIFY**: During the collision, linear momentum is conserved. After the collision, mechanical energy is conserved and the motion is SHM.

SET UP: The linear momentum is $p_x = mv_x$, the kinetic energy is $\frac{1}{2}mv^2$, and the potential energy is $\frac{1}{2}kx^2$. The period is $T = 2\pi\sqrt{\dfrac{m}{k}}$, which is the target variable.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: Apply conservation of linear momentum to the collision:

$(8.00\times10^{-3}\text{ kg})(280\text{ m/s}) = (1.00\text{ kg})v$. $v = 2.24$ m/s. This is $v_{\max}$ for the SHM. $A = 0.180$ m (given).

So $\frac{1}{2}mv_{\max}^2 = \frac{1}{2}kA^2$. $k = \left(\frac{v_{\max}}{A}\right)^2 m = \left(\frac{2.24\text{ m/s}}{0.180\text{ m}}\right)^2 (1.00\text{ kg}) = 154.9$ N/m.

$T = 2\pi\sqrt{\frac{m}{k}} = 2\pi\sqrt{\frac{1.00\text{ kg}}{154.9\text{ N/m}}} = 0.505$ s.

EVALUATE: This block would weigh about 2 pounds, which is rather heavy, but the spring constant is large enough to keep the period within an easily observable range.

14.92. **IDENTIFY**: $U(x) - U(x_0) = \int_{x_0}^{x} F_x dx$. In part (b) follow the steps outlined in the hint.

SET UP: In part (a), let $x_0 = 0$ and $U(x_0) = U(0) = 0$. The time for the object to go from $x = 0$ to $x = A$ is $T/4$.

EXECUTE: **(a)** $U = -\int_0^x F_x dx = c\int_0^x x^3 dx = \frac{c}{4}x^4$.

(b) From conservation of energy, $\frac{1}{2}mv_x^2 = \frac{c}{4}(A^4 - x^4)$. $v_x = \frac{dx}{dt}$, so $\frac{dx}{\sqrt{A^4 - x^4}} = \sqrt{\frac{c}{2m}}dt$. Integrating from 0 to A with respect to x and from 0 to $T/4$ with respect to t, $\int_0^A \frac{dx}{\sqrt{A^4 - x^4}} = \sqrt{\frac{c}{2m}}\frac{T}{4}$. To use the hint, let $u = \frac{x}{A}$, so that $dx = A\,du$ and the upper limit of the u-integral is $u = 1$. Factoring A^2 out of the square root, $\frac{1}{A}\int_0^1 \frac{du}{\sqrt{1-u^4}} = \frac{1.31}{A} = \sqrt{\frac{c}{32m}}T$, which may be expressed as $T = \frac{7.41}{A}\sqrt{\frac{m}{c}}$.

(c) The period does depend on amplitude, and the motion is not simple harmonic.

EVALUATE: Simple harmonic motion requires $F_x = -kx$, where k is a constant, and that is not the case here.

14.93. **IDENTIFY**: $F_r = -dU/dr$. The equilibrium separation r_{eq} is given by $F(r_{\text{eq}}) = 0$. The force constant k is defined by $F_r = -kx$. $f = \frac{1}{2\pi}\sqrt{\frac{k}{m}}$, where m is the reduced mass.

SET UP: $d(r^{-n})/dr = -nr^{-(n+1)}$, for $n \geq 1$.

EXECUTE: **(a)** $F_r = -\frac{dU}{dr} = A\left[\left(\frac{R_0^7}{r^9}\right) - \frac{1}{r^2}\right]$.

(b) Setting the above expression for F_r equal to zero, the term in square brackets vanishes, so that

$\frac{R_0^7}{r_{\text{eq}}^9} = \frac{1}{r_{\text{eq}}^2}$, or $R_0^7 = r_{\text{eq}}^7$, and $r_{\text{eq}} = R_0$.

(c) $U(R_0) = -\frac{7A}{8R_0} = -7.57\times10^{-19}$ J.

(d) The above expression for F_r can be expressed as

$$F_r = \frac{A}{R_0^2}\left[\left(\frac{r}{R_0}\right)^{-9} - \left(\frac{r}{R_0}\right)^{-2}\right] = \frac{A}{R_0^2}\left[(1 + (x/R_0))^{-9} - (1 + (x/R_0))^{-2}\right]$$

$$F_r \approx \frac{A}{R_0^2}[(1 - 9(x/R_0)) - (1 - 2(x/R_0))] = \frac{A}{R_0^2}(-7\,x/R_0) = -\left(\frac{7A}{R_0^3}\right)x.$$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(e) $f = \dfrac{1}{2\pi}\sqrt{k/m} = \dfrac{1}{2\pi}\sqrt{\dfrac{7A}{R_0^3 m}} = 8.39 \times 10^{12}$ Hz.

EVALUATE: The force constant depends on the parameters A and R_0 in the expression for $U(r)$. The minus sign in the expression in part (d) shows that for small displacements from equilibrium, F_r is a restoring force.

14.94. **IDENTIFY:** Newton's second law, in both its linear and rotational form, applies to this system. The motion is SHM.

SET UP: $\Sigma F = ma_{\text{cm}}$ and $\Sigma\tau = I\alpha$, where $I = \dfrac{2}{5}MR^2$ for a solid sphere, and $R\alpha = a_{\text{cm}}$ with no slipping.

EXECUTE: For each sphere, $f_s R = \left(\dfrac{2}{5}MR^2\right)\alpha$. $R\alpha = a_{\text{cm}}$. $f_s = \dfrac{2}{5}Ma_{\text{cm}}$. For the system of two spheres,

$2f_s - kx = -2Ma_{\text{cm}}$. $\dfrac{4}{5}Ma_{\text{cm}} - kx = -2Ma_{\text{cm}}$. $kx = \dfrac{14}{5}Ma_{\text{cm}}$ and $a_{\text{cm}} = \dfrac{5}{14}\left(\dfrac{k}{M}\right)x$. $a_x = -\dfrac{5}{14}\left(\dfrac{k}{M}\right)x$.

$a_x = -\omega^2 x$ so $\omega = \sqrt{\dfrac{5k}{14M}}$. $T = \dfrac{2\pi}{\omega} = 2\pi\sqrt{\dfrac{14M}{5k}} = 2\pi\sqrt{\dfrac{14(0.800\text{ kg})}{5(160\text{ N/m})}} = 0.743$ s.

EVALUATE: If the surface were smooth, there would be no rolling, but the presence of friction provides the torque to cause the spheres to rotate.

14.95. **IDENTIFY**: Apply conservation of energy to the motion before and after the collision. Apply conservation of linear momentum to the collision. After the collision the system moves as a simple pendulum. If the maximum angular displacement is small, $f = \dfrac{1}{2\pi}\sqrt{\dfrac{g}{L}}$.

SET UP: In the motion before and after the collision there is energy conversion between gravitational potential energy mgh, where h is the height above the lowest point in the motion, and kinetic energy.

EXECUTE: Energy conservation during downward swing: $m_2 g h_0 = \frac{1}{2}m_2 v^2$ and

$v = \sqrt{2gh_0} = \sqrt{2(9.8\text{ m/s}^2)(0.100\text{ m})} = 1.40$ m/s.

Momentum conservation during collision: $m_2 v = (m_2 + m_3)V$ and

$V = \dfrac{m_2 v}{m_2 + m_3} = \dfrac{(2.00\text{ kg})(1.40\text{ m/s})}{5.00\text{ kg}} = 0.560$ m/s.

Energy conservation during upward swing: $Mgh_{\text{f}} = \dfrac{1}{2}MV^2$ and

$h_{\text{f}} = V^2/2g = \dfrac{(0.560\text{ m/s})^2}{2(9.80\text{ m/s}^2)} = 0.0160\text{ m} = 1.60\text{ cm}.$

Figure 14.95 shows how the maximum angular displacement is calculated from h_{f}. $\cos\theta = \dfrac{48.4\text{ cm}}{50.0\text{ cm}}$ and

$\theta = 14.5°$. $f = \dfrac{1}{2\pi}\sqrt{\dfrac{g}{l}} = \dfrac{1}{2\pi}\sqrt{\dfrac{9.80\text{ m/s}^2}{0.500\text{ m}}} = 0.705$ Hz.

EVALUATE: $14.5° = 0.253$ rad. $\sin(0.253\text{ rad}) = 0.250$. $\sin\theta \approx \theta$ and Eq. (14.34) is accurate.

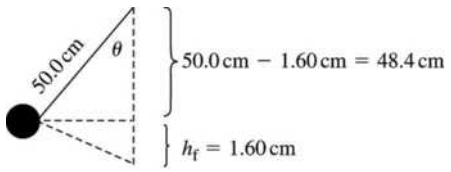


Figure 14.95

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

14.96. **IDENTIFY**: $T = 2\pi\sqrt{I/mgd}$

SET UP: The model for the leg is sketched in Figure 14.96. $T = 2\pi\sqrt{I/mgd}$, $m = 3M$.

$d = y_{\text{cg}} = \dfrac{m_1y_1 + m_2y_2}{m_1 + m_2}$. For a rod with the axis at one end, $I = \frac{1}{3}ML^2$. For a rod with the axis at its center, $I = \frac{1}{12}ML^2$.

EXECUTE: $d = \dfrac{2M([1.55\text{ m}]/2) + M(1.55\text{ m} + (1.55\text{ m})/2)}{3M} = 1.292\text{ m}$. $I + I_1 + I_2$.

$I_1 = \frac{1}{3}(2M)(1.55\text{ m})^2 = (1.602\text{ m}^2)M$. $I_{2,\text{cm}} = \frac{1}{12}M(1.55\text{ m})^2$. The parallel-axis theorem (Eq. 9.19) gives $I_2 = I_{2,\text{cm}} + M(1.55\text{ m} + [1.55\text{ m}]/2)^2 = (5.606\text{ m}^2)M$. $I = I_1 + I_2 = (7.208\text{ m}^2)M$. Then

$$T = 2\pi\sqrt{I/mgd} = 2\pi\sqrt{\frac{(7.208\text{ m}^2)M}{(3M)(9.80\text{ m/s}^2)(1.292\text{ m})}} = 2.74\text{ s}.$$

EVALUATE: This is a little smaller than $T = 2.9$ s found in Example 14.10.

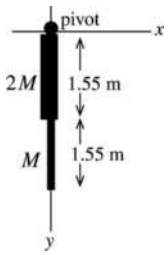

Figure 14.96

14.97. **IDENTIFY**: The motion is simple harmonic if the equation of motion for the angular oscillations is of the form $\dfrac{d^2\theta}{dt^2} = -\dfrac{\kappa}{I}\theta$, and in this case the period is $T = 2\pi\sqrt{I/\kappa}$.

SET UP: For a slender rod pivoted about its center, $I = \frac{1}{12}ML^2$.

EXECUTE: The torque on the rod about the pivot is $\tau = -\left(k\dfrac{L}{2}\theta\right)\dfrac{L}{2}$. $\tau = I\alpha = I\dfrac{d^2\theta}{dt^2}$ gives

$\dfrac{d^2\theta}{dt^2} = -k\dfrac{L^2/4}{I}\theta = -\dfrac{3k}{M}\theta$. $\dfrac{d^2\theta}{dt^2}$ is proportional to θ and the motion is angular SHM. $\dfrac{\kappa}{I} = \dfrac{3k}{M}$,

$T = 2\pi\sqrt{\dfrac{M}{3k}}$.

EVALUATE: The expression we used for the torque, $\tau = -\left(k\dfrac{L}{2}\theta\right)\dfrac{L}{2}$, is valid only when θ is small enough for $\sin\theta \approx \theta$ and $\cos\theta \approx 1$.

14.98. **IDENTIFY** and **SET UP:** Eq. (14.39) gives the period for the bell and Eq. (14.34) gives the period for the clapper.

EXECUTE: The bell swings as a physical pendulum so its period of oscillation is given by

$T = 2\pi\sqrt{I/mgd} = 2\pi\sqrt{18.0\text{ kg}\cdot\text{m}^2/(34.0\text{ kg})(9.80\text{ m/s}^2)(0.60\text{ m})} = 1.885\text{ s}$.

The clapper is a simple pendulum so its period is given by $T = 2\pi\sqrt{L/g}$.

Thus $L = g(T/2\pi)^2 = (9.80\text{ m/s}^2)(1.885\text{ s}/2\pi)^2 = 0.88\text{ m}$.

EVALUATE: If the cm of the bell were at the geometrical center of the bell, the bell would extend 1.20 m from the pivot, so the clapper is well inside tbe bell.

14.99. **IDENTIFY**: The object oscillates as a physical pendulum, with $f = \frac{1}{2\pi}\sqrt{\frac{mgd}{I}}$, where m is the total mass of the object.

SET UP: The moment of inertia about the pivot is $2(1/3)ML^2 = (2/3)\,ML^2$, and the center of gravity when balanced is a distance $d = L/(2\sqrt{2})$ below the pivot.

EXECUTE: The frequency is $f = \frac{1}{T} = \frac{1}{2\pi}\sqrt{\frac{6g}{4\sqrt{2}L}} = \frac{1}{4\pi}\sqrt{\frac{6g}{\sqrt{2}L}}$.

EVALUATE: If $f_{\text{sp}} = \frac{1}{2\pi}\sqrt{\frac{g}{L}}$ is the frequency for a simple pendulum of length L,

$f = \frac{1}{2}\sqrt{\frac{6}{\sqrt{2}}}f_{\text{sp}} = 1.03 f_{\text{sp}}$.

14.100. **IDENTIFY**: The angular frequency is given by Eq. (14.38). Use the parallel-axis theorem to calculate I in terms of x.

(a) SET UP:

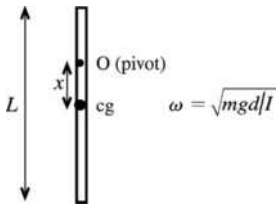

Figure 14.100

$d = x$, the distance from the cg of the object (which is at its geometrical center) to the pivot

EXECUTE: I is the moment of inertia about the axis of rotation through O. By the parallel axis theorem $I_0 = md^2 + I_{\text{cm}}$. $I_{\text{cm}} = \frac{1}{12}mL^2$ (Table 9.2), so $I_0 = mx^2 + \frac{1}{12}mL^2$. $\omega = \sqrt{\frac{mgx}{mx^2 + \frac{1}{12}mL^2}} = \sqrt{\frac{gx}{x^2 + L^2/12}}$.

(b) The maximum ω as x varies occurs when $d\omega/dx = 0$. $\frac{d\omega}{dx} = 0$ gives $\sqrt{g}\,\frac{d}{dx}\left(\frac{x^{1/2}}{(x^2 + L^2/12)^{1/2}}\right) = 0$.

$$\frac{\frac{1}{2}x^{-1/2}}{(x^2 + L^2/12)^{1/2}} - \frac{1}{2}\frac{2x}{(x^2 + L^2/12)^{3/2}}(x^{1/2}) = 0$$

$$x^{-1/2} - \frac{2x^{3/2}}{x^2 + L^2/12} = 0$$

$x^2 + L^2/12 = 2x^2$ so $x = L/\sqrt{12}$. Get maximum ω when the pivot is a distance $L/\sqrt{12}$ above the center of the rod.

(c) To answer this question we need an expression for ω_{max}:

In $\omega = \sqrt{\frac{gx}{x^2 + L^2/12}}$ substitute $x = L/\sqrt{12}$.

$$\omega_{\text{max}} = \sqrt{\frac{g(L/\sqrt{12})}{L^2/12 + L^2/12}} = \frac{g^{1/2}(12)^{-1/4}}{(L/6)^{1/2}} = \sqrt{g/L}\,(12)^{-1/4}(6)^{1/2} = \sqrt{g/L}\,(3)^{1/4}$$

$\omega_{\text{max}}^2 = (g/L)\sqrt{3}$ and $L = g\sqrt{3}/\omega_{\text{max}}^2$

$\omega_{\text{max}} = 2\pi$ rad/s gives $L = \frac{(9.80\ \text{m/s}^2)\sqrt{3}}{(2\pi\ \text{rad/s})^2} = 0.430$ m.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: $\omega \to 0$ as $x \to 0$ and $\omega \to \sqrt{3g/(2L)} = 1.225\sqrt{g/L}$ when $x \to L/2$. ω_{max} is greater than the $x = L/2$ value. A simple pendulum has $\omega = \sqrt{g/L}$; ω_{max} is greater than this.

14.101. **IDENTIFY**: In each situation, imagine the mass moves a distance Δx, the springs move distances Δx_1 and Δx_2, with forces $F_1 = -k_1\Delta x_1, F_2 = -k_2\Delta x_2$.

SET UP: Let Δx_1 and Δx_2 be positive if the springs are stretched, negative if compressed.

EXECUTE: **(a)** $\Delta x = \Delta x_1 = \Delta x_2, F = F_1 + F_2 = -(k_1 + k_2)\Delta x$, so $k_{eff} = k_1 + k_2$.

(b) Despite the orientation of the springs, and the fact that one will be compressed when the other is extended, $\Delta x = \Delta x_1 - \Delta x_2$ and both spring forces are in the same direction. The above result is still valid; $k_{eff} = k_1 + k_2$.

(c) For massless springs, the force on the block must be equal to the tension in any point of the spring combination, and $F = F_1 = F_2$. $\Delta x_1 = -\dfrac{F}{k_1}, \Delta x_2 == -\dfrac{F}{k_2}$, $\Delta x = -\left(\dfrac{1}{k_1} + \dfrac{1}{k_2}\right)F = -\dfrac{k_1 + k_2}{k_1 k_2}F$ and

$k_{eff} = \dfrac{k_1 k_2}{k_1 + k_2}$.

(d) The result of part (c) shows that when a spring is cut in half, the effective spring constant doubles, and so the frequency increases by a factor of $\sqrt{2}$.

EVALUATE: In cases (a) and (b) the effective force constant is greater than either k_1 or k_2 and in case (c) it is less.

14.102. **IDENTIFY**: Calculate F_{net} and define k_{eff} by $F_{net} = -k_{eff}x$. $T = 2\pi\sqrt{m/k_{eff}}$.

SET UP: If the elongations of the springs are x_1 and x_2, they must satisfy $x_1 + x_2 = 0.200$ m.

EXECUTE: **(a)** The net force on the block at equilibrium is zero, and so $k_1x_1 = k_2x_2$ and one spring (the one with $k_1 = 2.00$ N/m) must be stretched three times as much as the one with $k_2 = 6.00$ N/m. The sum of the elongations is 0.200 m, and so one spring stretches 0.150 m and the other stretches 0.050 m, and so the equilibrium lengths are 0.350 m and 0.250 m.

(b) When the block is displaced a distance x to the right, the net force on the block is $-k_1(x_1 + x) + k_2(x_2 - x) = -[k_1x_1 - k_2x_2] - (k_1 + k_2)x$. From the result of part (a), the term in square brackets is zero, and so the net force is $-(k_1 + k_2)x$, the effective spring constant is $k_{eff} = k_1 + k_2$ and the period of vibration is $T = 2\pi\sqrt{\dfrac{0.100\text{ kg}}{8.00\text{ N/m}}} = 0.702$ s.

EVALUATE: The motion is the same as if the block were attached to a single spring that has force constant k_{eff}.

14.103. **IDENTIFY**: Follow the procedure specified in the hint.

SET UP: Denote the position of a piece of the spring by l; $l = 0$ is the fixed point and $l = L$ is the moving end of the spring. Then the velocity of the point corresponding to l, denoted u, is $u(l) = v\dfrac{l}{L}$ (when the spring is moving, l will be a function of time, and so u is an implicit function of time).

EXECUTE: **(a)** $dm = \dfrac{M}{L}dl$, and so $dK = \dfrac{1}{2}dm\,u^2 = \dfrac{1}{2}\dfrac{Mv^2}{L^3}l^2\,dl$ and $K = \int dK = \dfrac{Mv^2}{2L^3}\int_0^L l^2\,dl = \dfrac{Mv^2}{6}$.

(b) $mv\dfrac{dv}{dt} + kx\dfrac{dx}{dt} = 0$, or $ma + kx = 0$, which is Eq. (14.4)

(c) m is replaced by $\dfrac{M}{3}$, so $\omega = \sqrt{\dfrac{3k}{M}}$ and $M' = \dfrac{M}{3}$.

EVALUATE: The effective mass of the spring is only one-third of its actual mass.

15

MECHANICAL WAVES

15.1. **IDENTIFY:** $v = f\lambda$. $T = 1/f$ is the time for one complete vibration.

SET UP: The frequency of the note one octave higher is 1568 Hz.

EXECUTE: **(a)** $\lambda = \dfrac{v}{f} = \dfrac{344 \text{ m/s}}{784 \text{ Hz}} = 0.439 \text{ m}$. $T = \dfrac{1}{f} = 1.28 \text{ ms}$.

(b) $\lambda = \dfrac{v}{f} = \dfrac{344 \text{ m/s}}{1568 \text{ Hz}} = 0.219 \text{ m}$.

EVALUATE: When f is doubled, λ is halved.

15.2. **IDENTIFY:** The distance between adjacent dots is λ. $v = f\lambda$. The long-wavelength sound has the lowest frequency, 20.0 Hz, and the short-wavelength sound has the highest frequency, 20.0 kHz.

SET UP: For sound in air, $v = 344$ m/s.

EXECUTE: **(a)** Red dots: $\lambda = \dfrac{v}{f} = \dfrac{344 \text{ m/s}}{20.0 \text{ Hz}} = 17.2 \text{ m}$.

Blue dots: $\lambda = \dfrac{344 \text{ m/s}}{20.0\times10^3 \text{ Hz}} = 0.0172 \text{ m} = 1.72 \text{ cm}$.

(b) In each case the separation easily can be measured with a meterstick.

(c) Red dots: $\lambda = \dfrac{v}{f} = \dfrac{1480 \text{ m/s}}{20.0 \text{ Hz}} = 74.0 \text{ m}$.

Blue dots: $\lambda = \dfrac{1480 \text{ m/s}}{20.0\times10^3 \text{ Hz}} = 0.0740 \text{ m} = 7.40 \text{ cm}$. In each case the separation easily can be measured with a meterstick, although for the red dots a long tape measure would be more convenient.

EVALUATE: Larger wavelengths correspond to smaller frequencies. When the wave speed increases, for a given frequency, the wavelength increases.

15.3. **IDENTIFY:** $v = f\lambda = \lambda/T$.

SET UP: 1.0 h = 3600 s. The crest to crest distance is λ.

EXECUTE: $v = \dfrac{800\times10^3 \text{ m}}{3600 \text{ s}} = 220 \text{ m/s}$. $v = \dfrac{800 \text{ km}}{1.0 \text{ h}} = 800 \text{ km/h}$.

EVALUATE: Since the wave speed is very high, the wave strikes with very little warning.

15.4. **IDENTIFY:** $f\lambda = v$

SET UP: 1.0 mm = 0.0010 m

EXECUTE: $f = \dfrac{v}{\lambda} = \dfrac{1500 \text{ m/s}}{0.0010 \text{ m}} = 1.5\times10^6 \text{ Hz}$

EVALUATE: The frequency is much higher than the upper range of human hearing.

15.5. **IDENTIFY:** We want to relate the wavelength and frequency for various waves.

SET UP: For waves $v = f\lambda$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: **(a)** $v = 344$ m/s. For $f = 20{,}000$ Hz, $\lambda = \dfrac{v}{f} = \dfrac{344 \text{ m/s}}{20{,}000 \text{ Hz}} = 1.7$ cm. For $f = 20$ Hz, $\lambda = \dfrac{v}{f} = \dfrac{344 \text{ m/s}}{20 \text{ Hz}} = 17$ m. The range of wavelengths is 1.7 cm to 17 m.

(b) $v = c = 3.00\times10^8$ m/s. For $\lambda = 700$ nm, $f = \dfrac{c}{\lambda} = \dfrac{3.00\times10^8 \text{ m/s}}{700\times10^{-9} \text{ m}} = 4.3\times10^{14}$ Hz. For $\lambda = 400$ nm, $f = \dfrac{c}{\lambda} = \dfrac{3.00\times10^8 \text{ m/s}}{400\times10^{-9} \text{ m}} = 7.5\times10^{14}$ Hz. The range of frequencies for visible light is 4.3×10^{14} Hz to 7.5×10^{14} Hz.

(c) $v = 344$ m/s. $\lambda = \dfrac{v}{f} = \dfrac{344 \text{ m/s}}{23\times10^3 \text{ Hz}} = 1.5$ cm.

(d) $v = 1480$ m/s. $\lambda = \dfrac{v}{f} = \dfrac{1480 \text{ m/s}}{23\times10^3 \text{ Hz}} = 6.4$ cm.

EVALUATE: For a given v, a larger f corresponds to smaller λ. For the same f, λ increases when v increases.

15.6. **IDENTIFY:** The fisherman observes the amplitude, wavelength, and period of the waves.

SET UP: The time from the highest displacement to lowest displacement is $T/2$. The distance from highest displacement to lowest displacement is $2A$. The distance between wave crests is λ, and the speed of the waves is $v = f\lambda = \lambda/T$.

EXECUTE: **(a)** $T = 2(2.5 \text{ s}) = 5.0$ s. $\lambda = 6.0$ m. $v = \dfrac{6.0 \text{ m}}{5.0 \text{ s}} = 1.2$ m/s.

(b) $A = (0.62 \text{ m})/2 = 0.31$ m

(c) The amplitude becomes 0.15 m but the wavelength, period and wave speed are unchanged.

EVALUATE: The wavelength, period and wave speed are independent of the amplitude of the wave.

15.7. **IDENTIFY:** Use Eq. (15.1) to calculate v. $T = 1/f$ and k is defined by Eq. (15.5). The general form of the wave function is given by Eq. (15.8), which is the equation for the transverse displacement.

SET UP: $v = 8.00$ m/s, $A = 0.0700$ m, $\lambda = 0.320$ m

EXECUTE: **(a)** $v = f\lambda$ so $f = v/\lambda = (8.00 \text{ m/s})/(0.320 \text{ m}) = 25.0$ Hz

$T = 1/f = 1/25.0 \text{ Hz} = 0.0400$ s

$k = 2\pi/\lambda = 2\pi \text{ rad}/0.320 \text{ m} = 19.6$ rad/m

(b) For a wave traveling in the $-x$-direction,

$y(x, t) = A\cos 2\pi(x/\lambda + t/T)$ (Eq. (15.8).)

At $x = 0$, $y(0, t) = A\cos 2\pi(t/T)$, so $y = A$ at $t = 0$. This equation describes the wave specified in the problem.

Substitute in numerical values:

$y(x, t) = (0.0700 \text{ m})\cos(2\pi(x/0.320 \text{ m} + t/0.0400 \text{ s}))$.

Or, $y(x, t) = (0.0700 \text{ m})\cos((19.6 \text{ m}^{-1})x + (157 \text{ rad/s})t)$.

(c) From part (b), $y = (0.0700 \text{ m})\cos(2\pi(x/0.320 \text{ m} + t/0.0400 \text{ s}))$.

Plug in $x = 0.360$ m and $t = 0.150$ s:

$y = (0.0700 \text{ m})\cos(2\pi(0.360 \text{ m}/0.320 \text{ m} + 0.150 \text{ s}/0.0400 \text{ s}))$

$y = (0.0700 \text{ m})\cos[2\pi(4.875 \text{ rad})] = +0.0495 \text{ m} = +4.95$ cm

(d) In part (c) $t = 0.150$ s.

$y = A$ means $\cos(2\pi(x/\lambda + t/T)) = 1$

$\cos\theta = 1$ for $\theta = 0, 2\pi, 4\pi, \ldots = n(2\pi)$ or $n = 0, 1, 2, \ldots$

So $y = A$ when $2\pi(x/\lambda + t/T) = n(2\pi)$ or $x/\lambda + t/T = n$

$t = T(n - x/\lambda) = (0.0400 \text{ s})(n - 0.360 \text{ m}/0.320 \text{ m}) = (0.0400 \text{ s})(n - 1.125)$

For $n = 4$, $t = 0.1150$ s (before the instant in part (c))

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

For $n = 5$, $t = 0.1550$ s (the first occurrence of $y = A$ after the instant in part (c)). Thus the elapsed time is $0.1550\text{ s} - 0.1500\text{ s} = 0.0050$ s.

EVALUATE: Part (d) says $y = A$ at 0.115 s and next at 0.155 s; the difference between these two times is 0.040 s, which is the period. At $t = 0.150$ s the particle at $x = 0.360$ m is at $y = 4.95$ cm and traveling upward. It takes $T/4 = 0.0100$ s for it to travel from $y = 0$ to $y = A$, so our answer of 0.0050 s is reasonable.

15.8. **IDENTIFY:** Compare $y(x, t)$ given in the problem to the general form of Eq. (15.4). $f = 1/T$ and $v = f\lambda$

SET UP: The comparison gives $A = 6.50$ mm, $\lambda = 28.0$ cm and $T = 0.0360$ s.

EXECUTE: **(a)** 6.50 mm

(b) 28.0 cm

(c) $f = \dfrac{1}{0.0360\text{ s}} = 27.8$ Hz

(d) $v = (0.280\text{ m})(27.8\text{ Hz}) = 7.78$ m/s

(e) Since there is a minus sign in front of the t/T term, the wave is traveling in the $+x$-direction.

EVALUATE: The speed of propagation does not depend on the amplitude of the wave.

15.9. **IDENTIFY:** Evaluate the partial derivatives and see if Eq. (15.12) is satisfied.

SET UP: $\dfrac{\partial}{\partial x}\cos(kx + \omega t) = -k\sin(kx + \omega t)$. $\dfrac{\partial}{\partial t}\cos(kx + \omega t) = -\omega\sin(kx + \omega t)$.

$\dfrac{\partial}{\partial x}\sin(kx + \omega t) = k\cos(kx + \omega t)$. $\dfrac{\partial}{\partial t}\sin(kx + \omega t) = \omega\cos(kx + \omega t)$.

EXECUTE: **(a)** $\dfrac{\partial^2 y}{\partial x^2} = -Ak^2\cos(kx + \omega t)$. $\dfrac{\partial^2 y}{\partial t^2} = -A\omega^2\cos(kx + \omega t)$. Eq. (15.12) is satisfied, if $v = \omega/k$.

(b) $\dfrac{\partial^2 y}{\partial x^2} = -Ak^2\sin(kx + \omega t)$. $\dfrac{\partial^2 y}{\partial t^2} = -A\omega^2\sin(kx + \omega t)$. Eq. (15.12) is satisfied, if $v = \omega/k$.

(c) $\dfrac{\partial y}{\partial x} = -kA\sin(kx)$. $\dfrac{\partial^2 y}{\partial x^2} = -k^2 A\cos(kx)$. $\dfrac{\partial y}{\partial t} = -\omega A\sin(\omega t)$. $\dfrac{\partial^2 y}{\partial t^2} = -\omega^2 A\cos(\omega t)$. Eq. (15.12) is not satisfied.

(d) $v_y = \dfrac{\partial y}{\partial t} = \omega A\cos(kx + \omega t)$. $a_y = \dfrac{\partial^2 y}{\partial t^2} = -A\omega^2\sin(kx + \omega t)$

EVALUATE: The functions $\cos(kx + \omega t)$ and $\sin(kx + \omega t)$ differ only in phase.

15.10. **IDENTIFY:** The general form of the wave function for a wave traveling in the $-x$-direction is given by Eq. (15.8). The time for one complete cycle to pass a point is the period *T* and the number that pass per second is the frequency *f*. The speed of a crest is the wave speed *v* and the maximum speed of a particle in the medium is $v_{\max} = \omega A$.

SET UP: Comparison to Eq. (15.8) gives $A = 3.75$ cm, $k = 0.450$ rad/cm and $\omega = 5.40$ rad/s.

EXECUTE: **(a)** $T = \dfrac{2\pi\text{ rad}}{\omega} = \dfrac{2\pi\text{ rad}}{5.40\text{ rad/s}} = 1.16$ s. In one cycle a wave crest travels a distance

$\lambda = \dfrac{2\pi\text{ rad}}{k} = \dfrac{2\pi\text{ rad}}{0.450\text{ rad/cm}} = 0.140$ m.

(b) $k = 0.450$ rad/cm. $f = 1/T = 0.862$ Hz $= 0.862$ waves/second.

(c) $v = f\lambda = (0.862\text{ Hz})(0.140\text{ m}) = 0.121$ m/s. $v_{\max} = \omega A = (5.40\text{ rad/s})(3.75\text{ cm}) = 0.202$ m/s.

EVALUATE: The transverse velocity of the particles in the medium (water) is not the same as the velocity of the wave.

15.11. **IDENTIFY** and **SET UP:** Read *A* and *T* from the graph. Apply Eq. (15.4) to determine λ and then use Eq. (15.1) to calculate *v*.

EXECUTE: **(a)** The maximum *y* is 4 mm (read from graph).

(b) For either *x* the time for one full cycle is 0.040 s; this is the period.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(c) Since $y = 0$ for $x = 0$ and $t = 0$ and since the wave is traveling in the $+x$-direction then $y(x, t) = A\sin[2\pi(t/T - x/\lambda)]$. (The phase is different from the wave described by Eq. (15.4); for that wave $y = A$ for $x = 0$, $t = 0$.) From the graph, if the wave is traveling in the $+x$-direction and if $x = 0$ and $x = 0.090$ m are within one wavelength the peak at $t = 0.01$ s for $x = 0$ moves so that it occurs at $t = 0.035$ s (read from graph so is approximate) for $x = 0.090$ m. The peak for $x = 0$ is the first peak past $t = 0$ so corresponds to the first maximum in $\sin[2\pi(t/T - x/\lambda)]$ and hence occurs at $2\pi(t/T - x/\lambda) = \pi/2$. If this same peak moves to $t_1 = 0.035$ s at $x_1 = 0.090$ m, then $2\pi(t/T - x/\lambda) = \pi/2$.

Solve for λ: $t_1/T - x_1/\lambda = 1/4$

$x_1/\lambda = t_1/T - 1/4 = 0.035 \text{ s}/0.040 \text{ s} - 0.25 = 0.625$

$\lambda = x_1/0.625 = 0.090 \text{ m}/0.625 = 0.14 \text{ m}.$

Then $v = f\lambda = \lambda/T = 0.14 \text{ m}/0.040 \text{ s} = 3.5 \text{ m/s}.$

(d) If the wave is traveling in the $-x$-direction, then $y(x, t) = A\sin(2\pi(t/T + x/\lambda))$ and the peak at $t = 0.050$ s for $x = 0$ corresponds to the peak at $t_1 = 0.035$ s for $x_1 = 0.090$ m. This peak at $x = 0$ is the second peak past the origin so corresponds to $2\pi(t/T + x/\lambda) = 5\pi/2$. If this same peak moves to $t_1 = 0.035$ s for $x_1 = 0.090$ m, then $2\pi(t_1/T + x_1/\lambda) = 5\pi/2$.

$t_1/T + x_1/\lambda = 5/4$

$x_1/\lambda = 5/4 - t_1/T = 5/4 - 0.035 \text{ s}/0.040 \text{ s} = 0.375$

$\lambda = x_1/0.375 = 0.090 \text{ m}/0.375 = 0.24 \text{ m}.$

Then $v = f\lambda = \lambda/T = 0.24 \text{ m}/0.040 \text{ s} = 6.0 \text{ m/s}.$

EVALUATE: **(e)** No. Wouldn't know which point in the wave at $x = 0$ moved to which point at $x = 0.090$ m.

15.12. **IDENTIFY:** $v_y = \dfrac{\partial y}{\partial t}$. $v = f\lambda = \lambda/T$.

SET UP: $\dfrac{\partial}{\partial t}A\cos\left(\dfrac{2\pi}{\lambda}(x - vt)\right) = +A\left(\dfrac{2\pi v}{\lambda}\right)\sin\left(\dfrac{2\pi}{\lambda}(x - vt)\right)$

EXECUTE: **(a)** $A\cos 2\pi\left(\dfrac{x}{\lambda} - \dfrac{t}{T}\right) = +A\cos\dfrac{2\pi}{\lambda}\left(x - \dfrac{\lambda}{T}t\right) = +A\cos\dfrac{2\pi}{\lambda}(x - vt)$ where $\dfrac{\lambda}{T} = \lambda f = v$ has been used.

(b) $v_y = \dfrac{\partial y}{\partial t} = \dfrac{2\pi v}{\lambda}A\sin\dfrac{2\pi}{\lambda}(x - vt).$

(c) The speed is the greatest when the sine is 1, and that speed is $2\pi vA/\lambda$. This will be equal to v if $A = \lambda/2\pi$, less than v if $A < \lambda/2\pi$ and greater than v if $A > \lambda/2\pi$.

EVALUATE: The propagation speed applies to all points on the string. The transverse speed of a particle of the string depends on both x and t.

15.13. **IDENTIFY:** Follow the procedure specified in the problem.

SET UP: For λ and x in cm, v in cm/s and t in s, the argument of the cosine is in radians.

EXECUTE: **(a)** $t = 0$:

***x*(cm)**	0.00	1.50	3.00	4.50	6.00	7.50	9.00	10.50	12.00
***y*(cm)**	0.300	0.212	0	–0.212	–0.300	–0.212	0	0.212	0.300

The graph is shown in Figure 15.13a.

(b) (i) $t = 0.400$ s:

***x*(cm)**	0.00	1.50	3.00	4.50	6.00	7.50	9.00	10.50	12.00
***y*(cm)**	–0.221	–0.0131	0.203	0.300	0.221	0.0131	–0.203	–0.300	–0.221

The graph is shown in Figure 15.13b.

(ii) $t = 0.800$ s:

***x*(cm)**	0.00	1.50	3.00	4.50	6.00	7.50	9.00	10.50	12.00
***y*(cm)**	0.0262	–0.193	–0.300	–0.230	–0.0262	0.193	0.300	0.230	0.0262

The graph is shown in Figure 15.13c.

(iii) The graphs show that the wave is traveling in the $+x$-direction.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: We know that Eq. (15.3) is for a wave traveling in the $+x$-direction, and $y(x,t)$ is derived from this. This is consistent with the direction of propagation we deduced from our graph.

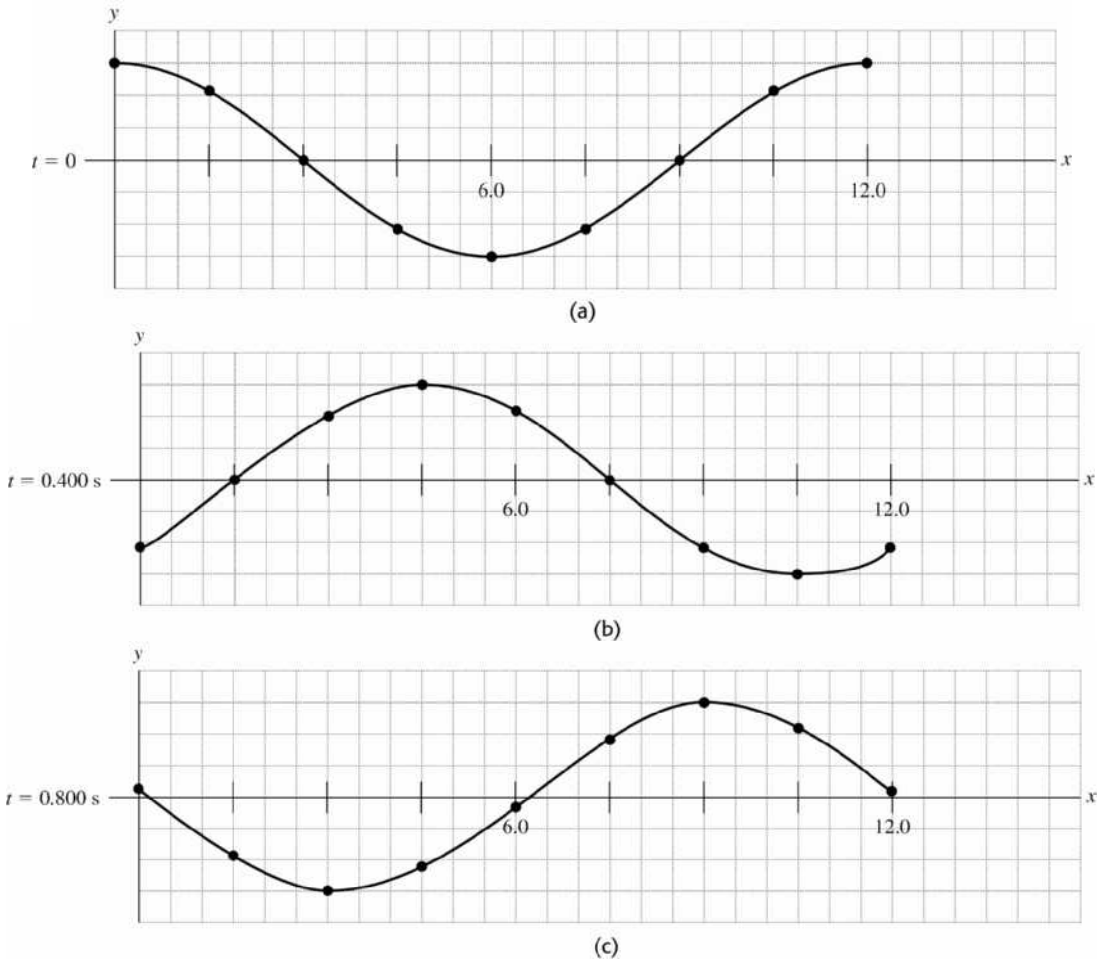

Figure 15.13

15.14. **IDENTIFY:** v_y and a_y are given by Eqs. (15.9) and (15.10).

SET UP: The sign of v_y determines the direction of motion of a particle on the string. If $v_y = 0$ and $a_y \neq 0$ the speed of the particle is increasing. If $v_y \neq 0$, the particle is speeding up if v_y and a_y have the same sign and slowing down if they have opposite signs.

EVALUATE: **(a)** The graphs are given in Figure 15.14.

(b) (i) $v_y = \omega A \sin(0) = 0$ and the particle is instantaneously at rest. $a_y = -\omega^2 A \cos(0) = -\omega^2 A$ and the particle is speeding up.

(ii) $v_y = \omega A \sin(\pi/4) = \omega A/\sqrt{2}$, and the particle is moving up. $a_y = -\omega^2 A \cos(\pi/4) = -\omega^2 A/\sqrt{2}$, and the particle is slowing down (v_y and a_y have opposite sign).

(iii) $v_y = \omega A \sin(\pi/2) = \omega A$ and the particle is moving up. $a_y = -\omega^2 A \cos(\pi/2) = 0$ and the particle is instantaneously not accelerating.

(iv) $v_y = \omega A \sin(3\pi/4) = \omega A/\sqrt{2}$, and the particle is moving up. $a_y = -\omega^2 A \cos(3\pi/4) = \omega^2 A/\sqrt{2}$, and the particle is speeding up.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(v) $v_y = \omega A \sin(\pi) = 0$ and the particle is instantaneously at rest. $a_y = -\omega^2 A \cos(\pi) = \omega^2 A$ and the particle is speeding up.

(vi) $v_y = \omega A \sin(5\pi/4) = -\omega A/\sqrt{2}$ and the particle is moving down. $a_y = -\omega^2 A \cos(5\pi/4) = \omega^2 A/\sqrt{2}$ and the particle is slowing down (v_y and a_y have opposite sign).

(vii) $v_y = \omega A \sin(3\pi/2) = -\omega A$ and the particle is moving down. $a_y = -\omega^2 A \cos(3\pi/2) = 0$ and the particle is instantaneously not accelerating.

(viii) $v_y = \omega A \sin(7\pi/4) = -\omega A/\sqrt{2}$, and the particle is moving down. $a_y = -\omega^2 A \cos(7\pi/4) = -\omega^2 A/\sqrt{2}$ and the particle is speeding up (v_y and a_y have the same sign).

EVALUATE: At $t = 0$ the wave is represented by Figure 15.10a in the textbook: point (i) in the problem corresponds to the origin, and points (ii)–(viii) correspond to the points in the figure labeled 1–7. Our results agree with what is shown in the figure.

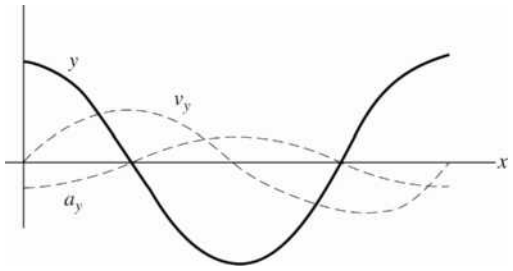

Figure 15.14

15.15. **IDENTIFY** and **SET UP:** Use Eq. (15.13) to calculate the wave speed. Then use Eq. (15.1) to calculate the wavelength.

EXECUTE: **(a)** The tension F in the rope is the weight of the hanging mass:

$F = mg = (1.50 \text{ kg})(9.80 \text{ m/s}^2) = 14.7 \text{ N}$

$v = \sqrt{F/\mu} = \sqrt{14.7 \text{ N}/(0.0550 \text{ kg/m})} = 16.3 \text{ m/s}$

(b) $v = f\lambda$ so $\lambda = v/f = (16.3 \text{ m/s})/120 \text{ Hz} = 0.136 \text{ m}$.

(c) EVALUATE: $v = \sqrt{F/\mu}$, where $F = mg$. Doubling m increases v by a factor of $\sqrt{2}$. $\lambda = v/f$. f remains 120 Hz and v increases by a factor of $\sqrt{2}$, so λ increases by a factor of $\sqrt{2}$.

15.16. **IDENTIFY:** The frequency and wavelength determine the wave speed and the wave speed depends on the tension.

SET UP: $v = \sqrt{\dfrac{F}{\mu}}$. $\mu = m/L$. $v = f\lambda$.

EXECUTE: $F = \mu v^2 = \mu(f\lambda)^2 = \dfrac{0.120 \text{ kg}}{2.50 \text{ m}}([40.0 \text{ Hz}][0.750 \text{ m}])^2 = 43.2 \text{ N}$

EVALUATE: If the frequency is held fixed, increasing the tension will increase the wavelength.

15.17. **IDENTIFY:** The speed of the wave depends on the tension in the wire and its mass density. The target variable is the mass of the wire of known length.

SET UP: $v = \sqrt{\dfrac{F}{\mu}}$ and $\mu = m/L$.

EXECUTE: First find the speed of the wave: $v = \dfrac{3.80 \text{ m}}{0.0492 \text{ s}} = 77.24 \text{ m/s}$. $v = \sqrt{\dfrac{F}{\mu}}$.

$\mu = \dfrac{F}{v^2} = \dfrac{(54.0 \text{ kg})(9.8 \text{ m/s}^2)}{(77.24 \text{ m/s})^2} = 0.08870 \text{ kg/m}$. The mass of the wire is

$m = \mu L = (0.08870 \text{ kg/m})(3.80 \text{ m}) = 0.337 \text{ kg}$.

EVALUATE: This mass is 337 g, which is a bit large for a wire 3.80 m long. It must be fairly thick.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

15.18. **IDENTIFY:** For transverse waves on a string, $v = \sqrt{F/\mu}$. The general form of the equation for waves traveling in the $+x$-direction is $y(x,t) = A\cos(kx - \omega t)$. For waves traveling in the $-x$-direction it is $y(x,t) = A\cos(kx + \omega t)$. $v = \omega/k$.

SET UP: Comparison to the general equation gives $A = 8.50$ mm, $k = 172$ rad/m and $\omega = 4830$ rad/s. The string has mass 0.00128 kg and $\mu = m/L = 0.000850$ kg/m.

EXECUTE: **(a)** $v = \dfrac{\omega}{k} = \dfrac{4830 \text{ rad/s}}{172 \text{ rad/m}} = 28.08$ m/s. $t = \dfrac{d}{v} = \dfrac{1.50 \text{ m}}{28.08 \text{ m/s}} = 0.0534$ s $=$ 53.4 ms.

(b) $W = F = \mu v^2 = (0.000850 \text{ kg/m})(28.08 \text{ m/s})^2 = 0.670$ N.

(c) $\lambda = \dfrac{2\pi \text{ rad}}{k} = \dfrac{2\pi \text{ rad}}{172 \text{ rad/m}} = 0.0365$ m. The number of wavelengths along the length of the string is $\dfrac{1.50 \text{ m}}{0.0365 \text{ m}} = 41.1$.

(d) For a wave traveling in the opposite direction, $y(x,t) = (8.50 \text{ mm})\cos([172 \text{ rad/m}]x + [4830 \text{ rad/s}]t)$.

EVALUATE: We have assumed that the tension in the string is constant and equal to W. This is reasonable since $W \gg 0.0125$ N, so the weight of the string has a negligible effect on the tension.

15.19. **IDENTIFY:** For transverse waves on a string, $v = \sqrt{F/\mu}$. $v = f\lambda$.

SET UP: The wire has $\mu = m/L = (0.0165 \text{ kg})/(0.750 \text{ m}) = 0.0220$ kg/m.

EXECUTE: **(a)** $v = f\lambda = (875 \text{ Hz})(3.33\times10^{-2} \text{ m}) = 29.1$ m/s. The tension is $F = \mu v^2 = (0.0220 \text{ kg/m})(29.1 \text{ m/s})^2 = 18.6$ N.

(b) $v = 29.1$ m/s

EVALUATE: If λ is kept fixed, the wave speed and the frequency increase when the tension is increased.

15.20. **IDENTIFY:** Apply $\Sigma F_y = 0$ to determine the tension at different points of the rope. $v = \sqrt{F/\mu}$.

SET UP: From Example 15.3, $m_{\text{samples}} = 20.0$ kg, $m_{\text{rope}} = 2.00$ kg and $\mu = 0.0250$ kg/m.

EXECUTE: **(a)** The tension at the bottom of the rope is due to the weight of the load, and the speed is the same 88.5m/s as found in Example 15.3.

(b) The tension at the middle of the rope is $(21.0 \text{ kg})(9.80\text{m/s}^2) = 205.8$ N and the wave speed is 90.7 m/s.

(c) The tension at the top of the rope is $(22.0 \text{ kg})(9.80 \text{ m/s}^2) = 215.6$ N and the speed is 92.9 m/s. (See Challenge Problem (15.84) for the effects of varying tension on the time it takes to send signals.)

EVALUATE: The tension increases toward the top of the rope, so the wave speed increases from the bottom of the rope to the top of the rope.

15.21. **IDENTIFY:** $v = \sqrt{F/\mu}$. $v = f\lambda$. The general form for $y(x,t)$ is given in Eq. (15.4), where $T = 1/f$. Eq. (15.10) says that the maximum transverse acceleration is $a_{\max} = \omega^2 A = (2\pi f)^2 A$.

SET UP: $\mu = 0.0500$ kg/m

EXECUTE: **(a)** $v = \sqrt{F/\mu} = \sqrt{(5.00 \text{ N})/(0.0500) \text{ kg/m}} = 10.0$ m/s

(b) $\lambda = v/f = (10.0 \text{ m/s})/(40.0 \text{ Hz}) = 0.250$ m

(c) $y(x,t) = A\cos(kx - \omega t)$. $k = 2\pi/\lambda = 8.00\pi$ rad/m; $\omega = 2\pi f = 80.0\pi$ rad/s.
$y(x,t) = (3.00 \text{ cm})\cos[\pi(8.00 \text{ rad/m})x - (80.0\pi \text{ rad/s})t]$

(d) $v_y = +A\omega\sin(kx - \omega t)$ and $a_y = -A\omega^2\cos(kx - \omega t)$. $a_{y,\max} = A\omega^2 = A(2\pi f)^2 = 1890$ m/s^2.

(e) $a_{y,\max}$ is much larger than g, so it is a reasonable approximation to ignore gravity.

EVALUATE: $y(x,t)$ in part (c) gives $y(0,0) = A$, which does correspond to the oscillator having maximum upward displacement at $t = 0$.

15.22. **IDENTIFY:** Apply Eq. (15.25).

SET UP: $\omega = 2\pi f$. $\mu = m/L$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: **(a)** $P_{\text{av}} = \frac{1}{2}\sqrt{\mu F}\omega^2 A^2$.

$P_{\text{av}} = \frac{1}{2}\sqrt{\left(\frac{3.00\times10^{-3}\text{ kg}}{0.80\text{ m}}\right)}(25.0\text{ N})(2\pi(120.0\text{ Hz}))^2(1.6\times10^{-3}\text{ m})^2 = 0.223\text{ W}$ or 0.22 W to two figures.

(b) P_{av} is proportional to A^2, so halving the amplitude quarters the average power, to 0.056 W.

EVALUATE: The average power is also proportional to the square of the frequency.

15.23. **IDENTIFY:** The average power carried by the wave depends on the mass density of the wire and the tension in it, as well as on the square of both the frequency and amplitude of the wave (the target variable).

SET UP: $P_{\text{av}} = \frac{1}{2}\sqrt{\mu F}\omega^2 A^2$, $v = \sqrt{\frac{F}{\mu}}$.

EXECUTE: Solving $P_{\text{av}} = \frac{1}{2}\sqrt{\mu F}\omega^2 A^2$ for A gives $A = \left(\frac{2P_{\text{av}}}{\omega^2\sqrt{\mu F}}\right)^{1/2}$. $P_{\text{av}} = 0.365$ W.

$\omega = 2\pi f = 2\pi(69.0\text{ Hz}) = 433.5$ rad/s. The tension is $F = 94.0$ N and $v = \sqrt{\frac{F}{\mu}}$ so

$\mu = \frac{F}{v^2} = \frac{94.0\text{ N}}{(492\text{ m/s})^2} = 3.883\times10^{-4}$ kg/m.

$A = \left(\frac{2(0.365\text{ W})}{(433.5\text{ rad/s})^2\sqrt{(3.883\times10^{-4}\text{ kg/m})(94.0\text{ N})}}\right)^{1/2} = 4.51\times10^{-3}\text{ m} = 4.51\text{ mm}$

EVALUATE: Vibrations of strings and wires normally have small amplitudes, which this wave does.

15.24. **IDENTIFY:** The average power (the target variable) is proportional to the square of the frequency of the wave and therefore it is inversely proportional to the square of the wavelength.

SET UP: $P_{\text{av}} = \frac{1}{2}\sqrt{\mu F}\omega^2 A^2$ where $\omega = 2\pi f$. The wave speed is $v = \sqrt{\frac{F}{\mu}}$.

EXECUTE: $\omega = 2\pi f = 2\pi\frac{v}{\lambda} = \frac{2\pi}{\lambda}\sqrt{\frac{F}{\mu}}$ so $P_{\text{av}} = \frac{1}{2}\sqrt{\mu F}\frac{4\pi^2}{\lambda^2}\left(\frac{F}{\mu}\right)A^2$. This shows that P_{av} is proportional to $\frac{1}{\lambda^2}$. Therefore $P_{\text{av},1}\lambda_1^2 = P_{\text{av},2}\lambda_2^2$ and $P_{\text{av},2} = P_{\text{av},1}\left(\frac{\lambda_1}{\lambda_2}\right)^2 = (0.400\text{ W})\left(\frac{\lambda_1}{2\lambda_1}\right)^2 = 0.100$ W.

EVALUATE: The wavelength is increased by a factor of 2, so the power is decreased by a factor of $2^2 = 4$.

15.25. **IDENTIFY:** For a point source, $I = \frac{P}{4\pi r^2}$ and $\frac{I_1}{I_2} = \frac{r_2^2}{r_1^2}$.

SET UP: $1\,\mu\text{W} = 10^{-6}$ W

EXECUTE: **(a)** $r_2 = r_1\sqrt{\frac{I_1}{I_2}} = (30.0\text{ m})\sqrt{\frac{10.0\text{ W/m}^2}{1\times10^{-6}\text{ W/m}^2}} = 95$ km

(b) $\frac{I_2}{I_3} = \frac{r_3^2}{r_2^2}$, with $I_2 = 1.0\,\mu\text{W/m}^2$ and $r_3 = 2r_2$. $I_3 = I_2\left(\frac{r_2}{r_3}\right)^2 = I_2/4 = 0.25\,\mu\text{W/m}^2$.

(c) $P = I(4\pi r^2) = (10.0\text{ W/m}^2)(4\pi)(30.0\text{ m})^2 = 1.1\times10^5$ W

EVALUATE: These are approximate calculations, that assume the sound is emitted uniformly in all directions and that ignore the effects of reflection, for example reflections from the ground.

15.26. **IDENTIFY:** Apply Eq. (15.26).

SET UP: $I_1 = 0.11\text{ W/m}^2$. $r_1 = 7.5$ m. Set $I_2 = 1.0\text{ W/m}^2$ and solve for r_2.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: $r_2 = r_1\sqrt{\dfrac{I_1}{I_2}} = (7.5\text{ m})\sqrt{\dfrac{0.11\text{ W/m}^2}{1.0\text{ W/m}^2}} = 2.5\text{ m}$, so it is possible to move $r_1 - r_2 = 7.5\text{ m} - 2.5\text{ m} = 5.0\text{ m}$ closer to the source.

EVALUATE: I increases as the distance r of the observer from the source decreases.

15.27. **IDENTIFY:** and **SET UP:** Apply Eq. (15.26) to relate I and r.

Power is related to intensity at a distance r by $P = I(4\pi r^2)$. Energy is power times time.

EXECUTE: **(a)** $I_1 r_1^2 = I_2 r_2^2$

$I_2 = I_1(r_1/r_2)^2 = (0.026\text{ W/m}^2)(4.3\text{ m}/3.1\text{ m})^2 = 0.050\text{ W/m}^2$

(b) $P = 4\pi r^2 I = 4\pi(4.3\text{ m})^2(0.026\text{ W/m}^2) = 6.04\text{ W}$

$\text{Energy} = Pt = (6.04\text{ W})(3600\text{ s}) = 2.2\times10^4\text{ J}$

EVALUATE: We could have used $r = 3.1\text{ m}$ and $I = 0.050\text{ W/m}^2$ in $P = 4\pi r^2 I$ and would have obtained the same P. Intensity becomes less as r increases because the radiated power spreads over a sphere of larger area.

15.28. **IDENTIFY:** The tension and mass per unit length of the rope determine the wave speed. Compare $y(x,t)$ given in the problem to the general form given in Eq. (15.8). $v = \omega/k$. The average power is given by Eq. (15.25).

SET UP: Comparison with Eq. (15.8) gives $A = 2.30\text{ mm}$, $k = 6.98\text{ rad/m}$ and $\omega = 742\text{ rad/s}$.

EXECUTE: **(a)** $A = 2.30\text{ mm}$

(b) $f = \dfrac{\omega}{2\pi} = \dfrac{742\text{ rad/s}}{2\pi} = 118\text{ Hz}.$

(c) $\lambda = \dfrac{2\pi}{k} = \dfrac{2\pi}{6.98\text{ rad/m}} = 0.90\text{ m}$

(d) $v = \dfrac{\omega}{k} = \dfrac{742\text{ rad/s}}{6.98\text{ rad/m}} = 106\text{ m/s}$

(e) The wave is traveling in the $-x$-direction because the phase of $y(x,t)$ has the form $kx + \omega t$.

(f) The linear mass density is $\mu = (3.38\times10^{-3}\text{ kg})/(1.35\text{ m}) = 2.504\times10^{-3}\text{ kg/m}$, so the tension is $F = \mu v^2 = (2.504\times10^{-3}\text{ kg/m})(106.3\text{ m/s})^2 = 28.3\text{ N}.$

(g) $P_{\text{av}} = \frac{1}{2}\sqrt{\mu F}\,\omega^2 A^2 = \frac{1}{2}\sqrt{(2.50\times10^{-3}\text{ kg/m})(28.3\text{ N})}(742\text{ rad/s})^2(2.30\times10^{-3}\text{ m})^2 = 0.39\text{ W}$

EVALUATE: In part (d) we could also calculate the wave speed as $v = f\lambda$ and we would obtain the same result.

15.29. **IDENTIFY:** The intensity obeys an inverse square law.

SET UP: $I = \dfrac{P}{4\pi r^2}$, where P is the target variable.

EXECUTE: Solving for the power gives $P = (4\pi r^2)I = 4\pi(7.00\times10^{12}\text{ m})^2(15.4\text{ W/m}^2) = 9.48\times10^{27}\text{ W}.$

EVALUATE: The intensity of the radiation is decreased enormously due to the great distance from the star.

15.30. **IDENTIFY:** The distance the wave shape travels in time t is vt. The wave pulse reflects at the end of the string, at point O.

SET UP: The reflected pulse is inverted when O is a fixed end and is not inverted when O is a free end.

EXECUTE: **(a)** The wave form for the given times, respectively, is shown in Figure 15.30a.

(b) The wave form for the given times, respectively, is shown in Figure 15.30b.

EVALUATE: For the fixed end the result of the reflection is an inverted pulse traveling to the left and for the free end the result is an upright pulse traveling to the left.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

SET UP: The net displacement is the algebraic sum of the displacements due to each pulse.
EXECUTE: The shape of the string at each specified time is shown in Figure 15.34.
EVALUATE: The pulses interfere when they overlap but resume their original shape after they have completely passed through each other.

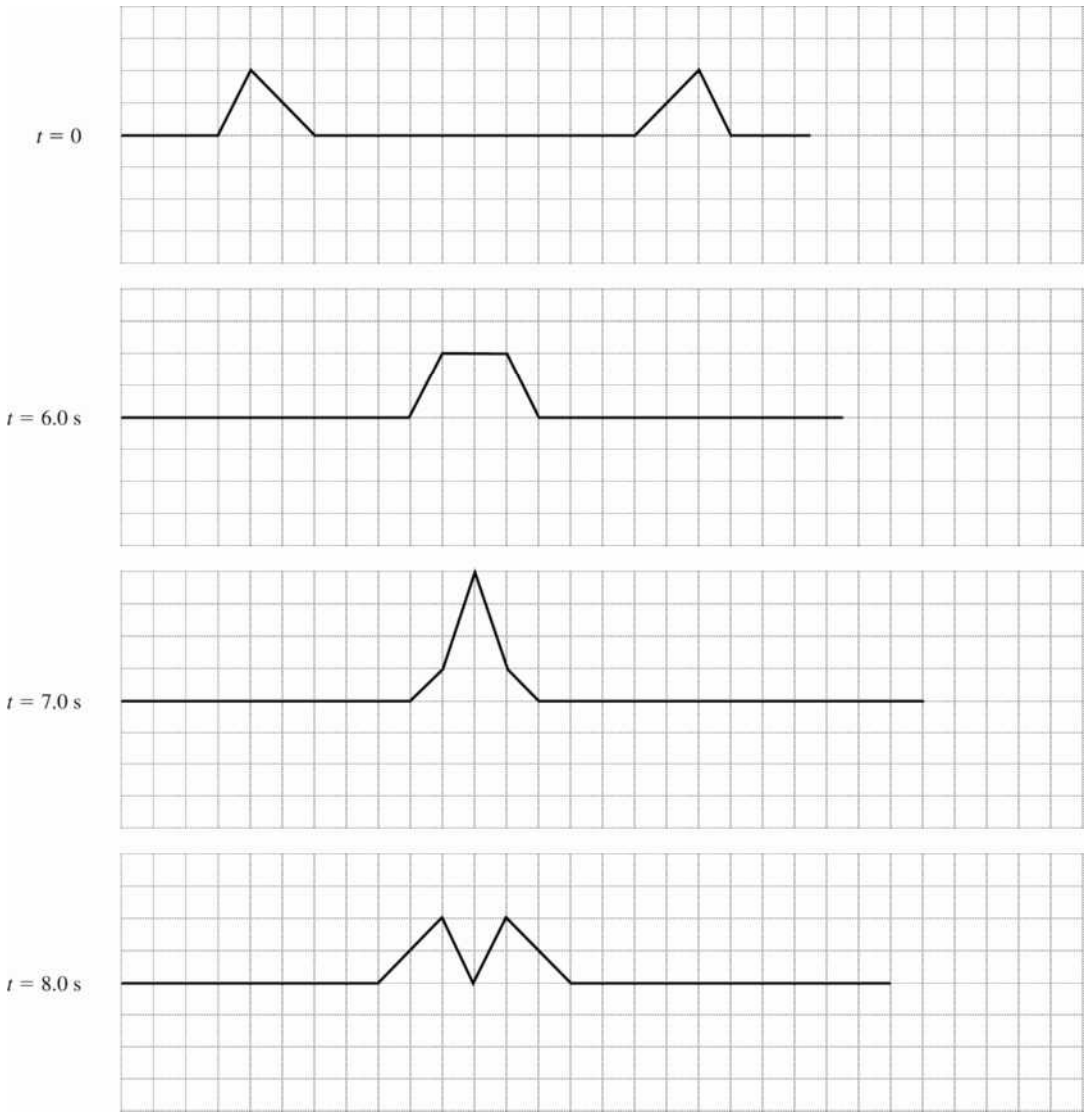

Figure 15.34

15.35. **IDENTIFY:** Apply the principle of superposition.
SET UP: The net displacement is the algebraic sum of the displacements due to each pulse.
EXECUTE: The shape of the string at each specified time is shown in Figure 15.35.
EVALUATE: The pulses interfere when they overlap but resume their original shape after they have completely passed through each other.

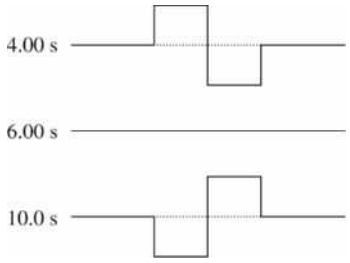

Figure 15.35

15.36. **IDENTIFY:** Apply Eqs. (15.28) and (15.1). At an antinode, $y(t) = A_{SW}\sin\omega t$. k and ω for the standing wave have the same values as for the two traveling waves.

SET UP: $A_{SW} = 0.850$ cm. The antinode to antinode distance is $\lambda/2$, so $\lambda = 30.0$ cm. $v_y = \partial y/\partial t$.

EXECUTE: **(a)** The node to node distance is $\lambda/2 = 15.0$ cm.

(b) λ is the same as for the standing wave, so $\lambda = 30.0$ cm. $A = \frac{1}{2}A_{SW} = 0.425$ cm.

$$v = f\lambda = \frac{\lambda}{T} = \frac{0.300\text{ m}}{0.0750\text{ s}} = 4.00\text{ m/s}.$$

(c) $v_y = \dfrac{\partial y}{\partial t} = A_{SW}\omega\sin kx\cos\omega t$. At an antinode $\sin kx = 1$, so $v_y = A_{SW}\omega\cos\omega t$. $v_{max} = A_{SW}\omega$.

$\omega = \dfrac{2\pi\text{ rad}}{T} = \dfrac{2\pi\text{ rad}}{0.0750\text{ s}} = 83.8$ rad/s. $v_{max} = (0.850\times10^{-2}\text{ m})(83.8\text{ rad/s}) = 0.0712$ m/s. $v_{min} = 0$.

(d) The distance from a node to an adjacent antinode is $\lambda/4 = 7.50$ cm.

EVALUATE: The maximum transverse speed for a point at an antinode of the standing wave is twice the maximum transverse speed for each traveling wave, since $A_{SW} = 2A$.

15.37. **IDENTIFY** and **SET UP:** Nodes occur where $\sin kx = 0$ and antinodes are where $\sin kx = \pm 1$.

EXECUTE: Eq. (15.28): $y = (A_{SW}\sin kx)\sin\omega t$

(a) At a node $y = 0$ for all t. This requires that $\sin kx = 0$ and this occurs for $kx = n\pi$, $n = 0, 1, 2,\ldots$

$$x = n\pi/k = \frac{n\pi}{0.750\pi\text{ rad/m}} = (1.33\text{ m})n, n = 0, 1, 2,\ldots$$

(b) At an antinode $\sin kx = \pm 1$ so y will have maximum amplitude. This occurs when $kx = \left(n + \frac{1}{2}\right)\pi$, $n = 0, 1, 2,\ldots$

$$x = \left(n + \tfrac{1}{2}\right)\pi/k = \left(n + \tfrac{1}{2}\right)\frac{\pi}{0.750\pi\text{ rad/m}} = (1.33\text{ m})\left(n + \tfrac{1}{2}\right), n = 0, 1, 2,\ldots$$

EVALUATE: $\lambda = 2\pi/k = 2.66$ m. Adjacent nodes are separated by $\lambda/2$, adjacent antinodes are separated by $\lambda/2$, and the node to antinode distance is $\lambda/4$.

15.38. **IDENTIFY:** Evaluate $\partial^2 y/\partial x^2$ and $\partial^2 y/\partial t^2$ and see if Eq. (15.12) is satisfied for $v = \omega/k$.

SET UP: $\dfrac{\partial}{\partial x}\sin kx = k\cos kx$. $\dfrac{\partial}{\partial x}\cos kx = -k\sin kx$. $\dfrac{\partial}{\partial t}\sin\omega t = \omega\cos\omega t$. $\dfrac{\partial}{\partial t}\cos\omega t = -\omega\sin\omega t$

EXECUTE: **(a)** $\dfrac{\partial^2 y}{\partial x^2} = -k^2[A_{sw}\sin\omega t]\sin kx$, $\dfrac{\partial^2 y}{\partial t^2} = -\omega^2[A_{sw}\sin\omega t]\sin kx$, so for $y(x,t)$ to be a solution of Eq. (15.12), $-k^2 = \dfrac{-\omega^2}{v^2}$, and $v = \dfrac{\omega}{k}$.

(b) A standing wave is built up by the superposition of traveling waves, to which the relationship $v = \lambda/k$ applies.

EVALUATE: $y(x,t) = (A_{SW}\sin kx)\sin\omega t$ is a solution of the wave equation because it is a sum of solutions to the wave equation.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

15.39. **IDENTIFY:** Evaluate $\partial^2 y/\partial x^2$ and $\partial^2 y/\partial t^2$ and show that Eq. (15.12) is satisfied.

SET UP: $\dfrac{\partial}{\partial x}(y_1+y_2)=\dfrac{\partial y_1}{\partial x}+\dfrac{\partial y_2}{\partial x}$ and $\dfrac{\partial}{\partial t}(y_1+y_2)=\dfrac{\partial y_1}{\partial t}+\dfrac{\partial y_2}{\partial t}$

EXECUTE: $\dfrac{\partial^2 y}{\partial x^2}=\dfrac{\partial^2 y_1}{\partial x^2}+\dfrac{\partial^2 y_2}{\partial x^2}$ and $\dfrac{\partial^2 y}{\partial t^2}=\dfrac{\partial^2 y_1}{\partial t^2}+\dfrac{\partial^2 y_2}{\partial t^2}$. The functions y_1 and y_2 are given as being solutions to the wave equation, so

$$\frac{\partial^2 y}{\partial x^2}=\frac{\partial^2 y_1}{\partial x^2}+\frac{\partial^2 y_2}{\partial x^2}=\left(\frac{1}{v^2}\right)\frac{\partial^2 y_1}{\partial t^2}+\left(\frac{1}{v^2}\right)\frac{\partial^2 y_2}{\partial t^2}=\left(\frac{1}{v^2}\right)\left[\frac{\partial^2 y_1}{\partial t^2}+\frac{\partial^2 y_2}{\partial t^2}\right]=\left(\frac{1}{v^2}\right)\frac{\partial^2 y}{\partial t^2}$$ and so $y=y_1+y_2$ is a solution of Eq. (15.12).

EVALUATE: The wave equation is a linear equation, as it is linear in the derivatives, and differentiation is a linear operation.

15.40. **IDENTIFY:** For a string fixed at both ends, $\lambda_n=\dfrac{2L}{n}$ and $f_n=n\left(\dfrac{v}{2L}\right)$.

SET UP: For the fundamental, $n=1$. For the second overtone, $n=3$. For the fourth harmonic, $n=4$.

EXECUTE: **(a)** $\lambda_1=2L=3.00$ m. $f_1=\dfrac{v}{2L}=\dfrac{(48.0\text{ m/s})}{2(1.50\text{ m})}=16.0$ Hz.

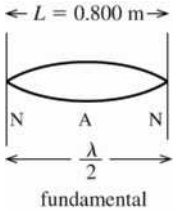
(b) $\lambda_3=\lambda_1/3=1.00$ m. $f_2=3f_1=48.0$ Hz.

(c) $\lambda_4=\lambda_1/4=0.75$ m. $f_3=4f_1=64.0$ Hz.

EVALUATE: As n increases, λ decreases and f increases.

15.41. **IDENTIFY:** Use Eq. (15.1) for v and Eq. (15.13) for the tension F. $v_y=\partial y/\partial t$ and $a_y=\partial v_y/\partial t$.

(a) SET UP: The fundamental standing wave is sketched in Figure 15.41.



$f=60.0$ Hz

From the sketch, $\lambda/2=L$ so $\lambda=2L=1.60$ m

Figure 15.41

EXECUTE: $v=f\lambda=(60.0\text{ Hz})(1.60\text{ m})=96.0$ m/s

(b) The tension is related to the wave speed by Eq. (15.13):

$v=\sqrt{F/\mu}$ so $F=\mu v^2$.

$\mu=m/L=0.0400\text{ kg}/0.800\text{ m}=0.0500$ kg/m

$F=\mu v^2=(0.0500\text{ kg/m})(96.0\text{ m/s})^2=461$ N.

(c) $\omega=2\pi f=377$ rad/s and $y(x,t)=A_{SW}\sin kx\sin\omega t$

$v_y=\omega A_{SW}\sin kx\cos\omega t$; $a_y=-\omega^2 A_{SW}\sin kx\sin\omega t$

$(v_y)_{max}=\omega A_{SW}=(377\text{ rad/s})(0.300\text{ cm})=1.13$ m/s.

$(a_y)_{max}=\omega^2 A_{SW}=(377\text{ rad/s})^2(0.300\text{ cm})=426\text{ m/s}^2$.

EVALUATE: The transverse velocity is different from the wave velocity. The wave velocity and tension are similar in magnitude to the values in the examples in the text. Note that the transverse acceleration is quite large.

15.42. **IDENTIFY:** The fundamental frequency depends on the wave speed, and that in turn depends on the tension.

SET UP: $v=\sqrt{\dfrac{F}{\mu}}$ where $\mu=m/L$. $f_1=\dfrac{v}{2L}$. The nth harmonic has frequency $f_n=nf_1$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: **(a)** $v=\sqrt{\dfrac{F}{m/L}}=\sqrt{\dfrac{FL}{m}}=\sqrt{\dfrac{(800\text{ N})(0.400\text{ m})}{3.00\times10^{-3}\text{ kg}}}=327\text{ m/s}.$ $f_1=\dfrac{v}{2L}=\dfrac{327\text{ m/s}}{2(0.400\text{ m})}=409\text{ Hz}.$

(b) $n=\dfrac{10{,}000\text{ Hz}}{f_1}=24.4.$ The 24th harmonic is the highest that could be heard.

EVALUATE: In part (b) we use the fact that a standing wave on the wire produces a sound wave in air of the same frequency.

15.43. **IDENTIFY:** Compare $y(x,t)$ given in the problem to Eq. (15.28). From the frequency and wavelength for the third harmonic find these values for the eighth harmonic.

(a) SET UP: The third harmonic standing wave pattern is sketched in Figure 15.43.

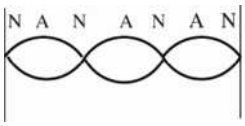


Figure 15.43

EXECUTE: **(b)** Eq. (15.28) gives the general equation for a standing wave on a string:

$y(x,t)=(A_{\text{SW}}\sin kx)\sin\omega t$

$A_{\text{SW}}=2A,$ so $A=A_{\text{SW}}/2=(5.60\text{ cm})/2=2.80\text{ cm}$

(c) The sketch in part (a) shows that $L=3(\lambda/2).$ $k=2\pi/\lambda,$ $\lambda=2\pi/k$

Comparison of $y(x,t)$ given in the problem to Eq. (15.28) gives $k=0.0340$ rad/cm. So,

$\lambda=2\pi/(0.0340\text{ rad/cm})=184.8\text{ cm}$

$L=3(\lambda/2)=277\text{ cm}$

(d) $\lambda=185$ cm, from part (c)

$\omega=50.0$ rad/s so $f=\omega/2\pi=7.96$ Hz

period $T=1/f=0.126$ s

$v=f\lambda=1470$ cm/s

(e) $v_y=\partial y/\partial t=\omega A_{\text{SW}}\sin kx\cos\omega t$

$v_{y,\,\max}=\omega A_{\text{SW}}=(50.0\text{ rad/s})(5.60\text{ cm})=280\text{ cm/s}$

(f) $f_3=7.96\text{ Hz}=3f_1,$ so $f_1=2.65\text{ Hz}$ is the fundamental

$f_8=8f_1=21.2\text{ Hz};$ $\omega_8=2\pi f_8=133\text{ rad/s}$

$\lambda=v/f=(1470\text{ cm/s})/(21.2\text{ Hz})=69.3\text{ cm}$ and $k=2\pi/\lambda=0.0906\text{ rad/cm}$

$y(x,t)=(5.60\text{ cm})\sin([0.0906\text{ rad/cm}]x)\sin([133\text{ rad/s}]t)$

EVALUATE: The wavelength and frequency of the standing wave equals the wavelength and frequency of the two traveling waves that combine to form the standing wave. In the 8th harmonic the frequency and wave number are larger than in the 3rd harmonic.

15.44. **IDENTIFY:** Compare the $y(x,t)$ specified in the problem to the general form of Eq. (15.28).

SET UP: The comparison gives $A_{\text{SW}}=4.44$ mm, $k=32.5$ rad/m and $\omega=754$ rad/s.

EXECUTE: **(a)** $A=\frac{1}{2}A_{\text{SW}}=\frac{1}{2}(4.44\text{ mm})=2.22\text{ mm}.$

(b) $\lambda=\dfrac{2\pi}{k}=\dfrac{2\pi}{32.5\text{ rad/m}}=0.193\text{ m}.$

(c) $f=\dfrac{\omega}{2\pi}=\dfrac{754\text{ rad/s}}{2\pi}=120\text{ Hz}.$

(d) $v=\dfrac{\omega}{k}=\dfrac{754\text{ rad/s}}{32.5\text{ rad/m}}=23.2\text{ m/s}.$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(e) If the wave traveling in the $+x$-direction is written as $y_1(x,t) = A\cos(kx - \omega t)$, then the wave traveling in the $-x$-direction is $y_2(x,t) = -A\cos(kx + \omega t)$, where $A = 2.22$ mm from part (a), $k = 32.5$ rad/m and $\omega = 754$ rad/s.

(f) The harmonic cannot be determined because the length of the string is not specified.

EVALUATE: The two traveling waves that produce the standing wave are identical except for their direction of propagation.

15.45. **(a) IDENTIFY** and **SET UP:** Use the angular frequency and wave number for the traveling waves in Eq. (15.28) for the standing wave.

EXECUTE: The traveling wave is $y(x,t) = (2.30 \text{ mm})\cos([6.98 \text{ rad/m}]x) + [742 \text{ rad/s}]t)$

$A = 2.30$ mm so $A_{SW} = 4.60$ mm; $k = 6.98$ rad/m and $\omega = 742$ rad/s

The general equation for a standing wave is $y(x,t) = (A_{SW}\sin kx)\sin\omega t$, so

$y(x,t) = (4.60 \text{ mm})\sin([6.98 \text{ rad/m}]x)\sin([742 \text{ rad/s}]t)$

(b) IDENTIFY and **SET UP**: Compare the wavelength to the length of the rope in order to identify the harmonic.

EXECUTE: $L = 1.35$ m (from Exercise 15.28)

$\lambda = 2\pi/k = 0.900$ m

$L = 3(\lambda/2)$, so this is the 3rd harmonic

(c) For this 3rd harmonic, $f = \omega/2\pi = 118$ Hz

$f_3 = 3f_1$ so $f_1 = (118 \text{ Hz})/3 = 39.3$ Hz

EVALUATE: The wavelength and frequency of the standing wave equals the wavelength and frequency of the two traveling waves that combine to form the standing wave. The nth harmonic has n node-to-node segments and the node-to-node distance is $\lambda/2$, so the relation between L and λ for the nth harmonic is $L = n(\lambda/2)$.

15.46. **IDENTIFY:** $v = \sqrt{F/\mu}$. $v = f\lambda$. The standing waves have wavelengths $\lambda_n = \dfrac{2L}{n}$ and frequencies $f_n = nf_1$. The standing wave on the string and the sound wave it produces have the same frequency.

SET UP: For the fundamental $n = 1$ and for the second overtone $n = 3$. The string has $\mu = m/L = (8.75\times10^{-3} \text{ kg})/(0.750 \text{ m}) = 1.17\times10^{-2}$ kg/m.

EXECUTE: **(a)** $\lambda = 2L/3 = 2(0.750 \text{ m})/3 = 0.500$ m. The sound wave has frequency

$f = \dfrac{v}{\lambda} = \dfrac{344 \text{ m/s}}{0.765 \text{ m}} = 449.7$ Hz. For waves on the string,

$v = f\lambda = (449.7 \text{ Hz})(0.500 \text{ m}) = 224.8$ m/s. The tension in the string is

$F = \mu v^2 = (1.17\times10^{-2} \text{ kg/m})(224.8 \text{ m/s})^2 = 591$ N.

(b) $f_1 = f_3/3 = (449.7 \text{ Hz})/3 = 150$ Hz.

EVALUATE: The waves on the string have a much longer wavelength than the sound waves in the air because the speed of the waves on the string is much greater than the speed of sound in air.

15.47. **IDENTIFY** and **SET UP:** Use the information given about the A_4 note to find the wave speed that depends on the linear mass density of the string and the tension. The wave speed isn't affected by the placement of the fingers on the bridge. Then find the wavelength for the D_5 note and relate this to the length of the vibrating portion of the string.

EXECUTE: **(a)** $f = 440$ Hz when a length $L = 0.600$ m vibrates; use this information to calculate the speed v of waves on the string. For the fundamental $\lambda/2 = L$ so $\lambda = 2L = 2(0.600 \text{ m}) = 1.20$ m. Then $v = f\lambda = (440 \text{ Hz})(1.20 \text{ m}) = 528$ m/s. Now find the length $L = x$ of the string that makes $f = 587$ Hz.

$\lambda = \dfrac{v}{f} = \dfrac{528 \text{ m/s}}{587 \text{ Hz}} = 0.900$ m

$L = \lambda/2 = 0.450$ m, so $x = 0.450 \text{ m} = 45.0$ cm.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) No retuning means same wave speed as in part (a). Find the length of vibrating string needed to produce $f = 392$ Hz.

$$\lambda = \frac{v}{f} = \frac{528 \text{ m/s}}{392 \text{ Hz}} = 1.35 \text{ m}$$

$L = \lambda/2 = 0.675$ m; string is shorter than this. No, not possible.

EVALUATE: Shortening the length of this vibrating string increases the frequency of the fundamental.

15.48. **IDENTIFY:** $y(x,t) = (A_{SW} \sin kx)\sin \omega t$. $v_y = \partial y/\partial t$. $a_y = \partial^2 y/\partial t^2$.

SET UP: $v_{max} = (A_{SW} \sin kx)\omega$. $a_{max} = (A_{SW} \sin kx)\omega^2$.

EXECUTE: **(a)** (i) $x = \frac{\lambda}{2}$ is a node, and there is no motion. (ii) $x = \frac{\lambda}{4}$ is an antinode, and $v_{max} = A(2\pi f) = 2\pi fA$, $a_{max} = (2\pi f)^2 v_{max} = 4\pi^2 f^2 A$. (iii) $\cos\frac{\pi}{4} = \frac{1}{\sqrt{2}}$ and this factor multiplies the results of (ii), so $v_{max} = \sqrt{2}\pi fA$, $a_{max} = 2\sqrt{2}\pi^2 f^2 A$.

(b) The amplitude is $2A\sin kx$, or (i) 0, (ii) $2A$, (iii) $2A/\sqrt{2}$.

(c) The time between the extremes of the motion is the same for any point on the string (although the period of the zero motion at a node might be considered indeterminate) and is $1/2f$.

EVALUATE: Any point in a standing wave moves in SHM. All points move with the same frequency but have different amplitude.

15.49. **IDENTIFY:** For the fundamental, $f_1 = \frac{v}{2L}$. $v = \sqrt{F/\mu}$. A standing wave on a string with frequency f produces a sound wave that also has frequency f.

SET UP: $f_1 = 245$ Hz. $L = 0.635$ m.

EXECUTE: **(a)** $v = 2f_1 L = 2(245 \text{ Hz})(0.635 \text{ m}) = 311$ m/s.

(b) The frequency of the fundamental mode is proportional to the speed and hence to the square root of the tension; $(245 \text{ Hz})\sqrt{1.01} = 246$ Hz.

(c) The frequency will be the same, 245 Hz. The wavelength will be $\lambda_{air} = v_{air}/f = (344 \text{ m/s})/(245 \text{ Hz}) = 1.40$ m, which is larger than the wavelength of standing wave on the string by a factor of the ratio of the speeds.

EVALUATE: Increasing the tension increases the wave speed and this in turn increases the frequencies of the standing waves. The wavelength of each normal mode depends only on the length of the string and doesn't change when the tension changes.

15.50. **IDENTIFY:** The ends of the stick are free, so they must be displacement antinodes. The first harmonic has one node, at the center of the stick, and each successive harmonic adds one node.

SET UP: The node to node and antinode to antinode distance is $\lambda/2$.

EXECUTE: The standing wave patterns for the first three harmonics are shown in Figure 15.50.

1st harmonic: $L = \frac{1}{2}\lambda_1 \rightarrow \lambda_1 = 2L = 4.0$ m. 2nd harmonic: $L = 1\lambda_2 \rightarrow \lambda_2 = L = 2.0$ m.

3rd harmonic: $L = \frac{3}{2}\lambda_3 \rightarrow \lambda_3 = \frac{2L}{3} = 1.33$ m.

EVALUATE: The higher the harmonic the shorter the wavelength.

Figure 15.50

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

15.51. **IDENTIFY** and **SET UP:** Calculate v, ω, and k from Eqs. (15.1), (15.5) and (15.6). Then apply Eq. (15.7) to obtain $y(x,t)$.

$A = 2.50\times10^{-3}$ m, $\lambda = 1.80$ m, $v = 36.0$ m/s

EXECUTE: **(a)** $v = f\lambda$ so $f = v/\lambda = (36.0 \text{ m/s})/1.80 \text{ m} = 20.0$ Hz

$\omega = 2\pi f = 2\pi(20.0 \text{ Hz}) = 126$ rad/s

$k = 2\pi/\lambda = 2\pi$ rad/1.80 m = 3.49 rad/m

(b) For a wave traveling to the right, $y(x,t) = A\cos(kx - \omega t)$. This equation gives that the $x = 0$ end of the string has maximum upward displacement at $t = 0$.

Put in the numbers: $y(x,t) = (2.50\times10^{-3} \text{ m})\cos((3.49 \text{ rad/m})x - (126 \text{ rad/s})t$.

(c) The left-hand end is located at $x = 0$. Put this value into the equation of part (b):

$y(0,t) = +(2.50\times10^{-3} \text{ m})\cos((126 \text{ rad/s})t)$.

(d) Put $x = 1.35$ m into the equation of part (b):

$y(1.35 \text{ m}, t) = (2.50\times10^{-3} \text{ m})\cos((3.49 \text{ rad/m})(1.35 \text{ m}) - (126 \text{ rad/s})t)$.

$y(1.35 \text{ m}, t) = (2.50\times10^{-3} \text{ m})\cos(4.71 \text{ rad} - (126 \text{ rad/s})t)$

$4.71 \text{ rad} = 3\pi/2$ and $\cos(\theta) = \cos(-\theta)$, so $y(1.35 \text{ m}, t) = (2.50\times10^{-3} \text{ m})\cos((126 \text{ rad/s})t - 3\pi/2 \text{ rad})$

(e) $y = A\cos(kx - \omega t)$ (part (b))

The transverse velocity is given by $v_y = \dfrac{\partial y}{\partial t} = A\dfrac{\partial}{\partial t}\cos(kx - \omega t) = +A\omega\sin(kx - \omega t)$.

The maximum v_y is $A\omega = (2.50\times10^{-3} \text{ m})(126 \text{ rad/s}) = 0.315$ m/s.

(f) $y(x,t) = (2.50\times10^{-3} \text{ m})\cos((3.49 \text{ rad/m})x - (126 \text{ rad/s})t)$

$t = 0.0625$ s and $x = 1.35$ m gives

$y = (2.50\times10^{-3} \text{ m})\cos((3.49 \text{ rad/m})(1.35 \text{ m}) - (126 \text{ rad/s})(0.0625 \text{ s})) = -2.50\times10^{-3}$ m.

$v_y = +A\omega\sin(kx - \omega t) = +(0.315 \text{ m/s})\sin((3.49 \text{ rad/m})x - (126 \text{ rad/s})t)$

$t = 0.0625$ s and $x = 1.35$ m gives

$v_y = (0.315 \text{ m/s})\sin((3.49 \text{ rad/m})(1.35 \text{ m}) - (126 \text{ rad/s})(0.0625 \text{ s})) = 0.0$

EVALUATE: The results of part (f) illustrate that $v_y = 0$ when $y = \pm A$, as we saw from SHM in Chapter 14.

15.52. **IDENTIFY:** Compare $y(x,t)$ given in the problem to the general form given in Eq. (15.8).

SET UP: The comparison gives $A = 0.750$ cm, $k = 0.400\pi$ rad/cm and $\omega = 250\pi$ rad/s.

EXECUTE: **(a)** $A = 0.750$ cm, $\lambda = \dfrac{2}{0.400 \text{ rad/cm}} = 5.00$ cm, $f = 125$ Hz, $T = \frac{1}{f} = 0.00800$ s and $v = \lambda f = 6.25$ m/s.

(b) The sketches of the shape of the rope at each time are given in Figure 15.52.

(c) To stay with a wavefront as t increases, x decreases and so the wave is moving in the $-x$-direction.

(d) From Eq. (15.13), the tension is $F = \mu v^2 = (0.50 \text{ kg/m})(6.25 \text{ m/s})^2 = 19.5$ N.

(e) $P_{\text{av}} = \frac{1}{2}\sqrt{\mu F}\,\omega^2 A^2 = 54.2$ W.

EVALUATE: The argument of the cosine is $(kx + \omega t)$ for a wave traveling in the $-x$-direction, and that is the case here.

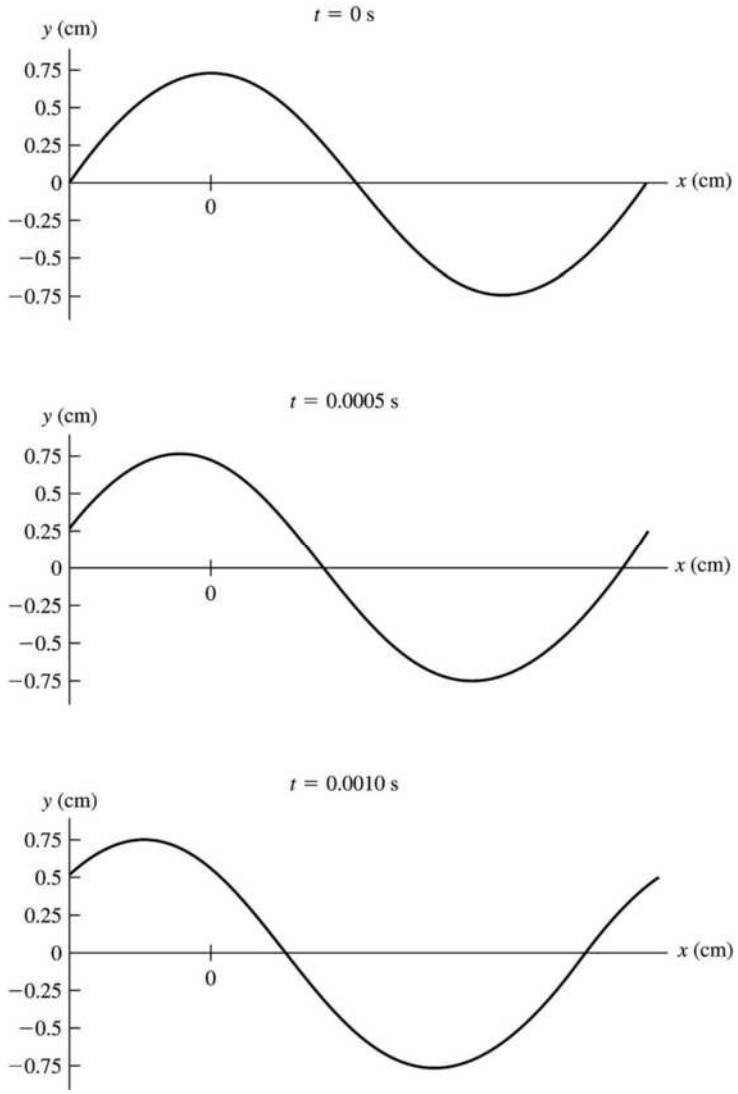

Figure 15.52

15.53. **IDENTIFY:** The speed in each segment is $v = \sqrt{F/\mu}$. The time to travel through a segment is $t = L/v$.

SET UP: The travel times for each segment are $t_1 = L\sqrt{\dfrac{\mu_1}{F}}$, $t_2 = L\sqrt{\dfrac{4\mu_1}{F}}$, and $t_3 = L\sqrt{\dfrac{\mu_1}{4F}}$.

EXECUTE: **(a)** Adding the travel times gives $t_{\text{total}} = L\sqrt{\dfrac{\mu_1}{F}} + 2L\sqrt{\dfrac{\mu_1}{F}} + \frac{1}{2}L\sqrt{\dfrac{\mu_1}{F}} = \frac{7}{2}L\sqrt{\dfrac{\mu_1}{F}}$.

(b) No. The speed in a segment depends only on F and μ for that segment.

EVALUATE: The wave speed is greater and its travel time smaller when the mass per unit length of the segment decreases.

15.54. **IDENTIFY:** Apply $\Sigma\tau_z = 0$ to find the tension in each wire. Use $v = \sqrt{F/\mu}$ to calculate the wave speed for each wire and then $t = L/v$ is the time for each pulse to reach the ceiling, where $L = 1.25$ m.

SET UP: The wires have $\mu = \dfrac{m}{L} = \dfrac{0.360 \text{ N}}{(9.80 \text{ m/s}^2)(1.25 \text{ m})} = 0.02939$ kg/m. The free-body diagram for the beam is given in Figure 15.54. Take the axis to be at the end of the beam where wire A is attached.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: $\Sigma\tau_z = 0$ gives $T_B L = w(L/3)$ and $T_B = w/3 = 583$ N. $T_A + T_B = 1750$ N, so $T_A = 1167$ N.

$v_A = \sqrt{\dfrac{T_A}{\mu}} = \sqrt{\dfrac{1167 \text{ N}}{0.02939 \text{ kg/m}}} = 199$ m/s. $t_A = \dfrac{1.25 \text{ m}}{199 \text{ m/s}} = 0.00627$ s = 6.27 ms.

$v_B = \sqrt{\dfrac{583 \text{ N}}{0.02939 \text{ kg/m}}} = 141$ m/s. $t_B = \dfrac{1.25 \text{ m}}{141 \text{ m/s}} = 0.00888 \text{ s} = 8.88$ ms.

$\Delta t = t_B - t_A = 8.88 \text{ ms} - 6.27 \text{ ms} = 2.6$ ms.

EVALUATE: The wave pulse travels faster in wire A, since that wire has the greater tension, so the pulse in wire A arrives first.

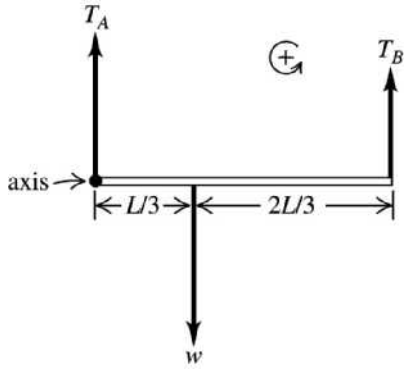

Figure 15.54

15.55. **IDENTIFY** and **SET UP:** The transverse speed of a point of the rope is $v_y = \partial y/\partial t$ where $y(x,t)$ is given by Eq. (15.7).

EXECUTE: **(a)** $y(x,t) = A\cos(kx - \omega t)$

$v_y = \partial y/\partial t = +A\omega\sin(kx - \omega t)$

$v_{y,\,\max} = A\omega = 2\pi fA$

$f = \dfrac{v}{\lambda}$ and $v = \sqrt{\dfrac{F}{(M/L)}}$, so $f = \left(\dfrac{1}{\lambda}\right)\sqrt{\dfrac{FL}{M}}$

$v_{y,\,\max} = \left(\dfrac{2\pi A}{\lambda}\right)\sqrt{\dfrac{FL}{M}}$

(b) To double $v_{y,\,\max}$ increase F by a factor of 4.

EVALUATE: Increasing the tension increases the wave speed v which in turn increases the oscillation frequency. With the amplitude held fixed, increasing the number of oscillations per second increases the transverse velocity.

15.56. **IDENTIFY:** The maximum vertical acceleration must be at least g.

SET UP: $a_{\max} = \omega^2 A$

EXECUTE: $g = \omega^2 A_{\min}$ and thus $A_{\min} = g/\omega^2$. Using $\omega = 2\pi f = 2\pi v/\lambda$ and $v = \sqrt{F/\mu}$, this becomes

$A_{\min} = \dfrac{g\lambda^2\mu}{4\pi^2 F}$.

EVALUATE: When the amplitude of the motion increases, the maximum acceleration of a point on the rope increases.

15.57. **IDENTIFY** and **SET UP:** Use Eq. (15.1) and $\omega = 2\pi f$ to replace v by ω in Eq. (15.13). Compare this equation to $\omega = \sqrt{k'/m}$ from Chapter 14 to deduce k'.

EXECUTE: **(a)** $\omega = 2\pi f$, $f = v/\lambda$, and $v = \sqrt{F/\mu}$. These equations combine to give

$\omega = 2\pi f = 2\pi(v/\lambda) = (2\pi/\lambda)\sqrt{F/\mu}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

But also $\omega = \sqrt{k'/m}$. Equating these expressions for ω gives $k' = m(2\pi/\lambda)^2(F/\mu)$.

But $m = \mu\,\Delta x$ so $k' = \Delta x(2\pi/\lambda)^2 F$

(b) EVALUATE: The "force constant" k' is independent of the amplitude A and mass per unit length μ, just as is the case for a simple harmonic oscillator. The force constant is proportional to the tension in the string F and inversely proportional to the wavelength λ. The tension supplies the restoring force and the $1/\lambda^2$ factor represents the dependence of the restoring force on the curvature of the string.

15.58. **IDENTIFY:** The frequencies at which a string vibrates depend on its tension, mass density and length.

SET UP: $f_1 = \dfrac{v}{4L}$, where $v = \sqrt{\dfrac{T}{\mu}} = \sqrt{\dfrac{TL}{m}}$. T is the tension in the string, L is its length and m is its mass.

EXECUTE: **(a)** $f_1 = \dfrac{v}{2L} = \dfrac{1}{2L}\sqrt{\dfrac{TL}{m}} = \dfrac{1}{2}\sqrt{\dfrac{T}{Lm}}$. Solving for T gives

$T = (2f_1)^2 Lm = 4(262\text{ Hz})^2(0.350\text{ m})(8.00\times10^{-3}\text{kg}) = 769\text{ N}.$

(b) $m = \dfrac{T}{L(2f_1)^2} = \dfrac{769\text{ N}}{(0.350\text{ m})(4)(466\text{ Hz})^2} = 2.53\text{ g}.$

(c) For S_1, $\mu = \dfrac{8.00\times10^{-3}\text{kg}}{0.350\text{ m}} = 0.0229\text{ kg/m}$. $T = 769\text{ N}$ and $v = \sqrt{T/\mu} = 183\text{ m/s}$. $f_1 = \dfrac{v}{2L}$ gives

$L = \dfrac{v}{2f_1} = \dfrac{183\text{ m/s}}{2(277\text{ Hz})} = 33.0\text{ cm}$. $x = 35.0\text{ cm} - 33.0\text{ cm} = 2.00\text{ cm}.$

(d) For S_2, $\mu = \dfrac{2.53\times10^{-3}\text{ kg}}{0.350\text{ m}} = 7.23\times10^{-3}\text{ kg/m}$. $T = 769\text{ N}$ and $v = \sqrt{T/\mu} = 326\text{ m/s}$. $L = 0.330\text{ m}$

and $f_1 = \dfrac{v}{2L} = \dfrac{326\text{ m/s}}{2(0.330\text{ m})} = 494\text{ Hz}.$

EVALUATE: If the tension is the same in the strings, the mass densities must be different to produce sounds of different pitch.

15.59. **IDENTIFY:** The frequency of the fundamental (the target variable) depends on the tension in the wire. The bar is in rotational equilibrium so the torques on it must balance.

SET UP: $v = \sqrt{\dfrac{F}{\mu}}$ and $f = \dfrac{v}{\lambda}$. $\Sigma\tau_z = 0$.

EXECUTE: $\lambda = 2L = 0.660\text{ m}$. The tension F in the wire is found by applying the rotational equilibrium methods of Chapter 11. Let l be the length of the bar. Then $\Sigma\tau_z = 0$ with the axis at the hinge gives

$Fl\cos30° = \dfrac{1}{2}lmg\sin30°$. $F = \dfrac{mg\tan30°}{2} = \dfrac{(45.0\text{ kg})(9.80\text{ m/s}^2)\tan30°}{2} = 127.3\text{ N}.$

$v = \sqrt{\dfrac{F}{\mu}} = \sqrt{\dfrac{127.3\text{ N}}{(0.0920\text{ kg}/0.330\text{ m})}} = 21.37\text{ m/s}$. $f = \dfrac{v}{\lambda} = \dfrac{21.37\text{ m/s}}{0.660\text{ m}} = 32.4\text{ Hz}$

EVALUATE: This is an audible frequency for humans.

15.60. **IDENTIFY:** The mass of the planet (the target variable) determines g at its surface, which in turn determines the weight of the lead object hanging from the string. The weight is the tension in the string, which determines the speed of a wave pulse on that string.

SET UP: At the surface of the planet $g = G\dfrac{m_\text{p}}{R_\text{p}^2}$. The pulse speed is $v = \sqrt{\dfrac{F}{\mu}}$.

EXECUTE: On earth, $v = \dfrac{4.00\text{ m}}{0.0390\text{ s}} = 1.0256\times10^2\text{ m/s}$. $\mu = \dfrac{0.0280\text{ kg}}{4.00\text{ m}} = 7.00\times10^{-3}\text{ kg/m}^3$. $F = Mg$, so

$v = \sqrt{\dfrac{Mg}{\mu}}$ and the mass of the lead weight is

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$M = \left(\frac{\mu}{g}\right)v^2 = \left(\frac{7.00\times10^{-3}\ \text{kg/m}}{9.8\ \text{m/s}^2}\right)(1.0256\times10^2\ \text{m/s})^2 = 7.513\ \text{kg}$. On the planet,

$v = \frac{4.00\ \text{m}}{0.0600\ \text{s}} = 66.67\ \text{m/s}$. Therefore $g = \left(\frac{\mu}{M}\right)v^2 = \left(\frac{7.00\times10^{-3}\ \text{kg/m}}{7.513\ \text{kg}}\right)(66.67\ \text{m/s})^2 = 4.141\ \text{m/s}^2$.

$g = G\frac{m_\text{p}}{R_\text{p}^2}$ and $m_p = \frac{gR_\text{p}^2}{G} = \frac{(4.141\ \text{m/s}^2)(7.20\times10^7\ \text{m})^2}{6.6742\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2} = 3.22\times10^{26}\ \text{kg}$.

EVALUATE: This mass is about 50 times that of Earth, but its radius is about 10 times that of Earth, so the result is reasonable.

15.61. **IDENTIFY:** The wavelengths of standing waves depend on the length of the string (the target variable), which in turn determine the frequencies of the waves.

SET UP: $f_n = nf_1$ where $f_1 = \frac{v}{2L}$.

EXECUTE: $f_n = nf_1$ and $f_{n+1} = (n+1)f_1$. We know the wavelengths of two adjacent modes, so

$f_1 = f_{n+1} - f_n = 630\ \text{Hz} - 525\ \text{Hz} = 105\ \text{Hz}$. Solving $f_1 = \frac{v}{2L}$ for L gives $L = \frac{v_1}{2f} = \frac{384\ \text{m/s}}{2(105\ \text{Hz})} = 1.83\ \text{m}$.

EVALUATE: The observed frequencies are both audible which is reasonable for a string that is about a half meter long.

15.62. **IDENTIFY:** Apply $\Sigma\tau_z = 0$ to one post and calculate the tension in the wire. $v = \sqrt{F/\mu}$ for waves on the wire. $v = f\lambda$. The standing wave on the wire and the sound it produces have the same frequency. For standing waves on the wire, $\lambda_n = \frac{2L}{n}$.

SET UP: For the 5th overtone, $n = 6$. The wire has $\mu = m/L = (0.732\ \text{kg})/(5.00\ \text{m}) = 0.146\ \text{kg/m}$. The free-body diagram for one of the posts is given in Figure 15.62. Forces at the pivot aren't shown. We take the rotation axis to be at the pivot, so forces at the pivot produce no torque.

EXECUTE: $\Sigma\tau_z = 0$ gives $w\left(\frac{L}{2}\cos57.0°\right) - T(L\sin57.0°) = 0$. $T = \frac{w}{2\tan57.0°} = \frac{235\ \text{N}}{2\tan57.0°} = 76.3\ \text{N}$. For waves on the wire, $v = \sqrt{\frac{F}{\mu}} = \sqrt{\frac{76.3\ \text{N}}{0.146\ \text{kg/m}}} = 22.9\ \text{m/s}$. For the 5th overtone standing wave on the wire,

$\lambda = \frac{2L}{6} = \frac{2(5.00\ \text{m})}{6} = 1.67\ \text{m}$. $f = \frac{v}{\lambda} = \frac{22.9\ \text{m/s}}{1.67\ \text{m}} = 13.7\ \text{Hz}$. The sound waves have frequency 13.7 Hz and wavelength $\lambda = \frac{344\ \text{m/s}}{13.7\ \text{Hz}} = 25.0\ \text{m}$.

EVALUATE: The frequency of the sound wave is just below the lower limit of audible frequencies. The wavelength of the standing wave on the wire is much less than the wavelength of the sound waves, because the speed of the waves on the wire is much less than the speed of sound in air.

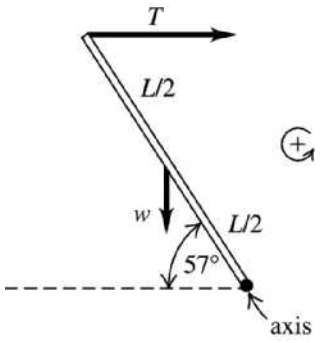

Figure 15.62

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

15.63. **IDENTIFY:** The tension in the wires along with their lengths determine the fundamental frequency in each one (the target variables). These frequencies are different because the wires have different linear mass densities. The bar is in equilibrium, so the forces and torques on it balance.

SET UP: $T_a + T_c = w$, $\Sigma\tau_z = 0$, $v = \sqrt{\dfrac{F}{\mu}}$, $f_1 = v/2L$ and $\mu = \dfrac{m}{L}$, where $m = \rho V = \rho\pi r^2 L$. The densities of copper and aluminum are given in a table in the text.

EXECUTE: Using the subscript "a" for aluminum and "c" for copper, we have $T_a + T_c = w = 536$ N. $\Sigma\tau_z = 0$, with the axis at left-hand end of bar, gives $T_c(1.40\text{ m}) = w(0.90\text{ m})$, so $T_c = 344.6$ N.

$T_a = 536\text{ N} - 344.6\text{ N} = 191.4\text{ N}$. $f_1 = \dfrac{v}{2L}$. $\mu = \dfrac{m}{L} = \dfrac{\rho\pi r^2 L}{L} = \rho\pi r^2$.

For the copper wire: $F = 344.6$ N and $\mu = (8.90\times10^3\text{ kg/m}^3)\pi(0.280\times10^{-3}\text{ m})^2 = 2.19\times10^{-3}$ kg/m, so

$v = \sqrt{\dfrac{F}{\mu}} = \sqrt{\dfrac{344.6\text{ N}}{2.19\times10^{-3}\text{ kg/m}}} = 396.7$ m/s. $f_1 = \dfrac{v}{2L} = \dfrac{396.7\text{ m/s}}{2(0.600\text{ m})} = 330$ Hz.

For the aluminum wire: $F = 191.4$ N and $\mu = (2.70\times10^3\text{ kg/m}^3)\pi(0.280\times10^{-3}\text{ m})^2 = 6.65\times10^{-4}$ kg/m,

so $v = \sqrt{\dfrac{F}{\mu}} = \sqrt{\dfrac{919.4\text{ N}}{6.65\times10^{-4}\text{ kg/m}}} = 536.5$ m/s, which gives $f_1 = \dfrac{536.5\text{ m/s}}{2(0.600\text{ m})} = 447$ Hz.

EVALUATE: The wires have different fundamental frequencies because they have different tensions and different linear mass densities.

15.64. **IDENTIFY:** The time it takes the wave to travel a given distance is determined by the wave speed v. A point on the string travels a distance $4A$ in time T.

SET UP: $v = f\lambda$. $T = 1/f$.

EXECUTE: **(a)** The wave travels a horizontal distance d in a time

$t = \dfrac{d}{v} = \dfrac{d}{\lambda f} = \dfrac{8.00\text{ m}}{(0.600\text{ m})(70.0\text{ Hz})} = 0.190$ s.

(b) A point on the string will travel a vertical distance of $4A$ each cycle. Although the transverse velocity $v_y(x,t)$ is not constant, a distance of $h = 8.00$ m corresponds to a whole number of cycles,

$n = h/(4A) = (8.00\text{ m})/[4(5.00\times10^{-3}\text{ m})] = 400$, so the amount of time is $t = nT = n/f = (400)/(70.0\text{ Hz}) = 5.71$ s.

EVALUATE: **(c)** The time in part (a) is independent of amplitude but the time in part (b) depends on the amplitude of the wave. For (b), the time is halved if the amplitude is doubled.

15.65. **IDENTIFY:** Follow the procedure specified in part (b).

SET UP: If $u = x - vt$, then $\dfrac{\partial u}{\partial t} = -v$ and $\dfrac{\partial u}{\partial x} = 1$.

EXECUTE: **(a)** As time goes on, someone moving with the wave would need to move in such a way that the wave appears to have the same shape. If this motion can be described by $x = vt + b$, with b a constant, then $y(x,t) = f(b)$, and the waveform is the same to such an observer.

(b) $\dfrac{\partial^2 y}{\partial x^2} = \dfrac{d^2 f}{du^2}$ and $\dfrac{\partial^2 y}{\partial t^2} = v^2\dfrac{d^2 f}{du^2}$, so $y(x,t) = f(x - vt)$ is a solution to the wave equation with wave speed v.

(c) This is of the form $y(x,t) = f(u)$, with $u = x - vt$ and $f(u) = De^{-B^2(x-Ct/B)^2}$. The result of part (b) may be used to determine the speed $v = C/B$.

EVALUATE: The wave in part (c) moves in the $+x$-direction. The speed of the wave is independent of the constant D.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

15.66. **IDENTIFY:** The wavelengths of the standing waves on the wire are given by $\lambda_n = \dfrac{2L}{n}$. When the ball is changed the wavelength changes because the length of the wire changes; $\Delta l = \dfrac{Fl_0}{AY}$.

SET UP: For the third harmonic, $n = 3$. For copper, $Y = 11\times10^{10}$ Pa. The wire has cross-sectional area $A = \pi r^2 = \pi(0.512\times10^{-3}\text{ m})^2 = 8.24\times10^{-7}\text{ m}^2$.

EXECUTE: **(a)** $\lambda_3 = \dfrac{2(1.20\text{ m})}{3} = 0.800\text{ m}$

(b) The increase in length when the 100.0 N ball is replaced by the 500.0 N ball is given by $\Delta l = \dfrac{(\Delta F)l_0}{AY}$, where $\Delta F = 400.0$ N is the increase in the force applied to the end of the wire.

$\Delta l = \dfrac{(400.0\text{ N})(1.20\text{ m})}{(8.24\times10^{-7}\text{ m}^2)(11\times10^{10}\text{ Pa})} = 5.30\times10^{-3}$ m. The change in wavelength is $\Delta\lambda = \frac{2}{3}\Delta l = 3.5$ mm.

EVALUATE: The change in tension changes the wave speed and that in turn changes the frequency of the standing wave, but the problem asks only about the wavelength.

15.67. **IDENTIFY** and **SET UP:** Use Eq. (15.13) to replace μ, and then Eq. (15.6) to replace v.

EXECUTE: **(a)** Eq. (15.25): $P_{\text{av}} = \frac{1}{2}\sqrt{\mu F}\,\omega^2A^2$

$v = \sqrt{F/\mu}$ says $\sqrt{\mu} = \sqrt{F}/v$ so $P_{\text{av}} = \frac{1}{2}(\sqrt{F}/v)\sqrt{F}\,\omega^2A^2 = \frac{1}{2}F\omega^2A^2/v$

$\omega = 2\pi f$ so $\omega/v = 2\pi f/v = 2\pi/\lambda = k$ and $P_{\text{av}} = \frac{1}{2}Fk\omega A^2$, as was to be shown.

(b) IDENTIFY: For the ω dependence, use Eq. (15.25) since it involves just ω, not k: $P_{\text{av}} = \frac{1}{2}\sqrt{\mu F}\,\omega^2A^2$.

SET UP: P_{av}, μ, A all constant so $\sqrt{F}\omega^2$ is constant, and $\sqrt{F_1}\omega_1^2 = \sqrt{F_2}\omega_2^2$.

EXECUTE: $\omega_2 = \omega_1(F_1/F_2)^{1/4} = \omega_1(F_1/4F_1)^{1/4} = \omega_1(4)^{-1/4} = \omega_1/\sqrt{2}$

ω must be changed by a factor of $1/\sqrt{2}$ (decreased)

IDENTIFY: For the k dependence, use the equation derived in part (a), $P_{\text{av}} = \frac{1}{2}Fk\omega A^2$.

SET UP: If P_{av} and A are constant then $Fk\omega$ must be constant, and $F_1k_1\omega_1 = F_2k_2\omega_2$.

EXECUTE: $k_2 = k_1\left(\dfrac{F_1}{F_2}\right)\left(\dfrac{\omega_1}{\omega_2}\right) = k_1\left(\dfrac{F_1}{4F_1}\right)\left(\dfrac{\omega_1}{\omega_1/\sqrt{2}}\right) = k_1\dfrac{\sqrt{2}}{4} = k_1\sqrt{\dfrac{2}{16}} = k_1/\sqrt{8}$

k must be changed by a factor of $1/\sqrt{8}$ (decreased).

EVALUATE: Power is the transverse force times the transverse velocity. To keep P_{av} constant the transverse velocity must be decreased when F is increased, and this is done by decreasing ω.

15.68. **IDENTIFY:** The phase angle determines the value of y for $x = 0$, $t = 0$ but does not affect the shape of the $y(x,t)$ versus x or t graph.

SET UP: $\dfrac{\partial\cos(kx-\omega t+\phi)}{\partial t} = -\omega\sin(kx-\omega t+\phi)$.

EXECUTE: **(a)** The graphs for each ϕ are sketched in Figure 15.68.

(b) $\dfrac{\partial y}{\partial t} = -\omega A\sin(kx-\omega t+\phi)$

(c) No. $\phi = \pi/4$ or $\phi = 3\pi/4$ would both give $A/\sqrt{2}$. If the particle is known to be moving downward, the result of part (b) shows that $\cos\phi < 0$, and so $\phi = 3\pi/4$.

(d) To identify ϕ uniquely, the quadrant in which ϕ lies must be known. In physical terms, the signs of both the position and velocity, and the magnitude of either, are necessary to determine ϕ (within additive multiples of 2π).

EVALUATE: The phase $\phi = 0$ corresponds to $y = A$ at $x = 0$, $t = 0$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

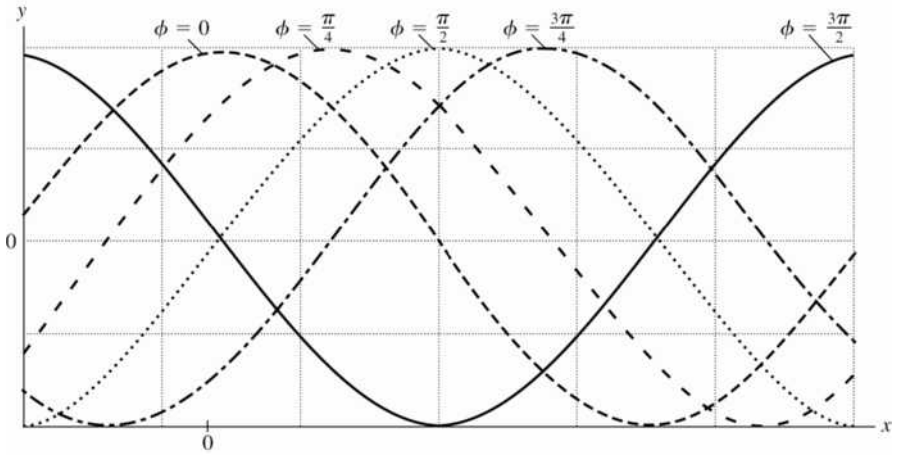

Figure 15.68

15.69. **IDENTIFY** and **SET UP:** The average power is given by Eq. (15.25). Rewrite this expression in terms of v and λ in place of F and ω.

EXECUTE: **(a)** $P_{\text{av}} = \frac{1}{2}\sqrt{\mu F}\,\omega^2 A^2$

$v = \sqrt{F/\mu}$ so $\sqrt{F} = v\sqrt{\mu}$

$\omega = 2\pi f = 2\pi(v/\lambda)$

Using these two expressions to replace $\sqrt{F}$ and ω gives $P_{\text{av}} = 2\mu\pi^2 v^3 A^2/\lambda^2$;

$\mu = (6.00\times10^{-3}\text{ kg})/(8.00\text{ m})$

$$A = \left(\frac{2\lambda^2 P_{\text{av}}}{4\pi^2 v^3 \mu}\right)^{1/2} = 7.07\text{ cm}$$

(b) EVALUATE: $P_{\text{av}} \sim v^3$ so doubling v increases P_{av} by a factor of 8.

$P_{\text{av}} = 8(50.0\text{ W}) = 400.0\text{ W}$

15.70. **IDENTIFY:** The wave moves in the $+x$ direction with speed v, so to obtain $y(x,t)$ replace x with $x - vt$ in the expression for $y(x,0)$.

SET UP: $P(x,t)$ is given by Eq. (15.21).

EXECUTE: **(a)** The wave pulse is sketched in Figure 15.70.

(b)

$$y(x,t) = \begin{cases} 0 & \text{for} \quad (x-vt) < -L \\ h(L+x-vt)/L & \text{for} \quad -L < (x-vt) < 0 \\ h(L-x+vt)/L & \text{for} \quad 0 < (x-vt) < L \\ 0 & \text{for} \quad (x-vt) > L \end{cases}$$

(c) From Eq. (15.21):

$$P(x,t) = -F\frac{\partial y(x,t)}{\partial x}\frac{\partial y(x,t)}{\partial t} = \begin{cases} -F(0)(0) = 0 & \text{for} \quad (x-vt) < -L \\ -F(h/L)(-hv/L) = Fv(h/L)^2 & \text{for} \quad -L < (x-vt) < 0 \\ -F(-h/L)(hv/L) = Fv(h/L)^2 & \text{for} \quad 0 < (x-vt) < L \\ -F(0)(0) = 0 & \text{for} \quad (x-vt) > L \end{cases}$$

Thus the instantaneous power is zero except for $-L < (x-vt) < L$, where it has the constant value $Fv(h/L)^2$.

EVALUATE: For this pulse the transverse velocity v_y is constant in magnitude and has opposite sign on either side of the peak of the pulse.

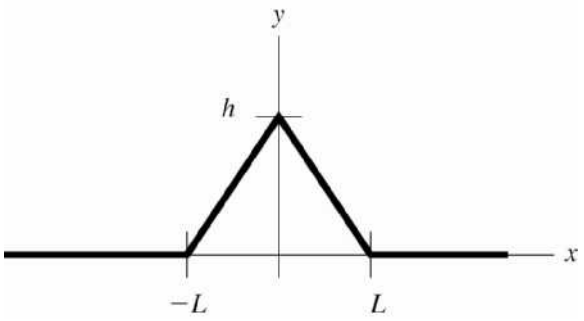

Figure 15.70

15.71. **IDENTIFY:** Draw the graphs specified in part (a).
SET UP: When $y(x,t)$ is a maximum, the slope $\partial y/\partial x$ is zero. The slope has maximum magnitude when $y(x,t) = 0$.

EXECUTE: **(a)** The graph is sketched in Figure 15.71a.
(b) The power is a maximum where the displacement is zero, and the power is a minimum of zero when the magnitude of the displacement is a maximum.
(c) The energy flow is always in the same direction.
(d) In this case, $\dfrac{\partial y}{\partial x} = -kA\sin(kx + \omega t)$ and Eq. (15.22) becomes $P(x,t) = -Fk\omega A^2\sin^2(kx + \omega t)$. The power is now negative (energy flows in the $-x$-direction), but the qualitative relations of part (b) are unchanged. The graph is sketched in Figure 15.71b.
EVALUATE: $\cos\theta$ and $\sin\theta$ are 180° out of phase, so for fixed t, maximum y corresponds to zero P and $y = 0$ corresponds to maximum P.

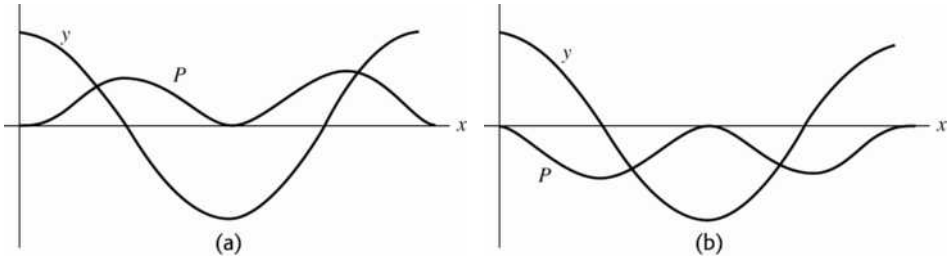

Figure 15.71

15.72. **IDENTIFY:** The time between positions 1 and 5 is equal to $T/2$. $v = f\lambda$. The velocity of points on the string is given by Eq. (15.9).

SET UP: Four flashes occur from position 1 to position 5, so the elapsed time is $4\left(\dfrac{60\text{ s}}{5000}\right) = 0.048$ s. The figure in the problem shows that $\lambda = L = 0.500$ m. At point P the amplitude of the standing wave is 1.5 cm.
EXECUTE: **(a)** $T/2 = 0.048$ s and $T = 0.096$ s. $f = 1/T = 10.4$ Hz. $\lambda = 0.500$ m.
(b) The fundamental standing wave has nodes at each end and no nodes in between. This standing wave has one additional node. This is the 1st overtone and 2nd harmonic.
(c) $v = f\lambda = (10.4\text{ Hz})(0.500\text{ m}) = 5.20$ m/s.
(d) In position 1, point P is at its maximum displacement and its speed is zero. In position 3, point P is passing through its equilibrium position and its speed is $v_{\max} = \omega A = 2\pi fA = 2\pi(10.4\text{ Hz})(0.015\text{ m}) = 0.980$ m/s.
(e) $v = \sqrt{\dfrac{F}{\mu}} = \sqrt{\dfrac{FL}{m}}$ and $m = \dfrac{FL}{v^2} = \dfrac{(1.00\text{ N})(0.500\text{ m})}{(5.20\text{ m/s})^2} = 18.5$ g.
EVALUATE: The standing wave is produced by traveling waves moving in opposite directions. Each point on the string moves in SHM, and the amplitude of this motion varies with position along the string.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

15.73. **IDENTIFY** and **SET UP:** There is a node at the post and there must be a node at the clothespin. There could be additional nodes in between. The distance between adjacent nodes is $\lambda/2$, so the distance between *any* two nodes is $n(\lambda/2)$ for $n = 1, 2, 3, \ldots$ This must equal 45.0 cm, since there are nodes at the post and clothespin. Use this in Eq. (15.1) to get an expression for the possible frequencies f.

EXECUTE: $45.0 \text{ cm} = n(\lambda/2)$, $\lambda = v/f$, so $f = n[v/(90.0 \text{ cm})] = (0.800 \text{ Hz})n$, $n = 1, 2, 3, \ldots$

EVALUATE: Higher frequencies have smaller wavelengths, so more node-to-node segments fit between the post and clothespin.

15.74. **IDENTIFY:** The displacement of the string at any point is $y(x,t) = (A_{SW} \sin kx)\sin \omega t$. For the fundamental mode $\lambda = 2L$, so at the midpoint of the string $\sin kx = \sin(2\pi/\lambda)(L/2) = 1$, and $y = A_{SW} \sin \omega t$. The transverse velocity is $v_y = \partial y/\partial t$ and the transverse acceleration is $a_y = \partial v_y/\partial t$.

SET UP: Taking derivatives gives $v_y = \dfrac{\partial y}{\partial t} = \omega A_{SW} \cos \omega t$, with maximum value $v_{y,\,\max} = \omega A_{SW}$, and

$a_y = \dfrac{\partial v_y}{\partial t} = -\omega^2 A_{SW} \sin \omega t$, with maximum value $a_{y,\,\max} = \omega^2 A_{SW}$.

EXECUTE: $\omega = a_{y,\,\max}/v_{y,\,\max} = (8.40\times10^3 \text{ m/s}^2)/(3.80 \text{ m/s}) = 2.21\times10^3 \text{ rad/s}$, and then

$A_{SW} = v_{y,\,\max}/\omega = (3.80 \text{ m/s})/(2.21\times10^3 \text{ rad/s}) = 1.72\times10^{-3} \text{ m}$.

(b) $v = \lambda f = (2L)(\omega/2\pi) = L\omega/\pi = (0.386 \text{ m})(2.21\times10^3 \text{ rad/s})/\pi = 272 \text{ m/s}$.

EVALUATE: The maximum transverse velocity and acceleration will have different (smaller) values at other points on the string.

15.75. **IDENTIFY:** Carry out the derivation as done in the text for Eq. (15.28). The transverse velocity is $v_y = \partial y/\partial t$ and the transverse acceleration is $a_y = \partial v_y/\partial t$.

(a) SET UP: For reflection from a free end of a string the reflected wave is *not* inverted, so $y(x,\ t) = y_1(x,\ t) + y_2(x,\ t)$, where

$y_1(x,\ t) = A\cos(kx + \omega t)$ (traveling to the left)

$y_2(x,t) = A\cos(kx - \omega t)$ (traveling to the right)

Thus $y(x,t) = A[\cos(kx + \omega t) + \cos(kx - \omega t)]$.

EXECUTE: Apply the trig identity $\cos(a \pm b) = \cos a \cos b \mp \sin a \sin b$ with $a = kx$ and $b = \omega t$:

$\cos(kx + \omega t) = \cos kx \cos \omega t - \sin kx \sin \omega t$ and

$\cos(kx - \omega t) = \cos kx \cos \omega t + \sin kx \sin \omega t$.

Then $y(x,t) = (2A\cos kx)\cos \omega t$ (the other two terms cancel)

(b) For $x = 0$, $\cos kx = 1$ and $y(x,t) = 2A\cos \omega t$. The amplitude of the simple harmonic motion at $x = 0$ is $2A$, which is the maximum for this standing wave, so $x = 0$ is an antinode.

(c) $y_{\max} = 2A$ from part (b).

$v_y = \dfrac{\partial y}{\partial t} = \dfrac{\partial}{\partial t}[(2A\cos kx)\cos \omega t] = 2A\cos kx \dfrac{\partial \cos \omega t}{\partial t} = -2A\omega \cos kx \sin \omega t$.

At $x = 0$, $v_y = -2A\omega \sin \omega t$ and $(v_y)_{\max} = 2A\omega$

$a_y = \dfrac{\partial^2 y}{\partial t^2} = \dfrac{\partial v_y}{\partial t} = -2A\omega \cos kx \dfrac{\partial \sin \omega t}{\partial t} = -2A\omega^2 \cos kx \cos \omega t$

At $x = 0$, $a_y = -2A\omega^2 \cos \omega t$ and $(a_y)_{\max} = 2A\omega^2$.

EVALUATE: The expressions for $(v_y)_{\max}$ and $(a_y)_{\max}$ are the same as at the antinodes for the standing wave of a string fixed at both ends.

15.76. **IDENTIFY:** The standing wave is given by Eq. (15.28).

SET UP: At an antinode, $\sin kx = 1$. $v_{y,\max} = \omega A$. $a_{y,\max} = \omega^2 A$.

EXECUTE: **(a)** $\lambda = v/f = (192.0 \text{ m/s})/(240.0 \text{ Hz}) = 0.800 \text{ m}$, and the wave amplitude is $A_{SW} = 0.400 \text{ cm}$. The amplitude of the motion at the given points is

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(i) (0.400 cm)sin(π) = 0 (a node) (ii) (0.400 cm) sin($\pi/2$) = 0.400 cm (an antinode)
(iii) (0.400 cm) sin($\pi/4$) = 0.283 cm

(b) The time is half of the period, or $1/(2f) = 2.08\times10^{-3}$ s.

(c) In each case, the maximum velocity is the amplitude multiplied by $\omega = 2\pi f$ and the maximum acceleration is the amplitude multiplied by $\omega^2 = 4\pi^2 f^2$:

(i) 0, 0; (ii) 6.03 m/s, 9.10×10^3 m/s^2; (iii) 4.27 m/s, 6.43×10^3 m/s^2.

EVALUATE: The amplitude, maximum transverse velocity, and maximum transverse acceleration vary along the length of the string. But the period of the simple harmonic motion of particles of the string is the same at all points on the string.

15.77. **IDENTIFY:** The standing wave frequencies are given by $f_n = n\left(\frac{v}{2L}\right)$. $v = \sqrt{F/\mu}$. Use the density of steel to calculate μ for the wire.

SET UP: For steel, $\rho = 7.8\times10^3$ kg/m^3. For the first overtone standing wave, $n = 2$.

EXECUTE: $v = \frac{2Lf_2}{2} = (0.550\text{ m})(311\text{ Hz}) = 171$ m/s. The volume of the wire is $V = (\pi r^2)L$. $m = \rho V$ so $\mu = \frac{m}{L} = \frac{\rho V}{L} = \rho\pi r^2 = (7.8\times10^3\text{ kg/m}^3)\pi(0.57\times10^{-3}\text{ m})^2 = 7.96\times10^{-3}$ kg/m. The tension is $F = \mu v^2 = (7.96\times10^{-3}\text{ kg/m})(171\text{ m/s})^2 = 233$ N.

EVALUATE: The tension is not large enough to cause much change in length of the wire.

15.78. **IDENTIFY:** The mass and breaking stress determine the length and radius of the string. $f_1 = \frac{v}{2L}$, with $v = \sqrt{\frac{F}{\mu}}$.

SET UP: The tensile stress is $F/\pi r^2$.

EXECUTE: **(a)** The breaking stress is $\frac{F}{\pi r^2} = 7.0\times10^8$ N/m^2 and the maximum tension is $F = 900$ N, so solving for r gives the minimum radius $r = \sqrt{\frac{900\text{ N}}{\pi(7.0\times10^8\text{ N/m}^2)}} = 6.4\times10^{-4}$ m. The mass and density are fixed, $\rho = \frac{M}{\pi r^2 L}$. so the minimum radius gives the maximum length

$$L = \frac{M}{\pi r^2\rho} = \frac{4.0\times10^{-3}\text{ kg}}{\pi(6.4\times10^{-4}\text{ m})^2(7800\text{ kg/m}^3)} = 0.40\text{ m}.$$

(b) The fundamental frequency is $f_1 = \frac{1}{2L}\sqrt{\frac{F}{\mu}} = \frac{1}{2L}\sqrt{\frac{F}{M/L}} = \frac{1}{2}\sqrt{\frac{F}{ML}}$. Assuming the maximum length of the string is free to vibrate, the highest fundamental frequency occurs when $F = 900$ N and

$$f_1 = \frac{1}{2}\sqrt{\frac{900\text{ N}}{(4.0\times10^{-3}\text{ kg})(0.40\text{ m})}} = 375\text{ Hz}.$$

EVALUATE: If the radius was any smaller the breaking stress would be exceeded. If the radius were greater, so the stress was less than the maximum value, then the length would be less to achieve the same total mass.

15.79. **IDENTIFY:** At a node, $y(x,t) = 0$ for all t. $y_1 + y_2$ is a standing wave if the locations of the nodes don't depend on t.

SET UP: The string is fixed at each end so for all harmonics the ends are nodes. The second harmonic is the first overtone and has one additional node.

EXECUTE: **(a)** The fundamental has nodes only at the ends, $x = 0$ and $x = L$.

(b) For the second harmonic, the wavelength is the length of the string, and the nodes are at $x = 0$, $x = L/2$ and $x = L$.

(c) The graphs are sketched in Figure 15.79.

(d) The graphs in part (c) show that the locations of the nodes and antinodes between the ends vary in time.

EVALUATE: The sum of two standing waves of different frequencies is not a standing wave.

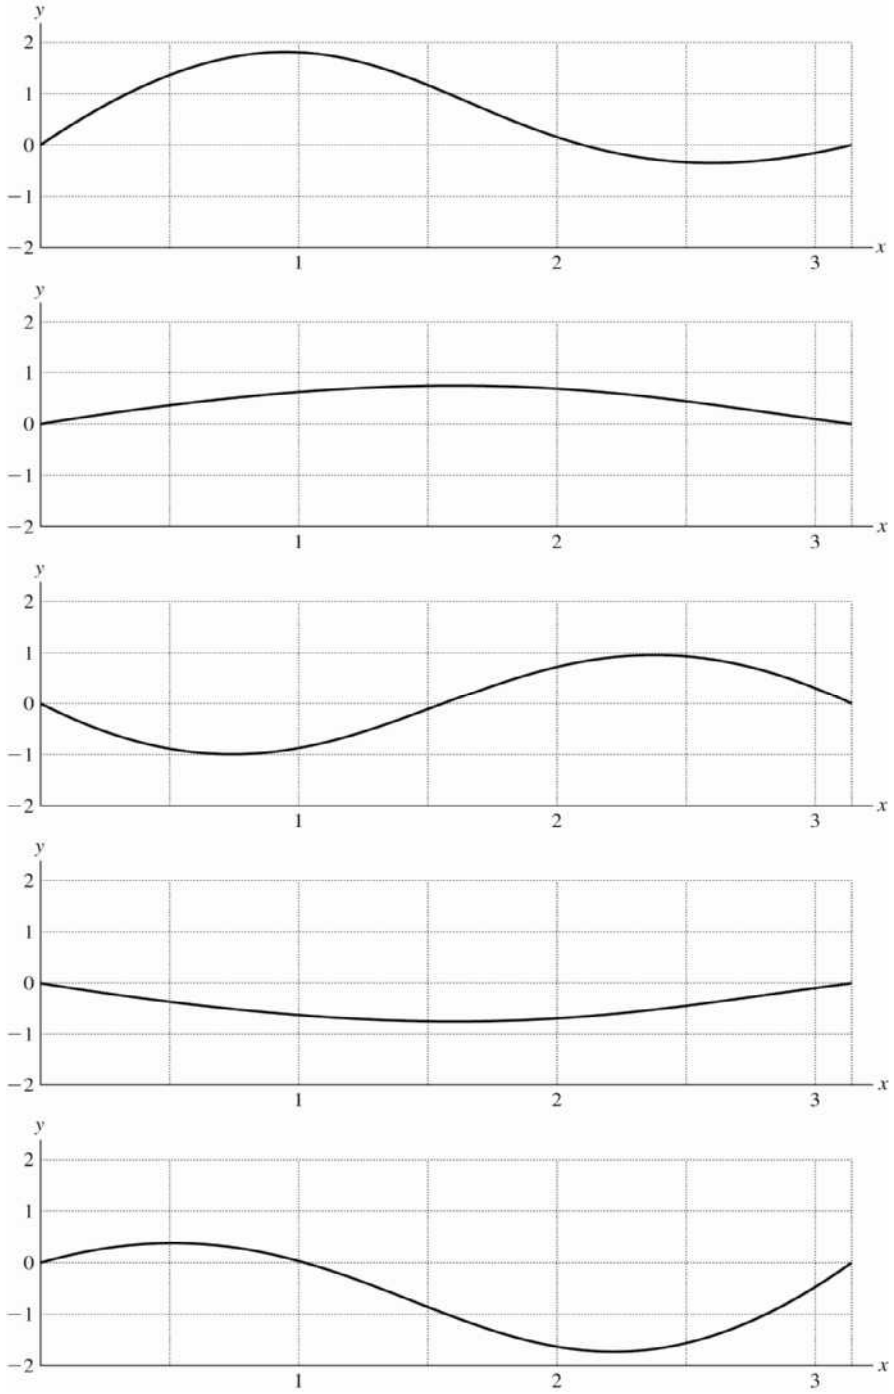

Figure 15.79

15.80. **IDENTIFY:** $f_1 = \dfrac{v}{2L}$. The buoyancy force B that the water exerts on the object reduces the tension in the wire. $B = \rho_{\text{fluid}} V_{\text{submerged}} g$.

SET UP: For aluminum, $\rho_a = 2700 \text{ kg/m}^3$. For water, $\rho_w = 1000 \text{ kg/m}^3$. Since the sculpture is completely submerged, $V_{\text{submerged}} = V_{\text{object}} = V$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: **(a)** L is constant, so $\frac{f_{\text{air}}}{v_{\text{air}}} = \frac{f_{\text{w}}}{v_{\text{w}}}$ and the fundamental frequency when the sculpture is submerged is $f_{\text{w}} = f_{\text{air}}\left(\frac{v_{\text{w}}}{v_{\text{air}}}\right)$, with $f_{\text{air}} = 250.0$ Hz. $v = \sqrt{\frac{F}{\mu}}$ so $\frac{v_{\text{w}}}{v_{\text{air}}} = \sqrt{\frac{F_{\text{w}}}{F_{\text{air}}}}$. When the sculpture is in air, $F_{\text{air}} = w = mg = \rho_{\text{a}} Vg$. When the sculpture is submerged in water, $F_{\text{w}} = w - B = (\rho_{\text{a}} - \rho_{\text{w}})Vg$.

$\frac{v_{\text{w}}}{v_{\text{air}}} = \sqrt{\frac{\rho_{\text{a}} - \rho_{\text{w}}}{\rho_{\text{a}}}}$ and $f_{\text{w}} = (250.0 \text{ Hz})\sqrt{1 - \frac{1000 \text{ kg/m}^3}{2700 \text{ kg/m}^3}} = 198 \text{ Hz}.$

(b) The sculpture has a large mass and therefore very little displacement.

EVALUATE: We have neglected the buoyant force on the wire itself.

15.81. **IDENTIFY:** When the rock is submerged in the liquid, the buoyant force on it reduces the tension in the wire supporting it. This in turn changes the frequency of the fundamental frequency of the vibrations of the wire. The buoyant force depends on the density of the liquid (the target variable). The vertical forces on the rock balance in both cases, and the buoyant force is equal to the weight of the liquid displaced by the rock (Archimedes's principle).

SET UP: The wave speed is $v = \sqrt{\frac{F}{\mu}}$ and $v = f\lambda$. $B = \rho_{\text{liq}} V_{\text{rock}} g$. $\Sigma F_y = 0$.

EXECUTE: $\lambda = 2L = 6.00$ m. In air, $v = f\lambda = (42.0 \text{ Hz})(6.00 \text{ m}) = 252$ m/s. $v = \sqrt{\frac{F}{\mu}}$ so

$\mu = \frac{F}{v^2} = \frac{164.0 \text{ N}}{(252 \text{ m/s})^2} = 0.002583$ kg/m. In the liquid, $v = f\lambda = (28.0 \text{ Hz})(6.00 \text{ m}) = 168$ m/s.

$F = \mu v^2 = (0.002583 \text{ kg/m})(168 \text{ m/s})^2 = 72.90$ N. $F + B - mg = 0$.

$B = mg - F = 164.0 \text{ N} - 72.9 \text{ N} = 91.10$ N. For the rock, $V = \frac{m}{\rho} = \frac{(164.0 \text{ N}/9.8 \text{ m/s}^2)}{3200 \text{ kg/m}^3} = 5.230 \times 10^{-3} \text{ m}^3$.

$B = \rho_{\text{liq}} V_{\text{rock}} g$ and $\rho_{\text{liq}} = \frac{B}{V_{\text{rock}} g} = \frac{91.10 \text{ N}}{(5.230 \times 10^{-3} \text{ m}^3)(9.8 \text{ m/s}^2)} = 1.78 \times 10^3 \text{ kg/m}^3$.

EVALUATE: This liquid has a density 1.78 times that of water, which is rather dense but not impossible.

15.82. **IDENTIFY:** Compute the wavelength from the length of the string. Use Eq. (15.1) to calculate the wave speed and then apply Eq. (15.13) to relate this to the tension.

(a) SET UP: The tension F is related to the wave speed by $v = \sqrt{F/\mu}$ (Eq. (15.13)), so use the information given to calculate v.

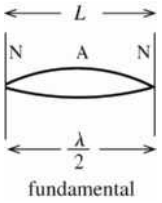

Figure 15.82

EXECUTE: $\lambda/2 = L$

$\lambda = 2L = 2(0.600 \text{ m}) = 1.20$ m

$v = f\lambda = (65.4 \text{ Hz})(1.20 \text{ m}) = 78.5$ m/s

$\mu = m/L = 14.4 \times 10^{-3}$ kg/0.600 m $= 0.024$ kg/m

Then $F = \mu v^2 = (0.024 \text{ kg/m})(78.5 \text{ m/s})^2 = 148$ N.

(b) SET UP: $F = \mu v^2$ and $v = f\lambda$ give $F = \mu f^2 \lambda^2$.

μ is a property of the string so is constant.

λ is determined by the length of the string so stays constant.

μ, λ constant implies $F/f^2 = \mu\lambda^2 = \text{constant}$, so $F_1/f_1^2 = F_2/f_2^2$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: $F_2 = F_1\left(\frac{f_2}{f_1}\right)^2 = (148\text{ N})\left(\frac{73.4\text{ Hz}}{65.4\text{ Hz}}\right)^2 = 186\text{ N}.$

The percent change in F is $\frac{F_2 - F_1}{F_1} = \frac{186\text{ N} - 148\text{ N}}{148\text{ N}} = 0.26 = 26\%.$

EVALUATE: The wave speed and tension we calculated are similar in magnitude to values in the examples. Since the frequency is proportional to $\sqrt{F}$, a 26% increase in tension is required to produce a 13% increase in the frequency.

15.83. **IDENTIFY:** Stress is F/A, where F is the tension in the string and A is its cross-sectional area.

SET UP: $A = \pi r^2$. For a string fixed at each end, $f_1 = \frac{v}{2L} = \frac{1}{2L}\sqrt{\frac{F}{\mu}} = \frac{1}{2}\sqrt{\frac{F}{mL}}$.

EXECUTE: **(a)** The cross-section area of the string would be $A = (900\text{ N})/(7.0\times10^8\text{ Pa}) = 1.29\times10^{-6}\text{ m}^2$, corresponding to a radius of 0.640 mm. The length is the volume divided by the area, and the volume is $V = m/\rho$, so

$$L = \frac{V}{A} = \frac{m/\rho}{A} = \frac{(4.00\times10^{-3}\text{ kg})}{(7.8\times10^3\text{ kg/m}^3)(1.29\times10^{-6}\text{ m}^2)} = 0.40\text{ m}.$$

(b) For the maximum tension of 900 N, $f_1 = \frac{1}{2}\sqrt{\frac{900\text{ N}}{(4.00\times10^{-3}\text{ kg})(0.40\text{ m})}} = 375\text{ Hz}$, or 380 Hz to two figures.

EVALUATE: The string could be shorter and thicker. A shorter string of the same mass would have a higher fundamental frequency.

15.84. **IDENTIFY:** Apply $\Sigma F_y = 0$ to segments of the cable. The forces are the weight of the diver, the weight of the segment of the cable, the tension in the cable and the buoyant force on the segment of the cable and on the diver.

SET UP: The buoyant force on an object of volume V that is completely submerged in water is $B = \rho_{\text{water}}Vg$.

EXECUTE: **(a)** The tension is the difference between the diver's weight and the buoyant force, $F = (m - \rho_{\text{water}}V)g = (120\text{ kg} - (1000\text{ kg/m}^3)(0.0800\text{ m}^3))(9.80\text{ m/s}^2) = 392\text{ N}.$

(b) The increase in tension will be the weight of the cable between the diver and the point at x, minus the buoyant force. This increase in tension is then $(\mu x - \rho(Ax))g = (1.10\text{ kg/m} - (1000\text{ kg/m}^3)\pi(1.00\times10^{-2}\text{ m})^2)(9.80\text{ m/s}^2)x = (7.70\text{ N/m})x$. The tension as a function of x is then $F(x) = (392\text{ N}) + (7.70\text{ N/m})x$.

(c) Denote the tension as $F(x) = F_0 + ax$, where $F_0 = 392\text{ N}$ and $a = 7.70\text{ N/m}$. Then the speed of transverse waves as a function of x is $v = \frac{dx}{dt} = \sqrt{(F_0 + ax)/\mu}$ and the time t needed for a wave to reach the surface is found from $t = \int dt = \int \frac{dx}{dx/dt} = \int \frac{\sqrt{\mu}}{\sqrt{F_0 + ax}}\,dx.$

Let the length of the cable be L, so $t = \sqrt{\mu}\int_0^L \frac{dx}{\sqrt{F_0 + ax}} = \sqrt{\mu}\,\frac{2}{a}\sqrt{F_0 + ax}\Big|_0^L = \frac{2\sqrt{\mu}}{a}(\sqrt{F_0 + aL} - \sqrt{F_0}).$

$$t = \frac{2\sqrt{1.10\text{ kg/m}}}{7.70\text{ N/m}}(\sqrt{392\text{ N} + (7.70\text{ N/m})(100\text{ m})} - \sqrt{392\text{ N}}) = 3.89\text{ s}.$$

EVALUATE: If the weight of the cable and the buoyant force on the cable are neglected, then the tension would have the constant value calculated in part (a). Then $v = \sqrt{\frac{F}{\mu}} = \sqrt{\frac{392\text{ N}}{1.10\text{ kg/m}}} = 18.9\text{ m/s}$ and $t = \frac{L}{v} = 5.29\text{ s}$.

The weight of the cable increases the tension along the cable and the time is reduced from this value.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

15.85. **IDENTIFY:** Carry out the analysis specified in the problem.

SET UP: The kinetic energy of a very short segment Δx is $\Delta K = \frac{1}{2}(\Delta m)v_y^2$. $v_y = \partial y/\partial t$. The work done by the tension is F times the increase in length of the segment. Let the potential energy be zero when the segment is unstretched.

EXECUTE: **(a)** $u_{\rm k} = \dfrac{\Delta K}{\Delta x} = \dfrac{(1/2)\Delta m v_y^2}{\Delta m/\mu} = \dfrac{1}{2}\mu\left(\dfrac{\partial y}{\partial t}\right)^2$.

(b) $\dfrac{\partial y}{\partial t} = \omega A\sin(kx-\omega t)$ and so $u_{\rm k} = \dfrac{1}{2}\mu\omega^2 A^2\sin^2(kx-\omega t)$.

(c) The piece has width Δx and height $\Delta x\dfrac{\partial y}{\partial x}$, and so the length of the piece is

$\left((\Delta x)^2 + \left(\Delta x\dfrac{\partial y}{\partial x}\right)^2\right)^{1/2} = \Delta x\left(1+\left(\dfrac{\partial y}{\partial x}\right)^2\right)^{1/2} \approx \Delta x\left[1+\dfrac{1}{2}\left(\dfrac{\partial y}{\partial x}\right)^2\right]$, where the relation given in the hint has been used.

(d) $u_{\rm p} = F\dfrac{\Delta x\left[1+\frac{1}{2}(\partial y/\partial x)^2\right]-\Delta x}{\Delta x} = \dfrac{1}{2}F\left(\dfrac{\partial y}{\partial x}\right)^2$.

(e) $\dfrac{\partial y}{\partial x} = -kA\sin(kx-\omega t)$, and so $u_{\rm p} = \dfrac{1}{2}Fk^2A^2\sin^2(kx-\omega t)$.

(f) Comparison with the result of part (c) with $k^2 = \omega^2/v^2 = \omega^2\mu/F$ shows that for a sinusoidal wave $u_{\rm k} = u_{\rm p}$.

(g) The graph is given in Figure 15.85. In this graph, $u_{\rm k}$ and $u_{\rm p}$ coincide, as shown in part (f). At $y = 0$, the string is stretched the most, and is moving the fastest, so $u_{\rm k}$and $u_{\rm p}$ are maximized. At the extremes of y, the string is unstretched and is not moving, so $u_{\rm k}$ and $u_{\rm p}$ are both at their minimum of zero.

(h) $u_{\rm k} + u_{\rm p} = Fk^2A^2\sin^2(kx-\omega t) = Fk(\omega/v)A^2\sin^2(kx-\omega t) = \dfrac{P}{v}$.

EVALUATE: The energy density travels with the wave, and the rate at which the energy is transported is the product of the density per unit length and the speed.

16

SOUND AND HEARING

16.1. **IDENTIFY** and **SET UP:** Eq. (15.1) gives the wavelength in terms of the frequency. Use Eq. (16.5) to relate the pressure and displacement amplitudes.

EXECUTE: **(a)** $\lambda = v/f = (344 \text{ m/s})/1000 \text{ Hz} = 0.344 \text{ m}$

(b) $p_{\max} = BkA$ and Bk is constant gives $p_{\max 1}/A_1 = p_{\max 2}/A_2$

$$A_2 = A_1\left(\frac{p_{\max 2}}{p_{\max 1}}\right) = 1.2\times10^{-8} \text{ m}\left(\frac{30 \text{ Pa}}{3.0\times10^{-2} \text{ Pa}}\right) = 1.2\times10^{-5} \text{ m}$$

(c) $p_{\max} = BkA = 2\pi BA/\lambda$

$p_{\max}\lambda = 2\pi BA = \text{constant}$ so $p_{\max 1}\lambda_1 = p_{\max 2}\lambda_2$ and

$$\lambda_2 = \lambda_1\left(\frac{p_{\max 1}}{p_{\max 2}}\right) = (0.344 \text{ m})\left(\frac{3.0\times10^{-2} \text{ Pa}}{1.5\times10^{-3} \text{ Pa}}\right) = 6.9 \text{ m}$$

$f = v/\lambda = (344 \text{ m/s})/6.9 \text{ m} = 50 \text{ Hz}$

EVALUATE: The pressure amplitude and displacement amplitude are directly proportional. For the same displacement amplitude, the pressure amplitude decreases when the frequency decreases and the wavelength increases.

16.2. **IDENTIFY:** Apply $p_{\max} = BkA$ and solve for A.

SET UP: $k = \dfrac{2\pi}{\lambda}$ and $v = f\lambda$, so $k = \dfrac{2\pi f}{v}$ and $p = \dfrac{2\pi fBA}{v}$.

EXECUTE: $A = \dfrac{p_{\max} v}{2\pi Bf} = \dfrac{(3.0\times10^{-2} \text{ Pa})(1480 \text{ m/s})}{2\pi(2.2\times10^{9} \text{ Pa})(1000 \text{ Hz})} = 3.21\times10^{-12} \text{ m}.$

EVALUATE: Both v and B are larger, but B is larger by a much greater factor, so v/B is a lot smaller and therefore A is a lot smaller.

16.3. **IDENTIFY:** Use Eq. (16.5) to relate the pressure and displacement amplitudes.

SET UP: As stated in Example 16.1 the adiabatic bulk modulus for air is $B = 1.42\times10^5$ Pa. Use Eq. (15.1) to calculate λ from f, and then $k = 2\pi/\lambda$.

EXECUTE: **(a)** $f = 150$ Hz

Need to calculate k: $\lambda = v/f$ and $k = 2\pi/\lambda$ so $k = 2\pi f/v = (2\pi \text{ rad})(150 \text{ Hz})/344 \text{ m/s} = 2.74 \text{ rad/m}$. Then $p_{\max} = BkA = (1.42\times10^5 \text{ Pa})(2.74 \text{ rad/m})(0.0200\times10^{-3} \text{ m}) = 7.78 \text{ Pa}$. This is below the pain threshold of 30 Pa.

(b) f is larger by a factor of 10 so $k = 2\pi f/v$ is larger by a factor of 10, and $p_{\max} = BkA$ is larger by a factor of 10. $p_{\max} = 77.8$ Pa, above the pain threshold.

(c) There is again an increase in f, k, and $p_{\max}$ of a factor of 10, so $p_{\max} = 778$ Pa, far above the pain threshold.

EVALUATE: When f increases, λ decreases so k increases and the pressure amplitude increases.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

16.4. **IDENTIFY:** Apply $p_{\max} = BkA$. $k = \dfrac{2\pi}{\lambda} = \dfrac{2\pi f}{v}$, so $p_{\max} = \dfrac{2\pi fBA}{v}$.

SET UP: $v = 344$ m/s

EXECUTE: $f = \dfrac{vp_{\max}}{2\pi BA} = \dfrac{(344 \text{ m/s})(10.0 \text{ Pa})}{2\pi(1.42\times10^5 \text{ Pa})(1.00\times10^{-6} \text{ m})} = 3.86\times10^3$ Hz

EVALUATE: Audible frequencies range from about 20 Hz to about 20,000 Hz, so this frequency is audible.

16.5. **IDENTIFY** and **SET UP:** Use the relation $v = f\lambda$ to find the wavelength or frequency of various sounds.

EXECUTE: **(a)** $\lambda = \dfrac{v}{f} = \dfrac{1531 \text{ m/s}}{17 \text{ Hz}} = 90$ m.

(b) $f = \dfrac{v}{\lambda} = \dfrac{1531 \text{ m/s}}{0.015 \text{ m}} = 102$ kHz.

(c) $\lambda = \dfrac{v}{f} = \dfrac{344 \text{ m/s}}{25\times10^3 \text{ Hz}} = 1.4$ cm.

(d) For $f = 78$ kHz, $\lambda = \dfrac{v}{f} = \dfrac{344 \text{ m/s}}{78\times10^3 \text{ Hz}} = 4.4$ mm. For $f = 39$ kHz, $\lambda = \dfrac{v}{f} = \dfrac{344 \text{ m/s}}{39\times10^3 \text{ Hz}} = 8.8$ mm.

The range of wavelengths is 4.4 mm to 8.8 mm.

(e) $\lambda = 0.25$ mm so $f = \dfrac{v}{\lambda} = \dfrac{1550 \text{ m/s}}{0.25\times10^{-3} \text{m}} = 6.2$ MHz.

EVALUATE: Nonaudible (to human) sounds cover a wide range of frequencies and wavelengths.

16.6. **IDENTIFY:** $v = f\lambda$. Apply Eq. (16.7) for the waves in the liquid and Eq. (16.8) for the waves in the metal bar.

SET UP: In part (b) the wave speed is $v = \dfrac{d}{t} = \dfrac{1.50 \text{ m}}{3.90\times10^{-4} \text{ s}}$.

EXECUTE: **(a)** Using Eq. (16.7), $B = v^2\rho = (\lambda f)^2\rho$, so

$B = [(8 \text{ m})(400 \text{ Hz})]^2(1300 \text{ kg/m}^3) = 1.33\times10^{10}$ Pa.

(b) Using Eq. (16.8), $Y = v^2\rho = (L/t)^2\rho = [(1.50 \text{ m})/(3.90\times10^{-4} \text{ s})]^2(6400 \text{ kg/m}^3) = 9.47\times10^{10}$ Pa.

EVALUATE: In the liquid, $v = 3200$ m/s and in the metal, $v = 3850$ m/s. Both these speeds are much greater than the speed of sound in air.

16.7. **IDENTIFY:** $d = vt$ for the sound waves in air and in water.

SET UP: Use $v_{\text{water}} = 1482$ m/s at 20°C, as given in Table 16.1. In air, $v = 344$ m/s.

EXECUTE: Since along the path to the diver the sound travels 1.2 m in air, the sound wave travels in water for the same time as the wave travels a distance $22.0 \text{ m} - 1.20 \text{ m} = 20.8$ m in air. The depth of the diver is

$(20.8 \text{ m})\dfrac{v_{\text{water}}}{v_{\text{air}}} = (20.8 \text{ m})\dfrac{1482 \text{ m/s}}{344 \text{ m/s}} = 89.6$ m. This is the depth of the diver; the distance from the horn is 90.8 m.

EVALUATE: The time it takes the sound to travel from the horn to the person on shore is $t_1 = \dfrac{22.0 \text{ m}}{344 \text{ m/s}} = 0.0640$ s. The time it takes the sound to travel from the horn to the diver is $t_2 = \dfrac{1.2 \text{ m}}{344 \text{ m/s}} + \dfrac{89.6 \text{ m}}{1482 \text{ m/s}} = 0.0035 \text{ s} + 0.0605 \text{ s} = 0.0640$ s. These times are indeed the same. For three figure accuracy the distance of the horn above the water can't be neglected.

16.8. **IDENTIFY:** Apply Eq. (16.10) to each gas.

SET UP: In each case, express M in units of kg/mol. For H_2, $\gamma = 1.41$. For He and Ar, $\gamma = 1.67$.

EXECUTE: **(a)** $v_{H_2} = \sqrt{\dfrac{(1.41)(8.3145 \text{ J/mol}\cdot\text{K})(300.15 \text{ K})}{(2.02\times10^{-3} \text{ kg/mol})}} = 1.32\times10^3$ m/s

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) $v_{\text{He}} = \sqrt{\dfrac{(1.67)(8.3145\ \text{J/mol}\cdot\text{K})(300.15\ \text{K})}{(4.00\times10^{-3}\ \text{kg/mol})}} = 1.02\times10^{3}\ \text{m/s}$

(c) $v_{\text{Ar}} = \sqrt{\dfrac{(1.67)(8.3145\ \text{J/mol}\cdot\text{K})(300.15\ \text{K})}{(39.9\times10^{-3}\ \text{kg/mol})}} = 323\ \text{m/s}.$

(d) Repeating the calculation of Example 16.4 at $T = 300.15$ K gives $v_{\text{air}} = 348$ m/s, and so $v_{\text{H}_2} = 3.80v_{\text{air}}$, $v_{\text{He}} = 2.94v_{\text{air}}$ and $v_{\text{Ar}} = 0.928v_{\text{air}}$.

EVALUATE: v is larger for gases with smaller M.

16.9. **IDENTIFY:** $v = f\lambda$. The relation of v to gas temperature is given by $v = \sqrt{\dfrac{\gamma RT}{M}}$.

SET UP: Let $T = 22.0°\text{C} = 295.15$ K.

EXECUTE: At 22.0°C, $\lambda = \dfrac{v}{f} = \dfrac{325\ \text{m/s}}{1250\ \text{Hz}} = 0.260\ \text{m} = 26.0\ \text{cm}$. $\lambda = \dfrac{v}{f} = \dfrac{1}{f}\sqrt{\dfrac{\gamma RT}{M}}$. $\dfrac{\lambda}{\sqrt{T}} = \dfrac{1}{f}\sqrt{\dfrac{\gamma R}{M}}$,

which is constant, so $\dfrac{\lambda_1}{\sqrt{T_1}} = \dfrac{\lambda_2}{\sqrt{T_2}}$. $T_2 = T_1\left(\dfrac{\lambda_2}{\lambda_1}\right)^2 = (295.15\ \text{K})\left(\dfrac{28.5\ \text{cm}}{26.0\ \text{cm}}\right)^2 = 354.6\ \text{K} = 81.4°\text{C}.$

EVALUATE: When T increases v increases and for fixed f, λ increases. Note that we did not need to know either γ or M for the gas.

16.10. **IDENTIFY:** $v = \sqrt{\dfrac{\gamma RT}{M}}$. Take the derivative of v with respect to T. In part (b) replace dv by Δv and dT by ΔT in the expression derived in part (a).

SET UP: $\dfrac{d(x^{1/2})}{dx} = \frac{1}{2}x^{-1/2}$. In Eq. (16.10), T must be in kelvins. $20°\text{C} = 293$ K. $\Delta T = 1\ \text{C}° = 1$ K.

EXECUTE: **(a)** $\dfrac{dv}{dT} = \sqrt{\dfrac{\gamma R}{M}}\dfrac{dT^{1/2}}{dT} = \sqrt{\dfrac{\gamma R}{M}}\frac{1}{2}T^{-1/2} = \dfrac{1}{2T}\sqrt{\dfrac{\gamma RT}{M}} = \dfrac{v}{2T}$. Rearranging gives $\dfrac{dv}{v} = \dfrac{1}{2}\dfrac{dT}{T}$, the desired result.

(b) $\dfrac{\Delta v}{v} = \dfrac{1}{2}\dfrac{\Delta T}{T}$. $\Delta v = \dfrac{v}{2}\dfrac{\Delta T}{T} = \left(\dfrac{344\ \text{m/s}}{2}\right)\left(\dfrac{1\ \text{K}}{293\ \text{K}}\right) = 0.59\ \text{m/s}.$

EVALUATE: Since $\dfrac{\Delta T}{T} = 3.4\times10^{-3}$ and $\dfrac{\Delta v}{v}$ is one-half this, replacing dT by ΔT and dv by Δv is accurate. Using the result from part (a) is much simpler than calculating v for 20°C and for 21°C and subtracting, and is not subject to round-off errors.

16.11. **IDENTIFY** and **SET UP:** Use t = distance/speed. Calculate the time it takes each sound wave to travel the $L = 80.0$ m length of the pipe. Use Eq. (16.8) to calculate the speed of sound in the brass rod.

EXECUTE: wave in air: $t = 80.0\ \text{m}/(344\ \text{m/s}) = 0.2326$ s

wave in the metal: $v = \sqrt{\dfrac{Y}{\rho}} = \sqrt{\dfrac{9.0\times10^{10}\ \text{Pa}}{8600\ \text{kg/m}^3}} = 3235\ \text{m/s}$

$$t = \frac{80.0\ \text{m}}{3235\ \text{m/s}} = 0.0247\ \text{s}$$

The time interval between the two sounds is $\Delta t = 0.2326\ \text{s} - 0.0247\ \text{s} = 0.208\ \text{s}$

EVALUATE: The restoring forces that propagate the sound waves are much greater in solid brass than in air, so v is much larger in brass.

16.12. **IDENTIFY:** For transverse waves, $v_{\text{trans}} = \sqrt{\dfrac{F}{\mu}}$. For longitudinal waves, $v_{\text{long}} = \sqrt{\dfrac{Y}{\rho}}$.

SET UP: The mass per unit length μ is related to the density (assumed uniform) and the cross-section area A by $\mu = A\rho$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: $v_{\text{long}} = 30v_{\text{trans}}$ gives $\sqrt{\dfrac{Y}{\rho}} = 30\sqrt{\dfrac{F}{\mu}}$ and $\dfrac{Y}{\rho} = 900\dfrac{F}{A\rho}$. Therefore, $F/A = \dfrac{Y}{900}$.

EVALUATE: Typical values of Y are on the order of 10^{11} Pa, so the stress must be about 10^8 Pa. If A is on the order of 1 mm^2 $= 10^{-6}$ m^2, this requires a force of about 100 N.

16.13. **IDENTIFY** and **SET UP:** Sound delivers energy (and hence power) to the ear. For a whisper, $I = 1\times10^{-10}$ W/m^2. The area of the tympanic membrane is $A = \pi r^2$, with $r = 4.2\times10^{-3}$ m. Intensity is energy per unit time per unit area.

EXECUTE: **(a)** $E = IAt = (1\times10^{-10}\text{ W/m}^2)\pi(4.2\times10^{-3}\text{ m})^2(1\text{ s}) = 5.5\times10^{-15}$ J.

(b) $K = \frac{1}{2}mv^2$ so $v = \sqrt{\dfrac{2K}{m}} = \sqrt{\dfrac{2(5.5\times10^{-15}\text{ J})}{2.0\times10^{-6}\text{ kg}}} = 7.4\times10^{-5}$ m/s $= 0.074$ mm/s.

EVALUATE: Compared to the energy of ordinary objects, it takes only a very small amount of energy for hearing. As part (b) shows, a mosquito carries a lot more energy than is needed for hearing.

16.14. **IDENTIFY:** The intensity I is given in terms of the displacement amplitude by Eq. (16.12) and in terms of the pressure amplitude by Eq. (16.14). $\omega = 2\pi f$. Intensity is energy per second per unit area.

SET UP: For part (a), $I = 10^{-12}$ W/m^2. For part (b), $I = 3.2\times10^{-3}$ W/m^2.

EXECUTE: **(a)** $I = \frac{1}{2}\sqrt{\rho B}\omega^2A^2$.

$$A = \frac{1}{\omega}\sqrt{\frac{2I}{\sqrt{\rho B}}} = \frac{1}{2\pi(1000\text{ Hz})}\sqrt{\frac{2(1\times10^{-12}\text{ W/m}^2)}{\sqrt{(1.20\text{ kg/m}^3)(1.42\times10^5\text{ Pa})}}} = 1.1\times10^{-11}\text{ m.}\quad I = \frac{p_{\max}^2}{2\sqrt{\rho B}}.$$

$$p_{\max} = \sqrt{2I\sqrt{\rho B}} = \sqrt{2(1\times10^{-12}\text{ W/m}^2)\sqrt{(1.20\text{ kg/m}^3)(1.42\times10^5\text{ Pa})}} = 2.9\times10^{-5}\text{ Pa} = 2.8\times10^{-10}\text{ atm}$$

(b) A is proportional to $\sqrt{I}$, so $A = (1.1\times10^{-11}\text{ m})\sqrt{\dfrac{3.2\times10^{-3}\text{ W/m}^2}{1\times10^{-12}\text{ W/m}^2}} = 6.2\times10^{-7}$ m. $p_{\max}$ is also proportional to $\sqrt{I}$, so $p_{\max} = (2.9\times10^{-5}\text{ Pa})\sqrt{\dfrac{3.2\times10^{-3}\text{ W/m}^2}{1\times10^{-12}\text{ W/m}^2}} = 1.6\text{ Pa} = 1.6\times10^{-5}$ atm.

(c) area $= (5.00\text{ mm})^2 = 2.5\times10^{-5}$ m^2. Part (a): $(1\times10^{-12}\text{ W/m}^2)(2.5\times10^{-5}\text{ m}^2) = 2.5\times10^{-17}$ J/s.

Part (b): $(3.2\times10^{-3}\text{ W/m}^2)(2.5\times10^{-5}\text{ m}^2) = 8.0\times10^{-8}$ J/s.

EVALUATE: For faint sounds the displacement and pressure variation amplitudes are very small. Intensities for audible sounds vary over a very wide range.

16.15. **IDENTIFY:** Apply Eq. (16.12) and solve for A. $\lambda = v/f$, with $v = \sqrt{B/\rho}$.

SET UP: $\omega = 2\pi f$. For air, $B = 1.42\times10^5$ Pa.

EXECUTE: **(a)** The amplitude is

$$A = \sqrt{\frac{2\text{I}}{\sqrt{\rho B}\omega^2}} = \sqrt{\frac{2(3.00\times10^{-6}\text{ W/m}^2)}{\sqrt{(1000\text{ kg/m}^3)(2.18\times10^9\text{ Pa})}(2\pi(3400\text{ Hz}))^2}} = 9.44\times10^{-11}\text{ m.}$$

The wavelength is $\lambda = \dfrac{v}{f} = \dfrac{\sqrt{B/\rho}}{f} = \dfrac{\sqrt{(2.18\times10^9\text{ Pa})/(1000\text{ kg/m}^3)}}{3400\text{ Hz}} = 0.434$ m.

(b) Repeating the above with $B = 1.42\times10^5$ Pa and the density of air gives $A = 5.66\times10^{-9}$ m and $\lambda = 0.100$ m.

EVALUATE: **(c)** The amplitude is larger in air, by a factor of about 60. For a given frequency, the much less dense air molecules must have a larger amplitude to transfer the same amount of energy.

16.16. **IDENTIFY:** Knowing the sound level in decibels, we can determine the rate at which energy is delivered to the eardrum.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

SET UP: Intensity is energy per unit time per unit area. $\beta = (10\text{ dB})\log\left(\dfrac{I}{I_0}\right)$, with $I_0 = 1\times10^{-12}$ W/m^2.

The area of the eardrum is $A = \pi r^2$, with $r = 4.2\times10^{-3}$ m. Part (b) of Problem 16.13 gave $v = 0.074$ mm/s.

EXECUTE: **(a)** $\beta = 110$ dB gives $11.0 = \log\left(\dfrac{I}{I_0}\right)$ and $I = (10^{11})I_0 = 0.100$ W/m^2.

$E = IAt = (0.100\text{ W/m}^2)\pi(4.2\times10^{-3}\text{ m})^2(1\text{ s}) = 5.5\ \mu\text{J}$.

(b) $K = \frac{1}{2}mv^2$ so $v = \sqrt{\dfrac{2K}{m}} = \sqrt{\dfrac{2(5.5\times10^{-6}\text{ J})}{2.0\times10^{-6}\text{ kg}}} = 2.3$ m/s. This is about 31,000 times faster than the speed in Problem 16.13b.

EVALUATE: Even though the sound wave intensity level is very high, the rate at which energy is delivered to the eardrum is very small, because the area of the eardrum is very small.

16.17. **IDENTIFY** and **SET UP:** Apply Eqs. (16.5), (16.11) and (16.15).

EXECUTE: **(a)** $\omega = 2\pi f = (2\pi\text{ rad})(150\text{ Hz}) = 942.5$ rad/s

$$k = \frac{2\pi}{\lambda} = \frac{2\pi f}{v} = \frac{\omega}{v} = \frac{942.5\text{ rad/s}}{344\text{ m/s}} = 2.74\text{ rad/m}$$

$B = 1.42\times10^5$ Pa (Example 16.1)

Then $p_{\max} = BkA = (1.42\times10^5\text{ Pa})(2.74\text{ rad/m})(5.00\times10^{-6}\text{ m}) = 1.95$ Pa.

(b) Eq. (16.11): $I = \frac{1}{2}\omega BkA^2$

$I = \frac{1}{2}(942.5\text{ rad/s})(1.42\times10^5\text{ Pa})(2.74\text{ rad/m})(5.00\times10^{-6}\text{ m})^2 = 4.58\times10^{-3}$ W/m^2.

(c) Eq. (16.15): $\beta = (10\text{ dB})\log(I/I_0)$, with $I_0 = 1\times10^{-12}$ W/m^2.

$\beta = (10\text{ dB})\log((4.58\times10^{-3}\text{ W/m}^2)/(1\times10^{-12}\text{ W/m}^2)) = 96.6$ dB.

EVALUATE: Even though the displacement amplitude is very small, this is a very intense sound. Compare the sound intensity level to the values in Table 16.2.

16.18. **IDENTIFY:** Changing the sound intensity level will decrease the rate at which energy reaches the ear.

SET UP: Example 16.9 shows that $\beta_2 - \beta_1 = (10\text{ dB})\log\left(\dfrac{I_2}{I_1}\right)$.

EXECUTE: **(a)** $\Delta\beta = -30$ dB so $\log\left(\dfrac{I_2}{I_1}\right) = -3$ and $\dfrac{I_2}{I_1} = 10^{-3} = 1/1000$.

(b) $I_2/I_1 = \frac{1}{2}$ so $\Delta\beta = 10\log\left(\frac{1}{2}\right) = -3.0$ dB

EVALUATE: Because of the logarithmic relationship between the intensity and intensity level of sound, a small change in the intensity level produces a large change in the intensity.

16.19. **IDENTIFY:** Use Eq. (16.13) to relate I and $p_{\max}$. $\beta = (10\text{ dB})\log(I/I_0)$. Eq. (16.4) says the pressure amplitude and displacement amplitude are related by $p_{\max} = BkA = B\left(\dfrac{2\pi f}{v}\right)A$.

SET UP: At 20°C the bulk modulus for air is 1.42×10^5 Pa and $v = 344$ m/s. $I_0 = 1\times10^{-12}$ W/m^2.

EXECUTE: **(a)** $I = \dfrac{vp_{\max}^2}{2B} = \dfrac{(344\text{ m/s})(6.0\times10^{-5}\text{ Pa})^2}{2(1.42\times10^5\text{ Pa})} = 4.4\times10^{-12}$ W/m^2

(b) $\beta = (10\text{ dB})\log\left(\dfrac{4.4\times10^{-12}\text{ W/m}^2}{1\times10^{-12}\text{ W/m}^2}\right) = 6.4$ dB

(c) $A = \dfrac{vp_{\max}}{2\pi fB} = \dfrac{(344\text{ m/s})(6.0\times10^{-5}\text{ Pa})}{2\pi(400\text{ Hz})(1.42\times10^5\text{ Pa})} = 5.8\times10^{-11}$ m

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: This is a very faint sound and the displacement and pressure amplitudes are very small. Note that the displacement amplitude depends on the frequency but the pressure amplitude does not.

16.20. **IDENTIFY** and **SET UP:** Apply the relation $\beta_2 - \beta_1 = (10\text{ dB})\log(I_2/I_1)$ that is derived in Example 16.9.

EXECUTE: **(a)** $\Delta\beta = (10\text{ dB})\log\left(\dfrac{4I}{I}\right) = 6.0\text{ dB}$

(b) The total number of crying babies must be multiplied by four, for an increase of 12 kids.

EVALUATE: For $I_2 = \alpha I_1$, where α is some factor, the increase in sound intensity level is $\Delta\beta = (10\text{ dB})\log\alpha$. For $\alpha = 4$, $\Delta\beta = 6.0$ dB.

16.21. **IDENTIFY** and **SET UP:** Let 1 refer to the mother and 2 to the father. Use the result derived in Example 16.9 for the difference in sound intensity level for the two sounds. Relate intensity to distance from the source using Eq. (15.26).

EXECUTE: From Example 16.9, $\beta_2 - \beta_1 = (10\text{ dB})\log(I_2/I_1)$

Eq. (15.26): $I_1/I_2 = r_2^2/r_1^2$ or $I_2/I_1 = r_1^2/r_2^2$

$\Delta\beta = \beta_2 - \beta_1 = (10\text{ dB})\log(I_2/I_1) = (10\text{ dB})\log(r_1/r_2)^2 = (20\text{ dB})\log(r_1/r_2)$

$\Delta\beta = (20\text{ dB})\log(1.50\text{ m}/0.30\text{ m}) = 14.0\text{ dB}$.

EVALUATE: The father is 5 times closer so the intensity at his location is 25 times greater.

16.22. **IDENTIFY:** $\beta = (10\text{ dB})\log\dfrac{I}{I_0}$. $\beta_2 - \beta_1 = (10\text{ dB})\log\dfrac{I_2}{I_1}$. Solve for $\dfrac{I_2}{I_1}$.

SET UP: If $\log y = x$ then $y = 10^x$. Let $\beta_2 = 70$ dB and $\beta_1 = 95$ dB.

EXECUTE: $70.0\text{ dB} - 95.0\text{ dB} = -25.0\text{ dB} = (10\text{ dB})\log\dfrac{I_2}{I_1}$. $\log\dfrac{I_2}{I_1} = -2.5$ and $\dfrac{I_2}{I_1} = 10^{-2.5} = 3.2\times10^{-3}$.

EVALUATE: $I_2 < I_1$ when $\beta_2 < \beta_1$.

16.23. **IDENTIFY:** The intensity of sound obeys an inverse square law.

SET UP: $\dfrac{I_2}{I_1} = \dfrac{r_1^2}{r_2^2}$. $\beta = (10\text{ dB})\log\left(\dfrac{I}{I_0}\right)$, with $I_0 = 1\times10^{-12}\text{ W/m}^2$.

EXECUTE: **(a)** $\beta = 53$ dB gives $5.3 = \log\left(\dfrac{I}{I_0}\right)$ and $I = (10^{5.3})I_0 = 2.0\times10^{-7}\text{ W/m}^2$.

(b) $r_2 = r_1\sqrt{\dfrac{I_1}{I_2}} = (3.0\text{ m})\sqrt{\dfrac{4}{1}} = 6.0\text{ m}$.

(c) $\beta = \dfrac{53\text{ dB}}{4} = 13.25\text{ dB}$ gives $1.325 = \log\left(\dfrac{I}{I_0}\right)$ and $I = 2.1\times10^{-11}\text{ W/m}^2$.

$r_2 = r_1\sqrt{\dfrac{I_1}{I_2}} = (3.0\text{ m})\sqrt{\dfrac{2.0\times10^{-7}\text{ W/m}^2}{2.1\times10^{-11}\text{ W/m}^2}} = 290\text{ m}$.

EVALUATE: **(d)** Intensity obeys the inverse square law but noise level does not.

16.24. **IDENTIFY:** We must use the relationship between intensity and sound level.

SET UP: Example 16.9 shows that $\beta_2 - \beta_1 = (10\text{ dB})\log\left(\dfrac{I_2}{I_1}\right)$.

EXECUTE: **(a)** $\Delta\beta = 5.00$ dB gives $\log\left(\dfrac{I_2}{I_1}\right) = 0.5$ and $\dfrac{I_2}{I_1} = 10^{0.5} = 3.16$.

(b) $\dfrac{I_2}{I_1} = 100$ gives $\Delta\beta = 10\log(100) = 20$ dB.

(c) $\dfrac{I_2}{I_1} = 2$ gives $\Delta\beta = 10\log2 = 3.0$ dB.

EVALUATE: Every doubling of the intensity increases the decibel level by 3.0 dB.

16.25. **IDENTIFY** and **SET UP:** An open end is a displacement antinode and a closed end is a displacement node. Sketch the standing wave pattern and use the sketch to relate the node-to-antinode distance to the length of the pipe. A displacement node is a pressure antinode and a displacement antinode is a pressure node.
EXECUTE: **(a)** The placement of the displacement nodes and antinodes along the pipe is as sketched in Figure 16.25a. The open ends are displacement antinodes.

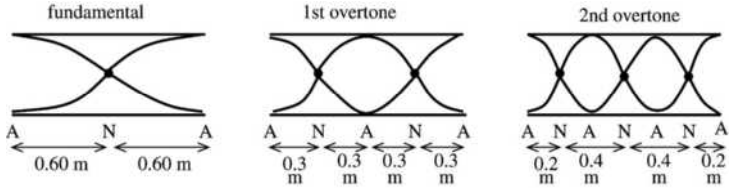

Figure 16.25a

Location of the displacement nodes (N) measured from the left end:
fundamental 0.60 m
1st overtone 0.30 m, 0.90 m
2nd overtone 0.20 m, 0.60 m, 1.00 m

Location of the pressure nodes (displacement antinodes (A)) measured from the left end:
fundamental 0, 1.20 m
1st overtone 0, 0.60 m, 1.20 m
2nd overtone 0, 0.40 m, 0.80 m, 1.20 m
(b) The open end is a displacement antinode and the closed end is a displacement node. The placement of the displacement nodes and antinodes along the pipe is sketched in Figure 16.25b.

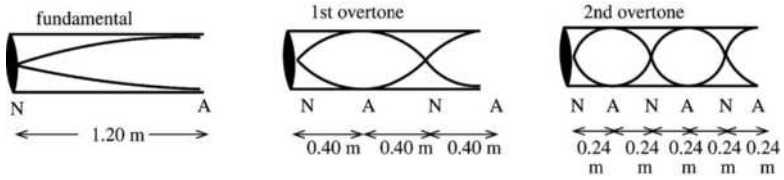

Figure 16.25b

Location of the displacement nodes (N) measured from the closed end:
fundamental 0
1st overtone 0, 0.80 m
2nd overtone 0, 0.48 m, 0.96 m

Location of the pressure nodes (displacement antinodes (A)) measured from the closed end:
fundamental 1.20 m
1st overtone 0.40 m, 1.20 m
2nd overtone 0.24 m, 0.72 m, 1.20 m
EVALUATE: The node-to-node or antinode-to-antinode distance is $\lambda/2$. For the higher overtones the frequency is higher and the wavelength is smaller.

16.26. **IDENTIFY:** For an open pipe, $f_1 = \dfrac{v}{2L}$. For a stopped pipe, $f_1 = \dfrac{v}{4L}$. $v = f\lambda$.

SET UP: $v = 344$ m/s. For a pipe, there must be a displacement node at a closed end and an antinode at the open end.

EXECUTE: **(a)** $L = \dfrac{v}{2f_1} = \dfrac{344 \text{ m/s}}{2(594 \text{ Hz})} = 0.290 \text{ m}.$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) There is a node at one end, an antinode at the other end and no other nodes or antinodes in between, so $\frac{\lambda_1}{4} = L$ and $\lambda_1 = 4L = 4(0.290 \text{ m}) = 1.16 \text{ m}$.

(c) $f_1 = \frac{v}{4L} = \frac{1}{2}\left(\frac{v}{2L}\right) = \frac{1}{2}(594 \text{ Hz}) = 297 \text{ Hz}$.

EVALUATE: We could also calculate f_1 for the stopped pipe as $f_1 = \frac{v}{\lambda_1} = \frac{344 \text{ m/s}}{1.16 \text{ m}} = 297 \text{ Hz}$, which agrees with our result in part (c).

16.27. **IDENTIFY:** For a stopped pipe, the standing wave frequencies are given by Eq. (16.22).
SET UP: The first three standing wave frequencies correspond to $n = 1,\ 3$ and 5.

EXECUTE: $f_1 = \frac{(344 \text{ m/s})}{4(0.17 \text{ m})} = 506 \text{ Hz}$, $f_3 = 3f_1 = 1517 \text{ Hz}$, $f_5 = 5f_1 = 2529 \text{ Hz}$.

EVALUATE: All three of these frequencies are in the audible range, which is about 20 Hz to 20,000 Hz.

16.28. **IDENTIFY:** The vocal tract is modeled as a stopped pipe, open at one end and closed at the other end, so we know the wavelength of standing waves in the tract.

SET UP: For a stopped pipe, $\lambda_n = 4L/n$ $(n = 1, 3, 5, \ldots)$ and $v = f\lambda$, so $f_1 = \frac{v}{4L}$ with $f_1 = 220 \text{ Hz}$.

EXECUTE: $L = \frac{v}{4f_1} = \frac{344 \text{ m/s}}{4(220 \text{ Hz})} = 39.1 \text{ cm}$. This result is a reasonable value for the mouth to diaphragm distance for a typical adult.

EVALUATE: 1244 Hz is not an integer multiple of the fundamental frequency of 220 Hz; it is 5.65 times the fundamental. The production of sung notes is more complicated than harmonics of an air column of fixed length.

16.29. **IDENTIFY:** For either type of pipe, stopped or open, the fundamental frequency is proportional to the wave speed v. The wave speed is given in turn by Eq. (16.10).
SET UP: For He, $\gamma = 5/3$ and for air, $\gamma = 7/5$.

EXECUTE: **(a)** The fundamental frequency is proportional to the square root of the ratio $\frac{\gamma}{M}$, so

$$f_{\text{He}} = f_{\text{air}}\sqrt{\frac{\gamma_{\text{He}}}{\gamma_{\text{air}}} \cdot \frac{M_{\text{air}}}{M_{\text{He}}}} = (262 \text{ Hz})\sqrt{\frac{(5/3)}{(7/5)} \cdot \frac{28.8}{4.00}} = 767 \text{ Hz}.$$

(b) No. In either case the frequency is proportional to the speed of sound in the gas.

EVALUATE: The frequency is much higher for helium, since the rms speed is greater for helium.

16.30. **IDENTIFY:** There must be a node at each end of the pipe. For the fundamental there are no additional nodes and each successive overtone has one additional node. $v = f\lambda$.

SET UP: $v = 344$ m/s. The node to node distance is $\lambda/2$.

EXECUTE: **(a)** $\frac{\lambda_1}{2} = L$ so $\lambda_1 = 2L$. Each successive overtone adds an additional $\lambda/2$ along the pipe, so

$n\left(\frac{\lambda_n}{2}\right) = L$ and $\lambda_n = \frac{2L}{n}$, where $n = 1, 2, 3, \ldots$ $f_n = \frac{v}{\lambda_n} = \frac{nv}{2L}$.

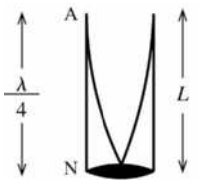
(b) $f_1 = \frac{v}{2L} = \frac{344 \text{ m/s}}{2(2.50 \text{ m})} = 68.8 \text{ Hz}$. $f_2 = 2f_1 = 138 \text{ Hz}$. $f_3 = 3f_1 = 206 \text{ Hz}$. All three of these frequencies are audible.

EVALUATE: A pipe of length L closed at both ends has the same standing wave wavelengths, frequencies and nodal patterns as for a string of length L that is fixed at both ends.

16.31. **IDENTIFY** and **SET UP:** Use the standing wave pattern to relate the wavelength of the standing wave to the length of the air column and then use Eq. (15.1) to calculate f. There is a displacement antinode at the top (open) end of the air column and a node at the bottom (closed) end, as shown in Figure 16.31.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: (a)



$\lambda/4 = L$

$\lambda = 4L = 4(0.140 \text{ m}) = 0.560 \text{ m}$

$f = \dfrac{v}{\lambda} = \dfrac{344 \text{ m/s}}{0.560 \text{ m}} = 614 \text{ Hz}$

Figure 16.31

(b) Now the length L of the air column becomes $\frac{1}{2}(0.140 \text{ m}) = 0.070 \text{ m}$ and $\lambda = 4L = 0.280 \text{ m}$.

$f = \dfrac{v}{\lambda} = \dfrac{344 \text{ m/s}}{0.280 \text{ m}} = 1230 \text{ Hz}$

EVALUATE: Smaller L means smaller λ which in turn corresponds to larger f.

16.32. **IDENTIFY:** The wire will vibrate in its second overtone with frequency f_3^{wire} when $f_3^{\text{wire}} = f_1^{\text{pipe}}$. For a stopped pipe, $f_1^{\text{pipe}} = \dfrac{v}{4L_{\text{pipe}}}$. The second overtone standing wave frequency for a wire fixed at both ends is $f_3^{\text{wire}} = 3\left(\dfrac{v_{\text{wire}}}{2L_{\text{wire}}}\right)$. $v_{\text{wire}} = \sqrt{F/\mu}$.

SET UP: The wire has $\mu = \dfrac{m}{L_{\text{wire}}} = \dfrac{7.25\times10^{-3} \text{ kg}}{0.850 \text{ m}} = 8.53\times10^{-3}$ kg/m. The speed of sound in air is $v = 344$ m/s.

EXECUTE: $v_{\text{wire}} = \sqrt{\dfrac{4110 \text{ N}}{8.53\times10^{-3} \text{ kg/m}}} = 694$ m/s. $f_3^{\text{wire}} = f_1^{\text{pipe}}$ gives $3\dfrac{v_{\text{wire}}}{2L_{\text{wire}}} = \dfrac{v}{4L_{\text{pipe}}}$.

$L_{\text{pipe}} = \dfrac{2L_{\text{wire}}v}{12v_{\text{wire}}} = \dfrac{2(0.850 \text{ m})(344 \text{ m/s})}{12(694 \text{ m/s})} = 0.0702 \text{ m} = 7.02 \text{ cm}.$

EVALUATE: The fundamental for the pipe has the same frequency as the third harmonic of the wire. But the wave speeds for the two objects are different and the two standing waves have different wavelengths.

16.33.

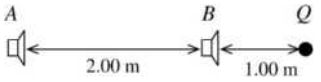


Figure 16.33

(a) IDENTIFY and **SET UP:** Path difference from points A and B to point Q is $3.00 \text{ m} - 1.00 \text{ m} = 2.00$ m, as shown in Figure 16.33. Constructive interference implies path difference $= n\lambda$, $n = 1, 2, 3, \ldots$

EXECUTE: $2.00 \text{ m} = n\lambda$ so $\lambda = 2.00 \text{ m}/n$

$f = \dfrac{v}{\lambda} = \dfrac{nv}{2.00 \text{ m}} = \dfrac{n(344 \text{ m/s})}{2.00 \text{ m}} = n(172 \text{ Hz}), \quad n = 1, 2, 3, \ldots$

The lowest frequency for which constructive interference occurs is 172 Hz.

(b) IDENTIFY and **SET UP:** Destructive interference implies path difference $= (n/2)\lambda$, $n = 1, 3, 5, \ldots$

EXECUTE: $2.00 \text{ m} = (n/2)\lambda$ so $\lambda = 4.00 \text{ m}/n$

$f = \dfrac{v}{\lambda} = \dfrac{nv}{4.00 \text{ m}} = \dfrac{n(344 \text{ m/s})}{(4.00 \text{ m})} = n(86 \text{ Hz}), \quad n = 1, 3, 5, \ldots.$

The lowest frequency for which destructive interference occurs is 86 Hz.

EVALUATE: As the frequency is slowly increased, the intensity at Q will fluctuate, as the interference changes between destructive and constructive.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

16.34. **IDENTIFY:** Constructive interference occurs when the difference of the distances of each source from point P is an integer number of wavelengths. The interference is destructive when this difference of path lengths is a half integer number of wavelengths.
SET UP: The wavelength is $\lambda = v/f = (344 \text{ m/s})/(206 \text{ Hz}) = 1.67 \text{ m}$. Since P is between the speakers, x must be in the range 0 to L, where $L = 2.00 \text{ m}$ is the distance between the speakers.
EXECUTE: The difference in path length is $\Delta l = (L - x) - x = L - 2x$, or $x = (L - \Delta l)/2$. For destructive interference, $\Delta l = (n + (1/2))\lambda$, and for constructive interference, $\Delta l = n\lambda$.
(a) Destructive interference: $n = 0$ gives $\Delta l = 0.835 \text{ m}$ and $x = 0.58 \text{ m}$. $n = -1$ gives $\Delta l = -0.835 \text{ m}$ and $x = 1.42 \text{ m}$. No other values of n place P between the speakers.
(b) Constructive interference: $n = 0$ gives $\Delta l = 0$ and $x = 1.00 \text{ m}$. $n = 1$ gives $\Delta l = 1.67 \text{ m}$ and $x = 0.17 \text{ m}$. $n = -1$ gives $\Delta l = -1.67 \text{ m}$ and $x = 1.83 \text{ m}$. No other values of n place P between the speakers.
(c) Treating the speakers as point sources is a poor approximation for these dimensions, and sound reaches these points after reflecting from the walls, ceiling and floor.
EVALUATE: Points of constructive interference are a distance $\lambda/2$ apart, and the same is true for the points of destructive interference.

16.35. **IDENTIFY:** For constructive interference the path difference is an integer number of wavelengths and for destructive interference the path difference is a half-integer number of wavelengths.
SET UP: $\lambda = v/f = (344 \text{ m/s})/(688 \text{ Hz}) = 0.500 \text{ m}$
EXECUTE: To move from constructive interference to destructive interference, the path difference must change by $\lambda/2$. If you move a distance x toward speaker B, the distance to B gets shorter by x and the distance to A gets longer by x so the path difference changes by $2x$. $2x = \lambda/2$ and $x = \lambda/4 = 0.125 \text{ m}$.
EVALUATE: If you walk an additional distance of 0.125 m farther, the interference again becomes constructive.

16.36. **IDENTIFY:** Destructive interference occurs when the path difference is a half integer number of wavelengths.
SET UP: $v = 344 \text{ m/s}$, so $\lambda = v/f = (344 \text{ m/s})/(172 \text{ Hz}) = 2.00 \text{ m}$. If $r_A = 8.00 \text{ m}$ and r_B are the distances of the person from each speaker, the condition for destructive interference is $r_B - r_A = \left(n + \frac{1}{2}\right)\lambda$, where n is any integer.
EXECUTE: Requiring $r_B = r_A + \left(n + \frac{1}{2}\right)\lambda > 0$ gives $n + \frac{1}{2} > -r_A/\lambda = 0 - (8.00 \text{ m})/(2.00 \text{ m}) = -4$, so the smallest value of r_B occurs when $n = -4$, and the closest distance to B is
$r_B = 8.00 \text{ m} + \left(-4 + \frac{1}{2}\right)(2.00 \text{ m}) = 1.00 \text{ m}$.
EVALUATE: For $r_B = 1.00 \text{ m}$, the path difference is $r_A - r_B = 7.00 \text{ m}$. This is 3.5λ.

16.37. **IDENTIFY:** Compare the path difference to the wavelength.
SET UP: $\lambda = v/f = (344 \text{ m/s})/(860 \text{ Hz}) = 0.400 \text{ m}$
EXECUTE: The path difference is $13.4 \text{ m} - 12.0 \text{ m} = 1.4 \text{ m}$. $\dfrac{\text{path difference}}{\lambda} = 3.5$. The path difference is a half-integer number of wavelengths, so the interference is destructive.
EVALUATE: The interference is destructive at any point where the path difference is a half-integer number of wavelengths.

16.38. **IDENTIFY:** For constructive interference, the path difference is an integer number of wavelengths. For destructive interference, the path difference is a half-integer number of wavelengths.
SET UP: One speaker is 4.50 m from the microphone and the other is 4.03 m from the microphone, so the path difference is 0.42 m. $f = v/\lambda$.
EXECUTE: **(a)** $\lambda = 0.42 \text{ m}$ gives $f = \dfrac{v}{\lambda} = 820 \text{ Hz}$; $2\lambda = 0.42 \text{ m}$ gives $\lambda = 0.21 \text{ m}$ and $f = \dfrac{v}{\lambda} = 1640 \text{ Hz}$; $3\lambda = 0.42 \text{ m}$ gives $\lambda = 0.14 \text{ m}$ and $f = \dfrac{v}{\lambda} = 2460 \text{ Hz}$, and so on. The frequencies for constructive interference are $n(820 \text{ Hz})$, $n = 1, 2, 3, \ldots$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) $\lambda/2 = 0.42$ m gives $\lambda = 0.84$ m and $f = \dfrac{v}{\lambda} = 410$ Hz; $3\lambda/2 = 0.42$ m gives $\lambda = 0.28$ m and $f = \dfrac{v}{\lambda} = 1230$ Hz; $5\lambda/2 = 0.42$ m gives $\lambda = 0.168$ m and $f = \dfrac{v}{\lambda} = 2050$ Hz, and so on. The frequencies for destructive interference are $(2n+1)(410\text{ Hz})$, $n = 0, 1, 2, \ldots$.

EVALUATE: The frequencies for constructive interference lie midway between the frequencies for destructive interference.

16.39. **IDENTIFY:** The beat is due to a difference in the frequencies of the two sounds.

SET UP: $f_{\text{beat}} = f_1 - f_2$. Tightening the string increases the wave speed for transverse waves on the string and this in turn increases the frequency.

EXECUTE: **(a)** If the beat frequency increases when she raises her frequency by tightening the string, it must be that her frequency is 433 Hz, 3 Hz above concert *A*.

(b) She needs to lower her frequency by loosening her string.

EVALUATE: The beat would only be audible if the two sounds are quite close in frequency. A musician with a good sense of pitch can come very close to the correct frequency just from hearing the tone.

16.40. **IDENTIFY:** $f_{\text{beat}} = |f_1 - f_2|$. $v = f\lambda$.

SET UP: $v = 344$ m/s. Let $\lambda_1 = 6.50$ cm and $\lambda_2 = 6.52$ cm. $\lambda_2 > \lambda_1$ so $f_1 > f_2$.

EXECUTE: $f_1 - f_2 = v\left(\dfrac{1}{\lambda_1} - \dfrac{1}{\lambda_2}\right) = \dfrac{v(\lambda_2 - \lambda_1)}{\lambda_1\lambda_2} = \dfrac{(344\text{ m/s})(0.02\times10^{-2}\text{ m})}{(6.50\times10^{-2}\text{ m})(6.52\times10^{-2}\text{ m})} = 16$ Hz. There are 16 beats per second.

EVALUATE: We could have calculated f_1 and f_2 and subtracted, but doing it this way we would have to be careful to retain enough figures in intermediate calculations to avoid round-off errors.

16.41. **IDENTIFY:** $f_{\text{beat}} = |f_a - f_b|$. For a stopped pipe, $f_1 = \dfrac{v}{4L}$.

SET UP: $v = 344$ m/s. Let $L_a = 1.14$ m and $L_b = 1.16$ m. $L_b > L_a$ so $f_{1a} > f_{1b}$.

EXECUTE: $f_{1a} - f_{1b} = \dfrac{v}{4}\left(\dfrac{1}{L_a} - \dfrac{1}{L_b}\right) = \dfrac{v(L_b - L_a)}{4L_aL_b} = \dfrac{(344\text{ m/s})(2.00\times10^{-2}\text{ m})}{4(1.14\text{ m})(1.16\text{ m})} = 1.3$ Hz. There are 1.3 beats per second.

EVALUATE: Increasing the length of the pipe increases the wavelength of the fundamental and decreases the frequency.

16.42. **IDENTIFY:** The motors produce sound having the same frequency as the motor. If the motors are almost, but not quite, the same, a beat will result.

SET UP: $f_{\text{beat}} = f_1 - f_2$. 1 rpm = 60 Hz.

EXECUTE: **(a)** 575 rpm = 9.58 Hz. The frequency of the other propeller differs by 2.0 Hz, so the frequency of the other propeller is either 11.6 Hz or 7.6 Hz. These frequencies correspond to 696 rpm or 456 rpm.

(b) When the speed and rpm of the second propeller is increased the beat frequency increases, so the frequency of the second propeller moves farther from the frequency of the first and the second propeller is turning at 696 rpm.

EVALUATE: If the frequency of the second propeller was 7.6 Hz then it would have moved close to the frequency of the first when its frequency was increased and the beat frequency would have decreased.

16.43. **IDENTIFY:** Apply the Doppler shift equation $f_{\text{L}} = \left(\dfrac{v + v_{\text{L}}}{v + v_{\text{S}}}\right) f_{\text{S}}$.

SET UP: The positive direction is from listener to source. $f_{\text{S}} = 1200$ Hz. $f_{\text{L}} = 1240$ Hz.

EXECUTE: $v_{\text{L}} = 0$. $v_{\text{S}} = -25.0$ m/s. $f_{\text{L}} = \left(\dfrac{v}{v + v_{\text{S}}}\right) f_{\text{S}}$ gives

$$v = \frac{v_{\text{S}} f_{\text{L}}}{f_{\text{S}} - f_{\text{L}}} = \frac{(-25\text{ m/s})(1240\text{ Hz})}{1200\text{ Hz} - 1240\text{ Hz}} = 780\text{ m/s}.$$

EVALUATE: $f_{\text{L}} > f_{\text{S}}$ since the source is approaching the listener.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

16.44. **IDENTIFY:** Follow the steps of Example 16.18.
SET UP: In the first step, $v_S = +20.0$ m/s instead of -30.0 m/s. In the second step, $v_L = -20.0$ m/s instead of $+30.0$ m/s.
EXECUTE: $f_W = \left(\frac{v}{v+v_S}\right)f_S = \left(\frac{340 \text{ m/s}}{340 \text{ m/s} + 20.0 \text{ m/s}}\right)(300 \text{ Hz}) = 283 \text{ Hz}$. Then

$$f_L = \left(\frac{v+v_L}{v}\right)f_W = \left(\frac{340 \text{ m/s} - 20.0 \text{ m/s}}{340 \text{ m/s}}\right)(283 \text{ Hz}) = 266 \text{ Hz}.$$

EVALUATE: When the car is moving toward the reflecting surface, the received frequency back at the source is higher than the emitted frequency. When the car is moving away from the reflecting surface, as is the case here, the received frequency back at the source is lower than the emitted frequency.

16.45. **IDENTIFY:** Apply the Doppler shift equation $f_L = \left(\frac{v+v_L}{v+v_S}\right)f_S$.
SET UP: The positive direction is from listener to source. $f_S = 392$ Hz.
(a) $v_S = 0$. $v_L = -15.0$ m/s. $f_L = \left(\frac{v+v_L}{v+v_S}\right)f_S = \left(\frac{344 \text{ m/s} - 15.0 \text{ m/s}}{344 \text{ m/s}}\right)(392 \text{ Hz}) = 375 \text{ Hz}$

(b) $v_S = +35.0$ m/s. $v_L = +15.0$ m/s. $f_L = \left(\frac{v+v_L}{v+v_S}\right)f_S = \left(\frac{344 \text{ m/s} + 15.0 \text{ m/s}}{344 \text{ m/s} + 35.0 \text{ m/s}}\right)(392 \text{ Hz}) = 371 \text{ Hz}$

(c) $f_{\text{beat}} = f_1 - f_2 = 4$ Hz
EVALUATE: The distance between whistle A and the listener is increasing, and for whistle A $f_L < f_S$. The distance between whistle B and the listener is also increasing, and for whistle B $f_L < f_S$.

16.46. **IDENTIFY** and **SET UP:** Apply Eqs. (16.27) and (16.28) for the wavelengths in front of and behind the source. Then $f = v/\lambda$. When the source is at rest $\lambda = \frac{v}{f_S} = \frac{344 \text{ m/s}}{400 \text{ Hz}} = 0.860$ m.
EXECUTE: **(a)** Eq. (16.27): $\lambda = \frac{v - v_S}{f_S} = \frac{344 \text{ m/s} - 25.0 \text{ m/s}}{400 \text{ Hz}} = 0.798$ m

(b) Eq. (16.28): $\lambda = \frac{v + v_S}{f_S} = \frac{344 \text{ m/s} + 25.0 \text{ m/s}}{400 \text{ Hz}} = 0.922$ m

(c) $f_L = v/\lambda$ (since $v_L = 0$), so $f_L = (344 \text{ m/s})/0.798 \text{ m} = 431$ Hz

(d) $f_L = v/\lambda = (344 \text{ m/s})/0.922 \text{ m} = 373$ Hz
EVALUATE: In front of the source (source moving toward listener) the wavelength is decreased and the frequency is increased. Behind the source (source moving away from listener) the wavelength is increased and the frequency is decreased.

16.47. **IDENTIFY:** The distance between crests is λ. In front of the source $\lambda = \frac{v - v_S}{f_S}$ and behind the source $\lambda = \frac{v + v_S}{f_S}$. $f_S = 1/T$.
SET UP: $T = 1.6$ s. $v = 0.32$ m/s. The crest to crest distance is the wavelength, so $\lambda = 0.12$ m.
EXECUTE: **(a)** $f_S = 1/T = 0.625$ Hz. $\lambda = \frac{v - v_S}{f_S}$ gives
$v_S = v - \lambda f_S = 0.32 \text{ m/s} - (0.12 \text{ m})(0.625 \text{ Hz}) = 0.25$ m/s.

(b) $\lambda = \frac{v + v_S}{f_S} = \frac{0.32 \text{ m/s} + 0.25 \text{ m/s}}{0.625 \text{ Hz}} = 0.91$ m

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: If the duck was held at rest but still paddled its feet, it would produce waves of wavelength $\lambda = \dfrac{0.32 \text{ m/s}}{0.625 \text{ Hz}} = 0.51 \text{ m}$. In front of the duck the wavelength is decreased and behind the duck the wavelength is increased. The speed of the duck is 78% of the wave speed, so the Doppler effects are large.

16.48. **IDENTIFY:** Apply $f_L = \left(\dfrac{v + v_L}{v + v_S}\right) f_S$.

SET UP: $f_S = 1000$ Hz. The positive direction is from the listener to the source. $v = 344$ m/s.

EXECUTE: **(a)** $v_S = -(344 \text{ m/s})/2 = -172$ m/s, $v_L = 0$.

$$f_L = \left(\frac{v + v_L}{v + v_S}\right) f_S = \left(\frac{344 \text{ m/s}}{344 \text{ m/s} - 172 \text{ m/s}}\right)(1000 \text{ Hz}) = 2000 \text{ Hz}$$

(b) $v_S = 0$, $v_L = +172$ m/s. $f_L = \left(\dfrac{v + v_L}{v + v_S}\right) f_S = \left(\dfrac{344 \text{ m/s} + 172 \text{ m/s}}{344 \text{ m/s}}\right)(1000 \text{ Hz}) = 1500 \text{ Hz}$

EVALUATE: The answer in (b) is much less than the answer in (a). It is the velocity of the source and listener relative to the air that determines the effect, not the relative velocity of the source and listener relative to each other.

16.49. **IDENTIFY:** Apply $f_L = \left(\dfrac{v + v_L}{v + v_S}\right) f_S$.

SET UP: The positive direction is from the motorcycle toward the car. The car is stationary, so $v_S = 0$.

EXECUTE: $f_L = \dfrac{v + v_L}{v + v_S} f_S = (1 + v_L/v) f_S$, which gives

$$v_L = v\left(\frac{f_L}{f_S} - 1\right) = (344 \text{ m/s})\left(\frac{490 \text{ Hz}}{520 \text{ Hz}} - 1\right) = -19.8 \text{ m/s}.$$ You must be traveling at 19.8 m/s.

EVALUATE: $v_L < 0$ means that the listener is moving away from the source.

16.50. **IDENTIFY:** Apply the Doppler effect formula, Eq. (16.29).

(a) SET UP: The positive direction is from the listener toward the source, as shown in Figure 16.50a.

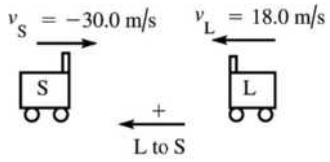

Figure 16.50a

EXECUTE: $f_L = \left(\dfrac{v + v_L}{v + v_S}\right) f_S = \left(\dfrac{344 \text{ m/s} + 18.0 \text{ m/s}}{344 \text{ m/s} - 30.0 \text{ m/s}}\right)(262 \text{ Hz}) = 302 \text{ Hz}$

EVALUATE: Listener and source are approaching and $f_L > f_S$.

(b) SET UP: See Figure 16.50b.

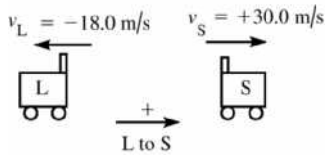

Figure 16.50b

EXECUTE: $f_L = \left(\dfrac{v + v_L}{v + v_S}\right) f_S = \left(\dfrac{344 \text{ m/s} - 18.0 \text{ m/s}}{344 \text{ m/s} + 30.3 \text{ m/s}}\right)(262 \text{ Hz}) = 288 \text{ Hz}$

EVALUATE: Listener and source are moving away from each other and $f_L < f_S$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

16.51. **IDENTIFY:** Each bird is a moving source of sound and a moving observer, so each will experience a Doppler shift.

SET UP: Let one bird be the listener and the other be the source. Use coordinates as shown in Figure 16.51, with the positive direction from listener to source. $f_L = \left(\frac{v + v_L}{v + v_S}\right) f_S$.

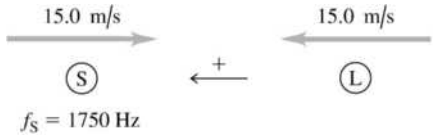

Figure 16.51

EXECUTE: **(a)** $f_S = 1750$ Hz, $v_S = -15.0$ m/s, and $v_L = +15.0$ m/s.

$f_L = \left(\frac{v + v_L}{v + v_S}\right) f_S = \left(\frac{344 \text{ m/s} + 15.0 \text{ m/s}}{344 \text{ m/s} - 15.0 \text{ m/s}}\right)(1750 \text{ Hz}) = 1910 \text{ Hz}.$

(b) One canary hears a frequency of 1910 Hz and the waves move past it at $344 \text{ m/s} + 15 \text{ m/s}$, so the wavelength it detects is $\lambda = \frac{344 \text{ m/s} + 15 \text{ m/s}}{1910 \text{ Hz}} = 0.188$ m. For a stationary bird, $\lambda = \frac{344 \text{ m/s}}{1750 \text{ Hz}} = 0.197$ m.

EVALUATE: The approach of the two birds raises the frequency, and the motion of the source toward the listener decreases the wavelength.

16.52. **IDENTIFY:** There is a Doppler shift due to the motion of the fire engine as well as due to the motion of the truck, which reflects the sound waves.

SET UP: We use the Doppler shift equation $f_L = \left(\frac{v + v_L}{v + v_S}\right) f_S$.

EXECUTE: **(a)** First consider the truck as the listener, as shown in Figure 16.52a.

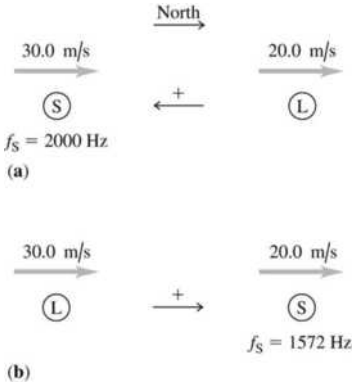

Figure 16.52

$f_L = \left(\frac{v + v_L}{v + v_S}\right) f_S = \left(\frac{344 \text{ m/s} - 20.0 \text{ m/s}}{344 \text{ m/s} - 30.0 \text{ m/s}}\right)(2000 \text{ Hz}) = 2064 \text{ Hz}.$ Now consider the truck as a source, with $f_S = 2064$ Hz, and the fire engine driver as the listener (Figure 16.52b).

$f_L = \left(\frac{v + v_L}{v + v_S}\right) f_S = \left(\frac{344 \text{ m/s} + 30.0 \text{ m/s}}{344 \text{ m/s} + 20.0 \text{ m/s}}\right)(2064 \text{ Hz}) = 2120 \text{ Hz}.$ The objects are getting closer together so the frequency is increased.

(b) The driver detects a frequency of 2120 Hz and the waves returning from the truck move past him at $344 \text{ m/s} + 30.0 \text{ m/s}$, so the wavelength he measures is $\lambda = \frac{344 \text{ m/s} + 30 \text{ m/s}}{2120 \text{ Hz}} = 0.176$ m. The wavelength of waves emitted by the fire engine when it is stationary is $\lambda = \frac{344 \text{ m/s}}{2000 \text{ Hz}} = 0.172$ m.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: In (a) the objects are getting closer together so the frequency is increased. In (b), the quantities to use in the equation $v = f\lambda$ are measured *relative to the observer.*

16.53. **IDENTIFY:** Apply Eq. (16.30).

SET UP: Require $f_R = 1.100 f_S$. Since $f_R > f_S$ the star would be moving toward us and $v < 0$, so $v = -|v|$. $c = 3.00\times10^8$ m/s.

EXECUTE: $f_R = \sqrt{\dfrac{c+|v|}{c-|v|}} f_S$. $f_R = 1.100 f_S$ gives $\dfrac{c+|v|}{c-|v|} = (1.100)^2$. Solving for $|v|$ gives

$$|v| = \frac{[(1.100)^2 - 1]c}{1+(1.100)^2} = 0.0950c = 2.85\times10^7 \text{ m/s}.$$

EVALUATE: $\dfrac{v}{c} = 9.5\%$. $\dfrac{\Delta f}{f_S} = \dfrac{f_R - f_S}{f_S} = 10.0\%$. $\dfrac{v}{c}$ and $\dfrac{\Delta f}{f_S}$ are approximately equal.

16.54. **IDENTIFY:** Apply Eq. (16.30). The source is moving away, so v is positive.

SET UP: $c = 3.00\times10^8$ m/s. $v = +50.0\times10^3$ m/s.

EXECUTE: $f_R = \sqrt{\dfrac{c-v}{c+v}} f_S = \sqrt{\dfrac{3.00\times10^8 \text{ m/s} - 50.0\times10^3 \text{ m/s}}{3.00\times10^8 \text{ m/s} + 50.0\times10^3 \text{ m/s}}}(3.330\times10^{14} \text{ Hz}) = 3.329\times10^{14} \text{ Hz}$

EVALUATE: $f_R < f_S$ since the source is moving away. The difference between f_R and f_S is very small since $v \ll c$.

16.55. **IDENTIFY:** Apply Eq. (16.31) to calculate α. Use the method of Example 16.19 to calculate t.

SET UP: Mach 1.70 means $v_S/v = 1.70$.

EXECUTE: **(a)** In Eq. (16.31), $v/v_S = 1/1.70 = 0.588$ and $\alpha = \arcsin(0.588) = 36.0°$.

(b) As in Example 16.19, $t = \dfrac{(950 \text{ m})}{(1.70)(344 \text{ m/s})(\tan(36.0°))} = 2.23$ s.

EVALUATE: The angle α decreases when the speed v_S of the plane increases.

16.56. **IDENTIFY:** Apply Eq. (16.31).

SET UP: The Mach number is the value of v_S/v, where v_S is the speed of the shuttle and v is the speed of sound at the altitude of the shuttle.

EXECUTE: **(a)** $\dfrac{v}{v_S} = \sin\alpha = \sin 58.0° = 0.848$. The Mach number is $\dfrac{v_S}{v} = \dfrac{1}{0.848} = 1.18$.

(b) $v_S = \dfrac{v}{\sin\alpha} = \dfrac{331 \text{ m/s}}{\sin 58.0°} = 390 \text{ m/s}$

(c) $\dfrac{v_S}{v} = \dfrac{390 \text{ m/s}}{344 \text{ m/s}} = 1.13$. The Mach number would be 1.13. $\sin\alpha = \dfrac{v}{v_S} = \dfrac{344 \text{ m/s}}{390 \text{ m/s}}$ and $\alpha = 61.9°$.

EVALUATE: The smaller the Mach number, the larger the angle of the shock-wave cone.

16.57. **IDENTIFY:** $f_{beat} = |f - f_0|$. $f = \dfrac{v}{2L}$. Changing the tension changes the wave speed and this alters the frequency.

SET UP: $v = \sqrt{\dfrac{FL}{m}}$ so $f = \dfrac{1}{2}\sqrt{\dfrac{F}{mL}}$, where $F = F_0 + \Delta F$. Let $f_0 = \dfrac{1}{2}\sqrt{\dfrac{F_0}{mL}}$. We can assume that $\Delta F/F_0$ is very small. Increasing the tension increases the frequency, so $f_{beat} = f - f_0$.

EXECUTE: **(a)** $f_{beat} = f - f_0 = \dfrac{1}{2\sqrt{mL}}\left(\sqrt{F_0 + \Delta F} - \sqrt{F_0}\right) = \dfrac{1}{2}\sqrt{\dfrac{F_0}{mL}}\left(\left[1 + \dfrac{\Delta F}{F_0}\right]^{1/2} - 1\right)$.

$\left[1 + \dfrac{\Delta F}{F_0}\right]^{1/2} = 1 + \dfrac{\Delta F}{2F_0}$ when $\Delta F/F_0$ is small. This gives that $f_{beat} = f_0\left(\dfrac{\Delta F}{2F_0}\right)$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) $\dfrac{\Delta F}{F_0} = \dfrac{2f_{\text{beat}}}{f_0} = \dfrac{2(1.5\text{ Hz})}{440\text{ Hz}} = 0.68\%.$

EVALUATE: The fractional change in frequency is one-half the fractional change in tension.

16.58. **IDENTIFY:** The displacement $y(x,t)$ is given in Eq. (16.1) and the pressure variation is given in Eq. (16.4). The pressure variation is related to the displacement by Eq. (16.3).

SET UP: $k = 2\pi/\lambda$

EXECUTE: **(a)** Mathematically, the waves given by Eq. (16.1) and Eq. (16.4) are out of phase. Physically, at a displacement node, the air is most compressed or rarefied on either side of the node, and the pressure gradient is zero. Thus, displacement nodes are pressure antinodes.

(b) The graphs have the same form as in Figure 16.3 in the textbook.

(c) $p(x,t) = -B\dfrac{\partial y(x,t)}{\partial x}$. When $y(x,t)$ versus x is a straight line with positive slope, $p(x,t)$ is constant and negative. When $y(x,t)$ versus x is a straight line with negative slope, $p(x,t)$ is constant and positive. The graph of $p(x,0)$ is given in Figure 16.58. The slope of the straightline segments for $y(x,0)$ is 1.6×10^{-4}, so for the wave in Figure P16.58 in the textbook, $p_{\text{max-non}} = (1.6\times10^{-4})B$. The sinusoidal wave has amplitude $p_{\text{max}} = BkA = (2.5\times10^{-4})B$. The difference in the pressure amplitudes is because the two $y(x,0)$ functions have different slopes.

EVALUATE: **(d)** $p(x,t)$ has its largest magnitude where $y(x,t)$ has the greatest slope. This is where $y(x,t) = 0$ for a sinusoidal wave but it is not true in general.

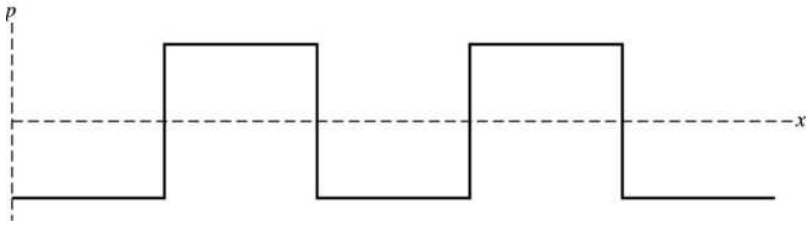

Figure 16.58

16.59. **IDENTIFY:** The sound intensity level is $\beta = (10\text{ dB})\log(I/I_0)$, so the same sound intensity level β means the same intensity I. The intensity is related to pressure amplitude by Eq. (16.13) and to the displacement amplitude by Eq. (16.12).

SET UP: $v = 344$ m/s. $\omega = 2\pi f$. Each octave higher corresponds to a doubling of frequency, so the note sung by the bass has frequency $(932\text{ Hz})/8 = 116.5$ Hz. Let 1 refer to the note sung by the soprano and 2 refer to the note sung by the bass. $I_0 = 1\times10^{-12}$ W/m^2.

EXECUTE: **(a)** $I = \dfrac{vp_{\text{max}}^2}{2B}$ and $I_1 = I_2$ gives $p_{\text{max},1} = p_{\text{max},2}$; the ratio is 1.00.

(b) $I = \frac{1}{2}\sqrt{\rho B}\omega^2A^2 = \frac{1}{2}\sqrt{\rho B}4\pi^2f^2A^2$. $I_1 = I_2$ gives $f_1A_1 = f_2A_2$. $\dfrac{A_2}{A_1} = \dfrac{f_1}{f_2} = 8.00.$

(c) $\beta = 72.0$ dB gives $\log(I/I_0) = 7.2$. $\dfrac{I}{I_0} = 10^{7.2}$ and $I = 1.585\times10^{-5}$ W/m^2. $I = \frac{1}{2}\sqrt{\rho B}4\pi^2f^2A^2$.

$$A = \frac{1}{2\pi f}\sqrt{\frac{2I}{\sqrt{\rho B}}} = \frac{1}{2\pi(932\text{ Hz})}\sqrt{\frac{2(1.585\times10^{-5}\text{ W/m}^2)}{\sqrt{(1.20\text{ kg/m}^3)(1.42\times10^5\text{ Pa})}}} = 4.73\times10^{-8}\text{ m} = 47.3\text{ nm}.$$

EVALUATE: Even for this loud note the displacement amplitude is very small. For a given intensity, the displacement amplitude depends on the frequency of the sound wave but the pressure amplitude does not.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

16.60. **IDENTIFY:** Use the equations that relate intensity level and intensity, intensity and pressure amplitude, pressure amplitude and displacement amplitude, and intensity and distance.

(a) SET UP: Use the intensity level β to calculate I at this distance. $\beta = (10\text{ dB})\log(I/I_0)$

EXECUTE: $52.0\text{ dB} = (10\text{ dB})\log(I/(10^{-12}\text{ W/m}^2))$

$\log(I/(10^{-12}\text{ W/m}^2)) = 5.20$ implies $I = 1.585\times10^{-7}\text{ W/m}^2$

SET UP: Then use Eq. (16.14) to calculate $p_{\max}$:

$I = \dfrac{p_{\max}^2}{2\rho v}$ so $p_{\max} = \sqrt{2\rho v I}$

From Example 16.5, $\rho = 1.20\text{ kg/m}^3$ for air at 20°C.

EXECUTE: $p_{\max} = \sqrt{2\rho v I} = \sqrt{2(1.20\text{ kg/m}^3)(344\text{ m/s})(1.585\times10^{-7}\text{ W/m}^2)} = 0.0114\text{ Pa}$

(b) SET UP: Eq. (16.5): $p_{\max} = BkA$ so $A = \dfrac{p_{\max}}{Bk}$

For air $B = 1.42\times10^5$ Pa (Example 16.1).

EXECUTE: $k = \dfrac{2\pi}{\lambda} = \dfrac{2\pi f}{v} = \dfrac{(2\pi\text{ rad})(587\text{ Hz})}{344\text{ m/s}} = 10.72\text{ rad/m}$

$A = \dfrac{p_{\max}}{Bk} = \dfrac{0.0114\text{ Pa}}{(1.42\times10^5\text{ Pa})(10.72\text{ rad/m})} = 7.49\times10^{-9}\text{ m}$

(c) SET UP: $\beta_2 - \beta_1 = (10\text{ dB})\log(I_2/I_1)$ (Example 16.9).

Eq. (15.26): $I_1/I_2 = r_2^2/r_1^2$ so $I_2/I_1 = r_1^2/r_2^2$

EXECUTE: $\beta_2 - \beta_1 = (10\text{ dB})\log(r_1/r_2)^2 = (20\text{ dB})\log(r_1/r_2)$.

$\beta_2 = 52.0\text{ dB}$ and $r_2 = 5.00$ m. Then $\beta_1 = 30.0\text{ dB}$ and we need to calculate r_1.

$52.0\text{ dB} - 30.0\text{ dB} = (20\text{ dB})\log(r_1/r_2)$

$22.0\text{ dB} = (20\text{ dB})\log(r_1/r_2)$

$\log(r_1/r_2) = 1.10$ so $r_1 = 12.6r_2 = 63.0$ m.

EVALUATE: The decrease in intensity level corresponds to a decrease in intensity, and this means an increase in distance. The intensity level uses a logarithmic scale, so simple proportionality between r and β doesn't apply.

16.61. **IDENTIFY:** The sound is first loud when the frequency f_0 of the speaker equals the frequency f_1 of the fundamental standing wave for the gas in the tube. The tube is a stopped pipe, and $f_1 = \dfrac{v}{4L}$. $v = \sqrt{\dfrac{\gamma RT}{M}}$.

The sound is next loud when the speaker frequency equals the first overtone frequency for the tube.

SET UP: A stopped pipe has only odd harmonics, so the frequency of the first overtone is $f_3 = 3f_1$.

EXECUTE: **(a)** $f_0 = f_1 = \dfrac{v}{4L} = \dfrac{1}{4L}\sqrt{\dfrac{\gamma RT}{M}}$. This gives $T = \dfrac{16L^2Mf_0^2}{\gamma R}$.

(b) $3f_0$.

EVALUATE: **(c)** Measure f_0 and L. Then $f_0 = \dfrac{v}{4L}$ gives $v = 4Lf_0$.

16.62. **IDENTIFY:** $f_{\text{beat}} = |f_A - f_B|$. $f_1 = \dfrac{v}{2L}$ and $v = \sqrt{\dfrac{FL}{m}}$ gives $f_1 = \dfrac{1}{2}\sqrt{\dfrac{F}{mL}}$. Apply $\Sigma\tau_z = 0$ to the bar to find the tension in each wire.

SET UP: For $\Sigma\tau_z = 0$ take the pivot at wire A and let counterclockwise torques be positive. The free-body diagram for the bar is given in Figure 16.62. Let L be the length of the bar.

EXECUTE: $\Sigma\tau_z = 0$ gives $F_BL - w_{\text{lead}}(3L/4) - w_{\text{bar}}(L/2) = 0$.

$F_B = 3w_{\text{lead}}/4 + w_{\text{bar}}/2 = 3(185\text{ N})/4 + (165\text{ N})/2 = 221$ N. $F_A + F_B = w_{\text{bar}} + w_{\text{lead}}$ so

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$F_A = w_{\text{bar}} + w_{\text{lead}} - F_B = 165\text{ N} + 185\text{ N} - 221\text{ N} = 129\text{ N}$. $f_{1A} = \frac{1}{2}\sqrt{\frac{129\text{ N}}{(5.50\times10^{-3}\text{ kg})(0.750\text{ m})}} = 88.4\text{ Hz}$.

$f_{1B} = f_{1A}\sqrt{\frac{221\text{ N}}{129\text{ N}}} = 115.7\text{ Hz}$. $f_{\text{beat}} = f_{1B} - f_{1A} = 27.3\text{ Hz}$.

EVALUATE: The frequency increases when the tension in the wire increases.

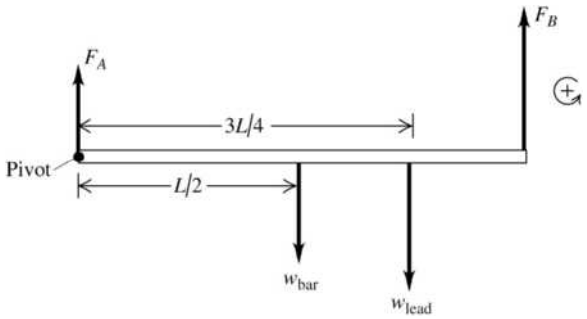

Figure 16.62

16.63. **IDENTIFY:** The flute acts as a stopped pipe and its harmonic frequencies are given by Eq. (16.23). The resonant frequencies of the string are $f_n = nf_1, n = 1, 2, 3, \ldots$ The string resonates when the string frequency equals the flute frequency.

SET UP: For the string $f_{1\text{s}} = 600.0$ Hz. For the flute, the fundamental frequency is $f_{1\text{f}} = \frac{v}{4L} = \frac{344.0\text{ m/s}}{4(0.1075\text{ m})} = 800.0$ Hz. Let n_{f} label the harmonics of the flute and let n_{s} label the harmonics of the string.

EXECUTE: For the flute and string to be in resonance, $n_{\text{f}}f_{1\text{f}} = n_{\text{s}}f_{1\text{s}}$, where $f_{1\text{s}} = 600.0$ Hz is the fundamental frequency for the string. $n_{\text{s}} = n_{\text{f}}(f_{1\text{f}}/f_{1\text{s}}) = \frac{4}{3}n_{\text{f}}$. n_{s} is an integer when $n_{\text{f}} = 3N, N = 1, 3, 5, \ldots$ (the flute has only odd harmonics). $n_{\text{f}} = 3N$ gives $n_{\text{s}} = 4N$.

Flute harmonic $3N$ resonates with string harmonic $4N, N = 1, 3, 5, ...$

EVALUATE: We can check our results for some specific values of N. For $N = 1$, $n_{\text{f}} = 3$ and $f_{3\text{f}} = 2400$ Hz. For this N, $n_{\text{s}} = 4$ and $f_{4\text{s}} = 2400$ Hz. For $N = 3$, $n_{\text{f}} = 9$ and $f_{9\text{f}} = 7200$ Hz, and $n_{\text{s}} = 12$, $f_{12\text{s}} = 7200$ Hz. Our general results do give equal frequencies for the two objects.

16.64. **IDENTIFY:** The harmonics of the string are $f_n = nf_1 = n\left(\frac{v}{2l}\right)$, where l is the length of the string. The tube is a stopped pipe and its standing wave frequencies are given by Eq. (16.22). For the string, $v = \sqrt{F/\mu}$, where F is the tension in the string.

SET UP: The length of the string is $d = L/10$, so its third harmonic has frequency $f_3^{\text{string}} = 3\frac{1}{2d}\sqrt{F/\mu}$.

The stopped pipe has length L, so its first harmonic has frequency $f_1^{\text{pipe}} = \frac{v_{\text{s}}}{4L}$.

EXECUTE: **(a)** Equating f_1^{string} and f_1^{pipe} and using $d = L/10$ gives $F = \frac{1}{3600}\mu v_{\text{s}}^2$.

(b) If the tension is doubled, all the frequencies of the string will increase by a factor of $\sqrt{2}$. In particular, the third harmonic of the string will no longer be in resonance with the first harmonic of the pipe because the frequencies will no longer match, so the sound produced by the instrument will be diminished.

(c) The string will be in resonance with a standing wave in the pipe when their frequencies are equal. Using $f_1^{\text{pipe}} = 3f_1^{\text{string}}$, the frequencies of the pipe are $nf_1^{\text{pipe}} = 3nf_1^{\text{string}}$ (where $n = 1, 3, 5, \ldots$). Setting this

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

equal to the frequencies of the string $n'f_1^{\text{string}}$, the harmonics of the string are $n' = 3n = 3, 9, 15, \ldots$ The nth harmonic of the pipe is in resonance with the $3n$th harmonic of the string.

EVALUATE: Each standing wave for the air column is in resonance with a standing wave on the string. But the reverse is not true; not all standing waves of the string are in resonance with a harmonic of the pipe.

16.65. **IDENTIFY** and **SET UP:** The frequency of any harmonic is an integer multiple of the fundamental. For a stopped pipe only odd harmonics are present. For an open pipe, all harmonics are present. See which pattern of harmonics fits to the observed values in order to determine which type of pipe it is. Then solve for the fundamental frequency and relate that to the length of the pipe.

EXECUTE: **(a)** For an open pipe the successive harmonics are $f_n = nf_1, \quad n = 1, 2, 3, \ldots$ For a stopped pipe the successive harmonics are $f_n = nf_1, \quad n = 1, 3, 5, \ldots$. If the pipe is open and these harmonics are successive, then $f_n = nf_1 = 1372$ Hz and $f_{n+1} = (n+1)f_1 = 1764$ Hz. Subtract the first equation from the second: $(n+1)f_1 - nf_1 = 1764\text{ Hz} - 1372\text{ Hz}$. This gives $f_1 = 392$ Hz. Then $n = \dfrac{1372\text{ Hz}}{392\text{ Hz}} = 3.5$. But n must be an integer, so the pipe can't be open. If the pipe is stopped and these harmonics are successive, then $f_n = nf_1 = 1372$ Hz and $f_{n+2} = (n+2)f_1 = 1764$ Hz (in this case successive harmonics differ in n by 2). Subtracting one equation from the other gives $2f_1 = 392$ Hz and $f_1 = 196$ Hz. Then $n = 1372\text{ Hz}/f_1 = 7$ so $1372\text{ Hz} = 7f_1$ and $1764\text{ Hz} = 9f_1$. The solution gives integer n as it should; the pipe is stopped.

(b) From part (a) these are the 7th and 9th harmonics.

(c) From part (a) $f_1 = 196$ Hz.

For a stopped pipe $f_1 = \dfrac{v}{4L}$ and $L = \dfrac{v}{4f_1} = \dfrac{344\text{ m/s}}{4(196\text{ Hz})} = 0.439$ m.

EVALUATE: It is essential to know that these are successive harmonics and to realize that 1372 Hz is not the fundamental. There are other lower frequency standing waves; these are just two successive ones.

16.66. **IDENTIFY:** The steel rod has standing waves much like a pipe open at both ends, since the ends are both displacement antinodes. An integral number of half wavelengths must fit on the rod, that is, $f_n = \dfrac{nv}{2L}$, with $n = 1, 2, 3, \ldots$

SET UP: Table 16.1 gives $v = 5941$ m/s for longitudinal waves in steel.

EXECUTE: **(a)** The ends of the rod are antinodes because the ends of the rod are free to oscillate.

(b) The fundamental can be produced when the rod is held at the middle because a node is located there.

(c) $f_1 = \dfrac{(1)(5941\text{ m/s})}{2(1.50\text{ m})} = 1980$ Hz

(d) The next harmonic is $n = 2$, or $f_2 = 3961$ Hz. We would need to hold the rod at an $n = 2$ node, which is located at $L/4 = 0.375$ m from either end.

EVALUATE: For the 1.50 m long rod the wavelength of the fundamental is $x = 2L = 3.00$ m. The node to antinode distance is $\lambda/4 = 0.75$ m. For the second harmonic $\lambda = L = 1.50$ m and the node to antinode distance is 0.375 m. There is a node at the middle of the rod, but forcing a node at 0.375 m from one end, by holding the rod there, prevents the rod from vibrating in the fundamental.

16.67. **IDENTIFY** and **SET UP:** There is a node at the piston, so the distance the piston moves is the node to node distance, $\lambda/2$. Use Eq. (15.1) to calculate v and Eq. (16.10) to calculate γ from v.

EXECUTE: **(a)** $\lambda/2 = 37.5$ cm, so $\lambda = 2(37.5\text{ cm}) = 75.0\text{ cm} = 0.750$ m.

$v = f\lambda = (500\text{ Hz})(0.750\text{ m}) = 375$ m/s

(b) $v = \sqrt{\gamma RT/M}$ (Eq. 16.10)

$\gamma = \dfrac{Mv^2}{RT} = \dfrac{(28.8\times10^{-3}\text{ kg/mol})(375\text{ m/s})^2}{(8.3145\text{ J/mol}\cdot\text{K})(350\text{ K})} = 1.39.$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(c) EVALUATE: There is a node at the piston so when the piston is 18.0 cm from the open end the node is inside the pipe, 18.0 cm from the open end. The node to antinode distance is $\lambda/4 = 18.8$ cm, so the antinode is 0.8 cm beyond the open end of the pipe.
The value of γ we calculated agrees with the value given for air in Example 16.4.

16.68. **IDENTIFY:** For a stopped pipe the frequency of the fundamental is $f_1 = \dfrac{v}{4L}$. The speed of sound in air depends on temperature, as shown by Eq. (16.10).
SET UP: Example 16.4 shows that the speed of sound in air at 20°C is 344 m/s.

EXECUTE: **(a)** $L = \dfrac{v}{4f} = \dfrac{344 \text{ m/s}}{4(349 \text{ Hz})} = 0.246 \text{ m}$

(b) The frequency will be proportional to the speed, and hence to the square root of the Kelvin temperature. The temperature necessary to have the frequency be higher is $(293.15 \text{ K})([370 \text{ Hz}]/[349 \text{ Hz}])^2 = 329.5 \text{ K}$, which is 56.3°C.
EVALUATE: $56.3°\text{C} = 133°\text{F}$, so this extreme rise in pitch won't occur in practical situations. But changes in temperature can have noticeable effects on the pitch of the organ notes.

16.69. **IDENTIFY:** $v = f\lambda$. $v = \sqrt{\dfrac{\gamma RT}{M}}$. Solve for γ.

SET UP: The wavelength is twice the separation of the nodes, so $\lambda = 2L$, where $L = 0.200$ m.

EXECUTE: $v = \lambda f = 2Lf = \sqrt{\dfrac{\gamma RT}{M}}$. Solving for γ,

$$\gamma = \frac{M}{RT}(2Lf)^2 = \frac{(16.0\times10^{-3} \text{ kg/mol})}{(8.3145 \text{ J/mol}\cdot\text{K})\ (293.15 \text{ K})}(2(0.200 \text{ m})(1100 \text{ Hz}))^2 = 1.27.$$

EVALUATE: This value of γ is smaller than that of air. We will see in Chapter 19 that this value of γ is a typical value for polyatomic gases.

16.70. **IDENTIFY:** Destructive interference occurs when the path difference is a half-integer number of wavelengths. Constructive interference occurs when the path difference is an integer number of wavelengths.

SET UP: $\lambda = \dfrac{v}{f} = \dfrac{344 \text{ m/s}}{784 \text{ Hz}} = 0.439 \text{ m}$

EXECUTE: **(a)** If the separation of the speakers is denoted h, the condition for destructive interference is $\sqrt{x^2 + h^2} - x = \beta\lambda$, where β is an odd multiple of one-half. Adding x to both sides, squaring, canceling the x^2 term from both sides and solving for x gives $x = \dfrac{h^2}{2\beta\lambda} - \dfrac{\beta}{2}\lambda$. Using $\lambda = 0.439$ m and $h = 2.00$ m yields 9.01 m for $\beta = \frac{1}{2}$, 2.71 m for $\beta = \frac{3}{2}$, 1.27 m for $\beta = \frac{5}{2}$, 0.53 m for $\beta = \frac{7}{2}$, and 0.026 m for $\beta = \frac{9}{2}$. These are the only allowable values of β that give positive solutions for x.
(b) Repeating the above for integral values of β, constructive interference occurs at 4.34 m, 1.84 m, 0.86 m, 0.26 m. Note that these are between, but not midway between, the answers to part (a).
(c) If $h = \lambda/2$, there will be destructive interference at speaker B. If $\lambda/2 > h$, the path difference can never be as large as $\lambda/2$. (This is also obtained from the above expression for x, with $x = 0$ and $\beta = \frac{1}{2}$.) The minimum frequency is then $v/2h = (344 \text{ m/s})/(4.0 \text{ m}) = 86$ Hz.
EVALUATE: When f increases, λ is smaller and there are more occurrences of points of constructive and destructive interference.

16.71. **IDENTIFY:** Apply $f_\text{L} = \left(\dfrac{v + v_\text{L}}{v + v_\text{S}}\right) f_\text{S}$.

SET UP: The positive direction is from the listener to the source. (a) The wall is the listener. $v_\text{S} = -30$ m/s. $v_\text{L} = 0$. $f_\text{L} = 600$ Hz. (b) The wall is the source and the car is the listener. $v_\text{S} = 0$. $v_\text{L} = +30$ m/s. $f_\text{S} = 600$ Hz.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: **(a)** $f_L = \left(\frac{v+v_L}{v+v_S}\right) f_S$. $f_S = \left(\frac{v+v_S}{v+v_L}\right) f_L = \left(\frac{344 \text{ m/s} - 30 \text{ m/s}}{344 \text{ m/s}}\right)(600 \text{ Hz}) = 548 \text{ Hz}$

(b) $f_L = \left(\frac{v+v_L}{v+v_S}\right) f_S = \left(\frac{344 \text{ m/s} + 30 \text{ m/s}}{344 \text{ m/s}}\right)(600 \text{ Hz}) = 652 \text{ Hz}$

EVALUATE: Since the singer and wall are moving toward each other the frequency received by the wall is greater than the frequency sung by the soprano, and the frequency she hears from the reflected sound is larger still.

16.72. **IDENTIFY:** Apply $f_L = \left(\frac{v+v_L}{v+v_S}\right) f_S$. The wall first acts as a listener and then as a source.

SET UP: The positive direction is from listener to source. The bat is moving toward the wall so the Doppler effect increases the frequency and the final frequency received, f_{L2}, is greater than the original source frequency, f_{S1}. $f_{S1} = 1700$ Hz. $f_{L2} - f_{S1} = 10.0$ Hz.

EXECUTE: The wall receives the sound: $f_S = f_{S1}$. $f_L = f_{L1}$. $v_S = -v_{bat}$ and $v_L = 0$. $f_L = \left(\frac{v+v_L}{v+v_S}\right) f_S$ gives $f_{L1} = \left(\frac{v}{v-v_{bat}}\right) f_{S1}$. The wall receives the sound: $f_{S2} = f_{L1}$. $v_S = 0$ and $v_L = +v_{bat}$.

$$f_{L2} = \left(\frac{v+v_{bat}}{v}\right) f_{S2} = \left(\frac{v+v_{bat}}{v}\right)\left(\frac{v}{v-v_{bat}}\right) f_{S1} = \left(\frac{v+v_{bat}}{v-v_{bat}}\right) f_{S1}.$$

$$f_{L2} - f_{S1} = \Delta f = \left(\frac{v+v_{bat}}{v-v_{bat}} - 1\right) f_{S1} = \left(\frac{2v_{bat}}{v-v_{bat}}\right) f_{S1}. \quad v_{bat} = \frac{v\Delta f}{2f_{S1} + \Delta f} = \frac{(344 \text{ m/s})(10.0 \text{ Hz})}{2(1700 \text{ Hz}) + 10.0 \text{ Hz}} = 1.01 \text{ m/s}.$$

EVALUATE: $f_{S1} < \Delta f$, so we can write our result as the approximate but accurate expression $\Delta f = \left(\frac{2v_{bat}}{v}\right) f_{S1}$.

16.73. **IDENTIFY:** For the sound coming directly to the observer at the top of the well, the source is moving away from the listener. For the reflected sound, the water at the bottom of the well is the "listener" so the source is moving toward the listener. The water reflects the same frequency sound it receives.

SET UP: $f_L = \left(\frac{v+v_L}{v+v_S}\right) f_S$. Take the positive direction to be from the listener to the source. For reflection off the bottom of the well the water surface first serves as a listener and then as a source. The falling siren has constant downward acceleration of g and obeys the equation $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$.

EXECUTE: For the falling siren, $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$, so the speed of the siren just before it hits the water is $\sqrt{2(9.80 \text{ m/s}^2)(125 \text{ m})} = 49.5$ m/s.

(a) The situation is shown in Figure 16.73a.

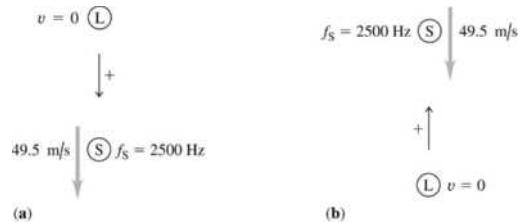

Figure 16.73

$$f_L = \left(\frac{v}{v + 49.5 \text{ m/s}}\right) f_S = \left(\frac{344 \text{ m/s}}{344 \text{ m/s} + 49.5 \text{ m/s}}\right)(2500 \text{ Hz}) = 2186 \text{ Hz}. \quad \lambda_L = \frac{v}{f_L} = \frac{344 \text{ m/s}}{2186 \text{ Hz}} = 0.157 \text{ m}.$$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) The water serves as a listener (Figure 16.73b). $f_L = \left(\frac{v}{v - 49.5 \text{ m/s}}\right) f_S = 2920$ Hz. The source and listener are approaching and the frequency is raised. $\lambda_L = \frac{v}{f_L} = 0.118$ m. Both the person and the water are at rest so there is no Doppler effect when the water serves as a source and the person is the listener. The person detects sound with frequency 2920 Hz and wavelength 0.118 m.

(c) $f_{beat} = f_1 - f_2 = 2920 \text{ Hz} - 2186 \text{ Hz} = 734$ Hz.

EVALUATE: In (a), the source is moving away from the listener and the frequency is lowered. In (b) the source is moving toward the "listener" so the frequency is increased.

16.74. **IDENTIFY:** Apply $f_L = \left(\frac{v + v_L}{v + v_S}\right) f_S$. The heart wall first acts as the listener and then as the source.

SET UP: The positive direction is from listener to source. The heart wall is moving toward the receiver so the Doppler effect increases the frequency and the final frequency received, f_{L2}, is greater than the source frequency, f_{S1}. $f_{L2} - f_{S1} = 72$ Hz.

EXECUTE: Heart wall receives the sound: $f_S = f_{S1}$. $f_L = f_{L1}$. $v_S = 0$. $v_L = -v_{wall}$. $f_L = \left(\frac{v + v_L}{v + v_S}\right) f_S$ gives $f_{L1} = \left(\frac{v - v_{wall}}{v}\right) f_{S1}$.

Heart wall emits the sound: $f_{S2} = f_{L1}$. $v_S = +v_{wall}$. $v_L = 0$.

$$f_{L2} = \left(\frac{v}{v + v_{wall}}\right) f_{S2} = \left(\frac{v}{v + v_{wall}}\right)\left(\frac{v - v_{wall}}{v}\right) f_{S1} = \left(\frac{v - v_{wall}}{v + v_{wall}}\right) f_{S1}.$$

$$f_{L2} - f_{S1} = \left(1 - \frac{v - v_{wall}}{v + v_{wall}}\right) f_{S1} = \left(\frac{2v_{wall}}{v + v_{wall}}\right) f_{S1}. \quad v_{wall} = \frac{(f_{L2} - f_{S1})v}{2f_{S1} - (f_{L2} - f_{S1})}. \quad f_{S1} \gg f_{L2} - f_{S1} \text{ and}$$

$$v_{wall} = \frac{(f_{L2} - f_{S1})v}{2f_{S1}} = \frac{(72 \text{ Hz})(1500 \text{ m/s})}{2(2.00 \times 10^6 \text{ Hz})} = 0.0270 \text{ m/s} = 2.70 \text{ cm/s}.$$

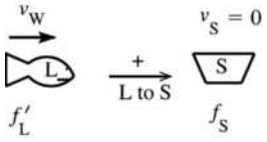
EVALUATE: $f_{S1} = 2.00 \times 10^6$ Hz and $f_{L2} - f_{S1} = 72$ Hz, so the approximation we made is very accurate. Within this approximation, the frequency difference between the reflected and transmitted waves is directly proportional to the speed of the heart wall.

16.75. **(a) IDENTIFY** and **SET UP:** Use Eq. (15.1) to calculate λ.

EXECUTE: $\lambda = \frac{v}{f} = \frac{1482 \text{ m/s}}{22.0 \times 10^3 \text{ Hz}} = 0.0674$ m

(b) IDENTIFY: Apply the Doppler effect equation, Eq. (16.29). The Problem-Solving Strategy in the text (Section 16.8) describes how to do this problem. The frequency of the directly radiated waves is $f_S = 22{,}000$ Hz. The moving whale first plays the role of a moving listener, receiving waves with frequency f'_L. The whale then acts as a moving source, emitting waves with the same frequency, $f'_S = f'_L$ with which they are received. Let the speed of the whale be v_W.

SET UP: whale receives waves (Figure 16.75a)



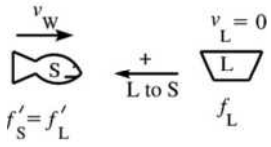
EXECUTE: $v_L = +v_W$

$$f'_L = f_S\left(\frac{v + v_L}{v + v_S}\right) = f_S\left(\frac{v + v_W}{v}\right)$$

Figure 16.75a

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

SET UP: whale re-emits the waves (Figure 16.75b)



EXECUTE: $v_S = -v_W$

$$f_L = f_S\left(\frac{v+v_L}{v+v_S}\right) = f'_S\left(\frac{v}{v-v_W}\right)$$

Figure 16.75b

But $f'_S = f'_L$ so $f_L = f_S\left(\frac{v+v_W}{v}\right)\left(\frac{v}{v-v_W}\right) = f_S\left(\frac{v+v_W}{v-v_W}\right)$.

Then $\Delta f = f_S - f_L = f_S\left(1-\frac{v+v_W}{v-v_W}\right) = f_S\left(\frac{v-v_W-v-v_W}{v-v_W}\right) = \frac{-2f_S v_W}{v-v_W}$.

$$\Delta f = \frac{-2(2.20\times10^4\text{ Hz})(4.95\text{ m/s})}{1482\text{ m/s}-4.95\text{ m/s}} = 147\text{ Hz}.$$

EVALUATE: Listener and source are moving toward each other so frequency is raised.

16.76. **IDENTIFY:** Apply the Doppler effect formula $f_L = \left(\frac{v+v_L}{v+v_S}\right)f_S$. In the SHM the source moves toward and away from the listener, with maximum speed $\omega_P A_P$.

SET UP: The direction from listener to source is positive.

EXECUTE: **(a)** The maximum velocity of the siren is $\omega_P A_P = 2\pi f_P A_P$. You hear a sound with frequency $f_L = f_{siren}v/(v+v_S)$, where v_S varies between $+2\pi f_P A_P$ and $-2\pi f_P A_P$. $f_{L-max} = f_{siren}v/(v-2\pi f_P A_P)$ and $f_{L-min} = f_{siren}v/(v+2\pi f_P A_P)$.

(b) The maximum (minimum) frequency is heard when the platform is passing through equilibrium and moving up (down).

EVALUATE: When the platform is moving upward the frequency you hear is greater than f_{siren} and when it is moving downward the frequency you hear is less than f_{siren}. When the platform is at its maximum displacement from equilibrium its speed is zero and the frequency you hear is f_{siren}.

16.77. **IDENTIFY:** Follow the method of Example 16.18 and apply the Doppler shift formula twice, once with the insect as the listener and again with the insect as the source.

SET UP: Let v_{bat} be the speed of the bat, v_{insect} be the speed of the insect, and f_i be the frequency with which the sound waves both strike and are reflected from the insect. The positive direction in each application of the Doppler shift formula is from the listener to the source.

EXECUTE: The frequencies at which the bat sends and receives the signals are related by

$f_L = f_i\left(\frac{v+v_{bat}}{v-v_{insect}}\right) = f_S\left(\frac{v+v_{insect}}{v-v_{bat}}\right)\left(\frac{v+v_{bat}}{v-v_{insect}}\right)$. Solving for v_{insect},

$$v_{insect} = v\left[\frac{1-\frac{f_S}{f_L}\left(\frac{v+v_{bat}}{v-v_{bat}}\right)}{1+\frac{f_S}{f_L}\left(\frac{v+v_{bat}}{v-v_{bat}}\right)}\right] = v\left[\frac{f_L(v-v_{bat})-f_S(v+v_{bat})}{f_L(v-v_{bat})+f_S(v+v_{bat})}\right].$$

Letting $f_L = f_{refl}$ and $f_S = f_{bat}$ gives the result.

(b) If $f_{bat} = 80.7$ kHz, $f_{refl} = 83.5$ kHz, and $v_{bat} = 3.9$ m/s, then $v_{insect} = 2.0$ m/s.

EVALUATE: $f_{refl} > f_{bat}$ because the bat and insect are approaching each other.

16.78. **IDENTIFY:** Follow the steps specified in the problem. v is positive when the source is moving away from the receiver and v is negative when the source is moving toward the receiver. $|f_L - f_R|$ is the beat frequency.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

SET UP: The source and receiver are approaching, so $f_R > f_S$ and $f_R - f_S = 46.0$ Hz.

EXECUTE: **(a)** $f_R = f_S\sqrt{\dfrac{c-v}{c+v}} = f_S\dfrac{\sqrt{1-v/c}}{\sqrt{1+v/c}} = f_S\left(1-\dfrac{v}{c}\right)^{1/2}\left(1+\dfrac{v}{c}\right)^{-1/2}$.

(b) For small x, the binomial theorem (see Appendix B) gives $(1-x)^{1/2} \approx 1-x/2,\ \ (1+x)^{-1/2} \approx 1-x/2$.

Therefore $f_L \approx f_S\left(1-\dfrac{v}{2c}\right)^2 \approx f_S\left(1-\dfrac{v}{c}\right)$, where the binomial theorem has been used to approximate $(1-x/2)^2 \approx 1-x$.

(c) For an airplane, the approximation $v \ll c$ is certainly valid. Solving the expression found in part (b) for v, $v = c\dfrac{f_S - f_R}{f_S} = c\dfrac{f_{beat}}{f_S} = (3.00\times10^8 \text{ m/s})\dfrac{-46.0 \text{ Hz}}{2.43\times10^8 \text{ Hz}} = -56.8 \text{ m/s}$. The speed of the aircraft is 56.8 m/s.

EVALUATE: The approximation $v \ll c$ is seen to be valid. v is negative because the source and receiver are approaching. Since $v \ll c$, the fractional shift in frequency, $\dfrac{\Delta f}{f}$, is very small.

16.79. **IDENTIFY:** Apply the result derived in part (b) of Problem 16.78. The radius of the nebula is $R = vt$, where t is the time since the supernova explosion.

SET UP: When the source and receiver are moving toward each other, v is negative and $f_R > f_S$. The light from the explosion reached earth 952 years ago, so that is the amount of time the nebula has expanded. $1 \text{ ly} = 9.46\times10^{15}$ m.

EXECUTE: **(a)** $v = c\dfrac{f_S - f_R}{f_S} = (3.00\times10^8 \text{m/s})\dfrac{-0.018\times10^{14} \text{ Hz}}{4.568\times10^{14} \text{ Hz}} = -1.2\times10^6 \text{m/s}$, with the minus sign indicating that the gas is approaching the earth, as is expected since $f_R > f_S$.

(b) The radius is $(952 \text{ yr})(3.156\times10^7 \text{ s/yr})(1.2\times10^6 \text{ m/s}) = 3.6\times10^{16} \text{ m} = 3.8 \text{ ly}$.

(c) The ratio of the width of the nebula to 2π times the distance from the earth is the ratio of the angular width (taken as 5 arc minutes) to an entire circle, which is 60×360 arc minutes. The distance to the nebula is then $\left(\dfrac{2}{2\pi}\right)(3.75 \text{ ly})\dfrac{(60)(360)}{5} = 5.2\times10^3$ ly. The time it takes light to travel this distance is 5200 yr, so the explosion actually took place 5200 yr before 1054 C.E., or about 4100 B.C.E.

EVALUATE: $\left|\dfrac{v}{c}\right| = 4.0\times10^{-3}$, so even though $|v|$ is very large the approximation required for $v = c\dfrac{\Delta f}{f}$ is accurate.
