16.80. **IDENTIFY:** The sound from the speaker moving toward the listener will have an increased frequency, while the sound from the speaker moving away from the listener will have a decreased frequency. The difference in these frequencies will produce a beat.

SET UP: The greatest frequency shift from the Doppler effect occurs when one speaker is moving away and one is moving toward the person. The speakers have speed $v_0 = r\omega$, where $r = 0.75$ m.

$f_L = \left(\dfrac{v + v_L}{v + v_S}\right)f_S$, with the positive direction from the listener to the source. $v = 344$ m/s.

EXECUTE: **(a)** $f = \dfrac{v}{\lambda} = \dfrac{344 \text{ m/s}}{0.313 \text{ m}} = 1100$ Hz. $\omega = (75 \text{ rpm})\left(\dfrac{2\pi \text{ rad}}{1 \text{ rev}}\right)\left(\dfrac{1 \text{ min}}{60 \text{ s}}\right) = 7.85$ rad/s and $v_0 = (0.75 \text{ m})(7.85 \text{ rad/s}) = 5.89$ m/s.

For speaker A, moving toward the listener: $f_{LA} = \left(\dfrac{v}{v - 5.89 \text{ m/s}}\right)(1100 \text{ Hz}) = 1119$ Hz.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

For speaker *B*, moving toward the listener: $f_{LB} = \left(\frac{v}{v + 5.89 \text{ m/s}}\right)(1100 \text{ Hz}) = 1081 \text{ Hz}.$

$f_{beat} = f_1 - f_2 = 1119 \text{ Hz} - 1081 \text{ Hz} = 38 \text{ Hz}.$

(b) A person can hear individual beats only up to about 7 Hz and this beat frequency is much larger than that.

EVALUATE: As the turntable rotates faster the beat frequency at this position of the speakers increases.

16.81. **IDENTIFY:** Follow the method of Example 16.18 and apply the Doppler shift formula twice, once for the wall as a listener and then again with the wall as a source.

SET UP: In each application of the Doppler formula, the positive direction is from the listener to the source

EXECUTE: **(a)** The wall will receive and reflect pulses at a frequency $\frac{v}{v - v_w} f_0,$ and the woman will hear this reflected wave at a frequency $\frac{v + v_w}{v}\frac{v}{v - v_w} f_0 = \frac{v + v_w}{v - v_w} f_0.$ The beat frequency is

$$f_{beat} = f_0\left(\frac{v + v_w}{v - v_w} - 1\right) = f_0\left(\frac{2v_w}{v - v_w}\right).$$

(b) In this case, the sound reflected from the wall will have a lower frequency, and using $f_0(v - v_w)/(v + v_w)$ as the detected frequency, v_w is replaced by $-v_w$ in the calculation of part (a) and

$$f_{beat} = f_0\left(1 - \frac{v - v_w}{v + v_w}\right) = f_0\left(\frac{2v_w}{v + v_w}\right).$$

EVALUATE: The beat frequency is larger when she runs toward the wall, even though her speed is the same in both cases.

16.82. **IDENTIFY** and **SET UP:** Use Figure (16.37) to relate α and *T*.
Use this in Eq. (16.31) to eliminate $\sin\alpha$.

EXECUTE: Eq. (16.31): $\sin\alpha = v/v_S$ From Figure 16.37 $\tan\alpha = h/v_S T$. And $\tan\alpha = \frac{\sin\alpha}{\cos\alpha} = \frac{\sin\alpha}{\sqrt{1 - \sin^2\alpha}}.$

Combining these equations we get $\frac{h}{v_S T} = \frac{v/v_S}{\sqrt{1 - (v/v_S)^2}}$ and $\frac{h}{T} = \frac{v}{\sqrt{1 - (v/v_S)^2}}.$

$1 - (v/v_S)^2 = \frac{v^2 T^2}{h^2}$ and $v_S^2 = \frac{v^2}{1 - v^2T^2/h^2}$

$v_S = \frac{hv}{\sqrt{h^2 - v^2T^2}}$ as was to be shown.

EVALUATE: For a given *h*, the faster the speed v_S of the plane, the greater is the delay time *T*. The maximum delay time is $h/v,$ and *T* approaches this value as $v_S \to \infty.$ $T \to 0$ as $v \to v_S.$

16.83. **IDENTIFY:** The phase of the wave is determined by the value of $x - vt,$ so *t* increasing is equivalent to *x* decreasing with *t* constant. The pressure fluctuation and displacement are related by Eq. (16.3).

SET UP: $y(x,t) = -\frac{1}{B}\int p(x,t)dx.$ If $p(x,t)$ versus *x* is a straight line, then $y(x,t)$ versus *x* is a parabola.

For air, $B = 1.42 \times 10^5$ Pa.

EXECUTE: **(a)** The graph is sketched in Figure 16.83a.

(b) From Eq. (16.4), the function that has the given $p(x,0)$ at $t = 0$ is given graphically in Figure 16.83b. Each section is a parabola, not a portion of a sine curve. The period is $\lambda/v = (0.200 \text{ m})/(344 \text{ m/s}) = 5.81 \times 10^{-4}$ s and the amplitude is equal to the area under the *p* versus *x* curve between $x = 0$ and $x = 0.0500$ m divided by *B*, or 7.04×10^{-6} m.

(c) Assuming a wave moving in the $+x$-direction, $y(0,t)$ is as shown in Figure 16.83c.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(d) The maximum velocity of a particle occurs when a particle is moving through the origin, and the particle speed is $v_y = -\dfrac{\partial y}{\partial x} v = \dfrac{pv}{B}$. The maximum velocity is found from the maximum pressure, and $v_{y\max} = (40\text{ Pa})(344\text{ m/s})/(1.42\times10^5\text{ Pa}) = 9.69\text{ cm/s}$. The maximum acceleration is the maximum pressure gradient divided by the density,

$$a_{\max} = \frac{(80.0\text{ Pa})/(0.100\text{ m})}{(1.20\text{ kg/m}^3)} = 6.67\times10^2\text{ m/s}^2.$$

(e) The speaker cone moves with the displacement as found in part (c); the speaker cone alternates between moving forward and backward with constant magnitude of acceleration (but changing sign). The acceleration as a function of time is a square wave with amplitude 667 m/s^2 and frequency $f = v/\lambda = (344\text{ m/s})/(0.200\text{ m}) = 1.72\text{ kHz}$.

EVALUATE: We can verify that $p(x,t)$ versus x has a shape proportional to the slope of the graph of $y(x,t)$ versus x. The same is also true of the graphs versus t.

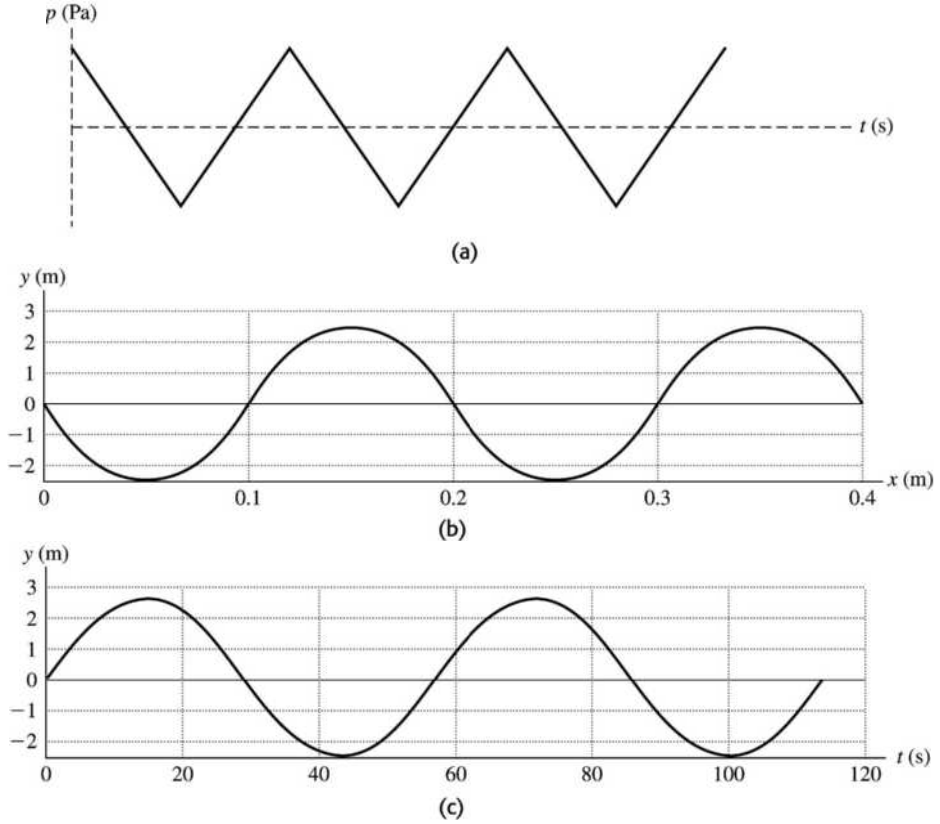

Figure 16.83

16.84. **IDENTIFY** and **SET UP:** Consider the derivation of the speed of a longitudinal wave in Section 16.2.
EXECUTE: **(a)** The quantity of interest is the change in force per fractional length change. The force constant k' is the change in force per length change, so the force change per fractional length change is $k'L$, the applied force at one end is $F = (k'L)(v_y/v)$ and the longitudinal impulse when this force is applied for a time t is $k'Lt v_y/v$. The change in longitudinal momentum is $((vt)m/L)v_y$ and equating the expressions, canceling a factor of t and solving for v gives $v^2 = L^2k'/m$.
(b) $v = (2.00\text{ m})\sqrt{(1.50\text{ N/m})/(0.250\text{ kg})} = 4.90\text{ m/s}$
EVALUATE: A larger k' corresponds to a stiffer spring and for a stiffer spring the wave speed is greater.

17

TEMPERATURE AND HEAT

17.1. **IDENTIFY** and **SET UP:** $T_F = \frac{9}{5}T_C + 32°$.

EXECUTE: **(a)** $T_F = (9/5)(-62.8) + 32 = -81.0°F$

(b) $T_F = (9/5)(56.7) + 32 = 134.1°F$

(c) $T_F = (9/5)(31.1) + 32 = 88.0°F$

EVALUATE: Fahrenheit degrees are smaller than Celsius degrees, so it takes more F° than C° to express the difference of a temperature from the ice point.

17.2. **IDENTIFY** and **SET UP:** To convert a temperature between °C and K use $T_C = T_K - 273.15$. To convert from °F to °C, subtract 32° and multiply by 5/9. To convert from °C to °F, multiply by 9/5 and add 32°. To convert a temperature difference, use that Celsius and Kelvin degrees are the same size and that $9\ F° = 5\ C°$.

EXECUTE: **(a)** $T_C = T_K - 273.15 = 310 - 273.15 = 36.9°C$; $T_F = \frac{9}{5}T_C + 32° = \frac{9}{5}(36.9°) + 32° = 98.4°F$.

(b) $T_K = T_C + 273.15 = 40 + 273.15 = 313\ K$; $T_F = \frac{9}{5}T_C + 32° = \frac{9}{5}(40°) + 32° = 104°F$.

(c) $7\ C° = 7\ K$; $7\ C° = (7\ C°)(9\ F°/5\ C°) = 13\ F°$.

(d) 4.0°C: $T_F = \frac{9}{5}T_C + 32° = \frac{9}{5}(4.0°) + 32° = 39.2°F$; $T_K = T_C + 273.15 = 4.0 + 273.15 = 277\ K$.

−160°C: $T_F = \frac{9}{5}T_C + 32° = \frac{9}{5}(-160°) + 32° = -256°F$; $T_K = T_C + 273.15 = -160 + 273.15 = 113\ K$.

(e) $T_C = \frac{5}{9}(T_F - 32°) = \frac{5}{9}(105° - 32°) = 41°C$; $T_K = T_C + 273.15 = 41 + 273.15 = 314\ K$.

EVALUATE: Celsius-Fahrenheit conversions do not involve simple proportions due to the additive constant of 32°, but Celsius-Kelvin conversions require only simple addition/subtraction of 273.15.

17.3. **IDENTIFY:** Convert ΔT between different scales.

SET UP: ΔT is the same on the Celsius and Kelvin scales. $180\ F° = 100\ C°$, so $1\ C° = \frac{9}{5}F°$.

EXECUTE: **(a)** $\Delta T = 49.0\ F°$. $\Delta T = (49.0\ F°)\left(\frac{1\ C°}{\frac{9}{5}\ F°}\right) = 27.2\ C°$.

(b) $\Delta T = -100\ F°$. $\Delta T = (-100.0\ F°)\left(\frac{1\ C°}{\frac{9}{5}\ F°}\right) = -55.6\ C°$

EVALUATE: The magnitude of the temperature change is larger in F° than in C°.

17.4. **IDENTIFY:** Set $T_C = T_F$ and $T_F = T_K$.

SET UP: $T_F = \frac{9}{5}T_C + 32°C$ and $T_K = T_C + 273.15 = \frac{5}{9}(T_F - 32°) + 273.15$

EXECUTE: **(a)** $T_F = T_C = T$ gives $T = \frac{9}{5}T + 32°$ and $T = -40°$; $-40°C = -40°F$.

(b) $T_F = T_K = T$ gives $T = \frac{5}{9}(T - 32°) + 273.15$ and $T = \frac{9}{4}\left(-\left(\frac{5}{9}\right)(32°) + 273.15\right) = 575°$; $575°F = 575\ K$.

EVALUATE: Since $T_K = T_C + 273.15$ there is no temperature at which Celsius and Kelvin thermometers agree.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

17.5. **IDENTIFY:** Convert ΔT in kelvins to C° and to F°.

SET UP: $1\text{ K} = 1\text{ C°} = \frac{9}{5}\text{F°}$

EXECUTE: **(a)** $\Delta T_F = \frac{9}{5}\Delta T_C = \frac{9}{5}(-10.0\text{ C°}) = -18.0\text{ F°}$

(b) $\Delta T_C = \Delta T_K = -10.0\text{ C°}$

EVALUATE: Kelvin and Celsius degrees are the same size. Fahrenheit degrees are smaller, so it takes more of them to express a given ΔT value.

17.6. **IDENTIFY:** Convert T_K to T_C and then convert T_C to T_F.

SET UP: $T_K = T_C + 273.15$ and $T_F = \frac{9}{5}T_C + 32°$.

EXECUTE: **(a)** $T_C = 400 - 273.15 = 127°\text{C}$, $T_F = (9/5)(126.85) + 32 = 260°\text{F}$

(b) $T_C = 95 - 273.15 = -178°\text{C}$, $T_F = (9/5)(-178.15) + 32 = -289°\text{F}$

(c) $T_C = 1.55\times10^7 - 273.15 = 1.55\times10^7°\text{C}$, $T_F = (9/5)(1.55\times10^7) + 32 = 2.79\times10^7°\text{F}$

EVALUATE: All temperatures on the Kelvin scale are positive. T_C is negative if the temperature is below the freezing point of water.

17.7. **IDENTIFY:** When the volume is constant, $\frac{T_2}{T_1} = \frac{p_2}{p_1}$, for T in kelvins.

SET UP: $T_{\text{triple}} = 273.16$ K. Figure 17.7 in the textbook gives that the temperature at which CO_2 solidifies is $T_{CO_2} = 195$ K.

EXECUTE: $p_2 = p_1\left(\frac{T_2}{T_1}\right) = (1.35\text{ atm})\left(\frac{195\text{ K}}{273.16\text{ K}}\right) = 0.964\text{ atm}$

EVALUATE: The pressure decreases when T decreases.

17.8. **IDENTIFY:** Apply Eq. (17.5) and solve for p.

SET UP: $p_{\text{triple}} = 325$ mm of mercury

EXECUTE: $p = (325.0\text{ mm of mercury})\left(\frac{373.15\text{ K}}{273.16\text{ K}}\right) = 444\text{ mm of mercury}$

EVALUATE: mm of mercury is a unit of pressure. Since Eq. (17.5) involves a ratio of pressures, it is not necessary to convert the pressure to units of Pa.

17.9. **IDENTIFY** and **SET UP:** Fit the data to a straight line for $p(T)$ and use this equation to find T when $p = 0$.

EXECUTE: **(a)** If the pressure varies linearly with temperature, then $p_2 = p_1 + \gamma(T_2 - T_1)$.

$$\gamma = \frac{p_2 - p_1}{T_2 - T_1} = \frac{6.50\times10^4\text{ Pa} - 4.80\times10^4\text{ Pa}}{100°\text{C} - 0.01°\text{C}} = 170.0\text{ Pa/C°}$$

Apply $p = p_1 + \gamma(T - T_1)$ with $T_1 = 0.01°\text{C}$ and $p = 0$ to solve for T.

$0 = p_1 + \gamma(T - T_1)$

$$T = T_1 - \frac{p_1}{\gamma} = 0.01°\text{C} - \frac{4.80\times10^4\text{ Pa}}{170\text{ Pa/C°}} = -282°\text{C}.$$

(b) Let $T_1 = 100°\text{C}$ and $T_2 = 0.01°\text{C}$; use Eq. (17.4) to calculate p_2. Eq. (17.4) says $T_2/T_1 = p_2/p_1$, where T is in kelvins.

$p_2 = p_1\left(\frac{T_2}{T_1}\right) = 6.50\times10^4\text{ Pa}\left(\frac{0.01 + 273.15}{100 + 273.15}\right) = 4.76\times10^4\text{ Pa}$; this differs from the 4.80×10^4 Pa that was measured so Eq. (17.4) is not precisely obeyed.

EVALUATE: The answer to part (a) is in reasonable agreement with the accepted value of $-273°\text{C}$.

17.10. **IDENTIFY:** $1\text{ K} = 1\text{ C°}$ and $1\text{ C°} = \frac{9}{5}\text{F°}$, so $1\text{ K} = \frac{9}{5}\text{R°}$.

SET UP: On the Kelvin scale, the triple point is 273.16 K.

EXECUTE: $T_{\text{triple}} = (9/5)273.16\text{ K} = 491.69°\text{R}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: One could also look at Figure 17.7 in the textbook and note that the Fahrenheit scale extends from $-460°\text{F}$ to $+32°\text{F}$ and conclude that the triple point is about $492°\text{R}$.

17.11. **IDENTIFY:** $\Delta L = L_0 \alpha \Delta T$

SET UP: For steel, $\alpha = 1.2\times10^{-5}\ (\text{C}°)^{-1}$

EXECUTE: $\Delta L = (1.2\times10^{-5}(\text{C}°)^{-1})(1410\ \text{m})(18.0°\text{C} - (-5.0°\text{C})) = +0.39\ \text{m}$

EVALUATE: The length increases when the temperature increases. The fractional increase is very small, since $\alpha\Delta T$ is small.

17.12. **IDENTIFY:** Apply $\Delta L = \alpha L_0 \Delta T$ and calculate ΔT. Then $T_2 = T_1 + \Delta T$, with $T_1 = 15.5°\text{C}$.

SET UP: Table 17.1 gives $\alpha = 1.2\times10^{-5}\ (\text{C}°)^{-1}$ for steel.

EXECUTE: $\Delta T = \dfrac{\Delta L}{\alpha L_0} = \dfrac{0.471\ \text{ft}}{[1.2\times10^{-5}\ (\text{C}°)^{-1}][1671\ \text{ft}]} = 23.5\ \text{C}°$. $T_2 = 15.5°\text{C} + 23.5\ \text{C}° = 39.0°\text{C}$.

EVALUATE: Since then the lengths enter in the ratio $\Delta L/L_0$, we can leave the lengths in ft.

17.13. **IDENTIFY:** Apply $L = L_0(1+\alpha\Delta T)$ to the diameter D of the penny.

SET UP: $1\ \text{K} = 1\ \text{C}°$, so we can use temperatures in °C.

EXECUTE: Death Valley: $\alpha D_0 \Delta T = (2.6\times10^{-5}\ (\text{C}°)^{-1})(1.90\ \text{cm})(28.0\ \text{C}°) = 1.4\times10^{-3}\ \text{cm}$, so the diameter is 1.9014 cm. Greenland: $\alpha D_0 \Delta T = -3.6\times10^{-3}\ \text{cm}$, so the diameter is 1.8964 cm.

EVALUATE: When T increases the diameter increases and when T decreases the diameter decreases.

17.14. **IDENTIFY:** Apply $L = L_0(1+\alpha\Delta T)$ to the diameter d of the rivet.

SET UP: For aluminum, $\alpha = 2.4\times10^{-5}\ (\text{C}°)^{-1}$. Let d_0 be the diameter at $-78.0°\text{C}$ and d be the diameter at $23.0°\text{C}$.

EXECUTE: $d = d_0 + \Delta d = d_0(1+\alpha\Delta T) = (0.4500\ \text{cm})(1 + (2.4\times10^{-5}(\text{C}°)^{-1})(23.0°\text{C} - [-78.0°\text{C}])$.

$d = 0.4511\ \text{cm} = 4.511\ \text{mm}$.

EVALUATE: We could have let d_0 be the diameter at $23.0°\text{C}$ and d be the diameter at $-78.0°\text{C}$. Then $\Delta T = -78.0°\text{C} - 23.0°\text{C}$.

17.15. **IDENTIFY:** Find the change ΔL in the diameter of the lid. The diameter of the lid expands according to Eq. (17.6).

SET UP: Assume iron has the same α as steel, so $\alpha = 1.2\times10^{-5}\ (\text{C}°)^{-1}$.

EXECUTE: $\Delta L = \alpha L_0 \Delta T = (1.2\times10^{-5}\ (\text{C}°)^{-1})(725\ \text{mm})(30.0\ \text{C}°) = 0.26\ \text{mm}$

EVALUATE: In Eq. (17.6), ΔL has the same units as L.

17.16. **IDENTIFY:** $\Delta V = \beta V_0 \Delta T$. Use the diameter at $-15°\text{C}$ to calculate the value of V_0 at that temperature.

SET UP: For a hemisphere of radius R, the volume is $V = \frac{2}{3}\pi R^3$. Table 17.2 gives $\beta = 7.2\times10^{-5}\ (\text{C}°)^{-1}$ for aluminum.

EXECUTE: $V_0 = \frac{2}{3}\pi R^3 = \frac{2}{3}\pi(27.5\ \text{m})^3 = 4.356\times10^4\ \text{m}^3$.

$\Delta V = (7.2\times10^{-5}\ (\text{C}°)^{-1})(4.356\times10^4\ \text{m}^3)(35°\text{C} - [-15°\text{C}]) = 160\ \text{m}^3$

EVALUATE: We could also calculate $R = R_0(1+\alpha\Delta T)$ and calculate the new V from R. The increase in volume is $V - V_0$, but we would have to be careful to avoid round-off errors when two large volumes of nearly the same size are subtracted.

17.17. **IDENTIFY:** Apply $\Delta V = V_0 \beta \Delta T$.

SET UP: For copper, $\beta = 5.1\times10^{-5}\ (\text{C}°)^{-1}$. $\Delta V/V_0 = 0.150\times10^{-2}$.

EXECUTE: $\Delta T = \dfrac{\Delta V/V_0}{\beta} = \dfrac{0.150\times10^{-2}}{5.1\times10^{-5}\ (\text{C}°)^{-1}} = 29.4\ \text{C}°$. $T_\text{f} = T_\text{i} + \Delta T = 49.4°\text{C}$.

EVALUATE: The volume increases when the temperature increases.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

17.18. **IDENTIFY:** Apply $\Delta V = V_0 \beta \Delta T$ to the tank and to the ethanol.

SET UP: For ethanol, $\beta_e = 75\times10^{-5}\ (\text{C}°)^{-1}$. For steel, $\beta_s = 3.6\times10^{-5}\ (\text{C}°)^{-1}$.

EXECUTE: The volume change for the tank is

$\Delta V_s = V_0 \beta_s \Delta T = (2.80\ \text{m}^3)(3.6\times10^{-5}(\text{C}°)^{-1})(-14.0\ \text{C}°) = -1.41\times10^{-3}\ \text{m}^3 = -1.41\ \text{L}.$

The volume change for the ethanol is

$\Delta V_e = V_0 \beta_e \Delta T = (2.80\ \text{m}^3)(75\times10^{-5}\ (\text{C}°)^{-1})(-14.0\ \text{C}°) = -2.94\times10^{-2}\ \text{m}^3 = -29.4\ \text{L}.$

The empty volume in the tank is $\Delta V_e - \Delta V_s = -29.4\ \text{L} - (-1.4\ \text{L}) = -28.0\ \text{L}$. 28.0 L of ethanol can be added to the tank.

EVALUATE: Both volumes decrease. But $\beta_e > \beta_s$, so the magnitude of the volume decrease for the ethanol is greater than it is for the tank.

17.19. **IDENTIFY:** Apply $\Delta V = V_0 \beta \Delta T$ to the volume of the flask and to the mercury. When heated, both the volume of the flask and the volume of the mercury increase.

SET UP: For mercury, $\beta_{Hg} = 18\times10^{-5}\ (\text{C}°)^{-1}$.

EXECUTE: 8.95 cm^3 of mercury overflows, so $\Delta V_{Hg} - \Delta V_{glass} = 8.95\ \text{cm}^3$.

EXECUTE: $\Delta V_{Hg} = V_0 \beta_{Hg} \Delta T = (1000.00\ \text{cm}^3)(18\times10^{-5}\ (\text{C}°)^{-1})(55.0\ \text{C}°) = 9.9\ \text{cm}^3$.

$\Delta V_{glass} = \Delta V_{Hg} - 8.95\ \text{cm}^3 = 0.95\ \text{cm}^3$. $\beta_{glass} = \dfrac{\Delta V_{glass}}{V_0 \Delta T} = \dfrac{0.95\ \text{cm}^3}{(1000.00\ \text{cm}^3)(55.0\ \text{C}°)} = 1.7\times10^{-5}\ (\text{C}°)^{-1}$.

EVALUATE: The coefficient of volume expansion for the mercury is larger than for glass. When they are heated, both the volume of the mercury and the inside volume of the flask increase. But the increase for the mercury is greater and it no longer all fits inside the flask.

17.20. **IDENTIFY:** Apply $\Delta L = L_0 \alpha \Delta T$ to each linear dimension of the surface.

SET UP: The area can be written as $A = aL_1L_2$, where a is a constant that depends on the shape of the surface. For example, if the object is a sphere, $a = 4\pi$ and $L_1 = L_2 = r$. If the object is a cube, $a = 6$ and $L_1 = L_2 = L$, the length of one side of the cube. For aluminum, $\alpha = 2.4\times10^{-5}\ (\text{C}°)^{-1}$.

EXECUTE: **(a)** $A_0 = aL_{01}L_{02}$. $L_1 = L_{01}(1+\alpha\Delta T)$. $L_2 = L_{02}(1+\alpha\Delta T)$.

$A = aL_1L_2 = aL_{01}L_{02}(1+\alpha\Delta T)^2 = A_0(1+2\alpha\Delta T+[\alpha\Delta T]^2)$. $\alpha\Delta T$ is very small, so $[\alpha\Delta T]^2$ can be neglected and $A = A_0(1+2\alpha\Delta T)$. $\Delta A = A - A_0 = (2\alpha)A_0\Delta T$

(b) $\Delta A = (2\alpha)A_0\Delta T = (2)(2.4\times10^{-5}\ (\text{C}°)^{-1})(\pi(0.275\ \text{m})^2)(12.5\ \text{C}°) = 1.4\times10^{-4}\ \text{m}^2$

EVALUATE: The derivation assumes the object expands uniformly in all directions.

17.21. **IDENTIFY** and **SET UP:** Apply the result of Exercise 17.20a to calculate ΔA for the plate, and then $A = A_0 + \Delta A$.

EXECUTE: **(a)** $A_0 = \pi r_0^2 = \pi(1.350\ \text{cm}/2)^2 = 1.431\ \text{cm}^2$

(b) Exercise 17.20 says $\Delta A = 2\alpha A_0 \Delta T$, so

$\Delta A = 2(1.2\times10^{-5}\ \text{C}°^{-1})(1.431\ \text{cm}^2)(175°\text{C} - 25°\text{C}) = 5.15\times10^{-3}\ \text{cm}^2$

$A = A_0 + \Delta A = 1.436\ \text{cm}^2$

EVALUATE: A hole in a flat metal plate expands when the metal is heated just as a piece of metal the same size as the hole would expand.

17.22. **IDENTIFY:** Apply $\Delta L = L_0 \alpha \Delta T$ to the diameter D_{ST} of the steel cylinder and the diameter D_{BR} of the brass piston.

SET UP: For brass, $\alpha_{BR} = 2.0\times10^{-5}\ (\text{C}°)^{-1}$. For steel, $\alpha_{ST} = 1.2\times10^{-5}\ (\text{C}°)^{-1}$.

EXECUTE: **(a)** No, the brass expands more than the steel.

(b) Call D_0 the inside diameter of the steel cylinder at 20°C. At 150°C, $D_{ST} = D_{BR}$.

$D_0 + \Delta D_{ST} = 25.000\ \text{cm} + \Delta D_{BR}$. This gives $D_0 + \alpha_{ST} D_0 \Delta T = 25.000\ \text{cm} + \alpha_{BR}(25.000\ \text{cm})\Delta T$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$D_0 = \frac{25.000\text{ cm}(1+\alpha_{BR}\Delta T)}{1+\alpha_{ST}\Delta T} = \frac{(25.000\text{ cm})[1+(2.0\times10^{-5}\text{ (C°)}^{-1})(130\text{ C°})]}{1+(1.2\times10^{-5}\text{ (C°)}^{-1})(130\text{ C°})} = 25.026\text{ cm.}$$

EVALUATE: The space inside the steel cylinder expands just like a solid piece of steel of the same size.

17.23. **IDENTIFY** and **SET UP:** For part (a), apply Eq. (17.6) to the linear expansion of the wire. For part (b), apply Eq. (17.12) and calculate F/A.

EXECUTE: **(a)** $\Delta L = \alpha L_0 \Delta T$

$$\alpha = \frac{\Delta L}{L_0 \Delta T} = \frac{1.9\times10^{-2}\text{ m}}{(1.50\text{ m})(420°\text{C} - 20°\text{C})} = 3.2\times10^{-5}\text{ (C°)}^{-1}$$

(b) Eq. (17.12): stress $F/A = -Y\alpha\Delta T$

$\Delta T = 20°\text{C} - 420°\text{C} = -400\text{ C°}$ (ΔT always means final temperature minus initial temperature)

$F/A = -(2.0\times10^{11}\text{ Pa})(3.2\times10^{-5}(\text{C°})^{-1})(-400\text{ C°}) = +2.6\times10^{9}\text{ Pa}$

EVALUATE: F/A is positive means that the stress is a tensile (stretching) stress. The answer to part (a) is consistent with the values of α for metals in Table 17.1. The tensile stress for this modest temperature decrease is huge.

17.24. **IDENTIFY:** Apply Eq. (17.12) and solve for F.

SET UP: For brass, $Y = 0.9\times10^{11}$ Pa and $\alpha = 2.0\times10^{-5}\text{ (C°)}^{-1}$.

EXECUTE: $F = -Y\alpha\Delta T\,A = -(0.9\times10^{11}\text{ Pa})(2.0\times10^{-5}(\text{C°})^{-1})(-110\text{ C°})(2.01\times10^{-4}\text{ m}^2) = 4.0\times10^{4}\text{ N}$

EVALUATE: A large force is required. ΔT is negative and a positive tensile force is required.

17.25. **IDENTIFY:** Apply $\Delta L = L_0\alpha\Delta T$ and stress $= F/A = -Y\alpha\Delta T$.

SET UP: For steel, $\alpha = 1.2\times10^{-5}\text{ (C°)}^{-1}$ and $Y = 2.0\times10^{11}$ Pa.

EXECUTE: **(a)** $\Delta L = L_0\alpha\Delta T = (12.0\text{ m})(1.2\times10^{-5}\text{ (C°)}^{-1})(35.0\text{ C°}) = 5.0\text{ mm}$

(b) stress $= -Y\alpha\Delta T = -(2.0\times10^{11}\text{ Pa})(1.2\times10^{-5}\text{ (C°)}^{-1})(35.0\text{ C°}) = -8.4\times10^{7}$ Pa. The minus sign means the stress is compressive.

EVALUATE: Commonly occurring temperature changes result in very small fractional changes in length but very large stresses if the length change is prevented from occurring.

17.26. **IDENTIFY:** The heat required is $Q = mc\Delta T$. $P = 200\text{ W} = 200\text{ J/s}$, which is energy divided by time.

SET UP: For water, $c = 4.19\times10^{3}\text{ J/kg}\cdot\text{K}$.

EXECUTE: **(a)** $Q = mc\Delta T = (0.320\text{ kg})(4.19\times10^{3}\text{ J/kg}\cdot\text{K})(60.0\text{ C°}) = 8.04\times10^{4}\text{ J}$

(b) $t = \dfrac{8.04\times10^{4}\text{ J}}{200.0\text{ J/s}} = 402\text{ s} = 6.7\text{ min}$

EVALUATE: 0.320 kg of water has volume 0.320 L. The time we calculated in part (b) is consistent with our everyday experience.

17.27. **IDENTIFY** and **SET UP:** Apply Eq. (17.13) to the kettle and water.

EXECUTE: <u>kettle</u>

$Q = mc\Delta T$, $c = 910\text{ J/kg}\cdot\text{K}$ (from Table 17.3)

$Q = (1.50\text{ kg})(910\text{ J/kg}\cdot\text{K})(85.0°\text{C} - 20.0°\text{C}) = 8.873\times10^{4}\text{ J}$

<u>water</u>

$Q = mc\Delta T$, $c = 4190\text{ J/kg}\cdot\text{K}$ (from Table 17.3)

$Q = (1.80\text{ kg})(4190\text{ J/kg}\cdot\text{K})(85.0°\text{C} - 20.0°\text{C}) = 4.902\times10^{5}\text{ J}$

Total $Q = 8.873\times10^{4}\text{ J} + 4.902\times10^{5}\text{ J} = 5.79\times10^{5}\text{ J}$

EVALUATE: Water has a much larger specific heat capacity than aluminum, so most of the heat goes into raising the temperature of the water.

17.28. **IDENTIFY** and **SET UP:** Use Eq. (17.13)

EXECUTE: **(a)** $Q = mc\Delta T$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$m = \frac{1}{2}(1.3\times10^{-3}\text{ kg}) = 0.65\times10^{-3}\text{ kg}$

$Q = (0.65\times10^{-3}\text{ kg})(1020\text{ J/kg}\cdot\text{K})(37°\text{C} - (-20°\text{C})) = 38\text{ J}$

(b) 20 breaths/min $(60\text{ min}/1\text{ h}) = 1200$ breaths/h

So $Q = (1200)(38\text{ J}) = 4.6\times10^{4}$ J.

EVALUATE: The heat loss rate is $Q/t = 13$ W.

17.29. **IDENTIFY:** Apply $Q = mc\Delta T$. $m = w/g$.

SET UP: The temperature change is $\Delta T = 18.0$ K.

EXECUTE: $c = \dfrac{Q}{m\Delta T} = \dfrac{gQ}{w\Delta T} = \dfrac{(9.80\text{ m/s}^2)(1.25\times10^{4}\text{ J})}{(28.4\text{ N})(18.0\text{ K})} = 240\text{ J/kg}\cdot\text{K}.$

EVALUATE: The value for c is similar to that for silver in Table 17.3, so it is a reasonable result.

17.30. **IDENTIFY:** The heat input increases the temperature of 2.5 gal/min of water from 10°C to 49°C.

SET UP: 1.00 L of water has a mass of 1.00 kg, so
9.46 L/min = (9.46 L/min)(1.00 kg/L)(1 min/60 s) = 0.158 kg/s. For water, $c = 4190\text{ J/kg}\cdot\text{C°}$.

EXECUTE: $Q = mc\Delta T$ so $H = (Q/t) = (m/t)c\,\Delta T$. Putting in the numbers gives

$H = (0.158\text{ kg/s})(4190\text{ J/kg}\cdot\text{C°})(49°\text{C} - 10°\text{C}) = 2.6\times10^{4}\text{ W} = 26\text{ kW}.$

EVALUATE: The power requirement is large, the equivalent of 260 100-watt light bulbs, but this large power is needed only for short periods of time. The rest of the time, the unit uses no energy, unlike a conventional water heater which continues to replace lost heat even when hot water is not needed.

17.31. **IDENTIFY:** Apply $Q = mc\Delta T$ to find the heat that would raise the temperature of the student's body 7 C°.

SET UP: 1 W = 1 J/s

EXECUTE: Find Q to raise the body temperature from 37°C to 44°C.

$Q = mc\Delta T = (70\text{ kg})(3480\text{ J/kg}\cdot\text{K})(7\text{ C°}) = 1.7\times10^{6}\text{ J}.$

$t = \dfrac{1.7\times10^{6}\text{ J}}{1200\text{ J/s}} = 1400\text{ s} = 23\text{ min}.$

EVALUATE: Heat removal mechanisms are essential to the well-being of a person.

17.32. **IDENTIFY** and **SET UP:** Set the change in gravitational potential energy equal to the quantity of heat added to the water.

EXECUTE: The change in mechanical energy equals the decrease in gravitational potential energy, $\Delta U = -mgh;\ |\Delta U| = mgh$. $Q = |\Delta U| = mgh$ implies $mc\Delta T = mgh$

$\Delta T = gh/c = (9.80\text{ m/s}^2)(225\text{ m})/(4190\text{ J/kg}\cdot\text{K}) = 0.526\text{ K} = 0.526\text{ C°}$

EVALUATE: Note that the answer is independent of the mass of the object. Note also the small change in temperature that corresponds to this large change in height!

17.33. **IDENTIFY:** The work done by friction is the loss of mechanical energy. The heat input for a temperature change is $Q = mc\Delta T$.

SET UP: The crate loses potential energy mgh, with $h = (8.00\text{ m})\sin 36.9°$, and gains kinetic energy $\frac{1}{2}mv_2^2$.

EXECUTE: **(a)**

$W_f = -mgh + \frac{1}{2}mv_2^2 = -(35.0\text{ kg})((9.80\text{ m/s}^2)(8.00\text{ m})\sin 36.9° + \frac{1}{2}(2.50\text{ m/s})^2) = -1.54\times10^{3}\text{ J}.$

(b) Using the results of part (a) for Q gives $\Delta T = (1.54\times10^{3}\text{ J})/((35.0\text{ kg})(3650\text{ J/kg}\cdot\text{K})) = 1.21\times10^{-2}\text{ C°}$.

EVALUATE: The temperature rise is very small.

17.34. **IDENTIFY:** The work done by the brakes equals the initial kinetic energy of the train. Use the volume of the air to calculate its mass. Use $Q = mc\Delta T$ applied to the air to calculate ΔT for the air.

SET UP: $K = \frac{1}{2}mv^2$. $m = \rho V$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: The initial kinetic energy of the train is $K = \frac{1}{2}(25{,}000 \text{ kg})(15.5 \text{ m/s})^2 = 3.00\times10^6$ J.

Therefore, Q for the air is 3.00×10^6 J. $m = \rho V = (1.20 \text{ kg/m}^3)(65.0 \text{ m})(20.0 \text{ m})(12.0 \text{ m}) = 1.87\times10^4$ kg.

$Q = mc\Delta T$ gives $\Delta T = \dfrac{Q}{mc} = \dfrac{3.00\times10^6 \text{ J}}{(1.87\times10^4 \text{ kg})(1020 \text{ J/kg}\cdot\text{K})} = 0.157$ C°.

EVALUATE: The mass of air in the station is comparable to the mass of the train and the temperature rise is small.

17.35. **IDENTIFY:** Set $K = \frac{1}{2}mv^2$ equal to $Q = mc\Delta T$ for the nail and solve for ΔT.

SET UP: For aluminum, $c = 0.91\times10^3$ J/kg·K.

EXECUTE: The kinetic energy of the hammer before it strikes the nail is $K = \frac{1}{2}mv^2 = \frac{1}{2}(1.80 \text{ kg})(7.80 \text{ m/s})^2 = 54.8$ J. Each strike of the hammer transfers $0.60(54.8 \text{ J}) = 32.9$ J, and with 10 strikes $Q = 329$ J. $Q = mc\Delta T$ and $\Delta T = \dfrac{Q}{mc} = \dfrac{329 \text{ J}}{(8.00\times10^{-3} \text{ kg})(0.91\times10^3 \text{ J/kg}\cdot\text{K})} = 45.2$ C°.

EVALUATE: This agrees with our experience that hammered nails get noticeably warmer.

17.36. **IDENTIFY** and **SET UP:** Use the power and time to calculate the heat input Q and then use Eq. (17.13) to calculate c.

(a) EXECUTE: $P = Q/t$, so the total heat transferred to the liquid is $Q = Pt = (65.0 \text{ W})(120 \text{ s}) = 7800$ J.

Then $Q = mc\Delta T$ gives $c = \dfrac{Q}{m\Delta T} = \dfrac{7800 \text{ K}}{0.780 \text{ kg}(22.54°\text{C} - 18.55°\text{C})} = 2.51\times10^3$ J/kg·K

(b) EVALUATE: Then the actual Q transferred to the liquid is less than 7800 J so the actual c is less than our calculated value; our result in part (a) is an overestimate.

17.37. **IDENTIFY:** Some of the kinetic energy of the bullet is transformed through friction into heat, which raises the temperature of the water in the tank.

SET UP: Set the loss of kinetic energy of the bullet equal to the heat energy Q transferred to the water. $Q = mc\Delta T$. From Table 17.3, the specific heat of water is 4.19×10^3 J/kg·C°.

SOLVE: The kinetic energy lost by the bullet is $K_\text{i} - K_\text{f} = \frac{1}{2}m(v_\text{i}^2 - v_\text{f}^2) = \frac{1}{2}(15.0\times10^{-3} \text{ kg})[(865 \text{ m/s})^2 - (534 \text{ m/s})^2] = 3.47\times10^3$ J, so for the water $Q = 3.47\times10^3$ J. $Q = mc\Delta T$ gives $\Delta T = \dfrac{Q}{mc} = \dfrac{3.47\times10^3 \text{ J}}{(13.5 \text{ kg})(4.19\times10^3 \text{ J/kg}\cdot\text{C°})} = 0.0613$ C°.

EVALUATE: The heat energy required to change the temperature of ordinary-size objects is very large compared to the typical kinetic energies of moving objects.

17.38. **IDENTIFY:** The latent heat of fusion L_f is defined by $Q = mL_\text{f}$ for the solid → liquid phase transition. For a temperature change, $Q = mc\Delta T$.

SET UP: At $t = 1$ min the sample is at its melting point and at $t = 2.5$ min all the sample has melted.

EXECUTE: **(a)** It takes 1.5 min for all the sample to melt once its melting point is reached and the heat input during this time interval is $(1.5 \text{ min})(10.0\times10^3 \text{ J/min}) = 1.50\times10^4$ J. $Q = mL_\text{f}$.

$L_\text{f} = \dfrac{Q}{m} = \dfrac{1.50\times10^4 \text{ J}}{0.500 \text{ kg}} = 3.00\times10^4$ J/kg.

(b) The liquid's temperature rises 30 C° in 1.5 min. $Q = mc\Delta T$.

$c_\text{liquid} = \dfrac{Q}{m\Delta T} = \dfrac{1.50\times10^4 \text{ J}}{(0.500 \text{ kg})(30 \text{ C°})} = 1.00\times10^3$ J/kg·K.

The solid's temperature rises 15 C° in 1.0 min. $c_\text{solid} = \dfrac{Q}{m\Delta T} = \dfrac{1.00\times10^4 \text{ J}}{(0.500 \text{ kg})(15 \text{ C°})} = 1.33\times10^3$ J/kg·K.

EVALUATE: The specific heat capacities for the liquid and solid states are different. The values of c and L_f that we calculated are within the range of values in Tables 17.3 and 17.4.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

17.39. **IDENTIFY** and **SET UP:** Heat comes out of the metal and into the water. The final temperature is in the range $0 < T < 100°\text{C}$, so there are no phase changes. $Q_{\text{system}} = 0$.

(a) EXECUTE: $Q_{\text{water}} + Q_{\text{metal}} = 0$

$m_{\text{water}}c_{\text{water}}\Delta T_{\text{water}} + m_{\text{metal}}c_{\text{metal}}\Delta T_{\text{metal}} = 0$

$(1.00\text{ kg})(4190\text{ J/kg}\cdot\text{K})(2.0\text{ C°}) + (0.500\text{ kg})(c_{\text{metal}})(-78.0\text{ C°}) = 0$

$c_{\text{metal}} = 215\text{ J/kg}\cdot\text{K}$

(b) EVALUATE: Water has a larger specific heat capacity so stores more heat per degree of temperature change.

(c) If some heat went into the styrofoam then Q_{metal} should actually be larger than in part (a), so the true c_{metal} is larger than we calculated; the value we calculated would be smaller than the true value.

17.40. **IDENTIFY:** The heat that comes out of the person goes into the ice-water bath and causes some of the ice to melt.

SET UP: Normal body temperature is 98.6°F = 37.0°C, so for the person $\Delta T = -5\text{ C°}$. The ice-water bath stays at 0°C. A mass m of ice melts and $Q_{\text{ice}} = mL_{\text{f}}$. From Table 17.4, for water $L_{\text{f}} = 334\times10^3\text{ J/kg}$.

EXECUTE: $Q_{\text{person}} = mc\Delta T = (70.0\text{ kg})(3480\text{ J/kg}\cdot\text{C°})(-5.0\text{ C°}) = -1.22\times10^6\text{ J}$. Therefore, the amount of heat that goes into the ice is $1.22\times10^6\text{ J}$. $m_{\text{ice}}L_{\text{f}} = 1.22\times10^6\text{ J}$ and $m_{\text{ice}} = \dfrac{1.22\times10^6\text{ J}}{334\times10^3\text{ J/kg}} = 3.7\text{ kg}$.

EVALUATE: If less ice than this is used, all the ice melts and the temperature of the water in the bath rises above 0°C.

17.41. **IDENTIFY:** The heat lost by the cooling copper is absorbed by the water and the pot, which increases their temperatures.

SET UP: For copper, $c_{\text{c}} = 390\text{ J/kg}\cdot\text{K}$. For iron, $c_{\text{i}} = 470\text{ J/kg}\cdot\text{K}$. For water, $c_{\text{w}} = 4.19\times10^3\text{ J/kg}\cdot\text{K}$.

EXECUTE: For the copper pot,
$Q_{\text{c}} = m_{\text{c}}c_{\text{c}}\,\Delta T_{\text{c}} = (0.500\text{ kg})(390\text{ J/kg}\cdot\text{K})(T - 20.0°\text{C}) = (195\text{ J/K})T - 3900\text{ J}$. For the block of iron,
$Q_{\text{i}} = m_{\text{i}}c_{\text{i}}\,\Delta T_{\text{i}} = (0.250\text{ kg})(470\text{ J/kg}\cdot\text{K})(T - 85.0°\text{C}) = (117.5\text{ J/K})T - 9988\text{ J}$. For the water,
$Q_{\text{w}} = m_{\text{w}}c_{\text{w}}\,\Delta T_{\text{w}} = (0.170\text{ kg})(4190\text{ J/kg}\cdot\text{K})(T - 20.0°\text{C}) = (712.3\text{ J/K})T - 1.425\times10^4\text{ J}$. $\Sigma Q = 0$ gives

$(195\text{ J/K})T - 3900\text{ J} + (117.5\text{ J/K})T - 9988\text{ J} + (712.3\text{ J/K})T - 1.425\times10^4\text{ J}$. $T = \dfrac{2.814\times10^4\text{ J}}{1025\text{ J/K}} = 27.5°\text{C}$.

EVALUATE: The basic principle behind this problem is conservation of energy: no energy is lost; it is only transferred.

17.42. **IDENTIFY:** The energy generated in the body is used to evaporate water, which prevents the body from overheating.

SET UP: Energy is (power)(time); calculate the heat energy Q produced in one hour. The mass m of water that vaporizes is related to Q by $Q = mL_{\text{v}}$. 1.0 kg of water has a volume of 1.0 L.

EXECUTE: **(a)** $Q = (0.80)(500\text{ W})(3600\text{ s}) = 1.44\times10^6\text{ J}$. The mass of water that evaporates each hour is

$m = \dfrac{Q}{L_{\text{v}}} = \dfrac{1.44\times10^6\text{ J}}{2.42\times10^6\text{ J/kg}} = 0.60\text{ kg}$.

(b) (0.60 kg/h)(1.0 L/kg) = 0.60 L/h. The number of bottles of water is $\dfrac{0.60\text{ L/h}}{0.750\text{ L/bottle}} = 0.80\text{ bottles/h}$.

EVALUATE: It is not unreasonable to drink 8/10 of a bottle of water per hour during vigorous exercise.

17.43. **IDENTIFY:** If it cannot be gotten rid of in some way, the metabolic energy transformed to heat will increase the temperature of the body.

SET UP: From Problem 17.42, $Q = 1.44\times10^6\text{ J}$ and $m = 70\text{ kg}$. $Q = mc\Delta T$. Convert the temperature change in C° to F° using that 9 F° = 5 C°.

EXECUTE: **(a)** $Q = mc\Delta T$ so $\Delta T = \dfrac{Q}{mc} = \dfrac{1.44\times10^6\text{ J}}{(70\text{ kg})(3500\text{ J/kg}\cdot\text{C°})} = 5.9\text{ C°}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) $\Delta T = (5.9°\text{C})\left(\frac{9\ \text{F}°}{5\ \text{C}°}\right) = 10.6°\text{F}$. $T = 98.6°\text{F} + 10.6\ \text{F}° = 109°\text{F}$.

EVALUATE: A temperature this high can cause heat stroke and be lethal.

17.44. **IDENTIFY:** By energy conservation, the heat lost by the water is gained by the ice. This heat must first increase the temperature of the ice from −40.0°C to the melting point of 0.00°C, then melt the ice, and finally increase its temperature to 20.0°C. The target variable is the mass of the water m.

SET UP: $Q_{\text{ice}} = m_{\text{ice}}c_{\text{ice}}\Delta T_{\text{ice}} + m_{\text{ice}}L_{\text{f}} + m_{\text{ice}}c_{\text{w}}\Delta T_{\text{melted ice}}$ and $Q_{\text{water}} = mc_{\text{w}}\Delta T_{\text{w}}$.

EXECUTE: Using $Q_{\text{ice}} = m_{\text{ice}}c_{\text{ice}}\Delta T_{\text{ice}} + m_{\text{ice}}L_{\text{f}} + m_{\text{ice}}c_{\text{w}}\Delta T_{\text{melted ice}}$, with the values given in the table in the text, we have $Q_{\text{ice}} = (0.200\ \text{kg})[2100\ \text{J/(kg}\cdot\text{C°)}](40.0\text{C°}) + (0.200\ \text{kg})(3.34\times10^5\ \text{J/kg})$ $+(0.200\ \text{kg})[4190\ \text{J/(kg}\cdot\text{C°)}](20.0\text{C°}) = 1.004\times10^5\ \text{J}$.

$Q_{\text{water}} = mc_{\text{w}}\Delta T_{\text{w}} = m[4190\ \text{J/(kg}\cdot\text{C°)}](20.0\text{C°} - 80.0\text{C°}) = -(251{,}400\ \text{J/kg})m$. $Q_{\text{ice}} + Q_{\text{water}} = 0$ gives $1.004\times10^5\ \text{J} = (251{,}400\ \text{J/kg})m$. $m = 0.399$ kg.

EVALUATE: There is about twice as much water as ice because the water must provide the heat not only to melt the ice but also to increase its temperature.

17.45. **IDENTIFY:** By energy conservation, the heat lost by the copper is gained by the ice. This heat must first increase the temperature of the ice from −20.0°C to the melting point of 0.00°C, then melt some of the ice. At the final thermal equilibrium state, there is ice and water, so the temperature must be 0.00°C. The target variable is the initial temperature of the copper.

SET UP: For temperature changes, $Q = mc\Delta T$ and for a phase change from solid to liquid $Q = mL_{\text{F}}$.

EXECUTE: For the ice,

$Q_{\text{ice}} = (2.00\ \text{kg})[2100\ \text{J/(kg}\cdot\text{C°)}](20.0\text{C°}) + (0.80\ \text{kg})(3.34\times10^5\ \text{J/kg}) = 3.512\times10^5\ \text{J}$. For the copper, using the specific heat from the table in the text gives

$Q_{\text{copper}} = (6.00\ \text{kg})[390\ \text{J/(kg}\cdot\text{C°)}](0\text{°C} - T) = -(2.34\times10^3\ \text{J/C°})T$. Setting the sum of the two heats equal to zero gives $3.512\times10^5\ \text{J} = (2.34\times10^3\ \text{J/C°})T$, which gives $T = 150°\text{C}$.

EVALUATE: Since the copper has a smaller specific heat than that of ice, it must have been quite hot initially to provide the amount of heat needed.

17.46. **IDENTIFY:** Apply $Q = mc\Delta T$ to each object. The net heat flow Q_{system} for the system (man, soft drink) is zero.

SET UP: The mass of 1.00 L of water is 1.00 kg. Let the man be designated by the subscript m and the "'water" by w. T is the final equilibrium temperature. $c_{\text{w}} = 4190\ \text{J/kg}\cdot\text{K}$. $\Delta T_{\text{K}} = \Delta T_{\text{C}}$.

EXECUTE: **(a)** $Q_{\text{system}} = 0$ gives $m_{\text{m}}c_{\text{m}}\Delta T_{\text{m}} + m_{\text{w}}c_{\text{w}}\Delta T_{\text{w}} = 0$. $m_{\text{m}}c_{\text{m}}(T - T_{\text{m}}) + m_{\text{w}}c_{\text{w}}(T - T_{\text{w}}) = 0$.

$m_{\text{m}}c_{\text{m}}(T_{\text{m}} - T) = m_{\text{w}}c_{\text{w}}(T - T_{\text{w}})$. Solving for T, $T = \dfrac{m_{\text{m}}c_{\text{m}}T_{\text{m}} + m_{\text{w}}c_{\text{w}}T_{\text{w}}}{m_{\text{m}}c_{\text{m}} + m_{\text{w}}c_{\text{w}}}$.

$$T = \frac{(70.0\ \text{kg})(3480\ \text{J/kg}\cdot\text{K})(37.0\text{°C}) + (0.355\ \text{kg})(4190\ \text{J/kg}\cdot\text{C°})(12.0\text{°C})}{(70.0\ \text{kg})(3480\ \text{J/kg}\cdot\text{C°}) + (0.355\ \text{kg})(4190\ \text{J/kg}\cdot\text{C°})} = 36.85°\text{C}$$

(b) It is possible a sensitive digital thermometer could measure this change since they can read to 0.1°C. It is best to refrain from drinking cold fluids prior to orally measuring a body temperature due to cooling of the mouth.

EVALUATE: Heat comes out of the body and its temperature falls. Heat goes into the soft drink and its temperature rises.

17.47. **IDENTIFY:** For the man's body, $Q = mc\Delta T$.

SET UP: From Exercise 17.46, $\Delta T = 0.15\ \text{C°}$ when the body returns to 37.0°C.

EXECUTE: The rate of heat loss is Q/t. $\dfrac{Q}{t} = \dfrac{mc\Delta T}{t}$ and $t = \dfrac{mc\Delta T}{(Q/t)}$.

$$t = \frac{(70.355\ \text{kg})(3480\ \text{J/kg}\cdot\text{C°})(0.15\ \text{C°})}{7.00\times10^6\ \text{J/day}} = 0.00525\ \text{d} = 7.6\ \text{minutes}.$$

EVALUATE: Even if all the BMR energy stays in the body, it takes the body several minutes to return to its normal temperature.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

17.48. **IDENTIFY:** For a temperature change $Q = mc\Delta T$ and for the liquid to solid phase change $Q = -mL_f$.

SET UP: For water, $c = 4.19\times10^3$ J/kg · K and $L_f = 3.34\times10^5$ J/kg.

EXECUTE: $Q = mc\Delta T - mL_f = (0.350\text{ kg})([4.19\times10^3\text{ J/kg}\cdot\text{K}][-18.0\text{ C°}] - 3.34\times10^5\text{ J/kg}) = -1.43\times10^5$ J.

The minus sign says 1.43×10^5 J must be removed from the water.

$(1.43\times10^5\text{ J})\left(\dfrac{1\text{ cal}}{4.186\text{ J}}\right) = 3.42\times10^4\text{ cal} = 34.2\text{ kcal.}$

$(1.43\times10^5\text{ J})\left(\dfrac{1\text{ Btu}}{1055\text{ J}}\right) = 136\text{ Btu.}$

EVALUATE: $Q < 0$ when heat comes out of an object. The equation $Q = mc\Delta T$ puts in the correct sign automatically, from the sign of $\Delta T = T_f - T_i$. But in $Q = \pm L$ we must select the correct sign.

17.49. **IDENTIFY** and **SET UP:** Use Eq. (17.13) for the temperature changes and Eq. (17.20) for the phase changes.

EXECUTE: Heat must be added to do the following:

ice at $-10.0°\text{C} \rightarrow$ ice at 0°C

$Q_{ice} = mc_{ice}\Delta T = (12.0\times10^{-3}\text{ kg})(2100\text{ J/kg}\cdot\text{K})(0°\text{C} - (-10.0°\text{C})) = 252$ J

phase transition ice $(0°\text{C}) \rightarrow$ liquid water (0°C)(melting)

$Q_{melt} = +mL_f = (12.0\times10^{-3}\text{ kg})(334\times10^3\text{ J/kg}) = 4.008\times10^3$ J

water at 0°C (from melted ice) $\rightarrow$ water at 100°C

$Q_{water} = mc_{water}\Delta T = (12.0\times10^{-3}\text{ kg})(4190\text{ J/kg}\cdot\text{K})(100°\text{C} - 0°\text{C}) = 5.028\times10^3$ J

phase transition water $(100°\text{C}) \rightarrow$ steam (100°C)(boiling)

$Q_{boil} = +mL_v = (12.0\times10^{-3}\text{ kg})(2256\times10^3\text{ J/kg}) = 2.707\times10^4$ J

The total Q is $Q = 252\text{ J} + 4.008\times10^3\text{ J} + 5.028\times10^3\text{ J} + 2.707\times10^4\text{ J} = 3.64\times10^4$ J

$(3.64\times10^4\text{ J})(1\text{ cal}/4.186\text{ J}) = 8.70\times10^3$ cal

$(3.64\times10^4\text{ J})(1\text{ Btu}/1055\text{ J}) = 34.5$ Btu

EVALUATE: Q is positive and heat must be added to the material. Note that more heat is needed for the liquid to gas phase change than for the temperature changes.

17.50. **IDENTIFY:** $Q = mc\Delta T$ for a temperature change and $Q = +mL_f$ for the solid to liquid phase transition. The ice starts to melt when its temperature reaches 0.0°C. The system stays at 0.00°C until all the ice has melted.

SET UP: For ice, $c = 2.10\times10^3$ J/kg · K. For water, $L_f = 3.34\times10^5$ J/kg.

EXECUTE: **(a)** Q to raise the temperature of ice to 0.00°C:

$Q = mc\Delta T = (0.550\text{ kg})(2.10\times10^3\text{ J/kg}\cdot\text{K})(15.0\text{ C°}) = 1.73\times10^4$ J. $t = \dfrac{1.73\times10^4\text{ J}}{800.0\text{ J/min}} = 21.7$ min.

(b) To melt all the ice requires $Q = mL_f = (0.550\text{ kg})(3.34\times10^5\text{ J/kg}) = 1.84\times10^5$ J.

$t = \dfrac{1.84\times10^5\text{ J}}{800.0\text{ J/min}} = 230$ min. The total time after the start of the heating is 252 min.

(c) A graph of T versus t is sketched in Figure 17.50.

EVALUATE: It takes much longer for the ice to melt than it takes the ice to reach the melting point.

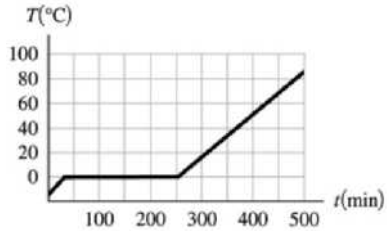

Figure 17.50

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

17.51. **IDENTIFY** and **SET UP:** The heat that must be added to a lead bullet of mass m to melt it is $Q = mc\Delta T + mL_f$ ($mc\Delta T$ is the heat required to raise the temperature from 25°C to the melting point of 327.3°C; mL_f is the heat required to make the solid $\rightarrow$ liquid phase change.) The kinetic energy of the bullet if its speed is v is $K = \frac{1}{2}mv^2$.

EXECUTE: $K = Q$ says $\frac{1}{2}mv^2 = mc\Delta T + mL_f$

$v = \sqrt{2(c\Delta T + L_f)}$

$v = \sqrt{2[(130\ \text{J/kg}\cdot\text{K})(327.3°\text{C} - 25°\text{C}) + 24.5\times10^3\ \text{J/kg}]} = 357\ \text{m/s}$

EVALUATE: This is a typical speed for a rifle bullet. A bullet fired into a block of wood does partially melt, but in practice not all of the initial kinetic energy is converted to heat that remains in the bullet.

17.52. **IDENTIFY:** For a temperature change, $Q = mc\Delta T$. For the vapor $\rightarrow$ liquid phase transition, $Q = -mL_v$.

SET UP: For water, $L_v = 2.256\times10^6$ J/kg and $c = 4.19\times10^3$ J/kg·K.

EXECUTE: **(a)** $Q = +m(-L_v + c\Delta T)$

$Q = +(25.0\times10^{-3}\ \text{kg})(-2.256\times10^6\ \text{J/kg} + [4.19\times10^3\ \text{J/kg}\cdot\text{K}][-66.0\ \text{C°}]) = -6.33\times10^4\ \text{J}$

(b) $Q = mc\Delta T = (25.0\times10^{-3}\ \text{kg})(4.19\times10^3\ \text{J/kg}\cdot\text{K})(-66.0\ \text{C°}) = -6.91\times10^3\ \text{J}$.

(c) The total heat released by the water that starts as steam is nearly a factor of ten larger than the heat released by water that starts at 100°C. Steam burns are much more severe than hot-water burns.

EVALUATE: For a given amount of material, the heat for a phase change is typically much more than the heat for a temperature change.

17.53. **IDENTIFY:** Use $Q = Mc\Delta T$ to find Q for a temperature rise from 34.0°C to 40.0°C. Set this equal to $Q = mL_v$ and solve for m, where m is the mass of water the camel would have to drink.

SET UP: $c = 3480$ J/kg·K and $L_v = 2.42\times10^6$ J/kg. For water, 1.00 kg has a volume 1.00 L. $M = 400$ kg is the mass of the camel.

EXECUTE: The mass of water that the camel saves is

$$m = \frac{Mc\Delta T}{L_v} = \frac{(400\ \text{kg})(3480\ \text{J/kg}\cdot\text{K})(6.0\ \text{K})}{(2.42\times10^6\ \text{J/kg})} = 3.45\ \text{kg}$$ which is a volume of 3.45 L.

EVALUATE: This is nearly a gallon of water, so it is an appreciable savings.

17.54. **IDENTIFY:** For a temperature change, $Q = mc\Delta T$. For the liquid $\rightarrow$ vapor phase change, $Q = +mL_v$.

SET UP: The density of water is 1000 kg/m^3.

EXECUTE: **(a)** The heat that goes into mass m of water to evaporate it is $Q = +mL_v$. The heat flow for the man is $Q = m_{man}c\Delta T$, where $\Delta T = -1.00$ C°. $\Sigma Q = 0$ so $mL_v + m_{man}c\Delta T = 0$ and

$$m = -\frac{m_{man}c\Delta T}{L_v} = -\frac{(70.0\ \text{kg})(3480\ \text{J/kg}\cdot\text{K})(-1.00\ \text{C°})}{2.42\times10^6\ \text{J/kg}} = 0.101\ \text{kg} = 101\ \text{g}.$$

(b) $V = \frac{m}{\rho} = \frac{0.101\ \text{kg}}{1000\ \text{kg/m}^3} = 1.01\times10^{-4}\ \text{m}^3 = 101\ \text{cm}^3$. This is about 35% of the volume of a soft-drink can.

EVALUATE: Fluid loss by evaporation from the skin can be significant.

17.55. **IDENTIFY:** The asteroid's kinetic energy is $K = \frac{1}{2}mv^2$. To boil the water, its temperature must be raised to 100.0°C and the heat needed for the phase change must be added to the water.

SET UP: For water, $c = 4190$ J/kg·K and $L_v = 2256\times10^3$ J/kg.

EXECUTE: $K = \frac{1}{2}(2.60\times10^{15}\ \text{kg})(32.0\times10^3\ \text{m/s})^2 = 1.33\times10^{24}$ J. $Q = mc\Delta T + mL_v$.

$$m = \frac{Q}{c\Delta T + L_v} = \frac{1.33\times10^{22}\ \text{J}}{(4190\ \text{J/kg}\cdot\text{K})(90.0\ \text{K}) + 2256\times10^3\ \text{J/kg}} = 5.05\times10^{15}\ \text{kg}.$$

EVALUATE: The mass of water boiled is 2.5 times the mass of water in Lake Superior.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

17.56. **IDENTIFY:** $Q = mc\Delta T$ for a temperature change. The net Q for the system (sample, can and water) is zero.

SET UP: For water, $c_w = 4.19\times10^3$ J/kg·K. For copper, $c_c = 390$ J/kg·K.

EXECUTE: For the water, $Q_w = m_w c_w \Delta T_w = (0.200 \text{ kg})(4.19\times10^3 \text{ J/kg}\cdot\text{K})(7.1 \text{ C°}) = 5.95\times10^3$ J.

For the copper can, $Q_c = m_c c_c \Delta T_c = (0.150 \text{ kg})(390 \text{ J/kg}\cdot\text{K})(7.1 \text{ C°}) = 415$ J.

For the sample, $Q_s = m_s c_s \Delta T_s = (0.085 \text{ kg})c_s(-73.9 \text{ C°})$.

$\Sigma Q = 0$ gives $(0.085 \text{ kg})(-73.9 \text{ C°})c_s + 415 \text{ J} + 5.95\times10^3 \text{ J} = 0$. $c_s = 1.01\times10^3$ J/kg·K.

EVALUATE: Heat comes out of the sample and goes into the water and the can. The value of c_s we calculated is consistent with the values in Table 17.3.

17.57. **IDENTIFY** and **SET UP:** Heat flows out of the water and into the ice. The net heat flow for the system is zero. The ice warms to 0°C, melts, and then the water from the melted ice warms from 0°C to the final temperature.

EXECUTE: $Q_{system} = 0$; calculate Q for each component of the system: (Beaker has small mass says that $Q = mc\Delta T$ for beaker can be neglected.)

<u>0.250 kg of water</u>: cools from 75.0°C to 40.0°C

$Q_{water} = mc\Delta T = (0.250 \text{ kg})(4190 \text{ J/kg}\cdot\text{K})(40.0°\text{C} - 75.0°\text{C}) = -3.666\times10^4$ J.

<u>ice</u>: warms to 0°C; melts; water from melted ice warms to 40.0°C

$Q_{ice} = mc_{ice}\Delta T + mL_f + mc_{water}\Delta T$.

$Q_{ice} = m[(2100 \text{ J/kg}\cdot\text{K})(0°\text{C} - (-20.0°\text{C})) + 334\times10^3 \text{ J/kg} + (4190 \text{ J/kg}\cdot\text{K})(40.0°\text{C} - 0°\text{C})]$.

$Q_{ice} = (5.436\times10^5 \text{ J/kg})m$. $Q_{system} = 0$ says $Q_{water} + Q_{ice} = 0$. $-3.666\times10^4 \text{ J} + (5.436\times10^5 \text{ J/kg})m = 0$.

$$m = \frac{3.666\times10^4 \text{ J}}{5.436\times10^5 \text{ J/kg}} = 0.0674 \text{ kg}.$$

EVALUATE: Since the final temperature is 40.0°C we know that all the ice melts and the final system is all liquid water. The mass of ice added is much less than the mass of the 75°C water; the ice requires a large heat input for the phase change.

17.58. **IDENTIFY:** For a temperature change $Q = mc\Delta T$. For a melting phase transition $Q = mL_f$. The net Q for the system (sample, vial and ice) is zero.

SET UP: Ice remains, so the final temperature is 0.0°C. For water, $L_f = 3.34\times10^5$ J/kg.

EXECUTE: For the sample, $Q_s = m_s c_s \Delta T_s = (16.0\times10^{-3} \text{ kg})(2250 \text{ J/kg}\cdot\text{K})(-19.5 \text{ C°}) = -702$ J. For the vial, $Q_v = m_v c_v \Delta T_v = (6.0\times10^{-3} \text{ kg})(2800 \text{ J/kg}\cdot\text{K})(-19.5 \text{ C°}) = -328$ J. For the ice that melts, $Q_i = mL_f$.

$\Sigma Q = 0$ gives $mL_f - 702 \text{ J} - 328 \text{ J} = 0$ and $m = 3.08\times10^{-3}$ kg $= 3.08$ g.

EVALUATE: Only a small fraction of the ice melts. The water for the melted ice remains at 0°C and has no heat flow.

17.59. **IDENTIFY** and **SET UP:** Large block of ice implies that ice is left, so $T_2 = 0°\text{C}$ (final temperature). Heat comes out of the ingot and into the ice. The net heat flow is zero. The ingot has a temperature change and the ice has a phase change.

EXECUTE: $Q_{system} = 0$; calculate Q for each component of the system:

<u>ingot</u>

$Q_{ingot} = mc\Delta T = (4.00 \text{ kg})(234 \text{ J/kg}\cdot\text{K})(0°\text{C} - 750°\text{C}) = -7.02\times10^5$ J

<u>ice</u>

$Q_{ice} = +mL_f$, where m is the mass of the ice that changes phase (melts)

$Q_{system} = 0$ says $Q_{ingot} + Q_{ice} = 0$

$-7.02\times10^5 \text{ J} + m(334\times10^3 \text{ J/kg}) = 0$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$m = \frac{7.02\times10^5 \text{ J}}{334\times10^3 \text{ J/kg}} = 2.10 \text{ kg}$$

EVALUATE: The liquid produced by the phase change remains at 0°C since it is in contact with ice.

17.60. **IDENTIFY:** The initial temperature of the ice and water mixture is 0.0°C. Assume all the ice melts. We will know that assumption is incorrect if the final temperature we calculate is less than 0.0°C. The net Q for the system (can, water, ice and lead) is zero.

SET UP: For copper, $c_c = 390 \text{ J/kg}\cdot\text{K}$. For lead, $c_l = 130 \text{ J/kg}\cdot\text{K}$. For water, $c_w = 4.19\times10^3 \text{ J/kg}\cdot\text{K}$ and $L_f = 3.34\times10^5 \text{ J/kg}$.

EXECUTE: For the copper can, $Q_c = m_c c_c \Delta T_c = (0.100 \text{ kg})(390 \text{ J/kg}\cdot\text{K})(T - 0.0°\text{C}) = (39.0 \text{ J/K})T$.

For the water, $Q_w = m_w c_w \Delta T_w = (0.160 \text{ kg})(4.19\times10^3 \text{ J/kg}\cdot\text{K})(T - 0.0°\text{C}) = (670.4 \text{ J/K})T$.

For the ice, $Q_i = m_i L_f + m_i c_w \Delta T_w$

$Q_i = (0.018 \text{ kg})(3.34\times10^5 \text{ J/kg}) + (0.018 \text{ kg})(4.19\times10^3 \text{ J/kg}\cdot\text{K})(T - 0.0°\text{C}) = 6012 \text{ J} + (75.4 \text{ J/K})T$

For the lead, $Q_l = m_l c_l \Delta T_l = (0.750 \text{ kg})(130 \text{ J/kg}\cdot\text{K})(T - 255°\text{C}) = (97.5 \text{ J/K})T - 2.486\times10^4 \text{ J}$

$\Sigma Q = 0$ gives $(39.0 \text{ J/K})T + (670.4 \text{ J/K})T + 6012 \text{ J} + (75.4 \text{ J/K})T + (97.5 \text{ J/K})T - 2.486\times10^4 \text{ J} = 0$.

$$T = \frac{1.885\times10^4 \text{ J}}{882.3 \text{ J/K}} = 21.4°\text{C}.$$

EVALUATE: $T > 0.0°\text{C}$, which confirms that all the ice melts.

17.61. **IDENTIFY:** Set $Q_{system} = 0$, for the system of water, ice and steam. $Q = mc\Delta T$ for a temperature change and $Q = \pm mL$ for a phase transition.

SET UP: For water, $c = 4190 \text{ J/kg}\cdot\text{K}$, $L_f = 334\times10^3 \text{ J/kg}$ and $L_v = 2256\times10^3 \text{ J/kg}$.

EXECUTE: The steam both condenses and cools, and the ice melts and heats up along with the original water. $m_i L_f + m_i c(28.0 \text{ C°}) + m_w c(28.0 \text{ C°}) - m_{steam} L_v + m_{steam} c(-72.0 \text{ C°}) = 0$. The mass of steam needed is

$$m_{steam} = \frac{(0.450 \text{ kg})(334\times10^3 \text{ J/kg}) + (2.85 \text{ kg})(4190 \text{ J/kg}\cdot\text{K})(28.0 \text{ C°})}{2256\times10^3 \text{ J/kg} + (4190 \text{ J/kg}\cdot\text{K})(72.0 \text{ C°})} = 0.190 \text{ kg}.$$

EVALUATE: Since the final temperature is greater than 0.0°C, we know that all the ice melts.

17.62. **IDENTIFY:** At steady state, the rate of heat flow is the same throughout both rods, as well as out of the boiling water and into the ice-water mixture. The heat that flows into the ice-water mixture goes only into melting ice since the temperature remains at 0.00°C.

SET UP: For steady state heat flow, $\frac{Q}{t} = \frac{kA\Delta T}{L}$. The heat to melt ice is $Q = mL_f$.

EXECUTE: **(a)** $\frac{Q}{t} = \frac{kA\Delta T}{L}$ is the same for both of the rods. Using the physical properties of brass and copper from the tables in the text, we have

$$\frac{[109.0 \text{ W/(m}\cdot\text{K)}](100.0°\text{C} - T)}{0.200 \text{ m}} = \frac{[385.0 \text{ W/(m}\cdot\text{K)}](T - 0.0°\text{C})}{0.800 \text{ m}}.$$

$436.0(100 - T) = 385.0T$. Solving for T gives $T = 53.1°\text{C}$.

(b) The heat entering the ice-water mixture is

$$Q = \frac{kAt\Delta T}{L} = \frac{[109.0 \text{ W/(m}\cdot\text{K)}](0.00500 \text{ m}^2)(300.0 \text{ s})(100.0°\text{C} - 53.1°\text{C})}{0.200 \text{ m}}. \; Q = 3.834\times10^4 \text{ J}. \text{ Then}$$

$$Q = mL_f \text{ so } m = \frac{3.834\times10^4 \text{ J}}{3.34\times10^5 \text{ J/kg}} = 0.115 \text{ kg}.$$

EVALUATE: The temperature of the interface between the two rods is between the two extremes (0°C and 100°C), but not midway between them.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

17.63. **IDENTIFY** and **SET UP:** The temperature gradient is $(T_H - T_C)/L$ and can be calculated directly. Use Eq. (17.21) to calculate the heat current H. In part (c) use H from part (b) and apply Eq. (17.21) to the 12.0-cm section of the left end of the rod. $T_2 = T_H$ and $T_1 = T$, the target variable.

EXECUTE: **(a)** temperature gradient $= (T_H - T_C)/L = (100.0°C - 0.0°C)/0.450\ \text{m} = 222\ \text{C°/m} = 222\ \text{K/m}$

(b) $H = kA(T_H - T_C)/L$. From Table 17.5, $k = 385\ \text{W/m}\cdot\text{K}$, so

$H = (385\ \text{W/m}\cdot\text{K})(1.25\times10^{-4}\ \text{m}^2)(222\ \text{K/m}) = 10.7\ \text{W}$

(c) $H = 10.7\ \text{W}$ for all sections of the rod.

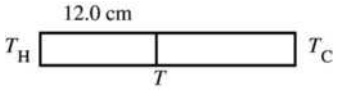

Figure 17.63

Apply $H = kA\Delta T/L$ to the 12.0 cm section (Figure 17.63): $T_H - T = LH/kA$ and

$$T = T_H - LH/Ak = 100.0°C - \frac{(0.120\ \text{m})(10.7\ \text{W})}{(1.25\times10^{-4}\ \text{m}^2)(385\ \text{W/m}\cdot\text{K})} = 73.3°C$$

EVALUATE: H is the same at all points along the rod, so $\Delta T/\Delta x$ is the same for any section of the rod with length Δx. Thus $(T_H - T)/(12.0\ \text{cm}) = (T_H - T_C)/(45.0\ \text{cm})$ gives that $T_H - T = 26.7\ \text{C°}$ and $T = 73.3°C$, as we already calculated.

17.64. **IDENTIFY:** For a melting phase transition, $Q = mL_f$. The rate of heat conduction is $\frac{Q}{t} = \frac{kA(T_H - T_C)}{L}$.

SET UP: For water, $L_f = 3.34\times10^5\ \text{J/kg}$.

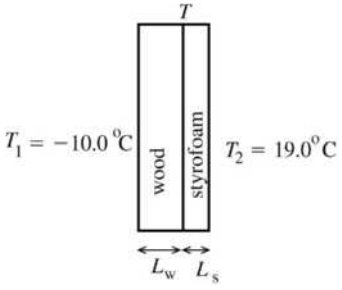
EXECUTE: The heat conducted by the rod in 10.0 min is

$Q = mL_f = (8.50\times10^{-3}\ \text{kg})(3.34\times10^5\ \text{J/kg}) = 2.84\times10^3\ \text{J}$. $\frac{Q}{t} = \frac{2.84\times10^3\ \text{J}}{600\ \text{s}} = 4.73\ \text{W}$.

$$k = \frac{(Q/t)L}{A(T_H - T_C)} = \frac{(4.73\ \text{W})(0.600\ \text{m})}{(1.25\times10^{-4}\ \text{m}^2)(100\ \text{C°})} = 227\ \text{W/m}\cdot\text{K}.$$

EVALUATE: The heat conducted by the rod is the heat that enters the ice and produces the phase change.

17.65. **IDENTIFY** and **SET UP:** Call the temperature at the interface between the wood and the styrofoam T. The heat current in each material is given by $H = kA(T_H - T_C)/L$.



See Figure 17.65.

Heat current through the wood: $H_w = k_w A(T - T_1)L_w$

Heat current through the styrofoam: $H_s = k_s A(T_2 - T)/L_s$

Figure 17.65

In steady-state heat does not accumulate in either material. The same heat has to pass through both materials in succession, so $H_w = H_s$.

EXECUTE: **(a)** This implies $k_w A(T - T_1)/L_w = k_s A(T_2 - T)/L_s$

$k_w L_s(T - T_1) = k_s L_w(T_2 - T)$

$$T = \frac{k_w L_s T_1 + k_s L_w T_2}{k_w L_s + k_s L_w} = \frac{-0.0176\ \text{W}\cdot°\text{C/K} + 00057\ \text{W}\cdot°\text{C/K}}{0.00206\ \text{W/K}} = -5.8°C$$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: The temperature at the junction is much closer in value to T_1 than to T_2. The styrofoam has a very small k, so a larger temperature gradient is required for than for wood to establish the same heat current.

(b) IDENTIFY and **SET UP:** Heat flow per square meter is $\frac{H}{A} = k\left(\frac{T_H - T_C}{L}\right)$. We can calculate this either for the wood or for the styrofoam; the results must be the same.

EXECUTE: wood

$$\frac{H_w}{A} = k_w \frac{T - T_1}{L_w} = (0.080 \text{ W/m} \cdot \text{K}) \frac{(-5.8°\text{C} - (-10.0°\text{C}))}{0.030 \text{ m}} = 11 \text{ W/m}^2.$$

styrofoam

$$\frac{H_s}{A} = k_s \frac{T_2 - T}{L_s} = (0.010 \text{ W/m} \cdot \text{K}) \frac{(19.0°\text{C} - (-5.8°\text{C}))}{0.022 \text{ m}} = 11 \text{ W/m}^2.$$

EVALUATE: H must be the same for both materials and our numerical results show this. Both materials are good insulators and the heat flow is very small.

17.66. **IDENTIFY:** $\frac{Q}{t} = \frac{kA(T_H - T_C)}{L}$

SET UP: $T_H - T_C = 175°\text{C} - 35°\text{C}$. $1 \text{ K} = 1 \text{ C}°$, so there is no need to convert the temperatures to kelvins.

EXECUTE: **(a)** $\frac{Q}{t} = \frac{(0.040 \text{ W/m} \cdot \text{K})(1.40 \text{ m}^2)(175°\text{C} - 35°\text{C})}{4.0 \times 10^{-2} \text{ m}} = 196 \text{ W}.$

(b) The power input must be 196 W, to replace the heat conducted through the walls.

EVALUATE: The heat current is small because k is small for fiberglass.

17.67. **IDENTIFY:** There is a temperature difference across the skin, so we have heat conduction through the skin.

SET UP: Apply $H = kA\frac{T_H - T_C}{L}$ and solve for k.

EXECUTE: $k = \frac{HL}{A(T_H - T_C)} = \frac{(75 \text{ W})(0.75 \times 10^{-3} \text{ m})}{(2.0 \text{ m}^2)(37°\text{C} - 30.0°\text{C})} = 4.0 \times 10^{-3} \text{ W/m} \cdot \text{C}°.$

EVALUATE: This is a small value; skin is a poor conductor of heat. But the thickness of the skin is small, so the rate of heat conduction through the skin is not small.

17.68. **IDENTIFY:** $\frac{Q}{t} = \frac{kA\Delta T}{L}$. Q/t is the same for both sections of the rod.

SET UP: For copper, $k_c = 385 \text{ W/m} \cdot \text{K}$. For steel, $k_s = 50.2 \text{ W/m} \cdot \text{K}$.

EXECUTE: **(a)** For the copper section, $\frac{Q}{t} = \frac{(385 \text{ W/m} \cdot \text{K})(4.00 \times 10^{-4} \text{ m}^2)(100°\text{C} - 65.0°\text{C})}{1.00 \text{ m}} = 5.39 \text{ J/s}.$

(b) For the steel section, $L = \frac{kA\Delta T}{(Q/t)} = \frac{(50.2 \text{ W/m} \cdot \text{K})(4.00 \times 10^{-4} \text{ m}^2)(65.0°\text{C} - 0°\text{C})}{5.39 \text{ J/s}} = 0.242 \text{ m}.$

EVALUATE: The thermal conductivity for steel is much less than that for copper, so for the same ΔT and A a smaller L for steel would be needed for the same heat current as in copper.

17.69. **IDENTIFY** and **SET UP:** The heat conducted through the bottom of the pot goes into the water at 100°C to convert it to steam at 100°C. We can calculate the amount of heat flow from the mass of material that changes phase. Then use Eq. (17.21) to calculate T_H, the temperature of the lower surface of the pan.

EXECUTE: $Q = mL_v = (0.390 \text{ kg})(2256 \times 10^3 \text{ J/kg}) = 8.798 \times 10^5 \text{ J}$

$H = Q/t = 8.798 \times 10^5 \text{ J}/180 \text{ s} = 4.888 \times 10^3 \text{ J/s}$

Then $H = kA(T_H - T_C)/L$ says that $T_H - T_C = \frac{HL}{kA} = \frac{(4.888 \times 10^3 \text{ J/s})(8.50 \times 10^{-3} \text{ m})}{(50.2 \text{ W/m} \cdot \text{K})(0.150 \text{ m}^2)} = 5.52 \text{ C}°$

$T_H = T_C + 5.52 \text{ C}° = 100°\text{C} + 5.52 \text{ C}° = 105.5°\text{C}$

EVALUATE: The larger $T_H - T_C$ is the larger H is and the faster the water boils.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

17.70. **IDENTIFY:** Apply Eq. (17.21) and solve for A.

SET UP: The area of each circular end of a cylinder is related to the diameter D by $A = \pi R^2 = \pi(D/2)^2$. For steel, $k = 50.2$ W/m · K. The boiling water has $T = 100°\text{C}$, so $\Delta T = 300$ K.

EXECUTE: $\frac{Q}{t} = kA\frac{\Delta T}{L}$ and $150 \text{ J/s} = (50.2 \text{ W/m} \cdot \text{K})A\left(\frac{300 \text{ K}}{0.500 \text{ m}}\right)$. This gives $A = 4.98\times10^{-3} \text{ m}^2$, and $D = \sqrt{4A/\pi} = \sqrt{4(4.98\times10^{-3} \text{ m}^2)/\pi} = 8.0\times10^{-2} \text{ m} = 8.0 \text{ cm}$.

EVALUATE: H increases when A increases.

17.71. **IDENTIFY:** Assume the temperatures of the surfaces of the window are the outside and inside temperatures. Use the concept of thermal resistance. For part (b) use the fact that when insulating materials are in layers, the R values are additive.

SET UP: From Table 17.5, $k = 0.8$ W/m · K for glass. $R = L/k$.

EXECUTE: **(a)** For the glass, $R_{\text{glass}} = \frac{5.20\times10^{-3} \text{ m}}{0.8 \text{ W/m} \cdot \text{K}} = 6.50\times10^{-3} \text{ m}^2 \cdot \text{K/W}$.

$H = \frac{A(T_\text{H} - T_\text{C})}{R} = \frac{(1.40 \text{ m})(2.50 \text{ m})(39.5 \text{ K})}{6.50\times10^{-3} \text{ m}^2 \cdot \text{K/W}} = 2.1\times10^4 \text{ W}$

(b) For the paper, $R_{\text{paper}} = \frac{0.750\times10^{-3} \text{ m}}{0.05 \text{ W/m} \cdot \text{K}} = 0.015 \text{ m}^2 \cdot \text{K/W}$. The total R is

$R = R_{\text{glass}} + R_{\text{paper}} = 0.0215 \text{ m}^2 \cdot \text{K/W}$. $H = \frac{A(T_\text{H} - T_\text{C})}{R} = \frac{(1.40 \text{ m})(2.50 \text{ m})(39.5 \text{ K})}{0.0215 \text{ m}^2 \cdot \text{K/W}} = 6.4\times10^3 \text{ W}$.

EVALUATE: The layer of paper decreases the rate of heat loss by a factor of about 3.

17.72. **IDENTIFY:** The rate of energy radiated per unit area is $\frac{H}{A} = e\sigma T^4$.

SET UP: A blackbody has $e = 1$.

EXECUTE: **(a)** $\frac{H}{A} = (1)(5.67\times10^{-8} \text{ W/m}^2 \cdot \text{K}^4)(273 \text{ K})^4 = 315 \text{ W/m}^2$

(b) $\frac{H}{A} = (1)(5.67\times10^{-8} \text{ W/m}^2 \cdot \text{K}^4)(2730 \text{ K})^4 = 3.15\times10^6 \text{ W/m}^2$

EVALUATE: When the Kelvin temperature increases by a factor of 10 the rate of energy radiation increases by a factor of 10^4.

17.73. **IDENTIFY:** Use Eq. (17.25) to calculate A.

SET UP: $H = Ae\sigma T^4$ so $A = H/e\sigma T^4$

150-W and all electrical energy consumed is radiated says $H = 150$ W

EXECUTE: $A = \frac{150 \text{ W}}{(0.35)(5.67\times10^{-8} \text{ W/m}^2 \cdot \text{K}^4)(2450 \text{ K})^4} = 2.1\times10^{-4} \text{ m}^2(1\times10^4 \text{ cm}^2/1 \text{ m}^2) = 2.1 \text{ cm}^2$

EVALUATE: Light bulb filaments are often in the shape of a tightly wound coil to increase the surface area; larger A means a larger radiated power H.

17.74. **IDENTIFY:** The net heat current is $H = Ae\sigma(T^4 - T_\text{s}^4)$. A power input equal to H is required to maintain constant temperature of the sphere.

SET UP: The surface area of a sphere is $4\pi r^2$.

EXECUTE: $H = 4\pi(0.0150 \text{ m})^2(0.35)(5.67\times10^{-8} \text{ W/m}^2 \cdot \text{K}^4)([3000 \text{ K}]^4 - [290 \text{ K}]^4) = 4.54\times10^3 \text{ W}$

EVALUATE: Since $3000 \text{ K} > 290 \text{ K}$ and H is proportional to T^4, the rate of emission of heat energy is much greater than the rate of absorption of heat energy from the surroundings.

17.75. **IDENTIFY:** Apply $H = Ae\sigma T^4$ and calculate A.

SET UP: For a sphere of radius R, $A = 4\pi R^2$. $\sigma = 5.67\times10^{-8} \text{ W/m}^2 \cdot \text{K}^4$. The radius of the earth is $R_\text{E} = 6.38\times10^6$ m, the radius of the sun is $R_{\text{sun}} = 6.96\times10^8$ m, and the distance between the earth and the sun is $r = 1.50\times10^{11}$ m.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: The radius is found from $R=\sqrt{\frac{A}{4\pi}}=\sqrt{\frac{H/(\sigma T^4)}{4\pi}}=\sqrt{\frac{H}{4\pi\sigma}}\frac{1}{T^2}$.

(a) $R_{\rm a}=\sqrt{\frac{(2.7\times10^{32}\ {\rm W})}{4\pi(5.67\times10^{-8}\ {\rm W/m^2\cdot K^4})}}\frac{1}{(11{,}000\ {\rm K})^2}=1.61\times10^{11}\ {\rm m}$

(b) $R_{\rm b}=\sqrt{\frac{(2.10\times10^{23}\ {\rm W})}{4\pi(5.67\times10^{-8}\ {\rm W/m^2\cdot K^4})}}\frac{1}{(10{,}000\ {\rm K})^2}=5.43\times10^{6}\ {\rm m}$

EVALUATE: **(c)** The radius of Procyon B is comparable to that of the earth, and the radius of Rigel is comparable to the earth-sun distance.

17.76. **IDENTIFY:** Apply $\Delta L=L_0\alpha\Delta T$ to the radius of the hoop. The thickness of the space equals the increase in radius of the hoop.

SET UP: The earth has radius $R_{\rm E}=6.38\times10^6$ m and this is the initial radius R_0 of the hoop. For steel, $\alpha=1.2\times10^{-5}\ {\rm K}^{-1}$. 1 K = 1 C°.

EXECUTE: The increase in the radius of the hoop would be

$$\Delta R=R\alpha\Delta T=(6.38\times10^6\ {\rm m})(1.2\times10^{-5}\ {\rm K}^{-1})(0.5\ {\rm K})=38\ {\rm m}.$$

EVALUATE: Even though ΔR is large, the fractional change in radius, $\Delta R/R_0$, is very small.

17.77. **IDENTIFY** and **SET UP:** Use the temperature difference in M° and in C° between the melting and boiling points of mercury to relate M° to C°. Also adjust for the different zero points on the two scales to get an equation for $T_{\rm M}$ in terms of $T_{\rm C}$.

(a) EXECUTE: normal melting point of mercury: $-39°{\rm C}=0.0°{\rm M}$
normal boiling point of mercury: $357°{\rm C}=100.0°{\rm M}$
$100.0\ {\rm M°}=396\ {\rm C°}$ so $1\ {\rm M°}=3.96\ {\rm C°}$

Zero on the M scale is -39 on the C scale, so to obtain $T_{\rm C}$ multiply $T_{\rm M}$ by 3.96 and then subtract 39°:

$T_{\rm C}=3.96T_M-39°$

Solving for $T_{\rm M}$ gives $T_{\rm M}=\frac{1}{3.96}(T_{\rm C}+39°)$

The normal boiling point of water is 100°C; $T_{\rm M}=\frac{1}{3.96}(100°+39°)=35.1°{\rm M}$

(b) $10.0\ {\rm M°}=39.6\ {\rm C°}$

EVALUATE: A M° is larger than a C° since it takes fewer of them to express the difference between the boiling and melting points for mercury.

17.78. **IDENTIFY:** $v=\sqrt{F/\mu}=\sqrt{FL/m}$. For the fundamental, $\lambda=2L$ and $f=\frac{v}{\lambda}=\frac{1}{2}\sqrt{\frac{F}{mL}}$. F, v and λ change when T changes because L changes. $\Delta L=L\alpha\Delta T$, where L is the original length.

SET UP: For copper, $\alpha=1.7\times10^{-5}\ ({\rm C°})^{-1}$.

EXECUTE: **(a)** We can use differentials to find the frequency change because all length changes are small percents. $\Delta f\approx\frac{\partial f}{\partial L}\Delta L$ (only L changes due to heating).

$$\Delta f=\tfrac{1}{2}\tfrac{1}{2}(F/mL)^{-1/2}(F/m)(-1/L^2)\Delta L=-\tfrac{1}{2}\left(\tfrac{1}{2}\sqrt{\frac{F}{mL}}\right)\frac{\Delta L}{L}=-\tfrac{1}{2}f\frac{\Delta L}{L}.$$

$\Delta f=-\frac{1}{2}(\alpha\Delta T)f=-\frac{1}{2}(1.7\times10^{-5}\ ({\rm C°})^{-1})(40\ {\rm C°})(440\ {\rm Hz})=-0.15\ {\rm Hz}$. The frequency decreases since the length increases.

(b) $\Delta v=\frac{\partial v}{\partial L}\Delta L$.

$$\frac{\Delta v}{v}=\frac{\frac{1}{2}(FL/m)^{-1/2}(F/m)\Delta L}{\sqrt{FL/m}}=\frac{\Delta L}{2L}=\frac{\alpha\Delta T}{2}=\frac{1}{2}(1.7\times10^{-5}\ ({\rm C°})^{-1})(40\ {\rm C°})=3.4\times10^{-4}=0.034\%.$$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(c) $\lambda = 2L$ so $\Delta\lambda = 2\Delta L \rightarrow \dfrac{\Delta\lambda}{\lambda} = \dfrac{2\Delta L}{2L} = \dfrac{\Delta L}{L} = \alpha\Delta T.$

$\dfrac{\Delta\lambda}{\lambda} = (1.7\times10^{-5}\ (\text{C°})^{-1})(40\ \text{C°}) = 6.8\times10^{-4} = 0.068\%.$ λ increases.

EVALUATE: The wave speed and wavelength increase when the length increases and the frequency decreases. The percentage change in the frequency is -0.034%. The fractional change in all these quantities is very small.

17.79. **IDENTIFY** and **SET UP:** Use Eq. (17.8) for the volume expansion of the oil and of the cup. Both the volume of the cup and the volume of the olive oil increase when the temperature increases, but β is larger for the oil so it expands more. When the oil starts to overflow, $\Delta V_{\text{oil}} = \Delta V_{\text{glass}} + (2.00\times10^{-3}\ \text{m})A,$ where A is the cross-sectional area of the cup.

EXECUTE: $\Delta V_{\text{oil}} = V_{0,\text{oil}}\beta_{\text{oil}}\Delta T = (9.8\ \text{cm})A\beta_{\text{oil}}\Delta T.$ $\Delta V_{\text{glass}} = V_{0,\text{glass}}\beta_{\text{glass}}\Delta T = (10.0\ \text{cm})A\beta_{\text{glass}}\Delta T.$ $(9.8\ \text{cm})A\beta_{\text{oil}}\Delta T = (10.0\ \text{cm})A\beta_{\text{glass}}\Delta T + (0.200\ \text{cm})A.$ The A divides out. Solving for ΔT gives $\Delta T = 31.3\ \text{C°}.$ $T_2 = T_1 + \Delta T = 53.3°\text{C}.$

EVALUATE: If the expansion of the cup is neglected, the olive oil will have expanded to fill the cup when $(0.200\ \text{cm})A = (9.8\ \text{cm})A\beta_{\text{oil}}\Delta T,$ so $\Delta T = 30.0\ \text{C°}$ and $T_2 = 52.0°\text{C}.$ Our result is slightly higher than this. The cup also expands but not very much since $\beta_{\text{glass}} << \beta_{\text{oil}}.$

17.80. **IDENTIFY:** As the tape changes temperature, the distances between the markings will increase, thus making the readings inaccurate.

SET UP: For steel, $\alpha = 1.2\times10^{-5}\,(\text{C°})^{-1}.$ The two points that match the length of the object are 25.970 m apart at $20.0°\text{C}.$ Find the distance between them at $5.00°\text{C}.$ For linear expansion, $L = L_0(1+\alpha\Delta T).$

EXECUTE: $L = L_0(1+\alpha\Delta T) = (25.970\ \text{m})(1+[1.2\times10^{-5}\,(\text{C°})^{-1}][5.00°\text{C} - 20.0°\text{C}]) = 25.965\ \text{m}.$ The true distance between the points is 25.965 m.

EVALUATE: The error in measurement is 25.970 m – 25.965 m = 0.005 m = 5 mm. This is not likely to be a very serious error in a measurement of nearly 30 m. If greater precision is needed, some sort of laser measuring device would probably be used.

17.81. **IDENTIFY:** Use Eq. (17.6) to find the change in diameter of the sphere and the change in length of the cable. Set the sum of these two increases in length equal to 2.00 mm.

SET UP: $\alpha_{\text{brass}} = 2.0\times10^{-5}\ \text{K}^{-1}$ and $\alpha_{\text{steel}} = 1.2\times10^{-5}\ \text{K}^{-1}.$

EXECUTE: $\Delta L = (\alpha_{\text{brass}}L_{0,\text{brass}} + \alpha_{\text{steel}}L_{0,\text{steel}})\Delta T.$

$$\Delta T = \frac{2.00\times10^{-3}\ \text{m}}{(2.0\times10^{-5}\ \text{K}^{-1})(0.350\ \text{m}) + (1.2\times10^{-5}\ \text{K}^{-1})(10.5\ \text{m})} = 15.0\ \text{C°}.$$ $T_2 = T_1 + \Delta T = 35.0°\text{C}.$

EVALUATE: The change in diameter of the brass sphere is 0.10 mm. This is small, but should not be neglected.

17.82. **IDENTIFY:** Conservation of energy says $Q_e + Q_c = 0,$ where Q_e and Q_c are the heat changes for the ethanol and cylinder. To find the volume of ethanol that overflows calculate ΔV for the ethanol and for the cylinder.

SET UP: For ethanol, $c_e = 2428\ \text{J/kg}\cdot\text{K}$ and $\beta_e = 75\times10^{-5}\ \text{K}^{-1}.$

EXECUTE: **(a)** $Q_e + Q_c = 0$ gives $m_e c_e(T_f - [-10.0°\text{C}]) + m_c c_c(T_f - 20.0°\text{C}) = 0.$

$$T_f = \frac{(20.0°\text{C})m_c c_c - (10.0°\text{C})m_e c_e}{m_e c_e + m_c c_c}.$$

$$T_f = \frac{(20.0°\text{C})(0.110\ \text{kg})(840\ \text{J/kg}\cdot\text{K}) - (10.0°\text{C})(0.0873\ \text{kg})(2428\ \text{J/kg}\cdot\text{K})}{(0.0873\ \text{kg})(2428\ \text{J/kg}\cdot\text{K}) + (0.110\ \text{kg})(840\ \text{J/kg}\cdot\text{K})}.$$

$$T_f = \frac{-271.6°\text{C}}{304.4} = -0.892°\text{C}.$$

(b) $\Delta V_e = \beta_e V_e \Delta T = (75\times10^{-5}\ \text{K}^{-1})(108\ \text{cm}^3)(-0.892°\text{C} - [-10.0°\text{C}]) = +0.738\ \text{cm}^3.$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$\Delta V_c = \beta_c V_c \Delta T = (1.2\times10^{-5}\ \text{K}^{-1})(108\ \text{cm}^3)(-0.892°\text{C} - 20.0°\text{C}) = -0.0271\ \text{cm}^3$. The volume that overflows is $0.738\ \text{cm}^3 - (-0.0271\ \text{cm}^3) = 0.765\ \text{cm}^3$.

EVALUATE: The cylinder cools so its volume decreases. The ethanol warms, so its volume increases. The sum of the magnitudes of the two volume changes gives the volume that overflows.

17.83. **IDENTIFY** and **SET UP:** Call the metals *A* and *B*. Use the data given to calculate α for each metal.

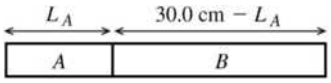
EXECUTE: $\Delta L = L_0 \alpha \Delta T$ so $\alpha = \Delta L/(L_0 \Delta T)$

metal *A*: $\alpha_A = \dfrac{\Delta L}{L_0 \Delta T} = \dfrac{0.0650\ \text{cm}}{(30.0\ \text{cm})(100\ \text{C°})} = 2.167\times10^{-5}\ (\text{C°})^{-1}$

metal *B*: $\alpha_B = \dfrac{\Delta L}{L_0 \Delta T} = \dfrac{0.0350\ \text{cm}}{(30.0\ \text{cm})(100\ \text{C°})} = 1.167\times10^{-5}\ (\text{C°})^{-1}$

EVALUATE: L_0 and ΔT are the same, so the rod that expands the most has the larger α.

IDENTIFY and **SET UP:** Now consider the composite rod (Figure 17.83). Apply Eq. (17.6). The target variables are L_A and L_B, the lengths of the metals *A* and *B* in the composite rod.



$\Delta T = 100\ \text{C°}$
$\Delta L = 0.058\ \text{cm}$

Figure 17.83

EXECUTE: $\Delta L = \Delta L_A + \Delta L_B = (\alpha_A L_A + \alpha_B L_B)\Delta T$

$\Delta L/\Delta T = \alpha_A L_A + \alpha_B (0.300\ \text{m} - L_A)$

$$L_A = \frac{\Delta L/\Delta T - (0.300\ \text{m})\alpha_B}{\alpha_A - \alpha_B} = \frac{(0.058\times10^{-2}\ \text{m/100 C°}) - (0.300\ \text{m})(1.167\times10^{-5}(\text{C°})^{-1})}{1.00\times10^{-5}\ (\text{C°})^{-1}} = 23.0\ \text{cm}$$

$L_B = 30.0\ \text{cm} - L_A = 30.0\ \text{cm} - 23.0\ \text{cm} = 7.0\ \text{cm}$

EVALUATE: The expansion of the composite rod is similar to that of rod *A*, so the composite rod is mostly metal *A*.

17.84. **IDENTIFY:** Apply $\Delta V = V_0 \beta \Delta T$ to the gasoline and to the volume of the tank.

SET UP: For aluminum, $\beta = 7.2\times10^{-5}\ \text{K}^{-1}$. $1\ \text{L} = 10^{-3}\ \text{m}^3$.

EXECUTE: **(a)** The lost volume, 2.6 L, is the difference between the expanded volume of the fuel and the tanks, and the maximum temperature difference is

$$\Delta T = \frac{\Delta V}{(\beta_{\text{fuel}} - \beta_{\text{Al}})V_0} = \frac{(2.6\times10^{-3}\ \text{m}^3)}{(9.5\times10^{-4}\ (\text{C°})^{-1} - 7.2\times10^{-5}\ (\text{C°})^{-1})(106.0\times10^{-3}\ \text{m}^3)} = 28\ \text{C°}.$$

The maximum temperature was 32°C.

(b) No fuel can spill if the tanks are filled just before takeoff.

EVALUATE: Both the volume of the gasoline and the capacity of the tanks increased when *T* increased. But β is larger for gasoline than for aluminum so the volume of the gasoline increased more. When the tanks have returned to 4.0°C on Sunday morning there is 2.6 L of air space in the tanks.

17.85. **IDENTIFY:** The change in length due to heating is $\Delta L_T = L_0 \alpha \Delta T$ and this need not equal ΔL. The change in length due to the tension is $\Delta L_F = \dfrac{FL_0}{AY}$. Set $\Delta L = \Delta L_F + \Delta L_T$.

SET UP: $\alpha_{\text{brass}} = 2.0\times10^{-5}\ (\text{C°})^{-1}$. $\alpha_{\text{steel}} = 1.5\times10^{-5}\ (\text{C°})^{-1}$. $Y_{\text{steel}} = 20\times10^{10}$ Pa.

EXECUTE: **(a)** The change in length is due to the tension and heating. $\dfrac{\Delta L}{L_0} = \dfrac{F}{AY} + \alpha\Delta T$. Solving for *F*/*A*,

$$\frac{F}{A} = Y\left(\frac{\Delta L}{L_0} - \alpha\Delta T\right).$$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) The brass bar is given as "heavy" and the wires are given as "fine," so it may be assumed that the stress in the bar due to the fine wires does not affect the amount by which the bar expands due to the temperature increase. This means that ΔL is not zero, but is the amount $\alpha_{\text{brass}} L_0 \Delta T$ that the brass expands, and so

$$\frac{F}{A} = Y_{\text{steel}}(\alpha_{\text{brass}} - \alpha_{\text{steel}})\Delta T = (20\times10^{10}\text{ Pa})(2.0\times10^{-5}\text{ (C°)}^{-1} - 1.2\times10^{-5}\text{ (C°)}^{-1})(120\text{ C°}) = 1.92\times10^{8}\text{ Pa}.$$

EVALUATE: The length of the brass bar increases more than the length of the steel wires. The wires remain taut and are under tension when the temperature of the system is raised above 20°C.

17.86. **IDENTIFY** and **SET UP:** $v = \sqrt{F/\mu}$. The coefficient of linear expansion α is defined by $\Delta L = L_0 \alpha \Delta T$. This can be combined with $Y = \dfrac{F/A}{\Delta L/L_0}$ to give $\Delta F = -Y\alpha A \Delta T$ for the change in tension when the temperature changes by ΔT. Combine the two equations and solve for α.

EXECUTE: $v_1 = \sqrt{F/\mu}$, $v_1^2 = F/\mu$ and $F = \mu v_1^2$

The length and hence μ stay the same but the tension decreases by $\Delta F = -Y\alpha A \Delta T$.

$v_2 = \sqrt{(F + \Delta F)/\mu} = \sqrt{(F - Y\alpha A \Delta T)/\mu}$

$v_2^2 = F/\mu - Y\alpha A\,\Delta T/\mu = v_1^2 - Y\alpha A\,\Delta T/\mu$

And $\mu = m/L$ so $A/\mu = AL/m = V/m = 1/\rho$. ($A$ is the cross-sectional area of the wire, V is the volume of a length L.) Thus $v_1^2 - v_2^2 = \alpha(Y\Delta T/\rho)$ and $\alpha = \dfrac{v_1^2 - v_2^2}{(Y/\rho)\,\Delta T}$.

EVALUATE: When T increases the tension decreases and v decreases.

17.87. **IDENTIFY:** For a string, $f_n = \dfrac{n}{2L}\sqrt{\dfrac{F}{\mu}}$.

SET UP: For the fundamental, $n = 1$. Solving for F gives $F = \mu 4L^2 f^2$. Note that $\mu = \pi r^2 \rho$, so $\mu = \pi(0.203\times10^{-3}\text{ m})^2(7800\text{ kg/m}^3) = 1.01\times10^{-3}$ kg/m.

EXECUTE: **(a)** $F = (1.01\times10^{-3}\text{ kg/m})4(0.635\text{ m})^2(247.0\text{ Hz})^2 = 99.4$ N

(b) To find the fractional change in the frequency we must take the ratio of Δf to f: $f = \dfrac{1}{2L}\sqrt{\dfrac{F}{\mu}}$ and

$$\Delta f = \Delta\left(\frac{1}{2L}\sqrt{\frac{F}{\mu}}\right) = \Delta\left(\frac{1}{2L\sqrt{\mu}}F^{\frac{1}{2}}\right) = \frac{1}{2L\sqrt{\mu}}\Delta\left(F^{\frac{1}{2}}\right) = \frac{1}{2L\sqrt{\mu}}\frac{1}{2}\frac{\Delta F}{\sqrt{F}}$$

Now divide both sides by the original equation for f and cancel terms: $\dfrac{\Delta f}{f} = \dfrac{\dfrac{1}{2L\sqrt{\mu}}\dfrac{1}{2}\dfrac{\Delta F}{\sqrt{F}}}{\dfrac{1}{2L}\sqrt{\dfrac{F}{\mu}}} = \frac{1}{2}\frac{\Delta F}{F}$.

(c) The coefficient of thermal expansion α is defined by $\Delta l = l_0 \alpha \Delta T$. Combining this with $Y = \dfrac{F/A}{\Delta l/l_0}$ gives $\Delta F = -Y\alpha A \Delta T$. $\Delta F = -(2.00\times10^{11}\text{ Pa})(1.20\times10^{-5}/\text{C°})\pi(0.203\times10^{-3}\text{ m})^2(11\text{ C°}) = -3.4$ N. Then $\Delta F/F - 0.034$, $\Delta f/f = -0.017$ and $\Delta f = -4.2$ Hz. The pitch falls. This also explains the constant tuning in the string sections of symphonic orchestras.

EVALUATE: An increase in temperature causes a decrease in tension of the string, and this lowers the frequency of each standing wave.

17.88. **IDENTIFY:** Apply the equation derived in part (a) of Problem 17.85 to the steel and aluminum sections. The sum of the ΔL values of the two sections must be zero.

SET UP: For steel, $Y = 20\times10^{10}$ Pa and $\alpha = 1.2\times10^{-5}\text{ (C°)}^{-1}$. For aluminum, $Y = 7.0\times10^{10}$ Pa and $\alpha = 2.4\times10^{-5}\text{ (C°)}^{-1}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: In deriving Eq. (17.12), it was assumed that $\Delta L = 0$; if this is not the case when there are both thermal and tensile stresses, Eq. (17.12) becomes $\Delta L = L_0\left(\alpha\Delta T + \frac{F}{AY}\right)$. (See Problem 17.85.) For the situation in this problem, there are two length changes which must sum to zero, and so Eq. (17.12) may be extended to two materials a and b in the form $L_{0\text{a}}\left(\alpha_\text{a}\Delta T + \frac{F}{AY_\text{a}}\right) + L_{0\text{b}}\left(\alpha_\text{b}\Delta T + \frac{F}{AY_\text{b}}\right) = 0$. Note that in the above, ΔT, F and A are the same for the two rods. Solving for the stress F/A,

$\frac{F}{A} = -\frac{\alpha_\text{a}L_{0\text{a}} + \alpha_\text{b}L_{0\text{b}}}{L_{0\text{a}}/Y_\text{a} + L_{0\text{b}}/Y_\text{b}}\Delta T$. Putting in the numbers gives

$$\frac{F}{A} = -\frac{(1.2\times10^{-5}\ (\text{C}^\circ)^{-1})(0.450\ \text{m}) + (2.4\times10^{-5}\ (\text{C}^\circ)^{-1})(0.250\ \text{m})}{(0.450\ \text{m})/(20\times10^{10}\ \text{Pa}) + (0.250\ \text{m})/(7\times10^{10}\ \text{Pa})}(60.0\ \text{C}^\circ) = -1.2\times10^{8}\ \text{Pa}.$$

EVALUATE: F/A is negative and the stress is compressive. If the steel rod was considered alone and its length was held fixed, the stress would be $-Y_\text{steel}\alpha_\text{steel}\Delta T = -1.4\times10^{8}$ Pa. For the aluminum rod alone the stress would be $-Y_\text{aluminum}\alpha_\text{aluminum}\Delta T = -1.0\times10^{8}$ Pa. The stress for the combined rod is the average of these two values.

17.89. **(a) IDENTIFY** and **SET UP:** The diameter of the ring undergoes linear expansion (increases with T) just like a solid steel disk of the same diameter as the hole in the ring. Heat the ring to make its diameter equal to 2.5020 in.

EXECUTE: $\Delta L = \alpha L_0\Delta T$ so $\Delta T = \frac{\Delta L}{L_0\alpha} = \frac{0.0020\ \text{in.}}{(2.5000\ \text{in.})(1.2\times10^{-5}(\text{C}^\circ)^{-1})} = 66.7\ \text{C}^\circ$

$T = T_0 + \Delta T = 20.0^\circ\text{C} + 66.7\ \text{C}^\circ = 87^\circ\text{C}$

(b) IDENTIFY and **SET UP:** Apply the linear expansion equation to the diameter of the brass shaft and to the diameter of the hole in the steel ring.

EXECUTE: $L = L_0(1 + \alpha\Delta T)$

Want L_s (steel) $= L_\text{b}$ (brass) for the same ΔT for both materials: $L_{0\text{s}}(1 + \alpha_\text{s}\Delta T) = L_{0\text{b}}(1 + \alpha_\text{b}\Delta T)$ so

$L_{0\text{s}} + L_{0\text{s}}\alpha_\text{s}\Delta T = L_{0\text{b}} + L_{0\text{b}}\alpha_\text{b}\Delta T$

$$\Delta T = \frac{L_{0\text{b}} - L_{0\text{s}}}{L_{0\text{s}}\alpha_\text{s} - L_{0\text{b}}\alpha_\text{b}} = \frac{2.5020\ \text{in.} - 2.5000\ \text{in.}}{(2.5000\ \text{in.})(1.2\times10^{-5}(\text{C}^\circ)^{-1}) - (2.5050\ \text{in.})(2.0\times10^{-5}(\text{C}^\circ)^{-1})}$$

$$\Delta T = \frac{0.0020}{3.00\times10^{-5} - 5.00\times10^{-5}}\ \text{C}^\circ = -100\ \text{C}^\circ$$

$T = T_0 + \Delta T = 20.0^\circ\text{C} - 100\ \text{C}^\circ = -80^\circ\text{C}$

EVALUATE: Both diameters decrease when the temperature is lowered but the diameter of the brass shaft decreases more since $\alpha_\text{b} > \alpha_\text{s}$; $|\Delta L_\text{b}| - |\Delta L_\text{s}| = 0.0020$ in.

17.90. **IDENTIFY:** Follow the derivation of Eq. (17.12).

SET UP: For steel, the bulk modulus is $B = 1.6\times10^{11}$ Pa and the volume expansion coefficient is $\beta = 3.6\times10^{-5}\ \text{K}^{-1}$.

EXECUTE: **(a)** The change in volume due to the temperature increase is $\beta V\Delta T$, and the change in volume due to the pressure increase is $-\frac{V}{B}\Delta p$. Setting the net change equal to zero,

$\beta V\Delta T = V\frac{\Delta p}{B}$, or $\Delta p = B\beta\Delta T$.

(b) From the above, $\Delta p = (1.6\times10^{11}\ \text{Pa})(3.6\times10^{-5}\ \text{K}^{-1})(15.0\ \text{K}) = 8.6\times10^{7}$ Pa.

EVALUATE: Δp in part (b) is about 850 atm. A small temperature increase corresponds to a very large pressure increase.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

17.91. **IDENTIFY:** Apply Eq. (11.14) to the volume increase of the liquid due to the pressure decrease. Eq. (17.8) gives the volume decrease of the cylinder and liquid when they are cooled. Can think of the liquid expanding when the pressure is reduced and then contracting to the new volume of the cylinder when the temperature is reduced.

SET UP: Let β_l and β_m be the coefficients of volume expansion for the liquid and for the metal. Let ΔT be the (negative) change in temperature when the system is cooled to the new temperature.

EXECUTE: Change in volume of cylinder when cool: $\Delta V_m = \beta_m V_0 \Delta T$ (negative)

Change in volume of liquid when cool: $\Delta V_l = \beta_l V_0 \Delta T$ (negative)

The difference $\Delta V_l - \Delta V_m$ must be equal to the negative volume change due to the increase in pressure, which is $-\Delta p V_0/B = -k\Delta p V_0$. Thus $\Delta V_l - \Delta V_m = -k\Delta p V_0$.

$$\Delta T = -\frac{k\Delta p}{\beta_l - \beta_m}$$

$$\Delta T = -\frac{(8.50\times10^{-10}\ \text{Pa}^{-1})(50.0\ \text{atm})(1.013\times10^5\ \text{Pa/1 atm})}{4.80\times10^{-4}\ \text{K}^{-1} - 3.90\times10^{-5}\ \text{K}^{-1}} = -9.8\ \text{C°}$$

$$T = T_0 + \Delta T = 30.0°\text{C} - 9.8\ \text{C°} = 20.2°\text{C}.$$

EVALUATE: A modest temperature change produces the same volume change as a large change in pressure; $B >> \beta$ for the liquid.

17.92. **IDENTIFY:** $Q_{\text{system}} = 0$. Assume that the normal melting point of iron is above 745°C so the iron initially is solid.

SET UP: For water, $c = 4190\ \text{J/kg}\cdot\text{K}$ and $L_v = 2256\times10^3\ \text{J/kg}$. For solid iron, $c = 470\ \text{J/kg}\cdot\text{K}$.

EXECUTE: The heat released when the iron slug cools to 100°C is $Q = mc\Delta T = (0.1000\ \text{kg})(470\ \text{J/kg}\cdot\text{K})(645\ \text{K}) = 3.03\times10^4\ \text{J}$. The heat absorbed when the temperature of the water is raised to 100°C is $Q = mc\Delta T = (0.0850\ \text{kg})(4190\ \text{J/kg}\cdot\text{K})(80.0\ \text{K}) = 2.85\times10^4\ \text{J}$. This is less than the heat released from the iron and $3.03\times10^4\ \text{J} - 2.85\times10^4\ \text{J} = 1.81\times10^3\ \text{J}$ of heat is available for converting some of the liquid water at 100°C to vapor. The mass *m* of water that boils is

$$m = \frac{1.81\times10^3\ \text{J}}{2256\times10^3\ \text{J/kg}} = 8.01\times10^{-4}\ \text{kg} = 0.801\ \text{g}.$$

(a) The final temperature is 100°C.

(b) There is $85.0\ \text{g} - 0.801\ \text{g} = 84.2\ \text{g}$ of liquid water remaining, so the final mass of the iron and remaining water is 184.2 g.

EVALUATE: If we ignore the phase change of the water and write $m_{\text{iron}}c_{\text{iron}}(T - 745°\text{C}) + m_{\text{water}}c_{\text{water}}(T - 20.0°\text{C}) = 0$, when we solve for *T* we will get a value slightly larger than 100°C. That result is unphysical and tells us that some of the water changes phase.

17.93. **(a) IDENTIFY:** Calculate *K*/*Q*. We don't know the mass *m* of the spacecraft, but it divides out of the ratio.

SET UP: The kinetic energy is $K = \frac{1}{2}mv^2$. The heat required to raise its temperature by 600 C° (but not to melt it) is $Q = mc\Delta T$.

EXECUTE: The ratio is $\frac{K}{Q} = \frac{\frac{1}{2}mv^2}{mc\Delta T} = \frac{v^2}{2c\Delta T} = \frac{(7700\ \text{m/s})^2}{2(910\ \text{J/kg}\cdot\text{K})(600\ \text{C°})} = 54.3.$

(b) EVALUATE: The heat generated when friction work (due to friction force exerted by the air) removes the kinetic energy of the spacecraft during reentry is very large, and could melt the spacecraft. Manned space vehicles must have heat shields made of very high melting temperature materials, and reentry must be made slowly.

17.94. **IDENTIFY:** The rate at which thermal energy is being generated equals the rate at which the net torque due to the rope is doing work. The energy input associated with a temperature change is $Q = mc\Delta T$.

SET UP: The rate at which work is being done is $P = \tau\omega$. For iron, $c = 470\ \text{J/kg}\cdot\text{K}$. $1\ \text{C°} = 1\ \text{K}$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: **(a)** The net torque that the rope exerts on the capstan, and hence the net torque that the capstan exerts on the rope, is the difference between the forces of the ends of the rope times the radius of the capstan. The capstan is doing work on the rope at a rate

$P = \tau\omega = F_{\text{net}} r \dfrac{2\pi \text{ rad}}{T} = (520 \text{ N})(5.0\times10^{-2} \text{ m})\dfrac{2\pi \text{ rad}}{(0.90 \text{ s})} = 182 \text{ W},$ or 180 W to two figures. A larger number of turns might increase the force, but for given forces, the torque is independent of the number of turns.

(b) $\dfrac{\Delta T}{t} = \dfrac{Q/t}{mc} = \dfrac{P}{mc} = \dfrac{(182 \text{ W})}{(6.00 \text{ kg})(470 \text{ J/kg}\cdot\text{K})} = 0.064 \text{ C°/s}.$

EVALUATE: The rate of temperature rise is proportional to the difference in tension between the ends of the rope and to the rate at which the capstan is rotating.

17.95. **IDENTIFY** and **SET UP:** To calculate Q, use Eq. (17.18) in the form $dQ = nC\,dT$ and integrate, using $C(T)$ given in the problem. C_{av} is obtained from Eq. (17.19) using the finite temperature range instead of an infinitesimal dT.

EXECUTE: **(a)** $dQ = nCdT$

$$Q = n\int_{T_1}^{T_2} C\,dT = n\int_{T_1}^{T_2} k(T^3/\Theta^3)dT = (nk/\Theta^3)\int_{T_1}^{T_2} T^3\,dt = (nk/\Theta^3)\left(\tfrac{1}{4}T^4\Big|_{T_1}^{T_2}\right)$$

$$Q = \frac{nk}{4\Theta^3}(T_2^4 - T_1^4) = \frac{(1.50 \text{ mol})(1940 \text{ J/mol}\cdot\text{K})}{4(281 \text{ K})^3}((40.0 \text{ K})^4 - (10.0 \text{ K})^4) = 83.6 \text{ J}$$

(b) $C_{\text{av}} = \dfrac{1}{n}\dfrac{\Delta Q}{\Delta T} = \dfrac{1}{1.50 \text{ mol}}\left(\dfrac{83.6 \text{ J}}{40.0 \text{ K} - 10.0 \text{ K}}\right) = 1.86 \text{ J/mol}\cdot\text{K}$

(c) $C = k(T/\Theta)^3 = (1940 \text{ J/mol}\cdot\text{K})(40.0 \text{ K}/281 \text{ K})^3 = 5.60 \text{ J/mol}\cdot\text{K}$

EVALUATE: C is increasing with T, so C at the upper end of the temperature integral is larger than its average value over the interval.

17.96. **IDENTIFY:** For a temperature change, $Q = mc\Delta T$, and for the liquid $\rightarrow$ solid phase change, $Q = -mL_{\text{f}}$.

SET UP: The volume V_{w} of the water determines its mass. $m_{\text{w}} = \rho_{\text{w}} V_{\text{w}}$. For water, $\rho_{\text{w}} = 1000 \text{ kg/m}^3$, $c = 4190 \text{ J/kg}\cdot\text{K}$ and $L_{\text{f}} = 334\times10^3 \text{ J/kg}$.

EXECUTE: Set the heat energy that flows into the water equal to the final gravitational potential energy. $L_{\text{f}}\rho_{\text{w}}V_{\text{w}} + c_{\text{w}}\rho_{\text{w}}V_{\text{w}}\Delta T = mgh$. Solving for h gives

$$h = \frac{(1000 \text{ kg/m}^3)(1.9\times0.80\times0.160 \text{ m}^3)[334\times10^3 \text{ J/kg} + (4190 \text{ J/kg}\cdot\text{K})(37 \text{ C°})]}{(70 \text{ kg})(9.8 \text{ m/s}^2)}.$$

$h = 1.73\times10^5 \text{ m} = 173 \text{ km}.$

EVALUATE: The heat associated with temperature and phase changes corresponds to a very large amount of mechanical energy.

17.97. **IDENTIFY:** Apply $Q = mc\Delta T$ to the air in the room.

SET UP: The mass of air in the room is $m = \rho V = (1.20 \text{ kg/m}^3)(3200 \text{ m}^3) = 3840 \text{ kg}$. 1 W = 1 J/s.

EXECUTE: **(a)** $Q = (3000 \text{ s})(90 \text{ students})(100 \text{ J/s}\cdot\text{student}) = 2.70\times10^7 \text{ J}.$

(b) $Q = mc\Delta T.$ $\Delta T = \dfrac{Q}{mc} = \dfrac{2.70\times10^7 \text{ J}}{(3840 \text{ kg})(1020 \text{ J/kg}\cdot\text{K})} = 6.89 \text{ C°}$

(c) $\Delta T = (6.89 \text{ C°})\left(\dfrac{280 \text{ W}}{100 \text{ W}}\right) = 19.3 \text{ C°}.$

EVALUATE: In the absence of a cooling mechanism for the air, the air temperature would rise significantly.

17.98. **IDENTIFY:** $dQ = nCdT$ so for the temperature change $T_1 \rightarrow T_2$, $Q = n\int_{T_1}^{T_2} C(T)dT$.

SET UP: $\int dT = T$ and $\int TdT = \frac{1}{2}T^2$. Express T_1 and T_2 in kelvins: $T_1 = 300 \text{ K}$, $T_2 = 500 \text{ K}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: Denoting C by $C = a + bT$, a and b independent of temperature, integration gives

$Q = n(a(T_2 - T_1) + \frac{b}{2}(T_2^2 - T_1^2))$.

$Q = (3.00 \text{ mol})[(29.5 \text{ J/mol} \cdot \text{K})(500 \text{ K} - 300 \text{ K}) + (4.10 \times 10^{-3} \text{ J/mol} \cdot \text{K}^2)((500 \text{ K})^2 - (300 \text{ K})^2)]$.

$Q = 1.97 \times 10^4$ J.

EVALUATE: If C is assumed to have the constant value 29.5 J/mol·K, then $Q = 1.77 \times 10^4$ J for this temperature change. At $T_1 = 300$ K, $C = 32.0$ J/mol·K and at $T_2 = 500$ K, $C = 33.6$ J/mol·K. The average value of C is 32.8 J/mol·K. If C is assumed to be constant and to have this average value, then $Q = 1.97 \times 10^4$ J, which is equal to the correct value.

17.99. **IDENTIFY:** Use $Q = mL_f$ to find the heat that goes into the ice to melt it. This amount of heat must be conducted through the walls of the box; $Q = Ht$. Assume the surfaces of the styrofoam have temperatures of 5.00°C and 21.0°C.

SET UP: For water $L_f = 334 \times 10^3$ J/kg. For styrofoam $k = 0.01$ W/m·K. One week is 6.048×10^5 s. The surface area of the box is $4(0.500 \text{ m})(0.800 \text{ m}) + 2(0.500 \text{ m})^2 = 2.10 \text{ m}^2$.

EXECUTE: $Q = mL_f = (24.0 \text{ kg})(334 \times 10^3 \text{ J/kg}) = 8.016 \times 10^6$ J. $H = kA\frac{T_H - T_C}{L}$. $Q = Ht$ gives

$$L = \frac{tkA(T_H - T_C)}{Q} = \frac{(6.048 \times 10^5 \text{ s})(0.01 \text{ W/m} \cdot \text{K})(2.10 \text{ m}^2)(21.0°\text{C} - 5.00°\text{C})}{8.016 \times 10^6 \text{ J}} = 2.5 \text{ cm}$$

EVALUATE: We have assumed that the liquid water that is produced by melting the ice remains in thermal equilibrium with the ice so has a temperature of 0°C. The interior of the box and the ice are not in thermal equilibrium, since they have different temperatures.

17.100. **IDENTIFY:** For a temperature change $Q = mc\Delta T$. For the vapor → liquid phase transition, $Q = -mL_v$.

SET UP: For water, $c = 4190$ J/kg·K and $L_v = 2256 \times 10^3$ J/kg.

EXECUTE: The requirement that the heat supplied in each case is the same gives $m_w c_w \Delta T_w = m_s(c_w \Delta T_s + L_v)$, where $\Delta T_w = 42.0$ K and $\Delta T_s = 65.0$ K. The ratio of the masses is

$$\frac{m_s}{m_w} = \frac{c_w \Delta T_w}{c_w \Delta T_s + L_v} = \frac{(4190 \text{ J/kg} \cdot \text{K})(42.0 \text{ K})}{(4190 \text{ J/kg} \cdot \text{K})(65.0 \text{ K}) + 2256 \times 10^3 \text{ J/kg}} = 0.0696,$$

so 0.0696 kg of steam supplies the same heat as 1.00 kg of water.

EVALUATE: Note the heat capacity of water is used to find the heat lost by the condensed steam, since the phase transition produces liquid water at an initial temperature of 100°C.

17.101. **(a) IDENTIFY** and **SET UP:** Assume that all the ice melts and that all the steam condenses. If we calculate a final temperature T that is outside the range 0°C to 100°C then we know that this assumption is incorrect. Calculate Q for each piece of the system and then set the total $Q_{system} = 0$.

EXECUTE: copper can (changes temperature from 0.0° to T; no phase change)

$Q_{can} = mc\Delta T = (0.446 \text{ kg})(390 \text{ J/kg} \cdot \text{K})(T - 0.0°\text{C}) = (173.9 \text{ J/K})T$

ice (melting phase change and then the water produced warms to T)

$Q_{ice} = +mL_f + mc\Delta T = (0.0950 \text{ kg})(334 \times 10^3 \text{ J/kg}) + (0.0950 \text{ kg})(4190 \text{ J/kg} \cdot \text{K})(T - 0.0°\text{C})$

$Q_{ice} = 3.173 \times 10^4 \text{ J} + (398.0 \text{ J/K})T$.

steam (condenses to liquid and then water produced cools to T)

$Q_{steam} = -mL_v + mc\Delta T = -(0.0350 \text{ kg})(2256 \times 10^3 \text{ J/kg}) + (0.0350 \text{ kg})(4190 \text{ J/kg} \cdot \text{K})(T - 100.0°\text{C})$

$Q_{steam} = -7.896 \times 10^4 \text{ J} + (146.6 \text{ J/K})T - 1.466 \times 10^4 \text{ J} = -9.362 \times 10^4 \text{ J} + (146.6 \text{ J/K})T$

$Q_{system} = 0$ implies $Q_{can} + Q_{ice} + Q_{steam} = 0$.

$(173.9 \text{ J/K})T + 3.173 \times 10^4 \text{ J} + (398.0 \text{ J/K})T - 9.362 \times 10^4 \text{ J} + (146.6 \text{ J/K})T = 0$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$(718.5 \text{ J/K})T = 6.189\times10^4 \text{ J}$

$$T = \frac{6.189\times10^4 \text{ J}}{718.5 \text{ J/K}} = 86.1°\text{C}$$

EVALUATE: This is between 0°C and 100°C so our assumptions about the phase changes being complete were correct.

(b) No ice, no steam and $0.0950 \text{ kg} + 0.0350 \text{ kg} = 0.130 \text{ kg}$ of liquid water.

17.102. **IDENTIFY:** The final amount of ice is less than the initial mass of water, so water remains and the final temperature is 0°C. The ice added warms to 0°C and heat comes out of water to convert that water to ice. Conservation of energy says $Q_\text{i} + Q_\text{w} = 0$, where Q_i and Q_w are the heat flows for the ice that is added and for the water that freezes.

SET UP: Let m_i be the mass of ice that is added and m_w is the mass of water that freezes. The mass of ice increases by 0.418 kg, so $m_\text{i} + m_\text{w} = 0.418$ kg. For water, $L_\text{f} = 334\times10^3$ J/kg and for ice $c_\text{i} = 2100 \text{ J/kg}\cdot\text{K}$. Heat comes out of the water when it freezes, so $Q_\text{w} = -mL_\text{f}$.

EXECUTE: $Q_\text{i} + Q_\text{w} = 0$ gives $m_\text{i}c_\text{i}(15.0 \text{ C°}) + (-m_\text{w}L_\text{f}) = 0$, $m_\text{w} = 0.418 \text{ kg} - m_\text{i}$, so $m_\text{i}c_\text{i}(15.0 \text{ C°}) + (-0.418 \text{ kg} + m_\text{i})L_\text{f} = 0$.

$$m_\text{i} = \frac{(0.418 \text{ kg})L_\text{f}}{c_\text{i}(15.0 \text{ C°}) + L_\text{f}} = \frac{(0.418 \text{ kg})(334\times10^3 \text{ J/kg})}{(2100 \text{ J/kg}\cdot\text{K})(15.0 \text{ K}) + 334\times10^3 \text{ J/kg}} = 0.382 \text{ kg}.$$

0.382 kg of ice was added.

EVALUATE: The mass of water that froze when the ice at -15.0C° was added was $0.868 \text{ kg} - 0.450 \text{ kg} - 0.382 \text{ kg} = 0.036 \text{ kg}$.

17.103. **IDENTIFY** and **SET UP:** Heat comes out of the steam when it changes phase and heat goes into the water and causes its temperature to rise. $Q_\text{system} = 0$. First determine what phases are present after the system has come to a uniform final temperature.

(a) EXECUTE: Heat that must be removed from steam if all of it condenses is

$Q = -mL_\text{v} = -(0.0400 \text{ kg})(2256\times10^3 \text{ J/kg}) = -9.02\times10^4 \text{ J}$

Heat absorbed by the water if it heats all the way to the boiling point of 100°C:

$Q = mc\Delta T = (0.200 \text{ kg})(4190 \text{ J/kg}\cdot\text{K})(50.0 \text{ C°}) = 4.19\times10^4 \text{ J}$

EVALUATE: The water can't absorb enough heat for all the steam to condense. Steam is left and the final temperature then must be 100°C.

(b) EXECUTE: Mass of steam that condenses is $m = Q/L_\text{v} = 4.19\times10^4 \text{ J}/2256\times10^3 \text{ J/kg} = 0.0186 \text{ kg}$. Thus there is $0.0400 \text{ kg} - 0.0186 \text{ kg} = 0.0214 \text{ kg}$ of steam left. The amount of liquid water is $0.0186 \text{ kg} + 0.200 \text{ kg} = 0.219 \text{ kg}$.

17.104. **IDENTIFY:** Heat is conducted out of the body. At steady state, the rate of heat flow is the same in both layers (fat and fur).

SET UP: Let the temperature of the fat-air boundary be T. A section of the two layers is sketched in Figure 17.104. A Kelvin degree is the same size as a Celsius degree, so $\text{W/m}\cdot\text{K}$ and $\text{W/m}\cdot\text{C°}$ are equivalent units. At steady state the heat current through each layer is equal to 50 W. The area of each layer is $A = 4\pi r^2$, with $r = 0.75$ m.

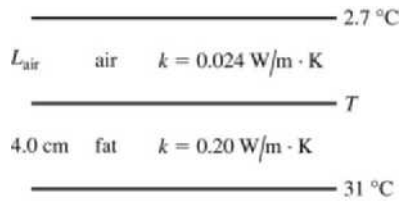


Figure 17.104

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: **(a)** Apply $H = kA\dfrac{T_H - T_C}{L}$ to the fat layer and solve for $T_C = T$. For the fat layer $T_H = 31°C$.

$$T = T_H - \frac{HL}{kA} = 31°C - \frac{(50\text{ W})(4.0\times10^{-2}\text{ m})}{(0.20\text{ W/m}\cdot\text{K})(4\pi)(0.75\text{ m})^2} = 31°C - 1.4°C = 29.6°C.$$

(b) Apply $H = kA\dfrac{T_H - T_C}{L}$ to the air layer and solve for $L = L_{air}$. For the air layer $T_H = T = 29.6°C$ and $T_C = 2.7°C$. $L = \dfrac{kA(T_H - T_C)}{H} = \dfrac{(0.024\text{ W/m}\cdot\text{K})(4\pi)(0.75\text{ m})^2(29.6°C - 2.7°C)}{50\text{ W}} = 9.1\text{ cm}.$

EVALUATE: The thermal conductivity of air is much lass than the thermal conductivity of fat, so the temperature gradient for the air must be much larger to achieve the same heat current. So, most of the temperature difference is across the air layer.

17.105. **IDENTIFY:** Heat Q_l comes out of the lead when it solidifies and the solid lead cools to T_f. If mass m_s of steam is produced, the final temperature is $T_f = 100°C$ and the heat that goes into the water is $Q_w = m_w c_w(25.0\text{ C°}) + m_s L_{v,w}$, where $m_w = 0.5000$ kg. Conservation of energy says $Q_l + Q_w = 0$. Solve for m_s. The mass that remains is $1.250\text{ kg} + 0.5000\text{ kg} - m_s$.

SET UP: For lead, $L_{f,l} = 24.5\times10^3$ J/kg, $c_l = 130\text{ J/kg}\cdot\text{K}$ and the normal melting point of lead is 327.3°C. For water, $c_w = 4190\text{ J/kg}\cdot\text{K}$ and $L_{v,w} = 2256\times10^3$ J/kg.

EXECUTE: $Q_l + Q_w = 0$. $-m_l L_{f,l} + m_l c_l(-227.3\text{ C°}) + m_w c_w(25.0\text{ C°}) + m_s L_{v,w} = 0$.

$$m_s = \frac{m_l L_{f,l} + m_l c_l(+227.3\text{ C°}) - m_w c_w(25.0\text{ C°})}{L_{v,w}}.$$

$$m_s = \frac{+(1.250\text{ kg})(24.5\times10^3\text{ J/kg}) + (1.250\text{ kg})(130\text{ J/kg}\cdot\text{K})(227.3\text{ K}) - (0.5000\text{ kg})(4190\text{ J/kg}\cdot\text{K})(25.0\text{ K})}{2256\times10^3\text{ J/kg}}$$

$$m_s = \frac{1.519\times10^4\text{ J}}{2256\times10^3\text{ J/kg}} = 0.0067\text{ kg}.$$ The mass of water and lead that remains is 1.743 kg.

EVALUATE: The magnitude of heat that comes out of the lead when it goes from liquid at 327.3°C to solid at 100.0°C is 6.76×10^4 J. The heat that goes into the water to warm it to 100°C is 5.24×10^4 J. The additional heat that goes into the water, $6.76\times10^4\text{ J} - 5.24\times10^4\text{ J} = 1.52\times10^4\text{ J}$ converts 0.0067 kg of water at 100°C to steam.

17.106. **IDENTIFY:** Apply $H = kA\dfrac{\Delta T}{L}$ and solve for *k*.

SET UP: *H* equals the power input required to maintain a constant interior temperature.

EXECUTE: $k = H\dfrac{L}{A\Delta T} = (180\text{ W})\dfrac{(3.9\times10^{-2}\text{ m})}{(2.18\text{ m}^2)(65.0\text{ K})} = 5.0\times10^{-2}\text{ W/m}\cdot\text{K}.$

EVALUATE: Our result is consistent with the values for insulating solids in Table 17.5.

17.107. **IDENTIFY:** Apply $H = kA\dfrac{\Delta T}{L}$.

SET UP: For the glass use $L = 12.45$ cm, to account for the thermal resistance of the air films on either side of the glass.

EXECUTE: **(a)** $H = (0.120\text{ W/m}\cdot\text{K})\ (2.00\times0.95\text{ m}^2)\left(\dfrac{28.0\text{ C°}}{5.0\times10^{-2}\text{ m} + 1.8\times10^{-2}\text{ m}}\right) = 93.9\text{ W}.$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) The heat flow through the wood part of the door is reduced by a factor of $1-\dfrac{(0.50)^2}{(2.00\times 0.95)}=0.868,$ so it becomes 81.5 W. The heat flow through the glass is

$H_{\text{glass}}=(0.80\text{ W/m}\cdot\text{K})(0.50\text{ m})^2\left(\dfrac{28.0\text{ C°}}{12.45\times10^{-2}\text{ m}}\right)=45.0\text{ W},$ and so the ratio is $\dfrac{81.5+45.0}{93.9}=1.35.$

EVALUATE: The single-pane window produces a significant increase in heat loss through the door. (See Problem 17.109).

17.108. **IDENTIFY:** Apply Eq. (17.23).

SET UP: Let $\Delta T_1=\dfrac{HR_1}{A}$ be the temperature difference across the wood and let $\Delta T_2=\dfrac{HR_2}{A}$ be the temperature difference across the insulation. The temperature difference across the combination is $\Delta T=\Delta T_1+\Delta T_2.$ The effective thermal resistance R of the combination is defined by $\Delta T=\dfrac{HR}{A}.$

EXECUTE: $\Delta T=\Delta T_1+\Delta T_2$ gives $\dfrac{H}{A}(R_1+R_2)=\dfrac{H}{A}R,$ and $R=R_1+R_2.$

EVALUATE: A good insulator has a large value of R. R for the combination is larger than the R for any one of the layers.

17.109. **IDENTIFY** and **SET UP:** Use H written in terms of the thermal resistance R: $H=A\Delta T/R,$ where $R=L/k$ and $R=R_1+R_2+\ldots$ (additive).

EXECUTE: <u>single pane</u> $R_{\text{s}}=R_{\text{glass}}+R_{\text{film}},$ where $R_{\text{film}}=0.15\text{ m}^2\cdot\text{K/W}$ is the combined thermal resistance of the air films on the room and outdoor surfaces of the window.

$R_{\text{glass}}=L/k=(4.2\times10^{-3}\text{ m})/(0.80\text{ W/m}\cdot\text{K})=0.00525\text{ m}^2\cdot\text{K/W}$

Thus $R_{\text{s}}=0.00525\text{ m}^2\cdot\text{K/W}+0.15\text{ m}^2\cdot\text{K/W}=0.1553\text{ m}^2\cdot\text{K/W}.$

<u>double pane</u> $R_{\text{d}}=2R_{\text{glass}}+R_{\text{air}}+R_{\text{film}},$ where R_{air} is the thermal resistance of the air space between the panes. $R_{\text{air}}=L/k=(7.0\times10^{-3}\text{ m})/(0.024\text{ W/m}\cdot\text{K})=0.2917\text{ m}^2\cdot\text{K/W}$

Thus $R_{\text{d}}=2(0.00525\text{ m}^2\cdot\text{K/W})+0.2917\text{ m}^2\cdot\text{K/W}+0.15\text{ m}^2\cdot\text{K/W}=0.4522\text{ m}^2\cdot\text{K/W}$

$H_{\text{s}}=A\Delta T/R_{\text{s}},\ H_{\text{d}}=A\Delta T/R_{\text{d}},$ so $H_{\text{s}}/H_{\text{d}}=R_{\text{d}}/R_{\text{s}}$ (since A and ΔT are same for both)

$H_{\text{s}}/H_{\text{d}}=(0.4522\text{ m}^2\cdot\text{K/W})/(0.1553\text{ m}^2\cdot\text{K/W})=2.9$

EVALUATE: The heat loss is about a factor of 3 less for the double-pane window. The increase in R for a double-pane is due mostly to the thermal resistance of the air space between the panes.

17.110. **IDENTIFY:** Apply $H=\dfrac{kA\Delta T}{L}$ to each rod. Conservation of energy requires that the heat current through the copper equals the sum of the heat currents through the brass and the steel.

SET UP: Denote the quantities for copper, brass and steel by 1, 2 and 3, respectively, and denote the temperature at the junction by T_0.

EXECUTE: (a) $H_1=H_2+H_3.$ Using Eq. (17.21) and dividing by the common area gives

$\dfrac{k_1}{L_1}(100°\text{C}-T_0)=\dfrac{k_2}{L_2}T_0+\dfrac{k_3}{L_3}T_0.$ Solving for T_0 gives $T_0=\dfrac{(k_1/L_1)}{(k_1/L_1)+(k_2/L_2)+(k_3/L_3)}(100°\text{C}).$ Substitution of numerical values gives $T_0=78.4°\text{C}.$

(b) Using $H=\dfrac{kA}{L}\Delta T$ for each rod, with $\Delta T_1=21.6\text{ C°},\ \Delta T_2=\Delta T_3=78.4\text{ C°}$ gives

$H_1=12.8\text{ W}, H_2=9.50\text{ W}$ and $H_3=3.30\text{ W}.$

EVALUATE: In part (b), H_1 is seen to be the sum of H_2 and H_3.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

17.111. **(a) EXECUTE:** Heat must be conducted from the water to cool it to 0°C and to cause the phase transition. The entire volume of water is not at the phase transition temperature, just the upper surface that is in contact with the ice sheet.

(b) IDENTIFY: The heat that must leave the water in order for it to freeze must be conducted through the layer of ice that has already been formed.

SET UP: Consider a section of ice that has area A. At time t let the thickness be h. Consider a short time interval t to $t + dt$. Let the thickness that freezes in this time be dh. The mass of the section that freezes in the time interval dt is $dm = \rho\, dV = \rho A\, dh$. The heat that must be conducted away from this mass of water to freeze it is $dQ = dmL_f = (\rho AL_f)dh$. $H = dQ/dt = kA(\Delta T/h)$, so the heat dQ conducted in time dt throughout the thickness h that is already there is $dQ = kA\left(\dfrac{T_H - T_C}{h}\right)dt$. Solve for dh in terms of dt and integrate to get an expression relating h and t.

EXECUTE: Equate these expressions for dQ.

$$\rho AL_f dh = kA\left(\frac{T_H - T_C}{h}\right)dt$$

$$h\, dh = \left(\frac{k(T_H - T_C)}{\rho L_f}\right)dt$$

Integrate from $t = 0$ to time t. At $t = 0$ the thickness h is zero.

$$\int_0^h h\, dh = [k(T_H - T_C)/\rho L_f]\int_0^t dt$$

$$\tfrac{1}{2}h^2 = \frac{k(T_H - T_C)}{\rho L_f}t \text{ and } h = \sqrt{\frac{2k(T_H - T_C)}{\rho L_f}}\sqrt{t}$$

The thickness after time t is proportional to $\sqrt{t}$.

(c) The expression in part (b) gives $t = \dfrac{h^2\rho L_f}{2k(T_H - T_C)} = \dfrac{(0.25\text{ m})^2(920\text{ kg/m}^3)(334\times10^3\text{ J/kg})}{2(1.6\text{ W/m}\cdot\text{K})(0°\text{C} - (-10°\text{C}))} = 6.0\times10^5\text{ s}$

$t = 170$ h.

(d) Find t for $h = 40$ m. t is proportional to h^2, so $t = (40\text{ m}/0.25\text{ m})^2(6.00\times10^5\text{ s}) = 1.5\times10^{10}$ s. This is about 500 years. With our current climate this will not happen.

EVALUATE: As the ice sheet gets thicker, the rate of heat conduction through it decreases. Part (d) shows that it takes a very long time for a moderately deep lake to totally freeze.

17.112. **IDENTIFY:** Apply Eq. (17.22) at each end of the short element. In part (b) use the fact that the net heat current into the element provides the Q for the temperature increase, according to $Q = mc\Delta T$.

SET UP: dT/dx is the temperature gradient.

EXECUTE: **(a)** $H = (380\text{ W/m}\cdot\text{K})(2.50\times10^{-4}\text{ m}^2)(140\text{ C°/m}) = 13.3\text{ W}$.

(b) Denoting the two ends of the element as 1 and 2, $H_2 - H_1 = \dfrac{Q}{t} = mc\dfrac{\Delta T}{t}$, where $\dfrac{\Delta T}{t} = 0.250$ C°/s.

$kA\left.\dfrac{dT}{dx}\right|_2 - kA\left.\dfrac{dT}{dx}\right|_1 = mc\left(\dfrac{\Delta T}{t}\right)$. The mass m is $\rho A\Delta x$, so $\left.\dfrac{dT}{dx}\right|_2 = \left.\dfrac{dT}{dx}\right|_1 + \dfrac{\rho c\Delta x}{k}\left(\dfrac{\Delta T}{t}\right)$.

$$kA\left.\frac{dT}{dx}\right|_2 = 140\text{ C°/m} + \frac{(1.00\times10^4\text{ kg/m}^3)(520\text{ J/kg}\cdot\text{K})(1.00\times10^{-2}\text{ m})(0.250\text{ C°/s})}{380\text{ W/m}\cdot\text{K}} = 174\text{ C°/m}.$$

EVALUATE: At steady-state the temperature of the short element is no longer changing and $H_1 = H_2$.

17.113. **IDENTIFY:** The rate of heat conduction through the walls is 1.25 kW. Use the concept of thermal resistance and the fact that when insulating materials are in layers, the R values are additive.

SET UP: The total area of the four walls is $2(3.50\text{ m})(2.50\text{ m}) + 2(3.00\text{ m})(2.50\text{ m}) = 32.5\text{ m}^2$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: $H = A\dfrac{T_H - T_C}{R}$ gives $R = \dfrac{A(T_H - T_C)}{H} = \dfrac{(32.5\ \text{m}^2)(17.0\ \text{K})}{1.25\times10^3\ \text{W}} = 0.442\ \text{m}^2\cdot\text{K/W}$. For the wood,

$R_w = \dfrac{L}{k} = \dfrac{1.80\times10^{-2}\ \text{m}}{0.060\ \text{W/m}\cdot\text{K}} = 0.300\ \text{m}^2\cdot\text{K/W}$. For the insulating material, $R_{in} = R - R_w = 0.142\ \text{m}^2\cdot\text{K/W}$.

$R_{in} = \dfrac{L_{in}}{k_{in}}$ and $k_{in} = \dfrac{L_{in}}{R_{in}} = \dfrac{1.50\times10^{-2}\ \text{m}}{0.142\ \text{m}^2\cdot\text{K/W}} = 0.106\ \text{W/m}\cdot\text{K}$.

EVALUATE: The thermal conductivity of the insulating material is larger than that of the wood, the thickness of the insulating material is less than that of the wood, and the thermal resistance of the wood is about three times that of the insulating material.

17.114. **IDENTIFY:** $I_1 r_1^2 = I_2 r_2^2$. Apply $H = Ae\sigma T^4$ (Eq. 17.25) to the sun.

SET UP: $I_1 = 1.50\times10^3\ \text{W/m}^2$ when $r = 1.50\times10^{11}\ \text{m}$.

EXECUTE: **(a)** The energy flux at the surface of the sun is

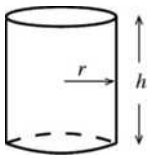
$$I_2 = (1.50\times10^3\ \text{W/m}^2)\left(\frac{1.50\times10^{11}\ \text{m}}{6.96\times10^8\ \text{m}}\right)^2 = 6.97\times10^7\ \text{W/m}^2.$$

(b) Solving Eq. (17.25) with $e = 1$, $T = \left[\dfrac{H}{A}\dfrac{1}{\sigma}\right]^{\frac{1}{4}} = \left[\dfrac{6.97\times10^7\ \text{W/m}^2}{5.67\times10^{-8}\ \text{W/m}^2\cdot\text{K}^4}\right]^{\frac{1}{4}} = 5920\ \text{K}$.

EVALUATE: The total power output of the sun is $P = 4\pi r_2^2 I_2 = 4\times10^{26}\ \text{W}$.

17.115. **IDENTIFY** and **SET UP:** Use Eq. (17.26) to find the net heat current into the can due to radiation. Use $Q = Ht$ to find the heat that goes into the liquid helium, set this equal to mL and solve for the mass m of helium that changes phase.

EXECUTE: Calculate the net rate of radiation of heat from the can. $H_{net} = Ae\sigma(T^4 - T_s^4)$.



The surface area of the cylindrical can is $A = 2\pi rh + 2\pi r^2$. (See Figure 17.115.)

Figure 17.115

$A = 2\pi r(h + r) = 2\pi(0.045\ \text{m})(0.250\ \text{m} + 0.045\ \text{m}) = 0.08341\ \text{m}^2$.

$H_{net} = (0.08341\ \text{m}^2)(0.200)(5.67\times10^{-8}\ \text{W/m}^2\cdot\text{K}^4)((4.22\ \text{K})^4 - (77.3\ \text{K})^4)$

$H_{net} = -0.0338\ \text{W}$ (the minus sign says that the net heat current is into the can). The heat that is put into the can by radiation in one hour is $Q = -(H_{net})t = (0.0338\ \text{W})(3600\ \text{s}) = 121.7\ \text{J}$. This heat boils a mass m of helium according to the equation $Q = mL_f$, so $m = \dfrac{Q}{L_f} = \dfrac{121.7\ \text{J}}{2.09\times10^4\ \text{J/kg}} = 5.82\times10^{-3}\ \text{kg} = 5.82\ \text{g}$.

EVALUATE: In the expression for the net heat current into the can the temperature of the surroundings is raised to the fourth power. The rate at which the helium boils away increases by about a factor of $(293/77)^4 = 210$ if the walls surrounding the can are at room temperature rather than at the temperature of the liquid nitrogen.

17.116. **IDENTIFY:** The nonmechanical part of the basal metabolic rate (i.e., the heat) leaves the body by radiation from the surface.

SET UP: In the radiation equation, $H_{net} = Ae\sigma(T^4 - T_s^4)$, the temperatures must be in kelvins; $e = 1.0$, $T = 30°\text{C} = 303\ \text{K}$, and $T_s = 18°\text{C} = 291\ \text{K}$. Call the basal metabolic rate BMR.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: **(a)** $H_{\text{net}} = Ae\sigma(T^4 - T_s^4)$.

$H_{\text{net}} = (2.0\ \text{m}^2)(1.0)(5.67\times10^{-8}\ \text{W/m}^2\cdot\text{K}^4)([303\ \text{K}]^4 - [291\ \text{K}]^4) = 140\ \text{W}.$

(b) $(0.80)\text{BMR} = 140\ \text{W},$ so $\text{BMR} = 180\ \text{W}.$

EVALUATE: If the emissivity of the skin were less than 1.0, the body would radiate less so the BMR would have to be lower than we found in (b).

17.117. **IDENTIFY:** The jogger radiates heat but the air radiates heat back into the jogger.

SET UP: The emissivity of a human body is taken to be 1.0. In the equation for the radiation heat current, $H_{\text{net}} = Ae\sigma(T^4 - T_s^4)$, the temperatures must be in kelvins.

EXECUTE: **(a)** $P_{\text{jog}} = (0.80)(1300\ \text{W}) = 1.04\times10^3\ \text{J/s}.$

(b) $H_{\text{net}} = Ae\sigma(T^4 - T_s^4),$ which gives

$H_{\text{net}} = (1.85\ \text{m}^2)(1.00)(5.67\times10^{-8}\ \text{W/m}^2\cdot\text{K}^4)([306\ \text{K}]^4 - [313\ \text{K}]^4) = -87.1\ \text{W}.$ The person gains 87.1 J of heat each second by radiation.

(c) The total excess heat per second is $1040\ \text{J/s} + 87\ \text{J/s} = 1130\ \text{J/s}.$

(d) In $1\ \text{min} = 60\ \text{s},$ the runner must dispose of $(60\ \text{s})(1130\ \text{J/s}) = 6.78\times10^4\ \text{J}.$ If this much heat goes to evaporate water, the mass m of water that evaporates in one minute is given by $Q = mL_v,$ so

$$m = \frac{Q}{L_v} = \frac{6.78\times10^4\ \text{J}}{2.42\times10^6\ \text{J/kg}} = 0.028\ \text{kg} = 28\ \text{g}.$$

(e) In a half-hour, or 30 minutes, the runner loses $(30\ \text{min})(0.028\ \text{kg/min}) = 0.84\ \text{kg}.$ The runner must drink 0.84 L, which is $\dfrac{0.84\ \text{L}}{0.750\ \text{L/bottle}} = 1.1\ \text{bottles}.$

EVALUATE: The person *gains* heat by radiation since the air temperature is greater than his skin temperature.

17.118. **IDENTIFY:** The heat generated will remain in the runner's body, which will increase his body temperature.

SET UP: Problem 17.117 calculates that the net rate of heat input to the person is 1130 W. $Q = mc\Delta T$. $9\ \text{F°} = 5\ \text{C°}.$

EXECUTE: **(a)** $Q = Pt = (1130\ \text{W})(1800\ \text{s}) = 2.03\times10^6\ \text{J}.$ $Q = mc\Delta T$ so

$$\Delta T = \frac{Q}{mc} = \frac{2.03\times10^6\ \text{J}}{(68\ \text{kg})(3480\ \text{J/kg}\cdot\text{C°})} = 8.6\ \text{C°}.$$

(b) $\Delta T = (8.6\ \text{C°})(9\ \text{F°}/5\ \text{C°}) = 15.5\ \text{F°}.$ $T = 98.6°\text{F} + 15.5\ \text{F°} = 114°\text{F}.$

EVALUATE: This body temperature is lethal.

17.119. **IDENTIFY:** For the water, $Q = mc\Delta T$.

SET UP: For water, $c = 4190\ \text{J/kg}\cdot\text{K}.$

EXECUTE: **(a)** At steady state, the input power all goes into heating the water, so $P = \dfrac{Q}{t} = \dfrac{mc\Delta T}{t}$ and

$$\Delta T = \frac{Pt}{cm} = \frac{(1800\ \text{W})(60\ \text{s/min})}{(4190\ \text{J/kg}\cdot\text{K})(0.500\ \text{kg/min})} = 51.6\ \text{K},$$ and the output temperature is

$18.0°\text{C} + 51.6\ \text{C°} = 69.6°\text{C}.$

EVALUATE: **(b)** At steady state, the temperature of the apparatus is constant and the apparatus will neither remove heat from nor add heat to the water.

17.120. **IDENTIFY:** For the air the heat input is related to the temperature change by $Q = mc\Delta T$.

SET UP: The rate P at which heat energy is generated is related to the rate P_0 at which food energy is consumed by the hamster by $P = 0.10P_0$.

EXECUTE: **(a)** The heat generated by the hamster is the heat added to the box;

$$P = \frac{Q}{t} = mc\frac{\Delta T}{t} = (1.20\ \text{kg/m}^3)(0.0500\ \text{m}^3)(1020\ \text{J/kg}\cdot\text{K})(1.60\ \text{C°/h}) = 97.9\ \text{J/h}.$$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) Taking the efficiency into account, the mass M of seed that must be eaten in time t is

$$\frac{M}{t}=\frac{P_0}{L_c}=\frac{P/(10\%)}{L_c}=\frac{979\text{ J/h}}{24\text{ J/g}}=40.8\text{ g/h}.$$

EVALUATE: This is about 1.5 ounces of seed consumed in one hour.

17.121. **IDENTIFY:** Heat Q_i goes into the ice when it warms to 0°C, melts, and the resulting water warms to the final temperature T_f. Heat Q_{ow} comes out of the ocean water when it cools to T_f. Conservation of energy gives $Q_i+Q_{ow}=0$.

SET UP: For ice, $c_i=2100\text{ J/kg}\cdot\text{K}$. For water, $L_f=334\times10^3$ J/kg and $c_w=4190\text{ J/kg}\cdot\text{K}$. Let m be the total mass of the water on the earth's surface. So $m_i=0.0175m$ and $m_{ow}=0.975m$.

EXECUTE: $Q_i+Q_{ow}=0$ gives $m_ic_i(30\text{ C°})+m_iL_f+m_ic_wT_f+m_{ow}c_w(T_f-5.00°\text{C})=0$.

$$T_f=\frac{-m_ic_i(30\text{ C°})-m_iL_f+m_{ow}c_w(5.00\text{ C°})}{(m_i+m_{ow})c_w}.$$

$$T_f=\frac{-(0.0175m)(2100\text{ J/kg}\cdot\text{K})(30\text{ K})-(0.0175m)(334\times10^3\text{ J/kg})+(0.975m)(4190\text{ J/kg}\cdot\text{K})(5.00\text{ K})}{(0.0175m+0.975m)(4190\text{ J/kg}\cdot\text{K})}$$

$$T_f=\frac{1.348\times10^4\text{ J/kg}}{4.159\times10^3\text{ J/kg}\cdot\text{K}}=3.24°\text{C}.$$ The temperature decrease is 1.76 C°.

EVALUATE: The mass of ice in the icecaps is much less than the mass of the water in the oceans, but much more heat is required to change the phase of 1 kg of ice than to change the temperature of 1 kg of water 1 C°, so the lowering of the temperature of the oceans would be appreciable.

17.122. **IDENTIFY:** The oceans take time to increase (or decrease) in temperature because they contain a large mass of water which has a high specific heat.

SET UP: The radius of the earth is $R_E=6.38\times10^6$ m. Since an ocean depth of 100 m is much less than the radius of the earth, we can calculate the volume of the water to this depth as the surface area of the oceans times 100 m. The total surface area of the earth is $A_{earth}=4\pi R_E{}^2$. The density of seawater is $1.03\times10^3\text{ kg/m}^3$ (Table12.1).

EXECUTE: The surface area of the oceans is $(2/3)A_{earth}=(2/3)(4\pi)(6.38\times10^6\text{ m})^2=3.41\times10^{14}\text{ m}^2$. The total rate of solar energy incident on the oceans is $(1050\text{ W/m}^2)(3.41\times10^{14}\text{ m}^2)=3.58\times10^{17}$ W. 12 hours per day for 30 days is $(12)(30)(3600)\text{ s}=1.30\times10^6\text{ s}$, so the total solar energy input to the oceans in one month is $(1.30\times10^6\text{ s})(3.58\times10^{17}\text{ W})=4.65\times10^{23}$ J. The volume of the seawater absorbing this energy is $(100\text{ m})(3.41\times10^{14}\text{ m}^2)=3.41\times10^{16}\text{ m}^3$. The mass of this water is

$m=\rho V=(1.03\times10^3\text{ kg/m}^3)(3.41\times10^{16}\text{ m}^3)=3.51\times10^{19}$ kg. $Q=mc\Delta T$, so

$$\Delta T=\frac{Q}{mc}=\frac{4.65\times10^{23}\text{ J}}{(3.51\times10^{19}\text{ kg})(3890\text{ J/kg}\cdot\text{C°})}=3.4\text{ C°}.$$

EVALUATE: A temperature rise of 3.4 C° is significant. The solar energy input is a very large number, but so is the total mass of the top 100 m of seawater in the oceans.

17.123. **IDENTIFY:** Apply Eq. (17.22) to different points along the rod, where $\frac{dT}{dx}$ is the temperature gradient at each point.

SET UP: For copper, $k=385\text{ W/m}\cdot\text{K}$.

EXECUTE: **(a)** The initial temperature distribution, $T=(100°\text{C})\sin\pi x/L$, is shown in Figure 17.123a.

(b) After a very long time, no heat will flow, and the entire rod will be at a uniform temperature which must be that of the ends, 0°C.

(c) The temperature distribution at successively greater times $T_1<T_2<T_3$ is sketched in Figure 17.123b.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(d) $\dfrac{dT}{dx} = (100°\text{C})(\pi/L)\cos\pi x/L.$ At the ends, $x = 0$ and $x = L,$ the cosine is ± 1 and the temperature gradient is $\pm(100°\text{C})(\pi/0.100\ \text{m}) = \pm 3.14\times10^3\ \text{C°/m}.$

(e) Taking the phrase "into the rod" to mean an absolute value, the heat current will be $kA\dfrac{dT}{dx} = (385.0\ \text{W/m}\cdot\text{K})(1.00\times10^{-4}\ \text{m}^2)(3.14\times10^3\ \text{C°/m}) = 121\ \text{W}.$

(f) Either by evaluating $\dfrac{dT}{dx}$ at the center of the rod, where $\pi x/L = \pi/2$ and $\cos(\pi/2) = 0,$ or by checking the figure in part (a), the temperature gradient is zero, and no heat flows through the center; this is consistent with the symmetry of the situation. There will not be any heat current at the center of the rod at any later time.

(g) $\dfrac{k}{\rho c} = \dfrac{(385\ \text{W/m}\cdot\text{K})}{(8.9\times10^3\ \text{kg/m}^3)(390\ \text{J/kg}\cdot\text{K})} = 1.1\times10^{-4}\ \text{m}^2\text{/s}.$

(h) Although there is no net heat current, the temperature of the center of the rod is decreasing; by considering the heat current at points just to either side of the center, where there is a non-zero temperature gradient, there must be a net flow of heat out of the region around the center. Specifically,

$$H((L/2)+\Delta x) - H((L/2)-\Delta x) = \rho A(\Delta x)c\frac{\partial T}{\partial t} = kA\left(\left.\frac{\partial T}{\partial x}\right|_{(L/2+\Delta x)} - \left.\frac{\partial T}{\partial x}\right|_{(L/2-\Delta x)}\right) = kA\frac{\partial^2 T}{\partial x^2}\Delta x, \text{ from}$$

which the Heat Equation, $\dfrac{\partial T}{\partial t} = \dfrac{k}{\rho c}\dfrac{\partial^2 T}{\partial x^2}$ is obtained. At the center of the rod,

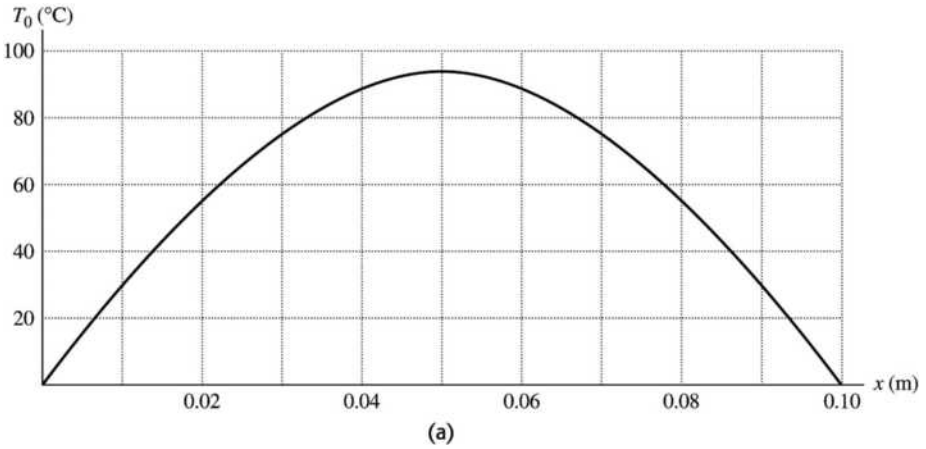
$\dfrac{\partial^2 T}{\partial x^2} = -(100\ \text{C°})(\pi/L)^2,$ and so $\dfrac{\partial T}{\partial t} = -(1.11\times10^{-4}\ \text{m}^2\text{/s})(100\ \text{C°})\left(\dfrac{\pi}{0.100\ \text{m}}\right)^2 = -10.9\ \text{C°/s},$ or $-11\ \text{C°/s}$ to two figures.

(i) $\dfrac{100\ \text{C°}}{10.9\ \text{C°/s}} = 9.17\ \text{s}$

(j) Decrease (that is, become less negative), since as T decreases, $\dfrac{\partial^2 T}{\partial x^2}$ decreases. This is consistent with the graphs, which correspond to equal time intervals.

(k) At the point halfway between the end and the center, at any given time $\dfrac{\partial^2 T}{\partial x^2}$ is a factor of $\sin(\pi/4) = 1/\sqrt{2}$ less than at the center, and so the initial rate of change of temperature is $-7.71\ \text{C°/s}.$

EVALUATE: A plot of temperature as a function of both position and time for $0 \le t \le 50$ s is shown in Figure 17.123c.



(a)

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

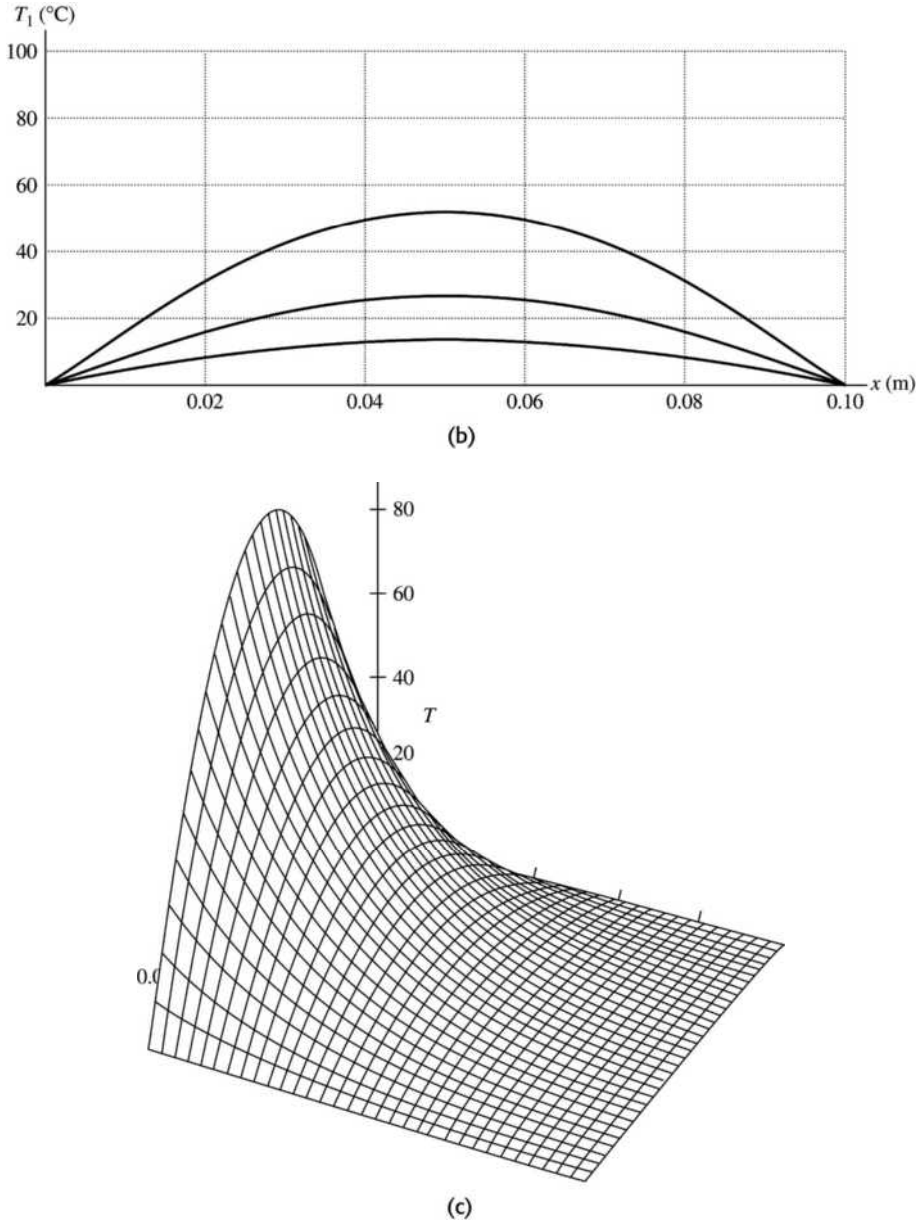


Figure 17.123

17.124. **IDENTIFY:** Apply Eq. (17.21). For a spherical or cylindrical surface, the area A in Eq. (17.21) is not constant, and the material must be considered to consist of shells with thickness dr and a temperature difference between the inside and outside of the shell dT. The heat current will be a constant, and must be found by integrating a differential equation.

SET UP: The surface area of a sphere is $4\pi r^2$. The surface area of the curved side of a cylinder is $2\pi rl$. $\ln(1+\varepsilon) \approx \varepsilon$ when $\varepsilon \ll 1$.

(a) Equation (17.21) becomes $H = k(4\pi r^2)\dfrac{dT}{dr}$ or $\dfrac{H\,dr}{4\pi r^2} = k\,dT$. Integrating both sides between the appropriate limits, $\dfrac{H}{4\pi}\left(\dfrac{1}{a}-\dfrac{1}{b}\right) = k(T_2 - T_1)$. In this case the "appropriate limits" have been chosen so that

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

if the inner temperature T_2 is at the higher temperature T_1, the heat flows outward; that is, $\frac{dT}{dr} < 0$.

Solving for the heat current, $H = \frac{k4\pi ab(T_2 - T_1)}{b - a}$.

(b) The rate of change of temperature with radius is of the form $\frac{dT}{dr} = \frac{B}{r^2}$, with B a constant. Integrating from $r = a$ to r and from $r = a$ to $r = b$ gives $T(r) - T_2 = B\left(\frac{1}{a} - \frac{1}{r}\right)$ and $T_1 - T_2 = B\left(\frac{1}{a} - \frac{1}{b}\right)$. Using the second of these to eliminate B and solving for $T(r)$ gives $T(r) = T_2 - (T_2 - T_1)\left(\frac{r-a}{b-a}\right)\left(\frac{b}{r}\right)$. There are, of course, many equivalent forms. As a check, note that at $r = a$, $T = T_2$ and at $r = b$, $T = T_1$.

(c) As in part (a), the expression for the heat current is $H = k(2\pi rL)\frac{dT}{dr}$ or $\frac{H}{2\pi r} = kL\,dT$, which integrates, with the same condition on the limits, to $\frac{H}{2\pi}\ln(b/a) = kL(T_2 - T_1)$, or $H = \frac{2\pi kL(T_2 - T_1)}{\ln(b/a)}$.

(d) A method similar to that used in part (b) gives $T(r) = T_2 + (T_1 - T_2)\frac{\ln(r/a)}{\ln(b/a)}$.

EVALUATE: **(e)** For the sphere: Let $b - a = l$, and approximate $b \sim a$, with a the common radius. Then the surface area of the sphere is $A = 4\pi a^2$, and the expression for H is that of Eq. (17.21) (with l instead of L, which has another use in this problem). For the cylinder: with the same notation, consider $\ln\left(\frac{b}{a}\right) = \ln\left(1 + \frac{l}{a}\right) \sim \frac{l}{a}$, where the approximation for $\ln(1+\varepsilon)$ for small ε has been used. The expression for H then reduces to $k(2\pi La)(\Delta T/l)$, which is Eq. (17.21) with $A = 2\pi La$.

17.125. **IDENTIFY:** From the result of Problem 17.124, the heat current through each of the jackets is related to the temperature difference by $H = \frac{2\pi lk}{\ln(b/a)}\Delta T$, where l is the length of the cylinder and b and a are the inner and outer radii of the cylinder.

SET UP: Let the temperature across the cork be ΔT_1 and the temperature across the styrofoam be ΔT_2, with similar notation for the thermal conductivities and heat currents.

EXECUTE: **(a)** $\Delta T_1 + \Delta T_2 = \Delta T = 125\ \text{C}°$. Setting $H_1 = H_2 = H$ and canceling the common factors, $\frac{\Delta T_1 k_1}{\ln 2} = \frac{\Delta T_2 k_2}{\ln 1.5}$. Eliminating ΔT_2 and solving for ΔT_1 gives $\Delta T_1 = \Delta T\left(1 + \frac{k_1}{k_2}\frac{\ln 1.5}{\ln 2}\right)^{-1}$. Substitution of numerical values gives $\Delta T_1 = 37\ \text{C}°$, and the temperature at the radius where the layers meet is $140°\text{C} - 37°\text{C} = 103°\text{C}$.

(b) Substitution of this value for ΔT_1 into the above expression for $H_1 = H$ gives

$$H = \frac{2\pi(2.00\ \text{m})(0.0400\ \text{W/m}\cdot\text{K})}{\ln 2}(37\ \text{C}°) = 27\ \text{W}.$$

EVALUATE: $\Delta T = 103°\text{C} - 15°\text{C} = 88\ \text{C}°$. $H_2 = \frac{2\pi(2.00\ \text{m})(0.0100\ \text{W/m}\cdot\text{K})}{\ln(6.00/4.00)}(88\ \text{C}°) = 27\ \text{W}$. This is the same as H_1, as it should be.

17.126. **IDENTIFY:** Apply the concept of thermal expansion. In part (b) the object can be treated as a simple pendulum.

SET UP: For steel $\alpha = 1.2\times10^{-5}\ (\text{C}°)^{-1}$. 1 yr = 86,400 s.

EXECUTE: **(a)** In hot weather, the moment of inertia I and the length d in Eq. (14.39) will both increase by the same factor, and so the period will be longer and the clock will run slow (lose time). Similarly, the clock will run fast (gain time) in cold weather.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) $\frac{\Delta L}{L_0} = \alpha \Delta T = (1.2\times10^{-5}\ (\text{C°})^{-1})(10.0\ \text{C°}) = 1.2\times10^{-4}$.

(c) To avoid possible confusion, denote the pendulum period by τ. For this problem, $\frac{\Delta\tau}{\tau} = \frac{1}{2}\frac{\Delta L}{L} = 6.0\times10^{-5}$ so in one day the clock will gain $(86{,}400\ \text{s})(6.0\times10^{-5}) = 5.2\ \text{s}$.

(d) $\left|\frac{\Delta\tau}{\tau}\right| = \frac{1}{2}\alpha\Delta T$. $\left|\frac{\Delta\tau}{\tau}\right| = \frac{1.0\ \text{s}}{86{,}400\ \text{s}}$ gives $\Delta T = 2[(1.2\times10^{-5}(\text{C°})^{-1})(86{,}400)]^{-1} = 1.9\ \text{C°}$. T must be controlled to within 1.9 C°.

EVALUATE: In part (d) the answer does not depend on the period of the pendulum. It depends only on the fractional change in the period.

17.127. **IDENTIFY:** The rate in (iv) is given by Eq. (17.26), with $T = 309\ \text{K}$ and $T_s = 320\ \text{K}$. The heat absorbed in the evaporation of water is $Q = mL$.

SET UP: $m = \rho V$, so $\frac{m}{V} = \rho$.

EXECUTE: **(a)** The rates are: (i) 280 W,

(ii) $(54\ \text{J/h}\cdot\text{C°}\cdot\text{m}^2)(1.5\ \text{m}^2)(11\ \text{C°})/(3600\ \text{s/h}) = 0.248\ \text{W}$,

(iii) $(1400\ \text{W/m}^2)(1.5\ \text{m}^2) = 2.10\times10^3\ \text{W}$,

(iv) $(5.67\times10^{-8}\ \text{W/m}^2\cdot\text{K}^4)(1.5\ \text{m}^2)((320\ \text{K})^4 - (309\ \text{K})^4) = 116\ \text{W}$.

The total is 2.50 kW, with the largest portion due to radiation from the sun.

(b) $\frac{P}{\rho L_v} = \frac{2.50\times10^3\ \text{W}}{(1000\ \text{kg/m}^3)(2.42\times10^6\ \text{J/kg}\cdot\text{K})} = 1.03\times10^{-6}\ \text{m}^3/\text{s}$. This is equal to 3.72 L/h.

(c) Redoing the above calculations with $e = 0$ and the decreased area gives a power of 945 W and a corresponding evaporation rate of 1.4 L/h. Wearing reflective clothing helps a good deal. Large areas of loose-weave clothing also facilitate evaporation.

EVALUATE: The radiant energy from the sun absorbed by the area covered by clothing is assumed to be zero, since $e \approx 0$ for the clothing and the clothing reflects almost all the radiant energy incident on it. For the same reason, the exposed skin area is the area used in Eq. (17.26).

18

THERMAL PROPERTIES OF MATTER

18.1. **(a) IDENTIFY:** We are asked about a single state of the system.
SET UP: Use Eq. (18.2) to calculate the number of moles and then apply the ideal-gas equation.

EXECUTE: $n = \dfrac{m_{\text{tot}}}{M} = \dfrac{4.86\times10^{-4}\text{ kg}}{4.00\times10^{-3}\text{ kg/mol}} = 0.122\text{ mol}.$

(b) $pV = nRT$ implies $p = nRT/V$. T must be in kelvins, so $T = (18+273)\text{ K} = 291\text{ K}$.

$$p = \frac{(0.122\text{ mol})(8.3145\text{ J/mol}\cdot\text{K})(291\text{ K})}{20.0\times10^{-3}\text{ m}^3} = 1.47\times10^4\text{ Pa}.$$

$$p = (1.47\times10^4\text{ Pa})(1.00\text{ atm}/1.013\times10^5\text{ Pa}) = 0.145\text{ atm}.$$

EVALUATE: The tank contains about 1/10 mole of He at around standard temperature, so a pressure around 1/10 atmosphere is reasonable.

18.2. **IDENTIFY:** $pV = nRT$.
SET UP: $T_1 = 41.0°\text{C} = 314\text{ K}$. $R = 0.08206\text{ L}\cdot\text{atm/mol}\cdot\text{K}$.

EXECUTE: n and R are constant so $\dfrac{pV}{T} = nR$ is constant. $\dfrac{p_1V_1}{T_1} = \dfrac{p_2V_2}{T_2}$.

$$T_2 = T_1\left(\frac{p_2}{p_1}\right)\left(\frac{V_2}{V_1}\right) = (314\text{ K})(2)(2) = 1.256\times10^3\text{ K} = 983°\text{C}.$$

(b) $$n = \frac{pV}{RT} = \frac{(0.180\text{ atm})(2.60\text{ L})}{(0.08206\text{ L}\cdot\text{atm/mol}\cdot\text{K})(314\text{ K})} = 0.01816\text{ mol}.$$

$$m_{\text{tot}} = nM = (0.01816\text{ mol})(4.00\text{ g/mol}) = 0.0727\text{ g}.$$

EVALUATE: T is directly proportional to p and to V, so when p and V are each doubled the Kelvin temperature increases by a factor of 4.

18.3. **IDENTIFY:** $pV = nRT$.
SET UP: T is constant.
EXECUTE: nRT is constant so $p_1V_1 = p_2V_2$.

$$p_2 = p_1\left(\frac{V_1}{V_2}\right) = (0.355\text{ atm})\left(\frac{0.110\text{ m}^3}{0.390\text{ m}^3}\right) = 0.100\text{ atm}.$$

EVALUATE: For T constant, p decreases as V increases.

18.4. **IDENTIFY:** $pV = nRT$.
SET UP: $T_1 = 20.0°\text{C} = 293\text{ K}$.

EXECUTE: **(a)** n, R and V are constant. $\dfrac{p}{T} = \dfrac{nR}{V} = \text{constant}$. $\dfrac{p_1}{T_1} = \dfrac{p_2}{T_2}$.

$$T_2 = T_1\left(\frac{p_2}{p_1}\right) = (293\text{ K})\left(\frac{1.00\text{ atm}}{3.00\text{ atm}}\right) = 97.7\text{ K} = -175°\text{C}.$$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) $p_2 = 1.00$ atm, $V_2 = 3.00$ L. $p_3 = 3.00$ atm. n, R and T are constant so $pV = nRT = \text{constant}$.

$p_2V_2 = p_3V_3$.

$$V_3 = V_2\left(\frac{p_2}{p_3}\right) = (3.00\text{ L})\left(\frac{1.00\text{ atm}}{3.00\text{ atm}}\right) = 1.00\text{ L}.$$

EVALUATE: The final volume is one-third the initial volume. The initial and final pressures are the same, but the final temperature is one-third the initial temperature.

18.5. **IDENTIFY:** We know the pressure and temperature and want to find the density of the gas. The ideal gas law applies.

SET UP: $M_{CO_2} = (12 + 2[16])\text{ g/mol} = 44\text{ g/mol}$. $M_{N_2} = 28\text{ g/mol}$. $\rho = \dfrac{pM}{RT}$.

$R = 8.315\text{ J/mol}\cdot\text{K}$. T must be in kelvins. Express M in kg/mol and p in Pa. 1 atm $= 1.013\times10^5$ Pa.

EXECUTE: **(a)** *Mars:* $\rho = \dfrac{(650\text{ Pa})(44\times10^{-3}\text{ kg/mol})}{(8.315\text{ J/mol}\cdot\text{K})(253\text{ K})} = 0.0136\text{ kg/m}^3$.

Venus: $\rho = \dfrac{(92\text{ atm})(1.013\times10^5\text{ Pa/atm})(44\times10^{-3}\text{ kg/mol})}{(8.315\text{ J/mol}\cdot\text{K})(730\text{ K})} = 67.6\text{ kg/m}^3$.

Titan: $T = -178 + 273 = 95$ K.

$$\rho = \frac{(1.5\text{ atm})(1.013\times10^5\text{ Pa/atm})(28\times10^{-3}\text{ kg/mol})}{(8.315\text{ J/mol}\cdot\text{K})(95\text{ K})} = 5.39\text{ kg/m}^3.$$

EVALUATE: **(b)** Table 12.1 gives the density of air at 20°C and $p = 1$ atm to be 1.20 kg/m^3. The density of the atmosphere of Mars is much less, the density for Venus is much greater and the density for Titan is somewhat greater.

18.6. **IDENTIFY:** $pV = nRT$ and the mass of the gas is $m_{tot} = nM$.

SET UP: The temperature is $T = 22.0°\text{C} = 295.15$ K. The average molar mass of air is $M = 28.8\times10^{-3}$ kg/mol. For helium $M = 4.00\times10^{-3}$ kg/mol.

EXECUTE: **(a)** $m_{tot} = nM = \dfrac{pV}{RT}M = \dfrac{(1.00\text{ atm})(0.900\text{ L})(28.8\times10^{-3}\text{ kg/mol})}{(0.08206\text{ L}\cdot\text{atm/mol}\cdot\text{K})(295.15\text{ K})} = 1.07\times10^{-3}$ kg.

(b) $m_{tot} = nM = \dfrac{pV}{RT}M = \dfrac{(1.00\text{ atm})(0.900\text{ L})(4.00\times10^{-3}\text{ kg/mol})}{(0.08206\text{ L}\cdot\text{atm/mol}\cdot\text{K})(295.15\text{ K})} = 1.49\times10^{-4}$ kg.

EVALUATE: $n = \dfrac{N}{N_A} = \dfrac{pV}{RT}$ says that in each case the balloon contains the same number of molecules. The mass is greater for air since the mass of one molecule is greater than for helium.

18.7. **IDENTIFY:** We are asked to compare two states. Use the ideal gas law to obtain T_2 in terms of T_1 and ratios of pressures and volumes of the gas in the two states.

SET UP: $pV = nRT$ and n, R constant implies $pV/T = nR = \text{constant}$ and $p_1V_1/T_1 = p_2V_2/T_2$

EXECUTE: $T_1 = (27 + 273)\text{ K} = 300\text{ K}$

$p_1 = 1.01\times10^5$ Pa

$p_2 = 2.72\times10^6\text{ Pa} + 1.01\times10^5\text{ Pa} = 2.82\times10^6$ Pa (in the ideal gas equation the pressures must be absolute, not gauge, pressures)

$$T_2 = T_1\left(\frac{p_2}{p_1}\right)\left(\frac{V_2}{V_1}\right) = 300\text{ K}\left(\frac{2.82\times10^6\text{ Pa}}{1.01\times10^5\text{ Pa}}\right)\left(\frac{46.2\text{ cm}^3}{499\text{ cm}^3}\right) = 776\text{ K}$$

$T_2 = (776 - 273)°\text{C} = 503°\text{C}$

EVALUATE: The units cancel in the V_2/V_1 volume ratio, so it was not necessary to convert the volumes in cm^3 to m^3. It was essential, however, to use T in kelvins.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

18.8. **IDENTIFY:** $pV = nRT$ and $m = nM$.

SET UP: We must use absolute pressure in $pV = nRT$. $p_1 = 4.01\times10^5$ Pa, $p_2 = 2.81\times10^5$ Pa. $T_1 = 310$ K, $T_2 = 295$ K.

EXECUTE: **(a)** $n_1 = \dfrac{p_1V_1}{RT_1} = \dfrac{(4.01\times10^5 \text{ Pa})(0.075 \text{ m}^3)}{(8.315 \text{ J/mol}\cdot\text{K})(310 \text{ K})} = 11.7$ mol.

$m = nM = (11.7 \text{ mol})(32.0 \text{ g/mol}) = 374$ g.

(b) $n_2 = \dfrac{p_2V_2}{RT_2} = \dfrac{(2.81\times10^5 \text{ Pa})(0.075 \text{ m}^3)}{(8.315 \text{ J/mol}\cdot\text{K})(295 \text{ K})} = 8.59$ mol. $m = 275$ g.

The mass that has leaked out is $374 \text{ g} - 275 \text{ g} = 99$ g.

EVALUATE: In the ideal gas law we must use absolute pressure, expressed in Pa, and T must be in kelvins.

18.9. **IDENTIFY:** $pV = nRT$.

SET UP: $T_1 = 300$ K, $T_2 = 430$ K.

EXECUTE: **(a)** n, R are constant so $\dfrac{pV}{T} = nR = \text{constant}$. $\dfrac{p_1V_1}{T_1} = \dfrac{p_2V_2}{T_2}$.

$$p_2 = p_1\left(\frac{V_1}{V_2}\right)\left(\frac{T_2}{T_1}\right) = (7.50\times10^3 \text{ Pa})\left(\frac{0.750 \text{ m}^3}{0.480 \text{ m}^3}\right)\left(\frac{430 \text{ K}}{300 \text{ K}}\right) = 1.68\times10^4 \text{ Pa}.$$

EVALUATE: Since the temperature increased while the volume decreased, the pressure must have increased. In $pV = nRT$, T must be in kelvins, even if we use a ratio of temperatures.

18.10. **IDENTIFY:** Use the ideal-gas equation to calculate the number of moles, n. The mass m_{total} of the gas is $m_{\text{total}} = nM$.

SET UP: The volume of the cylinder is $V = \pi r^2 l$, where $r = 0.450$ m and $l = 1.50$ m.

$T = 22.0°\text{C} = 293.15$ K. $1 \text{ atm} = 1.013\times10^5$ Pa. $M = 32.0\times10^{-3}$ kg/mol. $R = 8.314$ J/mol·K.

EXECUTE: **(a)** $pV = nRT$ gives

$$n = \frac{pV}{RT} = \frac{(21.0 \text{ atm})(1.013\times10^5 \text{ Pa/atm})\pi(0.450 \text{ m})^2(1.50 \text{ m})}{(8.314 \text{ J/mol}\cdot\text{K})(295.15 \text{ K})} = 827 \text{ mol}.$$

(b) $m_{\text{total}} = (827 \text{ mol})(32.0\times10^{-3} \text{ kg/mol}) = 26.5$ kg

EVALUATE: In the ideal-gas law, T must be in kelvins. Since we used R in units of J/mol·K we had to express p in units of Pa and V in units of m^3.

18.11. **IDENTIFY:** We are asked to compare two states. Use the ideal-gas law to obtain V_1 in terms of V_2 and the ratio of the temperatures in the two states.

SET UP: $pV = nRT$ and n, R, p are constant so $V/T = nR/p = \text{constant}$ and $V_1/T_1 = V_2/T_2$

EXECUTE: $T_1 = (19 + 273)$ K $= 292$ K (T must be in kelvins)

$V_2 = V_1(T_2/T_1) = (0.600 \text{ L})(77.3 \text{ K}/292 \text{ K}) = 0.159$ L

EVALUATE: p is constant so the ideal-gas equation says that a decrease in T means a decrease in V.

18.12. **IDENTIFY:** Apply $pV = nRT$ and the van der Waals equation (Eq. 18.7) to calculate p.

SET UP: $400 \text{ cm}^3 = 400\times10^{-6} \text{ m}^3$. $R = 8.314$ J/mol·K.

EXECUTE: **(a)** The ideal gas law gives $p = nRT/V = 7.28\times10^6$ Pa while Eq. (18.7) gives 5.87×10^6 Pa.

(b) The van der Waals equation, which accounts for the attraction between molecules, gives a pressure that is 20% lower.

(c) The ideal gas law gives $p = 7.28\times10^5$ Pa. Eq. (18.7) gives $p = 7.13\times10^5$ Pa, for a 2.1% difference.

EVALUATE: **(d)** As n/V decreases, the formulas and the numerical values for the two equations approach each other.

18.13. **IDENTIFY:** We know the volume of the gas at STP on the earth and want to find the volume it would occupy on Venus where the pressure and temperature are much greater.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

SET UP: STP is $T = 273$ K and $p = 1$ atm. Set up a ratio using $pV = nRT$ with nR constant.
$T_V = 1003 + 273 = 1276$ K.

EXECUTE: $pV = nRT$ gives $\frac{pV}{T} = nR = \text{constant}$, so $\frac{p_E V_E}{T_E} = \frac{p_V V_V}{T_V}$.

$$V_V = V_E\left(\frac{p_E}{p_V}\right)\left(\frac{T_V}{T_E}\right) = V\left(\frac{1\text{ atm}}{92\text{ atm}}\right)\left(\frac{1276\text{ K}}{273\text{ K}}\right) = 0.0508V.$$

EVALUATE: Even though the temperature on Venus is higher than it is on Earth, the pressure there is much greater than on Earth, so the volume of the gas on Venus is only about 5% what it is on Earth.

18.14. **IDENTIFY:** $pV = nRT$.

SET UP: $T_1 = 277$ K. $T_2 = 296$ K. Assume the number of moles of gas in the bubble remains constant.

EXECUTE: **(a)** n, R are constant so $\frac{pV}{T} = nR = \text{constant}$. $\frac{p_1V_1}{T_1} = \frac{p_2V_2}{T_2}$ and

$$\frac{V_2}{V_1} = \left(\frac{p_1}{p_2}\right)\left(\frac{T_2}{T_1}\right) = \left(\frac{3.50\text{ atm}}{1.00\text{ atm}}\right)\left(\frac{296\text{ K}}{277\text{ K}}\right) = 3.74.$$

(b) This increase in volume of air in the lungs would be dangerous.

EVALUATE: The large decrease in pressure results in a large increase in volume.

18.15. **IDENTIFY:** We are asked to compare two states. First use $pV = nRT$ to calculate p_1. Then use it to obtain T_2 in terms of T_1 and the ratio of pressures in the two states.

(a) SET UP: $pV = nRT$. Find the initial pressure p_1.

EXECUTE: $$p_1 = \frac{nRT_1}{V} = \frac{(11.0\text{ mol})(8.3145\text{ J/mol}\cdot\text{K})(23.0 + 273.15)\text{K}}{3.10\times10^{-3}\text{ m}^3} = 8.737\times10^6\text{ Pa}$$

SET UP: $p_2 = 100\text{ atm}(1.013\times10^5\text{ Pa/1 atm}) = 1.013\times10^7$ Pa

$p/T = nR/V = \text{constant}$, so $p_1/T_1 = p_2/T_2$

EXECUTE: $$T_2 = T_1\left(\frac{p_2}{p_1}\right) = (296.15\text{ K})\left(\frac{1.013\times10^7\text{ Pa}}{8.737\times10^6\text{ Pa}}\right) = 343.4\text{ K} = 70.2°\text{C}$$

(b) EVALUATE: The coefficient of volume expansion for a gas is much larger than for a solid, so the expansion of the tank is negligible.

18.16. **IDENTIFY:** $F = pA$ and $pV = nRT$

SET UP: For a cube, $V/A = L$.

EXECUTE: **(a)** The force of any side of the cube is $F = pA = (nRT/V)A = (nRT)/L$, since the ratio of area to volume is $A/V = 1/L$. For $T = 20.0°\text{C} = 293.15$ K,

$$F = \frac{nRT}{L} = \frac{(3\text{ mol})(8.3145\text{ J/mol}\cdot\text{K})(293.15\text{ K})}{0.200\text{ m}} = 3.66\times10^4\text{ N}.$$

(b) For $T = 100.00°\text{C} = 373.15$ K,

$$F = \frac{nRT}{L} = \frac{(3\text{ mol})(8.3145\text{ J/mol}\cdot\text{K})(373.15\text{ K})}{0.200\text{ m}} = 4.65\times10^4\text{ N}.$$

EVALUATE: When the temperature increases while the volume is kept constant, the pressure increases and therefore the force increases. The force increases by the factor T_2/T_1.

18.17. **IDENTIFY:** Example 18.4 assumes a temperature of 0°C at all altitudes and neglects the variation of g with elevation. With these approximations, $p = p_0e^{-Mgy/RT}$.

SET UP: $\ln(e^{-x}) = -x$. For air, $M = 28.8\times10^{-3}$ kg/mol.

EXECUTE: We want y for $p = 0.90p_0$ so $0.90 = e^{-Mgy/RT}$ and $y = -\frac{RT}{Mg}\ln(0.90) = 850$ m.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: This is a commonly occurring elevation, so our calculation shows that 10% variations in atmospheric pressure occur at many locations.

18.18. **IDENTIFY:** From Example 18.4, the pressure at elevation y above sea level is $p = p_0 e^{-Mgy/RT}$.

SET UP: The average molar mass of air is $M = 28.8\times10^{-3}$ kg/mol.

EXECUTE: At an altitude of 100 m, $\frac{Mgy_1}{RT} = \frac{(28.8\times10^{-3}\text{ kg/mol})(9.80\text{ m/s}^2)(100\text{ m})}{(8.3145\text{ J/mol}\cdot\text{K})(273.15\text{ K})} = 0.01243$, and the percent decrease in pressure is $1 - p/p_0 = 1 - e^{-0.01243} = 0.0124 = 1.24\%$. At an altitude of 1000 m, $Mgy_2/RT = 0.1243$ and the percent decrease in pressure is $1 - e^{-0.1243} = 0.117 = 11.7\%$.

EVALUATE: These answers differ by a factor of $(11.7\%)/(1.24\%) = 9.44$, which is less than 10 because the variation of pressure with altitude is exponential rather than linear.

18.19. **IDENTIFY:** We know the volume, pressure and temperature of the gas and want to find its mass and density.

SET UP: $V = 3.00\times10^{-3}\text{ m}^3$. $T = 295$ K. $p = 2.03\times10^{-8}$ Pa. The ideal gas law, $pV = nRT$, applies.

EXECUTE: **(a)** $pV = nRT$ gives

$n = \frac{pV}{RT} = \frac{(2.03\times10^{-8}\text{ Pa})(3.00\times10^{-3}\text{ m}^3)}{(8.315\text{ J/mol}\cdot\text{K})(295\text{ K})} = 2.48\times10^{-14}$ mol. The mass of this amount of gas is

$m = nM = (2.48\times10^{-14}\text{ mol})(28.0\times10^{-3}\text{ kg/mol}) = 6.95\times10^{-16}$ kg.

(b) $\rho = \frac{m}{V} = \frac{6.95\times10^{-16}\text{ kg}}{3.00\times10^{-3}\text{ m}^3} = 2.32\times10^{-13}\text{ kg/m}^3$.

EVALUATE: The density at this level of vacuum is 13 orders of magnitude less than the density of air at STP, which is 1.20 kg/m^3.

18.20. **IDENTIFY:** $p = p_0 e^{-Mgy/RT}$ from Example 18.4 gives the variation of air pressure with altitude. The density ρ of the air is $\rho = \frac{pM}{RT}$, so ρ is proportional to the pressure p. Let ρ_0 be the density at the surface, where the pressure is p_0.

SET UP: From Example 18.4, $\frac{Mg}{RT} = \frac{(28.8\times10^{-3}\text{ kg/mol})(9.80\text{ m/s}^2)}{(8.314\text{ J/mol}\cdot\text{K})(273\text{ K})} = 1.244\times10^{-4}\text{ m}^{-1}$.

EXECUTE: $p = p_0 e^{-(1.244\times10^{-4}\text{ m}^{-1})(1.00\times10^{3}\text{ m})} = 0.883 p_0$. $\frac{\rho}{p} = \frac{M}{RT} =$ constant, so $\frac{\rho}{p} = \frac{\rho_0}{p_0}$ and

$\rho = \rho_0\left(\frac{p}{p_0}\right) = 0.883\rho_0$.

The density at an altitude of 1.00 km is 88.3% of its value at the surface.

EVALUATE: If the temperature is assumed to be constant, then the decrease in pressure with increase in altitude corresponds to a decrease in density.

18.21. **IDENTIFY:** Use Eq. (18.5) and solve for p.

SET UP: $\rho = pM/RT$ and $p = RT\rho/M$

$T = (-56.5 + 273.15)\text{ K} = 216.6\text{ K}$

For air $M = 28.8\times10^{-3}$ kg/mol (Example 18.3)

EXECUTE: $p = \frac{(8.3145\text{ J/mol}\cdot\text{K})(216.6\text{ K})(0.364\text{ kg/m}^3)}{28.8\times10^{-3}\text{ kg/mol}} = 2.28\times10^{4}$ Pa

EVALUATE: The pressure is about one-fifth the pressure at sea-level.

18.22. **IDENTIFY:** The molar mass is $M = N_A m$, where m is the mass of one molecule.

SET UP: $N_A = 6.02\times10^{23}$ molecules/mol.

EXECUTE: $M = N_A m = (6.02\times10^{23}\text{ molecules/mol})(1.41\times10^{-21}\text{ kg/molecule}) = 849$ kg/mol.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: For a carbon atom, $M = 12\times10^{-3}$ kg/mol. If this molecule is mostly carbon, so the average mass of its atoms is the mass of carbon, the molecule would contain $\dfrac{849 \text{ kg/mol}}{12\times10^{-3} \text{ kg/mol}} = 71{,}000$ atoms.

18.23. **IDENTIFY:** The mass m_{tot} is related to the number of moles n by $m_{\text{tot}} = nM$. Mass is related to volume by $\rho = m/V$.

SET UP: For gold, $M = 196.97$ g/mol and $\rho = 19.3\times10^3$ kg/m^3. The volume of a sphere of radius r is $V = \frac{4}{3}\pi r^3$.

EXECUTE: **(a)** $m_{\text{tot}} = nM = (3.00 \text{ mol})(196.97 \text{ g/mol}) = 590.9$ g. The value of this mass of gold is $(590.9 \text{ g})(\$14.75/\text{g}) = \$8720$.

(b) $V = \dfrac{m}{\rho} = \dfrac{0.5909 \text{ kg}}{19.3\times10^3 \text{ kg/m}^3} = 3.06\times10^{-5} \text{ m}^3$. $V = \frac{4}{3}\pi r^3$ gives

$r = \left(\dfrac{3V}{4\pi}\right)^{1/3} = \left(\dfrac{3[3.06\times10^{-5} \text{ m}^3]}{4\pi}\right)^{1/3} = 0.0194 \text{ m} = 1.94 \text{ cm}$. The diameter is $2r = 3.88$ cm.

EVALUATE: The mass and volume are directly proportional to the number of moles.

18.24. **IDENTIFY:** Use $pV = nRT$ to calculate the number of moles and then the number of molecules would be $N = nN_{\text{A}}$.

SET UP: 1 atm $= 1.013\times10^5$ Pa. 1.00 cm$^3 = 1.00\times10^{-6}$ m^3. $N_{\text{A}} = 6.022\times10^{23}$ molecules/mol.

EXECUTE: **(a)** $n = \dfrac{pV}{RT} = \dfrac{(9.00\times10^{-14} \text{ atm})(1.013\times10^5 \text{ Pa/atm})(1.00\times10^{-6} \text{ m}^3)}{(8.314 \text{ J/mol}\cdot\text{K})(300.0 \text{ K})} = 3.655\times10^{-18}$ mol.

$N = nN_{\text{A}} = (3.655\times10^{-18} \text{ mol})(6.022\times10^{23} \text{ molecules/mol}) = 2.20\times10^6$ molecules.

(b) $N = \dfrac{pVN_{\text{A}}}{RT}$ so $\dfrac{N}{p} = \dfrac{VN_{\text{A}}}{RT} = \text{constant}$ and $\dfrac{N_1}{p_1} = \dfrac{N_2}{p_2}$.

$N_2 = N_1\left(\dfrac{p_2}{p_1}\right) = (2.20\times10^6 \text{ molecules})\left(\dfrac{1.00 \text{ atm}}{9.00\times10^{-14} \text{ atm}}\right) = 2.44\times10^{19}$ molecules.

EVALUATE: The number of molecules in a given volume is directly proportional to the pressure. Even at the very low pressure in part (a) the number of molecules in 1.00 cm^3 is very large.

18.25. **IDENTIFY:** We are asked about a single state of the system.

SET UP: Use the ideal-gas law. Write n in terms of the number of molecules N.

(a) EXECUTE: $pV = nRT$, $n = N/N_{\text{A}}$ so $pV = (N/N_{\text{A}})RT$

$p = \left(\dfrac{N}{V}\right)\left(\dfrac{R}{N_{\text{A}}}\right)T$

$p = \left(\dfrac{80 \text{ molecules}}{1\times10^{-6} \text{ m}^3}\right)\left(\dfrac{8.3145 \text{ J/mol}\cdot\text{K}}{6.022\times10^{23} \text{ molecules/mol}}\right)(7500 \text{ K}) = 8.28\times10^{-12}$ Pa

$p = 8.2\times10^{-17}$ atm. This is much lower than the laboratory pressure of 9×10^{-14} atm in Exercise 18.24.

(b) EVALUATE: The Lagoon Nebula is a very rarefied low pressure gas. The gas would exert *very* little force on an object passing through it.

18.26. **IDENTIFY:** $pV = nRT = NkT$

SET UP: At STP, $T = 273$ K, $p = 1.01\times10^5$ Pa. $N = 6\times10^9$ molecules.

EXECUTE: $V = \dfrac{NkT}{p} = \dfrac{(6\times10^9 \text{ molecules})(1.381\times10^{-23} \text{ J/molecule}\cdot\text{K})(273 \text{ K})}{1.01\times10^5 \text{ Pa}} = 2.24\times10^{-16}$ m^3.

$L^3 = V$ so $L = V^{1/3} = 6.1\times10^{-6}$ m.

EVALUATE: This is a small cube.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

18.27. **IDENTIFY:** $n = \dfrac{m}{M} = \dfrac{N}{N_A}$

SET UP: $N_A = 6.022\times10^{23}$ molecules/mol. For water, $M = 18\times10^{-3}$ kg/mol.

EXECUTE: $n = \dfrac{m}{M} = \dfrac{1.00 \text{ kg}}{18\times10^{-3} \text{ kg/mol}} = 55.6 \text{ mol}.$

$N = nN_A = (55.6 \text{ mol})(6.022\times10^{23} \text{ molecules/mol}) = 3.35\times10^{25}$ molecules.

EVALUATE: Note that we converted M to kg/mol.

18.28. **IDENTIFY:** Use $pV = nRT$ and $n = \dfrac{N}{N_A}$ with $N = 1$ to calculate the volume V occupied by 1 molecule.

The length l of the side of the cube with volume V is given by $V = l^3$.

SET UP: $T = 27°\text{C} = 300$ K. $p = 1.00$ atm $= 1.013\times10^5$ Pa. $R = 8.314$ J/mol·K.

$N_A = 6.022\times10^{23}$ molecules/mol.

The diameter of a typical molecule is about 10^{-10} m. 0.3 nm $= 0.3\times10^{-9}$ m.

EXECUTE: **(a)** $pV = nRT$ and $n = \dfrac{N}{N_A}$ gives

$V = \dfrac{NRT}{N_A p} = \dfrac{(1.00)(8.314 \text{ J/mol}\cdot\text{K})(300 \text{ K})}{(6.022\times10^{23} \text{ molecules/mol})(1.013\times10^5 \text{ Pa})} = 4.09\times10^{-26} \text{ m}^3.$ $l = V^{1/3} = 3.45\times10^{-9}$ m.

(b) The distance in part (a) is about 10 times the diameter of a typical molecule.

(c) The spacing is about 10 times the spacing of atoms in solids.

EVALUATE: There is space between molecules in a gas whereas in a solid the atoms are closely packed together.

18.29. **(a) IDENTIFY** and **SET UP:** Use the density and the mass of 5.00 mol to calculate the volume. $\rho = m/V$ implies $V = m/\rho$, where $m = m_{\text{tot}}$, the mass of 5.00 mol of water.

EXECUTE: $m_{\text{tot}} = nM = (5.00 \text{ mol})(18.0\times10^{-3} \text{ kg/mol}) = 0.0900$ kg

Then $V = \dfrac{m}{\rho} = \dfrac{0.0900 \text{ kg}}{1000 \text{ kg/m}^3} = 9.00\times10^{-5} \text{ m}^3$

(b) One mole contains $N_A = 6.022\times10^{23}$ molecules, so the volume occupied by one molecule is

$$\frac{9.00\times10^{-5} \text{ m}^3/\text{mol}}{(5.00 \text{ mol})(6.022\times10^{23} \text{ molecules/mol})} = 2.989\times10^{-29} \text{ m}^3/\text{molecule}$$

$V = a^3$, where a is the length of each side of the cube occupied by a molecule. $a^3 = 2.989\times10^{-29}$ m^3, so $a = 3.1\times10^{-10}$ m.

(c) EVALUATE: Atoms and molecules are on the order of 10^{-10} m in diameter, in agreement with the above estimates.

18.30. **IDENTIFY:** $K_{\text{av}} = \frac{3}{2}kT$. $v_{\text{rms}} = \sqrt{\dfrac{3RT}{M}}$.

SET UP: $M_{\text{Ne}} = 20.180$ g/mol, $M_{\text{Kr}} = 83.80$ g/mol and $M_{\text{Rn}} = 222$ g/mol.

EXECUTE: **(a)** $K_{\text{av}} = \frac{3}{2}kT$ depends only on the temperature so it is the same for each species of atom in the mixture.

(b) $\dfrac{v_{\text{rms,Ne}}}{v_{\text{rms,Kr}}} = \sqrt{\dfrac{M_{\text{Kr}}}{M_{\text{Ne}}}} = \sqrt{\dfrac{83.80 \text{ g/mol}}{20.18 \text{ g/mol}}} = 2.04.$ $\dfrac{v_{\text{rms,Ne}}}{v_{\text{rms,Rn}}} = \sqrt{\dfrac{M_{\text{Rn}}}{M_{\text{Ne}}}} = \sqrt{\dfrac{222 \text{ g/mol}}{20.18 \text{ g/mol}}} = 3.32.$

$\dfrac{v_{\text{rms,Kr}}}{v_{\text{rms,Rn}}} = \sqrt{\dfrac{M_{\text{Rn}}}{M_{\text{Kr}}}} = \sqrt{\dfrac{222 \text{ g/mol}}{83.80 \text{ g/mol}}} = 1.63.$

EVALUATE: The average kinetic energies are the same. The gas atoms with smaller mass have larger v_{rms}.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

18.31. **IDENTIFY** and **SET UP:** $v_{\text{rms}} = \sqrt{\dfrac{3RT}{M}}$.

EXECUTE: **(a)** v_{rms} is different for the two different isotopes, so the 235 isotope diffuses more rapidly.

(b) $\dfrac{v_{\text{rms},235}}{v_{\text{rms},238}} = \sqrt{\dfrac{M_{238}}{M_{235}}} = \sqrt{\dfrac{0.352 \text{ kg/mol}}{0.349 \text{ kg/mol}}} = 1.004.$

EVALUATE: The v_{rms} values each depend on T but their ratio is independent of T.

18.32. **IDENTIFY** and **SET UP:** With the multiplicity of each score denoted by n_i, the average score is $\left(\dfrac{1}{150}\right)\sum n_i x_i$ and the rms score is $\left[\left(\dfrac{1}{150}\right)\sum n_i x_i^2\right]^{1/2}$.

EXECUTE: **(a)** 54.6

(b) 61.1

EVALUATE: The rms score is higher than the average score since the rms calculation gives more weight to the higher scores.

18.33. **IDENTIFY:** $pV = nRT = \dfrac{N}{N_{\text{A}}}RT = \dfrac{m_{\text{tot}}}{M}RT.$

SET UP: We know that $V_A = V_B$ and that $T_A > T_B$.

EXECUTE: **(a)** $p = nRT/V$; we don't know n for each box, so either pressure could be higher.

(b) $pV = \left(\dfrac{N}{N_A}\right)RT$ so $N = \dfrac{pVN_{\text{A}}}{RT}$, where N_{A} is Avogadro's number. We don't know how the pressures compare, so either N could be larger.

(c) $pV = (m_{\text{tot}}/M)RT$. We don't know the mass of the gas in each box, so they could contain the same gas or different gases.

(d) $\frac{1}{2}m(v^2)_{\text{av}} = \frac{3}{2}kT$. $T_{\text{A}} > T_{\text{B}}$ and the average kinetic energy per molecule depends only on T, so the statement **must** be true.

(e) $v_{\text{rms}} = \sqrt{3kT/m}$. We don't know anything about the masses of the atoms of the gas in each box, so either set of molecules could have a larger v_{rms}.

EVALUATE: Only statement (d) must be true. We need more information in order to determine whether the other statements are true or false.

18.34. **IDENTIFY:** We can relate the temperature to the rms speed and the temperature to the pressure using the ideal gas law. The target variable is the pressure.

SET UP: $v_{\text{rms}} = \sqrt{\dfrac{3RT}{M}}$ and $pV = nRT$, where $n = m/M$.

EXECUTE: Use v_{rms} to calculate T: $v_{\text{rms}} = \sqrt{\dfrac{3RT}{M}}$ so

$$T = \frac{Mv_{\text{rms}}^2}{3R} = \frac{(28.014\times10^{-3} \text{ kg/mol})(182 \text{ m/s})^2}{3(8.314 \text{ J/mol}\cdot\text{K})} = 37.20 \text{ K}.$$ The ideal gas law gives $p = \dfrac{nRT}{V}$.

$$n = \frac{m}{M} = \frac{0.226\times10^{-3} \text{ kg}}{28.014\times10^{-3} \text{ kg/mol}} = 8.067\times10^{-3} \text{ mol}.$$ Solving for p gives

$$p = \frac{(8.067\times10^{-3} \text{ mol})(8.314 \text{ J/mol}\cdot\text{K})(37.20 \text{ K})}{1.48\times10^{-3} \text{ m}^3} = 1.69\times10^{3} \text{ Pa}.$$

EVALUATE: This pressure is around 1% of atmospheric pressure, which is not unreasonable since we have only around 1% of a mole of gas.

18.35. **IDENTIFY:** $v_{\text{rms}} = \sqrt{\dfrac{3kT}{m}}$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

SET UP: The mass of a deuteron is $m = m_p + m_n = 1.673\times10^{-27}\ \text{kg} + 1.675\times10^{-27}\ \text{kg} = 3.35\times10^{-27}\ \text{kg}$. $c = 3.00\times10^{8}$ m/s. $k = 1.381\times10^{-23}$ J/molecule · K.

EXECUTE: **(a)** $v_{\text{rms}} = \sqrt{\dfrac{3(1.381\times10^{-23}\ \text{J/molecule}\cdot\text{K})(300\times10^{6}\ \text{K})}{3.35\times10^{-27}\ \text{kg}}} = 1.93\times10^{6}$ m/s. $\dfrac{v_{\text{rms}}}{c} = 6.43\times10^{-3}$.

(b) $T = \left(\dfrac{m}{3k}\right)(v_{\text{rms}})^2 = \left(\dfrac{3.35\times10^{-27}\ \text{kg}}{3(1.381\times10^{-23}\ \text{J/molecule}\cdot\text{K})}\right)(3.0\times10^{7}\ \text{m/s})^2 = 7.3\times10^{10}$ K.

EVALUATE: Even at very high temperatures and for this light nucleus, v_{rms} is a small fraction of the speed of light.

18.36. **IDENTIFY:** $v_{\text{rms}} = \sqrt{\dfrac{3RT}{M}}$, where T is in kelvins. $pV = nRT$ gives $\dfrac{n}{V} = \dfrac{p}{RT}$.

SET UP: $R = 8.314$ J/mol · K. $M = 44.0\times10^{-3}$ kg/mol.

EXECUTE: **(a)** For $T = 0.0°\text{C} = 273.15$ K, $v_{\text{rms}} = \sqrt{\dfrac{3(8.314\ \text{J/mol}\cdot\text{K})(273.15\ \text{K})}{44.0\times10^{-3}\ \text{kg/mol}}} = 393$ m/s. For $T = -100.0°\text{C} = 173$ K, $v_{\text{rms}} = 313$ m/s. The range of speeds is 393 m/s to 313 m/s.

(b) For $T = 273.15$ K, $\dfrac{n}{V} = \dfrac{650\ \text{Pa}}{(8.314\ \text{J/mol}\cdot\text{K})(273.15\ \text{K})} = 0.286\ \text{mol/m}^3$. For $T = 173.15$ K, $\dfrac{n}{V} = 0.452\ \text{mol/m}^3$. The range of densities is $0.286\ \text{mol/m}^3$ to $0.452\ \text{mol/m}^3$.

EVALUATE: When the temperature decreases the rms speed decreases and the density increases.

18.37. **IDENTIFY** and **SET UP:** Apply the analysis of Section 18.3.

EXECUTE: **(a)** $\frac{1}{2}m(v^2)_{\text{av}} = \frac{3}{2}kT = \frac{3}{2}(1.38\times10^{-23}\ \text{J/molecule}\cdot\text{K})(300\ \text{K}) = 6.21\times10^{-21}$ J

(b) We need the mass m of one molecule:

$$m = \frac{M}{N_A} = \frac{32.0\times10^{-3}\ \text{kg/mol}}{6.022\times10^{23}\ \text{molecules/mol}} = 5.314\times10^{-26}\ \text{kg/molecule}$$

Then $\frac{1}{2}m(v^2)_{\text{av}} = 6.21\times10^{-21}$ J (from part (a)) gives

$$(v^2)_{\text{av}} = \frac{2(6.21\times10^{-21}\ \text{J})}{m} = \frac{2(6.21\times10^{-21}\ \text{J})}{5.314\times10^{-26}\ \text{kg}} = 2.34\times10^{5}\ \text{m}^2/\text{s}^2$$

(c) $v_{\text{rms}} = \sqrt{(v^2)_{\text{rms}}} = \sqrt{2.34\times10^{4}\ \text{m}^2/\text{s}^2} = 484$ m/s

(d) $p = mv_{\text{rms}} = (5.314\times10^{-26}\ \text{kg})(484\ \text{m/s}) = 2.57\times10^{-23}\ \text{kg}\cdot\text{m/s}$

(e) Time between collisions with one wall is $t = \dfrac{0.20\ \text{m}}{v_{\text{rms}}} = \dfrac{0.20\ \text{m}}{484\ \text{m/s}} = 4.13\times10^{-4}$ s

In a collision $\vec{v}$ changes direction, so $\Delta p = 2mv_{\text{rms}} = 2(2.57\times10^{-23}\ \text{kg}\cdot\text{m/s}) = 5.14\times10^{-23}\ \text{kg}\cdot\text{m/s}$

$F = \dfrac{dp}{dt}$ so $F_{\text{av}} = \dfrac{\Delta p}{\Delta t} = \dfrac{5.14\times10^{-23}\ \text{kg}\cdot\text{m/s}}{4.13\times10^{-4}\ \text{s}} = 1.24\times10^{-19}$ N

(f) pressure $= F/A = 1.24\times10^{-19}\ \text{N}/(0.10\ \text{m})^2 = 1.24\times10^{-17}$ Pa (due to one molecule)

(g) pressure $= 1$ atm $= 1.013\times10^{5}$ Pa

Number of molecules needed is $1.013\times10^{5}\ \text{Pa}/(1.24\times10^{-17}\ \text{Pa/molecule}) = 8.17\times10^{21}$ molecules

(h) $pV = NkT$ (Eq. 18.18), so $N = \dfrac{pV}{kT} = \dfrac{(1.013\times10^{5}\ \text{Pa})(0.10\ \text{m})^3}{(1.381\times10^{-23}\ \text{J/molecule}\cdot\text{K})(300\ \text{K})} = 2.45\times10^{22}$ molecules

(i) From the factor of $\frac{1}{3}$ in $(v_x^2)_{\text{av}} = \frac{1}{3}(v^2)_{\text{av}}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: This exercise shows that the pressure exerted by a gas arises from collisions of the molecules of the gas with the walls.

18.38. **IDENTIFY:** Apply Eq. (18.22) and calculate λ.

SET UP: 1 atm $= 1.013\times10^5$ Pa, so $p = 3.55\times10^{-8}$ Pa. $r = 2.0\times10^{-10}$ m and $k = 1.38\times10^{-23}$ J/K.

EXECUTE: $\lambda = \dfrac{kT}{4\pi\sqrt{2}r^2p} = \dfrac{(1.38\times10^{-23}\text{ J/K})(300\text{ K})}{4\pi\sqrt{2}(2.0\times10^{-10}\text{ m})^2(3.55\times10^{-8}\text{ Pa})} = 1.6\times10^5\text{ m}$

EVALUATE: At this very low pressure the mean free path is very large. If $v = 484$ m/s, as in Example 18.8, then $t_{\text{mean}} = \dfrac{\lambda}{v} = 330$ s. Collisions are infrequent.

18.39. **IDENTIFY** and **SET UP:** Use equal v_{rms} to relate T and M for the two gases. $v_{\text{rms}} = \sqrt{3RT/M}$ (Eq. 18.19), so $v_{\text{rms}}^2/3R = T/M$, where T must be in kelvins. Same v_{rms} so same T/M for the two gases and $T_{N_2}/M_{N_2} = T_{H_2}/M_{H_2}$.

EXECUTE: $T_{N_2} = T_{H_2}\left(\dfrac{M_{N_2}}{M_{H_2}}\right) = ((20+273)\text{K})\left(\dfrac{28.014\text{ g/mol}}{2.016\text{ g/mol}}\right) = 4.071\times10^3\text{ K}$

$T_{N_2} = (4071-273)°\text{C} = 3800°\text{C}$

EVALUATE: A N_2 molecule has more mass so N_2 gas must be at a higher temperature to have the same v_{rms}.

18.40. **IDENTIFY:** $v_{\text{rms}} = \sqrt{\dfrac{3kT}{m}}$.

SET UP: $k = 1.381\times10^{-23}$ J/molecule · K.

EXECUTE: **(a)** $v_{\text{rms}} = \sqrt{\dfrac{3(1.381\times10^{-23}\text{ J/molecule}\cdot\text{K})(300\text{ K})}{3.00\times10^{-16}\text{ kg}}} = 6.44\times10^{-3}\text{ m/s} = 6.44\text{ mm/s}$

EVALUATE: **(b)** No. The rms speed depends on the average kinetic energy of the particles. At this T, H_2 molecules would have larger v_{rms} than the typical air molecules but would have the same average kinetic energy and the average kinetic energy of the smoke particles would be the same.

18.41. **IDENTIFY:** Use Eq. (18.24), applied to a finite temperature change.

SET UP: $C_V = 5R/2$ for a diatomic ideal gas and $C_V = 3R/2$ for a monatomic ideal gas.

EXECUTE: **(a)** $Q = nC_V\Delta T = n\left(\frac{5}{2}R\right)\Delta T$. $Q = (2.5\text{ mol})(\frac{5}{2})(8.3145\text{ J/mol}\cdot\text{K})(50.0\text{ K}) = 2600\text{ J}$.

(b) $Q = nC_V\Delta T = n(\frac{3}{2}R)\,\Delta T$. $Q = (2.5\text{ mol})(\frac{3}{2})(8.3145\text{ J/mol}\cdot\text{K})(50.0\text{ K}) = 1560\text{ J}$.

EVALUATE: More heat is required for the diatomic gas; not all the heat that goes into the gas appears as translational kinetic energy, some goes into energy of the internal motion of the molecules (rotations).

18.42. **IDENTIFY:** The heat Q added is related to the temperature increase ΔT by $Q = nC_V\Delta T$.

SET UP: For ideal H_2 (a diatomic gas), $C_{V,H_2} = 5/2\,R$, and for ideal Ne (a monatomic gas), $C_{V,\text{Ne}} = 3/2\,R$.

EXECUTE: $C_V\Delta T = \dfrac{Q}{n} = \text{constant}$, so $C_{V,H_2}\Delta T_{H_2} = C_{V,\text{Ne}}\Delta T_{\text{Ne}}$.

$\Delta T_{\text{Ne}} = \left(\dfrac{C_{V,H_2}}{C_{V,\text{Ne}}}\right)\Delta T_{H_2} = \left(\dfrac{5/2\,R}{3/2\,R}\right)(2.50\text{ C°}) = 4.17\text{ C°} = 4.17\text{ K}.$

EVALUATE: The same amount of heat causes a smaller temperature increase for H_2 since some of the energy input goes into the internal degrees of freedom.

18.43. **IDENTIFY:** $C = Mc$, where C is the molar heat capacity and c is the specific heat capacity.

$pV = nRT = \dfrac{m}{M}RT.$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

SET UP: $M_{N_2} = 2(14.007 \text{ g/mol}) = 28.014\times10^{-3}$ kg/mol. For water, $c_w = 4190$ J/kg·K. For N_2, $C_V = 20.76$ J/mol·K.

EXECUTE: **(a)** $c_{N_2} = \dfrac{C}{M} = \dfrac{20.76 \text{ J/mol·K}}{28.014\times10^{-3} \text{ kg/mol}} = 741$ J/kg·K. $\dfrac{c_w}{c_{N_2}} = 5.65$; c_w is over five time larger.

(b) To warm the water, $Q = mc_w\Delta T = (1.00 \text{ kg})(4190 \text{ J/mol·K})(10.0 \text{ K}) = 4.19\times10^4$ J. For air,

$$m = \frac{Q}{c_{N_2}\Delta T} = \frac{4.19\times10^4 \text{ J}}{(741 \text{ J/kg·K})(10.0 \text{ K})} = 5.65 \text{ kg}.$$

$$V = \frac{mRT}{Mp} = \frac{(5.65 \text{ kg})(8.314 \text{ J/mol·K})(293 \text{ K})}{(28.014\times10^{-3} \text{ kg/mol})(1.013\times10^5 \text{ Pa})} = 4.85 \text{ m}^3.$$

EVALUATE: c is smaller for N_2, so less heat is needed for 1.0 kg of N_2 than for 1.0 kg of water.

18.44. **(a) IDENTIFY** and **SET UP:** $\frac{1}{2}R$ contribution to C_V for each degree of freedom. The molar heat capacity C is related to the specific heat capacity c by $C = Mc$.

EXECUTE: $C_V = 6\left(\frac{1}{2}R\right) = 3R = 3(8.3145 \text{ J/mol·K}) = 24.9$ J/mol·K. The specific heat capacity is $c_V = C_V/M = (24.9 \text{ J/mol·K})/(18.0\times10^{-3} \text{ kg/mol}) = 1380$ J/kg·K.

(b) For water vapor the specific heat capacity is $c = 2000$ J/kg·K. The molar heat capacity is $C = Mc = (18.0\times10^{-3} \text{ kg/mol})(2000 \text{ J/kg·K}) = 36.0$ J/mol·K.

EVALUATE: The difference is $36.0 \text{ J/mol·K} - 24.9 \text{ J/mol·K} = 11.1$ J/mol·K, which is about $2.7\left(\frac{1}{2}R\right)$; the vibrational degrees of freedom make a significant contribution.

18.45. **IDENTIFY:** $C_V = 3R$ gives C_V in units of J/mol·K. The atomic mass M gives the mass of one mole.

SET UP: For aluminum, $M = 26.982\times10^{-3}$ kg/mol.

EXECUTE: **(a)** $C_V = 3R = 24.9$ J/mol·K. $c_V = \dfrac{24.9 \text{ J/mol·K}}{26.982\times10^{-3} \text{ kg/mol}} = 923$ J/kg·K.

(b) Table 17.3 gives 910 J/kg·K. The value from Eq. (18.28) is too large by about 1.4%.

EVALUATE: As shown in Figure 18.21 in the textbook, C_V approaches the value $3R$ as the temperature increases. The values in Table 17.3 are at room temperature and therefore are somewhat smaller than $3R$.

18.46. **IDENTIFY:** Table 18.2 gives the value of v/v_{rms} for which 94.7% of the molecules have a smaller value of v/v_{rms}. $v_{rms} = \sqrt{\dfrac{3RT}{M}}$.

SET UP: For N_2, $M = 28.0\times10^{-3}$ kg/mol. $v/v_{rms} = 1.60$.

EXECUTE: $v_{rms} = \dfrac{v}{1.60} = \sqrt{\dfrac{3RT}{M}}$, so the temperature is

$$T = \frac{Mv^2}{3(1.60)^2R} = \frac{(28.0\times10^{-3} \text{ kg/mol})}{3(1.60)^2(8.3145 \text{ J/mol·K})}v^2 = (4.385\times10^{-4} \text{ K·s}^2/\text{m}^2)v^2.$$

(a) $T = (4.385\times10^{-4} \text{ K·s}^2/\text{m}^2)(1500 \text{ m/s})^2 = 987$ K

(b) $T = (4.385\times10^{-4}\text{K·s}^2/\text{m}^2)(1000 \text{ m/s})^2 = 438$ K

(c) $T = (4.385\times10^{-4} \text{ K·s}^2/\text{m}^2)(500 \text{ m/s})^2 = 110$ K

EVALUATE: As T decreases the distribution of molecular speeds shifts to lower values.

18.47. **IDENTIFY:** Apply Eqs. (18.34), (18.35) and (18.36).

SET UP: Note that $\dfrac{k}{m} = \dfrac{R/N_A}{M/N_A} = \dfrac{R}{M}$. $M = 44.0\times10^{-3}$ kg/mol.

EXECUTE: **(a)** $v_{mp} = \sqrt{2(8.3145 \text{ J/mol·K})(300 \text{ K})/(44.0\times10^{-3} \text{ kg/mol})} = 3.37\times10^2$ m/s.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) $v_{av} = \sqrt{8(8.3145 \text{ J/mol}\cdot\text{K})(300 \text{ K})/(\pi(44.0\times10^{-3} \text{ kg/mol}))} = 3.80\times10^2$ m/s.

(c) $v_{rms} = \sqrt{3(8.3145 \text{ J/mol}\cdot\text{K})(300 \text{ K})/(44.0\times10^{-3} \text{ kg/mol})} = 4.12\times10^2$ m/s.

EVALUATE: The average speed is greater than the most probable speed and the rms speed is greater than the average speed.

18.48. **IDENTIFY** and **SET UP:** Eq. (18.33): $f(v) = \dfrac{8\pi}{m}\left(\dfrac{m}{2\pi kT}\right)^{3/2} \epsilon e^{-\epsilon/kT}$

At the maximum of $f(\epsilon)$, $\dfrac{df}{d\epsilon} = 0$.

EXECUTE: $\dfrac{df}{d\epsilon} = \dfrac{8\pi}{m}\left(\dfrac{m}{2\pi kT}\right)^{3/2} \dfrac{d}{d\epsilon}(\epsilon e^{-\epsilon/kT}) = 0$

This requires that $\dfrac{d}{d\epsilon}(\epsilon e^{-\epsilon/kT}) = 0.$

$e^{-\epsilon/kT} - (\epsilon/kT)e^{-\epsilon/kT} = 0$

$(1-\epsilon/kT)e^{-\epsilon/kT} = 0$

This requires that $1-\epsilon/kT = 0$ so $\epsilon = kT$, as was to be shown. And then since $\epsilon = \frac{1}{2}mv^2$, this gives $\frac{1}{2}mv_{mp}^2 = kT$ and $v_{mp} = \sqrt{2kT/m}$, which is Eq. (18.34).

EVALUATE: $v_{rms} = \sqrt{\frac{3}{2}}v_{mp}$. The average of v^2 gives more weight to larger v.

18.49. **IDENTIFY:** Refer to the phase diagram in Figure 18.24 in the textbook.

SET UP: For water the triple-point pressure is 610 Pa and the critical-point pressure is 2.212×10^7 Pa.

EXECUTE: **(a)** To observe a solid to liquid (melting) phase transition the pressure must be greater than the triple-point pressure, so $p_1 = 610$ Pa. For $p < p_1$ the solid to vapor (sublimation) phase transition is observed.

(b) No liquid to vapor (boiling) phase transition is observed if the pressure is greater than the critical-point pressure. $p_2 = 2.212\times10^7$ Pa. For $p_1 < p < p_2$ the sequence of phase transitions are solid to liquid and then liquid to vapor.

EVALUATE: Normal atmospheric pressure is approximately 1.0×10^5 Pa, so the solid to liquid to vapor sequence of phase transitions is normally observed when the material is water.

18.50. **IDENTIFY** and **SET UP:** If the temperature at altitude y is below the freezing point only cirrus clouds can form. Use $T = T_0 - \alpha y$ to find the y that gives $T = 0.0°\text{C}$.

EXECUTE: $y = \dfrac{T_0 - T}{\alpha} = \dfrac{15.0°\text{C} - 0.0°\text{C}}{6.0 \text{ C°/km}} = 2.5 \text{ km}$

EVALUATE: The solid-liquid phase transition occurs at 0°C only for $p = 1.01\times10^5$ Pa. Use the results of Example 18.4 to estimate the pressure at an altitude of 2.5 km.

$p_2 = p_1 e^{Mg(y_2-y_1)/RT}$

$Mg(y_2 - y_1)/RT = 1.10(2500 \text{ m}/8863 \text{ m}) = 0.310$ (using the calculation in Example 18.4)

Then $p_2 = (1.01\times10^5 \text{ Pa})e^{-0.31} = 0.74\times10^5$ Pa.

This pressure is well above the triple point pressure for water. Figure 18.24 in the textbook shows that the fusion curve has large slope and it takes a large change in pressure to change the phase transition temperature very much. Using 0.0°C introduces little error.

18.51. **IDENTIFY:** Figure 18.24 in the textbook shows that there is no liquid phase below the triple point pressure.

SET UP: Table 18.3 gives the triple point pressure to be 610 Pa for water and 5.17×10^5 Pa for CO_2.

EXECUTE: The atmospheric pressure is below the triple point pressure of water, and there can be no liquid water on Mars. The same holds true for CO_2.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: On earth $p_{atm} = 1\times10^5$ Pa, so on the surface of the earth there can be liquid water but not liquid CO_2.

18.52. **IDENTIFY:** The ideal gas law will tell us the number of moles of gas in the room, which we can use to find the number of molecules.

SET UP: $pV = nRT$, $N = nN_A$, and $m = nM$.

EXECUTE: **(a)** $T = 27.0°\text{C} + 273 = 300$ K. $p = 1.013\times10^5$ Pa.

$$n = \frac{pV}{RT} = \frac{(1.013\times10^5\ \text{Pa})(216\ \text{m}^3)}{(8.314\ \text{J/mol}\cdot\text{K})(300\ \text{K})} = 8773\ \text{mol}.$$

$N = nN_A = (8773\ \text{mol})(6.022\times10^{23}\ \text{molecules/mol}) = 5.28\times10^{27}$ molecules.

(b) $V = (216\ \text{m}^3)(1\ \text{cm}^3/10^{-6}\ \text{m}^3) = 2.16\times10^8\ \text{cm}^3$. The particle density is

$$\frac{5.28\times10^{27}\ \text{molecules}}{2.16\times10^8\ \text{cm}^3} = 2.45\times10^{19}\ \text{molecules/cm}^3.$$

(c) $m = nM = (8773\ \text{mol})(28.014\times10^{-3}\ \text{kg/mol}) = 246$ kg.

EVALUATE: A cubic centimeter of air (about the size of a sugar cube) contains around 10^{19} molecules, and the air in the room weighs about 500 lb!

18.53. **IDENTIFY:** We can model the atmosphere as a fluid of constant density, so the pressure depends on the depth in the fluid, as we saw in Section 12.2.

SET UP: The pressure difference between two points in a fluid is $\Delta p = \rho gh$, where h is the difference in height of two points.

EXECUTE: **(a)** $\Delta p = \rho gh = (1.2\ \text{kg/m}^3)(9.80\ \text{m/s}^2)(1000\ \text{m}) = 1.18\times10^4$ Pa.

(b) At the bottom of the mountain, $p = 1.013\times10^5$ Pa. At the top, $p = 8.95\times10^4$ Pa.

$$pV = nRT = \text{constant}\ \text{ so }\ p_bV_b = p_tV_t \ \text{ and }\ V_t = V_b\left(\frac{p_b}{p_t}\right) = (0.50\ \text{L})\left(\frac{1.013\times10^5\ \text{Pa}}{8.95\times10^4\ \text{Pa}}\right) = 0.566\ \text{L}.$$

EVALUATE: The pressure variation with altitude is affected by changes in air density and temperature and we have neglected those effects. The pressure decreases with altitude and the volume increases. You may have noticed this effect: bags of potato chips "puff up" when taken to the top of a mountain.

18.54. **IDENTIFY:** As the pressure on the bubble changes, its volume will change. As we saw in Section 12.2, the pressure in a fluid depends on the depth.

SET UP: The pressure at depth h in a fluid is $p = p_0 + \rho gh$, where p_0 is the pressure at the surface.

$p_0 = p_{air} = 1.013\times10^5$ Pa. The density of water is $\rho = 1000\ \text{kg/m}^3$.

EXECUTE: $p_1 = p_0 + \rho gh = 1.013\times10^5\ \text{Pa} + (1000\ \text{kg/m}^3)(9.80\ \text{m/s}^2)(25\ \text{m}) = 3.463\times10^5$ Pa.

$p_2 = p_{air} = 1.013\times10^5$ Pa. $V_1 = 1.0\ \text{mm}^3$. n, R and T are constant so $pV = nRT = \text{constant}$. $p_1V_1 = p_2V_2$

and $V_2 = V_1\left(\frac{p_1}{p_2}\right) = (1.0\ \text{mm}^3)\left(\frac{3.463\times10^5\ \text{Pa}}{1.013\times10^5\ \text{Pa}}\right) = 3.4\ \text{mm}^3$.

EVALUATE: This is a large change and would have serious effects.

18.55. **IDENTIFY:** The buoyant force on the balloon must be equal to the weight of the load plus the weight of the gas.

SET UP: The buoyant force is $F_B = \rho_{air}Vg$. A lift of 290 kg means $\frac{F_B}{g} - m_{hot} = 290$ kg, where m_{hot} is the mass of hot air in the balloon. $m = \rho V$.

EXECUTE: $m_{hot} = \rho_{hot}V$. $\frac{F_B}{g} - m_{hot} = 290$ kg gives $(\rho_{air} - \rho_{hot})V = 290$ kg.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

Solving for ρ_{hot} gives $\rho_{\text{hot}} = \rho_{\text{air}} - \dfrac{290\text{ kg}}{V} = 1.23\text{ kg/m}^3 - \dfrac{290\text{ kg}}{500.0\text{ m}^3} = 0.65\text{ kg/m}^3$. $\rho_{\text{hot}} = \dfrac{pM}{RT_{\text{hot}}}$.

$\rho_{\text{air}} = \dfrac{pM}{RT_{\text{air}}}$. $\rho_{\text{hot}}T_{\text{hot}} = \rho_{\text{air}}T_{\text{air}}$ so

$$T_{\text{hot}} = T_{\text{air}}\left(\frac{\rho_{\text{air}}}{\rho_{\text{hot}}}\right) = (288\text{ K})\left(\frac{1.23\text{ kg/m}^3}{0.65\text{ kg/m}^3}\right) = 545\text{ K} = 272°\text{C}.$$

EVALUATE: This temperature is well above normal air temperatures, so the air in the balloon would need considerable heating.

18.56. **IDENTIFY:** $\Delta V = \beta V_0 \Delta T - V_0 k \Delta p$

SET UP: For steel, $\beta = 3.6\times10^{-5}\text{ K}^{-1}$ and $k = 6.25\times10^{-12}\text{ Pa}^{-1}$.

EXECUTE: $\beta V_0 \Delta T = (3.6\times10^{-5}\text{ K}^{-1})(11.0\text{ L})(21\text{ C°}) = 0.0083\text{ L}$.

$-kV_0\Delta p = -(6.25\times10^{-12}/\text{Pa})(11\text{ L})(2.1\times10^7\text{ Pa}) = -0.0014\text{ L}$. The total change in volume is

$\Delta V = 0.0083\text{ L} - 0.0014\text{ L} = 0.0069\text{ L}$.

(b) Yes; ΔV is much less than the original volume of 11.0 L.

EVALUATE: Even for a large pressure increase and a modest temperature increase, the magnitude of the volume change due to the temperature increase is much larger than that due to the pressure increase.

18.57. **IDENTIFY:** We are asked to compare two states. Use the ideal-gas law to obtain m_2 in terms of m_1 and the ratio of pressures in the two states. Apply Eq. (18.4) to the initial state to calculate m_1.

SET UP: $pV = nRT$ can be written $pV = (m/M)RT$

T, V, M, R are all constant, so $p/m = RT/MV = \text{constant}$.

So $p_1/m_1 = p_2/m_2$, where m is the mass of the gas in the tank.

EXECUTE: $p_1 = 1.30\times10^6\text{ Pa} + 1.01\times10^5\text{ Pa} = 1.40\times10^6\text{ Pa}$

$p_2 = 2.50\times10^5\text{ Pa} + 1.01\times10^5\text{ Pa} = 3.51\times10^5\text{ Pa}$

$m_1 = p_1VM/RT$; $V = hA = h\pi r^2 = (1.00\text{ m})\pi(0.060\text{ m})^2 = 0.01131\text{ m}^3$

$$m_1 = \frac{(1.40\times10^6\text{ Pa})(0.01131\text{ m}^3)(44.1\times10^{-3}\text{ kg/mol})}{(8.3145\text{ J/mol}\cdot\text{K})((22.0+273.15)\text{K})} = 0.2845\text{ kg}$$

Then $m_2 = m_1\left(\dfrac{p_2}{p_1}\right) = (0.2845\text{ kg})\left(\dfrac{3.51\times10^5\text{ Pa}}{1.40\times10^6\text{ Pa}}\right) = 0.0713\text{ kg}$.

m_2 is the mass that remains in the tank. The mass that has been used is

$m_1 - m_2 = 0.2845\text{ kg} - 0.0713\text{ kg} = 0.213\text{ kg}$.

EVALUATE: Note that we have to use absolute pressures. The absolute pressure decreases by a factor of four and the mass of gas in the tank decreases by a factor of four.

18.58. **IDENTIFY:** Apply $pV = nRT$ to the air inside the diving bell. The pressure p at depth y below the surface of the water is $p = p_{\text{atm}} + \rho g y$.

SET UP: $p = 1.013\times10^5$ Pa. $T = 300.15$ K at the surface and $T' = 280.15$ K at the depth of 13.0 m.

EXECUTE: **(a)** The height h' of the air column in the diving bell at this depth will be proportional to the volume, and hence inversely proportional to the pressure and proportional to the Kelvin temperature:

$$h' = h\frac{p}{p'}\frac{T'}{T} = h\frac{p_{\text{atm}}}{p_{\text{atm}} + \rho g y}\frac{T'}{T}.$$

$$h' = (2.30\text{ m})\frac{(1.013\times10^5\text{ Pa})}{(1.013\times10^5\text{ Pa}) + (1030\text{ kg/m}^3)(9.80\text{ m/s}^2)(73.0\text{ m})}\left(\frac{280.15\text{ K}}{300.15\text{ K}}\right) = 0.26\text{ m}.$$

The height of the water inside the diving bell is $h - h' = 2.04$ m.

(b) The necessary gauge pressure is the term $\rho g y$ from the above calculation, $p_{\text{gauge}} = 7.37\times10^5$ Pa.

EVALUATE: The gauge pressure required in part (b) is about 7 atm.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

18.59. **IDENTIFY:** $pV = NkT$ gives $\frac{N}{V} = \frac{p}{kT}$.

SET UP: 1 atm $= 1.013\times10^5$ Pa. $T_K = T_C + 273.15$. $k = 1.381\times10^{-23}$ J/molecule $\cdot$ K.

EXECUTE: **(a)** $T_C = T_K - 273.15 = 94\text{ K} - 273.15 = -179°\text{C}$

(b) $\frac{N}{V} = \frac{p}{kT} = \frac{(1.5\text{ atm})(1.013\times10^5\text{ Pa/atm})}{(1.381\times10^{-23}\text{ J/molecule}\cdot\text{K})(94\text{ K})} = 1.2\times10^{26}$ molecules/m^3

(c) For the earth, $p = 1.0$ atm $= 1.013\times10^5$ Pa and $T = 22°\text{C} = 295$ K.

$\frac{N}{V} = \frac{(1.0\text{ atm})(1.013\times10^5\text{ Pa/atm})}{(1.381\times10^{-23}\text{ J/molecule}\cdot\text{K})(295\text{ K})} = 2.5\times10^{25}$ molecules/m^3. The atmosphere of Titan is about five times denser than earth's atmosphere.

EVALUATE: Though it is smaller than Earth and has weaker gravity at its surface, Titan can maintain a dense atmosphere because of the very low temperature of that atmosphere.

18.60. **IDENTIFY:** For constant temperature, the variation of pressure with altitude is calculated in Example 18.4 to be $p = p_0e^{-Mgy/RT}$. $v_{rms} = \sqrt{\frac{3RT}{M}}$.

SET UP: $g_{Earth} = 9.80$ m/s^2. $T = 460°\text{C} = 733$ K. $M = 44.0$ g/mol $= 44.0\times10^{-3}$ kg/mol.

EXECUTE: **(a)** $\frac{Mgy}{RT} = \frac{(44.0\times10^{-3}\text{ kg/mol})(0.894)(9.80\text{ m/s}^2)(1.00\times10^3\text{ m})}{(8.314\text{ J/mol}\cdot\text{K})(733\text{ K})} = 0.06326.$

$p = p_0e^{-Mgy/RT} = (92\text{ atm})e^{-0.06326} = 86$ atm. The pressure is 86 earth-atmospheres, or 0.94 Venus-atmospheres.

(b) $v_{rms} = \sqrt{\frac{3RT}{M}} = \sqrt{\frac{3(8.314\text{ J/mol}\cdot\text{K})(733\text{ K})}{44.0\times10^{-3}\text{ kg/mol}}} = 645$ m/s. v_{rms} has this value both at the surface and at an altitude of 1.00 km.

EVALUATE: v_{rms} depends only on T and the molar mass of the gas. For Venus compared to earth, the surface temperature, in kelvins, is nearly a factor of three larger and the molecular mass of the gas in the atmosphere is only about 50% larger, so v_{rms} for the Venus atmosphere is larger than it is for the earth's atmosphere.

18.61. **IDENTIFY:** $pV = nRT$

SET UP: In $pV = nRT$ we must use the absolute pressure. $T_1 = 278$ K. $p_1 = 2.72$ atm. $T_2 = 318$ K.

EXECUTE: n, R constant, so $\frac{pV}{T} = nR = \text{constant}$. $\frac{p_1V_1}{T_1} = \frac{p_2V_2}{T_2}$ and

$p_2 = p_1\left(\frac{V_1}{V_2}\right)\left(\frac{T_2}{T_1}\right) = (2.72\text{ atm})\left(\frac{0.0150\text{ m}^3}{0.0159\text{ m}^3}\right)\left(\frac{318\text{ K}}{278\text{ K}}\right) = 2.94$ atm. The final gauge pressure is $2.94\text{ atm} - 1.02\text{ atm} = 1.92$ atm.

EVALUATE: Since a ratio is used, pressure can be expressed in atm. But absolute pressures must be used. The ratio of gauge pressures is not equal to the ratio of absolute pressures.

18.62. **IDENTIFY:** In part (a), apply $pV = nRT$ to the ethane in the flask. The volume is constant once the stopcock is in place. In part (b) apply $pV = \frac{m_{tot}}{M}RT$ to the ethane at its final temperature and pressure.

SET UP: 1.50 L $= 1.50\times10^{-3}$ m^3. $M = 30.1\times10^{-3}$ kg/mol. Neglect the thermal expansion of the flask.

EXECUTE: **(a)** $p_2 = p_1(T_2/T_1) = (1.013\times10^5\text{ Pa})(300\text{ K}/490\text{ K}) = 6.20\times10^4$ Pa.

(b) $m_{tot} = \left(\frac{p_2V}{RT_2}\right)M = \left(\frac{(6.20\times10^4\text{ Pa})(1.50\times10^{-3}\text{ m}^3)}{(8.3145\text{ J/mol}\cdot\text{K})(300\text{ K})}\right)(30.1\times10^{-3}\text{ Kg/mol}) = 1.12$ g.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: We could also calculate m_{tot} with $p = 1.013\times10^5$ Pa and $T = 490$ K, and we would obtain the same result. Originally, before the system was warmed, the mass of ethane in the flask was

$$m = (1.12\text{ g})\left(\frac{1.013\times10^5\text{ Pa}}{6.20\times10^4\text{ Pa}}\right) = 1.83\text{ g}.$$

18.63. **(a) IDENTIFY:** Consider the gas in one cylinder. Calculate the volume to which this volume of gas expands when the pressure is decreased from $(1.20\times10^6\text{ Pa} + 1.01\times10^5\text{ Pa}) = 1.30\times10^6$ Pa to 1.01×10^5 Pa. Apply the ideal-gas law to the two states of the system to obtain an expression for V_2 in terms of V_1 and the ratio of the pressures in the two states.

SET UP: $pV = nRT$

n, R, T constant implies $pV = nRT = \text{constant}$, so $p_1V_1 = p_2V_2$.

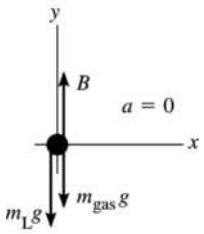
EXECUTE: $V_2 = V_1(p_1/p_2) = (1.90\text{ m}^3)\left(\frac{1.30\times10^6\text{ Pa}}{1.01\times10^5\text{ Pa}}\right) = 24.46\text{ m}^3$

The number of cylinders required to fill a 750 m^3 balloon is $750\text{ m}^3/24.46\text{ m}^3 = 30.7$ cylinders.

EVALUATE: The ratio of the volume of the balloon to the volume of a cylinder is about 400. Fewer cylinders than this are required because of the large factor by which the gas is compressed in the cylinders.

(b) IDENTIFY: The upward force on the balloon is given by Archimedes's principle (Chapter 12): $B = \text{weight of air displaced by balloon} = \rho_{\text{air}}Vg$. Apply Newton's second law to the balloon and solve for the weight of the load that can be supported. Use the ideal-gas equation to find the mass of the gas in the balloon.

SET UP: The free-body diagram for the balloon is given in Figure 18.63.



m_{gas} is the mass of the gas that is inside the balloon; m_{L} is the mass of the load that is supported by the balloon.

EXECUTE: $\sum F_y = ma_y$

$B - m_{\text{L}}g - m_{\text{gas}}g = 0$

Figure 18.63

$\rho_{\text{air}}Vg - m_{\text{L}}g - m_{\text{gas}}g = 0$

$m_{\text{L}} = \rho_{\text{air}}V - m_{\text{gas}}$

Calculate m_{gas}, the mass of hydrogen that occupies 750 m^3 at 15°C and $p = 1.01\times10^5$ Pa.

$pV = nRT = (m_{\text{gas}}/M)RT$ gives

$$m_{\text{gas}} = pVM/RT = \frac{(1.01\times10^5\text{ Pa})(750\text{ m}^3)(2.02\times10^{-3}\text{ kg/mol})}{(8.3145\text{ J/mol}\cdot\text{K})(288\text{ K})} = 63.9\text{ kg}$$

Then $m_{\text{L}} = (1.23\text{ kg/m}^3)(750\text{ m}^3) - 63.9\text{ kg} = 859\text{ kg}$, and the weight that can be supported is

$w_{\text{L}} = m_{\text{L}}g = (859\text{ kg})(9.80\text{ m/s}^2) = 8420$ N.

(c) $m_{\text{L}} = \rho_{\text{air}}V - m_{\text{gas}}$

$m_{\text{gas}} = pVM/RT = (63.9\text{ kg})((4.00\text{ g/mol})/(2.02\text{ g/mol})) = 126.5\text{ kg}$ (using the results of part (b)).

Then $m_{\text{L}} = (1.23\text{ kg/m}^3)(750\text{ m}^3) - 126.5\text{ kg} = 796\text{ kg}$.

$w_{\text{L}} = m_{\text{L}}g = (796\text{ kg})(9.80\text{ m/s}^2) = 7800$ N.

EVALUATE: A greater weight can be supported when hydrogen is used because its density is less.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

18.64. **IDENTIFY:** The upward force exerted by the gas on the piston must equal the piston's weight. Use $pV = nRT$ to calculate the volume of the gas, and from this the height of the column of gas in the cylinder.

SET UP: $F = pA = p\pi r^2$, with $r = 0.100$ m and $p = 0.500$ atm $= 5.065\times10^4$ Pa. For the cylinder, $V = \pi r^2 h$.

EXECUTE: **(a)** $p\pi r^2 = mg$ and $m = \dfrac{p\pi r^2}{g} = \dfrac{(5.065\times10^4\ \text{Pa})\pi(0.100\ \text{m})^2}{9.80\ \text{m/s}^2} = 162$ kg.

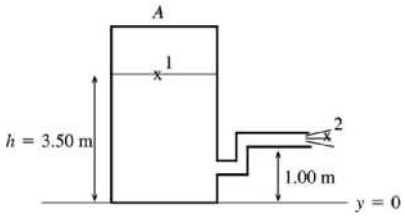
(b) $V = \pi r^2 h$ and $V = nRT/p$. Combining these equations gives $h = nRT/\pi r^2 p$, which gives

$$h = \frac{(1.80\ \text{mol})(8.314\ \text{J/mol}\cdot\text{K})(293.15\ \text{K})}{\pi(0.100\ \text{m})^2(5.065\times10^4\ \text{Pa})} = 276\ \text{m}.$$

EVALUATE: The calculation assumes a vacuum $(p = 0)$ in the tank above the piston.

18.65. **IDENTIFY:** Apply Bernoulli's equation to relate the efflux speed of water out the hose to the height of water in the tank and the pressure of the air above the water in the tank. Use the ideal-gas equation to relate the volume of the air in the tank to the pressure of the air.

(a) SET UP: Points 1 and 2 are shown in Figure 18.65.



$p_1 = 4.20\times10^5$ Pa

$p_2 = p_{\text{air}} = 1.00\times10^5$ Pa

large tank implies $v_1 \approx 0$

Figure 18.65

EXECUTE: $p_1 + \rho g y_1 + \frac{1}{2}\rho v_1^2 = p_2 + \rho g y_2 + \frac{1}{2}\rho v_2^2$

$\frac{1}{2}\rho v_2^2 = p_1 - p_2 + \rho g(y_1 - y_2)$

$v_2 = \sqrt{(2/\rho)(p_1 - p_2) + 2g(y_1 - y_2)}$

$v_2 = 26.2$ m/s

(b) $\underline{h = 3.00\ \text{m}}$

The volume of the air in the tank increases so its pressure decreases. $pV = nRT = \text{constant}$, so $pV = p_0V_0$ (p_0 is the pressure for $h_0 = 3.50$ m and p is the pressure for $h = 3.00$ m)

$p(4.00\ \text{m} - h)A = p_0(4.00\ \text{m} - h_0)A$

$$p = p_0\left(\frac{4.00\ \text{m} - h_0}{4.00\ \text{m} - h}\right) = (4.20\times10^5\ \text{Pa})\left(\frac{4.00\ \text{m} - 3.50\ \text{m}}{4.00\ \text{m} - 3.00\ \text{m}}\right) = 2.10\times10^5\ \text{Pa}$$

Repeat the calculation of part (a), but now $p_1 = 2.10\times10^5$ Pa and $y_1 = 3.00$ m.

$v_2 = \sqrt{(2/\rho)(p_1 - p_2) + 2g(y_1 - y_2)}$

$v_2 = 16.1$ m/s

$\underline{h = 2.00\ \text{m}}$

$$p = p_0\left(\frac{4.00\ \text{m} - h_0}{4.00\ \text{m} - h}\right) = (4.20\times10^5\ \text{Pa})\left(\frac{4.00\ \text{m} - 3.50\ \text{m}}{4.00\ \text{m} - 2.00\ \text{m}}\right) = 1.05\times10^5\ \text{Pa}$$

$v_2 = \sqrt{(2/\rho)(p_1 - p_2) + 2g(y_1 - y_2)}$

$v_2 = 5.44$ m/s

(c) $v_2 = 0$ means $(2/\rho)(p_1 - p_2) + 2g(y_1 - y_2) = 0$

$p_1 - p_2 = -\rho g(y_1 - y_2)$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$y_1 - y_2 = h - 1.00\ \text{m}$

$p = p_0\left(\dfrac{0.50\ \text{m}}{4.00\ \text{m} - h}\right) = (4.20\times10^5\ \text{Pa})\left(\dfrac{0.50\ \text{m}}{4.00\ \text{m} - h}\right)$. This is p_1, so

$(4.20\times10^5\ \text{Pa})\left(\dfrac{0.50\ \text{m}}{4.00\ \text{m} - h}\right) - 1.00\times10^5\ \text{Pa} = (9.80\ \text{m/s}^2)(1000\ \text{kg/m}^3)(1.00\ \text{m} - h)$

$(210/(4.00 - h)) - 100 = 9.80 - 9.80h,$ with h in meters.

$210 = (4.00 - h)(109.8 - 9.80h)$

$9.80h^2 - 149h + 229.2 = 0$ and $h^2 - 15.20h + 23.39 = 0$

quadratic formula: $h = \frac{1}{2}\left(15.20 \pm \sqrt{(15.20)^2 - 4(23.39)}\right) = (7.60 \pm 5.86)\ \text{m}$

h must be less than 4.00 m, so the only acceptable value is $h = 7.60\ \text{m} - 5.86\ \text{m} = 1.74\ \text{m}$

EVALUATE: The flow stops when $p + \rho g(y_1 - y_2)$ equals air pressure. For $h = 1.74$ m, $p = 9.3\times10^4$ Pa and $\rho g(y_1 - y_2) = 0.7\times10^4$ Pa, so $p + \rho g(y_1 - y_2) = 1.0\times10^5$ Pa, which is air pressure.

18.66. **IDENTIFY:** Use the ideal gas law to find the number of moles of air taken in with each breath and from this calculate the number of oxygen molecules taken in. Then find the pressure at an elevation of 2000 m and repeat the calculation.

SET UP: The number of molecules in a mole is $N_A = 6.022\times10^{23}$ molecules/mol. $R = 0.08206\ \text{L}\cdot\text{atm/mol}\cdot\text{K}$. Example 18.4 shows that the pressure variation with altitude y, when constant temperature is assumed, is $p = p_0e^{-Mgy/RT}$. For air, $M = 28.8\times10^{-3}$ kg/mol.

EXECUTE: **(a)** $pV = nRT$ gives $n = \dfrac{pV}{RT} = \dfrac{(1.00\ \text{atm})(0.50\ \text{L})}{(0.08206\ \text{L}\cdot\text{atm/mol}\cdot\text{K})(293.15\ \text{K})} = 0.0208\ \text{mol}.$

$N = (0.210)nN_A = (0.210)(0.0208\ \text{mol})(6.022\times10^{23}\ \text{molecules/mol}) = 2.63\times10^{21}\ \text{molecules}.$

(b) $\dfrac{Mgy}{RT} = \dfrac{(28.8\times10^{-3}\ \text{kg/mol})(9.80\ \text{m/s}^2)(2000\ \text{m})}{(8.314\ \text{J/mol}\cdot\text{K})(293.15\ \text{K})} = 0.2316.$

$p = p_0e^{-Mgy/RT} = (1.00\ \text{atm})e^{-0.2316} = 0.793\ \text{atm}.$

N is proportional to n, which is in turn proportional to p, so

$N = \left(\dfrac{0.793\ \text{atm}}{1.00\ \text{atm}}\right)(2.63\times10^{21}\ \text{molecules}) = 2.09\times10^{21}\ \text{molecules}.$

(c) Less O_2 is taken in with each breath at the higher altitude, so the person must take more breaths per minute.

EVALUATE: A given volume of gas contains fewer molecules when the pressure is lowered and the temperature is kept constant.

18.67. **IDENTIFY** and **SET UP:** Apply Eq.(18.2) to find n and then use Avogadro's number to find the number of molecules.

EXECUTE: Calculate the number of water molecules N.

Number of moles: $n = \dfrac{m_{\text{tot}}}{M} = \dfrac{50\ \text{kg}}{18.0\times10^{-3}\ \text{kg/mol}} = 2.778\times10^3\ \text{mol}$

$N = nN_A = (2.778\times10^3\ \text{mol})(6.022\times10^{23}\ \text{molecules/mol}) = 1.7\times10^{27}\ \text{molecules}$

Each water molecule has three atoms, so the number of atoms is $3(1.7\times10^{27}) = 5.1\times10^{27}$ atoms

EVALUATE: We could also use the masses in Example 18.5 to find the mass m of one H_2O molecule: $m = 2.99\times10^{-26}$ kg. Then $N = m_{\text{tot}}/m = 1.7\times10^{27}$ molecules, which checks.

18.68. **IDENTIFY:** $pV = nRT = \dfrac{N}{N_A}RT$. Deviations will be noticeable when the volume V of a molecule is on the order of 1% of the volume of gas that contains one molecule.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

SET UP: The volume of a sphere of radius r is $V = \frac{4}{3}\pi r^3$.

EXECUTE: The volume of gas per molecule is $\frac{RT}{N_A p}$, and the volume of a molecule is about $V_0 = \frac{4}{3}\pi(2.0\times10^{-10}\text{m})^3 = 3.4\times10^{-29}\text{m}^3$. Denoting the ratio of these volumes as f,

$$p = f\frac{RT}{N_A V_0} = f\frac{(8.3145\text{ J/mol}\cdot\text{K})(300\text{ K})}{(6.022\times10^{23}\text{ molecules/mol})(3.4\times10^{-29}\text{ m}^3)} = (1.2\times10^8\text{ Pa})f.$$

"Noticeable deviations" is a subjective term, but f on the order of 1.0% gives a pressure of 10^6 Pa.

EVALUATE: The forces between molecules also cause deviations from ideal-gas behavior.

18.69. **IDENTIFY:** Eq. (18.16) says that the average translational kinetic energy of each molecule is equal to $\frac{3}{2}kT$. $v_{\text{rms}} = \sqrt{\frac{3kT}{m}}$.

SET UP: $k = 1.381\times10^{-23}$ J/molecule·K.

EXECUTE: **(a)** $\frac{1}{2}m(v^2)_{\text{av}}$ depends only on T and both gases have the same T, so both molecules have the same average translational kinetic energy. v_{rms} is proportional to $m^{-1/2}$, so the lighter molecules, A, have the greater v_{rms}.

(b) The temperature of gas B would need to be raised.

(c) $\sqrt{\frac{T}{m}} = \frac{v_{\text{rms}}}{\sqrt{3k}} = \text{constant}$, so $\frac{T_A}{m_A} = \frac{T_B}{m_B}$.

$$T_B = \left(\frac{m_B}{m_A}\right)T_A = \left(\frac{5.34\times10^{-26}\text{ kg}}{3.34\times10^{-27}\text{ kg}}\right)(283.15\text{ K}) = 4.53\times10^3\text{ K} = 4250°\text{C}.$$

(d) $T_B > T_A$ so the B molecules have greater translational kinetic energy per molecule.

EVALUATE: In $\frac{1}{2}m(v^2)_{\text{av}} = \frac{3}{2}kT$ and $v_{\text{rms}} = \sqrt{\frac{3kT}{m}}$ the temperature T must be in kelvins.

18.70. **IDENTIFY:** The equations derived in the subsection Collisions Between Molecules in Section 18.3 can be applied to the bees. The average distance a bee travels between collisions is the mean free path, λ. The average time between collisions is the mean free time, t_{mean}. The number of collisions per second is $\frac{dN}{dt} = \frac{1}{t_{\text{mean}}}$.

SET UP: $V = (1.25\text{ m})^3 = 1.95\text{ m}^3$. $r = 0.750\times10^{-2}$ m. $v = 1.10$ m/s. $N = 2500$.

EXECUTE: **(a)** $\lambda = \frac{V}{4\pi\sqrt{2}r^2N} = \frac{1.95\text{ m}^3}{4\pi\sqrt{2}(0.750\times10^{-2}\text{ m})^2(2500)} = 0.780\text{ m} = 78.0\text{ cm}$

(b) $\lambda = vt_{\text{mean}}$, so $t_{\text{mean}} = \frac{\lambda}{v} = \frac{0.780\text{ m}}{1.10\text{ m/s}} = 0.709\text{ s}$.

(c) $\frac{dN}{dt} = \frac{1}{t_{\text{mean}}} = \frac{1}{0.709\text{ s}} = 1.41$ collisions/s

EVALUATE: The calculation is valid only if the motion of each bee is random.

18.71. **IDENTIFY:** The mass of one molecule is the molar mass, M, divided by the number of molecules in a mole, N_A. The average translational kinetic energy of a single molecule is $\frac{1}{2}m(v^2)_{\text{av}} = \frac{3}{2}kT$. Use $pV = NkT$ to calculate N, the number of molecules.

SET UP: $k = 1.381\times10^{-23}$ J/molecule·K. $M = 28.0\times10^{-3}$ kg/mol. $T = 295.15$ K. The volume of the balloon is $V = \frac{4}{3}\pi(0.250\text{ m})^3 = 0.0654\text{ m}^3$. $p = 1.25\text{ atm} = 1.27\times10^5$ Pa.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: **(a)** $m = \dfrac{M}{N_A} = \dfrac{28.0\times10^{-3}\ \text{kg/mol}}{6.022\times10^{23}\ \text{molecules/mol}} = 4.65\times10^{-26}\ \text{kg}$

(b) $\frac{1}{2}m(v^2)_{\text{av}} = \frac{3}{2}kT = \frac{3}{2}(1.381\times10^{-23}\ \text{J/molecule}\cdot\text{K})(295.15\ \text{K}) = 6.11\times10^{-21}\ \text{J}$

(c) $N = \dfrac{pV}{kT} = \dfrac{(1.27\times10^{5}\ \text{Pa})(0.0654\ \text{m}^3)}{(1.381\times10^{-23}\ \text{J/molecule}\cdot\text{K})(295.15\ \text{K})} = 2.04\times10^{24}\ \text{molecules}$

(d) The total average translational kinetic energy is
$N\left(\frac{1}{2}m(v^2)_{\text{av}}\right) = (2.04\times10^{24}\ \text{molecules})(6.11\times10^{-21}\ \text{J/molecule}) = 1.25\times10^{4}\ \text{J}.$

EVALUATE: The number of moles is $n = \dfrac{N}{N_A} = \dfrac{2.04\times10^{24}\ \text{molecules}}{6.022\times10^{23}\ \text{molecules/mol}} = 3.39\ \text{mol}.$

$K_{\text{tr}} = \frac{3}{2}nRT = \frac{3}{2}(3.39\ \text{mol})(8.314\ \text{J/mol}\cdot\text{K})(295.15\ \text{K}) = 1.25\times10^{4}\ \text{J},$ which agrees with our results in part (d).

18.72. **IDENTIFY:** $U = mgy$. The mass of one molecule is $m = M/N_A$. $K_{\text{av}} = \frac{3}{2}kT$.

SET UP: Let $y = 0$ at the surface of the earth and $h = 400$ m. $N_A = 6.022\times10^{23}$ molecules/mol and $k = 1.38\times10^{-23}$ J/K. $15.0°\text{C} = 288$ K.

EXECUTE: **(a)** $U = mgh = \dfrac{M}{N_A}gh = \left(\dfrac{28.0\times10^{-3}\ \text{kg/mol}}{6.022\times10^{23}\ \text{molecules/mol}}\right)(9.80\ \text{m/s}^2)(400\ \text{m}) = 1.82\times10^{-22}\ \text{J}.$

(b) Setting $U = \dfrac{3}{2}kT,\ T = \dfrac{2}{3}\left(\dfrac{1.82\times10^{-22}\ \text{J}}{1.38\times10^{-23}\ \text{J/K}}\right) = 8.80\ \text{K}.$

EVALUATE: **(c)** The average kinetic energy at 15.0°C is much larger than the increase in gravitational potential energy, so it is energetically possible for a molecule to rise to this height. But Example 18.8 shows that the mean free path will be very much less than this and a molecule will undergo many collisions as it rises. These numerous collisions transfer kinetic energy between molecules and make it highly unlikely that a given molecule can have very much of its translational kinetic energy converted to gravitational potential energy.

18.73. **IDENTIFY** and **SET UP:** At equilibrium $F(r) = 0$. The work done to increase the separation from r_2 to ∞ is $U(\infty) - U(r_2)$.

(a) EXECUTE: $U(r) = U_0[(R_0/r)^{12} - 2(R_0/r)^6]$

Eq. (14.26): $F(r) = 12(U_0/R_0)[(R_0/r)^{13} - (R_0/r)^7]$. The graphs are given in Figure 18.73.

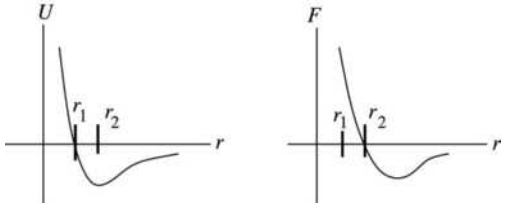


Figure 18.73

(b) equilibrium requires $F = 0$; occurs at point r_2. r_2 is where U is a minimum (stable equilibrium).

(c) $U = 0$ implies $[(R_0/r)^{12} 2(R_0/r)^6] = 0$

$(r_1/R_0)^6 = 1/2$ and $r_1 = R_0/(2)^{1/6}$

$F = 0$ implies $[(R_0/r)^{13} - (R_0/r)^7] = 0$

$(r_2/R_0)^6 = 1$ and $r_2 = R_0$

Then $r_1/r_2 = (R_0/2^{1/6})/R_0 = 2^{-1/6}$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(d) $W_{\text{other}} = \Delta U$

At $r \to \infty$, $U = 0$, so $W = -U(R_0) = -U_0[(R_0/R_0)^{12} - 2(R_0/R_0)^6] = +U_0$

EVALUATE: The answer to part (d), U_0, is the depth of the potential well shown in the graph of $U(r)$.

18.74. **IDENTIFY:** Use $pV = nRT$ to calculate the number of moles, n. Then $K_{\text{tr}} = \frac{3}{2}nRT$. The mass of the gas, m_{tot}, is given by $m_{\text{tot}} = nM$.

SET UP: $5.00\ \text{L} = 5.00\times10^{-3}\ \text{m}^3$

EXECUTE: **(a)** $n = \dfrac{pV}{RT} = \dfrac{(1.01\times10^5\ \text{Pa})(5.00\times10^{-3}\ \text{m}^3)}{(8.314\ \text{J/mol}\cdot\text{K})(300\ \text{K})} = 0.2025\ \text{moles}$

$K_{\text{tr}} = \frac{3}{2}(0.2025\ \text{mol})(8.314\ \text{J/mol}\cdot\text{K})(300\ \text{K}) = 758\ \text{J}.$

(b) $m_{\text{tot}} = nM = (0.2025\ \text{mol})(2.016\times10^{-3}\ \text{kg/mol}) = 4.08\times10^{-4}\ \text{kg}$. The kinetic energy due to the speed of the jet is $K = \frac{1}{2}mv^2 = \frac{1}{2}(4.08\times10^{-4}\ \text{kg})(300.0\ \text{m/s})^2 = 18.4\ \text{J}$. The total kinetic energy is $K_{\text{tot}} = K + K_{\text{tr}} = 18.4\ \text{J} + 758\ \text{J} = 776\ \text{J}$. The percentage increase is $\dfrac{K}{K_{\text{tot}}}\times100\% = \dfrac{18.4\ \text{J}}{776\ \text{J}}\times100\% = 2.37\%.$

(c) No. The temperature is associated with the random translational motion, and that hasn't changed.

EVALUATE: Eq. (18.13) gives $K_{\text{tr}} = \frac{3}{2}pV = \frac{3}{2}(1.01\times10^5\ \text{Pa})(5.00\times10^{-3}\ \text{m}^3) = 758\ \text{J}$, which agrees with our result in part (a). $v_{\text{rms}} = \sqrt{\dfrac{3RT}{M}} = 1.93\times10^3\ \text{m/s}$. v_{rms} is a lot larger than the speed of the jet, so the percentage increase in the total kinetic energy, calculated in part (b), is small.

18.75. **IDENTIFY** and **SET UP:** Apply Eq. (18.19) for v_{rms}. The equation preceeding Eq. (18.12) relates v_{rms} and $(v_x)_{\text{rms}}$.

EXECUTE: **(a)** $v_{\text{rms}} = \sqrt{3RT/M}$

$v_{\text{rms}} = \sqrt{\dfrac{3(8.3145\ \text{J/mol}\cdot\text{K})(300\ \text{K})}{28.0\times10^{-3}\ \text{kg/mol}}} = 517\ \text{m/s}$

(b) $(v_x^2)_{\text{av}} = \frac{1}{3}(v^2)_{\text{av}}$ so $\sqrt{(v_x^2)_{\text{av}}} = \left(1/\sqrt{3}\right)\sqrt{(v^2)_{\text{av}}} = \left(1/\sqrt{3}\right)v_{\text{rms}} = \left(1/\sqrt{3}\right)(517\ \text{m/s}) = 298\ \text{m/s}$

EVALUATE: The speed of sound is approximately equal to $(v_x)_{\text{rms}}$ since it is the motion along the direction of propagation of the wave that transmits the wave.

18.76. **IDENTIFY:** $v_{\text{rms}} = \sqrt{\dfrac{3kT}{m}}$

SET UP: $M = 1.99\times10^{30}\ \text{kg}$, $R = 6.96\times10^8\ \text{m}$ and $G = 6.673\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2$.

EXECUTE: **(a)** $v_{\text{rms}} = \sqrt{\dfrac{3kT}{m}} = \sqrt{\dfrac{3(1.38\times10^{-23}\text{J/K})(5800\ \text{K})}{(1.67\times10^{-27}\text{kg})}} = 1.20\times10^4\ \text{m/s}.$

(b) $v_{\text{escape}} = \sqrt{\dfrac{2GM}{R}} = \sqrt{\dfrac{2(6.673\times10^{-11}\text{N}\cdot\text{m}^2/\text{kg}^2)(1.99\times10^{30}\text{kg})}{(6.96\times10^8\ \text{m})}} = 6.18\times10^5\ \text{m/s}.$

EVALUATE: **(c)** The escape speed is about 50 times the rms speed, and any of Figure 18.23 in the textbook, Eq. (18.32) or Table (18.2) will indicate that there is a negligibly small fraction of molecules with the escape speed.

18.77. **(a) IDENTIFY** and **SET UP:** Apply conservation of energy $K_1 + U_1 + W_{\text{other}} = K_2 + U_2$, where $U = -Gmm_{\text{p}}/r$. Let point 1 be at the surface of the planet, where the projectile is launched, and let point 2 be far from the earth. Just barely escapes says $v_2 = 0$.

EXECUTE: Only gravity does work says $W_{\text{other}} = 0$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$U_1 = -Gmm_p/R_p$; $r_2 \to \infty$ so $U_2 = 0$; $v_2 = 0$ so $K_2 = 0$.

The conservation of energy equation becomes $K_1 - Gmm_p/R_p = 0$ and $K_1 = Gmm_p/R_p$.

But $g = Gm_p/R_p^2$ so $Gm_p/R_p = R_p g$ and $K_1 = mgR_p$, as was to be shown.

EVALUATE: The greater gR_p is, the more initial kinetic energy is required for escape.

(b) IDENTIFY and **SET UP:** Set K_1 from part (a) equal to the average kinetic energy of a molecule as given by Eq. (18.16). $\frac{1}{2}m(v^2)_{av} = mgR_p$ (from part (a)). But also, $\frac{1}{2}m(v^2)_{av} = \frac{3}{2}kT$, so $mgR_p = \frac{3}{2}kT$

EXECUTE: $T = \dfrac{2mgR_p}{3k}$

nitrogen

$m_{N_2} = (28.0\times10^{-3}\ \text{kg/mol})/(6.022\times10^{23}\ \text{molecules/mol}) = 4.65\times10^{-26}\ \text{kg/molecule}$

$$T = \frac{2mgR_p}{3k} = \frac{2(4.65\times10^{-26}\ \text{kg/molecule})(9.80\ \text{m/s}^2)(6.38\times10^6\ \text{m})}{3(1.381\times10^{-23}\ \text{J/molecule}\cdot\text{K})} = 1.40\times10^5\ \text{K}$$

hydrogen

$m_{H_2} = (2.02\times10^{-3}\ \text{kg/mol})/(6.022\times10^{23}\ \text{molecules/mol}) = 3.354\times10^{-27}\ \text{kg/molecule}$

$$T = \frac{2mgR_p}{3k} = \frac{2(3.354\times10^{-27}\ \text{kg/molecule})(9.80\ \text{m/s}^2)(6.38\times10^6\ \text{m})}{3(1.381\times10^{-23}\ \text{J/molecule}\cdot\text{K})} = 1.01\times10^4\ \text{K}$$

(c) $T = \dfrac{2mgR_p}{3k}$

nitrogen

$$T = \frac{2(4.65\times10^{-26}\ \text{kg/molecule})(1.63\ \text{m/s}^2)(1.74\times10^6\ \text{m})}{3(1.381\times10^{-23}\ \text{J/molecule}\cdot\text{K})} = 6370\ \text{K}$$

hydrogen

$$T = \frac{2(3.354\times10^{-27}\ \text{kg/molecule})(1.63\ \text{m/s}^2)(1.74\times10^6\ \text{m})}{3(1.381\times10^{-23}\ \text{J/molecule}\cdot\text{K})} = 459\ \text{K}$$

(d) EVALUATE: The "escape temperatures" are much less for the moon than for the earth. For the moon a larger fraction of the molecules at a given temperature will have speeds in the Maxwell-Boltzmann distribution larger than the escape speed. After a long time most of the molecules will have escaped from the moon.

18.78. **IDENTIFY:** $v_{rms} = \sqrt{\dfrac{3RT}{M}}$.

SET UP: $M_{H_2} = 2.02\times10^{-3}$ kg/mol. $M_{O_2} = 32.0\times10^{-3}$ kg/mol. For earth, $M = 5.97\times10^{24}$ kg and $R = 6.38\times10^6$ m. For Jupiter, $M = 1.90\times10^{27}$ kg and $R = 6.91\times10^7$ m. For a sphere, $M = \rho V = \rho\dfrac{4}{3}\pi r^3$.

The escape speed is $v_{escape} = \sqrt{\dfrac{2GM}{R}}$.

EXECUTE: **(a)** Jupiter: $v_{rms} = \sqrt{3(8.3145\text{J/mol}\cdot\text{K})(140\ \text{K})/(2.02\times10^{-3}\text{kg/mol})} = 1.31\times10^3\ \text{m/s}$.

$v_{escape} = 6.06\times10^4$ m/s. $v_{rms} = 0.022v_{escape}$.

Earth: $v_{rms} = \sqrt{3(8.3145\ \text{J/mol}\cdot\text{K})(220\ \text{K})/(2.02\times10^{-3}\text{kg/mol})} = 1.65\times10^3\ \text{m/s}$. $v_{escape} = 1.12\times10^4$ m/s.

$v_{rms} = 0.15v_{escape}$.

(b) Escape from Jupiter is not likely for any molecule, while escape from earth is much more probable.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(c) $v_{\text{rms}} = \sqrt{3(8.3145\ \text{J/mol}\cdot\text{K})(200\ \text{K})/(32.0\times10^{-3}\ \text{kg/mol})} = 395\ \text{m/s}$. The radius of the asteroid is $R = (3M/4\pi\rho)^{1/3} = 4.68\times10^{5}\ \text{m}$, and the escape speed is $v_{\text{escape}} = \sqrt{2GM/R} = 542\ \text{m/s}$. Over time the O_2 molecules would essentially all escape and there can be no such atmosphere.

EVALUATE: As Figure 18.23 in the textbook shows, there are some molecules in the velocity distribution that have speeds greater than v_{rms}. But as the speed increases above v_{rms} the number with speeds in that range decreases.

18.79. **IDENTIFY:** $v_{\text{rms}} = \sqrt{\dfrac{3kT}{m}}$. The number of molecules in an object of mass m is $N = nN_{\text{A}} = \dfrac{m}{M}N_{\text{A}}$.

SET UP: The volume of a sphere of radius r is $V = \dfrac{4}{3}\pi r^3$.

EXECUTE: **(a)** $m = \dfrac{3kT}{v_{\text{rms}}^2} = \dfrac{3(1.381\times10^{-23}\ \text{J/K})(300\ \text{K})}{(0.0010\ \text{m/s})^2} = 1.24\times10^{-14}\ \text{kg}$.

(b) $N = mN_{\text{A}}/M = (1.24\times10^{-14}\ \text{kg})(6.022\times10^{23}\ \text{molecules/mol})/(18.0\times10^{-3}\ \text{kg/mol})$

$N = 4.16\times10^{11}$ molecules.

(c) The diameter is $D = 2r = 2\left(\dfrac{3V}{4\pi}\right)^{1/3} = 2\left(\dfrac{3m/\rho}{4\pi}\right)^{1/3} = 2\left(\dfrac{3(1.24\times10^{-14}\ \text{kg})}{4\pi(920\ \text{kg/m}^3)}\right)^{1/3} = 2.95\times10^{-6}\ \text{m}$ which is too small to see.

EVALUATE: v_{rms} decreases as m increases.

18.80. **IDENTIFY:** For a simple harmonic oscillator, $x = A\cos\omega t$ and $v_x = -\omega A\sin\omega t$, with $\omega = \sqrt{k/m}$.

SET UP: The average value of $\cos(2\omega t)$ over one period is zero, so $(\sin^2\omega t)_{\text{av}} = (\cos^2\omega t)_{\text{av}} = \frac{1}{2}$.

EXECUTE: $x = A\cos\omega t$, $v_x = -\omega A\sin\omega t$, $U_{\text{av}} = \frac{1}{2}kA^2(\cos^2\omega t)_{\text{av}}$, $K_{\text{av}} = \frac{1}{2}m\omega^2A^2(\sin^2\omega t)_{\text{av}}$. Using $(\sin^2\omega t)_{\text{av}} = (\cos^2\omega t)_{\text{av}} = \frac{1}{2}$ and $m\omega^2 = k$ shows that $K_{\text{av}} = U_{\text{av}}$.

EVALUATE: In general, at any given instant of time $U \neq K$. It is only the values averaged over one period that are equal.

18.81. **IDENTIFY:** The equipartition principle says that each atom has an average kinetic energy of $\frac{1}{2}kT$ for each degree of freedom. There is an equal average potential energy.

SET UP: The atoms in a three-dimensional solid have three degrees of freedom and the atoms in a two-dimensional solid have two degrees of freedom.

EXECUTE: **(a)** In the same manner that Eq. (18.28) was obtained, the heat capacity of the two-dimensional solid would be $2R = 16.6\ \text{J/mol}\cdot\text{K}$.

(b) The heat capacity would behave qualitatively like those in Figure 18.21 in the textbook, and the heat capacity would decrease with decreasing temperature.

EVALUATE: At very low temperatures the equipartition theorem doesn't apply. Most of the atoms remain in their lowest energy states because the next higher energy level is not accessible.

18.82. **IDENTIFY:** The equipartition principle says that each molecule has average kinetic energy of $\frac{1}{2}kT$ for each degree of freedom. $I = 2m(L/2)^2$, where L is the distance between the two atoms in the molecule. $K_{\text{rot}} = \frac{1}{2}I\omega^2$. $\omega_{\text{rms}} = \sqrt{(\omega^2)_{\text{av}}}$.

SET UP: The mass of one atom is $m = M/N_{\text{A}} = (16.0\times10^{-3}\ \text{kg/mol})/(6.022\times10^{23}\ \text{molecules/mol}) = 2.66\times10^{-26}\ \text{kg}$.

EXECUTE: **(a)** The two degrees of freedom associated with the rotation for a diatomic molecule account for two-fifths of the total kinetic energy, so $K_{\text{rot}} = nRT = (1.00\ \text{mol})(8.3145\ \text{J/mol}\cdot\text{K})(300\ \text{K}) = 2.49\times10^{3}\ \text{J}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) $I = 2m(L/2)^2 = 2\left(\dfrac{16.0\times10^{-3}\ \text{kg/mol}}{6.022\times10^{23}\ \text{molecules/mol}}\right)(6.05\times10^{-11}\ \text{m})^2 = 1.94\times10^{-46}\ \text{kg}\cdot\text{m}^2$

(c) Since the result in part (b) is for one mole, the rotational kinetic energy for one atom is $K_{\text{rot}}/N_{\text{A}}$ and $\omega_{\text{rms}} = \sqrt{\dfrac{2K_{\text{rot}}/N_{\text{A}}}{I}} = \sqrt{\dfrac{2(2.49\times10^{3}\ \text{J})}{(1.94\times10^{-46}\ \text{kg}\cdot\text{m}^2)(6.022\times10^{23}\ \text{molecules/mol})}} = 6.52\times10^{12}$ rad/s. This is much larger than the typical value for a piece of rotating machinery.

EVALUATE: The average rotational period, $T = \dfrac{2\pi\ \text{rad}}{\omega_{\text{rms}}}$, for molecules is very short.

18.83. **IDENTIFY:** $C_V = N\left(\frac{1}{2}R\right)$, where N is the number of degrees of freedom.

SET UP: There are three translational degrees of freedom.

EXECUTE: For CO_2, $N = 5$ and the contribution to C_V other than from vibration is $\frac{5}{2}R = 20.79$ J/mol·K and $C_V - \frac{5}{2}R = 0.270\,C_V$. So 27% of C_V is due to vibration. For both SO_2 and H_2S, $N = 6$ and the contribution to C_V other than from vibration is $\frac{6}{2}R = 24.94$ J/mol·K. The respective fractions of C_V from vibration are 21% and 3.9%.

EVALUATE: The vibrational contribution is much less for H_2S. In H_2S the vibrational energy steps are larger because the two hydrogen atoms have small mass and $\omega = \sqrt{k/m}$.

18.84. **IDENTIFY:** Evaluate the integral, as specified in the problem.

SET UP: Use the integral formula given in Problem 18.85, with $\alpha = m/2kT$.

EXECUTE: **(a)** $\displaystyle\int_0^\infty f(v)\,dv = 4\pi\left(\frac{m}{2\pi kT}\right)^{3/2}\int_0^\infty v^2 e^{-mv^2/2kT}\,dv = 4\pi\left(\frac{m}{2\pi kT}\right)^{3/2}\left(\frac{1}{4(m/2kT)}\right)\sqrt{\frac{\pi}{m/2kT}} = 1$

EVALUATE: **(b)** $f(v)dv$ is the probability that a particle has speed between v and $v + dv$; the probability that the particle has some speed is unity, so the sum (integral) of $f(v)dv$ must be 1.

18.85. **IDENTIFY** and **SET UP:** Evaluate the integral in Eq. (18.31) as specified in the problem.

EXECUTE: $\displaystyle\int_0^\infty v^2 f(v)\,dv = 4\pi(m/2\pi kT)^{3/2}\int_0^\infty v^4 e^{-mv^2/2kT}\,dv$

The integral formula with $n = 2$ gives $\displaystyle\int_0^\infty v^4 e^{-av^2}\,dv = (3/8a^2)\sqrt{\pi/a}$.

Apply with $a = m/2kT$, $\displaystyle\int_0^\infty v^2 f(v)\,dv = 4\pi(m/2\pi kT)^{3/2}(3/8)(2kT/m)^2\sqrt{2\pi kT/m} = (3/2)(2kT/m) = 3kT/m.$

EVALUATE: Eq. (18.16) says $\frac{1}{2}m(v^2)_{\text{av}} = 3kT/2$, so $(v^2)_{\text{av}} = 3kT/m$, in agreement with our calculation.

18.86. **IDENTIFY:** Follow the procedure specified in the problem.

SET UP: If $v^2 = x$, then $dx = 2v\,dv$.

EXECUTE: $\displaystyle\int_0^\infty vf(v)dv = 4\pi\left(\frac{m}{2\pi kT}\right)^{3/2}\int_0^\infty v^3 e^{-mv^2/2kT}\,dv$. Making the suggested change of variable, $v^2 = x$. $2v\,dv = dx$, $v^3\,dv = (1/2)x\,dx$, and the integral becomes

$$\int_0^\infty vf(v)dv = 2\pi\left(\frac{m}{2\pi kT}\right)^{3/2}\int_0^\infty xe^{-mx/2kT}\,dx = 2\pi\left(\frac{m}{2\pi kT}\right)^{3/2}\left(\frac{2kT}{m}\right)^2 = \frac{2}{\sqrt{\pi}}\sqrt{\frac{2kT}{m}} = \sqrt{\frac{8kT}{\pi m}}$$

which is Eq. (18.35).

EVALUATE: The integral $\displaystyle\int_0^\infty vf(v)dv$ is the definition of v_{av}.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

18.87. **IDENTIFY:** $f(v)dv$ is the probability that a particle has a speed between v and $v+dv$. Eq. (18.32) gives $f(v)$. v_{mp} is given by Eq. (18.34).

SET UP: For O_2, the mass of one molecule is $m = M/N_A = 5.32\times10^{-26}$ kg.

EXECUTE: **(a)** $f(v)dv$ is the fraction of the particles that have speed in the range from v to $v+dv$. The number of particles with speeds between v and $v+dv$ is therefore $dN = Nf(v)dv$ and $\Delta N = N\int_v^{v+\Delta v} f(v)dv$.

(b) Setting $v = v_{mp} = \sqrt{\dfrac{2kT}{m}}$ in $f(v)$ gives $f(v_{mp}) = 4\pi\left(\dfrac{m}{2\pi kT}\right)^{3/2}\left(\dfrac{2kT}{m}\right)e^{-1} = \dfrac{4}{e\sqrt{\pi}v_{mp}}$. For oxygen gas at 300 K, $v_{mp} = 3.95\times10^2$ m/s and $f(v)\Delta v = 0.0421$.

(c) Increasing v by a factor of 7 changes f by a factor of 7^2e^{-48}, and $f(v)\Delta v = 2.94\times10^{-21}$.

(d) Multiplying the temperature by a factor of 2 increases the most probable speed by a factor of $\sqrt{2}$, and the answers are decreased by $\sqrt{2}$: 0.0297 and 2.08×10^{-21}.

(e) Similarly, when the temperature is one-half what it was in parts (b) and (c), the fractions increase by $\sqrt{2}$ to 0.0595 and 4.15×10^{-21}.

EVALUATE: **(f)** At lower temperatures, the distribution is more sharply peaked about the maximum (the most probable speed), as is shown in Figure 18.23a in the textbook.

18.88. **IDENTIFY:** Apply the definition of relative humidity given in the problem. $pV = nRT = \dfrac{m_{tot}}{M}RT$.

SET UP: $M = 18.0\times10^{-3}$ kg/mol.

EXECUTE: **(a)** The pressure due to water vapor is $(0.60)(2.34\times10^3\ \text{Pa}) = 1.40\times10^3$ Pa.

(b) $m_{tot} = \dfrac{MpV}{RT} = \dfrac{(18.0\times10^{-3}\ \text{kg/mol})(1.40\times10^3\ \text{Pa})(1.00\ \text{m}^3)}{(8.3145\ \text{J/mol}\cdot\text{K})(293.15\ \text{K})} = 10\ \text{g}$

EVALUATE: The vapor pressure of water vapor at this temperature is much less than the total atmospheric pressure of 1.0×10^5 Pa.

18.89. **IDENTIFY:** The measurement gives the dew point. Relative humidity is defined in Problem 18.88.

SET UP: $\text{relative humidity} = \dfrac{\text{partial pressure of water vapor at temperature } T}{\text{vapor pressure of water at temperature } T}$

EXECUTE: The experiment shows that the dew point is 16.0°C, so the partial pressure of water vapor at 30.0°C is equal to the vapor pressure at 16.0°C, which is 1.81×10^3 Pa.

Thus the relative humidity $= \dfrac{1.81\times10^3\ \text{Pa}}{4.25\times10^3\ \text{Pa}} = 0.426 = 42.6\%$.

EVALUATE: The lower the dew point is compared to the air temperature, the smaller the relative humidity.

18.90. **IDENTIFY:** Use the definition of relative humidity in Problem 18.88 and the vapor pressure table in Problem 18.89.

SET UP: At 28.0°C the vapor pressure of water is 3.78×10^3 Pa.

EXECUTE: For a relative humidity of 35%, the partial pressure of water vapor is $(0.35)(3.78\times10^3\ \text{Pa}) = 1.323\times10^3$ Pa. This is close to the vapor pressure at 12°C, which would be at an altitude $(30°\text{C} - 12°\text{C})/(0.6\ \text{C°}/100\ \text{m}) = 3$ km above the ground. For a relative humidity of 80%, the vapor pressure will be the same as the water pressure at around 24°C, corresponding to an altitude of about 1 km.

EVALUATE: Clouds form at a lower height when the relative humidity at the surface is larger.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

18.91. **IDENTIFY:** Eq. (18.21) gives the mean free path λ. In Eq. (18.20) use $v_{\text{rms}} = \sqrt{\dfrac{3RT}{M}}$ in place of v.

$pV = nRT = NkT$. The escape speed is $v_{\text{escape}} = \sqrt{\dfrac{2GM}{R}}$.

SET UP: For atomic hydrogen, $M = 1.008\times10^{-3}$ kg/mol.

EXECUTE: **(a)** From Eq. (18.21),
$\lambda = (4\pi\sqrt{2}r^2(N/V))^{-1} = (4\pi\sqrt{2}(5.0\times10^{-11}\text{ m})^2(50\times10^6\text{ m}^{-3}))^{-1} = 4.5\times10^{11}\text{ m}$.

(b) $v_{\text{rms}} = \sqrt{3RT/M} = \sqrt{3(8.3145\text{ J/mol}\cdot\text{K})(20\text{ K})/(1.008\times10^{-3}\text{ kg/mol})} = 703\text{ m/s}$, and the time between collisions is then $(4.5\times10^{11}\text{ m})/(703\text{ m/s}) = 6.4\times10^8$ s, about 20 yr. Collisions are not very important.

(c) $p = (N/V)kT = (50/1.0\times10^{-6}\text{ m}^3)(1.381\times10^{-23}\text{ J/K})(20\text{ K}) = 1.4\times10^{-14}$ Pa.

(d) $v_{\text{escape}} = \sqrt{\dfrac{2GM}{R}} = \sqrt{\dfrac{2G(Nm/V)(4\pi R^3/3)}{R}} = \sqrt{(8\pi/3)G(N/V)mR^2}$

$v_{\text{escape}} = \sqrt{(8\pi/3)(6.673\times10^{-11}\text{ N}\cdot\text{m}^2/\text{kg}^2)(50\times10^6\text{ m}^{-3})(1.67\times10^{-27}\text{ kg})(10\times9.46\times10^{15}\text{ m})^2}$

$v_{\text{escape}} = 650$ m/s. This is lower than v_{rms} and the cloud would tend to evaporate.

(e) In equilibrium (clearly not *thermal* equilibrium), the pressures will be the same; from $pV = NkT$, $kT_{\text{ISM}}(N/V)_{\text{ISM}} = kT_{\text{nebula}}(N/V)_{\text{nebula}}$ and the result follows.

(f) With the result of part (e),

$$T_{\text{ISM}} = T_{\text{nebula}}\left(\frac{(N/V)_{\text{nebula}}}{(N/V)_{\text{ISM}}}\right) = (20\text{ K})\left(\frac{50\times10^6\text{ m}^3}{(200\times10^{-6}\text{ m}^3)^{-1}}\right) = 2\times10^5\text{ K},$$

more than three times the temperature of the sun. This indicates a high average kinetic energy, but the thinness of the ISM means that a ship would not burn up.

EVALUATE: The temperature of a gas is determined by the average kinetic energy per atom of the gas. The energy density for the gas also depends on the number of atoms per unit volume, and this is very small for the ISM.

18.92. **IDENTIFY:** Follow the procedure of Example 18.4, but use $T = T_0 - \alpha y$.

SET UP: $\ln(1+x) \approx x$ when x is very small.

EXECUTE: **(a)** $\dfrac{dp}{dy} = -\dfrac{pM}{RT}$, which in this case becomes $\dfrac{dp}{p} = -\dfrac{Mg}{R}\dfrac{dy}{T_0 - \alpha y}$. This integrates to

$\ln\left(\dfrac{p}{p_0}\right) = \dfrac{Mg}{R\alpha}\ln\left(1-\dfrac{\alpha y}{T_0}\right)$, or $p = p_0\left(1-\dfrac{\alpha y}{T_0}\right)^{Mg/R\alpha}$.

(b) For sufficiently small α, $\ln\left(1-\dfrac{\alpha y}{T_0}\right) \approx -\dfrac{\alpha y}{T_0}$, and this gives the expression derived in Example 18.4.

(c) $\left(1-\dfrac{(0.6\times10^{-2}\text{ C°/m})(8863\text{ m})}{(288\text{ K})}\right) = 0.8154$, $\dfrac{Mg}{R\alpha} = \dfrac{(28.8\times10^{-3})(9.80\text{ m/s}^2)}{(8.3145\text{ J/mol}\cdot\text{K})(0.6\times10^{-2}\text{ C°/m})} = 5.6576$ and

$p_0(0.8154)^{5.6576} = 0.315$ atm, which is 0.95 of the result found in Example 18.4.

EVALUATE: The pressure is calculated to decrease more rapidly with altitude when we assume that T also decreases with altitude.

18.93. **IDENTIFY** and **SET UP:** For N particles, $v_{\text{av}} = \dfrac{\sum v_i}{N}$ and $v_{\text{rms}} = \sqrt{\dfrac{\sum v_i^2}{N}}$.

EXECUTE: **(a)** $v_{\text{av}} = \frac{1}{2}(v_1 + v_2)$, $v_{\text{rms}} = \dfrac{1}{\sqrt{2}}\sqrt{v_1^2 + v_2^2}$ and

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$v_{\text{rms}}^2 - v_{\text{av}}^2 = \frac{1}{2}(v_1^2 + v_2^2) - \frac{1}{4}(v_1^2 + v_2^2 + 2v_1v_2) = \frac{1}{4}(v_1^2 + v_2^2 - 2v_1v_2) = \frac{1}{4}(v_1 - v_2)^2$$

This shows that $v_{\text{rms}} \geq v_{\text{av}}$, with equality holding if and only if the particles have the same speeds.

(b) $v'^2_{\text{rms}} = \frac{1}{N+1}(Nv_{\text{rms}}^2 + u^2), v'_{\text{av}} = \frac{1}{N+1}(Nv_{\text{av}} + u),$ and the given forms follow immediately.

(c) The algebra is similar to that in part (a); it helps somewhat to express

$$v'^2_{\text{av}} = \frac{1}{(N+1)^2}(N((N+1)-1)v_{\text{av}}^2 + 2Nv_{\text{av}}u + ((N+1)-N)u^2).$$

$$v'^2_{\text{av}} = \frac{N}{N+1}v_{\text{av}}^2 + \frac{N}{(N+1)^2}(-v_{\text{av}}^2 + 2v_{\text{av}}u - u^2) + \frac{1}{N+1}u^2$$

Then,

$$v'^2_{\text{rms}} - v'^2_{\text{av}} = \frac{N}{(N+1)}(v_{\text{rms}}^2 - v_{\text{av}}^2) + \frac{N}{(N+1)^2}(v_{\text{av}}^2 - 2v_{\text{av}}u + u^2) = \frac{N}{N+1}(v_{\text{rms}}^2 - v_{\text{av}}^2) + \frac{N}{(N+1)^2}(v_{\text{av}} - u)^2.$$

If $v_{\text{rms}} > v_{\text{av}}$, then this difference is necessarily positive, and $v'_{\text{rms}} > v'_{\text{av}}$.

(d) The result has been shown for $N = 1,$ and it has been shown that validity for *N* implies validity for $N+1;$ by induction, the result is true for all N.

EVALUATE: $v_{\text{rms}} > v_{\text{av}}$ because v_{rms} gives more weight to particles that have greater speed.

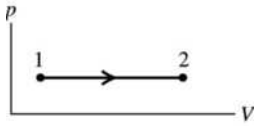
19

THE FIRST LAW OF THERMODYNAMICS

19.1. **(a) IDENTIFY** and **SET UP:** The pressure is constant and the volume increases.



The pV-diagram is sketched in Figure 19.1.

Figure 19.1

(b) $W = \int_{V_1}^{V_2} p\, dV$

Since p is constant, $W = p\int_{V_1}^{V_2} dV = p(V_2 - V_1)$

The problem gives T rather than p and V, so use the ideal gas law to rewrite the expression for W.

EXECUTE: $pV = nRT$ so $p_1V_1 = nRT_1$, $p_2V_2 = nRT_2$; subtracting the two equations gives $p(V_2 - V_1) = nR(T_2 - T_1)$

Thus $W = nR(T_2 - T_1)$ is an alternative expression for the work in a constant pressure process for an ideal gas.

Then $W = nR(T_2 - T_1) = (2.00 \text{ mol})(8.3145 \text{ J/mol}\cdot\text{K})(107°\text{C} - 27°\text{C}) = +1330 \text{ J}$.

EVALUATE: The gas expands when heated and does positive work.

19.2. **IDENTIFY:** At constant pressure, $W = p\Delta V = nR\Delta T$. Since the gas is doing work, it must be expanding, so ΔV is positive, which means that ΔT must also be positive.

SET UP: $R = 8.3145 \text{ J/mol}\cdot\text{K}$. ΔT has the same numerical value in kelvins and in C°.

EXECUTE: $\Delta T = \dfrac{W}{nR} = \dfrac{2.40\times10^3 \text{ J}}{(6 \text{ mol})\ (8.3145 \text{ J/mol}\cdot\text{K})} = 48.1 \text{ K}$. $\Delta T_K = \Delta T_C$ and $T_2 = 27.0°\text{C} + 48.1\,\text{C}° = 75.1°\text{C}$.

EVALUATE: When $W > 0$ the gas expands. When p is constant and V increases, T increases.

19.3. **IDENTIFY:** Example 19.1 shows that for an isothermal process $W = nRT\ln(p_1/p_2)$. $pV = nRT$ says V decreases when p increases and T is constant.

SET UP: $T = 65.0 + 273.15 = 338.15 \text{ K}$. $p_2 = 3p_1$.

EXECUTE: **(a)** The pV-diagram is sketched in Figure 19.3.

(b) $W = (2.00 \text{ mol})(8.314 \text{ J/mol}\cdot\text{K})(338.15 \text{ K})\ln\left(\dfrac{p_1}{3p_1}\right) = -6180 \text{ J}$.

EVALUATE: Since V decreases, W is negative.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

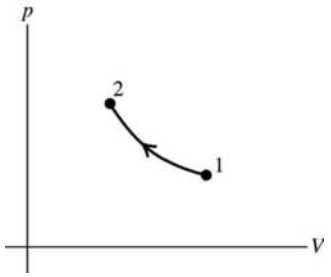


Figure 19.3

19.4. **IDENTIFY:** The work done in a cycle is the area enclosed by the cycle in a pV diagram.

SET UP: **(a)** 1 mm of Hg = 133.3 Pa. $p_{\text{gauge}} = p - p_{\text{air}}$. In calculating the enclosed area only changes in pressure enter and you can use gauge pressure. $1\text{ L} = 10^{-3}\text{ m}^3$.

(b) Since $pV = nRT$ and T is constant, the maximum number of moles of air in the lungs is when pV is a maximum. In the ideal gas law the absolute pressure $p = p_{\text{gauge}} + p_{\text{air}}$ must be used.

$p_{\text{air}} = 760$ mm of Hg. 1 mm of Hg = 1 torr.

EXECUTE: **(a)** By counting squares and noting that the area of 1 square is (1 mm of Hg)(0.1 L), we estimate that the area enclosed by the cycle is about $7.5\ (\text{mm of Hg}) \cdot \text{L} = 1.00\ \text{N} \cdot \text{m}$. The net work done is positive.

(b) The maximum pV is when $p = 11$ torr + 760 torr = 771 torr $= 1.028 \times 10^5$ Pa and $V = 1.4\text{ L} = 1.4 \times 10^{-3}\text{ m}^3$. The maximum pV is $(pV)_{\text{max}} = 144\ \text{N} \cdot \text{m}$. $pV = nRT$ so

$$n_{\text{max}} = \frac{(pV)_{\text{max}}}{RT} = \frac{144\ \text{N} \cdot \text{m}}{(8.315\ \text{J/mol} \cdot \text{K})(293\ \text{K})} = 0.059\ \text{mol}.$$

EVALUATE: While inhaling the gas does positive work on the lungs, but while exhaling the lungs do work on the gas, so the net work is positive.

19.5. **IDENTIFY:** Example 19.1 shows that for an isothermal process $W = nRT\ln(p_1/p_2)$. Solve for p_1.

SET UP: For a compression (V decreases) W is negative, so $W = -468$ J. $T = 295.15$ K.

EXECUTE: **(a)** $\dfrac{W}{nRT} = \ln\left(\dfrac{p_1}{p_2}\right)$. $\dfrac{p_1}{p_2} = e^{W/nRT}$.

$$\frac{W}{nRT} = \frac{-468\ \text{J}}{(0.305\ \text{mol})(8.314\ \text{J/mol} \cdot \text{K})(295.15\ \text{K})} = -0.6253.$$

$$p_1 = p_2 e^{W/nRT} = (1.76\ \text{atm})e^{-0.6253} = 0.942\ \text{atm}.$$

(b) In the process the pressure increases and the volume decreases. The pV-diagram is sketched in Figure 19.5.

EVALUATE: W is the work done by the gas, so when the surroundings do work on the gas, W is negative. The gas was compressed at constant temperature, so its pressure must have increased, which means that $p_1 < p_2$, which is what we found.

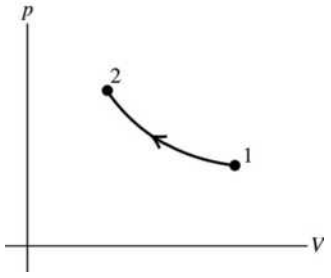

Figure 19.5

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

19.6. **(a) IDENTIFY** and **SET UP:** The pV-diagram is sketched in Figure 19.6.

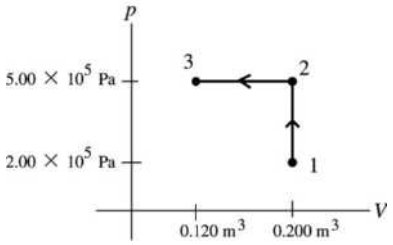

Figure 19.6

(b) Calculate W for each process, using the expression for W that applies to the specific type of process.
EXECUTE: $1 \to 2,\ \Delta V = 0,$ so $W = 0$

$2 \to 3$

p is constant; so $W = p\,\Delta V = (5.00\times10^5\ \text{Pa})(0.120\ \text{m}^3 - 0.200\ \text{m}^3) = -4.00\times10^4\ \text{J}$ (W is negative since the volume decreases in the process.)

$W_{\text{tot}} = W_{1\to2} + W_{2\to3} = -4.00\times10^4\ \text{J}$

EVALUATE: The volume decreases so the total work done is negative.

19.7. **IDENTIFY:** Calculate W for each step using the appropriate expression for each type of process.
SET UP: When p is constant, $W = p\Delta V$. When $\Delta V = 0,\ W = 0.$

EXECUTE: **(a)** $W_{13} = p_1(V_2 - V_1), W_{32} = 0, W_{24} = p_2(V_1 - V_2)$ and $W_{41} = 0.$ The total work done by the system is $W_{13} + W_{32} + W_{24} + W_{41} = (p_1 - p_2)(V_2 - V_1),$ which is the area in the pV plane enclosed by the loop.
(b) For the process in reverse, the pressures are the same, but the volume changes are all the negatives of those found in part (a), so the total work is negative of the work found in part (a).
EVALUATE: When $\Delta V > 0,\ W > 0$ and when $\Delta V < 0,\ W < 0.$

19.8. **IDENTIFY:** The gas is undergoing an isobaric compression, so its temperature and internal energy must be decreasing.
SET UP: The pV diagram shows that in the process the volume decreases while the pressure is constant.
$1\ \text{L} = 10^{-3}\ \text{m}^3$ and $1\ \text{atm} = 1.013\times10^5\ \text{Pa}.$

EXECUTE: **(a)** $pV = nRT.$ n, R and p are constant so $\dfrac{V}{T} = \dfrac{nR}{p} = \text{constant}.$ $\dfrac{V_\text{a}}{T_\text{a}} = \dfrac{V_\text{b}}{T_\text{b}}.$

$$V_\text{b} = V_\text{a}\left(\frac{T_\text{b}}{T_\text{a}}\right) = (0.500\ \text{L})\left(\frac{T_\text{a}/4}{T_\text{a}}\right) = 0.125\ \text{L}.$$

(b) For a constant pressure process, $W = p\,\Delta V = (1.50\ \text{atm})(0.125\ \text{L} - 0.500\ \text{L})$ and

$$W = (-0.5625\ \text{L}\cdot\text{atm})\left(\frac{10^{-3}\ \text{m}^3}{1\ \text{L}}\right)\left(\frac{1.013\times10^5\ \text{Pa}}{1\ \text{atm}}\right) = -57.0\ \text{J}.$$

W is negative since the volume decreases.
Since W is negative, work is done on the gas.
(c) For an ideal gas, $U = nCT$ so U decreases when T decreases. The internal energy of the gas decreases because the temperature decreases.
(d) For a constant pressure process, $Q = nC_p\ \Delta T.$ T decreases so ΔT is negative and Q is therefore negative. Negative Q means heat leaves the gas.
EVALUATE: $W = nR\ \Delta T$ and $Q = nC_p\Delta T.$ $C_p > R,$ so more energy leaves as heat than is added by work done on the gas, and the internal energy of the gas decreases.

19.9. **IDENTIFY:** $\Delta U = Q - W.$ For a constant pressure process, $W = p\Delta V.$

SET UP: $Q = +1.15\times10^5\ \text{J},$ since heat enters the gas.

EXECUTE: **(a)** $W = p\Delta V = (1.65\times10^5\ \text{Pa})(0.320\ \text{m}^3 - 0.110\ \text{m}^3) = 3.47\times10^4\ \text{J}.$

(b) $\Delta U = Q - W = 1.15\times10^5\ \text{J} - 3.47\times10^4\ \text{J} = 8.04\times10^4\ \text{J}.$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: **(c)** $W = p\Delta V$ for a constant pressure process and $\Delta U = Q - W$ both apply to any material. The ideal gas law wasn't used and it doesn't matter if the gas is ideal or not.

19.10. **IDENTIFY:** The type of process is not specified. We can use $\Delta U = Q - W$ because this applies to all processes. Calculate ΔU and then from it calculate ΔT.

SET UP: Q is positive since heat goes into the gas; $Q = +1200$ J.

W positive since gas expands; $W = +2100$ J.

EXECUTE: $\Delta U = 1200\text{ J} - 2100\text{ J} = -900\text{ J}$

We can also use $\Delta U = n\left(\frac{3}{2}R\right)\Delta T$ since this is true for any process for an ideal gas.

$$\Delta T = \frac{2\,\Delta U}{3nR} = \frac{2(-900\text{ J})}{3(5.00\text{ mol})(8.3145\text{ J/mol}\cdot\text{K})} = -14.4\text{C}^\circ$$

$$T_2 = T_1 + \Delta T = 127^\circ\text{C} - 14.4\text{C}^\circ = 113^\circ\text{C}$$

EVALUATE: More energy leaves the gas in the expansion work than enters as heat. The internal energy therefore decreases, and for an ideal gas this means the temperature decreases. We didn't have to convert ΔT to kelvins since ΔT is the same on the Kelvin and Celsius scales.

19.11. **IDENTIFY:** Part *ab* is isochoric, but *bc* is not any of the familiar processes.

SET UP: $pV = nRT$ determines the Kelvin temperature of the gas. The work done in the process is the area under the curve in the pV diagram. Q is positive since heat goes into the gas. $1\text{ atm} = 1.013\times10^5$ Pa. $1\text{ L} = 1\times10^{-3}\text{ m}^3$. $\Delta U = Q - W$.

EXECUTE: **(a)** The lowest T occurs when pV has its smallest value. This is at point *a*, and

$$T_a = \frac{p_aV_a}{nR} = \frac{(0.20\text{ atm})(1.013\times10^5\text{ Pa/atm})(2.0\text{ L})(1.0\times10^{-3}\text{ m}^3/\text{L})}{(0.0175\text{ mol})(8.315\text{ J/mol}\cdot\text{K})} = 278\text{ K}.$$

(b) *a to b*: $\Delta V = 0$ so $W = 0$.

b to c: The work done by the gas is positive since the volume increases. The magnitude of the work is the area under the curve so $W = \frac{1}{2}(0.50\text{ atm} + 0.30\text{ atm})(6.0\text{ L} - 2.0\text{ L})$ and

$$W = (1.6\text{ L}\cdot\text{atm})(1\times10^{-3}\text{ m}^3/\text{L})(1.013\times10^5\text{ Pa/atm}) = 162\text{ J}.$$

(c) For *abc*, $W = 162$ J. $\Delta U = Q - W = 215\text{ J} - 162\text{ J} = 53$ J.

EVALUATE: 215 J of heat energy went into the gas. 53 J of energy stayed in the gas as increased internal energy and 162 J left the gas as work done by the gas on its surroundings.

19.12. **IDENTIFY** and **SET UP:** Calculate W using the equation for a constant pressure process. Then use $\Delta U = Q - W$ to calculate Q.

(a) EXECUTE: $W = \int_{V_1}^{V_2} p\,dV = p(V_2 - V_1)$ for this constant pressure process.

$W = (1.80\times10^5\text{ Pa})(1.20\text{ m}^3 - 1.70\text{ m}^3) = -9.00\times10^4$ J. (The volume decreases in the process, so W is negative.)

(b) $\Delta U = Q - W$. $Q = \Delta U + W = -1.40\times10^5\text{ J} + (-9.00\times10^4\text{ J}) = -2.30\times10^5$ J. Negative Q means heat flows out of the gas.

(c) EVALUATE: $W = \int_{V_1}^{V_2} p\,dV = p(V_2 - V_1)$ (constant pressure) and $\Delta U = Q - W$ apply to *any* system, not just to an ideal gas. We did not use the ideal gas equation, either directly or indirectly, in any of the calculations, so the results are the same whether the gas is ideal or not.

19.13. **IDENTIFY:** Calculate the total food energy value for one doughnut. $K = \frac{1}{2}mv^2$.

SET UP: $1\text{ cal} = 4.186$ J

EXECUTE: **(a)** The energy is $(2.0\text{ g})(4.0\text{ kcal/g}) + (17.0\text{ g})(4.0\text{ kcal/g}) + (7.0\text{ g})(9.0\text{ kcal/g}) = 139\text{ kcal}$. The time required is $(139\text{ kcal})/(510\text{ kcal/h}) = 0.273\text{ h} = 16.4\text{ min}$.

(b) $v = \sqrt{2K/m} = \sqrt{2(139\times10^3\text{ cal})(4.186\text{ J/cal})/(60\text{ kg})} = 139\text{ m/s} = 501\text{ km/h}$.

EVALUATE: When we set $K = Q$, we must express Q in J, so we can solve for v in m/s.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

19.14. **IDENTIFY:** $\Delta U = Q - W$. For a constant pressure process, $W = p\Delta V$.

SET UP: $Q = +2.20\times10^6$ J; $Q > 0$ since this amount of heat goes into the water.

$p = 2.00$ atm $= 2.03\times10^5$ Pa.

EXECUTE: **(a)** $W = p\Delta V = (2.03\times10^5 \text{ Pa})(0.824 \text{ m}^3 - 1.00\times10^{-3} \text{ m}^3) = 1.67\times10^5$ J

(b) $\Delta U = Q - W = 2.20\times10^6 \text{ J} - 1.67\times10^5 \text{ J} = 2.03\times10^6$ J.

EVALUATE: 2.20×10^6 J of energy enters the water. 1.67×10^5 J of energy leaves the materials through expansion work and the remainder stays in the material as an increase in internal energy.

19.15. **IDENTIFY:** Apply $\Delta U = Q - W$ to the gas.

SET UP: For the process, $\Delta V = 0$. $Q = +700$ J since heat goes into the gas.

EXECUTE: **(a)** Since $\Delta V = 0$, $W = 0$.

(b) $pV = nRT$ says $\frac{p}{T} = \frac{nR}{V} =$ constant. Since p doubles, T doubles. $T_b = 2T_a$.

(c) Since $W = 0$, $\Delta U = Q = +700$ J. $U_b = U_a + 700$ J.

EVALUATE: For an ideal gas, when T increases, U increases.

19.16. **IDENTIFY:** Apply $\Delta U = Q - W$. $|W|$ is the area under the path in the pV-plane.

SET UP: $W > 0$ when V increases.

EXECUTE: **(a)** The greatest work is done along the path that bounds the largest area above the V-axis in the p-V plane, which is path 1. The least work is done along path 3.

(b) $W > 0$ in all three cases; $Q = \Delta U + W$, so $Q > 0$ for all three, with the greatest Q for the greatest work, that along path 1. When $Q > 0$, heat is absorbed.

EVALUATE: ΔU is path independent and depends only on the initial and final states. W and Q are path dependent and can have different values for different paths between the same initial and final states.

19.17. **IDENTIFY:** $\Delta U = Q - W$. W is the area under the path in the pV-diagram. When the volume increases, $W > 0$.

SET UP: For a complete cycle, $\Delta U = 0$.

EXECUTE: **(a)** and **(b)** The clockwise loop (I) encloses a larger area in the p-V plane than the counterclockwise loop (II). Clockwise loops represent positive work and counterclockwise loops negative work, so $W_{\text{I}} > 0$ and $W_{\text{II}} < 0$. Over one complete cycle, the net work $W_{\text{I}} + W_{\text{II}} > 0$, and the net work done by the system is positive.

(c) For the complete cycle, $\Delta U = 0$ and so $W = Q$. From part (a), $W > 0$, so $Q > 0$, and heat flows into the system.

(d) Consider each loop as beginning and ending at the intersection point of the loops. Around each loop, $\Delta U = 0$, so $Q = W$; then, $Q_{\text{I}} = W_{\text{I}} > 0$ and $Q_{\text{II}} = W_{\text{II}} < 0$. Heat flows into the system for loop I and out of the system for loop II.

EVALUATE: W and Q are path dependent and are in general not zero for a cycle.

19.18. **IDENTIFY:** $\Delta U = Q - W$

SET UP: $Q < 0$ when heat leaves the gas.

EXECUTE: For an isothermal process, $\Delta U = 0$, so $W = Q = -335$ J.

EVALUATE: In a compression the volume decreases and $W < 0$.

19.19. **IDENTIFY:** For a constant pressure process, $W = p\Delta V$, $Q = nC_p\Delta T$ and $\Delta U = nC_V\Delta T$. $\Delta U = Q - W$ and $C_p = C_V + R$. For an ideal gas, $p\Delta V = nR\Delta T$.

SET UP: From Table 19.1, $C_V = 28.46$ J/mol·K.

EXECUTE: **(a)** The pV diagram is given in Figure 19.19.

(b) $W = pV_2 - pV_1 = nR(T_2 - T_1) = (0.250 \text{ mol})(8.3145 \text{ J/mol}\cdot\text{K})(100.0 \text{ K}) = 208$ J.

(c) The work is done on the piston.

(d) Since Eq. (19.13) holds for any process,

$\Delta U = nC_V\Delta T = (0.250 \text{ mol})(28.46 \text{ J/mol}\cdot\text{K})(100.0 \text{ K}) = 712$ J.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(e) Either $Q = nC_p\Delta T$ or $Q = \Delta U + W$ gives $Q = 920$ J to three significant figures.

(f) The lower pressure would mean a correspondingly larger volume, and the net result would be that the work done would be the same as that found in part (b).

EVALUATE: $W = nR\Delta T$, so W, Q and ΔU all depend only on ΔT. When T increases at constant pressure, V increases and $W > 0$. ΔU and Q are also positive when T increases.

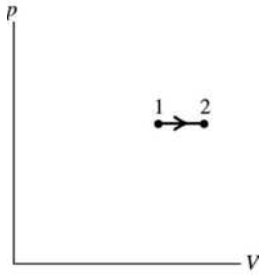

Figure 19.19

19.20. **IDENTIFY:** For constant volume $Q = nC_V\Delta T$. For constant pressure, $Q = nC_p\Delta T$. For any process of an ideal gas, $\Delta U = nC_V\Delta T$.

SET UP: $R = 8.315$ J/mol·K. For helium, $C_V = 12.47$ J/mol·K and $C_p = 20.78$ J/mol·K.

EXECUTE: **(a)** $Q = nC_V\Delta T = (0.0100 \text{ mol})(12.47 \text{J/mol}\cdot\text{K})(40.0 \text{ C°}) = 4.99$ J. The pV-diagram is sketched in Figure 19.20a.

(b) $Q = nC_p\Delta T = (0.0100 \text{ mol})(20.78 \text{ J/mol}\cdot\text{K})(40.0 \text{ C°}) = 8.31$ J. The pV-diagram is sketched in Figure 19.20b.

(c) More heat is required for the constant pressure process. ΔU is the same in both cases. For constant volume $W = 0$ and for constant pressure $W > 0$. The additional heat energy required for constant pressure goes into expansion work.

(d) $\Delta U = nC_V\Delta T = 4.99$ J for both processes. ΔU is path independent and for an ideal gas depends only on ΔT.

EVALUATE: $C_p = C_V + R$, so $C_p > C_V$.

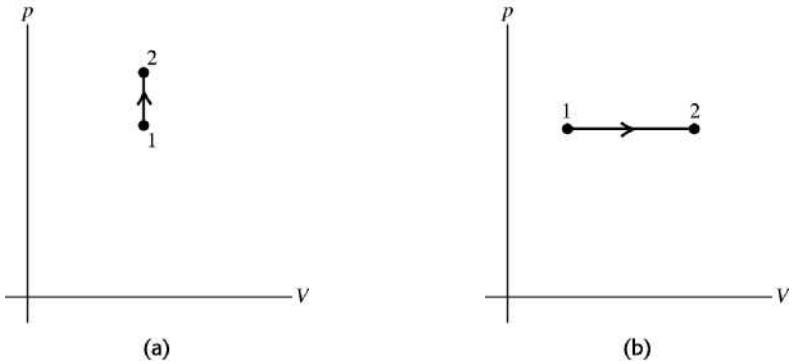

Figure 19.20

19.21. **IDENTIFY:** For constant volume, $Q = nC_V\Delta T$. For constant pressure, $Q = nC_p\Delta T$.

SET UP: From Table 19.1, $C_V = 20.76$ J/mol·K and $C_p = 29.07$ J/mol·K.

EXECUTE: **(a)** Using Eq. (19.12), $\Delta T = \dfrac{Q}{nC_V} = \dfrac{645 \text{ J}}{(0.185 \text{ mol})(20.76 \text{ J/mol}\cdot\text{K})} = 167.9$ K and $T = 948$ K.

The pV-diagram is sketched in Figure 19.21a.

(b) Using Eq. (19.14), $\Delta T = \dfrac{Q}{nC_p} = \dfrac{645 \text{ J}}{(0.185 \text{ mol})(29.07 \text{ J/mol}\cdot\text{K})} = 119.9 \text{ K}$ and $T = 900 \text{ K}$.

The pV-diagram is sketched in Figure 19.21b.

EVALUATE: At constant pressure some of the heat energy added to the gas leaves the gas as expansion work and the internal energy change is less than if the same amount of heat energy is added at constant volume. ΔT is proportional to ΔU.

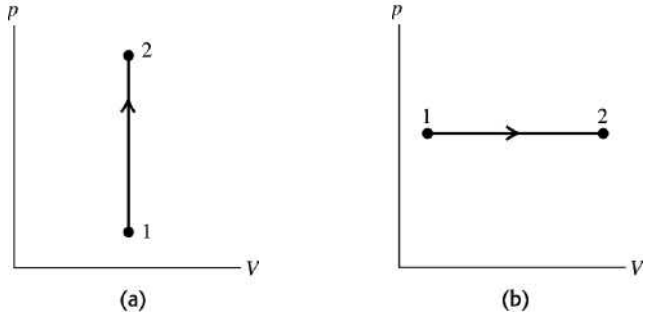

Figure 19.21

19.22. **IDENTIFY:** For an ideal gas, $\Delta U = C_V \Delta T$, and at constant pressure, $p\Delta V = nR\Delta T$.

SET UP: $C_V = \frac{3}{2}R$ for a monatomic gas.

EXECUTE: $\Delta U = n\left(\frac{3}{2}R\right)\Delta T = \frac{3}{2}p\Delta V = \frac{3}{2}(4.00\times10^4 \text{ Pa})(8.00\times10^{-3} \text{ m}^3 - 2.00\times10^{-3} \text{ m}^3) = 360 \text{ J}$.

EVALUATE: $W = nR\Delta T = \frac{2}{3}\Delta U = 240 \text{ J}$. $Q = nC_p\Delta T = n\left(\frac{5}{2}R\right)\Delta T = \frac{5}{3}\Delta U = 600 \text{ J}$. 600 J of heat energy flows into the gas. 240 J leaves as expansion work and 360 J remains in the gas as an increase in internal energy.

19.23. **IDENTIFY:** $\Delta U = Q - W$. For an ideal gas, $\Delta U = C_V \Delta T$, and at constant pressure, $W = p\Delta V = nR\Delta T$.

SET UP: $C_V = \frac{3}{2}R$ for a monatomic gas.

EXECUTE: $\Delta U = n\left(\frac{3}{2}R\right)\Delta T = \frac{3}{2}p\Delta V = \frac{3}{2}W$. Then $Q = \Delta U + W = \frac{5}{2}W$, so $W/Q = \frac{2}{5}$.

EVALUATE: For diatomic or polyatomic gases, C_V is a different multiple of R and the fraction of Q that is used for expansion work is different.

19.24. **IDENTIFY:** Apply $pV = nRT$ to calculate T. For this constant pressure process, $W = p\Delta V$. $Q = nC_p\Delta T$. Use $\Delta U = Q - W$ to relate Q, W and ΔU.

SET UP: $2.50 \text{ atm} = 2.53\times10^5 \text{ Pa}$. For a monatomic ideal gas, $C_V = 12.47 \text{ J/mol}\cdot\text{K}$ and $C_p = 20.78 \text{ J/mol}\cdot\text{K}$.

EXECUTE: **(a)** $T_1 = \dfrac{pV_1}{nR} = \dfrac{(2.53\times10^5 \text{ Pa})(3.20\times10^{-2} \text{ m}^3)}{(3.00 \text{ mol})(8.314 \text{ J/mol}\cdot\text{K})} = 325 \text{ K}$.

$T_2 = \dfrac{pV_2}{nR} = \dfrac{(2.53\times10^5 \text{ Pa})(4.50\times10^{-2} \text{ m}^3)}{(3.00 \text{ mol})(8.314 \text{ J/mol}\cdot\text{K})} = 456 \text{ K}$.

(b) $W = p\Delta V = (2.53\times10^5 \text{ Pa})(4.50\times10^{-2} \text{ m}^3 - 3.20\times10^{-2} \text{ m}^3) = 3.29\times10^3 \text{ J}$

(c) $Q = nC_p\Delta T = (3.00 \text{ mol})(20.78 \text{ J/mol}\cdot\text{K})(456 \text{ K} - 325 \text{ K}) = 8.17\times10^3 \text{ J}$

(d) $\Delta U = Q - W = 4.88\times10^3 \text{ J}$

EVALUATE: We could also calculate ΔU as $\Delta U = nC_V\Delta T = (3.00 \text{ mol})(12.47 \text{ J/mol}\cdot\text{K})(456 \text{ K} - 325 \text{ K}) = 4.90\times10^3 \text{ J}$, which agrees with the value we calculated in part (d).

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

19.25. **IDENTIFY:** For a constant volume process, $Q = nC_V\Delta T$. For a constant pressure process, $Q = nC_p\Delta T$. For any process of an ideal gas, $\Delta U = nC_V\Delta T$.

SET UP: From Table 19.1, for N_2, $C_V = 20.76$ J/mol·K and $C_p = 29.07$ J/mol·K. Heat is added, so Q is positive and $Q = +1557$ J.

EXECUTE: **(a)** $\Delta T = \dfrac{Q}{nC_V} = \dfrac{1557 \text{ J}}{(3.00 \text{ mol})(20.76 \text{ J/mol}\cdot\text{K})} = +25.0 \text{ K}$

(b) $\Delta T = \dfrac{Q}{nC_p} = \dfrac{1557 \text{ J}}{(3.00 \text{ mol})(29.07 \text{ J/mol}\cdot\text{K})} = +17.9 \text{ K}$

(c) $\Delta U = nC_V\Delta T$ for either process, so ΔU is larger when ΔT is larger. The final internal energy is larger for the constant volume process in (a).

EVALUATE: For constant volume $W = 0$ and all the energy added as heat stays in the gas as internal energy. For the constant pressure process the gas expands and $W > 0$. Part of the energy added as heat leaves the gas as expansion work done by the gas.

19.26. **IDENTIFY:** $C_p = C_V + R$ and $\gamma = \dfrac{C_p}{C_V}$.

SET UP: $R = 8.315$ J/mol·K

EXECUTE: $C_p = C_V + R$. $\gamma = \dfrac{C_p}{C_V} = 1 + \dfrac{R}{C_V}$. $C_V = \dfrac{R}{\gamma - 1} = \dfrac{8.315 \text{ J/mol}\cdot\text{K}}{0.127} = 65.5$ J/mol·K. Then

$C_p = C_V + R = 73.8$ J/mol·K.

EVALUATE: The value of C_V is about twice the values for the polyatomic gases in Table 19.1. A propane molecule has more atoms and hence more internal degrees of freedom than the polyatomic gases in the table.

19.27. **IDENTIFY:** Calculate W and ΔU and then use the first law to calculate Q.

(a) SET UP: $W = \int_{V_1}^{V_2} p\,dV$

$pV = nRT$ so $p = nRT/V$

$W = \int_{V_1}^{V_2} (nRT/V)\,dV = nRT\int_{V_1}^{V_2} dV/V = nRT\ln(V_2/V_1)$ (work done during an isothermal process).

EXECUTE: $W = (0.150 \text{ mol})(8.3145 \text{ J/mol}\cdot\text{K})(350 \text{ K})\ln(0.25V_1/V_1) = (436.5 \text{ J})\ln(0.25) = -605$ J.

EVALUATE: W for the gas is negative, since the volume decreases.

(b) EXECUTE: $\Delta U = nC_V\Delta T$ for any ideal gas process.

$\Delta T = 0$ (isothermal) so $\Delta U = 0$.

EVALUATE: $\Delta U = 0$ for any ideal gas process in which T doesn't change.

(c) EXECUTE: $\Delta U = Q - W$

$\Delta U = 0$ so $Q = W = -605$ J. (Q is negative; the gas liberates 605 J of heat to the surroundings.)

EVALUATE: $Q = nC_V\Delta T$ is only for a constant volume process so doesn't apply here.

$Q = nC_p\Delta T$ is only for a constant pressure process so doesn't apply here.

19.28. **IDENTIFY:** $\Delta U = Q - W$. Apply $Q = nC_p\Delta T$ to calculate C_p. Apply $\Delta U = nC_V\Delta T$ to calculate C_V. $\gamma = C_p/C_V$.

SET UP: $\Delta T = 15.0$ C° $= 15.0$ K. Since heat is added, $Q = +970$ J.

EXECUTE: **(a)** $\Delta U = Q - W = +970 \text{ J} - 223 \text{ J} = 747 \text{ J}$

(b) $C_p = \dfrac{Q}{n\Delta T} = \dfrac{970 \text{ J}}{(1.75 \text{ mol})(15.0 \text{ K})} = 37.0 \text{ J/mol}\cdot\text{K}$. $C_V = \dfrac{\Delta U}{n\Delta T} = \dfrac{747 \text{ J}}{(1.75 \text{ mol})(15.0 \text{ K})} = 28.5 \text{ J/mol}\cdot\text{K}$.

$\gamma = \dfrac{C_p}{C_V} = \dfrac{37.0 \text{ J/mol}\cdot\text{K}}{28.5 \text{ J/mol}\cdot\text{K}} = 1.30$

EVALUATE: The value of γ we calculated is similar to the values given in Tables 19.1 for polyatomic gases.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

19.29. **IDENTIFY:** For an adiabatic process of an ideal gas, $p_1V_1^{\gamma} = p_2V_2^{\gamma}$, $W = \dfrac{1}{\gamma - 1}(p_1V_1 - p_2V_2)$ and $T_1V_1^{\gamma-1} = T_2V_2^{\gamma-1}$.

SET UP: For a monatomic ideal gas $\gamma = 5/3$.

EXECUTE: **(a)** $p_2 = p_1\left(\dfrac{V_1}{V_2}\right)^{\gamma} = (1.50\times10^5\ \text{Pa})\left(\dfrac{0.0800\ \text{m}^3}{0.0400\ \text{m}^3}\right)^{5/3} = 4.76\times10^5\ \text{Pa}.$

(b) This result may be substituted into Eq. (19.26), or, substituting the above form for p_2,

$$W = \frac{1}{\gamma-1}p_1V_1\left(1-(V_1/V_2)^{\gamma-1}\right) = \frac{3}{2}(1.50\times10^5\ \text{Pa})(0.0800\ \text{m}^3)\left(1-\left(\frac{0.0800}{0.0400}\right)^{2/3}\right) = -1.06\times10^4\ \text{J}.$$

(c) From Eq. (19.22), $(T_2/T_1) = (V_2/V_1)^{\gamma-1} = (0.0800/0.0400)^{2/3} = 1.59$, and since the final temperature is higher than the initial temperature, the gas is heated.

EVALUATE: In an adiabatic compression $W < 0$ since $\Delta V < 0$. $Q = 0$ so $\Delta U = -W$. $\Delta U > 0$ and the temperature increases.

19.30. **IDENTIFY** and **SET UP:** For an ideal gas $\Delta U = nC_V\Delta T$. The sign of ΔU is the same as the sign of ΔT. Combine Eq. (19.22) and the ideal gas law to obtain an equation relating T and p, and use it to determine the sign of ΔT.

EXECUTE: $T_1V_1^{\gamma-1} = T_2V_2^{\gamma-1}$ and $V = nRT/p$ so, $T_1^{\gamma}p_1^{1-\gamma} = T_2^{\gamma}p_2^{1-\gamma}$ and $T_2^{\gamma} = T_1^{\gamma}(p_2/p_1)^{\gamma-1}$

$p_2 < p_1$ and $\gamma - 1$ is positive so $T_2 < T_1$. ΔT is negative so ΔU is negative; the energy of the gas decreases.

EVALUATE: Eq. (19.24) shows that the volume increases for this process, so it is an adiabatic expansion. In an adiabatic expansion the temperature decreases.

19.31. **IDENTIFY:** For an adiabatic process of an ideal gas, $W = \dfrac{1}{\gamma-1}(p_1V_1 - p_2V_2)$ and $p_1V_1^{\gamma} = p_2V_2^{\gamma}$.

SET UP: $\gamma = 1.40$ for an ideal diatomic gas. 1 atm $= 1.013\times10^5$ Pa and 1 L $= 10^{-3}$ m^3.

EXECUTE: $Q = \Delta U + W = 0$ for an adiabatic process, so $\Delta U = -W = \dfrac{1}{\gamma-1}(p_2V_2 - p_1V_1)$.

$p_1 = 1.22\times10^5$ Pa. $p_2 = p_1(V_1/V_2)^{\gamma} = (1.22\times10^5\ \text{Pa})(3)^{1.4} = 5.68\times10^5$ Pa.

$W = \dfrac{1}{0.40}([5.68\times10^5\ \text{Pa}][10\times10^{-3}\ \text{m}^{-3}] - [1.22\times10^5\ \text{Pa}][30\times10^{-3}\ \text{m}^{-3}]) = 5.05\times10^3$ J. The internal energy increases because work is done *on* the gas $(\Delta U > 0)$ and $Q = 0$. The temperature increases because the internal energy has increased.

EVALUATE: In an adiabatic compression $W < 0$ since $\Delta V < 0$. $Q = 0$ so $\Delta U = -W$. $\Delta U > 0$ and the temperature increases.

19.32. **IDENTIFY** and **SET UP:** **(a)** In the process the pressure increases and the volume decreases. The pV-diagram is sketched in Figure 19.32.

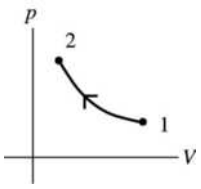

Figure 19.32

(b) For an adiabatic process for an ideal gas $T_1V_1^{\gamma-1} = T_2V_2^{\gamma-1}$, $p_1V_1^{\gamma} = p_2V_2^{\gamma}$, and $pV = nRT$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: From the first equation, $T_2 = T_1(V_1/V_2)^{\gamma-1} = (293\text{ K})(V_1/0.0900V_1)^{1.4-1}$

$T_2 = (293\text{ K})(11.11)^{0.4} = 768\text{ K} = 495°\text{C}$

(Note: In the equation $T_1V_1^{\gamma-1} = T_2V_2^{\gamma-1}$ the temperature *must* be in kelvins.)

$p_1V_1^{\gamma} = p_2V_2^{\gamma}$ implies $p_2 = p_1(V_1/V_2)^{\gamma} = (1.00\text{ atm})(V_1/0.0900V_1)^{1.4}$

$p_2 = (1.00\text{ atm})(11.11)^{1.4} = 29.1\text{ atm}$

EVALUATE: Alternatively, we can use $pV = nRT$ to calculate p_2: n, R constant implies

$pV/T = nR = \text{constant}$ so $p_1V_1/T_1 = p_2V_2/T_2$.

$p_2 = p_1(V_1/V_2)(T_2/T_1) = (1.00\text{ atm})(V_1/0.0900V_1)(768\text{ K}/293\text{ K}) = 29.1\text{ atm}$, which checks.

19.33. **(a) IDENTIFY** and **SET UP:** In the expansion the pressure decreases and the volume increases. The pV-diagram is sketched in Figure 19.33.

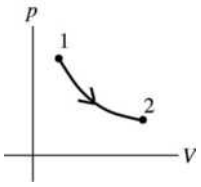

Figure 19.33

(b) Adiabatic means $Q = 0$.

Then $\Delta U = Q - W$ gives $W = -\Delta U = -nC_V\,\Delta T = nC_V(T_1 - T_2)$ (Eq. 19.25).

$C_V = 12.47\text{ J/mol}\cdot\text{K}$ (Table 19.1)

EXECUTE: $W = (0.450\text{ mol})(12.47\text{ J/mol}\cdot\text{K})(50.0°\text{C} - 10.0°\text{C}) = +224\text{ J}$

W positive for $\Delta V > 0$ (expansion)

(c) $\Delta U = -W = -224\text{ J}$.

EVALUATE: There is no heat energy input. The energy for doing the expansion work comes from the internal energy of the gas, which therefore decreases. For an ideal gas, when T decreases, U decreases.

19.34. **IDENTIFY:** Assume the expansion is adiabatic. $T_1V_1^{\gamma-1} = T_2V_2^{\gamma-1}$ relates V and T. Assume the air behaves as an ideal gas, so $\Delta U = nC_V\Delta T$. Use $pV = nRT$ to calculate n.

SET UP: For air, $C_V = 29.76\text{ J/mol}\cdot\text{K}$ and $\gamma = 1.40$. $V_2 = 0.800V_1$. $T_1 = 293.15\text{ K}$. $p_1 = 2.026\times10^5\text{ Pa}$.

For a sphere, $V = \frac{4}{3}\pi r^3$.

EXECUTE: **(a)** $T_2 = T_1\left(\dfrac{V_1}{V_2}\right)^{\gamma-1} = (293.15\text{ K})\left(\dfrac{V_1}{0.800V_1}\right)^{0.40} = 320.5\text{ K} = 47.4°\text{C}.$

(b) $V_1 = \frac{4}{3}\pi r^3 = \dfrac{4\pi}{3}(0.1195\text{ m})^3 = 7.15\times10^{-3}\text{ m}^3.$

$$n = \frac{p_1V_1}{RT_1} = \frac{(2.026\times10^5\text{ Pa})(7.15\times10^{-3}\text{ m}^3)}{(8.314\text{ J/mol}\cdot\text{K})(293.15\text{ K})} = 0.594\text{ mol}.$$

$\Delta U = nC_V\Delta T = (0.594\text{ mol})(20.76\text{ J/mol}\cdot\text{K})(321\text{ K} - 293\text{ K}) = 345\text{ J}.$

EVALUATE: We could also use $\Delta U = W = \dfrac{1}{\gamma-1}(p_1V_1 - p_2V_2)$ to calculate ΔU, if we first found p_2 from $pV = nRT$.

19.35. **IDENTIFY:** Combine $T_1V_1^{\gamma-1} = T_2V_2^{\gamma-1}$ with $pV = nRT$ to obtain an expression relating T and p for an adiabatic process of an ideal gas.

SET UP: $T_1 = 299.15\text{ K}$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: $V = \dfrac{nRT}{p}$ so $T_1\left(\dfrac{nRT_1}{p_1}\right)^{\gamma-1} = T_2\left(\dfrac{nRT_2}{p_2}\right)^{\gamma-1}$ and $\dfrac{T_1^{\gamma}}{p_1^{\gamma-1}} = \dfrac{T_2^{\gamma}}{p_2^{\gamma-1}}$.

$$T_2 = T_1\left(\frac{p_2}{p_1}\right)^{(\gamma-1)/\gamma} = (299.15\text{ K})\left(\frac{0.850\times10^5\text{ Pa}}{1.01\times10^5\text{ Pa}}\right)^{0.4/1.4} = 284.8\text{ K} = 11.6°\text{C}$$

EVALUATE: For an adiabatic process of an ideal gas, when the pressure decreases the temperature decreases.

19.36. **IDENTIFY:** $pV = nRT$ For an adiabatic process, $T_1V_1^{\gamma-1} = T_2V_2^{\gamma-1}$.

SET UP: For an ideal monatomic gas, $\gamma = 5/3$.

EXECUTE: **(a)** $T = \dfrac{pV}{nR} = \dfrac{(1.00\times10^5\text{ Pa})(2.50\times10^{-3}\text{ m}^3)}{(0.1\text{ mol})(8.3145\text{ J/mol}\cdot\text{K})} = 301\text{ K}.$

(b) (i) Isothermal: If the expansion is *isothermal*, the process occurs at constant temperature and the final temperature is the same as the initial temperature, namely 301 K. $p_2 = p_1(V_1/V_2) = \frac{1}{2}p_1 = 5.00\times10^4$ Pa.

(ii) Isobaric: $\Delta p = 0$ so $p_2 = 1.00\times10^5$ Pa. $T_2 = T_1(V_2/V_1) = 2T_1 = 602$ K.

(iii) Adiabatic: Using Eq. (19.22), $T_2 = \dfrac{T_1V_1^{\gamma-1}}{V_2^{\gamma-1}} = \dfrac{(301\text{ K})(V_1)^{0.67}}{(2V_1)^{0.67}} = (301\text{ K})\left(\frac{1}{2}\right)^{0.67} = 189$ K. Then

$pV = nRT$ gives $p_2 = 3.14\times10^4$ Pa.

EVALUATE: In an isobaric expansion, T increases. In an adiabatic expansion, T decreases.

19.37. **IDENTIFY:** The compression does work on the gas, but the heat transferred and the internal energy change depend on the process by which the compression occurs. The ideal gas law and the first law of thermodynamics apply to the gas.

SET UP: $Q = \Delta U + W$, $pV = nRT$, and $C_V = C_p - R$.

EXECUTE: **(a)** This is an isothermal process for an ideal gas, so $\Delta U = 0$ and $Q = W$. Since the volume decreases (compression), W is negative and $Q = -600$ J. Since Q is negative, heat flows out of the gas.

(b) $W = p\Delta V = nR\Delta T = -600$ J. $\Delta T = \dfrac{W}{nR} = \dfrac{-600\text{ J}}{(1)(8.314\text{ J/mol}\cdot\text{K})} = -72.2$ K.

$C_V = C_p - R = \dfrac{5R}{2} = 20.78\text{ J/mol}\cdot\text{K}$. $\Delta U = nC_V\Delta T = (1)(20.78\text{ J/mol}\cdot\text{K})(-72.2\text{ K}) = -1500$ J . Since ΔU is negative, the internal energy decreases.

EVALUATE: In part (a) work is done on the gas, so heat must flow out of it for its temperature to remain the same. In (b) gas is compressed, so the molecules must slow down if the pressure is to remain the same, which means that the internal energy (and the temperature) must decrease.

19.38. **IDENTIFY:** Apply $\Delta U = Q - W$. For any process of an ideal gas, $\Delta U = nC_V\Delta T$. For an isothermal expansion, $W = nRT\ln\left(\dfrac{V_2}{V_1}\right) = nRT\ln\left(\dfrac{p_1}{p_2}\right)$.

SET UP: $T = 288.15$ K. $\dfrac{p_1}{p_2} = \dfrac{V_2}{V_1} = 2.00$.

EXECUTE: **(a)** $\Delta U = 0$ since $\Delta T = 0$.

(b) $W = (1.50\text{ mol})(8.314\text{ J/mol}\cdot\text{K})(288.15\text{ K})\ln(2.00) = 2.49\times10^3$ J. $W > 0$ and work is done by the gas.

Since $\Delta U = 0$, $Q = W = +2.49\times10^3$ J. $Q > 0$ so heat flows into the gas.

EVALUATE: When the volume increases, W is positive.

19.39. **IDENTIFY** and **SET UP:** For an ideal gas, $pV = nRT$. The work done is the area under the path in the pV-diagram.

EXECUTE: **(a)** The product pV increases and this indicates a temperature increase.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) The work is the area in the pV plane bounded by the blue line representing the process and the verticals at V_a and V_b. The area of this trapezoid is $\frac{1}{2}(p_b + p_a)(V_b - V_a) = \frac{1}{2}(2.40\times10^5 \text{ Pa})(0.0400 \text{ m}^3) = 4800 \text{ J}$.

EVALUATE: The work done is the average pressure, $\frac{1}{2}(p_1 + p_2)$, times the volume increase.

19.40. **IDENTIFY:** Use $pV = nRT$ to calculate T. W is the area under the process in the pV-diagram. Use $\Delta U = nC_V\Delta T$ and $\Delta U = Q - W$ to calculate Q.

SET UP: In state c, $p_c = 2.0\times10^5$ Pa and $V_c = 0.0040 \text{ m}^3$. In state a, $p_a = 4.0\times10^5$ Pa and $V_a = 0.0020 \text{ m}^3$.

EXECUTE: **(a)** $T_c = \dfrac{p_cV_c}{nR} = \dfrac{(2.0\times10^5 \text{ Pa})(0.0040 \text{ m}^3)}{(0.500 \text{ mol})(8.314 \text{ J/mol}\cdot\text{K})} = 192 \text{ K}$

(b) $W = \frac{1}{2}(4.0\times10^5 \text{ Pa} + 2.0\times10^5 \text{ Pa})(0.0030 \text{ m}^3 - 0.0020 \text{ m}^3) + (2.0\times10^5 \text{ Pa})(0.0040 \text{ m}^3 - 0.0030 \text{ m}^3)$

$W = +500$ J. 500 J of work is done by the gas.

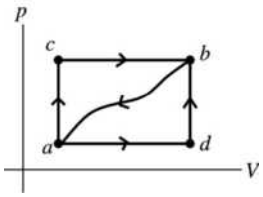
(c) $T_a = \dfrac{p_aV_a}{nR} = \dfrac{(4.0\times10^5 \text{ Pa})(0.0020 \text{ m}^3)}{(0.500 \text{ mol})(8.314 \text{ J/mol}\cdot\text{K})} = 192 \text{ K}$. For the process, $\Delta T = 0$, so $\Delta U = 0$ and $Q = W = +500$ J. 500 J of heat enters the system.

EVALUATE: The work done by the gas is positive since the volume increases.

19.41. **IDENTIFY:** Use $\Delta U = Q - W$ and the fact that ΔU is path independent.

$W > 0$ when the volume increases, $W < 0$ when the volume decreases, and $W = 0$ when the volume is constant. $Q > 0$ if heat flows into the system.

SET UP: The paths are sketched in Figure 19.41.



$Q_{acb} = +90.0$ J (positive since heat flows in)

$W_{acb} = +60.0$ J (positive since $\Delta V > 0$)

Figure 19.41

EXECUTE: **(a)** $\Delta U = Q - W$

ΔU is path independent; Q and W depend on the path.

$\Delta U = U_b - U_a$

This can be calculated for any path from a to b, in particular for path acb:

$\Delta U_{a\to b} = Q_{acb} - W_{acb} = 90.0 \text{ J} - 60.0 \text{ J} = 30.0 \text{ J}$.

Now apply $\Delta U = Q - W$ to path adb; $\Delta U = 30.0$ J for this path also.

$W_{adb} = +15.0$ J (positive since $\Delta V > 0$)

$\Delta U_{a\to b} = Q_{adb} - W_{adb}$ so $Q_{adb} = \Delta U_{a\to b} + W_{adb} = 30.0 \text{ J} + 15.0 \text{ J} = +45.0 \text{ J}$

(b) Apply $\Delta U = Q - W$ to path ba: $\Delta U_{b\to a} = Q_{ba} - W_{ba}$

$W_{ba} = -35.0$ J (negative since $\Delta V < 0$)

$\Delta U_{b\to a} = U_a - U_b = -(U_b - U_a) = -\Delta U_{a\to b} = -30.0 \text{ J}$

Then $Q_{ba} = \Delta U_{b\to a} + W_{ba} = -30.0 \text{ J} - 35.0 \text{ J} = -65.0$ J.

($Q_{ba} < 0$; the system liberates heat.)

(c) $U_a = 0$, $U_d = 8.0$ J

$\Delta U_{a\to b} = U_b - U_a = +30.0$ J, so $U_b = +30.0$ J.

process $a \to d$

$\Delta U_{a\to d} = Q_{ad} - W_{ad}$

$\Delta U_{a\to d} = U_d - U_a = +8.0$ J

$W_{adb} = +15.0$ J and $W_{adb} = W_{ad} + W_{db}$. But the work W_{db} for the process $d \to b$ is zero since $\Delta V = 0$ for that process. Therefore $W_{ad} = W_{adb} = +15.0$ J.

Then $Q_{ad} = \Delta U_{a\to d} + W_{ad} = +8.0$ J $+15.0$ J $= +23.0$ J (positive implies heat absorbed).

process $d \to b$

$\Delta U_{d\to b} = Q_{db} - W_{db}$

$W_{db} = 0$, as already noted.

$\Delta U_{d\to b} = U_b - U_d = 30.0$ J $- 8.0$ J $= +22.0$ J.

Then $Q_{db} = \Delta U_{d\to b} + W_{db} = +22.0$ J (positive; heat absorbed).

EVALUATE: The signs of our calculated Q_{ad} and Q_{db} agree with the problem statement that heat is absorbed in these processes.

19.42. **IDENTIFY:** $\Delta U = Q - W$.

SET UP: $W = 0$ when $\Delta V = 0$.

EXECUTE: For each process, $Q = \Delta U + W$. No work is done in the processes *ab* and *dc*, and so $W_{bc} = W_{abc} = 450$ J and $W_{ad} = W_{adc} = 120$ J. The heat flow for each process is: for *ab*, $Q = 90$ J. For *bc*, $Q = 440$ J $+ 450$ J $= 890$ J. For *ad*, $Q = 180$ J $+ 120$ J $= 300$ J. For *dc*, $Q = 350$ J. Heat is absorbed in each process. Note that the arrows representing the processes all point in the direction of increasing temperature (increasing *U*).

EVALUATE: ΔU is path independent so is the same for paths *adc* and *abc*. $Q_{adc} = 300$ J $+ 350$ J $= 650$ J. $Q_{abc} = 90$ J $+ 890$ J $= 980$ J. Q and W are path dependent and are different for these two paths.

19.43. **IDENTIFY:** Use $pV = nRT$ to calculate T_c/T_a. Calculate ΔU and W and use $\Delta U = Q - W$ to obtain Q.

SET UP: For path *ac*, the work done is the area under the line representing the process in the pV-diagram.

EXECUTE: **(a)** $\dfrac{T_c}{T_a} = \dfrac{p_cV_c}{p_aV_a} = \dfrac{(1.0\times10^5 \text{ J})(0.060 \text{ m}^3)}{(3.0\times10^5 \text{ J})(0.020 \text{ m}^3)} = 1.00$. $T_c = T_a$.

(b) Since $T_c = T_a$, $\Delta U = 0$ for process *abc*. For *ab*, $\Delta V = 0$ and $W_{ab} = 0$. For *bc*, *p* is constant and $W_{bc} = p\Delta V = (1.0\times10^5 \text{ Pa})(0.040 \text{ m}^3) = 4.0\times10^3$ J. Therefore, $W_{abc} = +4.0\times10^3$ J. Since $\Delta U = 0$, $Q = W = +4.0\times10^3$ J. 4.0×10^3 J of heat flows into the gas during process *abc*.

(c) $W = \frac{1}{2}(3.0\times10^5 \text{ Pa} + 1.0\times10^5 \text{ Pa})(0.040 \text{ m}^3) = +8.0\times10^3$ J. $Q_{ac} = W_{ac} = +8.0\times10^3$ J.

EVALUATE: The work done is path dependent and is greater for process *ac* than for process *abc*, even though the initial and final states are the same.

19.44. **IDENTIFY:** For a cycle, $\Delta U = 0$ and $Q = W$. Calculate *W*.

SET UP: The magnitude of the work done by the gas during the cycle equals the area enclosed by the cycle in the pV-diagram.

EXECUTE: **(a)** The cycle is sketched in Figure 19.44.

(b) $|W| = (3.50\times10^4 \text{ Pa} - 1.50\times10^4 \text{ Pa})(0.0435 \text{ m}^3 - 0.0280 \text{ m}^3) = +310$ J. More negative work is done for *cd* than positive work for *ab* and the net work is negative. $W = -310$ J.

(c) $Q = W = -310$ J. Since $Q < 0$, the net heat flow is out of the gas.

EVALUATE: During each constant pressure process $W = p\Delta V$ and during the constant volume process $W = 0$.

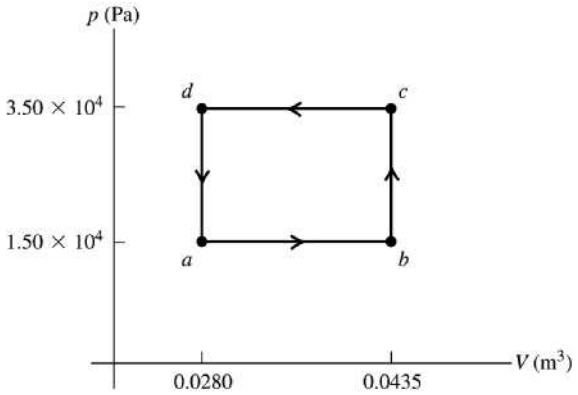

Figure 19.44

19.45. **IDENTIFY:** Use the 1st law to relate Q_{tot} to W_{tot} for the cycle.

Calculate W_{ab} and W_{bc} and use what we know about W_{tot} to deduce W_{ca}.

(a) SET UP: We aren't told whether the pressure increases or decreases in process *bc*. The two possibilities for the cycle are sketched in Figure 19.45.

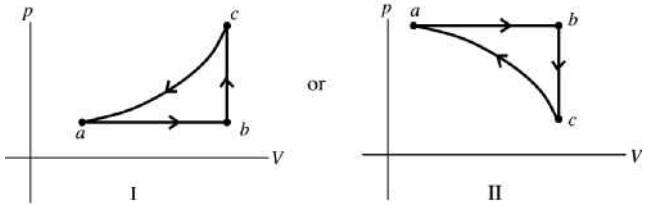

Figure 19.45

In cycle I, the total work is negative and in cycle II the total work is positive. For a cycle, $\Delta U = 0$, so $Q_{\text{tot}} = W_{\text{tot}}$.

The net heat flow for the cycle is out of the gas, so heat $Q_{\text{tot}} < 0$ and $W_{\text{tot}} < 0$. Sketch I is correct.

(b) EXECUTE: $W_{\text{tot}} = Q_{\text{tot}} = -800$ J

$W_{\text{tot}} = W_{ab} + W_{bc} + W_{ca}$

$W_{bc} = 0$ since $\Delta V = 0$.

$W_{ab} = p\Delta V$ since p is constant. But since it is an ideal gas, $p\Delta V = nR\Delta T$.

$W_{ab} = nR(T_b - T_a) = 1660$ J

$W_{ca} = W_{\text{tot}} - W_{ab} = -800\text{ J} - 1660\text{ J} = -2460$ J

EVALUATE: In process *ca* the volume decreases and the work W is negative.

19.46. **IDENTIFY:** Apply the appropriate expression for W for each type of process. $pV = nRT$ and $C_p = C_V + R$.

SET UP: $R = 8.315\text{ J/mol}\cdot\text{K}$

EXECUTE: Path ac has constant pressure, so $W_{ac} = p\Delta V = nR\Delta T$, and

$W_{ac} = nR(T_c - T_a) = (3\text{ mol})(8.3145\text{ J/mol}\cdot\text{K})(492\text{ K} - 300\text{ K}) = 4.789\times10^3$ J.

Path cb is adiabatic $(Q = 0)$, so $W_{cb} = Q - \Delta U = -\Delta U = -nC_V\Delta T$, and using $C_V = C_p - R$,

$W_{cb} = -n(C_p - R)(T_b - T_c) = -(3\text{ mol})(29.1\text{ J/mol}\cdot\text{K} - 8.3145\text{ J/mol}\cdot\text{K})(600\text{ K} - 492\text{ K}) = -6.735\times10^3$ J.

Path ba has constant volume, so $W_{ba} = 0$. So the total work done is

$$W = W_{ac} + W_{cb} + W_{ba} = 4.789\times10^3\text{ J} - 6.735\times10^3\text{ J} + 0 = -1.95\times10^3\text{ J}.$$

EVALUATE: $W > 0$ when $\Delta V > 0$, $W < 0$ when $\Delta V < 0$ and $W = 0$ when $\Delta V = 0$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

19.47. **IDENTIFY:** Segment *ab* is isochoric, *bc* is isothermal, and *ca* is isobaric.

SET UP: For *bc*, $\Delta T = 0$, $\Delta U = 0$, and $Q = W = nRT\ln(V_c/V_b)$. For ideal H_2 (diatomic), $C_V = \frac{5}{2}R$ and $C_p = \frac{7}{2}R$. $\Delta U = nC_V\,\Delta T$ for any process of an ideal gas.

EXECUTE: **(a)** $T_b = T_c$. For states *b* and *c*, $pV = nRT = \text{constant}$ so $p_bV_b = p_cV_c$ and

$$V_c = V_b\left(\frac{p_b}{p_c}\right) = (0.20\text{ L})\left(\frac{2.0\text{ atm}}{0.50\text{ atm}}\right) = 0.80\text{ L}.$$

(b) $T_a = \dfrac{p_aV_a}{nR} = \dfrac{(0.50\text{ atm})(1.013\times10^5\text{ Pa/atm})(0.20\times10^{-3}\text{ m}^3)}{(0.0040\text{ mol})(8.315\text{ J/mol}\cdot\text{K})} = 305\text{ K}$. $V_a = V_b$ so for states *a* and *b*,

$\dfrac{T}{p} = \dfrac{V}{nR} = \text{constant}$ so $\dfrac{T_a}{p_a} = \dfrac{T_b}{p_b}$. $T_b = T_c = T_a\left(\dfrac{p_b}{p_a}\right) = (305\text{ K})\left(\dfrac{2.0\text{ atm}}{0.50\text{ atm}}\right) = 1220\text{ K}$; $T_c = 1220\text{ K}$.

(c) *ab*: $Q = nC_V\,\Delta T = n\left(\frac{5}{2}R\right)\Delta T$, which gives

$Q = (0.0040\text{ mol})\left(\frac{5}{2}\right)(8.315\text{ J/mol}\cdot\text{K})(1220\text{ K} - 305\text{ K}) = +76\text{ J}$. Q is positive and heat goes into the gas.

ca: $Q = nC_p\,\Delta T = n\left(\frac{7}{2}R\right)\Delta T$, which gives

$Q = (0.0040\text{ mol})\left(\frac{7}{2}\right)(8.315\text{ J/mol}\cdot\text{K})(305\text{ K} - 1220\text{ K}) = -107\text{ J}$. Q is negative and heat comes out of the gas.

bc: $Q = W = nRT\ln(V_c/V_b)$, which gives

$Q = (0.0040\text{ mol})(8.315\text{ J/mol}\cdot\text{K})(1220\text{ K})\ln(0.80\text{ L}/0.20\text{ L}) = 56\text{ J}$. Q is positive and heat goes into the gas.

(d) *ab*: $\Delta U = nC_V\Delta T = n\left(\frac{5}{2}R\right)\Delta T$, which gives

$\Delta U = (0.0040\text{ mol})\left(\frac{5}{2}\right)(8.315\text{ J/mol}\cdot\text{K})(1220\text{ K} - 305\text{ K}) = +76\text{ J}$. The internal energy increased.

bc: $\Delta T = 0$ so $\Delta U = 0$. The internal energy does not change.

ca: $\Delta U = nC_V\Delta T = n\left(\frac{5}{2}R\right)\Delta T$, which gives

$\Delta U = (0.0040\text{ mol})\left(\frac{5}{2}\right)(8.315\text{ J/mol}\cdot\text{K})(305\text{ K} - 1220\text{ K}) = -76\text{ J}$. The internal energy decreased.

EVALUATE: The net internal energy change for the complete cycle $a \to b \to c \to a$ is $\Delta U_{\text{tot}} = +76\text{ J} + 0 + (-76\text{ J}) = 0$. For any complete cycle the final state is the same as the initial state and the net internal energy change is zero. For the cycle the net heat flow is $Q_{\text{tot}} = +76\text{ J} + (-107\text{ J}) + 56\text{ J} = +25\text{ J}$. $\Delta U_{\text{tot}} = 0$ so $Q_{\text{tot}} = W_{\text{tot}}$. The net work done in the cycle is positive and this agrees with our result that the net heat flow is positive.

19.48. **IDENTIFY:** Segment *ab* is isobaric, *bc* is isochoric, and *ca* is isothermal.

SET UP: He is a monatomic gas so $C_V = \frac{3}{2}R$ and $C_p = \frac{5}{2}R$. For any process of an ideal gas, $\Delta U = nC_V\Delta T$. For an isothermal process of an ideal gas, $\Delta U = 0$ so $Q = W = nRT\ln(V_2/V_1)$.

EXECUTE: **(a)** Apply $pV = nRT$ to states *a* and *c*. $T_a = T_c$ so *nRT* is constant and $p_aV_a = p_cV_c$.

$$p_a = p_c\left(\frac{V_c}{V_a}\right) = (2.0\times10^5\text{ Pa})\left(\frac{0.040\text{ m}^3}{0.010\text{ m}^3}\right) = 8.0\times10^5\text{ Pa}.$$

(b) $T_a = \dfrac{p_aV_a}{nR} = \dfrac{(8.0\times10^5\text{ Pa})(0.010\text{ m}^3)}{(3.25\text{ mol})(8.315\text{ J/mol}\cdot\text{K})} = 296\text{ K};$

$T_b = \dfrac{p_bV_b}{nR} = \dfrac{(8.0\times10^5\text{ Pa})(0.040\text{ m}^3)}{(3.25\text{ mol})(8.315\text{ J/mol}\cdot\text{K})} = 1184\text{ K};$

$T_c = \dfrac{p_cV_c}{nR} = \dfrac{(2.0\times10^5\text{ Pa})(0.040\text{ m}^3)}{(3.25\text{ mol})(8.315\text{ J/mol}\cdot\text{K})} = 296\text{ K} = T_a.$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(c) *ab*: $Q = nC_p\Delta T = (3.25\text{ mol})\left(\frac{5}{2}\right)(8.315\text{ J/mol}\cdot\text{K})(1184\text{ K} - 296\text{ K}) = 6.00\times10^4\text{ J}$; heat enters the gas.

bc: $Q = nC_V\Delta T = (3.25\text{ mol})\left(\frac{3}{2}\right)(8.315\text{ J/mol}\cdot\text{K})(296\text{ K} - 1184\text{ K}) = -3.60\times10^4\text{ J}$; heat leaves the gas.

ca: $Q = nRT\ln\left(\frac{V_a}{V_c}\right) = (3.25\text{ mol})(8.315\text{ J/mol}\cdot\text{K})(296\text{ K})\ln\left(\frac{0.010\text{ m}^3}{0.040\text{ m}^3}\right) = -1.11\times10^4\text{ J}$; heat leaves the gas.

(d) *ab*: $\Delta U = nC_V\Delta T = (3.25\text{ mol})\left(\frac{3}{2}\right)(8.315\text{ J/mol}\cdot\text{K})(1184\text{ K} - 296\text{ K}) = 3.60\times10^4\text{ J}$; the internal energy increased.

bc: $\Delta U = nC_V\Delta T = (3.25\text{ mol})\left(\frac{3}{2}\right)(8.315\text{ J/mol}\cdot\text{K})(296\text{ K} - 1184\text{ K}) = -3.60\times10^4\text{ J}$; the internal energy decreased.

ca: $\Delta T = 0$ so $\Delta U = 0$.

EVALUATE: As we saw in (d), for any closed path on a *pV* diagram, $\Delta U = 0$ because we are back at the same values of *P*, *V*, and *T*.

19.49. **IDENTIFY:** The segments *ab* and *bc* are not any of the familiar ones, such as isothermal, isobaric or isochoric, but *ac* is isobaric.

SET UP: For helium, $C_V = 12.47\text{ J/mol}\cdot\text{K}$ and $C_p = 20.78\text{ J/mol}\cdot\text{K}$. $\Delta U = Q - W$. W is the area under the *p* versus *V* curve. $\Delta U = nC_V\Delta T$ for any process of an ideal gas.

EXECUTE: **(a)** $W = \frac{1}{2}(1.0\times10^5\text{ Pa} + 3.5\times10^5\text{ Pa})(0.0060\text{ m}^3 - 0.0020\text{ m}^3)$

$$+ \tfrac{1}{2}(1.0\times10^5\text{ Pa} + 3.5\times10^5\text{ Pa})(0.0100\text{ m}^3 - 0.0060\text{ m}^3) = 1800\text{ J}.$$

Find $\Delta T = T_c - T_a$. p is constant so $\Delta T = \frac{p\Delta V}{nR} = \frac{(1.0\times10^5\text{ Pa})(0.0100\text{ m}^3 - 0.0020\text{ m}^3)}{\left(\frac{1}{3}\text{ mol}\right)(8.315\text{ J/mol}\cdot\text{K})} = 289\text{ K}$. Then

$\Delta U = nC_V\Delta T = \left(\frac{1}{3}\text{ mol}\right)(12.47\text{ J/mol}\cdot\text{K})(289\text{ K}) = 1.20\times10^3\text{ J}$.

$Q = \Delta U + W = 1.20\times10^3\text{ J} + 1800\text{ J} = 3.00\times10^3\text{ J}$. $Q > 0$, so this heat is transferred into the gas.

(b) This process is isobaric, so $Q = nC_p\Delta T = \left(\frac{1}{3}\text{ mol}\right)(20.78\text{ J/mol}\cdot\text{K})(289\text{ K}) = 2.00\times10^3\text{ J}$. $Q > 0$, so this heat is transferred into the gas.

(c) Q is larger in part (a).

EVALUATE: ΔU is the same in parts (a) and (b) because the initial and final states are the same, but in (a) more work is done.

19.50. **IDENTIFY:** We have an isobaric expansion followed by an adiabatic expansion.

SET UP: $T_1 = 300\text{ K}$. When the volume doubles at constant pressure the temperature doubles, so $T_2 = 600\text{ K}$. For helium, $C_p = 20.78\text{ J/mol}\cdot\text{K}$ and $\gamma = 1.67$. $\Delta U = nC_V\Delta T$ for any process of an ideal gas. $\Delta U = Q - W$.

EXECUTE: **(a)** The process is sketched in Figure 19.50.

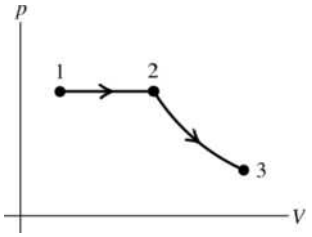

Figure 19.50

(b) For the isobaric step, $Q = nC_p\Delta T = (2.00\text{ mol})(20.78\text{ J/mol}\cdot\text{K})(300\text{ K}) = 1.25\times10^4\text{ J}$. For the adiabatic process, $Q = 0$. The total heat is Q is $1.25\times10^4\text{ J}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(c) $\Delta U = 0$ since $\Delta T = 0$.

(d) Since $\Delta U = 0$, $W = Q = 1.25 \times 10^4$ J.

(e) $T_3 = 300$ K, $T_2 = 600$ K and $V_2 = 0.0600$ m^3. $T_2 V_2^{\gamma - 1} = T_3 V_3^{\gamma - 1}$.

$$V_3 = V_2 \left(\frac{T_2}{T_3} \right)^{1/(\gamma - 1)} = (0.0600 \text{ m}^3) \left(\frac{600 \text{ K}}{300 \text{ K}} \right)^{1/0.67} = 0.169 \text{ m}^3.$$

EVALUATE: In both processes the internal energy changes. In the isobaric expansion the temperature increases and the internal energy increases. In the adiabatic expansion the temperature decreases and $\Delta U < 0$. The magnitudes of the two temperature changes are equal and the net change in internal energy is zero.

19.51. **IDENTIFY:** Use $Q = nC_V \Delta T$ to calculate the temperature change in the constant volume process and use $pV = nRT$ to calculate the temperature change in the constant pressure process. The work done in the constant volume process is zero and the work done in the constant pressure process is $W = p\Delta V$. Use $Q = nC_p \Delta T$ to calculate the heat flow in the constant pressure process. $\Delta U = nC_V \Delta T$, or $\Delta U = Q - W$.

SET UP: For N_2, $C_V = 20.76$ J/mol·K and $C_p = 29.07$ J/mol·K.

EXECUTE: **(a)** For process ab, $\Delta T = \dfrac{Q}{nC_V} = \dfrac{1.52 \times 10^4 \text{ J}}{(2.50 \text{ mol})(20.76 \text{ J/mol} \cdot \text{K})} = 293$ K. $T_a = 293$ K, so

$T_b = 586$ K. $pV = nRT$ says T doubles when V doubles and p is constant, so

$T_c = 2(586 \text{ K}) = 1172 \text{ K} = 899°\text{C}$.

(b) For process ab, $W_{ab} = 0$. For process bc,

$W_{bc} = p\Delta V = nR\Delta T = (2.50 \text{ mol})(8.314 \text{ J/mol} \cdot \text{K})(1172 \text{ K} - 586 \text{ K}) = 1.22 \times 10^4$ J.

$W = W_{ab} + W_{bc} = 1.22 \times 10^4$ J.

(c) For process bc, $Q = nC_p \Delta T = (2.50 \text{ mol})(29.07 \text{ J/mol} \cdot \text{K})(1172 \text{ K} - 586 \text{ K}) = 4.26 \times 10^4$ J.

(d) $\Delta U = nC_V \Delta T = (2.50 \text{ mol})(20.76 \text{ J/mol} \cdot \text{K})(1172 \text{ K} - 293 \text{ K}) = 4.56 \times 10^4$ J.

EVALUATE: The total Q is $1.52 \times 10^4 \text{ J} + 4.26 \times 10^4 \text{ J} = 5.78 \times 10^4$ J.

$\Delta U = Q - W = 5.78 \times 10^4 \text{ J} - 1.22 \times 10^4 \text{ J} = 4.56 \times 10^4$ J, which agrees with our results in part (d).

19.52. **IDENTIFY:** For a constant pressure process, $Q = nC_p \Delta T$. $\Delta U = Q - W$. $\Delta U = nC_V \Delta T$ for any ideal gas process.

SET UP: For N_2, $C_V = 20.76$ J/mol·K and $C_p = 29.07$ J/mol·K. $Q < 0$ if heat comes out of the gas.

EXECUTE: **(a)** $n = \dfrac{Q}{C_p \Delta T} = \dfrac{-2.5 \times 10^4 \text{ J}}{(29.07 \text{ J/mol} \cdot \text{K})(-40.0 \text{ K})} = 21.5$ mol.

(b) $\Delta U = nC_V \Delta T = Q(C_V / C_p) = (-2.5 \times 10^4 \text{ J})(20.76/29.07) = -1.79 \times 10^4$ J.

(c) $W = Q - \Delta U = -7.15 \times 10^3$ J.

(d) ΔU is the same for both processes, and if $\Delta V = 0$, $W = 0$ and $Q = \Delta U = -1.79 \times 10^4$ J.

EVALUATE: For a given ΔT, Q is larger in magnitude when the pressure is constant than when the volume is constant.

19.53. **IDENTIFY** and **SET UP:** Use the first law to calculate W and then use $W = p\Delta V$ for the constant pressure process to calculate ΔV.

EXECUTE: $\Delta U = Q - W$

$Q = -2.15 \times 10^5$ J (negative since heat energy goes out of the system)

$\Delta U = 0$ so $W = Q = -2.15 \times 10^5$ J

Constant pressure, so $W = \int_{V_1}^{V_2} p dV = p(V_2 - V_1) = p\Delta V$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

Then $\Delta V = \dfrac{W}{p} = \dfrac{-2.15\times10^5 \text{ J}}{9.50\times10^5 \text{ Pa}} = -0.226 \text{ m}^3$.

EVALUATE: Positive work is done on the system by its surroundings; this inputs to the system the energy that then leaves the system as heat. Both Eqs. (19.4) and (19.2) apply to all processes for any system, not just to an ideal gas.

19.54. **IDENTIFY:** $pV = nRT$. For an isothermal process $W = nRT\ln(V_2/V_1)$. For a constant pressure process, $W = p\Delta V$.

SET UP: $1 \text{ L} = 10^{-3} \text{ m}^3$.

EXECUTE: **(a)** The pV-diagram is sketched in Figure 19.54.

(b) At constant temperature, the product pV is constant, so

$V_2 = V_1(p_1/p_2) = (1.5 \text{ L})\left(\dfrac{1.00\times10^5 \text{ Pa}}{2.50\times10^4 \text{ Pa}}\right) = 6.00 \text{ L}$. The final pressure is given as being the same as $p_3 = p_2 = 2.5\times10^4$ Pa. The final volume is the same as the initial volume, so $T_3 = T_1(p_3/p_1) = 75.0$ K.

(c) Treating the gas as ideal, the work done in the first process is $W = nRT\ln(V_2/V_1) = p_1V_1\ln(p_1/p_2)$.

$W = (1.00\times10^5 \text{ Pa})(1.5\times10^{-3} \text{ m}^3)\ln\left(\dfrac{1.00\times10^5 \text{ Pa}}{2.50\times10^4 \text{ Pa}}\right) = 208 \text{ J}$.

For the second process, $W = p_2(V_3 - V_2) = p_2(V_1 - V_2) = p_2V_1(1 - (p_1/p_2))$.

$W = (2.50\times10^4 \text{ Pa})(1.5\times10^{-3} \text{ m}^3)\left(1 - \dfrac{1.00\times10^5 \text{ Pa}}{2.50\times10^4 \text{ Pa}}\right) = -113 \text{ J}$.

The total work done is $208 \text{ J} - 113 \text{ J} = 95 \text{ J}$.

(d) Heat at constant volume. No work would be done by the gas or on the gas during this process.

EVALUATE: When the volume increases, $W > 0$. When the volume decreases, $W < 0$.

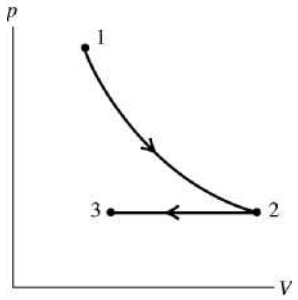

Figure 19.54

19.55. **IDENTIFY:** $\Delta V = V_0\beta\Delta T$. $W = p\Delta V$ since the force applied to the piston is constant. $Q = mc_p\Delta T$. $\Delta U = Q - W$.

SET UP: $m = \rho V$

EXECUTE: **(a)** The change in volume is

$\Delta V = V_0\beta\Delta T = (1.20\times10^{-2} \text{ m}^3)(1.20\times10^{-3} \text{ K}^{-1})(30.0 \text{ K}) = 4.32\times10^{-4} \text{ m}^3$.

(b) $W = p\Delta V = (F/A)\Delta V = ((3.00\times10^4 \text{ N})/(0.0200 \text{ m}^2))(4.32\times10^{-4} \text{ m}^3) = 648 \text{ J}$.

(c) $Q = mc_p\Delta T = V_0\rho c_p\Delta T = (1.20\times10^{-2} \text{ m}^3)(791 \text{ kg/m}^3)(2.51\times10^3 \text{ J/kg}\cdot\text{K})(30.0 \text{ K})$.

$Q = 7.15\times10^5$ J.

(d) $\Delta U = Q - W = 7.15\times10^5$ J to three figures.

(e) Under these conditions W is much less than Q and there is no substantial difference between c_V and c_p.

EVALUATE: $\Delta U = Q - W$ is valid for any material. For liquids the expansion work is much less than Q.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

19.56. **IDENTIFY:** $\Delta V = \beta V_0 \Delta T$. $W = p\Delta V$ since the applied pressure (air pressure) is constant. $Q = mc_p\Delta T$. $\Delta U = Q - W$.

SET UP: For copper, $\beta = 5.1\times10^{-5}\ (\text{C}°)^{-1}$, $c_p = 390\ \text{J/kg}\cdot\text{K}$ and $\rho = 8.90\times10^3\ \text{kg/m}^3$.

EXECUTE: **(a)** $\Delta V = \beta\Delta T V_0 = (5.1\times10^{-5}(\text{C}°)^{-1})(70.0\ \text{C}°)(2.00\times10^{-2}\ \text{m})^3 = 2.86\times10^{-8}\ \text{m}^3$.

(b) $W = p\Delta V = 2.88\times10^{-3}$ J.

(c) $Q = mc_p\Delta T = \rho V_0 c_p \Delta T = (8.9\times10^3\ \text{kg/m}^3)(8.00\times10^{-6}\ \text{m}^3)(390\ \text{J/kg}\cdot\text{K})(70.0\ \text{C}°) = 1944$ J.

(d) To three figures, $\Delta U = Q = 1940$ J.

(e) Under these conditions, the difference is not substantial, since W is much less than Q.

EVALUATE: $\Delta U = Q - W$ applies to any material. For solids the expansion work is much less than Q.

19.57. **IDENTIFY** and **SET UP:** The heat produced from the reaction is $Q_{\text{reaction}} = mL_{\text{reaction}}$, where L_{reaction} is the heat of reaction of the chemicals.

$Q_{\text{reaction}} = W + \Delta U_{\text{spray}}$

EXECUTE: For a mass m of spray, $W = \frac{1}{2}mv^2 = \frac{1}{2}m(19\ \text{m/s})^2 = (180.5\ \text{J/kg})m$ and

$\Delta U_{\text{spray}} = Q_{\text{spray}} = mc\Delta T = m(4190\ \text{J/kg}\cdot\text{K})(100°\text{C} - 20°\text{C}) = (335{,}200\ \text{J/kg})m.$

Then $Q_{\text{reaction}} = (180\ \text{J/kg} + 335{,}200\ \text{J/kg})m = (335{,}380\ \text{J/kg})m$ and $Q_{\text{reaction}} = mL_{\text{reaction}}$ implies $mL_{\text{reaction}} = (335{,}380\ \text{J/kg})m.$

The mass m divides out and $L_{\text{reaction}} = 3.4\times10^5$ J/kg.

EVALUATE: The amount of energy converted to work is negligible for the two significant figures to which the answer should be expressed. Almost all of the energy produced in the reaction goes into heating the compound.

19.58. **IDENTIFY:** The process is adiabatic. Apply $p_1V_1^\gamma = p_2V_2^\gamma$ and $pV = nRT$. $Q = 0$ so

$$\Delta U = -W = -\frac{1}{\gamma - 1}(p_1V_1 - p_2V_2).$$

SET UP: For helium, $\gamma = 1.67$. $p_1 = 1.00\ \text{atm} = 1.013\times10^5$ Pa. $V_1 = 2.00\times10^3\ \text{m}^3$.

$p_2 = 0.900\ \text{atm} = 9.117\times10^4$ Pa. $T_1 = 288.15$ K.

EXECUTE: **(a)** $V_2^\gamma = V_1^\gamma\left(\frac{p_1}{p_2}\right)$. $V_2 = V_1\left(\frac{p_1}{p_2}\right)^{1/\gamma} = (2.00\times10^3\ \text{m}^3)\left(\frac{1.00\ \text{atm}}{0.900\ \text{atm}}\right)^{1/1.67} = 2.13\times10^3\ \text{m}^3$.

(b) $pV = nRT$ gives $\frac{T_1}{p_1V_1} = \frac{T_2}{p_2V_2}$.

$$T_2 = T_1\left(\frac{p_2}{p_1}\right)\left(\frac{V_2}{V_1}\right) = (288.15\ \text{K})\left(\frac{0.900\ \text{atm}}{1.00\ \text{atm}}\right)\left(\frac{2.13\times10^3\ \text{m}^3}{2.00\times10^3\ \text{m}^3}\right) = 276.2\ \text{K} = 3.0°\text{C}.$$

(c) $\Delta U = -\frac{1}{0.67}([1.013\times10^5\ \text{Pa})(2.00\times10^3\ \text{m}^3)] - [9.117\times10^4\ \text{Pa})(2.13\times10^3\ \text{m}^3)] = -1.25\times10^7$ J.

EVALUATE: The internal energy decreases when the temperature decreases.

19.59. **IDENTIFY:** For an adiabatic process of an ideal gas, $T_1V_1^{\gamma-1} = T_2V_2^{\gamma-1}$. $pV = nRT$.

SET UP: For air, $\gamma = 1.40 = \frac{7}{5}$.

EXECUTE: **(a)** As the air moves to lower altitude its density increases; under an adiabatic compression, the temperature rises. If the wind is fast-moving, Q is not as likely to be significant, and modeling the process as adiabatic (no heat loss to the surroundings) is more accurate.

(b) $V = \frac{nRT}{p}$, so $T_1V_1^{\gamma-1} = T_2V_2^{\gamma-1}$ gives $T_1^\gamma p_1^{1-\gamma} = T_2^\gamma p_2^{1-\gamma}$. The temperature at the higher pressure is

$T_2 = T_1(p_1/p_2)^{(\gamma-1)/\gamma} = (258.15\ \text{K})([8.12\times10^4\ \text{Pa}]/[5.60\times10^4\ \text{Pa}])^{2/7} = 287.1\ \text{K} = 13.9°\text{C}$ so the temperature would rise by 11.9 C°.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: In an adiabatic compression, $Q = 0$ but the temperature rises because of the work done on the gas.

19.60. **IDENTIFY:** For constant pressure, $W = p\Delta V$. For an adiabatic process of an ideal gas, $W = \frac{C_V}{R}(p_1V_1 - p_2V_2)$ and $p_1V_1^\gamma = p_2V_2^\gamma$.

SET UP: $\gamma = \frac{C_p}{C_V} = \frac{C_p + C_V}{C_V} = 1 + \frac{R}{C_V}$

EXECUTE: **(a)** The pV-diagram is sketched in Figure 19.60.

(b) The work done is $W = p_0(2V_0 - V_0) + \frac{C_V}{R}(p_0(2V_0) - p_3(4V_0))$. $p_3 = p_0(2V_0/4V_0)^\gamma$ and so $W = p_0V_0\left[1 + \frac{C_V}{R}(2 - 2^{2-\gamma})\right]$. Note that p_0 is the absolute pressure.

(c) The most direct way to find the temperature is to find the ratio of the final pressure and volume to the original and treat the air as an ideal gas. $p_3 = p_2\left(\frac{V_2}{V_3}\right)^\gamma = p_1\left(\frac{V_2}{V_3}\right)^\gamma$, since $p_1 = p_2$. Then

$$T_3 = T_0\frac{p_3V_3}{p_1V_1} = T_0\left(\frac{V_2}{V_3}\right)^\gamma\left(\frac{V_3}{V_1}\right) = T_0\left(\frac{1}{2}\right)^\gamma 4 = T_0(2)^{2-\gamma}.$$

(d) Since $n = \frac{p_0V_0}{RT_0}$, $Q = \frac{p_0V_0}{RT_0}(C_V + R)(2T_0 - T_0) = p_0V_0\left(\frac{C_V}{R} + 1\right)$. This amount of heat flows into the gas, since $Q > 0$.

EVALUATE: In the isobaric expansion the temperature doubles and in the adiabatic expansion the temperature decreases. If the gas is diatomic, with $\gamma = \frac{7}{5}$, $2 - \gamma = \frac{3}{5}$ and $T_3 = 1.52T_0$, $W = 2.21p_0V_0$ and $Q = 3.50p_0V_0$. $\Delta U = 1.29p_0V_0$. $\Delta U > 0$ and this is consistent with an increase in temperature.

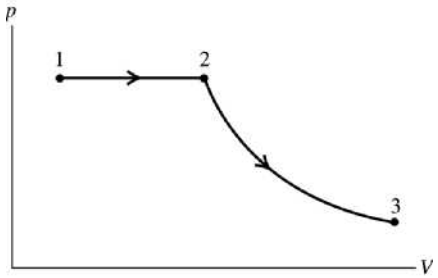

Figure 19.60

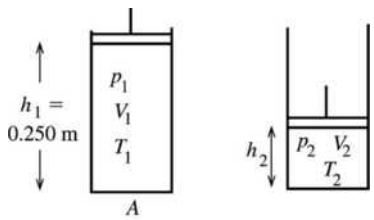
19.61. **IDENTIFY:** Assume that the gas is ideal and that the process is adiabatic. Apply Eqs. (19.22) and (19.24) to relate pressure and volume and temperature and volume. The distance the piston moves is related to the volume of the gas. Use Eq. (19.25) to calculate W.

(a) SET UP: $\gamma = C_p/C_V = (C_V + R)/C_V = 1 + R/C_V = 1.40$. The two positions of the piston are shown in Figure 19.61.



$p_1 = 1.01\times10^5$ Pa

$p_2 = 4.20\times10^5$ Pa + $p_{\text{air}} = 5.21\times10^5$ Pa

$V_1 = h_1A$

$V_2 = h_2A$

Figure 19.61

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: adiabatic process: $p_1V_1^{\gamma} = p_2V_2^{\gamma}$

$p_1h_1^{\gamma}A^{\gamma} = p_2h_2^{\gamma}A^{\gamma}$

$$h_2 = h_1\left(\frac{p_1}{p_2}\right)^{1/\gamma} = (0.250\text{ m})\left(\frac{1.01\times10^5\text{ Pa}}{5.21\times10^5\text{ Pa}}\right)^{1/1.40} = 0.0774\text{ m}$$

The piston has moved a distance $h_1 - h_2 = 0.250\text{ m} - 0.0774\text{ m} = 0.173\text{ m}$.

(b) $T_1V_1^{\gamma-1} = T_2V_2^{\gamma-1}$

$T_1h_1^{\gamma-1}A^{\gamma-1} = T_2h_2^{\gamma-1}A^{\gamma-1}$

$$T_2 = T_1\left(\frac{h_1}{h_2}\right)^{\gamma-1} = 300.1\text{ K}\left(\frac{0.250\text{ m}}{0.0774\text{ m}}\right)^{0.40} = 479.7\text{ K} = 207°\text{C}$$

(c) $W = nC_V(T_1 - T_2)$ (Eq. 19.25)

$W = (20.0\text{ mol})(20.8\text{ J/mol}\cdot\text{K})(300.1\text{ K} - 479.7\text{ K}) = -7.47\times10^4\text{ J}$

EVALUATE: In an adiabatic compression of an ideal gas the temperature increases. In any compression the work W is negative.

19.62. **IDENTIFY:** $m = \rho V$. The density of air is given by $\rho = \dfrac{pM}{RT}$. For an adiabatic process, $T_1V_1^{\gamma-1} = T_2V_2^{\gamma-1}$.

$pV = nRT$

SET UP: Using $V = \dfrac{nRT}{p}$ in $T_1V_1^{\gamma-1} = T_2V_2^{\gamma-1}$ gives $T_1p_1^{1-\gamma} = T_2p_2^{1-\gamma}$.

EXECUTE: **(a)** The pV-diagram is sketched in Figure 19.62.
(b) The final temperature is the same as the initial temperature, and the density is proportional to the absolute pressure. The mass needed to fill the cylinder is then

$$m = \rho_0 V\frac{p}{p_{\text{air}}} = (1.23\text{ kg/m}^3)(575\times10^{-6}\text{ m}^3)\frac{1.45\times10^5\text{ Pa}}{1.01\times10^5\text{ Pa}} = 1.02\times10^{-3}\text{ kg}.$$

Without the turbocharger or intercooler the mass of air at $T = 15.0°\text{C}$ and $p = 1.01\times10^5\text{ Pa}$ in a cylinder is $m = \rho_0 V = 7.07\times10^{-4}\text{ kg}$. The increase in power is proportional to the increase in mass of air in the cylinder; the percentage increase is $\dfrac{1.02\times10^{-3}\text{ kg}}{7.07\times10^{-4}\text{ kg}} - 1 = 0.44 = 44\%$.

(c) The temperature after the adiabatic process is $T_2 = T_1\left(\dfrac{p_2}{p_1}\right)^{(\gamma-1)/\gamma}$. The density becomes

$\rho = \rho_0\left(\dfrac{T_1}{T_2}\right)\left(\dfrac{p_2}{p_1}\right) = \rho_0\left(\dfrac{p_2}{p_1}\right)^{(1-\gamma)/\gamma}\left(\dfrac{p_2}{p_1}\right) = \rho_0\left(\dfrac{p_2}{p_1}\right)^{1/\gamma}$. The mass of air in the cylinder is

$$m = (1.23\text{ kg/m}^3)(575\times10^{-6}\text{ m}^3)\left(\frac{1.45\times10^5\text{ Pa}}{1.01\times10^5\text{ Pa}}\right)^{1/1.40} = 9.16\times10^{-4}\text{ kg},$$

The percentage increase in power is $\dfrac{9.16\times10^{-4}\text{ kg}}{7.07\times10^{-4}\text{ kg}} - 1 = 0.30 = 30\%$.

EVALUATE: The turbocharger and intercooler each have an appreciable effect on the engine power.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

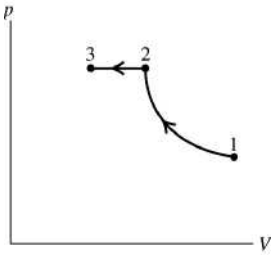


Figure 19.62

19.63. **IDENTIFY:** In each case calculate either ΔU or Q for the specific type of process and then apply the first law.

(a) SET UP: isothermal $(\Delta T = 0)$ $\Delta U = Q - W$; $W = +300$ J

For any process of an ideal gas, $\Delta U = nC_V \Delta T$.

EXECUTE: Therefore, for an ideal gas, if $\Delta T = 0$ then $\Delta U = 0$ and $Q = W = +300$ J.

(b) SET UP: adiabatic $(Q = 0)$

$\Delta U = Q - W$; $W = +300$ J

EXECUTE: $Q = 0$ says $\Delta U = -W = -300$ J

(c) SET UP: isobaric $\Delta p = 0$

Use W to calculate ΔT and then calculate Q.

EXECUTE: $W = p\Delta V = nR\Delta T$; $\Delta T = W/nR$

$Q = nC_p \Delta T$ and for a monatomic ideal gas $C_p = \frac{5}{2}R$.

Thus $Q = n\frac{5}{2}R\Delta T = (5Rn/2)(W/nR) = 5W/2 = +750$ J.

$\Delta U = nC_V \Delta T$ for any ideal gas process and $C_V = C_p - R = \frac{3}{2}R$.

Thus $\Delta U = 3W/2 = +450$ J

EVALUATE: 300 J of energy leaves the gas when it performs expansion work. In the isothermal process this energy is replaced by heat flow into the gas and the internal energy remains the same. In the adiabatic process the energy used in doing the work decreases the internal energy. In the isobaric process 750 J of heat energy enters the gas, 300 J leaves as the work done and 450 J remains in the gas as increased internal energy.

19.64. **IDENTIFY:** $pV = nRT$. For the isobaric process, $W = p\Delta V = nR\Delta T$. For the isothermal process, $W = nRT \ln\left(\frac{V_f}{V_i}\right)$.

SET UP: $R = 8.315$ J/mol · K

EXECUTE: **(a)** The pV diagram for these processes is sketched in Figure 19.64.

(b) Find T_2. For process $1 \to 2$, n, R and p are constant so $\frac{T}{V} = \frac{p}{nR} = \text{constant}$. $\frac{T_1}{V_1} = \frac{T_2}{V_2}$ and

$T_2 = T_1\left(\frac{V_2}{V_1}\right) = (355 \text{ K})(2) = 710 \text{ K}.$

(c) The maximum pressure is for state 3. For process $2 \to 3$, n, R and T are constant. $p_2V_2 = p_3V_3$ and

$p_3 = p_2\left(\frac{V_2}{V_3}\right) = (2.40 \times 10^5 \text{ Pa})(2) = 4.80 \times 10^5 \text{ Pa}.$

(d) process $1 \to 2$: $W = p\Delta V = nR\Delta T = (0.250 \text{ mol})(8.315 \text{ J/mol} \cdot \text{K})(710 \text{ K} - 355 \text{ K}) = 738 \text{ K}.$

process $2 \to 3$: $W = nRT \ln\left(\frac{V_3}{V_2}\right) = (0.250 \text{ mol})(8.315 \text{ J/mol} \cdot \text{K})(710 \text{ K}) \ln\left(\frac{1}{2}\right) = -1023 \text{ J}.$

process $3 \to 1$: $\Delta V = 0$ and $W = 0$.

The total work done is $738 \text{ J} + (-1023 \text{ J}) = -285$ J. This is the work done by the gas. The work done on the gas is 285 J.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: The final pressure and volume are the same as the initial pressure and volume, so the final state is the same as the initial state. For the cycle, $\Delta U = 0$ and $Q = W = -285$ J. During the cycle, 285 J of heat energy must leave the gas.

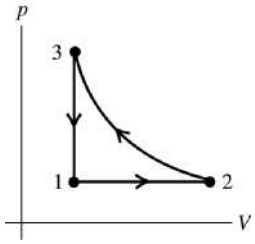

Figure 19.64

19.65. **IDENTIFY** and **SET UP:** Use the ideal gas law, the first law and expressions for Q and W for specific types of processes.

EXECUTE: **(a)** initial expansion (state 1 → state 2)

$p_1 = 2.40\times10^5$ Pa, $T_1 = 355$ K, $p_2 = 2.40\times10^5$ Pa, $V_2 = 2V_1$

$pV = nRT$; $T/V = p/nR =$ constant, so $T_1/V_1 = T_2/V_2$ and $T_2 = T_1(V_2/V_1) = 355\text{ K}(2V_1/V_1) = 710$ K

$\Delta p = 0$ so $W = p\Delta V = nR\Delta T = (0.250\text{ mol})(8.3145\text{ J/mol}\cdot\text{K})(710\text{ K} - 355\text{ K}) = +738$ J

$Q = nC_p\Delta T = (0.250\text{ mol})(29.17\text{ J/mol}\cdot\text{K})(710\text{ K} - 355\text{ K}) = +2590$ J

$\Delta U = Q - W = 2590\text{ J} - 738\text{ J} = 1850$ J

(b) At the beginning of the final cooling process (cooling at constant volume), $T = 710$ K. The gas returns to its original volume and pressure, so also to its original temperature of 355 K.

$\Delta V = 0$ so $W = 0$

$Q = nC_V\Delta T = (0.250\text{ mol})(20.85\text{ J/mol}\cdot\text{K})(355\text{ K} - 710\text{ K}) = -1850$ J

$\Delta U = Q - W = -1850$ J.

(c) For any ideal gas process $\Delta U = nC_V\Delta T$. For an isothermal process $\Delta T = 0$, so $\Delta U = 0$.

EVALUATE: The three processes return the gas to its initial state, so $\Delta U_{\text{total}} = 0$; our results agree with this.

19.66. **IDENTIFY:** $pV = nRT$. For an adiabatic process of an ideal gas, $T_1V_1^{\gamma-1} = T_2V_2^{\gamma-1}$.

SET UP: For N_2, $\gamma = 1.40$.

EXECUTE: **(a)** The pV-diagram is sketched in Figure 19.66.

(b) At constant pressure, halving the volume halves the Kelvin temperature, and the temperature at the beginning of the adiabatic expansion is 150 K. The volume doubles during the adiabatic expansion, and from Eq. (19.22), the temperature at the end of the expansion is $(150\text{ K})(1/2)^{0.40} = 114$ K.

(c) The minimum pressure occurs at the end of the adiabatic expansion (state 3). During the final heating the volume is held constant, so the minimum pressure is proportional to the Kelvin temperature,

$p_{\text{min}} = (1.80\times10^5\text{ Pa})(114\text{K}/300\text{ K}) = 6.82\times10^4$ Pa.

EVALUATE: In the adiabatic expansion the temperature decreases.

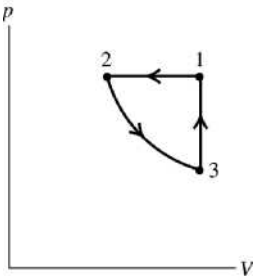

Figure 19.66

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

19.67. **IDENTIFY:** Use the appropriate expressions for Q, W and ΔU for each type of process. $\Delta U = Q - W$ can also be used.

SET UP: For N_2, $C_V = 20.76$ J/mol·K and $C_p = 29.07$ J/mol·K.

EXECUTE: **(a)** $W = p\Delta V = nR\Delta T = (0.150 \text{ mol})(8.3145 \text{ J/mol·K})(-150 \text{ K}) = -187$ J,

$Q = nC_p\Delta T = (0.150 \text{ mol})(29.07 \text{ mol·K})(-150 \text{ K}) = -654$ J, $\Delta U = Q - W = -467$ J.

(b) From Eq. (19.26), using the expression for the temperature found in Problem 19.66,

$W = \frac{1}{0.40}(0.150 \text{ mol})(8.3145 \text{ J/mol·K})(150 \text{ K})(1-(1/2^{0.40})) = 113$ J. $Q = 0$ for an adiabatic process, and

$\Delta U = Q - W = -W = -113$ J.

(c) $\Delta V = 0$, so $W = 0$. Using the temperature change as found in Problem 19.66 part (b),

$Q = nC_V\Delta T = (0.150 \text{ mol})(20.76 \text{ J/mol·K})(300 \text{ K} - 113.7 \text{ K}) = 580$ J and $\Delta U = Q - W = Q = 580$ J.

EVALUATE: For each process we could also use $\Delta U = nC_V\Delta T$ to calculate ΔU.

19.68. **IDENTIFY:** Use the appropriate expression for W for each type of process.

SET UP: For a monatomic ideal gas, $\gamma = 5/3$ and $C_V = 3R/2$.

EXECUTE: **(a)** $W = nRT\ \ln(V_2/V_1) = nRT\ln(3) = 3.29\times10^3$ J.

(b) $Q = 0$ so $W = -\Delta U = -nC_V\Delta T$. $T_1V_1^{\gamma-1} = T_2V_2^{\gamma-1}$ gives $T_2 = T_1(1/3)^{2/3}$. Then

$W = nC_VT_1(1-(1/3^{2/3})) = 2.33\times10^3$ J.

(c) $V_2 = 3V_1$, so $W = p\Delta V = 2pV_1 = 2nRT_1 = 6.00\times10^3$ J.

(d) Each process is shown in Figure 19.68. The most work done is in the isobaric process, as the pressure is maintained at its original value. The least work is done in the adiabatic process.

(e) The isobaric process involves the most work and the largest temperature increase, and so requires the most heat. Adiabatic processes involve no heat transfer, and so the magnitude is zero.

(f) The isobaric process doubles the Kelvin temperature, and so has the largest change in internal energy. The isothermal process necessarily involves no change in internal energy.

EVALUATE: The work done is the area under the path for the process in the pV-diagram. Figure 19.68 shows that the work done is greatest in the isobaric process and least in the adiabatic process.

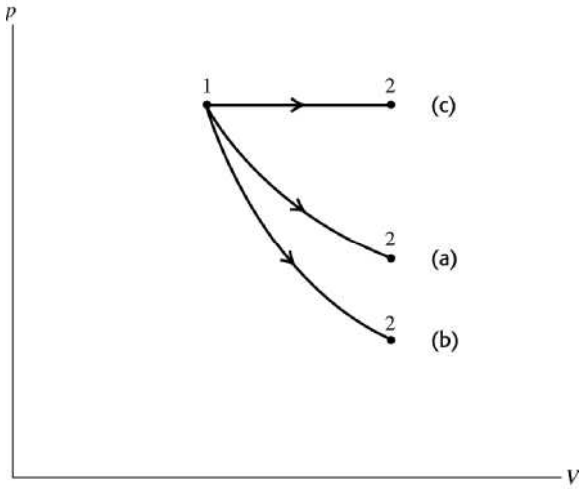

Figure 19.68

19.69. **IDENTIFY:** At equilibrium the net upward force of the gas on the piston equals the weight of the piston. When the piston moves upward the gas expands, the pressure of the gas drops and there is a net downward force on the piston. For simple harmonic motion the net force has the form $F_y = -ky$, for a displacement y from equilibrium, and $f = \frac{1}{2\pi}\sqrt{\frac{k}{m}}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

SET UP: $pV = nRT$. T is constant.

(a) The difference between the pressure, inside and outside the cylinder, multiplied by the area of the piston, must be the weight of the piston. The pressure in the trapped gas is $p_0 + \frac{mg}{A} = p_0 + \frac{mg}{\pi r^2}$.

(b) When the piston is a distance $h + y$ above the cylinder, the pressure in the trapped gas is $\left(p_0 + \frac{mg}{\pi r^2}\right)\left(\frac{h}{h+y}\right)$ and for values of y small compared to h, $\frac{h}{h+y} = \left(1 + \frac{y}{h}\right)^{-1} \sim 1 - \frac{y}{h}$. The net force, taking the positive direction to be upward, is then

$$F_y = \left[\left(p_0 + \frac{mg}{\pi r^2}\right)\left(1 - \frac{y}{h}\right) - p_0\right](\pi r^2) - mg = -\left(\frac{y}{h}\right)(p_0 \pi r^2 + mg).$$

This form shows that for positive h, the net force is down; the trapped gas is at a lower pressure than the equilibrium pressure, and so the net force tends to restore the piston to equilibrium.

(c) The angular frequency of small oscillations would be given by $\omega^2 = \frac{(p_0 \pi r^2 + mg)/h}{m} = \frac{g}{h}\left(1 + \frac{p_0 \pi r^2}{mg}\right)$.

$$f = \frac{\omega}{2\pi} = \frac{1}{2\pi}\sqrt{\frac{g}{h}\left(1 + \frac{p_0 \pi r^2}{mg}\right)^{1/2}}.$$

If the displacements are not small, the motion is not simple harmonic. This can be seen be considering what happens if $y \sim -h$; the gas is compressed to a very small volume, and the force due to the pressure of the gas would become unboundedly large for a finite displacement, which is not characteristic of simple harmonic motion. If $y >> h$ (but not so large that the piston leaves the cylinder), the force due to the pressure of the gas becomes small, and the restoring force due to the atmosphere and the weight would tend toward a constant, and this is not characteristic of simple harmonic motion.

EVALUATE: The assumption of small oscillations was made when $\frac{h}{h+y}$ was replaced by $1 - y/h$; this is accurate only when y/h is small.

20

THE SECOND LAW OF THERMODYNAMICS

20.1. **IDENTIFY:** For a heat engine, $W = |Q_H| - |Q_C|$. $e = \dfrac{W}{Q_H}$. $Q_H > 0$, $Q_C < 0$.

SET UP: $W = 2200$ J. $|Q_C| = 4300$ J.

EXECUTE: **(a)** $Q_H = W + |Q_C| = 6500$ J.

(b) $e = \dfrac{2200 \text{ J}}{6500 \text{ J}} = 0.34 = 34\%$.

EVALUATE: Since the engine operates on a cycle, the net Q equal the net W. But to calculate the efficiency we use the heat energy input, Q_H.

20.2. **IDENTIFY:** For a heat engine, $W = |Q_H| - |Q_C|$. $e = \dfrac{W}{Q_H}$. $Q_H > 0$, $Q_C < 0$.

SET UP: $|Q_H| = 9000$ J. $|Q_C| = 6400$ J.

EXECUTE: **(a)** $W = 9000 \text{ J} - 6400 \text{ J} = 2600$ J.

(b) $e = \dfrac{W}{Q_H} = \dfrac{2600 \text{ J}}{9000 \text{ J}} = 0.29 = 29\%$.

EVALUATE: Since the engine operates on a cycle, the net Q equal the net W. But to calculate the efficiency we use the heat energy input, Q_H.

20.3. **IDENTIFY** and **SET UP:** The problem deals with a heat engine. $W = +3700$ W and $Q_H = +16{,}100$ J. Use Eq. (20.4) to calculate the efficiency e and Eq. (20.2) to calculate $|Q_C|$. Power $= W/t$.

EXECUTE: **(a)** $e = \dfrac{\text{work output}}{\text{heat energy input}} = \dfrac{W}{Q_H} = \dfrac{3700 \text{ J}}{16{,}100 \text{ J}} = 0.23 = 23\%$.

(b) $W = Q = |Q_H| - |Q_C|$

Heat discarded is $|Q_C| = |Q_H| - W = 16{,}100 \text{ J} - 3700 \text{ J} = 12{,}400$ J.

(c) Q_H is supplied by burning fuel; $Q_H = mL_c$ where L_c is the heat of combustion.

$m = \dfrac{Q_H}{L_c} = \dfrac{16{,}100 \text{ J}}{4.60 \times 10^4 \text{ J/g}} = 0.350$ g.

(d) $W = 3700$ J per cycle

In $t = 1.00$ s the engine goes through 60.0 cycles.

$P = W/t = 60.0(3700 \text{ J})/1.00 \text{ s} = 222$ kW

$P = (2.22 \times 10^5 \text{ W})(1 \text{ hp}/746 \text{ W}) = 298$ hp

EVALUATE: $Q_C = -12{,}400$ J. In one cycle $Q_{tot} = Q_C + Q_H = 3700$ J. This equals W_{tot} for one cycle.

20.4. **IDENTIFY:** $W = |Q_H| - |Q_C|$. $e = \dfrac{W}{Q_H}$. $Q_H > 0$, $Q_C < 0$.

SET UP: For 1.00 s, $W = 180 \times 10^3$ J.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: **(a)** $Q_{\rm H} = \dfrac{W}{e} = \dfrac{180\times10^3\ {\rm J}}{0.280} = 6.43\times10^5\ {\rm J}$.

(b) $|Q_{\rm C}| = |Q_{\rm H}| - W = 6.43\times10^5\ {\rm J} - 1.80\times10^5\ {\rm J} = 4.63\times10^5\ {\rm J}$.

EVALUATE: Of the 6.43×10^5 J of heat energy supplied to the engine each second, 1.80×10^5 J is converted to mechanical work and the remaining 4.63×10^5 J is discarded into the low temperature reservoir.

20.5. **IDENTIFY:** This cycle involves adiabatic (*ab*), isobaric (*bc*), and isochoric (*ca*) processes.

SET UP: *ca* is at constant volume, *ab* has $Q = 0$, and *bc* is at constant pressure. For a constant pressure process $W = p\Delta V$ and $Q = nC_p\ \Delta T$. $pV = nRT$ gives $n\Delta T = \dfrac{p\Delta V}{R}$, so $Q = \left(\dfrac{C_p}{R}\right)p\Delta V$. If $\gamma = 1.40$ the gas is diatomic and $C_p = \frac{7}{2}R$. For a constant volume process $W = 0$ and $Q = nC_V\ \Delta T$. $pV = nRT$ gives $n\Delta T = \dfrac{V\Delta p}{R}$, so $Q = \left(\dfrac{C_V}{R}\right)V\Delta p$. For a diatomic ideal gas $C_V = \frac{5}{2}R$. $1\ {\rm atm} = 1.013\times10^5\ {\rm Pa}$.

EXECUTE: **(a)** $V_b = 9.0\times10^{-3}\ {\rm m}^3$, $p_b = 1.5\ {\rm atm}$ and $V_a = 2.0\times10^{-3}\ {\rm m}^3$. For an adiabatic process $p_aV_a^\gamma = p_bV_b^\gamma$. $p_a = p_b\left(\dfrac{V_b}{V_a}\right)^\gamma = (1.5\ {\rm atm})\left(\dfrac{9.0\times10^{-3}\ {\rm m}^3}{2.0\times10^{-3}\ {\rm m}^3}\right)^{1.4} = 12.3\ {\rm atm}$.

(b) Heat enters the gas in process *ca*, since *T* increases.

$Q = \left(\dfrac{C_V}{R}\right)V\Delta p = \left(\dfrac{5}{2}\right)(2.0\times10^{-3}\ {\rm m}^3)(12.3\ {\rm atm} - 1.5\ {\rm atm})(1.013\times10^5\ {\rm Pa/atm}) = 5470\ {\rm J}$. $Q_{\rm H} = 5470\ {\rm J}$.

(c) Heat leaves the gas in process *bc*, since *T* increases.

$Q = \left(\dfrac{C_p}{R}\right)p\Delta V = \left(\dfrac{7}{2}\right)(1.5\ {\rm atm})(1.013\times10^5\ {\rm Pa/atm})(-7.0\times10^{-3}\ {\rm m}^3) = -3723\ {\rm J}$. $Q_{\rm C} = -3723\ {\rm J}$.

(d) $W = Q_{\rm H} + Q_{\rm C} = +5470\ {\rm J} + (-3723\ {\rm J}) = 1747\ {\rm J}$.

(e) $e = \dfrac{W}{Q_{\rm H}} = \dfrac{1747\ {\rm J}}{5470\ {\rm J}} = 0.319 = 31.9\%$.

EVALUATE: We did not use the number of moles of the gas.

20.6. **IDENTIFY:** Apply $e = 1 - \dfrac{1}{r^{\gamma-1}}$. $e = 1 - \dfrac{|Q_{\rm C}|}{|Q_{\rm H}|}$.

SET UP: In part (b), $Q_{\rm H} = 10{,}000\ {\rm J}$. The heat discarded is $|Q_{\rm C}|$.

EXECUTE: **(a)** $e = 1 - \dfrac{1}{9.50^{0.40}} = 0.594 = 59.4\%$.

(b) $|Q_{\rm C}| = |Q_{\rm H}|(1-e) = (10{,}000\ {\rm J})(1-0.594) = 4060\ {\rm J}$.

EVALUATE: The work output of the engine is $W = |Q_{\rm H}| - |Q_{\rm C}| = 10{,}000\ {\rm J} - 4060\ {\rm J} = 5940\ {\rm J}$.

20.7. **IDENTIFY:** $e = 1 - r^{1-\gamma}$

SET UP: r is the compression ratio.

EXECUTE: **(a)** $e = 1 - (8.8)^{-0.40} = 0.581$, which rounds to 58%.

(b) $e = 1 - (9.6)^{-0.40} = 0.595$ an increase of 1.4%.

EVALUATE: An increase in r gives an increase in e.

20.8. **IDENTIFY:** Convert coefficient of performance (K) to energy efficiency rating (EER).

SET UP: $K = \dfrac{H_{\rm watts}}{P_{\rm watts}}$ and ${\rm EER} = \dfrac{H_{\rm Btu/h}}{P_{\rm watts}}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: 1 Btu/h = 0.293 W so $H_{\text{watts}} = H_{\text{Btu/h}}(0.293)$. $K = 0.293\dfrac{H_{\text{Btu/h}}}{P_{\text{watts}}} = (0.293)\text{EER}$ and $\text{EER} = 3.41K$. For $K = 3.0$, EER = (3.41)(3.0) = 10.2.

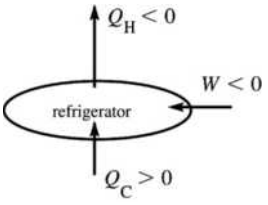
EVALUATE: The EER is larger than K, but this does not mean that the air conditioner is suddenly better at cooling!

20.9. **IDENTIFY** and **SET UP:** For the refrigerator $K = 2.10$ and $Q_{\text{C}} = +3.4\times10^4$ J. Use Eq. (20.9) to calculate $|W|$ and then Eq. (20.2) to calculate Q_{H}.

(a) EXECUTE: Performance coefficient $K = Q_{\text{C}}/|W|$ (Eq. 20.9)

$|W| = Q_{\text{C}}/K = 3.40\times10^4 \text{ J}/2.10 = 1.62\times10^4$ J

(b) SET UP: The operation of the device is illustrated in Figure 20.9.



EXECUTE:

$W = Q_{\text{C}} + Q_{\text{H}}$

$Q_{\text{H}} = W - Q_{\text{C}}$

$Q_{\text{H}} = -1.62\times10^4 \text{ J} - 3.40\times10^4 \text{ J} = -5.02\times10^4$ J

(negative because heat goes out of the system)

Figure 20.9

EVALUATE: $|Q_{\text{H}}| = |W| + |Q_{\text{C}}|$. The heat $|Q_{\text{H}}|$ delivered to the high temperature reservoir is greater than the heat taken in from the low temperature reservoir.

20.10. **IDENTIFY:** $K = \dfrac{|Q_{\text{C}}|}{|W|}$ and $|Q_{\text{H}}| = |Q_{\text{C}}| + |W|$.

SET UP: The heat removed from the room is $|Q_{\text{C}}|$ and the heat delivered to the hot outside is $|Q_{\text{H}}|$.

$|W| = (850 \text{ J/s})(60.0 \text{ s}) = 5.10\times10^4$ J.

EXECUTE: **(a)** $|Q_{\text{C}}| = K|W| = (2.9)(5.10\times10^4 \text{J}) = 1.48\times10^5$ J

(b) $|Q_{\text{H}}| = |Q_{\text{C}}| + |W| = 1.48\times10^5 \text{ J} + 5.10\times10^4 \text{ J} = 1.99\times10^5$ J.

EVALUATE: **(c)** $|Q_{\text{H}}| = |Q_{\text{C}}| + |W|$, so $|Q_{\text{H}}| > |Q_{\text{C}}|$.

20.11. **IDENTIFY:** The heat $Q = mc\Delta T$ that comes out of the water to cool it to 5.0°C is Q_{C} for the refrigerator.

SET UP: For water 1.0 L has a mass of 1.0 kg and $c = 4.19\times10^3 \text{ J/kg}\cdot\text{C°}$. $P = \dfrac{|W|}{t}$. The coefficient of performance is $K = \dfrac{|Q_{\text{C}}|}{|W|}$.

EXECUTE: $Q = mc\Delta T = (12.0 \text{ kg})(4.19\times10^3 \text{ J/kg}\cdot\text{C°})(5.0°\text{C} - 31°\text{C}) = -1.31\times10^6$ J. $|Q_{\text{C}}| = 1.31\times10^6$ J.

$K = \dfrac{|Q_{\text{C}}|}{|W|} = \dfrac{|Q_{\text{C}}|}{Pt}$ so $t = \dfrac{|Q_{\text{C}}|}{PK} = \dfrac{1.31\times10^6 \text{ J}}{(95 \text{ W})(2.25)} = 6129 \text{ s} = 102 \text{ min} = 1.7 \text{ h}$.

EVALUATE: 1.7 h seems like a reasonable time to cool down the dozen bottles.

20.12. **IDENTIFY:** $|Q_{\text{H}}| = |Q_{\text{C}}| + |W|$. $K = \dfrac{|Q_{\text{C}}|}{W}$.

SET UP: For water, $c_{\text{w}} = 4190 \text{ J/kg}\cdot\text{K}$ and $L_{\text{f}} = 3.34\times10^5$ J/kg. For ice, $c_{\text{ice}} = 2010 \text{ J/kg}\cdot\text{K}$.

EXECUTE: **(a)** $Q = mc_{\text{ice}}\Delta T_{\text{ice}} - mL_{\text{f}} + mc_{\text{w}}\Delta T_{\text{w}}$.

$Q = (1.80 \text{ kg})([2010 \text{ J/kg}\cdot\text{K}][-5.0 \text{ C°}] - 3.34\times10^5 \text{ J/kg} + [4190 \text{ J/kg}\cdot\text{K}][-25.0 \text{ C°}]) = -8.08\times10^5$ J

$Q = -8.08\times10^5$ J. Q is negative for the water since heat is removed from it.

(b) $|Q_{\text{C}}| = 8.08\times10^5$ J. $W = \dfrac{|Q_{\text{C}}|}{K} = \dfrac{8.08\times10^5 \text{ J}}{2.40} = 3.37\times10^5$ J.

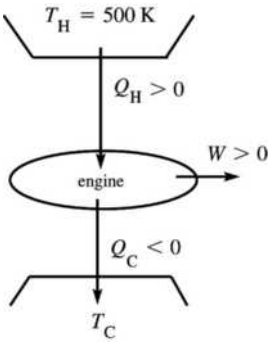
(c) $|Q_{\text{H}}| = 8.08\times10^5 \text{ J} + 3.37\times10^5 \text{ J} = 1.14\times10^6$ J.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: For this device, $Q_C > 0$ and $Q_H < 0$. More heat is rejected to the room than is removed from the water.

20.13. **IDENTIFY:** Use Eq. (20.2) to calculate $|W|$. Since it is a Carnot device we can use Eq. (20.13) to relate the heat flows out of the reservoirs. The reservoir temperatures can be used in Eq. (20.14) to calculate e.

(a) SET UP: The operation of the device is sketched in Figure 20.13.



EXECUTE:
$W = Q_C + Q_H$
$W = -335\text{ J} + 550\text{ J} = 215\text{ J}$

Figure 20.13

(b) For a Carnot cycle, $\dfrac{|Q_C|}{|Q_H|} = \dfrac{T_C}{T_H}$ (Eq. 20.13)

$$T_C = T_H \frac{|Q_C|}{|Q_H|} = 620\text{ K}\left(\frac{335\text{ J}}{550\text{ J}}\right) = 378\text{ K}$$

(c) $e(\text{Carnot}) = 1 - T_C/T_H = 1 - 378\text{ K}/620\text{ K} = 0.390 = 39.0\%$

EVALUATE: We could use the underlying definition of e (Eq. 20.4):
$e = W/Q_H = (215\text{ J})/(550\text{ J}) = 39\%,$ which checks.

20.14. **IDENTIFY:** $|W| = |Q_H| - |Q_C|$. $Q_C < 0$, $Q_H > 0$. $e = \dfrac{W}{Q_H}$. For a Carnot cycle, $\dfrac{Q_C}{Q_H} = -\dfrac{T_C}{T_H}$.

SET UP: $T_C = 300$ K, $T_H = 520$ K. $|Q_H| = 6.45\times10^3$ J.

EXECUTE: **(a)** $Q_C = -Q_H\left(\dfrac{T_C}{T_H}\right) = -(6.45\times10^3\text{ J})\left(\dfrac{300\text{ K}}{520\text{ K}}\right) = -3.72\times10^3\text{ J}.$

(b) $|W| = |Q_H| - |Q_C| = 6.45\times10^3\text{ J} - 3.72\times10^3\text{ J} = 2.73\times10^3\text{ J}$

(c) $e = \dfrac{W}{Q_H} = \dfrac{2.73\times10^3\text{ J}}{6.45\times10^3\text{ J}} = 0.423 = 42.3\%.$

EVALUATE: We can verify that $e = 1 - T_C/T_H$ also gives $e = 42.3\%$.

20.15. **IDENTIFY:** $e = \dfrac{W}{Q_H}$ for any engine. For the Carnot cycle, $\dfrac{Q_C}{Q_H} = -\dfrac{T_C}{T_H}$.

SET UP: $T_C = 20.0°\text{C} + 273.15\text{ K} = 293.15\text{ K}$

EXECUTE: **(a)** $Q_H = \dfrac{W}{e} = \dfrac{2.5\times10^4\text{ J}}{0.59} = 4.24\times10^4\text{ J}$

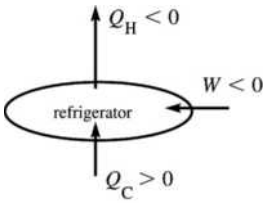
(b) $W = Q_H + Q_C$ so $Q_C = W - Q_H = 2.5\times10^4\text{ J} - 4.24\times10^4\text{ J} = -1.74\times10^4\text{ J}.$

$$T_H = -T_C\frac{Q_H}{Q_C} = -(293.15\text{ K})\left(\frac{4.24\times10^4\text{ J}}{-1.74\times10^4\text{ J}}\right) = 714\text{ K} = 441°\text{C}.$$

EVALUATE: For a heat engine, $W > 0$, $Q_H > 0$ and $Q_C < 0$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

20.16. **IDENTIFY** and **SET UP:** The device is a Carnot refrigerator.
We can use Eqs. (20.2) and (20.13).
(a) The operation of the device is sketched in Figure 20.16.



$T_H = 24.0°C = 297$ K
$T_C = 0.0°C = 273$ K

Figure 20.16

The amount of heat taken out of the water to make the liquid → solid phase change is $Q = -mL_f = -(85.0 \text{ kg})(334\times10^3 \text{ J/kg}) = -2.84\times10^7$ J. This amount of heat must go into the working substance of the refrigerator, so $Q_C = +2.84\times10^7$ J. For Carnot cycle $|Q_C|/|Q_H| = T_C/T_H$.

EXECUTE: $|Q_H| = |Q_C|(T_H/T_C) = 2.84\times10^7 \text{ J}(297 \text{ K}/273 \text{ K}) = 3.09\times10^7$ J

(b) $W = Q_C + Q_H = +2.84\times10^7 \text{ J} - 3.09\times10^7 \text{ J} = -2.5\times10^6$ J

EVALUATE: W is negative because this much energy must be supplied to the refrigerator rather than obtained from it. Note that in Eq. (20.13) we must use Kelvin temperatures.

20.17. **IDENTIFY:** $|Q_H| = |W| + |Q_C|$. $Q_H < 0$, $Q_C > 0$. $K = \dfrac{|Q_C|}{|W|}$. For a Carnot cycle, $\dfrac{Q_C}{Q_H} = -\dfrac{T_C}{T_H}$.

SET UP: $T_C = 270$ K, $T_H = 320$ K. $|Q_C| = 415$ J.

EXECUTE: **(a)** $Q_H = -\left(\dfrac{T_H}{T_C}\right)Q_C = -\left(\dfrac{320 \text{ K}}{270 \text{ K}}\right)(415 \text{ J}) = -492$ J.

(b) For one cycle, $|W| = |Q_H| - |Q_C| = 492 \text{ J} - 415 \text{ J} = 77$ J. $P = \dfrac{(165)(77 \text{ J})}{60 \text{ s}} = 212$ W.

(c) $K = \dfrac{|Q_C|}{|W|} = \dfrac{415 \text{ J}}{77 \text{ J}} = 5.4$.

EVALUATE: The amount of heat energy $|Q_H|$ delivered to the high-temperature reservoir is greater than the amount of heat energy $|Q_C|$ removed from the low-temperature reservoir.

20.18. **IDENTIFY:** The theoretical maximum performance coefficient is $K_{\text{Carnot}} = \dfrac{T_C}{T_H - T_C}$. $K = \dfrac{|Q_C|}{|W|}$. $|Q_C|$ is the heat removed from the water to convert it to ice. For the water, $|Q| = mc_w\Delta T + mL_f$.

SET UP: $T_C = -5.0°C = 268$ K. $T_H = 20.0°C = 293$ K. $c_w = 4190$ J/kg · K and $L_f = 334\times10^3$ J/kg.

EXECUTE: **(a)** In one year the freezer operates $(5 \text{ h/day})(365 \text{ days}) = 1825$ h.

$P = \dfrac{730 \text{ kWh}}{1825 \text{ h}} = 0.400 \text{ kW} = 400$ W.

(b) $K_{\text{Carnot}} = \dfrac{268 \text{ K}}{293 \text{ K} - 268 \text{ K}} = 10.7$

(c) $|W| = Pt = (400 \text{ W})(3600 \text{ s}) = 1.44\times10^6$ J. $|Q_C| = K|W| = 1.54\times10^7$ J. $|Q| = mc_w\Delta T + mL_f$ gives

$m = \dfrac{|Q_C|}{c_w\Delta T + L_f} = \dfrac{1.54\times10^7 \text{ J}}{(4190 \text{ J/kg} \cdot \text{K})(20.0 \text{ K}) + 334\times10^3 \text{ J/kg}} = 36.9$ kg.

EVALUATE: For any actual device, $K < K_{\text{Carnot}}$, $|Q_C|$ is less than we calculated and the freezer makes less ice in one hour than the mass we calculated in part (c).

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

20.19. **IDENTIFY:** $e=\dfrac{W}{Q_{\rm H}}=1-\dfrac{Q_{\rm C}}{Q_{\rm H}}$. For a Carnot cycle, $\dfrac{Q_{\rm C}}{Q_{\rm H}}=-\dfrac{T_{\rm C}}{T_{\rm H}}$ and $e=1-\dfrac{T_{\rm C}}{T_{\rm H}}$.

SET UP: $T_{\rm H}=800$ K. $Q_{\rm C}=-3000$ J.

EXECUTE: For a heat engine, $Q_{\rm H}=-Q_{\rm C}/(1-e)=-(-3000\text{ J})/(1-0.600)=7500$ J, and then $W=eQ_{\rm H}=(0.600)(7500\text{ J})=4500$ J.

EVALUATE: This does not make use of the given value of $T_{\rm H}$. If $T_{\rm H}$ is used, then $T_{\rm C}=T_{\rm H}(1-e)=(800\text{ K})(1-0.600)=320$ K and $Q_{\rm H}=-Q_{\rm C}T_{\rm H}/T_{\rm C}$, which gives the same result.

20.20. **IDENTIFY:** $W=Q_{\rm C}+Q_{\rm H}$. For a Carnot cycle, $\dfrac{Q_{\rm C}}{Q_{\rm H}}=-\dfrac{T_{\rm C}}{T_{\rm H}}$. For the ice to liquid water phase transition, $Q=mL_{\rm f}$.

SET UP: For water, $L_{\rm f}=334\times10^3$ J/kg.

EXECUTE: $Q_{\rm C}=-mL_{\rm f}=-(0.0400\text{ kg})(334\times10^3\text{ J/kg})=-1.336\times10^4$ J. $\dfrac{Q_{\rm C}}{Q_{\rm H}}=-\dfrac{T_{\rm C}}{T_{\rm H}}$ gives

$Q_{\rm H}=-(T_{\rm H}/T_{\rm C})Q_{\rm C}=-(-1.336\times10^4\text{ J})\left[(373.15\text{ K})/(273.15\text{ K})\right]=+1.825\times10^4$ J.

$W=Q_{\rm C}+Q_{\rm H}=4.89\times10^3$ J.

EVALUATE: For a heat engine, $Q_{\rm C}$ is negative and $Q_{\rm H}$ is positive. The heat that comes out of the engine ($Q<0$) goes into the ice ($Q>0$).

20.21. **IDENTIFY:** The power output is $P=\dfrac{W}{t}$. The theoretical maximum efficiency is $e_{\rm Carnot}=1-\dfrac{T_{\rm C}}{T_{\rm H}}$. $e=\dfrac{W}{Q_{\rm H}}$.

SET UP: $Q_{\rm H}=1.50\times10^4$ J. $T_{\rm C}=350$ K. $T_{\rm H}=650$ K. 1 hp = 746 W.

EXECUTE: $e_{\rm Carnot}=1-\dfrac{T_{\rm C}}{T_{\rm H}}=1-\dfrac{350\text{ K}}{650\text{ K}}=0.4615$. $W=eQ_{\rm H}=(0.4615)(1.50\times10^4\text{ J})=6.923\times10^3$ J; this is the work output in one cycle. $P=\dfrac{W}{t}=\dfrac{(240)(6.923\times10^3\text{ J})}{60.0\text{ s}}=2.77\times10^4$ W = 37.1 hp.

EVALUATE: We could also use $\dfrac{Q_{\rm C}}{Q_{\rm H}}=-\dfrac{T_{\rm C}}{T_{\rm H}}$ to calculate

$Q_{\rm C}=-\left(\dfrac{T_{\rm C}}{T_{\rm H}}\right)Q_{\rm H}=-\left(\dfrac{350\text{ K}}{650\text{ K}}\right)(1.50\times10^4\text{ J})=-8.08\times10^3$ J. Then $W=Q_{\rm C}+Q_{\rm H}=6.92\times10^3$ J, the same as previously calculated.

20.22. **IDENTIFY:** The immense ocean does not change temperature, but it does lose some entropy because it gives up heat to melt the ice. The ice does not change temperature as it melts, but it gains entropy by absorbing heat from the ocean.

SET UP: For a reversible isothermal process $\Delta S=\dfrac{Q}{T}$, where T is the Kelvin temperature at which the heat flow occurs. The heat flows in this problem are irreversible, but since ΔS is path-independent, the entropy change is the same as for a reversible heat flow. The heat flow when the ice melts is $Q=mL_{\rm f}$, with $L_{\rm f}=334\times10^3$ J/kg. Heat flows out of the ocean ($Q<0$) and into the ice ($Q>0$). The heat flow for the ice occurs at $T=0°\text{C}=273.15$ K. The heat flow for the ocean occurs at $T=3.50°\text{C}=276.65$ K.

EXECUTE: $Q=mL_{\rm f}=(4.50\text{ kg})(334\times10^3\text{ J/kg})=1.50\times10^6$ J. For the ice, $\Delta S=\dfrac{Q}{T}=\dfrac{+1.50\times10^6\text{ J}}{273.15\text{ K}}=5.49\times10^3$ J/K. For the ocean, $\Delta S=\dfrac{Q}{T}=\dfrac{-1.50\times10^6\text{ J}}{276.65\text{ K}}=-5.42\times10^3$ J/K. The net entropy change is $5.49\times10^3\text{ J/K}+(-5.42\times10^3\text{ J/K})=+70$ J/K. The entropy of the world increases by 70 J/K.

EVALUATE: Since this process is irreversible, we expect the entropy of the world to increase, as we have found.

20.23. **IDENTIFY:** $\Delta S = \dfrac{Q}{T}$ for each object, where T must be in kelvins. The temperature of each object remains constant.

SET UP: For water, $L_f = 3.34\times10^5$ J/kg.

EXECUTE: **(a)** The heat flow into the ice is $Q = mL_f = (0.350\text{ kg})(3.34\times10^5\text{ J/kg}) = 1.17\times10^5$ J. The heat flow occurs at $T = 273$ K, so $\Delta S = \dfrac{Q}{T} = \dfrac{1.17\times10^5\text{ J}}{273\text{ K}} = 429$ J/K. Q is positive and ΔS is positive.

(b) $Q = -1.17\times10^5$ J flows out of the heat source, at $T = 298$ K. $\Delta S = \dfrac{Q}{T} = \dfrac{-1.17\times10^5\text{ J}}{298\text{ K}} = -393$ J/K.

Q is negative and ΔS is negative.

(c) $\Delta S_{tot} = 429\text{ J/K} + (-393\text{ J/K}) = +36$ J/K.

EVALUATE: For the total isolated system, $\Delta S > 0$ and the process is irreversible.

20.24. **IDENTIFY:** Apply $Q_{system} = 0$ to calculate the final temperature. $Q = mc\Delta T$. Example 20.6 shows that $\Delta S = mc\ln(T_2/T_1)$ when an object undergoes a temperature change.

SET UP: For water $c = 4190$ J/kg·K. Boiling water has $T = 100.0°\text{C} = 373$ K.

EXECUTE: **(a)** The heat transfer between 100°C water and 30°C water occurs over a finite temperature difference and the process is irreversible.

(b) $(270\text{ kg})c(T_2 - 30.0°\text{C}) + (5.00\text{ kg})c(T_2 - 100°\text{C}) = 0$. $T_2 = 31.27°\text{C} = 304.42$ K.

(c) $\Delta S = (270\text{ kg})(4190\text{ J/kg}\cdot\text{K})\ln\left(\dfrac{304.42\text{ K}}{303.15\text{ K}}\right) + (5.00\text{ kg})(4190\text{ J/kg}\cdot\text{K})\ln\left(\dfrac{304.42\text{ K}}{373.15\text{ K}}\right)$.

$\Delta S = 4730\text{ J/K} + (-4265\text{ J/K}) = +470$ J/K.

EVALUATE: $\Delta S_{system} > 0$, as it should for an irreversible process.

20.25. **IDENTIFY:** Both the ice and the room are at a constant temperature, so $\Delta S = \dfrac{Q}{T}$. For the melting phase transition, $Q = mL_f$. Conservation of energy requires that the quantity of heat that goes into the ice is the amount of heat that comes out of the room.

SET UP: For ice, $L_f = 334\times10^3$ J/kg. When heat flows into an object, $Q > 0$, and when heat flows out of an object, $Q < 0$.

EXECUTE: **(a)** Irreversible because heat will not spontaneously flow out of 15 kg of water into a warm room to freeze the water.

(b) $\Delta S = \Delta S_{ice} + \Delta S_{room} = \dfrac{mL_f}{T_{ice}} + \dfrac{-mL_f}{T_{room}} = \dfrac{(15.0\text{ kg})(334\times10^3\text{ J/kg})}{273\text{ K}} + \dfrac{-(15.0\text{ kg})(334\times10^3\text{ J/kg})}{293\text{ K}}$.

$\Delta S = +1250$ J/K.

EVALUATE: This result is consistent with the answer in (a) because $\Delta S > 0$ for irreversible processes.

20.26. **IDENTIFY:** $Q = mc\Delta T$ for the water. Example 20.6 shows that $\Delta S = mc\ln(T_2/T_1)$ when an object undergoes a temperature change. $\Delta S = Q/T$ for an isothermal process.

SET UP: For water, $c = 4190$ J/kg·K. $85.0°\text{C} = 358.2$ K. $20.0°\text{C} = 293.2$ K.

EXECUTE: **(a)** $\Delta S = mc\ln\left(\dfrac{T_2}{T_1}\right) = (0.250\text{ kg})(4190\text{ J/kg}\cdot\text{K})\ln\left(\dfrac{293.2\text{ K}}{358.2\text{ K}}\right) = -210$ J/K. Heat comes out of the water and its entropy decreases.

(b) $Q = mc\Delta T = (0.250)(4190\text{ J/kg}\cdot\text{K})(-65.0\text{ K}) = -6.81\times10^4$ J. The amount of heat that goes into the air is $+6.81\times10^4$ J. For the air, $\Delta S = \dfrac{Q}{T} = \dfrac{+6.81\times10^4\text{ J}}{293.1\text{ K}} = +232$ J/K.

$\Delta S_{system} = -210\text{ J/K} + 232\text{ J/K} = +22$ J/K.

EVALUATE: $\Delta S_{system} > 0$ and the process is irreversible.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

20.27. **IDENTIFY:** The process is at constant temperature, so $\Delta S = \frac{Q}{T}$. $\Delta U = Q - W$.

SET UP: For an isothermal process of an ideal gas, $\Delta U = 0$ and $Q = W$. For a compression, $\Delta V < 0$ and $W < 0$.

EXECUTE: $Q = W = -1850$ J. $\Delta S = \frac{-1850 \text{ J}}{293 \text{ K}} = -6.31$ J/K.

EVALUATE: The entropy change of the gas is negative. Heat must be removed from the gas during the compression to keep its temperature constant and therefore the gas is not an isolated system.

20.28. **IDENTIFY** and **SET UP:** The initial and final states are at the same temperature, at the normal boiling point of 4.216 K. Calculate the entropy change for the irreversible process by considering a reversible isothermal process that connects the same two states, since ΔS is path independent and depends only on the initial and final states. For the reversible isothermal process we can use Eq. (20.18).
The heat flow for the helium is $Q = -mL_v$, negative since in condensation heat flows out of the helium.
The heat of vaporization L_v is given in Table 17.4 and is $L_v = 20.9 \times 10^3$ J/kg.

EXECUTE: $Q = -mL_v = -(0.130 \text{ kg})(20.9 \times 10^3 \text{ J/kg}) = -2717$ J
$\Delta S = Q/T = -2717 \text{ J}/4.216 \text{ K} = -644$ J/K.

EVALUATE: The system we considered is the 0.130 kg of helium; ΔS is the entropy change of the helium. This is not an isolated system since heat must flow out of it into some other material. Our result that $\Delta S < 0$ doesn't violate the 2nd law since it is not an isolated system. The material that receives the heat that flows out of the helium would have a positive entropy change and the total entropy change would be positive.

20.29. **IDENTIFY:** Each phase transition occurs at constant temperature and $\Delta S = \frac{Q}{T}$. $Q = mL_v$.

SET UP: For vaporization of water, $L_v = 2256 \times 10^3$ J/kg.

EXECUTE: **(a)** $\Delta S = \frac{Q}{T} = \frac{mLv}{T} = \frac{(1.00 \text{ kg})(2256 \times 10^3 \text{ J/kg})}{(373.15 \text{ K})} = 6.05 \times 10^3$ J/K. Note that this is the change of entropy of the water as it changes to steam.
(b) The magnitude of the entropy change is roughly five times the value found in Example 20.5.
EVALUATE: Water is less ordered (more random) than ice, but water is far less random than steam; a consideration of the density changes indicates why this should be so.

20.30. **IDENTIFY:** The phase transition occurs at constant temperature and $\Delta S = \frac{Q}{T}$. $Q = mL_v$. The mass of one mole is the molecular mass M.

SET UP: For water, $L_v = 2256 \times 10^3$ J/kg. For N_2, $M = 28.0 \times 10^{-3}$ kg/mol, the boiling point is 77.34 K and $L_v = 201 \times 10^3$ J/kg. For silver (Ag), $M = 107.9 \times 10^{-3}$ kg/mol, the boiling point is 2466 K and $L_v = 2336 \times 10^3$ J/kg. For mercury (Hg), $M = 200.6 \times 10^{-3}$ kg/mol, the boiling point is 630 K and $L_v = 272 \times 10^3$ J/kg.

EXECUTE: **(a)** $\Delta S = \frac{Q}{T} = \frac{mL_v}{T} = \frac{(18.0 \times 10^{-3} \text{kg})(2256 \times 10^3 \text{J/kg})}{(373.15 \text{ K})} = 109$ J/K.

(b) N_2: $\frac{(28.0 \times 10^{-3} \text{ kg})(201 \times 10^3 \text{ J/kg})}{(77.34 \text{ K})} = 72.8$ J/K. Ag: $\frac{(107.9 \times 10^{-3} \text{ kg})(2336 \times 10^3 \text{ J/kg})}{(2466 \text{ K})} = 102.2$ J/K.

Hg: $\frac{(200.6 \times 10^{-3} \text{ kg})(272 \times 10^3 \text{ J/kg})}{(630 \text{ K})} = 86.6$ J/K

(c) The results are the same order or magnitude, all around 100 J/K.
EVALUATE: The entropy change is a measure of the increase in randomness when a certain number (one mole) goes from the liquid to the vapor state. The entropy per particle for any substance in a vapor state is expected to be roughly the same, and since the randomness is much higher in the vapor state (see Exercise 20.29), the entropy change per molecule is roughly the same for these substances.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

20.31. **IDENTIFY:** No heat is transferred, but the entropy of the He increases because it occupies a larger volume and hence is more disordered. To calculate the entropy change, we need to find a reversible process that connects the same initial and final states.

SET UP: The reversible process that connects the same initial and final states is an isothermal expansion at $T = 293$ K, from $V_1 = 10.0$ L to $V_2 = 35.0$ L. For an isothermal expansion of an ideal gas $\Delta U = 0$ and $Q = W = nRT\ln(V_2/V_1)$.

EXECUTE:

(a) $Q = (3.20 \text{ mol})(8.315 \text{ J/mol}\cdot\text{K})(293 \text{ K})\ln(35.0 \text{ L}/10.0 \text{ L}) = 9767$ J. $\Delta S = \dfrac{Q}{T} = \dfrac{9767 \text{ J}}{293 \text{ K}} = +33.3$ J/K.

(b) The isolated system has $\Delta S > 0$ so the process is irreversible.

EVALUATE: The reverse process, where all the gas in 35.0 L goes through the hole and into the tank does not ever occur.

20.32. **IDENTIFY:** Apply Eq. (20.23) and follow the procedure used in Example 20.11.

SET UP: After the partition is punctured each molecule has equal probability of being on each side of the box. The probability of two independent events occurring simultaneously is the product of the probabilities of each separate event.

EXECUTE: **(a)** On the average, each half of the box will contain half of each type of molecule, 250 of nitrogen and 50 of oxygen.

(b) See Example 20.11. The total change in entropy is

$\Delta S = kN_1\ln(2) + kN_2\ln(2) = (N_1 + N_2)k\ \ln(2) = (600)(1.381\times10^{-23} \text{ J/K})\ \ln(2) = 5.74\times10^{-21}$ J/K.

(c) The probability is $(1/2)^{500}\times(1/2)^{100} = (1/2)^{600} = 2.4\times10^{-181}$, and is not likely to happen. The numerical result for part (c) above may not be obtained directly on some standard calculators. For such calculators, the result may be found by taking the log base ten of 0.5 and multiplying by 600, then adding 181 and then finding 10 to the power of the sum. The result is then $10^{-181}\times10^{0.87} = 2.4\times10^{-181}$.

EVALUATE: The contents of the box constitutes an isolated system. $\Delta S > 0$ and the process is irreversible.

20.33. **(a) IDENTIFY** and **SET UP:** The velocity distribution of Eq. (18.32) depends only on T, so in an isothermal process it does not change.

(b) EXECUTE: Calculate the change in the number of available microscopic states and apply Eq. (20.23). Following the reasoning of Example 20.11, the number of possible positions available to each molecule is altered by a factor of 3 (becomes larger). Hence the number of microscopic states the gas occupies at volume $3V$ is $w_2 = (3)^N w_1$, where N is the number of molecules and w_1 is the number of possible microscopic states at the start of the process, where the volume is V. Then, by Eq. (20.23),

$\Delta S = k\ln(w_2/w_1) = k\ln(3)^N = Nk\ln(3) = nN_A k\ln(3) = nR\ln(3)$

$\Delta S = (2.00 \text{ mol})(8.3145 \text{ J/mol}\cdot\text{K})\ln(3) = +18.3$ J/K

(c) IDENTIFY and **SET UP:** For an isothermal reversible process $\Delta S = Q/T$.

EXECUTE: Calculate W and then use the first law to calculate Q.

$\Delta T = 0$ implies $\Delta U = 0$, since system is an ideal gas.

Then by $\Delta U = Q - W$, $Q = W$.

For an isothermal process, $W = \int_{V_1}^{V_2} p\ dV = \int_{V_1}^{V_2} (nRT/V)\ dV = nRT\ln(V_2/V_1)$

Thus $Q = nRT\ln(V_2/V_1)$ and $\Delta S = Q/T = nR\ln(V_2/V_1)$

$\Delta S = (2.00 \text{ mol})(8.3145 \text{ J/mol}\cdot\text{K})\ln(3V_1/V_1) = +18.3$ J/K

EVALUATE: This is the same result as obtained in part (b).

20.34. **IDENTIFY:** Example 20.8 shows that for a free expansion, $\Delta S = nR\ln(V_2/V_1)$.

SET UP: $V_1 = 2.40 \text{ L} = 2.40\times10^{-3} \text{ m}^3$

EXECUTE: $\Delta S = (0.100 \text{ mol})(8.314 \text{ J/mol}\cdot\text{K})\ln\left(\dfrac{425 \text{ m}^3}{2.40\times10^{-3} \text{ m}^3}\right) = 10.0$ J/K

EVALUATE: $\Delta S_{\text{system}} > 0$ and the free expansion is irreversible.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

20.35. **IDENTIFY:** The total work that must be done is $W_{\text{tot}} = mg\Delta y$. $|W| = |Q_{\text{H}}| - |Q_{\text{C}}|$. $Q_{\text{H}} > 0$, $W > 0$ and $Q_{\text{C}} < 0$. For a Carnot cycle, $\dfrac{Q_{\text{C}}}{Q_{\text{H}}} = -\dfrac{T_{\text{C}}}{T_{\text{H}}}$,

SET UP: $T_{\text{C}} = 373$ K, $T_{\text{H}} = 773$ K. $|Q_{\text{H}}| = 250$ J.

EXECUTE: **(a)** $Q_{\text{C}} = -Q_{\text{H}}\left(\dfrac{T_{\text{C}}}{T_{\text{H}}}\right) = -(250\text{ J})\left(\dfrac{373\text{ K}}{773\text{ K}}\right) = -121\text{ J}$.

(b) $|W| = 250\text{ J} - 121\text{ J} = 129\text{ J}$. This is the work done in one cycle.

$W_{\text{tot}} = (500\text{ kg})(9.80\text{ m/s}^2)(100\text{ m}) = 4.90\times10^5$ J. The number of cycles required is

$\dfrac{W_{\text{tot}}}{|W|} = \dfrac{4.90\times10^5\text{ J}}{129\text{ J/cycle}} = 3.80\times10^3$ cycles.

EVALUATE: In $\dfrac{Q_{\text{C}}}{Q_{\text{H}}} = -\dfrac{T_{\text{C}}}{T_{\text{H}}}$, the temperatures must be in kelvins.

20.36. **IDENTIFY:** $W = Q_{\text{C}} + Q_{\text{H}}$. Since it is a Carnot cycle, $\dfrac{Q_{\text{C}}}{Q_{\text{H}}} = -\dfrac{T_{\text{C}}}{T_{\text{H}}}$. The heat required to melt the ice is $Q = mL_{\text{f}}$.

SET UP: For water, $L_{\text{f}} = 334\times10^3$ J/kg. $Q_{\text{H}} > 0$, $Q_{\text{C}} < 0$. $Q_{\text{C}} = -mL_{\text{f}}$. $T_{\text{H}} = 527°\text{C} = 800.15$ K.

EXECUTE: **(a)** $Q_{\text{H}} = +400$ J, $W = +300$ J. $Q_{\text{C}} = W - Q_{\text{H}} = -100$ J.

$T_{\text{C}} = -T_{\text{H}}(Q_{\text{C}}/Q_{\text{H}}) = -(800.15\text{ K})[(-100\text{ J})/(400\text{ J})] = +200\text{ K} = -73°\text{C}$

(b) The total Q_{C} required is $-mL_{\text{f}} = -(10.0\text{ kg})(334\times10^3\text{ J/kg}) = -3.34\times10^6$ J. Q_{C} for one cycle is -100 J, so the number of cycles required is $\dfrac{-3.34\times10^6\text{ J}}{-100\text{ J/cycle}} = 3.34\times10^4$ cycles.

EVALUATE: The results depend only on the maximum temperature of the gas, not on the number of moles or the maximum pressure.

20.37. **IDENTIFY:** We know the efficiency of this Carnot engine, the heat it absorbs at the hot reservoir and the temperature of the hot reservoir.

SET UP: For a heat engine $e = \dfrac{W}{|Q_{\text{H}}|}$ and $Q_{\text{H}} + Q_{\text{C}} = W$. For a Carnot cycle, $\dfrac{Q_{\text{C}}}{Q_{\text{H}}} = -\dfrac{T_{\text{C}}}{T_{\text{H}}}$. $Q_{\text{C}} < 0$, $W > 0$, and $Q_{\text{H}} > 0$. $T_{\text{H}} = 135°\text{C} = 408$ K. In each cycle, $|Q_{\text{H}}|$ leaves the hot reservoir and $|Q_{\text{C}}|$ enters the cold reservoir. The work done on the water equals its increase in gravitational potential energy, mgh.

EXECUTE: **(a)** $e = \dfrac{W}{Q_{\text{H}}}$ so $W = eQ_{\text{H}} = (0.22)(150\text{ J}) = 33$ J.

(b) $Q_{\text{C}} = W - Q_{\text{H}} = 33\text{ J} - 150\text{ J} = -117$ J.

(c) $\dfrac{Q_{\text{C}}}{Q_{\text{H}}} = -\dfrac{T_{\text{C}}}{T_{\text{H}}}$ so $T_{\text{C}} = -T_{\text{H}}\left(\dfrac{Q_{\text{C}}}{Q_{\text{H}}}\right) = -(408\text{ K})\left(\dfrac{-117\text{ J}}{150\text{ J}}\right) = 318\text{ K} = 45°\text{C}$.

(d) $\Delta S = \dfrac{-|Q_{\text{H}}|}{T_{\text{H}}} + \dfrac{|Q_{\text{C}}|}{T_{\text{C}}} = \dfrac{-150\text{ J}}{408\text{ K}} + \dfrac{117\text{ J}}{318\text{ K}} = 0$. The Carnot cycle is reversible and $\Delta S = 0$.

(e) $W = mgh$ so $m = \dfrac{W}{gh} = \dfrac{33\text{ J}}{(9.80\text{ m/s}^2)(35.0\text{ m})} = 0.0962\text{ kg} = 96.2\text{ g}$.

EVALUATE: The Carnot cycle is reversible so $\Delta S = 0$ for the world. However some parts of the world gain entropy while other parts lose it, making the sum equal to zero.

20.38. **IDENTIFY:** The same amount of heat that enters the person's body also leaves the body, but these transfers of heat occur at different temperatures, so the person's entropy changes.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

SET UP: We are asked to find the entropy change of the person. The person is not an isolated system. In 1.0 s, $0.80(80\text{ J}) = 64\text{ J}$ of heat enters the person's body at $37°\text{C} = 310\text{ K}$. This amount of heat leaves the person at a temperature of $30°\text{C} = 303\text{ K}$. $\Delta S = \frac{Q}{T}$.

EXECUTE: For the person, $\Delta S = \frac{+64\text{ J}}{310\text{ K}} + \frac{-64\text{ J}}{303\text{ K}} = -4.8\times10^{-3}\text{ J/K}$.

EVALUATE: The entropy of the person can decrease without violating the second law of thermodynamics because the person isn't an isolated system.

20.39. **IDENTIFY:** The same amount of heat that enters the person's body also leaves the body, but these transfers of heat occur at different temperatures, so the person's entropy changes.

SET UP: 1 food-calorie = 1000 cal = 4186 J. The heat enters the person's body at 37°C = 310 K and leaves at a temperature of 30°C = 303 K. $\Delta S = \frac{Q}{T}$.

EXECUTE: $|Q| = (0.80)(2.50\text{ g})(9.3\text{ food-calorie/g})\left(\frac{4186\text{ J}}{1\text{ food-calorie}}\right) = 7.79\times10^4\text{ J}$.

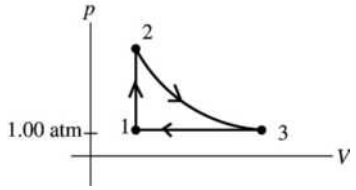
$\Delta S = \frac{+7.79\times10^4\text{ J}}{310\text{ K}} + \frac{-7.79\times10^4\text{ J}}{303\text{ K}} = -5.8\text{ J/K}$. Your body's entropy decreases.

EVALUATE: The entropy of your body can decrease without violating the second law of thermodynamics because you are not an isolated system.

20.40. **IDENTIFY:** Use the ideal gas law to calculate p and V for each state. Use the first law and specific expressions for Q, W and ΔU for each process. Use Eq. (20.4) to calculate e. Q_H is the net heat flow into the gas.

SET UP: $\gamma = 1.40$

$C_V = R/(\gamma-1) = 20.79\text{ J/mol}\cdot\text{K}$; $C_p = C_V + R = 29.10\text{ J/mol}\cdot\text{K}$. The cycle is sketched in Figure 20.40.



$T_1 = 300\text{ K}$
$T_2 = 600\text{ K}$
$T_3 = 492\text{ K}$

Figure 20.40

EXECUTE: **(a)** point 1

$p_1 = 1.00\text{ atm} = 1.013\times10^5\text{ Pa}$ (given); $pV = nRT$;

$V_1 = \frac{nRT_1}{p_1} = \frac{(0.350\text{ mol})(8.3145\text{ J/mol}\cdot\text{K})(300\text{ K})}{1.013\times10^5\text{ Pa}} = 8.62\times10^{-3}\text{ m}^3$

point 2

process $1\to2$ at constant volume so $V_2 = V_1 = 8.62\times10^{-3}\text{ m}^3$

$pV = nRT$ and n, R, V constant implies $p_1/T_1 = p_2/T_2$

$p_2 = p_1(T_2/T_1) = (1.00\text{ atm})(600\text{ K}/300\text{ K}) = 2.00\text{ atm} = 2.03\times10^5\text{ Pa}$

point 3

Consider the process $3\to1$, since it is simpler than $2\to3$.

Process $3\to1$ is at constant pressure so $p_3 = p_1 = 1.00\text{ atm} = 1.013\times10^5\text{ Pa}$

$pV = nRT$ and n, R, p constant implies $V_1/T_1 = V_3/T_3$

$V_3 = V_1(T_3/T_1) = (8.62\times10^{-3}\text{ m}^3)(492\text{ K}/300\text{ K}) = 14.1\times10^{-3}\text{ m}^3$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) process $1 \to 2$

constant volume $(\Delta V = 0)$

$Q = nC_V\Delta T = (0.350 \text{ mol})(20.79 \text{ J/mol}\cdot\text{K})(600 \text{ K} - 300 \text{ K}) = 2180 \text{ J}$

$\Delta V = 0$ and $W = 0$. Then $\Delta U = Q - W = 2180 \text{ J}$

process $2 \to 3$

Adiabatic means $Q = 0$.

$\Delta U = nC_V\Delta T$ (any process), so

$\Delta U = (0.350 \text{ mol})(20.79 \text{ J/mol}\cdot\text{K})(492 \text{ K} - 600 \text{ K}) = -780 \text{ J}$

Then $\Delta U = Q - W$ gives $W = Q - \Delta U = +780$ J. (It is correct for W to be positive since ΔV is positive.)

process $3 \to 1$

For constant pressure

$W = p\Delta V = (1.013\times10^5 \text{ Pa})(8.62\times10^{-3} \text{ m}^3 - 14.1\times10^{-3} \text{ m}^3) = -560 \text{ J}$

or $W = nR\Delta T = (0.350 \text{ mol})(8.3145 \text{ J/mol}\cdot\text{K})(300 \text{ K} - 492 \text{ K}) = -560 \text{ J}$, which checks. (It is correct for W to be negative, since ΔV is negative for this process.)

$Q = nC_p\Delta T = (0.350 \text{ mol})(29.10 \text{ J/mol}\cdot\text{K})(300 \text{ K} - 492 \text{ K}) = -1960 \text{ J}$

$\Delta U = Q - W = -1960 \text{ J} - (-560 \text{ K}) = -1400 \text{ J}$

or $\Delta U = nC_V\Delta T = (0.350 \text{ mol})(20.79 \text{ J/mol}\cdot\text{K})(300 \text{ K} - 492 \text{ K}) = -1400 \text{ J}$, which checks

(c) $W_{\text{net}} = W_{1\to2} + W_{2\to3} + W_{3\to1} = 0 + 780 \text{ J} - 560 \text{ J} = +220 \text{ J}$

(d) $Q_{\text{net}} = Q_{1\to2} + Q_{2\to3} + Q_{3\to1} = 2180 \text{ J} + 0 - 1960 \text{ J} = +220 \text{ J}$

(e) $e = \dfrac{\text{work output}}{\text{heat energy input}} = \dfrac{W}{Q_{\text{H}}} = \dfrac{220 \text{ J}}{2180 \text{ J}} = 0.101 = 10.1\%.$

$e(\text{Carnot}) = 1 - T_{\text{C}}/T_{\text{H}} = 1 - 300 \text{ K}/600 \text{ K} = 0.500.$

EVALUATE: For a cycle $\Delta U = 0$, so by $\Delta U = Q - W$ it must be that $Q_{\text{net}} = W_{\text{net}}$ for a cycle. We can also check that $\Delta U_{\text{net}} = 0$: $\Delta U_{\text{net}} = \Delta U_{1\to2} + \Delta U_{2\to3} + \Delta U_{3\to1} = 2180 \text{ J} - 1050 \text{ J} - 1130 \text{ J} = 0$

$e < e(\text{Carnot})$, as it must.

20.41. **IDENTIFY:** $pV = nRT$, so pV is constant when T is constant. Use the appropriate expression to calculate Q and W for each process in the cycle. $e = \dfrac{W}{Q_{\text{H}}}$.

SET UP: For an ideal diatomic gas, $C_V = \frac{5}{2}R$ and $C_p = \frac{7}{2}R$.

EXECUTE: **(a)** $p_aV_a = 2.0\times10^3$ J. $p_bV_b = 2.0\times10^3$ J. $pV = nRT$ so $p_aV_a = p_bV_b$ says $T_a = T_b$.

(b) For an isothermal process, $Q = W = nRT\ln(V_2/V_1)$. ab is a compression, with $V_b < V_a$, so $Q < 0$ and heat is rejected. bc is at constant pressure, so $Q = nC_p\Delta T = \dfrac{C_p}{R}p\Delta V$. ΔV is positive, so $Q > 0$ and heat is absorbed. ca is at constant volume, so $Q = nC_V\Delta T = \dfrac{C_V}{R}V\Delta p$. Δp is negative, so $Q < 0$ and heat is rejected.

(c) $T_a = \dfrac{p_aV_a}{nR} = \dfrac{2.0\times10^3 \text{ J}}{(1.00)(8.314 \text{ J/mol}\cdot\text{K})} = 241 \text{ K}.$ $T_b = \dfrac{p_bV_b}{nR} = T_a = 241 \text{ K}.$

$T_c = \dfrac{p_cV_c}{nR} = \dfrac{4.0\times10^3 \text{ J}}{(1.00)(8.314 \text{ J/mol}\cdot\text{K})} = 481 \text{ K}.$

(d) $Q_{ab} = nRT\ln\left(\dfrac{V_b}{V_a}\right) = (1.00 \text{ mol})(8.314 \text{ J/mol}\cdot\text{K})(241 \text{ K})\ln\left(\dfrac{0.0050 \text{ m}^3}{0.010 \text{ m}^3}\right) = -1.39\times10^3 \text{ J}.$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$Q_{bc} = nC_p\Delta T = (1.00)\left(\frac{7}{2}\right)(8.314\ \text{J/mol}\cdot\text{K})(241\ \text{K}) = 7.01\times10^3\ \text{J}.$

$Q_{ca} = nC_V\Delta T = (1.00)\left(\frac{5}{2}\right)(8.314\ \text{J/mol}\cdot\text{K})(-241\ \text{K}) = -5.01\times10^3\ \text{J}.$ $Q_{\text{net}} = Q_{ab} + Q_{bc} + Q_{ca} = 610\ \text{J}.$

$W_{\text{net}} = Q_{\text{net}} = 610\ \text{J}.$

(e) $e = \frac{W}{Q_{\text{H}}} = \frac{610\ \text{J}}{7.01\times10^3\ \text{J}} = 0.087 = 8.7\%$

EVALUATE: We can calculate W for each process in the cycle. $W_{ab} = Q_{ab} = -1.39\times10^3\ \text{J}.$

$W_{bc} = p\Delta V = (4.0\times10^5\ \text{Pa})(0.0050\ \text{m}^3) = 2.00\times10^3\ \text{J}.$ $W_{ca} = 0.$ $W_{\text{net}} = W_{ab} + W_{bc} + W_{ca} = 610\ \text{J},$ which does equal Q_{net}.

20.42. **(a) IDENTIFY** and **SET UP:** Combine Eqs. (20.13) and (20.2) to eliminate Q_{C} and obtain an expression for Q_{H} in terms of W, T_{C} and T_{H}.

$W = 1.00\ \text{J},\ T_{\text{C}} = 268.15\ \text{K},\ T_{\text{H}} = 290.15\ \text{K}$

For the heat pump $Q_{\text{C}} > 0$ and $Q_{\text{H}} < 0$

EXECUTE: $W = Q_{\text{C}} + Q_{\text{H}};$ combining this with $\frac{Q_{\text{C}}}{Q_{\text{H}}} = -\frac{T_{\text{C}}}{T_{\text{H}}}$ gives

$Q_{\text{H}} = \frac{W}{1 - T_{\text{C}}/T_{\text{H}}} = \frac{1.00\ \text{J}}{1-(268.15/290.15)} = 13.2\ \text{J}$

(b) Electrical energy is converted directly into heat, so an electrical energy input of 13.2 J would be required.

(c) EVALUATE: From part (a), $Q_{\text{H}} = \frac{W}{1 - T_{\text{C}}/T_{\text{H}}}.$ Q_{H} decreases as T_{C} decreases. The heat pump is less efficient as the temperature difference through which the heat has to be "pumped" increases. In an engine, heat flows from T_{H} to T_{C} and work is extracted. The engine is more efficient the larger the temperature difference through which the heat flows.

20.43. **IDENTIFY:** $T_b = T_c$ and is equal to the maximum temperature. Use the ideal gas law to calculate T_a. Apply the appropriate expression to calculate Q for each process. $e = \frac{W}{Q_{\text{H}}}.$ $\Delta U = 0$ for a complete cycle and for an isothermal process of an ideal gas.

SET UP: For helium, $C_V = 3R/2$ and $C_p = 5R/2.$ The maximum efficiency is for a Carnot cycle, and $e_{\text{Carnot}} = 1 - T_{\text{C}}/T_{\text{H}}.$

EXECUTE: **(a)** $Q_{\text{in}} = Q_{ab} + Q_{bc}.$ $Q_{\text{out}} = Q_{ca}.$ $T_{\text{max}} = T_b = T_c = 327°\text{C} = 600\ \text{K}.$

$\frac{p_aV_a}{T_a} = \frac{p_bV_b}{T_b} \rightarrow T_a = \frac{p_a}{p_b}T_b = \frac{1}{3}(600\ \text{K}) = 200\ \text{K}.$

$p_bV_b = nRT_b \rightarrow V_b = \frac{nRT_b}{p_b} = \frac{(2\ \text{moles})(8.31\ \text{J/mol}\cdot\text{K})(600\ \text{K})}{3.0\times10^5\ \text{Pa}} = 0.0332\ \text{m}^3.$

$\frac{p_bV_b}{T_b} = \frac{p_cV_c}{T_c} \rightarrow V_c = V_b\frac{p_b}{p_c} = (0.0332\ \text{m}^3)\left(\frac{3}{1}\right) = 0.0997\ \text{m}^3 = V_a.$

$Q_{ab} = nC_V\Delta T_{ab} = (2\ \text{mol})\left(\frac{3}{2}\right)(8.31\ \text{J/mol}\cdot\text{K})(400\ \text{K}) = 9.97\times10^3\ \text{J}$

$Q_{bc} = W_{bc} = \int_b^c pdV = \int_b^c \frac{nRT_b}{V}dV = nRT_b\ \ln\frac{V_c}{V_b} = nRT_b\ \ln 3.$

$Q_{bc} = (2.00\ \text{mol})(8.31\ \text{J/mol}\cdot\text{K})(600\ \text{K})\ln 3 = 1.10\times10^4\ \text{J}.$ $Q_{\text{in}} = Q_{ab} + Q_{bc} = 2.10\times10^4\ \text{J}.$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$Q_{\text{out}} = Q_{ca} = nC_p\Delta T_{ca} = (2.00\text{ mol})\left(\frac{5}{2}\right)(8.31\text{ J/mol}\cdot\text{K})(400\text{ K}) = 1.66\times10^4\text{ J}.$

(b) $Q = \Delta U + W = 0 + W \rightarrow W = Q_{\text{in}} - Q_{\text{out}} = 2.10\times10^4\text{ J} - 1.66\times10^4\text{ J} = 4.4\times10^3\text{ J}.$

$e = W/Q_{\text{in}} = \frac{4.4\times10^3\text{ J}}{2.10\times10^4\text{ J}} = 0.21 = 21\%.$

(c) $e_{\max} = e_{\text{Carnot}} = 1 - \frac{T_{\text{C}}}{T_{\text{H}}} = 1 - \frac{200\text{ k}}{600\text{ k}} = 0.67 = 67\%$

EVALUATE: The thermal efficiency of this cycle is about one-third of the efficiency of a Carnot cycle that operates between the same two temperatures.

20.44. **IDENTIFY:** For a Carnot engine, $\frac{Q_{\text{C}}}{Q_{\text{H}}} = -\frac{T_{\text{C}}}{T_{\text{H}}}$. $e_{\text{Carnot}} = 1 - \frac{T_{\text{C}}}{T_{\text{H}}}$. $|W| = |Q_{\text{H}}| - |Q_{\text{C}}|$. $Q_{\text{H}} > 0$, $Q_{\text{C}} < 0$. $pV = nRT$.

SET UP: The work done by the engine each cycle is $mg\Delta y$, with $m = 15.0$ kg and $\Delta y = 2.00$ m.

$T_{\text{H}} = 773$ K. $Q_{\text{H}} = 500$ J.

EXECUTE: **(a)** The pV diagram is sketched in Figure 20.44.

(b) $W = mg\Delta y = (15.0\text{ kg})(9.80\text{ m/s}^2)(2.00\text{ m}) = 294\text{ J}$. $|Q_{\text{C}}| = |Q_{\text{H}}| - |W| = 500\text{ J} - 294\text{ J} = 206\text{ J}$, and $Q_{\text{C}} = -206$ J.

$T_{\text{C}} = -T_{\text{H}}\left(\frac{Q_{\text{C}}}{Q_{\text{H}}}\right) = -(773\text{ K})\left(\frac{-206\text{ J}}{500\text{ J}}\right) = 318\text{ K} = 45°\text{C}.$

(c) $e = 1 - \frac{T_{\text{C}}}{T_{\text{H}}} = 1 - \frac{318\text{ K}}{773\text{ K}} = 0.589 = 58.9\%.$

(d) $|Q_{\text{C}}| = 206$ J.

(e) The maximum pressure is for state a. This is also where the volume is a minimum, so $V_a = 5.00\text{ L} = 5.00\times10^{-3}\text{ m}^3$. $T_a = T_{\text{H}} = 773$ K.

$p_a = \frac{nRT_a}{V_a} = \frac{(2.00\text{ mol})(8.315\text{ J/mol}\cdot\text{K})(773\text{ K})}{5.00\times10^{-3}\text{ m}^3} = 2.57\times10^6\text{ Pa}.$

EVALUATE: We can verify that $e = \frac{W}{Q_{\text{H}}}$ gives the same value for e as calculated in part (c).

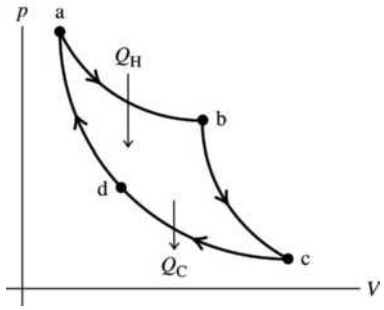


Figure 20.44

20.45. **IDENTIFY:** $e_{\max} = e_{\text{Carnot}} = 1 - T_{\text{C}}/T_{\text{H}}$. $e = \frac{W}{Q_{\text{H}}} = \frac{W/t}{Q_{\text{H}}/t}$. $W = Q_{\text{H}} + Q_{\text{C}}$ so $\frac{W}{t} = \frac{Q_{\text{C}}}{t} + \frac{Q_{\text{H}}}{t}$. For a temperature change $Q = mc\Delta T$.

SET UP: $T_{\text{H}} = 300.15$ K, $T_{\text{C}} = 279.15$ K. For water, $\rho = 1000\text{ kg/m}^3$, so a mass of 1 kg has a volume of 1 L. For water, $c = 4190\text{ J/kg}\cdot\text{K}$.

EXECUTE: **(a)** $e = 1 - \frac{279.15\text{K}}{300.15\text{K}} = 7.0\%.$

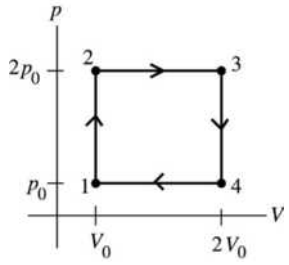
© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) $\frac{Q_H}{t}=\frac{P_{out}}{e}=\frac{210\text{ kW}}{0.070}=3.0\text{ MW}.$ $\frac{Q_C}{t}=\frac{Q_H}{t}-\frac{W}{t}=3.0\text{ MW}-210\text{ kW}=2.8\text{ MW}.$

(c) $\frac{m}{t}=\frac{|Q_C|/t}{c\Delta T}=\frac{(2.8\times10^6\text{ W})(3600\text{ s/h})}{(4190\text{ J/kg}\cdot\text{K})(4\text{ K})}=6\times10^5\text{ kg/h}=6\times10^5\text{ L/h}.$

EVALUATE: The efficiency is small since T_C and T_H don't differ greatly.

20.46. **IDENTIFY:** Use Eq. (20.4) to calculate e.
SET UP: The cycle is sketched in Figure 20.46.



$C_V=5R/2$
for an ideal gas $C_p=C_V+R=7R/2$

Figure 20.46

SET UP: Calculate Q and W for each process.

process $1\to2$

$\Delta V=0$ implies $W=0$

$\Delta V=0$ implies $Q=nC_V\Delta T=nC_V(T_2-T_1)$

But $pV=nRT$ and V constant says $p_1V=nRT_1$ and $p_2V=nRT_2$.

Thus $(p_2-p_1)V=nR(T_2-T_1)$; $V\Delta p=nR\Delta T$ (true when V is constant).

Then $Q=nC_V\Delta T=nC_V(V\Delta p/nR)=(C_V/R)V\Delta p=(C_V/R)V_0(2p_0-p_0)=(C_V/R)p_0V_0$. $Q>0$; heat is absorbed by the gas.)

process $2\to3$

$\Delta p=0$ so $W=p\Delta V=p(V_3-V_2)=2p_0(2V_0-V_0)=2p_0V_0$ (W is positive since V increases.)

$\Delta p=0$ implies $Q=nC_p\Delta T=nC_p(T_2-T_1)$

But $pV=nRT$ and p constant says $pV_1=nRT_1$ and $pV_2=nRT_2$.

Thus $p(V_2-V_1)=nR(T_2-T_1)$; $p\Delta V=nR\Delta T$ (true when p is constant).

Then $Q=nC_p\Delta T=nC_p(p\Delta V/nR)=(C_p/R)p\Delta V=(C_p/R)2p_0(2V_0-V_0)=(C_p/R)2p_0V_0$. ($Q>0$; heat is absorbed by the gas.)

process $3\to4$

$\Delta V=0$ implies $W=0$

$\Delta V=0$ so

$Q=nC_V\Delta T=nC_V(V\Delta p/nR)=(C_V/R)(2V_0)(p_0-2p_0)=-2(C_V/R)p_0V_0$

($Q<0$ so heat is rejected by the gas.)

process $4\to1$

$\Delta p=0$ so $W=p\Delta V=p(V_1-V_4)=p_0(V_0-2V_0)=-p_0V_0$ (W is negative since V decreases)

$\Delta p=0$ so $Q=nC_p\Delta T=nC_p(p\Delta V/nR)=(C_p/R)p\Delta V=(C_p/R)p_0(V_0-2V_0)=-(C_p/R)p_0V_0$ ($Q<0$ so heat is rejected by the gas.)

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

total work performed by the gas during the cycle:

$W_{\text{tot}} = W_{1\to2} + W_{2\to3} + W_{3\to4} + W_{4\to1} = 0 + 2p_0V_0 + 0 - p_0V_0 = p_0V_0$

(Note that W_{tot} equals the area enclosed by the cycle in the pV-diagram.)

total heat absorbed by the gas during the cycle (Q_{H}):

Heat is absorbed in processes $1\to2$ and $2\to3$.

$$Q_{\text{H}} = Q_{1\to2} + Q_{2\to3} = \frac{C_V}{R}p_0V_0 + 2\frac{C_p}{R}p_0V_0 = \left(\frac{C_V + 2C_p}{R}\right)p_0V_0$$

But $C_p = C_V + R$ so $Q_{\text{H}} = \dfrac{C_V + 2(C_V + R)}{R}p_0V_0 = \left(\dfrac{3C_V + 2R}{R}\right)p_0V_0.$

total heat rejected by the gas during the cycle (Q_{C}):

Heat is rejected in processes $3\to4$ and $4\to1$.

$$Q_{\text{C}} = Q_{3\to4} + Q_{4\to1} = -2\frac{C_V}{R}p_0V_0 - \frac{C_p}{R}p_0V_0 = -\left(\frac{2C_V + C_p}{R}\right)p_0V_0$$

But $C_p = C_V + R$ so $Q_{\text{C}} = -\dfrac{2C_V + (C_V + R)}{R}p_0V_0 = -\left(\dfrac{3C_V + R}{R}\right)p_0V_0.$

efficiency

$$e = \frac{W}{Q_{\text{H}}} = \frac{p_0V_0}{([3C_V + 2R]/R)(p_0V_0)} = \frac{R}{3C_V + 2R} = \frac{R}{3(5R/2) + 2R} = \frac{2}{19}.$$

$e = 0.105 = 10.5\%$

EVALUATE: As a check on the calculations note that

$Q_{\text{C}} + Q_{\text{H}} = -\left(\dfrac{3C_V + R}{R}\right)p_0V_0 + \left(\dfrac{3C_V + 2R}{R}\right)p_0V_0 = p_0V_0 = W,$ as it should.

20.47. **IDENTIFY:** Use $pV = nRT$. Apply the expressions for Q and W that apply to each type of process.

$e = \dfrac{W}{Q_{\text{H}}}.$

SET UP: For O_2, $C_V = 20.85$ J/mol·K and $C_p = 29.17$ J/mol·K.

EXECUTE: **(a)** $p_1 = 2.00$ atm, $V_1 = 4.00$ L, $T_1 = 300$ K.

$p_2 = 2.00$ atm. $\dfrac{V_1}{T_1} = \dfrac{V_2}{T_2}$. $V_2 = \left(\dfrac{T_2}{T_1}\right)V_1 = \left(\dfrac{450\text{ K}}{300\text{ K}}\right)(4.00\text{ L}) = 6.00\text{ L}.$

$V_3 = 6.00$ L. $\dfrac{p_2}{T_2} = \dfrac{p_3}{T_3}$. $p_3 = \left(\dfrac{T_3}{T_2}\right)p_2 = \left(\dfrac{250\text{ K}}{450\text{ K}}\right)(2.00\text{ atm}) = 1.11\text{ atm}$

$V_4 = 4.00$ L. $p_3V_3 = p_4V_4$. $p_4 = p_3\left(\dfrac{V_3}{V_4}\right) = (1.11\text{ atm})\left(\dfrac{6.00\text{ L}}{4.00\text{ L}}\right) = 1.67\text{ atm}.$

These processes are shown in Figure 20.47.

(b) $n = \dfrac{p_1V_1}{RT_1} = \dfrac{(2.00\text{ atm})(4.00\text{ L})}{(0.08206\text{ L}\cdot\text{atm/mol}\cdot\text{K})(300\text{ K})} = 0.325\text{ mol}$

process $1\to2$: $W = p\Delta V = nR\Delta T = (0.325\text{ mol})(8.315\text{ J/mol}\cdot\text{K})(150\text{ K}) = 405\text{ J}.$

$Q = nC_p\Delta T = (0.325\text{ mol})(29.17\text{ J/mol}\cdot\text{K})(150\text{ K}) = 1422\text{ J}.$

process $2\to3$: $W = 0$. $Q = nC_V\Delta T = (0.325\text{ mol})(20.85\text{ J/mol}\cdot\text{K})(-200\text{ K}) = -1355\text{ J}.$

process $3\to4$: $\Delta U = 0$ and

$$Q = W = nRT_3\ln\left(\frac{V_4}{V_3}\right) = (0.325\text{ mol})(8.315\text{ J/mol}\cdot\text{K})(250\text{ K})\ln\left(\frac{4.00\text{ L}}{6.00\text{ L}}\right) = -274\text{ J}.$$

process $4\to1$: $W = 0$. $Q = nC_V\Delta T = (0.325\text{ mol})(20.85\text{ J/mol}\cdot\text{K})(50\text{ K}) = 339\text{ J}.$

(c) $W = 405\text{ J} - 274\text{ J} = 131\text{ J}$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(d) $e = \dfrac{W}{Q_H} = \dfrac{131\text{ J}}{1422\text{ J} + 339\text{ J}} = 0.0744 = 7.44\%.$

$e_{\text{Carnot}} = 1 - \dfrac{T_C}{T_H} = 1 - \dfrac{250\text{ K}}{450\text{ K}} = 0.444 = 44.4\%;$ e_{Carnot} is much larger.

EVALUATE: $Q_{\text{tot}} = +1422\text{ J} + (-1355\text{ J}) + (-274\text{ J}) + 339\text{ J} = 132\text{ J}.$ This is equal to W_{tot}, apart from a slight difference due to rounding. For a cycle, $W_{\text{tot}} = Q_{\text{tot}}$, since $\Delta U = 0$.

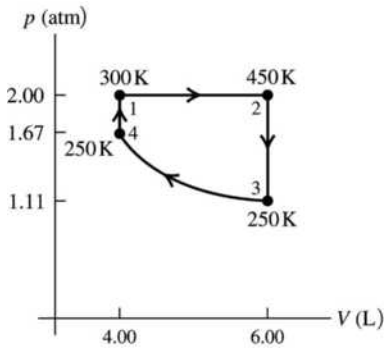


Figure 20.47

20.48. **IDENTIFY:** The air in the room receives heat radiated from the person at 30.0°C but radiates part of it back to the person at 20.0°C, so it undergoes an entropy change.

SET UP: A person with surface area A and surface temperature $T = 303\text{ K}$ radiates at a rate $H = Ae\sigma T^4$. The person absorbs heat from the room at a rate $H_s = Ae\sigma T_s^4$, where $T_s = 293\text{ K}$ is the temperature of the room. In $t = 1.0\text{ s}$, heat $Ae\sigma tT^4$ flows into the room and heat $Ae\sigma tT_s^4$ flows out of the room. The heat flows into and out of the room occur at a temperature of T_s.

EXECUTE: For the room, $\Delta S = \dfrac{Ae\sigma tT^4}{T_s} - \dfrac{Ae\sigma tT_s^4}{T_s} = \dfrac{Ae\sigma t(T^4 - T_s^4)}{T_s}$. Putting in the numbers gives

$$\Delta S = \frac{(1.85\text{ m}^2)(1.00)(5.67\times10^{-8}\text{ W/m}^2\cdot\text{K}^4)(1.0\text{ s})([303\text{ K}]^4 - [293\text{ K}]^4)}{293\text{ K}} = 0.379\text{ J/K}.$$

EVALUATE: The room gains entropy because its disorder increases.

20.49. **IDENTIFY:** Since there is temperature difference between the inside and outside of your body, you can use it as a heat engine.

SET UP: For a heat engine $e = \dfrac{W}{Q_H}$. For a Carnot engine $e = 1 - \dfrac{T_C}{T_H}$. Gravitational potential energy is $U_{\text{grav}} = mgh$. 1 food-calorie = 1000 cal = 4186 J.

EXECUTE: **(a)** $e = 1 - \dfrac{T_C}{T_H} = 1 - \dfrac{303\text{ K}}{310\text{ K}} = 0.0226 = 2.26\%.$ This engine has a very low thermal efficiency.

(b) $U_{\text{grav}} = mgh = (2.50\text{ kg})(9.80\text{ m/s}^2)(1.20\text{ m}) = 29.4\text{ J}.$ This equals the work output of the engine.

$e = \dfrac{W}{Q_H}$ so $Q_H = \dfrac{W}{e} = \dfrac{29.4\text{ J}}{0.0226} = 1.30\times10^3\text{ J}.$

(C) Since 80% of food energy goes into heat, you must eat food with a food energy of $\dfrac{1.30\times10^3\text{ J}}{0.80} = 1.63\times10^3\text{ J}.$ Each candy bar gives (350 food-calorie)(4186 J/food-calorie) $= 1.47\times10^6\text{ J}.$

The number of candy bars required is $\dfrac{1.63\times10^3\text{ J}}{1.47\times10^6\text{ J/candy bar}} = 1.11\times10^{-3}$ candy bars.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: A large amount of mechanical work must be done to use up the energy from one candy bar.

20.50. **IDENTIFY:** The sun radiates energy into the universe and therefore increases its entropy.

SET UP: The sun radiates heat energy at a rate $H = Ae\sigma T^4$. The rate at which the sun absorbs heat from the surrounding space is negligible, since space is so much colder. This heat flows out of the sun at 5800 K and into the surrounding space at 3 K. From Appendix F, the radius of the sun is 6.96×10^8 m. The surface area of a sphere with radius R is $A = 4\pi R^2$.

EXECUTE: **(a)** In 1 s the quantity of heat radiated by the sun is $|Q| = Ae\sigma tT^4 = 4\pi R^2 e\sigma tT^4$. Putting in the numbers gives

$|Q| = 4\pi(6.96\times10^8\text{ m})^2(1.0)(5.67\times10^{-8}\text{ W/m}^2\cdot\text{K}^4)(1.0\text{ s})(5800\text{ K})^4 = 3.91\times10^{26}\text{ J}.$

$$\Delta S = \frac{-3.91\times10^{26}\text{ J}}{5800\text{ K}} + \frac{+3.91\times10^{26}\text{ J}}{3\text{ K}} = +1.30\times10^{26}\text{ J/K}.$$

(b) The process of radiation is irreversible; this heat flows from the hot object (sun) to the cold object (space) and not in the reverse direction. This is consistent with the answer to part (a). We found $\Delta S_{\text{universe}} > 0$ and this is the case for an irreversible process.

EVALUATE: The entropy of the sun decreases because there is a net heat flow out of it. The entropy of space increases because there is a net heat flow into it. But the heat flow into space occurs at a lower temperature than the heat flow out of the sun and the net entropy change of the universe is positive.

20.51. **IDENTIFY:** Use $\Delta U = Q - W$ and the appropriate expressions for Q, W and ΔU for each type of process. $pV = nRT$ relates ΔT to p and V values. $e = \dfrac{W}{Q_{\text{H}}}$, where Q_{H} is the heat that enters the gas during the cycle.

SET UP: For a monatomic ideal gas, $C_p = \frac{5}{2}R$ and $C_V = \frac{3}{2}R$.

(a) *ab*: The temperature changes by the same factor as the volume, and so

$$Q = nC_p\Delta T = \frac{C_p}{R}p_a(V_a - V_b) = (2.5)(3.00\times10^5\text{ Pa})(0.300\text{ m}^3) = 2.25\times10^5\text{ J}.$$

The work $p\Delta V$ is the same except for the factor of $\frac{5}{2}$, so $W = 0.90\times10^5$ J.

$\Delta U = Q - W = 1.35\times10^5$ J.

bc: The temperature now changes in proportion to the pressure change, and

$Q = \frac{3}{2}(p_c - p_b)V_b = (1.5)(-2.00\times10^5\text{ Pa})(0.800\text{ m}^3) = -2.40\times10^5$ J, and the work is zero

$(\Delta V = 0).\ \Delta U = Q - W = -2.40\times10^5$ J.

ca: The easiest way to do this is to find the work done first; W will be the negative of area in the p-V plane bounded by the line representing the process *ca* and the verticals from points *a* and *c*. The area of this trapezoid is $\frac{1}{2}(3.00\times10^5\text{ Pa} + 1.00\times10^5\text{ Pa})(0.800\text{ m}^3 - 0.500\text{ m}^3) = 6.00\times10^4$ J and so the work is -0.60×10^5 J. ΔU must be 1.05×10^5 J (since $\Delta U = 0$ for the cycle, anticipating part (b)), and so Q must be $\Delta U + W = 0.45\times10^5$ J.

(b) See above; $Q = W = 0.30\times10^5$ J, $\Delta U = 0$.

(c) The heat added, during process *ab* and *ca*, is $2.25\times10^5\text{ J} + 0.45\times10^5\text{ J} = 2.70\times10^5$ J and the efficiency is $e = \dfrac{W}{Q_{\text{H}}} = \dfrac{0.30\times10^5}{2.70\times10^5} = 0.111 = 11.1\%$.

EVALUATE: For any cycle, $\Delta U = 0$ and $Q = W$.

20.52. **IDENTIFY:** Use the appropriate expressions for Q, W and ΔU for each process. $e = W/Q_{\text{H}}$ and $e_{\text{Carnot}} = 1 - T_{\text{C}}/T_{\text{H}}$.

SET UP: For this cycle, $T_{\text{H}} = T_2$ and $T_{\text{C}} = T_1$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: **(a)** *ab*: For the isothermal process, $\Delta T = 0$ and $\Delta U = 0$.
$W = nRT_1 \ln(V_b/V_a) = nRT_1\ln(1/r) = -nRT_1\ln(r)$ and $Q = W = -nRT_1 \ln(r)$.
bc: For the isochoric process, $\Delta V = 0$ and $W = 0$. $Q = \Delta U = nC_V\Delta T = nC_V(T_2 - T_1)$.
cd: As in the process *ab*, $\Delta U = 0$ and $W = Q = nRT_2\ln(r)$.
da: As in process *bc*, $\Delta V = 0$ and $W = 0$; $\Delta U = Q = nC_V(T_1 - T_2)$.
(b) The values of Q for the processes are the negatives of each other.
(c) The net work for one cycle is $W_{\text{net}} = nR(T_2 - T_1)\ln(r)$, and the heat added is $Q_{\text{cd}} = nRT_2 \ln(r)$, and the efficiency is $e = \dfrac{W_{\text{net}}}{Q_{cd}} = 1 - (T_1/T_2)$. This is the same as the efficiency of a Carnot-cycle engine operating between the two temperatures.
EVALUATE: For a Carnot cycle two steps in the cycle are isothermal and two are adiabatic and all the heat flow occurs in the isothermal processes. For the Stirling cycle all the heat flow is also in the isothermal steps, since the net heat flow in the two constant volume steps is zero.

20.53. **IDENTIFY:** The efficiency of the composite engine is $e_{12} = \dfrac{W_1 + W_2}{Q_{\text{H1}}}$, where Q_{H1} is the heat input to the first engine and W_1 and W_2 are the work outputs of the two engines. For any heat engine, $W = Q_{\text{C}} + Q_{\text{H}}$, and for a Carnot engine, $\dfrac{Q_{\text{low}}}{Q_{\text{high}}} = -\dfrac{T_{\text{low}}}{T_{\text{high}}}$, where Q_{low} and Q_{high} are the heat flows at the two reservoirs that have temperatures T_{low} and T_{high}.
SET UP: $Q_{\text{high},2} = -Q_{\text{low},1}$. $T_{\text{low},1} = T'$, $T_{\text{high},1} = T_{\text{H}}$, $T_{\text{low},2} = T_{\text{C}}$ and $T_{\text{high},2} = T'$.
EXECUTE: $e_{12} = \dfrac{W_1 + W_2}{Q_{\text{H1}}} = \dfrac{Q_{\text{high},1} + Q_{\text{low},1} + Q_{\text{high},2} + Q_{\text{low},2}}{Q_{\text{high},1}}$. Since $Q_{\text{high},2} = -Q_{\text{low},1}$, this reduces to $e_{12} = 1 + \dfrac{Q_{\text{low},2}}{Q_{\text{high},1}}$. $Q_{\text{low},2} = -Q_{\text{high},2}\dfrac{T_{\text{low},2}}{T_{\text{high},2}} = Q_{\text{low},1}\dfrac{T_{\text{C}}}{T'} = -Q_{\text{high},1}\left(\dfrac{T_{\text{low},1}}{T_{\text{high},1}}\right)\dfrac{T_{\text{C}}}{T'} = -Q_{\text{high},1}\left(\dfrac{T'}{T_{\text{H}}}\right)\dfrac{T_{\text{C}}}{T'}$. This gives $e_{12} = 1 - \dfrac{T_{\text{C}}}{T_{\text{H}}}$. The efficiency of the composite system is the same as that of the original engine.
EVALUATE: The overall efficiency is independent of the value of the intermediate temperature T'.

20.54. **IDENTIFY:** $e = \dfrac{W}{Q_{\text{H}}}$. 1 day $= 8.64\times10^4$ s. For the river water, $Q = mc\Delta T$, where the heat that goes into the water is the heat Q_{C} rejected by the engine. The density of water is 1000 kg/m^3. When an object undergoes a temperature change, $\Delta S = mc\ln(T_2/T_1)$.
SET UP: 18.0°C = 291.1 K. 18.5°C = 291.6 K.
EXECUTE: **(a)** $Q_{\text{H}} = \dfrac{W}{e}$ so $P_{\text{H}} = \dfrac{P_{\text{W}}}{e} = \dfrac{1000\text{ MW}}{0.40} = 2.50\times10^3$ MW.
(b) The heat input in one day is $(2.50\times10^9\text{ W})(8.64\times10^4\text{s}) = 2.16\times10^{14}$ J. The mass of coal used per day is $\dfrac{2.16\times10^{14}\text{ J}}{2.65\times10^7\text{ J/kg}} = 8.15\times10^6$ kg.
(c) $|Q_{\text{H}}| = |W| + |Q_{\text{C}}|$. $|Q_{\text{C}}| = |Q_{\text{H}}| - |W|$. $P_{\text{C}} = P_{\text{H}} - P_{\text{W}} = 2.50\times10^3\text{ MW} - 1000\text{ MW} = 1.50\times10^3$ MW.
(d) The heat input to the river is 1.50×10^9 J/s. $Q = mc\Delta T$ and $\Delta T = 0.5$ C° gives $m = \dfrac{Q}{c\Delta T} = \dfrac{1.50\times10^9\text{ J}}{(4190\text{ J/kg}\cdot\text{K})(0.5\text{ K})} = 7.16\times10^5$ kg. $V = \dfrac{m}{\rho} = 716$ m^3. The river flow rate must be 716 m^3/s.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(e) In one second, 7.16×10^5 kg of water goes from 291.1 K to 291.6 K.

$$\Delta S = mc\ln\left(\frac{T_2}{T_1}\right) = (7.16\times10^5\ \text{kg})(4190\ \text{J/kg}\cdot\text{K})\ln\left(\frac{291.6\ \text{K}}{291.1\ \text{K}}\right) = 5.1\times10^6\ \text{J/K}.$$

EVALUATE: The entropy of the river increases because heat flows into it. The mass of coal used per second is huge.

20.55. **(a) IDENTIFY** and **SET UP:** Calculate e from Eq. (20.6), Q_C from Eq. (20.4) and then W from Eq. (20.2).

EXECUTE: $e = 1-1/(r^{\gamma-1}) = 1-1/(10.6^{0.4}) = 0.6111$

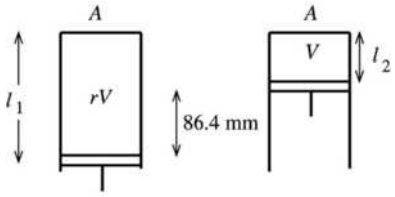
$e = (Q_H + Q_C)/Q_H$ and we are given $Q_H = 200$ J; calculate Q_C.

$Q_C = (e-1)Q_H = (0.6111-1)(200\ \text{J}) = -78\ \text{J}$ (Negative, since corresponds to heat leaving.)

Then $W = Q_C + Q_H = -78\ \text{J} + 200\ \text{J} = 122\ \text{J}$. (Positive, in agreement with Figure 20.6.)

EVALUATE: Q_H, $W > 0$, and $Q_C < 0$ for an engine cycle.

(b) IDENTIFY and **SET UP:** The stoke times the bore equals the change in volume. The initial volume is the final volume V times the compression ratio r. Combining these two expressions gives an equation for V. For each cylinder of area $A = \pi(d/2)^2$ the piston moves 0.864 m and the volume changes from rV to V, as shown in Figure 20.55a.



$l_1 A = rV$

$l_2 A = V$

and $l_1 - l_2 = 86.4\times10^{-3}$ m

Figure 20.55a

EXECUTE: $l_1A - l_2A = rV - V$ and $(l_1 - l_2)A = (r-1)V$

$$V = \frac{(l_1-l_2)A}{r-1} = \frac{(86.4\times10^{-3}\ \text{m})\pi(41.25\times10^{-3}\ \text{m})^2}{10.6-1} = 4.811\times10^{-5}\ \text{m}^3$$

At point a the volume is $rV = 10.6(4.811\times10^{-5}\ \text{m}^3) = 5.10\times10^{-4}\ \text{m}^3$.

(c) IDENTIFY and **SET UP:** The processes in the Otto cycle are either constant volume or adiabatic. Use the Q_H that is given to calculate ΔT for process bc. Use Eq. (19.22) and $pV = nRT$ to relate p, V and T for the adiabatic processes ab and cd.

EXECUTE: point a: $T_a = 300$ K, $p_a = 8.50\times10^4$ Pa and $V_a = 5.10\times10^{-4}\ \text{m}^3$

point b: $V_b = V_a/r = 4.81\times10^{-5}\ \text{m}^3$. Process $a \to b$ is adiabatic, so $T_aV_a^{\gamma-1} = T_bV_b^{\gamma-1}$.

$T_a(rV)^{\gamma-1} = T_bV^{\gamma-1}$

$T_b = T_ar^{\gamma-1} = 300\ \text{K}(10.6)^{0.4} = 771\ \text{K}$

$pV = nRT$ so $pV/T = nR = \text{constant}$, so $p_aV_a/T_a = p_bV_b/T_b$

$p_b = p_a(V_a/V_b)(T_b/T_a) = (8.50\times10^4\ \text{Pa})(rV/V)(771\ \text{K}/300\ \text{K}) = 2.32\times10^6\ \text{Pa}$

point c: Process $b \to c$ is at constant volume, so $V_c = V_b = 4.81\times10^{-5}\ \text{m}^3$

$Q_H = nC_V\Delta T = nC_V(T_c - T_b)$. The problem specifies $Q_H = 200$ J; use to calculate T_c. First use the p, V, T values at point a to calculate the number of moles n.

$$n = \frac{pV}{RT} = \frac{(8.50\times10^4\ \text{Pa})(5.10\times10^{-4}\ \text{m}^3)}{(8.3145\ \text{J/mol}\cdot\text{K})(300\ \text{K})} = 0.01738\ \text{mol}$$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

Then $T_c - T_b = \dfrac{Q_H}{nC_V} = \dfrac{200\text{ J}}{(0.01738\text{ mol})(20.5\text{ J/mol}\cdot\text{K})} = 561.3\text{ K},$ and

$T_c = T_b + 561.3\text{ K} = 771\text{ K} + 561\text{ K} = 1332\text{ K}$

$p/T = nR/V = \text{constant}$ so $p_b/T_b = p_c/T_c$

$p_c = p_b(T_c/T_b) = (2.32\times10^6\text{ Pa})(1332\text{ K}/771\text{ K}) = 4.01\times10^6\text{ Pa}$

point *d*: $V_d = V_a = 5.10\times10^{-4}\text{ m}^3$

process $c \to d$ is adiabatic, so $T_dV_d^{\gamma-1} = T_cV_c^{\gamma-1}$

$T_d(rV)^{\gamma-1} = T_cV^{\gamma-1}$

$T_d = T_c/r^{\gamma-1} = 1332\text{ K}/10.6^{0.4} = 518\text{ K}$

$p_cV_c/T_c = p_dV_d/T_d$

$p_d = p_c(V_c/V_d)(T_d/T_c) = (4.01\times10^6\text{ Pa})(V/rV)(518\text{ K}/1332\text{ K}) = 1.47\times10^5\text{ Pa}$

EVALUATE: Can look at process $d \to a$ as a check.

$Q_C = nC_V(T_a - T_d) = (0.01738\text{ mol})(20.5\text{ J/mol}\cdot\text{K})(300\text{ K} - 518\text{ K}) = -78\text{ J},$ which agrees with part (a).

The cycle is sketched in Figure 20.55b.

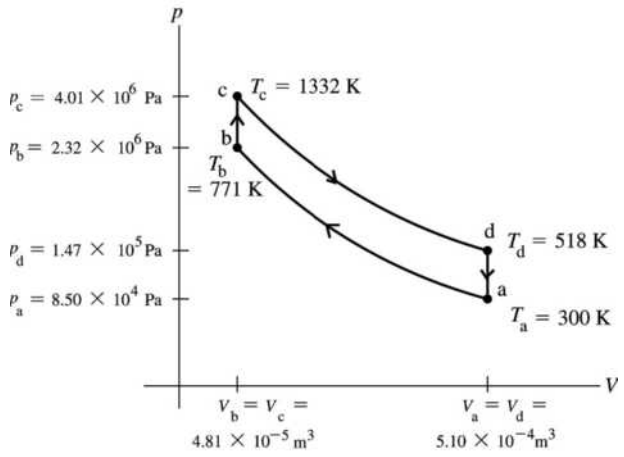


Figure 20.55b

(d) IDENTIFY and SET UP: The Carnot efficiency is given by Eq. (20.14). T_H is the highest temperature reached in the cycle and T_C is the lowest.

EXECUTE: From part (a) the efficiency of this Otto cycle is $e = 0.611 = 61.1\%$.

The efficiency of a Carnot cycle operating between 1332 K and 300 K is

$e(\text{Carnot}) = 1 - T_C/T_H = 1 - 300\text{ K}/1332\text{ K} = 0.775 = 77.5\%,$ which is larger.

EVALUATE: The 2nd law requires that $e \le e$ (Carnot), and our result obeys this law.

20.56. **IDENTIFY:** $K = \dfrac{|Q_C|}{|W|}$. $|Q_H| = |Q_C| + |W|$. The heat flows for the inside and outside air occur at constant *T*, so $\Delta S = Q/T$.

SET UP: 21.0°C = 294.1 K. 35.0°C = 308.1 K.

EXECUTE: **(a)** $|Q_C| = K|W|$. $P_C = KP_W = (2.80)(800\text{ W}) = 2.24\times10^3\text{ W}$.

(b) $P_H = P_C + P_W = 2.24\times10^3\text{ W} + 800\text{ W} = 3.04\times10^3\text{ W}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(c) In 1 h = 3600 s, $Q_H = P_H t = 1.094\times10^7$ J. $\Delta S_{out} = \dfrac{Q_H}{T_H} = \dfrac{1.094\times10^7 \text{ J}}{308.1 \text{ K}} = 3.55\times10^4$ J/K.

(d) $Q_C = P_C t = 8.064\times10^6$ J. Heat Q_C is removed from the inside air.

$\Delta S_{in} = \dfrac{-Q_C}{T_C} = \dfrac{-8.064\times10^6 \text{ J}}{294.1 \text{ K}} = -2.74\times10^4$ J/K. $\Delta S_{net} = \Delta S_{out} + \Delta S_{in} = 8.1\times10^3$ J/K.

EVALUATE: The increase in the entropy of the outside air is greater than the entropy decrease of the air in the room.

20.57. **IDENTIFY** and **SET UP:** Use Eq. (20.13) for an infinitesimal heat flow dQ_H from the hot reservoir and use that expression with Eq. (20.19) to relate ΔS_H, the entropy change of the hot reservoir, to $|Q_C|$.

(a) EXECUTE: Consider an infinitesimal heat flow dQ_H that occurs when the temperature of the hot reservoir is T':

$dQ_C = -(T_C/T')dQ_H$

$\int dQ_C = -T_C \int \dfrac{dQ_H}{T'}$

$|Q_C| = T_C \left| \int \dfrac{dQ_H}{T'} \right| = T_C |\Delta S_H|$

(b) The 1.00 kg of water (the high-temperature reservoir) goes from 373 K to 273 K.

$Q_H = mc\Delta T = (1.00 \text{ kg})(4190 \text{ J/kg}\cdot\text{K})(100 \text{ K}) = 4.19\times10^5$ J

$\Delta S_H = mc\ln(T_2/T_1) = (1.00 \text{ kg})(4190 \text{ J/kg}\cdot\text{K})\ln(273/373) = -1308$ J/K

The result of part (a) gives $|Q_C| = (273 \text{ K})(1308 \text{ J/K}) = 3.57\times10^5$ J.

Q_C comes out of the engine, so $Q_C = -3.57\times10^5$ J

Then $W = Q_C + Q_H = -3.57\times10^5 \text{ J} + 4.19\times10^5 \text{ J} = 6.2\times10^4$ J.

(c) 2.00 kg of water goes from 323 K to 273 K

$Q_H = -mc\Delta T = (2.00 \text{ kg})(4190 \text{ J/kg}\cdot\text{K})(50 \text{ K}) = 4.19\times10^5$ J

$\Delta S_H = mc\ln(T_2/T_1) = (2.00 \text{ kg})(4190 \text{ J/kg}\cdot\text{K})\ln(272/323) = -1.41\times10^3$ J/K

$Q_C = -T_C|\Delta S_H| = -3.85\times10^5$ J

$W = Q_C + Q_H = 3.4\times10^4$ J

(d) EVALUATE: More work can be extracted from 1.00 kg of water at 373 K than from 2.00 kg of water at 323 K even though the energy that comes out of the water as it cools to 273 K is the same in both cases. The energy in the 323 K water is less available for conversion into mechanical work.

20.58. **IDENTIFY:** The maximum power that can be extracted is the total kinetic energy *K* of the mass of air that passes over the turbine blades in time *t*.

SET UP: The volume of a cylinder of diameter *d* and length *L* is $(\pi d^2/4)L$. Kinetic energy is $\frac{1}{2}mv^2$.

EXECUTE: **(a)** The cylinder described contains a mass of air $m = \rho(\pi d^2/4)L$, and so the total kinetic energy is $K = \rho(\pi/8)d^2Lv^2$. This mass of air will pass by the turbine in a time $t = L/v$, and so the maximum power is $P = \dfrac{K}{t} = \rho(\pi/8)d^2v^3$. Numerically, the product $\rho_{air}(\pi/8) \approx 0.5 \text{ kg/m}^3 = 0.5 \text{ W}\cdot\text{s}^3/\text{m}^5$. This completes the proof.

(b) $v = \left(\dfrac{P/e}{kd^2}\right)^{1/3} = \left(\dfrac{(3.2\times10^6 \text{ W})/(0.25)}{(0.5 \text{ W}\cdot\text{s}^3/\text{m}^5)(97 \text{ m})^2}\right)^{1/3} = 14 \text{ m/s} = 50 \text{ km/h}.$

(c) Wind speeds tend to be higher in mountain passes.

EVALUATE: The maximum power is proportional to v^3, so increases rapidly with increase in wind speed.

20.59. **IDENTIFY:** Apply Eq. (20.19). From the derivation of Eq. (20.6), $T_b = r^{\gamma-1}T_a$ and $T_c = r^{\gamma-1}T_d$.

SET UP: For a constant volume process, $dQ = nC_V dT$.

EXECUTE: **(a)** For a constant-volume process for an ideal gas, where the temperature changes from T_1 to T_2, $\Delta S = nC_V \int_{T_1}^{T_2} \frac{dT}{T} = nC_V \ln\left(\frac{T_2}{T_1}\right)$. The entropy changes are $nC_V \ln(T_c/T_b)$ and $nC_V \ln(T_a/T_d)$.

(b) The total entropy change for one cycle is the sum of the entropy changes found in part (a); the other processes in the cycle are adiabatic, with $Q = 0$ and $\Delta S = 0$. The total is then

$$\Delta S = nC_V \ln\frac{T_c}{T_b} + nC_V \ln\frac{T_a}{T_d} = nC_V \ln\left(\frac{T_c T_a}{T_b T_d}\right). \quad \frac{T_c T_a}{T_b T_d} = \frac{r^{\gamma-1}T_d T_a}{r^{\gamma-1}T_d T_a} = 1. \ \ln(1) = 0, \text{ so } \Delta S = 0.$$

(c) The system is not isolated, and a zero change of entropy for an irreversible system is certainly possible.

EVALUATE: In an irreversible process for an isolated system, $\Delta S > 0$. But the entropy change for some of the components of the system can be negative or zero.

20.60. **IDENTIFY:** For a reversible isothermal process, $\Delta S = \frac{Q}{T}$. For a reversible adiabatic process, $Q = 0$ and $\Delta S = 0$. The Carnot cycle consists of two reversible isothermal processes and two reversible adiabatic processes.

SET UP: Use the results for the Stirling cycle from Problem 20.52.

EXECUTE: **(a)** The graph is given in Figure 20.60.

(b) For a reversible process, $dS = \frac{dQ}{T}$, and so $dQ = T\,dS$, and $Q = \int dQ = \int T\,dS$, which is the area under the curve in the *TS* plane.

(c) Q_H is the area under the rectangle bounded by the horizontal part of the rectangle at T_H and the verticals. $|Q_C|$ is the area bounded by the horizontal part of the rectangle at T_C and the verticals. The net work is then $Q_H - |Q_C|$, the area bounded by the rectangle that represents the process. The ratio of the areas is the ratio of the lengths of the vertical sides of the respective rectangles, and the efficiency is $e = \frac{W}{Q_H} = \frac{T_H - T_C}{T_H}$.

(d) As explained in Problem 20.52, the substance that mediates the heat exchange during the isochoric expansion and compression does not leave the system, and the diagram is the same as in part (a). As found in that problem, the ideal efficiency is the same as for a Carnot-cycle engine.

EVALUATE: The derivation of e_{Carnot} using the concept of entropy is much simpler than the derivation in Section 20.6, but yields the same result.

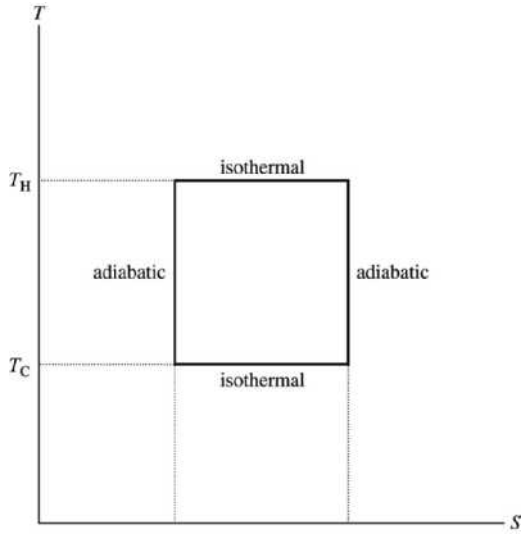

Figure 20.60

20.61. **IDENTIFY:** The temperatures of the ice-water mixture and of the boiling water are constant, so $\Delta S = \frac{Q}{T}$. The heat flow for the melting phase transition of the ice is $Q = +mL_f$.

SET UP: For water, $L_f = 3.34\times10^5$ J/kg.

EXECUTE: **(a)** The heat that goes into the ice-water mixture is $Q = mL_f = (0.120\text{ kg})(3.34\times10^5\text{ J/kg}) = 4.008\times10^4$ J. This same amount of heat leaves the boiling water, so $\Delta S = \frac{Q}{T} = \frac{-4.008\times10^4\text{ J}}{373\text{ K}} = -107$ J/K.

(b) $\Delta S = \frac{Q}{T} = \frac{4.008\times10^4\text{ J}}{273\text{ K}} = +147$ J/K.

(c) For any segment of the rod, the net heat flow is zero, so $\Delta S = 0$.

(d) $\Delta S_{tot} = -107\text{ J/K} + 147\text{ J/K} = +39.4$ J/K. (Carry extra figures when subtraction is involved.)

EVALUATE: The heat flow is irreversible, since the system is isolated and the total entropy change is positive.

20.62. **IDENTIFY:** Use the expression derived in Example 20.6 for the entropy change in a temperature change.

SET UP: For water, $c = 4190$ J/kg·K. $20°\text{C} = 293.15$ K, $78°\text{C} = 351.15$ K and $120°\text{C} = 393.15$ K.

EXECUTE:

(a) $\Delta S = mc\ln(T_2/T_1) = (250\times10^{-3}\text{ kg})(4190\text{ J/kg}\cdot\text{K})\ln(351.15\text{ K}/293.15\text{ K}) = 189$ J/K.

(b) $\Delta S = \frac{-mc\Delta T}{T_{element}} = \frac{-(250\times10^{-3}\text{ kg})(4190\text{ J/kg}\cdot\text{K})(351.15\text{ K} - 293.15\text{ K})}{393.15\text{ K}} = -155$ J/K.

(c) The sum of the result of parts (a) and (b) is $\Delta S_{system} = 34.6$ J/K. (Carry extra figures when subtraction is involved.)

EVALUATE: **(d)** Heating a liquid is not reversible. Whatever the energy source for the heating element, heat is being delivered at a higher temperature than that of the water, and the entropy loss of the source will be less in magnitude than the entropy gain of the water. The net entropy change is positive.

20.63. **IDENTIFY:** Use the expression derived in Example 20.6 for the entropy change in a temperature change. For the value of T for which ΔS is a maximum, $d(\Delta S)/dT = 0$.

SET UP: The heat flow for a temperature change is $Q = mc\Delta T$.

EXECUTE: **(a)** As in Example 20.10, the entropy change of the first object is $m_1c_1\ln(T/T_1)$ and that of the second is $m_2c_2\ln(T'/T_2)$, and so the net entropy change is as given. Neglecting heat transfer to the surroundings, $Q_1 + Q_2 = 0$, $m_1c_1(T - T_1) + m_2c_2(T' - T_2) = 0$, which is the given expression.

(b) Solving the energy-conservation relation for T' and substituting into the expression for ΔS gives $\Delta S = m_1c_1\ln\left(\frac{T}{T_1}\right) + m_2c_2\ln\left(1 - \frac{m_1c_1}{m_2c_2}\left(\frac{T}{T_2} - \frac{T_1}{T_2}\right)\right)$. Differentiating with respect to T and setting the derivative equal to 0 gives $0 = \frac{m_1c_1}{T} + \frac{(m_2c_2)(m_1c_1/m_2c_2)(-1/T_2)}{\left(1 - (m_1c_1/m_2c_2)\left(\frac{T}{T_2} - \frac{T_1}{T_2}\right)\right)}$. This may be solved for $T = \frac{m_1c_1T_1 + m_2c_2T_2}{m_1c_1 + m_2c_2}$. Using this value for T in the conservation of energy expression in part (a) and solving for T' gives $T' = \frac{m_1c_1T_1 + m_2c_2T_2}{m_1c_1 + m_2c_2}$. Therefore, $T = T'$ when ΔS is a maximum.

EVALUATE: **(c)** The final state of the system will be that for which no further entropy change is possible. If $T < T'$, it is possible for the temperatures to approach each other while increasing the total entropy, but when $T = T'$, no further spontaneous heat exchange is possible.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

20.64. **IDENTIFY:** Calculate Q_C and Q_H in terms of p and V at each point. Use the ideal gas law and the pressure-volume relation for adiabatic processes for an ideal gas. $e = 1 - \dfrac{|Q_C|}{|Q_H|}$.

SET UP: For an ideal gas, $C_p = C_V + R$, and taking air to be diatomic, $C_p = \frac{7}{2}R, C_V = \frac{5}{2}R$ and $\gamma = \frac{7}{5}$.

EXECUTE: Referring to Figure 20.7 in the textbook, $Q_H = n\frac{7}{2}R(T_c - T_b) = \frac{7}{2}(p_cV_c - p_bV_b)$. Similarly, $Q_C = n\frac{5}{2}R(p_aV_a - p_dV_d)$. What needs to be done is to find the relations between the product of the pressure and the volume at the four points. For an ideal gas, $\dfrac{p_cV_c}{T_c} = \dfrac{p_bV_b}{T_b}$ so $p_cV_c = p_aV_a\left(\dfrac{T_c}{T_a}\right)$. For a compression ratio r, and given that for the Diesel cycle the process ab is adiabatic, $p_bV_b = p_aV_a\left(\dfrac{V_a}{V_b}\right)^{\gamma-1} = p_aV_ar^{\gamma-1}$.

Similarly, $p_dV_d = p_cV_c\left(\dfrac{V_c}{V_a}\right)^{\gamma-1}$. Note that the last result uses the fact that process da is isochoric, and $V_d = V_a$; also, $p_c = p_b$ (process bc is isobaric), and so $V_c = V_b\left(\dfrac{T_c}{T_a}\right)$. Then,

$$\frac{V_c}{V_a} = \frac{T_c}{T_b}\cdot\frac{V_b}{V_a} = \frac{T_b}{T_a}\cdot\frac{T_a}{T_b}\cdot\frac{V_a}{V_b} = \frac{T_c}{T_a}\cdot\left(\frac{T_aV_a^{\gamma-1}}{T_bV_b^{\gamma-1}}\right)\left(\frac{V_a}{V_b}\right)^{-\gamma} = \frac{T_c}{T_a}r^{\gamma}$$

Combining the above results, $p_dV_d = p_aV_a\left(\dfrac{T_c}{T_a}\right)^{\gamma} r^{\gamma-\gamma^2}$. Substitution of the above results into Eq. (20.4) gives $e = 1 - \dfrac{5}{7}\left[\dfrac{\left(\dfrac{T_c}{T_a}\right)^{\gamma} r^{\gamma-\gamma^2} - 1}{\left(\dfrac{T_c}{T_a}\right) - r^{\gamma-1}}\right]$.

(b) $e = 1 - \dfrac{1}{1.4}\left[\dfrac{(5.002)r^{-0.56} - 1}{(3.167) - r^{0.40}}\right]$, where $\dfrac{T_c}{T_a} = 3.167$ and $\gamma = 1.40$ have been used. Substitution of $r = 21.0$ yields $e = 0.708 = 70.8\%$.

EVALUATE: The efficiency for an Otto cycle with $r = 21.0$ and $\gamma = 1.40$ is $e = 1 - r^{1-\gamma} = 1 - (21.0)^{-0.40} = 70.4\%$. This is very close to the value for the Diesel cycle.

21

ELECTRIC CHARGE AND ELECTRIC FIELD

21.1. **(a) IDENTIFY** and **SET UP:** Use the charge of one electron $(-1.602\times10^{-19}\ \text{C})$ to find the number of electrons required to produce the net charge.

EXECUTE: The number of excess electrons needed to produce net charge q is

$$\frac{q}{-e}=\frac{-3.20\times10^{-9}\ \text{C}}{-1.602\times10^{-19}\ \text{C/electron}}=2.00\times10^{10}\ \text{electrons.}$$

(b) IDENTIFY and **SET UP:** Use the atomic mass of lead to find the number of lead atoms in 8.00×10^{-3} kg of lead. From this and the total number of excess electrons, find the number of excess electrons per lead atom.

EXECUTE: The atomic mass of lead is 207×10^{-3} kg/mol, so the number of moles in 8.00×10^{-3} kg is $n=\frac{m_{\text{tot}}}{M}=\frac{8.00\times10^{-3}\ \text{kg}}{207\times10^{-3}\ \text{kg/mol}}=0.03865$ mol. N_{A} (Avogadro's number) is the number of atoms in 1 mole, so the number of lead atoms is $N=nN_{\text{A}}=(0.03865\ \text{mol})(6.022\times10^{23}\ \text{atoms/mol})=2.328\times10^{22}$ atoms.

The number of excess electrons per lead atom is $\frac{2.00\times10^{10}\ \text{electrons}}{2.328\times10^{22}\ \text{atoms}}=8.59\times10^{-13}$.

EVALUATE: Even this small net charge corresponds to a large number of excess electrons. But the number of atoms in the sphere is much larger still, so the number of excess electrons per lead atom is very small.

21.2. **IDENTIFY:** The charge that flows is the rate of charge flow times the duration of the time interval.

SET UP: The charge of one electron has magnitude $e=1.60\times10^{-19}$ C.

EXECUTE: The rate of charge flow is $20{,}000$ C/s and $t=100\ \mu\text{s}=1.00\times10^{-4}$ s.

$Q=(20{,}000\ \text{C/s})(1.00\times10^{-4}\ \text{s})=2.00$ C. The number of electrons is $n_{\text{e}}=\frac{Q}{1.60\times10^{-19}\ \text{C}}=1.25\times10^{19}$.

EVALUATE: This is a very large amount of charge and a large number of electrons.

21.3. **IDENTIFY:** From your mass estimate the number of protons in your body. You have an equal number of electrons.

SET UP: Assume a body mass of 70 kg. The charge of one electron is -1.60×10^{-19} C.

EXECUTE: The mass is primarily protons and neutrons of $m=1.67\times10^{-27}$ kg. The total number of protons and neutrons is $n_{\text{p and n}}=\frac{70\ \text{kg}}{1.67\times10^{-27}\ \text{kg}}=4.2\times10^{28}$. About one-half are protons, so $n_{\text{p}}=2.1\times10^{28}=n_{\text{e}}$. The number of electrons is about 2.1×10^{28}. The total charge of these electrons is

$Q=(-1.60\times10^{-19}\ \text{C/electron})(2.10\times10^{28}\ \text{electrons})=-3.35\times10^{9}$ C.

EVALUATE: This is a huge amount of negative charge. But your body contains an equal number of protons and your net charge is zero. If you carry a net charge, the number of excess or missing electrons is a very small fraction of the total number of electrons in your body.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

21.4. **IDENTIFY:** Use the mass m of the ring and the atomic mass M of gold to calculate the number of gold atoms. Each atom has 79 protons and an equal number of electrons.

SET UP: $N_A = 6.02\times10^{23}$ atoms/mol. A proton has charge $+e$.

EXECUTE: The mass of gold is 17.7 g and the atomic weight of gold is 197 g/mol. So the number of atoms is $N_A n = (6.02\times10^{23}\text{ atoms/mol})\left(\dfrac{17.7\text{ g}}{197\text{ g/mol}}\right) = 5.41\times10^{22}$ atoms. The number of protons is

$n_p = (79\text{ protons/atom})(5.41\times10^{22}\text{ atoms}) = 4.27\times10^{24}$ protons.

$Q = (n_p)(1.60\times10^{-19}\text{ C/proton}) = 6.83\times10^{5}$ C.

(b) The number of electrons is $n_e = n_p = 4.27\times10^{24}$.

EVALUATE: The total amount of positive charge in the ring is very large, but there is an equal amount of negative charge.

21.5. **IDENTIFY:** Each ion carries charge as it enters the axon.

SET UP: The total charge Q is the number N of ions times the charge of each one, which is e. So $Q = Ne$, where $e = 1.60\times10^{-19}$ C.

EXECUTE: The number N of ions is $N = (5.6\times10^{11}\text{ions/m})(1.5\times10^{-2}\text{ m}) = 8.4\times10^{9}\text{ions}$. The total charge Q carried by these ions is $Q = Ne = (8.4\times10^{9})(1.60\times10^{-19}\text{C}) = 1.3\times10^{-9}\text{C} = 1.3$ nC.

EVALUATE: The amount of charge is small, but these charges are close enough together to exert large forces on nearby charges.

21.6. **IDENTIFY:** Apply Coulomb's law and calculate the net charge q on each sphere.

SET UP: The magnitude of the charge of an electron is $e = 1.60\times10^{-19}$ C.

EXECUTE: $F = \dfrac{1}{4\pi\epsilon_0}\dfrac{q^2}{r^2}$. This gives

$|q| = \sqrt{4\pi\epsilon_0 F r^2} = \sqrt{4\pi\epsilon_0(4.57\times10^{-21}\text{ N})(0.200\text{ m})^2} = 1.43\times10^{-16}$ C. And therefore, the total number of electrons required is $n = |q|/e = (1.43\times10^{-16}\text{ C})/(1.60\times10^{-19}\text{ C/electron}) = 890$ electrons.

EVALUATE: Each sphere has 890 excess electrons and each sphere has a net negative charge. The two like charges repel.

21.7. **IDENTIFY:** Apply $F = \dfrac{k|q_1q_2|}{r^2}$ and solve for r.

SET UP: $F = 650$ N.

EXECUTE: $r = \sqrt{\dfrac{k|q_1q_2|}{F}} = \sqrt{\dfrac{(8.99\times10^{9}\text{ N}\cdot\text{m}^2/\text{C}^2)(1.0\text{ C})^2}{650\text{ N}}} = 3.7\times10^{3}\text{ m} = 3.7\text{ km}$

EVALUATE: Charged objects typically have net charges much less than 1 C.

21.8. **IDENTIFY:** Use the mass of a sphere and the atomic mass of aluminum to find the number of aluminum atoms in one sphere. Each atom has 13 electrons. Apply Coulomb's law and calculate the magnitude of charge $|q|$ on each sphere.

SET UP: $N_A = 6.02\times10^{23}$ atoms/mol. $|q| = n_e'e$, where n_e' is the number of electrons removed from one sphere and added to the other.

EXECUTE: **(a)** The total number of electrons on each sphere equals the number of protons.

$n_e = n_p = (13)(N_A)\left(\dfrac{0.0250\text{ kg}}{0.026982\text{ kg/mol}}\right) = 7.25\times10^{24}$ electrons.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) For a force of 1.00×10^4 N to act between the spheres, $F = 1.00\times10^4\ \text{N} = \dfrac{1}{4\pi\epsilon_0}\dfrac{q^2}{r^2}$. This gives $|q| = \sqrt{4\pi\epsilon_0(1.00\times10^4\ \text{N})(0.800\ \text{m})^2} = 8.43\times10^{-4}$ C. The number of electrons removed from one sphere and added to the other is $n_e' = |q|/e = 5.27\times10^{15}$ electrons.

(c) $n_e'/n_e = 7.27\times10^{-10}$.

EVALUATE: When ordinary objects receive a net charge the fractional change in the total number of electrons in the object is very small.

21.9. **IDENTIFY:** Apply Coulomb's law.

SET UP: Consider the force on one of the spheres.

(a) EXECUTE: $q_1 = q_2 = q$

$$F = \frac{1}{4\pi\epsilon_0}\frac{|q_1q_2|}{r^2} = \frac{q^2}{4\pi\epsilon_0 r^2} \text{ so } q = r\sqrt{\frac{F}{(1/4\pi\epsilon_0)}} = 0.150\ \text{m}\sqrt{\frac{0.220\ \text{N}}{8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2}} = 7.42\times10^{-7}\ \text{C (on each)}$$

(b) $q_2 = 4q_1$

$$F = \frac{1}{4\pi\epsilon_0}\frac{|q_1q_2|}{r^2} = \frac{4q_1^2}{4\pi\epsilon_0 r^2} \text{ so } q_1 = r\sqrt{\frac{F}{4(1/4\pi\epsilon_0)}} = \tfrac{1}{2}r\sqrt{\frac{F}{(1/4\pi\epsilon_0)}} = \tfrac{1}{2}(7.42\times10^{-7}\ \text{C}) = 3.71\times10^{-7}\ \text{C}.$$

And then $q_2 = 4q_1 = 1.48\times10^{-6}$ C.

EVALUATE: The force on one sphere is the same magnitude as the force on the other sphere, whether the spheres have equal charges or not.

21.10. **IDENTIFY:** We first need to determine the number of charges in each hand. Then we can use Coulomb's law to find the force these charges would exert on each hand.

SET UP: One mole of Ca contains $N_A = 6.02\times10^{23}$ atoms. Each proton has charge $e = 1.60\times10^{-19}$ C. The force each hand exerts on the other is $F = k\dfrac{q^2}{r^2}$.

EXECUTE: **(a)** The mass of one hand is $(0.010)(75\ \text{kg}) = 0.75\ \text{kg} = 750\ \text{g}$. The number of moles of Ca is $n = \dfrac{750\ \text{g}}{40.18\ \text{g/mol}} = 18.7$ mol. The number of atoms is

$N = nN_A = (18.7\ \text{mol})(6.02\times10^{23}\ \text{atoms/mol}) = 1.12\times10^{25}$ atoms.

(b) Each Ca atom contains positive charge $20e$. The total positive charge in each hand is $N_e = (1.12\times10^{25})(20)(1.60\times10^{-19}\ \text{C}) = 3.58\times10^7$ C. If 1.0% is unbalanced by negative charge, the net positive charge of each hand is $q = (0.010)(3.58\times10^7\ \text{C}) = 3.6\times10^5$ C.

(c) The repulsive force each hand exerts on the other would be

$F = k\dfrac{q^2}{r^2} = (8.99\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\dfrac{(3.6\times10^5\ \text{C})^2}{(1.7\ \text{m})^2} = 4.0\times10^{20}$ N. This is an immense force; our hands would fly off.

EVALUATE: Ordinary objects contain a very large amount of charge. But negative and positive charge is present in almost equal amounts and the net charge of a charged object is always a very small fraction of the total magnitude of charge that the object contains.

21.11. **IDENTIFY:** Apply $F = ma$, with $F = k\dfrac{|q_1q_2|}{r^2}$.

SET UP: $a = 25.0g = 245\ \text{m/s}^2$. An electron has charge $-e = -1.60\times10^{-19}$ C.

EXECUTE: $F = ma = (8.55\times10^{-3}\ \text{kg})(245\ \text{m/s}^2) = 2.09$ N. The spheres have equal charges q, so

$$F = k\frac{q^2}{r^2} \text{ and } |q| = r\sqrt{\frac{F}{k}} = (0.150\ \text{m})\sqrt{\frac{2.09\ \text{N}}{8.99\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2}} = 2.29\times10^{-6}\ \text{C}.$$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$N = \dfrac{|q|}{e} = \dfrac{2.29\times10^{-6}\ \text{C}}{1.60\times10^{-19}\ \text{C}} = 1.43\times10^{13}$ electrons. The charges on the spheres have the same sign so the electrical force is repulsive and the spheres accelerate away from each other.

EVALUATE: As the spheres move apart the repulsive force they exert on each other decreases and their acceleration decreases.

21.12. **IDENTIFY:** We need to determine the number of protons in each box and then use Coulomb's law to calculate the force each box would exert on the other.

SET UP: The mass of a proton is 1.67×10^{-27} kg and the charge of a proton is 1.60×10^{-19} C. The distance from the earth to the moon is 3.84×10^{8} m. The electrical force has magnitude $F_{\text{e}} = k\dfrac{|q_1 q_2|}{r^2}$, where $k = 8.99\times10^{9}\ \text{N}\cdot\text{m}^2/\text{C}^2$. The gravitational force has magnitude $F_{\text{grav}} = G\dfrac{m_1 m_2}{r^2}$, where $G = 6.67\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2$.

EXECUTE: **(a)** The number of protons in each box is $N = \dfrac{1.0\times10^{-3}\ \text{kg}}{1.67\times10^{-27}\ \text{kg}} = 5.99\times10^{23}$. The total charge of each box is $q = Ne = (5.99\times10^{23})(1.60\times10^{-19}\ \text{C}) = 9.58\times10^{4}\ \text{C}$. The electrical force on each box is $F_{\text{e}} = k\dfrac{q^2}{r^2} = (8.99\times10^{9}\ \text{N}\cdot\text{m}^2/\text{C}^2)\dfrac{(9.58\times10^{4}\ \text{C})^2}{(3.84\times10^{8}\ \text{m})^2} = 560\ \text{N} = 130\ \text{lb}$. The tension in the string must equal this repulsive electrical force. The weight of the box on earth is $w = mg = 9.8\times10^{-3}$ N and the weight of the box on the moon is even less, since g is less on the moon. The gravitational forces exerted on the boxes by the earth and by the moon are much less than the electrical force and can be neglected.

(b) $F_{\text{grav}} = G\dfrac{m_1 m_2}{r^2} = (6.67\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)\dfrac{(1.0\times10^{-3}\ \text{kg})^2}{(3.84\times10^{8}\ \text{m})^2} = 4.5\times10^{-34}\ \text{N}$.

EVALUATE: Both the electrical force and the gravitational force are proportional to $1/r^2$. But in SI units the coefficient k in the electrical force is much greater than the coefficient G in the gravitational force. And a small mass of protons contains a large amount of charge. It would be impossible to put 1.0 g of protons into a small box, because of the very large repulsive electrical forces the protons would exert on each other.

21.13. **IDENTIFY:** In a space satellite, the only force accelerating the free proton is the electrical repulsion of the other proton.

SET UP: Coulomb's law gives the force, and Newton's second law gives the acceleration: $a = F/m = (1/4\pi\epsilon_0)(e^2/r^2)/m$.

EXECUTE: **(a)** $a = (9.00\times10^{9}\ \text{N}\cdot\text{m}^2/\text{C}^2)(1.60\times10^{-19}\ \text{C})^2/[(0.00250\ \text{m})^2(1.67\times10^{-27}\ \text{kg})] = 2.21\times10^{4}\ \text{m/s}^2$.

(b) The graphs are sketched in Figure 21.13.

EVALUATE: The electrical force of a single stationary proton gives the moving proton an initial acceleration about 20,000 times as great as the acceleration caused by the gravity of the entire earth. As the protons move farther apart, the electrical force gets weaker, so the acceleration decreases. Since the protons continue to repel, the velocity keeps increasing, but at a decreasing rate.

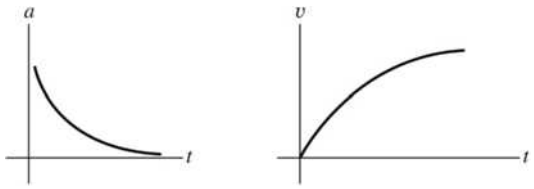

Figure 21.13

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

21.14. **IDENTIFY:** Apply Coulomb's law.
SET UP: Like charges repel and unlike charges attract.
EXECUTE: **(a)** $F = \dfrac{1}{4\pi\epsilon_0}\dfrac{|q_1 q_2|}{r^2}$. This gives $0.200\ \text{N} = \dfrac{1}{4\pi\epsilon_0}\dfrac{(0.550\times10^{-6}\ \text{C})|q_2|}{(0.30\ \text{m})^2}$ and $|q_2| = +3.64\times10^{-6}$ C. The force is attractive and $q_1 < 0$, so $q_2 = +3.64\times10^{-6}$ C.
(b) $F = 0.200$ N. The force is attractive, so is downward.
EVALUATE: The forces between the two charges obey Newton's third law.

21.15. **IDENTIFY:** Apply Coulomb's law. The two forces on q_3 must have equal magnitudes and opposite directions.
SET UP: Like charges repel and unlike charges attract.
EXECUTE: The force $\vec{F}_2$ that q_2 exerts on q_3 has magnitude $F_2 = k\dfrac{|q_2 q_3|}{r_2^2}$ and is in the $+x$-direction.
$\vec{F}_1$ must be in the $-x$-direction, so q_1 must be positive. $F_1 = F_2$ gives $k\dfrac{|q_1||q_3|}{r_1^2} = k\dfrac{|q_2||q_3|}{r_2^2}$.
$|q_1| = |q_2|\left(\dfrac{r_1}{r_2}\right)^2 = (3.00\ \text{nC})\left(\dfrac{2.00\ \text{cm}}{4.00\ \text{cm}}\right)^2 = 0.750\ \text{nC}$.
EVALUATE: The result for the magnitude of q_1 doesn't depend on the magnitude of q_2.

21.16. **IDENTIFY:** Apply Coulomb's law and find the vector sum of the two forces on Q.
SET UP: The force that q_1 exerts on Q is repulsive, as in Example 21.4, but now the force that q_2 exerts is attractive.
EXECUTE: The x-components cancel. We only need the y-components, and each charge contributes equally. $F_{1y} = F_{2y} = -\dfrac{1}{4\pi\epsilon_0}\dfrac{(2.0\times10^{-6}\ \text{C})(4.0\times10^{-6}\ \text{C})}{(0.500\ \text{m})^2}\sin\alpha = -0.173$ N (since $\sin\alpha = 0.600$).
Therefore, the total force is $2F = 0.35$ N, in the $-y$-direction.
EVALUATE: If q_1 is $-2.0\ \mu$C and q_2 is $+2.0\ \mu$C, then the net force is in the $+y$-direction.

21.17. **IDENTIFY:** Apply Coulomb's law and find the vector sum of the two forces on q_1.
SET UP: Like charges repel and unlike charges attract, so $\vec{F}_2$ and $\vec{F}_3$ are both in the $+x$-direction.
EXECUTE: $F_2 = k\dfrac{|q_1 q_2|}{r_{12}^2} = 6.749\times10^{-5}$ N, $F_3 = k\dfrac{|q_1 q_3|}{r_{13}^2} = 1.124\times10^{-4}$ N. $F = F_2 + F_3 = 1.8\times10^{-4}$ N.
$F = 1.8\times10^{-4}$ N and is in the $+x$-direction.
EVALUATE: Comparing our results to those in Example 21.3, we see that $\vec{F}_{1\text{ on }3} = -\vec{F}_{3\text{ on }1}$, as required by Newton's third law.

21.18. **IDENTIFY:** Apply Coulomb's law and find the vector sum of the two forces on q_2.
SET UP: $\vec{F}_{2\text{ on }1}$ is in the $+y$-direction.
EXECUTE: $F_{2\text{ on }1} = \dfrac{(9.0\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)(2.0\times10^{-6}\ \text{C})(2.0\times10^{-6}\ \text{C})}{(0.60\ \text{m})^2} = 0.100$ N. $(F_{2\text{ on }1})_x = 0$ and $(F_{2\text{ on }1})_y = +0.100$ N. $F_{Q\text{ on }1}$ is equal and opposite to $F_{1\text{ on }Q}$ (Example 21.4), so $(F_{Q\text{ on }1})_x = -0.23$ N and $(F_{Q\text{ on }1})_y = 0.17$ N. $F_x = (F_{2\text{ on }1})_x + (F_{Q\text{ on }1})_x = -0.23$ N.
$F_y = (F_{2\text{ on }1})_y + (F_{Q\text{ on }1})_y = 0.100\ \text{N} + 0.17\ \text{N} = 0.27$ N. The magnitude of the total force is $F = \sqrt{(0.23\ \text{N})^2 + (0.27\ \text{N})^2} = 0.35$ N. $\tan^{-1}\dfrac{0.23}{0.27} = 40°$, so $\vec{F}$ is $40°$ counterclockwise from the $+y$-axis, or $130°$ counterclockwise from the $+x$-axis.
EVALUATE: Both forces on q_1 are repulsive and are directed away from the charges that exert them.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

21.19. **IDENTIFY** and **SET UP:** Apply Coulomb's law to calculate the force exerted by q_2 and q_3 on q_1. Add these forces as vectors to get the net force. The target variable is the x-coordinate of q_3.

EXECUTE: $\vec{F}_2$ is in the x-direction.

$F_2 = k\dfrac{|q_1 q_2|}{r_{12}^2} = 3.37$ N, so $F_{2x} = +3.37$ N

$F_x = F_{2x} + F_{3x}$ and $F_x = -7.00$ N

$F_{3x} = F_x - F_{2x} = -7.00\text{ N} - 3.37\text{ N} = -10.37$ N

For F_{3x} to be negative, q_3 must be on the $-x$-axis.

$F_3 = k\dfrac{|q_1 q_3|}{x^2}$, so $|x| = \sqrt{\dfrac{k|q_1 q_3|}{F_3}} = 0.144$ m, so $x = -0.144$ m

EVALUATE: q_2 attracts q_1 in the $+x$-direction so q_3 must attract q_1 in the $-x$-direction, and q_3 is at negative x.

21.20. **IDENTIFY:** Apply Coulomb's law.

SET UP: Like charges repel and unlike charges attract. Let $\vec{F}_{21}$ be the force that q_2 exerts on q_1 and let $\vec{F}_{31}$ be the force that q_3 exerts on q_1.

EXECUTE: The charge q_3 must be to the right of the origin; otherwise both q_2 and q_3 would exert forces in the $+x$-direction. Calculating the two forces:

$$F_{21} = \frac{1}{4\pi\epsilon_0}\frac{|q_1 q_2|}{r_{12}^2} = \frac{(9\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)(3.00\times10^{-6}\ \text{C})(5.00\times10^{-6}\ \text{C})}{(0.200\ \text{m})^2} = 3.375\ \text{N},\ \text{in the } +x\text{-direction.}$$

$$F_{31} = \frac{(9\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)(3.00\times10^{-6}\ \text{C})(8.00\times10^{-6}\ \text{C})}{r_{13}^2} = \frac{0.216\ \text{N}\cdot\text{m}^2}{r_{13}^2},\ \text{in the } -x\text{-direction.}$$

We need $F_x = F_{21} - F_{31} = -7.00$ N, so $3.375\text{ N} - \dfrac{0.216\text{ N}\cdot\text{m}^2}{r_{13}^2} = -7.00$ N.

$$r_{13} = \sqrt{\frac{0.216\ \text{N}\cdot\text{m}^2}{3.375\ \text{N} + 7.00\ \text{N}}} = 0.144\ \text{m}.$$

q_3 is at $x = 0.144$ m.

EVALUATE: $F_{31} = 10.4$ N. F_{31} is larger than F_{21}, because $|q_3|$ is larger than $|q_2|$ and also because r_{13} is less than r_{12}.

21.21. **IDENTIFY:** Apply Coulomb's law to calculate the force each of the two charges exerts on the third charge. Add these forces as vectors.

SET UP: The three charges are placed as shown in Figure 21.21a.

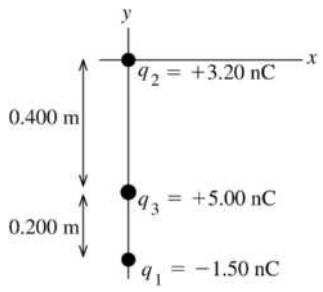

Figure 21.21a

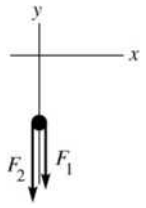
EXECUTE: Like charges repel and unlike attract, so the free-body diagram for q_3 is as shown in Figure 21.21b.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.



$$F_1 = \frac{1}{4\pi\epsilon_0}\frac{|q_1 q_3|}{r_{13}^2}$$

$$F_2 = \frac{1}{4\pi\epsilon_0}\frac{|q_2 q_3|}{r_{23}^2}$$

Figure 21.21b

$$F_1 = (8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\frac{(1.50\times10^{-9}\ \text{C})(5.00\times10^{-9}\ \text{C})}{(0.200\ \text{m})^2} = 1.685\times10^{-6}\ \text{N}$$

$$F_2 = (8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\frac{(3.20\times10^{-9}\ \text{C})(5.00\times10^{-9}\ \text{C})}{(0.400\ \text{m})^2} = 8.988\times10^{-7}\ \text{N}$$

The resultant force is $\vec{\boldsymbol{R}} = \vec{\boldsymbol{F}}_1 + \vec{\boldsymbol{F}}_2$.

$R_x = 0$.

$R_y = -(F_1 + F_2) = -(1.685\times10^{-6}\ \text{N} + 8.988\times10^{-7}\ \text{N}) = -2.58\times10^{-6}\ \text{N}$.

The resultant force has magnitude 2.58×10^{-6} N and is in the $-y$-direction.

EVALUATE: The force between q_1 and q_3 is attractive and the force between q_2 and q_3 is replusive.

21.22. **IDENTIFY:** Apply $F = k\frac{|qq'|}{r^2}$ to each pair of charges. The net force is the vector sum of the forces due to q_1 and q_2.

SET UP: Like charges repel and unlike charges attract. The charges and their forces on q_3 are shown in Figure 21.22.

EXECUTE: $F_1 = k\frac{|q_1 q_3|}{r_1^2} = (8.99\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\frac{(4.00\times10^{-9}\ \text{C})(6.00\times10^{-9}\ \text{C})}{(0.200\ \text{m})^2} = 5.394\times10^{-6}\ \text{N}.$

$$F_2 = k\frac{|q_2 q_3|}{r_2^2} = (8.99\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\frac{(5.00\times10^{-9}\ \text{C})(6.00\times10^{-9}\ \text{C})}{(0.300\ \text{m})^2} = 2.997\times10^{-6}\ \text{N}.$$

$F_x = F_{1x} + F_{2x} = +F_1 - F_2 = 2.40\times10^{-6}$ N. The net force has magnitude 2.40×10^{-6} N and is in the $+x$-direction.

EVALUATE: Each force is attractive, but the forces are in opposite directions because of the placement of the charges. Since the forces are in opposite directions, the net force is obtained by subtracting their magnitudes.

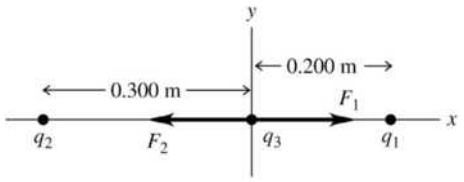


Figure 21.22

21.23. **IDENTIFY:** We use Coulomb's law to find each electrical force and combine these forces to find the net force.

SET UP: In the O-H-N combination the O^- is 0.170 nm from the H^+ and 0.280 nm from the N^-. In the N-H-N combination the N^- is 0.190 nm from the H^+ and 0.300 nm from the other N^-. Like charges repel and unlike charges attract. The net force is the vector sum of the individual forces. The force due to each pair of charges is $F = k\frac{|q_1 q_2|}{r^2} = k\frac{e^2}{r^2}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: **(a)** $F = k\dfrac{|q_1 q_2|}{r^2} = k\dfrac{e^2}{r^2}$.

O-H-N:

$$O^-\text{-}H^+\text{: } F = (8.99\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\frac{(1.60\times10^{-19}\ \text{C})^2}{(0.170\times10^{-9}\ \text{m})^2} = 7.96\times10^{-9}\ \text{N, attractive}$$

$$O^-\text{-}N^-\text{: } F = (8.99\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\frac{(1.60\times10^{-19}\ \text{C})^2}{(0.280\times10^{-9}\ \text{m})^2} = 2.94\times10^{-9}\ \text{N, repulsive}$$

N-H-N:

$$N^-\text{-}H^+\text{: } F = (8.99\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\frac{(1.60\times10^{-19}\ \text{C})^2}{(0.190\times10^{-9}\ \text{m})^2} = 6.38\times10^{-9}\ \text{N, attractive}$$

$$N^-\text{-}N^-\text{: } F = (8.99\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\frac{(1.60\times10^{-19}\ \text{C})^2}{(0.300\times10^{-9}\ \text{m})^2} = 2.56\times10^{-9}\ \text{N, repulsive}$$

The total attractive force is 1.43×10^{-8} N and the total repulsive force is 5.50×10^{-9} N. The net force is attractive and has magnitude $1.43\times10^{-8}\ \text{N} - 5.50\times10^{-9}\ \text{N} = 8.80\times10^{-9}$ N.

(b) $F = k\dfrac{e^2}{r^2} = (8.99\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\dfrac{(1.60\times10^{-19}\ \text{C})^2}{(0.0529\times10^{-9}\ \text{m})^2} = 8.22\times10^{-8}\ \text{N}$.

EVALUATE: The bonding force of the electron in the hydrogen atom is a factor of 10 larger than the bonding force of the adenine-thymine molecules.

21.24. **IDENTIFY:** We use Coulomb's law to find each electrical force and combine these forces to find the net force.

SET UP: In the O-H-O combination the O^- is 0.180 nm from the H^+ and 0.290 nm from the other O^-. In the N-H-N combination the N^- is 0.190 nm from the H^+ and 0.300 nm from the other N^-. In the O-H-N combination the O^- is 0.180 nm from the H^+ and 0.290 nm from the other N^-. Like charges repel and unlike charges attract. The net force is the vector sum of the individual forces. The force due to each pair of charges is $F = k\dfrac{|q_1 q_2|}{r^2} = k\dfrac{e^2}{r^2}$.

EXECUTE: Using $F = k\dfrac{|q_1 q_2|}{r^2} = k\dfrac{e^2}{r^2}$, we find that the attractive forces are: $O^-\text{-}H^+$, 7.10×10^{-9} N; $N^-\text{-}H^+$, 6.37×10^{-9} N; $O^-\text{-}H^+$, 7.10×10^{-9} N. The total attractive force is 2.06×10^{-8} N. The repulsive forces are: $O^-\text{-}O^-$, 2.74×10^{-9} N; $N^-\text{-}N^-$, 2.56×10^{-9} N; $O^-\text{-}N^-$, 2.74×10^{-9} N. The total repulsive force is 8.04×10^{-9} N. The net force is attractive and has magnitude 1.26×10^{-8} N.

EVALUATE: The net force is attractive, as it should be if the molecule is to stay together.

21.25. **IDENTIFY:** $F = |q|E$. Since the field is uniform, the force and acceleration are constant and we can use a constant acceleration equation to find the final speed.

SET UP: A proton has charge $+e$ and mass 1.67×10^{-27} kg.

EXECUTE: **(a)** $F = (1.60\times10^{-19}\ \text{C})(2.75\times10^3\ \text{N/C}) = 4.40\times10^{-16}\ \text{N}$

(b) $a = \dfrac{F}{m} = \dfrac{4.40\times10^{-16}\ \text{N}}{1.67\times10^{-27}\ \text{kg}} = 2.63\times10^{11}\ \text{m/s}^2$

(c) $v_x = v_{0x} + a_x t$ gives $v = (2.63\times10^{11}\ \text{m/s}^2)(1.00\times10^{-6}\ \text{s}) = 2.63\times10^5$ m/s

EVALUATE: The acceleration is very large and the gravity force on the proton can be ignored.

21.26. **IDENTIFY:** For a point charge, $E = k\dfrac{|q|}{r^2}$.

SET UP: $\vec{E}$ is toward a negative charge and away from a positive charge.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: **(a)** The field is toward the negative charge so is downward.

$$E = (8.99\times10^{9}\ \text{N}\cdot\text{m}^2/\text{C}^2)\frac{3.00\times10^{-9}\ \text{C}}{(0.250\ \text{m})^2} = 432\ \text{N/C}.$$

(b) $r = \sqrt{\dfrac{k|q|}{E}} = \sqrt{\dfrac{(8.99\times10^{9}\ \text{N}\cdot\text{m}^2/\text{C}^2)(3.00\times10^{-9}\ \text{C})}{12.0\ \text{N/C}}} = 1.50\ \text{m}$

EVALUATE: At different points the electric field has different directions, but it is always directed toward the negative point charge.

21.27. **IDENTIFY:** The acceleration that stops the charge is produced by the force that the electric field exerts on it. Since the field and the acceleration are constant, we can use the standard kinematics formulas to find acceleration and time.

(a) SET UP: First use kinematics to find the proton's acceleration. $v_x = 0$ when it stops. Then find the electric field needed to cause this acceleration using the fact that $F = qE$.

EXECUTE: $v_x^2 = v_{0x}^2 + 2a_x(x - x_0)$. $0 = (4.50\times10^{6}\ \text{m/s})^2 + 2a(0.0320\ \text{m})$ and $a = 3.16\times10^{14}\ \text{m/s}^2$. Now find the electric field, with $q = e$. $eE = ma$ and

$E = ma/e = (1.67\times10^{-27}\ \text{kg})(3.16\times10^{14}\ \text{m/s}^2)/(1.60\times10^{-19}\ \text{C}) = 3.30\times10^{6}\ \text{N/C}$, to the left.

(b) SET UP: Kinematics gives $v = v_0 + at$, and $v = 0$ when the electron stops, so $t = v_0/a$.

EXECUTE: $t = v_0/a = (4.50\times10^{6}\ \text{m/s})/(3.16\times10^{14}\ \text{m/s}^2) = 1.42\times10^{-8}\ \text{s} = 14.2\ \text{ns}$

(c) SET UP: In part (a) we saw that the electric field is proportional to m, so we can use the ratio of the electric fields. $E_e/E_p = m_e/m_p$ and $E_e = (m_e/m_p)E_p$.

EXECUTE: $E_e = [(9.11\times10^{-31}\ \text{kg})/(1.67\times10^{-27}\ \text{kg})](3.30\times10^{6}\ \text{N/C}) = 1.80\times10^{3}\ \text{N/C}$, to the right

EVALUATE: Even a modest electric field, such as the ones in this situation, can produce enormous accelerations for electrons and protons.

21.28. **IDENTIFY:** Use constant acceleration equations to calculate the upward acceleration a and then apply $\vec{F} = q\vec{E}$ to calculate the electric field.

SET UP: Let $+y$ be upward. An electron has charge $q = -e$.

EXECUTE: **(a)** $v_{0y} = 0$ and $a_y = a$, so $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$ gives $y - y_0 = \frac{1}{2}at^2$. Then

$$a = \frac{2(y - y_0)}{t^2} = \frac{2(4.50\ \text{m})}{(3.00\times10^{-6}\ \text{s})^2} = 1.00\times10^{12}\ \text{m/s}^2.$$

$$E = \frac{F}{q} = \frac{ma}{q} = \frac{(9.11\times10^{-31}\ \text{kg})(1.00\times10^{12}\ \text{m/s}^2)}{1.60\times10^{-19}\ \text{C}} = 5.69\ \text{N/C}$$

The force is up, so the electric field must be *downward* since the electron has negative charge.

(b) The electron's acceleration is $\sim10^{11}g$, so gravity must be negligibly small compared to the electrical force.

EVALUATE: Since the electric field is uniform, the force it exerts is constant and the electron moves with constant acceleration.

21.29. **(a) IDENTIFY:** Eq. (21.4) relates the electric field, charge of the particle, and the force on the particle. If the particle is to remain stationary the net force on it must be zero.

SET UP: The free-body diagram for the particle is sketched in Figure 21.29. The weight is mg, downward. For the net force to be zero the force exerted by the electric field must be upward. The electric field is downward. Since the electric field and the electric force are in opposite directions the charge of the particle is negative.

$$mg = |q|E$$

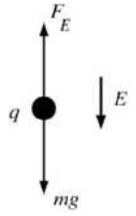

Figure 21.29

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: $|q| = \dfrac{mg}{E} = \dfrac{(1.45\times10^{-3}\ \text{kg})(9.80\ \text{m/s}^2)}{650\ \text{N/C}} = 2.19\times10^{-5}\ \text{C}$ and $q = -21.9\ \mu\text{C}$

(b) SET UP: The electrical force has magnitude $F_E = |q|E = eE$. The weight of a proton is $w = mg$. $F_E = w$ so $eE = mg$

EXECUTE: $E = \dfrac{mg}{e} = \dfrac{(1.673\times10^{-27}\ \text{kg})(9.80\ \text{m/s}^2)}{1.602\times10^{-19}\ \text{C}} = 1.02\times10^{-7}\ \text{N/C}.$

This is a very small electric field.

EVALUATE: In both cases $|q|E = mg$ and $E = (m/|q|)g$. In part (b) the $m/|q|$ ratio is much smaller $(\sim10^{-8})$ than in part (a) $(\sim10^{2})$ so E is much smaller in (b). For subatomic particles gravity can usually be ignored compared to electric forces.

21.30. **IDENTIFY:** The net electric field is the vector sum of the individual fields.

SET UP: The distance from a corner to the center of the square is $r = \sqrt{(a/2)^2 + (a/2)^2} = a/\sqrt{2}$. The magnitude of the electric field due to each charge is the same and equal to $E_q = \dfrac{kq}{r^2} = 2\dfrac{kq}{a^2}$. All four y-components add and the x-components cancel.

EXECUTE: Each y-component is equal to $E_{qy} = -E_q\cos45° = -\dfrac{E_q}{\sqrt{2}} = \dfrac{-2kq}{\sqrt{2}a^2} = -\dfrac{\sqrt{2}kq}{a^2}$. The resultant field is $\dfrac{4\sqrt{2}kq}{a^2}$, in the $-y$-direction.

EVALUATE: We must add the y-components of the fields, not their magnitudes.

21.31. **IDENTIFY:** For a point charge, $E = k\dfrac{|q|}{r^2}$. The net field is the vector sum of the fields produced by each charge. A charge q in an electric field $\vec{\boldsymbol{E}}$ experiences a force $\vec{\boldsymbol{F}} = q\vec{\boldsymbol{E}}$.

SET UP: The electric field of a negative charge is directed toward the charge. Point A is 0.100 m from q_2 and 0.150 m from q_1. Point B is 0.100 m from q_1 and 0.350 m from q_2.

EXECUTE: **(a)** The electric fields at point A due to the charges are shown in Figure 21.31a.

$$E_1 = k\frac{|q_1|}{r_{A1}^2} = (8.99\times10^{9}\ \text{N}\cdot\text{m}^2/\text{C}^2)\frac{6.25\times10^{-9}\ \text{C}}{(0.150\ \text{m})^2} = 2.50\times10^{3}\ \text{N/C}$$

$$E_2 = k\frac{|q_2|}{r_{A2}^2} = (8.99\times10^{9}\ \text{N}\cdot\text{m}^2/\text{C}^2)\frac{12.5\times10^{-9}\ \text{C}}{(0.100\ \text{m})^2} = 1.124\times10^{4}\ \text{N/C}$$

Since the two fields are in opposite directions, we subtract their magnitudes to find the net field.

$E = E_2 - E_1 = 8.74\times10^{3}\ \text{N/C},$ to the right.

(b) The electric fields at point B are shown in Figure 21.31b.

$$E_1 = k\frac{|q_1|}{r_{B1}^2} = (8.99\times10^{9}\ \text{N}\cdot\text{m}^2/\text{C}^2)\frac{6.25\times10^{-9}\ \text{C}}{(0.100\ \text{m})^2} = 5.619\times10^{3}\ \text{N/C}$$

$$E_2 = k\frac{|q_2|}{r_{B2}^2} = (8.99\times10^{9}\ \text{N}\cdot\text{m}^2/\text{C}^2)\frac{12.5\times10^{-9}\ \text{C}}{(0.350\ \text{m})^2} = 9.17\times10^{2}\ \text{N/C}$$

Since the fields are in the same direction, we add their magnitudes to find the net field.

$E = E_1 + E_2 = 6.54\times10^{3}\ \text{N/C},$ to the right.

(c) At A, $E = 8.74\times10^{3}\ \text{N/C},$ to the right. The force on a proton placed at this point would be

$F = qE = (1.60\times10^{-19}\ \text{C})(8.74\times10^{3}\ \text{N/C}) = 1.40\times10^{-15}\ \text{N},$ to the right.

EVALUATE: A proton has positive charge so the force that an electric field exerts on it is in the same direction as the field.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

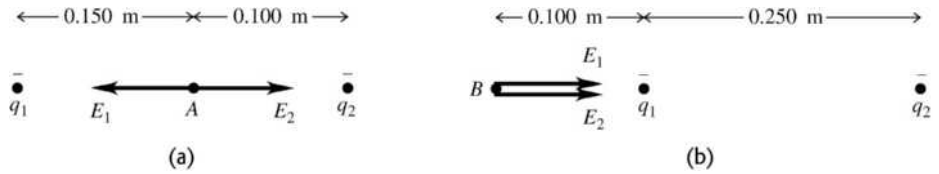

Figure 21.31

21.32. **IDENTIFY:** The electric force is $\vec{F} = q\vec{E}$.

SET UP: The gravity force (weight) has magnitude $w = mg$ and is downward.

EXECUTE: **(a)** To balance the weight the electric force must be upward. The electric field is downward, so for an upward force the charge q of the person must be negative. $w = F$ gives $mg = |q|E$ and

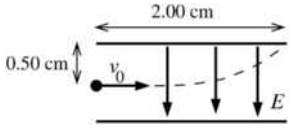
$$|q| = \frac{mg}{E} = \frac{(60\text{ kg})(9.80\text{ m/s}^2)}{150\text{ N/C}} = 3.9\text{ C}.$$

(b) $F = k\dfrac{|qq'|}{r^2} = (8.99\times10^9\text{ N}\cdot\text{m}^2/\text{C}^2)\dfrac{(3.9\text{ C})^2}{(100\text{ m})^2} = 1.4\times10^7\text{ N}$. The repulsive force is immense and this is not a feasible means of flight.

EVALUATE: The net charge of charged objects is typically much less than 1 C.

21.33. **IDENTIFY:** Eq. (21.3) gives the force on the particle in terms of its charge and the electric field between the plates. The force is constant and produces a constant acceleration. The motion is similar to projectile motion; use constant acceleration equations for the horizontal and vertical components of the motion.

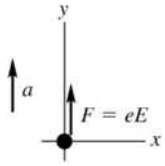
(a) SET UP: The motion is sketched in Figure 21.33a.



For an electron $q = -e$.

Figure 21.33a

$\vec{F} = q\vec{E}$ and q negative gives that $\vec{F}$ and $\vec{E}$ are in opposite directions, so $\vec{F}$ is upward. The free-body diagram for the electron is given in Figure 21.33b.



EXECUTE: $\sum F_y = ma_y$

$eE = ma$

Figure 21.33b

Solve the kinematics to find the acceleration of the electron: Just misses upper plate says that $x - x_0 = 2.00$ cm when $y - y_0 = +0.500$ cm.

<u>x-component</u>

$v_{0x} = v_0 = 1.60\times10^6$ m/s, $a_x = 0$, $x - x_0 = 0.0200$ m, $t = ?$

$x - x_0 = v_{0x}t + \frac{1}{2}a_xt^2$

$$t = \frac{x - x_0}{v_{0x}} = \frac{0.0200\text{ m}}{1.60\times10^6\text{ m/s}} = 1.25\times10^{-8}\text{ s}$$

In this same time t the electron travels 0.0050 m vertically:

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

y-component

$t = 1.25\times10^{-8}$ s, $v_{0y} = 0$, $y - y_0 = +0.0050$ m, $a_y = ?$

$y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$

$$a_y = \frac{2(y-y_0)}{t^2} = \frac{2(0.0050\text{ m})}{(1.25\times10^{-8}\text{ s})^2} = 6.40\times10^{13}\text{ m/s}^2$$

(This analysis is very similar to that used in Chapter 3 for projectile motion, except that here the acceleration is upward rather than downward.) This acceleration must be produced by the electric-field force: $eE = ma$

$$E = \frac{ma}{e} = \frac{(9.109\times10^{-31}\text{ kg})(6.40\times10^{13}\text{ m/s}^2)}{1.602\times10^{-19}\text{ C}} = 364\text{ N/C}$$

Note that the acceleration produced by the electric field is much larger than g, the acceleration produced by gravity, so it is perfectly ok to neglect the gravity force on the elctron in this problem.

(b) $$a = \frac{eE}{m_p} = \frac{(1.602\times10^{-19}\text{ C})(364\text{ N/C})}{1.673\times10^{-27}\text{ kg}} = 3.49\times10^{10}\text{ m/s}^2$$

This is much less than the acceleration of the electron in part (a) so the vertical deflection is less and the proton won't hit the plates. The proton has the same initial speed, so the proton takes the same time $t = 1.25\times10^{-8}$ s to travel horizontally the length of the plates. The force on the proton is downward (in the same direction as $\vec{E}$, since q is positive), so the acceleration is downward and $a_y = -3.49\times10^{10}$ m/s^2. $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2 = \frac{1}{2}(-3.49\times10^{10}\text{ m/s}^2)(1.25\times10^{-8}\text{ s})^2 = -2.73\times10^{-6}$ m. The displacement is 2.73×10^{-6} m, downward.

(c) EVALUATE: The displacements are in opposite directions because the electron has negative charge and the proton has positive charge. The electron and proton have the same magnitude of charge, so the force the electric field exerts has the same magnitude for each charge. But the proton has a mass larger by a factor of 1836 so its acceleration and its vertical displacement are smaller by this factor.

(d) In each case $a \gg g$ and it is reasonable to ignore the effects of gravity.

21.34. **IDENTIFY:** Apply Eq. (21.7) to calculate the electric field due to each charge and add the two field vectors to find the resultant field.

SET UP: For q_1, $\hat{r} = \hat{j}$. For q_2, $\hat{r} = \cos\theta\hat{i} + \sin\theta\hat{j}$, where θ is the angle between $\vec{E}_2$ and the $+x$-axis.

EXECUTE: **(a)** $$\vec{E}_1 = \frac{q_1}{4\pi\epsilon_0 r_1^2}\hat{j} = \frac{(9.0\times10^9\text{ N}\cdot\text{m}^2/\text{C}^2)(-5.00\times10^{-9}\text{ C})}{(0.0400\text{ m})^2}\hat{j} = (-2.813\times10^4\text{ N/C})\,\hat{j}.$$

$$|\vec{E}_2| = \frac{q_2}{4\pi\epsilon_0 r_2^2} = \frac{(9.0\times10^9\text{ N}\cdot\text{m}^2/\text{C}^2)(3.00\times10^{-9}\text{ C})}{(0.0300\text{ m})^2 + (0.0400\text{ m})^2} = 1.080\times10^4\text{ N/C}.$$ The angle of $\vec{E}_2$, measured from the x-axis, is $180° - \tan^{-1}\left(\frac{4.00\text{ cm}}{3.00\text{ cm}}\right) = 126.9°$ Thus

$$\vec{E}_2 = (1.080\times10^4\text{ N/C})(\hat{i}\cos126.9° + \hat{j}\sin126.9°) = (-6.485\times10^3\text{ N/C})\hat{i} + (8.64\times10^3\text{ N/C})\hat{j}$$

(b) The resultant field is $\vec{E}_1 + \vec{E}_2 = (-6.485\times10^3\text{ N/C})\hat{i} + (-2.813\times10^4\text{ N/C} + 8.64\times10^3\text{ N/C})\hat{j}$.

$$\vec{E}_1 + \vec{E}_2 = (-6.485\times10^3\text{ N/C})\hat{i} - (1.95\times10^4\text{ N/C})\hat{j}.$$

EVALUATE: $\vec{E}_1$ is toward q_1 since q_1 is negative. $\vec{E}_2$ is directed away from q_2, since q_2 is positive.

21.35. **IDENTIFY:** Apply constant acceleration equations to the motion of the electron.

SET UP: Let $+x$ be to the right and let $+y$ be downward. The electron moves 2.00 cm to the right and 0.50 cm downward.

EXECUTE: Use the horizontal motion to find the time when the electron emerges from the field. $x - x_0 = 0.0200$ m, $a_x = 0$, $v_{0x} = 1.60\times10^6$ m/s. $x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2$ gives $t = 1.25\times10^{-8}$ s. Since $a_x = 0$, $v_x = 1.60\times10^6$ m/s. $y - y_0 = 0.0050$ m, $v_{0y} = 0$, $t = 1.25\times10^{-8}$ s. $y - y_0 = \left(\frac{v_{0y} + v_y}{2}\right)t$ gives

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$v_y = 8.00\times10^5$ m/s. Then $v = \sqrt{v_x^2 + v_y^2} = 1.79\times10^6$ m/s.

EVALUATE: $v_y = v_{0y} + a_y t$ gives $a_y = 6.4\times10^{13}$ m/s^2. The electric field between the plates is

$$E = \frac{ma_y}{e} = \frac{(9.11\times10^{-31}\text{ kg})(6.4\times10^{13}\text{ m/s}^2)}{1.60\times10^{-19}\text{ C}} = 364\text{ V/m}.$$ This is not a very large field.

21.36. **IDENTIFY:** Use the components of $\vec{E}$ from Example 21.6 to calculate the magnitude and direction of $\vec{E}$. Use $\vec{F} = q\vec{E}$ to calculate the force on the -2.5 nC charge and use Newton's third law for the force on the -8.0 nC charge.

SET UP: From Example 21.6, $\vec{E} = (-11\text{ N/C})\,\hat{i} + (14\text{ N/C})\,\hat{j}$.

EXECUTE: **(a)** $E = \sqrt{E_x^2 + E_y^2} = \sqrt{(-11\text{ N/C})^2 + (14\text{ N/C})^2} = 17.8$ N/C.

$\tan^{-1}\left(\dfrac{|E_y|}{|E_x|}\right) = \tan^{-1}(14/11) = 51.8°$, so $\theta = 128°$ counterclockwise from the $+x$-axis.

(b) (i) $\vec{F} = \vec{E}q$ so $F = (17.8\text{ N/C})(2.5\times10^{-9}\text{ C}) = 4.45\times10^{-8}$ N, at 52° below the $+x$-axis.

(ii) 4.45×10^{-8} N at 128° counterclockwise from the $+x$-axis.

EVALUATE: The forces in part (b) are repulsive so they are along the line connecting the two charges and in each case the force is directed away from the charge that exerts it.

21.37. **IDENTIFY:** The forces the charges exert on each other are given by Coulomb's law. The net force on the proton is the vector sum of the forces due to the electrons.

SET UP: $q_e = -1.60\times10^{-19}$ C. $q_p = +1.60\times10^{-19}$ C. The net force is the vector sum of the forces exerted by each electron. Each force has magnitude $F = k\dfrac{|q_1 q_2|}{r^2} = k\dfrac{e^2}{r^2}$ and is attractive so is directed toward the electron that exerts it.

EXECUTE: Each force has magnitude

$$F_1 = F_2 = k\frac{|q_1 q_2|}{r^2} = k\frac{e^2}{r^2} = \frac{(8.988\times10^9\text{ N}\cdot\text{m}^2/\text{C}^2)(1.60\times10^{-19}\text{ C})^2}{(1.50\times10^{-10}\text{ m})^2} = 1.023\times10^{-8}\text{ N}.$$ The vector force diagram is shown in Figure 21.37.

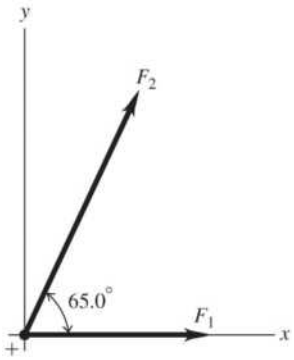


Figure 21. 37

Taking components, we get $F_{1x} = 1.023\times10^{-8}$ N; $F_{1y} = 0$. $F_{2x} = F_2\cos65.0° = 4.32\times10^{-9}$ N;

$F_{2y} = F_2\sin65.0° = 9.27\times10^{-9}$ N. $F_x = F_{1x} + F_{2x} = 1.46\times10^{-8}$ N; $F_y = F_{1y} + F_{2y} = 9.27\times10^{-9}$ N.

$F = \sqrt{F_x^2 + F_y^2} = 1.73\times10^{-8}$ N. $\tan\theta = \dfrac{F_y}{F_x} = \dfrac{9.27\times10^{-9}\text{ N}}{1.46\times10^{-8}\text{ N}} = 0.6349$ which gives

$\theta = 32.4°$. The net force is 1.73×10^{-8} N and is directed toward a point midway between the two electrons.

EVALUATE: Note that the net force is less than the algebraic sum of the individual forces.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

21.38. **IDENTIFY:** Apply constant acceleration equations to the motion of the proton. $E = F/|q|$.

SET UP: A proton has mass $m_p = 1.67\times10^{-27}$ kg and charge $+e$. Let $+x$ be in the direction of motion of the proton.

EXECUTE: **(a)** $v_{0x} = 0$. $a = \dfrac{eE}{m_p}$. $x - x_0 = v_{0x}t + \frac{1}{2}a_xt^2$ gives $x - x_0 = \dfrac{1}{2}a_xt^2 = \dfrac{1}{2}\dfrac{eE}{m_p}t^2$. Solving for E gives

$$E = \frac{2(0.0160\text{ m})(1.67\times10^{-27}\text{ kg})}{(1.60\times10^{-19}\text{ C})(1.50\times10^{-6}\text{ s})^2} = 148\text{ N/C}.$$

(b) $v_x = v_{0x} + a_xt = \dfrac{eE}{m_p}t = 2.13\times10^4$ m/s.

EVALUATE: The electric field is directed from the positively charged plate toward the negatively charged plate and the force on the proton is also in this direction.

21.39. **IDENTIFY:** Find the angle θ that $\hat{\boldsymbol{r}}$ makes with the $+x$-axis. Then $\hat{\boldsymbol{r}} = (\cos\theta)\hat{\boldsymbol{i}} + (\sin\theta)\hat{\boldsymbol{j}}$. .

SET UP: $\tan\theta = y/x$

EXECUTE: **(a)** $\tan^{-1}\left(\dfrac{-1.35}{0}\right) = -\dfrac{\pi}{2}$ rad. $\hat{\boldsymbol{r}} = -\hat{\boldsymbol{j}}$.

(b) $\tan^{-1}\left(\dfrac{12}{12}\right) = \dfrac{\pi}{4}$ rad. $\hat{\boldsymbol{r}} = \dfrac{\sqrt{2}}{2}\hat{\boldsymbol{i}} + \dfrac{\sqrt{2}}{2}\hat{\boldsymbol{j}}$.

(c) $\tan^{-1}\left(\dfrac{2.6}{+1.10}\right) = 1.97\text{ rad} = 112.9°$. $\hat{\boldsymbol{r}} = -0.39\hat{\boldsymbol{i}} + 0.92\hat{\boldsymbol{j}}$ (Second quadrant).

EVALUATE: In each case we can verify that $\hat{\boldsymbol{r}}$ is a unit vector, because $\hat{\boldsymbol{r}}\cdot\hat{\boldsymbol{r}} = 1$.

21.40. **IDENTIFY:** The net force on each charge must be zero.

SET UP: The force diagram for the $-6.50\,\mu$C charge is given in Figure 21.40. F_E is the force exerted on the charge by the uniform electric field. The charge is negative and the field is to the right, so the force exerted by the field is to the left. F_q is the force exerted by the other point charge. The two charges have opposite signs, so the force is attractive. Take the $+x$ axis to be to the right, as shown in the figure.

EXECUTE: **(a)** $F_E = |q|E = (6.50\times10^{-6}\text{ C})(1.85\times10^8\text{ N/C}) = 1.20\times10^3$ N

$$F_q = k\frac{|q_1q_2|}{r^2} = (8.99\times10^9\text{ N}\cdot\text{m}^2/\text{C}^2)\frac{(6.50\times10^{-6}\text{ C})(8.75\times10^{-6}\text{ C})}{(0.0250\text{ m})^2} = 8.18\times10^2\text{ N}$$

$\sum F_x = 0$ gives $T + F_q - F_E = 0$ and $T = F_E - F_q = 382$ N.

(b) Now F_q is to the left, since like charges repel.

$\sum F_x = 0$ gives $T - F_q - F_E = 0$ and $T = F_E + F_q = 2.02\times10^3$ N.

EVALUATE: The tension is much larger when both charges have the same sign, so the force one charge exerts on the other is repulsive.

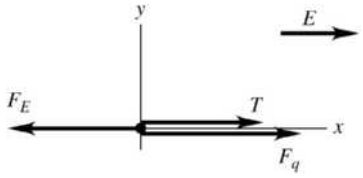

Figure 21.40

21.41. **IDENTIFY** and **SET UP:** Use $\vec{\boldsymbol{E}}$ in Eq. (21.3) to calculate $\vec{\boldsymbol{F}}$, $\vec{\boldsymbol{F}} = m\vec{\boldsymbol{a}}$ to calculate $\vec{\boldsymbol{a}}$, and a constant acceleration equation to calculate the final velocity. Let $+x$ be east.

(a) EXECUTE: $F_x = |q|E = (1.602\times10^{-19}\text{ C})(1.50\text{ N/C}) = 2.403\times10^{-19}$ N

$a_x = F_x/m = (2.403\times10^{-19}\text{ N})/(9.109\times10^{-31}\text{ kg}) = +2.638\times10^{11}\text{ m/s}^2$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$v_{0x} = +4.50\times10^5$ m/s, $a_x = +2.638\times10^{11}$ m/s^2, $x - x_0 = 0.375$ m, $v_x = ?$

$v_x^2 = v_{0x}^2 + 2a_x(x - x_0)$ gives $v_x = 6.33\times10^5$ m/s

EVALUATE: $\vec{E}$ is west and q is negative, so $\vec{F}$ is east and the electron speeds up.

(b) EXECUTE: $F_x = -|q|E = -(1.602\times10^{-19}\text{ C})(1.50\text{ N/C}) = -2.403\times10^{-19}$ N

$a_x = F_x/m = (-2.403\times10^{-19}\text{ N})/(1.673\times10^{-27}\text{ kg}) = -1.436\times10^8$ m/s^2

$v_{0x} = +1.90\times10^4$ m/s, $a_x = -1.436\times10^8$ m/s^2, $x - x_0 = 0.375$ m, $v_x = ?$

$v_x^2 = v_{0x}^2 + 2a_x(x - x_0)$ gives $v_x = 1.59\times10^4$ m/s

EVALUATE: $q > 0$ so $\vec{F}$ is west and the proton slows down.

21.42. **IDENTIFY:** The net electric field is the vector sum of the fields due to the individual charges.
SET UP: The electric field points toward negative charge and away from positive charge.

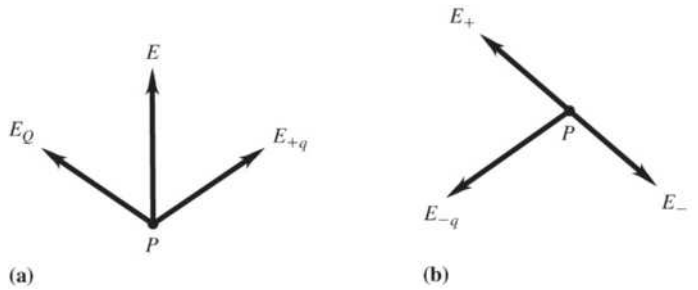

Figure 21.42

EXECUTE: **(a)** Figure 21.42a shows $\vec{E}_Q$ and $\vec{E}_{+q}$ at point P. $\vec{E}_Q$ must have the direction shown, to produce a resultant field in the specified direction. $\vec{E}_Q$ is toward Q, so Q is negative. In order for the horizontal components of the two fields to cancel, Q and q must have the same magnitude.
(b) No. If the lower charge were negative, its field would be in the direction shown in Figure 21.42b. The two possible directions for the field of the upper charge, when it is positive ($\vec{E}_+$) or negative ($\vec{E}_-$), are shown. In neither case is the resultant field in the direction shown in the figure in the problem.
EVALUATE: When combining electric fields, it is always essential to pay attention to their directions.

21.43. **IDENTIFY:** Calculate the electric field due to each charge and find the vector sum of these two fields.
SET UP: At points on the x-axis only the x component of each field is nonzero. The electric field of a point charge points away from the charge if it is positive and toward it if it is negative.
EXECUTE: **(a)** Halfway between the two charges, $E = 0$.

(b) For $|x| < a$, $E_x = \dfrac{1}{4\pi\epsilon_0}\left(\dfrac{q}{(a+x)^2} - \dfrac{q}{(a-x)^2}\right) = -\dfrac{4q}{4\pi\epsilon_0}\dfrac{ax}{(x^2-a^2)^2}$.

For $x > a$, $E_x = \dfrac{1}{4\pi\epsilon_0}\left(\dfrac{q}{(a+x)^2} + \dfrac{q}{(a-x)^2}\right) = \dfrac{2q}{4\pi\epsilon_0}\dfrac{x^2+a^2}{(x^2-a^2)^2}$.

For $x < -a$, $E_x = \dfrac{-1}{4\pi\epsilon_0}\left(\dfrac{q}{(a+x)^2} + \dfrac{q}{(a-x)^2}\right) = -\dfrac{2q}{4\pi\epsilon_0}\dfrac{x^2+a^2}{(x^2-a^2)^2}$.

The graph of E_x versus x is sketched in Figure 21.43.

EVALUATE: The magnitude of the field approaches infinity at the location of one of the point charges.

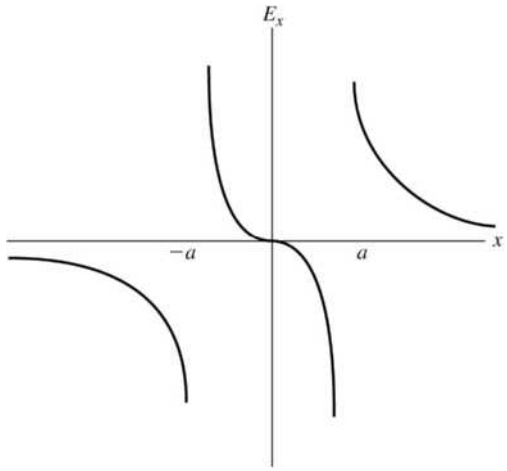

Figure 21.43

21.44. **IDENTIFY:** Add the individual electric fields to obtain the net field.
SET UP: The electric field points away from positive charge and toward negative charge.

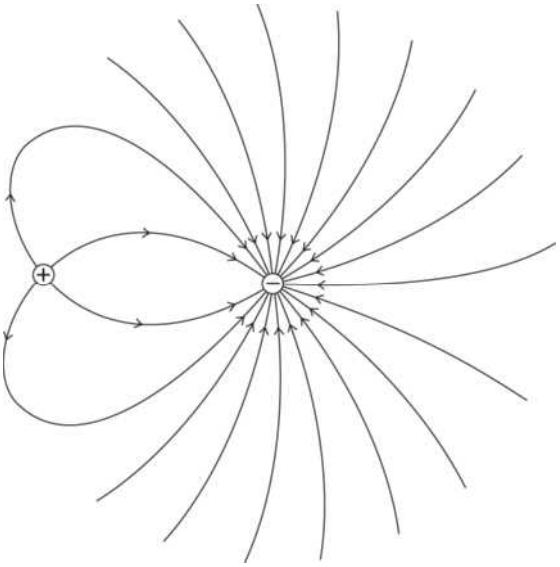

Figure 21.44

EXECUTE: **(a)** The electric fields $\vec{E}_1$ and $\vec{E}_2$ and their vector sum, the net field $\vec{E}$, are shown for each point in Figure 21.44a. The electric field is toward A at points B and C and the field is zero at A.
(b) The electric fields are shown in Figure 21.44b. The electric field is away from A at B and C. The field is zero at A.
(c) The electric fields are shown in Figure 21.44c. The field is horizontal and to the right at points A, B and C.
EVALUATE: Compare your results to the field lines shown in Figure 21.28a and b in the textbook.

21.45. **IDENTIFY:** Eq. (21.7) gives the electric field of each point charge. Use the principle of superposition and add the electric field vectors. In part (b) use Eq. (21.3) to calculate the force, using the electric field calculated in part (a).
(a) SET UP: The placement of charges is sketched in Figure 21.45a.

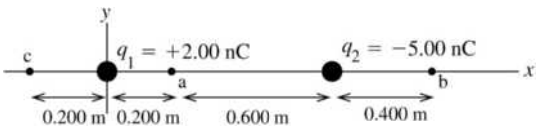

Figure 21.45a

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

The electric field of a point charge is directed away from the point charge if the charge is positive and toward the point charge if the charge is negative. The magnitude of the electric field is $E = \frac{1}{4\pi\epsilon_0}\frac{|q|}{r^2}$, where r is the distance between the point where the field is calculated and the point charge.

(i) At point a the fields $\vec{E}_1$ of q_1 and $\vec{E}_2$ of q_2 are directed as shown in Figure 21.45b.

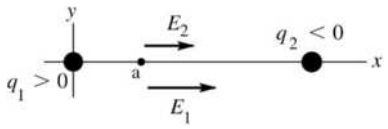

Figure 21.45b

EXECUTE: $E_1 = \frac{1}{4\pi\epsilon_0}\frac{|q_1|}{r_1^2} = (8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\frac{2.00\times10^{-9}\ \text{C}}{(0.200\ \text{m})^2} = 449.4\ \text{N/C}$

$E_2 = \frac{1}{4\pi\epsilon_0}\frac{|q_2|}{r_2^2} = (8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\frac{5.00\times10^{-9}\ \text{C}}{(0.600\ \text{m})^2} = 124.8\ \text{N/C}$

$E_{1x} = 449.4\ \text{N/C},\ E_{1y} = 0$

$E_{2x} = 124.8\ \text{N/C},\ E_{2y} = 0$

$E_x = E_{1x} + E_{2x} = +449.4\ \text{N/C} + 124.8\ \text{N/C} = +574.2\ \text{N/C}$

$E_y = E_{1y} + E_{2y} = 0$

The resultant field at point a has magnitude 574 N/C and is in the $+x$-direction.

(ii) **SET UP:** At point b the fields $\vec{E}_1$ of q_1 and $\vec{E}_2$ of q_2 are directed as shown in Figure 21.45c.

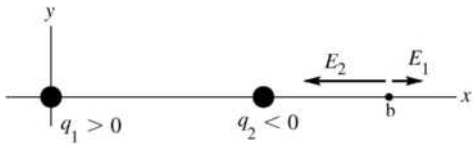

Figure 21.45c

EXECUTE: $E_1 = \frac{1}{4\pi\epsilon_0}\frac{|q_1|}{r_1^2} = (8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\frac{2.00\times10^{-9}\ \text{C}}{(1.20\ \text{m})^2} = 12.5\ \text{N/C}$

$E_2 = \frac{1}{4\pi\epsilon_0}\frac{|q_2|}{r_2^2} = (8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\frac{5.00\times10^{-9}\ \text{C}}{(0.400\ \text{m})^2} = 280.9\ \text{N/C}$

$E_{1x} = 12.5\ \text{N/C},\ E_{1y} = 0$

$E_{2x} = -280.9\ \text{N/C},\ E_{2y} = 0$

$E_x = E_{1x} + E_{2x} = +12.5\ \text{N/C} - 280.9\ \text{N/C} = -268.4\ \text{N/C}$

$E_y = E_{1y} + E_{2y} = 0$

The resultant field at point b has magnitude 268 N/C and is in the $-x$-direction.

(iii) **SET UP:** At point c the fields $\vec{E}_1$ of q_1 and $\vec{E}_2$ of q_2 are directed as shown in Figure 21.45d.

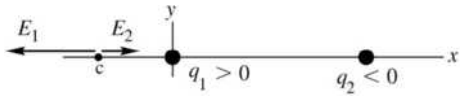

Figure 21.45d

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: $E_1 = \dfrac{1}{4\pi\epsilon_0}\dfrac{|q_1|}{r_1^2} = (8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\dfrac{2.00\times10^{-9}\ \text{C}}{(0.200\ \text{m})^2} = 449.4\ \text{N/C}$

$E_2 = \dfrac{1}{4\pi\epsilon_0}\dfrac{|q_2|}{r_2^2} = (8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\dfrac{5.00\times10^{-9}\ \text{C}}{(1.00\ \text{m})^2} = 44.9\ \text{N/C}$

$E_{1x} = -449.4\ \text{N/C}, E_{1y} = 0$

$E_{2x} = +44.9\ \text{N/C}, E_{2y} = 0$

$E_x = E_{1x} + E_{2x} = -449.4\ \text{N/C} + 44.9\ \text{N/C} = -404.5\ \text{N/C}$

$E_y = E_{1y} + E_{2y} = 0$

The resultant field at point b has magnitude 404 N/C and is in the $-x$-direction.

(b) SET UP: Since we have calculated $\vec{E}$ at each point the simplest way to get the force is to use $\vec{F} = -e\vec{E}$.

EXECUTE: (i) $F = (1.602\times10^{-19}\ \text{C})(574.2\ \text{N/C}) = 9.20\times10^{-17}\ \text{N}$, $-x$-direction

(ii) $F = (1.602\times10^{-19}\ \text{C})(268.4\ \text{N/C}) = 4.30\times10^{-17}\ \text{N}$, $+x$-direction

(iii) $F = (1.602\times10^{-19}\ \text{C})(404.5\ \text{N/C}) = 6.48\times10^{-17}\ \text{N}$, $+x$-direction

EVALUATE: The general rule for electric field direction is away from positive charge and toward negative charge. Whether the field is in the $+x$- or $-x$-direction depends on where the field point is relative to the charge that produces the field. In part (a), for (i) the field magnitudes were added because the fields were in the same direction and in (ii) and (iii) the field magnitudes were subtracted because the two fields were in opposite directions. In part (b) we could have used Coulomb's law to find the forces on the electron due to the two charges and then added these force vectors, but using the resultant electric field is much easier.

21.46. **IDENTIFY:** Apply Eq. (21.7) to calculate the field due to each charge and then require that the vector sum of the two fields to be zero.

SET UP: The field of each charge is directed toward the charge if it is negative and away from the charge if it is positive.

EXECUTE: The point where the two fields cancel each other will have to be closer to the negative charge, because it is smaller. Also, it can't be between the two charges, since the two fields would then act in the same direction. We could use Coulomb's law to calculate the actual values, but a simpler way is to note that the 8.00 nC charge is twice as large as the -4.00 nC charge. The zero point will therefore have to be a factor of $\sqrt{2}$ farther from the 8.00 nC charge for the two fields to have equal magnitude. Calling x the distance from the –4.00 nC charge: $1.20 + x = \sqrt{2}x$ and $x = 2.90$ m.

EVALUATE: This point is 4.10 m from the 8.00 nC charge. The two fields at this point are in opposite directions and have equal magnitudes.

21.47. **IDENTIFY:** $E = k\dfrac{|q|}{r^2}$. The net field is the vector sum of the fields due to each charge.

SET UP: The electric field of a negative charge is directed toward the charge. Label the charges q_1, q_2 and q_3, as shown in Figure 21.47a. This figure also shows additional distances and angles. The electric fields at point P are shown in Figure 21.47b. This figure also shows the xy coordinates we will use and the x and y components of the fields $\vec{E}_1$, $\vec{E}_2$ and $\vec{E}_3$.

EXECUTE: $E_1 = E_3 = (8.99\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\dfrac{5.00\times10^{-6}\ \text{C}}{(0.100\ \text{m})^2} = 4.49\times10^6\ \text{N/C}$

$E_2 = (8.99\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\dfrac{2.00\times10^{-6}\ \text{C}}{(0.0600\ \text{m})^2} = 4.99\times10^6\ \text{N/C}$

$E_y = E_{1y} + E_{2y} + E_{3y} = 0$ and $E_x = E_{1x} + E_{2x} + E_{3x} = E_2 + 2E_1\cos53.1° = 1.04\times10^7\ \text{N/C}$

$E = 1.04\times10^7\ \text{N/C}$, toward the $-2.00\ \mu\text{C}$ charge.

EVALUATE: The x-components of the fields of all three charges are in the same direction.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

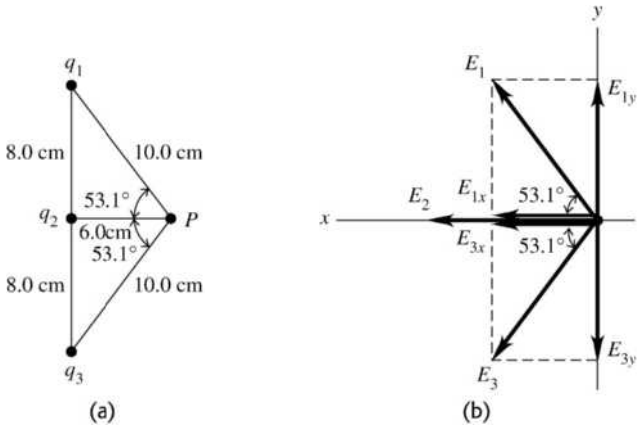

Figure 21.47

21.48. **IDENTIFY:** We can model a segment of the axon as a point charge.

SET UP: If the axon segment is modeled as a point charge, its electric field is $E = k\dfrac{q}{r^2}$. The electric field of a point charge is directed away from the charge if it is positive.

EXECUTE: **(a)** 5.6×10^{11} Na^+ ions enter per meter so in a 0.10 mm $= 1.0\times10^{-4}$ m section, 5.6×10^{7} Na^+ ions enter. This number of ions has charge $q = (5.6\times10^{7})(1.60\times10^{-19}\text{ C}) = 9.0\times10^{-12}$ C.

(b) $E = k\dfrac{|q|}{r^2} = (8.99\times10^{9}\text{ N}\cdot\text{m}^2/\text{C}^2)\dfrac{9.0\times10^{-12}\text{ C}}{(5.00\times10^{-2}\text{ m})^2} = 32\text{ N/C},$ directed away from the axon.

(c) $r = \sqrt{\dfrac{k|q|}{E}} = \sqrt{\dfrac{(8.99\times10^{9}\text{ N}\cdot\text{m}^2/\text{C}^2)(9.0\times10^{-12}\text{ C})}{1.0\times10^{-6}\text{ N/C}}} = 280\text{ m}.$

EVALUATE: The field in (b) is considerably smaller than ordinary laboratory electric fields.

21.49. **IDENTIFY:** The electric field of a positive charge is directed radially outward from the charge and has magnitude $E = \dfrac{1}{4\pi\epsilon_0}\dfrac{|q|}{r^2}$. The resultant electric field is the vector sum of the fields of the individual charges.

SET UP: The placement of the charges is shown in Figure 21.49a.

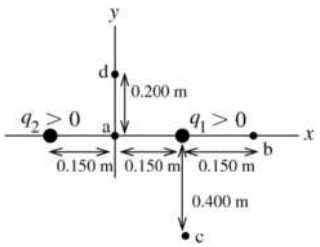

Figure 21.49a

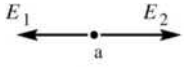
EXECUTE: **(a)** The directions of the two fields are shown in Figure 21.49b.



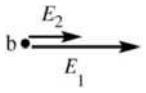
$$E_1 = E_2 = \frac{1}{4\pi\epsilon_0}\frac{|q|}{r^2} \text{ with } r = 0.150\text{ m}.$$

$$E = E_2 - E_1 = 0;\ E_x = 0,\ E_y = 0$$

Figure 21. 49b

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) The two fields have the directions shown in Figure 21.49c.



$E = E_1 + E_2$, in the $+x$-direction

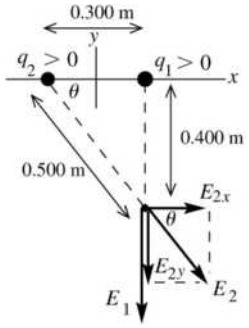
Figure 21. 49c

$$E_1 = \frac{1}{4\pi\epsilon_0}\frac{|q_1|}{r_1^2} = (8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\frac{6.00\times10^{-9}\ \text{C}}{(0.150\ \text{m})^2} = 2396.8\ \text{N/C}$$

$$E_2 = \frac{1}{4\pi\epsilon_0}\frac{|q_2|}{r_2^2} = (8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\frac{6.00\times10^{-9}\ \text{C}}{(0.450\ \text{m})^2} = 266.3\ \text{N/C}$$

$E = E_1 + E_2 = 2396.8\ \text{N/C} + 266.3\ \text{N/C} = 2660\ \text{N/C};\ E_x = +2660\ \text{N/C},\ E_y = 0$

(c) The two fields have the directions shown in Figure 21.49d.



$$\sin\theta = \frac{0.400\ \text{m}}{0.500\ \text{m}} = 0.800$$

$$\cos\theta = \frac{0.300\ \text{m}}{0.500\ \text{m}} = 0.600$$

Figure 21. 49d

$$E_1 = \frac{1}{4\pi\epsilon_0}\frac{|q_1|}{r_1^2}$$

$$E_1 = (8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\frac{6.00\times10^{-9}\ \text{C}}{(0.400\ \text{m})^2} = 337.1\ \text{N/C}$$

$$E_2 = \frac{1}{4\pi\epsilon_0}\frac{|q_2|}{r_2^2}$$

$$E_2 = (8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\frac{6.00\times10^{-9}\ \text{C}}{(0.500\ \text{m})^2} = 215.7\ \text{N/C}$$

$E_{1x} = 0,\ E_{1y} = -E_1 = -337.1\ \text{N/C}$

$E_{2x} = +E_2\cos\theta = +(215.7\ \text{N/C})(0.600) = +129.4\ \text{N/C}$

$E_{2y} = -E_2\sin\theta = -(215.7\ \text{N/C})(0.800) = -172.6\ \text{N/C}$

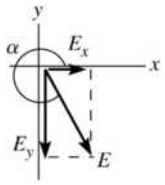
$E_x = E_{1x} + E_{2x} = +129\ \text{N/C}$

$E_y = E_{1y} + E_{2y} = -337.1\ \text{N/C} - 172.6\ \text{N/C} = -510\ \text{N/C}$

$E = \sqrt{E_x^2 + E_y^2} = \sqrt{(129\ \text{N/C})^2 + (-510\ \text{N/C})^2} = 526\ \text{N/C}$

$\vec{E}$ and its components are shown in Figure 21.49e.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.



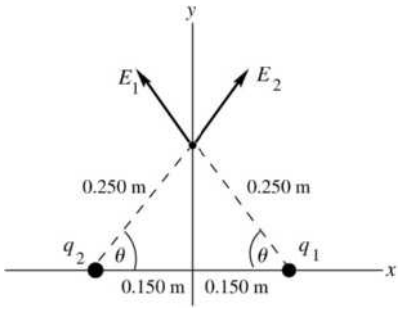
$$\tan\alpha = \frac{E_y}{E_x}$$

$$\tan\alpha = \frac{-510 \text{ N/C}}{+129 \text{ N/C}} = -3.953$$

$\alpha = 284°$, counterclockwise from $+x$-axis

Figure 21. 49e

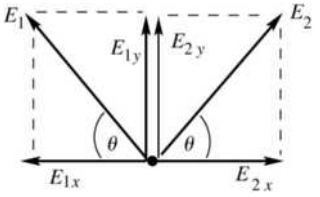
(d) The two fields have the directions shown in Figure 21.49f.



$$\sin\theta = \frac{0.200 \text{ m}}{0.250 \text{ m}} = 0.800$$

Figure 21. 49f

The components of the two fields are shown in Figure 21.49g.



$$E_1 = E_2 = \frac{1}{4\pi\epsilon_0}\frac{|q|}{r^2}$$

$$E_1 = (8.988\times10^9 \text{ N}\cdot\text{m}^2/\text{C}^2)\frac{6.00\times10^{-9} \text{ C}}{(0.250 \text{ m})^2}$$

$$E_1 = E_2 = 862.8 \text{ N/C}$$

Figure 21. 49g

$E_{1x} = -E_1\cos\theta,\ E_{2x} = +E_2\cos\theta$

$E_x = E_{1x} + E_{2x} = 0$

$E_{1y} = +E_1\sin\theta,\ E_{2y} = +E_2\sin\theta$

$E_y = E_{1y} + E_{2y} = 2E_{1y} = 2E_1\sin\theta = 2(862.8 \text{ N/C})(0.800) = 1380 \text{ N/C}$

$E = 1380$ N/C, in the $+y$-direction.

EVALUATE: Point a is symmetrically placed between identical charges, so symmetry tells us the electric field must be zero. Point b is to the right of both charges and both electric fields are in the $+x$-direction and the resultant field is in this direction. At point c both fields have a downward component and the field of q_2 has a component to the right, so the net $\vec{E}$ is in the 4th quadrant. At point d both fields have an upward component but by symmetry they have equal and opposite x-components so the net field is in the $+y$-direction. We can use this sort of reasoning to deduce the general direction of the net field before doing any calculations.

21.50. **IDENTIFY:** Apply Eq. (21.7) to calculate the field due to each charge and then calculate the vector sum of those fields.

SET UP: The fields due to q_1 and to q_2 are sketched in Figure 21.50.

EXECUTE: $\vec{E}_2 = \frac{1}{4\pi\epsilon_0}\frac{(6.00\times10^{-9} \text{ C})}{(0.6 \text{ m})^2}(-\hat{\imath}) = -150\hat{\imath}$ N/C.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$\vec{E}_1 = \frac{1}{4\pi\epsilon_0}(4.00\times10^{-9}\ \text{C})\left(\frac{1}{(1.00\ \text{m})^2}(0.600)\hat{\boldsymbol{i}} + \frac{1}{(1.00\ \text{m})^2}(0.800)\hat{\boldsymbol{j}}\right) = (21.6\hat{\boldsymbol{i}} + 28.8\hat{\boldsymbol{j}})\text{N/C}.$$

$\vec{E} = \vec{E}_1 + \vec{E}_2 = (-128.4\ \text{N/C})\hat{\boldsymbol{i}} + (28.8\ \text{N/C})\hat{\boldsymbol{j}}$. $E = \sqrt{(128.4\ \text{N/C})^2 + (28.8\ \text{N/C})^2} = 131.6\ \text{N/C}$ at

$\theta = \tan^{-1}\left(\frac{28.8}{128.4}\right) = 12.6°$ above the $-x$-axis and therefore 167.4° counterclockwise from the $+x$-axis.

EVALUATE: $\vec{E}_1$ is directed toward q_1 because q_1 is negative and $\vec{E}_2$ is directed away from q_2 because q_2 is positive.

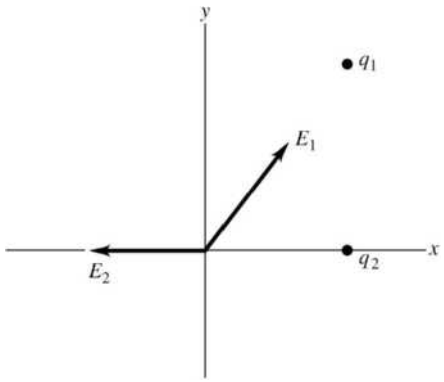


Figure 21.50

21.51. **IDENTIFY:** The resultant electric field is the vector sum of the field $\vec{E}_1$ of q_1 and $\vec{E}_2$ of q_2.

SET UP: The placement of the charges is shown in Figure 21.51a.

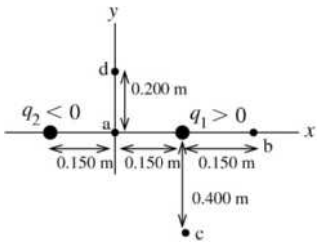

Figure 21.51a

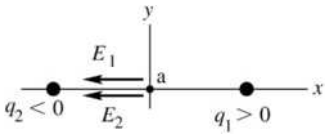
EXECUTE: **(a)** The directions of the two fields are shown in Figure 21.51b.



$$E_1 = E_2 = \frac{1}{4\pi\epsilon_0}\frac{|q_1|}{r_1^2}$$

$$E_1 = (8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\frac{6.00\times10^{-9}\ \text{C}}{(0.150\ \text{m})^2}$$

$$E_1 = E_2 = 2397\ \text{N/C}$$

Figure 21. 51b

$E_{1x} = -2397\ \text{N/C}$, $E_{1y} = 0$ $E_{2x} = -2397\ \text{N/C}$, $E_{2y} = 0$

$E_x = E_{1x} + E_{2x} = 2(-2397\ \text{N/C}) = -4790\ \text{N/C}$

$E_y = E_{1y} + E_{2y} = 0$

The resultant electric field at point a in the sketch has magnitude 4790 N/C and is in the $-x$-direction.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) The directions of the two fields are shown in Figure 21.51c.

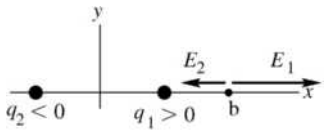


Figure 21.51c

$$E_1 = \frac{1}{4\pi\epsilon_0}\frac{|q_1|}{r_1^2} = (8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\frac{6.00\times10^{-9}\ \text{C}}{(0.150\ \text{m})^2} = 2397\ \text{N/C}$$

$$E_2 = \frac{1}{4\pi\epsilon_0}\frac{|q_2|}{r_2^2} = (8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\frac{6.00\times10^{-9}\ \text{C}}{(0.450\ \text{m})^2} = 266\ \text{N/C}$$

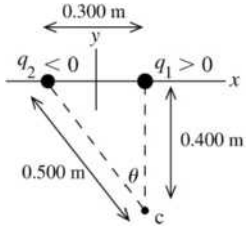
$E_{1x} = +2397$ N/C, $E_{1y} = 0$ $E_{2x} = -266$ N/C, $E_{2y} = 0$

$E_x = E_{1x} + E_{2x} = +2397\ \text{N/C} - 266\ \text{N/C} = +2130\ \text{N/C}$

$E_y = E_{1y} + E_{2y} = 0$

The resultant electric field at point b in the sketch has magnitude 2130 N/C and is in the $+x$-direction.

(c) The placement of the charges is shown in Figure 21.51d.

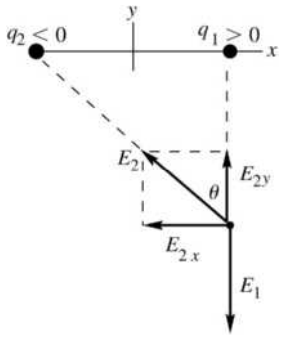


$$\sin\theta = \frac{0.300\ \text{m}}{0.500\ \text{m}} = 0.600$$

$$\cos\theta = \frac{0.400\ \text{m}}{0.500\ \text{m}} = 0.800$$

Figure 21. 51d

The directions of the two fields are shown in Figure 21.51e.



$$E_1 = \frac{1}{4\pi\epsilon_0}\frac{|q_1|}{r_1^2}$$

$$E_1 = (8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\frac{6.00\times10^{-9}\ \text{C}}{(0.400\ \text{m})^2}$$

$$E_1 = 337.0\ \text{N/C}$$

$$E_2 = \frac{1}{4\pi\epsilon_0}\frac{|q_2|}{r_2^2}$$

$$E_2 = (8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\frac{6.00\times10^{-9}\ \text{C}}{(0.500\ \text{m})^2}$$

$$E_2 = 215.7\ \text{N/C}$$

Figure 21. 51e

$E_{1x} = 0$, $E_{1y} = -E_1 = -337.0$ N/C

$E_{2x} = -E_2\sin\theta = -(215.7\ \text{N/C})(0.600) = -129.4\ \text{N/C}$

$E_{2y} = +E_2\cos\theta = +(215.7\ \text{N/C})(0.800) = +172.6\ \text{N/C}$

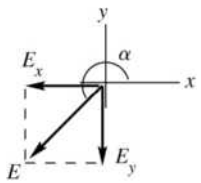
© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$E_x = E_{1x} + E_{2x} = -129 \text{ N/C}$

$E_y = E_{1y} + E_{2y} = -337.0 \text{ N/C} + 172.6 \text{ N/C} = -164 \text{ N/C}$

$E = \sqrt{E_x^2 + E_y^2} = 209 \text{ N/C}$

The field $\vec{E}$ and its components are shown in Figure 21.51f.



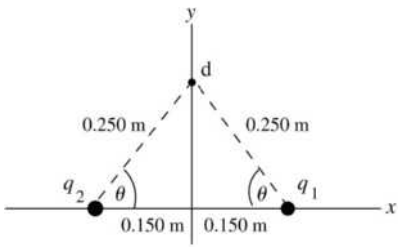
$$\tan\alpha = \frac{E_y}{E_x}$$

$$\tan\alpha = \frac{-164 \text{ N/C}}{-129 \text{ N/C}} = +1.271$$

$\alpha = 232°$, counterclockwise from $+x$-axis

Figure 21. 51f

(d) The placement of the charges is shown in Figure 21.51g.

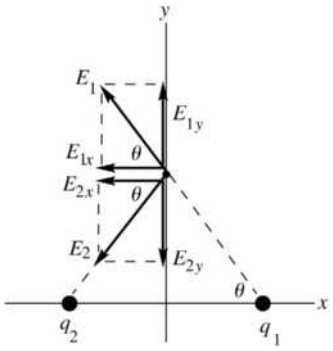


$$\sin\theta = \frac{0.200 \text{ m}}{0.250 \text{ m}} = 0.800$$

$$\cos\theta = \frac{0.150 \text{ m}}{0.250 \text{ m}} = 0.600$$

Figure 21. 51g

The directions of the two fields are shown in Figure 21.51h.



$$E_1 = E_2 = \frac{1}{4\pi\epsilon_0}\frac{|q|}{r^2}$$

$$E_1 = (8.988\times10^9 \text{ N}\cdot\text{m}^2/\text{C}^2)\frac{6.00\times10^{-9} \text{ C}}{(0.250 \text{ m})^2}$$

$E_1 = 862.8 \text{ N/C}$

$E_2 = E_1 = 862.8 \text{ N/C}$

Figure 21. 51h

$E_{1x} = -E_1\cos\theta,\ E_{2x} = -E_2\cos\theta$

$E_x = E_{1x} + E_{2x} = -2(862.8 \text{ N/C})(0.600) = -1040 \text{ N/C}$

$E_{1y} = +E_1\sin\theta,\ E_{2y} = -E_2\sin\theta$

$E_y = E_{1y} + E_{2y} = 0$

$E = 1040$ N/C, in the $-x$-direction.

EVALUATE: The electric field produced by a charge is toward a negative charge and away from a positive charge. As in Exercise 21.45, we can use this rule to deduce the direction of the resultant field at each point before doing any calculations.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

21.52. **IDENTIFY:** For a long straight wire, $E = \dfrac{\lambda}{2\pi\epsilon_0 r}$.

SET UP: $\dfrac{1}{2\pi\epsilon_0} = 1.80\times10^{10}\ \text{N}\cdot\text{m}^2/\text{C}^2$.

EXECUTE: $r = \dfrac{1.5\times10^{-10}\ \text{C/m}}{2\pi\epsilon_0(2.50\ \text{N/C})} = 1.08\ \text{m}$

EVALUATE: For a point charge, E is proportional to $1/r^2$. For a long straight line of charge, E is proportional to $1/r$.

21.53. **IDENTIFY:** For a ring of charge, the electric field is given by Eq. (21.8). $\vec{F} = q\vec{E}$. In part (b) use Newton's third law to relate the force on the ring to the force exerted by the ring.

SET UP: $Q = 0.125\times10^{-9}$ C, $a = 0.025$ m and $x = 0.400$ m.

EXECUTE: **(a)** $\vec{E} = \dfrac{1}{4\pi\epsilon_0}\dfrac{Qx}{(x^2+a^2)^{3/2}}\hat{\boldsymbol{i}} = (7.0\ \text{N/C})\hat{\boldsymbol{i}}$.

(b) $\vec{F}_{\text{on ring}} = -\vec{F}_{\text{on q}} = -q\vec{E} = -(-2.50\times10^{-6}\text{C})(7.0\ \text{N/C})\hat{\boldsymbol{i}} = (1.75\times10^{-5}\ \text{N})\hat{\boldsymbol{i}}$

EVALUATE: Charges q and Q have opposite sign, so the force that q exerts on the ring is attractive.

21.54. **(a) IDENTIFY:** The field is caused by a finite uniformly charged wire.

SET UP: The field for such a wire a distance x from its midpoint is

$$E = \frac{1}{2\pi\epsilon_0}\frac{\lambda}{x\sqrt{(x/a)^2+1}} = 2\left(\frac{1}{4\pi\epsilon_0}\right)\frac{\lambda}{x\sqrt{(x/a)^2+1}}.$$

EXECUTE: $E = \dfrac{(18.0\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)(175\times10^{-9}\ \text{C/m})}{(0.0600\ \text{m})\sqrt{\left(\dfrac{6.00\ \text{cm}}{4.25\ \text{cm}}\right)^2+1}} = 3.03\times10^4\ \text{N/C},$ directed upward.

(b) IDENTIFY: The field is caused by a uniformly charged circular wire.

SET UP: The field for such a wire a distance x from its midpoint is $E = \dfrac{1}{4\pi\epsilon_0}\dfrac{Qx}{(x^2+a^2)^{3/2}}$. We first find the radius of the circle using $2\pi r = l$.

EXECUTE: Solving for r gives $r = l/2\pi = (8.50\ \text{cm})/2\pi = 1.353$ cm.

The charge on this circle is $Q = \lambda l = (175\ \text{nC/m})(0.0850\ \text{m}) = 14.88$ nC.

The electric field is

$$E = \frac{1}{4\pi\epsilon_0}\frac{Qx}{(x^2+a^2)^{3/2}} = \frac{(9.00\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)(14.88\times10^{-9}\ \text{C/m})(0.0600\ \text{m})}{\left[(0.0600\ \text{m})^2+(0.01353\ \text{m})^2\right]^{3/2}}$$

$$E = 3.45\times10^4\ \text{N/C},\ \text{upward.}$$

EVALUATE: In both cases, the fields are of the same order of magnitude, but the values are different because the charge has been bent into different shapes.

21.55. **IDENTIFY:** We must use the appropriate electric field formula: a uniform disk in (a), a ring in (b) because all the charge is along the rim of the disk, and a point-charge in (c).

(a) SET UP: First find the surface charge density (Q/A), then use the formula for the field due to a disk of charge, $E_x = \dfrac{\sigma}{2\epsilon_0}\left[1-\dfrac{1}{\sqrt{(R/x)^2+1}}\right]$.

EXECUTE: The surface charge density is $\sigma = \dfrac{Q}{A} = \dfrac{Q}{\pi r^2} = \dfrac{6.50\times10^{-9}\text{C}}{\pi(0.0125\ \text{m})^2} = 1.324\times\text{C/m}^2$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

The electric field is

$$E_x = \frac{\sigma}{2\epsilon_0}\left[1 - \frac{1}{\sqrt{(R/x)^2+1}}\right] = \frac{1.324\times10^{-5}\ \text{C/m}^2}{2(8.85\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2)}\left[1 - \frac{1}{\sqrt{\left(\frac{1.25\ \text{cm}}{2.00\ \text{cm}}\right)^2+1}}\right]$$

$$E_x = 1.14\times10^5\ \text{N/C},\ \text{toward the center of the disk.}$$

(b) SET UP: For a ring of charge, the field is $E = \frac{1}{4\pi\epsilon_0}\frac{Qx}{(x^2+a^2)^{3/2}}$.

EXECUTE: Substituting into the electric field formula gives

$$E = \frac{1}{4\pi\epsilon_0}\frac{Qx}{(x^2+a^2)^{3/2}} = \frac{(9.00\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)(6.50\times10^{-9}\ \text{C})(0.0200\ \text{m})}{\left[(0.0200\ \text{m})^2+(0.0125\ \text{m})^2\right]^{3/2}}$$

$$E = 8.92\times10^4\ \text{N/C},\ \text{toward the center of the disk.}$$

(c) SET UP: For a point charge, $E = (1/4\pi\epsilon_0)q/r^2$.

EXECUTE: $E = (9.00\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)(6.50\times10^{-9}\ \text{C})/(0.0200\ \text{m})^2 = 1.46\times10^5\ \text{N/C}$

(d) EVALUATE: With the ring, more of the charge is farther from P than with the disk. Also with the ring the component of the electric field parallel to the plane of the ring is greater than with the disk, and this component cancels. With the point charge in (c), all the field vectors add with no cancellation, and all the charge is closer to point P than in the other two cases.

21.56. **(a) IDENTIFY:** The potential energy is given by Eq. (21.17).

SET UP: $U(\phi) = -\vec{\boldsymbol{p}}\cdot\vec{\boldsymbol{E}} = -pE\cos\phi$, where ϕ is the angle between $\vec{\boldsymbol{p}}$ and $\vec{\boldsymbol{E}}$.

EXECUTE: parallel: $\phi = 0$ and $U(0°) = -pE$

perpendicular: $\phi = 90°$ and $U(90°) = 0$

$\Delta U = U(90°) - U(0°) = pE = (5.0\times10^{-30}\ \text{C}\cdot\text{m})(1.6\times10^6\ \text{N/C}) = 8.0\times10^{-24}\ \text{J}.$

(b) $\frac{3}{2}kT = \Delta U$ so $T = \frac{2\Delta U}{3k} = \frac{2(8.0\times10^{-24}\ \text{J})}{3(1.381\times10^{-23}\ \text{J/K})} = 0.39\ \text{K}$

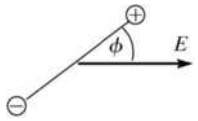
EVALUATE: Only at very low temperatures are the dipoles of the molecules aligned by a field of this strength. A much larger field would be required for alignment at room temperature.

21.57. **(a) IDENTIFY and SET UP:** Use Eq. (21.14) to relate the dipole moment to the charge magnitude and the separation d of the two charges. The direction is from the negative charge toward the positive charge.

EXECUTE: $p = qd = (4.5\times10^{-9}\ \text{C})(3.1\times10^{-3}\ \text{m}) = 1.4\times10^{-11}\ \text{C}\cdot\text{m}$; The direction of $\vec{\boldsymbol{p}}$ is from q_1 toward q_2.

(b) IDENTIFY and SET UP: Use Eq. (21.15) to relate the magnitudes of the torque and field.

EXECUTE: $\tau = pE\sin\phi$, with ϕ as defined in Figure 21.57, so



$$E = \frac{\tau}{p\sin\phi}$$

$$E = \frac{7.2\times10^{-9}\ \text{N}\cdot\text{m}}{(1.4\times10^{-11}\ \text{C}\cdot\text{m})\sin 36.9°} = 860\ \text{N/C}$$

Figure 21. 57

EVALUATE: Eq. (21.15) gives the torque about an axis through the center of the dipole. But the forces on the two charges form a couple (Problem 11.21) and the torque is the same for any axis parallel to this one. The force on each charge is $|q|E$ and the maximum moment arm for an axis at the center is $d/2$, so the maximum torque is $2(|q|E)(d/2) = 1.2\times10^{-8}\ \text{N}\cdot\text{m}$. The torque for the orientation of the dipole in the problem is less than this maximum.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

21.58. **IDENTIFY:** Calculate the electric field due to the dipole and then apply $\vec{F} = q\vec{E}$.

SET UP: From Example 21.14, $E_{\text{dipole}}(x) = \dfrac{p}{2\pi\epsilon_0 x^3}$.

EXECUTE: $E_{\text{dipole}} = \dfrac{6.17\times10^{-30}\ \text{C}\cdot\text{m}}{2\pi\epsilon_0(3.0\times10^{-9}\ \text{m})^3} = 4.11\times10^{6}\ \text{N/C}$. The electric force is $F = qE = (1.60\times10^{-19}\ \text{C})(4.11\times10^{6}\ \text{N/C}) = 6.58\times10^{-13}\ \text{N}$ and is toward the water molecule (negative x-direction).

EVALUATE: $\vec{E}_{\text{dipole}}$ is in the direction of $\vec{p}$, so is in the $+x$-direction. The charge q of the ion is negative, so $\vec{F}$ is directed opposite to $\vec{E}$ and is therefore in the $-x$-direction.

21.59. **IDENTIFY:** The torque on a dipole in an electric field is given by $\vec{\tau} = \vec{p}\times\vec{E}$.

SET UP: $\tau = pE\sin\phi$, where ϕ is the angle between the direction of $\vec{p}$ and the direction of $\vec{E}$.

EXECUTE: **(a)** The torque is zero when $\vec{p}$ is aligned either in the *same* direction as $\vec{E}$ or in the *opposite* direction, as shown in Figure 21.59a.

(b) The stable orientation is when $\vec{p}$ is aligned in the *same* direction as $\vec{E}$. In this case a small rotation of the dipole results in a torque directed so as to bring $\vec{p}$ back into alignment with $\vec{E}$. When $\vec{p}$ is directed opposite to $\vec{E}$, a small displacement results in a torque that takes $\vec{p}$ farther from alignment with $\vec{E}$.

(c) Field lines for E_{dipole} in the stable orientation are sketched in Figure 21.59b.

EVALUATE: The field of the dipole is directed from the + charge toward the − charge.

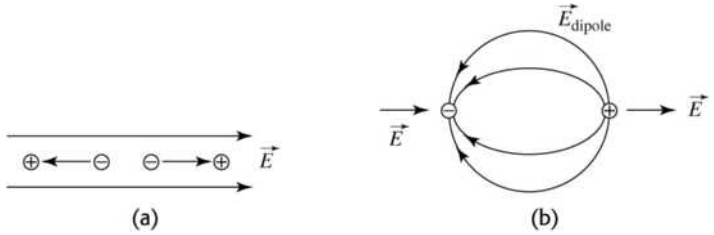


Figure 21. 59

21.60. **IDENTIFY:** Find the vector sum of the fields due to each charge in the dipole.

SET UP: A point on the x-axis with coordinate x is a distance $r = \sqrt{(d/2)^2 + x^2}$ from each charge.

EXECUTE: **(a)** The magnitude of the field the due to each charge is $E = \dfrac{1}{4\pi\epsilon_0}\dfrac{q}{r^2} = \dfrac{q}{4\pi\epsilon_0}\left(\dfrac{1}{(d/2)^2 + x^2}\right)$, where d is the distance between the two charges. The x-components of the forces due to the two charges are equal and oppositely directed and so cancel each other. The two fields have equal y-components, so $E = 2E_y = \dfrac{2q}{4\pi\epsilon_0}\left(\dfrac{1}{(d/2)^2 + x^2}\right)\sin\theta$, where θ is the angle below the x-axis for both fields.

$\sin\theta = \dfrac{d/2}{\sqrt{(d/2)^2 + x^2}}$ and $E_{\text{dipole}} = \left(\dfrac{2q}{4\pi\epsilon_0}\right)\left(\dfrac{1}{(d/2)^2 + x^2}\right)\left(\dfrac{d/2}{\sqrt{(d/2)^2 + x^2}}\right) = \dfrac{qd}{4\pi\epsilon_0((d/2)^2 + x^2)^{3/2}}$. The field is the $-y$-direction.

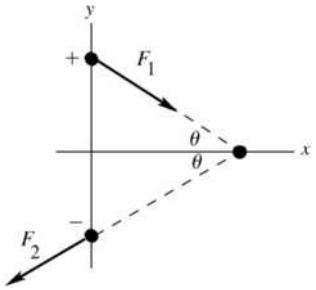
(b) At large x, $x^2 \gg (d/2)^2$, so the expression in part (a) reduces to the approximation $E_{\text{dipole}} \approx \dfrac{qd}{4\pi\epsilon_0 x^3}$.

EVALUATE: Example 21.14 shows that at points on the $+y$-axis far from the dipole, $E_{\text{dipole}} \approx \dfrac{qd}{2\pi\epsilon_0 y^3}$. The expression in part (b) for points on the x-axis has a similar form.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

21.61. **(a) IDENTIFY:** Use Coulomb's law to calculate each force and then add them as vectors to obtain the net force. Torque is force times moment arm.

SET UP: The two forces on each charge in the dipole are shown in Figure 21.61a.



$\sin\theta = 1.50/2.00$ so $\theta = 48.6°$

Opposite charges attract and like charges repel.

$F_x = F_{1x} + F_{2x} = 0$

Figure 21. 61a

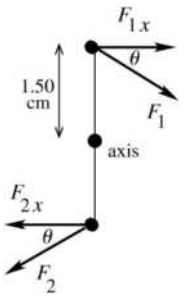
EXECUTE: $F_1 = k\dfrac{|qq'|}{r^2} = k\dfrac{(5.00\times10^{-6}\text{ C})(10.0\times10^{-6}\text{ C})}{(0.0200\text{ m})^2} = 1.124\times10^{3}\text{ N}$

$F_{1y} = -F_1\sin\theta = -842.6\text{ N}$

$F_{2y} = -842.6$ N so $F_y = F_{1y} + F_{2y} = -1680$ N (in the direction from the $+5.00$-μC charge toward the -5.00-μC charge).

EVALUATE: The x-components cancel and the y-components add.

(b) SET UP: Refer to Figure 21.61b.



The y-components have zero moment arm and therefore zero torque.

F_{1x} and F_{2x} both produce clockwise torques.

Figure 21. 61b

EXECUTE: $F_{1x} = F_1\cos\theta = 743.1$ N

$\tau = 2(F_{1x})(0.0150\text{ m}) = 22.3\text{ N}\cdot\text{m}$, clockwise

EVALUATE: The electric field produced by the $-10.00\ \mu$C charge is not uniform so Eq. (21.15) does not apply.

21.62. **IDENTIFY:** The plates produce a uniform electric field in the space between them. This field exerts torque on a dipole and gives it potential energy.

SET UP: The electric field between the plates is given by $E = \sigma/\epsilon_0$, and the dipole moment is $p = ed$. The potential energy of the dipole due to the field is $U = -\vec{\boldsymbol{p}}\cdot\vec{\boldsymbol{E}} = -pE\cos\phi$, and the torque the field exerts on it is $\tau = pE\sin\phi$.

EXECUTE: **(a)** The potential energy, $U = -\vec{\boldsymbol{p}}\cdot\vec{\boldsymbol{E}} = -pE\cos\phi$, is a maximum when $\phi = 180°$. The field between the plates is $E = \sigma/\epsilon_0$, giving

$U_{\max} = (1.60\times10^{-19}\text{ C})(220\times10^{-9}\text{ m})(125\times10^{-6}\text{ C/m}^2)/(8.85\times10^{-12}\text{ C}^2/\text{N}\cdot\text{m}^2) = 4.97\times10^{-19}\text{ J}$

The orientation is parallel to the electric field (perpendicular to the plates) with the positive charge of the dipole toward the positive plate.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) The torque, $\tau = pE\sin\phi$, is a maximum when $\phi = 90°$ or 270°. In this case

$$\tau_{max} = pE = p\sigma/\epsilon_0 = ed\sigma/\epsilon_0$$

$$\tau_{max} = (1.60\times10^{-19}\text{ C})(220\times10^{-9}\text{ m})(125\times10^{-6}\text{ C/m}^2)/(8.85\times10^{-12}\text{ C}^2/\text{N}\cdot\text{m}^2)$$

$$\tau_{max} = 4.97\times10^{-19}\text{ N}\cdot\text{m}$$

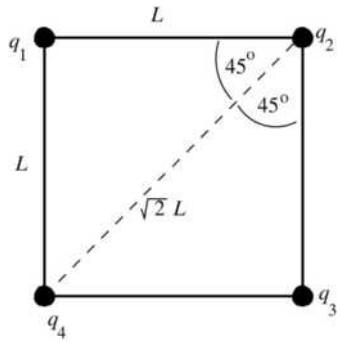
The dipole is oriented perpendicular to the electric field (parallel to the plates).

(c) $F = 0$.

EVALUATE: When the potential energy is a maximum, the torque is zero. In both cases, the net force on the dipole is zero because the forces on the charges are equal but opposite (which would not be true in a nonuniform electric field).

21.63. **IDENTIFY:** Apply Coulomb's law to calculate the force exerted on one of the charges by each of the other three and then add these forces as vectors.

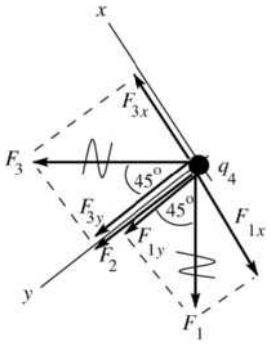
(a) SET UP: The charges are placed as shown in Figure 21.63a.



$$q_1 = q_2 = q_3 = q_4 = Q$$

Figure 21.63a

Consider forces on q_4. The free-body diagram is given in Figure 21.63b. Take the y-axis to be parallel to the diagonal between q_2 and q_4 and let $+y$ be in the direction away from q_2. Then $\vec{F}_2$ is in the $+y$-direction.



EXECUTE: $F_3 = F_1 = \dfrac{1}{4\pi\epsilon_0}\dfrac{Q^2}{L^2}$

$$F_2 = \frac{1}{4\pi\epsilon_0}\frac{Q^2}{2L^2}$$

$$F_{1x} = -F_1\sin 45° = -F_1/\sqrt{2}$$

$$F_{1y} = +F_1\cos 45° = +F_1/\sqrt{2}$$

$$F_{3x} = +F_3\sin 45° = +F_3/\sqrt{2}$$

$$F_{3y} = +F_3\cos 45° = +F_3/\sqrt{2}$$

$$F_{2x} = 0,\ F_{2y} = F_2$$

Figure 21.63b

(b) $R_x = F_{1x} + F_{2x} + F_{3x} = 0$

$$R_y = F_{1y} + F_{2y} + F_{3y} = (2/\sqrt{2})\frac{1}{4\pi\epsilon_0}\frac{Q^2}{L^2} + \frac{1}{4\pi\epsilon_0}\frac{Q^2}{2L^2} = \frac{Q^2}{8\pi\epsilon_0 L^2}(1+2\sqrt{2})$$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$R = \dfrac{Q^2}{8\pi\epsilon_0 L^2}(1+2\sqrt{2})$. Same for all four charges.

EVALUATE: In general the resultant force on one of the charges is directed away from the opposite corner. The forces are all repulsive since the charges are all the same. By symmetry the net force on one charge can have no component perpendicular to the diagonal of the square.

21.64. **IDENTIFY:** Apply $F = \dfrac{k|qq'|}{r^2}$ to find the force of each charge on $+q$. The net force is the vector sum of the individual forces.

SET UP: Let $q_1 = +2.50\ \mu\text{C}$ and $q_2 = -3.50\ \mu\text{C}$. The charge $+q$ must be to the left of q_1 or to the right of q_2 in order for the two forces to be in opposite directions. But for the two forces to have equal magnitudes, $+q$ must be closer to the charge q_1, since this charge has the smaller magnitude. Therefore, the two forces can combine to give zero net force only in the region to the left of q_1. Let $+q$ be a distance d to the left of q_1, so it is a distance $d + 0.600$ m from q_2.

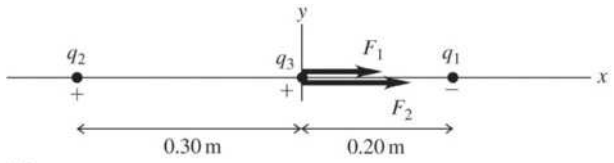
EXECUTE: $F_1 = F_2$ gives $\dfrac{kq|q_1|}{d^2} = \dfrac{kq|q_2|}{(d+0.600\text{ m})^2}$. $d = \pm\sqrt{\dfrac{|q_1|}{|q_2|}}(d+0.600\text{ m}) = \pm(0.8452)(d+0.600\text{ m})$.

d must be positive, so $d = \dfrac{(0.8452)(0.600\text{ m})}{1-0.8452} = 3.27$ m. The net force would be zero when $+q$ is at $x = -3.27$ m.

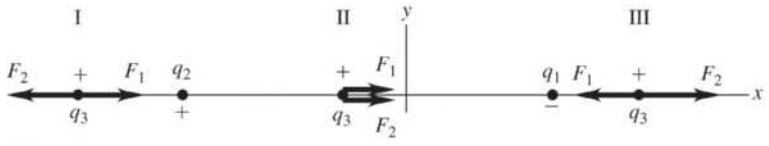
EVALUATE: When $+q$ is at $x = -3.27$ m, $\vec{F}_1$ is in the $-x$ direction and $\vec{F}_2$ is in the $+x$ direction.

21.65. **IDENTIFY:** The forces obey Coulomb's law, and the net force is the vector sum of the individual forces.

SET UP: $F = k\dfrac{|qq'|}{r^2}$. Like charges repel and unlike charges attract. Charges q_1 and q_2 and the forces they exert on q_3 at the origin are sketched in Figure 21.65a. For the net force on q_3 to be zero, $\vec{F}_1$ and $\vec{F}_2$ from q_1 and q_2 must be equal in magnitude and opposite in direction.



(a)



(b)

Figure 21.65

EXECUTE: **(a)** Since $\vec{F}_1$, $\vec{F}_2$ and $\vec{F}_{\text{net}}$ are all in the $+x$-direction, $F = F_1 + F_2$. This gives

$4.00\times10^{-6}\text{ N} = k\dfrac{|q_1q_3|}{r_1^2} + k\dfrac{|q_2q_3|}{r_2^2}$. $\dfrac{4.00\times10^{-6}\text{ N}}{8.99\times10^9\text{ N}\cdot\text{m}^2/\text{C}^2} = q_3\left(\dfrac{4.50\times10^{-9}\text{ C}}{[0.200\text{ m}]^2} + \dfrac{2.50\times10^{-9}\text{ C}}{[0.300\text{ m}]^2}\right)$ and

$q_3 = 3.17\times10^{-9}\text{ C} = 3.17$ nC.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) Both $\vec{F}_1$ and $\vec{F}_2$ are in the $+x$-direction, so $\vec{F}_{\text{net}} = \vec{F}_1 + \vec{F}_2$ is in the $+x$-direction.

(c) The forces $\vec{F}_1$ and $\vec{F}_2$ on q_3 in each of the three regions are sketched in Figure 21.65b. Only in regions I (to the left of q_2) and III (to the right of q_1) are $\vec{F}_1$ and $\vec{F}_2$ in opposite directions. But since $|q_2| < |q_1|$, q_3 must be closer to q_2 than to q_1 in order for $F_1 = F_2$, and this is the case only in region I. Let q_3 be a distance d to the left of q_2, so it is a distance $d + 0.500$ m from q_1. $F_1 = F_2$ gives $k\dfrac{4.50\text{ nC}}{(d+0.500\text{ m})^2} = k\dfrac{2.50\text{ nC}}{d^2}$. $1.80d^2 = (d+0.500\text{ m})^2$. $\sqrt{1.80}d = \pm(d+0.500\text{ m})$. The positive solution is $d = 1.46$ m. This point is at $x = -0.300\text{ m} - 1.46\text{ m} = -1.76$ m.

EVALUATE: At the point found in part (c) the electric field is zero. The force on any charge placed at this point will be zero.

21.66. **IDENTIFY:** Apply $F = k\dfrac{|qq'|}{r^2}$ for each pair of charges and find the vector sum of the forces that q_1 and q_2 exert on q_3.

SET UP: Like charges repel and unlike charges attract. The three charges and the forces on q_3 are shown in Figure 21.66.

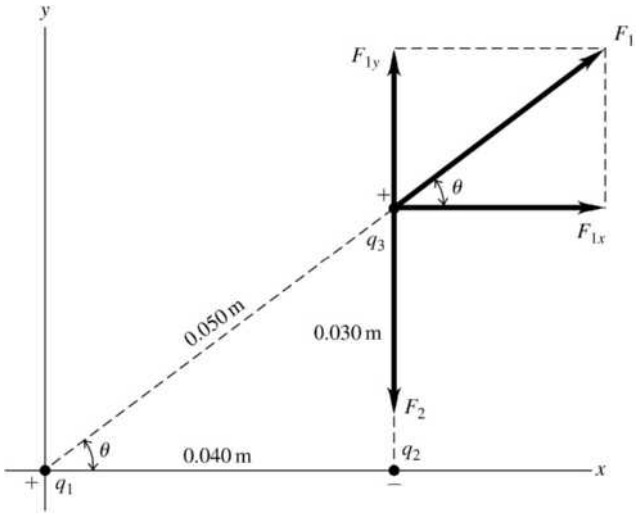


Figure 21.66

EXECUTE: **(a)** $F_1 = k\dfrac{|q_1 q_3|}{r_1^2} = (8.99\times10^9\text{ N}\cdot\text{m}^2/\text{C}^2)\dfrac{(5.00\times10^{-9}\text{ C})(6.00\times10^{-9}\text{ C})}{(0.0500\text{ m})^2} = 1.079\times10^{-4}\text{ C}$.

$\theta = 36.9°$. $F_{1x} = +F_1\cos\theta = 8.63\times10^{-5}$ N. $F_{1y} = +F_1\sin\theta = 6.48\times10^{-5}$ N.

$F_2 = k\dfrac{|q_2 q_3|}{r_2^2} = (8.99\times10^9\text{ N}\cdot\text{m}^2/\text{C}^2)\dfrac{(2.00\times10^{-9}\text{ C})(6.00\times10^{-9}\text{ C})}{(0.0300\text{ m})^2} = 1.20\times10^{-4}\text{ C}$.

$F_{2x} = 0$, $F_{2y} = -F_2 = -1.20\times10^{-4}$ N. $F_x = F_{1x} + F_{2x} = 8.63\times10^{-5}$ N.

$F_y = F_{1y} + F_{2y} = 6.48\times10^{-5}\text{ N} + (-1.20\times10^{-4}\text{ N}) = -5.52\times10^{-5}$ N.

(b) $F = \sqrt{F_x^2 + F_y^2} = 1.02\times10^{-4}$ N. $\tan\phi = \left|\dfrac{F_y}{F_x}\right| = 0.640$. $\phi = 32.6°$, below the $+x$-axis.

EVALUATE: The individual forces on q_3 are computed from Coulomb's law and then added as vectors, using components.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

21.67. **(a) IDENTIFY:** Use Coulomb's law to calculate the force exerted by each Q on q and add these forces as vectors to find the resultant force. Make the approximation $x \gg a$ and compare the net force to $F = -kx$ to deduce k and then $f = (1/2\pi)\sqrt{k/m}$.

SET UP: The placement of the charges is shown in Figure 21.67a.

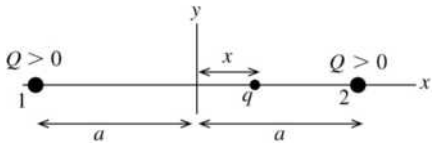

Figure 21. 67a

EXECUTE: Find the net force on q.

$F_x = F_{1x} + F_{2x}$ and $F_{1x} = +F_1, F_{2x} = -F_2$

Figure 21. 67b

$$F_1 = \frac{1}{4\pi\epsilon_0}\frac{qQ}{(a+x)^2}, F_2 = \frac{1}{4\pi\epsilon_0}\frac{qQ}{(a-x)^2}$$

$$F_x = F_1 - F_2 = \frac{qQ}{4\pi\epsilon_0}\left[\frac{1}{(a+x)^2} - \frac{1}{(a-x)^2}\right]$$

$$F_x = \frac{qQ}{4\pi\epsilon_0 a^2}\left[+\left(1+\frac{x}{a}\right)^{-2} - \left(1-\frac{x}{a}\right)^{-2}\right]$$

Since $x \ll a$ we can use the binomial expansion for $(1-x/a)^{-2}$ and $(1+x/a)^{-2}$ and keep only the first two terms: $(1+z)^n \approx 1+nz$. For $(1-x/a)^{-2}$, $z = -x/a$ and $n = -2$ so $(1-x/a)^{-2} \approx 1+2x/a$. For $(1+x/a)^{-2}$, $z = +x/a$ and $n = -2$ so $(1+x/a)^{-2} \approx 1-2x/a$. Then $F \approx \frac{qQ}{4\pi\epsilon_0 a^2}\left[\left(1-\frac{2x}{a}\right)-\left(1+\frac{2x}{a}\right)\right] = -\left(\frac{qQ}{\pi\epsilon_0 a^3}\right)x.$

For simple harmonic motion $F = -kx$ and the frequency of oscillation is $f = (1/2\pi)\sqrt{k/m}$. The net force here is of this form, with $k = qQ/\pi\epsilon_0 a^3$. Thus $f = \frac{1}{2\pi}\sqrt{\frac{qQ}{\pi\epsilon_0 m a^3}}$.

(b) The forces and their components are shown in Figure 21.67c.

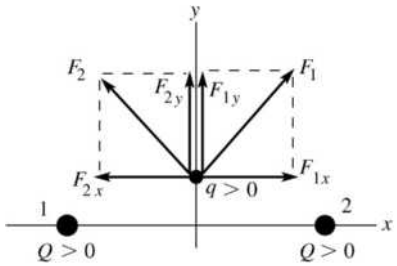

Figure 21.67c

The x-components of the forces exerted by the two charges cancel, the y-components add, and the net force is in the $+y$-direction when $y > 0$ and in the $-y$-direction when $y < 0$. The charge moves away from the origin on the y-axis and never returns.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: The directions of the forces and of the net force depend on where q is located relative to the other two charges. In part (a), $F = 0$ at $x = 0$ and when the charge q is displaced in the $+x$- or $-x$-direction the net force is a restoring force, directed to return q to $x = 0$. The charge oscillates back and forth, similar to a mass on a spring.

21.68. **IDENTIFY:** Apply $\sum F_x = 0$ and $\sum F_y = 0$ to one of the spheres.

SET UP: The free-body diagram is sketched in Figure 21.68. F_e is the repulsive Coulomb force between the spheres. For small θ, $\sin\theta \approx \tan\theta$.

EXECUTE: $\sum F_x = T\sin\theta - F_e = 0$ and $\sum F_y = T\cos\theta - mg = 0$. So $\dfrac{mg\sin\theta}{\cos\theta} = F_e = \dfrac{kq^2}{d^2}$. But

$\tan\theta \approx \sin\theta = \dfrac{d}{2L}$, so $d^3 = \dfrac{2kq^2L}{mg}$ and $d = \left(\dfrac{q^2L}{2\pi\epsilon_0 mg}\right)^{1/3}$.

EVALUATE: d increases when q increases.

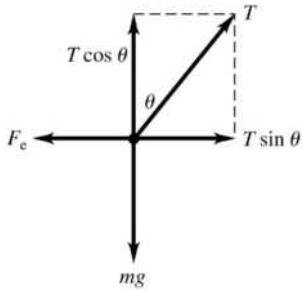

Figure 21.68

21.69. **IDENTIFY:** Use Coulomb's law for the force that one sphere exerts on the other and apply the 1st condition of equilibrium to one of the spheres.

(a) SET UP: The placement of the spheres is sketched in Figure 21.69a.

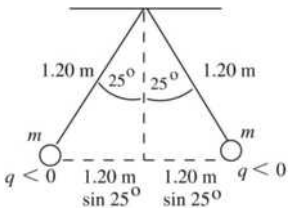

Figure 21.69a

The free-body diagrams for each sphere are given in Figure 21.69b.

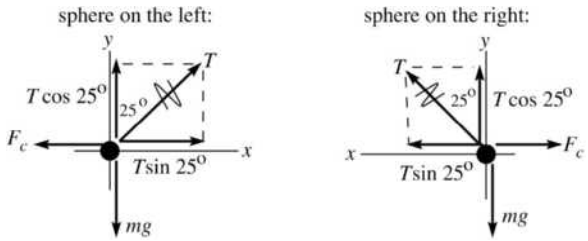

Figure 21.69b

F_c is the repulsive Coulomb force exerted by one sphere on the other.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) EXECUTE: From either force diagram in part (a): $\sum F_y = ma_y$

$T\cos 25.0° - mg = 0$ and $T = \dfrac{mg}{\cos 25.0°}$

$\sum F_x = ma_x$

$T\sin 25.0° - F_c = 0$ and $F_c = T\sin 25.0°$

Use the first equation to eliminate T in the second: $F_c = (mg/\cos 25.0°)(\sin 25.0°) = mg\tan 25.0°$

$$F_c = \frac{1}{4\pi\epsilon_0}\frac{|q_1q_2|}{r^2} = \frac{1}{4\pi\epsilon_0}\frac{q^2}{r^2} = \frac{1}{4\pi\epsilon_0}\frac{q^2}{\left[2(1.20\text{ m})\sin 25.0°\right]^2}$$

Combine this with $F_c = mg\tan 25.0°$ and get $mg\tan 25.0° = \dfrac{1}{4\pi\epsilon_0}\dfrac{q^2}{\left[2(1.20\text{ m})\sin 25.0°\right]^2}$

$$q = (2.40\text{ m})\sin 25.0°\sqrt{\frac{mg\tan 25.0°}{(1/4\pi\epsilon_0)}}$$

$$q = (2.40\text{ m})\sin 25.0°\sqrt{\frac{(15.0\times10^{-3}\text{ kg})(9.80\text{ m/s}^2)\tan 25.0°}{8.988\times10^{9}\text{ N}\cdot\text{m}^2/\text{C}^2}} = 2.80\times10^{-6}\text{ C}$$

(c) The separation between the two spheres is given by $2L\sin\theta$. $q = 2.80\mu\text{C}$ as found in part (b).

$F_c = (1/4\pi\epsilon_0)q^2/(2L\sin\theta)^2$ and $F_c = mg\tan\theta$. Thus $(1/4\pi\epsilon_0)q^2/(2L\sin\theta)^2 = mg\tan\theta$.

$$(\sin\theta)^2\tan\theta = \frac{1}{4\pi\epsilon_0}\frac{q^2}{4L^2mg} = (8.988\times10^{9}\text{ N}\cdot\text{m}^2/\text{C}^2)\frac{(2.80\times10^{-6}\text{ C})^2}{4(0.600\text{ m})^2(15.0\times10^{-3}\text{ kg})(9.80\text{ m/s}^2)} = 0.3328.$$

Solve this equation by trial and error. This will go quicker if we can make a good estimate of the value of θ that solves the equation. For θ small, $\tan\theta \approx \sin\theta$. With this approximation the equation becomes $\sin^3\theta = 0.3328$ and $\sin\theta = 0.6930$, so $\theta = 43.9°$. Now refine this guess:

θ	$\sin^2\theta\tan\theta$	
45.0°	0.5000	
40.0°	0.3467	
39.6°	0.3361	
39.5°	0.3335	
39.4°	0.3309	so $\theta = 39.5°$

EVALUATE: The expression in part (c) says $\theta \to 0$ as $L \to \infty$ and $\theta \to 90°$ as $L \to 0$. When L is decreased from the value in part (a), θ increases.

21.70. IDENTIFY: Apply $\sum F_x = 0$ and $\sum F_y = 0$ to each sphere.

SET UP: (a) Free body diagrams are given in Figure 21.70. F_e is the repulsive electric force that one sphere exerts on the other.

EXECUTE: (b) $T = mg/\cos 20° = 0.0834$ N, so $F_e = T\sin 20° = 0.0285\text{ N} = \dfrac{kq_1q_2}{r_1^2}$.

(Note: $r_1 = 2(0.500\text{ m})\sin 20° = 0.342$ m.)

(c) From part (b), $q_1q_2 = 3.71\times10^{-13}\text{ C}^2$.

(d) The charges on the spheres are made equal by connecting them with a wire, but we still have

$F_e = mg\tan\theta = 0.0453\text{ N} = \dfrac{1}{4\pi\epsilon_0}\dfrac{Q^2}{r_2^2}$, where $Q = \dfrac{q_1+q_2}{2}$. But the separation r_2 is known:

$r_2 = 2(0.500\text{ m})\sin 30° = 0.500$ m. Hence: $Q = \dfrac{q_1+q_2}{2} = \sqrt{4\pi\epsilon_0F_er_2^2} = 1.12\times10^{-6}$ C. This equation, along with that from part (c), gives us two equations in q_1 and q_2: $q_1 + q_2 = 2.24\times10^{-6}$ C and

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$q_1q_2 = 3.71\times10^{-13}\ \text{C}^2$. By elimination, substitution and after solving the resulting quadratic equation, we find: $q_1 = 2.06\times10^{-6}\ \text{C}$ and $q_2 = 1.80\times10^{-7}\ \text{C}$.

EVALUATE: After the spheres are connected by the wire, the charge on sphere 1 decreases and the charge on sphere 2 increases. The product of the charges on the sphere increases and the thread makes a larger angle with the vertical.

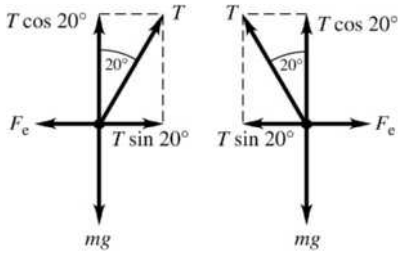

Figure 21.70

21.71. **IDENTIFY** and **SET UP:** Use Avogadro's number to find the number of Na^+ and Cl^- ions and the total positive and negative charge. Use Coulomb's law to calculate the electric force and $\vec{F} = m\vec{a}$ to calculate the acceleration.

(a) EXECUTE: The number of Na^+ ions in 0.100 mol of NaCl is $N = nN_A$. The charge of one ion is $+e$, so the total charge is $q_1 = nN_Ae = (0.100\ \text{mol})(6.022\times10^{23}\ \text{ions/mol})(1.602\times10^{-19}\text{C/ion}) = 9.647\times10^3\ \text{C}$. There are the same number of Cl^- ions and each has charge $-e$, so $q_2 = -9.647\times10^3\ \text{C}$.

$$F = \frac{1}{4\pi\epsilon_0}\frac{|q_1q_2|}{r^2} = (8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\frac{(9.647\times10^3\ \text{C})^2}{(0.0200\ \text{m})^2} = 2.09\times10^{21}\ \text{N}$$

(b) $a = F/m$. Need the mass of 0.100 mol of Cl^- ions. For Cl, $M = 35.453\times10^{-3}$ kg/mol, so $m = (0.100\,\text{mol})(35.453\times10^{-3}\,\text{kg/mol}) = 35.45\times10^{-4}\,\text{kg}$. Then $a = \frac{F}{m} = \frac{2.09\times10^{21}\ \text{N}}{35.45\times10^{-4}\ \text{kg}} = 5.90\times10^{23}\ \text{m/s}^2$.

(c) EVALUATE: Is is not reasonable to have such a huge force. The net charges of objects are rarely larger than $1\,\mu\text{C}$; a charge of $10^4\ \text{C}$ is immense. A small amount of material contains huge amounts of positive and negative charges.

21.72. **IDENTIFY:** The net electric field at the origin is the vector sum of the fields due to the two charges.

SET UP: $E = k\frac{|q|}{r^2}$. $\vec{E}$ is toward a negative charge and away from a positive charge. At the origin, $\vec{E}_1$ due to the -5.00 nC charge is in the $+x$-direction, toward the charge.

EXECUTE: **(a)** $E_1 = (8.99\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\frac{(5.00\times10^{-9}\ \text{C})}{(1.20\ \text{m})^2} = 31.2\ \text{N/C}$. $E_{1x} = +31.2\ \text{N/C}$.

$E_x = E_{1x} + E_{2x}$. $E_x = +45.0$ N/C, so $E_{2x} = E_x - E_{1x} = +45.0\ \text{N/C} - 31.2\ \text{N/C} = 13.8\ \text{N/C}$. $\vec{E}$ is away from Q so Q is positive. $E_2 = k\frac{|Q|}{r^2}$ gives $|Q| = \frac{E_2r^2}{k} = \frac{(13.8\ \text{N/C})(0.600\ \text{m})^2}{8.99\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2} = 5.53\times10^{-10}\ \text{C}$.

(b) $E_x = -45.0$ N/C, so $E_{2x} = E_x - E_{1x} = -45.0\ \text{N/C} - 31.2\ \text{N/C} = -76.2\ \text{N/C}$. $\vec{E}$ is toward Q so Q is negative. $|Q| = \frac{E_2r^2}{k} = \frac{(76.2\ \text{N/C})(0.600\ \text{m})^2}{8.99\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2} = 3.05\times10^{-9}\ \text{C}$.

EVALUATE: Use of the equation $E = k\frac{|q|}{r^2}$ gives only the *magnitude* of the electric field. When combining fields, you still must figure out whether to add or subtract the magnitudes depending on the direction in which the fields point.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

21.73. **IDENTIFY:** The electric field exerts a horizontal force away from the wall on the ball. When the ball hangs at rest, the forces on it (gravity, the tension in the string, and the electric force due to the field) add to zero.
SET UP: The ball is in equilibrium, so for it $\sum F_x = 0$ and $\sum F_y = 0$. The force diagram for the ball is given in Figure 21.73. F_E is the force exerted by the electric field. $\vec{\boldsymbol{F}} = q\vec{\boldsymbol{E}}$. Since the electric field is horizontal, $\vec{\boldsymbol{F}}_E$ is horizontal. Use the coordinates shown in the figure. The tension in the string has been replaced by its x- and y-components.

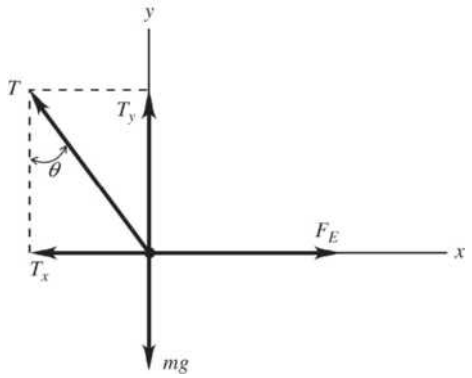

Figure 21.73

EXECUTE: $\sum F_y = 0$ gives $T_y - mg = 0$. $T\cos\theta - mg = 0$ and $T = \dfrac{mg}{\cos\theta}$. $\sum F_x = 0$ gives $F_E - T_x = 0$.
$F_E - T\sin\theta = 0$. Combing the equations and solving for F_E gives
$F_E = \left(\dfrac{mg}{\cos\theta}\right)\sin\theta = mg\tan\theta = (12.3\times10^{-3}\text{ kg})(9.80\text{ m/s}^2)(\tan 17.4°) = 3.78\times10^{-2}\text{ N}$. $F_E = |q|E$ so
$E = \dfrac{F_E}{|q|} = \dfrac{3.78\times10^{-2}\text{ N}}{1.11\times10^{-6}\text{ C}} = 3.41\times10^{4}\text{ N/C}$. Since q is negative and $\vec{\boldsymbol{F}}_E$ is to the right, $\vec{\boldsymbol{E}}$ is to the left in the figure.
EVALUATE: The larger the electric field E the greater the angle the string makes with the wall.

21.74. **IDENTIFY:** We can find the force on the charged particle due to the electric field. Then we can use Newton's second law to find its acceleration and the constant-acceleration kinematics formulas to find the components of the distance it moves.
SET UP: The x-component of the electric force on a charged particle is $F_x = qE_x$ and $F_x = ma_x$. For constant acceleration in the x-direction, $x - x_0 = v_{0x}t + \dfrac{1}{2}a_x t^2$. Similar equations apply in the y-direction.
EXECUTE: The only nonzero acceleration is in the y-direction, so $a_x = 0$ and
$F_y = qE_y = (9.00\times10^{-6}\text{ C})(895\text{ N/C}) = 8.055\times10^{-3}\text{ N}$. $a_y = \dfrac{F_y}{m} = \dfrac{8.055\times10^{-3}\text{ N}}{0.400\times10^{-6}\text{ kg}} = 2.014\times10^{4}\text{ m/s}^2$.
$x - x_0 = v_{0x}t + \dfrac{1}{2}a_x t^2 = (-125\text{ m/s})(7.00\times10^{-3}\text{ s}) = -0.875\text{ m}$.
$y - y_0 = v_{0y}t + \dfrac{1}{2}a_y t^2 = \dfrac{1}{2}(2.014\times10^{4}\text{ m/s}^2)(7.00\times10^{-3}\text{ s})^2 = 0.4934\text{ m}$. $r = \sqrt{x^2 + y^2} = 1.00\text{ m}$.
EVALUATE: The 1.00 m is the distance of the particle from the origin at the end of 7.00 ms, but it is *not* the distance the particle has traveled in 7.00 ms.

21.75. **IDENTIFY:** For a point charge, $E = k\dfrac{|q|}{r^2}$. For the net electric field to be zero, $\vec{\boldsymbol{E}}_1$ and $\vec{\boldsymbol{E}}_2$ must have equal magnitudes and opposite directions.
SET UP: Let $q_1 = +0.500$ nC and $q_2 = +8.00$ nC. $\vec{\boldsymbol{E}}$ is toward a negative charge and away from a positive charge.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: The two charges and the directions of their electric fields in three regions are shown in Figure 21.75. Only in region II are the two electric fields in opposite directions. Consider a point a distance x from q_1 so a distance $1.20\text{ m} - x$ from q_2. $E_1 = E_2$ gives $k\dfrac{0.500\text{ nC}}{x^2} = k\dfrac{8.00\text{ nC}}{(1.20\text{ m} - x)^2}$. $16x^2 = (1.20\text{ m} - x)^2$. $4x = \pm(1.20\text{ m} - x)$ and $x = 0.24$ m is the positive solution. The electric field is zero at a point between the two charges, 0.24 m from the 0.500 nC charge and 0.96 m from the 8.00 nC charge.

EVALUATE: There is only one point along the line connecting the two charges where the net electric field is zero. This point is closer to the charge that has the smaller magnitude.

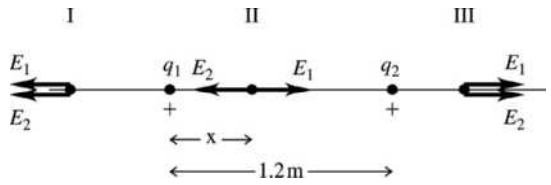

Figure 21.75

21.76. **IDENTIFY:** For the acceleration (and hence the force) on Q to be upward, as indicated, the forces due to q_1 and q_2 must have equal strengths, so q_1 and q_2 must have equal magnitudes. Furthermore, for the force to be upward, q_1 must be positive and q_2 must be negative.

SET UP: Since we know the acceleration of Q, Newton's second law gives us the magnitude of the force on it. We can then add the force components using $F = F_{Qq_1}\cos\theta + F_{Qq_2}\cos\theta = 2F_{Qq_1}\cos\theta$. The electrical force on Q is given by Coulomb's law, $F_{Qq_1} = \dfrac{1}{4\pi\epsilon_0}\dfrac{Qq_1}{r^2}$ (for q_1) and likewise for q_2.

EXECUTE: First find the net force: $F = ma = (0.00500\text{ kg})(324\text{ m/s}^2) = 1.62$ N. Now add the force components, calling θ the angle between the line connecting q_1 and q_2 and the line connecting q_1 and Q. $F = F_{Qq_1}\cos\theta + F_{Qq_2}\cos\theta = 2F_{Qq_1}\cos\theta$ and $F_{Qq_1} = \dfrac{F}{2\cos\theta} = \dfrac{1.62\text{ N}}{2\left(\dfrac{2.25\text{ cm}}{3.00\text{ cm}}\right)} = 1.08$ N. Now find the charges by solving for q_1 in Coulomb's law and use the fact that q_1 and q_2 have equal magnitudes but opposite signs. $F_{Qq_1} = \dfrac{1}{4\pi\epsilon_0}\dfrac{|Q|q_1}{r^2}$ and $q_1 = \dfrac{r^2F_{Qq_1}}{\dfrac{1}{4\pi\epsilon_0}|Q|} = \dfrac{(0.0300\text{ m})^2(1.08\text{ N})}{(9.00\times10^9\text{ N}\cdot\text{m}^2/\text{C}^2)(1.75\times10^{-6}\text{ C})} = 6.17\times10^{-8}$ C.

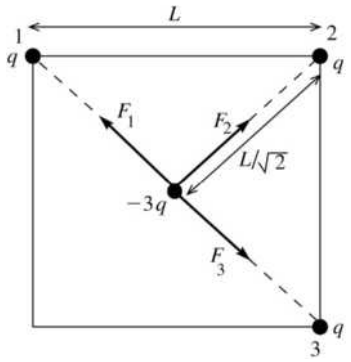
$q_2 = -q_1 = -6.17\times10^{-8}$ C.

EVALUATE: Simple reasoning allows us first to conclude that q_1 and q_2 must have equal magnitudes but opposite signs, which makes the equations much easier to set up than if we had tried to solve the problem in the general case. As Q accelerates and hence moves upward, the magnitude of the acceleration vector will change in a complicated way.

21.77. **IDENTIFY:** Use Coulomb's law to calculate the forces between pairs of charges and sum these forces as vectors to find the net charge.

(a) SET UP: The forces are sketched in Figure 21.77a.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

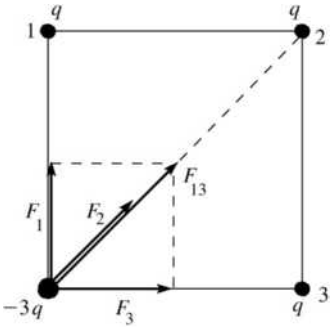


EXECUTE: $\vec{F}_1 + \vec{F}_3 = 0$, so the net force is $\vec{F} = \vec{F}_2$.

$F = \dfrac{1}{4\pi\epsilon_0}\dfrac{q(3q)}{(L/\sqrt{2})^2} = \dfrac{6q^2}{4\pi\epsilon_0 L^2}$, away from the vacant corner.

Figure 21. 77a

(b) SET UP: The forces are sketched in Figure 21.77b.



EXECUTE: $F_2 = \dfrac{1}{4\pi\epsilon_0}\dfrac{q(3q)}{(\sqrt{2}L)^2} = \dfrac{3q^2}{4\pi\epsilon_0(2L^2)}$

$F_1 = F_3 = \dfrac{1}{4\pi\epsilon_0}\dfrac{q(3q)}{L^2} = \dfrac{3q^2}{4\pi\epsilon_0 L^2}$

The vector sum of F_1 and F_3 is $F_{13} = \sqrt{F_1^2 + F_3^2}$.

Figure 21. 77b

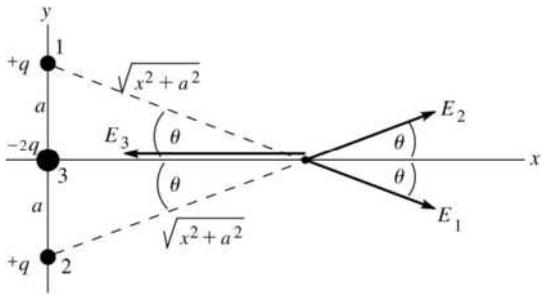
$F_{13} = \sqrt{2}F_1 = \dfrac{3\sqrt{2}q^2}{4\pi\epsilon_0 L^2}$; $\vec{F}_{13}$ and $\vec{F}_2$ are in the same direction.

$F = F_{13} + F_2 = \dfrac{3q^2}{4\pi\epsilon_0 L^2}\left(\sqrt{2} + \dfrac{1}{2}\right)$, and is directed toward the center of the square.

EVALUATE: By symmetry the net force is along the diagonal of the square. The net force is only slightly larger when the $-3q$ charge is at the center. Here it is closer to the charge at point 2 but the other two forces cancel.

21.78. **IDENTIFY:** Use Eq. (21.7) for the electric field produced by each point charge. Apply the principle of superposition and add the fields as vectors to find the net field.

(a) SET UP: The fields due to each charge are shown in Figure 21.78a.

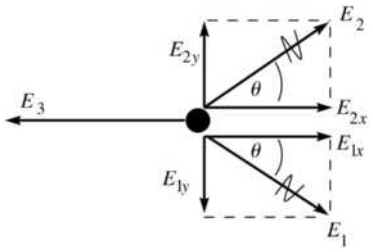


$\cos\theta = \dfrac{x}{\sqrt{x^2 + a^2}}$

Figure 21.78a

EXECUTE: The components of the fields are given in Figure 21.78b.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.



$$E_1 = E_2 = \frac{1}{4\pi\epsilon_0}\left(\frac{q}{a^2+x^2}\right)$$

$$E_3 = \frac{1}{4\pi\epsilon_0}\left(\frac{2q}{x^2}\right)$$

Figure 21.78b

$E_{1y} = -E_1\sin\theta, E_{2y} = +E_2\sin\theta$ so $E_y = E_{1y} + E_{2y} = 0.$

$$E_{1x} = E_{2x} = +E_1\cos\theta = \frac{1}{4\pi\epsilon_0}\left(\frac{q}{a^2+x^2}\right)\left(\frac{x}{\sqrt{x^2+a^2}}\right), E_{3x} = -E_3$$

$$E_x = E_{1x} + E_{2x} + E_{3x} = 2\left(\frac{1}{4\pi\epsilon_0}\left(\frac{q}{a^2+x^2}\right)\left(\frac{x}{\sqrt{x^2+a^2}}\right)\right) - \frac{2q}{4\pi\epsilon_0 x^2}$$

$$E_x = -\frac{2q}{4\pi\epsilon_0}\left(\frac{1}{x^2} - \frac{x}{(a^2+x^2)^{3/2}}\right) = -\frac{2q}{4\pi\epsilon_0 x^2}\left(1 - \frac{1}{(1+a^2/x^2)^{3/2}}\right)$$

Thus $E = \dfrac{2q}{4\pi\epsilon_0 x^2}\left(1 - \dfrac{1}{(1+a^2/x^2)^{3/2}}\right)$, in the $-x$-direction.

(b) $x \gg a$ implies $a^2/x^2 \ll 1$ and $(1+a^2/x^2)^{-3/2} \approx 1 - 3a^2/2x^2$.

Thus $E \approx \dfrac{2q}{4\pi\epsilon_0 x^2}\left(1 - \left(1 - \dfrac{3a^2}{2x^2}\right)\right) = \dfrac{3qa^2}{4\pi\epsilon_0 x^4}.$

EVALUATE: $E \sim 1/x^4$. For a point charge $E \sim 1/x^2$ and for a dipole $E \sim 1/x^3$. The total charge is zero so at large distances the electric field should decrease faster with distance than for a point charge. By symmetry $\vec{E}$ must lie along the x-axis, which is the result we found in part (a).

21.79. **IDENTIFY:** The small bags of protons behave like point-masses and point-charges since they are extremely far apart.

SET UP: For point-particles, we use Newton's formula for universal gravitation $(F = Gm_1m_2/r^2)$ and Coulomb's law. The number of protons is the mass of protons in the bag divided by the mass of a single proton.

EXECUTE: **(a)** $(0.0010\text{ kg})/(1.67\times10^{-27}\text{ kg}) = 6.0\times10^{23}$ protons

(b) Using Coulomb's law, where the separation is twice the radius of the earth, we have

$F_{\text{electrical}} = (9.00\times10^9\text{ N}\cdot\text{m}^2/\text{C}^2)(6.0\times10^{23}\times1.60\times10^{-19}\text{ C})^2/(2\times6.38\times10^6\text{ m})^2 = 5.1\times10^5\text{ N}$

$F_{\text{grav}} = (6.67\times10^{-11}\text{ N}\cdot\text{m}^2/\text{kg}^2)(0.0010\text{ kg})^2/(2\times6.38\times10^6\text{ m})^2 = 4.1\times10^{-31}\text{ N}$

(c) EVALUATE: The electrical force (≈200,000 lb!) is certainly large enough to feel, but the gravitational force clearly is not since it is about 10^{36} times weaker.

21.80. **IDENTIFY:** We can treat the protons as point-charges and use Coulomb's law.

SET UP: **(a)** Coulomb's law is $F = (1/4\pi\epsilon_0)|q_1q_2|/r^2$.

EXECUTE: $F = (9.00\times10^9\text{ N}\cdot\text{m}^2/\text{C}^2)(1.60\times10^{-19}\text{ C})^2/(2.0\times10^{-15}\text{ m})^2 = 58\text{ N} = 13\text{ lb},$ which is certainly large enough to feel.

(b) EVALUATE: Something must be holding the nucleus together by opposing this enormous repulsion. This is the strong nuclear force.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

21.81. **IDENTIFY:** Estimate the number of protons in the textbook and from this find the net charge of the textbook. Apply Coulomb's law to find the force and use $F_{\text{net}} = ma$ to find the acceleration.

SET UP: With the mass of the book about 1.0 kg, most of which is protons and neutrons, we find that the number of protons is $\frac{1}{2}(1.0\text{ kg})/(1.67\times10^{-27}\text{ kg}) = 3.0\times10^{26}$.

EXECUTE: **(a)** The charge difference present if the electron's charge was 99.999% of the proton's is $\Delta q = (3.0\times10^{26})(0.00001)(1.6\times10^{-19}\text{ C}) = 480\text{ C}$.

(b) $F = k(\Delta q)^2/r^2 = k(480\text{ C})^2/(5.0\text{ m})^2 = 8.3\times10^{13}\text{ N}$, and is repulsive.

$a = F/m = (8.3\times10^{13}\text{ N})/(1\text{ kg}) = 8.3\times10^{13}\text{ m/s}^2$.

EXECUTE: **(c)** Even the slightest charge imbalance in matter would lead to explosive repulsion!

21.82. **IDENTIFY:** The positive sphere will be deflected in the direction of the electric field but the negative sphere will be deflected in the direction opposite to the electric field. Since the spheres hang at rest, they are in equilibrium so the forces on them must balance. The external forces on each sphere are gravity, the tension in the string, the force due to the uniform electric field and the electric force due to the other sphere.

SET UP: The electric force on one sphere due to the other is $F_{\text{C}} = k\dfrac{|q^2|}{r^2}$ in the horizontal direction, the force on it due to the uniform electric field is $F_E = qE$ in the horizontal direction, the gravitational force is mg vertically downward and the force due to the string is T directed along the string. For equilibrium $\sum F_x = 0$ and $\sum F_y = 0$.

EXECUTE: **(a)** The positive sphere is deflected in the same direction as the electric field, so the one that is deflected to the left is positive.

(b) The separation between the two spheres is $2(0.530\text{ m})\sin25^{\text{o}} = 0.4480\text{ m}$.

$F_{\text{C}} = k\dfrac{|q^2|}{r^2} = \dfrac{(8.99\times10^9\text{ N}\cdot\text{m}^2/\text{C}^2)(72.0\times10^{-9}\text{ C})^2}{(0.4480\text{ m})^2} = 2.322\times10^{-4}\text{ N}$. $F_E = qE$. $\sum F_y = 0$ gives

$T\cos25^{\text{o}} - mg = 0$ and $T = \dfrac{mg}{\cos25^{\text{o}}}$. $\sum F_x = 0$ gives $T\sin25^{\text{o}} + F_C - F_{\text{E}} = 0$. $mg\tan25^{\text{o}} + F_C = qE$.

Combining the equations and solving for E gives

$$E = \frac{mg\tan25^{\text{o}} + F_{\text{C}}}{q} = \frac{(6.80\times10^{-6}\text{ kg})(9.8\text{ m/s}^2)\tan25^{\text{o}} + 2.322\times10^{-4}\text{ N}}{72.0\times10^{-9}\text{ C}} = 3.66\times10^3\text{ N/C}.$$

EVALUATE: Since the charges have opposite signs, they attract each other, which tends to reduce the angle between the strings. Therefore if their charges were negligibly small, the angle between the strings would be greater than 50°.

21.83. **IDENTIFY:** The only external force acting on the electron is the electrical attraction of the proton, and its acceleration is toward the center of its circular path (that is, toward the proton). Newton's second law applies to the proton and Coulomb's law gives the electrical force on it due to the proton.

SET UP: Newton's second law gives $F_{\text{C}} = m\dfrac{v^2}{r}$. Using the electrical force for F_{C} gives $k\dfrac{e^2}{r^2} = m\dfrac{v^2}{r}$.

EXECUTE: Solving for v gives $v = \sqrt{\dfrac{ke^2}{mr}} = \sqrt{\dfrac{(8.99\times10^9\text{ N}\cdot\text{m}^2/\text{C}^2)(1.60\times10^{-19}\text{ C})^2}{(9.109\times10^{-31}\text{ kg})(5.29\times10^{-11}\text{ m})}} = 2.19\times10^6\text{ m/s}$.

EVALUATE: This speed is less than 1% the speed of light, so it is reasonably safe to use Newtonian physics.

21.84. **IDENTIFY:** Since we can ignore gravity, the only external force acting on the moving sphere is the electrical attraction of the stationary sphere, and its acceleration is toward the center of its circular path (that is, toward the stationary sphere). Newton's second law applies to the moving sphere and Coulomb's law gives the electrical force on it due to the stationary sphere.

SET UP: Newton's second law gives $F_{\text{C}} = m\dfrac{v^2}{r}$. Using the electrical force for F_{C} gives $k\dfrac{|q_1q_2|}{r^2} = m\dfrac{v^2}{r}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: Solving for r gives $r = \dfrac{k|q_1 q_2|}{mv^2} = \dfrac{(8.99\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)(4.3\times10^{-6}\ \text{C})(7.5\times10^{-6}\ \text{C})}{(9.00\times10^{-9}\ \text{kg})(5.9\times10^3\ \text{m/s})^2} = 0.925\ \text{m}.$

EVALUATE: We can safely ignore gravity in most cases because it is normally *much* weaker than the electric force.

21.85. **IDENTIFY** and **SET UP:** Use the density of copper to calculate the number of moles and then the number of atoms. Calculate the net charge and then use Coulomb's law to calculate the force.

EXECUTE: **(a)** $m = \rho V = \rho\left(\dfrac{4}{3}\pi r^3\right) = (8.9\times10^3\ \text{kg/m}^3)\left(\dfrac{4}{3}\pi\right)(1.00\times10^{-3}\ \text{m})^3 = 3.728\times10^{-5}\ \text{kg}$

$n = m/M = (3.728\times10^{-5}\ \text{kg})/(63.546\times10^{-3}\ \text{kg/mol}) = 5.867\times10^{-4}\ \text{mol}$

$N = nN_\text{A} = 3.5\times10^{20}$ atoms

(b) $N_e = (29)(3.5\times10^{20}) = 1.015\times10^{22}$ electrons and protons

$q_\text{net} = eN_e - (0.99900)eN_e = (0.100\times10^{-2})(1.602\times10^{-19}\ \text{C})(1.015\times10^{22}) = 1.6\ \text{C}$

$F = k\dfrac{q^2}{r^2} = k\dfrac{(1.6\ \text{C})^2}{(1.00\ \text{m})^2} = 2.3\times10^{10}\ \text{N}$

EVALUATE: The amount of positive and negative charge in even small objects is immense. If the charge of an electron and a proton weren't exactly equal, objects would have large net charges.

21.86. **IDENTIFY:** Apply constant acceleration equations to a drop to find the acceleration. Then use $F = ma$ to find the force and $F = |q|E$ to find $|q|$.

SET UP: Let $D = 2.0$ cm be the horizontal distance the drop travels and $d = 0.30$ mm be its vertical displacement. Let $+x$ be horizontal and in the direction from the nozzle toward the paper and let $+y$ be vertical, in the direction of the deflection of the drop. $a_x = 0$ and $a_y = a$.

EXECUTE: Find the time of flight: $t = D/v = (0.020\ \text{m})/(20\ \text{m/s}) = 0.00100\ \text{s}$. $d = \dfrac{1}{2}at^2$.

$a = \dfrac{2d}{t^2} = \dfrac{2(3.00\times10^{-4}\ \text{m})}{(0.001\,\text{s})^2} = 600\ \text{m/s}^2.$

Then $a = F/m = qE/m$ gives $q = ma/E = \dfrac{(1.4\times10^{-11}\ \text{kg})(600\ \text{m/s}^2)}{8.00\times10^4\ \text{N/C}} = 1.05\times10^{-13}\ \text{C}.$

EVALUATE: Since q is positive the vertical deflection is in the direction of the electric field.

21.87. **IDENTIFY:** Eq. (21.3) gives the force exerted by the electric field. This force is constant since the electric field is uniform and gives the proton a constant acceleration. Apply the constant acceleration equations for the x- and y-components of the motion, just as for projectile motion.

(a) SET UP: The electric field is upward so the electric force on the positively charged proton is upward and has magnitude $F = eE$. Use coordinates where positive y is downward. Then applying $\sum \vec{F} = m\vec{a}$ to the proton gives that $a_x = 0$ and $a_y = -eE/m$. In these coordinates the initial velocity has components $v_x = +v_0\cos\alpha$ and $v_y = +v_0\sin\alpha$, as shown in Figure 21.87a.

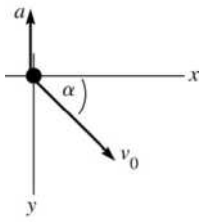


Figure 21.87a

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: Finding h_{max}: At $y = h_{max}$ the y-component of the velocity is zero.

$v_y = 0, v_{0y} = v_0 \sin\alpha, a_y = -eE/m, y - y_0 = h_{max} = ?$

$v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$

$$y - y_0 = \frac{v_y^2 - v_{0y}^2}{2a_y}$$

$$h_{max} = \frac{-v_0^2 \sin^2\alpha}{2(-eE/m)} = \frac{mv_0^2 \sin^2\alpha}{2eE}$$

(b) Use the vertical motion to find the time t: $y - y_0 = 0, v_{0y} = v_0 \sin\alpha, a_y = -eE/m, t = ?$

$y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$

With $y - y_0 = 0$ this gives $t = -\dfrac{2v_{0y}}{a_y} = -\dfrac{2(v_0 \sin\alpha)}{-eE/m} = \dfrac{2mv_0 \sin\alpha}{eE}$

Then use the x-component motion to find d: $a_x = 0, v_{0x} = v_0 \cos\alpha, t = 2mv_0 \sin\alpha/eE, x - x_0 = d = ?$

$x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2$ gives $d = v_0 \cos\alpha\left(\dfrac{2mv_0 \sin\alpha}{eE}\right) = \dfrac{mv_0^2 2\sin\alpha\cos\alpha}{eE} = \dfrac{mv_0^2 \sin 2\alpha}{eE}$

(c) The trajectory of the proton is sketched in Figure 21.87b.

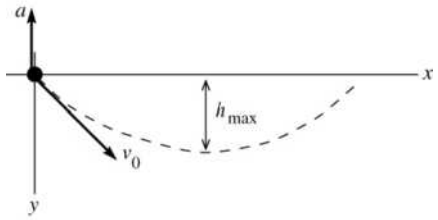

Figure 21.87b

(d) Use the expression in part (a): $h_{max} = \dfrac{[(4.00\times10^5 \text{ m/s})(\sin 30.0°)]^2(1.673\times10^{-27} \text{ kg})}{2(1.602\times10^{-19} \text{ C})(500 \text{ N/C})} = 0.418 \text{ m}$

Use the expression in part (b): $d = \dfrac{(1.673\times10^{-27} \text{ kg})(4.00\times10^5 \text{ m/s})^2 \sin 60.0°}{(1.602\times10^{-19} \text{ C})(500 \text{ N/C})} = 2.89 \text{ m}$

EVALUATE: In part (a), $a_y = -eE/m = -4.8\times10^{10} \text{ m/s}^2$. This is much larger in magnitude than g, the acceleration due to gravity, so it is reasonable to ignore gravity. The motion is just like projectile motion, except that the acceleration is upward rather than downward and has a much different magnitude. h_{max} and d increase when α or v_0 increase and decrease when E increases.

21.88. **IDENTIFY:** $E_x = E_{1x} + E_{2x}$. Use Eq. (21.7) for the electric field due to each point charge.

SET UP: $\vec{E}$ is directed away from positive charges and toward negative charges.

EXECUTE: **(a)** $E_x = +50.0$ N/C. $E_{1x} = \dfrac{1}{4\pi\epsilon_0}\dfrac{|q_1|}{r_1^2} = (8.99\times10^9 \text{ N}\cdot\text{m}^2/\text{C}^2)\dfrac{4.00\times10^{-9} \text{ C}}{(0.60 \text{ m})^2} = +99.9 \text{ N/C}.$

$E_x = E_{1x} + E_{2x}$, so $E_{2x} = E_x - E_{1x} = +50.0 \text{ N/C} - 99.9 \text{ N/C} = -49.9 \text{ N/C}$. Since E_{2x} is negative, q_2 must be negative. $|q_2| = \dfrac{|E_{2x}|r_2^2}{(1/4\pi\epsilon_0)} = \dfrac{(49.9 \text{ N/C})(1.20 \text{ m})^2}{8.99\times10^9 \text{ N}\cdot\text{m}^2/\text{C}^2} = 7.99\times10^{-9} \text{ C}$. $q_2 = -7.99\times10^{-9} \text{ C}$

(b) $E_x = -50.0$ N/C. $E_{1x} = +99.9$ N/C, as in part (a). $E_{2x} = E_x - E_{1x} = -149.9$ N/C. q_2 is negative.

$|q_2| = \dfrac{|E_{2x}|r_2^2}{(1/4\pi\epsilon_0)} = \dfrac{(149.9 \text{ N/C})(1.20 \text{ m})^2}{8.99\times10^9 \text{ N}\cdot\text{m}^2/\text{C}^2} = 2.40\times10^{-8} \text{ C}$. $q_2 = -2.40\times10^{-8} \text{ C}$.

EVALUATE: q_2 would be positive if E_{2x} were positive.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

21.89. **IDENTIFY:** Divide the charge distribution into infinitesimal segments of length dx. Calculate E_x and E_y due to a segment and integrate to find the total field.

SET UP: The charge dQ of a segment of length dx is $dQ = (Q/a)dx$. The distance between a segment at x and the charge q is $a + r - x$. $(1-y)^{-1} \approx 1 + y$ when $|y| \ll 1$.

EXECUTE: **(a)** $dE_x = \dfrac{1}{4\pi\epsilon_0}\dfrac{dQ}{(a+r-x)^2}$ so $E_x = \dfrac{1}{4\pi\epsilon_0}\displaystyle\int_0^a \frac{Q dx}{a(a+r-x)^2} = \frac{1}{4\pi\epsilon_0}\frac{Q}{a}\left(\frac{1}{r} - \frac{1}{a+r}\right)$.

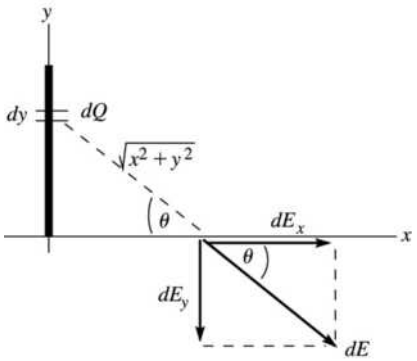
$a + r = x$, so $E_x = \dfrac{1}{4\pi\epsilon_0}\dfrac{Q}{a}\left(\dfrac{1}{x-a} - \dfrac{1}{x}\right)$. $E_y = 0$.

(b) $\vec{F} = q\vec{E} = \dfrac{1}{4\pi\epsilon_0}\dfrac{qQ}{a}\left(\dfrac{1}{r} - \dfrac{1}{a+r}\right)\hat{i}$.

EVALUATE: **(c)** For $x \gg a$, $F = \dfrac{kqQ}{ax}((1-a/x)^{-1} - 1) = \dfrac{kqQ}{ax}(1 + a/x + \cdots - 1) \approx \dfrac{kqQ}{x^2} \approx \dfrac{1}{4\pi\epsilon_0}\dfrac{qQ}{r^2}$. (Note that for $x \gg a$, $r = x - a \approx x$.) The charge distribution looks like a point charge from far away, so the force takes the form of the force between a pair of point charges.

21.90. **IDENTIFY:** Use Eq. (21.7) to calculate the electric field due to a small slice of the line of charge and integrate as in Example 21.10. Use Eq. (21.3) to calculate $\vec{F}$.

SET UP: The electric field due to an infinitesimal segment of the line of charge is sketched in Figure 21.90.



$$\sin\theta = \frac{y}{\sqrt{x^2+y^2}}$$

$$\cos\theta = \frac{x}{\sqrt{x^2+y^2}}$$

Figure 21.90

Slice the charge distribution up into small pieces of length dy. The charge dQ in each slice is $dQ = Q(dy/a)$. The electric field this produces at a distance x along the x-axis is dE. Calculate the components of $d\vec{E}$ and then integrate over the charge distribution to find the components of the total field.

EXECUTE: $dE = \dfrac{1}{4\pi\epsilon_0}\left(\dfrac{dQ}{x^2+y^2}\right) = \dfrac{Q}{4\pi\epsilon_0 a}\left(\dfrac{dy}{x^2+y^2}\right)$

$$dE_x = dE\cos\theta = \frac{Qx}{4\pi\epsilon_0 a}\left(\frac{dy}{(x^2+y^2)^{3/2}}\right)$$

$$dE_y = -dE\sin\theta = -\frac{Q}{4\pi\epsilon_0 a}\left(\frac{ydy}{(x^2+y^2)^{3/2}}\right)$$

$$E_x = \int dE_x = -\frac{Qx}{4\pi\epsilon_0 a}\int_0^a \frac{dy}{(x^2+y^2)^{3/2}} = \frac{Qx}{4\pi\epsilon_0 a}\left[\frac{1}{x^2}\frac{y}{\sqrt{x^2+y^2}}\right]_0^a = \frac{Q}{4\pi\epsilon_0 x}\frac{1}{\sqrt{x^2+a^2}}$$

$$E_y = \int dEy = -\frac{Q}{4\pi\epsilon_0 a}\int_0^a \frac{ydy}{(x^2+y^2)^{3/2}} = -\frac{Q}{4\pi\epsilon_0 a}\left[-\frac{1}{\sqrt{x^2+y^2}}\right]_0^a = -\frac{Q}{4\pi\epsilon_0 a}\left(\frac{1}{x} - \frac{1}{\sqrt{x^2+a^2}}\right)$$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) $\vec{F} = q_0\vec{E}$

$$F_x = -qE_x = \frac{-qQ}{4\pi\epsilon_0 x}\frac{1}{\sqrt{x^2+a^2}};\ F_y = -qE_y = \frac{qQ}{4\pi\epsilon_0 a}\left(\frac{1}{x} - \frac{1}{\sqrt{x^2+a^2}}\right)$$

(c) For $x \gg a$, $\frac{1}{\sqrt{x^2+a^2}} = \frac{1}{x}\left(1+\frac{a^2}{x^2}\right)^{-1/2} = \frac{1}{x}\left(1-\frac{a^2}{2x^2}\right) = \frac{1}{x} - \frac{a^2}{2x^3}$

$$F_x \approx -\frac{qQ}{4\pi\epsilon_0 x^2},\ F_y \approx \frac{qQ}{4\pi\epsilon_0 a}\left(\frac{1}{x} - \frac{1}{x} + \frac{a^2}{2x^3}\right) = \frac{qQa}{8\pi\epsilon_0 x^3}$$

EVALUATE: For $x \gg a$, $F_y \ll F_x$ and $F \approx |F_x| = \frac{qQ}{4\pi\epsilon_0 x^2}$ and $\vec{F}$ is in the $-x$-direction. For $x \gg a$ the charge distribution Q acts like a point charge.

21.91. **IDENTIFY:** Apply Eq. (21.9) from Example 21.10.

SET UP: $a = 2.50$ cm. Replace Q by $|Q|$. Since Q is negative, $\vec{E}$ is toward the line of charge and $\vec{E} = -\frac{1}{4\pi\epsilon_0}\frac{|Q|}{x\sqrt{x^2+a^2}}\hat{\imath}$.

EXECUTE: $\vec{E} = -\frac{1}{4\pi\epsilon_0}\frac{|Q|}{x\sqrt{x^2+a^2}}\hat{\imath} = -\frac{1}{4\pi\epsilon_0}\frac{7.00\times10^{-9}\text{ C}}{(0.100\text{ m})\sqrt{(0.100\text{ m})^2+(0.025\text{ m})^2}}\hat{\imath} = (-6110\text{ N/C})\hat{\imath}$.

(b) The electric field is less than that at the same distance from a point charge (6300 N/C). For large x, $(x+a)^{-1/2} = \frac{1}{x}(1+a^2/x^2)^{-1/2} \approx \frac{1}{x}\left(1-\frac{a^2}{2x^2}\right)$, which gives $E_{x\to\infty} = \frac{1}{4\pi\epsilon_0}\frac{Q}{x^2}\left(1-\frac{a^2}{2x^2}+\cdots\right)$. The first correction term to the point charge result is negative.

(c) For a 1% difference, we need the first term in the expansion beyond the point charge result to be less than 0.010: $\frac{a^2}{2x^2} \approx 0.010 \Rightarrow x \approx a\sqrt{1/(2(0.010))} = (0.025\text{ m})\sqrt{1/0.020} \Rightarrow x \approx 0.177$ m.

EVALUATE: At $x = 10.0$ cm (part b), the exact result for the line of charge is 3.1% smaller than for a point charge. It is sensible, therefore, that the difference is 1.0% at a somewhat larger distance, 17.7 cm.

21.92. **IDENTIFY:** The electrical force has magnitude $F = \frac{kQ^2}{r^2}$ and is attractive. Apply $\sum\vec{F} = m\vec{a}$ to the earth.

SET UP: For a circular orbit, $a = \frac{v^2}{r}$. The period T is $\frac{2\pi r}{v}$. The mass of the earth is $m_E = 5.97\times10^{24}$ kg, the orbit radius of the earth is 1.50×10^{11} m and its orbital period is 3.146×10^7 s.

EXECUTE: $F = ma$ gives $\frac{kQ}{r^2} = m_E\frac{v^2}{r}$. $v^2 = \frac{4\pi^2r^2}{T^2}$, so

$$Q = \sqrt{\frac{m_E 4\pi^2 r^3}{kT^2}} = \sqrt{\frac{(5.97\times10^{24}\text{ kg})(4)(\pi^2)(1.50\times10^{11}\text{ m})^3}{(8.99\times10^9\text{ N}\cdot\text{m}^2/\text{C}^2)(3.146\times10^7\text{ s})^2}} = 2.99\times10^{17}\text{ C}.$$

EVALUATE: A very large net charge would be required.

21.93. **IDENTIFY:** Apply Eq. (21.11).

SET UP: $\sigma = Q/A = Q/\pi R^2$. $(1+y^2)^{-1/2} \approx 1 - y^2/2$, when $y^2 \ll 1$.

EXECUTE: **(a)** $E = \frac{\sigma}{2\epsilon_0}[1-(R^2/x^2+1)^{-1/2}]$.

$$E = \frac{7.00\text{ pC}/\pi(0.025\text{ m})^2}{2\epsilon_0}\left[1-\left(\frac{(0.025\text{ m})^2}{(0.200\text{ m})^2}+1\right)^{-1/2}\right] = 1.56\text{ N/C},\ \text{in the } +x\text{-direction.}$$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) For $x \gg R$, $E = \frac{\sigma}{2\epsilon_0}[1-(1-R^2/2x^2+\cdots)] \approx \frac{\sigma}{2\epsilon_0}\frac{R^2}{2x^2} = \frac{\sigma\pi R^2}{4\pi\epsilon_0 x^2} = \frac{Q}{4\pi\epsilon_0 x^2}$.

(c) The electric field of (a) is less than that of the point charge (0.90 N/C) since the first correction term to the point charge result is negative.

(d) For $x = 0.200$ m, the percent difference is $\frac{(1.58-1.56)}{1.56} = 0.01 = 1\%$. For $x = 0.100$ m, $E_{\text{disk}} = 6.00$ N/C and $E_{\text{point}} = 6.30$ N/C, so the percent difference is $\frac{(6.30-6.00)}{6.30} = 0.047 \approx 5\%$.

EVALUATE: The field of a disk becomes closer to the field of a point charge as the distance from the disk increases. At $x = 10.0$ cm, $R/x = 25\%$ and the percent difference between the field of the disk and the field of a point charge is 5%.

21.94. **IDENTIFY:** When the forces on it balance, the acceleration of a molecule is zero and it moves with constant velocity.

SET UP: The electrical force is $F_E = qE$ and the viscous drag force is $F_D = KRv$.

EXECUTE: **(a)** $F = F_D$ so $qE = KRv$ and $\frac{q}{R} = \frac{Kv}{E}$.

(b) The speed is constant and has magnitude $v = \frac{Eq}{KR}$. Therefore $x = vt = \left(\frac{Eq}{KR}\right)T = \left(\frac{ET}{K}\right)\frac{q}{R}$.

(c) $x = \left(\frac{ET}{K}\right)\frac{q}{R}$, where $\frac{ET}{K}$ is constant. $\left(\frac{q}{R}\right)_2 = 2\left(\frac{q}{R}\right)_1$ and $\left(\frac{q}{R}\right)_3 = 3\left(\frac{q}{R}\right)_1$.

$x_2 = \left(\frac{ET}{K}\right)\left(\frac{q}{R}\right)_2 = 2\left(\frac{ET}{K}\right)\left(\frac{q}{R}\right)_1 = 2x_1$; $x_3 = \left(\frac{ET}{K}\right)\left(\frac{q}{R}\right)_3 = 3\left(\frac{ET}{K}\right)\left(\frac{q}{R}\right)_1 = 3x_1$.

EVALUATE: The distance a particle moves is not proportional to its charge, but rather is proportional to the ratio of its charge to its radius (size).

21.95. **IDENTIFY:** Find the resultant electric field due to the two point charges. Then use $\vec{F} = q\vec{E}$ to calculate the force on the point charge.

SET UP: Use the results of Problems 21.90 and 21.89.

EXECUTE: **(a)** The y-components of the electric field cancel, and the x-component from both charges, as given in Problem 21.90, is $E_x = \frac{1}{4\pi\epsilon_0}\frac{-2Q}{a}\left(\frac{1}{y} - \frac{1}{(y^2+a^2)^{1/2}}\right)$. Therefore,

$\vec{F} = \frac{1}{4\pi\epsilon_0}\frac{-2Qq}{a}\left(\frac{1}{y} - \frac{1}{(y^2+a^2)^{1/2}}\right)\hat{\boldsymbol{i}}$. If $y \gg a$, $\vec{F} \approx \frac{1}{4\pi\epsilon_0}\frac{-2Qq}{ay}(1-(1-a^2/2y^2+\cdots))\hat{\boldsymbol{i}} = -\frac{1}{4\pi\epsilon_0}\frac{Qqa}{y^3}\hat{\boldsymbol{i}}$.

(b) If the point charge is now on the x-axis the two halves of the charge distribution provide different forces, though still along the x-axis, as given in Problem 21.89: $\vec{F}_+ = q\vec{E}_+ = \frac{1}{4\pi\epsilon_0}\frac{Qq}{a}\left(\frac{1}{x-a} - \frac{1}{x}\right)\hat{\boldsymbol{i}}$

and $\vec{F}_- = q\vec{E}_- = -\frac{1}{4\pi\epsilon_0}\frac{Qq}{a}\left(\frac{1}{x} - \frac{1}{x+a}\right)\hat{\boldsymbol{i}}$. Therefore, $\vec{F} = \vec{F}_+ + \vec{F}_- = \frac{1}{4\pi\epsilon_0}\frac{Qq}{a}\left(\frac{1}{x-a} - \frac{2}{x} + \frac{1}{x+a}\right)\hat{\boldsymbol{i}}$. For

$x \gg a$, $\vec{F} \approx \frac{1}{4\pi\epsilon_0}\frac{Qq}{ax}\left(\left(1+\frac{a}{x}+\frac{a^2}{x^2}+\ldots\right) - 2 + \left(1-\frac{a}{x}+\frac{a^2}{x^2}-\ldots\right)\right)\hat{\boldsymbol{i}} = \frac{1}{4\pi\epsilon_0}\frac{2Qqa}{x^3}\hat{\boldsymbol{i}}$.

EVALUATE: If the charge distributed along the x-axis were all positive or all negative, the force would be proportional to $1/y^2$ in part (a) and to $1/x^2$ in part (b), when y or x is very large.

21.96. **IDENTIFY:** Apply $\sum F_x = 0$ and $\sum F_y = 0$ to the sphere, with x horizontal and y vertical.

SET UP: The free-body diagram for the sphere is given in Figure 21.96. The electric field $\vec{E}$ of the sheet is directed away from the sheet and has magnitude $E = \frac{\sigma}{2\epsilon_0}$ (Eq. 21.12).

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: $\sum F_y = 0$ gives $T\cos\alpha = mg$ and $T = \dfrac{mg}{\cos\alpha}$. $\sum F_x = 0$ gives $T\sin\alpha = \dfrac{q\sigma}{2\epsilon_0}$ and $T = \dfrac{q\sigma}{2\epsilon_0 \sin\alpha}$. Combining these two equations we have $\dfrac{mg}{\cos\alpha} = \dfrac{q\sigma}{2\epsilon_0\sin\alpha}$ and $\tan\alpha = \dfrac{q\sigma}{2\epsilon_0 mg}$. Therefore, $\alpha = \arctan\left(\dfrac{q\sigma}{2\epsilon_0 mg}\right)$.

EVALUATE: The electric field of the sheet, and hence the force it exerts on the sphere, is independent of the distance of the sphere from the sheet.

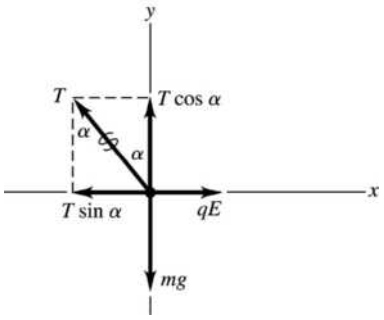


Figure 21.96

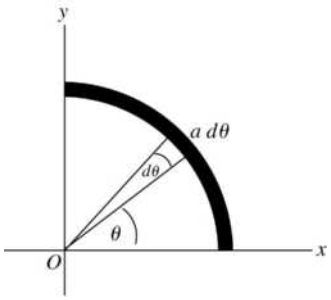
21.97. **IDENTIFY:** Divide the charge distribution into small segments, use the point charge formula for the electric field due to each small segment and integrate over the charge distribution to find the x and y components of the total field.

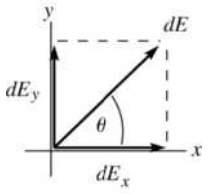
SET UP: Consider the small segment shown in Figure 21.97a.



EXECUTE: A small segment that subtends angle $d\theta$ has length $a\,d\theta$ and contains charge $dQ = \left(\dfrac{ad\theta}{\frac{1}{2}\pi a}\right)Q = \dfrac{2Q}{\pi}d\theta$. ($\frac{1}{2}\pi a$ is the total length of the charge distribution.)

Figure 21.97a

The charge is negative, so the field at the origin is directed toward the small segment. The small segment is located at angle θ as shown in the sketch. The electric field due to dQ is shown in Figure 21.97b, along with its components.



$$dE = \frac{1}{4\pi\epsilon_0}\frac{|dQ|}{a^2}$$

$$dE = \frac{Q}{2\pi^2\epsilon_0 a^2}d\theta$$

Figure 21.97b

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$dE_x = dE\cos\theta = (Q/2\pi^2\epsilon_0 a^2)\cos\theta d\theta$

$E_x = \int dE_x = \dfrac{Q}{2\pi^2\epsilon_0 a^2}\int_0^{\pi/2}\cos\theta d\theta = \dfrac{Q}{2\pi^2\epsilon_0 a^2}(\sin\theta\Big|_0^{\pi/2}) = \dfrac{Q}{2\pi^2\epsilon_0 a^2}$

$dE_y = dE\sin\theta = (Q/2\pi^2\epsilon_0 a^2)\sin\theta d\theta$

$E_y = \int dE_y = \dfrac{Q}{2\pi^2\epsilon_0 a^2}\int_0^{\pi/2}\sin\theta d\theta = \dfrac{Q}{2\pi^2\epsilon_0 a^2}(-\cos\theta\Big|_0^{\pi/2}) = \dfrac{Q}{2\pi^2\epsilon_0 a^2}$

EVALUATE: Note that $E_x = E_y$, as expected from symmetry.

21.98. **IDENTIFY:** We must add the electric field components of the positive half and the negative half.

SET UP: From Problem 21.97, the electric field due to the quarter-circle section of positive charge has components $E_x = +\dfrac{Q}{2\pi^2\epsilon_0 a^2}$, $E_y = -\dfrac{Q}{2\pi^2\epsilon_0 a^2}$. The field due to the quarter-circle section of negative charge has components $E_x = +\dfrac{Q}{2\pi^2\epsilon_0 a^2}$, $E_y = +\dfrac{Q}{2\pi^2\epsilon_0 a^2}$.

EXECUTE: The components of the resultant field is the sum of the x- and y-components of the fields due to each half of the semicircle. The y-components cancel, but the x-components add, giving $E_x = +\dfrac{Q}{\pi^2\epsilon_0 a^2}$, in the $+x$-direction.

EVALUATE: Even though the net charge on the semicircle is zero, the field it produces is *not* zero because of the way the charge is arranged.

21.99. **IDENTIFY:** Each wire produces an electric field at P due to a finite wire. These fields add by vector addition.

SET UP: Each field has magnitude $\dfrac{1}{4\pi\epsilon_0}\dfrac{Q}{x\sqrt{x^2+a^2}}$. The field due to the negative wire points to the left, while the field due to the positive wire points downward, making the two fields perpendicular to each other and of equal magnitude. The net field is the vector sum of these two, which is $E_{\text{net}} = 2E_1\cos 45° = 2\dfrac{1}{4\pi\epsilon_0}\dfrac{Q}{x\sqrt{x^2+a^2}}\cos 45°$. In part (b), the electrical force on an electron at P is eE.

EXECUTE: **(a)** The net field is $E_{\text{net}} = 2\dfrac{1}{4\pi\epsilon_0}\dfrac{Q}{x\sqrt{x^2+a^2}}\cos 45°$.

$$E_{\text{net}} = \frac{2(9.00\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)(2.50\times10^{-6}\ \text{C})\cos 45°}{(0.600\ \text{m})\sqrt{(0.600\ \text{m})^2+(0.600\ \text{m})^2}} = 6.25\times10^4\ \text{N/C}.$$

The direction is 225° counterclockwise from an axis pointing to the right at point P.

(b) $F = eE = (1.60\times10^{-19}\ \text{C})(6.25\times10^4\ \text{N/C}) = 1.00\times10^{-14}\ \text{N}$, opposite to the direction of the electric field, since the electron has negative charge.

EVALUATE: Since the electric fields due to the two wires have equal magnitudes and are perpendicular to each other, we only have to calculate one of them in the solution.

21.100. **IDENTIFY:** Each sheet produces an electric field that is independent of the distance from the sheet. The net field is the vector sum of the two fields.

SET UP: The formula for each field is $E = \sigma/2\epsilon_0$, and the net field is the vector sum of these, $E_{\text{net}} = \dfrac{\sigma_B}{2\epsilon_0} \pm \dfrac{\sigma_A}{2\epsilon_0} = \dfrac{\sigma_B \pm \sigma_A}{2\epsilon_0}$, where we use the + or − sign depending on whether the fields are in the same or opposite directions and σ_B and σ_A are the magnitudes of the surface charges.

EXECUTE: **(a)** The two fields oppose and the field of B is stronger than that of A, so

$$E_{\text{net}} = \frac{\sigma_B}{2\epsilon_0} - \frac{\sigma_A}{2\epsilon_0} = \frac{\sigma_B - \sigma_A}{2\epsilon_0} = \frac{11.6\ \mu\text{C/m}^2 - 9.50\ \mu\text{C/m}^2}{2(8.85\times10^{-12}\text{C}^2/\text{N}\cdot\text{m}^2)} = 1.19\times10^5\ \text{N/C},\ \text{to the right.}$$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) The fields are now in the same direction, so their magnitudes add.

$$E_{\text{net}} = (11.6\ \mu\text{C/m}^2 + 9.50\ \mu\text{C/m}^2)/2\epsilon_0 = 1.19\times10^6\ \text{N/C, to the right}$$

(c) The fields add but now point to the left, so $E_{\text{net}} = 1.19\times10^6$ N/C, to the left.

EVALUATE: We can simplify the calculations by sketching the fields and doing an algebraic solution first.

21.101. **IDENTIFY:** Each sheet produces an electric field that is independent of the distance from the sheet. The net field is the vector sum of the two fields.

SET UP: The formula for each field is $E = \sigma/2\epsilon_0$, and the net field is the vector sum of these,

$E_{\text{net}} = \dfrac{\sigma_B}{2\epsilon_0} \pm \dfrac{\sigma_A}{2\epsilon_0} = \dfrac{\sigma_B \pm \sigma_A}{2\epsilon_0}$, where we use the + or − sign depending on whether the fields are in the same or opposite directions and σ_B and σ_A are the magnitudes of the surface charges.

EXECUTE: **(a)** The fields add and point to the left, giving $E_{\text{net}} = 1.19\times10^6$ N/C.

(b) The fields oppose and point to the left, so $E_{\text{net}} = 1.19\times10^5$ N/C.

(c) The fields oppose but now point to the right, giving $E_{\text{net}} = 1.19\times10^5$ N/C.

EVALUATE: We can simplify the calculations by sketching the fields and doing an algebraic solution first.

21.102. **IDENTIFY:** The sheets produce an electric field in the region between them which is the vector sum of the fields from the two sheets.

SET UP: The force on the negative oil droplet must be upward to balance gravity. The net electric field between the sheets is $E = \sigma/\epsilon_0$, and the electrical force on the droplet must balance gravity, so $qE = mg$.

EXECUTE: **(a)** The electrical force on the drop must be upward, so the field should point downward since the drop is negative.

(b) The charge of the drop is $5e$, so $qE = mg$. $(5e)(\sigma/\epsilon_0) = mg$ and

$$\sigma = \frac{mg\epsilon_0}{5e} = \frac{(324\times10^{-9}\text{ kg})(9.80\text{ m/s}^2)(8.85\times10^{-12}\text{ C}^2/\text{N}\cdot\text{m}^2)}{5(1.60\times10^{-19}\text{ C})} = 35.1\text{ C/m}^2$$

EVALUATE: Balancing oil droplets between plates was the basis of the Milliken Oil-Drop Experiment which produced the first measurement of the mass of an electron.

21.103. **IDENTIFY** and **SET UP:** Example 21.11 gives the electric field due to one infinite sheet. Add the two fields as vectors.

EXECUTE: The electric field due to the first sheet, which is in the xy-plane, is $\vec{E}_1 = (\sigma/2\epsilon_0)\hat{k}$ for $z > 0$ and $\vec{E}_1 = -(\sigma/2\epsilon_0)\hat{k}$ for $z < 0$. We can write this as $\vec{E}_1 = (\sigma/2\epsilon_0)(z/|z|)\hat{k}$, since $z/|z| = +1$ for $z > 0$ and $z/|z| = -z/z = -1$ for $z < 0$. Similarly, we can write the electric field due to the second sheet as $\vec{E}_2 = -(\sigma/2\epsilon_0)(x/|x|)\hat{i}$, since its charge density is $-\sigma$. The net field is $\vec{E} = \vec{E}_1 + \vec{E}_2 = (\sigma/2\epsilon_0)(-(x/|x|)\hat{i} + (z/|z|)\hat{k})$.

EVALUATE: The electric field is independent of the y-component of the field point since displacement in the $\pm y$-direction is parallel to both planes. The field depends on which side of each plane the field is located.

21.104. **IDENTIFY:** Apply Eq. (21.11) for the electric field of a disk. The hole can be described by adding a disk of charge density $-\sigma$ and radius R_1 to a solid disk of charge density $+\sigma$ and radius R_2.

SET UP: The area of the annulus is $\pi(R_2^2 - R_1^2)\sigma$. The electric field of a disk, Eq. (21.11) is

$$E = \frac{\sigma}{2\epsilon_0}\left[1 - 1/\sqrt{(R/x)^2 + 1}\right].$$

EXECUTE: **(a)** $Q = A\sigma = \pi(R_2^2 - R_1^2)\sigma$

(b) $\vec{E}(x) = \dfrac{\sigma}{2\epsilon_0}\left(\left[1 - 1/\sqrt{(R_2/x)^2 + 1}\right] - \left[1 - 1/\sqrt{(R_1/x)^2 + 1}\right]\right)\dfrac{|x|}{x}\hat{i}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$\vec{E}(x)=\dfrac{\sigma}{2\epsilon_0}\left(1/\sqrt{(R_1/x)^2+1}-1/\sqrt{(R_2/x)^2+1}\right)\dfrac{|x|}{x}\hat{\imath}$. The electric field is in the $+x$-direction at points above the disk and in the $-x$-direction at points below the disk, and the factor $\dfrac{|x|}{x}\hat{\imath}$ specifies these directions.

(c) Note that $1/\sqrt{(R_1/x)^2+1}=\dfrac{|x|}{R_1}(1+(x/R_1)^2)^{-1/2}\approx\dfrac{|x|}{R_1}$. This gives

$\vec{E}(x)=\dfrac{\sigma}{2\epsilon_0}\left(\dfrac{1}{R_1}-\dfrac{1}{R_2}\right)\dfrac{|x|^2}{x}\hat{\imath}=\dfrac{\sigma}{2\epsilon_0}\left(\dfrac{1}{R_1}-\dfrac{1}{R_2}\right)x\hat{\imath}$. Sufficiently close means that $(x/R_1)^2\ll 1$.

(d) $F_x=-qE_x=-\dfrac{q\sigma}{2\epsilon_0}\left(\dfrac{1}{R_1}-\dfrac{1}{R_2}\right)x$. The force is in the form of Hooke's law: $F_x=-kx$, with

$k=\dfrac{q\sigma}{2\epsilon_0}\left(\dfrac{1}{R_1}-\dfrac{1}{R_2}\right)$. $f=\dfrac{1}{2\pi}\sqrt{\dfrac{k}{m}}=\dfrac{1}{2\pi}\sqrt{\dfrac{q\sigma}{2\epsilon_0 m}\left(\dfrac{1}{R_1}-\dfrac{1}{R_2}\right)}$.

EVALUATE: The frequency is independent of the initial position of the particle, so long as this position is sufficiently close to the center of the annulus for $(x/R_1)^2$ to be small.

21.105. **IDENTIFY:** Apply Coulomb's law to calculate the forces that q_1 and q_2 exert on q_3, and add these force vectors to get the net force.

SET UP: Like charges repel and unlike charges attract. Let $+x$ be to the right and $+y$ be toward the top of the page.

EXECUTE: **(a)** The four possible force diagrams are sketched in Figure 21.105a.
Only the last picture can result in a net force in the $-x$-direction.

(b) $q_1=-2.00\ \mu\text{C}$, $q_3=+4.00\ \mu\text{C}$, and $q_2>0$.

(c) The forces $\vec{F}_1$ and $\vec{F}_2$ and their components are sketched in Figure 21.105b.

$F_y=0=-\dfrac{1}{4\pi\epsilon_0}\dfrac{|q_1||q_3|}{(0.0400\ \text{m})^2}\sin\theta_1+\dfrac{1}{4\pi\epsilon_0}\dfrac{|q_2||q_3|}{(0.0300\ \text{m})^2}\sin\theta_2$. This gives

$q_2=\dfrac{9}{16}|q_1|\dfrac{\sin\theta_1}{\sin\theta_2}=\dfrac{9}{16}|q_1|\dfrac{3/5}{4/5}=\dfrac{27}{64}|q_1|=0.843\ \mu\text{C}$.

(d) $F_x=F_{1x}+F_{2x}$ and $F_y=0$, so $F=|q_3|\dfrac{1}{4\pi\epsilon_0}\left(\dfrac{|q_1|}{(0.0400\ \text{m})^2}\dfrac{4}{5}+\dfrac{|q_2|}{(0.0300\ \text{m})^2}\dfrac{3}{5}\right)=56.2\ \text{N}$.

EVALUATE: The net force $\vec{F}$ on q_3 is in the same direction as the resultant electric field at the location of q_3 due to q_1 and q_2.

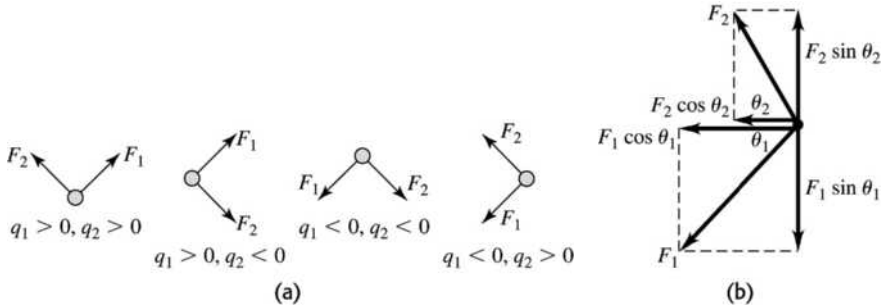


Figure 21.105

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

21.106. **IDENTIFY:** Calculate the electric field at P due to each charge and add these field vectors to get the net field.

SET UP: The electric field of a point charge is directed away from a positive charge and toward a negative charge. Let $+x$ be to the right and let $+y$ be toward the top of the page.

EXECUTE: **(a)** The four possible diagrams are sketched in Figure 21.106a.
The first diagram is the only one in which the electric field must point in the negative y-direction.
(b) $q_1 = -3.00\ \mu\text{C}$, and $q_2 < 0$.

(c) The electric fields $\vec{\boldsymbol{E}}_1$ and $\vec{\boldsymbol{E}}_2$ and their components are sketched in Figure 24.106b. $\cos\theta_1 = \dfrac{5}{13}$, $\sin\theta_1 = \dfrac{12}{13}$, $\cos\theta_2 = \dfrac{12}{13}$ and $\sin\theta_2 = \dfrac{5}{13}$. $E_x = 0 = -\dfrac{k|q_1|}{(0.050\ \text{m})^2}\dfrac{5}{13} + \dfrac{k|q_2|}{(0.120\ \text{m})^2}\dfrac{12}{13}$. This gives $\dfrac{k|q_2|}{(0.120\ \text{m})^2} = \dfrac{k|q_1|}{(0.050\ \text{m})^2}\dfrac{5}{12}$. Solving for $|q_2|$ gives $|q_2| = 7.2\ \mu\text{C}$, so $q_2 = -7.2\ \mu\text{C}$. Then

$$E_y = -\frac{k|q_1|}{(0.050\ \text{m})^2}\frac{12}{13} - \frac{kq_2}{(0.120\ \text{m})^2}\frac{5}{13} = -1.17\times10^7\ \text{N/C}. \quad E = 1.17\times10^7\ \text{N/C}.$$

EVALUATE: With q_1 known, specifying the direction of $\vec{\boldsymbol{E}}$ determines both q_2 and E.

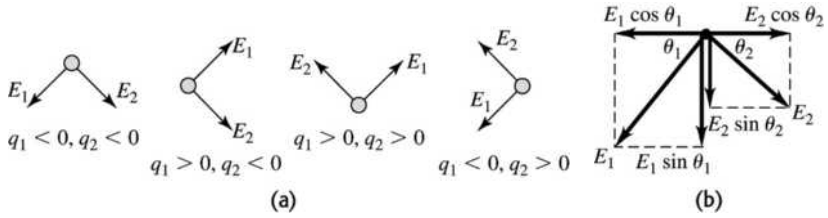

Figure 21.106

21.107. **IDENTIFY:** To find the electric field due to the second rod, divide that rod into infinitesimal segments of length dx, calculate the field dE due to each segment and integrate over the length of the rod to find the total field due to the rod. Use $d\vec{\boldsymbol{F}} = dq\,\vec{\boldsymbol{E}}$ to find the force the electric field of the second rod exerts on each infinitesimal segment of the first rod.

SET UP: An infinitesimal segment of the second rod is sketched in Figure 21.107. $dQ = (Q/L)dx'$.

EXECUTE: **(a)** $dE = \dfrac{k\,dQ}{(x + a/2 + L - x')^2} = \dfrac{kQ}{L}\dfrac{dx'}{(x + a/2 + L - x')^2}$.

$$E_x = \int_0^L dE_x = \frac{kQ}{L}\int_0^L \frac{dx'}{(x + a/2 + L - x')^2} = \frac{kQ}{L}\left[\frac{1}{x + a/2 + L - x'}\right]_0^L = \frac{kQ}{L}\left(\frac{1}{x + a/2} - \frac{1}{x + a/2 + L}\right).$$

$$E_x = \frac{2kQ}{L}\left(\frac{1}{2x + a} - \frac{1}{2L + 2x + a}\right).$$

(b) Now consider the force that the field of the second rod exerts on an infinitesimal segment dq of the first rod. This force is in the $+x$-direction. $dF = dq\,E$.

$$F = \int E\,dq = \int_{a/2}^{L+a/2} \frac{EQ}{L}\,dx = \frac{2kQ^2}{L^2}\int_{a/2}^{L+a/2}\left(\frac{1}{2x + a} - \frac{1}{2L + 2x + a}\right)dx.$$

$$F = \frac{2kQ^2}{L^2}\frac{1}{2}\left(\left[\ln(a + 2x)\right]_{a/2}^{L+a/2} - \left[\ln(2L + 2x + a)\right]_{a/2}^{L+a/2}\right) = \frac{kQ^2}{L^2}\ln\left(\left(\frac{a + 2L + a}{2a}\right)\left(\frac{2L + 2a}{4L + 2a}\right)\right).$$

$$F = \frac{kQ^2}{L^2}\ln\left(\frac{(a + L)^2}{a(a + 2L)}\right).$$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(c) For $a \gg L$, $F = \dfrac{kQ^2}{L^2}\ln\left(\dfrac{a^2(1+L/a)^2}{a^2(1+2L/a)}\right) = \dfrac{kQ^2}{L^2}(2\ln(1+L/a) - \ln(1+2L/a))$.

For small z, $\ln(1+z) \approx z - \dfrac{z^2}{2}$. Therefore, for $a \gg L$,

$$F \approx \frac{kQ^2}{L^2}\left(2\left(\frac{L}{a} - \frac{L^2}{2a^2} + \cdots\right) - \left(\frac{2L}{a} - \frac{2L^2}{a^2} + \cdots\right)\right) \approx \frac{kQ^2}{a^2}.$$

EVALUATE: The distance between adjacent ends of the rods is a. When $a \gg L$ the distance between the rods is much greater than their lengths and they interact as point charges.

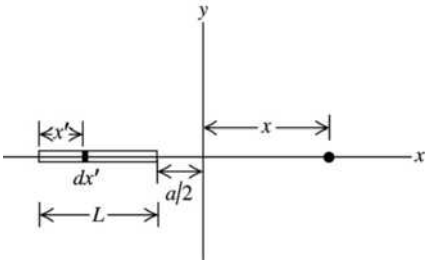

Figure 21.107

22

GAUSS'S LAW

22.1. **(a) IDENTIFY** and **SET UP:** $\Phi_E = \int E\cos\phi dA$, where ϕ is the angle between the normal to the sheet $\hat{\boldsymbol{n}}$ and the electric field $\vec{\boldsymbol{E}}$.

EXECUTE: In this problem E and $\cos\phi$ are constant over the surface so $\Phi_E = E\cos\phi\int dA = E\cos\phi A = (14\text{ N/C})(\cos 60°)(0.250\text{ m}^2) = 1.8\text{ N}\cdot\text{m}^2/\text{C}$.

(b) EVALUATE: Φ_E is independent of the shape of the sheet as long as ϕ and E are constant at all points on the sheet.

(c) EXECUTE: (i) $\Phi_E = E\cos\phi A$. Φ_E is largest for $\phi = 0°$, so $\cos\phi = 1$ and $\Phi_E = EA$.

(ii) Φ_E is smallest for $\phi = 90°$, so $\cos\phi = 0$ and $\Phi_E = 0$.

EVALUATE: Φ_E is 0 when the surface is parallel to the field so no electric field lines pass through the surface.

22.2. **IDENTIFY:** The field is uniform and the surface is flat, so use $\Phi_E = EA\cos\phi$.

SET UP: ϕ is the angle between the normal to the surface and the direction of $\vec{\boldsymbol{E}}$, so $\phi = 70°$.

EXECUTE: $\Phi_E = (75.0\text{ N/C})(0.400\text{ m})(0.600\text{ m})\cos 70° = 6.16\text{ N}\cdot\text{m}^2/\text{C}$

EVALUATE: If the field were perpendicular to the surface the flux would be $\Phi_E = EA = 18.0\text{ N}\cdot\text{m}^2/\text{C}$. The flux in this problem is much less than this because only the component of $\vec{\boldsymbol{E}}$ perpendicular to the surface contributes to the flux.

22.3. **IDENTIFY:** The electric flux through an area is defined as the product of the component of the electric field perpendicular to the area times the area.

(a) SET UP: In this case, the electric field is perpendicular to the surface of the sphere, so $\Phi_E = EA = E(4\pi r^2)$.

EXECUTE: Substituting in the numbers gives

$$\Phi_E = (1.25\times10^6\text{ N/C})4\pi(0.150\text{ m})^2 = 3.53\times10^5\text{ N}\cdot\text{m}^2/\text{C}$$

(b) IDENTIFY: We use the electric field due to a point charge.

SET UP: $E = \dfrac{1}{4\pi\epsilon_0}\dfrac{q}{r^2}$

EXECUTE: Solving for q and substituting the numbers gives

$$q = 4\pi\epsilon_0 r^2 E = \frac{1}{9.00\times10^9\text{ N}\cdot\text{m}^2/\text{C}^2}(0.150\text{ m})^2(1.25\times10^6\text{ N/C}) = 3.13\times10^{-6}\text{ C}$$

EVALUATE: The flux would be the same no matter how large the sphere, since the area is proportional to r^2 while the electric field is proportional to $1/r^2$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

22.4. **(a) IDENTIFY:** Use Eq. (22.5) to calculate the flux through the surface of the cylinder.
SET UP: The line of charge and the cylinder are sketched in Figure 22.4.

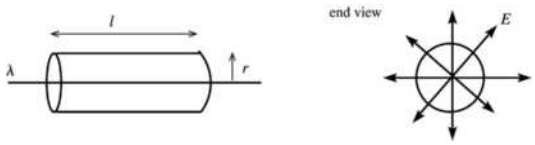

Figure 22.4

EXECUTE: The area of the curved part of the cylinder is $A = 2\pi rl$.
The electric field is parallel to the end caps of the cylinder, so $\vec{E} \cdot \vec{A} = 0$ for the ends and the flux through the cylinder end caps is zero.
The electric field is normal to the curved surface of the cylinder and has the same magnitude $E = \lambda/2\pi\epsilon_0 r$ at all points on this surface. Thus $\phi = 0°$ and

$$\Phi_E = EA\cos\phi = EA = (\lambda/2\pi\epsilon_0 r)(2\pi rl) = \frac{\lambda l}{\epsilon_0} = \frac{(3.00\times10^{-6}\ \text{C/m})(0.400\ \text{m})}{8.854\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2} = 1.36\times10^5\ \text{N}\cdot\text{m}^2/\text{C}.$$

(b) In the calculation in part (a) the radius r of the cylinder divided out, so the flux remains the same, $\Phi_E = 1.36\times10^5\ \text{N}\cdot\text{m}^2/\text{C}$.

(c) $\Phi_E = \dfrac{\lambda l}{\epsilon_0} = \dfrac{(3.00\times10^{-6}\ \text{C/m})(0.800\ \text{m})}{8.854\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2} = 2.71\times10^5\ \text{N}\cdot\text{m}^2/\text{C}$ (twice the flux calculated in parts (a) and (b)).

EVALUATE: The flux depends on the number of field lines that pass through the surface of the cylinder.

22.5. **IDENTIFY:** The flux through the curved upper half of the hemisphere is the same as the flux through the flat circle defined by the bottom of the hemisphere because every electric field line that passes through the flat circle also must pass through the curved surface of the hemisphere.
SET UP: The electric field is perpendicular to the flat circle, so the flux is simply the product of E and the area of the flat circle of radius r.
EXECUTE: $\Phi_E = EA = E(\pi r^2) = \pi r^2 E$
EVALUATE: The flux would be the same if the hemisphere were replaced by any other surface bounded by the flat circle.

22.6. **IDENTIFY:** Use Eq. (22.3) to calculate the flux for each surface.
SET UP: $\Phi = \vec{E} \cdot \vec{A} = EA\cos\phi$ where $\vec{A} = A\hat{n}$.
EXECUTE: **(a)** $\hat{n}_{S_1} = -\hat{j}$ (left). $\Phi_{S_1} = -(4\times10^3\ \text{N/C})(0.10\ \text{m})^2\cos(90° - 53.1°) = -32\ \text{N}\cdot\text{m}^2/\text{C}$.

$\hat{n}_{S_2} = +\hat{k}$ (top). $\Phi_{S_2} = -(4\times10^3\ \text{N/C})(0.10\ \text{m})^2\cos 90° = 0$.

$\hat{n}_{S_3} = +\hat{j}$ (right). $\Phi_{S_3} = +(4\times10^3\ \text{N/C})(0.10\ \text{m})^2\cos(90° - 53.1°) = +32\ \text{N}\cdot\text{m}^2/\text{C}$.

$\hat{n}_{S_4} = -\hat{k}$ (bottom). $\Phi_{S_4} = (4\times10^3\ \text{N/C})(0.10\ \text{m})^2\cos 90° = 0$.

$\hat{n}_{S_5} = +\hat{i}$ (front). $\Phi_{S_5} = +(4\times10^3\ \text{N/C})(0.10\ \text{m})^2\cos 53.1° = 24\ \text{N}\cdot\text{m}^2/\text{C}$.

$\hat{n}_{S_6} = -\hat{i}$ (back). $\Phi_{S_6} = -(4\times10^3\ \text{N/C})(0.10\ \text{m})^2\cos 53.1° = -24\ \text{N}\cdot\text{m}^2/\text{C}$.

EVALUATE: **(b)** The total flux through the cube must be zero; any flux entering the cube must also leave it, since the field is uniform. Our calculation gives the result; the sum of the fluxes calculated in part (a) is zero.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

22.7. **IDENTIFY:** Apply Gauss's law to a Gaussian surface that coincides with the cell boundary.

SET UP: $\Phi_E = \dfrac{Q_{\text{encl}}}{\epsilon_0}$.

EXECUTE: $\Phi_E = \dfrac{Q_{\text{encl}}}{\epsilon_0} = \dfrac{-8.65\times10^{-12}\ \text{C}}{8.854\times10^{-12}\ \text{C}^2/(\text{N}\cdot\text{m}^2)} = -0.977\ \text{N}\cdot\text{m}^2/\text{C}$. Q_{encl} is negative, so the flux is inward.

EVALUATE: If the cell were positive, the field would point outward, so the flux would be positive.

22.8. **IDENTIFY:** Apply Gauss's law to each surface.

SET UP: Q_{encl} is the algebraic sum of the charges enclosed by each surface. Flux out of the volume is positive and flux into the enclosed volume is negative.

EXECUTE: **(a)** $\Phi_{S_1} = q_1/\epsilon_0 = (4.00\times10^{-9}\ \text{C})/\epsilon_0 = 452\ \text{N}\cdot\text{m}^2/\text{C}$.

(b) $\Phi_{S_2} = q_2/\epsilon_0 = (-7.80\times10^{-9}\ \text{C})/\epsilon_0 = -881\ \text{N}\cdot\text{m}^2/\text{C}$.

(c) $\Phi_{S_3} = (q_1+q_2)/\epsilon_0 = ((4.00-7.80)\times10^{-9}\ \text{C})/\epsilon_0 = -429\ \text{N}\cdot\text{m}^2/\text{C}$.

(d) $\Phi_{S_4} = (q_1+q_3)/\epsilon_0 = ((4.00+2.40)\times10^{-9}\ \text{C})/\epsilon_0 = 723\ \text{N}\cdot\text{m}^2/\text{C}$.

(e) $\Phi_{S_5} = (q_1+q_2+q_3)/\epsilon_0 = ((4.00-7.80+2.40)\times10^{-9}\ \text{C})/\epsilon_0 = -158\ \text{N}\cdot\text{m}^2/\text{C}$.

EVALUATE: **(f)** All that matters for Gauss's law is the total amount of charge enclosed by the surface, not its distribution within the surface.

22.9. **IDENTIFY:** Apply the results in Example 22.5 for the field of a spherical shell of charge.

SET UP: Example 22.5 shows that $E = 0$ inside a uniform spherical shell and that $E = k\dfrac{|q|}{r^2}$ outside the shell.

EXECUTE: **(a)** $E = 0$.

(b) $r = 0.060\ \text{m}$ and $E = (8.99\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\dfrac{35.0\times10^{-6}\ \text{C}}{(0.060\ \text{m})^2} = 8.74\times10^7\ \text{N/C}$.

(c) $r = 0.110\ \text{m}$ and $E = (8.99\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\dfrac{35.0\times10^{-6}\ \text{C}}{(0.110\ \text{m})^2} = 2.60\times10^7\ \text{N/C}$.

EVALUATE: Outside the shell the electric field is the same as if all the charge were concentrated at the center of the shell. But inside the shell the field is not the same as for a point charge at the center of the shell, inside the shell the electric field is zero.

22.10. **IDENTIFY:** Apply Gauss's law to the spherical surface.

SET UP: Q_{encl} is the algebraic sum of the charges enclosed by the sphere.

EXECUTE: **(a)** No charge enclosed so $\Phi_E = 0$.

(b) $\Phi_E = \dfrac{q_2}{\epsilon_0} = \dfrac{-6.00\times10^{-9}\ \text{C}}{8.85\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2} = -678\ \text{N}\cdot\text{m}^2/\text{C}$.

(c) $\Phi_E = \dfrac{q_1+q_2}{\epsilon_0} = \dfrac{(4.00-6.00)\times10^{-9}\ \text{C}}{8.85\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2} = -226\ \text{N}\cdot\text{m}^2/\text{C}$.

EVALUATE: Negative flux corresponds to flux directed into the enclosed volume. The net flux depends only on the net charge enclosed by the surface and is not affected by any charges outside the enclosed volume.

22.11. **(a) IDENTIFY** and **SET UP:** It is rather difficult to calculate the flux directly from $\Phi_E = \int \vec{E}\cdot d\vec{A}$ since the magnitude of $\vec{E}$ and its angle with $d\vec{A}$ varies over the surface of the cube. A much easier approach is to use Gauss's law to calculate the total flux through the cube. Let the cube be the Gaussian surface. The charge enclosed is the point charge.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: $\Phi_E = Q_{\text{encl}}/\epsilon_0 = \dfrac{6.20\times10^{-6}\ \text{C}}{8.854\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2} = 7.002\times10^5\ \text{N}\cdot\text{m}^2/\text{C}$. By symmetry the flux is the same through each of the six faces, so the flux through one face is $\frac{1}{6}(7.002\times10^5\ \text{N}\cdot\text{m}^2/\text{C}) = 1.17\times10^5\ \text{N}\cdot\text{m}^2/\text{C}$.

(b) EVALUATE: In part (a) the size of the cube did not enter into the calculations. The flux through one face depends only on the amount of charge at the center of the cube. So the answer to (a) would not change if the size of the cube were changed.

22.12. **IDENTIFY:** Apply the results of Examples 22.9 and 22.10.

SET UP: $E = k\dfrac{|q|}{r^2}$ outside the sphere. A proton has charge $+e$.

EXECUTE: **(a)** $E = k\dfrac{|q|}{r^2} = (8.99\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\dfrac{92(1.60\times10^{-19}\ \text{C})}{(7.4\times10^{-15}\ \text{m})^2} = 2.4\times10^{21}\ \text{N/C}$

(b) For $r = 1.0\times10^{-10}$ m, $E = (2.4\times10^{21}\ \text{N/C})\left(\dfrac{7.4\times10^{-15}\ \text{m}}{1.0\times10^{-10}\ \text{m}}\right)^2 = 1.3\times10^{13}\ \text{N/C}$

(c) $E = 0$, inside a spherical shell.

EVALUATE: The electric field in an atom is very large.

22.13. **IDENTIFY:** The electric fields are produced by point charges.

SET UP: We use Coulomb's law, $E = \dfrac{1}{4\pi\epsilon_0}\dfrac{|q|}{r^2}$, to calculate the electric fields.

EXECUTE: **(a)** $E = (9.00\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\dfrac{5.00\times10^{-6}\ \text{C}}{(1.00\ \text{m})^2} = 4.50\times10^4\ \text{N/C}$

(b) $E = (9.00\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\dfrac{5.00\times10^{-6}\ \text{C}}{(7.00\ \text{m})^2} = 9.18\times10^2\ \text{N/C}$

(c) Every field line that enters the sphere on one side leaves it on the other side, so the net flux through the surface is zero.

EVALUATE: The flux would be zero no matter what shape the surface had, providing that no charge was inside the surface.

22.14. **IDENTIFY:** Apply the results of Example 22.5.

SET UP: At a point 0.100 m outside the surface, $r = 0.550$ m.

EXECUTE: **(a)** $E = \dfrac{1}{4\pi\epsilon_0}\dfrac{q}{r^2} = \dfrac{1}{4\pi\epsilon_0}\dfrac{(2.50\times10^{-10}\ \text{C})}{(0.550\ \text{m})^2} = 7.44\ \text{N/C}$.

(b) $E = 0$ inside of a conductor or else free charges would move under the influence of forces, violating our electrostatic assumptions (i.e., that charges aren't moving).

EVALUATE: Outside the sphere its electric field is the same as would be produced by a point charge at its center, with the same charge.

22.15. **IDENTIFY:** Each line lies in the electric field of the other line, and therefore each line experiences a force due to the other line.

SET UP: The field of one line at the location of the other is $E = \dfrac{\lambda}{2\pi\epsilon_0 r}$. For charge $dq = \lambda dx$ on one line, the force on it due to the other line is $dF = Edq$. The total force is $F = \int Edq = E\int dq = Eq$.

EXECUTE: $E = \dfrac{\lambda}{2\pi\epsilon_0 r} = \dfrac{5.20\times10^{-6}\ \text{C/m}}{2\pi(8.854\times10^{-12}\ \text{C}^2/(\text{N}\cdot\text{m}^2))(0.300\ \text{m})} = 3.116\times10^5\ \text{N/C}$. The force on one line due to the other is $F = Eq$, where $q = \lambda(0.0500\ \text{m}) = 2.60\times10^{-7}$ C. The net force is $F = Eq = (3.116\times10^5\ \text{N/C})(2.60\times10^{-7}\ \text{C}) = 0.0810$ N.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: Since the electric field at each line due to the other line is uniform, each segment of line experiences the same force, so all we need to use is $F = Eq$, even though the line is *not* a point charge.

22.16. **IDENTIFY:** According to Exercise 21.32, the Earth's electric field points toward its center. Since Mars's electric field is similar to that of Earth, we assume it points toward the center of Mars. Therefore the charge on Mars must be negative. We use Gauss's law to relate the electric flux to the charge causing it.

SET UP: Gauss's law is $\Phi_E = \dfrac{q}{\epsilon_0}$ and the electric flux is $\Phi_E = EA$.

EXECUTE: **(a)** Solving Gauss's law for q, putting in the numbers, and recalling that q is negative, gives $q = -\epsilon_0\Phi_E = -(3.63\times10^{16}\ \text{N}\cdot\text{m}^2/\text{C})(8.85\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2) = -3.21\times10^{5}\ \text{C}$.

(b) Use the definition of electric flux to find the electric field. The area to use is the surface area of Mars.

$$E = \frac{\Phi_E}{A} = \frac{3.63\times10^{16}\ \text{N}\cdot\text{m}^2/\text{C}}{4\pi(3.40\times10^{6}\ \text{m})^2} = 2.50\times10^{2}\ \text{N/C}$$

(c) The surface charge density on Mars is therefore $\sigma = \dfrac{q}{A_{\text{Mars}}} = \dfrac{-3.21\times10^{5}\ \text{C}}{4\pi(3.40\times10^{6}\ \text{m})^2} = -2.21\times10^{-9}\ \text{C/m}^2$

EVALUATE: Even though the charge on Mars is very large, it is spread over a large area, giving a small surface charge density.

22.17. **IDENTIFY** and **SET UP:** Example 22.5 derived that the electric field just outside the surface of a spherical conductor that has net charge q is $E = \dfrac{1}{4\pi\epsilon_0}\dfrac{q}{R^2}$. Calculate q and from this the number of excess electrons.

EXECUTE: $q = \dfrac{R^2E}{(1/4\pi\epsilon_0)} = \dfrac{(0.160\ \text{m})^2(1150\ \text{N/C})}{8.988\times10^{9}\ \text{N}\cdot\text{m}^2/\text{C}^2} = 3.275\times10^{-9}\ \text{C}$.

Each electron has a charge of magnitude $e = 1.602\times10^{-19}\ \text{C}$, so the number of excess electrons needed is

$$\frac{3.275\times10^{-9}\ \text{C}}{1.602\times10^{-19}\ \text{C}} = 2.04\times10^{10}.$$

EVALUATE: The result we obtained for q is a typical value for the charge of an object. Such net charges correspond to a large number of excess electrons since the charge of each electron is very small.

22.18. **IDENTIFY:** Apply Gauss's law.

SET UP: Draw a cylindrical Gaussian surface with the line of charge as its axis. The cylinder has radius 0.400 m and is 0.0200 m long. The electric field is then 840 N/C at every point on the cylindrical surface and is directed perpendicular to the surface.

EXECUTE: $\oint \vec{E}\cdot d\vec{A} = EA_{\text{cylinder}} = E(2\pi rL) = (840\ \text{N/C})(2\pi)(0.400\ \text{m})(0.0200\ \text{m}) = 42.2\ \text{N}\cdot\text{m}^2/\text{C}$.

The field is parallel to the end caps of the cylinder, so for them $\oint \vec{E}\cdot d\vec{A} = 0$. From Gauss's law,

$q = \epsilon_0\Phi_E = (8.854\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2)(42.2\ \text{N}\cdot\text{m}^2/\text{C}) = 3.74\times10^{-10}\ \text{C}$.

EVALUATE: We could have applied the result in Example 22.6 and solved for λ. Then $q = \lambda L$.

22.19. **IDENTIFY:** Add the vector electric fields due to each line of charge. $E(r)$ for a line of charge is given by Example 22.6 and is directed toward a negative line of charge and away from a positive line.

SET UP: The two lines of charge are shown in Figure 22.19.

$$E = \frac{1}{2\pi\epsilon_0}\frac{\lambda}{r}$$

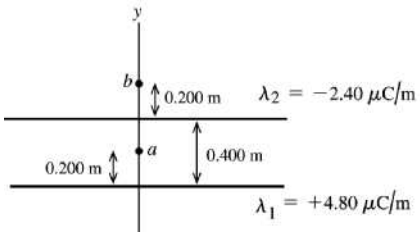

Figure 22.19

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: **(a)** At point a, $\vec{E}_1$ and $\vec{E}_2$ are in the $+y$-direction (toward negative charge, away from positive charge).

$E_1 = (1/2\pi\epsilon_0)[(4.80\times10^{-6}\ \text{C/m})/(0.200\ \text{m})] = 4.314\times10^5\ \text{N/C}$

$E_2 = (1/2\pi\epsilon_0)[(2.40\times10^{-6}\ \text{C/m})/(0.200\ \text{m})] = 2.157\times10^5\ \text{N/C}$

$E = E_1 + E_2 = 6.47\times10^5\ \text{N/C},$ in the y-direction.

(b) At point b, $\vec{E}_1$ is in the $+y$-direction and $\vec{E}_2$ is in the $-y$-direction.

$E_1 = (1/2\pi\epsilon_0)[(4.80\times10^{-6}\ \text{C/m})/(0.600\ \text{m})] = 1.438\times10^5\ \text{N/C}$

$E_2 = (1/2\pi\epsilon_0)[(2.40\times10^{-6}\ \text{C/m})/(0.200\ \text{m})] = 2.157\times10^5\ \text{N/C}$

$E = E_2 - E_1 = 7.2\times10^4\ \text{N/C},$ in the $-y$-direction.

EVALUATION: At point a the two fields are in the same direction and the magnitudes add. At point b the two fields are in opposite directions and the magnitudes subtract.

22.20. **IDENTIFY:** Apply the results of Examples 22.5, 22.6 and 22.7.

SET UP: Gauss's law can be used to show that the field outside a long conducting cylinder is the same as for a line of charge along the axis of the cylinder.

EXECUTE: **(a)** For points outside a uniform spherical charge distribution, all the charge can be considered to be concentrated at the center of the sphere. The field outside the sphere is thus inversely proportional to the square of the distance from the center. In this case,

$$E = (480\ \text{N/C})\left(\frac{0.200\ \text{cm}}{0.600\ \text{cm}}\right)^2 = 53\ \text{N/C}$$

(b) For points outside a long cylindrically symmetrical charge distribution, the field is identical to that of a long line of charge: $E = \dfrac{\lambda}{2\pi\epsilon_0 r}$, that is, inversely proportional to the distance from the axis of the cylinder.

In this case $E = (480\ \text{N/C})\left(\dfrac{0.200\ \text{cm}}{0.600\ \text{cm}}\right) = 160\ \text{N/C}.$

(c) The field of an infinite sheet of charge is $E = \sigma/2\epsilon_0$; i.e., it is independent of the distance from the sheet. Thus in this case $E = 480\ \text{N/C}$.

EVALUATE: For each of these three distributions of charge the electric field has a different dependence on distance.

22.21. **IDENTIFY:** The electric field inside the conductor is zero, and all of its initial charge lies on its outer surface. The introduction of charge into the cavity induces charge onto the surface of the cavity, which induces an equal but opposite charge on the outer surface of the conductor. The net charge on the outer surface of the conductor is the sum of the positive charge initially there and the additional negative charge due to the introduction of the negative charge into the cavity.

(a) SET UP: First find the initial positive charge on the outer surface of the conductor using $q_\text{i} = \sigma A$, where A is the area of its outer surface. Then find the net charge on the surface after the negative charge has been introduced into the cavity. Finally, use the definition of surface charge density.

EXECUTE: The original positive charge on the outer surface is

$$q_\text{i} = \sigma A = \sigma(4\pi r^2) = (6.37\times10^{-6}\ \text{C/m}^2)4\pi(0.250\ \text{m})^2 = 5.00\times10^{-6}\ \text{C}$$

After the introduction of $-0.500\ \mu\text{C}$ into the cavity, the outer charge is now

$$5.00\ \mu\text{C} - 0.500\ \mu\text{C} = 4.50\ \mu\text{C}$$

The surface charge density is now $\sigma = \dfrac{q}{A} = \dfrac{q}{4\pi r^2} = \dfrac{4.50\times10^{-6}\ \text{C}}{4\pi(0.250\ \text{m})^2} = 5.73\times10^{-6}\ \text{C/m}^2$

(b) SET UP: Using Gauss's law, the electric field is $E = \dfrac{\Phi_E}{A} = \dfrac{q}{\epsilon_0 A} = \dfrac{q}{\epsilon_0 4\pi r^2}.$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: Substituting numbers gives

$$E = \frac{4.50\times10^{-6}\ \text{C}}{(8.85\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2)(4\pi)(0.250\ \text{m})^2} = 6.47\times10^{5}\ \text{N/C}.$$

(c) SET UP: We use Gauss's law again to find the flux. $\Phi_E = \frac{q}{\epsilon_0}$.

EXECUTE: Substituting numbers gives

$$\Phi_E = \frac{-0.500\times10^{-6}\ \text{C}}{8.85\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2} = -5.65\times10^{4}\ \text{N}\cdot\text{m}^2/\text{C}.$$

EVALUATE: The excess charge on the conductor is still $+5.00\ \mu\text{C}$, as it originally was. The introduction of the $-0.500\ \mu\text{C}$ inside the cavity merely induced equal but opposite charges (for a net of zero) on the surfaces of the conductor.

22.22. **IDENTIFY:** We apply Gauss's law, taking the Gaussian surface beyond the cavity but inside the solid.

SET UP: Because of the symmetry of the charge, Gauss's law gives us $E_1 = \frac{q_{\text{total}}}{\epsilon_0 A}$, where A is the surface area of a sphere of radius $R = 9.50$ cm centered on the point-charge, and q_{total} is the total charge contained within that sphere. This charge is the sum of the $-2.00\ \mu\text{C}$ point charge at the center of the cavity plus the charge within the solid between $r = 6.50$ cm and $R = 9.50$ cm. The charge within the solid is $q_{\text{solid}} = \rho V = \rho([4/3]\pi R^3 - [4/3]\pi r^3) = ([4\pi/3]\rho)(R^3 - r^3)$.

EXECUTE: First find the charge within the solid between $r = 6.50$ cm and $R = 9.50$ cm:

$$q_{\text{solid}} = \frac{4\pi}{3}(7.35\times10^{-4}\ \text{C/m}^3)[(0.0950\ \text{m})^3 - (0.0650\ \text{m})^3] = 1.794\times10^{-6}\ \text{C}$$

Now find the total charge within the Gaussian surface:

$$q_{\text{total}} = q_{\text{solid}} + q_{\text{point}} = -2.00\ \mu\text{C} + 1.794\ \mu\text{C} = -0.2059\ \mu\text{C}$$

Now find the magnitude of the electric field from Gauss's law:

$$E = \frac{|q|}{\epsilon_0 A} = \frac{|q|}{\epsilon_0 4\pi r^2} = \frac{0.2059\times10^{-6}\ \text{C}}{(8.85\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2)(4\pi)(0.0950\ \text{m})^2} = 2.05\times10^{5}\ \text{N/C}.$$

The fact that the charge is negative means that the electric field points radially inward.

EVALUATE: Because of the uniformity of the charge distribution, the charge beyond 9.50 cm does not contribute to the electric field.

22.23. **IDENTIFY:** The magnitude of the electric field is constant at any given distance from the center because the charge density is uniform inside the sphere. We can use Gauss's law to relate the field to the charge causing it.

(a) SET UP: Gauss's law tells us that $EA = \frac{q}{\epsilon_0}$, and the charge density is given by $\rho = \frac{q}{V} = \frac{q}{(4/3)\pi R^3}$.

EXECUTE: Solving for q and substituting numbers gives $q = EA\epsilon_0 = E(4\pi r^2)\epsilon_0 = (1750\ \text{N/C})(4\pi)(0.500\ \text{m})^2(8.85\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2) = 4.866\times10^{-8}\ \text{C}$. Using the formula for charge density we get $\rho = \frac{q}{V} = \frac{q}{(4/3)\pi R^3} = \frac{4.866\times10^{-8}\ \text{C}}{(4/3)\pi(0.355\ \text{m})^3} = 2.60\times10^{-7}\ \text{C/m}^3$.

(b) SET UP: Take a Gaussian surface of radius $r = 0.200$ m, concentric with the insulating sphere. The charge enclosed within this surface is $q_{\text{encl}} = \rho V = \rho\left(\frac{4}{3}\pi r^3\right)$, and we can treat this charge as a point-charge, using Coulomb's law $E = \frac{1}{4\pi\epsilon_0}\frac{q_{\text{encl}}}{r^2}$. The charge beyond $r = 0.200$ m makes no contribution to the electric field.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: First find the enclosed charge:

$$q_{\text{encl}} = \rho\left(\frac{4}{3}\pi r^3\right) = (2.60\times10^{-7}\ \text{C/m}^3)\left[\frac{4}{3}\pi(0.200\ \text{m})^3\right] = 8.70\times10^{-9}\ \text{C}$$

Now treat this charge as a point-charge and use Coulomb's law to find the field:

$$E = (9.00\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\frac{8.70\times10^{-9}\ \text{C}}{(0.200\ \text{m})^2} = 1.96\times10^3\ \text{N/C}$$

EVALUATE: Outside this sphere, it behaves like a point-charge located at its center. Inside of it, at a distance r from the center, the field is due only to the charge between the center and r.

22.24. **IDENTIFY:** The sheet repels the charge electrically, slowing it down and eventually stopping it at its closest approach.

SET UP: Let $+y$ be in the direction toward the sheet. The electric field due to the sheet is $E = \dfrac{\sigma}{2\epsilon_0}$ and the magnitude of the force the sheet exerts on the object is $F = qE$. Newton's second law, and the constant-acceleration kinematics formulas, apply to the object as it is slowing down.

EXECUTE: $E = \dfrac{\sigma}{2\epsilon_0} = \dfrac{5.90\times10^{-8}\ \text{C/m}^2}{2(8.854\times10^{-12}\ \text{C}^2/(\text{N}\cdot\text{m}^2))} = 3.332\times10^3\ \text{N/C}.$

$a_y = -\dfrac{F}{m} = -\dfrac{Eq}{m} = -\dfrac{(3.332\times10^3\ \text{N/C})(6.50\times10^{-9}\ \text{C})}{8.20\times10^{-9}\ \text{kg}} = -2.641\times10^3\ \text{m/s}^2$. Using $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ gives $v_{0y} = \sqrt{-2a_y(y - y_0)} = \sqrt{-2(-2.64\times10^3\ \text{m/s}^2)(0.300\ \text{m})} = 39.8\ \text{m/s}.$

EVALUATE: We can use the constant-acceleration kinematics equations because the uniform electric field of the sheet exerts a constant force on the object, giving it a constant acceleration. We could *not* use this approach if the sheet were replaced with a sphere, for example.

22.25. **IDENTIFY:** The uniform electric field of the sheet exerts a constant force on the proton perpendicular to the sheet, and therefore does not change the parallel component of its velocity. Newton's second law allows us to calculate the proton's acceleration perpendicular to the sheet, and uniform-acceleration kinematics allows us to determine its perpendicular velocity component.

SET UP: Let $+x$ be the direction of the initial velocity and let $+y$ be the direction perpendicular to the sheet and pointing away from it. $a_x = 0$ so $v_x = v_{0x} = 9.70\times10^2$ m/s. The electric field due to the sheet is $E = \dfrac{\sigma}{2\epsilon_0}$ and the magnitude of the force the sheet exerts on the proton is $F = eE$.

EXECUTE: $E = \dfrac{\sigma}{2\epsilon_0} = \dfrac{2.34\times10^{-9}\ \text{C/m}^2}{2(8.854\times10^{-12}\ \text{C}^2/(\text{N}\cdot\text{m}^2))} = 132.1\ \text{N/C}.$ Newton's second law gives

$a_y = \dfrac{Eq}{m} = \dfrac{(132.1\ \text{N/C})(1.602\times10^{-19}\ \text{C})}{1.673\times10^{-27}\ \text{kg}} = 1.265\times10^{10}\ \text{m/s}^2$. Kinematics gives

$v_y = v_{0y} + a_y y = (1.265\times10^{10}\ \text{m/s}^2)(5.00\times10^{-8}\ \text{s}) = 632.7\ \text{m/s}.$ The speed of the proton is the magnitude of its velocity, so $v = \sqrt{v_x^2 + v_y^2} = \sqrt{(9.70\times10^2\ \text{m/s})^2 + (632.7\ \text{m/s})^2} = 1.16\times10^3\ \text{m/s}.$

EVALUATE: We can use the constant-acceleration kinematics equations because the uniform electric field of the sheet exerts a constant force on the proton, giving it a constant acceleration. We could *not* use this approach if the sheet were replaced with a sphere, for example.

22.26. **IDENTIFY:** The charged sheet exerts a force on the electron and therefore does work on it.

SET UP: The electric field is uniform so the force on the electron is constant during the displacement. The electric field due to the sheet is $E = \dfrac{\sigma}{2\epsilon_0}$ and the magnitude of the force the sheet exerts on the electron is $F = qE$. The work the force does on the electron is $W = Fs$. In (b) we can use the work-energy theorem, $W_{\text{tot}} = \Delta K = K_2 - K_1$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: **(a)** $W = Fs$, where $s = 0.250$ m. $F = Eq$, where

$E = \dfrac{\sigma}{2\epsilon_0} = \dfrac{2.90\times10^{-12}\ \text{C/m}^2}{2(8.854\times10^{-12}\ \text{C}^2/(\text{N}\cdot\text{m}^2))} = 0.1638$ N/C. Therefore the force is

$F = (0.1638\ \text{N/C})(1.602\times10^{-19}\ \text{C}) = 2.624\times10^{-20}$ N. The work this force does is $W = Fs = 6.56\times10^{-21}$ J.

(b) Use the work-energy theorem: $W_{\text{tot}} = \Delta K = K_2 - K_1$. $K_1 = 0$. $K_2 = \dfrac{1}{2}mv_2^2$. So, $\dfrac{1}{2}mv_2^2 = W$, which

gives $v_2 = \sqrt{\dfrac{2W}{m}} = \sqrt{\dfrac{2(6.559\times10^{-21}\ \text{J})}{9.109\times10^{-31}\ \text{kg}}} = 1.2\times10^5$ m/s.

EVALUATE: If the field were not constant, we would have to integrate in (a), but we could still use the work-energy theorem in (b).

22.27. **IDENTIFY:** The field of the sphere exerts a force on the object as it accelerates away from the sphere, and therefore does work on it. Coulomb's law gives the force that the sphere exerts on the object.

SET UP: The sphere carries charge $Q = \rho V = \rho\left(\dfrac{4}{3}\pi R^3\right)$ and produces an electric field $E = \dfrac{kQ}{r^2}$ for points outside its surface. The work done on the object is $W = \int_R^\infty F(r)dr$.

EXECUTE: $Q = \rho V = \rho\left(\dfrac{4}{3}\pi R^3\right) = (7.20\times10^{-9}\ \text{C/m}^3)\left(\dfrac{4}{3}\pi\right)(0.160\ \text{m})^3 = 1.235\times10^{-10}$ C. Outside the sphere, $E = \dfrac{kQ}{r^2}$. The work done on the object is

$W = \int_R^\infty F(r)dr = kQq\int_R^\infty \dfrac{dr}{r^2} = \dfrac{kQq}{R} = \dfrac{(8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)(1.235\times10^{-10}\ \text{C})(3.40\times10^{-6}\ \text{C})}{0.160\ \text{m}}$.

$W = 2.36\times10^{-5}$ J.

EVALUATE: Even though the force on the sphere extends to infinity, it does finite work because it gets weaker and weaker as the distance from the sphere increases.

22.28. **IDENTIFY:** Apply Gauss's law and conservation of charge.

SET UP: Use a Gaussian surface that lies wholly within the conducting material.

EXECUTE: **(a)** Positive charge is attracted to the inner surface of the conductor by the charge in the cavity. Its magnitude is the same as the cavity charge: $q_{\text{inner}} = +6.00$ nC, since $E = 0$ inside a conductor and a Gaussian surface that lies wholly within the conductor must enclose zero net charge.

(b) On the outer surface the charge is a combination of the net charge on the conductor and the charge "left behind" when the $+6.00$ nC moved to the inner surface:

$$q_{\text{tot}} = q_{\text{inner}} + q_{\text{outer}} \Rightarrow q_{\text{outer}} = q_{\text{tot}} - q_{\text{inner}} = 5.00\ \text{nC} - 6.00\ \text{nC} = -1.00\ \text{nC}.$$

EVALUATE: The electric field outside the conductor is due to the charge on its surface.

22.29. **IDENTIFY:** Apply Gauss's law to each surface.

SET UP: The field is zero within the plates. By symmetry the field is perpendicular to a plate outside the plate and can depend only on the distance from the plate. Flux into the enclosed volume is positive.

EXECUTE: S_2 and S_3 enclose no charge, so the flux is zero, and electric field outside the plates is zero. Between the plates, S_4 shows that $-EA = -q/\epsilon_0 = -\sigma A/\epsilon_0$ and $E = \sigma/\epsilon_0$.

EVALUATE: Our result for the field between the plates agrees with the result stated in Example 22.8.

22.30. **IDENTIFY:** Close to a finite sheet the field is the same as for an infinite sheet. Very far from a finite sheet the field is that of a point charge.

SET UP: For an infinite sheet, $E = \dfrac{\sigma}{2\epsilon_0}$. For a positive point charge, $E = \dfrac{1}{4\pi\epsilon_0}\dfrac{q}{r^2}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: **(a)** At a distance of 0.1 mm from the center, the sheet appears "infinite," so

$$E \approx \frac{q}{2\epsilon_0 A} = \frac{7.50\times10^{-9}\ \text{C}}{2\epsilon_0(0.800\ \text{m})^2} = 662\ \text{N/C}.$$

(b) At a distance of 100 m from the center, the sheet looks like a point, so:

$$E \approx \frac{1}{4\pi\epsilon_0}\frac{q}{r^2} = \frac{1}{4\pi\epsilon_0}\frac{(7.50\times10^{-9}\ \text{C})}{(100\ \text{m})^2} = 6.75\times10^{-3}\ \text{N/C}.$$

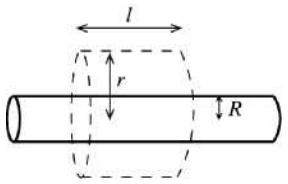
(c) There would be no difference if the sheet was a conductor. The charge would automatically spread out evenly over both faces, giving it half the charge density on either face as the insulator but the same electric field. Far away, they both look like points with the same charge.

EVALUATE: The sheet can be treated as infinite at points where the distance to the sheet is much less than the distance to the edge of the sheet. The sheet can be treated as a point charge at points for which the distance to the sheet is much greater than the dimensions of the sheet.

22.31. **IDENTIFY:** Apply Gauss's law to a Gaussian surface and calculate *E*.

(a) SET UP: Consider the charge on a length *l* of the cylinder. This can be expressed as $q = \lambda l$. But since the surface area is $2\pi Rl$ it can also be expressed as $q = \sigma 2\pi Rl$. These two expressions must be equal, so $\lambda l = \sigma 2\pi Rl$ and $\lambda = 2\pi R\sigma$.

(b) Apply Gauss's law to a Gaussian surface that is a cylinder of length *l*, radius *r*, and whose axis coincides with the axis of the charge distribution, as shown in Figure 22.31.



EXECUTE:
$Q_{\text{encl}} = \sigma(2\pi Rl)$
$\Phi_E = 2\pi rlE$

Figure 22.31

$\Phi_E = \dfrac{Q_{\text{encl}}}{\epsilon_0}$ gives $2\pi rlE = \dfrac{\sigma(2\pi Rl)}{\epsilon_0}$

$E = \dfrac{\sigma R}{\epsilon_0 r}$

(c) EVALUATE: Example 22.6 shows that the electric field of an infinite line of charge is $E = \lambda/2\pi\epsilon_0 r$.

$\sigma = \dfrac{\lambda}{2\pi R}$, so $E = \dfrac{\sigma R}{\epsilon_0 r} = \dfrac{R}{\epsilon_0 r}\left(\dfrac{\lambda}{2\pi R}\right) = \dfrac{\lambda}{2\pi\epsilon_0 r}$, the same as for an infinite line of charge that is along the axis of the cylinder.

22.32. **IDENTIFY:** The net electric field is the vector sum of the fields due to each of the four sheets of charge.

SET UP: The electric field of a large sheet of charge is $E = \sigma/2\epsilon_0$. The field is directed away from a positive sheet and toward a negative sheet.

EXECUTE: **(a)** At A: $E_A = \dfrac{|\sigma_2|}{2\epsilon_0} + \dfrac{|\sigma_3|}{2\epsilon_0} + \dfrac{|\sigma_4|}{2\epsilon_0} - \dfrac{|\sigma_1|}{2\epsilon_0} = \dfrac{1}{2\epsilon_0}(|\sigma_2| + |\sigma_3| + |\sigma_4| - |\sigma_1|)$.

$E_A = \dfrac{1}{2\epsilon_0}(5\ \mu\text{C/m}^2 + 2\ \mu\text{C/m}^2 + 4\ \mu\text{C/m}^2 - 6\ \mu\text{C/m}^2) = 2.82\times10^5\ \text{N/C}$ to the left.

(b) $E_B = \dfrac{|\sigma_1|}{2\epsilon_0} + \dfrac{|\sigma_3|}{2\epsilon_0} + \dfrac{|\sigma_4|}{2\epsilon_0} - \dfrac{|\sigma_2|}{2\epsilon_0} = \dfrac{1}{2\epsilon_0}(|\sigma_1| + |\sigma_3| + |\sigma_4| - |\sigma_2|)$.

$E_B = \dfrac{1}{2\epsilon_0}(6\ \mu\text{C/m}^2 + 2\ \mu\text{C/m}^2 + 4\ \mu\text{C/m}^2 - 5\ \mu\text{C/m}^2) = 3.95\times10^5\ \text{N/C}$ to the left.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(c) $E_C = \dfrac{|\sigma_4|}{2\epsilon_0} + \dfrac{|\sigma_1|}{2\epsilon_0} - \dfrac{|\sigma_2|}{2\epsilon_0} - \dfrac{|\sigma_3|}{2\epsilon_0} = \dfrac{1}{2\epsilon_0}(|\sigma_4| + |\sigma_1| - |\sigma_2| - |\sigma_3|).$

$E_C = \dfrac{1}{2\epsilon_0}(4\ \mu\text{C/m}^2 + 6\ \mu\text{C/m}^2 - 5\ \mu\text{C/m}^2 - 2\ \mu\text{C/m}^2) = 1.69\times10^5\ \text{N/C}$ to the left.

EVALUATE: The field at C is not zero. The pieces of plastic are not conductors.

22.33. **IDENTIFY:** Apply Gauss's law and conservation of charge.

SET UP: $E = 0$ in a conducting material.

EXECUTE: **(a)** Gauss's law says $+Q$ on inner surface, so $E = 0$ inside metal.

(b) The outside surface of the sphere is grounded, so no excess charge.

(c) Consider a Gaussian sphere with the $-Q$ charge at its center and radius less than the inner radius of the metal. This sphere encloses net charge $-Q$ so there is an electric field flux through it; there is electric field in the cavity.

(d) In an electrostatic situation $E = 0$ inside a conductor. A Gaussian sphere with the $-Q$ charge at its center and radius greater than the outer radius of the metal encloses zero net charge (the $-Q$ charge and the $+Q$ on the inner surface of the metal), so there is no flux through it and $E = 0$ outside the metal.

(e) No, $E = 0$ there. Yes, the charge has been shielded by the grounded conductor. There is nothing like positive and negative mass (the gravity force is always attractive), so this cannot be done for gravity.

EVALUATE: Field lines within the cavity terminate on the charges induced on the inner surface.

22.34. **IDENTIFY:** Use Eq. (22.3) to calculate the flux for each surface. Use Eq. (22.8) to calculate the total enclosed charge.

SET UP: $\vec{E} = (-5.00\ \text{N/C}\cdot\text{m})x\hat{\boldsymbol{i}} + (3.00\ \text{N/C}\cdot\text{m})z\hat{\boldsymbol{k}}$. The area of each face is L^2, where $L = 0.300$ m.

EXECUTE: **(a)** $\hat{\boldsymbol{n}}_{S_1} = -\hat{\boldsymbol{j}} \Rightarrow \Phi_1 = \vec{\boldsymbol{E}}\cdot\hat{\boldsymbol{n}}_{S_1}A = 0.$

$\hat{\boldsymbol{n}}_{S_2} = +\hat{\boldsymbol{k}} \Rightarrow \Phi_2 = \vec{\boldsymbol{E}}\cdot\hat{\boldsymbol{n}}_{S_2}A = (3.00\ \text{N/C}\cdot\text{m})(0.300\ \text{m})^2 z = (0.27\ \text{(N/C)}\cdot\text{m})z.$

$\Phi_2 = (0.27\ \text{(N/C)}\cdot\text{m})(0.300\ \text{m}) = 0.081\text{(N/C)}\cdot\text{m}^2.$

$\hat{\boldsymbol{n}}_{S_3} = +\hat{\boldsymbol{j}} \Rightarrow \Phi_3 = \vec{\boldsymbol{E}}\cdot\hat{\boldsymbol{n}}_{S_3}A = 0.$

$\hat{\boldsymbol{n}}_{S_4} = -\hat{\boldsymbol{k}} \Rightarrow \Phi_4 = \vec{\boldsymbol{E}}\cdot\hat{\boldsymbol{n}}_{S_4}A = -(0.27\ \text{(N/C)}\cdot\text{m})z = 0\ (\text{since } z = 0).$

$\hat{\boldsymbol{n}}_{S_5} = +\hat{\boldsymbol{i}} \Rightarrow \Phi_5 = \vec{\boldsymbol{E}}\cdot\hat{\boldsymbol{n}}_{S_5}A = (-5.00\ \text{N/C}\cdot\text{m})(0.300\ \text{m})^2 x = -(0.45\ \text{(N/C)}\cdot\text{m})x.$

$\Phi_5 = -(0.45\ \text{(N/C)}\cdot\text{m})(0.300\ \text{m}) = -(0.135\text{(N/C)}\cdot\text{m}^2).$

$\hat{\boldsymbol{n}}_{S_6} = -\hat{\boldsymbol{i}} \Rightarrow \Phi_6 = \vec{\boldsymbol{E}}\cdot\hat{\boldsymbol{n}}_{S_6}A = +(0.45\ \text{(N/C)}\cdot\text{m})x = 0\ (\text{since } x = 0).$

(b) Total flux: $\Phi = \Phi_2 + \Phi_5 = (0.081 - 0.135)\text{(N/C)}\cdot\text{m}^2 = -0.054\ \text{N}\cdot\text{m}^2/\text{C}$. Therefore,

$q = \epsilon_0\Phi = -4.78\times10^{-13}\ \text{C}.$

EVALUATE: Flux is positive when $\vec{\boldsymbol{E}}$ is directed out of the volume and negative when it is directed into the volume.

22.35. **IDENTIFY:** Use Eq. (22.3) to calculate the flux through each surface and use Gauss's law to relate the net flux to the enclosed charge.

SET UP: Flux into the enclosed volume is negative and flux out of the volume is positive.

EXECUTE: **(a)** $\Phi = EA = (125\ \text{N/C})(6.0\ \text{m}^2) = 750\ \text{N}\cdot\text{m}^2/\text{C}.$

(b) Since the field is parallel to the surface, $\Phi = 0$.

(c) Choose the Gaussian surface to equal the volume's surface. Then $750\ \text{N}\cdot\text{m}^2/\text{C} - EA = q/\epsilon_0$ and

$E = \dfrac{1}{6.0\ \text{m}^2}(2.40\times10^{-8}\ \text{C}/\epsilon_0 + 750\ \text{N}\cdot\text{m}^2/\text{C}) = 577\ \text{N/C},$ in the positive x-direction. Since $q < 0$ we must have some net flux flowing *in* so the flux is $-|EA|$ on second face.

EVALUATE: **(d)** $q < 0$ but we have E pointing *away* from face I. This is due to an external field that does not affect the flux but affects the value of E. The electric field is produced by charges both inside and outside the slab.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

22.36. **IDENTIFY:** The electric field is perpendicular to the square but varies in magnitude over the surface of the square, so we will need to integrate to find the flux.

SET UP and **EXECUTE:** $\vec{\boldsymbol{E}} = (964\ \text{N/(C}\cdot\text{m)})x\hat{\boldsymbol{k}}$. Consider a thin rectangular slice parallel to the y-axis and at coordinate x with width dx. $d\vec{\boldsymbol{A}} = (Ldx)\hat{\boldsymbol{k}}$. $d\Phi_E = \vec{\boldsymbol{E}}\cdot d\vec{\boldsymbol{A}} = (964\ \text{N/(C}\cdot\text{m)})Lxdx$.

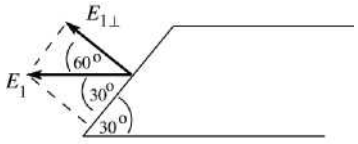
$$\Phi_E = \int_0^L d\Phi_E = (964\ \text{N/(C}\cdot\text{m)})L\int_0^L xdx = (964\ \text{N/(C}\cdot\text{m)})L\left(\frac{L^2}{2}\right).$$

$$\Phi_E = \frac{1}{2}(964\ \text{N/(C}\cdot\text{m)})(0.350\ \text{m})^3 = 20.7\ \text{N}\cdot\text{m}^2/\text{C}.$$

EVALUATE: To set up the integral, we take rectangular slices parallel to the y-axis (and not the x-axis) because the electric field is constant over such a slice. It would not be constant over a slice parallel to the x-axis.

22.37. **(a) IDENTIFY:** Find the net flux through the parallelepiped surface and then use that in Gauss's law to find the net charge within. Flux out of the surface is positive and flux into the surface is negative.

SET UP: $\vec{\boldsymbol{E}}_1$ gives flux out of the surface. See Figure 22.37a.



EXECUTE: $\Phi_1 = +E_{1\perp}A$

$A = (0.0600\ \text{m})(0.0500\ \text{m}) = 3.00\times10^{-3}\ \text{m}^2$

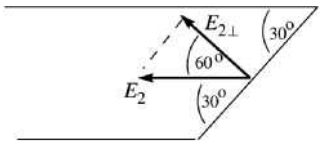
$E_{1\perp} = E_1\cos 60° = (2.50\times10^4\ \text{N/C})\cos 60°$

$E_{1\perp} = 1.25\times10^4\ \text{N/C}$

Figure 22.37a

$\Phi_{E_1} = +E_{1\perp}A = +(1.25\times10^4\ \text{N/C})(3.00\times10^{-3}\ \text{m}^2) = 37.5\ \text{N}\cdot\text{m}^2/\text{C}$

SET UP: $\vec{\boldsymbol{E}}_2$ gives flux into the surface. See Figure 22.37b.



EXECUTE: $\Phi_2 = -E_{2\perp}A$

$A = (0.0600\ \text{m})(0.0500\ \text{m}) = 3.00\times10^{-3}\ \text{m}^2$

$E_{2\perp} = E_2\cos 60° = (7.00\times10^4\ \text{N/C})\cos 60°$

$E_{2\perp} = 3.50\times10^4\ \text{N/C}$

Figure 22.37b

$\Phi_{E_2} = -E_{2\perp}A = -(3.50\times10^4\ \text{N/C})(3.00\times10^{-3}\ \text{m}^2) = -105.0\ \text{N}\cdot\text{m}^2/\text{C}$

The net flux is $\Phi_E = \Phi_{E_1} + \Phi_{E_2} = +37.5\ \text{N}\cdot\text{m}^2/\text{C} - 105.0\ \text{N}\cdot\text{m}^2/\text{C} = -67.5\ \text{N}\cdot\text{m}^2/\text{C}$.

The net flux is negative (inward), so the net charge enclosed is negative.

Apply Gauss's law: $\Phi_E = \dfrac{Q_{\text{encl}}}{\epsilon_0}$

$Q_{\text{encl}} = \Phi_E\epsilon_0 = (-67.5\ \text{N}\cdot\text{m}^2/\text{C})(8.854\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2) = -5.98\times10^{-10}\ \text{C}$.

(b) EVALUATE: If there were no charge within the parallelpiped the net flux would be zero. This is not the case, so there is charge inside. The electric field lines that pass out through the surface of the parallelpiped must terminate on charges, so there also must be charges outside the parallelpiped.

22.38. **IDENTIFY:** The α particle feels no force where the net electric field due to the two distributions of charge is zero.

SET UP: The fields can cancel only in the regions A and B shown in Figure 22.38, because only in these two regions are the two fields in opposite directions.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: $E_{\text{line}} = E_{\text{sheet}}$ gives $\dfrac{\lambda}{2\pi\epsilon_0 r} = \dfrac{\sigma}{2\epsilon_0}$ and $r = \lambda/\pi\sigma = \dfrac{50\ \mu\text{C/m}}{\pi(100\ \mu\text{C/m}^2)} = 0.16\ \text{m} = 16\ \text{cm}.$

The fields cancel 16 cm from the line in regions *A* and *B*.

EVALUATE: The result is independent of the distance between the line and the sheet. The electric field of an infinite sheet of charge is uniform, independent of the distance from the sheet.

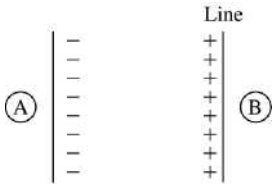


Figure 22.38

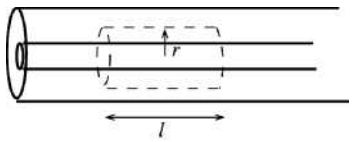
22.39. **(a) IDENTIFY:** Apply Gauss's law to a Gaussian cylinder of length *l* and radius *r*, where $a < r < b$, and calculate *E* on the surface of the cylinder.

SET UP: The Gaussian surface is sketched in Figure 22.39a.



EXECUTE: $\Phi_E = E(2\pi rl)$

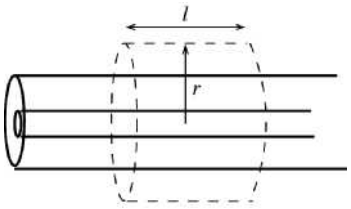
$Q_{\text{encl}} = \lambda l$ (the charge on the length *l* of the inner conductor that is inside the Gaussian surface).

Figure 22.39a

$\Phi_E = \dfrac{Q_{\text{encl}}}{\epsilon_0}$ gives $E(2\pi rl) = \dfrac{\lambda l}{\epsilon_0}$

$E = \dfrac{\lambda}{2\pi\epsilon_0 r}$. The enclosed charge is positive so the direction of $\vec{E}$ is radially outward.

(b) SET UP: Apply Gauss's law to a Gaussian cylinder of length *l* and radius *r*, where $r > c$, as shown in Figure 22.39b.



EXECUTE: $\Phi_E = E(2\pi rl)$

$Q_{\text{encl}} = \lambda l$ (the charge on the length *l* of the inner conductor that is inside the Gaussian surface; the outer conductor carries no net charge).

Figure 22.39b

$\Phi_E = \dfrac{Q_{\text{encl}}}{\epsilon_0}$ gives $E(2\pi rl) = \dfrac{\lambda l}{\epsilon_0}$

$E = \dfrac{\lambda}{2\pi\epsilon_0 r}$. The enclosed charge is positive so the direction of $\vec{E}$ is radially outward.

(c) $E = 0$ within a conductor. Thus $E = 0$ for $r < a$;

$E = \dfrac{\lambda}{2\pi\epsilon_0 r}$ for $a < r < b$; $E = 0$ for $b < r < c$;

$E = \dfrac{\lambda}{2\pi\epsilon_0 r}$ for $r > c$. The graph of *E* versus *r* is sketched in Figure 22.39c.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

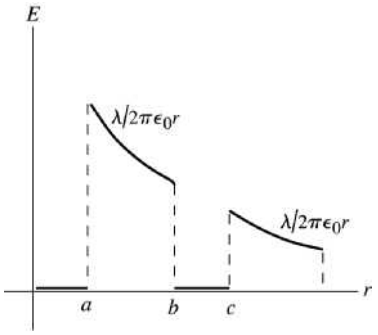


Figure 22.39c

EVALUATE: Inside either conductor $E = 0$. Between the conductors and outside both conductors the electric field is the same as for a line of charge with linear charge density λ lying along the axis of the inner conductor.

(d) IDENTIFY and **SET UP:** inner surface: Apply Gauss's law to a Gaussian cylinder with radius r, where $b < r < c$. We know E on this surface; calculate Q_{encl}.

EXECUTE: This surface lies within the conductor of the outer cylinder, where $E = 0$, so $\Phi_E = 0$. Thus by Gauss's law $Q_{\text{encl}} = 0$. The surface encloses charge λl on the inner conductor, so it must enclose charge $-\lambda l$ on the inner surface of the outer conductor. The charge per unit length on the inner surface of the outer cylinder is $-\lambda$.

outer surface: The outer cylinder carries no net charge. So if there is charge per unit length $-\lambda$ on its inner surface there must be charge per unit length $+\lambda$ on the outer surface.

EVALUATE: The electric field lines between the conductors originate on the surface charge on the outer surface of the inner conductor and terminate on the surface charges on the inner surface of the outer conductor. These surface charges are equal in magnitude (per unit length) and opposite in sign. The electric field lines outside the outer conductor originate from the surface charge on the outer surface of the outer conductor.

22.40. **IDENTIFY:** Apply Gauss's law.

SET UP: Use a Gaussian surface that is a cylinder of radius r, length l and that has the line of charge along its axis. The charge on a length l of the line of charge or of the tube is $q = \alpha l$.

EXECUTE: **(a)** (i) For $r < a$, Gauss's law gives $E(2\pi rl) = \dfrac{Q_{\text{encl}}}{\epsilon_0} = \dfrac{\alpha l}{\epsilon_0}$ and $E = \dfrac{\alpha}{2\pi\epsilon_0 r}$.

(ii) The electric field is zero because these points are within the conducting material.

(iii) For $r > b$, Gauss's law gives $E(2\pi rl) = \dfrac{Q_{\text{encl}}}{\epsilon_0} = \dfrac{2\alpha l}{\epsilon_0}$ and $E = \dfrac{\alpha}{\pi\epsilon_0 r}$.

The graph of E versus r is sketched in Figure 22.40.

(b) (i) The Gaussian cylinder with radius r, for $a < r < b$, must enclose zero net charge, so the charge per unit length on the inner surface is $-\alpha$. (ii) Since the net charge per length for the tube is $+\alpha$ and there is $-\alpha$ on the inner surface, the charge per unit length on the outer surface must be $+2\alpha$.

EVALUATE: For $r > b$ the electric field is due to the charge on the outer surface of the tube.

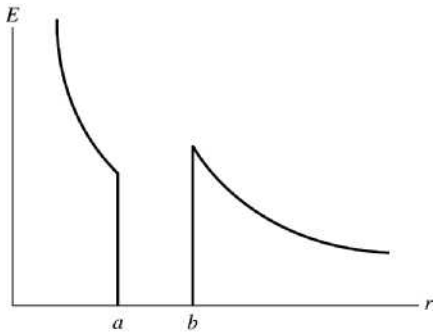

Figure 22.40

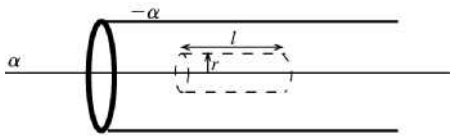
22.41. **(a) IDENTIFY:** Use Gauss's law to calculate $E(r)$.

(i) **SET UP:** $\underline{r < a}$: Apply Gauss's law to a cylindrical Gaussian surface of length l and radius r, where $r < a$, as sketched in Figure 22.41a.



EXECUTE: $\Phi_E = E(2\pi rl)$
$Q_{\text{encl}} = \alpha l$ (the charge on the length l of the line of charge)

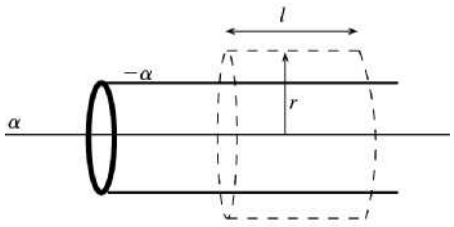
Figure 22.41a

$\Phi_E = \dfrac{Q_{\text{encl}}}{\epsilon_0}$ gives $E(2\pi rl) = \dfrac{\alpha l}{\epsilon_0}$

$E = \dfrac{\alpha}{2\pi\epsilon_0 r}$. The enclosed charge is positive so the direction of $\vec{\boldsymbol{E}}$ is radially outward.

(ii) $\underline{a < r < b}$: Points in this region are within the conducting tube, so. $E = 0$.

(iii) **SET UP:** $\underline{r > b}$: Apply Gauss's law to a cylindrical Gaussian surface of length l and radius r, where $r > b$, as sketched in Figure 22.41b.



EXECUTE: $\Phi_E = E(2\pi rl)$
$Q_{\text{encl}} = \alpha l$ (the charge on length l of the line of charge) $-\alpha l$ (the charge on length l of the tube)
Thus $Q_{\text{encl}} = 0$.

Figure 22.41b

$\Phi_E = \dfrac{Q_{\text{encl}}}{\epsilon_0}$ gives $E(2\pi rl) = 0$ and $E = 0$. The graph of E versus r is sketched in Figure 22.41c.

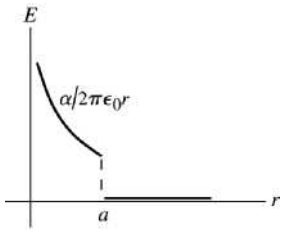


Figure 22.41c

(b) IDENTIFY: Apply Gauss's law to cylindrical surfaces that lie just outside the inner and outer surfaces of the tube. We know E so can calculate Q_{encl}.

(i) **SET UP:** $\underline{\text{inner surface}}$
Apply Gauss's law to a cylindrical Gaussian surface of length l and radius r, where $a < r < b$.

EXECUTE: This surface lies within the conductor of the tube, where $E = 0$, so $\Phi_E = 0$. Then by Gauss's law $Q_{\text{encl}} = 0$. The surface encloses charge αl on the line of charge so must enclose charge $-\alpha l$ on the inner surface of the tube. The charge per unit length on the inner surface of the tube is $-\alpha$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(ii) outer surface

The net charge per unit length on the tube is $-\alpha$. We have shown in part (i) that this must all reside on the inner surface, so there is no net charge on the outer surface of the tube.

EVALUATE: For $r < a$ the electric field is due only to the line of charge. For $r > b$ the electric field of the tube is the same as for a line of charge along its axis. The fields of the line of charge and of the tube are equal in magnitude and opposite in direction and sum to zero. For $r < a$ the electric field lines originate on the line of charge and terminate on the surface charge on the inner surface of the tube. There is no electric field outside the tube and no surface charge on the outer surface of the tube.

22.42. **IDENTIFY:** Apply Gauss's law.

SET UP: Use a Gaussian surface that is a cylinder of radius r and length l, and that is coaxial with the cylindrical charge distributions. The volume of the Gaussian cylinder is $\pi r^2 l$ and the area of its curved surface is $2\pi rl$. The charge on a length l of the charge distribution is $q = \lambda l$, where $\lambda = \rho\pi R^2$.

EXECUTE: **(a)** For $r < R$, $Q_{\text{encl}} = \rho\pi r^2 l$ and Gauss's law gives $E(2\pi rl) = \dfrac{Q_{\text{encl}}}{\epsilon_0} = \dfrac{\rho\pi r^2 l}{\epsilon_0}$ and $E = \dfrac{\rho r}{2\epsilon_0}$, radially outward.

(b) For $r > R$, $Q_{\text{encl}} = \lambda l = \rho\pi R^2 l$ and Gauss's law gives $E(2\pi rl) = \dfrac{Q_{\text{encl}}}{\epsilon_0} = \dfrac{\rho\pi R^2 l}{\epsilon_0}$ and

$E = \dfrac{\rho R^2}{2\epsilon_0 r} = \dfrac{\lambda}{2\pi\epsilon_0 r}$, radially outward.

(c) At $r = R$, the electric field for BOTH regions is $E = \dfrac{\rho R}{2\epsilon_0}$, so they are consistent.

(d) The graph of E versus r is sketched in Figure 22.42.

EVALUATE: For $r > R$ the field is the same as for a line of charge along the axis of the cylinder.

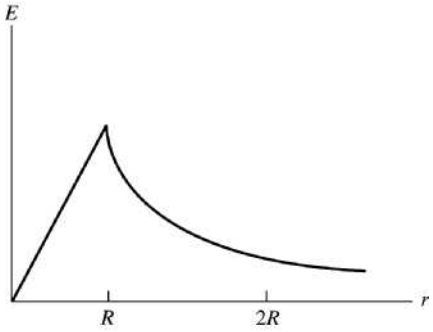

Figure 22.42

22.43. **IDENTIFY:** First make a free-body diagram of the sphere. The electric force acts to the left on it since the electric field due to the sheet is horizontal. Since it hangs at rest, the sphere is in equilibrium so the forces on it add to zero, by Newton's first law. Balance horizontal and vertical force components separately.

SET UP: Call T the tension in the thread and E the electric field. Balancing horizontal forces gives $T\sin\theta = qE$. Balancing vertical forces we get $T\cos\theta = mg$. Combining these equations gives $\tan\theta = qE/mg$, which means that $\theta = \arctan(qE/mg)$. The electric field for a sheet of charge is $E = \sigma/2\varepsilon_0$.

EXECUTE: Substituting the numbers gives us

$E = \dfrac{\sigma}{2\epsilon_0} = \dfrac{2.50\times10^{-9}\ \text{C/m}^2}{2(8.85\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2)} = 1.41\times10^2\ \text{N/C}$. Then

$\theta = \arctan\left[\dfrac{(5.00\times10^{-8}\ \text{C})(1.41\times10^2\ \text{N/C})}{(4.00\times10^{-6}\ \text{kg})(9.80\ \text{m/s}^2)}\right] = 10.2°.$

EVALUATE: Increasing the field, or decreasing the mass of the sphere, would cause the sphere to hang at a larger angle.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

22.44. **IDENTIFY:** Apply Gauss's law.
SET UP: Use a Gaussian surface that is a sphere of radius r and that is concentric with the conducting spheres.
EXECUTE: **(a)** For $r < a, E = 0,$ since these points are within the conducting material.

For $a < r < b, E = \frac{1}{4\pi\epsilon_0}\frac{q}{r^2},$ since there is $+q$ inside a radius r.

For $b < r < c, E = 0,$ since these points are within the conducting material.

For $r > c, E = \frac{1}{4\pi\epsilon_0}\frac{q}{r^2},$ since again the total charge enclosed is $+q$.

(b) The graph of E versus r is sketched in Figure 22.44a.
(c) Since the Gaussian sphere of radius r, for $b < r < c,$ must enclose zero net charge, the charge on the inner shell surface is $-q$.
(d) Since the hollow sphere has no net charge and has charge $-q$ on its inner surface, the charge on the outer shell surface is $+q$.
(e) The field lines are sketched in Figure 22.44b. Where the field is nonzero, it is radially outward.
EVALUATE: The net charge on the inner solid conducting sphere is on the surface of that sphere. The presence of the hollow sphere does not affect the electric field in the region $r < b$.

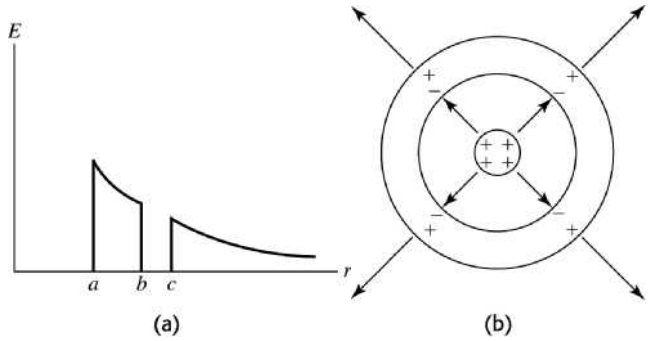

Figure 22.44

22.45. **IDENTIFY:** Apply Gauss's law.
SET UP: Use a Gaussian surface that is a sphere of radius r and that is concentric with the charge distributions.
EXECUTE: **(a)** For $r < R, E = 0,$ since these points are within the conducting material. For $R < r < 2R,$ $E = \frac{1}{4\pi\epsilon_0}\frac{Q}{r^2},$ since the charge enclosed is Q. The field is radially outward. For $r > 2R,$ $E = \frac{1}{4\pi\epsilon_0}\frac{2Q}{r^2}$ since the charge enclosed is $2Q$. The field is radially outward.
(b) The graph of E versus r is sketched in Figure 22.45.
EVALUATE: For $r < 2R$ the electric field is unaffected by the presence of the charged shell.

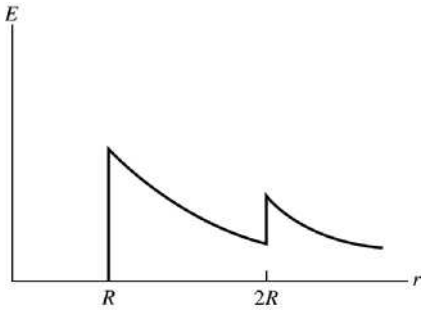

Figure 22.45

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

22.46. **IDENTIFY:** Apply Gauss's law and conservation of charge.
SET UP: Use a Gaussian surface that is a sphere of radius r and that has the point charge at its center.
EXECUTE: **(a)** For $r < a$, $E = \dfrac{1}{4\pi\epsilon_0}\dfrac{Q}{r^2}$, radially outward, since the charge enclosed is Q, the charge of the point charge. For $a < r < b$, $E = 0$ since these points are within the conducting material. For $r > b$, $E = \dfrac{1}{4\pi\epsilon_0}\dfrac{2Q}{r^2}$, radially inward, since the total enclosed charge is $-2Q$.
(b) Since a Gaussian surface with radius r, for $a < r < b$, must enclose zero net charge, the total charge on the inner surface is $-Q$ and the surface charge density on the inner surface is $\sigma = -\dfrac{Q}{4\pi a^2}$.
(c) Since the net charge on the shell is $-3Q$ and there is $-Q$ on the inner surface, there must be $-2Q$ on the outer surface. The surface charge density on the outer surface is $\sigma = -\dfrac{2Q}{4\pi b^2}$.
(d) The field lines and the locations of the charges are sketched in Figure 22.46a.
(e) The graph of E versus r is sketched in Figure 22.46b.

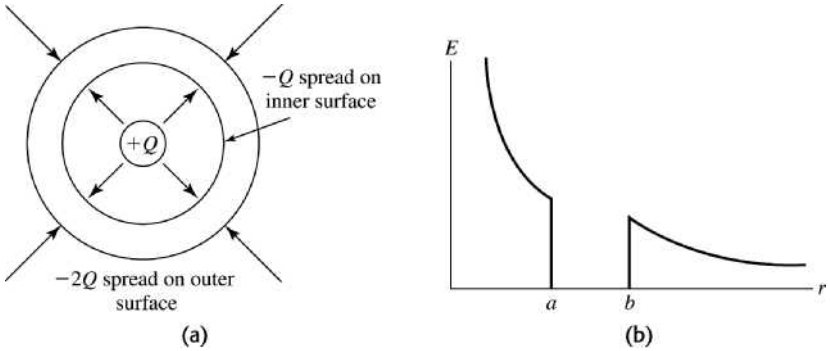

Figure 22.46

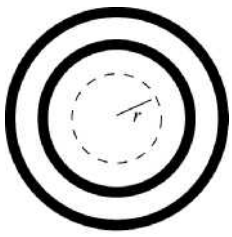
EVALUATE: For $r < a$ the electric field is due solely to the point charge Q. For $r > b$ the electric field is due to the charge $-2Q$ that is on the outer surface of the shell.

22.47. **IDENTIFY:** Apply Gauss's law to a spherical Gaussian surface with radius r. Calculate the electric field at the surface of the Gaussian sphere.
(a) SET UP: (i) $r < a$: The Gaussian surface is sketched in Figure 22.47a.

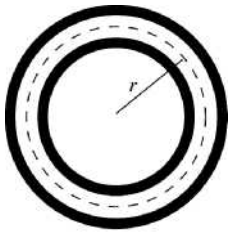


EXECUTE: $\Phi_E = EA = E(4\pi r^2)$
$Q_{\text{encl}} = 0$; no charge is enclosed
$\Phi_E = \dfrac{Q_{\text{encl}}}{\epsilon_0}$ says
$E(4\pi r^2) = 0$ and $E = 0$.

Figure 22.47a

(ii) $a < r < b$: Points in this region are in the conductor of the small shell, so $E = 0$.
(iii) **SET UP:** $b < r < c$: The Gaussian surface is sketched in Figure 22.47b.
Apply Gauss's law to a spherical Gaussian surface with radius $b < r < c$.

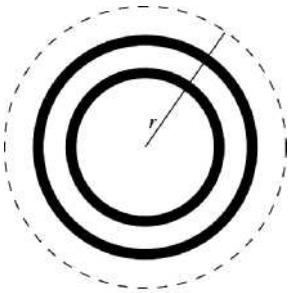
© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist.
No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.



EXECUTE: $\Phi_E = EA = E(4\pi r^2)$
The Gaussian surface encloses all of the small shell and none of the large shell, so $Q_{\text{encl}} = +2q$.

Figure 22.47b

$\Phi_E = \dfrac{Q_{\text{encl}}}{\epsilon_0}$ gives $E(4\pi r^2) = \dfrac{2q}{\epsilon_0}$ so $E = \dfrac{2q}{4\pi\epsilon_0 r^2}$. Since the enclosed charge is positive the electric field is radially outward.
(iv) $c < r < d$: Points in this region are in the conductor of the large shell, so $E = 0$.
(v) **SET UP:** $r > d$: Apply Gauss's law to a spherical Gaussian surface with radius $r > d$, as shown in Figure 22.47c.



EXECUTE: $\Phi_E = EA = E(4\pi r^2)$
The Gaussian surface encloses all of the small shell and all of the large shell, so $Q_{\text{encl}} = +2q + 4q = 6q$.

Figure 22.47c

$\Phi_E = \dfrac{Q_{\text{encl}}}{\epsilon_0}$ gives $E(4\pi r^2) = \dfrac{6q}{\epsilon_0}$

$E = \dfrac{6q}{4\pi\epsilon_0 r^2}$. Since the enclosed charge is positive the electric field is radially outward.
The graph of E versus r is sketched in Figure 22.47d.

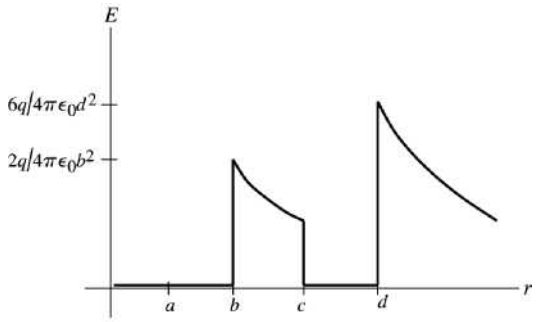


Figure 22.47d

(b) IDENTIFY and **SET UP:** Apply Gauss's law to a sphere that lies outside the surface of the shell for which we want to find the surface charge.
EXECUTE: (i) charge on inner surface of the small shell: Apply Gauss's law to a spherical Gaussian surface with radius $a < r < b$. This surface lies within the conductor of the small shell, where $E = 0$, so $\Phi_E = 0$. Thus by Gauss's law $Q_{\text{encl}} = 0$, so there is zero charge on the inner surface of the small shell.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(ii) charge on outer surface of the small shell: The total charge on the small shell is $+2q$. We found in part (i) that there is zero charge on the inner surface of the shell, so all $+2q$ must reside on the outer surface.
(iii) charge on inner surface of large shell: Apply Gauss's law to a spherical Gaussian surface with radius $c < r < d$. The surface lies within the conductor of the large shell, where $E = 0$, so $\Phi_E = 0$. Thus by Gauss's law $Q_{\text{encl}} = 0$. The surface encloses the $+2q$ on the small shell so there must be charge $-2q$ on the inner surface of the large shell to make the total enclosed charge zero.
(iv) charge on outer surface of large shell: The total charge on the large shell is $+4q$. We showed in part (iii) that the charge on the inner surface is $-2q$, so there must be $+6q$ on the outer surface.

EVALUATE: The electric field lines for $b < r < c$ originate from the surface charge on the outer surface of the inner shell and all terminate on the surface charge on the inner surface of the outer shell. These surface charges have equal magnitude and opposite sign. The electric field lines for $r > d$ originate from the surface charge on the outer surface of the outer sphere.

22.48. **IDENTIFY:** Apply Gauss's law.
SET UP: Use a Gaussian surface that is a sphere of radius r and that is concentric with the charged shells.
EXECUTE: **(a)** (i) For $r < a, E = 0$, since the charge enclosed is zero. (ii) For $a < r < b, E = 0$, since the points are within the conducting material. (iii) For $b < r < c, E = \frac{1}{4\pi\epsilon_0}\frac{2q}{r^2}$, outward, since the charge enclosed is $+2q$. (iv) For $c < r < d, E = 0$, since the points are within the conducting material. (v) For $r > d, E = 0$, since the net charge enclosed is zero. The graph of E versus r is sketched in Figure 22.48.
(b) (i) small shell inner surface: Since a Gaussian surface with radius r, for $a < r < b$, must enclose zero net charge, the charge on this surface is zero. (ii) small shell outer surface: $+2q$. (iii) large shell inner surface: Since a Gaussian surface with radius r, for $c < r < d$, must enclose zero net charge, the charge on this surface is $-2q$. (iv) large shell outer surface: Since there is $-2q$ on the inner surface and the total charge on this conductor is $-2q$, the charge on this surface is zero.
EVALUATE: The outer shell has no effect on the electric field for $r < c$. For $r > d$ the electric field is due only to the charge on the outer surface of the larger shell.

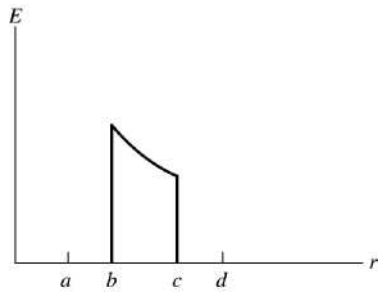

Figure 22.48

22.49. **IDENTIFY:** Apply Gauss's law
SET UP: Use a Gaussian surface that is a sphere of radius r and that is concentric with the charged shells.
EXECUTE: **(a)** (i) For $r < a, E = 0$, since the charge enclosed is zero. (ii) $a < r < b, E = 0$, since the points are within the conducting material. (iii) For $b < r < c, E = \frac{1}{4\pi\epsilon_0}\frac{2q}{r^2}$, outward, since the charge enclosed is $+2q$. (iv) For $c < r < d, E = 0$, since the points are within the conducting material. (v) For $r > d, E = \frac{1}{4\pi\epsilon_0}\frac{2q}{r^2}$, inward, since the charge enclosed is $-2q$. The graph of the radial component of the electric field versus r is sketched in Figure 22.49, where we use the convention that outward field is positive and inward field is negative.

(b) (i) small shell inner surface: Since a Gaussian surface with radius r, for $a < r < b$, must enclose zero net charge, the charge on this surface is zero. (ii) small shell outer surface: $+2q$. (iii) large shell inner surface: Since a Gaussian surface with radius r, for $c < r < d$, must enclose zero net charge, the charge on this surface is $-2q$. (iv) large shell outer surface: Since there is $-2q$ on the inner surface and the total charge on this conductor is $-4q$, the charge on this surface is $-2q$.

EVALUATE: The outer shell has no effect on the electric field for $r < c$. For $r > d$ the electric field is due only to the charge on the outer surface of the larger shell.

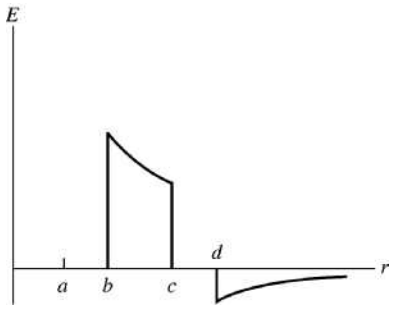

Figure 22.49

22.50. **IDENTIFY:** Apply Gauss's law.

SET UP: Use a Gaussian surface that is a sphere of radius r and that is concentric with the sphere and shell. The volume of the insulating shell is $V = \frac{4}{3}\pi([2R]^3 - R^3) = \frac{28\pi}{3}R^3$.

EXECUTE: **(a)** Zero net charge requires that $-Q = \frac{28\pi\rho R^3}{3}$, so $\rho = -\frac{3Q}{28\pi R^3}$.

(b) For $r < R, E = 0$ since this region is within the conducting sphere. For $r > 2R, E = 0$, since the net charge enclosed by the Gaussian surface with this radius is zero. For $R < r < 2R$, Gauss's law gives $E(4\pi r^2) = \frac{Q}{\epsilon_0} + \frac{4\pi\rho}{3\epsilon_0}(r^3 - R^3)$ and $E = \frac{Q}{4\pi\epsilon_0 r^2} + \frac{\rho}{3\epsilon_0 r^2}(r^3 - R^3)$. Substituting ρ from part (a) gives $E = \frac{2}{7\pi\epsilon_0}\frac{Q}{r^2} - \frac{Qr}{28\pi\epsilon_0 R^3}$. The net enclosed charge for each r in this range is positive and the electric field is outward.

(c) The graph is sketched in Figure 22.50. We see a discontinuity in going from the conducting sphere to the insulator due to the thin surface charge of the conducting sphere. But we see a smooth transition from the uniform insulator to the surrounding space.

EVALUATE: The expression for E within the insulator gives $E = 0$ at $r = 2R$.

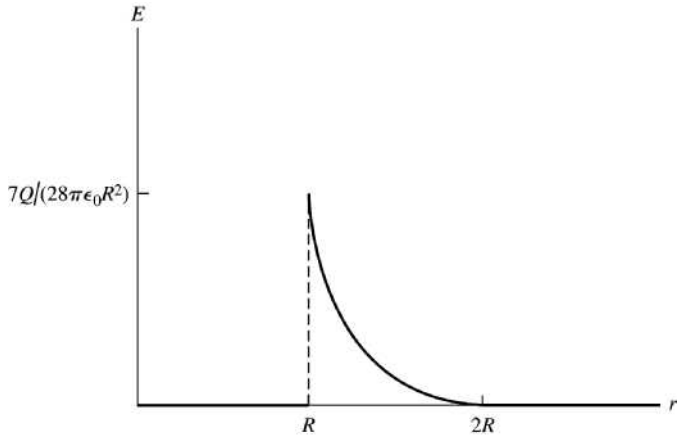

Figure 22.50

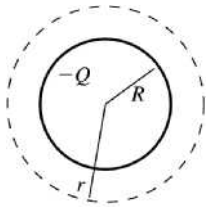
22.51. **IDENTIFY:** Use Gauss's law to find the electric field $\vec{E}$ produced by the shell for $r < R$ and $r > R$ and then use $\vec{F} = q\vec{E}$ to find the force the shell exerts on the point charge.

(a) SET UP: Apply Gauss's law to a spherical Gaussian surface that has radius $r > R$ and that is concentric with the shell, as sketched in Figure 22.51a.



EXECUTE: $\Phi_E = -E(4\pi r^2)$

$Q_{\text{encl}} = -Q$

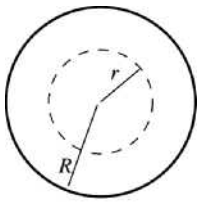
Figure 22.51a

$\Phi_E = \dfrac{Q_{\text{encl}}}{\epsilon_0}$ gives $-E(4\pi r^2) = \dfrac{-Q}{\epsilon_0}$

The magnitude of the field is $E = \dfrac{Q}{4\pi\epsilon_0 r^2}$ and it is directed toward the center of the shell. Then

$F = qE = \dfrac{qQ}{4\pi\epsilon_0 r^2}$, directed toward the center of the shell. (Since q is positive, $\vec{E}$ and $\vec{F}$ are in the same direction.)

(b) SET UP: Apply Gauss's law to a spherical Gaussian surface that has radius $r < R$ and that is concentric with the shell, as sketched in Figure 22.51b.



EXECUTE: $\Phi_E = E(4\pi r^2)$

$Q_{\text{encl}} = 0$

Figure 22.51b

$\Phi_E = \dfrac{Q_{\text{encl}}}{\epsilon_0}$ gives $E(4\pi r^2) = 0$

Then $E = 0$ so $F = 0$.

EVALUATE: Outside the shell the electric field and the force it exerts is the same as for a point charge $-Q$ located at the center of the shell. Inside the shell $E = 0$ and there is no force.

22.52. **IDENTIFY:** The method of Example 22.9 shows that the electric field outside the sphere is the same as for a point charge of the same charge located at the center of the sphere.

SET UP: The charge of an electron has magnitude $e = 1.60\times10^{-19}$ C.

EXECUTE: **(a)** $E = k\dfrac{|q|}{r^2}$. For $r = R = 0.150$ m, $E = 1390$ N/C so

$|q| = \dfrac{Er^2}{k} = \dfrac{(1390\text{ N/C})(0.150\text{ m})^2}{8.99\times10^9\text{ N}\cdot\text{m}^2/\text{C}^2} = 3.479\times10^{-9}$ C. The number of excess electrons is

$\dfrac{3.479\times10^{-9}\text{ C}}{1.60\times10^{-19}\text{ C/electron}} = 2.17\times10^{10}$ electrons.

(b) $r = R + 0.100\text{ m} = 0.250$ m. $E = k\dfrac{|q|}{r^2} = (8.99\times10^9\text{ N}\cdot\text{m}^2/\text{C}^2)\dfrac{3.479\times10^{-9}\text{ C}}{(0.250\text{ m})^2} = 5.00\times10^2$ N/C.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: The magnitude of the electric field decreases according to the square of the distance from the center of the sphere.

22.53. **IDENTIFY:** We apply Gauss's law in (a) and take a spherical Gaussian surface because of the spherical symmetry of the charge distribution. In (b), the net field is the vector sum of the field due to q and the field due to the sphere.

(a) SET UP: $\rho(r)=\dfrac{\alpha}{r}$, $dV=4\pi r^2 dr$, and $Q=\int_a^r \rho(r')dV$.

EXECUTE: For a Gaussian sphere of radius r, $Q_{\text{encl}}=\int_a^r \rho(r')dV=4\pi\alpha\int_a^r r'dr'=4\pi\alpha\dfrac{1}{2}(r^2-a^2)$. Gauss's law says that $E(4\pi r^2)=\dfrac{2\pi\alpha(r^2-a^2)}{\epsilon_0}$, which gives $E=\dfrac{\alpha}{2\epsilon_0}\left(1-\dfrac{a^2}{r^2}\right)$.

(b) The electric field of the point charge is $E_q=\dfrac{q}{4\pi\epsilon_0 r^2}$. The total electric field is $E_{\text{total}}=\dfrac{\alpha}{2\epsilon_0}-\dfrac{\alpha}{2\epsilon_0}\dfrac{a^2}{r^2}+\dfrac{q}{4\pi\epsilon_0 r^2}$. For E_{total} to be constant, $-\dfrac{\alpha a^2}{2\epsilon_0}+\dfrac{q}{4\pi\epsilon_0}=0$ and $q=2\pi\alpha a^2$. The constant electric field is $\dfrac{\alpha}{2\epsilon_0}$.

EVALUATE: The net field is constant, but not zero.

22.54. **IDENTIFY:** Example 22.9 gives the expression for the electric field both inside and outside a uniformly charged sphere. Use $\vec{\boldsymbol{F}}=-e\vec{\boldsymbol{E}}$ to calculate the force on the electron.

SET UP: The sphere has charge $Q=+e$.

EXECUTE: **(a)** Only at $r=0$ is $E=0$ for the uniformly charged sphere.

(b) At points inside the sphere, $E_r=\dfrac{er}{4\pi\epsilon_0 R^3}$. The field is radially outward. $F_r=-eE=-\dfrac{1}{4\pi\epsilon_0}\dfrac{e^2 r}{R^3}$. The minus sign denotes that F_r is radially inward. For simple harmonic motion, $F_r=-kr=-m\omega^2 r$, where $\omega=\sqrt{k/m}=2\pi f$. $F_r=-m\omega^2 r=-\dfrac{1}{4\pi\epsilon_0}\dfrac{e^2 r}{R^3}$ so $\omega=\sqrt{\dfrac{1}{4\pi\epsilon_0}\dfrac{e^2}{mR^3}}$ and $f=\dfrac{1}{2\pi}\sqrt{\dfrac{1}{4\pi\epsilon_0}\dfrac{e^2}{mR^3}}$.

(c) If $f=4.57\times10^{14}\text{ Hz}=\dfrac{1}{2\pi}\sqrt{\dfrac{1}{4\pi\epsilon_0}\dfrac{e^2}{mR^3}}$ then $R=\sqrt[3]{\dfrac{1}{4\pi\epsilon_0}\dfrac{(1.60\times10^{-19}\text{ C})^2}{4\pi^2(9.11\times10^{-31}\text{ kg})(4.57\times10^{14}\text{ Hz})^2}}=3.13\times10^{-10}\text{ m}$. The atom radius in this model is the correct order of magnitude.

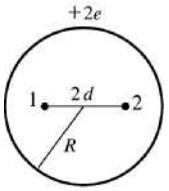
(d) If $r>R$, $E_r=\dfrac{e}{4\pi\epsilon_0 r^2}$ and $F_r=-\dfrac{e^2}{4\pi\epsilon_0 r^2}$. The electron would still oscillate because the force is directed toward the equilibrium position at $r=0$. But the motion would not be simple harmonic, since F_r is proportional to $1/r^2$ and simple harmonic motion requires that the restoring force be proportional to the displacement from equilibrium.

EVALUATE: As long as the initial displacement is less than R the frequency of the motion is independent of the initial displacement.

22.55. **IDENTIFY:** There is a force on each electron due to the other electron and a force due to the sphere of charge. Use Coulomb's law for the force between the electrons. Example 22.9 gives E inside a uniform sphere and Eq. (21.3) gives the force.

SET UP: The positions of the electrons are sketched in Figure 22.55a.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.



If the electrons are in equilibrium the net force on each one is zero.

Figure 22.55a

EXECUTE: Consider the forces on electron 2. There is a repulsive force F_1 due to the other electron, electron 1.

$$F_1 = \frac{1}{4\pi\epsilon_0}\frac{e^2}{(2d)^2}$$

The electric field inside the uniform distribution of positive charge is $E = \dfrac{Qr}{4\pi\epsilon_0 R^3}$ (Example 22.9), where $Q = +2e$. At the position of electron 2, $r = d$. The force F_{cd} exerted by the positive charge distribution is $F_{cd} = eE = \dfrac{e(2e)d}{4\pi\epsilon_0 R^3}$ and is attractive.

The force diagram for electron 2 is given in Figure 22.55b.

Figure 22.55b

Net force equals zero implies $F_1 = F_{cd}$ and $\dfrac{1}{4\pi\epsilon_0}\dfrac{e^2}{4d^2} = \dfrac{2e^2 d}{4\pi\epsilon_0 R^3}$.

Thus $(1/4d^2) = 2d/R^3$, so $d^3 = R^3/8$ and $d = R/2$.

EVALUATE: The electric field of the sphere is radially outward; it is zero at the center of the sphere and increases with distance from the center. The force this field exerts on one of the electrons is radially inward and increases as the electron is farther from the center. The force from the other electron is radially outward, is infinite when $d = 0$ and decreases as d increases. It is reasonable therefore for there to be a value of d for which these forces balance.

22.56. **IDENTIFY:** Use Gauss's law to find the electric field both inside and outside the slab.

SET UP: Use a Gaussian surface that has one face of area A in the yz plane at $x = 0$, and the other face at a general value x. The volume enclosed by such a Gaussian surface is Ax.

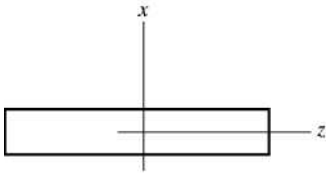
EXECUTE: **(a)** The electric field of the slab must be zero by symmetry. There is no preferred direction in the yz plane, so the electric field can only point in the x-direction. But at the origin, neither the positive nor negative x-directions should be singled out as special, and so the field must be zero.

(b) For $|x| \leq d$, Gauss's law gives $EA = \dfrac{Q_{encl}}{\epsilon_0} = \dfrac{\rho A|x|}{\epsilon_0}$ and $E = \dfrac{\rho|x|}{\epsilon_0}$, with direction given by $\dfrac{x}{|x|}\hat{\boldsymbol{i}}$ (away from the center of the slab). Note that this expression does give $E = 0$ at $x = 0$. Outside the slab, the enclosed charge does not depend on x and is equal to ρAd. For $|x| \geq d$, Gauss's law gives $EA = \dfrac{Q_{encl}}{\epsilon_0} = \dfrac{\rho Ad}{\epsilon_0}$ and $E = \dfrac{\rho d}{\epsilon_0}$, again with direction given by $\dfrac{x}{|x|}\hat{\boldsymbol{i}}$.

EVALUATE: At the surfaces of the slab, $x = \pm d$. For these values of x the two expressions for E (for inside and outside the slab) give the same result. The charge per unit area σ of the slab is given by $\sigma A = \rho A(2d)$ and $\rho d = \sigma/2$. The result for E outside the slab can therefore be written as $E = \sigma/2\epsilon_0$ and is the same as for a thin sheet of charge.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

22.57. **(a) IDENTIFY** and **SET UP:** Consider the direction of the field for x slightly greater than and slightly less than zero. The slab is sketched in Figure 22.57a.



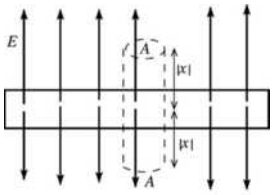
$$\rho(x) = \rho_0(x/d)^2$$

Figure 22.57a

EXECUTE: The charge distribution is symmetric about $x = 0$, so by symmetry $E(x) = E(-x)$. But for $x > 0$ the field is in the $+x$ direction and for $x < 0$ the field is in the $-x$ direction. At $x = 0$ the field can't be both in the $+x$ and $-x$ directions so must be zero. That is, $E_x(x) = -E_x(-x)$. At point $x = 0$ this gives $E_x(0) = -E_x(0)$ and this equation is satisfied only for $E_x(0) = 0$.

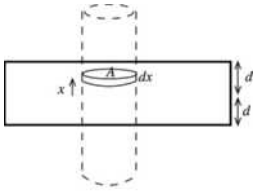
(b) IDENTIFY and **SET UP:** $|x| > d$ (outside the slab)

Apply Gauss's law to a cylindrical Gaussian surface whose axis is perpendicular to the slab and whose end caps have area A and are the same distance $|x| > d$ from $x = 0$, as shown in Figure 22.57b.



EXECUTE: $\Phi_E = 2EA$

Figure 22.57b



To find Q_{encl} consider a thin disk at coordinate x and with thickness dx, as shown in Figure 22.57c. The charge within this disk is $dq = \rho dV = \rho A dx = (\rho_0 A/d^2)\, x^2 dx$.

Figure 22.57c

The total charge enclosed by the Gaussian cylinder is

$$Q_{\text{encl}} = 2\int_0^d dq = (2\rho_0 A/d^2)\int_0^d x^2 dx = (2\rho_0 A/d^2)(d^3/3) = \tfrac{2}{3}\rho_0 A d.$$

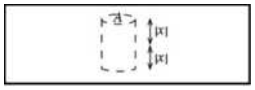
Then $\Phi_E = \dfrac{Q_{\text{encl}}}{\epsilon_0}$ gives $2EA = 2\rho_0 A d/3\epsilon_0$.

$$E = \rho_0 d/3\epsilon_0$$

$\vec{E}$ is directed away from $x = 0$, so $\vec{E} = (\rho_0 d/3\epsilon_0)(x/|x|)\hat{\imath}$.

(c) IDENTIFY and **SET UP:** $|x| < d$ (inside the slab)

Apply Gauss's law to a cylindrical Gaussian surface whose axis is perpendicular to the slab and whose end caps have area A and are the same distance $|x| < d$ from $x = 0$, as shown in Figure 22.57d



EXECUTE: $\Phi_E = 2EA$

Figure 22.57d

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

Q_{encl} is found as above, but now the integral on dx is only from 0 to x instead of 0 do d.

$$Q_{\text{encl}} = 2\int_0^x dq = (2\rho_0 A/d^2)\int_0^x x^2 dx = (2\rho_0 A/d^2)(x^3/3).$$

Then $\Phi_E = \dfrac{Q_{\text{encl}}}{\epsilon_0}$ gives $2EA = 2\rho_0 A x^3/3\epsilon_0 d^2$.

$$E = \rho_0 x^3/3\epsilon_0 d^2$$

$\vec{E}$ is directed away from $x = 0$, so $\vec{E} = (\rho_0 x^3/3\epsilon_0 d^2)\hat{i}$.

EVALUATE: Note that $E = 0$ at $x = 0$ as stated in part (a). Note also that the expressions for $|x| > d$ and $|x| < d$ agree for $x = d$.

22.58. **IDENTIFY:** Apply Gauss's law.

SET UP: Use a Gaussian surface that is a sphere of radius r and that is concentric with the spherical distribution of charge. The volume of a thin spherical shell of radius r and thickness dr is $dV = 4\pi r^2 dr$.

EXECUTE: **(a)** $Q = \int \rho(r) dV = 4\pi\int_0^\infty \rho(r) r^2 dr = 4\pi\rho_0\int_0^R \left(1 - \dfrac{4r}{3R}\right) r^2 dr = 4\pi\rho_0\left[\int_0^R r^2 dr - \dfrac{4}{3R}\int_0^R r^3 dr\right]$

$Q = 4\pi\rho_0\left[\dfrac{R^3}{3} - \dfrac{4}{3R}\dfrac{R^4}{4}\right] = 0$. The total charge is zero.

(b) For $r \geq R$, $\oint \vec{E}\cdot d\vec{A} = \dfrac{Q_{\text{encl}}}{\epsilon_0} = 0$, so $E = 0$.

(c) For $r \leq R$, $\oint \vec{E}\cdot d\vec{A} = \dfrac{Q_{\text{encl}}}{\epsilon_0} = \dfrac{4\pi}{\epsilon_0}\int_0^r \rho(r') r'^2 dr'$. $E 4\pi r^2 = \dfrac{4\pi\rho_0}{\epsilon_0}\left[\int_0^r r'^2 dr' - \dfrac{4}{3R}\int_0^r r'^3 dr'\right]$ and

$E = \dfrac{\rho_0}{\epsilon_0}\dfrac{1}{r^2}\left[\dfrac{r^3}{3} - \dfrac{r^4}{3R}\right] = \dfrac{\rho_0}{3\epsilon_0} r\left[1 - \dfrac{r}{R}\right]$.

(d) The graph of E versus r is sketched in Figure 22.58.

(e) Where E is a maximum, $\dfrac{dE}{dr} = 0$. This gives $\dfrac{\rho_0}{3\epsilon_0} - \dfrac{2\rho_0 r_{\max}}{3\epsilon_0 R} = 0$ and $r_{\max} = \dfrac{R}{2}$. At this r,

$E = \dfrac{\rho_0}{3\epsilon_0}\dfrac{R}{2}\left[1 - \dfrac{1}{2}\right] = \dfrac{\rho_0 R}{12\epsilon_0}$.

EVALUATE: The result in part (b) for $r \leq R$ gives $E = 0$ at $r = R$; the field is continuous at the surface of the charge distribution.

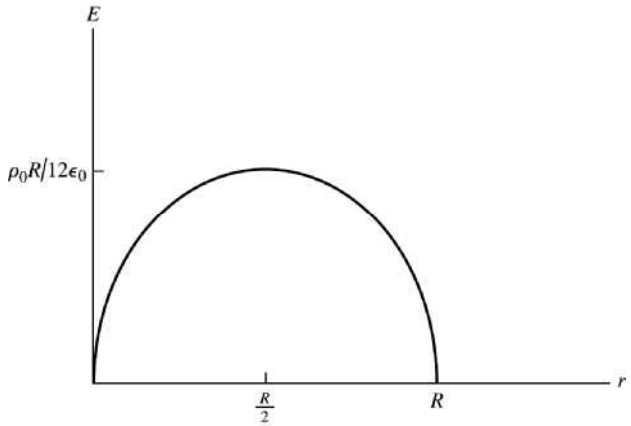


Figure 22.58

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

22.59. **IDENTIFY:** Follow the steps specified in the problem.

SET UP: In spherical polar coordinates $d\vec{A} = r^2 \sin\theta\, d\theta\, d\phi\, \hat{r}$. $\oint \sin\theta\, d\theta\, d\phi = 4\pi$.

EXECUTE: **(a)** $\Phi_g = \oint \vec{g} \cdot d\vec{A} = -Gm \oint \dfrac{r^2 \sin\theta\, d\theta\, d\phi}{r^2} = -4\pi Gm.$

(b) For any closed surface, mass OUTSIDE the surface contributes zero to the flux passing through the surface. Thus the formula above holds for any situation where m is the mass enclosed by the Gaussian surface.

That is, $\Phi_g = \oint \vec{g} \cdot d\vec{A} = -4\pi G M_{\text{encl}}$.

EVALUATE: The minus sign in the expression for the flux signifies that the flux is directed inward.

22.60. **IDENTIFY:** Apply $\oint \vec{g} \cdot d\vec{A} = -4\pi G M_{\text{encl}}$.

SET UP: Use a Gaussian surface that is a sphere of radius r, concentric with the mass distribution. Let Φ_g denote $\oint \vec{g} \cdot d\vec{A}$

EXECUTE: **(a)** Use a Gaussian sphere with radius $r > R$, where R is the radius of the mass distribution. g is constant on this surface and the flux is inward. The enclosed mass is M. Therefore,

$\Phi_g = -g 4\pi r^2 = -4\pi GM$ and $g = \dfrac{GM}{r^2}$, which is the same as for a point mass.

(b) For a Gaussian sphere of radius $r < R$, where R is the radius of the shell, $M_{\text{encl}} = 0$, so $g = 0$.

(c) Use a Gaussian sphere of radius $r < R$, where R is the radius of the planet. Then

$M_{\text{encl}} = \rho\left(\dfrac{4}{3}\pi r^3\right) = Mr^3/R^3$. This gives $\Phi_g = -g 4\pi r^2 = -4\pi G M_{\text{encl}} = -4\pi G\left(M\dfrac{r^3}{R^3}\right)$ and $g = \dfrac{GMr}{R^3}$,

which is linear in r.

EVALUATE: The spherically symmetric distribution of mass results in an acceleration due to gravity $\vec{g}$ that is radical and that depends only on r, the distance from the center of the mass distribution.

22.61. **(a) IDENTIFY:** Use $\vec{E}(\vec{r})$ from Example (22.9) (inside the sphere) and relate the position vector of a point inside the sphere measured from the origin to that measured from the center of the sphere.

SET UP: For an insulating sphere of uniform charge density ρ and centered at the origin, the electric field inside the sphere is given by $E = Qr'/4\pi\epsilon_0 R^3$ (Example 22.9), where $\vec{r}'$ is the vector from the center of the sphere to the point where E is calculated.

But $\rho = 3Q/4\pi R^3$ so this may be written as $E = \rho r/3\epsilon_0$. And $\vec{E}$ is radially outward, in the direction of $\vec{r}'$, so $\vec{E} = \rho\vec{r}'/3\epsilon_0$.

For a sphere whose center is located by vector $\vec{b}$, a point inside the sphere and located by $\vec{r}$ is located by the vector $\vec{r}' = \vec{r} - \vec{b}$ relative to the center of the sphere, as shown in Figure 22.61.

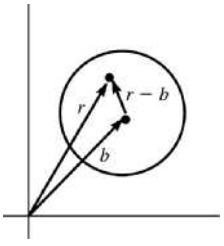

Figure 22.61

EXECUTE: Thus $\vec{E} = \dfrac{\rho(\vec{r} - \vec{b})}{3\epsilon_0}$

EVALUATE: When $b = 0$ this reduces to the result of Example 22.9. When $\vec{r} = \vec{b}$, this gives $E = 0$, which is correct since we know that $E = 0$ at the center of the sphere.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) IDENTIFY: The charge distribution can be represented as a uniform sphere with charge density ρ and centered at the origin added to a uniform sphere with charge density $-\rho$ and centered at $\vec{r} = \vec{b}$.

SET UP: $\vec{E} = \vec{E}_{\text{uniform}} + \vec{E}_{\text{hole}}$, where $\vec{E}_{\text{uniform}}$ is the field of a uniformly charged sphere with charge density ρ and $\vec{E}_{\text{hole}}$ is the field of a sphere located at the hole and with charge density $-\rho$. (Within the spherical hole the net charge density is $+\rho - \rho = 0$.)

EXECUTE: $\vec{E}_{\text{uniform}} = \dfrac{\rho\vec{r}}{3\epsilon_0}$, where $\vec{r}$ is a vector from the center of the sphere.

$\vec{E}_{\text{hole}} = \dfrac{-\rho(\vec{r} - \vec{b})}{3\epsilon_0}$, at points inside the hole.

Then $\vec{E} = \dfrac{\rho\vec{r}}{3\epsilon_0} + \left(\dfrac{-\rho(\vec{r} - \vec{b})}{3\epsilon_0}\right) = \dfrac{\rho\vec{b}}{3\epsilon_0}$.

EVALUATE: $\vec{E}$ is independent of $\vec{r}$ so is uniform inside the hole. The direction of $\vec{E}$ inside the hole is in the direction of the vector $\vec{b}$, the direction from the center of the insulating sphere to the center of the hole.

22.62. **IDENTIFY:** We first find the field of a cylinder off-axis, then the electric field in a hole in a cylinder is the difference between two electric fields: that of a solid cylinder on-axis, and one off-axis, at the location of the hole.

SET UP: Let $\vec{r}$ locate a point within the hole, relative to the axis of the cylinder and let $\vec{r}'$ locate this point relative to the axis of the hole. Let $\vec{b}$ locate the axis of the hole relative to the axis of the cylinder. As shown in Figure 22.62, $\vec{r}' = \vec{r} - \vec{b}$. Problem 22.42 shows that at points within a long insulating cylinder, $\vec{E} = \dfrac{\rho\vec{r}}{2\epsilon_0}$.

EXECUTE: $\vec{E}_{\text{off-axis}} = \dfrac{\rho\vec{r}'}{2\epsilon_0} = \dfrac{\rho(\vec{r} - \vec{b})}{2\epsilon_0}$. $\vec{E}_{\text{hole}} = \vec{E}_{\text{cylinder}} - \vec{E}_{\text{off-axis}} = \dfrac{\rho\vec{r}}{2\epsilon_0} - \dfrac{\rho(\vec{r} - \vec{b})}{2\epsilon_0} = \dfrac{\rho\vec{b}}{2\epsilon_0}$.

Note that $\vec{E}$ is uniform.

EVALUATE: If the hole is coaxial with the cylinder, $b = 0$ and $E_{\text{hole}} = 0$.

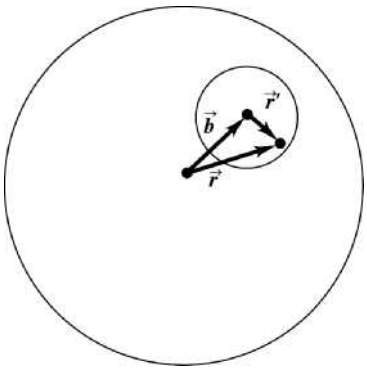

Figure 22.62

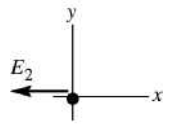
22.63. **IDENTIFY:** The electric field at each point is the vector sum of the fields of the two charge distributions.

SET UP: Inside a sphere of uniform positive charge, $E = \dfrac{\rho r}{3\epsilon_0}$.

$\rho = \dfrac{Q}{\frac{4}{3}\pi R^3} = \dfrac{3Q}{4\pi R^3}$ so $E = \dfrac{Qr}{4\pi\epsilon_0 R^3}$, directed away from the center of the sphere. Outside a sphere of uniform positive charge, $E = \dfrac{Q}{4\pi\epsilon_0 r^2}$, directed away from the center of the sphere.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: **(a)** $x = 0$. This point is inside sphere 1 and outside sphere 2. The fields are shown in Figure 22.63a.



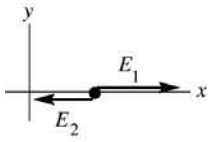
$$E_1 = \frac{Qr}{4\pi\epsilon_0 R^3} = 0, \text{ since } r = 0.$$

Figure 22.63a

$E_2 = \dfrac{Q}{4\pi\epsilon_0 r^2}$ with $r = 2R$ so $E_2 = \dfrac{Q}{16\pi\epsilon_0 R^2}$, in the $-x$-direction.

Thus $\vec{\boldsymbol{E}} = \vec{\boldsymbol{E}}_1 + \vec{\boldsymbol{E}}_2 = -\dfrac{Q}{16\pi\epsilon_0 R^2}\hat{\boldsymbol{i}}$.

(b) $x = R/2$. This point is inside sphere 1 and outside sphere 2. Each field is directed away from the center of the sphere that produces it. The fields are shown in Figure 22.63b.



$$E_1 = \frac{Qr}{4\pi\epsilon_0 R^3} \text{ with } r = R/2 \text{ so}$$
$$E_1 = \frac{Q}{8\pi\epsilon_0 R^2}$$

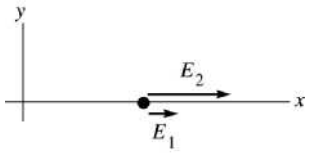
Figure 22.63b

$E_2 = \dfrac{Q}{4\pi\epsilon_0 r^2}$ with $r = 3R/2$ so $E_2 = \dfrac{Q}{9\pi\epsilon_0 R^2}$

$E = E_1 - E_2 = \dfrac{Q}{72\pi\epsilon_0 R^2}$, in the $+x$-direction and $\vec{\boldsymbol{E}} = \dfrac{Q}{72\pi\epsilon_0 R^2}\hat{\boldsymbol{i}}$

(c) $x = R$. This point is at the surface of each sphere. The fields have equal magnitudes and opposite directions, so $E = 0$.

(d) $x = 3R$. This point is outside both spheres. Each field is directed away from the center of the sphere that produces it. The fields are shown in Figure 22.63c.



$$E_1 = \frac{Q}{4\pi\epsilon_0 r^2} \text{ with } r = 3R \text{ so}$$
$$E_1 = \frac{Q}{36\pi\epsilon_0 R^2}$$

Figure 22.63c

$E_2 = \dfrac{Q}{4\pi\epsilon_0 r^2}$ with $r = R$ so $E_2 = \dfrac{Q}{4\pi\epsilon_0 R^2}$

$E = E_1 + E_2 = \dfrac{5Q}{18\pi\epsilon_0 R^2}$, in the $+x$-direction and $\vec{\boldsymbol{E}} = \dfrac{5Q}{18\pi\epsilon_0 R^2}\hat{\boldsymbol{i}}$

EVALUATE: The field of each sphere is radially outward from the center of the sphere. We must use the correct expression for $E(r)$ for each sphere, depending on whether the field point is inside or outside that sphere.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

22.64. **IDENTIFY:** The net electric field at any point is the vector sum of the fields at each sphere.
SET UP: Example 22.9 gives the electric field inside and outside a uniformly charged sphere. For the positively charged sphere the field is radially outward and for the negatively charged sphere the electric field is radially inward.
EXECUTE: **(a)** At this point the field of the left-hand sphere is zero and the field of the right-hand sphere is toward the center of that sphere, in the $+x$-direction. This point is outside the right-hand sphere, a distance $r = 2R$ from its center. $\vec{\boldsymbol{E}} = +\dfrac{1}{4\pi\epsilon_0}\dfrac{Q}{4R^2}\hat{\boldsymbol{i}}$.

(b) This point is inside the left-hand sphere, at $r = R/2$, and is outside the right-hand sphere, at $r = 3R/2$. Both fields are in the $+x$-direction.

$$\vec{\boldsymbol{E}} = \frac{1}{4\pi\epsilon_0}\left[\frac{Q(R/2)}{R^3} + \frac{Q}{(3R/2)^2}\right]\hat{\boldsymbol{i}} = \frac{1}{4\pi\epsilon_0}\left[\frac{Q}{2R^2} + \frac{4Q}{9R^2}\right]\hat{\boldsymbol{i}} = \frac{1}{4\pi\epsilon_0}\frac{17Q}{18R^2}\hat{\boldsymbol{i}}.$$

(c) This point is outside both spheres, at a distance $r = R$ from their centers. Both fields are in the $+x$-direction. $\vec{\boldsymbol{E}} = \dfrac{1}{4\pi\epsilon_0}\left[\dfrac{Q}{R^2} + \dfrac{Q}{R^2}\right]\hat{\boldsymbol{i}} = \dfrac{Q}{2\pi\epsilon_0 R^2}\hat{\boldsymbol{i}}$.

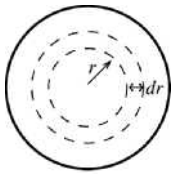
(d) This point is outside both spheres, a distance $r = 3R$ from the center of the left-hand sphere and a distance $r = R$ from the center of the right-hand sphere. The field of the left-hand sphere is in the $+x$-direction and the field of the right-hand sphere is in the $-x$-direction.

$$\vec{\boldsymbol{E}} = \frac{1}{4\pi\epsilon_0}\left[\frac{Q}{(3R)^2} - \frac{Q}{R^2}\right]\hat{\boldsymbol{i}} = \frac{1}{4\pi\epsilon_0}\left[\frac{Q}{9R^2} - \frac{Q}{R^2}\right]\hat{\boldsymbol{i}} = \frac{-1}{4\pi\epsilon_0}\frac{8Q}{9R^2}\hat{\boldsymbol{i}}.$$

EVALUATE: At all points on the x-axis the net field is parallel to the x-axis.

22.65. $\rho(r) = \rho_0(1 - r/R)$ for $r \le R$ where $\rho_0 = 3Q/\pi R^3$. $\rho(r) = 0$ for $r \ge R$

(a) IDENTIFY: The charge density varies with r inside the spherical volume. Divide the volume up into thin concentric shells, of radius r and thickness dr. Find the charge dq in each shell and integrate to find the total charge.
SET UP: The thin shell is sketched in Figure 22.65a.



EXECUTE: The volume of such a shell is $dV = 4\pi r^2 dr$.
The charge contained within the shell is $dq = \rho(r)dV = 4\pi r^2\rho_0(1 - r/R)dr$.

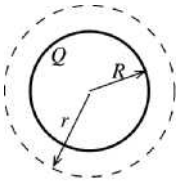
Figure 22.65a

The total charge Q in the charge distribution is obtained by integrating dq over all such shells into which the sphere can be subdivided:

$$Q = \int dq = \int_0^R 4\pi r^2\rho_0(1 - r/R)dr = 4\pi\rho_0\int_0^R (r^2 - r^3/R)dr$$

$$Q = 4\pi\rho_0\left[\frac{r^3}{3} - \frac{r^4}{4R}\right]_0^R = 4\pi\rho_0\left(\frac{R^3}{3} - \frac{R^4}{4R}\right) = 4\pi\rho_0(R^3/12) = 4\pi(3Q/\pi R^3)(R^3/12) = Q,$$ as was to be shown.

(b) IDENTIFY: Apply Gauss's law to a spherical surface of radius r, where $r > R$.
SET UP: The Gaussian surface is shown in Figure 22.65b.



EXECUTE: $\Phi_E = \dfrac{Q_{\text{encl}}}{\epsilon_0}$

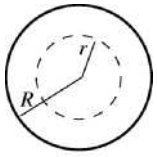
$$E(4\pi r^2) = \frac{Q}{\epsilon_0}$$

Figure 22.65b

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$E = \dfrac{Q}{4\pi\epsilon_0 r^2}$; same as for point charge of charge Q.

(c) IDENTIFY: Apply Gauss's law to a spherical surface of radius r, where $r < R$:
SET UP: The Gaussian surface is shown in Figure 22.65c.



EXECUTE: $\Phi_E = \dfrac{Q_{\text{encl}}}{\epsilon_0}$

$\Phi_E = E(4\pi r^2)$

Figure 22.65c

To calculate the enclosed charge Q_{encl} use the same technique as in part (a), except integrate dq out to r rather than R. (We want the charge that is inside radius r.)

$$Q_{\text{encl}} = \int_0^r 4\pi r'^2 \rho_0 \left(1 - \frac{r'}{R}\right) dr' = 4\pi\rho_0 \int_0^r \left(r'^2 - \frac{r'^3}{R}\right) dr'$$

$$Q_{\text{encl}} = 4\pi\rho_0 \left[\frac{r'^3}{3} - \frac{r'^4}{4R}\right]_0^r = 4\pi\rho_0 \left(\frac{r^3}{3} - \frac{r^4}{4R}\right) = 4\pi\rho_0 r^3 \left(\frac{1}{3} - \frac{r}{4R}\right)$$

$\rho_0 = \dfrac{3Q}{\pi R^3}$ so $Q_{\text{encl}} = 12Q\dfrac{r^3}{R^3}\left(\dfrac{1}{3} - \dfrac{r}{4R}\right) = Q\left(\dfrac{r^3}{R^3}\right)\left(4 - 3\dfrac{r}{R}\right)$.

Thus Gauss's law gives $E(4\pi r^2) = \dfrac{Q}{\epsilon_0}\left(\dfrac{r^3}{R^3}\right)\left(4 - 3\dfrac{r}{R}\right)$.

$$E = \frac{Qr}{4\pi\epsilon_0 R^3}\left(4 - \frac{3r}{R}\right), r \le R$$

(d) The graph of E versus r is sketched in Figure 22.65d.

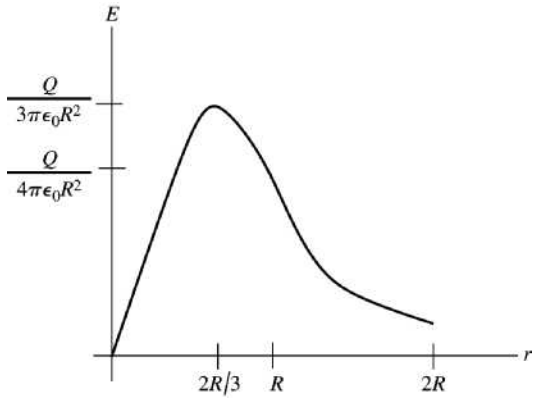


Figure 22.65d

(e) Where the electric field is a maximum, $\dfrac{dE}{dr} = 0$. Thus $\dfrac{d}{dr}\left(4r - \dfrac{3r^2}{R}\right) = 0$ so $4 - 6r/R = 0$ and $r = 2R/3$.

At this value of r, $E = \dfrac{Q}{4\pi\epsilon_0 R^3}\left(\dfrac{2R}{3}\right)\left(4 - \dfrac{3}{R}\dfrac{2R}{3}\right) = \dfrac{Q}{3\pi\epsilon_0 R^2}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: Our expressions for $E(r)$ for $r < R$ and for $r > R$ agree at $r = R$. The results of part (e) for the value of r where $E(r)$ is a maximum agrees with the graph in part (d).

22.66. **IDENTIFY:** The charge in a spherical shell of radius r and thickness dr is $dQ = \rho(r)4\pi r^2\,dr$. Apply Gauss's law.

SET UP: Use a Gaussian surface that is a sphere of radius r. Let Q_i be the charge in the region $r \le R/2$ and let Q_0 be the charge in the region where $R/2 \le r \le R$.

EXECUTE: **(a)** The total charge is $Q = Q_i + Q_0$, where $Q_i = \alpha\dfrac{4\pi(R/2)^3}{3} = \dfrac{\alpha\pi R^3}{6}$ and

$Q_0 = 4\pi(2\alpha)\displaystyle\int_{R/2}^{R}(r^2 - r^3/R)\,dr = 8\alpha\pi\left(\frac{(R^3 - R^3/8)}{3} - \frac{(R^4 - R^4/16)}{4R}\right) = \frac{11\alpha\pi R^3}{24}$. Therefore, $Q = \dfrac{15\alpha\pi R^3}{24}$

and $\alpha = \dfrac{8Q}{5\pi R^3}$.

(b) For $r \le R/2$, Gauss's law gives $E4\pi r^2 = \dfrac{\alpha 4\pi r^3}{3\epsilon_0}$ and $E = \dfrac{\alpha r}{3\epsilon_0} = \dfrac{8Qr}{15\pi\epsilon_0 R^3}$. For $R/2 \le r \le R$,

$E4\pi r^2 = \dfrac{Q_i}{\epsilon_0} + \dfrac{1}{\epsilon_0}\left(8\alpha\pi\left(\dfrac{(r^3 - R^3/8)}{3} - \dfrac{(r^4 - R^4/16)}{4R}\right)\right)$ and

$E = \dfrac{\alpha\pi R^3}{24\epsilon_0(4\pi r^2)}(64(r/R)^3 - 48(r/R)^4 - 1) = \dfrac{kQ}{15r^2}(64(r/R)^3 - 48(r/R)^4 - 1).$

For $r \ge R$, $E(4\pi r^2) = \dfrac{Q}{\epsilon_0}$ and $E = \dfrac{Q}{4\pi\epsilon_0 r^2}$.

(c) $\dfrac{Q_i}{Q} = \dfrac{(4Q/15)}{Q} = \dfrac{4}{15} = 0.267.$

(d) For $r \le R/2$, $F_r = -eE = -\dfrac{8eQ}{15\pi\epsilon_0 R^3}r$, so the restoring force depends upon displacement to the first power, and we have simple harmonic motion.

(e) Comparing to $F = -kr$, $k = \dfrac{8eQ}{15\pi\epsilon_0 R^3}$. Then $\omega = \sqrt{\dfrac{k}{m_e}} = \sqrt{\dfrac{8eQ}{15\pi\epsilon_0 R^3 m_e}}$ and $T = \dfrac{2\pi}{\omega} = 2\pi\sqrt{\dfrac{15\pi\epsilon_0 R^3 m_e}{8eQ}}$.

EVALUATE: **(f)** If the amplitude of oscillation is greater than $R/2$, the force is no longer linear in r, and is thus no longer simple harmonic.

22.67. **IDENTIFY:** The charge in a spherical shell of radius r and thickness dr is $dQ = \rho(r)4\pi r^2\,dr$. Apply Gauss's law.

SET UP: Use a Gaussian surface that is a sphere of radius r. Let Q_i be the charge in the region $r \le R/2$ and let Q_0 be the charge in the region where $R/2 \le r \le R$.

EXECUTE: **(a)** The total charge is $Q = Q_i + Q_0$, where $Q_i = 4\pi\displaystyle\int_0^{R/2}\frac{3\alpha r^3}{2R}dr = \frac{6\pi\alpha}{R}\frac{1}{4}\frac{R^4}{16} = \frac{3}{32}\pi\alpha R^3$ and

$Q_0 = 4\pi\alpha\displaystyle\int_{R/2}^{R}(1 - (r/R)^2)r^2\,dr = 4\pi\alpha R^3\left(\frac{7}{24} - \frac{31}{160}\right) = \frac{47}{120}\pi\alpha R^3$. Therefore,

$Q = \left(\dfrac{3}{32} + \dfrac{47}{120}\right)\pi\alpha R^3 = \dfrac{233}{480}\pi\alpha R^3$ and $\alpha = \dfrac{480Q}{233\pi R^3}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) For $r \le R/2$, Gauss's law gives $E4\pi r^2 = \frac{4\pi}{\epsilon_0}\int_0^r \frac{3\alpha r'^3}{2R}dr' = \frac{3\pi\alpha r^4}{2\epsilon_0 R}$ and $E = \frac{6\alpha r^2}{16\epsilon_0 R} = \frac{180Qr^2}{233\pi\epsilon_0 R^4}$. For $R/2 \le r \le R$, $E4\pi r^2 = \frac{Q_i}{\epsilon_0} + \frac{4\pi\alpha}{\epsilon_0}\int_{R/2}^r (1-(r'/R)^2)r'^2\,dr' = \frac{Q_i}{\epsilon_0} + \frac{4\pi\alpha}{\epsilon_0}\left(\frac{r^3}{3} - \frac{R^3}{24} - \frac{r^5}{5R^2} + \frac{R^3}{160}\right)$.

$E4\pi r^2 = \frac{3}{128}\frac{4\pi\alpha R^3}{\epsilon_0} + \frac{4\pi\alpha R^3}{\epsilon_0}\left(\frac{1}{3}\left(\frac{r}{R}\right)^3 - \frac{1}{5}\left(\frac{r}{R}\right)^5 - \frac{17}{480}\right)$ and $E = \frac{480Q}{233\pi\epsilon_0 r^2}\left(\frac{1}{3}\left(\frac{r}{R}\right)^3 - \frac{1}{5}\left(\frac{r}{R}\right)^5 - \frac{23}{1920}\right)$.

For $r \ge R$, $E = \frac{Q}{4\pi\epsilon_0 r^2}$, since all the charge is enclosed.

(c) The fraction of Q between $R/2 \le r \le R$ is $\frac{Q_0}{Q} = \frac{47}{120}\frac{480}{233} = 0.807$.

(d) $E = \frac{180}{233}\frac{Q}{4\pi\epsilon_0 R^2}$ using either of the electric field expressions above, evaluated at $r = R/2$.

EVALUATE: **(e)** The force an electron would feel never is proportional to $-r$ which is necessary for simple harmonic oscillations. It is oscillatory since the force is always attractive, but it has the wrong power of r to be simple harmonic motion.

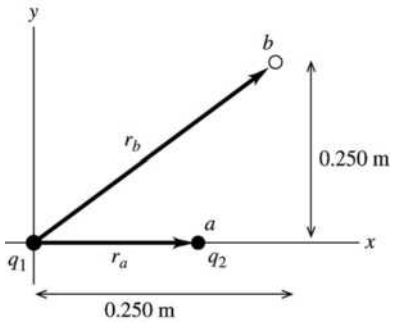
23

ELECTRIC POTENTIAL

23.1. **IDENTIFY:** Apply Eq. (23.2) to calculate the work. The electric potential energy of a pair of point charges is given by Eq. (23.9).

SET UP: Let the initial position of q_2 be point a and the final position be point b, as shown in Figure 23.1.



$r_a = 0.150$ m

$r_b = \sqrt{(0.250 \text{ m})^2 + (0.250 \text{ m})^2}$

$r_b = 0.3536$ m

Figure 23.1

EXECUTE: $W_{a\to b} = U_a - U_b$

$$U_a = \frac{1}{4\pi\epsilon_0}\frac{q_1 q_2}{r_a} = (8.988\times10^9 \text{ N}\cdot\text{m}^2/\text{C}^2)\frac{(+2.40\times10^{-6} \text{ C})(-4.30\times10^{-6} \text{ C})}{0.150 \text{ m}}$$

$$U_a = -0.6184 \text{ J}$$

$$U_b = \frac{1}{4\pi\epsilon_0}\frac{q_1 q_2}{r_b} = (8.988\times10^9 \text{ N}\cdot\text{m}^2/\text{C}^2)\frac{(+2.40\times10^{-6} \text{ C})(-4.30\times10^{-6} \text{ C})}{0.3536 \text{ m}}$$

$$U_b = -0.2623 \text{ J}$$

$$W_{a\to b} = U_a - U_b = -0.6184 \text{ J} - (-0.2623 \text{ J}) = -0.356 \text{ J}$$

EVALUATE: The attractive force on q_2 is toward the origin, so it does negative work on q_2 when q_2 moves to larger r.

23.2. **IDENTIFY:** Apply $W_{a\to b} = U_a - U_b$.

SET UP: $U_a = +5.4\times10^{-8}$ J. Solve for U_b.

EXECUTE: $W_{a\to b} = -1.9\times10^{-8}$ J $= U_a - U_b$. $U_b = U_a - W_{a\to b} = +5.4\times10^{-8}$ J $-(-1.9\times10^{-8}$ J$) = 7.3\times10^{-8}$ J.

EVALUATE: When the electric force does negative work the electrical potential energy increases.

23.3. **IDENTIFY:** The work needed to assemble the nucleus is the sum of the electrical potential energies of the protons in the nucleus, relative to infinity.

SET UP: The total potential energy is the scalar sum of all the individual potential energies, where each potential energy is $U = (1/4\pi\epsilon_0)(qq_0/r)$. Each charge is e and the charges are equidistant from each other, so the total potential energy is $U = \dfrac{1}{4\pi\epsilon_0}\left(\dfrac{e^2}{r} + \dfrac{e^2}{r} + \dfrac{e^2}{r}\right) = \dfrac{3e^2}{4\pi\epsilon_0 r}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: Adding the potential energies gives

$$U = \frac{3e^2}{4\pi\epsilon_0 r} = \frac{3(1.60\times10^{-19}\ \text{C})^2(9.00\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)}{2.00\times10^{-15}\ \text{m}} = 3.46\times10^{-13}\ \text{J} = 2.16\ \text{MeV}$$

EVALUATE: This is a small amount of energy on a macroscopic scale, but on the scale of atoms, 2 MeV is quite a lot of energy.

23.4. **IDENTIFY:** The work required is the change in electrical potential energy. The protons gain speed after being released because their potential energy is converted into kinetic energy.

(a) SET UP: Using the potential energy of a pair of point charges relative to infinity, $U = (1/4\pi\epsilon_0)(qq_0/r)$, we have $W = \Delta U = U_2 - U_1 = \dfrac{1}{4\pi\epsilon_0}\left(\dfrac{e^2}{r_2} - \dfrac{e^2}{r_1}\right)$.

EXECUTE: Factoring out the e^2 and substituting numbers gives

$$W = (9.00\times10^9\,\text{N}\cdot\text{m}^2/\text{C}^2)(1.60\times10^{-19}\ \text{C})^2\left(\frac{1}{3.00\times10^{-15}\ \text{m}} - \frac{1}{2.00\times10^{-10}\ \text{m}}\right) = 7.68\times10^{-14}\ \text{J}$$

(b) SET UP: The protons have equal momentum, and since they have equal masses, they will have equal speeds and hence equal kinetic energy. $\Delta U = K_1 + K_2 = 2K = 2\left(\dfrac{1}{2}mv^2\right) = mv^2$.

EXECUTE: Solving for v gives $v = \sqrt{\dfrac{\Delta U}{m}} = \sqrt{\dfrac{7.68\times10^{-14}\ \text{J}}{1.67\times10^{-27}\ \text{kg}}} = 6.78\times10^6\ \text{m/s}$.

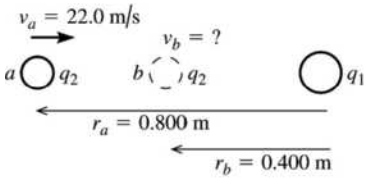
EVALUATE: The potential energy may seem small (compared to macroscopic energies), but it is enough to give each proton a speed of nearly 7 million m/s.

23.5. **(a) IDENTIFY:** Use conservation of energy:

$$K_a + U_a + W_{\text{other}} = K_b + U_b$$

U for the pair of point charges is given by Eq. (23.9).

SET UP:



Let point a be where q_2 is 0.800 m from q_1 and point b be where q_2 is 0.400 m from q_1, as shown in Figure 23.5a.

Figure 23.5a

EXECUTE: Only the electric force does work, so $W_{\text{other}} = 0$ and $U = \dfrac{1}{4\pi\epsilon_0}\dfrac{q_1q_2}{r}$.

$$K_a = \tfrac{1}{2}mv_a^2 = \tfrac{1}{2}(1.50\times10^{-3}\ \text{kg})(22.0\ \text{m/s})^2 = 0.3630\ \text{J}$$

$$U_a = \frac{1}{4\pi\epsilon_0}\frac{q_1q_2}{r_a} = (8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\frac{(-2.80\times10^{-6}\ \text{C})(-7.80\times10^{-6}\ \text{C})}{0.800\ \text{m}} = +0.2454\ \text{J}$$

$$K_b = \tfrac{1}{2}mv_b^2$$

$$U_b = \frac{1}{4\pi\epsilon_0}\frac{q_1q_2}{r_b} = (8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\frac{(-2.80\times10^{-6}\ \text{C})(-7.80\times10^{-6}\ \text{C})}{0.400\ \text{m}} = +0.4907\ \text{J}$$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

The conservation of energy equation then gives $K_b = K_a + (U_a - U_b)$

$$\tfrac{1}{2}mv_b^2 = +0.3630\text{ J} + (0.2454\text{ J} - 0.4907\text{ J}) = 0.1177\text{ J}$$

$$v_b = \sqrt{\frac{2(0.1177\text{ J})}{1.50\times10^{-3}\text{ kg}}} = 12.5\text{ m/s}$$

EVALUATE: The potential energy increases when the two positively charged spheres get closer together, so the kinetic energy and speed decrease.

(b) IDENTIFY: Let point *c* be where q_2 has its speed momentarily reduced to zero. Apply conservation of energy to points *a* and *c*: $K_a + U_a + W_{\text{other}} = K_c + U_c$.

SET UP: Points *a* and *c* are shown in Figure 23.5b.

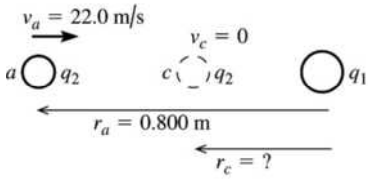


Figure 23.5b

EXECUTE: $K_a = +0.3630$ J (from part (a))

$U_a = +0.2454$ J (from part (a))

$K_c = 0$ (at distance of closest approach the speed is zero)

$$U_c = \frac{1}{4\pi\epsilon_0}\frac{q_1q_2}{r_c}$$

Thus conservation of energy $K_a + U_a = U_c$ gives $\dfrac{1}{4\pi\epsilon_0}\dfrac{q_1q_2}{r_c} = +0.3630\text{ J} + 0.2454\text{ J} = 0.6084\text{ J}$

$$r_c = \frac{1}{4\pi\epsilon_0}\frac{q_1q_2}{0.6084\text{ J}} = (8.988\times10^9\text{ N}\cdot\text{m}^2/\text{C}^2)\frac{(-2.80\times10^{-6}\text{ C})(-7.80\times10^{-6}\text{ C})}{+0.6084\text{ J}} = 0.323\text{ m}.$$

EVALUATE: $U \to \infty$ as $r \to 0$ so q_2 will stop no matter what its initial speed is.

23.6. IDENTIFY: The total potential energy is the scalar sum of the individual potential energies of each pair of charges.

SET UP: For a pair of point charges the electrical potential energy is $U = k\dfrac{qq'}{r}$. In the O-H-N combination the O^- is 0.170 nm from the H^+ and 0.280 nm from the N^-. In the N-H-N combination the N^- is 0.190 nm from the H^+ and 0.300 nm from the other N^-. *U* is positive for like charges and negative for unlike charges.

EXECUTE: **(a)** O-H-N:

$$O^- - H^+: U = -(8.99\times10^9\text{ N}\cdot\text{m}^2/\text{C}^2)\frac{(1.60\times10^{-19}\text{ C})^2}{0.170\times10^{-9}\text{ m}} = -1.35\times10^{-18}\text{ J}.$$

$$O^- - N^-: U = (8.99\times10^9\text{ N}\cdot\text{m}^2/\text{C}^2)\frac{(1.60\times10^{-19}\text{ C})^2}{0.280\times10^{-9}\text{ m}} = +8.22\times10^{-19}\text{ J}.$$

N-H-N:

$$N^- - H^+: U = -(8.99\times10^9\text{ N}\cdot\text{m}^2/\text{C}^2)\frac{(1.60\times10^{-19}\text{ C})^2}{0.190\times10^{-9}\text{ m}} = -1.21\times10^{-18}\text{ J}.$$

$$N^- - N^-: U = (8.99\times10^9\text{ N}\cdot\text{m}^2/\text{C}^2)\frac{(1.60\times10^{-19}\text{ C})^2}{0.300\times10^{-9}\text{ m}} = +7.67\times10^{-19}\text{ J}.$$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

The total potential energy is

$U_{\text{tot}} = -1.35\times10^{-18}\ \text{J} + 8.22\times10^{-19}\ \text{J} - 1.21\times10^{-18}\ \text{J} + 7.67\times10^{-19}\ \text{J} = -9.71\times10^{-19}\ \text{J}.$

(b) In the hydrogen atom the electron is 0.0529 nm from the proton.

$$U = -(8.99\times10^{9}\ \text{N}\cdot\text{m}^2/\text{C}^2)\frac{(1.60\times10^{-19}\ \text{C})^2}{0.0529\times10^{-9}\ \text{m}} = -4.35\times10^{-18}\ \text{J}.$$

EVALUATE: The magnitude of the potential energy in the hydrogen atom is about a factor of 4 larger than what it is for the adenine-thymine bond.

23.7. **IDENTIFY:** The total potential energy is the scalar sum of the individual potential energies of each pair of charges.

SET UP: For a pair of point charges the electrical potential energy is $U = k\dfrac{qq'}{r}$. In the O-H-O combination the O^- is 0.180 nm from the H^+ and 0.290 nm from the other O^-. In the N-H-N combination the N^- is 0.190 nm from the H^+ and 0.300 nm from the other N^-. In the O-H-N combination the O^- is 0.180 nm from the H^+ and 0.290 nm from the N^-. U is positive for like charges and negative for unlike charges.

EXECUTE: O-H-O $O^- - H^+$, $U = -1.28\times10^{-18}$ J; $O^- - O^-$, $U = +7.93\times10^{-19}$ J.

N-H-N $N^- - H^+$, $U = -1.21\times10^{-18}$ J; $N^- - N^-$, $U = +7.67\times10^{-19}$ J.

O-H-N $O^- - H^+$, $U = -1.28\times10^{-18}$ J; $O^- - N^-$, $U = +7.93\times10^{-19}$ J.

The total potential energy is $-3.77\times10^{-18}\ \text{J} + 2.35\times10^{-18}\ \text{J} = -1.42\times10^{-18}\ \text{J}$.

EVALUATE: For pairs of opposite sign the potential energy is negative and for pairs of the same sign the potential energy is positive. The net electrical potential energy is the algebraic sum of the potential energy of each pair.

23.8. **IDENTIFY:** Call the three charges 1, 2 and 3. $U = U_{12} + U_{13} + U_{23}$

SET UP: $U_{12} = U_{23} = U_{13}$ because the charges are equal and each pair of charges has the same separation, 0.500 m.

EXECUTE: $$U = \frac{3kq^2}{0.500\ \text{m}} = \frac{3k(1.2\times10^{-6}\ \text{C})^2}{0.500\ \text{m}} = 0.078\ \text{J}.$$

EVALUATE: When the three charges are brought in from infinity to the corners of the triangle, the repulsive electrical forces between each pair of charges do negative work and electrical potential energy is stored.

23.9. **IDENTIFY:** The protons repel each other and therefore accelerate away from one another. As they get farther and farther away, their kinetic energy gets greater and greater but their acceleration keeps decreasing. Conservation of energy and Newton's laws apply to these protons.

SET UP: Let a be the point when they are 0.750 nm apart and b be the point when they are very far apart. A proton has charge $+e$ and mass 1.67×10^{-27} kg. As they move apart the protons have equal kinetic energies and speeds. Their potential energy is $U = ke^2/r$ and $K = \frac{1}{2}mv^2$. $K_a + U_a = K_b + U_b$.

EXECUTE: **(a)** They have maximum speed when they are far apart and all their initial electrical potential energy has been converted to kinetic energy. $K_a + U_a = K_b + U_b$.

$K_a = 0$ and $U_b = 0$, so

$$K_b = U_a = k\frac{e^2}{r_a} = (8.99\times10^{9}\ \text{N}\cdot\text{m}^2/\text{C}^2)\frac{(1.60\times10^{-19}\ \text{C})^2}{0.750\times10^{-9}\ \text{m}} = 3.07\times10^{-19}\ \text{J}.$$

$K_b = \frac{1}{2}mv_b^2 + \frac{1}{2}mv_b^2$, so $K_b = mv_b^2$ and $$v_b = \sqrt{\frac{K_b}{m}} = \sqrt{\frac{3.07\times10^{-19}\ \text{J}}{1.67\times10^{-27}\ \text{kg}}} = 1.36\times10^{4}\ \text{m/s}.$$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) Their acceleration is largest when the force between them is largest and this occurs at $r = 0.750$ nm, when they are closest.

$$F = k\frac{e^2}{r^2} = (8.99\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\left(\frac{1.60\times10^{-19}\ \text{C}}{0.750\times10^{-9}\ \text{m}}\right)^2 = 4.09\times10^{-10}\ \text{N}.$$

$$a = \frac{F}{m} = \frac{4.09\times10^{-10}\ \text{N}}{1.67\times10^{-27}\ \text{kg}} = 2.45\times10^{17}\ \text{m/s}^2.$$

EVALUATE: The acceleration of the protons decreases as they move farther apart, but the force between them is repulsive so they continue to increase their speeds and hence their kinetic energies.

23.10. **IDENTIFY:** The work done on the alpha particle is equal to the difference in its potential energy when it is moved from the midpoint of the square to the midpoint of one of the sides.

SET UP: We apply the formula $W_{a\to b} = U_a - U_b$. In this case, a is the center of the square and b is the midpoint of one of the sides. Therefore $W_{\text{center}\to\text{side}} = U_{\text{center}} - U_{\text{side}}$ is the work done by the Coulomb force. There are 4 electrons, so the potential energy at the center of the square is 4 times the potential energy of a single alpha-electron pair. At the center of the square, the alpha particle is a distance $r_1 = \sqrt{50}$ nm from each electron. At the midpoint of the side, the alpha is a distance $r_2 = 5.00$ nm from the two nearest electrons and a distance $r_3 = \sqrt{125}$ nm from the two most distant electrons. Using the formula for the potential energy (relative to infinity) of two point charges, $U = (1/4\pi\epsilon_0)(qq_0/r)$, the total work done by the Coulomb force is

$$W_{\text{center}\to\text{side}} = U_{\text{center}} - U_{\text{side}} = 4\frac{1}{4\pi\epsilon_0}\frac{q_\alpha q_\text{e}}{r_1} - \left(2\frac{1}{4\pi\epsilon_0}\frac{q_\alpha q_\text{e}}{r_2} + 2\frac{1}{4\pi\epsilon_0}\frac{q_\alpha q_\text{e}}{r_3}\right)$$

Substituting $q_\text{e} = -e$ and $q_\alpha = 2e$ and simplifying gives

$$W_{\text{center}\to\text{side}} = -4e^2\frac{1}{4\pi\epsilon_0}\left[\frac{2}{r_1} - \left(\frac{1}{r_2} + \frac{1}{r_3}\right)\right]$$

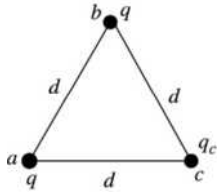
EXECUTE: Substituting the numerical values into the equation for the work gives

$$W = -4(1.60\times10^{-19}\ \text{C})^2(9.00\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\left[\frac{2}{\sqrt{50}\ \text{nm}} - \left(\frac{1}{5.00\ \text{nm}} + \frac{1}{\sqrt{125}\ \text{nm}}\right)\right] = 6.08\times10^{-21}\ \text{J}$$

EVALUATE: Since the work done by the Coulomb force is positive, the system has more potential energy with the alpha particle at the center of the square than it does with it at the midpoint of a side. To move the alpha particle to the midpoint of a side and leave it there at rest an external force must do -6.08×10^{-21} J of work.

23.11. **IDENTIFY:** Apply Eq. (23.2). The net work to bring the charges in from infinity is equal to the change in potential energy. The total potential energy is the sum of the potential energies of each pair of charges, calculated from Eq. (23.9).

SET UP: Let 1 be where all the charges are infinitely far apart. Let 2 be where the charges are at the corners of the triangle, as shown in Figure 23.11.



Let q_c be the third, unknown charge.

Figure 23.11

EXECUTE: $W = -\Delta U = -(U_2 - U_1)$, where W is the work done by the Coulomb force.

$$U_1 = 0$$

$$U_2 = U_{ab} + U_{ac} + U_{bc} = \frac{1}{4\pi\epsilon_0 d}(q^2 + 2qq_c)$$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

Want $W = 0$, so $W = -(U_2 - U_1)$ gives $0 = -U_2$

$$0 = \frac{1}{4\pi\epsilon_0 d}(q^2 + 2qq_c)$$

$q^2 + 2qq_c = 0$ and $q_c = -q/2$.

EVALUATE: The potential energy for the two charges q is positive and for each q with q_c it is negative. There are two of the q, q_c terms so must have $q_c < q$.

23.12. **IDENTIFY**: Use conservation of energy $U_a + K_a = U_b + K_b$ to find the distance of closest approach r_b. The maximum force is at the distance of closest approach, $F = k\dfrac{|q_1 q_2|}{r_b^2}$.

SET UP: $K_b = 0$. Initially the two protons are far apart, so $U_a = 0$. A proton has mass 1.67×10^{-27} kg and charge $q = +e = +1.60\times10^{-19}$ C.

EXECUTE: $K_a = U_b$. $2\left(\frac{1}{2}mv_a^2\right) = k\dfrac{q_1 q_2}{r_b}$. $mv_a^2 = k\dfrac{e^2}{r_b}$ and

$$r_b = \frac{ke^2}{mv_a^2} = \frac{(8.99\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)(1.60\times10^{-19}\ \text{C})^2}{(1.67\times10^{-27}\ \text{kg})(1.00\times10^6\ \text{m/s})^2} = 1.38\times10^{-13}\ \text{m}.$$

$$F = k\frac{e^2}{r_b^2} = (8.99\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\frac{(1.60\times10^{-19}\ \text{C})^2}{(1.38\times10^{-13}\ \text{m})^2} = 0.012\ \text{N}.$$

EVALUATE: The acceleration $a = F/m$ of each proton produced by this force is extremely large.

23.13. **IDENTIFY** and **SET UP:** Apply conservation of energy to points A and B.

EXECUTE: $K_A + U_A = K_B + U_B$

$U = qV$, so $K_A + qV_A = K_B + qV_B$

$K_B = K_A + q(V_A - V_B) = 0.00250\ \text{J} + (-5.00\times10^{-6}\ \text{C})(200\ \text{V} - 800\ \text{V}) = 0.00550\ \text{J}$

$v_B = \sqrt{2K_B/m} = 7.42\ \text{m/s}$

EVALUATE: It is faster at B; a negative charge gains speed when it moves to higher potential.

23.14. **IDENTIFY**: The work-energy theorem says $W_{a\to b} = K_b - K_a$. $\dfrac{W_{a\to b}}{q} = V_a - V_b$.

SET UP: Point a is the starting point and point b is the ending point. Since the field is uniform, $W_{a\to b} = Fs\cos\phi = E|q|s\cos\phi$. The field is to the left so the force on the positive charge is to the left. The particle moves to the left so $\phi = 0°$ and the work $W_{a\to b}$ is positive.

EXECUTE: **(a)** $W_{a\to b} = K_b - K_a = 1.50\times10^{-6}\ \text{J} - 0 = 1.50\times10^{-6}\ \text{J}$

(b) $V_a - V_b = \dfrac{W_{a\to b}}{q} = \dfrac{1.50\times10^{-6}\ \text{J}}{4.20\times10^{-9}\ \text{C}} = 357\ \text{V}$. Point a is at higher potential than point b.

(c) $E|q|s = W_{a\to b}$, so $E = \dfrac{W_{a\to b}}{|q|s} = \dfrac{V_a - V_b}{s} = \dfrac{357\ \text{V}}{6.00\times10^{-2}\ \text{m}} = 5.95\times10^3\ \text{V/m}.$

EVALUATE: A positive charge gains kinetic energy when it moves to lower potential; $V_b < V_a$.

23.15. **IDENTIFY**: Apply the equation that precedes Eq. (23.17): $W_{a\to b} = q'\int_a^b \vec{\boldsymbol{E}}\cdot d\vec{\boldsymbol{l}}$.

SET UP: Use coordinates where $+y$ is upward and $+x$ is to the right. Then $\vec{\boldsymbol{E}} = E\hat{\boldsymbol{j}}$ with $E = 4.00\times10^4$ N/C.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(a) The path is sketched in Figure 23.15a.

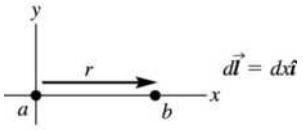


Figure 23.15a

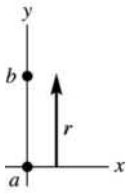
EXECUTE: $\vec{E} \cdot d\vec{l} = (E\hat{j}) \cdot (dx\hat{i}) = 0$ so $W_{a\to b} = q'\int_a^b \vec{E} \cdot d\vec{l} = 0$.

EVALUATE: The electric force on the positive charge is upward (in the direction of the electric field) and does no work for a horizontal displacement of the charge.

(b) SET UP: The path is sketched in Figure 23.15b.



$d\vec{l} = dy\hat{j}$

Figure 23.15b

EXECUTE: $\vec{E} \cdot d\vec{l} = (E\hat{j}) \cdot (dy\hat{j}) = E\,dy$

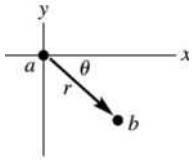
$$W_{a\to b} = q'\int_a^b \vec{E} \cdot d\vec{l} = q'E\int_a^b dy = q'E(y_b - y_a)$$

$y_b - y_a = +0.670$ m, positive since the displacement is upward and we have taken $+y$ to be upward.

$$W_{a\to b} = q'E(y_b - y_a) = (+28.0\times10^{-9}\ \text{C})(4.00\times10^{4}\ \text{N/C})(+0.670\ \text{m}) = +7.50\times10^{-4}\ \text{J}.$$

EVALUATE: The electric force on the positive charge is upward so it does positive work for an upward displacement of the charge.

(c) SET UP: The path is sketched in Figure 23.15c.



$y_a = 0$

$y_b = -r\sin\theta = -(2.60\ \text{m})\sin 45° = -1.838$ m

The vertical component of the 2.60 m displacement is 1.838 m downward.

Figure 23.15c

EXECUTE: $d\vec{l} = dx\hat{i} + dy\hat{j}$ (The displacement has both horizontal and vertical components.)

$\vec{E} \cdot d\vec{l} = (E\hat{j}) \cdot (dx\hat{i} + dy\hat{j}) = E\,dy$ (Only the vertical component of the displacement contributes to the work.)

$$W_{a\to b} = q'\int_a^b \vec{E} \cdot d\vec{l} = q'E\int_a^b dy = q'E(y_b - y_a)$$

$$W_{a\to b} = q'E(y_b - y_a) = (+28.0\times10^{-9}\text{C})(4.00\times10^{4}\ \text{N/C})(-1.838\ \text{m}) = -2.06\times10^{-3}\ \text{J}.$$

EVALUATE: The electric force on the positive charge is upward so it does negative work for a displacement of the charge that has a downward component.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

23.16. **IDENTIFY:** Apply $K_a + U_a = K_b + U_b$.

SET UP: Let $q_1 = +3.00$ nC and $q_2 = +2.00$ nC. At point a, $r_{1a} = r_{2a} = 0.250$ m. At point b, $r_{1b} = 0.100$ m and $r_{2b} = 0.400$ m. The electron has $q = -e$ and $m_e = 9.11\times10^{-31}$ kg. $K_a = 0$ since the electron is released from rest.

EXECUTE: $-\dfrac{keq_1}{r_{1a}} - \dfrac{keq_2}{r_{2a}} = -\dfrac{keq_1}{r_{1b}} - \dfrac{keq_2}{r_{2b}} + \dfrac{1}{2}m_e v_b^2$.

$$E_a = K_a + U_a = k(-1.60\times10^{-19}\text{ C})\left(\frac{(3.00\times10^{-9}\text{ C})}{0.250\text{ m}} + \frac{(2.00\times10^{-9}\text{ C})}{0.250\text{ m}}\right) = -2.88\times10^{-17}\text{ J}.$$

$$E_b = K_b + U_b = k(-1.60\times10^{-19}\text{ C})\left(\frac{(3.00\times10^{-9}\text{ C})}{0.100\text{ m}} + \frac{(2.00\times10^{-9}\text{ C})}{0.400\text{ m}}\right) + \frac{1}{2}m_e v_b^2 = -5.04\times10^{-17}\text{ J} + \frac{1}{2}m_e v_b^2$$

Setting $E_a = E_b$ gives $v_b = \sqrt{\dfrac{2}{9.11\times10^{-31}\text{ kg}}(5.04\times10^{-17}\text{ J} - 2.88\times10^{-17}\text{ J})} = 6.89\times10^6$ m/s.

EVALUATE: $V_a = V_{1a} + V_{2a} = 180$ V. $V_b = V_{1b} + V_{2b} = 315$ V. $V_b > V_a$. The negatively charged electron gains kinetic energy when it moves to higher potential.

23.17. **IDENTIFY:** The potential at any point is the scalar sum of the potentials due to individual charges.

SET UP: $V = kq/r$ and $W_{ab} = q(V_a - V_b)$.

EXECUTE: **(a)** $r_{a1} = r_{a2} = \dfrac{1}{2}\sqrt{(0.0300\text{ m})^2 + (0.0300\text{ m})^2} = 0.0212$ m. $V_a = k\left(\dfrac{q_1}{r_{a1}} + \dfrac{q_2}{r_{a2}}\right) = 0$.

(b) $r_{b1} = 0.0424$ m, $r_{b2} = 0.0300$ m.

$$V_b = k\left(\frac{q_1}{r_{b1}} + \frac{q_2}{r_{b2}}\right) = (8.99\times10^9\text{ N}\cdot\text{m}^2/\text{C}^2)\left(\frac{+2.00\times10^{-6}\text{ C}}{0.0424\text{ m}} + \frac{-2.00\times10^{-6}\text{ C}}{0.0300\text{ m}}\right) = -1.75\times10^5\text{ V}.$$

(c) $W_{ab} = q_3(V_a - V_b) = (-5.00\times10^{-6}\text{ C})[0 - (-1.75\times10^5\text{ V})] = -0.875$ J.

EVALUATE: Since $V_b < V_a$, a positive charge would be pulled by the existing charges from a to b, so they would do positive work on this charge. But they would repel a negative charge and hence do negative work on it, as we found in part (c).

23.18. **IDENTIFY:** The total potential is the *scalar* sum of the individual potentials, but the net electric field is the *vector* sum of the two fields.

SET UP: The net potential can only be zero if one charge is positive and the other is negative, since it is a scalar. The electric field can only be zero if the two fields point in opposite directions.

EXECUTE: **(a)** (i) Since both charges have the same sign, there are no points for which the potential is zero.

(ii) The two electric fields are in opposite directions only between the two charges, and midway between them the fields have equal magnitudes. So $E = 0$ midway between the charges, but V is never zero.

(b) (i) The two potentials have equal magnitude but opposite sign midway between the charges, so $V = 0$ midway between the charges, but $E \neq 0$ there since the fields point in the same direction.

(ii) Between the two charges, the fields point in the same direction, so E cannot be zero there. In the other two regions, the field due to the nearer charge is always greater than the field due to the more distant charge, so they cannot cancel. Hence E is not zero anywhere.

EVALUATE: It does *not* follow that the electric field is zero where the potential is zero, or that the potential is zero where the electric field is zero.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

23.19. **IDENTIFY:** $V = \dfrac{1}{4\pi\epsilon_0}\sum_i \dfrac{q_i}{r_i}$

SET UP: The locations of the changes and points A and B are sketched in Figure 23.19.

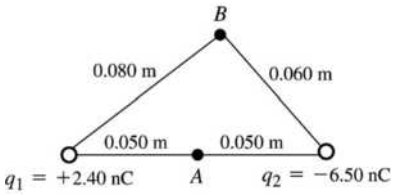


Figure 23.19

EXECUTE: **(a)** $V_A = \dfrac{1}{4\pi\epsilon_0}\left(\dfrac{q_1}{r_{A1}} + \dfrac{q_2}{r_{A2}}\right)$

$$V_A = (8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\left(\frac{+2.40\times10^{-9}\ \text{C}}{0.050\ \text{m}} + \frac{-6.50\times10^{-9}\ \text{C}}{0.050\ \text{m}}\right) = -737\ \text{V}$$

(b) $V_B = \dfrac{1}{4\pi\epsilon_0}\left(\dfrac{q_1}{r_{B1}} + \dfrac{q_2}{r_{B2}}\right)$

$$V_B = (8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\left(\frac{+2.40\times10^{-9}\ \text{C}}{0.080\ \text{m}} + \frac{-6.50\times10^{-9}\ \text{C}}{0.060\ \text{m}}\right) = -704\ \text{V}$$

(c) IDENTIFY and **SET UP:** Use Eq. (23.13) and the results of parts (a) and (b) to calculate W.

EXECUTE: $W_{B\to A} = q'(V_B - V_A) = (2.50\times10^{-9}\ \text{C})(-704\ \text{V} - (-737\ \text{V})) = +8.2\times10^{-8}\ \text{J}$

EVALUATE: The electric force does positive work on the positive charge when it moves from higher potential (point B) to lower potential (point A).

23.20. **IDENTIFY:** For a point charge, $V = \dfrac{kq}{r}$. The total potential at any point is the algebraic sum of the potentials of the two charges.

SET UP: Consider the distances from the point on the y-axis to each charge for the three regions $-a \le y \le a$ (between the two charges), $y > a$ (above both charges) and $y < -a$ (below both charges).

EXECUTE: **(a)** $|y| < a: V = \dfrac{kq}{(a+y)} - \dfrac{kq}{(a-y)} = \dfrac{2kqy}{y^2 - a^2}$. $y > a: V = \dfrac{kq}{(a+y)} - \dfrac{kq}{y-a} = \dfrac{-2kqa}{y^2-a^2}$.

$y < -a: V = \dfrac{-kq}{(a+y)} - \dfrac{kq}{(-y+a)} = \dfrac{2kqa}{y^2-a^2}$.

A general expression valid for any y is $V = k\left(\dfrac{-q}{|y-a|} + \dfrac{q}{|y+a|}\right)$.

(b) The graph of V versus y is sketched in Figure 23.20.

(c) $y >> a: V = \dfrac{-2kqa}{y^2-a^2} \approx \dfrac{-2kqa}{y^2}$.

(d) If the charges are interchanged, then the potential is of the opposite sign.

EVALUATE: $V = 0$ at $y = 0$. $V \to +\infty$ as the positive charge is approached and $V \to -\infty$ as the negative charge is approached.

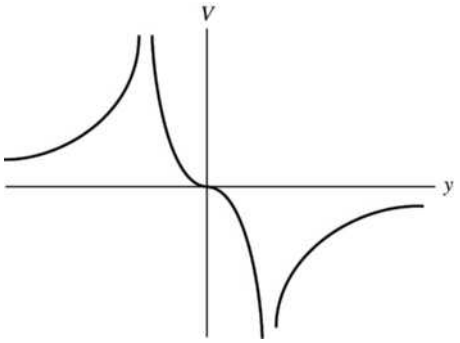

Figure 23.20

23.21. **IDENTIFY:** For a point charge, $V = \frac{kq}{r}$. The total potential at any point is the algebraic sum of the potentials of the two charges.

SET UP: **(a)** The positions of the two charges are shown in Figure 23.21a.

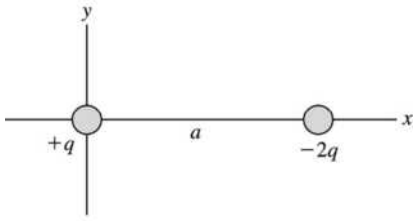

Figure 23.21a

(b) $x > a: V = \frac{kq}{x} - \frac{2kq}{x-a} = \frac{-kq(x+a)}{x(x-a)}$. $0 < x < a: V = \frac{kq}{x} - \frac{2kq}{a-x} = \frac{kq(3x-a)}{x(x-a)}$.

$x < 0: V = \frac{-kq}{x} + \frac{2kq}{x-a} = \frac{kq(x+a)}{x(x-a)}$. A general expression valid for any y is $V = k\left(\frac{q}{|x|} - \frac{2q}{|x-a|}\right)$.

(c) The potential is zero at $x = -a$ and $a/3$.

(d) The graph of V versus x is sketched in Figure 23.21b.

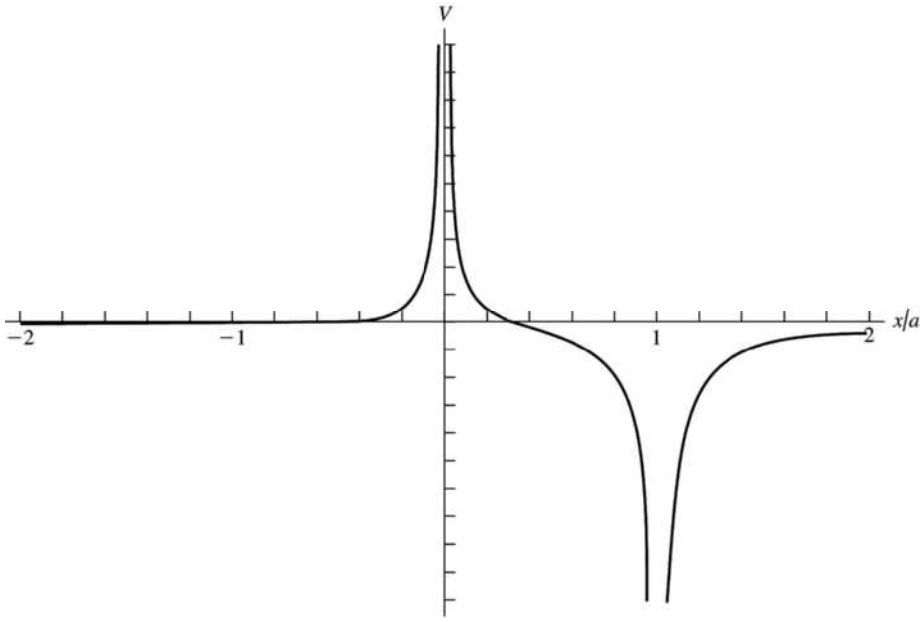

Figure 23.21 b

EVALUATE: **(e)** For $x >> a: V \approx \dfrac{-kqx}{x^2} = \dfrac{-kq}{x}$, which is the same as the potential of a point charge $-q$. Far from the two charges they appear to be a point charge with a charge that is the algebraic sum of their two charges.

23.22. **IDENTIFY:** For a point charge, $V = \dfrac{kq}{r}$. The total potential at any point is the algebraic sum of the potentials of the two charges.

SET UP: The distance of a point with coordinate y from the positive charge is $|y|$ and the distance from the negative charge is $r = \sqrt{a^2 + y^2}$.

EVALUATE: **(a)** $V = \dfrac{kq}{|y|} - \dfrac{2kq}{r} = kq\left(\dfrac{1}{|y|} - \dfrac{2}{\sqrt{a^2 + y^2}}\right)$.

(b) $V = 0$, when $y^2 = \dfrac{a^2 + y^2}{4} \Rightarrow 3y^2 = a^2 \Rightarrow y = \pm\dfrac{a}{\sqrt{3}}$.

(c) The graph of V versus y is sketched in Figure 23.22. $V \to \infty$ as the positive charge at the origin is approached.

EVALUATE: **(d)** $y >> a: V \approx kq\left(\dfrac{1}{y} - \dfrac{2}{y}\right) = -\dfrac{kq}{y}$, which is the potential of a point charge $-q$. Far from the two charges they appear to be a point charge with a charge that is the algebraic sum of their two charges.

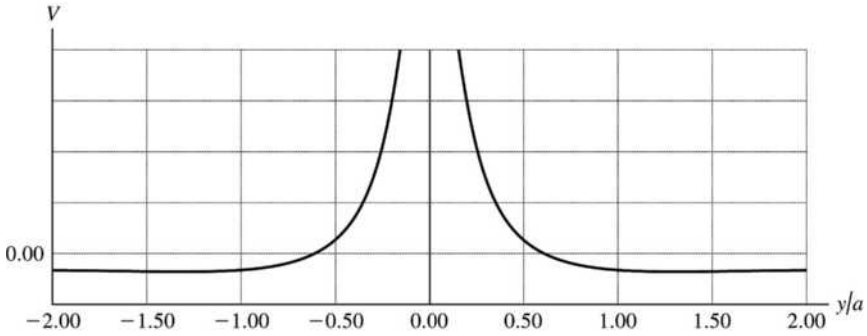

Figure 23.22

23.23. **IDENTIFY** and **SET UP:** Apply conservation of energy, Eq. (23.3). Use Eq. (23.12) to express U in terms of V.

(a) EXECUTE: $K_1 + qV_1 = K_2 + qV_2$, $q(V_2 - V_1) = K_1 - K_2$; $q = -1.602\times10^{-19}$ C.

$K_1 = \frac{1}{2}m_e v_1^2 = 4.099\times10^{-18}$ J; $K_2 = \frac{1}{2}m_e v_2^2 = 2.915\times10^{-17}$ J. $\Delta V = V_2 - V_1 = \dfrac{K_1 - K_2}{q} = 156$ V.

EVALUATE: The electron gains kinetic energy when it moves to higher potential.

(b) EXECUTE: Now $K_1 = 2.915\times10^{-17}$ J, $K_2 = 0$. $V_2 - V_1 = \dfrac{K_1 - K_2}{q} = -182$ V.

EVALUATE: The electron loses kinetic energy when it moves to lower potential.

23.24. **IDENTIFY:** For a point charge, $E = \dfrac{k|q|}{r^2}$ and $V = \dfrac{kq}{r}$.

SET UP: The electric field is directed toward a negative charge and away from a positive charge.

EXECUTE: **(a)** $V > 0$ so $q > 0$. $\dfrac{V}{E} = \dfrac{kq/r}{k|q|/r^2} = \left(\dfrac{kq}{r}\right)\left(\dfrac{r^2}{kq}\right) = r$. $r = \dfrac{4.98\text{ V}}{12.0\text{ V/m}} = 0.415$ m.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) $q = \dfrac{rV}{k} = \dfrac{(0.415\text{ m})(4.98\text{ V})}{8.99\times10^{9}\text{ N}\cdot\text{m}^2/\text{C}^2} = 2.30\times10^{-10}\text{ C}$

(c) $q > 0$, so the electric field is directed away from the charge.

EVALUATE: The ratio of V to E due to a point charge increases as the distance r from the charge increases, because E falls off as $1/r^2$ and V falls off as $1/r$.

23.25. **(a) IDENTIFY** and **SET UP:** The direction of $\vec{E}$ is always from high potential to low potential so point b is at higher potential.

(b) Apply Eq. (23.17) to relate $V_b - V_a$ to E.

EXECUTE: $V_b - V_a = -\int_a^b \vec{E}\cdot d\vec{l} = \int_a^b E\,dx = E(x_b - x_a)$.

$$E = \frac{V_b - V_a}{x_b - x_a} = \frac{+240\text{ V}}{0.90\text{ m} - 0.60\text{ m}} = 800\text{ V/m}$$

(c) $W_{b\to a} = q(V_b - V_a) = (-0.200\times10^{-6}\text{ C})(+240\text{ V}) = -4.80\times10^{-5}\text{ J}$.

EVALUATE: The electric force does negative work on a negative charge when the negative charge moves from high potential (point b) to low potential (point a).

23.26. **IDENTIFY:** For a point charge, $V = \dfrac{kq}{r}$. The total potential at any point is the algebraic sum of the potentials of the two charges. For a point charge, $E = \dfrac{k|q|}{r^2}$. The net electric field is the vector sum of the electric fields of the two charges.

SET UP: $\vec{E}$ produced by a point charge is directed away from the point charge if it is positive and toward the charge if it is negative.

EXECUTE: **(a)** $V = V_Q + V_{2Q} > 0$, so V is zero nowhere except for infinitely far from the charges. The fields can cancel only between the charges, because only there are the fields of the two charges in opposite directions. Consider a point a distance x from Q and $d - x$ from $2Q$, as shown in Figure 23.26a.

$E_Q = E_{2Q} \to \dfrac{kQ}{x^2} = \dfrac{k(2Q)}{(d-x)^2} \to (d-x)^2 = 2x^2$. $x = \dfrac{d}{1+\sqrt{2}}$. The other root, $x = \dfrac{d}{1-\sqrt{2}}$, does not lie between the charges.

(b) V can be zero in 2 places, A and B, as shown in Figure 23.26b. Point A is a distance x from $-Q$ and $d - x$ from $2Q$. B is a distance y from $-Q$ and $d + y$ from $2Q$. At A: $\dfrac{k(-Q)}{x} + \dfrac{k(2Q)}{d-x} = 0 \to x = d/3$.

At B: $\dfrac{k(-Q)}{y} + \dfrac{k(2Q)}{d+y} = 0 \to y = d$.

The two electric fields are in opposite directions to the left of $-Q$ or to the right of $2Q$ in Figure 23.26c. But for the magnitudes to be equal, the point must be closer to the charge with smaller magnitude of charge. This can be the case only in the region to the left of $-Q$. $E_Q = E_{2Q}$ gives $\dfrac{kQ}{x^2} = \dfrac{k(2Q)}{(d+x)^2}$ and $x = \dfrac{d}{\sqrt{2}-1}$.

EVALUATE: **(d)** E and V are not zero at the same places. $\vec{E}$ is a vector and V is a scalar. E is proportional to $1/r^2$ and V is proportional to $1/r$. $\vec{E}$ is related to the force on a test charge and ΔV is related to the work done on a test charge when it moves from one point to another.

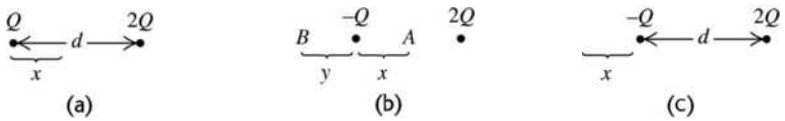

Figure 23.26

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

23.27. **IDENTIFY:** The potential at any point is the scalar sum of the potential due to each shell.

SET UP: $V = \dfrac{kq}{R}$ for $r \le R$ and $V = \dfrac{kq}{r}$ for $r > R$.

EXECUTE: **(a)** (i) $r = 0$. This point is inside both shells so

$$V = k\left(\frac{q_1}{R_1} + \frac{q_2}{R_2}\right) = (8.99\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\left(\frac{6.00\times10^{-9}\ \text{C}}{0.0300\ \text{m}} + \frac{-9.00\times10^{-9}\ \text{C}}{0.0500\ \text{m}}\right).$$

$V = +1.798\times10^3\ \text{V} + (-1.618\times10^3\ \text{V}) = 180\ \text{V}$.

(ii) $r = 4.00$ cm. This point is outside shell 1 and inside shell 2.

$$V = k\left(\frac{q_1}{r} + \frac{q_2}{R_2}\right) = (8.99\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\left(\frac{6.00\times10^{-9}\ \text{C}}{0.0400\ \text{m}} + \frac{-9.00\times10^{-9}\ \text{C}}{0.0500\ \text{m}}\right).$$

$V = +1.348\times10^3\ \text{V} + (-1.618\times10^3\ \text{V}) = -270\ \text{V}$.

(iii) $r = 6.00$ cm. This point is outside both shells.

$$V = k\left(\frac{q_1}{r} + \frac{q_2}{r}\right) = \frac{k}{r}(q_1 + q_2) = \frac{8.99\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2}{0.0600\ \text{m}}(6.00\times10^{-9}\ \text{C} + (-9.00\times10^{-9}\ \text{C})).\quad V = -450\ \text{V}.$$

(b) At the surface of the inner shell, $r = R_1 = 3.00$ cm. This point is inside the larger shell,

so $V_1 = k\left(\dfrac{q_1}{R_1} + \dfrac{q_2}{R_2}\right) = 180\ \text{V}$. At the surface of the outer shell, $r = R_2 = 5.00$ cm. This point is outside the smaller shell, so

$$V = k\left(\frac{q_1}{r} + \frac{q_2}{R_2}\right) = (8.99\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\left(\frac{6.00\times10^{-9}\ \text{C}}{0.0500\ \text{m}} + \frac{-9.00\times10^{-9}\ \text{C}}{0.0500\ \text{m}}\right).$$

$V_2 = +1.079\times10^3\ \text{V} + (-1.618\times10^3\ \text{V}) = -539\ \text{V}$. The potential difference is $V_1 - V_2 = 719\ \text{V}$. The inner shell is at higher potential. The potential difference is due entirely to the charge on the inner shell.

EVALUATE: Inside a uniform spherical shell, the electric field is zero so the potential is constant (but *not* necessarily zero).

23.28. **IDENTIFY** and **SET UP:** Expressions for the electric potential inside and outside a solid conducting sphere are derived in Example 23.8.

EXECUTE: **(a)** This is outside the sphere, so $V = \dfrac{kq}{r} = \dfrac{k(3.50\times10^{-9}\ \text{C})}{0.480\ \text{m}} = 65.6\ \text{V}$.

(b) This is at the surface of the sphere, so $V = \dfrac{k(3.50\times10^{-9}\ \text{C})}{0.240\ \text{m}} = 131\ \text{V}$.

(c) This is inside the sphere. The potential has the same value as at the surface, 131 V.

EVALUATE: All points of a conductor are at the same potential.

23.29. **(a) IDENTIFY** and **SET UP**: The electric field on the ring's axis is calculated in Example 21.9. The force on the electron exerted by this field is given by Eq. (21.3).

EXECUTE: When the electron is on either side of the center of the ring, the ring exerts an attractive force directed toward the center of the ring. This restoring force produces oscillatory motion of the electron along the axis of the ring, with amplitude 30.0 cm. The force on the electron is *not* of the form $F = -kx$ so the oscillatory motion is not simple harmonic motion.

(b) IDENTIFY: Apply conservation of energy to the motion of the electron.

SET UP: $K_a + U_a = K_b + U_b$ with a at the initial position of the electron and b at the center of the ring.

From Example 23.11, $V = \dfrac{1}{4\pi\epsilon_0}\dfrac{Q}{\sqrt{x^2 + R^2}}$, where R is the radius of the ring.

EXECUTE: $x_a = 30.0$ cm, $x_b = 0$.

$K_a = 0$ (released from rest), $K_b = \frac{1}{2}mv^2$

Thus $\frac{1}{2}mv^2 = U_a - U_b$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

And $U = qV = -eV$ so $v = \sqrt{\dfrac{2e(V_b - V_a)}{m}}$.

$$V_a = \frac{1}{4\pi\epsilon_0}\frac{Q}{\sqrt{x_a^2 + R^2}} = (8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\frac{24.0\times10^{-9}\ \text{C}}{\sqrt{(0.300\ \text{m})^2 + (0.150\ \text{m})^2}}$$

$$V_a = 643\ \text{V}$$

$$V_b = \frac{1}{4\pi\epsilon_0}\frac{Q}{\sqrt{x_b^2 + R^2}} = (8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\frac{24.0\times10^{-9}\ \text{C}}{0.150\ \text{m}} = 1438\ \text{V}$$

$$v = \sqrt{\frac{2e(V_b - V_a)}{m}} = \sqrt{\frac{2(1.602\times10^{-19}\ \text{C})(1438\ \text{V} - 643\ \text{V})}{9.109\times10^{-31}\ \text{kg}}} = 1.67\times10^7\ \text{m/s}$$

EVALUATE: The positively charged ring attracts the negatively charged electron and accelerates it. The electron has its maximum speed at this point. When the electron moves past the center of the ring the force on it is opposite to its motion and it slows down.

23.30. **IDENTIFY:** Example 23.10 shows that for a line of charge, $V_a - V_b = \dfrac{\lambda}{2\pi\epsilon_0}\ln(r_b/r_a)$. Apply conservation of energy to the motion of the proton.

SET UP: Let point *a* be 18.0 cm from the line and let point *b* be at the distance of closest approach, where $K_b = 0$.

EXECUTE: **(a)** $K_a = \frac{1}{2}mv^2 = \frac{1}{2}(1.67\times10^{-27}\ \text{kg})(1.50\times10^3\ \text{m/s})^2 = 1.88\times10^{-21}\ \text{J}$.

(b) $K_a + qV_a = K_b + qV_b$. $V_a - V_b = \dfrac{K_b - K_a}{q} = \dfrac{-1.88\times10^{-21}\ \text{J}}{1.60\times10^{-19}\ \text{C}} = -0.01175\ \text{V}$.

$$\ln(r_b/r_a) = \left(\frac{2\pi\epsilon_0}{\lambda}\right)(-0.01175\ \text{V}).$$

$$r_b = r_a\exp\left(\frac{2\pi\epsilon_0(-0.01175\ \text{V})}{\lambda}\right) = (0.180\ \text{m})\exp\left(-\frac{2\pi\epsilon_0(0.01175\ \text{V})}{5.00\times10^{-12}\ \text{C/m}}\right) = 0.158\ \text{m}.$$

EVALUATE: The potential increases with decreasing distance from the line of charge. As the positively charged proton approaches the line of charge it gains electrical potential energy and loses kinetic energy.

23.31. **IDENTIFY:** The voltmeter measures the potential difference between the two points. We must relate this quantity to the linear charge density on the wire.

SET UP: For a very long (infinite) wire, the potential difference between two points is $\Delta V = \dfrac{\lambda}{2\pi\epsilon_0}\ln(r_b/r_a)$.

EXECUTE: **(a)** Solving for λ gives

$$\lambda = \frac{(\Delta V)2\pi\epsilon_0}{\ln(r_b/r_a)} = \frac{575\ \text{V}}{(18\times10^9\,\text{N}\cdot\text{m}^2/\text{C}^2)\ln\left(\dfrac{3.50\ \text{cm}}{2.50\ \text{cm}}\right)} = 9.49\times10^{-8}\ \text{C/m}$$

(b) The meter will read less than 575 V because the electric field is weaker over this 1.00-cm distance than it was over the 1.00-cm distance in part (a).

(c) The potential difference is zero because both probes are at the same distance from the wire, and hence at the same potential.

EVALUATE: Since a voltmeter measures potential difference, we are actually given ΔV, even though that is not stated explicitly in the problem.

23.32. **IDENTIFY:** The voltmeter reads the potential difference between the two points where the probes are placed. Therefore we must relate the potential difference to the distances of these points from the center of the cylinder. For points outside the cylinder, its electric field behaves like that of a line of charge.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

SET UP: Using $\Delta V = \dfrac{\lambda}{2\pi\epsilon_0}\ln(r_b/r_a)$ and solving for r_b, we have $r_b = r_a e^{2\pi\epsilon_0 \Delta V/\lambda}$.

EXECUTE: The exponent is $\dfrac{\left(\dfrac{1}{2\times 9.00\times 10^9\ \text{N}\cdot\text{m}^2/\text{C}^2}\right)(175\ \text{V})}{15.0\times 10^{-9}\ \text{C/m}} = 0.648$, which gives

$$r_b = (2.50\ \text{cm})\, e^{0.648} = 4.78\ \text{cm}.$$

The distance above the *surface* is $4.78\ \text{cm} - 2.50\ \text{cm} = 2.28\ \text{cm}$.

EVALUATE: Since a voltmeter measures potential difference, we are actually given ΔV, even though that is not stated explicitly in the problem. We must also be careful when using the formula for the potential difference because each r is the distance from the *center* of the cylinder, not from the surface.

23.33. **IDENTIFY:** For points outside the cylinder, its electric field behaves like that of a line of charge. Since a voltmeter reads potential difference, that is what we need to calculate.

SET UP: The potential difference is $\Delta V = \dfrac{\lambda}{2\pi\epsilon_0}\ln(r_b/r_a)$.

EXECUTE: **(a)** Substituting numbers gives

$$\Delta V = \frac{\lambda}{2\pi\epsilon_0}\ln(r_b/r_a) = (8.50\times 10^{-6}\ \text{C/m})(2\times 9.00\times 10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\ln\left(\frac{10.0\ \text{cm}}{6.00\ \text{cm}}\right)$$

$$\Delta V = 7.82\times 10^4\ \text{V} = 78{,}200\ \text{V} = 78.2\ \text{kV}$$

(b) $E = 0$ inside the cylinder, so the potential is constant there, meaning that the voltmeter reads zero.

EVALUATE: Caution! The fact that the voltmeter reads zero in part (b) does not mean that $V = 0$ inside the cylinder. The electric field is zero, but the potential is constant and equal to the potential at the surface.

23.34. **IDENTIFY:** The work required is equal to the change in the electrical potential energy of the charge-ring system. We need only look at the beginning and ending points, since the potential difference is independent of path for a conservative field.

SET UP: **(a)** $W = \Delta U = q\Delta V = q(V_{\text{center}} - V_\infty) = q\left(\dfrac{1}{4\pi\epsilon_0}\dfrac{Q}{a} - 0\right)$

EXECUTE: Substituting numbers gives

$$\Delta U = (3.00\times 10^{-6}\ \text{C})(9.00\times 10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)(5.00\times 10^{-6}\ \text{C})/(0.0400\ \text{m}) = 3.38\ \text{J}$$

(b) We can take any path since the potential is independent of path.

(c) SET UP: The net force is away from the ring, so the ball will accelerate away. Energy conservation gives $U_0 = K_{\max} = \frac{1}{2}mv^2$.

EXECUTE: Solving for v gives

$$v = \sqrt{\frac{2U_0}{m}} = \sqrt{\frac{2(3.38\ \text{J})}{0.00150\ \text{kg}}} = 67.1\ \text{m/s}.$$

EVALUATE: Direct calculation of the work from the electric field would be extremely difficult, and we would need to know the path followed by the charge. But, since the electric field is conservative, we can bypass all this calculation just by looking at the end points (infinity and the center of the ring) using the potential.

23.35. **IDENTIFY:** The electric field of the line of charge does work on the sphere, increasing its kinetic energy.

SET UP: $K_1 + U_1 = K_2 + U_2$ and $K_1 = 0$. $U = qV$ so $qV_1 = K_2 + qV_2$. $V = \dfrac{\lambda}{2\pi\epsilon_0}\ln\left(\dfrac{r_0}{r}\right)$.

EXECUTE: $V_1 = \dfrac{\lambda}{2\pi\epsilon_0}\ln\left(\dfrac{r_0}{r_1}\right)$. $V_2 = \dfrac{\lambda}{2\pi\epsilon_0}\ln\left(\dfrac{r_0}{r_2}\right)$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$K_2 = q(V_1 - V_2) = \frac{\lambda}{2\pi\epsilon_0}\left(\ln\left(\frac{r_0}{r_1}\right) - \ln\left(\frac{r_0}{r_2}\right)\right) = \frac{\lambda q}{2\pi\epsilon_0}(\ln r_2 - \ln r_1) = \frac{\lambda q}{2\pi\epsilon_0}\ln\left(\frac{r_2}{r_1}\right).$$

$$K_2 = \frac{(3.00\times10^{-6}\text{ C/m})(8.00\times10^{-6}\text{ C})}{2\pi(8.854\times10^{-12}\text{ C}^2/(\text{N}\cdot\text{m}^2))}\ln\left(\frac{4.50}{1.50}\right) = 0.474\text{ J}.$$

EVALUATE: The potential due to the line of charge does *not* go to zero at infinity but is defined to be zero at an arbitrary distance r_0 from the line.

23.36. **IDENTIFY:** If the small sphere is to have its *minimum* speed, it must just stop at 8.00 cm from the surface of the large sphere. In that case, the initial kinetic energy of the small sphere is all converted to electrical potential energy at its point of closest approach.

SET UP: $K_1 + U_1 = K_2 + U_2$. $K_2 = 0$. $U_1 = 0$. Therefore, $K_1 = U_2$. Outside a spherical charge distribution the potential is the same as for a point charge at the location of the center of the sphere, so $U = kqQ/r$. $K = \frac{1}{2}mv^2$.

EXECUTE: $U_2 = \dfrac{kqQ}{r_2}$, with $r_2 = 12.0\text{ cm} + 8.0\text{ cm} = 0.200\text{ m}$. $\dfrac{1}{2}mv_1^2 = \dfrac{kqQ}{r_2}$.

$$v_1 = \sqrt{\frac{2kqQ}{mr_2}} = \sqrt{\frac{2(8.99\times10^9\text{ N}\cdot\text{m}^2/\text{C}^2)(3.00\times10^{-6}\text{ C})(5.00\times10^{-6}\text{ C})}{(6.00\times10^{-5}\text{ kg})(0.200\text{ m})}} = 150\text{ m/s}.$$

EVALUATE: If the small sphere had enough initial speed to actually penetrate the surface of the large sphere, we could no longer treat the large sphere as a point charge once the small sphere was inside.

23.37. **IDENTIFY:** We can model the axon membrane as a large sheet having equal but opposite charges on its opposite faces.

SET UP: For two oppositely charged sheets of charge, $V_{ab} = Ed$. The positively charged sheet is the one at higher potential.

EXECUTE: **(a)** $E = \dfrac{V_{ab}}{d} = \dfrac{70\times10^{-3}\text{ V}}{7.5\times10^{-9}\text{ m}} = 9.3\times10^6\text{ V/m}$. The electric field is directed inward, toward the interior of the axon, since the outer surface of the membrane has positive charge and $\vec{\boldsymbol{E}}$ points away from positive charge and toward negative charge.

(b) The outer surface has positive charge so it is at higher potential than the inner surface.

EVALUATE: The electric field is quite strong compared to ordinary laboratory fields in devices such as student oscilloscopes. The potential difference is only 70 mV, but it occurs over a distance of only 7.5 nm.

23.38. **IDENTIFY** and **SET UP:** For oppositely charged parallel plates, $E = \sigma/\epsilon_0$ between the plates and the potential difference between the plates is $V = Ed$.

EXECUTE: **(a)** $E = \dfrac{\sigma}{\epsilon_0} = \dfrac{47.0\times10^{-9}\text{ C/m}^2}{\epsilon_0} = 5310\text{ N/C}$.

(b) $V = Ed = (5310\text{ N/C})(0.0220\text{ m}) = 117\text{ V}$.

(c) The electric field stays the same if the separation of the plates doubles. The potential difference between the plates doubles.

EVALUATE: The electric field of an infinite sheet of charge is uniform, independent of distance from the sheet. The force on a test charge between the two plates is constant because the electric field is constant. The potential difference is the work per unit charge on a test charge when it moves from one plate to the other. When the distance doubles, the work, which is force times distance, doubles and the potential difference doubles.

23.39. **IDENTIFY** and **SET UP:** Use the result of Example 23.9 to relate the electric field between the plates to the potential difference between them and their separation. The force this field exerts on the particle is given by Eq. (21.3). Use the equation that precedes Eq. (23.17) to calculate the work.

EXECUTE: **(a)** From Example 23.9, $E = \dfrac{V_{ab}}{d} = \dfrac{360\text{ V}}{0.0450\text{ m}} = 8000\text{ V/m}$.

(b) $F = |q|E = (2.40\times10^{-9}\text{ C})(8000\text{ V/m}) = +1.92\times10^{-5}\text{ N}$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(c) The electric field between the plates is shown in Figure 23.39.

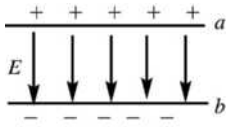

Figure 22.39

The plate with positive charge (plate *a*) is at higher potential. The electric field is directed from high potential toward low potential (or, $\vec{\boldsymbol{E}}$ is from + charge toward − charge), so $\vec{\boldsymbol{E}}$ points from *a* to *b*. Hence the force that $\vec{\boldsymbol{E}}$ exerts on the positive charge is from *a* to *b*, so it does positive work.

$W = \int_a^b \vec{\boldsymbol{F}} \cdot d\vec{\boldsymbol{l}} = Fd$, where *d* is the separation between the plates.

$W = Fd = (1.92\times10^{-5}\ \text{N})(0.0450\ \text{m}) = +8.64\times10^{-7}\ \text{J}$

(d) $V_a - V_b = +360\ \text{V}$ (plate *a* is at higher potential)

$\Delta U = U_b - U_a = q(V_b - V_a) = (2.40\times10^{-9}\ \text{C})(-360\ \text{V}) = -8.64\times10^{-7}\ \text{J}.$

EVALUATE: We see that $W_{a\to b} = -(U_b - U_a) = U_a - U_b$.

23.40. **IDENTIFY** and **SET UP:** $V_{ab} = Ed$ for parallel plates.

EXECUTE: $d = \dfrac{V_{ab}}{E} = \dfrac{1.5\ \text{V}}{1.0\times10^{-6}\ \text{V/m}} = 1.5\times10^{6}\ \text{m} = 1.5\times10^{3}\ \text{km}.$

EVALUATE: The plates would have to be nearly a thousand miles apart with only a AA battery across them! This is a small field!

23.41. **IDENTIFY** and **SET UP:** Consider the electric field outside and inside the shell and use that to deduce the potential.

EXECUTE: **(a)** The electric field outside the shell is the same as for a point charge at the center of the shell, so the potential outside the shell is the same as for a point charge:

$$V = \frac{q}{4\pi\epsilon_0 r} \text{ for } r > R.$$

The electric field is zero inside the shell, so no work is done on a test charge as it moves inside the shell and all points inside the shell are at the same potential as the surface of the shell: $V = \dfrac{q}{4\pi\epsilon_0 R}$ for $r \le R$.

(b) $V = \dfrac{kq}{R}$ so $q = \dfrac{RV}{k} = \dfrac{(0.15\ \text{m})(-1200\ \text{V})}{k} = -20\ \text{nC}$

(c) EVALUATE: No, the amount of charge on the sphere is very small. Since $U = qV$ the total amount of electric energy stored on the balloon is only $(20\ \text{nC})(1200\ \text{nC}) = 2.4\times10^{-5}\ \text{J}$.

23.42. **IDENTIFY:** The electric field is zero inside the sphere, so the potential is constant there. Thus the potential at the center must be the same as at the surface, where it is equivalent to that of a point-charge.

SET UP: At the surface, and hence also at the center of the sphere, the potential is that of a point-charge, $V = Q/(4\pi\epsilon_0 R)$.

EXECUTE: **(a)** Solving for *Q* and substituting the numbers gives

$$Q = 4\pi\epsilon_0 RV = (0.125\ \text{m})(1500\ \text{V})/(9.00\times10^{9}\ \text{N}\cdot\text{m}^2/\text{C}^2) = 2.08\times10^{-8}\ \text{C} = 20.8\ \text{nC}$$

(b) Since the potential is constant inside the sphere, its value at the surface must be the same as at the center, 1.50 kV.

EVALUATE: The electric field inside the sphere is zero, so the potential is constant but is not zero.

23.43. **IDENTIFY:** Example 23.8 shows that the potential of a solid conducting sphere is the same at every point inside the sphere and is equal to its value $V = q/4\pi\epsilon_0 R$ at the surface. Use the given value of *E* to find *q*.

SET UP: For negative charge the electric field is directed toward the charge.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

For points outside this spherical charge distribution the field is the same as if all the charge were concentrated at the center.

EXECUTE: $E = \dfrac{|q|}{4\pi\epsilon_0 r^2}$ and $|q| = 4\pi\epsilon_0 E r^2 = \dfrac{(3800\ \text{N/C})(0.200\ \text{m})^2}{8.99\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2} = 1.69\times10^{-8}\ \text{C}$.

Since the field is directed inward, the charge must be negative. The potential of a point charge, taking ∞ as zero, is $V = \dfrac{q}{4\pi\epsilon_0 r} = \dfrac{(8.99\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)(-1.69\times10^{-8}\ \text{C})}{0.200\ \text{m}} = -760\ \text{V}$ at the surface of the sphere.

Since the charge all resides on the surface of a conductor, the field inside the sphere due to this symmetrical distribution is zero. No work is therefore done in moving a test charge from just inside the surface to the center, and the potential at the center must also be –760 V.

EVALUATE: Inside the sphere the electric field is zero and the potential is constant.

23.44. **IDENTIFY:** By the definition of electric potential, if a positive charge gains potential along a path, then the potential along that path must have increased. The electric field produced by a very large sheet of charge is uniform and is independent of the distance from the sheet.

(a) SET UP: No matter what the reference point, we must do work on a positive charge to move it away from the negative sheet.

EXECUTE: Since we must do work on the positive charge, it gains potential energy, so the potential increases.

(b) SET UP: Since the electric field is uniform and is equal to $\sigma/2\varepsilon_0$, we have $\Delta V = Ed = \dfrac{\sigma}{2\epsilon_0} d$.

EXECUTE: Solving for d gives

$$d = \frac{2\epsilon_0 \Delta V}{\sigma} = \frac{2(8.85\times10^{-12}\,\text{C}^2/\text{N}\cdot\text{m}^2)(1.00\text{V})}{6.00\times10^{-9}\text{C/m}^2} = 0.00295\ \text{m} = 2.95\ \text{mm}$$

EVALUATE: Since the spacing of the equipotential surfaces (d = 2.95 mm) is independent of the distance from the sheet, the equipotential surfaces are planes parallel to the sheet and spaced 2.95 mm apart.

23.45. **IDENTIFY** and **SET UP:** Use Eq. (23.19) to calculate the components of $\vec{E}$.

EXECUTE: $V = Axy - Bx^2 + Cy$

(a) $E_x = -\dfrac{\partial V}{\partial x} = -Ay + 2Bx$

$E_y = -\dfrac{\partial V}{\partial y} = -Ax - C$

$E_z = \dfrac{\partial V}{\partial z} = 0$

(b) $E = 0$ requires that $E_x = E_y = E_z = 0$.

$E_z = 0$ everywhere.

$E_y = 0$ at $x = -C/A$.

And E_x is also equal to zero for this x, any value of z and $y = 2Bx/A = (2B/A)(-C/A) = -2BC/A^2$.

EVALUATE: V doesn't depend on z so $E_z = 0$ everywhere.

23.46. **IDENTIFY:** Apply Eq. (23.19).

SET UP: Eq. (21.7) says $\vec{E} = \dfrac{1}{4\pi\epsilon_0}\dfrac{|q|}{r^2}\hat{\boldsymbol{r}}$ is the electric field due to a point charge q.

EXECUTE: **(a)** $E_x = -\dfrac{\partial V}{\partial x} = -\dfrac{\partial}{\partial x}\left(\dfrac{kQ}{\sqrt{x^2+y^2+z^2}}\right) = \dfrac{kQx}{(x^2+y^2+z^2)^{3/2}} = \dfrac{kQx}{r^3}$.

Similarly, $E_y = \dfrac{kQy}{r^3}$ and $E_z = \dfrac{kQz}{r^3}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) From part (a), $E=\frac{kQ}{r^2}\left(\frac{x\hat{\boldsymbol{i}}}{r}+\frac{y\hat{\boldsymbol{j}}}{r}+\frac{z\hat{\boldsymbol{k}}}{r}\right)=\frac{kQ}{r^2}\hat{\boldsymbol{r}}$, which agrees with Eq. (21.7).

EVALUATE: V is a scalar. $\vec{\boldsymbol{E}}$ is a vector and has components.

23.47. **IDENTIFY** and **SET UP:** For a solid metal sphere or for a spherical shell, $V=\frac{kq}{r}$ outside the sphere and $V=\frac{kq}{R}$ at all points inside the sphere, where R is the radius of the sphere. When the electric field is radial, $E=-\frac{\partial V}{\partial r}$.

EXECUTE: **(a)** (i) $r<r_a$: This region is inside both spheres. $V=\frac{kq}{r_a}-\frac{kq}{r_b}=kq\left(\frac{1}{r_a}-\frac{1}{r_b}\right)$.

(ii) $r_a<r<r_b$: This region is outside the inner shell and inside the outer shell. $V=\frac{kq}{r}-\frac{kq}{r_b}=kq\left(\frac{1}{r}-\frac{1}{r_b}\right)$.

(iii) $r>r_b$: This region is outside both spheres and $V=0$ since outside a sphere the potential is the same as for a point charge. Therefore the potential is the same as for two oppositely charged point charges at the same location. These potentials cancel.

(b) $V_a=\frac{1}{4\pi\epsilon_0}\left(\frac{q}{r_a}-\frac{q}{r_b}\right)$ and $V_b=0$, so $V_{ab}=\frac{1}{4\pi\epsilon_0}q\left(\frac{1}{r_a}-\frac{1}{r_b}\right)$.

(c) Between the spheres $r_a<r<r_b$ and $V=kq\left(\frac{1}{r}-\frac{1}{r_b}\right)$.

$$E=-\frac{\partial V}{\partial r}=-\frac{q}{4\pi\epsilon_0}\frac{\partial}{\partial r}\left(\frac{1}{r}-\frac{1}{r_b}\right)=+\frac{1}{4\pi\epsilon_0}\frac{q}{r^2}=\frac{V_{ab}}{\left(\frac{1}{r_a}-\frac{1}{r_b}\right)}\frac{1}{r^2}.$$

(d) From Eq. (23.23): $E=0$, since V is constant (zero) outside the spheres.

(e) If the outer charge is different, then outside the outer sphere the potential is no longer zero but is $V=\frac{1}{4\pi\epsilon_0}\frac{q}{r}-\frac{1}{4\pi\epsilon_0}\frac{Q}{r}=\frac{1}{4\pi\epsilon_0}\frac{(q-Q)}{r}$. All potentials inside the outer shell are just shifted by an amount $V=\frac{1}{4\pi\epsilon_0}\frac{Q}{r_b}$. Therefore relative potentials within the shells are not affected. Thus (b) and (c) do not change. However, now that the potential does vary outside the spheres, there is an electric field there:

$$E=-\frac{\partial V}{\partial r}=-\frac{\partial}{\partial r}\left(\frac{kq}{r}+\frac{-kQ}{r}\right)=\frac{kq}{r^2}\left(1-\frac{Q}{q}\right)=\frac{k}{r^2}(q-Q).$$

EVALUATE: In part (a) the potential is greater than zero for all $r<r_b$.

23.48. **IDENTIFY:** Exercise 23.47 shows that $V=kq\left(\frac{1}{r_a}-\frac{1}{r_b}\right)$ for $r<r_a$, $V=kq\left(\frac{1}{r}-\frac{1}{r_b}\right)$ for $r_a<r<r_b$ and $V_{ab}=kq\left(\frac{1}{r_a}-\frac{1}{r_b}\right)$.

SET UP: $E=\frac{kq}{r^2}$, radially outward, for $r_a\le r\le r_b$.

EXECUTE: **(a)** $V_{ab}=kq\left(\frac{1}{r_a}-\frac{1}{r_b}\right)=500\text{ V}$ gives $q=\frac{500\text{ V}}{k\left(\frac{1}{0.012\text{ m}}-\frac{1}{0.096\text{ m}}\right)}=7.62\times10^{-10}\text{ C}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) $V_b = 0$ so $V_a = 500$ V. The inner metal sphere is an equipotential with $V = 500$ V. $\frac{1}{r} = \frac{1}{r_a} + \frac{V}{kq}$.

$V = 400$ V at $r = 1.45$ cm, $V = 300$ V at $r = 1.85$ cm, $V = 200$ V at $r = 2.53$ cm, $V = 100$ V at $r = 4.00$ cm, $V = 0$ at $r = 9.60$ cm. The equipotential surfaces are sketched in Figure 23.48.

EVALUATE: **(c)** The equipotential surfaces are concentric spheres and the electric field lines are radial, so the field lines and equipotential surfaces are mutually perpendicular. The equipotentials are closest at smaller r, where the electric field is largest.

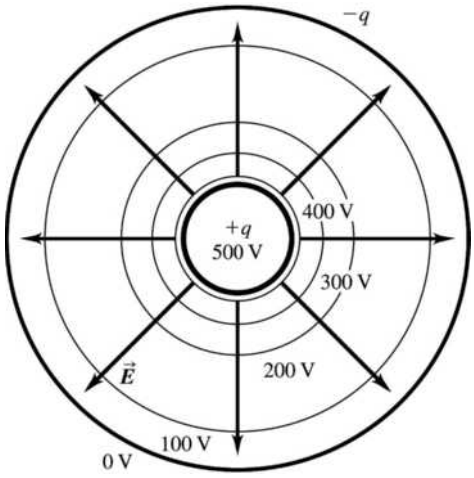

Figure 23.48

23.49. **IDENTIFY:** Outside the cylinder it is equivalent to a line of charge at its center.
SET UP: The difference in potential between the surface of the cylinder (a distance R from the central axis) and a general point a distance r from the central axis is given by $\Delta V = \frac{\lambda}{2\pi\epsilon_0}\ln(r/R)$.

EXECUTE: **(a)** The potential difference depends only on r, and not direction. Therefore all points at the same value of r will be at the same potential. Thus the equipotential surfaces are cylinders coaxial with the given cylinder.

(b) Solving $\Delta V = \frac{\lambda}{2\pi\epsilon_0}\ln(r/R)$ for r, gives $r = Re^{2\pi\epsilon_0\Delta V/\lambda}$.

For 10 V, the exponent is $(10\text{ V})/[(2\times 9.00\times 10^9\text{ N}\cdot\text{m}^2/\text{C}^2)(1.50\times 10^{-9}\text{ C/m})] = 0.370$, which gives $r = (2.00\text{ cm})e^{0.370} = 2.90$ cm. Likewise, the other radii are 4.20 cm (for 20 V) and 6.08 cm (for 30 V).

(c) $\Delta r_1 = 2.90\text{ cm} - 2.00\text{ cm} = 0.90$ cm; $\Delta r_2 = 4.20\text{ cm} - 2.90\text{ cm} = 1.30$ cm; $\Delta r_3 = 6.08\text{ cm} - 4.20\text{ cm} = 1.88$ cm

EVALUATE: As we can see, Δr increases, so the surfaces get farther apart. This is very different from a sheet of charge, where the surfaces are equally spaced planes.

23.50. **IDENTIFY:** As the sphere approaches the point charge, the speed of the sphere decreases because it loses kinetic energy, but its acceleration increases because the electric force on it increases. Its mechanical energy is conserved during the motion, and Newton's second law and Coulomb's law both apply.

SET UP: $K_a + U_a = K_b + U_b$, $K = \frac{1}{2}mv^2$, $U = kq_1q_2/r$, $F = kq_1q_2/r^2$, and $F = ma$.

EXECUTE: Find the distance between the two charges when $v_2 = 25.0$ m/s.

$K_a + U_a = K_b + U_b$.

$K_a = \frac{1}{2}mv_a^2 = \frac{1}{2}(4.00\times 10^{-3}\text{ kg})(40.0\text{ m/s})^2 = 3.20$ J.

$K_b = \frac{1}{2}mv_b^2 = \frac{1}{2}(4.00\times 10^{-3}\text{ kg})(25.0\text{ m/s})^2 = 1.25$ J.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$U_a = k\frac{q_1 q_2}{r_a} = \frac{(8.99\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)(5.00\times10^{-6}\ \text{C})(5.00\times10^{-6}\ \text{C})}{0.0600\ \text{m}} = 1.498\ \text{J}.$$

$U_b = K_a + U_a - K_b = 3.20\ \text{J} + 1.498\ \text{J} - 1.25\ \text{J} = 3.448\ \text{J}$. $U_b = k\frac{q_1 q_2}{r_b}$ and

$$r_b = \frac{kq_1 q_2}{U_b} = \frac{(8.99\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)(5.00\times10^{-6}\ \text{C})(2.00\times10^{-6}\ \text{C})}{3.448\ \text{J}} = 0.02607\ \text{m}.$$

$$F_b = \frac{kq_1 q_2}{r_b^2} = \frac{(8.99\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)(5.00\times10^{-6}\ \text{C})(2.00\times10^{-6}\ \text{C})}{(0.02607\ \text{m})^2} = 132.3\ \text{N}.$$

$$a = \frac{F}{m} = \frac{132.3\ \text{N}}{4.00\times10^{-3}\ \text{kg}} = 3.31\times10^4\ \text{m/s}^2.$$

EVALUATE: As the sphere approaches the point charge, its speed decreases but its acceleration keeps increasing because the electric force on it keeps increasing.

23.51. **IDENTIFY:** $U = k\left(\frac{q_1 q_2}{r_{12}} + \frac{q_1 q_3}{r_{13}} + \frac{q_2 q_3}{r_{23}}\right)$

SET UP: In part (a), $r_{12} = 0.200$ m, $r_{23} = 0.100$ m and $r_{13} = 0.100$ m. In part (b) let particle 3 have coordinate x, so $r_{12} = 0.200$ m, $r_{13} = x$ and $r_{23} = 0.200 - x$.

EXECUTE: **(a)** $U = k\left(\frac{(4.00\ \text{nC})(-3.00\ \text{nC})}{(0.200\ \text{m})} + \frac{(4.00\ \text{nC})(2.00\ \text{nC})}{(0.100\ \text{m})} + \frac{(-3.00\ \text{nC})(2.00\ \text{nC})}{(0.100\ \text{m})}\right) = -3.60\times10^{-7}\ \text{J}$

(b) If $U = 0$, then $0 = k\left(\frac{q_1 q_2}{r_{12}} + \frac{q_1 q_3}{x} + \frac{q_2 q_3}{r_{12} - x}\right)$. Solving for x we find:

$0 = -60 + \frac{8}{x} - \frac{6}{0.2 - x} \Rightarrow 60x^2 - 26x + 1.6 = 0 \Rightarrow x = 0.074\ \text{m}, 0.360\ \text{m}$. Therefore, $x = 0.074$ m since it is the only value between the two charges.

EVALUATE: U_{13} is positive and both U_{23} and U_{12} are negative. If $U = 0$, then $|U_{13}| = |U_{23}| + |U_{12}|$. For $x = 0.074$ m, $U_{13} = +9.7\times10^{-7}$ J, $U_{23} = -4.3\times10^{-7}$ J and $U_{12} = -5.4\times10^{-7}$ J. It is true that $U = 0$ at this x.

23.52. **IDENTIFY:** Two forces do work on the sphere as it falls: gravity and the electrical force due to the sheet. The energy of the sphere is conserved.

SET UP: The gravity force is mg, downward. The electric field of the sheet is $E = \frac{\sigma}{2\varepsilon_0}$ upward, and the force it exerts on the sphere is $F = qE$. The sphere gains kinetic energy $K = \frac{1}{2}mv^2$ as it falls.

EXECUTE: $mg = 4.90\times10^{-6}$ N. $E = \frac{\sigma}{2\varepsilon_0} = \frac{8.00\times10^{-12}\ \text{C/m}^2}{2(8.854\times10^{-12}\ \text{C}^2/(\text{N}\cdot\text{m}^2))} = 0.4518$ N/C. The electric force is $qE = (3.00\times10^{-6}\ \text{C})(0.4518\ \text{N/C}) = 1.355\times10^{-6}$ N, upward. The net force is downward, so the sphere moves downward when released. Let $y = 0$ at the sheet. $U_{\text{grav}} = mgy$. For the electric force, $\frac{W_{a\to b}}{q} = V_a - V_b$. Let point a be at the sheet and let point b be a distance y above the sheet. Take $V_a = 0$.

The force on q is qE, upward, so $\frac{W_{a\to b}}{q} = Ey$ and $V_b = -Ey$. $U_b = -Eyq$. $K_1 + U_1 = K_2 + U_2$. $K_1 = 0$.

$y_1 = 0.400$ m, $y_2 = 0.100$ m. $K_2 = U_1 - U_2 = mg(y_1 - y_2) - E(y_1 - y_2)q$.

$K_2 = (5.00\times10^{-7}\ \text{kg})(9.8\ \text{m/s}^2)(0.300\ \text{m}) - (0.4518\ \text{N/C})(0.300\ \text{m})(3.00\times10^{-6}\ \text{C})$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$K_2 = 1.470\times10^{-6}\ \text{J} - 0.407\times10^{-6}\ \text{J} = 1.063\times10^{-6}\ \text{J}$. $K_2 = \frac{1}{2}mv_2^2$ so

$$v_2 = \sqrt{\frac{2K_2}{m}} = \sqrt{\frac{2(1.063\times10^{-6}\ \text{J})}{5.00\times10^{-7}\ \text{kg}}} = 2.06\ \text{m/s}.$$

EVALUATE: Because the weight is greater than the electric force, the sphere will accelerate downward, but if it were light enough the electric force would exceed the weight. In that case it would never get closer to the sheet after being released.

23.53. **IDENTIFY:** The remaining nucleus (radium minus the ejected alpha particle) repels the alpha particle, giving it 4.79 MeV of kinetic energy when it is far from the nucleus. The mechanical energy of the system is conserved.

SET UP: $U = k\frac{qq'}{r}$. $U_a + K_a = U_b + K_b$. The charge of the alpha particle is $+2e$ and the charge of the radon nucleus is $+86e$.

EXECUTE: **(a)** The final energy of the alpha particle, 4.79 MeV, equals the electrical potential energy of the alpha-radon combination just before the decay. $U = 4.79\ \text{MeV} = 7.66\times10^{-13}\ \text{J}$.

(b) $$r = \frac{kqq'}{U} = \frac{(8.99\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)(2)(86)(1.60\times10^{-19}\ \text{C})^2}{7.66\times10^{-13}\ \text{J}} = 5.17\times10^{-14}\ \text{m}.$$

EVALUATE: Although we have made some simplifying assumptions (such as treating the atomic nucleus as a spherically symmetric charge, even when very close to it), this result gives a fairly reasonable estimate for the size of a nucleus.

23.54. **IDENTIFY:** The charged particles repel each other and therefore accelerate away from one another, causing their speeds and kinetic energies to continue to increase. They do not have equal speeds because they have different masses. The mechanical energy and momentum of the system are conserved.

SET UP: The proton has charge $q_\text{p} = +e$ and mass $m_\text{p} = 1.67\times10^{-27}$ kg. The alpha particle has charge $q_\text{a} = +4e$ and mass $m_\text{a} = 4m_\text{p} = 6.68\times10^{-27}$ kg. We can apply both conservation of energy and conservation of linear momentum to the system. $a = \frac{F}{m}$, where $F = k\frac{|q_1q_2|}{r^2}$.

EXECUTE: *Acceleration:* The maximum force and hence the maximum acceleration occurs just after they are released, when $r = 0.225$ nm. $F = (8.99\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\frac{(2)(1.60\times10^{-19}\ \text{C})^2}{(0.225\times10^{-9}\ \text{m})^2} = 9.09\times10^{-9}\ \text{N}$.

$a_\text{p} = \frac{F}{m_\text{p}} = \frac{9.09\times10^{-9}\ \text{N}}{1.67\times10^{-27}\ \text{kg}} = 5.44\times10^{18}\ \text{m/s}^2$; $a_\text{a} = \frac{F}{m_\text{a}} = \frac{9.09\times10^{-9}\ \text{N}}{6.68\times10^{-27}\ \text{kg}} = 1.36\times10^{18}\ \text{m/s}^2$. The acceleration of the proton is larger by a factor of m_a/m_p.

Speed: Conservation of energy says $U_1 + K_1 = U_2 + K_2$. $K_1 = 0$ and $U_2 = 0$, so $K_2 = U_1$.

$U_1 = k\frac{qq'}{r} = (8.99\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\frac{(2)(1.60\times10^{-19}\ \text{C})^2}{0.225\times10^{-9}\ \text{m}} = 2.05\times10^{-18}\ \text{J}$, so the total kinetic energy of the two particles when they are far apart is $K_2 = 2.05\times10^{-18}$ J. Conservation of linear momentum says how this energy is divided between the proton and alpha particle. $p_1 = p_2$. $0 = m_\text{p}v_\text{p} - m_\text{a}v_\text{a}$ so $v_\text{a} = \left(\frac{m_\text{p}}{m_\text{a}}\right)v_\text{p}$.

$$K_2 = \tfrac{1}{2}m_\text{p}v_\text{p}^2 + \tfrac{1}{2}m_\text{a}v_\text{a}^2 = \tfrac{1}{2}m_\text{p}v_\text{p}^2 + \tfrac{1}{2}m_\text{a}\left(\frac{m_\text{p}}{m_\text{a}}\right)^2 v_\text{p}^2 = \tfrac{1}{2}m_\text{p}v_\text{p}^2\left(1 + \frac{m_\text{p}}{m_\text{a}}\right).$$

$$v_\text{p} = \sqrt{\frac{2K_2}{m_\text{p}(1 + (m_\text{p}/m_\text{a}))}} = \sqrt{\frac{2(2.05\times10^{-18}\ \text{J})}{(1.67\times10^{-27}\ \text{kg})\left(1 + \frac{1}{4}\right)}} = 4.43\times10^4\ \text{m/s}.$$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$v_a = \left(\frac{m_p}{m_a}\right)v_p = \frac{1}{4}(4.43\times10^4 \text{ m/s}) = 1.11\times10^4 \text{ m/s}$. The maximum acceleration occurs just after they are released. The maximum speed occurs after a long time.

EVALUATE: The proton and alpha particle have equal momenum, but proton has a greater acceleration and more kinetic energy.

23.55. **(a) IDENTIFY:** Apply the work-energy theorem, Eq. (6.6).

SET UP: Points *a* and *b* are shown in Figure 23.55a.

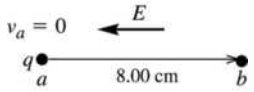

Figure 23.55a

EXECUTE: $W_{tot} = \Delta K = K_b - K_a = K_b = 4.35\times10^{-5}$ J

The electric force F_E and the additional force F both do work, so that $W_{tot} = W_{F_E} + W_F$.

$$W_{F_E} = W_{tot} - W_F = 4.35\times10^{-5}\text{ J} - 6.50\times10^{-5}\text{ J} = -2.15\times10^{-5}\text{ J}$$

EVALUATE: The forces on the charged particle are shown in Figure 23.55b.

Figure 23.55b

The electric force is to the left (in the direction of the electric field since the particle has positive charge). The displacement is to the right, so the electric force does negative work. The additional force F is in the direction of the displacement, so it does positive work.

(b) IDENTIFY and **SET UP**: For the work done by the electric force, $W_{a\to b} = q(V_a - V_b)$.

EXECUTE: $V_a - V_b = \frac{W_{a\to b}}{q} = \frac{-2.15\times10^{-5}\text{ J}}{7.60\times10^{-9}\text{ C}} = -2.83\times10^3$ V.

EVALUATE The starting point (point *a*) is at 2.83×10^3 V lower potential than the ending point (point *b*). We know that $V_b > V_a$ because the electric field always points from high potential toward low potential.

(c) IDENTIFY: Calculate *E* from $V_a - V_b$ and the separation *d* between the two points.

SET UP: Since the electric field is uniform and directed opposite to the displacement $W_{a\to b} = -F_E d = -qEd$, where $d = 8.00$ cm is the displacement of the particle.

EXECUTE: $E = -\frac{W_{a\to b}}{qd} = -\frac{V_a - V_b}{d} = -\frac{-2.83\times10^3\text{ V}}{0.0800\text{ m}} = 3.54\times10^4$ V/m.

EVALUATE: In part (a), W_{tot} is the total work done by both forces. In parts (b) and (c) $W_{a\to b}$ is the work done just by the electric force.

23.56. **IDENTIFY:** The electric force between the electron and proton is attractive and has magnitude $F = \frac{ke^2}{r^2}$.

For circular motion the acceleration is $a_{rad} = v^2/r$. $U = -k\frac{e^2}{r}$.

SET UP: $e = 1.60\times10^{-19}$ C. 1 eV $= 1.60\times10^{-19}$ J.

EXECUTE: **(a)** $\frac{mv^2}{r} = \frac{ke^2}{r^2}$ and $v = \sqrt{\frac{ke^2}{mr}}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) $K=\frac{1}{2}mv^2=\frac{1}{2}\frac{ke^2}{r}=-\frac{1}{2}U$

(c) $E=K+U=\frac{1}{2}U=-\frac{1}{2}\frac{ke^2}{r}=-\frac{1}{2}\frac{k(1.60\times10^{-19}\text{ C})^2}{5.29\times10^{-11}\text{ m}}=-2.17\times10^{-18}\text{ J}=-13.6\text{ eV}.$

EVALUATE: The total energy is negative, so the electron is bound to the proton. Work must be done on the electron to take it far from the proton.

23.57. **IDENTIFY** and **SET UP:** Calculate the components of $\vec{E}$ from Eq. (23.19). Eq. (21.3) gives $\vec{F}$ from $\vec{E}$.

EXECUTE: **(a)** $V=Cx^{4/3}$

$$C=V/x^{4/3}=240\text{ V}/(13.0\times10^{-3}\text{ m})^{4/3}=7.85\times10^4\text{ V/m}^{4/3}$$

(b) $E_x=-\frac{\partial V}{\partial x}=-\frac{4}{3}Cx^{1/3}=-(1.05\times10^5\text{ V/m}^{4/3})x^{1/3}$

The minus sign means that E_x is in the $-x$-direction, which says that $\vec{E}$ points from the positive anode toward the negative cathode.

(c) $\vec{F}=q\vec{E}$ so $F_x=-eE_x=\frac{4}{3}eCx^{1/3}$

Halfway between the electrodes means $x=6.50\times10^{-3}$ m.

$$F_x=\tfrac{4}{3}(1.602\times10^{-19}\text{ C})(7.85\times10^4\text{ V/m}^{4/3})(6.50\times10^{-3}\text{ m})^{1/3}=3.13\times10^{-15}\text{ N}$$

F_x is positive, so the force is directed toward the positive anode.

EVALUATE: V depends only on x, so $E_y=E_z=0$. $\vec{E}$ is directed from high potential (anode) to low potential (cathode). The electron has negative charge, so the force on it is directed opposite to the electric field.

23.58. **IDENTIFY:** At each point (a and b), the potential is the sum of the potentials due to *both* spheres. The voltmeter reads the difference between these two potentials. The spheres behave like point charges since the meter is connected to the surface of each one.

SET UP: **(a)** Call a the point on the surface of one sphere and b the point on the surface of the other sphere, call r the radius of each sphere and call d the center-to-center distance between the spheres. The potential difference V_{ba} between points a and b is then

$$V_b-V_a=V_{ba}=\frac{1}{4\pi\epsilon_0}\left[\frac{-q}{r}+\frac{q}{d-r}-\left(\frac{q}{r}+\frac{-q}{d-r}\right)\right]=\frac{2q}{4\pi\epsilon_0}\left(\frac{1}{d-r}-\frac{1}{r}\right).$$

EXECUTE: Substituting the numbers gives

$V_b-V_a=2(250\ \mu\text{C})\ (9.00\times10^9\text{ N}\cdot\text{m}^2/\text{C}^2)\left(\frac{1}{0.750\text{ m}}-\frac{1}{0.250\text{ m}}\right)=-12.0\times10^6\text{ V}$. The meter reads 12.0 MV.

(b) Since V_b-V_a is negative, $V_a>V_b$, so point a is at the higher potential.

EVALUATE: An easy way to see that the potential at a is higher than the potential at b is that it would require positive work to move a positive test charge from b to a since this charge would be attracted by the negative sphere and repelled by the positive sphere.

23.59. **IDENTIFY:** $U=\frac{kq_1q_2}{r}$

SET UP: Eight charges means there are $8(8-1)/2=28$ pairs. There are 12 pairs of q and $-q$ separated by d, 12 pairs of equal charges separated by $\sqrt{2}d$ and 4 pairs of q and $-q$ separated by $\sqrt{3}d$.

EXECUTE: **(a)** $U=kq^2\left(-\frac{12}{d}+\frac{12}{\sqrt{2}d}-\frac{4}{\sqrt{3}d}\right)=-\frac{12kq^2}{d}\left(1-\frac{1}{\sqrt{2}}+\frac{1}{3\sqrt{3}}\right)=-1.46q^2/\pi\epsilon_0 d$

EVALUATE: **(b)** The fact that the electric potential energy is less than zero means that it is energetically favorable for the crystal ions to be together.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

23.60. **IDENTIFY:** For two small spheres, $U = \dfrac{kq_1q_2}{r}$. For part (b) apply conservation of energy.

SET UP: Let $q_1 = 2.00\ \mu\text{C}$ and $q_2 = -3.50\ \mu\text{C}$. Let $r_a = 0.250$ m and $r_b \to \infty$.

EXECUTE: **(a)** $U = \dfrac{(8.99\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)(2.00\times10^{-6}\ \text{C})(-3.50\times10^{-6}\ \text{C})}{0.250\ \text{m}} = -0.252\ \text{J}$

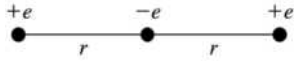
(b) $K_b = 0$. $U_b = 0$. $U_a = -0.252$ J. $K_a + U_a = K_b + U_b$ gives $K_a = 0.252$ J. $K_a = \frac{1}{2}mv_a^2$, so

$$v_a = \sqrt{\frac{2K_a}{m}} = \sqrt{\frac{2(0.252\ \text{J})}{1.50\times10^{-3}\ \text{kg}}} = 18.3\ \text{m/s}$$

EVALUATE: As the sphere moves away, the attractive electrical force exerted by the other sphere does negative work and removes all the kinetic energy it initially had. Note that it doesn't matter which sphere is held fixed and which is shot away; the answer to part (b) is unaffected.

23.61. **(a) IDENTIFY:** Use Eq. (23.10) for the electron and each proton.

SET UP: The positions of the particles are shown in Figure 23.61a.



$r = (1.07\times10^{-10}\ \text{m})/2 = 0.535\times10^{-10}\ \text{m}$

Figure 23.61a

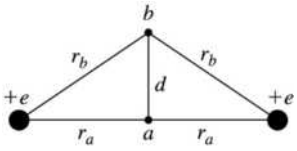
EXECUTE: The potential energy of interaction of the electron with each proton is $U = \dfrac{1}{4\pi\epsilon_0}\dfrac{(-e^2)}{r}$, so the total potential energy is

$$U = -\frac{2e^2}{4\pi\epsilon_0 r} = -\frac{2(8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)(1.60\times10^{-19}\ \text{C})^2}{0.535\times10^{-10}\ \text{m}} = -8.60\times10^{-18}\ \text{J}$$

$$U = -8.60\times10^{-18}\ \text{J}(1\ \text{eV}/1.602\times10^{-19}\ \text{J}) = -53.7\ \text{eV}$$

EVALUATE: The electron and proton have charges of opposite signs, so the potential energy of the system is negative.

(b) IDENTIFY and **SET UP:** The positions of the protons and points *a* and *b* are shown in Figure 23.61b.



$r_b = \sqrt{r_a^2 + d^2}$

$r_a = r = 0.535\times10^{-10}\ \text{m}$

Figure 23.61b

Apply $K_a + U_a + W_{\text{other}} = K_b + U_b$ with point *a* midway between the protons and point *b* where the electron instantaneously has $v = 0$ (at its maximum displacement *d* from point *a*).

EXECUTE: Only the Coulomb force does work, so $W_{\text{other}} = 0$.

$U_a = -8.60\times10^{-18}$ J (from part (a))

$K_a = \frac{1}{2}mv^2 = \frac{1}{2}(9.109\times10^{-31}\ \text{kg})(1.50\times10^6\ \text{m/s})^2 = 1.025\times10^{-18}$ J

$K_b = 0$

$U_b = -2ke^2/r_b$

Then $U_b = K_a + U_a - K_b = 1.025\times10^{-18}\ \text{J} - 8.60\times10^{-18}\ \text{J} = -7.575\times10^{-18}$ J.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$r_b = -\frac{2ke^2}{U_b} = -\frac{2(8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)(1.60\times10^{-19}\ \text{C})^2}{-7.575\times10^{-18}\ \text{J}} = 6.075\times10^{-11}\ \text{m}$$

Then $d = \sqrt{r_b^2 - r_a^2} = \sqrt{(6.075\times10^{-11}\ \text{m})^2 - (5.35\times10^{-11}\ \text{m})^2} = 2.88\times10^{-11}\ \text{m}$.

EVALUATE: The force on the electron pulls it back toward the midpoint. The transverse distance the electron moves is about 0.27 times the separation of the protons.

23.62. **IDENTIFY:** Apply $\sum F_x = 0$ and $\sum F_y = 0$ to the sphere. The electric force on the sphere is $F_e = qE$. The potential difference between the plates is $V = Ed$.

SET UP: The free-body diagram for the sphere is given in Figure 23.62.

EXECUTE: $T\cos\theta = mg$ and $T\sin\theta = F_e$ gives

$F_e = mg\tan\theta = (1.50\times10^{-3}\ \text{kg})(9.80\ \text{m/s}^2)\tan(30°) = 0.0085\ \text{N}$.

$F_e = Eq = \dfrac{Vq}{d}$ and $V = \dfrac{Fd}{q} = \dfrac{(0.0085\ \text{N})(0.0500\ \text{m})}{8.90\times10^{-6}\ \text{C}} = 47.8\ \text{V}$.

EVALUATE: $E = V/d = 956\ \text{V/m}$. $E = \sigma/\epsilon_0$ and $\sigma = E\epsilon_0 = 8.46\times10^{-9}\ \text{C/m}^2$.

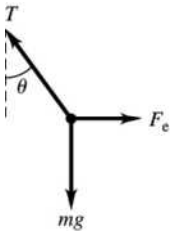


Figure 23.62

23.63. **(a) IDENTIFY:** The potential at any point is the sum of the potentials due to each of the two charged conductors.

SET UP: From Example 23.10, for a conducting cylinder with charge per unit length λ the potential outside the cylinder is given by $V = (\lambda/2\pi\epsilon_0)\ln(r_0/r)$ where r is the distance from the cylinder axis and r_0 is the distance from the axis for which we take $V = 0$. Inside the cylinder the potential has the same value as on the cylinder surface. The electric field is the same for a solid conducting cylinder or for a hollow conducting tube so this expression for V applies to both. This problem says to take $r_0 = b$.

EXECUTE: For the hollow tube of radius b and charge per unit length $-\lambda$: outside $V = -(\lambda/2\pi\epsilon_0)\ln(b/r)$; inside $V = 0$ since $V = 0$ at $r = b$.

For the metal cylinder of radius a and charge per unit length λ:
outside $V = (\lambda/2\pi\epsilon_0)\ln(b/r)$, inside $V = (\lambda/2\pi\epsilon_0)\ln(b/a)$, the value at $r = a$.

(i) $r < a$; inside both $V = (\lambda/2\pi\epsilon_0)\ln(b/a)$

(ii) $a < r < b$; outside cylinder, inside tube $V = (\lambda/2\pi\epsilon_0)\ln(b/r)$

(iii) $r > b$; outside both the potentials are equal in magnitude and opposite in sign so $V = 0$.

(b) For $r = a$, $V_a = (\lambda/2\pi\epsilon_0)\ln(b/a)$.

For $r = b$, $V_b = 0$.

Thus $V_{ab} = V_a - V_b = (\lambda/2\pi\epsilon_0)\ln(b/a)$.

(c) IDENTIFY and **SET UP:** Use Eq. (23.23) to calculate E.

EXECUTE: $E = -\dfrac{\partial V}{\partial r} = -\dfrac{\lambda}{2\pi\epsilon_0}\dfrac{\partial}{\partial r}\ln\left(\dfrac{b}{r}\right) = -\dfrac{\lambda}{2\pi\epsilon_0}\left(\dfrac{r}{b}\right)\left(-\dfrac{b}{r^2}\right) = \dfrac{V_{ab}}{\ln(b/a)}\dfrac{1}{r}$.

(**d**) The electric field between the cylinders is due only to the inner cylinder, so V_{ab} is not changed, $V_{ab} = (\lambda/2\pi\epsilon_0)\ln(b/a)$.

EVALUATE: The electric field is not uniform between the cylinders, so $V_{ab} \neq E(b-a)$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

23.64. **IDENTIFY:** The wire and hollow cylinder form coaxial cylinders. Problem 23.63 gives $E(r)=\dfrac{V_{ab}}{\ln(b/a)}\dfrac{1}{r}$.

SET UP: $a=145\times10^{-6}$ m, $b=0.0180$ m.

EXECUTE: $E=\dfrac{V_{ab}}{\ln(b/a)}\dfrac{1}{r}$ and

$V_{ab}=E\ln(b/a)r=(2.00\times10^{4}\text{ N/C})(\ln(0.018\text{ m}/145\times10^{-6}\text{ m}))0.012\text{ m}=1157\text{ V}$.

EVALUATE: The electric field at any r is directly proportional to the potential difference between the wire and the cylinder.

23.65. **IDENTIFY** and **SET UP:** Use Eq. (21.3) to calculate $\vec{F}$ and then $\vec{F}=m\vec{a}$ gives $\vec{a}$. $E=V/d$.

EXECUTE: **(a)** $\vec{F}_E=q\vec{E}$. Since $q=-e$ is negative $\vec{F}_E$ and $\vec{E}$ are in opposite directions; $\vec{E}$ is upward so $\vec{F}_E$ is downward. The magnitude of E is $E=\dfrac{V}{d}=\dfrac{22.0\text{ V}}{0.0200\text{ m}}=1.10\times10^{3}\text{ V/m}=1.10\times10^{3}\text{ N/C}$. The magnitude of F_E is $F_E=|q|E=eE=(1.602\times10^{-19}\text{ C})(1.10\times10^{3}\text{ N/C})=1.76\times10^{-16}\text{ N}$.

(b) Calculate the acceleration of the electron produced by the electric force:

$a=\dfrac{F}{m}=\dfrac{1.76\times10^{-16}\text{ N}}{9.109\times10^{-31}\text{ kg}}=1.93\times10^{14}\text{ m/s}^2$.

EVALUATE: This acceleration is much larger than $g=9.80\text{ m/s}^2$, so the gravity force on the electron can be neglected. $\vec{F}_E$ is downward, so $\vec{a}$ is downward.

(c) IDENTIFY and **SET UP:** The acceleration is constant and downward, so the motion is like that of a projectile. Use the horizontal motion to find the time and then use the time to find the vertical displacement.

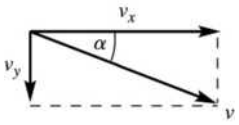
EXECUTE: x-component: $v_{0x}=6.50\times10^{6}$ m/s; $a_x=0$; $x-x_0=0.060$ m; $t=?$

$x-x_0=v_{0x}t+\frac{1}{2}a_xt^2$ and the a_x term is zero, so $t=\dfrac{x-x_0}{v_{0x}}=\dfrac{0.060\text{ m}}{6.50\times10^{6}\text{ m/s}}=9.231\times10^{-9}$ s.

y-component: $v_{0y}=0$; $a_y=1.93\times10^{14}\text{ m/s}^2$; $t=9.231\times10^{-9}$ m/s; $y-y_0=?$

$y-y_0=v_{0y}t+\frac{1}{2}a_yt^2$. $y-y_0=\frac{1}{2}(1.93\times10^{14}\text{ m/s}^2)(9.231\times10^{-9}\text{ s})^2=0.00822\text{ m}=0.822\text{ cm}$.

(d) The velocity and its components as the electron leaves the plates are sketched in Figure 23.65.



$v_x=v_{0x}=6.50\times10^{6}$ m/s (since $a_x=0$)

$v_y=v_{0y}+a_yt$

$v_y=0+(1.93\times10^{14}\text{ m/s}^2)(9.231\times10^{-9}\text{ s})$

$v_y=1.782\times10^{6}$ m/s

Figure 23.65

$\tan\alpha=\dfrac{v_y}{v_x}=\dfrac{1.782\times10^{6}\text{ m/s}}{6.50\times10^{6}\text{ m/s}}=0.2742$ so $\alpha=15.3°$.

EVALUATE: The greater the electric field or the smaller the initial speed the greater the downward deflection.

(e) IDENTIFY and **SET UP:** Consider the motion of the electron after it leaves the region between the plates. Outside the plates there is no electric field, so a = 0. (Gravity can still be neglected since the electron is traveling at such high speed and the times are small.) Use the horizontal motion to find the time it takes the electron to travel 0.120 m horizontally to the screen. From this time find the distance downward that the electron travels.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: x-component: $v_{0x} = 6.50\times10^6$ m/s; $a_x = 0$; $x - x_0 = 0.120$ m; $t = ?$

$x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2$ and the a_x term is term is zero, so $t = \dfrac{x - x_0}{v_{0x}} = \dfrac{0.120 \text{ m}}{6.50\times10^6 \text{ m/s}} = 1.846\times10^{-8}$ s.

y-component: $v_{0y} = 1.782\times10^6$ m/s (from part (b)); $a_y = 0$; $t = 1.846\times10^{-8}$ m/s; $y - y_0 = ?$

$y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2 = (1.782\times10^6 \text{ m/s})(1.846\times10^{-8} \text{ s}) = 0.0329 \text{ m} = 3.29 \text{ cm}.$

EVALUATE: The electron travels downward a distance 0.822 cm while it is between the plates and a distance 3.29 cm while traveling from the edge of the plates to the screen. The total downward deflection is 0.822 cm + 3.29 cm = 4.11 cm. The horizontal distance between the plates is half the horizontal distance the electron travels after it leaves the plates. And the vertical velocity of the electron increases as it travels between the plates, so it makes sense for it to have greater downward displacement during the motion after it leaves the plates.

23.66. **IDENTIFY:** The charge on the plates and the electric field between them depend on the potential difference across the plates.

(a) SET UP: For two parallel plates, the potential difference between them is $V = Ed = \dfrac{\sigma}{\epsilon_0}d = \dfrac{Qd}{\epsilon_0 A}$.

EXECUTE: Solving for Q gives $Q = \epsilon_0 AV/d = \dfrac{(8.85\times10^{-12} \text{ C}^2/\text{N}\cdot\text{m}^2)(0.030 \text{ m})^2(25.0 \text{ V})}{0.0050 \text{ m}}$.

$Q = 3.98\times10^{-11}\text{C} = 39.8$ pC.

(b) $E = V/d = (25.0 \text{ V})/(0.0050 \text{ m}) = 5.00\times10^3$ V/m.

(c) SET UP: Energy conservation gives $\frac{1}{2}mv^2 = eV$.

EXECUTE: Solving for v gives $v = \sqrt{\dfrac{2eV}{m}} = \sqrt{\dfrac{2(1.60\times10^{-19}\text{C})(25.0 \text{ V})}{9.11\times10^{-31} \text{ kg}}} = 2.96\times10^6 \text{m/s}.$

EVALUATE: Typical voltages in student laboratory work run up to around 25 V, so typical reasonable values for the charge on the plates is about 40 pC and a reasonable value for the electric field is about 5000 V/m, as we found here. The electron speed would be about 3 million m/s.

23.67. **(a) IDENTIFY** and **SET UP:** Problem 23.63 derived that $E = \dfrac{V_{ab}}{\ln(b/a)}\dfrac{1}{r}$, where a is the radius of the inner cylinder (wire) and b is the radius of the outer hollow cylinder. The potential difference between the two cylinders is V_{ab}. Use this expression to calculate E at the specified r.

EXECUTE: Midway between the wire and the cylinder wall is at a radius of

$r = (a + b)/2 = (90.0\times10^{-6} \text{ m} + 0.140 \text{ m})/2 = 0.07004$ m.

$$E = \frac{V_{ab}}{\ln(b/a)}\frac{1}{r} = \frac{50.0\times10^3 \text{ V}}{\ln(0.140 \text{ m}/90.0\times10^{-6} \text{ m})(0.07004 \text{ m})} = 9.71\times10^4 \text{ V/m}$$

(b) IDENTIFY and **SET UP:** The electric force is given by Eq. (21.3). Set this equal to ten times the weight of the particle and solve for $|q|$, the magnitude of the charge on the particle.

EXECUTE: $F_E = 10mg$

$$|q|E = 10mg \text{ and } |q| = \frac{10mg}{E} = \frac{10(30.0\times10^{-9} \text{ kg})(9.80 \text{ m/s}^2)}{9.71\times10^4 \text{ V/m}} = 3.03\times10^{-11} \text{ C}$$

EVALUATE: It requires only this modest net charge for the electric force to be much larger than the weight.

23.68. **(a) IDENTIFY:** Calculate the potential due to each thin ring and integrate over the disk to find the potential. V is a scalar so no components are involved.

SET UP: Consider a thin ring of radius y and width dy. The ring has area $2\pi y\,dy$ so the charge on the ring is $dq = \sigma(2\pi y\,dy)$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: The result of Example 23.11 then says that the potential due to this thin ring at the point on the axis at a distance x from the ring is

$$dV = \frac{1}{4\pi\epsilon_0}\frac{dq}{\sqrt{x^2+y^2}} = \frac{2\pi\sigma}{4\pi\epsilon_0}\frac{y\,dy}{\sqrt{x^2+y^2}}$$

$$V = \int dV = \frac{\sigma}{2\epsilon_0}\int_0^R \frac{y\,dy}{\sqrt{x^2+y^2}} = \frac{\sigma}{2\epsilon_0}\left[\sqrt{x^2+y^2}\right]_0^R = \frac{\sigma}{2\epsilon_0}\left(\sqrt{x^2+R^2}-x\right)$$

EVALUATE: For $x \gg R$ this result should reduce to the potential of a point charge with $Q = \sigma\pi R^2$.

$$\sqrt{x^2+R^2} = x(1+R^2/x^2)^{1/2} \approx x(1+R^2/2x^2) \text{ so } \sqrt{x^2+R^2}-x \approx R^2/2x$$

Then $V \approx \frac{\sigma}{2\epsilon_0}\frac{R^2}{2x} = \frac{\sigma\pi R^2}{4\pi\epsilon_0 x} = \frac{Q}{4\pi\epsilon_0 x}$, as expected.

(b) IDENTIFY and **SET UP:** Use Eq. (23.19) to calculate E_x.

EXECUTE: $E_x = -\frac{\partial V}{\partial x} = -\frac{\sigma}{2\epsilon_0}\left(\frac{x}{\sqrt{x^2+R^2}}-1\right) = \frac{\sigma x}{2\epsilon_0}\left(\frac{1}{x}-\frac{1}{\sqrt{x^2+R^2}}\right)$.

EVALUATE: Our result agrees with Eq. (21.11) in Example 21.11.

23.69. **(a) IDENTIFY:** Use $V_a - V_b = \int_a^b \vec{\boldsymbol{E}}\cdot d\vec{\boldsymbol{l}}$.

SET UP: From Problem 22.42, $E(r) = \frac{\lambda r}{2\pi\epsilon_0 R^2}$ for $r \le R$ (inside the cylindrical charge distribution) and $E(r) = \frac{\lambda}{2\pi\epsilon_0 r}$ for $r \ge R$. Let $V = 0$ at $r = R$ (at the surface of the cylinder).

EXECUTE: $r > R$

Take point a to be at R and point b to be at r, where $r > R$. Let $d\vec{\boldsymbol{l}} = d\vec{\boldsymbol{r}}$. $\vec{\boldsymbol{E}}$ and $d\vec{\boldsymbol{r}}$ are both radially outward, so $\vec{\boldsymbol{E}}\cdot d\vec{\boldsymbol{r}} = E\,dr$. Thus $V_R - V_r = \int_R^r E\,dr$. Then $V_R = 0$ gives $V_r = -\int_R^r E\,dr$. In this interval $(r > R)$, $E(r) = \lambda/2\pi\epsilon_0 r$, so

$$V_r = -\int_R^r \frac{\lambda}{2\pi\epsilon_0 r}dr = -\frac{\lambda}{2\pi\epsilon_0}\int_R^r \frac{dr}{r} = -\frac{\lambda}{2\pi\epsilon_0}\ln\left(\frac{r}{R}\right).$$

EVALUATE: This expression gives $V_r = 0$ when $r = R$ and the potential decreases (becomes a negative number of larger magnitude) with increasing distance from the cylinder.

EXECUTE: $r < R$

Take point a at r, where $r < R$, and point b at R. $\vec{\boldsymbol{E}}\cdot d\vec{\boldsymbol{r}} = E\,dr$ as before. Thus $V_r - V_R = \int_r^R E\,dr$. Then $V_R = 0$ gives $V_r = \int_r^R E\,dr$. In this interval $(r < R)$, $E(r) = \lambda r/2\pi\epsilon_0 R^2$, so

$$V_r = \int_r^R \frac{\lambda r}{2\pi\epsilon_0 R^2}\,dr = \frac{\lambda}{2\pi\epsilon_0 R^2}\int_r^R r\,dr = \frac{\lambda}{2\pi\epsilon_0 R^2}\left(\frac{R^2}{2}-\frac{r^2}{2}\right).$$

$$V_r = \frac{\lambda}{4\pi\epsilon_0}\left(1-\left(\frac{r}{R}\right)^2\right).$$

EVALUATE: This expression also gives $V_r = 0$ when $r = R$. The potential is $\lambda/4\pi\epsilon_0$ at $r = 0$ and decreases with increasing r.

(b) EXECUTE: Graphs of V and E as functions of r are sketched in Figure 23.69.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

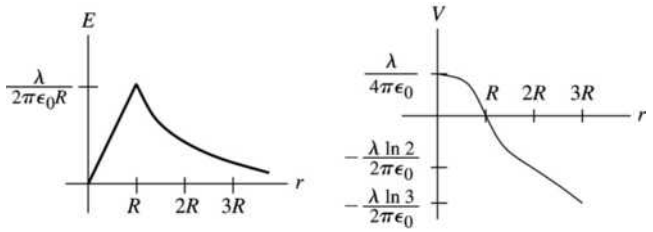


Figure 23.69

EVALUATE: E at any r is the negative of the slope of $V(r)$ at that r (Eq. 23.23).

23.70. **IDENTIFY:** Divide the rod into infinitesimal segments with charge dq. The potential dV due to the segment is $dV = \frac{1}{4\pi\epsilon_0}\frac{dq}{r}$. Integrate over the rod to find the total potential.

SET UP: $dq = \lambda dl$, with $\lambda = Q/\pi a$ and $dl = a\,d\theta$.

EXECUTE: $dV = \frac{1}{4\pi\epsilon_0}\frac{dq}{r} = \frac{1}{4\pi\epsilon_0}\frac{\lambda\,dl}{a} = \frac{1}{4\pi\epsilon_0}\frac{Q}{\pi a}\frac{dl}{a} = \frac{1}{4\pi\epsilon_0}\frac{Q\,d\theta}{\pi a}$. $V = \frac{1}{4\pi\epsilon_0}\int_0^{\pi}\frac{Q\,d\theta}{\pi a} = \frac{1}{4\pi\epsilon_0}\frac{Q}{a}$.

EVALUATE: All the charge of the ring is the same distance a from the center of curvature.

23.71. **IDENTIFY:** We must integrate to find the total energy because the energy to bring in more charge depends on the charge already present.

SET UP: If ρ is the uniform volume charge density, the charge of a spherical shell or radius r and thickness dr is $dq = \rho 4\pi r^2\,dr$, and $\rho = Q/(4/3\,\pi R^3)$. The charge already present in a sphere of radius r is $q = \rho(4/3\,\pi r^3)$. The energy to bring the charge dq to the surface of the charge q is Vdq, where V is the potential due to q, which is $q/4\pi\epsilon_0 r$.

EXECUTE: The total energy to assemble the entire sphere of radius R and charge Q is sum (integral) of the tiny increments of energy.

$$U = \int V dq = \int \frac{q}{4\pi\epsilon_0 r}\,dq = \int_0^R \frac{\rho\frac{4}{3}\pi r^3}{4\pi\epsilon_0 r}(\rho 4\pi r^2 dr) = \frac{3}{5}\left(\frac{1}{4\pi\epsilon_0}\frac{Q^2}{R}\right)$$

where we have substituted $\rho = Q/(4/3\,\pi R^3)$ and simplified the result.

EVALUATE: For a point charge, $R \to 0$ so $U \to \infty$, which means that a point charge should have infinite self-energy. This suggests that either point charges are impossible, or that our present treatment of physics is not adequate at the extremely small scale, or both.

23.72. **IDENTIFY:** $V_a - V_b = \int_a^b \vec{\boldsymbol{E}}\cdot d\vec{\boldsymbol{l}}$. The electric field is radially outward, so $\vec{\boldsymbol{E}}\cdot d\vec{\boldsymbol{l}} = E\,dr$.

SET UP: Let $a = \infty$, so $V_a = 0$.

EXECUTE: From Example 22.9, we have the following. For $r > R$: $E = \frac{kQ}{r^2}$ and $V = -kQ\int_{\infty}^{r}\frac{dr'}{r'^2} = \frac{kQ}{r}$.

For $r < R$: $E = \frac{kQr}{R^3}$ and

$$V = -\int_{\infty}^{R}\vec{\boldsymbol{E}}\cdot d\vec{\boldsymbol{r}}' - \int_R^r \vec{\boldsymbol{E}}\cdot d\vec{\boldsymbol{r}}' = \frac{kQ}{R} - \frac{kQ}{R^3}\int_R^r r'dr' = \frac{kQ}{R} - \frac{kQ}{R^3}\frac{1}{2}r'^2\Big|_R^r = \frac{kQ}{R} + \frac{kQ}{2R} - \frac{kQr^2}{2R^3} = \frac{kQ}{2R}\left[3 - \frac{r^2}{R^2}\right].$$

(b) The graphs of V and E versus r are sketched in Figure 23.72.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: For $r < R$ the potential depends on the electric field in the region r to ∞.

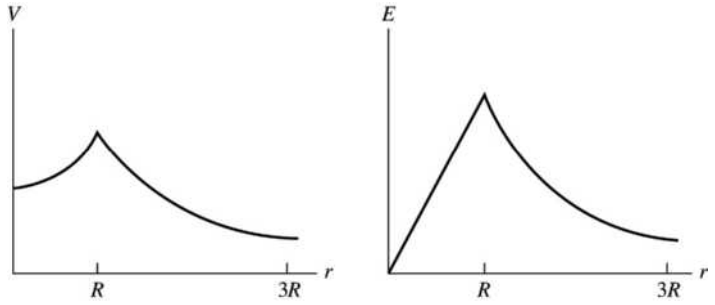

Figure 23.72

23.73. **IDENTIFY:** The sphere no longer behaves as a point charge because we are inside of it. We know how the electric field varies with distance from the center of the sphere and want to use this to find the potential difference between the center and surface, which requires integration.

SET UP: Use the result of Problem 23.72. For $r < R$, $V = \dfrac{kQ}{2R}\left(3 - \dfrac{r^2}{R^2}\right)$.

EXECUTE: At the center of the sphere, $r = 0$ and $V_1 = \dfrac{3kQ}{2R}$. At the surface of the sphere, $r = R$ and $V_2 = \dfrac{kQ}{R}$. The potential difference is $V_1 - V_2 = \dfrac{kQ}{2R} = \dfrac{(8.99\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)(4.00\times10^{-6}\ \text{C})}{2(0.0500\ \text{m})} = 3.60\times10^5\ \text{V}$.

EVALUATE: To check our answer, we could actually do the integration. We can use the fact that $E = \dfrac{kQr}{R^3}$ so $V_1 - V_2 = \int_0^R E\,dr = \dfrac{kQ}{R^3}\int_0^R r\,dr = \dfrac{kQ}{R^3}\left(\dfrac{R^2}{2}\right) = \dfrac{kQ}{2R}$.

23.74. **IDENTIFY:** For $r < c$, $E = 0$ and the potential is constant. For $r > c$, E is the same as for a point charge and $V = \dfrac{kq}{r}$.

SET UP: $V_\infty = 0$

EXECUTE: **(a)** Points a, b and c are all at the same potential, so $V_a - V_b = V_b - V_c = V_a - V_c = 0$.

$$V_c - V_\infty = \frac{kq}{R} = \frac{(8.99\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)(150\times10^{-6}\ \text{C})}{0.60\ \text{m}} = 2.25\times10^6\ \text{V}$$

(b) They are all at the same potential.

(c) Only $V_c - V_\infty$ would change; it would be -2.25×10^6 V.

EVALUATE: The voltmeter reads the potential difference between the two points to which it is connected.

23.75. **IDENTIFY** and **SET UP:** Apply $F_r = -dU/dr$ and Newton's third law.

EXECUTE: **(a)** The electrical potential energy for a spherical shell with uniform surface charge density and a point charge q outside the shell is the same as if the shell is replaced by a point charge at its center. Since $F_r = -dU/dr$, this means the force the shell exerts on the point charge is the same as if the shell were replaced by a point charge at its center. But by Newton's third law, the force q exerts on the shell is the same as if the shell were a point charge. But q can be replaced by a spherical shell with uniform surface charge and the force is the same, so the force between the shells is the same as if they were both replaced by point charges at their centers. And since the force is the same as for point charges, the electrical potential energy for the pair of spheres is the same as for a pair of point charges.

(b) The potential for solid insulating spheres with uniform charge density is the same outside of the sphere as for a spherical shell, so the same result holds.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(c) The result doesn't hold for conducting spheres or shells because when two charged conductors are brought close together, the forces between them cause the charges to redistribute and the charges are no longer distributed uniformly over the surfaces.

EVALUATE: For the insulating shells or spheres, $F = k\dfrac{|q_1 q_2|}{r^2}$ and $U = \dfrac{kq_1 q_2}{r}$, where q_1 and q_2 are the charges of the objects and r is the distance between their centers.

23.76. **IDENTIFY:** Apply Newton's second law to calculate the acceleration. Apply conservation of energy and conservation of momentum to the motions of the spheres.

SET UP: Problem 23.75 shows that $F = k\dfrac{|q_1 q_2|}{r^2}$ and $U = \dfrac{kq_1 q_2}{r}$, where q_1 and q_2 are the charges of the objects and r is the distance between their centers.

EXECUTE: Maximum speed occurs when the spheres are very far apart. Energy conservation gives $\dfrac{kq_1 q_2}{r} = \dfrac{1}{2}m_{50}v_{50}^2 + \dfrac{1}{2}m_{150}v_{150}^2$. Momentum conservation gives $m_{50}v_{50} = m_{150}v_{150}$ and $v_{50} = 3v_{150}$. $r = 0.50$ m. Solve for v_{50} and v_{150}: $v_{50} = 12.7$ m/s, $v_{150} = 4.24$ m/s. Maximum acceleration occurs just after spheres are released. $\sum F = ma$ gives $\dfrac{kq_1 q_2}{r^2} = m_{150}a_{150}$.

$$\frac{(9\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)(10^{-5}\ \text{C})(3\times10^{-5}\ \text{C})}{(0.50\ \text{m})^2} = (0.15\ \text{kg})a_{150}.\quad a_{150} = 72.0\ \text{m/s}^2 \text{ and } a_{50} = 3a_{150} = 216\ \text{m/s}^2.$$

EVALUATE: The more massive sphere has a smaller acceleration and a smaller final speed.

23.77. **IDENTIFY:** Use Eq. (23.17) to calculate V_{ab}.

SET UP: From Problem 22.45, for $R \le r \le 2R$ (between the sphere and the shell) $E = Q/4\pi\epsilon_0 r^2$. Take a at R and b at $2R$.

EXECUTE: $$V_{ab} = V_a - V_b = \int_R^{2R} E\,dr = \frac{Q}{4\pi\epsilon_0}\int_R^{2R}\frac{dr}{r^2} = \frac{Q}{4\pi\epsilon_0}\left[-\frac{1}{r}\right]_R^{2R} = \frac{Q}{4\pi\epsilon_0}\left(\frac{1}{R} - \frac{1}{2R}\right)$$

$$V_{ab} = \frac{Q}{8\pi\epsilon_0 R}$$

EVALUATE: The electric field is radially outward and points in the direction of decreasing potential, so the sphere is at higher potential than the shell.

23.78. **IDENTIFY:** $V_a - V_b = \int_a^b \vec{\boldsymbol{E}}\cdot d\vec{\boldsymbol{l}}$

SET UP: $\vec{\boldsymbol{E}}$ is radially outward, so $\vec{\boldsymbol{E}}\cdot d\vec{\boldsymbol{l}} = E\,dr$. Problem 22.44 shows that $E(r) = 0$ for $r \le a$, $E(r) = kq/r^2$ for $a < r < b$, $E(r) = 0$ for $b < r < c$ and $E(r) = kq/r^2$ for $r > c$.

EXECUTE: **(a)** At $r = c$: $V_c = -\int_\infty^c \frac{kq}{r^2}dr = \frac{kq}{c}$.

(b) At $r = b$: $V_b = -\int_\infty^c \vec{\boldsymbol{E}}\cdot d\vec{\boldsymbol{r}} - \int_c^b \vec{\boldsymbol{E}}\cdot d\vec{\boldsymbol{r}} = \frac{kq}{c} - 0 = \frac{kq}{c}$.

(c) At $r = a$: $V_a = -\int_\infty^c \vec{\boldsymbol{E}}\cdot d\vec{\boldsymbol{r}} - \int_c^b \vec{\boldsymbol{E}}\cdot d\vec{\boldsymbol{r}} - \int_b^a \vec{\boldsymbol{E}}\cdot d\vec{\boldsymbol{r}} = \frac{kq}{c} - kq\int_b^a \frac{dr}{r^2} = kq\left[\frac{1}{c} - \frac{1}{b} + \frac{1}{a}\right]$

(d) At $r = 0$: $V_0 = kq\left[\frac{1}{c} - \frac{1}{b} + \frac{1}{a}\right]$ since it is inside a metal sphere, and thus at the same potential as its surface.

EVALUATE: The potential difference between the two conductors is $V_a - V_b = kq\left[\frac{1}{a} - \frac{1}{b}\right]$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

23.79. **IDENTIFY:** Slice the rod into thin slices and use Eq. (23.14) to calculate the potential due to each slice. Integrate over the length of the rod to find the total potential at each point.

(a) SET UP: An infinitesimal slice of the rod and its distance from point *P* are shown in Figure 23.79a.

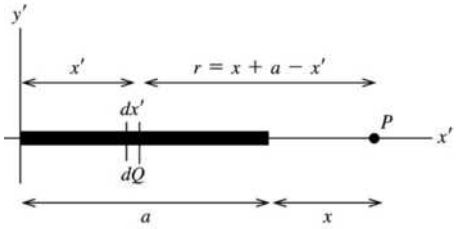

Figure 23.79a

Use coordinates with the origin at the left-hand end of the rod and one axis along the rod. Call the axes x' and y' so as not to confuse them with the distance x given in the problem.

EXECUTE: Slice the charged rod up into thin slices of width dx'. Each slice has charge $dQ = Q(dx'/a)$ and a distance $r = x + a - x'$ from point *P*. The potential at *P* due to the small slice dQ is

$$dV = \frac{1}{4\pi\epsilon_0}\left(\frac{dQ}{r}\right) = \frac{1}{4\pi\epsilon_0}\frac{Q}{a}\left(\frac{dx'}{x + a - x'}\right).$$

Compute the total V at *P* due to the entire rod by integrating dV over the length of the rod ($x' = 0$ to $x' = a$):

$$V = \int dV = \frac{Q}{4\pi\epsilon_0 a}\int_0^a \frac{dx'}{(x + a - x')} = \frac{Q}{4\pi\epsilon_0 a}[-\ln(x + a - x')]_0^a = \frac{Q}{4\pi\epsilon_0 a}\ln\left(\frac{x + a}{x}\right).$$

EVALUATE: As $x \to \infty$, $V \to \dfrac{Q}{4\pi\epsilon_0 a}\ln\left(\dfrac{x}{x}\right) = 0.$

(b) SET UP: An infinitesimal slice of the rod and its distance from point *R* are shown in Figure 23.79b.

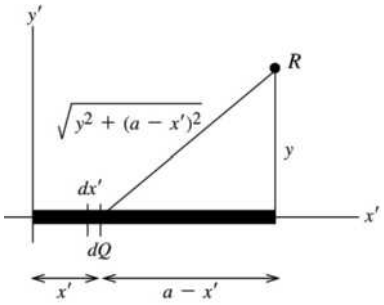

Figure 23.79b

$dQ = (Q/a)dx'$ as in part (a)

Each slice dQ is a distance $r = \sqrt{y^2 + (a - x')^2}$ from point *R*.

EXECUTE: The potential dV at *R* due to the small slice dQ is

$$dV = \frac{1}{4\pi\epsilon_0}\left(\frac{dQ}{r}\right) = \frac{1}{4\pi\epsilon_0}\frac{Q}{a}\frac{dx'}{\sqrt{y^2 + (a - x')^2}}.$$

$$V = \int dV = \frac{Q}{4\pi\epsilon_0 a}\int_0^a \frac{dx'}{\sqrt{y^2 + (a - x')^2}}.$$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

In the integral make the change of variable $u = a - x'; du = -dx'$

$$V = -\frac{Q}{4\pi\epsilon_0 a}\int_a^0 \frac{du}{\sqrt{y^2+u^2}} = -\frac{Q}{4\pi\epsilon_0 a}\left[\ln\left(u+\sqrt{y^2+u^2}\right)\right]_a^0.$$

$$V = -\frac{Q}{4\pi\epsilon_0 a}\left[\ln y - \ln\left(a+\sqrt{y^2+a^2}\right)\right] = \frac{Q}{4\pi\epsilon_0 a}\left[\ln\left(\frac{a+\sqrt{a^2+y^2}}{y}\right)\right].$$

(The expression for the integral was found in Appendix B.)

EVALUATE: As $y \to \infty$, $V \to \frac{Q}{4\pi\epsilon_0 a}\ln\left(\frac{y}{y}\right) = 0.$

(c) SET UP: *part (a):* $V = \frac{Q}{4\pi\epsilon_0 a}\ln\left(\frac{x+a}{x}\right) = \frac{Q}{4\pi\epsilon_0 a}\ln\left(1+\frac{a}{x}\right).$

From Appendix B, $\ln(1+u) = u - u^2/2\ldots$, so $\ln(1+a/x) = a/x - a^2/2x^2$ and this becomes a/x when x is large.

EXECUTE: Thus $V \to \frac{Q}{4\pi\epsilon_0 a}\left(\frac{a}{x}\right) = \frac{Q}{4\pi\epsilon_0 x}$. For large x, V becomes the potential of a point charge.

part (b): $V = \frac{Q}{4\pi\epsilon_0 a}\left[\ln\left(\frac{a+\sqrt{a^2+y^2}}{y}\right)\right] = \frac{Q}{4\pi\epsilon_0 a}\ln\left(\frac{a}{y}+\sqrt{1+\frac{a^2}{y^2}}\right).$

From Appendix B, $\sqrt{1+a^2/y^2} = (1+a^2/y^2)^{1/2} = 1 + a^2/2y^2 + \ldots$

Thus $a/y + \sqrt{1+a^2/y^2} \to 1 + a/y + a^2/2y^2 + \ldots \to 1 + a/y$. And then using $\ln(1+u) \approx u$ gives

$$V \to \frac{Q}{4\pi\epsilon_0 a}\ln(1+a/y) \to \frac{Q}{4\pi\epsilon_0 a}\left(\frac{a}{y}\right) = \frac{Q}{4\pi\epsilon_0 y}.$$

EVALUATE: For large y, V becomes the potential of a point charge.

23.80. **IDENTIFY:** The potential at the surface of a uniformly charged sphere is $V = \frac{kQ}{R}$.

SET UP: For a sphere, $V = \frac{4}{3}\pi R^3$. When the raindrops merge, the total charge and volume are conserved.

EXECUTE: **(a)** $V = \frac{kQ}{R} = \frac{k(-3.60\times10^{-12}\text{ C})}{6.50\times10^{-4}\text{ m}} = -49.8\text{ V}.$

(b) The volume doubles, so the radius increases by the cube root of two: $R_{\text{new}} = \sqrt[3]{2}\,R = 8.19\times10^{-4}$ m and the new charge is $Q_{\text{new}} = 2Q = -7.20\times10^{-12}$ C. The new potential is

$$V_{\text{new}} = \frac{kQ_{\text{new}}}{R_{\text{new}}} = \frac{k(-7.20\times10^{-12}\text{ C})}{8.19\times10^{-4}\text{ m}} = -79.0\text{ V}.$$

EVALUATE: The charge doubles but the radius also increases and the potential at the surface increases by only a factor of $\frac{2}{2^{1/3}} = 2^{2/3} \approx 1.6$.

23.81. **(a) IDENTIFY** and **SET UP:** The potential at the surface of a charged conducting sphere is given by Example 23.8: $V = \frac{1}{4\pi\epsilon_0}\frac{q}{R}$. For spheres A and B this gives

$$V_A = \frac{Q_A}{4\pi\epsilon_0 R_A} \text{ and } V_B = \frac{Q_B}{4\pi\epsilon_0 R_B}.$$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: $V_A = V_B$ gives $Q_A/4\pi\epsilon_0 R_A = Q_B/4\pi\epsilon_0 R_B$ and $Q_B/Q_A = R_B/R_A$. And then $R_A = 3R_B$ implies $Q_B/Q_A = 1/3$.

(b) IDENTIFY and **SET UP:** The electric field at the surface of a charged conducting sphere is given in Example 22.5:

$$E = \frac{1}{4\pi\epsilon_0}\frac{|q|}{R^2}.$$

EXECUTE: For spheres A and B this gives

$$E_A = \frac{|Q_A|}{4\pi\epsilon_0 R_A^2} \text{ and } E_B = \frac{|Q_B|}{4\pi\epsilon_0 R_B^2}.$$

$$\frac{E_B}{E_A} = \left(\frac{|Q_B|}{4\pi\epsilon_0 R_B^2}\right)\left(\frac{4\pi\epsilon_0 R_A^2}{|Q_A|}\right) = |Q_B/Q_A|(R_A/R_B)^2 = (1/3)(3)^2 = 3.$$

EVALUATE: The sphere with the larger radius needs more net charge to produce the same potential. We can write $E = V/R$ for a sphere, so with equal potentials the sphere with the smaller R has the larger E.

23.82. **IDENTIFY:** Apply conservation of energy, $K_a + U_a = K_b + U_b$.

SET UP: Assume the particles initially are far apart, so $U_a = 0$. The alpha particle has zero speed at the distance of closest approach, so $K_b = 0$. $1\text{ eV} = 1.60\times10^{-19}$ J. The alpha particle has charge $+2e$ and the lead nucleus has charge $+82e$.

EXECUTE: Set the alpha particle's kinetic energy equal to its potential energy: $K_a = U_b$ gives

$$11.0\text{ MeV} = \frac{k(2e)(82e)}{r} \text{ and } r = \frac{k(164)(1.60\times10^{-19}\text{ C})^2}{(11.0\times10^6\text{ eV})(1.60\times10^{-19}\text{ J/eV})} = 2.15\times10^{-14}\text{ m}.$$

EVALUATE: The calculation assumes that at the distance of closest approach the alpha particle is outside the radius of the lead nucleus.

23.83. **IDENTIFY** and **SET UP:** The potential at the surface is given by Example 23.8 and the electric field at the surface is given by Example 22.5. The charge initially on sphere 1 spreads between the two spheres such as to bring them to the same potential.

EXECUTE: **(a)** $E_1 = \frac{1}{4\pi\epsilon_0}\frac{Q_1}{R_1^2}$, $V_1 = \frac{1}{4\pi\epsilon_0}\frac{Q_1}{R_1} = R_1E_1$

(b) Two conditions must be met:

1) Let q_1 and q_2 be the final charges of each sphere. Then $q_1 + q_2 = Q_1$ (charge conservation)

2) Let V_1 and V_2 be the final potentials of each sphere. All points of a conductor are at the same potential, so $V_1 = V_2$.

$V_1 = V_2$ requires that $\frac{1}{4\pi\epsilon_0}\frac{q_1}{R_1} = \frac{1}{4\pi\epsilon_0}\frac{q_2}{R_2}$ and then $q_1/R_1 = q_2/R_2$

$$q_1R_2 = q_2R_1 = (Q_1 - q_1)R_1$$

This gives $q_1 = (R_1/[R_1 + R_2])Q_1$ and $q_2 = Q_1 - q_1 = Q_1(1 - R_1/[R_1 + R_2]) = Q_1(R_2/[R_1 + R_2])$.

(c) $V_1 = \frac{1}{4\pi\epsilon_0}\frac{q_1}{R_1} = \frac{Q_1}{4\pi\epsilon_0(R_1 + R_2)}$ and $V_2 = \frac{1}{4\pi\epsilon_0}\frac{q_2}{R_2} = \frac{Q_1}{4\pi\epsilon_0(R_1 + R_2)}$, which equals V_1 as it should.

(d) $E_1 = \frac{V_1}{R_1} = \frac{Q_1}{4\pi\epsilon_0 R_1(R_1 + R_2)}$. $E_2 = \frac{V_2}{R_2} = \frac{Q_1}{4\pi\epsilon_0 R_2(R_1 + R_2)}$.

EVALUATE: Part (a) says $q_2 = q_1(R_2/R_1)$. The sphere with the larger radius needs more charge to produce the same potential at its surface. When $R_1 = R_2$, $q_1 = q_2 = Q_1/2$. The sphere with the larger radius has the smaller electric field at its surface.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

23.84. **IDENTIFY:** Apply $V_a - V_b = \int_a^b \vec{\boldsymbol{E}} \cdot d\vec{\boldsymbol{l}}$.

SET UP: From Problem 22.65, for $r \geq R$, $E = \dfrac{kQ}{r^2}$. For $r \leq R$, $E = \dfrac{kQ}{r^2}\left[4\dfrac{r^3}{R^3} - 3\dfrac{r^4}{R^4}\right]$.

EXECUTE: **(a)** $r \geq R$: $E = \dfrac{kQ}{r^2} \Rightarrow V = -\int_\infty^r \dfrac{kQ}{r'^2}dr' = \dfrac{kQ}{r}$, which is the potential of a point charge.

(b) $r \leq R$: $E = \dfrac{kQ}{r^2}\left[4\dfrac{r^3}{R^3} - 3\dfrac{r^4}{R^4}\right]$ and

$$V = -\int_\infty^R E dr' - \int_R^r E dr' = \frac{kQ}{R}\left[1 - 2\frac{r^2}{R^2} + 2\frac{R^2}{R^2} + \frac{r^3}{R^3} - \frac{R^3}{R^3}\right] = \frac{kQ}{R}\left[\frac{r^3}{R^3} - 2\frac{r^2}{R^2} + 2\right].$$

EVALUATE: At $r = R$, $V = \dfrac{kQ}{R}$. At $r = 0$, $V = \dfrac{2kQ}{R}$. The electric field is radially outward and V increases as r decreases.

23.85. **IDENTIFY:** Apply conservation of energy: $E_1 = E_2$.

SET UP: In the collision the initial kinetic energy of the two particles is converted into potential energy at the distance of closest approach.

EXECUTE: **(a)** The two protons must approach to a distance of $2r_\text{p}$, where r_p is the radius of a proton.

$E_1 = E_2$ gives $2\left[\dfrac{1}{2}m_\text{p}v^2\right] = \dfrac{ke^2}{2r_\text{p}}$ and $v = \sqrt{\dfrac{k(1.60\times10^{-19}\text{ C})^2}{2(1.2\times10^{-15}\text{ m})(1.67\times10^{-27}\text{ kg})}} = 7.58\times10^6\text{ m/s}$.

(b) For a helium-helium collision, the charges and masses change from (a) and

$$\boldsymbol{v} = \sqrt{\frac{k(2(1.60\times10^{-19}\text{ C}))^2}{(3.5\times10^{-15}\text{ m})(2.99)(1.67\times10^{-27}\text{ kg})}} = 7.26\times10^6\text{ m/s}.$$

(c) $K = \dfrac{3kT}{2} = \dfrac{mv^2}{2}$. $T_\text{P} = \dfrac{m_\text{p}v^2}{3k} = \dfrac{(1.67\times10^{-27}\text{kg})(7.58\times10^6\text{m/s})^2}{3(1.38\times10^{-23}\text{J/K})} = 2.3\times10^9\text{K}$.

$$T_\text{He} = \frac{m_\text{He}v^2}{3k} = \frac{(2.99)(1.67\times10^{-27}\text{ kg})(7.26\times10^6\text{ m/s})^2}{3(1.38\times10^{-23}\text{ J/K})} = 6.4\times10^9\text{ K}.$$

(d) These calculations were based on the particles' average speed. The distribution of speeds ensures that there is always a certain percentage with a speed greater than the average speed, and these particles can undergo the necessary reactions in the sun's core.

EVALUATE: The kinetic energies required for fusion correspond to very high temperatures.

23.86. **IDENTIFY** and **SET UP:** Apply Eq. (23.20). $\dfrac{W_{a\to b}}{q_0} = V_a - V_b$ and $V_a - V_b = \int_a^b \vec{\boldsymbol{E}} \cdot d\vec{\boldsymbol{l}}$.

EXECUTE: **(a)** $\vec{\boldsymbol{E}} = -\dfrac{\partial V}{\partial x}\hat{\boldsymbol{i}} - \dfrac{\partial V}{\partial y}\hat{\boldsymbol{j}} - \dfrac{\partial V}{\partial z}\hat{\boldsymbol{k}} = -2Ax\hat{\boldsymbol{i}} + 6Ay\hat{\boldsymbol{j}} - 2Az\hat{\boldsymbol{k}}$

(b) A charge is moved in along the z-axis. The work done is given by

$W = q\int_{z_0}^0 \vec{\boldsymbol{E}} \cdot \hat{\boldsymbol{k}}dz = q\int_{z_0}^0 (-2Az)dz = +(Aq)z_0^2$. Therefore, $A = \dfrac{W_{a\to b}}{qz_0^2} = \dfrac{6.00\times10^{-5}\text{ J}}{(1.5\times10^{-6}\text{ C})(0.250\text{ m})^2} = 640\text{ V/m}^2$.

(c) $\vec{\boldsymbol{E}}(0,0,0.250) = -2(640\text{ V/m}^2)(0.250\text{ m})\hat{\boldsymbol{k}} = -(320\text{ V/m})\hat{\boldsymbol{k}}$.

(d) In every plane parallel to the xz-plane, y is constant, so $V(x,y,z) = Ax^2 + Az^2 - C$, where $C = 3Ay^2$.

$x^2 + z^2 = \dfrac{V + C}{A} = R^2$, which is the equation for a circle since R is constant as long as we have constant potential on those planes.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(e) $V = 1280\text{ V}$ and $y = 2.00\text{ m}$, so $x^2 + z^2 = \dfrac{1280\text{ V} + 3(640\text{ V/m}^2)(2.00\text{ m})^2}{640\text{ V/m}^2} = 14.0\text{ m}^2$ and the radius of the circle is 3.74 m.

EVALUATE: In any plane parallel to the xz-plane, $\vec{E}$ projected onto the plane is radial and hence perpendicular to the equipotential circles.

23.87. **IDENTIFY:** Apply conservation of energy to the motion of the daughter nuclei.

SET UP: Problem 23.72 shows that the electrical potential energy of the two nuclei is the same as if all their charge was concentrated at their centers.

EXECUTE: **(a)** The two daughter nuclei have half the volume of the original uranium nucleus, so their radii are smaller by a factor of the cube root of 2: $r = \dfrac{7.4\times10^{-15}\text{ m}}{\sqrt[3]{2}} = 5.9\times10^{-15}\text{ m}$.

(b) $U = \dfrac{k(46e)^2}{2r} = \dfrac{k(46)^2(1.60\times10^{-19}\text{ C})^2}{1.18\times10^{-14}\text{ m}} = 4.14\times10^{-11}\text{ J}$. $U = 2K$, where K is the final kinetic energy of each nucleus. $K = U/2 = (4.14\times10^{-11}\text{ J})/2 = 2.07\times10^{-11}\text{ J}$.

(c) If we have 10.0 kg of uranium, then the number of nuclei is

$n = \dfrac{10.0\text{ kg}}{(236\text{ u})(1.66\times10^{-27}\text{ kg/u})} = 2.55\times10^{25}$ nuclei. And each releases energy U, so

$E = nU = (2.55\times10^{25})(4.14\times10^{-11}\text{ J}) = 1.06\times10^{15}\text{ J} = 253\text{ kilotons of TNT}$.

(d) We could call an atomic bomb an "electric" bomb since the electric potential energy provides the kinetic energy of the particles.

EVALUATE: This simple model considers only the electrical force between the daughter nuclei and neglects the nuclear force.

23.88. **IDENTIFY** and **SET UP:** In part (a) apply $E = -\dfrac{\partial V}{\partial r}$. In part (b) apply Gauss's law.

EXECUTE: **(a)** For $r \le a$, $E = -\dfrac{\partial V}{\partial r} = -\dfrac{\rho_0 a^2}{18\epsilon_0}\left[-6\dfrac{r}{a^2} + 6\dfrac{r^2}{a^3}\right] = \dfrac{\rho_0 a}{3\epsilon_0}\left[\dfrac{r}{a} - \dfrac{r^2}{a^2}\right]$. For $r \ge a$, $E = -\dfrac{\partial V}{\partial r} = 0$.

$\vec{E}$ has only a radial component because V depends only on r.

(b) For $r \le a$, Gauss's law gives $E_r 4\pi r^2 = \dfrac{Q_r}{\epsilon_0} = \dfrac{\rho_0 a}{3\epsilon_0}\left[\dfrac{r}{a} - \dfrac{r^2}{a^2}\right]4\pi r^2$ and

$E_{r+dr}4\pi(r^2 + 2rdr) = \dfrac{Q_{r+dr}}{\epsilon_0} = \dfrac{\rho_0 a}{3\epsilon_0}\left[\dfrac{r+dr}{a} - \dfrac{(r^2+2rdr)}{a^2}\right]4\pi(r^2+2rdr)$. Therefore,

$\dfrac{Q_{r+dr} - Q_r}{\epsilon_0} = \dfrac{\rho(r)4\pi r^2\,dr}{\epsilon_0} \approx \dfrac{\rho_0 a 4\pi r^2 dr}{3\epsilon_0}\left[-\dfrac{2r}{a^2} + \dfrac{2}{a} - \dfrac{2r}{a^2} + \dfrac{1}{a}\right]$ and $\rho(r) = \dfrac{\rho_0}{3}\left[3 - \dfrac{4r}{a}\right] = \rho_0\left[1 - \dfrac{4r}{3a}\right]$.

(c) For $r \ge a$, $\rho(r) = 0$, so the total charge enclosed will be given by

$$Q = 4\pi\int_0^a \rho(r)r^2 dr = 4\pi\rho_0\int_0^a\left[r^2 - \frac{4r^3}{3a}\right]dr = 4\pi\rho_0\left[\frac{1}{3}r^3 - \frac{r^4}{3a}\right]_0^a = 0.$$

EVALUATE: Apply Gauss's law to a sphere of radius $r > R$. The result of part (c) says that $Q_{\text{encl}} = 0$, so $E = 0$. This agrees with the result we calculated in part (a)

23.89. **IDENTIFY:** Angular momentum and energy must be conserved.

SET UP: At the distance of closest approach the speed is not zero. $E = K + U$. $q_1 = 2e$, $q_2 = 82e$.

EXECUTE: $mv_1 b = mv_2 r_2$. $E_1 = E_2$ gives $E_1 = \dfrac{1}{2}mv_2{}^2 + \dfrac{kq_1q_2}{r_2}$. $E_1 = 11\text{ MeV} = 1.76\times10^{-12}\text{ J}$. r_2 is the distance of closest approach. Substituting in for $v_2 = v_1\left(\dfrac{b}{r_2}\right)$ we find $E_1 = E_1\dfrac{b^2}{r_2{}^2} + \dfrac{kq_1q_2}{r_2}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$(E_1)r_2^2-(kq_1q_2)r_2-E_1b^2=0$. For $b=10^{-12}$ m, $r_2=1.01\times10^{-12}$ m. For $b=10^{-13}$ m, $r_2=1.11\times10^{-13}$ m. And for $b=10^{-14}$ m, $r_2=2.54\times10^{-14}$ m.

EVALUATE: As b decreases the collision is closer to being head-on and the distance of closest approach decreases. Problem 23.82 shows that the distance of closest approach is 2.15×10^{-14} m when $b=0$.

23.90. **IDENTIFY:** Consider the potential due to an infinitesimal slice of the cylinder and integrate over the length of the cylinder to find the total potential. The electric field is along the axis of the tube and is given by $E=-\dfrac{\partial V}{\partial x}$.

SET UP: Use the expression from Example 23.11 for the potential due to each infinitesimal slice. Let the slice be at coordinate z along the x-axis, relative to the center of the tube.

EXECUTE: **(a)** For an infinitesimal slice of the finite cylinder, we have the potential

$dV=\dfrac{k\,dQ}{\sqrt{(x-z)^2+R^2}}=\dfrac{kQ}{L}\dfrac{dz}{\sqrt{(x-z)^2+R^2}}$. Integrating gives

$V=\dfrac{kQ}{L}\displaystyle\int_{-L/2}^{L/2}\dfrac{dz}{\sqrt{(x-z)^2+R^2}}=\dfrac{kQ}{L}\int_{-L/2-x}^{L/2-x}\dfrac{du}{\sqrt{u^2+R^2}}$ where $u=x-z$. Therefore,

$$V=\frac{kQ}{L}\ln\left[\frac{\sqrt{(L/2-x)^2+R^2}+(L/2-x)}{\sqrt{(L/2+x)^2+R^2}-L/2-x}\right]$$ on the cylinder axis.

(b) For $L\ll R$, $V\approx\dfrac{kQ}{L}\ln\left[\dfrac{\sqrt{(L/2-x)^2+R^2}+L/2-x}{\sqrt{(L/2+x)^2+R^2}-L/2-x}\right]\approx\dfrac{kQ}{L}\ln\left[\dfrac{\sqrt{x^2-xL+R^2}+L/2-x}{\sqrt{x^2+xL+R^2}-L/2-x}\right]$.

$$V\approx\frac{kQ}{L}\ln\left[\frac{\sqrt{1-xL/(R^2+x^2)}+(L/2-x)/\sqrt{R^2+x^2}}{\sqrt{1+xL/(R^2+x^2)}+(-L/2-x)/\sqrt{R^2+x^2}}\right]=\frac{kQ}{L}\ln\left[\frac{1-xL/2(R^2+x^2)+(L/2-x)/\sqrt{R^2+x^2}}{1+xL/2(R^2+x^2)+(-L/2-x)/\sqrt{R^2+x^2}}\right].$$

$$V\approx\frac{kQ}{L}\ln\left[\frac{1+L/2\sqrt{R^2+x^2}}{1-L/2\sqrt{R^2+x^2}}\right]=\frac{kQ}{L}\left(\ln\left[1+\frac{L}{2\sqrt{R^2+x^2}}\right]-\ln\left[1-\frac{L}{2\sqrt{R^2+x^2}}\right]\right).$$

$V\approx\dfrac{kQ}{L}\dfrac{2L}{2\sqrt{x^2+R^2}}=\dfrac{kQ}{\sqrt{x^2+R^2}}$, which is the same as for a ring.

(c) $E_x=-\dfrac{\partial V}{\partial x}=\dfrac{2kQ\left(\sqrt{(L-2x)^2+4R^2}-\sqrt{(L+2x)^2+4R^2}\right)}{\sqrt{(L-2x)^2+4R^2}\sqrt{(L+2x)^2+4R^2}}$

EVALUATE: For $L\ll R$ the expression for E_x reduces to that for a ring of charge, as given in Example 23.14.

23.91. **IDENTIFY:** When the oil drop is at rest, the upward force $|q|E$ from the electric field equals the downward weight of the drop. When the drop is falling at its terminal speed, the upward viscous force equals the downward weight of the drop.

SET UP: The volume of the drop is related to its radius r by $V=\dfrac{4}{3}\pi r^3$.

EXECUTE: **(a)** $F_g=mg=\dfrac{4\pi r^3}{3}\rho g$. $F_e=|q|E=|q|V_{AB}/d$. $F_e=F_g$ gives $|q|=\dfrac{4\pi}{3}\dfrac{\rho r^3 gd}{V_{AB}}$.

(b) $\dfrac{4\pi r^3}{3}\rho g=6\pi\eta r v_t$ gives $r=\sqrt{\dfrac{9\eta v_t}{2\rho g}}$. Using this result to replace r in the expression in part (a) gives

$|q|=\dfrac{4\pi}{3}\dfrac{\rho gd}{V_{AB}}\left[\sqrt{\dfrac{9\eta v_t}{2\rho g}}\right]^3=18\pi\dfrac{d}{V_{AB}}\sqrt{\dfrac{\eta^3 v_t^3}{2\rho g}}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(c) $|q| = 18\pi \dfrac{10^{-3}\text{ m}}{9.16\text{ V}}\sqrt{\dfrac{(1.81\times10^{-5}\text{ N}\cdot\text{s/m}^2)^3(1.00\times10^{-3}\text{ m/39.3 s})^3}{2(824\text{ kg/m}^3)(9.80\text{ m/s}^2)}} = 4.80\times10^{-19}\text{ C} = 3e$. The drop has acquired three excess electrons.

$$r = \sqrt{\frac{9(1.81\times10^{-5}\text{ N}\cdot\text{s/m}^2)(1.00\times10^{-3}\text{ m/39.3 s})}{2(824\text{ kg/m}^3)(9.80\text{ m/s}^2)}} = 5.07\times10^{-7}\text{ m} = 0.507\ \mu\text{m}.$$

EVALUATE: The weight of the drop is $\left(\dfrac{4\pi r^3}{3}\right)\rho g = 4.4\times10^{-15}$ N. The density of air at room temperature is 1.2 kg/m^3, so the buoyancy force is $\rho_{\text{air}} Vg = 6.4\times10^{-18}$ N and can be neglected.

23.92. **IDENTIFY:** $\boldsymbol{v}_{\text{cm}} = \dfrac{m_1\boldsymbol{v}_1 + m_2\boldsymbol{v}_2}{m_1 + m_2}$

SET UP: $E = K_1 + K_2 + U$, where $U = \dfrac{kq_1q_2}{r}$.

EXECUTE: **(a)** $v_{\text{cm}} = \dfrac{(6\times10^{-5}\text{ kg})(400\text{m/s}) + (3\times10^{-5}\text{ kg})(1300\text{ m/s})}{6.0\times10^{-5}\text{ kg} + 3.0\times10^{-5}\text{ kg}} = 700\text{ m/s}$

(b) $E_{\text{rel}} = \dfrac{1}{2}m_1v_1^{\,2} + \dfrac{1}{2}m_2v_2^{\,2} + \dfrac{kq_1q_2}{r} - \dfrac{1}{2}(m_1 + m_2)v_{\text{cm}}^2$. After expanding the center of mass velocity and collecting like terms $E_{\text{rel}} = \dfrac{1}{2}\dfrac{m_1m_2}{m_1 + m_2}[v_1^2 + v_2^2 - 2v_1v_2] + \dfrac{kq_1q_2}{r} = \dfrac{1}{2}\mu(v_1 - v_2)^2 + \dfrac{kq_1q_2}{r}$.

(c) $E_{\text{rel}} = \dfrac{1}{2}(2.0\times10^{-5}\text{ kg})(900\text{ m/s})^2 + \dfrac{k(2.0\times10^{-6}\text{ C})(-5.0\times10^{-6}\text{ C})}{0.0090\text{ m}} = -1.9\text{ J}$

(d) Since the energy is less than zero, the system is "bound."

(e) The maximum separation is when the velocity is zero: $-1.9\text{ J} = \dfrac{kq_1q_2}{r}$ gives

$$r = \frac{k(2.0\times10^{-6}\text{ C})(-5.0\times10^{-6}\text{ C})}{-1.9\text{ J}} = 0.047\text{ m}.$$

(f) Now using $v_1 = 400$ m/s, and $\boldsymbol{v}_2 = 1800$ m/s, we find $E_{\text{rel}} = +9.6$ J. The particles do escape, and the final relative velocity is $|v_1 - v_2| = \sqrt{\dfrac{2E_{\text{rel}}}{\mu}} = \sqrt{\dfrac{2(9.6\text{ J})}{2.0\times10^{-5}\text{ kg}}} = 980\text{ m/s}$.

EVALUATE: For an isolated system the velocity of the center of mass is constant and the system must retain the kinetic energy associated with the motion of the center of mass.

24

CAPACITANCE AND DIELECTRICS

24.1. **IDENTIFY:** The capacitance depends on the geometry (area and plate separation) of the plates.

SET UP: For a parallel-plate capacitor, $V_{ab} = Ed$, $E = \dfrac{Q}{\epsilon_0 A}$, and $C = \dfrac{Q}{V_{ab}}$.

EXECUTE: **(a)** $V_{ab} = Ed = (4.00\times10^{6}\ \text{V/m})(2.50\times10^{-3}\ \text{m}) = 1.00\times10^{4}\ \text{V}$.

(b) Solving for the area gives

$$A = \frac{Q}{E\epsilon_0} = \frac{80.0\times10^{-9}\ \text{C}}{(4.00\times10^{6}\ \text{V/m})[8.854\times10^{-12}\ \text{C}^2/(\text{N}\cdot\text{m}^2)]} = 2.26\times10^{-3}\ \text{m}^2 = 22.6\ \text{cm}^2.$$

(c) $C = \dfrac{Q}{V_{ab}} = \dfrac{80.0\times10^{-9}\ \text{C}}{1.00\times10^{4}\ \text{V}} = 8.00\times10^{-12}\ \text{F} = 8.00\ \text{pF}.$

EVALUATE: The capacitance is reasonable for laboratory capacitors, but the area is rather large.

24.2. **IDENTIFY** and **SET UP:** $C = \dfrac{\epsilon_0 A}{d}$, $C = \dfrac{Q}{V}$ and $V = Ed$.

(a) $C = \epsilon_0 \dfrac{A}{d} = \epsilon_0 \dfrac{0.00122\ \text{m}^2}{0.00328\ \text{m}} = 3.29\ \text{pF}$

(b) $V = \dfrac{Q}{C} = \dfrac{4.35\times10^{-8}\ \text{C}}{3.29\times10^{-12}\ \text{F}} = 13.2\ \text{kV}$

(c) $E = \dfrac{V}{d} = \dfrac{13.2\times10^{3}\ \text{V}}{0.00328\ \text{m}} = 4.02\times10^{6}\ \text{V/m}$

EVALUATE: The electric field is uniform between the plates, at points that aren't close to the edges.

24.3. **IDENTIFY** and **SET UP:** It is a parallel-plate air capacitor, so we can apply the equations of Section 24.1.

EXECUTE: **(a)** $C = \dfrac{Q}{V_{ab}}$ so $V_{ab} = \dfrac{Q}{C} = \dfrac{0.148\times10^{-6}\ \text{C}}{245\times10^{-12}\ \text{F}} = 604\ \text{V}$

(b) $C = \dfrac{\epsilon_0 A}{d}$ so $A = \dfrac{Cd}{\epsilon_0} = \dfrac{(245\times10^{-12}\ \text{F})(0.328\times10^{-3}\ \text{m})}{8.854\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2} = 9.08\times10^{-3}\ \text{m}^2 = 90.8\ \text{cm}^2$

(c) $V_{ab} = Ed$ so $E = \dfrac{V_{ab}}{d} = \dfrac{604\ \text{V}}{0.328\times10^{-3}\ \text{m}} = 1.84\times10^{6}\ \text{V/m}$

(d) $E = \dfrac{\sigma}{\epsilon_0}$ so $\sigma = E\epsilon_0 = (1.84\times10^{6}\ \text{V/m})(8.854\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2) = 1.63\times10^{-5}\ \text{C/m}^2$

EVALUATE: We could also calculate σ directly as Q/A. $\sigma = \dfrac{Q}{A} = \dfrac{0.148\times10^{-6}\ \text{C}}{9.08\times10^{-3}\ \text{m}^2} = 1.63\times10^{-5}\ \text{C/m}^2$, which checks.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

24.4. **IDENTIFY:** $C = \epsilon_0 \dfrac{A}{d}$ when there is air between the plates.

SET UP: $A = (3.0\times10^{-2}\ \text{m})^2$ is the area of each plate.

EXECUTE: $C = \dfrac{(8.854\times10^{-12}\ \text{F/m})(3.0\times10^{-2}\ \text{m})^2}{5.0\times10^{-3}\ \text{m}} = 1.59\times10^{-12}\ \text{F} = 1.59\ \text{pF}$

EVALUATE: C increases when A increases and C increases when d decreases.

24.5. **IDENTIFY:** $C = \dfrac{Q}{V_{ab}}$. $C = \dfrac{\epsilon_0 A}{d}$.

SET UP: When the capacitor is connected to the battery, $V_{ab} = 12.0$ V.

EXECUTE: **(a)** $Q = CV_{ab} = (10.0\times10^{-6}\ \text{F})(12.0\ \text{V}) = 1.20\times10^{-4}\ \text{C} = 120\ \mu\text{C}$

(b) When d is doubled C is halved, so Q is halved. $Q = 60\ \mu$C.

(c) If r is doubled, A increases by a factor of 4. C increases by a factor of 4 and Q increases by a factor of 4. $Q = 480\ \mu$C.

EVALUATE: When the plates are moved apart, less charge on the plates is required to produce the same potential difference. With the separation of the plates constant, the electric field must remain constant to produce the same potential difference. The electric field depends on the surface charge density, σ. To produce the same σ, more charge is required when the area increases.

24.6. **IDENTIFY:** $C = \dfrac{Q}{V_{ab}}$. $C = \dfrac{\epsilon_0 A}{d}$.

SET UP: When the capacitor is connected to the battery, enough charge flows onto the plates to make $V_{ab} = 12.0$ V.

EXECUTE: **(a)** 12.0 V

(b) (i) When d is doubled, C is halved. $V_{ab} = \dfrac{Q}{C}$ and Q is constant, so V doubles. $V = 24.0$ V.

(ii) When r is doubled, A increases by a factor of 4. V decreases by a factor of 4 and $V = 3.0$ V.

EVALUATE: The electric field between the plates is $E = Q/\epsilon_0 A$. $V_{ab} = Ed$. When d is doubled E is unchanged and V doubles. When A is increased by a factor of 4, E decreases by a factor of 4 so V decreases by a factor of 4.

24.7. **IDENTIFY:** $C = \dfrac{\epsilon_0 A}{d}$. Solve for d.

SET UP: Estimate $r = 1.0$ cm. $A = \pi r^2$.

EXECUTE: $C = \dfrac{\epsilon_0 A}{d}$ so $d = \dfrac{\epsilon_0 \pi r^2}{C} = \dfrac{\epsilon_0 \pi (0.010\ \text{m})^2}{1.00\times10^{-12}\ \text{F}} = 2.8$ mm.

EVALUATE: The separation between the pennies is nearly a factor of 10 smaller than the diameter of a penny, so it is a reasonable approximation to treat them as infinite sheets.

24.8. **INCREASE:** $C = \dfrac{Q}{V_{ab}}$. $V_{ab} = Ed$. $C = \dfrac{\epsilon_0 A}{d}$.

SET UP: We want $E = 1.00\times10^4$ N/C when $V = 100$ V.

EXECUTE: **(a)** $d = \dfrac{V_{ab}}{E} = \dfrac{1.00\times10^2\ \text{V}}{1.00\times10^4\ \text{N/C}} = 1.00\times10^{-2}\ \text{m} = 1.00\ \text{cm}.$

$A = \dfrac{Cd}{\epsilon_0} = \dfrac{(5.00\times10^{-12}\ \text{F})(1.00\times10^{-2}\ \text{m})}{8.854\times10^{-12}\ \text{C}^2/(\text{N}\cdot\text{m}^2)} = 5.65\times10^{-3}\ \text{m}^2$. $A = \pi r^2$ so

$r = \sqrt{\dfrac{A}{\pi}} = 4.24\times10^{-2}\ \text{m} = 4.24\ \text{cm}.$

(b) $Q = CV_{ab} = (5.00\times10^{-12}\ \text{F})(1.00\times10^2\ \text{V}) = 5.00\times10^{-10}\ \text{C} = 500\ \text{pC}$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: $C = \dfrac{\epsilon_0 A}{d}$. We could have a larger d, along with a larger A, and still achieve the required C without exceeding the maximum allowed E.

24.9. **IDENTIFY:** The energy stored in a capacitor depends on its capacitance, which in turn depends on its geometry.

SET UP: $C = Q/V$ for any capacitor, and $C = \dfrac{\epsilon_0 A}{d}$ for a parallel-plate capacitor.

EXECUTE: **(a)** $C = \dfrac{Q}{V} = \dfrac{2.40\times10^{-10}\text{ C}}{42.0\text{ V}} = 5.714\times10^{-12}\text{ F}$. Using $C = \dfrac{\epsilon_0 A}{d}$ gives

$$d = \frac{\epsilon_0 A}{C} = \frac{(8.854\times10^{-12}\text{ C}^2/(\text{N}\cdot\text{m}^2))(6.80\times10^{-4}\text{ m}^2)}{5.714\times10^{-12}\text{ F}} = 1.05\text{ mm}.$$

(b) $d = 2.10\times10^{-3}$ m. $C = \dfrac{\epsilon_0 A}{d} = \dfrac{5.714\times10^{-12}\text{ F}}{2} = 2.857\times10^{-12}$ F. $V = \dfrac{Q}{C}$, so $V = 2(42.0\text{ V}) = 84.0$ V.

EVALUATE: Doubling the plate separation halves the capacitance, so twice the potential difference is required to keep the same charge on the plates.

24.10. **IDENTIFY:** Capacitance depends on the geometry of the object.

(a) SET UP: The capacitance of a cylindrical capacitor is $C = \dfrac{2\pi\epsilon_0 L}{\ln(r_b/r_a)}$. Solving for r_b gives $r_b = r_a e^{2\pi\epsilon_0 L/C}$.

EXECUTE: Substituting in the numbers for the exponent gives

$$\frac{2\pi(8.85\times10^{-12}\text{ C}^2/\text{N}\cdot\text{m}^2)(0.120\text{ m})}{3.67\times10^{-11}\text{ F}} = 0.182$$

Now use this value to calculate r_b: $r_b = r_a e^{0.182} = (0.250\text{ cm})e^{0.182} = 0.300$ cm

(b) SET UP: For any capacitor, $C = Q/V$ and $\lambda = Q/L$. Combining these equations and substituting the numbers gives $\lambda = Q/L = CV/L$.

EXECUTE: Numerically we get

$$\lambda = \frac{CV}{L} = \frac{(3.67\times10^{-11}\text{ F})(125\text{ V})}{0.120\text{ m}} = 3.82\times10^{-8}\text{ C/m} = 38.2\text{ nC/m}$$

EVALUATE: The distance between the surfaces of the two cylinders would be only 0.050 cm, which is just 0.50 mm. These cylinders would have to be carefully constructed.

24.11. **IDENTIFY:** Apply the results of Example 24.4. $C = Q/V$.

SET UP: $r_a = 0.50$ mm, $r_b = 5.00$ mm

EXECUTE: **(a)** $C = \dfrac{L2\pi\epsilon_0}{\ln(r_b/r_a)} = \dfrac{(0.180\text{ m})2\pi\epsilon_0}{\ln(5.00/0.50)} = 4.35\times10^{-12}$ F.

(b) $V = Q/C = (10.0\times10^{-12}\text{ C})/(4.35\times10^{-12}\text{ F}) = 2.30$ V

EVALUATE: $\dfrac{C}{L} = 24.2$ pF. This value is similar to those in Example 24.4. The capacitance is determined entirely by the dimensions of the cylinders.

24.12. **IDENTIFY** and **SET UP:** Use the expression for C/L derived in Example 24.4. Then use Eq. (24.1) to calculate Q.

EXECUTE: **(a)** From Example 24.4, $\dfrac{C}{L} = \dfrac{2\pi\epsilon_0}{\ln(r_b/r_a)}$

$$\frac{C}{L} = \frac{2\pi(8.854\times10^{-12}\text{ C}^2/\text{N}\cdot\text{m}^2)}{\ln(3.5\text{ mm}/1.5\text{ mm})} = 6.57\times10^{-11}\text{ F/m} = 66\text{ pF/m}$$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) $C = (6.57\times10^{-11}\ \text{F/m})(2.8\ \text{m}) = 1.84\times10^{-10}\ \text{F}$.

$Q = CV = (1.84\times10^{-10}\ \text{F})(350\times10^{-3}\ \text{V}) = 6.4\times10^{-11}\ \text{C} = 64\ \text{pC}$

The conductor at higher potential has the positive charge, so there is +64 pC on the inner conductor and −64 pC on the outer conductor.

EVALUATE: C depends only on the dimensions of the capacitor. Q and V are proportional.

24.13. **IDENTIFY:** We can use the definition of capacitance to find the capacitance of the capacitor, and then relate the capacitance to geometry to find the inner radius.

(a) SET UP: By the definition of capacitance, $C = Q/V$.

EXECUTE: $C = \dfrac{Q}{V} = \dfrac{3.30\times10^{-9}\ \text{C}}{2.20\times10^{2}\ \text{V}} = 1.50\times10^{-11}\ \text{F} = 15.0\ \text{pF}$

(b) SET UP: The capacitance of a spherical capacitor is $C = 4\pi\epsilon_0\dfrac{r_a r_b}{r_b - r_a}$.

EXECUTE: Solve for r_a and evaluate using $C = 15.0$ pF and $r_b = 4.00$ cm, giving $r_a = 3.09$ cm.

(c) SET UP: We can treat the inner sphere as a point charge located at its center and use Coulomb's law, $E = \dfrac{1}{4\pi\epsilon_0}\dfrac{q}{r^2}$.

EXECUTE: $E = \dfrac{(9.00\times10^{9}\ \text{N}\cdot\text{m}^2/\text{C}^2)(3.30\times10^{-9}\ \text{C})}{(0.0309\ \text{m})^2} = 3.12\times10^{4}\ \text{N/C}$

EVALUATE: Outside the capacitor, the electric field is zero because the charges on the spheres are equal in magnitude but opposite in sign.

24.14. **IDENTIFY:** Apply the results of Example 24.3. $C = Q/V$.

SET UP: $r_a = 15.0$ cm. Solve for r_b.

EXECUTE: **(a)** For two concentric spherical shells, the capacitance is $C = \dfrac{1}{k}\left(\dfrac{r_a r_b}{r_b - r_a}\right)$. $kCr_b - kCr_a = r_a r_b$

and $r_b = \dfrac{kCr_a}{kC - r_a} = \dfrac{k(116\times10^{-12}\ \text{F})(0.150\ \text{m})}{k(116\times10^{-12}\ \text{F}) - 0.150\ \text{m}} = 0.175\ \text{m}$.

(b) $V = 220$ V and $Q = CV = (116\times10^{-12}\ \text{F})(220\ \text{V}) = 2.55\times10^{-8}\ \text{C}$.

EVALUATE: A parallel-plate capacitor with $A = 4\pi r_a r_b = 0.33\ \text{m}^2$ and $d = r_b - r_a = 2.5\times10^{-2}$ m has $C = \dfrac{\epsilon_0 A}{d} = 117$ pF, in excellent agreement with the value of C for the spherical capacitor.

24.15. **IDENTIFY:** For capacitors in series the voltage across the combination equals the sum of the voltages in the individual capacitors. For capacitors in parallel the voltage across the combination is the same as the voltage across each individual capacitor.

SET UP and **EXECUTE:** **(a)** Connect the capacitors in series so their voltages will add.

(b) $V = V_1 + V_2 + V_3 + \cdots = NV_1$, where N is the number of capacitors in the series combination, since the capacitors are identical. $N = \dfrac{V}{V_1} = \dfrac{500\ \text{V}}{0.10\ \text{V}} = 5000$.

EVALUATE: It requires many small cells to produce a large voltage surge.

24.16. **IDENTIFY:** The capacitors between b and c are in parallel. This combination is in series with the 15 pF capacitor.

SET UP: Let $C_1 = 15$ pF, $C_2 = 9.0$ pF and $C_3 = 11$ pF.

EXECUTE: **(a)** For capacitors in parallel, $C_{\text{eq}} = C_1 + C_2 + \cdots$ so $C_{23} = C_2 + C_3 = 20$ pF.

(b) $C_1 = 15$ pF is in series with $C_{23} = 20$ pF. For capacitors in series, $\dfrac{1}{C_{\text{eq}}} = \dfrac{1}{C_1} + \dfrac{1}{C_2} + \cdots$ so

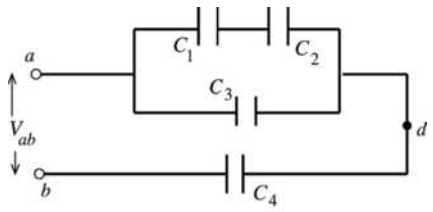
$\dfrac{1}{C_{123}} = \dfrac{1}{C_1} + \dfrac{1}{C_{23}}$ and $C_{123} = \dfrac{C_1 C_{23}}{C_1 + C_{23}} = \dfrac{(15\ \text{pF})(20\ \text{pF})}{15\ \text{pF} + 20\ \text{pF}} = 8.6\ \text{pF}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: For capacitors in parallel the equivalent capacitance is larger than any of the individual capacitors. For capacitors in series the equivalent capacitance is smaller than any of the individual capacitors.

24.17. **IDENTIFY:** Replace series and parallel combinations of capacitors by their equivalents. In each equivalent network apply the rules for Q and V for capacitors in series and parallel; start with the simplest network and work back to the original circuit.

SET UP: Do parts (a) and (b) together. The capacitor network is drawn in Figure 24.17a.

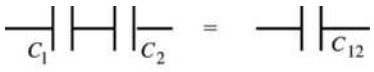


$C_1 = C_2 = C_3 = C_4 = 4.00\ \mu\text{F}$

$V_{ab} = 28.0\ \text{V}$

Figure 24.17a

EXECUTE: Simplify the circuit by replacing the capacitor combinations by their equivalents: C_1 and C_2 are in series and are equivalent to C_{12} (Figure 24.17b).

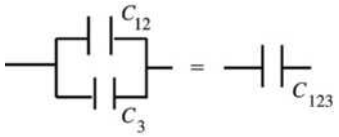


$$\frac{1}{C_{12}} = \frac{1}{C_1} + \frac{1}{C_2}$$

Figure 24.17b

$$C_{12} = \frac{C_1 C_2}{C_1 + C_2} = \frac{(4.00\times10^{-6}\ \text{F})(4.00\times10^{-6}\ \text{F})}{4.00\times10^{-6}\ \text{F} + 4.00\times10^{-6}\ \text{F}} = 2.00\times10^{-6}\ \text{F}$$

C_{12} and C_3 are in parallel and are equivalent to C_{123} (Figure 24.17c).



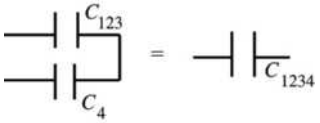
$C_{123} = C_{12} + C_3$

$C_{123} = 2.00\times10^{-6}\ \text{F} + 4.00\times10^{-6}\ \text{F}$

$C_{123} = 6.00\times10^{-6}\ \text{F}$

Figure 24.17c

C_{123} and C_4 are in series and are equivalent to C_{1234} (Figure 24.17d).

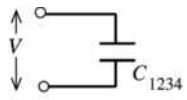


$$\frac{1}{C_{1234}} = \frac{1}{C_{123}} + \frac{1}{C_4}$$

Figure 24.17d

$$C_{1234} = \frac{C_{123} C_4}{C_{123} + C_4} = \frac{(6.00\times10^{-6}\ \text{F})(4.00\times10^{-6}\ \text{F})}{6.00\times10^{-6}\ \text{F} + 4.00\times10^{-6}\ \text{F}} = 2.40\times10^{-6}\ \text{F}$$

The circuit is equivalent to the circuit shown in Figure 24.17e.



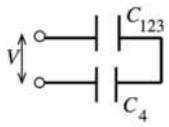
$V_{1234} = V = 28.0\ \text{V}$

$Q_{1234} = C_{1234} V = (2.40\times10^{-6}\ \text{F})(28.0\ \text{V}) = 67.2\ \mu\text{C}$

Figure 24.17e

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

Now build back up the original circuit, step by step. C_{1234} represents C_{123} and C_4 in series (Figure 24.17f).



$Q_{123} = Q_4 = Q_{1234} = 67.2\ \mu\text{C}$
(charge same for capacitors in series)

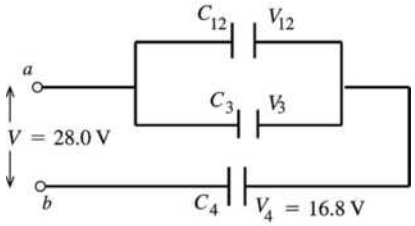
Figure 24.17f

Then $V_{123} = \dfrac{Q_{123}}{C_{123}} = \dfrac{67.2\ \mu\text{C}}{6.00\ \mu\text{F}} = 11.2\ \text{V}$

$V_4 = \dfrac{Q_4}{C_4} = \dfrac{67.2\ \mu\text{C}}{4.00\ \mu\text{F}} = 16.8\ \text{V}$

Note that $V_4 + V_{123} = 16.8\ \text{V} + 11.2\ \text{V} = 28.0\ \text{V}$, as it should.

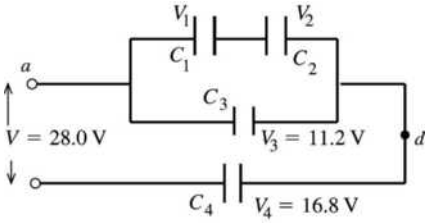
Next consider the circuit as written in Figure 24.17g.



$V_3 = V_{12} = 28.0\ \text{V} - V_4$
$V_3 = 11.2\ \text{V}$
$Q_3 = C_3 V_3 = (4.00\ \mu\text{F})(11.2\ \text{V})$
$Q_3 = 44.8\ \mu\text{C}$
$Q_{12} = C_{12} V_{12} = (2.00\ \mu\text{F})(11.2\ \text{V})$
$Q_{12} = 22.4\ \mu\text{C}$

Figure 24.17g

Finally, consider the original circuit, as shown in Figure 24.17h.



$Q_1 = Q_2 = Q_{12} = 22.4\ \mu\text{C}$
(charge same for capacitors in series)
$V_1 = \dfrac{Q_1}{C_1} = \dfrac{22.4\ \mu\text{C}}{4.00\ \mu\text{F}} = 5.6\ \text{V}$
$V_2 = \dfrac{Q_2}{C_2} = \dfrac{22.4\ \mu\text{C}}{4.00\ \mu\text{F}} = 5.6\ \text{V}$

Figure 24.17h

Note that $V_1 + V_2 = 11.2\ \text{V},$ which equals V_3 as it should.

Summary: $Q_1 = 22.4\ \mu\text{C}, V_1 = 5.6\ \text{V}$

$Q_2 = 22.4\ \mu\text{C}, V_2 = 5.6\ \text{V}$

$Q_3 = 44.8\ \mu\text{C}, V_3 = 11.2\ \text{V}$

$Q_4 = 67.2\ \mu\text{C}, V_4 = 16.8\ \text{V}$

(c) $V_{ad} = V_3 = 11.2\ \text{V}$

EVALUATE: $V_1 + V_2 + V_4 = V,$ or $V_3 + V_4 = V$. $Q_1 = Q_2, Q_1 + Q_3 = Q_4$ and $Q_4 = Q_{1234}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

24.18. **IDENTIFY:** The two capacitors are in series. The equivalent capacitance is given by $\frac{1}{C_{eq}}=\frac{1}{C_1}+\frac{1}{C_2}$.

SET UP: For capacitors in series the charges are the same and the potentials add to give the potential across the network.

EXECUTE: **(a)** $\frac{1}{C_{eq}}=\frac{1}{C_1}+\frac{1}{C_2}=\frac{1}{(3.0\times10^{-6}\text{ F})}+\frac{1}{(5.0\times10^{-6}\text{ F})}=5.33\times10^{5}\text{ F}^{-1}$. $C_{eq}=1.88\times10^{-6}$ F. Then $Q=VC_{eq}=(52.0\text{ V})(1.88\times10^{-6}\text{ F})=9.75\times10^{-5}$ C. Each capacitor has charge 9.75×10^{-5} C.

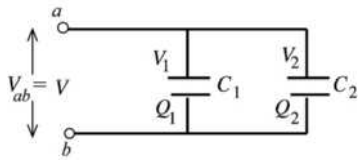
(b) $V_1=Q/C_1=9.75\times10^{-5}\text{ C}/3.0\times10^{-6}\text{ F}=32.5\text{ V}$.

$V_2=Q/C_2=9.75\times10^{-5}\text{ C}/5.0\times10^{-6}\text{ F}=19.5\text{ V}$.

EVALUATE: $V_1+V_2=52.0$ V, which is equal to the applied potential V_{ab}. The capacitor with the smaller C has the larger V.

24.19. **IDENTIFY:** The two capacitors are in parallel so the voltage is the same on each, and equal to the applied voltage V_{ab}.

SET UP: Do parts (a) and (b) together. The network is sketched in Figure 24.19.



EXECUTE: $V_1=V_2=V$

$V_1=52.0$ V

$V_2=52.0$ V

Figure 24.19

$C=Q/V$ so $Q=CV$

$Q_1=C_1V_1=(3.00\ \mu\text{F})(52.0\text{ V})=156\ \mu\text{C}$. $Q_2=C_2V_2=(5.00\ \mu\text{F})(52.0\text{ V})=260\ \mu\text{C}$.

EVALUATE: To produce the same potential difference, the capacitor with the larger C has the larger Q.

24.20. **IDENTIFY:** For capacitors in parallel the voltages are the same and the charges add. For capacitors in series, the charges are the same and the voltages add. $C=Q/V$.

SET UP: C_1 and C_2 are in parallel and C_3 is in series with the parallel combination of C_1 and C_2.

EXECUTE: **(a)** C_1 and C_2 are in parallel and so have the same potential across them:

$V_1=V_2=\frac{Q_2}{C_2}=\frac{40.0\times10^{-6}\text{ C}}{3.00\times10^{-6}\text{ F}}=13.33\text{ V}$. Therefore, $Q_1=V_1C_1=(13.33\text{ V})(6.00\times10^{-6}\text{ F})=80.0\times10^{-6}$ C.

Since C_3 is in series with the parallel combination of C_1 and C_2, its charge must be equal to their combined charge: $Q_3=40.0\times10^{-6}\text{ C}+80.0\times10^{-6}\text{ C}=120.0\times10^{-6}$ C.

(b) The total capacitance is found from $\frac{1}{C_{tot}}=\frac{1}{C_{12}}+\frac{1}{C_3}=\frac{1}{9.00\times10^{-6}\text{ F}}+\frac{1}{5.00\times10^{-6}\text{ F}}$ and

$C_{tot}=3.21\ \mu\text{F}$. $V_{ab}=\frac{Q_{tot}}{C_{tot}}=\frac{120.0\times10^{-6}\text{ C}}{3.21\times10^{-6}\text{ F}}=37.4\text{ V}$.

EVALUATE: $V_3=\frac{Q_3}{C_3}=\frac{120.0\times10^{-6}\text{ C}}{5.00\times10^{-6}\text{ F}}=24.0\text{ V}$. $V_{ab}=V_1+V_3$.

24.21. **IDENTIFY:** Three of the capacitors are in series, and this combination is in parallel with the other two capacitors.

SET UP: For capacitors in series the voltages add and the charges are the same; $\frac{1}{C_{eq}}=\frac{1}{C_1}+\frac{1}{C_2}+\cdots$. For capacitors in parallel the voltages are the same and the charges add; $C_{eq}=C_1+C_2+\text{L}$. $C=\frac{Q}{V}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: **(a)** The equivalent capacitance of the 18.0 nF, 30.0 nF and 10.0 nF capacitors in series is 5.29 nF. When these capacitors are replaced by their equivalent we get the network sketched in Figure 24.21. The equivalent capacitance of these three capacitors in parallel is 19.3 nF, and this is the equivalent capacitance of the original network.

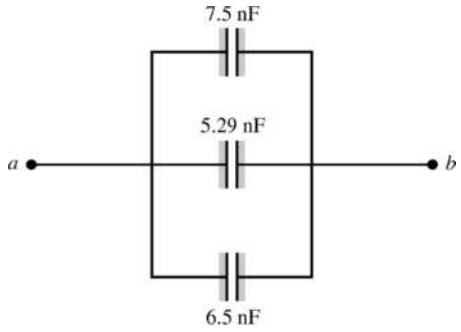


Figure 24.21

(b) $Q_{\text{tot}} = C_{\text{eq}}V = (19.3\text{ nF})(25\text{ V}) = 482\text{ nC}$.

(c) The potential across each capacitor in the parallel network of Figure 24.21 is 25 V.
$Q_{6.5} = C_{6.5}V_{6.5} = (6.5\text{ nF})(25\text{ V}) = 162\text{ nC}$.

d) 25 V.

EVALUATE: As with most circuits, we must go through a series of steps to simplify it as we solve for the unknowns.

24.22. **IDENTIFY:** Simplify the network by replacing series and parallel combinations of capacitors by their equivalents.

SET UP: For capacitors in series the voltages add and the charges are the same; $\frac{1}{C_{\text{eq}}} = \frac{1}{C_1} + \frac{1}{C_2} + \cdots$ For capacitors in parallel the voltages are the same and the charges add; $C_{\text{eq}} = C_1 + C_2 + \cdots$ $C = \frac{Q}{V}$.

EXECUTE: **(a)** The equivalent capacitance of the $5.0\ \mu\text{F}$ and $8.0\ \mu\text{F}$ capacitors in parallel is $13.0\ \mu\text{F}$. When these two capacitors are replaced by their equivalent we get the network sketched in Figure 24.22. The equivalent capacitance of these three capacitors in series is $3.47\ \mu\text{F}$.

(b) $Q_{\text{tot}} = C_{\text{tot}}V = (3.47\ \mu\text{F})(50.0\text{ V}) = 174\ \mu\text{C}$

(c) Q_{tot} is the same as Q for each of the capacitors in the series combination shown in Figure 24.22, so Q for each of the capacitors is $174\ \mu\text{C}$.

EVALUATE: The voltages across each capacitor in Figure 24.22 are $V_{10} = \frac{Q_{\text{tot}}}{C_{10}} = 17.4\text{ V}$,

$V_{13} = \frac{Q_{\text{tot}}}{C_{13}} = 13.4\text{ V}$ and $V_9 = \frac{Q_{\text{tot}}}{C_9} = 19.3\text{ V}$. $V_{10} + V_{13} + V_9 = 17.4\text{ V} + 13.4\text{ V} + 19.3\text{ V} = 50.1\text{ V}$. The sum of the voltages equals the applied voltage, apart from a small difference due to rounding.

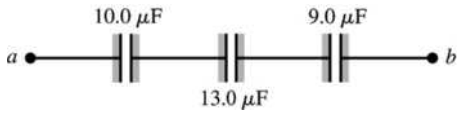

Figure 24.22

24.23. **IDENTIFY:** Refer to Figure 24.10b in the textbook. For capacitors in parallel, $C_{\text{eq}} = C_1 + C_2 + \cdots$. For capacitors in series, $\dfrac{1}{C_{\text{eq}}} = \dfrac{1}{C_1} + \dfrac{1}{C_2} + \cdots$.

SET UP: The $11\ \mu\text{F}$, $4\ \mu\text{F}$ and replacement capacitor are in parallel and this combination is in series with the $9.0\ \mu\text{F}$ capacitor.

EXECUTE: $\dfrac{1}{C_{\text{eq}}} = \dfrac{1}{8.0\ \mu\text{F}} = \left(\dfrac{1}{(11 + 4.0 + x)\mu\text{F}} + \dfrac{1}{9.0\ \mu\text{F}}\right)$. $(15 + x)\mu\text{F} = 72\ \mu\text{F}$ and $x = 57\ \mu\text{F}$.

EVALUATE: Increasing the capacitance of the one capacitor by a large amount makes a small increase in the equivalent capacitance of the network.

24.24. **IDENTIFY:** Apply $C = Q/V$. $C = \dfrac{\epsilon_0 A}{d}$. The work done to double the separation equals the change in the stored energy.

SET UP: $U = \dfrac{1}{2}CV^2 = \dfrac{Q^2}{2C}$.

EXECUTE: **(a)** $V = Q/C = (2.55\ \mu\text{C})/(920 \times 10^{-12}\ \text{F}) = 2770\ \text{V}$

(b) $C = \dfrac{\epsilon_0 A}{d}$ says that since the charge is kept constant while the separation doubles, that means that the capacitance halves and the voltage doubles to 5540 V.

(c) $U = \dfrac{Q^2}{2C} = \dfrac{(2.55 \times 10^{-6}\ \text{C})^2}{2(920 \times 10^{-12}\ \text{F})} = 3.53 \times 10^{-3}\ \text{J}$. If the separation is doubled while Q stays the same, the capacitance halves, and the energy stored doubles. So the amount of work done to move the plates equals the difference in energy stored in the capacitor, which is $3.53 \times 10^{-3}\ \text{J}$.

EVALUATE: The oppositely charged plates attract each other and positive work must be done by an external force to pull them farther apart.

24.25. **IDENTIFY** and **SET UP:** The energy density is given by Eq. (24.11): $u = \frac{1}{2}\epsilon_0 E^2$. Use $V = Ed$ to solve for E.

EXECUTE: Calculate E: $E = \dfrac{V}{d} = \dfrac{400\ \text{V}}{5.00 \times 10^{-3}\ \text{m}} = 8.00 \times 10^4\ \text{V/m}$.

Then $u = \frac{1}{2}\epsilon_0 E^2 = \frac{1}{2}(8.854 \times 10^{-12}\ \text{C}^2/\text{N} \cdot \text{m}^2)(8.00 \times 10^4\ \text{V/m})^2 = 0.0283\ \text{J/m}^3$.

EVALUATE: E is smaller than the value in Example 24.8 by about a factor of 6 so u is smaller by about a factor of $6^2 = 36$.

24.26. **IDENTIFY:** $C = \dfrac{Q}{V_{ab}}$. $C = \dfrac{\epsilon_0 A}{d}$. $V_{ab} = Ed$. The stored energy is $\frac{1}{2}QV$.

SET UP: $d = 1.50 \times 10^{-3}\ \text{m}$. $1\ \mu\text{C} = 10^{-6}\ \text{C}$

EXECUTE: **(a)** $C = \dfrac{0.0180 \times 10^{-6}\ \text{C}}{200\ \text{V}} = 9.00 \times 10^{-11}\ \text{F} = 90.0\ \text{pF}$

(b) $C = \dfrac{\epsilon_0 A}{d}$ so $A = \dfrac{Cd}{\epsilon_0} = \dfrac{(9.00 \times 10^{-11}\ \text{F})(1.50 \times 10^{-3}\ \text{m})}{8.854 \times 10^{-12}\ \text{C}^2/(\text{N} \cdot \text{m}^2)} = 0.0152\ \text{m}^2$.

(c) $V = Ed = (3.0 \times 10^6\ \text{V/m})(1.50 \times 10^{-3}\ \text{m}) = 4.5 \times 10^3\ \text{V}$

(d) Energy $= \frac{1}{2}QV = \frac{1}{2}(0.0180 \times 10^{-6}\ \text{C})(200\ \text{V}) = 1.80 \times 10^{-6}\ \text{J} = 1.80\ \mu\text{J}$

EVALUATE: We could also calculate the stored energy as $\dfrac{Q^2}{2C} = \dfrac{(0.0180 \times 10^{-6}\ \text{C})^2}{2(9.00 \times 10^{-11}\ \text{F})} = 1.80\ \mu\text{J}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

24.27. **IDENTIFY** and **SET UP:** Combine Eqs. (24.9) and (24.2) to write the stored energy in terms of the separation between the plates.

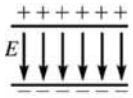
EXECUTE: **(a)** $U = \dfrac{Q^2}{2C}$; $C = \dfrac{\epsilon_0 A}{x}$ so $U = \dfrac{xQ^2}{2\epsilon_0 A}$

(b) $x \to x + dx$ gives $U = \dfrac{(x+dx)Q^2}{2\epsilon_0 A}$

$$dU = \frac{(x+dx)Q^2}{2\epsilon_0 A} - \frac{xQ^2}{2\epsilon_0 A} = \left(\frac{Q^2}{2\epsilon_0 A}\right)dx$$

(c) $dW = F\,dx = dU$, so $F = \dfrac{Q^2}{2\epsilon_0 A}$

(d) EVALUATE: The capacitor plates and the field between the plates are shown in Figure 24.27a.

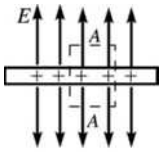


$$E = \frac{\sigma}{\epsilon_0} = \frac{Q}{\epsilon_0 A}$$

$F = \frac{1}{2}QE$, not QE

Figure 24.27a

The reason for the difference is that E is the field due to both plates. If we consider the positive plate only and calculate its electric field using Gauss's law (Figure 24.27b):



$$\oint \vec{E} \cdot d\vec{A} = \frac{Q_{\text{encl}}}{\epsilon_0}$$

$$2EA = \frac{\sigma A}{\epsilon_0}$$

$$E = \frac{\sigma}{2\epsilon_0} = \frac{Q}{2\epsilon_0 A}$$

Figure 24.27b

The force this field exerts on the other plate, that has charge $-Q$, is $F = \dfrac{Q^2}{2\epsilon_0 A}$.

24.28. **IDENTIFY:** $C = \dfrac{\epsilon_0 A}{d}$. The stored energy can be expressed either as $\dfrac{Q^2}{2C}$ or as $\dfrac{CV^2}{2}$, whichever is more convenient for the calculation.

SET UP: Since d is halved, C doubles.

EXECUTE: **(a)** If the separation distance is halved while the charge is kept fixed, then the capacitance increases and the stored energy, which was 8.38 J, decreases since $U = Q^2/2C$. Therefore the new energy is 4.19 J.

(b) If the voltage is kept fixed while the separation is decreased by one half, then the doubling of the capacitance leads to a doubling of the stored energy to 16.8 J, using $U = CV^2/2$, when V is held constant throughout.

EVALUATE: When the capacitor is disconnected, the stored energy decreases because of the positive work done by the attractive force between the plates. When the capacitor remains connected to the battery, $Q = CV$ tells us that the charge on the plates increases. The increased stored energy comes from the battery when it puts more charge onto the plates.

24.29. **IDENTIFY:** Use the rules for series and for parallel capacitors to express the voltage for each capacitor in terms of the applied voltage. Express U, Q and E in terms of the capacitor voltage.

SET UP: Let the applied voltage be V. Let each capacitor have capacitance C. $U = \frac{1}{2}CV^2$ for a single capacitor with voltage V.

EXECUTE: **(a) series**

Voltage across each capacitor is $V/2$. The total energy stored is $U_s = 2\left(\frac{1}{2}C[V/2]^2\right) = \frac{1}{4}CV^2$.

parallel

Voltage across each capacitor is V. The total energy stored is $U_p = 2\left(\frac{1}{2}CV^2\right) = CV^2$.

$U_p = 4U_s$

(b) $Q = CV$ for a single capacitor with voltage V. $Q_s = 2(C[V/2]) = CV$; $Q_p = 2(CV) = 2CV$; $Q_p = 2Q_s$

(c) $E = V/d$ for a capacitor with voltage V. $E_s = V/2d$; $E_p = V/d$; $E_p = 2E_s$

EVALUATE: The parallel combination stores more energy and more charge since the voltage for each capacitor is larger for parallel. More energy stored and larger voltage for parallel means larger electric field in the parallel case.

24.30. **IDENTIFY:** The two capacitors are in series. $\frac{1}{C_{eq}} = \frac{1}{C_1} + \frac{1}{C_2} + \cdots$ $C = \frac{Q}{V}$. $U = \frac{1}{2}CV^2$.

SET UP: For capacitors in series the voltages add and the charges are the same.

EXECUTE: **(a)** $\frac{1}{C_{eq}} = \frac{1}{C_1} + \frac{1}{C_2}$ so $C_{eq} = \frac{C_1C_2}{C_1 + C_2} = \frac{(150\text{ nF})(120\text{ nF})}{150\text{ nF} + 120\text{ nF}} = 66.7\text{ nF}$.

$Q = CV = (66.7\text{ nF})(36\text{ V}) = 2.4\times10^{-6}\text{ C} = 2.4\ \mu\text{C}$

(b) $Q = 2.4\ \mu$C for each capacitor.

(c) $U = \frac{1}{2}C_{eq}V^2 = \frac{1}{2}(66.7\times10^{-9}\text{ F})(36\text{ V})^2 = 43.2\ \mu$J

(d) We know C and Q for each capacitor so rewrite U in terms of these quantities.

$U = \frac{1}{2}CV^2 = \frac{1}{2}C(Q/C)^2 = Q^2/2C$

150 nF: $U = \frac{(2.4\times10^{-6}\text{ C})^2}{2(150\times10^{-9}\text{ F})} = 19.2\ \mu\text{J}$; 120 nF: $U = \frac{(2.4\times10^{-6}\text{ C})^2}{2(120\times10^{-9}\text{ F})} = 24.0\ \mu\text{J}$

Note that $19.2\ \mu\text{J} + 24.0\ \mu\text{J} = 43.2\ \mu\text{J}$, the total stored energy calculated in part (c).

(e) 150 nF: $V = \frac{Q}{C} = \frac{2.4\times10^{-6}\text{ C}}{150\times10^{-9}\text{ F}} = 16\text{ V}$; 120 nF: $V = \frac{Q}{C} = \frac{2.4\times10^{-6}\text{ C}}{120\times10^{-9}\text{ F}} = 20\text{ V}$

Note that these two voltages sum to 36 V, the voltage applied across the network.

EVALUATE: Since Q is the same, the capacitor with smaller C stores more energy $(U = Q^2/2C)$ and has a larger voltage $(V = Q/C)$.

24.31. **IDENTIFY:** The two capacitors are in parallel. $C_{eq} = C_1 + C_2$. $C = \frac{Q}{V}$. $U = \frac{1}{2}CV^2$.

SET UP: For capacitors in parallel, the voltages are the same and the charges add.

EXECUTE: **(a)** $C_{eq} = C_1 + C_2 = 35\text{ nF} + 75\text{ nF} = 110\text{ nF}$. $Q_{tot} = C_{eq}V = (110\times10^{-9}\text{ F})(220\text{ V}) = 24.2\ \mu$C

(b) $V = 220$ V for each capacitor.

35 nF: $Q_{35} = C_{35}V = (35\times10^{-9}\text{ F})(220\text{ V}) = 7.7\ \mu$C; 75 nF: $Q_{75} = C_{75}V = (75\times10^{-9}\text{ F})(220\text{ V}) = 16.5\ \mu$C.

Note that $Q_{35} + Q_{75} = Q_{tot}$.

(c) $U_{tot} = \frac{1}{2}C_{eq}V^2 = \frac{1}{2}(110\times10^{-9}\text{ F})(220\text{ V})^2 = 2.66\text{ mJ}$

(d) 35 nF: $U_{35} = \frac{1}{2}C_{35}V^2 = \frac{1}{2}(35\times10^{-9}\text{ F})(220\text{ V})^2 = 0.85\text{ mJ}$;

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

75 nF: $U_{75} = \frac{1}{2}C_{75}V^2 = \frac{1}{2}(75\times10^{-9}\text{ F})(220\text{ V})^2 = 1.81\text{ mJ}$. Since V is the same the capacitor with larger C stores more energy.

(e) 220 V for each capacitor.

EVALUATE: The capacitor with the larger C has the larger Q.

24.32. **IDENTIFY:** Capacitance depends on the geometry of the object.

(a) SET UP: The potential difference between the core and tube is $V = \dfrac{\lambda}{2\pi\epsilon_0}\ln(r_b/r_a)$. Solving for the linear charge density gives $\lambda = \dfrac{2\pi\epsilon_0 V}{\ln(r_b/r_a)} = \dfrac{4\pi\epsilon_0 V}{2\ln(r_b/r_a)}$.

EXECUTE: Using the given values gives $\lambda = \dfrac{6.00\text{ V}}{2(9.00\times10^9\text{ N}\cdot\text{m}^2/\text{C}^2)\ln\left(\dfrac{2.00}{1.20}\right)} = 6.53\times10^{-10}\text{ C/m}$.

(b) SET UP: $Q = \lambda L$

EXECUTE: $Q = (6.53\times10^{-10}\text{ C/m})(0.350\text{ m}) = 2.29\times10^{-10}\text{ C}$

(c) SET UP: The definition of capacitance is $C = Q/V$.

EXECUTE: $C = \dfrac{2.29\times10^{-10}\text{ C}}{6.00\text{ V}} = 3.81\times10^{-11}\text{ F}$

(d) SET UP: The energy stored in a capacitor is $U = \frac{1}{2}CV^2$.

EXECUTE: $U = \frac{1}{2}(3.81\times10^{-11}\text{ F})(6.00\text{ V})^2 = 6.85\times10^{-10}\text{ J}$

EVALUATE: The stored energy could be converted to heat or other forms of energy.

24.33. **IDENTIFY:** $U = \frac{1}{2}QV$. Solve for Q. $C = Q/V$.

SET UP: Example 24.4 shows that for a cylindrical capacitor, $\dfrac{C}{L} = \dfrac{2\pi\epsilon_0}{\ln(r_b/r_a)}$.

EXECUTE: **(a)** $U = \frac{1}{2}QV$ gives $Q = \dfrac{2U}{V} = \dfrac{2(3.20\times10^{-9}\text{ J})}{4.00\text{ V}} = 1.60\times10^{-9}\text{ C}$.

(b) $\dfrac{C}{L} = \dfrac{2\pi\epsilon_0}{\ln(r_b/r_a)}$.

$\dfrac{r_b}{r_a} = \exp(2\pi\epsilon_0 L/C) = \exp(2\pi\epsilon_0\ LV/Q) = \exp(2\pi\epsilon_0(15.0\text{ m})(4.00\text{ V})/(1.60\times10^{-9}\text{ C})) = 8.05.$

The radius of the outer conductor is 8.05 times the radius of the inner conductor.

EVALUATE: When the ratio r_b/r_a increases, C/L decreases and less charge is stored for a given potential difference.

24.34. **IDENTIFY:** Apply Eq. (24.11).

SET UP: Example 24.3 shows that $E = \dfrac{Q}{4\pi\epsilon_0 r^2}$ between the conducting shells and that

$\dfrac{Q}{4\pi\epsilon_0} = \left(\dfrac{r_a r_b}{r_b - r_a}\right)V_{ab}.$

EXECUTE: $E = \left(\dfrac{r_a r_b}{r_b - r_a}\right)\dfrac{V_{ab}}{r^2} = \left(\dfrac{[0.125\text{ m}][0.148\text{ m}]}{0.148\text{ m} - 0.125\text{ m}}\right)\dfrac{120\text{ V}}{r^2} = \dfrac{96.5\text{ V}\cdot\text{m}}{r^2}$

(a) For $r = 0.126$ m, $E = 6.08\times10^3$ V/m. $u = \frac{1}{2}\epsilon_0 E^2 = 1.64\times10^{-4}\text{ J/m}^3$.

(b) For $r = 0.147$ m, $E = 4.47\times10^3$ V/m. $u = \frac{1}{2}\epsilon_0 E^2 = 8.85\times10^{-5}\text{ J/m}^3$.

EVALUATE: **(c)** No, the results of parts (a) and (b) show that the energy density is not uniform in the region between the plates. E decreases as r increases, so u decreases also.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

24.35. **IDENTIFY:** $C = KC_0$. $U = \frac{1}{2}CV^2$.

SET UP: $C_0 = 12.5\ \mu\text{F}$ is the value of the capacitance without the dielectric present.

EXECUTE: **(a)** With the dielectric, $C = (3.75)(12.5\ \mu\text{F}) = 46.9\ \mu\text{F}$.

before: $U = \frac{1}{2}C_0V^2 = \frac{1}{2}(12.5\times10^{-6}\ \text{F})(24.0\ \text{V})^2 = 3.60\ \text{mJ}$

after: $U = \frac{1}{2}CV^2 = \frac{1}{2}(46.9\times10^{-6}\ \text{F})(24.0\ \text{V})^2 = 13.5\ \text{mJ}$

(b) $\Delta U = 13.5\ \text{mJ} - 3.6\ \text{mJ} = 9.9\ \text{mJ}$. The energy increased.

EVALUATE: The power supply must put additional charge on the plates to maintain the same potential difference when the dielectric is inserted. $U = \frac{1}{2}QV$, so the stored energy increases.

24.36. **IDENTIFY:** $V = Ed$ and $C = Q/V$. With the dielectric present, $C = KC_0$.

SET UP: $V = Ed$ holds both with and without the dielectric.

EXECUTE: **(a)** $V = Ed = (3.00\times10^4\ \text{V/m})(1.50\times10^{-3}\ \text{m}) = 45.0\ \text{V}$.

$Q = C_0V = (5.00\times10^{-12}\ \text{F})(45.0\ \text{V}) = 2.25\times10^{-10}\ \text{C}$.

(b) With the dielectric, $C = KC_0 = (2.70)(5.00\ \text{pF}) = 13.5\ \text{pF}$. V is still 45.0 V, so

$Q = CV = (13.5\times10^{-12}\ \text{F})(45.0\ \text{V}) = 6.08\times10^{-10}\ \text{C}$.

EVALUATE: The presence of the dielectric increases the amount of charge that can be stored for a given potential difference and electric field between the plates. Q increases by a factor of K.

24.37. **IDENTIFY** and **SET UP:** Q is constant so we can apply Eq. (24.14). The charge density on each surface of the dielectric is given by Eq. (24.16).

EXECUTE: $E = \frac{E_0}{K}$ so $K = \frac{E_0}{E} = \frac{3.20\times10^5\ \text{V/m}}{2.50\times10^5\ \text{V/m}} = 1.28$

(a) $\sigma_\text{i} = \sigma(1 - 1/K)$

$\sigma = \epsilon_0E_0 = (8.854\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2)(3.20\times10^5\ \text{N/C}) = 2.833\times10^{-6}\ \text{C/m}^2$

$\sigma_\text{i} = (2.833\times10^{-6}\ \text{C/m}^2)(1 - 1/1.28) = 6.20\times10^{-7}\ \text{C/m}^2$

(b) As calculated above, $K = 1.28$.

EVALUATE: The surface charges on the dielectric produce an electric field that partially cancels the electric field produced by the charges on the capacitor plates.

24.38. **IDENTIFY:** Capacitance depends on geometry, and the introduction of a dielectric increases the capacitance.

SET UP: For a parallel-plate capacitor, $C = K\epsilon_0A/d$.

EXECUTE: **(a)** Solving for d gives

$$d = \frac{K\epsilon_0A}{C} = \frac{(3.0)(8.85\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2)(0.22\ \text{m})(0.28\ \text{m})}{1.0\times10^{-9}\ \text{F}} = 1.64\times10^{-3}\ \text{m} = 1.64\ \text{mm}.$$

Dividing this result by the thickness of a sheet of paper gives $\frac{1.64\ \text{mm}}{0.20\ \text{mm/sheet}} \approx 8$ sheets.

(b) Solving for the area of the plates gives $A = \frac{Cd}{K\epsilon_0} = \frac{(1.0\times10^{-9}\ \text{F})(0.012\ \text{m})}{(3.0)(8.85\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2)} = 0.45\ \text{m}^2$.

(c) Teflon has a smaller dielectric constant (2.1) than the posterboard, so she will need more area to achieve the same capacitance.

EVALUATE: The use of dielectric makes it possible to construct reasonable-sized capacitors since the dielectric increases the capacitance by a factor of K.

24.39. **IDENTIFY** and **SET UP:** For a parallel-plate capacitor with a dielectric we can use the equation $C = K\epsilon_0A/d$. Minimum A means smallest possible d. d is limited by the requirement that E be less than $1.60\times10^7\ \text{V/m}$ when V is as large as 5500 V.

EXECUTE: $V = Ed$ so $d = \frac{V}{E} = \frac{5500\ \text{V}}{1.60\times10^7\ \text{V/m}} = 3.44\times10^{-4}\ \text{m}$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

Then $A = \dfrac{Cd}{K\epsilon_0} = \dfrac{(1.25\times10^{-9}\ \text{F})(3.44\times10^{-4}\ \text{m})}{(3.60)(8.854\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2)} = 0.0135\ \text{m}^2$.

EVALUATE: The relation $V = Ed$ applies with or without a dielectric present. A would have to be larger if there were no dielectric.

24.40. **IDENTIFY:** We can model the cell wall as a large sheet carrying equal but opposite charges, which makes it equivalent to a parallel-plate capacitor.

SET UP: With air between the layers, $E_0 = \dfrac{Q}{\epsilon_0 A} = \dfrac{\sigma}{\epsilon_0}$ and $V_0 = E_0 d$. The energy density in the electric field is $u = \frac{1}{2}\epsilon_0 E^2$. The volume of a shell of thickness t and average radius R is $4\pi R^2 t$. The volume of a solid sphere of radius R is $\frac{4}{3}\pi R^3$. With the dielectric present, $E = \dfrac{E_0}{K}$ and $V = \dfrac{V_0}{K}$.

EXECUTE: **(a)** $E_0 = \dfrac{\sigma}{\epsilon_0} = \dfrac{0.50\times10^{-3}\ \text{C/m}^2}{8.854\times10^{-12}\ \text{C}^2/(\text{N}\cdot\text{m}^2)} = 5.6\times10^7\ \text{V/m}$.

(b) $V_0 = E_0 d = (5.6\times10^7\ \text{V/m})(5.0\times10^{-9}\ \text{m}) = 0.28\ \text{V}$. The outer wall of the cell is at higher potential, since it has positive charge.

(c) For the cell, $V_{\text{cell}} = \frac{4}{3}\pi R^3$, which gives $R = \left(\dfrac{3V_{\text{cell}}}{4\pi}\right)^{1/3} = \left(\dfrac{3(10^{-16}\ \text{m}^3)}{4\pi}\right)^{1/3} = 2.9\times10^{-6}\ \text{m}$. The volume of the cell wall is $V_{\text{wall}} = 4\pi R^2 t = 4\pi(2.9\times10^{-6}\ \text{m})^2(5.0\times10^{-9}\ \text{m}) = 5.3\times10^{-19}\ \text{m}^3$. The energy density in the cell wall is $u_0 = \frac{1}{2}\epsilon_0 E_0^2 = \frac{1}{2}(8.854\times10^{-12}\ \text{C}^2/(\text{N}\cdot\text{m}^2))(5.6\times10^7\ \text{V/m})^2 = 1.39\times10^4\ \text{J/m}^3$. The total electric-field energy in the cell wall is $(1.39\times10^4\ \text{J/m}^3)(5.3\times10^{-19}\ \text{m}^3) = 7\times10^{-15}\ \text{J}$.

(d) $E = \dfrac{E_0}{K} = \dfrac{5.6\times10^7\ \text{V/m}}{5.4} = 1.0\times10^7\ \text{V/m}$ and $V = \dfrac{V_0}{K} = \dfrac{0.28\ \text{V}}{5.4} = 0.052\ \text{V}$.

EVALUATE: To a first approximation, many biological structures can be modeled as basic circuit elements.

24.41. **IDENTIFY:** The permittivity ϵ of a material is related to its dielectric constant by $\epsilon = K\epsilon_0$. The maximum voltage is related to the maximum possible electric field before dielectric breakdown by $V_{\max} = E_{\max} d$.

$E = \dfrac{E_0}{K} = \dfrac{\sigma}{K\epsilon_0}$, where σ is the surface charge density on each plate. The induced surface charge density on the surface of the dielectric is given by $\sigma_{\text{i}} = \sigma(1 - 1/K)$.

SET UP: From Table 24.2, for polystyrene $K = 2.6$ and the dielectric strength (maximum allowed electric field) is $2\times10^7\ \text{V/m}$.

EXECUTE: **(a)** $\epsilon = K\epsilon_0 = (2.6)\epsilon_0 = 2.3\times10^{-11}\ \text{C}^2/\text{N}\cdot\text{m}^2$

(b) $V_{\max} = E_{\max} d = (2.0\times10^7\ \text{V/m})(2.0\times10^{-3}\ \text{m}) = 4.0\times10^4\ \text{V}$

(c) $E = \dfrac{\sigma}{K\epsilon_0}$ and $\sigma = \epsilon E = (2.3\times10^{-11}\ \text{C}^2/\text{N}\cdot\text{m}^2)(2.0\times10^7\ \text{V/m}) = 0.46\times10^{-3}\ \text{C/m}^2$.

$\sigma_{\text{i}} = \sigma\left(1 - \dfrac{1}{K}\right) = (0.46\times10^{-3}\ \text{C/m}^2)(1 - 1/2.6) = 2.8\times10^{-4}\ \text{C/m}^2$.

EVALUATE: The net surface charge density is $\sigma_{\text{net}} = \sigma - \sigma_{\text{i}} = 1.8\times10^{-4}\ \text{C/m}^2$ and the electric field between the plates is $E = \sigma_{\text{net}}/\epsilon_0$.

24.42. **IDENTIFY:** $C = Q/V$. $C = KC_0$. $V = Ed$.

SET UP: Table 24.1 gives $K = 3.1$ for mylar.

EXECUTE: **(a)** $\Delta Q = Q - Q_0 = (K-1)Q_0 = (K-1)C_0 V_0 = (2.1)(2.5\times10^{-7}\ \text{F})(12\ \text{V}) = 6.3\times10^{-6}\ \text{C}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) $\sigma_i = \sigma(1-1/K)$ so $Q_i = Q(1-1/K) = (9.3\times10^{-6}\ \text{C})(1-1/3.1) = 6.3\times10^{-6}\ \text{C}$.

(c) The addition of the mylar doesn't affect the electric field since the induced charge cancels the additional charge drawn to the plates.

EVALUATE: $E = V/d$ and V is constant so E doesn't change when the dielectric is inserted.

24.43. **(a) IDENTIFY** and **SET UP:** Since the capacitor remains connected to the power supply the potential difference doesn't change when the dielectric is inserted. Use Eq. (24.9) to calculate V and combine it with Eq. (24.12) to obtain a relation between the stored energies and the dielectric constant and use this to calculate K.

EXECUTE: Before the dielectric is inserted $U_0 = \frac{1}{2}C_0V^2$ so $V = \sqrt{\dfrac{2U_0}{C_0}} = \sqrt{\dfrac{2(1.85\times10^{-5}\ \text{J})}{360\times10^{-9}\ \text{F}}} = 10.1\ \text{V}$.

(b) $K = C/C_0$

$U_0 = \frac{1}{2}C_0V^2$, $U = \frac{1}{2}CV^2$ so $C/C_0 = U/U_0$

$$K = \frac{U}{U_0} = \frac{1.85\times10^{-5}\ \text{J} + 2.32\times10^{-5}\ \text{J}}{1.85\times10^{-5}\ \text{J}} = 2.25$$

EVALUATE: K increases the capacitance and then from $U = \frac{1}{2}CV^2$, with V constant an increase in C gives an increase in U.

24.44. **IDENTIFY:** $C = KC_0$. $C = Q/V$. $V = Ed$.

SET UP: Since the capacitor remains connected to the battery the potential between the plates of the capacitor doesn't change.

EXECUTE: **(a)** The capacitance changes by a factor of K when the dielectric is inserted. Since V is unchanged (the battery is still connected), $\dfrac{C_{\text{after}}}{C_{\text{before}}} = \dfrac{Q_{\text{after}}}{Q_{\text{before}}} = \dfrac{45.0\ \text{pC}}{25.0\ \text{pC}} = K = 1.80$.

(b) The area of the plates is $\pi r^2 = \pi(0.0300\ \text{m})^2 = 2.827\times10^{-3}\ \text{m}^2$ and the separation between them is thus $d = \dfrac{\epsilon_0 A}{C} = \dfrac{(8.85\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2)(2.827\times10^{-3}\ \text{m}^2)}{12.5\times10^{-12}\ \text{F}} = 2.00\times10^{-3}\ \text{m}$. Before the dielectric is inserted, $C = \dfrac{\epsilon_0 A}{d} = \dfrac{Q}{V}$ and $V = \dfrac{Qd}{\epsilon_0 A} = \dfrac{(25.0\times10^{-12}\ \text{C})(2.00\times10^{-3}\ \text{m})}{(8.85\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2)(2.827\times10^{-3}\ \text{m}^2)} = 2.00\ \text{V}$. The battery remains connected, so the potential difference is unchanged after the dielectric is inserted.

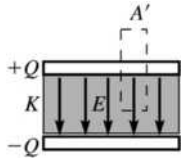
(c) Before the dielectric is inserted, $E = \dfrac{Q}{\epsilon_0 A} = \dfrac{25.0\times10^{-12}\ \text{C}}{(8.85\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2)(2.827\times10^{-3}\ \text{m}^2)} = 1000\ \text{N/C}$.

Again, since the voltage is unchanged after the dielectric is inserted, the electric field is also unchanged.

EVALUATE: $E = \dfrac{V}{d} = \dfrac{2.00\ \text{V}}{2.00\times10^{-3}\ \text{m}} = 1000\ \text{N/C}$, whether or not the dielectric is present. This agrees with the result in part (c). The electric field has this value at any point between the plates. We need d to calculate E because V is the potential difference between points separated by distance d.

24.45. **IDENTIFY:** Apply Eq. (24.23) to calculate E. $V = Ed$ and $C = Q/V$ apply whether there is a dielectric between the plates or not.

(a) SET UP: Apply Eq. (24.23) to the dashed surface in Figure 24.45:



EXECUTE: $\oint K\vec{\boldsymbol{E}}\cdot d\vec{\boldsymbol{A}} = \dfrac{Q_{\text{encl-free}}}{\epsilon_0}$

$\oint K\vec{\boldsymbol{E}}\cdot d\vec{\boldsymbol{A}} = KEA'$

since $E = 0$ outside the plates

$Q_{\text{encl-free}} = \sigma A' = (Q/A)A'$

Figure 24.45

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

Thus $KEA' = \dfrac{(Q/A)A'}{\epsilon_0}$ and $E = \dfrac{Q}{\epsilon_0 AK}$

(b) $V = Ed = \dfrac{Qd}{\epsilon_0 AK}$

(c) $C = \dfrac{Q}{V} = \dfrac{Q}{(Qd/\epsilon_0 AK)} = K\dfrac{\epsilon_0 A}{d} = KC_0$.

EVALUATE: Our result shows that $K = C/C_0$, which is Eq. (24.12).

24.46. **IDENTIFY:** Gauss's law in dielectrics has the same form as in vacuum except that the electric field is multiplied by a factor of K and the charge enclosed by the Gaussian surface is the free charge. The capacitance of an object depends on its geometry.

(a) SET UP: The capacitance of a parallel-plate capacitor is $C = K\epsilon_0 A/d$ and the charge on its plates is $Q = CV$.

EXECUTE: First find the capacitance:

$$C = \frac{K\epsilon_0 A}{d} = \frac{(2.1)(8.85\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2)(0.0225\ \text{m}^2)}{1.00\times10^{-3}\ \text{m}} = 4.18\times10^{-10}\ \text{F}.$$

Now find the charge on the plates: $Q = CV = (4.18\times10^{-10}\ \text{F})(12.0\ \text{V}) = 5.02\times10^{-9}\ \text{C}$.

(b) SET UP: Gauss's law within the dielectric gives $KEA = Q_{\text{free}}/\epsilon_0$.

EXECUTE: Solving for E gives

$$E = \frac{Q_{\text{free}}}{KA\epsilon_0} = \frac{5.02\times10^{-9}\ \text{C}}{(2.1)(0.0225\ \text{m}^2)(8.85\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2)} = 1.20\times10^{4}\ \text{N/C}$$

(c) SET UP: Without the Teflon and the voltage source, the charge is unchanged but the potential increases, so $C = \epsilon_0 A/d$ and Gauss's law now gives $EA = Q/\epsilon_0$.

EXECUTE: First find the capacitance:

$$C = \frac{\epsilon_0 A}{d} = \frac{(8.85\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2)(0.0225\ \text{m}^2)}{1.00\times10^{-3}\ \text{m}} = 1.99\times10^{-10}\ \text{F}.$$

The potential difference is $V = \dfrac{Q}{C} = \dfrac{5.02\times10^{-9}\ \text{C}}{1.99\times10^{-10}\ \text{F}} = 25.2\ \text{V}$. From Gauss's law, the electric field is

$$E = \frac{Q}{\epsilon_0 A} = \frac{5.02\times10^{-9}\ \text{C}}{(8.85\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2)(0.0225\ \text{m}^2)} = 2.52\times10^{4}\ \text{N/C}.$$

EVALUATE: The dielectric reduces the electric field inside the capacitor because the electric field due to the dipoles of the dielectric is opposite to the external field due to the free charge on the plates.

24.47. **IDENTIFY:** $P = E/t$, where E is the total light energy output. The energy stored in the capacitor is $U = \frac{1}{2}CV^2$.

SET UP: $E = 0.95U$

EXECUTE: **(a)** The power output is 2.70×10^5 W, and 95% of the original energy is converted, so

$E = Pt = (2.70\times10^5\ \text{W})(1.48\times10^{-3}\ \text{s}) = 400\ \text{J}$. $U = \dfrac{400\ \text{J}}{0.95} = 421\ \text{J}$.

(b) $U = \frac{1}{2}CV^2$ so $C = \dfrac{2U}{V^2} = \dfrac{2(421\ \text{J})}{(125\ \text{V})^2} = 0.054\ \text{F}$.

EVALUATE: For a given V, the stored energy increases linearly with C.

24.48. **IDENTIFY** and **SET UP:** $C = \dfrac{\epsilon_0 A}{d}$. $C = Q/V$. $V = Ed$. $U = \frac{1}{2}CV^2$. With the battery disconnected, Q is constant. When the separation d is doubled, C is halved.

EXECUTE: **(a)** $C = \dfrac{\epsilon_0 A}{d} = \dfrac{\epsilon_0(0.16\ \text{m})^2}{3.7\times10^{-3}\ \text{m}} = 6.1\times10^{-11}\ \text{F}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) $Q = CV = (6.1\times10^{-11}\text{ F})(12\text{ V}) = 0.74\times10^{-9}\text{ C}$.

(c) $E = V/d = (12\text{ V})/(3.7\times10^{-3}\text{ m}) = 3200\text{ V/m}$.

(d) $U = \frac{1}{2}CV^2 = \frac{1}{2}(6.1\times10^{-11}\text{ F})(12\text{ V})^2 = 4.4\times10^{-9}\text{ J}$.

(e) If the battery is disconnected, so the charge remains constant, and the plates are pulled farther apart to 0.0074 m, then the calculations above can be carried out just as before, and we find: (a) $C = 3.1\times10^{-11}\text{ F}$ (b) $Q = 0.74\times10^{-9}\text{ C}$ (c) $E = 3200\text{ V/m}$ (d) $U = \dfrac{Q^2}{2C} = \dfrac{(0.74\times10^{-9}\text{ C})^2}{2(3.1\times10^{-11}\text{ F})} = 8.8\times10^{-9}\text{ J}$.

EVALUATE: Q is unchanged. $E = \dfrac{Q}{\epsilon_0 A}$ so E is unchanged. U doubles because C is halved. The additional stored energy comes from the work done by the force that pulled the plates apart.

24.49. **IDENTIFY** and **SET UP:** If the capacitor remains connected to the battery, the battery keeps the potential difference between the plates constant by changing the charge on the plates. $C = \dfrac{\epsilon_0 A}{d}$.

EXECUTE: **(a)** Using $C = \dfrac{\epsilon_0 A}{d}$ gives $C = \dfrac{(8.854\times10^{-12}\text{ C}^2/\text{N}\cdot\text{m}^2)(0.16\text{ m})^2}{7.4\times10^{-3}\text{ m}} = 3.1\times10^{-11}\text{ F} = 31\text{ pF}$.

(b) Remains connected to the battery says that V stays 12 V.

$Q = CV = (3.1\times10^{-11}\text{ F})(12\text{ V}) = 3.7\times10^{-10}\text{ C}$.

(c) $E = \dfrac{V}{d} = \dfrac{12\text{ V}}{7.4\times10^{-3}\text{ m}} = 1.6\times10^{3}\text{ V/m}$.

(d) $U = \frac{1}{2}QV = \frac{1}{2}(3.7\times10^{-10}\text{ C})(12.0\text{ V}) = 2.2\times10^{-9}\text{ J}$.

EVALUATE: Increasing the separation decreases C. With V constant, this means that Q decreases and U decreases. Q decreases and $E = Q/\epsilon_0 A$ so E decreases. We come to the same conclusion from $E = V/d$.

24.50. **IDENTIFY:** $C = KC_0 = K\epsilon_0\dfrac{A}{d}$. $V = Ed$ for a parallel plate capacitor; this equation applies whether or not a dielectric is present.

SET UP: $A = 1.0\text{ cm}^2 = 1.0\times10^{-4}\text{ m}^2$.

EXECUTE: **(a)** $C = (10)\dfrac{(8.85\times10^{-12}\text{ F/m})(1.0\times10^{-4}\text{ m}^2)}{7.5\times10^{-9}\text{ m}} = 1.18\,\mu\text{F per cm}^2$.

(b) $E = \dfrac{V}{d} = \dfrac{85\text{ mV}}{7.5\times10^{-9}\text{ m}} = 1.13\times10^{7}\text{ V/m}$.

EVALUATE: The dielectric material increases the capacitance. If the dielectric were not present, the same charge density on the faces of the membrane would produce a larger potential difference across the membrane.

24.51. **IDENTIFY:** Both the electric field and the potential difference depend on the linear charge density on the cylinders. We can use this fact to relate the field to the potential difference between the cylinders.

SET UP: $E = \dfrac{\lambda}{2\pi\epsilon_0 r}$ and $V = \dfrac{\lambda}{2\pi\epsilon_0}\ln(r_b/r_a)$, so $E = \dfrac{V}{r\ln(r_b/r_a)}$.

EXECUTE: $E = \dfrac{V}{r\ln(r_b/r_a)} = \dfrac{80.0\text{ V}}{(2.80\times10^{-3}\text{ m})(\ln(3.10/2.50))} = 1.33\times10^{5}\text{ V/m}$.

EVALUATE: At any point between the cylinders, E is directly proportional to V because V is proportional to the charge on the inner cylinder. This is the charge that causes the electric field.

24.52. **IDENTIFY:** $C = \dfrac{\epsilon_0 A}{d}$

SET UP: $A = 4.2\times10^{-5}\text{ m}^2$. The original separation between the plates is $d = 0.700\times10^{-3}\text{ m}$. d' is the separation between the plates at the new value of C.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: $C_0 = \dfrac{A\epsilon_0}{d} = \dfrac{(4.20\times10^{-5}\ \text{m}^2)\epsilon_0}{7.00\times10^{-4}\ \text{m}} = 5.31\times10^{-13}\ \text{F}$. The new value of C is

$C = C_0 + 0.25\ \text{pF} = 7.81\times10^{-13}\ \text{F}$. But $C = \dfrac{A\epsilon_0}{d'}$, so $d' = \dfrac{A\epsilon_0}{C} = \dfrac{(4.20\times10^{-5}\ \text{m}^2)\epsilon_0}{7.81\times10^{-13}\ \text{F}} = 4.76\times10^{-4}\text{m}$.

Therefore the key must be depressed by a distance of $7.00\times10^{-4}\ \text{m} - 4.76\times10^{-4}\ \text{m} = 0.224\ \text{mm}$.

EVALUATE: When the key is depressed, d decreases and C increases.

24.53. **IDENTIFY:** Some of the charge from the original capacitor flows onto the uncharged capacitor until the potential differences across the two capacitors are the same.

SET UP: $C = \dfrac{Q}{V_{ab}}$. Let $C_1 = 20.0\ \mu\text{F}$ and $C_2 = 10.0\ \mu\text{F}$. The energy stored in a capacitor is

$\frac{1}{2}QV_{ab} = \frac{1}{2}CV_{ab}^2 = \frac{1}{2}\dfrac{Q^2}{C}$.

EXECUTE: **(a)** The initial charge on the $20.0\ \mu\text{F}$ capacitor is

$Q = C_1(800\ \text{V}) = (20.0\times10^{-6}\ \text{F})(800\ \text{V}) = 0.0160\ \text{C}$.

(b) In the final circuit, charge Q is distributed between the two capacitors and $Q_1 + Q_2 = Q$. The final circuit contains only the two capacitors, so the voltage across each is the same, $V_1 = V_2$. $V = \dfrac{Q}{C}$ so $V_1 = V_2$ gives $\dfrac{Q_1}{C_1} = \dfrac{Q_2}{C_2}$. $Q_1 = \dfrac{C_1}{C_2}Q_2 = 2Q_2$. Using this in $Q_1 + Q_2 = 0.0160\ \text{C}$ gives $3Q_2 = 0.0160\ \text{C}$ and

$Q_2 = 5.33\times10^{-3}\ \text{C}$. $Q = 2Q_2 = 1.066\times10^{-2}\ \text{C}$. $V_1 = \dfrac{Q_1}{C_1} = \dfrac{1.066\times10^{-2}\ \text{C}}{20.0\times10^{-6}\ \text{F}} = 533\ \text{V}$.

$V_2 = \dfrac{Q_2}{C_2} = \dfrac{5.33\times10^{23}\ \text{C}}{10.0\times10^{26}\ \text{F}} = 533\ \text{V}$. The potential differences across the capacitors are the same, as they should be.

(c) $\text{Energy} = \frac{1}{2}C_1V^2 + \frac{1}{2}C_2V^2 = \frac{1}{2}(C_1 + C_2)V^2$ gives

$\text{Energy} = \frac{1}{2}(20.0\times10^{-6}\ \text{F} + 10.0\times10^{-6}\ \text{F})(533\ \text{V})^2 = 4.26\ \text{J}$.

(d) The $20.0\ \mu\text{F}$ capacitor initially has $\text{energy} = \frac{1}{2}C_1V^2 = \frac{1}{2}(20.0\times10^{-6}\ \text{F})(800\ \text{V})^2 = 6.40\ \text{J}$. The decrease in stored energy that occurs when the capacitors are connected is $6.40\ \text{J} - 4.26\ \text{J} = 2.14\ \text{J}$.

EVALUATE: The decrease in stored energy is because of conversion of electrical energy to other forms during the motion of the charge when it becomes distributed between the two capacitors. Thermal energy is generated by the current in the wires and energy is emitted in electromagnetic waves.

24.54. **IDENTIFY:** Initially the capacitors are connected in parallel to the source and we can calculate the charges Q_1 and Q_2 on each. After they are reconnected to each other the total charge is $Q = Q_2 - Q_1$.

$U = \frac{1}{2}CV^2 = \dfrac{Q^2}{2C}$.

SET UP: After they are reconnected, the charges add and the voltages are the same, so $C_{\text{eq}} = C_1 + C_2$, as for capacitors in parallel.

EXECUTE: Originally $Q_1 = C_1V_1 = (9.0\ \mu\text{F})\ (36\ \text{V}) = 3.24\times10^{-4}\ \text{C}$ and

$Q_2 = C_2V_2 = (4.0\ \mu\text{F})(36\ \text{V}) = 1.44\times10^{-4}\ \text{C}$. $C_{\text{eq}} = C_1 + C_2 = 13.0\ \mu\text{F}$. The original energy stored is $U = \frac{1}{2}C_{\text{eq}}V^2 = \frac{1}{2}(13.0\times10^{-6}\ \text{F})(36\ \text{V})^2 = 8.42\times10^{-3}\ \text{J}$. Disconnect and flip the capacitors, so now the total charge is $Q = Q_2 - Q_1 = 1.8\times10^{-4}\ \text{C}$ and the equivalent capacitance is still the same, $C_{\text{eq}} = 13.0\ \mu\text{F}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

The new energy stored is $U = \dfrac{Q^2}{2C_{\text{eq}}} = \dfrac{(1.8\times10^{-4}\text{ C})^2}{2(13.0\times10^{-6}\text{ F})} = 1.25\times10^{-3}$ J. The change in stored energy is

$\Delta U = 1.25\times10^{-3}\text{ J} - 8.42\times10^{-3}\text{ J} = -7.17\times10^{-3}$ J.

EVALUATE: When they are reconnected, charge flows and thermal energy is generated and energy is radiated as electromagnetic waves.

24.55. **IDENTIFY:** Simplify the network by replacing series and parallel combinations by their equivalent. The stored energy in a capacitor is $U = \frac{1}{2}CV^2$.

SET UP: For capacitors in series the voltages add and the charges are the same; $\dfrac{1}{C_{\text{eq}}} = \dfrac{1}{C_1} + \dfrac{1}{C_2} + \cdots$. For capacitors in parallel the voltages are the same and the charges add; $C_{\text{eq}} = C_1 + C_2 + \cdots$ $C = \dfrac{Q}{V}$.

$U = \frac{1}{2}CV^2$.

EXECUTE: **(a)** Find C_{eq} for the network by replacing each series or parallel combination by its equivalent. The successive simplified circuits are shown in Figure 24.55a–c.

$U_{\text{tot}} = \frac{1}{2}C_{\text{eq}}V^2 = \frac{1}{2}(2.19\times10^{-6}\text{ F})(12.0\text{ V})^2 = 1.58\times10^{-4}\text{ J} = 158\ \mu\text{J}$

(b) From Figure 24.55c, $Q_{\text{tot}} = C_{\text{eq}}V = (2.19\times10^{-6}\text{ F})(12.0\text{ V}) = 2.63\times10^{-5}$ C. From Figure 24.55b,

$Q_{4.8} = 2.63\times10^{-5}$ C. $V_{4.8} = \dfrac{Q_{4.8}}{C_{4.8}} = \dfrac{2.63\times10^{-5}\text{ C}}{4.80\times10^{-6}\text{ F}} = 5.48$ V.

$U_{4.8} = \frac{1}{2}CV^2 = \frac{1}{2}(4.80\times10^{-6}\text{ F})(5.48\text{ V})^2 = 7.21\times10^{-5}\text{ J} = 72.1\ \mu\text{J}$

This one capacitor stores nearly half the total stored energy.

EVALUATE: $U = \dfrac{Q^2}{2C}$. For capacitors in series the capacitor with the smallest C stores the greatest amount of energy.

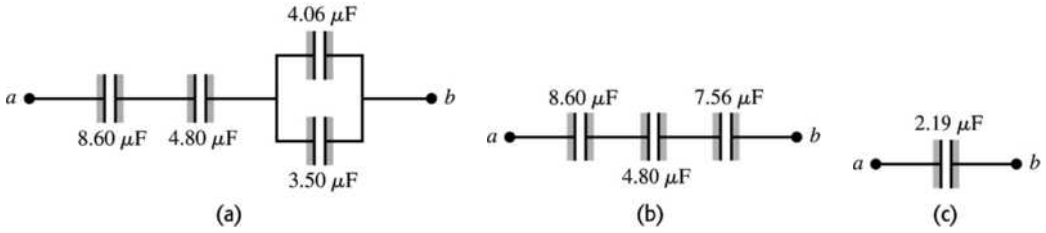


Figure 24.55

24.56. **IDENTIFY:** Apply the rules for combining capacitors in series and parallel. For capacitors in series the voltages add and in parallel the voltages are the same.

SET UP: When a capacitor is a moderately good conductor it can be replaced by a wire and the potential across it is zero.

EXECUTE: **(a)** A network that has the desired properties is sketched in Figure 24.56a. $C_{\text{eq}} = \dfrac{C}{2} + \dfrac{C}{2} = C$.

The total capacitance is the same as each individual capacitor, and the voltage is divided equally between the two capacitors, so that $V = 480$ V.

(b) If one capacitor is a moderately good conductor, then it can be treated as a "short" and thus removed from the circuit, and one capacitor will have greater than 600 V across it.

EVALUATE: An alternative solution is two in parallel in series with two in parallel, as sketched in Figure 24.56b.

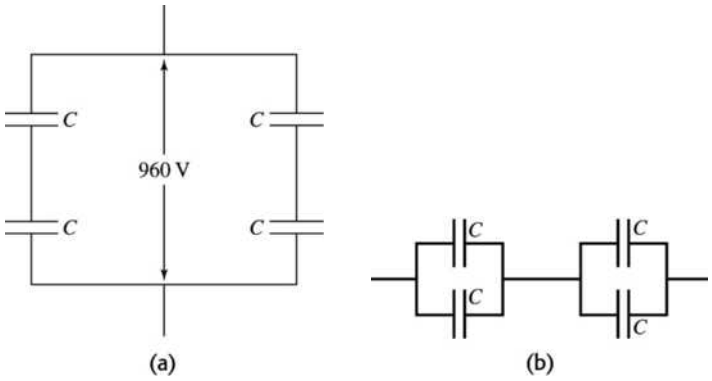

Figure 24.56

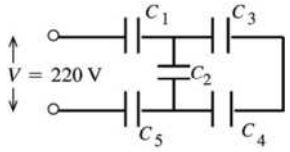
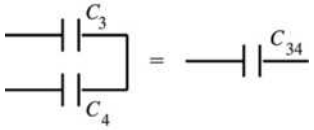
24.57. **(a) IDENTIFY:** Replace series and parallel combinations of capacitors by their equivalents.
SET UP: The network is sketched in Figure 24.57a.



$$C_1 = C_5 = 8.4\ \mu\text{F}$$
$$C_2 = C_3 = C_4 = 4.2\ \mu\text{F}$$

Figure 24.57a

EXECUTE: Simplify the circuit by replacing the capacitor combinations by their equivalents: C_3 and C_4 are in series and can be replaced by C_{34} (Figure 24.57b):

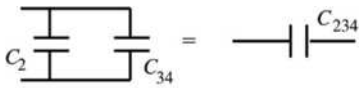


$$\frac{1}{C_{34}} = \frac{1}{C_3} + \frac{1}{C_4}$$
$$\frac{1}{C_{34}} = \frac{C_3 + C_4}{C_3 C_4}$$

Figure 24.57b

$$C_{34} = \frac{C_3 C_4}{C_3 + C_4} = \frac{(4.2\ \mu\text{F})(4.2\ \mu\text{F})}{4.2\ \mu\text{F} + 4.2\ \mu\text{F}} = 2.1\ \mu\text{F}$$

C_2 and C_{34} are in parallel and can be replaced by their equivalent (Figure 24.57c):

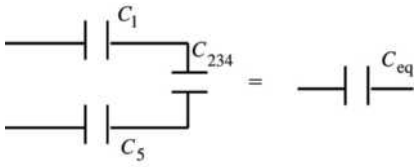


$$C_{234} = C_2 + C_{34}$$
$$C_{234} = 4.2\ \mu\text{F} + 2.1\ \mu\text{F}$$
$$C_{234} = 6.3\ \mu\text{F}$$

Figure 24.57c

C_1, C_5 and C_{234} are in series and can be replaced by C_{eq} (Figure 24.57d):

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist.
No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.



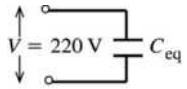
$$\frac{1}{C_{eq}} = \frac{1}{C_1} + \frac{1}{C_5} + \frac{1}{C_{234}}$$
$$\frac{1}{C_{eq}} = \frac{2}{8.4\ \mu\text{F}} + \frac{1}{6.3\ \mu\text{F}}$$
$$C_{eq} = 2.5\ \mu\text{F}$$

Figure 24.57d

EVALUATE: For capacitors in series the equivalent capacitor is smaller than any of those in series. For capacitors in parallel the equivalent capacitance is larger than any of those in parallel.

(b) IDENTIFY and **SET UP:** In each equivalent network apply the rules for Q and V for capacitors in series and parallel; start with the simplest network and work back to the original circuit.

EXECUTE: The equivalent circuit is drawn in Figure 24.57e.



$$Q_{eq} = C_{eq}V$$
$$Q_{eq} = (2.5\ \mu\text{F})(220\ \text{V}) = 550\ \mu\text{C}$$

Figure 24.57e

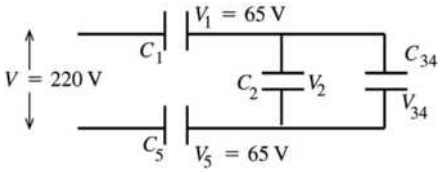
$Q_1 = Q_5 = Q_{234} = 550\ \mu\text{C}$ (capacitors in series have same charge)

$$V_1 = \frac{Q_1}{C_1} = \frac{550\ \mu\text{C}}{8.4\ \mu\text{F}} = 65\ \text{V}$$

$$V_5 = \frac{Q_5}{C_5} = \frac{550\ \mu\text{C}}{8.4\ \mu\text{F}} = 65\ \text{V}$$

$$V_{234} = \frac{Q_{234}}{C_{234}} = \frac{550\ \mu\text{C}}{6.3\ \mu\text{F}} = 87\ \text{V}$$

Now draw the network as in Figure 24.57f.



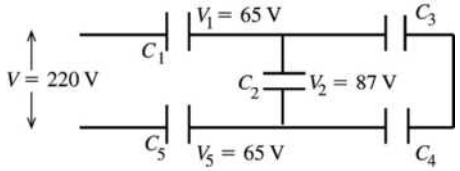
$V_2 = V_{34} = V_{234} = 87\ \text{V}$
capacitors in parallel have the same potential

Figure 24.57f

$Q_2 = C_2V_2 = (4.2\ \mu\text{F})(87\ \text{V}) = 370\ \mu\text{C}$

$Q_{34} = C_{34}V_{34} = (2.1\ \mu\text{F})(87\ \text{V}) = 180\ \mu\text{C}$

Finally, consider the original circuit (Figure 24.57g).



$Q_3 = Q_4 = Q_{34} = 180\ \mu\text{C}$
capacitors in series have the same charge

Figure 24.57g

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$V_3 = \dfrac{Q_3}{C_3} = \dfrac{180\ \mu\text{C}}{4.2\ \mu\text{F}} = 43\ \text{V}$

$V_4 = \dfrac{Q_4}{C_4} = \dfrac{180\ \mu\text{C}}{4.2\ \mu\text{F}} = 43\ \text{V}$

Summary: $Q_1 = 550\ \mu\text{C},\ V_1 = 65\ \text{V}$

$Q_2 = 370\ \mu\text{C},\ V_2 = 87\ \text{V}$

$Q_3 = 180\ \mu\text{C},\ V_3 = 43\ \text{V}$

$Q_4 = 180\ \mu\text{C},\ V_4 = 43\ \text{V}$

$Q_5 = 550\ \mu\text{C},\ V_5 = 65\ \text{V}$

EVALUATE: $V_3 + V_4 = V_2$ and $V_1 + V_2 + V_5 = 220\ \text{V}$ (apart from some small rounding error)

$Q_1 = Q_2 + Q_3$ and $Q_5 = Q_2 + Q_4$

24.58. **IDENTIFY:** We can make series and parallel combinations.

SET UP: For capacitors in series, $\dfrac{1}{C_{\text{eq}}} = \dfrac{1}{C_1} + \dfrac{1}{C_2} + \cdots$, so for N equivalent capacitors in series, $C_{\text{eq}} = C/N$.

For capacitors in parallel, $C_{\text{eq}} = C_1 + C_2 + \cdots$, so for N equivalent capacitors in parallel, $C_{\text{eq}} = NC$.

EXECUTE: There are many ways to achieve the required equivalent capacitance. In each case one simple solution is shown in Figure 24.58.

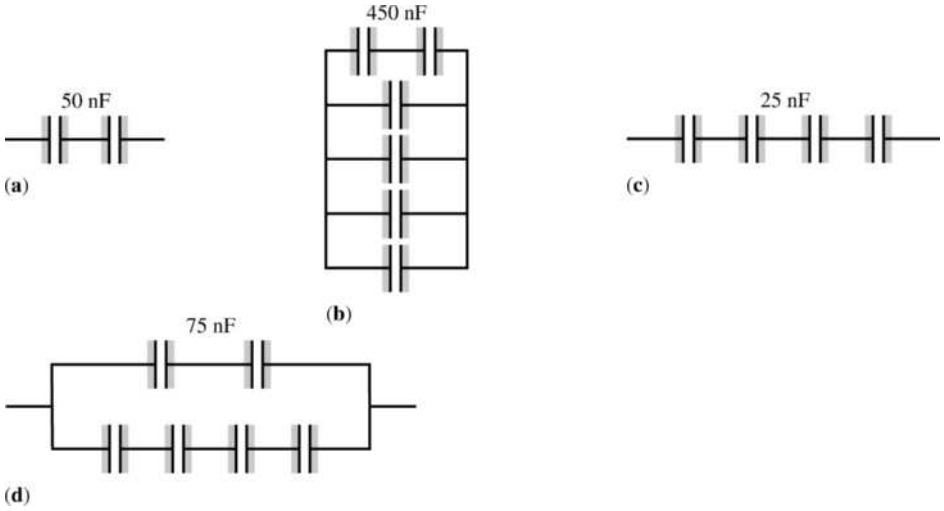


Figure 24.58

EVALUATE: By combining capacitors in series and parallel combinations, we can produce a wide variety of equivalent capacitances.

24.59. **IDENTIFY:** Capacitors in series carry the same charge, while capacitors in parallel have the same potential difference across them.

SET UP: $V_{ab} = 150\ \text{V},\ Q_1 = 150\ \mu\text{C},\ Q_3 = 450\ \mu\text{C},$ and $V = Q/C$.

EXECUTE: $C_1 = 3.00\ \mu\text{F}$ so $V_1 = \dfrac{Q_1}{C_1} = \dfrac{150\ \mu\text{C}}{3.00\ \mu\text{F}} = 50.0\ \text{V}$ and $V_1 = V_2 = 50.0\ \text{V}$. $V_1 + V_3 = V_{ab}$ so

$V_3 = 100\ \text{V}$. $C_3 = \dfrac{Q_3}{V_3} = \dfrac{450\ \mu\text{C}}{100\ \text{V}} = 4.50\ \mu\text{F}$. $Q_1 + Q_2 = Q_3$ so $Q_2 = Q_3 - Q_1 = 450\ \mu\text{C} - 150\ \mu\text{C} = 300\ \mu\text{C}$

and $C_2 = \dfrac{Q_2}{V_2} = \dfrac{300\ \mu\text{C}}{50.0\ \text{V}} = 6.00\ \mu\text{F}$.

EVALUATE: Capacitors in parallel only carry the same charge if they have the same capacitance.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

24.60. **IDENTIFY:** Apply the rules for combining capacitors in series and in parallel.
SET UP: With the switch open, each pair of $3.00\ \mu$F and $6.00\ \mu$F capacitors are in series with each other and each pair is in parallel with the other pair. When the switch is closed, each pair of $3.00\ \mu$F and $6.00\ \mu$F capacitors are in parallel with each other and the two pairs are in series.

EXECUTE: **(a)** With the switch open $C_{\text{eq}} = \left(\left(\frac{1}{3\ \mu\text{F}} + \frac{1}{6\ \mu\text{F}} \right)^{-1} + \left(\frac{1}{3\ \mu\text{F}} + \frac{1}{6\ \mu\text{F}} \right)^{-1} \right) = 4.00\ \mu\text{F}.$

$Q_{\text{total}} = C_{\text{eq}}V = (4.00\ \mu\text{F})(210\ \text{V}) = 8.40\times10^{-4}$ C. By symmetry, each capacitor carries 4.20×10^{-4} C. The voltages are then calculated via $V = Q/C$. This gives $V_{ad} = Q/C_3 = 140$ V and $V_{ac} = Q/C_6 = 70$ V.
$V_{cd} = V_{ad} - V_{ac} = 70$ V.

(b) When the switch is closed, the points *c* and *d* must be at the same potential, so the equivalent capacitance is $C_{\text{eq}} = \left(\frac{1}{(3.00+6.00)\ \mu\text{F}} + \frac{1}{(3.00+6.00)\ \mu\text{F}} \right)^{-1} = 4.5\ \mu\text{F}.$

$Q_{\text{total}} = C_{\text{eq}}V = (4.50\ \mu\text{F})(210\ \text{V}) = 9.5\times10^{-4}$ C, and each capacitor has the same potential difference of 105 V (again, by symmetry).

(c) The only way for the sum of the positive charge on one plate of C_2 and the negative charge on one plate of C_1 to change is for charge to flow through the switch. That is, the quantity of charge that flows through the switch is equal to the change in $Q_2 - Q_1$. With the switch open, $Q_1 = Q_2$ and $Q_2 - Q_1 = 0$. After the switch is closed, $Q_2 - Q_1 = 315\ \mu$C, so $315\ \mu$C of charge flowed through the switch.

EVALUATE: When the switch is closed the charge must redistribute to make points *c* and *d* be at the same potential.

24.61. **(a) IDENTIFY:** Replace the three capacitors in series by their equivalent. The charge on the equivalent capacitor equals the charge on each of the original capacitors.
SET UP: The three capacitors can be replaced by their equivalent as shown in Figure 24.61a.

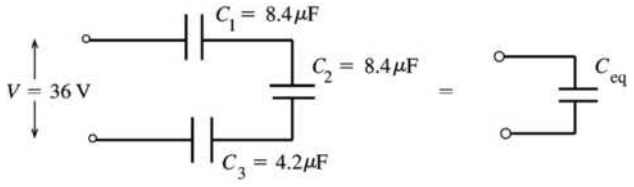

Figure 24.61a

EXECUTE: $C_3 = C_1/2$ so $\frac{1}{C_{\text{eq}}} = \frac{1}{C_1} + \frac{1}{C_2} + \frac{1}{C_3} = \frac{4}{8.4\ \mu\text{F}}$ and $C_{\text{eq}} = 8.4\ \mu\text{F}/4 = 2.1\ \mu\text{F}$

$Q = C_{\text{eq}}V = (2.1\ \mu\text{F})(36\ \text{V}) = 76\ \mu\text{C}$

The three capacitors are in series so they each have the same charge: $Q_1 = Q_2 = Q_3 = 76\ \mu$C

EVALUATE: The equivalent capacitance for capacitors in series is smaller than each of the original capacitors.

(b) IDENTIFY and **SET UP:** Use $U = \frac{1}{2}QV$. We know each Q and we know that $V_1 + V_2 + V_3 = 36$ V.

EXECUTE: $U = \frac{1}{2}Q_1V_1 + \frac{1}{2}Q_2V_2 + \frac{1}{2}Q_3V_3$

But $Q_1 = Q_2 = Q_3 = Q$ so $U = \frac{1}{2}Q(V_1 + V_2 + V_3)$

But also $V_1 + V_2 + V_3 = V = 36$ V, so $U = \frac{1}{2}QV = \frac{1}{2}(76\ \mu\text{C})(36\ \text{V}) = 1.4\times10^{-3}$ J.

EVALUATE: We could also use $U = Q^2/2C$ and calculate U for each capacitor.

(c) IDENTIFY: The charges on the plates redistribute to make the potentials across each capacitor the same.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

SET UP: The capacitors before and after they are connected are sketched in Figure 24.61b.

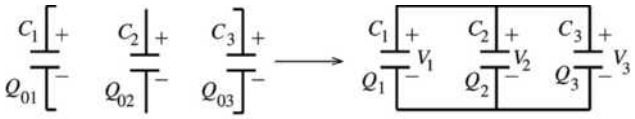

Figure 24.61b

EXECUTE: The total positive charge that is available to be distributed on the upper plates of the three capacitors is $Q_0 = Q_{01} + Q_{02} + Q_{03} = 3(76\ \mu\text{C}) = 228\ \mu\text{C}$. Thus $Q_1 + Q_2 + Q_3 = 228\ \mu\text{C}$. After the circuit is completed the charge distributes to make $V_1 = V_2 = V_3$. $V = Q/C$ and $V_1 = V_2$ so $Q_1/C_1 = Q_2/C_2$ and then $C_1 = C_2$ says $Q_1 = Q_2$. $V_1 = V_3$ says $Q_1/C_1 = Q_3/C_3$ and $Q_1 = Q_3(C_1/C_3) = Q_3(8.4\ \mu\text{F}/4.2\ \mu\text{F}) = 2Q_3$.
Using $Q_2 = Q_1$ and $Q_1 = 2Q_3$ in the above equation gives $2Q_3 + 2Q_3 + Q_3 = 228\ \mu\text{C}$.
$5Q_3 = 228\ \mu\text{C}$ and $Q_3 = 45.6\ \mu\text{C}$, $Q_1 = Q_2 = 91.2\ \mu\text{C}$

Then $V_1 = \dfrac{Q_1}{C_1} = \dfrac{91.2\ \mu\text{C}}{8.4\ \mu\text{F}} = 11\ \text{V}$, $V_2 = \dfrac{Q_2}{C_2} = \dfrac{91.2\ \mu\text{C}}{8.4\ \mu\text{F}} = 11\ \text{V}$, and $V_3 = \dfrac{Q_3}{C_3} = \dfrac{45.6\ \mu\text{C}}{4.2\ \mu\text{F}} = 11\ \text{V}$.
The voltage across each capacitor in the parallel combination is 11 V.
(d) $U = \frac{1}{2}Q_1V_1 + \frac{1}{2}Q_2V_2 + \frac{1}{2}Q_3V_3$.

But $V_1 = V_2 = V_3$ so $U = \frac{1}{2}V_1(Q_1 + Q_2 + Q_3) = \frac{1}{2}(11\ \text{V})(228\ \mu\text{C}) = 1.3\times10^{-3}\ \text{J}$.

EVALUATE: This is less than the original energy of 1.4×10^{-3} J. The stored energy has decreased, as in Example 24.7.

24.62. **IDENTIFY:** $C = \dfrac{\epsilon_0 A}{d}$. $C = \dfrac{Q}{V}$. $V = Ed$. $U = \frac{1}{2}QV$.

SET UP: $d = 3.0\times10^3$ m. $A = \pi r^2$, with $r = 1.0\times10^3$ m.

EXECUTE: **(a)** $C = \dfrac{\epsilon_0 A}{d} = \dfrac{(8.854\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2)\pi(1.0\times10^3\ \text{m})^2}{3.0\times10^3\ \text{m}} = 9.3\times10^{-9}\ \text{F}$.

(b) $V = \dfrac{Q}{C} = \dfrac{20\ \text{C}}{9.3\times10^{-9}\ \text{F}} = 2.2\times10^9\ \text{V}$

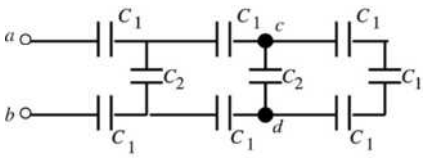
(c) $E = \dfrac{V}{d} = \dfrac{2.2\times10^9\ \text{V}}{3.0\times10^3\ \text{m}} = 7.3\times10^5\ \text{V/m}$

(d) $U = \frac{1}{2}QV = \frac{1}{2}(20\ \text{C})(2.2\times10^9\ \text{V}) = 2.2\times10^{10}\ \text{J}$

EVALUATE: Thunderclouds involve very large potential differences and large amounts of stored energy.

24.63. **IDENTIFY:** Replace series and parallel combinations of capacitors by their equivalents. In each equivalent network apply the rules for Q and V for capacitors in series and parallel; start with the simplest network and work back to the original circuit.

(a) SET UP: The network is sketched in Figure 24.63a.



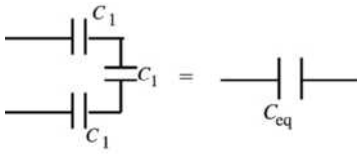
$C_1 = 6.9\ \mu\text{F}$

$C_2 = 4.6\ \mu\text{F}$

Figure 24.63a

EXECUTE: Simplify the network by replacing the capacitor combinations by their equivalents. Make the replacement shown in Figure 24.63b.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

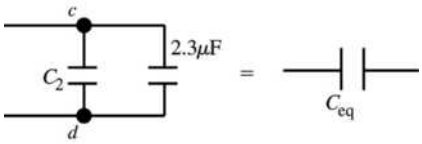


$$\frac{1}{C_{eq}} = \frac{3}{C_1}$$

$$C_{eq} = \frac{C_1}{3} = \frac{6.9\,\mu\text{F}}{3} = 2.3\,\mu\text{F}$$

Figure 24.63b

Next make the replacement shown in Figure 24.63c.

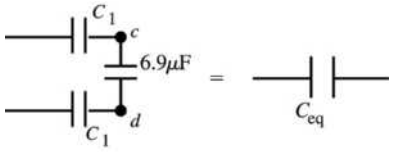


$$C_{eq} = 2.3\,\mu\text{F} + C_2$$

$$C_{eq} = 2.3\,\mu\text{F} + 4.6\,\mu\text{F} = 6.9\,\mu\text{F}$$

Figure 24.63c

Make the replacement shown in Figure 24.63d.

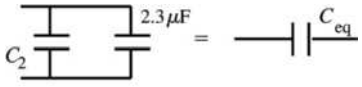


$$\frac{1}{C_{eq}} = \frac{2}{C_1} + \frac{1}{6.9\,\mu\text{F}} = \frac{3}{6.9\,\mu\text{F}}$$

$$C_{eq} = 2.3\,\mu\text{F}$$

Figure 24.63d

Make the replacement shown in Figure 24.63e.

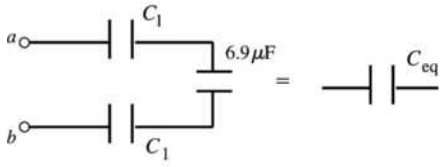


$$C_{eq} = C_2 + 2.3\,\mu\text{F} = 4.6\,\mu\text{F} + 2.3\,\mu\text{F}$$

$$C_{eq} = 6.9\,\mu\text{F}$$

Figure 24.63e

Make the replacement shown in Figure 24.63f.

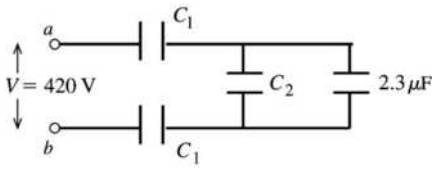


$$\frac{1}{C_{eq}} = \frac{2}{C_1} + \frac{1}{6.9\,\mu\text{F}} = \frac{3}{6.9\,\mu\text{F}}$$

$$C_{eq} = 2.3\,\mu\text{F}$$

Figure 24.63f

(b) Consider the network as drawn in Figure 24.63g.

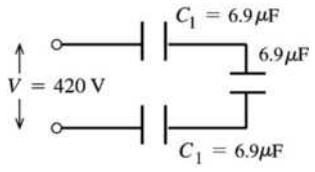


From part (a) $2.3\,\mu\text{F}$ is the equivalent capacitance of the rest of the network.

Figure 24.63g

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

The equivalent network is shown in Figure 24.63h.

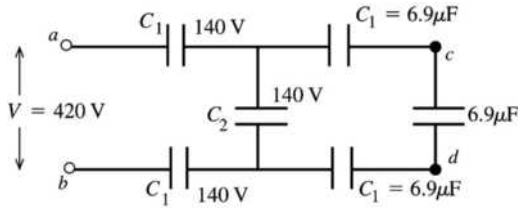


The capacitors are in series, so all three capacitors have the same Q.

Figure 24.63h

But here all three have the same C, so by $V = Q/C$ all three must have the same V. The three voltages must add to 420 V, so each capacitor has $V = 140$ V. The $6.9\ \mu$F to the right is the equivalent of C_2 and the $2.3\ \mu$F capacitor in parallel, so $V_2 = 140$ V. (Capacitors in parallel have the same potential difference.) Hence $Q_1 = C_1V_1 = (6.9\ \mu\text{F})(140\text{ V}) = 9.7\times10^{-4}$ C and $Q_2 = C_2V_2 = (4.6\ \mu\text{F})(140\text{ V}) = 6.4\times10^{-4}$ C.

(c) From the potentials deduced in part (b) we have the situation shown in Figure 24.63i.



From part (a) $6.9\ \mu$F is the equivalent capacitance of the rest of the network.

Figure 24.63i

The three right-most capacitors are in series and therefore have the same charge. But their capacitances are also equal, so by $V = Q/C$ they each have the same potential difference. Their potentials must sum to 140 V, so the potential across each is 47 V and $V_{cd} = 47$ V.

EVALUATE: In each capacitor network the rules for combining V for capacitors in series and parallel are obeyed. Note that $V_{cd} < V$, in fact $V - 2(140\text{ V}) - 2(47\text{ V}) = V_{cd}$.

24.64. **IDENTIFY:** Find the total charge on the capacitor network when it is connected to the battery. This is the amount of charge that flows through the signal device when the switch is closed.

Circuit(a):

SET UP: For capacitors in parallel, $C_{\text{eq}} = C_1 + C_2 + C_3 + \cdots$

EXECUTE: $C_{\text{equiv}} = C_1 + C_2 + C_3 = 60.0\ \mu$F. $Q = CV = (60.0\ \mu\text{F})(120\text{ V}) = 7200\ \mu$C.

EVALUATE: More charge is stored by the three capacitors in parallel than would be stored in each capacitor used alone

Circuit(b):

SET UP: $C_{\text{equiv}} = \left(\dfrac{1}{C_1} + \dfrac{1}{C_2} + \dfrac{1}{C_3}\right)^{-1}$

EXECUTE: $C_{\text{equiv}} = 5.45\ \mu$F. $Q = (5.45\ \mu\text{F})(120\text{V}) = 654\ \mu$C

EVALUATE: Less charge is stored by the three capacitors in series than would be stored in each capacitor used alone.

24.65. **(a) IDENTIFY** and **SET UP:** Q is constant. $C = KC_0$; use Eq. (24.1) to relate the dielectric constant K to the ratio of the voltages without and with the dielectric.

EXECUTE: With the dielectric: $V = Q/C = Q/(KC_0)$

without the dielectric: $V_0 = Q/C_0$

$V_0/V = K$, so $K = (45.0\text{ V})/(11.5\text{ V}) = 3.91$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: Our analysis agrees with Eq. (24.13).

(b) IDENTIFY: The capacitor can be treated as equivalent to two capacitors C_1 and C_2 in parallel, one with area $2A/3$ and air between the plates and one with area $A/3$ and dielectric between the plates.

SET UP: The equivalent network is shown in Figure 24.65.

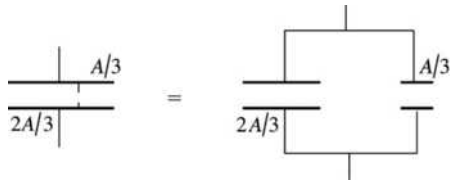


Figure 24.65

EXECUTE: Let $C_0 = \epsilon_0 A/d$ be the capacitance with only air between the plates. $C_1 = KC_0/3, C_2 = 2C_0/3$; $C_{eq} = C_1 + C_2 = (C_0/3)(K+2)$

$$V = \frac{Q}{C_{eq}} = \frac{Q}{C_0}\left(\frac{3}{K+2}\right) = V_0\left(\frac{3}{K+2}\right) = (45.0\text{ V})\left(\frac{3}{5.91}\right) = 22.8\text{ V}$$

EVALUATE: The voltage is reduced by the dielectric. The voltage reduction is less when the dielectric doesn't completely fill the volume between the plates.

24.66. **IDENTIFY:** This situation is analogous to having two capacitors C_1 in series, each with separation $\frac{1}{2}(d-a)$.

SET UP: For capacitors in series, $\frac{1}{C_{eq}} = \frac{1}{C_1} + \frac{1}{C_2}$.

EXECUTE: **(a)** $C = \left(\frac{1}{C_1} + \frac{1}{C_1}\right)^{-1} = \frac{1}{2}C_1 = \frac{1}{2}\frac{\epsilon_0 A}{(d-a)/2} = \frac{\epsilon_0 A}{d-a}$

(b) $C = \frac{\epsilon_0 A}{d-a} = \frac{\epsilon_0 A}{d}\frac{d}{d-a} = C_0\frac{d}{d-a}$

(c) As $a \to 0$, $C \to C_0$. The metal slab has no effect if it is very thin. And as $a \to d$, $C \to \infty$. $V = Q/C$. $V = Ey$ is the potential difference between two points separated by a distance y parallel to a uniform electric field. When the distance is very small, it takes a very large field and hence a large Q on the plates for a given potential difference. Since $Q = CV$ this corresponds to a very large C.

24.67. **IDENTIFY:** The conductor can be at some potential V, where $V = 0$ far from the conductor. This potential depends on the charge Q on the conductor so we can define $C = Q/V$ where C will not depend on V or Q.

SET UP: Use the expression for the potential at the surface of the sphere in the analysis in part (a).

EXECUTE: **(a)** For any point on a solid conducting sphere $V = Q/4\pi\epsilon_0 R$ if $V = 0$ at $r \to \infty$.

$$C = \frac{Q}{V} = \frac{Q}{\frac{Q}{4\pi\epsilon_0 R}} = 4\pi\epsilon_0 R.$$

(b) $C = 4\pi\epsilon_0 R = 4\pi(8.854\times10^{-12}\text{ F/m})(6.38\times10^{6}\text{ m}) = 7.10\times10^{-4}\text{ F} = 710\,\mu\text{F}$.

EVALUATE: The capacitance of the earth is about ten times larger than typical electronic circuit capacitances in the range of 10 pF to 100 pF. Nevertheless, the capacitance of the earth is quite small, in view of its large size.

24.68. **IDENTIFY:** Capacitors in series carry the same charge, but capacitors in parallel have the same potential difference across them.

SET UP: $V_{ab} = 48.0$ V. $C = Q/V$ and $U = \frac{1}{2}CV^2$. For capacitors in parallel, $C = C_1 + C_2$, and for capacitors in series, $1/C = 1/C_1 + 1/C_2$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: Using $U=\frac{1}{2}CV^2$ gives $C=\frac{2U}{V^2}=\frac{2(2.90\times10^{-3}\text{ J})}{(48.0\text{ V})^2}=2.517\times10^{-6}\text{ F}$, which is the equivalent capacitance of the network. The equivalent capacitance for C_1 and C_2 in series is $C_{12}=\frac{1}{2}(4.00\ \mu\text{F})=2.00\ \mu\text{F}$. If C_{123} is the equivalent capacitance for C_{12} and C_3 in parallel, then $\frac{1}{C_{123}}+\frac{1}{C_4}=\frac{1}{C}$. Solving for C_{123} gives

$$\frac{1}{C_{123}}=\frac{1}{C}-\frac{1}{C_4}=\frac{1}{2.517\times10^{-6}\text{ F}}-\frac{1}{8.00\times10^{-6}\text{ F}}=2.722\times10^{5}\text{ F}^{-1},\text{ so }C_{123}=3.673\times10^{-6}\text{ F}.$$

$C_{12}+C_3=C_{123}$. $C_3=C_{123}-C_{12}=3.673\ \mu\text{F}-2.00\ \mu\text{F}=1.67\ \mu\text{F}$.

EVALUATE: As with most circuits, it is necessary to solve them in a series of steps rather than using a single step.

24.69. **IDENTIFY:** We model the earth as a spherical capacitor.

SET UP: The capacitance of the earth is $C=4\pi\epsilon_0\frac{r_ar_b}{r_b-r_a}$ and, the charge on it is $Q=CV$, and its stored energy is $U=\frac{1}{2}CV^2$.

EXECUTE: **(a)** $C=\frac{1}{9.00\times10^{9}\text{ N}\cdot\text{m}^2/\text{C}^2}\frac{(6.38\times10^{6}\text{ m})(6.45\times10^{6}\text{ m})}{6.45\times10^{6}\text{ m}-6.38\times10^{6}\text{ m}}=6.5\times10^{-2}\text{ F}$

(b) $Q=CV=(6.54\times10^{-2}\text{ F})(350{,}000\text{ V})=2.3\times10^{4}\text{ C}$

(c) $U=\frac{1}{2}CV^2=\frac{1}{2}(6.54\times10^{-2}\text{ F})(350{,}000\text{ V})^2=4.0\times10^{9}\text{ J}$

EVALUATE: While the capacitance of the earth is larger than ordinary laboratory capacitors, capacitors much larger than this, such as 1 F, are readily available.

24.70. **IDENTIFY:** The electric field energy density is $u=\frac{1}{2}\epsilon_0E^2$. $U=\frac{Q^2}{2C}$.

SET UP: For this charge distribution, $E=0$ for $r<r_a$, $E=\frac{\lambda}{2\pi\epsilon_0r}$ for $r_a<r<r_b$ and $E=0$ for $r>r_b$. Example 24.4 shows that $\frac{U}{L}=\frac{2\pi\epsilon_0}{\ln(r_b/r_a)}$ for a cylindrical capacitor.

EXECUTE: **(a)** $u=\frac{1}{2}\epsilon_0E^2=\frac{1}{2}\epsilon_0\left(\frac{\lambda}{2\pi\epsilon_0r}\right)^2=\frac{\lambda^2}{8\pi^2\epsilon_0r^2}$

(b) $U=\int udV=2\pi L\int urdr=\frac{L\lambda^2}{4\pi\epsilon_0}\int_{r_a}^{r_b}\frac{dr}{r}$ and $\frac{U}{L}=\frac{\lambda^2}{4\pi\epsilon_0}\ln(r_b/r_a)$.

(c) Using Eq. (24.9), $U=\frac{Q^2}{2C}=\frac{Q^2}{4\pi\epsilon_0L}\ln(r_b/r_a)=\frac{\lambda^2L}{4\pi\epsilon_0}\ln(r_b/r_a)$. This agrees with the result of part (b).

EVALUATE: We could have used the results of part (b) and $U=\frac{Q^2}{2C}$ to calculate C/L and would obtain the same result as in Example 24.4.

24.71. **IDENTIFY:** The increase in temperature of the wire allows us to find out how much heat it gained, which is the energy initially stored in the capacitor. We can use this energy to find the capacitance of the capacitor.

SET UP: The heat in the wire is $Q=mc\Delta T$ and the energy stored in the capacitor is $U=\frac{1}{2}CV^2$, which is equal to the heat Q.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: The heat that goes into the wire is

$Q = mc\Delta T = (12.0\times10^{-3}\text{ kg})(910\text{ J/(kg}\cdot\text{K)})(11.2\text{ K}) = 122.3\text{ J}$. For the capacitor, $U = \frac{1}{2}CV^2$.

$$C = \frac{2U}{V^2} = \frac{2(122.3\text{ J})}{(2.25\times10^3\text{ V})^2} = 4.83\times10^{-5}\text{ F} = 48.3\ \mu\text{F}.$$

EVALUATE: A capacitance of 48.3 μF is quite reasonable for ordinary laboratory capacitors.

24.72. **IDENTIFY:** The capacitor is equivalent to two capacitors in parallel, as shown in Figure 24.72.

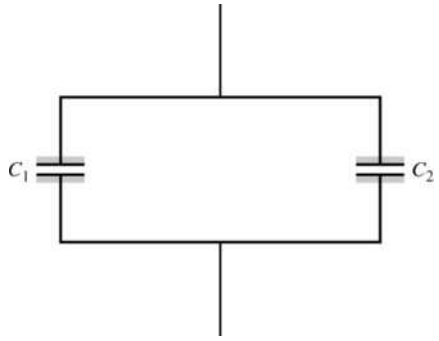

Figure 24.72

SET UP: Each of these two capacitors have plates that are 12.0 cm by 6.0 cm. For a parallel-plate capacitor with dielectric filling the volume between the plates, $C = K\epsilon_0\frac{A}{d}$. For two capacitors in parallel, $C = C_1 + C_2$. The energy stored in a capacitor is $U = \frac{1}{2}CV^2$.

EXECUTE: **(a)** $C = C_1 + C_2$.

$$C_2 = \epsilon_0\frac{A}{d} = \frac{(8.854\times10^{-12}\text{ F/m})(0.120\text{ m})(0.060\text{ m})}{4.50\times10^{-3}\text{ m}} = 1.42\times10^{-11}\text{ F}.$$

$C_1 = KC_2 = (3.40)(1.42\times10^{-11}\text{ F}) = 4.83\times10^{-11}\text{ F}$. $C = C_1 + C_2 = 6.25\times10^{-11}\text{ F} = 62.5\text{ pF}$.

(b) $U = \frac{1}{2}CV^2 = \frac{1}{2}(6.25\times10^{-11}\text{ F})(18.0\text{ V})^2 = 1.01\times10^{-8}\text{ J}$.

(c) Now $C_1 = C_2$ and $C = 2(1.42\times10^{-11}\text{ F}) = 2.84\times10^{-11}\text{ F}$.

$U = \frac{1}{2}CV^2 = \frac{1}{2}(2.84\times10^{-11}\text{ F})(18.0\text{ V})^2 = 4.60\times10^{-9}\text{ J}$.

EVALUATE: The plexiglass increases the capacitance and that increases the energy stored for the same voltage across the capacitor.

24.73. **IDENTIFY:** The two slabs of dielectric are in series with each other.

SET UP: The capacitor is equivalent to C_1 and C_2 in series, so $\frac{1}{C_1} + \frac{1}{C_2} = \frac{1}{C}$, which gives $C = \frac{C_1C_2}{C_1 + C_2}$.

EXECUTE: With $d = 1.90$ mm, $C_1 = \frac{K_1\epsilon_0 A}{d}$ and $C_2 = \frac{K_2\epsilon_0 A}{d}$.

$$C = \left(\frac{K_1K_2}{K_1 + K_2}\right)\frac{\epsilon_0 A}{d} = \frac{(8.854\times10^{-12}\text{ C}^2/(\text{N}\cdot\text{m}^2))(0.0800\text{ m})^2}{1.90\times10^{-3}\text{ m}}\left(\frac{(4.7)(2.6)}{4.7 + 2.6}\right) = 4.992\times10^{-11}\text{ F}.$$

$$U = \frac{1}{2}CV^2 = \frac{1}{2}(4.992\times10^{-11}\text{ F})(86.0\text{ V})^2 = 1.85\times10^{-7}\text{ J}.$$

EVALUATE: The dielectrics increase the capacitance, allowing the capacitor to store more energy than if it were air-filled.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

24.74. **IDENTIFY:** The system is equivalent to two capacitors in parallel. One of the capacitors has plate separation d, plate area $w(L-h)$ and air between the plates. The other has the same plate separation d, plate area wh and dielectric constant K.

SET UP: Define K_{eff} by $C_{\text{eq}} = \dfrac{K_{\text{eff}}\epsilon_0 A}{d}$, where $A = wL$. For two capacitors in parallel, $C_{\text{eq}} = C_1 + C_2$.

EXECUTE: **(a)** The capacitors are in parallel, so $C = \dfrac{\epsilon_0 w(L-h)}{d} + \dfrac{K\epsilon_0 wh}{d} = \dfrac{\epsilon_0 wL}{d}\left(1 + \dfrac{Kh}{L} - \dfrac{h}{L}\right)$. This gives $K_{\text{eff}} = \left(1 + \dfrac{Kh}{L} - \dfrac{h}{L}\right)$.

(b) For gasoline, with $K = 1.95$: $\dfrac{1}{4}$ full: $K_{\text{eff}}\left(h = \dfrac{L}{4}\right) = 1.24$; $\dfrac{1}{2}$ full: $K_{\text{eff}}\left(h = \dfrac{L}{2}\right) = 1.48$;

$\dfrac{3}{4}$ full: $K_{\text{eff}}\left(h = \dfrac{3L}{4}\right) = 1.71$.

(c) For methanol, with $K = 33$: $\dfrac{1}{4}$ full: $K_{\text{eff}}\left(h = \dfrac{L}{4}\right) = 9$; $\dfrac{1}{2}$ full: $K_{\text{eff}}\left(h = \dfrac{L}{2}\right) = 17$;

$\dfrac{3}{4}$ full: $K_{\text{eff}}\left(h = \dfrac{3L}{4}\right) = 25$.

(d) This kind of fuel tank sensor will work best for methanol since it has the greater range of K_{eff} values.

EVALUATE: When $h = 0$, $K_{\text{eff}} = 1$. When $h = L$, $K_{\text{eff}} = K$.

24.75. **IDENTIFY:** The object is equivalent to two identical capacitors in parallel, where each has the same area A, plate separation d and dielectric with dielectric constant K.

SET UP: For each capacitor in the parallel combination, $C = \dfrac{\epsilon_0 A}{d}$.

EXECUTE: **(a)** The charge distribution on the plates is shown in Figure 24.75.

(b) $C = 2\left(\dfrac{\epsilon_0 A}{d}\right) = \dfrac{2(4.2)\epsilon_0 (0.120\ \text{m})^2}{4.5\times10^{-4}\ \text{m}} = 2.38\times10^{-9}\ \text{F}$.

EVALUATE: If two of the plates are separated by both sheets of paper to form a capacitor, $C = \dfrac{\epsilon_0 A}{2d} = \dfrac{2.38\times10^{-9}\ \text{F}}{4}$, smaller by a factor of 4 compared to the capacitor in the problem.

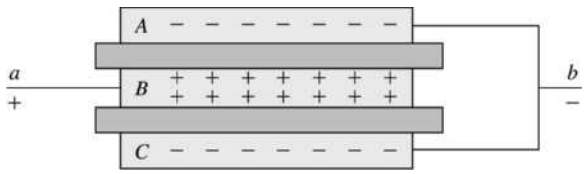

Figure 24.75

24.76. **IDENTIFY:** The force on one plate is due to the electric field of the other plate. The electrostatic force must be balanced by the forces from the springs.

SET UP: The electric field due to one plate is $E = \dfrac{\sigma}{2\epsilon_0}$. The force exerted by a spring compressed a distance $z_0 - z$ from equilibrium is $k(z_0 - z)$.

EXECUTE: **(a)** The force between the two parallel plates is $F = qE = \dfrac{q\sigma}{2\epsilon_0} = \dfrac{q^2}{2\epsilon_0 A} = \dfrac{(CV)^2}{2\epsilon_0 A} = \dfrac{\epsilon_0^2 A^2}{z^2}\dfrac{V^2}{2\epsilon_0 A} = \dfrac{\epsilon_0 A V^2}{2z^2}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) When $V = 0$, the separation is just z_0. When $V \neq 0$, the total force from the four springs must equal the electrostatic force calculated in part (a). $F_{4\text{ springs}} = 4k(z_0 - z) = \dfrac{\epsilon_0 A V^2}{2z^2}$ and $2z^3 - 2z^3 z_0 + \dfrac{\epsilon_0 A V^2}{4k} = 0$.

(c) For $A = 0.300\text{ m}^2$, $z_0 = 1.2\times10^{-3}$ m, $k = 25$ N/m and $V = 120$ V, so $2z^3 - (2.4\times10^{-3}\text{ m})z^2 + 3.82\times10^{-10}\text{ m}^3 = 0$. The physical solutions to this equation are $z = 0.537$ mm and 1.014 mm.

EVALUATE: **(d)** Stable equilibrium occurs if a slight displacement from equilibrium yields a force back toward the equilibrium point. If one evaluates the forces at small displacements from the equilibrium positions above, the 1.014 mm separation is seen to be stable, but not the 0.537 mm separation.

24.77. **IDENTIFY:** The system can be considered to be two capacitors in parallel, one with plate area $L(L-x)$ and air between the plates and one with area Lx and dielectric filling the space between the plates.

SET UP: $C = \dfrac{K\epsilon_0 A}{d}$ for a parallel-plate capacitor with plate area A.

EXECUTE: **(a)** $C = \dfrac{\epsilon_0}{D}((L-x)L + xKL) = \dfrac{\epsilon_0 L}{D}(L + (K-1)x)$

(b) $dU = \frac{1}{2}(dC)V^2$, where $C = C_0 + \dfrac{\epsilon_0 L}{D}(-dx + dxK)$, with $C_0 = \dfrac{\epsilon_0 L}{D}(L + (K-1)x)$. This gives

$$dU = \tfrac{1}{2}\left(\frac{\epsilon_0 L dx}{D}(K-1)\right)V^2 = \frac{(K-1)\epsilon_0 V^2 L}{2D}dx.$$

(c) If the charge is kept constant on the plates, then $Q = \dfrac{\epsilon_0 LV}{D}(L + (K-1)x)$ and

$U = \frac{1}{2}CV^2 = \frac{1}{2}C_0V^2\left(\dfrac{C}{C_0}\right)$. $U \approx \dfrac{C_0V^2}{2}\left(1 - \dfrac{\epsilon_0 L}{DC_0}(K-1)dx\right)$ and $\Delta U = U - U_0 = -\dfrac{(K-1)\epsilon_0 V^2 L}{2D}dx$.

(d) Since $dU = -F dx = -\dfrac{(K-1)\epsilon_0 V^2 L}{2D}dx$, the force is in the opposite direction to the motion dx, meaning that the slab feels a force pushing it out.

EVALUATE: **(e)** When the plates are connected to the battery, the plates plus slab are not an isolated system. In addition to the work done on the slab by the charges on the plates, energy is also transferred between the battery and the plates. Comparing the results for dU in part (c) to $dU = -F dx$ gives

$$F = \frac{(K-1)\epsilon_0 V^2 L}{2D}.$$

24.78. **IDENTIFY:** $C = Q/V$. Apply Gauss's law and the relation between potential difference and electric field.

SET UP: Each conductor is an equipotential surface. $V_a - V_b = \int_{r_a}^{r_b}\vec{\boldsymbol{E}}_{\text{U}}\cdot d\vec{\boldsymbol{r}} = \int_{r_a}^{r_b}\vec{\boldsymbol{E}}_{\text{L}}\cdot d\vec{\boldsymbol{r}}$, so $E_{\text{U}} = E_{\text{L}}$, where these are the fields between the upper and lower hemispheres. The electric field is the same in the air space as in the dielectric.

EXECUTE: **(a)** For a normal spherical capacitor with air between the plates, $C_0 = 4\pi\epsilon_0\left(\dfrac{r_a r_b}{r_b - r_a}\right)$. The capacitor in this problem is equivalent to two parallel capacitors, C_{L} and C_{U}, each with half the plate area of the normal capacitor. $C_{\text{L}} = \dfrac{KC_0}{2} = 2\pi K\epsilon_0\left(\dfrac{r_a r_b}{r_b - r_a}\right)$ and $C_{\text{U}} = \dfrac{C_0}{2} = 2\pi\epsilon_0\left(\dfrac{r_a r_b}{r_b - r_a}\right)$.

$$C = C_{\text{U}} + C_{\text{L}} = 2\pi\epsilon_0(1+K)\left(\frac{r_a r_b}{r_b - r_a}\right).$$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) Using a hemispherical Gaussian surface for each respective half, $E_{\rm L}\dfrac{4\pi r^2}{2}=\dfrac{Q_{\rm L}}{K\epsilon_0}$, so $E_{\rm L}=\dfrac{Q_{\rm L}}{2\pi K\epsilon_0 r^2}$, and $E_{\rm U}\dfrac{4\pi r^2}{2}=\dfrac{Q_{\rm U}}{\epsilon_0}$, so $E_{\rm U}=\dfrac{Q_{\rm U}}{2\pi\epsilon_0 r^2}$. But $Q_{\rm L}=VC_{\rm L}$ and $Q_{\rm U}=VC_{\rm U}$. Also, $Q_{\rm L}+Q_{\rm U}=Q$. Therefore, $Q_{\rm L}=\dfrac{VC_0K}{2}=KQ_{\rm U}$ and $Q_{\rm U}=\dfrac{Q}{1+K}$, $Q_{\rm L}=\dfrac{KQ}{1+K}$. This gives $E_{\rm L}=\dfrac{KQ}{1+K}\dfrac{1}{2\pi K\epsilon_0 r^2}=\dfrac{2}{1+K}\dfrac{Q}{4\pi\epsilon_0 r^2}$ and $E_{\rm U}=\dfrac{Q}{1+K}\dfrac{1}{2\pi K\epsilon_0 r^2}=\dfrac{2}{1+K}\dfrac{Q}{4\pi K\epsilon_0 r^2}$. We do find that $E_{\rm U}=E_{\rm L}$.

(c) The free charge density on upper and lower hemispheres are: $(\sigma_{{\rm f},r_a})_{\rm U}=\dfrac{Q_{\rm U}}{2\pi r_a^2}=\dfrac{Q}{2\pi r_a^2(1+K)}$ and $(\sigma_{{\rm f},r_b})_{\rm U}=\dfrac{Q_{\rm U}}{2\pi r_b^2}=\dfrac{Q}{2\pi r_b^2(1+K)}$; $(\sigma_{{\rm f},r_a})_{\rm L}=\dfrac{Q_{\rm L}}{2\pi r_a^2}=\dfrac{KQ}{2\pi r_a^2(1+K)}$ and $(\sigma_{{\rm f},r_b})_{\rm L}=\dfrac{Q_{\rm L}}{2\pi r_b^2}=\dfrac{KQ}{2\pi r_b^2(1+K)}$.

(d) $\sigma_{{\rm i},r_a}=\sigma_{{\rm f},r_a}(1-1/K)=\left(\dfrac{(K-1)}{K}\right)\dfrac{Q}{2\pi r_a^2}\left(\dfrac{K}{K+1}\right)=\left(\dfrac{K-1}{K+1}\right)\dfrac{Q}{2\pi r_a^2}$

$\sigma_{{\rm i},r_b}=\sigma_{{\rm f},r_b}(1-1/K)=\left(\dfrac{(K-1)}{K}\right)\dfrac{Q}{2\pi r_b^2}\left(\dfrac{K}{K+1}\right)=\left(\dfrac{K-1}{K+1}\right)\dfrac{Q}{2\pi r_b^2}$

(e) There is zero bound charge on the flat surface of the dielectric-air interface, or else that would imply a circumferential electric field, or that the electric field changed as we went around the sphere.

EVALUATE: The charge is not equally distributed over the surface of each conductor. There must be more charge on the lower half, by a factor of *K*, because the polarization of the dielectric means more free charge is needed on the lower half to produce the same electric field.

25

CURRENT, RESISTANCE, AND ELECTROMOTIVE FORCE

25.1. **IDENTIFY** and **SET UP:** The lightning is a current that lasts for a brief time. $I = \dfrac{\Delta Q}{\Delta t}$.

EXECUTE: $\Delta Q = I\Delta t = (25{,}000\text{ A})(40\times10^{-6}\text{ s}) = 1.0\text{ C}$.

EVALUATE: Even though it lasts for only 40 μs, the lightning carries a huge amount of charge since it is an enormous current.

25.2. **IDENTIFY:** $I = Q/t$. Use $I = n|q|v_d A$ to calculate the drift velocity v_d.

SET UP: $n = 5.8\times10^{28}\text{ m}^{-3}$. $|q| = 1.60\times10^{-19}\text{ C}$.

EXECUTE: **(a)** $I = \dfrac{Q}{t} = \dfrac{420\text{ C}}{80(60\text{ s})} = 8.75\times10^{-2}\text{ A}$.

(b) $I = n|q|v_d A$. This gives $v_d = \dfrac{I}{n|q|A} = \dfrac{8.75\times10^{-2}\text{ A}}{(5.8\times10^{28})(1.60\times10^{-19}\text{ C})(\pi(1.3\times10^{-3}\text{ m})^2)} = 1.78\times10^{-6}\text{ m/s}$.

EVALUATE: v_d is smaller than in Example 25.1, because I is smaller in this problem.

25.3. **IDENTIFY:** $I = Q/t$. $J = I/A$. $J = n|q|v_d$

SET UP: $A = (\pi/4)D^2$, with $D = 2.05\times10^{-3}$ m. The charge of an electron has magnitude $+e = 1.60\times10^{-19}$ C.

EXECUTE: **(a)** $Q = It = (5.00\text{ A})(1.00\text{ s}) = 5.00\text{ C}$. The number of electrons is $\dfrac{Q}{e} = 3.12\times10^{19}$.

(b) $J = \dfrac{I}{(\pi/4)D^2} = \dfrac{5.00\text{ A}}{(\pi/4)(2.05\times10^{-3}\text{ m})^2} = 1.51\times10^{6}\text{ A/m}^2$.

(c) $v_d = \dfrac{J}{n|q|} = \dfrac{1.51\times10^{6}\text{ A/m}^2}{(8.5\times10^{28}\text{ m}^{-3})(1.60\times10^{-19}\text{ C})} = 1.11\times10^{-4}\text{ m/s} = 0.111\text{ mm/s}$.

EVALUATE: **(d)** If I is the same, $J = I/A$ would decrease and v_d would decrease. The number of electrons passing through the light bulb in 1.00 s would not change.

25.4. **(a) IDENTIFY:** By definition, $J = I/A$ and radius is one-half the diameter.

SET UP: Solve for the current: $I = JA = J\pi(D/2)^2$

EXECUTE: $I = (1.50\times10^6\text{ A/m}^2)(\pi)[(0.00102\text{ m})/2]^2 = 1.23\text{ A}$

EVALUATE: This is a realistic current.

(b) IDENTIFY: The current density is $J = n|q|v_d$.

SET UP: Solve for the drift velocity: $v_d = J/n|q|$

EXECUTE: Since most laboratory wire is copper, we use the value of n for copper, giving $v_d = (1.50\times10^{6}\text{ A/m}^2)/[(8.5\times10^{28}/\text{m}^3)(1.60\times10^{-19}\text{ C})] = 1.1\times10^{-4}\text{ m/s} = 0.11\text{ mm/s}$.

EVALUATE: This is a typical drift velocity for ordinary currents and wires.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

25.5. **IDENTIFY** and **SET UP:** Use Eq. (25.3) to calculate the drift speed and then use that to find the time to travel the length of the wire.

EXECUTE: **(a)** Calculate the drift speed v_d:

$$J = \frac{I}{A} = \frac{I}{\pi r^2} = \frac{4.85\text{ A}}{\pi(1.025\times10^{-3}\text{ m})^2} = 1.469\times10^{6}\text{ A/m}^2$$

$$v_d = \frac{J}{n|q|} = \frac{1.469\times10^{6}\text{ A/m}^2}{(8.5\times10^{28}/\text{m}^3)(1.602\times10^{-19}\text{ C})} = 1.079\times10^{-4}\text{ m/s}$$

$$t = \frac{L}{v_d} = \frac{0.710\text{ m}}{1.079\times10^{-4}\text{ m/s}} = 6.58\times10^{3}\text{ s} = 110\text{ min.}$$

(b) $v_d = \dfrac{I}{\pi r^2 n|q|}$

$$t = \frac{L}{v_d} = \frac{\pi r^2 n|q|L}{I}$$

t is proportional to r^2 and hence to d^2 where $d = 2r$ is the wire diameter.

$$t = (6.58\times10^{3}\text{ s})\left(\frac{4.12\text{ mm}}{2.05\text{ mm}}\right)^2 = 2.66\times10^{4}\text{ s} = 440\text{ min.}$$

(c) EVALUATE: The drift speed is proportional to the current density and therefore it is inversely proportional to the square of the diameter of the wire. Increasing the diameter by some factor decreases the drift speed by the square of that factor.

25.6. **IDENTIFY:** The number of moles of copper atoms is the mass of 1.00 m^3 divided by the atomic mass of copper. There are $N_A = 6.022\times10^{23}$ atoms per mole.

SET UP: The atomic mass of copper is 63.55 g/mole, and its density is 8.96 g/cm^3. Example 25.1 says there are 8.5×10^{28} free electrons per m^3.

EXECUTE: The number of copper atoms in 1.00 m^3 is

$$\frac{(8.96\text{ g/cm}^3)(1.00\times10^{6}\text{ cm}^3/\text{m}^3)(6.022\times10^{23}\text{ atoms/mole})}{63.55\text{ g/mole}} = 8.49\times10^{28}\text{ atoms/m}^3.$$

EVALUATE: Since there are the same number of free electrons/m^3 as there are atoms of copper/m^3, the number of free electrons per copper atom is one.

25.7. **IDENTIFY** and **SET UP:** Apply Eq. (25.1) to find the charge dQ in time dt. Integrate to find the total charge in the whole time interval.

EXECUTE: **(a)** $dQ = I\,dt$

$$Q = \int_0^{8.0\text{s}} (55\text{ A} - (0.65\text{ A/s}^2)t^2)dt = \left[(55\text{ A})t - (0.217\text{ A/s}^2)t^3\right]_0^{8.0\text{ s}}$$

$$Q = (55\text{ A})(8.0\text{ s}) - (0.217\text{ A/s}^2)(8.0\text{ s})^3 = 330\text{ C}$$

(b) $I = \dfrac{Q}{t} = \dfrac{330\text{ C}}{8.0\text{ s}} = 41\text{ A}$

EVALUATE: The current decreases from 55 A to 13.4 A during the interval. The decrease is not linear and the average current is not equal to $(55\text{A} + 13.4\text{ A})/2$.

25.8. **IDENTIFY:** $I = Q/t$. Positive charge flowing in one direction is equivalent to negative charge flowing in the opposite direction, so the two currents due to Cl^- and Na^+ are in the same direction and add.

SET UP: Na^+ and Cl^- each have magnitude of charge $|q| = +e$.

EXECUTE: **(a)** $Q_{\text{total}} = (n_{\text{Cl}} + n_{\text{Na}})e = (3.92\times10^{16} + 2.68\times10^{16})(1.60\times10^{-19}\text{ C}) = 0.0106\text{ C}$. Then

$$I = \frac{Q_{\text{total}}}{t} = \frac{0.0106\text{ C}}{1.00\text{ s}} = 0.0106\text{ A} = 10.6\text{ mA.}$$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) Current flows, by convention, in the direction of positive charge. Thus, current flows with Na^+ toward the negative electrode.

EVALUATE: The Cl^- ions have negative charge and move in the direction opposite to the conventional current direction.

25.9. **IDENTIFY** and **SET UP:** The number of ions that enter gives the charge that enters the axon in the specified time. $I = \dfrac{\Delta Q}{\Delta t}$.

EXECUTE: $\Delta Q = (5.6\times10^{11}\text{ ions})(1.60\times10^{-19}\text{ C/ion}) = 9.0\times10^{-8}\text{ C}$. $I = \dfrac{\Delta Q}{\Delta t} = \dfrac{9.0\times10^{-8}\text{ C}}{10\times10^{-3}\text{ s}} = 9.0\,\mu\text{A}$.

EVALUATE: This current is much smaller than household currents but are comparable to many currents in electronic equipment.

25.10. **(a) IDENTIFY:** Start with the definition of resistivity and solve for E.

SET UP: $E = \rho J = \rho I/\pi r^2$

EXECUTE: $E = (1.72\times10^{-8}\ \Omega\cdot\text{m})(2.75\text{ A})/[\pi(0.001025\text{ m})^2] = 1.43\times10^{-2}\text{ V/m}$

EVALUATE: The field is quite weak, since the potential would drop only a volt in 70 m of wire.

(b) IDENTIFY: Take the ratio of the field in silver to the field in copper.

SET UP: Take the ratio and solve for the field in silver: $E_S = E_C(\rho_S/\rho_C)$

EXECUTE: $E_S = (0.0143\text{ V/m})[(1.47)/(1.72)] = 1.22\times10^{-2}\text{ V/m}$

EVALUATE: Since silver is a better conductor than copper, the field in silver is smaller than the field in copper.

25.11. **IDENTIFY:** First use Ohm's law to find the resistance at 20.0°C; then calculate the resistivity from the resistance. Finally use the dependence of resistance on temperature to calculate the temperature coefficient of resistance.

SET UP: Ohm's law is $R = V/I$, $R = \rho L/A$, $R = R_0[1+\alpha(T-T_0)]$, and the radius is one-half the diameter.

EXECUTE: **(a)** At 20.0°C, $R = V/I = (15.0\text{ V})/(18.5\text{ A}) = 0.811\,\Omega$. Using $R = \rho L/A$ and solving for ρ gives $\rho = RA/L = R\pi(D/2)^2/L = (0.811\ \Omega)\pi[(0.00500\text{ m})/2]^2/(1.50\text{ m}) = 1.06\times10^{-5}\ \Omega\cdot\text{m}$.

(b) At 92.0°C, $R = V/I = (15.0\text{ V})/(17.2\text{ A}) = 0.872\ \Omega$. Using $R = R_0[1+\alpha(T-T_0)]$ with T_0 taken as 20.0°C, we have $0.872\ \Omega = (0.811\ \Omega)[1+\alpha(92.0°\text{C} - 20.0°\text{C})]$. This gives $\alpha = 0.00105\ (\text{C}°)^{-1}$.

EVALUATE: The results are typical of ordinary metals.

25.12. **IDENTIFY:** $E = \rho J$, where $J = I/A$. The drift velocity is given by $I = n|q|v_d A$.

SET UP: For copper, $\rho = 1.72\times10^{-8}\ \Omega\cdot\text{m}$. $n = 8.5\times10^{28}/\text{m}^3$.

EXECUTE: **(a)** $J = \dfrac{I}{A} = \dfrac{3.6\text{ A}}{(2.3\times10^{-3}\text{ m})^2} = 6.81\times10^5\text{ A/m}^2$.

(b) $E = \rho J = (1.72\times10^{-8}\ \Omega\cdot\text{m})(6.81\times10^5\text{ A/m}^2) = 0.012\text{ V/m}$.

(c) The time to travel the wire's length l is

$$t = \frac{l}{v_d} = \frac{lnAq}{I} = \frac{(4.0\text{ m})(8.5\times10^{28}/\text{m}^3)(1.6\times10^{-19}\text{ C})(2.3\times10^{-3}\text{ m})^2}{3.6\text{ A}} = 8.0\times10^4\text{ s}.$$

$t = 1333\text{ min} \approx 22\text{ hrs}$!

EVALUATE: The currents propagate very quickly along the wire but the individual electrons travel very slowly.

25.13. **IDENTIFY:** Knowing the resistivity of a metal, its geometry and the current through it, we can use Ohm's law to find the potential difference across it.

SET UP: $V = IR$. For copper, Table 25.1 gives that $\rho = 1.72\times10^{-8}\ \Omega\cdot\text{m}$ and for silver, $\rho = 1.47\times10^{-8}\ \Omega\cdot\text{m}$. $R = \dfrac{\rho L}{A}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: **(a)** $R=\dfrac{\rho L}{A}=\dfrac{(1.72\times10^{-8}\ \Omega\cdot\text{m})(2.00\ \text{m})}{\pi(0.814\times10^{-3}\ \text{m})^2}=1.65\times10^{-2}\ \Omega.$

$V=(12.5\times10^{-3}\ \text{A})(1.65\times10^{-2}\ \Omega)=2.06\times10^{-4}\ \text{V}.$

(b) $V=\dfrac{I\rho L}{A}.\ \ \dfrac{V}{\rho}=\dfrac{IL}{A}=\text{constant, so }\ \dfrac{V_\text{s}}{\rho_\text{s}}=\dfrac{V_\text{c}}{\rho_\text{c}}.$

$$V_\text{s}=V_\text{c}\left(\frac{\rho_\text{s}}{\rho_\text{c}}\right)=(2.06\times10^{-4}\ \text{V})\left(\frac{1.47\times10^{-8}\ \Omega\cdot\text{m}}{1.72\times10^{-8}\ \Omega\cdot\text{m}}\right)=1.76\times10^{-4}\ \text{V}.$$

EVALUATE: The potential difference across a 2-m length of wire is less than 0.2 mV, so normally we do not need to worry about these potential drops in laboratory circuits.

25.14. **IDENTIFY:** The resistivity of the wire should identify what the material is.

SET UP: $R=\rho L/A$ and the radius of the wire is half its diameter.

EXECUTE: Solve for ρ and substitute the numerical values.

$$\rho=AR/L=\pi(D/2)^2R/L=\frac{\pi([0.00205\ \text{m}]/2)^2(0.0290\,\Omega)}{6.50\ \text{m}}=1.47\times10^{-8}\ \Omega\cdot\text{m}$$

EVALUATE: This result is the same as the resistivity of silver, which implies that the material is silver.

25.15. **(a) IDENTIFY:** Start with the definition of resistivity and use its dependence on temperature to find the electric field.

SET UP: $E=\rho J=\rho_{20}[1+\alpha(T-T_0)]\dfrac{I}{\pi r^2}$

EXECUTE: $E=(5.25\times10^{-8}\ \Omega\cdot\text{m})[1+(0.0045/\text{C}^\circ)(120^\circ\text{C}-20^\circ\text{C})](12.5\ \text{A})/[\pi(0.000500\ \text{m})^2]=1.21\ \text{V/m}.$

(Note that the resistivity at 120°C turns out to be $7.61\times10^{-8}\ \Omega\cdot\text{m}$.)

EVALUATE: This result is fairly large because tungsten has a larger resistivity than copper.

(b) IDENTIFY: Relate resistance and resistivity.

SET UP: $R=\rho L/A=\rho L/\pi r^2$

EXECUTE: $R=(7.61\times10^{-8}\Omega\cdot\text{m})(0.150\ \text{m})/[\pi(0.000500\ \text{m})^2]=0.0145\ \Omega$

EVALUATE: Most metals have very low resistance.

(c) IDENTIFY: The potential difference is proportional to the length of wire.

SET UP: $V=EL$

EXECUTE: $V=(1.21\ \text{V/m})(0.150\ \text{m})=0.182\ \text{V}$

EVALUATE: We could also calculate $V=IR=(12.5\ \text{A})(0.0145\,\Omega)=0.181\ \text{V},$ in agreement with part (c).

25.16. **IDENTIFY:** The geometry of the wire is changed, so its resistance will also change.

SET UP: $R=\dfrac{\rho L}{A}.\ \ L_\text{new}=3L.$ The volume of the wire remains the same when it is stretched.

EXECUTE: Volume $=LA$ so $LA=L_\text{new}\,A_\text{new}.\ \ A_\text{new}=\dfrac{L}{L_\text{new}}A=\dfrac{A}{3}.$

$$R_\text{new}=\frac{\rho L_\text{new}}{A_\text{new}}=\frac{\rho(3L)}{A/3}=9\frac{\rho L}{A}=9R.$$

EVALUATE: When the length increases the resistance increases and when the area decreases the resistance increases.

25.17. **IDENTIFY:** $R=\dfrac{\rho L}{A}.$

SET UP: For copper, $\rho=1.72\times10^{-8}\ \Omega\cdot\text{m}.\ \ A=\pi r^2.$

EXECUTE: $R=\dfrac{(1.72\times10^{-8}\ \Omega\cdot\text{m})(24.0\ \text{m})}{\pi(1.025\times10^{-3}\ \text{m})^2}=0.125\,\Omega$

EVALUATE: The resistance is proportional to the length of the piece of wire.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

25.18. **IDENTIFY:** $R = \dfrac{\rho L}{A} = \dfrac{\rho L}{\pi d^2/4}$.

SET UP: For aluminum, $\rho_{\text{al}} = 2.63\times10^{-8}\ \Omega\cdot\text{m}$. For copper, $\rho_{\text{c}} = 1.72\times10^{-8}\ \Omega\cdot\text{m}$.

EXECUTE: $\dfrac{\rho}{d^2} = \dfrac{R\pi}{4L} =$ constant, so $\dfrac{\rho_{\text{al}}}{d_{\text{al}}^2} = \dfrac{\rho_{\text{c}}}{d_{\text{c}}^2}$.

$$d_{\text{c}} = d_{\text{al}}\sqrt{\frac{\rho_{\text{c}}}{\rho_{\text{al}}}} = (3.26\ \text{mm})\sqrt{\frac{1.72\times10^{-8}\ \Omega\cdot\text{m}}{2.63\times10^{-8}\ \Omega\cdot\text{m}}} = 2.64\ \text{mm}.$$

EVALUATE: Copper has a smaller resistivity, so the copper wire has a smaller diameter in order to have the same resistance as the aluminum wire.

25.19. **IDENTIFY** and **SET UP:** Use Eq. (25.10) to calculate A. Find the volume of the wire and use the density to calculate the mass.

EXECUTE: Find the volume of one of the wires:

$R = \dfrac{\rho L}{A}$ so $A = \dfrac{\rho L}{R}$ and

$$\text{Volume} = AL = \frac{\rho L^2}{R} = \frac{(1.72\times10^{-8}\ \Omega\cdot\text{m})(3.50\ \text{m})^2}{0.125\ \Omega} = 1.686\times10^{-6}\ \text{m}^3$$

$$m = (\text{density})V = (8.9\times10^3\ \text{kg/m}^3)(1.686\times10^{-6}\ \text{m}^3) = 15\ \text{g}$$

EVALUATE: The mass we calculated is reasonable for a wire.

25.20. **IDENTIFY:** $R = \dfrac{\rho L}{A}$.

SET UP: The length of the wire in the spring is the circumference πd of each coil times the number of coils.

EXECUTE: $L = (75)\pi d = (75)\pi(3.50\times10^{-2}\ \text{m}) = 8.25\ \text{m}$.

$A = \pi r^2 = \pi d^2/4 = \pi(3.25\times10^{-3}\ \text{m})^2/4 = 8.30\times10^{-6}\ \text{m}^2$.

$$\rho = \frac{RA}{L} = \frac{(1.74\ \Omega)(8.30\times10^{-6}\ \text{m}^2)}{8.25\ \text{m}} = 1.75\times10^{-6}\ \Omega\,.\,\text{m}.$$

EVALUATE: The value of ρ we calculated is about a factor of 100 times larger than ρ for copper. The metal of the spring is not a very good conductor.

25.21. **IDENTIFY:** $R = \dfrac{\rho L}{A}$.

SET UP: $L = 1.80\ \text{m}$, the length of one side of the cube. $A = L^2$.

EXECUTE: $R = \dfrac{\rho L}{A} = \dfrac{\rho L}{L^2} = \dfrac{\rho}{L} = \dfrac{2.75\times10^{-8}\ \Omega\cdot\text{m}}{1.80\ \text{m}} = 1.53\times10^{-8}\ \Omega$

EVALUATE: The resistance is very small because A is very much larger than the typical value for a wire.

25.22. **IDENTIFY:** Apply $R = \dfrac{\rho L}{A}$ and $V = IR$.

SET UP: $A = \pi r^2$

EXECUTE: $\rho = \dfrac{RA}{L} = \dfrac{VA}{IL} = \dfrac{(4.50\ \text{V})\pi(6.54\times10^{-4}\ \text{m})^2}{(17.6\ \text{A})(2.50\ \text{m})} = 1.37\times10^{-7}\ \Omega\cdot\text{m}.$

EVALUATE: Our result for ρ shows that the wire is made of a metal with resistivity greater than that of good metallic conductors such as copper and aluminum.

25.23. **IDENTIFY** and **SET UP:** Eq. (25.5) relates the electric field that is given to the current density. $V = EL$ gives the potential difference across a length L of wire and Eq. (25.11) allows us to calculate R.

EXECUTE: **(a)** Eq. (25.5): $\rho = E/J$ so $J = E/\rho$

From Table 25.1 the resistivity for gold is $2.44\times10^{-8}\ \Omega\cdot\text{m}$.

$$J = \frac{E}{\rho} = \frac{0.49\ \text{V/m}}{2.44\times10^{-8}\ \Omega\cdot\text{m}} = 2.008\times10^7\ \text{A/m}^2$$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$I = JA = J\pi r^2 = (2.008\times10^7\ \text{A/m}^2)\pi(0.42\times10^{-3}\ \text{m})^2 = 11\ \text{A}$

(b) $V = EL = (0.49\ \text{V/m})(6.4\ \text{m}) = 3.1\ \text{V}$

(c) We can use Ohm's law (Eq. (25.11)): $V = IR$.

$$R = \frac{V}{I} = \frac{3.1\ \text{V}}{11\ \text{A}} = 0.28\ \Omega$$

EVALUATE: We can also calculate R from the resistivity and the dimensions of the wire (Eq. 25.10):

$$R = \frac{\rho L}{A} = \frac{\rho L}{\pi r^2} = \frac{(2.44\times10^{-8}\ \Omega\cdot\text{m})(6.4\ \text{m})}{\pi(0.42\times10^{-3}\ \text{m})^2} = 0.28\ \Omega, \text{ which checks.}$$

25.24. **IDENTIFY:** When the ohmmeter is connected between the opposite faces, the current flows along its length, but when the meter is connected between the inner and outer surfaces, the current flows radially outward.

(a) SET UP: For a hollow cylinder, $R = \rho L/A$, where $A = \pi(b^2 - a^2)$.

EXECUTE: $$R = \rho L/A = \frac{\rho L}{\pi(b^2 - a^2)} = \frac{(2.75\times10^{-8}\ \Omega\cdot\text{m})(2.50\ \text{m})}{\pi[(0.0460\ \text{m})^2 - (0.0320\ \text{m})^2]} = 2.00\times10^{-5}\Omega$$

(b) SET UP: For a thin cylindrical shell of inner radius r and thickness dr, the resistance is $dR = \dfrac{\rho dr}{2\pi rL}$.

For radial current flow from $r = a$ to $r = b$, $R = \int dR = \dfrac{\rho}{2\pi L}\int_a^b \dfrac{1}{r}dr = (\rho/2\pi L)\ln(b/a)$ (Example 25.4).

EXECUTE: $$R = \frac{\rho}{2\pi L}\ln(b/a) = \frac{2.75\times10^{-8}\ \Omega\cdot\text{m}}{2\pi(2.50\ \text{m})}\ln\left(\frac{4.60\ \text{cm}}{3.20\ \text{cm}}\right) = 6.35\times10^{-10}\ \Omega$$

EVALUATE: The resistance is much smaller for the radial flow because the current flows through a much smaller distance and the area through which it flows is much larger.

25.25. **IDENTIFY:** Apply $R = R_0[1 + \alpha(T - T_0)]$ to calculate the resistance at the second temperature.

(a) SET UP: $\alpha = 0.0004\ (\text{C°})^{-1}$ (Table 25.2). Let T_0 be 0.0°C and T be 11.5°C.

EXECUTE: $$R_0 = \frac{R}{1 + \alpha(T - T_0)} = \frac{100.0\ \Omega}{1 + (0.0004\ (\text{C°})^{-1}(11.5\ \text{C°}))} = 99.54\ \Omega$$

(b) SET UP: $\alpha = -0.0005\ (\text{C°})^{-1}$ (Table 25.2). Let $T_0 = 0.0°\text{C}$ and $T = 25.8°\text{C}$.

EXECUTE: $R = R_0[1 + \alpha(T - T_0)] = 0.0160\ \Omega[1 + (-0.0005\ (\text{C°})^{-1})(25.8\ \text{C°})] = 0.0158\ \Omega$

EVALUATE: Nichrome, like most metallic conductors, has a positive α and its resistance increases with temperature. For carbon, α is negative and its resistance decreases as T increases.

25.26. **IDENTIFY:** $R_T = R_0[1 + \alpha(T - T_0)]$

SET UP: $R_0 = 217.3\ \Omega$. $R_T = 215.8\ \Omega$. For carbon, $\alpha = -0.00050(\text{C°})^{-1}$.

EXECUTE: $$T - T_0 = \frac{(R_T/R_0) - 1}{\alpha} = \frac{(215.8\ \Omega/217.3\ \Omega) - 1}{-0.00050\ (\text{C°})^{-1}} = 13.8\ \text{C°}.\quad T = 13.8\ \text{C°} + 4.0°\text{C} = 17.8°\text{C}.$$

EVALUATE: For carbon, α is negative so R decreases as T increases.

25.27. **IDENTIFY** and **SET UP:** Apply $R = \dfrac{\rho L}{A}$ to determine the effect of increasing A and L.

EXECUTE: **(a)** If 120 strands of wire are placed side by side, we are effectively increasing the area of the current carrier by 120. So the resistance is smaller by that factor: $R = (5.60\times10^{-6}\ \Omega)/120 = 4.67\times10^{-8}\ \Omega$.

(b) If 120 strands of wire are placed end to end, we are effectively increasing the length of the wire by 120, and so $R = (5.60\times10^{-6}\ \Omega)120 = 6.72\times10^{-4}\ \Omega$.

EVALUATE: Placing the strands side by side decreases the resistance and placing them end to end increases the resistance.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

25.28. **IDENTIFY:** When current passes through a battery in the direction from the $-$ terminal toward the $+$ terminal, the terminal voltage V_{ab} of the battery is $V_{ab} = \mathcal{E} - Ir$. Also, $V_{ab} = IR$, the potential across the circuit resistor.

SET UP: $\mathcal{E} = 24.0$ V. $I = 4.00$ A.

EXECUTE: **(a)** $V_{ab} = \mathcal{E} - Ir$ gives $r = \dfrac{\mathcal{E} - V_{ab}}{I} = \dfrac{24.0\text{ V} - 21.2\text{ V}}{4.00\text{ A}} = 0.700\,\Omega$.

(b) $V_{ab} - IR = 0$ so $R = \dfrac{V_{ab}}{I} = \dfrac{21.2\text{ V}}{4.00\text{ A}} = 5.30\,\Omega$.

EVALUATE: The voltage drop across the internal resistance of the battery causes the terminal voltage of the battery to be less than its emf. The total resistance in the circuit is $R + r = 6.00\,\Omega$.

$I = \dfrac{24.0\text{ V}}{6.00\,\Omega} = 4.00$ A, which agrees with the value specified in the problem.

25.29. **IDENTIFY:** Use $R = \dfrac{\rho L}{A}$ to calculate R and then apply $V = IR$. $P = VI$ and energy $= Pt$.

SET UP: For copper, $\rho = 1.72\times10^{-8}\ \Omega\cdot$m. $A = \pi r^2$, where $r = 0.050$ m.

EXECUTE: **(a)** $R = \dfrac{\rho L}{A} = \dfrac{(1.72\times10^{-8}\ \Omega\cdot\text{m})(100\times10^{3}\text{m})}{\pi(0.050\text{ m})^2} = 0.219\,\Omega$. $V = IR = (125\text{ A})(0.219\,\Omega) = 27.4$ V.

(b) $P = VI = (27.4\text{ V})(125\text{ A}) = 3422\text{ W} = 3422\text{ J/s}$ and energy $= Pt = (3422\text{ J/s})(3600\text{ s}) = 1.23\times10^{7}$ J.

EVALUATE: The rate of electrical energy loss in the cable is large, over 3 kW.

25.30. **(a) IDENTIFY:** The *idealized* ammeter has no resistance so there is no potential drop across it. Therefore it acts like a short circuit across the terminals of the battery and removes the $4.00\text{-}\Omega$ resistor from the circuit. Thus the only resistance in the circuit is the $2.00\text{-}\Omega$ internal resistance of the battery.

SET UP: Use Ohm's law: $I = \mathcal{E}/r$.

EXECUTE: $I = (10.0\text{ V})/(2.00\ \Omega) = 5.00$ A.

(b) The zero-resistance ammeter is in parallel with the $4.00\text{-}\Omega$ resistor, so all the current goes through the ammeter. If no current goes through the $4.00\text{-}\Omega$ resistor, the potential drop across it must be zero.

(c) The terminal voltage is zero since there is no potential drop across the ammeter.

EVALUATE: An ammeter should *never* be connected this way because it would seriously alter the circuit!

25.31. **IDENTIFY:** The terminal voltage of the battery is $V_{ab} = \mathcal{E} - Ir$. The voltmeter reads the potential difference between its terminals.

SET UP: An ideal voltmeter has infinite resistance.

EXECUTE: **(a)** Since an ideal voltmeter has infinite resistance, so there would be NO current through the $2.0\,\Omega$ resistor.

(b) $V_{ab} = \mathcal{E} = 5.0$ V; Since there is no current there is no voltage lost over the internal resistance.

(c) The voltmeter reading is therefore 5.0 V since with no current flowing there is no voltage drop across either resistor.

EVALUATE: This not the proper way to connect a voltmeter. If we wish to measure the terminal voltage of the battery in a circuit that does not include the voltmeter, then connect the voltmeter across the terminals of the battery.

25.32. **IDENTIFY:** The sum of the potential changes around the circuit loop is zero. Potential decreases by IR when going through a resistor in the direction of the current and increases by $\mathcal{E}$ when passing through an emf in the direction from the $-$ to $+$ terminal.

SET UP: The current is counterclockwise, because the 16-V battery determines the direction of current flow.

EXECUTE: $+16.0\text{ V} - 8.0\text{ V} - I(1.6\,\Omega + 5.0\,\Omega + 1.4\,\Omega + 9.0\,\Omega) = 0$

$$I = \frac{16.0\text{ V} - 8.0\text{ V}}{1.6\,\Omega + 5.0\,\Omega + 1.4\,\Omega + 9.0\,\Omega} = 0.47\text{ A}$$

(b) $V_b + 16.0\text{ V} - I(1.6\,\Omega) = V_a$, so $V_a - V_b = V_{ab} = 16.0\text{ V} - (1.6\,\Omega)(0.47\text{ A}) = 15.2$ V.

(c) $V_c + 8.0\text{ V} + I(1.4\,\Omega + 5.0\,\Omega) = V_a$ so $V_{ac} = (5.0\,\Omega)(0.47\text{ A}) + (1.4\,\Omega)(0.47\text{ A}) + 8.0\text{ V} = 11.0$ V.

(d) The graph is sketched in Figure 25.32.

EVALUATE: $V_{cb} = (0.47\text{ A})(9.0\,\Omega) = 4.2\text{ V}$. The potential at point b is 15.2 V below the potential at point a and the potential at point c is 11.0 V below the potential at point a, so the potential of point c is $15.2\text{ V} - 11.0\text{ V} = 4.2\text{ V}$ above the potential of point b.

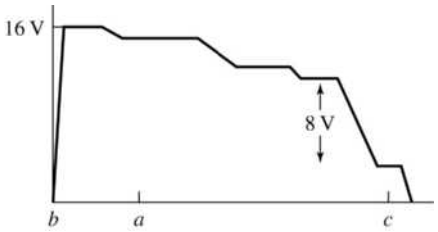

Figure 25.32

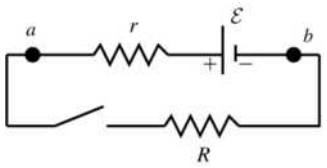
25.33. **IDENTIFY:** The voltmeter reads the potential difference V_{ab} between the terminals of the battery.

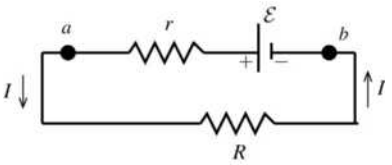
SET UP: open circuit $I = 0$. The circuit is sketched in Figure 25.33a.



EXECUTE: $V_{ab} = \mathcal{E} = 3.08\text{ V}$

Figure 25.33a

SET UP: switch closed The circuit is sketched in Figure 25.33b.



EXECUTE: $V_{ab} = \mathcal{E} - Ir = 2.97\text{ V}$

$$r = \frac{\mathcal{E} - 2.97\text{ V}}{I}$$

$$r = \frac{3.08\text{ V} - 2.97\text{ V}}{1.65\text{ A}} = 0.067\,\Omega$$

Figure 25.33b

And $V_{ab} = IR$ so $R = \dfrac{V_{ab}}{I} = \dfrac{2.97\text{ V}}{1.65\text{ A}} = 1.80\,\Omega$.

EVALUATE: When current flows through the battery there is a voltage drop across its internal resistance and its terminal voltage V is less than its emf.

25.34. **IDENTIFY:** The sum of the potential changes around the loop is zero.

SET UP: The voltmeter reads the IR voltage across the 9.0-Ω resistor. The current in the circuit is counterclockwise because the 16-V battery determines the direction of the current flow.

EXECUTE: **(a)** $V_{bc} = 1.9\text{ V}$ gives $I = V_{bc}/R_{bc} = 1.9\text{ V}/9.0\,\Omega = 0.21\text{ A}$.

(b) $16.0\text{ V} - 8.0\text{ V} = (1.6\,\Omega + 9.0\,\Omega + 1.4\,\Omega + R)(0.21\text{ A})$ and $R = \dfrac{5.48\text{ V}}{0.21\text{ A}} = 26.1\,\Omega$.

(c) The graph is sketched in Figure 25.34.

EVALUATE: In Exercise 25.32 the current is 0.47 A. When the 5.0-Ω resistor is replaced by the 26.1-Ω resistor the current decreases to 0.21 A.

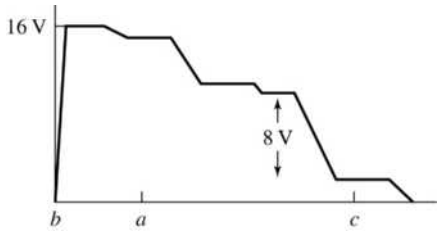

Figure 25.34

25.35. **(a) IDENTIFY** and **SET UP:** Assume that the current is clockwise. The circuit is sketched in Figure 25.35a.

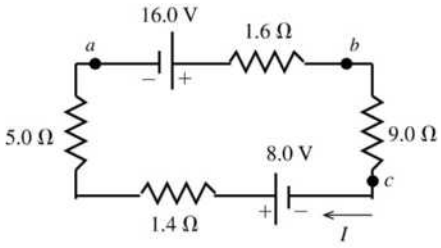

Figure 25.35a

Add up the potential rises and drops as travel clockwise around the circuit.

EXECUTE: $16.0\ \text{V} - I(1.6\ \Omega) - I(9.0\ \Omega) + 8.0\ \text{V} - I(1.4\ \Omega) - I(5.0\ \Omega) = 0$

$$I = \frac{16.0\ \text{V} + 8.0\ \text{V}}{9.0\ \Omega + 1.4\ \Omega + 5.0\ \Omega + 1.6\ \Omega} = \frac{24.0\ \text{V}}{17.0\ \Omega} = 1.41\ \text{A},\ \text{clockwise}$$

EVALUATE: The 16.0-V battery and the 8.0-V battery both drive the current in the same direction.

(b) IDENTIFY and **SET UP:** Start at point *a* and travel through the battery to point *b*, keeping track of the potential changes. At point *b* the potential is V_b.

EXECUTE: $V_a + 16.0\ \text{V} - I(1.6\ \Omega) = V_b$

$V_a - V_b = -16.0\ \text{V} + (1.41\ \text{A})(1.6\ \Omega)$

$V_{ab} = -16.0\ \text{V} + 2.3\ \text{V} = -13.7\ \text{V}$ (point *a* is at lower potential; it is the negative terminal). Therefore, $V_{ba} = 13.7\,\text{V}$.

EVALUATE: Could also go counterclockwise from *a* to *b:*

$V_a + (1.41\ \text{A})(5.0\ \Omega) + (1.41\ \text{A})(1.4\ \Omega) - 8.0\ \text{V} + (1.41\ \text{A})(9.0\ \Omega) = V_b$

$V_{ab} = -13.7\ \text{V},$ which checks.

(c) IDENTIFY and **SET UP:** Start at point *a* and travel through the battery to point *c*, keeping track of the potential changes.

EXECUTE: $V_a + 16.0\ \text{V} - I(1.6\ \Omega) - I(9.0\ \Omega) = V_c$

$V_a - V_c = -16.0\ \text{V} + (1.41\ \text{A})(1.6\ \Omega + 9.0\ \Omega)$

$V_{ac} = -16.0\ \text{V} + 15.0\ \text{V} = -1.0\ \text{V}$ (point *a* is at lower potential than point *c*)

EVALUATE: Could also go counterclockwise from *a* to *c*:

$V_a + (1.41\ \text{A})(5.0\ \Omega) + (1.41\ \text{A})(1.4\ \Omega) - 8.0\ \text{V} = V_c$

$V_{ac} = -1.0\ \text{V},$ which checks.

(d) Call the potential zero at point *a*. Travel clockwise around the circuit. The graph is sketched in Figure 25.35b.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

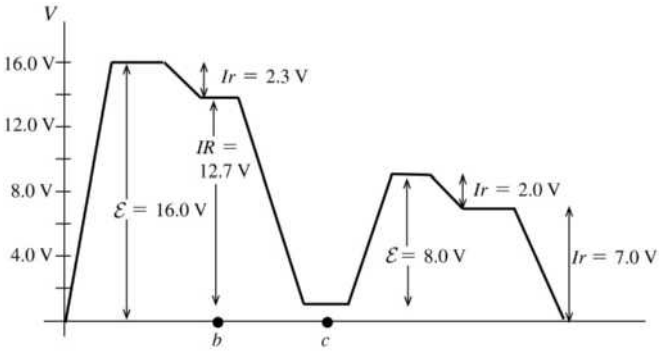

Figure 25.35b

25.36. **IDENTIFY:** Ohm's law says $R = \dfrac{V_{ab}}{I}$ is a constant.

SET UP: **(a)** The graph is given in Figure 25.36a.

EXECUTE: **(b)** No. The graph of V_{ab} versus I is not a straight line so thyrite does not obey Ohm's law.

(c) The graph of R versus I is given in Figure 25.36b. R is not constant; it decreases as I increases.

EVALUATE: Not all materials obey Ohm's law.

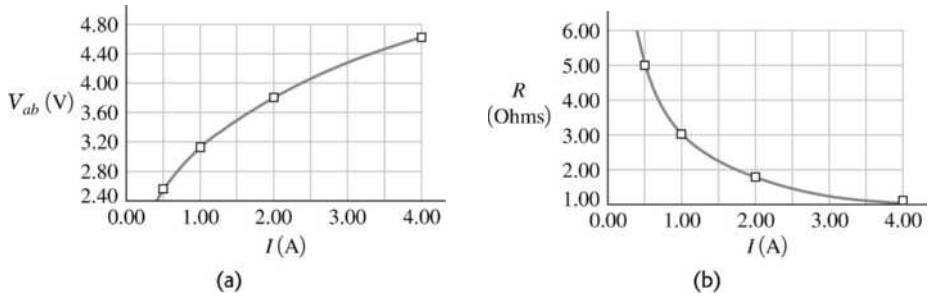

Figure 25.36

25.37. **IDENTIFY:** Ohm's law says $R = \dfrac{V_{ab}}{I}$ is a constant.

SET UP: **(a)** The graph is given in Figure 25.37.

EXECUTE: **(b)** The graph of V_{ab} versus I is a straight line so nichrome obeys Ohm's law.

(c) R is the slope of the graph in part (a). $R = \dfrac{15.52\ \text{V} - 1.94\ \text{V}}{4.00\ \text{A} - 0.50\ \text{A}} = 3.88\ \Omega$.

EVALUATE: V_{ab}/I for every I gives the same result for R, $R = 3.88\ \Omega$.

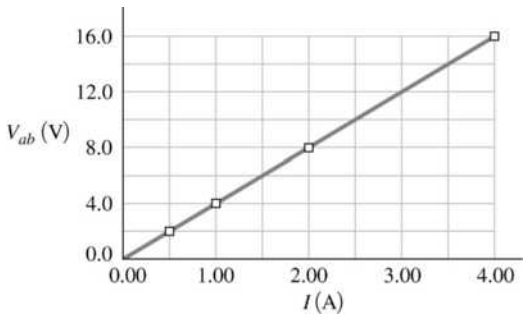

Figure 25.37

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

25.38. **IDENTIFY** and **SET UP:** There is a single current path so the current is the same at all points in the circuit. Assume the current is counterclockwise and apply Kirchhoff's loop rule.

EXECUTE: **(a)** Apply the loop rule, traveling around the circuit in the direction of the current.

$+16.0\ \text{V} - I(1.6\ \Omega + 5.0\ \Omega + 1.4\ \Omega + 9.0\ \Omega) - 8.0\ \text{V} = 0$. $I = \dfrac{16.0\ \text{V} - 8.0\ \text{V}}{17.0\ \Omega} = 0.471\ \text{A}$. Our calculated I is positive so I is counterclockwise, as we assumed.

(b) $V_b + 16.0\ \text{V} - I(1.6\ \Omega) = V_a$. $V_{ab} = 16.0\ \text{V} - (0.471\ \text{A})(1.6\ \Omega) = 15.2\ \text{V}$.

EVALUATE: If we traveled around the circuit in the direction opposite to the current, the final answers would be the same.

25.39. **IDENTIFY:** The bulbs are each connected across a 120-V potential difference.

SET UP: Use $P = V^2/R$ to solve for R and Ohm's law $(I = V/R)$ to find the current.

EXECUTE: **(a)** $R = V^2/P = (120\ \text{V})^2/(100\ \text{W}) = 144\ \Omega$.

(b) $R = V^2/P = (120\ \text{V})^2/(60\ \text{W}) = 240\ \Omega$

(c) For the 100-W bulb: $I = V/R = (120\ \text{V})/(144\ \Omega) = 0.833\ \text{A}$

For the 60-W bulb: $I = (120\ \text{V})/(240\ \Omega) = 0.500\ \text{A}$

EVALUATE: The 60-W bulb has *more* resistance than the 100-W bulb, so it draws less current.

25.40. **IDENTIFY:** Across 120 V, a 75-W bulb dissipates 75 W. Use this fact to find its resistance, and then find the power the bulb dissipates across 220 V.

SET UP: $P = V^2/R$, so $R = V^2/P$

EXECUTE: Across 120 V: $R = (120\ \text{V})^2/(75\ \text{W}) = 192\ \Omega$. Across a 220-V line, its power will be

$P = V^2/R = (220\ \text{V})^2/(192\ \Omega) = 252\ \text{W}$.

EVALUATE: The bulb dissipates much more power across 220 V, so it would likely blow out at the higher voltage. An alternative solution to the problem is to take the ratio of the powers.

$\dfrac{P_{220}}{P_{120}} = \dfrac{V_{220}^2/R}{V_{120}^2/R} = \left(\dfrac{V_{220}}{V_{120}}\right)^2 = \left(\dfrac{220}{120}\right)^2$. This gives $P_{220} = (75\ \text{W})\left(\dfrac{220}{120}\right)^2 = 252\ \text{W}$.

25.41. **IDENTIFY:** A "100-W" European bulb dissipates 100 W when used across 220 V.

(a) SET UP: Take the ratio of the power in the U.S. to the power in Europe, as in the alternative method for Problem 25.40, using $P = V^2/R$.

EXECUTE: $\dfrac{P_{\text{US}}}{P_{\text{E}}} = \dfrac{V_{\text{US}}^2/R}{V_{\text{E}}^2/R} = \left(\dfrac{V_{\text{US}}}{V_{\text{E}}}\right)^2 = \left(\dfrac{120\ \text{V}}{220\ \text{V}}\right)^2$. This gives $P_{\text{US}} = (100\ \text{W})\left(\dfrac{120\ \text{V}}{220\ \text{V}}\right)^2 = 29.8\ \text{W}$.

(b) SET UP: Use $P = IV$ to find the current.

EXECUTE: $I = P/V = (29.8\ \text{W})/(120\ \text{V}) = 0.248\ \text{A}$

EVALUATE: The bulb draws considerably less power in the U.S., so it would be much dimmer than in Europe.

25.42. **IDENTIFY:** $P = VI$. Energy $= Pt$.

SET UP: $P = (9.0\ \text{V})(0.13\ \text{A}) = 1.17\ \text{W}$

EXECUTE: Energy $= (1.17\ \text{W})(1.5\ \text{h})(3600\ \text{s/h}) = 6320\ \text{J}$

EVALUATE: The energy consumed is proportional to the voltage, to the current and to the time.

25.43. **IDENTIFY** and **SET UP:** By definition $p = \dfrac{P}{LA}$. Use $P = VI$, $E = VL$ and $I = JA$ to rewrite this expression in terms of the specified variables.

EXECUTE: **(a)** E is related to V and J is related to I, so use $P = VI$. This gives $p = \dfrac{VI}{LA}$.

$\dfrac{V}{L} = E$ and $\dfrac{I}{A} = J$ so $p = EJ$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) J is related to I and ρ is related to R, so use $P = IR^2$. This gives $p = \dfrac{I^2R}{LA}$.

$I = JA$ and $R = \dfrac{\rho L}{A}$ so $p = \dfrac{J^2A^2\rho L}{LA^2} = \rho J^2$

(c) E is related to V and ρ is related to R, so use $P = V^2/R$. This gives $p = \dfrac{V^2}{RLA}$.

$V = EL$ and $R = \dfrac{\rho L}{A}$ so $p = \dfrac{E^2L^2}{LA}\left(\dfrac{A}{\rho L}\right) = \dfrac{E^2}{\rho}$.

EVALUATE: For a given material (ρ constant), p is proportional to J^2 or to E^2.

25.44. **IDENTIFY:** Knowing the current and potential difference, we can find the power.
SET UP: $P = VI$ and energy is the product of power and time.

EXECUTE: $P = (500\text{ V})(80\times10^{-3}\text{ A}) = 40\text{ W}$.

$\text{Energy} = Pt = (40\text{ W})(10\times10^{-3}\text{ s}) = 0.40\text{ J}$.

EVALUATE: The energy delivered depends not only on the voltage and current but also on the length of the pulse. The pulse is short but the voltage is large.

25.45. **IDENTIFY:** We know the current, voltage and time the current lasts, so we can calculate the power and the energy delivered.
SET UP: Power is energy per unit time. The power delivered by a voltage source is $P = V_{ab}I$.

EXECUTE: **(a)** $P = (25\text{ V})(12\text{ A}) = 300\text{ W}$.

(b) $\text{Energy} = Pt = (300\text{ W})(3.0\times10^{-3}\text{ s}) = 0.90\text{ J}$.

EVALUATE: The energy is not very great, but it is delivered in a short time (3 ms) so the power is large, which produces a short shock.

25.46. **IDENTIFY:** Calculate the current in the circuit. The power output of a battery is its terminal voltage times the current through it. The power dissipated in a resistor is I^2R.
SET UP: The sum of the potential changes around the circuit is zero.

EXECUTE: **(a)** $I = \dfrac{8.0\text{ V}}{17\,\Omega} = 0.47\text{ A}$. Then $P_{5\Omega} = I^2R = (0.47\text{ A})^2(5.0\,\Omega) = 1.1\text{ W}$ and

$P_{9\Omega} = I^2R = (0.47\text{ A})^2(9.0\,\Omega) = 2.0\text{ W}$, so the total is 3.1 W.

(b) $P_{16\text{V}} = \mathcal{E}I - I^2r = (16\text{ V})(0.47\text{ A}) - (0.47\text{ A})^2(1.6\,\Omega) = 7.2\text{ W}$.

(c) $P_{8\text{V}} = \mathcal{E}I + Ir^2 = (8.0\text{ V})(0.47\text{ A}) + (0.47\text{ A})^2(1.4\,\Omega) = 4.1\text{ W}$.

EVALUATE: **(d)** (b) = (a) + (c). The rate at which the 16.0-V battery delivers electrical energy to the circuit equals the rate at which it is consumed in the 8.0-V battery and the 5.0-Ω and 9.0-Ω resistors.

25.47. **(a) IDENTIFY** and **SET UP:** $P = VI$ and energy = (power) × (time).

EXECUTE: $P = VI = (12\text{ V})(60\text{ A}) = 720\text{ W}$

The battery can provide this for 1.0 h, so the energy the battery has stored is

$U = Pt = (720\text{ W})(3600\text{ s}) = 2.6\times10^6\text{ J}$.

(b) IDENTIFY and **SET UP:** For gasoline the heat of combustion is $L_c = 46\times10^6$ J/kg. Solve for the mass m required to supply the energy calculated in part (a) and use density $\rho = m/V$ to calculate V.

EXECUTE: The mass of gasoline that supplies 2.6×10^6 J is $m = \dfrac{2.6\times10^6\text{ J}}{46\times10^6\text{ J/kg}} = 0.0565\text{ kg}$.

The volume of this mass of gasoline is

$V = \dfrac{m}{\rho} = \dfrac{0.0565\text{ kg}}{900\text{ kg/m}^3} = 6.3\times10^{-5}\text{ m}^3\left(\dfrac{1000\text{ L}}{1\text{ m}^3}\right) = 0.063\text{ L}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(c) IDENTIFY and **SET UP:** Energy = (power) × (time); the energy is that calculated in part (a).

EXECUTE: $U = Pt, t = \dfrac{U}{P} = \dfrac{2.6\times10^6\ \text{J}}{450\ \text{W}} = 5800\ \text{s} = 97\ \text{min} = 1.6\ \text{h}.$

EVALUATE: The battery discharges at a rate of 720 W (for 60 A) and is charged at a rate of 450 W, so it takes longer to charge than to discharge.

25.48. **IDENTIFY:** The rate of conversion of chemical to electrical energy in an emf is $\mathcal{E}I$. The rate of dissipation of electrical energy in a resistor R is I^2R.

SET UP: Example 25.9 finds that $I = 1.2$ A for this circuit. In Example 25.8, $\mathcal{E}I = 24$ W and $I^2r = 8$ W. In Example 25.9, $I^2R = 12$ W, or 11.5 W if expressed to three significant figures.

EXECUTE: **(a)** $P = \mathcal{E}I = (12\ \text{V})(1.2\ \text{A}) = 14.4\ \text{W}$. This is less than the previous value of 24 W.

(b) The energy dissipated in the battery is $P = I^2r = (1.2\ \text{A})^2(2.0\ \Omega) = 2.9\ \text{W}$. This is less than 8 W, the amount found in Example (25.8).

(c) The net power output of the battery is $14.4\ \text{W} - 2.9\ \text{W} = 11.5\ \text{W}$. This is the same as the power dissipated in the 8.0-Ω resistor.

EVALUATE: With the larger circuit resistance the current is less and the power input and power consumption are less.

25.49. **IDENTIFY:** Some of the power generated by the internal emf of the battery is dissipated across the battery's internal resistance, so it is not available to the bulb.

SET UP: Use $P = I^2R$ and take the ratio of the power dissipated in the internal resistance r to the total power.

EXECUTE: $\dfrac{P_r}{P_{\text{Total}}} = \dfrac{I^2r}{I^2(r+R)} = \dfrac{r}{r+R} = \dfrac{3.5\ \Omega}{28.5\ \Omega} = 0.123 = 12.3\%$

EVALUATE: About 88% of the power of the battery goes to the bulb. The rest appears as heat in the internal resistance.

25.50. **IDENTIFY:** The voltmeter reads the terminal voltage of the battery, which is the potential difference across the appliance. The terminal voltage is less than 15.0 V because some potential is lost across the internal resistance of the battery.

(a) SET UP: $P = V^2/R$ gives the power dissipated by the appliance.

EXECUTE: $P = (11.3\ \text{V})^2/(75.0\ \Omega) = 1.70\ \text{W}$

(b) SET UP: The drop in terminal voltage $(\mathcal{E} - V_{ab})$ is due to the potential drop across the internal resistance r. Use $Ir = \mathcal{E} - V_{ab}$ to find the internal resistance r, but first find the current using $P = IV$.

EXECUTE: $I = P/V = (1.70\ \text{W})/(11.3\ \text{V}) = 0.151\ \text{A}$. Then $Ir = \mathcal{E} - V_{ab}$ gives $(0.151\ \text{A})r = 15.0\ \text{V} - 11.3\ \text{V}$ and $r = 24.5\ \Omega$.

EVALUATE: The full 15.0-V of the battery would be available only when no current (or a very small current) is flowing in the circuit. This would be the case if the appliance had a resistance much greater than 24.5 Ω.

25.51. **IDENTIFY:** Solve for the current I in the circuit. Apply Eq. (25.17) to the specified circuit elements to find the rates of energy conversion.

SET UP: The circuit is sketched in Figure 25.51

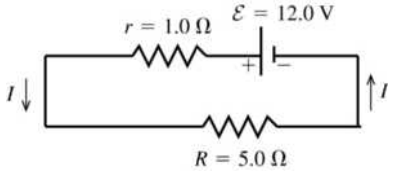

Figure 25.51

EXECUTE: Compute I:

$\mathcal{E} - Ir - IR = 0$

$I = \dfrac{\mathcal{E}}{r+R} = \dfrac{12.0\ \text{V}}{1.0\ \Omega + 5.0\ \Omega} = 2.00\ \text{A}$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(a) The rate of conversion of chemical energy to electrical energy in the emf of the battery is $P = \mathcal{E}I = (12.0\text{ V})(2.00\text{ A}) = 24.0\text{ W}$.

(b) The rate of dissipation of electrical energy in the internal resistance of the battery is $P = I^2r = (2.00\text{ A})^2(1.0\,\Omega) = 4.0\text{ W}$.

(c) The rate of dissipation of electrical energy in the external resistor R is $P = I^2R = (2.00\text{ A})^2(5.0\,\Omega) = 20.0\text{ W}$.

EVALUATE: The rate of production of electrical energy in the circuit is 24.0 W. The total rate of consumption of electrical energy in the circuit is $4.00\text{ W} + 20.0\text{ W} = 24.0\text{ W}$. Equal rate of production and consumption of electrical energy are required by energy conservation.

25.52. **IDENTIFY:** The power delivered to the bulb is I^2R. Energy $= Pt$.

SET UP: The circuit is sketched in Figure 25.52. r_{total} is the combined internal resistance of both batteries.

EXECUTE: **(a)** $r_{\text{total}} = 0$. The sum of the potential changes around the circuit is zero, so $1.5\text{ V} + 1.5\text{ V} - I(17\,\Omega) = 0$. $I = 0.1765\text{ A}$. $P = I^2R = (0.1765\text{ A})^2(17\,\Omega) = 0.530\text{ W}$. This is also $(3.0\text{ V})(0.1765\text{ A})$.

(b) Energy $= (0.530\text{ W})(5.0\text{ h})(3600\text{ s/h}) = 9540\text{ J}$

(c) $P = \dfrac{0.530\text{ W}}{2} = 0.265\text{ W}$. $P = I^2R$ so $I = \sqrt{\dfrac{P}{R}} = \sqrt{\dfrac{0.265\text{ W}}{17\,\Omega}} = 0.125\text{ A}$.

The sum of the potential changes around the circuit is zero, so $1.5\text{ V} + 1.5\text{ V} - IR - Ir_{\text{total}} = 0$.

$$r_{\text{total}} = \frac{3.0\text{ V} - (0.125\text{ A})(17\,\Omega)}{0.125\text{ A}} = 7.0\,\Omega.$$

EVALUATE: When the power to the bulb has decreased to half its initial value, the total internal resistance of the two batteries is nearly half the resistance of the bulb. Compared to a single battery, using two identical batteries in series doubles the emf but also doubles the total internal resistance.

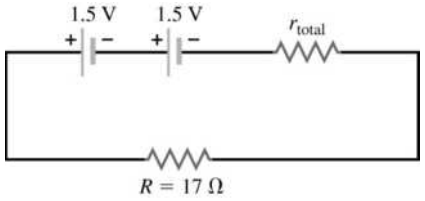

Figure 25.52

25.53. **IDENTIFY:** $P = I^2R = \dfrac{V^2}{R} = VI$. $V = IR$.

SET UP: The heater consumes 540 W when $V = 120$ V. Energy $= Pt$.

EXECUTE: **(a)** $P = \dfrac{V^2}{R}$ so $R = \dfrac{V^2}{P} = \dfrac{(120\text{ V})^2}{540\text{ W}} = 26.7\,\Omega$

(b) $P = VI$ so $I = \dfrac{P}{V} = \dfrac{540\text{ W}}{120\text{ V}} = 4.50\text{ A}$

(c) Assuming that R remains $26.7\,\Omega$, $P = \dfrac{V^2}{R} = \dfrac{(110\text{ V})^2}{26.7\,\Omega} = 453\text{ W}$. P is smaller by a factor of $(110/120)^2$.

EVALUATE: **(d)** With the lower line voltage the current will decrease and the operating temperature will decrease. R will be less than $26.7\,\Omega$ and the power consumed will be greater than the value calculated in part (c).

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

25.54. **IDENTIFY:** From Eq. (25.24), $\rho = \dfrac{m}{ne^2\tau}$.

SET UP: For silicon, $\rho = 2300\ \Omega \cdot \text{m}$.

EXECUTE: **(a)** $\tau = \dfrac{m}{ne^2\rho} = \dfrac{9.11\times10^{-31}\ \text{kg}}{(1.0\times10^{16}\ \text{m}^{-3})(1.60\times10^{-19}\ \text{C})^2(2300\ \Omega\cdot\text{m})} = 1.55\times10^{-12}\ \text{s}.$

EVALUATE: **(b)** The number of free electrons in copper $(8.5\times10^{28}\ \text{m}^{-3})$ is much larger than in pure silicon $(1.0\times10^{16}\ \text{m}^{-3})$. A smaller density of current carriers means a higher resistivity.

25.55. **(a) IDENTIFY** and **SET UP:** Use $R = \dfrac{\rho L}{A}$.

EXECUTE: $\rho = \dfrac{RA}{L} = \dfrac{(0.104\ \Omega)\pi(1.25\times10^{-3}\ \text{m})^2}{14.0\ \text{m}} = 3.65\times10^{-8}\ \Omega\cdot\text{m}$

EVALUATE: This value is similar to that for good metallic conductors in Table 25.1.

(b) IDENTIFY and **SET UP:** Use $V = EL$ to calculate E and then Ohm's law gives I.

EXECUTE: $V = EL = (1.28\ \text{V/m})(14.0\ \text{m}) = 17.9\ \text{V}$

$$I = \frac{V}{R} = \frac{17.9\ \text{V}}{0.104\ \Omega} = 172\ \text{A}$$

EVALUATE: We could do the calculation another way:

$$E = \rho J \text{ so } J = \frac{E}{\rho} = \frac{1.28\ \text{V/m}}{3.65\times10^{-8}\ \Omega\cdot\text{m}} = 3.51\times10^{7}\ \text{A/m}^2$$

$I = JA = (3.51\times10^{7}\ \text{A/m}^2)\pi(1.25\times10^{-3}\ \text{m})^2 = 172\ \text{A},$ which checks.

(c) IDENTIFY and **SET UP:** Calculate $J = I/A$ or $J = E/\rho$ and then use Eq. (25.3) for the target variable v_d.

EXECUTE: $J = n|q|v_\text{d} = nev_\text{d}$

$$v_\text{d} = \frac{J}{ne} = \frac{3.51\times10^{7}\ \text{A/m}^2}{(8.5\times10^{28}\ \text{m}^{-3})(1.602\times10^{-19}\ \text{C})} = 2.58\times10^{-3}\ \text{m/s} = 2.58\ \text{mm/s}$$

EVALUATE: Even for this very large current the drift speed is small.

25.56. **IDENTIFY:** Use $R = \dfrac{\rho L}{A}$ to calculate the resistance of the silver tube. Then $I = V/R$.

SET UP: For silver, $\rho = 1.47\times10^{-8}\ \Omega\cdot\text{m}$. The silver tube is sketched in Figure 25.56. Since the thickness $T = 0.100\ \text{mm}$ is much smaller than the radius, $r = 2.00\ \text{cm}$, the cross-sectional area of the silver is $2\pi rT$. The length of the tube is $l = 25.0\ \text{m}$.

EXECUTE: $I = \dfrac{V}{R} = \dfrac{V}{\rho l/A} = \dfrac{VA}{\rho l} = \dfrac{V(2\pi rT)}{\rho l} = \dfrac{(12\ \text{V})(2\pi)(2.00\times10^{-2}\ \text{m})(0.100\times10^{-3}\ \text{m})}{(1.47\times10^{-8}\ \Omega\cdot\text{m})(25.0\ \text{m})} = 410\ \text{A}$

EVALUATE: The resistance is small, $R = 0.0292\ \Omega$, so 12.0 V produces a large current.

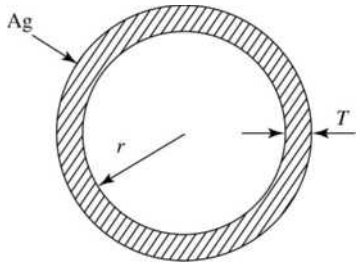

Figure 25.56

25.57. **IDENTIFY** and **SET UP:** With the voltmeter connected across the terminals of the battery there is no current through the battery and the voltmeter reading is the battery emf; $\mathcal{E} = 12.6$ V.
With a wire of resistance R connected to the battery current I flows and $\mathcal{E} - Ir - IR = 0$, where r is the internal resistance of the battery. Apply this equation to each piece of wire to get two equations in the two unknowns.

EXECUTE: Call the resistance of the 20.0-m piece R_1; then the resistance of the 40.0-m piece is $R_2 = 2R_1$.

$\mathcal{E} - I_1 r - I_1 R_1 = 0$; $\quad 12.6\text{ V} - (7.00\text{ A})r - (7.00\text{ A})R_1 = 0$

$\mathcal{E} - I_2 r - I_2(2R_1) = 0$; $\quad 12.6\text{ V} - (4.20\text{ A})r - (4.20\text{ A})(2R_1) = 0$

Solving these two equations in two unknowns gives $R_1 = 1.20\,\Omega$. This is the resistance of 20.0 m, so the resistance of one meter is $[1.20\,\Omega/(20.0\text{ m})](1.00\text{ m}) = 0.060\,\Omega$.

EVALUATE: We can also solve for r and we get $r = 0.600\,\Omega$. When measuring small resistances, the internal resistance of the battery has a large effect.

25.58. **IDENTIFY:** Conservation of charge requires that the current is the same in both sections. The voltage drops across each section add, so $R = R_{\text{Cu}} + R_{\text{Ag}}$. The total resistance is the sum of the resistances of each section. $E = \rho J = \dfrac{\rho I}{A}$, so $E = \dfrac{IR}{L}$, where R is the resistance of a section and L is its length.

SET UP: For copper, $\rho_{\text{Cu}} = 1.72\times10^{-8}\,\Omega\cdot\text{m}$. For silver, $\rho_{\text{Ag}} = 1.47\times10^{-8}\,\Omega\cdot\text{m}$.

EXECUTE: **(a)** $I = \dfrac{V}{R} = \dfrac{V}{R_{\text{Cu}} + R_{\text{Ag}}}$. $R_{\text{Cu}} = \dfrac{\rho_{\text{Cu}} L_{\text{Cu}}}{A_{\text{Cu}}} = \dfrac{(1.72\times10^{-8}\,\Omega\cdot\text{m})(0.8\text{ m})}{(\pi/4)(6.0\times10^{-4}\text{m})^2} = 0.049\,\Omega$ and

$R_{\text{Ag}} = \dfrac{\rho_{\text{Ag}} L_{\text{Ag}}}{A_{\text{Ag}}} = \dfrac{(1.47\times10^{-8}\,\Omega\cdot\text{m})(1.2\text{ m})}{(\pi/4)(6.0\times10^{-4}\text{ m})^2} = 0.062\,\Omega$. This gives $I = \dfrac{5.0\text{ V}}{0.049\,\Omega + 0.062\,\Omega} = 45$ A.

The current in the copper wire is 45 A.

(b) The current in the silver wire is 45 A, the same as that in the copper wire or else charge would build up at their interface.

(c) $E_{\text{Cu}} = J\rho_{\text{Cu}} = \dfrac{IR_{\text{Cu}}}{L_{\text{Cu}}} = \dfrac{(45\text{ A})(0.049\,\Omega)}{0.8\text{ m}} = 2.76$ V/m.

(d) $E_{\text{Ag}} = J\rho_{\text{Ag}} = \dfrac{IR_{\text{Ag}}}{L_{\text{Ag}}} = \dfrac{(45\text{ A})(0.062\,\Omega)}{1.2\text{ m}} = 2.33$ V/m.

(e) $V_{\text{Ag}} = IR_{\text{Ag}} = (45\text{ A})(0.062\,\Omega) = 2.79$ V.

EVALUATE: For the copper section, $V_{\text{Cu}} = IR_{\text{Cu}} = 2.21$ V. Note that $V_{\text{Cu}} + V_{\text{Ag}} = 5.0$ V, the voltage applied across the ends of the composite wire.

25.59. **IDENTIFY:** Conservation of charge requires that the current be the same in both sections of the wire.

$E = \rho J = \dfrac{\rho I}{A}$. For each section, $V = IR = JAR = \left(\dfrac{EA}{\rho}\right)\left(\dfrac{\rho L}{A}\right) = EL$. The voltages across each section add.

SET UP: $A = (\pi/4)D^2$, where D is the diameter.

EXECUTE: **(a)** The current must be the same in both sections of the wire, so the current in the thin end is 2.5 mA.

(b) $E_{1.6\text{mm}} = \rho J = \dfrac{\rho I}{A} = \dfrac{(1.72\times10^{-8}\,\Omega\cdot\text{m})(2.5\times10^{-3}\text{ A})}{(\pi/4)(1.6\times10^{-3}\text{ m})^2} = 2.14\times10^{-5}$ V/m.

(c) $E_{0.8\text{mm}} = \rho J = \dfrac{\rho I}{A} = \dfrac{(1.72\times10^{-8}\,\Omega\cdot\text{m})(2.5\times10^{-3}\text{ A})}{(\pi/4)(0.80\times10^{-3}\text{ m})^2} = 8.55\times10^{-5}$ V/m. This is $4E_{1.6\text{mm}}$.

(d) $V = E_{1.6\text{mm}}L_{1.6\text{ mm}} + E_{0.8\text{ mm}}L_{0.8\text{ mm}}$. $V = (2.14\times10^{-5}\text{ V/m})(1.20\text{ m}) + (8.55\times10^{-5}\text{ V/m})(1.80\text{ m}) = 1.80\times10^{-4}$ V.

EVALUATE: The currents are the same but the current density is larger in the thinner section and the electric field is larger there.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

25.60. **IDENTIFY:** $I = JA$.

SET UP: From Example 25.1, an 18-gauge wire has $A = 8.17\times10^{-3}\ \text{cm}^2$.

EXECUTE: **(a)** $I = JA = (1.0\times10^5\ \text{A/cm}^2)(8.17\times10^{-3}\ \text{cm}^2) = 820\ \text{A}$

(b) $A = I/J = (1000\ \text{A})/(1.0\times10^6\ \text{A/cm}^2) = 1.0\times10^{-3}\ \text{cm}^2$. $A = \pi r^2$ so

$r = \sqrt{A/\pi} = \sqrt{(1.0\times10^{-3}\ \text{cm}^2)/\pi} = 0.0178\ \text{cm}$ and $d = 2r = 0.36\ \text{mm}$.

EVALUATE: These wires can carry very large currents.

25.61. **IDENTIFY:** The current generates heat in the nichrome heating element. This heat increases the temperature of the water and its aluminum container.

SET UP: The rate of heating in the nichrome is $P = I^2R$, the power is Q/t, and the current in the circuit is $I = \dfrac{\mathcal{E}}{R+r}$, where $\mathcal{E}$ is the internal emf of the battery.

EXECUTE: $I = \dfrac{\mathcal{E}}{R+r} = \dfrac{96.0\ \text{V}}{28.0\ \Omega + 1.2\ \Omega} = 3.288\ \text{A}$.

$P = I^2R = (3.288\ \text{A})^2(28.0\ \Omega) = 302.6\ \text{W}$. The total heat needed is:

Cup: $Q = mc\Delta T = (0.130\ \text{kg})(910\ \text{J/(kg}\cdot\text{K)})(34.5^\circ\text{C} - 21.2^\circ\text{C}) = 1573\ \text{J}$.

Water: $Q = mc\Delta T = (0.200\ \text{kg})(4190\ \text{J/(kg}\cdot\text{K)})(34.5^\circ\text{C} - 21.2^\circ\text{C}) = 11{,}145\ \text{J}$.

Total: $Q = 12{,}718\ \text{J}$. $t = \dfrac{Q}{P} = \dfrac{12{,}718\ \text{J}}{302.6\ \text{W}} = 42.0\ \text{s}$.

EVALUATE: A current of about 3 A is rather large and would generate heat at a considerable rate. It could reasonably change the temperature of the water and aluminum by about $13\ \text{C}^\circ$ in 42 s.

25.62. **IDENTIFY:** The current in the circuit depends on R and on the internal resistance of the battery, as well as the emf of the battery. It is only the current in R that dissipates energy in the resistor R.

SET UP: $I = \dfrac{\mathcal{E}}{R+r}$, where $\mathcal{E}$ is the emf of the battery, and $P = I^2R$.

EXECUTE: $P = I^2R = \dfrac{\mathcal{E}^2}{(R+r)^2}R$, which gives $\mathcal{E}^2R = (R^2 + 2Rr + r^2)P$.

$$R^2 + \left(2r - \frac{\mathcal{E}^2}{P}\right)R + r^2 = 0.\quad R = \frac{1}{2}\left[\left(\frac{\mathcal{E}^2}{P} - 2r\right) \pm \sqrt{\left(\frac{\mathcal{E}^2}{P} - 2r\right)^2 - 4r^2}\right].$$

$$R = \frac{1}{2}\left[\left(\frac{(12.0\ \text{V})^2}{80.0\ \text{W}} - 2(0.40\ \Omega)\right) \pm \sqrt{\left(\frac{(12.0\ \text{V})^2}{80.0\ \text{W}} - 2(0.40\ \Omega)\right)^2 - 4(0.40\ \Omega)^2}\right].$$

$R = 0.50\ \Omega \pm 0.30\ \Omega$. $R = 0.20\ \Omega$ and $R = 0.80\ \Omega$.

EVALUATE: There are two values for R because there are two ways for the power dissipated in R to be 80 W. The power is $P = I^2R$, so we can have a small $R(0.20\ \Omega)$ and large current, or a larger $R(0.80\ \Omega)$ and a smaller current.

25.63. **IDENTIFY:** Knowing the current and the time for which it lasts, plus the resistance of the body, we can calculate the energy delivered.

SET UP: Electrical energy is deposited in his body at the rate $P = I^2R$. Heat energy Q produces a temperature change ΔT according to $Q = mc\Delta T$, where $c = 4190\ \text{J/kg}\cdot\text{C}^\circ$.

EXECUTE: **(a)** $P = I^2R = (25{,}000\ \text{A})^2(1.0\ \text{k}\,\Omega) = 6.25\times10^{11}\ \text{W}$. The energy deposited is

$Pt = (6.15\times10^{11}\ \text{W})(40\times10^{-6}\ \text{s}) = 2.5\times10^7\ \text{J}$. Find ΔT when $Q = 2.5\times10^7\ \text{J}$.

$$\Delta T = \frac{Q}{mc} = \frac{2.5\times10^7\ \text{J}}{(75\ \text{kg})(4190\ \text{J/kg}\cdot\text{C}^\circ)} = 80\ \text{C}^\circ.$$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) An increase of only $63\,\text{C}^\circ$ brings the water in the body to the boiling point; part of the person's body will be vaporized.

EVALUATE: Even this approximate calculation shows that being hit by lightning is very dangerous.

25.64. **IDENTIFY:** The moving electron carries its charge around the nucleus and therefore produces a current.

SET UP: $I = \dfrac{\Delta Q}{\Delta t}$. In 1.00 s the electron passes a point on the orbit 6.0×10^{15} times. The charge of an electron has magnitude e.

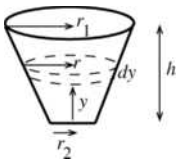
EXECUTE: The magnitude of the average current is

$I = \dfrac{(6.0\times10^{15})e}{1.00\text{ s}} = \dfrac{(6.0\times10^{15})(1.60\times10^{-19}\text{ C})}{1.00\text{ s}} = 9.6\times10^{-4}\text{ A} = 0.96\text{ mA}$. The direction of the current is opposite to the direction of circulation of the electron, since the electron has negative charge.

EVALUATE: This current is comparable to currents in electronic equipment.

25.65. **(a) IDENTIFY:** Apply Eq. (25.10) to calculate the resistance of each thin disk and then integrate over the truncated cone to find the total resistance.

SET UP:



EXECUTE: The radius of a truncated cone a distance y above the bottom is given by $r = r_2 + (y/h)(r_1 - r_2) = r_2 + y\beta$ with $\beta = (r_1 - r_2)/h$.

Figure 25.65

Consider a thin slice a distance y above the bottom. The slice has thickness dy and radius r (see Figure 25.65.) The resistance of the slice is $dR = \dfrac{\rho dy}{A} = \dfrac{\rho dy}{\pi r^2} = \dfrac{\rho dy}{\pi(r_2+\beta y)^2}$.

The total resistance of the cone if obtained by integrating over these thin slices:

$$R = \int dR = \frac{\rho}{\pi}\int_0^h \frac{dy}{(r_2+\beta y)^2} = \frac{\rho}{\pi}\left[-\frac{1}{\beta}(r_2+y\beta)^{-1}\right]_0^h = -\frac{\rho}{\pi\beta}\left[\frac{1}{r_2+h\beta} - \frac{1}{r_2}\right]$$

But $r_2 + h\beta = r_1$

$$R = \frac{\rho}{\pi\beta}\left[\frac{1}{r_2} - \frac{1}{r_1}\right] = \frac{\rho}{\pi}\left(\frac{h}{r_1 - r_2}\right)\left(\frac{r_1 - r_2}{r_1 r_2}\right) = \frac{\rho h}{\pi r_1 r_2}$$

(b) EVALUATE: Let $r_1 = r_2 = r$. Then $R = \rho h/\pi r^2 = \rho L/A$ where $A = \pi r^2$ and $L = h$. This agrees with Eq. (25.10).

25.66. **IDENTIFY:** Divide the region into thin spherical shells of radius r and thickness dr. The total resistance is the sum of the resistances of the thin shells and can be obtained by integration.

SET UP: $I = V/R$ and $J = I/4\pi r^2$, where $4\pi r^2$ is the surface area of a shell of radius r.

EXECUTE: **(a)** $dR = \dfrac{\rho dr}{4\pi r^2} \Rightarrow R = \dfrac{\rho}{4\pi}\displaystyle\int_a^b \frac{dr}{r^2} = -\frac{\rho}{4\pi}\frac{1}{r}\Big|_a^b = \frac{\rho}{4\pi}\left(\frac{1}{a} - \frac{1}{b}\right) = \frac{\rho}{4\pi}\left(\frac{b-a}{ab}\right)$.

(b) $I = \dfrac{V_{ab}}{R} = \dfrac{V_{ab}4\pi ab}{\rho(b-a)}$ and $J = \dfrac{I}{A} = \dfrac{V_{ab}4\pi ab}{\rho(b-a)4\pi r^2} = \dfrac{V_{ab}ab}{\rho(b-a)r^2}$.

(c) If the thickness of the shells is small, then $4\pi ab \approx 4\pi a^2$ is the surface area of the conducting material.

$R = \dfrac{\rho}{4\pi}\left(\dfrac{1}{a} - \dfrac{1}{b}\right) = \dfrac{\rho(b-a)}{4\pi ab} \approx \dfrac{\rho L}{4\pi a^2} = \dfrac{\rho L}{A}$, where $L = b - a$.

EVALUATE: The current density in the material is proportional to $1/r^2$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

25.67. **IDENTIFY:** Apply $R = \dfrac{\rho L}{A}$.

SET UP: For mercury at 20°C, $\rho = 9.5\times10^{-7}\ \Omega\cdot\text{m}$, $\alpha = 0.00088\ (\text{C}°)^{-1}$ and $\beta = 18\times10^{-5}(\text{C}°)^{-1}$.

EXECUTE: **(a)** $R = \dfrac{\rho L}{A} = \dfrac{(9.5\times10^{-7}\ \Omega\cdot\text{m})(0.12\ \text{m})}{(\pi/4)(0.0016\ \text{m})^2} = 0.057\ \Omega$.

(b) $\rho(T) = \rho_0(1+\alpha\Delta T)$ gives

$\rho(60°\ \text{C}) = (9.5\times10^{-7}\ \Omega\cdot\text{m})(1+(0.00088\ (\text{C}°)^{-1})(40\ \text{C}°) = 9.83\times10^{-7}\ \Omega\cdot\text{m}$, so $\Delta\rho = 3.34\times10^{-8}\ \Omega\cdot\text{m}$.

(c) $\Delta V = \beta V_0\Delta T$ gives $A\Delta L = A(\beta L_0\Delta T)$. Therefore

$\Delta L = \beta L_0\Delta T = (18\times10^{-5}\ (\text{C}°)^{-1})(0.12\ \text{m})(40\ \text{C}°) = 8.64\times10^{-4}\ \text{m} = 0.86\ \text{mm}$. The cross-sectional area of the mercury remains constant because the diameter of the glass tube doesn't change. All of the change in volume of the mercury must be accommodated by a change in length of the mercury column.

(d) $R = \dfrac{\rho L}{A}$ gives $\Delta R = \dfrac{L\Delta\rho}{A} + \dfrac{\rho\Delta L}{A}$.

$$\Delta R = \frac{(3.34\times10^{-8}\ \Omega\cdot\text{m})(0.12\ \text{m})}{(\pi/4)(0.0016\ \text{m})^2} + \frac{(95\times10^{-8}\ \Omega\cdot\text{m})(0.86\times10^{-3}\ \text{m})}{(\pi/4)(0.0016\ \text{m})^2} = 2.40\times10^{-3}\ \Omega.$$

EVALUATE: **(e)** From Eq. (25.12),

$$\alpha = \frac{1}{\Delta T}\left(\frac{R}{R_0}-1\right) = \frac{1}{40\ \text{C}°}\left(\frac{(0.057\ \Omega + 2.40\times10^{-3}\ \Omega)}{0.057\ \Omega}-1\right) = 1.1\times10^{-3}\ (\text{C}°)^{-1}.$$

This value is 25% greater than the temperature coefficient of resistivity and the length increase is important.

25.68. **IDENTIFY:** Consider the potential changes around the circuit. For a complete loop the sum of the potential changes is zero.

SET UP: There is a potential drop of IR when you pass through a resistor in the direction of the current.

EXECUTE: **(a)** $I = \dfrac{8.0\ \text{V} - 4.0\ \text{V}}{24.0\ \Omega} = 0.167\ \text{A}$. $V_d + 8.00\ \text{V} - I(0.50\ \Omega + 8.00\ \Omega) = V_a$, so

$V_{ad} = 8.00\ \text{V} - (0.167\ \text{A})(8.50\ \Omega) = 6.58\ \text{V}$.

(b) The terminal voltage is $V_{bc} = V_b - V_c$. $V_c + 4.00\ \text{V} + I(0.50\ \Omega) = V_b$ and

$V_{bc} = +4.00\ \text{V} + (0.167\ \text{A})(0.50\ \Omega) = +4.08\ \text{V}$.

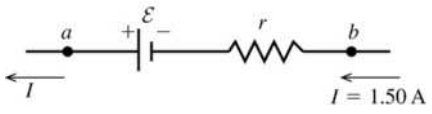
(c) Adding another battery at point d in the opposite sense to the 8.0-V battery produces a counterclockwise current with magnitude $I = \dfrac{10.3\ \text{V} - 8.0\ \text{V} + 4.0\ \text{V}}{24.5\ \Omega} = 0.257\ \text{A}$. Then $V_c + 4.00\ \text{V} - I(0.50\ \Omega) = V_b$ and

$V_{bc} = 4.00\ \text{V} - (0.257\ \text{A})\ (0.50\ \Omega) = 3.87\ \text{V}$.

EVALUATE: When current enters the battery at its negative terminal, as in part (c), the terminal voltage is less than its emf. When current enters the battery at the positive terminal, as in part (b), the terminal voltage is greater than its emf.

25.69. **IDENTIFY:** In each case write the terminal voltage in terms of $\mathcal{E}$, I and r. Since I is known, this gives two equations in the two unknowns $\mathcal{E}$ and r.

SET UP: The battery with the 1.50-A current is sketched in Figure 25.69a.



$V_{ab} = 8.4\ \text{V}$

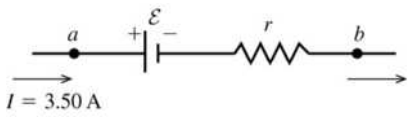
$V_{ab} = \mathcal{E} - Ir$

$\mathcal{E} - (1.50\ \text{A})r = 8.4\ \text{V}$

Figure 25.69a

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

The battery with the 3.50-A current is sketched in Figure 25.69b.



$$V_{ab} = 9.4 \text{ V}$$
$$V_{ab} = \mathcal{E} + Ir$$
$$\mathcal{E} + (3.5 \text{ A})r = 9.4 \text{ V}$$

Figure 25.69b

EXECUTE: **(a)** Solve the first equation for $\mathcal{E}$ and use that result in the second equation:
$\mathcal{E} = 8.4 \text{ V} + (1.50 \text{ A})r$
$8.4 \text{ V} + (1.50 \text{ A})r + (3.50 \text{ A})r = 9.4 \text{ V}$

$(5.00 \text{ A})r = 1.0 \text{ V}$ so $r = \dfrac{1.0 \text{ V}}{5.00 \text{ A}} = 0.20 \ \Omega$

(b) Then $\mathcal{E} = 8.4 \text{ V} + (1.50 \text{ A})r = 8.4 \text{ V} + (1.50 \text{ A})(0.20 \ \Omega) = 8.7 \text{ V}$

EVALUATE: When the current passes through the emf in the direction from $-$ to $+$, the terminal voltage is less than the emf and when it passes through from $+$ to $-$, the terminal voltage is greater than the emf.

25.70. **IDENTIFY:** $V = IR$. $P = I^2R$.

SET UP: The total resistance is the resistance of the person plus the internal resistance of the power supply.

EXECUTE: **(a)** $I = \dfrac{V}{R_{\text{tot}}} = \dfrac{14 \times 10^3 \text{ V}}{10 \times 10^3 \ \Omega + 2000 \ \Omega} = 1.17 \text{ A}$

(b) $P = I^2R = (1.17 \text{ A})^2(10 \times 10^3 \ \Omega) = 1.37 \times 10^4 \text{ J} = 13.7 \text{ kJ}$

(c) $R_{\text{tot}} = \dfrac{V}{I} = \dfrac{14 \times 10^3 \text{ V}}{1.00 \times 10^{-3} \text{ A}} = 14 \times 10^6 \ \Omega$. The resistance of the power supply would need to be

$14 \times 10^6 \ \Omega - 10 \times 10^3 \ \Omega = 14 \times 10^6 \ \Omega = 14 \ \text{M}\Omega$.

EVALUATE: The current through the body in part (a) is large enough to be fatal.

25.71. **IDENTIFY:** $R = \dfrac{\rho L}{A}$. $V = IR$. $P = I^2R$.

SET UP: The area of the end of a cylinder of radius r is πr^2.

EXECUTE: **(a)** $R = \dfrac{(5.0 \ \Omega \cdot \text{m})(1.6 \text{ m})}{\pi(0.050 \text{ m})^2} = 1.0 \times 10^3 \ \Omega$

(b) $V = IR = (100 \times 10^{-3} \text{ A})(1.0 \times 10^3 \ \Omega) = 100 \text{ V}$

(c) $P = I^2R = (100 \times 10^{-3} \text{ A})^2(1.0 \times 10^3 \ \Omega) = 10 \text{ W}$

EVALUATE: The resistance between the hands when the skin is wet is about a factor of ten less than when the skin is dry (Problem 25.70).

25.72. **IDENTIFY:** The cost of operating an appliance is proportional to the amount of energy consumed. The energy depends on the power the item consumes and the length of time for which it is operated.

SET UP: At a constant power, the energy is equal to Pt, and the total cost is the cost per kilowatt-hour (kWh) times the energy (in kWh).

EXECUTE: **(a)** Use the fact that $1.00 \text{ kWh} = (1000 \text{ J/s})(3600 \text{ s}) = 3.60 \times 10^6 \text{ J}$, and one year contains 3.156×10^7 s.

$$(75 \text{ J/s})\left(\frac{3.156 \times 10^7 \text{ s}}{1 \text{ yr}}\right)\left(\frac{\$0.120}{3.60 \times 10^6 \text{ J}}\right) = \$78.90$$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) At 8 h/day, the refrigerator runs for 1/3 of a year. Using the same procedure as above gives

$$(400\text{ J/s})\left(\frac{1}{3}\right)\left(\frac{3.156\times10^{7}\text{ s}}{1\text{ yr}}\right)\left(\frac{\$0.120}{3.60\times10^{6}\text{ J}}\right)=\$140.27$$

EVALUATE: Electric lights can be a substantial part of the cost of electricity in the home if they are left on for a long time!

25.73. **IDENTIFY:** Set the sum of the potential rises and drops around the circuit equal to zero and solve for I.
SET UP: The circuit is sketched in Figure 25.73.

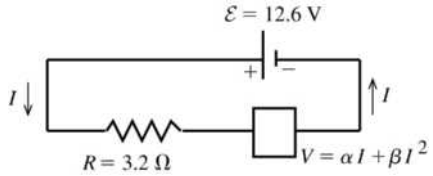


Figure 25.73

EXECUTE: $\mathcal{E}-IR-V=0$

$\mathcal{E}-IR-\alpha I-\beta I^2=0$

$\beta I^2+(R+\alpha)I-\mathcal{E}=0$

The quadratic formula gives $I=(1/2\beta)\left[-(R+\alpha)\pm\sqrt{(R+\alpha)^2+4\beta\mathcal{E}}\right]$

I must be positive, so take the + sign

$I=(1/2\beta)\left[-(R+\alpha)+\sqrt{(R+\alpha)^2+4\beta\mathcal{E}}\right]$

$I=-2.692\text{ A}+4.116\text{ A}=1.42\text{ A}$

EVALUATE: For this I the voltage across the thermistor is 8.0 V. The voltage across the resistor must then be $12.6\text{ V}-8.0\text{ V}=4.6\text{ V}$, and this agrees with Ohm's law for the resistor.

25.74. **(a) IDENTIFY:** The rate of heating (power) in the cable depends on the potential difference across the cable and the resistance of the cable.

SET UP: The power is $P=V^2/R$ and the resistance is $R=\rho L/A$. The diameter D of the cable is twice its radius. $P=\dfrac{V^2}{R}=\dfrac{V^2}{(\rho L/A)}=\dfrac{AV^2}{\rho L}=\dfrac{\pi r^2V^2}{\rho L}$. The electric field in the cable is equal to the potential difference across its ends divided by the length of the cable: $E=V/L$.

EXECUTE: Solving for r and using the resistivity of copper gives

$$r=\sqrt{\frac{P\rho L}{\pi V^2}}=\sqrt{\frac{(50.0\text{ W})(1.72\times10^{-8}\ \Omega\cdot\text{m})(1500\text{ m})}{\pi(220.0\text{ V})^2}}=9.21\times10^{-5}\text{ m}.\quad D=2r=0.184\text{ mm}$$

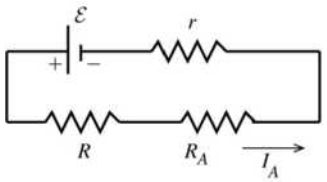
(b) SET UP: $E=V/L$

EXECUTE: $E=(220\text{ V})/(1500\text{ m})=0.147\text{ V/m}$

EVALUATE: This would be an extremely thin (and hence fragile) cable.

25.75. **IDENTIFY:** The ammeter acts as a resistance in the circuit loop. Set the sum of the potential rises and drops around the circuit equal to zero.

(a) SET UP: The circuit with the ammeter is sketched in Figure 25.75a.



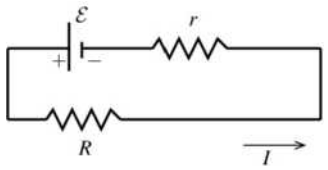
EXECUTE: $I_A=\dfrac{\mathcal{E}}{r+R+R_A}$

$\mathcal{E}=I_A(r+R+R_A)$

Figure 25.75a

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

SET UP: The circuit with the ammeter removed is sketched in Figure 25.75b.



EXECUTE: $I = \dfrac{\mathcal{E}}{R+r}$

Figure 25.75b

Combining the two equations gives

$$I = \left(\frac{1}{R+r}\right) I_A(r+R+R_A) = I_A\left(1+\frac{R_A}{r+R}\right)$$

(b) Want $I_A = 0.990I$. Use this in the result for part (a).

$$I = 0.990I\left(1+\frac{R_A}{r+R}\right)$$

$$0.010 = 0.990\left(\frac{R_A}{r+R}\right)$$

$$R_A = (r+R)(0.010/0.990) = (0.45\,\Omega + 3.80\,\Omega)(0.010/0.990) = 0.0429\,\Omega$$

(c) $I - I_A = \dfrac{\mathcal{E}}{r+R} - \dfrac{\mathcal{E}}{r+R+R_A}$

$$I - I_A = \mathcal{E}\left(\frac{r+R+R_A-r-R}{(r+R)(r+R+R_A)}\right) = \frac{\mathcal{E}R_A}{(r+R)(r+R+R_A)}.$$

EVALUATE: The difference between I and I_A increases as R_A increases. If R_A is larger than the value calculated in part (b) then I_A differs from I by more than 1.0%.

25.76. **IDENTIFY:** Since the resistivity is a function of the position along the length of the cylinder, we must integrate to find the resistance.

(a) SET UP: The resistance of a cross-section of thickness dx is $dR = \rho dx/A$.

EXECUTE: Using the given function for the resistivity and integrating gives

$$R = \int \frac{\rho dx}{A} = \int_0^L \frac{(a+bx^2)dx}{\pi r^2} = \frac{aL + bL^3/3}{\pi r^2}.$$

Now get the constants a and b: $\rho(0) = a = 2.25\times10^{-8}\ \Omega\cdot\text{m}$ and $\rho(L) = a + bL^2$ gives $8.50\times10^{-8}\ \Omega\cdot\text{m} = 2.25\times10^{-8}\ \Omega\cdot\text{m} + b(1.50\ \text{m})^2$ which gives $b = 2.78\times10^{-8}\ \Omega/\text{m}$. Now use the above result to find R.

$$R = \frac{(2.25\times10^{-8}\ \Omega\cdot\text{m})(1.50\ \text{m}) + (2.78\times10^{-8}\ \Omega/\text{m})(1.50\ \text{m})^3/3}{\pi(0.0110\ \text{m})^2} = 1.71\times10^{-4}\ \Omega = 171\,\mu\Omega$$

(b) IDENTIFY: Use the definition of resistivity to find the electric field at the midpoint of the cylinder, where $x = L/2$.

SET UP: $E = \rho J$. Evaluate the resistivity, using the given formula, for $x = L/2$.

EXECUTE: At the midpoint, $x = L/2$, giving $E = \dfrac{\rho I}{\pi r^2} = \dfrac{[a + b(L/2)^2]I}{\pi r^2}$.

$$E = \frac{[2.25\times10^{-8}\ \Omega\cdot\text{m} + (2.78\times10^{-8}\ \Omega/\text{m})(0.750\ \text{m})^2](1.75\ \text{A})}{\pi(0.0110\ \text{m})^2} = 1.76\times10^{-4}\ \text{V/m}$$

(c) IDENTIFY: For the first segment, the result is the same as in part (a) except that the upper limit of the integral is $L/2$ instead of L.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

SET UP: Integrating using the upper limit of $L/2$ gives $R_1 = \dfrac{a(L/2)+(b/3)(L^3/8)}{\pi r^2}$.

EXECUTE: Substituting the numbers gives

$$R_1 = \frac{(2.25\times10^{-8}\ \Omega\cdot\text{m})(0.750\ \text{m})+(2.78\times10^{-8}\ \Omega/\text{m})/3((1.50\ \text{m})^3/8)}{\pi(0.0110\ \text{m})^2} = 5.47\times10^{-5}\ \Omega$$

The resistance R_2 of the second half is equal to the total resistance minus the resistance of the first half.

$$R_2 = R - R_1 = 1.71\times10^{-4}\ \Omega - 5.47\times10^{-5}\ \Omega = 1.16\times10^{-4}\ \Omega$$

EVALUATE: The second half has a greater resistance than the first half because the resistance increases with distance along the cylinder.

25.77. **IDENTIFY:** The power supplied to the house is $P = VI$. The rate at which electrical energy is dissipated in the wires is I^2R, where $R = \dfrac{\rho L}{A}$.

SET UP: For copper, $\rho = 1.72\times10^{-8}\ \Omega\cdot\text{m}$.

EXECUTE: **(a)** The line voltage, current to be drawn, and wire diameter are what must be considered in household wiring.

(b) $P = VI$ gives $I = \dfrac{P}{V} = \dfrac{4200\ \text{W}}{120\ \text{V}} = 35\ \text{A}$, so the 8-gauge wire is necessary, since it can carry up to 40 A.

(c) $P = I^2R = \dfrac{I^2\rho L}{A} = \dfrac{(35\ \text{A})^2\,(1.72\times10^{-8}\ \Omega\cdot\text{m})(42.0\ \text{m})}{(\pi/4)(0.00326\ \text{m})^2} = 106\ \text{W}$.

(d) If 6-gauge wire is used, $P = \dfrac{I^2\rho L}{A} = \dfrac{(35\ \text{A})^2\,(1.72\times10^{-8}\ \Omega\cdot\text{m})\,(42\ \text{m})}{(\pi/4)\,(0.00412\ \text{m})^2} = 66\ \text{W}$. The decrease in energy consumption is $\Delta E = \Delta P t = (40\ \text{W})(365\ \text{days/yr})\,(12\ \text{h/day}) = 175\ \text{kWh/yr}$ and the savings is $(175\ \text{kWh/yr})(\$0.11/\text{kWh}) = \$19.25$ per year.

EVALUATE: The cost of the 4200 W used by the appliances is \$2020. The savings is about 1%.

25.78. **IDENTIFY:** Compact fluorescent bulbs draw much less power than incandescent bulbs and last much longer. Hence they cost less to operate.

SET UP: A kWh is power of 1 kW for a time of 1 h. $P = \dfrac{V^2}{R}$.

EXECUTE: **(a)** In 3.0 yr the bulbs are on for $(3.0\ \text{yr})(365.24\ \text{days/yr})(4.0\ \text{h/day}) = 4.38\times10^3\ \text{h}$.

Compact bulb: The energy used is $(23\ \text{W})(4.38\times10^3\ \text{h}) = 1.01\times10^5\ \text{Wh} = 101\ \text{kWh}$. The cost of this energy is $(\$0.080/\text{kWh})\,(101\,\text{kWh}) = \$8.08$. One bulb will last longer than this. The bulb cost is \$11.00, so the total cost is \$19.08.

Incandescent: The energy used is $(100\ \text{W})(4.38\times10^3\ \text{h}) = 4.38\times10^5\ \text{Wh} = 438\ \text{kWh}$. The cost of this energy is $(\$0.080/\text{kWh})(438\ \text{kWh}) = \$35.04$. Six bulbs will be used during this time and the bulb cost will be \$4.50. The total cost will be \$39.54.

(b) The compact bulb will save $\$39.54 - \$19.08 = \$20.46$.

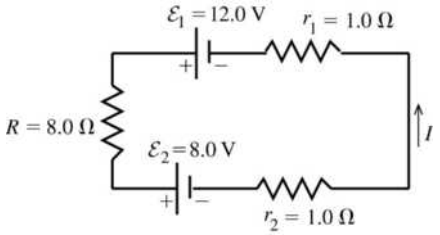
(c) $R = \dfrac{V^2}{P} = \dfrac{(120\ \text{V})^2}{23\ \text{W}} = 626\ \Omega$.

EVALUATE: The initial cost of the bulb is much greater for the compact fluorescent bulb but the savings soon repay the cost of the bulb. The compact bulb should last for over six years, so over a 6-year period the savings per year will be even greater. The cost of compact fluorescent bulbs has come down dramatically, so the savings today would be considerably greater than indicated here.

25.79. **(a) IDENTIFY:** Set the sum of the potential rises and drops around the circuit equal to zero and solve the resulting equation for the current *I*. Apply Eq. (25.17) to each circuit element to find the power associated with it.

SET UP: The circuit is sketched in Figure 25.79.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.



EXECUTE: $\mathcal{E}_1 - \mathcal{E}_2 - I(r_1 + r_2 + R) = 0$

$$I = \frac{\mathcal{E}_1 - \mathcal{E}_2}{r_1 + r_2 + R}$$

$$I = \frac{12.0\ \text{V} - 8.0\ \text{V}}{1.0\ \Omega + 1.0\ \Omega + 8.0\ \Omega}$$

$$I = 0.40\ \text{A}$$

Figure 25.79

(b) $P = I^2R + I^2r_1 + I^2r_2 = I^2(R + r_1 + r_2) = (0.40\ \text{A})^2(8.0\ \Omega + 1.0\ \Omega + 1.0\ \Omega)$

$P = 1.6$ W

(c) Chemical energy is converted to electrical energy in a battery when the current goes through the battery from the negative to the positive terminal, so the electrical energy of the charges increases as the current passes through. This happens in the 12.0-V battery, and the rate of production of electrical energy is $P = \mathcal{E}_1 I = (12.0\ \text{V})(0.40\ \text{A}) = 4.8$ W.

(d) Electrical energy is converted to chemical energy in a battery when the current goes through the battery from the positive to the negative terminal, so the electrical energy of the charges decreases as the current passes through. This happens in the 8.0-V battery, and the rate of consumption of electrical energy is $P = \mathcal{E}_2 I = (8.0\ \text{V})(0.40\ \text{V}) = 3.2$ W.

(e) EVALUATE: Total rate of production of electrical energy = 4.8 W. Total rate of consumption of electrical energy = 1.6 W + 3.2 W = 4.8 W, which equals the rate of production, as it must.

25.80. **IDENTIFY:** Apply $R = \dfrac{\rho L}{A}$ for each material. The total resistance is the sum of the resistances of the rod and the wire. The rate at which energy is dissipated is I^2R.

SET UP: For steel, $\rho = 2.0\times10^{-7}\ \Omega\cdot\text{m}$. For copper, $\rho = 1.72\times10^{-8}\ \Omega\cdot\text{m}$.

EXECUTE: **(a)** $R_{\text{steel}} = \dfrac{\rho L}{A} = \dfrac{(2.0\times10^{-7}\ \Omega\cdot\text{m})(2.0\ \text{m})}{(\pi/4)(0.018\ \text{m})^2} = 1.57\times10^{-3}\ \Omega$ and

$R_{\text{Cu}} = \dfrac{\rho L}{A} = \dfrac{(1.72\times10^{-8}\ \Omega\cdot\text{m})(35\ \text{m})}{(\pi/4)(0.008\ \text{m})^2} = 0.012\ \Omega$. This gives

$V = IR = I(R_{\text{steel}} + R_{\text{Cu}}) = (15000\ \text{A})\ (1.57\times10^{-3}\ \Omega + 0.012\ \Omega) = 204$ V.

(b) $E = Pt = I^2Rt = (15000\ \text{A})^2(0.0136\ \Omega)(65\times10^{-6}\ \text{s}) = 199$ J.

EVALUATE: I^2R is large but t is very small, so the energy deposited is small. The wire and rod each have a mass of about 1 kg, so their temperature rise due to the deposited energy will be small.

25.81. **IDENTIFY** and **SET UP:** The terminal voltage is $V_{ab} = \mathcal{E} - Ir = IR$, where R is the resistance connected to the battery. During the charging the terminal voltage is $V_{ab} = \mathcal{E} + Ir$. $P = VI$ and energy is $E = Pt$. I^2r is the rate at which energy is dissipated in the internal resistance of the battery.

EXECUTE: **(a)** $V_{ab} = \mathcal{E} + Ir = 12.0\ \text{V} + (10.0\ \text{A})\ (0.24\ \Omega) = 14.4$ V.

(b) $E = Pt = IVt = (10\ \text{A})\ (14.4\ \text{V})\ (5)\ (3600\ \text{s}) = 2.59\times10^6$ J.

(c) $E_{\text{diss}} = P_{\text{diss}}t = I^2rt = (10\ \text{A})^2\ (0.24\ \Omega)\ (5)\ (3600\ \text{s}) = 4.32\times10^5$ J.

(d) Discharged at 10 A: $I = \dfrac{\mathcal{E}}{r + R} \Rightarrow R = \dfrac{\mathcal{E} - Ir}{I} = \dfrac{12.0\ \text{V} - (10\ \text{A})\ (0.24\ \Omega)}{10\ \text{A}} = 0.96\ \Omega$.

(e) $E = Pt = IVt = (10\ \text{A})\ (9.6\ \text{V})\ (5)\ (3600\ \text{s}) = 1.73\times10^6$ J.

(f) Since the current through the internal resistance is the same as before, there is the same energy dissipated as in (c): $E_{\text{diss}} = 4.32\times10^5$ J.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: **(g)** Part of the energy originally supplied was stored in the battery and part was lost in the internal resistance. So the stored energy was less than what was supplied during charging. Then when discharging, even more energy is lost in the internal resistance, and only what is left is dissipated by the external resistor.

25.82. **IDENTIFY** and **SET UP:** The terminal voltage is $V_{ab} = \mathcal{E} - Ir = IR$, where R is the resistance connected to the battery. During the charging the terminal voltage is $V_{ab} = \mathcal{E} + Ir$. $P = VI$ and energy is $E = Pt$. I^2r is the rate at which energy is dissipated in the internal resistance of the battery.

EXECUTE: **(a)** $V_{ab} = \mathcal{E} + Ir = 12.0\text{ V} + (30\text{ A})(0.24\ \Omega) = 19.2\text{ V}$.

(b) $E = Pt = IVt = (30\text{ A})\,(19.2\text{ V})\,(1.7)\,(3600\text{ s}) = 3.53\times10^6\text{ J}$.

(c) $E_{\text{diss}} = P_{\text{diss}}t = I^2Rt = (30\text{ A})^2\,(0.24\ \Omega)\,(1.7)\,(3600\text{ s}) = 1.32\times10^6\text{ J}$.

(d) Discharged at 30 A: $I = \dfrac{\mathcal{E}}{r+R}$ gives $R = \dfrac{\mathcal{E} - Ir}{I} = \dfrac{12.0\text{ V} - (30\text{ A})(0.24\ \Omega)}{30\text{ A}} = 0.16\ \Omega$.

(e) $E = Pt = I^2Rt = (30\text{ A})^2\,(0.16\ \Omega)\,(1.7)\,(3600\text{ s}) = 8.81\times10^5\text{ J}$.

(f) Since the current through the internal resistance is the same as before, there is the same energy dissipated as in (c): $E_{\text{diss}} = 1.32\times10^6\text{ J}$.

EVALUATE: **(g)** Again, part of the energy originally supplied was stored in the battery and part was lost in the internal resistance. So the stored energy was less than what was supplied during charging. Then when discharging, even more energy is lost in the internal resistance, and what is left is dissipated over the external resistor. This time, at a higher current, much more energy is lost in the internal resistance. Slow charging and discharging is more energy efficient.

25.83. **IDENTIFY:** No current flows through the capacitor when it is fully charged.

SET UP: With the capacitor fully charged, $I = \dfrac{\mathcal{E}}{R_1 + R_2}$. $V_R = IR$ and $V_C = Q/C$.

EXECUTE: $V_C = \dfrac{Q}{C} = \dfrac{36.0\ \mu\text{C}}{9.00\ \mu\text{F}} = 4.00\text{ V}$. $V_{R_1} = V_C = 4.00\text{ V}$ and $I = \dfrac{V_{R_1}}{R_1} = \dfrac{4.00\text{ V}}{6.00\ \Omega} = 0.667\text{ A}$.

$V_{R_2} = IR_2 = (0.667\text{ A})(4.00\ \Omega) = 2.668\text{ V}$. $\mathcal{E} = V_{R_1} + V_{R_2} = 4.00\text{ V} + 2.668\text{ V} = 6.67\text{ V}$.

EVALUATE: When a capacitor is fully charged, it acts like an open circuit and prevents any current from flowing though it.

25.84. **IDENTIFY:** No current flows to the capacitors when they are fully charged.

SET UP: $V_R = RI$ and $V_C = Q/C$.

EXECUTE: **(a)** $V_{C_1} = \dfrac{Q_1}{C_1} = \dfrac{18.0\ \mu\text{C}}{3.00\ \mu\text{F}} = 6.00\text{ V}$. $V_{C_2} = V_{C_1} = 6.00\text{ V}$.

$Q_2 = C_2V_{C_2} = (6.00\ \mu\text{F})(6.00\text{ V}) = 36.0\ \mu\text{C}$.

(b) No current flows to the capacitors when they are fully charged, so $\mathcal{E} = IR_1 + IR_2$.

$V_{R_2} = V_{C_1} = 6.00\text{ V}$. $I = \dfrac{V_{R_2}}{R_2} = \dfrac{6.00\text{ V}}{2.00\ \Omega} = 3.00\text{ A}$.

$R = \dfrac{\mathcal{E} - IR_2}{I} = \dfrac{60.0\text{ V} - 6.00\text{ V}}{3.00\text{ A}} = 18.0\ \Omega$.

EVALUATE: When a capacitor is fully charged, it acts like an open circuit and prevents any current from flowing though it.

25.85. **IDENTIFY** and **SET UP:** Follow the steps specified in the problem.

EXECUTE: **(a)** $\sum F = ma = |q|E$ gives $\dfrac{|q|}{m} = \dfrac{a}{E}$.

(b) If the electric field is constant, $V_{bc} = EL$ and $\dfrac{|q|}{m} = \dfrac{aL}{V_{bc}}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(c) The free charges are "left behind" so the left end of the rod is negatively charged, while the right end is positively charged. Thus the right end, point *c*, is at the higher potential.

(d) $a = \dfrac{V_{bc}|q|}{mL} = \dfrac{(1.0\times10^{-3}\text{ V})(1.6\times10^{-19}\text{ C})}{(9.11\times10^{-31}\text{ kg})(0.50\text{ m})} = 3.5\times10^{8}\text{ m/s}^2$.

EVALUATE: **(e)** Performing the experiment in a rotational way enables one to keep the experimental apparatus in a localized area—whereas an acceleration like that obtained in (d), if linear, would quickly have the apparatus moving at high speeds and large distances. Also, the rotating spool of thin wire can have many turns of wire and the total potential is the sum of the potentials in each turn, the potential in each turn times the number of turns.

25.86. **IDENTIFY:** The power output of the source is $VI = (\mathcal{E} - Ir)I$.

SET UP: The short-circuit current is $I_{\text{short circuit}} = \mathcal{E}/r$.

EXECUTE: **(a)** $P = \mathcal{E}I - I^2r$, so $\dfrac{dP}{dI} = \mathcal{E} - 2Ir = 0$ for maximum power output and

$I_{P\text{ max}} = \dfrac{1}{2}\dfrac{\mathcal{E}}{r} = \dfrac{1}{2}I_{\text{short circuit}}$.

(b) For the maximum power output of part (a), $I = \dfrac{\mathcal{E}}{r+R} = \dfrac{1}{2}\dfrac{\mathcal{E}}{r}$. $r + R = 2r$ and $R = r$.

Then, $P = I^2R = \left(\dfrac{\mathcal{E}}{2r}\right)^2 r = \dfrac{\mathcal{E}^2}{4r}$.

EVALUATE: When *R* is smaller than *r*, *I* is large and the I^2r losses in the battery are large. When *R* is larger than *r*, *I* is small and the power output $\mathcal{E}I$ of the battery emf is small.

25.87. **IDENTIFY:** Apply $R = \dfrac{\rho L}{A}$ to find the resistance of a thin slice of the rod and integrate to find the total *R*. $V = IR$. Also find $R(x)$, the resistance of a length *x* of the rod.

SET UP: $E(x) = \rho(x)J$

EXECUTE: **(a)** $dR = \dfrac{\rho dx}{A} = \dfrac{\rho_0 \exp[-x/L]\,dx}{A}$ so

$R = \dfrac{\rho_0}{A}\int_0^L \exp\left[-x/L\right]dx = \dfrac{\rho_0}{A}\left[-L\exp[-x/L]\right]_0^L = \dfrac{\rho_0 L}{A}(1-e^{-1})$ and $I = \dfrac{V_0}{R} = \dfrac{V_0 A}{\rho_0 L(1-e^{-1})}$. With an upper limit of *x* rather than *L* in the integration, $R(x) = \dfrac{\rho_0 L}{A}(1-e^{-x/L})$.

(b) $E(x) = \rho(x)J = \dfrac{I\,\rho_0 e^{-x/L}}{A} = \dfrac{V_0 e^{-x/L}}{L(1-e^{-1})}$.

(c) $V = V_0 - IR(x)$. $V = V_0 - \left(\dfrac{V_0 A}{\rho_0 L[1-e^{-1}]}\right)\left(\dfrac{\rho_0 L}{A}\right)(1-e^{-x/L}) = V_0\dfrac{(e^{-x/L}-e^{-1})}{(1-e^{-1})}$

(d) Graphs of resistivity, electric field and potential from $x = 0$ to L are given in Figure 25.87. Each quantity is given in terms of the indicated unit.

EVALUATE: The current is the same at all points in the rod. Where the resistivity is larger the electric field must be larger, in order to produce the same current density.

26

DIRECT-CURRENT CIRCUITS

26.1. **IDENTIFY:** The newly-formed wire is a combination of series and parallel resistors.
SET UP: Each of the three linear segments has resistance $R/3$. The circle is two $R/6$ resistors in parallel.
EXECUTE: The resistance of the circle is $R/12$ since it consists of two $R/6$ resistors in parallel. The equivalent resistance is two $R/3$ resistors in series with an $R/12$ resistor, giving $R_{\text{equiv}} = R/3 + R/3 + R/12 = 3R/4$.
EVALUATE: The equivalent resistance of the original wire has been reduced because the circle's resistance is less than it was as a linear wire.

26.2. **IDENTIFY:** It may appear that the meter measures X directly. But note that X is in parallel with three other resistors, so the meter measures the equivalent parallel resistance between *ab*.
SET UP: We use the formula for resistors in parallel.
EXECUTE: $1/(2.00\ \Omega) = 1/X + 1/(15.0\ \Omega) + 1/(5.0\ \Omega) + 1/(10.0\ \Omega)$, so $X = 7.5\ \Omega$.
EVALUATE: X is *greater* than the equivalent parallel resistance of $2.00\ \Omega$.

26.3. **IDENTIFY:** The emf of the battery remains constant, but changing the resistance across it changes its power output.
SET UP: The power output across a resistor is $P = \dfrac{V^2}{R}$.
EXECUTE: With just R_1, $P_1 = \dfrac{V^2}{R_1}$ and $V = \sqrt{P_1 R_1} = \sqrt{(36.0\ \text{W})(25.0\ \Omega)} = 30.0\ \text{V}$ is the battery voltage.
With R_2 added, $R_{\text{tot}} = 40.0\ \Omega$. $P = \dfrac{V^2}{R_{\text{tot}}} = \dfrac{(30.0\ \text{V})^2}{40.0\ \Omega} = 22.5\ \text{W}$.
EVALUATE: The two resistors in series dissipate electrical energy at a smaller rate than R_1 alone.

26.4. **IDENTIFY:** For resistors in parallel the voltages are the same and equal to the voltage across the equivalent resistance.
SET UP: $V = IR$. $\dfrac{1}{R_{\text{eq}}} = \dfrac{1}{R_1} + \dfrac{1}{R_2}$.
EXECUTE: **(a)** $R_{\text{eq}} = \left(\dfrac{1}{32\ \Omega} + \dfrac{1}{20\ \Omega}\right)^{-1} = 12.3\ \Omega$.
(b) $I = \dfrac{V}{R_{\text{eq}}} = \dfrac{240\ \text{V}}{12.3\ \Omega} = 19.5\ \text{A}$.
(c) $I_{32\Omega} = \dfrac{V}{R} = \dfrac{240\ \text{V}}{32\ \Omega} = 7.5\ \text{A}$; $I_{20\Omega} = \dfrac{V}{R} = \dfrac{240\ \text{V}}{20\ \Omega} = 12\ \text{A}$.
EVALUATE: More current flows through the resistor that has the smaller R.

26.5. **IDENTIFY:** The equivalent resistance will vary for the different connections because the series-parallel combinations vary, and hence the current will vary.
SET UP: First calculate the equivalent resistance using the series-parallel formulas, then use Ohm's law $(V = RI)$ to find the current.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: **(a)** $1/R = 1/(15.0\ \Omega) + 1/(30.0\ \Omega)$ gives $R = 10.0\ \Omega$. $I = V/R = (35.0\ \text{V})/(10.0\ \Omega) = 3.50\ \text{A}$.

(b) $1/R = 1/(10.0\ \Omega) + 1/(35.0\ \Omega)$ gives $R = 7.78\ \Omega$. $I = (35.0\ \text{V})/(7.78\ \Omega) = 4.50\ \text{A}$.

(c) $1/R = 1/(20.0\ \Omega) + 1/(25.0\ \Omega)$ gives $R = 11.11\ \Omega$, so $I = (35.0\ \text{V})/(11.11\ \Omega) = 3.15\ \text{A}$.

(d) From part (b), the resistance of the triangle alone is 7.78 Ω. Adding the 3.00-Ω internal resistance of the battery gives an equivalent resistance for the circuit of 10.78 Ω. Therefore the current is $I = (35.0\text{V})/(10.78\ \Omega) = 3.25\ \text{A}$.

EVALUATE: It makes a big difference how the triangle is connected to the battery.

26.6. **IDENTIFY:** The potential drop is the same across the resistors in parallel, and the current into the parallel combination is the same as the current through the 45.0-Ω resistor.

(a) SET UP: Apply Ohm's law in the parallel branch to find the current through the 45.0-Ω resistor. Then apply Ohm's law to the 45.0-Ω resistor to find the potential drop across it.

EXECUTE: The potential drop across the $25.0\text{-}\Omega$ resistor is $V_{25} = (25.0\ \Omega)(1.25\ \text{A}) = 31.25\ \text{V}$. The potential drop across each of the parallel branches is 31.25 V. For the $15.0\text{-}\Omega$ resistor: $I_{15} = (31.25\text{V})/(15.0\ \Omega) = 2.083\ \text{A}$. The resistance of the $10.0\text{-}\Omega + 15.0\text{-}\Omega$ combination is $25.0\ \Omega$, so the current through it must be the same as the current through the upper $25.0\text{-}\Omega$ resistor: $I_{10+15} = 1.25\ \text{A}$. The sum of currents in the parallel branch will be the current through the $45.0\text{-}\Omega$ resistor.

$$I_{\text{Total}} = 1.25\ \text{A} + 2.083\ \text{A} + 1.25\ \text{A} = 4.58\ \text{A}$$

Apply Ohm's law to the $45.0\text{-}\Omega$ resistor: $V_{45} = (4.58\ \text{A})(45.0\ \Omega) = 206\ \text{V}$

(b) SET UP: First find the equivalent resistance of the circuit and then apply Ohm's law to it.

EXECUTE: The resistance of the parallel branch is $1/R = 1/(25.0\ \Omega) + 1/(15.0\ \Omega) + 1/(25.0\ \Omega)$, so $R = 6.82\ \Omega$. The equivalent resistance of the circuit is $6.82\ \Omega + 45.0\ \Omega + 35.00\ \Omega = 86.82\ \Omega$. Ohm's law gives $V_{\text{Bat}} = (86.62\ \Omega)(4.58\ \text{A}) = 398\ \text{V}$.

EVALUATE: The emf of the battery is the sum of the potential drops across each of the three segments (parallel branch and two series resistors).

26.7. **IDENTIFY:** First do as much series-parallel reduction as possible.

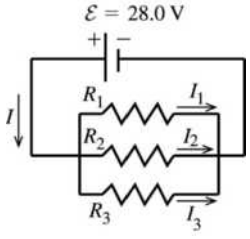
SET UP: The 45.0-Ω and 15.0-Ω resistors are in parallel, so first reduce them to a single equivalent resistance. Then find the equivalent series resistance of the circuit.

EXECUTE: $1/R_{\text{p}} = 1/(45.0\ \Omega) + 1/(15.0\ \Omega)$ and $R_{\text{p}} = 11.25\ \Omega$. The total equivalent resistance is $18.0\ \Omega + 11.25\ \Omega + 3.26\ \Omega = 32.5\ \Omega$. Ohm's law gives $I = (25.0\ \text{V})/(32.5\ \Omega) = 0.769\ \text{A}$.

EVALUATE: The circuit appears complicated until we realize that the 45.0-Ω and 15.0-Ω resistors are in parallel.

26.8. **IDENTIFY:** Eq. (26.2) gives the equivalent resistance of the three resistors in parallel. For resistors in parallel, the voltages are the same and the currents add.

(a) SET UP: The circuit is sketched in Figure 26.8a.



EXECUTE: parallel

$$\frac{1}{R_{\text{eq}}} = \frac{1}{R_1} + \frac{1}{R_2} + \frac{1}{R_3}$$

$$\frac{1}{R_{\text{eq}}} = \frac{1}{1.60\ \Omega} + \frac{1}{2.40\ \Omega} + \frac{1}{4.80\ \Omega}$$

$$R_{\text{eq}} = 0.800\ \Omega$$

Figure 26.8a

(b) For resistors in parallel the voltage is the same across each and equal to the applied voltage;

$V_1 = V_2 = V_3 = \mathcal{E} = 28.0\ \text{V}$

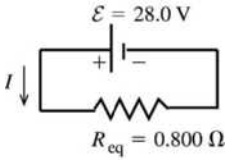
$V = IR$ so $I_1 = \dfrac{V_1}{R_1} = \dfrac{28.0\ \text{V}}{1.60\ \Omega} = 17.5\ \text{A}$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$I_2 = \dfrac{V_2}{R_2} = \dfrac{28.0\text{ V}}{2.40\ \Omega} = 11.7\text{ A}$ and $I_3 = \dfrac{V_3}{R_3} = \dfrac{28.0\text{ V}}{4.8\ \Omega} = 5.8\text{ A}$

(c) The currents through the resistors add to give the current through the battery:
$I = I_1 + I_2 + I_3 = 17.5\text{ A} + 11.7\text{ A} + 5.8\text{ A} = 35.0\text{ A}$

EVALUATE: Alternatively, we can use the equivalent resistance R_{eq} as shown in Figure 26.8b.



$\varepsilon - IR_{eq} = 0$

$I = \dfrac{\varepsilon}{R_{eq}} = \dfrac{28.0\text{ V}}{0.800\ \Omega} = 35.0\text{ A},$ which checks

Figure 26.8b

(d) As shown in part (b), the voltage across each resistor is 28.0 V.

(e) IDENTIFY and **SET UP:** We can use any of the three expressions for P: $P = VI = I^2R = V^2/R$. They will all give the same results, if we keep enough significant figures in intermediate calculations.

EXECUTE: Using $P = V^2/R$, $P_1 = V_1^2/R_1 = \dfrac{(28.0\text{ V})^2}{1.60\ \Omega} = 490\text{ W}$, $P_2 = V_2^2/R_2 = \dfrac{(28.0\text{ V})^2}{2.40\ \Omega} = 327\text{ W}$, and

$P_3 = V_3^2/R_3 = \dfrac{(28.0\text{ V})^2}{4.80\ \Omega} = 163\text{W}.$

EVALUATE: The total power dissipated is $P_{out} = P_1 + P_2 + P_3 = 980\text{ W}$. This is the same as the power $P_{in} = \varepsilon I = (2.80\text{ V})(35.0\text{ A}) = 980\text{ W}$ delivered by the battery.

(f) $P = V^2/R$. The resistors in parallel each have the same voltage, so the power P is largest for the one with the least resistance.

26.9. **IDENTIFY:** For a series network, the current is the same in each resistor and the sum of voltages for each resistor equals the battery voltage. The equivalent resistance is $R_{eq} = R_1 + R_2 + R_3$. $P = I^2R$.

SET UP: Let $R_1 = 1.60\ \Omega$, $R_2 = 2.40\ \Omega$, $R_3 = 4.80\ \Omega$.

EXECUTE: **(a)** $R_{eq} = 1.60\ \Omega + 2.40\ \Omega + 4.80\ \Omega = 8.80\ \Omega$

(b) $I = \dfrac{V}{R_{eq}} = \dfrac{28.0\text{ V}}{8.80\ \Omega} = 3.18\text{ A}$

(c) $I = 3.18\text{ A},$ the same as for each resistor.

(d) $V_1 = IR_1 = (3.18\text{ A})(1.60\ \Omega) = 5.09\text{ V}$. $V_2 = IR_2 = (3.18\text{ A})(2.40\ \Omega) = 7.63\text{ V}$.

$V_3 = IR_3 = (3.18\text{ A})(4.80\ \Omega) = 15.3\text{ V}$. Note that $V_1 + V_2 + V_3 = 28.0\text{ V}$.

(e) $P_1 = I^2R_1 = (3.18\text{ A})^2(1.60\ \Omega) = 16.2\text{ W}$. $P_2 = I^2R_2 = (3.18\text{ A})^2(2.40\ \Omega) = 24.3\text{ W}$.

$P_3 = I^2R_3 = (3.18\text{ A})^2(4.80\ \Omega) = 48.5\text{ W}.$

(f) Since $P = I^2R$ and the current is the same for each resistor, the resistor with the greatest R dissipates the greatest power.

EVALUATE: When resistors are connected in parallel, the resistor with the smallest R dissipates the greatest power.

26.10. **(a) IDENTIFY:** The current, and hence the power, depends on the potential difference across the resistor.

SET UP: $P = V^2/R$

EXECUTE: **(a)** $V = \sqrt{PR} = \sqrt{(5.0\text{ W})(15{,}000\ \Omega)} = 274\text{ V}$

(b) $P = V^2/R = (120\text{ V})^2/(9{,}000\ \Omega) = 1.6\text{ W}$

SET UP: **(c)** If the larger resistor generates 2.00 W, the smaller one will generate less and hence will be safe. Therefore the maximum power in the larger resistor must be 2.00 W. Use $P = I^2R$ to find the maximum current through the series combination and use Ohm's law to find the potential difference across the combination.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: $P = I^2R$ gives $I = \sqrt{P/R = (2.00\text{ W})/(150\ \Omega)} = 0.115$ A. The same current flows through both resistors, and their equivalent resistance is $250\ \Omega$. Ohm's law gives $V = IR = (0.115\text{ A})(250\ \Omega) = 28.8$ V.

Therefore $P_{150} = 2.00$ W and $P_{100} = I^2R = (0.115\text{ A})^2(100\ \Omega) = 1.32$ W.

EVALUATE: If the resistors in a series combination all have the same power rating, it is the *largest* resistance that limits the amount of current.

26.11. **IDENTIFY** and **SET UP:** Ohm's law applies to the resistors, the potential drop across resistors in parallel is the same for each of them, and at a junction the currents in must equal the currents out.

EXECUTE: **(a)** $V_2 = I_2R_2 = (4.00\text{ A})(6.00\ \Omega) = 24.0$ V. $V_1 = V_2 = 24.0$ V.

$$I_1 = \frac{V_1}{R_1} = \frac{24.0\text{ V}}{3.00\ \Omega} = 8.00\text{ A}.\quad I_3 = I_1 + I_2 = 4.00\text{ A} + 8.00\text{ A} = 12.0\text{ A}.$$

(b) $V_3 = I_3R_3 = (12.0\text{ A})(5.00\ \Omega) = 60.0$ V. $\mathcal{E} = V_1 + V_3 = 24.0\text{ V} + 60.0\text{ V} = 84.0$ V.

EVALUATE: Series/parallel reduction was not necessary in this case.

26.12. **IDENTIFY** and **SET UP:** Ohm's law applies to the resistors, and at a junction the currents in must equal the currents out.

EXECUTE: $V_1 = I_1R_1 = (1.50\text{ A})(5.00\ \Omega) = 7.50$ V. $V_2 = 7.50$ V. $I_1 + I_2 = I_3$ so

$$I_2 = I_3 - I_1 = 4.50\text{ A} - 1.50\text{ A} = 3.00\text{ A}.\quad R_2 = \frac{V_2}{I_2} = \frac{7.50\text{ V}}{3.00\text{ A}} = 2.50\ \Omega.$$

$$V_3 = \mathcal{E} - V_1 = 25.0\text{ V} - 7.50\text{ V} = 17.5\text{ V}.\quad R_3 = \frac{V_3}{I_3} = \frac{17.5\text{ V}}{4.50\text{ A}} = 3.89\ \Omega.$$

EVALUATE: Series/parallel reduction was not necessary in this case.

26.13. **IDENTIFY:** For resistors in parallel, the voltages are the same and the currents add. $\frac{1}{R_{\text{eq}}} = \frac{1}{R_1} + \frac{1}{R_2}$ so

$R_{\text{eq}} = \frac{R_1R_2}{R_1 + R_2}$, For resistors in series, the currents are the same and the voltages add. $R_{\text{eq}} = R_1 + R_2$.

SET UP: The rules for combining resistors in series and parallel lead to the sequences of equivalent circuits shown in Figure 26.13.

EXECUTE: $R_{\text{eq}} = 5.00\ \Omega$. In Figure 26.13c, $I = \frac{60.0\text{ V}}{5.00\ \Omega} = 12.0$ A. This is the current through each of the resistors in Figure 26.13b. $V_{12} = IR_{12} = (12.0\text{ A})(2.00\ \Omega) = 24.0$ V.

$V_{34} = IR_{34} = (12.0\text{ A})(3.00\ \Omega) = 36.0$ V. Note that $V_{12} + V_{34} = 60.0$ V. V_{12} is the voltage across R_1 and across R_2, so $I_1 = \frac{V_{12}}{R_1} = \frac{24.0\text{ V}}{3.00\ \Omega} = 8.00$ A and $I_2 = \frac{V_{12}}{R_2} = \frac{24.0\text{ V}}{6.00\ \Omega} = 4.00$ A. V_{34} is the voltage across R_3 and across R_4, so $I_3 = \frac{V_{34}}{R_3} = \frac{36.0\text{ V}}{12.0\ \Omega} = 3.00$ A and $I_4 = \frac{V_{34}}{R_4} = \frac{36.0\text{ V}}{4.00\ \Omega} = 9.00$ A.

EVALUATE: Note that $I_1 + I_2 = I_3 + I_4$.

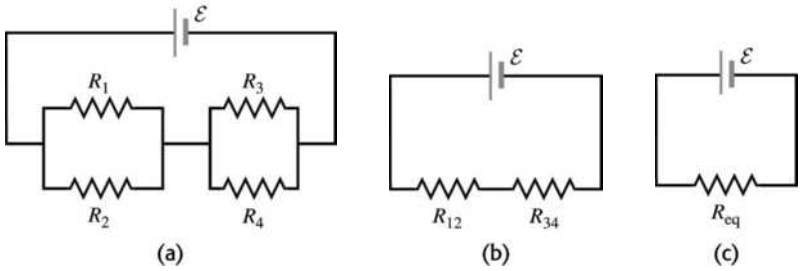


Figure 26.13

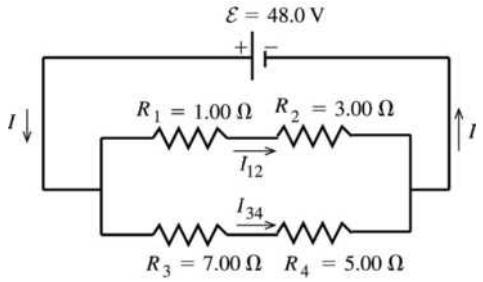
© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

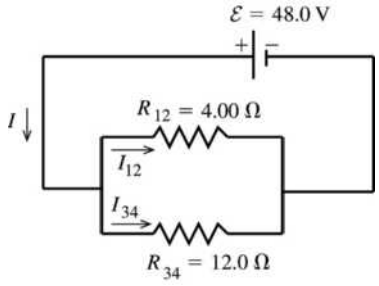
26.14. **IDENTIFY:** Replace the series combinations of resistors by their equivalents. In the resulting parallel network the battery voltage is the voltage across each resistor.
SET UP: The circuit is sketched in Figure 26.14a.



EXECUTE: R_1 and R_2 in series have an equivalent resistance of $R_{12} = R_1 + R_2 = 4.00\ \Omega$. R_3 and R_4 in series have an equivalent resistance of $R_{34} = R_3 + R_4 = 12.0\ \Omega$.

Figure 26.14a

The circuit is equivalent to the circuit sketched in Figure 26.14b.



R_{12} and R_{34} in parallel are equivalent to R_{eq} given by $\dfrac{1}{R_{\text{eq}}} = \dfrac{1}{R_{12}} + \dfrac{1}{R_{34}} = \dfrac{R_{12} + R_{34}}{R_{12}R_{34}}$

$$R_{\text{eq}} = \frac{R_{12}R_{34}}{R_{12} + R_{34}}$$

$$R_{\text{eq}} = \frac{(4.00\ \Omega)(12.0\ \Omega)}{4.00\ \Omega + 12.0\ \Omega} = 3.00\ \Omega$$

Figure 26.14b

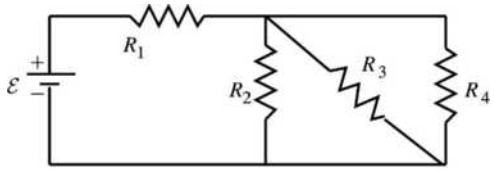
The voltage across each branch of the parallel combination is ε, so $\varepsilon - I_{12}R_{12} = 0$.

$$I_{12} = \frac{\varepsilon}{R_{12}} = \frac{48.0\ \text{V}}{4.00\ \Omega} = 12.0\ \text{A}$$

$$\varepsilon - I_{34}R_{34} = 0 \text{ so } I_{34} = \frac{\varepsilon}{R_{34}} = \frac{48.0\ \text{V}}{12.0\ \Omega} = 4.0\ \text{A}$$

The current is 12.0 A through the 1.00-Ω and 3.00-Ω resistors, and it is 4.0 A through the 7.00-Ω and 5.00-Ω resistors.
EVALUATE: The current through the battery is $I = I_{12} + I_{34} = 12.0\ \text{A} + 4.0\ \text{A} = 16.0\ \text{A}$, and this is equal to $\varepsilon/R_{\text{eq}} = 48.0\ \text{V}/3.00\ \Omega = 16.0\ \text{A}$.

26.15. **IDENTIFY:** In both circuits, with and without R_4, replace series and parallel combinations of resistors by their equivalents. Calculate the currents and voltages in the equivalent circuit and infer from this the currents and voltages in the original circuit. Use $P = I^2R$ to calculate the power dissipated in each bulb.
(a) SET UP: The circuit is sketched in Figure 26.15a.



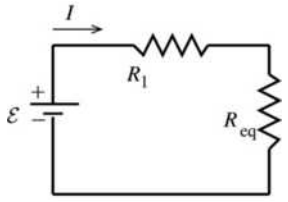
EXECUTE: R_2, R_3, and R_4 are in parallel, so their equivalent resistance R_{eq} is given by $\dfrac{1}{R_{\text{eq}}} = \dfrac{1}{R_2} + \dfrac{1}{R_3} + \dfrac{1}{R_4}$.

Figure 26.15a

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$\frac{1}{R_{eq}} = \frac{3}{4.50\ \Omega}$ and $R_{eq} = 1.50\ \Omega$.

The equivalent circuit is drawn in Figure 26.15b.



$$\varepsilon - I(R_1 + R_{eq}) = 0$$

$$I = \frac{\varepsilon}{R_1 + R_{eq}}$$

Figure 26.15b

$I = \frac{9.00\ \text{V}}{4.50\ \Omega + 1.50\ \Omega} = 1.50\ \text{A}$ and $I_1 = 1.50\ \text{A}$

Then $V_1 = I_1 R_1 = (1.50\ \text{A})(4.50\ \Omega) = 6.75\ \text{V}$

$I_{eq} = 1.50\ \text{A}$, $V_{eq} = I_{eq} R_{eq} = (1.50\ \text{A})(1.50\ \Omega) = 2.25\ \text{V}$

For resistors in parallel the voltages are equal and are the same as the voltage across the equivalent resistor, so $V_2 = V_3 = V_4 = 2.25\ \text{V}$.

$I_2 = \frac{V_2}{R_2} = \frac{2.25\ \text{V}}{4.50\ \Omega} = 0.500\ \text{A}$, $I_3 = \frac{V_3}{R_3} = 0.500\ \text{A}$, $I_4 = \frac{V_4}{R_4} = 0.500\ \text{A}$

EVALUATE: Note that $I_2 + I_3 + I_4 = 1.50\ \text{A}$, which is I_{eq}. For resistors in parallel the currents add and their sum is the current through the equivalent resistor.

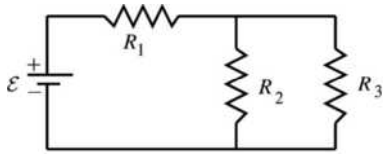
(b) SET UP: $P = I^2 R$

EXECUTE: $P_1 = (1.50\ \text{A})^2 (4.50\ \Omega) = 10.1\ \text{W}$

$P_2 = P_3 = P_4 = (0.500\ \text{A})^2 (4.50\ \Omega) = 1.125\ \text{W}$, which rounds to 1.12 W. R_1 glows brightest.

EVALUATE: Note that $P_2 + P_3 + P_4 = 3.37\ \text{W}$. This equals $P_{eq} = I_{eq}^2 R_{eq} = (1.50\ \text{A})^2 (1.50\ \Omega) = 3.37\ \text{W}$, the power dissipated in the equivalent resistor.

(c) SET UP: With R_4 removed the circuit becomes the circuit in Figure 26.15c.

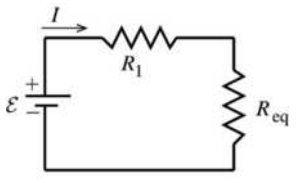


EXECUTE: R_2 and R_3 are in parallel and their equivalent resistance R_{eq} is given by

$\frac{1}{R_{eq}} = \frac{1}{R_2} + \frac{1}{R_3} = \frac{2}{4.50\ \Omega}$ and $R_{eq} = 2.25\ \Omega$.

Figure 26.15c

The equivalent circuit is shown in Figure 26.15d.



$$\varepsilon - I(R_1 + R_{eq}) = 0$$

$$I = \frac{\varepsilon}{R_1 + R_{eq}}$$

$$I = \frac{9.00\ \text{V}}{4.50\ \Omega + 2.25\ \Omega} = 1.333\ \text{A}$$

Figure 26.15d

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$I_1 = 1.33$ A, $V_1 = I_1 R_1 = (1.333\text{ A})(4.50\,\Omega) = 6.00$ V

$I_{eq} = 1.33$ A, $V_{eq} = I_{eq} R_{eq} = (1.333\text{ A})(2.25\,\Omega) = 3.00$ V and $V_2 = V_3 = 3.00$ V.

$I_2 = \dfrac{V_2}{R_2} = \dfrac{3.00\text{ V}}{4.50\,\Omega} = 0.667$ A, $I_3 = \dfrac{V_3}{R_3} = 0.667$ A

(d) SET UP: $P = I^2 R$

EXECUTE: $P_1 = (1.333\text{ A})^2(4.50\,\Omega) = 8.00$ W

$P_2 = P_3 = (0.667\text{ A})^2(4.50\,\Omega) = 2.00$ W.

(e) EVALUATE: When R_4 is removed, P_1 decreases and P_2 and P_3 increase. Bulb R_1 glows less brightly and bulbs R_2 and R_3 glow more brightly. When R_4 is removed the equivalent resistance of the circuit increases and the current through R_1 decreases. But in the parallel combination this current divides into two equal currents rather than three, so the currents through R_2 and R_3 increase. Can also see this by noting that with R_4 removed and less current through R_1 the voltage drop across R_1 is less so the voltage drop across R_2 and across R_3 must become larger.

26.16. **IDENTIFY:** Apply Ohm's law to each resistor.

SET UP: For resistors in parallel the voltages are the same and the currents add. For resistors in series the currents are the same and the voltages add.

EXECUTE: From Ohm's law, the voltage drop across the $6.00\text{-}\Omega$ resistor is $V = IR = (4.00\text{ A})(6.00\,\Omega) = 24.0$ V. The voltage drop across the $8.00\text{-}\Omega$ resistor is the same, since these two resistors are wired in parallel. The current through the $8.00\text{-}\Omega$ resistor is then $I = V/R = 24.0\text{ V}/8.00\,\Omega = 3.00$ A. The current through the $25.0\text{-}\Omega$ resistor is the sum of the current through these two resistors: 7.00 A. The voltage drop across the $25.0\text{-}\Omega$ resistor is $V = IR = (7.00\text{ A})(25.0\,\Omega) = 175$ V, and total voltage drop across the top branch of the circuit is $175\text{ V} + 24.0\text{ V} = 199$ V, which is also the voltage drop across the $20.0\text{-}\Omega$ resistor. The current through the $20.0\text{-}\Omega$ resistor is then $I = V/R = 199\text{ V}/20\,\Omega = 9.95$ A.

EVALUATE: The total current through the battery is $7.00\text{ A} + 9.95\text{ A} = 16.95$ A. Note that we did not need to calculate the emf of the battery.

26.17. **IDENTIFY:** Apply Ohm's law to each resistor.

SET UP: For resistors in parallel the voltages are the same and the currents add. For resistors in series the currents are the same and the voltages add.

EXECUTE: The current through the $2.00\text{-}\Omega$ resistor is 6.00 A. Current through the $1.00\text{-}\Omega$ resistor also is 6.00 A and the voltage is 6.00 V. Voltage across the $6.00\text{-}\Omega$ resistor is $12.0\text{ V} + 6.0\text{ V} = 18.0$ V. Current through the $6.00\text{-}\Omega$ resistor is $(18.0\text{ V})/(6.00\,\Omega) = 3.00$ A. The battery emf is 18.0 V.

EVALUATE: The current through the battery is $6.00\text{ A} + 3.00\text{ A} = 9.00$ A. The equivalent resistor of the resistor network is $2.00\,\Omega$, and this equals (18.0 V)/(9.00 A).

26.18. **IDENTIFY:** The filaments must be connected such that the current can flow through each separately, and also through both in parallel, yielding three possible current flows. The parallel situation always has less resistance than any of the individual members, so it will give the highest power output of 180 W, while the other two must give power outputs of 60 W and 120 W.

SET UP: $P = V^2/R$, where R is the equivalent resistance.

EXECUTE: **(a)** $60\text{ W} = \dfrac{V^2}{R_1}$ gives $R_1 = \dfrac{(120\text{ V})^2}{60\text{ W}} = 240\,\Omega$. $120\text{ W} = \dfrac{V^2}{R_2}$ gives $R_2 = \dfrac{(120\text{ V})^2}{120\text{ W}} = 120\,\Omega$.

For these two resistors in parallel, $R_{eq} = \dfrac{R_1 R_2}{R_1 + R_2} = 80\,\Omega$ and $P = \dfrac{V^2}{R_{eq}} = \dfrac{(120\text{ V})^2}{80\,\Omega} = 180$ W, which is the desired value.

(b) If R_1 burns out, the 120-W setting stays the same, the 60-W setting does not work and the 180 W setting goes to 120 W: brightnesses of zero, medium and medium.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(c) If R_2 burns out, the 60-W setting stays the same, the 120-W setting does not work, and the 180-W setting is now 60 W: brightnesses of low, zero and low.

EVALUATE: Since in each case 120 V is supplied to each filament network, the lowest resistance dissipates the greatest power.

26.19. **IDENTIFY:** Using only10.0-Ω resistors in series and parallel combinations, we want to produce a series of equivalent resistances.

SET UP: A network of N of the resistors in series has resistance $N(10.0\ \Omega)$ and a network of N of the resistors in parallel has resistance $(10.0\ \Omega)/N$.

EXECUTE: **(a)** A parallel combination of two resistors in series with three others (Figure 26.19a).

(b) Ten in parallel.

(c) Three in parallel.

(d) Two in parallel in series with four in parallel (Figure 26.19b).

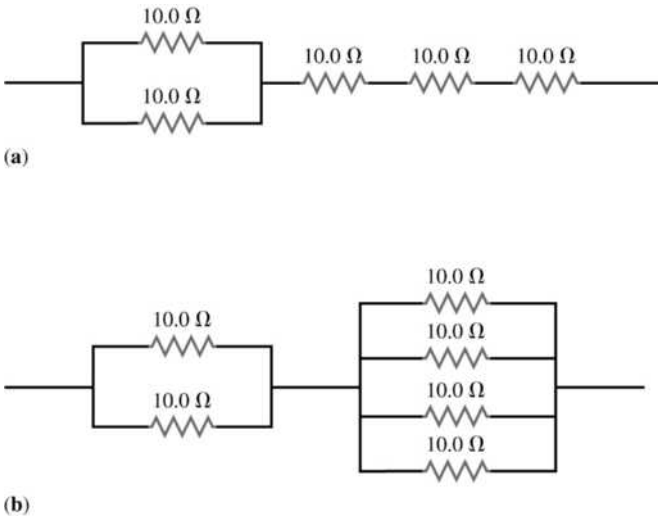


Figure 26.19

EVALUATE: There are other networks that also have the required resistance. An important additional consideration is the power dissipated by each resistor, whether the power dissipated by any resistor in the network exceeds the maximum power rating of the resistor.

26.20. **IDENTIFY:** $P = I^2R$ determines R_1. R_1, R_2 and the 10.0-Ω resistor are all in parallel so have the same voltage. Apply the junction rule to find the current through R_2.

SET UP: $P = I^2R$ for a resistor and $P = \mathcal{E}I$ for an emf. The emf inputs electrical energy into the circuit and electrical energy is removed in the resistors.

EXECUTE: **(a)** $P_1 = I_1^2R_1$. $20\ \text{W} = (2\ \text{A})^2 R_1$ and $R_1 = 5.00\ \Omega$. R_1 and $10\ \Omega$ are in parallel, so $(10\ \Omega)I_{10} = (5\ \Omega)(2\ \text{A})$ and $I_{10} = 1\ \text{A}$. So $I_2 = 3.50\ \text{A} - I_1 - I_{10} = 0.50\ \text{A}$. R_1 and R_2 are in parallel, so $(0.50\ \text{A})R_2 = (2\ \text{A})(5\ \Omega)$ and $R_2 = 20.0\ \Omega$.

(b) $\mathcal{E} = V_1 = (2.00\ \text{A})(5.00\ \Omega) = 10.0\ \text{V}$

(c) From part (a), $I_2 = 0.500\ \text{A}$, $I_{10} = 1.00\ \text{A}$

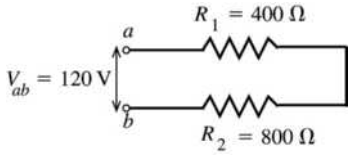
(d) $P_1 = 20.0\ \text{W}$ (given). $P_2 = I_2^2R_2 = (0.50\ \text{A})^2(20\ \Omega) = 5.00\ \text{W}$. $P_{10} = I_{10}^2R_{10} = (1.0\ \text{A})^2(10\ \Omega) = 10.0\ \text{W}$. The total rate at which the resistors remove electrical energy is $P_{\text{Resist}} = 20\ \text{W} + 5\ \text{W} + 10\ \text{W} = 35.0\ \text{W}$. The total rate at which the battery inputs electrical energy is $P_{\text{Battery}} = I\mathcal{E} = (3.50\ \text{A})(10.0\ \text{V}) =$ $35.0\ \text{W} \cdot P_{\text{Resist}} = P_{\text{Battery}}$, which agrees with conservation of energy.

EVALUATE: The three resistors are in parallel, so the voltage for each is the battery voltage, 10.0 V. The currents in the three resistors add to give the current in the battery.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

26.21. **IDENTIFY:** For resistors in series, the voltages add and the current is the same. For resistors in parallel, the voltages are the same and the currents add. $P = I^2R$.

(a) SET UP: The circuit is sketched in Figure 26.21a.



For resistors in series the current is the same through each.

Figure 26.21a

EXECUTE: $R_{eq} = R_1 + R_2 = 1200\ \Omega$. $I = \dfrac{V}{R_{eq}} = \dfrac{120\text{ V}}{1200\ \Omega} = 0.100$ A. This is the current drawn from the line.

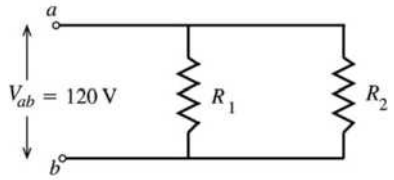
(b) $P_1 = I_1^2 R_1 = (0.100\text{ A})^2(400\ \Omega) = 4.0$ W

$P_2 = I_2^2 R_2 = (0.100\text{ A})^2(800\ \Omega) = 8.0$ W

(c) $P_{out} = P_1 + P_2 = 12.0$ W, the total power dissipated in both bulbs. Note that

$P_{in} = V_{ab} I = (120\text{ V})(0.100\text{ A}) = 12.0$ W, the power delivered by the potential source, equals P_{out}.

(d) SET UP: The circuit is sketched in Figure 26.21b.



For resistors in parallel the voltage across each resistor is the same.

Figure 26.21b

EXECUTE: $I_1 = \dfrac{V_1}{R_1} = \dfrac{120\text{ V}}{400\ \Omega} = 0.300$ A, $I_2 = \dfrac{V_2}{R_2} = \dfrac{120\text{ V}}{800\ \Omega} = 0.150$ A

EVALUATE: Note that each current is larger than the current when the resistors are connected in series.

(e) EXECUTE: $P_1 = I_1^2 R_1 = (0.300\text{ A})^2(400\ \Omega) = 36.0$ W

$P_2 = I_2^2 R_2 = (0.150\text{ A})^2(800\ \Omega) = 18.0$ W

(f) $P_{out} = P_1 + P_2 = 54.0$ W

EVALUATE: Note that the total current drawn from the line is $I = I_1 + I_2 = 0.450$ A. The power input from the line is $P_{in} = V_{ab} I = (120\text{ V})(0.450\text{ A}) = 54.0$ W, which equals the total power dissipated by the bulbs.

(g) The bulb that is dissipating the most power glows most brightly. For the series connection the currents are the same and by $P = I^2R$ the bulb with the larger R has the larger P; the 800-Ω bulb glows more brightly. For the parallel combination the voltages are the same and by $P = V^2/R$ the bulb with the smaller R has the larger P; the 400-Ω bulb glows more brightly.

(h) The total power output P_{out} equals $P_{in} = V_{ab} I$, so P_{out} is larger for the parallel connection where the current drawn from the line is larger (because the equivalent resistance is smaller.)

26.22. **IDENTIFY:** Use $P = V^2/R$ with $V = 120$ V and the wattage for each bulb to calculate the resistance of each bulb. When connected in series the voltage across each bulb will not be 120 V and the power for each bulb will be different.

SET UP: For resistors in series the currents are the same and $R_{eq} = R_1 + R_2$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: **(a)** $R_{60\text{W}} = \dfrac{V^2}{P} = \dfrac{(120\text{ V})^2}{60\text{ W}} = 240\,\Omega$; $R_{200\text{W}} = \dfrac{V^2}{P} = \dfrac{(120\text{ V})^2}{200\text{ W}} = 72\,\Omega$.

Therefore, $I_{60\text{W}} = I_{200\text{W}} = \dfrac{\mathcal{E}}{R} = \dfrac{240\text{ V}}{(240\,\Omega + 72\,\Omega)} = 0.769\text{ A}$.

(b) $P_{60\text{W}} = I^2R = (0.769\text{ A})^2(240\,\Omega) = 142\text{ W}$; $P_{200\text{W}} = I^2R = (0.769\text{ A})^2(72\,\Omega) = 42.6\text{ W}$.

(c) The 60 W bulb burns out quickly because the power it delivers (142 W) is 2.4 times its rated value.

EVALUATE: In series the largest resistance dissipates the greatest power.

26.23. **IDENTIFY** and **SET UP:** Replace series and parallel combinations of resistors by their equivalents until the circuit is reduced to a single loop. Use the loop equation to find the current through the 20.0-Ω resistor. Set $P = I^2R$ for the 20.0-Ω resistor equal to the rate Q/t at which heat goes into the water and set $Q = mc\Delta T$.

EXECUTE: Replace the network by the equivalent resistor, as shown in Figure 26.23.

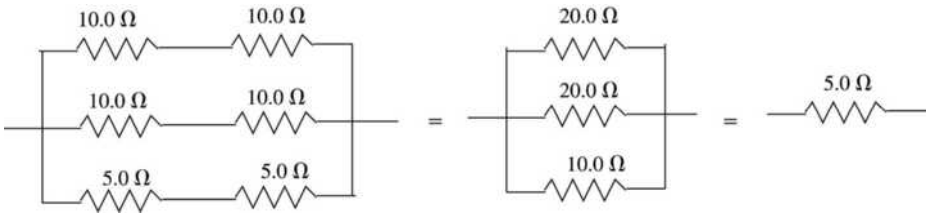


Figure 26.23

$30.0\text{ V} - I(20.0\,\Omega + 5.0\,\Omega + 5.0\,\Omega) = 0;\ I = 1.00\text{ A}$

For the 20.0-Ω resistor thermal energy is generated at the rate $P = I^2R = 20.0$ W. $Q = Pt$ and $Q = mc\Delta T$ gives $t = \dfrac{mc\Delta T}{P} = \dfrac{(0.100\text{ kg})(4190\text{ J/kg}\cdot\text{ K})(48.0\text{ C°})}{20.0\text{ W}} = 1.01 \times 10^3\text{ s}$

EVALUATE: The battery is supplying heat at the rate $P = \mathcal{E}I = 30.0$ W. In the series circuit, more energy is dissipated in the larger resistor $(20.0\,\Omega)$ than in the smaller ones $(5.00\,\Omega)$.

26.24. **IDENTIFY:** This circuit cannot be reduced using series/parallel combinations, so we apply Kirchhoff's rules. The target variables are the currents in each segment.

SET UP: Assume the unknown currents have the directions shown in Figure 26.24. We have used the junction rule to write the current through the 10.0 V battery as $I_1 + I_2$. There are two unknowns, I_1 and I_2, so we will need two equations. Three possible circuit loops are shown in the figure.

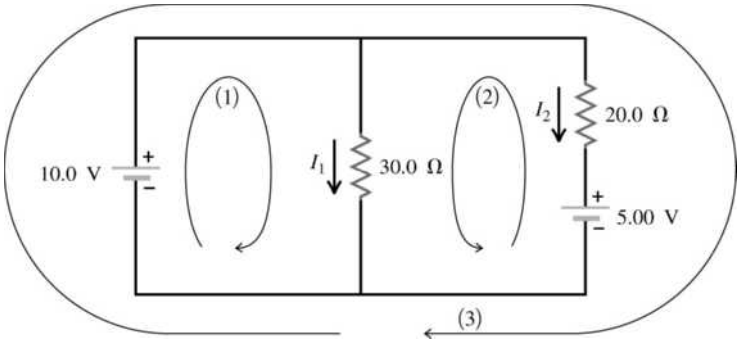

Figure 26.24

EXECUTE: **(a)** Apply the loop rule to loop (1), going around the loop in the direction shown: $+10.0\text{ V} - (30.0\,\Omega)I_1 = 0$ and $I_1 = 0.333$ A.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) Apply the loop rule to loop (3): $+10.0\text{ V} - (20.0\ \Omega)I_2 - 5.00\text{ V} = 0$ and $I_2 = 0.250\text{ A}$.

(c) $I_1 + I_2 = 0.333\text{ A} + 0.250\text{ A} = 0.583\text{ A}$

EVALUATE: For loop (2) we get
$+5.00\text{ V} + I_2(20.0\ \Omega) - I_1(30.0\ \Omega) = 5.00\text{ V} + (0.250\text{ A})(20.0\ \Omega) - (0.333\text{ A})(30.0\ \Omega) =$
$5.00\text{ V} + 5.00\text{ V} - 10.0\text{ V} = 0,$ so that with the currents we have calculated the loop rule is satisfied for this third loop.

26.25. **IDENTIFY:** Apply Kirchhoff's point rule at point *a* to find the current through *R*. Apply Kirchhoff's loop rule to loops (1) and (2) shown in Figure 26.25a to calculate *R* and $\mathcal{E}$. Travel around each loop in the direction shown.

(a) SET UP:

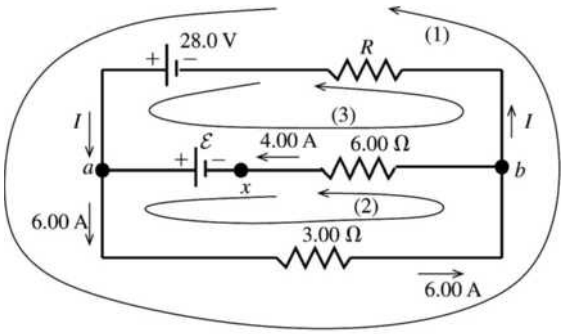

Figure 26.25a

EXECUTE: Apply Kirchhoff's point rule to point *a*: $\sum I = 0$ so $I + 4.00\text{ A} - 6.00\text{ A} = 0$
$I = 2.00\text{ A}$ (in the direction shown in the diagram).

(b) Apply Kirchhoff's loop rule to loop (1): $-(6.00\text{ A})(3.00\ \Omega) - (2.00\text{ A})R + 28.0\text{ V} = 0$
$-18.0\text{ V} - (2.00\ \Omega)R + 28.0\text{ V} = 0$

$$R = \frac{28.0\text{ V} - 18.0\text{ V}}{2.00\text{ A}} = 5.00\ \Omega$$

(c) Apply Kirchhoff's loop rule to loop (2): $-(6.00\text{ A})(3.00\ \Omega) - (4.00\text{ A})(6.00\ \Omega) + \mathcal{E} = 0$
$\mathcal{E} = 18.0\text{ V} + 24.0\text{ V} = 42.0\text{ V}$

EVALUATE: Can check that the loop rule is satisfied for loop (3), as a check of our work:
$28.0\text{ V} - \mathcal{E} + (4.00\text{ A})(6.00\ \Omega) - (2.00\text{ A})R = 0$
$28.0\text{ V} - 42.0\text{ V} + 24.0\text{ V} - (2.00\text{ A})(5.00\ \Omega) = 0$
$52.0\text{ V} = 42.0\text{ V} + 10.0\text{ V}$
$52.0\text{ V} = 52.0\text{ V},$ so the loop rule is satisfied for this loop.

(d) IDENTIFY: If the circuit is broken at point *x* there can be no current in the $6.00\text{-}\Omega$ resistor. There is now only a single current path and we can apply the loop rule to this path.

SET UP: The circuit is sketched in Figure 26.25b.

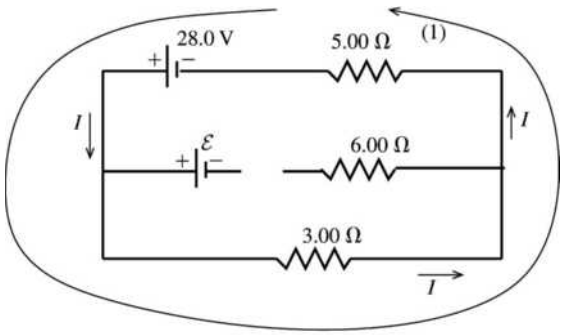

Figure 26.25b

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: $+28.0\text{ V} - (3.00\,\Omega)I - (5.00\,\Omega)I = 0$

$$I = \frac{28.0\text{ V}}{8.00\,\Omega} = 3.50\text{ A}$$

EVALUATE: Breaking the circuit at x removes the 42.0-V emf from the circuit and the current through the $3.00\text{-}\Omega$ resistor is reduced.

26.26. **IDENTIFY:** Apply the loop rule and junction rule.

SET UP: The circuit diagram is given in Figure 26.26. The junction rule has been used to find the magnitude and direction of the current in the middle branch of the circuit. There are no remaining unknown currents.

EXECUTE: The loop rule applied to loop (1) gives:

$+20.0\text{V} - (1.00\text{ A})(1.00\,\Omega) + (1.00\text{ A})(4.00\,\Omega) + (1.00\text{ A})(1.00\,\Omega) - \mathcal{E}_1 - (1.00\text{ A})(6.00\,\Omega) = 0$

$\mathcal{E}_1 = 20.0\text{ V} - 1.00\text{ V} + 4.00\text{ V} + 1.00\text{ V} - 6.00\text{ V} = 18.0\text{ V}$. The loop rule applied to loop (2) gives:

$+20.0\text{ V} - (1.00\text{ A})(1.00\,\Omega) - (2.00\text{ A})(1.00\,\Omega) - \mathcal{E}_2 - (2.00\text{ A})(2.00\,\Omega) - (1.00\text{ A})(6.00\,\Omega) = 0$

$\mathcal{E}_2 = 20.0\text{ V} - 1.00\text{ V} - 2.00\text{ V} - 4.00\text{ V} - 6.00\text{ V} = 7.0\text{ V}$. Going from b to a along the lower branch,

$V_b + (2.00\text{ A})(2.00\,\Omega) + 7.0\text{ V} + (2.00\text{ A})(1.00\,\Omega) = V_a \cdot V_b - V_a = -13.0\text{ V}$; point b is at 13.0 V lower potential than point a.

EVALUATE: We can also calculate $V_b - V_a$ by going from b to a along the upper branch of the circuit.

$V_b - (1.00\text{ A})(6.00\,\Omega) + 20.0\text{ V} - (1.00\text{ A})(1.00\,\Omega) = V_a$ and $V_b - V_a = -13.0\text{ V}$. This agrees with $V_b - V_a$ calculated along a different path between b and a.

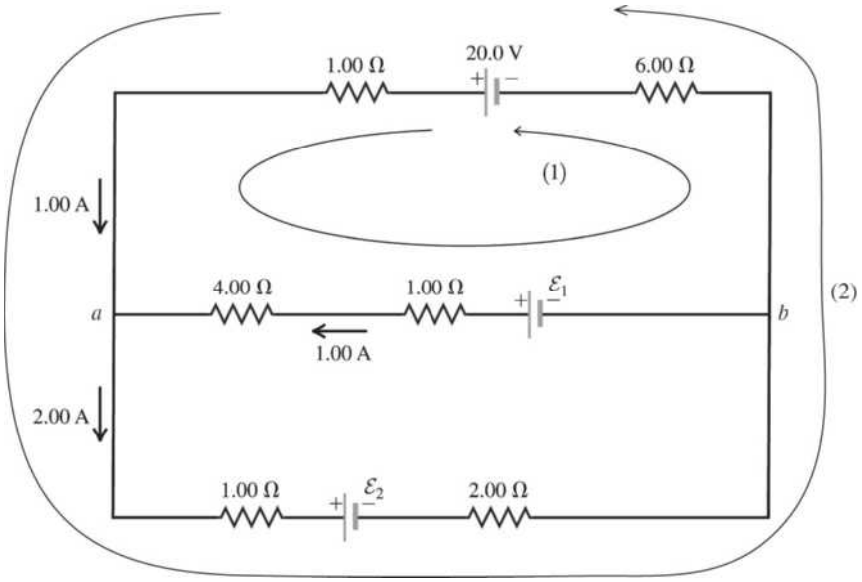

Figure 26.26

26.27. **IDENTIFY:** Apply the junction rule at points a, b, c and d to calculate the unknown currents. Then apply the loop rule to three loops to calculate $\mathcal{E}_1, \mathcal{E}_2$ and R.

(a) SET UP: The circuit is sketched in Figure 26.27.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

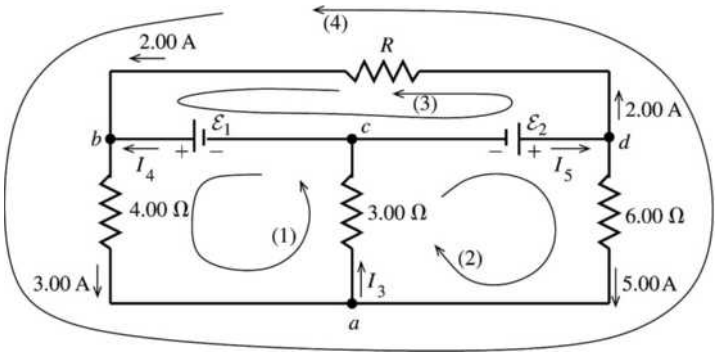

Figure 26.27

EXECUTE: Apply the junction rule to point *a*: $3.00\text{ A} + 5.00\text{ A} - I_3 = 0$

$I_3 = 8.00\text{ A}$

Apply the junction rule to point *b*: $2.00\text{ A} + I_4 - 3.00\text{ A} = 0$

$I_4 = 1.00\text{ A}$

Apply the junction rule to point *c*: $I_3 - I_4 - I_5 = 0$

$I_5 = I_3 - I_4 = 8.00\text{ A} - 1.00\text{ A} = 7.00\text{ A}$

EVALUATE: As a check, apply the junction rule to point *d*: $I_5 - 2.00\text{ A} - 5.00\text{ A} = 0$

$I_5 = 7.00\text{ A}$

(b) EXECUTE: Apply the loop rule to loop (1): $\mathcal{E}_1 - (3.00\text{ A})(4.00\,\Omega) - I_3(3.00\,\Omega) = 0$

$\mathcal{E}_1 = 12.0\text{ V} + (8.00\text{ A})(3.00\,\Omega) = 36.0\text{ V}$

Apply the loop rule to loop (2): $\mathcal{E}_2 - (5.00\text{ A})(6.00\,\Omega) - I_3(3.00\,\Omega) = 0$

$\mathcal{E}_2 = 30.0\text{ V} + (8.00\text{ A})(3.00\,\Omega) = 54.0\text{ V}$

(c) Apply the loop rule to loop (3): $-(2.00\text{ A})R - \mathcal{E}_1 + \mathcal{E}_2 = 0$

$$R = \frac{\mathcal{E}_2 - \mathcal{E}_1}{2.00\text{ A}} = \frac{54.0\text{ V} - 36.0\text{ V}}{2.00\text{ A}} = 9.00\,\Omega$$

EVALUATE: Apply the loop rule to loop (4) as a check of our calculations:

$-(2.00\text{ A})R - (3.00\text{ A})(4.00\,\Omega) + (5.00\text{ A})(6.00\,\Omega) = 0$

$-(2.00\text{ A})(9.00\,\Omega) - 12.0\text{ V} + 30.0\text{ V} = 0$

$-18.0\text{ V} + 18.0\text{ V} = 0$

26.28. **IDENTIFY:** Use Kirchhoff's rules to find the currents.

SET UP: Since the 10.0-V battery has the larger voltage, assume I_1 is to the left through the 10-V battery, I_2 is to the right through the 5 V battery, and I_3 is to the right through the 10-Ω resistor. Go around each loop in the counterclockwise direction.

EXECUTE: Upper loop: $10.0\text{ V} - (2.00\,\Omega + 3.00\,\Omega)I_1 - (1.00\,\Omega + 4.00\,\Omega)I_2 - 5.00\text{ V} = 0$. This gives

$5.0\text{ V} - (5.00\,\Omega)I_1 - (5.00\,\Omega)I_2 = 0$, and $\Rightarrow I_1 + I_2 = 1.00\text{ A}$.

Lower loop: $5.00\text{ V} + (1.00\,\Omega + 4.00\,\Omega)I_2 - (10.0\,\Omega)I_3 = 0$. This gives

$5.00\text{ V} + (5.00\,\Omega)I_2 - (10.0\,\Omega)I_3 = 0$, and $I_2 - 2I_3 = -1.00\text{ A}$.

Along with $I_1 = I_2 + I_3$, we can solve for the three currents and find:

$$I_1 = 0.800\text{ A},\ I_2 = 0.200\text{ A},\ I_3 = 0.600\text{ A}.$$

(b) $V_{ab} = -(0.200\text{ A})(4.00\,\Omega) - (0.800\text{ A})(3.00\,\Omega) = -3.20\text{ V}$.

EVALUATE: Traveling from *b* to *a* through the 4.00-Ω and 3.00-Ω resistors you pass through the resistors in the direction of the current and the potential decreases; point *b* is at higher potential than point *a*.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

26.29. **IDENTIFY:** Apply the junction rule to reduce the number of unknown currents. Apply the loop rule to two loops to obtain two equations for the unknown currents I_1 and I_2.

(a) SET UP: The circuit is sketched in Figure 26.29.

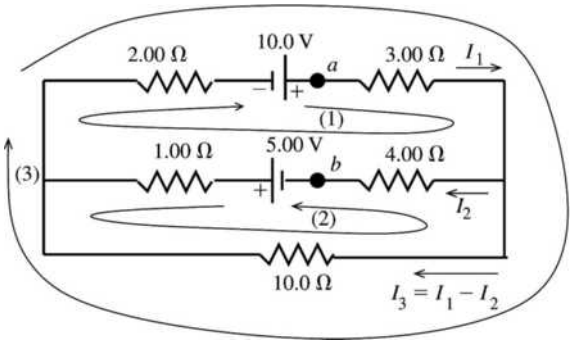

Figure 26.29

Let I_1 be the current in the $3.00\,\Omega$ resistor and I_2 be the current in the $4.00\,\Omega$ resistor and assume that these currents are in the directions shown. Then the current in the 10.0-Ω resistor is $I_3 = I_1 - I_2$, in the direction shown, where we have used Kirchhoff's point rule to relate I_3 to I_1 and I_2. If we get a negative answer for any of these currents we know the current is actually in the opposite direction to what we have assumed. Three loops and directions to travel around the loops are shown in the circiut diagram. Apply Kirchhoff's loop rule to each loop.

EXECUTE: loop (1)

$+10.0\text{ V} - I_1(3.00\,\Omega) - I_2(4.00\,\Omega) + 5.00\text{ V} - I_2(1.00\,\Omega) - I_1(2.00\,\Omega) = 0$

$15.00\text{ V} - (5.00\,\Omega)I_1 - (5.00\,\Omega)I_2 = 0$

$3.00\text{ A} - I_1 - I_2 = 0$

loop (2)

$+5.00\text{ V} - I_2(1.00\,\Omega) + (I_1 - I_2)10.0\,\Omega - I_2(4.00\,\Omega) = 0$

$5.00\text{ V} + (10.0\,\Omega)I_1 - (15.0\,\Omega)I_2 = 0$

$1.00\text{ A} + 2.00I_1 - 3.00I_2 = 0$

The first equation says $I_2 = 3.00\text{ A} - I_1$.

Use this in the second equation: $1.00\text{ A} + 2.00I_1 - 9.00\text{ A} + 3.00I_1 = 0$

$5.00I_1 = 8.00\text{ A}$, $I_1 = 1.60\text{ A}$

Then $I_2 = 3.00\text{ A} - I_1 = 3.00\text{ A} - 1.60\text{ A} = 1.40\text{ A}$.

$I_3 = I_1 - I_2 = 1.60\text{ A} - 1.40\text{ A} = 0.20\text{ A}$

EVALUATE: Loop (3) can be used as a check.

$+10.0\text{ V} - (1.60\text{ A})(3.00\,\Omega) - (0.20\text{ A})(10.00\,\Omega) - (1.60\text{ A})(2.00\,\Omega) = 0$

$10.0\text{ V} = 4.8\text{ V} + 2.0\text{ V} + 3.2\text{ V}$

$10.0\text{ V} = 10.0\text{ V}$

We find that with our calculated currents the loop rule is satisfied for loop (3). Also, all the currents came out to be positive, so the current directions in the circuit diagram are correct.

(b) IDENTIFY and **SET UP:** To find $V_{ab} = V_a - V_b$ start at point *b* and travel to point *a*. Many different routes can be taken from *b* to *a* and all must yield the same result for V_{ab}.

EXECUTE: Travel through the $4.00\text{-}\Omega$ resistor and then through the $3.00\text{-}\Omega$ resistor:

$V_b + I_2(4.00\,\Omega) + I_1(3.00\,\Omega) = V_a$

$V_a - V_b = (1.40\text{ A})(4.00\,\Omega) + (1.60\text{ A})(3.00\,\Omega) = 5.60\text{ V} + 4.8\text{ V} = 10.4\text{ V}$ (point *a* is at higher potential than point *b*)

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: Alternatively, travel through the 5.00-V emf, the 1.00-Ω resistor, the 2.00-Ω resistor, and the 10.0-V emf.

$V_b + 5.00\ \text{V} - I_2(1.00\ \Omega) - I_1(2.00\ \Omega) + 10.0\ \text{V} = V_a$

$V_a - V_b = 15.0\ \text{V} - (1.40\ \text{A})(1.00\ \Omega) - (1.60\ \text{A})(2.00\ \Omega) = 15.0\ \text{V} - 1.40\ \text{V} - 3.20\ \text{V} = 10.4\ \text{V},$ the same as before.

26.30. **IDENTIFY:** Use Kirchhoff's rules to find the currents

SET UP: Since the 20.0-V battery has the largest voltage, assume I_1 is to the right through the 10.0-V battery, I_2 is to the left through the 20.0-V battery, and I_3 is to the right through the 10-Ω resistor. Go around each loop in the counterclockwise direction.

EXECUTE: Upper loop: $10.0\ \text{V} + (2.00\ \Omega + 3.00\ \Omega)I_1 + (1.00\ \Omega + 4.00\ \Omega)I_2 - 20.00\ \text{V} = 0.$

$-10.0\ \text{V} + (5.00\ \Omega)I_1 + (5.00\ \Omega)I_2 = 0,$ so $I_1 + I_2 = +2.00\text{A}.$

Lower loop: $20.00\ \text{V} - (1.00\ \Omega + 4.00\ \Omega)I_2 - (10.0\ \Omega)I_3 = 0.$

$20.00\ \text{V} - (5.00\ \Omega)I_2 - (10.0\ \Omega)I_3 = 0,$ so $I_2 + 2I_3 = 4.00\ \text{A}.$

Along with $I_2 = I_1 + I_3,$ we can solve for the three currents and find $I_1 = +0.4\ \text{A}$, $I_2 = +1.6\ \text{A}$, $I_3 = +1.2\ \text{A}$.

(b) $V_{ab} = I_2(4\ \Omega) + I_1(3\ \Omega) = (1.6\ \text{A})(4\ \Omega) + (0.4\ \text{A})(3\ \Omega) = 7.6\ \text{V}$

EVALUATE: Traveling from *b* to *a* through the 4.00-Ω and 3.00-Ω resistors you pass through each resistor opposite to the direction of the current and the potential increases; point *a* is at higher potential than point *b*.

26.31. **(a) IDENTIFY:** With the switch open, the circuit can be solved using series-parallel reduction.

SET UP: Find the current through the unknown battery using Ohm's law. Then use the equivalent resistance of the circuit to find the emf of the battery.

EXECUTE: The 30.0-Ω and 50.0-Ω resistors are in series, and hence have the same current. Using Ohm's law $I_{50} = (15.0\ \text{V})/(50.0\ \Omega) = 0.300\ \text{A} = I_{30}.$ The potential drop across the 75.0-Ω resistor is the same as the potential drop across the 80.0-Ω series combination. We can use this fact to find the current through the 75.0-Ω resistor using Ohm's law: $V_{75} = V_{80} = (0.300\ \text{A})(80.0\ \Omega) = 24.0\ \text{V}$ and $I_{75} = (24.0\ \text{V})/(75.0\ \Omega) = 0.320\ \text{A}.$

The current through the unknown battery is the sum of the two currents we just found:

$$I_{\text{Total}} = 0.300\ \text{A} + 0.320\ \text{A} = 0.620\ \text{A}$$

The equivalent resistance of the resistors in parallel is $1/R_{\text{p}} = 1/(75.0\ \Omega) + 1/(80.0\ \Omega).$ This gives $R_{\text{p}} = 38.7\ \Omega.$ The equivalent resistance "seen" by the battery is $R_{\text{equiv}} = 20.0\ \Omega + 38.7\ \Omega = 58.7\ \Omega.$

Applying Ohm's law to the battery gives $\mathcal{E} = R_{\text{equiv}} I_{\text{Total}} = (58.7\ \Omega)(0.620\ \text{A}) = 36.4\ \text{V}.$

(b) IDENTIFY: With the switch closed, the 25.0-V battery is connected across the 50.0-Ω resistor.

SET UP: Take a loop around the right part of the circuit.

EXECUTE: Ohm's law gives $I = (25.0\ \text{V})/(50.0\ \Omega) = 0.500\ \text{A}.$

EVALUATE: The current through the 50.0-Ω resistor, and the rest of the circuit, depends on whether or not the switch is open.

26.32. **IDENTIFY:** We need to use Kirchhoff's rules.

SET UP: Take a loop around the outside of the circuit, use the current at the upper junction, and then take a loop around the right side of the circuit.

EXECUTE: The outside loop gives $75.0\ \text{V} - (12.0\ \Omega)(1.50\ \text{A}) - (48.0\ \Omega)I_{48} = 0,$ so $I_{48} = 1.188\ \text{A}.$ At a junction we have $1.50\text{A} = I_{\mathcal{E}} + 1.188\ \text{A},$ and $I_{\mathcal{E}} = 0.313\ \text{A}.$ A loop around the right part of the circuit gives $\mathcal{E} - (48\ \Omega)(1.188\ \text{A}) + (15.0\ \Omega)(0.313\ \text{A}).$ $\mathcal{E} = 52.3\ \text{V}$, with the polarity shown in the figure in the problem.

EVALUATE: The unknown battery has a smaller emf than the known one, so the current through it goes against its polarity.

26.33. **(a) IDENTIFY:** With the switch open, we have a series circuit with two batteries.

SET UP: Take a loop to find the current, then use Ohm's law to find the potential difference between *a* and *b*.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: Taking the loop: $I = (40.0\text{ V})/(175\ \Omega) = 0.229$ A. The potential difference between a and b is $V_b - V_a = +15.0\text{ V} - (75.0\ \Omega)(0.229\text{ A}) = -2.14$ V.

EVALUATE: The minus sign means that a is at a higher potential than b.

(b) IDENTIFY: With the switch closed, the ammeter part of the circuit divides the original circuit into two circuits. We can apply Kirchhoff's rules to both parts.

SET UP: Take loops around the left and right parts of the circuit, and then look at the current at the junction.

EXECUTE: The left-hand loop gives $I_{100} = (25.0\text{ V})/(100.0\ \Omega) = 0.250$ A. The right-hand loop gives $I_{75} = (15.0\text{ V})/(75.0\ \Omega) = 0.200$ A. At the junction just above the switch we have $I_{100} = 0.250$ A (in) and $I_{75} = 0.200$ A (out), so $I_A = 0.250\text{ A} - 0.200\text{ A} = 0.050$ A, downward. The voltmeter reads zero because the potential difference across it is zero with the switch closed.

EVALUATE: The ideal ammeter acts like a short circuit, making a and b at the same potential. Hence the voltmeter reads zero.

26.34. **IDENTIFY:** We first reduce the parallel combination of the $20.0\text{-}\Omega$ resistors and then apply Kirchhoff's rules.

SET UP: $P = I^2R$ so the power consumption of the $6.0\text{-}\Omega$ resistor allows us to calculate the current through it. Unknown currents I_1, I_2 and I_3 are shown in Figure 26.34. The junction rule says that $I_1 = I_2 + I_3$. In Figure 26.34 the two $20.0\text{-}\Omega$ resistors in parallel have been replaced by their equivalent $(10.0\ \Omega)$.

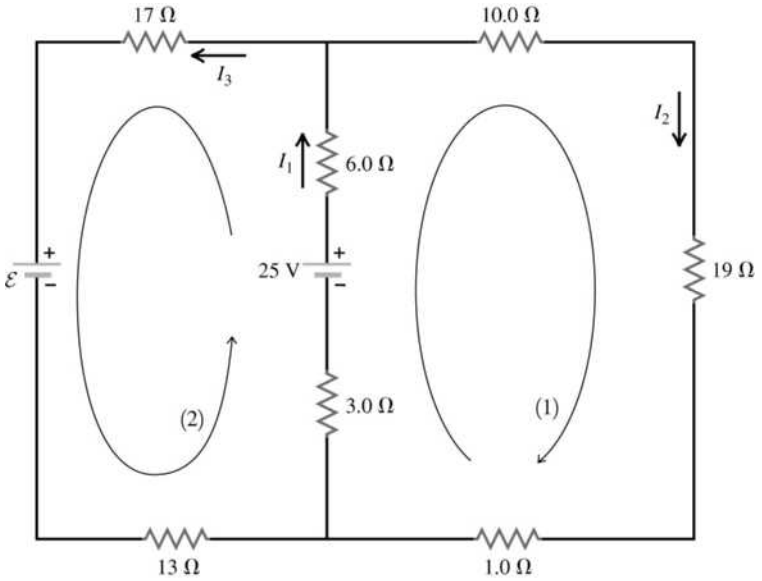

Figure 26.34

EXECUTE: **(a)** $P = I^2R$ gives $I_1 = \sqrt{\dfrac{P}{R}} = \sqrt{\dfrac{24\text{ J/s}}{6.0\ \Omega}} = 2.0$ A. The loop rule applied to loop (1) gives:

$-(2.0\text{ A})(3.0\ \Omega) - (2.0\text{ A})(6.0\ \Omega) + 25\text{ V} - I_2(10.0\ \Omega + 19.0\ \Omega + 1.0\ \Omega) = 0$. $I_2 = \dfrac{25\text{ V} - 18\text{ V}}{30.0\ \Omega} = 0.233$ A.

(b) $I_3 = I_1 - I_2 = 2.0\text{ A} - 0.233\text{ A} = 1.77$ A. The loop rule applied to loop (2) gives:

$-(2.0\text{ A})(3.0\ \Omega + 6.0\ \Omega) + 25\text{ V} - (1.77\text{ A})(17\ \Omega) - \mathcal{E} - (1.77\text{ A})(13\ \Omega) = 0$.

$\mathcal{E} = 25\text{ V} - 18\text{ V} - 53.1\text{ V} = -46.1$ V. The emf is 46.1 V.

EVALUATE: Because of the minus sign for the emf, the polarity of the battery is opposite to what is shown in the figure in the problem; the + terminal is adjacent to the $13\text{-}\Omega$ resistor.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

26.35. **IDENTIFY:** To construct an ammeter, add a shunt resistor in parallel with the galvanometer coil. To construct a voltmeter, add a resistor in series with the galvanometer coil.
SET UP: The full-scale deflection current is $500\ \mu\text{A}$ and the coil resistance is $25.0\ \Omega$.
EXECUTE: **(a)** For a 20-mA ammeter, the two resistances are in parallel and the voltages across each are the same. $V_c = V_s$ gives $I_c R_c = I_s R_s$. $(500\times10^{-6}\text{ A})(25.0\ \Omega) = (20\times10^{-3}\text{ A} - 500\times10^{-6}\text{ A})R_s$ and $R_s = 0.641\ \Omega$.
(b) For a 500-mV voltmeter, the resistances are in series and the current is the same through each:
$V_{ab} = I(R_c + R_s)$ and $R_s = \dfrac{V_{ab}}{I} - R_c = \dfrac{500\times10^{-3}\text{ V}}{500\times10^{-6}\text{ A}} - 25.0\ \Omega = 975\ \Omega$.
EVALUATE: The equivalent resistance of the voltmeter is $R_{eq} = R_s + R_c = 1000\ \Omega$. The equivalent resistance of the ammeter is given by $\dfrac{1}{R_{eq}} = \dfrac{1}{R_{sh}} + \dfrac{1}{R_c}$ and $R_{eq} = 0.625\ \Omega$. The voltmeter is a high-resistance device and the ammeter is a low-resistance device.

26.36. **IDENTIFY:** The galvanometer is represented in the circuit as a resistance R_c. Use the junction rule to relate the current through the galvanometer and the current through the shunt resistor. The voltage drop across each parallel path is the same; use this to write an equation for the resistance R.
SET UP: The circuit is sketched in Figure 26.36.

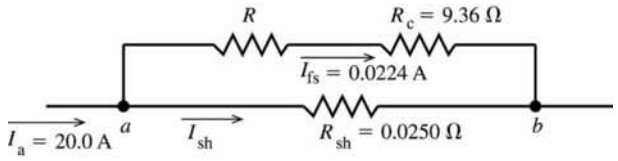

Figure 26.36

We want that $I_a = 20.0$ A in the external circuit to produce $I_{fs} = 0.0224$ A through the galvanometer coil.
EXECUTE: Applying the junction rule to point a gives $I_a - I_{fs} - I_{sh} = 0$.
$I_{sh} = I_a - I_{fs} = 20.0\text{ A} - 0.0224\text{ A} = 19.98\text{ A}$
The potential difference V_{ab} between points a and b must be the same for both paths between these two points: $I_{fs}(R + R_c) = I_{sh}R_{sh}$
$R = \dfrac{I_{sh}R_{sh}}{I_{fs}} - R_c = \dfrac{(19.98\text{ A})(0.0250\ \Omega)}{0.0224\text{ A}} - 9.36\ \Omega = 22.30\ \Omega - 9.36\ \Omega = 12.9\ \Omega$
EVALUATE: $R_{sh} << R + R_c$; most of the current goes through the shunt. Adding R decreases the fraction of the current that goes through R_c.

26.37. **IDENTIFY:** The meter introduces resistance into the circuit, which affects the current through the $5.00\text{-k}\Omega$ resistor and hence the potential drop across it.
SET UP: Use Ohm's law to find the current through the $5.00\text{-k}\Omega$ resistor and then the potential drop across it.
EXECUTE: **(a)** The parallel resistance with the voltmeter is $3.33\ \text{k}\Omega$, so the total equivalent resistance across the battery is $9.33\ \text{k}\Omega$, giving $I = (50.0\text{ V})/(9.33\ \text{k}\Omega) = 5.36$ mA. Ohm's law gives the potential drop across the $5.00\text{-k}\Omega$ resistor: $V_{5\ \text{k}\Omega} = (3.33\ \text{k}\Omega)(5.36\text{ mA}) = 17.9$ V
(b) The current in the circuit is now $I = (50.0\text{ V})/(11.0\ \text{k}\Omega) = 4.55$ mA.
$V_{5\ \text{k}\Omega} = (5.00\ \text{k}\Omega)(4.55\text{ mA}) = 22.7$ V.
(c) % error $= (22.7\text{ V} - 17.9\text{ V})/(22.7\text{ V}) = 0.214 = 21.4\%$. (We carried extra decimal places for accuracy since we had to subtract our answers.)

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: The presence of the meter made a very large percent error in the reading of the "true" potential across the resistor.

26.38. **IDENTIFY:** The resistance of the galvanometer can alter the resistance in a circuit.

SET UP: The shunt is in parallel with the galvanometer, so we find the parallel resistance of the ammeter. Then use Ohm's law to find the current in the circuit.

EXECUTE: **(a)** The resistance of the ammeter is given by $1/R_{\text{A}} = 1/(1.00\ \Omega) + 1/(25.0\ \Omega)$, so $R_A = 0.962\ \Omega$. The current through the ammeter, and hence the current it measures, is $I = V/R = (25.0\ \text{V})/(15.96\ \Omega) = 1.57\ \text{A}$.

(b) Now there is no meter in the circuit, so the total resistance is only $15.0\ \Omega$. $I = (25.0\ \text{V})/(15.0\ \Omega) = 1.67\ \text{A}$

(c) $(1.67\ \text{A} - 1.57\ \text{A})/(1.67\ \text{A}) = 0.060 = 6.0\%$

EVALUATE: A $1\text{-}\Omega$ shunt can introduce noticeable error in the measurement of an ammeter.

26.39. **IDENTIFY:** Apply $\mathcal{E} = IR_{\text{total}}$ to relate the resistance R_x to the current in the circuit.

SET UP: R, R_x and the meter are in series, so $R_{\text{total}} = R + R_x + R_{\text{M}}$, where $R_{\text{M}} = 65.0\ \Omega$ is the resistance of the meter. $I_{\text{fsd}} = 2.50\ \text{mA}$ is the current required for full-scale deflection.

EXECUTE: **(a)** When the wires are shorted, the full-scale deflection current is obtained: $\mathcal{E} = IR_{\text{total}}$.

$1.52\ \text{V} = (2.50\times10^{-3}\ \text{A})(65.0\ \Omega + R)$ and $R = 543\ \Omega$.

(b) If the resistance $R_x = 200\ \Omega$: $I = \dfrac{V}{R_{\text{total}}} = \dfrac{1.52\ \text{V}}{65.0\ \Omega + 543\ \Omega + R_x} = 1.88\ \text{mA}$.

(c) $I_x = \dfrac{\mathcal{E}}{R_{\text{total}}} = \dfrac{1.52\ \text{V}}{65.0\ \Omega + 543\ \Omega + R_x}$ and $R_x = \dfrac{1.52\ \text{V}}{I_x} - 608\ \Omega$. For each value of I_x we have:

For $I_x = \dfrac{1}{4}I_{\text{fsd}} = 6.25\times10^{-4}\ \text{A}$, $R_x = \dfrac{1.52\ \text{V}}{6.25\times10^{-4}\ \text{A}} - 608\ \Omega = 1824\ \Omega$.

For $I_x = \dfrac{1}{2}I_{\text{fsd}} = 1.25\times10^{-3}\ \text{A}$, $R_x = \dfrac{1.52\ \text{V}}{1.25\times10^{-3}\ \text{A}} - 608\ \Omega = 608\ \Omega$.

For $I_x = \dfrac{3}{4}I_{\text{fsd}} = 1.875\times10^{-3}\ \text{A}$, $R_x = \dfrac{1.52\ \text{V}}{1.875\times10^{-3}\ \text{A}} - 608\ \Omega = 203\ \Omega$.

EVALUATE: The deflection of the meter increases when the resistance R_x decreases.

26.40. **IDENTIFY:** An uncharged capacitor is placed into a circuit. Apply the loop rule at each time.

SET UP: The voltage across a capacitor is $V_C = q/C$.

EXECUTE: **(a)** At the instant the circuit is completed, there is no voltage across the capacitor, since it has no charge stored.

(b) Since $V_C = 0$, the full battery voltage appears across the resistor $V_R = \mathcal{E} = 245\ \text{V}$.

(c) There is no charge on the capacitor.

(d) The current through the resistor is $i = \dfrac{\mathcal{E}}{R_{\text{total}}} = \dfrac{245\ \text{V}}{7500\ \Omega} = 0.0327\ \text{A}$.

(e) After a long time has passed the full battery voltage is across the capacitor and $i = 0$. The voltage across the capacitor balances the emf: $V_C = 245\ \text{V}$. The voltage across the resistor is zero. The capacitor's charge is $q = CV_C = (4.60\times10^{-6}\ \text{F})\,(245\ \text{V}) = 1.13\times10^{-3}\ \text{C}$. The current in the circuit is zero.

EVALUATE: The current in the circuit starts at 0.0327 A and decays to zero. The charge on the capacitor starts at zero and rises to $q = 1.13\times10^{-3}\ \text{C}$.

26.41. **IDENTIFY:** The capacitor discharges exponentially through the voltmeter. Since the potential difference across the capacitor is directly proportional to the charge on the plates, the voltage across the plates decreases exponentially with the same time constant as the charge.

SET UP: The reading of the voltmeter obeys the equation $V = V_0 e^{-t/RC}$, where RC is the time constant.

EXECUTE: **(a)** Solving for C and evaluating the result when $\pm = 4.00\text{s}$ gives

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$C = \frac{t}{R\ln(V/V_0)} = \frac{4.00\text{ s}}{(3.40\times10^6\ \Omega)\ln\left(\frac{12.0\text{ V}}{3.00\text{ V}}\right)} = 8.49\times10^{-7}\text{ F}$$

(b) $\tau = RC = (3.40\times10^6\ \Omega)(8.49\times10^{-7}\text{ F}) = 2.89\text{ s}$

EVALUATE: In most laboratory circuits, time constants are much shorter than this one.

26.42. **IDENTIFY:** For a charging capacitor $q(t) = C\varepsilon(1-e^{-t/\tau})$ and $i(t) = \frac{\varepsilon}{R}e^{-t/\tau}$.

SET UP: The time constant is $RC = (0.895\times10^6\ \Omega)\,(12.4\times10^{-6}\text{ F}) = 11.1\text{ s}$.

EXECUTE: **(a)** At $t = 0$ s: $q = C\varepsilon(1-e^{-t/RC}) = 0$.

At $t = 5$ s: $q = C\varepsilon(1-e^{-t/RC}) = (12.4\times10^{-6}\text{ F})(60.0\text{ V})(1-e^{-(5.0\text{ s})/(11.1\text{ s})}) = 2.70\times10^{-4}$ C.

At $t = 10$ s: $q = C\varepsilon(1-e^{-t/RC}) = (12.4\times10^{-6}\text{ F})(60.0\text{ V})(1-e^{-(10.0\text{ s})/(11.1\text{ s})}) = 4.42\times10^{-4}$ C.

At $t = 20$ s: $q = C\varepsilon(1-e^{-t/RC}) = (12.4\times10^{-6}\text{ F})(60.0\text{ V})(1-e^{-(20.0\text{ s})/(11.1\text{ s})}) = 6.21\times10^{-4}$ C.

At $t = 100$ s: $q = C\varepsilon(1-e^{-t/RC}) = (12.4\times10^{-6}\text{ F})(60.0\text{ V})(1-e^{-(100\text{ s})/(11.1\text{ s})}) = 7.44\times10^{-4}$ C.

(b) The current at time t is given by: $i = \frac{\varepsilon}{R}e^{-t/RC}$.

At $t = 0$ s: $i = \frac{60.0\text{ V}}{8.95\times10^5\ \Omega}e^{-0/11.1} = 6.70\times10^{-5}$ A.

At $t = 5$ s: $i = \frac{60.0\text{ V}}{8.95\times10^5\ \Omega}e^{-5/11.1} = 4.27\times10^{-5}$ A.

At $t = 10$ s: $i = \frac{60.0\text{ V}}{8.95\times10^5\ \Omega}e^{-10/11.1} = 2.72\times10^{-5}$ A.

At $t = 20$ s: $i = \frac{60.0\text{ V}}{8.95\times10^5\ \Omega}e^{-20/11.1} = 1.11\times10^{-5}$ A.

At $t = 100$ s: $i = \frac{60.0\text{ V}}{8.95\times10^5\ \Omega}e^{-100/11.1} = 8.20\times10^{-9}$ A.

(c) The graphs of $q(t)$ and $i(t)$ are given in Figure 26.42a and b.

EVALUATE: The charge on the capacitor increases in time as the current decreases.

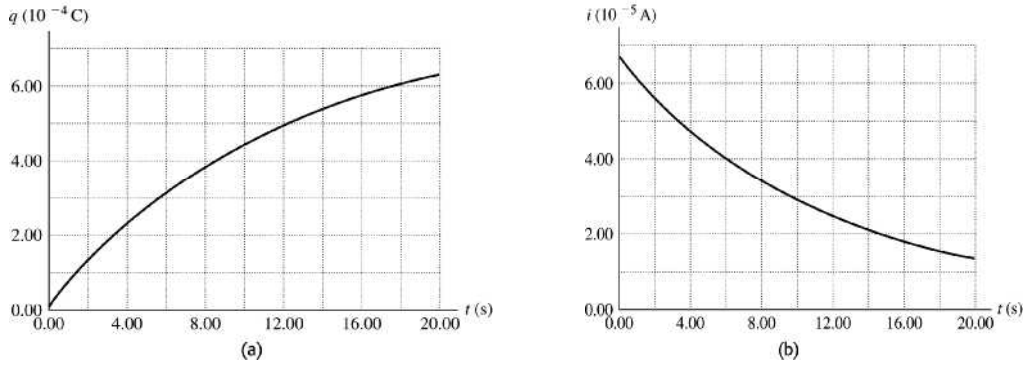

Figure 26.42

26.43. **IDENTIFY:** The capacitors, which are in parallel, will discharge exponentially through the resistors.

SET UP: Since V is proportional to Q, V must obey the same exponential equation as Q, $V = V_0e^{-t/RC}$. The current is $I = (V_0/R)\,e^{-t/RC}$.

EXECUTE: **(a)** Solve for time when the potential across each capacitor is 10.0 V:

$$t = -RC\ln(V/V_0) = -(80.0\ \Omega)(35.0\ \mu\text{F})\ln(10/45) = 4210\ \mu\text{s} = 4.21\text{ ms}$$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) $I = (V_0/R)\,e^{-t/RC}$. Using the above values, with $V_0 = 45.0$ V, gives $I = 0.125$ A.

EVALUATE: Since the current and the potential both obey the same exponential equation, they are both reduced by the same factor (0.222) in 4.21 ms.

26.44. **IDENTIFY:** In $\tau = RC$ use the equivalent capacitance of the two capacitors.

SET UP: For capacitors in series, $\frac{1}{C_{\text{eq}}} = \frac{1}{C_1} + \frac{1}{C_2}$. For capacitors in parallel, $C_{\text{eq}} = C_1 + C_2$. Originally, $\tau = RC = 0.870$ s.

EXECUTE: **(a)** The combined capacitance of the two identical capacitors in series is given by $\frac{1}{C_{\text{eq}}} = \frac{1}{C} + \frac{1}{C} = \frac{2}{C}$, so $C_{\text{eq}} = \frac{C}{2}$. The new time constant is thus $R(C/2) = \frac{0.870\text{ s}}{2} = 0.435$ s.

(b) With the two capacitors in parallel the new total capacitance is simply $2C$. Thus the time constant is $R(2C) = 2(0.870\text{ s}) = 1.74$ s.

EVALUATE: The time constant is proportional to C_{eq}. For capacitors in series the capacitance is decreased and for capacitors in parallel the capacitance is increased.

26.45. **IDENTIFY** and **SET UP:** Apply the loop rule. The voltage across the resistor depends on the current through it and the voltage across the capacitor depends on the charge on its plates.

EXECUTE: $\mathcal{E} - V_R - V_C = 0$

$\mathcal{E} = 120$ V, $V_R = IR = (0.900\text{ A})(80.0\,\Omega) = 72$ V, so $V_C = 48$ V

$Q = CV = (4.00\times10^{-6}\text{ F})(48\text{ V}) = 192\,\mu\text{C}$

EVALUATE: The initial charge is zero and the final charge is $C\mathcal{E} = 480\,\mu$C. Since current is flowing at the instant considered in the problem the capacitor is still being charged and its charge has not reached its final value.

26.46. **IDENTIFY:** The charge is increasing while the current is decreasing. Both obey exponential equations, but they are not the same equation.

SET UP: The charge obeys the equation $Q = Q_{\max}(1 - e^{-t/RC})$, but the equation for the current is $I = I_{\max}e^{-t/RC}$.

EXECUTE: When the charge has reached $\frac{1}{4}$ of its maximum value, we have $Q_{\max}/4 = Q_{\max}(1 - e^{-t/RC})$, which says that the exponential term has the value $e^{-t/RC} = \frac{3}{4}$. The current at this time is

$I = I_{\max}e^{-t/RC} = \text{I}_{\max}(3/4) = (3/4)[(10.0\text{ V})/(12.0\,\Omega)] = 0.625$ A.

EVALUATE: Notice that the current will be $\frac{3}{4}$, not $\frac{1}{4}$, of its maximum value when the charge is $\frac{1}{4}$ of its maximum. Although current and charge both obey exponential equations, the equations have different forms for a charging capacitor.

26.47. **IDENTIFY:** The stored energy is proportional to the square of the charge on the capacitor, so it will obey an exponential equation, but not the same equation as the charge.

SET UP: The energy stored in the capacitor is $U = Q^2/2C$ and the charge on the plates is $Q_0e^{-t/RC}$. The current is $I = I_0e^{-t/RC}$.

EXECUTE: $U = Q^2/2C = (Q_0e^{-t/RC})^2/2\text{C} = U_0e^{-2t/RC}$. When the capacitor has lost 80% of its stored energy, the energy is 20% of the initial energy, which is $U_0/5$. $U_0/5 = U_0\ e^{-2t/RC}$ gives $t = (RC/2)\ \ln 5 = (25.0\,\Omega)(4.62\text{ pF})(\ln 5)/2 = 92.9$ ps.

At this time, the current is $I = I_0\ e^{-t/RC} = (Q_0/RC)\,e^{-t/RC}$, so

$$I = (3.5\text{ nC})/[(25.0\,\Omega)(4.62\text{ pF})]\ \text{e}^{-(92.9\text{ ps})/[(25.0\,\Omega)(4.62\text{ pF})]} = 13.6\text{ A}.$$

EVALUATE: When the energy is reduced by 80%, neither the current nor the charge are reduced by that percent.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

26.48. **IDENTIFY:** Both the charge and energy decay exponentially, but not with the same time constant since the energy is proportional to the *square* of the charge.

SET UP: The charge obeys the equation $Q = Q_0 e^{-t/RC}$ but the energy obeys the equation $U = Q^2/2C = (Q_0 e^{-t/RC})/2\text{C} = U_0 e^{-2t/RC}$.

EXECUTE: **(a)** The charge is reduced by half: $Q_0/2 = Q_0 e^{-t/RC}$. This gives

$$t = RC \ln 2 = (175\ \Omega)(12.0\ \mu\text{F})(\ln 2) = 1.456\ \text{ms} = 1.46\ \text{ms}.$$

(b) The energy is reduced by half: $U_0/2 = U_0 e^{-2t/RC}$. This gives

$$t = (RC \ln 2)/2 = (1.456\ \text{ms})/2 = 0.728\ \text{ms}.$$

EVALUATE: The energy decreases faster than the charge because it is proportional to the square of the charge.

26.49. **IDENTIFY:** In both cases, simplify the complicated circuit by eliminating the appropriate circuit elements. The potential across an uncharged capacitor is initially zero, so it behaves like a short circuit. A fully charged capacitor allows no current to flow through it.

(a) SET UP: Just after closing the switch, the uncharged capacitors all behave like short circuits, so any resistors in parallel with them are eliminated from the circuit.

EXECUTE: The equivalent circuit consists of $50\ \Omega$ and $25\ \Omega$ in parallel, with this combination in series with $75\ \Omega$, $15\ \Omega$, and the 100-V battery. The equivalent resistance is $90\ \Omega + 16.7\ \Omega = 106.7\ \Omega$, which gives $I = (100\text{V})/(106.\Omega) = 0.937$ A.

(b) SET UP: Long after closing the switch, the capacitors are essentially charged up and behave like open circuits since no charge can flow through them. They effectively eliminate any resistors in series with them since no current can flow through these resistors.

EXECUTE: The equivalent circuit consists of resistances of $75\ \Omega$, $15\ \Omega$ and three $25\text{-}\Omega$ resistors, all in series with the 100-V battery, for a total resistance of $165\ \Omega$. Therefore $I = (100\text{V})/(165\ \Omega) = 0.606$ A

EVALUATE: The initial and final behavior of the circuit can be calculated quite easily using simple series-parallel circuit analysis. Intermediate times would require much more difficult calculations!

26.50. **IDENTIFY:** When the capacitor is fully charged the voltage V across the capacitor equals the battery emf and $Q = CV$. For a charging capacitor, $q = Q(1 - e^{-t/RC})$.

SET UP: $\ln e^x = x$

EXECUTE: **(a)** $Q = CV = (5.90 \times 10^{-6}\ \text{F})(28.0\ \text{V}) = 1.65 \times 10^{-4}$ C.

(b) $q = Q(1 - e^{-t/RC})$, so $e^{-t/RC} = 1 - \dfrac{q}{Q}$ and $R = \dfrac{-t}{C \ln(1 - q/Q)}$. After $t = 3 \times 10^{-3}$ s:

$$R = \frac{-3 \times 10^{-3}\ \text{s}}{(5.90 \times 10^{-6}\ \text{F})(\ln(1 - 110/165))} = 463\ \Omega.$$

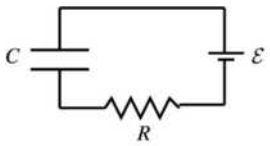
(c) If the charge is to be 99% of final value: $\dfrac{q}{Q} = (1 - e^{-t/RC})$ gives

$$t = -RC \ln(1 - q/Q) = -(463\ \Omega)(5.90 \times 10^{-6}\ \text{F}) \ln(0.01) = 0.0126\ \text{s}.$$

EVALUATE: The time constant is $\tau = RC = 2.73$ ms. The time in part (b) is a bit more than one time constant and the time in part (c) is about 4.6 time constants.

26.51. **IDENTIFY:** For each circuit apply the loop rule to relate the voltages across the circuit elements.

(a) SET UP: With the switch in position 2 the circuit is the charging circuit shown in Figure 26.51a.



At $t = 0$, $q = 0$.

Figure 26.51a

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: The charge q on the capacitor is given as a function of time by Eq. (26.12):

$q = C\mathcal{E}(1 - e^{-t/RC})$

$Q_f = C\mathcal{E} = (1.50\times10^{-5}\ \text{F})(18.0\ \text{V}) = 2.70\times10^{-4}\ \text{C}.$

$RC = (980\ \Omega)(1.50\times10^{-5}\ \text{F}) = 0.0147\ \text{s}$

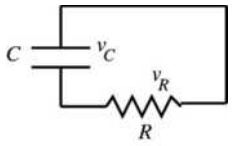
Thus, at $t = 0.0100$ s, $q = (2.70\times10^{-4}\ \text{C})(1 - e^{-(0.0100\ \text{s})/(0.0147\ \text{s})}) = 133\ \mu\text{C}.$

(b) $v_C = \dfrac{q}{C} = \dfrac{133\ \mu\text{C}}{1.50\times10^{-5}\ \text{F}} = 8.87\ \text{V}$

The loop rule says $\mathcal{E} - v_C - v_R = 0.$

$v_R = \mathcal{E} - v_C = 18.0\ \text{V} - 8.87\ \text{V} = 9.13\ \text{V}$

(c) SET UP: Throwing the switch back to position 1 produces the discharging circuit shown in Figure 26.51b.



The initial charge Q_0 is the charge calculated in part (b), $Q_0 = 133\ \mu\text{C}$.

Figure 26.51b

EXECUTE: $v_C = \dfrac{q}{C} = \dfrac{133\ \mu\text{C}}{1.50\times10^{-5}\ \text{F}} = 8.87\ \text{V},$ the same as just before the switch is thrown. But now $v_C - v_R = 0$, so $v_R = v_C = 8.87$ V.

(d) SET UP: In the discharging circuit the charge on the capacitor as a function of time is given by Eq. (26.16): $q = Q_0 e^{-t/RC}$.

EXECUTE: $RC = 0.0147$ s, the same as in part (a). Thus at $t = 0.0100$ s, $q = (133\ \mu\text{C})e^{-((0.0100\ \text{s})/(0.0147\ \text{s}))} = 67.4\ \mu\text{C}.$

EVALUATE: $t = 10.0$ ms is less than one time constant, so at the instant described in part (a) the capacitor is not fully charged; its voltage (8.87 V) is less than the emf. There is a charging current and a voltage drop across the resistor. In the discharging circuit the voltage across the capacitor starts at 8.87 V and decreases. After $t = 10.0$ ms it has decreased to $v_C = q/C = 4.49$ V.

26.52. **IDENTIFY:** $P = VI = I^2R$

SET UP: Problem 25.77 says that for 12-gauge wire the maximum safe current is 25 A.

EXECUTE: **(a)** $I = \dfrac{P}{V} = \dfrac{4100\ \text{W}}{240\ \text{V}} = 17.1\ \text{A}.$ So we need at least 14-gauge wire (good up to 18 A). 12-gauge is also ok (good up to 25 A).

(b) $P = \dfrac{V^2}{R}$ and $R = \dfrac{V^2}{P} = \dfrac{(240\ \text{V})^2}{4100\ \text{W}} = 14\ \Omega.$

(c) At 11¢ per kWH, for 1 hour the cost is $(11¢/\text{kWh})(1\ \text{h})(4.1\ \text{kW}) = 45¢.$

EVALUATE: The cost to operate the device is proportional to its power consumption.

26.53. **IDENTIFY** and **SET UP:** The heater and hair dryer are in parallel so the voltage across each is 120 V and the current through the fuse is the sum of the currents through each appliance. As the power consumed by the dryer increases, the current through it increases. The maximum power setting is the highest one for which the current through the fuse is less than 20 A.

EXECUTE: Find the current through the heater. $P = VI$ so $I = P/V = 1500\ \text{W}/120\ \text{V} = 12.5\ \text{A}.$ The maximum total current allowed is 20 A, so the current through the dryer must be less than $20\ \text{A} - 12.5\ \text{A} = 7.5\ \text{A}.$ The power dissipated by the dryer if the current has this value is $P = VI = (120\ \text{V})(7.5\ \text{A}) = 900\ \text{W}.$ For P at this value or larger the circuit breaker trips.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: $P = V^2/R$ and for the dryer V is a constant 120 V. The higher power settings correspond to a smaller resistance R and larger current through the device.

26.54. **IDENTIFY** and **SET UP:** Ohm's law and Eq. (25.18) can be used to calculate I and P given V and R. Use Eq. (25.12) to calculate the resistance at the higher temperature.

(a) EXECUTE: When the heater element is first turned on it is at room temperature and has resistance $R = 20\ \Omega$.

$$I = \frac{V}{R} = \frac{120\ \text{V}}{20\ \Omega} = 6.0\ \text{A}$$

$$P = \frac{V^2}{R} = \frac{(120\ \text{V})^2}{20\ \Omega} = 720\ \text{W}$$

(b) Find the resistance $R(T)$ of the element at the operating temperature of 280°C.

Take $T_0 = 23.0°\text{C}$ and $R_0 = 20\ \Omega$. Eq. (25.12) gives

$$R(T) = R_0(1 + \alpha(T - T_0)) = 20\ \Omega(1 + (2.8 \times 10^{-3}(\text{C°})^{-1})(280°\text{C} - 23.0°\text{C})) = 34.4\ \Omega.$$

$$I = \frac{V}{R} = \frac{120\ \text{V}}{34.4\ \Omega} = 3.5\ \text{A}$$

$$P = \frac{V^2}{R} = \frac{(120\ \text{V})^2}{34.4\ \Omega} = 420\ \text{W}$$

EVALUATE: When the temperature increases, R increases and I and P decrease. The changes are substantial.

26.55. **IDENTIFY:** We need to do series/parallel reduction to solve this circuit.

SET UP: $P = \dfrac{\mathcal{E}^2}{R}$, where R is the equivalent resistance of the network. For resistors in series, $R_{\text{eq}} = R_1 + R_2$, and for resistors in parallel $1/R_{\text{P}} = 1/R_1 + 1/R_2$.

EXECUTE: $R = \dfrac{\mathcal{E}^2}{P} = \dfrac{(48.0\ \text{V})^2}{295\ \text{W}} = 7.810\ \Omega$. $R_{12} = R_1 + R_2 = 8.00\ \Omega$. $R = R_{123} + R_4$.

$R_{123} = R - R_4 = 7.810\ \Omega - 3.00\ \Omega = 4.810\ \Omega$. $\dfrac{1}{R_{12}} + \dfrac{1}{R_3} = \dfrac{1}{R_{123}}$. $\dfrac{1}{R_3} = \dfrac{1}{R_{123}} - \dfrac{1}{R_{12}} = \dfrac{R_{12} - R_{123}}{R_{123}R_{12}}$.

$$R_3 = \frac{R_{123}R_{12}}{R_{12} - R_{123}} = \frac{(4.810\ \Omega)(8.00\ \Omega)}{8.00\ \Omega - 4.810\ \Omega} = 12.1\ \Omega.$$

EVALUATE: The resistance R_3 is greater than R, since the equivalent parallel resistance is less than any of the resistors in parallel.

26.56. **(a) IDENTIFY:** Two of the resistors in series would each dissipate one-half the total, or 1.2 W, which is ok. But the series combination would have an equivalent resistance of $800\ \Omega$, not the $400\ \Omega$ that is required. Resistors in parallel have an equivalent resistance that is less than that of the individual resistors, so a solution is two in series in parallel with another two in series.

SET UP: The network can be simplified as shown in Figure 26.56a.

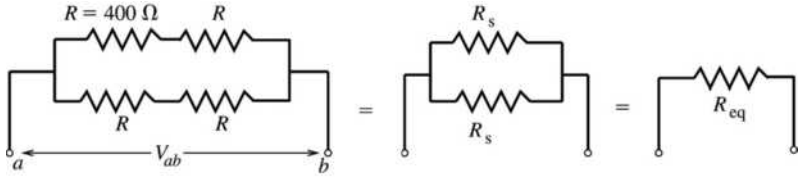


Figure 26.56a

EXECUTE: R_{s} is the resistance equivalent to two of the $400\text{-}\Omega$ resistors in series. $R_{\text{s}} = R + R = 800\ \Omega$.

R_{eq} is the resistance equivalent to the two $R_{\text{s}} = 800\text{-}\Omega$ resistors in parallel:

$$\frac{1}{R_{\text{eq}}} = \frac{1}{R_{\text{s}}} + \frac{1}{R_{\text{s}}} = \frac{2}{R_{\text{s}}};\ R_{\text{eq}} = \frac{800\ \Omega}{2} = 400\ \Omega.$$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: This combination does have the required 400-Ω equivalent resistance. It will be shown in part (b) that a total of 2.4 W can be dissipated without exceeding the power rating of each individual resistor.

IDENTIFY: Another solution is two resistors in parallel in series with two more in parallel.

SET UP: The network can be simplified as shown in Figure 26.56b.

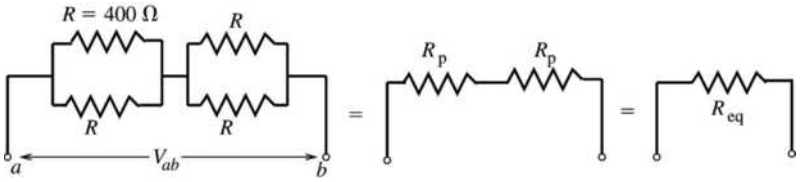

Figure 26.56b

EXECUTE: $\frac{1}{R_p}=\frac{1}{R}+\frac{1}{R}=\frac{2}{400\,\Omega}$; $R_p = 200\,\Omega$; $R_{eq} = R_p + R_p = 400\,\Omega$

EVALUATE: This combination has the required 400-Ω equivalent resistance. It will be shown in part (b) that a total of 2.4 W can be dissipated without exceeding the power rating of each individual resistor.

(b) IDENTIFY and **SET UP:** Find the applied voltage V_{ab} such that a total of 2.4 W is dissipated and then for this V_{ab} find the power dissipated by each resistor.

EXECUTE: For a combination with equivalent resistance $R_{eq} = 400\,\Omega$ to dissipate 2.4 W the voltage V_{ab} applied to the network must be given by $P = V_{ab}^2/R_{eq}$ so $V_{ab} = \sqrt{PR_{eq}} = \sqrt{(2.4\text{ W})(400\,\Omega)} = 31.0\text{ V}$ and the current through the equivalent resistance is $I = V_{ab}/R = 31.0\text{ V}/400\,\Omega = 0.0775\text{ A}$. For the first combination this means 31.0 V across each parallel branch and $\frac{1}{2}(31.0\text{ V}) = 15.5\text{ V}$ across each 400-Ω resistor. The power dissipated by each individual resistor is then $P = V^2/R = (15.5\text{ V})^2/400\,\Omega = 0.60\text{ W}$, which is less than the maximum allowed value of 1.20 W. For the second combination this means a voltage of $IR_p = (0.0775\text{ A})(200\,\Omega) = 15.5\text{ V}$ across each parallel combination and hence across each separate resistor. The power dissipated by each resistor is again $P = V^2/R = (15.5\text{ V})^2/400\,\Omega = 0.60\text{ W}$, which is less than the maximum allowed value of 1.20 W.

EVALUATE: The symmetry of each network says that each resistor in the network dissipates the same power. So, for a total of 2.4 W dissipated by the network, each resistor dissipates $(2.4\text{ W})/4 = 0.60\text{ W}$, which agrees with the above analysis.

26.57. **IDENTIFY:** The Cu and Ni cables are in parallel. For each, $R = \frac{\rho L}{A}$.

SET UP: The composite cable is sketched in Figure 26.57. The cross-sectional area of the nickel segment is πa^2 and the area of the copper portion is $\pi(b^2 - a^2)$. For nickel $\rho = 7.8\times10^{-8}\,\Omega\cdot\text{m}$. and for copper $\rho = 1.72\times10^{-8}\,\Omega\cdot\text{m}$.

EXECUTE: **(a)** $\frac{1}{R_{Cable}}=\frac{1}{R_{Ni}}+\frac{1}{R_{Cu}}$. $R_{Ni} = \rho_{Ni}L/A = \rho_{Ni}\frac{L}{\pi a^2}$ and $R_{Cu} = \rho_{Cu}\,L/A = \rho_{Cu}\frac{L}{\pi(b^2-a^2)}$.

Therefore, $\frac{1}{R_{cable}}=\frac{\pi a^2}{\rho_{Ni}L}+\frac{\pi(b^2-a^2)}{\rho_{Cu}L}$.

$\frac{1}{R_{cable}}=\frac{\pi}{L}\left(\frac{a^2}{\rho_{Ni}}+\frac{b^2-a^2}{\rho_{Cu}}\right)=\frac{\pi}{20\text{ m}}\left[\frac{(0.050\text{ m})^2}{7.8\times10^{-8}\,\Omega\cdot\text{m}}+\frac{(0.100\text{ m})^2-(0.050\text{ m})^2}{1.72\times10^{-8}\,\Omega\cdot\text{m}}\right]$ and

$R_{Cable} = 13.6\times10^{-6}\,\Omega = 13.6\,\mu\Omega$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) $R = \rho_{\text{eff}} \dfrac{L}{A} = \rho_{\text{eff}} \dfrac{L}{\pi b^2}$. This gives $\rho_{\text{eff}} = \dfrac{\pi b^2 R}{L} = \dfrac{\pi(0.10\text{ m})^2(13.6\times10^{-6}\ \Omega)}{20\text{ m}} = 2.14\times10^{-8}\ \Omega\cdot\text{m}$

EVALUATE: The effective resistivity of the cable is about 25% larger than the resistivity of copper. If nickel had infinite resitivity and only the copper portion conducted, the resistance of the cable would be $14.6\ \mu\Omega$, which is not much larger than the resistance calculated in part (a).

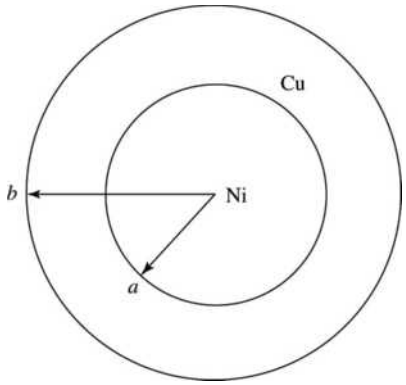

Figure 26.57

26.58. **IDENTIFY** and **SET UP:** Let $R = 3.00\ \Omega$, the resistance of one wire. Each half of the wire has $R_{\text{h}} = R/2 = 1.50\ \Omega$. The combined wires are the same as a resistor network. Use the rules for equivalent resistance for resistors in series and parallel to find the resistance of the network, as shown in Figure 26.58.
EXECUTE:

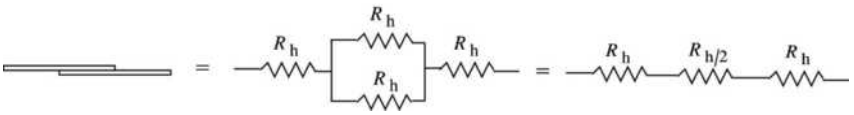

Figure 26.58

The equivalent resistance is $R_{\text{h}} + R_{\text{h}}/2 + R_{\text{h}} = 5R_{\text{h}}/2 = \frac{5}{2}(1.50\ \Omega) = 3.75\ \Omega$.

EVALUATE: If the two wires were connected end-to-end, the total resistance would be $6.00\ \Omega$. If they were joined side-by-side, the total resistance would be $1.50\ \Omega$. Our answer is between these two limiting values.

26.59. **IDENTIFY:** The terminal voltage of the battery depends on the current through it and therefore on the equivalent resistance connected to it. The power delivered to each bulb is $P = I^2R$, where I is the current through it.
SET UP: The terminal voltage of the source is $\mathcal{E} - Ir$.
EXECUTE: **(a)** The equivalent resistance of the two bulbs is $1.0\ \Omega$. This equivalent resistance is in series with the internal resistance of the source, so the current through the battery is $I = \dfrac{V}{R_{\text{total}}} = \dfrac{8.0\text{ V}}{1.0\ \Omega + 0.80\ \Omega} = 4.4\text{ A}$. and the current through each bulb is 2.2 A. The voltage applied to each bulb is $\mathcal{E} - Ir = 8.0\text{ V} - (4.4\text{ A})(0.80\ \Omega) = 4.4\text{ V}$. Therefore, $P_{\text{bulb}} = I^2R = (2.2\text{ A})^2(2.0\ \Omega) = 9.7\text{ W}$.

(b) If one bulb burns out, then $I = \dfrac{V}{R_{\text{total}}} = \dfrac{8.0\text{ V}}{2.0\ \Omega + 0.80\ \Omega} = 2.9\text{ A}$. The current through the remaining bulb is 2.9 A, and $P = I^2R = (2.9\text{ A})^2(2.0\ \Omega) = 16.3\text{ W}$. The remaining bulb is brighter than before, because it is consuming more power.
EVALUATE: In Example 26.2 the internal resistance of the source is negligible and the brightness of the remaining bulb doesn't change when one burns out.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

26.60. **IDENTIFY:** Half the current flows through each parallel resistor and the full current flows through the third resistor, that is in series with the parallel combination. Therefore, only the series resistor will be at its maximum power.

SET UP: $P = I^2R$

EXECUTE: The maximum allowed power is when the total current is the maximum allowed value of $I = \sqrt{P/R} = \sqrt{48\ \text{W}/2.4\ \Omega} = 4.47\ \text{A}$. Then half the current flows through the parallel resistors and the maximum power is $P_{\max} = (I/2)^2R + (I/2)^2R + I^2R = \frac{3}{2}I^2R = \frac{3}{2}(4.47\ \text{A})^2(2.4\ \Omega) = 72\ \text{W}$.

EVALUATE: If all three resistors were in series or all three were in parallel, then the maximum power would be $3(48\ \text{W}) = 144\ \text{W}$. For the network in this problem, the maximum power is half this value.

26.61. **IDENTIFY:** The ohmmeter reads the equivalent resistance between points *a* and *b*. Replace series and parallel combinations by their equivalent.

SET UP: For resistors in parallel, $\frac{1}{R_{\text{eq}}} = \frac{1}{R_1} + \frac{1}{R_2}$. For resistors in series, $R_{\text{eq}} = R_1 + R_2$.

EXECUTE: Circuit (a): The $75.0\text{-}\Omega$ and $40.0\text{-}\Omega$ resistors are in parallel and have equivalent resistance $26.09\ \Omega$. The $25.0\text{-}\Omega$ and $50.0\text{-}\Omega$ resistors are in parallel and have an equivalent resistance of $16.67\ \Omega$. The equivalent network is given in Figure 26.61a. $\frac{1}{R_{\text{eq}}} = \frac{1}{100.0\ \Omega} + \frac{1}{23.05\ \Omega}$, so $R_{\text{eq}} = 18.7\ \Omega$.

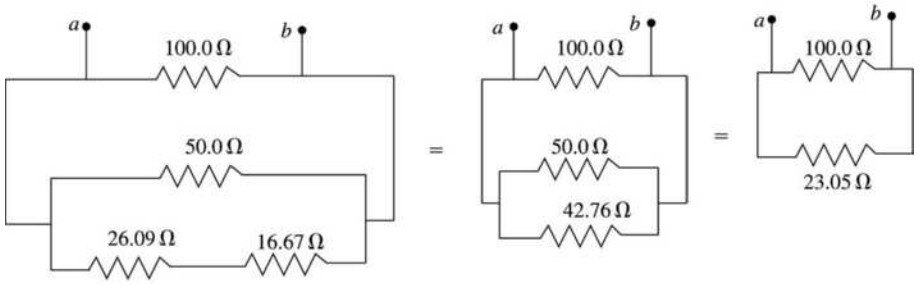

Figure 26.61a

Circuit (b): The $30.0\text{-}\Omega$ and $45.0\text{-}\Omega$ resistors are in parallel and have equivalent resistance $18.0\ \Omega$. The equivalent network is given in Figure 26.61b. $\frac{1}{R_{\text{eq}}} = \frac{1}{10.0\ \Omega} + \frac{1}{30.3\ \Omega}$, so $R_{\text{eq}} = 7.5\ \Omega$.

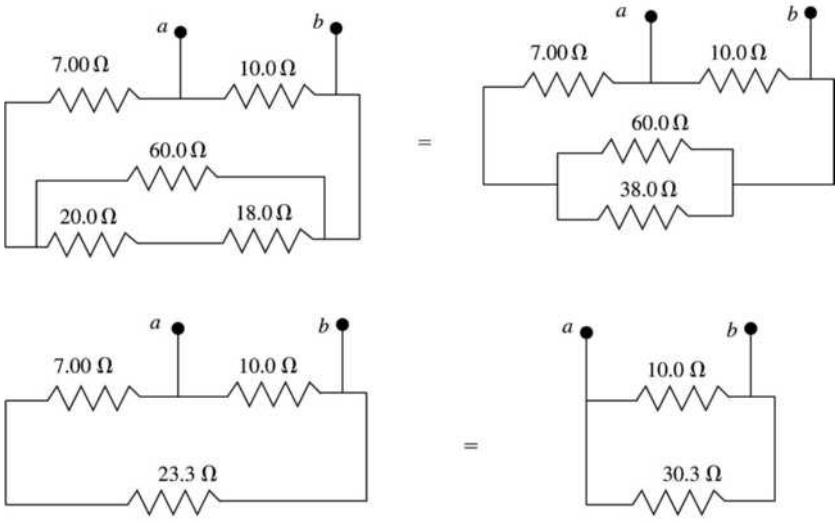

Figure 26.61b

EVALUATE: In circuit (a) the resistance along one path between a and b is $100.0\ \Omega$, but that is not the equivalent resistance between these points. A similar comment can be made about circuit (b).

26.62. **IDENTIFY:** Heat, which is generated in the resistor, melts the ice.

SET UP: Find the rate at which heat is generated in the $20.0\text{-}\Omega$ resistor using $P = V^2/R$. Then use the heat of fusion of ice to find the rate at which the ice melts. The heat dH to melt a mass of ice dm is $dH = L_F\ dm$, where L_F is the latent heat of fusion. The rate at which heat enters the ice, dH/dt, is the power P in the resistor, so $P = L_F\ dm/dt$. Therefore the rate of melting of the ice is $dm/dt = P/L_F$.

EXECUTE: The equivalent resistance of the parallel branch is $5.00\ \Omega$, so the total resistance in the circuit is $35.0\ \Omega$. Therefore the total current in the circuit is $I_{\text{Total}} = (45.0\text{ V})/(35.0\ \Omega) = 1.286\text{ A}$. The potential difference across the $20.0\text{-}\Omega$ resistor in the ice is the same as the potential difference across the parallel branch: $V_{\text{ice}} = I_{\text{Total}}R_p = (1.286\text{ A})(5.00\ \Omega) = 6.429\text{ V}$. The rate of heating of the ice is $P_{\text{ice}} = V_{\text{ice}}^2/R = (6.429\text{ V})^2/(20.0\ \Omega) = 2.066\text{ W}$. This power goes into to heat to melt the ice, so

$$dm/dt = P/L_F = (2.066\text{ W})/(3.34\times10^5\text{ J/kg}) = 6.19\times10^{-6}\text{ kg/s} = 6.19\times10^{-3}\text{ g/s}$$

EVALUATE: The melt rate is about 6 mg/s, which is not much. It would take 1000 s to melt just 6 g of ice.

26.63. **IDENTIFY:** Apply the junction rule to express the currents through the $5.00\text{-}\Omega$ and $8.00\text{-}\Omega$ resistors in terms of I_1, I_2 and I_3. Apply the loop rule to three loops to get three equations in the three unknown currents.

SET UP: The circuit is sketched in Figure 26.63.

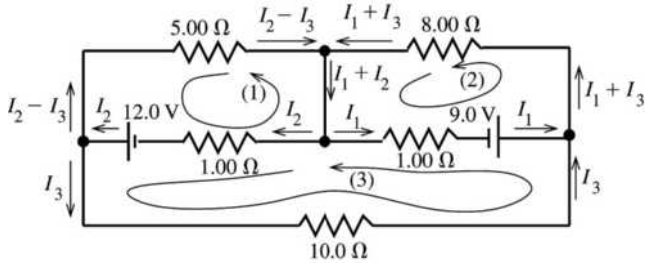

Figure 26.63

The current in each branch has been written in terms of I_1, I_2 and I_3 such that the junction rule is satisfied at each junction point.

EXECUTE: Apply the loop rule to loop (1).

$$-12.0\text{ V} + I_2(1.00\ \Omega) + (I_2 - I_3)(5.00\ \Omega) = 0$$

$$I_2(6.00\ \Omega) - I_3(5.00\ \Omega) = 12.0\text{ V} \qquad \text{eq. (1)}$$

Apply the loop rule to loop (2).

$$-I_1(1.00\ \Omega) + 9.00\text{ V} - (I_1 + I_3)(8.00\ \Omega) = 0$$

$$I_1(9.00\ \Omega) + I_3(8.00\ \Omega) = 9.00\text{ V} \qquad \text{eq. (2)}$$

Apply the loop rule to loop (3).

$$-I_3(10.0\ \Omega) - 9.00\text{ V} + I_1(1.00\ \Omega) - I_2(1.00\ \Omega) + 12.0\text{ V} = 0$$

$$-I_1(1.00\ \Omega) + I_2(1.00\ \Omega) + I_3(10.0\ \Omega) = 3.00\text{ V} \qquad \text{eq. (3)}$$

Eq. (1) gives $I_2 = 2.00\text{ A} + \frac{5}{6}I_3$; eq. (2) gives $I_1 = 1.00\text{ A} - \frac{8}{9}I_3$

Using these results in eq. (3) gives $-(1.00\text{ A} - \frac{8}{9}I_3)(1.00\ \Omega) + (2.00\text{ A} + \frac{5}{6}I_3)(1.00\ \Omega) + I_3(10.0\ \Omega) = 3.00\text{ V}$

$(\frac{16+15+180}{18})I_3 = 2.00\text{ A}$; $I_3 = \frac{18}{211}(2.00\text{ A}) = 0.171\text{ A}$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

Then $I_2 = 2.00\text{ A} + \frac{5}{6}I_3 = 2.00\text{ A} + \frac{5}{6}(0.171\text{ A}) = 2.14\text{ A}$ and

$I_1 = 1.00\text{ A} - \frac{8}{9}I_3 = 1.00\text{ A} - \frac{8}{9}(0.171\text{ A}) = 0.848\text{ A}.$

EVALUATE: We could check that the loop rule is satisfied for a loop that goes through the 5.00-Ω, 8.00-Ω and 10.0-Ω resistors. Going around the loop clockwise:

$-(I_2 - I_3)(5.00\,\Omega) + (I_1 + I_3)(8.00\,\Omega) + I_3(10.0\,\Omega) = -9.85\text{ V} + 8.15\text{ V} + 1.71\text{ V},$ which does equal zero, apart from rounding.

26.64. **IDENTIFY:** Apply the junction rule and the loop rule to the circuit.

SET UP: Because of the polarity of each emf, the current in the 7.00-Ω resistor must be in the direction shown in Figure 26.64a. Let I be the current in the 24.0-V battery.

EXECUTE: The loop rule applied to loop (1) gives: $+24.0\text{ V} - (1.80\text{ A})(7.00\,\Omega) - I(3.00\,\Omega) = 0.$

$I = 3.80$ A. The junction rule then says that the current in the middle branch is 2.00 A, as shown in Figure 26.64b. The loop rule applied to loop (2) gives: $+\mathcal{E} - (1.80\text{ A})(7.00\,\Omega) + (2.00\text{ A})(2.00\,\Omega) = 0$ and $\mathcal{E} = 8.6$ V.

EVALUATE: We can check our results by applying the loop rule to loop (3) in Figure 26.64b: $+24.0\text{ V} - \mathcal{E} - (2.00\text{ A})(2.00\,\Omega) - (3.80\text{ A})(3.00\,\Omega) = 0$ and $\mathcal{E} = 24.0\text{ V} - 4.0\text{ V} - 11.4\text{ V} = 8.6\text{ V},$ which agrees with our result from loop (2).

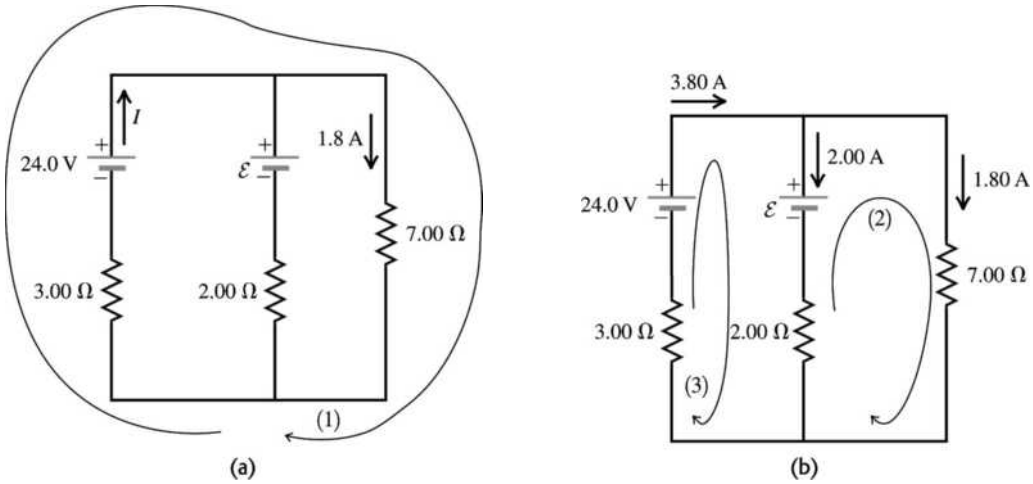

Figure 26.64

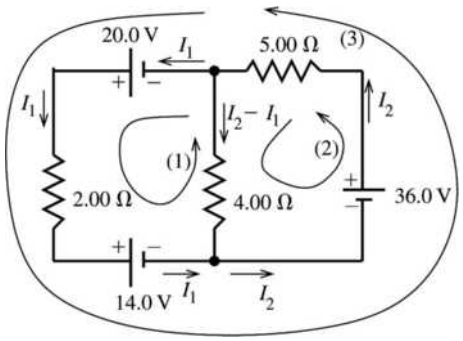
26.65. **IDENTIFY** and **SET UP:** The circuit is sketched in Figure 26.65.



Two unknown currents I_1 (through the 2.00-Ω resistor) and I_2 (through the 5.00-Ω resistor) are labeled on the circuit diagram. The current through the 4.00-Ω resistor has been written as $I_2 - I_1$ using the junction rule.

Figure 26.65

Apply the loop rule to loops (1) and (2) to get two equations for the unknown currents, I_1 and I_2. Loop (3) can then be used to check the results.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: loop (1): $+20.0\text{ V} - I_1(2.00\,\Omega) - 14.0\text{ V} + (I_2 - I_1)(4.00\,\Omega) = 0$

$6.00I_1 - 4.00I_2 = 6.00\text{ A}$

$3.00I_1 - 2.00I_2 = 3.00\text{ A}$ eq. (1)

loop (2): $+36.0\text{ V} - I_2(5.00\,\Omega) - (I_2 - I_1)(4.00\,\Omega) = 0$

$-4.00I_1 + 9.00I_2 = 36.0\text{ A}$ eq. (2)

Solving eq. (1) for I_1 gives $I_1 = 1.00\text{ A} + \frac{2}{3}I_2$

Using this in eq. (2) gives $-4.00(1.00\text{ A} + \frac{2}{3}I_2) + 9.00I_2 = 36.0\text{ A}$

$(-\frac{8}{3} + 9.00)I_2 = 40.0\text{ A}$ and $I_2 = 6.32\text{ A}$.

Then $I_1 = 1.00\text{ A} + \frac{2}{3}I_2 = 1.00\text{ A} + \frac{2}{3}(6.32\text{ A}) = 5.21\text{ A}$.

In summary then

Current through the $2.00\text{-}\Omega$ resistor: $I_1 = 5.21\text{ A}$.

Current through the $5.00\text{-}\Omega$ resistor: $I_2 = 6.32\text{ A}$.

Current through the $4.00\text{-}\Omega$ resistor: $I_2 - I_1 = 6.32\text{ A} - 5.21\text{ A} = 1.11\text{ A}$.

EVALUATE: Use loop (3) to check. $+20.0\text{ V} - I_1(2.00\,\Omega) - 14.0\text{ V} + 36.0\text{ V} - I_2(5.00\,\Omega) = 0$

$(5.21\text{ A})(2.00\,\Omega) + (6.32\text{ A})(5.00\,\Omega) = 42.0\text{ V}$

$10.4\text{ V} + 31.6\text{ V} = 42.0\text{ V}$, so the loop rule is satisfied for this loop.

26.66. **IDENTIFY:** Apply the loop and junction rules.

SET UP: Use the currents as defined on the circuit diagram in Figure 26.66 and obtain three equations to solve for the currents.

EXECUTE: Left loop: $14 - I_1 - 2(I_1 - I_2) = 0$ and $3I_1 - 2I_2 = 14$.

Top loop: $-2(I - I_1) + I_2 + I_1 = 0$ and $-2I + 3I_1 + I_2 = 0$.

Bottom loop: $-(I - I_1 + I_2) + 2(I_1 - I_2) - I_2 = 0$ and $-I + 3I_1 - 4I_2 = 0$.

Solving these equations for the currents we find: $I = I_{\text{battery}} = 10.0\text{ A}$; $I_1 = I_{R_1} = 6.0\text{ A}$; $I_2 = I_{R_3} = 2.0\text{ A}$.

So the other currents are: $I_{R_2} = I - I_1 = 4.0\text{ A}$; $I_{R_4} = I_1 - I_2 = 4.0\text{ A}$; $I_{R_5} = I - I_1 + I_2 = 6.0\text{ A}$.

(b) $R_{\text{eq}} = \dfrac{V}{I} = \dfrac{14.0\text{ V}}{10.0\text{ A}} = 1.40\,\Omega$.

EVALUATE: It isn't possible to simplify the resistor network using the rules for resistors in series and parallel. But the equivalent resistance is still defined by $V = IR_{\text{eq}}$.

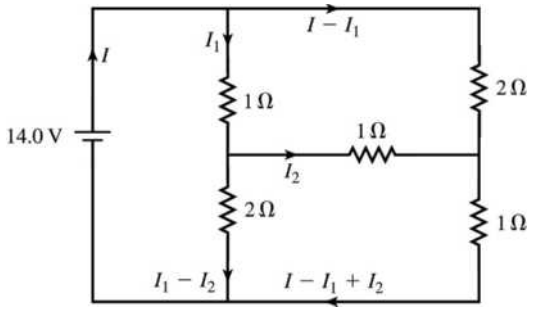


Figure 26.66

26.67. **(a) IDENTIFY:** Break the circuit between points *a* and *b* means no current in the middle branch that contains the 3.00-Ω resistor and the 10.0-V battery. The circuit therefore has a single current path. Find the current, so that potential drops across the resistors can be calculated. Calculate V_{ab} by traveling from *a* to *b*, keeping track of the potential changes along the path taken.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

SET UP: The circuit is sketched in Figure 26.67a.

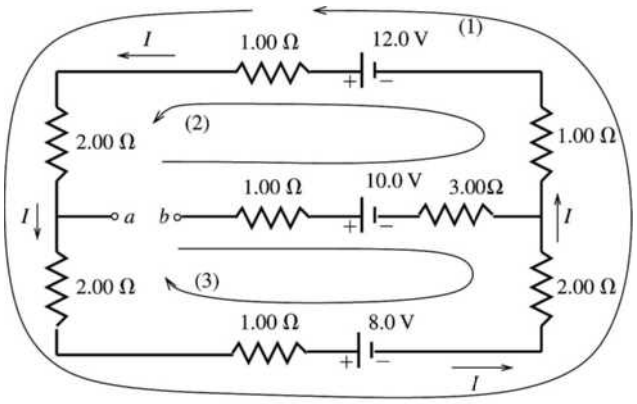

Figure 26.67a

EXECUTE: Apply the loop rule to loop (1).

$+12.0\ \text{V} - I(1.00\ \Omega + 2.00\ \Omega + 2.00\ \Omega + 1.00\ \Omega) - 8.0\ \text{V} - I(2.00\ \Omega + 1.00\ \Omega) = 0$

$$I = \frac{12.0\ \text{V} - 8.0\ \text{V}}{9.00\ \Omega} = 0.4444\ \text{A}.$$

To find V_{ab} start at point *b* and travel to *a*, adding up the potential rises and drops. Travel on path (2) shown on the diagram. The 1.00-Ω and 3.00-Ω resistors in the middle branch have no current through them and hence no voltage across them. Therefore,

$V_b - 10.0\ \text{V} + 12.0\ \text{V} - I(1.00\ \Omega + 1.00\ \Omega + 2.00\ \Omega) = V_a$; thus

$V_a - V_b = 2.0\ \text{V} - (0.4444\ \text{A})(4.00\ \Omega) = +0.22\ \text{V}$ (point *a* is at higher potential)

EVALUATE: As a check on this calculation we also compute V_{ab} by traveling from *b* to *a* on path (3).

$V_b - 10.0\ \text{V} + 8.0\ \text{V} + I(2.00\ \Omega + 1.00\ \Omega + 2.00\ \Omega) = V_a$

$V_{ab} = -2.00\ \text{V} + (0.4444\ \text{A})(5.00\ \Omega) = +0.22\ \text{V}$, which checks.

(b) IDENTIFY and **SET UP:** With points *a* and *b* connected by a wire there are three current branches, as shown in Figure 26.67b.

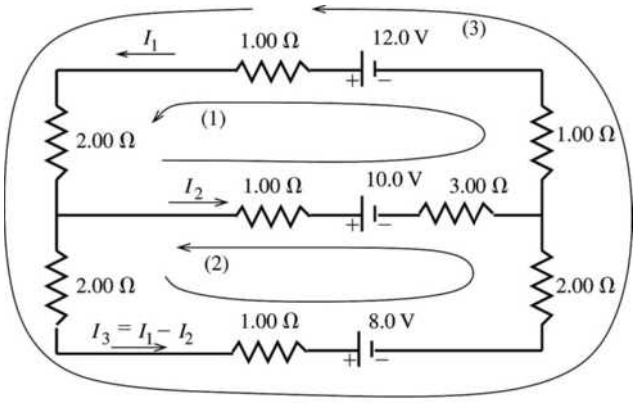

Figure 26.67b

The junction rule has been used to write the third current (in the 8.0-V battery) in terms of the other currents. Apply the loop rule to loops (1) and (2) to obtain two equations for the two unknowns I_1 and I_2.

EXECUTE: Apply the loop rule to loop (1).

$12.0\ \text{V} - I_1(1.00\ \Omega) - I_1(2.00\ \Omega) - I_2(1.00\ \Omega) - 10.0\ \text{V} - I_2(3.00\ \Omega) - I_1(1.00\ \Omega) = 0$

$2.0\ \text{V} - I_1(4.00\ \Omega) - I_2(4.00\ \Omega) = 0$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$(2.00\ \Omega)I_1 + (2.00\ \Omega)I_2 = 1.0\ \text{V}$ eq. (1)

Apply the loop rule to loop (2).

$-(I_1 - I_2)(2.00\ \Omega) - (I_1 - I_2)(1.00\ \Omega) - 8.0\ \text{V} - (I_1 - I_2)(2.00\ \Omega) + I_2(3.00\ \Omega) + 10.0\ \text{V} + I_2(1.00\ \Omega) = 0$

$2.0\ \text{V} - (5.00\ \Omega)I_1 + (9.00\ \Omega)I_2 = 0$ eq. (2)

Solve eq. (1) for I_2 and use this to replace I_2 in eq. (2).

$I_2 = 0.50\ \text{A} - I_1$

$2.0\ \text{V} - (5.00\ \Omega)I_1 + (9.00\ \Omega)(0.50\ \text{A} - I_1) = 0$

$(14.0\ \Omega)I_1 = 6.50\ \text{V}$ so $I_1 = (6.50\ \text{V})/(14.0\ \Omega) = 0.464\ \text{A}$.

$I_2 = 0.500\ \text{A} - 0.464\ \text{A} = 0.036\ \text{A}$.

The current in the 12.0-V battery is $I_1 = 0.464\ \text{A}$.

EVALUATE: We can apply the loop rule to loop (3) as a check.

$+12.0\ \text{V} - I_1(1.00\ \Omega + 2.00\ \Omega + 1.00\ \Omega) - (I_1 - I_2)(2.00\ \Omega + 1.00\ \Omega + 2.00\ \Omega) - 8.0\ \text{V} = 4.0\ \text{V} - 1.86\ \text{V} - 2.14\ \text{V} = 0,$ as it should.

26.68. **IDENTIFY:** Simplify the resistor networks as much as possible using the rule for series and parallel combinations of resistors. Then apply Kirchhoff's laws.

SET UP: First do the series/parallel reduction. This gives the circuit in Figure 26.68. The rate at which the $10.0\text{-}\Omega$ resistor generates thermal energy is $P = I^2R$.

EXECUTE: Apply Kirchhoff's laws and solve for $\mathcal{E}$. $\Delta V_{\text{adefa}} = 0$: $-(20\ \Omega)(2\ \text{A}) - 5\ \text{V} - (20\ \Omega)I_2 = 0$.

This gives $I_2 = -2.25\ \text{A}$. Then $I_1 + I_2 = 2\ \text{A}$ gives $I_1 = 2\ \text{A} - (-2.25\ \text{A}) = 4.25\ \text{A}$.

$\Delta V_{\text{abcdefa}} = 0$: $(15\ \Omega)(4.25\ \text{A}) + \mathcal{E} - (20\ \Omega)(-2.25\ \text{A}) = 0$. This gives $\mathcal{E} = -109\ \text{V}$. Since $\mathcal{E}$ is calculated to be negative, its polarity should be reversed.

(b) The parallel network that contains the $10.0\text{-}\Omega$ resistor in one branch has an equivalent resistance of $10\ \Omega$. The voltage across each branch of the parallel network is $V_{\text{par}} = RI = (10\ \Omega)(2\text{A}) = 20\ \text{V}$. The current in the upper branch is $I = \dfrac{V}{R} = \dfrac{20\ \text{V}}{30\ \Omega} = \dfrac{2}{3}\ \text{A}$. $Pt = E$, so $I^2\,Rt = E$, where $E = 60.0\ \text{J}$.

$\left(\frac{2}{3}\text{A}\right)^2(10\ \Omega)t = 60\ \text{J},$ and $t = 13.5\ \text{s}$.

EVALUATE: For the $10.0\text{-}\Omega$ resistor, $P = I^2R = 4.44\ \text{W}$. The total rate at which electrical energy is inputted to the circuit in the emf is $(5.0\ \text{V})(2.0\ \text{A}) + (109\ \text{V})(4.25\ \text{A}) = 473\ \text{J}$. Only a small fraction of the energy is dissipated in the $10.0\text{-}\Omega$ resistor.

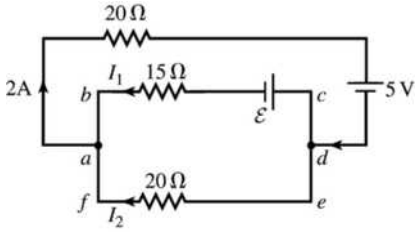

Figure 26.68

26.69. **IDENTIFY:** In one case, the copper and aluminum lengths are in parallel, while in the other case they are in series.

SET UP: $R = \dfrac{\rho L}{A}$. Table 25.1 in the text gives the resistivities of copper and aluminum to be $\rho_{\text{c}} = 1.72 \times 10^{-8}\ \Omega \cdot \text{m}$ and $\rho_{\text{a}} = 2.75 \times 10^{-8}\ \Omega \cdot \text{m}$. For the cables in series (end-to-end), $R_{\text{eq}} = R_{\text{c}} + R_{\text{a}}$.

For the cables in parallel the equivalent resistance R_{eq} is given by $\dfrac{1}{R_{\text{eq}}} = \dfrac{1}{R_{\text{c}}} + \dfrac{1}{R_{\text{a}}}$. Note that in the two

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

configurations the copper and aluminum sections have different lengths. And, for the parallel cables the cross-sectional area of each cable is half what it is for the end-to-end configuration.

EXECUTE: *End-to-end:* $L = 0.50 \times 10^3$ m for each cable.

$$R_c = \frac{\rho_c L}{A} = \frac{(1.72 \times 10^{-8}\ \Omega \cdot \text{m})(0.50 \times 10^3\ \text{m})}{0.500 \times 10^{-4}\ \text{m}^2} = 0.172\ \Omega.$$

$$R_a = \frac{\rho_a L}{A} = \frac{(2.75 \times 10^{-8}\ \Omega \cdot \text{m})(0.50 \times 10^3\ \text{m})}{0.500 \times 10^{-4}\ \text{m}^2} = 0.275\ \Omega.$$

$$R_{eq} = 0.172\ \Omega + 0.275\ \Omega = 0.447\ \Omega.$$

In parallel: Now $L = 1.00 \times 10^3$ m for each cable. L is doubled and A is halved compared to the other configuration, so $R_c = 4(0.172\ \Omega) = 0.688\ \Omega$ and $R_a = 4(0.275\ \Omega) = 1.10\ \Omega$.

$\frac{1}{R_{eq}} = \frac{1}{R_c} + \frac{1}{R_a} = \frac{1}{0.688\ \Omega} + \frac{1}{1.10\ \Omega}$ and $R_{eq} = 0.423\ \Omega$. The least resistance is for the cables in parallel.

EVALUATE: The parallel combination has less equivalent resistance even though both cables contain the same volume of each metal.

26.70. **IDENTIFY:** The current through the 40.0-Ω resistor equals the current through the emf, and the current through each of the other resistors is less than or equal to this current. So, set $P_{40} = 2.00$ W, and use this to solve for the current I through the emf. If $P_{40} = 2.00$ W, then P for each of the other resistors is less than 2.00 W.

SET UP: Use the equivalent resistance for series and parallel combinations to simplify the circuit.

EXECUTE: $I^2R = P$ gives $I^2(40\ \Omega) = 2.00$ W, and $I = 0.2236$ A. Now use series/parallel reduction to simplify the circuit. The upper parallel branch is $6.38\ \Omega$ and the lower one is $25\ \Omega$. The series sum is now $126\ \Omega$. Ohm's law gives $\varepsilon = (126\ \Omega)(0.2236\ \text{A}) = 28.2$ V.

EVALUATE: The power input from the emf is $\varepsilon I = 6.30$ W, so nearly one-third of the total power is dissipated in the $40.0\text{-}\Omega$ resistor.

26.71. **IDENTIFY** and **SET UP:** Simplify the circuit by replacing the parallel networks of resistors by their equivalents. In this simplified circuit apply the loop and junction rules to find the current in each branch.

EXECUTE: The 20.0-Ω and 30.0-Ω resistors are in parallel and have equivalent resistance 12.0 Ω. The two resistors R are in parallel and have equivalent resistance $R/2$. The circuit is equivalent to the circuit sketched in Figure 26.71.

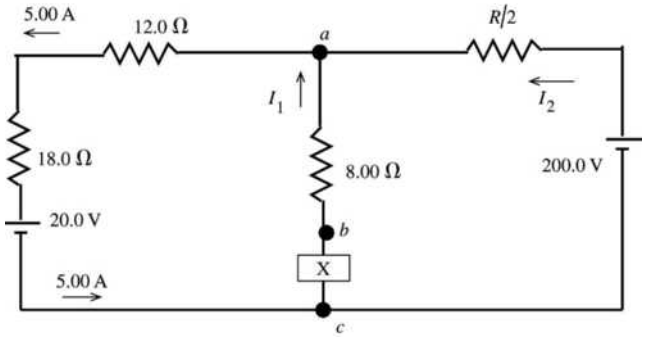

Figure 26.71

(a) Calculate V_{ca} by traveling along the branch that contains the 20.0-V battery, since we know the current in that branch.

$V_a - (5.00\ \text{A})(12.0\ \Omega) - (5.00\ \text{A})(18.0\ \Omega) - 20.0\ \text{V} = V_c$

$V_a - V_c = 20.0\ \text{V} + 90.0\ \text{V} + 60.0\ \text{V} = 170.0\ \text{V}$

$V_b - V_a = V_{ab} = 16.0\ \text{V}$

$X - V_{ba} = 170.0\ \text{V}$ so $X = 186.0\ \text{V}$, with the upper terminal +

(b) $I_1 = (16.0\ \text{V}) / (8.0\ \Omega) = 2.00\ \text{A}$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

The junction rule applied to point a gives $I_2 + I_1 = 5.00$ A, so $I_2 = 3.00$ A. The current through the 200.0-V battery is in the direction from the $-$ to the $+$ terminal, as shown in the diagram.

(c) $200.0\text{ V} - I_2(R/2) = 170.0\text{ V}$

$(3.00\text{ A})(R/2) = 30.0\text{ V}$ so $R = 20.0\ \Omega$

EVALUATE: We can check the loop rule by going clockwise around the outer circuit loop. This gives $+20.0\text{ V} + (5.00\text{ A})(18.0\ \Omega + 12.0\ \Omega) + (3.00\text{ A})(10.0\ \Omega) - 200.0\text{ V} = 20.0\text{ V} + 150.0\text{ V} + 30.0\text{ V} - 200.0\text{ V}$, which does equal zero.

26.72. **IDENTIFY:** $P_{\text{tot}} = \dfrac{V^2}{R_{\text{eq}}}$.

SET UP: Let R be the resistance of each resistor.

EXECUTE: When the resistors are in series, $R_{\text{eq}} = 3R$ and $P_{\text{s}} = \dfrac{V^2}{3R}$. When the resistors are in parallel, $R_{\text{eq}} = R/3$. $P_{\text{p}} = \dfrac{V^2}{R/3} = 3\dfrac{V^2}{R} = 9P_{\text{s}} = 9(36\text{ W}) = 324\text{ W}$.

EVALUATE: In parallel, the voltage across each resistor is the full applied voltage V. In series, the voltage across each resistor is $V/3$ and each resistor dissipates less power.

26.73. **IDENTIFY** and **SET UP:** For part (a) use that the full emf is across each resistor. In part (b), calculate the power dissipated by the equivalent resistance, and in this expression express R_1 and R_2 in terms of P_1, P_2 and ε.

EXECUTE: $P_1 = \varepsilon^2/R_1$ so $R_1 = \varepsilon^2/P_1$

$P_2 = \varepsilon^2/R_2$ so $R_2 = \varepsilon^2/P_2$

(a) When the resistors are connected in parallel to the emf, the voltage across each resistor is ε and the power dissipated by each resistor is the same as if only the one resistor were connected. $P_{\text{tot}} = P_1 + P_2$

(b) When the resistors are connected in series the equivalent resistance is $R_{\text{eq}} = R_1 + R_2$.

$$P_{\text{tot}} = \frac{\varepsilon^2}{R_1 + R_2} = \frac{\varepsilon^2}{\varepsilon^2/P_1 + \varepsilon^2/P_2} = \frac{P_1 P_2}{P_1 + P_2}$$

EVALUATE: The result in part (b) can be written as $\dfrac{1}{P_{\text{tot}}} = \dfrac{1}{P_1} + \dfrac{1}{P_2}$. Our results are that for parallel the powers add and that for series the reciprocals of the power add. This is opposite the result for combining resistance. Since $P = \varepsilon^2/R$ tells us that P is proportional to $1/R$, this makes sense.

26.74. **IDENTIFY** and **SET UP:** Just after the switch is closed the charge on the capacitor is zero, the voltage across the capacitor is zero and the capacitor can be replaced by a wire in analyzing the circuit. After a long time the current to the capacitor is zero, so the current through R_3 is zero. After a long time the capacitor can be replaced by a break in the circuit.

EXECUTE: **(a)** Ignoring the capacitor for the moment, the equivalent resistance of the two parallel resistors is $\dfrac{1}{R_{\text{eq}}} = \dfrac{1}{6.00\ \Omega} + \dfrac{1}{3.00\ \Omega} = \dfrac{3}{6.00\ \Omega}$; $R_{\text{eq}} = 2.00\ \Omega$. In the absence of the capacitor, the total current in the circuit (the current through the $8.00\text{-}\Omega$ resistor) would be $i = \dfrac{\varepsilon}{R} = \dfrac{42.0\text{ V}}{8.00\ \Omega + 2.00\ \Omega} = 4.20\text{ A}$, of which 2/3, or 2.80 A, would go through the $3.00\text{-}\Omega$ resistor and 1/3, or 1.40 A, would go through the 6.00-Ω resistor. Since the current through the capacitor is given by $i = \dfrac{V}{R}e^{-t/RC}$, at the instant $t = 0$ the circuit behaves as through the capacitor were not present, so the currents through the various resistors are as calculated above.

(b) Once the capacitor is fully charged, no current flows through that part of the circuit. The 8.00-Ω and the 6.00-Ω resistors are now in series, and the current through them is $i = \varepsilon/R = (42.0\text{ V})/(8.00\ \Omega + 6.00\ \Omega) = 3.00\text{ A}$. The voltage drop across both the $6.00\text{-}\Omega$ resistor and the capacitor is thus

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$V = iR = (3.00\ \text{A})(6.00\ \Omega) = 18.0\ \text{V}$. (There is no current through the $3.00\text{-}\Omega$ resistor and so no voltage drop across it.) The charge on the capacitor is $Q = CV = (4.00\times10^{-6}\ \text{F})(18.0\ \text{V}) = 7.2\times10^{-5}\ \text{C}$.

EVALUATE: The equivalent resistance of R_2 and R_3 in parallel is less than R_3, so initially the current through R_1 is larger than its value after a long time has elapsed.

26.75. **IDENTIFY:** An initially uncharged capacitor is charged up by an emf source. The current in the circuit and the charge on the capacitor both obey exponential equations.

SET UP: $U_C = \dfrac{q^2}{2C}$, $P_R = i^2R$, $q = Q_{\text{f}}(1-e^{-t/RC})$, and $i = I_0e^{-t/RC}$.

EXECUTE: **(a)** Initially, $q = 0$ so $V_R = \varepsilon$ and $I = \dfrac{\varepsilon}{R} = \dfrac{90.0\ \text{V}}{6.00\times10^3\ \Omega} = 0.0150\ \text{A}$. $P_R = I^2R = 1.35\ \text{W}$.

(b) $U_C = \dfrac{q^2}{2C}$. $P_C = \dfrac{dU_C}{dt} = \dfrac{qi}{C}$. $P_R = i^2R$. $P_C = P_R$ gives $\dfrac{qi}{C} = i^2R$. $\dfrac{q}{RC} = i$.

$q = Q_{\text{f}}(1-e^{-t/RC}) = \varepsilon C(1-e^{-t/RC})$. $i = I_0e^{-t/RC} = \dfrac{\varepsilon}{R}e^{-t/RC}$. $i = \dfrac{q}{RC}$ gives

$\dfrac{\varepsilon}{R}e^{-t/RC} = \dfrac{\varepsilon C}{RC}(1-e^{-t/RC})$. $e^{-t/RC} = 1-e^{-t/RC}$ and $e^{t/RC} = 2$.

$t = RC\ln 2 = (6.00\times10^3\ \Omega)(2.00\times10^{-6}\ \text{F})\ln 2 = 8.31\times10^{-3}\ \text{s} = 8.31\ \text{ms}$.

(c) $i = \dfrac{\varepsilon}{R}e^{-t/RC} = \dfrac{90.0\ \text{V}}{6.00\times10^3\ \Omega}e^{-(8.318\times10^{-3}\ \text{s})/[(6.00\times10^3\ \Omega)(2.00\times10^{-6}\ \text{F})]} = 7.50\times10^{-3}\ \text{A}$.

$P_R = i^2R = (7.50\times10^{-3}\ \text{A})^2(6.00\times10^3\ \Omega) = 0.337\ \text{W}$.

EVALUATE: Initially energy is dissipated in the resistor at a higher rate because the current is high, but as time goes by the current deceases, as does the power dissipated in the resistor.

26.76. **IDENTIFY** and **SET UP:** $P_R = i^2R$, $\varepsilon - iR - \dfrac{q}{C} = 0$, and $U_C = \dfrac{q^2}{2C}$.

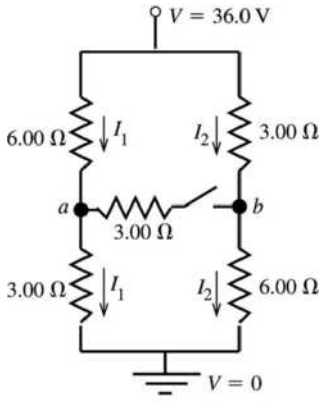
EXECUTE: $P_R = i^2R$ so $i = \sqrt{\dfrac{P_R}{R}} = \sqrt{\dfrac{250\ \text{W}}{5.00\ \Omega}} = 7.071\ \text{A}$. $\varepsilon - iR - \dfrac{q}{C} = 0$ so

$q = C(\varepsilon - iR) = (6.00\times10^{-6}\ \text{F})(50.0\ \text{V} - 35.33\ \text{V}) = 8.787\times10^{-5}\ \text{C}$.

$U_C = \dfrac{q^2}{2C} = \dfrac{(8.787\times10^{-5}\ \text{C})^2}{2(6.00\times10^{-6}\ \text{F})} = 6.43\times10^{-4}\ \text{J}$.

EVALUATE: The energy stores in the capacitor can be returned to a circuit as current, but the energy dissipated in a resistor cannot.

26.77. **(a) IDENTIFY** and **SET UP:** The circuit is sketched in Figure 26.77a.



With the switch open there is no current through it and there are only the two currents I_1 and I_2 indicated in the sketch.

Figure 26.77a

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

The potential drop across each parallel branch is 36.0 V. Use this fact to calculate I_1 and I_2. Then travel from point *a* to point *b* and keep track of the potential rises and drops in order to calculate V_{ab}.

EXECUTE: $-I_1(6.00\,\Omega + 3.00\,\Omega) + 36.0\text{ V} = 0$

$$I_1 = \frac{36.0\text{ V}}{6.00\,\Omega + 3.00\,\Omega} = 4.00\text{ A}$$

$$-I_2(3.00\,\Omega + 6.00\,\Omega) + 36.0\text{ V} = 0$$

$$I_2 = \frac{36.0\text{ V}}{3.00\,\Omega + 6.00\,\Omega} = 4.00\text{ A}$$

To calculate $V_{ab} = V_a - V_b$ start at point *b* and travel to point *a*, adding up all the potential rises and drops along the way. We can do this by going from *b* up through the 3.00-Ω resistor:

$V_b + I_2(3.00\,\Omega) - I_1(6.00\,\Omega) = V_a$

$V_a - V_b = (4.00\text{ A})(3.00\,\Omega) - (4.00\text{ A})(6.00\,\Omega) = 12.0\text{ V} - 24.0\text{ V} = -12.0\text{ V}$

$V_{ab} = -12.0\text{ V}$ (point *a* is 12.0 V lower in potential than point *b*)

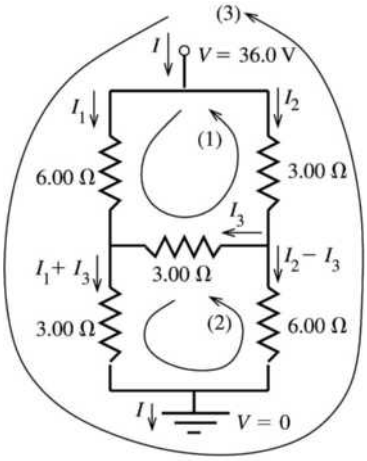
EVALUATE: Alternatively, we can go from point *b* down through the 6.00-Ω resistor.

$V_b - I_2(6.00\,\Omega) + I_1(3.00\,\Omega) = V_a$

$V_a - V_b = -(4.00\text{ A})(6.00\,\Omega) + (4.00\text{ A})(3.00\,\Omega) = -24.0\text{ V} + 12.0\text{ V} = -12.0\text{ V}$, which checks.

(b) IDENTIFY: Now there are multiple current paths, as shown in Figure 26.77b. Use the junction rule to write the current in each branch in terms of three unknown currents I_1, I_2 and I_3. Apply the loop rule to three loops to get three equations for the three unknowns. The target variable is I_3, the current through the switch. R_{eq} is calculated from $V = IR_{eq}$, where *I* is the total current that passes through the network.

SET UP:



The three unknown currents I_1, I_2 and I_3 are labeled on Figure 26.77b.

Figure 26.77b

EXECUTE: Apply the loop rule to loops (1), (2) and (3).

loop (1): $-I_1(6.00\,\Omega) + I_3(3.00\,\Omega) + I_2(3.00\,\Omega) = 0$

$I_2 = 2I_1 - I_3$ eq. (1)

loop (2): $-(I_1 + I_3)(3.00\,\Omega) + (I_2 - I_3)(6.00\,\Omega) - I_3(3.00\,\Omega) = 0$

$6I_2 - 12I_3 - 3I_1 = 0$ so $2I_2 - 4I_3 - I_1 = 0$

Use eq (1) to replace I_2:

$4I_1 - 2I_3 - 4I_3 - I_1 = 0$

$3I_1 = 6I_3$ and $I_1 = 2I_3$ eq. (2)

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

loop (3) (This loop is completed through the battery [not shown], in the direction from the $-$ to the $+$ terminal.):

$-I_1(6.00\ \Omega) - (I_1 + I_3)(3.00\ \Omega) + 36.0\ \text{V} = 0$

$9I_1 + 3I_3 = 36.0\ \text{A}$ and $3I_1 + I_3 = 12.0\ \text{A}$ eq. (3)

Use eq. (2) in eq. (3) to replace I_1:

$3(2I_3) + I_3 = 12.0\ \text{A}$

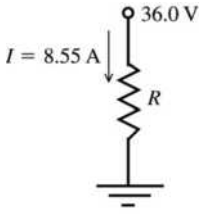
$I_3 = 12.0\ \text{A}/7 = 1.71\ \text{A}$

$I_1 = 2I_3 = 3.42\ \text{A}$

$I_2 = 2I_1 - I_3 = 2(3.42\ \text{A}) - 1.71\ \text{A} = 5.13\ \text{A}$

The current through the switch is $I_3 = 1.71$ A.

(c) From the results in part (a) the current through the battery is $I = I_1 + I_2 = 3.42\ \text{A} + 5.13\ \text{A} = 8.55\ \text{A}$. The equivalent circuit is a single resistor that produces the same current through the 36.0-V battery, as shown in Figure 26.77c.



$-IR + 36.0\ \text{V} = 0$

$R = \dfrac{36.0\ \text{V}}{I} = \dfrac{36.0\ \text{V}}{8.55\ \text{A}} = 4.21\ \Omega$

Figure 26.77c

EVALUATE: With the switch open (part a), point *b* is at higher potential than point *a*, so when the switch is closed the current flows in the direction from *b* to *a*. With the switch closed the circuit cannot be simplified using series and parallel combinations but there is still an equivalent resistance that represents the network.

26.78. **(a) IDENTIFY:** With *S* open and after equilibrium has been reached, no current flows and the voltage across each capacitor is 18.0 V. When *S* is closed, current *I* flows through the 6.00-Ω and 3.00-Ω resistors.

SET UP: With the switch closed, *a* and *b* are at the same potential and the voltage across the 6.00-Ω resistor equals the voltage across the 6.00-μF capacitor and the voltage is the same across the 3.00-μF capacitor and 3.00-Ω resistor.

EXECUTE: **(a)** With an open switch: $V_{ab} = \mathcal{E} = 18.0$ V.

(b) Point *a* is at a higher potential since it is directly connected to the positive terminal of the battery.

(c) When the switch is closed $18.0\ \text{V} = I(6.00\ \Omega + 3.00\ \Omega)$. $I = 2.00$ A and

$V_b = (2.00\ \text{A})(3.00\ \Omega) = 6.00\ \text{V}$.

(d) Initially the capacitor's charges were $Q_3 = CV = (3.00\times10^{-6}\ \text{F})(18.0\ \text{V}) = 5.40\times10^{-5}\ \text{C}$ and

$Q_6 = CV = (6.00\times10^{-6}\ \text{F})(18.0\ \text{V}) = 1.08\times10^{-4}\ \text{C}$. After the switch is closed

$Q_3 = CV = (3.00\times10^{-6}\ \text{F})(18.0\ \text{V} - 12.0\ \text{V}) = 1.80\times10^{-5}\ \text{C}$ and

$Q_6 = CV = (6.00\times10^{-6}\ \text{F})(18.0\ \text{V} - 6.0\ \text{V}) = 7.20\times10^{-5}\ \text{C}$. Both capacitors lose 3.60×10^{-5} C.

EVALUATE: The voltage across each capacitor decreases when the switch is closed, because there is then current through each resistor and therefore a potential drop across each resistor.

26.79. **(a) IDENTIFY:** Connecting the voltmeter between point *b* and ground gives a resistor network and we can solve for the current through each resistor. The voltmeter reading equals the potential drop across the 200-kΩ resistor.

SET UP: For resistors in parallel, $\dfrac{1}{R_{\text{eq}}} = \dfrac{1}{R_1} + \dfrac{1}{R_2}$. For resistors in series, $R_{\text{eq}} = R_1 + R_2$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: **(a)** $R_{\text{eq}} = 100\ \text{k}\Omega + \left(\frac{1}{200\ \text{k}\Omega} + \frac{1}{50\ \text{k}\Omega}\right)^{-1} = 140\ \text{k}\Omega$. The total current is

$I = \frac{0.400\ \text{kV}}{140\ \text{k}\Omega} = 2.86 \times 10^{-3}\ \text{A}$. The voltage across the 200-kΩ resistor is

$V_{200\text{k}\Omega} = IR = (2.86 \times 10^{-3}\ \text{A})\left(\frac{1}{200\ \text{k}\Omega} + \frac{1}{50\ \text{k}\Omega}\right)^{-1} = 114.4\ \text{V}.$

(b) If $V_R = 5.00 \times 10^6\ \Omega$, then we carry out the same calculations as above to find $R_{\text{eq}} = 292\ \text{k}\Omega$, $I = 1.37 \times 10^{-3}\ \text{A}$ and $V_{200\text{k}\Omega} = 263\ \text{V}$.

(c) If $V_R = \infty$, then we find $R_{\text{eq}} = 300\ \text{k}\Omega$, $I = 1.33 \times 10^{-3}\ \text{A}$ and $V_{200\text{k}\Omega} = 266\ \text{V}$.

EVALUATE: When a voltmeter of finite resistance is connected to a circuit, current flows through the voltmeter and the presence of the voltmeter alters the currents and voltages in the original circuit. The effect of the voltmeter on the circuit decreases as the resistance of the voltmeter increases.

26.80. **IDENTIFY:** The circuit consists of two resistors in series with 110 V applied across the series combination.
SET UP: The circuit resistance is $30\ \text{k}\Omega + R$. The voltmeter reading of 74 V is the potential across the voltmeter terminals, equal to $I(30\ \text{k}\Omega)$.

EXECUTE: $I = \frac{110\ \text{V}}{(30\ \text{k}\Omega + R)}$. $I(30\ \text{k}\Omega) = 74\ \text{V}$ gives $(74\ \text{V})(30\ \text{k}\Omega + R) = (110\ \text{V})30\ \text{k}\Omega$ and $R = 14.6\ \text{k}\Omega$.

EVALUATE: This is a method for measuring large resistances.

26.81. **IDENTIFY** and **SET UP:** Zero current through the galvanometer means the current I_1 through N is also the current through M and the current I_2 through P is the same as the current through X. And it means that points b and c are at the same potential, so $I_1 N = I_2 P$.

EXECUTE: **(a)** The voltage between points a and d is $\mathcal{E}$, so $I_1 = \frac{\mathcal{E}}{N+M}$ and $I_2 = \frac{\mathcal{E}}{P+X}$. Using these expressions in $I_1 N = I_2 P$ gives $\frac{\mathcal{E}}{N+M} N = \frac{\mathcal{E}}{P+X} P$. $N(P+X) = P(N+M)$. $NX = PM$ and $X = MP/N$.

(b) $X = \frac{MP}{N} = \frac{(850.0\ \Omega)(33.48\ \Omega)}{15.00\ \Omega} = 1897\ \Omega$

EVALUATE: The measurement of X does not require that we know the value of the emf.

26.82. **IDENTIFY:** Just after the connection is made, $q = 0$ and the voltage across the capacitor is zero. After a long time $i = 0$.

SET UP: The rate at which the resistor dissipates electrical energy is $P_R = V^2/R$, where V is the voltage across the resistor. The energy stored in the capacitor is $q^2/2C$. The power output of the source is $P_{\mathcal{E}} = \mathcal{E}i$.

EXECUTE: **(a)** (i) $P_R = \frac{V^2}{R} = \frac{(120\ \text{V})^2}{5.86\ \Omega} = 2460\ \text{W}$.

(ii) $P_C = \frac{dU}{dt} = \frac{1}{2C}\frac{d(q^2)}{dt} = \frac{iq}{C} = 0$.

(iii) $P_{\mathcal{E}} = \mathcal{E}I = (120\ \text{V})\frac{120\ \text{V}}{5.86\ \Omega} = 2460\ \text{W}$.

The power output of the source is the sum of the power dissipated in the resistor and the power stored in the capacitor.

(b) After a long time, $i = 0$, so $P_R = 0, P_C = 0, P_{\mathcal{E}} = 0$.

(c) (i) Since $q = q_{\max}(1 - e^{-t/RC})$, when $q = q_{\max}/2, e^{-t/RC} = \frac{1}{2}$. $P_R = i^2 R$, so

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$P_R = (i_0 e^{-t/RC})^2 R = i_0^2 R (e^{-t/RC})^2 = (i_0^2 R)\left(\frac{1}{2}\right)^2 = \frac{i_0^2 R}{4} = \frac{(\varepsilon/R)^2 R}{4} = \frac{\varepsilon^2}{4R}$, which gives

$P_R = \frac{(120\ \text{V})^2}{4(5.86\ \Omega)} = 614\ \text{W}.$

(ii) $\frac{dU_C}{dt} = \frac{d}{dt}\left[\frac{q_{\max}^2}{2C}(1 - e^{-t/RC})^2\right] = \frac{\varepsilon^2}{4R} = 614\ \text{W}.$

(iii) $P_\varepsilon = \varepsilon i = \varepsilon(i_0 e^{-t/RC}) = (120\ \text{V})\left(\frac{120\ \text{V}}{5.86\ \Omega}\right)\left(\frac{1}{2}\right) = 1230\ \text{W}.$

The power output of the source is the sum of the power dissipated in the resistor and the power stored in the capacitor.

EVALUATE: Initially all the power output of the source is dissipated in the resistor. After a long time energy is stored in the capacitor but the amount stored isn't changing. For intermediate times, part of the energy of the power source is dissipated in the resistor and part of it is stored in the capacitor. Conservation of energy tells us that the power output of the source should be equal to the power dissipated in the resistor plus the power stored in the capacitor, which is exactly what we have found in part (iii).

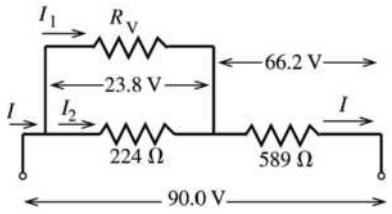
26.83. **IDENTIFY** and **SET UP:** Without the meter, the circuit consists of the two resistors in series. When the meter is connected, its resistance is added to the circuit in parallel with the resistor it is connected across.

(a) EXECUTE: $I = I_1 = I_2$

$I = \frac{90.0\ \text{V}}{R_1 + R_2} = \frac{90.0\ \text{V}}{224\ \Omega + 589\ \Omega} = 0.1107\ \text{A}$

$V_1 = I_1 R_1 = (0.1107\ \text{A})(224\ \Omega) = 24.8\ \text{V};\ V_2 = I_2 R_2 = (0.1107\ \text{A})(589\ \Omega) = 65.2\ \text{V}$

(b) SET UP: The resistor network is sketched in Figure 26.83a.



The voltmeter reads the potential difference across its terminals, which is 23.8 V. If we can find the current I_1 through the voltmeter then we can use Ohm's law to find its resistance.

Figure 26.83a

EXECUTE: The voltage drop across the 589-Ω resistor is $90.0\ \text{V} - 23.8\ \text{V} = 66.2\ \text{V}$, so $I = \frac{V}{R} = \frac{66.2\ \text{V}}{589\ \Omega} = 0.1124\ \text{A}$. The voltage drop across the 224-Ω resistor is 23.8 V, so

$I_2 = \frac{V}{R} = \frac{23.8\ \text{V}}{224\ \Omega} = 0.1062\ \text{A}$. Then $I = I_1 + I_2$ gives $I_1 = I - I_2 = 0.1124\ \text{A} - 0.1062\ \text{A} = 0.0062\ \text{A}$.

$R_V = \frac{V}{I_1} = \frac{23.8\ \text{V}}{0.0062\ A} = 3840\ \Omega$

(c) SET UP: The circuit with the voltmeter connected is sketched in Figure 26.83b.

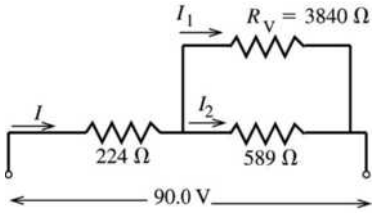


Figure 26.83b

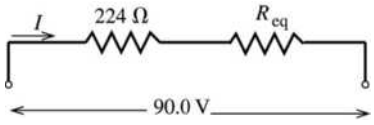
© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: Replace the two resistors in parallel by their equivalent, as shown in Figure 26.83c.



$$\frac{1}{R_{eq}} = \frac{1}{3840\,\Omega} + \frac{1}{589\,\Omega};$$

$$R_{eq} = \frac{(3840\,\Omega)(589\,\Omega)}{3840\,\Omega + 589\,\Omega} = 510.7\,\Omega$$

Figure 26.83c

$$I = \frac{90.0\text{ V}}{224\,\Omega + 510.7\,\Omega} = 0.1225\text{ A}$$

The potential drop across the $224\text{-}\Omega$ resistor then is $IR = (0.1225\text{ A})(224\,\Omega) = 27.4\text{ V},$ so the potential drop across the $589\text{-}\Omega$ resistor and across the voltmeter (what the voltmeter reads) is $90.0\text{ V} - 27.4\text{ V} = 62.6\text{ V}.$

EVALUATE: **(d)** No, any real voltmeter will draw some current and thereby reduce the current through the resistance whose voltage is being measured. Thus the presence of the voltmeter connected in parallel with the resistance lowers the voltage drop across that resistance. The resistance of the voltmeter in this problem is only about a factor of ten larger than the resistances in the circuit, so the voltmeter has a noticeable effect on the circuit.

26.84. **IDENTIFY:** The energy stored in a capacitor is $U = q^2/2C.$ The electrical power dissipated in the resistor is $P = i^2R.$

SET UP: For a discharging capacitor, $i = -\frac{q}{RC}.$

EXECUTE: **(a)** $U_0 = \frac{Q_0^2}{2C} = \frac{(0.0069\text{ C})^2}{2(4.62\times10^{-6}\text{ F})} = 5.15\text{ J}.$

(b) $P_0 = I_0^2R = \left(\frac{Q_0}{RC}\right)^2 R = \frac{(0.0069\text{ C})^2}{(850\,\Omega)(4.62\times10^{-6}\text{ F})^2} = 2620\text{ W}.$

(c) Since $U = q^2/2C,$ when $U \to U_0/2, q \to Q_0/\sqrt{2}.$ Since $q = Q_0e^{-t/RC},$ this means that $e^{-t/RC} = 1/\sqrt{2}.$ Therefore the current is $i = i_0e^{-t/RC} = i_0/\sqrt{2}.$ Therefore

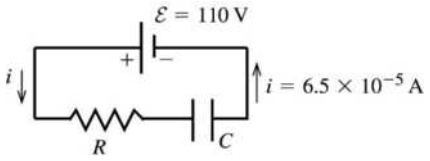
$P_R = \left(\frac{i_0}{\sqrt{2}}\right)^2 R = \frac{1}{2}\left(\frac{V_0}{R}\right)^2 R = \frac{1}{2}\left(\frac{Q_0}{RC}\right)^2 R = \frac{1}{RC}\left(\frac{Q_0^2}{2C}\right) = \frac{U_0}{RC}.$ Putting in the numbers gives

$$P_R = \frac{5.15\text{ J}}{(850\,\Omega)(4.62\,\mu\text{F})} = 1310\text{ W}.$$

EVALUATE: All the energy originally stored in the capacitor is eventually dissipated as current flows through the resistor.

26.85. **IDENTIFY:** Apply the loop rule to the circuit. The initial current determines R. We can then use the time constant to calculate C.

SET UP: The circuit is sketched in Figure 26.85.



Initially, the charge of the capacitor is zero, so by $V = q/C$ the voltage across the capacitor is zero.

Figure 26.85

EXECUTE: The loop rule therefore gives $\mathcal{E} - iR = 0$ and $R = \frac{\mathcal{E}}{i} = \frac{110\text{ V}}{6.5\times10^{-5}\text{ A}} = 1.7\times10^6\,\Omega.$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

The time constant is given by $\tau = RC$ (Eq. 26.14), so $C = \dfrac{\tau}{R} = \dfrac{5.2\text{ s}}{1.7\times10^6\ \Omega} = 3.1\ \mu\text{F}$.

EVALUATE: The resistance is large so the initial current is small and the time constant is large.

26.86. **IDENTIFY:** The energy changes exponentially, but it does not obey exactly the same equation as the charge since it is proportional to the *square* of the charge.

(a) SET UP: For charging, $U = Q^2/2C = (Q_0e^{-t/RC})^2/2C = U_0e^{-2t/RC}$.

EXECUTE: To reduce the energy to $1/e$ of its initial value:

$$U_0/e = U_0e^{-2t/RC}$$

$$t = RC/2$$

(b) SET UP: For discharging, $U = Q^2/2C = [Q_0(1-e^{-t/RC})]^2/2C = U_{\max}(1-e^{-t/RC}.)^2$

EXECUTE: To reach $1/e$ of the maximum energy, $U_{\max}/e = U_{\max}(1-e^{-t/RC})^2$ and $t = -RC\ln\left(1-\dfrac{1}{\sqrt{e}}\right)$.

EVALUATE: The time to reach $1/e$ of the maximum energy is not the same as the time to discharge to $1/e$ of the maximum energy.

26.87. **IDENTIFY:** $q = Q_0e^{-t/RC}$. The time constant is $\tau = RC$.

SET UP: The charge of one electron has magnitude $e = 1.60\times10^{-19}$ C.

EXECUTE: **(a)** We will say that a capacitor is discharged if its charge is less than that of one electron. The time this takes is then given by $q = Q_0e^{-t/RC}$, so

$t = RC\ln(Q_0/e) = (6.7\times10^5\ \Omega)(9.2\times10^{-7}\ \text{F})\ln(7.0\times10^{-6}\ \text{C}/1.6\times10^{-19}\ \text{C}) = 19.4\text{ s},$ or 31.4 time constants.

EVALUATE: **(b)** As shown in part (a), $t = \tau\ln(Q_0/q)$ and so the number of time constants required to discharge the capacitor is independent of R and C, and depends only on the initial charge.

26.88. **IDENTIFY** and **SET UP:** For parts (a) and (b) evaluate the integrals as specified in the problem. The current as a function of time is given by Eq. (26.13) $i = \dfrac{\mathcal{E}}{R}e^{-t/RC}$. The energy stored in the capacitor is given by $Q^2/2C$.

EXECUTE: **(a)** $P = \mathcal{E}i$

The total energy supplied by the battery is

$$\int_0^\infty P\,dt = \int_0^\infty \mathcal{E}i\,dt = (\mathcal{E}^2/R)\int_0^\infty e^{-t/RC}dt = (\mathcal{E}^2/R)\left[-RCe^{-t/RC}\right]_0^\infty = C\mathcal{E}^2.$$

(b) $P = i^2R$

The total energy dissipated in the resistor is

$$\int_0^\infty P\,dt = \int_0^\infty i^2R\,dt = (\mathcal{E}^2/R)\int_0^\infty e^{-2t/RC}dt = (\mathcal{E}^2/R)\left[-(RC/2)e^{-2t/RC}\right]_0^\infty = \tfrac{1}{2}C\mathcal{E}^2.$$

(c) The final charge on the capacitor is $Q = C\mathcal{E}$. The energy stored is $U = Q^2/(2C) = \frac{1}{2}C\mathcal{E}^2$. The final energy stored in the capacitor $\left(\frac{1}{2}C\mathcal{E}^2\right)$ = total energy supplied by the battery $(C\mathcal{E}^2)$ − energy dissipated in the resistor $\left(\frac{1}{2}C\mathcal{E}^2\right)$.

(d) EVALUATE: $\frac{1}{2}$ of the energy supplied by the battery is stored in the capacitor. This fraction is independent of R. The other $\frac{1}{2}$ of the energy supplied by the battery is dissipated in the resistor. When R is small the current initially is large but dies away quickly. When R is large the current initially is small but lasts longer.

26.89. **IDENTIFY:** $E = \int_0^\infty P\,dt$. The energy stored in a capacitor is $U = q^2/2C$.

SET UP: $i = -\dfrac{Q_0}{RC}e^{-t/RC}$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: **(a)** $i = -\dfrac{Q_0}{RC}e^{-t/RC}$ gives $P = i^2R = \dfrac{{Q_0}^2}{RC^2}e^{-2t/RC}$

(b) $E = \dfrac{{Q_0}^2}{RC^2}\int_0^\infty e^{-2t/RC}dt = \dfrac{{Q_0}^2}{RC^2}\dfrac{RC}{2} = \dfrac{{Q_0}^2}{2C} = U_0$.

EVALUATE: Increasing the energy stored in the capacitor increases current through the resistor as the capacitor discharges.

26.90. **IDENTIFY** and **SET UP:** When C changes after the capacitor is charged, the voltage across the capacitor changes. Current flows through the resistor until the voltage across the capacitor again equals the emf.

EXECUTE: **(a)** Fully charged: $Q = CV = (10.0\times10^{-12}\text{ F})(1000\text{ V}) = 1.00\times10^{-8}\text{ C}$.

(b) The initial current just after the capacitor is charged is $I_0 = \dfrac{\varepsilon - V_{C'}}{R} = \dfrac{\varepsilon}{R} - \dfrac{q}{RC'}$. This gives

$i(t) = \left(\dfrac{\varepsilon}{R} - \dfrac{q}{RC'}\right)e^{-t/RC'}$, where $C' = 1.1C$.

(c) We need a resistance such that the current will be greater than 1 μA for longer than 200 μs. Current equal to this value requires that at $t = 200\,\mu\text{s}$, $i = 1.0\times10^{-6}\text{ A} = \dfrac{1}{R}\left(1000\text{ V} - \dfrac{1.0\times10^{-8}\text{ C}}{1.1(1.0\times10^{-11}\text{ F})}\right)$

$e^{-(2.0\times10^{-4}\text{ s})/R(11\times10^{-12}\text{ F})}$. This says $1.0\times10^{-6}\text{ A} = \dfrac{1}{R}(90.9)e^{-(1.8\times10^7\,\Omega)/R}$ and

$18.3R - R\ln R - 1.8\times10^7 = 0$. Solving for R numerically we find $7.15\times10^6\,\Omega \le R \le 7.01\times10^7\,\Omega$.

EVALUATE: If the resistance is too small, then the capacitor discharges too quickly, and if the resistance is too large, the current is not large enough.

26.91. **IDENTIFY:** Consider one segment of the network attached to the rest of the network.

SET UP: We can re-draw the circuit as shown in Figure 26.91.

EXECUTE: $R_T = 2R_1 + \left(\dfrac{1}{R_2} + \dfrac{1}{R_T}\right)^{-1} = 2R_1 + \dfrac{R_2R_T}{R_2 + R_T}$. ${R_T}^2 - 2R_1R_T - 2R_1R_2 = 0$.

$R_T = R_1 \pm \sqrt{{R_1}^2 + 2R_1R_2}$. $R_T > 0$, so $R_T = R_1 + \sqrt{{R_1}^2 + 2R_1R_2}$.

EVALUATE: Even though there are an infinite number of resistors, the equivalent resistance of the network is finite.

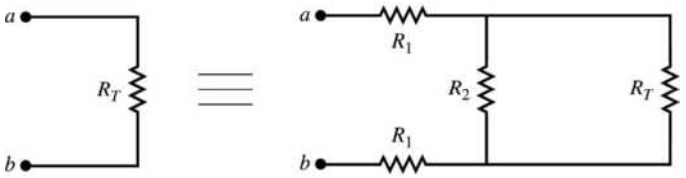


Figure 26.91

26.92. **IDENTIFY:** Assume a voltage V applied between points a and b and consider the currents that flow along each path between a and b.

SET UP: The currents are shown in Figure 26.92.

EXECUTE: Let current I enter at a and exit at b. At a there are three equivalent branches, so current is $I/3$ in each. At the next junction point there are two equivalent branches so each gets current $I/6$. Then at b there are three equivalent branches with current $I/3$ in each. The voltage drop from a to b then is

$V = \left(\dfrac{I}{3}\right)R + \left(\dfrac{I}{6}\right)R + \left(\dfrac{I}{3}\right)R = \frac{5}{6}IR$. This must be the same as $V = IR_{\text{eq}}$, so $R_{\text{eq}} = \frac{5}{6}R$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: The equivalent resistance is less than R, even though there are 12 resistors in the network.

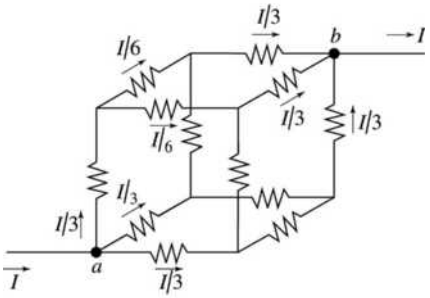

Figure 26.92

26.93. **IDENTIFY:** The network is the same as the one in Challenge Problem 26.91, and that problem shows that the equivalent resistance of the network is $R_T = \sqrt{R_1^2 + 2R_1R_2}$.

SET UP: The circuit can be redrawn as shown in Figure 26.93.

EXECUTE: **(a)** $V_{cd} = V_{ab}\dfrac{R_{\text{eq}}}{2R_1 + R_{\text{eq}}} = V_{ab}\dfrac{1}{2R_1/R_{\text{eq}} + 1}$ and $R_{\text{eq}} = \dfrac{R_2R_T}{R_2 + R_T}$. But $\beta = \dfrac{2R_1(R_T + R_2)}{R_TR_2} = \dfrac{2R_1}{R_{\text{eq}}}$,

so $V_{cd} = V_{ab}\dfrac{1}{1+\beta}$.

(b) $V_1 = \dfrac{V_0}{(1+\beta)} \Rightarrow V_2 = \dfrac{V_1}{(1+\beta)} = \dfrac{V_0}{(1+\beta)^2} \Rightarrow V_n = \dfrac{V_{n-1}}{(1+\beta)} = \dfrac{V_0}{(1+\beta)^n}$.

If $R_1 = R_2$, then $R_T = R_1 + \sqrt{R_1^2 + 2R_1R_1} = R_1(1+\sqrt{3})$ and $\beta = \dfrac{2(2+\sqrt{3})}{1+\sqrt{3}} = 2.73$. So, for the nth segment to have 1% of the original voltage, we need: $\dfrac{1}{(1+\beta)^n} = \dfrac{1}{(1+2.73)^n} \le 0.01$. This says $n = 4$, and then $V_4 = 0.005V_0$.

(c) $R_T = R_1 + \sqrt{R_1^2 + 2R_1R_2}$ gives $R_T = 6400\ \Omega + \sqrt{(6400\ \Omega)^2 + 2(6400\ \Omega)(8.0\times10^8\ \Omega)} = 3.2\times10^6\ \Omega$ and

$\beta = \dfrac{2(6400\ \Omega)(3.2\times10^6\ \Omega + 8.0\times10^8\ \Omega)}{(3.2\times10^6\ \Omega)(8.0\times10^8\ \Omega)} = 4.0\times10^{-3}$.

(d) Along a length of 2.0 mm of axon, there are 2000 segments each 1.0 μm long. The voltage therefore attenuates by $V_{2000} = \dfrac{V_0}{(1+\beta)^{2000}}$, so $\dfrac{V_{2000}}{V_0} = \dfrac{1}{(1+4.0\times10^{-3})^{2000}} = 3.4\times10^{-4}$.

(e) If $R_2 = 3.3\times10^{12}\ \Omega$, then $R_T = 2.1\times10^8\ \Omega$ and $\beta = 6.2\times10^{-5}$. This gives

$\dfrac{V_{2000}}{V_0} = \dfrac{1}{(1+6.2\times10^{-5})^{2000}} = 0.88$.

EVALUATE: As R_2 increases, β decreases and the potential difference decrease from one section to the next is less.

27

MAGNETIC FIELD AND MAGNETIC FORCES

27.1. **IDENTIFY** and **SET UP:** Apply Eq. (27.2) to calculate $\vec{F}$. Use the cross products of unit vectors from Section 1.10.

EXECUTE: $\vec{v} = (+4.19\times10^4 \text{ m/s})\hat{i} + (-3.85\times10^4 \text{ m/s})\hat{j}$

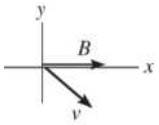
(a) $\vec{B} = (1.40 \text{ T})\hat{i}$

$\vec{F} = q\vec{v}\times\vec{B} = (-1.24\times10^{-8} \text{ C})(1.40 \text{ T})[(4.19\times10^4 \text{ m/s})\hat{i}\times\hat{i} - (3.85\times10^4 \text{ m/s})\hat{j}\times\hat{i}]$

$\hat{i}\times\hat{i} = 0,\ \hat{j}\times\hat{i} = -\hat{k}$

$\vec{F} = (-1.24\times10^{-8} \text{ C})(1.40 \text{ T})(-3.85\times10^4 \text{ m/s})(-\hat{k}) = (-6.68\times10^{-4} \text{ N})\hat{k}$

EVALUATE: The directions of $\vec{v}$ and $\vec{B}$ are shown in Figure 27.1a.



The right-hand rule gives that $\vec{v}\times\vec{B}$ is directed out of the paper $(+z\text{-direction})$. The charge is negative so $\vec{F}$ is opposite to $\vec{v}\times\vec{B}$.

Figure 27.1a

$\vec{F}$ is in the $-z$-direction. This agrees with the direction calculated with unit vectors.

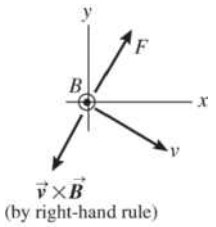
(b) EXECUTE: $\vec{B} = (1.40 \text{ T})\hat{k}$

$\vec{F} = q\vec{v}\times\vec{B} = (-1.24\times10^{-8} \text{ C})(1.40 \text{ T})[(+4.19\times10^4 \text{ m/s})\hat{i}\times\hat{k} - (3.85\times10^4 \text{ m/s})\hat{j}\times\hat{k}]$

$\hat{i}\times\hat{k} = -\hat{j},\ \hat{j}\times\hat{k} = \hat{i}$

$\vec{F} = (-7.27\times10^{-4} \text{ N})(-\hat{j}) + (6.68\times10^{-4} \text{ N})\hat{i} = [(6.68\times10^{-4} \text{ N})\hat{i} + (7.27\times10^{-4} \text{ N})\hat{j}]$

EVALUATE: The directions of $\vec{v}$ and $\vec{B}$ are shown in Figure 27.1b.



The direction of $\vec{F}$ is opposite to $\vec{v}\times\vec{B}$ since q is negative. The direction of $\vec{F}$ computed from the right-hand rule agrees qualitatively with the direction calculated with unit vectors.

Figure 27.1b

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

27.2. **IDENTIFY:** The net force must be zero, so the magnetic and gravity forces must be equal in magnitude and opposite in direction.

SET UP: The gravity force is downward so the force from the magnetic field must be upward. The charge's velocity and the forces are shown in Figure 27.2. Since the charge is negative, the magnetic force is opposite to the right-hand rule direction. The minimum magnetic field is when the field is perpendicular to $\vec{\boldsymbol{v}}$. The force is also perpendicular to $\vec{\boldsymbol{B}}$, so $\vec{\boldsymbol{B}}$ is either eastward or westward.

EXECUTE: If $\vec{\boldsymbol{B}}$ is eastward, the right-hand rule direction is into the page and $\vec{\boldsymbol{F}}_B$ is out of the page, as required. Therefore, $\vec{\boldsymbol{B}}$ is eastward. $mg = |q|vB\sin\phi$. $\phi = 90°$ and

$$B = \frac{mg}{v|q|} = \frac{(0.195\times10^{-3}\text{ kg})(9.80\text{ m/s}^2)}{(4.00\times10^{4}\text{ m/s})(2.50\times10^{-8}\text{ C})} = 1.91\text{ T}.$$

EVALUATE: The magnetic field could also have a component along the north-south direction, that would not contribute to the force, but then the field wouldn't have minimum magnitude.

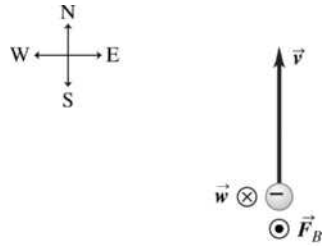


Figure 27.2

27.3. **IDENTIFY:** The force $\vec{\boldsymbol{F}}$ on the particle is in the direction of the deflection of the particle. Apply the right-hand rule to the directions of $\vec{\boldsymbol{v}}$ and $\vec{\boldsymbol{B}}$. See if your thumb is in the direction of $\vec{\boldsymbol{F}}$, or opposite to that direction. Use $F = |q|vB\sin\phi$ with $\phi = 90°$ to calculate F.

SET UP: The directions of $\vec{\boldsymbol{v}}$, $\vec{\boldsymbol{B}}$ and $\vec{\boldsymbol{F}}$ are shown in Figure 27.3.

EXECUTE: **(a)** When you apply the right-hand rule to $\vec{\boldsymbol{v}}$ and $\vec{\boldsymbol{B}}$, your thumb points east. $\vec{\boldsymbol{F}}$ is in this direction, so the charge is positive.

(b) $F = |q|vB\sin\phi = (8.50\times10^{-6}\text{ C})(4.75\times10^{3}\text{ m/s})(1.25\text{ T})\sin 90° = 0.0505\text{ N}$

EVALUATE: If the particle had negative charge and $\vec{\boldsymbol{v}}$ and $\vec{\boldsymbol{B}}$ are unchanged, the particle would be deflected toward the west.

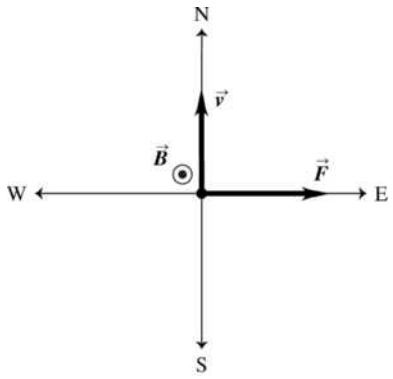

Figure 27.3

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

27.4. **IDENTIFY:** Apply Newton's second law, with the force being the magnetic force.
SET UP: $\hat{\boldsymbol{j}}\times\hat{\boldsymbol{i}}=-\hat{\boldsymbol{k}}$

EXECUTE: $\vec{\boldsymbol{F}}=m\vec{\boldsymbol{a}}=q\vec{\boldsymbol{v}}\times\vec{\boldsymbol{B}}$ gives $\vec{\boldsymbol{a}}=\dfrac{q\vec{\boldsymbol{v}}\times\vec{\boldsymbol{B}}}{m}$ and

$$\vec{\boldsymbol{a}}=\frac{(1.22\times10^{-8}\text{ C})(3.0\times10^{4}\text{ m/s})(1.63\text{ T})(\hat{\boldsymbol{j}}\times\hat{\boldsymbol{i}})}{1.81\times10^{-3}\text{ kg}}=-(0.330\text{ m/s}^2)\hat{\boldsymbol{k}}.$$

EVALUATE: The acceleration is in the $-z$-direction and is perpendicular to both $\vec{\boldsymbol{v}}$ and $\vec{\boldsymbol{B}}$.

27.5. **IDENTIFY:** Apply $F=|q|vB\sin\phi$ and solve for v.

SET UP: An electron has $q=-1.60\times10^{-19}$ C.

EXECUTE: $v=\dfrac{F}{|q|B\sin\phi}=\dfrac{4.60\times10^{-15}\text{ N}}{(1.6\times10^{-19}\text{ C})(3.5\times10^{-3}\text{ T})\sin60^\circ}=9.49\times10^{6}\text{ m/s}$

EVALUATE: Only the component $B\sin\phi$ of the magnetic field perpendicular to the velocity contributes to the force.

27.6. **IDENTIFY:** Apply Newton's second law and $F=|q|vB\sin\phi$.

SET UP: ϕ is the angle between the direction of $\vec{\boldsymbol{v}}$ and the direction of $\vec{\boldsymbol{B}}$.

EXECUTE: **(a)** The smallest possible acceleration is zero, when the motion is parallel to the magnetic field. The greatest acceleration is when the velocity and magnetic field are at right angles:

$$a=\frac{|q|vB}{m}=\frac{(1.6\times10^{-19}\text{ C})(2.50\times10^{6}\text{ m/s})(7.4\times10^{-2}\text{ T})}{(9.11\times10^{-31}\text{ kg})}=3.25\times10^{16}\text{ m/s}^2.$$

(b) If $a=\frac{1}{4}(3.25\times10^{16}\text{ m/s}^2)=\dfrac{|q|vB\sin\phi}{m}$, then $\sin\phi=0.25$ and $\phi=14.5^\circ$.

EVALUATE: The force and acceleration decrease as the angle ϕ approaches zero.

27.7. **IDENTIFY:** Apply $\vec{\boldsymbol{F}}=q\vec{\boldsymbol{v}}\times\vec{\boldsymbol{B}}$.

SET UP: $\vec{\boldsymbol{v}}=v_y\hat{\boldsymbol{j}}$, with $v_y=-3.80\times10^{3}$ m/s. $F_x=+7.60\times10^{-3}$ N, $F_y=0$, and $F_z=-5.20\times10^{-3}$ N.

EXECUTE: **(a)** $F_x=q(v_yB_z-v_zB_y)=qv_yB_z$.

$B_z=F_x/qv_y=(7.60\times10^{-3}\text{ N})/[(7.80\times10^{-6}\text{ C})(-3.80\times10^{3}\text{ m/s})]=-0.256\text{ T}$

$F_y=q(v_zB_x-v_xB_z)=0$, which is consistent with $\vec{\boldsymbol{F}}$ as given in the problem. There is no force component along the direction of the velocity.

$F_z=q(v_xB_y-v_yB_x)=-qv_yB_x$. $B_x=-F_z/qv_y=-0.175$ T.

(b) B_y is not determined. No force due to this component of $\vec{\boldsymbol{B}}$ along $\vec{\boldsymbol{v}}$; measurement of the force tells us nothing about B_y.

(c) $\vec{\boldsymbol{B}}\cdot\vec{\boldsymbol{F}}=B_xF_x+B_yF_y+B_zF_z=(-0.175\text{ T})(+7.60\times10^{-3}\text{ N})+(-0.256\text{ T})(-5.20\times10^{-3}\text{ N})$

$\vec{\boldsymbol{B}}\cdot\vec{\boldsymbol{F}}=0$. $\vec{\boldsymbol{B}}$ and $\vec{\boldsymbol{F}}$ are perpendicular (angle is 90°).

EVALUATE: The force is perpendicular to both $\vec{\boldsymbol{v}}$ and $\vec{\boldsymbol{B}}$, so $\vec{\boldsymbol{v}}\cdot\vec{\boldsymbol{F}}$ is also zero.

27.8. **IDENTIFY** and **SET UP:** $\vec{\boldsymbol{F}}=q\vec{\boldsymbol{v}}\times\vec{\boldsymbol{B}}=qB_z[v_x(\hat{\boldsymbol{i}}\times\hat{\boldsymbol{k}})+v_y(\hat{\boldsymbol{j}}\times\hat{\boldsymbol{k}})+v_z(\hat{\boldsymbol{k}}\times\hat{\boldsymbol{k}})]=qB_z[v_x(-\hat{\boldsymbol{j}})+v_y(\hat{\boldsymbol{i}})]$.

EXECUTE: **(a)** Set the expression for $\vec{\boldsymbol{F}}$ equal to the given value of $\vec{\boldsymbol{F}}$ to obtain:

$$v_x=\frac{F_y}{-qB_z}=\frac{(7.40\times10^{-7}\text{ N})}{-(-5.60\times10^{-9}\text{ C})(-1.25\text{ T})}=-106\text{ m/s}$$

$$v_y=\frac{F_x}{qB_z}=\frac{-(3.40\times10^{-7}\text{ N})}{(-5.60\times10^{-9}\text{ C})(-1.25\text{ T})}=-48.6\text{ m/s}.$$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) v_z does not contribute to the force, so is not determined by a measurement of $\vec{F}$.

(c) $\vec{v}\cdot\vec{F} = v_xF_x + v_yF_y + v_zF_z = \dfrac{F_y}{-qB_z}F_x + \dfrac{F_x}{qB_z}F_y = 0;\ \theta = 90°.$

EVALUATE: The force is perpendicular to both $\vec{v}$ and $\vec{B}$, so $\vec{B}\cdot\vec{F}$ is also zero.

27.9. **IDENTIFY:** Apply $\vec{F} = q\vec{v}\times\vec{B}$ to the force on the proton and to the force on the electron. Solve for the components of $\vec{B}$ and use them to find its magnitude and direction.

SET UP: $\vec{F}$ is perpendicular to both $\vec{v}$ and $\vec{B}$. Since the force on the proton is in the $+y$-direction, $B_y = 0$ and $\vec{B} = B_x\hat{i} + B_z\hat{k}$. For the proton, $\vec{v}_\text{p} = (1.50\text{ km/s})\hat{i} = v_\text{p}\hat{i}$ and $\vec{F}_\text{p} = (2.25\times10^{-16}\text{ N})\hat{j} = F_\text{p}\hat{j}$. For the electron, $\vec{v}_\text{e} = -(4.75\text{ km/s})\hat{k} = -v_\text{e}\hat{k}$ and $\vec{F}_\text{e} = (8.50\times10^{-16}\text{ N})\hat{j} = F_\text{e}\hat{j}$. The magnetic force is $\vec{F} = q\vec{v}\times\vec{B}$.

EXECUTE: **(a)** For the proton, $\vec{F}_\text{p} = q\vec{v}_\text{p}\times\vec{B}$ gives $F_\text{p}\hat{j} = ev_\text{p}\hat{i}\times(B_x\hat{i} + B_z\hat{k}) = -ev_\text{p}B_z\hat{j}$. Solving for B_z gives $B_z = -\dfrac{F_\text{p}}{ev_\text{p}} = -\dfrac{2.25\times10^{-16}\text{ N}}{(1.60\times10^{-19}\text{ C})(1500\text{ m/s})} = -0.9375\text{ T}$. For the electron, $\vec{F}_\text{e} = -e\vec{v}_\text{e}\times\vec{B}$, which gives $F_\text{e}\hat{j} = (-e)(-v_\text{e}\hat{k})\times(B_x\hat{i} + B_z\hat{k}) = ev_\text{e}B_x\hat{j}$. Solving for B_x gives $B_x = \dfrac{F_\text{e}}{ev_\text{e}} = \dfrac{8.50\times10^{-16}\text{ N}}{(1.60\times10^{-19}\text{ C})(4750\text{ m/s})} = 1.118\text{ T}$. Therefore $\vec{B} = 1.118\text{ T}\hat{i} - 0.9375\text{ T}\hat{k}$. The magnitude of the field is $B = \sqrt{B_x^2 + B_z^2} = \sqrt{(1.118\text{ T})^2 + (-0.9375\text{ T})^2} = 1.46\text{ T}$. Calling θ the angle that the magnetic field makes with the $+x$-axis, we have $\tan\theta = \dfrac{B_z}{B_x} = \dfrac{-0.9375\text{ T}}{1.118\text{ T}} = -0.8386$, so $\theta = -40.0°$. Therefore the magnetic field is in the xz-plane directed at 40.0° from the $+x$-axis toward the $-z$-axis, having a magnitude of 1.46 T.

(b) $\vec{B} = B_x\hat{i} + B_z\hat{k}$ and $\vec{v} = (3.2\text{ km/s})(-\hat{j})$.

$\vec{F} = q\vec{v}\times\vec{B} = (-e)(3.2\text{ km/s})(-\hat{j})\times(B_x\hat{i} + B_z\hat{k}) = e(3.2\times10^3\text{ m/s})[B_x(-\hat{k}) + B_z\hat{i}]$.

$\vec{F} = e(3.2\times10^3\text{ m/s})(-1.118\text{ T}\hat{k} - 0.9375\text{ T}\hat{i}) = -4.80\times10^{-16}\text{ N}\hat{i} - 5.724\times10^{-16}\text{ N}\hat{k}$.

$F = \sqrt{F_x^2 + F_z^2} = 7.47\times10^{-16}\text{ N}$. Calling θ the angle that the force makes with the $-x$-axis, we have $\tan\theta = \dfrac{F_z}{F_x} = \dfrac{-5.724\times10^{-16}\text{ N}}{-4.800\times10^{-16}\text{ N}}$, which gives $\theta = 50.0°$. The force is in the xz-plane and is directed at 50.0° from the $-x$-axis toward either the $-z$-axis.

EVALUATE: The force on the electrons in parts (a) and (b) are comparable in magnitude because the electron speeds are comparable in both cases.

27.10. **IDENTIFY:** Knowing the area of a surface and the magnetic field it is in, we want to calculate the flux through it.

SET UP: $d\vec{A} = dA\hat{k}$, so $d\Phi_B = \vec{B}\cdot d\vec{A} = B_z\,dA$.

EXECUTE: $\Phi_B = B_zA = (-0.500\text{ T})(0.0340\text{ m})^2 = -5.78\times10^{-4}\text{ T}\cdot\text{m}^2$. $|\Phi_B| = 5.78\times10^{-4}\text{ Wb}$.

EVALUATE: Since the field is uniform over the surface, it is not necessary to integrate to find the flux.

27.11. **IDENTIFY** and **SET UP:** $\Phi_B = \int\vec{B}\cdot d\vec{A}$

Circular area in the xy-plane, so $A = \pi r^2 = \pi(0.0650\text{ m})^2 = 0.01327\text{ m}^2$ and $d\vec{A}$ is in the z-direction. Use Eq. (1.18) to calculate the scalar product.

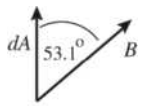
EXECUTE: **(a)** $\vec{B} = (0.230\text{ T})\hat{k}$; $\vec{B}$ and $d\vec{A}$ are parallel ($\phi = 0°$) so $\vec{B}\cdot d\vec{A} = B\,dA$.

B is constant over the circular area so

$\Phi_B = \int\vec{B}\cdot d\vec{A} = \int B\,dA = B\int dA = BA = (0.230\text{ T})(0.01327\text{ m}^2) = 3.05\times10^{-3}\text{ Wb}$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) The directions of $\vec{B}$ and $d\vec{A}$ are shown in Figure 27.11a.



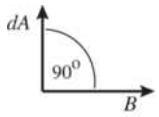
$\vec{B}\cdot d\vec{A} = B\cos\phi\, dA$
with $\phi = 53.1°$

Figure 27.11a

B and ϕ are constant over the circular area so $\Phi_B = \int \vec{B}\cdot d\vec{A} = \int B\cos\phi\, dA = B\cos\phi\int dA = B\cos\phi A$

$\Phi_B = (0.230\text{ T})\cos 53.1°(0.01327\text{ m}^2) = 1.83\times10^{-3}$ Wb.

(c) The directions of $\vec{B}$ and $d\vec{A}$ are shown in Figure 27.11b.



$\vec{B}\cdot d\vec{A} = 0$ since $d\vec{A}$ and $\vec{B}$ are perpendicular ($\phi = 90°$)
$\Phi_B = \int \vec{B}\cdot d\vec{A} = 0.$

Figure 27.11b

EVALUATE: Magnetic flux is a measure of how many magnetic field lines pass through the surface. It is maximum when $\vec{B}$ is perpendicular to the plane of the loop (part a) and is zero when $\vec{B}$ is parallel to the plane of the loop (part c).

27.12. **IDENTIFY:** Knowing the area of a surface and the magnetic flux through it, we want to find the magnetic field needed to produce this flux.

SET UP: $\Phi_B = BA\cos\phi$ where $\phi = 60.0°$.

EXECUTE: Solving $\Phi_B = BA\cos\phi$ for B gives $B = \dfrac{\Phi_B}{A\cos\phi} = \dfrac{4.20\times10^{-4}\text{ Wb}}{(0.0280\text{ m})(0.0320\text{ m})\cos 60.0°} = 0.938$ T.

EVALUATE: This is a fairly strong magnetic field, but not impossible to achieve in modern laboratories.

27.13. **IDENTIFY:** The total flux through the bottle is zero because it is a closed surface.

SET UP: The total flux through the bottle is the flux through the plastic plus the flux through the open cap, so the sum of these must be zero. $\Phi_{\text{plastic}} + \Phi_{\text{cap}} = 0$.

$\Phi_{\text{plastic}} = -\Phi_{\text{cap}} = -BA\cos\phi = -B(\pi r^2)\cos\phi$

EXECUTE: Substituting the numbers gives $\Phi_{\text{plastic}} = -(1.75\text{ T})\pi(0.0125\text{ m})^2\cos 25° = -7.8\times10^{-4}$ Wb

EVALUATE: It would be very difficult to calculate the flux through the plastic directly because of the complicated shape of the bottle, but with a little thought we can find this flux through a simple calculation.

27.14. **IDENTIFY:** When $\vec{B}$ is uniform across the surface, $\Phi_B = \vec{B}\cdot\vec{A} = BA\cos\phi$.

SET UP: $\vec{A}$ is normal to the surface and is directed outward from the enclosed volume. For surface *abcd*, $\vec{A} = -A\hat{\boldsymbol{i}}$. For surface *befc*, $\vec{A} = -A\hat{\boldsymbol{k}}$. For surface *aefd*, $\cos\phi = 3/5$ and the flux is positive.

EXECUTE: **(a)** $\Phi_B(abcd) = \vec{B}\cdot\vec{A} = 0$.

(b) $\Phi_B(befc) = \vec{B}\cdot\vec{A} = -(0.128\text{ T})(0.300\text{ m})(0.300\text{ m}) = -0.0115$ Wb.

(c) $\Phi_B(aefd) = \vec{B}\cdot\vec{A} = BA\cos\phi = \frac{3}{5}(0.128\text{ T})(0.500\text{ m})(0.300\text{ m}) = +0.0115$ Wb.

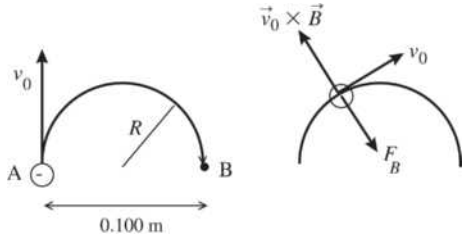
(d) The net flux through the rest of the surfaces is zero since they are parallel to the x-axis. The total flux is the sum of all parts above, which is zero.

EVALUATE: The total flux through any closed surface, that encloses a volume, is zero.

27.15. **(a) IDENTIFY:** Apply Eq. (27.2) to relate the magnetic force $\vec{F}$ to the directions of $\vec{v}$ and $\vec{B}$. The electron has negative charge so $\vec{F}$ is opposite to the direction of $\vec{v}\times\vec{B}$. For motion in an arc of a circle the acceleration is toward the center of the arc so $\vec{F}$ must be in this direction. $a = v^2/R$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

SET UP:



As the electron moves in the semicircle, its velocity is tangent to the circular path. The direction of $\vec{\boldsymbol{v}}_0 \times \vec{\boldsymbol{B}}$ at a point along the path is shown in Figure 27.15.

Figure 27.15

EXECUTE: For circular motion the acceleration of the electron $\vec{\boldsymbol{a}}_{\text{rad}}$ is directed in toward the center of the circle. Thus the force $\vec{\boldsymbol{F}}_B$ exerted by the magnetic field, since it is the only force on the electron, must be radially inward. Since q is negative, $\vec{\boldsymbol{F}}_B$ is opposite to the direction given by the right-hand rule for $\vec{\boldsymbol{v}}_0 \times \vec{\boldsymbol{B}}$. Thus $\vec{\boldsymbol{B}}$ is directed into the page. Apply Newton's second law to calculate the magnitude of $\vec{\boldsymbol{B}}$:

$\sum \vec{\boldsymbol{F}} = m\vec{\boldsymbol{a}}$ gives $\sum F_{\text{rad}} = ma \quad F_B = m(v^2/R)$

$F_B = |q| v B \sin\phi = |q| v B$, so $|q| v B = m(v^2/R)$

$$B = \frac{mv}{|q|R} = \frac{(9.109\times10^{-31}\ \text{kg})(1.41\times10^{6}\ \text{m/s})}{(1.602\times10^{-19}\ \text{C})(0.050\ \text{m})} = 1.60\times10^{-4}\ \text{T}$$

(b) IDENTIFY and **SET UP:** The speed of the electron as it moves along the path is constant. ($\vec{\boldsymbol{F}}_B$ changes the direction of $\vec{\boldsymbol{v}}$ but not its magnitude.) The time is given by the distance divided by v_0.

EXECUTE: The distance along the semicircular path is πR, so $t = \dfrac{\pi R}{v_0} = \dfrac{\pi(0.050\ \text{m})}{1.41\times10^{6}\ \text{m/s}} = 1.11\times10^{-7}$ s.

EVALUATE: The magnetic field required increases when v increases or R decreases and also depends on the mass to charge ratio of the particle.

27.16. **IDENTIFY:** Newton's second law gives $|q| v B = mv^2/R$. The speed v is constant and equals v_0. The direction of the magnetic force must be in the direction of the acceleration and is toward the center of the semicircular path.

SET UP: A proton has $q = +1.60\times10^{-19}$ C and $m = 1.67\times10^{-27}$ kg. The direction of the magnetic force is given by the right-hand rule.

EXECUTE: **(a)** $$B = \frac{mv}{qR} = \frac{(1.67\times10^{-27}\ \text{kg})(1.41\times10^{6}\ \text{m/s})}{(1.60\times10^{-19}\ \text{C})(0.0500\ \text{m})} = 0.294\ \text{T}$$

The direction of the magnetic field is out of the page (the charge is positive), in order for $\vec{\boldsymbol{F}}$ to be directed to the right at point A.

(b) The time to complete half a circle is $t = \pi R/v_0 = 1.11\times10^{-7}$ s.

EVALUATE: The magnetic field required to produce this path for a proton has a different magnitude (because of the different mass) and opposite direction (because of opposite sign of the charge) than the field required to produce the path for an electron.

27.17. **IDENTIFY** and **SET UP:** Use conservation of energy to find the speed of the ball when it reaches the bottom of the shaft. The right-hand rule gives the direction of $\vec{\boldsymbol{F}}$ and Eq. (27.1) gives its magnitude. The number of excess electrons determines the charge of the ball.

EXECUTE: $q = (4.00\times10^{8})(-1.602\times10^{-19}\ \text{C}) = -6.408\times10^{-11}$ C

speed at bottom of shaft: $\frac{1}{2}mv^2 = mgy;\ v = \sqrt{2gy} = 49.5$ m/s

$\vec{\boldsymbol{v}}$ is downward and $\vec{\boldsymbol{B}}$ is west, so $\vec{\boldsymbol{v}} \times \vec{\boldsymbol{B}}$ is north. Since $q < 0$, $\vec{\boldsymbol{F}}$ is south.

$F = |q| v B \sin\theta = (6.408\times10^{-11}\ \text{C})(49.5\ \text{m/s})(0.250\ \text{T})\sin 90° = 7.93\times10^{-10}$ N

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: Both the charge and speed of the ball are relatively small so the magnetic force is small, much less than the gravity force of 1.5 N.

27.18. **IDENTIFY:** Since the particle moves perpendicular to the uniform magnetic field, the radius of its path is $R = \dfrac{mv}{|q|B}$. The magnetic force is perpendicular to both $\vec{v}$ and $\vec{B}$.

SET UP: The alpha particle has charge $q = +2e = 3.20\times10^{-19}$ C.

EXECUTE: **(a)** $R = \dfrac{(6.64\times10^{-27}\text{ kg})(35.6\times10^{3}\text{ m/s})}{(3.20\times10^{-19}\text{ C})(1.10\text{ T})} = 6.73\times10^{-4}\text{ m} = 0.673\text{ mm}$. The alpha particle moves in a circular arc of diameter $2R = 1.35$ mm.

(b) For a very short time interval the displacement of the particle is in the direction of the velocity. The magnetic force is always perpendicular to this direction so it does no work. The work-energy theorem therefore says that the kinetic energy of the particle, and hence its speed, is constant.

(c) The acceleration is

$a = \dfrac{F_B}{m} = \dfrac{|q|vB\sin\phi}{m} = \dfrac{(3.20\times10^{-19}\text{ C})(35.6\times10^{3}\text{ m/s})(1.10\text{ T})\sin90°}{6.64\times10^{-27}\text{ kg}} = 1.88\times10^{12}\text{ m/s}^2$. We can also use $a = \dfrac{v^2}{R}$ and the result of part (a) to calculate $a = \dfrac{(35.6\times10^{3}\text{ m/s})^2}{6.73\times10^{-4}\text{ m}} = 1.88\times10^{12}\text{ m/s}^2$, the same result.

The acceleration is perpendicular to $\vec{v}$ and $\vec{B}$ and so is horizontal, toward the center of curvature of the particle's path.

EVALUATE: **(d)** The unbalanced force ($\vec{F}_B$) is perpendicular to $\vec{v}$, so it changes the direction of $\vec{v}$ but not its magnitude, which is the speed.

27.19. **IDENTIFY:** $p = mv$ and $L = Rp$, since the velocity and linear momentum are tangent to the circular path.

SET UP: $|q|vB = mv^2/R$.

EXECUTE: **(a)** $p = mv = m\left(\dfrac{RqB}{m}\right) = RqB = (4.68\times10^{-3}\text{ m})(6.4\times10^{-19}\text{ C})(1.65\text{ T}) = 4.94\times10^{-21}\text{ kg}\cdot\text{m/s}$.

(b) $L = Rp = R^2qB = (4.68\times10^{-3}\text{ m})^2(6.4\times10^{-19}\text{ C})(1.65\text{ T}) = 2.31\times10^{-23}\text{ kg}\cdot\text{m}^2/\text{s}$.

EVALUATE: $\vec{p}$ is tangent to the orbit and $\vec{L}$ is perpendicular to the orbit plane.

27.20. **IDENTIFY:** $F = |q|vB\sin\phi$. The direction of $\vec{F}$ is given by the right-hand rule.

SET UP: An electron has $q = -e$.

EXECUTE: **(a)** $F = |q|vB\sin\phi$. $B = \dfrac{F}{|q|v\sin\phi} = \dfrac{0.00320\times10^{-9}\text{ N}}{8(1.60\times10^{-19}\text{ C})(500{,}000\text{ m/s})\sin90°} = 5.00\text{ T}$. If the angle ϕ is less than 90°, a larger field is needed to produce the same force. The direction of the field must be toward the south so that $\vec{v}\times\vec{B}$ is downward.

(b) $F = |q|vB\sin\phi$. $v = \dfrac{F}{|q|B\sin\phi} = \dfrac{4.60\times10^{-12}\text{ N}}{(1.60\times10^{-19}\text{ C})(2.10\text{ T})\sin90°} = 1.37\times10^{7}\text{ m/s}$. If ϕ is less than 90°, the speed would have to be larger to have the same force. The force is upward, so $\vec{v}\times\vec{B}$ must be downward since the electron is negative, and the velocity must be toward the south.

EVALUATE: The component of $\vec{B}$ along the direction of $\vec{v}$ produces no force and the component of $\vec{v}$ along the direction of $\vec{B}$ produces no force.

27.21. **(a) IDENTIFY** and **SET UP:** Apply Newton's second law, with $a = v^2/R$ since the path of the particle is circular.

EXECUTE: $\sum\vec{F} = m\vec{a}$ says $|q|vB = m(v^2/R)$

$v = \dfrac{|q|BR}{m} = \dfrac{(1.602\times10^{-19}\text{ C})(2.50\text{ T})(6.96\times10^{-3}\text{ m})}{3.34\times10^{-27}\text{ kg}} = 8.35\times10^{5}\text{ m/s}$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) IDENTIFY and **SET UP:** The speed is constant so t = distance/v.

EXECUTE: $t = \dfrac{\pi R}{v} = \dfrac{\pi(6.96\times10^{-3}\text{ m})}{8.35\times10^{5}\text{ m/s}} = 2.62\times10^{-8}\text{ s}$

(c) IDENTIFY and **SET UP:** kinetic energy gained = electric potential energy lost

EXECUTE: $\frac{1}{2}mv^2 = |q|V$

$V = \dfrac{mv^2}{2|q|} = \dfrac{(3.34\times10^{-27}\text{ kg})(8.35\times10^{5}\text{ m/s})^2}{2(1.602\times10^{-19}\text{ C})} = 7.27\times10^{3}\text{ V} = 7.27\text{ kV}$

EVALUATE: The deutron has a much larger mass to charge ratio than an electron so a much larger B is required for the same v and R. The deutron has positive charge so gains kinetic energy when it goes from high potential to low potential.

27.22. **IDENTIFY:** For motion in an arc of a circle, $a = \dfrac{v^2}{R}$ and the net force is radially inward, toward the center of the circle.

SET UP: The direction of the force is shown in Figure 27.22. The mass of a proton is 1.67×10^{-27} kg.

EXECUTE: **(a)** $\vec{F}$ is opposite to the right-hand rule direction, so the charge is negative. $\vec{F} = m\vec{a}$ gives $|q|vB\sin\phi = m\dfrac{v^2}{R}$. $\phi = 90°$ and $v = \dfrac{|q|BR}{m} = \dfrac{3(1.60\times10^{-19}\text{ C})(0.250\text{ T})(0.475\text{ m})}{12(1.67\times10^{-27}\text{ kg})} = 2.84\times10^{6}\text{ m/s}$.

(b) $F_B = |q|vB\sin\phi = 3(1.60\times10^{-19}\text{ C})(2.84\times10^{6}\text{ m/s})(0.250\text{ T})\sin90° = 3.41\times10^{-13}\text{ N}$.

$w = mg = 12(1.67\times10^{-27}\text{ kg})(9.80\text{ m/s}^2) = 1.96\times10^{-25}\text{ N}$. The magnetic force is much larger than the weight of the particle, so it is a very good approximation to neglect gravity.

EVALUATE: **(c)** The magnetic force is always perpendicular to the path and does no work. The particles move with constant speed.

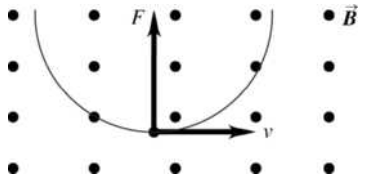


Figure 27.22

27.23. **IDENTIFY:** Example 27.3 shows that $B = \dfrac{m2\pi f}{|q|}$, where f is the frequency, in Hz, of the electromagnetic waves that are produced.

SET UP: An electron has charge $q = -e$ and mass $m = 9.11\times10^{-31}$ kg. A proton has charge $q = +e$ and mass $m = 1.67\times10^{-27}$ kg.

EXECUTE: **(a)** $B = \dfrac{m2\pi f}{|q|} = \dfrac{(9.11\times10^{-31}\text{ kg})2\pi(3.00\times10^{12}\text{ Hz})}{(1.60\times10^{-19}\text{ C})} = 107\text{ T}$. This is about 2.4 times the greatest magnitude of magnetic field yet obtained on earth.

(b) Protons have a greater mass than the electrons, so a greater magnetic field would be required to accelerate them with the same frequency and there would be no advantage in using them.

EVALUATE: Electromagnetic waves with frequency $f = 3.0$ THz have a wavelength in air of $\lambda = \dfrac{v}{f} = 1.0\times10^{-4}$ m. The shorter the wavelength the greater the frequency and the greater the magnetic field that is required. B depends only on f and on the mass-to-charge ratio of the particle that moves in the circular path.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

27.24. **IDENTIFY:** The magnetic force on the beam bends it through a quarter circle.
SET UP: The distance that particles in the beam travel is $s = R\theta$, and the radius of the quarter circle is $R = mv/qB$.
EXECUTE: Solving for R gives $R = s/\theta = s/(\pi/2) = 1.18 \text{ cm}/(\pi/2) = 0.751 \text{ cm}$. Solving for the magnetic field: $B = mv/qR = (1.67\times10^{-27} \text{ kg})(1200 \text{ m/s})/[(1.60\times10^{-19} \text{ C})(0.00751 \text{ m})] = 1.67\times10^{-3} \text{ T}$.
EVALUATE: This field is about 10 times stronger than the Earth's magnetic field, but much weaker than many laboratory fields.

27.25. **IDENTIFY:** When a particle of charge $-e$ is accelerated through a potential difference of magnitude V, it gains kinetic energy eV. When it moves in a circular path of radius R, its acceleration is $\dfrac{v^2}{R}$.
SET UP: An electron has charge $q = -e = -1.60\times10^{-19}$ C and mass 9.11×10^{-31} kg.
EXECUTE: $\frac{1}{2}mv^2 = eV$ and $v = \sqrt{\dfrac{2eV}{m}} = \sqrt{\dfrac{2(1.60\times10^{-19} \text{ C})(2.00\times10^{3} \text{ V})}{9.11\times10^{-31} \text{ kg}}} = 2.65\times10^{7}$ m/s. $\vec{F} = m\vec{a}$ gives $|q|vB\sin\phi = m\dfrac{v^2}{R}$. $\phi = 90°$ and $B = \dfrac{mv}{|q|R} = \dfrac{(9.11\times10^{-31} \text{ kg})(2.65\times10^{7} \text{ m/s})}{(1.60\times10^{-19} \text{ C})(0.180 \text{ m})} = 8.38\times10^{-4}$ T.
EVALUATE: The smaller the radius of the circular path, the larger the magnitude of the magnetic field that is required.

27.26. **IDENTIFY:** After being accelerated through a potential difference V the ion has kinetic energy qV. The acceleration in the circular path is v^2/R.
SET UP: The ion has charge $q = +e$.
EXECUTE: $K = qV = +eV$. $\frac{1}{2}mv^2 = eV$ and $v = \sqrt{\dfrac{2eV}{m}} = \sqrt{\dfrac{2(1.60\times10^{-19} \text{ C})(220 \text{ V})}{1.16\times10^{-26} \text{ kg}}} = 7.79\times10^{4}$ m/s.
$F_B = |q|vB\sin\phi$. $\phi = 90°$. $\vec{F} = m\vec{a}$ gives $|q|vB = m\dfrac{v^2}{R}$.
$R = \dfrac{mv}{|q|B} = \dfrac{(1.16\times10^{-26} \text{ kg})(7.79\times10^{4} \text{ m/s})}{(1.60\times10^{-19} \text{ C})(0.723 \text{ T})} = 7.81\times10^{-3} \text{ m} = 7.81 \text{ mm}$.
EVALUATE: The larger the accelerating voltage, the larger the speed of the particle and the larger the radius of its path in the magnetic field.

27.27. **(a) IDENTIFY** and **SET UP:** Eq. (27.4) gives the total force on the proton. At $t = 0$,
$\vec{F} = q\vec{v}\times\vec{B} = q(v_x\hat{i} + v_z\hat{k})\times B_x\hat{i} = qv_zB_x\hat{j}$.
$\vec{F} = (1.60\times10^{-19} \text{ C})(2.00\times10^{5} \text{ m/s})(0.500 \text{ T})\hat{j} = (1.60\times10^{-14} \text{ N})\hat{j}$.
(b) Yes. The electric field exerts a force in the direction of the electric field, since the charge of the proton is positive, and there is a component of acceleration in this direction.
(c) EXECUTE: In the plane perpendicular to $\vec{B}$ (the yz-plane) the motion is circular. But there is a velocity component in the direction of $\vec{B}$, so the motion is a helix. The electric field in the $+\hat{i}$ direction exerts a force in the $+\hat{i}$ direction. This force produces an acceleration in the $+\hat{i}$ direction and this causes the pitch of the helix to vary. The force does not affect the circular motion in the yz-plane, so the electric field does not affect the radius of the helix.
(d) IDENTIFY and **SET UP:** Eq. (27.12) and $T = 2\pi/\omega$ to calculate the period of the motion. Calculate a_x produced by the electric force and use a constant acceleration equation to calculate the displacement in the x-direction in time $T/2$.
EXECUTE: Calculate the period T: $\omega = |q|B/m$
$T = \dfrac{2\pi}{\omega} = \dfrac{2\pi m}{|q|B} = \dfrac{2\pi(1.67\times10^{-27} \text{ kg})}{(1.60\times10^{-19} \text{ C})(0.500 \text{ T})} = 1.312\times10^{-7}$ s. Then $t = T/2 = 6.56\times10^{-8}$ s.
$v_{0x} = 1.50\times10^{5}$ m/s

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$a_x = \frac{F_x}{m} = \frac{(1.60\times10^{-19}\text{ C})(2.00\times10^{4}\text{ V/m})}{1.67\times10^{-27}\text{ kg}} = +1.916\times10^{12}\text{ m/s}^2$$

$$x - x_0 = v_{0x}t + \tfrac{1}{2}a_x t^2$$

$$x - x_0 = (1.50\times10^{5}\text{ m/s})(6.56\times10^{-8}\text{ s}) + \tfrac{1}{2}(1.916\times10^{12}\text{ m/s}^2)(6.56\times10^{-8}\text{ s})^2 = 1.40\text{ cm}$$

EVALUATE: The electric and magnetic fields are in the same direction but produce forces that are in perpendicular directions to each other.

27.28. **IDENTIFY:** For no deflection the magnetic and electric forces must be equal in magnitude and opposite in direction.

SET UP: $v = E/B$ for no deflection. With only the magnetic force, $|q|vB = mv^2/R$.

EXECUTE: **(a)** $v = E/B = (1.56\times10^{4}\text{ V/m})/(4.62\times10^{-3}\text{ T}) = 3.38\times10^{6}\text{ m/s}$.

(b) The directions of the three vectors $\vec{\boldsymbol{v}}$, $\vec{\boldsymbol{E}}$ and $\vec{\boldsymbol{B}}$ are sketched in Figure 27.28.

(c) $$R = \frac{mv}{|q|B} = \frac{(9.11\times10^{-31}\text{ kg})(3.38\times10^{6}\text{ m/s})}{(1.60\times10^{-19}\text{ C})(4.62\times10^{-3}\text{ T})} = 4.17\times10^{-3}\text{ m}.$$

$$T = \frac{2\pi m}{|q|B} = \frac{2\pi R}{v} = \frac{2\pi(4.17\times10^{-3}\text{ m})}{(3.38\times10^{6}\text{ m/s})} = 7.74\times10^{-9}\text{ s}.$$

EVALUATE: For the field directions shown in Figure 27.28, the electric force is toward the top of the page and the magnetic force is toward the bottom of the page.

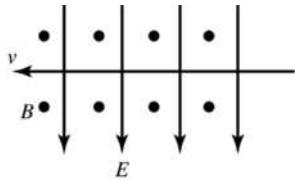

Figure 27.28

27.29. **IDENTIFY:** In a velocity selector, the electric force and the magnetic force on the moving ions must exactly cancel so the ions can move through undeflected.

SET UP: For the ions to pass through undeflected, the net force must be zero and therefore the electric and magnetic forces must be in opposite directions and have magnitudes such that $v = E/B$. For positive charges the electric force is in the same direction as the electric field and for negative charges the field and force are in opposite directions.

EXECUTE: **(a)** $E = vB = (8.75\times10^{3}\text{ m/s})(0.550\text{ T}) = 4.81\times10^{3}\text{ N/C}$.

(b) Take the velocity to be to the right and let the electric field be downward, as shown in Figure 27.29. Since the charge is positive, the electric force is downward. For an ion to pass through undeflected, the net force must be zero, so the magnetic force must be upward. Using the right-hand rule for $\vec{v}$ and $\vec{\boldsymbol{B}}$ we deduce that $\vec{\boldsymbol{B}}$ must be directed into the plane of the figure.

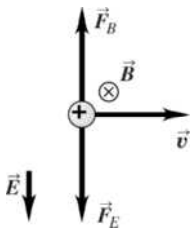

Figure 27.29

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(c) For a negative charge and the $\vec{E}$ and $\vec{B}$ fields of Figure 27.29, the direction of each force is reversed. But they are still in opposite directions from each other, so they will cancel if their magnitudes are the same. The magnitude of the charge divides out in the derivation of the equation $v = E/B$, so the same velocity selector works for negative ions and positive ions of any charge.

EVALUATE: The velocity selector *selects* ions having a speed of 8.75 km/s. It does not change their speeds to that value.

27.30. **IDENTIFY:** For no deflection the magnetic and electric forces must be equal in magnitude and opposite in direction.

SET UP: $v = E/B$ for no deflection.

EXECUTE: To pass undeflected in both cases, $E = vB = (5.85\times10^3 \text{ m/s})(1.35 \text{ T}) = 7898 \text{ N/C}$.

(a) If $q = 0.640\times10^{-9}$ C, the electric field direction is given by $-(\hat{\boldsymbol{j}}\times(-\hat{\boldsymbol{k}})) = \hat{\boldsymbol{i}}$, since it must point in the opposite direction to the magnetic force.

(b) If $q = -0.320\times10^{-9}$ C, the electric field direction is given by $((-\hat{\boldsymbol{j}})\times(-\hat{\boldsymbol{k}})) = \hat{\boldsymbol{i}}$, since the electric force must point in the opposite direction as the magnetic force. Since the particle has negative charge, the electric force is opposite to the direction of the electric field and the magnetic force is opposite to the direction it has in part (a).

EVALUATE: The same configuration of electric and magnetic fields works as a velocity selector for both positively and negatively charged particles.

27.31. **IDENTIFY:** For the alpha particles to emerge from the plates undeflected, the magnetic force on them must exactly cancel the electric force. The battery produces an electric field between the plates, which acts on the alpha particles.

SET UP: First use energy conservation to find the speed of the alpha particles as they enter the region between the plates: $qV = 1/2\ mv^2$. The electric field between the plates due to the battery is $E = V_b d$. For the alpha particles not to be deflected, the magnetic force must cancel the electric force, so $qvB = qE$, giving $B = E/v$.

EXECUTE: Solve for the speed of the alpha particles just as they enter the region between the plates. Their charge is $2e$.

$$v_\alpha = \sqrt{\frac{2(2e)V}{m}} = \sqrt{\frac{4(1.60\times10^{-19}\text{ C})(1750\text{V})}{6.64\times10^{-27}\text{ kg}}} = 4.11\times10^5 \text{ m/s}$$

The electric field between the plates, produced by the battery, is

$$E = V_b/d = (150 \text{ V})/(0.00820 \text{ m}) = 18{,}300 \text{ V/m}$$

The magnetic force must cancel the electric force:

$$B = E/v_\alpha = (18{,}300 \text{ V/m})/(4.11\times10^5 \text{ m/s}) = 0.0445 \text{ T}$$

The magnetic field is perpendicular to the electric field. If the charges are moving to the right and the electric field points upward, the magnetic field is out of the page.

EVALUATE: The sign of the charge of the alpha particle does not enter the problem, so negative charges of the same magnitude would also not be deflected.

27.32. **IDENTIFY:** The velocity selector eliminates all ions not having the desired velocity. Then the magnetic field bends the ions in a circular arc.

SET UP: In a velocity selector, $E = vB$. For motion in a circular arc in a magnetic field of magnitude B', $R = \dfrac{mv}{|q|B'}$. The ion has charge $+e$.

EXECUTE: **(a)** $E = vB = (4.50\times10^3 \text{ m/s})(0.0250 \text{ T}) = 112 \text{ V/m}$.

(b) $B' = \dfrac{mv}{|q|R} = \dfrac{(6.64\times10^{-26}\text{ kg})(4.50\times10^3\text{ m/s})}{(1.60\times10^{-19}\text{ C})(0.125\text{ m})} = 1.49\times10^{-2}\text{ T}$.

EVALUATE: By laboratory standards, both the electric field and the magnetic field are rather weak and should easily be achievable.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

27.33. **IDENTIFY:** The velocity selector eliminates all ions not having the desired velocity. Then the magnetic field bends the ions in a circular arc.

SET UP: In a velocity selector, $E = vB$. For motion in a circular arc in a magnetic field of magnitude B, $R = \dfrac{mv}{|q|B}$. The ion has charge $+e$.

EXECUTE: **(a)** $v = \dfrac{E}{B} = \dfrac{155 \text{ V/m}}{0.0315 \text{ T}} = 4.92\times10^3 \text{ m/s}$.

(b) $m = \dfrac{R|q|B}{v} = \dfrac{(0.175 \text{ m})(1.60\times10^{-19} \text{ C})(0.0175 \text{ T})}{4.92\times10^3 \text{ m/s}} = 9.96\times10^{-26} \text{ kg}$.

EVALUATE: Ions with larger ratio $\dfrac{m}{|q|}$ will move in a path of larger radius.

27.34. **IDENTIFY** and **SET UP:** For a velocity selector, $E = vB$. For parallel plates with opposite charge, $V = Ed$.

EXECUTE: **(a)** $E = vB = (1.82\times10^6 \text{ m/s})(0.650 \text{ T}) = 1.18\times10^6 \text{ V/m}$.

(b) $V = Ed = (1.18\times10^6 \text{ V/m})(5.20\times10^{-3} \text{ m}) = 6.14 \text{ kV}$.

EVALUATE: Any charged particle with $v = 1.82\times10^6$ m/s will pass through undeflected, regardless of the sign and magnitude of its charge.

27.35. **IDENTIFY:** A mass spectrometer separates ions by mass. Since ^{14}N and ^{15}N have different masses they will be separated and the relative amounts of these isotopes can be determined.

SET UP: $R = \dfrac{mv}{|q|B}$. For $m = 1.99\times10^{-26}$ kg (^{12}C), $R_{12} = 12.5$ cm. The separation of the isotopes at the detector is $2(R_{15} - R_{14})$.

EXECUTE: Since $R = \dfrac{mv}{|q|B}$, $\dfrac{R}{m} = \dfrac{v}{|q|B} = \text{constant}$. Therefore $\dfrac{R_{14}}{m_{14}} = \dfrac{R_{12}}{m_{12}}$ which gives

$R_{14} = R_{12}\left(\dfrac{m_{14}}{m_{12}}\right) = (12.5 \text{ cm})\left(\dfrac{2.32\times10^{-26} \text{ kg}}{1.99\times10^{-26} \text{ kg}}\right) = 14.6 \text{ cm}$ and

$R_{15} = R_{12}\left(\dfrac{m_{15}}{m_{12}}\right) = (12.5 \text{ cm})\left(\dfrac{2.49\times10^{-26} \text{ kg}}{1.99\times10^{-26} \text{ kg}}\right) = 15.6 \text{ cm}$. The separation of the isotopes at the detector is

$2(R_{15} - R_{14}) = 2(15.6 \text{ cm} - 14.6 \text{ cm}) = 2.0 \text{ cm}$.

REFLECT: The separation is large enough to be easily detectable. Since the diameter of the ion path is large, about 30 cm, the uniform magnetic field within the instrument must extend over a large area.

27.36. **IDENTIFY:** The earth's magnetic field exerts a force on the moving charges in the wire.

SET UP: $F = IlB\sin\phi$. The direction of $\vec{F}$ is determined by applying the right-hand rule to the directions of I and $\vec{B}$. 1 gauss $= 10^{-4}$ T.

EXECUTE: **(a)** The directions of I and $\vec{B}$ are sketched in Figure 27.36a. $\phi = 90°$ so $F = (1.5 \text{ A})(2.5 \text{ m})(0.55\times10^{-4} \text{ T}) = 2.1\times10^{-4}$ N. The right-hand rule says that $\vec{F}$ is directed out of the page, so it is upward.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

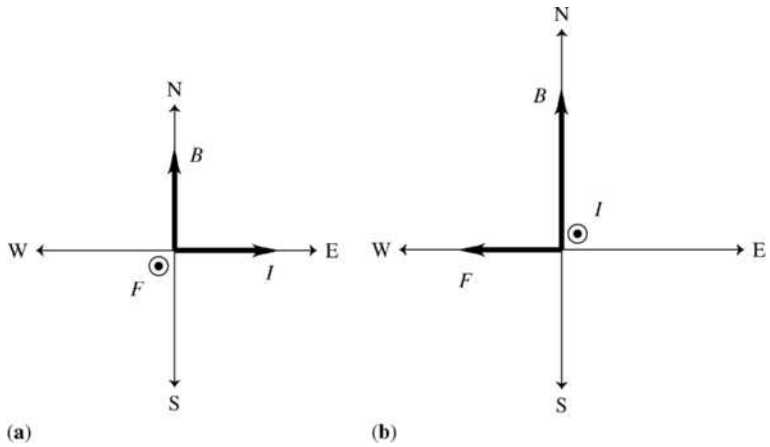

Figure 27.36

(b) The directions of I and $\vec{B}$ are sketched in Figure 27.36b. $\phi = 90°$ and $F = 2.1\times10^{-4}$ N. $\vec{F}$ is directed east to west.

(c) $\vec{B}$ and the direction of the current are antiparallel. $\phi = 180°$ so $F = 0$.

(d) The magnetic force of 2.1×10^{-4} N is not large enough to cause significant effects.

EVALUATE: The magnetic force is a maximum when the directions of I and $\vec{B}$ are perpendicular and it is zero when the current and magnetic field are either parallel or antiparallel.

27.37. **IDENTIFY:** The magnetic force is $F = IlB\sin\phi$. For the wire to be completely supported by the field requires that $F = mg$ and that $\vec{F}$ and $\vec{w}$ are in opposite directions.

SET UP: The magnetic force is maximum when $\phi = 90°$. The gravity force is downward.

EXECUTE: **(a)** $IlB = mg$. $I = \dfrac{mg}{lB} = \dfrac{(0.150\text{ kg})(9.80\text{ m/s}^2)}{(2.00\text{ m})(0.55\times10^{-4}\text{ T})} = 1.34\times10^{4}$ A. This is a very large current and ohmic heating due to the resistance of the wire would be severe; such a current isn't feasible.

(b) The magnetic force must be upward. The directions of I, $\vec{B}$ and $\vec{F}$ are shown in Figure 27.37, where we have assumed that $\vec{B}$ is south to north. To produce an upward magnetic force, the current must be to the east. The wire must be horizontal and perpendicular to the earth's magnetic field.

EVALUATE: The magnetic force is perpendicular to both the direction of I and the direction of $\vec{B}$.

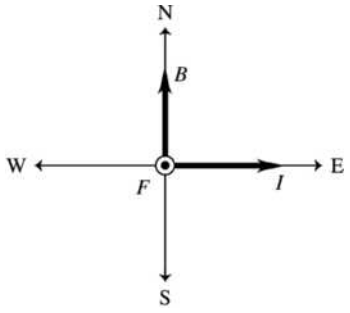

Figure 27.37

27.38. **IDENTIFY:** Apply $F = IlB\sin\phi$.

SET UP: $l = 0.0500$ m is the length of wire in the magnetic field. Since the wire is perpendicular to $\vec{B}$, $\phi = 90°$.

EXECUTE: $F = IlB = (10.8\text{ A})(0.0500\text{ m})(0.550\text{ T}) = 0.297$ N.

EVALUATE: The force per unit length of wire is proportional to both B and I.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

27.39. **IDENTIFY:** Apply $F = IlB\sin\phi$.

SET UP: Label the three segments in the field as a, b, and c. Let x be the length of segment a. Segment b has length 0.300 m and segment c has length $0.600\ \text{m} - x$. Figure 27.39a shows the direction of the force on each segment. For each segment, $\phi = 90°$. The total force on the wire is the vector sum of the forces on each segment.

EXECUTE: $F_a = IlB = (4.50\ \text{A})x(0.240\ \text{T})$. $F_c = (4.50\ \text{A})(0.600\ \text{m} - x)(0.240\ \text{T})$. Since $\vec{F}_a$ and $\vec{F}_c$ are in the same direction their vector sum has magnitude

$F_{ac} = F_a + F_c = (4.50\ \text{A})(0.600\ \text{m})(0.240\ \text{T}) = 0.648\ \text{N}$ and is directed toward the bottom of the page in Figure 27.39a. $F_b = (4.50\ \text{A})(0.300\ \text{m})(0.240\ \text{T}) = 0.324\ \text{N}$ and is directed to the right. The vector addition diagram for $\vec{F}_{ac}$ and $\vec{F}_b$ is given in Figure 27.39b.

$F = \sqrt{F_{ac}^2 + F_b^2} = \sqrt{(0.648\ \text{N})^2 + (0.324\ \text{N})^2} = 0.724\ \text{N}$. $\tan\theta = \dfrac{F_{ac}}{F_b} = \dfrac{0.648\ \text{N}}{0.324\ \text{N}}$ and $\theta = 63.4°$. The net force has magnitude 0.724 N and its direction is specified by $\theta = 63.4°$ in Figure 27.39b.

EVALUATE: All three current segments are perpendicular to the magnetic field, so $\phi = 90°$ for each in the force equation. The direction of the force on a segment depends on the direction of the current for that segment.

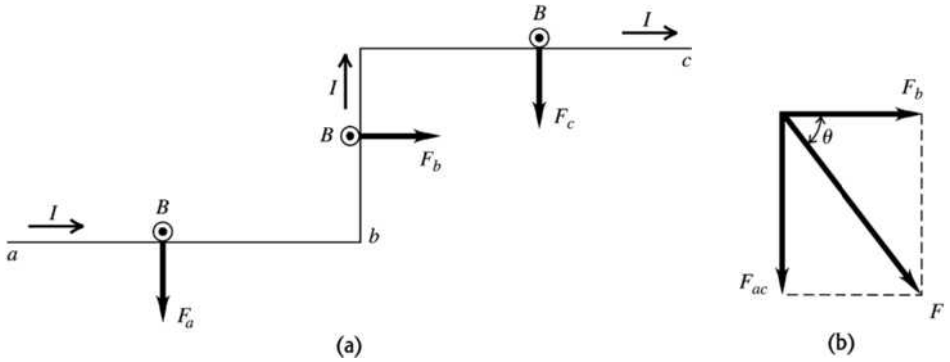

Figure 27.39

27.40. **IDENTIFY** and **SET UP:** $F = IlB\sin\phi$. The direction of $\vec{F}$ is given by applying the right-hand rule to the directions of I and $\vec{B}$.

EXECUTE: **(a)** The current and field directions are shown in Figure 27.40a. The right-hand rule gives that $\vec{F}$ is directed to the south, as shown. $\phi = 90°$ and $F = (1.20\ \text{A})(1.00\times10^{-2}\ \text{m})(0.588\ \text{T}) = 7.06\times10^{-3}\ \text{N}$.

(b) The right-hand rule gives that $\vec{F}$ is directed to the west, as shown in Figure 27.40b. $\phi = 90°$ and $F = 7.06\times10^{-3}\ \text{N}$, the same as in part (a).

(c) The current and field directions are shown in Figure 27.40c. The right-hand rule gives that $\vec{F}$ is 60.0° north of west. $\phi = 90°$ so $F = 7.06\times10^{-3}\ \text{N}$, the same as in part (a).

EVALUATE: In each case the current direction is perpendicular to the magnetic field. The magnitude of the magnetic force is the same in each case but its direction depends on the direction of the magnetic field.

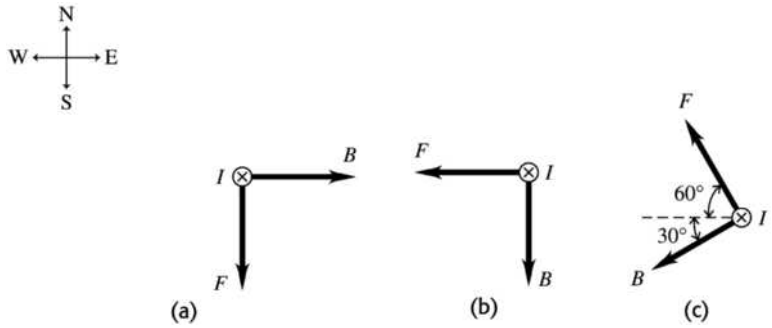

Figure 27.40

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

27.41. **IDENTIFY** and **SET UP:** The magnetic force is given by Eq. (27.19). $F_I = mg$ when the bar is just ready to levitate. When I becomes larger, $F_I > mg$ and $F_I - mg$ is the net force that accelerates the bar upward. Use Newton's second law to find the acceleration.

(a) EXECUTE: $IlB = mg,\ I = \dfrac{mg}{lB} = \dfrac{(0.750\ \text{kg})(9.80\ \text{m/s}^2)}{(0.500\ \text{m})(0.450\ \text{T})} = 32.67\ \text{A}$

$\mathcal{E} = IR = (32.67\ \text{A})(25.0\ \Omega) = 817\ \text{V}$

(b) $R = 2.0\ \Omega,\ I = \mathcal{E}/R = (816.7\ \text{V})/(2.0\ \Omega) = 408\ \text{A}$

$F_I = IlB = 92\ \text{N}$

$a = (F_I - mg)/m = 113\ \text{m/s}^2$

EVALUATE: I increases by over an order of magnitude when R changes to $F_I >> mg$ and a is an order of magnitude larger than g.

27.42. **IDENTIFY:** The magnetic force $\vec{F}_B$ must be upward and equal to mg. The direction of $\vec{F}_B$ is determined by the direction of I in the circuit.

SET UP: $F_B = IlB\sin\phi,$ with $\phi = 90°.\ I = \dfrac{V}{R},$ where V is the battery voltage.

EXECUTE: **(a)** The forces are shown in Figure 27.42. The current I in the bar must be to the right to produce $\vec{F}_B$ upward. To produce current in this direction, point a must be the positive terminal of the battery.

(b) $F_B = mg.\ \ IlB = mg.\ \ m = \dfrac{IlB}{g} = \dfrac{VlB}{Rg} = \dfrac{(175\ \text{V})(0.600\ \text{m})(1.50\ \text{T})}{(5.00\ \Omega)(9.80\ \text{m/s}^2)} = 3.21\ \text{kg}.$

EVALUATE: If the battery had opposite polarity, with point a as the negative terminal, then the current would be clockwise and the magnetic force would be downward.

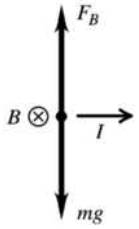

Figure 27.42

27.43. **IDENTIFY:** Apply $\vec{F} = I\vec{l} \times \vec{B}$ to each segment of the conductor: the straight section parallel to the x axis, the semicircular section and the straight section that is perpendicular to the plane of the figure in Example 27.8.

SET UP: $\vec{B} = B_x\hat{i}$. The force is zero when the current is along the direction of $\vec{B}$.

EXECUTE: **(a)** The force on the straight section along the $-x$-axis is zero. For the half of the semicircle at negative x the force is out of the page. For the half of the semicircle at positive x the force is into the page. The net force on the semicircular section is zero. The force on the straight section that is perpendicular to the plane of the figure is in the $-y$-direction and has magnitude $F = ILB$. The total magnetic force on the conductor is ILB in the $-y$-direction.

EVALUATE: **(b)** If the semicircular section is replaced by a straight section along the x-axis, then the magnetic force on that straight section would be zero, the same as it is for the semicircle.

27.44. **IDENTIFY:** $\tau = IAB\sin\phi.$ The magnetic moment of the loop is $\mu = IA.$

SET UP: Since the plane of the loop is parallel to the field, the field is perpendicular to the normal to the loop and $\phi = 90°$.

EXECUTE: **(a)** $\tau = IAB = (6.2\ \text{A})(0.050\ \text{m})(0.080\ \text{m})(0.19\ \text{T}) = 4.7\times10^{-3}\ \text{N}\cdot\text{m}$

(b) $\mu = IA = (6.2\ \text{A})(0.050\ \text{m})(0.080\ \text{m}) = 0.025\ \text{A}\cdot\text{m}^2$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(c) Maximum area is when the loop is circular. $R = \dfrac{0.050\text{ m} + 0.080\text{ m}}{\pi} = 0.0414\text{ m}$

$A = \pi R^2 = 5.38\times10^{-3}\text{ m}^2$ and $\tau = (6.2\text{ A})(5.38\times10^{-3}\text{ m}^2)(0.19\text{ T}) = 6.34\times10^{-3}\text{ N}\cdot\text{m}$

EVALUATE: The torque is a maximum when the field is in the plane of the loop and $\phi = 90°$.

27.45. **IDENTIFY:** The wire segments carry a current in an external magnetic field. Only segments *ab* and *cd* will experience a magnetic force since the other two segments carry a current parallel (and antiparallel) to the magnetic field. Only the force on segment *cd* will produce a torque about the hinge.

SET UP: $F = IlB\sin\phi$. The direction of the magnetic force is given by the right-hand rule applied to the directions of I and $\vec{\boldsymbol{B}}$. The torque due to a force equals the force times the moment arm, the perpendicular distance between the axis and the line of action of the force.

EXECUTE: **(a)** The direction of the magnetic force on each segment of the circuit is shown in Figure 27.45. For segments *bc* and *da* the current is parallel or antiparallel to the field and the force on these segments is zero.

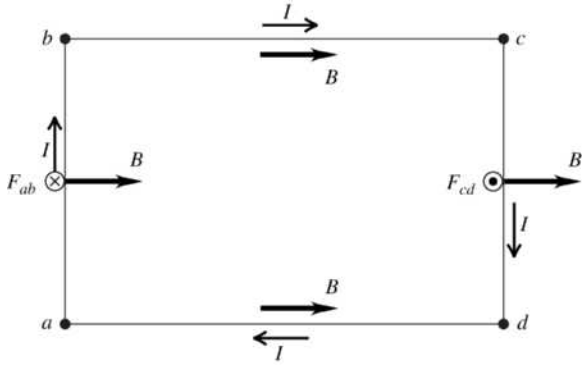

Figure 27.45

(b) $\vec{\boldsymbol{F}}_{ab}$ acts at the hinge and therefore produces no torque. $\vec{\boldsymbol{F}}_{cd}$ tends to rotate the loop about the hinge so it does produce a torque about this axis. $F_{cd} = IlB\sin\phi = (5.00\text{ A})(0.200\text{ m})(1.20\text{ T})\sin 90° = 1.20\text{ N}$

(c) $\tau = Fl = (1.20\text{ N})(0.350\text{ m}) = 0.420\text{ N}\cdot\text{m}$.

EVALUATE: The torque is directed so as to rotate side *cd* out of the plane of the page in Figure 27.45.

27.46. **IDENTIFY:** $\tau = IAB\sin\phi$, where ϕ is the angle between $\vec{\boldsymbol{B}}$ and the normal to the loop.

SET UP: The coil as viewed along the axis of rotation is shown in Figure 27.46a for its original position and in Figure 27.46b after it has rotated $30.0°$.

EXECUTE: **(a)** The forces on each side of the coil are shown in Figure 27.46a. $\vec{\boldsymbol{F}}_1 + \vec{\boldsymbol{F}}_2 = 0$ and $\vec{\boldsymbol{F}}_3 + \vec{\boldsymbol{F}}_4 = 0$. The net force on the coil is zero. $\phi = 0°$ and $\sin\phi = 0$, so $\tau = 0$. The forces on the coil produce no torque.

(b) The net force is still zero. $\phi = 30.0°$ and the net torque is $\tau = (1)(1.40\text{ A})(0.220\text{ m})(0.350\text{ m})(1.50\text{ T})\sin 30.0° = 0.0808\text{ N}\cdot\text{m}$. The net torque is clockwise in Figure 27.46b and is directed so as to increase the angle ϕ.

EVALUATE: For any current loop in a uniform magnetic field the net force on the loop is zero. The torque on the loop depends on the orientation of the plane of the loop relative to the magnetic field direction.

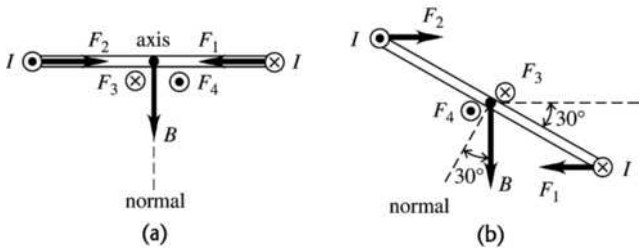

Figure 27.46

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

27.47. **IDENTIFY:** The magnetic field exerts a torque on the current-carrying coil, which causes it to turn. We can use the rotational form of Newton's second law to find the angular acceleration of the coil.

SET UP: The magnetic torque is given by $\vec{\boldsymbol{\tau}} = \vec{\boldsymbol{\mu}} \times \vec{\boldsymbol{B}}$, and the rotational form of Newton's second law is $\sum \tau = I\alpha$. The magnetic field is parallel to the plane of the loop.

EXECUTE: **(a)** The coil rotates about axis A_2 because the only torque is along top and bottom sides of the coil.

(b) To find the moment of inertia of the coil, treat the two 1.00-m segments as point-masses (since all the points in them are 0.250 m from the rotation axis) and the two 0.500-m segments as thin uniform bars rotated about their centers. Since the coil is uniform, the mass of each segment is proportional to its fraction of the total perimeter of the coil. Each 1.00-m segment is 1/3 of the total perimeter, so its mass is $(1/3)(210\ \text{g}) = 70\ \text{g} = 0.070\ \text{kg}$. The mass of each 0.500-m segment is half this amount, or 0.035 kg. The result is

$$I = 2(0.070\ \text{kg})(0.250\ \text{m})^2 + 2\tfrac{1}{12}(0.035\ \text{kg})(0.500\ \text{m})^2 = 0.0102\ \text{kg}\cdot\text{m}^2$$

The torque is

$$\left|\vec{\boldsymbol{\tau}}\right| = \left|\vec{\boldsymbol{\mu}} \times \vec{\boldsymbol{B}}\right| = IAB\sin 90° = (2.00\text{A})(0.500\text{m})(1.00\text{m})(3.00\text{T}) = 3.00\ \text{N}\cdot\text{m}$$

Using the above values, the rotational form of Newton's second law gives

$$\alpha = \frac{\tau}{I} = 290\ \text{rad/s}^2$$

EVALUATE: This angular acceleration will not continue because the torque changes as the coil turns.

27.48. **IDENTIFY:** $\vec{\boldsymbol{\tau}} = \vec{\boldsymbol{\mu}} \times \vec{\boldsymbol{B}}$ and $U = -\mu B\cos\phi$, where $\mu = NIB$. $\tau = \mu B\sin\phi$.

SET UP: ϕ is the angle between $\vec{\boldsymbol{B}}$ and the normal to the plane of the loop.

EXECUTE: **(a)** $\phi = 90°$. $\tau = NIAB\sin(90°) = NIAB$, direction $\hat{\boldsymbol{k}} \times \hat{\boldsymbol{j}} = -\hat{\boldsymbol{i}}$. $U = -\mu B\cos\phi = 0$.

(b) $\phi = 0$. $\tau = NIAB\sin(0) = 0$, no direction. $U = -\mu B\cos\phi = -NIAB$.

(c) $\phi = 90°$. $\tau = NIAB\sin(90°) = NIAB$, direction $-\hat{\boldsymbol{k}} \times \hat{\boldsymbol{j}} = \hat{\boldsymbol{i}}$. $U = -\mu B\cos\phi = 0$.

(d) $\phi = 180°$: $\tau = NIAB\sin(180°) = 0$, no direction, $U = -\mu B\cos(180°) = NIAB$.

EVALUATE: When τ is maximum, $U = 0$. When $|U|$ is maximum, $\tau = 0$.

27.49. **IDENTIFY** and **SET UP:** The potential energy is given by Eq. (27.27): $U = -\vec{\boldsymbol{\mu}} \cdot \vec{\boldsymbol{B}}$. The scalar product depends on the angle between $\vec{\boldsymbol{\mu}}$ and $\vec{\boldsymbol{B}}$.

EXECUTE: For $\vec{\boldsymbol{\mu}}$ and $\vec{\boldsymbol{B}}$ parallel, $\phi = 0°$ and $\vec{\boldsymbol{\mu}} \cdot \vec{\boldsymbol{B}} = \mu B\cos\phi = \mu B$. For $\vec{\boldsymbol{\mu}}$ and $\vec{\boldsymbol{B}}$ antiparallel, $\phi = 180°$ and $\vec{\boldsymbol{\mu}} \cdot \vec{\boldsymbol{B}} = \mu B\cos\phi = -\mu B$.

$U_1 = +\mu B$, $U_2 = -\mu B$

$\Delta U = U_2 - U_1 = -2\mu B = -2(1.45\ \text{A}\cdot\text{m}^2)(0.835\ \text{T}) = -2.42\ \text{J}$

EVALUATE: U is maximum when $\vec{\boldsymbol{\mu}}$ and $\vec{\boldsymbol{B}}$ are antiparallel and minimum when they are parallel. When the coil is rotated as specified its magnetic potential energy decreases.

27.50. **IDENTIFY:** Apply Eq. (27.29) in order to calculate I. The power drawn from the line is $P_{\text{supplied}} = IV_{ab}$. The mechanical power is the power supplied minus the I^2r electrical power loss in the internal resistance of the motor.

SET UP: $V_{ab} = 120\ \text{V}$, $\mathcal{E} = 105\ \text{V}$, and $r = 3.2\ \Omega$.

EXECUTE: **(a)** $V_{ab} = \mathcal{E} + Ir \Rightarrow I = \dfrac{V_{ab} - \mathcal{E}}{r} = \dfrac{120\ \text{V} - 105\ \text{V}}{3.2\ \Omega} = 4.7\ \text{A}$.

(b) $P_{\text{supplied}} = IV_{ab} = (4.7\ \text{A})(120\ \text{V}) = 564\ \text{W}$.

(c) $P_{\text{mech}} = IV_{ab} - I^2r = 564\ \text{W} - (4.7\ \text{A})^2(3.2\ \Omega) = 493\ \text{W}$.

EVALUATE: If the rotor isn't turning, when the motor is first turned on or if the rotor bearings fail, then $\mathcal{E} = 0$ and $I = \dfrac{120\text{V}}{3.2\ \Omega} = 37.5\ \text{A}$. This large current causes large I^2r heating and can trip the circuit breaker.

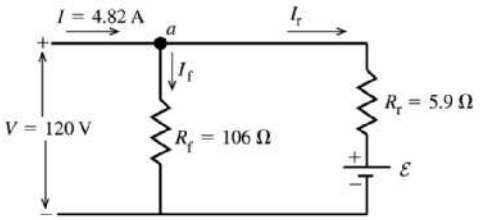
27.51. **IDENTIFY:** The circuit consists of two parallel branches with the potential difference of 120 V applied across each. One branch is the rotor, represented by a resistance R_r and an induced emf that opposes the applied potential. Apply the loop rule to each parallel branch and use the junction rule to relate the currents through the field coil and through the rotor to the 4.82 A supplied to the motor.
SET UP: The circuit is sketched in Figure 27.51.



$\mathcal{E}$ is the induced emf developed by the motor. It is directed so as to oppose the current through the rotor.

Figure 27.51

EXECUTE: **(a)** The field coils and the rotor are in parallel with the applied potential difference V, so $V = I_f R_f$. $I_f = \dfrac{V}{R_f} = \dfrac{120\text{ V}}{106\ \Omega} = 1.13\text{ A}$.

(b) Applying the junction rule to point a in the circuit diagram gives $I - I_f - I_r = 0$.

$I_r = I - I_f = 4.82\text{ A} - 1.13\text{ A} = 3.69\text{ A}$.

(c) The potential drop across the rotor, $I_r R_r + \mathcal{E}$, must equal the applied potential difference V: $V = I_r R_r + \mathcal{E}$

$\mathcal{E} = V - I_r R_r = 120\text{ V} - (3.69\text{ A})(5.9\ \Omega) = 98.2\text{ V}$

(d) The mechanical power output is the electrical power input minus the rate of dissipation of electrical energy in the resistance of the motor:
electrical power input to the motor
$P_{in} = IV = (4.82\text{ A})(120\text{ V}) = 578\text{ W}$
electrical power loss in the two resistances
$P_{loss} = I_f^2 R_f + I_r^2 R_r = (1.13\text{ A})^2(106\ \Omega) + (3.69\text{ A})^2(5.9\ \Omega) = 216\text{ W}$
mechanical power output
$P_{out} = P_{in} - P_{loss} = 578\text{ W} - 216\text{ W} = 362\text{ W}$
The mechanical power output is the power associated with the induced emf $\mathcal{E}$.
$P_{out} = P_{\mathcal{E}} = \mathcal{E} I_r = (98.2\text{ V})(3.69\text{ A}) = 362\text{ W}$, which agrees with the above calculation.

EVALUATE: The induced emf reduces the amount of current that flows through the rotor. This motor differs from the one described in Example 27.11. In that example the rotor and field coils are connected in series and in this problem they are in parallel.

27.52. **IDENTIFY:** The field and rotor coils are in parallel, so $V_{ab} = I_f R_f = \mathcal{E} + I_r R_r$ and $I = I_f + I_r$, where I is the current drawn from the line. The power input to the motor is $P = V_{ab} I$. The power output of the motor is the power input minus the electrical power losses in the resistances and friction losses.
SET UP: $V_{ab} = 120$ V. $I = 4.82$ A.

EXECUTE: **(a)** Field current $I_f = \dfrac{120\text{ V}}{218\ \Omega} = 0.550\text{ A}$.

(b) Rotor current $I_r = I_{total} - I_f = 4.82\text{ A} - 0.550\text{ A} = 4.27\text{ A}$.

(c) $V = \mathcal{E} + I_r R_r$ and $\mathcal{E} = V - I_r R_r = 120\text{ V} - (4.27\text{ A})(5.9\ \Omega) = 94.8\text{ V}$.

(d) $P_f = I_f^2 R_f = (0.550\text{ A})^2(218\ \Omega) = 65.9\text{ W}$.

(e) $P_r = I_r^2 R_r = (4.27\text{ A})^2(5.9\ \Omega) = 108\text{ W}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

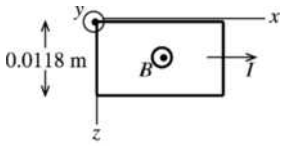
(f) Power input $= (120\text{ V})(4.82\text{ A}) = 578\text{ W}$.

(g) Efficiency $= \dfrac{P_{\text{output}}}{P_{\text{input}}} = \dfrac{(578\text{ W} - 65.9\text{ W} - 108\text{ W} - 45\text{ W})}{578\text{ W}} = \dfrac{359\text{ W}}{578\text{ W}} = 0.621.$

EVALUATE: I^2R losses in the resistance of the rotor and field coils are larger than the friction losses for this motor.

27.53. **IDENTIFY:** The drift velocity is related to the current density by Eq. (25.4). The electric field is determined by the requirement that the electric and magnetic forces on the current-carrying charges are equal in magnitude and opposite in direction.

(a) SET UP: The section of the silver ribbon is sketched in Figure 27.53a.



$J_x = n|q|v_{\text{d}}$

so $v_{\text{d}} = \dfrac{J_x}{n|q|}$

Figure 27.53a

EXECUTE: $J_x = \dfrac{I}{A} = \dfrac{I}{y_1 z_1} = \dfrac{120\text{ A}}{(0.23\times10^{-3}\text{ m})(0.0118\text{ m})} = 4.42\times10^{7}\text{ A/m}^2$

$$v_{\text{d}} = \frac{J_x}{n|q|} = \frac{4.42\times10^{7}\text{ A/m}^2}{(5.85\times10^{28}/\text{m}^3)(1.602\times10^{-19}\text{ C})} = 4.7\times10^{-3}\text{ m/s} = 4.7\text{ mm/s}$$

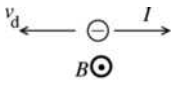
(b) magnitude of $\vec{E}$

$|q|E_z = |q|v_{\text{d}}B_y$

$E_z = v_{\text{d}}B_y = (4.7\times10^{-3}\text{ m/s})(0.95\text{ T}) = 4.5\times10^{-3}\text{ V/m}$

direction of $\vec{E}$

The drift velocity of the electrons is in the opposite direction to the current, as shown in Figure 27.53b.



$\vec{v}\times\vec{B}\uparrow$

$\vec{F}_B = q\vec{v}\times\vec{B} = -e\vec{v}\times\vec{B}\downarrow$

Figure 27.53b

The directions of the electric and magnetic forces on an electron in the ribbon are shown in Figure 27.53c.

$\vec{F}_E$ must oppose $\vec{F}_B$ so $\vec{F}_E$ is in the $-z$-direction.

Figure 27.53c

$\vec{F}_E = q\vec{E} = -e\vec{E}$ so $\vec{E}$ is opposite to the direction of $\vec{F}_E$ and thus $\vec{E}$ is in the $+z$-direction.

(c) The Hall emf is the potential difference between the two edges of the strip (at $z = 0$ and $z = z_1$) that results from the electric field calculated in part (b). $\mathcal{E}_{\text{Hall}} = Ez_1 = (4.5\times10^{-3}\text{ V/m})(0.0118\text{ m}) = 53\,\mu\text{V}$.

EVALUATE: Even though the current is quite large the Hall emf is very small. Our calculated Hall emf is more than an order of magnitude larger than in Example 27.12. In this problem the magnetic field and current density are larger than in the example, and this leads to a larger Hall emf.

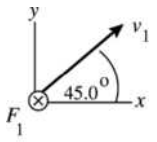
© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

27.54. **IDENTIFY:** Apply Eq. (27.30).
SET UP: $A = y_1 z_1$. $E = \mathcal{E}/z_1$. $|q| = e$.
EXECUTE: $n = \dfrac{J_x B_y}{|q|E_z} = \dfrac{IB_y}{A|q|E_z} = \dfrac{IB_y z_1}{A|q|\mathcal{E}} = \dfrac{IB_y}{y_1|q|\mathcal{E}}$

$$n = \frac{(78.0\text{ A})(2.29\text{ T})}{(2.3\times10^{-4}\text{ m})(1.6\times10^{-19}\text{ C})(1.31\times10^{-4}\text{ V})} = 3.7\times10^{28}\text{ electrons/m}^3$$

EVALUATE: The value of n for this metal is about one-third the value of n calculated in Example 27.12 for copper.

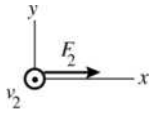
27.55. **(a) IDENTIFY:** Use Eq. (27.2) to relate $\vec{v}$, $\vec{B}$ and $\vec{F}$.
SET UP: The directions of $\vec{v}_1$ and $\vec{F}_1$ are shown in Figure 27.55a.



$\vec{F} = q\vec{v}\times\vec{B}$ says that $\vec{F}$ is perpendicular to $\vec{v}$ and $\vec{B}$. The information given here means that $\vec{B}$ can have no z-component.

Figure 27.55a

The directions of $\vec{v}_2$ and $\vec{F}_2$ are shown in Figure 27.55b.



$\vec{F}$ is perpendicular to $\vec{v}$ and $\vec{B}$, so $\vec{B}$ can have no x-component.

Figure 27.55b

Both pieces of information taken together say that $\vec{B}$ is in the y-direction; $\vec{B} = B_y\hat{j}$.
EXECUTE: Use the information given about $\vec{F}_2$ to calculate B_y: $\vec{F}_2 = F_2\hat{i}$, $\vec{v}_2 = v_2\hat{k}$, $\vec{B} = B_y\hat{j}$.
$\vec{F}_2 = q\vec{v}_2\times\vec{B}$ says $F_2\hat{i} = qv_2B_y\hat{k}\times\hat{j} = qv_2B_y(-\hat{i})$ and $F_2 = -qv_2B_y$
$B_y = -F_2/(qv_2) = -F_2/(qv_1)$. $\vec{B}$ has the magnitude $F_2/(qv_1)$ and is in the $-y$-direction.
(b) $F_1 = qvB\sin\phi = qv_1|B_y|/\sqrt{2} = F_2/\sqrt{2}$
EVALUATE: $v_1 = v_2$. $\vec{v}_2$ is perpendicular to $\vec{B}$ whereas only the component of $\vec{v}_1$ perpendicular to $\vec{B}$ contributes to the force, so it is expected that $F_2 > F_1$, as we found.

27.56. **IDENTIFY:** Apply $\vec{F} = q\vec{v}\times\vec{B}$.
SET UP: $B_x = 0.650$ T. $B_y = 0$ and $B_z = 0$.
EXECUTE: $F_x = q(v_yB_z - v_zB_y) = 0$.
$F_y = q(v_zB_x - v_xB_z) = (9.45\times10^{-8}\text{ C})(5.85\times10^4\text{ m/s})(0.650\text{ T}) = 3.59\times10^{-3}$ N.
$F_z = q(v_xB_y - v_yB_x) = -(9.45\times10^{-8}\text{ C})(-3.11\times10^4\text{ m/s})(0.650\text{ T}) = 1.91\times10^{-3}$ N.
EVALUATE: $\vec{F}$ is perpendicular to both $\vec{v}$ and $\vec{B}$. We can verify that $\vec{F}\cdot\vec{v} = 0$. Since $\vec{B}$ is along the x-axis, v_x does not affect the force components.

27.57. **IDENTIFY:** In part (a), apply conservation of energy to the motion of the two nuclei. In part (b) apply $|q|vB = mv^2/R$.
SET UP: In part (a), let point 1 be when the two nuclei are far apart and let point 2 be when they are at their closest separation.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: **(a)** $K_1+U_1=K_2+U_2$. $U_1=K_2=0$, so $K_1=U_2$. There are two nuclei having equal kinetic energy, so $\frac{1}{2}mv^2+\frac{1}{2}mv^2=ke^2/r$. Solving for v gives

$$v=e\sqrt{\frac{k}{mr}}=(1.602\times10^{-19}\text{ C})\sqrt{\frac{8.99\times10^{9}\text{ N}\cdot\text{m}^2/\text{C}^2}{(3.34\times10^{-27}\text{ kg})(1.0\times10^{-15}\text{ m})}}=8.3\times10^{6}\text{ m/s}.$$

(b) $\sum\vec{F}=m\vec{a}$ gives $qvB=mv^2/r$. $B=\dfrac{mv}{qr}=\dfrac{(3.34\times10^{-27}\text{ kg})(8.3\times10^{6}\text{ m/s})}{(1.602\times10^{-19}\text{ C})(1.25\text{ m})}=0.14\text{ T}.$

EVALUATE: The speed calculated in part (a) is large, nearly 3% of the speed of light.

27.58. **IDENTIFY:** The period is $T=2\pi r/v$, the current is Q/t and the magnetic moment is $\mu=IA$.

SET UP: The electron has charge $-e$. The area enclosed by the orbit is πr^2.

EXECUTE: **(a)** $T=2\pi r/v=1.5\times10^{-16}$ s

(b) Charge $-e$ passes a point on the orbit once during each period, so $I=Q/t=e/t=1.1$ mA.

(c) $\mu=IA=I\pi r^2=9.3\times10^{-24}\text{ A}\cdot\text{m}^2$

EVALUATE: Since the electron has negative charge, the direction of the current is opposite to the direction of motion of the electron.

27.59. **IDENTIFY:** The sum of the magnetic, electrical and gravitational forces must be zero to aim at and hit the target.

SET UP: The magnetic field must point to the left when viewed in the direction of the target for no net force. The net force is zero, so $\sum F=F_B-F_E-mg=0$ and $qvB-qE-mg=0$.

EXECUTE: Solving for B gives

$$B=\frac{qE+mg}{qv}=\frac{(2500\times10^{-6}\text{ C})(27.5\text{ N/C})+(0.00425\text{ kg})(9.80\text{ m/s}^2)}{(2500\times10^{-6}\text{ C})(12.8\text{ m/s})}=3.45\text{ T}$$

The direction should be perpendicular to the initial velocity of the coin.

EVALUATE: This is a very strong magnetic field, but achievable in some labs.

27.60. **IDENTIFY:** Apply $R=mv/|q|B$. $\omega=v/R$

SET UP: $1\text{ eV}=1.60\times10^{-19}$ J

EXECUTE: **(a)** $K=2.7\text{ MeV}=(2.7\times10^{6}\text{ eV})(1.6\times10^{-19}\text{ J/eV})=4.32\times10^{-13}$ J.

$$v=\sqrt{\frac{2K}{m}}=\sqrt{\frac{2(4.32\times10^{-13}\text{ J})}{1.67\times10^{-27}\text{ kg}}}=2.27\times10^{7}\text{ m/s}.$$

$$R=\frac{mv}{qB}=\frac{(1.67\times10^{-27}\text{ kg})(2.27\times10^{7}\text{ m/s})}{(1.6\times10^{-19}\text{ C})(2.9\text{ T})}=0.082\text{ m}.\text{ Also, }\omega=\frac{v}{R}=\frac{2.27\times10^{7}\text{ m/s}}{0.082\text{ m}}=2.8\times10^{8}\text{ rad/s}.$$

(b) If the energy reaches the final value of 5.4 MeV, the velocity increases by $\sqrt{2}$, as does the radius, to 0.12 m. The angular frequency is unchanged from part (a) so is 2.8×10^{8} rad/s.

EVALUATE: $\omega=|q|B/m$, so ω is independent of the energy of the protons. The orbit radius increases when the energy of the proton increases.

27.61. **(a) IDENTIFY** and **SET UP:** The maximum radius of the orbit determines the maximum speed v of the protons. Use Newton's second law and $a_{\text{rad}}=v^2/R$ for circular motion to relate the variables. The energy of the particle is the kinetic energy $K=\frac{1}{2}mv^2$.

EXECUTE: $\sum\vec{F}=m\vec{a}$ gives $|q|vB=m(v^2/R)$

$$v=\frac{|q|BR}{m}=\frac{(1.60\times10^{-19}\text{ C})(0.85\text{ T})(0.40\text{ m})}{1.67\times10^{-27}\text{ kg}}=3.257\times10^{7}\text{ m/s}.$$ The kinetic energy of a proton moving with this speed is $K=\frac{1}{2}mv^2=\frac{1}{2}(1.67\times10^{-27}\text{ kg})(3.257\times10^{7}\text{ m/s})^2=8.9\times10^{-13}\text{ J}=5.5\text{ MeV}$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) The time for one revolution is the period $T = \dfrac{2\pi R}{v} = \dfrac{2\pi(0.40\text{ m})}{3.257\times10^7\text{ m/s}} = 7.7\times10^{-8}$ s.

(c) $K = \frac{1}{2}mv^2 = \frac{1}{2}m\left(\dfrac{|q|BR}{m}\right)^2 = \frac{1}{2}\dfrac{|q|^2B^2R^2}{m}$. Or, $B = \dfrac{\sqrt{2Km}}{|q|R}$. B is proportional to $\sqrt{K}$, so if K is increased by a factor of 2 then B must be increased by a factor of $\sqrt{2}$. $B = \sqrt{2}(0.85\text{ T}) = 1.2$ T.

(d) $v = \dfrac{|q|BR}{m} = \dfrac{(3.20\times10^{-19}\text{ C})(0.85\text{ T})(0.40\text{ m})}{6.65\times10^{-27}\text{ kg}} = 1.636\times10^7$ m/s

$K = \frac{1}{2}mv^2 = \frac{1}{2}(6.65\times10^{-27}\text{ kg})(1.636\times10^7\text{ m/s})^2 = 8.9\times10^{-13}\text{ J} = 5.5\text{ MeV}$, the same as the maximum energy for protons.

EVALUATE: We can see that the maximum energy must be approximately the same as follows: From part (c), $K = \frac{1}{2}m\left(\dfrac{|q|BR}{m}\right)^2$. For alpha particles $|q|$ is larger by a factor of 2 and m is larger by a factor of 4 (approximately). Thus $|q|^2/m$ is unchanged and K is the same.

27.62. **IDENTIFY:** Apply $\vec{F} = q\vec{v}\times\vec{B}$.

SET UP: $\vec{v} = -v\hat{j}$

EXECUTE: **(a)** $\vec{F} = -qv[B_x(\hat{j}\times\hat{i}) + B_y(\hat{j}\times\hat{j}) + B_z(\hat{j}\times\hat{k})] = qvB_x\hat{k} - qvB_z\hat{i}$

(b) $B_x > 0$, $B_z < 0$, sign of B_y doesn't matter.

(c) $\vec{F} = |q|vB_x\hat{i} - |q|vB_x\hat{k}$ and $|\vec{F}| = \sqrt{2}|q|vB_x$.

EVALUATE: $\vec{F}$ is perpendicular to $\vec{v}$, so $\vec{F}$ has no y-component.

27.63. **IDENTIFY** and **SET UP:** Use Eq. (27.2) to relate q, $\vec{v}$, $\vec{B}$ and $\vec{F}$. The force $\vec{F}$ and $\vec{a}$ are related by Newton's second law. $\vec{B} = -(0.120\text{ T})\hat{k}$, $\vec{v} = (1.05\times10^6\text{ m/s})(-3\hat{i} + 4\hat{j} + 12\hat{k})$, $F = 2.45$ N.

(a) EXECUTE: $\vec{F} = q\vec{v}\times\vec{B}$. $\vec{F} = q(-0.120\text{ T})(1.05\times10^6\text{ m/s})(-3\hat{i}\times\hat{k} + 4\hat{j}\times\hat{k} + 12\hat{k}\times\hat{k})$

$\hat{i}\times\hat{k} = -\hat{j}$, $\hat{j}\times\hat{k} = \hat{i}$, $\hat{k}\times\hat{k} = 0$. $\vec{F} = -q(1.26\times10^5\text{ N/C})(+3\hat{j} + 4\hat{i}) = -q(1.26\times10^5\text{ N/C})(+4\hat{i} + 3\hat{j})$. The magnitude of the vector $+4\hat{i} + 3\hat{j}$ is $\sqrt{3^2 + 4^2} = 5$. Thus $F = -q(1.26\times10^5\text{ N/C})(5)$.

$$q = -\frac{F}{5(1.26\times10^5\text{ N/C})} = -\frac{2.45\text{ N}}{5(1.26\times10^5\text{ N/C})} = -3.89\times10^{-6}\text{ C}.$$

(b) $\Sigma\vec{F} = m\vec{a}$ so $\vec{a} = \vec{F}/m$.

$\vec{F} = -q(1.26\times10^5\text{ N/C})(+4\hat{i} + 3\hat{j}) = -(-3.89\times10^{-6}\text{ C})(1.26\times10^5\text{ N/C})(+4\hat{i} + 3\hat{j}) = +0.490\text{ N}(+4\hat{i} + 3\hat{j})$.

Then

$$\vec{a} = \vec{F}/m = \left(\frac{0.490\text{ N}}{2.58\times10^{-15}\text{ kg}}\right)(+4\hat{i} + 3\hat{j}) = (1.90\times10^{14}\text{ m/s}^2)(+4\hat{i} + 3\hat{j}) = 7.60\times10^{14}\text{ m/s}^2\hat{i} + 5.70\times10^{14}\text{ m/s}^2\hat{j}.$$

(c) IDENTIFY and **SET UP:** $\vec{F}$ is in the xy-plane, so in the z-direction the particle moves with constant speed 12.6×10^6 m/s. In the xy-plane the force $\vec{F}$ causes the particle to move in a circle, with $\vec{F}$ directed in toward the center of the circle.

EXECUTE: $\sum\vec{F} = m\vec{a}$ gives $F = m(v^2/R)$ and $R = mv^2/F$.

$v^2 = v_x^2 + v_y^2 = (-3.15\times10^6\text{ m/s})^2 + (+4.20\times10^6\text{ m/s})^2 = 2.756\times10^{13}\text{ m}^2/\text{s}^2$.

$F = \sqrt{F_x^2 + F_y^2} = (0.490\text{ N})\sqrt{4^2 + 3^2} = 2.45$ N.

$$R = \frac{mv^2}{F} = \frac{(2.58\times10^{-15}\text{ kg})(2.756\times10^{13}\text{ m}^2/\text{s}^2)}{2.45\text{ N}} = 0.0290\text{ m} = 2.90\text{ cm}.$$

(d) IDENTIFY and **SET UP:** By Eq. (27.12) the cyclotron frequency is $f = \omega/2\pi = v/2\pi R$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: The circular motion is in the *xy*-plane, so $v=\sqrt{v_x^2+v_y^2}=5.25\times10^6$ m/s.

$f=\dfrac{v}{2\pi R}=\dfrac{5.25\times10^6\text{ m/s}}{2\pi(0.0290\text{ m})}=2.88\times10^7$ Hz, and $\omega=2\pi f=1.81\times10^8$ rad/s.

(e) IDENTIFY and **SET UP:** Compare t to the period T of the circular motion in the *xy*-plane to find the x and y coordinates at this t. In the z-direction the particle moves with constant speed, so $z=z_0+v_zt$.

EXECUTE: The period of the motion in the *xy*-plane is given by $T=\dfrac{1}{f}=\dfrac{1}{2.88\times10^7\text{ Hz}}=3.47\times10^{-8}$ s. In $t=2T$ the particle has returned to the same x and y coordinates. The z-component of the motion is motion with a constant velocity of $v_z=+12.6\times10^6$ m/s. Thus

$z=z_0+v_zt=0+(12.6\times10^6\text{ m/s})(2)(3.47\times10^{-8}\text{ s})=+0.874$ m. The coordinates at $t=2T$ are $x=R=0.0290$ m, $y=0$, $z=+0.874$ m.

EVALUATE: The circular motion is in the plane perpendicular to $\vec{\boldsymbol{B}}$. The radius of this motion gets smaller when B increases and it gets larger when v increases. There is no magnetic force in the direction of $\vec{\boldsymbol{B}}$ so the particle moves with constant velocity in that direction. The superposition of circular motion in the *xy*-plane and constant speed motion in the z-direction is a helical path.

27.64. **IDENTIFY:** We know the radius of the proton's path and its kinetic energy, and we want to find the speed of the proton and the magnetic field necessary to bend it in a circle of circumference 6.4 km.

SET UP: $1\text{ eV}=1.60\times10^{-19}$ J. The kinetic energy of the proton is $K=\frac{1}{2}mv^2$ and its mass is 1.67×10^{-27} kg. The radius of the proton's path is $R=\dfrac{mv}{|q|B}$. The radius R is related to the circumference C by $C=2\pi R$.

EXECUTE: **(a)** $K=1.25\text{ MeV}=(1.25\times10^6\text{ eV})\left(\dfrac{1.60\times10^{-19}\text{ J}}{1\text{ eV}}\right)=2.00\times10^{-13}$ J. $K=\frac{1}{2}mv^2$ gives

$v=\sqrt{\dfrac{2K}{m}}=\sqrt{\dfrac{2(2.00\times10^{-13}\text{ J})}{1.67\times10^{-27}\text{ kg}}}=1.55\times10^7$ m/s.

(b) $R=\dfrac{mv}{|q|B}$ gives $B=\dfrac{mv}{|q|R}$. $R=\dfrac{C}{2\pi}=\dfrac{6.4\times10^3\text{ m}}{2\pi}=1.02\times10^3$ m.

$B=\dfrac{(1.67\times10^{-27}\text{ kg})(1.55\times10^7\text{ m/s})}{(1.60\times10^{-19}\text{ C})(1.02\times10^3\text{ m})}=1.59\times10^{-4}$ T.

EVALUATE: The speed is about 5% the speed of light, so we need not worry about special relativity. The magnetic field is quite small by laboratory standards, so should be readily attainable.

27.65. **IDENTIFY:** $\tau=NIAB\sin\phi$.

SET UP: The area A is related to the diameter D by $A=\frac{1}{4}\pi D^2$.

EXECUTE: $\tau=NI(\frac{1}{4}\pi D^2)B\sin\phi$. τ is proportional to D^2. Increasing D by a factor of 3 increases τ by a factor of $3^2=9$.

EVALUATE: The larger diameter means larger length of wire in the loop and also larger moment arms because parts of the loop are farther from the axis.

27.66. **IDENTIFY:** Apply $\vec{\boldsymbol{F}}=q\vec{\boldsymbol{v}}\times\vec{\boldsymbol{B}}$.

SET UP: $\vec{\boldsymbol{v}}=v\hat{\boldsymbol{k}}$

EXECUTE: **(a)** $\vec{\boldsymbol{F}}=-qvB_y\hat{\boldsymbol{i}}+qvB_x\hat{\boldsymbol{j}}$. But $\vec{\boldsymbol{F}}=3F_0\hat{\boldsymbol{i}}+4F_0\hat{\boldsymbol{j}}$, so $3F_0=-qvB_y$ and $4F_0=qvB_x$.

Therefore, $B_y=-\dfrac{3F_0}{qv}$, $B_x=\dfrac{4F_0}{qv}$ and B_z is undetermined.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) $B=\dfrac{6F_0}{qv}=\sqrt{B_x^2+B_y^2+B_z^2}=\dfrac{F_0}{qv}\sqrt{9+16+\left(\dfrac{qv}{F_0}\right)^2 B_z^2}=\dfrac{F_0}{qv}\sqrt{25+\left(\dfrac{qv}{F_0}\right)^2 B_z^2}$, so $B_z=\pm\dfrac{\sqrt{11}F_0}{qv}$.

EVALUATE: The force doesn't depend on B_z, since $\vec{v}$ is along the z-direction.

27.67. **IDENTIFY:** For the velocity selector, $E=vB$. For circular motion in the field B', $R=\dfrac{mv}{|q|B'}$.

SET UP: $B=B'=0.682$ T.

EXECUTE: $v=\dfrac{E}{B}=\dfrac{1.88\times10^4 \text{ N/C}}{0.682 \text{ T}}=2.757\times10^4$ m/s. $R=\dfrac{mv}{qB'}$, so

$$R_{82}=\frac{82(1.66\times10^{-27}\text{ kg})(2.757\times10^4\text{ m/s})}{(1.60\times10^{-19}\text{ C})(0.682\text{ T})}=0.0344\text{ m}=3.44\text{ cm}.$$

$$R_{84}=\frac{84(1.66\times10^{-27}\text{ kg})(2.757\times10^4\text{ m/s})}{(1.60\times10^{-19}\text{ C})(0.682\text{ T})}=0.0352\text{ m}=3.52\text{ cm}.$$

$$R_{86}=\frac{86(1.66\times10^{-27}\text{ kg})(2.757\times10^4\text{ m/s})}{(1.60\times10^{-19}\text{ C})(0.682\text{ T})}=0.0361\text{ m}=3.61\text{ cm}.$$

The distance between two adjacent lines is $2\Delta R=2(3.52\text{ cm}-3.44\text{ cm})=0.16\text{ cm}=1.6\text{ mm}$.

EVALUATE: The distance between the ^{82}Kr line and the ^{84}Kr line is 1.6 mm and the distance between the ^{84}Kr line and the ^{86}Kr line is 1.6 mm. Adjacent lines are equally spaced since the ^{82}Kr versus ^{84}Kr and ^{84}Kr versus ^{86}Kr mass differences are the same.

27.68. **IDENTIFY:** Apply conservation of energy to the acceleration of the ions and Newton's second law to their motion in the magnetic field.

SET UP: The singly ionized ions have $q=+e$. A ^{12}C ion has mass 12 u and a ^{14}C ion has mass 14 u, where $1\text{ u}=1.66\times10^{-27}$ kg.

EXECUTE: **(a)** During acceleration of the ions, $qV=\frac{1}{2}mv^2$ and $v=\sqrt{\dfrac{2qV}{m}}$. In the magnetic field,

$R=\dfrac{mv}{qB}=\dfrac{m\sqrt{2qV/m}}{qB}$ and $m=\dfrac{qB^2R^2}{2V}$.

(b) $V=\dfrac{qB^2R^2}{2m}=\dfrac{(1.60\times10^{-19}\text{ C})(0.150\text{ T})^2(0.500\text{ m})^2}{2(12)(1.66\times10^{-27}\text{ kg})}=2.26\times10^4$ V

(c) The ions are separated by the differences in the diameters of their paths. $D=2R=2\sqrt{\dfrac{2Vm}{qB^2}}$, so

$$\Delta D=D_{14}-D_{12}=2\sqrt{\frac{2Vm}{qB^2}}\bigg|_{14}-2\sqrt{\frac{2Vm}{qB^2}}\bigg|_{12}=2\sqrt{\frac{2V(1\text{ u})}{qB^2}}(\sqrt{14}-\sqrt{12}).$$

$\Delta D=2\sqrt{\dfrac{2(2.26\times10^4\text{ V})(1.66\times10^{-27}\text{ kg})}{(1.6\times10^{-19}\text{ C})(0.150\text{ T})^2}}(\sqrt{14}-\sqrt{12})=8.01\times10^{-2}$ m. This is about 8 cm and is easily distinguishable.

EVALUATE: The speed of the ^{12}C ion is $v=\sqrt{\dfrac{2(1.60\times10^{-19}\text{ C})(2.26\times10^4\text{V})}{12(1.66\times10^{-27}\text{ kg})}}=6.0\times10^5$ m/s. This is very fast, but well below the speed of light, so relativistic mechanics is not needed.

27.69. **IDENTIFY:** The force exerted by the magnetic field is given by Eq. (27.19). The net force on the wire must be zero.

SET UP: For the wire to remain at rest the force exerted on it by the magnetic field must have a component directed up the incline. To produce a force in this direction, the current in the wire must be

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

directed from right to left in Figure P27.69 in the textbook. Or, viewing the wire from its left-hand end the directions are shown in Figure 27.69a.

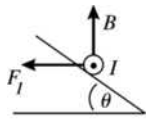


Figure 27.69a

The free-body diagram for the wire is given in Figure 27.69b.

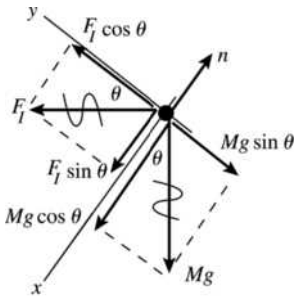

Figure 27.69b

EXECUTE: $\sum F_y = 0$

$F_I \cos\theta - Mg\sin\theta = 0$

$F_I = ILB\sin\phi$

$\phi = 90°$ since $\vec{\boldsymbol{B}}$ is perpendicular to the current direction.

Thus $(ILB)\ \cos\theta - Mg\sin\theta = 0$ and $I = \dfrac{Mg\tan\theta}{LB}$.

EVALUATE: The magnetic and gravitational forces are in perpendicular directions so their components parallel to the incline involve different trig functions. As the tilt angle θ increases there is a larger component of Mg down the incline and the component of F_I up the incline is smaller; I must increase with θ to compensate. As $\theta \to 0$, $I \to 0$ and as $\theta \to 90°$, $I \to \infty$.

27.70. **IDENTIFY:** The current in the bar is downward, so the magnetic force on it is vertically upwards. The net force on the bar is equal to the magnetic force minus the gravitational force, so Newton's second law gives the acceleration. The bar is in parallel with the 10.0-Ω resistor, so we must use circuit analysis to find the initial current through it.

SET UP: First find the current. The equivalent resistance across the battery is $30.0\ \Omega$, so the total current is $4.00\,\text{A}$, half of which goes through the bar. Applying Newton's second law to the bar gives $\sum F = ma = F_B - mg = ILB - mg$.

EXECUTE: Equivalent resistance of the $10.0\text{-}\Omega$ resistor and the bar is $5.0\,\Omega$. Current through the $25.0\text{-}\Omega$ resistor is $I_{\text{tot}} = \dfrac{120.0\ \text{V}}{30.0\,\Omega} = 4.00\ \text{A}$. The current in the bar is 2.00 A, toward the bottom of the page. The force $\vec{\boldsymbol{F}}_I$ that the magnetic field exerts on the bar has magnitude $F_I = IlB$ and is directed to the right. $a = \dfrac{F_I}{m} = \dfrac{IlB}{m} = \dfrac{(2.00\ \text{A})(1.50\ \text{m})(1.60\ \text{T})}{(2.60\ \text{N})/(9.80\text{m/s}^2)} = 18.1\ \text{m/s}^2$. $\vec{\boldsymbol{a}}$ is directed to the right.

EVALUATE: Once the bar has acquired a non-zero speed there will be an induced emf (Chapter 29) and the current and acceleration will start to decrease.

27.71. **IDENTIFY:** Eq. (27.8) says that the magnetic field through any closed surface is zero.

SET UP: The cylindrical Gaussian surface has its top at $z = L$ and its bottom at $z = 0$. The rest of the surface is the curved portion of the cylinder and has radius r and length L. $B = 0$ at the bottom of the surface, since $z = 0$ there.

EXECUTE: **(a)** $\vec{\boldsymbol{B}} \cdot d\vec{\boldsymbol{A}} = \int_{\text{top}} B_z dA + \int_{\text{curved}} B_r dA = \int_{\text{top}} (\beta L) dA + \int_{\text{curved}} B_r dA = 0$. This gives $0 = \beta L \pi r^2 + B_r 2\pi r L$,

and $B_r(r) = -\dfrac{\beta r}{2}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) The two diagrams in Figure 27.71 show views of the field lines from the top and side of the Gaussian surface.

EVALUATE: Only a portion of each field line is shown; the field lines are closed loops.

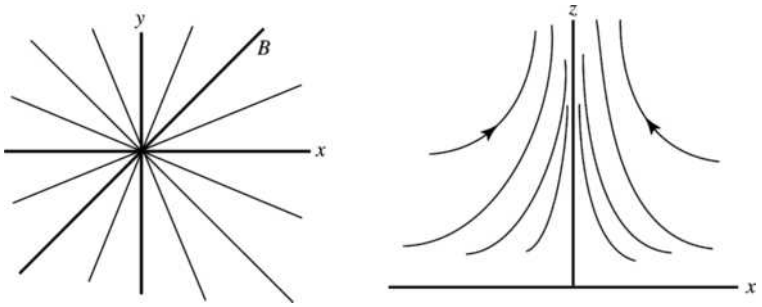

Figure 27.71

27.72. **IDENTIFY:** Turning the charged loop creates a current, and the external magnetic field exerts a torque on that current.

SET UP: The current is $I = q/T = q/(1/f) = qf = q(\omega/2\pi) = q\omega/2\pi$. The torque is $\tau = \mu B \sin\phi$.

EXECUTE: In this case, $\phi = 90°$ and $\mu = AB$, giving $\tau = IAB$. Combining the results for the torque and current and using $A = \pi r^2$ gives $\tau = \left(\frac{q\omega}{2\pi}\right)\pi r^2 B = \frac{1}{2}q\omega r^2 B$.

EVALUATE: Any moving charge is a current, so turning the loop creates a current causing a magnetic force.

27.73. **IDENTIFY:** $R = \dfrac{mv}{|q|B}$.

SET UP: After completing one semicircle the separation between the ions is the difference in the diameters of their paths, or $2(R_{13} - R_{12})$. A singly ionized ion has charge $+e$.

EXECUTE: **(a)** $B = \dfrac{mv}{|q|R} = \dfrac{(1.99\times10^{-26}\text{ kg})(8.50\times10^{3}\text{ m/s})}{(1.60\times10^{-19}\text{ C})(0.125\text{ m})} = 8.46\times10^{-3}\text{ T}$.

(b) The only difference between the two isotopes is their masses. $\dfrac{R}{m} = \dfrac{v}{|q|B} = \text{constant}$ and $\dfrac{R_{12}}{m_{12}} = \dfrac{R_{13}}{m_{13}}$.

$R_{13} = R_{12}\left(\dfrac{m_{13}}{m_{12}}\right) = (12.5\text{ cm})\left(\dfrac{2.16\times10^{-26}\text{ kg}}{1.99\times10^{-26}\text{ kg}}\right) = 13.6\text{ cm}$. The diameter is 27.2 cm.

(c) The separation is $2(R_{13} - R_{12}) = 2(13.6\text{ cm} - 12.5\text{ cm}) = 2.2\text{ cm}$. This distance can be easily observed.

EVALUATE: Decreasing the magnetic field increases the separation between the two isotopes at the detector.

27.74. **IDENTIFY:** The force exerted by the magnetic field is $F = ILB\sin\phi$. $a = F/m$ and is constant. Apply a constant acceleration equation to relate v and d.

SET UP: $\phi = 90°$. The direction of $\vec{F}$ is given by the right-hand rule.

EXECUTE: **(a)** $F = ILB$, to the right.

(b) $v_x^2 = v_{0x}^2 + 2a_x(x - x_0)$ gives $v^2 = 2ad$ and $d = \dfrac{v^2}{2a} = \dfrac{v^2 m}{2ILB}$.

(c) $d = \dfrac{(1.12\times10^{4}\text{ m/s})^2(25\text{ kg})}{2(2000\text{ A})(0.50\text{ m})(0.80\text{ T})} = 1.96\times10^{6}\text{ m} = 1960\text{ km}$.

EVALUATE: $a = \dfrac{ILB}{m} = \dfrac{(2.0\times10^{3}\text{ A})(0.50\text{ m})(0.80\text{ T})}{25\text{ kg}} = 32\text{ m/s}^2$. The acceleration due to gravity is not negligible. Since the bar would have to travel nearly 2000 km, this would not be a very effective launch mechanism using the numbers given.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

27.75. **IDENTIFY:** Apply $F = IlB\sin\phi$ to calculate the force on each segment of the wire that is in the magnetic field. The net force is the vector sum of the forces on each segment.

SET UP: The direction of the magnetic force on each current segment in the field is shown in Figure 27.75. By symmetry, $F_a = F_b$. $\vec{F}_a$ and $\vec{F}_b$ are in opposite directions so their vector sum is zero. The net force equals F_c. For F_c, $\phi = 90°$ and $l = 0.450$ m.

EXECUTE: $F_c = IlB = (6.00\text{ A})(0.450\text{ m})(0.666\text{ T}) = 1.80$ N. The net force is 1.80 N, directed to the left.

EVALUATE: The shape of the region of uniform field doesn't matter, as long as all of segment *c* is in the field and as long as the lengths of the portions of segments *a* and *b* that are in the field are the same.

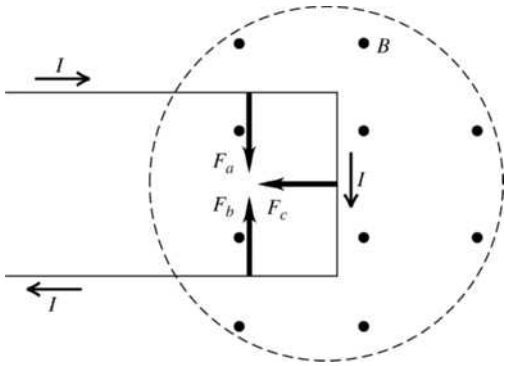

Figure 27.75

27.76. **IDENTIFY:** Apply $\vec{F} = I\vec{l}\times\vec{B}$.

SET UP: $\vec{l} = l\hat{k}$

EXECUTE: **(a)** $\vec{F} = I(l\hat{k})\times\vec{B} = Il[(-B_y)\hat{i} + (B_x)\hat{j}]$. This gives

$F_x = -IlB_y = -(7.40\text{ A})(0.250\text{ m})(-0.985\text{ T}) = 1.82$ N and

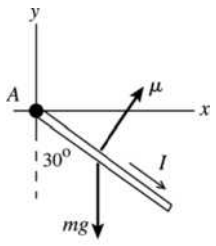
$F_y = IlB_x = (7.40\text{ A})(0.250\text{ m})(-0.242\text{ T}) = -0.448$ N. $F_z = 0$, since the wire is in the z-direction.

(b) $F = \sqrt{F_x^2 + F_y^2} = \sqrt{(1.82\text{ N})^2 + (0.448\text{ N})^2} = 1.88$ N.

EVALUATE: $\vec{F}$ must be perpendicular to the current direction, so $\vec{F}$ has no z component.

27.77. **IDENTIFY:** For the loop to be in equilibrium the net torque on it must be zero. Use Eq. (27.26) to calculate the torque due to the magnetic field and use Eq. (10.3) for the torque due to the gravity force.

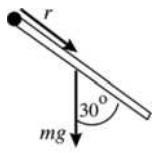
SET UP: See Figure 27.77a.



Use $\sum\tau_A = 0$, where point *A* is at the origin.

Figure 27.77a

EXECUTE: See Figure 27.77b.



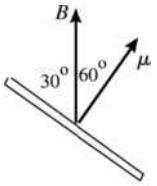
$\tau_{mg} = mgr\sin\phi = mg(0.400\text{ m})\sin 30.0°$

The torque is clockwise; $\vec{\tau}_{mg}$ is directed into the paper.

Figure 27.77b

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

For the loop to be in equilibrium the torque due to $\vec{B}$ must be counterclockwise (opposite to $\vec{\tau}_{mg}$) and it must be that $\tau_B = \tau_{mg}$. See Figure 27.77c.



$\vec{\tau}_B = \vec{\mu} \times \vec{B}$. For this torque to be counterclockwise ($\vec{\tau}_B$ directed out of the paper), $\vec{B}$ must be in the $+y$-direction.

Figure 27.77c

$\tau_B = \mu B \sin\phi = IAB \sin 60.0°$

$\tau_B = \tau_{mg}$ gives $IAB \sin 60.0° = mg(0.0400 \text{ m}) \sin 30.0°$

$m = (0.15 \text{ g/cm})2(8.00 \text{ cm} + 6.00 \text{ cm}) = 4.2 \text{ g} = 4.2 \times 10^{-3} \text{ kg}$

$A = (0.0800 \text{ m})(0.0600 \text{ m}) = 4.80 \times 10^{-3} \text{ m}^2$

$$B = \frac{mg(0.0400 \text{ m})(\sin 30.0°)}{IA \sin 60.0°}$$

$$B = \frac{(4.2 \times 10^{-3} \text{ kg})(9.80 \text{ m/s}^2)(0.0400 \text{ m}) \sin 30.0°}{(8.2 \text{ A})(4.80 \times 10^{-3} \text{ m}^2) \sin 60.0°} = 0.024 \text{ T}$$

EVALUATE: As the loop swings up the torque due to $\vec{B}$ decreases to zero and the torque due to mg increases from zero, so there must be an orientation of the loop where the net torque is zero.

27.78. **IDENTIFY:** The torque exerted by the magnetic field is $\vec{\tau} = \vec{\mu} \times \vec{B}$. The torque required to hold the loop in place is $-\vec{\tau}$.

SET UP: $\mu = IA$. $\vec{\mu}$ is normal to the plane of the loop, with a direction given by the right-hand rule that is illustrated in Figure 27.32 in the textbook. $\tau = IAB \sin\phi$, where ϕ is the angle between the normal to the loop and the direction of $\vec{B}$.

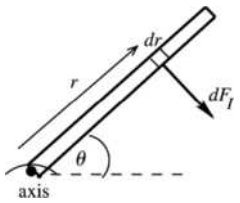
EXECUTE: **(a)** $\tau = IAB \sin 60° = (15.0 \text{ A})(0.060 \text{ m})(0.080 \text{ m})(0.48 \text{ T}) \sin 60° = 0.030 \text{ N} \cdot \text{m}$, in the $-\hat{j}$ direction. To keep the loop in place, you must provide a torque in the $+\hat{j}$ direction.

(b) $\tau = IAB \sin 30° = (15.0 \text{ A})(0.60 \text{ m})(0.080 \text{ m})(0.48 \text{ T}) \sin 30° = 0.017 \text{ N} \cdot \text{m}$, in the $+\hat{j}$ direction. You must provide a torque in the $-\hat{j}$ direction to keep the loop in place.

EVALUATE: **(c)** If the loop was pivoted through its center, then there would be a torque on both sides of the loop parallel to the rotation axis. However, the lever arm is only half as large, so the total torque in each case is identical to the values found in parts (a) and (b).

27.79. **IDENTIFY:** Use Eq. (27.20) to calculate the force and then the torque on each small section of the rod and integrate to find the total magnetic torque. At equilibrium the torques from the spring force and from the magnetic force cancel. The spring force depends on the amount x the spring is stretched and then $U = \frac{1}{2}kx^2$ gives the energy stored in the spring.

(a) SET UP:



Divide the rod into infinitesimal sections of length dr, as shown in Figure 27.79.

Figure 27.79

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: The magnetic force on this section is $dF_I = IBdr$ and is perpendicular to the rod. The torque $d\tau$ due to the force on this section is $d\tau = rdF_I = IBr\,dr$. The total torque is

$\int d\tau = IB\int_0^l r\,dr = \frac{1}{2}Il^2B = 0.0442\ \text{N}\cdot\text{m}$, clockwise.

(b) SET UP: F_I produces a clockwise torque so the spring force must produce a counterclockwise torque. The spring force must be to the left; the spring is stretched.

EXECUTE: Find x, the amount the spring is stretched:

$\sum\tau = 0$, axis at hinge, counterclockwise torques positive

$(kx)l\sin 53° - \frac{1}{2}Il^2B = 0$

$$x = \frac{IlB}{2k\sin 53.0°} = \frac{(6.50\ \text{A})(0.200\ \text{m})(0.340\ \text{T})}{2(4.80\ \text{N/m})\sin 53.0°} = 0.05765\ \text{m}$$

(c) $U = \frac{1}{2}kx^2 = 7.98\times10^{-3}$ J

EVALUATE: The magnetic torque calculated in part (a) is the same torque calculated from a force diagram in which the total magnetic force $F_I = IlB$ acts at the center of the rod. We didn't include a gravity torque since the problem said the rod had negligible mass.

27.80. **IDENTIFY:** Apply $\vec{F} = I\vec{l}\times\vec{B}$ to calculate the force on each side of the loop.

SET UP: The net force is the vector sum of the forces on each side of the loop.

EXECUTE: **(a)** $F_{PQ} = (5.00\ \text{A})(0.600\ \text{m})(3.00\ \text{T})\sin(0°) = 0$ N.

$F_{RP} = (5.00\ \text{A})(0.800\ \text{m})(3.00\ \text{T})\sin(90°) = 12.0$ N, into the page.

$F_{QR} = (5.00\ \text{A})(1.00\ \text{m})(3.00\ \text{T})(0.800/1.00) = 12.0$ N, out of the page.

(b) The net force on the triangular loop of wire is zero.

(c) For calculating torque on a straight wire we can assume that the force on a wire is applied at the wire's center. Also, note that we are finding the torque with respect to the *PR*-axis (not about a point), and consequently the lever arm will be the distance from the wire's center to the x-axis. $\tau = rF\sin\phi$ gives $\tau_{PQ} = r(0\ \text{N}) = 0$, $\tau_{RP} = (0\ \text{m})F\sin\phi = 0$ and $\tau_{QR} = (0.300\ \text{m})(12.0\ \text{N})\sin(90°) = 3.60\ \text{N}\cdot\text{m}$. The net torque is $3.60\ \text{N}\cdot\text{m}$.

(d) According to Eq. (27.28),

$\tau = NIAB\sin\phi = (1)(5.00\ \text{A})\left(\frac{1}{2}\right)(0.600\ \text{m})(0.800\ \text{m})(3.00\ \text{T})\sin(90°) = 3.60\ \text{N}\cdot\text{m}$, which agrees with part (c).

(e) Since F_{QR} is out of the page and since this is the force that produces the net torque, the point Q will be rotated out of the plane of the figure.

EVALUATE: In the expression $\tau = NIAB\sin\phi$, ϕ is the angle between the plane of the loop and the direction of $\vec{B}$. In this problem, $\phi = 90°$.

27.81. **IDENTIFY:** The contact at a will break if the bar rotates about b. The magnetic field is directed into the page, so the magnetic torque is counterclockwise, whereas the gravity torque is clockwise in the figure in the problem. The maximum current corresponds to zero net torque, in which case the torque due to gravity is just equal to the torque due to the magnetic field.

SET UP: The magnetic force is perpendicular to the bar and has moment arm $l/2$, where $l = 0.750$ m is the length of the bar. The gravity torque is $mg\left(\frac{l}{2}\cos 60.0°\right)$ and $F_B = IlB\sin\phi = IlB$. The results of Problem 27.79 show that we can take F_B to act at the center of the bar. F_B is perpendicular to the bar. Apply $\sum\tau_z = 0$ with the axis at b and counterclockwise torques positive.

EXECUTE: $F_B\frac{l}{2} - mg\left(\frac{l}{2}\cos 60.0°\right) = 0$. $IlB = mg\cos 60.0°$.

$$I = \frac{mg\cos 60.0°}{lB} = \frac{(0.458\ \text{kg})(9.80\ \text{m/s}^2)\cos 60.0°}{(0.750\ \text{m})(1.25\ \text{T})} = 2.39\ \text{A}.$$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: Once contact is broken, the magnetic torque ceases.

27.82. **IDENTIFY:** Conservation of energy relates the accelerating potential difference V to the final speed of the ions. In the magnetic field region the ions travel in an arc of a circle that has radius $R = \dfrac{mv}{|q|B}$.

SET UP: The quarter-circle paths of the two ions are shown in Figure 27.82. The separation at the detector is $\Delta r = R_{18} - R_{16}$. Each ion has charge $q = +e$.

EXECUTE: **(a)** Conservation of energy gives $|q|V = \frac{1}{2}mv^2$ and $v = \sqrt{\dfrac{2|q|V}{m}}$.

$R = \dfrac{m}{|q|B}\sqrt{\dfrac{2|q|V}{m}} = \dfrac{\sqrt{2|q|mV}}{|q|B}$. $|q| = e$ for each ion. $\Delta r = R_{18} - R_{16} = \dfrac{\sqrt{2eV}}{eB}(\sqrt{m_{18}} - \sqrt{m_{16}})$.

(b) $V = \dfrac{(\Delta reB)^2}{2e\left(\sqrt{m_{18}} - \sqrt{m_{16}}\right)^2} = \dfrac{e(\Delta r)^2 B^2}{2\left(\sqrt{m_{18}} - \sqrt{m_{16}}\right)^2} = \dfrac{(1.60\times10^{-19}\text{ C})(4.00\times10^{-2}\text{ m})^2(0.050\text{ T})^2}{2\left(\sqrt{2.99\times10^{-26}\text{ kg}} - \sqrt{2.66\times10^{-26}\text{ kg}}\right)^2}$

$V = 3.32\times10^3$ V.

EVALUATE: The speed of the ^{16}O ion after it has been accelerated through a potential difference of $V = 3.32\times10^3$ V is 2.00×10^5 m/s. Increasing the accelerating voltage increases the separation of the two isotopes at the detector. But it does this by increasing the radius of the path for each ion, and this increases the required size of the magnetic field region.

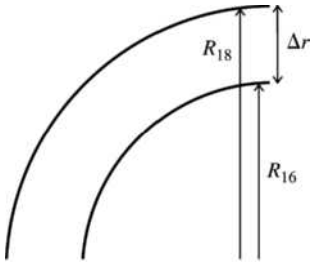


Figure 27.82

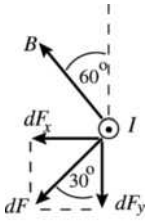
27.83. **IDENTIFY:** Use Eq. (27.20) to calculate the force on a short segment of the coil and integrate over the entire coil to find the total force.

SET UP: See Figure 27.83a.

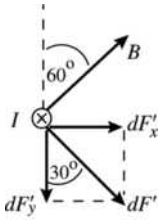


Consider the force $d\vec{F}$ on a short segment *dl* at the left-hand side of the coil, as viewed in Figure P27.83 in the textbook. The current at this point is directed out of the page. $d\vec{F}$ is perpendicular both to $\vec{B}$ and to the direction of *I*.

Figure 27.83a

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

See Figure 27.83b.



Consider also the force $d\vec{F}'$ on a short segment on the opposite side of the coil, at the right-hand side of the coil in Figure P27.83 in the textbook. The current at this point is directed into the page.

Figure 27.83b

The two sketches show that the *x*-components cancel and that the *y*-components add. This is true for all pairs of short segments on opposite sides of the coil. The net magnetic force on the coil is in the *y*-direction and its magnitude is given by $F = \int dF_y$.

EXECUTE: $dF = Idl\,B\sin\phi$. But $\vec{B}$ is perpendicular to the current direction so $\phi = 90°$.

$dF_y = dF\cos 30.0 = IB\cos 30.0°\,dl$

$F = \int dF_y = IB\cos 30.0° \int dl$

But $\int dl = N(2\pi r)$, the total length of wire in the coil.

$F = IB\cos 30.0°N(2\pi r) = (0.950\text{ A})(0.220\text{ T})(\cos 30.0°)(50)2\pi(0.0078\text{ m}) = 0.444\text{ N}$ and $\vec{F} = -(0.444\text{ N})\hat{j}$

EVALUATE: The magnetic field makes a constant angle with the plane of the coil but has a different direction at different points around the circumference of the coil so is not uniform. The net force is proportional to the magnitude of the current and reverses direction when the current reverses direction.

27.84. **IDENTIFY:** $I = \dfrac{\Delta q}{\Delta t}$ and $\mu = IA$.

SET UP: The direction of $\vec{\mu}$ is given by the right-hand rule that is illustrated in Figure 27.32 in the textbook. *I* is in the direction of flow of positive charge and opposite to the direction of flow of negative charge.

EXECUTE: **(a)** $I_u = \dfrac{dq}{dt} = \dfrac{\Delta q}{\Delta t} = \dfrac{q_u v}{2\pi r} = \dfrac{ev}{3\pi r}$.

(b) $\mu_u = I_u A = \dfrac{ev}{3\pi r}\pi r^2 = \dfrac{evr}{3}$.

(c) Since there are two down quarks, each of half the charge of the up quark, $\mu_d = \mu_u = \dfrac{evr}{3}$. Therefore,

$\mu_{\text{total}} = \dfrac{2evr}{3}$.

(d) $v = \dfrac{3\mu}{2er} = \dfrac{3(9.66\times10^{-27}\text{ A}\cdot\text{m}^2)}{2(1.60\times10^{-19}\text{ C})(1.20\times10^{-15}\text{ m})} = 7.55\times10^7\text{ m/s}$.

EVALUATE: The speed calculated in part (d) is 25% of the speed of light.

27.85. **IDENTIFY:** Apply $d\vec{F} = Id\vec{l}\times\vec{B}$ to each side of the loop.

SET UP: For each side of the loop, $d\vec{l}$ is parallel to that side of the loop and is in the direction of *I*. Since the loop is in the *xy*-plane, $z = 0$ at the loop and $B_y = 0$ at the loop.

EXECUTE: **(a)** The magnetic field lines in the *yz*-plane are sketched in Figure 27.85.

(b) Side 1, that runs from (0,0) to (0,*L*): $\vec{F} = \int_0^L Id\vec{l}\times\vec{B} = I\int_0^L \dfrac{B_0 y\,dy}{L}\hat{i} = \frac{1}{2}B_0 LI\hat{i}$.

Side 2, that runs from (0,*L*) to (*L*,*L*): $\vec{F} = \int_{0,y=L}^{L} Id\vec{l}\times\vec{B} = I\int_{0,y=L}^{L}\dfrac{B_0 y\,dx}{L}\hat{j} = -IB_0 L\hat{j}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

Side 3, that runs from (L,L) to (L,0): $\vec{\boldsymbol{F}} = \int_{L,x=L}^{0} Id\vec{\boldsymbol{l}} \times \vec{\boldsymbol{B}} = I\int_{L,x=L}^{0} \frac{B_0 y\, dy}{L}(-\hat{\boldsymbol{i}}) = -\tfrac{1}{2} IB_0 L\hat{\boldsymbol{i}}$.

Side 4, that runs from (L,0) to (0,0): $\vec{\boldsymbol{F}} = \int_{L,y=0}^{0} Id\vec{\boldsymbol{l}} \times \vec{\boldsymbol{B}} = I\int_{L,y=0}^{0} \frac{B_0 y\, dx}{L}\hat{\boldsymbol{j}} = 0$.

(c) The sum of all forces is $\vec{\boldsymbol{F}}_{\text{total}} = -IB_0 L\hat{\boldsymbol{j}}$.

EVALUATE: The net force on sides 1 and 3 is zero. The force on side 4 is zero, since $y = 0$ and $z = 0$ at that side and therefore $B = 0$ there. The net force on the loop equals the force on side 2.

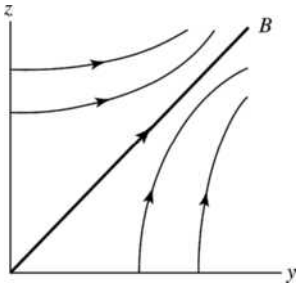


Figure 27.85

27.86. **IDENTIFY:** Apply $d\vec{\boldsymbol{F}} = Id\vec{\boldsymbol{l}} \times \vec{\boldsymbol{B}}$ to each side of the loop. $\vec{\boldsymbol{\tau}} = \vec{\boldsymbol{r}} \times \vec{\boldsymbol{F}}$.

SET UP: For each side of the loop, $d\vec{\boldsymbol{l}}$ is parallel to that side of the loop and is in the direction of I.

EXECUTE: **(a)** The magnetic field lines in the xy-plane are sketched in Figure 27.86.

(b) Side 1, that runs from (0,0) to (0,L): $\vec{\boldsymbol{F}} = \int_{0}^{L} Id\vec{\boldsymbol{l}} \times \vec{\boldsymbol{B}} = I\int_{0}^{L} \frac{B_0 y\, dy}{L}(-\hat{\boldsymbol{k}}) = -\tfrac{1}{2} B_0 LI\hat{\boldsymbol{k}}$.

Side 2, that runs from (0,L) to (L,L): $\vec{\boldsymbol{F}} = \int_{0}^{L} Id\vec{\boldsymbol{l}} \times \vec{\boldsymbol{B}} = I\int_{0}^{L} \frac{B_0 x\, dx}{L}\hat{\boldsymbol{k}} = \tfrac{1}{2} IB_0 L\hat{\boldsymbol{k}}$.

Side 3, that runs from (L,L) to (L,0): $\vec{\boldsymbol{F}} = \int_{0}^{L} Id\vec{\boldsymbol{l}} \times \vec{\boldsymbol{B}} = I\int_{0}^{L} \frac{B_0 y dy}{L}\hat{\boldsymbol{k}} = +\tfrac{1}{2} IB_0 L\hat{\boldsymbol{k}}$.

Side 4, that runs from (L,0) to (0,0): $\vec{\boldsymbol{F}} = \int_{0}^{L} Id\vec{\boldsymbol{l}} \times \vec{\boldsymbol{B}} = I\int_{0}^{L} \frac{B_0 x dx}{L}(-\hat{\boldsymbol{k}}) = -\tfrac{1}{2} IB_0 L\hat{\boldsymbol{k}}$.

(c) If free to rotate about the x-axis, the torques due to the forces on sides 1 and 3 cancel and the torque due to the forces on side 4 is zero. For side 2, $\vec{\boldsymbol{r}} = L\hat{\boldsymbol{j}}$. Therefore, $\vec{\boldsymbol{\tau}} = \vec{\boldsymbol{r}} \times \vec{\boldsymbol{F}} = \frac{IB_0 L^2}{2}\hat{\boldsymbol{i}} = \tfrac{1}{2} IAB_0\hat{\boldsymbol{i}}$.

(d) If free to rotate about the y-axis, the torques due to the forces on sides 2 and 4 cancel and the torque due to the forces on side 1 is zero. For side 3, $\vec{\boldsymbol{r}} = L\hat{\boldsymbol{i}}$. Therefore, $\vec{\boldsymbol{\tau}} = \vec{\boldsymbol{r}} \times \vec{\boldsymbol{F}} = -\frac{IB_0 L^2}{2}\hat{\boldsymbol{j}} = -\tfrac{1}{2} IAB_0\hat{\boldsymbol{j}}$.

EVALUATE: **(e)** The equation for the torque $\vec{\boldsymbol{\tau}} = \vec{\boldsymbol{\mu}} \times \vec{\boldsymbol{B}}$ is not appropriate, since the magnetic field is not constant.

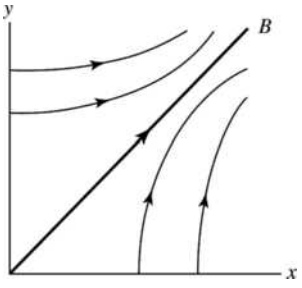

Figure 27.86

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

27.87. **IDENTIFY:** While the ends of the wire are in contact with the mercury and current flows in the wire, the magnetic field exerts an upward force and the wire has an upward acceleration. After the ends leave the mercury the electrical connection is broken and the wire is in free-fall.

(a) SET UP: After the wire leaves the mercury its acceleration is g, downward. The wire travels upward a total distance of 0.350 m from its initial position. Its ends lose contact with the mercury after the wire has traveled 0.025 m, so the wire travels upward 0.325 m after it leaves the mercury. Consider the motion of the wire after it leaves the mercury. Take $+y$ to be upward and take the origin at the position of the wire as it leaves the mercury.

$a_y = -9.80\ \text{m/s}^2$, $y - y_0 = +0.325\ \text{m}$, $v_y = 0$ (at maximum height), $v_{0y} = ?$

$v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$

EXECUTE: $v_{0y} = \sqrt{-2a_y(y - y_0)} = \sqrt{-2(-9.80\ \text{m/s}^2)(0.325\ \text{m})} = 2.52\ \text{m/s}$

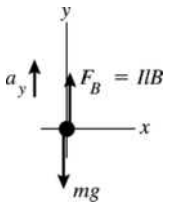
(b) SET UP: Now consider the motion of the wire while it is in contact with the mercury. Take $+y$ to be upward and the origin at the initial position of the wire. Calculate the acceleration:

$y - y_0 = +0.025\ \text{m}$, $v_{0y} = 0$ (starts from rest), $v_y = +2.52\ \text{m/s}$ (from part (a)), $a_y = ?$

$v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$

EXECUTE: $a_y = \dfrac{v_y^2}{2(y - y_0)} = \dfrac{(2.52\ \text{m/s})^2}{2(0.025\ \text{m})} = 127\ \text{m/s}^2$

SET UP: The free-body diagram for the wire is given in Figure 27.87.



EXECUTE: $\sum F_y = ma_y$

$F_B - mg = ma_y$

$IlB = m(g + a_y)$

$I = \dfrac{m(g + a_y)}{lB}$

Figure 27.87

l is the length of the horizontal section of the wire; $l = 0.150\ \text{m}$

$I = \dfrac{(5.40\times10^{-5}\ \text{kg})(9.80\ \text{m/s}^2 + 127\ \text{m/s}^2)}{(0.150\ \text{m})(0.00650\ \text{T})} = 7.58\ \text{A}$

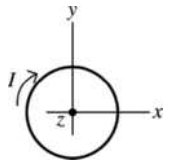
(c) IDENTIFY and SET UP: Use Ohm's law.

EXECUTE: $V = IR$ so $R = \dfrac{V}{I} = \dfrac{1.50\ \text{V}}{7.58\ \text{A}} = 0.198\ \Omega$

EVALUATE: The current is large and the magnetic force provides a large upward acceleration. During this upward acceleration the wire moves a much shorter distance as it gains speed than the distance it moves while in free-fall with a much smaller acceleration, as it loses the speed it gained. The large current means the resistance of the wire must be small.

27.88. **(a) IDENTIFY:** Use Eq. (27.27) to relate U, μ and $\vec{B}$ and use Eq. (27.26) to relate $\vec{\tau}, \vec{\mu}$ and $\vec{B}$. We also know that $B_0^2 = B_x^2 + B_y^2 + B_z^2$. This gives three equations for the three components of $\vec{B}$.

SET UP: The loop and current are shown in Figure 27.88.



$\vec{\mu}$ is into the plane of the paper, in the $-z$-direction.

Figure 27.88

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$\vec{\boldsymbol{\mu}} = -\mu\hat{\boldsymbol{k}} = -IA\hat{\boldsymbol{k}}$

(b) EXECUTE: $\vec{\boldsymbol{\tau}} = D(+4\hat{\boldsymbol{i}} - 3\hat{\boldsymbol{j}})$, where $D > 0$.

$\vec{\boldsymbol{\mu}} = -IA\hat{\boldsymbol{k}}$, $\vec{\boldsymbol{B}} = B_x\hat{\boldsymbol{i}} + B_y\hat{\boldsymbol{j}} + B_y\hat{\boldsymbol{k}}$

$\vec{\boldsymbol{\tau}} = \vec{\boldsymbol{\mu}} \times \vec{\boldsymbol{B}} = (-IA)(B_x\hat{\boldsymbol{k}} \times \hat{\boldsymbol{i}} + B_y\hat{\boldsymbol{k}} \times \hat{\boldsymbol{j}} + B_z\hat{\boldsymbol{k}} \times \hat{\boldsymbol{k}}) = IAB_y\hat{\boldsymbol{i}} - IAB_x\hat{\boldsymbol{j}}$

Compare this to the expression given for $\vec{\boldsymbol{\tau}}$: $IAB_y = 4D$ so $B_y = 4D/IA$ and $-IAB_x = -3D$ so $B_x = 3D/IA$

B_z doesn't contribute to the torque since $\vec{\boldsymbol{\mu}}$ is along the z-direction. But $B = B_0$ and $B_x^2 + B_y^2 + B_z^2 = B_0^2$; with $B_0 = 13D/IA$. Thus $B_z = \pm\sqrt{B_0^2 - B_x^2 - B_y^2} = \pm(D/IA)\sqrt{169 - 9 - 16} = \pm 12(D/IA)$.

That $U = -\vec{\boldsymbol{\mu}} \cdot \vec{\boldsymbol{B}}$ is negative determines the sign of B_z: $U = -\vec{\boldsymbol{\mu}} \cdot \vec{\boldsymbol{B}} = -(-IA\hat{\boldsymbol{k}}) \cdot (B_x\hat{\boldsymbol{i}} + B_y\hat{\boldsymbol{j}} + B_z\hat{\boldsymbol{k}}) = +IAB_z$. So U negative says that B_z is negative, and thus $B_z = -12D/IA$.

EVALUATE: $\vec{\boldsymbol{\mu}}$ is along the z-axis so only B_x and B_y contribute to the torque. B_x produces a y-component of $\vec{\boldsymbol{\tau}}$ and B_y produces an x-component of $\vec{\boldsymbol{\tau}}$. Only B_z affects U, and U is negative when $\vec{\boldsymbol{\mu}}$ and $\vec{\boldsymbol{B}}_z$ are parallel.

27.89. **IDENTIFY** and **SET UP:** In the magnetic field, $R = \dfrac{mv}{qB}$. Once the particle exits the field it travels in a straight line. Throughout the motion the speed of the particle is constant.

EXECUTE: **(a)** $R = \dfrac{mv}{qB} = \dfrac{(3.20\times10^{-11}\text{ kg})(1.45\times10^{5}\text{ m/s})}{(2.15\times10^{-6}\text{ C})(0.420\text{ T})} = 5.14\text{ m}.$

(b) See Figure 27.89. The distance along the curve, d, is given by $d = R\theta$. $\sin\theta = \dfrac{0.25\text{ m}}{5.14\text{ m}}$, so $\theta = 2.79° = 0.0486$ rad. $d = R\theta = (5.14\text{ m})(0.0486\text{ rad}) = 0.25\text{ m}$. And

$t = \dfrac{d}{v} = \dfrac{0.25\text{ m}}{1.45\times10^{5}\text{ m/s}} = 1.72\times10^{-6}\text{s}.$

(c) $\Delta x_1 = d\tan(\theta/2) = (0.25\text{ m})\tan(2.79°/2) = 6.08\times10^{-3}\text{ m}.$

(d) $\Delta x = \Delta x_1 + \Delta x_2$, where Δx_2 is the horizontal displacement of the particle from where it exits the field region to where it hits the wall. $\Delta x_2 = (0.50\text{ m})\tan 2.79° = 0.0244\text{ m}$. Therefore,

$\Delta x = 6.08\times10^{-3}\text{ m} + 0.0244\text{ m} = 0.0305\text{ m}.$

EVALUATE: d is much less than R, so the horizontal deflection of the particle is much smaller than the distance it travels in the y-direction.

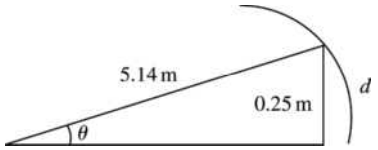


Figure 27.89

27.90. **IDENTIFY:** The current direction is perpendicular to $\vec{\boldsymbol{B}}$, so $F = IlB$. If the liquid doesn't flow, a force $(\Delta p)A$ from the pressure difference must oppose F.

SET UP: $J = I/A$, where $A = hw$.

EXECUTE: **(a)** $\Delta p = F/A = IlB/A = JlB$.

(b) $J = \dfrac{\Delta p}{lB} = \dfrac{(1.00\text{ atm})(1.013\times10^{5}\text{ Pa/atm})}{(0.0350\text{ m})(2.20\text{ T})} = 1.32\times10^{6}\text{ A/m}^2.$

EVALUATE: A current of 1 A in a wire with diameter 1 mm corresponds to a current density of $J = 1.3\times10^{6}$ A/m^2, so the current density calculated in part (c) is a typical value for circuits.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

27.91. **IDENTIFY:** The electric and magnetic fields exert forces on the moving charge. The work done by the electric field equals the change in kinetic energy. At the top point, $a_y = \dfrac{v^2}{R}$ and this acceleration must correspond to the net force.

SET UP: The electric field is uniform so the work it does for a displacement y in the y-direction is $W = Fy = qEy$. At the top point, $\vec{F}_B$ is in the $-y$-direction and $\vec{F}_E$ is in the $+y$-direction.

EXECUTE: **(a)** The maximum speed occurs at the top of the cycloidal path, and hence the radius of curvature is greatest there. Once the motion is beyond the top, the particle is being slowed by the electric field. As it returns to $y = 0$, the speed decreases, leading to a smaller magnetic force, until the particle stops completely. Then the electric field again provides the acceleration in the y-direction of the particle, leading to the repeated motion.

(b) $W = qEy = \dfrac{1}{2}mv^2$ and $v = \sqrt{\dfrac{2qEy}{m}}$.

(c) At the top, $F_y = qE - qvB = -\dfrac{mv^2}{R} = -\dfrac{m}{2y}\dfrac{2qEy}{m} = -qE$. $2qE = qvB$ and $v = \dfrac{2E}{B}$.

EVALUATE: The speed at the top depends on B because B determines the y-displacement and the work done by the electric force depends on the y-displacement.

28

SOURCES OF MAGNETIC FIELD

28.1. **IDENTIFY** and **SET UP:** Use Eq. (28.2) to calculate $\vec{B}$ at each point.

$\vec{B} = \dfrac{\mu_0}{4\pi}\dfrac{q\vec{v}\times\hat{r}}{r^2} = \dfrac{\mu_0}{4\pi}\dfrac{q\vec{v}\times\vec{r}}{r^3}$, since $\hat{r} = \dfrac{\vec{r}}{r}$.

$\vec{v} = (8.00\times10^6\ \text{m/s})\hat{j}$ and $\vec{r}$ is the vector from the charge to the point where the field is calculated.

EXECUTE: **(a)** $\vec{r} = (0.500\ \text{m})\hat{i}, r = 0.500\ \text{m}$

$\vec{v}\times\vec{r} = vr\hat{j}\times\hat{i} = -vr\hat{k}$

$$\vec{B} = -\frac{\mu_0}{4\pi}\frac{qv}{r^2}\hat{k} = -(1\times10^{-7}\ \text{T}\cdot\text{m/A})\frac{(6.00\times10^{-6}\ \text{C})(8.00\times10^6\ \text{m/s})}{(0.500\ \text{m})^2}\hat{k}$$

$$\vec{B} = -(1.92\times10^{-5}\ \text{T})\hat{k}$$

(b) $\vec{r} = -(0.500\ \text{m})\hat{j}, r = 0.500\ \text{m}$

$\vec{v}\times\vec{r} = -vr\hat{j}\times\hat{j} = 0$ and $\vec{B} = 0$.

(c) $\vec{r} = (0.500\ \text{m})\hat{k}, r = 0.500\ \text{m}$

$\vec{v}\times\vec{r} = vr\hat{j}\times\hat{k} = vr\hat{i}$

$$\vec{B} = (1\times10^{-7}\ \text{T}\cdot\text{m/A})\frac{(6.00\times10^{-6}\ \text{C})(8.00\times10^6\ \text{m/s})}{(0.500\ \text{m})^2}\hat{i} = +(1.92\times10^{-5}\ \text{T})\hat{i}$$

(d) $\vec{r} = -(0.500\ \text{m})\hat{j} + (0.500\ \text{m})\hat{k}, r = \sqrt{(0.500\ \text{m})^2 + (0.500\ \text{m})^2} = 0.7071\ \text{m}$

$\vec{v}\times\vec{r} = v(0.500\ \text{m})(-\hat{j}\times\hat{j} + \hat{j}\times\hat{k}) = (4.00\times10^6\ \text{m}^2/\text{s})\hat{i}$

$$\vec{B} = (1\times10^{-7}\ \text{T}\cdot\text{m/A})\frac{(6.00\times10^{-6}\ \text{C})(4.00\times10^6\ \text{m}^2/\text{s})}{(0.7071\ \text{m})^3}\hat{i} = +(6.79\times10^{-6}\ \text{T})\hat{i}$$

EVALUATE: At each point $\vec{B}$ is perpendicular to both $\vec{v}$ and $\vec{r}$. $B = 0$ along the direction of $\vec{v}$.

28.2. **IDENTIFY:** A moving charge creates a magnetic field as well as an electric field.

SET UP: The magnetic field caused by a moving charge is $B = \dfrac{\mu_0}{4\pi}\dfrac{qv\sin\phi}{r^2}$, and its electric field is

$E = \dfrac{1}{4\pi\epsilon_0}\dfrac{e}{r^2}$ since $q = e$.

EXECUTE: Substitute the appropriate numbers into the above equations.

$$B = \frac{\mu_0}{4\pi}\frac{qv\sin\phi}{r^2} = \frac{4\pi\times10^{-7}\ \text{T}\cdot\text{m/A}}{4\pi}\frac{(1.60\times10^{-19}\text{C})(2.2\times10^6\text{m/s})\sin90^\circ}{(5.3\times10^{-11}\text{m})^2} = 13\ \text{T},\ \text{out of the page.}$$

$$E = \frac{1}{4\pi\epsilon_0}\frac{e}{r^2} = \frac{(9.00\times10^9\text{N}\cdot\text{m}^2/\text{C}^2)(1.60\times10^{-19}\text{C})}{(5.3\times10^{-11}\text{m})^2} = 5.1\times10^{11}\text{N/C},\ \text{toward the electron.}$$

EVALUATE: There are enormous fields within the atom!

28.3. **IDENTIFY:** A moving charge creates a magnetic field.

SET UP: The magnetic field due to a moving charge is $B = \dfrac{\mu_0}{4\pi}\dfrac{qv\sin\phi}{r^2}$.

EXECUTE: Substituting numbers into the above equation gives

(a) $B = \dfrac{\mu_0}{4\pi}\dfrac{qv\sin\phi}{r^2} = \dfrac{4\pi\times10^{-7}\ \text{T}\cdot\text{m/A}}{4\pi}\dfrac{(1.6\times10^{-19}\text{C})(3.0\times10^{7}\text{m/s})\sin30^\circ}{(2.00\times10^{-6}\text{m})^2}$.

$B = 6.00\times10^{-8}$ T, out of the paper, and it is the same at point B.

(b) $B = (1.00\times10^{-7}\ \text{T}\cdot\text{m/A})(1.60\times10^{-19}\ \text{C})(3.00\times10^{7}\ \text{m/s})/(2.00\times10^{-6}\ \text{m})^2$

$B = 1.20\times10^{-7}$ T, out of the page.

(c) $B = 0$ T since $\sin(180^\circ) = 0$.

EVALUATE: Even at high speeds, these charges produce magnetic fields much less than the earth's magnetic field.

28.4. **IDENTIFY:** Both moving charges produce magnetic fields, and the net field is the vector sum of the two fields.

SET UP: Both fields point out of the paper, so their magnitudes add, giving

$$B = B_{\text{alpha}} + B_{\text{el}} = \frac{\mu_0 v}{4\pi r^2}(e\sin40^\circ + 2e\sin140^\circ)$$

EXECUTE: Factoring out an e and putting in the numbers gives

$$B = \frac{4\pi\times10^{-7}\ \text{T}\cdot\text{m/A}}{4\pi}\frac{(1.60\times10^{-19}\ \text{C})(2.50\times10^{5}\ \text{m/s})}{(1.75\times10^{-9}\ \text{m})^2}(\sin40^\circ + 2\sin140^\circ)$$

$$B = 2.52\times10^{-3}\ \text{T} = 2.52\ \text{mT}, \text{ out of the page.}$$

EVALUATE: At distances very close to the charges, the magnetic field is strong enough to be important.

28.5. **IDENTIFY:** Apply $\vec{\boldsymbol{B}} = \dfrac{\mu_0}{4\pi}\dfrac{q\vec{\boldsymbol{v}}\times\vec{\boldsymbol{r}}}{r^3}$.

SET UP: Since the charge is at the origin, $\vec{\boldsymbol{r}} = x\hat{\boldsymbol{i}} + y\hat{\boldsymbol{j}} + z\hat{\boldsymbol{k}}$.

EXECUTE: **(a)** $\vec{\boldsymbol{v}} = v\hat{\boldsymbol{i}}$, $\vec{\boldsymbol{r}} = r\hat{\boldsymbol{i}}$; $\vec{\boldsymbol{v}}\times\vec{\boldsymbol{r}} = 0$, $B = 0$.

(b) $\vec{\boldsymbol{v}} = v\hat{\boldsymbol{i}}$, $\vec{\boldsymbol{r}} = r\hat{\boldsymbol{j}}$; $\vec{\boldsymbol{v}}\times\vec{\boldsymbol{r}} = vr\hat{\boldsymbol{k}}$, $r = 0.500$ m.

$$B = \left(\frac{\mu_0}{4\pi}\right)\frac{|q|v}{r^2} = \frac{(1.0\times10^{-7}\ \text{N}\cdot\text{s}^2/\text{C}^2)(4.80\times10^{-6}\ \text{C})(6.80\times10^{5}\ \text{m/s})}{(0.500\ \text{m})^2} = 1.31\times10^{-6}\ \text{T}.$$

q is negative, so $\vec{\boldsymbol{B}} = -(1.31\times10^{-6}\ \text{T})\hat{\boldsymbol{k}}$.

(c) $\vec{\boldsymbol{v}} = v\hat{\boldsymbol{i}}$, $\vec{\boldsymbol{r}} = (0.500\ \text{m})(\hat{\boldsymbol{i}} + \hat{\boldsymbol{j}})$; $\vec{\boldsymbol{v}}\times\vec{\boldsymbol{r}} = (0.500\ \text{m})v\hat{\boldsymbol{k}}$, $r = 0.7071$ m.

$$B = \left(\frac{\mu_0}{4\pi}\right)\left(|q|\left|\vec{\boldsymbol{v}}\times\vec{\boldsymbol{r}}\right|/r^3\right) = \frac{(1.0\times10^{-7}\ \text{N}\cdot\text{s}^2/\text{C}^2)(4.80\times10^{-6}\ \text{C})(0.500\ \text{m})(6.80\times10^{5}\ \text{m/s})}{(0.7071\ \text{m})^3}.$$

$B = 4.62\times10^{-7}$ T. $\vec{\boldsymbol{B}} = -(4.62\times10^{-7}\ \text{T})\hat{\boldsymbol{k}}$.

(d) $\vec{\boldsymbol{v}} = v\hat{\boldsymbol{i}}$, $\vec{\boldsymbol{r}} = r\hat{\boldsymbol{k}}$; $\vec{\boldsymbol{v}}\times\vec{\boldsymbol{r}} = -vr\hat{\boldsymbol{j}}$, $r = 0.500$ m

$$B = \left(\frac{\mu_0}{4\pi}\right)\frac{|q|v}{r^2} = \frac{(1.0\times10^{-7}\ \text{N}\cdot\text{s}^2/\text{C}^2)(4.80\times10^{-6}\ \text{C})(6.80\times10^{5}\ \text{m/s})}{(0.500\ \text{m})^2} = 1.31\times10^{-6}\ \text{T}.$$

$\vec{\boldsymbol{B}} = (1.31\times10^{-6}\ \text{T})\hat{\boldsymbol{j}}$.

EVALUATE: In each case, $\vec{\boldsymbol{B}}$ is perpendicular to both $\vec{\boldsymbol{r}}$ and $\vec{\boldsymbol{v}}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

28.6. **IDENTIFY:** Apply $\vec{B}=\frac{\mu_0}{4\pi}\frac{q\vec{v}\times\vec{r}}{r^3}$. For the magnetic force, apply the results of Example 28.1, except here the two charges and velocities are different.

SET UP: In part (a), $r=d$ and $\vec{r}$ is perpendicular to $\vec{v}$ in each case, so $\frac{|\vec{v}\times\vec{r}|}{r^3}=\frac{v}{d^2}$. For calculating the force between the charges, $r=2d$.

EXECUTE: **(a)** $B_{\text{total}}=B+B'=\frac{\mu_0}{4\pi}\left(\frac{qv}{d^2}+\frac{q'v'}{d^2}\right)$.

$$B=\frac{\mu_0}{4\pi}\left(\frac{(8.0\times10^{-6}\text{ C})(4.5\times10^{6}\text{ m/s})}{(0.120\text{ m})^2}+\frac{(3.0\times10^{-6}\text{ C})(9.0\times10^{6}\text{ m/s})}{(0.120\text{ m})^2}\right)=4.38\times10^{-4}\text{ T}.$$

The direction of $\vec{B}$ is into the page.

(b) Following Example 28.1 we can find the magnetic force between the charges:

$$F_B=\frac{\mu_0}{4\pi}\frac{qq'vv'}{r^2}=(10^{-7}\text{ T}\cdot\text{m/A})\frac{(8.00\times10^{-6}\text{ C})(3.00\times10^{-6}\text{ C})(4.50\times10^{6}\text{ m/s})(9.00\times10^{6}\text{ m/s})}{(0.240\text{ m})^2}$$

$F_B=1.69\times10^{-3}$ N. The force on the upper charge points up and the force on the lower charge points down. The Coulomb force between the charges is

$F_{\text{C}}=k\frac{q_1q_2}{r^2}=(8.99\times10^{9}\text{ N}\cdot\text{m}^2/\text{C}^2)\frac{(8.0\times10^{-6}\text{ C})(3.0\times10^{-6}\text{ C})}{(0.240\text{ m})^2}=3.75$ N. The force on the upper charge points up and the force on the lower charge points down. The ratio of the Coulomb force to the magnetic force is $\frac{F_{\text{C}}}{F_B}=\frac{c^2}{v_1v_2}=\frac{3.75\text{ N}}{1.69\times10^{-3}\text{ N}}=2.22\times10^{3}$; the Coulomb force is much larger.

(c) The magnetic forces are reversed in direction when the direction of only one velocity is reversed but the magnitude of the force is unchanged.

EVALUATE: When two charges have the same sign and move in opposite directions, the force between them is repulsive. When two charges of the same sign move in the same direction, the force between them is attractive.

28.7. **IDENTIFY:** Apply $\vec{B}=\frac{\mu_0}{4\pi}\frac{q\vec{v}\times\vec{r}}{r^3}$. For the magnetic force on q', use $\vec{F}_B=q'\vec{v}'\times\vec{B}_q$ and for the magnetic force on q use $\vec{F}_B=q\vec{v}\times\vec{B}_{q'}$.

SET UP: In part (a), $r=d$ and $\frac{|\vec{v}\times\vec{r}|}{r^3}=\frac{v}{d^2}$.

EXECUTE: **(a)** $q'=-q$; $B_q=\frac{\mu_0qv}{4\pi d^2}$, into the page; $B_{q'}=\frac{\mu_0qv'}{4\pi d^2}$, out of the page.

(i) $v'=\frac{v}{2}$ gives $B=\frac{\mu_0qv}{4\pi d^2}\left(1-\frac{1}{2}\right)=\frac{\mu_0qv}{4\pi(2d^2)}$, into the page. (ii) $v'=v$ gives $B=0$.

(iii) $v'=2v$ gives $B=\frac{\mu_0qv}{4\pi d^2}$, out of the page.

(b) The force that q exerts on q' is given by $\vec{F}=q'\vec{v}'\times\vec{B}_q$, so $F=\frac{\mu_0q^2v'v}{4\pi(2d)^2}$. $\vec{B}_q$ is into the page, so the force on q' is toward q. The force that q' exerts on q is toward q'. The force between the two charges is attractive.

(c) $F_B=\frac{\mu_0q^2vv'}{4\pi(2d)^2}$, $F_{\text{C}}=\frac{q^2}{4\pi\epsilon_0(2d)^2}$ so $\frac{F_B}{F_{\text{C}}}=\mu_0\epsilon_0vv'=\mu_0\epsilon_0(3.00\times10^{5}\text{ m/s})^2=1.00\times10^{-6}$.

EVALUATE: When charges of opposite sign move in opposite directions, the force between them is attractive. For the values specified in part (c), the magnetic force between the two charges is much smaller in magnitude than the Coulomb force between them.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

28.8. **IDENTIFY:** Both moving charges create magnetic fields, and the net field is the vector sum of the two. The magnetic force on a moving charge is $F_{\text{mag}} = qvB\sin\phi$ and the electrical force obeys Coulomb's law.

SET UP: The magnetic field due to a moving charge is $B = \dfrac{\mu_0}{4\pi}\dfrac{qv\sin\phi}{r^2}$.

EXECUTE: **(a)** Both fields are into the page, so their magnitudes add, giving

$$B = B_{\text{e}} + B_{\text{p}} = \frac{\mu_0}{4\pi}\left(\frac{ev}{r_{\text{e}}^2} + \frac{ev}{r_{\text{p}}^2}\right)\sin 90°$$

$$B = \frac{\mu_0}{4\pi}(1.60\times10^{-19}\text{C})(845{,}000\text{ m/s})\left[\frac{1}{(5.00\times10^{-9}\text{m})^2} + \frac{1}{(4.00\times10^{-9}\text{m})^2}\right]$$

$$B = 1.39\times10^{-3}\text{ T} = 1.39\text{ mT, into the page.}$$

(b) Using $B = \dfrac{\mu_0}{4\pi}\dfrac{qv\sin\phi}{r^2}$, where $r = \sqrt{41}$ nm and $\phi = 180° - \arctan(5/4) = 128.7°$, we get

$$B = \frac{4\pi\times10^{-7}\text{ T}\cdot\text{m/A}}{4\pi}\frac{(1.6\times10^{-19}\text{C})(845{,}000\text{ m/s})\sin 128.7°}{(\sqrt{41}\times10^{-9}\text{m})^2} = 2.58\times10^{-4}\text{ T, into the page.}$$

(c) $F_{\text{mag}} = qvB\sin 90° = (1.60\times10^{-19}\text{ C})(845{,}000\text{ m/s})(2.58\times10^{-4}\text{ T}) = 3.48\times10^{-17}\text{ N,}$ in the $+x$-direction.

$F_{\text{elec}} = (1/4\pi\epsilon_0)e^2/r^2 = \dfrac{(9.00\times10^9\,\text{N}\cdot\text{m}^2/\text{C}^2)(1.60\times10^{-19}\text{C})^2}{(\sqrt{41}\times10^{-9}\text{m})^2} = 5.62\times10^{-12}\text{ N,}$ at $51.3°$ below the $+x$-axis measured clockwise.

EVALUATE: The electric force is much stronger than the magnetic force.

28.9. **IDENTIFY:** A moving charge creates a magnetic field.

SET UP: Apply $\vec{\boldsymbol{B}} = \dfrac{\mu_0}{4\pi}\dfrac{q\vec{\boldsymbol{v}}\times\vec{\boldsymbol{r}}}{r^3}$. $\vec{\boldsymbol{r}} = (0.200\text{ m})\hat{\boldsymbol{i}} + (-0.300\text{ m})\hat{\boldsymbol{j}}$, and $r = 0.3606$ m.

EXECUTE: $\vec{\boldsymbol{v}}\times\vec{\boldsymbol{r}} = [(7.50\times10^4\text{ m/s})\hat{\boldsymbol{i}} + (-4.90\times10^4\text{ m/s})\hat{\boldsymbol{j}}]\times[(0.200\text{ m})\hat{\boldsymbol{i}} + (-0.300\text{ m})\hat{\boldsymbol{j}}]$, which simplifies to

$\vec{\boldsymbol{v}}\times\vec{\boldsymbol{r}} = (-2.25\times10^4\text{ m}^2/\text{s})\hat{\boldsymbol{k}} + (9.80\times10^3\text{ m}^2/\text{s})\hat{\boldsymbol{k}} = (-1.27\times10^4\text{ m}^2/\text{s})\hat{\boldsymbol{k}}$.

$$\vec{\boldsymbol{B}} = (1.00\times10^{-7}\text{ T}\cdot\text{m/A})\frac{(-3.00\times10^{-6}\text{ C})(-1.27\times10^4\text{ m}^2/\text{s})}{(0.3606\text{ m})^3}\hat{\boldsymbol{k}} = (9.75\times10^{-8}\text{ T})\hat{\boldsymbol{k}}.$$

EVALUATE: We can check the direction of the magnetic field using the right-hand rule, which shows that the field points in the $+z$-direction.

28.10. **IDENTIFY:** Apply the Biot-Savart law.

SET UP: Apply $d\vec{\boldsymbol{B}} = \dfrac{\mu_0}{4\pi}\dfrac{q\,d\vec{\boldsymbol{l}}\times\vec{\boldsymbol{r}}}{r^3}$. $r = \sqrt{(-0.730\text{ m})^2 + (0.390\text{ m})^2} = 0.8267$ m.

EXECUTE:

$d\vec{\boldsymbol{l}}\times\vec{\boldsymbol{r}} = [0.500\times10^{-3}\text{ m}]\hat{\boldsymbol{j}}\times[(-0.730\text{ m})\hat{\boldsymbol{i}} + (0.390\text{ m})\hat{\boldsymbol{k}}] = (+3.65\times10^{-4}\text{ m}^2)\hat{\boldsymbol{k}} + (+1.95\times10^{-4}\text{ m}^2)\hat{\boldsymbol{i}}$

$$d\vec{\boldsymbol{B}} = (1.00\times10^{-7}\text{ T}\cdot\text{m/A})\frac{8.20\text{ A}}{(0.8276\text{ m})^3}[(3.65\times10^{-4}\text{ m}^2)\hat{\boldsymbol{k}} + (1.95\times10^{-4}\text{ m}^2)\hat{\boldsymbol{i}}].$$

$d\vec{\boldsymbol{B}} = (2.83\times10^{-10}\text{ T})\hat{\boldsymbol{i}} + (5.28\times10^{-10}\text{ T})\hat{\boldsymbol{k}}$.

EVALUATE: The magnetic field lies in the xz-plane.

28.11. **IDENTIFY:** A current segment creates a magnetic field.

SET UP: The law of Biot and Savart gives $dB = \dfrac{\mu_0}{4\pi}\dfrac{Idl\sin\phi}{r^2}$.

EXECUTE: Applying the law of Biot and Savart gives

(a) $$dB = \frac{4\pi\times10^{-7}\text{ T}\cdot\text{m/A}}{4\pi}\frac{(10.0\text{ A})(0.00110\text{ m})\sin 90°}{(0.0500\text{ m})^2} = 4.40\times10^{-7}\text{ T, out of the paper.}$$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) The same as above, except $r = \sqrt{(5.00\text{ cm})^2 + (14.0\text{ cm})^2}$ and $\phi = \arctan(5/14) = 19.65°$, giving $dB = 1.67\times10^{-8}$ T, out of the page.

(c) $dB = 0$ since $\phi = 0°$.

EVALUATE: This is a very small field, but it comes from a very small segment of current.

28.12. **IDENTIFY:** Apply $d\vec{B} = \frac{\mu_0}{4\pi}\frac{Id\vec{l}\times\hat{r}}{r^2} = \frac{\mu_0}{4\pi}\frac{Id\vec{l}\times\vec{r}}{r^3}$.

SET UP: The magnitude of the field due to the current element is $dB = \frac{\mu_0}{4\pi}\frac{Idl\sin\phi}{r^2}$, where ϕ is the angle between $\vec{r}$ and the current direction.

EXECUTE: The magnetic field at the given points is:

$$dB_a = \frac{\mu_0}{4\pi}\frac{Idl\sin\phi}{r^2} = \frac{\mu_0}{4\pi}\frac{(200\text{ A})(0.00100\text{ m})}{(0.100\text{ m})^2} = 2.00\times10^{-6}\text{ T}.$$

$$dB_b = \frac{\mu_0}{4\pi}\frac{Idl\sin\phi}{r^2} = \frac{\mu_0}{4\pi}\frac{(200\text{ A})(0.00100\text{ m})\sin45°}{2(0.100\text{ m})^2} = 0.705\times10^{-6}\text{ T}.$$

$$dB_c = \frac{\mu_0}{4\pi}\frac{Idl\sin\phi}{r^2} = \frac{\mu_0}{4\pi}\frac{(200\text{ A})(0.00100\text{ m})}{(0.100\text{ m})^2} = 2.00\times10^{-6}\text{ T}.$$

$$dB_d = \frac{\mu_0}{4\pi}\frac{Idl\sin\phi}{r^2} = \frac{\mu_0}{4\pi}\frac{Idl\sin(0°)}{r^2} = 0.$$

$$dB_e = \frac{\mu_0}{4\pi}\frac{Idl\sin\phi}{r^2} = \frac{\mu_0}{4\pi}\frac{(200\text{ A})(0.00100\text{ m})}{3(0.100\text{ m})^2}\frac{\sqrt{2}}{\sqrt{3}} = 0.545\times10^{-6}\text{ T}$$

The field vectors at each point are shown in Figure 28.12.

EVALUATE: In each case $d\vec{B}$ is perpendicular to the current direction.

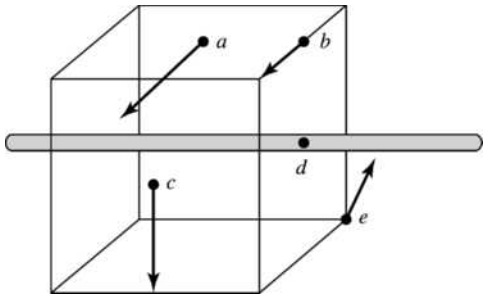

Figure 28.12

28.13. **IDENTIFY** and **SET UP:** The magnetic field produced by an infinitesimal current element is given by Eq. (28.6). $d\vec{B} = \frac{\mu_0}{4\pi}\frac{I\vec{l}\times\hat{r}}{r^2}$. As in Example 28.2, use this equation for the finite 0.500-mm segment of wire since the $\Delta l = 0.500$-mm length is much smaller than the distances to the field points.

$$\vec{B} = \frac{\mu_0}{4\pi}\frac{I\Delta\vec{l}\times\hat{r}}{r^2} = \frac{\mu_0}{4\pi}\frac{I\Delta\vec{l}\times\vec{r}}{r^3}$$

I is in the $+z$-direction, so $\Delta\vec{l} = (0.500\times10^{-3}\text{ m})\hat{k}$

EXECUTE: **(a)** Field point is at $x = 2.00$ m, $y = 0$, $z = 0$ so the vector $\vec{r}$ from the source point (at the origin) to the field point is $\vec{r} = (2.00\text{ m})\hat{i}$.

$$\Delta\vec{l}\times\vec{r} = (0.500\times10^{-3}\text{ m})(2.00\text{ m})\hat{k}\times\hat{i} = +(1.00\times10^{-3}\text{ m}^2)\hat{j}$$

$$\vec{B} = \frac{(1\times10^{-7}\text{ T}\cdot\text{m/A})(4.00\text{ A})(1.00\times10^{-3}\text{ m}^2)}{(2.00\text{ m})^3}\hat{j} = (5.00\times10^{-11}\text{ T})\hat{j}$$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) $\vec{r} = (2.00\text{ m})\hat{j}$, $r = 2.00$ m.

$\Delta\vec{l} \times \vec{r} = (0.500\times10^{-3}\text{ m})(2.00\text{ m})\hat{k}\times\hat{j} = -(1.00\times10^{-3}\text{ m}^2)\hat{i}$

$$\vec{B} = \frac{(1\times10^{-7}\text{ T}\cdot\text{m/A})(4.00\text{ A})(-1.00\times10^{-3}\text{ m}^2)}{(2.00\text{ m})^3}\hat{i} = -(5.00\times10^{-11}\text{ T})\hat{i}$$

(c) $\vec{r} = (2.00\text{ m})(\hat{i}+\hat{j})$, $r = \sqrt{2}(2.00\text{ m})$.

$\Delta\vec{l} \times \vec{r} = (0.500\times10^{-3}\text{ m})(2.00\text{ m})\hat{k}\times(\hat{i}+\hat{j}) = (1.00\times10^{-3}\text{ m}^2)(\hat{j}-\hat{i})$

$$\vec{B} = \frac{(1\times10^{-7}\text{ T}\cdot\text{m/A})(4.00\text{ A})(1.00\times10^{-3}\text{ m}^2)}{\left[\sqrt{2}(2.00\text{ m})\right]^3}(\hat{j}-\hat{i}) = (-1.77\times10^{-11}\text{ T})(\hat{i}-\hat{j})$$

(d) $\vec{r} = (2.00\text{ m})\hat{k}$, $r = 2.00$ m.

$\Delta\vec{l} \times \vec{r} = (0.500\times10^{-3}\text{ m})(2.00\text{ m})\hat{k}\times\hat{k} = 0$; $\vec{B} = 0$.

EVALUATE: At each point $\vec{B}$ is perpendicular to both $\vec{r}$ and $\Delta\vec{l}$. $B = 0$ along the length of the wire.

28.14. **IDENTIFY:** A current segment creates a magnetic field.

SET UP: The law of Biot and Savart gives $dB = \dfrac{\mu_0}{4\pi}\dfrac{Idl\sin\phi}{r^2}$.

Both fields are into the page, so their magnitudes add.

EXECUTE: Applying the law of Biot and Savart for the 12.0-A current gives

$$dB = \frac{4\pi\times10^{-7}\text{ T}\cdot\text{m/A}}{4\pi}\frac{(12.0\text{ A})(0.00150\text{ m})\left(\dfrac{2.50\text{ cm}}{8.00\text{ cm}}\right)}{(0.0800\text{ m})^2} = 8.79\times10^{-8}\text{ T}$$

The field from the 24.0-A segment is twice this value, so the total field is 2.64×10^{-7} T, into the page.

EVALUATE: The rest of each wire also produces field at P. We have calculated just the field from the two segments that are indicated in the problem.

28.15. **IDENTIFY:** A current segment creates a magnetic field.

SET UP: The law of Biot and Savart gives $dB = \dfrac{\mu_0}{4\pi}\dfrac{Idl\sin\phi}{r^2}$. Both fields are into the page, so their magnitudes add.

EXECUTE: Applying the Biot and Savart law, where $r = \frac{1}{2}\sqrt{(3.00\text{ cm})^2 + (3.00\text{ cm})^2} = 2.121\text{ cm}$, we have

$$dB = 2\frac{4\pi\times10^{-7}\text{ T}\cdot\text{m/A}}{4\pi}\frac{(28.0\text{ A})(0.00200\text{ m})\sin 45.0^\circ}{(0.02121\text{ m})^2} = 1.76\times10^{-5}\text{ T, into the paper.}$$

EVALUATE: Even though the two wire segments are at right angles, the magnetic fields they create are in the same direction.

28.16. **IDENTIFY:** A current segment creates a magnetic field.

SET UP: The law of Biot and Savart gives $dB = \dfrac{\mu_0}{4\pi}\dfrac{Idl\sin\phi}{r^2}$. All four fields are of equal magnitude and into the page, so their magnitudes add.

EXECUTE: $dB = 4\dfrac{4\pi\times10^{-7}\text{ T}\cdot\text{m/A}}{4\pi}\dfrac{(15.0\text{ A})(0.00120\text{ m})\ \sin 90^\circ}{(0.0500\text{ m})^2} = 2.88\times10^{-6}$ T, into the page.

EVALUATE: A small current element causes a small magnetic field.

28.17. **IDENTIFY:** We can model the lightning bolt and the household current as very long current-carrying wires.

SET UP: The magnetic field produced by a long wire is $B = \dfrac{\mu_0 I}{2\pi r}$.

EXECUTE: Substituting the numerical values gives

(a) $B = \dfrac{(4\pi\times10^{-7}\text{ T}\cdot\text{m/A})(20{,}000\text{ A})}{2\pi(5.0\text{ m})} = 8\times10^{-4}$ T

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) $B = \dfrac{(4\pi\times10^{-7}\ \text{T}\cdot\text{m/A})(10\ \text{A})}{2\pi(0.050\ \text{m})} = 4.0\times10^{-5}\ \text{T}.$

EVALUATE: The field from the lightning bolt is about 20 times as strong as the field from the household current.

28.18. **IDENTIFY:** The long current-carrying wire produces a magnetic field.

SET UP: The magnetic field due to a long wire is $B = \dfrac{\mu_0 I}{2\pi r}$.

EXECUTE: First find the current: $I = (3.50\times10^{18}\ \text{el/s})(1.60\times10^{-19}\ \text{C/el}) = 0.560\ \text{A}$

Now find the magnetic field: $\dfrac{(4\pi\times10^{-7}\ \text{T}\cdot\text{m/A})(0.560\ \text{A})}{2\pi(0.0400\ \text{m})} = 2.80\times10^{-6}\ \text{T}$

Since electrons are negative, the conventional current runs from east to west, so the magnetic field above the wire points toward the north.

EVALUATE: This magnetic field is much less than that of the earth, so any experiments involving such a current would have to be shielded from the earth's magnetic field, or at least would have to take it into consideration.

28.19. **IDENTIFY:** We can model the current in the heart as that of a long straight wire. It produces a magnetic field around it.

SET UP: For a long straight wire, $B = \dfrac{\mu_0 I}{2\pi r}$. $\mu_0 = 4\pi\times10^{-7}\ \text{T}\cdot\text{m/A}$. 1 gauss $= 10^{-4}$ T.

EXECUTE: Solving for the current gives $I = \dfrac{2\pi rB}{\mu_0} = \dfrac{2\pi(0.050\ \text{m})(1.0\times10^{-10}\ \text{T})}{4\pi\times10^{-7}\ \text{T}\cdot\text{m/A}} = 2.5\times10^{-5}\ \text{A} = 25\ \mu\text{A}.$

EVALUATE: By household standards, this is a very small current. But the magnetic field around the heart $(\approx 1\ \mu\text{G})$ is also very small.

28.20. **IDENTIFY:** The current in the transmission line creates a magnetic field. If this field is greater than 5% of the earth's magnetic field, it will interfere with the navigation of the bacteria.

SET UP: $B = \dfrac{\mu_0 I}{2\pi r}$ due to a long straight wire.

EXECUTE: We know the field is $B = (0.05)(5\times10^{-5}\ \text{T}) = 2.5\times10^{-6}\ \text{T}$. Solving $B = \dfrac{\mu_0 I}{2\pi r}$ for r gives

$$r = \frac{\mu_0 I}{2\pi B} = (2\times10^{-7}\ \text{T}\cdot\text{m/A})\frac{100\ \text{A}}{2.5\times10^{-6}\ \text{T}} = 8\ \text{m}.$$

EVALUATE: If the bacteria are within 8 m $(\approx 25\ \text{ft})$ of the cable, its magnetic field may be strong enough to affect their navigation.

28.21. **IDENTIFY:** The long current-carrying wire produces a magnetic field.

SET UP: The magnetic field due to a long wire is $B = \dfrac{\mu_0 I}{2\pi r}$.

EXECUTE: First solve for the current, then substitute the numbers using the above equation.

(a) Solving for the current gives

$$I = 2\pi rB/\mu_0 = 2\pi(0.0200\ \text{m})(1.00\times10^{-4}\ \text{T})/(4\pi\times10^{-7}\ \text{T}\cdot\text{m/A}) = 10.0\ \text{A}$$

(b) The earth's horizontal field points northward, so at all points directly above the wire the field of the wire would point northward.

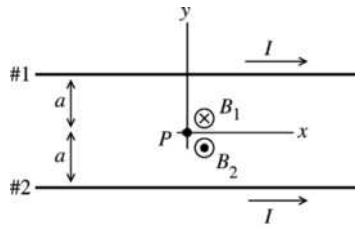
(c) At all points directly east of the wire, its field would point northward.

EVALUATE: Even though the earth's magnetic field is rather weak, it requires a fairly large current to cancel this field.

28.22. **IDENTIFY:** For each wire $B = \dfrac{\mu_0 I}{2\pi r}$ (Eq. 28.9), and the direction of $\vec{\boldsymbol{B}}$ is given by the right-hand rule (Figure 28.6 in the textbook). Add the field vectors for each wire to calculate the total field.

(a) SET UP: The two fields at this point have the directions shown in Figure 28.22a.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

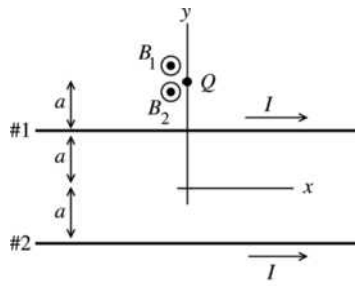


EXECUTE: At point P midway between the two wires the fields $\vec{\boldsymbol{B}}_1$ and $\vec{\boldsymbol{B}}_2$ due to the two currents are in opposite directions, so $B = B_2 - B_1$.

Figure 28.22a

But $B_1 = B_2 = \dfrac{\mu_0 I}{2\pi a}$, so $B = 0$.

(b) SET UP: The two fields at this point have the directions shown in Figure 28.22b.



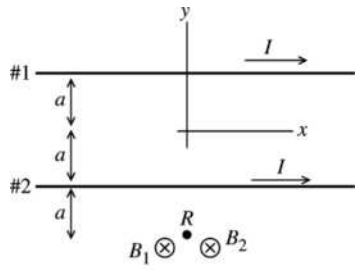
EXECUTE: At point Q above the upper wire $\vec{\boldsymbol{B}}_1$ and $\vec{\boldsymbol{B}}_2$ are both directed out of the page ($+z$-direction), so $B = B_1 + B_2$.

Figure 28.22b

$$B_1 = \frac{\mu_0 I}{2\pi a},\ B_2 = \frac{\mu_0 I}{2\pi(3a)}$$

$$B = \frac{\mu_0 I}{2\pi a}\left(1 + \tfrac{1}{3}\right) = \frac{2\mu_0 I}{3\pi a};\ \vec{\boldsymbol{B}} = \frac{2\mu_0 I}{3\pi a}\hat{\boldsymbol{k}}$$

(c) SET UP: The two fields at this point have the directions shown in Figure 28.22c.



EXECUTE: At point R below the lower wire $\vec{\boldsymbol{B}}_1$ and $\vec{\boldsymbol{B}}_2$ are both directed into the page ($-z$-direction), so $B = B_1 + B_2$.

Figure 28.22c

$$B_1 = \frac{\mu_0 I}{2\pi(3a)},\ B_2 = \frac{\mu_0 I}{2\pi a}$$

$$B_1 = \frac{\mu_0 I}{2\pi a}\left(1 + \tfrac{1}{3}\right) = \frac{2\mu_0 I}{3\pi a};\ \vec{\boldsymbol{B}} = -\frac{2\mu_0 I}{3\pi a}\hat{\boldsymbol{k}}$$

EVALUATE: In the figures we have drawn, $\vec{\boldsymbol{B}}$ due to each wire is out of the page at points above the wire and into the page at points below the wire. If the two field vectors are in opposite directions the magnitudes subtract.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

28.23. **IDENTIFY:** The total magnetic field is the vector sum of the constant magnetic field and the wire's magnetic field.

SET UP: For the wire, $B_{\text{wire}} = \dfrac{\mu_0 I}{2\pi r}$ and the direction of B_{wire} is given by the right-hand rule that is illustrated in Figure 28.6 in the textbook. $\vec{\boldsymbol{B}}_0 = (1.50\times10^{-6}\ \text{T})\hat{\boldsymbol{i}}$.

EXECUTE: **(a)** At (0, 0, 1 m), $\vec{\boldsymbol{B}} = \vec{\boldsymbol{B}}_0 - \dfrac{\mu_0 I}{2\pi r}\hat{\boldsymbol{i}} = (1.50\times10^{-6}\ \text{T})\hat{\boldsymbol{i}} - \dfrac{\mu_0(8.00\ \text{A})}{2\pi(1.00\ \text{m})}\hat{\boldsymbol{i}} = -(1.0\times10^{-7}\ \text{T})\hat{\boldsymbol{i}}$.

(b) At (1 m, 0, 0), $\vec{\boldsymbol{B}} = \vec{\boldsymbol{B}}_0 + \dfrac{\mu_0 I}{2\pi r}\hat{\boldsymbol{k}} = (1.50\times10^{-6}\ \text{T})\hat{\boldsymbol{i}} + \dfrac{\mu_0(8.00\ \text{A})}{2\pi(1.00\ \text{m})}\hat{\boldsymbol{k}}$.

$\vec{\boldsymbol{B}} = (1.50\times10^{-6}\ \text{T})\hat{\boldsymbol{i}} + (1.6\times10^{-6}\ \text{T})\hat{\boldsymbol{k}} = 2.19\times10^{-6}\ \text{T}$, at $\theta = 46.8°$ from x to z.

(c) At (0, 0, –0.25 m), $\vec{\boldsymbol{B}} = \vec{\boldsymbol{B}}_0 + \dfrac{\mu_0 I}{2\pi r}\hat{\boldsymbol{i}} = (1.50\times10^{-6}\ \text{T})\hat{\boldsymbol{i}} + \dfrac{\mu_0(8.00\ \text{A})}{2\pi(0.25\ \text{m})}\hat{\boldsymbol{i}} = (7.9\times10^{-6}\ \text{T})\hat{\boldsymbol{i}}$.

EVALUATE: At point c the two fields are in the same direction and their magnitudes add. At point a they are in opposite directions and their magnitudes subtract. At point b the two fields are perpendicular.

28.24. **IDENTIFY:** The magnetic field is that of a long current-carrying wire.

SET UP: $B = \dfrac{\mu_0 I}{2\pi r}$.

EXECUTE: $B = \dfrac{\mu_0 I}{2\pi r} = \dfrac{(2.0\times10^{-7}\ \text{T}\cdot\text{m/A})(150\ \text{A})}{8.0\ \text{m}} = 3.8\times10^{-6}\ \text{T}$. This is 7.5% of the earth's field.

EVALUATE: Since this field is much smaller than the earth's magnetic field, it would be expected to have less effect than the earth's field.

28.25. **IDENTIFY:** $B = \dfrac{\mu_0 I}{2\pi r}$. The direction of $\vec{\boldsymbol{B}}$ is given by the right-hand rule.

SET UP: Call the wires a and b, as indicated in Figure 28.25. The magnetic fields of each wire at points P_1 and P_2 are shown in Figure 28.25a. The fields at point 3 are shown in Figure 28.25b.

EXECUTE: **(a)** At P_1, $B_a = B_b$ and the two fields are in opposite directions, so the net field is zero.

(b) $B_a = \dfrac{\mu_0 I}{2\pi r_a}$. $B_b = \dfrac{\mu_0 I}{2\pi r_b}$. $\vec{\boldsymbol{B}}_a$ and $\vec{\boldsymbol{B}}_b$ are in the same direction so

$$B = B_a + B_b = \frac{\mu_0 I}{2\pi}\left(\frac{1}{r_a} + \frac{1}{r_b}\right) = \frac{(4\pi\times10^{-7}\ \text{T}\cdot\text{m/A})(4.00\ \text{A})}{2\pi}\left[\frac{1}{0.300\ \text{m}} + \frac{1}{0.200\ \text{m}}\right] = 6.67\times10^{-6}\ \text{T}$$

$\vec{\boldsymbol{B}}$ has magnitude $6.67\ \mu\text{T}$ and is directed toward the top of the page.

(c) In Figure 28.25b, $\vec{\boldsymbol{B}}_a$ is perpendicular to $\vec{\boldsymbol{r}}_a$ and $\vec{\boldsymbol{B}}_b$ is perpendicular to $\vec{\boldsymbol{r}}_b$. $\tan\theta = \dfrac{5\ \text{cm}}{20\ \text{cm}}$ and $\theta = 14.04°$. $r_a = r_b = \sqrt{(0.200\ \text{m})^2 + (0.050\ \text{m})^2} = 0.206\ \text{m}$ and $B_a = B_b$.

$$B = B_a\cos\theta + B_b\cos\theta = 2B_a\cos\theta = 2\left(\frac{\mu_0 I}{2\pi r_a}\right)\cos\theta = \frac{2(4\pi\times10^{-7}\ \text{T}\cdot\text{m/A})(4.0\ \text{A})\cos14.04°}{2\pi(0.206\ \text{m})} = 7.54\ \mu\text{T}$$

B has magnitude $7.53\ \mu\text{T}$ and is directed to the left.

EVALUATE: At points directly to the left of both wires the net field is directed toward the bottom of the page.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

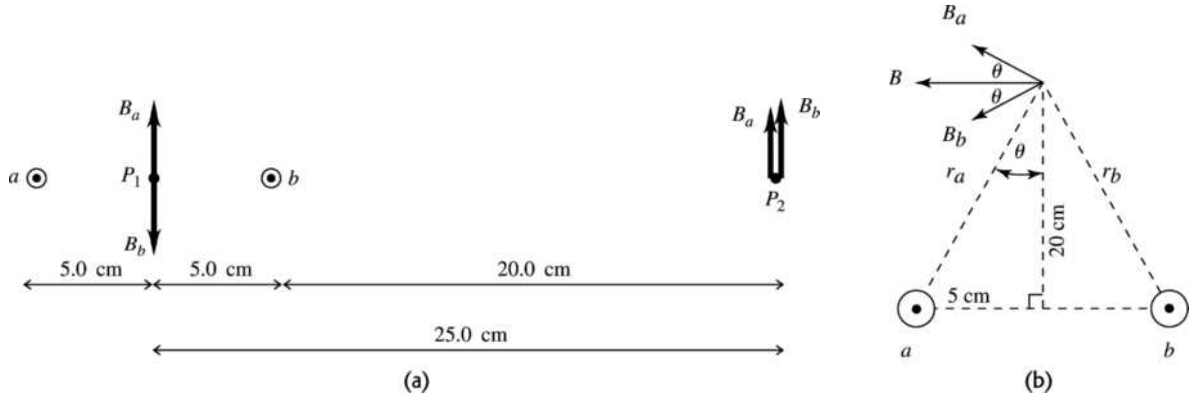


Figure 28.25

28.26. **IDENTIFY:** Each segment of the rectangular loop creates a magnetic field at the center of the loop, and all these fields are in the same direction.

SET UP: The field due to each segment is $B = \dfrac{\mu_0 I}{4\pi}\dfrac{2a}{x\sqrt{x^2+a^2}}$. $\vec{\boldsymbol{B}}$ is into paper so I is clockwise around the loop.

EXECUTE: *Long sides*: $a = 4.75$ cm. $x = 2.10$ cm. For the two long sides,

$$B = 2(1.00\times10^{-7}\ \text{T}\cdot\text{m/A})I\frac{2(4.75\times10^{-2}\ \text{m})}{(2.10\times10^{-2}\ \text{m})\sqrt{(0.0210\ \text{m})^2+(0.0475\ \text{m})^2}} = (1.742\times10^{-5}\ \text{T/A})I.$$

Short sides: $a = 2.10$ cm. $x = 4.75$ cm. For the two short sides,

$$B = 2(1.00\times10^{-7}\ \text{T}\cdot\text{m/A})I\frac{2(2.10\times10^{-2}\ \text{m})}{(4.75\times10^{-2}\ \text{m})\sqrt{(0.0475\ \text{m})^2+(0.0210\ \text{m})^2}} = (3.405\times10^{-6}\ \text{T/A})I.$$

Using the known field, we have $B = (2.082\times10^{-5}\ \text{T/A})I = 5.50\times10^{-5}\ \text{T}$, which gives $I = 2.64$ A.

EVALUATE: This is a typical household current, yet it produces a magnetic field which is about the same as the earth's magnetic field.

28.27. **IDENTIFY:** The net magnetic field at the center of the square is the vector sum of the fields due to each wire.

SET UP: For each wire, $B = \dfrac{\mu_0 I}{2\pi r}$ and the direction of $\vec{\boldsymbol{B}}$ is given by the right-hand rule that is illustrated in Figure 28.6 in the textbook.

EXECUTE: **(a)** and **(b)** $B = 0$ since the magnetic fields due to currents at opposite corners of the square cancel.

(c) The fields due to each wire are sketched in Figure 28.27.

$$B = B_a\cos45° + B_b\cos45° + B_c\cos45° + B_d\cos45° = 4B_a\cos45° = 4\left(\frac{\mu_0 I}{2\pi r}\right)\cos45°.$$

$$r = \sqrt{(10\ \text{cm})^2+(10\ \text{cm})^2} = 10\sqrt{2}\ \text{cm} = 0.10\sqrt{2}\ \text{m, so}$$

$$B = 4\frac{(4\pi\times10^{-7}\ \text{T}\cdot\text{m/A})(100\ \text{A})}{2\pi(0.10\sqrt{2}\ \text{m})}\cos45° = 4.0\times10^{-4}\ \text{T, to the left.}$$

EVALUATE: In part (c), if all four currents are reversed in direction, the net field at the center of the square would be to the right.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

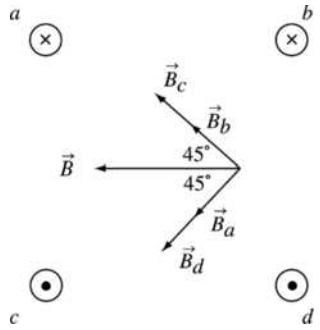

Figure 28.27

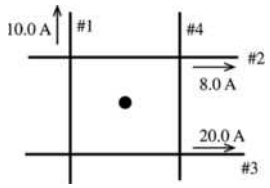
28.28. **IDENTIFY:** Use Eq. (28.9) and the right-hand rule to determine the field due to each wire. Set the sum of the four fields equal to zero and use that equation to solve for the field and the current of the fourth wire.
SET UP: The three known currents are shown in Figure 28.28.



$\vec{B}_1 \otimes, \vec{B}_2 \otimes, \vec{B}_3 \odot$

$B = \dfrac{\mu_0 I}{2\pi r}$; $r = 0.200$ m for each wire

Figure 28.28

EXECUTE: Let $\odot$ be the positive z-direction. $I_1 = 10.0$ A, $I_2 = 8.0$ A, $I_3 = 20.0$ A. Then

$B_1 = 1.00\times10^{-5}$ T, $B_2 = 0.80\times10^{-5}$ T, and $B_3 = 2.00\times10^{-5}$ T.

$B_{1z} = -1.00\times10^{-5}$ T, $B_{2z} = -0.80\times10^{-5}$ T, $B_{3z} = +2.00\times10^{-5}$ T

$B_{1z} + B_{2z} + B_{3z} + B_{4z} = 0$

$B_{4z} = -(B_{1z} + B_{2z} + B_{3z}) = -2.0\times10^{-6}$ T

To give $\vec{B}_4$ in the $\otimes$ direction the current in wire 4 must be toward the bottom of the page.

$$B_4 = \frac{\mu_0 I}{2\pi r} \text{ so } I_4 = \frac{rB_4}{(\mu_0/2\pi)} = \frac{(0.200\text{ m})(2.0\times10^{-6}\text{ T})}{(2\times10^{-7}\text{ T}\cdot\text{m/A})} = 2.0\text{ A}$$

EVALUATE: The fields of wires #2 and #3 are in opposite directions and their net field is the same as due to a current $20.0\text{ A} - 8.0\text{ A} = 12.0\text{ A}$ in one wire. The field of wire #4 must be in the same direction as that of wire #1, and $10.0\text{ A} + I_4 = 12.0$ A.

28.29. **IDENTIFY:** The net magnetic field at any point is the vector sum of the magnetic fields of the two wires.

SET UP: For each wire $B = \dfrac{\mu_0 I}{2\pi r}$ and the direction of $\vec{B}$ is determined by the right-hand rule described in the text. Let the wire with 12.0 A be wire 1 and the wire with 10.0 A be wire 2.

EXECUTE: **(a)** *Point Q*: $B_1 = \dfrac{\mu_0 I_1}{2\pi r_1} = \dfrac{(4\pi\times10^{-7}\text{T}\cdot\text{m/A})(12.0\text{ A})}{2\pi(0.15\text{ m})} = 1.6\times10^{-5}$ T.

The direction of $\vec{B}_1$ is out of the page. $B_2 = \dfrac{\mu_0 I_2}{2\pi r_2} = \dfrac{(4\pi\times10^{-7}\text{T}\cdot\text{m/A})(10.0\text{ A})}{2\pi(0.80\text{ m})} = 2.5\times10^{-5}$ T.

The direction of $\vec{B}_2$ is out of the page. Since $\vec{B}_1$ and $\vec{B}_2$ are in the same direction,

$B = B_1 + B_2 = 4.1\times10^{-5}$ T and $\vec{B}$ is directed out of the page.

Point P: $B_1 = 1.6\times10^{-5}$ T, directed into the page. $B_2 = 2.5\times10^{-5}$ T, directed into the page.

$B = B_1 + B_2 = 4.1\times10^{-5}$ T and $\vec{B}$ is directed into the page.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) $\vec{B}_1$ is the same as in part (a), out of the page at Q and into the page at P. The direction of $\vec{B}_2$ is reversed from what it was in (a) so is into the page at Q and out of the page at P.

Point Q: $\vec{B}_1$ and $\vec{B}_2$ are in opposite directions so $B = B_2 - B_1 = 2.5\times10^{-5}\ \text{T} - 1.6\times10^{-5}\ \text{T} = 9.0\times10^{-6}\ \text{T}$ and $\vec{B}$ is directed into the page.

Point P: $\vec{B}_1$ and $\vec{B}_2$ are in opposite directions so $B = B_2 - B_1 = 9.0\times10^{-6}\ \text{T}$ and $\vec{B}$ is directed out of the page.

EVALUATE: Points P and Q are the same distances from the two wires. The only difference is that the fields point in either the same direction or in opposite directions.

28.30. **IDENTIFY:** Apply Eq. (28.11) for the force from each wire.

SET UP: Two parallel conductors carrying current in the same direction attract each other. Parallel conductors carrying currents in opposite directions repel each other.

EXECUTE: On the top wire $\frac{F}{L} = \frac{\mu_0 I^2}{2\pi}\left(\frac{1}{d} - \frac{1}{2d}\right) = \frac{\mu_0 I^2}{4\pi d}$, upward. On the middle wire, the magnetic forces cancel so the net force is zero. On the bottom wire $\frac{F}{L} = \frac{\mu_0 I^2}{2\pi}\left(\frac{1}{d} - \frac{1}{2d}\right) = \frac{\mu_0 I^2}{4\pi d}$, downward.

EVALUATE: The net force on the middle wire is zero because at the location of the middle wire the net magnetic field due to the other two wires is zero.

28.31. **IDENTIFY:** Apply Eq. (28.11).

SET UP: Two parallel conductors carrying current in the same direction attract each other. Parallel conductors carrying currents in opposite directions repel each other.

EXECUTE: **(a)** $F = \frac{\mu_0 I_1 I_2 L}{2\pi r} = \frac{\mu_0 (5.00\ \text{A})(2.00\ \text{A})(1.20\ \text{m})}{2\pi(0.400\ \text{m})} = 6.00\times10^{-6}\ \text{N}$, and the force is repulsive since the currents are in opposite directions.

(b) Doubling the currents makes the force increase by a factor of four to $F = 2.40\times10^{-5}\ \text{N}$.

EVALUATE: Doubling the current in a wire doubles the magnetic field of that wire. For fixed magnetic field, doubling the current in a wire doubles the force that the magnetic field exerts on the wire.

28.32. **IDENTIFY:** Apply Eq. (28.11).

SET UP: Two parallel conductors carrying current in the same direction attract each other. Parallel conductors carrying currents in opposite directions repel each other.

EXECUTE: **(a)** $\frac{F}{L} = \frac{\mu_0 I_1 I_2}{2\pi r}$ gives $I_2 = \frac{F}{L}\frac{2\pi r}{\mu_0 I_1} = (4.0\times10^{-5}\ \text{N/m})\frac{2\pi(0.0250\ \text{m})}{\mu_0(0.60\ \text{A})} = 8.33\ \text{A}$.

(b) The two wires repel so the currents are in opposite directions.

EVALUATE: The force between the two wires is proportional to the product of the currents in the wires.

28.33. **IDENTIFY:** The lamp cord wires are two parallel current-carrying wires, so they must exert a magnetic force on each other.

SET UP: First find the current in the cord. Since it is connected to a light bulb, the power consumed by the bulb is $P = IV$. Then find the force per unit length using $F/L = \frac{\mu_0}{2\pi}\frac{I'I}{r}$.

EXECUTE: For the light bulb, $100\ \text{W} = I(120\ \text{V})$ gives $I = 0.833\ \text{A}$. The force per unit length is

$$F/L = \frac{4\pi\times10^{-7}\ \text{T}\cdot\text{m/A}}{2\pi}\frac{(0.833\ \text{A})^2}{0.003\ \text{m}} = 4.6\times10^{-5}\ \text{N/m}$$

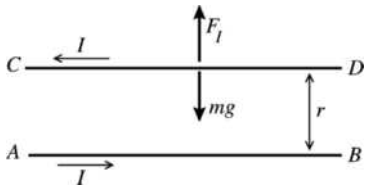
Since the currents are in opposite directions, the force is repulsive.

EVALUATE: This force is too small to have an appreciable effect for an ordinary cord.

28.34. **IDENTIFY:** The wire CD rises until the upward force F_I due to the currents balances the downward force of gravity.

SET UP: The forces on wire CD are shown in Figure 28.34.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.



Currents in opposite directions so the force is repulsive and F_I is upward, as shown.

Figure 28.34

Eq. (28.11) says $F_I = \dfrac{\mu_0 I^2 L}{2\pi h}$ where L is the length of wire CD and h is the distance between the wires.

EXECUTE: $mg = \lambda Lg$

Thus $F_I - mg = 0$ says $\dfrac{\mu_0 I^2 L}{2\pi h} = \lambda Lg$ and $h = \dfrac{\mu_0 I^2}{2\pi g\lambda}$.

EVALUATE: The larger I is or the smaller λ is, the larger h will be.

28.35. **IDENTIFY:** We can model the current in the brain as a ring. Since we know the magnetic field at the center of the ring, we can calculate the current.

SET UP: At the center of a ring, $B = \dfrac{\mu_0 I}{2R}$. In this case, $R = 8$ cm. 1 gauss $= 1\times10^{-4}$ T.

EXECUTE: Solving for I gives $I = \dfrac{2RB}{\mu_0} = \dfrac{2(8\times10^{-2}\text{ m})(3.0\times10^{-12}\text{ T})}{4\times10^{-7}\text{ T}\cdot\text{m/A}} = 3.8\times10^{-7}$ A.

EVALUATE: This current is about a third of a microamp, which is a very small current by household standards. However, the magnetic field in the brain is a very weak field, about a hundreth of the earth's magnetic field.

28.36. **IDENTIFY:** The magnetic field at the center of a circular loop is $B = \dfrac{\mu_0 I}{2R}$. By symmetry each segment of the loop that has length Δl contributes equally to the field, so the field at the center of a semicircle is $\frac{1}{2}$ that of a full loop.

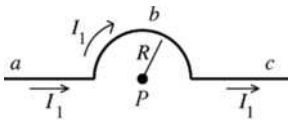
SET UP: Since the straight sections produce no field at P, the field at P is $B = \dfrac{\mu_0 I}{4R}$.

EXECUTE: $B = \dfrac{\mu_0 I}{4R}$. The direction of $\vec{\boldsymbol{B}}$ is given by the right-hand rule: $\vec{\boldsymbol{B}}$ is directed into the page.

EVALUATE: For a quarter-circle section of wire the magnetic field at its center of curvature is $B = \dfrac{\mu_0 I}{8R}$.

28.37. **IDENTIFY:** Calculate the magnetic field vector produced by each wire and add these fields to get the total field.

SET UP: First consider the field at P produced by the current I_1 in the upper semicircle of wire. See Figure 28.37a.



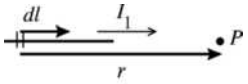
Consider the three parts of this wire
a: long straight section
b: semicircle
c: long, straight section

Figure 28.37a

Apply the Biot-Savart law $d\vec{\boldsymbol{B}} = \dfrac{\mu_0}{4\pi}\dfrac{Id\vec{\boldsymbol{l}}\times\hat{\boldsymbol{r}}}{r^2} = \dfrac{\mu_0}{4\pi}\dfrac{Id\vec{\boldsymbol{l}}\times\vec{\boldsymbol{r}}}{r^3}$ to each piece.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

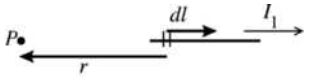
EXECUTE: part *a* See Figure 28.37b.



$d\vec{\boldsymbol{l}} \times \vec{\boldsymbol{r}} = 0,$
so $dB = 0$

Figure 28.37b

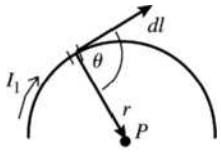
The same is true for all the infinitesimal segments that make up this piece of the wire, so $B = 0$ for this piece.
part *c* See Figure 28.37c.



$d\vec{\boldsymbol{l}} \times \vec{\boldsymbol{r}} = 0,$
so $dB = 0$ and $B = 0$ for this piece.

Figure 28.37c

part *b* See Figure 28.37d.



$d\vec{\boldsymbol{l}} \times \vec{\boldsymbol{r}}$ is directed into the paper for all infinitesimal segments that make up this semicircular piece, so $\vec{\boldsymbol{B}}$ is directed into the paper and $B = \int dB$ (the vector sum of the $d\vec{\boldsymbol{B}}$ is obtained by adding their magnitudes since they are in the same direction).

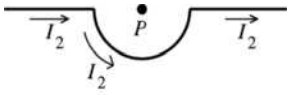
Figure 28.37d

$\left|d\vec{\boldsymbol{l}} \times \vec{\boldsymbol{r}}\right| = rdl\sin\theta.$ The angle θ between $d\vec{\boldsymbol{l}}$ and $\vec{\boldsymbol{r}}$ is 90° and $r = R,$ the radius of the semicircle. Thus $\left|d\vec{\boldsymbol{l}} \times \vec{\boldsymbol{r}}\right| = R\,dl$

$$dB = \frac{\mu_0}{4\pi}\frac{I\left|d\vec{\boldsymbol{l}} \times \vec{\boldsymbol{r}}\right|}{r^3} = \frac{\mu_0 I_1}{4\pi}\frac{R}{R^3}dl = \left(\frac{\mu_0 I_1}{4\pi R^2}\right)dl$$

$$B = \int dB = \left(\frac{\mu_0 I_1}{4\pi R^2}\right)\int dl = \left(\frac{\mu_0 I_1}{4\pi R^2}\right)(\pi R) = \frac{\mu_0 I_1}{4R}$$

(We used that $\int dl$ is equal to $\pi R,$ the length of wire in the semicircle.) We have shown that the two straight sections make zero contribution to $\vec{\boldsymbol{B}},$ so $B_1 = \mu_0 I_1/4R$ and is directed into the page.



For current in the direction shown in Figure 28.37e, a similar analysis gives $B_2 = \mu_0 I_2/4R,$ out of the paper.

Figure 28.37e

$\vec{\boldsymbol{B}}_1$ and $\vec{\boldsymbol{B}}_2$ are in opposite directions, so the magnitude of the net field at P is $B = \left|B_1 - B_2\right| = \dfrac{\mu_0\left|I_1 - I_2\right|}{4R}.$

EVALUATE: When $I_1 = I_2,\ B = 0.$

No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

28.38. **IDENTIFY:** Apply Eq. (28.16).
SET UP: At the center of the coil, $x = 0$. a is the radius of the coil, 0.0240 m.

EXECUTE: **(a)** $B_x = \mu_0 NI/2a$, so $I = \dfrac{2aB_x}{\mu_0 N} = \dfrac{2(0.024\text{ m})\,(0.0580\text{ T})}{(4\pi\times10^{-7}\text{ T}\cdot\text{m/A})(800)} = 2.77\text{ A}$

(b) At the center, $B_c = \mu_0 NI/2a$. At a distance x from the center,

$B_x = \dfrac{\mu_0 NIa^2}{2(x^2+a^2)^{3/2}} = \left(\dfrac{\mu_0 NI}{2a}\right)\left(\dfrac{a^3}{(x^2+a^2)^{3/2}}\right) = B_c\left(\dfrac{a^3}{(x^2+a^2)^{3/2}}\right)$. $B_x = \frac{1}{2}B_c$ says $\dfrac{a^3}{(x^2+a^2)^{3/2}} = \frac{1}{2}$, and $(x^2+a^2)^3 = 4a^6$. Since $a = 0.024$ m, $x = 0.0184$ m.

EVALUATE: As shown in Figure 28.14 in the textbook, the field has its largest magnitude at the center of the coil and decreases with distance along the axis from the center.

28.39. **IDENTIFY:** Apply Eq. (28.16).
SET UP: At the center of the coil, $x = 0$. a is the radius of the coil, 0.020 m.

EXECUTE: **(a)** $B_{\text{center}} = \dfrac{\mu_0 NI}{2a} = \dfrac{\mu_0(600)\,(0.500\text{ A})}{2(0.020\text{ m})} = 9.42\times10^{-3}\text{ T}$.

(b) $B(x) = \dfrac{\mu_0 NIa^2}{2(x^2+a^2)^{3/2}}$. $B(0.08\text{ m}) = \dfrac{\mu_0(600)(0.500\text{ A})(0.020\text{ m})^2}{2((0.080\text{ m})^2+(0.020\text{ m})^2)^{3/2}} = 1.34\times10^{-4}\text{ T}$.

EVALUATE: As shown in Figure 28.14 in the textbook, the field has its largest magnitude at the center of the coil and decreases with distance along the axis from the center.

28.40. **IDENTIFY** and **SET UP:** The magnetic field at a point on the axis of N circular loops is given by $B_x = \dfrac{\mu_0 NIa^2}{2(x^2+a^2)^{3/2}}$. Solve for N and set $x = 0.0600$ m.

EXECUTE: $N = \dfrac{2B_x(x^2+a^2)^{3/2}}{\mu_0 Ia^2} = \dfrac{2(6.39\times10^{-4}\text{ T})[(0.0600\text{ m})^2+(0.0600\text{ m})^2]^{3/2}}{(4\pi\times10^{-7}\text{ T}\cdot\text{m/A})(2.50\text{ A})(0.0600\text{ m})^2} = 69.$

EVALUATE: At the center of the coil the field is $B_x = \dfrac{\mu_0 NI}{2a} = 1.8\times10^{-3}$ T. The field 6.00 cm from the center is a factor of $1/2^{3/2}$ times smaller.

28.41. **IDENTIFY:** The field at the center of the loops is the vector sum of the field due to each loop. They must be in opposite directions in order to add to zero.
SET UP: Let wire 1 be the inner wire with diameter 20.0 cm and let wire 2 be the outer wire with diameter 30.0 cm. To produce zero net field, the fields $\vec{\boldsymbol{B}}_1$ and $\vec{\boldsymbol{B}}_2$ of the two wires must have equal magnitudes and opposite directions. At the center of a wire loop $B = \dfrac{\mu_0 I}{2R}$. The direction of $\vec{\boldsymbol{B}}$ is given by the right-hand rule applied to the current direction.

EXECUTE: $B_1 = \dfrac{\mu_0 I}{2R_1}$, $B_2 = \dfrac{\mu_0 I}{2R_2}$. $B_1 = B_2$ gives $\dfrac{\mu_0 I_1}{2R_1} = \dfrac{\mu_0 I_2}{2R_2}$. Solving for I_2 gives $I_2 = \left(\dfrac{R_2}{R_1}\right)I_1 = \left(\dfrac{15.0\text{ cm}}{10.0\text{ cm}}\right)(12.0\text{ A}) = 18.0\text{ A}$. The directions of I_1 and of its field are shown in Figure 28.41. Since $\vec{\boldsymbol{B}}_1$ is directed into the page, $\vec{\boldsymbol{B}}_2$ must be directed out of the page and I_2 is counterclockwise.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

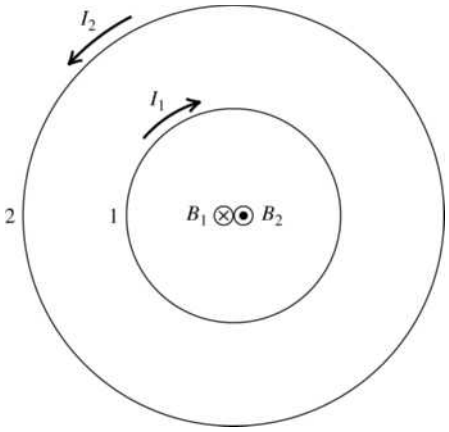

Figure 28.41

EVALUATE: The outer current, I_2, must be larger than the inner current, I_1, because the outer ring is larger than the inner ring, which makes the outer current farther from the center than the inner current is.

28.42. **IDENTIFY:** Apply Ampere's law.

SET UP: From the right-hand rule, when going around the path in a counterclockwise direction currents out of the page are positive and currents into the page are negative.

EXECUTE: Path a: $I_{\text{encl}} = 0 \Rightarrow \oint \vec{\boldsymbol{B}} \cdot d\vec{\boldsymbol{l}} = 0.$

Path b: $I_{\text{encl}} = -I_1 = -4.0 \text{ A} \Rightarrow \oint \vec{\boldsymbol{B}} \cdot d\vec{\boldsymbol{l}} = -\mu_0(4.0 \text{ A}) = -5.03\times10^{-6} \text{ T} \cdot \text{m}.$

Path c: $I_{\text{encl}} = -I_1 + I_2 = -4.0 \text{ A} + 6.0 \text{ A} = 2.0 \text{ A} \Rightarrow \oint \vec{\boldsymbol{B}} \cdot d\vec{\boldsymbol{l}} = \mu_0(2.0 \text{ A}) = 2.51\times10^{-6} \text{ T} \cdot \text{m}$

Path d: $I_{\text{encl}} = -I_1 + I_2 + I_3 = 4.0 \text{ A} \Rightarrow \oint \vec{\boldsymbol{B}} \cdot d\vec{\boldsymbol{l}} = +\mu_0(4.0 \text{ A}) = 5.03\times10^{-6} \text{ T} \cdot \text{m}.$

EVALUATE: If we instead went around each path in the clockwise direction, the sign of the line integral would be reversed.

28.43. **IDENTIFY:** Apply Ampere's law.

SET UP: $\mu_0 = 4\pi\times10^{-7} \text{ T} \cdot \text{m/A}$

EXECUTE: **(a)** $\oint \vec{\boldsymbol{B}} \cdot d\vec{\boldsymbol{l}} = \mu_0 I_{\text{encl}} = 3.83\times10^{-4} \text{ T} \cdot \text{m}$ and $I_{\text{encl}} = 305 \text{ A}.$

(b) $-3.83\times10^{-4} \text{ T} \cdot \text{m}$ since at each point on the curve the direction of $d\vec{\boldsymbol{l}}$ is reversed.

EVALUATE: The line integral $\oint \vec{\boldsymbol{B}} \cdot d\vec{\boldsymbol{l}}$ around a closed path is proportional to the net current that is enclosed by the path.

28.44. **IDENTIFY** and **SET UP:** At the center of a long solenoid $B = \mu_0 nI = \mu_0 \dfrac{N}{L} I.$

EXECUTE: $I = \dfrac{BL}{\mu_0 N} = \dfrac{(0.150 \text{ T})(1.40 \text{ m})}{(4\pi\times10^{-7} \text{ T} \cdot \text{m/A})(4000)} = 41.8 \text{ A}.$

EVALUATE: The magnetic field inside the solenoid is independent of the radius of the solenoid, if the radius is much less than the length, as is the case here.

28.45. **IDENTIFY:** Apply Ampere's law.

SET UP: To calculate the magnetic field at a distance r from the center of the cable, apply Ampere's law to a circular path of radius r. By symmetry, $\oint \vec{\boldsymbol{B}} \cdot d\vec{\boldsymbol{l}} = B(2\pi r)$ for such a path.

EXECUTE: **(a)** For $a < r < b, I_{\text{encl}} = I \Rightarrow \oint \vec{\boldsymbol{B}} \cdot d\vec{\boldsymbol{l}} = \mu_0 I \Rightarrow B2\pi r = \mu_0 I \Rightarrow B = \dfrac{\mu_0 I}{2\pi r}.$

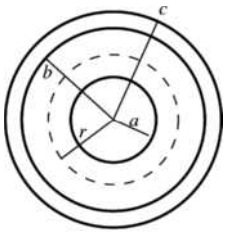
(b) For $r > c,$ the enclosed current is zero, so the magnetic field is also zero.

EVALUATE: A useful property of coaxial cables for many applications is that the current carried by the cable doesn't produce a magnetic field outside the cable.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

28.46. **IDENTIFY:** Apply Ampere's law to calculate $\vec{B}$.

(a) SET UP: For $a < r < b$ the end view is shown in Figure 28.46a.



Apply Ampere's law to a circle of radius r, where $a < r < b$. Take currents I_1 and I_2 to be directed into the page. Take this direction to be positive, so go around the integration path in the clockwise direction.

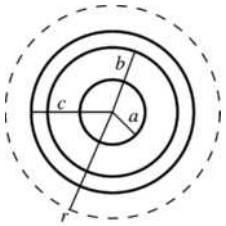
Figure 28.46a

EXECUTE: $\oint \vec{B} \cdot d\vec{l} = \mu_0 I_{\text{encl}}$

$\oint \vec{B} \cdot d\vec{l} = B(2\pi r), I_{\text{encl}} = I_1$

Thus $B(2\pi r) = \mu_0 I_1$ and $B = \dfrac{\mu_0 I_1}{2\pi r}$

(b) SET UP: $\underline{r > c}$: See Figure 28.46b.



Apply Ampere's law to a circle of radius r, where $r > c$. Both currents are in the positive direction.

Figure 28.46b

EXECUTE: $\oint \vec{B} \cdot d\vec{l} = \mu_0 I_{\text{encl}}$

$\oint \vec{B} \cdot d\vec{l} = B(2\pi r), I_{\text{encl}} = I_1 + I_2$

Thus $B(2\pi r) = \mu_0 (I_1 + I_2)$ and $B = \dfrac{\mu_0 (I_1 + I_2)}{2\pi r}$

EVALUATE: For $a < r < b$ the field is due only to the current in the central conductor. For $r > c$ both currents contribute to the total field.

28.47. **IDENTIFY:** The largest value of the field occurs at the surface of the cylinder. Inside the cylinder, the field increases linearly from zero at the center, and outside the field decreases inversely with distance from the central axis of the cylinder.

SET UP: At the surface of the cylinder, $B = \dfrac{\mu_0 I}{2\pi R}$, inside the cylinder, Eq. 28.21 gives $B = \dfrac{\mu_0 I}{2\pi} \dfrac{r}{R^2}$ and outside the field is $B = \dfrac{\mu_0 I}{2\pi r}$.

EXECUTE: For points inside the cylinder, the field is half its maximum value when $\dfrac{\mu_0 I}{2\pi} \dfrac{r}{R^2} = \dfrac{1}{2}\left(\dfrac{\mu_0 I}{2\pi R}\right)$, which gives $r = R/2$. Outside the cylinder, we have $\dfrac{\mu_0 I}{2\pi r} = \dfrac{1}{2}\left(\dfrac{\mu_0 I}{2\pi R}\right)$, which gives $r = 2R$.

EVALUATE: The field has half its maximum value at all points on cylinders coaxial with the wire but of radius $R/2$ and of radius $2R$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

28.48. **IDENTIFY:** $B = \mu_0 nI = \dfrac{\mu_0 NI}{L}$.

SET UP: $L = 0.150$ m

EXECUTE: $B = \dfrac{\mu_0\,(600)(8.00\text{ A})}{(0.150\text{ m})} = 0.0402$ T.

EVALUATE: The field near the center of the solenoid is independent of the radius of the solenoid, as long as the radius is much less than the length, as it is here.

28.49. **(a) IDENTIFY** and **SET UP:** The magnetic field near the center of a long solenoid is given by Eq. (28.23), $B = \mu_0 nI$.

EXECUTE: Turns per unit length $n = \dfrac{B}{\mu_0 I} = \dfrac{0.0270\text{ T}}{(4\pi\times10^{-7}\text{ T}\cdot\text{m/A})(12.0\text{ A})} = 1790$ turns/m

(b) $N = nL = (1790\text{ turns/m})(0.400\text{ m}) = 716$ turns

Each turn of radius R has a length $2\pi R$ of wire. The total length of wire required is

$N(2\pi R) = (716)(2\pi)(1.40\times10^{-2}\text{ m}) = 63.0$ m.

EVALUATE: A large length of wire is required. Due to the length of wire the solenoid will have appreciable resistance.

28.50. **IDENTIFY:** Knowing the magnetic field at the center of the toroidal solenoid, we can find the current causing that field.

SET UP: $B = \dfrac{\mu_0 NI}{2\pi r}$. $r = 0.140$ m is the distance from the center of the torus to the point where B is to be calculated. This point must be between the inner and outer radii of the solenoid, but otherwise the field doesn't depend on those radii.

EXECUTE: Solving for N gives $N = \dfrac{2\pi rB}{\mu_0 I} = \dfrac{2\pi(0.140\text{ m})(3.75\times10^{-3}\text{ T})}{(4\pi\times10^{-7}\text{ T}\cdot\text{m/A})(1.50\text{ A})} = 1750$ turns.

EVALUATE: With an outer radius of 15 cm, the outer circumference of the toroid is about 100 cm, or about a meter. It is reasonable that the toroid could have 1750 turns spread over a circumference of one meter.

28.51. **IDENTIFY** and **SET UP:** Use the appropriate expression for the magnetic field produced by each current configuration.

EXECUTE: **(a)** $B = \dfrac{\mu_0 I}{2\pi r}$ so $I = \dfrac{2\pi rB}{\mu_0} = \dfrac{2\pi(2.00\times10^{-2}\text{ m})(37.2\text{ T})}{4\pi\times10^{-7}\text{ T}\cdot\text{m/A}} = 3.72\times10^{6}$ A.

(b) $B = \dfrac{N\mu_0 I}{2R}$ so $I = \dfrac{2RB}{N\mu_0} = \dfrac{2(0.210\text{ m})(37.2\text{ T})}{(100)(4\pi\times10^{-7}\text{ T}\cdot\text{m/A})} = 1.24\times10^{5}$ A.

(c) $B = \mu_0 \dfrac{N}{L} I$ so $I = \dfrac{BL}{\mu_0 N} = \dfrac{(37.2\text{ T})(0.320\text{ m})}{(4\pi\times10^{-7}\text{ T}\cdot\text{m/A})(40{,}000)} = 237$ A.

EVALUATE: Much less current is needed for the solenoid, because of its large number of turns per unit length.

28.52. **IDENTIFY:** Example 28.10 shows that outside a toroidal solenoid there is no magnetic field and inside it the magnetic field is given by $B = \dfrac{\mu_0 NI}{2\pi r}$.

SET UP: The torus extends from $r_1 = 15.0$ cm to $r_2 = 18.0$ cm.

EXECUTE: **(a)** $r = 0.12$ m, which is outside the torus, so $B = 0$.

(b) $r = 0.16$ m, so $B = \dfrac{\mu_0 NI}{2\pi r} = \dfrac{\mu_0(250)(8.50\text{ A})}{2\pi(0.160\text{ m})} = 2.66\times10^{-3}$ T.

(c) $r = 0.20$ m, which is outside the torus, so $B = 0$.

EVALUATE: The magnetic field inside the torus is proportional to $1/r$, so it varies somewhat over the cross-section of the torus.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

28.53. **IDENTIFY:** Example 28.10 shows that inside a toroidal solenoid, $B = \dfrac{\mu_0 NI}{2\pi r}$.

SET UP: $r = 0.070$ m

EXECUTE: $B = \dfrac{\mu_0 NI}{2\pi r} = \dfrac{\mu_0(600)(0.650\text{ A})}{2\pi(0.070\text{ m})} = 1.11\times10^{-3}$ T.

EVALUATE: If the radial thickness of the torus is small compared to its mean diameter, B is approximately uniform inside its windings.

28.54. **IDENTIFY:** Use Eq. (28.24), with μ_0 replaced by $\mu = K_m\mu_0$, with $K_m = 80$.

SET UP: The contribution from atomic currents is the difference between B calculated with μ and B calculated with μ_0.

EXECUTE: **(a)** $B = \dfrac{\mu NI}{2\pi r} = \dfrac{K_m\mu_0 NI}{2\pi r} = \dfrac{\mu_0(80)(400)(0.25\text{ A})}{2\pi(0.060\text{ m})} = 0.0267$ T.

(b) The amount due to atomic currents is $B' = \dfrac{79}{80}B = \dfrac{79}{80}(0.0267\text{ T}) = 0.0263$ T.

EVALUATE: The presence of the core greatly enhances the magnetic field produced by the solenoid.

28.55. **IDENTIFY** and **SET UP:** $B = \dfrac{K_m\mu_0 NI}{2\pi r}$ (Eq. 28.24, with μ_0 replaced by $K_m\mu_0$)

EXECUTE: **(a)** $K_m = 1400$

$$I = \frac{2\pi rB}{\mu_0 K_m N} = \frac{(2.90\times10^{-2}\text{ m})(0.350\text{ T})}{(2\times10^{-7}\text{ T}\cdot\text{m/A})(1400)(500)} = 0.0725\text{ A}$$

(b) $K_m = 5200$

$$I = \frac{2\pi rB}{\mu_0 K_m N} = \frac{(2.90\times10^{-2}\text{ m})(0.350\text{ T})}{(2\times10^{-7}\text{ T}\cdot\text{m/A})(5200)(500)} = 0.0195\text{ A}$$

EVALUATE: If the solenoid were air-filled instead, a much larger current would be required to produce the same magnetic field.

28.56. **IDENTIFY:** Apply $B = \dfrac{K_m\mu_0 NI}{2\pi r}$.

SET UP: K_m is the relative permeability and $\chi_m = K_m - 1$ is the magnetic susceptibility.

EXECUTE: **(a)** $K_m = \dfrac{2\pi rB}{\mu_0 NI} = \dfrac{2\pi(0.2500\text{ m})(1.940\text{ T})}{\mu_0(500)(2.400\text{ A})} = 2021.$

(b) $\chi_m = K_m - 1 = 2020.$

EVALUATE: Without the magnetic material the magnetic field inside the windings would be $B/2021 = 9.6\times10^{-4}$ T. The presence of the magnetic material greatly enhances the magnetic field inside the windings.

28.57. **IDENTIFY:** The magnetic field from the solenoid alone is $B_0 = \mu_0 nI$. The total magnetic field is $B = K_m B_0$. M is given by Eq. (28.29).

SET UP: $n = 6000$ turns/m

EXECUTE: **(a)** (i) $B_0 = \mu_0 nI = \mu_0(6000\text{ m}^{-1})(0.15\text{ A}) = 1.13\times10^{-3}$ T.

(ii) $M = \dfrac{K_m - 1}{\mu_0}B_0 = \dfrac{5199}{\mu_0}(1.13\times10^{-3}\text{ T}) = 4.68\times10^{6}$ A/m.

(iii) $B = K_m B_0 = (5200)(1.13\times10^{-3}\text{ T}) = 5.88$ T.

(b) The directions of $\vec{\boldsymbol{B}}$, $\vec{\boldsymbol{B}}_0$ and $\vec{\boldsymbol{M}}$ are shown in Figure 28.57. Silicon steel is paramagnetic and $\vec{\boldsymbol{B}}_0$ and $\vec{\boldsymbol{M}}$ are in the same direction.

EVALUATE: The total magnetic field is much larger than the field due to the solenoid current alone.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

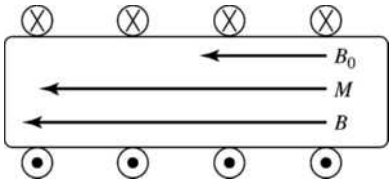


Figure 28.57

28.58. **IDENTIFY:** The presence of the magnetic material causes the net field to be slightly stronger than it would be in air.

SET UP: $K_m = B_{inside}/B_{outside}$. $\mu = K_m \mu_0$.

EXECUTE: **(a)** $K_m = \dfrac{1.5023\ \text{T}}{1.5000\ \text{T}} = 1.0015$.

(b) $\mu = K_m \mu_0 = (1.0015)(4\pi\times10^{-7}\ \text{T}\cdot\text{m/A}) = 1.259\times10^{-6}\ \text{T}\cdot\text{m/A}$

EVALUATE: μ is not much different from μ_0 since this is a paramagnetic material.

28.59. **IDENTIFY:** Moving charges create magnetic fields. The net field is the vector sum of the two fields. A charge moving in an external magnetic field feels a force.

(a) SET UP: The magnetic field due to a moving charge is $B = \dfrac{\mu_0}{4\pi}\dfrac{qv\sin\phi}{r^2}$. Both fields are into the paper, so their magnitudes add, giving $B_{net} = B + B' = \dfrac{\mu_0}{4\pi}\left(\dfrac{qv\sin\phi}{r^2} + \dfrac{q'v'\sin\phi'}{r'^2}\right)$.

EXECUTE: Substituting numbers gives

$$B_{net} = \frac{\mu_0}{4\pi}\left[\frac{(8.00\ \mu\text{C})(9.00\times10^4\ \text{m/s})\sin90°}{(0.300\ \text{m})^2} + \frac{(5.00\ \mu\text{C})(6.50\times10^4\ \text{m/s})\sin90°}{(0.400\ \text{m})^2}\right]$$

$B_{net} = 1.00\times10^{-6}\ \text{T} = 1.00\mu\text{T}$, into the paper.

(b) SET UP: The magnetic force on a moving charge is $\vec{F} = q\vec{v}\times\vec{B}$, and the magnetic field of charge q' at the location of charge q is into the page. The force on q is

$$\vec{F} = q\vec{v}\times\vec{B}' = (qv)\hat{i}\times\frac{\mu_0}{4\pi}\frac{q\vec{v}'\times\hat{r}}{r^2} = (qv)\hat{i}\times\left(\frac{\mu_0}{4\pi}\frac{qv'\sin\phi}{r^2}\right)(-\hat{k}) = \left(\frac{\mu_0}{4\pi}\frac{qq'vv'\sin\phi}{r^2}\right)\hat{j}$$

where ϕ is the angle between $\vec{v}'$ and $\hat{r}'$.

EXECUTE: Substituting numbers gives

$$\vec{F} = \frac{\mu_0}{4\pi}\left[\frac{(8.00\times10^{-6}\ \text{C})(5.00\times10^{-6}\ \text{C})(9.00\times10^4\ \text{m/s})(6.50\times10^4\ \text{m/s})}{(0.500\ \text{m})^2}\left(\frac{0.400}{0.500}\right)\right]\hat{j}$$

$$\vec{F} = (7.49\times10^{-8}\ \text{N})\hat{j}.$$

EVALUATE: These are small fields and small forces, but if the charge has small mass, the force can affect its motion.

28.60. **IDENTIFY:** Charge q_1 creates a magnetic field due to its motion. This field exerts a magnetic force on q_2, which is moving in that field.

SET UP: Find $\vec{B}_1$, the field produced by q_1 at the location of q_2. $\vec{B}_1 = \dfrac{\mu_0}{4\pi}\dfrac{q\vec{v}\times\vec{r}}{r^3}$, since $\hat{r} = \vec{r}/r$.

EXECUTE: $\vec{r} = (0.150\ \text{m})\hat{i} + (-0.250\ \text{m})\hat{j}$, so $r = 0.2915$ m.

$\vec{v}\times\vec{r} = [(9.20\times10^5\ \text{m/s})\hat{i}]\times[(0.150\ \text{m})\hat{i} + (-0.250\ \text{m})\hat{j}] = (9.20\times10^5\ \text{m/s})(-0.250\ \text{m})\hat{k}$.

$$\vec{B}_1 = (1.00\times10^{-7}\ \text{T}\cdot\text{m/A})\frac{(4.80\times10^{-6}\ \text{C})(9.20\times10^5\ \text{m/s})(-0.250\ \text{m})}{(0.2915\ \text{m})^3}\hat{k} = -(4.457\times10^{-6}\ \text{T})\hat{k}.$$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

The force that $\vec{\boldsymbol{B}}_1$ exerts on q_2 is

$F_2 = q_2\vec{v}_2 \times \vec{\boldsymbol{B}}_1 = (-2.90\times10^{-6}\ \text{C})(-5.30\times10^{5}\ \text{m/s})(-4.457\times10^{-6}\ \text{T})\hat{\boldsymbol{j}}\times\hat{\boldsymbol{k}} = -(6.850\times10^{-6}\ \text{N})\hat{\boldsymbol{i}}$.

EVALUATE: If we think of the moving charge q_1 as a current, we can use the right-hand rule for the direction of the magnetic field due to a current to find the direction of the magnetic field it creates in the vicinity of q_2. Then we can use the cross product right-hand rule to find the direction of the force this field exerts on q_2, which is in the $-x$-direction, in agreement with our result.

28.61. **IDENTIFY:** Use Eq. (28.9) and the right-hand rule to determine points where the fields of the two wires cancel.

(a) SET UP: The only place where the magnetic fields of the two wires are in opposite directions is between the wires, in the plane of the wires. Consider a point a distance x from the wire carrying $I_2 = 75.0$ A. B_{tot} will be zero where $B_1 = B_2$.

EXECUTE: $\dfrac{\mu_0 I_1}{2\pi(0.400\ \text{m} - x)} = \dfrac{\mu_0 I_2}{2\pi x}$

$I_2(0.400\ \text{m} - x) = I_1 x$; $I_1 = 25.0$ A, $I_2 = 75.0$ A

$x = 0.300$ m; $B_{\text{tot}} = 0$ along a line 0.300 m from the wire carrying 75.0 A and 0.100 m from the wire carrying current 25.0 A.

(b) SET UP: Let the wire with $I_1 = 25.0$ A be 0.400 m above the wire with $I_2 = 75.0$ A. The magnetic fields of the two wires are in opposite directions in the plane of the wires and at points above both wires or below both wires. But to have $B_1 = B_2$ must be closer to wire #1 since $I_1 < I_2$, so can have $B_{\text{tot}} = 0$ only at points above both wires. Consider a point a distance x from the wire carrying $I_1 = 25.0$ A. B_{tot} will be zero where $B_1 = B_2$.

EXECUTE: $\dfrac{\mu_0 I_1}{2\pi x} = \dfrac{\mu_0 I_2}{2\pi(0.400\ \text{m} + x)}$

$I_2 x = I_1(0.400\ \text{m} + x)$; $x = 0.200$ m

$B_{\text{tot}} = 0$ along a line 0.200 m from the wire carrying current 25.0 A and 0.600 m from the wire carrying current $I_2 = 75.0$ A.

EVALUATE: For parts (a) and (b) the locations of zero field are in different regions. In each case the points of zero field are closer to the wire that has the smaller current.

28.62. **IDENTIFY:** The wire creates a magnetic field near it, and the moving electron feels a force due to this field.

SET UP: The magnetic field due to the wire is $B = \dfrac{\mu_0 I}{2\pi r}$, and the force on a moving charge is $F = |q|vB\sin\phi$.

EXECUTE: $F = |q|vB\sin\phi = (ev\mu_0 I\sin\phi)/2\pi r$. Substituting numbers gives

$F = (1.60\times10^{-19}\ \text{C})(6.00\times10^{4}\ \text{m/s})(4\pi\times10^{-7}\ \text{T}\cdot\text{m/A})(5.20\ \text{A})(\sin 90°)/[2\pi(0.0450\ \text{m})]$.

$F = 2.22\times10^{-19}$ N. From the right-hand rule for the cross product, the direction of $\vec{\boldsymbol{v}}\times\vec{\boldsymbol{B}}$ is opposite to the current, but since the electron is negative, the force is in the same direction as the current.

EVALUATE: This force is small at an everyday level, but it would give the electron an acceleration of about $10^{11}\ \text{m/s}^2$.

28.63. **IDENTIFY:** Find the force that the magnetic field of the wire exerts on the electron.

SET UP: The force on a moving charge has magnitude $F = |q|vB\sin\phi$ and direction given by the right-hand rule. For a long straight wire, $B = \dfrac{\mu_0 I}{2\pi r}$ and the direction of $\vec{\boldsymbol{B}}$ is given by the right-hand rule.

EXECUTE: **(a)** $a = \dfrac{F}{m} = \dfrac{|q|vB\sin\phi}{m} = \dfrac{ev}{m}\left(\dfrac{\mu_0 I}{2\pi r}\right)$. Substituting numbers gives

$a = \dfrac{(1.6\times10^{-19}\text{C})(2.50\times10^{5}\ \text{m/s})(4\pi\times10^{-7}\ \text{T}\cdot\text{m/A})(13.0\ \text{A})}{(9.11\times10^{-31}\ \text{kg})(2\pi)(0.0200\ \text{m})} = 5.7\times10^{12}\ \text{m/s}^2$, away from the wire.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) The electric force must balance the magnetic force. $eE = evB$, and

$E = vB = v\dfrac{\mu_0 I}{2\pi r} = \dfrac{(250{,}000 \text{ m/s})(4\pi\times10^{-7} \text{ T}\cdot\text{m/A})(13.0 \text{ A})}{2\pi(0.0200 \text{ m})} = 32.5 \text{ N/C}$. The magnetic force is directed away from the wire so the force from the electric field must be toward the wire. Since the charge of the electron is negative, the electric field must be directed away from the wire to produce a force in the desired direction.

EVALUATE: **(c)** $mg = (9.11\times10^{-31} \text{ kg})(9.8 \text{ m/s}^2) \approx 10^{-29}$ N.

$F_{\text{el}} = eE = (1.6\times10^{-19} \text{ C})(32.5 \text{ N/C}) \approx 5\times10^{-18}$ N. $F_{\text{el}} \approx 5\times10^{11}\, F_{\text{grav}}$, so we can neglect gravity.

28.64. **IDENTIFY:** The net magnetic field is the vector sum of the fields due to each wire.

SET UP: $B = \dfrac{\mu_0 I}{2\pi r}$. The direction of $\vec{B}$ is given by the right-hand rule.

EXECUTE: **(a)** The currents are the same so points where the two fields are equal in magnitude are equidistant from the two wires. The net field is zero along the dashed line shown in Figure 28.64a.
(b) For the magnitudes of the two fields to be the same at a point, the point must be 3 times closer to the wire with the smaller current. The net field is zero along the dashed line shown in Figure 28.64b.
(c) As in (a), the points are equidistant from both wires. The net field is zero along the dashed line shown in Figure 28.64c.

EVALUATE: The lines of zero net field consist of points at which the fields of the two wires have opposite directions and equal magnitudes.

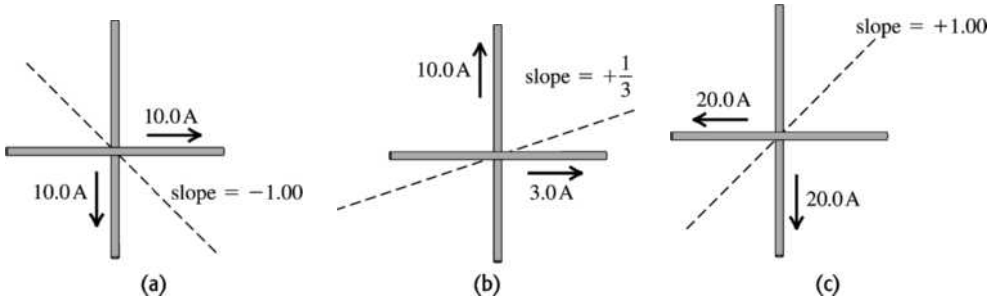

Figure 28.64

28.65. **IDENTIFY:** Find the net magnetic field due to the two loops at the location of the proton and then find the force these fields exert on the proton.

SET UP: For a circular loop, the field on the axis, a distance x from the center of the loop is $B = \dfrac{\mu_0 I R^2}{2(R^2+x^2)^{3/2}}$. $R = 0.200$ m and $x = 0.125$ m.

EXECUTE: The fields add, so $B = B_1 + B_2 = 2B_1 = 2\left[\dfrac{\mu_0 I R^2}{2(R^2+x^2)^{3/2}}\right]$. Putting in the numbers gives

$B = \dfrac{(4\pi\times10^{-7} \text{ T}\cdot\text{m/A})(3.80 \text{ A})(0.200 \text{ m})^2}{[(0.200 \text{ m})^2 + (0.125 \text{ m})^2]^{3/2}} = 1.46\times10^{-5}$ T. The magnetic force is

$F = |q|vB\sin\phi = (1.6\times10^{-19} \text{ C})(2{,}400{,}000 \text{ m/s})(1.46\times10^{-5} \text{ T})\sin 90° = 5.59\times10^{-18}$ N.

EVALUATE: The weight of a proton is $w = mg = 1.6\times10^{-24}$ N, so the force from the loops is much greater than the gravity force on the proton.

28.66. **IDENTIFY:** $\vec{B} = \dfrac{\mu_0}{4\pi}\dfrac{q\vec{v}_0\times\hat{r}}{r^2}$

SET UP: $\hat{r} = \hat{i}$ and $r = 0.250$ m, so $\vec{v}_0\times\hat{r} = v_{0z}\hat{j} - v_{0y}\hat{k}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: $\vec{B} = \dfrac{\mu_0}{4\pi}\dfrac{q}{r^2}(v_{0z}\hat{\boldsymbol{j}} - v_{0y}\hat{\boldsymbol{k}}) = (6.00\times10^{-6}\ \text{T})\hat{\boldsymbol{j}}$. $v_{0y} = 0$. $\dfrac{\mu_0}{4\pi}\dfrac{q}{r^2}v_{0z} = 6.00\times10^{-6}\ \text{T}$ and

$$v_{0z} = \frac{4\pi(6.00\times10^{-6}\ \text{T})(0.25\ \text{m})^2}{\mu_0(-7.20\times10^{-3}\ \text{C})} = -521\ \text{m/s}.$$

$v_{0x} = \pm\sqrt{v_0^2 - v_{0y}^2 - v_{0z}^2} = \pm\sqrt{(800\ \text{m/s})^2 - (-521\ \text{m/s})^2} = \pm 607\ \text{m/s}$. The sign of v_{0x} isn't determined.

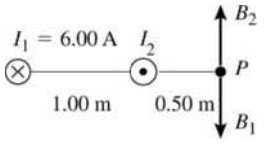
(b) Now $\vec{r} = \hat{\boldsymbol{j}}$ and $r = 0.250$ m. $\vec{B} = \dfrac{\mu_0}{4\pi}\dfrac{q\vec{v}_0\times\hat{\boldsymbol{r}}}{r^2} = \dfrac{\mu_0}{4\pi}\dfrac{q}{r^2}(v_{0x}\hat{\boldsymbol{k}} - v_{0z}\hat{\boldsymbol{i}})$.

$$B = \frac{\mu_0}{4\pi}\frac{|q|}{r^2}\sqrt{v_{0x}^2 + v_{0z}^2} = \frac{\mu_0}{4\pi}\frac{|q|}{r^2}v_0 = \frac{\mu_0}{4\pi}\frac{(7.20\times10^{-3}\ \text{C})}{(0.250\ \text{m})^2}800\ \text{m/s} = 9.20\times10^{-6}\ \text{T}.$$

EVALUATE: The magnetic field in part (b) doesn't depend on the sign of v_{0x}.

28.67. **IDENTIFY:** Use Eq. (28.9) and the right-hand rule to calculate the magnitude and direction of the magnetic field at P produced by each wire. Add these two field vectors to find the net field.

(a) SET UP: The directions of the fields at point P due to the two wires are sketched in Figure 28.67a.



EXECUTE: $\vec{B}_1$ and $\vec{B}_2$ must be equal and opposite for the resultant field at P to be zero. $\vec{B}_2$ is to the right so I_2 is out of the page.

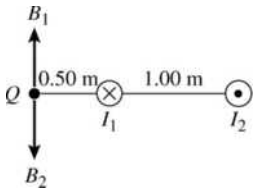
Figure 28.67a

$$B_1 = \frac{\mu_0 I_1}{2\pi r_1} = \frac{\mu_0}{2\pi}\left(\frac{6.00\ \text{A}}{1.50\ \text{m}}\right) \qquad B_2 = \frac{\mu_0 I_2}{2\pi r_2} = \frac{\mu_0}{2\pi}\left(\frac{I_2}{0.50\ \text{m}}\right)$$

$B_1 = B_2$ says $\dfrac{\mu_0}{2\pi}\left(\dfrac{6.00\ \text{A}}{1.50\ \text{m}}\right) = \dfrac{\mu_0}{2\pi}\left(\dfrac{I_2}{0.50\ \text{m}}\right)$

$$I_2 = \left(\frac{0.50\ \text{m}}{1.50\ \text{m}}\right)(6.00\ \text{A}) = 2.00\ \text{A}$$

(b) SET UP: The directions of the fields at point Q are sketched in Figure 28.67b.



EXECUTE: $B_1 = \dfrac{\mu_0 I_1}{2\pi r_1}$

$$B_1 = (2\times10^{-7}\ \text{T}\cdot\text{m/A})\left(\frac{6.00\ \text{A}}{0.50\ \text{m}}\right) = 2.40\times10^{-6}\ \text{T}$$

$$B_2 = \frac{\mu_0 I_2}{2\pi r_2}$$

$$B_2 = (2\times10^{-7}\ \text{T}\cdot\text{m/A})\left(\frac{2.00\ \text{A}}{1.50\ \text{m}}\right) = 2.67\times10^{-7}\ \text{T}$$

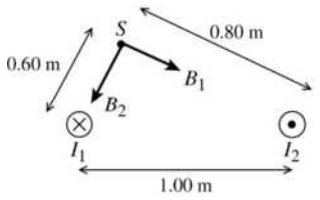
Figure 28.67b

$\vec{B}_1$ and $\vec{B}_2$ are in opposite directions and $B_1 > B_2$ so

$B = B_1 - B_2 = 2.40\times10^{-6}\ \text{T} - 2.67\times10^{-7}\ \text{T} = 2.13\times10^{-6}\ \text{T}$, and $\vec{B}$ is to the right.

(c) SET UP: The directions of the fields at point S are sketched in Figure 28.67c.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.



EXECUTE: $B_1 = \dfrac{\mu_0 I_1}{2\pi r_1}$

$$B_1 = (2\times10^{-7}\ \text{T}\cdot\text{m/A})\left(\frac{6.00\ \text{A}}{0.60\ \text{m}}\right) = 2.00\times10^{-6}\ \text{T}$$

$$B_2 = \frac{\mu_0 I_2}{2\pi r_2}$$

$$B_2 = (2\times10^{-7}\ \text{T}\cdot\text{m/A})\left(\frac{2.00\ \text{A}}{0.80\ \text{m}}\right) = 5.00\times10^{-7}\ \text{T}$$

Figure 28.67c

$\vec{B}_1$ and $\vec{B}_2$ are right angles to each other, so the magnitude of their resultant is given by

$B = \sqrt{B_1^2 + B_2^2} = \sqrt{(2.00\times10^{-6}\ \text{T})^2 + (5.00\times10^{-7}\ \text{T})^2} = 2.06\times10^{-6}\ \text{T}.$

EVALUATE: The magnetic field lines for a long, straight wire are concentric circles with the wire at the center. The magnetic field at each point is tangent to the field line, so $\vec{B}$ is perpendicular to the line from the wire to the point where the field is calculated.

28.68. **IDENTIFY:** Find the vector sum of the magnetic fields due to each wire.

SET UP: For a long straight wire $B = \dfrac{\mu_0 I}{2\pi r}$. The direction of $\vec{B}$ is given by the right-hand rule and is perpendicular to the line from the wire to the point where the field is calculated.

EXECUTE: **(a)** The magnetic field vectors are shown in Figure 28.68a.

(b) At a position on the x-axis $B_{\text{net}} = 2\dfrac{\mu_0 I}{2\pi r}\sin\theta = \dfrac{\mu_0 I}{\pi\sqrt{x^2+a^2}}\dfrac{a}{\sqrt{x^2+a^2}} = \dfrac{\mu_0 Ia}{\pi(x^2+a^2)}$, in the positive x-direction.

(c) The graph of B versus x/a is given in Figure 28.68b.

EVALUATE: **(d)** The magnetic field is a maximum at the origin, $x = 0$.

(e) When $x \gg a$, $B \approx \dfrac{\mu_0 Ia}{\pi x^2}$.

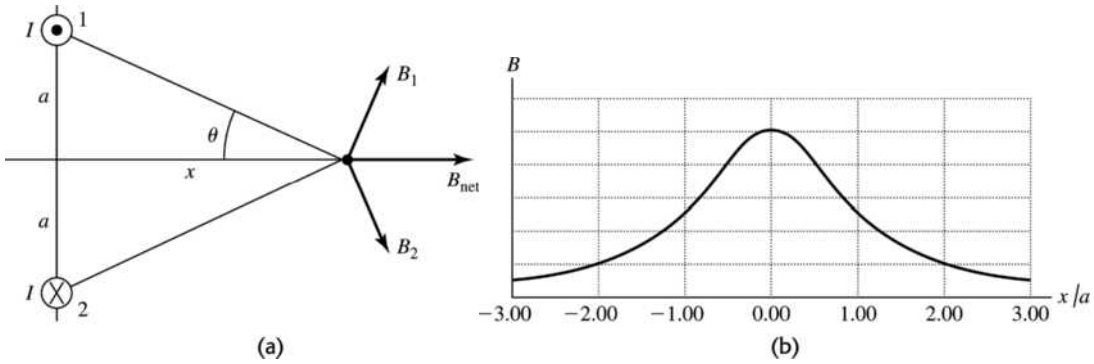


Figure 28.68

28.69. **IDENTIFY:** Apply $F = lB\sin\phi$, with the magnetic field at point P that is calculated in Problem 28.68.

SET UP: The net field of the first two wires at the location of the third wire is $B = \dfrac{\mu_0 Ia}{\pi(x^2+a^2)}$, in the $+x$-direction.

EXECUTE: **(a)** Wire is carrying current into the page, so it feels a force in the $-y$-direction.

$$\frac{F}{L} = IB = I\left(\frac{\mu_0 Ia}{\pi(x^2+a^2)}\right) = \frac{\mu_0(6.00\ \text{A})^2(0.400\ \text{m})}{\pi((0.600\ \text{m})^2+(0.400\ \text{m})^2)} = 1.11\times10^{-5}\ \text{N/m}.$$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) If the wire carries current out of the page then the force felt will be in the opposite direction as in part (a). Thus the force will be 1.11×10^{-5} N/m, in the $+y$-direction.

EVALUATE: We could also calculate the force exerted by each of the first two wires and find the vector sum of the two forces.

28.70. **IDENTIFY:** The wires repel each other since they carry currents in opposite directions, so the wires will move away from each other until the magnetic force is just balanced by the force due to the spring.

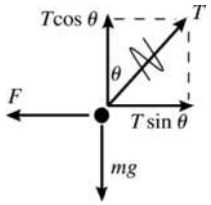
SET UP: Call x the distance the springs each stretch. The force of the spring is kx and the magnetic force on each wire is $F_{\text{mag}} = \dfrac{\mu_0}{2\pi}\dfrac{I^2L}{x}$.

EXECUTE: On each wire, $F_{\text{spr}} = F_{\text{mag}}$, and there are two spring forces on each wire. Therefore $2kx = \dfrac{\mu_0}{2\pi}\dfrac{I^2L}{x}$, which gives $x = \sqrt{\dfrac{\mu_0}{4\pi}\dfrac{I^2L}{k}}$.

EVALUATE: Since $\mu_0/4\pi$ is small, x will likely be much less than the length of the wires.

28.71. **IDENTIFY:** Apply $\sum\vec{\boldsymbol{F}} = 0$ to one of the wires. The force one wire exerts on the other depends on I so $\sum\vec{\boldsymbol{F}} = 0$ gives two equations for the two unknowns T and I.

SET UP: The force diagram for one of the wires is given in Figure 28.71.



The force one wire exerts on the other is $F = \left(\dfrac{\mu_0 I^2}{2\pi r}\right)L$, where $r = 2(0.040\text{ m})\sin\theta = 8.362\times10^{-3}$ m is the distance between the two wires.

Figure 28.71

EXECUTE: $\sum F_y = 0$ gives $T\cos\theta = mg$ and $T = mg/\cos\theta$

$\sum F_x = 0$ gives $F = T\sin\theta = (mg/\cos\theta)\sin\theta = mg\tan\theta$

And $m = \lambda L$, so $F = \lambda Lg\tan\theta$

$$\left(\frac{\mu_0 I^2}{2\pi r}\right)L = \lambda Lg\tan\theta$$

$$I = \sqrt{\frac{\lambda g r\tan\theta}{(\mu_0/2\pi)}}$$

$$I = \sqrt{\frac{(0.0125\text{ kg/m})(9.80\text{ m/s}^2)(\tan 6.00^\circ)(8.362\times10^{-3}\text{ m})}{2\times10^{-7}\text{ T}\cdot\text{m/A}}} = 23.2\text{ A}$$

EVALUATE: Since the currents are in opposite directions the wires repel. When I is increased, the angle θ from the vertical increases; a large current is required even for the small displacement specified in this problem.

28.72. **IDENTIFY:** Consider the forces on each side of the loop.

SET UP: The forces on the left and right sides cancel. The forces on the top and bottom segments of the loop are in opposite directions, so the magnitudes subtract.

EXECUTE: $F = F_{\text{t}} - F_{\text{b}} = \left(\dfrac{\mu_0 I_{\text{wire}}}{2\pi}\right)\left(\dfrac{Il}{r_{\text{t}}} - \dfrac{Il}{r_{\text{b}}}\right) = \dfrac{\mu_0 Il I_{\text{wire}}}{2\pi}\left(\dfrac{1}{r_{\text{t}}} - \dfrac{1}{r_{\text{b}}}\right)$.

$F = \dfrac{\mu_0(5.00\text{ A})(0.200\text{ m})(14.0\text{ A})}{2\pi}\left(-\dfrac{1}{0.100\text{ m}} + \dfrac{1}{0.026\text{ m}}\right) = 7.97\times10^{-5}$ N. The force on the top segment is away from the wire, so the net force is away from the wire.

EVALUATE: The net force on a current loop in a uniform magnetic field is zero, but the magnetic field of the wire is not uniform; it is stronger closer to the wire.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

28.73. **IDENTIFY:** Knowing the magnetic field at the center of the ring, we can calculate the current running through it. We can then use this current to calculate the torque that the external magnetic field exerts on the ring.
SET UP: The torque on a current loop is $\tau = IAB\sin\phi$. We can use the magnetic field of the ring, $B = \dfrac{\mu_0 I}{2R}$, to calculate the current in the ring.

EXECUTE: $I = \dfrac{2RB_{\text{ring}}}{\mu_0} = \dfrac{2(2.50\times10^{-2}\text{ m})(75.4\times10^{-6}\text{ T})}{4\pi\times10^{-7}\text{ T}\cdot\text{m/A}} = 3.00\text{ A}$. The torque is a maximum when $\phi = 90°$ and the plane of the ring is parallel to the field.

$\tau_{\max} = IAB = (3.00\text{ A})(0.375\text{ T})\pi(2.50\times10^{-2}\text{ m})^2 = 2.21\times10^{-3}\text{ N}\cdot\text{m}$.

EVALUATE: When the external field is perpendicular to the plane of the ring the torque on the ring is zero.

28.74. **IDENTIFY:** Apply $d\vec{\boldsymbol{B}} = \dfrac{\mu_0}{4\pi}\dfrac{Id\vec{\boldsymbol{l}}\times\hat{\boldsymbol{r}}}{r^2}$.

SET UP: The two straight segments produce zero field at P. The field at the center of a circular loop of radius R is $B = \dfrac{\mu_0 I}{2R}$, so the field at the center of curvature of a semicircular loop is $B = \dfrac{\mu_0 I}{4R}$.

EXECUTE: The semicircular loop of radius a produces field out of the page at P and the semicircular loop of radius b produces field into the page. Therefore, $B = B_a - B_b = \dfrac{1}{2}\left(\dfrac{\mu_0 I}{2}\right)\left(\dfrac{1}{a}-\dfrac{1}{b}\right) = \dfrac{\mu_0 I}{4a}\left(1-\dfrac{a}{b}\right)$, out of page.

EVALUATE: If $a = b$, $B = 0$.

28.75. **IDENTIFY:** Find the vector sum of the fields due to each loop.

SET UP: For a single loop $B = \dfrac{\mu_0 Ia^2}{2(x^2+a^2)^{3/2}}$. Here we have two loops, each of N turns, and measuring the field along the x-axis from between them means that the "x" in the formula is different for each case:
EXECUTE:

$$\text{Left coil: } x \to x+\frac{a}{2} \Rightarrow B_{\text{l}} = \frac{\mu_0 NIa^2}{2((x+a/2)^2+a^2)^{3/2}}.$$

$$\text{Right coil: } x \to x-\frac{a}{2} \Rightarrow B_{\text{r}} = \frac{\mu_0 NIa^2}{2((x-a/2)^2+a^2)^{3/2}}.$$

So, the total field at a point a distance x from the point between them is

$$B = \frac{\mu_0 NIa^2}{2}\left(\frac{1}{((x+a/2)^2+a^2)^{3/2}}+\frac{1}{((x-a/2)^2+a^2)^{3/2}}\right).$$

(b) B versus x is graphed in Figure 28.75. Figure 28.75a is the total field and Figure 28.75b is the field from the right-hand coil.

(c) At point P, $x = 0$ and $B = \dfrac{\mu_0 NIa^2}{2}\left(\dfrac{1}{((a/2)^2+a^2)^{3/2}}+\dfrac{1}{((-a/2)^2+a^2)^{3/2}}\right) = \dfrac{\mu_0 NIa^2}{(5a^2/4)^{3/2}} = \left(\dfrac{4}{5}\right)^{3/2}\dfrac{\mu_0 NI}{a}$

(d) $B = \left(\dfrac{4}{5}\right)^{3/2}\dfrac{\mu_0 NI}{a} = \left(\dfrac{4}{5}\right)^{3/2}\dfrac{\mu_0(300)(6.00\text{ A})}{(0.080\text{ m})} = 0.0202\text{ T}.$

(e) $\dfrac{dB}{dx} = \dfrac{\mu_0 NIa^2}{2}\left(\dfrac{-3(x+a/2)}{((x+a/2)^2+a^2)^{5/2}}+\dfrac{-3(x-a/2)}{((x-a/2)^2+a^2)^{5/2}}\right)$. At $x = 0$,

$$\left.\frac{dB}{dx}\right|_{x=0} = \frac{\mu_0 NIa^2}{2}\left(\frac{-3(a/2)}{((a/2)^2+a^2)^{5/2}}+\frac{-3(-a/2)}{((-a/2)^2+a^2)^{5/2}}\right) = 0.$$

$$\frac{d^2B}{dx^2} = \frac{\mu_0 NIa^2}{2}\left(\frac{-3}{((x+a/2)^2+a^2)^{5/2}}+\frac{6(x+a/2)^2(5/2)}{((x+a/2)^2+a^2)^{7/2}}+\frac{-3}{((x-a/2)^2+a^2)^{5/2}}+\frac{6(x-a/2)^2(5/2)}{((x-a/2)^2+a^2)^{7/2}}\right)$$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

At $x = 0$,

$$\left.\frac{d^2B}{dx^2}\right|_{x=0} = \frac{\mu_0 NIa^2}{2}\left(\frac{-3}{((a/2)^2+a^2)^{5/2}} + \frac{6(a/2)^2(5/2)}{((a/2)^2+a^2)^{7/2}} + \frac{-3}{((a/2)^2+a^2)^{5/2}} + \frac{6(-a/2)^2(5/2)}{((a/2)^2+a^2)^{7/2}}\right) = 0.$$

EVALUATE: Since both first and second derivatives are zero, the field can only be changing very slowly.

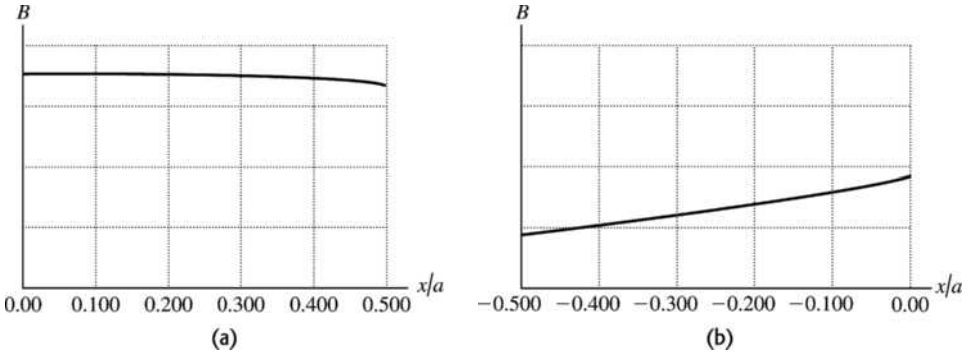


Figure 28.75

28.76. **IDENTIFY:** A current-carrying wire produces a magnetic field, but the strength of the field depends on the shape of the wire.

SET UP: The magnetic field at the center of a circular wire of radius a is $B = \mu_0 I/2a$, and the field a distance x from the center of a straight wire of length $2a$ is $B = \dfrac{\mu_0 I}{4\pi x}\dfrac{2a}{\sqrt{x^2+a^2}}$.

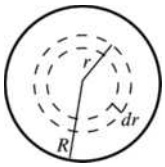
EXECUTE: **(a)** Since the diameter $D = 2a$, we have $B = \mu_0 I/2a = \mu_0 I/D$.

(b) In this case, the length of the wire is equal to the diameter of the circle, so $2a = \pi D$, giving $a = \pi D/2$, and $x = D/2$. Therefore $B = \dfrac{\mu_0 I}{4\pi}\dfrac{2(\pi D/2)}{(D/2)\sqrt{D^2/4+\pi^2 D^2/4}} = \dfrac{\mu_0 I}{D\sqrt{1+\pi^2}}$.

EVALUATE: The field in part (a) is greater by a factor of $\sqrt{1+\pi^2}$. It is reasonable that the field due to the circular wire is greater than the field due to the straight wire because more of the current is close to point A for the circular wire than it is for the straight wire.

28.77. **(a) IDENTIFY:** Consider current density J for a small concentric ring and integrate to find the total current in terms of α and R.

SET UP: We can't say $I = JA = J\pi R^2$, since J varies across the cross section.



To integrate J over the cross section of the wire, divide the wire cross section up into thin concentric rings of radius r and width dr, as shown in Figure 28.77.

Figure 28.77

EXECUTE: The area of such a ring is dA, and the current through it is $dI = J\,dA$; $dA = 2\pi r dr$ and

$dI = J\,dA = \alpha r(2\pi r\,dr) = 2\pi\alpha r^2 dr$

$I = \int dI = 2\pi\alpha\int_0^R r^2 dr = 2\pi\alpha(R^3/3)$ so $\alpha = \dfrac{3I}{2\pi R^3}$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) IDENTIFY and **SET UP:** (i) $r \le R$
Apply Ampere's law to a circle of radius $r < R$. Use the method of part (a) to find the current enclosed by Ampere's law path.

EXECUTE: $\oint \vec{\boldsymbol{B}} \cdot d\vec{\boldsymbol{l}} = \oint B\, dl = B\oint dl = B(2\pi r)$, by the symmetry and direction of $\vec{\boldsymbol{B}}$. The current passing through the path is $I_{\text{encl}} = \int dl$, where the integration is from 0 to r.

$I_{\text{encl}} = 2\pi\alpha\int_0^r r^2 dr = \dfrac{2\pi\alpha r^3}{3} = \dfrac{2\pi}{3}\left(\dfrac{3I}{2\pi R^3}\right)r^3 = \dfrac{Ir^3}{R^3}$. Thus $\oint \vec{\boldsymbol{B}} \cdot d\vec{\boldsymbol{l}} = \mu_0 I_{\text{encl}}$ gives

$B(2\pi r) = \mu_0\left(\dfrac{Ir^3}{R^3}\right)$ and $B = \dfrac{\mu_0 I r^2}{2\pi R^3}$.

(ii) **IDENTIFY** and **SET UP:** $r \ge R$
Apply Ampere's law to a circle of radius $r > R$.

EXECUTE: $\oint \vec{\boldsymbol{B}} \cdot d\vec{\boldsymbol{l}} = \oint B\, dl = B\oint dl = B(2\pi r)$

$I_{\text{encl}} = I$; all the current in the wire passes through this path. Thus $\oint \vec{\boldsymbol{B}} \cdot d\vec{\boldsymbol{l}} = \mu_0 I_{\text{encl}}$ gives $B(2\pi r) = \mu_0 I$ and $B = \dfrac{\mu_0 I}{2\pi r}$.

EVALUATE: Note that at $r = R$ the expression in (i) (for $r \le R$) gives $B = \dfrac{\mu_0 I}{2\pi R}$. At $r = R$ the expression in (ii) (for $r \ge R$) gives $B = \dfrac{\mu_0 I}{2\pi R}$, which is the same.

28.78. **IDENTIFY:** Apply $d\vec{\boldsymbol{B}} = \dfrac{\mu_0}{4\pi}\dfrac{I d\vec{\boldsymbol{l}} \times \hat{\boldsymbol{r}}}{r^2}$.

SET UP: The horizontal wire yields zero magnetic field since $d\vec{\boldsymbol{l}} \times \vec{\boldsymbol{r}} = 0$. The vertical current provides the magnetic field of half of an infinite wire. (The contributions from all infinitesimal pieces of the wire point in the same direction, so there is no vector addition or components to worry about.)

EXECUTE: $B = \frac{1}{2}\left(\dfrac{\mu_0 I}{2\pi R}\right) = \dfrac{\mu_0 I}{4\pi R}$ and is directed out of the page.

EVALUATE: In the equation preceding Eq. (28.8) the limits on the integration are 0 to a rather than $-a$ to a and this introduces a factor of $\frac{1}{2}$ into the expression for B.

28.79. **IDENTIFY:** Apply Ampere's law to a circular path of radius r.
SET UP: Assume the current is uniform over the cross section of the conductor.
EXECUTE: **(a)** $r < a \Rightarrow I_{\text{encl}} = 0 \Rightarrow B = 0$.

(b) $a < r < b \Rightarrow I_{\text{encl}} = I\left(\dfrac{A_{a\to r}}{A_{a\to b}}\right) = I\left(\dfrac{\pi(r^2 - a^2)}{\pi(b^2 - a^2)}\right) = I\dfrac{(r^2 - a^2)}{(b^2 - a^2)}$. $\oint \vec{\boldsymbol{B}} \cdot d\vec{\boldsymbol{l}} = B2\pi r = \mu_0 I\dfrac{(r^2 - a^2)}{(b^2 - a^2)}$ and

$B = \dfrac{\mu_0 I}{2\pi r}\dfrac{(r^2 - a^2)}{(b^2 - a^2)}$.

(c) $r > b \Rightarrow I_{\text{encl}} = I$. $\oint \vec{\boldsymbol{B}} \cdot d\vec{\boldsymbol{l}} = B2\pi r = \mu_0 I$ and $B = \dfrac{\mu_0 I}{2\pi r}$.

EVALUATE: The expression in part (b) gives $B = 0$ at $r = a$ and this agrees with the result of part (a). The expression in part (b) gives $B = \dfrac{\mu_0 I}{2\pi b}$ at $r = b$ and this agrees with the result of part (c).

28.80. **IDENTIFY:** The net field is the vector sum of the fields due to the circular loop and to the long straight wire.

SET UP: For the long wire, $B = \dfrac{\mu_0 I_1}{2\pi D}$, and for the loop, $B = \dfrac{\mu_0 I_2}{2R}$.

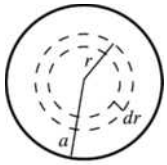
© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: At the center of the circular loop the current I_2 generates a magnetic field that is into the page, so the current I_1 must point to the right. For complete cancellation the two fields must have the same magnitude: $\frac{\mu_0 I_1}{2\pi D} = \frac{\mu_0 I_2}{2R}$. Thus, $I_1 = \frac{\pi D}{R} I_2$.

EVALUATE: If I_1 is to the left the two fields add.

28.81. **IDENTIFY:** Use the current density J to find dI through a concentric ring and integrate over the appropriate cross section to find the current through that cross section. Then use Ampere's law to find $\vec{B}$ at the specified distance from the center of the wire.

(a) SET UP:

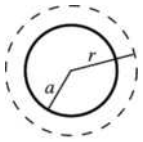


Divide the cross section of the cylinder into thin concentric rings of radius r and width dr, as shown in Figure 28.81a. The current through each ring is $dI = J\,dA = J 2\pi r\,dr$.

Figure 28.81a

EXECUTE: $dI = \frac{2I_0}{\pi a^2}[1-(r/a)^2]2\pi r\,dr = \frac{4I_0}{a^2}[1-(r/a)^2]r\,dr$. The total current I is obtained by integrating dI over the cross section $I = \int_0^a dI = \left(\frac{4I_0}{a^2}\right)\int_0^a (1-r^2/a^2)r\,dr = \left(\frac{4I_0}{a^2}\right)\left[\frac{1}{2}r^2 - \frac{1}{4}r^4/a^2\right]_0^a = I_0$, as was to be shown.

(b) SET UP: Apply Ampere's law to a path that is a circle of radius $r > a$, as shown in Figure 28.81b.



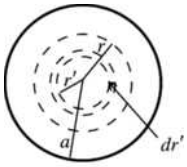
$\oint \vec{B}\cdot d\vec{l} = B(2\pi r)$

$I_{\text{encl}} = I_0$ (the path encloses the entire cylinder)

Figure 28.81b

EVALUATE: $\oint \vec{B}\cdot d\vec{l} = \mu_0 I_{\text{encl}}$ says $B(2\pi r) = \mu_0 I_0$ and $B = \frac{\mu_0 I_0}{2\pi r}$.

(c) SET UP:



Divide the cross section of the cylinder into concentric rings of radius r' and width dr', as was done in part (a). See Figure 28.81c. The current dI through each ring is $dI = \frac{4I_0}{a^2}\left[1-\left(\frac{r'}{a}\right)^2\right]r'\,dr'$.

Figure 28.81c

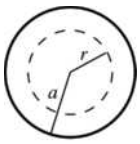
EXECUTE: The current I is obtained by integrating dI from $r' = 0$ to $r' = r$:

$$I = \int dI = \frac{4I_0}{a^2}\int_0^r \left[1-\left(\frac{r'}{a}\right)^2\right]r'\,dr' = \frac{4I_0}{a^2}\left[\tfrac{1}{2}(r')^2 - \tfrac{1}{4}(r')^4/a^2\right]_0^r$$

$$I = \frac{4I_0}{a^2}(r^2/2 - r^4/4a^2) = \frac{I_0 r^2}{a^2}\left(2-\frac{r^2}{a^2}\right)$$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(d) SET UP: Apply Ampere's law to a path that is a circle of radius $r < a$, as shown in Figure 28.81d.



$$\oint \vec{\boldsymbol{B}} \cdot d\vec{\boldsymbol{l}} = B(2\pi r)$$

$$I_{\text{encl}} = \frac{I_0 r^2}{a^2}\left(2 - \frac{r^2}{a^2}\right) \text{ (from part (c))}$$

Figure 28.81d

EXECUTE: $\oint \vec{\boldsymbol{B}} \cdot d\vec{\boldsymbol{l}} = \mu_0 I_{\text{encl}}$ says $B(2\pi r) = \mu_0 \frac{I_0 r^2}{a^2}(2 - r^2/a^2)$ and $B = \frac{\mu_0 I_0}{2\pi}\frac{r}{a^2}(2 - r^2/a^2)$

EVALUATE: Result in part (b) evaluated at $r = a$: $B = \frac{\mu_0 I_0}{2\pi a}$. Result in part (d) evaluated at $r = a$: $B = \frac{\mu_0 I_0}{2\pi}\frac{a}{a^2}(2 - a^2/a^2) = \frac{\mu_0 I_0}{2\pi a}$. The two results, one for $r > a$ and the other for $r < a$, agree at $r = a$.

28.82. IDENTIFY: Apply Ampere's law to a circle of radius *r*.

SET UP: The current within a radius *r* is $I = \int \vec{\boldsymbol{J}} \cdot d\vec{\boldsymbol{A}}$, where the integration is over a disk of radius *r*.

EXECUTE: (a) $I_0 = \int \vec{\boldsymbol{J}} \cdot d\vec{\boldsymbol{A}} = \int\!\!\int \left(\frac{b}{r}e^{(r-a)/\delta}\right) r\,dr\,d\theta = 2\pi b \int_0^a e^{(r-a)/\delta} dr = 2\pi b\delta\, e^{(r-a)/\delta}\Big|_0^a = 2\pi b\delta(1 - e^{-a/\delta})$.

$I_0 = 2\pi(600 \text{ A/m})(0.025 \text{ m})(1 - e^{(0.050/0.025)}) = 81.5 \text{ A}$.

(b) For $r \geq a$, $\oint \vec{\boldsymbol{B}} \cdot d\vec{\boldsymbol{l}} = B2\pi r = \mu_0 I_{\text{encl}} = \mu_0 I_0$ and $B = \frac{\mu_0 I_0}{2\pi r}$.

(c) For $r \leq a$, $I(r) = \int \vec{\boldsymbol{J}} \cdot d\vec{\boldsymbol{A}} = \int\!\!\int \left(\frac{b}{r'}e^{(r'-a)/\delta}\right) r'\,dr'\,d\theta = 2\pi b \int_0^r e^{(r-a)/\delta} dr = 2\pi b\delta e^{(r'-a)/\delta}\Big|_0^r$.

$I(r) = 2\pi b\delta(e^{(r-a)/\delta} - e^{-a/\delta}) = 2\pi b\delta e^{-a/\delta}(e^{r/\delta} - 1)$ and $I(r) = I_0 \frac{(e^{r/\delta} - 1)}{(e^{a/\delta} - 1)}$.

(d) For $r \leq a$, $\oint \vec{\boldsymbol{B}} \cdot d\vec{\boldsymbol{l}} = B(r)2\pi r = \mu_0 I_{\text{encl}} = \mu_0 I_0 \frac{(e^{r/\delta} - 1)}{(e^{a/\delta} - 1)}$ and $B = \frac{\mu_0 I_0 (e^{r/\delta} - 1)}{2\pi r(e^{a/\delta} - 1)}$.

(e) At $r = \delta = 0.025$ m, $B = \frac{\mu_0 I_0 (e-1)}{2\pi\delta(e^{a/\delta} - 1)} = \frac{\mu_0(81.5 \text{ A})}{2\pi(0.025 \text{ m})}\frac{(e-1)}{(e^{0.050/0.025} - 1)} = 1.75\times10^{-4}$ T.

At $r = a = 0.050$ m, $B = \frac{\mu_0 I_0}{2\pi a}\frac{(e^{a/\delta} - 1)}{(e^{a/\delta} - 1)} = \frac{\mu_0(81.5 \text{ A})}{2\pi(0.050 \text{ m})} = 3.26\times10^{-4}$ T.

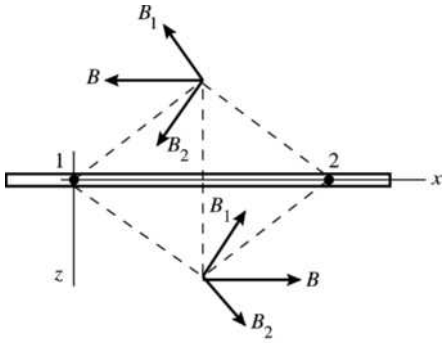
At $r = 2a = 0.100$ m, $B = \frac{\mu_0 I_0}{2\pi r} = \frac{\mu_0(81.5 \text{ A})}{2\pi(0.100 \text{ m})} = 1.63\times10^{-4}$ T.

EVALUATE: At points outside the cylinder, the magnetic field is the same as that due to a long wire running along the axis of the cylinder.

28.83. IDENTIFY: Use what we know about the magnetic field of a long, straight conductor to deduce the symmetry of the magnetic field. Then apply Ampere's law to calculate the magnetic field at a distance *a* above and below the current sheet.

SET UP: Do parts (a) and (b) together.

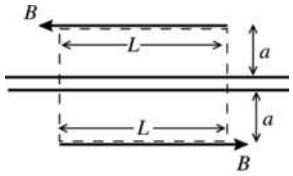
© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.



Consider the individual currents in pairs, where the currents in each pair are equidistant on either side of the point where $\vec{B}$ is being calculated. Figure 28.83a shows that for each pair the z-components cancel, and that above the sheet the field is in the $-x$-direction and that below the sheet it is in the $+x$-direction.

Figure 28.83a

Also, by symmetry the magnitude of $\vec{B}$ a distance a above the sheet must equal the magnitude of $\vec{B}$ a distance a below the sheet. Now that we have deduced the symmetry of $\vec{B}$, apply Ampere's law. Use a path that is a rectangle, as shown in Figure 28.83b.



$$\oint \vec{B} \cdot d\vec{l} = \mu_0 I_{\text{encl}}$$

Figure 28.83b

I is directed out of the page, so for I to be positive the integral around the path is taken in the counterclockwise direction.

EXECUTE: Since $\vec{B}$ is parallel to the sheet, on the sides of the rectangle that have length $2a$, $\oint \vec{B} \cdot d\vec{l} = 0.$ On the long sides of length L, $\vec{B}$ is parallel to the side, in the direction we are integrating around the path, and has the same magnitude, B, on each side. Thus $\oint \vec{B} \cdot d\vec{l} = 2BL.$ n conductors per unit length and current I out of the page in each conductor gives $I_{\text{encl}} = InL.$ Ampere's law then gives $2BL = \mu_0 InL$ and $B = \frac{1}{2}\mu_0 In.$

EVALUATE: Note that B is independent of the distance a from the sheet. Compare this result to the electric field due to an infinite sheet of charge (Example 22.7).

28.84. **IDENTIFY:** Find the vector sum of the fields due to each sheet.

SET UP: Problem 28.83 shows that for an infinite sheet $B = \frac{1}{2}\mu_0 In.$ If I is out of the page, $\vec{B}$ is to the left above the sheet and to the right below the sheet. If I is into the page, $\vec{B}$ is to the right above the sheet and to the left below the sheet. B is independent of the distance from the sheet. The directions of the two fields at points P, R and S are shown in Figure 28.84.

EXECUTE: **(a)** Above the two sheets, the fields cancel (since there is no dependence upon the distance from the sheets).

(b) In between the sheets the two fields add up to yield $B = \mu_0 nI,$ to the right.

(c) Below the two sheets, their fields again cancel (since there is no dependence upon the distance from the sheets).

EVALUATE: The two sheets with currents in opposite directions produce a uniform field between the sheets and zero field outside the two sheets. This is analogous to the electric field produced by large parallel sheets of charge of opposite sign.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

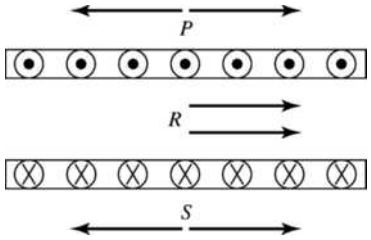


Figure 28.84

28.85. **IDENTIFY** and **SET UP:** Use Eq. (28.28) to calculate the total magnetic moment of a volume V of the iron. Use the density and atomic mass of iron to find the number of atoms in this volume and use that to find the magnetic dipole moment per atom.

EXECUTE: $M = \dfrac{\mu_{\text{total}}}{V}$, so $\mu_{\text{total}} = MV$. The average magnetic moment per atom is

$\mu_{\text{atom}} = \mu_{\text{total}}/N = MV/N$, where N is the number of atoms in volume V. The mass of volume V is $m = \rho V$, where ρ is the density. ($\rho_{\text{iron}} = 7.8\times10^3$ kg/m^3). The number of moles of iron in volume V is

$n = \dfrac{m}{55.847\times10^{-3}\ \text{kg/mol}} = \dfrac{\rho V}{55.847\times10^{-3}\ \text{kg/mol}}$, where 55.847×10^{-3} kg/mol is the atomic mass of iron from Appendix D. $N = nN_{\text{A}}$, where $N_{\text{A}} = 6.022\times10^{23}$ atoms/mol is Avogadro's number. Thus

$N = nN_{\text{A}} = \dfrac{\rho V N_{\text{A}}}{55.847\times10^{-3}\ \text{kg/mol}}$.

$\mu_{\text{atom}} = \dfrac{MV}{N} = MV\left(\dfrac{55.847\times10^{-3}\ \text{kg/mol}}{\rho V N_{\text{A}}}\right) = \dfrac{M(55.847\times10^{-3}\ \text{kg/mol})}{\rho N_{\text{A}}}$.

$\mu_{\text{atom}} = \dfrac{(6.50\times10^4\ \text{A/m})(55.847\times10^{-3}\ \text{kg/mol})}{(7.8\times10^3\ \text{kg/m}^3)(6.022\times10^{23}\ \text{atoms/mol})}$

$\mu_{\text{atom}} = 7.73\times10^{-25}\ \text{A}\cdot\text{m}^2 = 7.73\times10^{-25}$ J/T

$\mu_{\text{B}} = 9.274\times10^{-24}\ \text{A}\cdot\text{m}^2$, so $\mu_{\text{atom}} = 0.0834\mu_{\text{B}}$.

EVALUATE: The magnetic moment per atom is much less than one Bohr magneton. The magnetic moments of each electron in the iron must be in different directions and mostly cancel each other.

28.86. **IDENTIFY:** Approximate the moving belt as an infinite current sheet.

SET UP: Problem 28.83 shows that $B = \frac{1}{2}\mu_0 In$ for an infinite current sheet. Let L be the width of the sheet, so $n = 1/L$.

EXECUTE: The amount of charge on a length Δx of the belt is $\Delta Q = L\Delta x\sigma$, so $I = \dfrac{\Delta Q}{\Delta t} = L\dfrac{\Delta x}{\Delta t}\sigma = Lv\sigma$.

Approximating the belt as an infinite sheet $B = \dfrac{\mu_0 I}{2L} = \dfrac{\mu_0 v\sigma}{2}$. $\vec{\boldsymbol{B}}$ is directed out of the page, as shown in Figure 28.86.

EVALUATE: The field is uniform above the sheet, for points close enough to the sheet for it to be considered infinite.

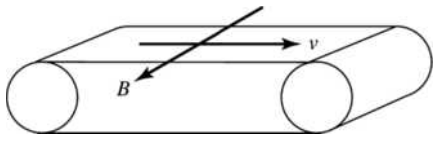

Figure 28.86

28.87. **IDENTIFY:** The current-carrying wires repel each other magnetically, causing them to accelerate horizontally. Since gravity is vertical, it plays no initial role.

SET UP: The magnetic force per unit length is $\frac{F}{L}=\frac{\mu_0}{2\pi}\frac{I^2}{d}$, and the acceleration obeys the equation $F/L = m/L\ a$. The rms current over a short discharge time is $I_0/\sqrt{2}$.

EXECUTE: **(a)** First get the force per unit length:

$$\frac{F}{L}=\frac{\mu_0}{2\pi}\frac{I^2}{d}=\frac{\mu_0}{2\pi d}\left(\frac{I_0}{\sqrt{2}}\right)^2=\frac{\mu_0}{4\pi d}\left(\frac{V}{R}\right)^2=\frac{\mu_0}{4\pi d}\left(\frac{Q_0}{RC}\right)^2$$

Now apply Newton's second law using the result above: $\frac{F}{L}=\frac{m}{L}a=\lambda a=\frac{\mu_0}{4\pi d}\left(\frac{Q_0}{RC}\right)^2$. Solving for a gives $a=\frac{\mu_0 Q_0^2}{4\pi\lambda R^2C^2d}$. From the kinematics equation $v_x=v_{0x}+a_xt$, we have $v_0=at=aRC=\frac{\mu_0Q_0^2}{4\pi\lambda RCd}$.

(b) Conservation of energy gives $\frac{1}{2}mv_0^2=mgh$ and $h=\frac{v_0^2}{2g}=\frac{\left(\frac{\mu_0Q_0^2}{4\pi\lambda RCd}\right)^2}{2g}=\frac{1}{2g}\left(\frac{\mu_0Q_0^2}{4\pi\lambda RCd}\right)^2$.

EVALUATE: Once the wires have swung apart, we would have to consider gravity in applying Newton's second law.

28.88. **IDENTIFY:** There are two parts to the magnetic field: that from the half loop and that from the straight wire segment running from $-a$ to a.

SET UP: Apply Eq. (28.14). Let the ϕ be the angle that locates dl around the ring.

EXECUTE: $B_x(ring)=\frac{1}{2}B_{\text{loop}}=-\frac{\mu_0Ia^2}{4(x^2+a^2)^{3/2}}$.

$dB_y(ring)=dB\sin\theta\sin\phi=\frac{\mu_0I}{4\pi}\frac{dl}{(x^2+a^2)}\frac{x}{(x^2+a^2)^{1/2}}\sin\phi=\frac{\mu_0Iax\sin\phi\,d\phi}{4\pi(x^2+a^2)^{3/2}}$ and

$B_y(ring)=\int_0^{\pi}dB_y(ring)=\int_0^{\pi}\frac{\mu_0Iax\sin\phi d\phi}{4\pi(x^2+a^2)^{3/2}}=\frac{\mu_0Iax}{4\pi(x^2+a^2)^{3/2}}\cos\phi\Big|_0^{\pi}=-\frac{\mu_0Iax}{2\pi(x^2+a^2)^{3/2}}$.

$B_y(rod)=\frac{\mu_0Ia}{2\pi x(x^2+a^2)^{1/2}}$, using Eq. (28.8). The total field components are:

$B_x=-\frac{\mu_0Ia^2}{4(x^2+a^2)^{3/2}}$ and $B_y=\frac{\mu_0Ia}{2\pi x(x^2+a^2)^{1/2}}\left(1-\frac{x^2}{x^2+a^2}\right)=\frac{\mu_0Ia^3}{2\pi x(x^2+a^2)^{3/2}}$.

EVALUATE: $B_y=-\frac{2}{\pi}\frac{a}{x}B_x$. B_y decreases faster than B_x as x increases. For very small x, $B_x=-\frac{\mu_0I}{4a}$ and $B_y=\frac{\mu_0I}{2\pi x}$. In this limit B_x is the field at the center of curvature of a semicircle and B_y is the field of a long straight wire.

ELECTROMAGNETIC INDUCTION

29.1. **IDENTIFY:** The changing magnetic field causes a changing magnetic flux through the loop. This induces an emf in the loop which causes a current to flow in it.

SET UP: $|\mathcal{E}| = \left|\frac{d\Phi_B}{dt}\right|$, $\Phi_B = BA\cos\phi$, $\phi = 0°$. A is constant and B is changing.

EXECUTE: **(a)** $|\mathcal{E}| = A\frac{dB}{dt} = (0.0900\ \text{m}^2)(0.190\ \text{T/s}) = 0.0171\ \text{V}$.

(b) $I = \frac{\mathcal{E}}{R} = \frac{0.0171\text{V}}{0.600\ \Omega} = 0.0285\ \text{A}$.

EVALUATE: These are small emfs and currents by everyday standards.

29.2. **IDENTIFY:** $|\mathcal{E}| = \left|\frac{d\Phi_B}{dt}\right|$. $\Phi_B = BA\cos\phi$. Φ_B is the flux through each turn of the coil.

SET UP: $\phi_\text{i} = 0°$. $\phi_\text{f} = 90°$.

EXECUTE: **(a)** $\Phi_{B,\text{i}} = BA\cos 0° = (6.0\times10^{-5}\ \text{T})(12\times10^{-4}\ \text{m}^2)(1) = 7.2\times10^{-8}\ \text{Wb}$. The total flux through the coil is $N\Phi_{B,\text{i}} = (200)(7.2\times10^{-8}\ \text{Wb}) = 1.44\times10^{-5}\ \text{Wb}$. $\Phi_{B,\text{f}} = BA\cos 90° = 0$.

(b) $|\mathcal{E}_\text{av}| = \left|\frac{N\Phi_\text{i} - N\Phi_\text{f}}{\Delta t}\right| = \frac{1.44\times10^{-5}\ \text{Wb}}{0.040\ \text{s}} = 3.6\times10^{-4}\ \text{V} = 0.36\ \text{mV}$.

EVALUATE: The average induced emf depends on how rapidly the flux changes.

29.3. **IDENTIFY** and **SET UP:** Use Faraday's law to calculate the average induced emf and apply Ohm's law to the coil to calculate the average induced current and charge that flows.

(a) EXECUTE: The magnitude of the average emf induced in the coil is $|\mathcal{E}_\text{av}| = N\left|\frac{\Delta\Phi_B}{\Delta t}\right|$. Initially, $\Phi_{B\text{i}} = BA\cos\phi = BA$. The final flux is zero, so $|\mathcal{E}_\text{av}| = N\frac{|\Phi_{B\text{f}} - \Phi_{B\text{i}}|}{\Delta t} = \frac{NBA}{\Delta t}$. The average induced current is $I = \frac{|\mathcal{E}_\text{av}|}{R} = \frac{NBA}{R\Delta t}$. The total charge that flows through the coil is $Q = I\Delta t = \left(\frac{NBA}{R\Delta t}\right)\Delta t = \frac{NBA}{R}$.

EVALUATE: The charge that flows is proportional to the magnetic field but does not depend on the time Δt.

(b) The magnetic stripe consists of a pattern of magnetic fields. The pattern of charges that flow in the reader coil tells the card reader the magnetic field pattern and hence the digital information coded onto the card.

(c) According to the result in part (a) the charge that flows depends only on the change in the magnetic flux and it does not depend on the rate at which this flux changes.

29.4. **IDENTIFY** and **SET UP:** Apply the result derived in Exercise 29.3: $Q = NBA/R$. In the present exercise the flux changes from its maximum value of $\Phi_B = BA$ to zero, so this equation applies. R is the total resistance so here $R = 60.0\ \Omega + 45.0\ \Omega = 105.0\ \Omega$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: $Q = \dfrac{NBA}{R}$ says $B = \dfrac{QR}{NA} = \dfrac{(3.56\times10^{-5}\text{ C})(105.0\ \Omega)}{120(3.20\times10^{-4}\text{ m}^2)} = 0.0973\text{ T}$.

EVALUATE: A field of this magnitude is easily produced.

29.5. **IDENTIFY:** Apply Faraday's law.

SET UP: Let $+z$ be the positive direction for $\vec{A}$. Therefore, the initial flux is positive and the final flux is zero.

EXECUTE: **(a)** and **(b)** $\mathcal{E} = -\dfrac{\Delta\Phi_B}{\Delta t} = -\dfrac{0-(1.5\text{ T})\pi(0.120\text{ m})^2}{2.0\times10^{-3}\text{ s}} = +34\text{ V}$. Since $\mathcal{E}$ is positive and $\vec{A}$ is toward us, the induced current is counterclockwise.

EVALUATE: The shorter the removal time, the larger the average induced emf.

29.6. **IDENTIFY:** Apply Eq. (29.4). $I = \mathcal{E}/R$.

SET UP: $d\Phi_B/dt = AdB/dt$.

EXECUTE: **(a)** $|\mathcal{E}| = \dfrac{Nd\Phi_B}{dt} = NA\dfrac{d}{dt}(B) = NA\dfrac{d}{dt}((0.012\text{ T/s})t + (3.00\times10^{-5}\text{ T/s}^4)t^4)$

$|\mathcal{E}| = NA((0.012\text{ T/s}) + (1.2\times10^{-4}\text{ T/s}^4)t^3) = 0.0302\text{ V} + (3.02\times10^{-4}\text{ V/s}^3)t^3$.

(b) At $t = 5.00$ s, $|\mathcal{E}| = 0.0302\text{ V} + (3.02\times10^{-4}\text{ V/s}^3)(5.00\text{ s})^3 = 0.0680\text{ V}$.

$I = \dfrac{\mathcal{E}}{R} = \dfrac{0.0680\text{ V}}{600\ \Omega} = 1.13\times10^{-4}\text{ A}$.

EVALUATE: The rate of change of the flux is increasing in time, so the induced current is not constant but rather increases in time.

29.7. **IDENTIFY:** Calculate the flux through the loop and apply Faraday's law.

SET UP: To find the total flux integrate $d\Phi_B$ over the width of the loop. The magnetic field of a long straight wire, at distance r from the wire, is $B = \dfrac{\mu_0 I}{2\pi r}$. The direction of $\vec{B}$ is given by the right-hand rule.

EXECUTE: **(a)** $B = \dfrac{\mu_0 i}{2\pi r}$, into the page.

(b) $d\Phi_B = BdA = \dfrac{\mu_0 i}{2\pi r}Ldr$.

(c) $\Phi_B = \int_a^b d\Phi_B = \dfrac{\mu_0 iL}{2\pi}\int_a^b \dfrac{dr}{r} = \dfrac{\mu_0 iL}{2\pi}\ln(b/a)$.

(d) $|\mathcal{E}| = \dfrac{d\Phi_B}{dt} = \dfrac{\mu_0 L}{2\pi}\ln(b/a)\dfrac{di}{dt}$.

(e) $|\mathcal{E}| = \dfrac{\mu_0(0.240\text{ m})}{2\pi}\ln(0.360/0.120)(9.60\text{ A/s}) = 5.06\times10^{-7}\text{ V}$.

EVALUATE: The induced emf is proportional to the rate at which the current in the long straight wire is changing

29.8. **IDENTIFY:** Apply Faraday's law.

SET UP: Let $\vec{A}$ be upward in Figure E29.8 in the textbook.

EXECUTE: **(a)** $|\mathcal{E}_{\text{ind}}| = \left|\dfrac{d\Phi_B}{dt}\right| = \left|\dfrac{d}{dt}(B_\perp A)\right|$

$|\mathcal{E}_{\text{ind}}| = A\sin60°\left|\dfrac{dB}{dt}\right| = A\sin60°\left|\dfrac{d}{dt}\left((1.4\text{ T})e^{-(0.057\text{s}^{-1})t}\right)\right| = (\pi r^2)(\sin60°)(1.4\text{ T})(0.057\text{ s}^{-1})e^{-(0.057\text{s}^{-1})t}$

$|\mathcal{E}_{\text{ind}}| = \pi(0.75\text{ m})^2(\sin60°)(1.4\text{ T})(0.057\text{ s}^{-1})e^{-(0.057\text{s}^{-1})t} = (0.12\text{ V})\,e^{-(0.057\text{ s}^{-1})t}$.

(b) $\mathcal{E} = \frac{1}{10}\mathcal{E}_0 = \frac{1}{10}(0.12\text{ V})$. $\frac{1}{10}(0.12\text{ V}) = (0.12\text{ V})\,e^{-(0.057\text{ s}^{-1})t}$. $\ln(1/10) = -(0.057\text{ s}^{-1})t$ and $t = 40.4$ s.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(c) $\vec{B}$ is in the direction of $\vec{A}$ so Φ_B is positive. B is getting weaker, so the magnitude of the flux is decreasing and $d\Phi_B/dt < 0$. Faraday's law therefore says $\mathcal{E} > 0$. Since $\mathcal{E} > 0$, the induced current must flow *counterclockwise* as viewed from above.

EVALUATE: The flux changes because the magnitude of the magnetic field is changing.

29.9. **IDENTIFY** and **SET UP:** Use Faraday's law to calculate the emf (magnitude and direction). The direction of the induced current is the same as the direction of the emf. The flux changes because the area of the loop is changing; relate dA/dt to dc/dt, where c is the circumference of the loop.

(a) EXECUTE: $c = 2\pi r$ and $A = \pi r^2$ so $A = c^2/4\pi$

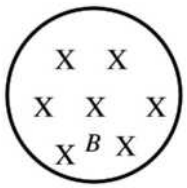
$\Phi_B = BA = (B/4\pi)c^2$

$$|\mathcal{E}| = \left|\frac{d\Phi_B}{dt}\right| = \left(\frac{B}{2\pi}\right)c\left|\frac{dc}{dt}\right|$$

At $t = 9.0$ s, $c = 1.650\text{ m} - (9.0\text{ s})(0.120\text{ m/s}) = 0.570$ m

$|\mathcal{E}| = (0.500\text{ T})(1/2\pi)(0.570\text{ m})(0.120\text{ m/s}) = 5.44$ mV

(b) SET UP: The loop and magnetic field are sketched in Figure 29.9.



Take into the page to be the positive direction for $\vec{A}$.
Then the magnetic flux is positive.

Figure 29.9

EXECUTE: The positive flux is decreasing in magnitude; $d\Phi_B/dt$ is negative and $\mathcal{E}$ is positive. By the right-hand rule, for $\vec{A}$ into the page, positive $\mathcal{E}$ is clockwise.

EVALUATE: Even though the circumference is changing at a constant rate, dA/dt is not constant and $|\mathcal{E}|$ is not constant. Flux $\otimes$ is decreasing so the flux of the induced current is $\otimes$ and this means that I is clockwise, which checks.

29.10. **IDENTIFY:** Rotating the coil changes the angle between it and the magnetic field, which changes the magnetic flux through it. This change induces an emf in the coil.

SET UP: $\mathcal{E}_{\text{av}} = \left|\frac{\Delta\Phi_B}{\Delta t}\right|$, $\Phi_B = BA\cos\phi$. ϕ is the angle between the normal to the loop and $\vec{B}$, so

$\phi_{\text{i}} = 90.0° - 37.0° = 53.0°$ and $\phi_{\text{f}} = 0°$.

EXECUTE: $$\mathcal{E}_{\text{av}} = \frac{NBA|\cos\phi_{\text{f}} - \cos\phi_{\text{i}}|}{\Delta t} = \frac{(80)(1.10\text{ T})(0.250\text{ m})(0.400\text{ m})}{0.0600\text{ s}}|\cos 0° - \cos 53.0°| = 58.4\text{ V}.$$

EVALUATE: The flux changes because the orientation of the coil relative to the magnetic field changes, even though the field remains constant.

29.11. **IDENTIFY:** A change in magnetic flux through a coil induces an emf in the coil.

SET UP: The flux through a coil is $\Phi_B = NBA\cos\phi$ and the induced emf is $\mathcal{E} = -d\Phi_B/dt$.

EXECUTE: **(a)** $|\mathcal{E}| = d\Phi_B/dt = d[A(B_0 + bx)]/dt = bA\,dx/dt = bAv$

(b) clockwise

(c) Same answers except the current is counterclockwise.

EVALUATE: Even though the coil remains within the magnetic field, the flux through it changes because the strength of the field is changing.

29.12. **IDENTIFY:** Use the results of Examples 29.3 and 29.4.

SET UP: $\mathcal{E}_{\max} = NBA\omega$. $\mathcal{E}_{av} = \frac{2}{\pi}\mathcal{E}_{\max}$. $\omega = (440\text{ rev/min})\left(\frac{2\pi\text{ rad/rev}}{60\text{ s/min}}\right) = 46.1$ rad/s.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: **(a)** $\mathcal{E}_{max} = NBA\omega = (150)(0.060\text{ T})\pi(0.025\text{ m})^2(46.1\text{ rad/s}) = 0.814\text{ V}$

(b) $\mathcal{E}_{av} = \frac{2}{\pi}\mathcal{E}_{max} = \frac{2}{\pi}(0.815\text{ V}) = 0.519\text{ V}$

EVALUATE: In $\mathcal{E}_{max} = NBA\omega$, ω must be in rad/s.

29.13. **IDENTIFY:** Apply the results of Example 29.3.

SET UP: $\mathcal{E}_{max} = NBA\omega$

EXECUTE: $\omega = \frac{\mathcal{E}_{max}}{NBA} = \frac{2.40\times10^{-2}\text{ V}}{(120)(0.0750\text{ T})(0.016\text{ m})^2} = 10.4\text{ rad/s}$

EVALUATE: We may also express ω as 99.3 rev/min or 1.66 rev/s.

29.14. **IDENTIFY:** A change in magnetic flux through a coil induces an emf in the coil.

SET UP: The flux through a coil is $\Phi_B = NBA\cos\phi$ and the induced emf is $\mathcal{E} = -d\Phi_B/dt$.

EXECUTE: The flux is constant in each case, so the induced emf is zero in all cases.

EVALUATE: Even though the coil is moving within the magnetic field and has flux through it, this flux is not *changing*, so no emf is induced in the coil.

29.15. **IDENTIFY** and **SET UP:** The field of the induced current is directed to oppose the change in flux.

EXECUTE: **(a)** The field is into the page and is increasing so the flux is increasing. The field of the induced current is out of the page. To produce field out of the page the induced current is counterclockwise.

(b) The field is into the page and is decreasing so the flux is decreasing. The field of the induced current is into the page. To produce field into the page the induced current is clockwise.

(c) The field is constant so the flux is constant and there is no induced emf and no induced current.

EVALUATE: The direction of the induced current depends on the direction of the external magnetic field and whether the flux due to this field is increasing or decreasing.

29.16. **IDENTIFY:** By Lenz's law, the induced current flows to oppose the flux change that caused it.

SET UP and **EXECUTE:** The magnetic field is outward through the round coil and is decreasing, so the magnetic field due to the induced current must also point outward to oppose this decrease. Therefore the induced current is counterclockwise.

EVALUATE: Careful! Lenz's law does not say that the induced current flows to oppose the magnetic flux. Instead it says that the current flows to oppose the *change* in flux.

29.17. **IDENTIFY** and **SET UP:** Apply Lenz's law, in the form that states that the flux of the induced current tends to oppose the change in flux.

EXECUTE: **(a)** With the switch closed the magnetic field of coil *A* is to the right at the location of coil *B*. When the switch is opened the magnetic field of coil *A* goes away. Hence by Lenz's law the field of the current induced in coil *B* is to the right, to oppose the decrease in the flux in this direction. To produce magnetic field that is to the right the current in the circuit with coil *B* must flow through the resistor in the direction *a* to *b*.

(b) With the switch closed the magnetic field of coil *A* is to the right at the location of coil *B*. This field is stronger at points closer to coil *A* so when coil *B* is brought closer the flux through coil *B* increases. By Lenz's law the field of the induced current in coil *B* is to the left, to oppose the increase in flux to the right. To produce magnetic field that is to the left the current in the circuit with coil *B* must flow through the resistor in the direction *b* to *a*.

(c) With the switch closed the magnetic field of coil *A* is to the right at the location of coil *B*. The current in the circuit that includes coil *A* increases when *R* is decreased and the magnetic field of coil *A* increases when the current through the coil increases. By Lenz's law the field of the induced current in coil *B* is to the left, to oppose the increase in flux to the right. To produce magnetic field that is to the left the current in the circuit with coil *B* must flow through the resistor in the direction *b* to *a*.

EVALUATE: In parts (b) and (c) the change in the circuit causes the flux through circuit *B* to increase and in part (a) it causes the flux to decrease. Therefore, the direction of the induced current is the same in parts (b) and (c) and opposite in part (a).

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

29.18. **IDENTIFY:** Apply Lenz's law.
SET UP: The field of the induced current is directed to oppose the change in flux in the primary circuit.
EXECUTE: **(a)** The magnetic field in A is to the left and is increasing. The flux is increasing so the field due to the induced current in B is to the right. To produce magnetic field to the right, the induced current flows through R from right to left.
(b) The magnetic field in A is to the right and is decreasing. The flux is decreasing so the field due to the induced current in B is to the right. To produce magnetic field to the right the induced current flows through R from right to left.
(c) The magnetic field in A is to the right and is increasing. The flux is increasing so the field due to the induced current in B is to the left. To produce magnetic field to the left the induced current flows through R from left to right.
EVALUATE: The direction of the induced current depends on the direction of the external magnetic field and whether the flux due to this field is increasing or decreasing.

29.19. **IDENTIFY** and **SET UP:** Lenz's law requires that the flux of the induced current opposes the change in flux.
EXECUTE: **(a)** Φ_B is $\odot$ and increasing so the flux Φ_{ind} of the induced current is $\otimes$ and the induced current is clockwise.
(b) The current reaches a constant value so Φ_B is constant. $d\Phi_B/dt = 0$ and there is no induced current.
(c) Φ_B is $\odot$ and decreasing, so Φ_{ind} is $\odot$ and current is counterclockwise.
EVALUATE: Only a change in flux produces an induced current. The induced current is in one direction when the current in the outer ring is increasing and is in the opposite direction when that current is decreasing.

29.20. **IDENTIFY:** The changing flux through the loop due to the changing magnetic field induces a current in the wire. Energy is dissipated by the resistance of the wire due to the induced current in it.
SET UP: The magnitude of the induced emf is $|\mathcal{E}| = \left|\frac{d\Phi_B}{dt}\right| = \pi r^2 \left|\frac{dB}{dt}\right|$, $P = I^2R$, $I = \mathcal{E}/R$.
EXECUTE: **(a)** $\vec{B}$ is out of page and Φ_B is decreasing, so the field of the induced current is directed out of the page inside the loop and the induced current is counterclockwise.
(b) $|\mathcal{E}| = \left|\frac{d\Phi_B}{dt}\right| = \pi r^2 \left|\frac{dB}{dt}\right|$. The current due to the emf is
$I = \frac{|\mathcal{E}|}{R} = \frac{\pi r^2}{R}\left|\frac{dB}{dt}\right| = \frac{\pi(0.0480\text{ m})^2}{0.160\ \Omega}(0.680\text{ T/s}) = 0.03076\text{ A}$. The rate of energy dissipation is
$P = I^2R = (0.03076\text{ A})^2(0.160\ \Omega) = 1.51\times10^{-4}\text{ W}$.
EVALUATE: Both the current and resistance are small, so the power is also small.

29.21. **IDENTIFY:** The changing flux through the loop due to the changing magnetic field induces a current in the wire.
SET UP: The magnitude of the induced emf is $|\mathcal{E}| = \left|\frac{d\Phi_B}{dt}\right| = \pi r^2 \left|\frac{dB}{dt}\right|$, $I = \mathcal{E}/R$.
EXECUTE: $\vec{B}$ is into the page and Φ_B is increasing, so the field of the induced current is directed out of the page inside the loop and the induced current is counterclockwise.
$|\mathcal{E}| = \left|\frac{d\Phi_B}{dt}\right| = \pi r^2 \left|\frac{dB}{dt}\right| = \pi(0.0250\text{ m})^2(0.380\text{ T/s}^3)(3t^2) = (2.238\times10^{-3}\text{ V/s}^2)t^2$.
$I = \frac{|\mathcal{E}|}{R} = (5.739\times10^{-3}\text{ A/s}^2)t^2$. When $B = 1.33\text{ T}$, we have $1.33\text{ T} = (0.380\text{ T/s}^3)t^3$, which gives
$t = 1.518\text{ s}$. At this t, $I = (5.739\times10^{-3}\text{ A/s}^2)(1.518\text{ s})^2 = 0.0132\text{ A}$.
EVALUATE: As the field changes, the current will also change.

29.22. **IDENTIFY:** The magnetic flux through the loop is decreasing, so an emf will be induced in the loop, which will induce a current in the loop. The magnetic field will exert a force on the loop due to this current.
SET UP: The motional $\mathcal{E}$ is $\mathcal{E} = vBL$, $I = \mathcal{E}/R$, and $F_B = ILB$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: $I = \dfrac{\mathcal{E}}{R} = \dfrac{BLv}{R}$. $F_B = ILB = v\dfrac{B^2L^2}{R} = \dfrac{3.00 \text{ m/s}}{0.600\ \Omega}(3.50 \text{ T})^2(0.0150 \text{ m})^2 = 0.0138 \text{ N}$.

$\vec{\boldsymbol{B}}$ is into the page and Φ_B is decreasing, so the field of the induced current is into the page inside the loop and the induced current is clockwise. Using $\vec{\boldsymbol{F}} = I\vec{\boldsymbol{l}} \times \vec{\boldsymbol{B}}$, we see that the force on the left-hand end of the loop to be to the left.

EVALUATE: The force is very small by everyday standards.

29.23. **IDENTIFY:** A conductor moving in a magnetic field may have a potential difference induced across it, depending on how it is moving.

SET UP: The induced emf is $\mathcal{E} = vBL \sin\phi$, where ϕ is the angle between the velocity and the magnetic field.

EXECUTE: **(a)** $\mathcal{E} = vBL \sin\phi = (5.00 \text{ m/s})(0.450 \text{ T})(0.300 \text{ m})(\sin 90°) = 0.675 \text{ V}$

(b) The positive charges are moved to end *b*, so *b* is at the higher potential.

(c) $E = V/L = (0.675 \text{ V})/(0.300 \text{ m}) = 2.25 \text{ V/m}$. The direction of $\vec{\boldsymbol{E}}$ is from *b* to *a*.

(d) The positive charges are pushed to *b*, so *b* has an excess of positive charge.

(e) (i) If the rod has no appreciable thickness, $L = 0$, so the emf is zero. (ii) The emf is zero because no magnetic force acts on the charges in the rod since it moves parallel to the magnetic field.

EVALUATE: The motional emf is large enough to have noticeable effects in some cases.

29.24. **IDENTIFY:** A change in magnetic flux through a coil induces an emf in the coil.

SET UP: The flux through a coil is $\Phi_B = NBA\cos\phi$ and the induced emf is $\mathcal{E} = -d\Phi_B/dt$.

EXECUTE: **(a)** and **(c)** The magnetic flux is constant, so the induced emf is zero.

(b) The area inside the field is changing. If we let x be the length (along the 30.0-cm side) in the field, then $A = (0.400 \text{ m})x$. $\Phi_B = BA = (0.400 \text{ m})x$

$$|\mathcal{E}| = |d\Phi_B/dt| = B\ d[(0.400 \text{ m})x]/dt = B(0.400 \text{ m})dx/dt = B(0.400 \text{ m})v$$

$$\mathcal{E} = (1.25 \text{ T})(0.400 \text{ m})(0.0200 \text{ m/s}) = 0.0100 \text{ V}$$

EVALUATE: It is not a large *flux* that induces an emf, but rather a large *rate of change* of the flux. The induced emf in part (b) is small enough to be ignored in many instances.

29.25. **IDENTIFY:** $\mathcal{E} = vBL$

SET UP: $L = 5.00\times10^{-2}$ m. 1 mph = 0.4470 m/s.

EXECUTE: $v = \dfrac{\mathcal{E}}{BL} = \dfrac{1.50 \text{ V}}{(0.650 \text{ T})(5.00\times10^{-2} \text{ m})} = 46.2 \text{ m/s} = 103 \text{ mph}$.

EVALUATE: This is a large speed and not practical. It is also difficult to produce a 5.00-cm wide region of 0.650 T magnetic field.

29.26. **IDENTIFY:** $\mathcal{E} = vBL$.

SET UP: 1 mph = 0.4470 m/s. $1 \text{ G} = 10^{-4}$ T.

EXECUTE: **(a)** $\mathcal{E} = (180 \text{ mph})\left(\dfrac{0.4470 \text{ m/s}}{1 \text{ mph}}\right)(0.50\times10^{-4} \text{ T})(1.5 \text{ m}) = 6.0 \text{ mV}$. This is much too small to be noticeable.

(b) $\mathcal{E} = (565 \text{ mph})\left(\dfrac{0.4470 \text{ m/s}}{1 \text{ mph}}\right)(0.50\times10^{-4} \text{ T})(64.4 \text{ m}) = 0.813 \text{ V}$. This is too small to be noticeable.

EVALUATE: Even though the speeds and values of L are large, the earth's field is small and motional emfs due to the earth's field are not important in these situations.

29.27. **IDENTIFY** and **SET UP:** $\mathcal{E} = vBL$. Use Lenz's law to determine the direction of the induced current. The force F_{ext} required to maintain constant speed is equal and opposite to the force F_I that the magnetic field exerts on the rod because of the current in the rod.

EXECUTE: **(a)** $\mathcal{E} = vBL = (7.50 \text{ m/s})(0.800 \text{ T})(0.500 \text{ m}) = 3.00 \text{ V}$

(b) $\vec{\boldsymbol{B}}$ is into the page. The flux increases as the bar moves to the right, so the magnetic field of the induced current is out of the page inside the circuit. To produce magnetic field in this direction the induced current must be counterclockwise, so from *b* to *a* in the rod.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(c) $I = \dfrac{\mathcal{E}}{R} = \dfrac{3.00\text{ V}}{1.50\ \Omega} = 2.00$ A. $F_I = ILB\sin\phi = (2.00\text{ A})(0.500\text{ m})(0.800\text{ T})\sin 90° = 0.800$ N. $\vec{F}_I$ is to the left. To keep the bar moving to the right at constant speed an external force with magnitude $F_{\text{ext}} = 0.800$ N and directed to the right must be applied to the bar.

(d) The rate at which work is done by the force F_{ext} is $F_{\text{ext}}v = (0.800\text{ N})(7.50\text{ m/s}) = 6.00$ W. The rate at which thermal energy is developed in the circuit is $I^2R = (2.00\text{ A})^2(1.50\ \Omega) = 6.00$ W. These two rates are equal, as is required by conservation of energy.

EVALUATE: The force on the rod due to the induced current is directed to oppose the motion of the rod. This agrees with Lenz's law.

29.28. **IDENTIFY:** Use the results of Example 29.5. Use the three approaches specified in the problem for determining the direction of the induced current. $I = \mathcal{E}/R$.

SET UP: Let $\vec{A}$ be directed into the figure, so a clockwise emf is positive.

EXECUTE: **(a)** $\mathcal{E} = vBl = (5.0\text{ m/s})(0.750\text{ T})(1.50\text{ m}) = 5.6$ V

(b) (i) Let q be a positive charge in the moving bar, as shown in Figure 29.28a. The magnetic force on this charge is $\vec{F} = q\vec{v}\times\vec{B}$, which points *upward*. This force pushes the current in a *counterclockwise* direction through the circuit.

(ii) Φ_B is positive and is increasing in magnitude, so $d\Phi_B/dt > 0$. Then by Faraday's law $\mathcal{E} < 0$ and the emf and induced current are counterclockwise.

(iii) The flux through the circuit is increasing, so the induced current must cause a magnetic field out of the paper to oppose this increase. Hence this current must flow in a *counterclockwise sense*, as shown in Figure 29.28b.

(c) $\mathcal{E} = RI$. $I = \dfrac{\mathcal{E}}{R} = \dfrac{5.6\text{ V}}{25\ \Omega} = 0.22$ A.

EVALUATE: All three methods agree on the direction of the induced current.

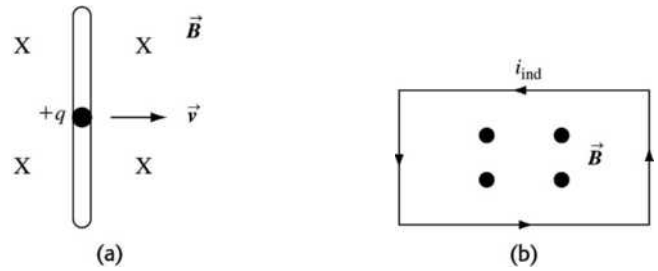


Figure 29.28

29.29. **IDENTIFY:** The motion of the bar due to the applied force causes a motional emf to be induced across the ends of the bar, which induces a current through the bar. The magnetic field exerts a force on the bar due to this current.

SET UP: The applied force is to the left and equal to $F_{\text{applied}} = F_B = ILB$. $\mathcal{E} = BvL$ and $I = \dfrac{\mathcal{E}}{R} = \dfrac{BvL}{R}$.

EXECUTE: **(a)** $\vec{B}$ out of page and Φ_B decreasing, so the field of the induced current is out of the page inside the loop and the induced current is counterclockwise.

(b) Combining $F_{\text{applied}} = F_B = ILB$ and $\mathcal{E} = BvL$, we have $I = \dfrac{\mathcal{E}}{R} = \dfrac{BvL}{R}$. $F_{\text{applied}} = \dfrac{vB^2L^2}{R}$. The rate at which this force does work is $P_{\text{applied}} = F_{\text{applied}}v = \dfrac{(vBL)^2}{R} = \dfrac{[(5.90\text{ m/s})(0.650\text{ T})(0.360\text{ m})]^2}{45.0\ \Omega} = 0.0424$ W.

EVALUATE: The power is small because the magnetic force is usually small compared to everyday forces.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

29.30. **IDENTIFY:** The motion of the bar due to the applied force causes a motional emf to be induced across the ends of the bar, which induces a current through the bar and through the resistor. This current dissipates energy in the resistor.

SET UP: $P_R = I^2R,\ \varepsilon = BvL = IR.$

EXECUTE: **(a)** $\vec{B}$ is out of the page and Φ_B is increasing, so the field of the induced current is into the page inside the loop and the induced current is clockwise.

(b) $P_R = I^2R$ so $I = \sqrt{\dfrac{P_R}{R}} = \sqrt{\dfrac{0.840\ \text{W}}{45.0\ \Omega}} = 0.1366\ \text{A}.$ $I = \dfrac{\text{emf}}{R} = \dfrac{BvL}{R}.$

$$v = \frac{IR}{BL} = \frac{(0.1366\ \text{A})(45.0\ \Omega)}{(0.650\ \text{T})(0.360\ \text{m})} = 26.3\ \text{m/s}.$$

EXECUTE: This speed is around 60 mph, so it would not be very practical to generate energy this way.

29.31. **IDENTIFY:** The motion of the bar causes an emf to be induced across its ends, which induces a current in the circuit.

SET UP: $\varepsilon = BvL,\ I = \varepsilon/R.$

EXECUTE: $\vec{F}_B$ on the bar is to the left so $\vec{v}$ is to the right. Using $\varepsilon = BvL$ and $I = \varepsilon/R$, we have $I = \dfrac{BvL}{R}.$

$$v = \frac{IR}{BL} = \frac{(1.75\ \text{A})(6.00\ \Omega)}{(1.20\ \text{T})(0.250\ \text{m})} = 35.0\ \text{m/s}.$$

EVALUATE: This speed is greater than 60 mph!

29.32. **IDENTIFY:** A motional emf is induced across the blood vessel.

SET UP and **SOLVE:** **(a)** Each slab of flowing blood has maximum width d and is moving perpendicular to the field with speed v. $\varepsilon = vBL$ becomes $\varepsilon = vBd$.

(b) $$B = \frac{\varepsilon}{vd} = \frac{1.0\times10^{-3}\ \text{V}}{(0.15\ \text{m/s})(5.0\times10^{-3}\ \text{m})} = 1.3\ \text{T}.$$

(c) The blood vessel has cross-sectional area $A = \pi d^2/4$. The volume of blood that flows past a cross section of the vessel in time t is $\pi(d^2/4)vt$. The volume flow rate is volume/time $= R = \pi d^2 v/4.$ $v = \dfrac{\varepsilon}{Bd}$

so $R = \dfrac{\pi d^2}{4}\left(\dfrac{\varepsilon}{Bd}\right) = \dfrac{\pi\varepsilon d}{4B}.$

EVALUATE: A very strong magnetic field (1.3 T) is required to produce a small potential difference of only 1 mV.

29.33. **IDENTIFY:** A bar moving in a magnetic field has an emf induced across its ends.

SET UP: The induced potential is $\varepsilon = vBL\sin\phi$.

EXECUTE: Note that $\phi = 90°$ in all these cases because the bar moved perpendicular to the magnetic field. But the effective length of the bar, $L\sin\theta$, is different in each case.

(a) $\varepsilon = vBL\sin\theta$ = (2.50 m/s)(1.20 T)(1.41 m) sin (37.0°) = 2.55 V, with a at the higher potential because positive charges are pushed toward that end.

(b) Same as (a) except $\theta = 53.0°$, giving 3.38 V, with a at the higher potential.

(c) Zero, since the velocity is parallel to the magnetic field.

(d) The bar must move perpendicular to its length, for which the emf is 4.23 V. For $V_b > V_a$, it must move upward and to the left (toward the second quadrant) perpendicular to its length.

EVALUATE: The orientation of the bar affects the potential induced across its ends.

29.34. **IDENTIFY:** While the circuit is entering and leaving the region of the magnetic field, the flux through it will be changing. This change will induce an emf in the circuit.

SET UP: When the loop is entering or leaving the region of magnetic field the flux through it is changing and there is an induced emf. The magnitude of this induced emf is $\varepsilon = BLv$. The length L is 0.750 m. When the loop is totally within the field the flux through the loop is not changing so there is no induced emf. The induced current has magnitude $I = \dfrac{\varepsilon}{R}$ and direction given by Lenz's law.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: **(a)** $I = \dfrac{\mathcal{E}}{R} = \dfrac{BLv}{R} = \dfrac{(1.25\text{ V})(0.750\text{ m})(3.0\text{ m/s})}{12.5\,\Omega} = 0.225\text{ A}$. The magnetic field through the loop is directed out of the page and is increasing, so the magnetic field of the induced current is into the page inside the loop and the induced current is clockwise.

(b) The flux is not changing so $\mathcal{E}$ and I are zero.

(c) $I = \dfrac{\mathcal{E}}{R} = 0.225\text{ A}$. The magnetic field through the loop is directed out of the page and is decreasing, so the magnetic field of the induced current is out of the page inside the loop and the induced current is counterclockwise.

(d) Let clockwise currents be positive. At $t = 0$ the loop is entering the field. It is totally in the field at time t_a and beginning to move out of the field at time t_b. The graph of the induced current as a function of time is sketched in Figure 29.34.

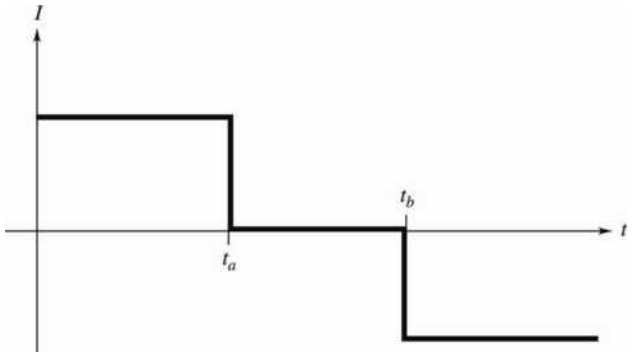

Figure 29.34

EVALUATE: Even though the circuit is moving throughout all parts of this problem, an emf is induced in it only when the flux through it is changing. While the coil is entirely within the field, the flux is constant, so no emf is induced.

29.35. **IDENTIFY:** Apply Eqs. (29.9) and (29.10).

SET UP: Evaluate the integral if Eq. (29.10) for a path which is a circle of radius r and concentric with the solenoid. The magnetic field of the solenoid is confined to the region inside the solenoid, so $B(r) = 0$ for $r > R$.

EXECUTE: **(a)** $\dfrac{d\Phi_B}{dt} = A\dfrac{dB}{dt} = \pi r_1^2 \dfrac{dB}{dt}$.

(b) $E = \dfrac{1}{2\pi r_1}\dfrac{d\Phi_B}{dt} = \dfrac{\pi r_1^2}{2\pi r_1}\dfrac{dB}{dt} = \dfrac{r_1}{2}\dfrac{dB}{dt}$. The direction of $\vec{\boldsymbol{E}}$ is shown in Figure 29.35a.

(c) All the flux is within $r < R$, so outside the solenoid $E = \dfrac{1}{2\pi r_2}\dfrac{d\Phi_B}{dt} = \dfrac{\pi R^2}{2\pi r_2}\dfrac{dB}{dt} = \dfrac{R^2}{2r_2}\dfrac{dB}{dt}$.

(d) The graph is sketched in Figure 29.35b.

(e) At $r = R/2$, $|\mathcal{E}| = \dfrac{d\Phi_B}{dt} = \pi(R/2)^2\dfrac{dB}{dt} = \dfrac{\pi R^2}{4}\dfrac{dB}{dt}$.

(f) At $r = R$, $|\mathcal{E}| = \dfrac{d\Phi_B}{dt} = \pi R^2\dfrac{dB}{dt}$.

(g) At $r = 2R$, $|\mathcal{E}| = \dfrac{d\Phi_B}{dt} = \pi R^2\dfrac{dB}{dt}$.

EVALUATE: The emf is independent of the distance from the center of the cylinder at all points outside it. Even though the magnetic field is zero for $r > R$, the induced electric field is nonzero outside the solenoid and a nonzero emf is induced in a circular turn that has $r > R$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

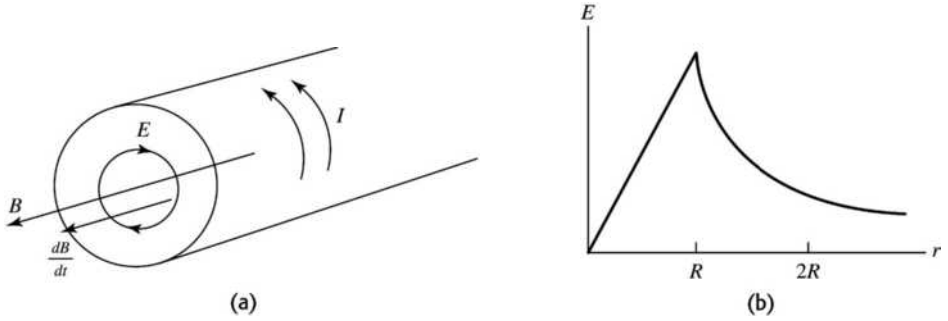

Figure 29.35

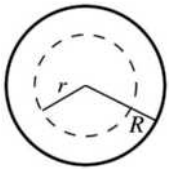
29.36. **IDENTIFY:** Use Eq. (29.10) to calculate the induced electric field E at a distance r from the center of the solenoid. Away from the ends of the solenoid, $B = \mu_0 nI$ inside and $B = 0$ outside.

(a) SET UP: The end view of the solenoid is sketched in Figure 29.36.



Let R be the radius of the solenoid.

Figure 29.36

Apply $\oint \vec{E} \cdot d\vec{l} = -\dfrac{d\Phi_B}{dt}$ to an integration path that is a circle of radius r, where $r < R$. We need to calculate just the magnitude of E so we can take absolute values.

EXECUTE: $\left|\oint \vec{E} \cdot d\vec{l}\right| = E(2\pi r)$

$\Phi_B = B\pi r^2, \left|-\dfrac{d\Phi_B}{dt}\right| = \pi r^2 \left|\dfrac{dB}{dt}\right|$

$\left|\oint \vec{E} \cdot d\vec{l}\right| = \left|-\dfrac{d\Phi_B}{dt}\right|$ implies $E(2\pi r) = \pi r^2 \left|\dfrac{dB}{dt}\right|$

$E = \frac{1}{2} r \left|\dfrac{dB}{dt}\right|$

$B = \mu_0 nI$, so $\dfrac{dB}{dt} = \mu_0 n \dfrac{dI}{dt}$

Thus $E = \frac{1}{2} r \mu_0 n \dfrac{dI}{dt} = \frac{1}{2}(0.00500 \text{ m})(4\pi \times 10^{-7} \text{ T} \cdot \text{m/A})(900 \text{ m}^{-1})(60.0 \text{ A/s}) = 1.70 \times 10^{-4} \text{ V/m}$.

(b) $r = 0.0100$ cm is still inside the solenoid so the expression in part (a) applies.

$E = \frac{1}{2} r \mu_0 n \dfrac{dI}{dt} = \frac{1}{2}(0.0100 \text{ m})(4\pi \times 10^{-7} \text{ T} \cdot \text{m/A})(900 \text{ m}^{-1})(60.0 \text{ A/s}) = 3.39 \times 10^{-4} \text{ V/m}$

EVALUATE: Inside the solenoid E is proportional to r, so E doubles when r doubles.

29.37. **IDENTIFY:** Apply Eq. (29.11) with $\Phi_B = \mu_0 niA$.

SET UP: $A = \pi r^2$, where $r = 0.0110$ m. In Eq. (29.11), $r = 0.0350$ m.

EXECUTE: $|\varepsilon| = \left|\dfrac{d\Phi_B}{dt}\right| = \left|\dfrac{d}{dt}(BA)\right| = \left|\dfrac{d}{dt}(\mu_0 niA)\right| = \mu_0 nA \left|\dfrac{di}{dt}\right|$ and $|\varepsilon| = E(2\pi r)$. Therefore, $\left|\dfrac{di}{dt}\right| = \dfrac{E 2\pi r}{\mu_0 nA}$.

$\left|\dfrac{di}{dt}\right| = \dfrac{(8.00 \times 10^{-6} \text{ V/m}) 2\pi (0.0350 \text{ m})}{\mu_0 (400 \text{ m}^{-1}) \pi (0.0110 \text{ m})^2} = 9.21 \text{ A/s}.$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: Outside the solenoid the induced electric field decreases with increasing distance from the axis of the solenoid.

29.38. **IDENTIFY:** A changing magnetic flux through a coil induces an emf in that coil, which means that an electric field is induced in the material of the coil.

SET UP: According to Faraday's law, the induced electric field obeys the equation $\oint \vec{E} \cdot d\vec{l} = -\frac{d\Phi_B}{dt}$.

EXECUTE: **(a)** For the magnitude of the induced electric field, Faraday's law gives

$$E2\pi r = d(B\pi r^2)/dt = \pi r^2\, dB/dt$$

$$E = \frac{r}{2}\frac{dB}{dt} = \frac{0.0225\text{ m}}{2}(0.250\text{ T/s}) = 2.81\times10^{-3}\text{ V/m}$$

(b) The field points toward the south pole of the magnet and is decreasing, so the induced current is counterclockwise.

EVALUATE: This is a very small electric field compared to most others found in laboratory equipment.

29.39. **IDENTIFY:** Apply Faraday's law in the form $|\mathcal{E}_{\text{av}}| = N\left|\frac{\Delta\Phi_B}{\Delta t}\right|$.

SET UP: The magnetic field of a large straight solenoid is $B = \mu_0 nI$ inside the solenoid and zero outside. $\Phi_B = BA$, where A is 8.00 cm^2, the cross-sectional area of the long straight solenoid.

EXECUTE: $|\mathcal{E}_{\text{av}}| = N\left|\frac{\Delta\Phi_B}{\Delta t}\right| = \left|\frac{NA(B_{\text{f}} - B_{\text{i}})}{\Delta t}\right| = \frac{NA\mu_0 nI}{\Delta t}$.

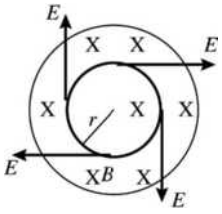
$$\mathcal{E}_{\text{av}} = \frac{\mu_0(12)(8.00\times10^{-4}\text{ m}^2)(9000\text{ m}^{-1})(0.350\text{ A})}{0.0400\text{ s}} = 9.50\times10^{-4}\text{ V}.$$

EVALUATE: An emf is induced in the second winding even though the magnetic field of the solenoid is zero at the location of the second winding. The changing magnetic field induces an electric field outside the solenoid and that induced electric field produces the emf.

29.40. **IDENTIFY:** Use Eq. (29.10) to calculate the induced electric field E and use this E in Eq. (29.9) to calculate $\mathcal{E}$ between two points.

(a) SET UP: Because of the axial symmetry and the absence of any electric charge, the field lines are concentric circles.

(b) See Figure 29.40.



$\vec{E}$ is tangent to the ring. The direction of $\vec{E}$ (clockwise or counterclockwise) is the direction in which current will be induced in the ring.

Figure 29.40

EXECUTE: Use the sign convention for Faraday's law to deduce this direction. Let $\vec{A}$ be into the paper. Then Φ_B is positive. B decreasing then means $\frac{d\Phi_B}{dt}$ is negative, so by $\mathcal{E} = -\frac{d\Phi_B}{dt}$, $\mathcal{E}$ is positive and therefore clockwise. Thus $\vec{E}$ is clockwise around the ring. To calculate E apply $\oint \vec{E} \cdot d\vec{l} = -\frac{d\Phi_B}{dt}$ to a circular path that coincides with the ring.

$\oint \vec{E} \cdot d\vec{l} = E(2\pi r)$

$\Phi_B = B\pi r^2$; $\left|\frac{d\Phi_B}{dt}\right| = \pi r^2\left|\frac{dB}{dt}\right|$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$E(2\pi r) = \pi r^2 \left|\frac{dB}{dt}\right|$ and $E = \frac{1}{2} r \left|\frac{dB}{dt}\right| = \frac{1}{2}(0.100 \text{ m})(0.0350 \text{ T/s}) = 1.75\times10^{-3}$ V/m

(c) The induced emf has magnitude

$\mathcal{E} = \oint \vec{E} \cdot d\vec{l} = E(2\pi r) = (1.75\times10^{-3} \text{ V/m})(2\pi)(0.100 \text{ m}) = 1.100\times10^{-3}$ V. Then

$I = \frac{\mathcal{E}}{R} = \frac{1.100\times10^{-3} \text{ V}}{4.00\,\Omega} = 2.75\times10^{-4}$ A.

(d) Points *a* and *b* are separated by a distance around the ring of πr so

$\mathcal{E} = E(\pi r) = (1.75\times10^{-3} \text{ V/m})(\pi)(0.100 \text{ m}) = 5.50\times10^{-4}$ V

(e) The ends are separated by a distance around the ring of $2\pi r$ so $\mathcal{E} = 1.10\times10^{-3}$ V as calculated in part (c).

EVALUATE: The induced emf, calculated from Faraday's law and used to calculate the induced current, is associated with the induced electric field integrated around the total circumference of the ring.

29.41. **IDENTIFY:** Apply Eq. (29.14), where $\epsilon = K\epsilon_0$.

SET UP: $d\Phi_E/dt = 4(8.76\times10^3 \text{ V}\cdot\text{m/s}^4)t^3$. $\epsilon_0 = 8.854\times10^{-12}$ F/m.

EXECUTE: $\epsilon = \frac{i_D}{(d\Phi_E/dt)} = \frac{12.9\times10^{-12} \text{ A}}{4(8.76\times10^3 \text{ V}\cdot\text{m/s}^4)(26.1\times10^{-3} \text{ s})^3} = 2.07\times10^{-11}$ F/m. The dielectric constant is $K = \frac{\epsilon}{\epsilon_0} = 2.34$.

EVALUATE: The larger the dielectric constant, the larger is the displacement current for a given $d\Phi_E/dt$.

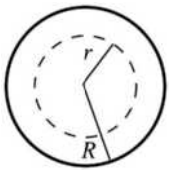
29.42. **IDENTIFY** and **SET UP:** Eqs. (29.13) and (29.14) show that $i_C = i_D$ and also relate i_D to the rate of change of the electric field flux between the plates. Use this to calculate dE/dt and apply the generalized form of Ampere's law (Eq. 29.15) to calculate *B*.

(a) EXECUTE: $i_C = i_D$, so $j_D = \frac{i_D}{A} = \frac{i_C}{A} = \frac{0.280 \text{ A}}{\pi r^2} = \frac{0.280 \text{ A}}{\pi(0.0400 \text{ m})^2} = 55.7$ A/m^2

(b) $j_D = \epsilon_0 \frac{dE}{dt}$ so $\frac{dE}{dt} = \frac{j_D}{\epsilon_0} = \frac{55.7 \text{ A/m}^2}{8.854\times10^{-12} \text{ C}^2/\text{N}\cdot\text{m}^2} = 6.29\times10^{-2}$ V/m·s

(c) SET UP: Apply Ampere's law $\oint \vec{B} . d\vec{l} = \mu_0(i_C + i_D)_{\text{encl}}$ (Eq. (28.20)) to a circular path with radius $r = 0.0200$ m.

An end view of the solenoid is given in Figure 29.42.



By symmetry the magnetic field is tangent to the path and constant around it.

Figure 29.42

EXECUTE: Thus $\oint \vec{B} . d\vec{l} = \oint B dl = B\int dl = B(2\pi r)$.

$i_C = 0$ (no conduction current flows through the air space between the plates)

The displacement current enclosed by the path is $j_D\pi r^2$.

Thus $B(2\pi r) = \mu_0(j_D\pi r^2)$ and

$B = \frac{1}{2}\mu_0 j_D r = \frac{1}{2}(4\pi\times10^{-7} \text{ T}\cdot\text{m/A})(55.7 \text{ A/m}^2)(0.0200 \text{ m}) = 7.00\times10^{-7}$ T

(d) $B = \frac{1}{2}\mu_0 j_D r$. Now *r* is $\frac{1}{2}$ the value in (c), so *B* is $\frac{1}{2}$ also: $B = \frac{1}{2}(7.00\times10^{-7} \text{ T}) = 3.50\times10^{-7}$ T

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: The definition of displacement current allows the current to be continuous at the capacitor. The magnetic field between the plates is zero on the axis $(r = 0)$ and increases as r increases.

29.43. **IDENTIFY:** $q = CV$. For a parallel-plate capacitor, $C = \dfrac{\epsilon A}{d}$, where $\epsilon = K\epsilon_0$. $i_C = dq/dt$. $j_D = \epsilon \dfrac{E}{dt}$.

SET UP: $E = q/\epsilon A$ so $dE/dt = i_C/\epsilon A$.

EXECUTE: **(a)** $q = CV = \left(\dfrac{\epsilon A}{d}\right)V = \dfrac{(4.70)\epsilon_0(3.00\times10^{-4}\ \text{m}^2)(120\ \text{V})}{2.50\times10^{-3}\ \text{m}} = 5.99\times10^{-10}\ \text{C}$.

(b) $\dfrac{dq}{dt} = i_C = 6.00\times10^{-3}\ \text{A}$.

(c) $j_D = \epsilon\dfrac{dE}{dt} = K\epsilon_0\dfrac{i_C}{K\epsilon_0 A} = \dfrac{i_C}{A} = j_C$, so $i_D = i_C = 6.00\times10^{-3}\ \text{A}$.

EVALUATE: $i_D = i_C$, so Kirchhoff's junction rule is satisfied where the wire connects to each capacitor plate.

29.44. **IDENTIFY** and **SET UP:** Use $i_C = q/t$ to calculate the charge q that the current has carried to the plates in time t. The two equations preceeding Eq. (24.2) relate q to the electric field E and the potential difference between the plates. The displacement current density is defined by Eq. (29.16).

EXECUTE: **(a)** $i_C = 1.80\times10^{-3}\ \text{A}$

$q = 0$ at $t = 0$

The amount of charge brought to the plates by the charging current in time t is

$q = i_C t = (1.80\times10^{-3}\ \text{A})(0.500\times10^{-6}\ \text{s}) = 9.00\times10^{-10}\ \text{C}$

$$E = \frac{\sigma}{\epsilon_0} = \frac{q}{\epsilon_0 A} = \frac{9.00\times10^{-10}\ \text{C}}{(8.854\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2)(5.00\times10^{-4}\ \text{m}^2)} = 2.03\times10^5\ \text{V/m}$$

$V = Ed = (2.03\times10^5\ \text{V/m})(2.00\times10^{-3}\text{m}) = 406\ \text{V}$

(b) $E = q/\epsilon_0 A$

$$\frac{dE}{dt} = \frac{dq/dt}{\epsilon_0 A} = \frac{i_C}{\epsilon_0 A} = \frac{1.80\times10^{-3}\ \text{A}}{(8.854\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2)(5.00\times10^{-4}\ \text{m}^2)} = 4.07\times10^{11}\ \text{V/m}\cdot\text{s}$$

Since i_C is constant dE/dt does not vary in time.

(c) $j_D = \epsilon_0\dfrac{dE}{dt}$ (Eq. (29.16)), with ϵ replaced by ϵ_0 since there is vacuum between the plates.)

$j_D = (8.854\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2)(4.07\times10^{11}\ \text{V/m}\cdot\text{s}) = 3.60\ \text{A/m}^2$

$i_D = j_D A = (3.60\ \text{A/m}^2)(5.00\times10^{-4}\ \text{m}^2) = 1.80\times10^{-3}\ \text{A}$; $i_D = i_C$

EVALUATE: $i_C = i_D$. The constant conduction current means the charge q on the plates and the electric field between them both increase linearly with time and i_D is constant.

29.45. **IDENTIFY:** Ohm's law relates the current in the wire to the electric field in the wire. $j_D = \epsilon\dfrac{dE}{dt}$. Use Eq. (29.15) to calculate the magnetic fields.

SET UP: Ohm's law says $E = \rho J$. Apply Ohm's law to a circular path of radius r.

EXECUTE: **(a)** $E = \rho J = \dfrac{\rho I}{A} = \dfrac{(2.0\times10^{-8}\ \Omega\cdot\text{m})(16\ \text{A})}{2.1\times10^{-6}\ \text{m}^2} = 0.15\ \text{V/m}$.

(b) $\dfrac{dE}{dt} = \dfrac{d}{dt}\left(\dfrac{\rho I}{A}\right) = \dfrac{\rho}{A}\dfrac{dI}{dt} = \dfrac{2.0\times10^{-8}\ \Omega\cdot\text{m}}{2.1\times10^{-6}\ \text{m}^2}(4000\ \text{A/s}) = 38\ \text{V/m}\cdot\text{s}$.

(c) $j_D = \epsilon_0\dfrac{dE}{dt} = \epsilon_0(38\ \text{V/m}\cdot\text{s}) = 3.4\times10^{-10}\ \text{A/m}^2$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(d) $i_D = j_D A = (3.4\times10^{-10}\ \text{A/m}^2)(2.1\times10^{-6}\ \text{m}^2) = 7.14\times10^{-16}\ \text{A}$. Eq. (29.15) applied to a circular path of radius r gives $B_D = \dfrac{\mu_0 I_D}{2\pi r} = \dfrac{\mu_0(7.14\times10^{-16}\ \text{A})}{2\pi(0.060\ \text{m})} = 2.38\times10^{-21}\ \text{T}$, and this is a negligible contribution.

$B_C = \dfrac{\mu_0 I_C}{2\pi r} = \dfrac{\mu_0}{2\pi}\dfrac{(16\ \text{A})}{(0.060\ \text{m})} = 5.33\times10^{-5}\ \text{T}$.

EVALUATE: In this situation the displacement current is much less than the conduction current.

29.46. **IDENTIFY:** Apply Eq. (28.29): $\vec{B} = \vec{B}_0 + \mu_0\vec{M}$.

SET UP: For magnetic fields less than the critical field, there is no internal magnetic field. For fields greater than the critical field, $\vec{B}$ is very nearly equal to $\vec{B}_0$.

EXECUTE: **(a)** The external field is less than the critical field, so inside the superconductor $\vec{B} = 0$ and $\vec{M} = -\dfrac{\vec{B}_0}{\mu_0} = -\dfrac{(0.130\ \text{T})\hat{\boldsymbol{i}}}{\mu_0} = -(1.03\times10^5\ \text{A/m})\hat{\boldsymbol{i}}$. Outside the superconductor, $\vec{B} = \vec{B}_0 = (0.130\ \text{T})\hat{\boldsymbol{i}}$ and $\vec{M} = 0$.

(b) The field is greater than the critical field and $\vec{B} = \vec{B}_0 = (0.260\ \text{T})\hat{\boldsymbol{i}}$, both inside and outside the superconductor.

EVALUATE: Below the critical field the external field is expelled from the superconducting material.

29.47. **IDENTIFY:** Apply $\vec{B} = \vec{B}_0 + \mu_0\vec{M}$.

SET UP: When the magnetic flux is expelled from the material the magnetic field $\vec{B}$ in the material is zero. When the material is completely normal, the magnetization is close to zero.

EXECUTE: **(a)** When $\vec{B}_0$ is just under $\vec{B}_{c1}$ (threshold of superconducting phase), the magnetic field in the material must be zero, and $\vec{M} = -\dfrac{\vec{B}_{c1}}{\mu_0} = -\dfrac{(55\times10^{-3}\ \text{T})\hat{\boldsymbol{i}}}{\mu_0} = -(4.38\times10^4\ \text{A/m})\hat{\boldsymbol{i}}$.

(b) When $\vec{B}_0$ is just over $\vec{B}_{c2}$ (threshold of normal phase), there is zero magnetization, and $\vec{B} = \vec{B}_{c2} = (15.0\ \text{T})\hat{\boldsymbol{i}}$.

EVALUATE: Between B_{c1} and B_{c2} there are filaments of normal phase material and there is magnetic field along these filaments.

29.48. **IDENTIFY** and **SET UP:** Use Faraday's law to calculate the magnitude of the induced emf and Lenz's law to determine its direction. Apply Ohm's law to calculate I. Use Eq. (25.10) to calculate the resistance of the coil.

(a) EXECUTE: The angle ϕ between the normal to the coil and the direction of $\vec{B}$ is 30.0°.

$|\mathcal{E}| = \left|\dfrac{d\Phi_B}{dt}\right| = (N\pi r^2)(\cos\phi)(dB/dt)$ and $I = |\mathcal{E}|/R$.

For $t < 0$ and $t > 1.00$ s, $dB/dt = 0$, $|\mathcal{E}| = 0$ and $I = 0$.

For $0 \le t \le 1.00$ s, $dB/dt = (0.120\ \text{T/s})\pi\sin\pi t$

$|\mathcal{E}| = (N\pi r^2)(\cos\phi)\pi(0.120\ \text{T/s})\sin\pi t = (0.8206\ \text{V})\sin\pi t$

R for wire: $R_w = \dfrac{\rho L}{A} = \dfrac{\rho L}{\pi r^2}$; $\rho = 1.72\times10^{-8}\ \Omega\cdot\text{m}$, $r = 0.0150\times10^{-3}$ m

$L = Nc = N2\pi r = (500)(2\pi)(0.0400\ \text{m}) = 125.7$ m

$R_w = 3058\ \Omega$ and the total resistance of the circuit is $R = 3058\ \Omega + 600\ \Omega = 3658\ \Omega$

$I = |\mathcal{E}|/R = (0.224\ \text{mA})\sin\pi t$. The graph of I versus t is sketched in Figure 29.48a.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

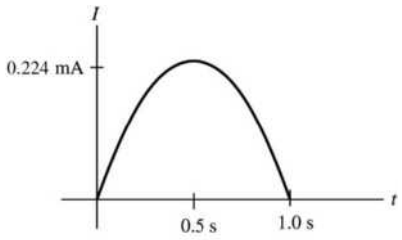


Figure 29.48a

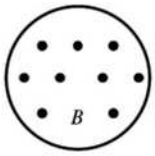
(b) The coil and the magnetic field are shown in Figure 29.48b.



B increasing so Φ_B is $\odot$ and increasing. Φ_{ind} is $\otimes$ so I is clockwise.

Figure 29.48b

EVALUATE: The long length of small diameter wire used to make the coil has a rather large resistance, larger than the resistance of the 600-Ω resistor connected to it in the circuit. The flux has a cosine time dependence so the rate of change of flux and the current have a sine time dependence. There is no induced current for $t < 0$ or $t > 1.00$ s.

29.49. **IDENTIFY:** Apply Faraday's law and Lenz's law.

SET UP: For a discharging RC circuit, $i(t) = \dfrac{V_0}{R}e^{-t/RC}$, where V_0 is the initial voltage across the capacitor. The resistance of the small loop is $(25)(0.600\text{ m})(1.0\,\Omega/\text{m}) = 15.0\,\Omega$.

EXECUTE: **(a)** The large circuit is an RC circuit with a time constant of $\tau = RC = (10\,\Omega)(20\times10^{-6}\text{ F}) = 200\ \mu\text{s}$. Thus, the current as a function of time is $i = ((100\text{ V})/(10\,\Omega))\,e^{-t/200\,\mu\text{s}}$. At $t = 200\ \mu s$, we obtain $i = (10\text{ A})(e^{-1}) = 3.7$ A.

(b) Assuming that only the long wire nearest the small loop produces an appreciable magnetic flux through the small loop and referring to the solution of Exercise 29.7 we obtain $\Phi_B = \int_c^{c+a}\dfrac{\mu_0 ib}{2\pi r}dr = \dfrac{\mu_0 ib}{2\pi}\ln\left(1+\dfrac{a}{c}\right)$.

Therefore, the emf induced in the small loop at $t = 200\ \mu$s is $\varepsilon = -N\dfrac{d\Phi_B}{dt} = -\dfrac{N\mu_0 b}{2\pi}\ln\left(1+\dfrac{a}{c}\right)\dfrac{di}{dt}$.

$\varepsilon = -\dfrac{(25)(4\pi\times10^{-7}\text{ Wb/A}\cdot\text{m}^2)(0.200\text{ m})}{2\pi}\ln(3.0)\left(-\dfrac{3.7\text{ A}}{200\times10^{-6}\text{ s}}\right) = +20.0$ mV. Thus, the induced current in the small loop is $i' = \dfrac{\varepsilon}{R} = \dfrac{20.0\text{ mV}}{15.0\,\Omega} = 1.33$ mA.

(c) The magnetic field from the large loop is directed out of the page within the small loop.The induced current will act to oppose the decrease in flux from the large loop. Thus, the induced current flows counterclockwise.

EVALUATE: **(d)** Three of the wires in the large loop are too far away to make a significant contribution to the flux in the small loop—as can be seen by comparing the distance c to the dimensions of the large loop.

29.50. **IDENTIFY:** The changing current in the large RC circuit produces a changing magnetic flux through the small circuit, which induces an emf in the small circuit. This emf causes a current in the small circuit.

SET UP: For a charging RC circuit, $i(t) = \dfrac{\varepsilon}{R}e^{-t/RC}$, where ε is the emf (90.0 V) added to the large circuit.

Exercise 29.7 shows that $\Phi_B = \dfrac{\mu_0 ib}{2\pi}\ln(1+a/c)$ for each turn of the small circuit, and $\varepsilon_{\text{induced}} = -\dfrac{d\Phi_B}{dt}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: $\dfrac{d\Phi_B}{dt} = \dfrac{\mu_0 b}{2\pi}\ln(1+a/c)\dfrac{di}{dt}$. $\dfrac{di}{dt} = -\dfrac{\varepsilon}{R^2 C}e^{-t/RC}$ and

$|\varepsilon_{\text{induced}}| = N\left|\dfrac{d\Phi_B}{dt}\right| = \dfrac{N\mu_0 b}{2\pi}\ln(1+a/c)\dfrac{\varepsilon}{R^2 C}e^{-t/RC} = \dfrac{N\mu_0 b}{2\pi}\ln(1+a/c)\dfrac{1}{RC}i$. The resistance of the small loop is $(25)(0.600\text{ m})(1.0\ \Omega/\text{m}) = 15.0\ \Omega$.

$|\varepsilon_{\text{induced}}| = (25)(2.00\times10^{-7}\ \text{T}\cdot\text{m/A})(0.200\text{ m})\ln(1+10.0/5.0)\dfrac{1}{(10\ \Omega)(20\times10^{-6}\ \text{F})}(5.00\text{ A})$.

$|\varepsilon_{\text{induced}}| = 0.02747$ V. The induced current is $\dfrac{|\varepsilon_{\text{induced}}|}{R} = \dfrac{0.02747\text{ V}}{15.0\ \Omega} = 1.83\times10^{-3}\text{ A} = 1.83\text{ mA}$. The current in the large loop is counterclockwise. The magnetic field through the small loop is into the page and the flux is increasing, so the flux due to the induced current in the small loop is out of the page and the induced current in the small loop is counterclockwise.

EVALUATE: The answer is actually independent of N because the emf induced in the small coil is proportional to N and the resistance of that coil is also proportional to N. Since $I = \varepsilon/R$, the N will cancel out.

29.51. **IDENTIFY:** The changing current in the solenoid will cause a changing magnetic field (and hence changing flux) through the secondary winding, which will induce an emf in the secondary coil.

SET UP: The magnetic field of the solenoid is $B = \mu_0 ni$, and the induced emf is $|\varepsilon| = N\left|\dfrac{d\Phi_B}{dt}\right|$.

EXECUTE: $B = \mu_0 ni = (4\pi\times10^{-7}\ \text{T}\cdot\text{m/A})(90.0\times10^2\ \text{m}^{-1})(0.160\ \text{A/s}^2)t^2 = (1.810\times10^{-3}\ \text{T/s}^2)t^2$. The total flux through secondary winding is $(5.0)B(2.00\times10^{-4}\ \text{m}^2) = (1.810\times10^{-6}\ \text{Wb/s}^2)t^2$.

$|\varepsilon| = N\left|\dfrac{d\Phi_B}{dt}\right| = (3.619\times10^{-6}\ \text{V/s})t$. $i = 3.20$ A says $3.20\text{ A} = (0.160\ \text{A/s}^2)t^2$ and $t = 4.472$ s. This gives

$|\varepsilon| = (3.619\times10^6\ \text{V/s})(4.472\text{ s}) = 1.62\times10^{-5}$ V.

EVALUATE: This a very small voltage, about 16 μV.

29.52. **IDENTIFY:** A changing magnetic field causes a changing flux through a coil and therefore induces an emf in the coil.

SET UP: Faraday's law says that the induced emf is $\varepsilon = -\dfrac{d\Phi_B}{dt}$ and the magnetic flux through a coil is defined as $\Phi_B = BA\cos\phi$.

EXECUTE: In this case, $\Phi_B = BA$, where A is constant. So the emf is proportional to the *negative* slope of the magnetic field. The result is shown in Figure 29.52.

EVALUATE: It is the rate at which the magnetic field is *changing*, not the field's magnitude, that determines the induced emf. When the field is constant, even though it may have a large value, the induced emf is zero.

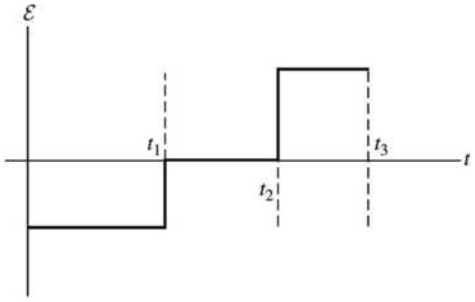


Figure 29.52

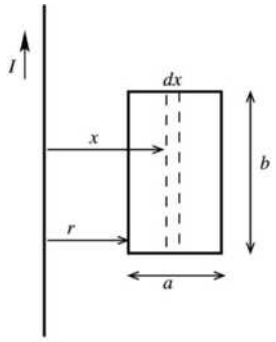
© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

29.53. **(a) IDENTIFY:** (i) $|\varepsilon| = \left|\frac{d\Phi_B}{dt}\right|$. The flux is changing because the magnitude of the magnetic field of the wire decreases with distance from the wire. Find the flux through a narrow strip of area and integrate over the loop to find the total flux.

SET UP:



Consider a narrow strip of width dx and a distance x from the long wire, as shown in Figure 29.53a. The magnetic field of the wire at the strip is $B = \mu_0 I/2\pi x$.

The flux through the strip is $d\Phi_B = Bb\,dx = (\mu_0 Ib/2\pi)(dx/x)$.

Figure 29.53a

EXECUTE: The total flux through the loop is $\Phi_B = \int d\Phi_B = \left(\frac{\mu_0 Ib}{2\pi}\right)\int_r^{r+a}\frac{dx}{x}$.

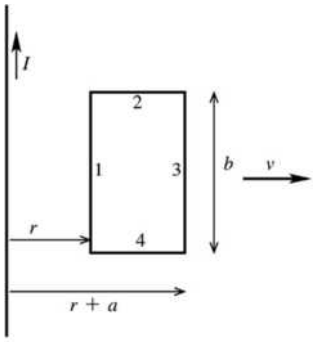
$$\Phi_B = \left(\frac{\mu_0 Ib}{2\pi}\right)\ln\left(\frac{r+a}{r}\right)$$

$$\frac{d\Phi_B}{dt} = \frac{d\Phi_B}{dr}\frac{dr}{dt} = \frac{\mu_0 Ib}{2\pi}\left(-\frac{a}{r(r+a)}\right)v$$

$$|\varepsilon| = \frac{\mu_0 Iabv}{2\pi r(r+a)}$$

(ii) **IDENTIFY:** $\varepsilon = Bvl$ for a bar of length l moving at speed v perpendicular to a magnetic field B. Calculate the induced emf in each side of the loop, and combine the emfs according to their polarity.

SET UP: The four segments of the loop are shown in Figure 29.53b.



EXECUTE: The emf in each side of the loop is $\varepsilon_1 = \left(\frac{\mu_0 I}{2\pi r}\right)vb$,

$\varepsilon_2 = \left(\frac{\mu_0 I}{2\pi(r+a)}\right)vb$, $\varepsilon_2 = \varepsilon_4 = 0$.

Figure 29.53b

Both emfs ε_1 and ε_2 are directed toward the top of the loop so oppose each other. The net emf is

$$\varepsilon = \varepsilon_1 - \varepsilon_2 = \frac{\mu_0 Ivb}{2\pi}\left(\frac{1}{r} - \frac{1}{r+a}\right) = \frac{\mu_0 Iabv}{2\pi r(r+a)}.$$

This expression agrees with what was obtained in (i) using Faraday's law.

(b) (i) **IDENTIFY** and **SET UP:** The flux of the induced current opposes the change in flux.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: $\vec{B}$ is $\otimes$. Φ_B is decreasing, so the flux Φ_{ind} of the induced current is $\otimes$ and the current is clockwise.

(ii) **IDENTIFY** and **SET UP:** Use the right-hand rule to find the force on the positive charges in each side of the loop. The forces on positive charges in segments 1 and 2 of the loop are shown in Figure 29.53c.

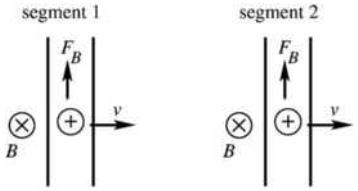


Figure 29.53c

EXECUTE: B is larger at segment 1 since it is closer to the long wire, so F_B is larger in segment 1 and the induced current in the loop is clockwise. This agrees with the direction deduced in (i) using Lenz's law.

(c) EVALUATE: When $v = 0$ the induced emf should be zero; the expression in part (a) gives this. When $a \to 0$ the flux goes to zero and the emf should approach zero; the expression in part (a) gives this. When $r \to \infty$ the magnetic field through the loop goes to zero and the emf should go to zero; the expression in part (a) gives this.

29.54. **IDENTIFY:** Apply Faraday's law.

SET UP: For rotation about the y-axis the situation is the same as in Examples 29.3 and 29.4 and we can apply the results from those examples.

EXECUTE: **(a)** Rotating about the y-axis: the flux is given by $\Phi_B = BA\cos\phi$ and

$\mathcal{E}_{\max} = \omega BA = (35.0 \text{ rad/s})(0.450 \text{ T})(6.00\times10^{-2} \text{ m}) = 0.945 \text{ V}.$

(b) Rotating about the x-axis: $\dfrac{d\Phi_B}{dt} = 0$ and $\mathcal{E} = 0.$

(c) Rotating about the z-axis: the flux is given by $\Phi_B = BA\cos\phi$ and

$\mathcal{E}_{\max} = \omega BA = (35.0 \text{ rad/s})(0.450 \text{ T})(6.00\times10^{-2} \text{ m}) = 0.945 \text{ V}.$

EVALUATE: The maximum emf is the same if the loop is rotated about an edge parallel to the z-axis as it is when it is rotated about the z-axis.

29.55. **IDENTIFY:** Apply the results of Example 29.3, so $\mathcal{E}_{\max} = N\omega BA$ for N loops.

SET UP: For the minimum ω, let the rotating loop have an area equal to the area of the uniform magnetic field, so $A = (0.100 \text{ m})^2$.

EXECUTE: $N = 400$, $B = 1.5 \text{ T}$, $A = (0.100 \text{ m})^2$ and $\mathcal{E}_{\max} = 120 \text{ V}$ gives

$\omega = \mathcal{E}_{\max}/NBA = (20 \text{ rad/s})(1 \text{ rev}/2\pi \text{ rad})(60 \text{ s}/1 \text{ min}) = 190 \text{ rpm}.$

EVALUATE: In $\mathcal{E}_{\max} = \omega BA$, ω is in rad/s.

29.56. **IDENTIFY:** Apply the results of Example 29.3, generalized to N loops: $\mathcal{E}_{\max} = N\omega BA$. $v = r\omega$.

SET UP: In the expression for $\mathcal{E}_{\max}$, ω must be in rad/s. 30 rpm = 3.14 rad/s

EXECUTE: **(a)** Solving for A we obtain $A = \dfrac{\mathcal{E}_{\max}}{\omega NB} = \dfrac{9.0 \text{ V}}{(3.14 \text{ rad/s})(2000 \text{ turns})(8.0\times10^{-5} \text{ T})} = 18 \text{ m}^2.$

(b) Assuming a point on the coil at maximum distance from the axis of rotation we have

$v = r\omega = \sqrt{\dfrac{A}{\pi}}\,\omega = \sqrt{\dfrac{18 \text{ m}^2}{\pi}}\,(3.14 \text{ rad/s}) = 7.5 \text{ m/s}.$

EVALUATE: The device is not very feasible. The coil would need a rigid frame and the effects of air resistance would be appreciable.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

29.57. **IDENTIFY:** Apply Faraday's law in the form $\mathcal{E}_{\text{av}} = -N\dfrac{\Delta\Phi_B}{\Delta t}$ to calculate the average emf. Apply Lenz's law to calculate the direction of the induced current.

SET UP: $\Phi_B = BA$. The flux changes because the area of the loop changes.

EXECUTE: **(a)** $\mathcal{E}_{\text{av}} = \left|\dfrac{\Delta\Phi_B}{\Delta t}\right| = B\left|\dfrac{\Delta A}{\Delta t}\right| = B\dfrac{\pi r^2}{\Delta t} = (1.35\text{ T})\dfrac{\pi(0.0650/2\text{ m})^2}{0.250\text{ s}} = 0.0179\text{ V} = 17.9\text{ mV}.$

(b) Since the magnetic field is directed into the page and the magnitude of the flux through the loop is decreasing, the induced current must produce a field that goes into the page. Therefore the current flows from point a through the resistor to point b.

EVALUATE: Faraday's law can be used to find the direction of the induced current. Let $\vec{A}$ be into the page. Then Φ_B is positive and decreasing in magnitude, so $d\Phi_B/dt < 0$. Therefore $\mathcal{E} > 0$ and the induced current is clockwise around the loop.

29.58. **IDENTIFY:** The movement of the rod causes an emf to be induced across its ends, which causes a current to flow through the circuit. The magnetic field exerts a force on this current.

SET UP: The magnetic force is $F_{\text{mag}} = ILB$, the induced emf is $\mathcal{E} = vBL$. $\sum F = ma$ applies to the rod, and $a = dv/dt$.

EXECUTE: The net force on the rod is $F - iLB = ma$. $i = \dfrac{vBL}{R}$. $F - \dfrac{vB^2L^2}{R} = ma$. $F - \dfrac{vB^2L^2}{R} = m\dfrac{dv}{dt}$.

Integrating to find the time gives $\dfrac{F}{m}\displaystyle\int_0^t dt' = \int_0^v \frac{dv'}{1 - \dfrac{v'B^2L^2}{FR}}$, which gives $\dfrac{Ft}{m} = -\dfrac{FR}{B^2L^2}\ln\left(1 - \dfrac{vB^2L^2}{FR}\right)$.

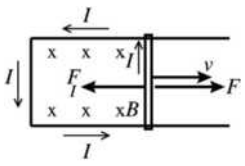
Solving for t and putting in the numbers gives

$$t = -\frac{Rm}{B^2L^2}\ln\left(1 - \frac{vB^2L^2}{FR}\right) = -(0.120\text{ kg})(888.9\text{ s/kg})\ln\left(1 - \frac{25.0\text{ m/s}}{(1.90\text{ N})(888.9\text{ s/kg})}\right) = 1.59\text{ s}.$$

EVALUATE: We cannot use the constant-acceleration kinematics formulas because as the speed v of the rod changes, the magnetic force on it also changes. Therefore the acceleration of the rod is not constant.

29.59. **IDENTIFY:** Use Faraday's law to calculate the induced emf and Ohm's law to find the induced current. Use Eq. (27.19) to calculate the magnetic force F_I on the induced current. Use the net force $F - F_I$ in Newton's second law to calculate the acceleration of the rod and use that to describe its motion.

(a) SET UP: The forces in the rod are shown in Figure 29.59a.



EXECUTE: $|\mathcal{E}| = \left|\dfrac{d\Phi_B}{dt}\right| = BLv$

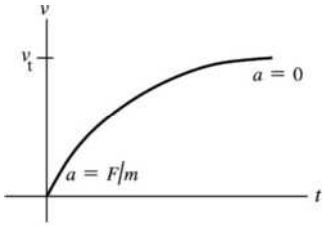
$I = \dfrac{BLv}{R}$

Figure 29.59a

Use $\mathcal{E} = -\dfrac{d\Phi_B}{dt}$ to find the direction of I: Let $\vec{A}$ be into the page. Then $\Phi_B > 0$. The area of the circuit is increasing, so $\dfrac{d\Phi_B}{dt} > 0$. Then $\mathcal{E} < 0$ and with our direction for $\vec{A}$ this means that $\mathcal{E}$ and I are counterclockwise, as shown in the sketch. The force F_I on the rod due to the induced current is given by $\vec{F}_I = I\vec{l} \times \vec{B}$. This gives $\vec{F}_I$ to the left with magnitude $F_I = ILB = (BLv/R)LB = B^2L^2v/R$. Note that $\vec{F}_I$ is directed to oppose the motion of the rod, as required by Lenz's law.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: The net force on the rod is $F - F_I$, so its acceleration is $a = (F - F_I)/m = (F - B^2L^2v/R)/m$. The rod starts with $v = 0$ and $a = F/m$. As the speed v increases the acceleration a decreases. When $a = 0$ the rod has reached its terminal speed v_t. The graph of v versus t is sketched in Figure 29.59b.



(Recall that a is the slope of the tangent to the v versus t curve.)

Figure 29.59b

(b) EXECUTE: $v = v_t$ when $a = 0$ so $\dfrac{F - B^2L^2v_t/R}{m} = 0$ and $v_t = \dfrac{RF}{B^2L^2}$.

EVALUATE: A large F produces a large v_t. If B is larger, or R is smaller, the induced current is larger at a given v so F_I is larger and the terminal speed is less.

29.60. **IDENTIFY:** Apply Newton's second law to the bar. The bar will experience a magnetic force due to the induced current in the loop. Use $a = dv/dt$ to solve for v. At the terminal speed, $a = 0$.
SET UP: The induced emf in the loop has a magnitude BLv. The induced emf is counterclockwise, so it opposes the voltage of the battery, $\mathcal{E}$.

EXECUTE: **(a)** The net current in the loop is $I = \dfrac{\mathcal{E} - BLv}{R}$. The acceleration of the bar is $a = \dfrac{F}{m} = \dfrac{ILB\sin(90°)}{m} = \dfrac{(\mathcal{E} - BLv)LB}{mR}$. To find $v(t)$, set $\dfrac{dv}{dt} = a = \dfrac{(\mathcal{E} - BLv)LB}{mR}$ and solve for v using the method of separation of variables:
$\displaystyle\int_0^v \frac{dv}{(\mathcal{E} - BLv)} = \int_0^t \frac{LB}{mR}dt \rightarrow v = \frac{\mathcal{E}}{BL}(1 - e^{-B^2L^2t/mR}) = (22 \text{ m/s})(1 - e^{-t/15 \text{ s}})$. The graph of v versus t is sketched in Figure 29.60. Note that the graph of this function is similar in appearance to that of a charging capacitor.
(b) Just after the switch is closed, $v = 0$ and $I = \mathcal{E}/R = 2.4$ A, $F = ILB = 1.296$ N, and $a = F/m = 1.4$ m/s^2.
(c) When $v = 2.0$ m/s, $a = \dfrac{[12 \text{ V} - (1.5 \text{ T})(0.36 \text{ m})(2.0 \text{ m/s})](0.36 \text{ m})(1.5 \text{ T})}{(0.90 \text{ kg})(5.0\ \Omega)} = 1.3 \text{ m/s}^2$.
(d) Note that as the speed increases, the acceleration decreases. The speed will asymptotically approach the terminal speed $\dfrac{\mathcal{E}}{BL} = \dfrac{12 \text{ V}}{(1.5 \text{ T})(0.36 \text{ m})} = 22$ m/s, which makes the acceleration zero.

EVALUATE: The current in the circuit is counterclockwise and the magnetic force on the bar is to the right. The energy that appears as kinetic energy of the moving bar is supplied by the battery.

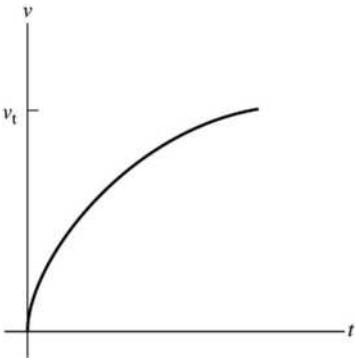


Figure 29.60

29.61. **IDENTIFY:** Apply $\varepsilon = BvL$. Use $\sum \vec{F} = m\vec{a}$ applied to the satellite motion to find the speed v of the satellite.

SET UP: The gravitational force on the satellite is $F_g = G\frac{mm_E}{r^2}$, where m is the mass of the satellite and r is the radius of its orbit.

EXECUTE: $B = 8.0\times10^{-5}$ T, $L = 2.0$ m. $G\frac{mm_E}{r^2} = m\frac{v^2}{r}$ and $r = 400\times10^3$ m $+ R_E$ gives $v = \sqrt{\frac{Gm_E}{r}} = 7.665\times10^3$ m/s. Using this v in $\varepsilon = vBL$ gives $\varepsilon = (8.0\times10^{-5}\text{ T})(7.665\times10^3\text{ m/s})(2.0\text{ m}) = 1.2$ V.

EVALUATE: The induced emf is large enough to be measured easily.

29.62. **IDENTIFY:** The induced emf is $\varepsilon = BvL$, where L is measured in a direction that is perpendicular to both the magnetic field and the velocity of the bar.

SET UP: The magnetic force pushed positive charge toward the high potential end of the bullet.

EXECUTE: **(a)** $\varepsilon = BLv = (8\times10^{-5}\text{ T})(0.004\text{ m})(300\text{ m/s}) = 96\ \mu$V. Since a positive charge moving to the east would be deflected upward, the top of the bullet will be at a higher potential.

(b) For a bullet that travels south, $\vec{v}$ and $\vec{B}$ are along the same line, there is no magnetic force and the induced emf is zero.

(c) If $\vec{v}$ is horizontal, the magnetic force on positive charges in the bullet is either upward or downward, perpendicular to the line between the front and back of the bullet. There is no emf induced between the front and back of the bullet.

EVALUATE: Since the velocity of a bullet is always in the direction from the back to the front of the bullet, and since the magnetic force is perpendicular to the velocity, there is never an induced emf between the front and back of the bullet, no matter what the direction of the magnetic field is.

29.63. **IDENTIFY:** Find the magnetic field at a distance r from the center of the wire. Divide the rectangle into narrow strips of width dr, find the flux through each strip and integrate to find the total flux.

SET UP: Example 28.8 uses Ampere's law to show that the magnetic field inside the wire, a distance r from the axis, is $B(r) = \mu_0 Ir/2\pi R^2$.

EXECUTE: Consider a small strip of length W and width dr that is a distance r from the axis of the wire, as shown in Figure 29.63. The flux through the strip is $d\Phi_B = B(r)W\,dr = \frac{\mu_0 IW}{2\pi R^2} r\,dr$. The total flux through the rectangle is $\Phi_B = \int d\Phi_B = \left(\frac{\mu_0 IW}{2\pi R^2}\right)\int_0^R r\,dr = \frac{\mu_0 IW}{4\pi}$.

EVALUATE: Note that the result is independent of the radius R of the wire.

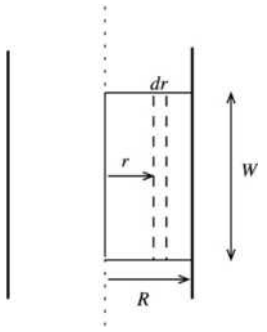

Figure 29.63

29.64. **IDENTIFY:** Apply Faraday's law to calculate the magnitude and direction of the induced emf.

SET UP: Let $\vec{A}$ be directed out of the page in Figure P29.64 in the textbook. This means that counterclockwise emf is positive.

EXECUTE: **(a)** $\Phi_B = BA = B_0\pi r_0^2(1 - 3(t/t_0)^2 + 2(t/t_0)^3)$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) $\varepsilon = -\dfrac{d\Phi_B}{dt} = -B_0\pi r_0^2 \dfrac{d}{dt}(1-3(t/t_0)^2+2(t/t_0)^3) = -\dfrac{B_0\pi r_0^2}{t_0}(-6(t/t_0)+6(t/t_0)^2).$

$\varepsilon = -\dfrac{6\,B_0\pi r_0^2}{t_0}\left(\left(\dfrac{t}{t_0}\right)^2-\left(\dfrac{t}{t_0}\right)\right)$. At $t = 5.0\times10^{-3}$s,

$\varepsilon = -\dfrac{6B_0\pi(0.0420\text{ m})^2}{0.010\text{ s}}\left(\left(\dfrac{5.0\times10^{-3}\text{ s}}{0.010\text{ s}}\right)^2-\left(\dfrac{5.0\times10^{-3}\text{ s}}{0.010\text{ s}}\right)\right) = 0.0665\text{ V}.$ ε is positive so it is counterclockwise.

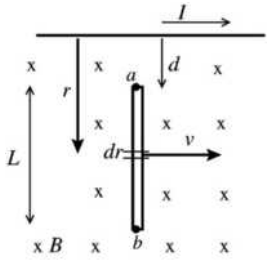
(c) $I = \dfrac{\varepsilon}{R_{\text{total}}} \Rightarrow R_{\text{total}} = r+R = \dfrac{\varepsilon}{I} \Rightarrow r = \dfrac{0.0665\text{ V}}{3.0\times10^{-3}\text{ A}} - 12\,\Omega = 10.2\,\Omega.$

(d) Evaluating the emf at $t = 1.21\times10^{-2}$ s and using the equations of part (b), $\varepsilon = -0.0676$ V, and the current flows clockwise, from *b* to *a* through the resistor.

(e) $\varepsilon = 0$ when $0 = \left(\left(\dfrac{t}{t_0}\right)^2-\left(\dfrac{t}{t_0}\right)\right)$. $1 = \dfrac{t}{t_0}$ and $t = t_0 = 0.010$ s.

EVALUATE: At $t = t_0$, $B = 0$. At $t = 5.00\times10^{-3}$ s, $\vec{\boldsymbol{B}}$ is in the $+\hat{\boldsymbol{k}}$ direction and is decreasing in magnitude. Lenz's law therefore says ε is counterclockwise. At $t = 0.0121$ s, $\vec{\boldsymbol{B}}$ is in the $+\hat{\boldsymbol{k}}$ direction and is increasing in magnitude. Lenz's law therefore says ε is clockwise. These results for the direction of ε agree with the results we obtained from Faraday's law.

29.65. **(a)** and **(b)** **IDENTIFY** and **SET UP:**



The magnetic field of the wire is given by $B = \dfrac{\mu_0 I}{2\pi r}$ and varies along the length of the bar. At every point along the bar $\vec{\boldsymbol{B}}$ has direction into the page. Divide the bar up into thin slices, as shown in Figure 29.65a.

Figure 29.65a

EXECUTE: The emf $d\varepsilon$ induced in each slice is given by $d\varepsilon = \vec{\boldsymbol{v}}\times\vec{\boldsymbol{B}}\cdot d\vec{\boldsymbol{l}}$. $\vec{\boldsymbol{v}}\times\vec{\boldsymbol{B}}$ is directed toward the wire, so $d\varepsilon = -vB\,dr = -v\left(\dfrac{\mu_0 I}{2\pi r}\right)dr$. The total emf induced in the bar is

$V_{ba} = \int_a^b d\varepsilon = -\int_d^{d+L}\left(\dfrac{\mu_0 Iv}{2\pi r}\right)dr = -\dfrac{\mu_0 Iv}{2\pi}\int_d^{d+L}\dfrac{dr}{r} = -\dfrac{\mu_0 Iv}{2\pi}\left[\ln(r)\right]_d^{d+L}$

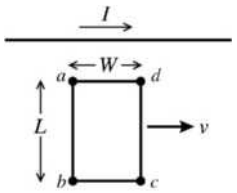
$V_{ba} = -\dfrac{\mu_0 Iv}{2\pi}(\ln(d+L)-\ln(d)) = -\dfrac{\mu_0 Iv}{2\pi}\ln(1+L/d)$

EVALUATE: The minus sign means that V_{ba} is negative, point *a* is at higher potential than point *b*. (The force $\vec{\boldsymbol{F}} = q\vec{\boldsymbol{v}}\times\vec{\boldsymbol{B}}$ on positive charge carriers in the bar is towards *a*, so *a* is at higher potential.) The potential difference increases when *I* or *v* increase, or *d* decreases.

(c) **IDENTIFY:** Use Faraday's law to calculate the induced emf.

SET UP: The wire and loop are sketched in Figure 29.65b.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.



EXECUTE: As the loop moves to the right the magnetic flux through it doesn't change.

Thus $\mathcal{E} = -\dfrac{d\Phi_B}{dt} = 0$ and $I = 0$.

Figure 29.65b

EVALUATE: This result can also be understood as follows. The induced emf in section *ab* puts point *a* at higher potential; the induced emf in section *dc* puts point *d* at higher potential. If you travel around the loop then these two induced emf's sum to zero. There is no emf in the loop and hence no current.

29.66. **IDENTIFY:** $\mathcal{E} = vBL$, where v is the component of velocity perpendicular to the field direction and perpendicular to the bar.

SET UP: Wires A and C have a length of 0.500 m and wire D has a length of $\sqrt{2(0.500\text{ m})^2} = 0.707$ m.

EXECUTE: Wire A: $\vec{v}$ is parallel to $\vec{B}$, so the induced emf is zero.

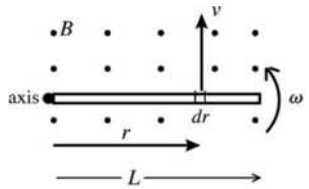
Wire C: $\vec{v}$ is perpendicular to $\vec{B}$. The component of $\vec{v}$ perpendicular to the bar is $v\cos 45°$.
$\mathcal{E} = (0.350\text{ m/s})(\cos 45°)(0.120\text{ T})(0.500\text{ m}) = 0.0148\text{ V}$.

Wire D: $\vec{v}$ is perpendicular to $\vec{B}$. The component of $\vec{v}$ perpendicular to the bar is $v\cos 45°$.
$\mathcal{E} = (0.350\text{ m/s})(\cos 45°)(0.120\text{ T})(0.707\text{ m}) = 0.0210\text{ V}$.

EVALUATE: The induced emf depends on the angle between $\vec{v}$ and $\vec{B}$ and also on the angle between $\vec{v}$ and the bar.

29.67. **(a) IDENTIFY:** Use the expression for motional emf to calculate the emf induced in the rod.

SET UP: The rotating rod is shown in Figure 29.67a.



The emf induced in a thin slice is $d\mathcal{E} = \vec{v} \times \vec{B} \cdot d\vec{l}$.

Figure 29.67a

EXECUTE: Assume that $\vec{B}$ is directed out of the page. Then $\vec{v} \times \vec{B}$ is directed radially outward and $dl = dr$, so $\vec{v} \times \vec{B} \cdot d\vec{l} = vB\,dr$

$v = r\omega$ so $d\mathcal{E} = \omega Br\,dr$.

The $d\mathcal{E}$ for all the thin slices that make up the rod are in series so they add:

$$\mathcal{E} = \int d\mathcal{E} = \int_0^L \omega Br\,dr = \tfrac{1}{2}\omega BL^2 = \tfrac{1}{2}(8.80\text{ rad/s})(0.650\text{ T})(0.240\text{ m})^2 = 0.165\text{ V}$$

EVALUATE: $\mathcal{E}$ increases with ω, B or L^2.

(b) No current flows so there is no IR drop in potential. Thus the potential difference between the ends equals the emf of 0.165 V calculated in part (a).

(c) SET UP: The rotating rod is shown in Figure 29.67b.

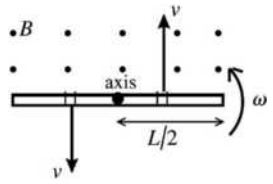


Figure 29.67b

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: The emf between the center of the rod and each end is $\varepsilon = \frac{1}{2}\omega B(L/2)^2 = \frac{1}{4}(0.165\text{ V}) = 0.0412\text{ V},$ with the direction of the emf from the center of the rod toward each end. The emfs in each half of the rod thus oppose each other and there is no net emf between the ends of the rod.

EVALUATE: ω and B are the same as in part (a) but L of each half is $\frac{1}{2}L$ for the whole rod. ε is proportional to $L^2,$ so is smaller by a factor of $\frac{1}{4}$.

29.68. **IDENTIFY:** The power applied by the person in moving the bar equals the rate at which the electrical energy is dissipated in the resistance.

SET UP: From Example 29.6, the power required to keep the bar moving at a constant velocity is $P = \dfrac{(BLv)^2}{R}$.

EXECUTE: **(a)** $R = \dfrac{(BLv)^2}{P} = \dfrac{[(0.25\text{ T})(3.0\text{ m})(2.0\text{ m/s})]^2}{25\text{ W}} = 0.090\ \Omega.$

(b) For a 50-W power dissipation we would require that the resistance be decreased to half the previous value.

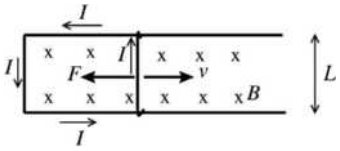
(c) Using the resistance from part (a) and a bar length of 0.20 m,

$$P = \frac{(BLv)^2}{R} = \frac{[(0.25\text{ T})(0.20\text{ m})(2.0\text{ m/s})]^2}{0.090\ \Omega} = 0.11\text{ W}.$$

EVALUATE: When the bar is moving to the right the magnetic force on the bar is to the left and an applied force directed to the right is required to maintain constant speed. When the bar is moving to the left the magnetic force on the bar is to the right and an applied force directed to the left is required to maintain constant speed.

29.69. **(a) IDENTIFY:** Use Faraday's law to calculate the induced emf, Ohm's law to calculate I, and Eq. (27.19) to calculate the force on the rod due to the induced current.

SET UP: The force on the wire is shown in Figure 29.69.



EXECUTE: When the wire has speed v the induced emf is $\varepsilon = BvL$ and the induced current is $I = \varepsilon/R = \dfrac{BvL}{R}$.

Figure 29.69

The induced current flows upward in the wire as shown, so the force $\vec{F} = I\vec{l} \times \vec{B}$ exerted by the magnetic field on the induced current is to the left. $\vec{F}$ opposes the motion of the wire, as it must by Lenz's law. The magnitude of the force is $F = ILB = B^2L^2v/R.$

(b) Apply $\sum \vec{F} = m\vec{a}$ to the wire. Take $+x$ to be toward the right and let the origin be at the location of the wire at $t = 0,$ so $x_0 = 0.$

$\sum F_x = ma_x$ says $-F = ma_x$

$$a_x = -\frac{F}{m} = -\frac{B^2L^2v}{mR}$$

Use this expression to solve for $v(t)$:

$$a_x = \frac{dv}{dt} = -\frac{B^2L^2v}{mR} \text{ and } \frac{dv}{v} = -\frac{B^2L^2}{mR}dt$$

$$\int_{v_0}^{v} \frac{dv'}{v'} = -\frac{B^2L^2}{mR}\int_0^t dt'$$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$\ln(v)-\ln(v_0)=-\frac{B^2L^2t}{mR}$$

$$\ln\left(\frac{v}{v_0}\right)=-\frac{B^2L^2t}{mR} \text{ and } v=v_0e^{-B^2L^2t/mR}$$

Note: At $t=0, v=v_0$ and $v\to 0$ when $t\to\infty$

Now solve for $x(t)$:

$$v=\frac{dx}{dt}=v_0e^{-B^2L^2t/mR} \text{ so } dx=v_0e^{-B^2L^2t/mR}dt$$

$$\int_0^x dx'=\int_0^t v_0e^{-B^2L^2t/mR}dt'$$

$$x=v_0\left(-\frac{mR}{B^2L^2}\right)\left[e^{-B^2L^2t'/mR}\right]_0^t=\frac{mRv_0}{B^2L^2}(1-e^{-B^2L^2t/mR})$$

Comes to rest implies $v=0$. This happens when $t\to\infty$.

$t\to\infty$ gives $x=\dfrac{mRv_0}{B^2L^2}$. Thus this is the distance the wire travels before coming to rest.

EVALUATE: The motion of the slide wire causes an induced emf and current. The magnetic force on the induced current opposes the motion of the wire and eventually brings it to rest. The force and acceleration depend on v and are constant. If the acceleration were constant, not changing from its initial value of $a_x=-B^2L^2v_0/mR$, then the stopping distance would be $x=-v_0^2/2a_x=mRv_0/2B^2L^2$. The actual stopping distance is twice this.

29.70. **IDENTIFY:** Since the bar is straight and the magnetic field is uniform, integrating $d\mathcal{E}=\vec{\boldsymbol{v}}\times\vec{\boldsymbol{B}}\cdot d\vec{\boldsymbol{l}}$ along the length of the bar gives $\mathcal{E}=(\vec{\boldsymbol{v}}\times\vec{\boldsymbol{B}})\cdot\vec{\boldsymbol{L}}$

SET UP: $\vec{\boldsymbol{v}}=(6.80\text{ m/s})\hat{\boldsymbol{i}}$. $\vec{\boldsymbol{L}}=(0.250\text{ m})(\cos 36.9°\,\hat{\boldsymbol{i}}+\sin 36.9°\,\hat{\boldsymbol{j}})$.

EXECUTE: **(a)** $\mathcal{E}=(\vec{\boldsymbol{v}}\times\vec{\boldsymbol{B}})\cdot\vec{\boldsymbol{L}}=(6.80\text{ m/s})\hat{\boldsymbol{i}}\times((0.120\text{ T})\hat{\boldsymbol{i}}-(0.220\text{ T})\hat{\boldsymbol{j}}-(0.0900\text{ T})\hat{\boldsymbol{k}})\cdot\vec{\boldsymbol{L}}$.

$\mathcal{E}=((0.612\text{ V/m})\hat{\boldsymbol{j}}-(1.496\text{ V/m})\hat{\boldsymbol{k}})\cdot((0.250\text{ m})(\cos 36.9°\,\hat{\boldsymbol{i}}+\sin 36.9°\,\hat{\boldsymbol{j}}))$.

$\mathcal{E}=(0.612\text{ V/m})(0.250\text{ m})\sin 36.9°=0.0919\text{ V}=91.9\text{ mV}$.

(b) The higher potential end is the end to which positive charges in the rod are pushed by the magnetic force. $\vec{\boldsymbol{v}}\times\vec{\boldsymbol{B}}$ has a positive y-component, so the end of the rod marked + in Figure 29.70 is at higher potential.

EVALUATE: Since $\vec{\boldsymbol{v}}\times\vec{\boldsymbol{B}}$ has nonzero $\hat{\boldsymbol{j}}$ and $\hat{\boldsymbol{k}}$ components, and $\vec{\boldsymbol{L}}$ has nonzero $\hat{\boldsymbol{i}}$ and $\hat{\boldsymbol{j}}$ components, only the $\hat{\boldsymbol{k}}$ component of $\vec{\boldsymbol{B}}$ contributes to $\mathcal{E}$. In fact,

$|\mathcal{E}|=|v_xB_zL_y|=(6.80\text{ m/s})(0.0900\text{ T})(0.250\text{ m})\sin 36.9°=0.0919\text{ V}=91.9\text{ mV}$.

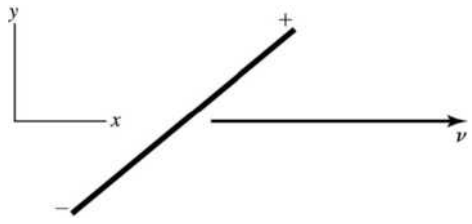


Figure 29.70

29.71. **IDENTIFY:** Use Eq. (29.10) to calculate the induced electric field at each point and then use $\vec{F} = q\vec{E}$.

SET UP:

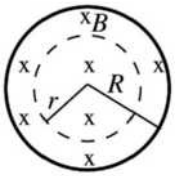

Figure 29.71a

Apply $\oint \vec{E} \cdot d\vec{l} = -\dfrac{d\Phi_B}{dt}$ to a concentric circle of radius r, as shown in Figure 29.71a. Take $\vec{A}$ to be into the page, in the direction of $\vec{B}$.

EXECUTE: B increasing then gives $\dfrac{d\Phi_B}{dt} > 0$, so $\oint \vec{E} \cdot d\vec{l}$ is negative. This means that E is tangent to the circle in the counterclockwise direction, as shown in Figure 29.71b.

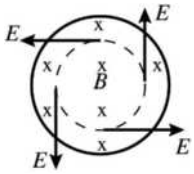

Figure 29.71b

$$\oint \vec{E} \cdot d\vec{l} = -E(2\pi r)$$

$$\frac{d\Phi_B}{dt} = \pi r^2 \frac{dB}{dt}$$

$$-E(2\pi r) = -\pi r^2 \frac{dB}{dt} \text{ so } E = \tfrac{1}{2} r \frac{dB}{dt}$$

point *a* The induced electric field and the force on q are shown in Figure 29.71c.

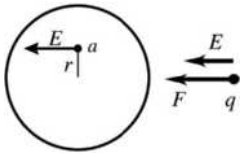

Figure 29.71c

$$F = qE = \tfrac{1}{2} qr \frac{dB}{dt}$$

$\vec{F}$ is to the left ($\vec{F}$ is in the same direction as $\vec{E}$ since q is positive).

point *b* The induced electric field and the force on q are shown in Figure 29.71d.

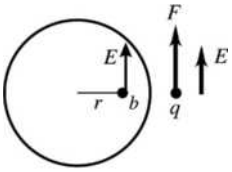

Figure 29.71d

$$F = qE = \tfrac{1}{2} qr \frac{dB}{dt}$$

$\vec{F}$ is toward the top of the page.

point *c* $r = 0$ here, so $E = 0$ and $F = 0$.

EVALUATE: If there were a concentric conducting ring of radius r in the magnetic field region, Lenz's law tells us that the increasing magnetic field would induce a counterclockwise current in the ring. This agrees with the direction of the force we calculated for the individual positive point charges.

29.72. **IDENTIFY:** A bar moving in a magnetic field has an emf induced across its ends. The propeller acts as such a bar.

SET UP: Different parts of the propeller are moving at different speeds, so we must integrate to get the total induced emf. The potential induced across an element of length dx is $d\varepsilon = vBdx$, where B is uniform.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: **(a)** Call x the distance from the center to an element of length dx, and L the length of the propeller. The speed of dx is $x\omega$, giving $d\mathcal{E} = vBdx = x\omega Bdx$. $\mathcal{E} = \int_0^{L/2} x\omega Bdx = \omega BL^2/8$.

(b) The potential difference is zero since the potential is the same at both ends of the propeller.

(c) $\mathcal{E} = (2\pi \text{ rad/rev})\left(\frac{220 \text{ rev}}{60 \text{ s}}\right)(0.50\times10^{-4} \text{ T})\frac{(2.0 \text{ m})^2}{8} = 5.8\times10^{-4} \text{ V} = 0.58 \text{ mV}$

EVALUATE: A potential difference of about $\frac{1}{2}$ mV is not large enough to be concerned about in a propeller.

29.73. **IDENTIFY:** Apply Eq. (29.14).

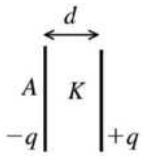
SET UP: $\epsilon = 3.5\times10^{-11}$ F/m

EXECUTE: $i_D = \epsilon\frac{d\Phi_E}{dt} = (3.5\times10^{-11} \text{ F/m})(24.0\times10^3 \text{ V}\cdot\text{m/s}^3)t^2$. $i_D = 21\times10^{-6}$ A gives $t = 5.0$ s.

EVALUATE: i_D depends on the rate at which Φ_E is changing.

29.74. **IDENTIFY** and **SET UP:** Apply Ohm's law to the dielectric to relate the current in the dielectric to the charge on the plates. Use Eq. (25.1) for the current and obtain a differential equation for $q(t)$. Integrate this equation to obtain $q(t)$ and $i(t)$. Use $E = q/\epsilon A$ and Eq. (29.16) to calculate j_D.

EXECUTE: **(a)** Apply Ohm's law to the dielectric: The capacitor is sketched in Figure 29.74.



$$i(t) = \frac{v(t)}{R}$$

$$v(t) = \frac{q(t)}{C} \text{ and } C = K\frac{\epsilon_0 A}{d}$$

Figure 29.74

$$v(t) = \left(\frac{d}{K\epsilon_0 A}\right)q(t)$$

The resistance R of the dielectric slab is $R = \rho d/A$. Thus $i(t) = \frac{v(t)}{R} = \left(\frac{q(t)d}{K\epsilon_0 A}\right)\left(\frac{A}{\rho d}\right) = \frac{q(t)}{K\epsilon_0\rho}$. But the current $i(t)$ in the dielectric is related to the rate of change dq/dt of the charge $q(t)$ on the plates by $i(t) = -dq/dt$ (a positive i in the direction from the + to the – plate of the capacitor corresponds to a decrease in the charge). Using this in the above gives $-\frac{dq}{dt} = \left(\frac{1}{K\rho\epsilon_0}\right)q(t)$. $\frac{dq}{q} = -\frac{dt}{K\rho\epsilon_0}$. Integrate both sides of this equation from $t = 0$, where $q = Q_0$, to a later time t when the charge is $q(t)$.

$\int_{Q_0}^{q}\frac{dq}{q} = -\left(\frac{1}{K\rho\epsilon_0}\right)\int_0^t dt$. $\ln\left(\frac{q}{Q_0}\right) = -\frac{t}{K\rho\epsilon_0}$ and $q(t) = Q_0 e^{-t/K\rho\epsilon_0}$. Then $i(t) = -\frac{dq}{dt} = \left(\frac{Q_0}{K\rho\epsilon_0}\right)e^{-t/K\rho\epsilon_0}$ and $j_C = \frac{i(t)}{A} = \left(\frac{Q_0}{AK\rho\epsilon_0}\right)e^{-t/K\rho\epsilon_0}$. The conduction current flows from the positive to the negative plate of the capacitor.

(b) $E(t) = \frac{q(t)}{\epsilon A} = \frac{q(t)}{K\epsilon_0 A}$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$j_D(t) = \epsilon\frac{dE}{dt} = K\epsilon_0\frac{dE}{dt} = K\epsilon_0\frac{dq(t)/dt}{K\epsilon_0 A} = -\frac{i_C(t)}{A} = -j_C(t)$$

The minus sign means that $j_D(t)$ is directed from the negative to the positive plate. $\vec{\boldsymbol{E}}$ is from + to – but dE/dt is negative (E decreases) so $j_D(t)$ is from – to +.

EVALUATE: There is no conduction current to and from the plates so the concept of displacement current, with $\vec{\boldsymbol{j}}_D = -\vec{\boldsymbol{j}}_C$ in the dielectric, allows the current to be continuous at the capacitor.

29.75. **IDENTIFY:** The conduction current density is related to the electric field by Ohm's law. The displacement current density is related to the rate of change of the electric field by Eq. (29.16).

SET UP: $dE/dt = \omega E_0\cos\omega t$

EXECUTE: **(a)** $j_C(\text{max}) = \dfrac{E_0}{\rho} = \dfrac{0.450\text{ V/m}}{2300\ \Omega\cdot\text{m}} = 1.96\times10^{-4}\text{ A/m}^2$

(b) $j_D(\text{max}) = \epsilon_0\left(\dfrac{dE}{dt}\right)_{\text{max}} = \epsilon_0\omega E_0 = 2\pi\epsilon_0 f E_0 = 2\pi\epsilon_0(120\text{ Hz})(0.450\text{ V/m}) = 3.00\times10^{-9}\text{ A/m}^2$

(c) If $j_C = j_D$ then $\dfrac{E_0}{\rho} = \omega\epsilon_0 E_0$ and $\omega = \dfrac{1}{\rho\epsilon_0} = 4.91\times10^7$ rad/s

$$f = \frac{\omega}{2\pi} = \frac{4.91\times10^7\text{ rad/s}}{2\pi} = 7.82\times10^6\text{ Hz}.$$

EVALUATE: **(d)** The two current densities are out of phase by $90°$ because one has a sine function and the other has a cosine, so the displacement current leads the conduction current by $90°$.

29.76. **IDENTIFY:** A current is induced in the loop because of its motion and because of this current the magnetic field exerts a torque on the loop.

SET UP: Each side of the loop has mass $m/4$ and the center of mass of each side is at the center of each side. The flux through the loop is $\Phi_B = BA\cos\phi$.

EXECUTE: **(a)** $\vec{\boldsymbol{\tau}}_g = \sum\vec{r}_{cm}\times m\vec{\boldsymbol{g}}$ summed over each leg.

$$\tau_g = \left(\frac{L}{2}\right)\left(\frac{m}{4}\right)g\sin(90°-\phi) + \left(\frac{L}{2}\right)\left(\frac{m}{4}\right)g\sin(90°-\phi) + (L)\left(\frac{m}{4}\right)g\sin(90°-\phi)$$

$\tau_g = \dfrac{mgL}{2}\cos\phi$ (clockwise).

$\tau_B = \left|\vec{\boldsymbol{\tau}}\times\vec{\boldsymbol{B}}\right| = IAB\sin\phi$ (counterclockwise).

$I = \dfrac{\varepsilon}{R} = -\dfrac{BA}{R}\dfrac{d}{dt}\cos\phi = \dfrac{BA}{R}\dfrac{d\phi}{dt}\sin\phi = \dfrac{BA\omega}{R}\sin\phi$. The current is going counterclockwise looking to the $-\hat{\boldsymbol{k}}$ direction. Therefore, $\tau_B = \dfrac{B^2A^2\omega}{R}\sin^2\phi = \dfrac{B^2L^4\omega}{R}\sin^2\phi$. The net torque is $\tau = \dfrac{mgL}{2}\cos\phi - \dfrac{B^2L^4\omega}{R}\sin^2\phi$, opposite to the direction of the rotation.

(b) $\tau = I\alpha$ (I being the moment of inertia). About this axis $I = \dfrac{5}{12}mL^2$. Therefore,

$$\alpha = \frac{12}{5}\frac{1}{mL^2}\left[\frac{mgL}{2}\cos\phi - \frac{B^2L^4\omega}{R}\sin^2\phi\right] = \frac{6g}{5L}\cos\phi - \frac{12B^2L^2\omega}{5mR}\sin^2\phi.$$

EVALUATE: **(c)** The magnetic torque slows down the fall (since it opposes the gravitational torque).
(d) Some energy is lost through heat from the resistance of the loop.

29.77. **IDENTIFY:** The motion of the bar produces an induced current and that results in a magnetic force on the bar.

SET UP: $\vec{\boldsymbol{F}}_B$ is perpendicular to $\vec{\boldsymbol{B}}$, so is horizontal. The vertical component of the normal force equals $mg\cos\phi$, so the horizontal component of the normal force equals $mg\tan\phi$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: **(a)** As the bar starts to slide, the flux is decreasing, so the current flows to increase the flux, which means it flows from a to b. $F_B = iLB = \dfrac{LB}{R}\mathcal{E} = \dfrac{LB}{R}\dfrac{d\Phi_B}{dt} = \dfrac{LB}{R}B\dfrac{dA}{dt} = \dfrac{LB^2}{R}(vL\cos\phi) = \dfrac{vL^2B^2}{R}\cos\phi.$

(b) At the terminal speed the horizontal forces balance, so $mg\tan\phi = \dfrac{v_t L^2 B^2}{R}\cos\phi$ and $v_t = \dfrac{Rmg\tan\phi}{L^2B^2\cos\phi}$.

(c) $i = \dfrac{\mathcal{E}}{R} = \dfrac{1}{R}\dfrac{d\Phi_B}{dt} = \dfrac{1}{R}B\dfrac{dA}{dt} = \dfrac{B}{R}(v_t L\cos\phi) = \dfrac{v_t LB\cos\phi}{R} = \dfrac{mg\tan\phi}{LB}$.

(d) $P = i^2R = \dfrac{Rm^2g^2\tan^2\phi}{L^2B^2}$.

(e) $P_g = Fv_t\cos(90° - \phi) = mg\left(\dfrac{Rmg\tan\phi}{L^2B^2\cos\phi}\right)\sin\phi$ and $P_g = \dfrac{Rm^2g^2\tan^2\phi}{L^2B^2}$.

EVALUATE: The power in part (e) equals that in part (d), as is required by conservation of energy.

30

INDUCTANCE

30.1. **IDENTIFY** and **SET UP:** Apply Eq. (30.4).

EXECUTE: **(a)** $|\mathcal{E}_2| = M\left|\frac{di_1}{dt}\right| = (3.25\times10^{-4}\text{ H})(830\text{ A/s}) = 0.270\text{ V}$; yes, it is constant.

(b) $|\mathcal{E}_1| = M\left|\frac{di_2}{dt}\right|$; M is a property of the pair of coils so is the same as in part (a). Thus $|\mathcal{E}_1| = 0.270$ V.

EVALUATE: The induced emf is the same in either case. A constant di/dt produces a constant emf.

30.2. **IDENTIFY:** $\mathcal{E}_1 = M\left|\frac{\Delta i_2}{\Delta t}\right|$ and $\mathcal{E}_2 = M\left|\frac{\Delta i_1}{\Delta t}\right|$. $M = \left|\frac{N_2\Phi_{B2}}{i_1}\right|$, where Φ_{B2} is the flux through one turn of the second coil.

SET UP: M is the same whether we consider an emf induced in coil 1 or in coil 2.

EXECUTE: **(a)** $M = \frac{\mathcal{E}_2}{|\Delta i_1/\Delta t|} = \frac{1.65\times10^{-3}\text{ V}}{0.242\text{ A/s}} = 6.82\times10^{-3}\text{ H} = 6.82\text{ mH}$

(b) $\Phi_{B2} = \frac{Mi_1}{N_2} = \frac{(6.82\times10^{-3}\text{ H})(1.20\text{ A})}{25} = 3.27\times10^{-4}\text{ Wb}$

(c) $\mathcal{E}_1 = M\left|\frac{\Delta i_2}{\Delta t}\right| = (6.82\times10^{-3}\text{ H})(0.360\text{ A/s}) = 2.46\times10^{-3}\text{ V} = 2.46\text{ mV}$

EVALUATE: We can express M either in terms of the total flux through one coil produced by a current in the other coil, or in terms of the emf induced in one coil by a changing current in the other coil.

30.3. **IDENTIFY:** A coil is wound around a solenoid, so magnetic flux from the solenoid passes through the coil.

SET UP: Example 30.1 shows that the mutual inductance for this configuration of coils is $M = \frac{\mu_0 N_1 N_2 A}{l}$, where l is the length of coil 1.

EXECUTE: Using the formula for M gives

$$M = \frac{(4\pi\times10^{-7}\text{ Wb/m}\cdot\text{A})(800)(50)\pi(0.200\times10^{-2}\text{ m})^2}{0.100\text{ m}} = 6.32\times10^{-6}\text{ H} = 6.32\ \mu\text{H}.$$

EVALUATE: This result is a physically reasonable mutual inductance.

30.4. **IDENTIFY:** Changing flux from one object induces an emf in another object.

(a) SET UP: The magnetic field due to a solenoid is $B = \mu_0 nI$.

EXECUTE: The above formula gives

$$B_1 = \frac{(4\pi\times10^{-7}\text{ T}\cdot\text{m/A})(300)(0.120\text{ A})}{0.250\text{ m}} = 1.81\times10^{-4}\text{ T}$$

The average flux through each turn of the inner solenoid is therefore

$$\Phi_B = B_1 A = (1.81\times10^{-4}\text{ T})\pi(0.0100\text{ m})^2 = 5.68\times10^{-8}\text{ Wb}$$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) SET UP: The flux is the same through each turn of both solenoids due to the geometry, so

$$M = \frac{N_2\Phi_{B,2}}{i_1} = \frac{N_2\Phi_{B,1}}{i_1}$$

EXECUTE: $M = \dfrac{(25)(5.68\times10^{-8}\text{ Wb})}{0.120\text{ A}} = 1.18\times10^{-5}\text{ H}$

(c) SET UP: The induced emf is $\mathcal{E}_2 = -M\dfrac{di_1}{dt}$.

EXECUTE: $\mathcal{E}_2 = -(1.18\times10^{-5}\text{ H})(1750\text{ A/s}) = -0.0207\text{ V}$

EVALUATE: A mutual inductance around 10^{-5} H is not unreasonable.

30.5. **IDENTIFY** and **SET UP:** Apply Eq. (30.5).

EXECUTE: **(a)** $M = \dfrac{N_2\Phi_{B2}}{i_1} = \dfrac{400(0.0320\text{ Wb})}{6.52\text{ A}} = 1.96\text{ H}$

(b) $M = \dfrac{N_1\Phi_{B1}}{i_2}$ so $\Phi_{B1} = \dfrac{Mi_2}{N_1} = \dfrac{(1.96\text{ H})(2.54\text{ A})}{700} = 7.11\times10^{-3}\text{ Wb}$

EVALUATE: M relates the current in one coil to the flux through the other coil. Eq. (30.5) shows that M is the same for a pair of coils, no matter which one has the current and which one has the flux.

30.6. **IDENTIFY:** One toroidal solenoid is wound around another, so the flux of one of them passes through the other.

SET UP: $B_1 = \dfrac{\mu_0 N_1 i_1}{2\pi r}$ for a toroidal solenoid, $M = \dfrac{N_2|\Phi_{B2}|}{i_1}$.

EXECUTE: **(a)** $B_1 = \dfrac{\mu_0 N_1 i_1}{2\pi r}$. For each turn in the second solenoid the flux is $|\Phi_{B2}| = B_1 A = \dfrac{\mu_0 N_1 i_1 A}{2\pi r}$.

Therefore $M = \dfrac{N_2|\Phi_{B2}|}{i_1} = \dfrac{\mu_0 N_1 N_2 A}{2\pi r}$.

(b) $M = \dfrac{\mu_0 N_1 N_2 A}{2\pi r} = (2\times10^{-7}\text{ T}\cdot\text{m/A})\dfrac{(500)(300)(0.800\times10^{-4}\text{ m}^2)}{0.100\text{ m}} = 2.40\times10^{-5}\text{ H} = 24.0\ \mu\text{H}.$

EVALUATE: This result is a physically reasonable mutual inductance.

30.7. **IDENTIFY:** We can relate the known self-inductance of the toroidal solenoid to its geometry to calculate the number of coils it has. Knowing the induced emf, we can find the rate of change of the current.

SET UP: Example 30.3 shows that the self-inductance of a toroidal solenoid is $L = \dfrac{\mu_0 N^2 A}{2\pi r}$. The voltage across the coil is related to the rate at which the current in it is changing by $\mathcal{E} = L\left|\dfrac{di}{dt}\right|$.

EXECUTE: **(a)** Solving $L = \dfrac{\mu_0 N^2 A}{2\pi r}$ for N gives

$$N = \sqrt{\frac{2\pi rL}{\mu_0 A}} = \sqrt{\frac{2\pi(0.0600\text{ m})(2.50\times10^{-3}\text{ H})}{(4\pi\times10^{-7}\text{ T}\cdot\text{m/A})(2.00\times10^{-4}\text{ m}^2)}} = 1940\text{ turns}.$$

(b) $\left|\dfrac{di}{dt}\right| = \dfrac{\mathcal{E}}{L} = \dfrac{2.00\text{ V}}{2.50\times10^{-3}\text{ H}} = 800\text{ A/s}.$

EVALUATE: The inductance is determined solely by how the coil is constructed. The induced emf depends on the rate at which the current through the coil is changing.

30.8. **IDENTIFY:** A changing current in an inductor induces an emf in it.

(a) SET UP: The self-inductance of a toroidal solenoid is $L = \dfrac{\mu_0 N^2 A}{2\pi r}$.

EXECUTE: $L = \dfrac{(4\pi\times10^{-7}\text{ T}\cdot\text{m/A})(500)^2(6.25\times10^{-4}\text{ m}^2)}{2\pi(0.0400\text{ m})} = 7.81\times10^{-4}\text{ H}$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) SET UP: The magnitude of the induced emf is $\mathcal{E} = L\dfrac{di}{dt}$.

EXECUTE: $\mathcal{E} = (7.81\times10^{-4}\text{ H})\left(\dfrac{5.00\text{ A} - 2.00\text{ A}}{3.00\times10^{-3}\text{ s}}\right) = 0.781\text{ V}$

(c) The current is decreasing, so the induced emf will be in the same direction as the current, which is from a to b, making b at a higher potential than a.

EVALUATE: This is a reasonable value for self-inductance, in the range of a mH.

30.9. **IDENTIFY:** $\mathcal{E} = L\left|\dfrac{\Delta i}{\Delta t}\right|$ and $L = \dfrac{N\Phi_B}{i}$.

SET UP: $\dfrac{\Delta i}{\Delta t} = 0.0640\text{ A/s}$

EXECUTE: **(a)** $L = \dfrac{\mathcal{E}}{|\Delta i/\Delta t|} = \dfrac{0.0160\text{ V}}{0.0640\text{ A/s}} = 0.250\text{ H}$

(b) The average flux through each turn is $\Phi_B = \dfrac{Li}{N} = \dfrac{(0.250\text{ H})(0.720\text{ A})}{400} = 4.50\times10^{-4}\text{ Wb}$.

EVALUATE: The self-induced emf depends on the rate of change of flux and therefore on the rate of change of the current, not on the value of the current.

30.10. **IDENTIFY:** Combine the two expressions for L: $L = N\Phi_B/i$ and $L = \mathcal{E}/|di/dt|$.

SET UP: Φ_B is the average flux through one turn of the solenoid.

EXECUTE: Solving for N we have $N = \mathcal{E}i/\Phi_B|di/dt| = \dfrac{(12.6\times10^{-3}\text{ V})(1.40\text{ A})}{(0.00285\text{ Wb})(0.0260\text{ A/s})} = 238\text{ turns}$.

EVALUATE: The induced emf depends on the time rate of change of the total flux through the solenoid.

30.11. **IDENTIFY** and **SET UP:** Apply $|\mathcal{E}| = L|di/dt|$. Apply Lenz's law to determine the direction of the induced emf in the coil.

EXECUTE: **(a)** $|\mathcal{E}| = L|di/dt| = (0.260\text{ H})(0.0180\text{ A/s}) = 4.68\times10^{-3}\text{ V}$

(b) Terminal a is at a higher potential since the coil pushes current through from b to a and if replaced by a battery it would have the + terminal at a.

EVALUATE: The induced emf is directed so as to oppose the decrease in the current.

30.12. **IDENTIFY:** Apply $\mathcal{E} = -L\dfrac{di}{dt}$.

SET UP: The induced emf points from low potential to high potential across the inductor.

EXECUTE: **(a)** The induced emf points from b to a, in the direction of the current. Therefore, the current is decreasing and the induced emf is directed to oppose this decrease.

(b) $|\mathcal{E}| = L|di/dt|$, so $|di/dt| = V_{ab}/L = (1.04\text{ V})/(0.260\text{ H}) = 4.00\text{ A/s}$. In 2.00 s the decrease in i is 8.00 A and the current at 2.00 s is 12.0 A −8.0 A = 4.0 A.

EVALUATE: When the current is decreasing the end of the inductor where the current enters is at the lower potential. This agrees with our result and with Figure 30.6d in the textbook.

30.13. **IDENTIFY:** The inductance depends only on the geometry of the object, and the resistance of the wire depends on its length.

SET UP: $L = \dfrac{\mu_0 N^2 A}{2\pi r}$.

EXECUTE: **(a)** $N = \sqrt{\dfrac{2\pi rL}{\mu_0 A}} = \sqrt{\dfrac{(0.120\text{ m})(0.100\times10^{-3}\text{ H})}{(2\times10^{-7}\text{ T}\cdot\text{m/A})(0.600\times10^{-4}\text{ m}^2)}} = 1.00\times10^3\text{ turns}$.

(b) $A = \pi d^2/4$ and $c = \pi d$, so $c = \sqrt{4\pi A} = \sqrt{4\pi(0.600\times10^{-4}\text{ m}^2)} = 0.02746\text{ m}$. The total length of the wire is $(1000)(0.02746\text{ m}) = 27.46\text{ m}$. Therefore $R = (0.0760\,\Omega/\text{m})(27.46\text{ m}) = 2.09\,\Omega$.

EVALUATE: A resistance of $2\,\Omega$ is large enough to be significant in a circuit.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

30.14. **IDENTIFY:** The changing current induces an emf in the solenoid.

SET UP: By definition of self-inductance, $L = \dfrac{N\Phi_B}{i}$. The magnitude of the induced emf is $|\mathcal{E}| = L\left|\dfrac{di}{dt}\right|$.

EXECUTE: $L = \dfrac{N\Phi_B}{i} = \dfrac{(800)(3.25\times10^{-3}\text{ Wb})}{2.90\text{ A}} = 0.8966\text{ H}.$

$\left|\dfrac{di}{dt}\right| = \dfrac{|\mathcal{E}|}{L} = \dfrac{7.50\times10^{-3}\text{ V}}{0.8966\text{ H}} = 8.37\times10^{-3}\text{ A/s} = 8.37\text{ mA/s}.$

EVALUATE: An inductance of nearly a henry is rather large. For ordinary laboratory inductors, which are around a few millihenries, the current would have to be changing much faster to induce 7.5 mV.

30.15. **IDENTIFY:** Use the definition of inductance and the geometry of a solenoid to derive its self-inductace.

SET UP: The magnetic field inside a solenoid is $B = \mu_0\dfrac{N}{l}i$, and the definition of self-inductance is $L = \dfrac{N\Phi_B}{i}$.

EXECUTE: **(a)** $B = \mu_0\dfrac{N}{l}i$, $L = \dfrac{N\Phi_B}{i}$, and $\Phi_B = \dfrac{\mu_0 NAi}{l}$. Combining these expressions gives

$L = \dfrac{N\Phi_B}{i} = \dfrac{\mu_0 N^2 A}{l}.$

(b) $L = \dfrac{\mu_0 N^2 A}{l}$. $A = \pi r^2 = \pi(0.0750\times10^{-2}\text{ m})^2 = 1.767\times10^{-6}\text{ m}^2.$

$L = \dfrac{(4\pi\times10^{-7}\text{ T}\cdot\text{m/A})(50)^2(1.767\times10^{-6}\text{ m}^2)}{5.00\times10^{-2}\text{ m}} = 1.11\times10^{-7}\text{ H} = 0.111\,\mu\text{H}.$

EVALUATE: This is a physically reasonable value for self-inductance.

30.16. **IDENTIFY** and **SET UP:** The stored energy is $U = \frac{1}{2}LI^2$. The rate at which thermal energy is developed is $P = I^2R$.

EXECUTE: **(a)** $U = \frac{1}{2}LI^2 = \frac{1}{2}(12.0\text{ H})(0.300\text{ A})^2 = 0.540\text{ J}$

(b) $P = I^2R = (0.300\text{ A})^2(180\,\Omega) = 16.2\text{ W} = 16.2\text{ J/s}$

EVALUATE: **(c)** No. If I is constant then the stored energy U is constant. The energy being consumed by the resistance of the inductor comes from the emf source that maintains the current; it does not come from the energy stored in the inductor.

30.17. **IDENTIFY** and **SET UP:** Use Eq. (30.9) to relate the energy stored to the inductance. Example 30.3 gives the inductance of a toroidal solenoid to be $L = \dfrac{\mu_0 N^2 A}{2\pi r}$, so once we know L we can solve for N.

EXECUTE: $U = \frac{1}{2}LI^2$ so $L = \dfrac{2U}{I^2} = \dfrac{2(0.390\text{ J})}{(12.0\text{ A})^2} = 5.417\times10^{-3}\text{ H}$

$N = \sqrt{\dfrac{2\pi rL}{\mu_0 A}} = \sqrt{\dfrac{2\pi(0.150\text{ m})(5.417\times10^{-3}\text{ H})}{(4\pi\times10^{-7}\text{ T}\cdot\text{m/A})(5.00\times10^{-4}\text{ m}^2)}} = 2850.$

EVALUATE: L and hence U increase according to the square of N.

30.18. **IDENTIFY:** A current-carrying inductor has a magnetic field inside of itself and hence stores magnetic energy.

(a) SET UP: The magnetic field inside a toroidal solenoid is $B = \dfrac{\mu_0 NI}{2\pi r}$.

EXECUTE: $B = \dfrac{\mu_0(300)(5.00\text{ A})}{2\pi(0.120\text{ m})} = 2.50\times10^{-3}\text{ T} = 2.50\text{ mT}$

(b) SET UP: The self-inductance of a toroidal solenoid is $L = \dfrac{\mu_0 N^2 A}{2\pi r}$.

EXECUTE: $L = \dfrac{(4\pi\times10^{-7}\text{ T}\cdot\text{m/A})(300)^2(4.00\times10^{-4}\text{ m}^2)}{2\pi(0.120\text{ m})} = 6.00\times10^{-5}\text{ H}$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(c) SET UP: The energy stored in an inductor is $U_L = \frac{1}{2}LI^2$.

EXECUTE: $U_L = \frac{1}{2}(6.00\times10^{-5}\text{ H})(5.00\text{ A})^2 = 7.50\times10^{-4}\text{ J}$

(d) SET UP: The energy density in a magnetic field is $u = \dfrac{B^2}{2\mu_0}$.

EXECUTE: $u = \dfrac{(2.50\times10^{-3}\text{ T})^2}{2(4\pi\times10^{-7}\text{ T}\cdot\text{m/A})} = 2.49\text{ J/m}^3$

(e) $u = \dfrac{\text{energy}}{\text{volume}} = \dfrac{\text{energy}}{2\pi rA} = \dfrac{7.50\times10^{-4}\text{ J}}{2\pi(0.120\text{ m})(4.00\times10^{-4}\text{ m}^2)} = 2.49\text{ J/m}^3$

EVALUATE: An inductor stores its energy in the magnetic field inside of it.

30.19. **IDENTIFY:** A current-carrying inductor has a magnetic field inside of itself and hence stores magnetic energy.

(a) SET UP: The magnetic field inside a solenoid is $B = \mu_0 nI$.

EXECUTE: $B = \dfrac{(4\pi\times10^{-7}\text{ T}\cdot\text{m/A})(400)(80.0\text{ A})}{0.250\text{ m}} = 0.161\text{ T}$

(b) SET UP: The energy density in a magnetic field is $u = \dfrac{B^2}{2\mu_0}$.

EXECUTE: $u = \dfrac{(0.161\text{ T})^2}{2(4\pi\times10^{-7}\text{ T}\cdot\text{m/A})} = 1.03\times10^4\text{ J/m}^3$

(c) SET UP: The total stored energy is $U = uV$.

EXECUTE: $U = uV = u(lA) = (1.03\times10^4\text{ J/m}^3)(0.250\text{ m})(0.500\times10^{-4}\text{ m}^2) = 0.129\text{ J}$

(d) SET UP: The energy stored in an inductor is $U = \frac{1}{2}LI^2$.

EXECUTE: Solving for L and putting in the numbers gives

$$L = \frac{2U}{I^2} = \frac{2(0.129\text{ J})}{(80.0\text{ A})^2} = 4.02\times10^{-5}\text{ H}$$

EVALUATE: An inductor stores its energy in the magnetic field inside of it.

30.20. **IDENTIFY:** Energy $= Pt$. $U = \frac{1}{2}LI^2$.

SET UP: $P = 200\text{ W} = 200\text{ J/s}$

EXECUTE: **(a)** Energy $= (200\text{ W})(24\text{ h})(3600\text{ s/h}) = 1.73\times10^7\text{ J}$

(b) $L = \dfrac{2U}{I^2} = \dfrac{2(1.73\times10^7\text{ J})}{(80.0\text{ A})^2} = 5.41\times10^3\text{ H}$

EVALUATE: A large value of L and a large current would be required, just for one light bulb. Also, the resistance of the inductor would have to be very small, to avoid a large $P = I^2R$ rate of electrical energy loss.

30.21. **IDENTIFY:** The energy density depends on the strength of the magnetic field, and the energy depends on the volume in which the magnetic field exists.

SET UP: The energy density is $u = \dfrac{B^2}{2\mu_0}$.

EXECUTE: First find the energy density: $u = \dfrac{B^2}{2\mu_0} = \dfrac{(4.80\text{ T})^2}{2(4\pi\times10^{-7}\text{ T}\cdot\text{m/A})} = 9.167\times10^6\text{ J/m}^3$. The energy U in a volume V is $U = uV = (9.167\times10^6\text{ J/m}^3)(10.0\times10^{-6}\text{ m}^3) = 91.7\text{ J}$.

EVALUATE: A field of 4.8 T is very strong, so this is a high energy density for a magnetic field.

30.22. **IDENTIFY** and **SET UP:** The energy density (energy per unit volume) in a magnetic field (in vacuum) is given by $u = \dfrac{U}{V} = \dfrac{B^2}{2\mu_0}$ (Eq. 30.10).

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: **(a)** $V = \dfrac{2\mu_0 U}{B^2} = \dfrac{2(4\pi\times10^{-7}\ \text{T}\cdot\text{m/A})(3.60\times10^{6}\ \text{J})}{(0.600\ \text{T})^2} = 25.1\ \text{m}^3.$

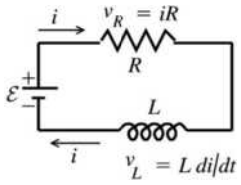
(b) $u = \dfrac{U}{V} = \dfrac{B^2}{2\mu_0}$

$B = \sqrt{\dfrac{2\mu_0 U}{V}} = \sqrt{\dfrac{2(4\pi\times10^{-7}\ \text{T}\cdot\text{m/A})(3.60\times10^{6}\ \text{J})}{(0.400\ \text{m})^3}} = 11.9\ \text{T}$

EVALUATE: Large-scale energy storage in a magnetic field is not practical. The volume in part (a) is quite large and the field in part (b) would be very difficult to achieve.

30.23. **IDENTIFY:** Apply Kirchhoff's loop rule to the circuit. $i(t)$ is given by Eq. (30.14).

SET UP: The circuit is sketched in Figure 30.23.



$\dfrac{di}{dt}$ is positive as the current increases from its initial value of zero.

Figure 30.23

EXECUTE: $\mathcal{E} - v_R - v_L = 0$

$\mathcal{E} - iR - L\dfrac{di}{dt} = 0$ so $i = \dfrac{\mathcal{E}}{R}(1 - e^{-(R/L)t})$

(a) Initially $(t = 0)$, $i = 0$ so $\mathcal{E} - L\dfrac{di}{dt} = 0$

$\dfrac{di}{dt} = \dfrac{\mathcal{E}}{L} = \dfrac{6.00\ \text{V}}{2.50\ \text{H}} = 2.40\ \text{A/s}$

(b) $\mathcal{E} - iR - L\dfrac{di}{dt} = 0$ (Use this equation rather than Eq. (30.15) since i rather than t is given.)

Thus $\dfrac{di}{dt} = \dfrac{\mathcal{E} - iR}{L} = \dfrac{6.00\ \text{V} - (0.500\ \text{A})(8.00\ \Omega)}{2.50\ \text{H}} = 0.800\ \text{A/s}$

(c) $i = \dfrac{\mathcal{E}}{R}(1 - e^{-(R/L)t}) = \left(\dfrac{6.00\ \text{V}}{8.00\ \Omega}\right)(1 - e^{-(8.00\ \Omega/2.50\ \text{H})(0.250\ \text{s})}) = 0.750\ \text{A}(1 - e^{-0.800}) = 0.413\ \text{A}$

(d) Final steady state means $t \to \infty$ and $\dfrac{di}{dt} \to 0$, so $\mathcal{E} - iR = 0.$

$i = \dfrac{\mathcal{E}}{R} = \dfrac{6.00\ \text{V}}{8.00\ \Omega} = 0.750\ \text{A}$

EVALUATE: Our results agree with Figure 30.12 in the textbook. The current is initially zero and increases to its final value of $\mathcal{E}/R$. The slope of the current in the figure, which is di/dt, decreases with t.

30.24. **IDENTIFY:** With S_1 closed and S_2 open, the current builds up to a steady value. Then with S_1 open and S_2 closed, the current decreases exponentially.

SET UP: The decreasing current is $i = I_0 e^{-(R/L)t}$.

EXECUTE: **(a)** $i = I_0 e^{-(R/L)t} = \dfrac{\mathcal{E}}{R} e^{-(R/L)t}$. $e^{-(R/L)t} = \dfrac{iR}{\mathcal{E}} = \dfrac{(0.320\ \text{A})(15.0\ \Omega)}{6.30\ \text{V}} = 0.7619.$ $\dfrac{Rt}{L} = -\ln(0.7619).$

$L = -\dfrac{Rt}{\ln(0.7619)} = -\dfrac{(15.0\ \Omega)(2.00\times10^{-3}\ \text{s})}{\ln(0.7619)} = 0.110\ \text{H}.$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) $\dfrac{i}{I_0} = e^{-(R/L)t}$. $e^{-(R/L)t} = 0.0100$. $\dfrac{Rt}{L} = -\ln(0.0100)$.

$$t = -\frac{\ln(0.0100)L}{R} = -\frac{\ln(0.0100)(0.110\ \text{H})}{15.0\ \Omega} = 0.0338\ \text{s} = 33.8\ \text{ms}.$$

EVALUATE: Typical *LR* circuits change rapidly compared to human time scales, so 33.8 ms is not unusual.

30.25. **IDENTIFY:** $i = \mathcal{E}/R(1-e^{-t/\tau})$, with $\tau = L/R$. The energy stored in the inductor is $U = \frac{1}{2}Li^2$.

SET UP: The maximum current occurs after a long time and is equal to $\mathcal{E}/R$.

EXECUTE: **(a)** $i_{\max} = \mathcal{E}/R$ so $i = i_{\max}/2$ when $(1-e^{-t/\tau}) = \frac{1}{2}$ and $e^{-t/\tau} = \frac{1}{2}$. $-t/\tau = \ln\left(\frac{1}{2}\right)$.

$$t = \frac{L\ln 2}{R} = \frac{(\ln 2)(1.25\times10^{-3}\ \text{H})}{50.0\ \Omega} = 17.3\ \mu\text{s}$$

(b) $U = \frac{1}{2}U_{\max}$ when $i = i_{\max}/\sqrt{2}$. $1-e^{-t/\tau} = 1/\sqrt{2}$, so $e^{-t/\tau} = 1-1/\sqrt{2} = 0.2929$.

$t = -L\ln(0.2929)/R = 30.7\ \mu\text{s}$.

EVALUATE: $\tau = L/R = 2.50\times10^{-5}$ s $= 25.0\ \mu s$. The time in part (a) is 0.692τ and the time in part (b) is 1.23τ.

30.26. **IDENTIFY:** With S_1 closed and S_2 open, $i(t)$ is given by Eq. (30.14). With S_1 open and S_2 closed, $i(t)$ is given by Eq. (30.18).

SET UP: $U = \frac{1}{2}Li^2$. After S_1 has been closed a long time, i has reached its final value of $I = \mathcal{E}/R$.

EXECUTE: **(a)** $U = \frac{1}{2}LI^2$ and $I = \sqrt{\dfrac{2U}{L}} = \sqrt{\dfrac{2(0.260\ \text{J})}{0.115\ \text{H}}} = 2.13$ A. $\mathcal{E} = IR = (2.13\ \text{A})(120\ \Omega) = 256$ V.

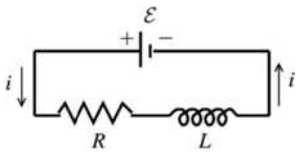
(b) $i = Ie^{-(R/L)t}$ and $U = \frac{1}{2}Li^2 = \frac{1}{2}LI^2e^{-2(R/L)t} = \frac{1}{2}U_0 = \frac{1}{2}\left(\frac{1}{2}LI^2\right)$. $e^{-2(R/L)t} = \frac{1}{2}$, so

$$t = -\frac{L}{2R}\ln\left(\tfrac{1}{2}\right) = -\frac{0.115\ \text{H}}{2(120\ \Omega)}\ln\left(\tfrac{1}{2}\right) = 3.32\times10^{-4}\ \text{s}.$$

EVALUATE: $\tau = L/R = 9.58\times10^{-4}$ s. The time in part (b) is $\tau\ln(2)/2 = 0.347\tau$.

30.27. **IDENTIFY:** Apply the concepts of current decay in an *R*-*L* circuit. Apply the loop rule to the circuit. $i(t)$ is given by Eq. (30.18). The voltage across the resistor depends on i and the voltage across the inductor depends on di/dt.

SET UP: The circuit with S_1 closed and S_2 open is sketched in Figure 30.27a.



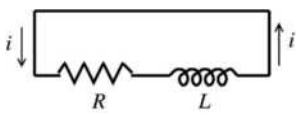
$$\mathcal{E} - iR - L\frac{di}{dt} = 0$$

Figure 30.27a

Constant current established means $\dfrac{di}{dt} = 0$.

EXECUTE: $i = \dfrac{\mathcal{E}}{R} = \dfrac{60.0\ \text{V}}{240\ \Omega} = 0.250$ A

(a) SET UP: The circuit with S_2 closed and S_1 open is shown in Figure 30.27b.



$$i = I_0e^{-(R/L)t}$$

At $t = 0, i = I_0 = 0.250$ A

Figure 30.27b

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

The inductor prevents an instantaneous change in the current; the current in the inductor just after S_2 is closed and S_1 is opened equals the current in the inductor just before this is done.

(b) EXECUTE: $i = I_0 e^{-(R/L)t} = (0.250\text{ A})e^{-(240\,\Omega/0.160\text{ H})(4.00\times10^{-4}\text{ s})} = (0.250\text{ A})e^{-0.600} = 0.137\text{ A}$

(c) SET UP: See Figure 30.27c.

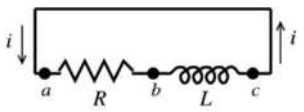


Figure 30.27c

EXECUTE: If we trace around the loop in the direction of the current the potential falls as we travel through the resistor so it must rise as we pass through the inductor: $v_{ab} > 0$ and $v_{bc} < 0$. So point *c* is at a higher potential than point *b*.

$v_{ab} + v_{bc} = 0$ and $v_{bc} = -v_{ab}$

Or, $v_{cb} = v_{ab} = iR = (0.137\text{ A})(240\ \Omega) = 32.9\text{ V}$

(d) $i = I_0 e^{-(R/L)t}$

$i = \frac{1}{2} I_0$ says $\frac{1}{2} I_0 = I_0 e^{-(R/L)t}$ and $\frac{1}{2} = e^{-(R/L)t}$

Taking natural logs of both sides of this equation gives $\ln\left(\frac{1}{2}\right) = -Rt/L$.

$$t = \left(\frac{0.160\text{ H}}{240\,\Omega}\right)\ln 2 = 4.62\times10^{-4}\text{ s}$$

EVALUATE: The current decays, as shown in Figure 30.13 in the textbook. The time constant is $\tau = L/R = 6.67\times10^{-4}$ s. The values of *t* in the problem are less than one time constant. At any instant the potential drop across the resistor (in the direction of the current) equals the potential rise across the inductor.

30.28. IDENTIFY: Apply Eq. (30.14).

SET UP: $v_{ab} = iR$. $v_{bc} = L\dfrac{di}{dt}$. The current is increasing, so di/dt is positive.

EXECUTE: **(a)** At $t = 0$, $i = 0$. $v_{ab} = 0$ and $v_{bc} = 60$ V.

(b) As $t \to \infty$, $i \to \mathcal{E}/R$ and $di/dt \to 0$. $v_{ab} \to 60$ V and $v_{bc} \to 0$.

(c) When $i = 0.150$ A, $v_{ab} = iR = 36.0$ V and $v_{bc} = 60.0\text{ V} - 36.0\text{ V} = 24.0$ V.

EVALUATE: At all times, $\mathcal{E} = v_{ab} + v_{bc}$, as required by the loop rule.

30.29. IDENTIFY: $i(t)$ is given by Eq. (30.14).

SET UP: The power input from the battery is $\mathcal{E}i$. The rate of dissipation of energy in the resistance is i^2R. The voltage across the inductor has magnitude Ldi/dt, so the rate at which energy is being stored in the inductor is $iLdi/dt$.

EXECUTE: **(a)** $P = \mathcal{E}i = \mathcal{E}I_0(1 - e^{-(R/L)t}) = \dfrac{\mathcal{E}^2}{R}(1 - e^{-(R/L)t}) = \dfrac{(6.00\text{ V})^2}{8.00\,\Omega}(1 - e^{-(8.00\,\Omega/2.50\text{ H})t})$.

$P = (4.50\text{ W})(1 - e^{-(3.20\text{ s}^{-1})t})$.

(b) $P_R = i^2R = \dfrac{\mathcal{E}^2}{R}(1 - e^{-(R/L)t})^2 = \dfrac{(6.00\text{ V})^2}{8.00\,\Omega}(1 - e^{-(8.00\,\Omega/2.50\text{ H})t})^2 = (4.50\text{ W})(1 - e^{-(3.20\text{ s}^{-1})t})^2$

(c) $P_L = iL\dfrac{di}{dt} = \dfrac{\mathcal{E}}{R}(1 - e^{-(R/L)t})L\left(\dfrac{\mathcal{E}}{L}e^{-(R/L)t}\right) = \dfrac{\mathcal{E}^2}{R}(e^{-(R/L)t} - e^{-2(R/L)t})$

$P_L = (4.50\text{ W})(e^{-(3.20\text{ s}^{-1})t} - e^{-(6.40\text{ s}^{-1})t})$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: **(d)** Note that if we expand the square in part (b), then parts (b) and (c) add to give part (a), and the total power delivered is dissipated in the resistor and inductor. Conservation of energy requires that this be so.

30.30. **IDENTIFY:** With S_1 closed and S_2 open, the current builds up to a steady value.

SET UP: Applying Kirchhoff's loop rule gives $\mathcal{E} - iR - L\frac{di}{dt} = 0$.

EXECUTE: $v_R = \mathcal{E} - L\frac{di}{dt} = 18.0\text{ V} - (0.380\text{ H})(7.20\text{ A/s}) = 15.3\text{ V}$.

EVALUATE: The rest of the 18.0 V of the emf is across the inductor.

30.31. **IDENTIFY:** Evaluate $\frac{d^2q}{dt^2}$ and insert into Eq. (30.20).

SET UP: Eq. (30.20) is $\frac{d^2q}{dt^2} + \frac{1}{LC}q = 0$.

EXECUTE: $q = Q\cos(\omega t + \phi) \Rightarrow \frac{dq}{dt} = -\omega Q\sin(\omega t + \phi) \Rightarrow \frac{d^2q}{dt^2} = -\omega^2 Q\cos(\omega t + \phi)$.

$\frac{d^2q}{dt^2} + \frac{1}{LC}q = -\omega^2 Q\cos(\omega t + \phi) + \frac{Q}{LC}\cos(\omega t + \phi) = 0 \Rightarrow \omega^2 = \frac{1}{LC} \Rightarrow \omega = \frac{1}{\sqrt{LC}}$.

EVALUATE: The value of ϕ depends on the initial conditions, the value of q at $t = 0$.

30.32. **IDENTIFY:** An L-C circuit oscillates, with the energy going back and forth between the inductor and capacitor.

(a) SET UP: The frequency is $f = \frac{\omega}{2\pi}$ and $\omega = \frac{1}{\sqrt{LC}}$, giving $f = \frac{1}{2\pi\sqrt{LC}}$.

EXECUTE: $f = \frac{1}{2\pi\sqrt{(0.280\times10^{-3}\text{ H})(20.0\times10^{-6}\text{ F})}} = 2.13\times10^{3}\text{ Hz} = 2.13\text{ kHz}$

(b) SET UP: The energy stored in a capacitor is $U = \frac{1}{2}CV^2$.

EXECUTE: $U = \frac{1}{2}(20.0\times10^{-6}\text{ F})(150.0\text{ V})^2 = 0.225\text{ J}$

(c) SET UP: The current in the circuit is $i = -\omega Q\sin\omega t$, and the energy stored in the inductor is $U = \frac{1}{2}Li^2$.

EXECUTE: First find ω and Q. $\omega = 2\pi f = 1.336\times10^{4}$ rad/s.

$$Q = CV = (20.0\times10^{-6}\text{ F})(150.0\text{ V}) = 3.00\times10^{-3}\text{ C}$$

Now calculate the current:

$$i = -(1.336\times10^{4}\text{ rad/s})(3.00\times10^{-3}\text{ C})\sin[(1.336\times10^{4}\text{ rad/s})(1.30\times10^{-3}\text{ s})]$$

Notice that the argument of the sine is in *radians*, so convert it to degrees if necessary. The result is $i = 39.92$ A.

Now find the energy in the inductor: $U = \frac{1}{2}Li^2 = \frac{1}{2}(0.280\times10^{-3}\text{ H})(39.92\text{ A})^2 = 0.223\text{ J}$

EVALUATE: At the end of 1.30 ms, nearly all the energy is now in the inductor, leaving very little in the capacitor.

30.33. **IDENTIFY:** The energy moves back and forth between the inductor and capacitor.

(a) SET UP: The period is $T = \frac{1}{f} = \frac{1}{\omega/2\pi} = \frac{2\pi}{\omega} = 2\pi\sqrt{LC}$.

EXECUTE: Solving for L gives

$$L = \frac{T^2}{4\pi^2 C} = \frac{(8.60\times10^{-5}\text{ s})^2}{4\pi^2(7.50\times10^{-9}\text{ C})} = 2.50\times10^{-2}\text{ H} = 25.0\text{ mH}$$

(b) SET UP: The charge on a capacitor is $Q = CV$.

EXECUTE: $Q = CV = (7.50\times10^{-9}\text{ F})(12.0\text{ V}) = 9.00\times10^{-8}\text{ C}$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(c) SET UP: The stored energy is $U = Q^2/2C$.

EXECUTE: $U = \dfrac{(9.00\times10^{-8}\text{ C})^2}{2(7.50\times10^{-9}\text{ F})} = 5.40\times10^{-7}\text{ J}$

(d) SET UP: The maximum current occurs when the capacitor is discharged, so the inductor has all the initial energy. $U_L + U_C = U_{\text{Total}}$. $\frac{1}{2}LI^2 + 0 = U_{\text{Total}}$.

EXECUTE: Solve for the current:

$$I = \sqrt{\frac{2U_{\text{Total}}}{L}} = \sqrt{\frac{2(5.40\times10^{-7}\text{ J})}{2.50\times10^{-2}\text{ H}}} = 6.58\times10^{-3}\text{ A} = 6.58\text{ mA}$$

EVALUATE: The energy oscillates back and forth forever. However, if there is any resistance in the circuit, no matter how small, all this energy will eventually be dissipated as heat in the resistor.

30.34. **IDENTIFY:** The circuit is described in Figure 30.14 of the textbook.

SET UP: The energy stored in the inductor is $U_L = \frac{1}{2}Li^2$ and the energy stored in the capacitor is $U_C = q^2/2C$. Initially, $U_C = \frac{1}{2}CV^2$, with $V = 22.5$ V. The period of oscillation is $T = 2\pi\sqrt{LC} = 2\pi\sqrt{(12.0\times10^{-3}\text{ H})(18.0\times10^{-6}\text{ F})} = 2.92$ ms.

EXECUTE: **(a)** Energy conservation says $U_L(\max) = U_C(\max)$, and $\frac{1}{2}Li_{\max}^2 = \frac{1}{2}CV^2$.

$i_{\max} = V\sqrt{C/L} = (22.5\text{ V})\sqrt{\dfrac{18\times10^{-6}\text{ F}}{12\times10^{-3}\text{ H}}} = 0.871$ A. The charge on the capacitor is zero because all the energy is in the inductor.

(b) From Figure 30.14 in the textbook, $q = 0$ at $t = T/4 = 0.730$ ms and at $t = 3T/4 = 2.19$ ms.

(c) $q_0 = CV = (18\ \mu\text{F})(22.5\text{ V}) = 405\ \mu\text{C}$ is the maximum charge on the plates. The graphs are sketched in Figure 30.34. q refers to the charge on one plate and the sign of i indicates the direction of the current.

EVALUATE: If the capacitor is fully charged at $t = 0$ it is fully charged again at $t = T/2$, but with the opposite polarity.

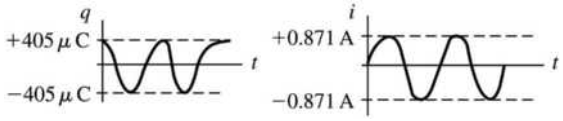

Figure 30.34

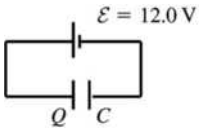
30.35. **IDENTIFY** and **SET UP:** The angular frequency is given by Eq. (30.22). $q(t)$ and $i(t)$ are given by Eqs. (30.21) and (30.23). The energy stored in the capacitor is $U_C = \frac{1}{2}CV^2 = q^2/2C$. The energy stored in the inductor is $U_L = \frac{1}{2}Li^2$.

EXECUTE: **(a)** $\omega = \dfrac{1}{\sqrt{LC}} = \dfrac{1}{\sqrt{(1.50\text{ H})(6.00\times10^{-5}\text{ F})}} = 105.4$ rad/s, which rounds to 105 rad/s. The period is given by $T = \dfrac{2\pi}{\omega} = \dfrac{2\pi}{105.4\text{ rad/s}} = 0.0596$ s.

(b) The circuit containing the battery and capacitor is sketched in Figure 30.35.



$$\mathcal{E} - \frac{Q}{C} = 0$$

$$Q = \mathcal{E}C = (12.0\text{ V})(6.00\times10^{-5}\text{ F}) = 7.20\times10^{-4}\text{ C}$$

Figure 30.35

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(c) $U = \frac{1}{2}CV^2 = \frac{1}{2}(6.00\times10^{-5}\text{ F})(12.0\text{ V})^2 = 4.32\times10^{-3}\text{ J}$

(d) $q = Q\cos(\omega t + \phi)$ (Eq. 30.21)

$q = Q$ at $t = 0$ so $\phi = 0$

$q = Q\cos\omega t = (7.20\times10^{-4}\text{ C})\cos([105.4\text{ rad/s}][0.0230\text{ s}]) = -5.42\times10^{-4}\text{ C}$

The minus sign means that the capacitor has discharged fully and then partially charged again by the current maintained by the inductor; the plate that initially had positive charge now has negative charge and the plate that initially had negative charge now has positive charge.

(e) $i = -\omega Q\sin(\omega t + \phi)$ (Eq. 30.23)

$i = -(105\text{ rad/s})(7.20\times10^{-4}\text{ C})\sin([105.4\text{ rad/s}][0.0230\text{ s}]) = -0.050\text{ A}$

The negative sign means the current is counterclockwise in Figure 30.15 in the textbook.

or

$\frac{1}{2}Li^2 + \frac{q^2}{2C} = \frac{Q^2}{2C}$ gives $i = \pm\sqrt{\frac{1}{LC}}\sqrt{Q^2 - q^2}$ (Eq. 30.26)

$i = \pm(105\text{ rad/s})\sqrt{(7.20\times10^{-4}\text{ C})^2 - (-5.42\times10^{-4}\text{ C})^2} = \pm0.050\text{ A},$ which checks.

(f) $U_C = \frac{q^2}{2C} = \frac{(-5.42\times10^{-4}\text{ C})^2}{2(6.00\times10^{-5}\text{ F})} = 2.45\times10^{-3}\text{ J}$

$U_L = \frac{1}{2}Li^2 = \frac{1}{2}(1.50\text{ H})(0.050\text{ A})^2 = 1.87\times10^{-3}\text{ J}$

EVALUATE: Note that $U_C + U_L = 2.45\times10^{-3}\text{ J} + 1.87\times10^{-3}\text{ J} = 4.32\times10^{-3}\text{ J}$.

This agrees with the total energy initially stored in the capacitor,

$U = \frac{Q^2}{2C} = \frac{(7.20\times10^{-4}\text{ C})^2}{2(6.00\times10^{-5}\text{ F})} = 4.32\times10^{-3}\text{ J}.$

Energy is conserved. At some times there is energy stored in both the capacitor and the inductor. When $i = 0$ all the energy is stored in the capacitor and when $q = 0$ all the energy is stored in the inductor. But at all times the total energy stored is the same.

30.36. **IDENTIFY:** $\omega = \frac{1}{\sqrt{LC}} = 2\pi f$

SET UP: ω is the angular frequency in rad/s and f is the corresponding frequency in Hz.

EXECUTE: **(a)** $L = \frac{1}{4\pi^2 f^2 C} = \frac{1}{4\pi^2(1.6\times10^6\text{ Hz})^2(4.18\times10^{-12}\text{ F})} = 2.37\times10^{-3}\text{ H}.$

(b) The maximum capacitance corresponds to the minimum frequency.

$C_{\max} = \frac{1}{4\pi^2 f_{\min}^2 L} = \frac{1}{4\pi^2(5.40\times10^5\text{ Hz})^2(2.37\times10^{-3}\text{ H})} = 3.67\times10^{-11}\text{ F} = 36.7\text{ pF}$

EVALUATE: To vary f by a factor of three (approximately the range in this problem), C must be varied by a factor of nine.

30.37. **IDENTIFY:** Apply energy conservation and Eqs. (30.22) and (30.23).

SET UP: If I is the maximum current, $\frac{1}{2}LI^2 = \frac{Q^2}{2C}$. For the inductor, $U_L = \frac{1}{2}Li^2$.

EXECUTE: **(a)** $\frac{1}{2}LI^2 = \frac{Q^2}{2C}$ gives $Q = I\sqrt{LC} = (0.750\text{ A})\sqrt{(0.0800\text{ H})(1.25\times10^{-9}\text{ F})} = 7.50\times10^{-6}\text{ C}.$

(b) $\omega = \frac{1}{\sqrt{LC}} = \frac{1}{\sqrt{(0.0800\text{ H})(1.25\times10^{-9}\text{ F})}} = 1.00\times10^5\text{ rad/s}.$ $f = \frac{\omega}{2\pi} = 1.59\times10^4\text{ Hz}.$

(c) $q = Q$ at $t = 0$ means $\phi = 0$. $i = -\omega Q\sin(\omega t)$, so

$i = -(1.00\times10^5\text{ rad/s})(7.50\times10^{-6}\text{ C})\sin([1.00\times10^5\text{ rad/s}][2.50\times10^{-3}\text{ s}]) = 0.7279\text{ A}.$

$U_L = \frac{1}{2}Li^2 = \frac{1}{2}(0.0800\text{ H})(0.7279\text{ A})^2 = 0.0212\text{ J}.$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: The total energy of the system is $\frac{1}{2}LI^2 = 0.0225$ J. At $t = 2.50$ ms, the current is close to its maximum value and most of the system's energy is stored in the inductor.

30.38. **IDENTIFY:** Apply Eq. (30.25).

SET UP: $q = Q$ when $i = 0$. $i = i_{\max}$ when $q = 0$. $1/\sqrt{LC} = 1917\ \text{s}^{-1}$.

EXECUTE: **(a)** $\frac{1}{2}Li_{\max}^2 = \frac{Q^2}{2C}$.

$$Q = i_{\max}\sqrt{LC} = (0.850\times10^{-3}\ \text{A})\sqrt{(0.0850\ \text{H})(3.20\times10^{-6}\ \text{F})} = 4.43\times10^{-7}\ \text{C}$$

(b) $$q = \sqrt{Q^2 - LCi^2} = \sqrt{(4.43\times10^{-7}\ \text{C})^2 - \left(\frac{5.00\times10^{-4}\ \text{A}}{1917\ \text{s}^{-1}}\right)^2} = 3.58\times10^{-7}\ \text{C}.$$

EVALUATE: The value of q calculated in part (b) is less than the maximum value Q calculated in part (a).

30.39. **IDENTIFY:** Evaluate Eq. (30.29).

SET UP: The angular frequency of the circuit is ω'.

EXECUTE: **(a)** When $R = 0$, $\omega_0 = \frac{1}{\sqrt{LC}} = \frac{1}{\sqrt{(0.450\ \text{H})(2.50\times10^{-5}\ \text{F})}} = 298$ rad/s.

(b) We want $\frac{\omega'}{\omega_0} = 0.95$, so $\frac{(1/LC - R^2/4L^2)}{1/LC} = 1 - \frac{R^2C}{4L} = (0.95)^2$. This gives

$$R = \sqrt{\frac{4L}{C}(1-(0.95)^2)} = \sqrt{\frac{4(0.450\ \text{H})(0.0975)}{(2.50\times10^{-5}\ \text{F})}} = 83.8\ \Omega.$$

EVALUATE: When R increases, the angular frequency decreases and approaches zero as $R \to 2\sqrt{L/C}$.

30.40. **IDENTIFY:** The presence of resistance in an L-R-C circuit affects the frequency of oscillation and causes the amplitude of the oscillations to decrease over time.

(a) SET UP: The frequency of damped oscillations is $\omega' = \sqrt{\frac{1}{LC} - \frac{R^2}{4L^2}}$.

EXECUTE: $$\omega' = \sqrt{\frac{1}{(22\times10^{-3}\ \text{H})(15.0\times10^{-9}\ \text{F})} - \frac{(75.0\ \Omega)^2}{4(22\times10^{-3}\ \text{H})^2}} = 5.5\times10^4\ \text{rad/s}$$

The frequency f is $f = \frac{\omega}{2\pi} = \frac{5.50\times10^4\ \text{rad/s}}{2\pi} = 8.76\times10^3\ \text{Hz} = 8.76\ \text{kHz}.$

(b) SET UP: The amplitude decreases as $A(t) = A_0\ e^{-(R/2L)t}$.

Execute**:** Solving for t and putting in the numbers gives:

$$t = \frac{-2L\ln(A/A_0)}{R} = \frac{-2(22.0\times10^{-3}\ \text{H})\ln(0.100)}{75.0\ \Omega} = 1.35\times10^{-3}\ \text{s} = 1.35\ \text{ms}$$

(c) SET UP: At critical damping, $R = \sqrt{4L/C}$.

EXECUTE: $$R = \sqrt{\frac{4(22.0\times10^{-3}\ \text{H})}{15.0\times10^{-9}\ \text{F}}} = 2420\ \Omega$$

EVALUATE: The frequency with damping is almost the same as the resonance frequency of this circuit $(1/\sqrt{LC})$, which is plausible because the 75-Ω resistance is considerably less than the 2420 Ω required for critical damping.

30.41. **IDENTIFY:** Follow the procedure specified in the problem.

SET UP: Make the substitutions $x \to q, m \to L, b \to R, k \to \frac{1}{C}$.

EXECUTE: **(a)** Eq. (14.41): $\frac{d^2x}{dt^2} + \frac{b}{m}\frac{dx}{dt} + \frac{kx}{m} = 0$. This becomes $\frac{d^2q}{dt^2} + \frac{R}{L}\frac{dq}{dt} + \frac{q}{LC} = 0$, which is Eq. (30.27).

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) Eq. (14.43): $\omega' = \sqrt{\frac{k}{m} - \frac{b^2}{4m^2}}$. This becomes $\omega' = \sqrt{\frac{1}{LC} - \frac{R^2}{4L^2}}$, which is Eq. (30.29).

(c) Eq. (14.42): $x = Ae^{-(b/2m)t}\cos(\omega' t + \phi)$. This becomes $q = Ae^{-(R/2L)t}\cos(\omega' t + \phi)$, which is Eq. (30.28).

EVALUATE: Equations for the *L*-*R*-*C* circuit and for a damped harmonic oscillator have the same form.

30.42. **IDENTIFY:** For part (a), evaluate the derivatives as specified in the problem. For part (b) set $q = Q$ in Eq. (30.28) and set $dq/dt = 0$ in the expression for dq/dt.

SET UP: In terms of ω', Eq. (30.28) is $q(t) = Ae^{-(R/2L)t}\cos(\omega' t + \phi)$.

EXECUTE: **(a)** $q = Ae^{-(R/2L)t}\cos(\omega' t + \phi)$. $\frac{dq}{dt} = -A\frac{R}{2L}e^{-(R/2L)t}\cos(\omega' t + \phi) - \omega' Ae^{-(R/2L)t}\sin(\omega' t + \phi)$.

$\frac{d^2q}{dt^2} = A\left(\frac{R}{2L}\right)^2 e^{-(R/2L)t}\cos(\omega' t + \phi) + 2\omega' A\frac{R}{2L}e^{-(R/2L)t}\sin(\omega' t + \phi) - \omega'^2 Ae^{-(R/2L)t}\cos(\omega' t + \phi)$.

$\frac{d^2q}{dt^2} + \frac{R}{L}\frac{dq}{dt} + \frac{q}{LC} = q\left(\left(\frac{R}{2L}\right)^2 - \omega'^2 - \frac{R^2}{2L^2} + \frac{1}{LC}\right) = 0$, so $\omega'^2 = \frac{1}{LC} - \frac{R^2}{4L^2}$.

(b) At $t = 0, q = Q, i = \frac{dq}{dt} = 0$, so $q = A\cos\phi = Q$ and $\frac{dq}{dt} = -\frac{R}{2L}A\cos\phi - \omega' A\sin\phi = 0$. This gives

$A = \frac{Q}{\cos\phi}$ and $\tan\phi = -\frac{R}{2L\omega'} = -\frac{R}{2L\sqrt{1/LC - R^2/4L^2}}$.

EVALUATE: If $R = 0$, then $A = Q$ and $\phi = 0$.

30.43. **IDENTIFY** and **SET UP:** The emf $\mathcal{E}_2$ in solenoid 2 produced by changing current i_1 in solenoid 1 is given by $\mathcal{E}_2 = M\left|\frac{di_1}{dt}\right|$. The mutual inductance of two solenoids is derived in Example 30.1. For the two solenoids in this problem $M = \frac{\mu_0 AN_1N_2}{l}$, where A is the cross-sectional area of the inner solenoid and l is the length of the outer solenoid. Let the outer solenoid be solenoid 1.

EXECUTE: **(a)** $M = \frac{(4\pi\times10^{-7}\ \text{T}\cdot\text{m/A})\pi(6.00\times10^{-4}\ \text{m})^2(6750)(15)}{0.500\ \text{m}} = 2.88\times10^{-7}\ \text{H} = 0.288\ \mu\text{H}$.

(b) $\mathcal{E}_2 = M\left|\frac{di_1}{dt}\right| = (2.88\times10^{-7}\ \text{H})(49.2\ \text{A/s}) = 1.42\times10^{-5}\ \text{V}$.

EVALUATE: If current in the inner solenoid changed at 49.2 A/s, the emf induced in the outer solenoid would be 1.42×10^{-5} V.

30.44. **IDENTIFY:** Apply $\mathcal{E} = -L\frac{di}{dt}$ and $Li = N\Phi_B$.

SET UP: Φ_B is the flux through one turn.

EXECUTE: **(a)** $\mathcal{E} = -L\frac{di}{dt} = -(4.80\times10^{-3}\ \text{H})\frac{d}{dt}\{(0.680\ \text{A})\cos[\pi t/(0.0250\ \text{s})]\}$.

$\mathcal{E} = (4.80\times10^{-3}\ \text{H})(0.680\ \text{A})\frac{\pi}{0.0250\ \text{s}}\sin(\pi t/[0.0250\ \text{s}])$. Therefore,

$\mathcal{E}_{\max} = (4.80\times10^{-3}\ \text{H})(0.680\ \text{A})\frac{\pi}{0.0250\ \text{s}} = 0.410\ \text{V}$.

(b) $\Phi_{B\max} = \frac{Li_{\max}}{N} = \frac{(4.80\times10^{-3}\ \text{H})(0.680\ \text{A})}{400} = 8.16\times10^{-6}\ \text{Wb}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(c) $\mathcal{E}(t) = -L\dfrac{di}{dt} = (4.80\times10^{-3}\,\text{H})(0.680\,\text{A})(\pi/0.0250\,\text{s})\sin(\pi t/0.0250\,\text{s})$. $\mathcal{E}(t) = (0.410\,\text{V})\sin[(125.6\,\text{s}^{-1})t]$.

Therefore, at $t = 0.0180$ s, $\mathcal{E}(0.0180\,\text{s}) = (0.410\,\text{V})\sin[(125.6\,\text{s}^{-1})(0.0180\,\text{s})] = 0.316\,\text{V}$. The magnitude of the induced emf is 0.316 V.

EVALUATE: The maximum emf is when $i = 0$ and at this instant $\Phi_B = 0$.

30.45. **IDENTIFY:** $\mathcal{E} = -L\dfrac{di}{dt}$.

SET UP: During an interval in which the graph of i versus t is a straight line, di/dt is constant and equal to the slope of that line.

EXECUTE: **(a)** The pattern on the oscilloscope is sketched in Figure 30.45.

EVALUATE: **(b)** Since the voltage is determined by the derivative of the current, the V versus t graph is indeed proportional to the derivative of the current graph

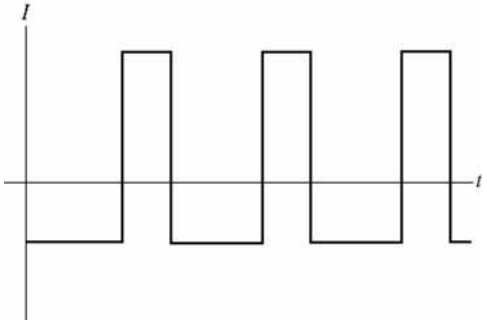


Figure 30.45

30.46. **IDENTIFY:** Apply $\mathcal{E} = -L\dfrac{di}{dt}$.

SET UP: $\dfrac{d}{dt}\cos(\omega t) = -\omega\sin(\omega t)$

EXECUTE: **(a)** $\mathcal{E} = -L\dfrac{di}{dt} = -L\dfrac{d}{dt}((0.124\,\text{A})\cos[(240\,\pi/\text{s})t]$.

$\mathcal{E} = +(0.250\,\text{H})(0.124\,\text{A})(240\,\pi/\text{s})\sin((240\pi/\text{s})t) = +(23.4\,\text{V})\sin((240\pi/\text{s})t)$.

The graphs are given in Figure 30.46.

(b) $\mathcal{E}_{\text{max}} = 23.4$ V; $i = 0$, since the emf and current are $90°$ out of phase.

(c) $i_{\text{max}} = 0.124$ A; $\mathcal{E} = 0$, since the emf and current are $90°$ out of phase.

EVALUATE: The induced emf depends on the rate at which the current is changing.

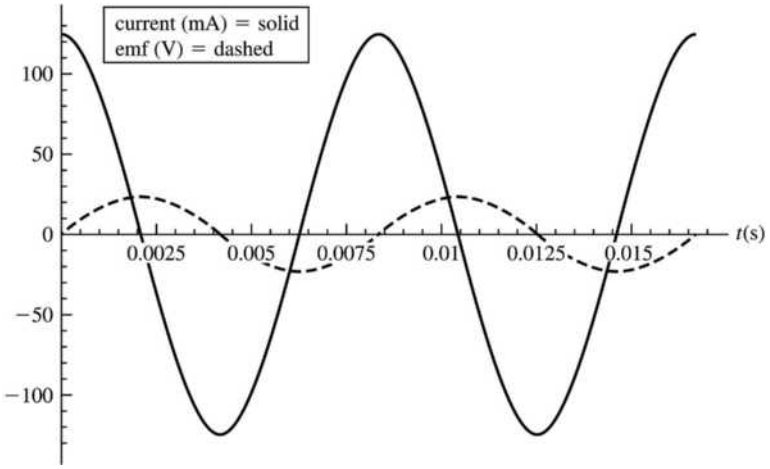

Figure 30.46

30.47. **IDENTIFY:** Set $U_B = K$, where $K = \frac{1}{2}mv^2$.

SET UP: The energy density in the magnetic field is $u_B = B^2/2\mu_0$. Consider volume $V = 1\ \text{m}^3$ of sunspot material.

EXECUTE: The energy density in the sunspot is $u_B = B^2/2\mu_0 = 6.366\times10^4\ \text{J/m}^3$. The total energy stored in volume V of the sunspot is $U_B = u_B V$. The mass of the material in volume V of the sunspot is $m = \rho V$. $K = U_B$ so $\frac{1}{2}mv^2 = U_B$. $\frac{1}{2}\rho V v^2 = u_B V$. The volume divides out, and $v = \sqrt{2u_B/\rho} = 2\times10^4$ m/s.

EVALUATE: The speed we calculated is about 30 times smaller than the escape speed.

30.48. **IDENTIFY:** Follow the steps outlined in the problem.

SET UP: The energy stored is $U = \frac{1}{2}Li^2$.

EXECUTE: **(a)** $\oint \vec{\boldsymbol{B}}\cdot d\vec{\boldsymbol{l}} = \mu_0 I_{\text{encl}} \Rightarrow B2\pi r = \mu_0 i \Rightarrow B = \dfrac{\mu_0 i}{2\pi r}$.

(b) $d\Phi_B = BdA = \dfrac{\mu_0 i}{2\pi r} l\,dr$.

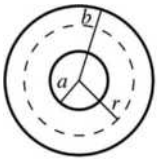
(c) $\Phi_B = \int_a^b d\Phi_B = \dfrac{\mu_0 i l}{2\pi}\int_a^b \dfrac{dr}{r} = \dfrac{\mu_0 i l}{2\pi}\ln(b/a)$.

(d) $L = \dfrac{N\Phi_B}{i} = l\dfrac{\mu_0}{2\pi}\ln(b/a)$.

(e) $U = \dfrac{1}{2}Li^2 = \dfrac{1}{2}l\dfrac{\mu_0}{2\pi}\ln(b/a)i^2 = \dfrac{\mu_0 l i^2}{4\pi}\ln(b/a)$.

EVALUATE: The magnetic field between the conductors is due only to the current in the inner conductor.

30.49. **(a) IDENTIFY** and **SET UP:** An end view is shown in Figure 30.49.



Apply Ampere's law to a circular path of radius r.
$\oint \vec{\boldsymbol{B}}\cdot d\vec{\boldsymbol{l}} = \mu_0 I_{\text{encl}}$

Figure 30.49

EXECUTE: $\oint \vec{\boldsymbol{B}}\cdot d\vec{\boldsymbol{l}} = B(2\pi r)$

$I_{\text{encl}} = i$, the current in the inner conductor

Thus $B(2\pi r) = \mu_0 i$ and $B = \dfrac{\mu_0 i}{2\pi r}$.

(b) IDENTIFY and **SET UP:** Follow the procedure specified in the problem.

EXECUTE: $u = \dfrac{B^2}{2\mu_0}$

$dU = u\,dV$, where $dV = 2\pi r l dr$

$$dU = \frac{1}{2\mu_0}\left(\frac{\mu_0 i}{2\pi r}\right)^2 (2\pi r l)dr = \frac{\mu_0 i^2 l}{4\pi r}dr$$

(c) $U = \int dU = \dfrac{\mu_0 i^2 l}{4\pi}\int_a^b \dfrac{dr}{r} = \dfrac{\mu_0 i^2 l}{4\pi}[\ln r]_a^b$

$$U = \frac{\mu_0 i^2 l}{4\pi}(\ln b - \ln a) = \frac{\mu_0 i^2 l}{4\pi}\ln\left(\frac{b}{a}\right)$$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(d) Eq. (30.9): $U = \frac{1}{2}Li^2$

Part (c): $U = \dfrac{\mu_0 i^2 l}{4\pi}\ln\left(\dfrac{b}{a}\right)$

$\frac{1}{2}Li^2 = \dfrac{\mu_0 i^2 l}{4\pi}\ln\left(\dfrac{b}{a}\right)$

$L = \dfrac{\mu_0 l}{2\pi}\ln\left(\dfrac{b}{a}\right)$.

EVALUATE: The value of L we obtain from these energy considerations agrees with L calculated in part (d) of Problem 30.48 by considering flux and Eq. (30.6).

30.50. **IDENTIFY:** Apply $L = \dfrac{N\Phi_B}{i}$ to each solenoid, as in Example 30.3. Use $M = \dfrac{N_2\Phi_{B2}}{i_1}$ to calculate the mutual inductance M.

SET UP: The magnetic field produced by solenoid 1 is confined to the space within its windings and is equal to $B_1 = \dfrac{\mu_0 N_1 i_1}{2\pi r}$.

EXECUTE: **(a)** $L_1 = \dfrac{N_1\Phi_{B_1}}{i_1} = \dfrac{N_1 A}{i_1}\left(\dfrac{\mu_0 N_1 i_1}{2\pi r}\right) = \dfrac{\mu_0 N_1^2 A}{2\pi r}$, $L_2 = \dfrac{N_2\Phi_{B_2}}{i_2} = \dfrac{N_2 A}{i_2}\left(\dfrac{\mu_0 N_2 i_2}{2\pi r}\right) = \dfrac{\mu_0 N_2^2 A}{2\pi r}$.

(b) $M = \dfrac{N_2 A B_1}{i_1} = \dfrac{\mu_0 N_1 N_2 A}{2\pi r}$. $M^2 = \left(\dfrac{\mu_0 N_1 N_2 A}{2\pi r}\right)^2 = \dfrac{\mu_0 N_1^2 A}{2\pi r}\dfrac{\mu_0 N_2^2 A}{2\pi r} = L_1 L_2$.

EVALUATE: If the two solenoids are identical, so that $N_1 = N_2$, then $M = L$.

30.51. **IDENTIFY:** $U = \frac{1}{2}LI^2$. The self-inductance of a solenoid is found in Exercise 30.15 to be $L = \dfrac{\mu_0 A N^2}{l}$.

SET UP: The length l of the solenoid is the number of turns divided by the turns per unit length.

EXECUTE: **(a)** $L = \dfrac{2U}{I^2} = \dfrac{2(10.0\text{ J})}{(2.00\text{ A})^2} = 5.00\text{ H}$.

(b) $L = \dfrac{\mu_0 A N^2}{l}$. If α is the number of turns per unit length, then $N = \alpha l$ and $L = \mu_0 A\alpha^2 l$. For this coil $\alpha = 10$ coils/mm $= 10\times10^3$ coils/m. Solving for l gives $l = \dfrac{L}{\mu_0 A\alpha^2} = \dfrac{5.00\text{ H}}{(4\pi\times10^{-7}\text{ T}\cdot\text{m/A})\pi(0.0200\text{ m})^2(10\times10^3\text{ coils/m})^2} = 31.7\text{ m}$. This is not a practical length for laboratory use.

EVALUATE: The number of turns is $N = (31.7\text{ m})(10\times10^3\text{ coils/m}) = 3.17\times10^5$ turns. The length of wire in the solenoid is the circumference C of one turn times the number of turns. $C = \pi d = \pi(4.00\times10^{-2}\text{ m}) = 0.126\text{ m}$. The length of wire is $(0.126\text{ m})(3.17\times10^5) = 4.0\times10^4\text{ m} = 40\text{ km}$. This length of wire will have a large resistance and I^2R electrical energy loses will be very large.

30.52. **IDENTIFY:** This is an R-L circuit and $i(t)$ is given by Eq. (30.14).

SET UP: When $t\to\infty$, $i\to i_f = V/R$.

EXECUTE: **(a)** $R = \dfrac{V}{i_f} = \dfrac{12.0\text{ V}}{6.45\times10^{-3}\text{ A}} = 1860\,\Omega$.

(b) $i = i_f(1-e^{-(R/L)t})$ so $\dfrac{Rt}{L} = -\ln(1-i/i_f)$ and $L = \dfrac{-Rt}{\ln(1-i/i_f)} = \dfrac{-(1860\,\Omega)(9.40\times10^{-4}\text{s})}{\ln(1-(4.86/6.45))} = 1.25\text{ H}$.

EVALUATE: The current after a long time depends only on R and is independent of L. The value of R/L determines how rapidly the final value of i is reached.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

30.53. **IDENTIFY** and **SET UP:** Follow the procedure specified in the problem. $L = 2.50$ H, $R = 8.00\ \Omega$, $\mathcal{E} = 6.00$ V. $i = (\mathcal{E}/R)(1 - e^{-t/\tau})$, $\tau = L/R$

EXECUTE: **(a)** Eq. (30.9): $U_L = \frac{1}{2}Li^2$

$t = \tau$ so $i = (\mathcal{E}/R)(1 - e^{-1}) = (6.00\text{ V}/8.00\ \Omega)(1 - e^{-1}) = 0.474$ A

Then $U_L = \frac{1}{2}Li^2 = \frac{1}{2}(2.50\text{ H})(0.474\ A)^2 = 0.281$ J

Exercise 30.29 (c): $P_L = \dfrac{dU_L}{dt} = Li\dfrac{di}{dt}$

$$i = \left(\frac{\mathcal{E}}{R}\right)(1 - e^{-t/\tau});\ \frac{di}{dt} = \left(\frac{\mathcal{E}}{L}\right)e^{-(R/L)t} = \frac{\mathcal{E}}{L}e^{-t/\tau}$$

$$P_L = L\left(\frac{\mathcal{E}}{R}(1 - e^{-t/\tau})\right)\left(\frac{\mathcal{E}}{L}e^{-t/\tau}\right) = \frac{\mathcal{E}^2}{R}(e^{-t/\tau} - e^{-2t/\tau})$$

$$U_L = \int_0^\tau P_L dt = \frac{\mathcal{E}^2}{R}\int_0^\tau (e^{-t/\tau} - e^{-2t/\tau})dt = \frac{\mathcal{E}^2}{R}\left[-\tau e^{-t/\tau} + \frac{\tau}{2}e^{-2t/\tau}\right]_0^\tau$$

$$U_L = -\frac{\mathcal{E}^2}{R}\tau\left[e^{-t/\tau} - \tfrac{1}{2}e^{-2t/\tau}\right]_0^\tau = \frac{\mathcal{E}^2}{R}\tau\left[1 - \tfrac{1}{2} - e^{-1} + \tfrac{1}{2}e^{-2}\right]$$

$$U_L = \left(\frac{\mathcal{E}^2}{2R}\right)\left(\frac{L}{R}\right)(1 - 2e^{-1} + e^{-2}) = \tfrac{1}{2}\left(\frac{\mathcal{E}}{R}\right)^2 L(1 - 2e^{-1} + e^{-2})$$

$$U_L = \tfrac{1}{2}\left(\frac{6.00\text{ V}}{8.00\ \Omega}\right)^2(2.50\text{ H})(0.3996) = 0.281\text{ J},\ \text{which checks.}$$

(b) Exercise 30.29(a): The rate at which the battery supplies energy is

$$P_\mathcal{E} = \mathcal{E}i = \mathcal{E}\left(\frac{\mathcal{E}}{R}(1 - e^{-t/\tau})\right) = \frac{\mathcal{E}^2}{R}(1 - e^{-t/\tau})$$

$$U_\mathcal{E} = \int_0^\tau P_\mathcal{E} dt = \frac{\mathcal{E}^2}{R}\int_0^\tau (1 - e^{-t/\tau})dt = \frac{\mathcal{E}^2}{R}[t + \tau e^{-t/\tau}]_0^\tau = \left(\frac{\mathcal{E}^2}{R}\right)(\tau + \tau e^{-1} - \tau)$$

$$U_\mathcal{E} = \left(\frac{\mathcal{E}^2}{R}\right)\tau e^{-1} = \left(\frac{\mathcal{E}^2}{R}\right)\left(\frac{L}{R}\right)e^{-1} = \left(\frac{\mathcal{E}}{R}\right)^2 Le^{-1}$$

$$U_\mathcal{E} = \left(\frac{6.00\text{ V}}{8.00\ \Omega}\right)^2(2.50\text{ H})(0.3679) = 0.517\text{ J}$$

(c) $P_R = i^2R = \left(\dfrac{\mathcal{E}^2}{R}\right)(1 - e^{-t/\tau})^2 = \dfrac{\mathcal{E}^2}{R}(1 - 2e^{-t/\tau} + e^{-2t/\tau})$

$$U_R = \int_0^\tau P_R dt = \frac{\mathcal{E}^2}{R}\int_0^\tau (1 - 2e^{-t/\tau} + e^{-2t/\tau})dt = \frac{\mathcal{E}^2}{R}\left[t + 2\tau e^{-t/\tau} - \frac{\tau}{2}e^{-2t/\tau}\right]_0^\tau$$

$$U_R = \frac{\mathcal{E}^2}{R}\left[\tau + 2\tau e^{-1} - \frac{\tau}{2}e^{-2} - 2\tau + \frac{\tau}{2}\right] = \frac{\mathcal{E}^2}{R}\left[-\frac{\tau}{2} + 2\tau e^{-1} - \frac{\tau}{2}e^{-2}\right]$$

$$U_R = \left(\frac{\mathcal{E}^2}{2R}\right)\left(\frac{L}{R}\right)[-1 + 4e^{-1} - e^{-2}]$$

$$U_R = \left(\frac{\mathcal{E}}{R}\right)^2\left(\tfrac{1}{2}L\right)[-1 + 4e^{-1} - e^{-2}] = \left(\frac{6.00\text{ V}}{8.00\ \Omega}\right)^2\tfrac{1}{2}(2.50\text{ H})(0.3362) = 0.236\text{ J}$$

(d) EVALUATE: $U_\mathcal{E} = U_R + U_L$. $(0.517\text{ J} = 0.236\text{ J} + 0.281\text{ J})$

The energy supplied by the battery equals the sum of the energy stored in the magnetic field of the inductor and the energy dissipated in the resistance of the inductor.

30.54. **IDENTIFY:** This is a decaying R-L circuit with $I_0 = \mathcal{E}/R$. $i(t) = I_0 e^{-(R/L)t}$.

SET UP: $\mathcal{E} = 60.0$ V, $R = 240\,\Omega$ and $L = 0.160$ H. The rate at which energy stored in the inductor is decreasing is $iLdi/dt$.

EXECUTE: **(a)** $U = \frac{1}{2}LI_0^2 = \frac{1}{2}L\left(\frac{\mathcal{E}}{R}\right)^2 = \frac{1}{2}(0.160\text{ H})\left(\frac{60\text{ V}}{240\,\Omega}\right)^2 = 5.00\times10^{-3}$ J.

(b) $i = \frac{\mathcal{E}}{R}e^{-(R/L)t} \Rightarrow \frac{di}{dt} = -\frac{R}{L}i \Rightarrow \frac{dU_L}{dt} = iL\frac{di}{dt} = -Ri^2 = \frac{\mathcal{E}^2}{R}e^{-2(R/L)t}$.

$\frac{dU_L}{dt} = -\frac{(60\text{ V})^2}{240\,\Omega}e^{-2(240/0.160)(4.00\times10^{-4})} = -4.52$ W.

(c) In the resistor, $P_R = \frac{dU_R}{dt} = i^2R = \frac{\mathcal{E}^2}{R}e^{-2(R/L)t} = \frac{(60\text{ V})^2}{240\,\Omega}e^{-2(240/0.160)(4.00\times10^{-4})} = 4.52$ W.

(d) $P_R(t) = i^2R = \frac{\mathcal{E}^2}{R}e^{-2(R/L)t}$. $U_R = \frac{\mathcal{E}^2}{R}\int_0^\infty e^{-2(R/L)t} = \frac{\mathcal{E}^2}{R}\frac{L}{2R} = \frac{(60\text{ V})^2(0.160\text{ H})}{2(240\,\Omega)^2} = 5.00\times10^{-3}$ J, which is the same as part (a).

EVALUATE: During the decay of the current all the electrical energy originally stored in the inductor is dissipated in the resistor.

30.55. **IDENTIFY** and **SET UP:** Follow the procedure specified in the problem. $\frac{1}{2}Li^2$ is the energy stored in the inductor and $q^2/2C$ is the energy stored in the capacitor. The equation is $-iR - L\frac{di}{dt} - \frac{q}{C} = 0$.

EXECUTE: Multiplying by $-i$ gives $i^2R + Li\frac{di}{dt} + \frac{qi}{C} = 0$.

$\frac{d}{dt}U_L = \frac{d}{dt}\left(\frac{1}{2}Li^2\right) = \frac{1}{2}L\frac{d}{dt}(i^2) = \frac{1}{2}L\left(2i\frac{di}{dt}\right) = Li\frac{di}{dt}$, the second term.

$\frac{d}{dt}U_C = \frac{d}{dt}\left(\frac{q^2}{2C}\right) = \frac{1}{2C}\frac{d}{dt}(q^2) = \frac{1}{2C}(2q)\frac{dq}{dt} = \frac{qi}{C}$, the third term. $i^2R = P_R$, the rate at which electrical energy is dissipated in the resistance. $\frac{d}{dt}U_L = P_L$, the rate at which the amount of energy stored in the inductor is changing. $\frac{d}{dt}U_C = P_C$, the rate at which the amount of energy stored in the capacitor is changing.

EVALUATE: The equation says that $P_R + P_L + P_C = 0$; the net rate of change of energy in the circuit is zero. Note that at any given time one of P_C or P_L is negative. If the current and U_L are increasing the charge on the capacitor and U_C are decreasing, and vice versa.

30.56. **IDENTIFY:** The energy stored in a capacitor is $U_C = \frac{1}{2}Cv^2$. The energy stored in an inductor is $U_L = \frac{1}{2}Li^2$. Energy conservation requires that the total stored energy be constant.

SET UP: The current is a maximum when the charge on the capacitor is zero and the energy stored in the capacitor is zero.

EXECUTE: **(a)** Initially $v = 16.0$ V and $i = 0$. $U_L = 0$ and $U_C = \frac{1}{2}Cv^2 = \frac{1}{2}(7.00\times10^{-6}\text{ F})(16.0\text{ V})^2 = 8.96\times10^{-4}$ J. The total energy stored is 0.896 mJ.

(b) The current is maximum when $q = 0$ and $U_C = 0$. $U_C + U_L = 8.96\times10^{-4}$ J so $U_L = 8.96\times10^{-4}$ J.

$\frac{1}{2}Li_{\max}^2 = 8.96\times10^{-4}$ J and $i_{\max} = \sqrt{\frac{2(8.96\times10^{-4}\text{ J})}{3.75\times10^{-3}\text{ H}}} = 0.691$ A.

EVALUATE: The maximum charge on the capacitor is $Q = CV = 112\,\mu C$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

30.57. **IDENTIFY** and **SET UP:** Use $U_C = \frac{1}{2}CV_C^2$ (energy stored in a capacitor) to solve for C. Then use Eq. (30.22) and $\omega = 2\pi f$ to solve for the L that gives the desired current oscillation frequency.

EXECUTE: $V_C = 12.0$ V; $U_C = \frac{1}{2}CV_C^2$ so $C = 2U_C/V_C^2 = 2(0.0160\text{ J})/(12.0\text{ V})^2 = 222\ \mu\text{F}$

$f = \dfrac{1}{2\pi\sqrt{LC}}$ so $L = \dfrac{1}{(2\pi f)^2 C}$

$f = 3500$ Hz gives $L = 9.31\ \mu$H

EVALUATE: f is in Hz and ω is in rad/s; we must be careful not to confuse the two.

30.58. **IDENTIFY:** Apply energy conservation to the circuit.

SET UP: For a capacitor $V = q/C$ and $U = q^2/2C$. For an inductor $U = \frac{1}{2}Li^2$.

EXECUTE: **(a)** $V_{\max} = \dfrac{Q}{C} = \dfrac{6.00\times10^{-6}\text{ C}}{2.50\times10^{-4}\text{ F}} = 0.0240\text{ V}.$

(b) $\frac{1}{2}Li_{\max}^2 = \dfrac{Q^2}{2C}$, so $i_{\max} = \dfrac{Q}{\sqrt{LC}} = \dfrac{6.00\times10^{-6}\text{ C}}{\sqrt{(0.0600\text{ H})(2.50\times10^{-4}\text{ F})}} = 1.55\times10^{-3}\text{ A}$

(c) $U_{\max} = \frac{1}{2}Li_{\max}^2 = \frac{1}{2}(0.0600\text{ H})(1.55\times10^{-3}\text{ A})^2 = 7.21\times10^{-8}\text{ J}.$

(d) If $i = \frac{1}{2}i_{\max}$ then $U_L = \frac{1}{4}U_{\max} = 1.80\times10^{-8}$ J and $U_C = \frac{3}{4}U_{\max} = \dfrac{\left(\sqrt{(3/4)}Q\right)^2}{2C} = \dfrac{q^2}{2C}$. This gives

$q = \sqrt{\dfrac{3}{4}}Q = 5.20\times10^{-6}$ C.

EVALUATE: $U_{\max} = \dfrac{1}{2}Li^2 + \dfrac{1}{2}\dfrac{q^2}{C}$ for all times.

30.59. **IDENTIFY:** The initial energy stored in the capacitor is shared between the inductor and the capacitor.

SET UP: The potential across the capacitor and inductor is always the same, so $\dfrac{q}{C} = L\left|\dfrac{di}{dt}\right|$. The capacitor energy is $U_C = \dfrac{q^2}{2C}$ and the inductor energy is $U_L = \frac{1}{2}Li^2$.

EXECUTE: $\dfrac{q^2}{2C} + \dfrac{1}{2}Li^2 = \dfrac{Q_{\max}^2}{2C}$. $Q_{\max} = (84.0\times10^{-9}\text{ F})(12.0\text{ V}) = 1.008\times10^{-6}$ C

$\frac{1}{2}Li^2 = \dfrac{1}{2C}(Q_{\max}^2 - q^2) = \dfrac{1}{2(84.0\times10^{-9}\text{ F})}((1.008\times10^{-6}\text{ C})^2 - (0.650\times10^{-6}\text{ C})^2) = 3.533\times10^{-6}\text{ J}.$

$i = \sqrt{\dfrac{2(3.533\times10^{-6}\text{ J})}{0.0420\text{ H}}} = 0.0130\text{ A} = 13.0\text{ mA}.$

$\left|\dfrac{di}{dt}\right| = \dfrac{q}{LC} = \dfrac{0.650\times10^{-6}\text{ C}}{(0.0420\text{ H})(84.0\times10^{-9}\text{ F})} = 184\text{ A/s}.$

EVALUATE: The current is only 13 mA but is changing at a rate of 184 A/s. However, it only changes at that rate for a tiny fraction of a second.

30.60. **IDENTIFY:** The total energy is shared between the inductor and the capacitor.

SET UP: The potential across the capacitor and inductor is always the same, so $\dfrac{q}{C} = L\left|\dfrac{di}{dt}\right|$. The capacitor energy is $U_C = \dfrac{q^2}{2C}$ and the inductor energy is $U_L = \frac{1}{2}Li^2$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: The total energy is $\frac{q^2}{2C}+\frac{1}{2}Li^2=\frac{Q_{\max}^2}{2C}=\frac{1}{2}CV_{\max}^2$.

$q=LC\left|\frac{di}{dt}\right|=(0.330\text{ H})(5.90\times10^{-4}\text{ F})(89.0\text{ A/s})=1.733\times10^{-2}\text{ C}.$

$\frac{1}{2}CV_{\max}^2=\frac{(1.733\times10^{-2}\text{ C})^2}{2(5.90\times10^{-4}\text{ F})}+\frac{1}{2}(0.330\text{ H})(2.50\text{ A})^2=1.286\text{ J}.$

$V_{\max}=\sqrt{\frac{2(1.286\text{ J})}{5.90\times10^{-4}\text{ F}}}=66.0\text{ V}.$

EVALUATE: By energy conservation, the maximum potential across the inductor will also be 66.0 V, but that will occur only at the instants when the capacitor is uncharged.

30.61. **IDENTIFY:** The current through an inductor doesn't change abruptly. After a long time the current isn't changing and the voltage across each inductor is zero.

SET UP: First combine the inductors.

EXECUTE: **(a)** Just after the switch is closed there is no current in the inductors. There is no current in the resistors so there is no voltage drop across either resistor. A reads zero and V reads 20.0 V.

(b) After a long time the currents are no longer changing, there is no voltage across the inductors, and the inductors can be replaced by short-circuits. The circuit becomes equivalent to the circuit shown in Figure 30.61a. $I=(20.0\text{ V})/(75.0\,\Omega)=0.267$ A. The voltage between points a and b is zero, so the voltmeter reads zero.

(c) Combine the inductor network into its equivalent, as shown in Figure 30.61b. $R=75.0\,\Omega$ is the equivalent resistance. Eq. (30.14) says $i=(\mathcal{E}/R)(1-e^{-t/\tau})$ with $\tau=L/R=(10.8\text{ mH})/(75.0\,\Omega)=0.144$ ms. $\mathcal{E}=20.0$ V, $R=75.0\,\Omega$, $t=0.115$ ms so $i=0.147$ A. $V_R=iR=(0.147\text{ A})(75.0\,\Omega)=11.0$ V. $20.0\text{ V}-V_R-V_L=0$ and $V_L=20.0\text{ V}-V_R=9.0$ V. The ammeter reads 0.147 A and the voltmeter reads 9.0 V.

EVALUATE: The current through the battery increases from zero to a final value of 0.267 A. The voltage across the inductor network drops from 20.0 V to zero.

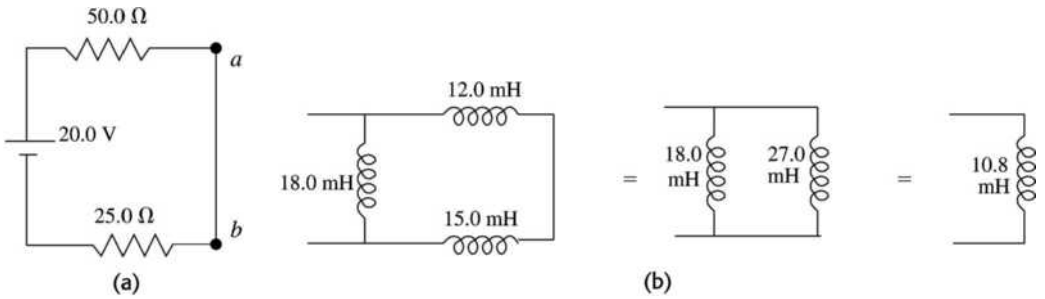

Figure 30.61

30.62. **IDENTIFY:** $i(t)$ is given by Eq. (30.14).

SET UP: The graph shows $V=0$ at $t=0$ and V approaches the constant value of 25 V at large times.

EXECUTE: **(a)** The voltage behaves the same as the current. Since V_R is proportional to i, the scope must be across the 150-Ω resistor.

(b) From the graph, as $t\to\infty, V_R\to25$ V, so there is no voltage drop across the inductor, so its internal resistance must be zero. $V_R=V_{\max}(1-e^{-t/r})$. When $t=\tau$, $V_R=V_{\max}\left(1-\frac{1}{e}\right)\approx0.63V_{\max}$. From the graph, $V=0.63V_{\max}=16$ V at $t\approx0.5$ ms. Therefore $\tau=0.5$ ms. $L/R=0.5$ ms gives $L=(0.5\text{ ms})(150\,\Omega)=0.075$ H.

(c) The graph if the scope is across the inductor is sketched in Figure 30.62

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: At all times $V_R + V_L = 25.0$ V. At $t = 0$ all the battery voltage appears across the inductor since $i = 0$. At $t \to \infty$ all the battery voltage is across the resistance, since $di/dt = 0$.

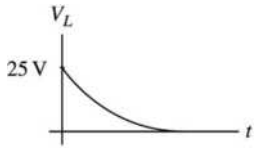

Figure 30.62

30.63. **IDENTIFY** and **SET UP:** The current grows in the circuit as given by Eq. (30.14). In an *R-L* circuit the full emf initially is across the inductance and after a long time is totally across the resistance. A solenoid in a circuit is represented as a resistance in series with an inductance. Apply the loop rule to the circuit; the voltage across a resistance is given by Ohm's law.

EXECUTE: **(a)** In the *R-L* circuit the voltage across the resistor starts at zero and increases to the battery voltage. The voltage across the solenoid (inductor) starts at the battery voltage and decreases to zero. In the graph, the voltage drops, so the oscilloscope is across the solenoid.

(b) At $t \to \infty$ the current in the circuit approaches its final, constant value. The voltage doesn't go to zero because the solenoid has some resistance R_L. The final voltage across the solenoid is IR_L, where I is the final current in the circuit.

(c) The emf of the battery is the initial voltage across the inductor, 50 V. Just after the switch is closed, the current is zero and there is no voltage drop across any of the resistance in the circuit.

(d) As $t \to \infty$, $\mathcal{E} - IR - IR_L = 0$

$\mathcal{E} = 50$ V and from the graph $IR_L = 15$ V (the final voltage across the inductor), so

$IR_L = 35$ V and $I = (35\text{ V})/R = 3.5$ A

(e) $IR_L = 15$ V, so $R_L = (15\text{ V})/(3.5\text{ A}) = 4.3\ \Omega$

$\mathcal{E} - V_L - iR = 0$, where V_L includes the voltage across the resistance of the solenoid.

$$V_L = \mathcal{E} - iR,\ i = \frac{\mathcal{E}}{R_{\text{tot}}}(1 - e^{-t/\tau}),\ \text{so } V_L = \mathcal{E}\left[1 - \frac{R}{R_{\text{tot}}}(1 - e^{-t/\tau})\right]$$

$\mathcal{E} = 50$ V, $R = 10\ \Omega$, $R_{\text{tot}} = 14.3\ \Omega$, so when $t = \tau$, $V_L = 27.9$ V. From the graph, V_L has this value when $t = 3.0$ ms (read approximately from the graph), so $\tau = L/R_{\text{tot}} = 3.0$ ms. Then $L = (3.0\text{ ms})(14.3\ \Omega) = 43$ mH.

EVALUATE: At $t = 0$ there is no current and the 50 V measured by the oscilloscope is the induced emf due to the inductance of the solenoid. As the current grows, there are voltage drops across the two resistances in the circuit. We derived an equation for V_L, the voltage across the solenoid. At $t = 0$ it gives $V_L = \mathcal{E}$ and at $t \to \infty$ it gives $V_L = \mathcal{E}R/R_{\text{tot}} = iR$.

30.64. **IDENTIFY:** At $t = 0$, $i = 0$ through each inductor. At $t \to \infty$, the voltage is zero across each inductor.

SET UP: In each case redraw the circuit. At $t = 0$ replace each inductor by a break in the circuit and at $t \to \infty$ replace each inductor by a wire.

EXECUTE: **(a)** Initially the inductor blocks current through it, so the simplified equivalent circuit is shown in Figure 30.64a. $i = \dfrac{\mathcal{E}}{R} = \dfrac{50\text{ V}}{150\ \Omega} = 0.333$ A. $V_1 = (100\ \Omega)(0.333\text{ A}) = 33.3$ V.

$V_4 = (50\ \Omega)(0.333\text{ A}) = 16.7$ V. $V_3 = 0$ since no current flows through it. $V_2 = V_4 = 16.7$ V, since the inductor is in parallel with the 50-Ω resistor. $A_1 = A_3 = 0.333$ A, $A_2 = 0$.

(b) Long after *S* is closed, steady state is reached, so the inductor has no potential drop across it. The simplified circuit is sketched in Figure 30.64b. $i = \mathcal{E}/R = \dfrac{50\text{ V}}{130\ \Omega} = 0.385$ A.

$V_1 = (100\ \Omega)(0.385\text{ A}) = 38.5$ V; $V_2 = 0$; $V_3 = V_4 = 50\text{ V} - 38.5\text{ V} = 11.5$ V.

$i_1 = 0.385$ A; $i_2 = \dfrac{11.5\text{ V}}{75\ \Omega} = 0.153$ A; $i_3 = \dfrac{11.5\text{ V}}{50\ \Omega} = 0.230$ A.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: Just after the switch is closed the current through the battery is 0.333 A. After a long time the current through the battery is 0.385 A. After a long time there is an additional current path, the equivalent resistance of the circuit is decreased and the current has increased.

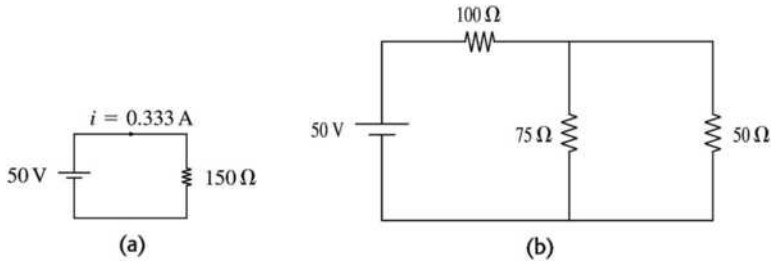

Figure 30.64

30.65. **IDENTIFY** and **SET UP:** Just after the switch is closed, the current in each branch containing an inductor is zero and the voltage across any capacitor is zero. The inductors can be treated as breaks in the circuit and the capacitors can be replaced by wires. After a long time there is no voltage across each inductor and no current in any branch containing a capacitor. The inductors can be replaced by wires and the capacitors by breaks in the circuit.

EXECUTE: **(a)** Just after the switch is closed the voltage V_5 across the capacitor is zero and there is also no current through the inductor, so $V_3 = 0$. $V_2 + V_3 = V_4 = V_5$, and since $V_5 = 0$ and $V_3 = 0, V_4$ and V_2 are also zero. $V_4 = 0$ means V_3 reads zero. V_1 then must equal 40.0 V, and this means the current read by A_1 is $(40.0\text{ V})/(50.0\ \Omega) = 0.800$ A. $A_2 + A_3 + A_4 = A_1$, but $A_2 = A_3 = 0$ so $A_4 = A_1 = 0.800$ A. $A_1 = A_4 = 0.800$ A; all other ammeters read zero. $V_1 = 40.0$ V and all other voltmeters read zero.

(b) After a long time the capacitor is fully charged so $A_4 = 0$, The current through the inductor isn't changing, so $V_2 = 0$. The currents can be calculated from the equivalent circuit that replaces the inductor by a short circuit, as shown in Figure 30.65a.

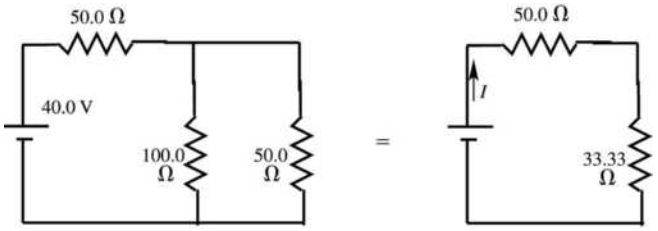

Figure 30.65a

$I = (40.0\text{ V})/(83.33\ \Omega) = 0.480$ A; A_1 reads 0.480 A

$V_1 = I(50.0\ \Omega) = 24.0$ V

The voltage across each parallel branch is $40.0\text{ V} - 24.0\text{ V} = 16.0$ V.

$V_2 = 0, V_3 = V_4 = V_5 = 16.0$ V

$V_3 = 16.0$ V means A_2 reads 0.160 A. $V_4 = 16.0$ V means A_3 reads 0.320 A. A_4 reads zero. Note that $A_2 + A_3 = A_1$.

(c) $V_5 = 16.0$ V so $Q = CV = (12.0\ \mu\text{F})(16.0\text{ V}) = 192\ \mu\text{C}$

(d) At $t = 0$ and $t \to \infty, V_2 = 0$. As the current in this branch increases from zero to 0.160 A the voltage V_2 reflects the rate of change of the current. The graph is sketched in Figure 30.65b.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

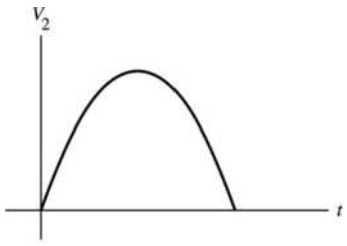

Figure 30.65b

EVALUATE: This reduction of the circuit to resistor networks only apply at $t = 0$ and $t \to \infty$. At intermediate times the analysis is complicated.

30.66. **IDENTIFY:** At all times $v_1 + v_2 = 25.0$ V. The voltage across the resistor depends on the current through it and the voltage across the inductor depends on the rate at which the current through it is changing.

SET UP: Immediately after closing the switch the current through the inductor is zero. After a long time the current is no longer changing.

EXECUTE: **(a)** $i = 0$ so $v_1 = 0$ and $v_2 = 25.0$ V. The ammeter reading is $A = 0$.

(b) After a long time, $v_2 = 0$ and $v_1 = 25.0$ V. $v_1 = iR$ and $i = \dfrac{v_1}{R} = \dfrac{25.0\text{ V}}{15.0\,\Omega} = 1.67$ A. The ammeter reading is $A = 1.67$A.

(c) None of the answers in (a) and (b) depend on L so none of them would change.

EVALUATE: The inductance L of the circuit affects the rate at which current reaches its final value. But after a long time the inductor doesn't affect the circuit and the final current does not depend on L.

30.67. **IDENTIFY:** At $t = 0$, $i = 0$ through each inductor. At $t \to \infty$, the voltage is zero across each inductor.

SET UP: In each case redraw the circuit. At $t = 0$ replace each inductor by a break in the circuit and at $t \to \infty$ replace each inductor by a wire.

EXECUTE: **(a)** Just after the switch is closed there is no current through either inductor and they act like breaks in the circuit. The current is the same through the 40.0-Ω and 15.0-Ω resistors and is equal to $(25.0\text{ V})/(40.0\,\Omega + 15.0\,\Omega) = 0.455$ A. $A_1 = A_4 = 0.455$ A; $A_2 = A_3 = 0$.

(b) After a long time the currents are constant, there is no voltage across either inductor, and each inductor can be treated as a short-circuit. The circuit is equivalent to the circuit sketched in Figure 30.67.

$I = (25.0\text{ V})/(42.73\,\Omega) = 0.585$ A. A_1 reads 0.585 A. The voltage across each parallel branch is $25.0\text{ V} - (0.585\text{ A})(40.0\,\Omega) = 1.60$ V. A_2 reads $(1.60\text{ V})/(5.0\,\Omega) = 0.320$ A. A_3 reads $(1.60\text{ V})/(10.0\,\Omega) = 0.160$ A. A_4 reads $(1.60\text{ V})/(15.0\,\Omega) = 0.107$ A.

EVALUATE: Just after the switch is closed the current through the battery is 0.455 A. After a long time the current through the battery is 0.585 A. After a long time there are additional current paths, the equivalent resistance of the circuit is decreased and the current has increased.

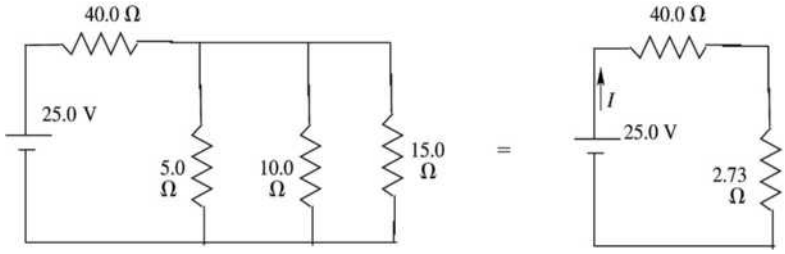

Figure 30.67

30.68. **IDENTIFY:** Closing S_2 and simultaneously opening S_1 produces an L-C circuit with initial current through the inductor of 3.50 A. When the current is a maximum the charge q on the capacitor is zero and

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

when the charge q is a maximum the current is zero. Conservation of energy says that the maximum energy $\frac{1}{2}Li_{\max}^2$ stored in the inductor equals the maximum energy $\frac{1}{2}\frac{q_{\max}^2}{C}$ stored in the capacitor.

SET UP: $i_{\max} = 3.50$ A, the current in the inductor just after the switch is closed.

EXECUTE: **(a)** $\frac{1}{2}Li_{\max}^2 = \frac{1}{2}\frac{q_{\max}^2}{C}$.

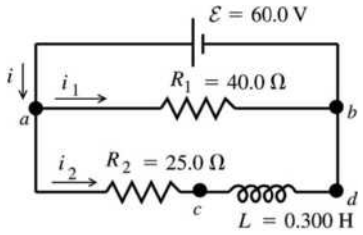
$q_{\max} = (\sqrt{LC})i_{\max} = \sqrt{(2.0\times10^{-3}\text{ H})(5.0\times10^{-6}\text{ F})}(3.50\text{ A}) = 3.50\times10^{-4}\text{ C} = 0.350\text{ mC}$.

(b) When q is maximum, $i = 0$.

EVALUATE: In the final circuit the current will oscillate.

30.69. **IDENTIFY:** Apply the loop rule to each parallel branch. The voltage across a resistor is given by iR and the voltage across an inductor is given by $L|di/dt|$. The rate of change of current through the inductor is limited.

SET UP: With S closed the circuit is sketched in Figure 30.69a.



The rate of change of the current through the inductor is limited by the induced emf. Just after the switch is closed the current in the inductor has not had time to increase from zero, so $i_2 = 0$.

Figure 30.69a

EXECUTE: **(a)** $\mathcal{E} - v_{ab} = 0$, so $v_{ab} = 60.0$ V

(b) The voltage drops across R, as we travel through the resistor in the direction of the current, so point a is at higher potential.

(c) $i_2 = 0$ so $v_{R_2} = i_2R_2 = 0$

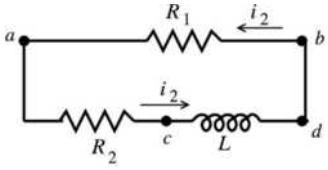
$\mathcal{E} - v_{R_2} - v_L = 0$ so $v_L = \mathcal{E} = 60.0$ V

(d) The voltage rises when we go from b to a through the emf, so it must drop when we go from a to b through the inductor. Point c must be at higher potential than point d.

(e) After the switch has been closed a long time, $\frac{di_2}{dt} \to 0$ so $v_L = 0$. Then $\mathcal{E} - v_{R_2} = 0$ and $i_2R_2 = \mathcal{E}$

so $i_2 = \frac{\mathcal{E}}{R_2} = \frac{60.0\text{ V}}{25.0\ \Omega} = 2.40$ A.

SET UP: The rate of change of the current through the inductor is limited by the induced emf. Just after the switch is opened again the current through the inductor hasn't had time to change and is still $i_2 = 2.40$ A. The circuit is sketched in Figure 30.69b.



EXECUTE: The current through R_1 is $i_2 = 2.40$ A in the direction b to a.

Thus $v_{ab} = -i_2R_1 = -(2.40\text{ A})(40.0\ \Omega)$

$v_{ab} = -96.0$ V.

Figure 30.69b

(f) Point where current enters resistor is at higher potential; point b is at higher potential.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(g) $v_L - v_{R_1} - v_{R_2} = 0$

$v_L = v_{R_1} + v_{R_2}$

$v_{R_1} = -v_{ab} = 96.0\text{ V}$; $v_{R_2} = i_2 R_2 = (2.40\text{ A})(25.0\ \Omega) = 60.0\text{ V}$

Then $v_L = v_{R_1} + v_{R_2} = 96.0\text{ V} + 60.0\text{ V} = 156\text{ V}$.

As you travel counterclockwise around the circuit in the direction of the current, the voltage drops across each resistor, so it must rise across the inductor and point *d* is at higher potential than point *c*. The current is decreasing, so the induced emf in the inductor is directed in the direction of the current. Thus, $v_{cd} = -156\text{ V}$.

(h) Point *d* is at higher potential.

EVALUATE: The voltage across R_1 is constant once the switch is closed. In the branch containing R_2, just after S is closed the voltage drop is all across *L* and after a long time it is all across R_2. Just after S is opened the same current flows in the single loop as had been flowing through the inductor and the sum of the voltage across the resistors equals the voltage across the inductor. This voltage dies away, as the energy stored in the inductor is dissipated in the resistors.

30.70. **IDENTIFY:** Apply the loop rule to the two loops. The current through the inductor doesn't change abruptly.

SET UP: For the inductor $|\mathcal{E}| = L\left|\frac{di}{dt}\right|$ and $\mathcal{E}$ is directed to oppose the change in current.

EXECUTE: **(a)** Switch is closed, then at some later time

$$\frac{di}{dt} = 50.0\text{ A/s} \Rightarrow v_{cd} = L\frac{di}{dt} = (0.300\text{ H})(50.0\text{ A/s}) = 15.0\text{ V}.$$

The top circuit loop: $60.0\text{ V} = i_1 R_1 \Rightarrow i_1 = \dfrac{60.0\text{ V}}{40.0\ \Omega} = 1.50\text{ A}$.

The bottom loop: $60.0\text{ V} - i_2 R_2 - 15.0\text{ V} = 0 \Rightarrow i_2 = \dfrac{45.0\text{ V}}{25.0\ \Omega} = 1.80\text{ A}$.

(b) After a long time: $i_2 = \dfrac{60.0\text{ V}}{25.0\ \Omega} = 2.40\text{ A}$, and immediately when the switch is opened, the inductor maintains this current, so $i_1 = i_2 = 2.40\text{ A}$.

EVALUATE: The current through R_1 changes abruptly when the switch is closed.

30.71. **IDENTIFY** and **SET UP:** The circuit is sketched in Figure 30.71a. Apply the loop rule. Just after S_1 is closed, $i = 0$. After a long time *i* has reached its final value and $di/dt = 0$. The voltage across a resistor depends on *i* and the voltage across an inductor depends on di/dt.

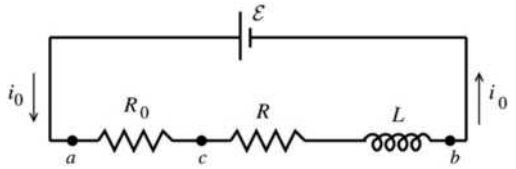


Figure 30.71a

EXECUTE: **(a)** At time $t = 0$, $i_0 = 0$ so $v_{ac} = i_0 R_0 = 0$. By the loop rule $\mathcal{E} - v_{ac} - v_{cb} = 0$ so $v_{cb} = \mathcal{E} - v_{ac} = \mathcal{E} = 36.0\text{ V}$. ($i_0 R = 0$ so this potential difference of 36.0 V is across the inductor and is an induced emf produced by the changing current.)

(b) After a long time $\dfrac{di_0}{dt} \to 0$ so the potential $-L\dfrac{di_0}{dt}$ across the inductor becomes zero. The loop rule gives $\mathcal{E} - i_0(R_0 + R) = 0$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$i_0 = \frac{\mathcal{E}}{R_0 + R} = \frac{36.0\text{ V}}{50.0\ \Omega + 150\ \Omega} = 0.180\text{ A}$$

$$v_{ac} = i_0 R_0 = (0.180\text{ A})(50.0\ \Omega) = 9.0\text{ V}$$

Thus $v_{cb} = i_0 R + L\frac{di_0}{dt} = (0.180\text{ A})(150\ \Omega) + 0 = 27.0\text{ V}$ (Note that $v_{ac} + v_{cb} = \mathcal{E}$.)

(c) $\mathcal{E} - v_{ac} - v_{cb} = 0$

$$\mathcal{E} - iR_0 - iR - L\frac{di}{dt} = 0$$

$$L\frac{di}{dt} = \mathcal{E} - i(R_0 + R) \text{ and } \left(\frac{L}{R + R_0}\right)\frac{di}{dt} = -i + \frac{\mathcal{E}}{R + R_0}$$

$$\frac{di}{-i + \mathcal{E}/(R + R_0)} = \left(\frac{R + R_0}{L}\right)dt$$

Integrate from $t = 0,$ when $i = 0,$ to t, when $i = i_0$:

$$\int_0^{i_0} \frac{di}{-i + \mathcal{E}/(R + R_0)} = \frac{R + R_0}{L}\int_0^t dt = -\ln\left[-i + \frac{\mathcal{E}}{R + R_0}\right]_0^{i_0} = \left(\frac{R + R_0}{L}\right)t, \text{ so}$$

$$\ln\left(-i_0 + \frac{\mathcal{E}}{R + R_0}\right) - \ln\left(\frac{\mathcal{E}}{R + R_0}\right) = -\left(\frac{R + R_0}{L}\right)t$$

$$\ln\left(\frac{-i_0 + \mathcal{E}/(R + R_0)}{\mathcal{E}/(R + R_0)}\right) = -\left(\frac{R + R_0}{L}\right)t$$

Taking exponentials of both sides gives $\frac{-i_0 + \mathcal{E}/(R + R_0)}{\mathcal{E}/(R + R_0)} = e^{-(R + R_0)t/L}$ and $i_0 = \frac{\mathcal{E}}{R + R_0}(1 - e^{-(R + R_0)t/L})$.

Substituting in the numerical values gives $i_0 = \frac{36.0\text{ V}}{50\ \Omega + 150\ \Omega}(1 - e^{-(200\ \Omega/4.00\text{ H})t}) = (0.180\text{ A})(1 - e^{-t/0.020\text{ s}})$.

At $t \to 0, i_0 = (0.180\text{ A})(1 - 1) = 0$ (agrees with part (a)). At $t \to \infty, i_0 = (0.180\text{ A})(1 - 0) = 0.180\text{ A}$ (agrees with part (b)).

$$v_{ac} = i_0 R_0 = \frac{\mathcal{E} R_0}{R + R_0}(1 - e^{-(R + R_0)t/L}) = 9.0\text{ V}(1 - e^{-t/0.020\text{ s}})$$

$$v_{cb} = \mathcal{E} - v_{ac} = 36.0\text{ V} - 9.0\text{ V}(1 - e^{-t/0.020\text{ s}}) = 9.0\text{ V}(3.00 + e^{-t/0.020\text{ s}})$$

At $t \to 0, v_{ac} = 0, v_{cb} = 36.0$ V (agrees with part (a)). At $t \to \infty, v_{ac} = 9.0$ V, $v_{cb} = 27.0$ V (agrees with part (b)). The graphs are given in Figure 30.71b.

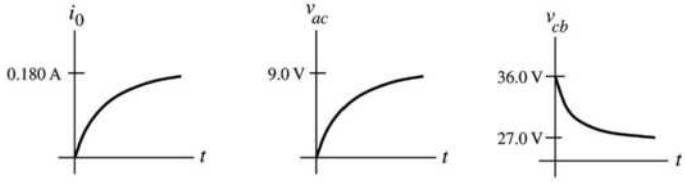

Figure 30.71b

EVALUATE: The expression for $i(t)$ we derived becomes Eq. (30.14) if the two resistors R_0 and R in series are replaced by a single equivalent resistance $R_0 + R$.

30.72. **IDENTIFY:** Apply the loop rule. The current through the inductor doesn't change abruptly.
SET UP: With S_2 closed, v_{cb} must be zero.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: **(a)** Immediately after S_2 is closed, the inductor maintains the current $i = 0.180$ A through R. The loop rule around the outside of the circuit yields

$\mathcal{E} + \mathcal{E}_L - iR - i_0R_0 = 36.0\text{ V} + (0.18\text{ A})(150\,\Omega) - (0.18\text{ A})(150\,\Omega) - i_0(50\,\Omega) = 0.$ $i_0 = \dfrac{36\text{ V}}{50\,\Omega} = 0.720\text{ A}.$

$v_{ac} = (0.72\text{ A})(50\,\Omega) = 36.0\text{ V}$ and $v_{cb} = 0.$

(b) After a long time, $v_{ac} = 36.0$ V, and $v_{cb} = 0.$ Thus $i_0 = \dfrac{\mathcal{E}}{R_0} = \dfrac{36.0\text{ V}}{50\,\Omega} = 0.720\text{ A},$ $i_R = 0$ and

$i_{s2} = 0.720$ A.

(c) $i_0 = 0.720$ A, $i_R(t) = \dfrac{\mathcal{E}}{R_{\text{total}}}e^{-(R/L)t}$ and $i_R(t) = (0.180\text{ A})e^{-(12.5\text{ s}^{-1})t}.$

$i_{s2}(t) = (0.720\text{ A}) - (0.180\text{ A})e^{-(12.5\text{ s}^{-1})t} = (0.180\text{ A})(4 - e^{-(12.5\text{ s}^{-1})t}).$ The graphs of the currents are given in Figure 30.72.

EVALUATE: R_0 is in a loop that contains just $\mathcal{E}$ and R_0, so the current through R_0 is constant. After a long time the current through the inductor isn't changing and the voltage across the inductor is zero. Since v_{cb} is zero, the voltage across R must be zero and i_R becomes zero.

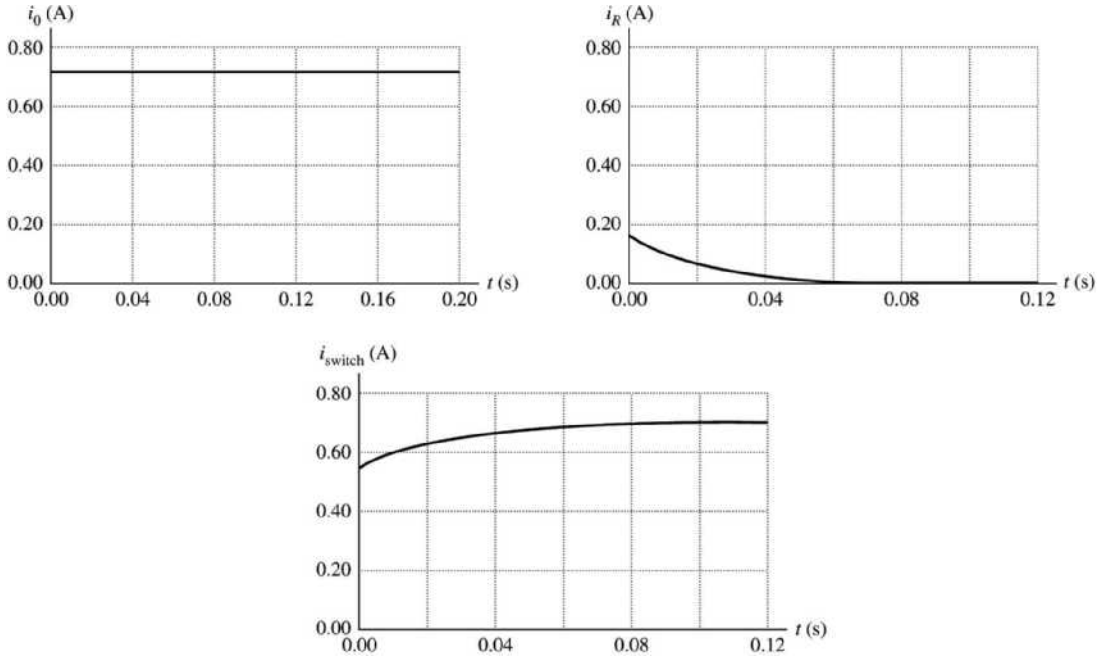

Figure 30.72

30.73. **IDENTIFY:** Follow the steps specified in the problem.

SET UP: Find the flux through a ring of height h, radius r and thickness dr. Example 28.10 shows that $B = \dfrac{\mu_0 Ni}{2\pi r}$ inside the toroid.

EXECUTE: **(a)** $\Phi_B = \int_a^b B(h\,dr) = \int_a^b \left(\dfrac{\mu_0 Ni}{2\pi r}\right)(h\,dr) = \dfrac{\mu_0 Nih}{2\pi}\int_a^b \dfrac{dr}{r} = \dfrac{\mu_0 Nih}{2\pi}\ln(b/a).$

(b) $L = \dfrac{N\Phi_B}{i} = \dfrac{\mu_0 N^2 h}{2\pi}\ln(b/a).$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(c) $\ln(b/a) = \ln(1-(b-a)/a) \approx \dfrac{b-a}{a} + \dfrac{(b-a)^2}{2a^2} + \cdots \Rightarrow L \approx \dfrac{\mu_0 N^2 h}{2\pi}\left(\dfrac{b-a}{a}\right)$.

EVALUATE: $h(b-a)$ is the cross-sectional area A of the toroid and a is approximately the radius r, so this result is approximately the same as the result derived in Example 30.3.

30.74. **IDENTIFY:** At steady state with the switch in position 1, no current flows to the capacitors and the inductors can be replaced by wires. Apply conservation of energy to the circuit with the switch in position 2.

SET UP: Replace the series combinations of inductors and capacitors by their equivalents.

EXECUTE: **(a)** At steady state $i = \dfrac{\mathcal{E}}{R} = \dfrac{75.0\text{ V}}{125\,\Omega} = 0.600\text{ A}$.

(b) The equivalent circuit capacitance of the two capacitors is given by $\dfrac{1}{C_s} = \dfrac{1}{25\,\mu\text{F}} + \dfrac{1}{35\,\mu\text{F}}$ and $C_s = 14.6\,\mu\text{F}$. $L_s = 15.0\text{ mH} + 5.0\text{ mH} = 20.0\text{ mH}$. The equivalent circuit is sketched in Figure 30.74a.

Energy conservation: $\dfrac{q^2}{2C} = \dfrac{1}{2}Li_0^2$. $q = i_0\sqrt{LC} = (0.600\text{ A})\sqrt{(20\times10^{-3}\text{ H})(14.6\times10^{-6}\text{ F})} = 3.24\times10^{-4}\text{ C}$.

As shown in Figure 30.74b, the capacitors have their maximum charge at $t = T/4$.

$t = \frac{1}{4}T = \frac{1}{4}(2\pi\sqrt{LC}) = \dfrac{\pi}{2}\sqrt{LC} = \dfrac{\pi}{2}\sqrt{(20\times10^{-3}\text{ H})(14.6\times10^{-6}\text{ F})} = 8.49\times10^{-4}\text{ s}$

EVALUATE: With the switch closed the battery stores energy in the inductors. This then is the energy in the L-C circuit when the switch is in position 2.

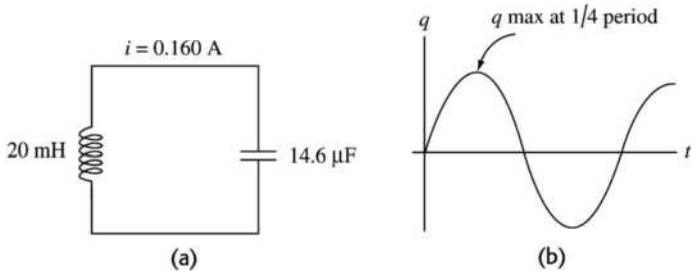

Figure 30.74

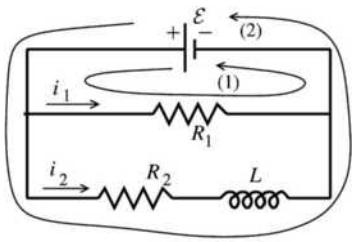
30.75. **(a) IDENTIFY** and **SET UP:** With switch S closed the circuit is shown in Figure 30.75a.



Apply the loop rule to loops 1 and 2.

EXECUTE:

loop 1

$\mathcal{E} - i_1R_1 = 0$

$i_1 = \dfrac{\mathcal{E}}{R_1}$ (independent of t)

Figure 30.75a

loop (2)

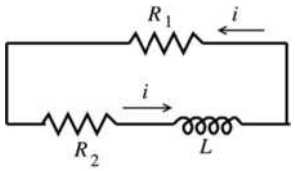
$\mathcal{E} - i_2R_2 - L\dfrac{di_2}{dt} = 0$

This is in the form of Eq. (30.12), so the solution is analogous to Eq. (30.14): $i_2 = \dfrac{\mathcal{E}}{R_2}(1 - e^{-R_2t/L})$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) EVALUATE: The expressions derived in part (a) give that as $t \to \infty, i_1 = \dfrac{\mathcal{E}}{R_1}$ and $i_2 = \dfrac{\mathcal{E}}{R_2}$. Since $\dfrac{di_2}{dt} \to 0$ at steady state, the inductance then has no effect on the circuit. The current in R_1 is constant; the current in R_2 starts at zero and rises to $\mathcal{E}/R_2$.

(c) IDENTIFY and **SET UP:** The circuit now is as shown in Figure 30.75b.



Let $t = 0$ now be when S is opened.

At $t = 0$, $i = \dfrac{\mathcal{E}}{R_2}$.

Figure 30.75b

Apply the loop rule to the single current loop.

EXECUTE: $-i(R_1 + R_2) - L\dfrac{di}{dt} = 0$. (Now $\dfrac{di}{dt}$ is negative.)

$L\dfrac{di}{dt} = -i(R_1 + R_2)$ gives $\dfrac{di}{i} = -\left(\dfrac{R_1 + R_2}{L}\right)dt$

Integrate from $t = 0$, when $i = I_0 = \mathcal{E}/R_2$, to t.

$\displaystyle\int_{I_0}^{i} \frac{di}{i} = -\left(\frac{R_1 + R_2}{L}\right)\int_0^t dt$ and $\displaystyle\ln\left(\frac{i}{I_0}\right) = -\left(\frac{R_1 + R_2}{L}\right)t$

Taking exponentials of both sides of this equation gives $i = I_0 e^{-(R_1+R_2)t/L} = \dfrac{\mathcal{E}}{R_2}e^{-(R_1+R_2)t/L}$.

(d) IDENTIFY and **SET UP:** Use the equation derived in part (c) and solve for R_2 and $\mathcal{E}$.

EXECUTE: $L = 22.0$ H

$P_{R_1} = \dfrac{V^2}{R_1} = 40.0$ W gives $R_1 = \dfrac{V^2}{P_{R_1}} = \dfrac{(120\text{ V})^2}{40.0\text{ W}} = 360\ \Omega$.

We are asked to find R_2 and $\mathcal{E}$. Use the expression derived in part (c).

$I_0 = 0.600$ A so $\mathcal{E}/R_2 = 0.600$ A

$i = 0.150$ A when $t = 0.080$ s, so $i = \dfrac{\mathcal{E}}{R_2}e^{-(R_1+R_2)t/L}$ gives $0.150\text{ A} = (0.600\text{ A})e^{-(R_1+R_2)t/L}$

$\dfrac{1}{4} = e^{-(R_1+R_2)t/L}$ so $\ln 4 = (R_1 + R_2)t/L$

$R_2 = \dfrac{L\ln 4}{t} - R_1 = \dfrac{(22.0\text{ H})\ln 4}{0.080\text{ s}} - 360\ \Omega = 381.2\ \Omega - 360\ \Omega = 21.2\ \Omega$

Then $\mathcal{E} = (0.600\text{ A})R_2 = (0.600\text{ A})(21.2\ \Omega) = 12.7$ V.

(e) IDENTIFY and **SET UP:** Use the expressions derived in part (a).

EXECUTE: The current through the light bulb before the switch is opened is $i_1 = \dfrac{\mathcal{E}}{R_1} = \dfrac{12.7\text{ V}}{360\ \Omega} = 0.0353$ A

EVALUATE: When the switch is opened the current through the light bulb jumps from 0.0353 A to 0.600 A. Since the electrical power dissipated in the bulb (brightness) depend on i^2, the bulb suddenly becomes much brighter.

30.76. **IDENTIFY:** Follow the steps specified in the problem.

SET UP: The current in an inductor does not change abruptly.

EXECUTE: **(a)** Using Kirchhoff's loop rule on the left and right branches:

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

Left: $\mathcal{E}-(i_1+i_2)R-L\dfrac{di_1}{dt}=0\Rightarrow R(i_1+i_2)+L\dfrac{di_1}{dt}=\mathcal{E}.$

Right: $\mathcal{E}-(i_1+i_2)R-\dfrac{q_2}{C}=0\Rightarrow R(i_1+i_2)+\dfrac{q_2}{C}=\mathcal{E}.$

(b) Initially, with the switch just closed, $i_1=0, i_2=\dfrac{\mathcal{E}}{R}$ and $q_2=0.$

(c) The substitution of the solutions into the circuit equations to show that they satisfy the equations is a somewhat tedious exercise but straightforward exercise. We will show that the initial conditions are satisfied: At $t=0, q_2=\dfrac{\mathcal{E}}{\omega R}e^{-\beta t}\sin(\omega t)=\dfrac{\mathcal{E}}{\omega R}\sin(0)=0.$

$i_1(t)=\dfrac{\mathcal{E}}{R}(1-e^{-\beta t}[(2\omega RC)^{-1}\sin(\omega t)+\cos(\omega t)]\Rightarrow i_1(0)=\dfrac{\mathcal{E}}{R}(1-[\cos(0)])=0.$

(d) When does i_2 first equal zero? $\omega=\sqrt{\dfrac{1}{LC}-\dfrac{1}{(2RC)^2}}=625\text{ rad/s}.$

$i_2(t)=0=\dfrac{\mathcal{E}}{R}e^{-\beta t}[-(2\omega RC)^{-1}\sin(\omega t)+\cos(\omega t)]\Rightarrow -(2\omega RC)^{-1}\tan(\omega t)+1=0$ and

$\tan(\omega t)=+2\omega RC=+2(625\text{ rad/s})(400\,\Omega)(2.00\times10^{-6}\text{ F})=+1.00.$

$\omega t=\arctan(+1.00)=+0.785\Rightarrow t=\dfrac{0.785}{625\text{ rad/s}}=1.256\times10^{-3}\text{s}.$

EVALUATE: As $t\to\infty$, $i_1\to\mathcal{E}/R$, $q_2\to0$ and $i_2\to0.$

30.77. **IDENTIFY:** Apply $L=\dfrac{N\Phi_B}{i}$ to calculate L.

SET UP: In the air the magnetic field is $B_{\text{Air}}=\dfrac{\mu_0 Ni}{W}$. In the liquid, $B_{\text{L}}=\dfrac{\mu Ni}{W}$.

EXECUTE: **(a)** $\Phi_B=BA=B_{\text{L}}A_{\text{L}}+B_{\text{Air}}A_{\text{Air}}=\dfrac{\mu_0 Ni}{W}((D-d)W)+\dfrac{K\mu_0 Ni}{W}(dW)=\mu_0 Ni\left[(D-d)+Kd\right].$

$L=\dfrac{N\Phi_B}{i}=\mu_0N^2[(D-d)+Kd]=L_0-L_0\dfrac{d}{D}+L_{\text{f}}\dfrac{d}{D}=L_0+\left(\dfrac{L_{\text{f}}-L_0}{D}\right)d.$

$d=\left(\dfrac{L-L_0}{L_{\text{f}}-L_0}\right)D$, where $L_0=\mu_0N^2D$, and $L_{\text{f}}=K\mu_0N^2D.$

(b) and **(c)** Using $K=\chi_{\text{m}}+1$ we can find the inductance for any height $L=L_0\left(1+\chi_{\text{m}}\dfrac{d}{D}\right).$

Height of Fluid	Inductance of Liquid Oxygen	Inductance of Mercury
$d=D/4$	0.63024 H	0.63000 H
$d=D/2$	0.63048 H	0.62999 H
$d=3D/4$	0.63072 H	0.62999 H
$d=D$	0.63096 H	0.62998 H

The values $\chi_{\text{m}}(\text{O}_2)=1.52\times10^{-3}$ and $\chi_{\text{m}}(\text{Hg})=-2.9\times10^{-5}$ have been used.

EVALUATE: **(d)** The volume gauge is much better for the liquid oxygen than the mercury because there is an easily detectable spread of values for the liquid oxygen, but not for the mercury.

30.78. **IDENTIFY:** The induced emf across the two coils is due to both the self-inductance of each and the mutual inductance of the pair of coils.

SET UP: The equivalent inductance is defined by $\mathcal{E}=L_{\text{eq}}\dfrac{di}{dt}$, where $\mathcal{E}$ and i are the total emf and current across the combination.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: Series: $L_1\frac{di_1}{dt}+L_2\frac{di_2}{dt}+M_{21}\frac{di_1}{dt}+M_{12}\frac{di_2}{dt}\equiv L_{\text{eq}}\frac{di}{dt}$.

But $i=i_1+i_2\Rightarrow\frac{di}{dt}=\frac{di_1}{dt}+\frac{di_2}{dt}$ and $M_{12}=M_{21}\equiv M$, so $(L_1+L_2+2M)\frac{di}{dt}=L_{\text{eq}}\frac{di}{dt}$ and $L_{\text{eq}}=L_1+L_2+2M$.

Parallel: We have $L_1\frac{di_1}{dt}+M_{12}\frac{di_2}{dt}=L_{\text{eq}}\frac{di}{dt}$ and $L_2\frac{di_2}{dt}+M_{21}\frac{di_1}{dt}=L_{\text{eq}}\frac{di}{dt}$, with $\frac{di_1}{dt}+\frac{di_2}{dt}=\frac{di}{dt}$ and $M_{12}=M_{21}\equiv M$. To simplify the algebra let $A=\frac{di_1}{dt}$, $B=\frac{di_2}{dt}$, and $C=\frac{di}{dt}$. So $L_1A+MB=L_{\text{eq}}C, L_2B+MA=L_{\text{eq}}C, A+B=C$. Now solve for A and B in terms of C.

$(L_1-M)A+(M-L_2)B=0$ using $A=C-B$. $(L_1-M)(C-B)+(M-L_2)B=0$.

$(L_1-M)C-(L_1-M)B+(M-L_2)B=0$. $(2M-L_1-L_2)B=(M-L_1)C$ and $B=\frac{(M-L_1)}{(2M-L_1-L_2)}C$. But

$A=C-B=C-\frac{(M-L_1)C}{(2M-L_1-L_2)}=\frac{(2M-L_1-L_2)-M+L_1}{(2M-L_1-L_2)}C$, or $A=\frac{M-L_2}{2M-L_1-L_2}C$. Substitute A in B back into original equation: $\frac{L_1(M-L_2)C}{2M-L_1-L_2}+\frac{M(M-L_1)}{(2M-L_1-L_2)}C=L_{\text{eq}}C$ and $\frac{M^2-L_1L_2}{2M-L_1-L_2}C=L_{\text{eq}}C$. Finally,

$L_{\text{eq}}=\frac{L_1L_2-M^2}{L_1+L_2-2M}$.

EVALUATE: If the flux of one coil doesn't pass through the other coil, so $M=0$, then the results reduce to those of inductors in parallel.

30.79. **IDENTIFY:** Apply Kirchhoff's loop rule to the top and bottom branches of the circuit.

SET UP: Just after the switch is closed the current through the inductor is zero and the charge on the capacitor is zero.

EXECUTE: **(a)** $\mathcal{E}-i_1R_1-L\frac{di_1}{dt}=0\Rightarrow i_1=\frac{\mathcal{E}}{R_1}(1-e^{-(R_1/L)t})$.

$\mathcal{E}-i_2R_2-\frac{q_2}{C}=0\Rightarrow-\frac{di_2}{dt}R_2-\frac{i_2}{C}=0\Rightarrow i_2=\frac{\mathcal{E}}{R_2}e^{-(1/R_2C)t})$.

$q_2=\int_0^t i_2dt'=-\frac{\mathcal{E}}{R_2}R_2Ce^{-(1/R_2C)t'}\Big|_0^t=\mathcal{E}C(1-e^{-(1/R_2C)t})$.

(b) $i_1(0)\frac{\mathcal{E}}{R_1}(1-e^0)=0, i_2=\frac{\mathcal{E}}{R_2}e^0=\frac{48.0\text{ V}}{5000\ \Omega}=9.60\times10^{-3}$ A.

(c) As $t\to\infty$: $i_1(\infty)=\frac{\mathcal{E}}{R_1}(1-e^{-\infty})=\frac{\mathcal{E}}{R_1}=\frac{48.0\text{ V}}{25.0\ \Omega}=1.92$ A, $i_2=\frac{\mathcal{E}}{R_2}e^{-\infty}=0$. A good definition of a "long time" is many time constants later.

(d) $i_1=i_2\Rightarrow\frac{\mathcal{E}}{R_1}(1-e^{-(R_1/L)t})=\frac{\mathcal{E}}{R_2}e^{-(1/R_2C)t}\Rightarrow(1-e^{-(R_1/L)t})=\frac{R_1}{R_2}e^{-(1/R_2C)t}$. Expanding the exponentials like $e^x=1+x+\frac{x^2}{2}+\frac{x^3}{3!}+\cdots$, we find: $\frac{R_1}{L}t-\frac{1}{2}\left(\frac{R_1}{L}\right)^2t^2+\cdots=\frac{R_1}{R_2}\left(1-\frac{t}{RC}+\frac{t^2}{2R^2C^2}-\cdots\right)$ and

$t\left(\frac{R_1}{L}+\frac{R_1}{R_2{}^2C}\right)+O(t^2)+\cdots=\frac{R_1}{R_2}$, if we have assumed that $t\ll1$. Therefore:

$t\approx\frac{1}{R_2}\left(\frac{1}{(1/L)+(1/R_2^2C)}\right)=\left(\frac{LR_2C}{L+R_2^2C}\right)=\left(\frac{(8.0\text{ H})(5000\ \Omega)(2.0\times10^{-5}\text{ F})}{8.0\text{ H}+(5000\ \Omega)^2(2.0\times10^{-5}\text{ F})}\right)=1.6\times10^{-3}$ s.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(e) At $t = 1.57\times10^{-3}$ s: $i_1 = \dfrac{\mathcal{E}}{R_1}(1-e^{-(R_1/L)t}) = \dfrac{48\text{ V}}{25\,\Omega}(1-e^{-(25/8)t}) = 9.4\times10^{-3}$ A.

(f) We want to know when the current is half its final value. We note that the current i_2 is very small to begin with, and just gets smaller, so we ignore it and find:

$i_{1/2} = 0.960\text{ A} = i_1 = \dfrac{\mathcal{E}}{R_1}(1-e^{-(R_1/L)t}) = (1.92\text{ A})(1-e^{-(R_1/L)t})$.

$e^{-(R_1/L)t} = 0.500 \Rightarrow t = -\dfrac{L}{R_1}\ln(0.5) = -\dfrac{8.0\text{ H}}{25\,\Omega}\ln(0.5) = 0.22\text{ s}.$

EVALUATE: i_1 is initially zero and rises to a final value of 1.92 A. i_2 is initially 9.60 mA and falls to zero, q_2 is initially zero and rises to $q_2 = \mathcal{E}C = 960\,\mu$C.

31

ALTERNATING CURRENT

31.1. **IDENTIFY:** The maximum current is the current amplitude, and it must not ever exceed 1.50 A.

SET UP: $I_{\text{rms}} = I/\sqrt{2}$. I is the current amplitude, the maximum value of the current.

EXECUTE: $I = 1.50\text{A}$ gives $I_{\text{rms}} = \dfrac{1.50\text{ A}}{\sqrt{2}} = 1.06\text{ A}$.

EVALUATE: The current amplitude is larger than the root-mean-square current.

31.2. **IDENTIFY** and **SET UP:** Apply Eqs. (31.3) and (31.4).

EXECUTE: **(a)** $I = \sqrt{2}I_{\text{rms}} = \sqrt{2}(2.10\text{ A}) = 2.97\text{ A}$.

(b) $I_{\text{rav}} = \dfrac{2}{\pi}I = \dfrac{2}{\pi}(2.97\text{ A}) = 1.89\text{ A}$.

EVALUATE: **(c)** The root-mean-square current is always greater than the rectified average, because squaring the current before averaging, and then taking the square root to get the root-mean-square value will always give a larger value than just averaging.

31.3. **IDENTIFY** and **SET UP:** Apply Eq. (31.5).

EXECUTE: **(a)** $V_{\text{rms}} = \dfrac{V}{\sqrt{2}} = \dfrac{45.0\text{ V}}{\sqrt{2}} = 31.8\text{ V}$.

(b) Since the voltage is sinusoidal, the average is zero.

EVALUATE: The voltage amplitude is larger than V_{rms}.

31.4. **IDENTIFY:** We want the phase angle for the source voltage relative to the current, and we want the capacitance if we know the current amplitude.

SET UP: $X_C = \dfrac{V}{I}$ and $X_C = \dfrac{1}{2\pi fC}$.

EXECUTE: **(a)** $\phi = -90°$. The source voltage lags the current by $90°$.

(b) $X_C = \dfrac{V}{I} = \dfrac{60.0\text{ V}}{5.30\text{ A}} = 11.3\,\Omega$. Solving $X_C = \dfrac{1}{2\pi fC}$ for C gives

$$C = \frac{1}{2\pi f X_C} = \frac{1}{2\pi(80.0\text{ Hz})(11.3\,\Omega)} = 1.76\times10^{-4}\text{ F}.$$

EVALUATE: This is a 176-μF capacitor, which is not unreasonable.

31.5. **IDENTIFY:** We want the phase angle for the source voltage relative to the current, and we want the inductance if we know the current amplitude.

SET UP: $X_L = \dfrac{V}{I}$ and $X_L = 2\pi fL$.

EXECUTE: **(a)** $\phi = +90°$. The source voltage leads the current by $90°$.

(b) $X_L = \dfrac{V}{I} = \dfrac{45.0\text{ V}}{3.90\text{ A}} = 11.54\,\Omega$. Solving $X_L = 2\pi fL$ for f gives $f = \dfrac{X_L}{2\pi L} = \dfrac{11.54\,\Omega}{2\pi(9.50\times10^{-3}\text{ H})} = 193\text{ Hz}$.

EVALUATE: The angular frequency is about 1200 rad/s.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

31.6. **IDENTIFY:** The reactance of capacitors and inductors depends on the angular frequency at which they are operated, as well as their capacitance or inductance.

SET UP: The reactances are $X_C = 1/\omega C$ and $X_L = \omega L$.

EXECUTE: **(a)** Equating the reactances gives $\omega L = \dfrac{1}{\omega C} \Rightarrow \omega = \dfrac{1}{\sqrt{LC}}$

(b) Using the numerical values we get $\omega = \dfrac{1}{\sqrt{LC}} = \dfrac{1}{\sqrt{(5.00\text{ mH})(3.50\ \mu\text{F})}} = 7560\text{ rad/s}$

$$X_C = X_L = \omega L = (7560\text{ rad/s})(5.00\text{ mH}) = 37.8\ \Omega$$

EVALUATE: At other angular frequencies, the two reactances could be very different.

31.7. **IDENTIFY** and **SET UP:** Apply Eqs. (31.18) and (31.19).

EXECUTE: $V = IX_C$ so $X_C = \dfrac{V}{I} = \dfrac{170\text{ V}}{0.850\text{ A}} = 200\ \Omega$

$X_C = \dfrac{1}{\omega C}$ gives $C = \dfrac{1}{2\pi f X_C} = \dfrac{1}{2\pi(60.0\text{ Hz})(200\ \Omega)} = 1.33\times10^{-5}\text{ F} = 13.3\ \mu\text{F}$

EVALUATE: The reactance relates the voltage amplitude to the current amplitude and is similar to Ohm's law.

31.8. **IDENTIFY:** The reactance of an inductor is $X_L = \omega L = 2\pi fL$. The reactance of a capacitor is $X_C = \dfrac{1}{\omega C} = \dfrac{1}{2\pi fC}$.

SET UP: The frequency f is in Hz.

EXECUTE: **(a)** At 60.0 Hz, $X_L = 2\pi(60.0\text{ Hz})(0.450\text{ H}) = 170\ \Omega$. X_L is proportional to f so at 600 Hz, $X_L = 1700\ \Omega$.

(b) At 60.0 Hz, $X_C = \dfrac{1}{2\pi(60.0\text{ Hz})(2.50\times10^{-6}\text{ F})} = 1.06\times10^{3}\ \Omega$. X_C is proportional to $1/f$, so at 600 Hz, $X_C = 106\ \Omega$.

(c) $X_L = X_C$ says $2\pi fL = \dfrac{1}{2\pi fC}$ and $f = \dfrac{1}{2\pi\sqrt{LC}} = \dfrac{1}{2\pi\sqrt{(0.450\text{ H})(2.50\times10^{-6}\text{ F})}} = 150\text{ Hz}$.

EVALUATE: X_L increases when f increases. X_C decreases when f increases.

31.9. **IDENTIFY** and **SET UP:** Use Eqs. (31.12) and (31.18).

EXECUTE: **(a)** $X_L = \omega L = 2\pi fL = 2\pi(80.0\text{ Hz})(3.00\text{ H}) = 1510\ \Omega$

(b) $X_L = 2\pi fL$ gives $L = \dfrac{X_L}{2\pi f} = \dfrac{120\ \Omega}{2\pi(80.0\text{ Hz})} = 0.239\text{ H}$

(c) $X_C = \dfrac{1}{\omega C} = \dfrac{1}{2\pi fC} = \dfrac{1}{2\pi(80.0\text{ Hz})(4.00\times10^{-6}\text{ F})} = 497\ \Omega$

(d) $X_C = \dfrac{1}{2\pi fC}$ gives $C = \dfrac{1}{2\pi f X_C} = \dfrac{1}{2\pi(80.0\text{ Hz})(120\ \Omega)} = 1.66\times10^{-5}\text{ F}$

EVALUATE: X_L increases when L increases; X_C decreases when C increases.

31.10. **IDENTIFY:** $V_L = I\omega L$

SET UP: ω is the angular frequency, in rad/s. $f = \dfrac{\omega}{2\pi}$ is the frequency in Hz.

EXECUTE: $V_L = I\omega L$ so $f = \dfrac{V_L}{2\omega IL} = \dfrac{(12.0\text{ V})}{2\pi(2.60\times10^{-3}\text{ A})(4.50\times10^{-4}\text{ H})} = 1.63\times10^{6}\text{ Hz}$.

EVALUATE: When f is increased, I decreases.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

31.11. **IDENTIFY:** In an *L*-*R* ac circuit, we want to find out how the voltage across a resistor varies with time if we know how the voltage varies across the inductor.

SET UP: $v_L = -I\omega L\sin\omega t$ and $v_R = V_R\cos(\omega t)$.

EXECUTE: **(a)** $v_L = -I\omega L\sin\omega t$. $\omega = 480$ rad/s. $I\omega L = 12.0$ V.

$$I = \frac{12.0\text{ V}}{\omega L} = \frac{12.0\text{ V}}{(480\text{ rad/s})(0.180\text{ H})} = 0.1389\text{ A}.\quad V_R = IR = (0.1389\text{ A})(90.0\,\Omega) = 12.5\text{ V}.$$

$v_R = V_R\cos(\omega t) = (12.5\text{ V})\cos[(480\text{ rad/s})t]$.

(b) $v_R = (12.5\text{ V})\cos[(480\text{ rad/s})(2.00\times10^{-3}\text{ s})] = 7.17$ V.

EVALUATE: The instantaneous voltage (7.17 V) is less than the voltage amplitude (12.5 V).

31.12. **IDENTIFY:** Compare v_C that is given in the problem to the general form $v_C = \dfrac{I}{\omega C}\sin\omega t$ and determine ω.

SET UP: $X_C = \dfrac{1}{\omega C}$. $v_R = iR$ and $i = I\cos\omega t$.

EXECUTE: **(a)** $X_C = \dfrac{1}{\omega C} = \dfrac{1}{(120\text{ rad/s})(4.80\times10^{-6}\text{ F})} = 1736\,\Omega$

(b) $I = \dfrac{V_C}{X_C} = \dfrac{7.60\text{ V}}{1736\,\Omega} = 4.378\times10^{-3}$ A and $i = I\cos\omega t = (4.378\times10^{-3}\text{ A})\cos[(120\text{ rad/s})t]$. Then

$v_R = iR = (4.38\times10^{-3}\text{ A})(250\,\Omega)\cos((120\text{ rad/s})t) = (1.10\text{ V})\cos((120\text{ rad/s})t)$.

EVALUATE: The voltage across the resistor has a different phase than the voltage across the capacitor.

31.13. **IDENTIFY** and **SET UP:** The voltage and current for a resistor are related by $v_R = iR$. Deduce the frequency of the voltage and use this in Eq. (31.12) to calculate the inductive reactance. Eq. (31.10) gives the voltage across the inductor.

EXECUTE: **(a)** $v_R = (3.80\text{ V})\cos[(720\text{ rad/s})t]$

$$v_R = iR,\text{ so } i = \frac{v_R}{R} = \left(\frac{3.80\text{ V}}{150\,\Omega}\right)\cos[(720\text{ rad/s})t] = (0.0253\text{ A})\cos[(720\text{ rad/s})t]$$

(b) $X_L = \omega L$

$\omega = 720$ rad/s, $L = 0.250$ H, so $X_L = \omega L = (720\text{ rad/s})(0.250\text{ H}) = 180\,\Omega$

(c) If $i = I\cos\omega t$ then $v_L = V_L\cos(\omega t + 90°)$ (from Eq. 31.10).

$V_L = I\omega L = IX_L = (0.02533\text{ A})(180\,\Omega) = 4.56$ V

$v_L = (4.56\text{ V})\cos[(720\text{ rad/s})t + 90°]$

But $\cos(a + 90°) = -\sin a$ (Appendix B), so $v_L = -(4.56\text{ V})\sin[(720\text{ rad/s})t]$.

EVALUATE: The current is the same in the resistor and inductor and the voltages are $90°$ out of phase, with the voltage across the inductor leading.

31.14. **IDENTIFY:** Calculate the reactance of the inductor and of the capacitor. Calculate the impedance and use that result to calculate the current amplitude.

SET UP: With no capacitor, $Z = \sqrt{R^2 + X_L^2}$ and $\tan\phi = \dfrac{X_L}{R}$. $X_L = \omega L$. $I = \dfrac{V}{Z}$. $V_L = IX_L$ and $V_R = IR$.

For an inductor, the voltage leads the current.

EXECUTE: **(a)** $X_L = \omega L = (250\text{ rad/s})(0.400\text{ H}) = 100\,\Omega$. $Z = \sqrt{(200\,\Omega)^2 + (100\,\Omega)^2} = 224\,\Omega$.

(b) $I = \dfrac{V}{Z} = \dfrac{30.0\text{ V}}{224\,\Omega} = 0.134$ A

(c) $V_R = IR = (0.134\text{ A})(200\,\Omega) = 26.8$ V. $V_L = IX_L = (0.134\text{ A})(100\,\Omega) = 13.4$ V.

(d) $\tan\phi = \dfrac{X_L}{R} = \dfrac{100\,\Omega}{200\,\Omega}$ and $\phi = +26.6°$. Since ϕ is positive, the source voltage leads the current.

(e) The phasor diagram is sketched in Figure 31.14.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: Note that $V_R + V_L$ is greater than V. The loop rule is satisfied at each instance of time but the voltages across R and L reach their maxima at different times.

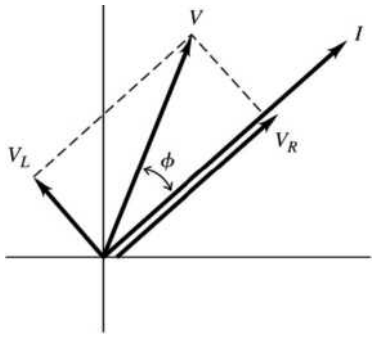

Figure 31.14

31.15. **IDENTIFY:** Apply the equations in Section 31.3.
SET UP: $\omega = 250$ rad/s, $R = 200\,\Omega$, $L = 0.400$ H, $C = 6.00\,\mu$F and $V = 30.0$ V.

EXECUTE: **(a)** $Z = \sqrt{R^2 + (\omega L - 1/\omega C)^2}$.

$Z = \sqrt{(200\,\Omega)^2 + ((250\text{ rad/s})(0.400\text{ H}) - 1/((250\text{ rad/s})(6.00\times10^{-6}\text{ F})))^2} = 601\,\Omega$

(b) $I = \dfrac{V}{Z} = \dfrac{30\text{ V}}{601\,\Omega} = 0.0499$ A.

(c) $\phi = \arctan\left(\dfrac{\omega L - 1/\omega C}{R}\right) = \arctan\left(\dfrac{100\,\Omega - 667\,\Omega}{200\,\Omega}\right) = -70.6°$, and the voltage lags the current.

(d) $V_R = IR = (0.0499\text{ A})(200\,\Omega) = 9.98$ V; $V_L = I\omega L = (0.0499\text{ A})(250\text{ rad/s})(0.400\text{ H}) = 4.99$ V;

$V_C = \dfrac{I}{\omega C} = \dfrac{(0.0499\text{ A})}{(250\text{ rad/s})(6.00\times10^{-6}\text{ F})} = 33.3$ V.

EVALUATE: **(e)** At any instant, $v = v_R + v_C + v_L$. But v_C and v_L are 180° out of phase, so v_C can be larger than v at a value of t, if $v_L + v_R$ is negative at that t.

31.16. **IDENTIFY:** For an L-R-C series ac circuit, we want to find the voltages and voltage amplitudes across all the circuit elements.

SET UP: $X_C = \dfrac{1}{\omega C}$, $X_L = \omega L$, $Z = \sqrt{R^2 + (X_L - X_C)^2}$, $I = \dfrac{V}{Z}$ and $\tan\phi = \dfrac{X_L - X_C}{R}$. The instantaneous voltages are $v_R = V_R\cos(\omega t) = IR\cos(\omega t)$, $v_L = -V_L\sin(\omega t) = -IX_L\sin(\omega t)$, $v_C = V_C\sin(\omega t) = IX_C\sin(\omega t)$ and $v = V\cos(\omega t + \phi)$.

EXECUTE: $X_C = \dfrac{1}{\omega C} = \dfrac{1}{(250\text{ rad/s})(6.00\times10^{-6}\text{ F})} = 666.7\,\Omega$.

$X_L = \omega L = (250\text{ rad/s})(0.900\text{ H}) = 225\,\Omega$.

$Z = \sqrt{R^2 + (X_L - X_C)^2} = \sqrt{(200\,\Omega)^2 + (225\,\Omega - 666.7\,\Omega)^2} = 484.9\,\Omega$.

$I = \dfrac{V}{Z} = \dfrac{30.0\text{ V}}{484.9\,\Omega} = 0.06187\text{ A} = 61.87\text{ mA}$.

$\tan\phi = \dfrac{X_L - X_C}{R} = \dfrac{225\,\Omega - 666.7\,\Omega}{200\,\Omega} = -2.2085$ and $\phi = -1.146$ rad.

(a) $v_R = V_R\cos(\omega t) = IR\cos(\omega t) = (0.06187\text{ A})(200\,\Omega)\cos[(250\text{ rad/s})(20.0\times10^{-3}\text{ s})] = 3.51$ V.

$v_L = -V_L\sin(\omega t) = -IX_L\sin(\omega t) = -(0.06187\text{ A})(225\,\Omega)\sin[(250\text{ rad/s})(20.0\times10^{-3}\text{ s})] = 13.35$ V.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$v_C = V_C \sin(\omega t) = IX_C \sin(\omega t) = (0.06187\text{ A})(666.7\ \Omega)\sin[(250\text{ rad/s})(20.0\times10^{-3}\text{ s})] = -39.55\text{ V}.$

$v = V\cos(\omega t + \phi) = (30.0\text{ V})\cos[(250\text{ rad/s})(20.0\times10^{-3}\text{ s}) - 1.146\text{ rad}] = -22.70\text{ V}.$

$v_R + v_L + v_C = 3.51\text{ V} + 13.35\text{ V} + (-39.55\text{ V}) = -22.7\text{ V}.$ $v_R + v_L + v_C$ is equal to v.

(b) $V_R = IR = 12.4\text{ V}.$ $V_C = 41.2\text{ V}.$ $V_L = 13.9\text{ V}.$

$V_R + V_C + V_L = 12.4\text{ V} + 41.2\text{ V} + 13.9\text{ V} = 67.5\text{ V}.$ $V_R + V_C + V_L$ is not equal to V.

EVALUATE: The instantaneous voltages do add up to v because they all occur at the same time, so they must add to v by Kirchhoff's loop rule. The amplitudes do not add to V because the maxima do not occur at the same time due to phase differences between the inductor, capacitor and resistor.

31.17. **IDENTIFY** and **SET UP:** Use the equation that preceeds Eq. (31.20): $V^2 = V_R^2 + (V_L - V_C)^2$

EXECUTE: $V = \sqrt{(30.0\text{ V})^2 + (50.0\text{ V} - 90.0\text{ V})^2} = 50.0\text{ V}$

EVALUATE: The equation follows directly from the phasor diagrams of Fig. 31.13 (b or c) in the textbook. Note that the voltage amplitudes do not simply add to give 170.0 V for the source voltage.

31.18. **IDENTIFY:** For an *L*-*R* ac circuit, we want to use the resistance, voltage amplitude of the source and power in the resistor to find the impedance, the voltage amplitude across the inductor and the power factor.

SET UP: $P_{\text{av}} = \frac{1}{2}I^2R$, $Z = \frac{V}{I}$, $V_R = IR$, and $\tan\phi = \frac{X_L}{R}$.

EXECUTE: **(a)** $P_{\text{av}} = \frac{1}{2}I^2R.$ $I = \sqrt{\frac{2P_{\text{av}}}{R}} = \sqrt{\frac{2(216\text{ W})}{300\ \Omega}} = 1.20\text{ A}.$ $Z = \frac{V}{I} = \frac{500\text{ V}}{1.20\text{ A}} = 417\ \Omega.$

(b) $V_R = IR = (1.20\text{ A})(300\ \Omega) = 360\text{ V}.$ $V_L = \sqrt{V^2 - V_R^2} = \sqrt{(500\text{ V})^2 - (360\text{ V})^2} = 347\text{ V}.$

(c) $\tan\phi = \frac{X_L}{R} = \frac{V_L}{V_R} = \frac{347\text{ V}}{360\text{ V}}$ gives $\phi = 43.95°$. The power factor is $\cos\phi = 0.720$.

EVALUATE: The voltage amplitude across the resistor cannot exceed the voltage amplitude (500 V) of the ac source.

31.19. **IDENTIFY:** For a pure resistance, $P_{\text{av}} = V_{\text{rms}}I_{\text{rms}} = I_{\text{rms}}^2R.$

SET UP: 20.0 W is the average power P_{av}.

EXECUTE: **(a)** The average power is one-half the maximum power, so the maximum instantaneous power is 40.0 W.

(b) $I_{\text{rms}} = \frac{P_{\text{av}}}{V_{\text{rms}}} = \frac{20.0\text{ W}}{120\text{ V}} = 0.167\text{ A}$

(c) $R = \frac{P_{\text{av}}}{I_{\text{rms}}^2} = \frac{20.0\text{ W}}{(0.167\text{ A})^2} = 720\ \Omega$

EVALUATE: We can also calculate the average power as $P_{\text{av}} = \frac{V_{R,\text{rms}}^2}{R} = \frac{V_{\text{rms}}^2}{R} = \frac{(120\text{ V})^2}{720\ \Omega} = 20.0\text{ W}.$

31.20. **IDENTIFY:** The average power supplied by the source is $P_{\text{av}} = V_{\text{rms}}I_{\text{rms}}\cos\phi.$ The power consumed in the resistance is $P_{\text{av}} = I_{\text{rms}}^2R.$

SET UP: $\omega = 2\pi f = 2\pi(1.25\times10^3\text{ Hz}) = 7.854\times10^3\text{ rad/s}.$ $X_L = \omega L = 157\ \Omega.$ $X_C = \frac{1}{\omega C} = 909\ \Omega.$

EXECUTE: **(a)** First, let us find the phase angle between the voltage and the current:

$\tan\phi = \frac{X_L - X_C}{R} = \frac{157\ \Omega - 909\ \Omega}{350\ \Omega}$ and $\phi = -65.04°$. The impedance of the circuit is

$Z = \sqrt{R^2 + (X_L - X_C)^2} = \sqrt{(350\ \Omega)^2 + (-752\ \Omega)^2} = 830\ \Omega.$ The average power provided by the generator is then $P_{\text{av}} = V_{\text{rms}}I_{\text{rms}}\cos(\phi) = \frac{V_{\text{rms}}^2}{Z}\cos(\phi) = \frac{(120\text{ V})^2}{830\ \Omega}\cos(-65.04°) = 7.32\text{ W}.$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) The average power dissipated by the resistor is $P_R = I_{\text{rms}}^2 R = \left(\frac{120\text{ V}}{830\ \Omega}\right)^2 (350\ \Omega) = 7.32\text{ W}$.

EVALUATE: Conservation of energy requires that the answers to parts (a) and (b) are equal.

31.21. **IDENTIFY:** Relate the power factor to R and Z for an L-R-C series ac circuit. Then use this result to find the voltage amplitude across a resistor.

SET UP and **EXECUTE:** **(a)** From Figure 31.13(a) or (b), $\cos\phi = \frac{IR}{IZ} = \frac{R}{Z}$.

(b) Using the result from (a) gives $Z = \frac{R}{\cos\phi}$. $I = \frac{V}{Z} = \frac{V\cos\phi}{R}$.

$V_R = IR = V\cos\phi = (90.0\text{ V})\cos(-31.5°) = 76.7\text{ V}$.

EVALUATE: The voltage amplitude for the resistor is less than the voltage amplitude of the ac source.

31.22. **IDENTIFY:** We want to relate the average power delivered by the source in an L-R-C circuit to the rms current and resistance.

SET UP: From Exercise 31.21 we know that the power factor is $\cos\phi = \frac{R}{Z}$. We also know that $P_{\text{av}} = V_{\text{rms}} I_{\text{rms}} \cos\phi$.

EXECUTE: **(a)** $P_{\text{av}} = V_{\text{rms}} I_{\text{rms}} \cos\phi$. $\cos\phi = \frac{R}{Z}$ so $P_{\text{av}} = V_{\text{rms}} I_{\text{rms}} \frac{R}{Z}$. But $\frac{V_{\text{rms}}}{Z} = I_{\text{rms}}$ so $P_{\text{av}} = I_{\text{rms}}^2 R$.

(b) $I_{\text{rms}} = \frac{V_{\text{rms}}}{R}$ and $V_{\text{rms}} = V/\sqrt{2}$, so $P_{\text{av}} = \frac{V_{\text{rms}}^2}{R} = \frac{\left(\frac{36.0\text{ V}}{\sqrt{2}}\right)^2}{96.0\ \Omega} = 6.75\text{ W}$.

EVALUATE: The instantaneous power can be greater than 6.75 W at times, but it can also be less than that at other times, giving an average of 6.75 W.

31.23. **IDENTIFY** and **SET UP:** Use the equations of Section 31.3 to calculate ϕ, Z and V_{rms}. The average power delivered by the source is given by Eq. (31.31) and the average power dissipated in the resistor is $I_{\text{rms}}^2 R$.

EXECUTE: **(a)** $X_L = \omega L = 2\pi fL = 2\pi(400\text{ Hz})(0.120\text{ H}) = 301.6\ \Omega$

$X_C = \frac{1}{\omega C} = \frac{1}{2\pi fC} = \frac{1}{2\pi(400\text{ Hz})(7.3\times10^{-6}\text{ F})} = 54.51\ \Omega$

$\tan\phi = \frac{X_L - X_C}{R} = \frac{301.6\ \Omega - 54.41\ \Omega}{240\ \Omega}$, so $\phi = +45.8°$. The power factor is $\cos\phi = +0.697$.

(b) $Z = \sqrt{R^2 + (X_L - X_C)^2} = \sqrt{(240\ \Omega)^2 + (301.6\ \Omega - 54.51\ \Omega)^2} = 344\ \Omega$

(c) $V_{\text{rms}} = I_{\text{rms}} Z = (0.450\text{ A})(344\ \Omega) = 155\text{ V}$

(d) $P_{\text{av}} = I_{\text{rms}} V_{\text{rms}} \cos\phi = (0.450\text{ A})(155\text{ V})(0.697) = 48.6\text{ W}$

(e) $P_{\text{av}} = I_{\text{rms}}^2 R = (0.450\text{ A})^2(240\ \Omega) = 48.6\text{ W}$

EVALUATE: The average electrical power delivered by the source equals the average electrical power consumed in the resistor.

(f) All the energy stored in the capacitor during one cycle of the current is released back to the circuit in another part of the cycle. There is no net dissipation of energy in the capacitor.

(g) The answer is the same as for the capacitor. Energy is repeatedly being stored and released in the inductor, but no net energy is dissipated there.

31.24. **IDENTIFY** and **SET UP:** $P_{\text{av}} = V_{\text{rms}} I_{\text{rms}} \cos\phi$. $I_{\text{rms}} = \frac{V_{\text{rms}}}{Z}$. $\cos\phi = \frac{R}{Z}$.

EXECUTE: $I_{\text{rms}} = \frac{80.0\text{ V}}{105\ \Omega} = 0.762\text{ A}$. $\cos\phi = \frac{75.0\ \Omega}{105\ \Omega} = 0.714$. $P_{\text{av}} = (80.0\text{ V})(0.762\text{ A})(0.714) = 43.5\text{ W}$.

EVALUATE: Since the average power consumed by the inductor and by the capacitor is zero, we can also calculate the average power as $P_{\text{av}} = I_{\text{rms}}^2 R = (0.762\text{ A})^2(75.0\ \Omega) = 43.5\text{ W}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

31.25. **IDENTIFY:** The angular frequency and the capacitance can be used to calculate the reactance X_C of the capacitor. The angular frequency and the inductance can be used to calculate the reactance X_L of the inductor. Calculate the phase angle ϕ and then the power factor is $\cos\phi$. Calculate the impedance of the circuit and then the rms current in the circuit. The average power is $P_{\text{av}} = V_{\text{rms}} I_{\text{rms}} \cos\phi$. On the average no power is consumed in the capacitor or the inductor, it is all consumed in the resistor.

SET UP: The source has rms voltage $V_{\text{rms}} = \dfrac{V}{\sqrt{2}} = \dfrac{45\text{ V}}{\sqrt{2}} = 31.8\text{ V}$.

EXECUTE: **(a)** $X_L = \omega L = (360\text{ rad/s})(15\times10^{-3}\text{ H}) = 5.4\ \Omega$.

$X_C = \dfrac{1}{\omega C} = \dfrac{1}{(360\text{ rad/s})(3.5\times10^{-6}\text{ F})} = 794\ \Omega$. $\tan\phi = \dfrac{X_L - X_C}{R} = \dfrac{5.4\ \Omega - 794\ \Omega}{250\ \Omega}$ and $\phi = -72.4°$.

The power factor is $\cos\phi = 0.302$.

(b) $Z = \sqrt{R^2 + (X_L - X_C)^2} = \sqrt{(250\ \Omega)^2 + (5.4\ \Omega - 794\ \Omega)^2} = 827\ \Omega$. $I_{\text{rms}} = \dfrac{V_{\text{rms}}}{Z} = \dfrac{31.8\text{ V}}{827\ \Omega} = 0.0385\text{ A}$.

$P_{\text{av}} = V_{\text{rms}} I_{\text{rms}} \cos\phi = (31.8\text{ V})(0.0385\text{ A})(0.302) = 0.370\text{ W}$.

(c) The average power delivered to the resistor is $P_{\text{av}} = I_{\text{rms}}^2 R = (0.0385\text{ A})^2(250\ \Omega) = 0.370\text{ W}$. The average power delivered to the capacitor and to the inductor is zero.

EVALUATE: On average the power delivered to the circuit equals the power consumed in the resistor. The capacitor and inductor store electrical energy during part of the current oscillation but each return the energy to the circuit during another part of the current cycle.

31.26. **IDENTIFY:** At resonance in an *L*-*R*-*C* ac circuit, we know the reactance of the capacitor and the voltage amplitude across it. From this information, we want to find the voltage amplitude of the source.

SET UP: At resonance, $Z = R$. $V_C = IX_C$.

EXECUTE: $I = \dfrac{V}{X} = \dfrac{600\text{ V}}{200\ \Omega} = 3.00\text{ A}$. $Z = R = 300\ \Omega$. $V = IZ = (3.00\text{ A})(300\ \Omega) = 900\text{ V}$.

EVALUATE: At resonance, $Z = R$, but X_C is not zero.

31.27. **IDENTIFY** and **SET UP:** The current is largest at the resonance frequency. At resonance, $X_L = X_C$ and $Z = R$. For part (b), calculate *Z* and use $I = V/Z$.

EXECUTE: **(a)** $f_0 = \dfrac{1}{2\pi\sqrt{LC}} = 113\text{ Hz}$. $I = V/R = 15.0\text{ mA}$.

(b) $X_C = 1/\omega C = 500\ \Omega$. $X_L = \omega L = 160\ \Omega$.

$Z = \sqrt{R^2 + (X_L - X_C)^2} = \sqrt{(200\ \Omega)^2 + (160\ \Omega - 500\ \Omega)^2} = 394.5\ \Omega$. $I = V/Z = 7.61\text{ mA}$. $X_C > X_L$ so the source voltage lags the current.

EVALUATE: $\omega_0 = 2\pi f_0 = 710$ rad/s. $\omega = 400$ rad/s and is less than ω_0. When $\omega < \omega_0$, $X_C > X_L$. Note that *I* in part (b) is less than *I* in part (a).

31.28. **IDENTIFY:** The impedance and individual reactances depend on the angular frequency at which the circuit is driven.

SET UP: The impedance is $Z = \sqrt{R^2 + \left(\omega L - \dfrac{1}{\omega C}\right)^2}$, the current amplitude is $I = V/Z$ and the instantaneous values of the potential and current are $v = V\cos(\omega t + \phi)$, where $\tan\phi = (X_L - X_C)/R$, and $i = I\cos\omega t$.

EXECUTE: **(a)** *Z* is a minimum when $\omega L = \dfrac{1}{\omega C}$, which gives

$\omega = \dfrac{1}{\sqrt{LC}} = \dfrac{1}{\sqrt{(8.00\text{ mH})(12.5\ \mu\text{F})}} = 3162$ rad/s, which rounds to 3160 rad/s. $Z = R = 175\ \Omega$.

(b) $I = V/Z = (25.0\text{ V})/(175\ \Omega) = 0.143\text{ A}$

(c) $i = I\cos\omega t = I/2$, so $\cos\omega t = \frac{1}{2}$, which gives $\omega t = 60° = \pi/3$ rad. $v = V\cos(\omega t + \phi)$, where $\tan\phi = (X_L - X_C)/R = 0/R = 0$. So, $v = (25.0\text{ V})\cos\omega t = (25.0\text{ V})(1/2) = 12.5\text{ V}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$v_R = Ri = (175\ \Omega)(1/2)(0.143\ \text{A}) = 12.5\ \text{V}.$

$v_C = V_C \cos(\omega t - 90°) = IX_C \cos(\omega t - 90°) = \dfrac{0.143\ \text{A}}{(3162\ \text{rad/s})(12.5\ \mu\text{F})} \cos(60° - 90°) = +3.13\ \text{V}.$

$v_L = V_L \cos(\omega t + 90°) = IX_L \cos(\omega t + 90°) = (0.143\ \text{A})(3162\ \text{rad/s})(8.00\ \text{mH}) \cos(60° + 90°).$

$v_L = -3.13\ \text{V}.$

(d) $v_R + v_L + v_C = 12.5\ \text{V} + (-3.13\ \text{V}) + 3.13\ \text{V} = 12.5\ \text{V} = v_{\text{source}}$

EVALUATE: The instantaneous potential differences across all the circuit elements always add up to the value of the source voltage at that instant. In this case (resonance), the potentials across the inductor and capacitor have the same magnitude but are $180°$ out of phase, so they add to zero, leaving all the potential difference across the resistor.

31.29. **IDENTIFY** and **SET UP:** At the resonance frequency, $Z = R$. Use that $V = IZ$, $V_R = IR$, $V_L = IX_L$ and $V_C = IX_C$. P_{av} is given by Eq. (31.31).

(a) EXECUTE: $V = IZ = IR = (0.500\ \text{A})(300\ \Omega) = 150\ \text{V}$

(b) $V_R = IR = 150\ \text{V}$

$X_L = \omega L = L(1/\sqrt{LC}) = \sqrt{L/C} = 2582\ \Omega; V_L = IX_L = 1290\ \text{V}$

$X_C = 1/(\omega C) = \sqrt{L/C} = 2582\ \Omega; V_C = IX_C = 1290\ \text{V}$

(c) $P_{\text{av}} = \frac{1}{2} VI \cos\phi = \frac{1}{2} I^2 R$, since $V = IR$ and $\cos\phi = 1$ at resonance.

$P_{\text{av}} = \frac{1}{2}(0.500\ \text{A})^2(300\ \Omega) = 37.5\ \text{W}$

EVALUATE: At resonance $V_L = V_C$. Note that $V_L + V_C > V$. However, at any instant $v_L + v_C = 0$.

31.30. **IDENTIFY:** The current is maximum at the resonance frequency, so choose C such that $\omega = 50.0$ rad/s is the resonance frequency. At the resonance frequency $Z = R$.

SET UP: $V_L = I\omega L$

EXECUTE: **(a)** The amplitude of the current is given by $I = \dfrac{V}{\sqrt{R^2 + \left(\omega L - \dfrac{1}{\omega C}\right)^2}}$. Thus, the current will have a maximum amplitude when $\omega L = \dfrac{1}{\omega C}$. Therefore, $C = \dfrac{1}{\omega^2 L} = \dfrac{1}{(50.0\ \text{rad/s})^2(9.00\ \text{H})} = 44.4\ \mu\text{F}.$

(b) With the capacitance calculated above we find that $Z = R$, and the amplitude of the current is $I = \dfrac{V}{R} = \dfrac{120\ \text{V}}{400\ \Omega} = 0.300\ \text{A}.$ Thus, the amplitude of the voltage across the inductor is

$V_L = I(\omega L) = (0.300\ \text{A})(50.0\ \text{rad/s})(9.00\ \text{H}) = 135\ \text{V}.$

EVALUATE: Note that V_L is greater than the source voltage amplitude.

31.31. **IDENTIFY** and **SET UP:** At resonance $X_L = X_C$, $\phi = 0$ and $Z = R$. $R = 150\ \Omega$, $L = 0.750$ H, $C = 0.0180\ \mu\text{F}$, $V = 150$ V

EXECUTE: **(a)** At the resonance frequency $X_L = X_C$ and from $\tan\phi = \dfrac{X_L - X_C}{R}$ we have that $\phi = 0°$ and the power factor is $\cos\phi = 1.00$.

(b) $P_{\text{av}} = \frac{1}{2} VI \cos\phi$ (Eq. 31.31)

At the resonance frequency $Z = R$, so $I = \dfrac{V}{Z} = \dfrac{V}{R}$.

$P_{\text{av}} = \frac{1}{2} V\left(\dfrac{V}{R}\right)\cos\phi = \frac{1}{2}\dfrac{V^2}{R} = \frac{1}{2}\dfrac{(150\ \text{V})^2}{150\ \Omega} = 75.0\ \text{W}$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(c) EVALUATE: When C and f are changed but the circuit is kept on resonance, nothing changes in $P_{av} = V^2/(2R)$, so the average power is unchanged: $P_{av} = 75.0$ W. The resonance frequency changes but since $Z = R$ at resonance the current doesn't change.

31.32. **IDENTIFY:** $\omega_0 = \dfrac{1}{\sqrt{LC}}$. $V_C = IX_C$. $V = IZ$.

SET UP: At resonance, $Z = R$.

EXECUTE: **(a)** $\omega_0 = \dfrac{1}{\sqrt{LC}} = \dfrac{1}{\sqrt{(0.350\text{ H})(0.0120\times10^{-6}\text{ F})}} = 1.54\times10^4$ rad/s

(b) $V = IZ = \left(\dfrac{V_C}{X_C}\right)Z = \left(\dfrac{V_C}{X_C}\right)R$. $X_C = \dfrac{1}{\omega C} = \dfrac{1}{(1.54\times10^4\text{ rad/s})(0.0120\times10^{-6}\text{ F})} = 5.41\times10^3\ \Omega$.

$V = \left(\dfrac{550\text{ V}}{5.41\times10^3\ \Omega}\right)(400\ \Omega) = 40.7$ V.

EVALUATE: The voltage amplitude for the capacitor is more than a factor of 10 times greater than the voltage amplitude of the source.

31.33. **IDENTIFY** and **SET UP:** The resonance angular frequency is $\omega_0 = \dfrac{1}{\sqrt{LC}}$. $X_L = \omega L$. $X_C = \dfrac{1}{\omega C}$ and $Z = \sqrt{R^2 + (X_L - X_C)^2}$. At the resonance frequency $X_L = X_C$ and $Z = R$.

EXECUTE: **(a)** $Z = R = 115\ \Omega$

(b) $\omega_0 = \dfrac{1}{\sqrt{(4.50\times10^{-3}\text{ H})(1.26\times10^{-6}\text{ F})}} = 1.33\times10^4$ rad/s. $\omega = 2\omega_0 = 2.66\times10^4$ rad/s.

$X_L = \omega L = (2.66\times10^4\text{ rad/s})(4.50\times10^{-3}\text{ H}) = 120\ \Omega$. $X_C = \dfrac{1}{\omega C} = \dfrac{1}{(2.66\times10^4\text{ rad/s})(1.25\times10^{-6}\text{ F})} = 30\ \Omega$

$Z = \sqrt{(115\ \Omega)^2 + (120\ \Omega - 30\ \Omega)^2} = 146\ \Omega$

(c) $\omega = \omega_0/2 = 6.65\times10^3$ rad/s. $X_L = 30\ \Omega$. $X_C = \dfrac{1}{\omega C} = 120\ \Omega$.

$Z = \sqrt{(115\ \Omega)^2 + (30\ \Omega - 120\ \Omega)^2} = 146\ \Omega$, the same value as in part (b).

EVALUATE: For $\omega = 2\omega_0$, $X_L > X_C$. For $\omega = \omega_0/2$, $X_L < X_C$. But $(X_L - X_C)^2$ has the same value at these two frequencies, so Z is the same.

31.34. **IDENTIFY:** At resonance $Z = R$ and $X_L = X_C$.

SET UP: $\omega_0 = \dfrac{1}{\sqrt{LC}}$. $V = IZ$. $V_R = IR$, $V_L = IX_L$ and $V_C = V_L$.

EXECUTE: **(a)** $\omega_0 = \dfrac{1}{\sqrt{LC}} = \dfrac{1}{\sqrt{(0.280\text{ H})(4.00\times10^{-6}\text{ F})}} = 945$ rad/s.

(b) $I = 1.70$ A at resonance, so $R = Z = \dfrac{V}{I} = \dfrac{120\text{ V}}{1.70\text{ A}} = 70.6\ \Omega$

(c) At resonance, $V_R = 120$ V, $V_L = V_C = I\omega L = (1.70\text{ A})(945\text{ rad/s})(0.280\text{ H}) = 450$ V.

EVALUATE: At resonance, $V_R = V$ and $V_L - V_C = 0$.

31.35. **IDENTIFY** and **SET UP:** Eq. (31.35) relates the primary and secondary voltages to the number of turns in each. $I = V/R$ and the power consumed in the resistive load is $I_{rms}^2 = V_{rms}^2/R$. Let I_1, V_1 and I_2, V_2 be rms values for the primary and secondary.

EXECUTE: **(a)** $\dfrac{V_2}{V_1} = \dfrac{N_2}{N_1}$ so $\dfrac{N_1}{N_2} = \dfrac{V_1}{V_2} = \dfrac{120\text{ V}}{12.0\text{ V}} = 10$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) $I_2 = \dfrac{V_2}{R} = \dfrac{12.0\text{ V}}{5.00\ \Omega} = 2.40\text{ A}$

(c) $P_{\text{av}} = I_2^2 R = (2.40\text{ A})^2(5.00\ \Omega) = 28.8\text{ W}$

(d) The power drawn from the line by the transformer is the 28.8 W that is delivered by the load.

$$P_{\text{av}} = \frac{V_1^2}{R} \text{ so } R = \frac{V_1^2}{P_{\text{av}}} = \frac{(120\text{ V})^2}{28.8\text{ W}} = 500\ \Omega$$

And $\left(\dfrac{N_1}{N_2}\right)^2 (5.00\ \Omega) = (10)^2(5.00\ \Omega) = 500\ \Omega,$ as was to be shown.

EVALUATE: The resistance is "transformed." A load of resistance R connected to the secondary draws the same power as a resistance $(N_1/N_2)^2 R$ connected directly to the supply line, without using the transformer.

31.36. **IDENTIFY:** $P_{\text{av}} = V_{\text{rms}} I_{\text{rms}}$ and $P_{\text{av},1} = P_{\text{av},2}$. $\dfrac{N_1}{N_2} = \dfrac{V_1}{V_2}$. Let I_1, V_1 and I_2, V_2 be rms values for the primary and secondary.

SET UP: $V_1 = 120$ V. $V_2 = 13{,}000$ V.

EXECUTE: **(a)** $\dfrac{N_2}{N_1} = \dfrac{V_2}{V_1} = \dfrac{13{,}000\text{ V}}{120\text{ V}} = 108$

(b) $P_{\text{av}} = V_2 I_2 = (13{,}000\text{ V})(8.50\times10^{-3}\text{ A}) = 110\text{ W}$

(c) $I_1 = \dfrac{P_{\text{av}}}{V_1} = \dfrac{110\text{ W}}{120\text{ V}} = 0.917\text{ A}$

EVALUATE: Since the power supplied to the primary must equal the power delivered by the secondary, in a step-up transformer the current in the primary is greater than the current in the secondary.

31.37. **IDENTIFY:** Let I_1, V_1 and I_2, V_2 be rms values for the primary and secondary. A transformer transforms voltages according to $\dfrac{V_2}{V_1} = \dfrac{N_2}{N_1}$. The effective resistance of a secondary circuit of resistance R is $R_{\text{eff}} = \dfrac{R}{(N_2/N_1)^2}$. Resistance R is related to P_{av} and V_{rms} by $P_{\text{av}} = \dfrac{V_{\text{rms}}^2}{R}$. Conservation of energy requires $P_{\text{av},1} = P_{\text{av},2}$ so $V_1 I_1 = V_2 I_2$.

SET UP: Let $V_1 = 240$ V and $V_2 = 120$ V, so $P_{2,\text{av}} = 1600$ W. These voltages are rms.

EXECUTE: **(a)** $V_1 = 240$ V and we want $V_2 = 120$ V, so use a step-down transformer with $N_2/N_1 = \frac{1}{2}$.

(b) $P_{\text{av}} = V_1 I_1$, so $I_1 = \dfrac{P_{\text{av}}}{V_1} = \dfrac{1600\text{ W}}{240\text{ V}} = 6.67\text{ A}.$

(c) The resistance R of the blower is $R = \dfrac{V_1^2}{P_{\text{av}}} = \dfrac{(120\text{ V})^2}{1600\text{ W}} = 9.00\ \Omega.$ The effective resistance of the blower is

$R_{\text{eff}} = \dfrac{9.00\ \Omega}{(1/2)^2} = 36.0\ \Omega.$

EVALUATE: $I_2 V_2 = (13.3\text{ A})(120\text{ V}) = 1600$ W. Energy is provided to the primary at the same rate that it is consumed in the secondary. Step-down transformers step up resistance and the current in the primary is less than the current in the secondary.

31.38. **IDENTIFY:** $Z = \sqrt{R^2 + (X_L - X_C)^2}$, with $X_L = \omega L$ and $X_C = \dfrac{1}{\omega C}$.

SET UP: The woofer has a R and L in series and the tweeter has a R and C in series.

EXECUTE: **(a)** $Z_{\text{tweeter}} = \sqrt{R^2 + (1/\omega C)^2}$

(b) $Z_{\text{woofer}} = \sqrt{R^2 + (\omega L)^2}$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(c) If $Z_{\text{tweeter}} = Z_{\text{woofer}}$, then the current splits evenly through each branch.

(d) At the crossover point, where currents are equal, $R^2 + (1/\omega C^2) = R^2 + (\omega L)^2$. $\omega = \dfrac{1}{\sqrt{LC}}$ and $f = \dfrac{\omega}{2\pi} = \dfrac{1}{2\pi\sqrt{LC}}$.

EVALUATE: The crossover frequency corresponds to the resonance frequency of a *R*-*C*-*L* circuit, since the crossover frequency is where $X_L = X_C$.

31.39. **IDENTIFY** and **SET UP:** Use Eq. (31.24) to relate *L* and *R* to ϕ. The voltage across the coil leads the current in it by 52.3°, so $\phi = +52.3°$.

EXECUTE: $\tan\phi = \dfrac{X_L - X_C}{R}$. But there is no capacitance in the circuit so $X_C = 0$. Thus

$\tan\phi = \dfrac{X_L}{R}$ and $X_L = R\tan\phi = (48.0\ \Omega)\tan 52.3° = 62.1\ \Omega$.

$X_L = \omega L = 2\pi f L$ so $L = \dfrac{X_L}{2\pi f} = \dfrac{62.1\ \Omega}{2\pi(80.0\ \text{Hz})} = 0.124\ \text{H}$.

EVALUATE: $\phi > 45°$ when $(X_L - X_C) > R$, which is the case here.

31.40. **IDENTIFY:** $Z = \sqrt{R^2 + (X_L - X_C)^2}$. $I_{\text{rms}} = \dfrac{V_{\text{rms}}}{Z}$. $V_{\text{rms}} = I_{\text{rms}}R$. $V_{C,\text{rms}} = I_{\text{rms}}X_C$. $V_{L,\text{rms}} = I_{\text{rms}}X_L$.

SET UP: $V_{\text{rms}} = \dfrac{V}{\sqrt{2}} = \dfrac{30.0\ \text{V}}{\sqrt{2}} = 21.2\ \text{V}$.

EXECUTE: **(a)** $\omega = 200$ rad/s, so $X_L = \omega L = (200\ \text{rad/s})(0.400\ \text{H}) = 80.0\ \Omega$ and

$X_C = \dfrac{1}{\omega C} = \dfrac{1}{(200\ \text{rad/s})(6.00\times10^{-6}\ \text{F})} = 833\ \Omega$. $Z = \sqrt{(200\ \Omega)^2 + (80.0\ \Omega - 833\ \Omega)^2} = 779\ \Omega$.

$I_{\text{rms}} = \dfrac{V_{\text{rms}}}{Z} = \dfrac{21.2\ \text{V}}{779\ \Omega} = 0.0272\ \text{A}$. V_1 reads $V_{R,\text{rms}} = I_{\text{rms}}R = (0.0272\ \text{A})(200\ \Omega) = 5.44\ \text{V}$. V_2 reads $V_{L,\text{rms}} = I_{\text{rms}}X_L = (0.0272\ \text{A})(80.0\ \Omega) = 2.18\ \text{V}$. V_3 reads $V_{C,\text{rms}} = I_{\text{rms}}X_C = (0.0272\ \text{A})(833\ \Omega) = 22.7\ \text{V}$.

V_4 reads $\left|\dfrac{V_L - V_C}{\sqrt{2}}\right| = \left|V_{L,\text{rms}} - V_{C,\text{rms}}\right| = \left|2.18\ \text{V} - 22.7\ \text{V}\right| = 20.5\ \text{V}$. V_5 reads $V_{\text{rms}} = 21.2\ \text{V}$.

(b) $\omega = 1000$ rad/s so $X_L = \omega L = (5)(80.0\ \Omega) = 400\ \Omega$ and $X_C = \dfrac{1}{\omega C} = \dfrac{833\ \Omega}{5} = 167\ \Omega$.

$Z = \sqrt{(200\ \Omega)^2 + (400\ \Omega - 167\ \Omega)^2} = 307\ \Omega$. $I_{\text{rms}} = \dfrac{V_{\text{rms}}}{Z} = \dfrac{21.2\ \text{V}}{307\ \Omega} = 0.0691\ \text{A}$. V_1 reads $V_{R,\text{rms}} = 13.8\ \text{V}$.

V_2 reads $V_{L,\text{rms}} = 27.6\ \text{V}$. V_3 reads $V_{C,\text{rms}} = 11.5\ \text{V}$.

V_4 reads $\left|V_{L,\text{rms}} - V_{C,\text{rms}}\right| = \left|27.6\ \text{V} - 11.5\ \text{V}\right| = 16.1\ \text{V}$. V_5 reads $V_{\text{rms}} = 21.2\ \text{V}$.

EVALUATE: The resonance frequency for this circuit is $\omega_0 = \dfrac{1}{\sqrt{LC}} = 645$ rad/s. 200 rad/s is less than the resonance frequency and $X_C > X_L$. 1000 rad/s is greater than the resonance frequency and $X_L > X_C$.

31.41. **IDENTIFY:** We can use geometry to calculate the capacitance and inductance, and then use these results to calculate the resonance angular frequency.

SET UP: The capacitance of an air-filled parallel plate capacitor is $C = \dfrac{\varepsilon_0 A}{d}$. The inductance of a long solenoid is $L = \dfrac{\mu_0 A N^2}{l}$. The inductor has $N = (125\ \text{coils/cm})(9.00\ \text{cm}) = 1125$ coils. The resonance frequency is $f_0 = \dfrac{1}{2\pi\sqrt{LC}}$. $\varepsilon_0 = 8.85\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2$. $\mu_0 = 4\pi\times10^{-7}\ \text{T}\cdot\text{m/A}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: $C = \dfrac{\varepsilon_0 A}{d} = \dfrac{(8.85\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2)(4.50\times10^{-2}\ \text{m})^2}{8.00\times10^{-3}\ \text{m}} = 2.24\times10^{-12}\ \text{F}.$

$L = \dfrac{\mu_0 AN^2}{l} = \dfrac{(4\pi\times10^{-7}\ \text{T}\cdot\text{m/A})\pi(0.250\times10^{-2}\ \text{m})^2(1125)^2}{9.00\times10^{-2}\ \text{m}} = 3.47\times10^{-4}\ \text{H}.$

$\omega_0 = \dfrac{1}{\sqrt{(3.47\times10^{-4}\ \text{H})(2.24\times10^{-12}\ \text{F})}} = 3.59\times10^{7}\ \text{rad/s}.$

EVALUATE: The result is a rather high angular frequency.

31.42. **IDENTIFY:** Use geometry to calculate the self-inductance of the toroidal solenoid. Then find its reactance and use this to find the impedance, and finally the current amplitude, of the circuit.

SET UP: $L = \dfrac{\mu_0 N^2 A}{2\pi r}$, $X_L = 2\pi fL$, $Z = \sqrt{R^2 + X_L^2}$, and $I = V/Z$.

EXECUTE: $L = \dfrac{\mu_0 N^2 A}{2\pi r} = (2\times10^{-7}\ \text{T}\cdot\text{m/A})\dfrac{(2900)^2(0.450\times10^{-4}\ \text{m}^2)}{9.00\times10^{-2}\ \text{m}} = 8.41\times10^{-4}\ \text{H}.$

$X_L = 2\pi fL = (2\pi)(365\ \text{Hz})(8.41\times10^{-4}\ \text{H}) = 1.929\ \Omega.$ $Z = \sqrt{R^2 + X_L^2} = 3.40\ \Omega.$ $I = \dfrac{V}{Z} = \dfrac{24.0\ \text{V}}{3.40\ \Omega} = 7.06\ \text{A}.$

EVALUATE: The inductance is physically reasonable.

31.43. **IDENTIFY:** An *L*-*R*-*C* ac circuit operates at resonance. We know *L*, *C*, and *V* and want to find *R*.

SET UP: At resonance, $Z = R$ and $\omega = \omega_0 = \dfrac{1}{\sqrt{LC}}$. $X_C = \dfrac{1}{\omega C}$, $I = V/Z$.

EXECUTE: $\omega = \dfrac{1}{\sqrt{LC}} = 633.0\ \text{rad/s}$ $X_C = \dfrac{1}{\omega C} = \dfrac{1}{(633\ \text{rad/s})(4.80\times10^{-6}\ \text{F})} = 329.1\ \Omega.$

$I = \dfrac{V_C}{X_C} = \dfrac{80.0\ \text{V}}{329.1\ \Omega} = 0.2431\ \text{A}.$ At resonance $Z = R$, so $I = \dfrac{V}{R}$. $R = \dfrac{V}{I} = \dfrac{56.0\ \text{V}}{0.2431\ \text{A}} = 230\ \Omega.$

EVALUATE: At resonance, the impedance is a minimum.

31.44. **IDENTIFY:** $X_L = \omega L$. $P_{\text{av}} = V_{\text{rms}} I_{\text{rms}} \cos\phi$

SET UP: $f = 120\ \text{Hz}$; $\omega = 2\pi f$.

EXECUTE: **(a)** $X_L = \omega L \Rightarrow L = \dfrac{X_L}{\omega} = \dfrac{250\ \Omega}{2\pi(120\ \text{Hz})} = 0.332\ \text{H}$

(b) $Z = \sqrt{R^2 + X_L^2} = \sqrt{(400\ \Omega)^2 + (250\ \Omega)^2} = 472\ \Omega.$ $\cos\phi = \dfrac{R}{Z}$ and $I_{\text{rms}} = \dfrac{V_{\text{rms}}}{Z}$. $P_{\text{av}} = \dfrac{V_{\text{rms}}^2}{Z}\dfrac{R}{Z}$, so

$V_{\text{rms}} = Z\sqrt{\dfrac{P_{\text{av}}}{R}} = (472\ \Omega)\sqrt{\dfrac{800\ \text{W}}{400\ \Omega}} = 668\ \text{V}.$

EVALUATE: $I_{\text{rms}} = \dfrac{V_{\text{rms}}}{Z} = \dfrac{668\ \text{V}}{472\ \Omega} = 1.415\ \text{A}.$ We can calculate P_{av} as

$I_{\text{rms}}^2 R = (1.415\ \text{A})^2(400\ \Omega) = 800\ \text{W},$ which checks.

31.45. **(a) IDENTIFY** and **SET UP:** Source voltage lags current so it must be that $X_C > X_L$ and we must add an inductor in series with the circuit. When $X_C = X_L$ the power factor has its maximum value of unity, so calculate the additional *L* needed to raise X_L to equal X_C.

(b) EXECUTE: Power factor $\cos\phi$ equals 1 so $\phi = 0$ and $X_C = X_L$. Calculate the present value of $X_C - X_L$ to see how much more X_L is needed: $R = Z\cos\phi = (60.0\ \Omega)(0.720) = 43.2\ \Omega$

$\tan\phi = \dfrac{X_L - X_C}{R}$ so $X_L - X_C = R\tan\phi$

$\cos\phi = 0.720$ gives $\phi = -43.95°$ (ϕ is negative since the voltage lags the current)

Then $X_L - X_C = R\tan\phi = (43.2\ \Omega)\tan(-43.95°) = -41.64\ \Omega.$

Therefore need to add $41.64\ \Omega$ of X_L.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$X_L = \omega L = 2\pi fL$ and $L = \dfrac{X_L}{2\pi f} = \dfrac{41.64\ \Omega}{2\pi(50.0\ \text{Hz})} = 0.133\ \text{H},$ amount of inductance to add.

EVALUATE: From the information given we can't calculate the original value of L in the circuit, just how much to add. When this L is added the current in the circuit will increase.

31.46. **IDENTIFY:** We know $R, X_L, X_C,$ and V_L for a series *L*-*R*-*C* ac circuit. We want to find V_R, V_C, V and the power delivered by the source.

SET UP: $I = \dfrac{V_L}{X_L},\ V = IX,\ P_{\text{av}} = I_{\text{rms}}^2 R.$

EXECUTE: **(a)** $I = \dfrac{V_L}{X_L} = \dfrac{450\ \text{V}}{900\ \Omega} = 0.500\ \text{A}.$ $V_R = IR = (0.500\ \text{A})(300\ \Omega) = 150\ \text{V}.$

(b) $V_C = IX_C = (0.500\ \text{A})(500\ \Omega) = 250\ \text{V}.$

(c) $V = \sqrt{V_R^2 + (V_L - V_C)^2} = \sqrt{(150\ \text{V})^2 + (450\ \text{V} - 250\ \text{V})^2} = 250\ \text{V}.$

(d) $P_{\text{av}} = I_{\text{rms}}^2 R = \dfrac{1}{2} I^2 R = \dfrac{1}{2}\dfrac{V_R^2}{R} = \dfrac{1}{2}\dfrac{(150\ \text{V})^2}{300\ \Omega} = 37.5\ \text{W}.$

EVALUATE: The voltage amplitude of the source is not the sum of the voltage amplitudes of the other circuit elements since the voltages have their maxima at different times and are hence out of phase.

31.47. **IDENTIFY:** We know the impedances and the average power consumed. From these we want to find the power factor and the rms voltage of the source.

SET UP: $P = I_{\text{rms}}^2 R.$ $\cos\phi = \dfrac{R}{Z}.$ $Z = \sqrt{R^2 + (X_L - X_C)^2}.$ $V_{\text{rms}} = I_{\text{rms}} Z.$

EXECUTE: **(a)** $I_{\text{rms}} = \sqrt{\dfrac{P}{R}} = \sqrt{\dfrac{60.0\ \text{W}}{300\ \Omega}} = 0.447\ \text{A}.$ $Z = \sqrt{(300\ \Omega)^2 + (500\ \Omega - 300\ \Omega)^2} = 361\ \Omega.$

$\cos\phi = \dfrac{R}{Z} = \dfrac{300\ \Omega}{361\ \Omega} = 0.831.$

(b) $V_{\text{rms}} = I_{\text{rms}} Z = (0.447\ \text{A})(361\ \Omega) = 161\ \text{V}.$

EVALUATE: The voltage amplitude of the source is $V_{\text{rms}}\sqrt{2} = 228\ \text{V}.$

31.48. **IDENTIFY:** Use $V_{\text{rms}} = I_{\text{rms}} Z$ to calculate Z and then find $R.$ $P_{\text{av}} = I_{\text{rms}}^2 R$

SET UP: $X_C = 50.0\ \Omega$

EXECUTE: $Z = \dfrac{V_{\text{rms}}}{I_{\text{rms}}} = \dfrac{240\ \text{V}}{3.00\ \text{A}} = 80.0\ \Omega = \sqrt{R^2 + X_C^2} = \sqrt{R^2 + (50.0\ \Omega)^2}.$ Thus,

$R = \sqrt{(80.0\ \Omega)^2 - (50.0\ \Omega)^2} = 62.4\ \Omega.$ The average power supplied to this circuit is equal to the power dissipated by the resistor, which is $P = I_{\text{rms}}^2 R = (3.00\ \text{A})^2(62.4\ \Omega) = 562\ \text{W}.$

EVALUATE: $\tan\phi = \dfrac{X_L - X_C}{R} = \dfrac{-50.0\ \Omega}{62.4\ \Omega}$ and $\phi = -38.7°.$

$P_{\text{av}} = V_{\text{rms}} I_{\text{rms}} \cos\phi = (240\ \text{V})(3.00\ \text{A})\cos(-38.7°) = 562\ \text{W},$ which checks.

31.49. **IDENTIFY:** The voltage and current amplitudes are the maximum values of these quantities, not necessarily the instantaneous values.

SET UP: The voltage amplitudes are $V_R = RI, V_L = X_L I,$ and $V_C = X_C I,$ where $I = V/Z$ and $Z = \sqrt{R^2 + \left(\omega L - \dfrac{1}{\omega C}\right)^2}.$

EXECUTE: **(a)** $\omega = 2\pi f = 2\pi(1250\ \text{Hz}) = 7854\ \text{rad/s}.$ Carrying extra figures in the calculator gives

$X_L = \omega L = (7854\ \text{rad/s})(3.50\ \text{mH}) = 27.5\ \Omega;$ $XC = 1/\omega C = 1/[(7854\ \text{rad/s})(10.0\ \mu\text{F})] = 12.7\ \Omega;$

$Z = \sqrt{R^2 + (X_L - X_C)^2} = \sqrt{(50.0\ \Omega)^2 + (27.5\ \Omega - 12.7\ \Omega)^2} = 57.5\ \Omega;$

$I = V/Z = (60.0\ \text{V})/(52.1\ \Omega) = 1.15\ \text{A};$ $V_R = RI = (50.0\ \Omega)(1.15\ \text{A}) = 57.5\ \text{V};$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$V_L = X_L I = (27.5\ \Omega)(1.15\ \text{A}) = 31.6\ \text{V};\ V_C = X_C I = (12.7\ \Omega)(1.15\ \text{A}) = 14.6\ \text{V}.$

The voltage amplitudes can add to more than 60.0 V because the voltage maxima do not all occur at the same instant of time. At any instant, the instantaneous voltages across the resistor, inductor and capacitor all add to equal the instantaneous source voltage.

(b) All of them will change because they all depend on $\omega.\ X_L = \omega L$ will double to $55.0\ \Omega,$ and $X_C = 1/\omega C$ will decrease by half to 6.35 Ω. Therefore $Z = \sqrt{(50.0\ \Omega)^2 + (55.0\ \Omega - 6.35\ \Omega)^2} = 69.8\ \Omega;$

$I = V/Z = (60.0\text{V})/(69.8\ \Omega) = 0.860\ \text{A};\ V_R = IR = (0.860\ \text{A})(50.0\ \Omega) = 43.0\ \text{V};$

$V_L = IX_L = (0.860\ \text{A})(55.0\ \Omega) = 47.3\ \text{V};\ V_C = IX_C = (0.860\ \text{A})(6.35\ \Omega) = 5.46\ \text{V}.$

EVALUATE: The new amplitudes in part (b) are not simple multiples of the values in part (a) because the impedance and reactances are not all the same simple multiple of the angular frequency.

31.50. **IDENTIFY** and **SET UP:** $X_C = \dfrac{1}{\omega C}.\ X_L = \omega L.$

EXECUTE: **(a)** $\dfrac{1}{\omega_1 C} = \omega_1 L$ and $LC = \dfrac{1}{\omega_1^2}.$ At angular frequency $\omega_2,$

$\dfrac{X_L}{X_C} = \dfrac{\omega_2 L}{1/\omega_2 C} = \omega_2^2 LC = (2\omega_1)^2 \dfrac{1}{\omega_1^2} = 4.\ \ X_L > X_C.$

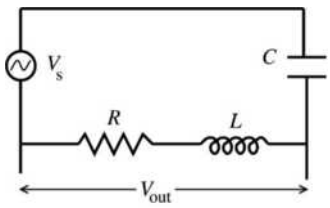
(b) At angular frequency $\omega_3,\ \dfrac{X_L}{X_C} = \omega_3^2 LC = \left(\dfrac{\omega_1}{3}\right)^2 \left(\dfrac{1}{\omega_1^2}\right) = \dfrac{1}{9}.\ \ X_C > X_L.$

EVALUATE: When ω increases, X_L increases and X_C decreases. When ω decreases, X_L decreases and X_C increases.

(c) The resonance angular frequency ω_0 is the value of ω for which $X_C = X_L,$ so $\omega_0 = \omega_1.$

31.51. **IDENTIFY** and **SET UP:** Express Z and I in terms of $\omega,\ L,\ C$ and R. The voltages across the resistor and the inductor are $90°$ out of phase, so $V_{\text{out}} = \sqrt{V_R^2 + V_L^2}.$

EXECUTE: The circuit is sketched in Figure 31.51.



$$X_L = \omega L,\ X_C = \frac{1}{\omega C}$$

$$Z = \sqrt{R^2 + \left(\omega L - \frac{1}{\omega C}\right)^2}$$

$$I = \frac{V_s}{Z} = \frac{V_s}{\sqrt{R^2 + \left(\omega L - \frac{1}{\omega C}\right)^2}}$$

Figure 31.51

$$V_{\text{out}} = I\sqrt{R^2 + X_L^2} = I\sqrt{R^2 + \omega^2 L^2} = V_s \sqrt{\frac{R^2 + \omega^2 L^2}{R^2 + \left(\omega L - \frac{1}{\omega C}\right)^2}}$$

$$\frac{V_{\text{out}}}{V_s} = \sqrt{\frac{R^2 + \omega^2 L^2}{R^2 + \left(\omega L - \frac{1}{\omega C}\right)^2}}$$

$\underline{\omega \text{ small}}$

As ω gets small, $R^2 + \left(\omega L - \dfrac{1}{\omega C}\right)^2 \to \dfrac{1}{\omega^2 C^2},\ R^2 + \omega^2 L^2 \to R^2.$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

Therefore $\frac{V_{\text{out}}}{V_s} \to \sqrt{\frac{R^2}{(1/\omega^2 C^2)}} = \omega RC$ as ω becomes small.

$\underline{\omega \text{ large}}$

As ω gets large, $R^2 + \left(\omega L - \frac{1}{\omega C}\right)^2 \to R^2 + \omega^2 L^2 \to \omega^2 L^2, R^2 + \omega^2 L^2 \to \omega^2 L^2$

Therefore, $\frac{V_{\text{out}}}{V_s} \to \sqrt{\frac{\omega^2 L^2}{\omega^2 L^2}} = 1$ as ω becomes large.

EVALUATE: $V_{\text{out}}/V_s \to 0$ as ω becomes small, so there is V_{out} only when the frequency ω of V_s is large. If the source voltage contains a number of frequency components, only the high frequency ones are passed by this filter.

31.52. **IDENTIFY:** $V = V_C = IX_C$. $I = V/Z$.

SET UP: $X_L = \omega L$, $X_C = \frac{1}{\omega C}$.

EXECUTE: $V_{\text{out}} = V_C = \frac{I}{\omega C} \Rightarrow \frac{V_{\text{out}}}{V_s} = \frac{1}{\omega C\sqrt{R^2 + (\omega L - 1/\omega C)^2}}$.

If ω is large: $\frac{V_{\text{out}}}{V_s} = \frac{1}{\omega C\sqrt{R^2 + (\omega L - 1/\omega C)^2}} \approx \frac{1}{\omega C\sqrt{(\omega L)^2}} = \frac{1}{(LC)\omega^2}$.

If ω is small: $\frac{V_{\text{out}}}{V_s} \approx \frac{1}{\omega C\sqrt{(1/\omega C)^2}} = \frac{\omega C}{\omega C} = 1$.

EVALUATE: When ω is large, X_C is small and X_L is large so Z is large and the current is small. Both factors in $V_C = IX_C$ are small. When ω is small, X_C is large and the voltage amplitude across the capacitor is much larger than the voltage amplitudes across the resistor and the inductor.

31.53. **IDENTIFY:** $I = V/Z$ and $P_{\text{av}} = \frac{1}{2}I^2 R$.

SET UP: $Z = \sqrt{R^2 + (\omega L - 1/\omega C)^2}$

EXECUTE: **(a)** $I = \frac{V}{Z} = \frac{V}{\sqrt{R^2 + (\omega L - 1/\omega C)^2}}$.

(b) $P_{\text{av}} = \frac{1}{2}I^2 R = \frac{1}{2}\left(\frac{V}{Z}\right)^2 R = \frac{V^2 R/2}{R^2 + (\omega L - 1/\omega C)^2}$.

(c) The average power and the current amplitude are both greatest when the denominator is smallest, which occurs for $\omega_0 L = \frac{1}{\omega_0 C}$, so $\omega_0 = \frac{1}{\sqrt{LC}}$.

(d) $P_{\text{av}} = \frac{(100\ \text{V})^2(200\ \Omega)/2}{(200\ \Omega)^2 + (\omega(2.00\ \text{H}) - 1/[\omega(0.500\times10^{-6}\ \text{F})])^2} = \frac{25\omega^2}{40{,}000\omega^2 + (2\omega^2 - 2{,}000{,}000\ \text{s}^{-2})^2}\ \text{W}$.

The graph of P_{av} versus ω is sketched in Figure 31.53.

EVALUATE: Note that as the angular frequency goes to zero, the power and current are zero, just as they are when the angular frequency goes to infinity. This graph exhibits the same strongly peaked nature as the light purple curve in Figure 31.19 in the textbook.

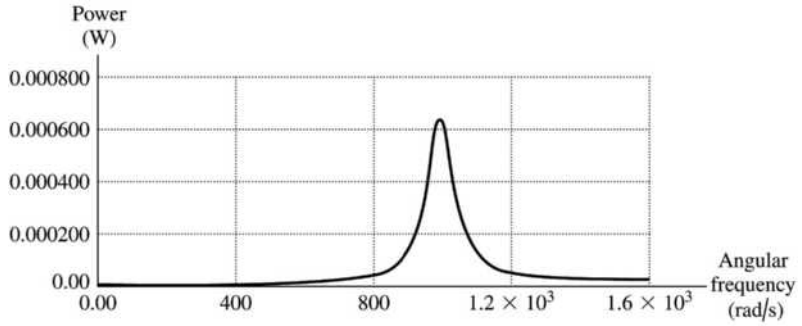

Figure 31.53

31.54. **IDENTIFY:** $V_L = I\omega L$ and $V_C = \dfrac{I}{\omega C}$.

SET UP: Problem 31.53 shows that $I = \dfrac{V}{\sqrt{R^2 + (\omega L - 1/[\omega C])^2}}$.

EXECUTE: **(a)** $V_L = I\omega L = \dfrac{V\omega L}{\sqrt{R^2 + (\omega L - 1/[\omega C])^2}}$.

(b) $V_C = \dfrac{I}{\omega C} = \dfrac{V}{\omega C\sqrt{R^2 + (\omega L - 1/[\omega C])^2}}$.

(c) The graphs are given in Figure 31.54.

EVALUATE: **(d)** When the angular frequency is zero, the inductor has zero voltage while the capacitor has voltage of 100 V (equal to the total source voltage). At very high frequencies, the capacitor voltage goes to zero, while the inductor's voltage goes to 100 V. At resonance, $\omega_0 = \dfrac{1}{\sqrt{LC}} = 1000$ rad/s, the two voltages are equal, and are a maximum, 1000 V.

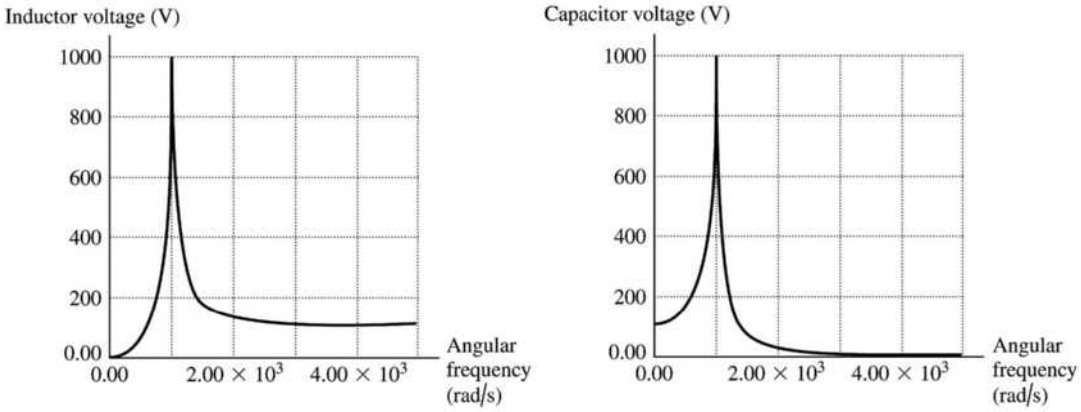

Figure 31.54

31.55. **IDENTIFY:** We know R, X_C and ϕ so Eq. (31.24) tells us X_L. Use $P_{\text{av}} = I_{\text{rms}}^2 R$ to calculate I_{rms}. Then calculate Z and use Eq. (31.26) to calculate V_{rms} for the source.

SET UP: Source voltage lags current so $\phi = -54.0°$. $X_C = 350\,\Omega$, $R = 180\,\Omega$, $P_{\text{av}} = 140$ W

EXECUTE: **(a)** $\tan\phi = \dfrac{X_L - X_C}{R}$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$X_L = R\tan\phi + X_C = (180\ \Omega)\tan(-54.0°) + 350\ \Omega = -248\ \Omega + 350\ \Omega = 102\ \Omega$

(b) $P_{\text{av}} = V_{\text{rms}} I_{\text{rms}} \cos\phi = I_{\text{rms}}^2 R$ (Exercise 31.22). $I_{\text{rms}} = \sqrt{\frac{P_{\text{av}}}{R}} = \sqrt{\frac{140\ \text{W}}{180\ \Omega}} = 0.882\ \text{A}$

(c) $Z = \sqrt{R^2 + (X_L - X_C)^2} = \sqrt{(180\ \Omega)^2 + (102\ \Omega - 350\ \Omega)^2} = 306\ \Omega$

$V_{\text{rms}} = I_{\text{rms}} Z = (0.882\ \text{A})(306\ \Omega) = 270\ \text{V}.$

EVALUATE: We could also use Eq. (31.31): $P_{\text{av}} = V_{\text{rms}} I_{\text{rms}} \cos\phi$

$V_{\text{rms}} = \frac{P_{\text{av}}}{I_{\text{rms}} \cos\phi} = \frac{140\ \text{W}}{(0.882\ \text{A})\cos(-54.0°)} = 270\ \text{V},$ which agrees. The source voltage lags the current when $X_C > X_L,$ and this agrees with what we found.

31.56. **IDENTIFY:** At any instant of time the same rules apply to the parallel ac circuit as to the parallel dc circuit: the voltages are the same and the currents add.

SET UP: For a resistor the current and voltage in phase. For an inductor the voltage leads the current by $90°$ and for a capacitor the voltage lags the current by $90°$.

EXECUTE: **(a)** The parallel *L*-*R*-*C* circuit must have equal potential drops over the capacitor, inductor and resistor, so $v_R = v_L = v_C = v.$ Also, the sum of currents entering any junction must equal the current leaving the junction. Therefore, the sum of the currents in the branches must equal the current through the source: $i = i_R + i_L + i_C.$

(b) $i_R = \frac{v}{R}$ is always in phase with the voltage. $i_L = \frac{v}{\omega L}$ lags the voltage by $90°,$ and $i_C = v\omega C$ leads the voltage by $90°.$ The phase diagram is sketched in Figure 31.56.

(c) From the diagram, $I^2 = I_R^2 + (I_C - I_L)^2 = \left(\frac{V}{R}\right)^2 + \left(V\omega C - \frac{V}{\omega L}\right)^2.$

(d) From part (c): $I = V\sqrt{\frac{1}{R^2} + \left(\omega C - \frac{1}{\omega L}\right)^2}.$ But $I = \frac{V}{Z},$ so $\frac{1}{Z} = \sqrt{\frac{1}{R^2} + \left(\omega C - \frac{1}{\omega L}\right)^2}.$

EVALUATE: For large $\omega,$ $Z \to \frac{1}{\omega C}.$ The current in the capacitor branch is much larger than the current in the other branches. For small $\omega,$ $Z \to \omega L.$ The current in the inductive branch is much larger than the current in the other branches.

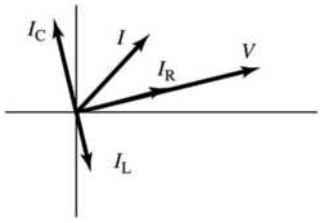

Figure 31.56

31.57. **IDENTIFY:** Apply the expression for *I* from Problem 31.56 when $\omega_0 = 1/\sqrt{LC}.$

SET UP: From Problem 31.56, $I = V\sqrt{\frac{1}{R^2} + \left(\omega C - \frac{1}{\omega L}\right)^2}.$

EXECUTE: **(a)** At resonance, $\omega_0 = \frac{1}{\sqrt{LC}} \Rightarrow \omega_0 C = \frac{1}{\omega_0 L} \Rightarrow I_C = V\omega_0 C = \frac{V}{\omega_0 L} = I_L$ so $I = I_R$ and *I* is a minimum.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) $P_{\text{av}} = \dfrac{V_{\text{rms}}^2}{Z}\cos\phi = \dfrac{V^2}{R}$ at resonance where $R < Z$ so power is a maximum.

(c) At $\omega = \omega_0$, I and V are in phase, so the phase angle is zero, which is the same as a series resonance.

EVALUATE: (d) The parallel circuit is sketched in Figure 31.57. At resonance, $|i_C| = |i_L|$ and at any instant of time these two currents are in opposite directions. Therefore, the net current between *a* and *b* is always zero.

(e) If the inductor and capacitor each have some resistance, and these resistances aren't the same, then it is no longer true that $i_C + i_L = 0$ and the statement in part (d) isn't valid.

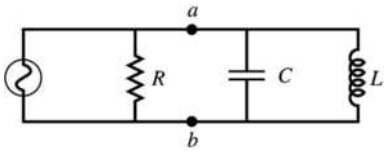

Figure 31.57

31.58. **IDENTIFY:** Refer to the results and the phasor diagram in Problem 31.56. The source voltage is applied across each parallel branch.

SET UP: $V = \sqrt{2}V_{\text{rms}} = 311\text{ V}$

EXECUTE: (a) $I_R = \dfrac{V}{R} = \dfrac{311\text{ V}}{400\ \Omega} = 0.778\text{ A}.$

(b) $I_C = V\omega C = (311\text{ V})(360\text{ rad/s})(6.00\times10^{-6}\text{ F}) = 0.672\text{ A}.$

(c) $\phi = \arctan\left(\dfrac{I_C}{I_R}\right) = \arctan\left(\dfrac{0.672\text{ A}}{0.778\text{ A}}\right) = 40.8°.$

(d) $I = \sqrt{I_R^2 + I_C^2} = \sqrt{(0.778\text{ A})^2 + (0.672\text{ A})^2} = 1.03\text{ A}.$

(e) Leads since $\phi > 0$.

EVALUATE: The phasor diagram shows that the current in the capacitor always leads the source voltage.

31.59. **IDENTIFY** and **SET UP:** Refer to the results and the phasor diagram in Problem 31.56. The source voltage is applied across each parallel branch.

EXECUTE: (a) $I_R = \dfrac{V}{R};\ I_C = V\omega C;\ I_L = \dfrac{V}{\omega L}.$

(b) The graph of each current versus ω is given in Figure 31.59a.

(c) $\omega \to 0 : I_C \to 0;\ I_L \to \infty.$ $\omega \to \infty : I_C \to \infty;\ I_L \to 0.$

At low frequencies, the current is not changing much so the inductor's back-emf doesn't "resist." This allows the current to pass fairly freely. However, the current in the capacitor goes to zero because it tends to "fill up" over the slow period, making it less effective at passing charge. At high frequency, the induced emf in the inductor resists the violent changes and passes little current. The capacitor never gets a chance to fill up so passes charge freely.

(d) $\omega = \dfrac{1}{\sqrt{LC}} = \dfrac{1}{\sqrt{(2.0\text{ H})(0.50\times10^{-6}\text{ F})}} = 1000\text{ rad/sec}$ and $f = 159\text{ Hz}.$ The phasor diagram is sketched in Figure 31.59b.

(e) $I = \sqrt{\left(\dfrac{V}{R}\right)^2 + \left(V\omega C - \dfrac{V}{\omega L}\right)^2}.$

$$I = \sqrt{\left(\frac{100\text{ V}}{200\ \Omega}\right)^2 + \left((100\text{ V})(1000\text{ s}^{-1})(0.50\times10^{-6}\text{ F}) - \frac{100\text{ V}}{(1000\text{ s}^{-1})(2.0\text{ H})}\right)^2} = 0.50\text{ A}$$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(f) At resonance $I_L = I_C = V\omega C = (100\text{ V})(1000\text{ s}^{-1})(0.50\times10^{-6}\text{ F}) = 0.0500\text{ A}$ and $I_R = \dfrac{V}{R} = \dfrac{100\text{ V}}{200\,\Omega} = 0.50\text{ A}$.

EVALUATE: At resonance $i_C = i_L = 0$ at all times and the current through the source equals the current through the resistor.

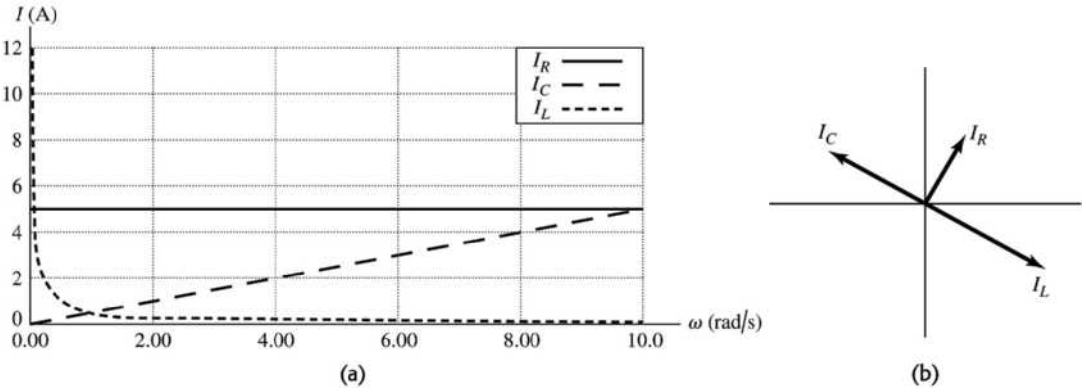

Figure 31.59

31.60. **IDENTIFY:** The circuit is in resonance, and we know R, L, C and V. We want the resonance angular frequency, the current amplitude through the source and resistor and the maximum energy stored in the inductor and capacitor.

SET UP: $\omega_0 = \dfrac{1}{\sqrt{LC}}$ and at resonance, $Z = R$. $I = \dfrac{V}{Z}$. $V_R = V_C = V_L = V$. $V_R = I_R R$, $V_C = I_C X_C$, $V_L = I_L X_L$. The maximum energy stored in the inductor is $U_L = \frac{1}{2}LI_L^2$. The maximum energy stored in the capacitor is $U_C = \frac{1}{2}CV_C^2$.

EXECUTE: **(a)** $\omega_0 = \dfrac{1}{\sqrt{(0.300\text{ H})(0.100\times10^{-6}\text{ F})}} = 5.77\times10^3\text{ rad/s}$.

(b) $I = \dfrac{V}{Z} = \dfrac{V}{R} = \dfrac{240\text{ V}}{100\,\Omega} = 2.40\text{ A}$.

(c) $I_R = \dfrac{V}{R} = 2.40\text{ A}$.

(d) $X_L = \omega L = (5.77\times10^3\text{ rad/s})(0.300\text{ H}) = 1.73\times10^3\,\Omega$.

$I_L = \dfrac{V}{X_L} = \dfrac{240\text{ V}}{1.73\times10^3\,\Omega} = 0.139\text{ A}$.

(e) $X_C = \dfrac{1}{\omega C} = \dfrac{1}{(5.77\times10^3\text{ rad/s})(0.100\times10^{-6}\text{ F})} = 1.73\times10^3\,\Omega$. $I_C = I_L = 0.139\text{ A}$.

(f) $U_L = \frac{1}{2}LI_L^2 = \frac{1}{2}(0.300\text{ H})(0.139\text{ A})^2 = 2.90\times10^{-3}\text{ J} = 2.90\text{ mJ}$.

$U_C = \frac{1}{2}CV_C^2 = \frac{1}{2}(0.100\times10^{-6}\text{ F})(240\text{ V})^2 = 2.90\times10^{-3}\text{ J} = 2.90\text{ mJ}$.

EVALUATE: The maximum energy stored in the inductor and capacitor is the same, but not at the same time.

31.61. **IDENTIFY:** The resonance angular frequency is $\omega_0 = \dfrac{1}{\sqrt{LC}}$ and the resonance frequency is $f_0 = \dfrac{1}{2\pi\sqrt{LC}}$.

SET UP: ω_0 is independent of R.

EXECUTE: **(a)** ω_0 (or f_0) depends only on L and C so change these quantities.

(b) To double ω_0, decrease L and C by multiplying each of them by $\frac{1}{2}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: Increasing L and C decreases the resonance frequency; decreasing L and C increases the resonance frequency.

31.62. **IDENTIFY:** The average power depends on the phase angle ϕ.

SET UP: The average power is $P_{\text{av}} = V_{\text{rms}} I_{\text{rms}} \cos\phi$, and the impedance is $Z = \sqrt{R^2 + \left(\omega L - \dfrac{1}{\omega C}\right)^2}$.

EXECUTE: **(a)** $P_{\text{av}} = V_{\text{rms}} I_{\text{rms}} \cos\phi = \frac{1}{2}(V_{\text{rms}} I_{\text{rms}})$, which gives $\cos\phi = \frac{1}{2}$, so $\phi = \pi/3 = 60°$.

$\tan\phi = (X_L - X_C)/R$, which gives $\tan 60° = (\omega L - 1/\omega C)/R$. Using $R = 75.0\ \Omega$, $L = 5.00$ mH and $C = 2.50\ \mu$F and solving for ω we get $\omega = 28760$ rad/s $= 28{,}800$ rad/s.

(b) $Z = \sqrt{R^2 + (X_L - X_C)^2}$, where $X_L = \omega L = (28{,}760 \text{ rad/s})(5.00 \text{ mH}) = 144\ \Omega$ and

$X_C = 1/\omega C = 1/[(28{,}760 \text{ rad/s})(2.50\ \mu\text{F})] = 13.9\ \Omega$, giving $Z = \sqrt{(75\ \Omega)^2 + (144\ \Omega - 13.9\ \Omega)^2} = 150\ \Omega$;

$I = V/Z = (15.0 \text{ V})/(150\ \Omega) = 0.100$ A and $P_{\text{av}} = \frac{1}{2} VI \cos\phi = \frac{1}{2}(15.0 \text{ V})(0.100 \text{ A})(1/2) = 0.375$ W.

EVALUATE: All this power is dissipated in the resistor because the average power delivered to the inductor and capacitor is zero.

31.63. **IDENTIFY** and **SET UP:** Eq. (31.19) allows us to calculate I and then Eq. (31.22) gives Z. Solve Eq. (31.21) for X_L.

EXECUTE: **(a)** $V_C = IX_C$ so $I = \dfrac{V_C}{X_C} = \dfrac{360 \text{ V}}{480\ \Omega} = 0.750$ A

(b) $V = IZ$ so $Z = \dfrac{V}{I} = \dfrac{120 \text{ V}}{0.750 \text{ A}} = 160\ \Omega$

(c) $Z^2 = R^2 + (X_L - X_C)^2$

$X_L - X_C = \pm\sqrt{Z^2 - R^2}$, so

$X_L = X_C \pm \sqrt{Z^2 - R^2} = 480\ \Omega \pm \sqrt{(160\ \Omega)^2 - (80.0\ \Omega)^2} = 480\ \Omega \pm 139\ \Omega$

$X_L = 619\ \Omega$ or $341\ \Omega$

(d) EVALUATE: $X_C = \dfrac{1}{\omega C}$ and $X_L = \omega L$. At resonance, $X_C = X_L$. As the frequency is lowered below the resonance frequency X_C increases and X_L decreases. Therefore, for $\omega < \omega_0$, $X_L < X_C$. So for $X_L = 341\ \Omega$ the angular frequency is less than the resonance angular frequency. ω is greater than ω_0 when $X_L = 619\ \Omega$. But at these two values of X_L, the magnitude of $X_L - X_C$ is the same so Z and I are the same. In one case $(X_L = 691\ \Omega)$ the source voltage leads the current and in the other $(X_L = 341\ \Omega)$ the source voltage lags the current.

31.64. **IDENTIFY** and **SET UP:** Calculate Z and $I = V/Z$.

EXECUTE: **(a)** For $\omega = 800$ rad/s:

$Z = \sqrt{R^2 + (\omega L - 1/\omega C)^2} = \sqrt{(500\ \Omega)^2 + ((800 \text{ rad/s})(2.0 \text{ H}) - 1/((800 \text{ rad/s})(5.0 \times 10^{-7} \text{ F})))^2}$. $Z = 1030\ \Omega$.

$I = \dfrac{V}{Z} = \dfrac{100 \text{ V}}{1030\ \Omega} = 0.0971$ A. $V_R = IR = (0.0971 \text{ A})(500\ \Omega) = 48.6$ V,

$V_C = \dfrac{1}{\omega C} = \dfrac{0.0971 \text{ A}}{(800 \text{ rad/s})(5.0 \times 10^{-7} \text{ F})} = 243$ V and $V_L = I\omega L = (0.0971 \text{ A})(800 \text{ rad/s})(2.00 \text{ H}) = 155$ V.

$\phi = \arctan\left(\dfrac{\omega L - 1/(\omega C)}{R}\right) = -60.9°$. The graph of each voltage versus time is given in Figure 31.64a.

(b) Repeating exactly the same calculations as above for $\omega = 1000$ rad/s:

$Z = R = 500\ \Omega$; $\phi = 0$; $I = 0.200$ A; $V_R = V = 100$ V; $V_C = V_L = 400$ V. The graph of each voltage versus time is given in Figure 31.64b.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(c) Repeating exactly the same calculations as part (a) for $\omega = 1250$ rad/s:
$Z = 1030\ \Omega$; $\phi = +60.9°$; $I = 0.0971$ A; $V_R = 48.6$ V; $V_C = 155$ V; $V_L = 243$ V. The graph of each voltage versus time is given in Figure 31.64c.

EVALUATE: The resonance frequency is $\omega_0 = \dfrac{1}{\sqrt{LC}} = \dfrac{1}{\sqrt{(2.00\ \text{H})(0.500\ \mu\text{F})}} = 1000$ rad/s. For $\omega < \omega_0$ the phase angle is negative and for $\omega > \omega_0$ the phase angle is positive.

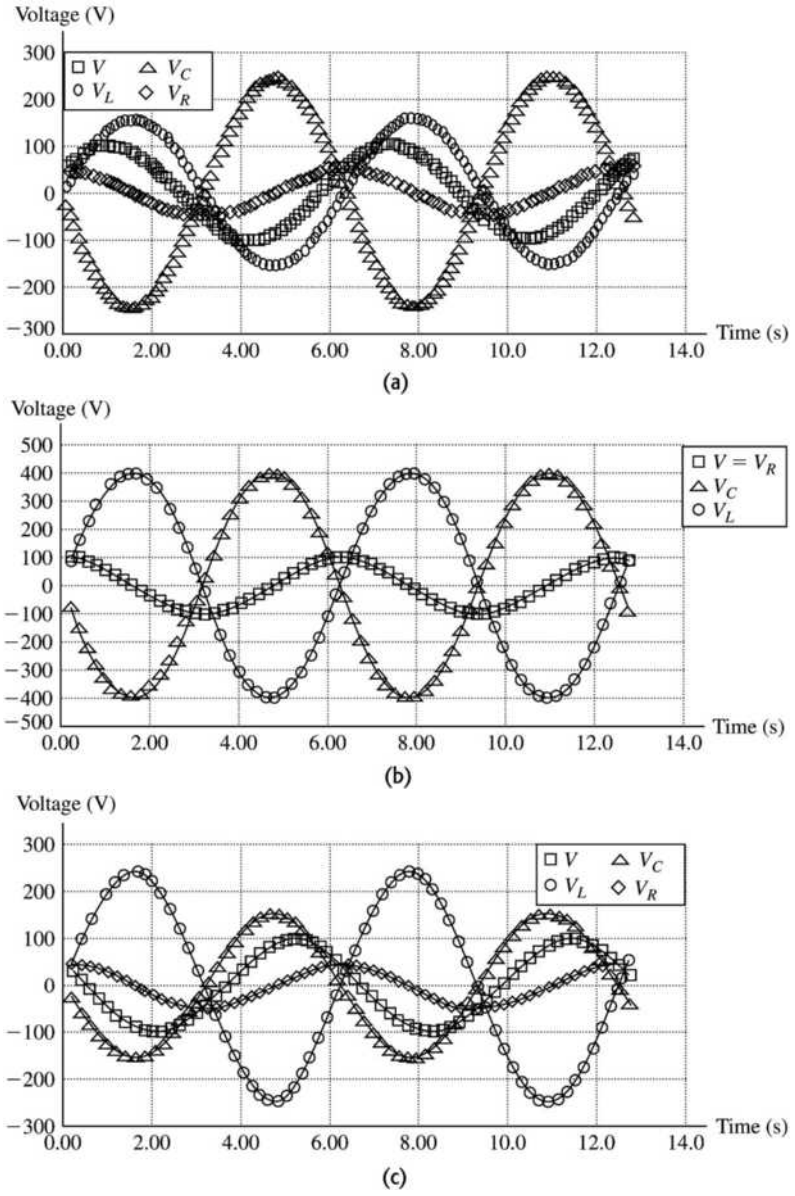

Figure 31.64

31.65. **IDENTIFY** and **SET UP:** Consider the cycle of the repeating current that lies between $t_1 = \tau/2$ and $t_2 = 3\tau/2$. In this interval $i = \dfrac{2I_0}{\tau}(t - \tau)$. $I_{\text{av}} = \dfrac{1}{t_2 - t_1}\displaystyle\int_{t_1}^{t_2} i\,dt$ and $I_{\text{rms}}^2 = \dfrac{1}{t_2 - t_1}\displaystyle\int_{t_1}^{t_2} i^2\,dt$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: $I_{\text{av}} = \dfrac{1}{t_2 - t_1}\int_{t_1}^{t_2} i\,dt = \dfrac{1}{\tau}\int_{\tau/2}^{3\tau/2} \dfrac{2I_0}{\tau}(t-\tau)\,dt = \dfrac{2I_0}{\tau^2}\left[\dfrac{1}{2}t^2 - \tau t\right]_{\tau/2}^{3\tau/2}$

$I_{\text{av}} = \left(\dfrac{2I_0}{\tau^2}\right)\left(\dfrac{9\tau^2}{8} - \dfrac{3\tau^2}{2} - \dfrac{\tau^2}{8} + \dfrac{\tau^2}{2}\right) = (2I_0)\tfrac{1}{8}(9-12-1+4) = \dfrac{I_0}{4}(13-13) = 0.$

$I_{\text{rms}}^2 = (I^2)_{\text{av}} = \dfrac{1}{t_2 - t_1}\int_{t_1}^{t_2} i^2 dt = \dfrac{1}{\tau}\int_{\tau/2}^{3\tau/2} \dfrac{4I_0^2}{\tau^2}(t-\tau)^2\,dt$

$I_{\text{rms}}^2 = \dfrac{4I_0^2}{\tau^3}\int_{\tau/2}^{3\tau/2}(t-\tau)^2\,dt = \dfrac{4I_0^2}{\tau^3}\left[\tfrac{1}{3}(t-\tau)^3\right]_{\tau/2}^{3\tau/2} = \dfrac{4I_0^2}{3\tau^3}\left[\left(\dfrac{\tau}{2}\right)^3 - \left(-\dfrac{\tau}{2}\right)^3\right]$

$I_{\text{rms}}^2 = \dfrac{I_0^2}{6}[1+1] = \tfrac{1}{3}I_0^2$

$I_{\text{rms}} = \sqrt{I_{\text{rms}}^2} = \dfrac{I_0}{\sqrt{3}}.$

EVALUATE: In each cycle the current has as much negative value as positive value and its average is zero. i^2 is always positive and its average is not zero. The relation between I_{rms} and the current amplitude for this current is different from that for a sinusoidal current (Eq. 31.4).

31.66. **IDENTIFY:** Apply $V_{\text{rms}} = I_{\text{rms}}Z$.

SET UP: $\omega_0 = \dfrac{1}{\sqrt{LC}}$ and $Z = \sqrt{R^2 + (X_L - X_C)^2}$.

EXECUTE: **(a)** $\omega_0 = \dfrac{1}{\sqrt{LC}} = \dfrac{1}{\sqrt{(1.80\text{ H})(9.00\times10^{-7}\text{ F})}} = 786\text{ rad/s}.$

(b) $Z = \sqrt{R^2 + (\omega L - 1/\omega C)^2}$.

$Z = \sqrt{(300\ \Omega)^2 + ((786\text{ rad/s})(1.80\text{ H}) - 1/((786\text{ rad/s})(9.00\times10^{-7}\text{ F})))^2} = 300\ \Omega.$

$I_{\text{rms-0}} = \dfrac{V_{\text{rms}}}{Z} = \dfrac{60\text{ V}}{300\ \Omega} = 0.200\text{ A}.$

(c) We want $I = \dfrac{1}{2}I_{\text{rms-0}} = \dfrac{V_{\text{rms}}}{Z} = \dfrac{V_{\text{rms}}}{\sqrt{R^2 + (\omega L - 1/\omega C)^2}}$. $R^2 + (\omega L - 1/\omega C)^2 = \dfrac{4V_{\text{rms}}^2}{I_{\text{rms-0}}^2}$.

$\omega^2 L^2 + \dfrac{1}{\omega^2 C^2} - \dfrac{2L}{C} + R^2 - \dfrac{4V_{\text{rms}}^2}{I_{\text{rms-0}}^2} = 0$ and $(\omega^2)^2 L^2 + \omega^2\left(R^2 - \dfrac{2L}{C} - \dfrac{4V_{\text{rms}}^2}{I_{\text{rms-0}}^2}\right) + \dfrac{1}{C^2} = 0.$

Substituting in the values for this problem, the equation becomes $(\omega^2)^2(3.24) + \omega^2(-4.27\times10^6) + 1.23\times10^{12} = 0$. Solving this quadratic equation in ω^2 we find $\omega^2 = 8.90\times10^5\text{ rad}^2/\text{s}^2$ or $4.28\times10^5\text{ rad}^2/\text{s}^2$ and $\omega = 943\text{ rad/s}$ or 654 rad/s.

(d) (i) $R = 300\ \Omega$, $I_{\text{rms-0}} = 0.200$ A, $|\omega_1 - \omega_2| = 289$ rad/s. (ii) $R = 30\ \Omega$, $I_{\text{rms-0}} = 2$A, $|\omega_1 - \omega_2| = 28$ rad/s. (iii) $R = 3\ \Omega$, $I_{\text{rms-0}} = 20$ A, $|\omega_1 - \omega_2| = 2.88$ rad/s.

EVALUATE: The width gets smaller as R gets smaller; $I_{\text{rms}-0}$ gets larger as R gets smaller.

31.67. **IDENTIFY:** The resonance frequency, the reactances, and the impedance all depend on the values of the circuit elements.

SET UP: The resonance frequency is $\omega_0 = 1/\sqrt{LC}$, the reactances are $X_L = \omega L$ and $X_C = 1/\omega C$, and the impedance is $Z = \sqrt{R^2 + (X_L - X_C)^2}$.

EXECUTE: **(a)** $\omega_0 = 1/\sqrt{LC}$ becomes $\dfrac{1}{\sqrt{2L}\sqrt{2C}} \to 1/2$, so ω_0 decreases by $\frac{1}{2}$.

(b) Since $X_L = \omega L$, if L is doubled, X_L increases by a factor of 2.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(c) Since $X_C = 1/\omega C$, doubling C decreases X_C by a factor of $\frac{1}{2}$.

(d) $Z = \sqrt{R^2 + (X_L - X_C)^2} \rightarrow Z = \sqrt{(2R)^2 + (2X_L - \frac{1}{2}X_C)^2}$, so Z does not change by a simple factor of 2 or $\frac{1}{2}$.

EVALUATE: The impedance does not change by a simple factor, even though the other quantities do.

31.68. **IDENTIFY:** At resonance, $Z = R$. $I = V/R$. $V_R = IR$, $V_C = IX_C$ and $V_L = IX_L$. $U_C = \frac{1}{2}CV_C^2$ and $U_L = \frac{1}{2}LI^2$.

SET UP: The amplitudes of each time-dependent quantity correspond to the maximum values of those quantities.

EXECUTE: **(a)** $I = \dfrac{V}{Z} = \dfrac{V}{\sqrt{R^2 + (\omega L - 1/\omega C)^2}}$. At resonance $\omega L = \dfrac{1}{\omega C}$ and $I_{\max} = \dfrac{V}{R}$.

(b) $V_C = IX_C = \dfrac{V}{R\omega_0 C} = \dfrac{V}{R}\sqrt{\dfrac{L}{C}}$.

(c) $V_L = IX_L = \dfrac{V}{R}\omega_0 L = \dfrac{V}{R}\sqrt{\dfrac{L}{C}}$.

(d) $U_C = \dfrac{1}{2}CV_C^2 = \dfrac{1}{2}C\dfrac{V^2}{R^2}\dfrac{L}{C} = \dfrac{1}{2}L\dfrac{V^2}{R^2}$.

(e) $U_L = \dfrac{1}{2}LI^2 = \dfrac{1}{2}L\dfrac{V^2}{R^2}$.

EVALUATE: At resonance $V_C = V_L$ and the maximum energy stored in the inductor equals the maximum energy stored in the capacitor.

31.69. **IDENTIFY:** $I = V/R$. $V_R = IR$, $V_C = IX_C$ and $V_L = IX_L$. $U_C = \frac{1}{2}CV_C^2$ and $U_L = \frac{1}{2}LI^2$.

SET UP: The amplitudes of each time-dependent quantity correspond to the maximum values of those quantities.

EXECUTE: $\omega = \dfrac{\omega_0}{2}$.

(a) $I = \dfrac{V}{Z} = \dfrac{V}{\sqrt{R^2 + \left(\dfrac{\omega_0 L}{2} - 2/\omega_0 C\right)^2}} = \dfrac{V}{\sqrt{R^2 + \dfrac{9}{4}\dfrac{L}{C}}}$.

(b) $V_C = IX_C = \dfrac{2}{\omega_0 C}\dfrac{V}{\sqrt{R^2 + \dfrac{9}{4}\dfrac{L}{C}}} = \sqrt{\dfrac{L}{C}}\dfrac{2V}{\sqrt{R^2 + \dfrac{9}{4}\dfrac{L}{C}}}$.

(c) $V_L = IX_L = \dfrac{\omega_0 L}{2}\dfrac{V}{\sqrt{R^2 + \dfrac{9}{4}\dfrac{L}{C}}} = \sqrt{\dfrac{L}{C}}\dfrac{V/2}{\sqrt{R^2 + \dfrac{9}{4}\dfrac{L}{C}}}$.

(d) $U_C = \dfrac{1}{2}CV_C^2 = \dfrac{2LV^2}{R^2 + \dfrac{9}{4}\dfrac{L}{C}}$.

(e) $U_L = \dfrac{1}{2}LI^2 = \dfrac{1}{2}\dfrac{LV^2}{R^2 + \dfrac{9}{4}\dfrac{L}{C}}$.

EVALUATE: For $\omega < \omega_0$, $V_C > V_L$ and the maximum energy stored in the capacitor is greater than the maximum energy stored in the inductor.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

31.70. **IDENTIFY:** $I = V/R$. $V_R = IR$, $V_C = IX_C$ and $V_L = IX_L$. $U_C = \frac{1}{2}CV_C^2$ and $U_L = \frac{1}{2}LI^2$.

SET UP: The amplitudes of each time dependent quantity correspond to the maximum values of those quantities.

EXECUTE: $\omega = 2\omega_0$.

(a) $I = \dfrac{V}{Z} = \dfrac{V}{\sqrt{R^2 + (2\omega_0 L - 1/2\omega_0 C)^2}} = \dfrac{V}{\sqrt{R^2 + \dfrac{9}{4}\dfrac{L}{C}}}$.

(b) $V_C = IX_C = \dfrac{1}{2\omega_0 C}\dfrac{V}{\sqrt{R^2 + \dfrac{9}{4}\dfrac{L}{C}}} = \sqrt{\dfrac{L}{C}}\dfrac{V/2}{\sqrt{R^2 + \dfrac{9}{4}\dfrac{L}{C}}}$.

(c) $V_L = IX_L = 2\omega_0 L\dfrac{V}{\sqrt{R^2 + \dfrac{9}{4}\dfrac{L}{C}}} = \sqrt{\dfrac{L}{C}}\dfrac{2V}{\sqrt{R^2 + \dfrac{9}{4}\dfrac{L}{C}}}$.

(d) $U_C = \dfrac{1}{2}CV_C^2 = \dfrac{LV^2}{8\sqrt{R^2 + \dfrac{9}{4}\dfrac{L}{C}}}$.

(e) $U_L = \dfrac{1}{2}LI^2 = \dfrac{LV^2}{2\sqrt{R^2 + \dfrac{9}{4}\dfrac{L}{C}}}$.

EVALUATE: For $\omega > \omega_0$, $V_L > V_C$ and the maximum energy stored in the inductor is greater than the maximum energy stored in the capacitor.

31.71. **IDENTIFY:** A transformer transforms voltages according to $\dfrac{V_2}{V_1} = \dfrac{N_2}{N_1}$. The effective resistance of a secondary circuit of resistance R is $R_{\text{eff}} = \dfrac{R}{(N_2/N_1)^2}$.

SET UP: $N_2 = 275$ and $V_1 = 25.0$ V.

EXECUTE: **(a)** $V_2 = V_1(N_2/N_1) = (25.0\text{ V})(834/275) = 75.8$ V

(b) $R_{\text{eff}} = \dfrac{R}{(N_2/N_1)^2} = \dfrac{125\,\Omega}{(834/275)^2} = 13.6\,\Omega$

EVALUATE: The voltage across the secondary is greater than the voltage across the primary since $N_2 > N_1$. The effective load resistance of the secondary is less than the resistance R connected across the secondary.

31.72. **IDENTIFY:** $P_{\text{av}} = V_{\text{rms}}I_{\text{rms}}\cos\phi$ and $I_{\text{rms}} = \dfrac{V_{\text{rms}}}{Z}$. Calculate Z. $R = Z\cos\phi$.

SET UP: $f = 50.0$ Hz and $\omega = 2\pi f$. The power factor is $\cos\phi$.

EXECUTE: **(a)** $P_{\text{av}} = \dfrac{V_{\text{rms}}^2}{Z}\cos\phi$. $Z = \dfrac{V_{\text{rms}}^2\cos\phi}{P_{\text{av}}} = \dfrac{(120\text{ V})^2(0.560)}{(220\text{ W})} = 36.7\,\Omega$.

$R = Z\cos\phi = (36.7\,\Omega)(0.560) = 20.6\,\Omega$.

(b) $Z = \sqrt{R^2 + X_L^2}\cdot X_L = \sqrt{Z^2 - R^2} = \sqrt{(36.7\,\Omega)^2 - (20.6\,\Omega)^2} = 30.4\,\Omega$. But $\phi = 0$ is at resonance, so the inductive and capacitive reactances equal each other. Therefore we need to add $X_C = 30.4\,\Omega$. $X_C = \dfrac{1}{\omega C}$ therefore gives $C = \dfrac{1}{\omega X_C} = \dfrac{1}{2\pi f X_C} = \dfrac{1}{2\pi(50.0\text{ Hz})(30.4\,\Omega)} = 1.05\times10^{-4}$ F.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(c) At resonance, $P_{\text{av}} = \dfrac{V^2}{R} = \dfrac{(120\ \text{V})^2}{20.6\ \Omega} = 699\ \text{W}$.

EVALUATE: $P_{\text{av}} = I_{\text{rms}}^2 R$ and I_{rms} is maximum at resonance, so the power drawn from the line is maximum at resonance.

31.73. **IDENTIFY:** $p_R = i^2 R$. $p_L = iL\dfrac{di}{dt}$. $p_C = \dfrac{q}{C} i$.

SET UP: $i = I\cos\omega t$

EXECUTE: **(a)** $p_R = i^2 R = I^2\cos^2(\omega t)R = V_R I\cos^2(\omega t) = \dfrac{1}{2}V_R I(1+\cos(2\omega t))$.

$P_{\text{av}}(R) = \dfrac{1}{T}\int_0^T p_R dt = \dfrac{V_R I}{2T}\int_0^T (1+\cos(2\omega t))dt = \dfrac{V_R I}{2T}[t]_0^T = \frac{1}{2}V_R I$.

(b) $p_L = Li\dfrac{di}{dt} = -\omega L I^2\cos(\omega t)\sin(\omega t) = -\frac{1}{2}V_L I\sin(2\omega t)$. But $\int_0^T \sin(2\omega t)dt = 0 \Rightarrow P_{\text{av}}(L) = 0$.

(c) $p_C = \dfrac{q}{C} i = v_C i = V_C I\sin(\omega t)\cos(\omega t) = \frac{1}{2}V_C I\sin(2\omega t)$. But $\int_0^T \sin(2\omega t)dt = 0 \Rightarrow P_{\text{av}}(C) = 0$.

(d) $p = p_R + p_L + p_c = V_R I\cos^2(\omega t) - \frac{1}{2}V_L I\sin(2\omega t) + \frac{1}{2}V_C I\sin(2\omega t)$ and

$p = I\cos(\omega t)(V_R\cos(\omega t) - V_L\sin(\omega t) + V_C\sin(\omega t))$. But $\cos\phi = \dfrac{V_R}{V}$ and $\sin\phi = \dfrac{V_L - V_C}{V}$, so

$p = VI\cos(\omega t)(\cos\phi\cos(\omega t) - \sin\phi\sin(\omega t))$, at any instant of time.

EVALUATE: At an instant of time the energy stored in the capacitor and inductor can be changing, but there is no net consumption of electrical energy in these components.

31.74. **IDENTIFY:** $V_L = IX_L$. $\dfrac{dV_L}{d\omega} = 0$ at the ω where V_L is a maximum. $V_C = IX_C$. $\dfrac{dV_C}{d\omega} = 0$ at the ω where V_C is a maximum.

SET UP: Problem 31.53 shows that $I = \dfrac{V}{\sqrt{R^2 + (\omega L - 1/\omega C)^2}}$.

EXECUTE: **(a)** $V_R = \text{maximum}$ when $V_C = V_L \Rightarrow \omega = \omega_0 = \dfrac{1}{\sqrt{LC}}$.

(b) $V_L = \text{maximum}$ when $\dfrac{dV_L}{d\omega} = 0$. Therefore: $\dfrac{dV_L}{d\omega} = 0 = \dfrac{d}{d\omega}\left(\dfrac{V\omega L}{\sqrt{R^2 + (\omega L - 1/\omega C)^2}}\right)$.

$0 = \dfrac{VL}{\sqrt{R^2 + (\omega L - 1/\omega C)^2}} - \dfrac{V\omega^2 L(L - 1/\omega^2 C)(L + 1/\omega^2 C)}{(R^2 + (\omega L - 1/\omega C)^2)^{3/2}}$. $R^2 + (\omega L - 1/\omega C)^2 = \omega^2(L^2 - 1/\omega^4 C^2)$.

$R^2 + \dfrac{1}{\omega^2 C^2} - \dfrac{2L}{C} = -\dfrac{1}{\omega^2 C^2}$. $\dfrac{1}{\omega^2} = LC - \dfrac{R^2 C^2}{2}$ and $\omega = \dfrac{1}{\sqrt{LC - R^2 C^2/2}}$.

(c) $V_C = \text{maximum}$ when $\dfrac{dV_C}{d\omega} = 0$. Therefore: $\dfrac{dV_C}{d\omega} = 0 = \dfrac{d}{d\omega}\left(\dfrac{V}{\omega C\sqrt{R^2 + (\omega L - 1/\omega C)^2}}\right)$.

$0 = -\dfrac{V}{\omega^2 C\sqrt{R^2 + (\omega L - 1/\omega C)^2}} - \dfrac{V(L - 1/\omega^2 C)(L + 1/\omega^2 C)}{C(R^2 + (\omega L - 1/\omega C)^2)^{3/2}}$. $R^2 + (\omega L - 1/\omega C)^2 = -\omega^2(L^2 - 1/\omega^4 C^2)$.

$R^2 + \omega^2 L^2 - \dfrac{2L}{C} = -\omega^2 L^2$ and $\omega = \sqrt{\dfrac{1}{LC} - \dfrac{R^2}{2L^2}}$.

$R^2 + \omega^2 L^2 - \dfrac{2L}{C} = -\omega^2 L^2$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: V_L is maximum at a frequency greater than the resonance frequency and V_C is a maximum at a frequency less than the resonance frequency. These frequencies depend on R, as well as on L and on C.

31.75. **IDENTIFY:** Follow the steps specified in the problem.

SET UP: In part (a) use Eq. (31.23) to calculate Z and then $I = V/Z$ ϕ is given by Eq. (31.24). In part (b) let $Z = R + iX$.

EXECUTE: **(a)** From the current phasors we know that $Z = \sqrt{R^2 + (\omega L - 1/\omega C)^2}$.

$$Z = \sqrt{(400\ \Omega)^2 + \left((1000\ \text{rad/s})(0.50\ \text{H}) - \frac{1}{(1000\ \text{rad/s})(1.25\times10^{-6}\ \text{F})}\right)^2} = 500\ \Omega.$$

$$I = \frac{V}{Z} = \frac{200\ \text{V}}{500\ \Omega} = 0.400\ \text{A}.$$

(b) $\phi = \arctan\left(\frac{\omega L - 1/(\omega C)}{R}\right)$. $\phi = \arctan\left(\frac{(1000\ \text{rad/s})(0.500\ \text{H}) - 1/(1000\ \text{rad/s})(1.25\times10^{-6}\ \text{F})}{400\ \Omega}\right) = +36.9°$

(c) $Z_{\text{cpx}} = R + i\left(\omega L - \frac{1}{\omega C}\right)$. $Z_{\text{cpx}} = 400\ \Omega - i\left((1000\ \text{rad/s})(0.50\ \text{H}) - \frac{1}{(1000\ \text{rad/s})(1.25\times10^{-6}\ \text{F})}\right) =$

$400\ \Omega - 300\ \Omega i$.

$$Z = \sqrt{(400\ \Omega)^2 + (-300\ \Omega)^2} = 500\ \Omega.$$

(d) $I_{\text{cpx}} = \frac{V}{Z_{\text{cpx}}} = \frac{200\ \text{V}}{(400 - 300i)\ \Omega} = \left(\frac{8+6i}{25}\right)\text{A} = (0.320\ \text{A}) + (0.240\ \text{A})i$. $I = \sqrt{\left(\frac{8+6i}{25}\right)\left(\frac{8-6i}{25}\right)}\ \text{A} = 0.400\ \text{A}.$

(e) $\tan\phi = \frac{\text{Im}(I_{\text{cpx}})}{\text{Re}(I_{\text{cpx}})} = \frac{6/25}{8/25} = 0.75 \Rightarrow \phi = +36.9°.$

(f) $V_{R\text{cpx}} = I_{\text{cpx}}R = \left(\frac{8+6i}{25}\right)(400\ \Omega) = (128 + 96i)\text{V}.$

$$V_{L\text{cpx}} = iI_{\text{cpx}}\omega L = i\left(\frac{8+6i}{25}\right)(1000\ \text{rad/s})(0.500\ \text{H}) = (-120 + 160i)\text{V}.$$

$$V_{C\text{cpx}} = i\frac{I_{\text{cpx}}}{\omega C} = i\left(\frac{8+6i}{25}\right)\frac{1}{(1000\ \text{rad/s})(1.25\times10^{-6}\ \text{F})} = (+192 - 256i)\text{V}.$$

(g) $V_{\text{cpx}} = V_{R\text{cpx}} + V_{L\text{cpx}} + V_{C\text{cpx}} = (128 + 96i)\ \text{V} + (-120 + 160i)\text{V} + (192 - 256i)\ \text{V} = 200\ \text{V}.$

EVALUATE: Both approaches yield the same value for I and for ϕ.

32

ELECTROMAGNETIC WAVES

32.1. **IDENTIFY:** Since the speed is constant, distance $x = ct$.

SET UP: The speed of light is $c = 3.00\times10^8$ m/s. $1\text{ y} = 3.156\times10^7$ s.

EXECUTE: **(a)** $t = \dfrac{x}{c} = \dfrac{3.84\times10^8\text{ m}}{3.00\times10^8\text{ m/s}} = 1.28\text{ s}$

(b) $x = ct = (3.00\times10^8\text{ m/s})(8.61\text{ y})(3.156\times10^7\text{ s/y}) = 8.15\times10^{16}\text{ m} = 8.15\times10^{13}\text{ km}$

EVALUATE: The speed of light is very great. The distance between stars is very large compared to terrestrial distances.

32.2. **IDENTIFY:** Find the direction of propagation of an electromagnetic wave if we know the directions of the electric and magnetic fields.

SET UP: The direction of propagation of an electromagnetic wave is in the direction of $\vec{E}\times\vec{B}$, which is related to the directions of $\vec{E}$ and $\vec{B}$ according to the right-hand rule for the cross product. The directions of $\vec{E}$ and $\vec{B}$ in each case are shown in Figures 32.2a-d.

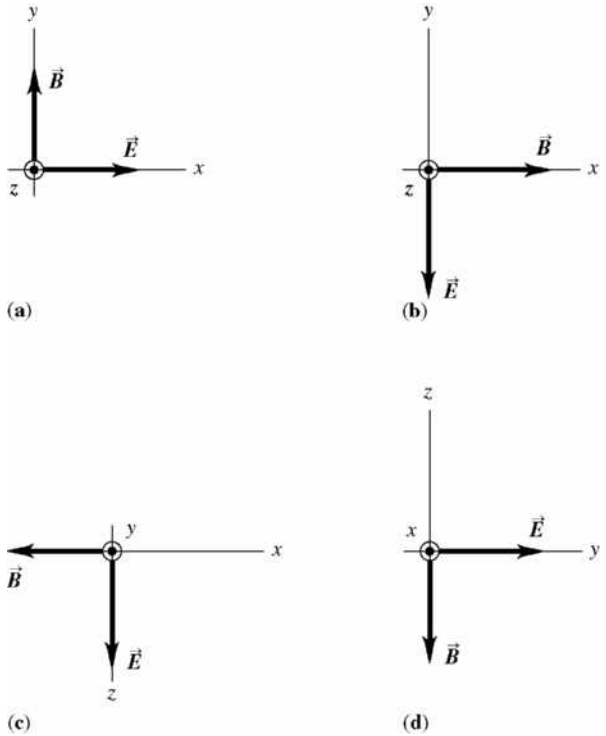

Figure 32.2

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: **(a)** The wave is propagating in the $+z$ direction.

(b) $+z$ direction.

(c) $-y$ direction.

(d) $-x$ direction.

EVALUATE: In each case, the direction of propagation is perpendicular to the plane of $\vec{E}$ and $\vec{B}$.

32.3. **IDENTIFY:** $E_{\max} = cB_{\max}$. $\vec{E} \times \vec{B}$ is in the direction of propagation.

SET UP: $c = 3.00 \times 10^8$ m/s. $E_{\max} = 4.00$ V/m.

EXECUTE: $B_{\max} = E_{\max}/c = 1.33 \times 10^{-8}$ T. For $\vec{E}$ in the $+x$-direction, $\vec{E} \times \vec{B}$ is in the $+z$-direction when $\vec{B}$ is in the $+y$-direction.

EVALUATE: $\vec{E}$, $\vec{B}$ and the direction of propagation are all mutually perpendicular.

32.4. **IDENTIFY** and **SET UP:** The direction of propagation is given by $\vec{E} \times \vec{B}$.

EXECUTE: **(a)** $\hat{S} = \hat{i} \times (-\hat{j}) = -\hat{k}$.

(b) $\hat{S} = \hat{j} \times \hat{i} = -\hat{k}$.

(c) $\hat{S} = (-\hat{k}) \times (-\hat{i}) = \hat{j}$.

(d) $\hat{S} = \hat{i} \times (-\hat{k}) = \hat{j}$.

EVALUATE: In each case the directions of $\vec{E}$, $\vec{B}$ and the direction of propagation are all mutually perpendicular.

32.5. **IDENTIFY:** Knowing the wavelength and speed of x rays, find their frequency, period, and wave number. All electromagnetic waves travel through vacuum at the speed of light.

SET UP: $c = 3.00 \times 10^8$ m/s. $c = f\lambda$. $T = \dfrac{1}{f}$. $k = \dfrac{2\pi}{\lambda}$.

EXECUTE: $f = \dfrac{c}{\lambda} = \dfrac{3.0 \times 10^8 \text{ m/s}}{0.10 \times 10^{-9} \text{ m}} = 3.0 \times 10^{18}$ Hz,

$T = \dfrac{1}{f} = \dfrac{1}{3.0 \times 10^{18} \text{ Hz}} = 3.3 \times 10^{-19}$ s, $k = \dfrac{2\pi}{\lambda} = \dfrac{2\pi}{0.10 \times 10^{-9} \text{ m}} = 6.3 \times 10^{10}$ m^{-1}.

EVALUATE: The frequency of the x rays is much higher than the frequency of visible light, so their period is much shorter.

32.6. **IDENTIFY:** $c = f\lambda$ and $k = \dfrac{2\pi}{\lambda}$.

SET UP: $c = 3.00 \times 10^8$ m/s.

EXECUTE: **(a)** $f = \dfrac{c}{\lambda}$. UVA: 7.50×10^{14} Hz to 9.38×10^{14} Hz. UVB: 9.38×10^{14} Hz to 1.07×10^{15} Hz.

(b) $k = \dfrac{2\pi}{\lambda}$. UVA: 1.57×10^7 rad/m to 1.96×10^7 rad/m. UVB: 1.96×10^7 rad/m to 2.24×10^7 rad/m.

EVALUATE: Larger λ corresponds to smaller f and k.

32.7. **IDENTIFY:** $c = f\lambda$. $E_{\max} = cB_{\max}$. $k = 2\pi/\lambda$. $\omega = 2\pi f$.

SET UP: Since the wave is traveling in empty space, its wave speed is $c = 3.00 \times 10^8$ m/s.

EXECUTE: **(a)** $f = \dfrac{c}{\lambda} = \dfrac{3.00 \times 10^8 \text{ m/s}}{432 \times 10^{-9} \text{ m}} = 6.94 \times 10^{14}$ Hz

(b) $E_{\max} = cB_{\max} = (3.00 \times 10^8 \text{ m/s})(1.25 \times 10^{-6} \text{ T}) = 375$ V/m

(c) $k = \dfrac{2\pi}{\lambda} = \dfrac{2\pi \text{ rad}}{432 \times 10^{-9} \text{ m}} = 1.45 \times 10^7$ rad/m. $\omega = (2\pi \text{ rad})(6.94 \times 10^{14} \text{ Hz}) = 4.36 \times 10^{15}$ rad/s.

$E = E_{\max} \cos(kx - \omega t) = (375 \text{ V/m}) \cos([1.45 \times 10^7 \text{ rad/m}]x - [4.36 \times 10^{15} \text{ rad/s}]t)$

$B = B_{\max} \cos(kx - \omega t) = (1.25 \times 10^{-6} \text{ T}) \cos([1.45 \times 10^7 \text{ rad/m}]x - [4.36 \times 10^{15} \text{ rad/s}]t)$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: The $\cos(kx-\omega t)$ factor is common to both the electric and magnetic field expressions, since these two fields are in phase.

32.8. **IDENTIFY:** $c=f\lambda$. $E_{\max}=cB_{\max}$. Apply Eqs. (32.17) and (32.19).

SET UP: The speed of the wave is $c=3.00\times10^8$ m/s.

EXECUTE: **(a)** $f=\dfrac{c}{\lambda}=\dfrac{3.00\times10^8\text{ m/s}}{435\times10^{-9}\text{ m}}=6.90\times10^{14}$ Hz

(b) $B_{\max}=\dfrac{E_{\max}}{c}=\dfrac{2.70\times10^{-3}\text{ V/m}}{3.00\times10^8\text{ m/s}}=9.00\times10^{-12}$ T

(c) $k=\dfrac{2\pi}{\lambda}=1.44\times10^7$ rad/m. $\omega=2\pi f=4.34\times10^{15}$ rad/s. If $\vec{E}(z,t)=\hat{i}E_{\max}\cos(kz+\omega t)$, then $\vec{B}(z,t)=-\hat{j}B_{\max}\cos(kz+\omega t)$, so that $\vec{E}\times\vec{B}$ will be in the $-\hat{k}$ direction.

$\vec{E}(z,t)=\hat{i}(2.70\times10^{-3}\text{ V/m})\cos([1.44\times10^7\text{ rad/m})z+[4.34\times10^{15}\text{ rad/s}]t)$ and

$\vec{B}(z,t)=-\hat{j}(9.00\times10^{-12}\text{ T})\cos([1.44\times10^7\text{ rad/m})z+[4.34\times10^{15}\text{ rad/s}]t)$.

EVALUATE: The directions of $\vec{E}$ and $\vec{B}$ and of the propagation of the wave are all mutually perpendicular. The argument of the cosine is $kz+\omega t$ since the wave is traveling in the $-z$-direction. Waves for visible light have very high frequencies.

32.9. **IDENTIFY:** Electromagnetic waves propagate through air at essentially the speed of light. Therefore, if we know their wavelength, we can calculate their frequency or vice versa.

SET UP: The wave speed is $c=3.00\times10^8$ m/s. $c=f\lambda$.

EXECUTE: **(a)** (i) $f=\dfrac{c}{\lambda}=\dfrac{3.00\times10^8\text{ m/s}}{5.0\times10^3\text{ m}}=6.0\times10^4$ Hz.

(ii) $f=\dfrac{3.00\times10^8\text{ m/s}}{5.0\times10^{-6}\text{ m}}=6.0\times10^{13}$ Hz.

(iii) $f=\dfrac{3.00\times10^8\text{ m/s}}{5.0\times10^{-9}\text{ m}}=6.0\times10^{16}$ Hz.

(b) (i) $\lambda=\dfrac{c}{f}=\dfrac{3.00\times10^8\text{ m/s}}{6.50\times10^{21}\text{ Hz}}=4.62\times10^{-14}\text{ m}=4.62\times10^{-5}$ nm.

(ii) $\lambda=\dfrac{3.00\times10^8\text{ m/s}}{590\times10^3\text{ Hz}}=508\text{ m}=5.08\times10^{11}$ nm.

EVALUATE: Electromagnetic waves cover a huge range in frequency and wavelength.

32.10. **IDENTIFY:** For an electromagnetic wave propagating in the negative x direction, $E=E_{\max}\cos(kx+\omega t)$. $\omega=2\pi f$ and $k=\dfrac{2\pi}{\lambda}$. $T=\dfrac{1}{f}$. $E_{\max}=cB_{\max}$.

SET UP: $E_{\max}=375$ V/m, $k=1.99\times10^7$ rad/m and $\omega=5.97\times10^{15}$ rad/s.

EXECUTE: **(a)** $B_{\max}=\dfrac{E_{\max}}{c}=1.25\,\mu$T.

(b) $f=\dfrac{\omega}{2\pi}=9.50\times10^{14}$ Hz. $\lambda=\dfrac{2\pi}{k}=3.16\times10^{-7}\text{ m}=316$ nm. $T=\dfrac{1}{f}=1.05\times10^{-15}$ s. This wavelength is too short to be visible.

(c) $c=f\lambda=(9.50\times10^{14}\text{ Hz})(3.16\times10^{-7}\text{ m})=3.00\times10^8$ m/s. This is what the wave speed should be for an electromagnetic wave propagating in vacuum.

EVALUATE: $c=f\lambda=\left(\dfrac{\omega}{2\pi}\right)\left(\dfrac{2\pi}{k}\right)=\dfrac{\omega}{k}$ is an alternative expression for the wave speed.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

32.11. **IDENTIFY** and **SET UP:** Compare the $\vec{E}(y,t)$ given in the problem to the general form given by Eq. (32.17). Use the direction of propagation and of $\vec{E}$ to find the direction of $\vec{B}$.

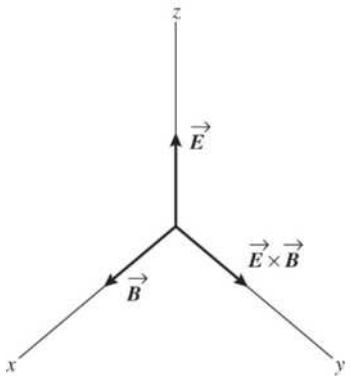
(a) EXECUTE: The equation for the electric field contains the factor $\cos(ky-\omega t)$ so the wave is traveling in the $+y$-direction.

(b) $\vec{E}(y,t)=(3.10\times10^5\ \text{V/m})\hat{k}\cos[ky-(12.65\times10^{12}\ \text{rad/s})t]$

Comparing to Eq. (32.17) gives $\omega=12.65\times10^{12}$ rad/s

$$\omega=2\pi f=\frac{2\pi c}{\lambda}\ \text{so}\ \lambda=\frac{2\pi c}{\omega}=\frac{2\pi(2.998\times10^8\ \text{m/s})}{(12.65\times10^{12}\ \text{rad/s})}=1.49\times10^{-4}\ \text{m}$$

(c)



$\vec{E}\times\vec{B}$ must be in the $+y$-direction (the direction in which the wave is traveling). When $\vec{E}$ is in the $+z$-direction then $\vec{B}$ must be in the $+x$-direction, as shown in Figure 32.11.

Figure 32.11

$$k=\frac{2\pi}{\lambda}=\frac{\omega}{c}=\frac{12.65\times10^{12}\ \text{rad/s}}{2.998\times10^8\ \text{m/s}}=4.22\times10^4\ \text{rad/m}$$

$$E_{\max}=3.10\times10^5\ \text{V/m}$$

Then $B_{\max}=\dfrac{E_{\max}}{c}=\dfrac{3.10\times10^5\ \text{V/m}}{2.998\times10^8\ \text{m/s}}=1.03\times10^{-3}\ \text{T}$

Using Eq. (32.17) and the fact that $\vec{B}$ is in the $+\hat{i}$ direction when $\vec{E}$ is in the $+\hat{k}$ direction,

$\vec{B}=+(1.03\times10^{-3}\ \text{T})\hat{i}\cos[(4.22\times10^4\ \text{rad/m})y-(12.65\times10^{12}\ \text{rad/s})t]$

EVALUATE: $\vec{E}$ and $\vec{B}$ are perpendicular and oscillate in phase.

32.12. **IDENTIFY:** Apply Eqs. (32.17) and (32.19). $f=c/\lambda$ and $k=2\pi/\lambda$.

SET UP: $B_y(x,t)=-B_{\max}\cos(kx+\omega t)$.

EXECUTE: **(a)** The phase of the wave is given by $kx+\omega t$, so the wave is traveling in the $-x$ direction.

(b) $k=\dfrac{2\pi}{\lambda}=\dfrac{2\pi f}{c}$. $f=\dfrac{kc}{2\pi}=\dfrac{(1.38\times10^4\ \text{rad/m})(3.0\times10^8\ \text{m/s})}{2\pi}=6.59\times10^{11}\ \text{Hz}$.

(c) Since the magnetic field is in the $-y$-direction, and the wave is propagating in the $-x$-direction, then the electric field is in the $-z$-direction so that $\vec{E}\times\vec{B}$ will be in the $-x$-direction.

$\vec{E}(x,t)=+cB(x,t)\hat{k}=-cB_{\max}\cos(kx+\omega t)\hat{k}$.

$\vec{E}(x,t)=-(c(8.25\times10^{-9}\ \text{T}))\cos((1.38\times10^4\ \text{rad/m})x+(4.14\times10^{12}\ \text{rad/s})t)\hat{k}$.

$\vec{E}(x,t)=-(2.48\ \text{V/m})\cos((1.38\times10^4\ \text{rad/m})x+(4.14\times10^{12}\ \text{rad/s})t)\hat{k}$.

EVALUATE: $\vec{E}$ and $\vec{B}$ have the same phase and are in perpendicular directions.

32.13. **IDENTIFY** and **SET UP:** $c = f\lambda$ allows calculation of λ. $k = 2\pi/\lambda$ and $\omega = 2\pi f$. Eq. (32.18) relates the electric and magnetic field amplitudes.

EXECUTE: **(a)** $c = f\lambda$ so $\lambda = \dfrac{c}{f} = \dfrac{2.998\times10^{8}\text{ m/s}}{830\times10^{3}\text{ Hz}} = 361\text{ m}$

(b) $k = \dfrac{2\pi}{\lambda} = \dfrac{2\pi\text{ rad}}{361\text{ m}} = 0.0174\text{ rad/m}$

(c) $\omega = 2\pi f = (2\pi)(830\times10^{3}\text{ Hz}) = 5.22\times10^{6}\text{ rad/s}$

(d) Eq. (32.18): $E_{\max} = cB_{\max} = (2.998\times10^{8}\text{ m/s})(4.82\times10^{-11}\text{ T}) = 0.0144\text{ V/m}$

EVALUATE: This wave has a very long wavelength; its frequency is in the AM radio braodcast band. The electric and magnetic fields in the wave are very weak.

32.14. **IDENTIFY:** Apply Eq. (32.21). $E_{\max} = cB_{\max}$. $v = f\lambda$.

SET UP: $K = 3.64$. $K_{\text{m}} = 5.18$

EXECUTE: **(a)** $v = \dfrac{c}{\sqrt{KK_{\text{m}}}} = \dfrac{(3.00\times10^{8}\text{m/s})}{\sqrt{(3.64)(5.18)}} = 6.91\times10^{7}\text{ m/s.}$

(b) $\lambda = \dfrac{v}{f} = \dfrac{6.91\times10^{7}\text{m/s}}{65.0\text{ Hz}} = 1.06\times10^{6}\text{ m.}$

(c) $B_{\max} = \dfrac{E_{\max}}{v} = \dfrac{7.20\times10^{-3}\text{ V/m}}{6.91\times10^{7}\text{ m/s}} = 1.04\times10^{-10}\text{ T.}$

EVALUATE: The wave travels slower in this material than in air.

32.15. **IDENTIFY** and **SET UP:** $v = f\lambda$ relates frequency and wavelength to the speed of the wave. Use Eq. (32.22) to calculate n and K.

EXECUTE: **(a)** $\lambda = \dfrac{v}{f} = \dfrac{2.17\times10^{8}\text{ m/s}}{5.70\times10^{14}\text{ Hz}} = 3.81\times10^{-7}\text{ m}$

(b) $\lambda = \dfrac{c}{f} = \dfrac{2.998\times10^{8}\text{ m/s}}{5.70\times10^{14}\text{ Hz}} = 5.26\times10^{-7}\text{ m}$

(c) $n = \dfrac{c}{v} = \dfrac{2.998\times10^{8}\text{ m/s}}{2.17\times10^{8}\text{ m/s}} = 1.38$

(d) $n = \sqrt{KK_{\text{m}}} \approx \sqrt{K}$ so $K = n^2 = (1.38)^2 = 1.90$

EVALUATE: In the material $v < c$ and f is the same, so λ is less in the material than in air. $v < c$ always, so n is always greater than unity.

32.16. **IDENTIFY:** We want to find the amount of energy given to each receptor cell and the amplitude of the magnetic field at the cell.

SET UP: Intensity is average power per unit area and power is energy per unit time.

$I = \frac{1}{2}\epsilon_0 cE_{\max}^2$, $I = P/A$, and $E_{\max} = cB_{\max}$.

EXECUTE: **(a)** For the beam, the energy is $U = Pt = (2.0\times10^{12}\text{ W})(4.0\times10^{-9}\text{ s}) = 8.0\times10^{3}\text{ J} = 8.0\text{ kJ}$. This energy is spread uniformly over 100 cells, so the energy given to each cell is 80 J.

(b) The cross-sectional area of each cell is $A = \pi r^2$, with $r = 2.5\times10^{-6}$ m.

$$I = \frac{P}{A} = \frac{2.0\times10^{12}\text{ W}}{(100)\pi(2.5\times10^{-6}\text{ m})^2} = 1.0\times10^{21}\text{ W/m}^2.$$

(c) $E_{\max} = \sqrt{\dfrac{2I}{\epsilon_0 c}} = \sqrt{\dfrac{2(1.0\times10^{21}\text{ W/m}^2)}{(8.85\times10^{-12}\text{ C}^2/\text{N}\cdot\text{m}^2)(3.00\times10^{8}\text{ m/s})}} = 8.7\times10^{11}\text{ V/m.}$

$$B_{\max} = \frac{E_{\max}}{c} = 2.9\times10^{3}\text{ T.}$$

EVALUATE: Both the electric field and magnetic field are very strong compared to ordinary fields.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

32.17. **IDENTIFY:** $I = P/A$. $I = \frac{1}{2}\epsilon_0 c E_{\max}^2$. $E_{\max} = cB_{\max}$.

SET UP: The surface area of a sphere of radius r is $A = 4\pi r^2 \cdot \epsilon_0 = 8.85\times10^{-12}$ C^2/N$\cdot$m^2.

EXECUTE: **(a)** $I = \dfrac{P}{A} = \dfrac{(0.05)(75\text{ W})}{4\pi(3.0\times10^{-2}\text{ m})^2} = 330\text{ W/m}^2$.

(b) $E_{\max} = \sqrt{\dfrac{2I}{\epsilon_0 c}} = \sqrt{\dfrac{2(330\text{ W/m}^2)}{(8.85\times10^{-12}\text{ C}^2/\text{N}\cdot\text{m}^2)(3.00\times10^8\text{ m/s})}} = 500\text{ V/m}$.

$B_{\max} = \dfrac{E_{\max}}{c} = 1.7\times10^{-6}\text{ T} = 1.7\ \mu\text{T}$.

EVALUATE: At the surface of the bulb the power radiated by the filament is spread over the surface of the bulb. Our calculation approximates the filament as a point source that radiates uniformly in all directions.

32.18. **IDENTIFY:** The intensity of the electromagnetic wave is given by Eq. (32.29): $I = \frac{1}{2}\epsilon_0 c E_{\max}^2 = \epsilon_0 c E_{\text{rms}}^2$.

The total energy passing through a window of area A during a time t is IAt.

SET UP: $\epsilon_0 = 8.85\times10^{-12}$ F/m

EXECUTE: Energy $= \epsilon_0 c E_{\text{rms}}^2 At = (8.85\times10^{-12}\text{ F/m})(3.00\times10^8\text{ m/s})(0.0200\text{ V/m})^2(0.500\text{ m}^2)(30.0\text{ s}) = 15.9\ \mu\text{J}$

EVALUATE: The intensity is proportional to the square of the electric field amplitude.

32.19. **IDENTIFY** and **SET UP:** Use Eq. (32.29) to calculate I, Eq. (32.18) to calculate $B_{\max}$, and use $I = P_{\text{av}}/4\pi r^2$ to calculate P_{av}.

(a) EXECUTE: $I = \frac{1}{2}\epsilon_0 c E_{\max}^2$; $E_{\max} = 0.090$ V/m, so $I = 1.1\times10^{-5}$ W/m^2

(b) $E_{\max} = cB_{\max}$ so $B_{\max} = E_{\max}/c = 3.0\times10^{-10}$ T

(c) $P_{\text{av}} = I(4\pi r^2) = (1.075\times10^{-5}\text{ W/m}^2)(4\pi)(2.5\times10^3\text{ m})^2 = 840$ W

(d) EVALUATE: The calculation in part (c) assumes that the transmitter emits uniformly in all directions.

32.20. **IDENTIFY** and **SET UP:** $I = P_{\text{av}}/A$ and $I = \epsilon_0 c E_{\text{rms}}^2$.

EXECUTE: **(a)** The average power from the beam is $P_{\text{av}} = IA = (0.800\text{ W/m}^2)(3.0\times10^{-4}\text{ m}^2) = 2.4\times10^{-4}$ W.

(b) $E_{\text{rms}} = \sqrt{\dfrac{I}{\epsilon_0 c}} = \sqrt{\dfrac{0.800\text{ W/m}^2}{(8.85\times10^{-12}\text{ F/m})(3.00\times10^8\text{ m/s})}} = 17.4\text{ V/m}$

EVALUATE: The laser emits radiation only in the direction of the beam.

32.21. **IDENTIFY:** $I = P_{\text{av}}/A$

SET UP: At a distance r from the star, the radiation from the star is spread over a spherical surface of area $A = 4\pi r^2$.

EXECUTE: $P_{\text{av}} = I(4\pi r^2) = (5.0\times10^3\text{ W/m}^2)(4\pi)(2.0\times10^{10}\text{ m})^2 = 2.5\times10^{25}$ W

EVALUATE: The intensity decreases with distance from the star as $1/r^2$.

32.22. **IDENTIFY** and **SET UP**: $c = f\lambda$, $E_{\max} = cB_{\max}$ and $I = E_{\max}B_{\max}/2\mu_0$

EXECUTE: **(a)** $f = \dfrac{c}{\lambda} = \dfrac{3.00\times10^8\text{ m/s}}{0.354\text{ m}} = 8.47\times10^8$ Hz.

(b) $B_{\max} = \dfrac{E_{\max}}{c} = \dfrac{0.0540\text{ V/m}}{3.00\times10^8\text{ m/s}} = 1.80\times10^{-10}$ T.

(c) $I = S_{\text{av}} = \dfrac{E_{\max}B_{\max}}{2\mu_0} = \dfrac{(0.0540\text{ V/m})(1.80\times10^{-10}\text{ T})}{2\mu_0} = 3.87\times10^{-6}\text{ W/m}^2$.

EVALUATE: Alternatively, $I = \frac{1}{2}\epsilon_0 c E_{\max}^2$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

32.23. **IDENTIFY:** $P_{av} = IA$ and $I = E_{max}^2/2\mu_0 c$

SET UP: The surface area of a sphere is $A = 4\pi r^2$.

EXECUTE: $P_{av} = S_{av}A = \left(\dfrac{E_{max}^2}{2c\mu_0}\right)(4\pi r^2)$. $E_{max} = \sqrt{\dfrac{P_{av}c\mu_0}{2\pi r^2}} = \sqrt{\dfrac{(60.0\text{ W})(3.00\times10^8\text{ m/s})\mu_0}{2\pi(5.00\text{ m})^2}} = 12.0\text{ V/m}.$

$$B_{max} = \frac{E_{max}}{c} = \frac{12.0\text{ V/m}}{3.00\times10^8\text{ m/s}} = 4.00\times10^{-8}\text{ T}.$$

EVALUATE: E_{max} and B_{max} are both inversely proportional to the distance from the source.

32.24. **IDENTIFY:** The Poynting vector is $\vec{S} = \vec{E}\times\vec{B}$.

SET UP: The electric field is in the $-y$-direction, and the magnetic field is in the $+z$-direction.

$\cos^2\phi = \frac{1}{2}(1+\cos 2\phi)$

EXECUTE: **(a)** $\hat{S} = \hat{E}\times\hat{B} = (-\hat{j})\times\hat{k} = -\hat{i}$. The Poynting vector is in the $-x$-direction, which is the direction of propagation of the wave.

(b) $S(x,t) = \dfrac{E(x,t)B(x,t)}{\mu_0} = \dfrac{E_{max}B_{max}}{\mu_0}\cos^2(kx+\omega t) = \dfrac{E_{max}B_{max}}{2\mu_0}(1+\cos(2(\omega t+kx)))$. But over one period, the cosine function averages to zero, so we have $S_{av} = \dfrac{E_{max}B_{max}}{2\mu_0}$. This is Eq. (32.29).

EVALUATE: We can also show that these two results also apply to the wave represented by Eq. (32.17).

32.25. **IDENTIFY:** Use the radiation pressure to find the intensity, and then $P_{av} = I(4\pi r^2)$.

SET UP: For a perfectly absorbing surface, $p_{rad} = \dfrac{I}{c}$.

EXECUTE: $p_{rad} = I/c$ so $I = cp_{rad} = 2.70\times10^3\text{ W/m}^2$. Then

$P_{av} = I(4\pi r^2) = (2.70\times10^3\text{ W/m}^2)(4\pi)(5.0\text{ m})^2 = 8.5\times10^5\text{ W}.$

EVALUATE: Even though the source is very intense the radiation pressure 5.0 m from the surface is very small.

32.26. **IDENTIFY:** The intensity and the energy density of an electromagnetic wave depends on the amplitudes of the electric and magnetic fields.

SET UP: Intensity is $I = P_{av}/A$, and the average radiation pressure is $P_{av} = 2I/c$, where $I = \frac{1}{2}\epsilon_0 cE_{max}^2$.

The energy density is $u = \epsilon_0 E^2$.

EXECUTE: **(a)** $I = P_{av}/A = \dfrac{316{,}000\text{ W}}{2\pi(5000\text{ m})^2} = 0.00201\text{ W/m}^2$. $p_{rad} = 2I/c = \dfrac{2(0.00201\text{ W/m}^2)}{3.00\times10^8\text{ m/s}} = 1.34\times10^{-11}\text{ Pa}$

(b) $I = \frac{1}{2}\epsilon_0 cE_{max}^2$ gives

$$E_{max} = \sqrt{\frac{2I}{\epsilon_0 c}} = \sqrt{\frac{2(0.00201\text{ W/m}^2)}{(8.85\times10^{-12}\text{ C}^2/\text{N}\cdot\text{m}^2)(3.00\times10^8\text{ m/s})}} = 1.23\text{ N/C}$$

$$B_{max} = E_{max}/c = (1.23\text{ N/C})/(3.00\times10^8\text{ m/s}) = 4.10\times10^{-9}\text{ T}$$

(c) $u = \epsilon_0 E^2$, so $u_{av} = \epsilon_0(E_{rms})^2$ and $E_{rms} = \dfrac{E_{max}}{\sqrt{2}}$, so

$$u_{av} = \frac{\epsilon_0 E_{max}^2}{2} = \frac{(8.85\times10^{-12}\text{ C}^2/\text{N}\cdot\text{m}^2)(1.23\text{ N/C})^2}{2} = 6.69\times10^{-12}\text{ J/m}^3$$

(d) As was shown in Section 32.4, the energy density is the same for the electric and magnetic fields, so each one has 50% of the energy density.

EVALUATE: Compared to most laboratory fields, the electric and magnetic fields in ordinary radiowaves are extremely weak and carry very little energy.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

32.27. **IDENTIFY:** We know the greatest intensity that the eye can safely receive.

SET UP: $I = \dfrac{P}{A}$. $I = \frac{1}{2}\epsilon_0 c E_{\max}^2$. $E_{\max} = cB_{\max}$.

EXECUTE: **(a)** $P = IA = (1.0\times10^2\ \text{W/m}^2)\pi(0.75\times10^{-3}\ \text{m})^2 = 1.8\times10^{-4}\ \text{W} = 0.18\ \text{mW}$.

(b) $E = \sqrt{\dfrac{2I}{\epsilon_0 c}} = \sqrt{\dfrac{2(1.0\times10^2\ \text{W/m}^2)}{(8.85\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2)(3.00\times10^8\ \text{m/s})}} = 274\ \text{V/m}$. $B_{\max} = \dfrac{E_{\max}}{c} = 9.13\times10^{-7}\ \text{T}$.

(c) $P = 0.18\ \text{mW} = 0.18\ \text{mJ/s}$.

(d) $I = (1.0\times10^2\ \text{W/m}^2)\left(\dfrac{1\ \text{m}}{10^2\ \text{cm}}\right)^2 = 0.010\ \text{W/cm}^2$.

EVALUATE: Both the electric and magnetic fields are quite weak compared to normal laboratory fields.

32.28. **IDENTIFY:** Apply Eqs. (32.32) and (32.33). The average momentum density is given by Eq. (32.30), with S replaced by $S_{\text{av}} = I$.

SET UP: $1\ \text{atm} = 1.013\times10^5\ \text{Pa}$

EXECUTE: **(a)** Absorbed light: $p_{\text{rad}} = \dfrac{I}{c} = \dfrac{2500\ \text{W/m}^2}{3.0\times10^8\ \text{m/s}} = 8.33\times10^{-6}\ \text{Pa}$. Then

$$p_{\text{rad}} = \frac{8.33\times10^{-6}\ \text{Pa}}{1.013\times10^5\ \text{Pa/atm}} = 8.23\times10^{-11}\ \text{atm}.$$

(b) Reflecting light: $p_{\text{rad}} = \dfrac{2I}{c} = \dfrac{2(2500\ \text{W/m}^2)}{3.0\times10^8\ \text{m/s}} = 1.67\times10^{-5}\ \text{Pa}$. Then

$$p_{\text{rad}} = \frac{1.67\times10^{-5}\ \text{Pa}}{1.013\times10^5\ \text{Pa/atm}} = 1.65\times10^{-10}\ \text{atm}.$$

(c) The momentum density is $\dfrac{dp}{dV} = \dfrac{S_{\text{av}}}{c^2} = \dfrac{2500\ \text{W/m}^2}{(3.0\times10^8\ \text{m/s})^2} = 2.78\times10^{-14}\ \text{kg/m}^2\cdot\text{s}$.

EVALUATE: The factor of 2 in p_{rad} for the reflecting surface arises because the momentum vector totally reverses direction upon reflection. Thus the *change* in momentum is twice the original momentum.

32.29. **IDENTIFY:** We know the wavelength and power of the laser beam, as well as the area over which it acts.

SET UP: $P = IA$. $A = \pi r^2$. $E_{\max} = cB_{\max}$. The intensity $I = S_{\text{av}}$ is related to the maximum electric field by $I = \frac{1}{2}\epsilon_0 c E_{\max}^2$. The average energy density u_{av} is related to the intensity I by $I = u_{\text{av}} c$.

EXECUTE: **(a)** $I = \dfrac{P}{A} = \dfrac{0.500\times10^{-3}\ \text{W}}{\pi(0.500\times10^{-3}\ \text{m})^2} = 637\ \text{W/m}^2$.

(b) $E_{\max} = \sqrt{\dfrac{2I}{\epsilon_0 c}} = \sqrt{\dfrac{2(637\ \text{W/m}^2)}{(8.85\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2)(3.00\times10^8\ \text{m/s})}} = 693\ \text{V/m}$. $B_{\max} = \dfrac{E_{\max}}{c} = 2.31\ \mu\text{T}$.

(c) $u_{\text{av}} = \dfrac{I}{c} = \dfrac{637\ \text{W/m}^2}{3.00\times10^8\ \text{m/s}} = 2.12\times10^{-6}\ \text{J/m}^3$.

EVALUATE: The fields are very weak, so a cubic meter of space contains only about $2\ \mu\text{J}$ of energy.

32.30. **IDENTIFY:** We know the intensity of the solar light and the area over which it acts. We can use the light intensity to find the force the light exerts on the sail, and then use the sail's density to find its mass. Newton's second law will then give the acceleration of the sail.

SET UP: For a reflecting surface the pressure is $\dfrac{2I}{c}$. Pressure is force per unit area, and $F_{\text{net}} = ma$. The mass of the sail is its volume V times its density ρ. The area of the sail is πr^2, with $r = 4.5$ m. Its volume is $\pi r^2 t$, where $t = 7.5\times10^{-6}$ m is its thickness.

EXECUTE: **(a)** $F = \left(\frac{2I}{c}\right)A = \frac{2(1400\ \text{W/m}^2)}{3.00\times10^8\ \text{m/s}}\pi(4.5\ \text{m})^2 = 5.9\times10^{-4}\ \text{N}.$

(b) $m = \rho V = (1.74\times10^3\ \text{kg/m}^3)\pi(4.5\ \text{m})^2(7.5\times10^{-6}\ \text{m}) = 0.83\ \text{kg}.$

$a = \frac{F}{m} = \frac{5.9\times10^{-4}\ \text{N}}{0.83\ \text{kg}} = 7.1\times10^{-4}\ \text{m/s}^2.$

(c) With this acceleration it would take the sail $1.4\times10^6\ \text{s} = 16\ \text{days}$ to reach a speed of 1 km/s. This would be useful only in specialized applications. The acceleration could be increased by decreasing the mass of the sail, either by reducing its density or its thickness.

EVALUATE: The calculation assumed the only force on the sail is that due to the radiation pressure. The sun would also exert a gravitational force on the sail, which could be significant.

32.31. **IDENTIFY:** The nodal and antinodal planes are each spaced one-half wavelength apart.

SET UP: $2\frac{1}{2}$ wavelengths fit in the oven, so $\left(2\frac{1}{2}\right)\lambda = L,$ and the frequency of these waves obeys the equation $f\lambda = c.$

EXECUTE: **(a)** Since $\left(2\frac{1}{2}\right)\lambda = L,$ we have $L = (5/2)(12.2\ \text{cm}) = 30.5\ \text{cm}.$

(b) Solving for the frequency gives $f = c/\lambda = (3.00\times10^8\ \text{m/s})/(0.122\ \text{m}) = 2.46\times10^9\ \text{Hz}.$

(c) $L = 35.5\ \text{cm}$ in this case. $\left(2\frac{1}{2}\right)\lambda = L,$ so $\lambda = 2L/5 = 2(35.5\ \text{cm})/5 = 14.2\ \text{cm}.$

$$f = c/\lambda = (3.00\times10^8\ \text{m/s})/(0.142\ \text{m}) = 2.11\times10^9\ \text{Hz}$$

EVALUATE: Since microwaves have a reasonably large wavelength, microwave ovens can have a convenient size for household kitchens. Ovens using radiowaves would need to be far too large, while ovens using visible light would have to be microscopic.

32.32. **IDENTIFY:** The electric field at the nodes is zero, so there is no force on a point charge placed at a node.

SET UP: The location of the nodes is given by Eq. (32.36), where x is the distance from one of the planes. $\lambda = c/f.$

EXECUTE: $\Delta x_{\text{nodes}} = \frac{\lambda}{2} = \frac{c}{2f} = \frac{3.00\times10^8\ \text{m/s}}{2(7.50\times10^8\ \text{Hz})} = 0.200\ \text{m} = 20.0\ \text{cm}.$ There must be nodes at the planes, which are 80.0 cm apart, and there are two nodes between the planes, each 20.0 cm from a plane. It is at 20 cm, 40 cm, and 60 cm from one plane that a point charge will remain at rest, since the electric fields there are zero.

EVALUATE: The magnetic field amplitude at these points isn't zero, but the magnetic field doesn't exert a force on a stationary charge.

32.33. **IDENTIFY** and **SET UP:** Apply Eqs. (32.36) and (32.37).

EXECUTE: **(a)** By Eq. (32.37) we see that the nodal planes of the $\vec{B}$ field are a distance $\lambda/2$ apart, so $\lambda/2 = 3.55\ \text{mm}$ and $\lambda = 7.10\ \text{mm}.$

(b) By Eq. (32.36) we see that the nodal planes of the $\vec{E}$ field are also a distance $\lambda/2 = 3.55\ \text{mm}$ apart.

(c) $v = f\lambda = (2.20\times10^{10}\ \text{Hz})(7.10\times10^{-3}\ \text{m}) = 1.56\times10^8\ \text{m/s}.$

EVALUATE: The spacing between the nodes of $\vec{E}$ is the same as the spacing between the nodes of $\vec{B}$. Note that $v < c,$ as it must.

32.34. **IDENTIFY:** The nodal planes of $\vec{E}$ and $\vec{B}$ are located by Eqs. (32.26) and (32.27).

SET UP: $\lambda = \frac{c}{f} = \frac{3.00\times10^8\ \text{m/s}}{75.0\times10^6\ \text{Hz}} = 4.00\ \text{m}$

EXECUTE: **(a)** $\Delta x = \frac{\lambda}{2} = 2.00\ \text{m}.$

(b) The distance between the electric and magnetic nodal planes is one-quarter of a wavelength, so is $\frac{\lambda}{4} = \frac{\Delta x}{2} = \frac{2.00\ \text{m}}{2} = 1.00\ \text{m}.$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: The nodal planes of $\vec{B}$ are separated by a distance $\lambda/2$ and are midway between the nodal planes of $\vec{E}$.

32.35. **(a) IDENTIFY** and **SET UP:** The distance between adjacent nodal planes of $\vec{B}$ is $\lambda/2$. There is an antinodal plane of $\vec{B}$ midway between any two adjacent nodal planes, so the distance between a nodal plane and an adjacent antinodal plane is $\lambda/4$. Use $v = f\lambda$ to calculate λ.

EXECUTE: $\lambda = \dfrac{v}{f} = \dfrac{2.10\times10^{8}\ \text{m/s}}{1.20\times10^{10}\ \text{Hz}} = 0.0175\ \text{m}$

$\dfrac{\lambda}{4} = \dfrac{0.0175\ \text{m}}{4} = 4.38\times10^{-3}\ \text{m} = 4.38\ \text{mm}$

(b) IDENTIFY and **SET UP:** The nodal planes of $\vec{E}$ are at $x = 0,\ \lambda/2, \lambda, 3\lambda/2, \ldots,$ so the antinodal planes of $\vec{E}$ are at $x = \lambda/4, 3\lambda/4, 5\lambda/4, \ldots$. The nodal planes of $\vec{B}$ are at $x = \lambda/4, 3\lambda/4, 5\lambda/4, \ldots,$ so the antinodal planes of $\vec{B}$ are at $\lambda/2, \lambda, 3\lambda/2, \ldots$.

EXECUTE: The distance between adjacent antinodal planes of $\vec{E}$ and antinodal planes of $\vec{B}$ is therefore $\lambda/4 = 4.38$ mm.

(c) From Eqs. (32.36) and (32.37) the distance between adjacent nodal planes of $\vec{E}$ and $\vec{B}$ is $\lambda/4 = 4.38$ mm.

EVALUATE: The nodes of $\vec{E}$ coincide with the antinodes of $\vec{B}$ and conversely. The nodes of $\vec{B}$ and the nodes of $\vec{E}$ are equally spaced.

32.36. **IDENTIFY:** Evaluate the derivatives of the expressions for $E_y(x,t)$ and $B_z(x,t)$ that are given in Eqs. (32.34) and (32.35).

SET UP: $\dfrac{\partial}{\partial x}\sin kx = k\cos kx,\ \dfrac{\partial}{\partial t}\sin\omega t = \omega\cos\omega t.\ \dfrac{\partial}{\partial x}\cos kx = -k\sin kx,\ \dfrac{\partial}{\partial t}\cos\omega t = -\omega\sin\omega t.$

EXECUTE: **(a)** $\dfrac{\partial^2 E_y(x,t)}{\partial x^2} = \dfrac{\partial^2}{\partial x^2}(-2E_{\max}\sin kx\sin\omega t) = \dfrac{\partial}{\partial x}(-2kE_{\max}\cos kx\sin\omega t)$ and

$$\frac{\partial^2 E_y(x,t)}{\partial x^2} = 2k^2E_{\max}\sin kx\sin\omega t = \frac{\omega^2}{c^2}2E_{\max}\sin kx\sin\omega t = \epsilon_0\mu_0\frac{\partial^2 E_y(x,t)}{\partial t^2}.$$

Similarly: $\dfrac{\partial^2 B_z(x,t)}{\partial x^2} = \dfrac{\partial^2}{\partial x^2}(-2B_{\max}\cos kx\cos\omega t) = \dfrac{\partial}{\partial x}(+2kB_{\max}\sin kx\cos\omega t)$ and

$$\frac{\partial^2 B_z(x,t)}{\partial x^2} = 2k^2B_{\max}\cos kx\cos\omega t = \frac{\omega^2}{c^2}2B_{\max}\cos kx\cos\omega t = \epsilon_0\mu_0\frac{\partial^2 B_z(x,t)}{\partial t^2}.$$

(b) $\dfrac{\partial E_y(x,t)}{\partial x} = \dfrac{\partial}{\partial x}(-2E_{\max}\sin kx\sin\omega t) = -2kE_{\max}\cos kx\sin\omega t.$

$$\frac{\partial E_y(x,t)}{\partial x} = -\frac{\omega}{c}2E_{\max}\cos kx\sin\omega t = -\omega 2\frac{E_{\max}}{c}\cos kx\sin\omega t = -\omega 2B_{\max}\cos kx\sin\omega t.$$

$$\frac{\partial E_y(x,t)}{\partial x} = +\frac{\partial}{\partial t}(2B_{\max}\cos kx\cos\omega t) = -\frac{\partial B_z(x,t)}{\partial t}.$$

Similarly: $-\dfrac{\partial B_z(x,t)}{\partial x} = \dfrac{\partial}{\partial x}(+2B_{\max}\cos kx\cos\omega t) = -2kB_{\max}\sin kx\cos\omega t.$

$$-\frac{\partial B_z(x,t)}{\partial x} = -\frac{\omega}{c}2B_{\max}\sin kx\cos\omega t = -\frac{\omega}{c^2}2cB_{\max}\sin kx\cos\omega t.$$

$$-\frac{\partial B_z(x,t)}{\partial x} = -\epsilon_0\mu_0\omega 2E_{\max}\sin kx\cos\omega t = \epsilon_0\mu_0\frac{\partial}{\partial t}(-2E_{\max}\sin kx\sin\omega t) = \epsilon_0\mu_0\frac{\partial E_y(x,t)}{\partial t}.$$

EVALUATE: The standing waves are linear superpositions of two traveling waves of the same k and ω.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

32.37. **IDENTIFY:** We know the wavelength and power of a laser beam as well as the area over which it acts and the duration of a pulse.

SET UP: The energy is $U = Pt$. For absorption the radiation pressure is $\frac{I}{c}$, where $I = \frac{P}{A}$. The wavelength in the eye is $\lambda = \frac{\lambda_0}{n}$. $I = \frac{1}{2}\epsilon_0 c E_{\max}^2$ and $E_{\max} = cB_{\max}$.

EXECUTE: **(a)** $U = Pt = (250\times10^{-3}\ \text{W})(1.50\times10^{-3}\ \text{s}) = 3.75\times10^{-4}\ \text{J} = 0.375\ \text{mJ}$.

(b) $I = \frac{P}{A} = \frac{250\times10^{-3}\ \text{W}}{\pi(255\times10^{-6}\ \text{m})^2} = 1.22\times10^{6}\ \text{W/m}^2$. The average pressure is

$\frac{I}{c} = \frac{1.22\times10^{6}\ \text{W/m}^2}{3.00\times10^{8}\ \text{m/s}} = 4.08\times10^{-3}\ \text{Pa}$.

(c) $\lambda = \frac{\lambda_0}{n} = \frac{810\ \text{nm}}{1.34} = 604\ \text{nm}$. $f = \frac{v}{\lambda} = \frac{c}{\lambda_0} = \frac{3.00\times10^{8}\ \text{m/s}}{810\times10^{-9}\ \text{m}} = 3.70\times10^{14}\ \text{Hz}$; f is the same in the air and in the vitreous humor.

(d) $E_{\max} = \sqrt{\frac{2I}{\epsilon_0 c}} = \sqrt{\frac{2(1.22\times10^{6}\ \text{W/m}^2)}{(8.85\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2)(3.00\times10^{8}\ \text{m/s})}} = 3.03\times10^{4}\ \text{V/m}$.

$B_{\max} = \frac{E_{\max}}{c} = 1.01\times10^{-4}\ \text{T}$.

EVALUATE: The intensity of the beam is high, as it must be to weld tissue, but the pressure it exerts on the retina is only around 10^{-8} that of atmospheric pressure. The magnetic field in the beam is about twice that of the earth's magnetic field.

32.38. **IDENTIFY:** Evaluate the partial derivatives of the expressions for $E_y(x,t)$ and $B_z(x,t)$.

SET UP: $\frac{\partial}{\partial x}\cos(kx-\omega t) = -k\sin(kx-\omega t)$, $\frac{\partial}{\partial t}\cos(kx-\omega t) = \omega\sin(kx-\omega t)\cdot$

$\frac{\partial}{\partial x}\sin(kx-\omega t) = k\cos(kx-\omega t)$, $\frac{\partial}{\partial t}\sin(kx-\omega t) = -\omega\cos(kx-\omega t)$

EXECUTE: Assume $\vec{\boldsymbol{E}} = E_{\max}\hat{\boldsymbol{j}}\cos(kx-\omega t)$ and $\vec{\boldsymbol{B}} = B_{\max}\hat{\boldsymbol{k}}\cos(kx-\omega t+\phi)$, with $-\pi < \phi < \pi$. Eq. (32.12) is $\frac{\partial E_y}{\partial x} = -\frac{\partial B_z}{\partial t}$. This gives $kE_{\max}\sin(kx-\omega t) = +\omega B_{\max}\sin(kx-\omega t+\phi)$, so $\phi = 0$, and $kE_{\max} = \omega B_{\max}$, so $E_{\max} = \frac{\omega}{k}B_{\max} = \frac{2\pi f}{2\pi/\lambda}B_{\max} = f\lambda B_{\max} = cB_{\max}$. Similarly for Eq. (32.14), $-\frac{\partial B_z}{\partial x} = \epsilon_0\mu_0\frac{\partial E_y}{\partial t}$ gives $kB_{\max}\sin(kx-\omega t+\phi) = \epsilon_0\mu_0\omega E_{\max}\sin(kx-\omega t)$, so $\phi = 0$ and $kB_{\max} = \epsilon_0\mu_0\omega E_{\max}$, so $B_{\max} = \frac{\epsilon_0\mu_0\omega}{k}E_{\max} = \frac{2\pi f}{c^2\,2\pi/\lambda}E_{\max} = \frac{f\lambda}{c^2}E_{\max} = \frac{1}{c}E_{\max}$.

EVALUATE: The $\vec{\boldsymbol{E}}$ and $\vec{\boldsymbol{B}}$ fields must oscillate in phase.

32.39. **IDENTIFY:** The light exerts pressure on the paper, which produces an upward force. This force must balance the weight of the paper.

SET UP: The weight of the paper is mg. For a totally absorbing surface the radiation pressure is $\frac{I}{c}$ and for a totally reflecting surface it is $\frac{2I}{c}$. The force is $F = PA$, and the intensity is $I = \frac{P}{A}$.

EXECUTE: **(a)** The radiation force must equal the weight of the paper, so $\left(\frac{I}{c}\right)A = mg$.

$I = \frac{mgc}{A} = \frac{(1.50\times10^{-3}\ \text{kg})(9.80\ \text{m/s}^2)(3.00\times10^{8}\ \text{m/s})}{(0.220\ \text{m})(0.280\ \text{m})} = 7.16\times10^{7}\ \text{W/m}^2$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) $I = \frac{1}{2}\epsilon_0 c E_{\max}^2$. Solving for $E_{\max}$ gives

$$E_{\max} = \sqrt{\frac{2I}{\epsilon_0 c}} = \sqrt{\frac{2(7.16\times10^7\ \text{W/m}^2)}{(8.85\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2)(3.00\times10^8\ \text{m/s})}} = 2.32\times10^5\ \text{V/m}.$$

$$B_{\max} = \frac{E_{\max}}{c} = \frac{2.32\times10^5\ \text{V/m}}{3.00\times10^8\ \text{m/s}} = 7.74\times10^{-4}\ \text{T}.$$

(c) The pressure is $\frac{2I}{c}$, so $\left(\frac{2I}{c}\right)A = mg$. $I = \frac{mgc}{2A} = 3.58\times10^7\ \text{W/m}^2$.

(d) $I = \frac{P}{A} = \frac{0.500\times10^{-3}\ \text{W}}{\pi(0.500\times10^{-3}\ \text{m})^2} = 637\ \text{W/m}^2$.

EVALUATE: The intensity of this laser is much less than what is needed to support a sheet of paper. And to support the paper, not only must the intensity be large, it also must be over a large area.

32.40. **IDENTIFY:** The average energy density in the electric field is $u_{E,\text{av}} = \frac{1}{2}\epsilon_0 (E^2)_{\text{av}}$ and the average energy density in the magnetic field is $u_{B,\text{av}} = \frac{1}{2\mu_0}(B^2)_{\text{av}}$.

SET UP: $(\cos^2(kx-\omega t))_{\text{av}} = \frac{1}{2}$.

EXECUTE: $E_y(x,t) = E_{\max}\cos(kx-\omega t)$. $u_E = \frac{1}{2}\epsilon_0 E_y^2 = \frac{1}{2}\epsilon_0 E_{\max}^2\cos^2(kx-\omega t)$ and $u_{E,\text{av}} = \frac{1}{4}\epsilon_0 E_{\max}^2$.

$B_z(x,t) = B_{\max}\cos(kx-\omega t)$, so $u_B = \frac{1}{2\mu_0}B_z^2 = \frac{1}{2\mu_0}B_{\max}^2\cos^2(kx-\omega t)$ and $u_{B,\text{av}} = \frac{1}{4\mu_0}B_{\max}^2$.

$E_{\max} = cB_{\max}$, so $u_{E,\text{av}} = \frac{1}{4}\epsilon_0 c^2 B_{\max}^2$. $c = \frac{1}{\sqrt{\epsilon_0\mu_0}}$, so $u_{E,\text{av}} = \frac{1}{2\mu_0}B_{\max}^2$, which equals $u_{B,\text{av}}$.

EVALUATE: Our result allows us to write $u_{\text{av}} = 2u_{E,\text{av}} = \frac{1}{2}\epsilon_0 E_{\max}^2$ and $u_{\text{av}} = 2u_{B,\text{av}} = \frac{1}{2\mu_0}B_{\max}^2$.

32.41. **IDENTIFY:** The intensity of an electromagnetic wave depends on the amplitude of the electric and magnetic fields. Such a wave exerts a force because it carries energy.

SET UP: The intensity of the wave is $I = P_{\text{av}}/A = \frac{1}{2}\epsilon_0 c E_{\max}^2$, and the force is $F = p_{\text{rad}}A$ where $p_{\text{rad}} = I/c$.

EXECUTE: **(a)** $I = P_{\text{av}}/A = (25{,}000\ \text{W})/[4\pi(575\ \text{m})^2] = 0.00602\ \text{W/m}^2$

(b) $I = \frac{1}{2}\epsilon_0 c E_{\max}^2$, so $E_{\max} = \sqrt{\frac{2I}{\epsilon_0 c}} = \sqrt{\frac{2(0.00602\ \text{W/m}^2)}{(8.85\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2)(3.00\times10^8\ \text{m/s})}} = 2.13\ \text{N/C}.$

$$B_{\max} = E_{\max}/c = (2.13\ \text{N/C})/(3.00\times10^8\ \text{m/s}) = 7.10\times10^{-9}\ \text{T}$$

(c) $F = p_{\text{rad}}A = (I/c)A = (0.00602\ \text{W/m}^2)(0.150\ \text{m})(0.400\ \text{m})/(3.00\times10^8\ \text{m/s}) = 1.20\times10^{-12}\ \text{N}$

EVALUATE: The fields are very weak compared to ordinary laboratory fields, and the force is hardly worth worrying about!

32.42. **IDENTIFY:** $c = f\lambda$. $E_{\max} = cB_{\max}$. $I = \frac{1}{2}\epsilon_0 c E_{\max}^2$. For a totally absorbing surface the radiation pressure is $\frac{I}{c}$.

SET UP: The wave speed in air is $c = 3.00\times10^8$ m/s.

EXECUTE: **(a)** $f = \frac{c}{\lambda} = \frac{3.00\times10^8\ \text{m/s}}{3.84\times10^{-2}\ \text{m}} = 7.81\times10^9\ \text{Hz}$

(b) $B_{\max} = \frac{E_{\max}}{c} = \frac{1.35\ \text{V/m}}{3.00\times10^8\ \text{m/s}} = 4.50\times10^{-9}\ \text{T}$

(c) $I = \frac{1}{2}\epsilon_0 c E_{\max}^2 = \frac{1}{2}(8.854\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2)(3.00\times10^8\ \text{m/s})(1.35\ \text{V/m})^2 = 2.42\times10^{-3}\ \text{W/m}^2$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(d) $F = (\text{pressure})A = \dfrac{IA}{c} = \dfrac{(2.42\times10^{-3}\ \text{W/m}^2)(0.240\ \text{m}^2)}{3.00\times10^{8}\ \text{m/s}} = 1.94\times10^{-12}\ \text{N}$

EVALUATE: The intensity depends only on the amplitudes of the electric and magnetic fields and is independent of the wavelength of the light.

32.43. **(a) IDENTIFY** and **SET UP:** Calculate I and then use Eq. (32.29) to calculate $E_{\max}$ and Eq. (32.18) to calculate $B_{\max}$.

EXECUTE: The intensity is power per unit area: $I = \dfrac{P}{A} = \dfrac{4.60\times10^{-3}\ \text{W}}{\pi(1.25\times10^{-3}\ \text{m})^2} = 937\ \text{W/m}^2$.

$I = \dfrac{E_{\max}^2}{2\mu_0 c}$, so $E_{\max} = \sqrt{2\mu_0 cI}$. $E_{\max} = \sqrt{2(4\pi\times10^{-7}\ \text{T}\cdot\text{m/A})(2.998\times10^{8}\ \text{m/s})(937\ \text{W/m}^2)} = 840\ \text{V/m}$.

$B_{\max} = \dfrac{E_{\max}}{c} = \dfrac{840\ \text{V/m}}{2.998\times10^{8}\ \text{m/s}} = 2.80\times10^{-6}\ \text{T}$.

EVALUATE: The magnetic field amplitude is quite small compared to laboratory fields.

(b) IDENTIFY and **SET UP:** Eqs. (24.11) and (30.10) give the energy density in terms of the electric and magnetic field values at any time. For sinusoidal fields average over E^2 and B^2 to get the average energy densities.

EXECUTE: The energy density in the electric field is $u_E = \frac{1}{2}\epsilon_0 E^2$. $E = E_{\max}\cos(kx-\omega t)$ and the average value of $\cos^2(kx-\omega t)$ is $\frac{1}{2}$. The average energy density in the electric field then is $u_{E,\text{av}} = \frac{1}{4}\epsilon_0 E_{\max}^2 = \frac{1}{4}(8.854\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2)(840\ \text{V/m})^2 = 1.56\times10^{-6}\ \text{J/m}^3$. The energy density in the magnetic field is $u_B = \dfrac{B^2}{2\mu_0}$. The average value is $u_{B,\text{av}} = \dfrac{B_{\max}^2}{4\mu_0} = \dfrac{(2.80\times10^{-6}\ \text{T})^2}{4(4\pi\times10^{-7}\ \text{T}\cdot\text{m/A})} = 1.56\times10^{-6}\ \text{J/m}^3$.

EVALUATE: Our result agrees with the statement in Section 32.4 that the average energy density for the electric field is the same as the average energy density for the magnetic field.

(c) IDENTIFY and **SET UP:** The total energy in this length of beam is the average energy density ($u_{\text{av}} = u_{E,\text{av}} + u_{B,\text{av}} = 3.12\times10^{-6}\ \text{J/m}^3$) times the volume of this part of the beam.

EXECUTE: $U = u_{\text{av}}LA = (3.12\times10^{-6}\ \text{J/m}^3)(1.00\ \text{m})\pi(1.25\times10^{-3}\ \text{m})^2 = 1.53\times10^{-11}\ \text{J}$.

EVALUATE: This quantity can also be calculated as the power output times the time it takes the light to travel $L = 1.00$ m: $U = P\left(\dfrac{L}{c}\right) = (4.60\times10^{-3}\ \text{W})\left(\dfrac{1.00\ \text{m}}{2.998\times10^{8}\ \text{m/s}}\right) = 1.53\times10^{-11}\ \text{J}$, which checks.

32.44. **IDENTIFY:** We know the electric field in the plastic.

SET UP: The general wave function for the electric field is $E = E_{\max}\cos(kx-\omega t)$. $f = \dfrac{\omega}{2\pi}$, $\lambda = \dfrac{2\pi}{k}$, $v = f\lambda$ and $v = \dfrac{c}{n}$.

EXECUTE: **(a)** By comparing the equation for E to the general form, we have $\omega = 3.02\times10^{15}$ rad/s and $k = 1.39\times10^{7}$ rad/m. $f = \dfrac{\omega}{2\pi} = 4.81\times10^{14}$ Hz. $\lambda = \dfrac{2\pi}{k} = 4.52\times10^{-7}\ \text{m} = 452\ \text{nm}$.

$v = f\lambda = 2.17\times10^{8}$ m/s.

(b) $n = \dfrac{c}{v} = \dfrac{3.00\times10^{8}\ \text{m/s}}{2.17\times10^{8}\ \text{m/s}} = 1.38$.

(c) In air, $\omega = 3.02\times10^{15}$ rad/s, the same as in the plastic. $\lambda_0 = \lambda n = (4.52\times10^{-7}\ \text{m})(1.38) = 6.24\times10^{-7}\ \text{m}$, so $k = \dfrac{2\pi}{\lambda} = 1.01\times10^{7}$ rad/m. The equation for E in air is

$E = (535\ \text{V/m})\cos\left[(1.01\times10^{7}\ \text{rad/m})x - (3.02\times10^{15}\ \text{rad/s})t\right]$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: In the plastic, k and λ are different from their values in air, but f and ω are the same in both media.

32.45. **IDENTIFY:** $I = P_{\text{av}}/A$. For an absorbing surface, the radiation pressure is $p_{\text{rad}} = \dfrac{I}{c}$.

SET UP: Assume the electromagnetic waves are formed at the center of the sun, so at a distance r from the center of the sun $I = P_{\text{av}}/(4\pi r^2)$.

EXECUTE: **(a)** At the sun's surface: $I = \dfrac{P_{\text{av}}}{4\pi R^2} = \dfrac{3.9\times10^{26}\ \text{W}}{4\pi(6.96\times10^{8}\ \text{m})^2} = 6.4\times10^{7}\ \text{W/m}^2$ and

$p_{\text{rad}} = \dfrac{I}{c} = \dfrac{6.4\times10^{7}\ \text{W/m}^2}{3.00\times10^{8}\ \text{m/s}} = 0.21\ \text{Pa}.$

Halfway out from the sun's center, the intensity is 4 times more intense, and so is the radiation pressure: $I = 2.6\times10^{8}\ \text{W/m}^2$ and $p_{\text{rad}} = 0.85\ \text{Pa}$. At the top of the earth's atmosphere, the measured sunlight intensity is $1400\ \text{W/m}^2$ and $p_{\text{rad}} = 5\times10^{-6}\ \text{Pa}$, which is about 100,000 times less than the values above.

EVALUATE: **(b)** The gas pressure at the sun's surface is 50,000 times greater than the radiation pressure, and halfway out of the sun the gas pressure is believed to be about 6×10^{13} times greater than the radiation pressure. Therefore it is reasonable to ignore radiation pressure when modeling the sun's interior structure.

32.46. **IDENTIFY:** The intensity of the wave, not the electric field strength, obeys an inverse-square distance law.

SET UP: The intensity is inversely proportional to the distance from the source, and it depends on the amplitude of the electric field by $I = \text{S}_{\text{av}} = \frac{1}{2}\epsilon_0 c E_{\text{max}}^2$.

EXECUTE: Since $I = \dfrac{1}{2}\epsilon_0 c E_{\text{max}}^2$, $E_{\text{max}} \propto \sqrt{I}$. A point at 20.0 cm (0.200 m) from the source is 50 times closer to the source than a point that is 10.0 m from it. Since $I \propto 1/r^2$ and (0.200 m)/(10.0 m) = 1/50, we have $I_{0.20} = 50^2 I_{10}$. Since $E_{\text{max}} \propto \sqrt{I}$, we have $E_{0.20} = 50E_{10} = (50)(1.50\ \text{N/C}) = 75.0\ \text{N/C}$.

EVALUATE: While the intensity increases by a factor of $50^2 = 2500$, the amplitude of the wave only increases by a factor of 50. Recall that the intensity of *any* wave is proportional to the *square* of its amplitude.

32.47. **IDENTIFY:** The same intensity light falls on both reflectors, but the force on the reflecting surface will be twice as great as the force on the absorbing surface. Therefore there will be a net torque about the rotation axis.

SET UP: For a totally absorbing surface, $F = p_{\text{rad}}A = (I/c)A$, while for a totally reflecting surface the force will be twice as great. The intensity of the wave is $I = \frac{1}{2}\epsilon_0 c E_{\text{max}}^2$. Once we have the torque, we can use the rotational form of Newton's second law, $\tau_{\text{net}} = I\alpha$, to find the angular acceleration.

EXECUTE: The force on the absorbing reflector is $F_{\text{Abs}} = p_{\text{rad}}A = (I/c)A = \dfrac{\frac{1}{2}\epsilon_0 c E_{\text{max}}^2 A}{c} = \frac{1}{2}\epsilon_0 A E_{\text{max}}^2$.

For a totally reflecting surface, the force will be twice as great, which is $\epsilon_0 c E_{\text{max}}^2$. The net torque is therefore $\tau_{\text{net}} = F_{\text{Refl}}(L/2) - F_{\text{Abs}}(L/2) = \epsilon_0 A E_{\text{max}}^2 L/4$.

Newton's second law for rotation gives $\tau_{\text{net}} = I\alpha$. $\epsilon_0 A E_{\text{max}}^2 L/4 = 2m(L/2)^2\alpha$.

Solving for α gives

$$\alpha = \epsilon_0 A E_{\text{max}}^2/(2mL) = \frac{(8.85\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2)(0.0150\ \text{m})^2(1.25\ \text{N/C})^2}{(2)(0.00400\ \text{kg})(1.00\ \text{m})} = 3.89\times10^{-13}\ \text{rad/s}^2.$$

EVALUATE: This is an extremely small angular acceleration. To achieve a larger value, we would have to greatly increase the intensity of the light wave or decrease the mass of the reflectors.

32.48. **IDENTIFY:** The changing magnetic field of the electromagnetic wave produces a changing flux through the wire loop, which induces an emf in the loop.

SET UP: $\Phi_B = B\pi r^2 = \pi r^2 B_{\max}\cos(kx-\omega t)$, taking x for the direction of propagation of the wave. Faraday's law says $|\mathcal{E}| = \left|\dfrac{d\Phi_B}{dt}\right|$. The intensity of the wave is $I = \dfrac{E_{\max}B_{\max}}{2\mu_0} = \dfrac{c}{2\mu_0}B_{\max}^2$, and $f = \dfrac{c}{\lambda}$.

EXECUTE: $|\mathcal{E}| = \left|\dfrac{d\Phi_B}{dt}\right| = \omega B_{\max}\sin(kx-\omega t)\pi r^2$. $|\mathcal{E}|_{\max} = 2\pi f B_{\max}\pi r^2$.

$f = \dfrac{c}{\lambda} = \dfrac{3.00\times10^8 \text{ m/s}}{6.90 \text{ m}} = 4.348\times10^7$ Hz. Solving $I = \dfrac{E_{\max}B_{\max}}{2\mu_0} = \dfrac{c}{2\mu_0}B_{\max}^2$ for $B_{\max}$ gives

$$B_{\max} = \sqrt{\frac{2\mu_0 I}{c}} = \sqrt{\frac{2(4\pi\times10^{-7}\ \text{T}\cdot\text{m/A})(0.0195\ \text{W/m}^2)}{3.00\times10^8\ \text{m/s}}} = 1.278\times10^{-8}\ \text{T}.$$

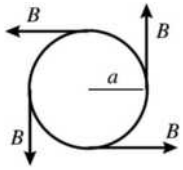
$$|\mathcal{E}|_{\max} = 2\pi(4.348\times10^7\ \text{Hz})(1.278\times10^{-8}\ \text{T})\pi(0.075\ \text{m})^2 = 6.17\times10^{-2}\ \text{V} = 61.7\ \text{mV}.$$

EVALUATE: This voltage is quite small compared to everyday voltages, so it normally would not be noticed. But in very delicate laboratory work, it could be large enough to take into consideration.

32.49. **IDENTIFY** and **SET UP:** In the wire the electric field is related to the current density by Eq. (25.7). Use Ampere's law to calculate $\vec{B}$. The Poynting vector is given by Eq. (32.28) and the equation that follows it relates the energy flow through a surface to $\vec{S}$.

EXECUTE: **(a)** The direction of $\vec{E}$ is parallel to the axis of the cylinder, in the direction of the current. From Eq. (25.7), $E = \rho J = \rho I/\pi a^2$. ($E$ is uniform across the cross section of the conductor.)

(b) A cross-sectional view of the conductor is given in Figure 32.49a; take the current to be coming out of the page.



Apply Ampere's law to a circle of radius a.

$\oint \vec{B}\cdot d\vec{l} = B(2\pi a)$

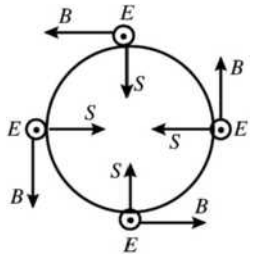
$I_{\text{encl}} = I$

Figure 32.49a

$\oint \vec{B}\cdot d\vec{l} = \mu_0 I_{\text{encl}}$ gives $B(2\pi a) = \mu_0 I$ and $B = \dfrac{\mu_0 I}{2\pi a}$

The direction of $\vec{B}$ is counterclockwise around the circle.

(c) The directions of $\vec{E}$ and $\vec{B}$ are shown in Figure 32.49b.



The direction of $\vec{S} = \dfrac{1}{\mu_0}\vec{E}\times\vec{B}$ is radially inward.

$$S = \frac{1}{\mu_0}EB = \frac{1}{\mu_0}\left(\frac{\rho I}{\pi a^2}\right)\left(\frac{\mu_0 I}{2\pi a}\right)$$

$$S = \frac{\rho I^2}{2\pi^2 a^3}$$

Figure 32.49b

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(d) EVALUATE: Since S is constant over the surface of the conductor, the rate of energy flow P is given by S times the surface of a length l of the conductor: $P = SA = S(2\pi al) = \dfrac{\rho I^2}{2\pi^2 a^3}(2\pi al) = \dfrac{\rho l I^2}{\pi a^2}$. But $R = \dfrac{\rho l}{\pi a^2}$, so the result from the Poynting vector is $P = RI^2$. This agrees with $P_R = I^2 R$, the rate at which electrical energy is being dissipated by the resistance of the wire. Since $\vec{\boldsymbol{S}}$ is radially inward at the surface of the wire and has magnitude equal to the rate at which electrical energy is being dissipated in the wire, this energy can be thought of as entering through the cylindrical sides of the conductor.

32.50. **IDENTIFY:** The nodal planes are one-half wavelength apart.

SET UP: The nodal planes of B are at $x = \lambda/4, 3\lambda/4, 5\lambda/4, \ldots$, which are $\lambda/2$ apart.

EXECUTE: **(a)** The wavelength is $\lambda = c/f = (3.000\times10^8 \text{ m/s})/(110.0\times10^6 \text{ Hz}) = 2.727 \text{ m}$. So the nodal planes are at $(2.727 \text{ m})/2 = 1.364 \text{ m}$ apart.

(b) For the nodal planes of E, we have $\lambda_n = 2L/n$, so $L = n\lambda/2 = (8)(2.727 \text{ m})/2 = 10.91 \text{ m}$.

EVALUATE: Because radiowaves have long wavelengths, the distances involved are easily measurable using ordinary metersticks.

32.51. **IDENTIFY** and **SET UP:** Find the force on you due to the momentum carried off by the light. Express this force in terms of the radiated power of the flashlight. Use this force to calculate your acceleration and use a constant acceleration equation to find the time.

(a) EXECUTE: $p_{\text{rad}} = I/c$ and $F = p_{\text{rad}}A$ gives $F = IA/c = P_{\text{av}}/c$

$a_x = F/m = P_{\text{av}}/(mc) = (200 \text{ W})/[(150 \text{ kg})(3.00\times10^8 \text{ m/s})] = 4.44\times10^{-9} \text{ m/s}^2$

Then $x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2$ gives

$t = \sqrt{2(x - x_0)/a_x} = \sqrt{2(16.0 \text{ m})/(4.44\times10^{-9} \text{ m/s}^2)} = 8.49\times10^4 \text{ s} = 23.6 \text{ h}$

EVALUATE: The radiation force is very small. In the calculation we have ignored any other forces on you. **(b)** You could throw the flashlight in the direction away from the ship. By conservation of linear momentum you would move toward the ship with the same magnitude of momentum as you gave the flashlight.

32.52. **IDENTIFY:** $P_{\text{av}} = IA$ and $I = \frac{1}{2}\epsilon_0 c E_{\max}^2$. $E_{\max} = cB_{\max}$

SET UP: The power carried by the current i is $P = Vi$.

EXECUTE: $I = \dfrac{P_{\text{av}}}{A} = \frac{1}{2}\epsilon_0 c E_{\max}^2$ and

$$E_{\max} = \sqrt{\frac{2P_{\text{av}}}{A\epsilon_0 c}} = \sqrt{\frac{2Vi}{A\epsilon_0 c}} = \sqrt{\frac{2(5.00\times10^5 \text{ V})(1000 \text{ A})}{(100 \text{ m}^2)\epsilon_0(3.00\times10^8 \text{ m/s})}} = 6.14\times10^4 \text{ V/m}.$$

$$B_{\max} = \frac{E_{\max}}{c} = \frac{6.14\times10^4 \text{ V/m}}{3.00\times10^8 \text{ m/s}} = 2.05\times10^{-4} \text{ T}.$$

EVALUATE: $I = Vi/A = \dfrac{(5.00\times10^5 \text{ V})(1000 \text{ A})}{100 \text{ m}^2} = 5.00\times10^6 \text{ W/m}^2$. This is a very intense beam spread over a large area.

32.53. **IDENTIFY:** The orbiting satellite obeys Newton's second law of motion. The intensity of the electromagnetic waves it transmits obeys the inverse-square distance law, and the intensity of the waves depends on the amplitude of the electric and magnetic fields.

SET UP: Newton's second law applied to the satellite gives $mv^2/r = GmM/r^2$, where M is the mass of the earth and m is the mass of the satellite. The intensity I of the wave is $I = S_{\text{av}} = \frac{1}{2}\epsilon_0 c E_{\max}{}^2$, and by definition, $I = P_{\text{av}}/A$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: **(a)** The period of the orbit is 12 hr. Applying Newton's second law to the satellite gives $mv^2/r = GmM/r^2$, which gives $\frac{m(2\pi r/T)^2}{r} = \frac{GmM}{r^2}$. Solving for r, we get

$$r = \left(\frac{GMT^2}{4\pi^2}\right)^{1/3} = \left[\frac{(6.67\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)(5.97\times10^{24}\ \text{kg})(12\times3600\ \text{s})^2}{4\pi^2}\right]^{1/3} = 2.66\times10^7\ \text{m}$$

The height above the surface is $h = 2.66\times10^7\ \text{m} - 6.38\times10^6\ \text{m} = 2.02\times10^7\ \text{m}$. The satellite only radiates its energy to the lower hemisphere, so the area is 1/2 that of a sphere. Thus, from the definition of intensity, the intensity at the ground is

$$I = P_{\text{av}}/A = P_{\text{av}}/(2\pi h^2) = (25.0\ \text{W})/[2\pi(2.02\times10^7\ \text{m})^2] = 9.75\times10^{-15}\ \text{W/m}^2$$

(b) $I = S_{\text{av}} = \frac{1}{2}\epsilon_0 c E_{\text{max}}^2$, so $E_{\text{max}} = \sqrt{\frac{2I}{\epsilon_0 c}} = \sqrt{\frac{2(9.75\times10^{-15}\ \text{W/m}^2)}{(8.85\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2)(3.00\times10^8\ \text{m/s})}} = 2.71\times10^{-6}\ \text{N/C}$

$$B_{\text{max}} = E_{\text{max}}/c = (2.71\times10^{-6}\ \text{N/C})/(3.00\times10^8\ \text{m/s}) = 9.03\times10^{-15}\ \text{T}$$

$$t = d/c = (2.02\times10^7\ \text{m})/(3.00\times10^8\ \text{m/s}) = 0.0673\ \text{s}$$

(c) $p_{\text{rad}} = I/\text{c} = (9.75\times10^{-15}\ \text{W/m}^2)/(3.00\times10^8\ \text{m/s}) = 3.25\times10^{-23}\ \text{Pa}$

(d) $\lambda = c/f = (3.00\times10^8\ \text{m/s})/(1575.42\times10^6\ \text{Hz}) = 0.190\ \text{m}$

EVALUATE: The fields and pressures due to these waves are very small compared to typical laboratory quantities.

32.54. **IDENTIFY:** For a totally reflective surface the radiation pressure is $\frac{2I}{c}$. Find the force due to this pressure and express the force in terms of the power output P of the sun. The gravitational force of the sun is $F_{\text{g}} = G\frac{mM_{\text{sun}}}{r^2}$.

SET UP: The mass of the sun is $M_{\text{sun}} = 1.99\times10^{30}$ kg. $G = 6.67\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2$.

EXECUTE: **(a)** The sail should be reflective, to produce the maximum radiation pressure.

(b) $F_{\text{rad}} = \left(\frac{2I}{c}\right)A$, where A is the area of the sail. $I = \frac{P}{4\pi r^2}$, where r is the distance of the sail from the sun. $F_{\text{rad}} = \left(\frac{2A}{c}\right)\left(\frac{P}{4\pi r^2}\right) = \frac{PA}{2\pi r^2 c}\cdot F_{\text{rad}} = F_{\text{g}}$ so $\frac{PA}{2\pi r^2 c} = G\frac{mM_{\text{sun}}}{r^2}$.

$$A = \frac{2\pi cGmM_{\text{sun}}}{P} = \frac{2\pi(3.00\times10^8\ \text{m/s})(6.67\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)(10{,}000\ \text{kg})(1.99\times10^{30}\ \text{kg})}{3.9\times10^{26}\ \text{W}}.$$

$A = 6.42\times10^6\ \text{m}^2 = 6.42\ \text{km}^2$.

(c) Both the gravitational force and the radiation pressure are inversely proportional to the square of the distance from the sun, so this distance divides out when we set $F_{\text{rad}} = F_{\text{g}}$.

EVALUATE: A very large sail is needed, just to overcome the gravitational pull of the sun.

32.55. **IDENTIFY** and **SET UP:** The gravitational force is given by Eq. (13.2). Express the mass of the particle in terms of its density and volume. The radiation pressure is given by Eq. (32.32); relate the power output L of the sun to the intensity at a distance r. The radiation force is the pressure times the cross-sectional area of the particle.

EXECUTE: **(a)** The gravitational force is $F_{\text{g}} = G\frac{mM}{r^2}$. The mass of the dust particle is $m = \rho V = \rho\frac{4}{3}\pi R^3$.

Thus $F_{\text{g}} = \frac{4\rho G\pi MR^3}{3r^2}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) For a totally absorbing surface $p_{\text{rad}} = \dfrac{I}{c}$. If L is the power output of the sun, the intensity of the solar radiation a distance r from the sun is $I = \dfrac{L}{4\pi r^2}$. Thus $p_{\text{rad}} = \dfrac{L}{4\pi c r^2}$. The force F_{rad} that corresponds to p_{rad} is in the direction of propagation of the radiation, so $F_{\text{rad}} = p_{\text{rad}} A_\perp$, where $A_\perp = \pi R^2$ is the component of area of the particle perpendicular to the radiation direction. Thus

$$F_{\text{rad}} = \left(\frac{L}{4\pi c r^2}\right)(\pi R^2) = \frac{LR^2}{4cr^2}.$$

(c) $F_g = F_{\text{rad}}$

$$\frac{4\rho G\pi MR^3}{3r^2} = \frac{LR^2}{4cr^2}$$

$$\left(\frac{4\rho G\pi M}{3}\right)R = \frac{L}{4c} \text{ and } R = \frac{3L}{16c\rho G\pi M}$$

$$R = \frac{3(3.9\times10^{26}\ \text{W})}{16(2.998\times10^{8}\ \text{m/s})(3000\ \text{kg/m}^3)(6.673\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)\pi(1.99\times10^{30}\ \text{kg})}$$

$$R = 1.9\times10^{-7}\ \text{m} = 0.19\ \mu\text{m}.$$

EVALUATE: The gravitational force and the radiation force both have a r^{-2} dependence on the distance from the sun, so this distance divides out in the calculation of R.

(d) $\dfrac{F_{\text{rad}}}{F_{\text{g}}} = \left(\dfrac{LR^2}{4cr^2}\right)\left(\dfrac{3r^2}{4\rho G\pi mR^3}\right) = \dfrac{3L}{16c\rho G\pi MR}$. F_{rad} is proportional to R^2 and F_{g} is proportional to R^3, so this ratio is proportional to $1/R$. If $R < 0.20\ \mu\text{m}$ then $F_{\text{rad}} > F_{\text{g}}$ and the radiation force will drive the particles out of the solar system.

32.56. **IDENTIFY** and **SET UP:** Follow the steps specified in the problem.

EXECUTE: **(a)** $E_y(x,t) = E_{\max}e^{-k_{\text{C}}x}\cos(k_{\text{C}}x - \omega t)$.

$$\frac{\partial E_y}{\partial x} = E_{\max}(-k_{\text{C}})e^{-k_{\text{C}}x}\cos(k_{\text{C}}x-\omega t) + E_{\max}(-k_{\text{C}})e^{-k_{\text{C}}x}\sin(k_{\text{C}}x-\omega t)$$

$$\frac{\partial^2 E_y}{\partial x^2} = E_{\max}(+k_{\text{C}}^2)e^{-k_{\text{C}}x}\cos(k_{\text{C}}x-\omega t) + E_{\max}(+k_{\text{C}}^2)e^{-k_{\text{C}}x}\sin(k_{\text{C}}x-\omega t)$$

$$+ E_{\max}(+k_{\text{C}}^2)e^{-k_{\text{C}}x}\sin(k_{\text{C}}x-\omega t) + E_{\max}(-k_{\text{C}}^2)e^{-k_{\text{C}}x}\cos(k_{\text{C}}x-\omega t).$$

$$\frac{\partial^2 E_y}{\partial x^2} = -2E_{\max}k_{\text{C}}^2e^{-k_{\text{C}}x}\cos(k_{\text{C}}x-\omega t). \quad \frac{\partial E_y}{\partial t} = -E_{\max}e^{-k_{\text{C}}x}\,\omega\sin(k_{\text{C}}x-\omega t).$$

Setting $\dfrac{\partial^2 E_y}{\partial x^2} = \dfrac{\mu\partial E_y}{\rho\partial t}$ gives $2E_{\max}k_{\text{C}}^2e^{-k_{\text{C}}x}\sin(k_{\text{C}}x-\omega t) = \mu/pE_{\max}e^{-k_{\text{C}}x}\,\omega\sin(k_{\text{C}}x-\omega t)$. This will only be true if $\dfrac{2k_{\text{C}}^2}{\omega} = \dfrac{\mu}{\rho}$, or $k_{\text{C}} = \sqrt{\dfrac{\omega\mu}{2\rho}}$.

(b) The energy in the wave is dissipated by the i^2R heating of the conductor.

(c) $E_y = \dfrac{E_{y0}}{e} \Rightarrow k_{\text{C}}x = 1$, $x = \dfrac{1}{k_{\text{C}}} = \sqrt{\dfrac{2\rho}{\omega\mu}} = \sqrt{\dfrac{2(1.72\times10^{-8}\ \Omega\cdot\text{m})}{2\pi(1.0\times10^{6}\ \text{Hz})\mu_0}} = 6.60\times10^{-5}\,\text{m}$.

EVALUATE: The lower the frequency of the waves, the greater is the distance they can penetrate into a conductor. A dielectric (insulator) has a much larger resistivity and these waves can penetrate a greater distance in these materials.

32.57. **IDENTIFY:** The orbiting particle has acceleration $a = \dfrac{v^2}{R}$.

SET UP: $K = \frac{1}{2}mv^2$. An electron has mass $m_e = 9.11\times10^{-31}$ kg and a proton has mass $m_p = 1.67\times10^{-27}$ kg.

EXECUTE: **(a)** $\left[\dfrac{q^2a^2}{6\pi\epsilon_0 c^3}\right] = \dfrac{\text{C}^2(\text{m/s}^2)^2}{(\text{C}^2/\text{N}\cdot\text{m}^2)(\text{m/s})^3} = \dfrac{\text{N}\cdot\text{m}}{\text{s}} = \dfrac{\text{J}}{\text{s}} = \text{W} = \left[\dfrac{dE}{dt}\right]$.

(b) For a proton moving in a circle, the acceleration is

$a = \dfrac{v^2}{R} = \dfrac{\frac{1}{2}mv^2}{\frac{1}{2}mR} = \dfrac{2(6.00\times10^6\text{ eV})(1.6\times10^{-19}\text{ J/eV})}{(1.67\times10^{-27}\text{ kg})(0.75\text{ m})} = 1.53\times10^{15}\text{ m/s}^2$. The rate at which it emits energy because of its acceleration is

$\dfrac{dE}{dt} = \dfrac{q^2a^2}{6\pi\epsilon_0 c^3} = \dfrac{(1.6\times10^{-19}\text{ C})^2(1.53\times10^{15}\text{ m/s}^2)^2}{6\pi\epsilon_0(3.0\times10^8\text{ m/s})^3} = 1.33\times10^{-23}\text{ J/s} = 8.32\times10^{-5}\text{ eV/s}.$

Therefore, the fraction of its energy that it radiates every second is

$\dfrac{(dE/dt)(1\text{ s})}{E} = \dfrac{8.32\times10^{-5}\text{ eV}}{6.00\times10^6\text{ eV}} = 1.39\times10^{-11}.$

(c) Carry out the same calculations as in part (b), but now for an electron at the same speed and radius. That means the electron's acceleration is the same as the proton, and thus so is the rate at which it emits energy, since they also have the same charge. However, the electron's initial energy differs from the proton's by the ratio of their masses: $E_e = E_p\dfrac{m_e}{m_p} = (6.00\times10^6\text{ eV})\dfrac{(9.11\times10^{-31}\text{ kg})}{(1.67\times10^{-27}\text{ kg})} = 3273\text{ eV}$. Therefore, the fraction of its energy that it radiates every second is $\dfrac{(dE/dt)(1\text{ s})}{E} = \dfrac{8.32\times10^{-5}\text{ eV}}{3273\text{ eV}} = 2.54\times10^{-8}$.

EVALUATE: The proton has speed $v = \sqrt{\dfrac{2E}{m_p}} = \sqrt{\dfrac{2(6.0\times10^6\text{ eV})(1.60\times10^{-19}\text{ J/eV})}{1.67\times10^{-27}\text{ kg}}} = 3.39\times10^7$ m/s. The electron has the same speed and kinetic energy 3.27 keV. The particles in the accelerator radiate at a much smaller rate than the electron in Problem 32.58 does, because in the accelerator the orbit radius is very much larger than in the atom, so the acceleration is much less.

32.58. **IDENTIFY:** The electron has acceleration $a = \dfrac{v^2}{R}$.

SET UP: $1\text{ eV} = 1.60\times10^{-19}$ C. An electron has $|q| = e = 1.60\times10^{-19}$ C.

EXECUTE: For the electron in the classical hydrogen atom, its acceleration is

$a = \dfrac{v^2}{R} = \dfrac{\frac{1}{2}mv^2}{\frac{1}{2}mR} = \dfrac{2(13.6\text{ eV})(1.60\times10^{-19}\text{ J/eV})}{(9.11\times10^{-31}\text{ kg})(5.29\times10^{-11}\text{ m})} = 9.03\times10^{22}\text{ m/s}^2$. Then using the formula for the rate of energy emission given in Problem 32.57:

$\dfrac{dE}{dt} = \dfrac{q^2a^2}{6\pi\epsilon_0 c^3} = \dfrac{(1.60\times10^{-19}\text{ C})^2(9.03\times10^{22}\text{ m/s}^2)^2}{6\pi\epsilon_0(3.00\times10^8\text{ m/s})^3} = 4.64\times10^{-8}\text{ J/s} = 2.89\times10^{11}\text{ eV/s}.$ This large value of $\dfrac{dE}{dt}$ would mean that the electron would almost immediately lose all its energy!

EVALUATE: The classical physics result in Problem 32.57 must not apply to electrons in atoms.

33

THE NATURE AND PROPAGATION OF LIGHT

33.1. **IDENTIFY:** For reflection, $\theta_r = \theta_a$.

SET UP: The desired path of the ray is sketched in Figure 33.1.

EXECUTE: $\tan\phi = \dfrac{14.0\text{ cm}}{11.5\text{ cm}}$, so $\phi = 50.6°$. $\theta_r = 90° - \phi = 39.4°$ and $\theta_r = \theta_a = 39.4°$.

EVALUATE: The angle of incidence is measured from the normal to the surface.

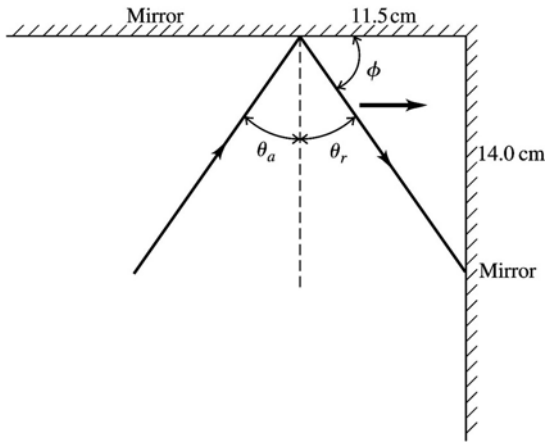

Figure 33.1

33.2. **IDENTIFY:** The speed and the wavelength of the light will be affected by the vitreous humor, but not the frequency.

SET UP: $n = \dfrac{c}{v}$. $v = f\lambda$. $\lambda = \dfrac{\lambda_0}{n}$.

EXECUTE: **(a)** $\lambda_v = \dfrac{\lambda_{0,v}}{n} = \dfrac{400\text{ nm}}{1.34} = 299\text{ nm}$. $\lambda_r = \dfrac{\lambda_{0,r}}{n} = \dfrac{700\text{ nm}}{1.34} = 522\text{ nm}$. The range is 299 nm to 522 nm.

(b) Calculate the frequency in air, where $v = c = 3.00\times10^8$ m/s. $f_r = \dfrac{c}{\lambda_r} = \dfrac{3.00\times10^8\text{ m/s}}{700\times10^{-9}\text{ m}} = 4.29\times10^{14}$ Hz.

$f_v = \dfrac{c}{\lambda_v} = \dfrac{3.00\times10^8\text{ m/s}}{400\times10^{-9}\text{ m}} = 7.50\times10^{14}$ Hz. The range is 4.29×10^{14} Hz to 7.50×10^{14} Hz.

(c) $v = \dfrac{c}{n} = \dfrac{3.00\times10^8\text{ m/s}}{1.34} = 2.24\times10^8$ m/s.

EVALUATE: The frequency range in air is the same as in the vitreous humor.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

33.3. **IDENTIFY** and **SET UP:** Use Eqs. (33.1) and (33.5) to calculate v and λ.

EXECUTE: **(a)** $n = \dfrac{c}{v}$ so $v = \dfrac{c}{n} = \dfrac{2.998\times10^8 \text{ m/s}}{1.47} = 2.04\times10^8 \text{ m/s}$

(b) $\lambda = \dfrac{\lambda_0}{n} = \dfrac{650 \text{ nm}}{1.47} = 442 \text{ nm}$

EVALUATE: Light is slower in the liquid than in vacuum. By $v = f\lambda$, when v is smaller, λ is smaller.

33.4. **IDENTIFY:** In air, $c = f\lambda_0$. In glass, $\lambda = \dfrac{\lambda_0}{n}$.

SET UP: $c = 3.00\times10^8$ m/s

EXECUTE: **(a)** $\lambda_0 = \dfrac{c}{f} = \dfrac{3.00\times10^8 \text{ m/s}}{5.80\times10^{14} \text{ Hz}} = 517 \text{ nm}$

(b) $\lambda = \dfrac{\lambda_0}{n} = \dfrac{517 \text{ nm}}{1.52} = 340 \text{ nm}$

EVALUATE: In glass the light travels slower than in vacuum and the wavelength is smaller.

33.5. **IDENTIFY:** $n = \dfrac{c}{v}$. $\lambda = \dfrac{\lambda_0}{n}$, where λ_0 is the wavelength in vacuum.

SET UP: $c = 3.00\times10^8$ m/s. n for air is only slightly larger than unity.

EXECUTE: **(a)** $n = \dfrac{c}{v} = \dfrac{3.00\times10^8 \text{ m/s}}{1.94\times10^8 \text{ m/s}} = 1.55.$

(b) $\lambda_0 = n\lambda = (1.55)(3.55\times10^{-7} \text{ m}) = 5.50\times10^{-7} \text{ m}.$

EVALUATE: In quartz the speed is lower and the wavelength is smaller than in air.

33.6. **IDENTIFY:** $\lambda = \dfrac{\lambda_0}{n}$.

SET UP: From Table 33.1, $n_{\text{water}} = 1.333$ and $n_{\text{benzene}} = 1.501$.

EXECUTE: $\lambda_{\text{water}} n_{\text{water}} = \lambda_{\text{benzene}} n_{\text{benzene}} = \lambda_0$. $\lambda_{\text{benzene}} = \lambda_{\text{water}}\left(\dfrac{n_{\text{water}}}{n_{\text{benzene}}}\right) = (438 \text{ nm})\left(\dfrac{1.333}{1.501}\right) = 389 \text{ nm}.$

EVALUATE: λ is smallest in benzene, since n is largest for benzene.

33.7. **IDENTIFY:** Apply Eqs. (33.2) and (33.4) to calculate θ_r and θ_b. The angles in these equations are measured with respect to the normal, not the surface.

(a) SET UP: The incident, reflected and refracted rays are shown in Figure 33.7.

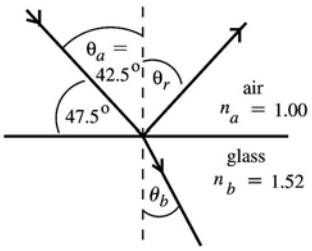

Figure 33.7

EVALUATE: $\theta_r = \theta_a = 42.5°$ The reflected ray makes an angle of $90.0° - \theta_r = 47.5°$ with the surface of the glass.

(b) $n_a \sin\theta_a = n_b \sin\theta_b$, where the angles are measured from the normal to the interface.

$$\sin\theta_b = \frac{n_a \sin\theta_a}{n_b} = \frac{(1.00)(\sin 42.5°)}{1.66} = 0.4070$$

$\theta_b = 24.0°$

The refracted ray makes an angle of $90.0° - \theta_b = 66.0°$ with the surface of the glass.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: The light is bent toward the normal when the light enters the material of larger refractive index.

33.8. **IDENTIFY:** The time delay occurs because the beam going through the transparent material travels slower than the beam in air.

SET UP: $v = \dfrac{c}{n}$ in the material, but $v = c$ in air.

EXECUTE: The time for the beam traveling in air to reach the detector is $t = \dfrac{d}{c} = \dfrac{2.50\text{ m}}{3.00\times10^8\text{ m/s}} = 8.33\times10^{-9}\text{ s}$. The light traveling in the block takes time $t = 8.33\times10^{-9}\text{ s} + 6.25\times10^{-9}\text{ s} = 1.46\times10^{-8}\text{ s}$. The speed of light in the block is $v = \dfrac{d}{t} = \dfrac{2.50\text{ m}}{1.46\times10^{-8}\text{ s}} = 1.71\times10^8\text{ m/s}$. The refractive index of the block is $n = \dfrac{c}{v} = \dfrac{3.00\times10^8\text{ m/s}}{1.71\times10^8\text{ m/s}} = 1.75$.

EVALUATE: $n > 1$, as it must be, and 1.75 is a reasonable index of refraction for a transparent material such as plastic.

33.9. **IDENTIFY** and **SET UP:** Use Snell's law to find the index of refraction of the plastic and then use Eq. (33.1) to calculate the speed v of light in the plastic.

EXECUTE: $n_a \sin\theta_a = n_b \sin\theta_b$

$$n_b = n_a\left(\frac{\sin\theta_a}{\sin\theta_b}\right) = 1.00\left(\frac{\sin 62.7^\circ}{\sin 48.1^\circ}\right) = 1.194$$

$n = \dfrac{c}{v}$ so $v = \dfrac{c}{n} = (3.00\times10^8\text{ m/s})/1.194 = 2.51\times10^8\text{ m/s}$

EVALUATE: Light is slower in plastic than in air. When the light goes from air into the plastic it is bent toward the normal.

33.10. **IDENTIFY:** Apply Snell's law at both interfaces.

SET UP: The path of the ray is sketched in Figure 33.10. Table 33.1 gives $n = 1.329$ for the methanol.

EXECUTE: **(a)** At the air-glass interface $(1.00)\sin 41.3^\circ = n_{\text{glass}} \sin\alpha$. At the glass-methanol interface $n_{\text{glass}} \sin\alpha = (1.329)\sin\theta$. Combining these two equations gives $\sin 41.3^\circ = 1.329\sin\theta$ and $\theta = 29.8^\circ$.

(b) The same figure applies apply as for part (a), except $\theta = 20.2^\circ$. $(1.00)\sin 41.3^\circ = n\sin 20.2^\circ$ and $n = 1.91$.

EVALUATE: The angle α is 25.2°. The index of refraction of methanol is less than that of the glass and the ray is bent away from the normal at the glass $\rightarrow$ methanol interface. The unknown liquid has an index of refraction greater than that of the glass, so the ray is bent toward the normal at the glass $\rightarrow$ liquid interface.

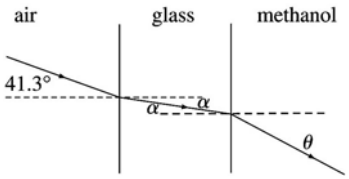

Figure 33.10

33.11. **IDENTIFY:** The figure shows the angle of incidence and angle of refraction for light going from the water into material X. Snell's law applies at the air-water and water-X boundaries.

SET UP: Snell's law says $n_a \sin\theta_a = n_b \sin\theta_b$. Apply Snell's law to the refraction from material X into the water and then from the water into the air.

EXECUTE: **(a)** Material X to water: $n_a = n_X$, $n_b = n_{\text{w}} = 1.333$. $\theta_a = 25^\circ$ and $\theta_b = 48^\circ$.

$$n_a = n_b\left(\frac{\sin\theta_b}{\sin\theta_a}\right) = (1.333)\left(\frac{\sin 48^\circ}{\sin 25^\circ}\right) = 2.34.$$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) Water to air: As Figure 33.11 shows, $\theta_a = 48°$. $n_a = 1.333$ and $n_b = 1.00$.

$$\sin\theta_b = \left(\frac{n_a}{n_b}\right)\sin\theta_a = (1.333)\sin 48° = 82°.$$

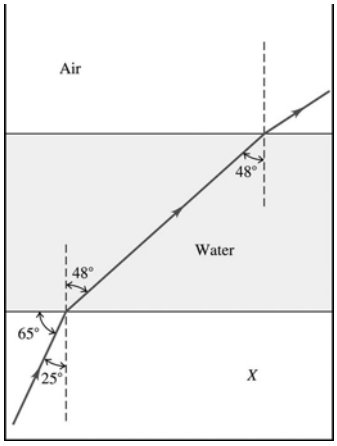

Figure 33.11

EVALUATE: $n > 1$ for material *X*, as it must be.

33.12. **IDENTIFY:** Apply Snell's law to the refraction at each interface.

SET UP: $n_{\text{air}} = 1.00$. $n_{\text{water}} = 1.333$.

EXECUTE: **(a)** $\theta_{\text{water}} = \arcsin\left(\frac{n_{\text{air}}}{n_{\text{water}}}\sin\theta_{\text{air}}\right) = \arcsin\left(\frac{1.00}{1.333}\sin 35.0^\circ\right) = 25.5^\circ.$

EVALUATE: **(b)** This calculation has no dependence on the glass because we can omit that step in the chain: $n_{\text{air}}\sin\theta_{\text{air}} = n_{\text{glass}}\sin\theta_{\text{glass}} = n_{\text{water}}\sin\theta_{\text{water}}$.

33.13. **IDENTIFY:** When a wave passes from one material into another, the number of waves per second that cross the boundary is the same on both sides of the boundary, so the frequency does not change. The wavelength and speed of the wave, however, do change.

SET UP: In a material having index of refraction *n*, the wavelength is $\lambda = \frac{\lambda_0}{n}$, where λ_0 is the wavelength in vacuum, and the speed is $\frac{c}{n}$.

EXECUTE: **(a)** The frequency is the same, so it is still *f*. The wavelength becomes $\lambda = \frac{\lambda_0}{n}$, so $\lambda_0 = n\lambda$. The speed is $v = \frac{c}{n}$, so $c = nv$.

(b) The frequency is still *f*. The wavelength becomes $\lambda' = \frac{\lambda_0}{n'} = \frac{n\lambda}{n'} = \left(\frac{n}{n'}\right)\lambda$ and the speed becomes

$$v' = \frac{c}{n'} = \frac{nv}{n'} = \left(\frac{n}{n'}\right)v$$

EVALUATE: These results give the speed and wavelength in a new medium in terms of the original medium without referring them to the values in vacuum (or air).

33.14. **IDENTIFY:** The wavelength of the light depends on the index of refraction of the material through which it is traveling, and Snell's law applies at the water-glass interface.

SET UP: $\lambda_0 = \lambda n$ so $\lambda_{\text{w}} n_{\text{w}} = \lambda_{\text{gl}} n_{\text{gl}}$. Snell's law gives $n_{\text{gl}}\sin\theta_{\text{gl}} = n_{\text{w}}\sin\theta_{\text{w}}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: $n_{\text{gl}} = n_{\text{w}}\left(\frac{\lambda_{\text{w}}}{\lambda_{\text{gl}}}\right) = (1.333)\left(\frac{726\text{ nm}}{544\text{ nm}}\right) = 1.779$. Now apply $n_{\text{gl}}\sin\theta_{\text{gl}} = n_{\text{w}}\sin\theta_{\text{w}}$.

$\sin\theta_{\text{gl}} = \left(\frac{n_{\text{w}}}{n_{\text{gl}}}\right)\sin\theta_{\text{w}} = \left(\frac{1.333}{1.779}\right)\sin 42.0° = 0.5014$. $\theta_{\text{gl}} = 30.1°$.

EVALUATE: $\theta_{\text{gl}} < \theta_{\text{air}}$ because $n_{\text{gl}} > n_{\text{air}}$.

33.15. **IDENTIFY:** Apply $n_a\sin\theta_a = n_b\sin\theta_b$.

SET UP: $n_a = 1.70$, $\theta_a = 62.0°$. $n_b = 1.58$.

EXECUTE: $\sin\theta_b = \left(\frac{n_a}{n_b}\right)\sin\theta_a = \left(\frac{1.70}{1.58}\right)\sin 62.0° = 0.950$ and $\theta_b = 71.8°$.

EVALUATE: The ray refracts into a material of smaller n, so it is bent away from the normal.

33.16. **IDENTIFY:** No light will enter the water if total internal reflection occurs at the glass-water boundary. Snell's law applies at the boundary.

SET UP: Find n_{g}, the refractive index of the glass. Then apply Snell's law at the boundary. $n_a\sin\theta_a = n_b\sin\theta_b$.

EXECUTE: $n_{\text{g}}\sin 36.2° = n_{\text{w}}\sin 49.8°$. $n_{\text{g}} = (1.333)\left(\frac{\sin 49.8°}{\sin 36.2°}\right) = 1.724$. Now find θ_{crit} for the glass to water refraction. $n_{\text{g}}\sin\theta_{\text{crit}} = n_{\text{w}}\sin 90.0°$. $\sin\theta_{\text{crit}} = \frac{1.333}{1.724}$ and $\theta_{\text{crit}} = 50.6°$.

EVALUATE: For $\theta > 50.6^{\text{o}}$ at the glass-water boundary, no light is refracted into the water.

33.17. **IDENTIFY:** The critical angle for total internal reflection is θ_a that gives $\theta_b = 90°$ in Snell's law.

SET UP: In Figure 33.17 the angle of incidence θ_a is related to angle θ by $\theta_a + \theta = 90°$.

EXECUTE: **(a)** Calculate θ_a that gives $\theta_b = 90°$. $n_a = 1.60$, $n_b = 1.00$ so $n_a\sin\theta_a = n_b\sin\theta_b$ gives $(1.60)\sin\theta_a = (1.00)\sin 90°$. $\sin\theta_a = \frac{1.00}{1.60}$ and $\theta_a = 38.7°$. $\theta = 90° - \theta_a = 51.3°$.

(b) $n_a = 1.60$, $n_b = 1.333$. $(1.60)\sin\theta_a = (1.333)\sin 90°$. $\sin\theta_a = \frac{1.333}{1.60}$ and $\theta_a = 56.4°$. $\theta = 90° - \theta_a = 33.6°$.

EVALUATE: The critical angle increases when the ratio $\frac{n_a}{n_b}$ decreases.

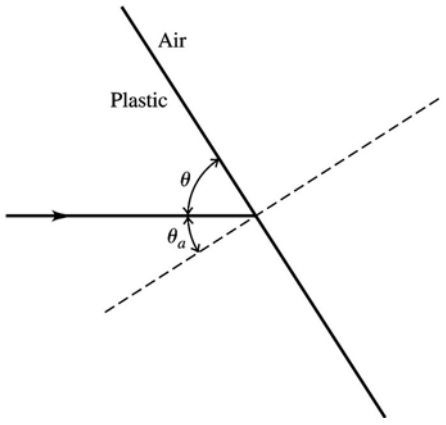

Figure 33.17

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

33.18. **IDENTIFY:** Since the refractive index of the glass is greater than that of air or water, total internal reflection will occur at the cube surface if the angle of incidence is greater than or equal to the critical angle.

SET UP: At the critical angle θ_{crit}, Snell's law gives $n_{\text{glass}} \sin\theta_{\text{crit}} = n_{\text{air}} \sin 90°$ and likewise for water.

EXECUTE: **(a)** At the critical angle θ_{crit}, $n_{\text{glass}} \sin\theta_{\text{crit}} = n_{\text{air}} \sin 90°$.

$1.53 \sin\theta_{\text{crit}} = (1.00)(1)$ and $\theta_{\text{crit}} = 40.8°$.

(b) Using the same procedure as in part (a), we have $1.53 \sin\theta_{\text{crit}} = 1.333 \sin 90°$ and $\theta_{\text{crit}} = 60.6°$.

EVALUATE: Since the refractive index of water is closer to the refractive index of glass than the refractive index of air is, the critical angle for glass-to-water is greater than for glass-to-air.

33.19. **IDENTIFY:** Use the critical angle to find the index of refraction of the liquid.

SET UP: Total internal reflection requires that the light be incident on the material with the larger n, in this case the liquid. Apply $n_a \sin\theta_a = n_b \sin\theta_b$ with $a =$ liquid and $b =$ air, so $n_a = n_{\text{liq}}$ and $n_b = 1.0$.

EXECUTE: $\theta_a = \theta_{\text{crit}}$ when $\theta_b = 90°$, so $n_{\text{liq}} \sin\theta_{\text{crit}} = (1.0) \sin 90°$

$$n_{\text{liq}} = \frac{1}{\sin\theta_{\text{crit}}} = \frac{1}{\sin 42.5°} = 1.48.$$

(a) $n_a \sin\theta_a = n_b \sin\theta_b$ ($a =$ liquid, $b =$ air)

$$\sin\theta_b = \frac{n_a \sin\theta_a}{n_b} = \frac{(1.48)\sin 35.0°}{1.0} = 0.8489 \text{ and } \theta_b = 58.1°$$

(b) Now $n_a \sin\theta_a = n_b \sin\theta_b$ with $a =$ air, $b =$ liquid

$$\sin\theta_b = \frac{n_a \sin\theta_a}{n_b} = \frac{(1.0)\sin 35.0°}{1.48} = 0.3876 \text{ and } \theta_b = 22.8°$$

EVALUATE: For light traveling liquid $\rightarrow$ air the light is bent away from the normal. For light traveling air $\rightarrow$ liquid the light is bent toward the normal.

33.20. **IDENTIFY:** The largest angle of incidence for which any light refracts into the air is the critical angle for water $\rightarrow$ air.

SET UP: Figure 33.20 shows a ray incident at the critical angle and therefore at the edge of the circle of light. The radius of this circle is r and $d = 10.0$ m is the distance from the ring to the surface of the water.

EXECUTE: From the figure, $r = d \tan\theta_{\text{crit}}$. θ_{crit} is calculated from $n_a \sin\theta_a = n_b \sin\theta_b$ with $n_a = 1.333$, $\theta_a = \theta_{\text{crit}}$, $n_b = 1.00$ and $\theta_b = 90°$. $\sin\theta_{\text{crit}} = \dfrac{(1.00)\sin 90°}{1.333}$ and $\theta_{\text{crit}} = 48.6°$.

$r = (10.0 \text{ m}) \tan 48.6° = 11.3 \text{ m}$.

$A = \pi r^2 = \pi (11.3 \text{ m})^2 = 401 \text{ m}^2$.

EVALUATE: When the incident angle in the water is larger than the critical angle, no light refracts into the air.

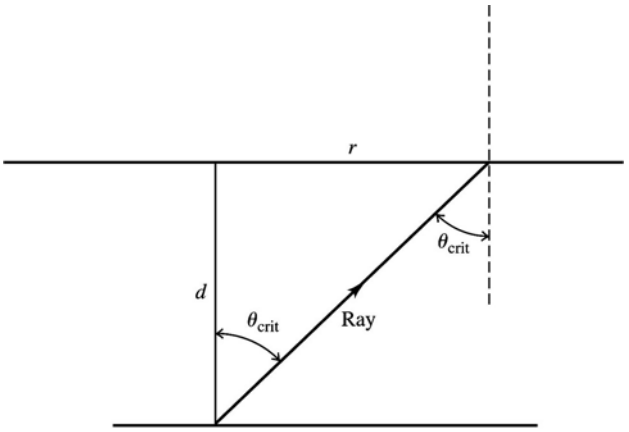

Figure 33.20

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

33.21. **IDENTIFY** and **SET UP:** For glass $\rightarrow$ water, $\theta_{\text{crit}} = 48.7°$. Apply Snell's law with $\theta_a = \theta_{\text{crit}}$ to calculate the index of refraction n_a of the glass.

EXECUTE: $n_a \sin\theta_{\text{crit}} = n_b \sin 90°$, so $n_a = \dfrac{n_b}{\sin\theta_{\text{crit}}} = \dfrac{1.333}{\sin 48.7°} = 1.77$

EVALUATE: For total internal reflection to occur the light must be incident in the material of larger refractive index. Our results give $n_{\text{glass}} > n_{\text{water}}$, in agreement with this.

33.22. **IDENTIFY:** If no light refracts out of the glass at the glass to air interface, then the incident angle at that interface is θ_{crit}.

SET UP: The ray has an angle of incidence of $0°$ at the first surface of the glass, so enters the glass without being bent, as shown in Figure 33.22. The figure shows that $\alpha + \theta_{\text{crit}} = 90°$.

EXECUTE: **(a)** For the glass-air interface $\theta_a = \theta_{\text{crit}}$, $n_a = 1.52$, $n_b = 1.00$ and $\theta_b = 90°$.

$n_a \sin\theta_a = n_b \sin\theta_b$ gives $\sin\theta_{\text{crit}} = \dfrac{(1.00)(\sin 90°)}{1.52}$ and $\theta_{\text{crit}} = 41.1°$. $\alpha = 90° - \theta_{\text{crit}} = 48.9°$.

(b) Now the second interface is glass $\rightarrow$ water and $n_b = 1.333$. $n_a \sin\theta_a = n_b \sin\theta_b$ gives

$\sin\theta_{\text{crit}} = \dfrac{(1.333)(\sin 90°)}{1.52}$ and $\theta_{\text{crit}} = 61.3°$. $\alpha = 90° - \theta_{\text{crit}} = 28.7°$.

EVALUATE: The critical angle increases when the air is replaced by water.

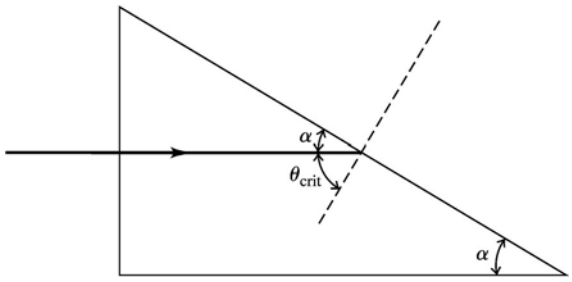

Figure 33.22

33.23. **IDENTIFY:** Total internal reflection must be occurring at the glass-water boundary. Snell's law applies there.

SET UP: $n_a \sin\theta_a = n_b \sin\theta_b$. $\lambda = \lambda_0/n$.

EXECUTE: Apply Snell's law to find n_{gl}: $n_{\text{gl}} \sin 62.0° = n_{\text{w}} \sin 90.0°$ and $n_{\text{gl}} = 1.510$. Then

$\lambda_{\text{w}} n_{\text{w}} = \lambda_{\text{gl}} n_{\text{gl}}$ and $\lambda_{\text{w}} = \lambda_{\text{gl}}\left(\dfrac{n_{\text{gl}}}{n_{\text{w}}}\right) = (408\text{ nm})\left(\dfrac{1.510}{1.333}\right) = 462\text{ nm}.$

EVALUATE: The wavelength is greater in the water than it is in the glass, as it must be, since $n_{\text{w}} < n_{\text{gl}}$.

33.24. **IDENTIFY:** We apply Snell's law to sound waves, making an appropriate definition of the index of refraction for sound. We cannot use the speed of sound in vacuum because sound does not travel through a vacuum.

SET UP: $n = \dfrac{v_{\text{air}}}{v}$. When $\theta_a = \theta_{\text{crit}}$, $\theta_b = 90°$. $n_a \sin\theta_a = n_b \sin\theta_b$.

EXECUTE: **(a)** For air, $n = \dfrac{v_{\text{air}}}{v} = 1.00$. For water, $n = \dfrac{v_{\text{air}}}{v} = \dfrac{344\text{ m/s}}{1320\text{ m/s}} = 0.261$. Air has a larger index of refraction for sound waves.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) Total internal reflection requires that the waves be incident in the material of larger refractive index. $n_a = 1.00$, $n_b = 0.261$, $\theta_a = \theta_{\text{crit}}$, and $\theta_b = 90°$. Applying $n_a \sin\theta_a = n_b \sin\theta_b$ gives

$$\sin\theta_{\text{crit}} = \left(\frac{0.261}{1.00}\right)\sin 90°, \text{ so } \theta_{\text{crit}} = 15.1°.$$

(c) The sound wave must be traveling in air.

(d) Sound waves can be totally reflected from the surface of the water.

EVALUATE: Light travels faster in vacuum than in any material and n is always greater than 1.00. Sound travels faster in solids and liquids than in air and n for sound is less than 1.00.

33.25. **IDENTIFY:** The index of refraction depends on the wavelength of light, so the light from the red and violet ends of the spectrum will be bent through different angles as it passes into the glass. Snell's law applies at the surface.

SET UP: $n_a \sin\theta_a = n_b \sin\theta_b$. From the graph in Figure 33.18 in the textbook, for $\lambda = 400$ nm (the violet end of the visible spectrum), $n = 1.67$ and for $\lambda = 700$ nm (the red end of the visible spectrum), $n = 1.62$. The path of a ray with a single wavelength is sketched in Figure 33.25.

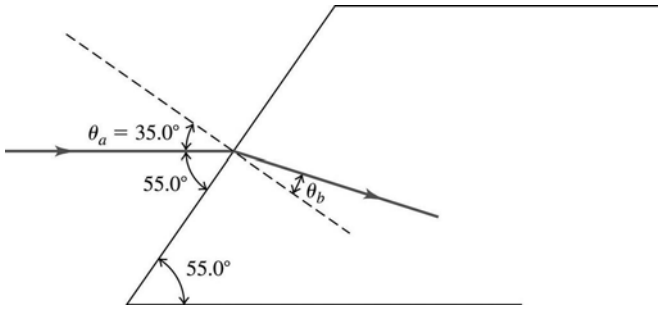

Figure 33.25

EXECUTE: For $\lambda = 400$ nm, $\sin\theta_b = \frac{n_a}{n_b}\sin\theta_a = \frac{1.00}{1.67}\sin 35.0°$, so $\theta_b = 20.1°$. For $\lambda = 700$ nm,

$$\sin\theta_b = \frac{1.00}{1.62}\sin 35.0°, \text{ so } \theta_b = 20.7°.$$ $\Delta\theta$ is about $0.6°$.

EVALUATE: This angle is small, but the separation of the beams could be fairly large if the light travels through a fairly large slab.

33.26. **IDENTIFY:** Snell's law is $n_a \sin\theta_a = n_b \sin\theta_b$. $v = \frac{c}{n}$.

SET UP: $a =$ air, $b =$ glass.

EXECUTE: **(a)** red: $n_b = \frac{n_a \sin\theta_a}{\sin\theta_b} = \frac{(1.00)\sin 57.0°}{\sin 38.1°} = 1.36$. violet: $n_b = \frac{(1.00)\sin 57.0°}{\sin 36.7°} = 1.40$.

(b) red: $v = \frac{c}{n} = \frac{3.00\times10^8 \text{ m/s}}{1.36} = 2.21\times10^8$ m/s; violet: $v = \frac{c}{n} = \frac{3.00\times10^8 \text{ m/s}}{1.40} = 2.14\times10^8$ m/s.

EVALUATE: n is larger for the violet light and therefore this light is bent more toward the normal, and the violet light has a smaller speed in the glass than the red light.

33.27. **IDENTIFY:** The first polarizer filters out half the incident light. The fraction filtered out by the second polarizer depends on the angle between the axes of the two filters.

SET UP: $I = I_0 \cos^2\phi$.

EXECUTE: After the first filter, $I = \frac{1}{2}I_0$. After the second filter, $I = \left(\frac{1}{2}I_0\right)\cos^2\phi$, which gives

$$I = \left(\frac{1}{2}I_0\right)\cos^2 30.0° = 0.375 I_0.$$

EVALUATE: The only variable that affects the answer is the angle between the axes of the two polarizers.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

33.28. **IDENTIFY:** The sunlight must be striking the lake surface at the Brewster's angle (the polarizing angle) since the reflected light is completely polarized.

SET UP: The reflected beam is completely polarized when $\theta_a = \theta_p$, with $\tan\theta_p = \frac{n_b}{n_a}$. n_a=1.00, $n_b = 1.333$. θ_p is measured relative to the normal to the surface.

EXECUTE: **(a)** $\tan\theta_p = \frac{1.333}{1.00}$, so $\theta_p = 53.1°$. The sunlight is incident at an angle of $90° - 53.1° = 36.9°$ above the horizontal.

(b) Figure 33.27 in the text shows that the plane of the electric field vector in the reflected light is horizontal.

EVALUATE: To reduce the glare (intensity of reflected light), sunglasses with polarizing filters should have the filter axis vertical.

33.29. **IDENTIFY:** When unpolarized light passes through a polarizer the intensity is reduced by a factor of $\frac{1}{2}$ and the transmitted light is polarized along the axis of the polarizer. When polarized light of intensity I_{max} is incident on a polarizer, the transmitted intensity is $I = I_{max}\cos^2\phi$, where ϕ is the angle between the polarization direction of the incident light and the axis of the filter.

SET UP: For the second polarizer $\phi = 60°$. For the third polarizer, $\phi = 90° - 60° = 30°$.

EXECUTE: **(a)** At point *A* the intensity is $I_0/2$ and the light is polarized along the vertical direction. At point *B* the intensity is $(I_0/2)(\cos 60°)^2 = 0.125I_0$, and the light is polarized along the axis of the second polarizer. At point *C* the intensity is $(0.125I_0)(\cos 30°)^2 = 0.0938I_0$.

(b) Now for the last filter $\phi = 90°$ and $I = 0$.

EVALUATE: Adding the middle filter increases the transmitted intensity.

33.30. **IDENTIFY:** Apply Snell's law.

SET UP: The incident, reflected and refracted rays are shown in Figure 33.30.

EXECUTE: From the figure, $\theta_b = 37.0°$ and $n_b = n_a\frac{\sin\theta_a}{\sin\theta_b} = 1.33\frac{\sin 53°}{\sin 37°} = 1.77$.

EVALUATE: The refractive index of *b* is greater than that of *a*, and the ray is bent toward the normal when it refracts.

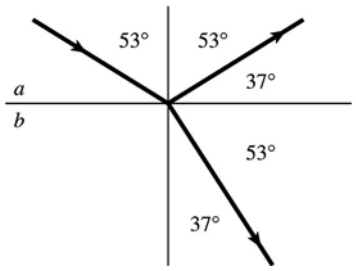

Figure 33.30

33.31. **IDENTIFY** and **SET UP:** Reflected beam completely linearly polarized implies that the angle of incidence equals the polarizing angle, so $\theta_p = 54.5°$. Use Eq. (33.8) to calculate the refractive index of the glass. Then use Snell's law to calculate the angle of refraction.

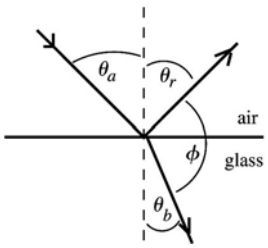
EXECUTE: **(a)** $\tan\theta_p = \frac{n_b}{n_a}$ gives $n_{glass} = n_{air}\tan\theta_p = (1.00)\tan 54.5° = 1.40$.

(b) $n_a\sin\theta_a = n_b\sin\theta_b$

$\sin\theta_b = \frac{n_a\sin\theta_a}{n_b} = \frac{(1.00)\sin 54.5°}{1.40} = 0.5815$ and $\theta_b = 35.5°$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE:



Note: $\phi = 180.0° - \theta_r - \theta_b$ and $\theta_r = \theta_a$. Thus $\phi = 180.0° - 54.5° - 35.5° = 90.0°$; the reflected ray and the refracted ray are perpendicular to each other. This agrees with Figure 33.28 in the text book.

Figure 33.31

33.32. **IDENTIFY:** Set $I = I_0/10$, where I is the intensity of light passed by the second polarizer.

SET UP: When unpolarized light passes through a polarizer the intensity is reduced by a factor of $\frac{1}{2}$ and the transmitted light is polarized along the axis of the polarizer. When polarized light of intensity $I_{\max}$ is incident on a polarizer, the transmitted intensity is $I = I_{\max}\cos^2\phi$, where ϕ is the angle between the polarization direction of the incident light and the axis of the filter.

EXECUTE: **(a)** After the first filter $I = \dfrac{I_0}{2}$ and the light is polarized along the vertical direction. After the second filter we want $I = \dfrac{I_0}{10}$, so $\dfrac{I_0}{10} = \left(\dfrac{I_0}{2}\right)(\cos\phi)^2$. $\cos\phi = \sqrt{2/10}$ and $\phi = 63.4°$.

(b) Now the first filter passes the full intensity I_0 of the incident light. For the second filter $\dfrac{I_0}{10} = I_0(\cos\phi)^2$. $\cos\phi = \sqrt{1/10}$ and $\phi = 71.6°$.

EVALUATE: When the incident light is polarized along the axis of the first filter, ϕ must be larger to achieve the same overall reduction in intensity than when the incident light is unpolarized.

33.33. **IDENTIFY:** From Malus's law, the intensity of the emerging light is proportional to the *square* of the cosine of the angle between the polarizing axes of the two filters.

SET UP: If the angle between the two axes is θ, the intensity of the emerging light is $I = I_{\max}\cos^2\theta$.

EXECUTE: At angle θ, $I = I_{\max}\cos^2\theta$, and at the new angle α, $\frac{1}{2}I = I_{\max}\cos^2\alpha$. Taking the ratio of the intensities gives $\dfrac{I_{\max}\cos^2\alpha}{I_{\max}\cos^2\theta} = \dfrac{\frac{1}{2}I}{I}$, which gives us $\cos\alpha = \dfrac{\cos\theta}{\sqrt{2}}$. Solving for α yields $\alpha = \arccos\left(\dfrac{\cos\theta}{\sqrt{2}}\right)$.

EVALUATE: For $\theta = 0°$, $I = I_{\max}$. The expression we derived then gives $\alpha = 45°$ and for this angle between the axes of the two filters, $I = I_{\max}/2$. So, our expression is seen to be correct for this special case.

33.34. **IDENTIFY:** The reflected light is completely polarized when the angle of incidence equals the polarizing angle θ_p, where $\tan\theta_p = \dfrac{n_b}{n_a}$.

SET UP: $n_b = 1.66$.

EXECUTE: **(a)** $n_a = 1.00$. $\tan\theta_p = \dfrac{1.66}{1.00}$ and $\theta_p = 58.9°$.

(b) $n_a = 1.333$. $\tan\theta_p = \dfrac{1.66}{1.333}$ and $\theta_p = 51.2°$.

EVALUATE: The polarizing angle depends on the refractive indicies of both materials at the interface.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

33.35. **IDENTIFY:** When unpolarized light of intensity I_0 is incident on a polarizing filter, the transmitted light has intensity $\frac{1}{2}I_0$ and is polarized along the filter axis. When polarized light of intensity I_0 is incident on a polarizing filter the transmitted light has intensity $I_0\cos^2\phi$.

SET UP: For the second filter, $\phi = 62.0° - 25.0° = 37.0°$.

EXECUTE: After the first filter the intensity is $\frac{1}{2}I_0 = 10.0\ \text{W/m}^2$ and the light is polarized along the axis of the first filter. The intensity after the second filter is $I = I_0\cos^2\phi$, where $I_0 = 10.0\ \text{W/m}^2$ and $\phi = 37.0°$. This gives $I = 6.38\ \text{W/m}^2$.

EVALUATE: The transmitted intensity depends on the angle between the axes of the two filters.

33.36. **IDENTIFY:** Use the transmitted intensity when all three polairzers are present to solve for the incident intensity I_0. Then repeat the calculation with only the first and third polarizers.

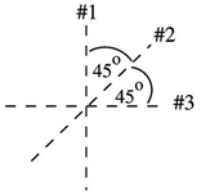
SET UP: For unpolarized light incident on a filter, $I = \frac{1}{2}I_0$ and the light is linearly polarized along the filter axis. For polarized light incident on a filter, $I = I_{\max}(\cos\phi)^2$, where $I_{\max}$ is the intensity of the incident light, and the emerging light is linearly polarized along the filter axis.

EXECUTE: With all three polarizers, if the incident intensity is I_0 the transmitted intensity is $I = (\frac{1}{2}I_0)(\cos 23.0°)^2(\cos[62.0° - 23.0°])^2 = 0.256I_0$. $I_0 = \dfrac{I}{0.256} = \dfrac{75.0\ \text{W/cm}^2}{0.256} = 293\ \text{W/cm}^2$. With only the first and third polarizers, $I = (\frac{1}{2}I_0)(\cos 62.0°)^2 = 0.110I_0 = (0.110)(293\ \text{W/cm}^2) = 32.2\ \text{W/cm}^2$.

EVALUATE: The transmitted intensity is greater when all three filters are present.

33.37. **IDENTIFY** and **SET UP:** Apply Eq. (33.7) to polarizers #2 and #3. The light incident on the first polarizer is unpolarized, so the transmitted light has half the intensity of the incident light, and the transmitted light is polarized.

(a) EXECUTE: The axes of the three filters are shown in Figure 33.37a.

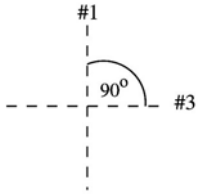


$I = I_{\max}\cos^2\phi$

Figure 33.37a

After the first filter the intensity is $I_1 = \frac{1}{2}I_0$ and the light is linearly polarized along the axis of the first polarizer. After the second filter the intensity is $I_2 = I_1\cos^2\phi = (\frac{1}{2}I_0)(\cos 45.0°)^2 = 0.250I_0$ and the light is linearly polarized along the axis of the second polarizer. After the third filter the intensity is $I_3 = I_2\cos^2\phi = 0.250I_0(\cos 45.0°)^2 = 0.125I_0$ and the light is linearly polarized along the axis of the third polarizer.

(b) The axes of the remaining two filters are shown in Figure 33.37b.



After the first filter the intensity is $I_1 = \frac{1}{2}I_0$ and the light is linearly polarized along the axis of the first polarizer.

Figure 33.37b

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

After the next filter the intensity is $I_3 = I_1 \cos^2\phi = \left(\frac{1}{2}I_0\right)(\cos 90.0°)^2 = 0$. No light is passed.

EVALUATE: Light is transmitted through all three filters, but no light is transmitted if the middle polarizer is removed.

33.38. **IDENTIFY:** The shorter the wavelength of light, the more it is scattered. The intensity is inversely proportional to the fourth power of the wavelength.

SET UP: The intensity of the scattered light is proportional to $1/\lambda^4$; we can write it as $I = (\text{constant})/\lambda^4$.

EXECUTE: **(a)** Since I is proportional to $1/\lambda^4$, we have $I = (\text{constant})/\lambda^4$. Taking the ratio of the intensity of the red light to that of the green light gives

$$\frac{I_R}{I} = \frac{(\text{constant})/\lambda_R^4}{(\text{constant})/\lambda_G^4} = \left(\frac{\lambda_G}{\lambda_R}\right)^4 = \left(\frac{520\text{ nm}}{665\text{ nm}}\right)^4 = 0.374, \text{ so } I_R = 0.374I.$$

(b) Following the same procedure as in part (a) gives $\frac{I_V}{I} = \left(\frac{\lambda_G}{\lambda_V}\right)^4 = \left(\frac{520\text{ nm}}{420\text{ nm}}\right)^4 = 2.35$, so $I_V = 2.35I$.

EVALUATE: In the scattered light, the intensity of the short-wavelength violet light is about 7 times as great as that of the red light, so this scattered light will have a blue-violet color.

33.39. **IDENTIFY:** Reflection reverses the sign of the component of light velocity perpendicular to the reflecting surface but leaves the other components unchanged.

SET UP: Consider three mirrors, M_1 in the (x,y)-plane, M_2 in the (y,z)-plane and M_3 in the (x,z)-plane.

EXECUTE: A light ray reflecting from M_1 changes the sign of the z-component of the velocity, reflecting from M_2 changes the x-component and from M_3 changes the y-component. Thus the velocity, and hence also the path, of the light beam flips by 180°.

EVALUATE: Example 33.3 discusses some uses of corner reflectors.

33.40. **IDENTIFY:** The light travels slower in the jelly than in the air and hence will take longer to travel the length of the tube when it is filled with jelly than when it contains just air.

SET UP: The definition of the index of refraction is $n = c/v$, where v is the speed of light in the jelly.

EXECUTE: First get the length L of the tube using air. In the air, we have $L = ct = (3.00\times10^8\text{ m/s})(8.72\text{ ns}) = 2.616\text{ m}$. The speed in the jelly is

$$v = \frac{L}{t} = (2.616\text{ m})/(8.72\text{ ns} + 2.04\text{ ns}) = 2.431\times10^8\text{ m/s}. \quad n = \frac{c}{v} = (3.00\times10^8\text{ m/s})/(2.431\times10^8\text{ m/s}) = 1.23$$

EVALUATE: A high-speed timer would be needed to measure times as short as a few nanoseconds.

33.41. **IDENTIFY:** Snell's law applies to the sound waves in the heart. (See Exercise 33.24.)

SET UP: $n_a \sin\theta_a = n_b \sin\theta_b$. If θ_a is the critical angle then $\theta_b = 90°$. For air, $n_{air} = 1.00$. For heart muscle, $n_{mus} = \frac{344\text{ m/s}}{1480\text{ m/s}} = 0.2324$.

EXECUTE: **(a)** $n_a \sin\theta_a = n_b \sin\theta_b$ gives $(1.00)\sin(9.73°) = (0.2324)\sin\theta_b$. $\sin\theta_b = \frac{\sin(9.73°)}{0.2324}$ so $\theta_b = 46.7°$.

(b) $(1.00)\sin\theta_{crit} = (0.2324)\sin 90°$ gives $\theta_{crit} = 13.4°$.

EVALUATE: To interpret a sonogram, it should be important to know the true direction of travel of the sound waves within muscle. This would require knowledge of the refractive index of the muscle.

33.42. **IDENTIFY:** Use the change in transit time to find the speed v of light in the slab, and then apply $n = \frac{c}{v}$ and $\lambda = \frac{\lambda_0}{n}$.

SET UP: It takes the light an additional 4.2 ns to travel 0.840 m after the glass slab is inserted into the beam.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: $\frac{0.840\text{ m}}{c/n}-\frac{0.840\text{ m}}{c}=(n-1)\frac{0.840\text{ m}}{c}=4.2\text{ ns}$. We can now solve for the index of refraction: $n=\frac{(4.2\times10^{-9}\text{s})(3.00\times10^{8}\text{m/s})}{0.840\text{ m}}+1=2.50$. The wavelength inside of the glass is $\lambda=\frac{490\text{ nm}}{2.50}=196\text{ nm}$.

EVALUATE: Light travels slower in the slab than in air and the wavelength is shorter.

33.43. **IDENTIFY:** The angle of incidence at *A* is to be the critical angle. Apply Snell's law at the air to glass refraction at the top of the block.

SET UP: The ray is sketched in Figure 33.43.

EXECUTE: For glass $\rightarrow$ air at point *A*, Snell's law gives $(1.38)\sin\theta_{\text{crit}}=(1.00)\sin90°$ and $\theta_{\text{crit}}=46.4°$. $\theta_b=90°-\theta_{\text{crit}}=43.6°$. Snell's law applied to the refraction from air to glass at the top of the block gives $(1.00)\sin\theta_a=(1.38)\sin(43.6°)$ and $\theta_a=72.1°$.

EVALUATE: If θ_a is larger than $72.1°$ then the angle of incidence at point *A* is less than the initial critical angle and total internal reflection doesn't occur.

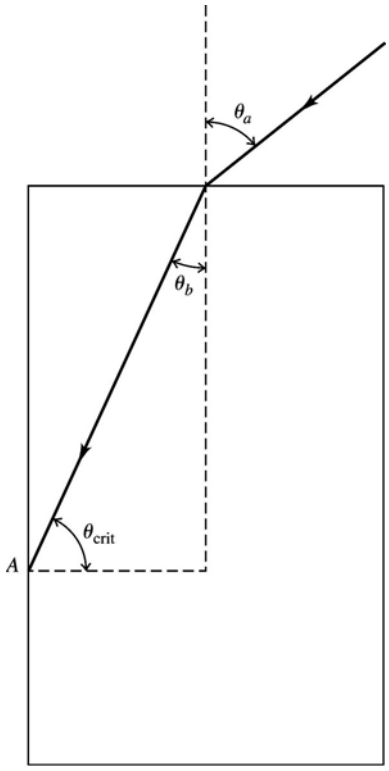


Figure 33.43

33.44. **IDENTIFY:** As the light crosses the glass-air interface along *AB*, it is refracted and obeys Snell's law.

SET UP: Snell's law is $n_a\sin\theta_a=n_b\sin\theta_b$ and $n=1.000$ for air. At point *B* the angle of the prism is $30.0°$.

EXECUTE: Apply Snell's law at *AB*. The prism angle at *A* is $60.0°$, so for the upper ray, the angle of incidence at *AB* is $60.0°+12.0°=72.0°$. Using this value gives $n_1\sin60.0°=\sin72.0°$ and $n_1=1.10$. For the lower ray, the angle of incidence at *AB* is $60.0°+12.0°+8.50°=80.5°$, giving $n_2\sin60.0°=\sin80.5°$ and $n_2=1.14$.

EVALUATE: The lower ray is deflected more than the upper ray because that wavelength has a slightly greater index of refraction than the upper ray.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

33.45. **IDENTIFY:** For total internal reflection, the angle of incidence must be at least as large as the critical angle.

SET UP: The angle of incidence for the glass-oil interface must be the critical angle, so $\theta_b = 90°$.

$n_a \sin\theta_a = n_b \sin\theta_b$.

EXECUTE: $n_a \sin\theta_a = n_b \sin\theta_b$ gives $(1.52)\sin 57.2° = n_{\text{oil}} \sin 90°$. $n_{\text{oil}} = (1.52)\sin 57.2° = 1.28$.

EVALUATE: $n_{\text{oil}} > 1$, which it must be, and 1.28 is a reasonable value for an oil.

33.46. **IDENTIFY:** Apply $\lambda = \dfrac{\lambda_0}{n}$. The number of wavelengths in a distance d of a material is $\dfrac{d}{\lambda}$ where λ is the wavelength in the material.

SET UP: The distance in glass is $d_{\text{glass}} = 0.00250$ m. The distance in air is

$d_{\text{air}} = 0.0180 \text{ m} - 0.00250 \text{ m} = 0.0155 \text{ m}$.

EXECUTE: number of wavelengths = number in air + number in glass.

$$\text{number of wavelengths} = \frac{d_{\text{air}}}{\lambda} + \frac{d_{\text{glass}}}{\lambda} n = \frac{0.0155 \text{ m}}{5.40\times10^{-7} \text{ m}} + \frac{0.00250 \text{ m}}{5.40\times10^{-7} \text{ m}}(1.40) = 3.52\times10^4.$$

EVALUATE: Without the glass plate the number of wavelengths between the source and screen is $\dfrac{0.0180 \text{ m}}{5.40\times10^{-3} \text{ m}} = 3.33\times10^4$. The wavelength is shorter in the glass so there are more wavelengths in a distance in glass than there are in the same distance in air.

33.47. **IDENTIFY:** Find the critical angle for glass $\rightarrow$ air. Light incident at this critical angle is reflected back to the edge of the halo.

SET UP: The ray incident at the critical angle is sketched in Figure 33.47.

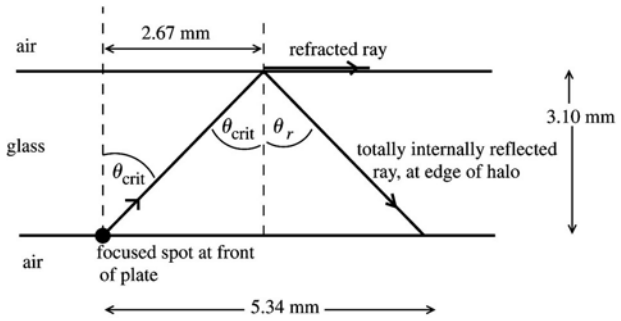

Figure 33.47

EXECUTE: From the distances given in the sketch, $\tan\theta_{\text{crit}} = \dfrac{2.67 \text{ mm}}{3.10 \text{ mm}} = 0.8613; \theta_{\text{crit}} = 40.7°$.

Apply Snell's law to the total internal reflection to find the refractive index of the glass:

$n_a \sin\theta_a = n_b \sin\theta_b$ $n_{\text{glass}} \sin\theta_{\text{crit}} = 1.00 \sin 90°$

$$n_{\text{glass}} = \frac{1}{\sin\theta_{\text{crit}}} = \frac{1}{\sin 40.7°} = 1.53$$

EVALUATE: Light incident on the back surface is also totally reflected if it is incident at angles greater than θ_{crit}. If it is incident at less than θ_{crit} it refracts into the air and does not reflect back to the emulsion.

33.48. **IDENTIFY:** Apply Snell's law to the refraction of the light as it passes from water into air.

SET UP: $\theta_a = \arctan\left(\dfrac{1.5 \text{ m}}{1.2 \text{ m}}\right) = 51°$. $n_a = 1.00$. $n_b = 1.333$.

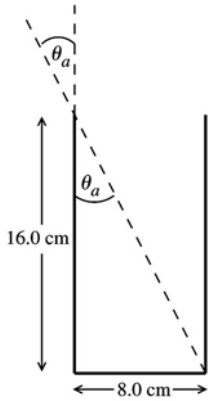
© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: $\theta_b = \arcsin\left(\frac{n_a}{n_b}\sin\theta_a\right) = \arcsin\left(\frac{1.00}{1.333}\sin 51°\right) = 36°$. Therefore, the distance along the bottom of the pool from directly below where the light enters to where it hits the bottom is $x = (4.0\text{ m})\tan\theta_b = (4.0\text{ m})\tan 36° = 2.9\text{ m}$. $x_{\text{total}} = 1.5\text{ m} + x = 1.5\text{ m} + 2.9\text{ m} = 4.4\text{ m}$.

EVALUATE: The light ray from the flashlight is bent toward the normal when it refracts into the water.

33.49. **IDENTIFY:** Use Snell's law to determine the effect of the liquid on the direction of travel of the light as it enters the liquid.

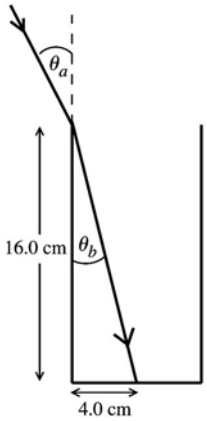
SET UP: Use geometry to find the angles of incidence and refraction. Before the liquid is poured in, the ray along your line of sight has the path shown in Figure 33.49a.



$$\tan\theta_a = \frac{8.0\text{ cm}}{16.0\text{ cm}} = 0.500$$
$$\theta_a = 26.57°$$

Figure 33.49a

After the liquid is poured in, θ_a is the same and the refracted ray passes through the center of the bottom of the glass, as shown in Figure 33.49b.



$$\tan\theta_b = \frac{4.0\text{ cm}}{16.0\text{ cm}} = 0.250$$
$$\theta_b = 14.04°$$

Figure 33.49b

EXECUTE: Use Snell's law to find n_b, the refractive index of the liquid:

$$n_a\sin\theta_a = n_b\sin\theta_b$$
$$n_b = \frac{n_a\sin\theta_a}{\sin\theta_b} = \frac{(1.00)(\sin 26.57°)}{\sin 14.04°} = 1.84$$

EVALUATE: When the light goes from air to liquid (larger refractive index) it is bent toward the normal.

33.50. **IDENTIFY:** The incident angle at the prism → water interface is to be the critical angle.

SET UP: The path of the ray is sketched in Figure 33.50. The ray enters the prism at normal incidence so is not bent. For water, $n_{\text{water}} = 1.333$.

EXECUTE: From the figure, $\theta_{\text{crit}} = 45°$. $n_a \sin\theta_a = n_b \sin\theta_b$ gives $n_{\text{glass}} \sin 45° = (1.333)\sin 90°$.

$$n_{\text{glass}} = \frac{1.333}{\sin 45°} = 1.89.$$

EVALUATE: For total internal reflection the ray must be incident in the material of greater refractive index. $n_{\text{glass}} > n_{\text{water}}$, so that is the case here.

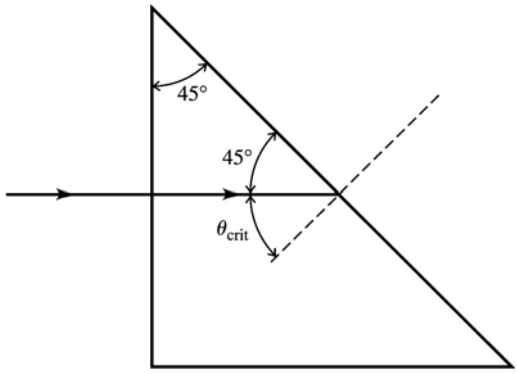

Figure 33.50

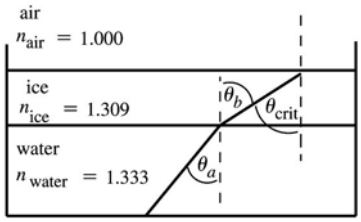
33.51. **IDENTIFY:** Apply Snell's law to the water → ice and ice → air interfaces.

(a) SET UP: Consider the ray shown in Figure 33.51.



We want to find the incident angle θ_a at the water-ice interface that causes the incident angle at the ice-air interface to be the critical angle.

Figure 33.51

EXECUTE: ice-air interface: $n_{\text{ice}} \sin\theta_{\text{crit}} = 1.0 \sin 90°$

$n_{\text{ice}} \sin\theta_{\text{crit}} = 1.0$ so $\sin\theta_{\text{crit}} = \dfrac{1}{n_{\text{ice}}}$

But from the diagram we see that $\theta_b = \theta_{\text{crit}}$, so $\sin\theta_b = \dfrac{1}{n_{\text{ice}}}$.

water-ice interface: $n_{\text{w}} \sin\theta_a = n_{\text{ice}} \sin\theta_b$

But $\sin\theta_b = \dfrac{1}{n_{\text{ice}}}$ so $n_w \sin\theta_a = 1.0$. $\sin\theta_a = \dfrac{1}{n_{\text{w}}} = \dfrac{1}{1.333} = 0.7502$ and $\theta_a = 48.6°$.

(b) EVALUATE: The angle calculated in part (a) is the critical angle for a water-air interface; the answer would be the same if the ice layer wasn't there!

33.52. **IDENTIFY:** The ray shown in the figure that accompanies the problem is to be incident at the critical angle.

SET UP: $\theta_b = 90°$. The incident angle for the ray in the figure is $60°$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: $n_a \sin\theta_a = n_b \sin\theta_b$ gives $n_b = \left(\frac{n_a \sin\theta_a}{\sin\theta_b}\right) = \left(\frac{1.62 \sin 60°}{\sin 90°}\right) = 1.40.$

EVALUATE: Total internal reflection occurs only when the light is incident in the material of the greater refractive index.

33.53. **IDENTIFY:** Apply Snell's law to the refraction of each ray as it emerges from the glass. The angle of incidence equals the angle $A = 25.0°$.

SET UP: The paths of the two rays are sketched in Figure 33.53.

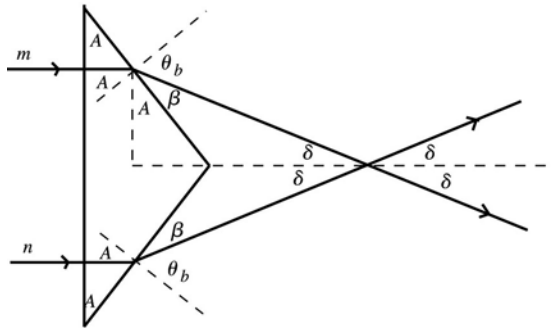


Figure 33.53

EXECUTE: $n_a \sin\theta_a = n_b \sin\theta_b$

$n_{\text{glass}} \sin 25.0° = 1.00 \sin\theta_b$

$\sin\theta_b = n_{\text{glass}} \sin 25.0°$

$\sin\theta_b = 1.66 \sin 25.0° = 0.7015$

$\theta_b = 44.55°$

$\beta = 90.0° - \theta_b = 45.45°$

Then $\delta = 90.0° - A - \beta = 90.0° - 25.0° - 45.45° = 19.55°$. The angle between the two rays is $2\delta = 39.1°$.

EVALUATE: The light is incident normally on the front face of the prism so the light is not bent as it enters the prism.

33.54. **IDENTIFY:** No light enters the gas because total internal reflection must have occurred at the water-gas interface.

SET UP: At the minimum value of S, the light strikes the water-gas interface at the critical angle. We apply Snell's law, $n_a \sin\theta_a = n_b \sin\theta_b$, at that surface.

EXECUTE: **(a)** In the water, $\theta = \frac{S}{R} = (1.09 \text{ m})/(1.10 \text{ m}) = 0.991 \text{ rad} = 56.77°$. This is the critical angle.

So, using the refractive index for water from Table 33.1, we get $n = (1.333)\sin 56.77° = 1.12$

(b) (i) The laser beam stays in the water all the time, so

$$t = 2R/v = 2R/\left(\frac{c}{n_{\text{water}}}\right) = \frac{Dn_{\text{water}}}{c} = (2.20 \text{ m})(1.333)/(3.00\times10^8 \text{ m/s}) = 9.78 \text{ ns}$$

(ii) The beam is in the water half the time and in the gas the other half of the time.

$$t_{\text{gas}} = \frac{Rn_{\text{gas}}}{c} = (1.10 \text{ m})(1.12)/(3.00\times10^8 \text{ m/s}) = 4.09 \text{ ns}$$

The total time is $4.09 \text{ ns} + (9.78 \text{ ns})/2 = 8.98 \text{ ns}$.

EVALUATE: The gas must be under considerable pressure to have a refractive index as high as 1.12.

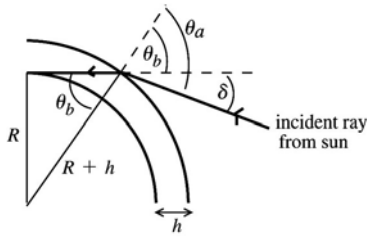
33.55. **(a) IDENTIFY:** Apply Snell's law to the refraction of the light as it enters the atmosphere.
SET UP: The path of a ray from the sun is sketched in Figure 33.55.



$\delta = \theta_a - \theta_b$

From the diagram $\sin\theta_b = \dfrac{R}{R+h}$

$\theta_b = \arcsin\left(\dfrac{R}{R+h}\right)$

Figure 33.55

EXECUTE: Apply Snell's law to the refraction that occurs at the top of the atmosphere: $n_a \sin\theta_a = n_b \sin\theta_b$
(a = vacuum of space, refractive, index 1.0; $b =$ atmosphere, refractive index n)

$\sin\theta_a = n\sin\theta_b = n\left(\dfrac{R}{R+h}\right)$ so $\theta_a = \arcsin\left(\dfrac{nR}{R+h}\right)$

$\delta = \theta_a - \theta_b = \arcsin\left(\dfrac{nR}{R+h}\right) - \arcsin\left(\dfrac{R}{R+h}\right)$

(b) $\dfrac{R}{R+h} = \dfrac{6.38\times10^6\ \text{m}}{6.38\times10^6\ \text{m} + 20\times10^3\ \text{m}} = 0.99688$

$\dfrac{nR}{R+h} = 1.0003(0.99688) = 0.99718$

$\theta_b = \arcsin\left(\dfrac{R}{R+h}\right) = 85.47°$

$\theta_a = \arcsin\left(\dfrac{nR}{R+h}\right) = 85.70°$

$\delta = \theta_a - \theta_b = 85.70° - 85.47° = 0.23°$

EVALUATE: The calculated δ is about the same as the angular radius of the sun.

33.56. **IDENTIFY** and **SET UP:** Follow the steps specified in the problem.
EXECUTE: **(a)** The distance traveled by the light ray is the sum of the two diagonal segments:
$d = (x^2 + y_1^2)^{1/2} + ((l-x)^2 + y_2^2)^{1/2}$. Then the time taken to travel that distance is

$t = \dfrac{d}{c} = \dfrac{(x^2 + y_1^2)^{1/2} + ((l-x)^2 + y_2^2)^{1/2}}{c}$.

(b) Taking the derivative with respect to x of the time and setting it to zero yields

$\dfrac{dt}{dx} = \dfrac{1}{c}\dfrac{d}{dx}\left[(x^2 + y_1^2)^{1/2} + ((l-x)^2 + y_2^2)^{1/2}\right] = \dfrac{1}{c}\left[x(x^2 + y_1^2)^{-1/2} - (l-x)((l-x)^2 + y_2^2)^{-1/2}\right] = 0$. This gives

$\dfrac{x}{\sqrt{x^2 + y_1^2}} = \dfrac{(l-x)}{\sqrt{(l-x)^2 + y_2^2}}$, $\sin\theta_1 = \sin\theta_2$ and $\theta_1 = \theta_2$.

EVALUATE: For any other path between points 1 and 2, that includes a point on the reflective surface, the distance traveled and therefore the travel time is greater than for this path.

33.57. **IDENTIFY** and **SET UP:** Find the distance that the ray travels in each medium. The travel time in each medium is the distance divided by the speed in that medium.

(a) EXECUTE: The light travels a distance $\sqrt{h_1^2 + x^2}$ in traveling from point A to the interface. Along this path the speed of the light is v_1, so the time it takes to travel this distance is $t_1 = \dfrac{\sqrt{h_1^2 + x^2}}{v_1}$. The light

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

travels a distance $\sqrt{h_2^2+(l-x)^2}$ in traveling from the interface to point B. Along this path the speed of the light is v_2, so the time it takes to travel this distance is $t_2=\dfrac{\sqrt{h_2^2+(l-x)^2}}{v_2}$. The total time to go from A to B is $t=t_1+t_2=\dfrac{\sqrt{h_1^2+x^2}}{v_1}+\dfrac{\sqrt{h_2^2+(l+x)^2}}{v_2}$.

(b) $\dfrac{dt}{dx}=\dfrac{1}{v_1}\left(\dfrac{1}{2}\right)(h_1^2+x^2)^{-1/2}(2x)+\dfrac{1}{v_2}\left(\dfrac{1}{2}\right)(h_2^2+(l-x)^2)^{-1/2}2(l-x)(-1)=0$

$$\frac{x}{v_1\sqrt{h_1^2+x^2}}=\frac{l-x}{v_2\sqrt{h_2^2+(l-x)^2}}$$

Multiplying both sides by c gives $\dfrac{c}{v_1}\dfrac{x}{\sqrt{h_1^2+x^2}}=\dfrac{c}{v_2}\dfrac{l-x}{\sqrt{h_2^2+(l-x)^2}}$

$\dfrac{c}{v_1}=n_1$ and $\dfrac{c}{v_2}=n_2$ (Eq. 33.1)

From Figure P33.57 in the textbook, $\sin\theta_1=\dfrac{x}{\sqrt{h_1^2+x^2}}$ and $\sin\theta_2=\dfrac{l-x}{\sqrt{h_2^2+(l-x)^2}}$.

So $n_1\sin\theta_1=n_2\sin\theta_2$, which is Snell's law.

EVALUATE: Snell's law is a result of a change in speed when light goes from one material to another.

33.58. **IDENTIFY:** Apply Snell's law to each refraction.

SET UP: Refer to the angles and distances defined in the figure that accompanies the problem.

EXECUTE: **(a)** For light in air incident on a parallel-faced plate, Snell's Law yields:
$n\sin\theta_a=n'\sin\theta_b'=n'\sin\theta_b=n\sin\theta_a'\Rightarrow\sin\theta_a=\sin\theta_a'\Rightarrow\theta_a=\theta_a'$.

(b) Adding more plates just adds extra steps in the middle of the above equation that always cancel out. The requirement of parallel faces ensures that the angle $\theta_n'=\theta_n$ and the chain of equations can continue.

(c) The lateral displacement of the beam can be calculated using geometry:

$d=L\sin(\theta_a-\theta_b')$ and $L=\dfrac{t}{\cos\theta_b'}\Rightarrow d=\dfrac{t\sin(\theta_a-\theta_b')}{\cos\theta_b'}$.

(d) $\theta_b'=\arcsin\left(\dfrac{n\sin\theta_a}{n'}\right)=\arcsin\left(\dfrac{\sin 66.0^\circ}{1.80}\right)=30.5^\circ$ and $d=\dfrac{(2.40\text{ cm})\sin(66.0^\circ-30.5^\circ)}{\cos 30.5^\circ}=1.62\text{ cm}$.

EVALUATE: The lateral displacement in part (d) is large, of the same order as the thickness of the plate.

33.59. **IDENTIFY:** Apply Snell's law to the two refractions of the ray.

SET UP: Refer to the figure that accompanies the problem.

EXECUTE: **(a)** $n_a\sin\theta_a=n_b\sin\theta_b$ gives $\sin\theta_a=n_b\sin\dfrac{A}{2}$. But $\theta_a=\dfrac{A}{2}+\alpha$, so

$\sin\left(\dfrac{A}{2}+\alpha\right)=\sin\dfrac{A+2\alpha}{2}=n\sin\dfrac{A}{2}$. At each face of the prism the deviation is α, so $2\alpha=\delta$ and

$\sin\dfrac{A+\delta}{2}=n\sin\dfrac{A}{2}$.

(b) From part (a), $\delta=2\arcsin\left(n\sin\dfrac{A}{2}\right)-A.\ \delta=2\arcsin\left((1.52)\sin\dfrac{60.0^\circ}{2}\right)-60.0^\circ=38.9^\circ$.

(c) If two colors have different indices of refraction for the glass, then the deflection angles for them will differ:

$$\delta_{\text{red}}=2\arcsin\left((1.61)\sin\frac{60.0^\circ}{2}\right)-60.0^\circ=47.2^\circ$$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$\delta_{\text{violet}} = 2\arcsin\left((1.66)\sin\frac{60.0°}{2}\right) - 60.0° = 52.2° \Rightarrow \Delta\delta = 52.2° - 47.2° = 5.0°$$

EVALUATE: The violet light has a greater refractive index and therefore the angle of deviation is greater for the violet light.

33.60. **IDENTIFY:** Apply Snell's law and the results of Problem 33.58.

SET UP: From Figure 33.18 in the textbook, $n_r = 1.61$ for red light and $n_v = 1.66$ for violet. In the notation of Problem 33.58, t is the thickness of the glass plate and the lateral displacement is d. We want the difference in d for the two colors of light to be 1.0 mm. $\theta_a = 70.0°$. For red light, $n_a \sin\theta_a = n_b \sin\theta'_b$ gives $\sin\theta'_b = \dfrac{(1.00)\sin 70.0°}{1.61}$ and $\theta'_b = 35.71°$. For violet light, $\sin\theta'_b = \dfrac{(1.00)\sin 70.0°}{1.66}$ and $\theta'_b = 34.48°$.

EXECUTE: **(a)** n decreases with increasing λ, so n is smaller for red than for blue. So beam a is the red one.

(b) Problem 33.58 says $d = t\dfrac{\sin(\theta_a - \theta'_b)}{\cos\theta'_b}$. For red light, $d_r = t\dfrac{\sin(70° - 35.71°)}{\cos 35.71°} = 0.6938t$ and for violet light, $d_v = t\dfrac{\sin(70° - 34.48°)}{\cos 34.48°} = 0.7048t$. $d_v - d_r = 1.0$ mm gives $t = \dfrac{0.10 \text{ cm}}{0.7048 - 0.6938} = 9.1$ cm.

EVALUATE: Our calculation shown that the violet light has greater lateral displacement and this is ray b.

33.61. **IDENTIFY** and **SET UP**: The polarizer passes $\frac{1}{2}$ of the intensity of the unpolarized component, independent of ϕ. Out of the intensity I_p of the polarized component the polarizer passes intensity $I_p\cos^2(\phi - \theta)$, where $\phi - \theta$ is the angle between the plane of polarization and the axis of the polarizer.

(a) Use the angle where the transmitted intensity is maximum or minimum to find θ. See Figure 33.61.

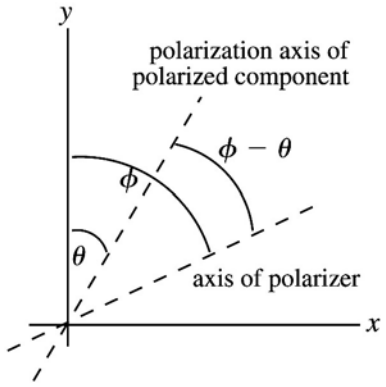


Figure 33.61

EXECUTE: The total transmitted intensity is $I = \frac{1}{2}I_0 + I_p\cos^2(\phi - \theta)$. This is maximum when $\theta = \phi$ and from the table of data this occurs for ϕ between 30° and 40°, say at 35° and $\theta = 35°$. Alternatively, the total transmitted intensity is minimum when $\phi - \theta = 90°$ and from the data this occurs for $\phi = 125°$. Thus, $\theta = \phi - 90° = 125° - 90° = 35°$, in agreement with the above.

(b) IDENTIFY and **SET UP:** $I = \frac{1}{2}I_0 + I_p\cos^2(\phi - \theta)$

Use data at two values of ϕ to determine the two constants I_0 and I_p. Use data where the I_p term is large $(\phi = 30°)$ and where it is small $(\phi = 130°)$ to have the greatest sensitivity to both I_0 and I_p.

EXECUTE: $\phi = 30°$ gives $24.8 \text{ W/m}^2 = \frac{1}{2}I_0 + I_p\cos^2(30° - 35°)$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$24.8\ \text{W/m}^2 = 0.500I_0 + 0.9924I_\text{p}$

$\phi = 130°$ gives $5.2\ \text{W/m}^2 = \frac{1}{2}I_0 + I_\text{p}\cos^2(130° - 35°)$

$5.2\ \text{W/m}^2 = 0.500I_0 + 0.0076I_\text{p}$

Subtracting the second equation from the first gives $19.6\ \text{W/m}^2 = 0.9848I_\text{p}$ and $I_\text{p} = 19.9\ \text{W/m}^2$. And then $I_0 = 2(5.2\ \text{W/m}^2 - 0.0076(19.9\ \text{W/m}^2)) = 10.1\ \text{W/m}^2$.

EVALUATE: Now that we have I_0, I_p and θ we can verify that $I = \frac{1}{2}I_0 + I_\text{p}\cos^2(\phi - \theta)$ describes that data in the table.

33.62. **IDENTIFY:** The angle by which the plane of polarization of light is rotated depends on the concentration of the compound.

SET UP: If we follow the hint in the problem and graph (not shown) the concentration C as a function of the rotation angle ϑ, *l*-leucine and *d*-glutamic acid both exhibit linear relationships between C and ϑ, with the *y*-intercept being zero in both cases. Using the slope *y*-intercept form of the equation of a straight line $(y = mx + b)$, we can find the equation for C as a function of ϑ.

EXECUTE: For *l*-leucine, the slope of the graph is $m = -9.09\dfrac{\text{g}}{100\ \text{mL}}\cdot\text{deg}^{-1}$, so the equation for C as a function of ϑ is $C = -\left(9.09\dfrac{\text{g}}{100\ \text{mL}}\cdot\text{deg}^{-1}\right)\vartheta$. For *d*-glutamic acid, the slope is $m = 8.06\dfrac{\text{g}}{100\ \text{mL}}\cdot\text{deg}^{-1}$, so the desired equation is $C = \left(8.06\dfrac{\text{g}}{100\ \text{mL}}\cdot\text{deg}^{-1}\right)\vartheta$. The opposite signs in the equations tell us that the two compounds rotate the plane of polarization in opposite directions.

EVALUATE: Inspection of the data indicates that the slope is constant and that the *y*-intercept is zero (no concentration, no rotation). We can use data points to find the slope. For example, using the second and third data points for *l*-leucine, the slope is

$$m = \frac{\Delta C}{\Delta\vartheta} = \frac{5.0\ \text{g/(100 mL)} - 2.0\ \text{g/(100 mL)}}{-0.55° - (-0.22°)} = \frac{3.0\ \text{g/(100 mL)}}{-0.33°} = -9.09\frac{\text{g}}{100\ \text{mL}}\cdot\text{deg}^{-1},$$

which is the same result we got from the graph, leading to the same equation.

33.63. **IDENTIFY:** The reflected light is totally polarized when light strikes a surface at Brewster's angle.

SET UP: At the plastic wall, Brewster's angle obeys the equation $\tan\theta_\text{p} = n_b/n_a$, and Snell's law, $n_a\sin\theta_a = n_b\sin\theta_b$, applies at the air-water surface.

EXECUTE: To be totally polarized, the reflected sunlight must have struck the wall at Brewster's angle. $\tan\theta_\text{p} = n_b/n_a = (1.61)/(1.00)$ and $\theta_\text{p} = 58.15°$.

This is the angle of incidence at the wall. A little geometry tells us that the angle of incidence at the water surface is $90.00° - 58.15° = 31.85°$. Applying Snell's law at the water surface gives

$$(1.00)\sin 31.85° = 1.333\sin\theta \text{ and } \theta = 23.3°$$

EVALUATE: We have two different principles involved here: Reflection at Brewster's angle at the wall and Snell's law at the water surface.

33.64. **IDENTIFY:** The number of wavelengths in a distance D of material is D/λ, where λ is the wavelength of the light in the material.

SET UP: The condition for a quarter-wave plate is $\dfrac{D}{\lambda_1} = \dfrac{D}{\lambda_2} + \dfrac{1}{4}$, where we have assumed $n_1 > n_2$ so $\lambda_2 > \lambda_1$.

EXECUTE: **(a)** $\dfrac{n_1 D}{\lambda_0} = \dfrac{n_2 D}{\lambda_0} + \dfrac{1}{4}$ and $D = \dfrac{\lambda_0}{4(n_1 - n_2)}$.

(b) $D = \dfrac{\lambda_0}{4(n_1 - n_2)} = \dfrac{5.89\times10^{-7}\ \text{m}}{4(1.875 - 1.635)} = 6.14\times10^{-7}\ \text{m}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: The thickness of the quarter-wave plate in part (b) is 614 nm, which is of the same order as the wavelength in vacuum of the light.

33.65. **IDENTIFY:** Follow the steps specified in the problem.

SET UP: $\cos(\alpha-\beta)=\sin\alpha\sin\beta+\cos\alpha\cos\beta$. $\sin(\alpha-\beta)=\sin\alpha\cos\beta-\cos\alpha\sin\beta$.

EXECUTE: **(a)** Multiplying Eq. (1) by $\sin\beta$ and Eq. (2) by $\sin\alpha$ yields:

(1): $\frac{x}{a}\sin\beta=\sin\omega t\cos\alpha\sin\beta-\cos\omega t\sin\alpha\sin\beta$ and (2): $\frac{y}{a}\sin\alpha=\sin\omega t\cos\beta\sin\alpha-\cos\omega t\sin\beta\sin\alpha$.

Subtracting yields: $\frac{x\sin\beta-y\sin\alpha}{a}=\sin\omega t(\cos\alpha\sin\beta-\cos\beta\sin\alpha)$.

(b) Multiplying Eq. (1) by $\cos\beta$ and Eq. (2) by $\cos\alpha$ yields:

(1): $\frac{x}{a}\cos\beta=\sin\omega t\cos\alpha\cos\beta-\cos\omega t\sin\alpha\cos\beta$ and (2): $\frac{y}{a}\cos\alpha=\sin\omega t\cos\beta\cos\alpha-\cos\omega t\sin\beta\cos\alpha$.

Subtracting yields: $\frac{x\cos\beta-y\cos\alpha}{a}=-\cos\omega t(\sin\alpha\cos\beta-\sin\beta\cos\alpha)$.

(c) Squaring and adding the results of parts (a) and (b) yields:

$$(x\sin\beta-y\sin\alpha)^2+(x\cos\beta-y\cos\alpha)^2=a^2(\sin\alpha\cos\beta-\sin\beta\cos\alpha)^2$$

(d) Expanding the left-hand side, we have:

$$x^2(\sin^2\beta+\cos^2\beta)+y^2(\sin^2\alpha+\cos^2\alpha)-2xy(\sin\alpha\sin\beta+\cos\alpha\cos\beta)$$
$$=x^2+y^2-2xy(\sin\alpha\sin\beta+\cos\alpha\cos\beta)=x^2+y^2-2xy\cos(\alpha-\beta).$$

The right-hand side can be rewritten: $a^2(\sin\alpha\cos\beta-\sin\beta\cos\alpha)^2=a^2\sin^2(\alpha-\beta)$. Therefore, $x^2+y^2-2xy\cos(\alpha-\beta)=a^2\sin^2(\alpha-\beta)$. Or, $x^2+y^2-2xy\cos\delta=a^2\sin^2\delta$, where $\delta=\alpha-\beta$.

EVALUATE: **(e)** $\delta=0: x^2+y^2-2xy=(x-y)^2=0\Rightarrow x=y$, which is a straight diagonal line

$\delta=\frac{\pi}{4}: x^2+y^2-\sqrt{2}xy=\frac{a^2}{2}$, which is an ellipse

$\delta=\frac{\pi}{2}: x^2+y^2=a^2$, which is a circle. This pattern repeats for the remaining phase differences.

33.66. **IDENTIFY:** Apply Snell's law to each refraction.

SET UP: Refer to the figure that accompanies the problem.

EXECUTE: **(a)** By the symmetry of the triangles, $\theta_b^A=\theta_a^B$, and $\theta_a^C=\theta_r^B=\theta_a^B=\theta_b^A$. Therefore, $\sin\theta_b^C=n\sin\theta_a^C=n\sin\theta_b^A=\sin\theta_a^A=\theta_b^C=\theta_a^A$.

(b) The total angular deflection of the ray is $\Delta=\theta_a^A-\theta_b^A+\pi-2\theta_a^B+\theta_b^C-\theta_a^C=2\theta_a^A-4\theta_b^A+\pi$.

(c) From Snell's Law, $\sin\theta_a^A=n\sin\theta_b^A\Rightarrow\theta_b^A=\arcsin\left(\frac{1}{n}\sin\theta_a^A\right)$.

$\Delta=2\theta_a^A-4\theta_b^A+\pi=2\theta_a^A-4\arcsin\left(\frac{1}{n}\sin\theta_a^A\right)+\pi$.

(d) $\frac{d\Delta}{d\theta_a^A}=0=2-4\frac{d}{d\theta_a^A}\left(\arcsin\left(\frac{1}{n}\sin\theta_a^A\right)\right)\Rightarrow 0=2-\frac{4}{\sqrt{1-\frac{\sin^2\theta_1}{n^2}}}\cdot\left(\frac{\cos\theta_1}{n}\right)\cdot 4\left(1-\frac{\sin^2\theta_1}{n^2}\right)=\left(\frac{16\cos^2\theta_1}{n^2}\right)$.

$4\cos^2\theta_1=n^2-1+\cos^2\theta_1$. $3\cos^2\theta_1=n^2-1$. $\cos^2\theta_1=\frac{1}{3}(n^2-1)$.

(e) For violet: $\theta_1=\arccos\left(\sqrt{\frac{1}{3}(n^2-1)}\right)=\arccos\left(\sqrt{\frac{1}{3}(1.342^2-1)}\right)=58.89°$.

$\Delta_{\text{violet}}=139.2°\Rightarrow\theta_{\text{violet}}=40.8°$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

For red: $\theta_1 = \arccos\left(\sqrt{\frac{1}{3}(n^2-1)}\right) = \arccos\left(\sqrt{\frac{1}{3}(1.330^2-1)}\right) = 59.58°.$

$\Delta_{\text{red}} = 137.5° \Rightarrow \theta_{\text{red}} = 42.5°.$

EVALUATE: The angles we have calculated agree with the values given in Figure 33.20d in the textbook. θ_1 is larger for red than for violet, so red in the rainbow is higher above the horizon.

33.67. **IDENTIFY:** Follow similar steps to Challenge Problem 33.66.

SET UP: Refer to Figure 33.20e in the textbook.

EXECUTE: **(a)** The total angular deflection of the ray is

$\Delta = \theta_a^A - \theta_b^A + \pi - 2\theta_b^A + \pi - 2\theta_b^A + \theta_a^A - \theta_b^A = 2\theta_a^A - 6\theta_b^A + 2\pi,$ where we have used the fact from the previous problem that all the internal angles are equal and the two external equals are equal. Also using the Snell's law relationship,

we have: $\theta_b^A = \arcsin\left(\frac{1}{n}\sin\theta_a^A\right).\ \Delta = 2\theta_a^A - 6\theta_b^A + 2\pi = 2\theta_a^A - 6\arcsin\left(\frac{1}{n}\sin\theta_a^A\right) + 2\pi.$

(b) $\frac{d\Delta}{d\theta_a^A} = 0 = 2 - 6\frac{d}{d\theta_a^A}\left(\arcsin\left(\frac{1}{n}\sin\theta_a^A\right)\right) \Rightarrow 0 = 2 - \frac{6}{\sqrt{1-\frac{\sin\theta_2}{n^2}}}.\left(\frac{\cos\theta_2}{n}\right).$

$n^2\left(1-\frac{\sin^2\theta_2}{n^2}\right) = (n^2 - 1 + \cos^2\theta_2) = 9\cos^2\theta_2.\ \cos^2\theta_2 = \frac{1}{8}(n^2-1).$

(c) For violet, $\theta_2 = \arccos\left(\sqrt{\frac{1}{8}(n^2-1)}\right) = \arccos\left(\sqrt{\frac{1}{8}(1.342^2-1)}\right) = 71.55°.\ \Delta_{\text{violet}} = 233.2°$ and

$\theta_{\text{violet}} = 53.2°.$

For red, $\theta_2 = \arccos\left(\sqrt{\frac{1}{8}(n^2-1)}\right) = \arccos\left(\sqrt{\frac{1}{8}(1.330^2-1)}\right) = 71.94°.\ \Delta_{\text{red}} = 230.1°$ and $\theta_{\text{red}} = 50.1°.$

EVALUATE: The angles we calculated agree with those given in Figure 33.20e in the textbook. The color that appears higher above the horizon is violet. The colors appear in reverse order in a secondary rainbow compared to a primary rainbow.

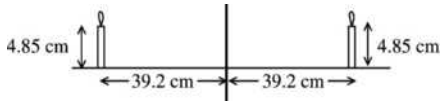
34

GEOMETRIC OPTICS

34.1. **IDENTIFY** and **SET UP:** Plane mirror: $s = -s'$ (Eq. 34.1) and $m = y'/y = -s'/s = +1$ (Eq. 34.2). We are given s and y and are asked to find s' and y'.

EXECUTE: The object and image are shown in Figure 34.1.



$s' = -s = -39.2$ cm

$|y'| = |m||y| = (+1)(4.85 \text{ cm})$

$|y'| = 4.85$ cm

Figure 34.1

The image is 39.2 cm to the right of the mirror and is 4.85 cm tall.

EVALUATE: For a plane mirror the image is always the same distance behind the mirror as the object is in front of the mirror. The image always has the same height as the object.

34.2. **IDENTIFY:** Similar triangles say $\dfrac{h_{\text{tree}}}{h_{\text{mirror}}} = \dfrac{d_{\text{tree}}}{d_{\text{mirror}}}$.

SET UP: $d_{\text{mirror}} = 0.350$ m, $h_{\text{mirror}} = 0.0400$ m and $d_{\text{tree}} = 28.0 \text{ m} + 0.350 \text{ m}$.

EXECUTE: $h_{\text{tree}} = h_{\text{mirror}} \dfrac{d_{\text{tree}}}{d_{\text{mirror}}} = 0.040 \text{ m} \dfrac{28.0 \text{ m} + 0.350 \text{ m}}{0.350 \text{ m}} = 3.24 \text{ m}.$

EVALUATE: The image of the tree formed by the mirror is 28.0 m behind the mirror and is 3.24 m tall.

34.3. **IDENTIFY** and **SET UP:** The virtual image formed by a plane mirror is the same size as the object and the same distance from the mirror as the object.

EXECUTE: $s' = -s$. The image of the tip is 12.0 cm behind the mirror surface and the image of the end of the eraser is 21.0 cm behind the mirror surface. The length of the image is 9.0 cm, the same as the length of the object. The image of the tip of the lead is the closest to the mirror surface.

EVALUATE: The same result would hold no matter how far the pencil was from the mirror.

34.4. **IDENTIFY:** $f = R/2$

SET UP: For a concave mirror $R > 0$.

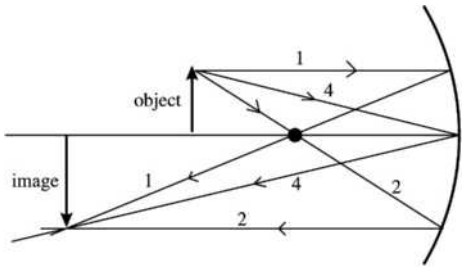
EXECUTE: **(a)** $f = \dfrac{R}{2} = \dfrac{34.0 \text{ cm}}{2} = 17.0 \text{ cm}$

EVALUATE: **(b)** The image formation by the mirror is determined by the law of reflection and that is unaffected by the medium in which the light is traveling. The focal length remains 17.0 cm.

34.5. **IDENTIFY** and **SET UP:** Use Eq. (34.6) to calculate s' and use Eq. (34.7) to calculate y'. The image is real if s' is positive and is erect if $m > 0$. Concave means R and f are positive, $R = +22.0$ cm; $f = R/2 = +11.0$ cm.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: (a)



Three principal rays, numbered as in Section 34.2, are shown in Figure 34.5. The principal ray diagram shows that the image is real, inverted, and enlarged.

Figure 34.5

(b) $\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}$

$\frac{1}{s'}=\frac{1}{f}-\frac{1}{s}=\frac{s-f}{sf}$ so $s'=\frac{sf}{s-f}=\frac{(16.5\text{ cm})(11.0\text{ cm})}{16.5\text{ cm}-11.0\text{ cm}}=+33.0\text{ cm}$

$s'>0$ so real image, 33.0 cm to left of mirror vertex

$m=-\frac{s'}{s}=-\frac{33.0\text{ cm}}{16.5\text{ cm}}=-2.00$ ($m<0$ means inverted image) $|y'|=|m||y|=2.00(0.600\text{ cm})=1.20\text{ cm}$

EVALUATE: The image is 33.0 cm to the left of the mirror vertex. It is real, inverted, and is 1.20 cm tall (enlarged). The calculation agrees with the image characterization from the principal ray diagram. A concave mirror used alone always forms a real, inverted image if $s>f$ and the image is enlarged if $f<s<2f$.

34.6. IDENTIFY: Apply $\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}$ and $m=-\frac{s'}{s}$.

SET UP: For a convex mirror, $R<0$. $R=-22.0\text{ cm}$ and $f=\frac{R}{2}=-11.0\text{ cm}$.

EXECUTE: (a) The principal-ray diagram is sketched in Figure 34.6.

(b) $\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}$. $s'=\frac{sf}{s-f}=\frac{(16.5\text{ cm})(-11.0\text{ cm})}{16.5\text{ cm}-(-11.0\text{ cm})}=-6.6\text{ cm}$. $m=-\frac{s'}{s}=-\frac{-6.6\text{ cm}}{16.5\text{ cm}}=+0.400$.

$|y'|=|m||y|=(0.400)(0.600\text{ cm})=0.240\text{ cm}$. The image is 6.6 cm to the right of the mirror. It is 0.240 cm tall. $s'<0$, so the image is virtual. $m>0$, so the image is erect.

EVALUATE: The calculated image properties agree with the image characterization from the principal-ray diagram.

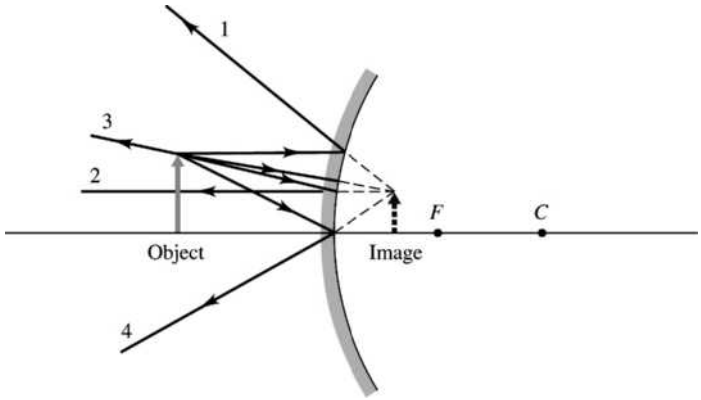


Figure 34.6

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

34.7. **IDENTIFY:** $\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}$. $m=-\frac{s'}{s}$. $|m|=\frac{|y'|}{y}$. Find m and calculate y'.

SET UP: $f=+1.75$ m.

EXECUTE: $s \gg f$ so $s'=f=1.75$ m.

$$m=-\frac{s'}{s}=-\frac{1.75 \text{ m}}{5.58\times10^{10} \text{ m}}=-3.14\times10^{-11}.$$

$$|y'|=|m||y|=(3.14\times10^{-11})(6.794\times10^{6} \text{ m})=2.13\times10^{-4} \text{ m}=0.213 \text{ mm}.$$

EVALUATE: The image is real and is 1.75 m in front of the mirror.

34.8. **IDENTIFY:** Apply $\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}$ and $m=-\frac{s'}{s}$.

SET UP: The mirror surface is convex so $R=-3.00$ cm. $s=24.0 \text{ cm}-3.00 \text{ cm}=21.0$ cm.

EXECUTE: $f=\frac{R}{2}=-1.50$ cm. $\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}$. $s'=\frac{sf}{s-f}=\frac{(21.0 \text{ cm})(-1.50 \text{ cm})}{21.0 \text{ cm}-(-1.50 \text{ cm})}=-1.40$ cm. The image is 1.40 cm behind the surface so it is $3.00 \text{ cm}-1.40 \text{ cm}=1.60$ cm from the center of the ornament, on the same side as the object. $m=-\frac{s'}{s}=-\frac{-1.40 \text{ cm}}{21.0 \text{ cm}}=+0.0667$. $|y'|=|m||y|=(0.0667)(3.80 \text{ mm})=0.253$ mm.

EVALUATE: The image is virtual, upright and smaller than the object.

34.9. **IDENTIFY:** The shell behaves as a spherical mirror.

SET UP: The equation relating the object and image distances to the focal length of a spherical mirror is $\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}$, and its magnification is given by $m=-\frac{s'}{s}$.

EXECUTE: $\frac{1}{s}+\frac{1}{s'}=\frac{1}{f} \Rightarrow \frac{1}{s}=\frac{2}{-18.0 \text{ cm}}-\frac{1}{-6.00 \text{ cm}} \Rightarrow s=18.0$ cm from the vertex.

$m=-\frac{s'}{s}=-\frac{-6.00 \text{ cm}}{18.0 \text{ cm}}=\frac{1}{3} \Rightarrow y'=\frac{1}{3}(1.5 \text{ cm})=0.50$ cm. The image is 0.50 cm tall, erect and virtual.

EVALUATE: Since the magnification is less than one, the image is smaller than the object.

34.10. **IDENTIFY:** The bottom surface of the bowl behaves as a spherical convex mirror.

SET UP: The equation relating the object and image distances to the focal length of a spherical mirror is $\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}$, and its magnification is given by $m=-\frac{s'}{s}$.

EXECUTE: $\frac{1}{s}+\frac{1}{s'}=\frac{1}{f} \Rightarrow \frac{1}{s'}=\frac{-2}{35 \text{ cm}}-\frac{1}{90 \text{ cm}} \Rightarrow s'=-15$ cm behind the bowl.

$m=-\frac{s'}{s}=\frac{15 \text{ cm}}{90 \text{ cm}}=0.167 \Rightarrow y'=(0.167)(2.0 \text{ cm})=0.33$ cm. The image is 0.33 cm tall, erect and virtual.

EVALUATE: Since the magnification is less than one, the image is smaller than the object.

34.11. **IDENTIFY:** Express the lateral magnification of a mirror in terms of its focal length and the object distance and then make use of the result.

SET UP: $\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}$. $m=-\frac{s'}{s}$.

EXECUTE: **(a)** Using $\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}$, we have $\frac{1}{s'}=\frac{1}{f}-\frac{1}{s}=\frac{s-f}{sf}$. $s'=\frac{sf}{s-f}$. The lateral magnification is

$$m=-\frac{s'}{s}=-\frac{f}{s-f}=\frac{f}{f-s}.$$

(b) $m=\pm1$. For $m=+1$, $f=f-s$ and $s=0$. This solution is excluded in the statement of the problem. For $m=-1$, $f=-(f-s)$ and $s=2f=28.0$ cm. The object is 28.0 cm from the mirror vertex. Negative m means the image is inverted.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(c) For a convex mirror all images are virtual and erect, so $m = +\frac{1}{2}$. $\frac{f}{f-s} = \frac{1}{2}$. $2f = f - s$ and $s = -f = +8.00$ cm. The object is 8.00 cm from the mirror vertex. Positive m means the image is erect.

EVALUATE: The sign of f can vary, depending on the type of mirror.

34.12. **IDENTIFY:** In part (a), the shell is a concave mirror, but in (b) it is a convex mirror. The magnitude of its focal length is the same in both cases, but the sign reverses.

SET UP: For the orientation of the shell shown in the figure in the problem, $R = +12.0$ cm. When the glass is reversed, so the seed faces a convex surface, $R = -12.0$ cm. $\frac{1}{s} + \frac{1}{s'} = \frac{2}{R}$ and $m = \frac{y'}{y} = -\frac{s'}{s}$.

EXECUTE: **(a)** $R = +12.0$ cm. $\frac{1}{s'} = \frac{2}{R} - \frac{1}{s} = \frac{2s - R}{Rs}$ and $s' = \frac{Rs}{2s - R} = \frac{(12.0 \text{ cm})(15.0 \text{ cm})}{30.0 \text{ cm} - 12.0 \text{ cm}} = +10.0$ cm.

$m = -\frac{s'}{s} = -\frac{10.0 \text{ cm}}{15.0 \text{ cm}} = -0.667$. $y' = my = -2.20$ mm. The image is 10.0 cm to the left of the shell vertex and is 2.20 mm tall.

(b) $R = -12.0$ cm. $s' = \frac{(-12.0 \text{ cm})(15.0 \text{ cm})}{30.0 \text{ cm} + 12.0 \text{ cm}} = -4.29$ cm. $m = -\frac{-4.29 \text{ cm}}{15.0 \text{ cm}} = +0.286$.

$y' = my = 0.944$ mm. The image is 4.29 cm to the right of the shell vertex and is 0.944 mm tall.

EVALUATE: In (a), $s > R/2$ and the mirror is concave, so the image is real. In (b) the image is virtual because a convex mirror always forms a virtual image.

34.13. **IDENTIFY:** $\frac{1}{s} + \frac{1}{s'} = \frac{1}{f}$ and $m = \frac{y'}{y} = -\frac{s'}{s}$.

SET UP: $m = +2.00$ and $s = 1.25$ cm. An erect image must be virtual.

EXECUTE: **(a)** $s' = \frac{sf}{s - f}$ and $m = -\frac{f}{s - f}$. For a concave mirror, m can be larger than 1.00. For a convex mirror, $|f| = -f$ so $m = +\frac{|f|}{s + |f|}$ and m is always less than 1.00. The mirror must be concave $(f > 0)$.

(b) $\frac{1}{f} = \frac{s' + s}{ss'}$. $f = \frac{ss'}{s + s'}$. $m = -\frac{s'}{s} = +2.00$ and $s' = -2.00s$. $f = \frac{s(-2.00s)}{s - 2.00s} = +2.00s = +2.50$ cm.

$R = 2f = +5.00$ cm.

(c) The principal-ray diagram is drawn in Figure 34.13.

EVALUATE: The principal-ray diagram agrees with the description from the equations.

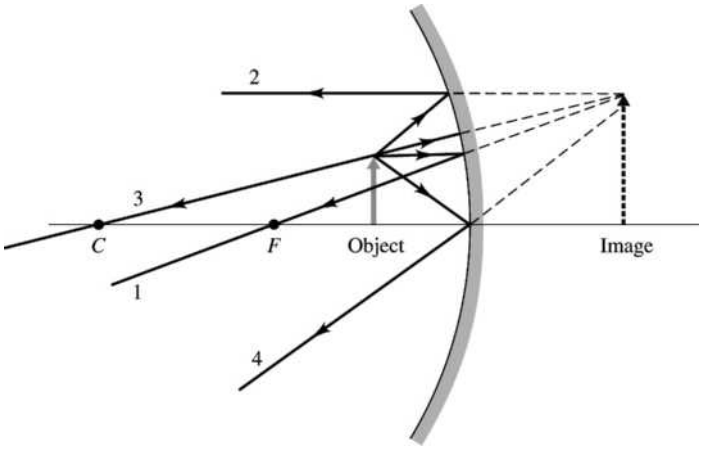

Figure 34.13

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

34.14. **IDENTIFY:** Apply $\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}$ and $m=-\frac{s'}{s}$.

SET UP: For a concave mirror, $R>0$. $R=32.0$ cm and $f=\frac{R}{2}=16.0$ cm.

EXECUTE: **(a)** $\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}$. $s'=\frac{sf}{s-f}=\frac{(12.0\text{ cm})(16.0\text{ cm})}{12.0\text{ cm}-16.0\text{ cm}}=-48.0$ cm. $m=-\frac{s'}{s}=-\frac{-48.0\text{ cm}}{12.0\text{ cm}}=+4.00$.

(b) $s'=-48.0$ cm, so the image is 48.0 cm to the right of the mirror. $s'<0$ so the image is virtual.

(c) The principal-ray diagram is sketched in Figure 34.14. The rules for principal rays apply only to paraxial rays. Principal ray 2, that travels to the mirror along a line that passes through the focus, makes a large angle with the optic axis and is not described well by the paraxial approximation. Therefore, principal ray 2 is not included in the sketch.

EVALUATE: A concave mirror forms a virtual image whenever $s<f$.

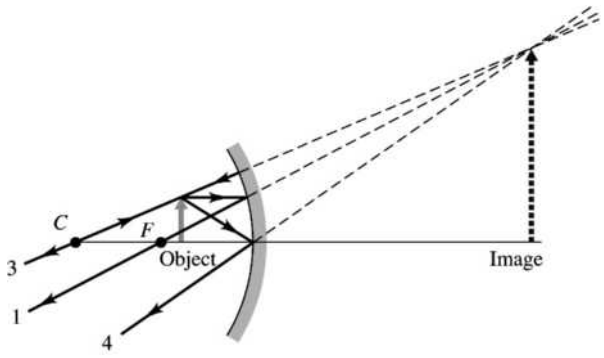

Figure 34.14

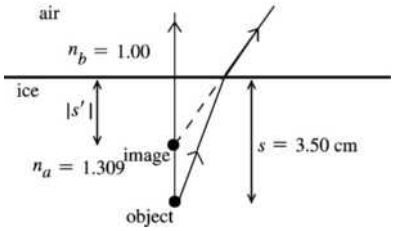
34.15. **IDENTIFY:** Apply Eq. (34.11), with $R\to\infty$. $|s'|$ is the apparent depth.

SET UP: The image and object are shown in Figure 34.15.



$\frac{n_a}{s}+\frac{n_b}{s'}=\frac{n_b-n_a}{R}$;
$R\to\infty$ (flat surface), so
$\frac{n_a}{s}+\frac{n_b}{s'}=0$

Figure 34.15

EXECUTE: $s'=-\frac{n_b s}{n_a}=-\frac{(1.00)(3.50\text{ cm})}{1.309}=-2.67$ cm

The apparent depth is 2.67 cm.

EVALUATE: When the light goes from ice to air (larger to smaller n), it is bent away from the normal and the virtual image is closer to the surface than the object is.

34.16. **IDENTIFY:** The surface is flat so $R\to\infty$ and $\frac{n_a}{s}+\frac{n_b}{s'}=0$.

SET UP: The light travels from the fish to the eye, so $n_a=1.333$ and $n_b=1.00$. When the fish is viewed, $s=7.0$ cm. The fish is $20.0\text{ cm}-7.0\text{ cm}=13.0$ cm above the mirror, so the image of the fish is 13.0 cm below the mirror and $20.0\text{ cm}+13.0\text{ cm}=33.0$ cm below the surface of the water. When the image is viewed, $s=33.0$ cm.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: **(a)** $s' = -\left(\frac{n_b}{n_a}\right)s = -\left(\frac{1.00}{1.333}\right)(7.0\text{ cm}) = -5.25\text{ cm}$. The apparent depth is 5.25 cm.

(b) $s' = -\left(\frac{n_b}{n_a}\right)s = -\left(\frac{1.00}{1.333}\right)(33.0\text{ cm}) = -24.8\text{ cm}$. The apparent depth of the image of the fish in the mirror is 24.8 cm.

EVALUATE: In each case the apparent depth is less than the actual depth of what is being viewed.

34.17. **IDENTIFY:** Think of the surface of the water as a section of a sphere having an infinite radius of curvature.

SET UP: $\frac{n_a}{s} + \frac{n_b}{s'} = 0$. $n_a = 1.00$. $n_b = 1.333$.

EXECUTE: The image is $5.20\text{ m} - 0.80\text{ m} = 4.40\text{ m}$ above the surface of the water, so $s' = -4.40$ m.

$$s = -\frac{n_a}{n_b}s' = -\left(\frac{1.00}{1.333}\right)(-4.40\text{ m}) = +3.30\text{ m}.$$

EVALUATE: The diving board is closer to the water than it looks to the swimmer.

34.18. **IDENTIFY:** Think of the surface of the water as a section of a sphere having an infinite radius of curvature.

SET UP: $\frac{n_a}{s} + \frac{n_b}{s'} = 0$. $n_a = 1.333$. $n_b = 1.00$.

EXECUTE: The image is 5.00 m below surface of the water, so $s' = -5.00$ m.

$$s = -\frac{n_a}{n_b}s' = -\left(\frac{1.333}{1.00}\right)(-5.00\text{ m}) = 6.66\text{ m}.$$

EVALUATE: The water is deeper than it appears to the person.

34.19. **IDENTIFY:** $\frac{n_a}{s} + \frac{n_b}{s'} = \frac{n_b - n_a}{R}$. $m = -\frac{n_a s'}{n_b s}$. Light comes from the fish to the person's eye.

SET UP: $R = -14.0$ cm. $s = +14.0$ cm. $n_a = 1.333$ (water). $n_b = 1.00$ (air). Figure 34.19 shows the object and the refracting surface.

EXECUTE: **(a)** $\frac{1.333}{14.0\text{ cm}} + \frac{1.00}{s'} = \frac{1.00 - 1.333}{-14.0\text{ cm}}$. $s' = -14.0$ cm. $m = -\frac{(1.333)(-14.0\text{ cm})}{(1.00)(14.0\text{ cm})} = +1.33$.

The fish's image is 14.0 cm to the left of the bowl surface so is at the center of the bowl and the magnification is 1.33.

(b) The focal point is at the image location when $s \to \infty$. $\frac{n_b}{s'} = \frac{n_b - n_a}{R}$. $n_a = 1.00$. $n_b = 1.333$.

$R = +14.0$ cm. $\frac{1.333}{s'} = \frac{1.333 - 1.00}{14.0\text{ cm}}$. $s' = +56.0$ cm. s' is greater than the diameter of the bowl, so the surface facing the sunlight does not focus the sunlight to a point inside the bowl. The focal point is outside the bowl and there is no danger to the fish.

EVALUATE: In part (b) the rays refract when they exit the bowl back into the air so the image we calculated is not the final image.

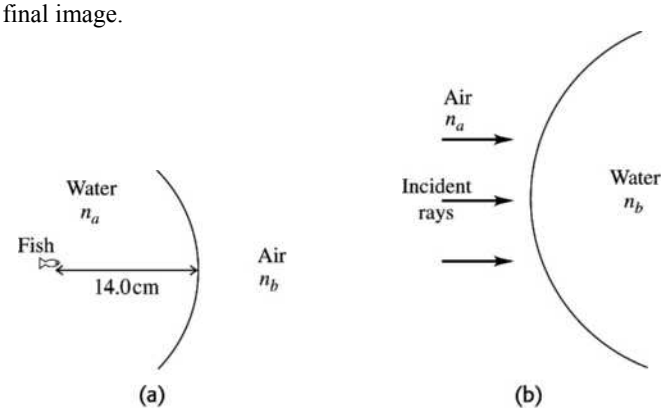


Figure 34.19

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

34.20. **IDENTIFY:** Apply $\frac{n_a}{s}+\frac{n_b}{s'}=\frac{n_b-n_a}{R}$.

SET UP: For a convex surface, $R>0$. $R=+3.00$ cm. $n_a=1.00$, $n_b=1.60$.

EXECUTE: **(a)** $s\to\infty$. $\frac{n_b}{s'}=\frac{n_b-n_a}{R}$. $s'=\left(\frac{n_b}{n_b-n_a}\right)R=\left(\frac{1.60}{1.60-1.00}\right)(+3.00\text{ cm})=+8.00$ cm. The image is 8.00 cm to the right of the vertex.

(b) $s=12.0$ cm. $\frac{1.00}{12.0\text{ cm}}+\frac{1.60}{s'}=\frac{1.60-1.00}{3.00\text{ cm}}$. $s'=+13.7$ cm. The image is 13.7 cm to the right of the vertex.

(c) $s=2.00$ cm. $\frac{1.00}{2.00\text{ cm}}+\frac{1.60}{s'}=\frac{1.60-1.00}{3.00\text{ cm}}$. $s'=-5.33$ cm. The image is 5.33 cm to the left of the vertex.

EVALUATE: The image can be either real $(s'>0)$ or virtual $(s'<0)$, depending on the distance of the object from the refracting surface.

34.21. **IDENTIFY:** The hemispherical glass surface forms an image by refraction. The location of this image depends on the curvature of the surface and the indices of refraction of the glass and oil.

SET UP: The image and object distances are related to the indices of refraction and the radius of curvature by the equation $\frac{n_a}{s}+\frac{n_b}{s'}=\frac{n_b-n_a}{R}$.

EXECUTE: $\frac{n_a}{s}+\frac{n_b}{s'}=\frac{n_b-n_a}{R}\Rightarrow\frac{1.45}{s}+\frac{1.60}{1.20\text{ m}}=\frac{0.15}{0.0300\text{ m}}\Rightarrow s=39.5$ cm

EVALUATE: The presence of the oil changes the location of the image.

34.22. **IDENTIFY:** $\frac{n_a}{s}+\frac{n_b}{s'}=\frac{n_b-n_a}{R}$. $m=-\frac{n_as'}{n_bs}$.

SET UP: $R=+4.00$ cm. $n_a=1.00$. $n_b=1.60$. $s=24.0$ cm.

EXECUTE: $\frac{1}{24.0\text{ cm}}+\frac{1.60}{s'}=\frac{1.60-1.00}{4.00\text{ cm}}$. $s'=+14.8$ cm. $m=-\frac{(1.00)(14.8\text{ cm})}{(1.60)(24.0\text{ cm})}=-0.385$.

$|y'|=|m||y|=(0.385)(1.50\text{ mm})=0.578$ mm. The image is 14.8 cm to the right of the vertex and is 0.578 mm tall. $m<0$, so the image is inverted.

EVALUATE: The image is real.

34.23. **IDENTIFY:** Apply Eqs. (34.11) and (34.12). Calculate s' and y'. The image is erect if $m>0$.

SET UP: The object and refracting surface are shown in Figure 34.23.

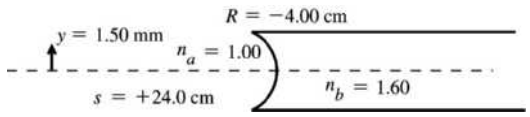

Figure 34.23

EXECUTE: $\frac{n_a}{s}+\frac{n_b}{s'}=\frac{n_b-n_a}{R}$

$\frac{1.00}{24.0\text{ cm}}+\frac{1.60}{s'}=\frac{1.60-1.00}{-4.00\text{ cm}}$

Multiplying by 24.0 cm gives $1.00+\frac{38.4}{s'}=-3.60$

$\frac{38.4\text{ cm}}{s'}=-4.60$ and $s'=-\frac{38.4\text{ cm}}{4.60}=-8.35$ cm

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

Eq. (34.12): $m = -\dfrac{n_a s'}{n_b s} = -\dfrac{(1.00)(-8.35\text{ cm})}{(1.60)(+24.0\text{ cm})} = +0.217$

$|y'| = |m||y| = (0.217)(1.50\text{ mm}) = 0.326\text{ mm}$

EVALUATE: The image is virtual $(s' < 0)$ and is 8.35 cm to the left of the vertex. The image is erect $(m > 0)$ and is 0.326 mm tall. R is negative since the center of curvature of the surface is on the incoming side.

34.24. **IDENTIFY:** The hemispherical glass surface forms an image by refraction. The location of this image depends on the curvature of the surface and the indices of refraction of the glass and liquid.

SET UP: The image and object distances are related to the indices of refraction and the radius of curvature by the equation $\dfrac{n_a}{s} + \dfrac{n_b}{s'} = \dfrac{n_b - n_a}{R}$.

EXECUTE: $\dfrac{n_a}{s} + \dfrac{n_b}{s'} = \dfrac{n_b - n_a}{R} \Rightarrow \dfrac{n_a}{14.0\text{ cm}} + \dfrac{1.60}{-9.00\text{ cm}} = \dfrac{1.60 - n_a}{-4.00\text{ cm}} \Rightarrow n_a = 1.24.$

EVALUATE: The result is a reasonable refractive index for liquids.

34.25. **IDENTIFY:** Use $\dfrac{1}{f} = (n-1)\left(\dfrac{1}{R_1} - \dfrac{1}{R_2}\right)$ to calculate f. Then apply $\dfrac{1}{s} + \dfrac{1}{s'} = \dfrac{1}{f}$ and $m = \dfrac{y'}{y} = -\dfrac{s'}{s}$.

SET UP: $R_1 \to \infty$. $R_2 = -13.0$ cm. If the lens is reversed, $R_1 = +13.0$ cm and $R_2 \to \infty$.

EXECUTE: **(a)** $\dfrac{1}{f} = (0.70)\left(\dfrac{1}{\infty} - \dfrac{1}{-13.0\text{ cm}}\right) = \dfrac{0.70}{13.0\text{ cm}}$ and $f = 18.6$ cm. $\dfrac{1}{s'} = \dfrac{1}{f} - \dfrac{1}{s} = \dfrac{s-f}{sf}$.

$s' = \dfrac{sf}{s-f} = \dfrac{(22.5\text{ cm})(18.6\text{ cm})}{22.5\text{ cm} - 18.6\text{ cm}} = 107\text{ cm}$. $m = -\dfrac{s'}{s} = -\dfrac{107\text{ cm}}{22.5\text{ cm}} = -4.76$.

$y' = my = (-4.76)(3.75\text{ mm}) = -17.8\text{ mm}$. The image is 107 cm to the right of the lens and is 17.8 mm tall. The image is real and inverted.

(b) $\dfrac{1}{f} = (n-1)\left(\dfrac{1}{13.0\text{ cm}} - \dfrac{1}{\infty}\right)$ and $f = 18.6$ cm. The image is the same as in part (a).

EVALUATE: Reversing a lens does not change the focal length of the lens.

34.26. **IDENTIFY:** $\dfrac{1}{s} + \dfrac{1}{s'} = \dfrac{1}{f}$. The sign of f determines whether the lens is converging or diverging.

SET UP: $s = 16.0$ cm. $s' = -12.0$ cm.

EXECUTE: **(a)** $f = \dfrac{ss'}{s+s'} = \dfrac{(16.0\text{ cm})(-12.0\text{ cm})}{16.0\text{ cm} + (-12.0\text{ cm})} = -48.0\text{ cm}$. $f < 0$ and the lens is diverging.

(b) $m = -\dfrac{s'}{s} = -\dfrac{-12.0\text{ cm}}{16.0\text{ cm}} = +0.750$. $|y'| = |m|\,y = (0.750)(8.50\text{ mm}) = 6.38\text{ mm}$. $m > 0$ and the image is erect.

(c) The principal-ray diagram is sketched in Figure 34.26.

EVALUATE: A diverging lens always forms an image that is virtual, erect and reduced in size.

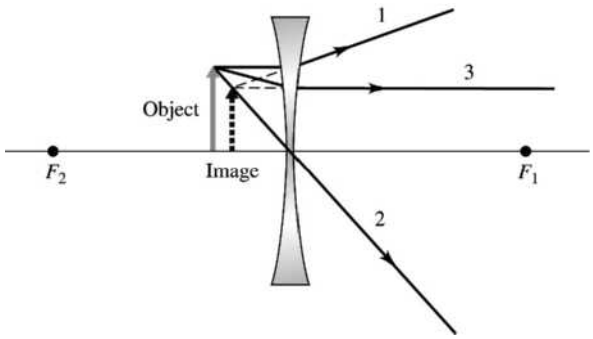

Figure 34.26

34.27. **IDENTIFY:** Use the lensmaker's equation to calculate f.

SET UP: The lensmaker's equation is $\frac{1}{s}+\frac{1}{s'}=(n-1)\left(\frac{1}{R_1}-\frac{1}{R_2}\right)$, and the magnification of the lens is $m=-\frac{s'}{s}$.

EXECUTE: **(a)** $\frac{1}{s}+\frac{1}{s'}=(n-1)\left(\frac{1}{R_1}-\frac{1}{R_2}\right)\Rightarrow\frac{1}{24.0\text{ cm}}+\frac{1}{s'}=(1.52-1)\left(\frac{1}{-7.00\text{ cm}}-\frac{1}{-4.00\text{ cm}}\right)$

$\Rightarrow s'=71.2\text{ cm}$, to the right of the lens.

(b) $m=-\frac{s'}{s}=-\frac{71.2\text{ cm}}{24.0\text{ cm}}=-2.97$

EVALUATE: Since the magnification is negative, the image is inverted.

34.28. **IDENTIFY:** Apply $m=\frac{y'}{y}=-\frac{s'}{s}$ to relate s' and s and then use $\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}$.

SET UP: Since the image is inverted, $y'<0$ and $m<0$.

EXECUTE: $m=\frac{y'}{y}=\frac{-4.50\text{ cm}}{3.20\text{ cm}}=-1.406$. $m=-\frac{s'}{s}$ gives $s'=+1.406s$. $\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}$ gives $\frac{1}{s}+\frac{1}{1.406s}=\frac{1}{90.0\text{ cm}}$ and $s=154$ cm. $s'=(1.406)(154\text{ cm})=217$ cm. The object is 154 cm to the left of the lens. The image is 217 cm to the right of the lens and is real.

EVALUATE: For a single lens an inverted image is always real.

34.29. **IDENTIFY:** The thin-lens equation applies in this case.

SET UP: The thin-lens equation is $\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}$, and the magnification is $m=-\frac{s'}{s}=\frac{y'}{y}$.

EXECUTE: $m=\frac{y'}{y}=\frac{34.0\text{ mm}}{8.00\text{ mm}}=4.25=-\frac{s'}{s}=-\frac{-12.0\text{ cm}}{s}\Rightarrow s=2.82$ cm. The thin-lens equation gives $\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}\Rightarrow f=3.69$ cm.

EVALUATE: Since the focal length is positive, this is a converging lens. The image distance is negative because the object is inside the focal point of the lens.

34.30. **IDENTIFY:** Apply $m=-\frac{s'}{s}$ to relate s and s'. Then use $\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}$.

SET UP: Since the image is to the right of the lens, $s'>0$. $s'+s=6.00$ m.

EXECUTE: **(a)** $s'=80.0s$ and $s+s'=6.00$ m gives $81.00s=6.00$ m and $s=0.0741$ m. $s'=5.93$ m.

(b) The image is inverted since both the image and object are real $(s'>0, s>0)$.

(c) $\frac{1}{f}=\frac{1}{s}+\frac{1}{s'}=\frac{1}{0.0741\text{ m}}+\frac{1}{5.93\text{ m}}\Rightarrow f=0.0732\text{ m}$, and the lens is converging.

EVALUATE: The object is close to the lens and the image is much farther from the lens. This is typical for slide projectors.

34.31. **IDENTIFY:** Apply $\frac{1}{f}=(n-1)\left(\frac{1}{R_1}-\frac{1}{R_2}\right)$.

SET UP: For a distant object the image is at the focal point of the lens. Therefore, $f=1.87$ cm. For the double-convex lens, $R_1=+R$ and $R_2=-R$, where $R=2.50$ cm.

EXECUTE: $\frac{1}{f}=(n-1)\left(\frac{1}{R}-\frac{1}{-R}\right)=\frac{2(n-1)}{R}$. $n=\frac{R}{2f}+1=\frac{2.50\text{ cm}}{2(1.87\text{ cm})}+1=1.67$.

EVALUATE: $f>0$ and the lens is converging. A double-convex lens is always converging.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

34.32. **IDENTIFY:** Use the lensmaker's formula to find the radius of curvature of the lens of the eye.

SET UP: $\frac{1}{f}=(n-1)\left(\frac{1}{R_1}-\frac{1}{R_2}\right)$. If R is the radius of the lens, then $R_1=R$ and $R_2=-R$. $\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}$.

$m=\frac{y'}{y}=-\frac{s'}{s}$.

EXECUTE: **(a)** $\frac{1}{f}=(n-1)\left(\frac{1}{R_1}-\frac{1}{R_2}\right)=(n-1)\left(\frac{1}{R}-\frac{1}{-R}\right)=\frac{2(n-1)}{R}$.

$R=2(n-1)f=2(0.44)(8.0\text{ mm})=7.0\text{ mm}$.

(b) $\frac{1}{s'}=\frac{1}{f}-\frac{1}{s}=\frac{s-f}{sf}$. $s'=\frac{sf}{s-f}=\frac{(30.0\text{ cm})(0.80\text{ cm})}{30.0\text{ cm}-0.80\text{ cm}}=0.82\text{ cm}=8.2\text{ mm}$. The image is 8.2 mm from the lens, on the side opposite the object. $m=-\frac{s'}{s}=-\frac{0.82\text{ cm}}{30.0\text{ cm}}=-0.0273$.

$y'=my=(-0.0273)(16\text{ cm})=0.44\text{ cm}=4.4\text{ mm}$. $s'>0$ so the image is real. $m<0$ so the image is inverted.

EVALUATE: The lens is converging and has a very short focal length. As long as the object is farther than 7.0 mm from the eye, the lens forms a real image.

34.33. **IDENTIFY:** First use the lensmaker's formula to find the radius of curvature of the cornea.

SET UP: $\frac{1}{f}=(n-1)\left(\frac{1}{R_1}-\frac{1}{R_2}\right)$. $R_1=+5.0\text{ mm}$. $\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}$. $m=\frac{y'}{y}=-\frac{s'}{s}$.

EXECUTE: **(a)** $\frac{1}{f(n-1)}=\frac{1}{R_1}-\frac{1}{R_2}$. $\frac{1}{R_2}=\frac{1}{R_1}-\frac{1}{f(n-1)}=\frac{1}{+5.0\text{ mm}}-\frac{1}{(18.0\text{ mm})(0.38)}$ so $R_2=18.6\text{ mm}$.

(b) $\frac{1}{s'}=\frac{1}{f}-\frac{1}{s}=\frac{s-f}{sf}$. $s'=\frac{sf}{s-f}=\frac{(25\text{ cm})(1.8\text{ cm})}{25\text{ cm}-1.8\text{ cm}}=1.9\text{ cm}=19\text{ mm}$.

(c) $m=-\frac{s'}{s}=-\frac{1.9\text{ cm}}{25\text{ cm}}=-0.076$. $y'=my=(-0.076)(8.0\text{ mm})=-0.61\text{ mm}$. $s'>0$ so the image is real. $m<0$ so the image is inverted.

EVALUATE: The cornea alone would focus an object at a distance of 19 mm, which is not at the retina. We must consider the effects of the lens of the eye and the fact that the eye is filled with liquid having an index of refraction.

34.34. **IDENTIFY:** We know where the image is formed and want to find where the object is.

SET UP: $m=\frac{y'}{y}=-\frac{s'}{s}$. Since the image is erect, $y'>0$ and $m>0$. $\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}$.

EXECUTE: $m=\frac{y'}{y}=\frac{1.30\text{ cm}}{0.400\text{ cm}}=+3.25$. $m=-\frac{s'}{s}=+3.25$ gives $s'=-3.25s$. $\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}$ gives $\frac{1}{s}+\frac{1}{-3.25s}=\frac{1}{7.00\text{ cm}}$ so $s=4.85\text{ cm}$. $s'=-(3.25)(4.85\text{ cm})=-15.8\text{ cm}$. The object is 4.85 cm to the left of the lens. The image is 15.8 cm to the left of the lens and is virtual.

EVALUATE: The image is virtual because the object distance is less than the focal length.

34.35. **IDENTIFY:** First use the figure that accompanies the problem to decide if each radius of curvature is positive or negative. Then apply the lensmaker's formula to calculate the focal length of each lens.

SET UP: Use $\frac{1}{f}=(n-1)\left(\frac{1}{R_1}-\frac{1}{R_2}\right)$ to calculate f and then use $\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}$ to locate the image.

$s=18.0\text{ cm}$.

EXECUTE: **(a)** $\frac{1}{f}=(0.5)\left(\frac{1}{10.0\text{ cm}}-\frac{1}{-15.0\text{ cm}}\right)$ and $f=+12.0\text{ cm}$. $\frac{1}{s'}=\frac{1}{f}-\frac{1}{s}=\frac{s-f}{sf}$.

$s'=\frac{f}{s-f}=\frac{(18.0\text{ cm})(12.0\text{ cm})}{18.0\text{ cm}-12.0\text{ cm}}=+36.0\text{ cm}$. The image is 36.0 cm to the right of the lens.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) $\frac{1}{f}=(0.5)\left(\frac{1}{10.0\text{ cm}}-\frac{1}{\infty}\right)$ so $f=+20.0$ cm. $s'=\frac{sf}{s-f}=\frac{(18.0\text{ cm})(20.0\text{ cm})}{18.0\text{ cm}-20.0\text{ cm}}=-180$ cm. The image is 180 cm to the left of the lens.

(c) $\frac{1}{f}=(0.5)\left(\frac{1}{-15.0\text{ cm}}-\frac{1}{10.0\text{ cm}}\right)$ so $f=-12.0$ cm. $s'=\frac{sf}{s-f}=\frac{(18.0\text{ cm})(-12.0\text{ cm})}{18.0\text{ cm}+12.0\text{ cm}}=-7.20$ cm. The image is 7.20 cm to the left of the lens.

(d) $\frac{1}{f}=(0.5)\left(\frac{1}{-10.0\text{ cm}}-\frac{1}{-15.0\text{ cm}}\right)$ so $f=-60.0$ cm. $s'=\frac{sf}{s-f}=\frac{(18.0\text{ cm})(-60.0\text{ cm})}{18.0\text{ cm}+60.0\text{ cm}}=-13.8$ cm. The image is 13.8 cm to the left of the lens.

EVALUATE: The focal length of a lens is determined by *both* of its radii of curvature.

34.36. **IDENTIFY:** Apply $\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}$ and $m=\frac{y'}{y}=-\frac{s'}{s}$.

SET UP: $f=+12.0$ cm and $s'=-17.0$ cm.

EXECUTE: $\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}\Rightarrow\frac{1}{s}=\frac{1}{12.0\text{ cm}}-\frac{1}{-17.0\text{ cm}}\Rightarrow s=7.0$ cm.

$m=-\frac{s'}{s}=-\frac{(-17.0)}{7.0}=+2.4\Rightarrow y=\frac{y'}{m}=\frac{0.800\text{ cm}}{+2.4}=+0.34$ cm, so the object is 0.34 cm tall, erect, same side as the image. The principal-ray diagram is sketched in Figure 34.36. The image is erect.

EVALUATE: When the object is inside the focal point, a converging lens forms a virtual, enlarged image.

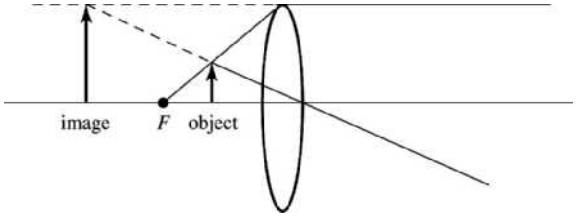

Figure 34.36

34.37. **IDENTIFY:** Use Eq. (34.16) to calculate the object distance s. m calculated from Eq. (34.17) determines the size and orientation of the image.

SET UP: $f=-48.0$ cm. Virtual image 17.0 cm from lens so $s'=-17.0$ cm.

EXECUTE: $\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}$, so $\frac{1}{s}=\frac{1}{f}-\frac{1}{s'}=\frac{s'-f}{s'f}$

$s=\frac{s'f}{s'-f}=\frac{(-17.0\text{ cm})(-48.0\text{ cm})}{-17.0\text{ cm}-(-48.0\text{ cm})}=+26.3$ cm

$m=-\frac{s'}{s}=-\frac{-17.0\text{ cm}}{+26.3\text{ cm}}=+0.646$

$m=\frac{y'}{y}$ so $|y|=\frac{|y'|}{|m|}=\frac{8.00\text{ mm}}{0.646}=12.4$ mm

The principal-ray diagram is sketched in Figure 34.37.

EVALUATE: Virtual image, real object $(s>0)$ so image and object are on same side of lens. $m>0$ so image is erect with respect to the object. The height of the object is 12.4 mm.

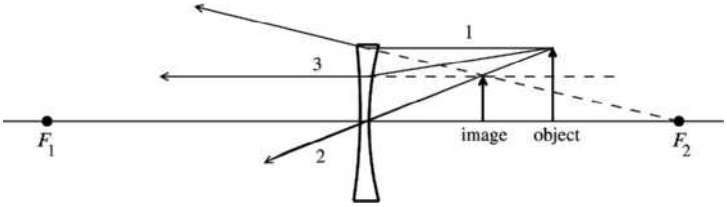

Figure 34.37

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

34.38. **IDENTIFY:** Apply $\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}$.

SET UP: The sign of f determines whether the lens is converging or diverging. $s=16.0$ cm. $s'=+36.0$ cm. Use $m=-\frac{s'}{s}$ to find the size and orientation of the image.

EXECUTE: **(a)** $f=\frac{ss'}{s+s'}=\frac{(16.0\text{ cm})(36.0\text{ cm})}{16.0\text{ cm}+36.0\text{ cm}}=11.1$ cm. $f>0$ and the lens is converging.

(b) $m=-\frac{s'}{s}=-\frac{36.0\text{ cm}}{16.0\text{ cm}}=-2.25$. $|y'|=|m|\,y=(2.25)(8.00\text{ mm})=18.0$ mm. $m<0$ so the image is inverted.

(c) The principal-ray diagram is sketched in Figure 34.38.

EVALUATE: The image is real so the lens must be converging.

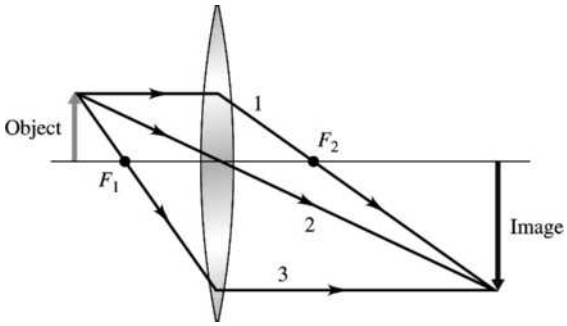

Figure 34.38

34.39. **IDENTIFY:** The first lens forms an image that is then the object for the second lens.

SET UP: Apply $\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}$ to each lens. $m_1=\frac{y_1'}{y_1}$ and $m_2=\frac{y_2'}{y_2}$.

EXECUTE: **(a)** *Lens 1:* $\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}$ gives $s_1'=\frac{s_1f_1}{s_1-f_1}=\frac{(50.0\text{ cm})(40.0\text{ cm})}{50.0\text{ cm}-40.0\text{ cm}}=+200$ cm.

$m_1=-\frac{s_1'}{s_1}=-\frac{200\text{ cm}}{50\text{ cm}}=-4.00$. $y_1'=m_1y_1=(-4.00)(1.20\text{ cm})=-4.80$ cm. The image I_1 is 200 cm to the right of lens 1, is 4.80 cm tall and is inverted.

(b) *Lens 2:* $y_2=-4.80$ cm. The image I_1 is $300\text{ cm}-200\text{ cm}=100$ cm to the left of lens 2, so $s_2=+100$ cm. $s_2'=\frac{s_2f_2}{s_2-f_2}=\frac{(100\text{ cm})(60.0\text{ cm})}{100\text{ cm}-60.0\text{ cm}}=+150$ cm. $m_2=-\frac{s_2'}{s_2}=-\frac{150\text{ cm}}{100\text{ cm}}=-1.50$.

$y_2'=m_2y_2=(-1.50)(-4.80\text{ cm})=+7.20$ cm. The image is 150 cm to the right of the second lens, is 7.20 cm tall, and is erect with respect to the original object.

EVALUATE: The overall magnification of the lens combination is $m_{\text{tot}}=m_1m_2$.

34.40. **IDENTIFY:** The first lens forms an image that is then the object for the second lens. We follow the same general procedure as in Problem 34.39.

SET UP: Apply $\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}$ to each lens. $m_1=\frac{y_1'}{y_1}$ and $m_2=\frac{y_2'}{y_2}$. For a diverging lens, $f<0$.

EXECUTE: **(a)** $f_1=+40.0$ cm. I_1 is the same as in Problem 34.39. For lens 2,

$s_2'=\frac{s_2f_2}{s_2-f_2}=\frac{(100\text{ cm})(-60.0\text{ cm})}{100\text{ cm}-(-60.0\text{ cm})}=-37.5$ cm. $m_2=-\frac{s_2'}{s_2}=-\frac{-37.5\text{ cm}}{100\text{ cm}}=+0.375$.

$y_2'=m_2y_2=(+0.375)(-4.80\text{ cm})=-1.80$ cm. The final image is 37.5 cm to the left of the second lens (262.5 cm to the right of the first lens). The final image is inverted and is 1.80 cm tall.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) $f_1 = -40.0$ cm. $s_1' = \dfrac{s_1 f_1}{s_1 - f_1} = \dfrac{(50.0 \text{ cm})(-40.0 \text{ cm})}{50.0 \text{ cm} - (-40.0 \text{ cm})} = -22.2$ cm. $m_1 = -\dfrac{s_1'}{s_1} = -\dfrac{-22.2 \text{ cm}}{50.0 \text{ cm}} = +0.444$.

$y_1' = m_1 y_1 = (0.444)(1.20 \text{ cm}) = 0.533$ cm. The image I_1 is 22.2 cm to the left of lens 1 so is $22.2 \text{ cm} + 300 \text{ cm} = 322.2$ cm to the left of lens 2 and $s_2 = +322.2$ cm. $y_2 = y_1' = 0.533$ cm.

$s_2' = \dfrac{s_2 f_2}{s_2 - f_2} = \dfrac{(322.2 \text{ cm})(60.0 \text{ cm})}{322.2 \text{ cm} - 60.0 \text{ cm}} = +73.7$ cm. $m_2 = -\dfrac{s_2'}{s_2} = -\dfrac{73.7 \text{ cm}}{322.2 \text{ cm}} = -0.229$.

$y_2' = m_2 y_2 = (-0.229)(0.533 \text{ cm}) = -0.122$ cm. The final image is 73.7 cm to the right of the second lens, is inverted and is 0.122 cm tall.

(c) $f_1 = -40.0$ cm. $f_2 = -60.0$ cm. I_1 is as calculated in part (b).

$s_2' = \dfrac{s_2 f_2}{s_2 - f_2} = \dfrac{(322.2 \text{ cm})(-60.0 \text{ cm})}{322.2 \text{ cm} - (-60.0 \text{ cm})} = -50.6$ cm. $m_2 = -\dfrac{s_2'}{s_2} = -\dfrac{-50.6 \text{ cm}}{322.2 \text{ cm}} = +0.157$.

$y_2' = m_2 y_2 = (0.157)(0.533 \text{ cm}) = 0.0837$ cm. The final image is 50.6 cm to the left of the second lens (249.4 cm to the right of the first lens), is upright and is 0.0837 cm tall.

EVALUATE: The overall magnification of the lens combination is $m_{\text{tot}} = m_1 m_2$.

34.41. **IDENTIFY:** The first lens forms an image that is then the object for the second lens. We follow the same general procedure as in Problem 34.39.

SET UP: $m_{\text{tot}} = m_1 m_2$. $\dfrac{1}{s} + \dfrac{1}{s'} = \dfrac{1}{f}$ gives $s' = \dfrac{sf}{s - f}$.

EXECUTE: **(a)** *Lens 1:* $f_1 = -12.0$ cm, $s_1 = 20.0$ cm. $s' = \dfrac{(20.0 \text{ cm})(-12.0 \text{ cm})}{20.0 \text{ cm} + 12.0 \text{ cm}} = -7.5$ cm.

$m_1 = -\dfrac{s_1'}{s_1} = -\dfrac{-7.5 \text{ cm}}{20.0 \text{ cm}} = +0.375$.

Lens 2: The image of lens 1 is 7.5 cm to the left of lens 1 so is $7.5 \text{ cm} + 9.00 \text{ cm} = 16.5$ cm to the left of lens 2.

$s_2 = +16.5$ cm. $f_2 = +12.0$ cm. $s_2' = \dfrac{(16.5 \text{ cm})(12.0 \text{ cm})}{16.5 \text{ cm} - 12.0 \text{ cm}} = 44.0$ cm. $m_2 = -\dfrac{s_2'}{s_2} = -\dfrac{44.0 \text{ cm}}{16.5 \text{ cm}} = -2.67$. The final image is 44.0 cm to the right of lens 2 so is 53.0 cm to the right of the first lens.

(b) $s_2' > 0$ so the final image is real.

(c) $m_{\text{tot}} = m_1 m_2 = (+0.375)(-2.67) = -1.00$. The image is 2.50 mm tall and is inverted.

EVALUATE: The light travels through the lenses in the direction from left to right. A real image for the second lens is to the right of that lens and a virtual image is to the left of the second lens.

34.42. **IDENTIFY:** The projector lens can be modeled as a thin lens.

SET UP: The thin-lens equation is $\dfrac{1}{s} + \dfrac{1}{s'} = \dfrac{1}{f}$, and the magnification of the lens is $m = -\dfrac{s'}{s}$.

EXECUTE: **(a)** $\dfrac{1}{s} + \dfrac{1}{s'} = \dfrac{1}{f} \Rightarrow \dfrac{1}{f} = \dfrac{1}{0.150 \text{ m}} + \dfrac{1}{9.00 \text{ m}} \Rightarrow f = 147.5$ mm, , so use a $f = 148$ mm lens.

(b) $m = -\dfrac{s'}{s} \Rightarrow |m| = 60 \Rightarrow$ Area $= 1.44 \text{ m} \times 2.16 \text{ m}$.

EVALUATE: The lens must produce a real image to be viewed on the screen. Since the magnification comes out negative, the slides to be viewed must be placed upside down in the tray.

34.43. **IDENTIFY:** Apply $\dfrac{1}{s} + \dfrac{1}{s'} = \dfrac{1}{f}$.

SET UP: The image is to be formed on the film, so $s' = +20.4$ cm.

EXECUTE: $\dfrac{1}{s} + \dfrac{1}{s'} = \dfrac{1}{f} \Rightarrow \dfrac{1}{s} + \dfrac{1}{20.4 \text{ cm}} = \dfrac{1}{20.0 \text{ cm}} \Rightarrow s = 1020 \text{ cm} = 10.2 \text{ m}$.

EVALUATE: The object distance is much greater than f, so the image is just outside the focal point of the lens.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

34.44. **IDENTIFY:** Apply $\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}$ and $m=\frac{y'}{y}=-\frac{s'}{s}$.

SET UP: $s=3.90$ m. $f=0.085$ m.

EXECUTE: $\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}\Rightarrow\frac{1}{3.90\text{ m}}+\frac{1}{s'}=\frac{1}{0.085\text{ m}}\Rightarrow s'=0.0869$ m.

$y'=-\frac{s'}{s}y=-\frac{0.0869}{3.90}1750\text{ mm}=-39.0\text{ mm}$, so it will not fit on the 24-mm×36-mm film.

EVALUATE: The image is just outside the focal point and $s'\approx f$. To have $|y'|=36$ mm, so that the image will fit on the film, $s=-\frac{s'y}{y'}\approx-\frac{(0.085\text{ m})(1.75\text{ m})}{-0.036\text{ m}}=4.1$ m. The person would need to stand about 4.1 m from the lens.

34.45. **IDENTIFY:** $|m|=\left|\frac{s'}{s}\right|$.

SET UP: $s\gg f$, so $s'\approx f$.

EXECUTE: **(a)** $|m|=\frac{s'}{s}\approx\frac{f}{s}\Rightarrow|m|=\frac{28\text{ mm}}{200{,}000\text{ mm}}=1.4\times10^{-4}$.

(b) $|m|=\frac{s'}{s}\approx\frac{f}{s}\Rightarrow|m|=\frac{105\text{ mm}}{200{,}000\text{ mm}}=5.3\times10^{-4}$.

(c) $|m|=\frac{s'}{s}\approx\frac{f}{s}\Rightarrow|m|=\frac{300\text{ mm}}{200{,}000\text{ mm}}=1.5\times10^{-3}$.

EVALUATE: The magnitude of the magnification increases when f increases.

34.46. **IDENTIFY:** $|m|=\left|\frac{s'}{s}\right|=\frac{|y'|}{y}$

SET UP: $s\gg f$, so $s'\approx f$.

EXECUTE: $|y'|=\frac{s'}{s}y\approx\frac{f}{s}y=\frac{5.00\text{ m}}{9.50\times10^{3}\text{ m}}(70.7\text{ m})=0.0372\text{ m}=37.2\text{ mm}$.

EVALUATE: A very long focal length lens is needed to photograph a distant object.

34.47. **IDENTIFY** and **SET UP:** Find the lateral magnification that results in this desired image size. Use Eq. (34.17) to relate m and s' and Eq. (34.16) to relate s and s' to f.

EXECUTE: **(a)** We need $m=-\frac{24\times10^{-3}\text{ m}}{160\text{ m}}=-1.5\times10^{-4}$. Alternatively, $m=-\frac{36\times10^{-3}\text{ m}}{240\text{ m}}=-1.5\times10^{-4}$.

$s\gg f$ so $s'\approx f$

Then $m=-\frac{s'}{s}=-\frac{f}{s}=-1.5\times10^{-4}$ and $f=(1.5\times10^{-4})(600\text{ m})=0.090\text{ m}=90\text{ mm}$.

A smaller f means a smaller s' and a smaller m, so with $f=85$ mm the object's image nearly fills the picture area.

(b) We need $m=-\frac{36\times10^{-3}\text{ m}}{9.6\text{ m}}=-3.75\times10^{-3}$. Then, as in part (a), $\frac{f}{s}=3.75\times10^{-3}$ and $f=(40.0\text{ m})(3.75\times10^{-3})=0.15\text{ m}=150\text{ mm}$. Therefore use the 135-mm lens.

EVALUATE: When $s\gg f$ and $s'\approx f$, $y'=-f(y/s)$. For the mobile home y/s is smaller so a larger f is needed. Note that m is very small; the image is much smaller than the object.

34.48. **IDENTIFY:** Apply $\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}$ to each lens. The image of the first lens serves as the object for the second lens.

SET UP: For a distant object, $s\to\infty$.

EXECUTE: **(a)** $s_1=\infty\Rightarrow s_1'=f_1=12$ cm.

(b) $s_2=4.0\text{ cm}-12\text{ cm}=-8$ cm.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(c) $\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}\Rightarrow\frac{1}{-8\text{ cm}}+\frac{1}{s_2'}=\frac{1}{-12\text{ cm}}\Rightarrow s_2'=24\text{ cm},$ to the right.

(d) $s_1=\infty\Rightarrow s_1'=f_1=12\text{ cm}.\ \ s_2=8.0\text{ cm}-12\text{ cm}=-4\text{ cm}.$

$\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}\Rightarrow\frac{1}{-4\text{ cm}}+\frac{1}{s_2'}=\frac{1}{-12\text{ cm}}\Rightarrow s_2'=6\text{ cm}.$

EVALUATE: In each case the image of the first lens serves as a virtual object for the second lens, and $s_2<0$.

34.49. **IDENTIFY:** The *f*-number of a lens is the ratio of its focal length to its diameter. To maintain the same exposure, the amount of light passing through the lens during the exposure must remain the same.

SET UP: The *f*-number is *f*/*D*.

EXECUTE: **(a)** $f\text{-number}=\frac{f}{D}\Rightarrow f\text{-number}=\frac{180.0\text{ mm}}{16.36\text{ mm}}\Rightarrow f\text{-number}=f/11.$ (The *f*-number is an integer.)

(b) *f*/11 to *f*/2.8 is four steps of 2 in intensity, so one needs $1/16^{\text{th}}$ the exposure. The exposure should be $1/480\text{ s}=2.1\times10^{-3}\text{ s}=2.1\text{ ms}.$

EVALUATE: When opening the lens from *f*/11 to *f*/2.8, the area increases by a factor of 16, so 16 times as much light is allowed in. Therefore the exposure time must be decreased by a factor of 1/16 to maintain the same exposure on the film or light receptors of a digital camera.

34.50. **IDENTIFY** and **SET UP:** The square of the aperture diameter is proportional to the length of the exposure time required.

EXECUTE: $\left(\frac{1}{30}\text{ s}\right)\left(\frac{8\text{ mm}}{23.1\text{ mm}}\right)^2\approx\left(\frac{1}{250}\text{ s}\right)$

EVALUATE: An increase in the aperture diameter decreases the exposure time.

34.51. **IDENTIFY** and **SET UP:** Apply $\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}$ to calculate s'.

EXECUTE: **(a)** A real image is formed at the film, so the lens must be convex.

(b) $\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}\text{ so }\frac{1}{s'}=\frac{s-f}{sf}\text{ and }s'=\frac{sf}{s-f},$ with $f=+50.0.0\text{ mm}.$ For $s=45\text{ cm}=450\text{ mm}, s'=56\text{ mm}.$

For $s=\infty, s'=f=50\text{ mm}.$ The range of distances between the lens and film is 50 mm to 56 mm.

EVALUATE: The lens is closer to the film when photographing more distant objects.

34.52. **IDENTIFY:** $\frac{n_a}{s}+\frac{n_b}{s'}=\frac{n_b-n_a}{R}$

SET UP: $n_a=1.00,\ \ n_b=1.40.\ \ s=40.0\text{ cm},\ \ s'=2.60\text{ cm}.$

EXECUTE: $\frac{1}{40.0\text{ cm}}+\frac{1.40}{2.60\text{ cm}}=\frac{0.40}{R}$ and $R=0.710\text{ cm}.$

EVALUATE: The cornea presents a convex surface to the object, so $R>0$.

34.53. **(a) IDENTIFY:** The purpose of the corrective lens is to take an object 25 cm from the eye and form a virtual image at the eye's near point. Use Eq. (34.16) to solve for the image distance when the object distance is 25 cm.

SET UP: $\frac{1}{f}=+2.75$ diopters means $f=+\frac{1}{2.75}\text{ m}=+0.3636\text{ m}$ (converging lens)

$f=36.36\text{ cm}; s=25\text{ cm}; s'=?$

EXECUTE: $\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}$ so

$s'=\frac{sf}{s-f}=\frac{(25\text{ cm})(36.36\text{ cm})}{25\text{ cm}-36.36\text{ cm}}=-80.0\text{ cm}$

The eye's near point is 80.0 cm from the eye.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) IDENTIFY: The purpose of the corrective lens is to take an object at infinity and form a virtual image of it at the eye's far point. Use Eq. (34.16) to solve for the image distance when the object is at infinity.

SET UP: $\frac{1}{f} = -1.30$ diopters means $f = -\frac{1}{1.30}\ \text{m} = -0.7692\ \text{m}$ (diverging lens)

$f = -76.92$ cm; $s = \infty$; $s' = ?$

EXECUTE: $\frac{1}{s} + \frac{1}{s'} = \frac{1}{f}$ and $s = \infty$ says $\frac{1}{s'} = \frac{1}{f}$ and $s' = f = -76.9$ cm. The eye's far point is 76.9 cm from the eye.

EVALUATE: In each case a virtual image is formed by the lens. The eye views this virtual image instead of the object. The object is at a distance where the eye can't focus on it, but the virtual image is at a distance where the eye can focus.

34.54. **IDENTIFY** and **SET UP:** For an object 25.0 cm from the eye, the corrective lens forms a virtual image at the near point of the eye. $\frac{1}{s} + \frac{1}{s'} = \frac{1}{f}$. $P(\text{in diopters}) = 1/f$ (in m).

EXECUTE: **(a)** The person is farsighted.

(b) A converging lens is needed.

(c) $\frac{1}{s} + \frac{1}{s'} = \frac{1}{f}$. $f = \frac{ss'}{s+s'} = \frac{(25.0\ \text{cm})(-45.0\ \text{cm})}{25.0\ \text{cm} - 45.0\ \text{cm}} = +56.2$ cm. The power is $\frac{1}{0.562\ \text{m}} = +1.78$ diopters.

EVALUATE: The object is inside the focal point of the lens, so it forms a virtual image.

34.55. **IDENTIFY** and **SET UP:** For an object 25.0 cm from the eye, the corrective lens forms a virtual image at the near point of the eye. The distances from the corrective lens are $s = 23.0$ cm and $s' = -43.0$ cm.

$\frac{1}{s} + \frac{1}{s'} = \frac{1}{f}$. $P(\text{in diopters}) = 1/f$ (in m).

EXECUTE: Solving $\frac{1}{s} + \frac{1}{s'} = \frac{1}{f}$ for f gives $f = \frac{ss'}{s+s'} = \frac{(23.0\ \text{cm})(-43.0\ \text{cm})}{23.0\ \text{cm} - 43.0\ \text{cm}} = +49.4$ cm. The power is $\frac{1}{0.494\ \text{m}} = 2.02$ diopters.

EVALUATE: In Problem 34.54 the contact lenses have power 1.78 diopters. The power of the lenses is different for ordinary glasses versus contact lenses.

34.56. **IDENTIFY** and **SET UP:** For an object very far from the eye, the corrective lens forms a virtual image at the far point of the eye. $\frac{1}{s} + \frac{1}{s'} = \frac{1}{f}$. $P(\text{in diopters}) = 1/f$ (in m).

EXECUTE: **(a)** The person is nearsighted.

(b) A diverging lens is needed.

(c) In $\frac{1}{s} + \frac{1}{s'} = \frac{1}{f}$, $s \to \infty$, so $f = s' = -75.0$ cm. The power is $\frac{1}{-0.750\ \text{m}} = -1.33$ diopters.

EVALUATE: A diverging lens is needed to form a virtual image of a distant object. A converging lens could not do this since distant objects cannot be inside its focal point.

34.57. **IDENTIFY** and **SET UP:** For an object very far from the eye, the corrective lens forms a virtual image at the far point of the eye. The distances from the lens are $s \to \infty$ and $s' = -73.0$ cm.

$\frac{1}{s} + \frac{1}{s'} = \frac{1}{f}$. $P(\text{in diopters}) = 1/f$ (in m).

EXECUTE: In $\frac{1}{s} + \frac{1}{s'} = \frac{1}{f}$, $s \to \infty$, so $f = s' = -73.0$ cm. The power is $\frac{1}{-0.730\ \text{m}} = -1.37$ diopters.

EVALUATE: A diverging lens is needed to form a virtual image of a distant object. A converging lens could not do this since distant objects cannot be inside its focal point.

34.58. **IDENTIFY:** When the object is at the focal point, $M = \frac{25.0\ \text{cm}}{f}$. In part (b), apply $\frac{1}{s} + \frac{1}{s'} = \frac{1}{f}$ to calculate s for $s' = -25.0$ cm.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

SET UP: Our calculation assumes the near point is 25.0 cm from the eye.

EXECUTE: **(a)** Angular magnification $M = \dfrac{25.0\text{ cm}}{f} = \dfrac{25.0\text{ cm}}{6.00\text{ cm}} = 4.17.$

(b) $\dfrac{1}{s} + \dfrac{1}{s'} = \dfrac{1}{f} \Rightarrow \dfrac{1}{s} + \dfrac{1}{-25.0\text{ cm}} = \dfrac{1}{6.00\text{ cm}} \Rightarrow s = 4.84\text{ cm}.$

EVALUATE: In part (b), $\theta' = \dfrac{y}{s}$, $\theta = \dfrac{y}{25.0\text{ cm}}$ and $M = \dfrac{25.0\text{ cm}}{s} = \dfrac{25.0\text{ cm}}{4.84\text{ cm}} = 5.17$. M is greater when the image is at the near point than when the image is at infinity.

34.59. **IDENTIFY:** Use Eqs. (34.16) and (34.17) to calculate s and y'.

(a) SET UP: $f = 8.00$ cm; $s' = -25.0$ cm; $s = ?$

$\dfrac{1}{s} + \dfrac{1}{s'} = \dfrac{1}{f}$, so $\dfrac{1}{s} = \dfrac{1}{f} - \dfrac{1}{s'} = \dfrac{s' - f}{s'f}$

EXECUTE: $s = \dfrac{s'f}{s' - f} = \dfrac{(-25.0\text{ cm})(+8.00\text{ cm})}{-25.0\text{ cm} - 8.00\text{ cm}} = +6.06\text{ cm}$

(b) $m = -\dfrac{s'}{s} = -\dfrac{-25.0\text{ cm}}{6.06\text{ cm}} = +4.125$

$|m| = \dfrac{|y'|}{|y|}$ so $|y'| = |m||y| = (4.125)(1.00\text{ mm}) = 4.12\text{ mm}$

EVALUATE: The lens allows the object to be much closer to the eye than the near point. The lens allows the eye to view an image at the near point rather than the object.

34.60. **IDENTIFY:** For a thin lens, $-\dfrac{s'}{s} = \dfrac{y'}{y}$, so $\left|\dfrac{y'}{s'}\right| = \left|\dfrac{y}{s}\right|$, and the angular size of the image equals the angular size of the object.

SET UP: The object has angular size $\theta = \dfrac{y}{f}$, with θ in radians.

EXECUTE: $\theta = \dfrac{y}{f} \Rightarrow f = \dfrac{y}{\theta} = \dfrac{2.00\text{ mm}}{0.025\text{ rad}} = 80.0\text{ mm} = 8.00\text{ cm}.$

EVALUATE: If the insect is at the near point of a normal eye, its angular size is $\dfrac{2.00\text{ mm}}{250\text{ mm}} = 0.0080\text{ rad}.$

34.61. **IDENTIFY:** Eq. (34.24) can be written $M = |m_1| M_2 = \left|\dfrac{s_1'}{f_1}\right| M_2.$

SET UP: $s_1' = f_1 + 120\text{ mm}$

EXECUTE: $f = 16\text{ mm}$: $s' = 120\text{ mm} + 16\text{ mm} = 136\text{ mm}$; $s = 16\text{ mm}$. $|m_1| = \dfrac{s'}{s} = \dfrac{136\text{ mm}}{16\text{ mm}} = 8.5.$

$f = 4\text{ mm}$: $s' = 120\text{ mm} + 4\text{ mm} = 124\text{ mm}$; $s = 4\text{ mm} \Rightarrow |m_1| = \dfrac{s'}{s} = \dfrac{124\text{ mm}}{4\text{ mm}} = 31.$

$f = 1.9\text{ mm}$: $s' = 120\text{ mm} + 1.9\text{ mm} = 122\text{ mm}$; $s = 1.9\text{ mm} \Rightarrow |m_1| = \dfrac{s'}{s} = \dfrac{122\text{ mm}}{1.9\text{ mm}} = 64.$

The eyepiece magnifies by either 5 or 10, so:

(a) The maximum magnification occurs for the 1.9-mm objective and $10\times$ eyepiece:

$M = |m_1| M_e = (64)(10) = 640.$

(b) The minimum magnification occurs for the 16-mm objective and $5\times$ eyepiece:

$M = |m_1| M_e = (8.5)(5) = 43.$

EVALUATE: The smaller the focal length of the objective, the greater the overall magnification.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

34.62. **IDENTIFY:** Apply Eq. (34.24).
SET UP: $s_1' = 160\text{ mm} + 5.0\text{ mm} = 165\text{ mm}$

EXECUTE: **(a)** $M = \dfrac{(250\text{ mm})s_1'}{f_1 f_2} = \dfrac{(250\text{ mm})(165\text{ mm})}{(5.00\text{ mm})(26.0\text{ mm})} = 317.$

(b) The minimum separation is $\dfrac{0.10\text{ mm}}{M} = \dfrac{0.10\text{ mm}}{317} = 3.15\times10^{-4}\text{ mm}.$

EVALUATE: The angular size of the image viewed by the eye when looking through the microscope is 317 times larger than if the object is viewed at the near-point of the unaided eye.

34.63. **(a) IDENTIFY** and **SET UP:**

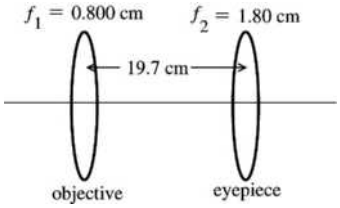

Figure 34.63

Final image is at ∞ so the object for the eyepiece is at its focal point. But the object for the eyepiece is the image of the objective so the image formed by the objective is $19.7\text{ cm} - 1.80\text{ cm} = 17.9\text{ cm}$ to the right of the lens. Apply Eq. (34.16) to the image formation by the objective, solve for the object distance s.
$f = 0.800$ cm; $s' = 17.9$ cm; $s = ?$

$\dfrac{1}{s} + \dfrac{1}{s'} = \dfrac{1}{f}$, so $\dfrac{1}{s} = \dfrac{1}{f} - \dfrac{1}{s'} = \dfrac{s'-f}{s'f}$

EXECUTE: $s = \dfrac{s'f}{s'-f} = \dfrac{(17.9\text{ cm})(+0.800\text{ cm})}{17.9\text{ cm} - 0.800\text{ cm}} = +8.37\text{ mm}$

(b) SET UP: Use Eq. (34.17).

EXECUTE: $m_1 = -\dfrac{s'}{s} = -\dfrac{17.9\text{ cm}}{0.837\text{ cm}} = -21.4$

The linear magnification of the objective is 21.4.
(c) SET UP: Use Eq. (34.24): $M = m_1 M_2$

EXECUTE: $M_2 = \dfrac{25\text{ cm}}{f_2} = \dfrac{25\text{ cm}}{1.80\text{ cm}} = 13.9$

$M = m_1 M_2 = (-21.4)(13.9) = -297$

EVALUATE: M is not accurately given by $(25\text{ cm})s_1'/f_1 f_2 = 311,$ because the object is not quite at the focal point of the objective $(s_1 = 0.837\text{ cm}$ and $f_1 = 0.800\text{ cm}).$

34.64. **IDENTIFY:** For a telescope, $M = -\dfrac{f_1}{f_2}.$

SET UP: $f_2 = 9.0$ cm. The distance between the two lenses equals $f_1 + f_2.$

EXECUTE: $f_1 + f_2 = 1.80\text{ m} \Rightarrow f_1 = 1.80\text{ m} - 0.0900\text{ m} = 1.71\text{ m}.$ $M = -\dfrac{f_1}{f_2} = -\dfrac{171}{9.00} = -19.0.$

EVALUATE: For a telescope, $f_1 \gg f_2.$

34.65. **(a) IDENTIFY** and **SET UP:** Use Eq. (34.25), with $f_1 = 95.0$ cm (objective) and $f_2 = 15.0$ cm (eyepiece).

EXECUTE: $M = -\dfrac{f_1}{f_2} = -\dfrac{95.0\text{ cm}}{15.0\text{ cm}} = -6.33$

(b) IDENTIFY: Use Eq. (34.17) to calculate y'.

SET UP: $s = 3.00\times10^3$ m
$s' = f_1 = 95.0$ cm (since s is very large, $s' \approx f$)

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: $m = -\dfrac{s'}{s} = -\dfrac{0.950\text{ m}}{3.00\times10^{3}\text{ m}} = -3.167\times10^{-4}$

$|y'| = |m||y| = (3.167\times10^{-4})(60.0\text{ m}) = 0.0190\text{ m} = 1.90\text{ cm}$

(c) IDENTIFY: Use Eq. (34.21) and the angular magnification M obtained in part (a) to calculate θ'. The angular size θ of the image formed by the objective (object for the eyepiece) is its height divided by its distance from the objective.

EXECUTE: The angular size of the object for the eyepiece is $\theta = \dfrac{0.0190\text{ m}}{0.950\text{ m}} = 0.0200$ rad.

(Note that this is also the angular size of the object for the objective: $\theta = \dfrac{60.0\text{ m}}{3.00\times10^{3}\text{ m}} = 0.0200$ rad. For a thin lens the object and image have the same angular size and the image of the objective is the object for the eyepiece.) $M = \dfrac{\theta'}{\theta}$ (Eq. 34.21) so the angular size of the image is $\theta' = M\theta = -(6.33)(0.0200\text{ rad}) =$ -0.127 rad. (The minus sign shows that the final image is inverted.)

EVALUATE: The lateral magnification of the objective is small; the image it forms is much smaller than the object. But the total angular magnification is larger than 1.00; the angular size of the final image viewed by the eye is 6.33 times larger than the angular size of the original object, as viewed by the unaided eye.

34.66. **IDENTIFY:** The angle subtended by Saturn with the naked eye is the same as the angle subtended by the image of Saturn formed by the objective lens (see Figure 34.53 in the textbook).

SET UP: The angle subtended by Saturn is $\theta = \dfrac{\text{diameter of Saturn}}{\text{distance to Saturn}} = \dfrac{y'}{f_1}$.

EXECUTE: Putting in the numbers gives $\theta = \dfrac{y'}{f_1} = \dfrac{1.7\text{ mm}}{18\text{ m}} = \dfrac{0.0017\text{ m}}{18\text{ m}} = 9.4\times10^{-5}\text{ rad} = 0.0054°$.

EVALUATE: The angle subtended by the final image, formed by the eyepiece, would be much larger than 0.0054°.

34.67. **IDENTIFY:** $f = R/2$ and $M = -\dfrac{f_1}{f_2}$.

SET UP: For object and image both at infinity, $f_1 + f_2$ equals the distance d between the eyepiece and the mirror vertex. $f_2 = 1.10$ cm. $R_1 = 1.30$ m.

EXECUTE: **(a)** $f_1 = \dfrac{R_1}{2} = 0.650\text{ m} \Rightarrow d = f_1 + f_2 = 0.661\text{ m}$.

(b) $|M| = \dfrac{f_1}{f_2} = \dfrac{0.650\text{ m}}{0.011\text{ m}} = 59.1$.

EVALUATE: For a telescope, $f_1 \gg f_2$.

34.68. **IDENTIFY:** Combine $\dfrac{1}{s} + \dfrac{1}{s'} = \dfrac{2}{R}$ and $m = -\dfrac{s'}{s}$.

SET UP: $m = +2.50$. $R > 0$.

EXECUTE: $m = -\dfrac{s'}{s} = +2.50$. $s' = -2.50s$. $\dfrac{1}{s} + \dfrac{1}{-2.50s} = \dfrac{2}{R}$. $\dfrac{0.600}{s} = \dfrac{2}{R}$ and $s = 0.300R$.

$s' = -2.50s = (-2.50)(0.300R) = -0.750R$. The object is a distance of $0.300R$ in front of the mirror and the image is a distance of $0.750R$ behind the mirror.

EVALUATE: For a single mirror an erect image is always virtual.

34.69. **IDENTIFY** and **SET UP:** For a plane mirror $s' = -s$. $v = \dfrac{ds}{dt}$ and $v' = \dfrac{ds'}{dt}$, so $v' = -v$.

EXECUTE: The velocities of the object and image relative to the mirror are equal in magnitude and opposite in direction. Thus both you and your image are receding from the mirror surface at 3.60 m/s, in opposite directions. Your image is therefore moving at 7.20 m/s relative to you.

EVALUATE: The result derives from the fact that for a plane mirror the image is the same distance behind the mirror as the object is in front of the mirror.

34.70. **IDENTIFY:** Apply the law of reflection.
SET UP: The image of one mirror can serve as the object for the other mirror.
EXECUTE: **(a)** There are three images formed, as shown in Figure 34.70a.
(b) The paths of rays for each image are sketched in Figure 34.70b.
EVALUATE: Our results agree with Figure 34.9 in the textbook.

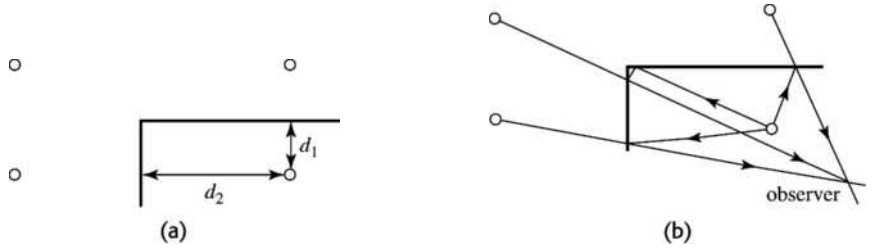

Figure 34.70

34.71. **IDENTIFY:** Apply the law of reflection for rays from the feet to the eyes and from the top of the head to the eyes.
SET UP: In Figure 34.71, ray 1 travels from the feet of the woman to her eyes and ray 2 travels from the top of her head to her eyes. The total height of the woman is h.
EXECUTE: The two angles labeled θ_1 are equal because of the law of reflection, as are the two angles labeled θ_2. Since these angles are equal, the two distances labeled y_1 are equal and the two distances labeled y_2 are equal. The height of the woman is $h_w = 2y_1 + 2y_2$. As the drawing shows, the height of the mirror is $h_m = y_1 + y_2$. Comparing, we find that $h_m = h_w/2$. The minimum height required is half the height of the woman.
EVALUATE: The height of the image is the same as the height of the woman, so the height of the image is twice the height of the mirror.

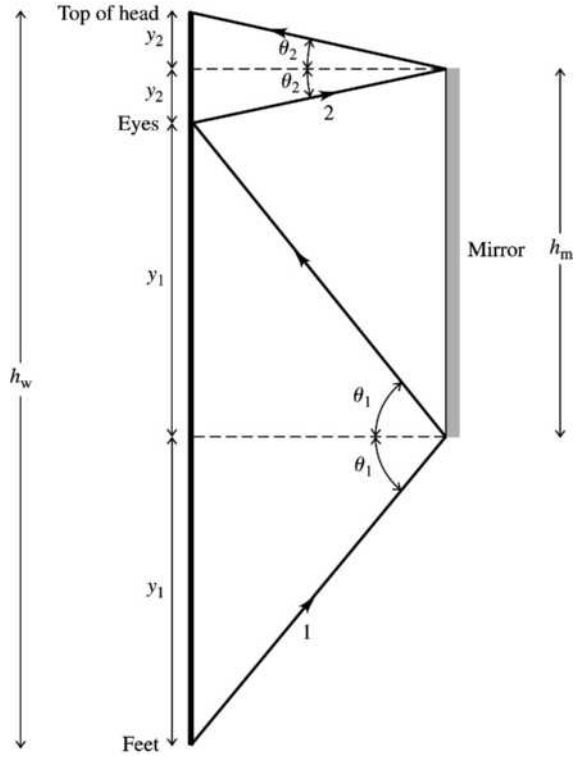

Figure 34.71

34.72. **IDENTIFY:** Apply $\frac{1}{s}+\frac{1}{s'}=\frac{2}{R}$ and $m=-\frac{s'}{s}$.

SET UP: Since the image is projected onto the wall it is real and $s'>0$. $m=-\frac{s'}{s}$ so m is negative and $m=-2.25$. The object, mirror and wall are sketched in Figure 34.72. The sketch shows that $s'-s=300$ cm.

EXECUTE: $m=-2.25=-\frac{s'}{s}$ and $s'=2.25s$. $s'-s=2.25s-s=300$ cm so $s=240$ cm.

$s'=300\text{ cm}+240\text{ cm}=540$ cm. The mirror should be 5.40 m from the wall. $\frac{1}{s}+\frac{1}{s'}=\frac{2}{R}$.

$\frac{1}{240\text{ cm}}+\frac{1}{540\text{ cm}}=\frac{2}{R}$. $R=3.32$ m.

EVALUATE: The focal length of the mirror is $f=R/2=166$ cm and $s>f$, as it must if the image is to be real.

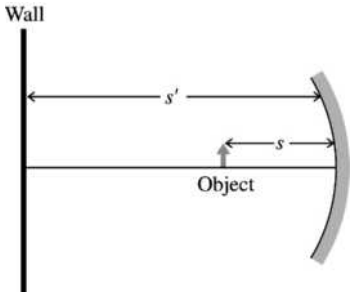

Figure 34.72

34.73. **IDENTIFY:** We are given the image distance, the image height, and the object height. Use Eq. (34.7) to calculate the object distance s. Then use Eq. (34.4) to calculate R.

SET UP: The image is to be formed on screen so it is a real image; $s'>0$. The mirror-to-screen distance is 8.00 m, so $s'=+800$ cm. $m=-\frac{s'}{s}<0$ since both s and s' are positive.

EXECUTE: **(a)** $|m|=\frac{|y'|}{|y|}=\frac{24.0\text{ cm}}{0.600\text{ cm}}=40.0$, so $m=-40.0$. Then $m=-\frac{s'}{s}$ gives

$s=-\frac{s'}{m}=-\frac{800\text{ cm}}{-40.0}=+20.0$ cm.

(b) $\frac{1}{s}+\frac{1}{s'}=\frac{2}{R}$, so $\frac{2}{R}=\frac{s+s'}{ss'}$. $R=2\left(\frac{ss'}{s+s'}\right)=2\left(\frac{(20.0\text{ cm})(800\text{ cm})}{20.0\text{ cm}+800\text{ cm}}\right)=39.0$ cm.

EVALUATE: R is calculated to be positive, which is correct for a concave mirror. Also, in part (a) s is calculated to be positive, as it should be for a real object.

34.74. **IDENTIFY:** Apply $\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}$ to calculate s' and then use $m=-\frac{s'}{s}=\frac{y'}{y}$ to find the height of the image.

SET UP: For a convex mirror, $R<0$, so $R=-18.0$ cm and $f=\frac{R}{2}=-9.00$ cm.

EXECUTE: **(a)** $\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}$. $s'=\frac{sf}{s-f}=\frac{(900\text{ cm})(-9.00\text{ cm})}{900\text{ cm}-(-9.00\text{ cm})}=-8.91$ cm.

$m=-\frac{s'}{s}=-\frac{-8.91\text{ cm}}{900\text{ cm}}=9.90\times10^{-3}$. $|y'|=|m|y=(9.90\times10^{-3})(1.5\text{ m})=0.0149\text{ m}=1.49$ cm.

(b) The height of the image is much less than the height of the car, so the car appears to be farther away than its actual distance.

EVALUATE: A plane mirror would form an image the same size as the car. Since the image formed by the convex mirror is smaller than the car, the car appears to be farther away compared to what it would appear using a plane mirror.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

34.75. **IDENTIFY:** Apply $\frac{1}{s}+\frac{1}{s'}=\frac{2}{R}$ and $m=-\frac{s'}{s}$.

SET UP: $R=+19.4$ cm.

EXECUTE: **(a)** $\frac{1}{s}+\frac{1}{s'}=\frac{2}{R}\Rightarrow\frac{1}{8.0\text{ cm}}+\frac{1}{s'}=\frac{2}{19.4\text{ cm}}\Rightarrow s'=-46$ cm, so the image is virtual.

(b) $m=-\frac{s'}{s}=-\frac{-46}{8.0}=5.8$, so the image is erect, and its height is $y'=(5.8)y=(5.8)(5.0\text{ mm})=29$ mm.

EVALUATE: **(c)** When the filament is 8 cm from the mirror, the image is virtual and cannot be projected onto a wall.

34.76. **IDENTIFY:** Apply $\frac{n_a}{s}+\frac{n_b}{s'}=\frac{n_b-n_a}{R}$, with $R\to\infty$ since the surfaces are flat.

SET UP: The image formed by the first interface serves as the object for the second interface.

EXECUTE: For the water-benzene interface, we get the apparent water depth:
$\frac{n_a}{s}+\frac{n_b}{s'}=0\Rightarrow\frac{1.33}{6.50\text{ cm}}+\frac{1.50}{s'}=0\Rightarrow s'=-7.33$ cm. For the benzene-air interface, we get the total apparent distance to the bottom: $\frac{n_a}{s}+\frac{n_b}{s'}=0\Rightarrow\frac{1.50}{(7.33\text{ cm}+4.20\text{ cm})}+\frac{1}{s'}=0\Rightarrow s'=-7.69$ cm.

EVALUATE: At the water-benzene interface the light refracts into material of greater refractive index and the overall effect is that the apparent depth is greater than the actual depth.

34.77. **IDENTIFY:** Since the truck is moving toward the mirror, its image will also be moving toward the mirror.
SET UP: The equation relating the object and image distances to the focal length of a spherical mirror is $\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}$, where $f=R/2$.

EXECUTE: Since the mirror is convex, $f=R/2=(-1.50\text{ m})/2=-0.75$ m. Applying the equation for a spherical mirror gives $\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}\Rightarrow s'=\frac{fs}{s-f}$. Using the chain rule from calculus and the fact that $v=ds/dt$, we have $v'=\frac{ds'}{dt}=\frac{ds'}{ds}\frac{ds}{dt}=v\frac{f^2}{(s-f)^2}$. Solving for v gives $v=v'\left(\frac{s-f}{f}\right)^2=(1.9\text{ m/s})\left[\frac{2.0\text{ m}-(-0.75\text{ m})}{-0.75\text{ m}}\right]^2=25.5$ m/s. This is the velocity of the truck relative to the mirror, so the truck is approaching the mirror at 25.5 m/s. You are traveling at 25 m/s, so the truck must be traveling at $25\text{ m/s}+25.5\text{ m/s}=51$ m/s relative to the highway.

EVALUATE: Even though the truck and car are moving at constant speed, the image of the truck is *not* moving at constant speed because its location depends on the distance from the mirror to the truck.

34.78. **IDENTIFY:** Apply $\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}$ and the concept of principal rays.

SET UP: $s=10.0$ cm. If extended backwards the ray comes from a point on the optic axis 18.0 cm from the lens and the ray is parallel to the optic axis after it passes through the lens.

EXECUTE: **(a)** The ray is bent toward the optic axis by the lens so the lens is converging.

(b) The ray is parallel to the optic axis after it passes through the lens so it comes from the focal point; $f=18.0$ cm.

(c) The principal-ray diagram is drawn in Figure 34.78. The diagram shows that the image is 22.5 cm to the left of the lens.

(d) $\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}$ gives $s'=\frac{sf}{s-f}=\frac{(10.0\text{ cm})(18.0\text{ cm})}{10.0\text{ cm}-18.0\text{ cm}}=-22.5$ cm. The calculated image position agrees with the principal ray diagram.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: The image is virtual. A converging lens produces a virtual image when the object is inside the focal point.

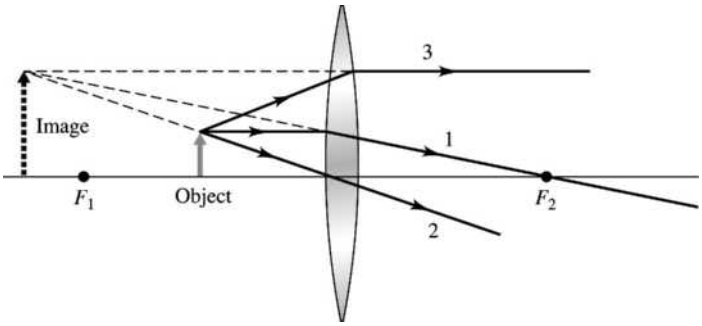

Figure 34.78

34.79. **IDENTIFY** and **SET UP:** Rays that pass through the hole are undeflected. All other rays are blocked. $m = -\dfrac{s'}{s}$.

EXECUTE: **(a)** The ray diagram is drawn in Figure 34.79. The ray shown is the only ray from the top of the object that reaches the film, so this ray passes through the top of the image. An inverted image is formed on the far side of the box, no matter how far this side is from the pinhole and no matter how far the object is from the pinhole.

(b) $s = 1.5$ m. $s' = 20.0$ cm. $m = -\dfrac{s'}{s} = -\dfrac{20.0 \text{ cm}}{150 \text{ cm}} = -0.133$. $y' = my = (-0.133)(18 \text{ cm}) = -2.4$ cm.

The image is 2.4 cm tall.

EVALUATE: A defect of this camera is that not much light energy passes through the small hole each second, so long exposure times are required.

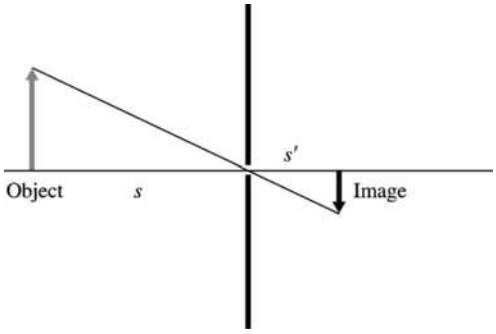

Figure 34.79

34.80. **IDENTIFY:** In this context, the microscope just looks at an image or object. Apply $\dfrac{n_a}{s} + \dfrac{n_b}{s'} = 0$ to the image formed by refraction at the top surface of the second plate. In this calculation the object is the bottom surface of the second plate.

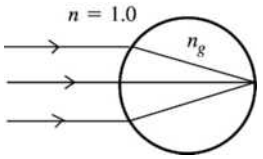
SET UP: The thickness of the second plate is $2.50 \text{ mm} + 0.78 \text{ mm}$, and this is s. The image is 2.50 mm below the top surface, so $s' = -2.50$ mm.

EXECUTE: $\dfrac{n_a}{s} + \dfrac{n_b}{s'} = 0 \Rightarrow \dfrac{n}{s} + \dfrac{1}{s'} = 0 \Rightarrow n = -\dfrac{s}{s'} = -\dfrac{2.50 \text{ mm} + 0.780 \text{ mm}}{-2.50 \text{ mm}} = 1.31.$

EVALUATE: The object and image distances are measured from the front surface of the second plate, and the image is virtual.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

34.81. **IDENTIFY:** Apply Eq. (34.11) to the image formed by refraction at the front surface of the sphere.
SET UP: Let n_g be the index of refraction of the glass. The image formation is shown in Figure 34.81.



$s = \infty$
$s' = +2r$, where r is the radius of the sphere
$n_a = 1.00, n_b = n_g, R = +r$

Figure 34.81

$$\frac{n_a}{s} + \frac{n_b}{s'} = \frac{n_b - n_a}{R}$$

EXECUTE: $\frac{1}{\infty} + \frac{n_g}{2r} = \frac{n_g - 1.00}{r}$

$\frac{n_g}{2r} = \frac{n_g}{r} - \frac{1}{r}; \frac{n_g}{2r} = \frac{1}{r}$ and $n_g = 2.00$

EVALUATE: The required refractive index of the glass does not depend on the radius of the sphere.

34.82. **IDENTIFY:** Apply $\frac{n_a}{s} + \frac{n_b}{s'} = \frac{n_b - n_a}{R}$ and $m = -\frac{n_a s'}{n_b s}$ to each refraction. The overall magnification is $m = m_1 m_2$.

SET UP: For the first refraction, $R = +6.0$ cm, $n_a = 1.00$ and $n_b = 1.60$. For the second refraction, $R = -12.0$ cm, $n_a = 1.60$ and $n_b = 1.00$.

EXECUTE: **(a)** The image from the left end acts as the object for the right end of the rod.

(b) $\frac{n_a}{s} + \frac{n_b}{s'} = \frac{n_b - n_a}{R} \Rightarrow \frac{1}{23.0\text{ cm}} + \frac{1.60}{s'} = \frac{0.60}{6.0\text{ cm}} \Rightarrow s' = 28.3\text{ cm}.$

So the second object distance is $s_2 = 40.0\text{ cm} - 28.3\text{ cm} = 11.7\text{ cm}$. $m_1 = -\frac{n_a s'}{n_b s} = -\frac{28.3}{(1.60)(23.0)} = -0.769.$

(c) The object is real and inverted.

(d) $\frac{n_a}{s_2} + \frac{n_b}{s_2'} = \frac{n_b - n_a}{R} \Rightarrow \frac{1.60}{11.7\text{ cm}} + \frac{1}{s_2'} = \frac{-0.60}{-12.0\text{ cm}} \Rightarrow s' = -11.5\text{ cm}.$

$m_2 = -\frac{n_a s'}{n_b s} = -\frac{(1.60)(-11.5)}{11.7} = 1.57 \Rightarrow m = m_1 m_2 = (-0.769)(1.57) = -1.21.$

(e) The final image is virtual, and inverted.

(f) $y' = (1.50\text{ mm})(-1.21) = -1.82$ mm.

EVALUATE: The first image is to the left of the second surface, so it serves as a real object for the second surface, with positive object distance.

34.83. **IDENTIFY:** Apply Eqs. (34.11) and (34.12) to the refraction as the light enters the rod and as it leaves the rod. The image formed by the first surface serves as the object for the second surface. The total magnification is $m_{\text{tot}} = m_1 m_2$, where m_1 and m_2 are the magnifications for each surface.

SET UP: The object and rod are shown in Figure 34.83.

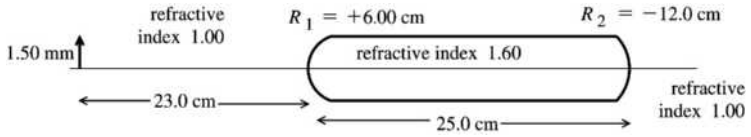


Figure 34.83

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(a) image formed by refraction at first surface (left end of rod):
$s = +23.0$ cm; $n_a = 1.00$; $n_b = 1.60$; $R = +6.00$ cm

$$\frac{n_a}{s} + \frac{n_b}{s'} = \frac{n_b - n_a}{R}$$

EXECUTE: $$\frac{1}{23.0 \text{ cm}} + \frac{1.60}{s'} = \frac{1.60 - 1.00}{6.00 \text{ cm}}$$

$$\frac{1.60}{s'} = \frac{1}{10.0 \text{ cm}} - \frac{1}{23.0 \text{ cm}} = \frac{23 - 10}{230 \text{ cm}} = \frac{13}{230 \text{ cm}}$$

$$s' = 1.60\left(\frac{230 \text{ cm}}{13}\right) = +28.3 \text{ cm};$$ image is 28.3 cm to right of first vertex.

This image serves as the object for the refraction at the second surface (right-hand end of rod). It is $28.3 \text{ cm} - 25.0 \text{ cm} = 3.3 \text{ cm}$ to the right of the second vertex. For the second surface $s = -3.3$ cm (virtual object).
(b) EVALUATE: Object is on side of outgoing light, so is a virtual object.
(c) SET UP: Image formed by refraction at second surface (right end of rod):
$s = -3.3$ cm; $n_a = 1.60$; $n_b = 1.00$; $R = -12.0$ cm

$$\frac{n_a}{s} + \frac{n_b}{s'} = \frac{n_b - n_a}{R}$$

EXECUTE: $$\frac{1.60}{-3.3 \text{ cm}} + \frac{1.00}{s'} = \frac{1.00 - 1.60}{-12.0 \text{ cm}}$$

$s' = +1.9$ cm; $s' > 0$ so image is 1.9 cm to right of vertex at right-hand end of rod.
(d) $s' > 0$ so final image is real.
Magnification for first surface:

$$m_1 = -\frac{n_a s'}{n_b s} = -\frac{(1.00)(+28.3 \text{ cm})}{(1.60)(+23.0 \text{ cm})} = -0.769$$

Magnification for second surface:

$$m_2 = -\frac{n_a s'}{n_b s} = -\frac{(1.60)(+1.9 \text{ cm})}{(1.00)(-3.3 \text{ cm})} = +0.92$$

The overall magnification is $m_{\text{tot}} = m_1 m_2 = (-0.769)(+0.92) = -0.71$ $m_{\text{tot}} < 0$ so final image is inverted with respect to the original object.
(e) $y' = m_{\text{tot}} y = (-0.71)(1.50 \text{ mm}) = -1.06$ mm
The final image has a height of 1.06 mm.
EVALUATE: The two refracting surfaces are not close together and Eq. (34.18) does not apply.

34.84. **IDENTIFY:** Apply $\frac{1}{s} + \frac{1}{s'} = \frac{1}{f}$ and $m = \frac{y'}{y} = -\frac{s'}{s}$. The type of lens determines the sign of f. The sign of s' determines whether the image is real or virtual.
SET UP: $s = +8.00$ cm. $s' = -3.00$ cm. s' is negative because the image is on the same side of the lens as the object.

EXECUTE: **(a)** $\frac{1}{f} = \frac{s + s'}{ss'}$ and $f = \frac{ss'}{s + s'} = \frac{(8.00 \text{ cm})(-3.00 \text{ cm})}{8.00 \text{ cm} - 3.00 \text{ cm}} = -4.80$ cm. f is negative so the lens is diverging.

(b) $m = -\frac{s'}{s} = -\frac{-3.00 \text{ cm}}{8.00 \text{ cm}} = +0.375$. $y' = my = (0.375)(6.50 \text{ mm}) = 2.44$ mm. $s' < 0$ and the image is virtual.
EVALUATE: A converging lens can also form a virtual image, if the object distance is less than the focal length. But in that case $|s'| > s$ and the image would be farther from the lens than the object is.

34.85. **IDENTIFY:** $\frac{1}{s} + \frac{1}{s'} = \frac{1}{f}$. The type of lens determines the sign of f. $m = \frac{y'}{y} = -\frac{s'}{s}$. The sign of s' depends on whether the image is real or virtual. $s = 16.0$ cm.
SET UP: $s' = -22.0$ cm; s' is negative because the image is on the same side of the lens as the object.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: **(a)** $\frac{1}{f}=\frac{s+s'}{ss'}$ and $f=\frac{ss'}{s+s'}=\frac{(16.0\text{ cm})(-22.0\text{ cm})}{16.0\text{ cm}-22.0\text{ cm}}=+58.7\text{ cm}$. f is positive so the lens is converging.

(b) $m=-\frac{s'}{s}=-\frac{-22.0\text{ cm}}{16.0\text{ cm}}=1.38$. $y'=my=(1.38)(3.25\text{ mm})=4.48\text{ mm}$. $s'<0$ and the image is virtual.

EVALUATE: A converging lens forms a virtual image when the object is closer to the lens than the focal point.

34.86. **IDENTIFY:** Apply $\frac{n_a}{s}+\frac{n_b}{s'}=\frac{n_b-n_a}{R}$. Use the image distance when viewed from the flat end to determine the refractive index n of the rod.

SET UP: When viewing from the flat end, $n_a=n$, $n_b=1.00$ and $R\to\infty$. When viewing from the curved end, $n_a=n$, $n_b=1.00$ and $R=-10.0$ cm.

EXECUTE: $\frac{n_a}{s}+\frac{n_b}{s'}=0\Rightarrow\frac{n}{15.0\text{ cm}}+\frac{1}{-9.50\text{ cm}}=0\Rightarrow n=\frac{15.0}{9.50}=1.58$. When viewed from the curved end of the rod $\frac{n_a}{s}+\frac{n_b}{s'}=\frac{n_b-n_a}{R}\Rightarrow\frac{n}{s}+\frac{1}{s'}=\frac{1-n}{R}\Rightarrow\frac{1.58}{15.0\text{ cm}}+\frac{1}{s'}=\frac{-0.58}{-10.0\text{ cm}}$, and $s'=-21.1\text{ cm}$. The image is 21.1 cm within the rod from the curved end.

EVALUATE: In each case the image is virtual and on the same side of the surface as the object.

34.87. **IDENTIFY:** The image formed by refraction at the surface of the eye is located by $\frac{n_a}{s}+\frac{n_b}{s'}=\frac{n_b-n_a}{R}$.

SET UP: $n_a=1.00$, $n_b=1.35$. $R>0$. For a distant object, $s\approx\infty$ and $\frac{1}{s}\approx 0$.

EXECUTE: **(a)** $s\approx\infty$ and $s'=2.5$ cm: $\frac{1.35}{2.5\text{ cm}}=\frac{1.35-1.00}{R}$ and $R=0.648\text{ cm}=6.48\text{ mm}$.

(b) $R=0.648$ cm and $s=25$ cm: $\frac{1.00}{25\text{ cm}}+\frac{1.35}{s'}=\frac{1.35-1.00}{0.648}$. $\frac{1.35}{s'}=0.500$ and $s'=2.70\text{ cm}=27.0\text{ mm}$. The image is formed behind the retina.

(c) Calculate s' for $s\approx\infty$ and $R=0.50$ cm: $\frac{1.35}{s'}=\frac{1.35-1.00}{0.50\text{ cm}}$. $s'=1.93\text{ cm}=19.3\text{ mm}$. The image is formed in front of the retina.

EVALUATE: The cornea alone cannot achieve focus of both close and distant objects.

34.88. **IDENTIFY:** Apply $\frac{n_a}{s}+\frac{n_b}{s'}=\frac{n_b-n_a}{R}$ and $m=-\frac{n_as'}{n_bs}$ to each surface. The overall magnification is $m=m_1m_2$. The image formed by the first surface is the object for the second surface.

SET UP: For the first surface, $n_a=1.00$, $n_b=1.60$ and $R=+15.0$ cm. For the second surface, $n_a=1.60$, $n_b=1.00$ and $R\to\infty$.

EXECUTE: **(a)** $\frac{n_a}{s}+\frac{n_b}{s'}=\frac{n_b-n_a}{R}\Rightarrow\frac{1}{12.0\text{ cm}}+\frac{1.60}{s'}=\frac{0.60}{15.0\text{ cm}}\Rightarrow s'=-36.9\text{ cm}$. The object distance for the far end of the rod is $50.0\text{ cm}-(-36.9\text{ cm})=86.9\text{ cm}$.

$\frac{n_a}{s}+\frac{n_b}{s'}=\frac{n_b-n_a}{R}\Rightarrow\frac{1.60}{86.9\text{ cm}}+\frac{1}{s'}=0\Rightarrow s'=-54.3\text{ cm}$. The final image is 4.3 cm to the left of the vertex of the hemispherical surface.

(b) The magnification is the product of the two magnifications:

$m_1=-\frac{n_as'}{n_bs}=-\frac{-36.9}{(1.60)(12.0)}=1.92$, $m_2=1.00\Rightarrow m=m_1m_2=1.92$.

EVALUATE: The final image is virtual, erect and larger than the object.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

34.89. **IDENTIFY:** Apply $\frac{n_a}{s}+\frac{n_b}{s'}=\frac{n_b-n_a}{R}$ to each surface. The image of the first surface is the object for the second surface. The relation between s_1' and s_2 involves the length d of the rod.

SET UP: For the first surface, $n_a=1.00$, $n_b=1.55$ and $R=+6.00$ cm. For the second surface, $n_a=1.55$, $n_b=1.00$ and $R=-6.00$ cm.

EXECUTE: We have images formed from both ends. From the first surface:

$$\frac{n_a}{s}+\frac{n_b}{s'}=\frac{n_b-n_a}{R}\Rightarrow\frac{1}{25.0\text{ cm}}+\frac{1.55}{s'}=\frac{0.55}{6.00\text{ cm}}\Rightarrow s'=30.0\text{ cm}.$$

This image becomes the object for the second end:

$$\frac{n_a}{s}+\frac{n_b}{s'}=\frac{n_b-n_a}{R}\Rightarrow\frac{1.55}{d-30.0\text{ cm}}+\frac{1}{65.0\text{ cm}}=\frac{-0.55}{-6.00\text{ cm}}.$$

$d-30.0\text{ cm}=20.3\text{ cm}\Rightarrow d=50.3\text{ cm}$.

EVALUATE: The final image is real. The first image is 20.3 cm to the left of the second surface and serves as a real object.

34.90. **IDENTIFY** and **SET UP:** Use $\frac{1}{f}=(n-1)\left(\frac{1}{R_1}-\frac{1}{R_2}\right)$ to calculate the focal length of the lenses. The image formed by the first lens serves at the object for the second lens. $m_{\text{tot}}=m_1m_2$. $\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}$ gives $s'=\frac{sf}{s-f}$.

EXECUTE: **(a)** $\frac{1}{f}=(0.60)\left(\frac{1}{12.0\text{ cm}}-\frac{1}{28.0\text{ cm}}\right)$ and $f=+35.0$ cm.

Lens 1: $f_1=+35.0$ cm. $s_1=+45.0$ cm. $s_1'=\frac{s_1f_1}{s_1-f_1}=\frac{(45.0\text{ cm})(35.0\text{ cm})}{45.0\text{ cm}-35.0\text{ cm}}=+158$ cm.

$m_1=-\frac{s_1'}{s_1}=-\frac{158\text{ cm}}{45.0\text{ cm}}=-3.51$. $|y_1'|=|m_1|y_1=(3.51)(5.00\text{ mm})=17.6$ mm. The image of the first lens is 158 cm to the right of lens 1 and is 17.6 mm tall.

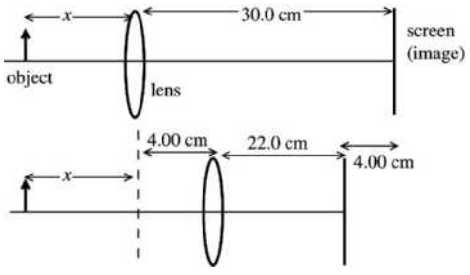
(b) The image of lens 1 is $315\text{ cm}-158\text{ cm}=157\text{ cm}$ to the left of lens 2. $f_2=+35.0$ cm. $s_2=+157$ cm.

$s_2'=\frac{s_2f_2}{s_2-f_2}=\frac{(157\text{ cm})(35.0\text{ cm})}{157\text{ cm}-35.0\text{ cm}}=+45.0$ cm. $m_2=-\frac{s_2'}{s_2}=-\frac{45.0\text{ cm}}{157\text{ cm}}=-0.287$.

$m_{\text{tot}}=m_1m_2=(-3.51)(-0.287)=+1.00$. The final image is 45.0 cm to the right of lens 2. The final image is 5.00 mm tall. $m_{\text{tot}}>0$ and the final image is erect.

EVALUATE: The final image is real. It is erect because each lens produces an inversion of the image, and two inversions return the image to the orientation of the object.

34.91. **IDENTIFY** and **SET UP:** Apply Eq. (34.16) for each lens position. The lens to screen distance in each case is the image distance. There are two unknowns, the original object distance x and the focal length f of the lens. But each lens position gives an equation, so there are two equations for these two unknowns. The object, lens and screen before and after the lens is moved are shown in Figure 34.91.



$s=x;\ s'=30.0$ cm

$$\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}$$

$$\frac{1}{x}+\frac{1}{30.0\text{ cm}}=\frac{1}{f}$$

Figure 34.91

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$s = x + 4.00\ \text{cm};\ s' = 22.0\ \text{cm}$

$\dfrac{1}{s} + \dfrac{1}{s'} = \dfrac{1}{f}$ gives $\dfrac{1}{x + 4.00\ \text{cm}} + \dfrac{1}{22.0\ \text{cm}} = \dfrac{1}{f}$

EXECUTE: Equate these two expressions for $1/f$:

$$\frac{1}{x} + \frac{1}{30.0\ \text{cm}} = \frac{1}{x + 4.00\ \text{cm}} + \frac{1}{22.0\ \text{cm}}$$

$$\frac{1}{x} - \frac{1}{x + 4.00\ \text{cm}} = \frac{1}{22.0\ \text{cm}} - \frac{1}{30.0\ \text{cm}}$$

$$\frac{x + 4.00\ \text{cm} - x}{x(x + 4.00\ \text{cm})} = \frac{30.0 - 22.0}{660\ \text{cm}} \text{ and } \frac{4.00\ \text{cm}}{x(x + 4.00\ \text{cm})} = \frac{8}{660\ \text{cm}}$$

$x^2 + (4.00\ \text{cm})x - 330\ \text{cm}^2 = 0$ and $x = \dfrac{1}{2}(-4.00 \pm \sqrt{16.0 + 4(330)})\ \text{cm}$

x must be positive so $x = \dfrac{1}{2}(-4.00 + 36.55)\ \text{cm} = 16.28\ \text{cm}$

Then $\dfrac{1}{x} + \dfrac{1}{30.0\ \text{cm}} = \dfrac{1}{f}$ and $\dfrac{1}{f} = \dfrac{1}{16.28\ \text{cm}} + \dfrac{1}{30.0\ \text{cm}}$

$f = +10.55\ \text{cm},$ which rounds to 10.6 cm. $f > 0;$ the lens is converging.

EVALUATE: We can check that $s = 16.28\ \text{cm}$ and $f = 10.55\ \text{cm}$ gives $s' = 30.0\ \text{cm}$ and that $s = (16.28 + 4.0)\ \text{cm} = 20.28\ \text{cm}$ and $f = 10.55\ \text{cm}$ gives $s' = 22.0\ \text{cm}$.

34.92. **IDENTIFY:** Apply $\dfrac{1}{s} + \dfrac{1}{s'} = \dfrac{1}{f}$ and $m = -\dfrac{s'}{s}$.

SET UP: $s + s' = 18.0\ \text{cm}$

EXECUTE: **(a)** $\dfrac{1}{18.0\ \text{cm} - s'} + \dfrac{1}{s'} = \dfrac{1}{3.00\ \text{cm}}$. $(s')^2 - (18.0\ \text{cm})s' + 54.0\ \text{cm}^2 = 0$ so $s' = 14.2\ \text{cm}$ or $3.80\ \text{cm}$.

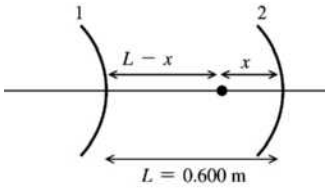
$s = 3.80\ \text{cm}$ or $14.2\ \text{cm},$ so the lens must either be 3.80 cm or 14.2 cm from the object.

(b) $s = 3.80\ \text{cm}$: $m = -\dfrac{s'}{s} = -\dfrac{14.2}{3.8} = -3.74.$ $s = 14.2\ \text{cm}$: $m = -\dfrac{s'}{s} = -\dfrac{3.8}{14.2} = -0.268.$

EVALUATE: Since the image is projected onto the screen, the image is real and s' is positive. We assumed this when we wrote the condition $s + s' = 18.0\ \text{cm}$.

34.93. **(a) IDENTIFY:** Use Eq. (34.6) to locate the image formed by each mirror. The image formed by the first mirror serves as the object for the second mirror.

SET UP: The positions of the object and the two mirrors are shown in Figure 34.93a.



$|R| = 0.360\ \text{m}$

$|f| = |R|/2 = 0.180\ \text{m}$

Figure 34.93a

EXECUTE: Image formed by convex mirror (mirror #1):

convex means $f_1 = -0.180\ \text{m};\ s_1 = L - x$

$$s_1' = \frac{s_1 f_1}{s_1 - f_1} = \frac{(L - x)(-0.180\ \text{m})}{L - x + 0.180\ \text{m}} = -(0.180\ \text{m})\left(\frac{0.600\ \text{m} - x}{0.780\ \text{m} - x}\right) < 0$$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

The image is $(0.180\text{ m})\left(\dfrac{0.600\text{ m}-x}{0.780\text{ m}-x}\right)$ to the left of mirror #1 so is

$0.600\text{ m}+(0.180\text{ m})\left(\dfrac{0.600\text{ m}-x}{0.780\text{ m}-x}\right)=\dfrac{0.576\text{ m}^2-(0.780\text{ m})x}{0.780\text{ m}-x}$ to the left of mirror #2.

Image formed by concave mirror (mirror #2):

concave implies $f_2=+0.180\text{ m}$

$$s_2=\frac{0.576\text{ m}^2-(0.780\text{ m})x}{0.780\text{ m}-x}$$

Rays return to the source implies $s_2'=x$. Using these expressions in $s_2=\dfrac{s_2'f_2}{s_2'-f_2}$ gives

$$\frac{0.576\text{ m}^2-(0.780\text{ m})x}{0.780\text{ m}-x}=\frac{(0.180\text{ m})x}{x-0.180\text{ m}}$$

$$0.600x^2-(0.576\text{ m})x+0.10368\text{ m}^2=0$$

$$x=\frac{1}{1.20}(0.576\pm\sqrt{(0.576)^2-4(0.600)(0.10368)})\text{ m}=\frac{1}{1.20}(0.576\pm0.288)\text{ m}$$

$x=0.72$ m (impossible; can't have $x>L=0.600$ m) or $x=0.24$ m.

(b) SET UP: Which mirror is #1 and which is #2 is now reversed form part (a). This is shown in Figure 34.93b.

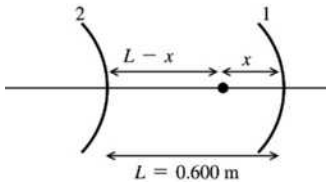


Figure 34.93b

EXECUTE: Image formed by concave mirror (mirror #1):

concave means $f_1=+0.180$ m; $s_1=x$

$$s_1'=\frac{s_1f_1}{s_1-f_1}=\frac{(0.180\text{ m})x}{x-0.180\text{ m}}$$

The image is $\dfrac{(0.180\text{ m})x}{x-0.180\text{ m}}$ to the left of mirror #1, so

$$s_2=0.600\text{ m}-\frac{(0.180\text{ m})x}{x-0.180\text{ m}}=\frac{(0.420\text{ m})x-0.180\text{ m}^2}{x-0.180\text{ m}}$$

Image formed by convex mirror (mirror #2):

convex means $f_2=-0.180$ m

rays return to the source means $s_2'=L-x=0.600\text{ m}-x$

$\dfrac{1}{s}+\dfrac{1}{s'}=\dfrac{1}{f}$ gives

$$\frac{x-0.180\text{ m}}{(0.420\text{ m})x-0.180\text{ m}^2}+\frac{1}{0.600\text{ m}-x}=-\frac{1}{0.180\text{ m}}$$

$$\frac{x-0.180\text{ m}}{(0.420\text{ m})x-0.180\text{ m}^2}=-\left(\frac{0.780\text{ m}-x}{0.180\text{ m}^2-(0.180\text{ m})x}\right)$$

$$0.600x^2-(0.576\text{ m})x+0.1036\text{ m}^2=0$$

This is the same quadratic equation as obtained in part (a), so again $x=0.24$ m.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: For $x = 0.24$ m the image is at the location of the source, both for rays that initially travel from the source toward the left and for rays that travel from the source toward the right.

34.94. **IDENTIFY:** $\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}$ gives $s'=\frac{sf}{s-f}$, for both the mirror and the lens.

SET UP: For the second image, the image formed by the mirror serves as the object for the lens. For the mirror, $f_m = +10.0$ cm. For the lens, $f = 32.0$ cm. The center of curvature of the mirror is $R = 2f_m = 20.0$ cm to the right of the mirror vertex.

EXECUTE: **(a)** The principal-ray diagrams from the two images are sketched in Figures 34.94a–b. In Figure 34.94b, only the image formed by the mirror is shown. This image is at the location of the candle so the principal-ray diagram that shows the image formation when the image of the mirror serves as the object for the lens is analogous to that in Figure 34.94a and is not drawn.

(b) Image formed by the light that passes directly through the lens: The candle is 85.0 cm to the left of the lens. $s'=\frac{sf}{s-f}=\frac{(85.0\text{ cm})(32.0\text{ cm})}{85.0\text{ cm}-32.0\text{ cm}}=+51.3\text{ cm}$. $m=-\frac{s'}{s}=-\frac{51.3\text{ cm}}{85.0\text{ cm}}=-0.604$. This image is 51.3 cm to the right of the lens. $s' > 0$ so the image is real. $m < 0$ so the image is inverted. Image formed by the light that first reflects off the mirror: First consider the image formed by the mirror. The candle is 20.0 cm to the right of the mirror, so $s = +20.0$ cm. $s'=\frac{sf}{s-f}=\frac{(20.0\text{ cm})(10.0\text{ cm})}{20.0\text{ cm}-10.0\text{ cm}}=20.0\text{ cm}$.

$m_1=-\frac{s_1'}{s_1}=-\frac{20.0\text{ cm}}{20.0\text{ cm}}=-1.00$. The image formed by the mirror is at the location of the candle, so $s_2 = +85.0$ cm and $s_2' = 51.3$ cm. $m_2 = -0.604$. $m_{tot} = m_1 m_2 = (-1.00)(-0.604) = 0.604$. The second image is 51.3 cm to the right of the lens. $s_2' > 0$, so the final image is real. $m_{tot} > 0$, so the final image is erect.

EVALUATE: The two images are at the same place. They are the same size. One is erect and one is inverted.

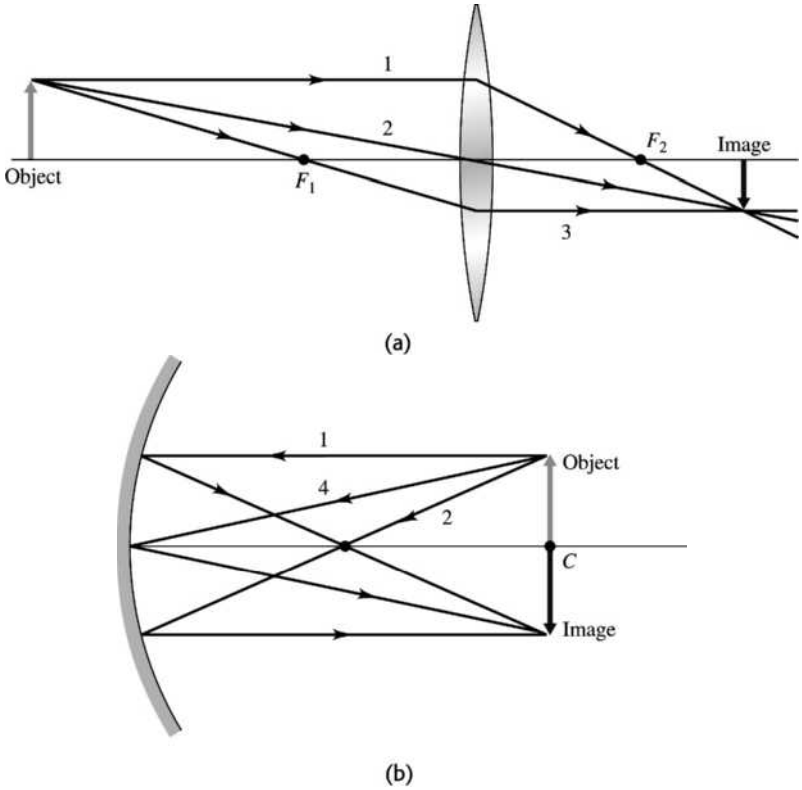

Figure 34.94

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

34.95. **IDENTIFY:** Apply $\frac{n_a}{s}+\frac{n_b}{s'}=\frac{n_b-n_a}{R}$ to each case.

SET UP: $s = 20.0$ cm. $R > 0$. Use $s' = +9.12$ cm to find R. For this calculation, $n_a = 1.00$ and $n_b = 1.55$. Then repeat the calculation with $n_a = 1.33$.

EXECUTE: $\frac{n_a}{s}+\frac{n_b}{s'}=\frac{n_b-n_a}{R}$ gives $\frac{1.00}{20.0\text{ cm}}+\frac{1.55}{9.12\text{ cm}}=\frac{1.55-1.00}{R}$. $R = 2.50$ cm.

Then $\frac{1.33}{20.0\text{ cm}}+\frac{1.55}{s'}=\frac{1.55-1.33}{2.50\text{ cm}}$ gives $s' = 72.1$ cm. The image is 72.1 cm to the right of the surface vertex.

EVALUATE: With the rod in air the image is real and with the rod in water the image is also real.

34.96. **IDENTIFY:** Apply $\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}$ to each lens. The image formed by the first lens serves as the object for the second lens. The focal length of the lens combination is defined by $\frac{1}{s_1}+\frac{1}{s_2'}=\frac{1}{f}$. In part (b) use $\frac{1}{f}=(n-1)\left(\frac{1}{R_1}-\frac{1}{R_2}\right)$ to calculate f for the meniscus lens and for the CCl_4, treated as a thin lens.

SET UP: With two lenses of different focal length in contact, the image distance from the first lens becomes exactly minus the object distance for the second lens.

EXECUTE: **(a)** $\frac{1}{s_1}+\frac{1}{s_1'}=\frac{1}{f_1}\Rightarrow\frac{1}{s_1'}=\frac{1}{f_1}-\frac{1}{s_1}$ and $\frac{1}{s_2}+\frac{1}{s_2'}=\frac{1}{-s_1'}+\frac{1}{s_2'}=\left(\frac{1}{s_1}-\frac{1}{f_1}\right)+\frac{1}{s_2'}=\frac{1}{f_2}$. But overall for the lens system, $\frac{1}{s_1}+\frac{1}{s_2'}=\frac{1}{f}\Rightarrow\frac{1}{f}=\frac{1}{f_2}+\frac{1}{f_1}$.

(b) With carbon tetrachloride sitting in a meniscus lens, we have two lenses in contact. All we need in order to calculate the system's focal length is calculate the individual focal lengths, and then use the formula from part (a). For the meniscus lens

$\frac{1}{f_m}=(n_b-n_a)\left(\frac{1}{R_1}-\frac{1}{R_2}\right)=(0.55)\left(\frac{1}{4.50\text{ cm}}-\frac{1}{9.00\text{ cm}}\right)=0.061\text{ cm}^{-1}$ and $f_m = 16.4$ cm.

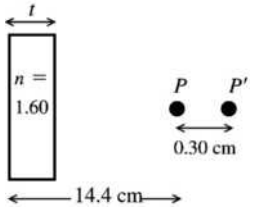
For the CCl_4: $\frac{1}{f_w}=(n_b-n_a)\left(\frac{1}{R_1}-\frac{1}{R_2}\right)=(0.46)\left(\frac{1}{9.00\text{ cm}}=\frac{1}{\infty}\right)=0.051\text{ cm}^{-1}$ and $f_w = 19.6$ cm.

$\frac{1}{f}=\frac{1}{f_w}+\frac{1}{f_m}=0.112\text{ cm}^{-1}$ and $f = 8.93$ cm.

EVALUATE: $f=\frac{f_1f_2}{f_1+f_2}$, so f for the combination is less than either f_1 or f_2.

34.97. **IDENTIFY:** Apply Eq. (34.11) with $R\to\infty$ to the refraction at each surface. For refraction at the first surface the point P serves as a virtual object. The image formed by the first refraction serves as the object for the second refraction.

SET UP: The glass plate and the two points are shown in Figure 34.97.



plane faces means $R\to\infty$ and

$\frac{n_a}{s}+\frac{n_b}{s'}=0$

$s'=-\frac{n_b}{n_a}s$

Figure 34.97

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: refraction at the first (left-hand) surface of the piece of glass:
The rays converging toward point P constitute a virtual object for this surface, so $s = -14.4$ cm.
$n_a = 1.00$, $n_b = 1.60$.

$$s' = -\frac{1.60}{1.00}(-14.4 \text{ cm}) = +23.0 \text{ cm}$$

This image is 23.0 cm to the right of the first surface so is a distance $23.0 \text{ cm} - t$ to the right of the second surface. This image serves as a virtual object for the second surface.
refraction at the second (right-hand) surface of the piece of glass:
The image is at P' so $s' = 14.4 \text{ cm} + 0.30 \text{ cm} - t = 14.7 \text{ cm} - t$. $s = -(23.0 \text{ cm} - t)$; $n_a = 1.60$; $n_b = 1.00$

$s' = -\frac{n_b}{n_a}s$ gives $14.7 \text{ cm} - t = -\left(\frac{1.00}{1.60}\right)(-[23.0 \text{ cm} - t])$. $14.7 \text{ cm} - t = +14.4 \text{ cm} - 0.625t$.

$0.375t = 0.30$ cm and $t = 0.80$ cm

EVALUATE: The overall effect of the piece of glass is to diverge the rays and move their convergence point to the right. For a real object, refraction at a plane surface always produces a virtual image, but with a virtual object the image can be real.

34.98. **IDENTIFY:** Apply the two equations $\frac{n_a}{s_1} + \frac{n_b}{s_1'} = \frac{n_b - n_a}{R_1}$ and $\frac{n_b}{s_2} + \frac{n_c}{s_2'} = \frac{n_c - n_b}{R_2}$.

SET UP: $n_a = n_{\text{liq}} = n_c$, $n_b = n$, and $s_1' = -s_2$.

EXECUTE: **(a)** $\frac{n_{\text{liq}}}{s_1} + \frac{n}{s_1'} = \frac{n - n_{\text{liq}}}{R_1}$ and $\frac{n}{-s_1'} + \frac{n_{\text{liq}}}{s_2'} = \frac{n_{\text{liq}} - n}{R_2}$. $\frac{1}{s_1} + \frac{1}{s_2'} = \frac{1}{s} + \frac{1}{s'} = \frac{1}{f'} = (n/n_{\text{liq}} - 1)\left(\frac{1}{R_1} - \frac{1}{R_2}\right)$.

(b) Comparing the equations for focal length in and out of air we have:

$$f(n-1) = f'(n/n_{\text{liq}} - 1) = f'\left(\frac{n - n_{\text{liq}}}{n_{\text{liq}}}\right) \Rightarrow f' = \left[\frac{n_{\text{liq}}(n-1)}{n - n_{\text{liq}}}\right] f.$$

EVALUATE: When $n_{\text{liq}} = 1$, $f' = f$, as it should.

34.99. **IDENTIFY:** Apply $\frac{1}{s} + \frac{1}{s'} = \frac{1}{f}$.

SET UP: The image formed by the converging lens is 30.0 cm from the converging lens, and becomes a virtual object for the diverging lens at a position 15.0 cm to the right of the diverging lens. The final image is projected $15 \text{ cm} + 19.2 \text{ cm} = 34.2 \text{ cm}$ from the diverging lens.

EXECUTE: $\frac{1}{s} + \frac{1}{s'} = \frac{1}{f} \Rightarrow \frac{1}{-15.0 \text{ cm}} + \frac{1}{34.2 \text{ cm}} = \frac{1}{f} \Rightarrow f = -26.7$ cm.

EVALUATE: Our calculation yields a negative value of f, which should be the case for a diverging lens.

34.100. **IDENTIFY:** The spherical mirror forms an image of the object. It forms another image when the image of the plane mirror serves as an object.

SET UP: For the convex mirror $f = -24.0$ cm. The image formed by the plane mirror is 10.0 cm to the right of the plane mirror, so is $20.0 \text{ cm} + 10.0 \text{ cm} = 30.0 \text{ cm}$ from the vertex of the spherical mirror.

EXECUTE: The first image formed by the spherical mirror is the one where the light immediately strikes its surface, without bouncing from the plane mirror.

$\frac{1}{s} + \frac{1}{s'} = \frac{1}{f} \Rightarrow \frac{1}{10.0 \text{ cm}} + \frac{1}{s'} = \frac{1}{-24.0 \text{ cm}} \Rightarrow s' = -7.06$ cm, and the image height is

$$y' = -\frac{s'}{s}y = -\frac{-7.06}{10.0}(0.250 \text{ cm}) = 0.177 \text{ cm}.$$

The second image of the plane mirror image is located 30.0 cm from the vertex of the spherical mirror.

$\frac{1}{s} + \frac{1}{s'} = \frac{1}{f} \Rightarrow \frac{1}{30.0 \text{ cm}} + \frac{1}{s'} = \frac{1}{-24.0 \text{ cm}} \Rightarrow s' = -13.3$ cm and the image height is

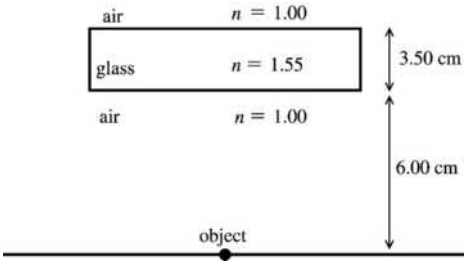
$$y' = -\frac{s'}{s}y = -\frac{-13.3}{30.0}(0.250 \text{ cm}) = 0.111 \text{ cm}.$$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: Other images are formed by additional reflections from the two mirrors.

34.101. **IDENTIFY:** In the sketch in Figure 34.101 the light travels upward from the object. Apply Eq. (34.11) with $R \to \infty$ to the refraction at each surface. The image formed by the first surface serves as the object for the second surface.

SET UP: The locations of the object and the glass plate are shown in Figure 34.101.



For a plane (flat) surface

$R \to \infty$ so $\frac{n_a}{s} + \frac{n_b}{s'} = 0$

$s' = -\frac{n_b}{n_a} s$

Figure 34.101

EXECUTE: First refraction (air → glass):

$n_a = 1.00;\ n_b = 1.55;\ s = 6.00\ \text{cm}$

$s' = -\frac{n_b}{n_a} s = -\frac{1.55}{1.00}(6.00\ \text{cm}) = -9.30\ \text{cm}.$

The image is 9.30 cm below the lower surface of the glass, so is $9.30\ \text{cm} + 3.50\ \text{cm} = 12.8\ \text{cm}$ below the upper surface.

Second refraction (glass → air):

$n_a = 1.55;\ n_b = 1.00;\ s = +12.8\ \text{cm}$

$s' = -\frac{n_b}{n_a} s = -\frac{1.00}{1.55}(12.8\ \text{cm}) = -8.26\ \text{cm}$

The image of the page is 8.26 cm below the top surface of the glass plate and therefore $9.50\ \text{cm} - 8.26\ \text{cm} = 1.24\ \text{cm}$ above the page.

EVALUATE: The image is virtual. If you view the object by looking down from above the plate, the image of the page that you see is closer to your eye than the page is.

34.102. **IDENTIFY:** Light refracts at the front surface of the lens, refracts at the glass-water interface, reflects from the plane mirror and passes through the two interfaces again, now traveling in the opposite direction.

SET UP: Use the focal length in air to find the radius of curvature R of the lens surfaces.

EXECUTE: **(a)** $\frac{1}{f} = (n-1)\left(\frac{1}{R_1} - \frac{1}{R_2}\right) \Rightarrow \frac{1}{40\ \text{cm}} = 0.52\left(\frac{2}{R}\right) \Rightarrow R = 41.6\ \text{cm}.$

At the air–lens interface: $\frac{n_a}{s} + \frac{n_b}{s'} = \frac{n_b - n_a}{R} \Rightarrow \frac{1}{70.0\ \text{cm}} + \frac{1.52}{s_1'} = \frac{0.52}{41.6\ \text{cm}}$ and

$s_1' = -851\ \text{cm}$ and $s_2 = 851\ \text{cm}.$

At the lens–water interface: $\Rightarrow \frac{1.52}{851\ \text{cm}} + \frac{1.33}{s_2'} = \frac{-0.187}{-41.6\ \text{cm}}$ and $s_2' = 491\ \text{cm}.$

The mirror reflects the image back (since there is just 90 cm between the lens and mirror.) So, the position of the image is 401 cm to the left of the mirror, or 311 cm to the left of the lens.

At the water–lens interface: $\Rightarrow \frac{1.33}{-311\ \text{cm}} + \frac{1.52}{s_3'} = \frac{0.187}{41.6\ \text{cm}}$ and $s_3' = +173\ \text{cm}.$

At the lens–air interface: $\Rightarrow \frac{1.52}{-173\ \text{cm}} + \frac{1}{s_4'} = \frac{-0.52}{-41.6\ \text{cm}}$ and $s_4' = +47.0\ \text{cm},$ to the left of the lens.

$$m = m_1 m_2 m_3 m_4 = \left(\frac{n_{a1} s_1'}{n_{b1} s_1}\right)\left(\frac{n_{a2} s_2'}{n_{b2} s_2}\right)\left(\frac{n_{a3} s_3'}{n_{b3} s_3}\right)\left(\frac{n_{a4} s_4'}{n_{b4} s_4}\right) = \left(\frac{-851}{70}\right)\left(\frac{491}{851}\right)\left(\frac{+173}{-311}\right)\left(\frac{+47.0}{-173}\right) = -1.06.$$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(Note all the indices of refraction cancel out.)
(b) The image is real.
(c) The image is inverted.
(d) The final height is $y' = my = (1.06)(4.00\text{ mm}) = 4.24\text{ mm}$.

EVALUATE: The final image is real even though it is on the same side of the lens as the object!

34.103. **IDENTIFY:** The camera lens can be modeled as a thin lens that forms an image on the film.

SET UP: The thin-lens equation is $\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}$, and the magnification of the lens is $m=-\frac{s'}{s}$.

EXECUTE: **(a)** $m=-\frac{s'}{s}=\frac{y'}{y}=\frac{1}{4}\frac{(0.0360\text{ m})}{(12.0\text{ m})}\Rightarrow s'=(7.50\times10^{-4})\,s$,

$$\frac{1}{s}+\frac{1}{s'}=\frac{1}{s}+\frac{1}{(7.50\times10^{-4})s}=\frac{1}{s}\left(1+\frac{1}{7.50\times10^{-4}}\right)=\frac{1}{f}=\frac{1}{0.0350\text{ m}}\Rightarrow s=46.7\text{ m}.$$

(b) To just fill the frame, the magnification must be 3.00×10^{-3} so:

$$\frac{1}{s}\left(1+\frac{1}{3.00\times10^{-3}}\right)=\frac{1}{f}=\frac{1}{0.0350\text{ m}}\Rightarrow s=11.7\text{ m}.$$

Since the boat is originally 46.7 m away, the distance you must move closer to the boat is $46.7\text{ m}-11.7\text{ m}=35.0\text{ m}$.

EVALUATE: This result seems to imply that if you are 4 times as far, the image is ¼ as large on the film. However, this result is only an approximation, and would not be true for very close distances. It is a better approximation for large distances.

34.104. **IDENTIFY:** The smallest image we can resolve occurs when the image is the size of a retinal cell.

SET UP: $m=-\frac{s'}{s}=\frac{y'}{y}$. $s'=2.50$ cm.

$|y'|=5.0\ \mu$m. The angle subtended (in radians) is height divided by distance from the eye.

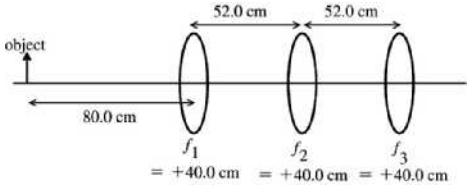
EXECUTE: **(a)** $m=-\frac{s'}{s}=-\frac{2.50\text{ cm}}{25\text{ cm}}=-0.10$. $y=\left|\frac{y'}{m}\right|=\frac{5.0\ \mu\text{m}}{0.10}=50\ \mu$m.

(b) $\theta=\frac{y}{s}=\frac{50\ \mu\text{m}}{25\text{ cm}}=\frac{50\times10^{-6}\text{ m}}{25\times10^{-2}\text{ m}}=2.0\times10^{-4}$ rad $=0.0115°=0.69$ min. This is only a bit smaller than the typical experimental value of 1.0 min.

EVALUATE: The angle subtended by the object equals the angular size of the image, $\frac{|y'|}{s'}=\frac{5.0\times10^{-6}\text{ m}}{2.50\times10^{-2}\text{ m}}=2.0\times10^{-4}$ rad.

34.105. **IDENTIFY:** Apply Eq. (34.16) to calculate the image distance for each lens. The image formed by the first lens serves as the object for the second lens, and the image formed by the second lens serves as the object for the third lens.

SET UP: The positions of the object and lenses are shown in Figure 34.105.



$$\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}$$
$$\frac{1}{s'}=\frac{1}{f}-\frac{1}{s}=\frac{s-f}{sf}$$
$$s'=\frac{sf}{s-f}$$

Figure 34.105

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: lens #1

$s = +80.0 \text{ cm}; f = +40.0 \text{ cm}$

$$s' = \frac{sf}{s-f} = \frac{(+80.0 \text{ cm})(+40.0 \text{ cm})}{+80.0 \text{ cm} - 40.0 \text{ cm}} = +80.0 \text{ cm}$$

The image formed by the first lens is 80.0 cm to the right of the first lens, so it is $80.0 \text{ cm} - 52.0 \text{ cm} = 28.0 \text{ cm}$ to the right of the second lens.

lens #2

$s = -28.0 \text{ cm}; f = +40.0 \text{ cm}$

$$s' = \frac{sf}{s-f} = \frac{(-28.0 \text{ cm})(+40.0 \text{ cm})}{-28.0 \text{ cm} - 40.0 \text{ cm}} = +16.47 \text{ cm}$$

The image formed by the second lens is 16.47 cm to the right of the second lens, so it is $52.0 \text{ cm} - 16.47 \text{ cm} = 35.53 \text{ cm}$ to the left of the third lens.

lens #3

$s = +35.53 \text{ cm}; f = +40.0 \text{ cm}$

$$s' = \frac{sf}{s-f} = \frac{(+35.53 \text{ cm})(+40.0 \text{ cm})}{+35.53 \text{ cm} - 40.0 \text{ cm}} = -318 \text{ cm}$$

The final image is 318 cm to the left of the third lens, so it is $318 \text{ cm} - 52 \text{ cm} - 52 \text{ cm} - 80 \text{ cm} = 134 \text{ cm}$ to the left of the object.

EVALUATE: We used the separation between the lenses and the sign conventions for s and s' to determine the object distances for the second and third lenses. The final image is virtual since the final s' is negative.

34.106. **IDENTIFY:** Apply $\frac{1}{s} + \frac{1}{s'} = \frac{1}{f}$ and calculate s' for each s.

SET UP: $f = 90 \text{ mm}$

EXECUTE: $\frac{1}{s} + \frac{1}{s'} = \frac{1}{f} \Rightarrow \frac{1}{1300 \text{ mm}} + \frac{1}{s'} = \frac{1}{90 \text{ mm}} \Rightarrow s' = 96.7 \text{ mm}.$

$\frac{1}{s} + \frac{1}{s'} = \frac{1}{f} \Rightarrow \frac{1}{6500 \text{ mm}} + \frac{1}{s'} = \frac{1}{90 \text{ mm}} \Rightarrow s' = 91.3 \text{ mm}.$

$\Rightarrow \Delta s' = 96.7 \text{ mm} - 91.3 \text{ mm} = 5.4 \text{ mm}$ toward the film

EVALUATE: $s' = \frac{sf}{s-f}$. For $f > 0$ and $s > f$, s' decreases as s increases.

34.107. **IDENTIFY** and **SET UP:** The generalization of Eq. (34.22) is $M = \frac{\text{near point}}{f}$, so $f = \frac{\text{near point}}{M}$.

EXECUTE: **(a)** age 10, near point = 7 cm

$$f = \frac{7 \text{ cm}}{2.0} = 3.5 \text{ cm}$$

(b) age 30, near point = 14 cm

$$f = \frac{14 \text{ cm}}{2.0} = 7.0 \text{ cm}$$

(c) age 60, near point = 200 cm

$$f = \frac{200 \text{ cm}}{2.0} = 100 \text{ cm}$$

(d) $f = 3.5 \text{ cm}$ (from part (a)) and near point = 200 cm (for 60-year-old)

$$M = \frac{200 \text{ cm}}{3.5 \text{ cm}} = 57$$

(e) EVALUATE: No. The reason $f = 3.5 \text{ cm}$ gives a larger M for a 60-year-old than for a 10-year-old is that the eye of the older person can't focus on as close an object as the younger person can. The unaided eye of the 60-year-old must view a much smaller angular size, and that is why the same f gives a much larger M. The angular size of the image depends only on f and is the same for the two ages.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

34.108. **IDENTIFY:** Use $\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}$ to calculate s that gives $s'=-25$ cm. $M=\frac{\theta'}{\theta}$.

SET UP: Let the height of the object be y, so $\theta'=\frac{y}{s}$ and $\theta=\frac{y}{25\text{ cm}}$.

EXECUTE: **(a)** $\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}\Rightarrow\frac{1}{s}+\frac{1}{-25\text{ cm}}=\frac{1}{f}\Rightarrow s=\frac{f(25\text{ cm})}{f+25\text{ cm}}$.

(b) $\theta'=\arctan\left(\frac{y}{s}\right)=\arctan\left(\frac{y(f+25\text{ cm})}{f(25\text{ cm})}\right)\approx\frac{y(f+25\text{ cm})}{f(25\text{ cm})}$.

(c) $M=\frac{\theta'}{\theta}=\frac{y(f+25\text{ cm})}{f(25\text{ cm})}\frac{1}{y/25\text{ cm}}=\frac{f+25\text{ cm}}{f}$.

(d) If $f=10\text{ cm}\Rightarrow M=\frac{10\text{ cm}+25\text{ cm}}{10\text{ cm}}=3.5$. This is 1.4 times greater than the magnification obtained if the image if formed at infinity $\left(M_\infty=\frac{25\text{ cm}}{f}=2.5\right)$.

EVALUATE: **(e)** Having the first image form just within the focal length puts one in the situation described above, where it acts as a source that yields an enlarged virtual image. If the first image fell just outside the second focal point, then the image would be real and diminished.

34.109. **IDENTIFY:** Apply $\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}$. The near point is at infinity, so that is where the image must be formed for any objects that are close.

SET UP: The power in diopters equals $\frac{1}{f}$, with f in meters.

EXECUTE: $\frac{1}{f}=\frac{1}{s}+\frac{1}{s'}=\frac{1}{24\text{ cm}}+\frac{1}{-\infty}=\frac{1}{0.24\text{ m}}=4.17$ diopters.

EVALUATE: To focus on closer objects, the power must be increased.

34.110. **IDENTIFY:** Apply $\frac{n_a}{s}+\frac{n_b}{s'}=\frac{n_b-n_a}{R}$.

SET UP: $n_a=1.00,\ n_b=1.40$.

EXECUTE: $\frac{1}{36.0\text{ cm}}+\frac{1.40}{s'}=\frac{0.40}{0.75\text{ cm}}\Rightarrow s'=2.77$ cm.

EVALUATE: This distance is greater than for the normal eye, which has a cornea vertex to retina distance of about 2.6 cm.

34.111. **IDENTIFY** and **SET UP:** The person's eye cannot focus on anything closer than 85.0 cm. The problem asks us to find the location of an object such that his old lenses produce a virtual image 85.0 cm from his eye. $\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}$. $P(\text{in diopters})=1/f(\text{in m})$.

EXECUTE: **(a)** $\frac{1}{f}=2.25$ diopters so $f=44.4$ cm. The image is 85.0 cm from his eye so is 83.0 cm from the eyeglass lens. Solving $\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}$ for s gives $s=\frac{s'f}{s'-f}=\frac{(-83.0\text{ cm})(44.4\text{ cm})}{-83.0\text{ cm}-44.4\text{ cm}}=+28.9$ cm. The object is 28.9 cm from the eyeglasses so is 30.9 cm from his eyes.

(b) Now $s'=-85.0$ cm. $s=\frac{s'f}{s'-f}=\frac{(-85.0\text{ cm})(44.4\text{ cm})}{-85.0\text{ cm}-44.4\text{ cm}}=+29.2$ cm.

EVALUATE: The old glasses allow him to focus on objects as close as about 30 cm from his eyes. This is much better than a closest distance of 85 cm with no glasses, but his current glasses probably allow him to focus as close as 25 cm.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

34.112. **IDENTIFY:** For u and u' as defined in Figure P34.112 in the textbook, $M = \dfrac{u'}{u}$.

SET UP: f_2 is negative. From Figure P34.112 in the textbook, the length of the telescope is $f_1 + f_2$, since f_2 is negative.

EXECUTE: **(a)** From the figure, $u = \dfrac{y}{f_1}$ and $u' = \dfrac{y}{|f_2|} = -\dfrac{y}{f_2}$. The angular magnification is $M = \dfrac{u'}{u} = -\dfrac{f_1}{f_2}$.

(b) $M = -\dfrac{f_1}{f_2} \Rightarrow f_2 = -\dfrac{f_1}{M} = -\dfrac{95.0\text{ cm}}{6.33} = -15.0\text{ cm}.$

(c) The length of the telescope is $95.0\text{ cm} - 15.0\text{ cm} = 80.0\text{ cm},$ compared to the length of 110 cm for the telescope in Exercise 34.65.

EVALUATE: An advantage of this construction is that the telescope is somewhat shorter.

34.113. **IDENTIFY:** Use similar triangles in Figure P34.113 in the textbook and Eq. (34.16) to derive the expressions called for in the problem.

(a) SET UP: The effect of the converging lens on the ray bundle is sketched in Figure 34.113a.

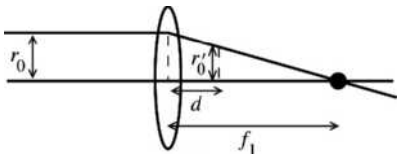


Figure 34.113a

EXECUTE: From similar triangles in Figure 34.113a, $\dfrac{r_0}{f_1} = \dfrac{r_0'}{f_1 - d}$.

Thus $r_0' = \left(\dfrac{f_1 - d}{f_1}\right) r_0,$ as was to be shown.

(b) SET UP: The image at the focal point of the first lens, a distance f_1 to the right of the first lens, serves as the object for the second lens. The image is a distance $f_1 - d$ to the right of the second lens, so $s_2 = -(f_1 - d) = d - f_1.$

EXECUTE: $s_2' = \dfrac{s_2 f_2}{s_2 - f_2} = \dfrac{(d - f_1) f_2}{d - f_1 - f_2}$

$f_2 < 0$ so $|f_2| = -f_2$ and $s_2' = \dfrac{(f_1 - d)|f_2|}{|f_2| - f_1 + d},$ as was to be shown.

(c) SET UP: The effect of the diverging lens on the ray bundle is sketched in Figure 34.113b.

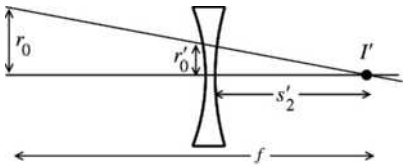

Figure 34.113b

EXECUTE: From similar triangles in the sketch, $\dfrac{r_0}{f} = \dfrac{r_0'}{s_2'}$

Thus $\dfrac{r_0}{r_0'} = \dfrac{f}{s_2'}$.

From the results of part (a), $\dfrac{r_0}{r_0'} = \dfrac{f_1}{f_1 - d}$. Combining the two results gives $\dfrac{f_1}{f_1 - d} = \dfrac{f}{s_2'}$.

$f = s_2'\left(\dfrac{f_1}{f_1 - d}\right) = \dfrac{(f_1 - d)|f_2| f_1}{(|f_2| - f_1 + d)(f_1 - d)} = \dfrac{f_1 |f_2|}{|f_2| - f_1 + d},$ as was to be shown.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(d) SET UP: Put the numerical values into the expression derived in part (c).

EXECUTE: $f = \dfrac{f_1|f_2|}{|f_2| - f_1 + d}$

$f_1 = 12.0$ cm, $|f_2| = 18.0$ cm, so $f = \dfrac{216\ \text{cm}^2}{6.0\ \text{cm} + d}$

$d = 0$ gives $f = 36.0$ cm; maximum f

$d = 4.0$ cm gives $f = 21.6$ cm; minimum f

$f = 30.0$ cm says $30.0\ \text{cm} = \dfrac{216\ \text{cm}^2}{6.0\ \text{cm} + d}$

$6.0\ \text{cm} + d = 7.2$ cm and $d = 1.2$ cm

EVALUATE: Changing d produces a range of effective focal lengths. The effective focal length can be both smaller and larger than $f_1 + |f_2|$.

34.114. **IDENTIFY:** $|M| = \dfrac{\theta'}{\theta}$. $\theta = \left|\dfrac{y_1'}{f_1}\right|$, and $\theta' = \left|\dfrac{y_2'}{s_2'}\right|$. This gives $|M| = \left|\dfrac{y_2'}{s_2'} \cdot \dfrac{f_1}{y_1'}\right|$.

SET UP: Since the image formed by the objective is used as the object for the eyepiece, $y_1' = y_2$.

EXECUTE: $|M| = \left|\dfrac{y_2'}{s_2'} \cdot \dfrac{f_1}{y_2}\right| = \left|\dfrac{y_2'}{y_2} \cdot \dfrac{f_1}{s_2'}\right| = \left|\dfrac{s_2'}{s_2} \cdot \dfrac{f_1}{s_2'}\right| = \left|\dfrac{f_1}{s_2}\right|$. Therefore, $s_2 = \dfrac{f_1}{|M|} = \dfrac{48.0\ \text{cm}}{36} = 1.33\ \text{cm}$, and this is just outside the eyepiece focal point.

Now the distance from the mirror vertex to the lens is $f_1 + s_2 = 49.3$ cm, and so $\dfrac{1}{s_2} + \dfrac{1}{s_2'} = \dfrac{1}{f_2} \Rightarrow$

$s_2' = \left(\dfrac{1}{1.20\ \text{cm}} - \dfrac{1}{1.33\ \text{cm}}\right)^{-1} = 12.3$ cm. Thus we have a final image which is real and 12.3 cm from the eyepiece. (Take care to carry plenty of figures in the calculation because two close numbers are subtracted.)

EVALUATE: Eq. (34.25) gives $|M| = 40$, somewhat larger than $|M|$ for this telescope.

34.115. **IDENTIFY** and **SET UP:** The image formed by the objective is the object for the eyepiece. The total lateral magnification is $m_{\text{tot}} = m_1 m_2$. $f_1 = 8.00$ mm (objective); $f_2 = 7.50$ cm (eyepiece)

(a) The locations of the object, lenses and screen are shown in Figure 34.115.

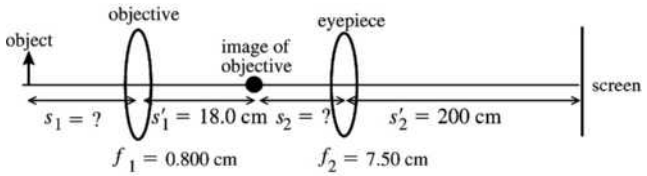

Figure 34.115

EXECUTE: Find the object distance s_1 for the objective:

$s_1' = +18.0$ cm, $f_1 = 0.800$ cm, $s_1 = ?$

$\dfrac{1}{s_1} + \dfrac{1}{s_1'} = \dfrac{1}{f_1}$, so $\dfrac{1}{s_1} = \dfrac{1}{f_1} - \dfrac{1}{s_1'} = \dfrac{s_1' - f_1}{s_1' f_1}$

$s_1 = \dfrac{s_1' f_1}{s_1' - f_1} = \dfrac{(18.0\ \text{cm})(0.800\ \text{cm})}{18.0\ \text{cm} - 0.800\ \text{cm}} = 0.8372$ cm

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

Find the object distance s_2 for the eyepiece:

$s_2' = +200$ cm, $f_2 = 7.50$ cm, $s_2 = ?$

$$\frac{1}{s_2} + \frac{1}{s_2'} = \frac{1}{f_2}$$

$$s_2 = \frac{s_2' f_2}{s_2' - f_2} = \frac{(200\text{ cm})(7.50\text{ cm})}{200\text{ cm} - 7.50\text{ cm}} = 7.792\text{ cm}$$

Now we calculate the magnification for each lens:

$$m_1 = -\frac{s_1'}{s_1} = -\frac{18.0\text{ cm}}{0.8372\text{ cm}} = -21.50$$

$$m_2 = -\frac{s_2'}{s_2} = -\frac{200\text{ cm}}{7.792\text{ cm}} = -25.67$$

$$m_{\text{tot}} = m_1 m_2 = (-21.50)(-25.67) = 552.$$

(b) From the sketch we can see that the distance between the two lenses is $s_1' + s_2 = 18.0\text{ cm} + 7.792\text{ cm} = 25.8\text{ cm}$.

EVALUATE: The microscope is not being used in the conventional way; it merely serves as a two-lens system. In particular, the final image formed by the eyepiece in the problem is real, not virtual as is the case normally for a microscope. Eq. (34.24) does not apply here, and in any event gives the angular not the lateral magnification.

34.116. **IDENTIFY** and **SET UP:** Consider the ray diagram drawn in Figure 34.116.

EXECUTE: **(a)** Using the diagram and law of sines, $\frac{\sin\theta}{(R-f)} = \frac{\sin\alpha}{g}$ but $\sin\theta = \frac{h}{R} = \sin\alpha$ (law of reflection), and $g = (R-f)$. Bisecting the triangle: $\cos\theta = \frac{R/2}{(R-f)} \Rightarrow R\cos\theta - f\cos\theta = \frac{R}{2}$.

$f = \frac{R}{2}\left[2 - \frac{1}{\cos\theta}\right] = f_0\left[2 - \frac{1}{\cos\theta}\right]$. $f_0 = \frac{R}{2}$ is the value of f for θ near zero (incident ray near the axis).

When θ increases, $(2 - 1/\cos\theta)$ decreases and f decreases.

(b) $\frac{f - f_0}{f_0} = -0.02 \Rightarrow \frac{f}{f_0} = 0.98$ so $2 - \frac{1}{\cos\theta} = 0.98$. $\cos\theta = \frac{1}{2 - 0.98} = 0.98$ and $\theta = 11.4°$.

EVALUATE: For $\theta = 45°$, $f = 0.586 f_0$, and f approaches zero as θ approaches $60°$.

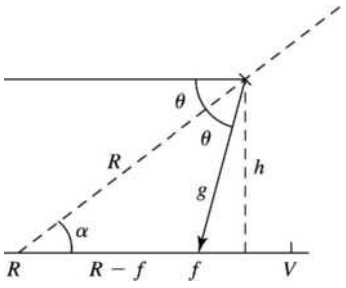

Figure 34.116

34.117. **IDENTIFY:** The distance between image and object can be calculated by taking the derivative of the separation distance and minimizing it.

SET UP: For a real image $s' > 0$ and the distance between the object and the image is $D = s + s'$. For a real image must have $s > f$.

EXECUTE: **(a)** $D = s + s'$ but $s' = \frac{sf}{s-f} \Rightarrow D = s + \frac{sf}{s-f} = \frac{s^2}{s-f}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$\frac{dD}{ds}=\frac{d}{ds}\left(\frac{s^2}{s-f}\right)=\frac{2s}{s-f}-\frac{s^2}{(s-f)^2}=\frac{s^2-2sf}{(s-f)^2}=0.$ $s^2-2sf=0.$ $s(s-2f)=0.$ $s=2f$ is the solution for which $s>f$. For $s=2f$, $s'=2f$. Therefore, the minimum separation is $2f+2f=4f$.

(b) A graph of D/f versus s/f is sketched in Figure 34.117. Note that the minimum does occur for $D=4f$.

EVALUATE: If, for example, $s=3f/2$, then $s'=3f$ and $D=s+s'=4.5f$, greater than the minimum value.

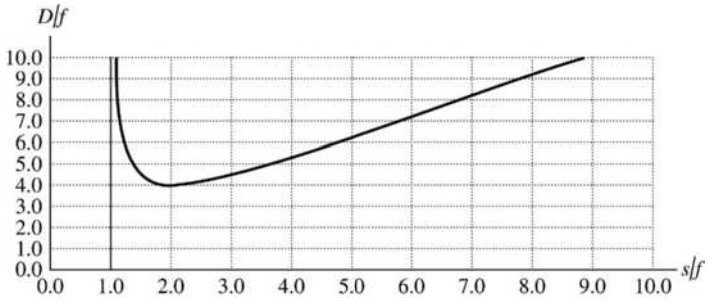

Figure 34.117

34.118. **IDENTIFY:** Use $\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}$ to calculate s' (the distance of each point from the lens), for points A, B and C.

SET UP: The object and lens are shown in Figure 34.118a.

EXECUTE: **(a)** For point C: $\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}\Rightarrow\frac{1}{45.0\text{ cm}}+\frac{1}{s'}=\frac{1}{20.0\text{ cm}}\Rightarrow s'=36.0\text{ cm}.$

$y'=-\frac{s'}{s}y=-\frac{36.0}{45.0}(15.0\text{ cm})=-12.0\text{ cm},$ so the image of point C is 36.0 cm to the right of the lens, and 12.0 cm below the axis.

For point A: $s=45.0\text{ cm}+8.00\text{ cm}(\cos 45°)=50.7\text{ cm}.$

$\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}\Rightarrow\frac{1}{50.7\text{ cm}}+\frac{1}{s'}=\frac{1}{20.0\text{ cm}}\Rightarrow s'=33.0\text{ cm}.$

$y'=-\frac{s'}{s}y=-\frac{33.0}{45.0}(15.0\text{ cm}-8.00\text{ cm}(\sin 45°))=-6.10\text{ cm},$ so the image of point A is 33.0 cm to the right of the lens, and 6.10 cm below the axis.

For point B: $s=45.0\text{ cm}-8.00\text{ cm}(\cos 45°)=39.3\text{ cm}.$

$\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}\Rightarrow\frac{1}{39.3\text{ cm}}+\frac{1}{s'}=\frac{1}{20.0\text{ cm}}\Rightarrow s'=40.7\text{ cm}.$

$y'=-\frac{s'}{s}y=-\frac{40.7}{39.3}(15.0\text{ cm}+8.00\text{ cm}(\sin 45°))=-21.4\text{ cm},$ so the image of point B is 40.7 cm to the right of the lens, and 21.4 cm below the axis. The image is shown in Figure 34.118b.

(b) The length of the pencil is the distance from point A to B:

$L=\sqrt{(x_A-x_B)^2+(y_A-y_B)^2}=\sqrt{(33.0\text{ cm}-40.7\text{ cm})^2+(6.10\text{ cm}-21.4\text{ cm})^2}=17.1\text{ cm}$

EVALUATE: The image is below the optic axis and is larger than the object.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

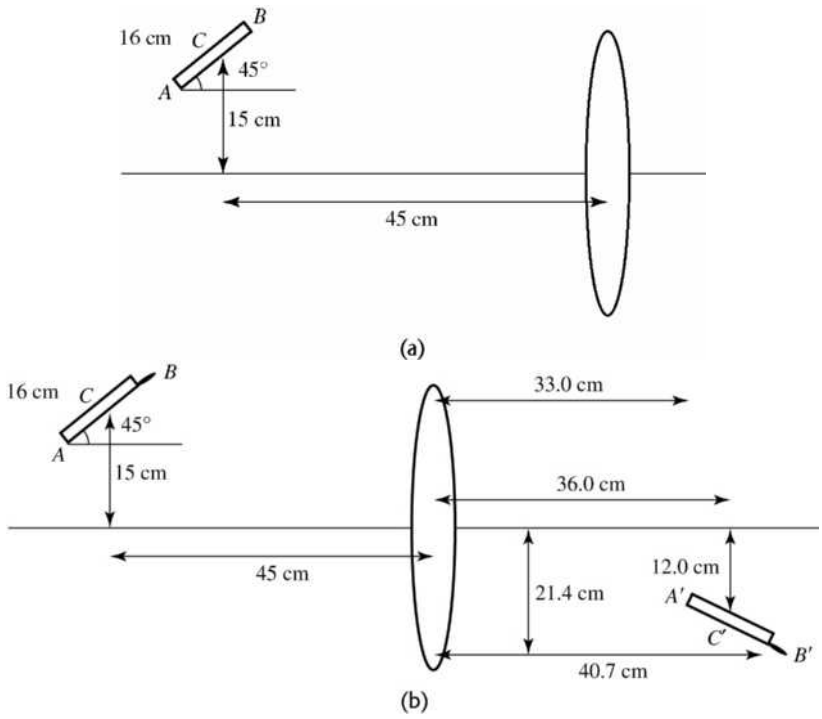

Figure 34.118

34.119. **IDENTIFY:** Apply $\frac{n_a}{s}+\frac{n_b}{s'}=\frac{n_b-n_a}{R}$ to refraction at the cornea to find where the object for the cornea must be in order for the image to be at the retina. Then use $\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}$ to calculate f so that the lens produces an image of a distant object at this point.

SET UP: For refraction at the cornea, $n_a=1.333$ and $n_b=1.40$. The distance from the cornea to the retina in this model of the eye is 2.60 cm. From Problem 34.52, $R=0.71$ cm.

EXECUTE: **(a)** People with normal vision cannot focus on distant objects under water because the image is unable to be focused in a short enough distance to form on the retina. Equivalently, the radius of curvature of the normal eye is about five or six times too great for focusing at the retina to occur.

(b) When introducing glasses, let's first consider what happens at the eye:

$\frac{n_a}{s_2}+\frac{n_b}{s_2'}=\frac{n_b-n_a}{R}\Rightarrow\frac{1.333}{s_2}+\frac{1.40}{2.6\text{ cm}}=\frac{0.067}{0.71\text{ cm}}\Rightarrow s_2=-3.00\text{ cm}$. That is, the object for the cornea must be 3.00 cm behind the cornea. Now, assume the glasses are 2.00 cm in front of the eye, so

$s_1'=2.00\text{ cm}+|s_2|=5.00\text{ cm}$. $\frac{1}{s_1}+\frac{1}{s_1'}=\frac{1}{f_1'}$ gives $\frac{1}{\infty}+\frac{1}{5.00\text{ cm}}=\frac{1}{f_1'}$ and $f_1'=5.00\text{ cm}$. This is the focal length in water, but to get it in air, we use the formula from Problem 34.98:

$$f_1=f_1'\left[\frac{n-n_{\text{liq}}}{n_{\text{liq}}(n-1)}\right]=(5.00\text{ cm})\left[\frac{1.62-1.333}{1.333(1.62-1)}\right]=1.74\text{ cm}.$$

EVALUATE: A converging lens is needed.

35

INTERFERENCE

35.1. **IDENTIFY:** The sound will be maximally reinforced when the path difference is an integral multiple of wavelengths and cancelled when it is an odd number of half wavelengths.

SET UP: Constructive interference occurs for $r_2 - r_1 = m\lambda,\ m = 0, \pm 1, \pm 2, \ldots$. Destructive interference occurs for $r_2 - r_1 = (m + \frac{1}{2})\lambda, m = 0, \pm 1, \pm 2 \ldots$. For this problem, $r_2 = 150$ cm and $r_1 = x$. The path taken by the person ensures that x is in the range $0 \le x \le 150$ cm.

EXECUTE: **(a)** 150 cm $- x = m(34$ cm). $x = 150$ cm $- m(34$ cm). For $m = 0, 1, 2, 3, 4$ the values of x are 150 cm, 116 cm, 82 cm, 48 cm, 14 cm.

(b) 150 cm $- x = (m + \frac{1}{2})(34$ cm). $x = 150$ cm $- (m + \frac{1}{2})(34$ cm). For $m = 0, 1, 2, 3$ the values of x are 133 cm, 99 cm, 65 cm, 31 cm.

EVALUATE: When $x = 116$ cm the path difference is 150 cm $- 116$ cm $= 34$ cm, which is one wavelength. When $x = 133$ cm the path difference is 17 cm, which is one-half wavelength.

35.2. **IDENTIFY:** The sound will be maximally reinforced when the path difference is an integral multiple of wavelengths and cancelled when it is an odd number of half wavelengths.

SET UP: When she is at the midpoint between the two speakers the path difference $r_2 - r_1$ is zero. When she walks a distance d toward one speaker, r_2 increases by d and r_1 decreases by d, so the path difference changes by $2d$. Path difference $= m\lambda$ $(m = 0, \pm 1, \pm 2, \ldots)$ gives constructive interference and path difference $= (m + \frac{1}{2})\lambda$ $(m = 0, \pm 1, \pm 2, \ldots)$ gives destructive interference.

EXECUTE: $\lambda = \dfrac{v}{f} = \dfrac{340.0 \text{ m/s}}{250.0 \text{ Hz}} = 1.36$ m.

(a) The path difference is zero, so the interference is constructive.

(b) Destructive interference occurs, so the path difference equals $\lambda/2$. $2d = \dfrac{\lambda}{2}$ which gives

$$d = \frac{\lambda}{4} = \frac{1.36 \text{ m}}{4} = 34.0 \text{ cm}.$$

(c) Constructive interference occurs, so the path difference equals λ. $2d = \lambda$ which gives

$$d = \frac{\lambda}{2} = \frac{1.36 \text{ m}}{2} = 68.0 \text{ cm}.$$

EVALUATE: If she keeps walking, she will possibly find additional places where constructive and destructive interference occur.

35.3. **IDENTIFY:** The sound will be maximally reinforced when the path difference is an integral multiple of wavelengths and cancelled when it is an odd number of half wavelengths.

SET UP: $v = f\lambda$. Constructive interference occurs when the path difference $r_2 - r_1$ from the two sources is $r_2 - r_1 = m\lambda, m = 0, \pm 1, \pm 2, \ldots$. Destructive interference occurs when the path difference $r_2 - r_1$ is $r_2 - r_1 = (m + \frac{1}{2})\lambda, m = 0, \pm 1, \pm 2, \ldots$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: **(a)** The path difference from the two speakers is a half-integer number of wavelengths and the interference is destructive.

(b) The path difference changes by $\frac{\lambda}{2}$, so $\frac{\lambda}{2} = 0.398$ m and $\lambda = 0.796$ m. $f = \frac{v}{\lambda} = \frac{340 \text{ m/s}}{0.796 \text{ m}} = 427$ Hz.

(c) The speaker must be moved a distance $\lambda = 0.796$ m, so the path difference will change by λ.

EVALUATE: In reality, sound interference effects are often difficult to hear clearly due to reflections off of surrounding surfaces, such as, wall, the ceiling and the floor.

35.4. **IDENTIFY:** For destructive interference the path difference is $(m + \frac{1}{2})\lambda, m = 0, \pm 1, \pm 2, \ldots$ The longest wavelength is for $m = 0$. For constructive interference the path difference is $m\lambda, m = 0, \pm 1, \pm 2, \ldots$ The longest wavelength is for $m = 1$.

SET UP: The path difference is 120 m.

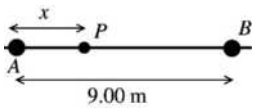
EXECUTE: **(a)** For destructive interference $\frac{\lambda}{2} = 120 \text{ m} \Rightarrow \lambda = 240$ m.

(b) The longest wavelength for constructive interference is $\lambda = 120$ m.

EVALUATE: The path difference doesn't depend on the distance of point Q from B.

35.5. **IDENTIFY:** Use $c = f\lambda$ to calculate the wavelength of the transmitted waves. Compare the difference in the distance from A to P and from B to P. For constructive interference this path difference is an integer multiple of the wavelength.

SET UP: Consider Figure 35.5.



The distance of point P from each coherent source is $r_A = x$ and $r_B = 9.00 \text{ m} - x$.

Figure 35.5

EXECUTE: The path difference is $r_B - r_A = 9.00 \text{ m} - 2x$.

$r_B - r_A = m\lambda, m = 0, \pm 1, \pm 2, \ldots$

$\lambda = \frac{c}{f} = \frac{2.998 \times 10^8 \text{ m/s}}{120 \times 10^6 \text{ Hz}} = 2.50$ m

Thus $9.00 \text{ m} - 2x = m(2.50 \text{ m})$ and $x = \frac{9.00 \text{ m} - m(2.50 \text{ m})}{2} = 4.50 \text{ m} - (1.25 \text{ m})m$. x must lie in the range 0 to 9.00 m since P is said to be between the two antennas.

$m = 0$ gives $x = 4.50$ m

$m = +1$ gives $x = 4.50 \text{ m} - 1.25 \text{ m} = 3.25$ m

$m = +2$ gives $x = 4.50 \text{ m} - 2.50 \text{ m} = 2.00$ m

$m = +3$ gives $x = 4.50 \text{ m} - 3.75 \text{ m} = 0.75$ m

$m = -1$ gives $x = 4.50 \text{ m} + 1.25 \text{ m} = 5.75$ m

$m = -2$ gives $x = 4.50 \text{ m} + 2.50 \text{ m} = 7.00$ m

$m = -3$ gives $x = 4.50 \text{ m} + 3.75 \text{ m} = 8.25$ m

All other values of m give values of x out of the allowed range. Constructive interference will occur for $x = 0.75$ m, 2.00 m, 3.25 m, 4.50 m, 5.75 m, 7.00 m and 8.25 m.

EVALUATE: Constructive interference occurs at the midpoint between the two sources since that point is the same distance from each source. The other points of constructive interference are symmetrically placed relative to this point.

35.6. **IDENTIFY:** For constructive interference the path difference d is related to λ by $d = m\lambda, m = 0, 1, 2, \ldots$

For destructive interference $d = (m + \frac{1}{2})\lambda, m = 0, 1, 2, \ldots$

SET UP: $d = 2040$ nm

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: **(a)** The brightest wavelengths are when constructive interference occurs:

$d = m\lambda_m \Rightarrow \lambda_m = \dfrac{d}{m} \Rightarrow \lambda_3 = \dfrac{2040\text{ nm}}{3} = 680\text{ nm}$, $\lambda_4 = \dfrac{2040\text{ nm}}{4} = 510\text{ nm}$ and $\lambda_5 = \dfrac{2040\text{ nm}}{5} = 408\text{ nm}$.

(b) The path-length difference is the same, so the wavelengths are the same as part (a).

(c) $d = (m + \frac{1}{2})\lambda_m$ so $\lambda_m = \dfrac{d}{m + \frac{1}{2}} = \dfrac{2040\text{ nm}}{m + \frac{1}{2}}$. The visible wavelengths are $\lambda_3 = 583$ nm and $\lambda_4 = 453$ nm.

EVALUATE: The wavelengths for constructive interference are between those for destructive interference.

35.7. **IDENTIFY:** If the path difference between the two waves is equal to a whole number of wavelengths, constructive interference occurs, but if it is an odd number of half-wavelengths, destructive interference occurs.

SET UP: We calculate the distance traveled by both waves and subtract them to find the path difference.

EXECUTE: Call P_1 the distance from the right speaker to the observer and P_2 the distance from the left speaker to the observer.

(a) $P_1 = 8.0$ m and $P_2 = \sqrt{(6.0\text{ m})^2 + (8.0\text{ m})^2} = 10.0$ m. The path distance is

$$\Delta P = P_2 - P_1 = 10.0\text{ m} - 8.0\text{ m} = 2.0\text{ m}$$

(b) The path distance is one wavelength, so constructive interference occurs.

(c) $P_1 = 17.0$ m and $P_2 = \sqrt{(6.0\text{ m})^2 + (17.0\text{ m})^2} = 18.0$ m. The path difference is $18.0\text{ m} - 17.0\text{ m} = 1.0$ m, which is one-half wavelength, so destructive interference occurs.

EVALUATE: Constructive interference also occurs if the path difference $2\lambda, 3\lambda, 4\lambda$, etc., and destructive interference occurs if it is $\lambda/2, 3\lambda/2, 5\lambda/2$, etc.

35.8. **IDENTIFY:** At an antinode the interference is constructive and the path difference is an integer number of wavelengths; path difference $= m\lambda, m = 0, \pm 1, \pm 2, \ldots$ at an antinode.

SET UP: The maximum magnitude of the path difference is the separation d between the two sources.

EXECUTE: **(a)** At $S_1, r_2 - r_1 = 4\lambda$, and this path difference stays the same all along the y-axis, so $m = +4$. At $S_2, r_2 - r_1 = -4\lambda$, and the path difference below this point, along the negative y-axis, stays the same, so $m = -4$.

(b) The wave pattern is sketched in Figure 35.8.

(c) The maximum and minimum m-values are determined by the largest integer less than or equal to $\dfrac{d}{\lambda}$.

(d) If $d = 7\dfrac{1}{2}\lambda \Rightarrow -7 \le m \le +7$, there will be a total of 15 antinodes between the sources.

EVALUATE: We are considering points close to the two sources and the antinodal curves are not straight lines.

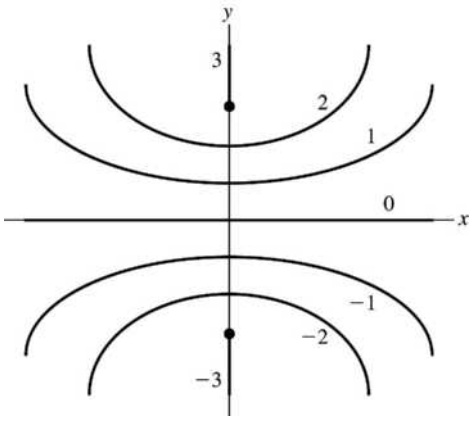


Figure 35.8

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

35.9. **IDENTIFY:** The value of y_{20} is much smaller than R and the approximate expression $y_m = R\dfrac{m\lambda}{d}$ is accurate.

SET UP: $y_{20} = 10.6\times10^{-3}$ m.

EXECUTE: $d = \dfrac{20R\lambda}{y_{20}} = \dfrac{(20)(1.20\text{ m})(502\times10^{-9}\text{ m})}{10.6\times10^{-3}\text{ m}} = 1.14\times10^{-3}\text{ m} = 1.14\text{ mm}$

EVALUATE: $\tan\theta_{20} = \dfrac{y_{20}}{R}$ so $\theta_{20} = 0.51°$ and the approximation $\sin\theta_{20} \approx \tan\theta_{20}$ is very accurate.

35.10. **IDENTIFY:** Since the dark fringes are eqully spaced, $R \gg y_m$, the angles are small and the dark bands are located by $y_{m+\frac{1}{2}} = R\dfrac{(m+\frac{1}{2})\lambda}{d}$.

SET UP: The separation between adjacent dark bands is $\Delta y = \dfrac{R\lambda}{d}$.

EXECUTE: $\Delta y = \dfrac{R\lambda}{d} \Rightarrow d = \dfrac{R\lambda}{\Delta y} = \dfrac{(1.80\text{ m})(4.50\times10^{-7}\text{ m})}{4.20\times10^{-3}\text{ m}} = 1.93\times10^{-4}\text{ m} = 0.193\text{ mm}.$

EVALUATE: When the separation between the slits decreases, the separation between dark fringes increases.

35.11. **IDENTIFY** and **SET UP:** The dark lines correspond to destructive interference and hence are located by Eq. (35.5):

$d\sin\theta = \left(m+\dfrac{1}{2}\right)\lambda$ so $\sin\theta = \dfrac{\left(m+\dfrac{1}{2}\right)\lambda}{d}$, $m = 0, \pm1, \pm2, \ldots$

Solve for θ that locates the second and third dark lines. Use $y = R\tan\theta$ to find the distance of each of the dark lines from the center of the screen.

EXECUTE: 1st dark line is for $m = 0$

2nd dark line is for $m = 1$ and $\sin\theta_1 = \dfrac{3\lambda}{2d} = \dfrac{3(500\times10^{-9}\text{ m})}{2(0.450\times10^{-3}\text{m})} = 1.667\times10^{-3}$ and $\theta_1 = 1.667\times10^{-3}$ rad

3rd dark line is for $m = 2$ and $\sin\theta_2 = \dfrac{5\lambda}{2d} = \dfrac{5(500\times10^{-9}\text{ m})}{2(0.450\times10^{-3}\text{m})} = 2.778\times10^{-3}$ and $\theta_2 = 2.778\times10^{-3}$ rad

(Note that θ_1 and θ_2 are small so that the approximation $\theta \approx \sin\theta \approx \tan\theta$ is valid.) The distance of each dark line from the center of the central bright band is given by $y_m = R\tan\theta$, where $R = 0.850$ m is the distance to the screen.

$\tan\theta \approx \theta$ so $y_m = R\theta_m$

$y_1 = R\theta_1 = (0.750\text{ m})(1.667\times10^{-3}\text{ rad}) = 1.25\times10^{-3}\text{ m}$

$y_2 = R\theta_2 = (0.750\text{ m})(2.778\times10^{-3}\text{ rad}) = 2.08\times10^{-3}\text{ m}$

$\Delta y = y_2 - y_1 = 2.08\times10^{-3}\text{ m} - 1.25\times10^{-3}\text{ m} = 0.83\text{ mm}$

EVALUATE: Since θ_1 and θ_2 are very small we could have used Eq. (35.6), generalized to destructive interference: $y_m = R\left(m+\dfrac{1}{2}\right)\lambda/d$.

35.12. **IDENTIFY:** The water changes the wavelength of the light, but the rest of the analysis is the same as in Exercise 35.11.

SET UP: Water has $n = 1.333$. In water the wavelength is $\lambda = \dfrac{\lambda_0}{n}$. θ is very small for these dark lines and the approximate expression $y_m = R\dfrac{(m+\frac{1}{2})\lambda}{d}$ is accurate. Adjacent dark lines are separated by

$\Delta y = y_{m+1} - y_m = \dfrac{R\lambda}{d}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: $\Delta y = \dfrac{R\lambda_0}{dn} = \dfrac{(0.750\text{ m})(500\times10^{-9}\text{ m})}{(0.450\times10^{-3}\text{ m})(1.333)} = 6.25\times10^{-4}\text{ m} = 0.625\text{ mm}.$

EVALUATE: λ is smaller in water and the dark lines are closer together when the apparatus is immersed in water.

35.13. **IDENTIFY:** Bright fringes are located at angles θ given by $d\sin\theta = m\lambda$.

SET UP: The largest value $\sin\theta$ can have is 1.00.

EXECUTE: **(a)** $m = \dfrac{d\sin\theta}{\lambda}$. For $\sin\theta = 1$, $m = \dfrac{d}{\lambda} = \dfrac{0.0116\times10^{-3}\text{ m}}{5.85\times10^{-7}\text{ m}} = 19.8$. Therefore, the largest m for fringes on the screen is $m = 19$. There are $2(19)+1 = 39$ bright fringes, the central one and 19 above and 19 below it.

(b) The most distant fringe has $m = \pm19$. $\sin\theta = m\dfrac{\lambda}{d} = \pm19\left(\dfrac{5.85\times10^{-7}\text{ m}}{0.0116\times10^{-3}\text{ m}}\right) = \pm0.958$ and $\theta = \pm73.3°$.

EVALUATE: For small θ the spacing Δy between adjacent fringes is constant but this is no longer the case for larger angles.

35.14. **IDENTIFY:** The width of a bright fringe can be defined to be the distance between its two adjacent destructive minima. Assuming the small angle formula for destructive interference $y_m = R\dfrac{(m+\frac{1}{2})\lambda}{d}$.

SET UP: $d = 0.200\times10^{-3}$ m. $R = 4.00$ m.

EXECUTE: The distance between any two successive minima is

$y_{m+1} - y_m = R\dfrac{\lambda}{d} = (4.00\text{ m})\dfrac{(400\times10^{-9}\text{m})}{(0.200\times10^{-3}\text{ m})} = 8.00\text{ mm}$. Thus, the answer to both part (a) and part (b) is that the width is 8.00 mm.

EVALUATE: For small angles, when $y_m \ll R$, the interference minima are equally spaced.

35.15. **IDENTIFY** and **SET UP:** The dark lines are located by $d\sin\theta = \left(m+\dfrac{1}{2}\right)\lambda$. The distance of each line from the center of the screen is given by $y = R\tan\theta$.

EXECUTE: First dark line is for $m = 0$ and $d\sin\theta_1 = \lambda/2$.

$\sin\theta_1 = \dfrac{\lambda}{2d} = \dfrac{550\times10^{-9}\text{ m}}{2(1.80\times10^{-6}\text{ m})} = 0.1528$ and $\theta_1 = 8.789°$. Second dark line is for $m = 1$ and $d\sin\theta_2 = 3\lambda/2$.

$\sin\theta_2 = \dfrac{3\lambda}{2d} = 3\left(\dfrac{550\times10^{-9}\text{ m}}{2(1.80\times10^{-6}\text{ m})}\right) = 0.4583$ and $\theta_2 = 27.28°$.

$y_1 = R\tan\theta_1 = (0.350\text{ m})\tan8.789° = 0.0541\text{ m}$

$y_2 = R\tan\theta_2 = (0.350\text{ m})\tan27.28° = 0.1805\text{ m}$

The distance between the lines is $\Delta y = y_2 - y_1 = 0.1805\text{ m} - 0.0541\text{ m} = 0.126\text{ m} = 12.6\text{ cm}$.

EVALUATE: $\sin\theta_1 = 0.1528$ and $\tan\theta_1 = 0.1546$. $\sin\theta_2 = 0.4583$ and $\tan\theta_2 = 0.5157$. As the angle increases, $\sin\theta \approx \tan\theta$ becomes a poorer approximation.

35.16. **IDENTIFY:** Using Eq. (35.6) for small angles: $y_m = R\dfrac{m\lambda}{d}$.

SET UP: First-order means $m = 1$.

EXECUTE: The distance between corresponding bright fringes is

$$\Delta y = \frac{Rm}{d}\Delta\lambda = \frac{(5.00\text{ m})(1)}{(0.300\times10^{-3}\text{ m})}(660-470)\times(10^{-9}\text{ m}) = 3.17\text{ mm}.$$

EVALUATE: The separation between these fringes for different wavelengths increases when the slit separation decreases.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

35.17. **IDENTIFY** and **SET UP:** Use the information given about the bright fringe to find the distance d between the two slits. Then use Eq. (35.5) and $y = R\tan\theta$ to calculate λ for which there is a first-order dark fringe at this same place on the screen.

EXECUTE: $y_1 = \dfrac{R\lambda_1}{d}$, so $d = \dfrac{R\lambda_1}{y_1} = \dfrac{(3.00\text{ m})(600\times10^{-9}\text{ m})}{4.84\times10^{-3}\text{ m}} = 3.72\times10^{-4}$ m. (R is much greater than d, so Eq. 35.6 is valid.) The dark fringes are located by $d\sin\theta = \left(m+\dfrac{1}{2}\right)\lambda,\ m = 0, \pm1, \pm2, \ldots$ The first-order dark fringe is located by $\sin\theta = \lambda_2/2d$, where λ_2 is the wavelength we are seeking.

$$y = R\tan\theta \approx R\sin\theta = \frac{\lambda_2 R}{2d}$$

We want λ_2 such that $y = y_1$. This gives $\dfrac{R\lambda_1}{d} = \dfrac{R\lambda_2}{2d}$ and $\lambda_2 = 2\lambda_1 = 1200$ nm.

EVALUATE: For $\lambda = 600$ nm the path difference from the two slits to this point on the screen is 600 nm. For this same path difference (point on the screen) the path difference is $\lambda/2$ when $\lambda = 1200$ nm.

35.18. **IDENTIFY:** Bright fringes are located at $y_m = R\dfrac{m\lambda}{d}$, when $y_m \ll R$. Dark fringes are at $d\sin\theta = (m+\frac{1}{2})\lambda$ and $y = R\tan\theta$.

SET UP: $\lambda = \dfrac{c}{f} = \dfrac{3.00\times10^8\text{ m/s}}{6.32\times10^{14}\text{ Hz}} = 4.75\times10^{-7}$ m. For the third bright fringe (not counting the central bright spot), $m = 3$. For the third dark fringe, $m = 2$.

EXECUTE: **(a)** $d = \dfrac{m\lambda R}{y_m} = \dfrac{3(4.75\times10^{-7}\text{ m})(0.850\text{ m})}{0.0311\text{ m}} = 3.89\times10^{-5}\text{ m} = 0.0389\text{ mm}$

(b) $\sin\theta = (2+\frac{1}{2})\dfrac{\lambda}{d} = (2.5)\left(\dfrac{4.75\times10^{-7}\text{ m}}{3.89\times10^{-5}\text{ m}}\right) = 0.0305$ and $\theta = 1.75°$.

$y = R\tan\theta = (85.0\text{ cm})\tan1.75° = 2.60$ cm.

EVALUATE: The third dark fringe is closer to the center of the screen than the third bright fringe on one side of the central bright fringe.

35.19. **IDENTIFY:** Eq. (35.10): $I = I_0\cos^2(\phi/2)$. Eq. (35.11): $\phi = (2\pi/\lambda)(r_2 - r_1)$.

SET UP: ϕ is the phase difference and $(r_2 - r_1)$ is the path difference.

EXECUTE: **(a)** $I = I_0(\cos 30.0°)^2 = 0.750I_0$

(b) $60.0° = (\pi/3)$ rad. $(r_2 - r_1) = (\phi/2\pi)\lambda = [(\pi/3)/2\pi]\lambda = \lambda/6 = 80$ nm.

EVALUATE: $\phi = 360°/6$ and $(r_2 - r_1) = \lambda/6$.

35.20. **IDENTIFY:** $\dfrac{\phi}{2\pi} = \dfrac{\text{path difference}}{\lambda}$ relates the path difference to the phase difference ϕ.

SET UP: The sources and point P are shown in Figure 35.20.

EXECUTE: $\phi = 2\pi\left(\dfrac{524\text{ cm} - 486\text{ cm}}{2\text{ cm}}\right) = 119$ radians

EVALUATE: The distances from B to P and A to P aren't important, only the difference in these distances.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

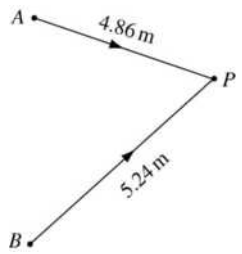

Figure 35.20

35.21. **IDENTIFY** and **SET UP:** The phase difference ϕ is given by $\phi = (2\pi d/\lambda)\sin\theta$ (Eq. 35.13.)

EXECUTE: $\phi = [2\pi(0.340\times10^{-3}\text{ m})/(500\times10^{-9}\text{ m})\sin 23.0° = 1670$ rad

EVALUATE: The mth bright fringe occurs when $\phi = 2\pi m$, so there are a large number of bright fringes within $23.0°$ from the centerline. Note that Eq. (35.13) gives ϕ in radians.

35.22. **(a) IDENTIFY** and **SET UP:** The minima are located at angles θ given by $d\sin\theta = \left(m+\frac{1}{2}\right)\lambda$. The first minimum corresponds to $m = 0$. Solve for θ. Then the distance on the screen is $y = R\tan\theta$.

EXECUTE: $\sin\theta = \dfrac{\lambda}{2d} = \dfrac{660\times10^{-9}\text{ m}}{2(0.260\times10^{-3}\text{ m})} = 1.27\times10^{-3}$ and $\theta = 1.27\times10^{-3}$ rad

$y = (0.700\text{ m})\tan(1.27\times10^{-3}\text{ rad}) = 0.889$ mm.

(b) IDENTIFY and **SET UP:** Eq. (35.15) given the intensity I as a function of the position y on the screen: $I = I_0\cos^2\left(\dfrac{\pi dy}{\lambda R}\right)$. Set $I = I_0/2$ and solve for y.

EXECUTE: $I = \dfrac{1}{2}I_0$ says $\cos^2\left(\dfrac{\pi dy}{\lambda R}\right) = \dfrac{1}{2}$

$\cos\left(\dfrac{\pi dy}{\lambda R}\right) = \dfrac{1}{\sqrt{2}}$ so $\dfrac{\pi dy}{\lambda R} = \dfrac{\pi}{4}$ rad

$y = \dfrac{\lambda R}{4d} = \dfrac{(660\times10^{-9}\text{ m})(0.700\text{ m})}{4(0.260\times10^{-3}\text{ m})} = 0.444$ mm

EVALUATE: $I = I_0/2$ at a point on the screen midway between where $I = I_0$ and $I = 0$.

35.23. **IDENTIFY:** The intensity decreases as we move away from the central maximum.

SET UP: The intensity is given by $I = I_0\cos^2\left(\dfrac{\pi dy}{\lambda R}\right)$.

EXECUTE: First find the wavelength: $\lambda = c/f = (3.00\times10^8\text{ m/s})/(12.5\text{ MHz}) = 24.00$ m

At the farthest the receiver can be placed, $I = I_0/4$, which gives

$$\frac{I_0}{4} = I_0\cos^2\left(\frac{\pi dy}{\lambda R}\right) \Rightarrow \cos^2\left(\frac{\pi dy}{\lambda R}\right) = \frac{1}{4} \Rightarrow \cos\left(\frac{\pi dy}{\lambda R}\right) = \pm\frac{1}{2}$$

The solutions are $\pi dy/\lambda R = \pi/3$ and $2\pi/3$. Using $\pi/3$, we get

$$y = \lambda R/3d = (24.00\text{ m})(500\text{ m})/[3(56.0\text{ m})] = 71.4\text{ m}$$

It must remain within 71.4 m of point C.

EVALUATE: Using $\pi dy/\lambda R = 2\pi/3$ gives $y = 142.8$ m. But to reach this point, the receiver would have to go beyond 71.4 m from C, where the signal would be too weak, so this second point is not possible.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

35.24. **IDENTIFY:** The phase difference ϕ and the path difference $r_1 - r_2$ are related by $\phi = \frac{2\pi}{\lambda}(r_1 - r_2)$. The intensity is given by $I = I_0 \cos^2\left(\frac{\phi}{2}\right)$.

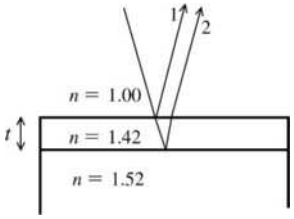
SET UP: $\lambda = \frac{c}{f} = \frac{3.00\times10^8 \text{ m/s}}{1.20\times10^8 \text{ Hz}} = 2.50 \text{ m}$. When the receiver measures intensity I_0, $\phi = 0$.

EXECUTE: **(a)** $\phi = \frac{2\pi}{\lambda}(r_1 - r_2) = \frac{2\pi}{2.50 \text{ m}}(1.8 \text{ m}) = 4.52 \text{ rad}$.

(b) $I = I_0 \cos^2\left(\frac{\phi}{2}\right) = I_0 \cos^2\left(\frac{4.52 \text{ rad}}{2}\right) = 0.404 I_0$.

EVALUATE: $(r_1 - r_2)$ is greater than $\lambda/2$, so one minimum has been passed as the receiver is moved.

35.25. **IDENTIFY:** Consider interference between rays reflected at the upper and lower surfaces of the film. Consider phase difference due to the path difference of $2t$ and any phase differences due to phase changes upon reflection.
SET UP: Consider Figure 35.25.



Both rays (1) and (2) undergo a $180°$ phase change on reflection, so there is no net phase difference introduced and the condition for destructive interference is $2t = \left(m + \frac{1}{2}\right)\lambda$.

Figure 35.25

EXECUTE: $t = \frac{\left(m + \frac{1}{2}\right)\lambda}{2}$; thinnest film says $m = 0$ so $t = \frac{\lambda}{4}$.

$\lambda = \frac{\lambda_0}{1.42}$ and $t = \frac{\lambda_0}{4(1.42)} = \frac{650\times10^{-9} \text{ m}}{4(1.42)} = 1.14\times10^{-7} \text{ m} = 114 \text{ nm}$

EVALUATE: We compared the path difference to the wavelength in the film, since that is where the path difference occurs.

35.26. **IDENTIFY:** Require destructive interference for light reflected at the front and rear surfaces of the film.
SET UP: At the front surface of the film, light in air $(n = 1.00)$ reflects from the film $(n = 2.62)$ and there is a $180°$ phase shift due to the reflection. At the back surface of the film, light in the film ($n = 2.62$) reflects from glass $(n = 1.62)$ and there is no phase shift due to reflection. Therefore, there is a net $180°$ phase difference produced by the reflections. The path difference for these two rays is $2t$, where t is the thickness of the film. The wavelength in the film is $\lambda = \frac{505 \text{ nm}}{2.62}$.

EXECUTE: **(a)** Since the reflection produces a net $180°$ phase difference, destructive interference of the reflected light occurs when $2t = m\lambda$. $t = m\left(\frac{505 \text{ nm}}{2[2.62]}\right) = (96.4 \text{ nm})m$. The minimum thickness is 96.4 nm.

(b) The next three thicknesses are for $m = 2, 3$ and 4: 192 nm, 289 nm and 386 nm.

EVALUATE: The minimum thickness is for $t = \lambda_0/2n$. Compare this to Problem 35.25, where the minimum thickness for destructive interference is $t = \lambda_0/4n$.

35.27. **IDENTIFY:** The fringes are produced by interference between light reflected from the top and bottom surfaces of the air wedge. The refractive index of glass is greater than that of air, so the waves reflected from the top surface of the air wedge have no reflection phase shift, and the waves reflected from the bottom surface of the air wedge do have a half-cycle reflection phase shift. The condition for constructive interference (bright fringes) is therefore $2t = (m + \frac{1}{2})\lambda$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

SET UP: The geometry of the air wedge is sketched in Figure 35.27. At a distance x from the point of contact of the two plates, the thickness of the air wedge is t.

EXECUTE: $\tan\theta = \dfrac{t}{x}$ so $t = x\tan\theta$. $t_m = (m+\frac{1}{2})\dfrac{\lambda}{2}$. $x_m = (m+\frac{1}{2})\dfrac{\lambda}{2\tan\theta}$ and $x_{m+1} = (m+\frac{3}{2})\dfrac{\lambda}{2\tan\theta}$. The distance along the plate between adjacent fringes is $\Delta x = x_{m+1} - x_m = \dfrac{\lambda}{2\tan\theta}$. 15.0 fringes/cm $= \dfrac{1.00}{\Delta x}$ and $\Delta x = \dfrac{1.00}{15.0 \text{ fringes/cm}} = 0.0667 \text{ cm}$. $\tan\theta = \dfrac{\lambda}{2\Delta x} = \dfrac{546\times10^{-9} \text{ m}}{2(0.0667\times10^{-2} \text{ m})} = 4.09\times10^{-4}$. The angle of the wedge is 4.09×10^{-4} rad $= 0.0234°$.

EVALUATE: The fringes are equally spaced; Δx is independent of m.

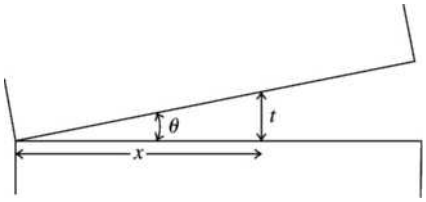


Figure 35.27

35.28. **IDENTIFY:** The fringes are produced by interference between light reflected from the top and from the bottom surfaces of the air wedge. The refractive index of glass is greater than that of air, so the waves reflected from the top surface of the air wedge have no reflection phase shift and the waves reflected from the bottom surface of the air wedge do have a half-cycle reflection phase shift. The condition for constructive interference (bright fringes) therefore is $2t = (m+\frac{1}{2})\lambda$.

SET UP: The geometry of the air wedge is sketched in Figure 35.28.

EXECUTE: $\tan\theta = \dfrac{0.0800 \text{ mm}}{90.0 \text{ mm}} = 8.89\times10^{-4}$. $\tan\theta = \dfrac{t}{x}$ so $t = (8.89\times10^{-4})x$. $t_m = (m+\frac{1}{2})\dfrac{\lambda}{2}$. $x_m = (m+\frac{1}{2})\dfrac{\lambda}{2(8.89\times10^{-4})}$ and $x_{m+1} = (m+\frac{3}{2})\dfrac{\lambda}{2(8.89\times10^{-4})}$. The distance along the plate between adjacent fringes is $\Delta x = x_{m+1} - x_m = \dfrac{\lambda}{2(8.89\times10^{-4})} = \dfrac{656\times10^{-9} \text{ m}}{2(8.89\times10^{-4})} = 3.69\times10^{-4} \text{ m} = 0.369 \text{ mm}$.

The number of fringes per cm is $\dfrac{1.00}{\Delta x} = \dfrac{1.00}{0.0369 \text{ cm}} = 27.1$ fringes/cm.

EVALUATE: As $t \to 0$ the interference is destructive and there is a dark fringe at the line of contact between the two plates.

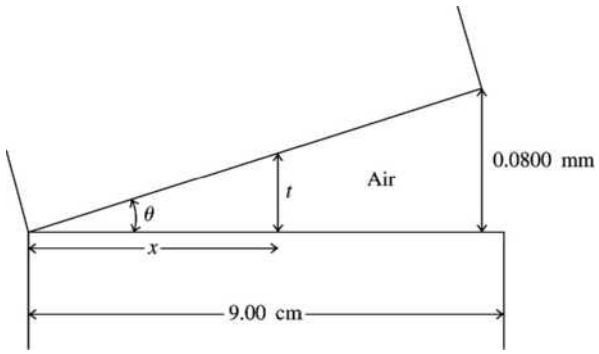

Figure 35.28

35.29. **IDENTIFY:** The light reflected from the top of the TiO_2 film interferes with the light reflected from the top of the glass surface. These waves are out of phase due to the path difference in the film and the phase differences caused by reflection.

SET UP: There is a π phase change at the TiO_2 surface but none at the glass surface, so for destructive interference the path difference must be $m\lambda$ in the film.

EXECUTE: **(a)** Calling T the thickness of the film gives $2T = m\lambda_0/n,$ which yields $T = m\lambda_0/(2n)$. Substituting the numbers gives

$$T = m\ (520.0\ \text{nm})/[2(2.62)] = 99.237nm$$

T must be greater than 1036 nm, so $m = 11,$ which gives $T = 1091.6$ nm, since we want to know the minimum thickness to add.

$$\Delta T = 1091.6\ \text{nm} - 1036\ \text{nm} = 55.6\ \text{nm}.$$

(b) (i) Path difference $= 2T = 2(1092\ \text{nm}) = 2184\ \text{nm} = 2180\ \text{nm}.$

(ii) The wavelength in the film is $\lambda = \lambda_0/n = (520.0\ \text{nm})/2.62 = 198.5\ \text{nm}.$

$$\text{Path difference} = (2180\ \text{nm})/[(198.5\ \text{nm})/\text{wavelength}] = 11.0\ \text{wavelengths}$$

EVALUATE: Because the path difference in the film is 11.0 wavelengths, the light reflected off the top of the film will be 180° out of phase with the light that traveled through the film and was reflected off the glass due to the phase change at reflection off the top of the film.

35.30. **IDENTIFY:** Consider the phase difference produced by the path difference and by the reflections. For destructive interference the total phase difference is an integer number of half cycles.

SET UP: The reflection at the top surface of the film produces a half-cycle phase shift. There is no phase shift at the reflection at the bottom surface.

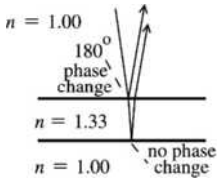
EXECUTE: **(a)** Since there is a half-cycle phase shift at just one of the interfaces, the minimum thickness for constructive interference is $t = \dfrac{\lambda}{4} = \dfrac{\lambda_0}{4n} = \dfrac{550\ \text{nm}}{4(1.85)} = 74.3\ \text{nm}.$

(b) The next smallest thickness for constructive interference is with another half wavelength thickness added: $t = \dfrac{3\lambda}{4} = \dfrac{3\lambda_0}{4n} = \dfrac{3(550\ \text{nm})}{4(1.85)} = 223\ \text{nm}.$

EVALUATE: Note that we must compare the path difference to the wavelength in the film.

35.31. **IDENTIFY:** Consider the interference between rays reflected from the two surfaces of the soap film. Strongly reflected means constructive interference. Consider phase difference due to the path difference of $2t$ and any phase difference due to phase changes upon reflection.

(a) SET UP: Consider Figure 35.31.



There is a 180° phase change when the light is reflected from the outside surface of the bubble and no phase change when the light is reflected from the inside surface.

Figure 35.31

EXECUTE: The reflections produce a net 180° phase difference and for there to be constructive interference the path difference $2t$ must correspond to a half-integer number of wavelengths to compensate for the $\lambda/2$ shift due to the reflections. Hence the condition for constructive interference is $2t = \left(m + \dfrac{1}{2}\right)(\lambda_0/n),\ m = 0, 1, 2, \ldots$ Here λ_0 is the wavelength in air and (λ_0/n) is the wavelength in the bubble, where the path difference occurs.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$\lambda_0 = \frac{2tn}{m+\frac{1}{2}} = \frac{2(290\text{ nm})(1.33)}{m+\frac{1}{2}} = \frac{771.4\text{ nm}}{m+\frac{1}{2}}$$

for $m = 0, \lambda = 1543$ nm; for $m = 1, \lambda = 514$ nm; for $m = 2, \lambda = 308$ nm;… Only 514 nm is in the visible region; the color for this wavelength is green.

(b) $\lambda_0 = \frac{2tn}{m+\frac{1}{2}} = \frac{2(340\text{ nm})(1.33)}{m+\frac{1}{2}} = \frac{904.4\text{ nm}}{m+\frac{1}{2}}$

for $m = 0, \lambda = 1809$ nm; for $m = 1, \lambda = 603$ nm; for $m = 2, \lambda = 362$ nm;… Only 603 nm is in the visible region; the color for this wavelength is orange.

EVALUATE: The dominant color of the reflected light depends on the thickness of the film. If the bubble has varying thickness at different points, these points will appear to be different colors when the light reflected from the bubble is viewed.

35.32. **IDENTIFY:** The number of waves along the path is the path length divided by the wavelength. The path difference and the reflections determine the phase difference.

SET UP: The path length is $2t = 17.52\times10^{-6}$ m. The wavelength in the film is $\lambda = \frac{\lambda_0}{n}$.

EXECUTE: **(a)** $\lambda = \frac{648\text{ nm}}{1.35} = 480$ nm. The number of waves is $\frac{2t}{\lambda} = \frac{17.52\times10^{-6}\text{ m}}{480\times10^{-9}\text{ m}} = 36.5$.

(b) The path difference introduces a $\lambda/2$, or 180°, phase difference. The ray reflected at the top surface of the film undergoes a 180° phase shift upon reflection. The reflection at the lower surface introduces no phase shift. Both rays undergo a 180° phase shift, one due to reflection and one due to the path difference. The two effects cancel and the two rays are in phase as they leave the film.

EVALUATE: Note that we must use the wavelength in the film to determine the number of waves in the film.

35.33. **IDENTIFY:** Require destructive interference between light reflected from the two points on the disc.

SET UP: Both reflections occur for waves in the plastic substrate reflecting from the reflective coating, so they both have the same phase shift upon reflection and the condition for destructive interference (cancellation) is $2t = (m+\frac{1}{2})\lambda$, where t is the depth of the pit. $\lambda = \frac{\lambda_0}{n}$. The minimum pit depth is for $m = 0$.

EXECUTE: $2t = \frac{\lambda}{2}$. $t = \frac{\lambda}{4} = \frac{\lambda_0}{4n} = \frac{790\text{ nm}}{4(1.8)} = 110\text{ nm} = 0.11\,\mu\text{m}$.

EVALUATE: The path difference occurs in the plastic substrate and we must compare the wavelength in the substrate to the path difference.

35.34. **IDENTIFY:** Consider light reflected at the front and rear surfaces of the film.

SET UP: At the front surface of the film, light in air $(n = 1.00)$ reflects from the film $(n = 1.33)$ and there is a 180° phase shift due to the reflection. At the back surface of the film, light in the film $(n = 1.33)$ reflects from air $(n = 1.00)$ and there is no phase shift due to reflection. Therefore, there is a net 180° phase difference produced by the reflections. The path difference for these two rays is $2t$, where t is the thickness of the film. The wavelength in the film is $\lambda = \frac{480\text{ nm}}{2.62}$.

EXECUTE: Since the reflection produces a net 180° phase difference, destructive interference of the reflected light occurs when $2t = m\lambda$. $t = m\left(\frac{480\text{ nm}}{2[1.33]}\right) = (180\text{ nm})m$. The minimum thickness is 180 nm.

EVALUATE: The minimum thickness is for $t = \lambda/2n$. Compare this to Problem 35.25, where the minimum thickness for destructive interference is $t = \lambda/4n$.

35.35. **IDENTIFY** and **SET UP:** Apply Eq. (35.19) and calculate y for $m = 1800$.

EXECUTE: Eq. (35.19): $y = m(\lambda/2) = 1800(633\times10^{-9}\text{ m})/2 = 5.70\times10^{-4}\text{ m} = 0.570$ mm

EVALUATE: A small displacement of the mirror corresponds to many wavelengths and a large number of fringes cross the line.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

35.36. **IDENTIFY:** Apply Eq. (35.19).
SET UP: $m = 818$. Since the fringes move in opposite directions, the two people move the mirror in opposite directions.

EXECUTE: **(a)** For Jan, the total shift was $y_1 = \dfrac{m\lambda_1}{2} = \dfrac{818(6.06\times10^{-7}\text{ m})}{2} = 2.48\times10^{-4}\text{m}$. For Linda, the total shift was $y_2 = \dfrac{m\lambda_2}{2} = \dfrac{818(5.02\times10^{-7}\text{ m})}{2} = 2.05\times10^{-4}\text{ m}$.

(b) The net displacement of the mirror is the difference of the above values:

$$\Delta y = y_1 - y_2 = 0.248\text{ mm} - 0.205\text{ mm} = 0.043\text{ mm}.$$

EVALUATE: The person using the larger wavelength moves the mirror the greater distance.

35.37. **IDENTIFY:** Consider the interference between light reflected from the top and bottom surfaces of the air film between the lens and the glass plate.
SET UP: For maximum intensity, with a net half-cycle phase shift due to reflections,
$2t = \left(m + \dfrac{1}{2}\right)\lambda.\ t = R - \sqrt{R^2 - r^2}$.

EXECUTE: $\dfrac{(2m+1)\lambda}{4} = R - \sqrt{R^2 - r^2} \Rightarrow \sqrt{R^2 - r^2} = R - \dfrac{(2m+1)\lambda}{4}$

$$\Rightarrow R^2 - r^2 = R^2 + \left[\frac{(2m+1)\lambda}{4}\right]^2 - \frac{(2m+1)\lambda R}{2} \Rightarrow r = \sqrt{\frac{(2m+1)\lambda R}{2} - \left[\frac{(2m+1)\lambda}{4}\right]^2}$$

$$\Rightarrow r \approx \sqrt{\frac{(2m+1)\lambda R}{2}}, \text{ for } R \gg \lambda.$$

The second bright ring is when $m = 1$:
$r \approx \sqrt{\dfrac{[2(1)+1](5.80\times10^{-7}\text{m})(0.684\text{ m})}{2}} = 7.71\times10^{-4}\text{m} = 0.771\text{ mm}$. So the diameter of the second bright ring is 1.54 mm.

EVALUATE: The diameter of the m^{th} ring is proportional to $\sqrt{2m+1}$, so the rings get closer together as m increases. This agrees with Figure 35.16b in the textbook.

35.38. **IDENTIFY:** As found in Problem 35.37, the radius of the m^{th} bright ring is $r \approx \sqrt{\dfrac{(2m+1)\lambda R}{2}}$, for $R \gg \lambda$.

SET UP: Introducing a liquid between the lens and the plate just changes the wavelength from λ to $\dfrac{\lambda}{n}$, where n is the refractive index of the liquid.

EXECUTE: $r(n) \approx \sqrt{\dfrac{(2m+1)\lambda R}{2n}} = \dfrac{r}{\sqrt{n}} = \dfrac{0.720\text{ mm}}{\sqrt{1.33}} = 0.624\text{ mm}$.

EVALUATE: The refractive index of the water is less than that of the glass plate, so the phase changes on reflection are the same as when air is in the space.

35.39. **IDENTIFY** and **SET UP:** Consider the interference of the rays reflected from each side of the film. At the front of the film light in air reflects off the film $(n = 1.432)$ and there is a 180° phase shift. At the back of the film light in the film $(n = 1.432)$ reflects off the glass $(n = 1.62)$ and there is a 180° phase shift. Therefore, the reflections introduce no net phase shift. The path difference is $2t$, where t is the thickness of the film. The wavelength in the film is $\lambda = \dfrac{\lambda_{\text{air}}}{n}$.

EXECUTE: **(a)** Since there is no net phase difference produced by the reflections, the condition for destructive interference is $2t = (m + \frac{1}{2})\lambda.\ t = (m + \frac{1}{2})\dfrac{\lambda}{2}$ and the minimum thickness is $t = \dfrac{\lambda}{4} = \dfrac{\lambda_{\text{air}}}{4n} = \dfrac{550\text{ nm}}{4(1.432)} = 96.0\text{ nm}$.

(b) For destructive interference, $2t = (m + \frac{1}{2})\dfrac{\lambda_{\text{air}}}{n}$ and $\lambda_{\text{air}} = \dfrac{2tn}{m + \frac{1}{2}} = \dfrac{275\text{ nm}}{m + \frac{1}{2}}$. $m = 0$: $\lambda_{\text{air}} = 550\text{ nm}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$m = 1$: $\lambda_{air} = 183$ nm. All other λ_{air} values are shorter. For constructive interference, $2t = m\dfrac{\lambda_{air}}{n}$ and $\lambda_{air} = \dfrac{2tn}{m} = \dfrac{275 \text{ nm}}{m}$. For $m = 1$, $\lambda_{air} = 275$ nm and all other λ_{air} values are shorter.

EVALUATE: The only visible wavelength in air for which there is destructive interference is 550 nm. There are no visible wavelengths in air for which there is constructive interference.

35.40. **IDENTIFY** and **SET UP:** Consider reflection from either side of the film. **(a)** At the front of the film, light in air $(n = 1.00)$ reflects off the film $(n = 1.45)$ and there is a 180° phase shift. At the back of the film, light in the film $(n = 1.45)$ reflects off the cornea $(n = 1.38)$ and there is no phase shift. The reflections produce a net 180° phase difference so the condition for constructive interference is $2t = (m + \frac{1}{2})\lambda$, where $\lambda = \dfrac{\lambda_{air}}{n}$. $t = (m + \frac{1}{2})\dfrac{\lambda_{air}}{2n}$.

EXECUTE: The minimum thickness is for $m = 0$, and is given by $t = \dfrac{\lambda_{air}}{4n} = \dfrac{600 \text{ nm}}{4(1.45)} = 103$ nm (103.4 nm with less rounding).

(b) $\lambda_{air} = \dfrac{2nt}{m + \frac{1}{2}} = \dfrac{2(1.45)(103.4 \text{ nm})}{m + \frac{1}{2}} = \dfrac{300 \text{ nm}}{m + \frac{1}{2}}$. For $m = 0$, $\lambda_{air} = 600$ nm. For $m = 1$, $\lambda_{air} = 200$ nm and all other values are smaller. No other visible wavelengths are reinforced. The condition for destructive interference is $2t = m\dfrac{\lambda_{air}}{n}$. $\lambda = \dfrac{2tn}{m} = \dfrac{300 \text{ nm}}{m}$. For $m = 1$, $\lambda_{air} = 300$ nm and all other values are shorter. There are no visible wavelengths for which there is destructive interference.

(c) Now both rays have a 180° phase change on reflection and the reflections don't introduce any net phase shift. The expression for constructive interference in parts (a) and (b) now gives destructive interference and the expression in (a) and (b) for destructive interference now gives constructive interference. The only visible wavelength for which there will be destructive interference is 600 nm and there are no visible wavelengths for which there will be constructive interference.

EVALUATE: Changing the net phase shift due to the reflections can convert the interference for a particular thickness from constructive to destructive, and vice versa.

35.41. **IDENTIFY:** The insertion of the metal foil produces a wedge of air, which is an air film of varying thickness. This film causes a path difference between light reflected off the top and bottom of this film.

SET UP: The two sheets of glass are sketched in Figure 35.41. The thickness of the air wedge at a distance x from the line of contact is $t = x \tan\theta$. Consider rays 1 and 2 that are reflected from the top and bottom surfaces, respectively, of the air film. Ray 1 has no phase change when it reflects and ray 2 has a 180° phase change when it reflects, so the reflections introduce a net 180° phase difference. The path difference is $2t$ and the wavelength in the film is $\lambda = \lambda_{air}$.

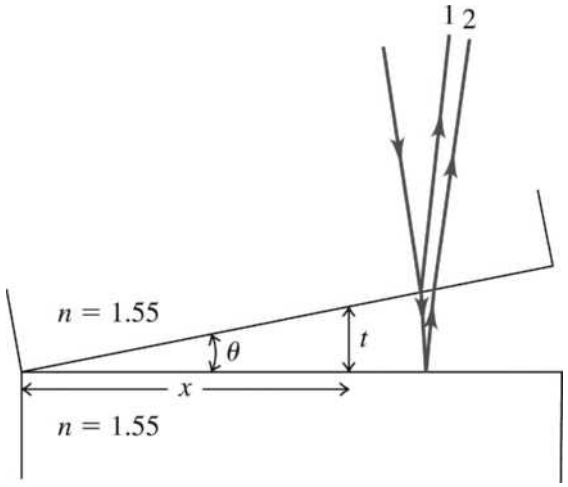


Figure 35.41

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: **(a)** Since there is a 180° phase difference from the reflections, the condition for constructive interference is $2t = (m + \frac{1}{2})\lambda$. The positions of first enhancement correspond to $m = 0$ and $2t = \frac{\lambda}{2}$.

$x \tan\theta = \frac{\lambda}{4}$. θ is a constant, so $\frac{x_1}{\lambda_1} = \frac{x_2}{\lambda_2}$. $x_1 = 1.15$ mm, $\lambda_1 = 400.0$ nm. $x_2 = x_1\left(\frac{\lambda_2}{\lambda_1}\right)$. For $\lambda_2 = 550$ nm (green), $x_2 = (1.15 \text{ mm})\left(\frac{550 \text{ nm}}{400 \text{ nm}}\right) = 1.58$ mm. For $\lambda_2 = 600$ nm (orange), $x_2 = (1.15 \text{ mm})\left(\frac{600 \text{ nm}}{400 \text{ nm}}\right) = 1.72$ mm.

(b) The positions of next enhancement correspond to $m = 1$ and $2t = \frac{3\lambda}{2}$. $x \tan\theta = \frac{3\lambda}{4}$. The values of x are 3 times what they are in part (a). Violet: 3.45 mm; green: 4.74 mm; orange: 5.16 mm.

(c) $\tan\theta = \frac{\lambda}{4x} = \frac{400.0\times10^{-9} \text{ m}}{4(1.15\times10^{-3} \text{ m})} = 8.70\times10^{-5}$. $\tan\theta = \frac{t_{\text{foil}}}{11.0 \text{ cm}}$, so $t_{\text{foil}} = 9.57\times10^{-4}$ cm $= 9.57$ μm.

EVALUATE: The thickness of the foil must be very small to cause these observable interference effects. If it is too thick, the film is no longer a "thin film."

35.42. **IDENTIFY** and **SET UP:** Figure 35.41 for Problem 35.41 also applies in this case, but now the wedge is jelly instead of air and $\lambda = \frac{\lambda_{\text{air}}}{n}$. Ray 1 has a 180° phase shift upon reflection and ray 2 has no phase change. As in Problem 35.41, the reflections introduce a net 180° phase difference. Since the reflections introduce a net 180° phase difference, the condition for destructive interference is $2t = m\frac{\lambda_{\text{air}}}{n}$.

EXECUTE: $2t = m\frac{\lambda_{\text{air}}}{n}$. $t = x\tan\theta$ so $x = m\frac{\lambda_{\text{air}}}{2n\tan\theta}$. The separation Δx between adjacent dark fringes is $\Delta x = \frac{\lambda_{\text{air}}}{2n\tan\theta}$ and $n = \frac{\lambda_{\text{air}}}{2(\Delta x)\tan\theta}$. $\Delta x = \frac{6.33 \text{ mm}}{10} = 0.633$ mm. $\tan\theta = \frac{0.015\times10^{-3} \text{ m}}{8.00\times10^{-2} \text{ m}} = 1.875\times10^{-4}$.

$$n = \frac{525\times10^{-9} \text{ m}}{2(0.633\times10^{-3} \text{ m})(1.875\times10^{-4})} = 2.21.$$

EVALUATE: $n > 1$, as it must be, and $n = 2.21$ is not unreasonable for jelly.

35.43. **IDENTIFY:** The liquid alters the wavelength of the light and that affects the locations of the interference minima.

SET UP: The interference minima are located by $d\sin\theta = (m + \frac{1}{2})\lambda$. For a liquid with refractive index n, $\lambda_{\text{liq}} = \frac{\lambda_{\text{air}}}{n}$.

EXECUTE: $\frac{\sin\theta}{\lambda} = \frac{(m+\frac{1}{2})}{d} =$ constant, so $\frac{\sin\theta_{\text{air}}}{\lambda_{\text{air}}} = \frac{\sin\theta_{\text{liq}}}{\lambda_{\text{liq}}}$. $\frac{\sin\theta_{\text{air}}}{\lambda_{\text{air}}} = \frac{\sin\theta_{\text{liq}}}{\lambda_{\text{air}}/n}$ and

$$n = \frac{\sin\theta_{\text{air}}}{\sin\theta_{\text{liq}}} = \frac{\sin 35.20°}{\sin 19.46°} = 1.730.$$

EVALUATE: In the liquid the wavelength is shorter and $\sin\theta = (m + \frac{1}{2})\frac{\lambda}{d}$ gives a smaller θ than in air, for the same m.

35.44. **IDENTIFY:** As the brass is heated, thermal expansion will cause the two slits to move farther apart.

SET UP: For destructive interference, $d\sin\theta = \lambda/2$. The change in separation due to thermal expansion is $dw = \alpha w_0 dT$, where w is the distance between the slits.

EXECUTE: The first dark fringe is at $d\sin\theta = \lambda/2 \Rightarrow \sin\theta = \lambda/2d$.

Call $d \equiv w$ for these calculations to avoid confusion with the differential. $\sin\theta = \lambda/2w$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

Taking differentials gives $d(\sin\theta) = d(\lambda/2w)$ and $\cos\theta\, d\theta = -\lambda/2\ dw/w^2$. For thermal expansion, $dw = \alpha w_0 dT$, which gives $\cos\theta d\theta = -\frac{\lambda}{2}\frac{\alpha w_0 dT}{w_0^2} = -\frac{\lambda\alpha dT}{2w_0}$. Solving for $d\theta$ gives $d\theta = -\frac{\lambda\alpha dT}{2w_0\cos\theta_0}$.

Get λ: $w_0\sin\theta_0 = \lambda/2 \rightarrow \lambda = 2w_0\sin\theta_0$. Substituting this quantity into the equation for $d\theta$ gives

$$d\theta = -\frac{2w_0\sin\theta_0\,\alpha dT}{2w_0\cos\theta_0} = -\tan\theta_0\,\alpha dT.$$

$d\theta = -\tan(32.5°)(2.0\times10^{-5}\ \text{K}^{-1})(115\ \text{K}) = -0.001465\ \text{rad} = -0.084°$

The minus sign tells us that the dark fringes move closer together.

EVALUATE: We can also see that the dark fringes move closer together because $\sin\theta$ is proportional to $1/d$, so as d increases due to expansion, θ decreases.

35.45. **IDENTIFY:** *Both* frequencies will interfere constructively when the path difference from both of them is an integral number of wavelengths.

SET UP: Constructive interference occurs when $\sin\theta = m\lambda/d$.

EXECUTE: First find the two wavelengths.

$$\lambda_1 = v/f_1 = (344\ \text{m/s})/(900\ \text{Hz}) = 0.3822\ \text{m}$$

$$\lambda_2 = v/f_2 = (344\ \text{m/s})/(1200\ \text{Hz}) = 0.2867\ \text{m}$$

To interfere constructively at the same angle, the angles must be the same, and hence the sines of the angles must be equal. Each sine is of the form $\sin\theta = m\lambda/d$, so we can equate the sines to get

$$m_1\lambda_1/d = m_2\lambda_2/d$$
$$m_1(0.3822\ \text{m}) = m_2(0.2867\ \text{m})$$
$$m_2 = 4/3\ m_1$$

Since both m_1 and m_2 must be integers, the allowed pairs of values of m_1 and m_2 are

$$m_1 = m_2 = 0$$
$$m_1 = 3,\ m_2 = 4$$
$$m_1 = 6,\ m_2 = 8$$
$$m_1 = 9,\ m_2 = 12$$
$$\text{etc.}$$

For $m_1 = m_2 = 0$, we have $\theta = 0$,

For $m_1 = 3$, $m_2 = 4$, we have $\sin\theta_1 = (3)(0.3822\ \text{m})/(2.50\ \text{m})$, giving $\theta_1 = 27.3°$.

For $m_1 = 6$, $m_2 = 8$, we have $\sin\theta_1 = (6)(0.3822\ \text{m})/(2.50\ \text{m})$, giving $\theta_1 = 66.5°$.

For $m_1 = 9$, $m_2 = 12$, we have $\sin\theta_1 = (9)(0.3822\ \text{m})/(2.50\ \text{m}) = 1.38 > 1$, so no angle is possible.

EVALUATE: At certain other angles, one frequency will interfere constructively, but the other will not.

35.46. **IDENTIFY:** For destructive interference, $d = r_2 - r_1 = \left(m + \frac{1}{2}\right)\lambda$.

SET UP: $r_2 - r_1 = \sqrt{(200\ \text{m})^2 + x^2} - x$

EXECUTE: $(200\ \text{m})^2 + x^2 = x^2 + \left[\left(m + \frac{1}{2}\right)\lambda\right]^2 + 2x\left(m + \frac{1}{2}\right)\lambda$.

$x = \frac{20{,}000\ \text{m}^2}{\left(m + \frac{1}{2}\right)\lambda} - \frac{1}{2}\left(m + \frac{1}{2}\right)\lambda$. The wavelength is calculated by $\lambda = \frac{c}{f} = \frac{3.00\times10^8\ \text{m/s}}{5.80\times10^6\ \text{Hz}} = 51.7\ \text{m}$.

$m = 0 : x = 761\ \text{m};\ m = 1 : x = 219\ \text{m};\ m = 2 : x = 90.1\ \text{m};\ m = 3; x = 20.0\ \text{m}$.

EVALUATE: For $m = 3$, $d = 3.5\lambda = 181\ \text{m}$. The maximum possible path difference is the separation of 200 m between the sources.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

35.47. **IDENTIFY:** The two scratches are parallel slits, so the light that passes through them produces an interference pattern. However, the light is traveling through a medium (plastic) that is different from air.
SET UP: The central bright fringe is bordered by a dark fringe on each side of it. At these dark fringes, $d \sin\theta = \frac{1}{2}\lambda/n$, where n is the refractive index of the plastic.

EXECUTE: First use geometry to find the angles at which the two dark fringes occur. At the first dark fringe $\tan\theta = [(5.82 \text{ mm})/2]/(3250 \text{ mm})$, giving $\theta = \pm 0.0513°$.

For destructive interference, we have $d \sin\theta = \frac{1}{2}\lambda/n$ and

$$n = \lambda/(2d \sin\theta) = (632.8 \text{ nm})/[2(0.000225 \text{ m})(\sin\ 0.0513°)] = 1.57$$

EVALUATE: The wavelength of the light in the plastic is reduced compared to what it would be in air.

35.48. **IDENTIFY:** Interference occurs due to the path difference of light in the thin film.
SET UP: Originally the path difference was an odd number of half-wavelengths for cancellation to occur. If the path difference decreases by ½ wavelength, it will be a multiple of the wavelength, so constructive interference will occur.
EXECUTE: Calling ΔT the thickness that must be removed, we have

$$\text{path difference} = 2\Delta T = \tfrac{1}{2}\lambda/n \text{ and } \Delta T = \lambda/4n = (525 \text{ nm})/[4(1.40)] = 93.75 \text{ nm}$$

At 4.20 nm/yr, we have $(4.20 \text{ nm/yr})t = 93.75 \text{ nm}$ and $t = 22.3$ yr.

EVALUATE: If you were giving a warranty on this film, you certainly could not give it a "lifetime guarantee"!

35.49. **IDENTIFY:** For destructive interference the net phase difference must be 180°, which is one-half a period, or $\lambda/2$. Part of this phase difference is due to the fact that the speakers are ¼ of a period out of phase, and the rest is due to the path difference between the sound from the two speakers.
SET UP: The phase of A is 90° or, $\lambda/4$, ahead of B. At points above the centerline, points are closer to A than to B and the signal from A gains phase relative to B because of the path difference. Destructive interference will occur when $d \sin\theta = (m + \frac{1}{4})\lambda$, $m = 0, 1, 2, \ldots$. At points at an angle θ below the centerline, the signal from B gains phase relative to A because of the phase difference. Destructive interference will occur when $d \sin\theta = (m + \frac{3}{4})\lambda$, $m = 0, 1, 2, \ldots$. $\lambda = \dfrac{v}{f}$.

EXECUTE: $\lambda = \dfrac{340 \text{ m/s}}{444 \text{ Hz}} = 0.766 \text{ m}$.

Points above the centerline: $\sin\theta = (m + \frac{1}{4})\dfrac{\lambda}{d} = (m + \frac{1}{4})\left(\dfrac{0.766 \text{ m}}{3.50 \text{ m}}\right) = 0.219(m + \frac{1}{4})$. $m = 0$: $\theta = 3.14°$;
$m = 1$: $\theta = 15.9°$; $m = 2$: $\theta = 29.5°$; $m = 3$: $\theta = 45.4°$; $m = 4$: $\theta = 68.6°$.

Points below the centerline: $\sin\theta = (m + \frac{3}{4})\dfrac{\lambda}{d} = (m + \frac{3}{4})\left(\dfrac{0.766 \text{ m}}{3.50 \text{ m}}\right) = 0.219(m + \frac{3}{4})$. $m = 0$: $\theta = 9.45°$;
$m = 1$: $\theta = 22.5°$; $m = 2$: $\theta = 37.0°$; $m = 3$: $\theta = 55.2°$.

EVALUATE: It is *not* always true that the path difference for destructive interference must be $(m + \frac{1}{2})\lambda$, but it *is* always true that the phase difference must be 180° (or odd multiples of 180°).

35.50. **IDENTIFY:** Follow the steps specified in the problem.
SET UP: Use $\cos(\omega t + \phi/2) = \cos(\omega t)\cos(\phi/2) - \sin(\omega t)\sin(\phi/2)$. Then
$2\cos(\phi/2)\cos(\omega t + \phi/2) = 2\cos(\omega t)\cos^2(\phi/2) - 2\sin(\omega t)\sin(\phi/2)\cos(\phi/2)$. Then use
$\cos^2(\phi/2) = \dfrac{1 + \cos(\phi)}{2}$ and $2\sin(\phi/2)\cos(\phi/2) = \sin\phi$. This gives
$\cos(\omega t) + (\cos(\omega t)\cos(\phi) - \sin(\omega t)\sin(\phi)) = \cos(\omega t) + \cos(\omega t + \phi)$, using again the trig identity for the cosine of the sum of two angles.
EXECUTE: **(a)** The electric field is the sum of the two fields and can be written as
$E_P(t) = E_2(t) + E_1(t) = E\cos(\omega t) + E\cos(\omega t + \phi)$. $E_P(t) = 2E\cos(\phi/2)\cos(\omega t + \phi/2)$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) $E_p(t) = A\cos(\omega t + \phi/2)$, so comparing with part (a), we see that the amplitude of the wave (which is always positive) must be $A = 2E\left|\cos(\phi/2)\right|$.

(c) To have an interference maximum, $\frac{\phi}{2} = 2\pi m$. So, for example, using $m = 1$, the relative phases are

E_2: 0; E_1: $\phi = 4\pi$; E_p: $\frac{\phi}{2} = 2\pi$, and all waves are in phase.

(d) To have an interference minimum, $\frac{\phi}{2} = \pi\left(m + \frac{1}{2}\right)$. So, for example using $m = 0$, relative phases are

E_2: 0; E_1: $\phi = \pi$; E_p: $\phi/2 = \pi/2$, and the resulting wave is out of phase by a quarter of a cycle from both of the original waves.

(e) The instantaneous magnitude of the Poynting vector is

$$|\vec{S}| = \varepsilon_0 c E_p^2(t) = \varepsilon_0 c(4E^2\cos^2(\phi/2)\cos^2(\omega t + \phi/2)).$$

For a time average, $\cos^2(\omega t + \phi/2) = \frac{1}{2}$, so $|S_{\text{av}}| = 2\varepsilon_0 c E^2\cos^2(\phi/2)$.

EVALUATE: The result of part (e) shows that the intensity at a point depends on the phase difference ϕ at that point for the waves from each source.

35.51. **IDENTIFY** and **SET UP:** Consider interference between rays reflected from the upper and lower surfaces of the film to relate the thickness of the film to the wavelengths for which there is destructive interference. The thermal expansion of the film changes the thickness of the film when the temperature changes.

EXECUTE: For this film on this glass, there is a net $\lambda/2$ phase change due to reflection and the condition for destructive interference is $2t = m(\lambda/n)$, where $n = 1.750$.

Smallest nonzero thickness is given by $t = \lambda/2n$.

At 20.0°C, $t_0 = (582.4\text{ nm})/[(2)(1.750)] = 166.4\text{ nm}$.

At 170°C, $t = (588.5\text{ nm})/[(2)(1.750)] = 168.1\text{ nm}$.

$t = t_0(1 + \alpha\Delta T)$ so

$\alpha = (t - t_0)/(t_0\Delta T) = (1.7\text{ nm})/[(166.4\text{ nm})(150\text{C°})] = 6.8\times10^{-5}(\text{C°})^{-1}$

EVALUATE: When the film is heated its thickness increases, and it takes a larger wavelength in the film to equal 2*t*.The value we calculated for α is the same order of magnitude as those given in Table 17.1.

35.52. **IDENTIFY:** The maximum intensity occurs at all the points of constructive interference. At these points, the path difference between waves from the two transmitters is an integral number of wavelengths.

SET UP: For constructive interference, $\sin\theta = m\lambda/d$.

EXECUTE: **(a)** First find the wavelength of the UHF waves:

$$\lambda = c/f = (3.00\times10^8\text{ m/s})/(1575.42\text{ MHz}) = 0.1904\text{ m}$$

For maximum intensity $(\pi d\sin\theta)/\lambda = m\pi$, so

$$\sin\theta = m\lambda/d = m[(0.1904\text{ m})/(5.18\text{ m})] = 0.03676m$$

The maximum possible *m* would be for $\theta = 90°$, or $\sin\theta = 1$, so

$$m_{\text{max}} = d/\lambda = (5.18\text{ m})/(0.1904\text{ m}) = 27.2$$

which must be ±27 since *m* is an integer. The total number of maxima is 27 on either side of the central fringe, plus the central fringe, for a total of $27 + 27 + 1 = 55$ bright fringes.

(b) Using $\sin\theta = m\lambda/d$, where $m = 0, \pm1, \pm2$, and ±3, we have

$$\sin\theta = m\lambda/d = m[(0.1904\text{ m})/(5.18\text{ m})] = 0.03676m$$

$m = \theta$: $\sin\theta = 0$, which gives $\theta = 0°$

$m = \pm1$: $\sin\theta = \pm(0.03676)(1)$, which gives $\theta = \pm2.11°$

$m = \pm2$: $\sin\theta = \pm(0.03676)(2)$, which gives $\theta = \pm4.22°$

$m = \pm3$: $\sin\theta = \pm(0.03676)(3)$, which gives $\theta = \pm6.33°$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(c) $I = I_0\cos^2\left(\dfrac{\pi d\sin\theta}{\lambda}\right) = (2.00\text{W/m}^2)\cos^2\left[\dfrac{\pi(5.18\text{ m})\sin(4.65°)}{0.1904\text{ m}}\right] = 1.28\text{ W/m}^2.$

EVALUATE: Notice that $\sin\theta$ increases in integer steps, but θ only increases in integer steps for small θ.

35.53. **IDENTIFY:** Apply $I = I_0\cos\left(\dfrac{\pi d}{\lambda}\sin\theta\right)$.

SET UP: $I = I_0/2$ when $\dfrac{\pi d}{\lambda}\sin\theta$ is $\dfrac{\pi}{4}$ rad, $\dfrac{3\pi}{4}$ rad,….

EXECUTE: First we need to find the angles at which the intensity drops by one-half from the value of the m^{th} bright fringe. $I = I_0\cos^2\left(\dfrac{\pi d}{\lambda}\sin\theta\right) = \dfrac{I_0}{2} \Rightarrow \dfrac{\pi d}{\lambda}\sin\theta \approx \dfrac{\pi d\theta_m}{\lambda} = (m+1/2)\dfrac{\pi}{2}.$

$m = 0: \theta = \theta_m^- = \dfrac{\lambda}{4d}$; $m = 1: \theta = \theta_m^+ = \dfrac{3\lambda}{4d} \Rightarrow \Delta\theta_m = \dfrac{\lambda}{2d}.$

EVALUATE: There is no dependence on the *m*-value of the fringe, so all fringes at small angles have the same half-width.

35.54. **IDENTIFY:** Consider the phase difference produced by the path difference and by the reflections.

SET UP: There is just one half-cycle phase change upon reflection, so for constructive interference $2t = (m_1 + \tfrac{1}{2})\lambda_1 = (m_2 + \tfrac{1}{2})\lambda_2,$ where these wavelengths are in the glass. The two different wavelengths differ by just one m-value, $m_2 = m_1 - 1$.

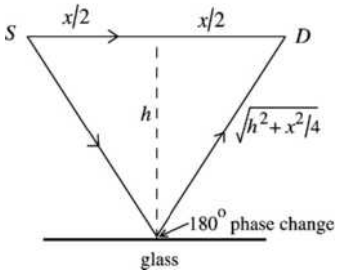
EXECUTE: $\left(m_1 + \dfrac{1}{2}\right)\lambda_1 = \left(m_1 - \dfrac{1}{2}\right)\lambda_2 \Rightarrow m_1(\lambda_2 - \lambda_1) = \dfrac{\lambda_1 + \lambda_2}{2} \Rightarrow m_1 = \dfrac{\lambda_1 + \lambda_2}{2(\lambda_2 - \lambda_1)}.$

$m_1 = \dfrac{477.0\text{ nm} + 540.6\text{ nm}}{2(540.6\text{ nm} - 477.0\text{ nm})} = 8.\ \ 2t = \left(8 + \dfrac{1}{2}\right)\dfrac{\lambda_{01}}{n} \Rightarrow t = \dfrac{17(477.0\text{ nm})}{4(1.52)} = 1334\text{ nm}.$

EVALUATE: Now that we have *t* we can calculate all the other wavelengths for which there is constructive interference.

35.55. **IDENTIFY:** Consider the phase difference due to the path difference and due to the reflection of one ray from the glass surface.

(a) SET UP: Consider Figure 35.55.



path difference =
$2\sqrt{h^2 + x^2/4} - x = \sqrt{4h^2 + x^2} - x$

Figure 35.55

Since there is a 180° phase change for the reflected ray, the condition for constructive interference is path difference $= \left(m + \dfrac{1}{2}\right)\lambda$ and the condition for destructive interference is path difference $= m\lambda$.

(b) EXECUTE: Constructive interference: $\left(m + \dfrac{1}{2}\right)\lambda = \sqrt{4h^2 + x^2} - x$ and $\lambda = \dfrac{\sqrt{4h^2 + x^2} - x}{m + \dfrac{1}{2}}$. Longest λ is for $m = 0$ and then $\lambda = 2\left(\sqrt{4h^2 + x^2} - x\right) = 2\left(\sqrt{4(0.24\text{ m})^2 + (0.14\text{ m})^2} - 0.14\text{ m}\right) = 0.72\text{ m}$

EVALUATE: For $\lambda = 0.72$ m the path difference is $\lambda/2$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

35.56. **IDENTIFY:** Require constructive interference for the reflection from the top and bottom surfaces of each cytoplasm layer and each guanine layer.
SET UP: At the water (or cytoplasm) to guanine interface, there is a half-cycle phase shift for the reflected light, but there is not one at the guanine to cytoplasm interface. Therefore there will always be one half-cycle phase difference between two neighboring reflected beams, just due to the reflections.
EXECUTE: For the guanine layers:

$$2t_g = \left(m + \frac{1}{2}\right)\frac{\lambda}{n_g} \Rightarrow \lambda = \frac{2t_g n_g}{(m+\frac{1}{2})} = \frac{2(74\text{ nm})(1.80)}{(m+\frac{1}{2})} = \frac{266\text{ nm}}{(m+\frac{1}{2})} \Rightarrow \lambda = 533\text{ nm } (m=0).$$

For the cytoplasm layers:

$$2t_c = \left(m + \frac{1}{2}\right)\frac{\lambda}{n_c} \Rightarrow \lambda = \frac{2t_c n_c}{(m+\frac{1}{2})} = \frac{2(100\text{ nm})(1.333)}{(m+\frac{1}{2})} = \frac{267\text{ nm}}{(m+\frac{1}{2})} \Rightarrow \lambda = 533\text{ nm } (m=0)\ .$$

(b) By having many layers the reflection is strengthened, because at each interface some more of the transmitted light gets reflected back, increasing the total percentage reflected.
(c) At different angles, the path length in the layers changes (always to a larger value than the normal incidence case). If the path length changes, then so do the wavelengths that will interfere constructively upon reflection.
EVALUATE: The thickness of the guanine and cytoplasm layers are inversely proportional to their refractive indices $\left(\frac{100}{74} = \frac{1.80}{1.333}\right)$, so both kinds of layers produce constructive interference for the same wavelength in air.

35.57. **IDENTIFY:** The slits will produce an interference pattern, but in the liquid, the wavelength of the light will be less than it was in air.
SET UP: The first bright fringe occurs when $d\ \sin\theta = \lambda/n$.
EXECUTE: In air: $d\sin 18.0° = \lambda$. In the liquid: $d\sin 12.6° = \lambda/n$. Dividing the equations gives

$$n = (\sin 18.0°)/(\sin 12.6°) = 1.42$$

EVALUATE: It was not necessary to know the spacing of the slits, since it was the same in both air and the liquid.

35.58. **IDENTIFY** and **SET UP:** At the $m = 3$ bright fringe for the red light there must be destructive interference at this same θ for the other wavelength.
EXECUTE: For constructive interference: $d\sin\theta = m\lambda_1 \Rightarrow d\sin\theta = 3(700\text{ nm}) = 2100\text{ nm}$. For destructive interference: $d\sin\theta = \left(m + \frac{1}{2}\right)\lambda_2 \Rightarrow \lambda_2 = \frac{d\sin\theta}{m+\frac{1}{2}} = \frac{2100\text{ nm}}{m+\frac{1}{2}}$. So the possible wavelengths are $\lambda_2 = 600$ nm, for $m = 3$, and $\lambda_2 = 467$ nm, for $m = 4$.
EVALUATE: Both d and θ drop out of the calculation since their combination is just the path difference, which is the same for both types of light.

35.59. **(a) IDENTIFY:** The wavelength in the glass is decreased by a factor of $1/n$, so for light through the upper slit a shorter path is needed to produce the same phase at the screen. Therefore, the interference pattern is shifted downward on the screen.
(b) SET UP: Consider the total phase difference produced by the path length difference and also by the different wavelength in the glass.
EXECUTE: At a point on the screen located by the angle θ the difference in path length is $d\sin\theta$. This introduces a phase difference of $\phi = \left(\frac{2\pi}{\lambda_0}\right)(d\sin\theta)$, where λ_0 is the wavelength of the light in air or vacuum. In the thickness L of glass the number of wavelengths is $\frac{L}{\lambda} = \frac{nL}{\lambda_0}$. A corresponding length L of the path of the ray through the lower slit, in air, contains L/λ_0 wavelengths. The phase difference this introduces is $\phi = 2\pi\left(\frac{nL}{\lambda_0} - \frac{L}{\lambda_0}\right)$ and $\phi = 2\pi(n-1)(L/\lambda_0)$. The total phase difference is the sum of these

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

two, $\left(\frac{2\pi}{\lambda_0}\right)(d\sin\theta)+2\pi(n-1)(L/\lambda_0)=(2\pi/\lambda_0)(d\sin\theta+L(n-1))$. Eq. (35.10) then gives

$$I=I_0\cos^2\left[\left(\frac{\pi}{\lambda_0}\right)(d\sin\theta+L(n-1))\right].$$

(c) Maxima means $\cos\phi/2=\pm1$ and $\phi/2=m\pi, m=0,\pm1,\pm2,\ldots$ $(\pi/\lambda_0)(d\sin\theta+L(n-1))=m\pi$

$$d\sin\theta+L(n-1)=m\lambda_0$$

$$\sin\theta=\frac{m\lambda_0-L(n-1)}{d}$$

EVALUATE: When $L\to0$ or $n\to1$ the effect of the plate goes away and the maxima are located by Eq. (35.4).

35.60. **IDENTIFY:** Dark fringes occur because the path difference is one-half of a wavelength.

SET UP: At the first dark fringe, $d\sin\theta=\lambda/2$. The intensity at any angle θ is given by

$$I=I_0\cos^2\left(\frac{\pi d\sin\theta}{\lambda}\right).$$

EXECUTE: **(a)** At the first dark fringe, we have $d\sin\theta=\lambda/2$. $d/\lambda=1/(2\sin19.0°)=1.54$.

(b) $I=I_0\cos^2\left(\frac{\pi d\sin\theta}{\lambda}\right)=\frac{I_0}{10}\Rightarrow\cos\left(\frac{\pi d\sin\theta}{\lambda}\right)=\frac{1}{\sqrt{10}}$. $\frac{\pi d\sin\theta}{\lambda}=\arccos\left(\frac{1}{\sqrt{10}}\right)=71.57°=1.249$ rad.

Using the result from part (a), that $d/\lambda=1.54$, we have

$\pi(1.54)\sin\theta=1.249$. $\sin\theta=0.2589$, so $\theta=\pm15.0°$.

EVALUATE: Since the first dark fringes occur at $\pm19.0°$, it is reasonable that at 15° the intensity is reduced to only $1/10$ of its maximum central value.

35.61. **IDENTIFY:** There are two effects to be considered: first, the expansion of the rod, and second, the change in the rod's refractive index.

SET UP: $\lambda=\frac{\lambda_0}{n}$ and $\Delta n=n_0(2.50\times10^{-5}\ (\text{C°})^{-1})\Delta T$. $\Delta L=L_0(5.00\times10^{-6}\ (\text{C°})^{-1})\Delta T$.

EXECUTE: The extra length of rod replaces a little of the air so that the change in the number of wavelengths due to this is given by: $\Delta N_1=\frac{2n_{\text{glass}}\Delta L}{\lambda_0}-\frac{2n_{\text{air}}\Delta L}{\lambda_0}=\frac{2(n_{\text{glass}}-1)L_0\alpha\Delta T}{\lambda_0}$ and

$$\Delta N_1=\frac{2(1.48-1)(0.030\text{ m})(5.00\times10^{-6}/\text{C°})(5.00\text{ C°})}{5.89\times10^{-7}\text{ m}}=1.22.$$

The change in the number of wavelengths due to the change in refractive index of the rod is:

$$\Delta N_2=\frac{2\Delta n_{\text{glass}}L_0}{\lambda_0}=\frac{2(2.50\times10^{-5}/\text{C°})(5.00\text{ C°/min})(1.00\text{ min})(0.0300\text{ m})}{5.89\times10^{-7}\text{m}}=12.73.$$

So, the total change in the number of wavelengths as the rod expands is

$\Delta N=12.73+1.22=14.0$ fringes/minute.

EVALUATE: Both effects increase the number of wavelengths along the length of the rod. Both ΔL and Δn_{glass} are very small and the two effects can be considered separately.

35.62. **IDENTIFY:** Apply Snell's law to the refraction at the two surfaces of the prism. S_1 and S_2 serve as coherent sources so the fringe spacing is $\Delta y=\frac{R\lambda}{d}$, where d is the distance between S_1 and S_2.

SET UP: For small angles, $\sin\theta\approx\theta$, with θ expressed in radians.

EXECUTE: **(a)** Since we can approximate the angles of incidence on the prism as being small, Snell's law tells us that an incident angle of θ on the flat side of the prism enters the prism at an angle of θ/n, where n is the index of refraction of the prism. Similarly on leaving the prism, the in-going angle is $\theta/n-A$ from the normal, and the outgoing angle, relative to the prism, is $n(\theta/n-A)$. So the beam leaving the prism is at an angle of $\theta'=n(\theta/n-A)+A$ from the optical axis. So $\theta-\theta'=(n-1)A$. At the plane of the

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

source S_0, we can calculate the height of one image above the source:

$$\frac{d}{2} = \tan(\theta - \theta')a \approx (\theta - \theta')a = (n-1)Aa \Rightarrow d = 2aA(n-1).$$

(b) To find the spacing of fringes on a screen, we use

$$\Delta y = \frac{R\lambda}{d} = \frac{R\lambda}{2aA(n-1)} = \frac{(2.00\text{ m} + 0.200\text{ m})\,(5.00\times10^{-7}\text{ m})}{2(0.200\text{ m})\,(3.50\times10^{-3}\text{ rad})\,(1.50-1.00)} = 1.57\times10^{-3}\text{ m}.$$

EVALUATE: The fringe spacing is proportional to the wavelength of the light. The biprism serves as an alternative to two closely spaced narrow slits.

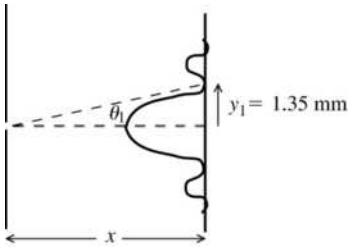
36

DIFFRACTION

36.1. **IDENTIFY:** Use $y = x\tan\theta$ to calculate the angular position θ of the first minimum. The minima are located by Eq. (36.2): $\sin\theta = \dfrac{m\lambda}{a}$, $m = \pm 1, \pm 2, \ldots$ First minimum means $m = 1$ and $\sin\theta_1 = \lambda/a$ and $\lambda = a\sin\theta_1$. Use this equation to calculate λ.

SET UP: The central maximum is sketched in Figure 36.1.



EXECUTE: $y_1 = x\tan\theta_1$

$\tan\theta_1 = \dfrac{y_1}{x} =$

$\dfrac{1.35\times10^{-3}\text{ m}}{2.00\text{ m}} = 0.675\times10^{-3}$

$\theta_1 = 0.675\times10^{-3}$ rad

Figure 36.1

$\lambda = a\sin\theta_1 = (0.750\times10^{-3}\text{ m})\sin(0.675\times10^{-3}\text{ rad}) = 506\text{ nm}$

EVALUATE: θ_1 is small so the approximation used to obtain Eq. (36.3) is valid and this equation could have been used.

36.2. **IDENTIFY:** The angle is small, so $y_m = x\dfrac{m\lambda}{a}$.

SET UP: $y_1 = 10.2$ mm

EXECUTE: $y_1 = \dfrac{x\lambda}{a} \Rightarrow a = \dfrac{x\lambda}{y_1} = \dfrac{(0.600\text{ m})(5.46\times10^{-7}\text{ m})}{10.2\times10^{-3}\text{ m}} = 3.21\times10^{-5}\text{ m}.$

EVALUATE: The diffraction pattern is observed at a distance of 60.0 cm from the slit.

36.3. **IDENTIFY:** The dark fringes are located at angles θ that satisfy $\sin\theta = \dfrac{m\lambda}{a}$, $m = \pm 1, \pm 2, \ldots$.

SET UP: The largest value of $|\sin\theta|$ is 1.00.

EXECUTE: **(a)** Solve for m that corresponds to $\sin\theta = 1$: $m = \dfrac{a}{\lambda} = \dfrac{0.0666\times10^{-3}\text{ m}}{585\times10^{-9}\text{ m}} = 113.8$. The largest value m can have is 113. $m = \pm 1, \pm 2, \ldots, \pm 113$ gives 226 dark fringes.

(b) For $m = \pm 113$, $\sin\theta = \pm 113\left(\dfrac{585\times10^{-9}\text{ m}}{0.0666\times10^{-3}\text{ m}}\right) = \pm 0.9926$ and $\theta = \pm 83.0°$.

EVALUATE: When the slit width a is decreased, there are fewer dark fringes. When $a < \lambda$ there are no dark fringes and the central maximum completely fills the screen.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

36.4. **IDENTIFY** and **SET UP:** λ/a is very small, so the approximate expression $y_m = R\dfrac{m\lambda}{a}$ is accurate. The distance between the two dark fringes on either side of the central maximum is $2y_1$.

EXECUTE: $y_1 = \dfrac{\lambda R}{a} = \dfrac{(633\times10^{-9}\text{ m})(3.50\text{ m})}{0.750\times10^{-3}\text{ m}} = 2.95\times10^{-3}\text{ m} = 2.95\text{ mm}.$ $2y_1 = 5.90\text{ mm}.$

EVALUATE: When a is decreased, the width $2y_1$ of the central maximum increases.

36.5. **IDENTIFY:** The minima are located by $\sin\theta = \dfrac{m\lambda}{a}$.

SET UP: $a = 12.0\text{ cm}.$ $x = 8.00\text{ m}.$

EXECUTE: The angle to the first minimum is $\theta = \arcsin\left(\dfrac{\lambda}{a}\right) = \arcsin\left(\dfrac{9.00\text{ cm}}{12.00\text{ cm}}\right) = 48.6°.$

So the distance from the central maximum to the first minimum is just
$y_1 = x\tan\theta = (8.00\text{ m})\tan(48.6°) = \pm(9.07\text{ m}).$

EVALUATE: $2\lambda/a$ is greater than 1, so only the $m = 1$ minimum is seen.

36.6. **IDENTIFY:** The angle that locates the first diffraction minimum on one side of the central maximum is given by $\sin\theta = \dfrac{\lambda}{a}$. The time between crests is the period T. $f = \dfrac{1}{T}$ and $\lambda = \dfrac{v}{f}$.

SET UP: The time between crests is the period, so $T = 1.0\text{ h}.$

EXECUTE: **(a)** $f = \dfrac{1}{T} = \dfrac{1}{1.0\text{ h}} = 1.0\text{ h}^{-1}.$ $\lambda = \dfrac{v}{f} = \dfrac{800\text{ km/h}}{1.0\text{ h}^{-1}} = 800\text{ km}.$

(b) Africa-Antarctica: $\sin\theta = \dfrac{800\text{ km}}{4500\text{ km}}$ and $\theta = 10.2°.$

Australia-Antarctica: $\sin\theta = \dfrac{800\text{ km}}{3700\text{ km}}$ and $\theta = 12.5°.$

EVALUATE: Diffraction effects are observed when the wavelength is about the same order of magnitude as the dimensions of the opening through which the wave passes.

36.7. **IDENTIFY:** We can model the hole in the concrete barrier as a single slit that will produce a single-slit diffraction pattern of the water waves on the shore.

SET UP: For single-slit diffraction, the angles at which destructive interference occurs are given by $\sin\theta_m = m\lambda/a$, where $m = 1, 2, 3, \ldots$.

EXECUTE: **(a)** The frequency of the water waves is $f = 75.0\text{ min}^{-1} = 1.25\text{ s}^{-1} = 1.25\text{ Hz},$ so their wavelength is $\lambda = v/f = (15.0\text{ cm/s})/(1.25\text{ Hz}) = 12.0\text{ cm}.$

At the first point for which destructive interference occurs, we have
$\tan\theta = (0.613\text{ m})/(3.20\text{ m}) \Rightarrow \theta = 10.84°.$ $a\sin\theta = \lambda$ and

$$a = \lambda/\sin\theta = (12.0\text{ cm})/(\sin 10.84°) = 63.8\text{ cm}.$$

(b) First find the angles at which destructive interference occurs.

$$\sin\theta_2 = 2\lambda/a = 2(12.0\text{ cm})/(63.8\text{ cm}) \rightarrow \theta_2 = \pm22.1°$$

$$\sin\theta_3 = 3\lambda/a = 3(12.0\text{ cm})/(63.8\text{ cm}) \rightarrow \theta_3 = \pm34.3°$$

$$\sin\theta_4 = 4\lambda/a = 4(12.0\text{ cm})/(63.8\text{ cm}) \rightarrow \theta_4 = \pm48.8°$$

$$\sin\theta_5 = 5\lambda/a = 5(12.0\text{ cm})/(63.8\text{ cm}) \rightarrow \theta_5 = \pm70.1°$$

EVALUATE: These are large angles, so we cannot use the approximation that $\theta_m \approx m\lambda/a$.

36.8. **IDENTIFY:** The angle is small, so $y_m = x\dfrac{m\lambda}{a}$ applies.

SET UP: The width of the central maximum is $2y_1,$ so $y_1 = 3.00\text{ mm}.$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: **(a)** $y_1 = \dfrac{x\lambda}{a} \Rightarrow a = \dfrac{x\lambda}{y_1} = \dfrac{(2.50\text{ m})(5.00\times10^{-7}\text{ m})}{3.00\times10^{-3}\text{ m}} = 4.17\times10^{-4}\text{ m}.$

(b) $a = \dfrac{x\lambda}{y_1} = \dfrac{(2.50\text{ m})(5.00\times10^{-5}\text{ m})}{3.00\times10^{-3}\text{ m}} = 4.17\times10^{-2}\text{ m} = 4.2\text{ cm}.$

(c) $a = \dfrac{x\lambda}{y_1} = \dfrac{(2.50\text{ m})(5.00\times10^{-10}\text{ m})}{3.00\times10^{-3}\text{ m}} = 4.17\times10^{-7}\text{ m}.$

EVALUATE: The ratio a/λ stays constant, so a is smaller when λ is smaller.

36.9. **IDENTIFY** and **SET UP:** $v = f\lambda$ gives λ. The person hears no sound at angles corresponding to diffraction minima. The diffraction minima are located by $\sin\theta = m\lambda/a$, $m = \pm1, \pm2, \ldots$ Solve for θ.

EXECUTE: $\lambda = v/f = (344\text{ m/s})/(1250\text{ Hz}) = 0.2752\text{ m}$; $a = 1.00\text{ m}$. $m = \pm1$, $\theta = \pm16.0°$; $m = \pm2$, $\theta = \pm33.4°$; $m = \pm3$, $\theta = \pm55.6°$; no solution for larger m

EVALUATE: $\lambda/a = 0.28$ so for the large wavelength sound waves diffraction by the doorway is a large effect. Diffraction would not be observable for visible light because its wavelength is much smaller and $\lambda/a \ll 1$.

36.10. **IDENTIFY:** Compare E_y to the expression $E_y = E_{\max}\sin(kx - \omega t)$ and determine k, and from that calculate λ. $f = c/\lambda$. The dark bands are located by $\sin\theta = \dfrac{m\lambda}{a}$.

SET UP: $c = 3.00\times10^8$ m/s. The first dark band corresponds to $m = 1$.

EXECUTE: **(a)** $E = E_{\max}\sin(kx - \omega t)$. $k = \dfrac{2\pi}{\lambda} \Rightarrow \lambda = \dfrac{2\pi}{k} = \dfrac{2\pi}{1.20\times10^7\text{ m}^{-1}} = 5.24\times10^{-7}\text{ m}.$

$f\lambda = c \Rightarrow f = \dfrac{c}{\lambda} = \dfrac{3.0\times10^8\text{ m/s}}{5.24\times10^{-7}\text{ m}} = 5.73\times10^{14}\text{ Hz}.$

(b) $a\sin\theta = \lambda$. $a = \dfrac{\lambda}{\sin\theta} = \dfrac{5.24\times10^{-7}\text{ m}}{\sin 28.6°} = 1.09\times10^{-6}\text{ m}.$

(c) $a\sin\theta = m\lambda (m = 1, 2, 3, \ldots)$. $\sin\theta_2 = \pm2\dfrac{\lambda}{a} = \pm2\dfrac{5.24\times10^{-7}\text{ m}}{1.09\times10^{-6}\text{ m}}$ and $\theta_2 = \pm74°$.

EVALUATE: For $m = 3$, $\dfrac{m\lambda}{a}$ is greater than 1 so only the first and second dark bands appear.

36.11. **IDENTIFY** and **SET UP:** $\sin\theta = \lambda/a$ locates the first minimum. $y = x\tan\theta$.

EXECUTE: $\tan\theta = y/x = (36.5\text{ cm})/(40.0\text{ cm})$ and $\theta = 42.38°$.

$a = \lambda/\sin\theta = (620\times10^{-9}\text{ m})/(\sin 42.38°) = 0.920\ \mu\text{m}$

EVALUATE: $\theta = 0.74$ rad and $\sin\theta = 0.67$, so the approximation $\sin\theta \approx \theta$ would not be accurate.

36.12. **IDENTIFY:** Calculate the angular positions of the minima and use $y = x\tan\theta$ to calculate the distance on the screen between them.

(a) SET UP: The central bright fringe is shown in Figure 36.12a.

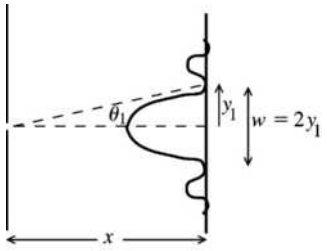


Figure 36.12a

EXECUTE: The first minimum is located by

$\sin\theta_1 = \dfrac{\lambda}{a} = \dfrac{633\times10^{-9}\text{ m}}{0.350\times10^{-3}\text{ m}} = 1.809\times10^{-3}$

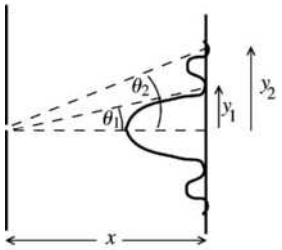
$\theta_1 = 1.809\times10^{-3}$ rad

$y_1 = x\tan\theta_1 = (3.00\text{ m})\tan(1.809\times10^{-3}\text{ rad}) = 5.427\times10^{-3}\text{ m}$

$w = 2y_1 = 2(5.427\times10^{-3}\text{ m}) = 1.09\times10^{-2}\text{ m} = 10.9\text{ mm}$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) SET UP: The first bright fringe on one side of the central maximum is shown in Figure 36.12b.



EXECUTE: $w = y_2 - y_1$

$y_1 = 5.427\times10^{-3}$ m (part (a))

$\sin\theta_2 = \dfrac{2\lambda}{a} = 3.618\times10^{-3}$

$\theta_2 = 3.618\times10^{-3}$ rad

$y_2 = x\tan\theta_2 = 1.085\times10^{-2}$ m

Figure 36.12b

$w = y_2 - y_1 = 1.085\times10^{-2}\text{ m} - 5.427\times10^{-3}\text{ m} = 5.4\text{ mm}$

EVALUATE: The central bright fringe is twice as wide as the other bright fringes.

36.13. **IDENTIFY:** The minima are located by $\sin\theta = \dfrac{m\lambda}{a}$. For part (b) apply Eq. (36.7).

SET UP: For the first minimum, $m = 1$. The intensity at $\theta = 0$ is I_0.

EXECUTE: **(a)** $\sin\theta = \dfrac{m\lambda}{a} = \sin 90.0° = 1 = \dfrac{m\lambda}{a} = \dfrac{\lambda}{a}$. Thus $a = \lambda = 580\text{ nm} = 5.80\times10^{-4}$ mm.

(b) According to Eq. (36.7),

$$\frac{I}{I_0} = \left\{\frac{\sin[\pi a(\sin\theta)/\lambda]}{\pi a(\sin\theta)/\lambda}\right\}^2 = \left\{\frac{\sin[\pi(\sin\pi/4)]}{\pi(\sin\pi/4)}\right\}^2 = 0.128.$$

EVALUATE: If $a = \lambda/2$, for example, then at $\theta = 45°$, $\dfrac{I}{I_0} = \left\{\dfrac{\sin[(\pi/2)(\sin\pi/4)]}{(\pi/2)(\sin\pi/4)}\right\}^2 = 0.65$. As a/λ decreases, the screen becomes more uniformly illuminated.

36.14. **IDENTIFY:** $I = I_0\left(\dfrac{\sin(\beta/2)}{\beta/2}\right)^2$. $\beta = \dfrac{2\pi}{\lambda}a\sin\theta$.

SET UP: The angle θ is small, so $\sin\theta \approx \tan\theta \approx y/x$.

EXECUTE: $\beta = \dfrac{2\pi a}{\lambda}\sin\theta \approx \dfrac{2\pi a}{\lambda}\dfrac{y}{x} = \dfrac{2\pi(4.50\times10^{-4}\text{ m})}{(6.20\times10^{-7}\text{ m})(3.00\text{ m})}y = (1520\text{ m}^{-1})y.$

(a) $y = 1.00\times10^{-3}$ m: $\dfrac{\beta}{2} = \dfrac{(1520\text{ m}^{-1})(1.00\times10^{-3}\text{ m})}{2} = 0.760.$

$$\Rightarrow I = I_0\left(\frac{\sin(\beta/2)}{\beta/2}\right)^2 = I_0\left(\frac{\sin(0.760)}{0.760}\right)^2 = 0.822I_0$$

(b) $y = 3.00\times10^{-3}$ m: $\dfrac{\beta}{2} = \dfrac{(1520\text{ m}^{-1})(3.00\times10^{-3}\text{ m})}{2} = 2.28.$

$$\Rightarrow I = I_0\left(\frac{\sin(\beta/2)}{\beta/2}\right)^2 = I_0\left(\frac{\sin(2.28)}{2.28}\right)^2 = 0.111I_0.$$

(c) $y = 5.00\times10^{-3}$ m: $\dfrac{\beta}{2} = \dfrac{(1520\text{ m}^{-1})(5.00\times10^{-3}\text{ m})}{2} = 3.80.$

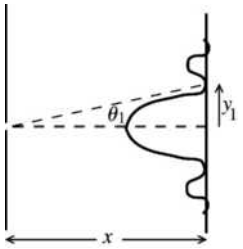
$$\Rightarrow I = I_0\left(\frac{\sin(\beta/2)}{\beta/2}\right)^2 = I_0\left(\frac{\sin(3.80)}{3.80}\right)^2 = 0.0259I_0.$$

EVALUATE: The first minimum occurs at $y_1 = \dfrac{\lambda x}{a} = \dfrac{(6.20\times10^{-7}\text{ m})(3.00\text{ m})}{4.50\times10^{-4}\text{ m}} = 4.1\text{ mm}$. The distances in parts (a) and (b) are within the central maximum. $y = 5.00$ mm is within the first secondary maximum.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

36.15. **(a) IDENTIFY:** Use Eq. (36.2) with $m = 1$ to locate the angular position of the first minimum and then use $y = x\tan\theta$ to find its distance from the center of the screen.

SET UP: The diffraction pattern is sketched in Figure 36.15.



$$\sin\theta_1 = \frac{\lambda}{a} = \frac{540\times10^{-9}\text{ m}}{0.240\times10^{-3}\text{ m}} = 2.25\times10^{-3}$$

$$\theta_1 = 2.25\times10^{-3}\text{ rad}$$

Figure 36.15

$$y_1 = x\tan\theta_1 = (3.00\text{ m})\tan(2.25\times10^{-3}\text{ rad}) = 6.75\times10^{-3}\text{ m} = 6.75\text{ mm}$$

(b) IDENTIFY and **SET UP:** Use Eqs. (36.5) and (36.6) to calculate the intensity at this point.

EXECUTE: Midway between the center of the central maximum and the first minimum implies $y = \frac{1}{2}(6.75\text{ mm}) = 3.375\times10^{-3}\text{ m}$.

$$\tan\theta = \frac{y}{x} = \frac{3.375\times10^{-3}\text{ m}}{3.00\text{ m}} = 1.125\times10^{-3};\ \theta = 1.125\times10^{-3}\text{ rad}$$

The phase angle β at this point on the screen is

$$\beta = \left(\frac{2\pi}{\lambda}\right)a\sin\theta = \frac{2\pi}{540\times10^{-9}\text{ m}}(0.240\times10^{-3}\text{ m})\sin(1.125\times10^{-3}\text{ rad}) = \pi.$$

Then $I = I_0\left(\frac{\sin\beta/2}{\beta/2}\right)^2 = (6.00\times10^{-6}\text{ W/m}^2)\left(\frac{\sin\pi/2}{\pi/2}\right)^2$.

$$I = \left(\frac{4}{\pi^2}\right)(6.00\times10^{-6}\text{ W/m}^2) = 2.43\times10^{-6}\text{ W/m}^2.$$

EVALUATE: The intensity at this point midway between the center of the central maximum and the first minimum is less than half the maximum intensity. Compare this result to the corresponding one for the two-slit pattern, Exercise 35.22.

36.16. **IDENTIFY:** The intensity on the screen varies as the light spreads out (diffracts) after passing through the single slit.

SET UP: $I = I_0\left[\frac{\sin(\beta/2)}{\beta/2}\right]^2$ where $\beta = \frac{2\pi}{\lambda}a\sin\theta$.

EXECUTE: $\beta = \frac{2\pi}{\lambda}a\sin\theta = \left(\frac{2\pi}{486\times10^{-9}\text{ m}}\right)(0.0290\times10^{-3}\text{ m})\sin1.20^\circ = 7.852\text{ rad}$.

$$I = I_0\left[\frac{\sin(\beta/2)}{\beta/2}\right]^2 = (4.00\times10^{-5}\text{ W/m}^2)\left[\frac{\sin(3.926\text{ rad})}{3.926\text{ rad}}\right]^2 = 1.29\times10^{-6}\text{ W/m}^2.$$

EVALUATE: The intensity is less than 1/30 of the intensity of the light at the slit.

36.17. **IDENTIFY** and **SET UP:** Use Eq. (36.6) to calculate λ and use Eq. (36.5) to calculate I. $\theta = 3.25°$, $\beta = 56.0$ rad, $a = 0.105\times10^{-3}$ m.

(a) EXECUTE: $\beta = \left(\frac{2\pi}{\lambda}\right)a\sin\theta$ so

$$\lambda = \frac{2\pi a\sin\theta}{\beta} = \frac{2\pi(0.105\times10^{-3}\text{ m})\sin3.25^\circ}{56.0\text{ rad}} = 668\text{ nm}$$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) $I = I_0\left(\dfrac{\sin\beta/2}{\beta/2}\right)^2 = I_0\left(\dfrac{4}{\beta^2}\right)(\sin(\beta/2))^2 = I_0\dfrac{4}{(56.0\text{ rad})^2}[\sin(28.0\text{ rad})]^2 = 9.36\times10^{-5}\ I_0$

EVALUATE: At the first minimum $\beta = 2\pi$ rad and at the point considered in the problem $\beta = 17.8\pi$ rad, so the point is well outside the central maximum. Since β is close to $m\pi$ with $m = 18$, this point is near one of the minima. The intensity here is much less than I_0.

36.18. **IDENTIFY:** Use $\beta = \dfrac{2\pi a}{\lambda}\sin\theta$ to calculate β.

SET UP: The total intensity is given by drawing an arc of a circle that has length E_0 and finding the length of the chord which connects the starting and ending points of the curve.

EXECUTE: **(a)** $\beta = \dfrac{2\pi a}{\lambda}\sin\theta = \dfrac{2\pi a}{\lambda}\dfrac{\lambda}{2a} = \pi$. From Figure 36.18a, $\pi\dfrac{E_p}{2} = E_0 \Rightarrow E_p = \dfrac{2}{\pi}E_0$.

The intensity is $I = \left(\dfrac{2}{\pi}\right)^2 I_0 = \dfrac{4I_0}{\pi^2} = 0.405I_0$. This agrees with Eq. (36.5).

(b) $\beta = \dfrac{2\pi a}{\lambda}\sin\theta = \dfrac{2\pi a}{\lambda}\dfrac{\lambda}{a} = 2\pi$. From Figure 36.18b, it is clear that the total amplitude is zero, as is the intensity. This also agrees with Eq. (36.5).

(c) $\beta = \dfrac{2\pi a}{\lambda}\sin\theta = \dfrac{2\pi a}{\lambda}\dfrac{3\lambda}{2a} = 3\pi$. From Figure 36.18c, $3\pi\dfrac{E_p}{2} = E_0 \Rightarrow E_p = \dfrac{2}{3\pi}E_0$. The intensity is $I = \left(\dfrac{2}{3\pi}\right)^2 I_0 = \dfrac{4}{9\pi^2}I_0$. This agrees with Eq. (36.5).

EVALUATE: In part (a) the point is midway between the center of the central maximum and the first minimum. In part (b) the point is at the first maximum and in (c) the point is approximately at the location of the first secondary maximum. The phasor diagrams help illustrate the rapid decrease in intensity at successive maxima.

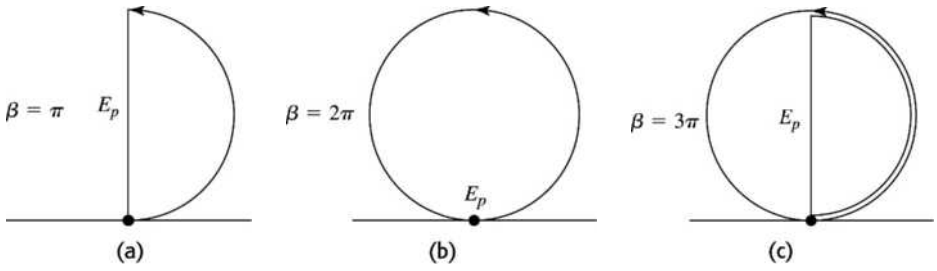


Figure 36.18

36.19. **IDENTIFY:** The space between the skyscrapers behaves like a single slit and diffracts the radio waves.
SET UP: Cancellation of the waves occurs when $a\ \sin\theta = m\lambda$, $m = 1, 2, 3, \ldots$, and the intensity of the waves is given by $I_0\left(\dfrac{\sin\beta/2}{\beta/2}\right)^2$, where $\beta/2 = \dfrac{\pi a\sin\theta}{\lambda}$.

EXECUTE: **(a)** First find the wavelength of the waves:
$\lambda = c/f = (3.00\times10^8\text{ m/s})/(88.9\text{ MHz}) = 3.375\text{ m}$
For no signal, $a\ \sin\theta = m\lambda$.
$m = 1$: $\sin\theta_1 = (1)(3.375\text{ m})/(15.0\text{ m}) \Rightarrow \theta_1 = \pm13.0°$
$m = 2$: $\sin\theta_2 = (2)(3.375\text{ m})/(15.0\text{ m}) \Rightarrow \theta_2 = \pm26.7°$
$m = 3$: $\sin\theta_3 = (3)(3.375\text{ m})/(15.0\text{ m}) \Rightarrow \theta_3 = \pm42.4°$
$m = 4$: $\sin\theta_4 = (4)(3.375\text{ m})/(15.0\text{ m}) \Rightarrow \theta_4 = \pm64.1°$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) $I_0\left(\dfrac{\sin\beta/2}{\beta/2}\right)^2$, where $\beta/2 = \dfrac{\pi a\sin\theta}{\lambda} = \dfrac{\pi(15.0\text{ m})\sin(5.00°)}{3.375\text{ m}} = 1.217\text{ rad}$

$$I = (3.50\text{ W/m}^2)\left[\frac{\sin(1.217\text{ rad})}{1.217\text{ rad}}\right]^2 = 2.08\text{ W/m}^2$$

EVALUATE: The wavelength of the radio waves is very long compared to that of visible light, but it is still considerably shorter than the distance between the buildings.

36.20. **IDENTIFY:** The net intensity is the *product* of the factor due to single-slit diffraction and the factor due to double slit interference.

SET UP: The double-slit factor is $I_{DS} = I_0\left(\cos^2\dfrac{\phi}{2}\right)$ and the single-slit factor is $I_{SS} = \left(\dfrac{\sin\beta/2}{\beta/2}\right)^2$.

EXECUTE: **(a)** $d\sin\theta = m\lambda \Rightarrow \sin\theta = m\lambda/d$.

$\sin\theta_1 = \lambda/d, \sin\theta_2 = 2\lambda/d, \sin\theta_3 = 3\lambda/d, \sin\theta_4 = 4\lambda/d$

(b) At the interference bright fringes, $\cos^2\phi/2 = 1$ and $\beta/2 = \dfrac{\pi a\sin\theta}{\lambda} = \dfrac{\pi(d/3)\sin\theta}{\lambda}$.

At θ_1, $\sin\theta_1 = \lambda/d$, so $\beta/2 = \dfrac{\pi(d/3)(\lambda/d)}{\lambda} = \pi/3$. The intensity is therefore

$$I_1 = I_0\left(\cos^2\frac{\phi}{2}\right)\left(\frac{\sin\beta/2}{\beta/2}\right)^2 = I_0(1)\left(\frac{\sin\pi/3}{\pi/3}\right)^2 = 0.684\,I_0$$

At θ_2, $\sin\theta_2 = 2\lambda/d$, so $\beta/2 = \dfrac{\pi(d/3)(2\lambda/d)}{\lambda} = 2\pi/3$. Using the same procedure as for θ_1, we have

$I_2 = I_0(1)\left(\dfrac{\sin 2\pi/3}{2\pi/3}\right)^2 = 0.171\,I_0$.

At θ_3, we get $\beta/2 = \pi$, which gives $I_3 = 0$ since $\sin\pi = 0$.

At θ_4, $\sin\theta_4 = 4\lambda/d$, so $\beta/2 = 4\pi/3$, which gives $I_4 = I_0\left(\dfrac{\sin 4\pi/3}{4\pi/3}\right)^2 = 0.0427\,I_0$

(c) Since $d = 3a$, every third interference maximum is missing.

(d) In Figure 36.12c in the textbook, every fourth interference maximum at the sides is missing because $d = 4a$.

EVALUATE: The result in this problem is different from that in Figure 36.12c in the textbook because in this case $d = 3a$, so every third interference maximum at the sides is missing. Also the "envelope" of the intensity function decreases more rapidly here than in Figure 36.12c in the text because the first diffraction minimum is reached sooner, and the decrease in intensity from one interference maximum to the next is faster for $a = d/3$ than for $a = d/4$.

36.21. **(a) IDENTIFY** and **SET UP:** The interference fringes (maxima) are located by $d\sin\theta = m\lambda$, with $m = 0, \pm1, \pm2, \ldots$. The intensity I in the diffraction pattern is given by $I = I_0\left(\dfrac{\sin\beta/2}{\beta/2}\right)^2$, with $\beta = \left(\dfrac{2\pi}{\lambda}\right)a\sin\theta$. We want $m = \pm3$ in the first equation to give θ that makes $I = 0$ in the second equation.

EXECUTE: $d\sin\theta = m\lambda$ gives $\beta = \left(\dfrac{2\pi}{\lambda}\right)a\left(\dfrac{3\lambda}{d}\right) = 2\pi(3a/d)$.

$I = 0$ says $\dfrac{\sin\beta/2}{\beta/2} = 0$ so $\beta = 2\pi$ and then $2\pi = 2\pi(3a/d)$ and $(d/a) = 3$.

(b) IDENTIFY and **SET UP:** Fringes $m = 0, \pm1, \pm2$ are within the central diffraction maximum and the $m = \pm3$ fringes coincide with the first diffraction minimum. Find the value of m for the fringes that coincide with the second diffraction minimum.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: Second minimum implies $\beta = 4\pi$.

$$\beta = \left(\frac{2\pi}{\lambda}\right) a \sin\theta = \left(\frac{2\pi}{\lambda}\right) a\left(\frac{m\lambda}{d}\right) = 2\pi m(a/d) = 2\pi(m/3)$$

Then $\beta = 4\pi$ says $4\pi = 2\pi(m/3)$ and $m = 6$. Therefore the $m = \pm 4$ and $m = +5$ fringes are contained within the first diffraction maximum on one side of the central maximum; two fringes.

EVALUATE: The central maximum is twice as wide as the other maxima so it contains more fringes.

36.22. **IDENTIFY** and **SET UP:** Use Figure 36.14b in the textbook. There is totally destructive interference between slits whose phasors are in opposite directions.

EXECUTE: By examining the diagram, we see that every fourth slit cancels each other.

EVALUATE: The total electric field is zero so the phasor diagram corresponds to a point of zero intensity. The first two maxima are at $\phi = 0$ and $\phi = \pi$, so this point is not midway between two maxima.

36.23. **(a) IDENTIFY** and **SET UP:** If the slits are very narrow then the central maximum of the diffraction pattern for each slit completely fills the screen and the intensity distribution is given solely by the two-slit interference. The maxima are given by $d\sin\theta = m\lambda$ so $\sin\theta = m\lambda/d$. Solve for θ.

EXECUTE: 1st order maximum: $m = 1$, so $\sin\theta = \dfrac{\lambda}{d} = \dfrac{580\times10^{-9}\text{ m}}{0.530\times10^{-3}\text{ m}} = 1.094\times10^{-3}$; $\theta = 0.0627°$

2nd order maximum: $m = 2$, so $\sin\theta = \dfrac{2\lambda}{d} = 2.188\times10^{-3}$; $\theta = 0.125°$

(b) IDENTIFY and **SET UP:** The intensity is given by Eq. (36.12): $I = I_0\cos^2(\phi/2)\left(\dfrac{\sin\beta/2}{\beta/2}\right)^2$. Calculate ϕ and β at each θ from part (a).

EXECUTE: $\phi = \left(\dfrac{2\pi d}{\lambda}\right)\sin\theta = \left(\dfrac{2\pi d}{\lambda}\right)\left(\dfrac{m\lambda}{d}\right) = 2\pi m$, so $\cos^2(\phi/2) = \cos^2(m\pi) = 1$

(Since the angular positions in part (a) correspond to interference maxima.)

$$\beta = \left(\frac{2\pi a}{\lambda}\right)\sin\theta = \left(\frac{2\pi a}{\lambda}\right)\left(\frac{m\lambda}{d}\right) = 2\pi m(a/d) = m2\pi\left(\frac{0.320\text{ mm}}{0.530\text{ mm}}\right) = m(3.794\text{ rad})$$

1st order maximum: $m = 1$, so $I = I_0(1)\left(\dfrac{\sin(3.794/2)\text{rad}}{(3.794/2)\text{rad}}\right)^2 = 0.249I_0$

2nd order maximum: $m = 2$, so $I = I_0(1)\left(\dfrac{\sin 3.794\text{ rad}}{3.794\text{ rad}}\right)^2 = 0.0256I_0$

EVALUATE: The first diffraction minimum is at an angle θ given by $\sin\theta = \lambda/a$ so $\theta = 0.104°$. The first order fringe is within the central maximum and the second order fringe is inside the first diffraction maximum on one side of the central maximum. The intensity here at this second fringe is much less than I_0.

36.24. **IDENTIFY:** The intensity at the screen is due to a combination of single-slit diffraction and double-slit interference.

SET UP: $I = I_0\left(\cos^2\dfrac{\phi}{2}\right)\left[\dfrac{\sin(\beta/2)}{\beta/2}\right]^2$, where $\phi = \dfrac{2\pi d}{\lambda}\sin\theta$ and $\beta = \dfrac{2\pi}{\lambda}a\sin\theta$.

EXECUTE: $\tan\theta = \dfrac{9.00\times10^{-4}\text{ m}}{0.750\text{ m}} = 1.200\times10^{-3}$. θ is small, so $\sin\theta \approx \tan\theta$.

$$\phi = \frac{2\pi d}{\lambda}\sin\theta = \frac{2\pi(0.640\times10^{-3}\text{ m})}{568\times10^{-9}\text{ m}}(1.200\times10^{-3}) = 8.4956\text{ rad.}$$

$$\beta = \frac{2\pi a}{\lambda}\sin\theta = \frac{2\pi(0.434\times10^{-3}\text{ m})}{568\times10^{-9}\text{ m}}(1.200\times10^{-3}) = 5.7611\text{ rad.}$$

$$I = (5.00\times10^{-4}\text{ W/m}^2)(\cos 4.2478\text{ rad})^2\left[\frac{\sin 2.8805\text{ rad}}{2.8805}\right]^2 = 8.06\times10^{-7}\text{ W/m}^2.$$

EVALUATE: The intensity as decreased by a factor of almost a thousand, so it would be difficult to see the light at the screen.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

36.25. **IDENTIFY** and **SET UP:** The phasor diagrams are similar to those in Figure 36.14. in the textbook. An interference minimum occurs when the phasors add to zero.
EXECUTE: **(a)** The phasor diagram is given in Figure 36.25a.

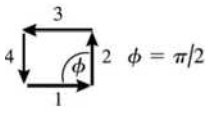

Figure 36.25a

There is destructive interference between the light through slits 1 and 3 and between 2 and 4.
(b) The phasor diagram is given in Figure 36.25b.

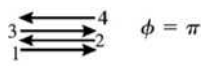

Figure 36.25b

There is destructive interference between the light through slits 1 and 2 and between 3 and 4.
(c) The phasor diagram is given in Figure 36.25c.

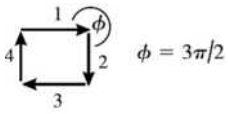

Figure 36.25c

There is destructive interference between light through slits 1 and 3 and between 2 and 4.
EVALUATE: Maxima occur when $\phi = 0, 2\pi, 4\pi$, etc. Our diagrams show that there are three minima between the maxima at $\phi = 0$ and $\phi = 2\pi$. This agrees with the general result that for N slits there are $N-1$ minima between each pair of principal maxima.

36.26. **IDENTIFY:** A double-slit bright fringe is missing when it occurs at the same angle as a double-slit dark fringe.
SET UP: Single-slit diffraction dark fringes occur when $a \sin\theta = m\lambda$, and double-slit interference bright fringes occur when $d \sin\theta = m'\lambda$.
EXECUTE: **(a)** The angle at which the first bright fringe occurs is given by
$\tan\theta_1 = (1.53 \text{ mm})/(2500 \text{ mm}) \Rightarrow \theta_1 = 0.03507°$. $d \sin\theta_1 = \lambda$ and

$$d = \lambda/(\sin\theta_1) = (632.8 \text{ nm})/\sin(0.03507°) = 0.00103 \text{ m} = 1.03 \text{ mm}$$

(b) The 7^{th} double-slit interference bright fringe is just cancelled by the 1^{st} diffraction dark fringe, so $\sin\theta_{\text{diff}} = \lambda/a$ and $\sin\theta_{\text{interf}} = 7\lambda/d$
The angles are equal, so $\lambda/a = 7\lambda/d \rightarrow a = d/7 = (1.03 \text{ mm})/7 = 0.148 \text{ mm}$.

EVALUATE: We can generalize that if $d = na$, where n is a positive integer, then every n^{th} double-slit bright fringe will be missing in the pattern.

36.27. **IDENTIFY:** The diffraction minima are located by $\sin\theta = \dfrac{m_{\text{d}}\lambda}{a}$ and the two-slit interference maxima are located by $\sin\theta = \dfrac{m_{\text{i}}\lambda}{d}$. The third bright band is missing because the first order single-slit minimum occurs at the same angle as the third order double-slit maximum.
SET UP: The pattern is sketched in Figure 36.27. $\tan\theta = \dfrac{3 \text{ cm}}{90 \text{ cm}}$, so $\theta = 1.91°$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: Single-slit dark spot: $a\sin\theta = \lambda$ and $a = \dfrac{\lambda}{\sin\theta} = \dfrac{500\text{ nm}}{\sin 1.91°} = 1.50\times10^4\text{ nm} = 15.0\ \mu\text{m}$ (width)

Double-slit bright fringe: $d\sin\theta = 3\lambda$ and $d = \dfrac{3\lambda}{\sin\theta} = \dfrac{3(500\text{ nm})}{\sin 1.91°} = 4.50\times10^4\text{ nm} = 45.0\ \mu\text{m}$ (separation).

EVALUATE: Note that $d/a = 3.0$.

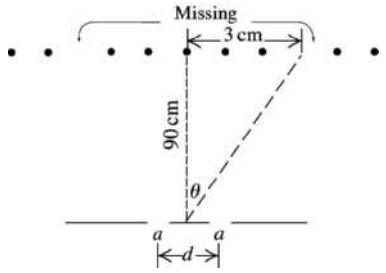

Figure 36.27

36.28. **IDENTIFY:** The maxima are located by $d\sin\theta = m\lambda$.
SET UP: The order corresponds to the values of m.
EXECUTE: First-order: $d\sin\theta_1 = \lambda$. Fourth-order: $d\sin\theta_4 = 4\lambda$.
$\dfrac{d\sin\theta_4}{d\sin\theta_1} = \dfrac{4\lambda}{\lambda}$, $\sin\theta_4 = 4\sin\theta_1 = 4\sin 8.94°$ and $\theta_4 = 38.4°$.
EVALUATE: We did not have to solve for d.

36.29. **IDENTIFY** and **SET UP:** The bright bands are at angles θ given by $d\sin\theta = m\lambda$. Solve for d and then solve for θ for the specified order.
EXECUTE: **(a)** $\theta = 78.4°$ for $m = 3$ and $\lambda = 681$ nm, so $d = m\lambda/\sin\theta = 2.086\times10^{-4}$ cm
The number of slits per cm is $1/d = 4790$ slits/cm.
(b) 1st order: $m = 1$, so $\sin\theta = \lambda/d = (681\times10^{-9}\text{ m})/(2.086\times10^{-6}\text{ m})$ and $\theta = 19.1°$
2nd order: $m = 2$, so $\sin\theta = 2\lambda/d$ and $\theta = 40.8°$
(c) For $m = 4$, $\sin\theta = 4\lambda/d$ is greater than 1.00, so there is no 4th-order bright band.
EVALUATE: The angular position of the bright bands for a particular wavelength increases as the order increases.

36.30. **IDENTIFY:** The bright spots are located by $d\sin\theta = m\lambda$.
SET UP: Third-order means $m = 3$ and second-order means $m = 2$.
EXECUTE: $\dfrac{m\lambda}{\sin\theta} = d = \text{constant}$, so $\dfrac{m_r\lambda_r}{\sin\theta_r} = \dfrac{m_v\lambda_v}{\sin\theta_v}$.
$\sin\theta_v = \sin\theta_r\left(\dfrac{m_v}{m_r}\right)\left(\dfrac{\lambda_v}{\lambda_r}\right) = (\sin 65.0°)\left(\dfrac{2}{3}\right)\left(\dfrac{400\text{ nm}}{700\text{ nm}}\right) = 0.345$ and $\theta_v = 20.2°$.
EVALUATE: The third-order line for a particular λ occurs at a larger angle than the second-order line. In a given order, the line for violet light (400 nm) occurs at a smaller angle than the line for red light (700 nm).

36.31. **IDENTIFY** and **SET UP:** Calculate d for the grating. Use Eq. (36.13) to calculate θ for the longest wavelength in the visible spectrum and verify that θ is small. Then use Eq. (36.3) to relate the linear separation of lines on the screen to the difference in wavelength.
EXECUTE: **(a)** $d = \left(\dfrac{1}{900}\right)\text{cm} = 1.111\times10^{-5}\text{ m}$
For $\lambda = 700$ nm, $\lambda/d = 6.3\times10^{-2}$. The first-order lines are located at $\sin\theta = \lambda/d$; $\sin\theta$ is small enough for $\sin\theta \approx \theta$ to be an excellent approximation.
(b) $y = x\lambda/d$, where $x = 2.50$ m.
The distance on the screen between first-order bright bands for two different wavelengths is
$\Delta y = x(\Delta\lambda)/d$, so $\Delta\lambda = d(\Delta y)/x = (1.111\times10^{-5}\text{ m})(3.00\times10^{-3}\text{ m})/(2.50\text{ m}) = 13.3$ nm.
EVALUATE: The smaller d is (greater number of lines per cm) the smaller the $\Delta\lambda$ that can be measured.

36.32. **IDENTIFY:** The maxima are located by $d\sin\theta = m\lambda$.

SET UP: $350 \text{ slits/mm} \Rightarrow d = \dfrac{1}{3.50\times10^5 \text{ m}^{-1}} = 2.86\times10^{-6} \text{ m}$

EXECUTE: **(a)** $m = 1$: $\theta_{400} = \arcsin\left(\dfrac{\lambda}{d}\right) = \arcsin\left(\dfrac{4.00\times10^{-7} \text{ m}}{2.86\times10^{-6} \text{ m}}\right) = 8.05°$.

$\theta_{700} = \arcsin\left(\dfrac{\lambda}{d}\right) = \arcsin\left(\dfrac{7.00\times10^{-7} \text{ m}}{2.86\times10^{-6} \text{ m}}\right) = 14.18°$. $\Delta\theta_1 = 14.18° - 8.05° = 6.13°$.

(b) $m = 3$: $\theta_{400} = \arcsin\left(\dfrac{3\lambda}{d}\right) = \arcsin\left(\dfrac{3(4.00\times10^{-7} \text{ m})}{2.86\times10^{-6} \text{ m}}\right) = 24.8°$.

$\theta_{700} = \arcsin\left(\dfrac{3\lambda}{d}\right) = \arcsin\left(\dfrac{3(7.00\times10^{-7} \text{ m})}{2.86\times10^{-6} \text{ m}}\right) = 47.3°$. $\Delta\theta_1 = 47.3° - 24.8° = 22.5°$.

EVALUATE: $\Delta\theta$ is larger in third order.

36.33. **IDENTIFY:** Knowing the wavelength of the light and the location of the first interference maxima, we can calculate the line density of the grating.

SET UP: The line density in lines/cm is $1/d$, with d in cm. The bright spots are located by $d\sin\theta = m\lambda$, $m = 0, \pm1, \pm2, \ldots$.

EXECUTE: **(a)** $d = \dfrac{m\lambda}{\sin\theta} = \dfrac{(1)(632.8\times10^{-9} \text{ m})}{\sin17.8°} = 2.07\times10^{-6} \text{ m} = 2.07\times10^{-4} \text{ cm}$. $\dfrac{1}{d} = 4830 \text{ lines/cm}$.

(b) $\sin\theta = \dfrac{m\lambda}{d} = m\left(\dfrac{632.8\times10^{-9} \text{ m}}{2.07\times10^{-6} \text{ m}}\right) = m(0.3057)$. For $m = \pm2$, $\theta = \pm37.7°$. For $m = \pm3$, $\theta = \pm66.5°$.

EVALUATE: The angles are large, so they are not equally spaced; $37.7° \neq 2(17.8°)$ and $66.5° \neq 3(17.8°)$

36.34. **IDENTIFY:** The maxima are located by $d\sin\theta = m\lambda$.

SET UP: $5000 \text{ slits/cm} \Rightarrow d = \dfrac{1}{5.00\times10^5 \text{ m}^{-1}} = 2.00\times10^{-6} \text{ m}$.

EXECUTE: **(a)** $\lambda = \dfrac{d\sin\theta}{m} = \dfrac{(2.00\times10^{-6} \text{ m})\sin13.5°}{1} = 4.67\times10^{-7} \text{ m}$.

(b) $m = 2$: $\theta = \arcsin\left(\dfrac{m\lambda}{d}\right) = \arcsin\left(\dfrac{2(4.67\times10^{-7} \text{ m})}{2.00\times10^{-6} \text{ m}}\right) = 27.8°$.

EVALUATE: Since the angles are fairly small, the second-order deviation is approximately twice the first-order deviation.

36.35. **IDENTIFY:** The maxima are located by $d\sin\theta = m\lambda$.

SET UP: $350 \text{ slits/mm} \Rightarrow d = \dfrac{1}{3.50\times10^5 \text{ m}^{-1}} = 2.86\times10^{-6} \text{ m}$

EXECUTE: $\theta = \arcsin\left(\dfrac{m\lambda}{d}\right) = \arcsin\left(\dfrac{m(5.20\times10^{-7} \text{ m})}{2.86\times10^{-6} \text{ m}}\right) = \arcsin((0.182)m)$.

$m = 1$: $\theta = 10.5°$; $m = 2$: $\theta = 21.3°$; $m = 3$: $\theta = 33.1°$.

EVALUATE: The angles are not precisely proportional to m, and deviate more from being proportional as the angles increase.

36.36. **IDENTIFY:** The resolution is described by $R = \dfrac{\lambda}{\Delta\lambda} = Nm$. Maxima are located by $d\sin\theta = m\lambda$.

SET UP: For 500 slits/mm, $d = (500 \text{ slits/mm})^{-1} = (500{,}000 \text{ slits/m})^{-1}$.

EXECUTE: **(a)** $N = \dfrac{\lambda}{m\Delta\lambda} = \dfrac{6.5645\times10^{-7} \text{ m}}{2(6.5645\times10^{-7} \text{ m} - 6.5627\times10^{-7} \text{ m})} = 1820 \text{ slits}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) $\theta = \sin^{-1}\left(\dfrac{m\lambda}{d}\right) \Rightarrow \theta_1 = \sin^{-1}((2)(6.5645\times10^{-7}\text{ m})(500{,}000\text{ m}^{-1})) = 41.0297°$ and

$\theta_2 = \sin^{-1}((2)(6.5627\times10^{-7}\text{ m})(500{,}000\text{ m}^{-1})) = 41.0160°$. $\Delta\theta = 0.0137°$

EVALUATE: $d\cos\theta\, d\theta = \lambda/N$, so for 1820 slits the angular interval $\Delta\theta$ between each of these maxima and the first adjacent minimum is $\Delta\theta = \dfrac{\lambda}{Nd\cos\theta} = \dfrac{6.56\times10^{-7}\text{ m}}{(1820)(2.0\times10^{-6}\text{ m})\cos 41°} = 0.0137°$. This is the same as the angular separation of the maxima for the two wavelengths and 1820 slits is just sufficient to resolve these two wavelengths in second order.

36.37. **IDENTIFY:** The resolving power depends on the line density and the width of the grating.

SET UP: The resolving power is given by $R = Nm = = \lambda/\Delta\lambda$.

EXECUTE: **(a)** $R = Nm = (5000\text{ lines/cm})(3.50\text{ cm})(1) = 17{,}500$

(b) The resolving power needed to resolve the sodium doublet is

$$R = \lambda/\Delta\lambda = (589\text{ nm})/(589.59\text{ nm} - 589.00\text{ nm}) = 998$$

so this grating can easily resolve the doublet.

(c) (i) $R = \lambda/\Delta\lambda$. Since $R = 17{,}500$ when $m = 1$, $R = 2\times17{,}500 = 35{,}000$ for $m = 2$. Therefore

$$\Delta\lambda = \lambda/R = (587.8\text{ nm})/35{,}000 = 0.0168\text{ nm}$$

$$\lambda_{\text{min}} = \lambda + \Delta\lambda = 587.8002\text{ nm} + 0.0168\text{ nm} = 587.8170\text{ nm}$$

(ii) $\lambda_{\text{max}} = \lambda - \Delta\lambda = 587.8002\text{ nm} - 0.0168\text{ nm} = 587.7834\text{ nm}$

EVALUATE: (iii) Therefore the range of resolvable wavelengths is $587.7834\text{ nm} < \lambda < 587.8170\text{ nm}$.

36.38. **IDENTIFY** and **SET UP:** $\dfrac{\lambda}{\Delta\lambda} = Nm$

EXECUTE: $N = \dfrac{\lambda}{m\Delta\lambda} = \dfrac{587.8002\text{ nm}}{(587.9782\text{ nm} - 587.8002\text{ nm})} = \dfrac{587.8002}{0.178} = 3302\text{ slits}.$

$\dfrac{N}{1.20\text{ cm}} = \dfrac{3302}{1.20\text{ cm}} = 2752\dfrac{\text{slits}}{\text{cm}}.$

EVALUATE: A smaller number of slits would be needed to resolve these two lines in higher order.

36.39. **IDENTIFY** and **SET UP:** The maxima occur at angles θ given by Eq. (36.16), $2d\sin\theta = m\lambda$, where d is the spacing between adjacent atomic planes. Solve for d.

EXECUTE: Second order says $m = 2$.

$$d = \frac{m\lambda}{2\sin\theta} = \frac{2(0.0850\times10^{-9}\text{ m})}{2\sin 21.5°} = 2.32\times10^{-10}\text{ m} = 0.232\text{ nm}$$

EVALUATE: Our result is similar to d calculated in Example 36.5.

36.40. **IDENTIFY:** The maxima are given by $2d\sin\theta = m\lambda$, $m = 1, 2, \ldots$

SET UP: $d = 3.50\times10^{-10}$ m.

EXECUTE: **(a)** $m = 1$ and $\lambda = \dfrac{2d\sin\theta}{m} = 2(3.50\times10^{-10}\text{ m})\sin 15.0° = 1.81\times10^{-10}\text{ m} = 0.181\text{ nm}$. This is an x ray.

(b) $\sin\theta = m\left(\dfrac{\lambda}{2d}\right) = m\left(\dfrac{1.81\times10^{-10}\text{ m}}{2[3.50\times10^{-10}\text{ m}]}\right) = m(0.2586)$. $m = 2$: $\theta = 31.1°$. $m = 3$: $\theta = 50.9°$. The equation doesn't have any solutions for $m > 3$.

EVALUATE: In this problem $\lambda/d = 0.52$.

36.41. **IDENTIFY:** The crystal behaves like a diffraction grating.

SET UP: The maxima are at angles θ given by $2d\sin\theta = m\lambda$, where $d = 0.440$ nm.

EXECUTE: $m = 1$. $\lambda = \dfrac{2d\sin\theta}{1} = 2(0.440\text{ nm})\sin 39.4° = 0.559\text{ nm}.$

EVALUATE: The result is a reasonable x ray wavelength.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

36.42. **IDENTIFY:** Apply $\sin\theta = 1.22\dfrac{\lambda}{D}$.

SET UP: $\theta = (1/60)°$

EXECUTE: $D = \dfrac{1.22\lambda}{\sin\theta} = \dfrac{1.22(5.5\times10^{-7}\text{ m})}{\sin(1/60)°} = 2.31\times10^{-3}\text{ m} = 2.3\text{ mm}$

EVALUATE: The larger the diameter the smaller the angle that can be resolved.

36.43. **IDENTIFY:** Apply $\sin\theta = 1.22\dfrac{\lambda}{D}$.

SET UP: $\theta = \dfrac{W}{h}$, where $W = 28$ km and $h = 1200$ km. θ is small, so $\sin\theta \approx \theta$.

EXECUTE: $D = \dfrac{1.22\lambda}{\sin\theta} = 1.22\lambda\dfrac{h}{W} = 1.22(0.036\text{ m})\dfrac{1.2\times10^{6}\text{ m}}{2.8\times10^{4}\text{ m}} = 1.88\text{ m}$

EVALUATE: D must be significantly larger than the wavelength, so a much larger diameter is needed for microwaves than for visible wavelengths.

36.44. **IDENTIFY:** The diameter D of the mirror determines the resolution.

SET UP: The resolving power is $\theta_{\text{res}} = 1.22\dfrac{\lambda}{D}$.

EXECUTE: The same θ_{res} means that $\dfrac{\lambda_1}{D_1} = \dfrac{\lambda_2}{D_2}$. $D_2 = D_1\dfrac{\lambda_2}{\lambda_1} = (8000\times10^{3}\text{ m})\left(\dfrac{550\times10^{-9}\text{ m}}{2.0\times10^{-2}\text{ m}}\right) = 220\text{ m}$.

EVALUATE: The Hubble telescope has an aperture of 2.4 m, so this would have to be an *enormous* optical telescope!

36.45. **IDENTIFY** and **SET UP:** The angular size of the first dark ring is given by $\sin\theta_1 = 1.22\lambda/D$ (Eq. 36.17). Calculate θ_1, and then the diameter of the ring on the screen is $2(4.5\text{ m})\tan\theta_1$.

EXECUTE: $\sin\theta_1 = 1.22\left(\dfrac{620\times10^{-9}\text{ m}}{7.4\times10^{-6}\text{ m}}\right) = 0.1022;\ \theta_1 = 0.1024\text{ rad}$

The radius of the Airy disk (central bright spot) is $r = (4.5\text{ m})\tan\theta_1 = 0.462\text{ m}$. The diameter is $2r = 0.92\text{ m} = 92\text{ cm}$.

EVALUATE: $\lambda/D = 0.084$. For this small D the central diffraction maximum is broad.

36.46. **IDENTIFY:** Rayleigh's criterion limits the angular resolution.

SET UP: Rayleigh's criterion is $\sin\theta \approx \theta = 1.22\lambda/D$.

EXECUTE: **(a)** Using Rayleigh's criterion

$$\sin\theta \approx \theta = 1.22\lambda/D = (1.22)(550\text{ nm})/(135/4\text{ mm}) = 1.99\times10^{-5}\text{ rad}$$

On the bear this angle subtends a distance x. $\theta = x/R$ and

$$x = R\theta = (11.5\text{ m})(1.99\times10^{-5}\text{ rad}) = 2.29\times10^{-4}\text{ m} = 0.23\text{ mm}$$

(b) At $f/22$, D is $4/22$ times as large as at $f/4$. Since θ is proportional to $1/D$, and x is proportional to θ, x is $1/(4/22) = 22/4$ times as large as it was at $f/4$. $x = (0.229\text{ mm})(22/4) = 1.3\text{ mm}$

EVALUATE: A wide-angle lens, such as one having a focal length of 28 mm, would have a much smaller opening at $f/2$ and hence would have an even less resolving ability.

36.47. **IDENTIFY** and **SET UP:** Resolved by Rayleigh's criterion means angular separation θ of the objects equals $1.22\lambda/D$. The angular separation θ of the objects is their linear separation divided by their distance from the telescope.

EXECUTE: $\theta = \dfrac{250\times10^{3}\text{ m}}{5.93\times10^{11}\text{ m}}$, where 5.93×10^{11} m is the distance from earth to Jupiter. Thus $\theta = 4.216\times10^{-7}$.

Then $\theta = 1.22\dfrac{\lambda}{D}$ and $D = \dfrac{1.22\lambda}{\theta} = \dfrac{1.22(500\times10^{-9}\text{ m})}{4.216\times10^{-7}} = 1.45\text{ m}$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: This is a very large telescope mirror. The greater the angular resolution the greater the diameter the lens or mirror must be.

36.48. **IDENTIFY:** Rayleigh's criterion says $\theta_{\text{res}} = 1.22\dfrac{\lambda}{D}$.

SET UP: $D = 7.20$ cm. $\theta_{\text{res}} = \dfrac{y}{s}$, where s is the distance of the object from the lens and $y = 4.00$ mm.

EXECUTE: $\dfrac{y}{s} = 1.22\dfrac{\lambda}{D}$. $s = \dfrac{yD}{1.22\lambda} = \dfrac{(4.00\times10^{-3}\text{ m})(7.20\times10^{-2}\text{ m})}{1.22(550\times10^{-9}\text{ m})} = 429$ m.

EVALUATE: The focal length of the lens doesn't enter into the calculation. In practice, it is difficult to achieve resolution that is at the diffraction limit.

36.49. **IDENTIFY** and **SET UP:** Let y be the separation between the two points being resolved and let s be their distance from the telescope. Then the limit of resolution corresponds to $1.22\ \dfrac{\lambda}{D} = \dfrac{y}{s}$.

EXECUTE: **(a)** Let the two points being resolved be the opposite edges of the crater, so y is the diameter of the crater. For the moon, $s = 3.8\times10^{8}$ m. $y = 1.22\lambda s/D$.

Hubble: $D = 2.4$ m and $\lambda = 400$ nm gives the maximum resolution, so $y = 77$ m

Arecibo: $D = 305$ m and $\lambda = 0.75$ m; $y = 1.1\times10^{6}$ m

(b) $s = \dfrac{yD}{1.22\lambda}$. Let $y \approx 0.30$ m (the size of a license plate).

$s = (0.30\text{ m})(2.4\text{ m})/[(1.22)(400\times10^{-9}\text{ m})] = 1500$ km.

EVALUATE: D/λ is much larger for the optical telescope and it has a much larger resolution even though the diameter of the radio telescope is much larger.

36.50. **IDENTIFY:** Apply $\sin\theta = 1.22\dfrac{\lambda}{D}$.

SET UP: θ is small, so $\sin\theta \approx \theta$. Smallest resolving angle is for short-wavelength light (400 nm).

EXECUTE: $\theta \approx 1.22\dfrac{\lambda}{D} = (1.22)\dfrac{400\times10^{-9}\text{ m}}{5.08\text{ m}} = 9.61\times10^{-8}$ rad. $\theta = \dfrac{10{,}000\text{ mi}}{R}$, where R is the distance to the star. $R = \dfrac{10{,}000\text{ mi}}{\theta} = \dfrac{16{,}000\text{ km}}{9.6\times10^{-8}\text{ rad}} = 1.7\times10^{11}$ km.

EVALUATE: This is less than a light year, so there are no stars this close.

36.51. **IDENTIFY:** We can apply the equation for single-slit diffraction to the hair, with the thickness of the hair replacing the thickness of the slit.

SET UP: The dark fringes are located by $\sin\theta = m\dfrac{\lambda}{a}$. The first dark fringes are for $m = \pm1$. $y = R\tan\theta$ is the distance from the center of the screen. From the center to one minimum is 2.61 cm.

EXECUTE: $\tan\theta = \dfrac{y}{R} = \dfrac{2.61\text{ cm}}{125\text{ cm}} = 0.02088$ so $\theta = 1.20°$. $a = \dfrac{\lambda}{\sin\theta} = \dfrac{632.8\times10^{-9}\text{ m}}{\sin1.20°} = 30.2\ \mu$m.

EVALUATE: Although the thickness of human hairs can vary considerably, $30\ \mu$m is a reasonable thickness.

36.52. **IDENTIFY:** If the apparatus of Exercise 36.4 is placed in water, then all that changes is the wavelength $\lambda \to \lambda' = \dfrac{\lambda}{n}$.

SET UP: For $y \ll x$, the distance between the two dark fringes on either side of the central maximum is $D' = 2y'$. Let $D = 2y$ be the separation of 5.91×10^{-3} m found in Exercise 36.4.

EXECUTE: $2y'_1 = \dfrac{2x\lambda'}{a} = \dfrac{2x\lambda}{an} = \dfrac{D}{n} = \dfrac{5.91\times10^{-3}\text{ m}}{1.33} = 4.44\times10^{-3}\text{ m} = 4.44$ mm.

EVALUATE: The water shortens the wavelength and this decreases the width of the central maximum.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

36.53. **IDENTIFY:** In the single-slit diffraction pattern, the intensity is a maximum at the center and zero at the dark spots. At other points, it depends on the angle at which one is observing the light.

SET UP: Dark fringes occur when $\sin\theta_m = m\lambda/a$, where $m = 1, 2, 3, \ldots$, and the intensity is given by $I_0\left(\dfrac{\sin\beta/2}{\beta/2}\right)^2$, where $\beta/2 = \dfrac{\pi a\sin\theta}{\lambda}$.

EXECUTE: **(a)** At the maximum possible angle, $\theta = 90°$, so

$$m_{\max} = (a\sin 90°)/\lambda = (0.0250\text{ mm})/(632.8\text{ nm}) = 39.5$$

Since m must be an integer and $\sin\theta$ must be ≤ 1, $m_{\max} = 39$. The total number of dark fringes is 39 on each side of the central maximum for a total of 78.

(b) The farthest dark fringe is for $m = 39$, giving

$$\sin\theta_{39} = (39)(632.8\text{ nm})/(0.0250\text{ mm}) \Rightarrow \theta_{39} = \pm 80.8°$$

(c) The next closer dark fringe occurs at $\sin\theta_{38} = (38)(632.8\text{ nm})/(0.0250\text{ mm}) \Rightarrow \theta_{38} = 74.1°$.

The angle midway these two extreme fringes is $(80.8° + 74.1°)/2 = 77.45°$, and the intensity at this angle is

$$I = I_0\left(\frac{\sin\beta/2}{\beta/2}\right)^2, \text{ where } \beta/2 = \frac{\pi a\sin\theta}{\lambda} = \frac{\pi(0.0250\text{ mm})\sin(77.45°)}{632.8\text{ nm}} = 121.15\text{ rad, which gives}$$

$$I = (8.50\text{W/m}^2)\left[\frac{\sin(121.15\text{ rad})}{121.15\text{ rad}}\right]^2 = 5.55\times 10^{-4}\text{ W/m}^2.$$

EVALUATE: At the angle in part (c), the intensity is so low that the light would be barely perceptible.

36.54. **IDENTIFY:** The two holes behave like double slits and cause the sound waves to interfere after they pass through the holes. The motion of the speakers causes a Doppler shift in the wavelength of the sound.

SET UP: The wavelength of the sound that strikes the wall is $\lambda = \lambda_0 - v_sT_s$, and destructive interference first occurs where $\sin\theta = \lambda/2$.

EXECUTE: **(a)** First find the wavelength of the sound that strikes the openings in the wall.

$\lambda = \lambda_0 - v_sT_s = v/f_s - v_s/f_s = (v - v_s)/f_s = (344\text{ m/s} - 80.0\text{ m/s})/(1250\text{ Hz}) = 0.211$ m. Destructive interference first occurs where $d\sin\theta = \lambda/2$, which gives $d = \lambda/(2\sin\theta) = (0.211\text{ m})/(2\sin 11.4°) = 0.534$ m.

(b) $\lambda = v/f = (344\text{ m/s})/(1250\text{ Hz}) = 0.275$ m. $\sin\theta = \lambda/2d = (0.275\text{ m})/[2(0.480\text{ m})] \rightarrow \theta = \pm 16.7°$.

EVALUATE: The moving source produces sound of shorter wavelength than the stationary source, so the angles at which destructive interference occurs are smaller for the moving source than for the stationary source.

36.55. **IDENTIFY** and **SET UP:** $\sin\theta = \lambda/a$ locates the first dark band. In the liquid the wavelength changes and this changes the angular position of the first diffraction minimum.

EXECUTE: $\sin\theta_{\text{air}} = \dfrac{\lambda_{\text{air}}}{a}$; $\sin\theta_{\text{liquid}} = \dfrac{\lambda_{\text{liquid}}}{a}$. $\lambda_{\text{liquid}} = \lambda_{\text{air}}\left(\dfrac{\sin\theta_{\text{liquid}}}{\sin\theta_{\text{air}}}\right) = \lambda_{\text{air}}\dfrac{\sin 21.6°}{\sin 38.2°} = 0.5953\lambda_{\text{air}}$.

$\lambda_{\text{liquid}} = \lambda_{\text{air}}/n$ (Eq. 33.5), so $n = \lambda_{\text{air}}/\lambda_{\text{liquid}} = \dfrac{\lambda_{\text{air}}}{0.5953\lambda_{\text{air}}} = 1.68$.

EVALUATE: Light travels faster in air and n must be > 1.00. The smaller λ in the liquid reduces θ that located the first dark band.

36.56. **IDENTIFY:** $d = \dfrac{1}{N}$, so the bright fringes are located by $\dfrac{1}{N}\sin\theta = \lambda$.

SET UP: Red: $\dfrac{1}{N}\sin\lambda_R = 700$ nm. Violet: $\dfrac{1}{N}\sin\lambda_V = 400$ nm.

EXECUTE: **(a)** $\dfrac{\sin\theta_R}{\sin\theta_V} = \dfrac{7}{4}$. $\theta_R - \theta_V = 21.0° \rightarrow \theta_R = \theta_V + 21.0°$. $\dfrac{\sin(\theta_V + 21.0°)}{\sin\theta_V} = \dfrac{7}{4}$. Using a trig identity from Appendix B gives $\dfrac{\sin\theta_V\cos 21.0° + \cos\theta_V\sin 21.0°}{\sin\theta_V} = 7/4$. $\cos 21.0° + \cot\theta_V\sin 21.0° = 7/4$.

$\tan\theta_V = 0.4390 \Rightarrow \theta_V = 23.7°$ and $\theta_R = \theta_V + 21.0° = 23.7° + 21.0° = 44.7°$. Then $\dfrac{1}{N}\sin\theta_R = 700$ nm

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

gives $N = \dfrac{\sin\theta_R}{700\text{ nm}} = \dfrac{\sin 44.7°}{700\times10^{-9}\text{ m}} = 1.00\times10^6\text{ lines/m} = 1.00\times10^4\text{ lines/cm}.$

(b) The spectrum begins at 23.7° and ends at 44.7°.

EVALUATE: As N is increased, the angular range of the visible spectrum increases.

36.57. **(a) IDENTIFY** and **SET UP:** The angular position of the first minimum is given by $a\sin\theta = m\lambda$ (Eq. 36.2), with $m = 1$. The distance of the minimum from the center of the pattern is given by $y = x\tan\theta$.

$\sin\theta = \dfrac{\lambda}{a} = \dfrac{540\times10^{-9}\text{ m}}{0.360\times10^{-3}\text{ m}} = 1.50\times10^{-3};\ \theta = 1.50\times10^{-3}\text{ rad}$

$y_1 = x\tan\theta = (1.20\text{ m})\tan(1.50\times10^{-3}\text{ rad}) = 1.80\times10^{-3}\text{ m} = 1.80\text{ mm}.$

(Note that θ is small enough for $\theta \approx \sin\theta \approx \tan\theta$, and Eq. (36.3) applies.)

(b) IDENTIFY and **SET UP:** Find the phase angle β where $I = I_0/2$. Then use Eq. (36.6) to solve for θ and $y = x\tan\theta$ to find the distance.

EXECUTE: Eq. (36.5) gives that $I = \dfrac{1}{2}I_0$ when $\beta = 2.78$ rad.

$\beta = \left(\dfrac{2\pi}{\lambda}\right)a\sin\theta$ (Eq. (36.6)), so $\sin\theta = \dfrac{\beta\lambda}{2\pi a}.$

$y = x\tan\theta \approx x\sin\theta \approx \dfrac{\beta\lambda x}{2\pi a} = \dfrac{(2.78\text{ rad})(540\times10^{-9}\text{ m})(1.20\text{ m})}{2\pi(0.360\times10^{-3}\text{ m})} = 7.96\times10^{-4}\text{ m} = 0.796\text{ mm}$

EVALUATE: The point where $I = I_0/2$ is not midway between the center of the central maximum and the first minimum; see Exercise 36.15.

36.58. **IDENTIFY:** $I = I_0\left(\dfrac{\sin\gamma}{\gamma}\right)^2$. The maximum intensity occurs when the derivative of the intensity function with respect to γ is zero.

SET UP: $\dfrac{d\sin\gamma}{d\gamma} = \cos\gamma.\ \dfrac{d}{d\gamma}\left(\dfrac{1}{\gamma}\right) = -\dfrac{1}{\gamma^2}.$

EXECUTE: $\dfrac{dI}{d\gamma} = I_0\dfrac{d}{d\gamma}\left(\dfrac{\sin\gamma}{\gamma}\right)^2 = 2\left(\dfrac{\sin\gamma}{\gamma}\right)\left(\dfrac{\cos\gamma}{\gamma} - \dfrac{\sin\gamma}{\gamma^2}\right) = 0.\ \dfrac{\cos\gamma}{\gamma} - \dfrac{\sin\gamma}{\gamma^2} \Rightarrow \gamma\cos\gamma = \sin\gamma \Rightarrow \gamma = \tan\gamma.$

(b) The graph in Figure 36.58 is a plot of $f(\gamma) = \gamma - \tan\gamma$. When $f(\gamma)$ equals zero, there is an intensity maximum. Getting estimates from the graph, and then using trial and error to narrow in on the value, we find that the three smallest γ-values are $\gamma = 4.49$ rad 7.73 rad, and 10.9 rad.

EVALUATE: $\gamma = 0$ is the central maximum. The three values of γ we found are the locations of the first three secondary maxima. The first four minima are at $\gamma = 3.14$ rad, 6.28 rad, 9.42 rad, and 12.6 rad. The maxima are between adjacent minima, but not precisely midway between them.

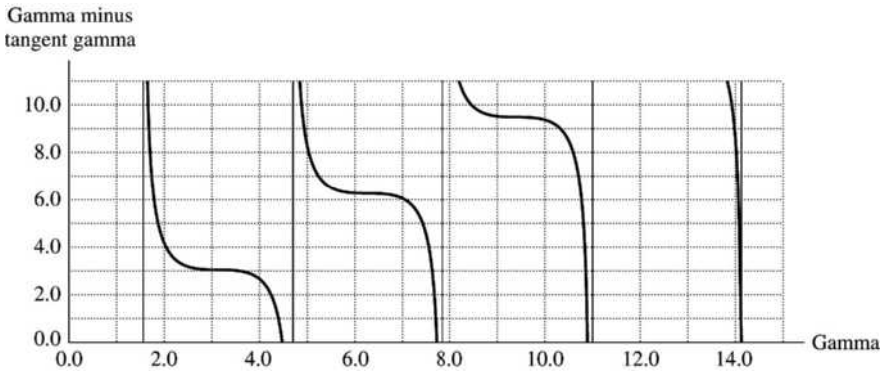

Figure 36.58

36.59. **IDENTIFY** and **SET UP:** Relate the phase difference between adjacent slits to the sum of the phasors for all slits. The phase difference between adjacent slits is $\phi = \frac{2\pi d}{\lambda}\sin\theta \approx \frac{2\pi d\theta}{\lambda}$ when θ is small and $\sin\theta \approx \theta$. Thus $\theta = \frac{\lambda\phi}{2\pi d}$.

EXECUTE: A principal maximum occurs when $\phi = \phi_{\max} = m2\pi$, where m is an integer, since then all the phasors add. The first minima on either side of the m^{th} principal maximum occur when $\phi = \phi_{\min}^{\pm} = m2\pi \pm (2\pi/N)$ and the phasor diagram for N slits forms a closed loop and the resultant phasor is zero. The angular position of a principal maximum is $\theta = \left(\frac{\lambda}{2\pi d}\right)\phi_{\max}$. The angular position of the adjacent minimum is $\theta_{\min}^{\pm} = \left(\frac{\lambda}{2\pi d}\right)\phi_{\min}^{\pm}$.

$$\theta_{\min}^{+} = \left(\frac{\lambda}{2\pi d}\right)\left(\phi_{\max} + \frac{2\pi}{N}\right) = \theta + \left(\frac{0}{2\pi d}\right)\left(\frac{2\pi}{N}\right) = \theta + \frac{\lambda}{Nd}$$

$$\theta_{\min}^{-} = \left(\frac{\lambda}{2\pi d}\right)\left(\phi_{\max} - \frac{2\pi}{N}\right) = \theta - \frac{\lambda}{Nd}$$

The angular width of the principal maximum is $\theta_{\min}^{+} - \theta_{\min}^{-} = \frac{2\lambda}{Nd}$, as was to be shown.

EVALUATE: The angular width of the principal maximum decreases like $1/N$ as N increases.

36.60. **IDENTIFY:** Heating the plate causes it to expand, which widens the slit. The increased slit width changes the angles at which destructive interference occurs.

SET UP: First minimum is at angle θ given by $\tan\theta = \frac{(2.75\times10^{-3}/2)}{0.620}$. Therefore, θ is small and the equation $y_m = x\frac{m\lambda}{a}$ is accurate. The width of the central maximum is $w = \frac{2x\lambda}{a}$. The change in slit width is $\Delta a = a\alpha\Delta T$.

EXECUTE: $dw = 2x\lambda\left(-\frac{da}{a^2}\right) = -\frac{2x\lambda}{a^2}da = -\frac{w}{a}da$. Therefore, $\Delta w = -\frac{w}{a}\Delta a$. The equation for thermal expansion says $\Delta a = a\alpha\Delta T$, so $\Delta w = -w\alpha\Delta T = -(2.75\text{ mm})(2.4\times10^{-5}\text{ K}^{-1})(500\text{ K}) = -0.033\text{ mm}$. When the temperature of the plate increases, the width of the slit increases and the width of the central maximum decreases.

EVALUATE: The fractional change in the width of the slit is $(0.033\text{ mm})/(2.75\text{ mm}) = 1.2\%$. This is small, but observable.

36.61. **IDENTIFY** and **SET UP:** Draw the specified phasor diagrams. There is totally destructive interference between two slits when their phasors are in opposite directions.

EXECUTE: **(a)** For eight slits, the phasor diagrams must have eight vectors. The diagrams for each specified value of ϕ are sketched in Figure 36.61a. In each case the phasors all sum to zero.

(b) The additional phasor diagrams for $\phi = 3\pi/2$ and $3\pi/4$ are sketched in Figure 36.61b.

For $\phi = \frac{3\pi}{4}, \phi = \frac{5\pi}{4}$, and $\phi = \frac{7\pi}{4}$, totally destructive interference occurs between slits four apart. For $\phi = \frac{3\pi}{2}$, totally destructive interference occurs with every second slit.

EVALUATE: At a minimum the phasors for all slits sum to zero.

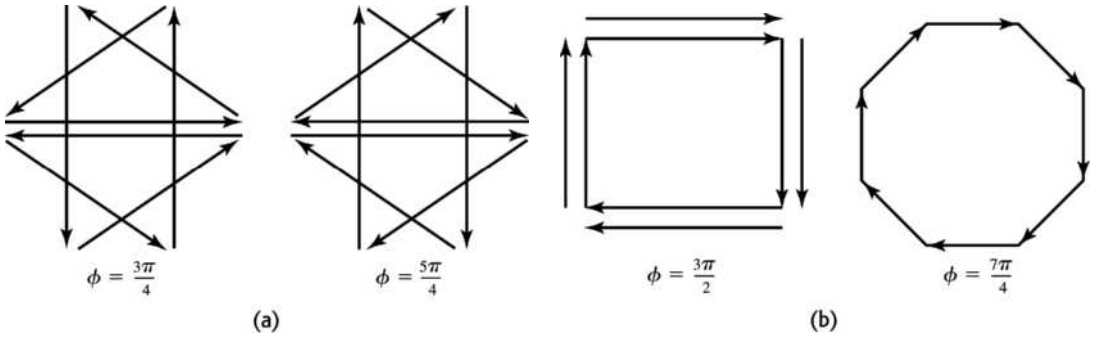

Figure 36.61

36.62. **IDENTIFY:** The wavelength of the helium spectral line from the receding galaxy will be different from the spectral line on earth due to the Doppler shift in the light from the galaxy.

SET UP: $d\sin\theta = m\lambda$. $\sin\theta_{\text{lab}} = \dfrac{2\lambda_{\text{lab}}}{d}$. $\sin\theta_{\text{galaxy}} = \dfrac{2\lambda_{\text{galaxy}}}{d}$. $\sin\theta_{\text{galaxy}} = \sin\theta_{\text{lab}}\left(\dfrac{\lambda_{\text{lab}}}{\lambda_{\text{galaxy}}}\right)$. The Doppler formula says $f_{\text{R}} = \sqrt{\dfrac{c-v}{c+v}}f_{\text{S}}$. Using $f = \dfrac{c}{\lambda}$, we have $\dfrac{1}{\lambda_{\text{R}}} = \dfrac{1}{\lambda_{\text{S}}}\sqrt{\dfrac{c-v}{c+v}}$. Since the lab is the receiver R and the galaxy is the source S, this becomes $\lambda_{\text{lab}} = \lambda_{\text{galaxy}}\sqrt{\dfrac{c+v}{c-v}}$.

EXECUTE: $\sin\theta_{\text{galaxy}} = \sin\theta_{\text{lab}}\sqrt{\dfrac{c+v}{c-v}} = \sin(18.9^{\text{o}})\sqrt{\dfrac{2.998\times10^{8}\ \text{m/s} + 2.65\times10^{7}\ \text{m/s}}{2.998\times10^{8}\ \text{m/s} - 2.65\times10^{7}\ \text{m/s}}}$ which gives $\theta_{\text{galaxy}} = 20.7^{\text{o}}$.

EVALUATE: The galaxy is moving away, so the wavelength of its light will be lengthened, which means that the angle should be increased compared to the angle from light on earth, as we have found.

36.63. **IDENTIFY** and **SET UP:** The condition for an intensity maximum is $d\sin\theta = m\lambda$, $m = 0, \pm1, \pm2,\ldots$ Third order means $m = 3$. The longest observable wavelength is the one that gives $\theta = 90°$ and hence $\theta = 1$.

EXECUTE: 9200 lines/cm so 9.2×10^{5} lines/m and $d = \dfrac{1}{9.2\times10^{5}}\ \text{m} = 1.087\times10^{-6}\ \text{m}$.

$$\lambda = \frac{d\sin\theta}{m} = \frac{(1.087\times10^{-6}\ \text{m})(1)}{3} = 3.6\times10^{-7}\ \text{m} = 360\ \text{nm}.$$

EVALUATE: The longest wavelength that can be obtained decreases as the order increases.

36.64. **IDENTIFY** and **SET UP:** As the rays first reach the slits there is already a phase difference between adjacent slits of $\dfrac{2\pi d\sin\theta'}{\lambda}$. This, added to the usual phase difference introduced after passing through the slits, yields the condition for an intensity maximum. For a maximum the total phase difference must equal $2\pi m$.

EXECUTE: $\dfrac{2\pi d\sin\theta}{\lambda} + \dfrac{2\pi d\sin\theta'}{\lambda} = 2\pi m \Rightarrow d(\sin\theta + \sin\theta') = m\lambda$

(b) 600 slits/mm $\Rightarrow d = \dfrac{1}{6.00\times10^{5}\ \text{m}^{-1}} = 1.67\times10^{-6}\ \text{m}$.

For $\theta' = \theta°$,

$m = 0$: $\theta = \arcsin(0) = 0$.

$m = 1$: $\theta = \arcsin\left(\dfrac{\lambda}{d}\right) = \arcsin\left(\dfrac{6.50\times10^{-7}\text{m}}{1.67\times10^{-6}\text{m}}\right) = 22.9°$.

$m = -1$: $\theta = \arcsin\left(-\dfrac{\lambda}{d}\right) = \arcsin\left(-\dfrac{6.50\times10^{-7}\text{m}}{1.67\times10^{-6}\text{m}}\right) = -22.9°$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

For $\theta' = 20.0°$,

$m = 0$: $\theta = \arcsin(-\sin 20.0°) = -20.0°$.

$m = 1$: $\theta = \arcsin\left(\dfrac{6.50\times10^{-7}\text{ m}}{1.67\times10^{-6}\text{ m}}\sin 20.0°\right) = 2.71°$.

$m = -1$: $\theta = \arcsin\left(-\dfrac{6.50\times10^{-7}\text{ m}}{1.67\times10^{-6}\text{ m}}\sin 20.0°\right) = -47.0°$.

EVALUATE: When $\theta' > 0$, the maxima are shifted downward on the screen, toward more negative angles.

36.65. **IDENTIFY:** The maxima are given by $d\sin\theta = m\lambda$. We need $\sin\theta = \dfrac{m\lambda}{d} \le 1$ in order for all the visible wavelengths to be seen.

SET UP: For 650 slits/mm $\Rightarrow d = \dfrac{1}{6.50\times10^5\text{ m}^{-1}} = 1.53\times10^{-6}$ m.

EXECUTE: $\lambda_1 = 4.00\times10^{-7}$m: $m = 1$: $\dfrac{\lambda_1}{d} = 0.26$; $m = 2$: $\dfrac{2\lambda_1}{d} = 0.52$; $m = 3$: $\dfrac{3\lambda_1}{d} = 0.78$.

$\lambda_2 = 7.00\times10^{-7}$m: $m = 1$: $\dfrac{\lambda_2}{d} = 0.46$; $m = 2$: $\dfrac{2\lambda_2}{d} = 0.92$; $m = 3$: $\dfrac{3\lambda_2}{d} = 1.37$. So, the third order does not contain the violet end of the spectrum, and therefore only the first- and second-order diffraction patterns contain all colors of the spectrum.

EVALUATE: θ for each maximum is larger for longer wavelengths.

36.66. **IDENTIFY:** Apply $\sin\theta = 1.22\dfrac{\lambda}{D}$.

SET UP: θ is small, so $\sin\theta \approx \dfrac{\Delta x}{R}$, where Δx is the size of the detail and $R = 7.2\times10^8$ ly.

1 ly $= 9.41\times10^{12}$ km. $\lambda = c/f$

EXECUTE: $\sin\theta = 1.22\dfrac{\lambda}{D} \approx \dfrac{\Delta x}{R} \Rightarrow \Delta x = \dfrac{1.22\lambda R}{D} = \dfrac{(1.22)cR}{Df} = \dfrac{(1.22)(3.00\times10^5\text{ km/s})(7.2\times10^8\text{ ly})}{(77.000\times10^3\text{ km})(1.665\times10^9\text{ Hz})} = 2.06$ ly.

$(9.41\times10^{12}\text{ km/ly})(2.06\text{ ly}) = 1.94\times10^{13}$ km.

EVALUATE: $\lambda = 18$ cm. λ/D is very small, so $\dfrac{\Delta x}{R}$ is very small. Still, R is very large and Δx is many orders of magnitude larger than the diameter of the sun.

36.67. **IDENTIFY** and **SET UP:** Add the phases between adjacent sources.

EXECUTE: **(a)** $d\sin\theta = m\lambda$. Place 1st maximum at ∞ or $\theta = 90°$. $d = \lambda$. If $d < \lambda$, this puts the first maximum "beyond ∞." Thus, if $d < \lambda$ there is only a single principal maximum.

(b) At a principal maximum when $\delta = 0$, the phase difference due to the path difference between adjacent slits is $\Phi_{\text{path}} = 2\pi\left(\dfrac{d\sin\theta}{\lambda}\right)$. This just scales 2π radians by the fraction the wavelength is of the path difference between adjacent sources. If we add a relative phase δ between sources, we still must maintain a total phase difference of zero to keep our principal maximum.

$$\Phi_{\text{path}} \pm \delta = 0 \Rightarrow \frac{2\pi d\sin\theta}{\lambda} = \pm\delta \text{ or } \theta = \sin^{-1}\left(\frac{\delta\lambda}{2\pi d}\right)$$

(c) $d = \dfrac{0.280\text{ m}}{14} = 0.0200$ m (count the number of spaces between 15 points). Let $\theta = 45°$. Also recall $f\lambda = c$, so

$$\delta_{\max} = \pm\frac{2\pi(0.0200\text{ m})(8.800\times10^9\text{ Hz})\sin 45°}{(3.00\times10^8\text{ m/s})} = \pm 2.61\text{ radians}.$$

EVALUATE: δ must vary over a wider range in order to sweep the beam through a greater angle.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

36.68. **IDENTIFY:** The wavelength of the light is smaller under water than it is in air, which will affect the resolving power of the lens, by Rayleigh's criterion.

SET UP: The wavelength under water is $\lambda = \lambda_0/n$, and for small angles Rayleigh's criterion is $\theta = 1.22\lambda/D$.

EXECUTE: **(a)** In air the wavelength is $\lambda_0 = c/f = (3.00\times10^8 \text{ m/s})/(6.00\times10^{14} \text{ Hz}) = 5.00\times10^{-7}$ m. In water the wavelength is $\lambda = \lambda_0/n = (5.00\times10^{-7}\text{ m})/1.33 = 3.76\times10^{-7}$ m. With the lens open all the way, we have $D = f/2.8 = (35.0 \text{ mm})/2.80 = (0.0350 \text{ m})/2.80$. In the water, we have

$$\sin\theta \approx \theta = 1.22\lambda/D = (1.22)(3.76\times10^{-7}\text{ m})[(0.0350 \text{ m})/2.80] = 3.67\times10^{-5} \text{ rad}.$$

Calling w the width of the resolvable detail, we have

$$\theta = w/x \rightarrow w = x\theta = (2750 \text{ mm})(3.67\times10^{-5}\text{ rad}) = 0.101 \text{ mm}$$

(b) $\theta = 1.22\lambda/D = (1.22)(5.00\times10^{-7}\text{ m})/[(0.0350 \text{ m})/2.80] = 4.88\times10^{-5}$ rad

$$w = x\theta = (2750 \text{ mm})(4.88\times10^{-5} \text{ rad}) = 0.134 \text{ mm}$$

EVALUATE: Due to the reduced wavelength underwater, the resolution of the lens is better under water than in air.

36.69. **IDENTIFY:** The diameter D of the aperture limits the resolution due to diffraction, by Rayleigh's criterion.

SET UP: Rayleigh's criterion says that $\theta_{\text{res}} = 1.22\dfrac{\lambda}{D}$. $D = 4.00$ mm. $\theta_{\text{res}} = \dfrac{y}{s}$, where s is the altitude and $y = 65.0$ m.

EXECUTE: Combining two equations above gives $\dfrac{y}{s} = 1.22\dfrac{\lambda}{D}$.

$$s = \frac{yD}{1.22\lambda} = \frac{(65.0 \text{ m})(4.00\times10^{-3} \text{ m})}{1.22(550\times10^{-9} \text{ m})} = 3.87\times10^5 \text{ m} = 387 \text{ km}.$$

EVALUATE: This is comparable to the altitude of the Hubble telescope.

36.70. **IDENTIFY:** The resolution of the eye is limited because light diffracts as it passes through the pupil. The size of the pupil determines the resolution.

SET UP: The smallest angular separation that can be resolved is $\theta_{\text{res}} = 1.22\dfrac{\lambda}{D}$. The angular size of the object is its height divided by its distance from the eye.

EXECUTE: **(a)** The angular size of the object is $\theta = \dfrac{50\times10^{-6} \text{ m}}{25\times10^{-2} \text{ m}} = 2.0\times10^{-4}$ rad.

$\theta_{\text{res}} = 1.22\dfrac{\lambda}{D} = 1.22\left(\dfrac{550\times10^{-9} \text{ m}}{2.0\times10^{-3} \text{ m}}\right) = 3.4\times10^{-4}$ rad. $\theta < \theta_{\text{res}}$ so the object cannot be resolved.

(b) $\theta_{\text{res}} = \dfrac{y}{s}$ and $y = s\theta_{\text{res}} = (25 \text{ cm})(3.4\times10^{-4} \text{ rad}) = 8.5\times10^{-3}$ cm $= 85$ μm.

(c) $\theta = \theta_{\text{res}} = 3.4\times10^{-4}$ rad $= 0.019° = 1.1$ min. This is very close to the experimental value of 1 min.

(d) Diffraction is more important.

EVALUATE: We could not see any clearer if our retinal cells were much smaller than they are now because diffraction is more important in limiting the resolution of our vision.

36.71. **IDENTIFY:** The liquid reduces the wavlength of the light (compared to its value in air), and the scratch causes light passing through it to undergo single-slit diffraction.

SET UP: $\sin\theta = \dfrac{\lambda}{a}$, where λ is the wavelength in the liquid. $n = \dfrac{\lambda_{\text{air}}}{\lambda}$.

EXECUTE: $\tan\theta = \dfrac{(22.4/2) \text{ cm}}{30.0 \text{ cm}}$ and $\theta = 20.47^{\text{o}}$.

$\lambda = a\sin\theta = (1.25\times10^{-6} \text{ m})\sin 20.47^{\text{o}} = 4.372\times10^{-7}$ m $= 437.2$ nm. $n = \dfrac{\lambda_{\text{air}}}{\lambda} = \dfrac{612 \text{ nm}}{437.2 \text{ nm}} = 1.40$.

EVALUATE: $n > 1$, as it must be, and $n = 1.40$ is reasonable for many transparent films.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

36.72. **IDENTIFY:** Apply $\sin\theta = 1.22\dfrac{\lambda}{D}$.

SET UP: θ is small, so $\sin\theta \approx \dfrac{\Delta x}{R}$, where Δx is the size of the details and R is the distance to the earth. $1\text{ ly} = 9.41\times10^{15}$ m.

EXECUTE: **(a)** $R = \dfrac{D\Delta x}{1.22\lambda} = \dfrac{(6.00\times10^6\text{ m})(2.50\times10^5\text{ m})}{(1.22)(1.0\times10^{-5}\text{ m})} = 1.23\times10^{17}\text{ m} = 13.1\text{ ly}$

(b) $\Delta x = \dfrac{1.22\lambda R}{D} = \dfrac{(1.22)(1.0\times10^{-5}\text{ m})(4.22\text{ ly})(9.41\times10^{15}\text{ m/ly})}{1.0\text{ m}} = 4.84\times10^8$ km. This is about 10,000 times the diameter of the earth! Not enough resolution to see an earth-like planet! Δx is about 3 times the distance from the earth to the sun.

(c) $\Delta x = \dfrac{(1.22)(1.0\times10^{-5}\text{ m})(59\text{ ly})(9.41\times10^{15}\text{ m/ly})}{6.00\times10^6\text{ m}} = 1.13\times10^6\text{ m} = 1130\text{ km}.$

$\dfrac{\Delta x}{D_{\text{planet}}} = \dfrac{1130\text{ km}}{1.38\times10^5\text{ km}} = 8.19\times10^{-3}$; Δx is small compared to the size of the planet.

EVALUATE: The very large diameter of *Planet Imager* allows it to resolve planet-sized detail at great distances.

36.73. **IDENTIFY** and **SET UP:** Follow the steps specified in the problem.

EXECUTE: **(a)** From the segment dy', the fraction of the amplitude of E_0 that gets through is

$E_0\left(\dfrac{dy'}{a}\right) \Rightarrow dE = E_0\left(\dfrac{dy'}{a}\right)\sin(kx-\omega t).$

(b) The path difference between each little piece is

$y'\sin\theta \Rightarrow kx = k(D - y'\sin\theta) \Rightarrow dE = \dfrac{E_0 dy'}{a}\sin(k(D-y'\sin\theta)-\omega t)$. This can be rewritten as

$dE = \dfrac{E_0 dy'}{a}(\sin(kD-\omega t)\cos(ky'\sin\theta) + \sin(ky'\sin\theta)\cos(kD-\omega t)).$

(c) So the total amplitude is given by the integral over the slit of the above.

$\Rightarrow E = \int_{-a/2}^{a/2} dE = \dfrac{E_0}{a}\int_{-a/2}^{a/2} dy'\,(\sin(kD-\omega t)\cos(ky'\sin\theta) + \sin(ky'\sin\theta)\cos(kD-\omega t)).$

But the second term integrates to zero, so we have:

$$E = \frac{E_0}{a}\sin(kD-\omega t)\int_{-a/2}^{a/2} dy'(\cos(ky'\sin\theta)) = E_0\sin(kD-\omega t)\left[\left(\frac{\sin(ky'\sin\theta)}{ka\sin\theta/2}\right)\right]_{-a/2}^{a/2}$$

$$\Rightarrow E = E_0\sin(kD-\omega x)\left(\frac{\sin(ka(\sin\theta)/2)}{ka(\sin\theta)/2}\right) = E_0\sin(kD-\omega x)\left(\frac{\sin(\pi a(\sin\theta)/\lambda)}{\pi a(\sin\theta)/\lambda)}\right).$$

At $\theta = 0, \dfrac{\sin[\ldots]}{[\ldots]} = 1 \Rightarrow E = E_0\sin(kD-\omega x).$

(d) Since $I \propto E^2 \Rightarrow I = I_0\left(\dfrac{\sin(ka(\sin\theta)/2)}{ka(\sin\theta)/2}\right)^2 = I_0\left(\dfrac{\sin(\beta/2)}{\beta/2}\right)^2$, where we have used $I_0 = E_0^2\sin^2(kx-\omega t)$.

EVALUATE: The same result for $I(\theta)$ is obtained as was obtained using phasors.

36.74. **IDENTIFY** and **SET UP:** Follow the steps specified in the problem.

EXECUTE: **(a)** Each source can be thought of as a traveling wave evaluated at $x = R$ with a maximum amplitude of E_0. However, each successive source will pick up an extra phase from its respective pathlength to point P. $\phi = 2\pi\left(\dfrac{d\sin\theta}{\lambda}\right)$ which is just 2π, the maximum phase, scaled by whatever fraction

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

the path difference, $d \sin\theta$, is of the wavelength, λ. By adding up the contributions from each source (including the accumulating phase difference) this gives the expression provided.

(b) $e^{i(kR-\omega t+n\phi)} = \cos(kR-\omega t+n\phi) + i\sin(kR-\omega t+n\phi)$. The real part is just $\cos(kR-\omega t+n\phi)$. So, $\mathrm{Re}\left[\sum_{n=0}^{N-1} E_0 e^{i(kR-\omega x+n\phi)}\right] = \sum_{n=0}^{N-1} E_0 \cos(kR-\omega x+n\phi)$. (Note: Re means "the real part of…."). But this is just

$E_0\cos(kR-\omega t) + E_0\cos(kR-\omega t+\phi) + E_0\cos(kR-\omega t+2\phi) + \cdots + E_0\cos(kR-\omega t+(N-1)\phi)$

(c) $\sum_{n=0}^{N-1} E_0\, e^{i(kR-\omega t+n\phi)} = E_0 \sum_{n=0}^{N-1} e^{-i\omega t}\, e^{+ikR} e^{in\phi} = E_0 e^{i(kR-\omega t)} \sum_{n=0}^{N-1} e^{in\phi}$. $\sum_{n=0}^{\infty} e^{in\phi} = \sum_{n=0}^{N-1} (e^{i\phi})^n$. But recall $\sum_{n=0}^{N-1} x^n = \dfrac{x^N-1}{x-1}$. Putting everything together:

$$\sum_{n=0}^{N-1} E_0 e^{i(kR-\omega t+n\phi)} = E_0 e^{i(kR-\omega t+(N-1)\phi/2)} \frac{(e^{iN\phi/2} - e^{-iN\phi/2})}{(e^{i\phi/2} - e^{-i\phi/2})}$$

$$= E_0[\cos(kR-\omega t+(N-1)\phi/2) + i\sin(kR-\omega t+(N-1)\phi/2)]\left[\frac{\cos N\phi/2 + \sin N\phi/2 - \cos N\phi/2 + i\sin N\phi/2}{\cos\phi/2 + i\sin\phi/2 - \cos\phi/2 + i\sin\phi/2}\right]$$

Taking only the real part gives $\Rightarrow E_0\cos(kR-\omega t+(N-1)\phi/2)\dfrac{\sin(N\phi/2)}{\sin\phi/2} = E.$

(d) $I = |E|^2_{\text{av}} = I_0 \dfrac{\sin^2(N\phi/2)}{\sin^2(\phi/2)}$. (The $\cos^2$ term goes to $\frac{1}{2}$ in the time average and is included in the definition of I_0.) $I_0 \propto \dfrac{E_0^2}{2}$.

EVALUATE: (e) $N = 2$. $I = I_0 \dfrac{\sin^2(2\phi/2)}{\sin^2\phi/2} = \dfrac{I_0(2\sin\phi/2\cos\phi/2)^2}{\sin^2\phi/2} = 4I_0\cos^2\dfrac{\phi}{2}$. Looking at Eq. (35.9), $I'_0 \propto 2E_0^2$ but for us $I_0 \propto \dfrac{E_0^2}{2} = \dfrac{I'_0}{4}$.

36.75. **IDENTIFY** and **SET UP:** From Problem 36.74, $I = I_0 \dfrac{\sin^2(N\phi/2)}{\sin^2\phi/2}$. Use this result to obtain each result specified in the problem.

EXECUTE: (a) $\lim_{\phi\to 0} I \to \dfrac{0}{0}$. Use 1'Hôpital's rule: $\lim_{\phi\to 0} \dfrac{\sin(N\phi/2)}{\sin\phi/2} = \lim_{\phi\to 0}\left(\dfrac{N/2}{1/2}\right)\dfrac{\cos(N\phi/2)}{\cos(\phi/2)} = N$. So $\lim_{\phi\to 0} I = N^2 I_0$.

(b) The location of the first minimum is when the numerator first goes to zero at $\dfrac{N}{2}\phi_{\min} = \pi$ or $\phi_{\min} = \dfrac{2\pi}{N}$. The width of the central maximum goes like $2\phi_{\min}$, so it is proportional to $\dfrac{1}{N}$.

(c) Whenever $\dfrac{N\phi}{2} = n\pi$ where n is an integer, the numerator goes to zero, giving a minimum in intensity. That is, I is a minimum wherever $\phi = \dfrac{2n\pi}{N}$. This is true assuming that the denominator doesn't go to zero as well, which occurs when $\dfrac{\phi}{2} = m\pi$, where m is an integer. When both go to zero, using the result from part(a), there is a maximum. That is, if $\dfrac{n}{N}$ is an integer, there will be a maximum.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(d) From part (c), if $\frac{n}{N}$ is an integer we get a maximum. Thus, there will be $N-1$ minima. (Places where $\frac{n}{N}$ is not an integer for fixed N and integer n.) For example, $n=0$ will be a maximum, but $n=1, 2\ldots, N-1$ will be minima with another maximum at $n=N$.

(e) Between maxima $\frac{\phi}{2}$ is a half-integer multiple of $\pi\left(\text{i.e.,}\frac{\pi}{2},\frac{3\pi}{2}\text{etc.}\right)$ and if N is odd then $\frac{\sin^2(N\phi/2)}{\sin^2\phi/2}\to 1$, so $I\to I_0$.

EVALUATE: These results show that the principal maxima become sharper as the number of slits is increased.

37

RELATIVITY

37.1. **IDENTIFY** and **SET UP:** Consider the distance A to O' and B to O' as observed by an observer on the ground (Figure 37.1).

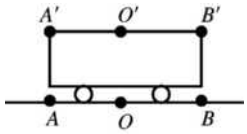

Figure 37.1

EXECUTE: Simultaneous to observer on train means light pulses from A' and B' arrive at O' at the same time. To observer at O light from A' has a longer distance to travel than light from B' so O will conclude that the pulse from $A(A')$ started before the pulse at $B(B')$. To observer at O bolt A appeared to strike first.

EVALUATE: Section 37.2 shows that if they are simultaneous to the observer on the ground then an observer on the train measures that the bolt at B' struck first.

37.2. **IDENTIFY:** Apply Eq. (37.8).

SET UP: The lifetime measured in the muon frame is the proper time Δt_0. $u = 0.900c$ is the speed of the muon frame relative to the laboratory frame. The distance the particle travels in the lab frame is its speed in that frame times its lifetime in that frame.

EXECUTE: **(a)** $\gamma = \dfrac{1}{\sqrt{1-(0.9)^2}} = 2.29$. $\Delta t = \gamma \Delta t_0 = (2.29)\,(2.20\times10^{-6}\text{s}) = 5.05\times10^{-6}$ s.

(b) $d = v\Delta t = (0.900)(3.00\times10^8 \text{ m/s})(5.05\times10^{-6}\text{s}) = 1.36\times10^3 \text{ m} = 1.36 \text{ km}$.

EVALUATE: The lifetime measured in the lab frame is larger than the lifetime measured in the muon frame.

37.3. **IDENTIFY** and **SET UP:** The problem asks for u such that $\Delta t_0/\Delta t = \dfrac{1}{2}$.

EXECUTE: $\Delta t = \dfrac{\Delta t_0}{\sqrt{1-u^2/c^2}}$ gives $u = c\sqrt{1-(\Delta t_0/\Delta t)^2} = (3.00\times10^8 \text{ m/s})\sqrt{1-\left(\dfrac{1}{2}\right)^2} = 2.60\times10^8$ m/s;

$\dfrac{u}{c} = 0.867$

Jet planes fly at less than ten times the speed of sound, less than about 3000 m/s. Jet planes fly at much lower speeds than we calculated for u.

37.4. **IDENTIFY:** Time dilation occurs because the rocket is moving relative to Mars.

SET UP: The time dilation equation is $\Delta t = \gamma \Delta t_0$, where t_0 is the proper time.

EXECUTE: **(a)** The two time measurements are made at the same place on Mars by an observer at rest there, so the observer on Mars measures the proper time.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) $\Delta t = \gamma \Delta t_0 = \dfrac{1}{\sqrt{1-(0.985)^2}}(75.0\ \mu\text{s}) = 435\ \mu\text{s}$

EVALUATE: The pulse lasts for a shorter time relative to the rocket than it does relative to the Mars observer.

37.5. **(a) IDENTIFY** and **SET UP:** $\Delta t_0 = 2.60\times10^{-8}$ s; $\Delta t = 4.20\times10^{-7}$ s. In the lab frame the pion is created and decays at different points, so this time is not the proper time.

EXECUTE: $\Delta t = \dfrac{\Delta t_0}{\sqrt{1-u^2/c^2}}$ says $1-\dfrac{u^2}{c^2} = \left(\dfrac{\Delta t_0}{\Delta t}\right)^2$

$$\frac{u}{c} = \sqrt{1-\left(\frac{\Delta t_0}{\Delta t}\right)^2} = \sqrt{1-\left(\frac{2.60\times10^{-8}\ \text{s}}{4.20\times10^{-7}\ \text{s}}\right)^2} = 0.998;\ u = 0.998c$$

EVALUATE: $u < c$, as it must be, but u/c is close to unity and the time dilation effects are large.

(b) IDENTIFY and **SET UP:** The speed in the laboratory frame is $u = 0.998c$; the time measured in this frame is Δt, so the distance as measured in this frame is $d = u\Delta t$.

EXECUTE: $d = (0.998)(2.998\times10^8\ \text{m/s})(4.20\times10^{-7}\ \text{s}) = 126\ \text{m}$

EVALUATE: The distance measured in the pion's frame will be different because the time measured in the pion's frame is different (shorter).

37.6. **IDENTIFY:** Apply Eq. (37.8).

SET UP: For part (a) the proper time is measured by the race pilot. $\gamma = 1.667$.

EXECUTE: **(a)** $\Delta t = \dfrac{1.20\times10^8\ \text{m}}{(0.800)(3.00\times10^8\ \text{m/s})} = 0.500\ \text{s}$. $\Delta t_0 = \dfrac{\Delta t}{\gamma} = \dfrac{0.500\ \text{s}}{1.667} = 0.300\ \text{s}$.

(b) $(0.300\ \text{s})(0.800c) = 7.20\times10^7\ \text{m}$.

(c) You read $\dfrac{1.20\times10^8\ \text{m}}{(0.800)(3\times10^8\ \text{m/s})} = 0.500\ \text{s}$.

EVALUATE: The two events are the spaceracer passing you and the spaceracer reaching a point 1.20×10^8 m from you. The timer traveling with the spaceracer measures the proper time between these two events.

37.7. **IDENTIFY** and **SET UP:** A clock moving with respect to an observer appears to run more slowly than a clock at rest in the observer's frame. The clock in the spacecraft measurers the proper time Δt_0.

$\Delta t = 365$ days $= 8760$ hours.

EXECUTE: The clock on the moving spacecraft runs slow and shows the smaller elapsed time.

$\Delta t_0 = \Delta t\sqrt{1-u^2/c^2} = (8760\ \text{h})\sqrt{1-(4.80\times10^6/3.00\times10^8)^2} = 8758.88\ \text{h}$. The difference in elapsed times is $8760\ \text{h} - 8758.88\ \text{h} = 1.12\ \text{h}$.

37.8. **IDENTIFY** and **SET UP:** The proper time is measured in the frame where the two events occur at the same point.

EXECUTE: **(a)** The time of 12.0 ms measured by the first officer on the craft is the proper time.

(b) $\Delta t = \dfrac{\Delta t_0}{\sqrt{1-u^2/c^2}}$ gives $u = c\sqrt{1-(\Delta t_0/\Delta t)^2} = c\sqrt{1-(12.0\times10^{-3}/0.190)^2} = 0.998c$.

EVALUATE: The observer at rest with respect to the searchlight measures a much shorter duration for the event.

37.9. **IDENTIFY** and **SET UP:** $l = l_0\sqrt{1-u^2/c^2}$. The length measured when the spacecraft is moving is $l = 74.0$ m; l_0 is the length measured in a frame at rest relative to the spacecraft.

EXECUTE: $l_0 = \dfrac{l}{\sqrt{1-u^2/c^2}} = \dfrac{74.0\ \text{m}}{\sqrt{1-(0.600c/c)^2}} = 92.5\ \text{m}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: $l_0 > l$. The moving spacecraft appears to an observer on the planet to be shortened along the direction of motion.

37.10. **IDENTIFY** and **SET UP:** When the meterstick is at rest with respect to you, you measure its length to be 1.000 m, and that is its proper length, l_0. $l = 0.3048$ m.

EXECUTE: $l = l_0\sqrt{1-u^2/c^2}$ gives $u = c\sqrt{1-(l/l_0)^2} = c\sqrt{1-(0.3048/1.00)^2} = 0.9524c = 2.86\times10^8$ m/s.

37.11. **IDENTIFY** and **SET UP:** The 2.2 μs lifetime is Δt_0 and the observer on earth measures Δt. The atmosphere is moving relative to the muon so in its frame the height of the atmosphere is l and l_0 is 10 km.

EXECUTE: **(a)** The greatest speed the muon can have is c, so the greatest distance it can travel in 2.2×10^{-6} s is $d = vt = (3.00\times10^8 \text{ m/s})(2.2\times10^{-6} \text{ s}) = 660 \text{ m} = 0.66 \text{ km}$.

(b) $\Delta t = \dfrac{\Delta t_0}{\sqrt{1-u^2/c^2}} = \dfrac{2.2\times10^{-6} \text{ s}}{\sqrt{1-(0.999)^2}} = 4.9\times10^{-5} \text{ s}$

$d = vt = (0.999)(3.00\times10^8 \text{ m/s})(4.9\times10^{-5} \text{ s}) = 15 \text{ km}$

In the frame of the earth the muon can travel 15 km in the atmosphere during its lifetime.

(c) $l = l_0\sqrt{1-u^2/c^2} = (10 \text{ km})\sqrt{1-(0.999)^2} = 0.45 \text{ km}$

In the frame of the muon the height of the atmosphere is less than the distance it moves during its lifetime.

37.12. **IDENTIFY** and **SET UP:** The scientist at rest on the earth's surface measures the proper length of the separation between the point where the particle is created and the surface of the earth, so $l_0 = 45.0$ km. The transit time measured in the particle's frame is the proper time, Δt_0.

EXECUTE: **(a)** $t = \dfrac{l_0}{v} = \dfrac{45.0\times10^3 \text{ m}}{(0.99540)(3.00\times10^8 \text{ m/s})} = 1.51\times10^{-4} \text{ s}$

(b) $l = l_0\sqrt{1-u^2/c^2} = (45.0 \text{ km})\sqrt{1-(0.99540)^2} = 4.31 \text{ km}$

(c) time dilation formula: $\Delta t_0 = \Delta t\sqrt{1-u^2/c^2} = (1.51\times10^{-4} \text{ s})\sqrt{1-(0.99540)^2} = 1.44\times10^{-5} \text{ s}$

from Δl: $t = \dfrac{l}{v} = \dfrac{4.31\times10^3 \text{ m}}{(0.99540)(3.00\times10^8 \text{ m/s})} = 1.44\times10^{-5} \text{ s}$

The two results agree.

37.13. **IDENTIFY:** Apply Eq. (37.16).

SET UP: The proper length l_0 of the runway is its length measured in the earth's frame. The proper time Δt_0 for the time interval for the spacecraft to travel from one end of the runway to the other is the time interval measured in the frame of the spacecraft.

EXECUTE: **(a)** $l_0 = 3600$ m.

$l = l_0\sqrt{1-\dfrac{u^2}{c^2}} = (3600 \text{ m})\sqrt{1-\dfrac{(4.00\times10^7 \text{ m/s})^2}{(3.00\times10^8 \text{ m/s})^2}} = (3600 \text{ m})(0.991) = 3568 \text{ m}.$

(b) $\Delta t = \dfrac{l_0}{u} = \dfrac{3600 \text{ m}}{4.00\times10^7 \text{ m/s}} = 9.00\times10^{-5} \text{ s}.$

(c) $\Delta t_0 = \dfrac{l}{u} = \dfrac{3568 \text{ m}}{4.00\times10^7 \text{ m/s}} = 8.92\times10^{-5} \text{ s}.$

EVALUATE: $\dfrac{1}{\gamma} = 0.991$, so Eq. (37.8) gives $\Delta t = \dfrac{8.92\times10^{-5}\text{s}}{0.991} = 9.00\times10^{-5}$ s. The result from length contraction is consistent with the result from time dilation.

37.14. **IDENTIFY:** The astronaut lies along the motion of the rocket, so his height will be Lorentz-contracted.

SET UP: The doctor in the rocket measures his proper length l_0.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: **(a)** $l_0 = 2.00$ m. $l = l_0\sqrt{1-u^2/c^2} = (2.00\text{ m})\sqrt{1-(0.850)^2} = 1.05$ m. The person on earth would measure his height to be 1.05 m.

(b) $l = 2.00$ m. $l_0 = \dfrac{l}{\sqrt{1-u^2/c^2}} = \dfrac{2.00\text{ m}}{\sqrt{1-(0.850)^2}} = 3.80$ m. This is not a reasonable height for a human.

(c) There is no length contraction in a direction perpendicular to the motion and both observers measure the same height, 2.00 m.

EVALUATE: The length of an object moving with respect to the observer is shortened in the direction of the motion, so in (a) and (b) the observer on earth measures a shorter height.

37.15. **IDENTIFY:** Apply Eq. (37.23).

SET UP: The velocities $\vec{v}'$ and $\vec{v}$ are both in the $+x$-direction, so $v_x' = v'$ and $v_x = v$.

EXECUTE: **(a)** $v = \dfrac{v'+u}{1+uv'/c^2} = \dfrac{0.400c+0.600c}{1+(0.400)(0.600)} = 0.806c$

(b) $v = \dfrac{v'+u}{1+uv'/c^2} = \dfrac{0.900c+0.600c}{1+(0.900)(0.600)} = 0.974c$

(c) $v = \dfrac{v'+u}{1+uv'/c^2} = \dfrac{0.990c+0.600c}{1+(0.990)(0.600)} = 0.997c.$

EVALUATE: Speed v is always less than c, even when $v'+u$ is greater than c.

37.16. **IDENTIFY:** Apply Eq. (37.6) and the equations for x and t that are developed in Example 37.6.

SET UP: S is Stanley's frame and S' is Mavis's frame. The proper time for the two events is the time interval measured in Mavis's frame. $\gamma = 1.667$ ($\gamma = 5/3$ if $u = (4/5)$c).

EXECUTE: **(a)** In Mavis's frame the event "light on" has space-time coordinates $x' = 0$ and $t' = 5.00$ s, so from the result of Example 37.6, $x = \gamma(x'+ut')$ and

$$t = \gamma\left(t' + \frac{ux'}{c^2}\right) \Rightarrow x = \gamma ut' = 2.00\times10^9\text{ m}, t = \gamma t' = 8.33\text{ s}.$$

(b) The 5.00-s interval in Mavis's frame is the proper time Δt_0 in Eq. (37.6), so $\Delta t = \gamma\Delta t_0 = 8.33$ s, the same as in part (a).

(c) $(8.33\text{ s})(0.800c) = 2.00\times10^9$ m, which is the distance x found in part (a).

EVALUATE: Mavis would measure that she would be a distance $(5.00\text{ s})(0.800c) = 1.20\times10^9$ m from Stanley when she turns on her light. In Eq. (37.16), $l_0 = 2.00\times10^9$ m and $l = 1.20\times10^9$ m.

37.17. **IDENTIFY:** The relativistic velocity addition formulas apply since the speeds are close to that of light.

SET UP: The relativistic velocity addition formula is $v_x' = \dfrac{v_x - u}{1-\dfrac{uv_x}{c^2}}$.

EXECUTE: **(a)** For the pursuit ship to catch the cruiser, the distance between them must be decreasing, so the velocity of the cruiser relative to the pursuit ship must be directed toward the pursuit ship.

(b) Let the unprimed frame be Tatooine and let the primed frame be the pursuit ship. We want the velocity v' of the cruiser knowing the velocity of the primed frame u and the velocity of the cruiser v in the unprimed frame (Tatooine).

$$v_x' = \frac{v_x - u}{1-\dfrac{uv_x}{c^2}} = \frac{0.600c - 0.800c}{1-(0.600)(0.800)} = -0.385c$$

The result implies that the cruiser is moving toward the pursuit ship at $0.385c$.

EVALUATE: The nonrelativistic formula would have given $-0.200c$, which is considerably different from the correct result.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

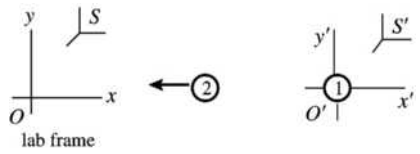
37.18. **IDENTIFY:** The observer on the spaceship measures the speed of the missile relative to the ship, and the earth observer measures the speed of the rocketship relative to earth.

SET UP: $u = 0.600c$. $v_x' = -0.800c$. $v_x = ?$. $v_x = \dfrac{v_x' + u}{1 + uv_x'/c^2}$.

EXECUTE: $v_x = \dfrac{v_x' + u}{1 + uv_x'/c^2} = \dfrac{-0.800c + 0.600c}{1 + (0.600)(-0.800)} = \dfrac{-0.200c}{0.520} = -0.385c$. The speed of the missile in the earth frame is $0.385c$.

EVALUATE: The observers on earth and in the spaceship measure different speeds for the missile because they are moving relative to each other.

37.19. **IDENTIFY** and **SET UP:** Reference frames S and S' are shown in Figure 37.19.



Frame S is at rest in the laboratory. Frame S' is attached to particle 1.

Figure 37.19

u is the speed of S' relative to S; this is the speed of particle 1 as measured in the laboratory. Thus $u = +0.650c$. The speed of particle 2 in S' is $0.950c$. Also, since the two particles move in opposite directions, 2 moves in the $-x'$-direction and $v_x' = -0.950c$. We want to calculate v_x, the speed of particle 2 in frame S; use Eq. (37.23).

EXECUTE: $v_x = \dfrac{v_x' + u}{1 + uv_x'/c^2} = \dfrac{-0.950c + 0.650c}{1 + (0.950c)(-0.650c)/c^2} = \dfrac{-0.300c}{1 - 0.6175} = -0.784c$. The speed of the second particle, as measured in the laboratory, is $0.784c$.

EVALUATE: The incorrect Galilean expression for the relative velocity gives that the speed of the second particle in the lab frame is $0.300c$. The correct relativistic calculation gives a result more than twice this.

37.20. **IDENTIFY** and **SET UP:** Let S be the laboratory frame and let S' be the frame of one of the particles, as shown in Figure 37.20. Let the positive x-direction for both frames be from particle 1 to particle 2. In the lab frame particle 1 is moving in the $+x$-direction and particle 2 is moving in the $-x$-direction. Then $u = 0.9520c$ and $v_x = -0.9520c$. v_x' is the velocity of particle 2 relative to particle 1.

EXECUTE: $v_x' = \dfrac{v_x - u}{1 - uv_x/c^2} = \dfrac{-0.9520c - 0.9520c}{1 - (0.9520c)(-0.9520c)/c^2} = -0.9988c$. The speed of particle 2 relative to particle 1 is $0.9988c$. $v_x' < 0$ shows particle 2 is moving toward particle 1.

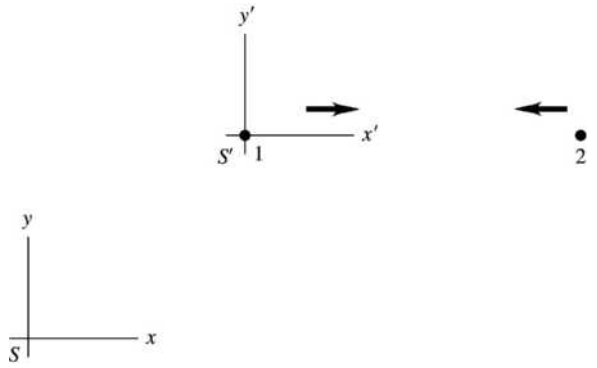


Figure 37.20

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

37.21. **IDENTIFY:** The relativistic velocity addition formulas apply since the speeds are close to that of light.

SET UP: The relativistic velocity addition formula is $v_x' = \dfrac{v_x - u}{1 - \dfrac{uv_x}{c^2}}$.

EXECUTE: In the relativistic velocity addition formula for this case, v_x' is the relative speed of particle 1 with respect to particle 2, v is the speed of particle 2 measured in the laboratory, and u is the speed of particle 1 measured in the laboratory, $u = -v$.

$v_x' = \dfrac{v-(-v)}{1-(-v)v/c^2} = \dfrac{2v}{1+v^2/c^2}$. $\dfrac{v_x'}{c^2}v^2 - 2v + v_x' = 0$ and $(0.890c)v^2 - 2c^2v + (0.890c^3) = 0$.

This is a quadratic equation with solution $v = 0.611c$ (v must be less than c).

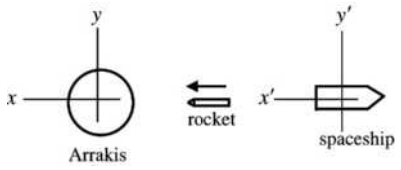
EVALUATE: The nonrelativistic result would be $0.445c$, which is considerably different from this result.

37.22. **IDENTIFY** and **SET UP:** Let the starfighter's frame be S and let the enemy spaceship's frame be S'. Let the positive x-direction for both frames be from the enemy spaceship toward the starfighter. Then $u = +0.400c$. $v' = +0.700c$. v is the velocity of the missile relative to you.

EXECUTE: **(a)** $v = \dfrac{v' + u}{1 + uv'/c^2} = \dfrac{0.700c + 0.400c}{1 + (0.400)(0.700)} = 0.859c$

(b) Use the distance it moves as measured in your frame and the speed it has in your frame to calculate the time it takes in your frame. $t = \dfrac{8.00\times10^9 \text{ m}}{(0.859)(3.00\times10^8 \text{ m/s})} = 31.0 \text{ s}$.

37.23. **IDENTIFY** and **SET UP:** The reference frames are shown in Figure 37.23.



S = Arrakis frame
S' = spaceship frame
The object is the rocket.

Figure 37.23

u is the velocity of the spaceship relative to Arrakis.
$v_x = +0.360c$; $v_x' = +0.920c$
(In each frame the rocket is moving in the positive coordinate direction.)

Use the Lorentz velocity transformation equation, Eq. (37.22): $v_x' = \dfrac{v_x - u}{1 - uv_x/c^2}$.

EXECUTE: $v_x' = \dfrac{v_x - u}{1 - uv_x/c^2}$ so $v_x' - u\left(\dfrac{v_x v_x'}{c^2}\right) = v_x - u$ and $u\left(1 - \dfrac{v_x v_x'}{c^2}\right) = v_x - v_x'$

$u = \dfrac{v_x - v_x'}{1 - v_x v_x'/c^2} = \dfrac{0.360c - 0.920c}{1 - (0.360c)(0.920c)/c^2} = -\dfrac{0.560c}{0.6688} = -0.837c$

The speed of the spacecraft relative to Arrakis is $0.837c = 2.51\times10^8$ m/s. The minus sign in our result for u means that the spacecraft is moving in the $-x$-direction, so it is moving away from Arrakis.

EVALUATE: The incorrect Galilean expression also says that the spacecraft is moving away from Arrakis, but with speed $0.920c - 0.360c = 0.560c$.

37.24. **IDENTIFY:** There is a Doppler effect in the frequency of the radiation due to the motion of the star.

SET UP: The star is moving away from the earth, so $f = \sqrt{\dfrac{c-u}{c+u}}\, f_0$.

EXECUTE: $f = \sqrt{\dfrac{c-0.600c}{c+0.600c}}\, f_0 = 0.500 f_0 = (0.500)(8.64\times10^{14} \text{ Hz}) = 4.32\times10^{14} \text{ Hz}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: The earth observer measures a lower frequency than the star emits because the star is moving away from the earth.

37.25. **IDENTIFY** and **SET UP:** Source and observer are approaching, so use Eq. (37.25): $f=\sqrt{\dfrac{c+u}{c-u}}f_0$. Solve for u, the speed of the light source relative to the observer.

(a) EXECUTE: $f^2=\left(\dfrac{c+u}{c-u}\right)f_0^2$

$(c-u)f^2=(c+u)f_0^2$ and $u=\dfrac{c(f^2-f_0^2)}{f^2+f_0^2}=c\left(\dfrac{(f/f_0)^2-1}{(f/f_0)^2+1}\right)$

$\lambda_0=675\text{ nm},\quad \lambda=575\text{ nm}$

$u=\left(\dfrac{(675\text{ nm}/575\text{ nm})^2-1}{(675\text{ nm}/575\text{ nm})^2+1}\right)c=0.159c=(0.159)(2.998\times10^8\text{ m/s})=4.77\times10^7\text{ m/s};$ definitely speeding

(b) $4.77\times10^7\text{ m/s}=(4.77\times10^7\text{ m/s})(1\text{ km}/1000\text{ m})(3600\text{ s}/1\text{ h})=1.72\times10^8\text{ km/h}$. Your fine would be $\$1.72\times10^8$ (172 million dollars).

EVALUATE: The source and observer are approaching, so $f>f_0$ and $\lambda<\lambda_0$. Our result gives $u<c$, as it must.

37.26. **IDENTIFY:** There is a Doppler effect in the frequency of the radiation due to the motion of the source.

SET UP: $f>f_0$ so the source is moving toward you. $f=\sqrt{\dfrac{c+u}{c-u}}f_0$.

EXECUTE: $(f/f_0)^2=\dfrac{c+u}{c-u}.\quad c(f/f_0)^2-(f/f_0)^2u=c+u.$

$u=\dfrac{c[(f/f_0)^2-1]}{(f/f_0)^2+1}=\left[\dfrac{(1.25)^2-1}{(1.25)^2+1}\right]c=0.220c,$ toward you.

EVALUATE: The difference in frequency is rather large (1.25 times), so the motion of the source must be a substantial fraction of the speed of light (around 20% in this case).

37.27. **IDENTIFY:** The speed of the proton is a substantial fraction of the speed of light, so we must use the relativistic formula for momentum.

SET UP: $p=\gamma mv.\quad p_0=\gamma_0 mv_0.\quad \dfrac{p}{p_0}=\dfrac{\gamma v}{\gamma_0 v_0}.\quad v/v_0=2.00.$

EXECUTE: $\gamma_0=\dfrac{1}{\sqrt{1-v_0^2/c^2}}=\dfrac{1}{\sqrt{1-(0.400)^2}}=1.0911.\quad \gamma=\dfrac{1}{\sqrt{1-(0.800)^2}}=1.667.$

$p=p_0(2)\left(\dfrac{1.667}{1.091}\right)=3.06p_0.$

EVALUATE: The speed doubles but the momentum more than triples.

37.28. **IDENTIFY** and **SET UP:** $\gamma=\dfrac{1}{\sqrt{1-v^2/c^2}}$. If γ is 1.0% greater than 1 then $\gamma=1.010$, if γ is 10% greater than 1 then $\gamma=1.10$ and if γ is 100% greater than 1 then $\gamma=2.00$.

EXECUTE: $v=c\sqrt{1-1/\gamma^2}$

(a) $v=c\sqrt{1-1/(1.010)^2}=0.140c$

(b) $v=c\sqrt{1-1/(1.10)^2}=0.417c$

(c) $v=c\sqrt{1-1/(2.00)^2}=0.866c$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

37.29. **IDENTIFY:** Apply Eqs. (37.27) and (37.32).
SET UP: For a particle at rest (or with $v \ll c$), $a = F/m$.

EXECUTE: **(a)** $p = \dfrac{mv}{\sqrt{1-v^2/c^2}} = 2mv.$

$$\Rightarrow 1 = 2\sqrt{1-v^2/c^2} \Rightarrow \frac{1}{4} = 1 - \frac{v^2}{c^2} \Rightarrow v^2 = \frac{3}{4}c^2 \Rightarrow v = \frac{\sqrt{3}}{2}c = 0.866c.$$

(b) $F = \gamma^3 ma = 2ma \Rightarrow \gamma^3 = 2 \Rightarrow \gamma = (2)^{1/3}$ so $\dfrac{1}{1-v^2/c^2} = 2^{2/3} \Rightarrow \dfrac{v}{c} = \sqrt{1-2^{-2/3}} = 0.608.$

EVALUATE: The momentum of a particle and the force required to give it a given acceleration both increase without bound as the speed of the particle approaches c.

37.30. **IDENTIFY:** The speed of the proton is a substantial fraction of the speed of light, so we must use the relativistic form of Newton's second law.

SET UP: $\vec{F}$ and $\vec{v}$ are along the same line, so $F = \dfrac{ma}{(1-v^2/c^2)^{3/2}}$.

EXECUTE: **(a)** $F = \dfrac{ma}{(1-v^2/c^2)^{3/2}} = \dfrac{(1.67\times10^{-27}\ \text{kg})(2.30\times10^{8}\ \text{m/s}^2)}{[1-(2.30\times10^{8}/3.00\times10^{8})^2]^{3/2}} = 1.45\times10^{-18}\ \text{N};$ $-x$-direction.

(b) $a = \dfrac{F}{m} = \dfrac{1.45\times10^{-18}\ \text{N}}{1.67\times10^{-27}\ \text{kg}} = 8.69\times10^{8}\ \text{m/s}^2.$

EVALUATE: The acceleration in part (b) is much greater than the acceleration given in the problem because the proton starting at rest is not relativistic.

37.31. **IDENTIFY:** When the speed of the electron is close to the speed of light, we must use the relativistic form of Newton's second law.

SET UP: When the force and velocity are parallel, as in part (b), $F = \dfrac{ma}{(1-v^2/c^2)^{3/2}}$. In part (a), $v \ll c$ so $F = ma$.

EXECUTE: **(a)** $a = \dfrac{F}{m} = \dfrac{5.00\times10^{-15}\ \text{N}}{9.11\times10^{-31}\ \text{kg}} = 5.49\times10^{15}\ \text{m/s}^2.$

(b) $\gamma = \dfrac{1}{(1-v^2/c^2)^{1/2}} = \dfrac{1}{(1-[2.50\times10^{8}/3.00\times10^{8}]^2)^{1/2}} = 1.81.$

$$a = \frac{F}{m\gamma^3} = \frac{5.49\times10^{15}\ \text{m/s}^2}{(1.81)^3} = 9.26\times10^{14}\ \text{m/s}^2.$$

EVALUATE: The acceleration for low speeds is over 5 times greater than it is near the speed of light as in part (b).

37.32. **IDENTIFY** and **SET UP:** The force is found from Eq. (37.32) or Eq. (37.33).
EXECUTE: **(a)** Indistinguishable from $F = ma = 0.145$ N.

(b) $\gamma^3 ma = 1.75$ N.

(c) $\gamma^3 ma = 51.7$ N.

(d) $\gamma ma = 0.145\ \text{N},\ 0.333\ \text{N}, 1.03\ \text{N}.$

EVALUATE: When v is large, much more force is required to produce a given magnitude of acceleration when the force is parallel to the velocity than when the force is perpendicular to the velocity.

37.33. **IDENTIFY:** Apply Eq. (37.36).

SET UP: The rest energy is mc^2.

EXECUTE: **(a)** $K = \dfrac{mc^2}{\sqrt{1-v^2/c^2}} - mc^2 = mc^2$

$$\Rightarrow \frac{1}{\sqrt{1-v^2/c^2}} = 2 \Rightarrow \frac{1}{4} = 1 - \frac{v^2}{c^2} \Rightarrow v = \sqrt{\frac{3}{4}}c = 0.866c.$$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) $K = 5mc^2 \Rightarrow \dfrac{1}{\sqrt{1-v^2/c^2}} = 6 \Rightarrow \dfrac{1}{36} = 1 - \dfrac{v^2}{c^2} \Rightarrow v = \sqrt{\dfrac{35}{36}}c = 0.986c.$

EVALUATE: If $v \ll c$, then K is much less than the rest energy of the particle.

37.34. **IDENTIFY:** At such a high speed, we must use the relativistic formulas for momentum and kinetic energy.

SET UP: $m_\mu = 207m_e = 1.89\times10^{-28}$ kg. v is very close to c and we must use relativistic expressions.

$$p = \frac{mv}{\sqrt{1-v^2/c^2}}, \quad K = \frac{mc^2}{\sqrt{1-v^2/c^2}} - mc^2.$$

EXECUTE: $p = \dfrac{mv}{\sqrt{1-v^2/c^2}} = \dfrac{(1.89\times10^{-28}\text{ kg})(0.999)(3.00\times10^8\text{ m/s})}{\sqrt{1-(0.999)^2}} = 1.27\times10^{-18}\text{ kg}\cdot\text{m/s}.$

Using $K = \dfrac{mc^2}{\sqrt{1-v^2/c^2}} - mc^2$ gives

$$K = (1.89\times10^{-28}\text{ kg})(3.00\times10^8\text{ m/s})^2\left(\frac{1}{\sqrt{1-(0.999)^2}} - 1\right) = 3.63\times10^{-10}\text{ J}.$$

EVALUATE: The nonrelativistic values are $p_{nr} = mv = 5.66\times10^{-20}$ kg·m/s and $K_{nr} = \frac{1}{2}mv^2 = 8.49\times10^{-12}$ J. Each relativistic result is much larger.

37.35. **IDENTIFY** and **SET UP:** Use Eqs. (37.38) and (37.39).

EXECUTE: **(a)** $E = mc^2 + K$, so $E = 4.00mc^2$ means $K = 3.00mc^2 = 4.50\times10^{-10}$ J

(b) $E^2 = (mc^2)^2 + (pc)^2$; $E = 4.00mc^2$, so $15.0(mc^2)^2 = (pc)^2$

$p = \sqrt{15}mc = 1.94\times10^{-18}$ kg·m/s

(c) $E = mc^2/\sqrt{1-v^2/c^2}$

$E = 4.00mc^2$ gives $1 - v^2/c^2 = 1/16$ and $v = \sqrt{15/16}c = 0.968c$

EVALUATE: The speed is close to c since the kinetic energy is greater than the rest energy. Nonrelativistic expressions relating E, K, p and v will be very inaccurate.

37.36. **IDENTIFY:** Apply the work energy theorem in the form $W = \Delta K$.

SET UP: K is given by Eq. (37.36). When $v = 0$, $\gamma = 1$.

EXECUTE: **(a)** $W = \Delta K = (\gamma_f - 1)mc^2 = (4.07\times10^{-3})\,mc^2$.

(b) $(\gamma_f - \gamma_i)\,mc^2 = 4.79mc^2$.

(c) The result of part (b) is far larger than that of part (a).

EVALUATE: The amount of work required to produce a given increase in speed (in this case an increase of $0.090c$) increases as the initial speed increases.

37.37. **IDENTIFY:** Use $E = mc^2$ to relate the mass increase to the energy increase.

(a) SET UP: Your total energy E increases because your gravitational potential energy mgy increases.

EXECUTE: $\Delta E = mg\Delta y$

$\Delta E = (\Delta m)c^2$ so $\Delta m = \Delta E/c^2 = mg(\Delta y)/c^2$

$\Delta m/m = (g\Delta y)/c^2 = (9.80\text{ m/s}^2)(30\text{ m})/(2.998\times10^8\text{ m/s})^2 = 3.3\times10^{-13}\%$

This increase is much, much too small to be noticed.

(b) SET UP: The energy increases because potential energy is stored in the compressed spring.

EXECUTE: $\Delta E = \Delta U = \frac{1}{2}kx^2 = \frac{1}{2}(2.00\times10^4\text{ N/m})(0.060\text{ m})^2 = 36.0\text{ J}$

$\Delta m = (\Delta E)/c^2 = 4.0\times10^{-16}$ kg

Energy increases so mass increases. The mass increase is much, much too small to be noticed.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: In both cases the energy increase corresponds to a mass increase. But since c^2 is a very large number the mass increase is very small.

37.38. **IDENTIFY:** Apply Eq. (37.38).

SET UP: When the person is at rest her total energy is $E_0 = mc^2$.

EXECUTE: **(a)** $E = 2mc^2$, so $\dfrac{1}{\sqrt{1-v^2/c^2}} = 2$.

$\dfrac{1}{4} = 1 - \dfrac{v^2}{c^2} \Rightarrow \dfrac{v^2}{c^2} = \dfrac{3}{4} \Rightarrow v = c\sqrt{3/4} = 0.866c = 2.60\times10^8$ m/s

(b) $E = 10mc^2$, so $\dfrac{1}{\sqrt{1-v^2/c^2}} = 10$. $1 - \dfrac{v^2}{c^2} = \dfrac{1}{100} \Rightarrow \dfrac{v^2}{c^2} = \dfrac{99}{100}$. $v = c\sqrt{\dfrac{99}{100}} = 0.995c = 2.98\times10^8$ m/s.

EVALUATE: Unless v approaches c, the total energy of an object is not much greater than its rest energy.

37.39. **IDENTIFY** and **SET UP:** The energy equivalent of mass is $E = mc^2$. $\rho = 7.86$ g/cm^3 $= 7.86\times10^3$ kg/m^3.

For a cube, $V = L^3$.

EXECUTE: **(a)** $m = \dfrac{E}{c^2} = \dfrac{1.0\times10^{20}\text{ J}}{(3.00\times10^8\text{ m/s})^2} = 1.11\times10^3$ kg

(b) $\rho = \dfrac{m}{V}$ so $V = \dfrac{m}{\rho} = \dfrac{1.11\times10^3\text{ kg}}{7.86\times10^3\text{ kg/m}^3} = 0.141\text{ m}^3$. $L = V^{1/3} = 0.521\text{ m} = 52.1\text{ cm}$

EVALUATE: Particle/antiparticle annihilation has been observed in the laboratory, but only with small quantities of antimatter.

37.40. **IDENTIFY:** With such a large potential difference, the electrons will be accelerated to relativistic speeds, so we must use the relativistic formula for kinetic energy.

SET UP: $K = \left(\dfrac{1}{\sqrt{1-v^2/c^2}} - 1\right)mc^2$. The classical expression for kinetic energy is $K = \frac{1}{2}mv^2$.

EXECUTE: For an electron $mc^2 = (9.11\times10^{-31}\text{ kg})(3.00\times10^8\text{ m/s})^2 = 8.20\times10^{-14}$ J.

$K = 7.50\times10^5$ eV $= 1.20\times10^{-13}$ J.

(a) $\dfrac{K}{mc^2} + 1 = \dfrac{1}{\sqrt{1-v^2/c^2}}$. $\dfrac{1}{\sqrt{1-v^2/c^2}} = \dfrac{1.20\times10^{-13}\text{ J}}{8.20\times10^{-14}\text{ J}} + 1 = 2.46$.

$v = c\sqrt{1-(1/2.46)^2} = 0.914c = 2.74\times10^8$ m/s.

(b) $K = \frac{1}{2}mv^2$ gives $v = \sqrt{\dfrac{2K}{m}} = \sqrt{\dfrac{2(1.20\times10^{-13}\text{ J})}{9.11\times10^{-31}\text{ kg}}} = 5.13\times10^8$ m/s.

EVALUATE: At a given speed the relativistic value of the kinetic energy is larger than the nonrelativistic value. Therefore, for a given kinetic energy the relativistic expression for kinetic energy gives a smaller speed than the nonrelativistic expression.

37.41. **IDENTIFY** and **SET UP:** The total energy is given in terms of the momentum by Eq. (37.39). In terms of the total energy E, the kinetic energy K is $K = E - mc^2$ (from Eq. 37.38). The rest energy is mc^2.

EXECUTE: **(a)** $E = \sqrt{(mc^2)^2 + (pc)^2} = \sqrt{[(6.64\times10^{-27})(2.998\times10^8)^2]^2 + [(2.10\times10^{-18})(2.998\times10^8)]^2}$ J

$E = 8.67\times10^{-10}$ J

(b) $mc^2 = (6.64\times10^{-27}\text{ kg})(2.998\times10^8\text{ m/s})^2 = 5.97\times10^{-10}$ J

$K = E - mc^2 = 8.67\times10^{-10}\text{ J} - 5.97\times10^{-10}\text{ J} = 2.70\times10^{-10}$ J

(c) $\dfrac{K}{mc^2} = \dfrac{2.70\times10^{-10}\text{ J}}{5.97\times10^{-10}\text{ J}} = 0.452$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: The incorrect nonrelativistic expressions for K and p give $K = p^2/2m = 3.3\times10^{-10}$ J; the correct relativistic value is less than this.

37.42. **IDENTIFY:** Since the final speed is close to the speed of light, there will be a considerable difference between the relativistic and nonrelativistic results.

SET UP: The nonrelativistic work-energy theorem is $F\Delta x = \frac{1}{2}mv^2 - \frac{1}{2}mv_0^2$, and the relativistic formula for a constant force is $F\Delta x = (\gamma - 1)mc^2$.

EXECUTE: **(a)** Using the classical work-energy theorem and solving for Δx, we obtain

$$\Delta x = \frac{m(v^2 - v_0^2)}{2F} = \frac{(0.100\times10^{-9}\text{ kg})[(0.900)(3.00\times10^8\text{ m/s})]^2}{2(1.00\times10^6\text{ N})} = 3.65\text{ m}.$$

(b) Using the relativistic work-energy theorem for a constant force, we obtain

$$\Delta x = \frac{(\gamma - 1)mc^2}{F}.$$

For the given speed, $\gamma = \frac{1}{\sqrt{1-0.900^2}} = 2.29$, thus

$$\Delta x = \frac{(2.29 - 1)(0.100\times10^{-9}\text{ kg})(3.00\times10^8\text{ m/s})^2}{(1.00\times10^6\text{N})} = 11.6\text{ m}.$$

EVALUATE: **(c)** The distance obtained from the relativistic treatment is greater. As we have seen, more energy is required to accelerate an object to speeds close to c, so that force must act over a greater distance.

37.43. **IDENTIFY** and **SET UP:** The nonrelativistic expression is $K_{\text{nonrel}} = \frac{1}{2}mv^2$ and the relativistic expression is $K_{\text{rel}} = (\gamma - 1)mc^2$.

EXECUTE: **(a)** $v = 8\times10^7$ m/s $\Rightarrow \gamma = \frac{1}{\sqrt{1 - v^2/c^2}} = 1.0376$. For $m = m_{\text{p}}$, $K_{\text{nonrel}} = \frac{1}{2}mv^2 = 5.34\times10^{-12}$ J.

$K_{\text{rel}} = (\gamma - 1)mc^2 = 5.65\times10^{-12}$ J. $\frac{K_{\text{rel}}}{K_{\text{nonrel}}} = 1.06$.

(b) $v = 2.85\times10^8$ m/s; $\gamma = 3.203$.

$K_{\text{nonrel}} = \frac{1}{2}mv^2 = 6.78\times10^{-11}$ J; $K_{\text{rel}} = (\gamma - 1)mc^2 = 3.31\times10^{-10}$ J; $K_{\text{rel}}/K_{\text{nonrel}} = 4.88$.

EVALUATE: $K_{\text{rel}}/K_{\text{nonrel}}$ increases without bound as v approaches c.

37.44. **IDENTIFY:** Since the speeds involved are close to that of light, we must use the relativistic formula for kinetic energy.

SET UP: The relativistic kinetic energy is $K = (\gamma - 1)mc^2 = \left(\frac{1}{\sqrt{1 - v^2/c^2}} - 1\right)mc^2$.

EXECUTE: **(a)**

$$K = (\gamma - 1)mc^2 = \left(\frac{1}{\sqrt{1 - v^2/c^2}} - 1\right)mc^2 = (1.67\times10^{-27}\text{ kg})(3.00\times10^8\text{ m/s})^2\left(\frac{1}{\sqrt{1 - (0.100c/c)^2}} - 1\right)$$

$$K = (1.50\times10^{-10}\text{ J})\left(\frac{1}{\sqrt{1 - 0.0100}} - 1\right) = 7.56\times10^{-13}\text{ J} = 4.73\text{ MeV}$$

(b) $K = (1.50\times10^{-10}\text{J})\left(\frac{1}{\sqrt{1 - (0.500)^2}} - 1\right) = 2.32\times10^{-11}\text{ J} = 145\text{ MeV}$

(c) $K = (1.50\times10^{-10}\text{ J})\left(\frac{1}{\sqrt{1 - (0.900)^2}} - 1\right) = 1.94\times10^{-10}\text{ J} = 1210\text{ MeV}$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(d) $\Delta E = 2.32\times10^{-11}\text{ J} - 7.56\times10^{-13}\text{ J} = 2.24\times10^{-11}\text{ J} = 140\text{ MeV}$

(e) $\Delta E = 1.94\times10^{-10}\text{ J} - 2.32\times10^{-11}\text{ J} = 1.71\times10^{-10}\text{ J} = 1070\text{ MeV}$

(f) Without relativity, $K = \frac{1}{2}mv^2$. The work done in accelerating a proton from $0.100c$ to $0.500c$ in the nonrelativistic limit is $\Delta E = \frac{1}{2}m(0.500c)^2 - \frac{1}{2}m(0.100c)^2 = 1.81\times10^{-11}\text{ J} = 113\text{ MeV}$.

The work done in accelerating a proton from $0.500c$ to $0.900c$ in the nonrelativistic limit is

$$\Delta E = \frac{1}{2}m(0.900c)^2 - \frac{1}{2}m(0.500c)^2 = 4.21\times10^{-11}\text{ J} = 263\text{ MeV}.$$

EVALUATE: We see in the first case the nonrelativistic result is within 20% of the relativistic result. In the second case, the nonrelativistic result is very different from the relativistic result since the velocities are closer to c.

37.45. **IDENTIFY** and **SET UP:** Use Eq. (23.12) and conservation of energy to relate the potential difference to the kinetic energy gained by the electron. Use Eq. (37.36) to calculate the kinetic energy from the speed.

EXECUTE: **(a)** $K = q\Delta V = e\Delta V$

$$K = mc^2\left(\frac{1}{\sqrt{1-v^2/c^2}} - 1\right) = 4.025mc^2 = 3.295\times10^{-13}\text{ J} = 2.06\text{ MeV}$$

$\Delta V = K/e = 2.06\times10^6\text{ V}$

(b) From part (a), $K = 3.30\times10^{-13}\text{ J} = 2.06\text{ MeV}$

EVALUATE: The speed is close to c and the kinetic energy is four times the rest mass.

37.46. **IDENTIFY:** The total energy is conserved in the collision.

SET UP: Use Eq. (37.38) for the total energy. Since all three particles are at rest after the collision, the final total energy is $2Mc^2 + mc^2$. The initial total energy of the two protons is $\gamma 2Mc^2$.

EXECUTE: **(a)** $2Mc^2 + mc^2 = \gamma 2Mc^2 \Rightarrow \gamma = 1 + \frac{m}{2M} = 1 + \frac{9.75}{2(16.7)} = 1.292.$

Note that since $\gamma = \frac{1}{\sqrt{1-v^2/c^2}}$, we have that $\frac{v}{c} = \sqrt{1-\frac{1}{\gamma^2}} = \sqrt{1-\frac{1}{(1.292)^2}} = 0.6331.$

(b) According to Eq. (37.36), the kinetic energy of each proton is

$$K = (\gamma - 1)Mc^2 = (1.292-1)(1.67\times10^{-27}\text{ kg})(3.00\times10^8\text{ m/s})^2\left(\frac{1.00\text{ MeV}}{1.60\times10^{-13}\text{ J}}\right) = 274\text{ MeV}.$$

(c) The rest energy of η^0 is $mc^2 = (9.75\times10^{-28}\text{ kg})(3.00\times10^8\text{ m/s})^2\left(\frac{1.00\text{ MeV}}{1.60\times10^{-13}\text{ J}}\right) = 548\text{ MeV}.$

EVALUATE: **(d)** The kinetic energy lost by the protons is the energy that produces the η^0, $548\text{ MeV} = 2(274\text{ MeV})$.

37.47. **IDENTIFY:** Use $E = mc^2$ to relate the mass decrease to the energy produced.

SET UP: 1 kg is equivalent to 2.2 lbs and 1 ton = 2000 lbs. $1\text{ W} = 1\text{ J/s}$.

EXECUTE: **(a)** $E = mc^2$, $m = E/c^2 = (3.8\times10^{26}\text{ J})/(2.998\times10^8\text{ m/s})^2 = 4.2\times10^9\text{ kg} = 4.6\times10^6$ tons.

(b) The current mass of the sun is 1.99×10^{30} kg, so it would take it

$(1.99\times10^{30}\text{ kg})/(4.2\times10^9\text{ kg/s}) = 4.7\times10^{20}\text{ s} = 1.5\times10^{13}$ years to use up all its mass.

EVALUATE: The power output of the sun is very large, but only a small fraction of the sun's mass is converted to energy each second.

37.48. **IDENTIFY** and **SET UP:** The astronaut in the spaceship measures the proper time, since the end of a swing occurs at the same location in his frame. $\Delta t = \frac{\Delta t_0}{\sqrt{1-u^2/c^2}}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: **(a)** $\Delta t_0 = 1.50\text{ s}$. $\Delta t = \dfrac{\Delta t_0}{\sqrt{1-u^2/c^2}} = \dfrac{1.50\text{ s}}{\sqrt{1-(0.75c/c)^2}} = 2.27\text{ s}$.

(b) $\Delta t = 1.50\text{ s}$. $\Delta t_0 = \Delta t\sqrt{1-u^2/c^2} = (1.50\text{ s})\sqrt{1-(0.75c/c)^2} = 0.992\text{ s}$.

EVALUATE: The motion of the spaceship makes a considerable difference in the measured values for the period of the pendulum!

37.49. **(a) IDENTIFY** and **SET UP:** $\Delta t_0 = 2.60\times10^{-8}\text{ s}$ is the proper time, measured in the pion's frame. The time measured in the lab must satisfy $d = c\Delta t$, where $u \approx c$. Calculate Δt and then use Eq. (37.6) to calculate u.

EXECUTE: $\Delta t = \dfrac{d}{c} = \dfrac{1.90\times10^3\text{ m}}{2.998\times10^8\text{ m/s}} = 6.3376\times10^{-6}\text{ s}$. $\Delta t = \dfrac{\Delta t_0}{\sqrt{1-u^2/c^2}}$ so $(1-u^2/c^2)^{1/2} = \dfrac{\Delta t_0}{\Delta t}$ and

$(1-u^2/c^2) = \left(\dfrac{\Delta t_0}{\Delta t}\right)^2$. Write $u = (1-\Delta)c$ so that $(u/c)^2 = (1-\Delta)^2 = 1-2\Delta+\Delta^2 \approx 1-2\Delta$ since Δ is small.

Using this in the above gives $1-(1-2\Delta) = \left(\dfrac{\Delta t_0}{\Delta t}\right)^2$. $\Delta = \dfrac{1}{2}\left(\dfrac{\Delta t_0}{\Delta t}\right)^2 = \dfrac{1}{2}\left(\dfrac{2.60\times10^{-8}\text{ s}}{6.3376\times10^{-6}\text{ s}}\right)^2 = 8.42\times10^{-6}$.

EVALUATE: An alternative calculation is to say that the length of the tube must contract relative to the moving pion so that the pion travels that length before decaying. The contracted length must be

$l = c\Delta t_0 = (2.998\times10^8\text{ m/s})(2.60\times10^{-8}\text{ s}) = 7.7948\text{ m}$. $l = l_0\sqrt{1-u^2/c^2}$ so $1-u^2/c^2 = \left(\dfrac{l}{l_0}\right)^2$. Then

$u = (1-\Delta)c$ gives $\Delta = \dfrac{1}{2}\left(\dfrac{l}{l_0}\right)^2 = \dfrac{1}{2}\left(\dfrac{7.7948\text{ m}}{1.90\times10^3\text{ m}}\right)^2 = 8.42\times10^{-6}$, which checks.

(b) IDENTIFY and **SET UP:** $E = \gamma mc^2$ Eq. (37.38).

EXECUTE: $\gamma = \dfrac{1}{\sqrt{1-u^2/c^2}} = \dfrac{1}{\sqrt{2\Delta}} = \dfrac{1}{\sqrt{2(8.42\times10^{-6})}} = 244$.

$E = (244)(139.6\text{ MeV}) = 3.40\times10^4\text{ MeV} = 34.0\text{ GeV}$.

EVALUATE: The total energy is 244 times the rest energy.

37.50. **IDENTIFY** and **SET UP:** The proper length of a side is $l_0 = a$. The side along the direction of motion is shortened to $l = l_0\sqrt{1-v^2/c^2}$. The sides in the two directions perpendicular to the motion are unaffected by the motion and still have a length a.

EXECUTE: $V = a^2 l = a^3\sqrt{1-v^2/c^2}$

37.51. **IDENTIFY** and **SET UP:** There must be a length contraction such that the length a becomes the same as b; $l_0 = a$, $l = b$. l_0 is the distance measured by an observer at rest relative to the spacecraft. Use Eq. (37.16) and solve for u.

EXECUTE: $\dfrac{l}{l_0} = \sqrt{1-u^2/c^2}$ so $\dfrac{b}{a} = \sqrt{1-u^2/c^2}$;

$a = 1.40b$ gives $b/1.40b = \sqrt{1-u^2/c^2}$ and thus $1-u^2/c^2 = 1/(1.40)^2$

$u = \sqrt{1-1/(1.40)^2}\,c = 0.700c = 2.10\times10^8\text{ m/s}$

EVALUATE: A length on the spacecraft in the direction of the motion is shortened. A length perpendicular to the motion is unchanged.

37.52. **IDENTIFY** and **SET UP:** The proper time Δt_0 is the time that elapses in the frame of the space probe. Δt is the time that elapses in the frame of the earth. The distance traveled is 42.2 light years, as measured in the earth frame.

EXECUTE: Light travels 42.2 light years in 42.2 y, so $\Delta t = \left(\dfrac{c}{0.9930c}\right)(42.2\text{ y}) = 42.5\text{ y}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$\Delta t_0 = \Delta t\sqrt{1-u^2/c^2} = (42.5\text{ y})\sqrt{1-(0.9930)^2} = 5.0\text{ y}$. She measures her biological age to be $19\text{ y} + 5.0\text{ y} = 24.0\text{ y}$.

EVALUATE: Her age measured by someone on earth is $19\text{ y} + 42.5\text{ y} = 61.5\text{ y}$.

37.53. **IDENTIFY** and **SET UP:** The total energy E is related to the rest mass mc^2 by $E = \gamma mc^2$.

EXECUTE: **(a)** $E = \gamma mc^2$, so $\gamma = 10 = \dfrac{1}{\sqrt{1-(v/c)^2}} \Rightarrow \dfrac{v}{c} = \sqrt{\dfrac{\gamma^2-1}{\gamma^2}} \Rightarrow \dfrac{v}{c} = \sqrt{\dfrac{99}{100}} = 0.995.$

(b) $(pc)^2 = m^2v^2\gamma^2c^2$, $E^2 = m^2c^4\gamma^2$

$$\Rightarrow \frac{E^2-(pc)^2}{E^2} = 1-(v/c)^2 = 0.01 = 1\%.$$

EVALUATE: When $E \gg mc^2$, $E \to pc$.

37.54. **IDENTIFY** and **SET UP:** The clock on the plane measures the proper time Δt_0.

$\Delta t = 4.00\text{ h} = 4.00\text{ h}(3600\text{ s}/1\text{ h}) = 1.44\times10^4\text{ s}$.

$\Delta t = \dfrac{\Delta t_0}{\sqrt{1-u^2/c^2}}$ and $\Delta t_0 = \Delta t\sqrt{1-u^2/c^2}$

EXECUTE: $\dfrac{u}{c}$ small so $\sqrt{1-u^2/c^2} = (1-u^2/c^2)^{1/2} \approx 1-\dfrac{1}{2}\dfrac{u^2}{c^2}$; thus $\Delta t_0 = \Delta t\left(1-\dfrac{1}{2}\dfrac{u^2}{c^2}\right)$

The difference in the clock readings is

$\Delta t - \Delta t_0 = \dfrac{1}{2}\dfrac{u^2}{c^2}\Delta t = \dfrac{1}{2}\left(\dfrac{250\text{ m/s}}{2.998\times10^8\text{ m/s}}\right)^2 (1.44\times10^4\text{ s}) = 5.01\times10^{-9}\text{ s}$. The clock on the plane has the shorter elapsed time.

EVALUATE: Δt_0 is always less than Δt; our results agree with this. The speed of the plane is much less than the speed of light, so the difference in the reading of the two clocks is very small.

37.55. **IDENTIFY:** Since the speed is very close to the speed of light, we must use the relativistic formula for kinetic energy.

SET UP: The relativistic formula for kinetic energy is $K = mc^2\left(\dfrac{1}{\sqrt{1-v^2/c^2}}-1\right)$ and the relativistic mass is $m_{\text{rel}} = \dfrac{m}{\sqrt{1-v^2/c^2}}$.

EXECUTE: **(a)** $K = 7\times10^{12}\text{ eV} = 1.12\times10^{-6}\text{ J}$. Using this value in the relativistic kinetic energy formula and substituting the mass of the proton for m, we get $K = mc^2\left(\dfrac{1}{\sqrt{1-v^2/c^2}}-1\right)$ which gives

$\dfrac{1}{\sqrt{1-v^2/c^2}} = 7.45\times10^3$ and $1-\dfrac{v^2}{c^2} = \dfrac{1}{(7.45\times10^3)^2}$. Solving for v gives $1-\dfrac{v^2}{c^2} = \dfrac{(c+v)(c-v)}{c^2} = \dfrac{2(c-v)}{c}$, since $c+v \approx 2c$. Substituting $v = (1-\Delta)c$, we have $1-\dfrac{v^2}{c^2} = \dfrac{2(c-v)}{c} = \dfrac{2[c-(1-\Delta)c]}{c} = 2\Delta$. Solving for Δ gives $\Delta = \dfrac{1-v^2/c^2}{2} = \dfrac{\frac{1}{(7.45\times10^3)^2}}{2} = 9\times10^{-9}$, to one significant digit.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) Using the relativistic mass formula and the result that $\dfrac{1}{\sqrt{1-v^2/c^2}} = 7.45\times10^3$, we have

$m_{\text{rel}} = \dfrac{m}{\sqrt{1-v^2/c^2}} = m\left(\dfrac{1}{\sqrt{1-v^2/c^2}}\right) = (7\times10^3)m$, to one significant digit.

EVALUATE: At such high speeds, the proton's mass is over 7000 times as great as its rest mass.

37.56. **IDENTIFY** and **SET UP:** The energy released is $E = (\Delta m)c^2$. $\Delta m = \left(\dfrac{1}{10^4}\right)(12.0\text{ kg})$. $P_{\text{av}} = \dfrac{E}{t}$.

The change in gravitational potential energy is $mg\Delta y$.

EXECUTE: **(a)** $E = (\Delta m)c^2 = \left(\dfrac{1}{10^4}\right)(12.0\text{ kg})(3.00\times10^8\text{ m/s})^2 = 1.08\times10^{14}\text{ J}$.

(b) $P_{\text{av}} = \dfrac{E}{t} = \dfrac{1.08\times10^{14}\text{ J}}{4.00\times10^{-6}\text{ s}} = 2.70\times10^{19}\text{ W}$.

(c) $E = \Delta U = mg\Delta y$. $m = \dfrac{E}{g\Delta y} = \dfrac{1.08\times10^{14}\text{ J}}{(9.80\text{ m/s}^2)(1.00\times10^3\text{ m})} = 1.10\times10^{10}\text{ kg}$.

EVALUATE: The mass decrease is only 1.2 grams, but the energy released is very large.

37.57. **IDENTIFY** and **SET UP:** In crown glass the speed of light is $v = \dfrac{c}{n}$. Calculate the kinetic energy of an electron that has this speed.

EXECUTE: $v = \dfrac{2.998\times10^8\text{ m/s}}{1.52} = 1.972\times10^8\text{ m/s}$.

$K = mc^2(\gamma - 1)$

$mc^2 = (9.109\times10^{-31}\text{ kg})(2.998\times10^8\text{ m/s})^2 = 8.187\times10^{-14}\text{ J}(1\text{ eV}/1.602\times10^{-19}\text{ J}) = 0.5111\text{ MeV}$

$\gamma = \dfrac{1}{\sqrt{1-v^2/c^2}} = \dfrac{1}{\sqrt{1-((1.972\times10^8\text{ m/s})/(2.998\times10^8\text{ m/s}))^2}} = 1.328$

$K = mc^2(\gamma - 1) = (0.5111\text{ MeV})(1.328 - 1) = 0.168\text{ MeV}$

EVALUATE: No object can travel faster than the speed of light in vacuum but there is nothing that prohibits an object from traveling faster than the speed of light in some material.

37.58. **IDENTIFY:** Apply conservation of momentum to the process of emitting a photon.

SET UP: A photon has zero rest mass and for it $E = pc$.

EXECUTE: **(a)** $v = \dfrac{p}{m} = \dfrac{(E/c)}{m} = \dfrac{E}{mc}$, where the atom and the photon have the same magnitude of momentum, E/c.

(b) $v = \dfrac{E}{mc} \ll c$, so $E \ll mc^2$.

EVALUATE: The rest energy of a hydrogen atom is about 940 MeV and typical energies of photons emitted by atoms are a few eV, so $E \ll mc^2$ is typical. If this is the case, then treating the motion of the atom nonrelativistically is an accurate approximation.

37.59. **IDENTIFY** and **SET UP:** Let S be the lab frame and S' be the frame of the proton that is moving in the $+x$-direction, so $u = +c/2$. The reference frames and moving particles are shown in Figure 37.59. The other proton moves in the $-x$-direction in the lab frame, so $v = -c/2$. A proton has rest mass $m_{\text{p}} = 1.67\times10^{-27}\text{ kg}$ and rest energy $m_{\text{p}}c^2 = 938\text{ MeV}$.

EXECUTE: **(a)** $v' = \dfrac{v-u}{1-uv/c^2} = \dfrac{-c/2 - c/2}{1-(c/2)(-c/2)/c^2} = -\dfrac{4c}{5}$

The speed of each proton relative to the other is $\dfrac{4}{5}c$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) In nonrelativistic mechanics the speeds just add and the speed of each relative to the other is c.

(c) $K = \dfrac{mc^2}{\sqrt{1-v^2/c^2}} - mc^2$

(i) Relative to the lab frame each proton has speed $v = c/2$. The total kinetic energy of each proton is

$$K = \frac{938\ \text{MeV}}{\sqrt{1-\left(\frac{1}{2}\right)^2}} - (938\ \text{MeV}) = 145\ \text{MeV}.$$

(ii) In its rest frame one proton has zero speed and zero kinetic energy and the other has speed $\frac{4}{5}c$. In this frame the kinetic energy of the moving proton is $K = \dfrac{938\ \text{MeV}}{\sqrt{1-\left(\frac{4}{5}\right)^2}} - (938\ \text{MeV}) = 625\ \text{MeV}.$

(d) (i) Each proton has speed $v = c/2$ and kinetic energy

$$K = \frac{1}{2}mv^2 = \left(\frac{1}{2}m\right)(c/2)^2 = \frac{mc^2}{8} = \frac{938\ \text{MeV}}{8} = 117\ \text{MeV}.$$

(ii) One proton has speed $v = 0$ and the other has speed c. The kinetic energy of the moving proton is

$$K = \frac{1}{2}mc^2 = \frac{938\ \text{MeV}}{2} = 469\ \text{MeV}.$$

EVALUATE: The relativistic expression for K gives a larger value than the nonrelativistic expression. The kinetic energy of the system is different in different frames.

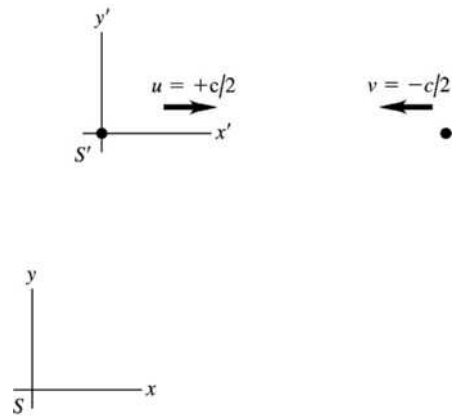


Figure 37.59

37.60. **IDENTIFY:** The protons are moving at speeds that are comparable to the speed of light, so we must use the relativistic velocity addition formula.

SET UP: S is lab frame and S' is frame of proton moving in $+x$-direction. $v_x = -0.600c$. In lab frame each proton has speed αc. $u = +\alpha c$. $v_x = -\alpha c$. $v_x = \dfrac{v_x' + u}{1 + uv_x'/c^2} = \dfrac{-0.600c + \alpha c}{1 - 0.600\alpha} = -\alpha c$.

EXECUTE: $(1 - 0.600\alpha)(-\alpha) = -0.600 + \alpha$. $0.600\alpha^2 - 2\alpha + 0.600 = 0$. Quadratic formula gives $\alpha = 3.00$ or $\alpha = 0.333$. Can't have $v > c$ so $\alpha = 0.333$. Each proton has speed $0.333c$ in the earth frame.

EVALUATE: To the earth observer, the protons are separating at $2(0.333c) = 0.666c$, but to the protons they are separating at $0.600c$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

37.61. **IDENTIFY** and **SET UP:** Follow the procedure specified in the problem.

EXECUTE: $x'^2 = c^2t'^2 \Rightarrow (x-ut)^2\gamma^2 = c^2\gamma^2(t-ux/c^2)^2$

$\Rightarrow x-ut = c(t-ux/c^2) \Rightarrow x\left(1+\frac{u}{c}\right) = \frac{1}{c}x(u+c) = t(u+c) \Rightarrow x = ct \Rightarrow x^2 = c^2t^2.$

EVALUATE: The light pulse has the same speed c in both frames.

37.62. **IDENTIFY** and **SET UP:** Let S be the lab frame and let S' be the frame of the nucleus. Let the $+x$-direction be the direction the nucleus is moving. $u = 0.7500c$.

EXECUTE: **(a)** $v' = +0.9995c$. $v = \dfrac{v'+u}{1+uv'/c^2} = \dfrac{0.9995c+0.7500c}{1+(0.7500)(0.9995)} = 0.999929c$

(b) $v' = -0.9995c$. $v = \dfrac{-0.9995c+0.7500c}{1+(0.7500)(-0.9995)} = -0.9965c$

(c) emitted in same direction:

(i) $K = \left(\dfrac{1}{\sqrt{1-v^2/c^2}}-1\right)mc^2 = (0.511\text{ MeV})\left(\dfrac{1}{\sqrt{1-(0.999929)^2}}-1\right) = 42.4\text{ MeV}$

(ii) $K' = \left(\dfrac{1}{\sqrt{1-v^2/c^2}}-1\right)mc^2 = (0.511\text{ MeV})\left(\dfrac{1}{\sqrt{1-(0.9995)^2}}-1\right) = 15.7\text{ MeV}$

(d) emitted in opposite direction:

(i) $K = \left(\dfrac{1}{\sqrt{1-v^2/c^2}}-1\right)mc^2 = (0.511\text{ MeV})\left(\dfrac{1}{\sqrt{1-(0.9965)^2}}-1\right) = 5.60\text{ MeV}$

(ii) $K' = \left(\dfrac{1}{\sqrt{1-v^2/c^2}}-1\right)mc^2 = (0.511\text{ MeV})\left(\dfrac{1}{\sqrt{1-(0.9995)^2}}-1\right) = 15.7\text{ MeV}$

37.63. **IDENTIFY** and **SET UP:** Use Eq. (37.30), with $a = dv/dt$, to obtain an expression for dv/dt. Separate the variables v and t and integrate to obtain an expression for $v(t)$. In this expression, let $t \to \infty$.

EXECUTE: $a = \dfrac{dv}{dt} = \dfrac{F}{m}(1-v^2/c^2)^{3/2}$. (One-dimensional motion is assumed, and all the F, v and a refer to x-components.)

$$\frac{dv}{(1-v^2/c^2)^{3/2}} = \left(\frac{F}{m}\right)dt$$

Integrate from $t = 0$, when $v = 0$, to time t, when the velocity is v.

$$\int_0^v \frac{dv}{(1-v^2/c^2)^{3/2}} = \int_0^t \left(\frac{F}{m}\right)dt$$

Since F is constant, $\int_0^t \left(\dfrac{F}{m}\right)dt = \dfrac{Ft}{m}$. In the velocity integral make the change of variable $y = v/c$; then $dy = dv/c$.

$$\int_0^v \frac{dv}{(1-v^2/c^2)^{3/2}} = c\int_0^{v/c} \frac{dy}{(1-y^2)^{3/2}} = c\left[\frac{y}{(1-y^2)^{1/2}}\right]_0^{v/c} = \frac{v}{\sqrt{1-v^2/c^2}}$$

Thus $\dfrac{v}{\sqrt{1-v^2/c^2}} = \dfrac{Ft}{m}$.

Solve this equation for v:

$$\frac{v^2}{1-v^2/c^2} = \left(\frac{Ft}{m}\right)^2 \text{ and } v^2 = \left(\frac{Ft}{m}\right)^2(1-v^2/c^2)$$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$v^2\left(1+\left(\frac{Ft}{mc}\right)^2\right)=\left(\frac{Ft}{m}\right)^2 \text{ so } v=\frac{(Ft/m)}{\sqrt{1+(Ft/mc)^2}}=c\frac{Ft}{\sqrt{m^2c^2+F^2t^2}}$$

As $t\to\infty, \dfrac{Ft}{\sqrt{m^2c^2+F^2t^2}}\to\dfrac{Ft}{\sqrt{F^2t^2}}\to 1$, so $v\to c$.

EVALUATE: Note that $\dfrac{Ft}{\sqrt{m^2c^2+F^2t^2}}$ is always less than 1, so $v<c$ always and v approaches c only when $t\to\infty$.

37.64. **IDENTIFY:** Apply the Lorentz coordinate transformation.

SET UP: Let t and t' be time intervals between the events as measured in the two frames and let x and x' be the difference in the positions of the two events as measured in the two frames.

EXECUTE: Setting $x=0$ in Eq. (37.21), the first equation becomes $x'=-\gamma ut$ and the last, upon multiplication by c, becomes $ct'=\gamma ct$. Squaring and subtracting gives $c^2t'^2-x'^2=\gamma^2t^2(c^2-u^2)$. But $\gamma^2=c^2/(c^2-v^2)$, so $\gamma^2t^2(c^2-v^2)=c^2t^2$. Therefore, $c^2t'^2-x'^2=c^2t^2$ and $x'=c\sqrt{t'^2-t^2}=4.53\times10^8$ m.

EVALUATE: We did not have to calculate the speed u of frame S' relative to frame S.

37.65. **(a) IDENTIFY** and **SET UP:** Use the Lorentz coordinate transformation (Eq. 37.21) for (x_1,t_1) and (x_2,t_2):

$$x_1'=\frac{x_1-ut_1}{\sqrt{1-u^2/c^2}},\quad x_2'=\frac{x_2-ut_2}{\sqrt{1-u^2/c^2}}$$

$$t_1'=\frac{t_1-ux_1/c^2}{\sqrt{1-u^2/c^2}},\quad t_2'=\frac{t_2-ux_2/c^2}{\sqrt{1-u^2/c^2}}$$

Same point in S' implies $x_1'=x_2'$. What then is $\Delta t'=t_2'-t_1'$?

EXECUTE: $x_1'=x_2'$ implies $x_1-ut_1=x_2-ut_2$

$u(t_2-t_1)=x_2-x_1$ and $u=\dfrac{x_2-x_1}{t_2-t_1}=\dfrac{\Delta x}{\Delta t}$

From the time transformation equations,

$$\Delta t'=t_2'-t_1'=\frac{1}{\sqrt{1-u^2/c^2}}(\Delta t-u\Delta x/c^2)$$

Using the result that $u=\dfrac{\Delta x}{\Delta t}$ gives

$$\Delta t'=\frac{1}{\sqrt{1-(\Delta x)^2/((\Delta t)^2c^2)}}(\Delta t-(\Delta x)^2/((\Delta t)c^2))$$

$$\Delta t'=\frac{\Delta t}{\sqrt{(\Delta t)^2-(\Delta x)^2/c^2}}(\Delta t-(\Delta x)^2/((\Delta t)c^2))$$

$$\Delta t'=\frac{(\Delta t)^2-(\Delta x)^2/c^2}{\sqrt{(\Delta t)^2-(\Delta x)^2/c^2}}=\sqrt{(\Delta t)^2-(\Delta x/c)^2},$$ as was to be shown.

This equation doesn't have a physical solution (because of a negative square root) if $(\Delta x/c)^2>(\Delta t)^2$ or $\Delta x\ge c\Delta t$.

(b) IDENTIFY and **SET UP:** Now require that $t_2'=t_1'$ (the two events are simultaneous in S') and use the Lorentz coordinate transformation equations.

EXECUTE: $t_2'=t_1'$ implies $t_1-ux_1/c^2=t_2-ux_2/c^2$

$$t_2-t_1=\left(\frac{x_2-x_1}{c^2}\right)u \text{ so } \Delta t=\left(\frac{\Delta x}{c^2}\right)u \text{ and } u=\frac{c^2\Delta t}{\Delta x}$$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

From the Lorentz transformation equations,

$$\Delta x' = x_2' - x_1' = \left(\frac{1}{\sqrt{1-u^2/c^2}}\right)(\Delta x - u\Delta t).$$

Using the result that $u = c^2\Delta t/\Delta x$ gives

$$\Delta x' = \frac{1}{\sqrt{1-c^2(\Delta t)^2/(\Delta x)^2}}(\Delta x - c^2(\Delta t)^2/\Delta x)$$

$$\Delta x' = \frac{\Delta x}{\sqrt{(\Delta x)^2 - c^2(\Delta t)^2}}(\Delta x - c^2(\Delta t)^2/\Delta x)$$

$$\Delta x' = \frac{(\Delta x)^2 - c^2(\Delta t)^2}{\sqrt{(\Delta x)^2 - c^2(\Delta t)^2}} = \sqrt{(\Delta x)^2 - c^2(\Delta t)^2}$$

(c) IDENTIFY and **SET UP:** The result from part (b) is $\Delta x' = \sqrt{(\Delta x)^2 - c^2(\Delta t)^2}$.

Solve for Δt: $(\Delta x')^2 = (\Delta x)^2 - c^2(\Delta t)^2$

EXECUTE: $\Delta t = \dfrac{\sqrt{(\Delta x)^2 - (\Delta x')^2}}{c} = \dfrac{\sqrt{(5.00\text{ m})^2 - (2.50\text{ m})^2}}{2.998\times10^8\text{ m/s}} = 1.44\times10^{-8}\text{ s}$

EVALUATE: This provides another illustration of the concept of simultaneity (Section 37.2): events observed to be simultaneous in one frame are not simultaneous in another frame that is moving relative to the first.

37.66. **IDENTIFY:** Apply the relativistic expressions for kinetic energy, velocity transformation, length contraction and time dilation.

SET UP: In part (c) let S' be the earth frame and let S be the frame of the ball. Let the direction from Einstein to Lorentz be positive, so $u = -1.80\times10^8$ m/s. In part (d) the proper length is $l_0 = 20.0$ m and in part (f) the proper time is measured by the rabbit.

EXECUTE: **(a)** 80.0 m/s is nonrelativistic, and $K = \frac{1}{2}mv^2 = 186$ J.

(b) $K = (\gamma - 1)mc^2 = 1.31\times10^{15}$ J.

(c) In Eq. (37.23), $v' = 2.20\times10^8$ m/s, $u = -1.80\times10^8$ m/s, and so $v = 7.14\times10^7$ m/s.

(d) $l = \dfrac{l_0}{\gamma} = \dfrac{20.0\text{ m}}{\gamma} = 13.6\text{ m}.$

(e) $\dfrac{20.0\text{ m}}{2.20\times10^8\text{ m/s}} = 9.09\times10^{-8}\text{ s}.$

(f) $\Delta t_0 = \dfrac{\Delta t}{\gamma} = 6.18\times10^{-8}\text{ s}$

EVALUATE: In part (f) we could also calculate Δt_0 as $\Delta t_0 = \dfrac{13.6\text{ m}}{2.20\times10^8\text{ m/s}} = 6.18\times10^{-8}\text{ s}.$

37.67. **IDENTIFY** and **SET UP:** An increase in wavelength corresponds to a decrease in frequency $(f = c/\lambda)$, so the atoms are moving away from the earth. Receding, so use Eq. (37.26): $f = \sqrt{\dfrac{c-u}{c+u}}f_0$

EXECUTE: Solve for u: $(f/f_0)^2(c+u) = c-u$ and $u = c\left(\dfrac{1-(f/f_0)^2}{1+(f/f_0)^2}\right)$

$f = c/\lambda$, $f_0 = c/\lambda_0$ so $f/f_0 = \lambda_0/\lambda$

$$u = c\left(\frac{1-(\lambda_0/\lambda)^2}{1+(\lambda_0/\lambda)^2}\right) = c\left(\frac{1-(656.3/953.4)^2}{1+(656.3/953.4)^2}\right) = 0.357c = 1.07\times10^8\text{ m/s}$$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: The relative speed is large, 36% of c. The cosmological implication of such observations will be discussed in Chapter 44.

37.68. **IDENTIFY:** The baseball is moving toward the radar gun, so apply the Doppler effect as expressed in Eq. (37.25).

SET UP: The baseball had better be moving nonrelativistically, so the Doppler shift formula (Eq. (37.25)) becomes $f \cong f_0(1-(u/c))$. In the baseball's frame, this is the frequency with which the radar waves strike the baseball, and the baseball reradiates at f. But in the coach's frame, the reflected waves are Doppler shifted again, so the detected frequency is $f(1-(u/c)) = f_0(1-(u/c))^2 \approx f_0(1-2(u/c))$.

EXECUTE: $\Delta f = 2f_0(u/c)$ and the fractional frequency shift is $\dfrac{\Delta f}{f_0} = 2(u/c)$.

$$u = \frac{\Delta f}{2f_0}c = \frac{(2.86\times10^{-7})}{2}(3.00\times10^8 \text{ m}) = 42.9 \text{ m/s} = 154 \text{ km/h} = 92.5 \text{ mi/h}.$$

EVALUATE: $u \ll c$, so using the approximate expression in place of Eq. (37.25) is very accurate.

37.69. **IDENTIFY** and **SET UP:** 500 light years $= 4.73\times10^{18}$ m. The proper distance l_0 to the star is 500 light years. The energy needed is the kinetic energy of the rocket at its final speed.

EXECUTE: **(a)** $u = 0.50c$. $\Delta t = \dfrac{d}{u} = \dfrac{4.73\times10^{18} \text{ m}}{(0.50)(3.00\times10^8 \text{ m/s})} = 3.2\times10^{10} \text{ s} = 1000 \text{ y}$

The proper time is measured by the astronauts. $\Delta t_0 = \Delta t\sqrt{1-u^2/c^2} = 866$ y

$$K = \frac{mc^2}{\sqrt{1-v^2/c^2}} - mc^2 = (1000 \text{ kg})(3.00\times10^8 \text{ m/s})^2\left(\frac{1}{\sqrt{1-(0.500)^2}} - 1\right) = 1.4\times10^{19} \text{ J}$$

This is 14% of the U.S. yearly use of energy.

(b) $u = 0.99c$. $\Delta t = \dfrac{d}{u} = \dfrac{4.73\times10^{18} \text{ m}}{(0.99)(3.00\times10^8 \text{ m/s})} = 1.6\times10^{10} \text{ s} = 505 \text{ yr}$, $\Delta t_0 = 71$ y

$$K = (9.00\times10^{19} \text{ J})\left(\frac{1}{\sqrt{1-(0.99)^2}} - 1\right) = 5.5\times10^{20} \text{ J}$$

This is 5.5 times (550%) the U.S. yearly use.

(c) $u = 0.9999c$. $\Delta t = \dfrac{d}{u} = \dfrac{4.73\times10^8 \text{ m}}{(0.9999)(3.00\times10^8 \text{ m/s})} = 1.58\times10^{10} \text{ s} = 501 \text{ y}$, $\Delta t_0 = 7.1$ y.

$$K = (9.00\times10^{19} \text{ J})\left(\frac{1}{\sqrt{1-(0.9999)^2}} - 1\right) = 6.3\times10^{21} \text{ J}.$$

This is 63 times (6300%) the U.S. yearly use.

EVALUATE: The energy cost of accelerating a rocket to these speeds is immense.

37.70. **IDENTIFY** and **SET UP:** For part (a) follow the procedure specified in the hint. For part (b) apply Eqs. (37.25) and (37.26).

EXECUTE: **(a)** As in the hint, both the sender and the receiver measure the same distance. However, in our frame, the ship has moved between emission of successive wavefronts, and we can use the time $T = 1/f$ as the proper time, with the result that $f = \gamma f_0 > f_0$.

(b) Toward: $f_1 = f_0\sqrt{\dfrac{c+u}{c-u}} = 345 \text{ MHz}\left(\dfrac{1+0.758}{1-0.758}\right)^{1/2} = 930 \text{ MHz}$ and

$f_1 - f_0 = 930 \text{ MHz} - 345 \text{ MHz} = 585 \text{ MHz}.$

Away: $f_2 = f_0\sqrt{\dfrac{c-u}{c+u}} = 345 \text{ MHz}\left(\dfrac{1-0.758}{1+0.758}\right)^{1/2} = 128 \text{ MHz}$ and $f_2 - f_0 = -217$ MHz.

(c) $f_3 = \gamma f_0 = 1.53 f_0 = 528$ MHz, $f_3 - f_0 = 183$ MHz.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: The frequency in part (c) is the average of the two frequencies in part (b). A little algebra shows that f_3 is precisely equal to $(f_1 + f_2)/2$.

37.71. **IDENTIFY:** We need to use the relativistic form of Newton's second law because the speed of the proton is close to the speed of light.

SET UP: $\vec{F}$ and $\vec{v}$ are perpendicular, so $F = \gamma ma = \gamma m\dfrac{v^2}{R}$. $\gamma = \dfrac{1}{\sqrt{1-v^2/c^2}} = \dfrac{1}{\sqrt{1-(0.750)^2}} = 1.512.$

EXECUTE: $F = (1.512)(1.67\times10^{-27}\text{ kg})\dfrac{[(0.750)(3.00\times10^8\text{ m/s}]^2}{628\text{ m}} = 2.04\times10^{-13}\text{ N}.$

EVALUATE: If we ignored relativity, the force would be

$F_{\text{rel}}/\gamma = \dfrac{2.04\times10^{-13}\text{ N}}{1.512} = 1.35\times10^{-13}\text{ N},$ which is substantially less than the relativistic force.

37.72. **IDENTIFY:** Apply the Lorentz velocity transformation.

SET UP: Let the tank and the light both be traveling in the $+x$-direction. Let S be the lab frame and let S' be the frame of the tank of water.

EXECUTE: In Eq. (37.23), $u = V, v' = (c/n)$. $v = \dfrac{(c/n)+V}{1+\dfrac{cV}{nc^2}} = \dfrac{(c/n)+V}{1+(V/nc)}$. For $V \ll c$,

$(1+V/nc)^{-1} \approx (1-V/nc)$. This gives

$v \approx ((cn)+V)(1-(V/nc)) = (nc/n)+V-(V/n^2)-(V^2/nc) \approx \dfrac{c}{n}+\left(1-\dfrac{1}{n^2}\right)V,$ so $k = \left(1-\dfrac{1}{n^2}\right)$. For water,

$n = 1.333$ and $k = 0.437$.

EVALUATE: The Lorentz transformation predicts a value of k in excellent agreement with the value that is measured experimentally.

37.73. **IDENTIFY** and **SET UP:** Follow the procedure specified in the hint.

EXECUTE: **(a)** $a' = \dfrac{dv}{dt'}$. $dt' = \gamma(dt - udx/c^2)$. $dv' = \dfrac{dv}{(1-uv/c^2)} + \dfrac{v-u}{(1-uv/c^2)^2}\dfrac{u}{c^2}dv$

$\dfrac{dv'}{dv} = \dfrac{1}{1-uv/c^2} + \dfrac{v-u}{(1-uv/c^2)^2}\left(\dfrac{u}{c^2}\right)$. $dv' = dv\left(\dfrac{1}{1-uv/c^2} + \dfrac{(v-u)u/c^2}{(1-uv/c^2)^2}\right) = dv\left(\dfrac{1-u^2/c^2}{(1-uv/c^2)^2}\right)$

$a' = \dfrac{dv\dfrac{(1-u^2/c^2)}{(1-uv/c^2)^2}}{\gamma dt - u\gamma dx/c^2} = \dfrac{dv}{dt}\dfrac{(1-u^2/c^2)}{(1-uv/c^2)^2}\dfrac{1}{\gamma(1-uv/c^2)} = a(1-u^2/c^2)^{3/2}\,(1-uv/c^2)^{-3}.$

(b) Changing frames from $S' \to S$ just involves changing

$a \to a', v \to -v' \Rightarrow a = a'(1-u^2/c^2)^{3/2}\left(1+\dfrac{uv'}{c^2}\right)^{-3}.$

EVALUATE: a_x' depends not only on a_x and u, but also on v_x, the component of the velocity of the object in frame S.

37.74. **IDENTIFY** and **SET UP:** Follow the procedures specified in the problem.

EXECUTE: **(a)** The speed v' is measured relative to the rocket, and so for the rocket and its occupant, $v' = 0$. The acceleration as seen in the rocket is given to be $a' = g$, and so the acceleration as measured on the earth is $a = \dfrac{du}{dt} = g\left(1-\dfrac{u^2}{c^2}\right)^{3/2}$.

(b) With $v_1 = 0$ when $t = 0$,

$dt = \dfrac{1}{g}\dfrac{du}{(1-u^2/c^2)^{3/2}}$. $\displaystyle\int_0^{t_1} dt = \frac{1}{g}\int_0^{v_1}\frac{du}{(1-u^2/c^2)^{3/2}}$. $t_1 = \dfrac{v_1}{g\sqrt{1-v_1^2/c^2}}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(c) $dt' = \gamma dt = dt/\sqrt{1-u^2/c^2}$, so the relation in part (b) between *dt* and *du,* expressed in terms of dt' and *du,* is $dt' = \gamma dt = \dfrac{1}{\sqrt{1-u^2/c^2}}\dfrac{du}{g(1-u^2/c^2)^{3/2}} = \dfrac{1}{g}\dfrac{du}{(1-u^2/c^2)^2}$.

Integrating as above (perhaps using the substitution $z = u/c$) gives $t_1' = \dfrac{c}{g}\operatorname{arctan h}\left(\dfrac{v_1}{c}\right)$. For those who wish to avoid inverse hyperbolic functions, the above integral may be done by the method of partial fractions; $gdt' = \dfrac{du}{(1+u/c)(1-u/c)} = \dfrac{1}{2}\left[\dfrac{du}{1+u/c} + \dfrac{du}{1-uc}\right]$, which integrates to $t_1' = \dfrac{c}{2g}\ln\left(\dfrac{c+v_1}{c-v_1}\right)$.

(d) Solving the expression from part (c) for v_1 in terms of t_1, $(v_1/c) = \tanh(gt_1'/c)$, so that $\sqrt{1-(v_1/c)^2} = 1/\cosh(gt_1'/c)$, using the appropriate indentities for hyperbolic functions. Using this in the expression found in part (b), $t_1 = \dfrac{c}{g}\dfrac{\tanh(gt_1'/c)}{1/\cosh(gt_1'/c)} = \dfrac{c}{g}\sinh(gt_1'/c)$, which may be rearranged slightly as $\dfrac{gt_1}{c} = \sinh\left(\dfrac{gt'}{c}\right)$. If hyperbolic functions are not used, v_1 in terms of t_1' is found to be $\dfrac{v_1}{c} = \dfrac{e^{gt_1'/c} - e^{-gt_1'/c}}{e^{gt_1'/c} + e^{-gt_1'/c}}$ which is the same as $\tanh(gt_1'/c)$. Inserting this expression into the result of part (b) gives, after much algebra, $t_1 = \dfrac{c}{2g}(e^{gt_1'/c} - e^{-gt_1'/c})$, which is equivalent to the expression found using hyperbolic functions.

(e) After the first acceleration period (of 5 years by Stella's clock), the elapsed time on earth is

$$t_1' = \frac{c}{g}\sinh(gt_1'/c) = 2.65\times10^9 \text{ s} = 84.0 \text{ yr}.$$

The elapsed time will be the same for each of the four parts of the voyage, so when Stella has returned, Terra has aged 336 yr and the year is 2436. (Keeping more precision than is given in the problem gives February 7 of that year.)

EVALUATE: Stella has aged only 20 yrs, much less than Terra.

37.75. **IDENTIFY:** Apply the Doppler effect equation.

SET UP: At the two positions shown in the figure given in the problem, the velocities of the star relative to the earth are $u+v$ and $u-v$, where *u* is the velocity of the center of mass and *v* is the orbital velocity.

EXECUTE: **(a)** $f_0 = 4.568110\times10^{14}$ Hz; $f_+ = 4.568910\times10^{14}$ Hz; $f_- = 4.567710\times10^{14}$ Hz

$$\left.\begin{aligned} f_+ &= \sqrt{\frac{c+(u+v)}{c-(u+v)}}f_0 \\ f_- &= \sqrt{\frac{c+(u-v)}{c-(u-v)}}f_0 \end{aligned}\right\} \Rightarrow \begin{aligned} f_+^2(c-(u+v)) &= f_0^2\,(c+(u+v)) \\ f_-^2(c-(u-v)) &= f_0^2(c+(u-v)) \end{aligned}$$

$(u+v) = \dfrac{(f_+/f_0)^2-1}{(f_+/f_0)^2+1}c$ and $(u-v) = \dfrac{(f_-^2/f_0^2)-1}{(f_-^2/f_0^2)+1}c$. $u+v = 5.25\times10^4$ m/s and $u-v = -2.63\times10^4$ m/s.

This gives $u = +1.31\times10^4$ m/s (moving toward at 13.1 km/s) and $v = 3.94\times10^4$ m/s.

(b) $v = 3.94\times10^4$ m/s; $T = 11.0$ days. $2\pi R = vt \Rightarrow$

$R = \dfrac{(3.94\times10^4 \text{ m/s})(11.0 \text{ days})(24 \text{ hrs/day})(3600 \text{ sec/hr})}{2\pi} = 5.96\times10^9$ m. This is about 0.040 times the earth-sun distance.

Also the gravitational force between them (a distance of 2*R*) must equal the centripetal force from the center of mass:

$\dfrac{(Gm^2)}{(2R)^2} = \dfrac{mv^2}{R} \Rightarrow m = \dfrac{4Rv^2}{G} = \dfrac{4(5.96\times10^9 \text{ m})(3.94\times10^4 \text{ m/s})^2}{6.672\times10^{-11} \text{ N}\cdot\text{m}^2/\text{kg}^2} = 5.55\times10^{29} \text{ kg} = 0.279\, m_{\text{sun}}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: u and v are both much less than c, so we could have used the approximate expression $\Delta f = \pm f_0 v_{\text{rev}}/c$, where v_{rev} is the speed of the source relative to the observer.

37.76. **IDENTIFY** and **SET UP:** Apply the procedures specified in the problem.

EXECUTE: For any function $f = f(x,t)$ and $x = x(x',t'), t = t(x',t')$, let $F(x',t') = f(x(x',t'),t(x',t'))$ and use the standard (but mathematically improper) notation $F(x',t') = f(x',t')$. The chain rule is then

$$\frac{\partial f(x',t')}{\partial x} = \frac{\partial f(x,t)}{\partial x'}\frac{\partial x'}{\partial x} + \frac{\partial f(x',t')}{\partial t'}\frac{\partial t'}{\partial x},$$
$$\frac{\partial f(x',t')}{\partial t} = \frac{\partial f(x,t)}{\partial x'}\frac{\partial x'}{\partial t} + \frac{\partial f(x',t')}{\partial x'}\frac{\partial t'}{\partial t}.$$

In this solution, the explicit dependence of the functions on the sets of dependent variables is suppressed, and the above relations are then $\frac{\partial f}{\partial x} = \frac{\partial f}{\partial x'}\frac{\partial x'}{\partial x} + \frac{\partial f}{\partial t'}\frac{\partial t'}{\partial x}$, $\frac{\partial f}{\partial t} = \frac{\partial f}{\partial x'}\frac{\partial x'}{\partial t} + \frac{\partial f}{\partial t'}\frac{\partial t'}{\partial t}$.

(a) $\frac{\partial x'}{\partial x} = 1, \frac{\partial x'}{\partial t} = -v, \frac{\partial t'}{\partial x} = 0$ and $\frac{\partial t'}{\partial t} = 1$. Then, $\frac{\partial E}{\partial x} = \frac{\partial E}{\partial x'}$, and $\frac{\partial^2 E}{\partial x^2} = \frac{\partial^2 E}{\partial x'^2}$. For the time derivative, $\frac{\partial E}{\partial t} = -v\frac{\partial E}{\partial x'} + \frac{\partial E}{\partial t'}$. To find the second time derivative, the chain rule must be applied to both terms; that is,

$$\frac{\partial}{\partial t}\frac{\partial E}{\partial x'} = -v\frac{\partial^2 E}{\partial x'^2} + \frac{\partial^2 E}{\partial t'\partial x'},$$
$$\frac{\partial}{\partial t}\frac{\partial E}{\partial t'} = -v\frac{\partial^2 E}{\partial x'\partial t'} + \frac{\partial^2 E}{\partial t'^2}.$$

Using these in $\frac{\partial^2 E}{\partial t^2}$, collecting terms and equating the mixed partial derivatives gives $\frac{\partial^2 E}{\partial t^2} = v^2\frac{\partial^2 E}{\partial x'^2} - 2v\frac{\partial^2 E}{\partial x'\partial t'} + \frac{\partial^2 E}{\partial t'^2}$, and using this and the above expression for $\frac{\partial^2 E}{\partial x'^2}$ gives the result.

(b) For the Lorentz transformation, $\frac{\partial x'}{\partial x} = \gamma, \frac{\partial x'}{\partial t} = \gamma v, \frac{\partial t'}{\partial x} = \gamma v/c^2$ and $\frac{\partial t'}{\partial t} = \gamma$.

The first partials are then

$$\frac{\partial E}{\partial x} = \gamma\frac{\partial E}{\partial x'} - \gamma\frac{v}{c^2}\frac{\partial E}{\partial t'}, \frac{\partial E}{\partial t} = -\gamma v\frac{\partial E}{\partial x'} + \gamma\frac{\partial E}{\partial t'}$$

and the second partials are (again equating the mixed partials)

$$\frac{\partial^2 E}{\partial x^2} = \gamma^2\frac{\partial^2 E}{\partial x'^2} + \gamma^2\frac{v^2}{c^4}\frac{\partial^2 E}{\partial t'^2} - 2\gamma^2\frac{v}{c^2}\frac{\partial^2 E}{\partial x'\partial t'}$$
$$\frac{\partial^2 E}{\partial t^2} = \gamma^2 v^2\frac{\partial^2 E}{\partial x'^2} + \gamma^2\frac{\partial^2 E}{\partial t'^2} - 2\gamma^2 v\frac{\partial^2 E}{\partial x'\partial t'}.$$

Substituting into the wave equation and combining terms (note that the mixed partials cancel),

$$\frac{\partial^2 E}{\partial x^2} - \frac{1}{c^2}\frac{\partial^2 E}{\partial t^2} = \gamma^2\left(1 - \frac{v^2}{c^2}\right)\frac{\partial^2 E}{\partial x'^2} + \gamma^2\left(\frac{v^2}{c^4} - \frac{1}{c^2}\right)\frac{\partial^2 E}{\partial t'^2} = \frac{\partial^2 E}{\partial x'^2} - \frac{1}{c^2}\frac{\partial^2 E}{\partial t'^2} = 0.$$

EVALUATE: The general form of the wave equation is given by Eq. (32.1). The coefficient of the $\partial^2/\partial t^2$ term is the inverse of the square of the wave speed. This coefficient is the same in both frames, so the wave speed is the same in both frames.

37.77. **IDENTIFY:** Apply conservation of total energy, in the frame in which the total momentum is zero (the center of momentum frame).

SET UP: In the center of momentum frame, the two protons approach each other with equal velocities (since the protons have the same mass). After the collision, the two protons are at rest—but now there are kaons as well. In this situation the kinetic energy of the protons must equal the total rest energy of the two kaons.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: **(a)** $2(\gamma_{\text{cm}}-1)m_{\text{p}}c^2 = 2m_{\text{k}}c^2 \Rightarrow \gamma_{\text{cm}} = 1+\dfrac{m_{\text{k}}}{m_{\text{p}}} = 1.526$. The velocity of a proton in the center of momentum frame is then $v_{\text{cm}} = c\sqrt{\dfrac{\gamma_{\text{cm}}^2-1}{\gamma_{\text{cm}}^2}} = 0.7554c$.

To get the velocity of this proton in the lab frame, we must use the Lorentz velocity transformations. This is the same as "hopping" into the proton that will be our target and asking what the velocity of the projectile proton is. Taking the lab frame to be the unprimed frame moving to the left, $u = v_{\text{cm}}$ and $v' = v_{\text{cm}}$ (the velocity of the projectile proton in the center of momentum frame).

$$v_{\text{lab}} = \frac{v'+u}{1+\dfrac{uv'}{c^2}} = \frac{2v_{\text{cm}}}{1+\dfrac{v_{\text{cm}}^2}{c^2}} = 0.9619c \Rightarrow \gamma_{\text{lab}} = \frac{1}{\sqrt{1-\dfrac{v_{\text{lab}}^2}{c^2}}} = 3.658 \Rightarrow K_{\text{lab}} = (\gamma_{\text{lab}}-1)m_{\text{p}}c^2 = 2494 \text{ MeV}.$$

(b) $\dfrac{K_{\text{lab}}}{2m_{\text{k}}} = \dfrac{2494 \text{ MeV}}{2(493.7 \text{ MeV})} = 2.526$.

(c) The center of momentum case considered in part (a) is the same as this situation. Thus, the kinetic energy required *is* just twice the rest mass energy of the kaons. $K_{\text{cm}} = 2(493.7 \text{ MeV}) = 987.4 \text{ MeV}$.

EVALUATE: The colliding beam situation of part (c) offers a substantial advantage over the fixed target experiment in part (b). It takes less energy to create two kaons in the proton center of momentum frame.

38

PHOTONS: LIGHT WAVES BEHAVING AS PARTICLES

38.1. **IDENTIFY:** Protons have mass and photons are massless.

(a) SET UP: For a particle with mass, $K = p^2/2m$.

EXECUTE: $p_2 = 2p_1$ means $K_2 = 4K_1$.

(b) SET UP: For a photon, $E = pc$.

EXECUTE: $p_2 = 2p_1$ means $E_2 = 2E_1$.

EVALUATE: The relation between E and p is different for particles with mass and particles without mass.

38.2. **IDENTIFY** and **SET UP:** $c = f\lambda$ relates frequency and wavelength and $E = hf$ relates energy and frequency for a photon. $c = 3.00\times10^8$ m/s. $1\text{ eV} = 1.60\times10^{-16}$ J.

EXECUTE: **(a)** $f = \dfrac{c}{\lambda} = \dfrac{3.00\times10^8\text{ m/s}}{505\times10^{-9}\text{ m}} = 5.94\times10^{14}\text{ Hz}$

(b) $E = hf = (6.626\times10^{-34}\text{ J}\cdot\text{s})(5.94\times10^{14}\text{ Hz}) = 3.94\times10^{-19}\text{ J} = 2.46\text{ eV}$

(c) $K = \frac{1}{2}mv^2$ so $v = \sqrt{\dfrac{2K}{m}} = \sqrt{\dfrac{2(3.94\times10^{-19}\text{ J})}{9.5\times10^{-15}\text{ kg}}} = 9.1\text{ mm/s}$

EVALUATE: Compared to kinetic energies of common objects moving at typical speeds, the energy of a visible-light photon is extremely small.

38.3. **IDENTIFY** and **SET UP:** Apply $c = f\lambda$, $p = h/\lambda$ and $E = pc$.

EXECUTE: $f = \dfrac{c}{\lambda} = \dfrac{3.00\times10^8\text{m/s}}{5.20\times10^{-7}\text{ m}} = 5.77\times10^{14}\text{ Hz}.$

$p = \dfrac{h}{\lambda} = \dfrac{6.63\times10^{-34}\text{ J}\cdot\text{s}}{5.20\times10^{-7}\text{ m}} = 1.28\times10^{-27}\text{ kg}\cdot\text{m/s}.$

$E = pc = (1.28\times10^{-27}\text{ kg}\cdot\text{m/s})\,(3.00\times10^8\text{m/s}) = 3.84\times10^{-19}\text{ J} = 2.40\text{ eV}.$

EVALUATE: Visible-light photons have energies of a few eV.

38.4. **IDENTIFY** and **SET UP:** $P_{\text{av}} = \dfrac{\text{energy}}{t}$. $1\text{ eV} = 1.60\times10^{-19}$ J. For a photon, $E = hf = \dfrac{hc}{\lambda}$.

$h = 6.63\times10^{-34}\text{ J}\cdot\text{s}$.

EXECUTE: **(a)** $\text{energy} = P_{\text{av}}t = (0.600\text{ W})(20.0\times10^{-3}\text{ s}) = 1.20\times10^{-2}\text{ J} = 7.5\times10^{16}\text{ eV}$

(b) $E = \dfrac{hc}{\lambda} = \dfrac{(6.63\times10^{-34}\text{ J}\cdot\text{s})(3.00\times10^8\text{ m/s})}{652\times10^{-9}\text{ m}} = 3.05\times10^{-19}\text{ J} = 1.91\text{ eV}$

(c) The number of photons is the total energy in a pulse divided by the energy of one photon:

$\dfrac{1.20\times10^{-2}\text{ J}}{3.05\times10^{-19}\text{ J/photon}} = 3.93\times10^{16}\text{ photons}.$

EVALUATE: The number of photons in each pulse is very large.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

38.5. **IDENTIFY** and **SET UP:** $c = f\lambda$. The source emits $(0.05)(75\text{ J}) = 3.75\text{ J}$ of energy as visible light each second. $E = hf$, with $h = 6.63\times10^{-34}\text{ J}\cdot\text{s}$.

EXECUTE: **(a)** $f = \dfrac{c}{\lambda} = \dfrac{3.00\times10^{8}\text{ m/s}}{600\times10^{-9}\text{ m}} = 5.00\times10^{14}\text{ Hz}$

(b) $E = hf = (6.63\times10^{-34}\text{ J}\cdot\text{s})(5.00\times10^{14}\text{ Hz}) = 3.32\times10^{-19}\text{ J}$. The number of photons emitted per second is $\dfrac{3.75\text{ J}}{3.32\times10^{-19}\text{ J/photon}} = 1.13\times10^{19}\text{ photons}$.

EVALUATE: **(c)** No. The frequency of the light depends on the energy of each photon. The number of photons emitted per second is proportional to the power output of the source.

38.6. **IDENTIFY** and **SET UP:** A photon has zero rest mass, so its energy and momentum are related by Eq. (37.40). Eq. (38.5) then relates its momentum and wavelength.

EXECUTE: **(a)** $E = pc = (8.24\times10^{-28}\text{ kg}\cdot\text{m/s})(2.998\times10^{8}\text{ m/s}) = 2.47\times10^{-19}\text{ J} =$ $(2.47\times10^{-19}\text{ J})(1\text{ eV}/1.602\times10^{-19}\text{ J}) = 1.54\text{ eV}$

(b) $p = \dfrac{h}{\lambda}$ so $\lambda = \dfrac{h}{p} = \dfrac{6.626\times10^{-34}\text{ J}\cdot\text{s}}{8.24\times10^{-28}\text{ kg}\cdot\text{m/s}} = 8.04\times10^{-7}\text{ m} = 804\text{ nm}$

EVALUATE: This wavelength is longer than visible wavelengths; it is in the infrared region of the electromagnetic spectrum. To check our result we could verify that the same E is given by Eq. (38.2), using the λ we have calculated.

38.7. **IDENTIFY** and **SET UP:** The stopping potential V_0 is related to the frequency of the light by $V_0 = \dfrac{h}{e}f - \dfrac{\phi}{e}$. The slope of V_0 versus f is h/e. The value f_{th} of f when $V_0 = 0$ is related to ϕ by $\phi = hf_{\text{th}}$.

EXECUTE: **(a)** From the graph, $f_{\text{th}} = 1.25\times10^{15}\text{ Hz}$. Therefore, with the value of h from part (b), $\phi = hf_{\text{th}} = 4.8\text{ eV}$.

(b) From the graph, the slope is $3.8\times10^{-15}\text{ V}\cdot\text{s}$.

$h = (e)(\text{slope}) = (1.60\times10^{-16}\text{ C})(3.8\times10^{-15}\text{ V}\cdot\text{s}) = 6.1\times10^{-34}\text{ J}\cdot\text{s}$

(c) No photoelectrons are produced for $f < f_{\text{th}}$.

(d) For a different metal f_{th} and ϕ are different. The slope is h/e so would be the same, but the graph would be shifted right or left so it has a different intercept with the horizontal axis.

EVALUATE: As the frequency f of the light is increased above f_{th} the energy of the photons in the light increases and more energetic photons are produced. The work function we calculated is similar to that for gold or nickel.

38.8. **IDENTIFY** and **SET UP:** $\lambda_{\text{th}} = 272\text{ nm}$. $c = f\lambda$. $\dfrac{1}{2}mv_{\text{max}}^2 = hf - \phi$. At the threshold frequency, f_{th}, $v_{\text{max}} \to 0$. $h = 4.136\times10^{-15}\text{ eV}\cdot\text{s}$.

EXECUTE: **(a)** $f_{\text{th}} = \dfrac{c}{\lambda_{\text{th}}} = \dfrac{3.00\times10^{8}\text{ m/s}}{272\times10^{-9}\text{ m}} = 1.10\times10^{15}\text{ Hz}$.

(b) $\phi = hf_{\text{th}} = (4.136\times10^{-15}\text{ eV}\cdot\text{s})(1.10\times10^{15}\text{ Hz}) = 4.55\text{ eV}$.

(c) $\dfrac{1}{2}mv_{\text{max}}^2 = hf - \phi = (4.136\times10^{-15}\text{ eV}\cdot\text{s})(1.45\times10^{15}\text{ Hz}) - 4.55\text{ eV} = 6.00\text{ eV} - 4.55\text{ eV} = 1.45\text{ eV}$

EVALUATE: The threshold wavelength depends on the work function for the surface.

38.9. **IDENTIFY** and **SET UP:** Eq. (38.3): $\dfrac{1}{2}mv_{\text{max}}^2 = hf - \phi = \dfrac{hc}{\lambda} - \phi$. Take the work function ϕ from Table 38.1. Solve for v_{max}. Note that we wrote f as c/λ.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: $\frac{1}{2}mv_{\max}^2 = \frac{(6.626\times10^{-34}\ \text{J}\cdot\text{s})(2.998\times10^{8}\ \text{m/s})}{235\times10^{-9}\ \text{m}} - (5.1\ \text{eV})(1.602\times10^{-19}\ \text{J/1 eV})$

$\frac{1}{2}mv_{\max}^2 = 8.453\times10^{-19}\ \text{J} - 8.170\times10^{-19}\ \text{J} = 2.83\times10^{-20}\ \text{J}$

$v_{\max} = \sqrt{\frac{2(2.83\times10^{-20}\ \text{J})}{9.109\times10^{-31}\ \text{kg}}} = 2.49\times10^{5}\ \text{m/s}$

EVALUATE: The work function in eV was converted to joules for use in Eq. (38.3). A photon with $\lambda = 235$ nm has energy greater then the work function for the surface.

38.10. **IDENTIFY** and **SET UP:** $\phi = hf_{\text{th}} = \frac{hc}{\lambda_{\text{th}}}$. The minimum ϕ corresponds to the minimum λ.

EXECUTE: $\phi = \frac{hc}{\lambda_{\text{th}}} = \frac{(4.136\times10^{-15}\ \text{eV}\cdot\text{s})(3.00\times10^{8}\ \text{m/s})}{700\times10^{-9}\ \text{m}} = 1.77\ \text{eV}$

EVALUATE: A photon of wavelength 700 nm has energy 1.77 eV.

38.11. **IDENTIFY**: The photoelectric effect occurs. The kinetic energy of the photoelectron is the difference between the initial energy of the photon and the work function of the metal.

SET UP: $\frac{1}{2}mv_{\max}^2 = hf - \phi$, $E = hc/\lambda$.

EXECUTE: Use the data for the 400.0-nm light to calculate ϕ. Solving for ϕ gives $\phi = \frac{hc}{\lambda} - \frac{1}{2}mv_{\max}^2 =$ $\frac{(4.136\times10^{-15}\ \text{eV}\cdot\text{s})(3.00\times10^{8}\ \text{m/s})}{400.0\times10^{-9}\ \text{m}} - 1.10\ \text{eV} = 3.10\ \text{eV} - 1.10\ \text{eV} = 2.00\ \text{eV}$. Then for 300.0 nm, we have $\frac{1}{2}mv_{\max}^2 = hf - \phi = \frac{hc}{\lambda} - \phi = \frac{(4.136\times10^{-15}\ \text{eV}\cdot\text{s})(3.00\times10^{8}\ \text{m/s})}{300.0\times10^{-9}\ \text{m}} - 2.00\ \text{eV}$, which gives $\frac{1}{2}mv_{\max}^2 = 4.14\ \text{eV} - 2.00\ \text{eV} = 2.14\ \text{eV}$.

EVALUATE: When the wavelength decreases the energy of the photons increases and the photoelectrons have a larger minimum kinetic energy.

38.12. **IDENTIFY** and **SET UP:** $eV_0 = \frac{1}{2}mv_{\max}^2$, where V_0 is the stopping potential. The stopping potential in volts equals eV_0 in electron volts. $\frac{1}{2}mv_{\max}^2 = hf - \phi$ and $f = c/\lambda$.

EXECUTE: **(a)** $eV_0 = \frac{1}{2}mv_{\max}^2$ so

$eV_0 = hf - \phi = \frac{(4.136\times10^{-15}\ \text{eV}\cdot\text{s})(3.00\times10^{8}\ \text{m/s})}{250\times10^{-9}\ \text{m}} - 2.3\ \text{eV} = 4.96\ \text{eV} - 2.3\ \text{eV} = 2.7\ \text{eV}$. The stopping potential is 2.7 electron volts.

(b) $\frac{1}{2}mv_{\max}^2 = 2.7\ \text{eV}$

(c) $v_{\max} = \sqrt{\frac{2(2.7\ \text{eV})(1.60\times10^{-19}\ \text{J/eV})}{9.11\times10^{-31}\ \text{kg}}} = 9.7\times10^{5}\ \text{m/s}$

EVALUATE: If the wavelength of the light is decreased, the maximum kinetic energy of the photoelectrons increases.

38.13. **(a) IDENTIFY:** First use Eq. (38.4) to find the work function ϕ.

SET UP: $eV_0 = hf - \phi$ so $\phi = hf - eV_0 = \frac{hc}{\lambda} - eV_0$

EXECUTE: $\phi = \frac{(6.626\times10^{-34}\ \text{J}\cdot\text{s})(2.998\times10^{8}\ \text{m/s})}{254\times10^{-9}\ \text{m}} - (1.602\times10^{-19}\ \text{C})(0.181\ \text{V})$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$\phi = 7.821\times10^{-19}\ \text{J} - 2.900\times10^{-20}\ \text{J} = 7.531\times10^{-19}\ \text{J}(1\ \text{eV}/1.602\times10^{-19}\ \text{J}) = 4.70\ \text{eV}$

IDENTIFY and **SET UP:** The threshold frequency f_{th} is the smallest frequency that still produces photoelectrons. It corresponds to $K_{\max} = 0$ in Eq. (38.3), so $hf_{\text{th}} = \phi$.

EXECUTE: $f = \dfrac{c}{\lambda}$ says $\dfrac{hc}{\lambda_{\text{th}}} = \phi$

$$\lambda_{\text{th}} = \frac{hc}{\phi} = \frac{(6.626\times10^{-34}\ \text{J}\cdot\text{s})(2.998\times10^{8}\ \text{m/s})}{7.531\times10^{-19}\ \text{J}} = 2.64\times10^{-7}\ \text{m} = 264\ \text{nm}$$

(b) EVALUATE: As calculated in part (a), $\phi = 4.70$ eV. This is the value given in Table 38.1 for copper.

38.14. **IDENTIFY:** The acceleration gives energy to the electrons which is then given to the x ray photons.

SET UP: $E = hc/\lambda$, so $\dfrac{hc}{\lambda} = eV$, where λ is the wavelength of the x ray and V is the accelerating voltage.

EXECUTE: $\lambda = \dfrac{hc}{eV} = \dfrac{(6.63\times10^{-34}\ \text{J}\cdot\text{s})(3.00\times10^{8}\ \text{m/s})}{(1.60\times10^{-19}\ \text{C})(15.0\times10^{3}\ \text{V})} = 8.29\times10^{-11}\ \text{m} = 0.0829\ \text{nm}.$

EVALUATE: This wavelength certainly is in the x ray region of the electromagnetic spectrum.

38.15. **IDENTIFY:** Apply Eq. (38.6).

SET UP: For a 4.00-keV electron, $eV_{\text{AC}} = 4000$ eV.

EXECUTE: $eV_{\text{AC}} = hf_{\max} = \dfrac{hc}{\lambda_{\min}} \Rightarrow \lambda_{\min} = \dfrac{hc}{eV_{\text{AC}}} = \dfrac{(6.63\times10^{-34}\ \text{J}\cdot\text{s})(3.00\times10^{8}\ \text{m/s})}{(1.60\times10^{-19}\ \text{C})(4000\ \text{V})} = 3.11\times10^{-10}\ \text{m}$

EVALUATE: This is the same answer as would be obtained if electrons of this energy were used. Electron beams are much more easily produced and accelerated than proton beams.

38.16. **IDENTIFY** and **SET UP:** $\dfrac{hc}{\lambda} = eV$, where λ is the wavelength of the x ray and V is the accelerating voltage.

EXECUTE: **(a)** $V = \dfrac{hc}{e\lambda} = \dfrac{(6.63\times10^{-34}\ \text{J}\cdot\text{s})(3.00\times10^{8}\ \text{m/s})}{(1.60\times10^{-19}\ \text{C})(0.150\times10^{-9}\ \text{m})} = 8.29\ \text{kV}$

(b) $\lambda = \dfrac{hc}{eV} = \dfrac{(6.63\times10^{-34}\ \text{J}\cdot\text{s})(3.00\times10^{8}\ \text{m/s})}{(1.60\times10^{-19}\ \text{C})(30.0\times10^{3}\ \text{V})} = 4.14\times10^{-11}\ \text{m} = 0.0414\ \text{nm}$

EVALUATE: Shorter wavelengths require larger potential differences.

38.17. **IDENTIFY:** Energy is conserved when the x ray collides with the stationary electron.

SET UP: $E = hc/\lambda$, and energy conservation gives $\dfrac{hc}{\lambda} = \dfrac{hc}{\lambda'} + K_{\text{e}}$.

EXECUTE: Solving for K_{e} gives $K_{\text{e}} = hc\left(\dfrac{1}{\lambda} - \dfrac{1}{\lambda'}\right) =$

$(6.63\times10^{-34}\ \text{J}\cdot\text{s})(3.00\times10^{8}\ \text{m/s})\left(\dfrac{1}{0.100\times10^{-9}\ \text{m}} - \dfrac{1}{0.110\times10^{-9}\ \text{m}}\right)$. $K_{\text{e}} = 1.81\times10^{-16}\ \text{J} = 1.13\ \text{keV}.$

EVALUATE: The electron does not get all the energy of the incident photon.

38.18. **IDENTIFY** and **SET UP:** The wavelength of the x rays produced by the tube is given by $\dfrac{hc}{\lambda} = eV$.

$\lambda' = \lambda + \dfrac{h}{mc}(1-\cos\phi)$. $\dfrac{h}{mc} = 2.426\times10^{-12}\ \text{m}$. The energy of the scattered x ray is $\dfrac{hc}{\lambda'}$.

EXECUTE: **(a)** $\lambda = \dfrac{hc}{eV} = \dfrac{(6.63\times10^{-34}\ \text{J}\cdot\text{s})(3.00\times10^{8}\ \text{m/s})}{(1.60\times10^{-19}\ \text{C})(18.0\times10^{3}\ \text{V})} = 6.91\times10^{-11}\ \text{m} = 0.0691\ \text{nm}$

(b) $\lambda' = \lambda + \dfrac{h}{mc}(1-\cos\phi) = 6.91\times10^{-11}\ \text{m} + (2.426\times10^{-12}\ \text{m})(1-\cos45.0°).$

$\lambda' = 6.98\times10^{-11}\ \text{m} = 0.0698\ \text{nm}.$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(c) $E = \dfrac{hc}{\lambda'} = \dfrac{(4.136\times10^{-15}\ \text{eV}\cdot\text{s})(3.00\times10^{8}\ \text{m/s})}{6.98\times10^{-11}\ \text{m}} = 17.8\ \text{keV}$

EVALUATE: The incident x ray has energy 18.0 keV. In the scattering event, the photon loses energy and its wavelength increases.

38.19. **IDENTIFY:** Apply Eq. (38.7): $\lambda' - \lambda = \dfrac{h}{mc}(1-\cos\phi) = \lambda_C(1-\cos\phi)$

SET UP: Solve for λ': $\lambda' = \lambda + \lambda_C(1-\cos\phi)$.

The largest λ' corresponds to $\phi = 180°$, so $\cos\phi = -1$.

EXECUTE: $\lambda' = \lambda + 2\lambda_C = 0.0665\times10^{-9}\ \text{m} + 2(2.426\times10^{-12}\ \text{m}) = 7.135\times10^{-11}\ \text{m} = 0.0714\ \text{nm}$. This wavelength occurs at a scattering angle of $\phi = 180°$.

EVALUATE: The incident photon transfers some of its energy and momentum to the electron from which it scatters. Since the photon loses energy its wavelength increases, $\lambda' > \lambda$.

38.20. **IDENTIFY:** Apply Eq. (38.7): $\cos\phi = 1 - \dfrac{\Delta\lambda}{(h/mc)}$.

SET UP: $\dfrac{h}{mc} = 0.002426\ \text{nm}$

EXECUTE: **(a)** $\Delta\lambda = 0.0542\ \text{nm} - 0.0500\ \text{nm}$, $\cos\phi = 1 - \dfrac{0.0042\ \text{nm}}{0.002426\ \text{nm}} = -0.731$, and $\phi = 137°$.

(b) $\Delta\lambda = 0.0521\ \text{nm} - 0.0500\ \text{nm}$. $\cos\phi = 1 - \dfrac{0.0021\ \text{nm}}{0.002426\ \text{nm}} = 0.134$. $\phi = 82.3°$.

(c) $\Delta\lambda = 0$, the photon is undeflected, $\cos\phi = 1$ and $\phi = 0$.

EVALUATE: The shift in wavelength is larger as ϕ approaches 180°. The photon loses energy in the collision, so the wavelength increases.

38.21. **IDENTIFY** and **SET UP:** The shift in wavelength of the photon is $\lambda' - \lambda = \dfrac{h}{mc}(1-\cos\phi)$ where λ' is the wavelength after the scattering and $\dfrac{h}{mc} = \lambda_C = 2.426\times10^{-12}$ m. The energy of a photon of wavelength λ is $E = \dfrac{hc}{\lambda} = \dfrac{1.24\times10^{-6}\ \text{eV}\cdot\text{m}}{\lambda}$. Conservation of energy applies to the collision, so the energy lost by the photon equals the energy gained by the electron.

EXECUTE: **(a)** $\lambda' - \lambda = \lambda_C(1-\cos\phi) = (2.426\times10^{-12}\ \text{m})(1-\cos35.0°) = 4.39\times10^{-13}\ \text{m} = 4.39\times10^{-4}\ \text{nm}$.

(b) $\lambda' = \lambda + 4.39\times10^{-4}\ \text{nm} = 0.04250\ \text{nm} + 4.39\times10^{-4}\ \text{nm} = 0.04294\ \text{nm}$.

(c) $E_\lambda = \dfrac{hc}{\lambda} = 2.918\times10^{4}\ \text{eV}$ and $E_{\lambda'} = \dfrac{hc}{\lambda'} = 2.888\times10^{4}\ \text{eV}$ so the photon loses 300 eV of energy.

(d) Energy conservation says the electron gains 300 eV of energy.

EVALUATE: The photon transfers energy to the electron. Since the photon loses energy, its wavelength increases.

38.22. **IDENTIFY:** The change in wavelength of the scattered photon is given by Eq. 38.7:

$\dfrac{\Delta\lambda}{\lambda} = \dfrac{h}{mc\lambda}(1-\cos\phi) \Rightarrow \lambda = \dfrac{h}{mc\left(\dfrac{\Delta\lambda}{\lambda}\right)}(1-\cos\phi)$.

SET UP: For backward scattering, $\phi = 180°$. Since the photon scatters from a proton, $m = 1.67\times10^{-27}$ kg.

EXECUTE: $\lambda = \dfrac{(6.63\times10^{-34}\ \text{J}\cdot\text{s})}{(1.67\times10^{-27}\ \text{kg})(3.00\times10^{8}\ \text{m/s})(0.100)}(1+1) = 2.65\times10^{-14}\ \text{m}$.

EVALUATE: The maximum change in wavelength, h/mc, is much smaller for scattering from a proton than from an electron.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

38.23. **IDENTIFY:** During the Compton scattering, the wavelength of the x ray increases by 1.0%, which means that the x ray loses energy to the electron.

SET UP: $\Delta\lambda = \dfrac{h}{mc}(1-\cos\phi)$ and $\dfrac{h}{mc} = 2.426\times10^{-12}$ m. $\lambda' = 1.010\lambda$ so $\Delta\lambda = 0.010\lambda$.

EXECUTE: $\cos\phi = 1 - \dfrac{\Delta\lambda}{h/mc} = 1 - \dfrac{(0.010)(0.900\times10^{-10}\text{ m})}{2.426\times10^{-12}\text{ m}} = 0.629$, so $\phi = 51.0°$.

EVALUATE: The scattering angle is less than 90°, so the x ray still has some forward momentum after scattering.

38.24. **IDENTIFY:** Compton scattering occurs. We know speed, and hence the kinetic energy, of the scattered electron. Energy is conserved.

SET UP: $\dfrac{hc}{\lambda} = \dfrac{hc}{\lambda'} + E_e$ where $E_e = \dfrac{1}{2}mv^2$.

EXECUTE: $E_e = \dfrac{1}{2}mv^2 = \dfrac{1}{2}(9.108\times10^{-31}\text{ kg})(8.90\times10^{6}\text{ m/s})^2 = 3.607\times10^{-17}$ J. Using $\dfrac{hc}{\lambda} = \dfrac{hc}{\lambda'} + E_e$, we have $\dfrac{hc}{\lambda} = \dfrac{(6.626\times10^{-34}\text{ J}\cdot\text{s})(2.998\times10^{8}\text{ m/s})}{0.1385\times10^{-9}\text{ m}} = 1.434\times10^{-15}$ J. Therefore,

$\dfrac{hc}{\lambda'} = \dfrac{hc}{\lambda} - E_e = 1.398\times10^{-15}$ J, which gives $\lambda' = \dfrac{(6.626\times10^{-34}\text{ J}\cdot\text{s})(2.998\times10^{8}\text{ m/s})}{1.398\times10^{-15}\text{ J}} = 0.1421$ nm.

$\lambda' - \lambda = \left(\dfrac{h}{mc}\right)(1-\cos\phi) = 3.573\times10^{-12}$ m, so $1-\cos\phi = 1.473$, which gives $\phi = 118°$.

EVALUATE: The photon partly backscatters, but not through 180°.

38.25. **(a) IDENTIFY** and **SET UP:** Use Eq. (37.36) to calculate the kinetic energy K.

EXECUTE: $K = mc^2\left(\dfrac{1}{\sqrt{1-v^2/c^2}} - 1\right) = 0.1547mc^2$

$m = 9.109\times10^{-31}$ kg, so $K = 1.27\times10^{-14}$ J

(b) IDENTIFY and **SET UP:** The total energy of the particles equals the sum of the energies of the two photons. Linear momentum must also be conserved.

EXECUTE: The total energy of each electron or positron is $E = K + mc^2 = 1.1547mc^2 = 9.46\times10^{-13}$ J. The total energy of the electron and positron is converted into the total energy of the two photons. The initial momentum of the system in the lab frame is zero (since the equal-mass particles have equal speeds in opposite directions), so the final momentum must also be zero. The photons must have equal wavelengths and must be traveling in opposite directions. Equal λ means equal energy, so each photon has energy 9.46×10^{-14} J.

(c) IDENTIFY and **SET UP:** Use Eq. (38.2) to relate the photon energy to the photon wavelength.

EXECUTE: $E = hc/\lambda$ so $\lambda = hc/E = hc/(9.46\times10^{-14}\text{ J}) = 2.10$ pm

EVALUATE: When the particles also have kinetic energy, the energy of each photon is greater, so its wavelength is less.

38.26. **IDENTIFY:** The uncertainty principle relates the uncertainty in the duration time of the pulse and the uncertainty in its energy, which we know.

SET UP: $E = hc/\lambda$ and $\Delta E\Delta t = \hbar/2$.

EXECUTE: $E = \dfrac{hc}{\lambda} = \dfrac{(6.626\times10^{-34}\text{ J}\cdot\text{s})(2.998\times10^{8}\text{ m/s})}{625\times10^{-9}\text{ m}} = 3.178\times10^{-19}$ J. The uncertainty in the energy is 1.0% of this amount, so $\Delta E = 3.178\times10^{-21}$ J. We now use the uncertainty principle. Solving $\Delta E\Delta t = \dfrac{\hbar}{2}$ for the time interval gives $\Delta t = \dfrac{\hbar}{2\Delta E} = \dfrac{1.055\times10^{-34}\text{ J}\cdot\text{s}}{2(3.178\times10^{-19}\text{ J})} = 1.66\times10^{-16}$ s $= 0.166$ fs.

EVALUATE: The uncertainty in the energy limits the duration of the pulse. The more precisely we know the energy, the longer the duration must be.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

38.27. **IDENTIFY:** The wavelength of the pulse tells us the momentum of the photon. The uncertainty in the momentum is determined by the uncertainty principle.

SET UP: $p = \dfrac{h}{\lambda}$ and $\Delta x \Delta p_x = \dfrac{\hbar}{2}$.

EXECUTE: $p = \dfrac{h}{\lambda} = \dfrac{6.626\times10^{-34}\ \text{J}\cdot\text{s}}{556\times10^{-9}\ \text{m}} = 1.19\times10^{-27}\ \text{kg}\cdot\text{m/s}$. The spatial length of the pulse is

$\Delta x = c\Delta t = (2.998\times10^{8}\ \text{m/s})(9.00\times10^{-15}\ \text{s}) = 2.698\times10^{-6}\ \text{m}$. The uncertainty principle gives $\Delta x \Delta p_x = \dfrac{\hbar}{2}$.

Solving for the uncertainty in the momentum, we have

$$\Delta p_x = \frac{\hbar}{2\Delta x} = \frac{1.055\times10^{-34}\ \text{J}\cdot\text{s}}{2(2.698\times10^{-6}\ \text{m})} = 1.96\times10^{-29}\ \text{kg}\cdot\text{m/s}.$$

EVALUATE: This is 1.6% of the average momentum.

38.28. **IDENTIFY:** We know the beam went through the slit, so the uncertainty in its vertical position is the width of the slit.

SET UP: $\Delta y \Delta p_y = \dfrac{\hbar}{2}$ and $p_x = \dfrac{h}{\lambda}$. Call the x-axis horizontal and the y-axis vertical.

EXECUTE: **(a)** Let $\Delta y = a = 6.20\times10^{-5}$ m. Solving $\Delta y \Delta p_y = \dfrac{\hbar}{2}$ for the uncertainty in momentum gives

$$\Delta p_y = \frac{\hbar}{2\Delta y} = \frac{1.055\times10^{-34}\ \text{J}\cdot\text{s}}{2(6.20\times10^{-5}\ \text{m})} = 8.51\times10^{-31}\ \text{kg}\cdot\text{m/s}.$$

(b) $p_x = \dfrac{h}{\lambda} = \dfrac{6.626\times10^{-34}\ \text{J}\cdot\text{s}}{585\times10^{-9}\ \text{m}} = 1.13\times10^{-27}\ \text{kg}\cdot\text{m/s}$. $\theta = \dfrac{\Delta p_y}{p_x} = \dfrac{8.51\times10^{-31}}{1.13\times10^{-27}} = 7.53\times10^{-4}$ rad. The width is $(2.00\ \text{m})(7.53\times10^{-4}) = 1.51\times10^{-3}\ \text{m} = 1.51\ \text{mm}$.

EVALUATE: We must be especially careful not to confuse the x- and y-components of the momentum.

38.29. **IDENTIFY** and **SET UP:** Use $c = f\lambda$ to relate frequency and wavelength and use $E = hf$ to relate photon energy and frequency.

EXECUTE: **(a)** One photon dissociates one AgBr molecule, so we need to find the energy required to dissociate a single molecule. The problem states that it requires 1.00×10^{5} J to dissociate one mole of AgBr, and one mole contains Avogadro's number (6.02×10^{23}) of molecules, so the energy required to dissociate one AgBr is $\dfrac{1.00\times10^{5}\ \text{J/mol}}{6.02\times10^{23}\ \text{molecules/mol}} = 1.66\times10^{-19}\ \text{J/molecule}$.

The photon is to have this energy, so $E = 1.66\times10^{-19}\ \text{J}(1\ \text{eV}/1.602\times10^{-19}\ \text{J}) = 1.04\ \text{eV}$.

(b) $E = \dfrac{hc}{\lambda}$ so $\lambda = \dfrac{hc}{E} = \dfrac{(6.626\times10^{-34}\ \text{J}\cdot\text{s})(2.998\times10^{8}\ \text{m/s})}{1.66\times10^{-19}\ \text{J}} = 1.20\times10^{-6}\ \text{m} = 1200\ \text{nm}$

(c) $c = f\lambda$ so $f = \dfrac{c}{\lambda} = \dfrac{2.998\times10^{8}\ \text{m/s}}{1.20\times10^{-6}\ \text{m}} = 2.50\times10^{14}\ \text{Hz}$

(d) $E = hf = (6.626\times10^{-34}\ \text{J}\cdot\text{s})(100\times10^{6}\ \text{Hz}) = 6.63\times10^{-26}\ \text{J}$

$E = 6.63\times10^{-26}\ \text{J}(1\ \text{eV}/1.602\times10^{-19}\ \text{J}) = 4.14\times10^{-7}\ \text{eV}$

(e) EVALUATE: A photon with frequency $f = 100$ MHz has too little energy, by a large factor, to dissociate a AgBr molecule. The photons in the visible light from a firefly do individually have enough energy to dissociate AgBr. The huge number of 100 MHz photons can't compensate for the fact that individually they have too little energy.

38.30. **IDENTIFY:** The number N of visible photons emitted per second is the visible power divided by the energy hf of one photon.

SET UP: At a distance r from the source, the photons are evenly spread over a sphere of area $A = 4\pi r^2$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: **(a)** $N = \dfrac{P}{hf} = \dfrac{(200\text{ W})(0.10)}{h(5.00\times10^{14}\text{ Hz})} = 6.03\times10^{19}$ photons/sec.

(b) $\dfrac{N}{4\pi r^2} = 1.00\times10^{11}$ photons/sec $\cdot$ cm^2 gives

$$r = \left(\frac{6.03\times10^{19}\text{ photons/sec}}{4\pi(1.00\times10^{11}\text{ photons/sec}\cdot\text{cm}^2)}\right)^{1/2} = 6930\text{ cm} = 69.3\text{ m}.$$

EVALUATE: The number of photons emitted per second by an ordinary household source is very large.

38.31. **IDENTIFY** and **SET UP:** $f = \dfrac{c}{\lambda}$. The $(f,\ V_0)$ values are: $(8.20\times10^{14}\text{ Hz}, 1.48\text{ V})$, $(7.41\times10^{14}\text{ Hz}, 1.15\text{ V})$, $(6.88\times10^{14}\text{ Hz}, 0.93\text{ V})$, $(6.10\times10^{14}\text{ Hz}, 0.62\text{ V})$, $(5.49\times10^{14}\text{ Hz}, 0.36\text{ V})$, $(5.18\times10^{14}\text{ Hz}, 0.24\text{ V})$. The graph of V_0 versus f is given in Figure 38.31.

EXECUTE: **(a)** The threshold frequency, f_{th}, is f where $V_0 = 0$. From the graph this is $f_{\text{th}} = 4.56\times10^{14}$ Hz.

(b) $\lambda_{\text{th}} = \dfrac{c}{f_{\text{th}}} = \dfrac{3.00\times10^{8}\text{ m/s}}{4.56\times10^{14}\text{ Hz}} = 658\text{ nm}$

(c) $\phi = hf_{\text{th}} = (4.136\times10^{-15}\text{ eV}\cdot\text{s})(4.56\times10^{14}\text{ Hz}) = 1.89\text{ eV}$

(d) $eV_0 = hf - \phi$ so $V_0 = \left(\dfrac{h}{e}\right)f - \dfrac{\phi}{e}$. The slope of the graph is $\dfrac{h}{e}$.

$$\frac{h}{e} = \left(\frac{1.48\text{ V} - 0.24\text{ V}}{8.20\times10^{14}\text{ Hz} - 5.18\times10^{14}\text{ Hz}}\right) = 4.11\times10^{-15}\text{ V/Hz}$$ and

$h = (4.11\times10^{-15}\text{ V/Hz})(1.60\times10^{-19}\text{ C}) = 6.58\times10^{-34}\text{ J}\cdot\text{s}$.

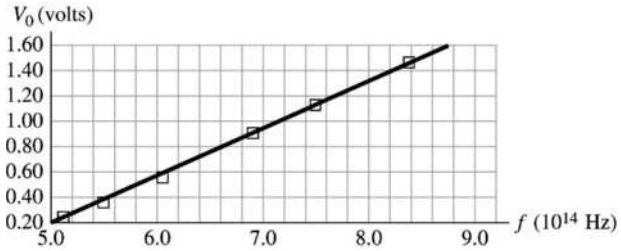

Figure 38.31

EVALUATE: The value of h from our calculation is within 1% of the accepted value.

38.32. **IDENTIFY:** The photoelectric effect occurs, so the energy of the photon is used to eject an electron, with any excess energy going into kinetic energy of the electron.

SET UP: Conservation of energy gives $hf = hc/\lambda = K_{\max} + \phi$.

EXECUTE: **(a)** Using $hc/\lambda = K_{\max} + \phi$, we solve for the work function:

$$\phi = hc/\lambda - K_{\max} = (4.136\times10^{-15}\text{ eV}\cdot\text{s})(3.00\times10^{8}\text{ m/s})/(124\text{ nm}) - 4.16\text{ eV} = 5.85\text{ eV}$$

(b) The number N of photoelectrons per second is equal to the number of photons per second that strike the metal per second. $N\times(\text{energy of a photon}) = 2.50$ W. $N(hc/\lambda) = 2.50$ W.

$N = (2.50\text{ W})(124\text{ nm})/[(6.626\times10^{-34}\text{ J}\cdot\text{s})(3.00\times10^{8}\text{ m/s})] = 1.56\times10^{18}$ electrons/s

(c) N is proportional to the power, so if the power is cut in half, so is N, which gives

$$N = (1.56\times10^{18}\text{ el/s})/2 = 7.80\times10^{17}\text{ el/s}$$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(d) If we cut the wavelength by half, the energy of each photon is doubled since $E = hc/\lambda$. To maintain the same power, the number of photons must be half of what they were in part (b), so N is cut in half to 7.80×10^{17} el/s. We could also see this from part (b), where N is proportional to λ. So if the wavelength is cut in half, so is N.

EVALUATE: In part (c), reducing the power does not reduce the maximum kinetic energy of the photons; it only reduces the number of ejected electrons. In part (d), reducing the wavelength *does* change the maximum kinetic energy of the photoelectrons because we have increased the energy of each photon.

38.33. **IDENTIFY** and **SET UP:** The energy added to mass m of the blood to heat it to $T_f = 100°C$ and to vaporize it is $Q = mc(T_f - T_i) + mL_v$, with $c = 4190$ J/kg · K and $L_v = 2.256\times10^6$ J/kg. The energy of one photon is $E = \dfrac{hc}{\lambda} = \dfrac{1.99\times10^{-25}\ \text{J}\cdot\text{m}}{\lambda}$.

EXECUTE: **(a)** $Q = (2.0\times10^{-9}\ \text{kg})(4190\ \text{J/kg}\cdot\text{K})(100°\text{C} - 33°\text{C}) + (2.0\times10^{-9}\ \text{kg})(2.256\times10^6\ \text{J/kg}) = 5.07\times10^{-3}$ J. The pulse must deliver 5.07 mJ of energy.

(b) $P = \dfrac{\text{energy}}{t} = \dfrac{5.07\times10^{-3}\ \text{J}}{450\times10^{-6}\ \text{s}} = 11.3\ \text{W}$

(c) One photon has energy $E = \dfrac{hc}{\lambda} = \dfrac{1.99\times10^{-25}\ \text{J}\cdot\text{m}}{585\times10^{-9}\ \text{m}} = 3.40\times10^{-19}$ J. The number N of photons per pulse is the energy per pulse divided by the energy of one photon:

$$N = \frac{5.07\times10^{-3}\ \text{J}}{3.40\times10^{-19}\ \text{J/photon}} = 1.49\times10^{16}\ \text{photons.}$$

EVALUATE: The power output of the laser is small but it is focused on a small area, so the laser intensity is large.

38.34. **IDENTIFY:** The threshold wavelength λ_0 is related to the work function ϕ by $\dfrac{hc}{\lambda_0} = \phi$.

SET UP: For ϕ in eV, use $h = 4.136\times10^{-15}$ eV · s.

EXECUTE: **(a)** $\lambda_0 = \dfrac{hc}{\phi}$, and the wavelengths are: cesium: 590 nm, copper: 264 nm, potassium: 539 nm, zinc: 288 nm.

EVALUATE: **(b)** The wavelengths for copper and zinc are in the ultraviolet, and visible light is not energetic enough to overcome the threshold energy of these metals. Therefore, copper and zinc will not emit photoelectrons when irradiated with visible light.

38.35. **IDENTIFY** and **SET UP:** $\lambda' = \lambda + \dfrac{h}{mc}(1 - \cos\phi)$

$\phi = 180°$ so $\lambda' = \lambda + \dfrac{2h}{mc} = 0.09485$ nm. Use Eq. (38.5) to calculate the momentum of the scattered photon. Apply conservation of energy to the collision to calculate the kinetic energy of the electron after the scattering. The energy of the photon is given by Eq. (38.2).

EXECUTE: **(a)** $p' = h/\lambda' = 6.99\times10^{-24}$ kg · m/s.

(b) $E = E' + E_e$; $hc/\lambda = hc/\lambda' + E_e$

$$E_e = hc\left(\frac{1}{\lambda} - \frac{1}{\lambda'}\right) = (hc)\frac{\lambda' - \lambda}{\lambda\lambda'} = 1.129\times10^{-16}\ \text{J} = 705\ \text{eV}$$

EVALUATE: The energy of the incident photon is 13.8 keV, so only about 5% of its energy is transferred to the electron. This corresponds to a fractional shift in the photon's wavelength that is also 5%.

38.36. **IDENTIFY:** Compton scattering occurs. For backscattering, the scattering angle of the photon is 180°.

SET UP: Let $+x$ be in the direction of propagation of the incident photon.

$\lambda' - \lambda = \left(\dfrac{h}{mc}\right)(1 - \cos\phi)$, where $\phi = 180°$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: $\lambda' = \lambda + 2\dfrac{h}{mc} = 0.0900\times10^{-9}\ \text{m} + 4.852\times10^{-12}\ \text{m} = 0.09485\times10^{-9}\ \text{m}$. $\dfrac{h}{\lambda} = -\dfrac{h}{\lambda'} + p_\text{e}$. Solving for p_e gives $p_\text{e} = \dfrac{h}{\lambda} + \dfrac{h}{\lambda'} = h\left(\dfrac{\lambda+\lambda'}{\lambda\lambda'}\right) = (6.626\times10^{-34}\ \text{J}\cdot\text{s})\dfrac{9.000\times10^{-11}\ \text{m} + 9.485\times10^{-11}\ \text{m}}{(9.000\times10^{-11}\ \text{m})(9.485\times10^{-11}\ \text{m})}$.

$p_\text{e} = 1.43\times10^{-23}\ \text{kg}\cdot\text{m/s}$.

EVALUATE: The electron gains the most amount of momentum when backscattering occurs.

38.37. **IDENTIFY:** Compton scattering occurs, and we know the angle of scattering and the initial wavelength (and hence momentum) of the incident photon.

SET UP: $\lambda' - \lambda = \left(\dfrac{h}{mc}\right)(1-\cos\phi)$ and $p = h/\lambda$. Let $+x$ be the direction of propagation of the incident photon and let the scattered photon be moving at $30.0°$ clockwise from the $+y$ axis.

EXECUTE: $\lambda' - \lambda = \left(\dfrac{h}{mc}\right)(1-\cos\phi) = 0.1050\times10^{-9}\ \text{m} + (2.426\times10^{-12}\ \text{m})(1-\cos60.0°) = 0.1062\times10^{-9}\ \text{m}$.

$P_\text{ix} = P_\text{fx}$. $\dfrac{h}{\lambda} = \dfrac{h}{\lambda'}\cos60.0° + p_\text{ex}$.

$p_\text{ex} = \dfrac{h}{\lambda} - \dfrac{h}{2\lambda'} = h\dfrac{2\lambda'-\lambda}{(2\lambda')(\lambda)} = (6.626\times10^{-34}\ \text{J}\cdot\text{s})\dfrac{2.1243\times10^{-10}\ \text{m} - 1.050\times10^{-10}\ \text{m}}{(2.1243\times10^{-10}\ \text{m})(1.050\times10^{-10}\ \text{m})}$.

$p_\text{ex} = 3.191\times10^{-24}\ \text{kg}\cdot\text{m/s}$. $P_\text{iy} = P_\text{fy}$. $0 = \dfrac{h}{\lambda'}\sin60.0° + p_\text{ey}$.

$p_\text{ey} = -\dfrac{(6.626\times10^{-34}\ \text{J}\cdot\text{s})\sin60.0°}{0.1062\times10^{-9}\ \text{m}} = -5.403\times10^{-24}\ \text{kg}\cdot\text{m/s}$. $p_\text{e} = \sqrt{p_\text{ex}^2 + p_\text{ey}^2} = 6.28\times10^{-24}\ \text{kg}\cdot\text{m/s}$.

$\tan\theta = \dfrac{p_\text{ey}}{p_\text{ex}} = \dfrac{-5.403}{3.191}$ and $\theta = -59.4°$.

EVALUATE: The electron gets only part of the momentum of the incident photon.

38.38. **IDENTIFY** and **SET UP:** Electrical power is VI. $Q = mc\Delta T$.

EXECUTE: **(a)** $(0.010)VI = (0.010)(18.0\times10^3\ \text{V})(60.0\times10^{-3}\ \text{A}) = 10.8\ \text{W} = 10.8\ \text{J/s}$

(b) The energy in the electron beam that isn't converted to x rays stays in the target and appears as thermal energy. For $t = 1.00$ s, $Q = (0.990)VI(1.00\ \text{s}) = 1.07\times10^3\ \text{J}$ and

$\Delta T = \dfrac{Q}{mc} = \dfrac{1.07\times10^3\ \text{J}}{(0.250\ \text{kg})(130\ \text{J/kg}\cdot\text{K})} = 32.9\ \text{K}$. The temperature rises at a rate of 32.9 K/s.

EVALUATE: The target must be made of a material that has a high melting point.

38.39. **IDENTIFY** and **SET UP:** Find the average change in wavelength for one scattering and use that in $\Delta\lambda$ in Eq. (38.7) to calculate the average scattering angle ϕ.

EXECUTE: **(a)** The wavelength of a 1 MeV photon is

$\lambda = \dfrac{hc}{E} = \dfrac{(4.136\times10^{-15}\ \text{eV}\cdot\text{s})(2.998\times10^8\ \text{m/s})}{1\times10^6\ \text{eV}} = 1\times10^{-12}\ \text{m}$

The total change in wavelength therefore is $500\times10^{-9}\ \text{m} - 1\times10^{-12}\ \text{m} = 500\times10^{-9}\ \text{m}$.

If this shift is produced in 10^{26} Compton scattering events, the wavelength shift in each scattering event is

$\Delta\lambda = \dfrac{500\times10^{-9}\ \text{m}}{1\times10^{26}} = 5\times10^{-33}\ \text{m}$.

(b) Use this $\Delta\lambda$ in $\Delta\lambda = \dfrac{h}{mc}(1-\cos\phi)$ and solve for ϕ. We anticipate that ϕ will be very small, since $\Delta\lambda$ is much less than h/mc, so we can use $\cos\phi \approx 1 - \phi^2/2$.

$\Delta\lambda = \dfrac{h}{mc}(1-(1-\phi^2/2)) = \dfrac{h}{2mc}\phi^2$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$\phi = \sqrt{\frac{2\Delta\lambda}{(h/mc)}} = \sqrt{\frac{2(5\times10^{-33}\text{ m})}{2.426\times10^{-12}\text{ m}}} = 6.4\times10^{-11}\text{ rad} = (4\times10^{-9})^\circ$$

ϕ in radians is much less than 1 so the approximation we used is valid.

(c) IDENTIFY and SET UP: We know the total transit time and the total number of scatterings, so we can calculate the average time between scatterings.

EXECUTE: The total time to travel from the core to the surface is $(10^6\text{ y})(3.156\times10^7\text{ s/y}) = 3.2\times10^{13}\text{ s}$. There are 10^{26} scatterings during this time, so the average time between scatterings is

$$t = \frac{3.2\times10^{13}\text{ s}}{10^{26}} = 3.2\times10^{-13}\text{ s}.$$

The distance light travels in this time is $d = ct = (3.0\times10^8\text{ m/s})(3.2\times10^{-13}\text{ s}) = 0.1\text{ mm}$

EVALUATE: The photons are on the average scattered through a very small angle in each scattering event. The average distance a photon travels between scatterings is very small.

38.40. **IDENTIFY:** Apply Eq. (38.7) to each scattering.

SET UP: $\cos(\theta/2) = \sqrt{\frac{1+\cos\theta}{2}}$, so $\cos\theta = 2\cos^2(\theta/2) - 1$

EXECUTE: **(a)** $\Delta\lambda_1 = (h/mc)(1-\cos\theta_1)$, $\Delta\lambda_2 = (h/mc)(1-\cos\theta_2)$, and so the overall wavelength shift is $\Delta\lambda = (h/mc)(2-\cos\theta_1-\cos\theta_2)$.

(b) For a single scattering through angle θ, $\Delta\lambda_s = (h/mc)(1-\cos\theta)$. For two successive scatterings through an angle of $\theta/2$ for each scattering,

$$\Delta\lambda_t = 2(h/mc)(1-\cos\theta/2).$$

$$1-\cos\theta = 2(1-\cos^2(\theta/2)) \text{ and } \Delta\lambda_s = (h/mc)2(1-\cos^2(\theta/2))$$

$$\cos(\theta/2) \le 1 \text{ so } 1-\cos^2(\theta/2) \ge (1-\cos(\theta/2)) \text{ and } \Delta\lambda_s \ge \Delta\lambda_t$$

Equality holds only when $\theta = 180^\circ$.

(c) $(h/mc)2(1-\cos30.0^\circ) = 0.268(h/mc)$.

(d) $(h/mc)(1-\cos60^\circ) = 0.500(h/mc)$, which is indeed greater than the shift found in part (c).

EVALUATE: When θ is small, $1-\cos\theta \approx \theta$ and $1-\cos(\theta/2) \approx \theta/2$. In this limit $\Delta\lambda_s$ and $\Delta\lambda_t$ are approximately equal.

38.41. **(a) IDENTIFY and SET UP:** Conservation of energy applied to the collision gives $E_\lambda = E_{\lambda'} + E_e$, where E_e is the kinetic energy of the electron after the collision and E_λ and $E_{\lambda'}$ are the energies of the photon before and after the collision. The energy of a photon is related to its wavelength according to Eq. (38.2).

EXECUTE: $E_e = hc\left(\frac{1}{\lambda} - \frac{1}{\lambda'}\right) = hc\left(\frac{\lambda'-\lambda}{\lambda\lambda'}\right)$

$$E_e = (6.626\times10^{-34}\text{ J}\cdot\text{s})(2.998\times10^8\text{ m/s})\left(\frac{0.0032\times10^{-9}\text{ m}}{(0.1100\times10^{-9}\text{ m})(0.1132\times10^{-9}\text{ m})}\right)$$

$$E_e = 5.105\times10^{-17}\text{ J} = 319\text{ eV}$$

$$E_e = \frac{1}{2}mv^2 \text{ so } v = \sqrt{\frac{2E_e}{m}} = \sqrt{\frac{2(5.105\times10^{-17}\text{ J})}{9.109\times10^{-31}\text{ kg}}} = 1.06\times10^7\text{ m/s}$$

(b) The wavelength λ of a photon with energy E_e is given by $E_e = hc/\lambda$ so

$$\lambda = \frac{hc}{E_e} = \frac{(6.626\times10^{-34}\text{ J}\cdot\text{s})(2.998\times10^8\text{ m/s})}{5.105\times10^{-17}\text{ J}} = 3.89\text{ nm}$$

EVALUATE: Only a small portion of the incident photon's energy is transferred to the struck electron; this is why the wavelength calculated in part (b) is much larger than the wavelength of the incident photon in the Compton scattering.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

38.42. **IDENTIFY:** Eq. (38.7) relates λ and λ' to ϕ. Apply conservation of energy to obtain an expression that relates λ and v to λ'.

SET UP: The kinetic energy of the electron is $K = (\gamma - 1)mc^2$. The energy of a photon is $E = \dfrac{hc}{\lambda}$.

EXECUTE: **(a)** The final energy of the photon is $E' = \dfrac{hc}{\lambda'}$, and $E = E' + K$, where K is the kinetic energy of the electron after the collision. Then,

$$\lambda = \frac{hc}{E' + K} = \frac{hc}{(hc/\lambda') + K} = \frac{hc}{(hc/\lambda') + (\gamma - 1)mc^2} = \frac{\lambda'}{1 + \dfrac{\lambda' mc}{h}\left[\dfrac{1}{(1 - v^2/c^2)^{1/2}} - 1\right]}.$$ ($K = mc^2(\gamma - 1)$ since the relativistic expression must be used for three-figure accuracy).

(b) $\phi = \arccos[1 - \Delta\lambda/(h/mc)]$.

(c) $\gamma - 1 = \dfrac{1}{\left(1 - \left(\frac{1.80}{3.00}\right)^2\right)^{1/2}} - 1 = 1.25 - 1 = 0.250, \dfrac{h}{mc} = 2.43 \times 10^{-12}$ m

$$\Rightarrow \lambda = \frac{5.10 \times 10^{-3} \text{ mm}}{1 + \dfrac{(5.10 \times 10^{-12} \text{ m})(9.11 \times 10^{-31} \text{ kg})(3.00 \times 10^8 \text{ m/s})(0.250)}{(6.63 \times 10^{-34} \text{ J} \cdot \text{s})}} = 3.34 \times 10^{-3} \text{ nm}.$$

$$\phi = \arccos\left(1 - \frac{(5.10 \times 10^{-12} \text{ m} - 3.34 \times 10^{-12} \text{ m})}{2.43 \times 10^{-12} \text{ m}}\right) = 74.0°.$$

EVALUATE: For this final electron speed, $v/c = 0.600$ and $K = \frac{1}{2}mv^2$ is not accurate.

38.43. **IDENTIFY:** Apply the Compton scattering formula $\lambda' - \lambda = \Delta\lambda = \dfrac{h}{mc}(1 - \cos\phi) = \lambda_C(1 - \cos\phi)$

(a) SET UP: Largest $\Delta\lambda$ is for $\phi = 180°$.

EXECUTE: For $\phi = 180°$, $\Delta\lambda = 2\lambda_C = 2(2.426 \text{ pm}) = 4.85$ pm.

(b) SET UP: $\lambda' - \lambda = \lambda_C(1 - \cos\phi)$

Wavelength doubles implies $\lambda' = 2\lambda$ so $\lambda' - \lambda = \lambda$. Thus $\lambda = \lambda_C(1 - \cos\phi)$. λ is related to E by Eq. (38.2).

EXECUTE: $E = hc/\lambda$, so smallest energy photon means largest wavelength photon, so $\phi = 180°$ and $\lambda = 2\lambda_C = 4.85$ pm. Then

$$E = \frac{hc}{\lambda} = \frac{(6.626 \times 10^{-34} \text{ J} \cdot \text{s})(2.998 \times 10^8 \text{ m/s})}{4.85 \times 10^{-12} \text{ m}} = 4.096 \times 10^{-14} \text{ J}(1 \text{ eV}/1.602 \times 10^{-19} \text{ J}) = 0.256 \text{ MeV}.$$

EVALUATE: Any photon Compton scattered at $\phi = 180°$ has a wavelength increase of $2\lambda_C = 4.85$ pm. 4.85 pm is near the short-wavelength end of the range of x-ray wavelengths.

38.44. **IDENTIFY:** Follow the derivation of Eq. (38.7). Apply conservation of energy and conservation of momentum to the collision.

SET UP: Use the coordinate direction specified in the problem.

EXECUTE: Momentum: $\vec{p} + \vec{P} = \vec{p}' + \vec{P}' \Rightarrow p - P = -p' - P' \Rightarrow p' = P - (p + P')$

energy: $pc + E = p'c + E' = p'c + \sqrt{(P'c)^2 + (mc^2)^2}$

$\Rightarrow (pc - p'c + E)^2 = (P'c)^2 + (mc^2)^2 = (Pc)^2 + ((p + p')c)^2 - 2P(p + p')c^2 + (mc^2)^2.$

$(pc - p'c)^2 + E^2 = E^2 + (pc + p'c)^2 - 2(Pc^2)(p + p') + 2Ec(p - p') - 4pp'c^2 + 2Ec(p - p')$

$$+2(Pc^2)(p + p') = 0$$

$$\Rightarrow p'(Pc^2 - 2pc^2 - Ec) = p(-Ec - Pc^2)$$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$\Rightarrow p' = p\frac{Ec + Pc^2}{2pc^2 + Ec - Pc^2} = p\frac{E + Pc}{2pc + (E - Pc)}$$

$$\Rightarrow \lambda' = \lambda\left(\frac{2hc/\lambda + (E - Pc)}{E + Pc}\right) = \lambda\left(\frac{E - Pc}{E + Pc}\right) + \frac{2hc}{E + Pc}$$

$$\Rightarrow \lambda' = \frac{\lambda(E - Pc) + 2hc}{E + Pc}$$

If $E \gg mc^2$, $Pc = \sqrt{E^2 - (mc^2)^2} = E\sqrt{1 - \left(\frac{mc^2}{E}\right)^2} \approx E\left(1 - \frac{1}{2}\left(\frac{mc^2}{E}\right)^2 + \cdots\right)$

$$\Rightarrow E - Pc \approx \frac{1}{2}\frac{(mc^2)^2}{E} \Rightarrow \lambda_1 \approx \frac{\lambda(mc^2)^2}{2E(2E)} + \frac{hc}{E} = \frac{hc}{E}\left(1 + \frac{m^2c^4\lambda}{4hcE}\right)$$

(b) If $\lambda = 10.6\times10^{-6}$ m, $E = 1.00\times10^{10}$ eV $= 1.60\times10^{-9}$ J

$$\Rightarrow \lambda' \approx \frac{hc}{1.60\times10^{-9}\text{ J}}\left(1 + \frac{(9.11\times10^{-31}\text{ kg})^2c^4(10.6\times10^{-6}\text{ m})}{4hc\,(1.6\times10^{-9}\text{ J})}\right) = (1.24\times10^{-16}\text{ m})(1 + 56.0) = 7.08\times10^{-15}\text{ m}.$$

(c) These photons are gamma rays. We have taken infrared radiation and converted it into gamma rays! Perhaps useful in nuclear medicine, nuclear spectroscopy, or high energy physics: wherever controlled gamma ray sources might be useful.

EVALUATE: The photon has gained energy from the initial kinetic energy of the electron. Since the photon gains energy, its wavelength decreases.

39

PARTICLES BEHAVING AS WAVES

39.1. **IDENTIFY** and **SET UP:** $\lambda = \dfrac{h}{p} = \dfrac{h}{mv}$. For an electron, $m = 9.11\times10^{-31}$ kg. For a proton, $m = 1.67\times10^{-27}$ kg.

EXECUTE: **(a)** $\lambda = \dfrac{6.63\times10^{-34}\ \text{J}\cdot\text{s}}{(9.11\times10^{-31}\ \text{kg})(4.70\times10^{6}\ \text{m/s})} = 1.55\times10^{-10}\ \text{m} = 0.155\ \text{nm}$

(b) λ is proportional to $\dfrac{1}{m}$, so $\lambda_\text{p} = \lambda_\text{e}\left(\dfrac{m_\text{e}}{m_\text{p}}\right) = (1.55\times10^{-10}\ \text{m})\left(\dfrac{9.11\times10^{-31}\ \text{kg}}{1.67\times10^{-27}\ \text{kg}}\right) = 8.46\times10^{-14}\ \text{m}$.

EVALUATE: For the same speed the proton has a smaller de Broglie wavelength.

39.2. **IDENTIFY** and **SET UP:** For a photon, $E = \dfrac{hc}{\lambda}$. For an electron or proton, $p = \dfrac{h}{\lambda}$ and $E = \dfrac{p^2}{2m}$, so $E = \dfrac{h^2}{2m\lambda^2}$.

EXECUTE: **(a)** $E = \dfrac{hc}{\lambda} = \dfrac{(4.136\times10^{-15}\ \text{eV}\cdot\text{s})(3.00\times10^{8}\ \text{m/s})}{0.20\times10^{-9}\ \text{m}} = 6.2\ \text{keV}$

(b) $E = \dfrac{h^2}{2m\lambda^2} = \left(\dfrac{6.63\times10^{-34}\ \text{J}\cdot\text{s}}{0.20\times10^{-9}\ \text{m}}\right)^2 \dfrac{1}{2(9.11\times10^{-31}\ \text{kg})} = 6.03\times10^{-18}\ \text{J} = 38\ \text{eV}$

(c) $E_\text{p} = E_\text{e}\left(\dfrac{m_\text{e}}{m_\text{p}}\right) = (38\ \text{eV})\left(\dfrac{9.11\times10^{-31}\ \text{kg}}{1.67\times10^{-27}\ \text{kg}}\right) = 0.021\ \text{eV}$

EVALUATE: For a given wavelength a photon has much more energy than an electron, which in turn has more energy than a proton.

39.3. **IDENTIFY:** For a particle with mass, $\lambda = \dfrac{h}{p}$ and $K = \dfrac{p^2}{2m}$.

SET UP: $1\ \text{eV} = 1.60\times10^{-19}\ \text{J}$

EXECUTE: **(a)** $\lambda = \dfrac{h}{p} \Rightarrow p = \dfrac{h}{\lambda} = \dfrac{(6.63\times10^{-34}\ \text{J}\cdot\text{s})}{(2.80\times10^{-10}\ \text{m})} = 2.37\times10^{-24}\ \text{kg}\cdot\text{m/s}$.

(b) $K = \dfrac{p^2}{2m} = \dfrac{(2.37\times10^{-24}\ \text{kg}\cdot\text{m/s})^2}{2(9.11\times10^{-31}\ \text{kg})} = 3.08\times10^{-18}\ \text{J} = 19.3\ \text{eV}$.

EVALUATE: This wavelength is on the order of the size of an atom. This energy is on the order of the energy of an electron in an atom.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

39.4. **IDENTIFY:** For a particle with mass, $\lambda = \dfrac{h}{p}$ and $E = \dfrac{p^2}{2m}$.

SET UP: $1\text{ eV} = 1.60\times10^{-19}$ J

EXECUTE: $\lambda = \dfrac{h}{p} = \dfrac{h}{\sqrt{2mE}} = \dfrac{(6.63\times10^{-34}\text{ J}\cdot\text{s})}{\sqrt{2(6.64\times10^{-27}\text{ kg})\,(4.20\times10^{6}\text{ eV})\,(1.60\times10^{-19}\text{ J/eV})}} = 7.02\times10^{-15}$ m.

EVALUATE: This wavelength is on the order of the size of a nucleus.

39.5. **IDENTIFY** and **SET UP:** The de Broglie wavelength is $\lambda = \dfrac{h}{p} = \dfrac{h}{mv}$. In the Bohr model, $mvr_n = n(h/2\pi)$, so $mv = nh/(2\pi r_n)$. Combine these two expressions and obtain an equation for λ in terms of n. Then $\lambda = h\left(\dfrac{2\pi r_n}{nh}\right) = \dfrac{2\pi r_n}{n}$.

EXECUTE: **(a)** For $n = 1$, $\lambda = 2\pi r_1$ with $r_1 = a_0 = 0.529\times10^{-10}$ m, so

$\lambda = 2\pi(0.529\times10^{-10}\text{ m}) = 3.32\times10^{-10}$ m.

$\lambda = 2\pi r_1$; the de Broglie wavelength equals the circumference of the orbit.

(b) For $n = 4$, $\lambda = 2\pi r_4/4$.

$r_n = n^2 a_0$ so $r_4 = 16a_0$.

$\lambda = 2\pi(16a_0)/4 = 4(2\pi a_0) = 4(3.32\times10^{-10}\text{ m}) = 1.33\times10^{-9}$ m

$\lambda = 2\pi r_4/4$; the de Broglie wavelength is $\dfrac{1}{n} = \dfrac{1}{4}$ times the circumference of the orbit.

EVALUATE: As n increases the momentum of the electron increases and its de Broglie wavelength decreases. For any n, the circumference of the orbits equals an integer number of de Broglie wavelengths.

39.6. **IDENTIFY:** $\lambda = \dfrac{h}{p}$

SET UP: $1\text{ eV} = 1.60\times10^{-19}$ J. An electron has mass 9.11×10^{-31} kg.

EXECUTE: **(a)** For a nonrelativistic particle, $K = \dfrac{p^2}{2m}$, so $\lambda = \dfrac{h}{p} = \dfrac{h}{\sqrt{2Km}}$.

(b) $(6.63\times10^{-34}\text{ J}\cdot\text{s})/\sqrt{2(800\text{ eV})(1.60\times10^{-19}\text{ J/eV})(9.11\times10^{-31}\text{ kg})} = 4.34\times10^{-11}$ m.

EVALUATE: The de Broglie wavelength decreases when the kinetic energy of the particle increases.

39.7. **IDENTIFY:** A person walking through a door is like a particle going through a slit and hence should exhibit wave properties.

SET UP: The de Broglie wavelength of the person is $\lambda = h/mv$.

EXECUTE: **(a)** Assume $m = 75$ kg and $v = 1.0$ m/s.

$$\lambda = h/mv = (6.626\times10^{-34}\text{ J}\cdot\text{s})/[(75\text{ kg})(1.0\text{ m/s})] = 8.8\times10^{-36}\text{ m}$$

EVALUATE: **(b)** A typical doorway is about 1 m wide, so the person's de Broglie wavelength is much too small to show wave behavior through a "slit" that is about 10^{35} times as wide as the wavelength. Hence ordinary objects do not show wave behavior in everyday life.

39.8. **IDENTIFY** and **SET UP:** Combining Eqs. 37.38 and 37.39 gives $p = mc\sqrt{\gamma^2 - 1}$.

EXECUTE: **(a)** $\lambda = \dfrac{h}{p} = (h/mc)/\sqrt{\gamma^2 - 1} = 4.43\times10^{-12}$ m. (The incorrect nonrelativistic calculation gives 5.05×10^{-12} m.)

(b) $(h/mc)/\sqrt{\gamma^2 - 1} = 7.07\times10^{-13}$ m.

EVALUATE: The de Broglie wavelength decreases when the speed increases.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

39.9. **IDENTIFY** and **SET UP:** A photon has zero mass and its energy and wavelength are related by Eq. (38.2). An electron has mass. Its energy is related to its momentum by $E = p^2/2m$ and its wavelength is related to its momentum by Eq. (39.1).

EXECUTE: **(a)** photon: $E = \dfrac{hc}{\lambda}$ so $\lambda = \dfrac{hc}{E} = \dfrac{(6.626\times10^{-34}\ \text{J}\cdot\text{s})(2.998\times10^{8}\ \text{m/s})}{(20.0\ \text{eV})(1.602\times10^{-19}\ \text{J/eV})} = 62.0\ \text{nm}.$

electron: $E = p^2/(2m)$ so $p = \sqrt{2mE} =$

$\sqrt{2(9.109\times10^{-31}\ \text{kg})(20.0\ \text{eV})(1.602\times10^{-19}\ \text{J/eV})} = 2.416\times10^{-24}\ \text{kg}\cdot\text{m/s}.$ $\lambda = h/p = 0.274\ \text{nm}.$

(b) photon: $E = hc/\text{R} = 7.946\times10^{-19}\ \text{J} = 4.96\ \text{eV}.$

electron: $\lambda = h/p$ so $p = h/\lambda = 2.650\times10^{-27}\ \text{kg}\cdot\text{m/s}.$

$E = p^2/(2m) = 3.856\times10^{-24}\ \text{J} = 2.41\times10^{-5}\ \text{eV}.$

(c) EVALUATE: You should use a probe of wavelength approximately 250 nm. An electron with $\lambda = 250\ \text{nm}$ has much less energy than a photon with $\lambda = 250\ \text{nm},$ so is less likely to damage the molecule. Note that $\lambda = h/p$ applies to all particles, those with mass and those with zero mass.

$E = hf = hc/\lambda$ applies only to photons and $E = p^2/2m$ applies only to particles with mass.

39.10. **IDENTIFY:** Knowing the de Broglie wavelength for an electron, we want to find its speed.

SET UP: $\lambda = \dfrac{h}{p} = \dfrac{h}{mv} = 1.00\ \text{mm},$ $m = 9.11\times10^{-31}\ \text{kg}.$

EXECUTE: $v = \dfrac{h}{m\lambda} = \dfrac{6.63\times10^{-34}\ \text{J}\cdot\text{s}}{(9.11\times10^{-31}\ \text{kg})(1.00\times10^{-3}\ \text{m})} = 0.728\ \text{m/s}.$

EVALUATE: Electrons normally move much faster than this, so their de Broglie wavelengths are much much smaller than a millimeter.

39.11. **IDENTIFY** and **SET UP:** Use Eq. (39.1).

EXECUTE: $\lambda = \dfrac{h}{p} = \dfrac{h}{mv} = \dfrac{6.626\times10^{-34}\ \text{J}\cdot\text{s}}{(5.00\times10^{-3}\ \text{kg})(340\ \text{m/s})} = 3.90\times10^{-34}\ \text{m}$

EVALUATE: This wavelength is extremely short; the bullet will not exhibit wavelike properties.

39.12. **IDENTIFY:** The kinetic energy of the electron is equal to the energy of the photon. We want to find the wavelengths of each of them.

SET UP: Both for particles with mass (electrons) and for massless particles (photons) the wavelength is related to the momentum p by $\lambda = \dfrac{h}{p}.$ But for each type of particle there is a different expression that relates the energy E and momentum p. For an electron $E = \frac{1}{2}mv^2 = \dfrac{p^2}{2m}$ but for a photon $E = pc.$

EXECUTE: photon: $p = \dfrac{E}{c}$ and $p = \dfrac{h}{\lambda}$ so $\dfrac{h}{\lambda} = \dfrac{E}{c}$ and $\lambda = \dfrac{hc}{E} = \dfrac{1.24\times10^{-6}\ \text{eV}\cdot\text{m}}{25\ \text{eV}} = 49.6\ \text{nm}.$

electron: Solving for p gives $p = \sqrt{2mE}.$ This gives

$p = \sqrt{2(9.11\times10^{-31}\ \text{kg})(25\ \text{eV})(1.60\times10^{-19}\ \text{J/eV})} = 2.70\times10^{-24}\ \text{kg}\cdot\text{m/s}.$ The wavelength is therefore

$\lambda = \dfrac{h}{p} = \dfrac{6.63\times10^{-34}\ \text{J}\cdot\text{s}}{2.70\times10^{-24}\ \text{kg}\cdot\text{m/s}} = 0.245\ \text{nm}.$

EVALUATE: The wavelengths are quite different. For the electron $\lambda = \dfrac{h}{\sqrt{2mE}}$ and for the photon $\lambda = \dfrac{hc}{E},$ so for an electron λ is proportional to $E^{-1/2}$ and for a photon λ is proportional to E^{-1}. It is *incorrect* to say $p = \dfrac{E}{c}$ for a particle such as an electron that has mass; the correct relation is $p = \dfrac{\sqrt{E^2 - (mc^2)^2}}{c}.$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

39.13. **IDENTIFY:** The acceleration gives momentum to the electrons. We can use this momentum to calculate their de Broglie wavelength.

SET UP: The kinetic energy K of the electron is related to the accelerating voltage V by $K = eV$. For an electron $E = \frac{1}{2}mv^2 = \dfrac{p^2}{2m}$ and $\lambda = \dfrac{h}{p}$. For a photon $E = \dfrac{hc}{\lambda}$.

EXECUTE: **(a)** For an electron $p = \dfrac{h}{\lambda} = \dfrac{6.63\times10^{-34}\ \text{J}\cdot\text{s}}{5.00\times10^{-9}\ \text{m}} = 1.33\times10^{-25}\ \text{kg}\cdot\text{m/s}$ and

$E = \dfrac{p^2}{2m} = \dfrac{(1.33\times10^{-25}\ \text{kg}\cdot\text{m/s})^2}{2(9.11\times10^{-31}\ \text{kg})} = 9.71\times10^{-21}\ \text{J}$. $V = \dfrac{K}{e} = \dfrac{9.71\times10^{-21}\ \text{J}}{1.60\times10^{-19}\ \text{C}} = 0.0607\ \text{V}$. The electrons would have kinetic energy 0.0607 eV.

(b) $E = \dfrac{hc}{\lambda} = \dfrac{1.24\times10^{-6}\ \text{eV}\cdot\text{m}}{5.00\times10^{-9}\ \text{m}} = 248\ \text{eV}$.

(c) $E = 9.71\times10^{-21}\ \text{J}$

so $\lambda = \dfrac{hc}{E} = \dfrac{(6.63\times10^{-34}\ \text{J}\cdot\text{s})(3.00\times10^{8}\ \text{m/s})}{9.71\times10^{-21}\ \text{J}} = 20.5\ \mu\text{m}$.

EVALUATE: If they have the same wavelength, the photon has vastly more energy than the electron.

39.14. **IDENTIFY:** $\lambda = \dfrac{h}{p}$. Apply conservation of energy to relate the potential difference to the speed of the electrons.

SET UP: The mass of an electron is $m = 9.11\times10^{-31}$ kg. The kinetic energy of a photon is $E = \dfrac{hc}{\lambda}$.

EXECUTE: **(a)** $\lambda = h/mv \rightarrow v = h/m\lambda$. Energy conservation: $e\Delta V = \dfrac{1}{2}mv^2$.

$$\Delta V = \frac{mv^2}{2e} = \frac{m\left(\dfrac{h}{m\lambda}\right)^2}{2e} = \frac{h^2}{2em\lambda^2} = \frac{(6.626\times10^{-34}\ \text{J}\cdot\text{s})^2}{2(1.60\times10^{-19}\ \text{C})(9.11\times10^{-31}\ \text{kg})\,(0.15\times10^{-9}\ \text{m})^2} = 66.9\ \text{V}.$$

(b) $E_{\text{photon}} = hf = \dfrac{hc}{\lambda} = \dfrac{(6.626\times10^{-34}\ \text{J}\cdot\text{s})\,(3.0\times10^{8}\ \text{m/s})}{0.15\times10^{-9}\ \text{m}} = 1.33\times10^{-15}\ \text{J}$. $e\Delta V = K = E_{\text{photon}}$ and

$\Delta V = \dfrac{E_{\text{photon}}}{e} = \dfrac{1.33\times10^{-15}\ \text{J}}{1.6\times10^{-19}\ \text{C}} = 8310\ \text{V}$.

EVALUATE: The electron in part (b) has wavelength $\lambda = \dfrac{h}{p} = \dfrac{h}{\sqrt{2mE}} = 0.0135$ nm, much shorter than the wavelength of a photon of the same energy.

39.15. **IDENTIFY:** For an electron, $\lambda = \dfrac{h}{p}$ and $K = \frac{1}{2}mv^2$. For a photon, $E = \dfrac{hc}{\lambda}$. The wavelength should be 0.10 nm.

SET UP: For an electron, $m = 9.11\times10^{-31}$ kg.

EXECUTE: **(a)** $\lambda = 0.10$ nm. $p = mv = h/\lambda$ so $v = h/(m\lambda) = 7.3\times10^{6}$ m/s.

(b) $K = \dfrac{1}{2}mv^2 = 150\ \text{eV}$.

(c) $E = hc/\lambda = 12\ \text{keV}$.

EVALUATE: **(d)** The electron is a better probe because for the same λ it has less energy and is less damaging to the structure being probed.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

39.16. **IDENTIFY:** The electrons behave like waves and are diffracted by the slit.
SET UP: We use conservation of energy to find the speed of the electrons, and then use this speed to find their de Broglie wavelength, which is $\lambda = h/mv$. Finally we know that the first dark fringe for single-slit diffraction occurs when $a \sin\theta = \lambda$.

EXECUTE: **(a)** Use energy conservation to find the speed of the electron: $\frac{1}{2}mv^2 = eV$.

$$v = \sqrt{\frac{2eV}{m}} = \sqrt{\frac{2(1.60\times10^{-19}\text{ C})(100\text{ V})}{9.11\times10^{-31}\text{ kg}}} = 5.93\times10^{6}\text{ m/s}$$

which is about 2% the speed of light, so we can ignore relativity.
(b) First find the de Broglie wavelength:

$$\lambda = \frac{h}{mv} = \frac{6.626\times10^{-34}\text{ J}\cdot\text{s}}{(9.11\times10^{-31}\text{ kg})(5.93\times10^{6}\text{ m/s})} = 1.23\times10^{-10}\text{ m} = 0.123\text{ nm}$$

For the first single-slit dark fringe, we have $a \sin\theta = \lambda$, which gives

$$a = \frac{\lambda}{\sin\theta} = \frac{1.23\times10^{-10}\text{ m}}{\sin(11.5°)} = 6.16\times10^{-10}\text{ m} = 0.616\text{ nm}$$

EVALUATE: The slit width is around 5 times the de Broglie wavelength of the electron, and both are much smaller than the wavelength of visible light.

39.17. **IDENTIFY:** The intensity maxima are located by Eq. (39.4). Use $\lambda = \frac{h}{p}$ for the wavelength of the neutrons. For a particle, $p = \sqrt{2mE}$.

SET UP: For a neutron, $m = 1.67\times10^{-27}$ kg.

EXECUTE: For $m = 1$, $\lambda = d\sin\theta = \frac{h}{\sqrt{2mE}}$.

$$E = \frac{h^2}{2md^2\sin^2\theta} = \frac{(6.63\times10^{-34}\text{ J}\cdot\text{s})^2}{2(1.675\times10^{-27}\text{ kg})(9.10\times10^{-11}\text{ m})^2\sin^2(28.6°)} = 6.91\times10^{-20}\text{ J} = 0.432\text{ eV}.$$

EVALUATE: The neutrons have $\lambda = 0.0436$ nm, comparable to the atomic spacing.

39.18. **IDENTIFY:** Intensity maxima occur when $d\sin\theta = m\lambda$. $\lambda = \frac{h}{p} = \frac{h}{\sqrt{2ME}}$ so $d\sin\theta = \frac{mh}{\sqrt{2ME}}$.

SET UP: Here m is the order of the maxima, whereas M is the mass of the incoming particle.

EXECUTE: **(a)** $d = \frac{mh}{\sqrt{2ME}\sin\theta} = \frac{(2)(6.63\times10^{-34}\text{ J}\cdot\text{s})}{\sqrt{2(9.11\times10^{-31}\text{ kg})(188\text{ eV})(1.60\times10^{-19}\text{ J/eV})}\sin(60.6°)} =$

2.06×10^{-10} m $= 0.206$ nm.

(b) $m = 1$ also gives a maximum.

$\theta = \arcsin\left(\frac{(1)(6.63\times10^{-34}\text{ J}\cdot\text{s})}{\sqrt{2(9.11\times10^{-31}\text{ kg})(188\text{ eV})(1.60\times10^{-19}\text{ J/eV})}(2.06\times10^{-10}\text{ m})}\right) = 25.8°$. This is the only other one. If we let $m \geq 3$, then there are no more maxima.

(c) $E = \frac{m^2h^2}{2Md^2\sin^2\theta} = \frac{(1)^2(6.63\times10^{-34}\text{ J}\cdot\text{s})^2}{2(9.11\times10^{-31}\text{ kg})(2.60\times10^{-10}\text{ m})^2\sin^2(60.6°)}$.

$= 7.49\times10^{-18}\text{ J} = 46.8\text{ eV}$.

Using this energy, if we let $m = 2$, then $\sin\theta > 1$. Thus, there is no $m = 2$ maximum in this case.

EVALUATE: As the energy of the electrons is lowered their wavelength increases and a given intensity maximum occurs at a larger angle.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

39.19. **IDENTIFY:** The condition for a maximum is $d\sin\theta = m\lambda$. $\lambda = \dfrac{h}{p} = \dfrac{h}{Mv}$, so $\theta = \arcsin\left(\dfrac{mh}{dMv}\right)$.

SET UP: Here m is the order of the maximum, whereas M is the incoming particle mass.

EXECUTE: **(a)** $m = 1 \Rightarrow \theta_1 = \arcsin\left(\dfrac{h}{dMv}\right)$

$$= \arcsin\left(\frac{6.63\times10^{-34}\ \text{J}\cdot\text{s}}{(1.60\times10^{-6}\ \text{m})(9.11\times10^{-31}\ \text{kg})(1.26\times10^{4}\ \text{m/s})}\right) = 2.07°.$$

$$m = 2 \Rightarrow \theta_2 = \arcsin\left(\frac{(2)(6.63\times10^{-34}\ \text{J}\cdot\text{s})}{(1.60\times10^{-6}\ \text{m})(9.11\times10^{-31}\ \text{kg})(1.26\times10^{4}\ \text{m/s})}\right) = 4.14°.$$

(b) For small angles (in radians!) $y \cong D\theta$, so $y_1 \approx (50.0\ \text{cm})\,(2.07°)\left(\dfrac{\pi\ \text{radians}}{180°}\right) = 1.81\ \text{cm}$,

$y_2 \approx (50.0\ \text{cm})\,(4.14°)\left(\dfrac{\pi\ \text{radians}}{180°}\right) = 3.61\ \text{cm}$ and $y_2 - y_1 = 3.61\ \text{cm} - 1.81\ \text{cm} = 1.80\ \text{cm}$.

EVALUATE: For these electrons, $\lambda = \dfrac{h}{mv} = 0.0577\ \mu\text{m}$. λ is much less than d and the intensity maxima occur at small angles.

39.20. **IDENTIFY:** $\lambda = \dfrac{h}{p}$. Conservation of energy gives $eV = K = \dfrac{p^2}{2m}$, where V is the accelerating voltage.

SET UP: The electron mass is 9.11×10^{-31} kg and the proton mass is 1.67×10^{-27} kg.

EXECUTE: **(a)** $eV = K = \dfrac{p^2}{2m} = \dfrac{(h/\lambda)^2}{2m}$, so $V = \dfrac{(h/\lambda)^2}{2me} = 419\ \text{V}$.

(b) The voltage is reduced by the ratio of the particle masses, $(419\ \text{V})\dfrac{9.11\times10^{-31}\ \text{kg}}{1.67\times10^{-27}\ \text{kg}} = 0.229\ \text{V}$.

EVALUATE: $\lambda = \dfrac{h}{p} = \dfrac{h}{\sqrt{2mE}}$. For the same λ, particles of greater mass have smaller E, so a smaller accelerating voltage is needed for protons.

39.21. **IDENTIFY** and **SET UP:** For a photon $E_{\text{ph}} = \dfrac{hc}{\lambda} = \dfrac{1.99\times10^{-25}\ \text{J}\cdot\text{m}}{\lambda}$. For an electron

$$E_{\text{e}} = \frac{p^2}{2m} = \frac{1}{2m}\left(\frac{h}{\lambda}\right)^2 = \frac{h^2}{2m\lambda^2}.$$

EXECUTE: **(a)** photon $E_{\text{ph}} = \dfrac{1.99\times10^{-25}\ \text{J}\cdot\text{m}}{10.0\times10^{-9}\ \text{m}} = 1.99\times10^{-17}\ \text{J}$

electron $E_{\text{e}} = \dfrac{(6.63\times10^{-34}\ \text{J}\cdot\text{s})^2}{2(9.11\times10^{-31}\ \text{kg})(10.0\times10^{-9}\ \text{m})^2} = 2.41\times10^{-21}\ \text{J}$

$$\frac{E_{\text{ph}}}{E_{\text{e}}} = \frac{1.99\times10^{-17}\ \text{J}}{2.41\times10^{-21}\ \text{J}} = 8.26\times10^{3}$$

(b) The electron has much less energy so would be less damaging.

EVALUATE: For a particle with mass, such as an electron, $E \sim \lambda^{-2}$. For a massless photon $E \sim \lambda^{-1}$.

39.22. **IDENTIFY:** The kinetic energy of the alpha particle is all converted to electrical potential energy at closest approach. The force on the alpha particle is the electrical repulsion of the nucleus.

SET UP: The electrical potential energy of the system is $U = \dfrac{1}{4\pi\varepsilon_0}\dfrac{q_1 q_2}{r}$ and the kinetic energy is $K = \frac{1}{2}mv^2$. The electrical force is $R = 2.5$ m (at closest approach).

(a) Equating the initial kinetic energy and the final potential energy and solving for the separation radius r gives

$$r = \frac{1}{4\pi\varepsilon_0}\frac{(92e)(2e)}{K} = \frac{1}{4\pi\varepsilon_0}\frac{(184)(1.60\times10^{-19}\text{ C})^2}{(4.78\times10^{6}\text{ eV})(1.60\times10^{-19}\text{ J/eV})} = 5.54\times10^{-14}\text{ m}.$$

(b) The above result may be substituted into Coulomb's law. Alternatively, the relation between the magnitude of the force and the magnitude of the potential energy in a Coulomb field is $F = \dfrac{|U|}{r}$. $|U| = K$, so $F = \dfrac{K}{r} = \dfrac{(4.78\times10^{6}\text{ eV})(1.6\times10^{-19}\text{ J/ev})}{(5.54\times10^{-14}\text{ m})} = 13.8$ N.

EVALUATE: The result in part (a) is comparable to the radius of a large nucleus, so it is reasonable. The force in part (b) is around 3 pounds, which is large enough to be easily felt by a person.

39.23. **(a) IDENTIFY:** If the particles are treated as point charges, $U = \dfrac{1}{4\pi\epsilon_0}\dfrac{q_1 q_2}{r}$.

SET UP: $q_1 = 2e$ (alpha particle); $q_2 = 82e$ (gold nucleus); r is given so we can solve for U.

EXECUTE: $U = (8.987\times10^{9}\text{ N}\cdot\text{m}^2/\text{C}^2)\dfrac{(2)(82)(1.602\times10^{-19}\text{ C})^2}{6.50\times10^{-14}\text{ m}} = 5.82\times10^{-13}$ J

$U = 5.82\times10^{-13}$ J $(1\text{ eV}/1.602\times10^{-19}\text{ J}) = 3.63\times10^{6}$ eV $= 3.63$ MeV

(b) IDENTIFY: Apply conservation of energy: $K_1 + U_1 = K_2 + U_2$.

SET UP: Let point 1 be the initial position of the alpha particle and point 2 be where the alpha particle momentarily comes to rest. Alpha particle is initially far from the lead nucleus implies $r_1 \approx \infty$ and $U_1 = 0$. Alpha particle stops implies $K_2 = 0$.

EXECUTE: Conservation of energy thus says $K_1 = U_2 = 5.82\times10^{-13}$ J $= 3.63$ MeV.

(c) $K = \dfrac{1}{2}mv^2$ so $v = \sqrt{\dfrac{2K}{m}} = \sqrt{\dfrac{2(5.82\times10^{-13}\text{ J})}{6.64\times10^{-27}\text{ kg}}} = 1.32\times10^{7}$ m/s

EVALUATE: $v/c = 0.044$, so it is ok to use the nonrelativistic expression to relate K and v. When the alpha particle stops, all its initial kinetic energy has been converted to electrostatic potential energy.

39.24. **IDENTIFY:** The minimum energy the photon would need is the 3.84 eV bond strength.

SET UP: The photon energy $E = hf = \dfrac{hc}{\lambda}$ must equal the bond strength.

EXECUTE: $\dfrac{hc}{\lambda} = 3.80$ eV, so $\lambda = \dfrac{hc}{3.80\text{ eV}} = \dfrac{(4.136\times10^{-15}\text{ eV}\cdot\text{s})(3.00\times10^{8}\text{ m/s})}{3.80\text{ eV}} = 327$ nm.

EVALUATE: Any photon having a shorter wavelength would also spell doom for the Horta!

39.25. **IDENTIFY** and **SET UP:** Use the energy to calculate n for this state. Then use the Bohr equation, Eq. (39.6), to calculate L.

EXECUTE: $E_n = -(13.6\text{ eV})/n^2$, so this state has $n = \sqrt{13.6/1.51} = 3$. In the Bohr model, $L = n\hbar$ so for this state $L = 3\hbar = 3.16\times10^{-34}$ kg $\cdot$ m^2/s.

EVALUATE: We will find in Section 41.1 that the modern quantum mechanical description gives a different result.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

39.26. **IDENTIFY** and **SET UP:** For a hydrogen atom $E_n = -\dfrac{13.6\text{ eV}}{n^2}$. $\Delta E = \dfrac{hc}{\lambda}$, where ΔE is the magnitude of the energy change for the atom and λ is the wavelength of the photon that is absorbed or emitted.

EXECUTE: $\Delta E = E_4 - E_1 = -(13.6\text{ eV})\left(\dfrac{1}{4^2} - \dfrac{1}{1^2}\right) = +12.75\text{ eV}.$

$\lambda = \dfrac{hc}{\Delta E} = \dfrac{(4.136\times10^{-15}\text{ eV}\cdot\text{s})(3.00\times10^8\text{ m/s})}{12.75\text{ eV}} = 97.3\text{ nm}.$ $f = \dfrac{c}{\lambda} = 3.08\times10^{15}\text{ Hz}.$

EVALUATE: This photon is in the ultraviolet region of the electromagnetic spectrum.

39.27. **IDENTIFY:** The force between the electron and the nucleus in Be^{3+} is $F = \dfrac{1}{4\pi\epsilon_0}\dfrac{Ze^2}{r^2}$, where $Z = 4$ is the nuclear charge. All the equations for the hydrogen atom apply to Be^{3+} if we replace e^2 by Ze^2.

(a) SET UP: Modify Eq. (39.14).

EXECUTE: $E_n = -\dfrac{1}{\epsilon_0^2}\dfrac{me^4}{8n^2h^2}$ (hydrogen) becomes

$$E_n = -\frac{1}{\epsilon_0^2}\frac{m(Ze^2)^2}{8n^2h^2} = Z^2\left(-\frac{1}{\epsilon_0^2}\frac{me^4}{8n^2h^2}\right) = Z^2\left(-\frac{13.60\text{ eV}}{n^2}\right)(\text{for } Be^{3+})$$

The ground-level energy of Be^{3+} is $E_1 = 16\left(-\dfrac{13.60\text{ eV}}{1^2}\right) = -218\text{ eV}.$

EVALUATE: The ground-level energy of Be^{3+} is $Z^2 = 16$ times the ground-level energy of H.

(b) SET UP: The ionization energy is the energy difference between the $n\to\infty$ level energy and the $n = 1$ level energy.

EXECUTE: The $n\to\infty$ level energy is zero, so the ionization energy of Be^{3+} is 218 eV.

EVALUATE: This is 16 times the ionization energy of hydrogen.

(c) SET UP: $\dfrac{1}{\lambda} = R\left(\dfrac{1}{n_1^2} - \dfrac{1}{n_2^2}\right)$ just as for hydrogen but now R has a different value.

EXECUTE: $R_{\text{H}} = \dfrac{me^4}{8\epsilon_0^2h^3c} = 1.097\times10^7\text{ m}^{-1}$ for hydrogen becomes

$R_{\text{Be}} = Z^2\dfrac{me^4}{8\epsilon_0^2h^3c} = 16(1.097\times10^7\text{ m}^{-1}) = 1.755\times10^8\text{ m}^{-1}$ for Be^{3+}.

For $n = 2$ to $n = 1$, $\dfrac{1}{\lambda} = R_{\text{Be}}\left(\dfrac{1}{1^2} - \dfrac{1}{2^2}\right) = 3R_{\text{Be}}/4.$

$\lambda = 4/(3R_{\text{Be}}) = 4/(3(1.755\times10^8\text{ m}^{-1})) = 7.60\times10^{-9}\text{ m} = 7.60\text{ nm}.$

EVALUATE: This wavelength is smaller by a factor of 16 compared to the wavelength for the corresponding transition in the hydrogen atom.

(d) SET UP: Modify Eq. (39.8): $r_n = \epsilon_0\dfrac{n^2h^2}{\pi me^2}$ (hydrogen).

EXECUTE: $r_n = \epsilon_0\dfrac{n^2h^2}{\pi m(Ze^2)}$ (Be^{3+}).

EVALUATE: For a given n the orbit radius for Be^{3+} is smaller by a factor of $Z = 4$ compared to the corresponding radius for hydrogen.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

39.28. **IDENTIFY** and **SET UP:** $E_n = -\dfrac{13.6\text{ eV}}{n^2}$.

EXECUTE: **(a)** $E_n = -\dfrac{13.6\text{ eV}}{n^2}$ and $E_{n+1} = -\dfrac{13.6\text{ eV}}{(n+1)^2}$.

$\Delta E = E_{n+1} - E_n = (-13.6\text{ eV})\left[\dfrac{1}{(n+1)^2} - \dfrac{1}{n^2}\right] = -(13.6\text{ eV})\dfrac{n^2-(n+1)^2}{(n^2)(n+1)^2}$. $\Delta E = (13.6\text{ eV})\dfrac{2n+1}{(n^2)(n+1)^2}$.

As n becomes large, $\Delta E \to (13.6\text{ eV})\dfrac{2n}{n^4} = (13.6\text{ eV})\dfrac{2}{n^3}$. Thus ΔE becomes small as n becomes large.

(b) $r_n = n^2 r_1$ so the orbits get farther apart in space as n increases.

EVALUATE: There are an infinite number of bound levels for the hydrogen atom. As n increases the energies of the bound levels converge to the ionization threshold.

39.29. **IDENTIFY:** Apply Eqs. (39.8) and (39.9).

SET UP: The orbital period for state n is the circumference of the orbit divided by the orbital speed.

EXECUTE: **(a)** $v_n = \dfrac{1}{\varepsilon_0}\dfrac{e^2}{2nh}: n=1 \Rightarrow v_1 = \dfrac{(1.60\times10^{-19}\text{ C})^2}{\varepsilon_0 2\,(6.63\times10^{-34}\text{ J}\cdot\text{s})} = 2.18\times10^6\text{ m/s}$.

$n=2 \Rightarrow v_2 = \dfrac{v_1}{2} = 1.09\times10^6\text{ m/s}$. $n=3 \Rightarrow v_3 = \dfrac{v_1}{3} = 7.27\times10^5\text{ m/s}$.

(b) Orbital period $= \dfrac{2\pi r_n}{v_n} = \dfrac{2\varepsilon_0 n^2h^2/me^2}{1/\varepsilon_0\cdot e^2/2nh} = \dfrac{4\varepsilon_0^2 n^3h^3}{me^4}$.

$n=1 \Rightarrow T_1 = \dfrac{4\varepsilon_0^2(6.63\times10^{-34}\text{ J}\cdot\text{s})^3}{(9.11\times10^{-31}\text{ kg})(1.60\times10^{-19}\text{ C})^4} = 1.53\times10^{-16}\text{ s}$

$n=2: T_2 = T_1(2)^3 = 1.22\times10^{-15}\text{ s}$. $n=3: T_3 = T_1(3)^3 = 4.13\times10^{-15}\text{ s}$.

(c) number of orbits $= \dfrac{1.0\times10^{-8}\text{s}}{1.22\times10^{-15}\text{ s}} = 8.2\times10^6$.

EVALUATE: The orbital speed is proportional to $1/n$, the orbital radius is proportional to n^2, and the orbital period is proportional to n^3.

39.30. **IDENTIFY** and **SET UP:** The ionization threshold is at $E = 0$. The energy of an absorbed photon equals the energy gained by the atom and the energy of an emitted photon equals the energy lost by the atom.

EXECUTE: **(a)** $\Delta E = 0 - (-20\text{ eV}) = 20\text{ eV}$

(b) When the atom in the $n=1$ level absorbs an 18-eV photon, the final level of the atom is $n = 4$. The possible transitions from $n=4$ and corresponding photon energies are $n=4 \to n=3$, 3 eV; $n=4 \to n=2$, 8 eV; $n=4 \to n=1$, 18 eV. Once the atom has gone to the $n=3$ level, the following transitions can occur: $n=3 \to n=2$, 5 eV; $n=3 \to n=1$, 15 eV. Once the atom has gone to the $n=2$ level, the following transition can occur: $n=2 \to n=1$, 10 eV. The possible energies of emitted photons are: 3 eV, 5 eV, 8 eV, 10 eV, 15 eV and 18 eV.

(c) There is no energy level 8 eV higher in energy than the ground state, so the photon cannot be absorbed.

(d) The photon energies for $n=3 \to n=2$ and for $n=3 \to n=1$ are 5 eV and 15 eV. The photon energy for $n=4 \to n=3$ is 3 eV. The work function must have a value between 3 eV and 5 eV.

EVALUATE: The atom has discrete energy levels, so the energies of emitted or absorbed photons have only certain discrete energies.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

39.31. **IDENTIFY** and **SET UP:** The wavelength of the photon is related to the transition energy $E_i - E_f$ of the atom by $E_i - E_f = \dfrac{hc}{\lambda}$ where $hc = 1.240 \times 10^{-6}$ eV · m.

EXECUTE: **(a)** The minimum energy to ionize an atom is when the upper state in the transition has $E = 0$, so $E_1 = -17.50$ eV. For $n = 5 \to n = 1$, $\lambda = 73.86$ nm and $E_5 - E_1 = \dfrac{1.240 \times 10^{-6} \text{ eV} \cdot \text{m}}{73.86 \times 10^{-9} \text{ m}} = 16.79$ eV.

$E_5 = -17.50 \text{ eV} + 16.79 \text{ eV} = -0.71$ eV. For $n = 4 \to n = 1$, $\lambda = 75.63$ nm and $E_4 = -1.10$ eV. For $n = 3 \to n = 1$, $\lambda = 79.76$ nm and $E_3 = -1.95$ eV. For $n = 2 \to n = 1$, $\lambda = 94.54$ nm and $E_2 = -4.38$ eV.

(b) $E_i - E_f = E_4 - E_2 = -1.10 \text{ eV} - (-4.38 \text{ eV}) = 3.28$ eV and $\lambda = \dfrac{hc}{E_i - E_f} = \dfrac{1.240 \times 10^{-6} \text{ eV} \cdot \text{m}}{3.28 \text{ eV}} = 378$ nm

EVALUATE: The $n = 4 \to n = 2$ transition energy is smaller than the $n = 4 \to n = 1$ transition energy so the wavelength is longer. In fact, this wavelength is longer than for any transition that ends in the $n = 1$ state.

39.32. **IDENTIFY** and **SET UP:** For the Lyman series the final state is $n = 1$ and the wavelengths are given by $\dfrac{1}{\lambda} = R\left(\dfrac{1}{1^2} - \dfrac{1}{n^2}\right)$, $n = 2, 3, \ldots$. For the Paschen series the final state is $n = 3$ and the wavelengths are given by $\dfrac{1}{\lambda} = R\left(\dfrac{1}{3^2} - \dfrac{1}{n^2}\right)$, $n = 4, 5, \ldots$. $R = 1.097 \times 10^7 \text{ m}^{-1}$. The longest wavelength is for the smallest n and the shortest wavelength is for $n \to \infty$.

EXECUTE: Lyman: Longest: $\dfrac{1}{\lambda} = R\left(\dfrac{1}{1^2} - \dfrac{1}{2^2}\right) = \dfrac{3R}{4}$. $\lambda = \dfrac{4}{3(1.097 \times 10^7 \text{ m}^{-1})} = 121.5$ nm.

Shortest: $\dfrac{1}{\lambda} = R\left(\dfrac{1}{1^2} - \dfrac{1}{\infty^2}\right) = R$. $\lambda = \dfrac{1}{1.097 \times 10^7 \text{ m}^{-1}} = 91.16$ nm

Paschen: Longest: $\dfrac{1}{\lambda} = R\left(\dfrac{1}{3^2} - \dfrac{1}{4^2}\right) = \dfrac{7R}{144}$. $\lambda = \dfrac{144}{7(1.097 \times 10^7 \text{ m}^{-1})} = 1875$ nm.

Shortest: $\dfrac{1}{\lambda} = R\left(\dfrac{1}{3^2} - \dfrac{1}{\infty^2}\right) = \dfrac{R}{9}$.

EVALUATE: The Lyman series is in the ultraviolet. The Paschen series is in the infrared.

39.33. **IDENTIFY:** Apply conservation of energy to the system of atom and photon.

SET UP: The energy of a photon is $E_\gamma = \dfrac{hc}{\lambda}$.

EXECUTE: **(a)** $E_\gamma = \dfrac{hc}{\lambda} = \dfrac{(6.63 \times 10^{-34} \text{ J} \cdot \text{s})(3.00 \times 10^8 \text{ m/s})}{8.60 \times 10^{-7} \text{ m}} = 2.31 \times 10^{-19}$ J $= 1.44$ eV. So the internal energy of the atom increases by 1.44 eV to $E = -6.52 \text{ eV} + 1.44 \text{ eV} = -5.08$ eV.

(b) $E_\gamma = \dfrac{hc}{\lambda} = \dfrac{(6.63 \times 10^{-34} \text{ J} \cdot \text{s})(3.00 \times 10^8 \text{ m/s})}{4.20 \times 10^{-7} \text{ m}} = 4.74 \times 10^{-19}$ J $= 2.96$ eV. So the final internal energy of the atom decreases to $E = -2.68 \text{ eV} - 2.96 \text{ eV} = -5.64$ eV.

EVALUATE: When an atom absorbs a photon the energy of the atom increases. When an atom emits a photon the energy of the atom decreases.

39.34. **IDENTIFY** and **SET UP:** Balmer's formula is $\dfrac{1}{\lambda} = R\left(\dfrac{1}{2^2} - \dfrac{1}{n^2}\right)$. For the H_γ spectral line $n = 5$. Once we have λ, calculate f from $f = c/\lambda$ and E from Eq. (38.2).

EXECUTE: **(a)** $\dfrac{1}{\lambda} = R\left(\dfrac{1}{2^2} - \dfrac{1}{5^2}\right) = R\left(\dfrac{25 - 4}{100}\right) = R\left(\dfrac{21}{100}\right)$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

Thus $\lambda = \dfrac{100}{21R} = \dfrac{100}{21(1.097\times10^{7})}\ \text{m} = 4.341\times10^{-7}\ \text{m} = 434.1\ \text{nm}.$

(b) $f = \dfrac{c}{\lambda} = \dfrac{2.998\times10^{8}\ \text{m/s}}{4.341\times10^{-7}\ \text{m}} = 6.906\times10^{14}\ \text{Hz}$

(c) $E = hf = (6.626\times10^{-34}\ \text{J}\cdot\text{s})(6.906\times10^{14}\ \text{Hz}) = 4.576\times10^{-19}\ \text{J} = 2.856\ \text{eV}$

EVALUATE: Section 39.3 shows that the longest wavelength in the Balmer series (H_α) is 656 nm and the shortest is 365 nm. Our result for H_γ falls within this range. The photon energies for hydrogen atom transitions are in the eV range, and our result is of this order.

39.35. **IDENTIFY:** We know the power of the laser beam, so we know the energy per second that it delivers. The wavelength of the light tells us the energy of each photon, so we can use that to calculate the number of photons delivered per second.

SET UP: The energy of each photon is $E = hf = \dfrac{hc}{\lambda} = \dfrac{1.99\times10^{-25}\ \text{J}\cdot\text{m}}{\lambda}$. The power is the total energy per second and the total energy E_{tot} is the number of photons N times the energy E of each photon.

EXECUTE: $\lambda = 10.6\times10^{-6}$ m, so $E = 1.88\times10^{-20}$ J. $P = \dfrac{E_{\text{tot}}}{t} = \dfrac{NE}{t}$ so

$$\frac{N}{t} = \frac{P}{E} = \frac{0.100\times10^{3}\ \text{W}}{1.88\times10^{-20}\ \text{J}} = 5.32\times10^{21}\ \text{photons/s}.$$

EVALUATE: At over 10^{21} photons per second, we can see why we do not detect individual photons.

39.36. **IDENTIFY:** We can calculate the energy of a photon from its wavelength. Knowing the intensity of the beam and the energy of a single photon, we can determine how many photons strike the blemish with each pulse.

SET UP: The energy of each photon is $E = hf = \dfrac{hc}{\lambda} = \dfrac{1.99\times10^{-25}\ \text{J}\cdot\text{m}}{\lambda}$. The power is the total energy per second and the total energy E_{tot} is the number of photons N times the energy E of each photon. The photon beam is spread over an area $A = \pi r^2$ with $r = 2.5$ mm.

EXECUTE: **(a)** $\lambda = 585\ \text{nm}$ and $E = \dfrac{hc}{\lambda} = 3.40\times10^{-19}\ \text{J} = 2.12\ \text{eV}.$

(b) $P = \dfrac{E_{\text{tot}}}{t} = \dfrac{NE}{t}$ so $N = \dfrac{Pt}{E} = \dfrac{(20.0\ \text{W})(0.45\times10^{-3}\ \text{s})}{3.40\times10^{-19}\ \text{J}} = 2.65\times10^{16}$ photons. These photons are spread over an area πr^2, so the number of photons per mm^2 is $\dfrac{2.65\times10^{16}\ \text{photons}}{\pi(2.5\ \text{mm})^2} = 1.35\times10^{15}\ \text{photons/mm}^2.$

EVALUATE: With so many photons per mm^2, it is impossible to detect individual photons.

39.37. **IDENTIFY** and **SET UP:** The number of photons emitted each second is the total energy emitted divided by the energy of one photon. The energy of one photon is given by Eq. (38.2). $E = Pt$ gives the energy emitted by the laser in time t.

EXECUTE: In 1.00 s the energy emitted by the laser is $(7.50\times10^{-3}\ \text{W})(1.00\ \text{s}) = 7.50\times10^{-3}\ \text{J}.$

The energy of each photon is $E = \dfrac{hc}{\lambda} = \dfrac{(6.626\times10^{-34}\ \text{J}\cdot\text{s})(2.998\times10^{8}\ \text{m/s})}{10.6\times10^{-6}\ \text{m}} = 1.874\times10^{-20}\ \text{J}.$

Therefore $\dfrac{7.50\times10^{-3}\ \text{J/s}}{1.874\times10^{-20}\ \text{J/photon}} = 4.00\times10^{17}\ \text{photons/s}$

EVALUATE: The number of photons emitted per second is extremely large.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

39.38. **IDENTIFY** and **SET UP:** Visible light has wavelengths from about 400 nm to about 700 nm. The energy of each photon is $E = hf = \dfrac{hc}{\lambda} = \dfrac{1.99\times10^{-25}\ \text{J}\cdot\text{m}}{\lambda}$. The power is the total energy per second and the total energy E_{tot} is the number of photons N times the energy E of each photon.

EXECUTE: **(a)** 193 nm is shorter than visible light so is in the ultraviolet.

(b) $E = \dfrac{hc}{\lambda} = 1.03\times10^{18}\ \text{J} = 6.44\ \text{eV}$

(c) $P = \dfrac{E_{\text{tot}}}{t} = \dfrac{NE}{t}$ so $N = \dfrac{Pt}{E} = \dfrac{(1.50\times10^{-3}\ \text{W})(12.0\times10^{-9}\ \text{s})}{1.03\times10^{-18}\ \text{J}} = 1.75\times10^{7}$ photons

EVALUATE: A very small amount of energy is delivered to the lens in each pulse, but this still corresponds to a large number of photons.

39.39. **IDENTIFY:** Apply Eq. (39.18): $\dfrac{n_{5s}}{n_{3p}} = e^{-(E_{5s}-E_{3p})/kT}$

SET UP: $E_{5s} = 20.66\ \text{eV}$ and $E_{3p} = 18.70\ \text{eV}$

EXECUTE: $E_{5s} - E_{3p} = 20.66\ \text{eV} - 18.70\ \text{eV} = 1.96\ \text{eV}(1.602\times10^{-19}\ \text{J/1 eV}) = 3.140\times10^{-19}\ \text{J}$

(a) $\dfrac{n_{5s}}{n_{3p}} = e^{-(3.140\times10^{-19}\ \text{J})/[(1.38\times10^{-23}\ \text{J/K})(300\ \text{K})]} = e^{-75.79} = 1.2\times10^{-33}$

(b) $\dfrac{n_{5s}}{n_{3p}} = e^{-(3.140\times10^{-19}\ \text{J})/[(1.38\times10^{-23}\ \text{J/K})(600\ \text{K})]} = e^{-37.90} = 3.5\times10^{-17}$

(c) $\dfrac{n_{5s}}{n_{3p}} = e^{-(3.140\times10^{-19}\ \text{J})/[(1.38\times10^{-23}\ \text{J/K})(1200\ \text{K})]} = e^{-18.95} = 5.9\times10^{-9}$

(d) EVALUATE: At each of these temperatures the number of atoms in the 5*s* excited state, the initial state for the transition that emits 632.8 nm radiation, is quite small. The ratio increases as the temperature increases.

39.40. **IDENTIFY:** Apply Eq. (39.18).

SET UP: The energy of each of these excited states above the ground state is hc/λ, where λ is the wavelength of the photon emitted in the transition from the excited state to the ground state.

EXECUTE: $\dfrac{n_{2P_{3/2}}}{n_{2P_{1/2}}} = e^{-(E_{2P3/2} - E_{2P1/2})/KT}$. From the diagram

$\Delta E_{3/2-\text{g}} = \dfrac{hc}{\lambda_1} = \dfrac{(6.626\times10^{-34}\ \text{J})(2.998\times10^{8}\ \text{m/s})}{5.890\times10^{-7}\ \text{m}} = 3.373\times10^{-19}\ \text{J}.$

$\Delta E_{1/2-\text{g}} = \dfrac{hc}{\lambda_2} = \dfrac{(6.626\times10^{-34}\ \text{J})(2.998\times10^{8}\ \text{m/s})}{5.896\times10^{-7}\ \text{m}} = 3.369\times10^{-19}\ \text{J}$. So $\Delta E_{3/2\,-1/2} =$

$3.373\times10^{-19}\ \text{J} - 3.369\times10^{-19}\ \text{J} = 4.00\times10^{-22}\ \text{J}.$

$\dfrac{n_{2P_{3/2}}}{n_{2P_{1/2}}} = e^{-(4.00\times10^{-22}\ \text{J})/(1.38\times10^{-23}\text{J/K}\cdot 500\ \text{K})} = 0.944.$ So more atoms are in the $2P_{1/2}$ state.

EVALUATE: At this temperature $kT = 6.9\times10^{-21}\ \text{J}$. This is greater than the energy separation between the states, so an atom has almost equal probability for being in either state, with only a small preference for the lower energy state.

39.41. **IDENTIFY:** Energy radiates at the rate $H = Ae\sigma T^4$.

SET UP: The surface area of a cylinder of radius r and length l is $A = 2\pi rl$.

EXECUTE: **(a)** $T = \left(\dfrac{H}{Ae\sigma}\right)^{1/4} = \left(\dfrac{100\ \text{W}}{2\pi(0.20\times10^{-3}\ \text{m})(0.30\ \text{m})(0.26)(5.671\times10^{-8}\ \text{W/m}^2\cdot\text{K}^4)}\right)^{1/4}.$

$T = 2.06\times10^{3}\ \text{K}.$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) $\lambda_m T = 2.90\times10^{-3}\ \text{m}\cdot\text{K};\ \lambda_m = 1410\ \text{nm}$.

EVALUATE: **(c)** λ_m is in the infrared. The incandescent bulb is not a very efficient source of visible light because much of the emitted radiation is in the infrared.

39.42. **IDENTIFY:** Apply Eq. (39.21) and $c = f\lambda$.

SET UP: T in kelvins gives λ in meters.

EXECUTE: **(a)** $\lambda_m = \dfrac{2.90\times10^{-3}\ \text{m}\cdot\text{K}}{3.00\ \text{K}} = 0.966\ \text{mm}$, and $f = \dfrac{c}{\lambda_m} = 3.10\times10^{11}\ \text{Hz}$.

(b) A factor of 100 increase in the temperature lowers λ_m by a factor of 100 to 9.66 μm and raises the frequency by the same factor, to 3.10×10^{13} Hz.

(c) Similarly, $\lambda_m = 966\ \text{nm}$ and $f = 3.10\times10^{14}$ Hz.

EVALUATE: λ_m decreases when T increases, as explained in the textbook.

39.43. **IDENTIFY** and **SET UP:** The wavelength λ_m where the Planck distribution peaks is given by Eq. (39.21).

EXECUTE: $\lambda_m = \dfrac{2.90\times10^{-3}\ \text{m}\cdot\text{K}}{2.728\ \text{K}} = 1.06\times10^{-3}\ \text{m} = 1.06\ \text{mm}$.

EVALUATE: This wavelength is in the microwave portion of the electromagnetic spectrum. This radiation is often referred to as the "microwave background" (Section 44.7). Note that in Eq. (39.21), T must be in kelvins.

39.44. **IDENTIFY** and **SET UP:** Apply Eq. (39.21).

EXECUTE: $T = \dfrac{2.90\times10^{-3}\ \text{m}\cdot\text{K}}{\lambda_m} = \dfrac{2.90\times10^{-3}\ \text{m}\cdot\text{K}}{400\times10^{-9}\ \text{m}} = 7.25\times10^{3}\ \text{K}$.

EVALUATE: 400 nm = 0.4 μm. This is shorter than any of the λ_m values shown in Figure 39.32 in the textbook, and the temperature is therefore higher than those in the figure.

39.45. **IDENTIFY:** Since the stars radiate as blackbodies, they obey the Stefan-Boltzmann law and Wien's displacement law.

SET UP: The Stefan-Boltzmann law says that the intensity of the radiation is $I = \sigma T^4$, so the total radiated power is $P = \sigma A T^4$. Wien's displacement law tells us that the peak-intensity wavelength is $\lambda_m = (\text{constant})/T$.

EXECUTE: **(a)** The hot and cool stars radiate the same total power, so the Stefan-Boltzmann law gives $\sigma A_h T_h^4 = \sigma A_c T_c^4 \Rightarrow 4\pi R_h^2 T_h^4 = 4\pi R_c^2 T_c^4 = 4\pi(3R_h)^2 T_c^4 \Rightarrow T_h^4 = 9T^4 \Rightarrow T_h = T\sqrt{3} = 1.7T$, rounded to two significant digits.

(b) Using Wien's law, we take the ratio of the wavelengths, giving

$$\frac{\lambda_m(\text{hot})}{\lambda_m(\text{cool})} = \frac{T_c}{T_h} = \frac{T}{T\sqrt{3}} = \frac{1}{\sqrt{3}} = 0.58,\ \text{rounded to two significant digits.}$$

EVALUATE: Although the hot star has only 1/9 the surface area of the cool star, its absolute temperature has to be only 1.7 times as great to radiate the same amount of energy.

39.46. **IDENTIFY:** Since the stars radiate as blackbodies, they obey the Stefan-Boltzmann law.

SET UP: The Stefan-Boltzmann law says that the intensity of the radiation is $I = \sigma T^4$, so the total radiated power is $P = \sigma A T^4$.

EXECUTE: **(a)** $I = \sigma T^4 = (5.67\times10^{-8}\ \text{W/m}^2\cdot\text{K}^4)(24{,}000\ \text{K})^4 = 1.9\times10^{10}\ \text{W/m}^2$

(b) Wien's law gives $\lambda_m = (0.00290\ \text{m}\cdot\text{K})/(24{,}000\ \text{K}) = 1.2\times10^{-7}\ \text{m} = 20\ \text{nm}$

This is not visible since the wavelength is less than 400 nm.

(c) $P = AI \Rightarrow 4\pi R^2 = P/I = (1.00\times10^{25}\ \text{W})/(1.9\times10^{10}\ \text{W/m}^2)$

which gives $R_{\text{Sirius}} = 6.51\times10^{6}\ \text{m} = 6510\ \text{km}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$R_{\text{Sirius}}/R_{\text{sun}} = (6.51\times10^6\ \text{m})/(6.96\times10^9\ \text{m}) = 0.0093$, which gives

$$R_{\text{Sirius}} = 0.0093\ R_{\text{sun}} \approx 1\%\ R_{\text{sun}}$$

(d) Using the Stefan-Boltzmann law, we have

$$\frac{P_{\text{sun}}}{P_{\text{Sirius}}} = \frac{\sigma A_{\text{sun}} T_{\text{sun}}^4}{\sigma A_{\text{Sirius}} T_{\text{Sirius}}^4} = \frac{4\pi R_{\text{sun}}^2 T_{\text{sun}}^4}{4\pi R_{\text{Sirius}}^2 T_{\text{Sirius}}^4} = \left(\frac{R_{\text{sun}}}{R_{\text{Sirius}}}\right)^2 \left(\frac{T_{\text{sun}}}{T_{\text{Sirius}}}\right)^4 \cdot \frac{P_{\text{sun}}}{P_{\text{Sirius}}} = \left(\frac{R_{\text{sun}}}{0.00935 R_{\text{sun}}}\right)^2 \left(\frac{5800\ \text{K}}{24{,}000\ \text{K}}\right)^4 = 39$$

EVALUATE: Even though the absolute surface temperature of Sirius B is about 4 times that of our sun, it radiates only 1/39 times as much energy per second as our sun because it is so small.

39.47. **IDENTIFY:** Apply the Wien displacement law to relate λ_{m} and T. Apply the Stefan-Boltzmann law to relate the power output of the star to its surface area and therefore to its radius.

SET UP: For a sphere $A = 4\pi r^2$. Since we assume a blackbody, $e = 1$.

EXECUTE: **(a)** Wien's law: $\lambda_{\text{m}} = \dfrac{k}{T}$. $\lambda_{\text{m}} = \dfrac{2.90\times10^{-3}\ \text{K}\cdot\text{m}}{30{,}000\ \text{K}} = 9.7\times10^{-8}\ \text{m} = 97\ \text{nm}$. This peak is in the ultraviolet region, which is *not* visible. The star is blue because the largest part of the visible light radiated is in the blue/violet part of the visible spectrum.

(b) $P = \sigma A T^4$ (Stefan-Boltzmann law)

$$(100{,}000)(3.86\times10^{26}\ \text{W}) = \left(5.67\times10^{-8}\frac{\text{W}}{\text{m}^2\text{K}^4}\right)(4\pi R^2)(30{,}000\ \text{K})^4$$

$$R = 8.2\times10^9\ \text{m}$$

$$R_{\text{star}}/R_{\text{sun}} = \frac{8.2\times10^9\ \text{m}}{6.96\times10^8\ \text{m}} = 12$$

EVALUATE: **(c)** The visual luminosity is proportional to the power radiated at visible wavelengths. Much of the power is radiated nonvisible wavelengths, which does not contribute to the visible luminosity.

39.48. **IDENTIFY:** Since we know only that the mosquito is somewhere in the room, there is an uncertainty in its position. The Heisenberg uncertainty principle tells us that there is an uncertainty in its momentum.

SET UP: The uncertainty principle is $\Delta x \Delta p_x \geq \hbar/2$.

EXECUTE: **(a)** You know the mosquito is somewhere in the room, so the maximum uncertainty in its horizontal position is $\Delta x = 5.0$ m.

(b) The uncertainty principle gives $\Delta x \Delta p_x \geq \hbar/2$, and $\Delta p_x = m\Delta v_x$ since we know the mosquito's mass. This gives $\Delta x\, m \Delta v_x \geq \hbar/2$, which we can solve for Δv_x to get the minimum uncertainty in v_x.

$$\Delta v_x = \frac{\hbar}{2m\Delta x} = \frac{1.055\times10^{-34}\ \text{J}\cdot\text{s}}{2(1.5\times10^{-6}\ \text{kg})(5.0\ \text{m})} = 7.0\times10^{-30}\ \text{m/s},$$ which is hardly a serious impediment!

EVALUATE: For something as "large" as a mosquito, the uncertainty principle places a negligible limitation on our ability to measure its speed.

39.49. **(a) IDENTIFY** and **SET UP:** Use $\Delta x \Delta p_x \geq \hbar/2$ to calculate Δp_x and obtain Δv_x from this.

EXECUTE: $\Delta p_x \geq \dfrac{\hbar}{2\Delta x} = \dfrac{1.055\times10^{-34}\ \text{J}\cdot\text{s}}{2(1.00\times10^{-6}\ \text{m})} = 5.725\times10^{-29}\ \text{kg}\cdot\text{m/s}.$

$$\Delta v_x = \frac{\Delta p_x}{m} = \frac{5.275\times10^{-29}\ \text{kg}\cdot\text{m/s}}{1200\ \text{kg}} = 4.40\times10^{-32}\ \text{m/s}.$$

(b) EVALUATE: Even for this very small Δx the minimum Δv_x required by the Heisenberg uncertainty principle is very small. The uncertainty principle does not impose any practical limit on the simultaneous measurements of the positions and velocities of ordinary objects.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

39.50. **IDENTIFY:** Since we know that the marble is somewhere on the table, there is an uncertainty in its position. The Heisenberg uncertainty principle tells us that there is therefore an uncertainty in its momentum.

SET UP: The uncertainty principle is $\Delta x \Delta p_x \geq \hbar/2$.

EXECUTE: **(a)** Since the marble is somewhere on the table, the maximum uncertainty in its horizontal position is $\Delta x = 1.75$ m.

(b) Following the same procedure as in part (b) of Problem 39.48, the minimum uncertainty in the horizontal velocity of the marble is $\Delta v_x = \dfrac{\hbar}{2m\Delta x} = \dfrac{1.055\times10^{-34}\ \text{J}\cdot\text{s}}{2(0.0100\ \text{kg})(1.75\ \text{m})} = 3.01\times10^{-33}$ m/s.

(c) The uncertainty principle tells us that we cannot know that the marble's horizontal velocity is *exactly* zero, so the smallest we could measure it to be is 3.01×10^{-33} m/s, from part (b). The longest time it could remain on the table is the time to travel the full width of the table (1.75 m), so $t = x/v_x = (1.75\ \text{m})/(3.01\times10^{-33}\ \text{m/s}) = 5.81\times10^{32}\ \text{s} = 1.84\times10^{25}$ years. Since the universe is about 14×10^9 years old, this time is about $\dfrac{1.8\times10^{25}\ \text{yr}}{14\times10^9\ \text{yr}} \approx 1.3\times10^{15}$ times the age of the universe! Don't hold your breath!

EVALUATE: For household objects, the uncertainty principle places a negligible limitation on our ability to measure their speed.

39.51. **IDENTIFY:** Heisenberg's Uncertainty Principles tells us that $\Delta x \Delta p_x \geq \hbar/2$.

SET UP: We can treat the standard deviation as a direct measure of uncertainty.

EXECUTE: Here $\Delta x \Delta p_x = (1.2\times10^{-10}\ \text{m})(3.0\times10^{-25}\ \text{kg}\cdot\text{m/s}) = 3.6\times10^{-35}\ \text{J}\cdot\text{s}$, but $\hbar/2 = 5.28\times10^{-35}\ \text{J}\cdot\text{s}$. Therefore $\Delta x \Delta p_x < \hbar/2$, so the claim is *not valid*.

EVALUATE: The uncertainty product $\Delta x \Delta p_x$ must increase by a factor of about 1.5 to become consistent with the Heisenberg Uncertainty Principle.

39.52. **IDENTIFY:** Apply the Heisenberg Uncertainty Principle.

SET UP: $\Delta p_x = m\Delta v_x$.

EXECUTE: **(a)** $(\Delta x)(m\Delta v_x) \geq \hbar/2$, and setting $\Delta v_x = (0.010)v_x$ and the product of the uncertainties equal to $\hbar/2$ (for the minimum uncertainty) gives $v_x = \hbar/[2m(0.010)\Delta x] = 29.0$ m/s.

(b) Repeating with the proton mass gives 15.8 mm/s.

EVALUATE: For a given Δp_x, Δv_x is smaller for a proton than for an electron, since the proton has larger mass.

39.53. **IDENTIFY:** Apply the Heisenberg Uncertainty Principle in the form $\Delta E \Delta t = \hbar/2$.

SET UP: Let $\Delta t = 5.2\times10^{-3}$ s, the lifetime of the state of the atom, and let ΔE be the uncertainty in the energy of the state.

EXECUTE: $\Delta E > \dfrac{\hbar}{2\Delta t} = \dfrac{(1.055\times10^{-34}\ \text{J}\cdot\text{s})}{2(5.2\times10^{-3}\ \text{s})} = 1.01\times10^{-32}\ \text{J} = 6.34\times10^{-14}\ \text{eV}$.

EVALUATE: The uncertainty in the energy is a very small fraction of the typical energy of atomic states, which is on the order of 1 eV.

39.54. **IDENTIFY** and **SET UP:** The Heisenberg Uncertainty Principle says $\Delta x \Delta p_x \geq \hbar/2$. The minimum allowed $\Delta x \Delta p_x$ is $\hbar/2$. $\Delta p_x = m\Delta v_x$.

EXECUTE: **(a)** $m\Delta x \Delta v_x = \hbar/2$. $\Delta v_x = \dfrac{\hbar}{2m\Delta x} = \dfrac{1.055\times10^{-34}\ \text{J}\cdot\text{s}}{2(1.67\times10^{-27}\ \text{kg})(2.0\times10^{-12}\ \text{m})} = 1.6\times10^4$ m/s.

(b) $\Delta x = \dfrac{\hbar}{2m\Delta v_x} = \dfrac{1.055\times10^{-34}\ \text{J}\cdot\text{s}}{2(9.11\times10^{-31}\ \text{kg})(0.250\ \text{m/s})} = 2.3\times10^{-4}$ m.

EVALUATE: The smaller Δx is, the larger Δv_x must be.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

39.55. **(a) IDENTIFY** and **SET UP:** Apply Eq. (39.17): $m_r = \dfrac{m_1 m_2}{m_1 + m_2} = \dfrac{207 m_e m_p}{207 m_e + m_p}$

EXECUTE: $m_r = \dfrac{207(9.109\times10^{-31}\text{ kg})(1.673\times10^{-27}\text{ kg})}{207(9.109\times10^{-31}\text{ kg}) + 1.673\times10^{-27}\text{ kg}} = 1.69\times10^{-28}\text{ kg}$

We have used m_e to denote the electron mass.

(b) IDENTIFY: In Eq. (39.14) replace $m = m_e$ by m_r: $E_n = -\dfrac{1}{\epsilon_0^2}\dfrac{m_r e^4}{8n^2h^2}$.

SET UP: Write as $E_n = \left(\dfrac{m_r}{m_H}\right)\left(-\dfrac{1}{\epsilon_0^2}\dfrac{m_H e^4}{8n^2h^2}\right)$, since we know that $\dfrac{1}{\epsilon_0^2}\dfrac{m_H e^4}{8h^2} = 13.60\text{ eV}$. Here m_H denotes the reduced mass for the hydrogen atom; $m_H = 0.99946(9.109\times10^{-31}\text{ kg}) = 9.104\times10^{-31}\text{ kg}$.

EXECUTE: $E_n = \left(\dfrac{m_r}{m_H}\right)\left(-\dfrac{13.60\text{ eV}}{n^2}\right)$

$E_1 = \dfrac{1.69\times10^{-28}\text{ kg}}{9.109\times10^{-31}\text{ kg}}(-13.60\text{ eV}) = 186(-13.60\text{ eV}) = -2.53\text{ keV}$

(c) SET UP: From part (b), $E_n = \left(\dfrac{m_r}{m_H}\right)\left(-\dfrac{R_H ch}{n^2}\right)$, where $R_H = 1.097\times10^7\text{ m}^{-1}$ is the Rydberg constant for the hydrogen atom. Use this result in $\dfrac{hc}{\lambda} = E_i - E_f$ to find an expression for $1/\lambda$. The initial level for the transition is the $n_i = 2$ level and the final level is the $n_f = 1$ level.

EXECUTE: $\dfrac{hc}{\lambda} = \dfrac{m_r}{m_H}\left(-\dfrac{R_H ch}{n_i^2} - \left(-\dfrac{R_H ch}{n_f^2}\right)\right)$

$\dfrac{1}{\lambda} = \dfrac{m_r}{m_H}R_H\left(\dfrac{1}{n_f^2} - \dfrac{1}{n_i^2}\right)$

$\dfrac{1}{\lambda} = \dfrac{1.69\times10^{-28}\text{ kg}}{9.109\times10^{-31}\text{ kg}}(1.097\times10^7\text{ m}^{-1})\left(\dfrac{1}{1^2} - \dfrac{1}{2^2}\right) = 1.527\times10^9\text{ m}^{-1}$

$\lambda = 0.655\text{ nm}$

EVALUATE: From Example 39.6 the wavelength of the radiation emitted in this transition in hydrogen is 122 nm. The wavelength for muonium is $\dfrac{m_H}{m_r} = 5.39\times10^{-3}$ times this. The reduced mass for hydrogen is very close to the electron mass because the electron mass is much less then the proton mass: $m_p/m_e = 1836$. The muon mass is $207m_e = 1.886\times10^{-28}$ kg. The proton is only about 10 times more massive than the muon, so the reduced mass is somewhat smaller than the muon mass. The muon-proton atom has much more strongly bound energy levels and much shorter wavelengths in its spectrum than for hydrogen.

39.56. **IDENTIFY:** Apply conservation of momentum to the system of atom and emitted photon.

SET UP: Assume the atom is initially at rest. For a photon $E = \dfrac{hc}{\lambda}$ and $p = \dfrac{h}{\lambda}$.

EXECUTE: **(a)** Assume a non-relativistic velocity and conserve momentum $\Rightarrow mv = \dfrac{h}{\lambda} \Rightarrow v = \dfrac{h}{m\lambda}$.

(b) $K = \dfrac{1}{2}mv^2 = \dfrac{1}{2}m\left(\dfrac{h}{m\lambda}\right)^2 = \dfrac{h^2}{2m\lambda^2}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(c) $\frac{K}{E}=\frac{h^2}{2m\lambda^2}\cdot\frac{\lambda}{hc}=\frac{h}{2mc\lambda}$. Recoil becomes an important concern for small m and small λ since this ratio becomes large in those limits.

(d) $E=10.2\text{ eV}\Rightarrow\lambda=\frac{hc}{E}=\frac{(6.63\times10^{-34}\text{ J}\cdot\text{s})(3.00\times10^{8}\text{ m/s})}{(10.2\text{ eV})(1.60\times10^{-19}\text{ J/eV})}=1.22\times10^{-7}\text{ m}=122\text{ nm}.$

$$K=\frac{(6.63\times10^{-34}\text{ J}\cdot\text{s})^2}{2(1.67\times10^{-27}\text{ kg})(1.22\times10^{-7}\text{ m})^2}=8.84\times10^{-27}\text{ J}=5.53\times10^{-8}\text{ eV}.$$

$\frac{K}{E}=\frac{5.53\times10^{-8}\text{ eV}}{10.2\text{ eV}}=5.42\times10^{-9}$. This is quite small so recoil can be neglected.

EVALUATE: For emission of photons with ultraviolet or longer wavelengths the recoil kinetic energy of the atom is much less than the energy of the emitted photon.

39.57. **IDENTIFY** and **SET UP:** The H_α line in the Balmer series corresponds to the $n=3$ to $n=2$ transition. $E_n=-\frac{13.6\text{ eV}}{n^2}$. $\frac{hc}{\lambda}=\Delta E$.

EXECUTE: **(a)** The atom must be given an amount of energy $E_3-E_1=-(13.6\text{ eV})\left(\frac{1}{3^2}-\frac{1}{1^2}\right)=12.1\text{ eV}$.

(b) There are three possible transitions. $n=3\to n=1$: $\Delta E=12.1\text{ eV}$ and $\lambda=\frac{hc}{\Delta E}=103\text{ nm}$;

$n=3\to n=2$: $\Delta E=-(13.6\text{ eV})\left(\frac{1}{3^2}-\frac{1}{2^2}\right)=1.89\text{ eV}$ and $\lambda=657\text{ nm}$; $n=2\to n=1$:

$\Delta E=-(13.6\text{ eV})\left(\frac{1}{2^2}-\frac{1}{1^2}\right)=10.2\text{ eV}$ and $\lambda=122\text{ nm}$.

EVALUATE: The larger the transition energy for the atom, the shorter the wavelength.

39.58. **IDENTIFY:** Apply $\frac{n_2}{n_1}=e^{-(E_{ex}-E_g)/kT}$.

SET UP: $E_{ex}=E_2=\frac{-13.6\text{ eV}}{4}=-3.4\text{ eV}$. $E_g=-13.6\text{ eV}$. $E_{ex}-E_g=10.2\text{ eV}=1.63\times10^{-18}\text{ J}$.

EXECUTE: **(a)** $T=\frac{-(E_{ex}-E_g)}{k\ln(n_2/n_1)}$. $\frac{n_2}{n_1}=10^{-12}$. $T=\frac{-(1.63\times10^{-18}\text{ J})}{(1.38\times10^{-23}\text{ J/K})\ln(10^{-12})}=4275\text{ K}$.

(b) $\frac{n_2}{n_1}=10^{-8}$. $T=\frac{-(1.63\times10^{-18}\text{ J})}{(1.38\times10^{-23}\text{ J/K})\ln(10^{-8})}=6412\text{ K}$.

(c) $\frac{n_2}{n_1}=10^{-4}$. $T=\frac{-(1.63\times10^{-18}\text{ J})}{(1.38\times10^{-23}\text{ J/K})\ln(10^{-4})}=12824\text{ K}$.

EVALUATE: **(d)** For absorption to take place in the Balmer series, hydrogen must *start* in the $n=2$ state. From part (a), colder stars have fewer atoms in this state leading to weaker absorption lines.

39.59. **(a) IDENTIFY** and **SET UP:** The photon energy is given to the electron in the atom. Some of this energy overcomes the binding energy of the atom and what is left appears as kinetic energy of the free electron. Apply $hf=E_f-E_i$, the energy given to the electron in the atom when a photon is absorbed.

EXECUTE: The energy of one photon is $\frac{hc}{\lambda}=\frac{(6.626\times10^{-34}\text{ J}\cdot\text{s})(2.998\times10^{8}\text{ m/s})}{85.5\times10^{-9}\text{ m}}$

$\frac{hc}{\lambda}=2.323\times10^{-18}\text{ J}(1\text{ eV}/1.602\times10^{-19}\text{ J})=14.50\text{ eV}$.

The final energy of the electron is $E_f=E_i+hf$. In the ground state of the hydrogen atom the energy of the electron is $E_i=-13.60$ eV. Thus $E_f=-13.60\text{ eV}+14.50\text{ eV}=0.90\text{ eV}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) EVALUATE: At thermal equilibrium a few atoms will be in the $n = 2$ excited levels, which have an energy of $-13.6\text{ eV}/4 = -3.40\text{ eV}, 10.2\text{ eV}$ greater than the energy of the ground state. If an electron with $E = -3.40\text{ eV}$ gains 14.5 eV from the absorbed photon, it will end up with $14.5\text{ eV} - 3.4\text{ eV} = 11.1\text{ eV}$ of kinetic energy.

39.60. **IDENTIFY:** For circular motion, $L = mvr$ and $a = \dfrac{v^2}{r}$. Newton's law of gravitation is $F_g = G\dfrac{mM}{r^2}$, with $G = 6.67\times10^{-11}\text{ N}\cdot\text{m}^2/\text{kg}^2$.

SET UP: The period T is 2.00 h = 7200 s.

EXECUTE: **(a)** $mvr = n\dfrac{h}{2\pi}.\ n = \dfrac{2\pi mvr}{h}.\ v = \dfrac{2\pi r}{T}$ So

$$n = \frac{(2\pi r)^2 m}{hT} = \frac{(2\pi)^2(8.06\times10^6\text{ m})^2(20.0\text{ kg})}{(6.63\times10^{-34}\text{ J}\,.\,\text{s})(7200\text{ s})} = 1.08\times10^{46}.$$

(b) $F = ma$ gives $G\dfrac{mm_E}{r^2} = m\dfrac{v^2}{r}.\ \dfrac{Gm_E}{r} = v^2$. The Bohr postulate says $v = \dfrac{nh}{2\pi mr}$ so $\dfrac{Gm_E}{r} = \dfrac{n^2h^2}{4\pi^2m^2r^2}$

$r = \left(\dfrac{h^2}{4\pi^2Gm_Em^2}\right)n^2$. This is in the form $r = kn^2$, with

$$k = \frac{h^2}{4\pi^2Gm_Em^2} = \frac{(6.63\times10^{-34}\text{ J.s})^2}{4\pi^2(6.67\times10^{-11}\text{ N}\cdot\text{m}^2/\text{kg}^2)(5.97\times10^{24}\text{ kg})^2} = 7.0\times10^{-86}\text{ m}$$

(c) $\Delta r = r_{n+1} - r_n = k([n+1]^2 - n^2) = (2n+1)k = (2[1.08\times10^{46}]+1)(7.0\times10^{-86}\text{ m}) = 1.5\times10^{-39}\text{ m}$

EVALUATE: **(d)** Δr is exceedingly small, so the separation of adjacent orbits is not observable.

(e) There is no measurable difference between quantized and classical orbits for this satellite; either method of calculation is totally acceptable.

39.61. **IDENTIFY:** Assuming that Betelgeuse radiates like a perfect blackbody, Wien's displacement and the Stefan-Boltzmann law apply to its radiation.

SET UP: Wien's displacement law is $\lambda_{peak} = \dfrac{2.90\times10^{-3}\text{ m}\cdot\text{K}}{T}$, and the Stefan-Boltzmann law says that the intensity of the radiation is $I = \sigma T^4$, so the total radiated power is $P = \sigma AT^4$.

EXECUTE: **(a)** First use Wien's law to find the peak wavelength:

$$\lambda_m = (2.90\times10^{-3}\text{ m}\cdot\text{K})/(3000\text{ K}) = 9.667\times10^{-7}\text{ m}$$

Call N the number of photons/second radiated. $N\times(\text{energy per photon}) = IA = \sigma AT^4$.

$N(hc/\lambda_m) = \sigma AT^4.\ N = \dfrac{\lambda_m\sigma AT^4}{hc}.$

$$N = \frac{(9.667\times10^{-7}\text{ m})(5.67\times10^{-8}\text{ W/m}^2\cdot\text{K}^4)(4\pi)(600\times6.96\times10^8\text{ m})^2(3000\text{ K})^4}{(6.626\times10^{-34}\text{ J}\cdot\text{s})(3.00\times10^8\text{ m/s})}.$$

$N = 5\times10^{49}$ photons/s.

(b) $\dfrac{I_BA_B}{I_SA_S} = \dfrac{\sigma A_BT_B^4}{\sigma A_ST_S^4} = \dfrac{4\pi R_B^2T_B^4}{4\pi R_S^2T_S^4} = \left(\dfrac{600R_S}{R_S}\right)^2\left(\dfrac{3000\text{ K}}{5800\text{ K}}\right)^4 = 3\times10^4$

EVALUATE: Betelgeuse radiates 30,000 times as much energy per second as does our sun!

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

39.62. **IDENTIFY:** The diffraction grating allows us to determine the peak-intensity wavelength of the light. Then Wien's displacement law allows us to calculate the temperature of the blackbody, and the Stefan-Boltzmann law allows us to calculate the rate at which it radiates energy.

SET UP: The bright spots for a diffraction grating occur when $d\sin\theta = m\lambda$. Wien's displacement law is $\lambda_{\text{peak}} = \dfrac{2.90\times10^{-3}\ \text{m}\cdot\text{K}}{T}$, and the Stefan-Boltzmann law says that the intensity of the radiation is $I = \sigma T^4$, so the total radiated power is $P = \sigma A T^4$.

EXECUTE: **(a)** First find the wavelength of the light:

$$\lambda = d\sin\theta = [1/(385{,}000\ \text{lines/m})]\sin(11.6°) = 5.22\times10^{-7}\ \text{m}$$

Now use Wien's law to find the temperature: $T = (2.90\times10^{-3}\ \text{m}\cdot\text{K})/(5.22\times10^{-7}\ \text{m}) = 5550\ \text{K}$.

(b) The energy radiated by the blackbody is equal to the power times the time, giving $U = Pt = IAt = \sigma A T^4 t$, which gives

$t = U/(\sigma A T^4) = (12.0\times10^6\ \text{J})/[(5.67\times10^{-8}\ \text{W/m}^2\cdot\text{K}^4)(4\pi)(0.0750\ \text{m})^2(5550\ \text{K})^4] = 3.16\ \text{s}$.

EVALUATE: By ordinary standards, this blackbody is very hot, so it does not take long to radiate 12.0 MJ of energy.

39.63. **IDENTIFY:** The energy of the peak-intensity photons must be equal to the energy difference between the $n = 1$ and the $n = 4$ states. Wien's law allows us to calculate what the temperature of the blackbody must be for it to radiate with its peak intensity at this wavelength.

SET UP: In the Bohr model, the energy of an electron in shell n is $E_n = -\dfrac{13.6\ \text{eV}}{n^2}$, and Wien's displacement law is $\lambda_{\text{m}} = \dfrac{2.90\times10^{-3}\ \text{m}\cdot\text{K}}{T}$. The energy of a photon is $E = hf = hc/\lambda$.

EXECUTE: First find the energy (ΔE) that a photon would need to excite the atom. The ground state of the atom is $n = 1$ and the third excited state is $n = 4$. This energy is the *difference* between the two energy levels. Therefore $\Delta E = (-13.6\ \text{eV})\left(\dfrac{1}{4^2} - \dfrac{1}{1^2}\right) = 12.8\ \text{eV}$. Now find the wavelength of the photon having this amount of energy. $hc/\lambda = 12.8\ \text{eV}$ and

$$\lambda = (4.136\times10^{-15}\ \text{eV}\cdot\text{s})(3.00\times10^8\ \text{m/s})/(12.8\ \text{eV}) = 9.73\times10^{-8}\ \text{m}$$

Now use Wien's law to find the temperature. $T = (0.00290\ \text{m}\cdot\text{K})/(9.73\times10^{-8}\ \text{m}) = 2.98\times10^4\ \text{K}$.

EVALUATE: This temperature is well above ordinary room temperatures, which is why hydrogen atoms are not in excited states during everyday conditions.

39.64. **IDENTIFY:** The blackbody radiates heat into the water, but the water also radiates heat back into the blackbody. The net heat entering the water causes evaporation. Wien's law tells us the peak wavelength radiated, but a thermophile in the water measures the wavelength and frequency of the light in the water.

SET UP: By the Stefan-Boltzman law, the net power radiated by the blackbody is $\dfrac{dQ}{dt} = \sigma A\left(T_{\text{sphere}}^4 - T_{\text{water}}^4\right)$. Since this heat evaporates water, the rate at which water evaporates is $\dfrac{dQ}{dt} = L_{\text{v}}\dfrac{dm}{dt}$. Wien's displacement law is $\lambda_{\text{m}} = \dfrac{2.90\times10^{-3}\ \text{m}\cdot\text{K}}{T}$, and the wavelength in the water is $\lambda_{\text{w}} = \lambda_0/n$.

EXECUTE: **(a)** The net radiated heat is $\dfrac{dQ}{dt} = \sigma A\left(T_{\text{sphere}}^4 - T_{\text{water}}^4\right)$ and the evaporation rate is $\dfrac{dQ}{dt} = L_{\text{v}}\dfrac{dm}{dt}$, where dm is the mass of water that evaporates in time dt. Equating these two rates gives

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$L_v \frac{dm}{dt} = \sigma A\left(T_{\text{sphere}}^4 - T_{\text{water}}^4\right). \quad \frac{dm}{dt} = \frac{\sigma(4\pi R^2)\left(T_{\text{sphere}}^4 - T_{\text{water}}^4\right)}{L_v}.$$

$$\frac{dm}{dt} = \frac{(5.67\times10^{-8}\ \text{W/m}^2\cdot\text{K}^4)(4\pi)(0.120\ \text{m})^2\left[(498\ \text{K})^4 - (373\ \text{K})^4\right]}{2256\times10^3\ \text{J/kg}} = 1.92\times10^{-4}\ \text{kg/s} = 0.193\ \text{g/s}$$

(b) (i) Wien's law gives $\lambda_m = (0.00290\ \text{m}\cdot\text{K})/(498\ \text{K}) = 5.82\times10^{-6}$ m

But this would be the wavelength in vacuum. In the water the thermophile organism would measure $\lambda_w = \lambda_0/n = (5.82\times10^{-6}\ \text{m})/1.333 = 4.37\times10^{-6}\ \text{m} = 4.37\ \mu\text{m}$

(ii) The frequency is the same as if the wave were in air, so

$$f = c/\lambda_0 = (3.00\times10^8\ \text{m/s})/(5.82\times10^{-6}\ \text{m}) = 5.15\times10^{13}\ \text{Hz}$$

EVALUATE: An alternative way is to use the quantities in the water: $f = \dfrac{c/n}{\lambda_0/n} = c/\lambda_0$, which gives the same answer for the frequency. An organism in the water would measure the light coming to it through the water, so the wavelength it would measure would be reduced by a factor of $1/n$.

39.65. **IDENTIFY:** Apply conservation of energy and conservation of linear momentum to the system of atom plus photon.

(a) SET UP: Let E_{tr} be the transition energy, E_{ph} be the energy of the photon with wavelength λ', and E_r be the kinetic energy of the recoiling atom. Conservation of energy gives $E_{ph} + E_r = E_{tr}$.

$E_{ph} = \dfrac{hc}{\lambda'}$ so $\dfrac{hc}{\lambda'} = E_{tr} - E_r$ and $\lambda' = \dfrac{hc}{E_{tr} - E_r}$.

EXECUTE: If the recoil energy is neglected then the photon wavelength is $\lambda = hc/E_{tr}$.

$$\Delta\lambda = \lambda' - \lambda = hc\left(\frac{1}{E_{tr} - E_r} - \frac{1}{E_{tr}}\right) = \left(\frac{hc}{E_{tr}}\right)\left(\frac{1}{1 - E_r/E_{tr}} - 1\right)$$

$$\frac{1}{1 - E_r/E_{tr}} = \left(1 - \frac{E_r}{E_{tr}}\right)^{-1} \approx 1 + \frac{E_r}{E_{tr}} \quad \text{since} \quad \frac{E_r}{E_{tr}} \ll 1$$

(We have used the binomial theorem, Appendix B.)

Thus $\Delta\lambda = \dfrac{hc}{E_{tr}}\left(\dfrac{E_r}{E_{tr}}\right)$, or since $E_{tr} = hc/\lambda$, $\Delta\lambda = \left(\dfrac{E_r}{hc}\right)\lambda^2$.

SET UP: Use conservation of linear momentum to find E_r: Assuming that the atom is initially at rest, the momentum p_r of the recoiling atom must be equal in magnitude and opposite in direction to the momentum $p_{ph} = h/\lambda$ of the emitted photon: $h/\lambda = p_r$.

EXECUTE: $E_r = \dfrac{p_r^2}{2m}$, where m is the mass of the atom, so $E_r = \dfrac{h^2}{2m\lambda^2}$.

Use this result in the above equation: $\Delta\lambda = \left(\dfrac{E_r}{hc}\right)\lambda^2 = \left(\dfrac{h^2}{2m\lambda^2}\right)\left(\dfrac{\lambda^2}{hc}\right) = \dfrac{h}{2mc}$;

note that this result for $\Delta\lambda$ is independent of the atomic transition energy.

(b) For a hydrogen atom $m = m_p$ and $\Delta\lambda = \dfrac{h}{2m_p c} = \dfrac{6.626\times10^{-34}\ \text{J}\cdot\text{s}}{2(1.673\times10^{-27}\ \text{kg})(2.998\times10^8\ \text{m/s})} = 6.61\times10^{-16}$ m

EVALUATE: The correction is independent of n. The wavelengths of photons emitted in hydrogen atom transitions are on the order of $100\ \text{nm} = 10^{-7}$ m, so the recoil correction is exceedingly small.

39.66. **IDENTIFY:** Combine $I = \sigma T^4$, $P = IA$, and $\Delta E = Pt$.

SET UP: In the Stefan-Boltzmann law the temperature must be in kelvins. 200°C = 473 K.

EXECUTE: $t = \dfrac{\Delta E}{A\sigma T^4} = \dfrac{(100\text{ J})}{(4.00\times10^{-6}\text{ m}^2)(5.67\times10^{-8}\text{ W/m}^2\cdot\text{K}^4)(473\text{ K})^4} = 8.81\times10^3\text{ s} = 2.45\text{ h}.$

EVALUATE: $P = 0.0114$ W. Since the area of the hole is small, the rate at which the cavity radiates energy through the hole is very small.

39.67. **IDENTIFY** and **SET UP:** Follow the procedures specified in the problem.

EXECUTE: **(a)** $I(\lambda) = \dfrac{2\pi hc^2}{\lambda^5(e^{hc/\lambda kT}-1)}$ but $\lambda = \dfrac{c}{f} \Rightarrow I(f) = \dfrac{2\pi hc^2}{(c/f)^5(e^{hf/kT}-1)} = \dfrac{2\pi hf^5}{c^3(e^{hf/kT}-1)}$

(b) $\int_0^\infty I(\lambda)\,d\lambda = \int_\infty^0 I(f)\,df\left(\dfrac{-c}{f^2}\right)$

$= \int_0^\infty \dfrac{2\pi hf^3\,df}{c^2(e^{hf/kT}-1)} = \dfrac{2\pi(kT)^4}{c^2h^3}\int_0^\infty \dfrac{x^3}{e^x-1}\,dx = \dfrac{2\pi(kT)^4}{c^2h^3}\,\dfrac{1}{240}(2\pi)^4 = \dfrac{(2\pi)^5(kT)^4}{240h^3c^2} = \dfrac{2\pi^5k^4T^4}{15c^2h^3}.$

(c) The expression $\dfrac{2\pi^5k^4}{15h^3c^2} = \sigma$ as shown in Eq. (39.28). Plugging in the values for the constants we get $\sigma = 5.67\times10^{-8}\text{ W/m}^2\cdot\text{K}^4$.

EVALUATE: The Planck radiation law, Eq. (39.24), predicts the Stefan-Boltzmann law, Eq. (39.19).

39.68. **IDENTIFY:** $\lambda = \dfrac{h}{p} = \dfrac{h}{\sqrt{2mE}}$. From Chapter 36, if $\lambda \ll a$ then the width w of the central maximum is $w = 2\dfrac{R\lambda}{a}$, where $R = 2.5$ m and a is the width of the slit.

SET UP: $v_x = \sqrt{\dfrac{2E}{m}}$, since the beam is traveling in the x-direction and $\Delta v_y \ll v_x$

EXECUTE: **(a)** $\lambda = \dfrac{h}{\sqrt{2mK}} = \dfrac{(6.63\times10^{-34}\text{ J}\cdot\text{s})}{\sqrt{2(9.11\times10^{-31}\text{ kg})(40\text{ eV})(1.60\times10^{-19}\text{ J/eV})}} = 1.94\times10^{-10}\text{ m}.$

(b) $\dfrac{R}{v} = \dfrac{R}{\sqrt{2E/m}} = \dfrac{(2.5\text{ m})(9.11\times10^{-31}\text{ kg})^{1/2}}{\sqrt{2(40\text{ eV})(1.6\times10^{-19}\text{ J/eV})}} = 6.67\times10^{-7}\text{ s}.$

(c) The width w is $w = 2R\dfrac{\lambda}{a}$' and $w = \Delta v_y t = \Delta p_y t/m$, where t is the time found in part (b) and a is the slit width. Combining the expressions for w, $\Delta p_y = \dfrac{2m\lambda R}{at} = 2.65\times10^{-28}\text{ kg}\cdot\text{m/s}.$

(d) $\Delta y = \dfrac{\hbar}{2\Delta p_y} = 0.20\ \mu\text{m}$, which is the same order of magnitude of the width of the slit.

EVALUATE: For these electrons $\lambda = 1.94\times10^{-10}$ m. This is much smaller than a and the approximate expression $w = \dfrac{2R\lambda}{a}$ is very accurate. Also, $v_x = \sqrt{\dfrac{2E}{m}} = 3.75\times10^6$ m/s. $\Delta v_y = \dfrac{\Delta p_y}{m} = 2.9\times10^2$ m/s, so it is the case that $v_x \gg \Delta v_y$.

39.69. **IDENTIFY:** For a photon $E = \dfrac{hc}{\lambda}$. For a particle with mass, $p = \dfrac{h}{\lambda}$ and $E = \dfrac{p^2}{2m} = q\Delta V$, where ΔV is the accelerating voltage. To exhibit wave nature when passing through an opening, the de Broglie wavelength of the particle must be comparable with the width of the opening.

SET UP: An electron has mass 9.109×10^{-31} kg. A proton has mass 1.673×10^{-27} kg.

EXECUTE: **(a)** $E = hc/\lambda = 12$ eV

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) Find E for an electron with $\lambda = 0.10\times10^{-6}$ m. $\lambda = h/p$ so $p = h/\lambda = 6.626\times10^{-27}$ kg · m/s.

$E = p^2/(2m) = 1.5\times10^{-4}$ eV. $E = q\Delta V$ so $\Delta V = 1.5\times10^{-4}$ V.

$v = p/m = (6.626\times10^{-27}\text{ kg}\cdot\text{m/s})/(9.109\times10^{-31}\text{ kg}) = 7.3\times10^{3}$ m/s

(c) Same λ so same p. $E = p^2/(2m)$ but now $m = 1.673\times10^{-27}$ kg so $E = 8.2\times10^{-8}$ eV and

$\Delta V = 8.2\times10^{-8}$ V. $v = p/m = (6.626\times10^{-27}\text{ kg}\cdot\text{m/s})/(1.673\times10^{-27}\text{ kg}) = 4.0$ m/s

EVALUATE: A proton must be traveling much slower than an electron in order to have the same de Broglie wavelength.

39.70. **IDENTIFY:** The de Broglie wavelength of the electrons must be such that the first diffraction minimum occurs at $\theta = 20.0°$.

SET UP: The single-slit diffraction minima occur at angles θ given by $a\sin\theta = m\lambda$. $p = \dfrac{h}{\lambda}$.

EXECUTE: **(a)** $\lambda = a\sin\theta = (150\times10^{-9}\text{ m})\sin 20° = 5.13\times10^{-8}$ m. $\lambda = h/mv \rightarrow v = h/m\lambda$.

$$v = \frac{6.626\times10^{-34}\text{ J}\cdot\text{s}}{(9.11\times10^{-31}\text{ kg})(5.13\times10^{-8}\text{ m})} = 1.42\times10^{4}\text{ m/s}.$$

(b) No electrons strike the screen at the location of the second diffraction minimum. $a\sin\theta_2 = 2\lambda$.

$$\sin\theta_2 = \pm2\frac{\lambda}{a} = \pm2\left(\frac{5.13\times10^{-8}\text{ m}}{150\times10^{-9}\text{ m}}\right) = \pm0.684.\ \theta_2 = \pm43.2°.$$

EVALUATE: The intensity distribution in the diffraction pattern depends on the wavelength λ and is the same for light of wavelength λ as for electrons with de Broglie wavelength λ.

39.71. **IDENTIFY:** The electrons behave like waves and produce a double-slit interference pattern after passing through the slits.

SET UP: The first angle at which destructive interference occurs is given by $d\sin\theta = \lambda/2$. The de Broglie wavelength of each of the electrons is $\lambda = h/mv$.

EXECUTE: **(a)** First find the wavelength of the electrons. For the first dark fringe, we have $d\sin\theta = \lambda/2$, which gives $(1.25\text{ nm})(\sin 18.0°) = \lambda/2$, and $\lambda = 0.7725$ nm. Now solve the de Broglie wavelength equation for the speed of the electron:

$$v = \frac{h}{m\lambda} = \frac{6.626\times10^{-34}\text{ J}\cdot\text{s}}{(9.11\times10^{-31}\text{ kg})(0.7725\times10^{-9}\text{ m})} = 9.42\times10^{5}\text{ m/s}$$

which is about 0.3% the speed of light, so they are *nonrelativistic*.

(b) Energy conservation gives $eV = \frac{1}{2}mv^2$ and

$$V = mv^2/2e = (9.11\times10^{-31}\text{ kg})(9.42\times10^{5}\text{ m/s})^2/[2(1.60\times10^{-19}\text{ C})] = 2.52\text{ V}$$

EVALUATE: The hole must be much smaller than the wavelength of visible light for the electrons to show diffraction.

39.72. **IDENTIFY:** The alpha particles and protons behave as waves and exhibit circular-aperture diffraction after passing through the hole.

SET UP: For a round hole, the first dark ring occurs at the angle θ for which $\sin\theta = 1.22\lambda/D$, where D is the diameter of the hole. The de Broglie wavelength for a particle is $\lambda = h/p = h/mv$.

EXECUTE: Taking the ratio of the sines for the alpha particle and proton gives

$$\frac{\sin\theta_\alpha}{\sin\theta_\text{p}} = \frac{1.22\lambda_\alpha}{1.22\lambda_\text{p}} = \frac{\lambda_\alpha}{\lambda_\text{p}}$$

The de Broglie wavelength gives $\lambda_\text{p} = h/p_\text{p}$ and $\lambda_\alpha = h/p_\alpha$, so $\dfrac{\sin\theta_\alpha}{\sin\theta_\text{p}} = \dfrac{h/p_\alpha}{h/p_\text{p}} = \dfrac{p_\text{p}}{p_\alpha}$. Using $K = p^2/2m$, we have $p = \sqrt{2mK}$. Since the alpha particle has twice the charge of the proton and both are accelerated

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

through the same potential difference, $K_\alpha = 2K_\text{p}$. Therefore $p_\text{p} = \sqrt{2m_\text{p}K_\text{p}}$ and $p_\alpha = \sqrt{2m_\alpha K_\alpha} = \sqrt{2m_\alpha(2K_\text{p})} = \sqrt{4m_\alpha K_\text{p}}$. Substituting these quantities into the ratio of the sines gives

$$\frac{\sin\theta_\alpha}{\sin\theta_\text{p}} = \frac{p_\text{p}}{p_\alpha} = \frac{\sqrt{2m_\text{p}K_\text{p}}}{\sqrt{4m_\alpha K_\text{p}}} = \sqrt{\frac{m_\text{p}}{2m_\alpha}}$$

Solving for sin θ_α gives $\sin\theta_\alpha = \sqrt{\frac{1.67\times10^{-27}\text{ kg}}{2(6.64\times10^{-27}\text{ kg})}}\sin 15.0°$ and $\theta_\alpha = 5.3°$.

EVALUATE: Since $\sin\theta$ is inversely proportional to the mass of the particle, the larger-mass alpha particles form their first dark ring at a smaller angle than the ring for the lighter protons.

39.73. **IDENTIFY:** Both the electrons and photons behave like waves and exhibit single-slit diffraction after passing through their respective slits.

SET UP: The energy of the photon is $E = hc/\lambda$ and the de Broglie wavelength of the electron is $\lambda = h/mv = h/p$. Destructive interference for a single slit first occurs when $a\ \sin\theta = \lambda$.

EXECUTE: **(a)** For the photon: $\lambda = hc/E$ and $a\ \sin\theta = \lambda$. Since the a and θ are the same for the photons and electrons, they must both have the same wavelength. Equating these two expressions for λ gives $a\sin\theta = hc/E$. For the electron, $\lambda = h/p = \frac{h}{\sqrt{2mK}}$ and $a\ \sin\theta = \lambda$. Equating these two expressions for λ gives $a\ \sin\theta = \frac{h}{\sqrt{2mK}}$. Equating the two expressions for $a\sin\theta$ gives $hc/E = \frac{h}{\sqrt{2mK}}$, which gives $E = c\sqrt{2mK} = (4.05\times10^{-7}\text{ J}^{1/2})\sqrt{K}$.

(b) $\frac{E}{K} = \frac{c\sqrt{2mK}}{K} = \sqrt{\frac{2mc^2}{K}}$. Since $v \ll c$, $mc^2 > K$, so the square root is >1. Therefore $E/K > 1$, meaning that the photon has more energy than the electron.

EVALUATE: When a photon and a particle have the same wavelength, the photon has more energy than the particle.

39.74. **IDENTIFY:** The de Broglie wavelength of the electrons must equal the wavelength of the light.

SET UP: The maxima in the two-slit interference pattern are located by $d\sin\theta = m\lambda$. For an electron, $\lambda = \frac{h}{p} = \frac{h}{mv}$.

EXECUTE: $\lambda = \frac{d\sin\theta}{m} = \frac{(40.0\times10^{-6}\text{ m})\sin(0.0300\text{ rad})}{2} = 600\text{ nm}$. The velocity of an electron with this wavelength is given by Eq. (39.1). $v = \frac{p}{m} = \frac{h}{m\lambda} = \frac{(6.63\times10^{-34}\text{ J}\cdot\text{s})}{(9.11\times10^{-31}\text{ kg})(600\times10^{-9}\text{ m})} = 1.21\times10^3\text{ m/s}$. Since this velocity is much smaller than c we can calculate the energy of the electron classically

$K = \frac{1}{2}mv^2 = \frac{1}{2}(9.11\times10^{-31}\text{ kg})(1.21\times10^3\text{ m/s})^2 = 6.70\times10^{-25}\text{ J} = 4.19\ \mu\text{eV}$.

EVALUATE: The energy of the photons of this wavelength is $E = \frac{hc}{\lambda} = 2.07\text{ eV}$. The photons and electrons have the same wavelength but very different energies.

39.75. **IDENTIFY** and **SET UP:** The de Broglie wavelength of the blood cell is $\lambda = \frac{h}{mv}$.

EXECUTE: $\lambda = \frac{6.63\times10^{-34}\text{ J}\cdot\text{s}}{(1.00\times10^{-14}\text{ kg})(4.00\times10^{-3}\text{ m/s})} = 1.66\times10^{-17}\text{ m}$.

EVALUATE: We need not be concerned about wave behavior.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

39.76. **IDENTIFY:** An electron and a photon both have the same wavelength. We want to use this fact to calculate the energy of each of them.

SET UP: The de Broglie wavelength is $\lambda = \dfrac{h}{p}$. The energy of the electron is its kinetic energy, $K = \frac{1}{2}mv^2 = p^2/2m$. The energy of the photon is $E = hf = hc/\lambda$.

EXECUTE: **(a)** $p = \dfrac{h}{\lambda} = \dfrac{6.626\times10^{-34}\ \text{J}\cdot\text{s}}{400\times10^{-9}\ \text{m}} = 1.656\times10^{-27}\ \text{kg}\cdot\text{m/s}$.

$$E = \frac{p^2}{2m} = \frac{(1.656\times10^{-27}\ \text{kg}\cdot\text{m/s})^2}{2(9.109\times10^{-31}\ \text{kg})} = 1.506\times10^{-24}\ \text{J} = 9.40\times10^{-6}\ \text{eV}$$

(b) $E = \dfrac{hc}{\lambda} = \dfrac{(6.626\times10^{-34}\ \text{J}\cdot\text{s})(2.998\times10^{8}\ \text{m/s})}{400\times10^{-9}\ \text{m}} = 4.966\times10^{-19}\ \text{J} = 3.10\ \text{eV}$

EVALUATE: The photon has around 300,000 times as much energy as the electron.

39.77. **IDENTIFY** and **SET UP:** Follow the procedures specified in the problem.

EXECUTE: **(a)** $\lambda = \dfrac{h}{p} = \dfrac{h\left(1-\dfrac{v^2}{c^2}\right)^{1/2}}{mv} \Rightarrow \lambda^2m^2v^2 = h^2\left(1-\dfrac{v^2}{c^2}\right) = h^2 - \dfrac{h^2v^2}{c^2} \Rightarrow \lambda^2m^2v^2 + h^2\dfrac{v^2}{c^2} = h^2$

$$\Rightarrow v^2 = \frac{h^2}{\left(\lambda^2m^2 + \dfrac{h^2}{c^2}\right)} = \frac{c^2}{\left(\dfrac{\lambda^2m^2c^2}{h^2}+1\right)} \Rightarrow v = \frac{c}{\left(1+\left(\dfrac{mc\lambda}{h}\right)^2\right)^{1/2}}.$$

(b) $v = \dfrac{c}{\left(1+\left(\dfrac{\lambda}{(h/mc)}\right)^2\right)^{1/2}} \approx c\left(1-\frac{1}{2}\left(\dfrac{mc\lambda}{h}\right)^2\right) = (1-\Delta)c.\ \ \Delta = \dfrac{m^2c^2\lambda^2}{2h^2}.$

(c) $\lambda = 1.00\times10^{-15}\,\text{m} \ll \dfrac{h}{mc}.\ \ \Delta = \dfrac{(9.11\times10^{-31}\ \text{kg})^2(3.00\times10^{8}\ \text{m/s})^2(1.00\times10^{-15}\ \text{m})^2}{2(6.63\times10^{-34}\ \text{J}\cdot\text{s})^2} = 8.50\times10^{-8}$

$\Rightarrow v = (1-\Delta)c = (1-8.50\times10^{-8})c.$

EVALUATE: As $\Delta \to 0$, $v \to c$ and $\lambda \to 0$.

39.78. **IDENTIFY** and **SET UP:** The minimum uncertainty product is $\Delta x\Delta p_x = \hbar/2$. $\Delta x = r_1$, where r_1 is the radius of the $n = 1$ Bohr orbit. In the $n = 1$ Bohr orbit, $mv_1r_1 = \dfrac{h}{2\pi}$ and $p_1 = mv_1 = \dfrac{h}{2\pi r_1}$.

EXECUTE: $\Delta p_x = \dfrac{\hbar}{2\Delta x} = \dfrac{\hbar}{2r_1} = \dfrac{1.055\times10^{-34}\ \text{J}\cdot\text{s}}{2(0.529\times10^{-10}\ \text{m})} = 1.0\times10^{-24}\ \text{kg}\cdot\text{m/s}$. This is the same as the magnitude of the momentum of the electron in the $n = 1$ Bohr orbit.

EVALUATE: Since the momentum is the same order of magnitude as the uncertainty in the momentum, the uncertainty principle plays a large role in the structure of atoms.

39.79. **IDENTIFY** and **SET UP:** Combining the two equations in the hint gives $pc = \sqrt{K(K+2mc^2)}$ and $\lambda = \dfrac{hc}{\sqrt{K(K+2mc^2)}}$.

EXECUTE: **(a)** With $K = 3mc^2$ this becomes $\lambda = \dfrac{hc}{\sqrt{3mc^2(3mc^2+2mc^2)}} = \dfrac{h}{\sqrt{15}mc}$.

(b) (i) $K = 3mc^2 = 3(9.109\times10^{-31}\ \text{kg})(2.998\times10^{8}\ \text{m/s})^2 = 2.456\times10^{13}\ \text{J} = 1.53\ \text{MeV}$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$\lambda = \frac{h}{\sqrt{15}mc} = \frac{6.626\times10^{-34}\ \text{J}\cdot\text{s}}{\sqrt{15}(9.109\times10^{-31}\ \text{kg})(2.998\times10^{8}\ \text{m/s})} = 6.26\times10^{-13}\ \text{m}$$

(ii) K is proportional to m, so for a proton $K = (m_p/m_e)(1.53\ \text{MeV}) = 1836(1.53\ \text{MeV}) = 2810\ \text{MeV}$

λ is proportional to $1/m$, so for a proton

$\lambda = (m_e/m_p)(6.26\times10^{-13}\ \text{m}) = (1/1836)(6.26\times10^{-13}\ \text{m}) = 3.41\times10^{-16}\ \text{m}.$

EVALUATE: The proton has a larger rest mass energy so its kinetic energy is larger when $K = 3mc^2$. The proton also has larger momentum so has a smaller λ.

39.80. **IDENTIFY:** Apply the Heisenberg Uncertainty Principle. Consider only one component of position and momentum.

SET UP: $\Delta x\Delta p_x \geq \hbar/2$. Take $\Delta x \approx 5.0\times10^{-15}$ m. $K = E - mc^2$. For a proton, $m = 1.67\times10^{-27}$ kg.

EXECUTE: **(a)** $\Delta p_x = \dfrac{\hbar}{2\Delta x} = \dfrac{(1.055\times10^{-34}\ \text{J}\cdot\text{s})}{2(5.0\times10^{-15}\ \text{m})} = 1.1\times10^{-20}\ \text{kg}\cdot\text{m/s}.$

(b) $K = \sqrt{(pc)^2 + (mc^2)^2} - mc^2 = 3.3\times10^{-14}\ \text{J} = 0.21\ \text{MeV}.$

EVALUATE: **(c)** The result of part (b), about 2×10^5 eV, is many orders of magnitude larger than the potential energy of an electron in a hydrogen atom.

39.81. **(a) IDENTIFY** and **SET UP:** $\Delta x\Delta p_x \geq \hbar/2$. Estimate Δx as $\Delta x \approx 5.0\times10^{-15}$ m.

EXECUTE: Then the minimum allowed Δp_x is $\Delta p_x \approx \dfrac{\hbar}{2\Delta x} = \dfrac{1.055\times10^{-34}\ \text{J}\cdot\text{s}}{2(5.0\times10^{-15}\ \text{m})} = 1.1\times10^{-20}\ \text{kg}\cdot\text{m/s}.$

(b) IDENTIFY and **SET UP:** Assume $p \approx 1.1\times10^{-20}$ kg · m/s. Use Eq. (37.39) to calculate E, and then $K = E - mc^2$.

EXECUTE: $E = \sqrt{(mc^2)^2 + (pc)^2}$. $mc^2 = (9.109\times10^{-31}\ \text{kg})(2.998\times10^{8}\ \text{m/s})^2 = 8.187\times10^{-14}$ J.

$pc = (1.1\times10^{-20}\ \text{kg}\cdot\text{m/s})(2.998\times10^{8}\ \text{m/s}) = 3.165\times10^{-12}$ J.

$E = \sqrt{(8.187\times10^{-14}\ \text{J})^2 + (3.165\times10^{-12}\ \text{J})^2} = 3.166\times10^{-12}$ J.

$K = E - mc^2 = 3.166\times10^{-12}\ \text{J} - 8.187\times10^{-14}\ \text{J} = 3.084\times10^{-12}\ \text{J}\times(1\ \text{eV}/1.602\times10^{-19}\ \text{J}) = 19\ \text{MeV}.$

(c) IDENTIFY and **SET UP:** The Coulomb potential energy for a pair of point charges is given by Eq. (23.9). The proton has charge $+e$ and the electron has charge $-e$.

EXECUTE: $U = -\dfrac{ke^2}{r} = -\dfrac{(8.988\times10^{9}\ \text{N}\cdot\text{m}^2/\text{C}^2)(1.602\times10^{-19}\ \text{C})^2}{5.0\times10^{-15}\ \text{m}} = -4.6\times10^{-14}\ \text{J} = -0.29\ \text{MeV}.$

EVALUATE: The kinetic energy of the electron required by the uncertainty principle would be much larger than the magnitude of the negative Coulomb potential energy. The total energy of the electron would be large and positive and the electron could not be bound within the nucleus.

39.82. **IDENTIFY:** Apply the Heisenberg Uncertainty Principle. Let the uncertainty product have its minimum possible value, so $\Delta x\Delta p_x = \hbar/2$.

SET UP: Take the direction of the electron beam to be the x-direction and the direction of motion perpendicular to the beam to be the y-direction.

EXECUTE: **(a)** $\Delta v_y = \dfrac{\Delta p_y}{m} = \dfrac{\hbar}{2m\Delta y} = \dfrac{1.055\times10^{-34}\ \text{J}\cdot\text{s}}{2(9.11\times10^{-31}\ \text{kg})(0.50\times10^{-3}\ \text{m})} = 0.12\ \text{m/s}.$

(b) The uncertainty Δr in the position of the point where the electrons strike the screen is

$\Delta r = \Delta v_y t = \dfrac{\Delta p_y}{m}\dfrac{x}{v_x} = \dfrac{\hbar}{2m\Delta y}\dfrac{x}{\sqrt{2K/m}} = 4.78\times10^{-10}\ \text{m}.$

EVALUATE: **(c)** This is far too small to affect the clarity of the picture.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

39.83. **IDENTIFY** and **SET UP:** $\Delta E\Delta t \geq \hbar/2$. Take the minimum uncertainty product, so $\Delta E = \dfrac{\hbar}{2\Delta t}$, with $\Delta t = 8.4\times10^{-17}$ s. $m = 264m_e$. $\Delta m = \dfrac{\Delta E}{c^2}$.

EXECUTE: $\Delta E = \dfrac{1.055\times10^{-34}\ \text{J}\cdot\text{s}}{2(8.4\times10^{-17}\ \text{s})} = 6.28\times10^{-19}$ J. $\Delta m = \dfrac{6.28\times10^{-19}\ \text{J}}{(3.00\times10^{8}\ \text{m/s})^2} = 7.0\times10^{-36}$ kg.

$$\frac{\Delta m}{m} = \frac{7.0\times10^{-36}\ \text{kg}}{(264)(9.11\times10^{-31}\ \text{kg})} = 2.9\times10^{-8}$$

EVALUATE: The fractional uncertainty in the mass is very small.

39.84. **IDENTIFY:** The insect behaves like a wave as it passes through the hole in the screen.

SET UP: **(a)** For wave behavior to show up, the wavelength of the insect must be of the order of the diameter of the hole. The de Broglie wavelength is $\lambda = h/mv$.

EXECUTE: The de Broglie wavelength of the insect must be of the order of the diameter of the hole in the screen, so $\lambda \approx 4.00$ mm. The de Broglie wavelength gives

$$v = \frac{h}{m\lambda} = \frac{6.626\times10^{-34}\ \text{J}\cdot\text{s}}{(1.25\times10^{-6}\ \text{kg})(0.00400\ \text{m})} = 1.33\times10^{-25}\ \text{m/s}$$

(b) $t = x/v = (0.000500\ \text{m})/(1.33\times10^{-25}\ \text{m/s}) = 3.77\times10^{21}\ \text{s} = 1.4\times10^{10}$ yr

The universe is about 14 billion years old $(1.4\times10^{10}\ \text{yr})$ so this time would be about 85,000 times the age of the universe.

EVALUATE: Don't expect to see a diffracting insect! Wave behavior of particles occurs only at the very small scale.

39.85. **IDENTIFY** and **SET UP:** Use Eq. (39.1) to relate your wavelength and speed.

EXECUTE: **(a)** $\lambda = \dfrac{h}{mv}$, so $v = \dfrac{h}{m\lambda} = \dfrac{6.626\times10^{-34}\ \text{J}\cdot\text{s}}{(60.0\ \text{kg})(1.0\ \text{m})} = 1.1\times10^{-35}$ m/s

(b) $t = \dfrac{\text{distance}}{\text{velocity}} = \dfrac{0.80\ \text{m}}{1.1\times10^{-35}\ \text{m/s}} = 7.3\times10^{34}\ \text{s}(1\ \text{y}/3.156\times10^{7}\ \text{s}) = 2.3\times10^{27}$ y

Since you walk through doorways much more quickly than this, you will not experience diffraction effects.

EVALUATE: A 1-kg object moving at 1 m/s has a de Broglie wavelength $\lambda = 6.6\times10^{-34}$ m, which is exceedingly small. An object like you has a very, very small λ at ordinary speeds and does not exhibit wavelike properties.

39.86. **IDENTIFY:** The transition energy E for the atom and the wavelength λ of the emitted photon are related by $E = \dfrac{hc}{\lambda}$. Apply the Heisenberg Uncertainty Principle in the form $\Delta E\Delta t \geq \dfrac{\hbar}{2}$.

SET UP: Assume the minimum possible value for the uncertainty product, so that $\Delta E\Delta t = \dfrac{\hbar}{2}$.

EXECUTE: **(a)** $E = 2.58\ \text{eV} = 4.13\times10^{-19}$ J, with a wavelength of $\lambda = \dfrac{hc}{E} = 4.82\times10^{-7}\text{m} = 482$ nm

(b) $\Delta E = \dfrac{\hbar}{2\Delta t} = \dfrac{(1.055\times10^{-34}\ \text{J}\cdot\text{s})}{2(1.64\times10^{-7}\ \text{s})} = 3.22\times10^{-28}\ \text{J} = 2.01\times10^{-9}\ \text{eV}.$

(c) $\lambda E = hc$, so $(\Delta\lambda)E + \lambda\Delta E = 0$, and $|\Delta E/E| = |\Delta\lambda/\lambda|$, so

$$\Delta\lambda = \lambda|\Delta E/E| = (4.82\times10^{-7}\ \text{m})\left(\frac{3.22\times10^{-28}\ \text{J}}{4.13\times10^{-19}\ \text{J}}\right) = 3.75\times10^{-16}\ \text{m} = 3.75\times10^{-7}\ \text{nm}.$$

EVALUATE: The finite lifetime of the excited state gives rise to a small spread in the wavelength of the emitted light.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

39.87. **IDENTIFY:** The electrons behave as waves whose wavelength is equal to the de Broglie wavelength.

SET UP: The de Broglie wavelength is $\lambda = h/mv$, and the energy of a photon is $E = hf = hc/\lambda$.

EXECUTE: **(a)** Use the de Broglie wavelength to find the speed of the electron.

$$v = \frac{h}{m\lambda} = \frac{6.626\times10^{-34}\ \text{J}\cdot\text{s}}{(9.11\times10^{-31}\ \text{kg})(1.00\times10^{-9}\ \text{m})} = 7.27\times10^{5}\ \text{m/s}$$

which is much less than the speed of light, so it is nonrelativistic.

(b) Energy conservation gives $eV = \frac{1}{2}mv^2$.

$V = mv^2/2e = (9.11\times10^{-31}\ \text{kg})(7.27\times10^{5}\ \text{m/s})^2/[2(1.60\times10^{-19}\ \text{C})] = 1.51\ \text{V}$

(c) $K = eV = e(1.51\ \text{V}) = 1.51\ \text{eV}$, which is about ¼ the potential energy of the NaCl molecule, so the electron would not be too damaging.

(d) $E = hc/\lambda = (4.136\times10^{-15}\ \text{eV s})(3.00\times10^{8}\ \text{m/s})/(1.00\times10^{-9}\ \text{m}) = 1240\ \text{eV}$

which would certainly destroy the molecules under study.

EVALUATE: As we have seen in Problems 39.73 and 39.76, when a particle and a photon have the same wavelength, the photon has much more energy.

39.88. **IDENTIFY:** Assume both the x rays and electrons are at normal incidence and scatter from the surface plane of the crystal, so the maxima are located by $d\sin\theta = m\lambda$, where d is the separation between adjacent atoms in the surface plane.

SET UP: Let primed variables refer to the electrons. $\lambda' = \dfrac{h}{p'} = \dfrac{h}{\sqrt{2mE'}}$.

EXECUTE: $\sin\theta' = \dfrac{\lambda'}{\lambda}\sin\theta$, and $\lambda' = (h/p') = (h/\sqrt{2mE'})$, and so $\theta' = \arcsin\left(\dfrac{h}{\lambda\sqrt{2mE'}}\sin\theta\right)$.

$$\theta' = \arcsin\left(\frac{(6.63\times10^{-34}\ \text{J}\cdot\text{s})\sin35.8^\circ}{(3.00\times10^{-11}\ \text{m})\sqrt{2(9.11\times10^{-31}\ \text{kg})(4.50\times10^{+3}\ \text{eV})(1.60\times10^{-19}\ \text{J/eV})}}\right) = 20.9^\circ.$$

EVALUATE: The x rays and electrons have different wavelengths and the $m = 1$ maxima occur at different angles.

39.89. **IDENTIFY:** The interference pattern for electrons with de Broglie wavelength λ is the same as for light with wavelength λ.

SET UP: For an electron, $\lambda = \dfrac{h}{p} = \dfrac{h}{\sqrt{2mE}}$.

EXECUTE: **(a)** The maxima occur when $2d\sin\theta = m\lambda$.

(b) $\lambda = \dfrac{(6.63\times10^{-34}\ \text{J}\cdot\text{s})}{\sqrt{2(9.11\times10^{-37}\ \text{kg})(71.0\ \text{eV})(1.60\times10^{-19}\ \text{J/eV})}} = 1.46\times10^{-10}\,\text{m} = 0.146\ \text{nm}$. $\theta = \sin^{-1}\left(\dfrac{m\lambda}{2d}\right)$.

(Note: This m is the order of the maximum, not the mass.) $\theta = \sin^{-1}\left(\dfrac{(1)(1.46\times10^{-10}\ \text{m})}{2(9.10\times10^{-11}\ \text{m})}\right) = 53.3^\circ$.

EVALUATE: **(c)** The work function of the metal acts like an attractive potential increasing the kinetic energy of incoming electrons by $e\phi$. An increase in kinetic energy is an increase in momentum that leads to a smaller wavelength. A smaller wavelength gives a smaller angle θ (see part (b)).

39.90. **IDENTIFY:** The photon is emitted as the atom returns to the lower energy state. The duration of the excited state limits the energy of that state due to the uncertainty principle.

SET UP: The wavelength λ of the photon is related to the transition energy E of the atom by $E = \dfrac{hc}{\lambda}$.

$\Delta E\,\Delta t \geq \hbar/2$. The minimum uncertainty in energy is $\Delta E \geq \dfrac{\hbar}{2\Delta t}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: **(a)** The photon energy equals the transition energy of the atom, 3.50 eV.

$$\lambda = \frac{hc}{E} = \frac{(4.136\times10^{-15}\ \text{eV}\cdot\text{s})(3.00\times10^{8}\ \text{m/s})}{3.50\ \text{eV}} = 355\ \text{nm}.$$

(b) $\Delta E = \dfrac{1.055\times10^{-34}\ \text{J}\cdot\text{s}}{2(4.0\times10^{-6}\ \text{s})} = 1.32\times10^{-29}\ \text{J} = 8.2\times10^{-11}\ \text{eV}.$

EVALUATE: The uncertainty in the energy could be larger than that found in (b), but never smaller.

39.91. **IDENTIFY:** The wave (light or electron matter wave) having less energy will cause less damage to the virus.

SET UP: For a photon $E_{\text{ph}} = \dfrac{hc}{\lambda} = \dfrac{1.24\times10^{-6}\ \text{eV}\cdot\text{m}}{\lambda}$. For an electron $E_{\text{e}} = \dfrac{p^2}{2m} = \dfrac{h^2}{2m\lambda^2}$.

EXECUTE: **(a)** $E = \dfrac{hc}{\lambda} = \dfrac{1.24\times10^{-6}\ \text{eV}\cdot\text{m}}{5.00\times10^{-9}\ \text{m}} = 248\ \text{eV}.$

(b) $E_{\text{e}} = \dfrac{h^2}{2m\lambda^2} = \dfrac{(6.63\times10^{-34}\ \text{J}\cdot\text{s})^2}{2(9.11\times10^{-31}\ \text{kg})(5.00\times10^{-9}\ \text{m})^2} = 9.65\times10^{-21}\ \text{J} = 0.0603\ \text{eV}.$

EVALUATE: The electron has much less energy than a photon of the same wavelength and therefore would cause much less damage to the virus.

39.92. **IDENTIFY** and **SET UP:** Assume $px \approx h$ and use this to express E as a function of x. E is a minimum for that x that satisfies $\dfrac{dE}{dx} = 0$.

EXECUTE: **(a)** Using the given approximation, $E = \dfrac{1}{2}((h/x)^2/m + kx^2),\ (dE/dx) = kx - (h^2/mx^3),$ and the minimum energy occurs when $kx = (h^2/mx^3)$, or $x^2 = \dfrac{h}{\sqrt{mk}}$. The minimum energy is then $h\sqrt{k/m}$.

EVALUATE: **(b)** $U = \frac{1}{2}kx^2 = \dfrac{h}{2}\sqrt{\dfrac{k}{m}}.$ $K = \dfrac{p^2}{2m} = \dfrac{h^2}{2mx^2} = \dfrac{h}{2}\sqrt{\dfrac{k}{m}}.$ At this x the kinetic and potential energies are the same.

39.93. **(a) IDENTIFY** and **SET UP:** $U = A|x|$. Eq. (7.17) relates force and potential. The slope of the function $A|x|$ is not continuous at $x = 0$ so we must consider the regions $x > 0$ and $x < 0$ separately.

EXECUTE: For $x > 0, |x| = x$ so $U = Ax$ and $F = -\dfrac{d(Ax)}{dx} = -A.$ For $x < 0,\ |x| = -x$ so $U = -Ax$ and $F = -\dfrac{d(-Ax)}{dx} = +A.$ We can write this result as $F = -A|x|/x$, valid for all x except for $x = 0$.

(b) IDENTIFY and **SET UP:** Use the uncertainty principle, expressed as $\Delta p \Delta x \approx h,$ and as in Problem 39.80 estimate Δp by p and Δx by x. Use this to write the energy E of the particle as a function of x. Find the value of x that gives the minimum E and then find the minimum E.

EXECUTE: $E = K + U = \dfrac{p^2}{2m} + A|x|$

$px \approx h$, so $p \approx h/x$

Then $E \approx \dfrac{h^2}{2mx^2} + A|x|.$

For $x > 0,\ E = \dfrac{h^2}{2mx^2} + Ax.$

To find the value of x that gives minimum E set $\dfrac{dE}{dx} = 0.$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$0 = \frac{-2h^2}{2mx^3} + A$$

$$x^3 = \frac{h^2}{mA} \text{ and } x = \left(\frac{h^2}{mA}\right)^{1/3}$$

With this x the minimum E is

$$E = \frac{h^2}{2m}\left(\frac{mA}{h^2}\right)^{2/3} + A\left(\frac{h^2}{mA}\right)^{1/3} = \frac{1}{2}h^{2/3}m^{-1/3}A^{2/3} + h^{2/3}m^{-1/3}A^{2/3}$$

$$E = \frac{3}{2}\left(\frac{h^2A^2}{m}\right)^{1/3}$$

EVALUATE: The potential well is shaped like a V. The larger A is, the steeper the slope of U and the smaller the region to which the particle is confined and the greater is its energy. Note that for the x that minimizes E, $2K = U$.

39.94. **(a) IDENTIFY** and **SET UP:** Let the y-direction be from the thrower to the catcher, and let the x-direction be horizontal and perpendicular to the y-direction. A cube with volume $V = 125\ \text{cm}^3 = 0.125 \times 10^{-3}\ \text{m}^3$ has side length $l = V^{1/3} = (0.125 \times 10^{-3}\ \text{m}^3)^{1/3} = 0.050$ m. Thus estimate Δx as $\Delta x \approx 0.050$ m. Use the uncertainty principle to estimate Δp_x.

EXECUTE: $\Delta x \Delta p_x \geq \hbar/2$ then gives $\Delta p_x \approx \dfrac{\hbar}{2\Delta x} = \dfrac{0.01055\ \text{J} \cdot \text{s}}{2(0.050\ \text{m})} = 0.11\ \text{kg} \cdot \text{m/s}$. (The value of $\hbar$ in this other universe has been used.)

(b) IDENTIFY and **SET UP:** $\Delta x = (\Delta v_x)t$ is the uncertainty in the x-coordinate of the ball when it reaches the catcher, where t is the time it takes the ball to reach the second student. Obtain Δv_x from Δp_x.

EXECUTE: The uncertainty in the ball's horizontal velocity is $\Delta v_x = \dfrac{\Delta p_x}{m} = \dfrac{0.11\ \text{kg} \cdot \text{m/s}}{0.25\ \text{kg}} = 0.42$ m/s.

The time it takes the ball to travel to the second student is $t = \dfrac{12\ \text{m}}{6.0\ \text{m/s}} = 2.0$ s. The uncertainty in the x-coordinate of the ball when it reaches the second student that is introduced by Δv_x is $\Delta x = (\Delta v_x)t = (0.42\ \text{m/s})(2.0\ \text{s}) = 0.84$ m. The ball could miss the second student by about 0.84 m.

EVALUATE: A game of catch would be very different in this universe. We don't notice the effects of the uncertainty principle in everyday life because h is so small.

39.95. **IDENTIFY** and **SET UP:** The period was found in Exercise 39.29b: $T = \dfrac{4\varepsilon_0^2 n^3 h^3}{me^4}$. Eq. (39.14) gives the energy of state n of a hydrogen atom.

EXECUTE: **(a)** The frequency is $f = \dfrac{1}{T} = \dfrac{me^4}{4\varepsilon_0^2 n^3 h^3}$.

(b) Eq. (39.5) tells us that $f = \dfrac{1}{h}(E_2 - E_1)$. So $f = \dfrac{me^4}{8\varepsilon_0^2 h^3}\left(\dfrac{1}{n_2^2} - \dfrac{1}{n_1^2}\right)$ (from Eq. (39.14)). If $n_2 = n$ and $n_1 = n + 1$, then $\dfrac{1}{n_2^2} - \dfrac{1}{n_1^2} = \dfrac{1}{n^2} - \dfrac{1}{(n+1)^2} = \dfrac{1}{n^2}\left(1 - \dfrac{1}{(1+1/n)^2}\right) \approx \dfrac{1}{n^2}\left(1 - \left(1 - \dfrac{2}{n} + \ldots\right)\right) = \dfrac{2}{n^3}$.

Therefore, for large n, $f \approx \dfrac{me^4}{4\varepsilon_0^2 n^3 h^3}$.

EVALUATE: We have shown that for large n we obtain the classical result that the frequency of revolution of the electron is equal to the frequency of the radiation it emits.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

39.96. **IDENTIFY:** Follow the steps specified in the hint.

SET UP: The value of Δx_i that minimizes Δx_f satisfies $\dfrac{d(\Delta x_f)}{d(\Delta x_i)} = 0.$

EXECUTE: Time of flight of the marble, from a free-fall kinematic equation is just $t = \sqrt{\dfrac{2y}{g}} = \sqrt{\dfrac{2(25.0\text{ m})}{9.80\text{ m/s}^2}} = 2.26\text{ s}.$ $\Delta x_f = \Delta x_i + (\Delta v_x)t = \Delta x_i + \left(\dfrac{\Delta p_x}{m}\right)t = \dfrac{\hbar t}{2\Delta x_i m} + \Delta x_i.$ To minimize Δx_f with respect to Δx_i, $\dfrac{d(\Delta x_f)}{d(\Delta x_i)} = 0 = \dfrac{-\hbar t}{2m(\Delta x_i)^2} + 1 \Rightarrow \Delta x_i(\text{min}) = \sqrt{\left(\dfrac{\hbar t}{2m}\right)}$

$\Rightarrow \Delta x_f(\text{min}) = \sqrt{\dfrac{\hbar t}{2m}} + \sqrt{\dfrac{\hbar t}{2m}} = \sqrt{\dfrac{2\hbar t}{m}} = \sqrt{\dfrac{2(1.055\times10^{-34}\text{ J}\cdot\text{s})(2.26\text{ s})}{0.0200\text{ kg}}} = 1.54\times10^{-16}\text{ m} = 1.54\times10^{-7}\text{ nm}.$

EVALUATE: The uncertainty introduced by the uncertainty principle is completely negligible in this situation.

40

QUANTUM MECHANICS

40.1. **IDENTIFY:** Using the momentum of the free electron, we can calculate k and ω and use these to express its wave function.

SET UP: $\Psi(x,t) = Ae^{ikx}e^{-i\omega t}$, $k = p/\hbar$, and $\omega = \hbar k^2/2m$.

EXECUTE: $k = \dfrac{p}{\hbar} = -\dfrac{4.50\times10^{-24}\ \text{kg}\cdot\text{m/s}}{1.055\times10^{-34}\ \text{J}\cdot\text{s}} = -4.27\times10^{10}\ \text{m}^{-1}$.

$\omega = \dfrac{\hbar k^2}{2m} = \dfrac{(1.055\times10^{-34}\ \text{J}\cdot\text{s})(4.27\times10^{10}\ \text{m}^{-1})^2}{2(9.108\times10^{-31}\ \text{kg})} = 1.05\times10^{17}\ \text{s}^{-1}$.

$\Psi(x,t) = Ae^{-i[4.27\times10^{10}\ \text{m}^{-1})x}e^{-i[1.05\times10^{17}\ \text{s}^{-1}]t}$.

EVALUATE: The wave function depends on position and time.

40.2. **IDENTIFY:** Using the known wave function for the particle, we want to find where its probability function is a maximum.

SET UP: $|\Psi(x,t)|^2 = |A|^2[e^{ikx}e^{-i\omega t} - e^{2ikx}e^{-4i\omega t}][e^{-ikx}e^{+i\omega t} - e^{-2ikx}e^{+4i\omega t}]$.

$|\Psi(x,t)|^2 = |A|^2(2-[e^{-i(kx-3\omega t)} + e^{+i(kx-3\omega t)}]) = 2|A|^2(1-\cos(kx-3\omega t))$.

EXECUTE: **(a)** For $t = 0$, $|\Psi(x,t)|^2 = 2|A|^2(1-\cos(kx))$. $|\Psi(x,t)|^2$ is a maximum when $\cos(kx) = -1$ and this happens when $kx = (2n+1)\pi$, $n = 0,1,\ldots$. $|\Psi(x,t)|^2$ is a maximum for $x = \dfrac{\pi}{k}, \dfrac{3\pi}{k}$, etc.

(b) $t = \dfrac{2\pi}{\omega}$ and $3\omega t = 6\pi$. $|\Psi(x,t)|^2 = 2|A|^2(1-\cos(kx-6\pi))$. Maximum for $kx - 6\pi = \pi, 3\pi,\ldots$, which gives maxima when $x = \dfrac{7\pi}{k}, \dfrac{9\pi}{k}$.

(c) From the results for parts (a) and (b), $v_{\text{av}} = \dfrac{7\pi/k - \pi/k}{2\pi/\omega} = \dfrac{3\omega}{k}$. $v_{\text{av}} = \dfrac{\omega_2 - \omega_1}{k_2 - k_1}$ with $\omega_2 = 4\omega$, $\omega_1 = \omega$, $k_2 = 2k$ and $k_1 = k$ gives $v_{\text{av}} = \dfrac{3\omega}{k}$.

EVALUATE: The expressions in part (c) agree.

40.3. **IDENTIFY:** Use the wave function from Example 40.1.

SET UP: $|\Psi(x,t)|^2 = 2|A|^2\{1+\cos[(k_2-k_1)x-(\omega_2-\omega_1)t]\}$. $k_2 = 3k_1 = 3k$. $\omega = \dfrac{\hbar k^2}{2m}$, so $\omega_2 = 9\omega_1 = 9\omega$.

$|\Psi(x,t)|^2 = 2|A|^2\{1+\cos(2kx-8\omega t)\}$.

EXECUTE: **(a)** At $t = 2\pi/\omega$, $|\Psi(x,t)|^2 = 2|A|^2\{1+\cos(2kx-16\pi)\}$. $|\Psi(x,t)|^2$ is maximum for $\cos(2kx-16\pi) = 1$. This happens for $2kx - 16\pi = 0, 2\pi,\ldots$. Smallest positive x where $|\Psi(x,t)|^2$ is a maximum is $x = \dfrac{8\pi}{k}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) From the result of part (a), $v_{\text{av}} = \dfrac{8\pi/k}{2\pi/\omega} = \dfrac{4\omega}{k}$. $v_{\text{av}} = \dfrac{\omega_2 - \omega_1}{k_2 - k_1} = \dfrac{8\omega}{2k} = \dfrac{4\omega}{k}$.

EVALUATE: The two expressions agree.

40.4. **IDENTIFY:** We have a free particle, described in Example 40.1.

SET UP and **EXECUTE:** $v_{\text{av}} = \dfrac{\omega_2 - \omega_1}{k_2 - k_1} = \dfrac{\hbar}{2m}\dfrac{(k_2^2 - k_1^2)}{k_2 - k_1} = \dfrac{\hbar}{2m}\dfrac{(k_2 + k_1)(k_2 - k_1)}{k_2 - k_1} = \dfrac{\hbar}{2m}(k_2 + k_1) = \dfrac{p_{\text{av}}}{m}$.

EVALUATE: This is the same as the classical physics result, $v = p/m = mv/m = v$.

40.5. **IDENTIFY** and **SET UP:** $\psi(x) = A\sin kx$. The position probability density is given by $|\psi(x)|^2 = A^2\sin^2 kx$.

EXECUTE: **(a)** The probability is highest where $\sin kx = 1$ so $kx = 2\pi x/\lambda = n\pi/2$, $n = 1, 3, 5, \ldots$
$x = n\lambda/4$, $n = 1, 3, 5, \ldots$ so $x = \lambda/4, 3\lambda/4, 5\lambda/4, \ldots$

(b) The probability of finding the particle is zero where $|\psi|^2 = 0$, which occurs where $\sin kx = 0$ and
$kx = 2\pi x/\lambda = n\pi$, $n = 0, 1, 2, \ldots$
$x = n\lambda/2, n = 0, 1, 2, \ldots$ so $x = 0, \lambda/2, \lambda, 3\lambda/2, \ldots$

EVALUATE: The situation is analogous to a standing wave, with the probability analogous to the square of the amplitude of the standing wave.

40.6. **IDENTIFY** and **SET UP:** $|\Psi|^2 = \Psi^*\Psi$

EXECUTE: $\Psi^* = \psi^* \sin\omega t$, so $|\Psi|^2 = \Psi^*\Psi = \psi^*\psi\sin^2\omega t = |\psi|^2\sin^2\omega t$. $|\Psi|^2$ is not time-independent, so Ψ is not the wavefunction for a stationary state.

EVALUATE: $\Psi = \psi e^{i\omega\phi} = \psi(\cos\omega t + i\sin\omega t)$ is a wavefunction for a stationary state, since for it $|\Psi|^2 = |\psi|^2$, which is time independent.

40.7. **IDENTIFY:** Determine whether or not $-\dfrac{\hbar^2}{2m}\dfrac{d^2\psi}{dx^2} + U\psi$ is equal to $E\psi$, for some value of E.

SET UP: $-\dfrac{\hbar^2}{2m}\dfrac{d^2\psi_1}{dx^2} + U\psi_1 = E_1\psi_1$ and $-\dfrac{\hbar^2}{2m}\dfrac{d^2\psi_2}{dx^2} + U\psi_2 = E_2\psi_2$

EXECUTE: $-\dfrac{\hbar^2}{2m}\dfrac{d^2\psi}{dx^2} + U\psi = BE_1\psi_1 + CE_2\psi_2$. If ψ were a solution with energy E, then $BE_1\psi_1 + CE_2\psi_2 = BE\psi_1 + CE\psi_2$ or $B(E_1 - E)\psi_1 = C(E - E_2)\psi_2$. This would mean that ψ_1 is a constant multiple of ψ_2, and ψ_1 and ψ_2 would be wave functions with the same energy. However, $E_1 \neq E_2$, so this is not possible, and ψ cannot be a solution to Eq. (40.23).

EVALUATE: ψ is a solution if $E_1 = E_2$; see Exercise 40.9.

40.8. **IDENTIFY:** Apply the Heisenberg Uncertainty Principle in the form $\Delta x\Delta p_x \geq \hbar/2$.

SET UP: The uncertainty in the particle position is proportional to the width of $\psi(x)$.

EXECUTE: The width of $\psi(x)$ is inversely proportional to $\sqrt{\alpha}$. This can be seen by either plotting the function for different values of α or by finding the full width at half-maximum. The particle's uncertainty in position decreases with increasing α.
(b) Since the uncertainty in position decreases, the uncertainty in momentum must increase.
EVALUATE: As α increases, the function $A(k)$ in Eq. (40.19) must become broader.

40.9. **IDENTIFY:** Determine whether or not $-\dfrac{\hbar^2}{2m}\dfrac{d^2\psi}{dx^2} + U\psi$ is equal to $E\psi$.

SET UP: ψ_1 and ψ_2 are solutions with energy E means that $-\dfrac{\hbar^2}{2m}\dfrac{d^2\psi_1}{dx^2} + U\psi_1 = E\psi_1$ and
$-\dfrac{\hbar^2}{2m}\dfrac{d^2\psi_2}{dx^2} + U\psi_2 = E\psi_2$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: Eq. (40.23): $\frac{-\hbar^2}{2m}\frac{d^2\psi}{dx^2}+U\psi=E\psi$. Let $\psi=A\psi_1+B\psi_2$

$\Rightarrow \frac{-\hbar^2}{2m}\frac{d^2}{dx^2}(A\psi_1+B\psi_2)+U(A\psi_1+B\psi_2)=E(A\psi_1+B\psi_2)$

$\Rightarrow A\left(-\frac{\hbar^2}{2m}\frac{d^2\psi_1}{dx^2}+U\psi_1-E\psi_1\right)+B\left(-\frac{\hbar^2}{2m}\frac{d^2\psi_2}{dx^2}+U\psi_2-E\psi_2\right)=0$. But each of ψ_1 and ψ_2 satisfy Schrödinger's equation separately so the equation still holds true, for any A or B.

EVALUATE: If ψ_1 and ψ_2 are solutions of the Schrodinger equation for different energies, then $\psi=B\psi_1+C\psi_2$ is not a solution (Exercise 40.7).

40.10. **IDENTIFY:** To describe a real situation, a wave function must be normalizable.

SET UP: $|\psi|^2\,dV$ is the probability that the particle is found in volume dV. Since the particle must be *somewhere*, ψ must have the property that $\int|\psi|^2dV=1$ when the integral is taken over all space.

EXECUTE: **(a)** For normalization of the one-dimensional wave function, we have

$1=\int_{-\infty}^{\infty}|\psi|^2dx=\int_{-\infty}^{0}(Ae^{bx})^2dx+\int_{0}^{\infty}(Ae^{-bx})^2dx=\int_{-\infty}^{0}A^2e^{2bx}dx+\int_{0}^{\infty}A^2e^{-2bx}dx.$

$1=A^2\left\{\frac{e^{2bx}}{2b}\Big|_{-\infty}^{0}+\frac{e^{-2bx}}{-2b}\Big|_{0}^{\infty}\right\}=\frac{A^2}{b}$, which gives $A=\sqrt{b}=\sqrt{2.00\text{ m}^{-1}}=1.41\text{ m}^{-1/2}$

(b) The graph of the wavefunction versus x is given in Figure 40.10.

(c) (i) $P=\int_{-0.500\text{ m}}^{+5.00\text{ m}}|\psi|^2dx=2\int_{0}^{+5.00\text{ m}}A^2e^{-2bx}dx$, where we have used the fact that the wave function is an even function of x. Evaluating the integral gives

$$P=\frac{-A^2}{b}(e^{-2b(0.500\text{ m})}-1)=\frac{-(2.00\text{ m}^{-1})}{2.00\text{ m}^{-1}}(e^{-2.00}-1)=0.865$$

There is a little more than an 86% probability that the particle will be found within 50 cm of the origin.

(ii) $P=\int_{-\infty}^{0}(Ae^{bx})^2dx=\int_{-\infty}^{0}A^2e^{2bx}dx=\frac{A^2}{2b}=\frac{2.00\text{ m}^{-1}}{2(2.00\text{ m}^{-1})}=\frac{1}{2}=0.500$

There is a 50-50 chance that the particle will be found to the left of the origin, which agrees with the fact that the wave function is symmetric about the y-axis.

(iii) $P=\int_{0.500\text{ m}}^{1.00\text{ m}}A^2e^{-2bx}dx$

$$=\frac{A^2}{-2b}(e^{-2(2.00\text{ m}^{-1})(1.00\text{ m})}-e^{-2(2.00\text{ m}^{-1})(0.500\text{ m})})=-\frac{1}{2}(e^{-4}-e^{-2})=0.0585$$

EVALUATE: There is little chance of finding the particle in regions where the wave function is small.

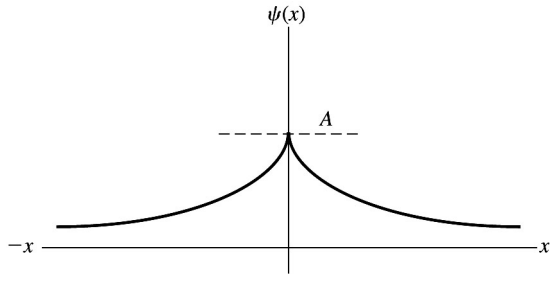

Figure 40.10

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

40.11. **IDENTIFY** and **SET UP:** The energy levels for a particle in a box are given by $E_n = \dfrac{n^2h^2}{8mL^2}$.

EXECUTE: **(a)** The lowest level is for $n = 1$, and $E_1 = \dfrac{(1)(6.626\times10^{-34}\ \text{J}\cdot\text{s})^2}{8(0.20\ \text{kg})(1.3\ \text{m})^2} = 1.6\times10^{-67}\ \text{J}$.

(b) $E = \dfrac{1}{2}mv^2$ so $v = \sqrt{\dfrac{2E}{m}} = \sqrt{\dfrac{2(1.2\times10^{-67}\ \text{J})}{0.20\ \text{kg}}} = 1.3\times10^{-33}\ \text{m/s}$. If the ball has this speed the time it would take it to travel from one side of the table to the other is

$t = \dfrac{1.3\ \text{m}}{1.3\times10^{-33}\ \text{m/s}} = 1.0\times10^{33}\ \text{s}$.

(c) $E_1 = \dfrac{h^2}{8mL^2}$, $E_2 = 4E_1$, so $\Delta E = E_2 - E_1 = 3E_1 = 3(1.6\times10^{-67}\ \text{J}) = 4.9\times10^{-67}\ \text{J}$.

(d) EVALUATE: No, quantum mechanical effects are not important for the game of billiards. The discrete, quantized nature of the energy levels is completely unobservable.

40.12. **IDENTIFY:** Solve Eq. (40.31) for L.

SET UP: The ground state has $n = 1$.

EXECUTE: $L = \dfrac{h}{\sqrt{8mE_1}} = \dfrac{(6.626\times10^{-34}\ \text{J}\cdot\text{s})}{\sqrt{8(1.673\times10^{-27}\ \text{kg})(5.0\times10^{6}\ \text{eV})(1.602\times10^{-19}\ \text{J/eV})}} = 6.4\times10^{-15}\ \text{m}$

EVALUATE: The value of L we calculated is on the order of the diameter of a nucleus.

40.13. **IDENTIFY:** An electron in the lowest energy state in this box must have the same energy as it would in the ground state of hydrogen.

SET UP: The energy of the n^{th} level of an electron in a box is $E_n = \dfrac{nh^2}{8mL^2}$.

EXECUTE: An electron in the ground state of hydrogen has an energy of -13.6 eV, so find the width corresponding to an energy of $E_1 = 13.6$ eV. Solving for L gives

$L = \dfrac{h}{\sqrt{8mE_1}} = \dfrac{(6.626\times10^{-34}\ \text{J}\cdot\text{s})}{\sqrt{8(9.11\times10^{-31}\ \text{kg})(13.6\ \text{eV})(1.602\times10^{-19}\ \text{J/eV})}} = 1.66\times10^{-10}\ \text{m}$.

EVALUATE: This width is of the same order of magnitude as the diameter of a Bohr atom with the electron in the K shell.

40.14. **IDENTIFY** and **SET UP:** The energy of a photon is $E = hf = h\dfrac{c}{\lambda}$. The energy levels of a particle in a box are given by Eq. (40.31).

EXECUTE: **(a)** $E = (6.63\times10^{-34}\ \text{J}\cdot\text{s})\dfrac{(3.00\times10^{8}\ \text{m/s})}{(122\times10^{-9}\ \text{m})} = 1.63\times10^{-18}\ \text{J}$. $\Delta E = \dfrac{h^2}{8mL^2}(n_1^2 - n_2^2)$.

$L = \sqrt{\dfrac{h^2(n_1^2 - n_2^2)}{8m\Delta E}} = \sqrt{\dfrac{(6.63\times10^{-34}\ \text{J}\cdot\text{s})^2(2^2 - 1^2)}{8(9.11\times10^{-31}\ \text{kg})(1.63\times10^{-18}\ \text{J})}} = 3.33\times10^{-10}\ \text{m}$.

(b) The ground state energy for an electron in a box of the calculated dimensions is

$E = \dfrac{h^2}{8mL^2} = \dfrac{(6.63\times10^{-34}\ \text{J}\cdot\text{s})^2}{8(9.11\times10^{-31}\ \text{kg})(3.33\times10^{-10}\ \text{m})^2} = 5.43\times10^{-19}\ \text{J} = 3.40\ \text{eV}$ (one-third of the original photon energy), which does not correspond to the -13.6 eV ground state energy of the hydrogen atom.

EVALUATE: **(c)** Note that the energy levels for a particle in a box are proportional to n^2, whereas the energy levels for the hydrogen atom are proportional to $-\dfrac{1}{n^2}$. A one-dimensional box is not a good model for a hydrogen atom.

40.15. **IDENTIFY** and **SET UP:** Eq. (40.31) gives the energy levels. Use this to obtain an expression for $E_2 - E_1$ and use the value given for this energy difference to solve for L.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: Ground state energy is $E_1 = \dfrac{h^2}{8mL^2}$; first excited state energy is $E_2 = \dfrac{4h^2}{8mL^2}$. The energy separation between these two levels is $\Delta E = E_2 - E_1 = \dfrac{3h^2}{8mL^2}$. This gives $L = h\sqrt{\dfrac{3}{8m\Delta E}} =$

$$L = 6.626\times10^{-34}\ \text{J}\cdot\text{s}\sqrt{\frac{3}{8(9.109\times10^{-31}\ \text{kg})(3.0\ \text{eV})(1.602\times10^{-19}\ \text{J/1 eV})}} = 6.1\times10^{-10}\ \text{m} = 0.61\ \text{nm}.$$

EVALUATE: This energy difference is typical for an atom and L is comparable to the size of an atom.

40.16. **IDENTIFY:** The energy of the absorbed photon must be equal to the energy difference between the two states.

SET UP and **EXECUTE:** The second excited state energy is $E_3 = \dfrac{9\pi^2\hbar^2}{2mL^2}$. The ground state energy is $E_1 = \dfrac{\pi^2\hbar^2}{2mL^2}$. $E_1 = 1.00$ eV, so $E_3 = 9.00$ eV. For the transition $\Delta E = \dfrac{4\pi^2\hbar^2}{mL^2}$. $\dfrac{hc}{\lambda} = \Delta E$.

$$\lambda = \frac{hc}{\Delta E} = \frac{(4.136\times10^{-15}\ \text{eV}\cdot\text{s})(2.998\times10^{8}\ \text{m/s})}{8.00\ \text{eV}} = 1.55\times10^{-7}\ \text{m} = 155\ \text{nm}.$$

EVALUATE: This wavelength is much shorter than those of visible light.

40.17. **IDENTIFY:** If the given wave function is a solution to the Schrödinger equation, we will get an identity when we substitute that wave function into the Schrödinger equation.

SET UP: We must substitute the equation $\Psi(x,t) = \sqrt{\dfrac{2}{L}}\sin\left(\dfrac{n\pi x}{L}\right)e^{-iE_nt/\hbar}$ into the one-dimensional Schrödinger equation $-\dfrac{\hbar^2}{2m}\dfrac{d^2\psi(x)}{dx^2} + U(x)\psi(x) = E\psi(x)$.

EXECUTE: Taking the second derivative of $\Psi(x,t)$ with respect to x gives $\dfrac{d^2\Psi(x,t)}{dx^2} = -\left(\dfrac{n\pi}{L}\right)^2\Psi(x,t)$.

Substituting this result into $-\dfrac{\hbar^2}{2m}\dfrac{d^2\psi(x)}{dx^2} + U(x)\psi(x) = E\psi(x)$, we get $\dfrac{\hbar^2}{2m}\left(\dfrac{n\pi}{L}\right)^2\Psi(x,t) = E\Psi(x,t)$ which gives $E_n = \dfrac{\hbar^2}{2m}\left(\dfrac{n\pi}{L}\right)^2$, the energies of a particle in a box.

EVALUATE: Since this process gives us the energies of a particle in a box, the given wave function is a solution to the Schrödinger equation

40.18. **IDENTIFY:** Find x where ψ_1 is zero and where it is a maximum.

SET UP: $\psi_1 = \sqrt{\dfrac{2}{L}}\sin\left(\dfrac{\pi x}{L}\right)$.

EXECUTE: **(a)** The wave function for $n = 1$ vanishes only at $x = 0$ and $x = L$ in the range $0 \le x \le L$.
(b) In the range for x, the sine term is a maximum only at the middle of the box, $x = L/2$.

EVALUATE: **(c)** The answers to parts (a) and (b) are consistent with the figure.

40.19. **IDENTIFY** and **SET UP:** For the $n = 2$ first excited state the normalized wave function is given by Eq. (40.35). $\psi_2(x) = \sqrt{\dfrac{2}{L}}\sin\left(\dfrac{2\pi x}{L}\right)$. $|\psi_2(x)|^2\,dx = \dfrac{2}{L}\sin^2\left(\dfrac{2\pi x}{L}\right)dx$. Examine $|\psi_2(x)|^2\,dx$ and find where it is zero and where it is maximum.

EXECUTE: **(a)** $|\psi_2|^2\,dx = 0$ implies $\sin\left(\dfrac{2\pi x}{L}\right) = 0$

$\dfrac{2\pi x}{L} = m\pi$, $m = 0, 1, 2, \ldots$; $x = m(L/2)$

For $m = 0$, $x = 0$; for $m = 1$, $x = L/2$; for $m = 2$, $x = L$

The probability of finding the particle is zero at $x = 0$, $L/2$, and L.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) $|\psi_2|^2\,dx$ is maximum when $\sin\left(\dfrac{2\pi x}{L}\right)=\pm 1$

$\dfrac{2\pi x}{L}=m(\pi/2),\ m=1,\ 3,\ 5,\ \ldots\ ;\ x=m(L/4)$

For $m=1,\ x=L/4;$ for $m=3,\ x=3L/4$

The probability of finding the particle is largest at $x=L/4$ and $3L/4$.

(c) EVALUATE: The answers to part (a) correspond to the zeros of $|\psi|^2$ shown in Figure 40.12 in the textbook and the answers to part (b) correspond to the two values of x where $|\psi|^2$ in the figure is maximum.

40.20. **IDENTIFY:** Evaluate $\dfrac{d^2\psi}{dx^2}$ and see if Eq. (40.25) is satisfied. $\psi(x)$ must be zero at the walls, where $U\to\infty$.

SET UP: $\dfrac{d}{dx}\sin kx=k\cos kx.\ \ \dfrac{d}{dx}\cos kx=-k\sin kx.$

EXECUTE: **(a)** $\dfrac{d^2\psi}{dx^2}=-k^2\psi,$ and for ψ to be a solution of Eq. (40.25), $k^2=E\dfrac{2m}{\hbar^2}.$

(b) The wave function must vanish at the rigid walls; the given function will vanish at $x=0$ for any k, but to vanish at $x=L,\ kL=n\pi$ for integer n.

EVALUATE: From Eq. (40.31), $E_n=\dfrac{n^2\pi^2\hbar^2}{2mL^2},$ so $k_n=\dfrac{n\pi}{L}$ and $\psi=A\sin kx$ is the same as ψ_n in Eq. (40.32), except for a different symbol for the normalization constant

40.21. **(a) IDENTIFY** and **SET UP:** $\psi=A\cos kx.$ Calculate $d\psi^2/dx^2$ and substitute into Eq. (40.25) to see if this equation is satisfied.

EXECUTE: Eq. (40.25): $-\dfrac{h^2}{8\pi^2 m}\dfrac{d^2\psi}{dx^2}=E\psi$

$\dfrac{d\psi}{dx}=A(-k\sin kx)=-Ak\sin kx$

$\dfrac{d^2\psi}{dx^2}=-Ak(k\cos kx)=-Ak^2\cos kx$

Thus Eq. (40.25) requires $-\dfrac{h^2}{8\pi^2 m}(-Ak^2\cos kx)=E(A\cos kx).$

This says $\dfrac{h^2k^2}{8\pi^2 m}=E;\ \ k=\dfrac{\sqrt{2mE}}{(h/2\pi)}=\dfrac{\sqrt{2mE}}{\hbar}$

$\psi=A\cos kx$ is a solution to Eq. (40.25) if $k=\dfrac{\sqrt{2mE}}{\hbar}.$

(b) EVALUATE: The wave function for a particle in a box with rigid walls at $x=0$ and $x=L$ must satisfy the boundary conditions $\psi=0$ at $x=0$ and $\psi=0$ at $x=L$. $\psi(0)=A\cos 0=A,$ since $\cos 0=1$. Thus ψ is not 0 at $x=0$ and this wave function isn't acceptable because it doesn't satisfy the required boundary condition, even though it is a solution to the Schrödinger equation.

40.22. **IDENTIFY:** The energy levels are given by Eq. (40.31). The wavelength λ of the photon absorbed in an atomic transition is related to the transition energy ΔE by $\lambda=\dfrac{hc}{\Delta E}.$

SET UP: For the ground state $n=1$ and for the third excited state $n=4$.

EXECUTE: **(a)** The third excited state is $n=4,$ so

$$\Delta E=(4^2-1)\frac{h^2}{8mL^2}=\frac{15(6.626\times10^{-34}\ \text{J}\cdot\text{s})^2}{8(9.11\times10^{-31}\ \text{kg})(0.125\times10^{-9}\ \text{m})^2}=5.78\times10^{-17}\ \text{J}=361\ \text{eV}.$$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) $\lambda = \dfrac{hc}{\Delta E} = \dfrac{(6.63\times10^{-34}\ \text{J}\cdot\text{s})(3.0\times10^{8}\ \text{m/s})}{5.78\times10^{-17}\ \text{J}} = 3.44\ \text{nm}$

EVALUATE: This photon is an x ray. As the width of the box increases the transition energy for this transition decreases and the wavelength of the photon increases.

40.23. **IDENTIFY** and **SET UP:** $\lambda = \dfrac{h}{p} = \dfrac{h}{\sqrt{2mE}}$. The energy of the electron in level n is given by Eq. (40.31).

EXECUTE: **(a)** $E_1 = \dfrac{h^2}{8mL^2} \Rightarrow \lambda_1 = \dfrac{h}{\sqrt{2mh^2/8mL^2}} = 2L = 2(3.0\times10^{-10}\ \text{m}) = 6.0\times10^{-10}\ \text{m}$. The wavelength is twice the width of the box. $p_1 = \dfrac{h}{\lambda_1} = \dfrac{(6.63\times10^{-34}\ \text{J}\cdot\text{s})}{6.0\times10^{-10}\ \text{m}} = 1.1\times10^{-24}\ \text{kg}\cdot\text{m/s}$.

(b) $E_2 = \dfrac{4h^2}{8mL^2} \Rightarrow \lambda_2 = L = 3.0\times10^{-10}\ \text{m}$. The wavelength is the same as the width of the box.

$p_2 = \dfrac{h}{\lambda_2} = 2p_1 = 2.2\times10^{-24}\ \text{kg}\cdot\text{m/s}$.

(c) $E_3 = \dfrac{9h^2}{8mL^2} \Rightarrow \lambda_3 = \dfrac{2}{3}L = 2.0\times10^{-10}\ \text{m}$. The wavelength is two-thirds the width of the box.

$p_3 = 3p_1 = 3.3\times10^{-24}\ \text{kg}\cdot\text{m/s}$.

EVALUATE: In each case the wavelength is an integer multiple of $\lambda/2$. In the n^{th} state, $p_n = np_1$.

40.24. **IDENTIFY:** To describe a real situation, a wave function must be normalizable.

SET UP: $|\psi|^2\ dV$ is the probability that the particle is found in volume dV. Since the particle must be *somewhere*, ψ must have the property that $\int|\psi|^2 dV = 1$ when the integral is taken over all space.

EXECUTE: **(a)** In one dimension, as we have here, the integral discussed above is of the form $\int_{-\infty}^{\infty}|\psi(x)|^2dx = 1$.

(b) Using the result from part (a), we have $\int_{-\infty}^{\infty}(e^{ax})^2dx = \int_{-\infty}^{\infty}e^{2ax}dx = \left.\dfrac{e^{2ax}}{2a}\right|_{-\infty}^{\infty} = \infty$. Hence this wave function cannot be normalized and therefore cannot be a valid wave function.

(c) We only need to integrate this wave function of 0 to ∞ because it is zero for $x < 0$. For normalization we have $1 = \int_{-\infty}^{\infty}|\psi|^2dx = \int_0^{\infty}(Ae^{-bx})^2dx = \int_0^{\infty}A^2e^{-2bx}dx = \left.\dfrac{A^2e^{-2bx}}{-2b}\right|_0^{\infty} = \dfrac{A^2}{2b}$, which gives $\dfrac{A^2}{2b} = 1$, so $A = \sqrt{2b}$.

EVALUATE: If b were negative, the given wave function could not be normalized, so it would not be allowable.

40.25. **IDENTIFY:** Compare $-\dfrac{\hbar^2}{2m}\dfrac{d^2\psi}{dx^2} + U\psi$ to $E\psi$ and see if there is a value of k for which they are equal.

SET UP: $\dfrac{d^2}{dx^2}\sin kx = -k^2\sin kx$.

EXECUTE: **(a)** Eq. (40.23): $\dfrac{-\hbar^2}{2m}\dfrac{d^2\psi}{dx^2} + U\psi = E\psi$.

Left-hand side: $\dfrac{-\hbar^2}{2m}\dfrac{d^2}{dx^2}(A\sin kx) + U_0A\sin kx = \dfrac{\hbar^2k^2}{2m}A\sin kx + U_0A\sin kx = \left(\dfrac{\hbar^2k^2}{2m} + U_0\right)\psi$. But $\dfrac{\hbar^2k^2}{2m} + U_0 > U_0 > E$ if k is real. But $\dfrac{\hbar^2k^2}{2m} + U_0$ should equal E. This is not the case, and there is no k for which this $|\psi|^2$ is a solution.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) If $E > U_0$, then $\frac{\hbar^2 k^2}{2m} + U_0 = E$ is consistent and so $\psi = A\sin kx$ is a solution of Eq. (40.23) for this case.

EVALUATE: For a square-well potential and $E < U_0$, Eq. (40.23) with $U = U_0$ applies outside the well and the wave function has the form of Eq. (40.40).

40.26. **IDENTIFY:** $\lambda = \frac{h}{p}$. p is related to E by $E = \frac{p^2}{2m} + U$.

SET UP: For $x > L$, $U = U_0$. For $0 < x < L$, $U = 0$.

EXECUTE: For $0 < x < L$, $p = \sqrt{2mE} = \sqrt{2m(3U_0)}$ and $\lambda_{\text{in}} = \frac{h}{\sqrt{2m(3U_0)}}$. For $x > L$, $p = \sqrt{2m(E - U_0)} = \sqrt{2m(2U_0)}$ and $\lambda_{\text{out}} = \frac{h}{\sqrt{2m(E-U_0)}} = \frac{h}{\sqrt{2m(2U_0)}}$. Thus, the ratio of the wavelengths is $\frac{\lambda_{\text{out}}}{\lambda_{\text{in}}} = \frac{\sqrt{2m(3U_0)}}{\sqrt{2m(2U_0)}} = \sqrt{\frac{3}{2}}$.

EVALUATE: For $x > L$ some of the energy is potential and the kinetic energy is less than it is for $0 < x < L$, where $U = 0$. Therefore, outside the box p is less and λ is greater than inside the box.

40.27. **IDENTIFY:** Figure 40.15b in the textbook gives values for the bound state energy of a square well for which $U_0 = 6E_{\text{1-1DW}}$.

SET UP: $E_{\text{1-1DW}} = \frac{\pi^2\hbar^2}{2mL^2}$.

EXECUTE: $E_1 = 0.625E_{\text{1-1DW}} = 0.625\frac{\pi^2\hbar^2}{2mL^2}$; $E_1 = 2.00\text{ eV} = 3.20\times10^{-19}$ J.

$$L = \pi\hbar\left(\frac{0.625}{2(9.109\times10^{-31}\text{ kg})(3.20\times10^{-19}\text{ J})}\right)^{1/2} = 3.43\times10^{-10}\text{ m}.$$

EVALUATE: As L increases the ground state energy decreases.

40.28. **IDENTIFY:** The energy of the photon is the energy given to the electron.

SET UP: Since $U_0 = 6E_{\text{1-1DW}}$ we can use the result $E_1 = 0.625E_{\text{1-1DW}}$ from Section 40.4. When the electron is outside the well it has potential energy U_0, so the minimum energy that must be given to the electron is $U_0 - E_1 = 5.375E_{\text{1-1DW}}$.

EXECUTE: The maximum wavelength of the photon would be

$$\lambda = \frac{hc}{U_0 - E_1} = \frac{hc}{(5.375)(h^2/8mL^2)} = \frac{8mL^2c}{(5.375)h} = \frac{8(9.11\times10^{-31}\text{ kg})(1.50\times10^{-9}\text{ m})^2(3.00\times10^8\text{ m/s})}{(5.375)(6.63\times10^{-34}\text{ J}\cdot\text{s})}$$

$$= 1.38\times10^{-6}\text{ m}.$$

EVALUATE: This photon is in the infrared. The wavelength of the photon decreases when the width of the well decreases.

40.29. **IDENTIFY:** Calculate $\frac{d^2\psi}{dx^2}$ and compare to $-\frac{2mE}{\hbar^2}\psi$.

SET UP: $\frac{d}{dx}\sin kx = k\cos kx$. $\frac{d}{dx}\cos kx = -k\sin kx$.

EXECUTE: Eq. (40.37): $\psi = A\sin\frac{\sqrt{2mE}}{\hbar}x + B\cos\frac{\sqrt{2mE}}{\hbar}x$.

$\frac{d^2\psi}{dx^2} = -A\left(\frac{2mE}{\hbar^2}\right)\sin\frac{\sqrt{2mE}}{\hbar}x - B\left(\frac{2mE}{\hbar^2}\right)\cos\frac{\sqrt{2mE}}{\hbar}x = \frac{-2mE}{\hbar^2}(\psi)$. This is Eq. (40.38), so this ψ is a solution.

EVALUATE: ψ in Eq. (40.38) is a solution to Eq. (40.37) for any values of the constants A and B.

40.30. **IDENTIFY:** The longest wavelength corresponds to the smallest energy change.

SET UP: The ground level energy level of the infinite well is $E_{1\text{-}1\text{DW}} = \dfrac{h^2}{8mL^2}$, and the energy of the photon must be equal to the energy difference between the two shells.

EXECUTE: The 400.0 nm photon must correspond to the $n = 1$ to $n = 2$ transition. Since $U_0 = 6E_{1\text{-}1\text{DW}}$, we have $E_2 = 2.43E_{1\text{-}1\text{DW}}$ and $E_1 = 0.625E_{1\text{-}1\text{DW}}$. The energy of the photon is equal to the energy difference between the two levels, and $E_{1\text{-}1\text{DW}} = \dfrac{h^2}{8mL^2}$, which gives

$E_\gamma = E_2 - E_1 \Rightarrow \dfrac{hc}{\lambda} = (2.43 - 0.625)E_{1\text{-}1\text{DW}} = \dfrac{1.805\,h^2}{8mL^2}$. Solving for L gives

$$L = \sqrt{\frac{(1.805)h\lambda}{8mc}} = \sqrt{\frac{(1.805)(6.626\times10^{-34}\ \text{J}\cdot\text{s})(4.00\times10^{-7}\ \text{m})}{8(9.11\times10^{-31}\ \text{kg})(3.00\times10^{8}\ \text{m/s})}} = 4.68\times10^{-10}\ \text{m} = 0.468\ \text{nm}.$$

EVALUATE: This width is approximately half that of a Bohr hydrogen atom.

40.31. **IDENTIFY:** Find the transition energy ΔE and set it equal to the energy of the absorbed photon. Use $E = hc/\lambda$, to find the wavelength of the photon.

SET UP: $U_0 = 6E_{1\text{-}1\text{DW}}$, as in Figure 40.15 in the textbook, so $E_1 = 0.625E_{1\text{-}1\text{DW}}$ and $E_3 = 5.09E_{1\text{-}1\text{DW}}$ with $E_{1\text{-}1\text{DW}} = \dfrac{\pi^2\hbar^2}{2mL^2}$. In this problem the particle bound in the well is a proton, so $m = 1.673\times10^{-27}$ kg.

EXECUTE: $E_{1\text{-}1\text{DW}} = \dfrac{\pi^2\hbar^2}{2mL^2} = \dfrac{\pi^2(1.055\times10^{-34}\ \text{J}\cdot\text{s})^2}{2(1.673\times10^{-27}\ \text{kg})(4.0\times10^{-15}\ \text{m})^2} = 2.052\times10^{-12}$ J. The transition energy is $\Delta E = E_3 - E_1 = (5.09 - 0.625)E_{1\text{-}1\text{DW}} = 4.465E_{1\text{-}1\text{DW}}$. $\Delta E = 4.465(2.052\times10^{-12}\ \text{J}) = 9.162\times10^{-12}$ J

The wavelength of the photon that is absorbed is related to the transition energy by $\Delta E = hc/\lambda$, so

$$\lambda = \frac{hc}{\Delta E} = \frac{(6.626\times10^{-34}\ \text{J}\cdot\text{s})(2.998\times10^{8}\ \text{m/s})}{9.162\times10^{-12}\ \text{J}} = 2.2\times10^{-14}\ \text{m} = 22\ \text{fm}.$$

EVALUATE: The wavelength of the photon is comparable to the size of the box.

40.32. **IDENTIFY:** The tunneling probability is $T = Ge^{-2\kappa L}$, with $G = 16\dfrac{E}{U_0}\left(1 - \dfrac{E}{U_0}\right)$ and $\kappa = \dfrac{\sqrt{2m(U_0 - E)}}{\hbar}$. so

$$T = 16\frac{E}{U_0}\left(1 - \frac{E}{U_0}\right)e^{\frac{-2\sqrt{2m(U_0-E)}}{\hbar}L}.$$

SET UP: $U_0 = 30.0\times10^{6}$ eV, $L = 2.0\times10^{-15}$ m, $m = 6.64\times10^{-27}$ kg.

EXECUTE: **(a)** $U_0 - E = 1.0\times10^{6}$ eV ($E = 29.0\times10^{6}$ eV), $T = 0.090$.

(b) If $U_0 - E = 10.0\times10^{6}$ eV ($E = 20.0\times10^{6}$ eV), $T = 0.014$.

EVALUATE: T is less when $U_0 - E$ s 10.0 MeV than when $U_0 - E$ is 1.0 MeV.

40.33. **IDENTIFY:** The tunneling probability is $T = 16\dfrac{E}{U_0}\left(1 - \dfrac{E}{U_0}\right)e^{-2L\sqrt{2m(U_0-E)}/\hbar}$.

SET UP: $\dfrac{E}{U_0} = \dfrac{6.0\ \text{eV}}{11.0\ \text{eV}}$ and $E - U_0 = 5\ \text{eV} = 8.0\times10^{-19}$ J.

EXECUTE: **(a)** $L = 0.80\times10^{-9}$ m:

$$T = 16\left(\frac{6.0\ \text{eV}}{11.0\ \text{eV}}\right)\left(1 - \frac{6.0\ \text{ev}}{11.0\ \text{eV}}\right)e^{-2(0.80\times10^{-9}\ \text{m})\sqrt{2(9.11\times10^{-31}\ \text{kg})(8.0\times10^{-19}\ \text{J})}/1.055\times10^{-34}\ \text{J}\cdot\text{s}} = 4.4\times10^{-8}.$$

(b) $L = 0.40\times10^{-9}$ m: $T = 4.2\times10^{-4}$.

EVALUATE: The tunneling probability is less when the barrier is wider.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

40.34. **IDENTIFY:** The transmission coefficient is $T = 16\dfrac{E}{U_0}\left(1-\dfrac{E}{U_0}\right)e^{-2\sqrt{2m(U_0-E)}L/\hbar}$.

SET UP: $E = 5.0$ eV, $L = 0.60\times10^{-9}$ m, and $m = 9.11\times10^{-31}$ kg

EXECUTE: **(a)** $U_0 = 7.0\text{ eV} \Rightarrow T = 5.5\times10^{-4}$.

(b) $U_0 = 9.0\text{ eV} \Rightarrow T = 1.8\times10^{-5}$.

(c) $U_0 = 13.0\text{ eV} \Rightarrow T = 1.1\times10^{-7}$.

EVALUATE: T decreases when the height of the barrier increases.

40.35. **IDENTIFY** and **SET UP:** Use Eq. (39.1), where $K = p^2/2m$ and $E = K + U$.

EXECUTE: $\lambda = h/p = h/\sqrt{2mK}$, so $\lambda\sqrt{K}$ is constant. $\lambda_1\sqrt{K_1} = \lambda_2\sqrt{K_2}$; λ_1 and K_1 are for $x > L$ where $K_1 = 2U_0$ and λ_2 and K_2 are for $0 < x < L$ where $K_2 = E - U_0 = U_0$.

$$\frac{\lambda_1}{\lambda_2} = \sqrt{\frac{K_2}{K_1}} = \sqrt{\frac{U_0}{2U_0}} = \frac{1}{\sqrt{2}}$$

EVALUATE: When the particle is passing over the barrier its kinetic energy is less and its wavelength is larger.

40.36. **IDENTIFY:** The probability of tunneling depends on the energy of the particle and the width of the barrier.

SET UP: The probability of tunneling is approximately $T = Ge^{-2\kappa L}$, where $G = 16\dfrac{E}{U_0}\left(1-\dfrac{E}{U_0}\right)$ and $\kappa = \dfrac{\sqrt{2m(U_0-E)}}{\hbar}$.

EXECUTE: $G = 16\dfrac{E}{U_0}\left(1-\dfrac{E}{U_0}\right) = 16\dfrac{50.0\text{ eV}}{70.0\text{ eV}}\left(1-\dfrac{50.0\text{ eV}}{70.0\text{ eV}}\right) = 3.27.$

$$\kappa = \frac{\sqrt{2m(U_0-E)}}{\hbar} = \frac{\sqrt{2(1.67\times10^{-27}\text{ kg})(70.0\text{ eV}-50.0\text{ eV})(1.60\times10^{-19}\text{ J/eV})}}{(6.63\times10^{-34}\text{ J}\cdot\text{s})/2\pi} = 9.8\times10^{11}\text{ m}^{-1}$$

Solving $T = Ge^{-2\kappa L}$ for L gives

$$L = \frac{1}{2\kappa}\ln(G/T) = \frac{1}{2(9.8\times10^{11}\text{ m}^{-1})}\ln\left(\frac{3.27}{0.0030}\right) = 3.6\times10^{-12}\text{ m} = 3.6\text{ pm}.$$

If the proton were replaced with an electron, the electron's mass is much smaller so L would be larger.

EVALUATE: An electron can tunnel through a much wider barrier than a proton of the same energy.

40.37. **IDENTIFY** and **SET UP:** The probability is $T = Ae^{-2\kappa L}$, with $A = 16\dfrac{E}{U_0}\left(1-\dfrac{E}{U_0}\right)$ and $\kappa = \dfrac{\sqrt{2m(U_0-E)}}{\hbar}$.

$E = 32$ eV, $U_0 = 41$ eV, $L = 0.25\times10^{-9}$ m. Calculate T.

EXECUTE: **(a)** $A = 16\dfrac{E}{U_0}\left(1-\dfrac{E}{U_0}\right) = 16\dfrac{32}{41}\left(1-\dfrac{32}{41}\right) = 2.741.$

$$\kappa = \frac{\sqrt{2m(U_0-E)}}{\hbar}$$

$$\kappa = \frac{\sqrt{2(9.109\times10^{-31}\text{ kg})(41\text{ eV}-32\text{ eV})(1.602\times10^{-19}\text{ J/eV})}}{1.055\times10^{-34}\text{ J}\cdot\text{s}} = 1.536\times10^{10}\text{ m}^{-1}$$

$$T = Ae^{-2\kappa L} = (2.741)e^{-2(1.536\times10^{10}\text{ m}^{-1})(0.25\times10^{-9}\text{ m})} = 2.741e^{-7.68} = 0.0013$$

(b) The only change in the mass m, which appears in κ.

$$\kappa = \frac{\sqrt{2m(U_0-E)}}{\hbar}$$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$\kappa = \frac{\sqrt{2(1.673\times10^{-27}\text{ kg})(41\text{ eV}-32\text{ eV})(1.602\times10^{-19}\text{ J/eV})}}{1.055\times10^{-34}\text{ J}\cdot\text{s}} = 6.584\times10^{11}\text{ m}^{-1}$$

Then $T = Ae^{-2\kappa L} = (2.741)e^{-2(6.584\times10^{11}\text{ m}^{-1})(0.25\times10^{-9}\text{ m})} = 2.741e^{-392.2} = 10^{-143}$

EVALUATE: The more massive proton has a much smaller probability of tunneling than the electron does.

40.38. **IDENTIFY:** Calculate $\frac{d^2\psi}{dx^2}$ and insert the result into Eq. (40.44).

SET UP: $\frac{d}{dx}e^{-\delta x^2} = -2\delta x e^{-\delta x^2}$ and $\frac{d^2}{dx^2}e^{-\delta x^2} = (4\delta^2x^2 - 2\delta)e^{-\delta x^2}$

EXECUTE: Let $\sqrt{mk'}/2\hbar = \delta$, and so $\frac{d\psi}{dx} = -2x\delta\psi$ and $\frac{d^2\psi}{dx^2} = (4x^2\delta^2 - 2\delta)\psi$, and ψ is a solution of Eq. (40.44) if $E = \frac{\hbar^2}{m}\delta = \frac{1}{2}\hbar\sqrt{k'/m} = \frac{1}{2}\hbar\omega$.

EVALUATE: $E = \frac{1}{2}\hbar\omega$ agrees with Eq. (40.46), for $n = 0$.

40.39. **IDENTIFY** and **SET UP:** The energy levels are given by Eq. (40.46), where $\omega = \sqrt{\frac{k'}{m}}$.

EXECUTE: $\omega = \sqrt{\frac{k'}{m}} = \sqrt{\frac{110\text{ N/m}}{0.250\text{ kg}}} = 21.0\text{ rad/s}$

The ground state energy is given by Eq. (40.46):

$E_0 = \frac{1}{2}\hbar\omega = \frac{1}{2}(1.055\times10^{-34}\text{ J}\cdot\text{s})(21.0\text{ rad/s}) = 1.11\times10^{-33}\text{ J}(1\text{ eV}/1.602\times10^{-19}\text{ J}) = 6.93\times10^{-15}\text{ eV}$

$E_n = \left(n+\frac{1}{2}\right)\hbar\omega,\quad E_{(n+1)} = \left(n+1+\frac{1}{2}\right)\hbar\omega$

The energy separation between these adjacent levels is

$\Delta E = E_{n+1} - E_n = \hbar\omega = 2E_0 = 2(1.11\times10^{-33}\text{ J}) = 2.22\times10^{-33}\text{ J} = 1.39\times10^{-14}\text{ eV}.$

EVALUATE: These energies are extremely small; quantum effects are not important for this oscillator.

40.40. **IDENTIFY:** The energy of the absorbed photon must be equal to the energy difference between the two states.

SET UP and **EXECUTE:** $\Delta E = \frac{hc}{\lambda} = \frac{(4.136\times10^{-15}\text{ eV}\cdot\text{s})(2.998\times10^{8}\text{ m/s})}{8.65\times10^{-6}\text{ m}} = 0.1433\text{ eV}.$ $\Delta E = \hbar\omega.$

$E_0 = \frac{\hbar\omega}{2} = \frac{0.1433\text{ eV}}{2} = 0.0717\text{ eV}.$

EVALUATE: The energy of the photon is not equal to the energy of the ground state, but rather it is the energy *difference* between the two states.

40.41. **IDENTIFY:** We can model the molecule as a harmonic oscillator. The energy of the photon is equal to the energy difference between the two levels of the oscillator.

SET UP: The energy of a photon is $E_\gamma = hf = hc/\lambda$, and the energy levels of a harmonic oscillator are given by $E_n = \left(n+\frac{1}{2}\right)\hbar\sqrt{\frac{k'}{m}} = \left(n+\frac{1}{2}\right)\hbar\omega.$

EXECUTE: **(a)** The photon's energy is $E_\gamma = \frac{hc}{\lambda} = \frac{(6.63\times10^{-34}\text{ J}\cdot\text{s})(3.00\times10^{8}\text{ m/s})}{5.8\times10^{-6}\text{ m}} = 0.21\text{ eV}.$

(b) The transition energy is $\Delta E = E_{n+1} - E_n = \hbar\omega = \hbar\sqrt{\frac{k'}{m}}$, which gives $\frac{2\pi\hbar c}{\lambda} = \hbar\sqrt{\frac{k'}{m}}$. Solving for k', we get $k' = \frac{4\pi^2c^2m}{\lambda^2} = \frac{4\pi^2(3.00\times10^{8}\text{ m/s})^2(5.6\times10^{-26}\text{ kg})}{(5.8\times10^{-6}\text{ m})^2} = 5{,}900\text{ N/m}.$

EVALUATE: This would be a rather strong spring in the physics lab.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

40.42. **IDENTIFY:** The photon energy equals the transition energy for the atom.
SET UP: According to Eq. (40.46), the energy released during the transition between two adjacent levels is twice the ground state energy $E_3 - E_2 = \hbar\omega = 2E_0 = 11.2$ eV.
EXECUTE: For a photon of energy E,

$$E = hf \Rightarrow \lambda = \frac{c}{f} = \frac{hc}{E} = \frac{(6.63\times10^{-34}\ \text{J}\cdot\text{s})(3.00\times10^{8}\ \text{m/s})}{(11.2\ \text{eV})(1.60\times10^{-19}\ \text{J/eV})} = 111\ \text{nm}.$$

EVALUATE: This photon is in the ultraviolet.

40.43. **IDENTIFY** and **SET UP:** Use the energies given in Eq. (40.46) to solve for the amplitude A and maximum speed $v_{\max}$ of the oscillator. Use these to estimate Δx and Δp_x and compute the uncertainty product $\Delta x \Delta p_x$.

EXECUTE: The total energy of a Newtonian oscillator is given by $E = \frac{1}{2}k'A^2$ where k' is the force constant and A is the amplitude of the oscillator. Set this equal to the energy $E = \left(n + \frac{1}{2}\right)\hbar\omega$ of an excited level that has quantum number n, where $\omega = \sqrt{\frac{k'}{m}}$, and solve for A: $\frac{1}{2}k'A^2 = \left(n + \frac{1}{2}\right)\hbar\omega$.

$A = \sqrt{\frac{(2n+1)\hbar\omega}{k'}}$. The total energy of the Newtonian oscillator can also be written as $E = \frac{1}{2}mv_{\max}^2$. Set this equal to $E = \left(n + \frac{1}{2}\right)\hbar\omega$ and solve for $v_{\max}$: $\frac{1}{2}mv_{\max}^2 = \left(n + \frac{1}{2}\right)\hbar\omega$. $v_{\max} = \sqrt{\frac{(2n+1)\hbar\omega}{m}}$. Thus the maximum linear momentum of the oscillator is $p_{\max} = mv_{\max} = \sqrt{(2n+1)\hbar m\omega}$. Now $A/\sqrt{2}$ represents the uncertainty Δx in position and that $p_{\max}/\sqrt{2}$ is the corresponding uncertainty Δp_x in momentum. Then the uncertainty product is

$$\Delta x \Delta p_x = \left(\frac{1}{\sqrt{2}}\sqrt{\frac{(2n+1)\hbar\omega}{k'}}\right)\left(\frac{1}{\sqrt{2}}\sqrt{(2n+1)\hbar m\omega}\right) = \frac{(2n+1)\hbar\omega}{2}\sqrt{\frac{m}{k'}} = \frac{(2n+1)\hbar\omega}{2}\left(\frac{1}{\omega}\right) = (2n+1)\frac{\hbar}{2}.$$

EVALUATE: For $n = 0$ this gives $\Delta x \Delta p_x = \hbar/2$, in agreement with the result derived in Section 40.5. The uncertainty product $\Delta x \Delta p_x$ increases with n.

40.44. **IDENTIFY:** Compute the ratio specified in the problem.
SET UP: For $n = 0$, $A = \sqrt{\frac{\hbar\omega}{k'}}$. $\omega = \sqrt{\frac{k'}{m}}$.
EXECUTE: **(a)** $\frac{|\psi(A)|^2}{|\psi(0)|^2} = \exp\left(-\frac{\sqrt{mk'}}{\hbar}A^2\right) = \exp\left(-\sqrt{mk'}\frac{\omega}{k'}\right) = e^{-1} = 0.368$. This is consistent with what is shown in Figure 40.27 in the textbook.
(b) $\frac{|\psi(2A)^2|}{|\psi(0)|^2} = \exp\left(-\frac{\sqrt{mk'}}{\hbar}(2A)^2\right) = \exp\left(-\sqrt{mk'}4\frac{\omega}{k'}\right) = e^{-4} = 1.83\times10^{-2}$. This figure cannot be read this precisely, but the qualitative decrease in amplitude with distance is clear.
EVALUATE: The wave function decays exponentially as x increases beyond $x = A$.

40.45. **IDENTIFY:** We model the atomic vibration in the crystal as a harmonic oscillator.
SET UP: The energy levels of a harmonic oscillator are given by $E_n = \left(n + \frac{1}{2}\right)\hbar\sqrt{\frac{k'}{m}} = \left(n + \frac{1}{2}\right)\hbar\omega$.
EXECUTE: **(a)** The ground state energy of a simple harmonic oscillator is

$$E_0 = \frac{1}{2}\hbar\omega = \frac{1}{2}\hbar\sqrt{\frac{k'}{m}} = \frac{(1.055\times10^{-34}\ \text{J}\cdot\text{s})}{2}\sqrt{\frac{12.2\ \text{N/m}}{3.82\times10^{-26}\ \text{kg}}} = 9.43\times10^{-22}\ \text{J} = 5.89\times10^{-3}\ \text{eV}$$

(b) $E_4 - E_3 = \hbar\omega = 2E_0 = 0.0118$ eV, so $\lambda = \frac{hc}{E} = \frac{(6.63\times10^{-34}\ \text{J}\cdot\text{s})(3.00\times10^{8}\ \text{m/s})}{1.88\times10^{-21}\ \text{J}} = 106\ \mu\text{m}$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(c) $E_{n+1} - E_n = \hbar\omega = 2E_0 = 0.0118$ eV

EVALUATE: These energy differences are much smaller than those due to electron transitions in the hydrogen atom.

40.46. **IDENTIFY:** For a stationary state, $|\Psi|^2$ is time independent.

SET UP: To calculate Ψ^* from Ψ, replace i by $-i$.

EXECUTE: For this wave function, $\Psi^* = \psi_1^* e^{i\omega_1 t} + \psi_2^* e^{i\omega_2 t}$, so

$$|\Psi|^2 = \Psi^*\Psi = (\psi_1^* e^{i\omega_1 t} + \psi_2^* e^{i\omega_2 t})(\psi_1 e^{-i\omega_1 t} + \psi_2 e^{-i\omega_2 t}) = \psi_1^*\psi_1 + \psi_2^*\psi_2 + \psi_1^*\psi_2 e^{i(\omega_1-\omega_2)t} + \psi_2^*\psi_1 e^{i(\omega_2-\omega_1)t}.$$

The frequencies ω_1 and ω_2 are given as not being the same, so $|\Psi|^2$ is not time-independent, and Ψ is not the wave function for a stationary state.

EVALUATE: If $\omega_1 = \omega_2$, then Ψ is the wave function for a stationary state.

40.47. **IDENTIFY:** We know the wave function of a particle in a box.

SET UP and **EXECUTE:** **(a)** $\Psi(x,t) = \frac{1}{\sqrt{2}}\psi_1(x)e^{-iE_1t/\hbar} + \frac{1}{\sqrt{2}}\psi_3(x)e^{-iE_3t/\hbar}$.

$$\Psi^*(x,t) = \frac{1}{\sqrt{2}}\psi_1(x)e^{+iE_1t/\hbar} + \frac{1}{\sqrt{2}}\psi_3(x)e^{+iE_3t/\hbar}.$$

$$|\Psi(x,t)|^2 = \frac{1}{2}[\psi_1^2 + \psi_3^2 + \psi_1\psi_3(e^{i(E_3-E_1)t/\hbar} + e^{-i(E_3-E_1)t/\hbar})] = \frac{1}{2}\left[\psi_1^2 + \psi_3^2 + 2\psi_1\psi_3\cos\left(\frac{[E_3-E_1]t}{\hbar}\right)\right].$$

$\psi_1 = \sqrt{\frac{2}{L}}\sin\left(\frac{\pi x}{L}\right)$. $\psi_3 = \sqrt{\frac{2}{L}}\sin\left(\frac{3\pi x}{L}\right)$. $E_3 = \frac{9\pi^2\hbar^2}{2mL^2}$ and $E_1 = \frac{\pi^2\hbar^2}{2mL^2}$, so $E_3 - E_1 = \frac{4\pi^2\hbar^2}{mL^2}$.

$$|\Psi(x,t)|^2 = \frac{1}{L}\left[\sin^2\left(\frac{\pi x}{L}\right) + \sin^2\left(\frac{3\pi x}{L}\right) + 2\sin\left(\frac{\pi x}{L}\right)\sin\left(\frac{3\pi x}{L}\right)\cos\left(\frac{4\pi^2\hbar t}{mL^2}\right)\right].$$ At $x = L/2$,

$\sin\left(\frac{\pi x}{L}\right) = \sin\left(\frac{\pi}{2}\right) = 1$. $\sin\left(\frac{3\pi x}{L}\right) = \sin\left(\frac{3\pi}{2}\right) = -1$. $|\Psi(x,t)|^2 = \frac{2}{L}\left[1 - \cos\left(\frac{4\pi^2\hbar t}{mL^2}\right)\right]$.

(b) $\omega_{\text{osc}} = \frac{E_3 - E_1}{\hbar} = \frac{4\pi^2\hbar}{mL^2}$.

EVALUATE: Note that $\Delta E = \hbar\omega$.

40.48. **IDENTIFY:** Carry out the calculations specified in the problem.

SET UP: A standard integral is $\int_0^\infty e^{-\alpha^2k^2}\cos(kx)dk = \frac{\sqrt{\pi}}{2\alpha}e^{-x^2/4\alpha^2}$.

EXECUTE: **(a)** $B(k) = e^{-\alpha^2k^2}$. $B(0) = B_{\max} = 1$. $B(k_{\text{h}}) = \frac{1}{2} = e^{-\alpha^2k_{\text{h}}^2} \Rightarrow \ln(1/2) = -\alpha^2k_{\text{h}}^2$

$\Rightarrow k_{\text{h}} = \frac{1}{\alpha}\sqrt{\ln(2)} = w_k$.

(b) $\psi(x) = \int_0^\infty e^{-\alpha^2k^2}\cos kx\,dk = \frac{\sqrt{\pi}}{2\alpha}(e^{-x^2/4\alpha^2})$. $\psi(x)$ is a maximum when $x = 0$.

(c) $\psi(x_{\text{h}}) = \frac{\sqrt{\pi}}{4\alpha}$ when $e^{-x_{\text{h}}^2/4\alpha^2} = \frac{1}{2} \Rightarrow \frac{-x_{\text{h}}^2}{4\alpha^2} = \ln(1/2) \Rightarrow x_{\text{h}} = 2\alpha\sqrt{\ln 2} = w_x$

(d) $w_p w_x = \left(\frac{hw_k}{2\pi}\right)w_x = \frac{h}{2\pi}\left(\frac{1}{\alpha}\sqrt{\ln 2}\right)(2\alpha\sqrt{\ln 2}) = \frac{h}{2\pi}(2\ln 2) = \frac{h\ln 2}{\pi} = (2\ln 2)\hbar$.

EVALUATE: The Heisenberg Uncertainty Principle says that $\Delta x\Delta p_x \geq \hbar/2$. If $\Delta x = w_x$ and $\Delta p_x = w_p$, then the uncertainty principle says $w_x w_p \geq \hbar/2$. So our result is consistent with the uncertainty principle since $(2\ln 2)\hbar > \hbar/2$.

40.49. **IDENTIFY:** Evaluate $\psi(x) = \int_0^\infty B(k)\cos kx\, dk$ for the function $B(k)$ specified in the problem.

SET UP: $\int \cos kx\, dk = \frac{1}{x}\sin kx.$

EXECUTE: **(a)** $\psi(x) = \int_0^\infty B(k)\cos kx dk = \int_0^{k_0}\left(\frac{1}{k_0}\right)\cos kx dk = \frac{\sin kx}{k_0 x}\Big|_0^{k_0} = \frac{\sin k_0 x}{k_0 x}$

(b) $\psi(x)$ has a maximum value at the origin $x = 0$. $\psi(x_0) = 0$ when $k_0 x_0 = \pi$ so $x_0 = \frac{\pi}{k_0}$. Thus the width of this function $w_x = 2x_0 = \frac{2\pi}{k_0}$. If $k_0 = \frac{2\pi}{L}$, $w_x = L$. $B(k)$ versus k is graphed in Figure 40.49a. The graph of $\psi(x)$ versus x is in Figure 40.49b.

(c) If $k_0 = \frac{\pi}{L}$, $w_x = 2L$.

EVALUATE: **(d)** $w_p w_x = \left(\frac{hw_k}{2\pi}\right)\left(\frac{2\pi}{k_0}\right) = \frac{hw_k}{k_0} = \frac{hk_0}{k_0} = h.$ If $\Delta x = w_x$ and $\Delta p_x = w_p$, then the uncertainty principle states that $w_p w_x \geq \frac{\hbar}{2}$. For us, no matter what k_0 is, $w_p w_x = h,$ which is greater than $\hbar/2$.

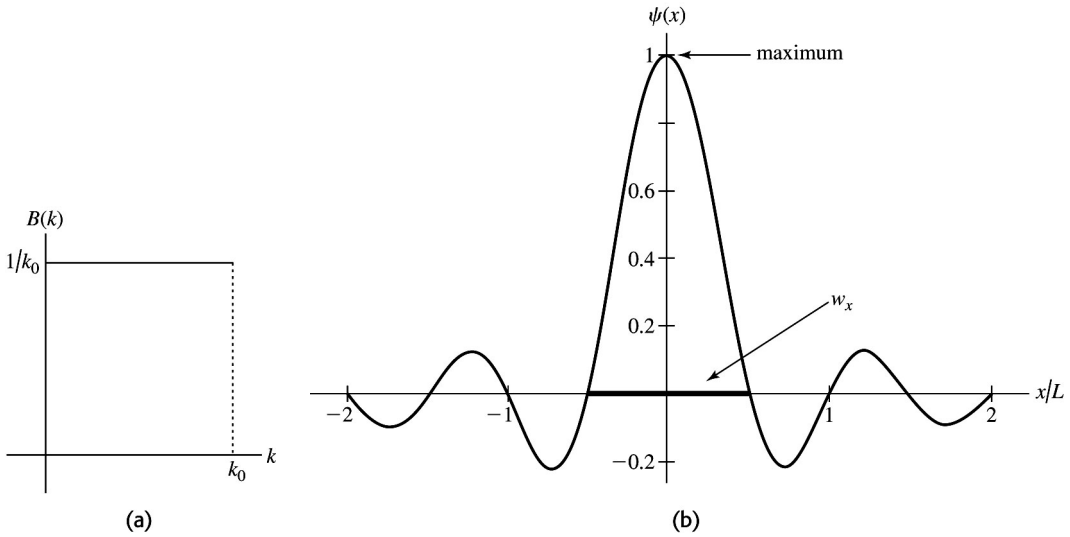

Figure 40.49

40.50. **IDENTIFY:** If the given wave function is a solution to the Schrödinger equation, we will get an identity when we substitute that wave function into the Schrödinger equation.

SET UP: The given function is $\psi(x) = Ae^{ikx}$, and the one-dimensional Schrödinger equation is

$$-\frac{\hbar}{2m}\frac{d^2\psi(x)}{dx^2} + U(x)\psi(x) = E\psi(x).$$

EXECUTE: Start with the given function and take the indicated derivatives: $\psi(x) = Ae^{ikx}$.

$\frac{d\psi(x)}{dx} = Aike^{ikx}$. $\frac{d^2\psi(x)}{dx^2} = Ai^2k^2e^{ikx} = -Ak^2e^{ikx}$. $\frac{d^2\psi(x)}{dx^2} = -k^2\psi(x)$. $-\frac{\hbar}{2m}\frac{d^2\psi(x)}{dx^2} = \frac{\hbar^2}{2m}k^2\psi(x).$

Substituting these results into the one-dimensional Schrödinger equation gives

$$\frac{\hbar^2k^2}{2m}\psi(x) + U_0\psi(x) = E\,\psi(x).$$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: $\psi(x) = A\,e^{ikx}$ is a solution to the one-dimensional Schrödinger equation if $E - U_0 = \dfrac{\hbar^2 k^2}{2m}$ or $k = \sqrt{\dfrac{2m(E-U_0)}{\hbar^2}}$. (Since $U_0 < E$ was given, k is the square root of a positive quantity.) In terms of the particle's momentum p: $k = p/\hbar$, and in terms of the particle's de Broglie wavelength λ: $k = 2\pi/\lambda$.

40.51. **IDENTIFY:** Let *I* refer to the region $x < 0$ and let *II* refer to the region $x > 0$, so $\psi_I(x) = Ae^{ik_1x} + Be^{-ik_1x}$ and $\psi_{II}(x) = Ce^{ik_2x}$. Set $\psi_I(0) = \psi_{II}(0)$ and $\dfrac{d\psi_I}{dx} = \dfrac{d\psi_{II}}{dx}$ at $x = 0$.

SET UP: $\dfrac{d}{dx}(e^{ikx}) = ike^{ikx}$.

EXECUTE: $\psi_I(0) = \psi_{II}(0)$ gives $A + B = C$. $\dfrac{d\psi_I}{dx} = \dfrac{d\psi_{II}}{dx}$ at $x = 0$ gives $ik_1A - ik_1B = ik_2C$. Solving this pair of equations for B and C gives $B = \left(\dfrac{k_1 - k_2}{k_1 + k_2}\right)A$ and $C = \left(\dfrac{2k_2}{k_1 + k_2}\right)A$.

EVALUATE: The probability of reflection is $R = \dfrac{B^2}{A^2} = \dfrac{(k_1 - k_2)^2}{(k_1 + k_2)^2}$. The probability of transmission is $T = \dfrac{C^2}{A^2} = \dfrac{4k_1^2}{(k_1 + k_2)^2}$. Note that $R + T = 1$.

40.52. **IDENTIFY:** For a particle in a box, $E_n = \dfrac{n^2h^2}{8mL^2}$.

SET UP: $\Delta E_n = E_{n+1} - E_n$

EXECUTE: **(a)** $R_n = \dfrac{(n+1)^2 - n^2}{n^2} = \dfrac{2n+1}{n^2} = \dfrac{2}{n} + \dfrac{1}{n^2}$. This is never larger than it is for $n = 1$, and $R_1 = 3$.

EVALUATE: **(b)** R_n approaches zero as n becomes very large. In the classical limit there is no quantization and the spacing of successive levels is vanishingly small compared to the energy levels. Therefore, R_n for a particle in a box approaches the classical value as n becomes very large.

40.53. **IDENTIFY** and **SET UP:** The energy levels are given by Eq. (40.31): $E_n = \dfrac{n^2h^2}{8mL^2}$. Calculate ΔE for the transition and set $\Delta E = hc/\lambda$, the energy of the photon.

EXECUTE: **(a)** Ground level, $n = 1$, $E_1 = \dfrac{h^2}{8mL^2}$. First excited level, $n = 2$, $E_2 = \dfrac{4h^2}{8mL^2}$. The transition energy is $\Delta E = E_2 - E_1 = \dfrac{3h^2}{8mL^2}$. Set the transition energy equal to the energy hc/λ of the emitted photon. This gives $\dfrac{hc}{\lambda} = \dfrac{3h^2}{8mL^2}$. $\lambda = \dfrac{8mcL^2}{3h} = \dfrac{8(9.109\times10^{-31}\text{ kg})(2.998\times10^{8}\text{ m/s})(4.18\times10^{-9}\text{ m})^2}{3(6.626\times10^{-34}\text{ J}\cdot\text{s})}$.

$\lambda = 1.92\times10^{-5}\text{ m} = 19.2\ \mu\text{m}$.

(b) Second excited level has $n = 3$ and $E_3 = \dfrac{9h^2}{8mL^2}$ The transition energy is

$\Delta E = E_3 - E_2 = \dfrac{9h^2}{8mL^2} - \dfrac{4h^2}{8mL^2} = \dfrac{5h^2}{8mL^2}$. $\dfrac{hc}{\lambda} = \dfrac{5h^2}{8mL^2}$ so $\lambda = \dfrac{8mcL^2}{5h} = \dfrac{3}{5}(19.2\ \mu\text{m}) = 11.5\ \mu\text{m}$.

EVALUATE: The energy spacing between adjacent levels increases with n, and this corresponds to a shorter wavelength and more energetic photon in part (b) than in part (a).

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

40.54. **IDENTIFY:** The probability of finding the particle between x_1 and x_2 is $\int_{x_1}^{x_2}|\psi|^2\,dx$.

SET UP: For the ground state $\psi_1=\sqrt{\frac{2}{L}}\sin\frac{\pi x}{L}$. $\sin^2\theta=\frac{1}{2}(1-\cos 2\theta)$. $\int\cos\alpha x\,dx=\frac{1}{\alpha}\sin\alpha x$.

EXECUTE: **(a)** $\frac{2}{L}\int_0^{L/4}\sin^2\frac{\pi x}{L}dx=\frac{2}{L}\int_0^{L/4}\frac{1}{2}\left(1-\cos\frac{2\pi x}{L}\right)dx=\frac{1}{L}\left(x-\frac{L}{2\pi}\sin\frac{2\pi x}{L}\right)_0^{L/4}=\frac{1}{4}-\frac{1}{2\pi}$, which is about 0.0908.

(b) Repeating with limits of $L/4$ and $L/2$ gives $\frac{1}{L}\left(x-\frac{L}{2\pi}\sin\frac{2\pi x}{L}\right)_{L/4}^{L/2}=\frac{1}{4}+\frac{1}{2\pi}$, about 0.409.

(c) The particle is much likely to be nearer the middle of the box than the edge.

EVALUATE: **(d)** The results sum to exactly $\frac{1}{2}$. Since the probability of the particle being anywhere in the box is unity, the probability of the particle being found between $x=L/2$ and $x=L$ is also $\frac{1}{2}$. This means that the particle is as likely to be between $x=0$ and $L/2$ as it is to be between $x=L/2$ and $x=L$.

(e) These results are consistent with Figure 40.12b in the textbook. This figure shows a greater probability near the center of the box. It also shows symmetry of $|\psi|^2$ about the center of the box.

40.55. **IDENTIFY:** The probability of the particle being between x_1 and x_2 is $\int_{x_1}^{x_2}|\psi|^2\,dx$, where ψ is the normalized wave function for the particle.

(a) SET UP: The normalized wave function for the ground state is $\psi_1=\sqrt{\frac{2}{L}}\sin\left(\frac{\pi x}{L}\right)$.

EXECUTE: The probability P of the particle being between $x=L/4$ and $x=3L/4$ is $P=\int_{L/4}^{3L/4}|\psi_1|^2dx=\frac{2}{L}\int_{L/4}^{3L/4}\sin^2\left(\frac{\pi x}{L}\right)dx$. Let $y=\pi x/L;\,dx=(L/\pi)\,dy$ and the integration limits become $\pi/4$ and $3\pi/4$.

$$P=\frac{2}{L}\left(\frac{L}{\pi}\right)\int_{\pi/4}^{3\pi/4}\sin^2y\,dy=\frac{2}{\pi}\left[\frac{1}{2}y-\frac{1}{4}\sin 2y\right]_{\pi/4}^{3\pi/4}$$

$$P=\frac{2}{\pi}\left[\frac{3\pi}{8}-\frac{\pi}{8}-\frac{1}{4}\sin\left(\frac{3\pi}{2}\right)+\frac{1}{4}\sin\left(\frac{\pi}{2}\right)\right]$$

$P=\frac{2}{\pi}\left(\frac{\pi}{4}-\frac{1}{4}(-1)+\frac{1}{4}(1)\right)=\frac{1}{2}+\frac{1}{\pi}=0.818$. (Note: The integral formula $\int\sin^2y\,dy=\frac{1}{2}y-\frac{1}{4}\sin 2y$ was used.)

(b) SET UP: The normalized wave function for the first excited state is $\psi_2=\sqrt{\frac{2}{L}}\sin\left(\frac{2\pi x}{L}\right)$.

EXECUTE: $P=\int_{L/4}^{3L/4}|\psi_2|^2dx=\frac{2}{L}\int_{L/4}^{3L/4}\sin^2\left(\frac{2\pi x}{L}\right)dx$. Let $y=2\pi x/L;\,dx=(L/2\pi)\,dy$ and the integration limits become $\pi/2$ and $3\pi/2$.

$$P=\frac{2}{L}\left(\frac{L}{2\pi}\right)\int_{\pi/2}^{3\pi/2}\sin^2y\,dy=\frac{1}{\pi}\left[\frac{1}{2}y-\frac{1}{4}\sin 2y\right]_{\pi/2}^{3\pi/2}=\frac{1}{\pi}\left(\frac{3\pi}{4}-\frac{\pi}{4}\right)=0.500$$

(c) EVALUATE: These results are consistent with Figure 40.11b in the textbook. That figure shows that $|\psi|^2$ is more concentrated near the center of the box for the ground state than for the first excited state; this is consistent with the answer to part (a) being larger than the answer to part (b). Also, this figure shows that for the first excited state half the area under $|\psi|^2$ curve lies between $L/4$ and $3L/4$, consistent with our answer to part (b).

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

40.56. **IDENTIFY:** The probability is $|\psi|^2\,dx$, with ψ evaluated at the specified value of x.

SET UP: For the ground state, the normalized wave function is $\psi_1 = \sqrt{2/L}\,\sin(\pi x/L)$.

EXECUTE: **(a)** $(2/L)\sin^2(\pi/4)dx = dx/L$.

(b) $(2/L)\sin^2(\pi/2)dx = 2dx/L$

(c) $(2/L)\sin^2(3\pi/4) = dx/L$

EVALUATE: Our results agree with Figure 40.12b in the textbook. $|\psi|^2$ is largest at the center of the box, at $x = L/2$. $|\psi|^2$ is symmetric about the center of the box, so is the same at $x = L/4$ as at $x = 3L/4$.

40.57. **IDENTIFY** and **SET UP:** The normalized wave function for the $n = 2$ first excited level is $\psi_2 = \sqrt{\frac{2}{L}}\sin\left(\frac{2\pi x}{L}\right)$. $P = |\psi(x)|^2\,dx$ is the probability that the particle will be found in the interval x to $x + dx$.

EXECUTE: **(a)** $x = L/4$

$$\psi(x) = \sqrt{\frac{2}{L}}\sin\left(\left(\frac{2\pi}{L}\right)\left(\frac{L}{4}\right)\right) = \sqrt{\frac{2}{L}}\sin\left(\frac{\pi}{2}\right) = \sqrt{\frac{2}{L}}.$$

$P = (2/L)dx$

(b) $x = L/2$

$$\psi(x) = \sqrt{\frac{2}{L}}\sin\left(\left(\frac{2\pi}{L}\right)\left(\frac{L}{2}\right)\right) = \sqrt{\frac{2}{L}}\sin(\pi) = 0.$$

$P = 0$

(c) $x = 3L/4$

$$\psi(x) = \sqrt{\frac{2}{L}}\sin\left(\left(\frac{2\pi}{L}\right)\left(\frac{3L}{4}\right)\right) = \sqrt{\frac{2}{L}}\sin\left(\frac{3\pi}{2}\right) = -\sqrt{\frac{2}{L}}.$$

$P = (2/L)dx$

EVALUATE: Our results are consistent with the $n = 2$ part of Figure 40.12 in the textbook. $|\psi|^2$ is zero at the center of the box and is symmetric about this point.

40.58. **IDENTIFY:** The impulse applied to a particle equals its change in momentum.

SET UP: For a particle in a box, the magnitude of its momentum is $p = \hbar k = \frac{nh}{2L}$ (Eq. 40.29).

EXECUTE: $\Delta\vec{\boldsymbol{p}} = \vec{\boldsymbol{p}}_{\text{final}} - \vec{\boldsymbol{p}}_{\text{initial}}$. $|\vec{\boldsymbol{p}}| = \hbar k = \frac{\hbar n\pi}{L} = \frac{hn}{2L}$. At $x = 0$ the initial momentum at the wall is $\vec{\boldsymbol{p}}_{\text{initial}} = -\frac{hn}{2L}\hat{\boldsymbol{i}}$ and the final momentum, after turning around, is $\vec{\boldsymbol{p}}_{\text{final}} = +\frac{hn}{2L}\hat{\boldsymbol{i}}$. So, $\Delta\vec{\boldsymbol{p}} = +\frac{hn}{2L}\hat{\boldsymbol{i}} - \left(-\frac{hn}{2L}\hat{\boldsymbol{i}}\right) = +\frac{hn}{L}\hat{\boldsymbol{i}}$. At $x = L$ the initial momentum is $\vec{\boldsymbol{p}}_{\text{initial}} = +\frac{hn}{2L}\hat{\boldsymbol{i}}$ and the final momentum, after turning around, is $\vec{\boldsymbol{p}}_{\text{final}} = -\frac{hn}{2L}\hat{\boldsymbol{i}}$. So, $\Delta\vec{\boldsymbol{p}} = -\frac{hn}{2L}\hat{\boldsymbol{i}} - \frac{hn}{2L}\hat{\boldsymbol{i}} = -\frac{hn}{L}\hat{\boldsymbol{i}}$.

EVALUATE: The impulse increases with n.

40.59. **IDENTIFY:** Carry out the calculations that are specified in the problem.

SET UP: For a free particle, $U(x) = 0$ so Schrödinger's equation becomes $\frac{d^2\psi(x)}{dx^2} = -\frac{2m}{\hbar^2}E\psi(x)$.

EXECUTE: **(a)** The graph is given in Figure 40.59.

(b) For $x < 0$: $\psi(x) = e^{+\kappa x}$. $\frac{d\psi(x)}{dx} = \kappa e^{+\kappa x}$. $\frac{d^2\psi(x)}{dx} = \kappa^2 e^{+\kappa x}$. So $\kappa^2 = -\frac{2m}{\hbar^2}E \Rightarrow E = -\frac{\hbar^2\kappa^2}{2m}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(c) For $x > 0$: $\psi(x) = e^{-\kappa x}$. $\dfrac{d\psi(x)}{dx} = -\kappa e^{-\kappa x}$. $\dfrac{d^2\psi(x)}{dx} = \kappa^2 e^{-\kappa x}$. So again $\kappa^2 = -\dfrac{2m}{\hbar^2}E \Rightarrow E = \dfrac{-\hbar^2\kappa^2}{2m}$.

Parts (b) and (c) show $\psi(x)$ satisfies the Schrödinger's equation, provided $E = \dfrac{-\hbar^2\kappa^2}{2m}$.

EVALUATE: **(d)** $\dfrac{d\psi(x)}{dx}$ is discontinuous at $x = 0$. (That is, it is negative for $x > 0$ and positive for $x < 0$.) Therefore, this ψ is not an acceptable wave function; $d\psi/dx$ must be continuous everywhere, except where $U \to \infty$.

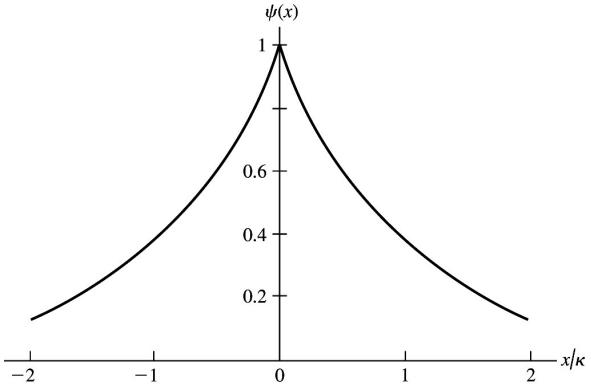

Figure 40.59

40.60. **IDENTIFY:** We start with the penetration distance formula given in the problem.

SET UP: The given formula is $\eta = \dfrac{\hbar}{\sqrt{2m(U_0 - E)}}$.

EXECUTE: **(a)** Substitute the given numbers into the formula:

$$\eta = \frac{\hbar}{\sqrt{2m(U_0 - E)}} = \frac{1.055\times10^{-34}\ \text{J}\cdot\text{s}}{\sqrt{2(9.11\times10^{-31}\ \text{kg})(20\ \text{eV} - 13\ \text{eV})(1.602\times10^{-19}\ \text{J/eV})}} = 7.4\times10^{-11}\ \text{m}$$

(b) $$\eta = \frac{1.055\times10^{-34}\ \text{J}\cdot\text{s}}{\sqrt{2(1.67\times10^{-27}\ \text{kg})(30\ \text{MeV} - 20\ \text{MeV})(1.602\times10^{-13}\ \text{J/MeV})}} = 1.44\times10^{-15}\ \text{m}$$

EVALUATE: The penetration depth varies widely depending on the mass and energy of the particle.

40.61. **IDENTIFY:** Eq. (40.38) applies for $0 \le x \le L$. Eq. (40.40) applies for $x < 0$ and $x > L$. $D = 0$ for $x < 0$ and $C = 0$ for $x > L$.

SET UP: Let $k = \dfrac{\sqrt{2mE}}{\hbar}$. $\dfrac{d}{dx}\sin kx = k\cos kx$. $\dfrac{d}{dx}\cos kx = -k\sin kx$. $\dfrac{d}{dx}e^{\kappa x} = \kappa e^{\kappa x}$. $\dfrac{d}{dx}e^{-\kappa x} = -\kappa e^{-\kappa x}$.

EXECUTE: **(a)** We set the solutions for inside and outside the well equal to each other at the well boundaries, $x = 0$ and L.

$x = 0$: $B\sin(0) + A = C \Rightarrow A = C$, since we must have $D = 0$ for $x < 0$.

$x = L$: $B\sin\dfrac{\sqrt{2mE}L}{\hbar} + A\cos\dfrac{\sqrt{2mE}L}{\hbar} = +De^{-\kappa L}$ since $C = 0$ for $x > L$.

This gives $B\sin kL + A\cos kL = De^{-\kappa L}$, where $k = \dfrac{\sqrt{2mE}}{\hbar}$.

(b) Requiring continuous derivatives at the boundaries yields

$x = 0$: $\dfrac{d\psi}{dx} = kB\cos(k\cdot 0) - kA\sin(k\cdot 0) = kB = \kappa Ce^{k\cdot 0} \Rightarrow kB = \kappa C$.

$x = L$: $kB\cos kL - kA\sin kL = -\kappa De^{-\kappa L}$

EVALUATE: These boundary conditions allow for B, C, and D to be expressed in terms of an overall normalization constant A.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

40.62. **IDENTIFY:** $T = Ge^{-2\kappa L}$ with $G = 16\dfrac{E}{U_0}\left(1-\dfrac{E}{U_0}\right)$ and $\kappa = \dfrac{\sqrt{2m(U_0-E)}}{\hbar}$, so $L = -\dfrac{1}{2\kappa}\ln\left(\dfrac{T}{G}\right)$.

SET UP: $E = 5.5$ eV, $U_0 = 10.0$ eV, $m = 9.11\times10^{-31}$ kg, and $T = 0.0010$.

EXECUTE: $\kappa = \dfrac{\sqrt{2(9.11\times10^{-31}\text{ kg})(4.5\text{ eV})(1.60\times10^{-19}\text{ J/eV})}}{(1.054\times10^{-34}\text{ J}\cdot\text{s})} = 1.09\times10^{10}\text{ m}^{-1}$

and $G = 16\dfrac{5.5\text{ eV}}{10.0\text{ eV}}\left(1-\dfrac{5.5\text{ eV}}{10.0\text{ eV}}\right) = 3.96,$

so $L = -\dfrac{1}{2(1.09\times10^{10}\text{ m}^{-1})}\ln\left(\dfrac{0.0010}{3.96}\right) = 3.8\times10^{-10}\text{ m} = 0.38\text{ nm}.$

EVALUATE: The energies here are comparable to those of electrons in atoms, and the barrier width we calculated is on the order of the diameter of an atom.

40.63. **IDENTIFY** and **SET UP:** When κL is large, then $e^{\kappa L}$ is large and $e^{-\kappa L}$ is small. When κL is small, $\sinh\ \kappa L \to \kappa L$. Consider both κL large and κL small limits.

EXECUTE: **(a)** $T = \left[1+\dfrac{(U_0\sinh\kappa L)^2}{4E(U_0-E)}\right]^{-1}$

$\sinh\ \kappa L = \dfrac{e^{\kappa L}-e^{-\kappa L}}{2}$

For $\kappa L \gg 1$, $\sinh\ \kappa L \to \dfrac{e^{\kappa L}}{2}$ and $T \to \left[1+\dfrac{U_0^2e^{2\kappa L}}{16E(U_0-E)}\right]^{-1} = \dfrac{16E(U_0-E)}{16E(U_0-E)+U_0^2e^{2\kappa L}}$

For $\kappa L \gg 1$, $16E(U_0-E)+U_0^2e^{2\kappa L} \to U_0^2e^{2\kappa L}$

$T \to \dfrac{16E(U_0-E)}{U_0^2e^{2\kappa L}} = 16\left(\dfrac{E}{U_0}\right)\left(1-\dfrac{E}{U_0}\right)e^{-2\kappa L}$, which is Eq. (40.42).

(b) $\kappa L = \dfrac{L\sqrt{2m(U_0-E)}}{\hbar}$. So $\kappa L \gg 1$ when L is large (barrier is wide) or $U_0 - E$ is large. (E is small compared to U_0.)

(c) $\kappa = \dfrac{\sqrt{2m(U_0-E)}}{\hbar}$; κ becomes small as E approaches U_0. For κ small, $\sinh\kappa L \to \kappa L$ and

$T \to \left[1+\dfrac{U_0^2\kappa^2L^2}{4E(U_0-E)}\right]^{-1} = \left[1+\dfrac{U_0^2\,2m(U_0-E)L^2}{\hbar^2\,4E(U_0-E)}\right]^{-1}$ (using the definition of κ).

Thus $T \to \left[1+\dfrac{2U_0^2L^2m}{4E\hbar^2}\right]^{-1}$

$U_0 \to E$ so $\dfrac{U_0^2}{E} \to E$ and $T \to \left[1+\dfrac{2EL^2m}{4\hbar^2}\right]^{-1}$

But $k^2 = \dfrac{2mE}{\hbar^2}$, so $T \to \left[1+\left(\dfrac{kL}{2}\right)^2\right]^{-1}$, as was to be shown.

EVALUATE: When κL is large Eq. (40.41) applies and T is small. When $E \to U_0$, T does not approach unity.

40.64. **IDENTIFY:** Compare the energy E of the oscillator to Eq. (40.46) in order to determine n.
SET UP: At the equilibrium position the potential energy is zero and the kinetic energy equals the total energy.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: **(a)** $E=\frac{1}{2}mv^2=[n+(1/2)]\hbar\omega=[n+(1/2)]hf$, and solving for n,

$$n=\frac{\frac{1}{2}mv^2}{hf}-\frac{1}{2}=\frac{(1/2)(0.020\text{ kg})(0.360\text{ m/s})^2}{(6.63\times10^{-34}\text{ J}\cdot\text{s})(1.50\text{ Hz})}-\frac{1}{2}=1.3\times10^{30}.$$

(b) The difference between energies is $\hbar\omega=hf=(6.63\times10^{-34}\text{ J}\cdot\text{s})(1.50\text{ Hz})=9.95\times10^{-34}$ J. This energy is too small to be detected with current technology.

EVALUATE: This oscillator can be described classically; quantum effects play no measurable role.

40.65. **IDENTIFY** and **SET UP:** Calculate the angular frequency ω of the pendulum and apply Eq. (40.46) for the energy levels.

EXECUTE: $\omega=\frac{2\pi}{T}=\frac{2\pi}{0.500\text{ s}}=4\pi\text{ s}^{-1}$

The ground-state energy is $E_0=\frac{1}{2}\hbar\omega=\frac{1}{2}(1.055\times10^{-34}\text{ J}\cdot\text{s})(4\pi\text{ s}^{-1})=6.63\times10^{-34}$ J.

$E_0=6.63\times10^{-34}\text{ J}(1\text{ eV}/1.602\times10^{-19}\text{ J})=4.14\times10^{-15}$ eV

$E_n=\left(n+\frac{1}{2}\right)\hbar\omega$

$E_{n+1}=\left(n+1+\frac{1}{2}\right)\hbar\omega$

The energy difference between the adjacent energy levels is

$\Delta E=E_{n+1}-E_n=\hbar\omega=2E_0=1.33\times10^{-33}\text{ J}=8.30\times10^{-15}$ eV.

EVALUATE: These energies are much too small to detect. Quantum effects are not important for ordinary size objects.

40.66. **IDENTIFY:** We model the electrons in the lattice as a particle in a box. The energy of the photon is equal to the energy difference between the two energy states in the box.

SET UP: The energy of an electron in the n^{th} level is $E_n=\frac{n^2h^2}{8mL^2}$. We do not know the initial or final levels, but we do know they differ by 1. The energy of the photon, hc/λ, is equal to the energy difference between the two states.

EXECUTE: The energy difference between the levels is $\Delta E=\frac{hc}{\lambda}=\frac{(6.63\times10^{-34}\text{ J}\cdot\text{s})(3.00\times10^8\text{ m/s})}{1.649\times10^{-7}\text{ m}}=$ 1.206×10^{-18} J. Using the formula for the energy levels in a box, this energy difference is equal to

$\Delta E=\left[n^2-(n-1)^2\right]\frac{h^2}{8mL^2}=(2n-1)\frac{h^2}{8mL^2}$.

Solving for n gives $n=\frac{1}{2}\left(\frac{\Delta E8mL^2}{h^2}+1\right)=\frac{1}{2}\left(\frac{(1.206\times10^{-18}\text{ J})8(9.11\times10^{-31}\text{ kg})(0.500\times10^{-9}\text{ m})^2}{(6.626\times10^{-34}\text{ J}\cdot\text{s})^2}+1\right)=3.$

The transition is from $n=3$ to $n=2$.

EVALUATE: We know the transition is not from the $n=4$ to the $n=3$ state because we let n be the higher state and $n-1$ the lower state.

40.67. **IDENTIFY:** At a maximum, the derivative of the probability function is zero.

SET UP and **EXECUTE:** $\psi(x)=Ce^{-\alpha x^2}$, where $\alpha=\frac{\sqrt{mk'}}{2\hbar}$. $|\psi(x)|^2=|C|^2e^{-2\alpha x^2}$. At values of x where $|\psi(x)|^2$ is a maximum, $\frac{d|\psi(x)|^2}{dx}=0$ and $\frac{d^2|\psi(x)|^2}{dx^2}<0$. $\frac{d|\psi(x)|^2}{dx}=|C|^2(-2\alpha x)e^{-2\alpha x^2}=0$. Only

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

solution is $x = 0$. $\dfrac{d^2|\psi(x)|^2}{dx^2} = |C|^2\left[-2\alpha e^{-2\alpha x^2} + 4\alpha^2 x\, e^{-2\alpha x^2}\right]$. At $x = 0$, $\dfrac{d^2|\psi(x)|^2}{dx^2} = |C|^2(-2\alpha) < 0$, so $|\psi(x)|^2$ is a maximum at $x = 0$.

EVALUATE: There is only one maximum, at $x = 0$, so the probability function peaks only there.

40.68. **IDENTIFY:** If the given wave function is a solution to the Schrödinger equation, we will get an identity when we substitute that wave function into the Schrödinger equation.

SET UP: The given wave function is $\psi_1(x) = A_1 x e^{-\alpha^2 x^2/2}$ and the Schrödinger equation is

$$-\frac{\hbar}{2m}\frac{d^2\psi(x)}{dx^2} + \frac{k'x^2}{2}\psi(x) = E\,\psi(x).$$

EXECUTE: **(a)** Start by taking the indicated derivatives: $\psi_1(x) = A_1 x e^{-\alpha^2 x^2/2}$.

$$\frac{d\psi_1(x)}{dx} = -\alpha^2 x^2 A_1 e^{-\alpha^2 x^2/2} + A_1 e^{-\alpha^2 x^2/2}.$$

$$\frac{d^2\psi_1(x)}{dx^2} = -A_1\alpha^2 2x e^{-\alpha^2 x^2/2} - A_1\alpha^2 x^2(-\alpha^2 x)e^{-\alpha^2 x^2/2} + A_1(-\alpha^2 x)e^{-\alpha^2 x^2/2}.$$

$$\frac{d^2\psi_1(x)}{dx^2} = \left[-2\alpha^2 + (\alpha^2)^2 x^2 - \alpha^2\right]\psi_1(x) = \left[-3\alpha^2 + (\alpha^2)^2 x^2\right]\psi_1(x).$$

$$-\frac{\hbar}{2m}\frac{d^2\psi_1(x)}{dx^2} = -\frac{\hbar^2}{2m}\left[-3\alpha^2 + (\alpha^2)^2 x^2\right]\psi_1(x).$$

Equation (40.44) is $-\dfrac{\hbar}{2m}\dfrac{d^2\psi(x)}{dx^2} + \dfrac{k'x^2}{2}\psi(x) = E\,\psi(x)$. Substituting the above result into that equation gives $-\dfrac{\hbar^2}{2m}\left[-3\alpha^2 + (\alpha^2)^2 x^2\right]\psi_1(x) + \dfrac{k'x^2}{2}\psi_1(x) = E\,\psi_1(x)$. Since $\alpha^2 = \dfrac{m\omega}{\hbar}$ and $\omega = \sqrt{\dfrac{k'}{m}}$, the coefficient of x^2 is $-\dfrac{\hbar^2}{2m}(\alpha^2)^2 + \dfrac{k'}{2} = -\dfrac{\hbar^2}{2m}\left(\dfrac{m\omega}{\hbar}\right)^2 + \dfrac{m\omega^2}{2} = 0$.

(b) $A_1 = \left(\dfrac{m\omega}{\hbar}\right)^{3/4}\left(\dfrac{4}{\pi}\right)^{1/4}$

(c) The probability density function $|\psi|^2$ is $|\psi_1(x)|^2 = A_1^2 x^2 e^{-\alpha^2 x^2}$

At $x = 0$, $|\psi_1|^2 = 0$. $\dfrac{d|\psi_1(x)|^2}{dx} = A_1^2 2x e^{-\alpha^2 x^2} + A_1^2 x^2(-\alpha^2 2x)e^{-\alpha^2 x^2} = A_1^2 2x e^{-\alpha^2 x^2} - A_1^2 2x^3\alpha^2 e^{-\alpha^2 x^2}$.

At $x = 0$, $\dfrac{d|\psi_1(x)|^2}{dx} = 0$. At $x = \pm\dfrac{1}{\alpha}$, $\dfrac{d|\psi_1(x)|^2}{dx} = 0$.

$$\frac{d^2|\psi_1(x)|^2}{dx^2} = A_1^2 2e^{-\alpha^2 x^2} + A_1^2 2x(-\alpha^2 2x)e^{-\alpha^2 x^2} - A_1^2 2(3x^2)\alpha^2 e^{-\alpha^2 x^2} - A_1^2 2x^3\alpha^2(-\alpha^2 2x)e^{-\alpha^2 x^2}.$$

$$\frac{d^2|\psi_1(x)|^2}{dx^2} = A_1^2 2e^{-\alpha^2 x^2} - A_1^2 4x^2\alpha^2 e^{-\alpha^2 x^2} - A_1^2 6x^2\alpha^2 e^{-\alpha^2 x^2} + A_1^2 8x^4(\alpha^2)^2 e^{-\alpha^2 x^2}.$$ At $x = 0$,

$\dfrac{d^2|\psi_1(x)|^2}{dx^2} > 0$. So at $x = 0$, the first derivative is zero and the second derivative is positive. Therefore, the probability density function has a minimum at $x = 0$. At $x = \pm\dfrac{1}{\alpha}$, $\dfrac{d^2|\psi_1(x)|^2}{dx^2} < 0$. So at $x = \pm\dfrac{1}{\alpha}$, the first derivative is zero and the second derivative is negative. Therefore, the probability density function has maxima at $x = \pm\dfrac{1}{\alpha}$, corresponding to the classical turning points for $n = 0$ as found in the previous question.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: $\psi_1(x) = A_1 x e^{-\alpha^2 x^2/2}$ is a solution to Eq. (40.44) if $-\frac{\hbar^2}{2m}(-3\alpha^2)\psi_1(x) = E\,\psi_1(x)$ or $E = \frac{3\hbar^2\alpha^2}{2m} = \frac{3\hbar\omega}{2}$. $E_1 = \frac{3\hbar\omega}{2}$ corresponds to $n = 1$ in Equation (40.46).

40.69. **IDENTIFY:** For a standing wave in the box, there must be a node at each wall and $n\left(\frac{\lambda}{2}\right) = L$.

SET UP: $p = \frac{h}{\lambda}$ so $mv = \frac{h}{\lambda}$.

EXECUTE: **(a)** For a standing wave, $n\lambda = 2L$, and $E_n = \frac{p^2}{2m} = \frac{(h/\lambda)^2}{2m} = \frac{n^2h^2}{8mL^2}$.

(b) With $L = a_0 = 0.5292\times10^{-10}$ m, $E_1 = 2.15\times10^{-17}$ J $= 134$ eV.

EVALUATE: For a hydrogen atom, E_n is proportional to $1/n^2$ so this is a very poor model for a hydrogen atom. In particular, it gives very inaccurate values for the separations between energy levels.

40.70. **IDENTIFY** and **SET UP:** Follow the steps specified in the problem.

EXECUTE: **(a)** As with the particle in a box, $\psi(x) = A\sin kx$, where A is a constant and $k^2 = 2mE/\hbar^2$. Unlike the particle in a box, however, k and hence E do not have simple forms.

(b) For $x > L$, the wave function must have the form of Eq. (40.40). For the wave function to remain finite as $x \to \infty$, $C = 0$. The constant $\kappa^2 = 2m(U_0 - E)/\hbar$, as in Eq. (40.40).

(c) At $x = L$, $A\sin kL = De^{-\kappa L}$ and $kA\cos kL = -\kappa De^{-\kappa L}$. Dividing the second of these by the first gives $k\cot kL = -\kappa$, a transcendental equation that must be solved numerically for different values of the length L and the ratio E/U_0.

EVALUATE: When $U_0 \to \infty$, $\kappa \to \infty$ and $\frac{\cos(kL)}{\sin(kL)} \to \infty$. The solutions become $k = \frac{n\pi}{L}$, $n = 1, 2, 3,\ldots$, the same as for a particle in a box.

40.71. **IDENTIFY:** Require $\psi(-L/2) = \psi(L/2) = 0$.

SET UP: $k = \frac{2\pi}{\lambda}$, $p = \frac{h}{\lambda}$ and $E = \frac{p^2}{2m}$.

EXECUTE: **(a)** $\psi(x) = A\sin kx$ and $\psi(-L/2) = 0 = \psi(+L/2)$

$$\Rightarrow 0 = A\sin\left(\frac{+kL}{2}\right) \Rightarrow \frac{+kL}{2} = n\pi \Rightarrow k = \frac{2n\pi}{L} = \frac{2\pi}{\lambda}$$

$$\Rightarrow \lambda = \frac{L}{n} \Rightarrow p_n = \frac{h}{\lambda} = \frac{nh}{L} \Rightarrow E_n = \frac{p^2}{2m} = \frac{n^2h^2}{2mL^2} = \frac{(2n)^2h^2}{8mL^2}, \text{ where } n = 1, 2\ldots$$

(b) $\psi(x) = A\cos kx$ and $\psi(-L/2) = 0 = \psi(+L/2)$

$$\Rightarrow 0 = A\cos\left(\frac{kL}{2}\right) \Rightarrow \frac{kL}{2} = (2n+1)\frac{\pi}{2} \Rightarrow k = \frac{(2n+1)\pi}{L} = \frac{2\pi}{\lambda}$$

$$\Rightarrow \lambda = \frac{2L}{(2n+1)} \Rightarrow p_n = \frac{(2n+1)h}{2L}$$

$$\Rightarrow E_n = \frac{(2n+1)^2h^2}{8mL^2}\ n = 0, 1, 2\ldots$$

(c) The combination of all the energies in parts (a) and (b) is the same energy levels as given in Eq. (40.31), where $E_n = \frac{n^2h^2}{8mL^2}$.

EVALUATE: **(d)** Part (a)'s wave functions are odd, and part (b)'s are even.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

40.72. **IDENTIFY** and **SET UP:** Follow the steps specified in the problem.

EXECUTE: **(a)** $E = K + U(x) = \dfrac{p^2}{2m} + U(x) \Rightarrow p = \sqrt{2m(E - U(x))}$. $\lambda = \dfrac{h}{p} \Rightarrow \lambda(x) = \dfrac{h}{\sqrt{2m(E - U(x))}}$.

(b) As $U(x)$ gets larger (i.e., $U(x)$ approaches E from below—recall $k \geq 0$), $E - U(x)$ gets smaller, so $\lambda(x)$ gets larger.

(c) When $E = U(x)$, $E - U(x) = 0$, so $\lambda(x) \to \infty$.

(d) $\displaystyle\int_a^b \frac{dx}{\lambda(x)} = \int_a^b \frac{dx}{h/\sqrt{2m(E - U(x))}} = \frac{1}{h}\int_a^b \sqrt{2m(E - U(x))}\, dx = \frac{n}{2} \Rightarrow \int_a^b \sqrt{2m(E - U(x))}\, dx = \frac{hn}{2}$.

(e) $U(x) = 0$ for $0 < x < L$ with classical turning points at $x = 0$ and $x = L$. So,

$\displaystyle\int_a^b \sqrt{2m(E - U(x))}\, dx = \int_0^L \sqrt{2mE}\, dx = \sqrt{2mE}\int_0^L dx = \sqrt{2mE}L$. So, from part (d),

$\displaystyle\sqrt{2mE}L = \frac{hn}{2} \Rightarrow E = \frac{1}{2m}\left(\frac{hn}{2L}\right)^2 = \frac{h^2 n^2}{8mL^2}$.

EVALUATE: **(f)** Since $U(x) = 0$ in the region between the turning points at $x = 0$ and $x = L$, the result is the *same* as part (e). The height U_0 never enters the calculation. WKB is best used with *smoothly* varying potentials $U(x)$.

40.73. **DENTIFY:** Perform the calculations specified in the problem.

SET UP: $U(x) = \frac{1}{2}k'x^2$.

EXECUTE: **(a)** At the turning points $\displaystyle E = \frac{1}{2}k'x_{\text{TP}}^2 \Rightarrow x_{\text{TP}} = \pm\sqrt{\frac{2E}{k'}}$.

(b) $\displaystyle\int_{-\sqrt{2E/k'}}^{+\sqrt{2E/k'}} \sqrt{2m\left(E - \frac{1}{2}k'x^2\right)}dx = \frac{nh}{2}$. To evaluate the integral, we want to get it into a form that matches the standard integral given. $\displaystyle\sqrt{2m\left(E - \frac{1}{2}k'x^2\right)} = \sqrt{2mE - mk'x^2} = \sqrt{mk'}\sqrt{\frac{2mE}{mk'} - x^2} = \sqrt{mk'}\sqrt{\frac{2E}{k'} - x^2}$.

Letting $\displaystyle A^2 = \frac{2E}{k'}$, $a = -\sqrt{\frac{2E}{k'}}$, *and* $b = +\sqrt{\frac{2E}{k'}}$

$\displaystyle\Rightarrow \sqrt{mk'}\int_a^b \sqrt{A^2 - x^2}\, dx = 2\frac{\sqrt{mk'}}{2}\left[x\sqrt{A^2 - x^2} + A^2 \arcsin\left(\frac{x}{|A|}\right)\right]\Bigg|_0^b$

$\displaystyle= \sqrt{mk'}\left[\sqrt{\frac{2E}{k'}}\sqrt{\frac{2E}{k'} - \frac{2E}{k'}} + \frac{2E}{k'}\arcsin\left(\frac{\sqrt{2E/k'}}{\sqrt{2E/k'}}\right)\right] = \sqrt{mk'}\,\frac{2E}{k'}\arcsin(1) = 2E\sqrt{\frac{m}{k'}}\left(\frac{1}{2}\right)$.

Using WKB, this is equal to $\dfrac{hn}{2}$, so $\displaystyle E\sqrt{\frac{m}{k'}}\pi = \frac{hn}{2}$. Recall $\displaystyle\omega = \sqrt{\frac{k'}{m}}$, so $\displaystyle E = \frac{h}{2\pi}\omega n = \hbar\omega n$.

EVALUATE: **(c)** We are missing the zero-point-energy offset of $\dfrac{\hbar\omega}{2}\left(\text{recall } E = \hbar\omega\left(n + \dfrac{1}{2}\right)\right)$. It underestimates the energy. However, our approximation isn't bad at all!

40.74. **IDENTIFY** and **SET UP:** Perform the calculations specified in the problem.

EXECUTE: **(a)** At the turning points $E = A|x_{\text{TP}}| \Rightarrow x_{\text{TP}} = \pm\dfrac{E}{A}$.

(b) $\displaystyle\int_{-E/A}^{+E/A} \sqrt{2m(E - A|x|)}dx = 2\int_0^{E/A} \sqrt{2m(E - Ax)}\, dx$. Let $y = 2m(E - Ax) \Rightarrow$

$dy = -2mA\, dx$ when $\displaystyle x = \frac{E}{A}$, $y = 0$, and when $x = 0$, $y = 2mE$. So

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$2\int_0^{\frac{E}{A}}\sqrt{2m(E-Ax)}dx = -\frac{1}{mA}\int_{2mE}^{0} y^{1/2}dy = -\frac{2}{3mA}y^{3/2}\Big|_{2mE}^{0} = \frac{2}{3mA}(2mE)^{3/2}$. Using WKB, this is equal to $\frac{hn}{2}$.

So, $\frac{2}{3mA}(2mE)^{3/2} = \frac{hn}{2} \Rightarrow E = \frac{1}{2m}\left(\frac{3mAh}{4}\right)^{2/3} n^{2/3}$.

EVALUATE: (c) The difference in energy decreases between successive levels. For example:

$$1^{2/3} - 0^{2/3} = 1,\ 2^{2/3} - 1^{2/3} = 0.59,\ 3^{3/2} - 2^{3/2} = 0.49,\ldots$$

- A sharp ∞ step gave ever-increasing level differences $(\sim n^2)$.
- A parabola $(\sim x^2)$ gave evenly spaced levels $(\sim n)$.
- Now, a linear potential $(\sim x)$ gives ever-decreasing level differences $(\sim n^{2/3})$.

Roughly speaking, if the curvature of the potential (~ second derivative) is bigger than that of a parabola, then the level differences will increase. If the curvature is less than a parabola, the differences will decrease.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

41

ATOMIC STRUCTURE

41.1. **IDENTIFY:** For a particle in a cubical box, different values of n_X, n_Y and n_Z can give the same energy.

SET UP: $E_{n_X, n_Y, n_Z} = \dfrac{(n_X^2 + n_Y^2 + n_Z^2)\pi^2\hbar^2}{2mL^2}$.

EXECUTE: **(a)** $n_X^2 + n_Y^2 + n_Z^2 = 3$. This only occurs for $n_X = 1, n_Y = 1, n_Z = 1$ and the degeneracy is 1.

(b) $n_X^2 + n_Y^2 + n_Z^2 = 9$. Occurs for $n_X = 2, n_Y = 1, n_Z = 1$, for $n_X = 1, n_Y = 2, n_Z = 1$ and for $n_X = 1, n_Y = 1, n_Z = 2$. The degeneracy is 3.

EVALUATE: In the second case, three different states all have the same energy.

41.2. **IDENTIFY:** Use an electron in a cubical box to model the hydrogen atom.

SET UP: $E_{1,1,1} = \dfrac{3\pi^2\hbar^2}{2mL^2}$. $E_{2,1,1} = \dfrac{6\pi^2\hbar^2}{2mL^2}$. $\Delta E = \dfrac{3\pi^2\hbar^2}{2mL^2}$. $L^3 = \dfrac{4}{3}\pi a^3$.

$L = \left(\dfrac{4\pi}{3}\right)^{1/3} a = 8.527\times10^{-11}$ m.

EXECUTE: $\Delta E = \dfrac{3\pi^2(1.055\times10^{-34}\ \text{J}\cdot\text{s})^2}{2(9.109\times10^{-31}\ \text{kg})(8.53\times10^{-11}\ \text{m})^2} = 2.49\times10^{-17}\ \text{J} = 155\ \text{eV}$. In the Bohr model, $E = -\dfrac{13.6\ \text{eV}}{n^2}$. The energy separation between the $n = 2$ and $n = 1$ levels is

$\Delta E_{\text{Bohr}} = (13.6\ \text{eV})\left(\dfrac{1}{1^2} - \dfrac{1}{2^2}\right) = \dfrac{3}{4}(13.6\ \text{eV}) = 10.2\ \text{eV}$.

EVALUATE: A particle in a box is not a good model for a hydrogen atom.

41.3. **IDENTIFY:** The energy of the photon is equal to the energy difference between the states. We can use this energy to calculate its wavelength.

SET UP: $E_{1,1,1} = \dfrac{3\pi^2\hbar^2}{2mL^2}$. $E_{2,2,1} = \dfrac{9\pi^2\hbar^2}{2mL^2}$. $\Delta E = \dfrac{3\pi^2\hbar^2}{mL^2}$. $\Delta E = \dfrac{hc}{\lambda}$.

EXECUTE: $\Delta E = \dfrac{3\pi^2(1.055\times10^{-34}\ \text{J}\cdot\text{s})^2}{(9.109\times10^{-31}\ \text{kg})(8.00\times10^{-11}\ \text{m})^2} = 5.653\times10^{-17}$ J. $\Delta E = \dfrac{hc}{\lambda}$ gives

$\lambda = \dfrac{hc}{\Delta E} = \dfrac{(6.626\times10^{-34}\ \text{J}\cdot\text{s})(2.998\times10^{8}\ \text{m/s})}{5.653\times10^{-17}\ \text{J}} = 3.51\times10^{-9}\ \text{m} = 3.51\ \text{nm}$.

EVALUATE: This wavelength is much shorter than that of visible light.

41.4. **IDENTIFY:** Use the probability function for a particle in a three-dimensional box to find the points where it is a maximum.

(a) SET UP: $n_X = 1, n_Y = 1, n_Z = 1$. $|\psi|^2 = \left(\dfrac{L}{2}\right)^3 \left(\sin^2\dfrac{\pi x}{L}\right)\left(\sin^2\dfrac{\pi y}{L}\right)\left(\sin^2\dfrac{\pi z}{L}\right)$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: $|\psi|^2$ is maximum where $\sin\frac{\pi x}{L}=\pm 1$, $\sin\frac{\pi y}{L}=\pm 1$, and $\sin\frac{\pi z}{L}=\pm 1$. $\frac{\pi x}{L}=\frac{\pi}{2}$ and $x=\frac{L}{2}$.

The next larger value is $\frac{\pi x}{L}=\frac{3\pi}{2}$ and $x=\frac{3L}{2}$, but this is outside the box. Similar results obtain for y and z, so $|\psi|^2$ is maximum at the point $x=y=z=L/2$. This point is at the center of the box.

(b) SET UP: $n_X=2, n_Y=2, n_Z=1$. $|\psi|^2=\left(\frac{L}{2}\right)^3\left(\sin^2\frac{2\pi x}{L}\right)\left(\sin^2\frac{2\pi y}{L}\right)\left(\sin^2\frac{\pi z}{L}\right)$.

EXECUTE: $|\psi|^2$ is maximum where $\sin\frac{2\pi x}{L}=\pm 1$, $\sin\frac{2\pi y}{L}=\pm 1$, and $\sin\frac{\pi z}{L}=\pm 1$. $\frac{2\pi x}{L}=\frac{\pi}{2}$ and $x=\frac{L}{4}$. $\frac{2\pi x}{L}=\frac{3\pi}{2}$ and $x=\frac{3L}{4}$. Similarly, $y=\frac{L}{4}$ and $\frac{3L}{4}$. As in part (a), $z=\frac{L}{2}$. $|\psi|^2$ is a maximum at the four points $\left(\frac{L}{4},\frac{L}{4},\frac{L}{2}\right)$, $\left(\frac{L}{4},\frac{3L}{4},\frac{L}{2}\right)$, $\left(\frac{3L}{4},\frac{L}{4},\frac{L}{2}\right)$ and $\left(\frac{3L}{4},\frac{3L}{4},\frac{L}{2}\right)$.

EVLUATE: The points are located symmetrically relative to the center of the box.

41.5. **IDENTIFY:** A particle is in a three-dimensional box. At what planes is its probability function zero?

SET UP: $|\psi_{2,2,1}|^2=\left(\frac{L}{2}\right)^3\left(\sin^2\frac{2\pi x}{L}\right)\left(\sin^2\frac{2\pi y}{L}\right)\left(\sin^2\frac{\pi z}{L}\right)$.

EXECUTE: $|\psi_{2,2,1}|^2=0$ for $\frac{2\pi x}{L}=0,\pi,2\pi,\ldots$. $x=0$ and $x=L$ correspond to walls of the box. $x=\frac{L}{2}$ is the other plane where $|\psi_{2,2,1}|^2=0$. Similarly, $|\psi_{2,2,1}|^2=0$ on the plane $y=\frac{L}{2}$. The $\sin^2\frac{\pi z}{L}$ factor is zero only on the walls of the box. Therefore, for this state $|\psi_{2,2,1}|^2=0$ on the following two planes other than walls of the box: $x=\frac{L}{2}$ and $y=\frac{L}{2}$.

$|\psi_{2,1,1}|^2=\left(\frac{L}{2}\right)^3\left(\sin^2\frac{2\pi x}{L}\right)\left(\sin^2\frac{\pi y}{L}\right)\left(\sin^2\frac{\pi z}{L}\right)$ is zero only on one plane $(x=L/2)$ other than the walls of the box.

$|\psi_{1,1,1}|^2=\left(\frac{L}{2}\right)^3\left(\sin^2\frac{\pi x}{L}\right)\left(\sin^2\frac{\pi y}{L}\right)\left(\sin^2\frac{\pi z}{L}\right)$ is zero only on the walls of the box; for this state there are zero additional planes.

EVALUATE: For comparison, (2,1,1) has two nodal planes, (2,1,1) has one nodal and (1,1,1) has no nodal planes. The number of nodal planes increases as the energy of the state increases.

41.6. **IDENTIFY:** A proton is in a cubical box approximately the size of the nucleus.

SET UP: $E_{1,1,1}=\frac{3\pi^2\hbar^2}{2mL^2}$. $E_{2,1,1}=\frac{6\pi^2\hbar^2}{2mL^2}$. $\Delta E=\frac{3\pi^2\hbar^2}{2mL^2}$.

EXECUTE: $\Delta E=\frac{3\pi^2(1.055\times10^{-34}\ \text{J}\cdot\text{s})^2}{2(1.673\times10^{-27}\ \text{kg})(1.00\times10^{-14}\ \text{m})^2}=9.85\times10^{-13}\ \text{J}=6.15\ \text{MeV}$

EVALUATE: This energy difference is much greater than the energy differences involving orbital electrons.

41.7. **IDENTIFY:** The possible values of the angular momentum are limited by the value of n.

SET UP: For the N shell $n=4$, $0\le l\le n-1$, $|m|\le l$, $m_s=\pm\frac{1}{2}$.

EXECUTE: **(a)** The smallest l is $l=0$. $L=\sqrt{l(l+1)}\hbar$, so $L_{\min}=0$.

(b) The largest l is $n-1=3$ so $L_{\max}=\sqrt{3(4)}\hbar=2\sqrt{3}\hbar=3.65\times10^{-34}\ \text{kg}\cdot\text{m}^2/\text{s}$.

(c) Let the chosen direction be the z-axis. The largest m is $m=l=3$.

$L_{z,\max}=m\hbar=3\hbar=3.16\times10^{-34}\ \text{kg}\cdot\text{m}^2/\text{s}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(d) $S_z = \pm\frac{1}{2}\hbar$. The maximum value is $S_z = \hbar/2 = 5.27\times10^{-35}\ \text{kg}\cdot\text{m}^2/\text{s}$.

(e) $\dfrac{S_z}{L_z} = \dfrac{\frac{1}{2}\hbar}{3\hbar} = \dfrac{1}{6}$.

EVALUATE: The orbital and spin angular momenta are of comparable sizes.

41.8. **IDENTIFY** and **SET UP:** $L = \sqrt{l(l+1)}\hbar$. $L_z = m_l\hbar$. $l = 0, 1, 2, \ldots, n-1$. $m_l = 0, \pm1, \pm2, ..., \pm l$. $\cos\theta = L_z/L$.

EXECUTE: **(a)** $l = 0$: $L = 0$, $L_z = 0$. $l = 1$: $L = \sqrt{2}\hbar$, $L_z = \hbar, 0, -\hbar$. $l = 2$: $L = \sqrt{6}\hbar$, $L_z = 2\hbar, \hbar, 0, -\hbar, -2\hbar$. $l = 3$: $L = 2\sqrt{3}\hbar$, $L_z = 3\hbar, 2\hbar, \hbar, 0, -\hbar, -2\hbar, -3\hbar$. $l = 4$: $L = 2\sqrt{5}\hbar$, $L_z = 4\hbar, 3\hbar, 2\hbar, \hbar, 0, -\hbar, -2\hbar, -3\hbar, -4\hbar$.

(b) $L = 0$: θ not defined. $L = \sqrt{2}\hbar$: 45.0°, 90.0°, 135.0°. $L = \sqrt{6}\hbar$: 35.3°, 65.9°, 90.0°, 114.1°, 144.7°.

$L = 2\sqrt{3}\hbar$: 30.0°, 54.7°, 73.2°, 90.0°, 106.8°, 125.3°, 150.0°.

$L = 2\sqrt{5}\hbar$: 26.6°, 47.9°, 63.4°, 77.1°, 90.0°, 102.9°, 116.6°, 132.1°, 153.4°.

(c) The minimum angle is 26.6° and occurs for $l = 4$, $m_l = +4$. The maximum angle is 153.4° and occurs for $l = 4$, $m_l = -4$.

EVALUATE: There is no state where $\vec{\boldsymbol{L}}$ is totally aligned along the z-axis.

41.9. **IDENTIFY** and **SET UP:** The magnitude of the orbital angular momentum L is related to the quantum number l by Eq. (41.22): $L = \sqrt{l(l+1)}\hbar$, $l = 0, 1, 2, \ldots$

EXECUTE: $l(l+1) = \left(\dfrac{L}{\hbar}\right)^2 = \left(\dfrac{4.716\times10^{-34}\ \text{kg}\cdot\text{m}^2/\text{s}}{1.055\times10^{-34}\ \text{J}\cdot\text{s}}\right)^2 = 20$

And then $l(l+1) = 20$ gives that $l = 4$.

EVALUATE: l must be integer.

41.10. **IDENTIFY** and **SET UP:** $L = \sqrt{l(l+1)}\hbar$. $L_z = m_l\hbar$. $m_l = 0, \pm1, \pm2, \ldots, \pm l$. $\cos\theta = L_z/L$.

EXECUTE: **(a)** $(m_l)_{\max} = 2$, so $(L_z)_{\max} = 2\hbar$.

(b) $L = \sqrt{l(l+1)}\hbar = \sqrt{6}\hbar = 2.45\hbar$. L is larger than $(L_z)_{\max}$.

(c) The angle is $\arccos\left(\dfrac{L_z}{L}\right) = \arccos\left(\dfrac{m_l}{\sqrt{6}}\right)$, and the angles are, for $m_l = -2$ to $m_l = 2$, 144.7°, 114.1°, 90.0°, 65.9°, 35.3°.

EVALUATE: The minimum angle for a given l is for $m_l = l$. The angle corresponding to $m_l = l$ will always be smaller for larger l.

41.11. **IDENTIFY** and **SET UP:** The angular momentum L is related to the quantum number l by Eq. (41.22), $L = \sqrt{l(l+1)}\hbar$. The maximum l, $l_{\max}$, for a given n is $l_{\max} = n-1$.

EXECUTE: For $n = 2$, $l_{\max} = 1$ and $L = \sqrt{2}\hbar = 1.414\hbar$.

For $n = 20$, $l_{\max} = 19$ and $L = \sqrt{(19)(20)}\hbar = 19.49\hbar$.

For $n = 200$, $l_{\max} = 199$ and $L = \sqrt{(199)(200)}\hbar = 199.5\hbar$.

EVALUATE: As n increases, the maximum L gets closer to the value $n\hbar$ postulated in the Bohr model.

41.12. **IDENTIFY:** $l = 0, 1, 2, \ldots, n-1$. $m_l = 0, \pm1, \pm2, \ldots, \pm l$.

SET UP: $E_n = -\dfrac{13.60\ \text{eV}}{n^2}$.

EXECUTE: The (l, m_l) combinations are $(0, 0), (1, 0), (1, \pm1), (2, 0), (2, \pm1), (2, \pm2), (3, 0), (3, \pm1), (3, \pm2), (3, \pm3), (4, 0), (4, \pm1), (4, \pm2), (4, \pm3)$ and $(4, \pm4)$ a total of 25.

(b) Each state has the same energy (n is the same), $-\dfrac{13.60\ \text{eV}}{25} = -0.544\ \text{eV}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: The number of l, m_l combinations is n^2. The energy depends only on n, so is the same for all l, m_l states for a given n.

41.13. **IDENTIFY:** For the 5g state, $l = 4$, which limits the other quantum numbers.

SET UP: $m_l = 0, \pm 1, \pm 2, \ldots, \pm l$. g means $l = 4$. $\cos\theta = L_z/L$, with $L = \sqrt{l(l+1)}\,\hbar$ and $L_z = m_l\hbar$.

EXECUTE: **(a)** There are eighteen 5g states: $m_l = 0, \pm 1, \pm 2, \pm 3, \pm 4$, with $m_s = \pm\frac{1}{2}$ for each.

(b) The largest θ is for the most negative m_l. $L = 2\sqrt{5}\hbar$. The most negative L_z is $L_z = -4\hbar$.

$\cos\theta = \dfrac{-4\hbar}{2\sqrt{5}\hbar}$ and $\theta = 153.4°$.

(c) The smallest θ is for the largest positive m_l, which is $m_l = +4$. $\cos\theta = \dfrac{4\hbar}{2\sqrt{5}\hbar}$ and $\theta = 26.6°$.

EVALUATE: The minimum angle between $\vec{\boldsymbol{L}}$ and the z-axis is for $m_l = +l$ and for that m_l, $\cos\theta = \dfrac{l}{\sqrt{l(l+1)}}$.

41.14. **IDENTIFY:** The probability is $P = \int_0^{a/2} |\psi_{1s}|^2\, 4\pi r^2 dr$.

SET UP: Use the expression for the integral given in Example 41.4.

EXECUTE: **(a)** $P = \dfrac{4}{a^3}\left[\left(-\dfrac{ar^2}{2} - \dfrac{a^2 r}{2} - \dfrac{a^3}{4}\right)e^{-2r/a}\right]_0^{a/2} = 1 - \dfrac{5e^{-1}}{2} = 0.0803.$

(b) Example 41.4 calculates the probability that the electron will be found at a distance less than a from the nucleus. The difference in the probabilities is $(1 - 5e^{-2}) - (1 - (5/2)e^{-1}) = (5/2)(e^{-1} - 2e^{-2}) = 0.243$.

EVALUATE: The probability for distances from $a/2$ to a is about three times the probability for distances between 0 and $a/2$. This agrees with Figure 41.8 in the textbook; $P(r)$ is maximum for $r = a$.

41.15. **IDENTIFY:** $P(a) = \int_0^a |\psi_{1s}|^2\, dV = \int_0^a \dfrac{1}{\pi a^3} e^{-2r/a}(4\pi r^2 dr)$.

SET UP: From Example 41.4, $\int r^2 e^{-2r/a} dr = \left(\dfrac{-ar^2}{2} - \dfrac{a^2 r}{2} - \dfrac{a^3}{4}\right)e^{-2r/a}$.

EXECUTE:

$$P(a) = \frac{4}{a^3}\int_0^a r^2 e^{-2r/a} dr = \frac{4}{a^3}\left[\left(\frac{-ar^2}{2} - \frac{a^2 r}{2} - \frac{a^3}{4}\right)e^{-2r/a}\right]_0^a = \frac{4}{a^3}\left[\left(\frac{-a^3}{2} - \frac{a^3}{2} - \frac{a^3}{4}\right)e^{-2} + \frac{a^3}{4}e^0\right] = 1 - 5e^{-2}.$$

EVALUATE: $P(a) < 1$, as it must be.

41.16. **IDENTIFY:** Require that $\Phi(\phi) = \Phi(\phi + 2\pi)$

SET UP: $e^{i(x_1 + x_2)} = e^{ix_1}e^{ix_2}$

EXECUTE: $\Phi(\phi + 2\pi) = e^{im_l(\phi + 2\pi)} = e^{im_l\phi}e^{im_l 2\pi}$. $e^{im_l 2\pi} = \cos(m_l 2\pi) + i\sin(m_l 2\pi)$. $e^{im_l 2\pi} = 1$ if m_l is an integer.

EVALUATE: If, for example, $m_l = \frac{1}{2}$, $e^{im_l 2\pi} = e^{i\pi} = \cos(\pi) + i\sin(\pi) = -1$ and $\Phi(\phi) = -\Phi(\phi + 2\pi)$. But if $m_l = 1$, $e^{im_l 2\pi} = e^{i2\pi} = \cos(2\pi) + i\sin(2\pi) = +1$ and $\Phi(\phi) = \Phi(\phi + 2\pi)$, as required.

41.17. **IDENTIFY:** Apply $\Delta U = \mu_B B$.

SET UP: For a 3p state, $l = 1$ and $m_l = 0, \pm 1$.

EXECUTE: **(a)** $B = \dfrac{U}{\mu_B} = \dfrac{(2.71\times10^{-5}\text{ eV})}{(5.79\times10^{-5}\text{ eV/T})} = 0.468\text{ T}.$

(b) Three: $m_l = 0, \pm 1$.

EVALUATE: The $m_l = +1$ level will be highest in energy and the $m_l = -1$ level will be lowest. The $m_l = 0$ level is unaffected by the magnetic field.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

41.18. **IDENTIFY:** Apply Eq. (41.36).

SET UP: $\mu_B = 5.788\times10^{-5}$ eV/T

EXECUTE: **(a)** $\Delta E = \mu_B B = (5.79\times10^{-5}\ \text{eV/T})(0.400\ \text{T}) = 2.32\times10^{-5}$ eV.

(b) $m_l = -2$ the lowest possible value of m_l.

(c) The energy level diagram is sketched in Figure 41.18.

EVALUATE: The splitting between m_l levels is independent of the n values for the state. The splitting is much less than the energy difference between the $n = 3$ level and the $n = 1$ level.

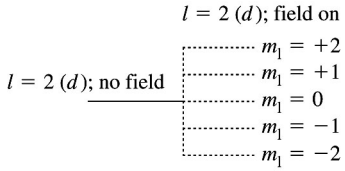

Figure 41.18

41.19. **IDENTIFY** and **SET UP:** The interaction energy between an external magnetic field and the orbital angular momentum of the atom is given by Eq. (41.36). The energy depends on m_l with the most negative m_l value having the lowest energy.

EXECUTE: **(a)** For the 5g level, $l = 4$ and there are $2l+1 = 9$ different m_l states. The 5g level is split into 9 levels by the magnetic field.

(b) Each m_l level is shifted in energy an amount given by $U = m_l\mu_B B$. Adjacent levels differ in m_l by one, so $\Delta U = \mu_B B$.

$$\mu_B = \frac{e\hbar}{2m} = \frac{(1.602\times10^{-19}\ \text{C})(1.055\times10^{-34}\ \text{J}\cdot\text{s})}{2(9.109\times10^{-31}\ \text{kg})} = 9.277\times10^{-24}\ \text{A}\cdot\text{m}^2$$

$$\Delta U = \mu_B B = (9.277\times10^{-24}\ \text{A/m}^2)(0.600\ \text{T}) = 5.566\times10^{-24}\ \text{J}(1\ \text{eV}/1.602\times10^{-19}\ \text{J}) = 3.47\times10^{-5}\ \text{eV}$$

(c) The level of highest energy is for the largest m_l, which is $m_l = l = 4$; $U_4 = 4\mu_B B$. The level of lowest energy is for the smallest m_l, which is $m_l = -l = -4; U_{-4} = -4\mu_B B$. The separation between these two levels is $U_4 - U_{-4} = 8\mu_B B = 8(3.47\times10^{-5}\ \text{eV}) = 2.78\times10^{-4}$ eV.

EVALUATE: The energy separations are proportional to the magnetic field. The energy of the $n = 5$ level in the absence of the external magnetic field is $(-13.6\ \text{eV})/5^2 = -0.544$ eV, so the interaction energy with the magnetic field is much less than the binding energy of the state.

41.20. **IDENTIFY:** The effect of the magnetic field on the energy levels is described by Eq. (41.36). In a transition m_l must change by 0 or ±1.

SET UP: For a 2p state, m_l can be $0, \pm1$. For a 1s state, m_l must be zero.

EXECUTE: **(a)** There are three different transitions that are consistent with the selection rules. The initial m_l values are 0, ±1; and the final m_l value is 0.

(b) The transition from $m_l = 0$ to $m_l = 0$ produces the same wavelength (122 nm) that was seen without the magnetic field.

(c) The larger wavelength (smaller energy) is produced from the $m_l = -1$ to $m_l = 0$ transition.

(d) The shorter wavelength (greater energy) is produced from the $m_l = +1$ to $m_l = 0$ transition.

EVALUATE: The magnetic field increases the energy of the $m_l = 1$ state, decreases the energy for $m_l = -1$ and leaves the $m_l = 0$ state unchanged.

41.21. **IDENTIFY** and **SET UP:** For a classical particle $L = I\omega$. For a uniform sphere with mass m and radius R, $I = \frac{2}{5}mR^2$, so $L = \left(\frac{2}{5}mR^2\right)\omega$. Solve for ω and then use $v = r\omega$ to solve for v.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: **(a)** $L=\sqrt{\frac{3}{4}}\hbar$ so $\frac{2}{5}mR^2\omega=\sqrt{\frac{3}{4}}\hbar$

$$\omega=\frac{5\sqrt{3/4}\hbar}{2mR^2}=\frac{5\sqrt{3/4}(1.055\times10^{-34}\text{ J}\cdot\text{s})}{2(9.109\times10^{-31}\text{ kg})(1.0\times10^{-17}\text{ m})^2}=2.5\times10^{30}\text{ rad/s}$$

(b) $v=r\omega=(1.0\times10^{-17}\text{ m})(2.5\times10^{30}\text{ rad/s})=2.5\times10^{13}\text{ m/s}$

EVALUATE: This is much greater than the speed of light c, so the model cannot be valid.

41.22. **IDENTIFY:** Apply Eq. (41.40), with $S_z=-\frac{\hbar}{2}$.

SET UP: $\mu_B=\frac{e\hbar}{2m}=5.788\times10^{-5}$ eV/T.

EXECUTE: **(a)** $U=+(2.00232)\left(\frac{e}{2m}\right)\left(\frac{-\hbar}{2}\right)B=-\frac{(2.00232)}{2}\mu_B B.$

$$U=-\frac{(2.00232)}{2}(5.788\times10^{-5}\text{ eV/T})(0.480\text{ T})=-2.78\times10^{-5}\text{ eV}.$$

(b) Since $n=1$, $l=0$ so there is no orbital magnetic dipole interaction. But if $n\neq1$ there could be orbital magnetic dipole interaction, since $l<n$ would then allow for $l\neq0$.

EVALUATE: The energy of the $m_s=-\frac{1}{2}$ state is lowered in the magnetic field. The energy of the $m_s=+\frac{1}{2}$ state is raised.

41.23. **IDENTIFY** and **SET UP:** The interaction energy is $U=-\vec{\boldsymbol{\mu}}\cdot\vec{\boldsymbol{B}}$, with μ_z given by Eq. (41.40).

EXECUTE: $U=-\vec{\boldsymbol{\mu}}\cdot\vec{\boldsymbol{B}}=+\mu_z B$, since the magnetic field is in the negative z-direction.

$\mu_z=-(2.00232)\left(\frac{e}{2m}\right)S_z$, so $U=-(2.00232)\left(\frac{e}{2m}\right)S_z B$

$S_z=m_s\hbar$, so $U=-2.00232\left(\frac{e\hbar}{2m}\right)m_s B$

$\frac{e\hbar}{2m}=\mu_B=5.788\times10^{-5}$ eV/T

$U=-2.00232\mu_B m_s B$

The $m_s=+\frac{1}{2}$ level has lower energy.

$$\Delta U=U\left(m_s=-\frac{1}{2}\right)-U\left(m_s=+\frac{1}{2}\right)=-2.00232\,\mu_B B\left(-\frac{1}{2}-\left(+\frac{1}{2}\right)\right)=+2.00232\,\mu_B B$$

$\Delta U=+2.00232(5.788\times10^{-5}\text{ eV/T})(1.45\text{ T})=1.68\times10^{-4}$ eV

EVALUATE: The interaction energy with the electron spin is the same order of magnitude as the interaction energy with the orbital angular momentum for states with $m_l\neq0$. But a 1s state has $l=0$ and $m_l=0$, so there is no orbital magnetic interaction.

41.24. **IDENTIFY:** The transition energy ΔE of the atom is related to the wavelength λ of the photon by $\Delta E=\frac{hc}{\lambda}$. For an electron in a magnetic field the spin magnetic interaction energy is $\pm\mu_B B$. Therefore the effective magnetic field is given by $\Delta E=2\mu_B B$ when ΔE is produced by the hyperfine interaction.

SET UP: $\mu_B=5.788\times10^{-5}$eV/T.

EXECUTE: **(a)** $\lambda=\frac{hc}{\Delta E}=\frac{(4.136\times10^{-15}\text{ eV}\cdot\text{s})(3.00\times10^{8}\text{ m/s})}{(5.9\times10^{-6}\text{ eV})}=21\text{ cm},$

$f=\frac{c}{\lambda}=\frac{(3.00\times10^{8}\text{ m/s})}{0.21\text{ m}}=1.4\times10^{9}$ Hz, a short radio wave.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) The effective field is $B \cong \Delta E/2\mu_B = 5.1\times10^{-2}$ T, far smaller than that found in Example 41.7 for spin-orbit coupling.

EVALUATE: The level splitting due to the hyperfine interaction is much smaller than the level splittings due to the spin-orbit interaction.

41.25. **IDENTIFY** and **SET UP:** j can have the values $l+1/2$ and $l-1/2$.

EXECUTE: If j takes the values 7/2 and 9/2 it must be that $l-1/2=7/2$ and $l=8/2=4$. The letter that labels this l is g.

EVALUATE: l must be an integer.

41.26. **IDENTIFY:** Fill the subshells in the order of increasing energy. An s subshell holds 2 electrons, a p subshell holds 6 and a d subshell holds 10 electrons.

SET UP: Germanium has 32 electrons.

EXECUTE: The electron configuration is $1s^2 2s^2 2p^6 3s^2 3p^6 4s^2 3d^{10} 4p^2$.

EVALUATE: The electron configuration is that of zinc $(Z=30)$ plus two electrons in the 4p subshell.

41.27. **IDENTIFY:** The ten lowest energy levels for electrons are in the $n=1$ and $n=2$ shells.

SET UP: $l=0,1,2,\ldots,n-1.\ m_l=0,\pm1,\pm2,\ldots,\pm l.\ m_s=\pm\frac{1}{2}$.

EXECUTE: $n=1, l=0, m_l=0, m_s=\pm\frac{1}{2}$: 2 states. $n=2, l=0, m_l=0, m_s=\pm\frac{1}{2}$: 2 states.

$n=2, l=1, m_l=0,\pm1, m_s=\pm\frac{1}{2}$: 6 states.

EVALUATE: The ground state electron configuration for neon is $1s^2 2s^2 2p^6$. The electron configuration specifies the n and l quantum numbers for each electron.

41.28. **IDENTIFY:** Write out the electron configuration for ground-state carbon.

SET UP: Carbon has 6 electrons.

EXECUTE: **(a)** $1s^2 2s^2 2p^2$.

(b) The element of next larger Z with a similar electron configuration has configuration $1s^2 2s^2 2p^6 3s^2 3p^2$. $Z=14$ and the element is silicon.

EVALUATE: Carbon and silicon are in the same column of the periodic table.

41.29. **IDENTIFY:** Write out the electron configuration for ground-state beryllium.

SET UP: Beryllium has 4 electrons.

EXECUTE: **(a)** $1s^2 2s^2$

(b) $1s^2 2s^2 2p^6 3s^2$. $Z=12$ and the element is magnesium.

(c) $1s^2 2s^2 2p^6 3s^2 3p^6 4s^2$. $Z=20$ and the element is calcium.

EVALUATE: Beryllium, calcium and magnesium are all in the same column of the periodic table.

41.30. **IDENTIFY** and **SET UP:** Apply Eq. (41.45). The ionization potential is $-E_n$, where E_n is the level energy for the least tightly bound electron.

EXECUTE: As electrons are removed, for the outermost electron the screening of the nucleus by the remaining electrons decreases. The ground state electron configuration of magnesium is $1s^2 2s^2 2p^6 3s^2$. For a 3s electron the other electrons screen the nucleus and $Z_{\text{eff}} \approx 1$. For Mg^+ the electron configuration is $1s^2 2s^2 2p^6 3s$ and the 10 inner electrons screen the nucleus from the 3s electron. $Z_{\text{eff}} \approx 2$. For Mg^{2+} the electron configuration is $1s^2 2s^2 2p^6$. The screening for an outershell electron is further reduced and now it is a $n=2$ rather than an $n=3$ electron that will be removed in ionization.

EVALUATE: Both screening and the shell structure of the atom determine the successive ionization potentials.

41.31. **IDENTIFY** and **SET UP:** The energy of an atomic level is given in terms of n and Z_{eff} by Eq. (41.45), $E_n = -\left(\frac{Z_{\text{eff}}^2}{n^2}\right)(13.6\text{ eV})$. The ionization energy for a level with energy $-E_n$ is $+E_n$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: $n = 5$ and $Z_{\text{eff}} = 2.771$ gives $E_5 = -\dfrac{(2.771)^2}{5^2}(13.6\text{ eV}) = -4.18\text{ eV}$

The ionization energy is 4.18 eV.

EVALUATE: The energy of an atomic state is proportional to Z_{eff}^2.

41.32. **IDENTIFY** and **SET UP:** Apply Eq. (41.45).

EXECUTE: For the $4s$ state, $E = -4.339$ eV and $Z_{\text{eff}} = 4\sqrt{(-4.339)/(-13.6)} = 2.26$. Similarly, $Z_{\text{eff}} = 1.79$ for the $4p$ state and 1.05 for the $4d$ state.

EVALUATE: The electrons in the states with higher l tend to be farther away from the filled subshells and the screening is more complete.

41.33. **IDENTIFY** and **SET UP:** Use the exclusion principle to determine the ground-state electron configuration, as in Table 41.3. Estimate the energy by estimating Z_{eff}, taking into account the electron screening of the nucleus.

EXECUTE: **(a)** $Z = 7$ for nitrogen so a nitrogen atom has 7 electrons. N^{2+} has 5 electrons: $1s^2 2s^2 2p$.

(b) $Z_{\text{eff}} = 7 - 4 = 3$ for the $2p$ level.

$$E_n = -\left(\frac{Z_{\text{eff}}^2}{n^2}\right)(13.6\text{ eV}) = -\frac{3^2}{2^2}(13.6\text{ eV}) = -30.6\text{ eV}$$

(c) $Z = 15$ for phosphorus so a phosphorus atom has 15 electrons.

P^{2+} has 13 electrons: $1s^2 2s^2 2p^6 3s^2 3p$

(d) $Z_{\text{eff}} = 15 - 12 = 3$ for the $3p$ level.

$$E_n = -\left(\frac{Z_{\text{eff}}^2}{n^2}\right)(13.6\text{ eV}) = -\frac{3^2}{3^2}(13.6\text{ eV}) = -13.6\text{ eV}$$

EVALUATE: In these ions there is one electron outside filled subshells, so it is a reasonable approximation to assume full screening by these inner-subshell electrons.

41.34. **IDENTIFY** and **SET UP:** Apply Eq. (41.45).

EXECUTE: **(a)** $E_2 = -\dfrac{13.6\text{ eV}}{4}Z_{\text{eff}}^2$, so $Z_{\text{eff}} = 1.26$.

(b) Similarly, $Z_{\text{eff}} = 2.26$.

EVALUATE: **(c)** Z_{eff} becomes larger going down a column in the periodic table. Screening is less complete as n of the outermost electron increases.

41.35. **IDENTIFY** and **SET UP:** Estimate Z_{eff} by considering electron screening and use Eq. (41.45) to calculate the energy. Z_{eff} is calculated as in Example 41.9.

EXECUTE: **(a)** The element Be has nuclear charge $Z = 4$. The ion Be^+ has 3 electrons. The outermost electron sees the nuclear charge screened by the other two electrons so $Z_{\text{eff}} = 4 - 2 = 2$.

$$E_n = -\left(\frac{Z_{\text{eff}}^2}{n^2}\right)(13.6\text{ eV})\text{ so }E_2 = -\frac{2^2}{2^2}(13.6\text{ eV}) = -13.6\text{ eV}$$

(b) The outermost electron in Ca^+ sees a $Z_{\text{eff}} = 2$. $E_4 = -\dfrac{2^2}{4^2}(13.6\text{ eV}) = -3.4\text{ eV}$

EVALUATE: For the electron in the highest l-state it is reasonable to assume full screening by the other electrons, as in Example 41.9. The highest l-states of Be^+, Mg^+, Ca^+, etc. all have a $Z_{\text{eff}} = 2$. But the energies are different because for each ion the outermost sublevel has a different n quantum number.

41.36. **IDENTIFY** and **SET UP:** Apply Eq. (41.48) and solve for Z.

EXECUTE: $E_{K\alpha} \cong (Z-1)^2(10.2\text{ eV})$. $Z \approx 1 + \sqrt{\dfrac{7.46\times10^3\text{ eV}}{10.2\text{ eV}}} = 28.0$, which corresponds to the element Nickel (Ni).

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: We use $Z-1$ rather than Z in the expression for the transition energy, in order to account for screening by the other K-shell electron.

41.37. **IDENTIFY** and **SET UP:** Apply Eq. (41.47). $E = hf$ and $c = f\lambda$.

EXECUTE: **(a)** $Z = 20$: $f = (2.48\times10^{15}\text{ Hz})(20-1)^2 = 8.95\times10^{17}\text{ Hz}$.

$E = hf = (4.14\times10^{-15}\text{ eV}\cdot\text{s})(8.95\times10^{17}\text{ Hz}) = 3.71\text{ keV}$. $\lambda = \dfrac{c}{f} = \dfrac{3.00\times10^{8}\text{ m/s}}{8.95\times10^{17}\text{ Hz}} = 3.35\times10^{-10}\text{ m}$.

(b) $Z = 27$: $f = 1.68\times10^{18}$ Hz. $E = 6.96$ keV. $\lambda = 1.79\times10^{-10}$ m.

(c) $Z = 48$: $f = 5.48\times10^{18}$ Hz, $E = 22.7$ keV, $\lambda = 5.47\times10^{-11}$ m.

EVALUATE: f and E increase and λ decreases as Z increases.

41.38. **IDENTIFY:** The energies of the x rays will be equal to the energy differences between the shells. From its energy, we can calculate the wavelength of the x ray.

SET UP: $\Delta E = \dfrac{hc}{\lambda}$. A K_α x ray is produced in a $L \to K$ transition and a K_β x ray is produced in a $M \to K$ transition.

EXECUTE: K_α: $\Delta E = E_L - E_K = -12{,}000\text{ eV} - (-69{,}500\text{ eV}) = +57{,}500\text{ eV}$.

$$\lambda = \frac{hc}{\Delta E} = \frac{(4.136\times10^{-15}\text{ eV}\cdot\text{s})(3.00\times10^{8}\text{ m/s})}{57{,}500\text{ eV}} = 0.0216\text{ nm}.$$

K_β: $\Delta E = E_M - E_K = -2200\text{ eV} - (-69{,}500\text{ eV}) = +67{,}300\text{ eV}$.

$$\lambda = \frac{hc}{\Delta E} = \frac{(4.136\times10^{-15}\text{ eV}\cdot\text{s})(3.00\times10^{8}\text{ m/s})}{67{,}300\text{ eV}} = 0.0184\text{ nm}.$$

EVALUATE: These wavelengths are much shorter than the wavelengths in the visible spectrum of hydrogen.

41.39. **IDENTIFY:** The electrons cannot all be in the same state in a cubical box.

SET UP and **EXECUTE:** The ground state can hold 2 electrons, the first excited state can hold 6 electrons and the second excited state can hold 6. Therefore, two electrons will be in the second excited state, which has energy $3E_{1,1,1}$.

EVALUATE: The second excited state is the third state, which has energy $3E_{1,1,1}$, as shown in Figure 41.4.

41.40. **IDENTIFY:** Calculate the probability of finding a particle in certain regions of a three-dimensional box.

SET UP: $|\psi_{1,1,1}|^2 = \left(\dfrac{L}{2}\right)^3\left(\sin^2\dfrac{\pi x}{L}\right)\left(\sin^2\dfrac{\pi y}{L}\right)\left(\sin^2\dfrac{\pi z}{L}\right)$

EXECUTE: **(a)** $P = \left(\dfrac{2}{L}\right)^3\left[\displaystyle\int_0^{L/2}\sin^2\frac{\pi x}{L}dx\right]\left[\int_0^{L}\sin^2\frac{\pi y}{L}dy\right]\left[\int_0^{L}\sin^2\frac{\pi z}{L}dz\right]$.

$\left[\displaystyle\int_0^{L}\sin^2\frac{\pi y}{L}dy\right] = \left[\int_0^{L}\sin^2\frac{\pi z}{L}dz\right] = \frac{L}{2}$. $\displaystyle\int_0^{L/2}\sin^2\frac{\pi x}{L}dx = \left[\frac{x}{2} - \frac{L}{4\pi}\sin\frac{2\pi x}{L}\right]_0^{L/2} = \left(\frac{L}{2}\right)\left(\frac{1}{2}\right)$.

$$P = \left(\frac{2}{L}\right)^3\left(\frac{L}{2}\right)^3\left(\frac{1}{2}\right) = \frac{1}{2} = 0.500.$$

(b) $P = \left(\dfrac{2}{L}\right)^3\left[\displaystyle\int_{L/4}^{L/2}\sin^2\frac{\pi x}{L}dx\right]\left[\int_0^{L}\sin^2\frac{\pi y}{L}dy\right]\left[\int_0^{L}\sin^2\frac{\pi z}{L}dz\right]$.

$\left[\displaystyle\int_0^{L}\sin^2\frac{\pi y}{L}dy\right] = \left[\int_0^{L}\sin^2\frac{\pi z}{L}dz\right] = \frac{L}{2}$. $\displaystyle\int_{L/4}^{L/2}\sin^2\frac{\pi x}{L}dx = \left[\frac{x}{2} - \frac{L}{4\pi}\sin\frac{2\pi x}{L}\right]_{L/4}^{L/2} = \left(\frac{L}{2}\right)\left(\frac{1}{4} + \frac{1}{2\pi}\right)$.

$$P = \left(\frac{2}{L}\right)^3\left(\frac{L}{2}\right)^3\left(\frac{1}{4} + \frac{1}{2\pi}\right) = \frac{1}{4} + \frac{1}{2\pi} = 0.409.$$

EVALUATE: In Example 41.1 for this state the probability for finding the particle between $x = 0$ and $x = L/4$ is 0.091. The sum of this result and our result in part (b) is $0.091 + 0.409 = 0.500$. This in turn equals the probability of finding the particle in half the box, as calculated in part (a).

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

41.41. **IDENTIFY:** Calculate the probability of finding a particle in a given region within a cubical box.

(a) SET UP and **EXECUTE:** The box has volume L^3. The specified cubical space has volume $(L/4)^3$. Its fraction of the total volume is $\frac{1}{64} = 0.0156$.

(b) SET UP and **EXECUTE:** $P = \left(\frac{2}{L}\right)^3 \left[\int_0^{L/4} \sin^2 \frac{\pi x}{L} dx\right]\left[\int_0^{L/4} \sin^2 \frac{\pi y}{L} dy\right]\left[\int_0^{L/4} \sin^2 \frac{\pi z}{L} dz\right]$.

From Example 41.1, each of the three integrals equals $\frac{L}{8} - \frac{L}{4\pi} = \frac{1}{2}\left(\frac{L}{2}\right)\left(\frac{1}{2} - \frac{1}{\pi}\right)$.

$$P = \left(\frac{2}{L}\right)^3 \left(\frac{L}{2}\right)^3 \left(\frac{1}{2}\right)^3 \left(\frac{1}{2} - \frac{1}{\pi}\right)^3 = 7.50 \times 10^{-4}.$$

EVALUATE: Note that this is the cube of the probability of finding the particle anywhere between $x = 0$ and $x = L/4$. This probability is much less that the fraction of the total volume that this space represents. In this quantum state the probability distribution function is much larger near the center of the box than near its walls.

(c) SET UP and **EXECUTE:** $|\psi_{2,1,1}|^2 = \left(\frac{L}{2}\right)^3 \left(\sin^2 \frac{2\pi x}{L}\right)\left(\sin^2 \frac{\pi y}{L}\right)\left(\sin^2 \frac{\pi z}{L}\right)$.

$$P = \left(\frac{2}{L}\right)^3 \left[\int_0^{L/4} \sin^2 \frac{2\pi x}{L} dx\right]\left[\int_0^{L/4} \sin^2 \frac{\pi y}{L} dy\right]\left[\int_0^{L/4} \sin^2 \frac{\pi z}{L} dz\right].$$

$\left[\int_0^{L/4} \sin^2 \frac{\pi y}{L} dy\right] = \left[\int_0^{L/4} \sin^2 \frac{\pi z}{L} dz\right] = \frac{L}{2}\left(\frac{1}{2}\right)\left(\frac{1}{2} - \frac{1}{\pi}\right)$. $\int_0^{L/4} \sin^2 \frac{2\pi x}{L} dx = \frac{L}{8}$.

$$P = \left(\frac{2}{L}\right)^3 \left(\frac{L}{2}\right)^2 \left(\frac{1}{2}\right)^2 \left(\frac{1}{2} - \frac{1}{\pi}\right)^2 \left(\frac{L}{8}\right) = 2.06 \times 10^{-3}.$$

EVALUATE: This is about a factor of three larger than the probability when the particle is in the ground state.

41.42. **IDENTIFY:** The probability is a maximum where $|\psi|^2$ is a maximum, and this is where $\frac{\partial}{\partial x}|\psi|^2 = 0$. The probability is zero where $|\psi|^2$ is zero.

SET UP: $|\psi^2| = A^2 x^2 e^{-2(\alpha x^2 + \beta y^2 + \gamma z^2)}$. To save some algebra, let $u = x^2$, so that $|\psi|^2 = u e^{-2\alpha u} f(y, z)$.

EXECUTE: **(a)** $\frac{\partial}{\partial u}|\psi|^2 = (1 - 2\alpha u)|\psi|^2$; the maximum occurs at $u_0 = \frac{1}{2\alpha}$, $x_0 = \pm\frac{1}{\sqrt{2\alpha}}$.

(b) ψ vanishes at $x = 0$, so the probability of finding the particle in the $x = 0$ plane is zero. The wave function also vanishes for $x = \pm\infty$.

EVALUATE: $|\psi|^2$ is a maximum at $y_0 = z_0 = 0$.

41.43. **(a) IDENTIFY** and **SET UP:** The probability is $P = |\psi|^2 dV$ with $dV = 4\pi r^2 dr$.

EXECUTE: $|\psi|^2 = A^2 e^{-2\alpha r^2}$ so $P = 4\pi A^2 r^2 e^{-2\alpha r^2} dr$

(b) IDENTIFY and **SET UP:** P is maximum where $\frac{dP}{dr} = 0$.

EXECUTE: $\frac{d}{dr}(r^2 e^{-2\alpha r^2}) = 0$

$2re^{-2\alpha r^2} - 4\alpha r^3 e^{-2\alpha r^2} = 0$ and this reduces to $2r - 4\alpha r^3 = 0$

$r = 0$ is a solution of the equation but corresponds to a minimum not a maximum. Seek r not equal to 0 so divide by r and get $2 - 4\alpha r^2 = 0$.

This gives $r = \frac{1}{\sqrt{2\alpha}}$. (We took the positive square root since r must be positive.)

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: This is different from the value of r, $r = 0$, where $|\psi|^2$ is a maximum. At $r = 0$, $|\psi|^2$ has a maximum but the volume element $dV = 4\pi r^2 dr$ is zero here so P does not have a maximum at $r = 0$.

41.44. **IDENTIFY** and **SET UP:** Evaluate $\partial^2\psi/\partial x^2$, $\partial^2\psi/\partial y^2$, and $\partial^2\psi/\partial z^2$ for the proposed ψ and put Eq. (41.5). Use that ψ_{n_x}, ψ_{n_y}, and ψ_{n_z} are each solutions to Eq. (40.44).

EXECUTE: **(a)** $-\dfrac{\hbar^2}{2m}\left(\dfrac{\partial^2\psi}{\partial x^2}+\dfrac{\partial^2\psi}{\partial y^2}+\dfrac{\partial^2\psi}{\partial z^2}\right)+U\psi = E\psi$

ψ_{n_x}, ψ_{n_y}, ψ_{n_z} are each solutions of Eq. (40.44), so $-\dfrac{\hbar^2}{2m}\dfrac{d^2\psi_{n_x}}{dx^2}+\dfrac{1}{2}k'x^2\psi_{n_x} = E_{n_x}\psi_{n_x}$.

$$-\frac{\hbar^2}{2m}\frac{d^2\psi_{n_y}}{dy^2}+\frac{1}{2}k'y^2\psi_{n_y} = E_{n_y}\psi_{n_y}$$

$$-\frac{\hbar^2}{2m}\frac{d^2\psi_{n_z}}{dz^2}+\frac{1}{2}k'z^2\psi_{n_z} = E_{n_z}\psi_{n_z}$$

$$\psi = \psi_{n_x}(x)\psi_{n_y}(y)\psi_{n_z}(z),\ U = \frac{1}{2}k'x^2+\frac{1}{2}k'y^2+\frac{1}{2}k'z^2$$

$$\frac{\partial^2\psi}{\partial x^2} = \left(\frac{d^2\psi_{n_x}}{dx^2}\right)\psi_{n_y}\psi_{n_z},\ \frac{\partial^2\psi}{\partial y^2} = \left(\frac{d^2\psi_{n_y}}{dy^2}\right)\psi_{n_x}\psi_{n_z},\ \frac{\partial^2\psi}{\partial z^2} = \left(\frac{d^2\psi_{n_z}}{dz^2}\right)\psi_{n_x}\psi_{n_y}$$

$$\text{So } -\frac{\hbar^2}{2m}\left(\frac{\partial^2\psi}{\partial x^2}+\frac{\partial^2\psi}{\partial y^2}+\frac{\partial^2\psi}{\partial z^2}\right)+U\psi = \left(-\frac{\hbar^2}{2m}\frac{d^2\psi_{n_x}}{dx^2}+\frac{1}{2}k'x^2\psi_{n_x}\right)\psi_{n_y}\psi_{n_z}$$

$$+\left(-\frac{\hbar^2}{2m}\frac{d^2\psi_{n_y}}{dy^2}+\frac{1}{2}k'y^2\psi_{n_y}\right)\psi_{n_x}\psi_{n_z}+\left(-\frac{\hbar^2}{2m}\frac{d^2\psi_{n_z}}{dz^2}+\frac{1}{2}k'z^2\psi_{n_z}\right)\psi_{n_x}\psi_{n_y}$$

$$-\frac{\hbar^2}{2m}\left(\frac{\partial^2\psi}{\partial x^2}+\frac{\partial^2\psi}{\partial y^2}+\frac{\partial^2\psi}{\partial z^2}\right)+U\psi = (E_{n_x}+E_{n_y}+E_{n_z})\psi$$

Therefore, we have shown that this ψ is a solution to Eq. (41.5), with energy

$$E_{n_xn_yn_z} = E_{n_x}+E_{n_y}+E_{n_z} = \left(n_x+n_y+n_z+\frac{3}{2}\right)\hbar\omega$$

(b) and **(c)** The ground state has $n_x = n_y = n_z = 0$, so the energy is $E_{000} = \dfrac{3}{2}\hbar\omega$. There is only one set of n_x, n_y and n_z that give this energy.

First-excited state:

$n_x = 1, n_y = n_z = 0$ or $n_y = 1, n_x = n_z = 0$ or $n_z = 1, n_x = n_y = 0$ and $E_{100} = E_{010} = E_{001} = \dfrac{5}{2}\hbar\omega$

There are three different sets of n_x, n_y, n_z quantum numbers that give this energy, so there are three different quantum states that have this same energy.

EVALUATE: For the three-dimensional isotropic harmonic oscillator, the wave function is a product of one-dimensional harmonic oscillator wavefunctions for each dimension. The energy is a sum of energies for three one-dimensional oscillators. All the excited states are degenerate, with more than one state having the same energy.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

41.45. **IDENTIFY:** Find solutions to Eq. (41.5).

SET UP: $\omega_1 = \sqrt{k_1'/m},\ \omega_2 = \sqrt{k_2'/m}$. Let $\psi_{n_x}(x)$ be a solution of Eq. (40.44) with $E_{n_x} = \left(n_x + \frac{1}{2}\right)\hbar\omega_1$, $\psi_{n_y}(y)$ be a similar solution, and let $\psi_{n_z}(z)$ be a solution of Eq. (40.44) but with z as the independent variable instead of x, and energy $E_{n_z} = \left(n_z + \frac{1}{2}\right)\hbar\omega_2$.

EXECUTE: **(a)** As in Problem 41.44, look for a solution of the form $\psi(x, y, z) = \psi_{n_x}(x)\psi_{n_y}(y)\psi_{n_z}(z)$.

Then, $-\frac{\hbar^2}{2m}\frac{\partial^2\psi}{\partial x^2} = \left(E_{n_x} - \frac{1}{2}k_1'x^2\right)\psi$ with similar relations for $\frac{\partial^2\psi}{\partial y^2}$ and $\frac{\partial^2\psi}{\partial z^2}$. Adding,

$$-\frac{\hbar^2}{2m}\left(\frac{\partial^2\psi}{\partial x^2} + \frac{\partial^2\psi}{\partial y^2} + \frac{\partial^2\psi}{\partial z^2}\right) = \left(E_{n_x} + E_{n_y} + E_{n_z} - \frac{1}{2}k_1'x^2 - \frac{1}{2}k_1'y^2 - \frac{1}{2}k_2'z^2\right)\psi$$

$$= (E_{n_x} + E_{n_y} + E_{n_z} - U)\psi = (E - U)\psi$$

where the energy E is $E = E_{n_x} + E_{n_y} + E_{n_z} = \hbar\left[(n_x + n_y + 1)\omega_1^2 + \left(n_z + \frac{1}{2}\right)\omega_2^2\right]$, with n_x, n_y and n_z all nonnegative integers.

(b) The ground level corresponds to $n_x = n_y = n_z = 0$, and $E = \hbar\left(\omega_1^2 + \frac{1}{2}\omega_2^2\right)$. The first excited level corresponds to $n_x = n_y = 0$ and $n_z = 1$, since $\omega_1^2 > \omega_2^2$, and $E = \hbar\left(\omega_1^2 + \frac{3}{2}\omega_2^2\right)$.

(c) There is only one set of quantum numbers for both the ground state and the first excited state.

EVALUATE: For the isotropic oscillator of Problem 41.44 there are three states for the first excited level but only one for the anisotropic oscillator.

41.46. **IDENTIFY:** An electron is in the 5*f* state in hydrogen. We want to find out about its angular mometum.

SET UP: For the 5*f* state, $l = 3$. $L_z = m_l\hbar$. $m_l = 0,\ \pm 1,\ \ldots, \pm l$. $L = \sqrt{l(l+1)}\hbar$.

EXECUTE: **(a)** The largest possible m_l is $m_l = 3$. $L_z = 3\hbar$.

(b) $L_x^2 + L_y^2 + L_z^2 = L^2$. $L^2 = 3(4)\hbar^2 = 12\hbar^2$.

$\sqrt{L_x^2 + L_x^2} = \sqrt{L^2 - L_z^2} = \sqrt{12\hbar^2 - 9\hbar^2} = \sqrt{3}\hbar$.

EVALUATE: The restriction on L_z also places restrictions on L_x and L_y.

41.47. **IDENTIFY** and **SET UP:** To calculate the total number of states for the n^{th} principal quantum number shell we must add up all the possibilities. The spin states multiply everything by 2. The maximum l value is $(n-1)$, and each l value has $(2l+1)$ different m_l values.

EXECUTE: The total number of states is

$$N = 2\sum_{l=0}^{n-1}(2l+1) = 2\sum_{l=0}^{n-1}1 + 4\sum_{l=0}^{n-1}l = 2n + \frac{4(n-1)(n)}{2} = 2n + 2n^2 - 2n = 2n^2.$$

(b) The $n = 5$ shell (*O*-shell) has 50 states.

EVALUATE: The $n = 1$ shell has 2 states, the $n = 2$ shell has 8 states, etc.

41.48. **IDENTIFY:** The orbital angular momentum is limited by the shell the electron is in.

SET UP: For an electron in the n shell, its orbital angular momentum quantum number l is limited by $0 \le l < n-1$, and its orbital angular momentum is given by $L = \sqrt{l(l+1)}\hbar$. The z-component of its angular momentum is $L_z = m_l\hbar$, where $m_l = 0, \pm 1, \ldots, \pm l$, and its spin angular momentum is $S = \sqrt{3/4}\hbar$ for all electrons. Its energy in the n^{th} shell is $E_n = -(13.6\text{ eV})/n^2$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: **(a)** $L = \sqrt{l(l+1)}\hbar = 12\hbar \Rightarrow l = 3$. Therefore the smallest that n can be is 4, so $E_n = -(13.6\text{eV})/n^2 = -(13.6\text{ eV})/4^2 = -0.8500\text{ eV}$.

(b) For $l = 3$, $m_l = \pm 3, \pm 2, \pm 1, 0$. Since $L_z = m_l\hbar$, the largest L_z can be is $3\hbar$ and the smallest it can be is $-3\hbar$.

(c) $S = \sqrt{3/4}\hbar$ for *all* electrons.

(d) In this case, $n = 3$, so $l = 2, 1, 0$. Therefore the maximum that L can be is $L_{\max} = \sqrt{2(2+1)}\hbar = \sqrt{6}\hbar$. The minimum L can be is zero when $l = 0$.

EVALUATE: At the quantum level, electrons in atoms can have only certain allowed values of their angular momentum.

41.49. **IDENTIFY:** The total energy determines what shell the electron is in, which limits its angular momentum.

SET UP: The electron's orbital angular momentum is given by $L = \sqrt{l(l+1)}\hbar$, and its total energy in the n^{th} shell is $E_n = -(13.6\text{ eV})/n^2$.

EXECUTE: **(a)** First find n: $E_n = -(13.6\text{eV})/n^2 = -0.5440\text{ eV}$ which gives $n = 5$, so $l = 4, 3, 2, 1, 0$. Therefore the possible values of L are given by $L = \sqrt{l(l+1)}\hbar$, giving $L = 0, \sqrt{2}\hbar, \sqrt{6}\hbar, \sqrt{12}\hbar, \sqrt{20}\hbar$.

(b) $E_6 = -(13.6\text{ eV})/6^2 = -0.3778\text{ eV}$. $\Delta E = E_6 - E_5 = -0.3778\text{ eV} - (-0.5440\text{ eV}) = +0.1662\text{ eV}$
This must be the energy of the photon, so $\Delta E = hc/\lambda$, which gives
$\lambda = hc/\Delta E = (4.136\times10^{-15}\text{eV}\cdot\text{s})(3.00\times10^8\text{m/s})/(0.1662\text{ eV}) = 7.47\times10^{-6}\text{m} = 7470\text{ nm}$, which is in the infrared and hence not visible.

EVALUATE: The electron can have any of the five possible values for its angular momentum, but it cannot have any others.

41.50. **IDENTIFY:** For the N shell, $n = 4$, which limits the values of the other quantum numbers.

SET UP: In the n^{th} shell, $0 \le l < n-1$, $m_l = 0, \pm 1, \ldots, \pm l$, and $m_s = \pm 1/2$. The orbital angular momentum of the electron is $L = \sqrt{l(l+1)}\hbar$ and its spin angular momentum is $S = \sqrt{3/4}\hbar$.

EXECUTE: **(a)** For $l = 3$ we can have $m_l = \pm 3, \pm 2\pm, \pm 1, 0$ and $m_s = \pm 1/2$; for $l = 2$ we can have $m_l = \pm 2$, $\pm 1, 0$ and $m_s = \pm 1/2$; for $l = 1$, we can have $m_l = \pm 1, 0$ and $m_s = \pm 1/2$; for $l = 0$, we can have $m_l = 0$ and $m_s = \pm 1/2$.

(b) For the N shell, $n = 4$, and for an f-electron, $l = 3$, giving $L = \sqrt{l(l+1)}\hbar = \sqrt{3(3+1)}\hbar = \sqrt{12}\hbar$.
$L_z = m_l\hbar = \pm 3\hbar, \pm 2\hbar, \pm\hbar, 0$, so the maximum value is $3\hbar$. $S = \sqrt{3/4}\hbar$ for all electrons.

(c) For a d-state electron, $l = 2$, giving $L = \sqrt{2(2+1)}\hbar = \sqrt{6}\hbar$. $L_z = m_l\hbar$, and the maximum value of m_l is 2, so the maximum value of L_z is $2\hbar$. The smallest angle occurs when L_z is most closely aligned along the angular momentum vector, which is when L_z is greatest. Therefore $\cos\theta_{\min} = \dfrac{L_z}{L} = \dfrac{2\hbar}{\sqrt{6}\hbar} = \dfrac{2}{\sqrt{6}}$ and $\theta_{\min} = 35.3°$. The largest angle occurs when L_z is as far as possible from the L-vector, which is when L_z is most negative. Therefore $\cos\theta_{\max} = \dfrac{-2\hbar}{\sqrt{6}\hbar} = -\dfrac{2}{\sqrt{6}}$ and $\theta_{\max} = 144.7°$.

(d) This is not possible since $l = 3$ for an f-electron, but in the M shell the maximum value of l is 2.

EVALUATE: The fact that the angle in part (c) cannot be zero tells us that the orbital angular momentum of the electron cannot be totally aligned along any specified direction.

41.51. **IDENTIFY:** The inner electrons shield part of the nuclear charge from the outer electron.

SET UP: The electron's energy in the n^{th} shell, due to shielding, is $E_n = -\dfrac{Z_{\text{eff}}^2}{n^2}(13.6\text{ eV})$, where $Z_{\text{eff}}e$ is the effective charge that the electron "sees" for the nucleus.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: **(a)** $E_n = -\dfrac{Z_{\text{eff}}^2}{n^2}(13.6\text{ eV})$ and $n = 4$ for the 4*s* state. Solving for Z_{eff} gives $Z_{\text{eff}} = \sqrt{-\dfrac{(4^2)(-1.947\text{ eV})}{13.6\text{ eV}}} = 1.51$. The nucleus contains a charge of $+11e$, so the average number of electrons that screen this nucleus must be $11 - 1.51 = 9.49$ electrons.

(b) (i) The charge of the nucleus is +19*e*, but 17.2*e* is screened by the electrons, so the outer electron "sees" $19e - 17.2e = 1.8e$ and $Z_{\text{eff}} = 1.8$.

(ii) $E_n = -\dfrac{Z_{\text{eff}}^2}{n^2}(13.6\text{ eV}) = -\dfrac{(1.8)^2}{4^2}(13.6\text{ eV}) = -2.75\text{ eV}$

EVALUATE: Sodium has 11 protons, so the inner 10 electrons shield a large portion of this charge from the outer electron. But they don't shield 10 of the protons, since the inner electrons are not totally equivalent to a uniform spherical shell. (They are lumpy.)

41.52. **IDENTIFY:** At the *r* where $P(r)$ has its maximum value, $\dfrac{d(r^2|\psi|^2)}{dr} = 0$.

SET UP: From Example 41.4, $r^2|\psi|^2 = Cr^2e^{-2r/a}$.

EXECUTE: $\dfrac{d(r^2|\psi|^2)}{dr} = Ce^{-2r/a}(2r - (2r^2/a))$. This is zero for $r = a$. Therefore, $P(r)$ has its maximum value at $r = a$, the distance of the electron from the nucleus in the Bohr model.

EVALUATE: Our result agrees with Figure 41.8 in the textbook.

41.53. **(a) IDENTIFY** and **SET UP:** The energy is given by Eq. (39.14), which is identical to Eq. (41.21). The potential energy is given by Eq. (23.9), with $q = +Ze$ and $q_0 = -e$.

EXECUTE: $E_{1s} = -\dfrac{1}{(4\pi\epsilon_0)^2}\dfrac{me^4}{2\hbar^2}$; $U(r) = -\dfrac{1}{4\pi\epsilon_0}\dfrac{e^2}{r}$

$E_{1s} = U(r)$ gives $-\dfrac{1}{(4\pi\epsilon_0)^2}\dfrac{me^4}{2\hbar^2} = -\dfrac{1}{4\pi\epsilon_0}\dfrac{e^2}{r}$

$r = \dfrac{(4\pi\epsilon_0)2\hbar^2}{me^2} = 2a$

EVALUATE: The turning point is twice the Bohr radius.

(b) IDENTIFY and **SET UP:** For the 1*s* state the probability that the electron is in the classically forbidden region is $P(r > 2a) = \int_{2a}^{\infty}|\psi_{1s}|^2\,dV = 4\pi\int_{2a}^{\infty}|\psi_{1s}|^2 r^2 dr$. The normalized wave function of the 1*s* state of hydrogen is given in Example 41.4: $\psi_{1s}(r) = \dfrac{1}{\sqrt{\pi a^3}}e^{-r/a}$. Evaluate the integral; the integrand is the same as in Example 41.4.

EXECUTE: $P(r > 2a) = 4\pi\left(\dfrac{1}{\pi a^3}\right)\int_{2a}^{\infty} r^2 e^{-2r/a}dr$

Use the integral formula $\int r^2 e^{-\alpha r}dr = -e^{-\alpha r}\left(\dfrac{r^2}{\alpha} + \dfrac{2r}{\alpha^2} + \dfrac{2}{\alpha^3}\right)$, with $\alpha = 2/a$.

$P(r > 2a) = -\dfrac{4}{a^3}\left[e^{-2r/a}\left(\dfrac{ar^2}{2} + \dfrac{a^2r}{2} + \dfrac{a^3}{4}\right)\right]_{2a}^{\infty} = +\dfrac{4}{a^3}e^{-4}(2a^3 + a^3 + a^3/4)$

$P(r > 2a) = 4e^{-4}(13/4) = 13e^{-4} = 0.238$.

EVALUATE: These is a 23.8% probability of the electron being found in the classically forbidden region, where classically its kinetic energy would be negative.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

41.54. **IDENTIFY** and **SET UP:** Apply Eq. (41.45) and the concept of screening. For a level with quantum number n the ionization energy is $-E_n$.

EXECUTE: **(a)** For large values of n, the inner electrons will completely shield the nucleus, so $Z_{\text{eff}} = 1$ and the ionization energy would be $\dfrac{13.60\text{ eV}}{n^2}$.

(b) $\dfrac{13.60\text{ eV}}{350^2} = 1.11\times10^{-4}$ eV, $r_{350} = (350)^2 a_0 = (350)^2(0.529\times10^{-10}\text{ m}) = 6.48\times10^{-6}$ m.

(c) Similarly for $n = 650$, $\dfrac{13.60\text{ eV}}{(650)^2} = 3.22\times10^{-5}$ eV, $r_{650} = (650)^2(0.529\times10^{-10}\text{ m}) = 2.24\times10^{-5}$ m.

EVALUATE: For a Rydberg atom with large n the Bohr radius of the electron's orbit is very large.

41.55. $\psi_{2s}(r) = \dfrac{1}{\sqrt{32\pi a^3}}\left(2-\dfrac{r}{a}\right)e^{-r/2a}$

(a) IDENTIFY and **SET UP:** Let $I = \int_0^\infty |\psi_{2s}|^2\, dV = 4\pi|\psi_{2s}|^2 r^2 dr$. If ψ_{2s} is normalized then we will find that $I = 1$.

EXECUTE: $I = 4\pi\left(\dfrac{1}{32\pi a^3}\right)\int_0^\infty\left(2-\dfrac{r}{a}\right)^2 e^{-r/a}r^2dr = \dfrac{1}{8a^3}\int_0^\infty\left(4r^2-\dfrac{4r^3}{a}+\dfrac{r^4}{a^2}\right)e^{-r/a}dr$

Use the integral formula $\int_0^\infty x^n e^{-\alpha x}dx = \dfrac{n!}{\alpha^{n+1}}$, with $\alpha = 1/a$.

$I = \dfrac{1}{8a^3}\left(4(2!)(a^3)-\dfrac{4}{a}(3!)(a)^4+\dfrac{1}{a^2}(4!)(a)^5\right) = \dfrac{1}{8}(8-24+24) = 1$; this ψ_{2s} is normalized.

(b) SET UP: For a spherically symmetric state such as the 2s, the probability that the electron will be found at $r < 4a$ is $P(r<4a) = \int_0^{4a}|\psi_{2s}|^2\, dV = 4\pi\int_0^{4a}|\psi_{2s}|^2 r^2dr$.

EXECUTE: $P(r<4a) = \dfrac{1}{8a^3}\int_0^{4a}\left(4r^2-\dfrac{4r^3}{a}+\dfrac{r^4}{a^2}\right)e^{-r/a}dr$

Let $P(r<4a) = \dfrac{1}{8a^3}(I_1+I_2+I_3)$.

$I_1 = 4\int_0^{4a} r^2e^{-r/a}dr$

Use the integral formula $\int r^2e^{-\alpha r}dr = -e^{-\alpha r}\left(\dfrac{r^2}{\alpha}+\dfrac{2r}{\alpha^2}+\dfrac{2}{\alpha^3}\right)$ with $\alpha = 1/a$.

$I_1 = -4\left[e^{-r/a}(r^2a+2ra^2+2a^3)\right]_0^{4a} = (-104e^{-4}+8)a^3$.

$I_2 = -\dfrac{4}{a}\int_0^{4a} r^3e^{-r/a}dr$

Use the integral formula $\int r^3e^{-\alpha r}dr = -e^{-\alpha r}\left(\dfrac{r^3}{\alpha}+\dfrac{3r^2}{\alpha^2}+\dfrac{6r}{a^3}+\dfrac{6}{\alpha^4}\right)$ with $\alpha = 1/a$.

$I_2 = \dfrac{4}{a}\left[e^{-r/a}(r^3a+3r^2a^2+6ra^3+6a^4)\right]_0^{4a} = (568e^{-4}-24)a^3$.

$I_3 = \dfrac{1}{a^2}\int_0^{4a} r^4e^{-r/a}dr$

Use the integral formula $\int r^4e^{-\alpha r}dr = -e^{-\alpha r}\left(\dfrac{r^4}{\alpha}+\dfrac{4r^3}{\alpha^2}+\dfrac{12r^2}{\alpha^3}+\dfrac{24r}{a^4}+\dfrac{24}{a^5}\right)$ with $\alpha = 1/a$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$I_3 = -\frac{1}{a^2}\left[e^{-r/a}(r^4a + 4r^3a^2 + 12r^2a^3 + 24ra^4 + 24a^5)\right]_0^{4a} = (-824e^{-4} + 24)a^3.$$

Thus $P(r<4a) = \frac{1}{8a^3}(I_1 + I_2 + I_3) = \frac{1}{8a^3}a^3([8-24+24] + e^{-4}[-104+568-824])$

$$P(r<4a) = \frac{1}{8}(8 - 360e^{-4}) = 1 - 45e^{-4} = 0.176.$$

EVALUATE: There is an 82.4% probability that the electron will be found at $r > 4a$. In the Bohr model the electron is for certain at $r = 4a$; this is a poor description of the radial probability distribution for this state.

41.56. **IDENTIFY:** $P(r)$ is a maximum or minimum when $\frac{d(r^2|\psi|^2)}{dr} = 0.$

SET UP: From Problem 41.55, $\psi_{2s}(r) = \frac{1}{\sqrt{32\pi a^3}}\left(2 - \frac{r}{a}\right)e^{-r/2a}.$

EXECUTE: **(a)** Since the given $\psi(r)$ is real, $r^2|\psi|^2 = r^2\psi^2$. The probability density will be an extreme when $\frac{d}{dr}(r^2\psi^2) = 2\left(r\psi^2 + r^2\psi\frac{d\psi}{dr}\right) = 2r\psi\left(\psi + r\frac{d\psi}{dr}\right) = 0$. This occurs at $r = 0,$ a minimum, and when $\psi = 0,$ also a minimum. A maximum must correspond to $\psi + r\frac{d\psi}{dr} = 0$. Within a multiplicative constant, $\psi(r) = (2 - r/a)e^{-r/2a}$, $\frac{d\psi}{dr} = -\frac{1}{a}(2 - r/2a)e^{-r/2a}$, and the condition for a maximum is $(2 - r/a) = (r/a)(2 - r/2a)$, or $r^2 - 6ra + 4a^2 = 0$ The solutions to the quadratic are $r = a(3 \pm \sqrt{5})$. The ratio of the probability densities at these radii is 3.68, with the larger density at $r = a(3 + \sqrt{5}) = 5.24a$ and the smaller density at $r = a(3 - \sqrt{5}) = 0.76a$. The maximum of $P(r)$ occurs at a value of r somewhat larger than the Bohr radius of $4a$.

(b) $\psi = 0$ at $r = 2a$

EVALUATE: Parts (a) and (b) are consistent with Figure 41.8 in the textbook; note the two relative maxima, one on each side of the minimum of zero at $r = 2a$.

41.57. **IDENTIFY:** Use Figure 41.6 in the textbook to relate θ_L to L_z and L: $\cos\theta_L = \frac{L_z}{L}$ so $\theta_L = \arccos\left(\frac{L_z}{L}\right).$

(a) SET UP: The smallest angle $(\theta_L)_{\min}$ is for the state with the largest L and the largest L_z. This is the state with $l = n-1$ and $m_l = l = n-1$.

EXECUTE: $L_z = m_l\hbar = (n-1)\hbar$

$L = \sqrt{l(l+1)}\hbar = \sqrt{(n-1)n}\hbar$

$$(\theta_L)_{\min} = \arccos\left(\frac{(n-1)h}{\sqrt{(n-1)n}h}\right) = \arccos\left(\frac{(n-1)}{\sqrt{(n-1)n}}\right) = \arccos\left(\sqrt{\frac{n-1}{n}}\right) = \arccos(\sqrt{(1-1)/n}).$$

EVALUATE: Note that $(\theta_L)_{\min}$ approaches $0°$ as $n \to \infty$.

(b) SET UP: The largest angle $(\theta_L)_{\max}$ is for $l = n-1$ and $m_l = -l = -(n-1)$.

EXECUTE: A similar calculation to part (a) yields $(\theta_L)_{\max} = \arccos\left(-\sqrt{1-1/n}\right)$

EVALUATE: Note that $(\theta_L)_{\max}$ approaches $180°$ as $n \to \infty$.

41.58. **IDENTIFY** and **SET UP:** $L_x^2 + L_y^2 + L_z^2 = L^2$. $L^2 = l(l+1)\hbar^2$. $L_z = m_l\hbar$.

EXECUTE: **(a)** $L_x^2 + L_y^2 = L^2 - L_z^2 = l(l+1)\hbar^2 - m_l^2\hbar^2$ so $\sqrt{L_x^2 + L_y^2} = \sqrt{l(l+1) - m_l^2}\,\hbar.$

(b) This is the magnitude of the component of angular momentum perpendicular to the z-axis.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(c) The maximum value is $\sqrt{l(l+1)}\hbar = L,$ when $m_l = 0.$ That is, if the electron is known to have no z-component of angular momentum, the angular momentum must be perpendicular to the z-axis. The minimum is $\sqrt{l}\hbar$ when $m_l = \pm l.$

EVALUATE: For $l \neq 0$ the minimum value of $L_x^2 + L_y^2$ is not zero. The angular momentum vector cannot be totally aligned along the z-axis. For $l \neq 0,$ $\vec{\boldsymbol{L}}$ must always have a component perpendicular to the z-axis.

41.59. **IDENTIFY:** At the value of r where $P(r)$ is a maximum, $\dfrac{dP}{dr} = 0.$

SET UP: $P(r) = \left(\dfrac{1}{24a^5}\right) r^4 e^{-r/a}.$

EXECUTE: $\dfrac{dP}{dr} = \left(\dfrac{1}{24a^5}\right)\left(4r^3 - \dfrac{r^4}{a}\right)e^{-r/a}.$ $\dfrac{dP}{dr} = 0$ when $4r^3 - \dfrac{r^4}{a} = 0;$ $r = 4a.$ In the Bohr model, $r_n = n^2 a$ so $r_2 = 4a,$ which agrees with the location of the maximum in $P(r).$

EVALUATE: Our result agrees with Figure 41.8. The figure shows that $P(r)$ for the $2p$ state has a single maximum and no zeros except at $r = 0$ and $r \to \infty.$

41.60. **IDENTIFY:** Apply constant acceleration equations to relate F_z to the motion of an atom.

SET UP: According to Eq. (41.40), the magnitude of μ_z is $|\mu_z| = 9.28 \times 10^{-24}$ A $\cdot$ m^2. The atomic mass of silver is 0.1079 kg/mol.

EXECUTE: The time required to transit the horizontal 50 cm region is $t = \dfrac{\Delta x}{v_x} = \dfrac{0.500 \text{ m}}{525 \text{ m/s}} = 0.952 \text{ ms}.$ The force required to deflect each spin component by 0.50 mm is

$$F_z = ma_z = \pm m\frac{2\Delta z}{t^2} = \pm\left(\frac{0.1079 \text{ kg/mol}}{6.022\times10^{23} \text{ atoms/mol}}\right)\frac{2(0.50\times10^{-3} \text{ m})}{(0.952\times10^{-3} \text{ s})^2} = \pm 1.98\times10^{-22} \text{ N}.$$

Thus, the required magnetic-field gradient is $\left|\dfrac{dB_z}{dz}\right| = \left|\dfrac{F_z}{\mu_z}\right| = \dfrac{1.98\times10^{-22} \text{ N}}{9.28\times10^{-24} \text{ J/T}} = 21.3 \text{ T/m}.$

EVALUATE: The two spin components are deflected in opposite directions.

41.61. **IDENTIFY:** Apply Eq. (41.36).

SET UP: Decay from a $3d$ to $2p$ state in hydrogen means that $n = 3 \to n = 2$ and $m_l = \pm 2, \pm 1, 0 \to m_l = \pm 1, 0.$ However, selection rules limit the possibilities for decay. The emitted photon carries off one unit of angular momentum so l must change by 1 and hence m_l must change by 0 or $\pm 1.$

EXECUTE: The shift in the transition energy from the zero field value is $U = (m_{l_3} - m_{l_2})\mu_B B = \dfrac{e\hbar B}{2m}(m_{l_3} - m_{l_2}),$ where m_{l_3} is the $3d$ m_l value and m_{l_2} is the $2p$ m_l value. Thus there are only three different energy shifts. The shifts and the transitions that have them, labeled by the m_l values, are:

$$\frac{e\hbar B}{2m}: 2 \to 1, 1 \to 0, 0 \to -1. \quad 0: 1 \to 1, \ 0 \to 0, -1 \to -1. \quad -\frac{e\hbar B}{2m}: 0 \to 1, -1 \to 0, -2 \to -1.$$

EVALUATE: Our results are consistent with Figure 41.15 in the textbook.

41.62. **IDENTIFY:** The presence of an external magnetic field shifts the energy levels up or down, depending upon the value of m_l.

SET UP: The selection rules tell us that for allowed transitions, $\Delta l = 1$ and $\Delta m_l = 0$ or $\pm 1.$

EXECUTE: **(a)** $E = hc/\lambda = (4.136\times10^{-15} \text{ eV}\cdot\text{s})(3.00\times10^8 \text{ m/s})/(475.082 \text{ nm}) = 2.612 \text{ eV}.$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) For allowed transitions, $\Delta l = 1$ and $\Delta m_l = 0$ or ± 1. For the $3d$ state, $n = 3$, $l = 2$, and m_l can have the values $2, 1, 0, -1, -2$. In the $2p$ state, $n = 2$, $l = 1$, and m_l can be $1, 0, -1$. Therefore the 9 allowed transitions from the $3d$ state in the presence of a magnetic field are:

$l = 2, m_l = 2 \rightarrow l = 1, m_l = 1$
$l = 2, m_l = 1 \rightarrow l = 1, m_l = 0$
$l = 2, m_l = 1 \rightarrow l = 1, m_l = 1$
$l = 2, m_l = 0 \rightarrow l = 1, m_l = 0$
$l = 2, m_l = 0 \rightarrow l = 1, m_l = 1$
$l = 2, m_l = 0 \rightarrow l = 1, m_l = -1$
$l = 2, m_l = -1 \rightarrow l = 1, m_l = 0$
$l = 2, m_l = -1 \rightarrow l = 1, m_l = -1$
$l = 2, m_l = -2 \rightarrow l = 1, m_l = -1$

(c) $\Delta E = \mu_B B = (5.788 \times 10^{-5}\ \text{eV/T})(3.500\ \text{T}) = 0.000203\ \text{eV}$

So the energies of the new states are $-8.50000\ \text{eV} + 0$ and $-8.50000\ \text{eV} \pm 0.000203\ \text{eV}$, giving energies of: -8.50020 eV, -8.50000 eV and -8.49980 eV.

(d) The energy differences of the allowed transitions are equal to the energy differences if no magnetic field were present (2.61176 eV, from part (a)), and that value $\pm\Delta E$ (0.000203 eV, from part (c)). Therefore we get the following:

For $E = 2.61176\ \text{eV}$: $\lambda = 475.082\ \text{nm}$ (which was given)

For $E = 2.61176\ \text{eV} + 0.000203\ \text{eV} = 2.611963\ \text{eV}$:

$$\lambda = hc/E = (4.136 \times 10^{-15}\ \text{eV} \cdot \text{s})(3.00 \times 10^8\ \text{m/s})/(2.611963\ \text{eV}) = 475.045\ \text{nm}$$

For $E = 2.61176\ \text{eV} - 0.000203\ \text{eV} = 2.61156\ \text{eV}$:

$$\lambda = hc/E = (4.136 \times 10^{-15}\ \text{eV} \cdot \text{s})(3.00 \times 10^8\ \text{m/s})/(2.61156\ \text{eV}) = 475.119\ \text{nm}$$

EVALUATE: Even a strong magnetic field produces small changes in the energy levels, and hence in the wavelengths of the emitted light.

41.63. **IDENTIFY:** The presence of an external magnetic field shifts the energy levels up or down, depending upon the value of m_l.

SET UP: The energy difference due to the magnetic field is $\Delta E = \mu_B B$ and the energy of a photon is $E = hc/\lambda$.

EXECUTE: For the p state, $m_l = 0$ or ± 1, and for the s state $m_l = 0$. Between any two adjacent lines, $\Delta E = \mu_B B$. Since the change in the wavelength $(\Delta\lambda)$ is very small, the energy change (ΔE) is also very small, so we can use differentials. $E = hc/\lambda$. $|dE| = \dfrac{hc}{\lambda^2} d\lambda$ and $\Delta E = \dfrac{hc\Delta\lambda}{\lambda^2}$. Since $\Delta E = \mu_B B$, we get

$\mu_B B = \dfrac{hc\Delta\lambda}{\lambda^2}$ and $B = \dfrac{hc\Delta\lambda}{\mu_B \lambda^2}$.

$B = (4.136 \times 10^{-15}\ \text{eV} \cdot \text{s})(3.00 \times 10^8\ \text{m/s})(0.0462\ \text{nm})/(5.788 \times 10^{-5}\ \text{eV/T})(575.050\ \text{nm})^2 = 3.00\ \text{T}$

EVALUATE: Even a strong magnetic field produces small changes in the energy levels, and hence in the wavelengths of the emitted light.

41.64. **IDENTIFY:** Apply Eq. (41.36). Problem 39.86c says $|\Delta\lambda/\lambda| = |\Delta E/E|$, when these quantities are small.

SET UP: $\mu_B = 5.79 \times 10^{-5}\ \text{eV/T}$

EXECUTE: **(a)** The energy shift from zero field is $\Delta U_0 = m_l \mu_B B$.

For $m_l = 2$, $\Delta U_0 = (2)(5.79 \times 10^{-5}\ \text{eV/T})(1.40\ \text{T}) = 1.62 \times 10^{-4}\ \text{eV}$.

For $m_l = 1$, $\Delta U_0 = (1)(5.79 \times 10^{-5}\ \text{eV/T})(1.40\ \text{T}) = 8.11 \times 10^{-5}\ \text{eV}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) $|\Delta\lambda| = \lambda_0 \dfrac{|\Delta E|}{E_0}$, where $E_0 = (13.6\text{ eV})((1/4)-(1/9))$, $\lambda_0 = \left(\dfrac{36}{5}\right)\dfrac{1}{R} = 6.563\times10^{-7}$ m

and $\Delta E = 1.62\times10^{-4}$ eV $- 8.11\times10^{-5}$ eV $= 8.09\times10^{-5}$ eV from part (a). Then,

$|\Delta\lambda| = 2.81\times10^{-11}$ m $= 0.0281$ nm. The wavelength corresponds to a larger energy change, and so the wavelength is smaller.

EVALUATE: $|\Delta\lambda/\lambda| = (0.0281\text{ nm})/(656\text{ nm}) = 4.3\times10^{-5}$. $|\Delta\lambda/\lambda|$ is very small and the approximate expression from Problem 39.86c is very accurate.

41.65. **IDENTIFY:** The ratio according to the Boltzmann distribution is given by Eq. (39.18): $\dfrac{n_1}{n_0} = e^{-(E_1-E_0)/kT}$, where 1 is the higher energy state and 0 is the lower energy state.

SET UP: The interaction energy with the magnetic field is $U = -\mu_z B = 2.00232\left(\dfrac{e\hbar}{2m}\right)m_s B$ (Example 41.6.).

The energy of the $m_s = +\dfrac{1}{2}$ level is increased and the energy of the $m_s = -\dfrac{1}{2}$ level is decreased.

$\dfrac{n_{1/2}}{n_{-1/2}} = e^{-(U_{1/2}-U_{-1/2})/kT}$

EXECUTE: $U_{1/2} - U_{-1/2} = 2.00232\left(\dfrac{e\hbar}{2m}\right)B\left(\dfrac{1}{2}-\left(-\dfrac{1}{2}\right)\right) = 2.00232\left(\dfrac{e\hbar}{2m}\right)B = 2.00232\mu_B B$

$\dfrac{n_{1/2}}{n_{-1/2}} = e^{-(2.00232)\mu_B B/kT}$

(a) $B = 5.00\times10^{-5}$ T

$\dfrac{n_{1/2}}{n_{-1/2}} = e^{-2.00232(9.274\times10^{-24}\text{ A/m}^2)(5.00\times10^{-5}\text{ T})/([1.381\times10^{-23}\text{ J/K}][300\text{ K}])}$

$\dfrac{n_{1/2}}{n_{-1/2}} = e^{-2.24\times10^{-7}} = 0.99999978 = 1 - 2.2\times10^{-7}$

(b) $B = 5.00\times10^{-5}$ T, $\dfrac{n_{1/2}}{n_{-1/2}} = e^{-2.24\times10^{-3}} = 0.9978$

(c) $B = 5.00\times10^{-5}$ T, $\dfrac{n_{1/2}}{n_{-1/2}} = e^{-2.24\times10^{-2}} = 0.978$

EVALUATE: For small fields the energy separation between the two spin states is much less than kT for $T = 300$ K and the states are equally populated. For $B = 5.00$ T the energy spacing is large enough for there to be a small excess of atoms in the lower state.

41.66. **IDENTIFY:** The magnetic field at the center of a current loop of radius r is $B = \dfrac{\mu_0 I}{2r}$ (Eq. 28.17).

$I = e\left(\dfrac{v}{2\pi r}\right)$.

SET UP: Using Eq. (41.22), $L = mvr = \sqrt{l(l+1)}\hbar$. The Bohr radius from Eq. (39.11) is $n^2 a_0$.

EXECUTE: $v = \dfrac{\sqrt{l(l+1)}\hbar}{m(n^2 a_0)} = \dfrac{\sqrt{2}(6.63\times10^{-34}\text{ J}\cdot\text{s})}{2\pi(9.11\times10^{-31}\text{ kg})(4)(5.29\times10^{-11}\text{ m})} = 7.74\times10^5$ m/s. The magnetic field generated by the "moving" proton at the electron's position is

$B = \dfrac{\mu_0 I}{2r} = \dfrac{\mu_0}{4\pi}\dfrac{ev}{r^2} = (10^{-7}\text{ T}\cdot\text{m/A})\dfrac{(1.60\times10^{-19}\text{C})(7.74\times10^5\text{ m/s})}{(4)^2(5.29\times10^{-11}\text{ m})^2} = 0.277\text{ T}.$

EVALUATE: The effective magnetic field calculated in Example 41.7 for 3*p* electrons in sodium is much larger than the value we calculated for 2*p* electrons in hydrogen.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

41.67. **IDENTIFY** and **SET UP:** m_s can take on 4 different values: $m_s = -\frac{3}{2}, -\frac{1}{2}, +\frac{1}{2}, +\frac{3}{2}$. Each nlm_l state can have 4 electrons, each with one of the four different m_s values. Apply the exclusion principle to determine the electron configurations.

EXECUTE: **(a)** For a filled $n = 1$ shell, the electron configuration would be $1s^4$; four electrons and $Z = 4$. For a filled $n = 2$ shell, the electron configuration would be $1s^4 2s^4 2p^{12}$; twenty electrons and $Z = 20$.

(b) Sodium has $Z = 11$; 11 electrons. The ground-state electron configuration would be $1s^4 2s^4 2p^3$.

EVALUATE: The chemical properties of each element would be very different.

41.68. **IDENTIFY:** Apply Eq. (41.43) and Eq. (41.26), with e^2 replaced by Ze^2. The photon wavelength λ is related to the transition energy ΔE for the atom by $\Delta E = \frac{hc}{\lambda}$.

SET UP: For N^{6+}, $Z = 7$.

EXECUTE: **(a)** $Z^2\,(-13.6\text{ eV}) = (7)^2\,(-13.6\text{ eV}) = -666\text{ eV}$.

(b) The negative of the result of part (a), 666 eV.

(c) The radius of the ground state orbit is inversely proportional to the nuclear charge, and $\frac{a}{Z} = (0.529\times10^{-10}\text{ m})/7 = 7.56\times10^{-12}\text{ m}$.

(d) $\lambda = \frac{hc}{\Delta E} = \frac{hc}{E_0\left(\frac{1}{1^2} - \frac{1}{2^2}\right)}$, where E_0 is the energy found in part (b), and $\lambda = 2.49$ nm.

EVALUATE: For hydrogen, the wavelength of the photon emitted in this transition is 122 nm (Section 39.3). The wavelength for N^{6+} is smaller by a factor of 7^2.

41.69. **(a) IDENTIFY** and **SET UP:** The energy of the photon equals the transition energy of the atom: $\Delta E = hc/\lambda$. The energies of the states are given by Eq. (41.21).

EXECUTE: $E_n = -\frac{13.60\text{ eV}}{n^2}$ so $E_2 = -\frac{13.60\ e\text{V}}{4}$ and $E_1 = -\frac{13.60\text{ eV}}{1}$

$$\Delta E = E_2 - E_1 = 13.60\text{ eV}\left(-\frac{1}{4}+1\right) = \frac{3}{4}(13.60\text{ eV}) = 10.20\text{ eV} = (10.20\text{ eV})(1.602\times10^{-19}\text{ J/eV}) = 1.634\times10^{-18}\text{ J}$$

$$\lambda = \frac{hc}{\Delta E} = \frac{(6.626\times10^{-34}\text{ J}\cdot\text{s})(2.998\times10^{8}\text{ m/s})}{1.634\times10^{-18}\text{ J}} = 1.22\times10^{-7}\text{ m} = 122\text{ nm}$$

(b) IDENTIFY and **SET UP:** Calculate the change in ΔE due to the orbital magnetic interaction energy, Eq. (41.36), and relate this to the shift $\Delta\lambda$ in the photon wavelength.

EXECUTE: The shift of a level due to the energy of interaction with the magnetic field in the z-direction is $U = m_l\mu_B B$. The ground state has $m_l = 0$ so is unaffected by the magnetic field. The $n = 2$ initial state has $m_l = -1$ so its energy is shifted downward an amount $U = m_l\mu_B B = (-1)(9.274\times10^{-24}\text{ A/m}^2)(2.20\text{ T}) = (-2.040\times10^{-23}\text{ J})(1\text{ eV}/1.602\times10^{-19}\text{ J}) = 1.273\times10^{-4}$ eV.

Note that the shift in energy due to the magnetic field is a very small fraction of the 10.2 eV transition energy. Problem 39.86c shows that in this situation $|\Delta\lambda/\lambda| = |\Delta E/E|$. This gives

$$|\Delta\lambda| = \lambda|\Delta E/E| = 122\text{ nm}\left(\frac{1.273\times10^{-4}\text{ eV}}{10.2\text{ eV}}\right) = 1.52\times10^{-3}\text{ nm} = 1.52\text{ pm}.$$

EVALUATE: The upper level in the transition is lowered in energy so the transition energy is decreased. A smaller ΔE means a larger λ; the magnetic field increases the wavelength. The fractional shift in wavelength, $\Delta\lambda/\lambda$ is small, only 1.2×10^{-5}.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

41.70. **IDENTIFY:** Apply Eq. (41.36), where B is the effective magnetic field. $\Delta E = \dfrac{hc}{\lambda}$.

SET UP: $\mu_B = \dfrac{e\hbar}{2m} = \dfrac{eh}{4\pi m}$.

EXECUTE: The effective field is that which gives rise to the observed difference in the energy level transition, $B = \dfrac{\Delta E}{\mu_B} = \dfrac{hc}{\mu_B}\left(\dfrac{\lambda_1 - \lambda_2}{\lambda_1\lambda_2}\right) = \dfrac{4\pi mc}{e}\left(\dfrac{\lambda_1 - \lambda_2}{\lambda_1\lambda_2}\right)$. Substitution of numerical values gives $B = 7.28\times10^{-3}$ T.

EVALUATE: The effective magnetic field we have calculated is much smaller than that calculated for sodium in Example 41.7.

41.71. **IDENTIFY:** Estimate the atomic transition energy and use Eq. (39.5) to relate this to the photon wavelength.

(a) SET UP: vanadium, $Z = 23$

minimum wavelength; corresponds to largest transition energy

EXECUTE: The highest occupied shell is the N shell $(n = 4)$. The highest energy transition is $N \to K$, with transition energy $\Delta E = E_N - E_K$. Since the shell energies scale like $1/n^2$ neglect E_N relative to E_K, so $\Delta E = E_K = (Z-1)^2(13.6\text{ eV}) = (23-1)^2(13.6\text{ eV}) = 6.582\times10^3$ eV $= 1.055\times10^{-15}$ J. The energy of the emitted photon equals this transition energy, so the photon's wavelength is given by $\Delta E = hc/\lambda$ so $\lambda = hc/\Delta E$.

$$\lambda = \frac{(6.626\times10^{-34}\text{ J}\cdot\text{s})(2.998\times10^8\text{ m/s})}{1.055\times10^{-15}\text{ J}} = 1.88\times10^{-10}\text{ m} = 0.188\text{ nm}.$$

SET UP: maximum wavelength; corresponds to smallest transition energy, so for the K_α transition

EXECUTE: The frequency of the photon emitted in this transition is given by Moseley's law (Eq. 41.47):

$$f = (2.48\times10^{15}\text{ Hz})(Z-1)^2 = (2.48\times10^{15}\text{ Hz})(23-1)^2 = 1.200\times10^{18}\text{ Hz}$$

$$\lambda = \frac{c}{f} = \frac{2.998\times10^8\text{ m/s}}{1.200\times10^{18}\text{ Hz}} = 2.50\times10^{-10}\text{ m} = 0.250\text{ nm}$$

(b) rhenium, $Z = 45$

Apply the analysis of part (a), just with this different value of Z.

minimum wavelength

$\Delta E = E_K = (Z-1)^2(13.6\text{ eV}) = (45-1)^2(13.6\text{ eV}) = 2.633\times10^4$ eV $= 4.218\times10^{-15}$ J.

$$\lambda = hc/\Delta E = \frac{(6.626\times10^{-34}\text{ J}\,.\,\text{s})(2.998\times10^8\text{ m/s})}{4.218\times10^{-15}\text{ J}} = 4.71\times10^{-11}\text{ m} = 0.0471\text{ nm}.$$

maximum wavelength

$$f = (2.48\times10^{15}\text{ Hz})(Z-1)^2 = (2.48\times10^{15}\text{ Hz})(45-1)^2 = 4.801\times10^{18}\text{ Hz}$$

$$\lambda = \frac{c}{f} = \frac{2.998\times10^8\text{ m/s}}{4.801\times10^{18}\text{ Hz}} = 6.24\times10^{-11}\text{ m} = 0.0624\text{ nm}$$

EVALUATE: Our calculated wavelengths have values corresponding to x rays. The transition energies increase when Z increases and the photon wavelengths decrease.

41.72. **IDENTIFY:** The interaction energy for an electron in a magnetic field is $U = -\mu_z B$, where μ_z is given by Eq. (41.40).

SET UP: $\Delta S_z = \hbar$

EXECUTE: **(a)** $\Delta E = (2.00232)\dfrac{e}{2m}B\Delta S_z \approx \dfrac{e\hbar}{m}B = \dfrac{hc}{\lambda} \Rightarrow B = \dfrac{2\pi mc}{\lambda e}$.

(b) $$B = \frac{2\pi(9.11\times10^{-31}\text{ kg})(3.00\times10^8\text{ m/s})}{(0.0350\text{ m})(1.60\times10^{-19}\text{ C})} = 0.307\text{ T}.$$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: As shown in Figure 41.18 in the textbook, the lower state in the transition has $m_s = -\frac{1}{2}$ and the upper state has $m_s = +\frac{1}{2}$.

41.73. **IDENTIFY** and **SET UP:** The potential $U(x) = \frac{1}{2}k'x^2$ is that of a simple harmonic oscillator. Treated quantum mechanically (see Section 40.5) each *energy* state has energy $E_n = \hbar\omega\left(n + \frac{1}{2}\right)$. Since electrons obey the exclusion principle, this allows us to put *two* electrons (one for each $m_s = \pm\frac{1}{2}$) for every value of n—each quantum state is then defined by the ordered pair of quantum numbers (n, m_s).

EXECUTE: By placing two electrons in each energy level the lowest energy is

$$2\left(\sum_{n=0}^{N-1} E_n\right) = 2\left(\sum_{n=0}^{N-1} \hbar\omega\left(n + \frac{1}{2}\right)\right) = 2\hbar\omega\left[\sum_{n=0}^{N-1} n + \sum_{n=0}^{N-1}\frac{1}{2}\right] = 2\hbar\omega\left[\frac{(N-1)(N)}{2} + \frac{N}{2}\right] =$$

$\hbar\omega[N^2 - N + N] = \hbar\omega N^2 = \hbar N^2\sqrt{\frac{k'}{m}}$. Here we realize that the first value of n is zero and the last value of n is $N-1$, giving us a total of N energy levels filled.

EVALUATE: The minimum energy for one electron moving in this potential is $\frac{1}{2}\hbar\omega$, with $\omega = \sqrt{\frac{k'}{m}}$. For $2N$ electrons the minimum energy is larger than $(2N)\left(\frac{1}{2}\hbar\omega\right)$, because only two electrons can be put into each energy state. For example, for $N = 2$ (4 electrons), there are two electrons in the $E = \frac{1}{2}\hbar\omega$ energy state and two in the $\frac{3}{2}\hbar\omega$ state, for a total energy of $2\left(\frac{1}{2}\hbar\omega\right) + 2\left(\frac{3}{2}\hbar\omega\right) = 4\hbar\omega$, which is in agreement with our general result.

41.74. **IDENTIFY** and **SET UP:** Apply Newton's second law and Bohr's quantization to one of the electrons.

EXECUTE: **(a)** Apply Coulomb's law to the orbiting electron and set it equal to the centripetal force. There is an attractive force with charge +2*e* a distance *r* away and a repulsive force a distance 2*r* away. So, $\frac{(+2e)(-e)}{4\pi\epsilon_0 r^2} + \frac{(-e)(-e)}{4\pi\epsilon_0(2r)^2} = \frac{-mv^2}{r}$. But, from the quantization of angular momentum in the first Bohr orbit,

$$L = mvr = \hbar \Rightarrow v = \frac{\hbar}{mr}. \text{ So } \frac{-2e^2}{4\pi\epsilon_0 r^2} + \frac{e^2}{4\pi\epsilon_0(2r)^2} = \frac{-mv^2}{r} = \frac{-m\left(\frac{\hbar}{mr}\right)^2}{r} = -\frac{\hbar^2}{mr^3} \Rightarrow \frac{-7}{4}\frac{e^2}{r^2} = -\frac{4\pi\epsilon_0\hbar^2}{mr^3}.$$

$r = \frac{4}{7}\left(\frac{4\pi\epsilon_0\hbar^2}{me^2}\right) = \frac{4}{7}a_0 = \frac{4}{7}(0.529\times10^{-10}\text{ m}) = 3.02\times10^{-11}\text{ m}$. And

$$v = \frac{\hbar}{mr} = \frac{7}{4}\frac{\hbar}{ma_0} = \frac{7}{4}\frac{(1.054\times10^{-34}\text{ J}\cdot\text{s})}{(9.11\times10^{-31}\text{ kg})(0.529\times10^{-10}\text{ m})} = 3.83\times10^6\text{ m/s}.$$

(b) $K = 2\left(\frac{1}{2}mv^2\right) = 9.11\times10^{-31}\text{ kg}\,(3.83\times10^6\text{ m/s})^2 = 1.34\times10^{-17}\text{ J} = 83.5\text{ eV}$.

(c) $U = 2\left(\frac{-2e^2}{4\pi\epsilon_0 r}\right) + \frac{e^2}{4\pi\epsilon_0(2r)} = \frac{-4e^2}{4\pi\epsilon_0 r} + \frac{e^2}{4\pi\epsilon_0(2r)} = \frac{-7}{2}\left(\frac{e^2}{4\pi\epsilon_0 r}\right) = -2.67\times10^{-17}\text{ J} = -166.9\text{ eV}$

(d) $E_\infty = -[-166.9\text{ eV} + 83.5\text{ eV}] = 83.4\text{ eV}$, which is only off by about 5% from the real value of 79.0 eV.

EVALUATE: The ground state energy of helium in this model is $K + U = -83.4$ eV. The ground state energy of He^+ is $4(-13.6\text{ eV}) = -54.4$ eV. Therefore, the energy required to remove one electron from helium in this model is $-(-83.4\text{ eV} + 54.4\text{ eV}) = 29.0$ eV. The experimental value for this quantity is 24.6 eV.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

41.75. **IDENTIFY** and **SET UP:** In the expression for the turning points and in the wave function replace a by a/Z
EXECUTE: **(a)** The radius is inversely proportional to Z, so the classical turning radius is $2a/Z$.

(b) The normalized wave function is $\psi_{1s}(r) = \dfrac{1}{\sqrt{\pi a^3/Z^3}} e^{-Zr/a}$ and the probability of the electron being found outside the classical turning point is $P = \int_{2a/Z}^{\infty} |\psi_{1s}|^2 \, 4\pi r^2 dr = \dfrac{4}{a^3/Z^3} \int_{2a/z}^{\infty} e^{-2Zr/a} r^2 dr$. Making the change of variable $u = Zr/a, dr = (a/Z)du$ changes the integral to $P = 4\int_2^{\infty} e^{-2u} u^2 du$, which is independent of Z. The probability is that found in Problem 41.53, 0.238, independent of Z.
EVALUATE: The probability of the electron being in the classically forbidden region is independent of Z.

42

MOLECULES AND CONDENSED MATTER

42.1. **IDENTIFY:** The minimum energy the photon must have is the energy of the covalent bond.

SET UP: The energy of the photon is $E = \frac{hc}{\lambda}$. Visible light has wavelengths between 400 nm and 700 nm.

EXECUTE: The photon must have energy 4.48 eV. Solving for the wavelength gives

$$\lambda = \frac{hc}{E} = \frac{1.24\times10^{-6}\ \text{eV}\cdot\text{m}}{4.48\ \text{eV}} = 277\ \text{nm}.$$

EVALUATE: This wavelength is shorter than the wavelengths of visible light so lies in the ultraviolet.

42.2. **IDENTIFY** and **SET UP:** $U = \frac{1}{4\pi\varepsilon_0}\frac{q_1q_2}{r}$. The binding energy of the molecule is equal to U plus the ionization energy of K minus the electron affinity of Br.

EXECUTE: **(a)** $U = -\frac{1}{4\pi\varepsilon_0}\frac{e^2}{r} = -5.0\ \text{eV}$.

(b) $-5.0\ \text{eV} + (4.3\ \text{eV} - 3.5\ \text{eV}) = -4.2\ \text{eV}$.

EVALUATE: We expect the magnitude of the binding energy to be somewhat less than this estimate. At this separation the two ions don't behave exactly like point charges and U is smaller in magnitude than our estimate. The experimental value for the binding energy is -4.0 eV, which is smaller in magnitude than our estimate.

42.3. **IDENTIFY:** Set $\frac{3}{2}kT$ equal to the specified bond energy E.

SET UP: $k = 1.38\times10^{-23}$ J/K.

EXECUTE: **(a)** $E = \frac{3}{2}kT \Rightarrow T = \frac{2E}{3k} = \frac{2(7.9\times10^{-4}\ \text{eV})(1.60\times10^{-19}\ \text{J/eV})}{3(1.38\times10^{-23}\ \text{J/K})} = 6.1\ \text{K}$.

(b) $T = \frac{2(4.48\ \text{eV})(1.60\times10^{-19}\,\text{J/eV})}{3(1.38\times10^{-23}\,\text{J/K})} = 34{,}600\ \text{K}$.

EVALUATE: **(c)** The thermal energy associated with room temperature (300 K) is much greater than the bond energy of He_2 (calculated in part (a)), so the typical collision at room temperature will be more than enough to break up He_2. However, the thermal energy at 300 K is much less than the bond energy of H_2, so we would expect it to remain intact at room temperature.

42.4. **IDENTIFY:** If the photon has too little energy, it cannot alter atomic energy levels.

SET UP: $\Delta E = \frac{hc}{\lambda}$. Atomic energy levels are separated by a few eV. Vibrational levels are separated by a few tenths of an eV. Rotational levels are separated by a few thousandths of an eV or less.

EXECUTE: **(a)** $\Delta E = \frac{hc}{\lambda} = \frac{(4.136\times10^{-15}\ \text{eV}\cdot\text{s})(3.00\times10^{8}\ \text{m/s})}{3.10\times10^{-3}\ \text{m}} = 4.00\times10^{-4}\ \text{eV}$. This is a typical transition energy for a rotational transition.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) $\Delta E = \dfrac{hc}{\lambda} = \dfrac{(4.136\times10^{-15}\ \text{eV}\cdot\text{s})(3.00\times10^{8}\ \text{m/s})}{207\times10^{-9}\ \text{m}} = 5.99\ \text{eV}$. This is a typical transition energy for a transition between atomic energy levels.

EVALUATE: As the transition energy increases, the photon requires a shorter and shorter wavelength to cause transitions.

42.5. **IDENTIFY:** The energy of the photon is equal to the energy difference between the $l = 1$ and $l = 2$ states. This energy determines its wavelength.

SET UP: The reduced mass of the molecule is $m_r = \dfrac{m_H m_H}{m_H + m_H} = \dfrac{1}{2}m_H$, its moment of inertia is $I = m_r r_0^2$, the photon energy is $\Delta E = \dfrac{hc}{\lambda}$, and the energy of the state l is $E_l = l(l+1)\dfrac{\hbar^2}{2I}$.

EXECUTE: $I = m_r r_0^2 = \dfrac{1}{2}(1.67\times10^{-27}\ \text{kg})(0.074\times10^{-9}\ \text{m})^2 = 4.57\times10^{-48}\ \text{kg}\cdot\text{m}^2$. Using $E_l = l(l+1)\dfrac{\hbar^2}{2I}$, the energy levels are $E_2 = 6\dfrac{\hbar^2}{2I} = 6\dfrac{(1.055\times10^{-34}\ \text{J}\cdot\text{s})^2}{2(4.57\times10^{-48}\ \text{kg}\cdot\text{m}^2)} = 6(1.218\times10^{-21}\ \text{J}) = 7.307\times10^{-21}\ \text{J}$ and $E_1 = 2\dfrac{\hbar^2}{2I} = 2(1.218\times10^{-21}\ \text{J}) = 2.436\times10^{-21}\ \text{J}$. $\Delta E = E_2 - E_1 = 4.87\times10^{-21}\ \text{J}$. Using $\Delta E = \dfrac{hc}{\lambda}$ gives

$$\lambda = \frac{hc}{\Delta E} = \frac{(6.626\times10^{-34}\ \text{J}\cdot\text{s})(2.998\times10^{8}\ \text{m/s})}{4.871\times10^{-21}\ \text{J}} = 4.08\times10^{-5}\ \text{m} = 40.8\ \mu\text{m}.$$

EVALUATE: This wavelength is much longer than that of visible light.

42.6. **IDENTIFY:** The energy decrease of the molecule or atom is equal to the energy of the emitted photon. From this energy, we can calculate the wavelength of the photon.

SET UP: $\Delta E = \dfrac{hc}{\lambda}$.

EXECUTE: **(a)** $\lambda = \dfrac{hc}{\Delta E} = \dfrac{(4.136\times10^{-15}\ \text{eV}\cdot\text{s})(3.00\times10^{8}\ \text{m/s})}{0.250\ \text{eV}} = 4.96\ \mu\text{m}$.

EVALUATE: This radiation is in the infrared.

(b) $\lambda = \dfrac{hc}{\Delta E} = \dfrac{(4.136\times10^{-15}\ \text{eV}\cdot\text{s})(3.00\times10^{8}\ \text{m/s})}{8.50\ \text{eV}} = 146\ \text{nm}$.

EVALUATE: This radiation is in the ultraviolet.

(c) $\lambda = \dfrac{hc}{\Delta E} = \dfrac{(4.136\times10^{-15}\ \text{eV}\cdot\text{s})(3.00\times10^{8}\ \text{m/s})}{3.20\times10^{-3}\ \text{eV}} = 388\ \mu\text{m}$.

EVALUATE: This radiation is in the microwave region.

42.7. **IDENTIFY:** The energy given to the photon comes from a transition between rotational states.

SET UP: The rotational energy of a molecule is $E = l(l+1)\dfrac{\hbar^2}{2I}$ and the energy of the photon is $E = hc/\lambda$.

EXECUTE: Use the energy formula, the energy difference between the $l = 3$ and $l = 1$ rotational levels of the molecule is $\Delta E = \dfrac{\hbar^2}{2I}[3(3+1) - 1(1+1)] = \dfrac{5\hbar^2}{I}$. Since $\Delta E = hc/\lambda$, we get $hc/\lambda = 5\hbar^2/I$. Solving for I gives

$$I = \frac{5\hbar\lambda}{2\pi c} = \frac{5(1.055\times10^{-34}\ \text{J}\cdot\text{s})(1.780\ \text{nm})}{2\pi(3.00\times10^{8}\ \text{m/s})} = 4.981\times10^{-52}\ \text{kg}\cdot\text{m}^2.$$

Using $I = m_r r_0^2$, we can solve for r_0:

$$r_0 = \sqrt{\frac{I(m_N + m_H)}{m_N m_H}} = \sqrt{\frac{(4.981\times10^{-52}\ \text{kg}\cdot\text{m}^2)(2.33\times10^{-26}\ \text{kg} + 1.67\times10^{-27}\ \text{kg})}{(2.33\times10^{-26}\ \text{kg})(1.67\times10^{-27}\ \text{kg})}} \quad r_0 = 5.65\times10^{-13}\ \text{m}$$

EVALUATE: This separation is much smaller than the diameter of a typical atom and is not very realistic. But we are treating a *hypothetical* NH molecule.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

42.8. **IDENTIFY:** The transition energy E and the frequency f of the absorbed photon are related by $E = hf$.

EXECUTE: The energy of the emitted photon is 1.01×10^{-5} eV, and so its frequency and wavelength are

$$f = \frac{E}{h} = \frac{(1.01\times10^{-5}\text{ eV})(1.60\times10^{-19}\text{ J/eV})}{(6.63\times10^{-34}\text{ J}\cdot\text{s})} = 2.44\text{ GHz} = 2440\text{ MHz and}$$

$$\lambda = \frac{c}{f} = \frac{(3.00\times10^{8}\text{ m/s})}{(2.44\times10^{9}\text{ Hz})} = 0.123\text{ m.}$$

EVALUATE: This frequency corresponds to that given for a microwave oven.

42.9. **IDENTIFY:** Apply Eq. (42.5).

SET UP: Let 1 refer to C and 2 to O. $m_1 = 1.993\times10^{-26}$ kg, $m_2 = 2.656\times10^{-26}$ kg, $r_0 = 0.1128$ nm.

EXECUTE: **(a)** $r_1 = \left(\frac{m_2}{m_1+m_2}\right)r_0 = 0.0644$ nm (carbon); $r_2 = \left(\frac{m_1}{m_1+m_2}\right)r_0 = 0.0484$ nm (oxygen)

(b) $I = m_1r_1^2 + m_2r_2^2 = 1.45\times10^{-46}\text{ kg}\cdot\text{m}^2$; yes, this agrees with Example 42.2.

EVALUATE: $I = m_1r_1^2 + m_2r_2^2$ and $I = m_\text{r}r_0^2$ give equivalent results.

42.10. **IDENTIFY:** $I = m_1r_1^2 + m_2r_2^2$. Since the two atoms are identical, the center of mass is midway between them.

SET UP: Each atom has a mass m and is at a distance $L/2$ from the center of mass.

EXECUTE: The moment of inertia is $2(m) = (L/2)^2 = mL^2/2 = 2.21\times10^{-44}\text{ kg}\cdot\text{m}^2$.

EVALUATE: $r_0 = L$ and $m_\text{r} = m/2$, so $I = m_\text{r}r_0^2$ gives the same result.

42.11. **IDENTIFY** and **SET UP:** Set $K = E_1$ from Example 42.2. Use $K = \frac{1}{2}I\omega^2$ to solve for ω and $v = r\omega$ to solve for v.

EXECUTE: **(a)** From Example 42.2, $E_1 = 0.479$ meV $= 7.674\times10^{-23}$ J and $I = 1.449\times10^{-46}\text{ kg}\cdot\text{m}^2$

$K = \frac{1}{2}I\omega^2$ and $K = E$ gives $\omega = \sqrt{2E_1/I} = 1.03\times10^{12}$ rad/s

(b) $v_1 = r_1\omega_1 = (0.0644\times10^{-9}\text{ m})(1.03\times10^{12}\text{ rad/s}) = 66.3$ m/s (carbon)

$v_2 = r_2\omega_2 = (0.0484\times10^{-9}\text{ m})(1.03\times10^{12}\text{ rad/s}) = 49.8$ m/s (oxygen)

(c) $T = 2\pi/\omega = 6.10\times10^{-12}$ s

EVALUATE: Even for fast rotation rates, $v \ll c$.

42.12. **IDENTIFY:** For a $n \to n-1$ vibrational transition, $\Delta E = \hbar\sqrt{\frac{k'}{m_\text{r}}}$. ΔE is related to λ of the photon by $\Delta E = \frac{hc}{\lambda}$.

SET UP: $m_\text{r} = \frac{m_\text{Na}m_\text{Cl}}{m_\text{Na}+m_\text{Cl}}$.

EXECUTE: $\Delta E = \frac{hc}{\lambda} = \hbar\sqrt{k'/m_\text{r}}$, and solving for k', $k' = \left(\frac{2\pi c}{\lambda}\right)^2 m_\text{r} = 205$ N/m.

EVALUATE: The value of k' we calculated for NaCl is comparable to that of a fairly stiff lab spring.

42.13. **IDENTIFY** and **SET UP:** The energy of a rotational level with quantum number l is $E_l = l(l+1)\hbar^2/2I$ (Eq. (42.3)). $I = m_\text{r}r^2$, with the reduced mass m_r given by Eq. (42.4). Calculate I and ΔE and then use $\Delta E = hc/\lambda$ to find λ.

EXECUTE: **(a)** $m_\text{r} = \frac{m_1m_2}{m_1+m_2} = \frac{m_\text{Li}m_\text{H}}{m_\text{Li}+m_\text{H}} = \frac{(1.17\times10^{-26}\text{ kg})(1.67\times10^{-27}\text{ kg})}{1.17\times10^{-26}\text{ kg}+1.67\times10^{-27}\text{ kg}} = 1.461\times10^{-27}\text{ kg}$

$I = m_\text{r}r^2 = (1.461\times10^{-27}\text{ kg})(0.159\times10^{-9}\text{ m})^2 = 3.694\times10^{-47}\text{ kg}\cdot\text{m}^2$

$l = 3: E = 3(4)\left(\frac{\hbar^2}{2I}\right) = 6\left(\frac{\hbar^2}{I}\right)$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$l = 4 : E = 4(5)\left(\frac{\hbar^2}{2I}\right) = 10\left(\frac{\hbar^2}{I}\right)$$

$$\Delta E = E_4 - E_3 = 4\left(\frac{\hbar^2}{I}\right) = 4\left(\frac{(1.055\times10^{-34}\ \text{J}\cdot\text{s})^2}{3.694\times10^{-47}\ \text{kg}\cdot\text{m}^2}\right) = 1.20\times10^{-21}\ \text{J} = 7.49\times10^{-3}\ \text{eV}$$

(b) $\Delta E = hc/\lambda$ so $\lambda = \dfrac{hc}{\Delta E} = \dfrac{(4.136\times10^{-15}\ \text{eV})(2.998\times10^{8}\ \text{m/s})}{7.49\times10^{-3}\ \text{eV}} = 166\,\mu\text{m}$

EVALUATE: LiH has a smaller reduced mass than CO and λ is somewhat smaller here than the λ calculated for CO in Example 42.2

42.14. **IDENTIFY:** The vibrational energy of the molecule is related to its force constant and reduced mass, while the rotational energy depends on its moment of inertia, which in turn depends on the reduced mass.

SET UP: The vibrational energy is $E_n = \left(n+\frac{1}{2}\right)\hbar\omega = \left(n+\frac{1}{2}\right)\hbar\sqrt{\frac{k'}{m_\text{r}}}$ and the rotational energy is $E_l = l(l+1)\dfrac{\hbar^2}{2I}$.

EXECUTE: For a vibrational transition, we have $\Delta E_\text{v} = \hbar\sqrt{\dfrac{k'}{m_\text{r}}}$, so we first need to find m_r. The energy for a rotational transition is $\Delta E_\text{R} = \dfrac{\hbar^2}{2I}[2(2+1)-1(1+1)] = \dfrac{2\hbar^2}{I}$. Solving for I and using the fact that $I = m_\text{r}{r_0}^2$, we have $m_\text{r}r_0^2 = \dfrac{2\hbar^2}{\Delta E_\text{R}}$, which gives

$$m_\text{r} = \frac{2\hbar^2}{r_0^2\Delta E_\text{R}} = \frac{2(1.055\times10^{-34}\ \text{J}\cdot\text{s})(6.583\times10^{-16}\ \text{eV}\cdot\text{s})}{(0.8860\times10^{-9}\ \text{m})^2(8.841\times10^{-4}\ \text{eV})} = 2.0014\times10^{-28}\ \text{kg}$$

Now look at the vibrational transition to find the force constant.

$$\Delta E_\text{v} = \hbar\sqrt{\frac{k'}{m_\text{r}}} \Rightarrow k' = \frac{m_\text{r}(\Delta E_\text{v})^2}{\hbar^2} = \frac{(2.0014\times10^{-28}\ \text{kg})(0.2560\ \text{eV})^2}{(6.583\times10^{-16}\ \text{eV}\cdot\text{s})^2} = 30.27\ \text{N/m}$$

EVALUATE: This would be a rather weak spring in the laboratory.

42.15. **IDENTIFY** and **SET UP:** The energy of a rotational level is given in Eq. (42.3). The transition energy ΔE and the frequency f of the photon are related by $\Delta E = hf$.

EXECUTE: **(a)** $E_l = \dfrac{l(l+1)\hbar^2}{2I}$, $E_{l-1} = \dfrac{l(l-1)\hbar^2}{2I} \Rightarrow \Delta E = \dfrac{\hbar^2}{2I}(l^2+l-l^2+l) = \dfrac{l\hbar^2}{I}$

(b) $f = \dfrac{\Delta E}{h} = \dfrac{\Delta E}{2\pi\hbar} = \dfrac{l\hbar}{2\pi I}$.

EVALUATE: ΔE and f increase with l because the separation between adjacent energy levels increases with l.

42.16. **IDENTIFY:** Find ΔE for the transition and compute λ from $\Delta E = hc/\lambda$.

SET UP: From Example 42.2, $E_l = l(l+1)\dfrac{\hbar^2}{2I}$, with $\dfrac{\hbar^2}{2I} = 0.2395\times10^{-3}$ eV. $\Delta E = 0.2690$ eV is the spacing between vibrational levels. Thus $E_n = (n+\frac{1}{2})\hbar\omega$, with $\hbar\omega = 0.2690$ eV. By Eq. (42.9),

$$E = E_n + E_l = (n+\tfrac{1}{2})\hbar\omega + l(l+1)\frac{\hbar^2}{2I}.$$

EXECUTE: **(a)** $n = 0 \to n = 1$ and $l = 1 \to l = 2$

For $n = 0, l = 1$, $E_i = \frac{1}{2}\hbar\omega + 2\left(\dfrac{\hbar^2}{2I}\right)$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

For $n=1, l=2, E_f = \frac{3}{2}\hbar\omega + 6\left(\frac{\hbar^2}{2I}\right)$.

$$\Delta E = E_f - E_i = \hbar\omega + 4\left(\frac{\hbar^2}{2I}\right) = 0.2690 \text{ eV} + 4(0.2395\times10^{-3} \text{ eV}) = 0.2700 \text{ eV}$$

$$\frac{hc}{\lambda} = \Delta E \text{ so } \lambda = \frac{hc}{\Delta E} = \frac{(4.136\times10^{-15} \text{ eV}\cdot\text{s})(2.998\times10^{8} \text{ m/s})}{0.2700 \text{ eV}} = 4.592\times10^{-6} \text{ m} = 4.592\,\mu\text{m}$$

(b) $n=0 \to n=1$ and $l=2 \to l=1$

For $n=0, l=2, E_i = \frac{1}{2}\hbar\omega + 6\left(\frac{\hbar^2}{2I}\right)$.

For $n=1, l=1, E_f = \frac{3}{2}\hbar\omega + 2\left(\frac{\hbar^2}{2I}\right)$.

$$\Delta E = E_f - E_i = \hbar\omega - 4\left(\frac{\hbar^2}{2I}\right) = 0.2690 \text{ eV} - 4(0.2395\times10^{-3} \text{ eV}) = 0.2680 \text{ eV}$$

$$\lambda = \frac{hc}{\Delta E} = \frac{(4.136\times10^{-15} \text{ eV}\cdot\text{s})(2.998\times10^{8} \text{ m/s})}{0.2680 \text{ eV}} = 4.627\times10^{-6} \text{ m} = 4.627\,\mu\text{m}$$

(c) $n=0 \to n=1$ and $l=3 \to l=2$

For $n=0, l=3, E_i = \frac{1}{2}\hbar\omega + 12\left(\frac{\hbar^2}{2I}\right)$.

For $n=1, l=2, E_f = \frac{3}{2}\hbar\omega + 6\left(\frac{\hbar^2}{2I}\right)$.

$$\Delta E = E_f - E_i = \hbar\omega - 6\left(\frac{\hbar^2}{2I}\right) = 0.2690 \text{ eV} - 6(0.2395\times10^{-3} \text{ eV}) = 0.2676 \text{ eV}$$

$$\lambda = \frac{hc}{\Delta E} = \frac{(4.136\times10^{-15} \text{ eV}\cdot\text{s})(2.998\times10^{8} \text{ m/s})}{0.2676 \text{ eV}} = 4.634\times10^{-6} \text{ m} = 4.634\,\mu\text{m}$$

EVALUATE: All three transitions are for $n=0 \to n=1$. The spacing between vibrational levels is larger than the spacing between rotational levels, so the difference in λ for the various rotational transitions is small. When the transition is to a larger l, $\Delta E > \hbar\omega$ and when the transition is to a smaller l, $\Delta E < \hbar\omega$.

42.17. **IDENTIFY** and **SET UP:** Find the volume occupied by each atom. The density is the average mass of Na and Cl divided by this volume.

EXECUTE: Each atom occupies a cube with side length 0.282 nm. Therefore, the volume occupied by each atom is $V = (0.282\times10^{-9} \text{ m})^3 = 2.24\times10^{-29} \text{ m}^3$. In NaCl there are equal numbers of Na and Cl atoms, so the average mass of the atoms in the crystal is

$$m = \tfrac{1}{2}(m_{\text{Na}} + m_{\text{Cl}}) = \tfrac{1}{2}(3.82\times10^{-26} \text{ kg} + 5.89\times10^{-26} \text{ kg}) = 4.855\times10^{-26} \text{ kg}$$

The density then is $\rho = \frac{m}{V} = \frac{4.855\times10^{-26} \text{ kg}}{2.24\times10^{-29} \text{ m}^3} = 2.17\times10^{3} \text{ kg/m}^3$.

EVALUATE: The density of water is $1.00\times10^{3} \text{ kg/m}^3$, so our result is reasonable.

42.18. **IDENTIFY** and **SET UP:** For an average spacing a, the density is $\rho = m/a^3$, where m is the average of the ionic masses.

EXECUTE: $a^3 = \frac{m}{\rho} = \frac{(6.49\times10^{-26} \text{ kg} + 1.33\times10^{-25} \text{ kg})/2}{(2.75\times10^{3} \text{ kg/m}^3)} = 3.60\times10^{-29} \text{ m}^3$, and

$a = 3.30\times10^{-10} \text{ m} = 0.330 \text{ nm}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: **(b)** Exercise 42.17 says that the average spacing for NaCl is 0.282 nm. The larger (higher atomic number) atoms have the larger spacing.

42.19. **IDENTIFY:** The energy gap is the energy of the maximum-wavelength photon.

SET UP: The energy difference is equal to the energy of the photon, so $\Delta E = hc/\lambda$.

EXECUTE: **(a)** Using the photon wavelength to find the energy difference gives

$$\Delta E = hc/\lambda = (4.136\times10^{-15}\ \text{eV}\cdot\text{s})(3.00\times10^{8}\ \text{m/s})/(1.11\times10^{-6}\ \text{m}) = 1.12\ \text{eV}$$

(b) A wavelength of $1.11\ \mu\text{m} = 1110\ \text{nm}$ is in the infrared, shorter than that of visible light.

EVALUATE: Since visible photons have more than enough energy to excite electrons from the valence to the conduction band, visible light will be absorbed, which makes silicon opaque.

42.20. **IDENTIFY** and **SET UP:** $\Delta E = \dfrac{hc}{\lambda}$, where ΔE is the band gap.

EXECUTE: **(a)** $\lambda = \dfrac{hc}{\Delta E} = 2.27\times10^{-7}\ \text{m} = 227\ \text{nm}$, in the ultraviolet.

EVALUATE: **(b)** Visible light lacks enough energy to excite the electrons into the conduction band, so visible light passes through the diamond unabsorbed.

(c) Impurities can lower the gap energy making it easier for the material to absorb shorter wavelength visible light. This allows longer wavelength visible light to pass through, giving the diamond color.

42.21. **IDENTIFY** and **SET UP:** The energy ΔE deposited when a photon with wavelength λ is absorbed is $\Delta E = \dfrac{hc}{\lambda}$.

EXECUTE: $\Delta E = \dfrac{hc}{\lambda} = \dfrac{(6.63\times10^{-34}\ \text{J}\cdot\text{s})(3.00\times10^{8}\ \text{m/s})}{9.31\times10^{-13}\ \text{m}} = 2.14\times10^{-13}\ \text{J} = 1.34\times10^{6}\ \text{eV}$. So the number of electrons that can be excited to the conduction band is $n = \dfrac{1.34\times10^{6}\ \text{eV}}{1.12\ \text{eV}} = 1.20\times10^{6}$ electrons.

EVALUATE: A photon of wavelength $\lambda = \dfrac{hc}{\Delta E} = \dfrac{(4.13\times10^{-15}\ \text{eV}\cdot\text{s})(3.00\times10^{8}\ \text{m/s})}{1.12\ \text{eV}} = 1.11\times10^{-6}\ \text{m} = 1110\ \text{nm}$ can excite one electron. This photon is in the infrared.

42.22. **IDENTIFY:** Set $\frac{3}{2}kT = \frac{1}{2}mv_{\text{rms}}^2$.

SET UP: $k = 1.38\times10^{-23}\ \text{J/K}$. $m = 9.11\times10^{-31}\ \text{kg}$.

EXECUTE: $v_{\text{rms}} = \sqrt{3kT/m} = 1.17\times10^{5}\ \text{m/s}$, as found in Example 42.8.

EVALUATE: Temperature plays a very small role in determining the properties of electrons in metals. Instead, the average energies and corresponding speeds are determined almost exclusively by the exclusion principle.

42.23. **IDENTIFY:** $g(E)$ is given by Eq. (42.10).

SET UP: $m = 9.11\times10^{-31}\ \text{kg}$, the mass of an electron.

EXECUTE: $g(E) = \dfrac{(2m)^{3/2}V}{2\pi^2\hbar^3}E^{1/2} = \dfrac{(2(9.11\times10^{-31}\ \text{kg}))^{3/2}(1.0\times10^{-6}\ \text{m}^3)(5.0\ \text{eV})^{1/2}(1.60\times10^{-19}\ \text{J/eV})^{1/2}}{2\pi^2(1.054\times10^{-34}\ \text{J}\cdot\text{s})^3}$.

$g(E) = (9.5\times10^{40}\ \text{states/J})(1.60\times10^{-19}\ \text{J/eV}) = 1.5\times10^{22}\ \text{states/eV}$.

EVALUATE: For a metal the density of states expressed as states/eV is very large.

42.24. **IDENTIFY** and **SET UP:** Combine Eqs. (42.11) and (42.12) to eliminate n_{rs}.

EXECUTE: Eq. (42.12) may be solved for $n_{\text{rs}} = (2mE)^{1/2}\,(L/\hbar\pi)$, and substituting this into Eq. (42.11), using $L^3 = V$, gives Eq. (42.13).

EVALUATE: n is the total number of states with energy of E or less.

42.25. **(a) IDENTIFY** and **SET UP:** The electron contribution to the molar heat capacity at constant volume of a metal is $C_V = \left(\dfrac{\pi^2 KT}{2E_{\text{F}}}\right)R$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: $C_V = \dfrac{\pi^2(1.381\times10^{-23}\text{ J/K})(300\text{ K})}{2(5.48\text{ eV})(1.602\times10^{-19}\text{ J/eV})}R = 0.0233R.$

(b) EVALUATE: The electron contribution found in part (a) is $0.0233R = 0.194\text{ J/mol}\cdot\text{K}$. This is $0.194/25.3 = 7.67\times10^{-3} = 0.767\%$ of the total C_V.

(c) Only a small fraction of C_V is due to the electrons. Most of C_V is due to the vibrational motion of the ions.

42.26. **IDENTIFY:** Eq. (42.21) relates E_{av} and E_{F0}, the Fermi energy at absolute zero. The speed v is related to E_{av} by $\frac{1}{2}mv^2 = E_{\text{av}}$.

SET UP: $k = 1.38\times10^{-23}$ J/K.

EXECUTE: **(a)** $E_{\text{av}} = \dfrac{3}{5}E_{\text{F}} = 1.94\text{ eV}.$

(b) $v = \sqrt{2E_{\text{av}}/m} = \sqrt{\dfrac{2(1.94\text{ eV})(1.60\times10^{-19}\text{ J/eV})}{9.11\times10^{-31}\text{ kg}}} = 8.25\times10^{5}\text{ m/s}.$

(c) $\dfrac{E_{\text{F}}}{k} = \dfrac{(3.23\text{ eV})(1.60\times10^{-19}\text{ J/eV})}{(1.38\times10^{-23}\text{ J/K})} = 3.74\times10^{4}\text{ K}.$

EVALUATE: The Fermi energy of sodium is less than that of copper. Therefore, the values of E_{av} and v we have calculated for sodium are less than those calculated for copper in Example 42.7.

42.27. **IDENTIFY:** The probability is given by the Fermi-Dirac distribution.

SET UP: The Fermi-Dirac distribution is $f(E) = \dfrac{1}{e^{(E-E_{\text{F}})/kT}+1}$.

EXECUTE: We calculate the value of $f(E)$, where $E = 8.520$ eV, $E_{\text{F}} = 8.500$ eV, $k = 1.38\times10^{-23}\text{J/K} = 8.625\times10^{-5}$ eV/K, and $T = 20°\text{C} = 293$ K. The result is $f(E) = 0.312 = 31.2\%$.

EVALUATE: Since the energy is close to the Fermi energy, the probability is quite high that the state is occupied by an electron.

42.28. **IDENTIFY** and **SET UP:** Follow the procedure of Example 42.9. Evaluate $f(E)$ in Eq. (42.16) for $E - E_{\text{F}} = E_{\text{g}}/2$, where E_{g} is the band gap.

EXECUTE: **(a)** The probabilities are 1.78×10^{-7}, 2.37×10^{-6}, and 1.51×10^{-5}.

(b) The Fermi distribution, Eq. (42.16), has the property that $f(E_{\text{F}} - E) = 1 - f(E)$ (see Problem (42.50)), and so the probability that a state at the top of the valence band is occupied is the same as the probability that a state of the bottom of the conduction band is filled (this result depends on having the Fermi energy in the middle of the gap). Therefore, the probabilities at each T are the same as in part (a).

EVALUATE: The probabilities increase with temperature.

42.29. **IDENTIFY:** Use Eq. (42.16), $f(E) = \dfrac{1}{e^{(E-E_{\text{F}})/kT}+1}$. Solve for $E - E_{\text{F}}$.

SET UP: $e^{(E-E_{\text{F}})/kT} = \dfrac{1}{f(E)} - 1$

The problem states that $f(E) = 4.4\times10^{-4}$ for E at the bottom of the conduction band.

EXECUTE: $e^{(E-E_{\text{F}})/kT} = \dfrac{1}{4.4\times10^{-4}} - 1 = 2.272\times10^{3}.$

$E - E_{\text{F}} = kT\ln(2.272\times10^{3}) = (1.3807\times10^{-23}\text{ J/T})(300\text{ K})\ln(2.272\times10^{3}) = 3.201\times10^{-20}\text{ J} = 0.20\text{ eV}$

$E_{\text{F}} = E - 0.20\text{ eV};$ the Fermi level is 0.20 eV below the bottom of the conduction band.

EVALUATE: The energy gap between the Fermi level and bottom of the conduction band is large compared to kT at $T = 300$ K and as a result $f(E)$ is small.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

42.30. **IDENTIFY:** The wavelength of the photon to be detected depends on its energy.

SET UP: $\Delta E = \dfrac{hc}{\lambda}$.

EXECUTE: **(a)** $\lambda = \dfrac{hc}{\Delta E} = \dfrac{(4.136\times10^{-15}\ \text{eV}\cdot\text{s})(3.00\times10^{8}\ \text{m/s})}{0.67\ \text{eV}} = 1.9\ \mu\text{m}.$

(b) $\lambda = (1.9\ \mu\text{m})\left(\dfrac{0.67\ \text{eV}}{1.14\ \text{eV}}\right) = 1.1\ \mu\text{m}.$

EVALUATE: Both of these photons are in the infrared.

42.31. **IDENTIFY:** Knowing the saturation current of a *p-n* junction at a given temperature, we want to find the current at that temperature for various voltages.

SET UP: $I = I_S(e^{eV/kT} - 1)$.

EXECUTE: **(a)** (i) For $V = 1.00$ mV, $\dfrac{eV}{kT} = \dfrac{(1.602\times10^{-19}\ \text{C})(1.00\times10^{-3}\ \text{V})}{(1.381\times10^{-23}\ \text{J/K})(290\ \text{K})} = 0.0400.$

$I = (0.500\ \text{mA})(e^{0.0400} - 1) = 0.0204\ \text{mA}.$

(ii) For $V = -1.00$ mV, $\dfrac{eV}{kT} = -0.0400$. $I = (0.500\ \text{mA})(e^{-0.0400} - 1) = -0.0196\ \text{mA}.$

(iii) For $V = 100$ mV, $\dfrac{eV}{kT} = 4.00$. $I = (0.500\ \text{mA})(e^{4.00} - 1) = 26.8\ \text{mA}.$

(iv) For $V = -100$ mV, $\dfrac{eV}{kT} = -4.00$. $I = (0.500\ \text{mA})(e^{-4.00} - 1) = -0.491\ \text{mA}.$

EXECUTE: **(b)** For small V, between ±1.00 mV, $R = V/I$ is approximately constant and the diode obeys Ohm's law to a good approximation. For larger V the deviation from Ohm's law is substantial.

42.32. **IDENTIFY:** The current depends on the voltage across the diode and its temperature, so the resistance also depends on these quantities.

SET UP: The current is $I = I_S\ (e^{eV/kT} - 1)$ and the resistance is $R = V/I$.

EXECUTE: **(a)** The resistance is $R = \dfrac{V}{I} = \dfrac{V}{I_s(e^{eV/kT} - 1)}$. The exponent is

$\dfrac{eV}{kT} = \dfrac{e(0.0850\ \text{V})}{(8.625\times10^{-5}\ \text{eV/K})(293\ \text{K})} = 3.3635,$ giving $R = \dfrac{85.0\ \text{mV}}{(0.750\ \text{mA})(e^{3.3635} - 1)} = 4.06\ \Omega.$

(b) In this case, the exponent is $\dfrac{eV}{kT} = \dfrac{e(-0.050\ \text{V})}{(8.625\times10^{-5}\ \text{eV/K})(293\ \text{K})} = -1.979$

which gives $R = \dfrac{-50.0\ \text{mV}}{(0.750\ \text{mA})(e^{-1.979} - 1)} = 77.4\ \Omega$

EVALUATE: Reversing the voltage can make a considerable change in the resistance of a diode.

42.33. **IDENTIFY** and **SET UP:** The voltage-current relation is given by Eq. (42.22): $I = I_s(e^{eV/kT} - 1)$. Use the current for $V = +15.0$ mV to solve for the constant I_s.

EXECUTE: **(a)** Find I_s : $V = +15.0\times10^{-3}$ V gives $I = 9.25\times10^{-3}$ A

$\dfrac{eV}{kT} = \dfrac{(1.602\times10^{-19}\ \text{C})(15.0\times10^{-3}\ \text{V})}{(1.381\times10^{-23}\ \text{J/K})(300\ \text{K})} = 0.5800$

$I_s = \dfrac{I}{e^{eV/kT} - 1} = \dfrac{9.25\times10^{-3}\ \text{A}}{e^{0.5800} - 1} = 1.177\times10^{-2} = 11.77\ \text{mA}$

Then can calculate I for $V = 10.0$ mV: $\dfrac{eV}{kT} = \dfrac{(1.602\times10^{-19}\ \text{C})(10.0\times10^{-3}\ \text{V})}{(1.381\times10^{-23}\ \text{J/K})(300\ \text{K})} = 0.3867$

$I = I_s(e^{eV/kT} - 1) = (11.77\ \text{mA})(e^{0.3867} - 1) = 5.56\ \text{mA}$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) $\frac{eV}{kT}$ has the same magnitude as in part (a) but not V is negative so $\frac{eV}{kT}$ is negative.

$\underline{V=-15.0\text{ mV}}: \frac{eV}{kT}=-0.5800$ and $I=I_S(e^{eV/kT}-1)=(11.77\text{ mA})(e^{-0.5800}-1)=-5.18\text{ mA}$

$\underline{V=-10.0\text{ mV}}: \frac{eV}{kT}=-0.3867$ and $I=I_S(e^{eV/kT}-1)=(11.77\text{ mA})(e^{-0.3867}-1)=-3.77\text{ mA}$

EVALUATE: There is a directional asymmetry in the current, with a forward-bias voltage producing more current than a reverse-bias voltage of the same magnitude, but the voltage is small enough for the asymmetry not be pronounced.

42.34. **IDENTIFY:** Apply Eq. (42.22).

SET UP: $I_S=3.60$ mA. $\ln e^x=x$

EXECUTE: **(a)** Solving Eq. (42.22) for the voltage as a function of current,

$$V=\frac{kT}{e}\ln\left(\frac{I}{I_S}+1\right)=\frac{kT}{e}\ln\left(\frac{40.0\text{ mA}}{3.60\text{ mA}}+1\right)=0.0645\text{ V}.$$

(b) From part (a), the quantity $e^{eV/kT}=12.11,$ so far a reverse-bias voltage of the same magnitude,

$$I=I_S\,(e^{-eV/kT}-1)=I_S\left(\frac{1}{12.11}-1\right)=-3.30\text{ mA}.$$

EVALUATE: The reverse bias current for a given magnitude of voltage is much less than the forward bias current.

42.35. **IDENTIFY:** During the transition, the molecule emits a photon of light having energy equal to the energy difference between the two vibrational states of the molecule.

SET UP: The vibrational energy is $E_n=\left(n+\frac{1}{2}\right)\hbar\omega=\left(n+\frac{1}{2}\right)\hbar\sqrt{\frac{k'}{m_r}}.$

EXECUTE: **(a)** The energy difference between two adjacent energy states is $\Delta E=\hbar\sqrt{\frac{k'}{m_r}},$ and this is the energy of the photon, so $\Delta E=hc/\lambda.$ Equating these two expressions for ΔE and solving for $k',$ we have $k'=m_r\left(\frac{\Delta E}{\hbar}\right)^2=\frac{m_H m_O}{m_H+m_O}\left(\frac{\Delta E}{\hbar}\right)^2,$ and using $\frac{\Delta E}{\hbar}=\frac{hc/\lambda}{\hbar}=\frac{2\pi c}{\lambda}$ with the appropriate numbers gives us

$$k'=\frac{(1.67\times10^{-27}\text{ kg})(2.656\times10^{-26}\text{ kg})}{1.67\times10^{-27}\text{ kg}+2.656\times10^{-26}\text{ kg}}\left[\frac{2\pi(3.00\times10^8\text{ m/s})}{2.39\times10^{-6}\text{ m}}\right]^2=977\text{ N/m}$$

(b) $f=\frac{\omega}{2\pi}=\frac{1}{2\pi}\sqrt{\frac{k'}{m_r}}=\frac{1}{2\pi}\sqrt{\frac{m_H m_O}{m_H+m_O}\,k'}.$ Substituting the appropriate numbers gives us

$$f=\frac{1}{2\pi}\sqrt{\frac{(1.67\times10^{-27}\text{ kg})(2.656\times10^{-26}\text{ kg})}{1.67\times10^{-27}\text{ kg}+2.656\times10^{-26}\text{ kg}}\,(977\text{ N/m})}=1.25\times10^{14}\text{ Hz}$$

EVALUATE: The frequency is close to, but not quite in, the visible range.

42.36. **IDENTIFY** and **SET UP:** $E_l=l(l+1)\frac{\hbar^2}{2I}.$ ΔE for the molecule is related to λ for the photon by $\Delta E=\frac{hc}{\lambda}.$

EXECUTE: $E_2=3\frac{\hbar^2}{I}$ and $E_1=\frac{\hbar^2}{I},$ so $\Delta E=\frac{2\hbar^2}{I}.$ $I=\frac{2\hbar^2}{\Delta E}=\frac{h\lambda}{2\pi^2 c}=7.14\times10^{-48}\text{ kg}\cdot\text{m}^2.$

EVALUATE: The I we calculated is approximately a factor of 20 times smaller than I calculated for the CO molecule in Example 42.2.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

42.37. **IDENTIFY** and **SET UP:** Eq. (21.14) gives the electric dipole moment as $p = qd$, where the dipole consists of charges $\pm q$ separated by distance d.

EXECUTE: **(a)** Point charges $+e$ and $-e$ separated by distance d, so

$p = ed = (1.602\times10^{-19}\ \text{C})(0.24\times10^{-9}\ \text{m}) = 3.8\times10^{-29}\ \text{C}\cdot\text{m}$

(b) $p = qd$ so $q = \dfrac{p}{d} = \dfrac{3.0\times10^{-29}\ \text{C}\cdot\text{m}}{0.24\times10^{-9}\ \text{m}} = 1.3\times10^{-19}\ \text{C}$

(c) $\dfrac{q}{e} = \dfrac{1.3\times10^{-19}\ \text{C}}{1.602\times10^{-19}\ \text{C}} = 0.81$

(d) $q = \dfrac{p}{d} = \dfrac{1.5\times10^{-30}\ \text{C}\cdot\text{m}}{0.16\times10^{-9}\ \text{m}} = 9.37\times10^{-21}\ \text{C}$

$\dfrac{q}{e} = \dfrac{9.37\times10^{-21}\ \text{C}}{1.602\times10^{-19}\ \text{C}} = 0.058$

EVALUATE: The fractional ionic character for the bond in HI is much less than the fractional ionic character for the bond in NaCl. The bond in HI is mostly covalent and not very ionic.

42.38. **IDENTIFY:** The electric potential energy U, the binding energy E_B, the electron affinity E_A, and the ionization energy E_I, where E_B, E_A and E_I are positive and U is negative, are related by $E_B = -U + E_A - E_I$.

SET UP: For two point charges q_1 and q_2 separated by a distance r, the electric potential energy is given by $U = \dfrac{1}{4\pi\varepsilon_0}\dfrac{q_1q_2}{r}$.

EXECUTE: The electrical potential energy is $U = -5.13\ \text{eV}$, and $r = -\dfrac{1}{4\pi\varepsilon_0}\dfrac{e^2}{U} = 2.8\times10^{-10}\ \text{m}$.

EVALUATE: We have neglected the kinetic energy of the ions in the molecule. Also, it is an approximation to treat the two ions as point charges.

42.39. **(a) IDENTIFY:** $E(\text{Na}) + E(\text{Cl}) = E(\text{Na}^+) + E(\text{Cl}^-) + U(r)$. Solving for $U(r)$ gives $U(r) = -[E(\text{Na}^+) - E(\text{Na})] + [E(\text{Cl}) - E(\text{Cl}^-)]$.

SET UP: $[E(\text{Na}^+) - E(\text{Na})]$ is the ionization energy of Na, the energy required to remove one electron, and is equal to 5.1 eV. $[E(\text{Cl}) - E(\text{Cl}^-)]$ is the electron affinity of Cl, the magnitude of the decrease in energy when an electron is attached to a neutral Cl atom, and is equal to 3.6 eV.

EXECUTE: $U = -5.1\ \text{eV} + 3.6\ \text{eV} = -1.5\ \text{eV} = -2.4\times10^{-19}\ \text{J}$, and $-\dfrac{1}{4\pi\epsilon_0}\dfrac{e^2}{r} = -2.4\times10^{-19}\ \text{J}$

$r = \left(\dfrac{1}{4\pi\epsilon_0}\right)\dfrac{e^2}{2.4\times10^{-19}\ \text{J}} = (8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\dfrac{(1.602\times10^{-19}\ \text{C})^2}{2.4\times10^{-19}\ \text{J}}$

$r = 9.6\times10^{-10}\ \text{m} = 0.96\ \text{nm}$

(b) ionization energy of $\text{K} = 4.3\ \text{eV}$; electron affinity of $\text{Br} = 3.5\ \text{eV}$

Thus $U = -4.3\ \text{eV} + 3.5\ \text{eV} = -0.8\ \text{eV} = -1.28\times10^{-19}\ \text{J}$, and $-\dfrac{1}{4\pi\epsilon_0}\dfrac{e^2}{r} = -1.28\times10^{-19}\ \text{J}$

$r = \left(\dfrac{1}{4\pi\epsilon_0}\right)\dfrac{e^2}{1.28\times10^{-19}\ \text{J}} = (8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\dfrac{(1.602\times10^{-19}\ \text{C})^2}{1.28\times10^{-19}\ \text{J}}$

$r = 1.8\times10^{-9}\ \text{m} = 1.8\ \text{nm}$

EVALUATE: K has a smaller ionization energy than Na and the electron affinities of Cl and Br are very similar, so it takes less energy to make $\text{K}^+ + \text{Br}^-$ from $\text{K} + \text{Br}$ than to make $\text{Na}^+ + \text{Cl}^-$ from $\text{Na} + \text{Cl}$. Thus, the stabilization distance is larger for KBr than for NaCl.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

42.40. **IDENTIFY:** The rotational energy levels are given by Eq. (42.3). The photon wavelength λ is related to the transition energy of the atom by $\Delta E = \dfrac{hc}{\lambda}$.

SET UP: For emission, $\Delta l = -1$. For such a transition, from state l to state $l-1$, $\Delta E_l = [l(l+1)-(l-1)l]\dfrac{\hbar^2}{2I} = \dfrac{l\hbar^2}{I}$. The difference in transition energies for adjacent lines in the spectrum is $\Delta = \Delta E_l - \Delta E_{l-1} = \dfrac{\hbar^2}{I}$.

EXECUTE: The transition energies corresponding to the observed wavelengths are 3.29×10^{-21} J, 2.87×10^{-21} J, 2.47×10^{-21} J, 2.06×10^{-21} J and 1.65×10^{-21} J. The average spacing of these energies is 0.410×10^{-21} J. Then, $\dfrac{\hbar^2}{I} = 0.410\times10^{-21}$ J, from which $I = 2.71\times10^{-47}\ \text{kg}\cdot\text{m}^2$.

EVALUATE: With $\dfrac{\hbar^2}{I} = 0.410\times10^{-21}$ J and $\Delta E_l = \dfrac{l\hbar^2}{I}$, we find that these wavelengths correspond to transitions from levels 8, 7, 6, 5 and 4 to the respective next lower levels.

42.41. **(a) IDENTIFY:** The rotational energies of a molecule depend on its moment of inertia, which in turn depends on the separation between the atoms in the molecule.

SET UP: Problem 42.40 gives $I = 2.71\times10^{-47}\ \text{kg}\cdot\text{m}^2$. $I = m_\text{r}r^2$. Calculate m_r and solve for r.

EXECUTE: $m_\text{r} = \dfrac{m_\text{H}m_\text{Cl}}{m_\text{H}+m_\text{Cl}} = \dfrac{(1.67\times10^{-27}\ \text{kg})(5.81\times10^{-26}\ \text{kg})}{1.67\times10^{-27}\ \text{kg}+5.81\times10^{-26}\ \text{kg}} = 1.623\times10^{-27}\ \text{kg}$

$r = \sqrt{\dfrac{I}{m_\text{r}}} = \sqrt{\dfrac{2.71\times10^{-47}\ \text{kg}\cdot\text{m}^2}{1.623\times10^{-27}\ \text{kg}}} = 1.29\times10^{-10}\ \text{m} = 0.129\ \text{nm}$

EVALUATE: This is a typical atomic separation for a diatomic molecule; see Example 42.2 for the corresponding distance for CO.

(b) IDENTIFY: Each transition is from the level l to the level $l-1$. The rotational energies are given by Eq. (42.3). The transition energy is related to the photon wavelength by $\Delta E = hc/\lambda$.

SET UP: $E_l = l(l+1)\hbar^2/2I$, so $\Delta E = E_l - E_{l-1} = [l(l+1)-l(l-1)]\left(\dfrac{\hbar^2}{2I}\right) = l\left(\dfrac{\hbar^2}{I}\right)$.

EXECUTE: $l\left(\dfrac{\hbar^2}{I}\right) = \dfrac{\hbar c}{\lambda}$

$l = \dfrac{2\pi cI}{\hbar\lambda} = \dfrac{2\pi(2.998\times10^8\ \text{m/s})(2.71\times10^{-47}\ \text{kg}\cdot\text{m}^2)}{(1.055\times10^{-34}\ \text{J}\cdot\text{s})\lambda} = \dfrac{4.843\times10^{-4}\ \text{m}}{\lambda}$

For $\lambda = 60.4\ \mu\text{m}$, $l = \dfrac{4.843\times10^{-4}\ \text{m}}{60.4\times10^{-6}\ \text{m}} = 8.$

For $\lambda = 69.0\ \mu\text{m}$, $l = \dfrac{4.843\times10^{-4}\ \text{m}}{69.0\times10^{-6}\ \text{m}} = 7.$

For $\lambda = 80.4\ \mu\text{m}$, $l = \dfrac{4.843\times10^{-4}\ \text{m}}{80.4\times10^{-6}\ \text{m}} = 6.$

For $\lambda = 96.4\ \mu\text{m}$, $l = \dfrac{4.843\times10^{-4}\ \text{m}}{96.4\times10^{-6}\ \text{m}} = 5.$

For $\lambda = 120.4\ \mu\text{m}$, $l = \dfrac{4.843\times10^{-4}\ \text{m}}{120.4\times10^{-6}\ \text{m}} = 4.$

EVALUATE: In each case l is an integer, as it must be.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(c) IDENTIFY and **SET UP:** Longest λ implies smallest ΔE, and this is for the transition from $l = 1$ to $l = 0$.

EXECUTE: $\Delta E = l\left(\frac{\hbar^2}{I}\right) = (1)\frac{(1.055\times10^{-34}\ \text{J}\cdot\text{s})^2}{2.71\times10^{-47}\ \text{kg}\cdot\text{m}^2} = 4.099\times10^{-22}\ \text{J}$

$\lambda = \frac{hc}{\Delta E} = \frac{(6.626\times10^{-34}\ \text{J}\cdot\text{s})(2.998\times10^{8}\ \text{m/s})}{4.099\times10^{-22}\ \text{J}} = 4.85\times10^{-4}\ \text{m} = 485\,\mu\text{m}.$

EVALUATE: This is longer than any wavelengths in part (b).

(d) IDENTIFY: What changes is m_r, the reduced mass of the molecule.

SET UP: The transition energy is $\Delta E = l\left(\frac{\hbar^2}{I}\right)$ and $\Delta E = \frac{hc}{\lambda}$, so $\lambda = \frac{2\pi cI}{l\hbar}$ (part (b)). $I = m_\text{r}r^2$, so λ is directly proportional to m_r. $\frac{\lambda(\text{HCl})}{m_\text{r}(\text{HCl})} = \frac{\lambda(\text{DCl})}{m_\text{r}(\text{DCl})}$ so $\lambda(\text{DCl}) = \lambda(\text{HCl})\frac{m_\text{r}(\text{DCl})}{m_\text{r}(\text{HCl})}$

EXECUTE: The mass of a deuterium atom is approximately twice the mass of a hydrogen atom, so $m_\text{D} = 3.34\times10^{-27}$ kg.

$m_\text{r}(\text{DCl}) = \frac{\text{m}_\text{D}\text{m}_\text{Cl}}{\text{m}_\text{D}+\text{m}_\text{Cl}} = \frac{(3.34\times10^{-27}\ \text{kg})(5.81\times10^{-27}\ \text{kg})}{3.34\times10^{-27}\ \text{kg}+5.81\times10^{-26}\ \text{kg}} = 3.158\times10^{-27}\ \text{kg}$

$\lambda(\text{DCl}) = \lambda(\text{HCl})\left(\frac{3.158\times10^{-27}\ \text{kg}}{1.623\times10^{-27}\ \text{kg}}\right) = (1.946)\lambda(\text{HCl})$

$l = 8 \to l = 7;\ \lambda = (60.4\ \mu\text{m})(1.946) = 118\ \mu\text{m}$

$l = 7 \to l = 6;\ \lambda = (69.0\ \mu\text{m})(1.946) = 134\ \mu\text{m}$

$l = 6 \to l = 5;\ \lambda = (80.4\ \mu\text{m})(1.946) = 156\ \mu\text{m}$

$l = 5 \to l = 4;\ \lambda = (96.4\ \mu\text{m})(1.946) = 188\ \mu\text{m}$

$l = 4 \to l = 3;\ \lambda = (120.4\ \mu\text{m})(1.946) = 234\ \mu\text{m}$

EVALUATE: The moment of inertia increases when H is replaced by D, so the transition energies decrease and the wavelengths increase. The larger the rotational inertia the smaller the rotational energy for a given l (Eq. 42.3).

42.42. **IDENTIFY:** Problem 42.15b shows that for the $l \to l-1$ transition, $\Delta E = \frac{l\hbar^2}{I}$. $I = m_\text{r}r_0^2$.

SET UP: $m_\text{r} = \frac{(3.82\times10^{-26}\text{kg})(3.15\times10^{-26}\ \text{kg})}{3.82\times10^{-26}\ \text{kg}+3.15\times10^{-26}\ \text{kg}} = 1.726\times10^{-26}\ \text{kg}.$

EXECUTE: $I = \frac{\hbar^2 l}{\Delta E} = \frac{hl\lambda}{4\pi^2 c} = 6.43\times10^{-46}\ \text{kg}\cdot\text{m}^2$ and from Eq. (42.6) the separation is

$r_0 = \sqrt{\frac{I}{m_\text{r}}} = 0.193\ \text{nm}.$

EVALUATE: Section 42.1 says $r_0 = 0.24$ nm for NaCl. Our result for NaF is smaller than this. This makes sense, since F is a smaller atom than Cl.

42.43. **IDENTIFY:** $E_\text{ex} = \frac{L^2}{2I} = \frac{\hbar^2 l(l+1)}{2I}$. $E_g = 0$ ($l = 0$), and there is an additional multiplicative factor of $2l+1$ because for each l state there are really $(2l+1)$ m_l -states with the same energy.

SET UP: From Example 42.3, $I = 1.449\times10^{-46}\ \text{kg}\cdot\text{m}^2$.

EXECUTE: **(a)** $\frac{n_l}{n_0} = (2l+1)e^{-\hbar^2 l(l+1)/(2IkT)}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) (i) $E_{l=1} = \dfrac{\hbar^2(1)(1+1)}{2(1.449\times10^{-46}\ \text{kg}\cdot\text{m}^2)} = 7.67\times10^{-23}$ J. $\dfrac{E_{l=1}}{kT} = \dfrac{7.67\times10^{-23}\ \text{J}}{(1.38\times10^{-23}\ \text{J/K})(300\ \text{K})} = 0.0185.$

$(2l+1) = 3,$ so $\dfrac{n_{l=1}}{n_0} = (3)e^{-0.0185} = 2.95.$

(ii) $\dfrac{E_{l=2}}{kT} = \dfrac{\hbar^2(2)\,(2+1)}{2(1.449\times10^{-46}\ \text{kg}\cdot\text{m}^2)(1.38\times10^{-23}\ \text{J/K})(300\ \text{K})} = 0.0556.$ $(2l+1) = 5,$ so

$\dfrac{n_{l=1}}{n_0} = (5)(e^{-0.0556}) = 4.73.$

(iii) $\dfrac{E_{l=10}}{kT} = \dfrac{\hbar^2(10)\,(10+1)}{2(1.449\times10^{-46}\ \text{kg}\cdot\text{m}^2)(1.38\times10^{-23}\ \text{J/K})(300\ \text{K})} = 1.02.$

$(2l+1) = 21,$ so $\dfrac{n_{l=10}}{n_0} = (21)(e^{-1.02}) = 7.57.$

(iv) $\dfrac{E_{l=20}}{kT} = \dfrac{\hbar^2(20)(20+1)}{2(1.449\times10^{-46}\ \text{kg}\cdot\text{m}^2)\,(1.38\times10^{-23}\ \text{J/K})\,(300\ \text{K})} = 3.89.$ $(2l+1) = 41,$ so

$\dfrac{n_{l=20}}{n_0} = (41)e^{-3.89} = 0.838.$

(v) $\dfrac{E_{l=50}}{kT} = \dfrac{\hbar^2(50)(50+1)}{2(1.449\times10^{-46}\ \text{kg}\cdot\text{m}^2)(1.38\times10^{-23}\ \text{J/K})(300\ \text{K})} = 23.6.$ $(2l+1) = 101,$ so

$\dfrac{n_{l=50}}{n_0} = (101)e^{-23.6} = 5.69\times10^{-9}.$

EVALUATE: **(c)** There is a competing effect between the $(2l+1)$ term and the decaying exponential. The $2l+1$ term dominates for small l, while the exponential term dominates for large l.

42.44. **IDENTIFY:** The rotational energy levels are given by Eq. (42.3). The transition energy ΔE for the molecule and λ for the photon are related by $\Delta E = \dfrac{hc}{\lambda}$.

SET UP: From Example 42.2, $I_{CO} = 1.449\times10^{-46}\ \text{kg}\cdot\text{m}^2$.

EXECUTE: **(a)** $E_{l=1} = \dfrac{\hbar^2 l(l+1)}{2I} = \dfrac{(1.054\times10^{-34}\ \text{J}\cdot\text{s})^2(1)(1+1)}{2(1.449\times10^{-46}\ \text{kg}\cdot\text{m}^2)} = 7.67\times10^{-23}$ J. $E_{l=0} = 0.$

$\Delta E = 7.67\times10^{-23}\,\text{J} = 4.79\times10^{-4}$ eV. $\lambda = \dfrac{hc}{\Delta E} = \dfrac{(6.63\times10^{-34}\ \text{J}\cdot\text{s})(3.00\times10^{8}\ \text{m/s})}{(7.67\times10^{-23}\ \text{J})} =$

$2.59\times10^{-3}\ \text{m} = 2.59\ \text{mm}.$

EVALUATE: **(b)** Let's compare the value of kT when $T = 20K$ to that of ΔE for the $l = 1 \to l = 0$ rotational transition: $kT = (1.38\times10^{-23}\ \text{J/K})(20\ \text{K}) = 2.76\times10^{-22}$ J.

$\Delta E = 7.67\times10^{-23}\,\text{J}$ (from part (a)). So $\dfrac{kT}{\Delta E} = 3.60.$ Therefore, although T is quite small, there is still plenty of energy to excite CO molecules into the first rotational level. This allows astronomers to detect the 2.59 mm wavelength radiation from such molecular clouds.

42.45. **IDENTIFY** and **SET UP:** $E_l = l(l+1)\hbar^2/2I,$ so E_l and the transition energy ΔE depend on I. Different isotopic molecules have different I.

EXECUTE: **(a)** Calculate I for $Na^{35}Cl$:

$m_r = \dfrac{m_{Na}m_{Cl}}{m_{Na}+m_{Cl}} = \dfrac{(3.8176\times10^{-26}\ \text{kg})(5.8068\times10^{-26}\ \text{kg})}{3.8176\times10^{-26}\ \text{kg} + 5.8068\times10^{-26}\ \text{kg}} = 2.303\times10^{-26}\ \text{kg}$

$I = m_r r^2 = (2.303\times10^{-26}\ \text{kg})(0.2361\times10^{-9}\ \text{m})^2 = 1.284\times10^{-45}\ \text{kg}\cdot\text{m}^2$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$\underline{l = 2 \to l = 1 \text{ transition}}$

$$\Delta E = E_2 - E_1 = (6-2)\left(\frac{\hbar^2}{2I}\right) = \frac{2\hbar^2}{I} = \frac{2(1.055\times10^{-34}\ \text{J}\cdot\text{s})^2}{1.284\times10^{-45}\ \text{kg}\cdot\text{m}^2} = 1.734\times10^{-23}\ \text{J}$$

$$\Delta E = \frac{hc}{\lambda} \text{ so } \lambda = \frac{hc}{\Delta E} = \frac{(6.626\times10^{-34}\ \text{J}\cdot\text{s})(2.998\times10^{8}\ \text{m/s})}{1.734\times10^{-23}\ \text{J}} = 1.146\times10^{-2}\ \text{m} = 1.146\ \text{cm}$$

$\underline{l = 1 \to l = 0 \text{ transition}}$

$$\Delta E = E_1 - E_0 = (2-0)\left(\frac{\hbar^2}{2I}\right) = \frac{\hbar^2}{I} = \frac{1}{2}(1.734\times10^{-23}\ \text{J}) = 8.67\times10^{-24}\ \text{J}$$

$$\lambda = \frac{hc}{\Delta E} = \frac{(6.626\times10^{-34}\ \text{J}\cdot\text{s})(2.998\times10^{8}\ \text{m/s})}{8.67\times10^{-24}\ \text{J}} = 2.291\ \text{cm}$$

(b) Calculate I for $Na^{37}Cl$: $m_r = \dfrac{m_{Na}m_{Cl}}{m_{Na}+m_{Cl}} = \dfrac{(3.8176\times10^{-26}\ \text{kg})(6.1384\times10^{-26}\ \text{kg})}{3.8176\times10^{-26}\ \text{kg} + 6.1384\times10^{-26}\ \text{kg}} = 2.354\times10^{-26}\ \text{kg}$

$$I = m_r r^2 = (2.354\times10^{-26}\ \text{kg})(0.2361\times10^{-9}\ \text{m})^2 = 1.312\times10^{-45}\ \text{kg}\cdot\text{m}^2$$

$\underline{l = 2 \to l = 1 \text{ transition}}$

$$\Delta E = \frac{2\hbar^2}{I} = \frac{2(1.055\times10^{-34}\ \text{J}\cdot\text{s})^2}{1.312\times10^{-45}\ \text{kg}\cdot\text{m}^2} = 1.697\times10^{-23}\ \text{J}$$

$$\lambda = \frac{hc}{\Delta E} = \frac{(6.626\times10^{-34}\ \text{J}\cdot\text{s})(2.998\times10^{8}\ \text{m/s})}{1.697\times10^{-23}\ \text{J}} = 1.171\times10^{-2}\ \text{m} = 1.171\ \text{cm}$$

$\underline{l = 1 \to l = 0 \text{ transition}}$

$$\Delta E = \frac{\hbar^2}{I} = \frac{1}{2}(1.697\times10^{-23}\ \text{J}) = 8.485\times10^{-24}\ \text{J}$$

$$\lambda = \frac{hc}{\Delta E} = \frac{(6.626\times10^{-34}\ \text{J}\cdot\text{s})(2.998\times10^{8}\ \text{m/s})}{8.485\times10^{-24}\ \text{J}} = 2.341\ \text{cm}$$

The differences in the wavelengths for the two isotopes are:
$l = 2 \to l = 1$ transition: 1.171 cm − 1.146 cm = 0.025 cm
$l = 1 \to l = 0$ transition: 2.341 cm − 2.291 cm = 0.050 cm

EVALUATE: Replacing ^{35}Cl by ^{37}Cl increases I, decreases ΔE and increases λ. The effect on λ is small but measurable.

42.46. **IDENTIFY:** $\Delta E = hf = \hbar\sqrt{\dfrac{k'}{m_r}}$.

SET UP: $m_r = \dfrac{m_O m_H}{m_O + m_H} = 1.57\times10^{-27}\ \text{kg}$

EXECUTE: The vibration frequency is $f = \dfrac{\Delta E}{h} = 1.12\times10^{14}\ \text{Hz}$. The force constant is

$k' = (2\pi f)^2 m_r = 777\ \text{N/m}$.

EVALUATE: This would be a fairly stiff spring in an ordinary physics lab.

42.47. **IDENTIFY:** The vibrational energy levels are given by $E_n = \left(n + \dfrac{1}{2}\right)\hbar\sqrt{\dfrac{k'}{m_r}}$. The zero-point energy is

$$E_0 = \frac{1}{2}\hbar\sqrt{\frac{2k'}{m_H}}.$$

SET UP: For H_2, $m_r = \dfrac{m_H}{2}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: $E_0 = \frac{1}{2}(1.054\times10^{-34}\ \text{J}\cdot\text{s})\sqrt{\frac{2(576\ \text{N/m})}{1.67\times10^{-27}\ \text{kg}}} = 4.38\times10^{-20}\ \text{J} = 0.274\ \text{eV}.$

EVALUATE: This is much less than the magnitude of the H_2 bond energy.

42.48. **IDENTIFY:** The frequency is proportional to the reciprocal of the square root of the reduced mass. The transition energy ΔE and the wavelength of the light emitted are related by $\Delta E = \frac{hc}{\lambda}$.

SET UP: $f_0 = 1.24\times10^{14}$ Hz.

EXECUTE: **(a)** In terms of the atomic masses, the frequency of the isotope with the deuterium atom is $f = f_0\left(\frac{m_\text{F}m_\text{H}/(m_\text{H}+m_\text{F})}{m_\text{F}m_\text{D}/(m_\text{D}+m_\text{F})}\right)^{1/2} = f_0\left(\frac{1+(m_\text{F}/m_\text{D})}{1+(m_\text{F}/m_\text{H})}\right)^{1/2}$. Using f_0 and the given masses, $f = 8.99\times10^{13}$ Hz.

(b) For the molecule, $\Delta E = hf$. $hf = \frac{hc}{\lambda}$, so $\lambda = \frac{c}{f} = \frac{3.00\times10^8\ \text{m/s}}{8.99\times10^{13}\ \text{Hz}} = 3.34\times10^{-6}\ \text{m} = 3340\ \text{nm}$. This wavelength is in the infrared.

EVALUATE: The vibrational frequency of the molecule equals the frequency of the light that is emitted.

42.49. **IDENTIFY** and **SET UP:** Use Eq. (42.6) to calculate I. The energy levels are given by Eq. (42.9). The transition energy ΔE is related to the photon wavelength by $\Delta E = hc/\lambda$.

EXECUTE: **(a)** $m_\text{r} = \frac{m_\text{H}m_\text{I}}{m_\text{H}+m_\text{I}} = \frac{(1.67\times10^{-27}\ \text{kg})(2.11\times10^{-25}\ \text{kg})}{1.67\times10^{-27}\ \text{kg}+2.11\times10^{-25}\ \text{kg}} = 1.657\times10^{-27}\ \text{kg}$

$I = m_\text{r}r^2 = (1.657\times10^{-27}\text{kg})(0.160\times10^{-9}\text{m})^2 = 4.24\times10^{-47}\ \text{kg}\cdot\text{m}^2$

(b) The energy levels are $E_{nl} = l(l+1)\left(\frac{\hbar^2}{2I}\right) + \left(n+\frac{1}{2}\right)\hbar\sqrt{\frac{k'}{m_\text{r}}}$ (Eq. (42.9))

$\sqrt{\frac{k'}{m}} = \omega = 2\pi f$ so $E_{nl} = l(l+1)\left(\frac{\hbar^2}{2I}\right) + (n+\frac{1}{2})hf$

(i) transition $n=1\to n=0, l=1\to l=0$

$\Delta E = (2-0)\left(\frac{\hbar^2}{2I}\right) + \left(1+\frac{1}{2}-\frac{1}{2}\right)hf = \frac{\hbar^2}{I} + hf$

$\Delta E = \frac{hc}{\lambda}$ so $\lambda = \frac{hc}{\Delta E} = \frac{hc}{(\hbar^2/I)+hf} = \frac{c}{(\hbar/2\pi I)+f}$

$\frac{\hbar}{2\pi I} = \frac{1.055\times10^{-34}\ \text{J}\cdot\text{s}}{2\pi(4.24\times10^{-47}\ \text{kg}\cdot\text{m}^2)} = 3.960\times10^{11}\ \text{Hz}$

$\lambda = \frac{c}{(\hbar/2\pi I)+f} = \frac{2.998+10^8\ \text{m/s}}{3.960\times10^{11}\ \text{Hz}+6.93\times10^{13}\ \text{Hz}} = 4.30\ \mu\text{m}$

(ii) transition $n=1\to n=0, l=2\to l=1$

$\Delta E = (6-2)\left(\frac{\hbar^2}{2I}\right) + hf = \frac{2\hbar^2}{I} + hf$

$\lambda = \frac{c}{2(\hbar/2\pi I)+f} = \frac{2.998\times10^8\ \text{m/s}}{2(3.960\times10^{11}\ \text{Hz})+6.93\times10^{13}\ \text{Hz}} = 4.28\ \mu\text{m}$

(iii) transition $n=2\to n=1, l=2\to l=3$

$\Delta E = (6-12)\left(\frac{\hbar^2}{2I}\right) + hf = -\frac{3\hbar^2}{I} + hf$

$\lambda = \frac{c}{-3(\hbar/2\pi I)+f} = \frac{2.998\times10^8\ \text{m/s}}{-3(3.960\times10^{11}\ \text{Hz})+6.93\times10^{13}\ \text{Hz}} = 4.40\ \mu\text{m}$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: The vibrational energy change for the $n=1\to n=0$ transition is the same as for the $n=2\to n=1$ transition. The rotational energies are much smaller than the vibrational energies, so the wavelengths for all three transitions don't differ much.

42.50. **IDENTIFY** and **SET UP:** $P(E)=f(E)=\dfrac{1}{e^{(E-E_F)/kT}+1}$.

EXECUTE: The sum of the probabilities is

$f(E_F-\Delta E)+f(E_F+\Delta E)=\dfrac{1}{e^{-\Delta E/kT}+1}+\dfrac{1}{e^{\Delta E/kT}+1}=\dfrac{1}{e^{-\Delta E/kT}+1}+\dfrac{e^{-\Delta E/kT}}{1+e^{-\Delta E/kT}}=1$. Therefore, $f(E_F-\Delta E)=1-f(E_F+\Delta E)$.

EVALUATE: This result is true for all T, even though P is strongly dependent on temperature.

42.51. **IDENTIFY:** E_{F0} is given by Eq. (42.20). Since potassium is a metal and E does not change much with T for metals, we approximate E_F by E_{F0}, so $E_F=\dfrac{3^{2/3}\pi^{4/3}\hbar^2n^{2/3}}{2m}$.

SET UP: The number of atoms per m^3 is ρ/m. If each atom contributes one free electron, the electron concentration is $n=\dfrac{\rho}{m}=\dfrac{851\text{ kg/m}^3}{6.49\times10^{-26}\text{ kg}}=1.31\times10^{28}$ electrons/m^3.

EXECUTE: $E_F=\dfrac{3^{2/3}\pi^{4/3}(1.054\times10^{-34}\text{ J}\cdot\text{s})^2(1.31\times10^{28}/\text{m}^3)^{2/3}}{2(9.11\times10^{-31}\text{ kg})}=3.24\times10^{-19}\text{ J}=2.03\text{ eV}$.

EVALUATE: The E_F we calculated for potassium is about a factor of three smaller than the E_F for copper that was calculated in Example 42.7.

42.52. **IDENTIFY:** The only difference between the two isotopes is their mass, which will affect their reduced mass and hence their moment of inertia.

SET UP: The rotational energy states are given by $E=l(l+1)\dfrac{\hbar^2}{2I}$ and the reduced mass is given by $m_1=m_1m_2/(m_2+m_2)$.

EXECUTE: **(a)** If we call m the mass of the H-atom, the mass of the deuterium atom is $2m$ and the reduced masses of the molecules are

H_2 (hydrogen): $m_r(\text{H})=mm/(m+m)=m/2$

D_2 (deuterium): $m_r(\text{D})=(2m)(2m)/(2m+2m)=m$

Using $I=m_r r_0^2$, the moments of inertia are $I_H=mr_0^2/2$ and $I_D=mr_0^2$. The ratio of the rotational energies is then $\dfrac{E_H}{E_D}=\dfrac{l(l+1)(\hbar^2/2I_H)}{l(l+1)(\hbar^2/2I_D)}=\dfrac{I_D}{I_H}=\dfrac{mr_0^2}{\frac{m}{2}r_0^2}=2$.

(b) The ratio of the vibrational energies is $\dfrac{E_H}{E_D}=\dfrac{\left(n+\frac{1}{2}\right)\hbar\sqrt{\dfrac{k'}{m_r(\text{H})}}}{\left(n+\frac{1}{2}\right)\hbar\sqrt{\dfrac{k'}{m_r(\text{D})}}}=\sqrt{\dfrac{m_r(\text{D})}{m_r(\text{H})}}=\sqrt{\dfrac{m}{m/2}}=\sqrt{2}$.

EVALUATE: The electrical force is the same for both molecules since both H and D have the same charge, so it is reasonable that the force constant would be the same for both of them.

42.53. **IDENTIFY** and **SET UP:** Use the description of the bcc lattice in Fig.42.11c in the textbook to calculate the number of atoms per unit cell and then the number of atoms per unit volume.

EXECUTE: **(a)** Each unit cell has one atom at its center and 8 atoms at its corners that are each shared by 8 other unit cells. So there are $1+8/8=2$ atoms per unit cell.

$\dfrac{n}{V}=\dfrac{2}{(0.35\times10^{-9}\text{ m})^3}=4.66\times10^{-8}$ atoms/m^3

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) $E_{F0} = \dfrac{3^{2/3}\pi^{4/3}\hbar^2}{2m}\left(\dfrac{N}{V}\right)^{2/3}$

In this equation N/V is the number of free electrons per m^3. But the problem says to assume one free electron per atom, so this is the same as n/V calculated in part (a).

$m = 9.109\times10^{-31}$ kg (the electron mass), so $E_{F0} = 7.563\times10^{-19}$ J $= 4.7$ eV

EVALUATE: Our result for metallic lithium is similar to that calculated for copper in Example 42.7.

42.54. **IDENTIFY** and **SET UP:** At r where U_{tot} is a minimum, $\dfrac{d}{dr}U_{tot} = 0$.

EXECUTE: **(a)** $\dfrac{d}{dr}U_{tot} = \dfrac{\alpha e^2}{4\pi\varepsilon_0}\dfrac{1}{r^2} - 8A\dfrac{1}{r^9}$. Setting this equal to zero when $r = r_0$ gives $r_0^7 = \dfrac{8A4\pi\varepsilon_0}{\alpha e^2}$ and so $U_{tot} = \dfrac{\alpha e^2}{4\pi\varepsilon_0}\left(-\dfrac{1}{r} + \dfrac{r_0^7}{8r^8}\right)$. At $r = r_0$, $U_{tot} = -\dfrac{7\alpha e^2}{32\pi\varepsilon_0 r_0} = -1.26\times10^{-18}$ J $= -7.85$ eV.

(b) To remove a Na^+Cl^- ion pair from the crystal requires 7.85 eV. When neutral Na and Cl atoms are formed from the Na^+ and Cl^- atoms there is a net release of energy $-5.14\text{ eV} + 3.61\text{ eV} = -1.53$ eV, so the net energy required to remove a neutral Na Cl pair from the crystal is $7.85\text{ eV} - 1.53\text{ eV} = 6.32$ eV.

EVALUATE: Our calculation is in good agreement with the experimental value.

42.55. **(a) IDENTIFY** and **SET UP:** $p = -\dfrac{dE_{tot}}{dV}$. Relate E_{tot} to E_{F0} and evaluate the derivative.

EXECUTE: $E_{tot} = NE_{av} = \dfrac{3N}{5}E_{F0} = \dfrac{3}{5}\left(\dfrac{3^{2/3}\pi^{4/3}\hbar^2}{2m}\right)N^{5/3}V^{-2/3}$

$\dfrac{dE_{tot}}{dV} = \dfrac{3}{5}\left(\dfrac{3^{2/3}\pi^{4/3}\hbar^2}{2m}\right)N^{5/3}\left(-\dfrac{2}{3}V^{-5/3}\right)$ so $p = \left(\dfrac{3^{2/3}\pi^{4/3}\hbar^2}{5m}\right)\left(\dfrac{N}{V}\right)^{5/3}$, as was to be shown.

(b) $N/V = 8.45\times10^{28}$ m^{-3}

$p = \left(\dfrac{3^{2/3}\pi^{4/3}(1.055\times10^{-34}\text{ J}\cdot\text{s})^2}{5(9.109\times10^{-31}\text{ kg})}\right)(8.45\times10^{28}\text{ m}^{-3})^{5/3} = 3.81\times10^{10}\text{ Pa} = 3.76\times10^5\text{ atm}.$

(c) EVALUATE: Normal atmospheric pressure is about 10^5 Pa, so these pressures are extremely large. The electrons are held in the metal by the attractive force exerted on them by the copper ions.

42.56. **(a) IDENTIFY** and **SET UP:** From Problem 42.53, $p = \dfrac{3^{2/3}\pi^{4/3}\hbar^2}{5m}\left(\dfrac{N}{V}\right)^{5/3}$. Use this expression to calculate dp/dV.

EXECUTE: **(a)** $B = -V\dfrac{dp}{dV} = -V\left[\dfrac{5}{3}\cdot\dfrac{3^{2/3}\pi^{4/3}\hbar^2}{5m}\cdot\left(\dfrac{N}{V}\right)^{2/3}\left(\dfrac{-N}{V^2}\right)\right] = \dfrac{5}{3}p.$

(b) $\dfrac{N}{V} = 8.45\times10^{28}$ m^{-3}. $B = \dfrac{5}{3}\cdot\dfrac{3^{2/3}\pi^{4/3}\hbar^2}{5m}(8.45\times10^{28}\text{m}^{-3})^{5/3} = 6.33\times10^{10}$ Pa.

EVALUATE: **(c)** The fraction of B due to the free electrons is $\dfrac{6.33\times10^{10}\text{ Pa}}{1.4\times10^{11}\text{ Pa}} = 0.45$. The copper ions themselves make up the remaining fraction.

42.57. **IDENTIFY** and **SET UP:** Follow the steps specified in the problem.

EXECUTE: **(a)** $E_{F0} = \dfrac{3^{2/3}\pi^{4/3}\hbar^2}{2m}\left(\dfrac{N}{V}\right)^{2/3}$. Let $E_{F0} = \dfrac{1}{100}mc^2$.

$\left(\dfrac{N}{V}\right) = \left[\dfrac{2m^2c^2}{(100)3^{2/3}\pi^{4/3}\hbar^2}\right]^{3/2} = \dfrac{2^{3/2}m^3c^3}{100^{3/2}3\pi^2\hbar^3} = \dfrac{2^{3/2}m^3c^3}{3000\pi^2\hbar^3} = 1.67\times10^{33}\text{ m}^{-3}.$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) $\dfrac{8.45\times10^{28}\ \text{m}^{-3}}{1.67\times10^{33}\ \text{m}^{-3}}=5.06\times10^{-5}$. Since the real concentration of electrons in copper is less than one part in 10^{-4} of the concentration where relativistic effects are important, it is safe to ignore relativistic effects for most applications.

(c) The number of electrons is $N_e=\dfrac{6(2\times10^{30}\ \text{kg})}{1.99\times10^{-26}\ \text{kg}}=6.03\times10^{56}$. The concentration is

$\dfrac{N_e}{V}=\dfrac{6.03\times10^{56}}{\frac{4}{3}\pi(6.00\times10^{6}\ \text{m})^3}=6.66\times10^{35}\ \text{m}^{-3}$.

EVALUATE: **(d)** Comparing this to the result from part (a) $\dfrac{6.66\times10^{35}\ \text{m}^{-3}}{1.67\times10^{33}\ \text{m}^{-3}}\cong 400$ so relativistic effects will be very important.

42.58. **IDENTIFY:** The current through the diode is related to the voltage across it.

SET UP: The current through the diode is given by $I=I_S\ (e^{eV/kT}-1)$.

EXECUTE: **(a)** The current through the resistor is $(35.0\ \text{V})/(125\ \Omega)=0.280\ \text{A}=280\ \text{mA}$, which is also the current through the diode. This current is given by $I=I_S\ (e^{eV/kT}-1)$, giving $280\ \text{mA}=0.625\ \text{mA}(e^{eV/kT}-1)$ and $1+(280/0.625)=449=e^{eV/kT}$. Solving for V at $T=293\ \text{K}$ gives $V=\dfrac{kT\ln 449}{e}=\dfrac{(1.38\times10^{-23}\ \text{J/K})(293\ \text{K})\ln 449}{1.60\times10^{-19}\ \text{C}}=0.154\ \text{V}$

(b) $R=V/I=(0.154\ \text{V})/(0.280\ \text{A})=0.551\ \Omega$

EVALUATE: At a different voltage, the diode would have different resistance.

42.59. **IDENTIFY** and **SET UP:** For a pair of point charges q_1 and q_2 separated by a distance r_{12} the electric potential energy is $U=\dfrac{1}{4\pi\varepsilon_0}\dfrac{q_1q_2}{r_{12}}$. Sum over all pairs of charges.

EXECUTE: **(a)**

$$U=\frac{1}{4\pi\varepsilon_0}\sum_{i<j}\frac{q_iq_j}{r_{ij}}=\frac{q^2}{4\pi\varepsilon_0}\left(\frac{-1}{d}+\frac{1}{r}-\frac{1}{r+d}-\frac{1}{r-d}+\frac{1}{r}-\frac{1}{d}\right)=\frac{q^2}{4\pi\varepsilon_0}\left(\frac{2}{r}-\frac{2}{d}-\frac{1}{r+d}-\frac{1}{r-d}\right).$$

$$\text{But }\frac{1}{r+d}+\frac{1}{r-d}=\frac{1}{r}\left(\frac{1}{1+\frac{d}{r}}+\frac{1}{1-\frac{d}{r}}\right)\approx\frac{1}{r}\left(1-\frac{d}{r}+\frac{d^2}{r^2}+\ldots+1+\frac{d}{r}+\frac{d^2}{r^2}\right)\approx\frac{2}{r}+\frac{2d^2}{r^3}$$

$$\Rightarrow U=\frac{-2q^2}{4\pi\varepsilon_0}\left(\frac{1}{d}+\frac{d^2}{r^3}\right)=\frac{-2p^2}{4\pi\varepsilon_0r^3}-\frac{2p^2}{4\pi\varepsilon_0d^3}.$$

(b) $$U=\frac{1}{4\pi\varepsilon_0}\sum_{i<j}\frac{q_iq_j}{r_{ij}}=\frac{q^2}{4\pi\varepsilon_0}\left(\frac{-1}{d}-\frac{1}{r}+\frac{1}{r+d}+\frac{1}{r-d}-\frac{1}{r}-\frac{1}{d}\right)=\frac{q^2}{4\pi\varepsilon_0}\left(\frac{-2}{d}-\frac{2}{r}+\frac{2}{r}+\frac{2d^2}{r^3}\right)=$$

$$\frac{-2q^2}{4\pi\varepsilon_0}\left(\frac{1}{d}-\frac{d^2}{r^3}\right)\Rightarrow U=\frac{-2p^2}{4\pi\varepsilon_0d^3}+\frac{2p^2}{4\pi\varepsilon_0r^3}.$$

If we ignore the potential energy involved in forming each individual molecule, which just involves a different choice for the zero of potential energy, then the answers are:

(a) $U=\dfrac{-2p^2}{4\pi\varepsilon_0r^3}$. The interaction is attractive.

(b) $U=\dfrac{+2p^2}{4\pi\varepsilon_0r^3}$. The interaction is repulsive.

EVALUATE: In each case the interactions between the two dipoles involve two interactions between like charges and two between unlike charges. But in part (a) the two closest charges are unlike and in (b) the two closest charges are alike.

42.60. **IDENTIFY:** Follow the procedure specified in the hint.

SET UP: According to Eq. (42.8), the vibrational level spacing is $\Delta E = \hbar\omega = \hbar\sqrt{k'/m}$.

EXECUTE: **(a)** Following the hint, $k'dr = -d\left(\frac{1}{4\pi\varepsilon_0}\frac{e^2}{r^2}\right)_{r=r_0} = \frac{1}{2\pi\varepsilon_0}\frac{e^2}{r_0^3}dr$ and $k' = \frac{1}{2\pi\varepsilon_0}\frac{e^2}{r_0^3}$. The energy level spacing therefore is $\hbar\omega = \hbar\sqrt{2k'/m} = \hbar\sqrt{\frac{1}{\pi\varepsilon_0}\frac{e^2}{mr_0^3}} = 1.23\times10^{-19}\ \text{J} = 0.77\ \text{eV}$, where $(m/2)$ has been used for the reduced mass.

(b) The reduced mass is doubled, and the energy is reduced by a factor of $\sqrt{2}$ to 0.54 eV.

EVALUATE: The vibrational level spacing is inversely proportional to the square root of the reduced mass of the molecule. The force constant depends on the bond between the two atoms.

43

NUCLEAR PHYSICS

43.1. **IDENTIFY** and **SET UP:** The pre-subscript is Z, the number of protons. The pre-superscript is the mass number A. $A = Z + N$, where N is the number of neutrons.

EXECUTE: **(a)** ${}^{28}_{14}\text{Si}$ has 14 protons and 14 neutrons.

(b) ${}^{85}_{37}\text{Rb}$ has 37 protons and 48 neutrons.

(c) ${}^{205}_{81}\text{Tl}$ has 81 protons and 124 neutrons.

EVALUATE: The number of protons determines the chemical element.

43.2. **IDENTIFY:** Calculate the spin magnetic energy shift for each spin component. Calculate the energy splitting between these states and relate this to the frequency of the photons.

(a) SET UP: From Example 43.2, when the z-component of $\vec{\boldsymbol{S}}$ (and $\vec{\boldsymbol{\mu}}$) is parallel to $\vec{\boldsymbol{B}}$, $U = -|\mu_z|B = -2.7928\mu_{\text{n}}B$. When the z-component of $\vec{\boldsymbol{S}}$ (and $\vec{\boldsymbol{\mu}}$) is antiparallel to $\vec{\boldsymbol{B}}$, $U = +|\mu_z|B = +2.7928\mu_{\text{n}}B$. The state with the proton spin component parallel to the field lies lower in energy. The energy difference between these two states is $\Delta E = 2(2.7928\mu_{\text{n}}B)$.

EXECUTE: $\Delta E = hf$ so $f = \dfrac{\Delta E}{h} = \dfrac{2(2.7928\mu_{\text{n}})B}{h} = \dfrac{2(2.7928)(5.051\times10^{-27}\ \text{J/T})(1.65\ \text{T})}{6.626\times10^{-34}\ \text{J}\cdot\text{s}}$

$f = 7.03\times10^{7}\ \text{Hz} = 70.3\ \text{MHz}$

And then $\lambda = \dfrac{c}{f} = \dfrac{2.998\times10^{8}\ \text{m/s}}{7.03\times10^{7}\ \text{Hz}} = 4.26\ \text{m}$

EVALUATE: From Figure 32.4 in the textbook, these are radio waves.

(b) SET UP: From Eqs. (27.27) and (41.40) and Figure 41.18 in the textbook, the state with the z-component of $\vec{\boldsymbol{\mu}}$ parallel to $\vec{\boldsymbol{B}}$ has lower energy. But, since the charge of the electron is negative, this is the state with the electron spin component antiparallel to $\vec{\boldsymbol{B}}$. That is, for $m_s = -\frac{1}{2}$, the state lies lower in energy.

EXECUTE: For the $m_s = +\frac{1}{2}$ state,

$$U = +(2.00232)\left(\frac{e}{2m}\right)\left(+\frac{\hbar}{2}\right)B = +\tfrac{1}{2}(2.00232)\left(\frac{e\hbar}{2m}\right)B = +\tfrac{1}{2}(2.00232)\mu_{\text{B}}B.$$

For the $m_s = -\frac{1}{2}$ state, $U = -\frac{1}{2}(2.00232)\mu_{\text{B}}B$. The energy difference between these two states is $\Delta E = (2.00232)\mu_{\text{B}}B$.

$$\Delta E = hf \text{ so } f = \frac{\Delta E}{h} = \frac{2.00232\mu_{\text{B}}B}{h} = \frac{(2.00232)(9.274\times10^{-24}\ \text{J/T})(1.65\ \text{T})}{6.626\times10^{-34}\ \text{J}\cdot\text{s}} = 4.62\times10^{10}\ \text{Hz} = 46.2\ \text{GHz}.$$

And $\lambda = \dfrac{c}{f} = \dfrac{2.998\times10^{8}\ \text{m/s}}{4.62\times10^{10}\ \text{Hz}} = 6.49\times10^{-3}\ \text{m} = 6.49\ \text{mm}.$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: From Figure 32.4 in the textbook, these are microwaves. The interaction energy with the magnetic field is inversely proportional to the mass of the particle, so it is less for the proton than for the electron. The smaller transition energy for the proton produces a larger wavelength.

43.3. **IDENTIFY:** Calculate the spin magnetic energy shift for each spin state of the 1*s* level. Calculate the energy splitting between these states and relate this to the frequency of the photons.

SET UP: When the spin component is parallel to the field the interaction energy is $U = -\mu_z B$. When the spin component is antiparallel to the field the interaction energy is $U = +\mu_z B$. The transition energy for a transition between these two states is $\Delta E = 2\mu_z B$, where $\mu_z = 2.7928\mu_n$. The transition energy is related to the photon frequency by $\Delta E = hf$, so $2\mu_z B = hf$.

EXECUTE: $B = \dfrac{hf}{2\mu_z} = \dfrac{(6.626\times10^{-34}\ \text{J}\cdot\text{s})(22.7\times10^{6}\ \text{Hz})}{2(2.7928)(5.051\times10^{-27}\ \text{J/T})} = 0.533\ \text{T}$

EVALUATE: This magnetic field is easily achievable. Photons of this frequency have wavelength $\lambda = c/f = 13.2$ m. These are radio waves.

43.4. **IDENTIFY:** The interaction energy of the nuclear spin angular momentum with the external field is $U = -\mu_z B$. The transition energy ΔE for the neutron is related to the frequency and wavelength of the photon by $\Delta E = hf = \dfrac{hc}{\lambda}$.

SET UP: $|\mu_z| = 1.9130\mu_n$, where $\mu_n = 3.15245\times10^{-8}$ eV/T.

EXECUTE: **(a)** As in Example 43.2, $\Delta E = 2(1.9130)(3.15245\times10^{-8}\ \text{eV/T})(2.30\ \text{T}) = 2.77\times10^{-7}$ eV. Since $\vec{\boldsymbol{\mu}}$ and $\vec{\boldsymbol{S}}$ are in opposite directions for a neutron, the antiparallel configuration is lower energy. This result is smaller than but comparable to that found in the example for protons.

(b) $f = \dfrac{\Delta E}{h} = 66.9$ MHz, $\lambda = \dfrac{c}{f} = 4.48$ m.

EVALUATE: ΔE and f for neutrons are smaller than the corresponding values for protons that were calculated in Example 43.2.

43.5. **(a) IDENTIFY:** Find the energy equivalent of the mass defect.

SET UP: A $^{11}_{5}\text{B}$ atom has 5 protons, $11-5=6$ neutrons, and 5 electrons. The mass defect therefore is $\Delta M = 5m_p + 6m_n + 5m_e - M(^{11}_{5}\text{B})$.

EXECUTE: $\Delta M = 5(1.0072765\ \text{u}) + 6(1.0086649\ \text{u}) + 5(0.0005485799\ \text{u}) - 11.009305\ \text{u} = 0.08181$ u. The energy equivalent is $E_B = (0.08181\ \text{u})(931.5\ \text{MeV/u}) = 76.21$ MeV.

(b) IDENTIFY and **SET UP:** Eq. (43.11): $E_B = C_1A - C_2A^{2/3} - C_3Z(Z-1)/A^{1/3} - C_4(A-2Z)^2/A$

The fifth term is zero since Z is odd but N is even. $A = 11$ and $Z = 5$.

EXECUTE: $E_B = (15.75\ \text{MeV})(11) - (17.80\ \text{MeV})(11)^{2/3} - (0.7100\ \text{MeV})5(4)/11^{1/3} - (23.69\ \text{MeV})(11-10)^2/11.$

$E_B = +173.25\ \text{MeV} - 88.04\ \text{MeV} - 6.38\ \text{MeV} - 2.15\ \text{MeV} = 76.68\ \text{MeV}$

The percentage difference between the calculated and measured E_B is $\dfrac{76.68\ \text{MeV} - 76.21\ \text{MeV}}{76.21\ \text{MeV}} = 0.6\%$.

EVALUATE: Eq. (43.11) has a greater percentage accuracy for ^{62}Ni. The semi-empirical mass formula is more accurate for heavier nuclei.

43.6. **IDENTIFY:** The mass defect is the total mass of the constituents minus the mass of the atom.

SET UP: 1 u is equivalent to 931.5 MeV. $^{238}_{92}\text{U}$ has 92 protons, 146 neutrons and 238 nucleons.

EXECUTE: **(a)** $146m_n + 92m_H - m_U = 1.93$ u.

(b) 1.80×10^{3} MeV.

(c) 7.56 MeV per nucleon (using 931.5 MeV/u and 238 nucleons).

EVALUATE: The binding energy per nucleon we calculated agrees with Figure 43.2 in the textbook.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

43.7. **IDENTIFY** and **SET UP:** The text calculates that the binding energy of the deuteron is 2.224 MeV. A photon that breaks the deuteron up into a proton and a neutron must have at least this much energy.

$E = \dfrac{hc}{\lambda}$ so $\lambda = \dfrac{hc}{E}$

EXECUTE: $\lambda = \dfrac{(4.136\times10^{-15}\ \text{eV}\cdot\text{s})(2.998\times10^{8}\ \text{m/s})}{2.224\times10^{6}\ \text{eV}} = 5.575\times10^{-13}\ \text{m} = 0.5575\ \text{pm}.$

EVALUATE: This photon has gamma-ray wavelength.

43.8. **IDENTIFY:** The binding energy of the nucleus is the energy of its constituent particles minus the energy of the carbon-12 nucleus.

SET UP: In terms of the masses of the particles involved, the binding energy is

$$E_{\text{B}} = (6m_{\text{H}} + 6m_{\text{n}} - m_{\text{C-12}})c^2.$$

EXECUTE: **(a)** Using the values from Table 43.2, we get

$$E_{\text{B}} = [6(1.007825\ \text{u}) + 6(1.008665\ \text{u}) - 12.000000\ \text{u})](931.5\ \text{MeV/u}) = 92.16\ \text{MeV}$$

(b) The binding energy per nucleon is (92.16 MeV)/(12 nucleons) = 7.680 MeV/nucleon

(c) The energy of the C-12 nucleus is (12.0000 u)(931.5 MeV/u) = 11178 MeV. Therefore the percent of the mass that is binding energy is $\dfrac{92.16\ \text{MeV}}{11178\ \text{MeV}} = 0.8245\%.$

EVALUATE: The binding energy of 92.16 MeV binds 12 nucleons. The binding energy per nucleon, rather than just the total binding energy, is a better indicator of the strength with which a nucleus is bound.

43.9. **IDENTIFY:** Conservation of energy tells us that the initial energy (photon plus deuteron) is equal to the energy after the split (kinetic energy plus energy of the proton and neutron). Therefore the kinetic energy released is equal to the energy of the photon minus the binding energy of the deuteron.

SET UP: The binding energy of a deuteron is 2.224 MeV and the energy of the photon is $E = hc/\lambda$. Kinetic energy is $K = \dfrac{1}{2}mv^2$.

EXECUTE: **(a)** The energy of the photon is

$$E_{\text{ph}} = \frac{hc}{\lambda} = \frac{(6.626\times10^{-34}\ \text{J}\cdot\text{s})(3.00\times10^{8}\ \text{m/s})}{3.50\times10^{-13}\ \text{m}} = 5.68\times10^{-13}\ \text{J}.$$

The binding of the deuteron is $E_{\text{B}} = 2.224\ \text{MeV} = 3.56\times10^{-13}\ \text{J}$. Therefore the kinetic energy is

$K = (5.68 - 3.56)\times10^{-13}\ \text{J} = 2.12\times10^{-13}\ \text{J} = 1.32\ \text{MeV}.$

(b) The particles share the energy equally, so each gets half. Solving the kinetic energy for v gives

$$v = \sqrt{\frac{2K}{m}} = \sqrt{\frac{2(1.06\times10^{-13}\ \text{J})}{1.6605\times10^{-27}\ \text{kg}}} = 1.13\times10^{7}\ \text{m/s}$$

EVALUATE: Considerable energy has been released, because the particle speeds are in the vicinity of the speed of light.

43.10. **IDENTIFY:** The mass defect is the total mass of the constituents minus the mass of the atom.

SET UP: 1 u is equivalent to 931.5 MeV. $^{14}_{7}\text{N}$ has 7 protons and 7 neutrons. $^{4}_{2}\text{He}$ has 2 protons and 2 neutrons.

EXECUTE: **(a)** $7(m_{\text{n}} + m_{\text{H}}) - m_{\text{N}} = 0.112\ \text{u}$, which is 105 MeV, or 7.48 MeV per nucleon.

(b) Similarly, $2(m_{\text{H}} + m_{\text{n}}) - m_{\text{He}} = 0.03038\ \text{u} = 28.3\ \text{MeV}$, or 7.07 MeV per nucleon.

EVALUATE: **(c)** The binding energy per nucleon is a little less for $^{4}_{2}\text{He}$ than for $^{14}_{7}\text{N}$. This is in agreement with Figure 43.2 in the textbook.

43.11. **IDENTIFY:** Use Eq. (43.11) to calculate the binding energy of two nuclei, and then calculate their binding energy per nucleon.

SET UP and **EXECUTE:** $^{86}_{36}\text{Kr}$: $A = 86$ and $Z = 36$. $N = A - Z = 50$, which is even, so for the last term in Eq. (43.11) we use the plus sign. Putting the given number in the equation and using the values for the constants given in the textbook, we have

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$E_B = (15.75\text{ MeV})(86) - (17.80\text{ MeV})(86)^{2/3} - (0.71\text{ MeV})\frac{(36)(35)}{86^{1/3}}$$
$$-(23.69\text{ MeV})\frac{(86-72)^2}{86} + (39\text{ MeV})(86)^{-4/3}.$$

$E_B = 751.1$ MeV and $\frac{E_B}{A} = 8.73$ MeV/nucleon.

$^{180}_{73}$Ta: $A = 180, Z = 73, N = 180 - 73 = 107,$ which is odd.

$$E_B = (15.75\text{ MeV})(180) - (17.80\text{ MeV})(180)^{2/3} - (0.71\text{ MeV})\frac{(73)(72)}{180^{1/3}}$$
$$-(23.69\text{ MeV})\frac{(180-146)^2}{180} + (39\text{ MeV})(180)^{-4/3}$$

$E_B = 1454.4$ MeV and $\frac{E_B}{A} = 8.08$ MeV/nucleon.

EVALUATE: The binding energy per nucleon is less for $^{180}_{73}$Ta than for $^{86}_{36}$Kr, in agreement with Figure 43.2.

43.12. **IDENTIFY:** Compare the total mass on each side of the reaction equation. Neglect the masses of the neutrino and antineutrino.

SET UP: 1 u is equivalent to 931.5 MeV.

EXECUTE: **(a)** The energy released is the energy equivalent of $m_n - m_p - m_e = 8.40\times10^{-4}$ u, or 783 keV.

(b) $m_n > m_p,$ and the decay is not possible.

EVALUATE: β^- and β^+ particles have the same mass, equal to the mass of an electron.

43.13. **IDENTIFY:** In each case determine how the decay changes A and Z of the nucleus. The β^+ and β^- particles have charge but their nucleon number is $A = 0$.

(a) SET UP: α-decay: Z increases by 2, $A = N + Z$ decreases by 4 (an α particle is a $^4_2$He nucleus)

EXECUTE: $^{239}_{94}\text{Pu} \rightarrow {}^4_2\text{He} + {}^{235}_{92}\text{U}$

(b) SET UP: β^- decay: Z increases by 1, $A = N + Z$ remains the same (a β^- particle is an electron, $^0_{-1}$e)

EXECUTE: $^{24}_{11}\text{Na} \rightarrow {}^0_{-1}\text{e} + {}^{24}_{12}\text{Mg}$

(c) SET UP: β^+ decay: Z decreases by 1, $A = N + Z$ remains the same (a β^+ particle is a positron, $^0_{+1}$e)

EXECUTE: $^{15}_{8}\text{O} \rightarrow {}^0_{+1}\text{e} + {}^{15}_{7}\text{N}$

EVALUATE: In each case the total charge and total number of nucleons for the decay products equals the charge and number of nucleons for the parent nucleus; these two quantities are conserved in the decay.

43.14. **IDENTIFY:** The energy released is equal to the mass defect of the initial and final nuclei.

SET UP: The mass defect is equal to the difference between the initial and final masses of the constituent particles.

EXECUTE: **(a)** The mass defect is 238.050788 u – 234.043601 u – 4.002603 u = 0.004584 u. The energy released is (0.004584 u)(931.5 MeV/u) = 4.270 MeV.

(b) Take the ratio of the two kinetic energies, using the fact that $K = p^2/2m$:

$$\frac{K_{Th}}{K_\alpha} = \frac{\frac{p_{Th}^2}{2m_{Th}}}{\frac{p_\alpha^2}{2m_\alpha}} = \frac{m_\alpha}{m_{Th}} = \frac{4}{234}.$$

The kinetic energy of the Th is

$$K_{Th} = \frac{4}{234+4}K_{Total} = \frac{4}{238}(4.270\text{ MeV}) = 0.07176\text{ MeV} = 1.148\times10^{-14}\text{ J}$$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

Solving for v in the kinetic energy gives

$$v = \sqrt{\frac{2K}{m}} = \sqrt{\frac{2(1.148\times10^{-14}\text{ J})}{(234.043601)(1.6605\times10^{-27}\text{ kg})}} = 2.431\times10^{5}\text{ m/s}$$

EVALUATE: As we can see by the ratio of kinetic energies in part (b), the alpha particle will have a much higher kinetic energy than the thorium.

43.15. **IDENTIFY:** Compare the mass of the original nucleus to the total mass of the decay products.

SET UP: Subtract the electron masses from the neutral atom mass to obtain the mass of each nucleus.

EXECUTE: If β^- decay of ^{14}C is possible, then we are considering the decay $^{14}_{6}\text{C} \rightarrow {}^{14}_{7}\text{N} + \beta^-$.

$\Delta m = M(^{14}_{6}\text{C}) - M(^{14}_{7}\text{N}) - m_e$

$\Delta m = (14.003242\text{ u} - 6(0.000549\text{ u})) - (14.003074\text{ u} - 7(0.000549\text{ u})) - 0.0005491\text{ u}$

$\Delta m = +1.68\times10^{-4}$ u. So $E = (1.68\times10^{-4}\text{ u})(931.5\text{ MeV/u}) = 0.156\text{ MeV} = 156\text{ keV}$

EVALUATE: In the decay the total charge and the nucleon number are conserved.

43.16. **IDENTIFY:** In each reaction the nucleon number and the total charge are conserved.

SET UP: An α particle has charge $+2e$ and nucleon number 4. An electron has charge $-e$ and nucleon number zero. A positron has charge $+e$ and nucleon number zero.

EXECUTE: **(a)** A proton changes to a neutron, so the emitted particle is a positron (β^+).

(b) The number of nucleons in the nucleus decreases by 4 and the number of protons by 2, so the emitted particle is an alpha-particle.

(c) A neutron changes to a proton, so the emitted particle is an electron (β^-).

EVALUATE: We have considered the conservation laws. We have not determined if the decays are energetically allowed.

43.17. **IDENTIFY:** The energy released is the energy equivalent of the difference in the masses of the original atom and the final atom produced in the capture. Apply conservation of energy to the decay products.

SET UP: 1 u is equivalent to 931.5 MeV.

EXECUTE: **(a)** As in the example, $(0.000897\text{ u})(931.5\text{ MeV/u}) = 0.836\text{ MeV}$.

(b) $0.836\text{ MeV} - 0.122\text{ MeV} - 0.014\text{ MeV} = 0.700\text{ MeV}$.

EVALUATE: We have neglected the rest mass of the neutrino that is emitted.

43.18. **IDENTIFY:** Determine the energy released during tritium decay.

SET UP: In beta decay an electron, e^-, is emitted by the nucleus. The beta decay reaction is $^{3}_{1}\text{H} \rightarrow e^- + {}^{3}_{2}\text{He}$. If neutral atom masses are used, $^{3}_{1}\text{H}$ includes one electron and $^{3}_{2}\text{He}$ includes two electrons. One electron mass cancels and the other electron mass in $^{3}_{2}\text{He}$ represents the emitted electron. Or, we can subtract the electron masses and use the nuclear masses. The atomic mass of $^{3}_{2}\text{He}$ is 3.016029 u.

EXECUTE: **(a)** The mass of the $^{3}_{1}\text{H}$ nucleus is $3.016049\text{ u} - 0.000549\text{ u} = 3.015500\text{ u}$. The mass of the $^{3}_{2}\text{He}$ nucleus is $3.016029\text{ u} - 2(0.000549\text{ u}) = 3.014931\text{ u}$. The nuclear mass of $^{3}_{2}\text{He}$ plus the mass of the emitted electron is $3.014931\text{ u} + 0.000549\text{ u} = 3.015480\text{ u}$. This is slightly less than the nuclear mass for $^{3}_{1}\text{H}$, so the decay is energetically allowed.

(b) The mass decrease in the decay is $3.015500\text{ u} - 3.015480\text{ u} = 2.0\times10^{-5}$ u. Note that this can also be calculated as $m(^{3}_{1}\text{H}) - m(^{4}_{2}\text{He})$, where atomic masses are used. The energy released is $(2.0\times10^{-5}\text{ u})(931.5\text{ MeV/u}) = 0.019\text{ MeV}$. The total kinetic energy of the decay products is 0.019 MeV, or 19 keV.

EVALUATE: The energy is not shared equally by the decay products because they have unequal masses.

43.19. **IDENTIFY** and **SET UP:** $T_{1/2} = \dfrac{\ln 2}{\lambda}$ The mass of a single nucleus is $124m_p = 2.07\times10^{-25}$ kg.

$|dN/dt| = 0.350\text{ Ci} = 1.30\times10^{10}\text{ Bq}$, $|dN/dt| = \lambda N$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: $N = \dfrac{6.13\times10^{-3}\ \text{kg}}{2.07\times10^{-25}\ \text{kg}} = 2.96\times10^{22}$; $\lambda = \dfrac{|dN/dt|}{N} = \dfrac{1.30\times10^{10}\ \text{Bq}}{2.96\times10^{22}} = 4.39\times10^{-13}\ \text{s}^{-1}$.

$T_{1/2} = \dfrac{\ln 2}{\lambda} = 1.58\times10^{12}\ \text{s} = 5.01\times10^{4}\ \text{y}$.

EVALUATE: Since $T_{1/2}$ is very large, the activity changes very slowly.

43.20. **IDENTIFY:** Eq. (43.17) can be written as $N = N_0 2^{-t/T_{1/2}}$.

SET UP: The amount of elapsed time since the source was created is roughly 2.5 years.

EXECUTE: The current activity is $N = (5000\ \text{Ci})2^{-(2.5\ \text{yr})/(5.271\ \text{yr})} = 3600\ \text{Ci}$. The source is barely usable.

EVALUATE: Alternatively, we could calculate $\lambda = \dfrac{\ln(2)}{T_{1/2}} = 0.132(\text{years})^{-1}$ and use Eq. 43.17 directly to obtain the same answer.

43.21. **IDENTIFY:** From the known half-life, we can find the decay constant, the rate of decay, and the activity.

SET UP: $\lambda = \dfrac{\ln 2}{T_{1/2}}$. $T_{1/2} = 4.47\times10^{9}\ \text{yr} = 1.41\times10^{17}\ \text{s}$. The activity is $\left|\dfrac{dN}{dt}\right| = \lambda N$. The mass of one ^{238}U is approximately $238m_\text{p}$. $1\ \text{Ci} = 3.70\times10^{10}$ decays/s.

EXECUTE: **(a)** $\lambda = \dfrac{\ln 2}{1.41\times10^{17}\ \text{s}} = 4.92\times10^{-18}\ \text{s}^{-1}$.

(b) $N = \dfrac{|dN/dt|}{\lambda} = \dfrac{3.70\times10^{10}\ \text{Bq}}{4.92\times10^{-18}\ \text{s}^{-1}} = 7.52\times10^{27}$ nuclei. The mass m of uranium is the number of nuclei times the mass of each one. $m = (7.52\times10^{27})(238)(1.67\times10^{-27}\ \text{kg}) = 2.99\times10^{3}\ \text{kg}$.

(c) $N = \dfrac{10.0\times10^{-3}\ \text{kg}}{238m_\text{p}} = \dfrac{10.0\times10^{-3}\ \text{kg}}{238(1.67\times10^{-27}\ \text{kg})} = 2.52\times10^{22}$ nuclei.

$\left|\dfrac{dN}{dt}\right| = \lambda N = (4.92\times10^{-18}\ \text{s}^{-1})(2.52\times10^{22}) = 1.24\times10^{5}$ decays/s.

EVALUATE: Because ^{238}U has a very long half-life, it requires a large amount (about 3000 kg) to have an activity of a 1.0 Ci.

43.22. **IDENTIFY:** From the half-life and mass of an isotope, we can find its initial activity rate. Then using the half-life, we can find its activity rate at a later time.

SET UP: The activity $|dN/dt| = \lambda N$. $\lambda = \dfrac{\ln 2}{T_{1/2}}$. The mass of one ^{103}Pd nucleus is $103m_\text{p}$. In a time of one half-life the number of radioactive nuclei and the activity decrease by a factor of 2.

EXECUTE: **(a)** $\lambda = \dfrac{\ln 2}{T_{1/2}} = \dfrac{\ln 2}{(17\ \text{days})(24\ \text{h/day})(3600\ \text{s/h})} = 4.7\times10^{-7}\ \text{s}^{-1}$.

$N = \dfrac{0.250\times10^{-3}\ \text{kg}}{103m_\text{p}} = 1.45\times10^{21}$. $|dN/dt| = (4.7\times10^{-7}\ \text{s}^{-1})(1.45\times10^{21}) = 6.8\times10^{14}$ Bq.

(b) 68 days is $4T_{1/2}$ so the activity is $(6.8\times10^{14}\ \text{Bq})/2^4 = 4.2\times10^{13}$ Bq.

EVALUATE: At the end of 4 half-lives, the activity rate is less than a tenth of its initial rate.

43.23. **IDENTIFY** and **SET UP:** As discussed in Section 43.4, the activity $A = |dN/dt|$ obeys the same decay equation as Eq. (43.17): $A = A_0 e^{-\lambda t}$. For ^{14}C, $T_{1/2} = 5730$ y and $\lambda = \ln 2/T_{1/2}$ so $A = A_0 e^{-(\ln 2)t/T_{1/2}}$; calculate A at each t; $A_0 = 180.0$ decays/min.

EXECUTE: **(a)** $t = 1000$ y, $A = 159$ decays/min

(b) $t = 50{,}000$ y, $A = 0.43$ decays/min

EVALUATE: The time in part (b) is 8.73 half-lives, so the decay rate has decreased by a factor or $(\tfrac{1}{2})^{8.73}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

43.24. **IDENTIFY** and **SET UP:** The decay rate decreases by a factor of 2 in a time of one half-life.

EXECUTE: **(a)** 24 d is $3T_{1/2}$ so the activity is $(375 \text{ Bq})/(2^3) = 46.9 \text{ Bq}$.

(b) The activity is proportional to the number of radioactive nuclei, so the percent is $\dfrac{17.0 \text{ Bq}}{46.9 \text{ Bq}} = 36.2\%$.

(c) ${}^{131}_{53}\text{I} \rightarrow {}^{0}_{-1}\text{e} + {}^{131}_{54}\text{Xe}$ The nucleus ${}^{131}_{54}\text{Xe}$ is produced.

EVALUATE: Both the activity and the number of radioactive nuclei present decrease by a factor of 2 in one half-life.

43.25. **IDENTIFY** and **SET UP:** Find λ from the half-life and the number N of nuclei from the mass of one nucleus and the mass of the sample. Then use Eq. (43.16) to calculate $|dN/dt|$, the number of decays per second.

EXECUTE: **(a)** $|dN/dt| = \lambda N$

$$\lambda = \frac{0.693}{T_{1/2}} = \frac{0.693}{(1.28\times10^{9} \text{ y})(3.156\times10^{7} \text{ s/1 y})} = 1.715\times10^{-17} \text{ s}^{-1}$$

The mass of one ${}^{40}\text{K}$ atom is approximately 40 u, so the number of ${}^{40}\text{K}$ nuclei in the sample is

$$N = \frac{1.63\times10^{-9} \text{ kg}}{40 \text{ u}} = \frac{1.63\times10^{-9} \text{ kg}}{40(1.66054\times10^{-27} \text{ kg})} = 2.454\times10^{16}.$$

Then $|dN/dt| = \lambda N = (1.715\times10^{-17} \text{ s}^{-1})(2.454\times10^{16}) = 0.421$ decays/s

(b) $|dN/dt| = (0.421 \text{ decays/s})(1 \text{ Ci}/(3.70\times10^{10} \text{ decays/s})) = 1.14\times10^{-11}$ Ci

EVALUATE: The very small sample still contains a very large number of nuclei. But the half-life is very large, so the decay rate is small.

43.26. **IDENTIFY:** Apply Eq. (43.16) to calculate N, the number of radioactive nuclei originally present in the spill. Since the activity is proportional to the number of radioactive nuclei, Eq. (43.17) leads to $A = A_0 e^{-\lambda t}$, where A is the activity.

SET UP: The mass of one ${}^{131}\text{Ba}$ nucleus is about 131 u.

EXECUTE: **(a)** $-\dfrac{dN}{dt} = 500\ \mu\text{Ci} = (500\times10^{-6})(3.70\times10^{10} \text{ s}^{-1}) = 1.85\times10^{7}$ decays/s.

$$T_{1/2} = \frac{\ln 2}{\lambda} \rightarrow \lambda = \frac{\ln 2}{T_{1/2}} = \frac{\ln 2}{(12 \text{ d})(86{,}400 \text{ s/d})} = 6.69\times10^{-7} \text{ s}.$$

$\dfrac{dN}{dt} = -\lambda N \Rightarrow N = \dfrac{-dN/dt}{\lambda} = \dfrac{1.85\times10^{7} \text{ decays/s}}{6.69\times10^{-7}\text{s}^{-1}} = 2.77\times10^{13}$ nuclei. The mass of this many ${}^{131}\text{Ba}$ nuclei is $m = 2.77\times10^{13} \text{ nuclei} \times (131\times1.66\times10^{-27} \text{ kg/nucleus}) = 6.0\times10^{-12} \text{ kg} = 6.0\times10^{-9} \text{ g} = 6.0 \text{ ng}$.

(b) $A = A_0 e^{-\lambda t}$. $1\ \mu\text{Ci} = (500\ \mu\text{Ci})\, e^{-\lambda t}$. $\ln(1/500) = -\lambda t$.

$$t = -\frac{\ln(1/500)}{\lambda} = -\frac{\ln(1/500)}{6.69\times10^{-7}\text{s}^{-1}} = 9.29\times10^{6} \text{ s}\left(\frac{1 \text{ d}}{86{,}400 \text{ s}}\right) = 108 \text{ days}.$$

EVALUATE: The time is about 9 half-lives and the activity after that time is $(500\ \mu\text{Ci})\left(\dfrac{1}{2}\right)^9$.

43.27. **IDENTIFY:** Apply $A = A_0 e^{-\lambda t}$ and $\lambda = \ln 2/T_{1/2}$.

SET UP: $\ln e^{x} = x$.

EXECUTE: $A = A_0 e^{-\lambda t} = A_0 e^{-t(\ln 2)/T_{1/2}}$. $-\dfrac{(\ln 2)t}{T_{1/2}} = \ln(A/A_0)$.

$$T_{1/2} = -\frac{(\ln 2)t}{\ln(A/A_0)} = -\frac{(\ln 2)(4.00 \text{ days})}{\ln(3091/8318)} = 2.80 \text{ days}.$$

EVALUATE: The activity has decreased by more than half and the elapsed time is more than one half-life.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

43.28. **IDENTIFY:** Apply Eq. (43.16), with $\lambda = \ln 2/T_{1/2}$.

SET UP: 1 mole of ^{226}Ra has a mass of 226 g. 1 Ci $= 3.70\times10^{10}$ Bq.

EXECUTE: $\left|\frac{dN}{dt}\right| = \lambda N$. $\lambda = \frac{\ln 2}{T_{1/2}} = \frac{\ln 2}{1620 \text{ y } (3.15\times10^7 \text{ s/y})} = 1.36\times10^{-11} \text{ s}^{-1}$.

$N = 1 \text{ g}\left(\frac{6.022\times10^{23}\text{ atoms}}{226 \text{ g}}\right) = 2.665\times10^{25}$ atoms.

$\left|\frac{dN}{dt}\right| = \lambda N = (2.665\times10^{25})(1.36\times10^{-11} \text{ s}^{-1}) = 3.62\times10^{10}$ decays/s $= 3.62\times10^{10}$ Bq. Convert to Ci:

$3.62\times10^{10} \text{ Bq}\left(\frac{1 \text{ Ci}}{3.70\times10^{10} \text{ Bq}}\right) = 0.98$ Ci.

EVALUATE: dN/dt is negative, since the number of radioactive nuclei decreases in time.

43.29. **IDENTIFY** and **SET UP:** Apply Eq. (43.16), with $\lambda = \ln 2/T_{1/2}$. In one half-life, one half of the nuclei decay.

EXECUTE: **(a)** $\left|\frac{dN}{dt}\right| = 7.56\times10^{11}$ Bq $= 7.56\times10^{11}$ decays/s.

$\lambda = \frac{0.693}{T_{1/2}} = \frac{0.693}{(30.8 \text{ min})(60 \text{ s/min})} = 3.75\times10^{-4} \text{ s}^{-1}$. $N_0 = \frac{1}{\lambda}\left|\frac{dN}{dt}\right| = \frac{7.56\times10^{11} \text{ decay/s}}{3.75\times10^{-4} \text{ s}^{-1}} = 2.02\times10^{15}$ nuclei.

(b) The number of nuclei left after one half-life is $\frac{N_0}{2} = 1.01\times10^{15}$ nuclei, and the activity is half:

$\left|\frac{dN}{dt}\right| = 3.78\times10^{11}$ decays/s.

(c) After three half-lives (92.4 minutes) there is an eighth of the original amount, so $N = 2.53\times10^{14}$ nuclei, and an eighth of the activity: $\left|\frac{dN}{dt}\right| = 9.45\times10^{10}$ decays/s.

EVALUATE: Since the activity is proportional to the number of radioactive nuclei that are present, the activity is halved in one half-life.

43.30. **IDENTIFY:** Apply $A = A_0 e^{-\lambda t}$.

SET UP: From Example 43.9, $\lambda = 1.21\times10^{-4}$ y^{-1}.

EXECUTE: The activity of the sample is $\frac{3070 \text{ decays/min}}{(60 \text{ sec/min})(0.500 \text{ kg})} = 102$ Bq/kg, while the activity of atmospheric carbon is 255 Bq/kg (see Example 43.9). The age of the sample is then

$t = -\frac{\ln (102/225)}{\lambda} = -\frac{\ln (102/225)}{1.21\times10^{-4}/\text{y}} = 7573$ y.

EVALUATE: For ^{14}C, $T_{1/2} = 5730$ y. The age is more than one half-life and the activity per kg of carbon is less than half the value when the tree died.

43.31. **IDENTIFY:** Knowing the equivalent dose in Sv, we want to find the absorbed energy.

SET UP: equivalent dose (Sv, rem) = RBE × absorbed dose(Gy, rad); 100 rad = 1 Gy

EXECUTE: **(a)** RBE = 1, so 0.25 mSv corresponds to 0.25 mGy.

Energy $= (0.25\times10^{-3} \text{ J/kg})/(5.0 \text{ kg}) = 1.2\times10^{-3}$ J.

(b) RBE = 1 so 0.10 mGy = 10 mrad and 10 mrem. $(0.10\times10^{-3} \text{ J/kg})(75 \text{ kg}) = 7.5\times10^{-3}$ J.

EVALUATE: **(c)** $\frac{7.5\times10^{-3} \text{ J}}{1.2\times10^{-3} \text{ J}} = 6.2$. Each chest x ray delivers only about 1/6 of the yearly background radiation energy.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

43.32. **IDENTIFY** and **SET UP:** The unit for absorbed dose is 1 rad = 0.01 J/kg = 0.01 Gy. Equivalent dose in rem is RBE times absorbed dose in rad.

EXECUTE: **(a)** rem = rad × RBE. $200 = x(10)$ and $x = 20$ rad.

(b) 1 rad deposits 0.010 J/kg, so 20 rad deposit 0.20 J/kg. This radiation affects 25 g (0.025 kg) of tissue, so the total energy is $(0.025\text{ kg})(0.20\text{ J/kg}) = 5.0\times10^{-3}\text{ J} = 5.0\text{ mJ}$.

(c) RBE = 1 for β-rays, so rem = rad. Therefore 20 rad = 20 rem.

EVALUATE: The same absorbed dose produces a larger equivalent dose when the radiation is neutrons than when it is electrons.

43.33. **IDENTIFY** and **SET UP:** The unit for absorbed dose is 1 rad = 0.01 J/kg = 0.01 Gy. Equivalent dose in rem is RBE times absorbed dose in rad.

EXECUTE: $1\text{ rad} = 10^{-2}$ Gy, so 1 Gy = 100 rad and the dose was 500 rad.

rem = (rad)(RBE) = (500 rad)(4.0) = 2000 rem. 1 Gy = 1 J/kg, so 5.0 J/kg.

EVALUATE: Gy, rad and J/kg are all units of absorbed dose. Rem is a unit of equivalent dose, which depends on the RBE of the radiation.

43.34. **IDENTIFY** and **SET UP:** For x rays RBE = 1 so the equivalent dose in Sv is the same as the absorbed dose in J/kg.

EXECUTE: One whole-body scan delivers $(75\text{ kg})(12\times10^{-3}\text{ J/kg}) = 0.90\text{ J}$. One chest x ray delivers $(5.0\text{ kg})(0.20\times10^{-3}\text{ J/kg}) = 1.0\times10^{-3}\text{ J}$. It takes $\dfrac{0.90\text{ J}}{1.0\times10^{-3}\text{ J}} = 900$ chest x rays to deliver the same total energy.

EVALUATE: For the CT scan the equivalent dose is much larger, and it is applied to the whole body.

43.35. **IDENTIFY** and **SET UP:** For x rays RBE = 1 and the equivalent dose equals the absorbed dose.

EXECUTE: **(a)** 175 krad = 175 krem = 1.75 kGy = 1.75 kSv. $(1.75\times10^{3}\text{ J/kg})(0.220\text{ kg}) = 385\text{ J}$.

(b) 175 krad = 1.75 kGy; (1.50)(175 krad) = 262.5 krem = 2.625 kSv. The energy deposited would be 385 J, the same as in (a).

EVALUATE: The energy required to raise the temperature of 0.150 kg of water 1 C° is 628 J, and 385 J is less than this. The energy deposited corresponds to a very small amount of heating.

43.36. **IDENTIFY:** 1 rem = 0.01 Sv. Equivalent dose in rem equals RBE times the absorbed dose in rad. 1 rad = 0.01 J/kg. To change the temperature of water, $Q = mc\Delta T$.

SET UP: For water, $c = 4190\text{ J/kg}\cdot\text{K}$.

EXECUTE: **(a)** 5.4 Sv(100 rem/sv) = 540 rem.

(b) The RBE of 1 gives an absorbed dose of 540 rad.

(c) The absorbed dose is 5.4 Gy, so the total energy absorbed is $(5.4\text{ Gy})(65\text{ kg}) = 351\text{ J}$. The energy required to raise the temperature of 65 kg by 0.010° C is $(65\text{ kg})(4190\text{ J/kg}\cdot\text{K})(0.01\text{ C°}) = 3\text{ kJ}$.

EVALUATE: The amount of energy received corresponds to a very small heating of his body.

43.37. **IDENTIFY:** Apply Eq. (43.16), with $\lambda = \ln 2/T_{1/2}$, to find the number of tritium atoms that were ingested. Then use Eq. (43.17) to find the number of decays in one week.

SET UP: 1 rad = 0.01 J/kg. rem = RBE × rad.

EXECUTE: **(a)** We need to know how many decays per second occur.

$\lambda = \dfrac{0.693}{T_{1/2}} = \dfrac{0.693}{(12.3\text{ y})(3.156\times10^{7}\text{ s/y})} = 1.785\times10^{-9}\text{ s}^{-1}$. The number of tritium atoms is

$N_0 = \dfrac{1}{\lambda}\left|\dfrac{dN}{dt}\right| = \dfrac{(0.35\text{ Ci})(3.70\times10^{10}\text{ Bq/Ci})}{1.79\times10^{-9}\text{ s}^{-1}} = 7.2540\times10^{18}$ nuclei. The number of remaining nuclei after one week is $N = N_0e^{-\lambda t} = (7.25\times10^{18})e^{-(1.79\times10^{-9}\text{ s}^{-1})(7)(24)(3600\text{ s})} = 7.2462\times10^{18}$ nuclei.

$\Delta N = N_0 - N = 7.8\times10^{15}$ decays. So the energy absorbed is

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$E_{\text{total}} = \Delta N\, E_\gamma = (7.8\times10^{15})(5000\text{ eV})(1.60\times10^{-19}\text{ J/eV}) = 6.25\text{ J}$. The absorbed dose is $\frac{6.25\text{ J}}{67\text{ kg}} = 0.0932\text{ J/kg} = 9.32\text{ rad}$. Since $\text{RBE} = 1$, then the equivalent dose is 9.32 rem.

EVALUATE: **(b)** In the decay, antineutrinos are also emitted. These are not absorbed by the body, and so some of the energy of the decay is lost.

43.38. **IDENTIFY:** Each photon delivers energy. The energy of a single photon depends on its wavelength.
SET UP: equivalent dose (rem) = RBE × absorbed dose (rad). 1 rad = 0.010 J/kg. For x rays, RBE = 1. Each photon has energy $E = \frac{hc}{\lambda}$.

EXECUTE: **(a)** $E = \frac{hc}{\lambda} = \frac{(6.63\times10^{-34}\text{ J}\cdot\text{s})(3.00\times10^{8}\text{ m/s})}{0.0200\times10^{-9}\text{ m}} = 9.94\times10^{-15}\text{ J}$. The absorbed energy is $(5.00\times10^{10}\text{ photons})(9.94\times10^{-15}\text{ J/photon}) = 4.97\times10^{-4}\text{ J} = 0.497\text{ mJ}$.

(b) The absorbed dose is $\frac{4.97\times10^{-4}\text{ J}}{0.600\text{ kg}} = 8.28\times10^{-4}\text{ J/kg} = 0.0828\text{ rad}$. Since $\text{RBE} = 1$, the equivalent dose is 0.0828 rem.

EVALUATE: The amount of energy absorbed is rather small (only ½ mJ), but it is absorbed by only 600 g of tissue.

43.39. **(a) IDENTIFY** and **SET UP:** Determine X by balancing the charge and nucleon number on the two sides of the reaction equation.

EXECUTE: X must have $A = 2+14-10 = 6$ and $Z = 1+7-5 = 3$. Thus X is ${}^{6}_{3}\text{Li}$ and the reaction is ${}^{2}_{1}\text{H} + {}^{14}_{7}\text{N} \rightarrow {}^{6}_{3}\text{Li} + {}^{10}_{5}\text{B}$.

(b) IDENTIFY and **SET UP:** Calculate the mass decrease and find its energy equivalent.
EXECUTE: The neutral atoms on each side of the reaction equation have a total of 8 electrons, so the electron masses cancel when neutral atom masses are used. The neutral atom masses are found in Table 43.2.
mass of ${}^{2}_{1}\text{H} + {}^{14}_{7}\text{N}$ is $2.014102\text{ u} + 14.003074\text{ u} = 16.017176\text{ u}$
mass of ${}^{6}_{3}\text{Li} + {}^{10}_{5}\text{B}$ is $6.015121\text{ u} + 10.012937\text{ u} = 16.028058\text{ u}$
The mass increases, so energy is absorbed by the reaction. The Q value is $(16.017176\text{ u} - 16.028058\text{ u})(931.5\text{ MeV/u}) = -10.14\text{ MeV}$

(c) IDENTIFY and **SET UP:** The available energy in the collision, the kinetic energy K_{cm} in the center of mass reference frame, is related to the kinetic energy K of the bombarding particle by Eq. (43.24).
EXECUTE: The kinetic energy that must be available to cause the reaction is 10.14 MeV. Thus $K_{\text{cm}} = 10.14\text{ MeV}$. The mass M of the stationary target $({}^{14}_{7}\text{N})$ is $M = 14\text{ u}$. The mass m of the colliding particle $({}^{2}_{1}\text{H})$ is 2 u. Then by Eq. (43.24) the minimum kinetic energy K that the ${}^{2}_{1}\text{H}$ must have is

$$K = \left(\frac{M+m}{M}\right)K_{\text{cm}} = \left(\frac{14\text{ u} + 2\text{ u}}{14\text{ u}}\right)(10.14\text{ MeV}) = 11.59\text{ MeV}.$$

EVALUATE: The projectile $({}^{2}_{1}\text{H})$ is much lighter than the target $({}^{14}_{7}\text{N})$ so K is not much larger than K_{cm}. The K we have calculated is what is required to allow the mass increase. We would also need to check to see if at this energy the projectile can overcome the Coulomb repulsion to get sufficiently close to the target nucleus for the reaction to occur.

43.40. **IDENTIFY:** The energy released is the energy equivalent of the mass decrease that occurs in the reaction.
SET UP: 1 u is equivalent to 931.5 MeV.
EXECUTE: $m_{{}^{3}_{2}\text{He}} + m_{{}^{2}_{1}\text{H}} - m_{{}^{4}_{2}\text{He}} - m_{{}^{1}_{1}\text{H}} = 1.97\times10^{-2}\text{ u}$, so the energy released is 18.4 MeV.

EVALUATE: Using neutral atom masses includes three electron masses on each side of the reaction equation and the same result is obtained as if nuclear masses had been used.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

43.41. **IDENTIFY** and **SET UP:** Determine X by balancing the charge and the nucleon number on the two sides of the reaction equation.

EXECUTE: X must have $A = +2 + 9 - 4 = 7$ and $Z = +1 + 4 - 2 = 3$. Thus X is ${}^{7}_{3}\text{Li}$ and the reaction is

${}^{2}_{1}\text{H} + {}^{9}_{4}\text{Be} = {}^{7}_{3}\text{Li} + {}^{4}_{2}\text{He}$

(b) IDENTIFY and **SET UP:** Calculate the mass decrease and find its energy equivalent.

EXECUTE: If we use the neutral atom masses then there are the same number of electrons (five) in the reactants as in the products. Their masses cancel, so we get the same mass defect whether we use nuclear masses or neutral atom masses. The neutral atoms masses are given in Table 43.2.

${}^{2}_{1}\text{H} + {}^{9}_{4}\text{Be}$ has mass $2.014102\ \text{u} + 9.012182\ \text{u} = 11.26284\ \text{u}$

${}^{7}_{3}\text{Li} + {}^{4}_{2}\text{He}$ has mass $7.016003\ \text{u} + 4.002603\ \text{u} = 11.018606\ \text{u}$

The mass decrease is $11.026284\ \text{u} - 11.018606\ \text{u} = 0.007678\ \text{u}$.

This corresponds to an energy release of $0.007678\ \text{u}(931.5\ \text{MeV/1 u}) = 7.152\ \text{MeV}$.

(c) IDENTIFY and **SET UP:** Estimate the threshold energy by calculating the Coulomb potential energy when the ${}^{2}_{1}\text{H}$ and ${}^{9}_{4}\text{Be}$ nuclei just touch. Obtain the nuclear radii from Eq. (43.1).

EXECUTE: The radius R_{Be} of the ${}^{9}_{4}\text{Be}$ nucleus is $R_{\text{Be}} = (1.2\times10^{-15}\ \text{m})(9)^{1/3} = 2.5\times10^{-15}\ \text{m}$.

The radius R_{H} of the ${}^{2}_{1}\text{H}$ nucleus is $R_{\text{H}} = (1.2\times10^{-15}\ \text{m})(2)^{1/3} = 1.5\times10^{-15}\ \text{m}$.

The nuclei touch when their center-to-center separation is

$R = R_{\text{Be}} + R_{\text{H}} = 4.0\times10^{-15}\ \text{m}$.

The Coulomb potential energy of the two reactant nuclei at this separation is

$$U = \frac{1}{4\pi\epsilon_0}\frac{q_1 q_2}{r} = \frac{1}{4\pi\epsilon_0}\frac{e(4e)}{r}$$

$$U = (8.988\times10^{9}\ \text{N}\cdot\text{m}^2/\text{C}^2)\frac{4(1.602\times10^{-19}\ \text{C})^2}{(4.0\times10^{-15}\ \text{m})(1.602\times10^{-19}\ \text{J/eV})} = 1.4\ \text{MeV}$$

This is an estimate of the threshold energy for this reaction.

EVALUATE: The reaction releases energy but the total initial kinetic energy of the reactants must be 1.4 MeV in order for the reacting nuclei to get close enough to each other for the reaction to occur. The nuclear force is strong but is very short-range.

43.42. **IDENTIFY** and **SET UP:** 0.7% of naturally occurring uranium is the isotope ${}^{235}\text{U}$. The mass of one ${}^{235}\text{U}$ nucleus is about $235m_{\text{p}}$.

EXECUTE: **(a)** The number of fissions needed is $\dfrac{1.0\times10^{19}\ \text{J}}{(200\times10^{6}\ \text{eV})(1.60\times10^{-19}\ \text{J/eV})} = 3.13\times10^{29}$. The mass of ${}^{235}\text{U}$ required is $(3.13\times10^{29})(235m_{\text{p}}) = 1.23\times10^{5}\ \text{kg}$.

(b) $\dfrac{1.23\times10^{5}\ \text{kg}}{0.7\times10^{-2}} = 1.76\times10^{7}\ \text{kg}$

EVALUATE: The calculation assumes 100% conversion of fission energy to electrical energy.

43.43. **IDENTIFY** and **SET UP:** The energy released is the energy equivalent of the mass decrease. 1 u is equivalent to 931.5 MeV. The mass of one ${}^{235}\text{U}$ nucleus is $235m_{\text{p}}$.

EXECUTE: **(a)** ${}^{235}_{92}\text{U} + {}^{1}_{0}\text{n} \rightarrow {}^{144}_{56}\text{Ba} + {}^{89}_{36}\text{Kr} + 3{}^{1}_{0}\text{n}$. We can use atomic masses since the same number of electrons are included on each side of the reaction equation and the electron masses cancel. The mass decrease is $\Delta M = m({}^{235}_{92}\text{U}) + m({}^{1}_{0}\text{n}) - [m({}^{144}_{56}\text{Ba}) + m({}^{89}_{36}\text{Kr}) + 3m({}^{1}_{0}\text{n})]$,

$\Delta M = 235.043930\ \text{u} + 1.0086649\ \text{u} - 143.922953\ \text{u} - 88.917630\ \text{u} - 3(1.0086649\ \text{u})$, $\Delta M = 0.1860\ \text{u}$. The energy released is $(0.1860\ \text{u})(931.5\ \text{MeV/u}) = 173.3\ \text{MeV}$.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) The number of ^{235}U nuclei in 1.00 g is $\dfrac{1.00\times10^{-3}\text{ kg}}{235m_\text{p}} = 2.55\times10^{21}$. The energy released per gram is

$(173.3\text{ MeV/nucleus})(2.55\times10^{21}\text{ nuclei/g}) = 4.42\times10^{23}\text{ MeV/g}$.

EVALUATE: The energy released is 7.1×10^{10} J/kg. This is much larger than typical heats of combustion, which are about 5×10^{4} J/kg.

43.44. **IDENTIFY:** The charge and the nucleon number are conserved. The energy of the photon must be at least as large as the energy equivalent of the mass increase in the reaction.
SET UP: 1 u is equivalent to 931.5 MeV.
EXECUTE: **(a)** $^{28}_{14}\text{Si} + \gamma \Rightarrow ^{24}_{12}\text{Mg} + ^{A}_{Z}\text{X}$. $A + 24 = 28$ so $A = 4$. $Z + 12 = 14$ so $Z = 2$. X is an α particle.
(b) $-\Delta m = m(^{24}_{12}\text{Mg}) + m(^{4}_{2}\text{He}) - m(^{28}_{14}\text{Si}) = 23.985042\text{ u} + 4.002603\text{ u} - 27.976927\text{ u} = 0.010718\text{ u}$.
$E_\gamma = (-\Delta m)c^2 = (0.010718\text{ u})(931.5\text{ MeV/u}) = 9.984\text{ MeV}$.
EVALUATE: The wavelength of the photon is
$\lambda = \dfrac{hc}{E} = \dfrac{(4.136\times10^{-15}\text{ eV}\cdot\text{s})(3.00\times10^{8}\text{ m/s})}{9.984\times10^{6}\text{ eV}} = 1.24\times10^{-13}\text{ m} = 1.24\times10^{-4}\text{ nm}$. This is a gamma ray photon.

43.45. **IDENTIFY:** The energy released is the energy equivalent of the mass decrease that occurs in the reaction.
SET UP: 1 u is equivalent to 931.5 MeV.
EXECUTE: The energy liberated will be
$M(^{3}_{2}\text{He}) + M(^{4}_{2}\text{He}) - M(^{7}_{4}\text{Be}) = (3.016029\text{ u} + 4.002603\text{ u} - 7.016929\text{ u})(931.5\text{ MeV/u}) = 1.586\text{ MeV}$.
EVALUATE: Using neutral atom masses includes four electrons on each side of the reaction equation and the result is the same as if nuclear masses had been used.

43.46. **IDENTIFY:** Charge and the number of nucleons are conserved in the reaction. The energy absorbed or released is determined by the mass change in the reaction.
SET UP: 1 u is equivalent to 931.5 MeV.
EXECUTE: **(a)** $Z = 3 + 2 - 0 = 5$ and $A = 4 + 7 - 1 = 10$.

(b) The nuclide is a boron nucleus, and $m_\text{He} + m_\text{Li} - m_\text{n} - m_\text{B} = -3.00\times10^{-3}$ u, and so 2.79 MeV of energy is absorbed.
EVALUATE: The absorbed energy must come from the initial kinetic energy of the reactants.

43.47. **IDENTIFY:** First find the number of deuterium nuclei in the water. Each fusion event requires two of them, and each such event releases 4.03 MeV of energy.
SET UP and **EXECUTE:** The molecular mass of water is 18.015×10^{-3} kg/mol. $m = \rho V$ so the 100.0 cm^3 sample has a mass of $m = (1000\text{ kg/m}^3)(100.0\times10^{-6}\text{ m}^3) = 0.100$ kg. The sample contains 5.551 moles and $(5.551\text{ mol})(6.022\times10^{23}\text{ molecules/mol}) = 3.343\times10^{24}$ molecules. The number of D_2O molecules is 5.014×10^{20}. Each molecule contains the two deuterons needed for one fusion reaction. Therefore, the energy liberated is $(5.014\times10^{20})(4.03\times10^{6}\text{ eV}) = 2.021\times10^{27}\text{ eV} = 3.24\times10^{8}$ J.
EVALUATE: This is about 300 million joules of energy! And after the fusion, essentially the same amount of water would remain since it is only the tiny percent that is deuterium that undergoes fusion.

43.48. **IDENTIFY** and **SET UP:** $m = \rho V$. 1 gal = 3.788 L = 3.788×10^{-3} m^3. The mass of a ^{235}U nucleus is $235m_\text{p}$. 1 MeV = 1.60×10^{-13} J
EXECUTE: **(a)** For 1 gallon, $m = \rho V = (737\text{ kg/m}^3)(3.788\times10^{-3}\text{ m}^3) = 2.79\text{ kg} = 2.79\times10^{3}$ g
$\dfrac{1.3\times10^{8}\text{ J/gal}}{2.79\times10^{3}\text{ g/gal}} = 4.7\times10^{4}\text{ J/g}$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) 1 g contains $\dfrac{1.00\times10^{-3}\text{ kg}}{235m_p}=2.55\times10^{21}$ nuclei

$(200\text{ MeV/nucleus})(1.60\times10^{-13}\text{ J/MeV})(2.55\times10^{21}\text{ nuclei})=8.2\times10^{10}\text{ J/g}$

(c) A mass of $6m_p$ produces 26.7 MeV.

$$\frac{(26.7\text{ MeV})(1.60\times10^{-13}\text{ J/MeV})}{6m_p}=4.26\times10^{14}\text{ J/kg}=4.26\times10^{11}\text{ J/g}$$

(d) The total energy available would be $(1.99\times10^{30}\text{ kg})(4.7\times10^{7}\text{ J/kg})=9.4\times10^{37}\text{ J}$

$$\text{power}=\frac{\text{energy}}{t}\text{ so }t=\frac{\text{energy}}{\text{power}}=\frac{9.4\times10^{37}\text{ J}}{3.86\times10^{26}\text{ W}}=2.4\times10^{11}\text{ s}=7600\text{ yr}$$

EVALUATE: If the mass of the sun were all proton fuel, it would contain enough fuel to last

$$(7600\text{ yr})\left(\frac{4.3\times10^{11}\text{ J/g}}{4.7\times10^{4}\text{ J/g}}\right)=7.0\times10^{10}\text{ yr.}$$

43.49. **IDENTIFY** and **SET UP:** Follow the procedure specified in the hint.

EXECUTE: Nuclei: ${}^{A}_{Z}\mathrm{X}^{Z+}\rightarrow{}^{A-4}_{Z-2}\mathrm{Y}^{(Z-2)+}+{}^{4}_{2}\mathrm{He}^{2+}$. Add the mass of Z electrons to each side and we find: $\Delta m=M({}^{A}_{Z}\mathrm{X})-M({}^{A-4}_{Z-2}\mathrm{Y})-M({}^{4}_{2}\mathrm{He})$, where now we have the mass of the neutral atoms. So as long as the mass of the original neutral atom is greater than the sum of the neutral products masses, the decay can happen.

EVALUATE: The energy released in the decay is the energy equivalent of Δm.

43.50. **IDENTIFY** and **SET UP:** Follow the procedure specified in the hint in Problem 43.49.

EXECUTE: Denote the reaction as ${}^{A}_{Z}\mathrm{X}\rightarrow{}_{Z+1}{}^{A}\mathrm{Y}+\mathrm{e}^{-}$. The mass defect is related to the change in the neutral atomic masses by $[m_X-Zm_e]-[m_Y-(Z+1)m_e]-m_e=(m_X-m_Y)$, where m_X and m_Y are the masses as tabulated in, for instance, Table (43.2).

EVALUATE: It is essential to correctly account for the electron masses.

43.51. **IDENTIFY** and **SET UP:** Follow the procedure specified in the hint in Problem 43.49.

EXECUTE: ${}^{A}_{Z}\mathrm{X}^{Z+}\rightarrow{}_{Z-1}{}^{A}\mathrm{Y}^{(Z-1)+}+\beta^{+}$. Adding $(Z-1)$ electrons to both sides yields ${}^{A}_{Z}\mathrm{X}^{+}\rightarrow{}_{Z-1}{}^{A}\mathrm{Y}+\beta^{+}$. So in terms of masses:

$\Delta m=M({}^{A}_{Z}\mathrm{X}^{+})-M({}_{Z-1}{}^{A}\mathrm{Y})-m_e=(M({}^{A}_{Z}\mathrm{X})-m_e)-M({}_{Z-1}{}^{A}\mathrm{Y})-m_e=M({}^{A}_{Z}\mathrm{X})-M({}_{Z-1}{}^{A}\mathrm{Y})-2m_e$.

So the decay will occur as long as the original neutral mass is greater than the sum of the neutral product mass and two electron masses.

EVALUATE: It is essential to correctly account for the electron masses.

43.52. **IDENTIFY:** The minimum energy to remove a proton from the nucleus is equal to the energy difference between the two states of the nucleus (before and after proton removal).

(a) SET UP: ${}^{12}_{6}\mathrm{C}={}^{1}_{1}\mathrm{H}+{}^{11}_{5}\mathrm{B}$. $\Delta m=m({}^{1}_{1}\mathrm{H})+m({}^{11}_{5}\mathrm{B})-m({}^{12}_{6}\mathrm{C})$. The electron masses cancel when neutral atom masses are used.

EXECUTE: $\Delta m=1.007825\text{ u}+11.009305\text{ u}-12.000000\text{ u}=0.01713\text{ u}$. The energy equivalent of this mass increase is $(0.01713\text{ u})(931.5\text{ MeV/u})=16.0\text{ MeV}$.

(b) SET UP and **EXECUTE:** We follow the same procedure as in part (a).

$\Delta M=6M_H+6M_n-{}^{12}_{6}M=6(1.007825\text{ u})+6(1.008665\text{ u})-12.000000\text{ u}=0.09894\text{ u}$.

$E_B=(0.09894\text{ u})(931.5\text{ MeV/u})=92.16\text{ MeV}$. $\dfrac{E_B}{A}=7.68\text{ MeV/u}$.

EVALUATE: The proton removal energy is about twice the binding energy per nucleon.

43.53. **IDENTIFY:** The minimum energy to remove a proton or a neutron from the nucleus is equal to the energy difference between the two states of the nucleus, before and after removal.

(a) SET UP: ${}^{17}_{8}\mathrm{O}={}^{1}_{0}\mathrm{n}+{}^{16}_{8}\mathrm{O}$. $\Delta m=m({}^{1}_{0}\mathrm{n})+m({}^{16}_{8}\mathrm{O})-m({}^{17}_{8}\mathrm{O})$. The electron masses cancel when neutral atom masses are used.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: $\Delta m = 1.008665\text{ u} + 15.994915\text{ u} - 16.999132\text{ u} = 0.004448\text{ u}$. The energy equivalent of this mass increase is $(0.004448\text{ u})(931.5\text{ MeV/u}) = 4.14\text{ MeV}$.

(b) SET UP and **EXECUTE:** Following the same procedure as in part (a) gives

$\Delta M = 8M_{\text{H}} + 9M_{\text{n}} - {}^{17}_{8}M = 8(1.007825\text{ u}) + 9(1.008665\text{ u}) - 16.999132\text{ u} = 0.1415\text{ u}$.

$E_{\text{B}} = (0.1415\text{ u})(931.5\text{ MeV/u}) = 131.8\text{ MeV}$. $\dfrac{E_{\text{B}}}{A} = 7.75\text{ MeV/nucleon}$.

EVALUATE: The neutron removal energy is about half the binding energy per nucleon.

43.54. **IDENTIFY:** The minimum energy to remove a proton or a neutron from the nucleus is equal to the energy difference between the two states of the nucleus, before and after removal.

SET UP and **EXECUTE:** proton removal: ${}^{15}_{7}\text{N} = {}^{1}_{1}\text{H} + {}^{14}_{6}\text{C}$, $\Delta m = m({}^{1}_{1}\text{H}) + m({}^{14}_{6}\text{C}) - m({}^{15}_{7}\text{N})$. The electron masses cancel when neutral atom masses are used.

$\Delta m = 1.007825\text{ u} + 14.003242\text{ u} - 15.000109\text{ u} = 0.01096\text{ u}$. The proton removal energy is 10.2 MeV.

neutron removal: ${}^{15}_{7}\text{N} = {}^{1}_{0}\text{n} + {}^{14}_{7}\text{N}$. $\Delta m = m({}^{1}_{0}\text{n}) + m({}^{14}_{7}\text{N}) - m({}^{15}_{7}\text{N})$. The electron masses cancel when neutral atom masses are used.

$\Delta m = 1.008665\text{ u} + 14.003074\text{ u} - 15.000109\text{ u} = 0.01163\text{ u}$. The neutron removal energy is 10.8 MeV.

EVALUATE: The neutron removal energy is 6% larger than the proton removal energy.

43.55. **IDENTIFY:** Use the decay scheme and half-life of ${}^{90}\text{Sr}$ to find out the product of its decay and the amount left after a given time.

SET UP: The particle emitted in β^- decay is an electron, ${}^{0}_{-1}\text{e}$. In a time of one half-life, the number of radioactive nuclei decreases by a factor of 2. $6.25\% = \dfrac{1}{16} = 2^{-4}$

EXECUTE: **(a)** ${}^{90}_{38}\text{Sr} \rightarrow {}^{0}_{-1}\text{e} + {}^{90}_{39}\text{Y}$. The daughter nucleus is ${}^{90}_{39}\text{Y}$.

(b) 56 y is $2T_{1/2}$ so $N = N_0/2^2 = N_0/4$; 25% is left.

(c) $\dfrac{N}{N_0} = 2^{-n}$; $\dfrac{N}{N_0} = 6.25\% = \dfrac{1}{16} = 2^{-4}$ so $t = 4T_{1/2} = 112$ y.

EVALUATE: After half a century, ¼ of the ${}^{90}\text{Sr}$ would still be left!

43.56. **IDENTIFY:** Calculate the mass defect for the decay. Example 43.5 uses conservation of linear momentum to determine how the released energy is divided between the decay partners.

SET UP: 1 u is equivalent to 931.5 MeV.

EXECUTE: The α-particle will have $\dfrac{226}{230}$ of the released energy (see Example 43.5).

$\dfrac{226}{230}(m_{\text{Th}} - m_{\text{Ra}} - m_{\alpha}) = 5.032\times10^{-3}$ u or 4.69 MeV.

EVALUATE: Most of the released energy goes to the α particle, since its mass is much less than that of the daughter nucleus.

43.57. **(a) IDENTIFY** and **SET UP:** The heavier nucleus will decay into the lighter one.

EXECUTE: ${}^{25}_{13}\text{Al}$ will decay into ${}^{25}_{12}\text{Mg}$.

(b) IDENTIFY and **SET UP:** Determine the emitted particle by balancing A and Z in the decay reaction.

EXECUTE: This gives ${}^{25}_{13}\text{Al} \rightarrow {}^{25}_{12}\text{Mg} + {}^{0}_{+1}\text{e}$. The emitted particle must have charge $+e$ and its nucleon number must be zero. Therefore, it is a β^+ particle, a positron.

(c) IDENTIFY and **SET UP:** Calculate the energy defect ΔM for the reaction and find the energy equivalent of ΔM. Use the nuclear masses for ${}^{25}_{13}\text{Al}$ and ${}^{25}_{12}\text{Mg}$, to avoid confusion in including the correct number of electrons if neutral atom masses are used.

EXECUTE: The nuclear mass for ${}^{25}_{13}\text{Al}$ is $M_{\text{nuc}}({}^{25}_{13}\text{Al}) = 24.990429\text{ u} - 13(0.000548580\text{ u}) = 24.983297\text{ u}$.

The nuclear mass for ${}^{25}_{12}\text{Mg}$ is $M_{\text{nuc}}({}^{25}_{12}\text{Mg}) = 24.985837\text{ u} - 12(0.000548580\text{ u}) = 24.979254\text{ u}$.

The mass defect for the reaction is

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$\Delta M = M_{\text{nuc}}({}^{25}_{13}\text{Al}) - M_{\text{nuc}}({}^{25}_{12}\text{Mg}) - M({}^{0}_{+1}\text{e}) = 24.983297\text{ u} - 24.979254\text{ u} - 0.00054858\text{ u} = 0.003494\text{ u}$

$Q = (\Delta M)c^2 = 0.003494\text{ u}(931.5\text{ MeV/1 u}) = 3.255\text{ MeV}$

EVALUATE: The mass decreases in the decay and energy is released. Note: ${}^{25}_{13}\text{Al}$ can also decay into ${}^{25}_{12}\text{Mg}$ by the electron capture.

${}^{25}_{13}\text{Al} + {}^{0}_{-1}\text{e} \rightarrow {}^{25}_{12}\text{Mg}$

The ${}^{0}_{-1}$ electron in the reaction is an orbital electron in the neutral ${}^{25}_{13}\text{Al}$ atom. The mass defect can be calculated using the nuclear masses:

$\Delta M = M_{\text{nuc}}({}^{25}_{13}\text{Al}) + M({}^{0}_{-1}\text{e}) - M_{\text{nuc}}({}^{25}_{12}\text{Mg}) = 24.983287\text{ u} + 0.00054858\text{ u} - 24.979254\text{ u} = 0.004592\text{ u}.$

$Q = (\Delta M)c^2 = (0.004592\text{ u})(931.5\text{ MeV/1 u}) = 4.277\text{ MeV}$

The mass decreases in the decay and energy is released.

43.58. **IDENTIFY:** Calculate the mass change in the decay. If the mass decreases the decay is energetically allowed.
SET UP: Example 43.5 shows how the released energy is distributed among the decay products for α decay.

EXECUTE: **(a)** $m_{{}^{210}_{84}\text{Po}} - m_{{}^{206}_{82}\text{Pb}} - m_{{}^{4}_{2}\text{He}} = 5.81\times10^{-3}$ u, or $Q = 5.41$ MeV. The energy of the alpha particle is $(206/210)$ times this, or 5.30 MeV (see Example 43.5).

(b) $m_{{}^{210}_{84}\text{Po}} - m_{{}^{209}_{83}\text{Bi}} - m_{{}^{1}_{1}\text{H}} = -5.35\times10^{-3}\text{ u} < 0,$ so the decay is not possible.

(c) $m_{{}^{210}_{84}\text{Po}} - m_{{}^{209}_{84}\text{Po}} - m_{\text{n}} = -8.22\times10^{-3}\text{ u} < 0,$ so the decay is not possible.

(d) $m_{{}^{210}_{85}\text{At}} > m_{{}^{210}_{84}\text{Po}},$ so the decay is not possible (see Problem (43.50)).

(e) $m_{{}^{210}_{83}\text{Bi}} + 2m_{\text{e}} > m_{{}^{210}_{84}\text{Po}},$ so the decay is not possible (see Problem (43.51)).

EVALUATE: Of the decay processes considered in the problem, only α decay is energetically allowed for ${}^{210}_{84}\text{Po}$.

43.59. **IDENTIFY** and **SET UP:** The amount of kinetic energy released is the energy equivalent of the mass change in the decay. $m_{\text{e}} = 0.0005486$ u and the atomic mass of ${}^{14}_{7}\text{N}$ is 14.003074 u. The energy equivalent of 1 u is 931.5 MeV. ${}^{14}\text{C}$ has a half-life of $T_{1/2} = 5730\text{ yr} = 1.81\times10^{11}$ s. The RBE for an electron is 1.0.

EXECUTE: **(a)** ${}^{14}_{6}\text{C} \rightarrow \text{e}^- + {}^{14}_{7}\text{N} + \overline{\nu}_{\text{e}}$.

(b) The mass decrease is $\Delta M = m({}^{14}_{6}\text{C}) - [m_{\text{e}} + m({}^{14}_{7}\text{N})]$. Use nuclear masses, to avoid difficulty in accounting for atomic electrons. The nuclear mass of ${}^{14}_{6}\text{C}$ is $14.003242\text{ u} - 6m_{\text{e}} = 13.999950$ u. The nuclear mass of ${}^{14}_{7}\text{N}$ is $14.003074\text{ u} - 7m_{\text{e}} = 13.999234$ u.

$\Delta M = 13.999950\text{ u} - 13.999234\text{ u} - 0.000549\text{ u} = 1.67\times10^{-4}$ u. The energy equivalent of ΔM is 0.156 MeV.

(c) The mass of carbon is $(0.18)(75\text{ kg}) = 13.5$ kg. From Example 43.9, the activity due to 1 g of carbon in a living organism is 0.255 Bq. The number of decay/s due to 13.5 kg of carbon is $(13.5\times10^3\text{ g})(0.255\text{ Bq/g}) = 3.4\times10^3$ decays/s.

(d) Each decay releases 0.156 MeV so 3.4×10^3 decays/s releases $530\text{ MeV/s} = 8.5\times10^{-11}$ J/s.

(e) The total energy absorbed in 1 year is $(8.5\times10^{-11}\text{ J/s})(3.156\times10^7\text{ s}) = 2.7\times10^{-3}$ J. The absorbed dose is $\dfrac{2.7\times10^{-3}\text{ J}}{75\text{ kg}} = 3.6\times10^{-5}\text{ J/kg} = 36\ \mu\text{Gy} = 3.6$ mrad. With RBE $= 1.0$, the equivalent dose is $36\ \mu\text{Sv} = 3.6$ mrem.

EVALUATE: Section 43.5 says that background radiation exposure is about 1.0 mSv per year. The radiation dose calculated in this problem is much less than this.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

43.60. **IDENTIFY** and **SET UP:** $m_\pi = 264m_e = 2.40\times10^{-28}$ kg. The total energy of the two photons equals the rest mass energy $m_\pi c^2$ of the pion.

EXECUTE: **(a)** $E_{ph} = \frac{1}{2}m_\pi c^2 = \frac{1}{2}(2.40\times10^{-28}\text{ kg})(3.00\times10^8\text{ m/s})^2 = 1.08\times10^{-11}\text{ J} = 67.5\text{ MeV}$

$E_{ph} = \dfrac{hc}{\lambda}$ so $\lambda = \dfrac{hc}{E_{ph}} = \dfrac{1.24\times10^{-6}\text{ eV}\cdot\text{m}}{67.5\times10^6\text{ eV}} = 1.84\times10^{-14}\text{ m} = 18.4\text{ fm}$

These are gamma ray photons, so they have RBE = 1.0.

(b) Each pion delivers $2(1.08\times10^{-11}\text{ J}) = 2.16\times10^{-11}\text{ J}$.

The absorbed dose is 200 rad = 2.00 Gy = 2.00 J/kg.

The energy deposited is $(25\times10^{-3}\text{ kg})(2.00\text{ J/kg}) = 0.050\text{ J}$.

The number of π^0 mesons needed is $\dfrac{0.050\text{ J}}{2.16\times10^{-11}\text{ J/meson}} = 2.3\times10^9$ mesons.

EVALUATE: Note that charge is conserved in the decay since the pion is neutral. If the pion is initially at rest the photons must have equal momenta in opposite directions so the two photons have the same λ and are emitted in opposite directions. The photons also have equal energies since they have the same momentum and $E = pc$.

43.61. **IDENTIFY** and **SET UP:** Find the energy equivalent of the mass decrease. Part of the released energy appears as the emitted photon and the rest as kinetic energy of the electron.

EXECUTE: ${}^{198}_{79}\text{Au} \rightarrow {}^{198}_{80}\text{Hg} + {}^{0}_{-1}\text{e}$

The mass change is $197.968225\text{ u} - 197.966752\text{ u} = 1.473\times10^{-3}\text{ u}$

(The neutral atom masses include 79 electrons before the decay and 80 electrons after the decay. This one additional electron in the product accounts correctly for the electron emitted by the nucleus.) The total energy released in the decay is $(1.473\times10^{-3}\text{ u})(931.5\text{ MeV/u}) = 1.372\text{ MeV}$. This energy is divided between the energy of the emitted photon and the kinetic energy of the β^- particle. Thus the β^- particle has kinetic energy equal to $1.372\text{ MeV} - 0.412\text{ MeV} = 0.960\text{ MeV}$.

EVALUATE: The emitted electron is much lighter than the ${}^{198}_{80}\text{Hg}$ nucleus, so the electron has almost all the final kinetic energy. The final kinetic energy of the ${}^{198}\text{Hg}$ nucleus is very small.

43.62. **IDENTIFY** and **SET UP:** Problem 43.51 shows how to calculate the mass defect using neutral atom masses.

EXECUTE: $m_{{}^{11}_{6}\text{C}} - m_{{}^{11}_{5}\text{B}} - 2m_e = 1.03\times10^{-3}$ u. Decay is energetically possible.

EVALUATE: The energy released in the decay is $(1.03\times10^{-3}\text{ u})(931.5\text{ MeV/u}) = 0.959\text{ MeV}$.

43.63. **IDENTIFY** and **SET UP:** The decay is energetically possible if the total mass decreases. Determine the nucleus produced by the decay by balancing A and Z on both sides of the equation. ${}^{13}_{7}\text{N} \rightarrow {}^{0}_{+1}\text{e} + {}^{13}_{6}\text{C}$. To avoid confusion in including the correct number of electrons with neutral atom masses, use nuclear masses, obtained by subtracting the mass of the atomic electrons from the neutral atom masses.

EXECUTE: The nuclear mass for ${}^{13}_{7}\text{N}$ is $M_{\text{nuc}}({}^{13}_{7}\text{N}) = 13.005739\text{ u} - 7(0.00054858\text{ u}) = 13.001899\text{ u}$.

The nuclear mass for ${}^{13}_{6}\text{C}$ is $M_{\text{nuc}}({}^{13}_{6}\text{C}) = 13.003355\text{ u} - 6(0.00054858\text{ u}) = 13.000064\text{ u}$.

The mass defect for the reaction is

$\Delta M = M_{\text{nuc}}({}^{13}_{7}\text{N}) - M_{\text{nuc}}({}^{13}_{6}\text{C}) - M({}^{0}_{+1}\text{e})$. $\Delta M = 13.001899\text{ u} - 13.000064\text{ u} - 0.00054858\text{ u} = 0.001286\text{ u}$.

EVALUATE: The mass decreases in the decay, so energy is released. This decay is energetically possible.

43.64. **IDENTIFY:** Apply $\left|\dfrac{dN}{dt}\right| = \lambda N_0 e^{-\lambda t}$, with $\lambda = \dfrac{\ln 2}{T_{1/2}}$.

SET UP: $\ln\left|dN/dt\right| = \ln \lambda N_0 - \lambda t$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: **(a)** A least-squares fit to log of the activity *vs.* time gives a slope of magnitude $\lambda = 0.5995\ \text{h}^{-1}$, for a half-life of $\frac{\ln 2}{\lambda} = 1.16\ \text{h}$.

(b) The initial activity is $N_0\lambda$, and this gives $N_0 = \frac{(2.00\times10^4\ \text{Bq})}{(0.5995\ \text{hr}^{-1})(1\ \text{hr}/3600\ \text{s})} = 1.20\times10^8$.

(c) $N = N_0e^{-\lambda t} = 1.81\times10^6$.

EVALUATE: The activity decreases by about $\frac{1}{2}$ in the first hour, so the half-life is about 1 hour.

43.65. **IDENTIFY:** Assume the activity is constant during the year and use the given value of the activity to find the number of decays that occur in one year. Absorbed dose is the energy absorbed per mass of tissue. Equivalent dose is RBE times absorbed dose.

SET UP: For α particles, $\text{RBE} = 20$ (from Table 43.3).

EXECUTE: $(0.63\times10^{-6}\ \text{Ci})(3.7\times10^{10}\ \text{Bq/Ci})(3.156\times10^7\ \text{s}) = 7.357\times10^{11}\ \alpha$ particles. The absorbed dose is $\frac{(7.357\times10^{11})(4.0\times10^6\ \text{eV})(1.602\times10^{-19}\ \text{J/eV})}{(0.50\ \text{kg})} = 0.943\ \text{Gy} = 94.3\ \text{rad}$. The equivalent dose is (20)(94.3 rad) = 1900 rem.

EVALUATE: The equivalent dose is 19 Sv. This is large enough for significant damage to the person.

43.66. **IDENTIFY** and **SET UP:** $T_{1/2} = \frac{\ln 2}{\lambda}$. The mass of a single nucleus is $149m_\text{p} = 2.49\times10^{-25}$ kg.

$dN/dt = -\lambda N$.

EXECUTE: $N = \frac{12.0\times10^{-3}\ \text{kg}}{2.49\times10^{-25}\ \text{kg}} = 4.82\times10^{22}$. $dN/dt = -2.65$ decays/s.

$\lambda = -\frac{dN/dt}{N} = \frac{2.65\ \text{decays/s}}{4.82\times10^{22}} = 5.50\times10^{-23}\ \text{s}^{-1}$; $T_{1/2} = \frac{\ln 2}{\lambda} = 1.26\times10^{22}\ \text{s} = 3.99\times10^{14}\ \text{y}$.

EVALUATE: The half-life determines the fraction of nuclei in a sample that decay each second.

43.67. **IDENTIFY** and **SET UP:** One-half of the sample decays in a time of $T_{1/2}$.

EXECUTE: **(a)** $\frac{10\times10^9\ \text{y}}{200{,}000\ \text{y}} = 5.0\times10^4$.

(b) $\left(\frac{1}{2}\right)^{5.0\times10^4}$. This exponent is too large for most hand-held calculators. But $\left(\frac{1}{2}\right) = 10^{-0.301}$, so $\left(\frac{1}{2}\right)^{5.0\times10^4} = (10^{-0.301})^{5.0\times10^4} = 10^{-15{,}000}$.

EVALUATE: For $N = 1$ after 16 billion years, $N_0 = 10^{15{,}000}$. The mass of this many ^{99}Tc nuclei would be $(99)(1.66\times10^{-27}\ \text{kg})(10^{15{,}000}) = 10^{14{,}750}$ kg, which is immense, far greater than the mass of any star.

43.68. **IDENTIFY:** One rad of absorbed dose is 0.01 J/kg. The equivalent dose in rem is the absorbed dose in rad times the RBE. For part (c) apply Eq. (43.16) with $\lambda = \frac{\ln 2}{T_{1/2}}$.

SET UP: For α particles, $\text{RBE} = 20$ (Table 43.3).

EXECUTE: **(a)** $(6.25\times10^{12})(4.77\times10^6\ \text{MeV})(1.602\times10^{-19}\ \text{J/eV})/(70.0\ \text{kg}) = 0.0682\ \text{Gy} = 0.682\ \text{rad}$.

(b) $(20)(6.82\ \text{rad}) = 136\ \text{rem}$.

(c) $\left|\frac{dN}{dt}\right| = \frac{m}{Am_\text{p}}\frac{\ln(2)}{T_{1/2}} = 1.17\times10^9\ \text{Bq} = 31.6\ \text{mCi}$.

(d) $t = \frac{6.25\times10^{12}}{1.17\times10^9\ \text{Bq}} = 5.34\times10^3\ \text{s}$, about an hour and a half.

EVALUATE: The time in part (d) is so small in comparison with the half-life that the decrease in activity of the source may be neglected.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

43.69. **IDENTIFY:** Use Eq. (43.17) to relate the initial number of radioactive nuclei, N_0, to the number, N, left after time t.

SET UP: We have to be careful; after ^{87}Rb has undergone radioactive decay it is no longer a rubidium atom. Let N_{85} be the number of ^{85}Rb atoms; this number doesn't change. Let N_0 be the number of ^{87}Rb atoms on earth when the solar system was formed. Let N be the present number of ^{87}Rb atoms.

EXECUTE: The present measurements say that $0.2783 = N/(N + N_{85})$.

$(N + N_{85})(0.2783) = N$, so $N = 0.3856N_{85}$. The percentage we are asked to calculate is $N_0/(N_0 + N_{85})$.

N and N_0 are related by $N = N_0e^{-\lambda t}$ so $N_0 = e^{+\lambda t}N$.

Thus $\dfrac{N_0}{N_0 + N_{85}} = \dfrac{Ne^{\lambda t}}{Ne^{\lambda t} + N_{85}} = \dfrac{(0.3855e^{\lambda t})N_{85}}{(0.3856e^{\lambda t})N_{85} + N_{85}} = \dfrac{0.3856e^{\lambda t}}{0.3856e^{\lambda t} + 1}$.

$t = 4.6\times10^9\ \text{y};\ \lambda = \dfrac{0.693}{T_{1/2}} = \dfrac{0.693}{4.75\times10^{10}\ \text{y}} = 1.459\times10^{-11}\ \text{y}^{-1}$

$e^{\lambda t} = e^{(1.459\times10^{-11}\ \text{y}^{-1})(4.6\times10^9\ \text{y})} = e^{0.06711} = 1.0694$

Thus $\dfrac{N_0}{N_0 + N_{85}} = \dfrac{(0.3856)(1.0694)}{(0.3856)(1.0694) + 1} = 29.2\%$.

EVALUATE: The half-life for ^{87}Rb is a factor of 10 larger than the age of the solar system, so only a small fraction of the ^{87}Rb nuclei initially present have decayed; the percentage of rubidium atoms that are radioactive is only a bit less now than it was when the solar system was formed.

43.70. **IDENTIFY:** From Example 43.5, the kinetic energy of the particle is $K = \dfrac{M_\alpha}{M_\alpha + m}K_\infty$, where K_∞ is the energy that the α-particle would have if the nucleus were infinitely massive. K_∞ is equal to the total energy released in the reaction. The energy released in the reaction is the energy equivalent of the mass decrease in the reaction.

SET UP: 1 u is equivalent to 931.5 MeV. The atomic mass of ^4_2He is 4.002603 u.

EXECUTE: $M = M_{\text{Os}} - M_\alpha - K_\infty = M_{\text{Os}} - M_\alpha - \dfrac{186}{182}(2.76\ \text{MeV}/c^2) = 181.94821\ \text{u}$.

EVALUATE: The daughter nucleus is $^{182}_{74}\text{W}$.

43.71. **IDENTIFY** and **SET UP:** Find the energy emitted and the energy absorbed each second. Convert the absorbed energy to absorbed dose and to equivalent dose.

EXECUTE: **(a)** First find the number of decays each second:

$2.6\times10^{-4}\ \text{Ci}\left(\dfrac{3.70\times10^{10}\ \text{decays/s}}{1\ \text{Ci}}\right) = 9.6\times10^6\ \text{decays/s}$. The average energy per decay is 1.25 MeV, and one-half of this energy is deposited in the tumor. The energy delivered to the tumor per second then is $\frac{1}{2}(9.6\times10^6\ \text{decays/s})(1.25\times10^6\ \text{eV/decay})(1.602\times10^{-19}\ \text{J/eV}) = 9.6\times10^{-7}\ \text{J/s}$.

(b) The absorbed dose is the energy absorbed divided by the mass of the tissue:

$\dfrac{9.6\times10^{-7}\ \text{J/s}}{0.200\ \text{kg}} = (4.8\times10^{-6}\ \text{J/kg}\cdot\text{s})(1\ \text{rad}/(0.01\ \text{J/kg})) = 4.8\times10^{-4}\ \text{rad/s}$.

(c) equivalent dose (REM) = RBE × absorbed dose (rad). In one second the equivalent dose is

$(0.70)(4.8\times10^{-4}\ \text{rad}) = 3.4\times10^{-4}\ \text{rem}$.

(d) $(200\ \text{rem})/(3.4\times10^{-4}\ \text{rem/s}) = (5.9\times10^5\ \text{s})(1\ \text{h}/3600\ \text{s}) = 164\ \text{h} = 6.9\ \text{days}$.

EVALUATE: The activity of the source is small so that absorbed energy per second is small and it takes several days for an equivalent dose of 200 rem to be absorbed by the tumor. A 200-rem dose equals 2.00 Sv and this is large enough to damage the tissue of the tumor.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

43.72. **IDENTIFY:** Apply Eq. (43.17), with $\lambda = \dfrac{\ln 2}{T_{1/2}}$.

SET UP: Let 1 refer to $^{15}_{8}\text{O}$ and 2 refer to $^{19}_{8}\text{O}$. $\dfrac{N_1}{N_2} = \dfrac{e^{-\lambda_1 t}}{e^{-\lambda_2 t}}$, since N_0 is the same for the two isotopes.

$e^{-\lambda t} = e^{-(\ln 2/T_{1/2})t} = (e^{-\ln 2})^{t/T_{1/2}} = (\frac{1}{2})^{t/T_{1/2}}$. $\dfrac{N_1}{N_2} = \left(\dfrac{1}{2}\right)^{(t/(T_{1/2})_1)/(t/(T_{1/2})_2)} = 2^{t\left(\frac{1}{(T_{1/2})_2} - \frac{1}{(T_{1/2})_1}\right)}$.

EXECUTE: **(a)** After $4.0 \text{ min} = 240 \text{ s}$, the ratio of the number of nuclei is

$$\frac{2^{-240/122.2}}{2^{-240/26.9}} = 2^{(240)\left(\frac{1}{26.9} - \frac{1}{122.2}\right)} = 124.$$

(b) After $15.0 \text{ min} = 900 \text{ s}$, the ratio is 7.15×10^7.

EVALUATE: The $^{19}_{8}\text{O}$ nuclei decay at a greater rate, so the ratio $N(^{15}_{8}\text{O})/N(^{19}_{8}\text{O})$ increases with time.

43.73. **IDENTIFY** and **SET UP:** The number of radioactive nuclei left after time t is given by $N = N_0 e^{-\lambda t}$. The problem says $N/N_0 = 0.29$; solve for t.

EXECUTE: $0.29 = e^{-\lambda t}$ so $\ln(0.29) = -\lambda t$ and $t = -\ln(0.29)/\lambda$. Example 43.9 gives $\lambda = 1.209 \times 10^{-4} \text{ y}^{-1}$ for ^{14}C. Thus $t = \dfrac{-\ln(0.29)}{1.209 \times 10^{-4} \text{ y}} = 1.0 \times 10^4 \text{ y}$.

EVALUATE: The half-life of ^{14}C is 5730 y, so our calculated t is about 1.75 half-lives, so the fraction remaining is around $\left(\frac{1}{2}\right)^{1.75} = 0.30$.

43.74. **IDENTIFY:** The tritium (H-3) decays to He-3. The ratio of the number of He-3 atoms to H-3 atoms allows us to calculate the time since the decay began, which is when the H-3 was formed by the nuclear explosion. The H-3 decay is exponential.

SET UP: The number of tritium (H-3) nuclei decreases exponentially as $N_{\text{H}} = N_{0,\text{H}} e^{-\lambda t}$, with a half-life of 12.3 years. The amount of He-3 present after a time t is equal to the original amount of tritium minus the number of tritium nuclei that are still undecayed after time t.

EXECUTE: The number of He-3 nuclei after time t is

$$N_{\text{He}} = N_{0,\text{H}} - N_{\text{H}} = N_{0,\text{H}} - N_{0,\text{H}} e^{-\lambda t} = N_{0,\text{H}}(1 - e^{-\lambda t}).$$

Taking the ratio of the number of He-3 atoms to the number of tritium (H-3) atoms gives

$$\frac{N_{\text{He}}}{N_{\text{H}}} = \frac{N_{0,\text{H}}(1 - e^{-\lambda t})}{N_{0,\text{H}} e^{-\lambda t}} = \frac{1 - e^{-\lambda t}}{e^{-\lambda t}} = e^{\lambda t} - 1.$$

Solving for t gives $t = \dfrac{\ln(1 + N_{\text{He}}/N_{\text{H}})}{\lambda}$. Using the given numbers and $T_{1/2} = \dfrac{\ln 2}{\lambda}$, we have

$\lambda = \dfrac{\ln 2}{T_{1/2}} = \dfrac{\ln 2}{12.3 \text{ y}} = 0.0563/\text{y}$ and $t = \dfrac{\ln(1 + 4.3)}{0.0563/\text{y}} = 30$ years.

EVALUATE: One limitation on this method would be that after many years the ratio of H to He would be too small to measure accurately.

43.75. **(a) IDENTIFY** and **SET UP:** Use Eq. (43.1) to calculate the radius R of a $^{2}_{1}\text{H}$ nucleus. Calculate the Coulomb potential energy (Eq. 23.9) of the two nuclei when they just touch.

EXECUTE: The radius of $^{2}_{1}\text{H}$ is $R = (1.2 \times 10^{-15} \text{ m})(2)^{1/3} = 1.51 \times 10^{-15} \text{ m}$. The barrier energy is the Coulomb potential energy of two $^{2}_{1}\text{H}$ nuclei with their centers separated by twice this distance:

$$U = \frac{1}{4\pi\epsilon_0}\frac{e^2}{r} = (8.988 \times 10^9 \text{ N} \cdot \text{m}^2/\text{C}^2)\frac{(1.602 \times 10^{-19} \text{ C})^2}{2(1.51 \times 10^{-15} \text{ m})} = 7.64 \times 10^{-14} \text{ J} = 0.48 \text{ MeV}$$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) IDENTIFY and **SET UP:** Find the energy equivalent of the mass decrease.

EXECUTE: ${}^2_1\text{H} + {}^2_1\text{H} \rightarrow {}^3_2\text{He} + {}^1_0\text{n}$

If we use neutral atom masses there are two electrons on each side of the reaction equation, so their masses cancel. The neutral atom masses are given in Table 43.2.

${}^2_1\text{H} + {}^2_1\text{H}$ has mass $2(2.014102\text{ u}) = 4.028204\text{ u}$

${}^3_2\text{He} + {}^1_0\text{n}$ has mass $3.016029\text{ u} + 1.008665\text{ u} = 4.024694\text{ u}$

The mass decrease is $4.028204\text{ u} - 4.024694\text{ u} = 3.510\times10^{-3}\text{ u}$. This corresponds to a liberated energy of $(3.510\times10^{-3}\text{ u})(931.5\text{ MeV/u}) = 3.270\text{ MeV}$, or $(3.270\times10^{6}\text{ eV})(1.602\times10^{-19}\text{ J/eV}) = 5.239\times10^{-13}\text{ J}$.

(c) IDENTIFY and **SET UP:** We know the energy released when two ${}^2_1\text{H}$ nuclei fuse. Find the number of reactions obtained with one mole of ${}^2_1\text{H}$.

EXECUTE: Each reaction takes two ${}^2_1\text{H}$ nuclei. Each mole of D_2 has 6.022×10^{23} molecules, so 6.022×10^{23} pairs of atoms. The energy liberated when one mole of deuterium undergoes fusion is $(6.022\times10^{23})(5.239\times10^{-13}\text{ J}) = 3.155\times10^{11}\text{ J/mol}$.

EVALUATE: The energy liberated per mole is more than a million times larger than from chemical combustion of one mole of hydrogen gas.

43.76. IDENTIFY: In terms of the number ΔN of cesium atoms that decay in one week and the mass $m = 1.0\text{ kg}$, the equivalent dose is $3.5\text{ Sv} = \dfrac{\Delta N}{m}((\text{RBE})_\gamma E_\gamma + (\text{RBE})_e E_e)$.

SET UP: $1\text{ day} = 8.64\times10^4\text{ s}$. $1\text{ year} = 3.156\times10^7\text{ s}$.

EXECUTE: $3.5\text{ Sv} = \dfrac{\Delta N}{m}((1)(0.66\text{ MeV}) + (1.5)(0.51\text{ MeV})) = \dfrac{\Delta N}{m}(2.283\times10^{-13}\text{ J})$, so

$$\Delta N = \frac{(1.0\text{ kg})(3.5\text{ Sv})}{(2.283\times10^{-13}\text{ J})} = 1.535\times10^{13}.\quad \lambda = \frac{\ln 2}{T_{1/2}} = \frac{0.693}{(30.07\text{ y})(3.156\times10^7\text{ sec/y})} = 7.30\times10^{-10}\text{ sec}^{-1}.$$

$$\Delta N = |dN/dt|t = \lambda N t,\text{ so } N = \frac{\Delta N}{\lambda t} = \frac{1.535\times10^{13}}{(7.30\times10^{-10}\text{ s}^{-1})(7\text{ days})(8.64\times10^4\text{ s/day})} = 3.48\times10^{16}.$$

EVALUATE: We have assumed that $|dN/dt|$ is constant during a time of one week. That is a very good approximation, since the half-life is much greater than one week.

43.77. IDENTIFY: The speed of the center of mass is $v_{\text{cm}} = v\dfrac{m}{m+M}$, where v is the speed of the colliding particle in the lab system. Let $K_{\text{cm}} \equiv K'$ be the kinetic energy in the center-of-mass system. K' is calculated from the speed of each particle relative to the center of mass.

SET UP: Let v'_m and v'_M be the speeds of the two particles in the center-of-mass system. Q is the reaction energy, as defined in Eq. (43.23). For an endoergic reaction, Q is negative.

EXECUTE: **(a)** $v'_m = v - v\dfrac{m}{m+M} = \left(\dfrac{M}{m+M}\right)v$. $v'_M = \dfrac{vm}{m+M}$.

$$K' = \frac{1}{2}mv'^2_m + \frac{1}{2}Mv'^2_M = \frac{1}{2}\frac{mM^2}{(m+M)^2}v^2 + \frac{1}{2}\frac{Mm^2}{(m+M)^2}v^2 = \frac{1}{2}\frac{M}{(m+M)}\left(\frac{mM}{m+M} + \frac{m^2}{m+M}\right)v^2.$$

$$K' = \frac{M}{m+M}\left(\frac{1}{2}mv^2\right) \Rightarrow K' = \frac{M}{m+M}K \equiv K_{\text{cm}}.$$

(b) For an endoergic reaction $K_{\text{cm}} = -Q (Q < 0)$ at threshold. Putting this into part (a) gives

$$-Q = \frac{M}{M+m}K_{\text{th}} \Rightarrow K_{\text{th}} = \frac{-(M+m)}{M}Q.$$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: For $m = M$, $K' = K/2$. In this case, only half the kinetic energy of the colliding particle, as measured in the lab, is available to the reaction. Conservation of linear momentum requires that half of K be retained as translational kinetic energy.

43.78. **IDENTIFY** and **SET UP:** Calculate the energy equivalent of the mass decrease.

EXECUTE: $\Delta m = M(^{235}_{92}\text{U}) - M(^{140}_{54}\text{Xe}) - M(^{94}_{38}\text{Sr}) - m_\text{n}$

$\Delta m = 235.043923\text{ u} - 139.921636\text{ u} - 93.915360\text{ u} - 1.008665\text{ u} = 0.1983\text{ u}$

$\Rightarrow E = (\Delta m)c^2 = (0.1983\text{ u})(931.5\text{ MeV/u}) = 185\text{ MeV}.$

EVALUATE: The calculation with neutral atom masses includes 92 electrons on each side of the reaction equation, so the electron masses cancel.

43.79. **IDENTIFY** and **SET UP:** $\left|\frac{dN}{dt}\right| = \lambda N = \lambda N_0 e^{-\lambda t}$ for each species. $\ln|dN/dt| = \ln(\lambda N_0) - \lambda t$. The longer-lived nuclide dominates the activity for the larger values of t and when this is the case a plot of $\ln|dN/dt|$ versus t gives a straight line with slope $-\lambda$.

EXECUTE: **(a)** A least-squares fit of the log of the activity *vs.* time for the times later than 4.0 h gives a fit with correlation $-(1 - 2\times10^{-6})$ and decay constant of 0.361 h^{-1}, corresponding to a half-life of 1.92 h. Extrapolating this back to time 0 gives a contribution to the rate of about 2500/s for this longer-lived species. A least-squares fit of the log of the activity *vs*. time for times earlier than 2.0 h gives a fit with correlation $= 0.994$, indicating the presence of only two species.

(b) By trial and error, the data is fit by a decay rate modeled by $R = (5000\text{ Bq})e^{-t(1.733/\text{h})} + (2500\text{ Bq})e^{-t(0.361/\text{h})}$. This would correspond to half-lives of 0.400 h and 1.92 h.

(c) In this model, there are 1.04×10^7 of the shorter-lived species and 2.49×10^7 of the longer-lived species.

(d) After 5.0h, there would be 1.80×10^3 of the shorter-lived species and 4.10×10^6 of the longer-lived species.

EVALUATE: After 5.0 h, the number of shorter-lived nuclei is much less than the number of longer-lived nuclei.

43.80. **IDENTIFY:** Apply $A = A_0 e^{-\lambda t}$, where A is the activity and $\lambda = \frac{\ln 2}{T_{1/2}}$. This equation can be written as $A = A_0 2^{-(t/T_{1/2})}$. The activity of the engine oil is proportional to the mass worn from the piston rings.

SET UP: $1\text{ Ci} = 3.7\times10^{10}\text{ Bq}$

EXECUTE: The activity of the original iron, after 1000 hours of operation, would be $(9.4\times10^{-6}\text{ Ci})\,(3.7\times10^{10}\text{ Bq/Ci})2^{-(1000\text{ h})/(45\text{ d}\times24\text{ h/d})} = 1.8306\times10^5\text{ Bq}$. The activity of the oil is 84 Bq, or 4.5886×10^{-4} of the total iron activity, and this must be the fraction of the mass worn, or mass of 4.59×10^{-2} g. The rate at which the piston rings lost their mass is then 4.59×10^{-5} g/h.

EVALUATE: This method is very sensitive and can measure very small amounts of wear.

44

PARTICLE PHYSICS AND COSMOLOGY

44.1. **IDENTIFY** and **SET UP:** By momentum conservation the two photons must have equal and opposite momenta. Then $E = pc$ says the photons must have equal energies. Their total energy must equal the rest mass energy $E = mc^2$ of the pion. Once we have found the photon energy we can use $E = hf$ to calculate the photon frequency and use $\lambda = c/f$ to calculate the wavelength.

EXECUTE: The mass of the pion is $270m_e$, so the rest energy of the pion is $270(0.511 \text{ MeV}) = 138 \text{ MeV}$. Each photon has half this energy, or 69 MeV.

$$E = hf \text{ so } f = \frac{E}{h} = \frac{(69\times10^6 \text{ eV})(1.602\times10^{-19} \text{ J/eV})}{6.626\times10^{-34} \text{ J}\cdot\text{s}} = 1.7\times10^{22} \text{ Hz}$$

$$\lambda = \frac{c}{f} = \frac{2.998\times10^8 \text{ m/s}}{1.7\times10^{22} \text{ Hz}} = 1.8\times10^{-14} \text{ m} = 18 \text{ fm}.$$

EVALUATE: These photons are in the gamma ray part of the electromagnetic spectrum.

44.2. **IDENTIFY:** The energy (rest mass plus kinetic) of the muons is equal to the energy of the photons.

SET UP: $\gamma + \gamma \to \mu^+ + \mu^-$, $E = hc/\lambda$. $K = (\gamma - 1)mc^2$.

EXECUTE: **(a)** $\gamma + \gamma \to \mu^+ + \mu^-$. Each photon must have energy equal to the rest mass energy of a μ^+ or a μ^-: $\frac{hc}{\lambda} = 105.7\times10^6$ eV. $\lambda = \frac{(4.136\times10^{-15} \text{ eV}\cdot\text{s})(2.998\times10^8 \text{ m/s})}{105.7\times10^6 \text{ eV}} = 1.17\times10^{-14} \text{ m} = 0.0117 \text{ pm}$.

Conservation of linear momentum requires that the μ^+ and μ^- move in opposite directions with equal speeds.

(b) $\lambda = \frac{0.0117 \text{ pm}}{2}$ so each photon has energy $2(105.7 \text{ MeV}) = 211.4 \text{ MeV}$. The energy released in the reaction is $2(211.4 \text{ MeV}) - 2(105.7 \text{ MeV}) = 211.4 \text{ MeV}$. The kinetic energy of each muon is half this, 105.7 MeV. Using $K = (\gamma - 1)mc^2$ gives $\gamma - 1 = \frac{K}{mc^2} = \frac{105.7 \text{ MeV}}{105.7 \text{ MeV}} = 1$. $\gamma = 2$. $\gamma = \frac{1}{\sqrt{1 - v^2/c^2}}$.

$\frac{v^2}{c^2} = 1 - \frac{1}{\gamma^2}$. $v = \sqrt{\frac{3}{4}}c = 0.866c = 2.60\times10^8$ m/s.

EVALUATE: The muon speeds are a substantial fraction of the speed of light, so special relativity must be used.

44.3. **IDENTIFY:** The energy released is the energy equivalent of the mass decrease that occurs in the decay.

SET UP: The mass of the pion is $m_{\pi^+} = 270m_e$ and the mass of the muon is $m_{\mu^+} = 207m_e$. The rest energy of an electron is 0.511 MeV.

EXECUTE: **(a)** $\Delta m = m_{\pi+} - m_{\mu+} = 270m_e - 207m_e = 63m_e \Rightarrow E = 63(0.511 \text{ MeV}) = 32 \text{ MeV}$.

EVALUATE: **(b)** A positive muon has less mass than a positive pion, so if the decay from muon to pion was to happen, you could always find a frame where energy was not conserved. This cannot occur.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

44.4. **IDENTIFY:** In the annihilation the total energy of the proton and antiproton is converted to the energy of the two photons.

SET UP: The rest energy of a proton or antiproton is 938.3 MeV. Conservation of linear momentum requires that the two photons have equal energies.

EXECUTE: **(a)** The energy will be the proton rest energy, 938.3 MeV, corresponding to a frequency of 2.27×10^{23} Hz and a wavelength of 1.32×10^{-15} m.

(b) The energy of each photon will be $938.3\text{ MeV}+830\text{ MeV}=1768\text{ MeV}$, with frequency 42.8×10^{22} Hz and wavelength 7.02×10^{-16} m.

EVALUATE: When the initial kinetic energy of the proton and antiproton increases, the wavelength of the photons decreases.

44.5. **IDENTIFY:** The kinetic energy of the alpha particle is due to the mass decrease.

SET UP and **EXECUTE:** ${}^1_0\text{n}+{}^{10}_5\text{B}\rightarrow{}^7_3\text{Li}+{}^4_2\text{He}$. The mass decrease in the reaction is

$m({}^1_0\text{n})+m({}^{10}_5\text{B})-m({}^7_3\text{Li})-m({}^4_2\text{He})=1.008665\text{ u}+10.012937\text{ u}-7.016004\text{ u}-4.002603\text{ u}=0.002995\text{ u}$

and the energy released is $E=(0.002995\text{ u})(931.5\text{ MeV/u})=2.79\text{ MeV}$. Assuming the initial momentum is zero, $m_{\text{Li}}v_{\text{Li}}=m_{\text{He}}v_{\text{He}}$ and $v_{\text{Li}}=\dfrac{m_{\text{He}}}{m_{\text{Li}}}v_{\text{He}}$. $\frac{1}{2}m_{\text{Li}}v_{\text{Li}}^2+\frac{1}{2}m_{\text{He}}v_{\text{He}}^2=E$ becomes

$\frac{1}{2}m_{\text{Li}}\left(\dfrac{m_{\text{He}}}{m_{\text{Li}}}\right)^2v_{\text{He}}^2+\frac{1}{2}m_{\text{He}}v_{\text{He}}^2=E$ and $v_{\text{He}}=\sqrt{\dfrac{2E}{m_{\text{He}}}\left(\dfrac{m_{\text{Li}}}{m_{\text{Li}}+m_{\text{He}}}\right)}$. $E=4.470\times10^{-13}$ J.

$m_{\text{He}}=4.002603\text{ u}-2(0.0005486\text{ u})=4.0015\text{ u}=6.645\times10^{-27}$ kg.

$m_{\text{Li}}=7.016004\text{ u}-3(0.0005486\text{ u})=7.0144\text{ u}$. This gives $v_{\text{He}}=9.26\times10^6$ m/s.

EVALUATE: The speed of the alpha particle is considerably less than the speed of light, so it is not necessary to use the more complicated relativistic formulas.

44.6. **IDENTIFY:** The range is limited by the lifetime of the particle, which itself is limited by the uncertainty principle.

SET UP: $\Delta E\Delta t=\hbar/2$.

EXECUTE: $\Delta t=\dfrac{\hbar}{2\Delta E}=\dfrac{(4.136\times10^{-15}\text{ eV}\cdot\text{s}/2\pi)}{2(783\times10^6\text{ eV})}=4.20\times10^{-25}$ s. The range of the force is

$c\Delta t=(2.998\times10^8\text{ m/s})(4.20\times10^{-25}\text{ s})=1.26\times10^{-16}\text{ m}=0.126\text{ fm}$.

EVALUATE: This range is less than the diameter of an atomic nucleus.

44.7. **IDENTIFY:** The antimatter annihilates with an equal amount of matter.

SET UP: The energy of the matter is $E=(\Delta m)c^2$.

EXECUTE: Putting in the numbers gives

$$E=(\Delta m)c^2=(400\text{ kg}+400\text{ kg})(3.00\times10^8\text{ m/s})^2=7.2\times10^{19}\text{ J}.$$

This is about 70% of the annual energy use in the U.S.

EVALUATE: If this huge amount of energy were released suddenly, it would blow up the *Enterprise*! Getting useable energy from matter-antimatter annihiliation is not so easy to do!

44.8. **IDENTIFY:** With a stationary target, only part of the initial kinetic energy of the moving electron is available. Momentum conservation tells us that there must be nonzero momentum after the collision, which means that there must also be leftover kinetic energy. Therefore not all of the initial energy is available.

SET UP: The available energy is given by $E_{\text{a}}^2=2mc^2(E_m+mc^2)$ for two particles of equal mass when one is initially stationary. In this case, the initial kinetic energy $(20.0\text{ GeV}=20{,}000\text{ MeV})$ is much more than the rest energy of the electron (0.511 MeV), so the formula for available energy reduces to $E_{\text{a}}=\sqrt{2mc^2E_m}$.

EXECUTE: **(a)** Using the formula for available energy gives

$$E_{\text{a}}=\sqrt{2mc^2E_m}=\sqrt{2(0.511\text{ MeV})(20.0\text{ GeV})}=143\text{ MeV}$$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) For colliding beams of equal mass, each particle has half the available energy, so each has 71.5 MeV. The *total* energy is twice this, or 143 MeV.

EVALUATE: Colliding beams provide considerably more available energy to do experiments than do beams hitting a stationary target. With a stationary electron target in part (a), we had to give the moving electron 20,000 MeV of energy to get the same available energy that we got with only 143 MeV of energy with the colliding beams.

44.9. **(a) IDENTIFY** and **SET UP:** Eq. (44.7) says $\omega = |q|B/m$ so $B = m\omega/|q|$. And since $\omega = 2\pi f$, this becomes $B = 2\pi mf/|q|$.

EXECUTE: A deuteron is a deuterium nucleus ($^2_1$H). Its charge is $q = +e$. Its mass is the mass of the neutral $^2_1$H atom (Table 43.2) minus the mass of the one atomic electron:

$m = 2.014102\ \text{u} - 0.0005486\ \text{u} = 2.013553\ \text{u}(1.66054\times10^{-27}\ \text{kg/1 u}) = 3.344\times10^{-27}\ \text{kg}$

$$B = \frac{2\pi mf}{|q|} = \frac{2\pi(3.344\times10^{-27}\ \text{kg})(9.00\times10^{6}\ \text{Hz})}{1.602\times10^{-19}\ \text{C}} = 1.18\ \text{T}$$

(b) Eq. (44.8): $K = \dfrac{q^2B^2R^2}{2m} = \dfrac{[(1.602\times10^{-19}\ \text{C})(1.18\ \text{T})(0.320\ \text{m})]^2}{2(3.344\times10^{-27}\ \text{kg})}$.

$K = 5.471\times10^{-13}\ \text{J} = (5.471\times10^{-13}\ \text{J})(1\ \text{eV}/1.602\times10^{-19}\ \text{J}) = 3.42\ \text{MeV}$

$K = \frac{1}{2}mv^2$ so $v = \sqrt{\dfrac{2K}{m}} = \sqrt{\dfrac{2(5.471\times10^{-13}\ \text{J})}{3.344\times10^{-27}\ \text{kg}}} = 1.81\times10^{7}\ \text{m/s}$

EVALUATE: $v/c = 0.06$, so it is ok to use the nonrelativistic expression for kinetic energy.

44.10. **IDENTIFY:** Apply Eqs. (44.6) and (44.7). $f = \dfrac{\omega}{2\pi}$. In part (c) apply conservation of energy.

SET UP: The relativistic form for the kinetic energy is $K = (\gamma - 1)mc^2$. A proton has mass 1.67×10^{-27} kg.

EXECUTE: **(a)** $2f = \dfrac{\omega}{\pi} = \dfrac{eB}{m\pi} = 3.97\times10^{7}/\text{s}$.

(b) $v = \omega R = \dfrac{eBR}{m} = 3.12\times10^{7}\ \text{m/s}$

(c) For three-figure precision, the relativistic form of the kinetic energy must be used, $eV = (\gamma - 1)mc^2$,

so $eV = (\gamma - 1)mc^2$, so $V = \dfrac{(\gamma - 1)mc^2}{e} = 5.11\times10^{6}\ \text{V}$.

EVALUATE: The kinetic energy of the protons in part (c) is 5.11 MeV. This is 0.5% of their rest energy. If the nonrelativistic expression for the kinetic energy is used, we obtain $V = 5.08\times10^{6}$ V.

44.11. **(a) IDENTIFY** and **SET UP:** The masses of the target and projectile particles are equal, so Eq. (44.10) can be used. $E_a^2 = 2mc^2(E_m + mc^2)$. E_a is specified; solve for the energy E_m of the beam particles.

EXECUTE: $E_m = \dfrac{E_a^2}{2mc^2} - mc^2$

The mass for the alpha particle can be calculated by subtracting two electron masses from the $^4_2$He atomic mass:

$m = m_\alpha = 4.002603\ \text{u} - 2(0.0005486\ \text{u}) = 4.001506\ \text{u}$

Then $mc^2 = (4.001506\ \text{u})(931.5\ \text{MeV/u}) = 3.727\ \text{GeV}$.

$$E_m = \frac{E_a^2}{2mc^2} - mc^2 = \frac{(16.0\ \text{GeV})^2}{2(3.727\ \text{GeV})} - 3.727\ \text{GeV} = 30.6\ \text{GeV}.$$

(b) Each beam must have $\frac{1}{2}E_a = 8.0$ GeV.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EVALUATE: For a stationary target the beam energy is nearly twice the available energy. In a colliding beam experiment all the energy is available and each beam needs to have just half the required available energy.

44.12. **IDENTIFY:** $E = \gamma mc^2$, where $\gamma = \dfrac{1}{\sqrt{1 - v^2/c^2}}$. The relativistic version of Eq. (44.7) is $\omega = \dfrac{|q|B}{m\gamma}$.

SET UP: A proton has rest energy $mc^2 = 938.3$ MeV.

EXECUTE: **(a)** $\gamma = \dfrac{E}{mc^2} = \dfrac{1000 \times 10^3 \text{ MeV}}{938.3 \text{ MeV}} = 1065.8$, so $v = 0.999999559c$.

(b) Nonrelativistic: $\omega = \dfrac{eB}{m} = 3.83 \times 10^8$ rad/s.

Relativistic: $\omega = \dfrac{eB}{m}\dfrac{1}{\gamma} = 3.59 \times 10^5$ rad/s.

EVALUATE: The relativistic expression gives a smaller value for ω.

44.13. **(a) IDENTIFY** and **SET UP:** For a proton beam on a stationary proton target and since E_a is much larger than the proton rest energy we can use Eq. (44.11): $E_a^2 = 2mc^2E_m$.

EXECUTE: $E_m = \dfrac{E_a^2}{2mc^2} = \dfrac{(77.4 \text{ GeV})^2}{2(0.938 \text{ GeV})} = 3200 \text{ GeV}$

(b) IDENTIFY and **SET UP:** For colliding beams the total momentum is zero and the available energy E_a is the total energy for the two colliding particles.

EXECUTE: For proton-proton collisions the colliding beams each have the same energy, so the total energy of each beam is $\frac{1}{2}E_a = 38.7$ GeV.

EVALUATE: For a stationary target less than 3% of the beam energy is available for conversion into mass. The beam energy for a colliding beam experiment is a factor of (1/83) times smaller than the required energy for a stationary target experiment.

44.14. **IDENTIFY:** Only part of the initial kinetic energy of the moving electron is available. Momentum conservation tells us that there must be nonzero momentum after the collision, which means that there must also be left over kinetic energy.

SET UP: To create the η^0, the minimum available energy must be equal to the rest mass energy of the products, which in this case is the η^0 plus two protons. In a collider, all of the initial energy is available, so the beam energy is the available energy.

EXECUTE: The minimum amount of available energy must be rest mass energy

$$E_a = 2m_p + m_\eta = 2(938.3 \text{ MeV}) + 547.3 \text{ MeV} = 2420 \text{ MeV}$$

Each incident proton has half of the rest mass energy, or $1210 \text{ MeV} = 1.21 \text{ GeV}$.

EVALUATE: As we saw in Problem 44.13, we would need much more initial energy if one of the initial protons were stationary. The result here (1.21 GeV) is the *minimum* amount of energy needed; the original protons could have more energy and still trigger this reaction.

44.15. **IDENTIFY:** The kinetic energy comes from the mass decrease.

SET UP: Table 44.3 gives $m(\text{K}^+) = 493.7 \text{ MeV}/c^2$, $m(\pi^0) = 135.0 \text{ MeV}/c^2$, and $m(\pi^\pm) = 139.6 \text{ MeV}/c^2$.

EXECUTE: **(a)** Charge must be conserved, so $\text{K}^+ \to \pi^0 + \pi^+$ is the only possible decay.

(b) The mass decrease is

$m(\text{K}^+) - m(\pi^0) - m(\pi^+) = 493.7 \text{ MeV}/c^2 - 135.0 \text{ MeV}/c^2 - 139.6 \text{ MeV}/c^2 = 219.1 \text{ MeV}/c^2$. The energy released is 219.1 MeV.

EVALUATE: The π mesons do not share this energy equally since they do not have equal masses.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

44.16. **IDENTIFY:** The energy is due to the mass difference.

SET UP: The energy released is the energy equivalent of the mass decrease. From Table 44.3, the μ^- has mass $105.7\ \text{MeV}/c^2$ and the e^- has mass $0.511\ \text{MeV}/c^2$.

EXECUTE: The mass decrease is $105.7\ \text{MeV}/c^2 - 0.511\ \text{MeV}/c^2 = 105.2\ \text{MeV}/c^2$ and the energy equivalent is 105.2 MeV.

EVALUATE: The electron does not get all of this energy; the neutrinos also get some of it.

44.17. **IDENTIFY:** Table 44.1 gives the mass in units of GeV/c^2. This is the value of mc^2 for the particle.

SET UP: $m(Z^0) = 91.2\ \text{GeV}/c^2$.

EXECUTE: $E = 91.2\times10^9\ \text{eV} = 1.461\times10^{-8}\ \text{J};\ m = E/c^2 = 1.63\times10^{-25}\ \text{kg};\ m(Z^0)/m(\text{p}) = 97.2$

EVALUATE: The rest energy of a proton is 938 MeV; the rest energy of the Z^0 is 97.2 times as great.

44.18. **IDENTIFY:** The energy of the photon equals the difference in the rest energies of the Σ^0 and Λ^0. For a photon, $p = E/c$.

SET UP: Table 44.3 gives the rest energies to be 1193 MeV for the Σ^0 and 1116 MeV for the Λ^0.

EXECUTE: **(a)** We shall assume that the kinetic energy of the Λ^0 is negligible. In that case we can set the value of the photon's energy equal to Q:

$$Q = (1193 - 1116)\ \text{MeV} = 77\ \text{MeV} = E_{\text{photon}}.$$

(b) The momentum of this photon is

$$p = \frac{E_{\text{photon}}}{c} = \frac{(77\times10^6\ \text{eV})(1.60\times10^{-18}\ \text{J/eV})}{(3.00\times10^8\ \text{m/s})} = 4.1\times10^{-20}\ \text{kg}\cdot\text{m/s}$$

EVALUATE: To justify our original assumption, we can calculate the kinetic energy of a Λ^0 that has this value of momentum

$$K_{\Lambda^0} = \frac{p^2}{2m} = \frac{E^2}{2mc^2} = \frac{(77\ \text{MeV})^2}{2(1116\ \text{MeV})} = 2.7\ \text{MeV} \ll Q = 77\ \text{MeV}.$$

Thus, we can ignore the momentum of the Λ^0 without introducing a large error.

44.19. **IDENTIFY** and **SET UP:** Find the energy equivalent of the mass decrease.

EXECUTE: The mass decrease is $m(\Sigma^+) - m(\text{p}) - m(\pi^0)$ and the energy released is $mc^2(\Sigma^+) - mc^2(\text{p}) - mc^2(\pi^0) = 1189\ \text{MeV} - 938.3\ \text{MeV} - 135.0\ \text{MeV} = 116\ \text{MeV}$. (The mc^2 values for each particle were taken from Table 44.3.)

EVALUATE: The mass of the decay products is less than the mass of the original particle, so the decay is energetically allowed and energy is released.

44.20. **IDENTIFY:** If the initial and final rest mass energies were equal, there would be no leftover energy for kinetic energy. Therefore the kinetic energy of the products is the difference between the mass energy of the initial particles and the final particles.

SET UP: The difference in mass is $\Delta m = M_{\Omega^-} - m_{\Lambda^0} - m_{\text{K}^-}$.

EXECUTE: Using Table 44.3, the energy difference is

$$E = (\Delta m)c^2 = 1672\ \text{MeV} - 1116\ \text{MeV} - 494\ \text{MeV} = 62\ \text{MeV}$$

EVALUATE: There is less rest mass energy after the reaction than before because 62 MeV of the initial energy was converted to kinetic energy of the products.

44.21. **IDENTIFY** and **SET UP:** The lepton numbers for the particles are given in Table 44.2.

EXECUTE: **(a)** $\mu^- \to e^- + \nu_e + \overline{\nu}_\mu \Rightarrow L_\mu: +1 \neq -1, L_e: 0 \neq +1+1,$ so lepton numbers are not conserved.

(b) $\tau^- \to e^- + \overline{\nu}_e + \nu_\tau \Rightarrow L_e: 0 = +1-1;\ L_\tau: +1 = +1,$ so lepton numbers are conserved.

(c) $\pi^+ \to e^+ + \gamma$. Lepton numbers are not conserved since just one lepton is produced from zero original leptons.

(d) $n \to p + e^- + \overline{\nu}_e \Rightarrow L_e: 0 = +1-1,$ so the lepton numbers are conserved.

EVALUATE: The decays where lepton numbers are conserved are among those listed in Tables 44.2 and 44.3.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

44.22. **IDENTIFY** and **SET UP:** p and n have baryon number $+1$ and $\bar{\text{p}}$ has baryon number -1. $\text{e}^+, \text{e}^-, \bar{\nu}_e$ and γ all have baryon number zero. Baryon number is conserved if the total baryon number of the products equals the total baryon number of the reactants.

EXECUTE: **(a)** reactants: $B = 1 + 1 = 2$. Products: $B = 1 + 0 = 1$. Not conserved.

(b) reactants: $B = 1 + 1 = 2$. Products: $B = 0 + 0 = 0$. Not conserved.

(c) reactants: $B = +1$. Products: $B = 1 + 0 + 0 = +1$. Conserved.

(d) reactants: $B = 1 - 1 = 0$. Products: $B = 0$. Conserved.

EVALUATE: Even though a reaction obeys conservation of baryon number it may still not occur spontaneously, if it is not energetically allowed or if other conservation laws are violated.

44.23. **IDENTIFY** and **SET UP:** Compare the sum of the strangeness quantum numbers for the particles on each side of the decay equation. The strangeness quantum numbers for each particle are given in Table 44.3.

EXECUTE: **(a)** $\text{K}^+ \to \mu^+ + \nu_\mu$; $S_{\text{K}^+} = +1, S_{\mu+} = 0, S_{\nu_\mu} = 0$

$S = 1$ initially; $S = 0$ for the products; S is <u>not conserved</u>

(b) $\text{n} + \text{K}^+ \to \text{p} + \pi^0$; $S_{\text{n}} = 0, S_{\text{K}^+} = +1, S_{\text{p}} = 0, S_{\pi^0} = 0$

$S = 1$ initially; $S = 0$ for the products; S is <u>not conserved</u>

(c) $\text{K}^+ + \text{K}^- \to \pi^0 + \pi^0$; $S_{\text{K}^+} = +1; S_{\text{K}^-} = -1; S_{\pi^0} = 0$

$S = +1 - 1 = 0$ initially; $S = 0$ for the products; S is <u>conserved</u>

(d) $\text{p} + \text{K}^- \to \Lambda^0 + \pi^0$; $S_{\text{p}} = 0, S_{\text{K}^-} = -1, S_{\Lambda^0} = -1, S_{\pi^0} = 0$.

$S = -1$ initially; $S = -1$ for the products; S is <u>conserved</u>

EVALUATE: Strangeness is not a conserved quantity in weak interactions, and strangeness nonconserving reactions or decays can occur.

44.24. **IDENTIFY** and **SET UP:** Numerical values for the fundamental physical constant are given in Appendix F.

EXECUTE: **(a)** Using the values of the constants from Appendix F,

$$\frac{e^2}{4\pi\epsilon_0\hbar c} = 7.29660475 \times 10^{-3} = \frac{1}{137.050044}, \text{ or } 1/137 \text{ to three figures.}$$

(b) From Section 39.3, $v_1 = \dfrac{e^2}{2\epsilon_0 h}$. But notice this is just $\left(\dfrac{e^2}{4\pi\epsilon_0\hbar c}\right)c$, as claimed.

EVALUATE: $U = \dfrac{q_1 q_2}{4\pi\epsilon_0 r}$, so $\dfrac{e^2}{4\pi\epsilon_0}$ has units of $\text{J} \cdot \text{m}$. $\hbar c$ has units of $(\text{J} \cdot \text{s})(\text{m/s}) = \text{J} \cdot \text{m}$, so $\dfrac{e^2}{4\pi\epsilon_0\hbar c}$ is indeed dimensionless.

44.25. **IDENTIFY** and **SET UP:** f^2 has units of energy times distance. $\hbar$ has units of $\text{J} \cdot \text{s}$ and c has units of m/s.

EXECUTE: $\left[\dfrac{f^2}{\hbar c}\right] = \dfrac{(\text{J} \cdot \text{m})}{(\text{J} \cdot \text{s})(\text{m} \cdot \text{s}^{-1})} = 1$ and thus $\dfrac{f^2}{\hbar c}$ is dimensionless.

EVALUATE: Since $\dfrac{f^2}{\hbar c}$ is dimensionless, it has the same numerical value in all system of units.

44.26. **IDENTIFY** and **SET UP:** Construct the diagram as specified in the problem. In part (b), use quark charges $\boldsymbol{u} = +\dfrac{2}{3}, \boldsymbol{d} = \dfrac{-1}{3}$, and $\boldsymbol{s} = \dfrac{-1}{3}$ as a guide.

EXECUTE: **(a)** The diagram is given in Figure 44.26. The Ω^- particle has $Q = -1$ (as its label suggests) and $S = -3$. Its appears as a "hole" in an otherwise regular lattice in the $S - Q$ plane.

(b) The quark composition of each particle is shown in the figure.

EVALUATE: The mass difference between each S row is around 145 MeV (or so). This puts the Ω^- mass at about the right spot. As it turns out, all the other particles on this lattice had been discovered already and it was this "hole" and mass regularity that led to an accurate prediction of the properties of the Ω^-!

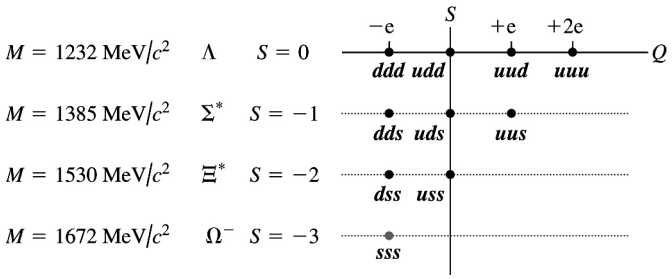

Figure 44.26

44.27. **IDENTIFY** and **SET UP:** Each value for the combination is the sum of the values for each quark. Use Table 44.4.

EXECUTE: **(a)** ***uds***

$Q = \frac{2}{3}e - \frac{1}{3}e - \frac{1}{3}e = 0$

$B = \frac{1}{3} + \frac{1}{3} + \frac{1}{3} = 1$

$S = 0 + 0 - 1 = -1$

$C = 0 + 0 + 0 = 0$

(b) $c\bar{u}$

The values for $\bar{u}$ are the negative for those for ***u***.

$Q = \frac{2}{3}e - \frac{2}{3}e = 0$

$B = \frac{1}{3} - \frac{1}{3} = 0$

$S = 0 + 0 = 0$

$C = +1 + 0 = +1$

(c) ***ddd***

$Q = -\frac{1}{3}e - \frac{1}{3}e - \frac{1}{3}e = -e$

$B = \frac{1}{3} + \frac{1}{3} + \frac{1}{3} = +1$

$S = 0 + 0 + 0 = 0$

$C = 0 + 0 + 0 = 0$

(d) $d\bar{c}$

$Q = -\frac{1}{3}e - \frac{2}{3}e = -e$

$B = \frac{1}{3} - \frac{1}{3} = 0$

$S = 0 + 0 = 0$

$C = 0 - 1 = -1$

EVALUATE: The charge, baryon number, strangeness and charm quantum numbers of a particle are determined by the particle's quark composition.

44.28. **IDENTIFY:** Quark combination produce various particles.

SET UP: The properties of the quarks are given in Table 44.5. An antiquark has charge and quantum numbers of opposite sign from the corresponding quark.

EXECUTE: **(a)** $Q/e = \frac{2}{3} + \frac{2}{3} + \left(-\frac{1}{3}\right) = +1.$ $B = \frac{1}{3} + \frac{1}{3} + \frac{1}{3} = 1.$ $S = 0 + 0 + (-1) = -1.$ $C = 0 + 0 + 0 = 0.$

(b) $Q/e = \frac{2}{3} + \frac{1}{3} = +1.$ $B = \frac{1}{3} + \left(-\frac{1}{3}\right) = 0.$ $S = 0 + 1 = 1.$ $C = 1 + 0 = 1.$

(c) $Q/e = \frac{1}{3} + \frac{1}{3} + \left(-\frac{2}{3}\right) = 0.$ $B = -\frac{1}{3} + \left(-\frac{1}{3}\right) + \left(-\frac{1}{3}\right) = -1.$ $S = 0 + 0 + 0 = 0.$ $C = 0 + 0 + 0 = 0.$

(d) $Q/e = -\frac{2}{3} + \left(-\frac{1}{3}\right) = -1.$ $B = -\frac{1}{3} + \frac{1}{3} = 0.$ $S = 0 + 0 = 0.$ $C = -1 + 0 = -1.$

EVALUATE: The charge must always come out to be a whole number.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

44.29. **IDENTIFY:** A proton is made up of ***uud*** quarks and a neutron consists of ***udd*** quarks.

SET UP and **EXECUTE:** If a proton decays by β^+ decay, we have $\mathrm{p} \to \mathrm{e}^+ + \mathrm{n} + \nu_e$ (both charge and lepton number are conserved).

EVALUATE: Since a proton consists of ***uud*** quarks and a neutron is ***udd*** quarks, it follows that in β^+ decay a ***u*** quark changes to a ***d*** quark.

44.30. **IDENTIFY:** The decrease in the rest energy of the particles that exist before and after the decay equals the energy that is released.

SET UP: The upsilon has rest energy 9460 MeV and each tau has rest energy 1777 MeV.

EXECUTE: $(m_\Upsilon - 2m_\tau)c^2 = (9460\ \text{MeV} - 2(1777\ \text{MeV})) = 5906\ \text{MeV}$

EVALUATE: Over half of the rest energy of the upsilon is released in the decay.

44.31. **IDENTIFY** and **SET UP:** To obtain the quark content of an antiparticle, replace quarks by antiquarks and antiquarks by quarks in the quark composition of the particle.

EXECUTE: **(a)** The antiparticle must consist of the antiquarks so $\overline{\mathrm{n}} = \bar{\boldsymbol{u}}\bar{\boldsymbol{u}}\bar{\boldsymbol{d}}$.

(b) $\mathrm{n} = \boldsymbol{udd}$ is not its own antiparticle, since n and $\overline{\mathrm{n}}$ have different quark content.

(c) $\psi = \boldsymbol{c}\bar{\boldsymbol{c}}$ so $\bar{\psi} = \bar{\boldsymbol{c}}\boldsymbol{c} = \psi$ so the ψ is its own antiparticle.

EVALUATE: We can see from Table 44.3 that none of the baryons are their own antiparticles and that none of the charged mesons are their own antiparticles. The ψ is a neutral meson and all the neutral mesons are their own antiparticles.

44.32. **IDENTIFY:** The charge, baryon number and strangeness of the particles are the sums of these values for their constituent quarks.

SET UP: The properties of the six quarks are given in Table 44.5.

EXECUTE: **(a)** $S = 1$ indicates the presence of one $\bar{\boldsymbol{s}}$ antiquark and no ***s*** quark. To have baryon number 0 there can be only one other quark, and to have net charge $+e$ that quark must be a ***u***, and the quark content is $\boldsymbol{u}\bar{\boldsymbol{s}}$.

(b) The particle has an $\bar{\boldsymbol{s}}$ antiquark, and for a baryon number of -1 the particle must consist of three antiquarks. For a net charge of $-e$, the quark content must be $\bar{\boldsymbol{d}}\bar{\boldsymbol{d}}\,\bar{\boldsymbol{s}}$.

(c) $S = -2$ means that there are two ***s*** quarks, and for baryon number 1 there must be one more quark. For a charge of 0 the third quark must be a ***u*** quark and the quark content is ***uss***.

EVALUATE: The particles with baryon number zero are mesons and consist of a quark-antiquark pair. Particles with baryon number 1 consist of three quarks and are baryons. Particles with baryon number -1 consist of three antiquarks and are antibaryons.

44.33. **(a) IDENTIFY** and **SET UP:** Use Eq. (44.14) to calculate v.

EXECUTE: $$v = \left[\frac{(\lambda_0/\lambda_\mathrm{S})^2 - 1}{(\lambda_0/\lambda_\mathrm{S})^2 + 1}\right]c = \left[\frac{(658.5\ \text{nm}/590\ \text{nm})^2 - 1}{(658.5\ \text{nm}/590\ \text{nm})^2 + 1}\right]c = 0.1094c$$

$v = (0.1094)(2.998 \times 10^8\ \text{m/s}) = 3.28 \times 10^7\ \text{m/s}$

(b) IDENTIFY and **SET UP:** Use Eq. (44.15) to calculate r.

EXECUTE: $$r = \frac{v}{H_0} = \frac{3.28 \times 10^4\ \text{km/s}}{(71(\text{km/s})/\text{Mpc})(1\ \text{Mpc}/3.26\ \text{Mly})} = 1510\ \text{Mly}$$

EVALUATE: The red shift $\lambda_0/\lambda_\mathrm{S} - 1$ for this galaxy is 0.116. It is therefore about twice as far from earth as the galaxy in Examples 44.8 and 44.9, that had a red shift of 0.053.

44.34. **IDENTIFY:** In Example 44.8, z is defined as $z = \dfrac{\lambda_0 - \lambda_\mathrm{S}}{\lambda_\mathrm{S}}$. Apply Eq. (44.13) to solve for v. Hubble's law is given by Eq. (44.15).

SET UP: The Hubble constant has a value of $H_0 = 7.1 \times 10^4\ \dfrac{\text{m/s}}{\text{Mpc}}$.

EXECUTE: **(a)** $1 + z = 1 + \dfrac{(\lambda_0 - \lambda_\mathrm{S})}{\lambda_\mathrm{S}} = \dfrac{\lambda_0}{\lambda_\mathrm{S}}$. Now we use Eq. (44.13) to obtain

$$1 + z = \sqrt{\frac{c+v}{c-v}} = \sqrt{\frac{1+v/c}{1-v/c}} = \sqrt{\frac{1+\beta}{1-\beta}}.$$

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(b) Solving the above equation for β we obtain $\beta = \dfrac{(1+z)^2-1}{(1+z)^2+1} = \dfrac{1.5^2-1}{1.5^2+1} = 0.3846$. Thus,

$v = 0.3846c = 1.15\times10^8$ m/s.

(c) We can use Eq. (44.15) to find the distance to the given galaxy,

$$r = \frac{v}{H_0} = \frac{(1.15\times10^8 \text{ m/s})}{(7.1\times10^4 \text{ (m/s)/Mpc})} = 1.6\times10^3 \text{ Mpc}$$

EVALUATE: 1 pc = 3.26 ly, so the distance in part (c) is 5.2×10^9 ly.

44.35. **(a) IDENTIFY** and **SET UP:** Hubble's law is Eq. (44.15), with $H_0 = 71$ (km/s)/(Mpc). 1 Mpc = 3.26 Mly.

EXECUTE: $r = 5210$ Mly so $v = H_0 r = ((71 \text{ km/s})/\text{Mpc})(1 \text{ Mpc}/3.26 \text{ Mly})(5210 \text{ Mly}) = 1.1\times10^5$ km/s

(b) IDENTIFY and **SET UP:** Use v from part (a) in Eq. (44.13).

EXECUTE: $\dfrac{\lambda_0}{\lambda_S} = \sqrt{\dfrac{c+v}{c-v}} = \sqrt{\dfrac{1+v/c}{1-v/c}}$

$\dfrac{v}{c} = \dfrac{1.1\times10^8 \text{ m/s}}{2.9980\times10^8 \text{ m/s}} = 0.367$ so $\dfrac{\lambda_0}{\lambda_S} = \sqrt{\dfrac{1+0.367}{1-0.367}} = 1.5$

EVALUATE: The galaxy in Examples 44.8 and 44.9 is 710 Mly away so has a smaller recession speed and redshift than the galaxy in this problem.

44.36. **IDENTIFY:** Set $v = c$ in Eq. (44.15).

SET UP: $H_0 = 71 \dfrac{\text{km/s}}{\text{Mpc}}$. 1 Mpc = 3.26 Mly, so $H_0 = 22 \dfrac{\text{km/s}}{\text{Mly}}$.

EXECUTE: **(a)** From Eq. (44.15), $r = \dfrac{c}{H_0} = \dfrac{3.00\times10^5 \text{ km/s}}{22 \text{ (km/s)/Mly}} = 1.4\times10^4$ Mly.

EVALUATE: **(b)** This distance represents looking back in time so far that the light has not been able to reach us.

44.37. **IDENTIFY** and **SET UP:** $m_H = 1.67\times10^{-27}$ kg. The ideal gas law says $pV = nRT$. Normal pressure is 1.013×10^5 Pa and normal temperature is about 27 °C = 300 K. 1 mole is 6.02×10^{23} atoms.

EXECUTE: **(a)** $\dfrac{6.3\times10^{-27} \text{ kg/m}^3}{1.67\times10^{-27} \text{ kg/atom}} = 3.8 \text{ atoms/m}^3$

(b) $V = (4 \text{ m})(7 \text{ m})(3 \text{ m}) = 84 \text{ m}^3$ and $(3.8 \text{ atoms/m}^3)(84 \text{ m}^3) = 320$ atoms

(c) With $p = 1.013\times10^5$ pa, $V = 84 \text{ m}^3$, $T = 300$ K the ideal gas law gives the number of moles to be

$n = \dfrac{pV}{RT} = \dfrac{(1.013\times10^5 \text{ Pa})(84 \text{ m}^3)}{(8.3145 \text{ J/mol}\cdot\text{K})(300 \text{ K})} = 3.4\times10^3$ moles.

$(3.4\times10^3 \text{ moles})(6.02\times10^{23} \text{ atoms/mol}) = 2.0\times10^{27}$ atoms

EVALUATE: The average density of the universe is very small. Interstellar space contains a very small number of atoms per cubic meter, compared to the number of atoms per cubit meter in ordinary material on the earth, such as air.

44.38. **IDENTIFY** and **SET UP:** The dimensions of $\hbar$ are energy times time, the dimensions of G are energy times length per mass squared. The numerical values of the physical constants are given in Appendix F.

EXECUTE: **(a)** The dimensions of $\sqrt{\hbar G/c^3}$ are

$$\left[\frac{(\text{E}\cdot\text{T})(\text{E}\cdot\text{L}/\text{M}^2)}{(\text{L}/\text{T})^3}\right]^{1/2} = \left[\frac{\text{E}}{\text{M}}\right]\left[\frac{\text{T}^2}{\text{L}}\right] = \left[\frac{\text{L}}{\text{T}}\right]^2\left[\frac{\text{T}^2}{\text{L}}\right] = \text{L}.$$

(b) $\left(\dfrac{\hbar G}{c^3}\right)^{1/2} = \left(\dfrac{(6.626\times10^{-34} \text{ J}\cdot\text{s})(6.673\times10^{-11} \text{ N}\cdot\text{m}^2/\text{kg}^2)}{2\pi(3.00\times10^8 \text{ m/s})^3}\right)^{1/2} = 1.616\times10^{-35}$ m.

EVALUATE: Both the dimensional analysis and the numerical calculation agree that the units of this quantity are meters.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

44.39. **IDENTIFY** and **SET UP:** Find the energy equivalent of the mass decrease.

EXECUTE: **(a)** $p + {}^2_1\text{H} \rightarrow {}^3_2\text{He}$ or can write as ${}^1_1\text{H} + {}^2_1\text{H} \rightarrow {}^3_2\text{He}$

If neutral atom masses are used then the masses of the two atomic electrons on each side of the reaction will cancel.

Taking the atomic masses from Table 43.2, the mass decrease is $m({}^1_1\text{H}) + m({}^2_1\text{H}) - m({}^3_2\text{He}) = 1.007825\text{ u} + 2.014102\text{ u} - 3.016029\text{ u} = 0.005898\text{ u}$. The energy released is the energy equivalent of this mass decrease: $(0.005898\text{ u})(931.5\text{ MeV/u}) = 5.494\text{ MeV}$.

(b) ${}^1_0\text{n} + {}^3_2\text{He} \rightarrow {}^4_2\text{He}$

If neutral helium masses are used then the masses of the two atomic electrons on each side of the reaction equation will cancel. The mass decrease is $m({}^1_0\text{n}) + m({}^3_2\text{He}) - m({}^4_2\text{He}) = 1.008665\text{ u} + 3.016029\text{ u} - 4.002603\text{ u} = 0.022091\text{ u}$. The energy released is the energy equivalent of this mass decrease: $(0.022091\text{ u})(931.15\text{ MeV/u}) = 20.58\text{ MeV}$.

EVALUATE: These are important nucleosynthesis reactions, discussed in Section 44.7.

44.40. **IDENTIFY:** The energy released in the reaction is the energy equivalent of the mass decrease that occurs in the reaction.

SET UP: 1 u is equivalent to 931.5 MeV. The neutral atom masses are given in Table 43.2.

EXECUTE: $3m({}^4\text{He}) - m({}^{12}\text{C}) = 7.80 \times 10^{-3}\text{ u}$, or 7.27 MeV.

EVALUATE: The neutral atom masses include 6 electrons on each side of the reaction equation. The electron masses cancel and we obtain the same mass change as would be calculated using nuclear masses.

44.41. **IDENTIFY:** The reaction energy Q is defined in Eq. (43.23) and is the energy equivalent of the mass change in the reaction. When Q is negative the reaction is endoergic. When Q is positive the reaction is exoergic.

SET UP: Use the particle masses given in Section 43.1. 1 u is equivalent to 931.5 MeV.

EXECUTE: $\Delta m = m_\text{e} + m_\text{p} - m_\text{n} - m_{\nu_\text{e}}$ so assuming $m_{\nu_\text{e}} \approx 0$,

$\Delta m = 0.0005486\text{ u} + 1.007276\text{ u} - 1.008665\text{ u} = -8.40 \times 10^{-4}\text{ u}$

$\Rightarrow E = (\Delta m)c^2 = (-8.40 \times 10^{-4}\text{ u})(931.5\text{ MeV/u}) = -0.783\text{ MeV}$ and is endoergic.

EVALUATE: The energy consumed in the reaction would have to come from the initial kinetic energy of the reactants.

44.42. **IDENTIFY:** The reaction energy Q is defined in Eq. (43.23) and is the energy equivalent of the mass change in the reaction. When Q is negative the reaction is endoergic. When Q is positive the reaction is exoergic.

SET UP: 1 u is equivalent to 931.5 MeV. Use the neutral atom masses that are given in Table 43.2.

EXECUTE: $m_{{}^{12}_6\text{C}} + m_{{}^4_2\text{He}} - m_{{}^{16}_8\text{O}} = 7.69 \times 10^{-3}\text{u}$, or 7.16 MeV, an exoergic reaction.

EVALUATE: 7.16 MeV of energy is released in the reaction.

44.43. **IDENTIFY** and **SET UP:** The Wien displacement law (Eq. 39.21) sys $\lambda_\text{m} T$ equals a constant. Use this to relate $\lambda_{\text{m},1}$ at T_1 to $\lambda_{\text{m},2}$ at T_2.

EXECUTE: $\lambda_{\text{m},1} T_1 = \lambda_{\text{m},2} T_2$

$$\lambda_{\text{m},1} = \lambda_{\text{m},2}\left(\frac{T_2}{T_1}\right) = 1.062 \times 10^{-3}\text{ m}\left(\frac{2.728\text{ K}}{3000\text{ K}}\right) = 966\text{ nm}$$

EVALUATE: The peak wavelength was much less when the temperature was much higher.

44.44. **IDENTIFY:** Use the Bohr model to calculate the ionization energy of positronium.

SET UP and **EXECUTE:** The reduced mass is $m_\text{r} = \dfrac{mm}{m+m} = m/2$. For a hydrogen with an infinitely massive nucleus, the ground state energy is $E_1 = -\dfrac{1}{\epsilon_0^2}\dfrac{me^4}{8n^2h^2} = -13.6\text{ eV}$. For positronium,

$$E_1 = -\frac{1}{\epsilon_0^2}\frac{m_\text{r}e^4}{8n^2h^2} = \frac{1}{2}\left(-\frac{1}{\epsilon_0^2}\frac{me^4}{8n^2h^2}\right) = -(13.6\text{ eV})/2 = -6.80\text{ eV}.$$ The ionization energy is 6.80 eV.

EVALUATE: This is half the ionization energy of hydrogen.

44.45. **IDENTIFY** and **SET UP:** For colliding beams the available energy is twice the beam energy. For a fixed-target experiment only a portion of the beam energy is available energy (Eqs. 44.9 and 44.10).

EXECUTE: **(a)** $E_a = 2(7.0 \text{ TeV}) = 14.0 \text{ TeV}$

(b) Need $E_a = 14.0 \text{ TeV} = 14.0 \times 10^6 \text{ MeV}$. Since the target and projectile particles are both protons Eq. (44.10) can be used: $E_a^2 = 2mc^2(E_m + mc^2)$

$$E_m = \frac{E_a^2}{2mc^2} - mc^2 = \frac{(14.0 \times 10^6 \text{ MeV})^2}{2(938.3 \text{ MeV})} - 938.3 \text{ MeV} = 1.0 \times 10^{11} \text{ MeV} = 1.0 \times 10^5 \text{ TeV}.$$

EVALUATE: This shows the great advantage of colliding beams at relativistic energies.

44.46. **IDENTIFY:** The initial total energy of the colliding proton and antiproton equals the total energy of the two photons.

SET UP: For a particle with mass, $E = K + mc^2$. For a proton, $m_p c^2 = 938 \text{ MeV}$.

EXECUTE: $K + m_p c^2 = \frac{hc}{\lambda}$, $K = \frac{hc}{\lambda} - m_p c^2 = 652 \text{ MeV}$.

EVALUATE: If the kinetic energies of the colliding particles increase, then the wavelength of each photon decreases.

44.47. **IDENTIFY:** The energy comes from a mass decrease.

SET UP: A charged pion decays into a muon plus a neutrino. The muon in turn decays into an electron or positron plus two neutrinos.

EXECUTE: **(a)** $\pi^- \to \mu^- + \text{neutrino} \to e^- + \text{three neutrinos}$.

(b) If we neglect the mass of the neutrinos, the mass decrease is

$m(\pi^-) - m(e^-) = 273m_e - m_e = 272m_e = 2.480 \times 10^{-28} \text{ kg}$.

$E = mc^2 = 2.23 \times 10^{-11} \text{ J} = 139 \text{ MeV}$.

(c) The total energy delivered to the tissue is $(50.0 \text{ J/kg})(10.0 \times 10^{-3} \text{ kg}) = 0.500 \text{ J}$. The number of π^- mesons required is $\frac{0.500 \text{ J}}{2.23 \times 10^{-11} \text{ J}} = 2.24 \times 10^{10}$.

(d) The RBE for the electrons that are produced is 1.0, so the equivalent dose is

$1.0(50.0 \text{ Gy}) = 50.0 \text{ Sv} = 5.0 \times 10^3 \text{ rem}$.

EVALUATE: The π are heavier than electrons and therefore behave differently as they hit the tissue.

44.48. **IDENTIFY:** Apply Eq. (44.9).

SET UP: In Eq. (44.9), $E_a = (m_{\Sigma^0} + m_{K^0})c^2$, and with $M = m_p, m = m_{\pi^-}$ and $E_m = (m_{\pi^-})c^2 + K$,

$$K = \frac{E_a^2 - (m_{\pi^-}c^2)^2 - (m_p c^2)^2}{2m_p c^2} - (m_{\pi^-})c^2.$$

EXECUTE: $K = \frac{(1193 \text{ MeV} + 497.7 \text{ MeV})^2 - (139.6 \text{ MeV})^2 - (938.3 \text{ MeV})^2}{2(938.3 \text{ MeV})} - 139.6 \text{ MeV} = 904 \text{ MeV}$.

EVALUATE: The increase in rest energy is

$(m_{\Sigma^0} + m_{K^0} - m_{\pi^-} - m_p)c^2 = 1193 \text{ MeV} + 497.7 \text{ MeV} - 139.6 \text{ MeV} - 938.3 \text{ MeV} = 613 \text{ MeV}$. The threshold kinetic energy is larger than this because not all the kinetic energy of the beam is available to form new particle states.

44.49. **IDENTIFY:** With a stationary target, only part of the initial kinetic energy of the moving proton is available. Momentum conservation tells us that there must be nonzero momentum after the collision, which means that there must also be leftover kinetic energy. Therefore not all of the initial energy is available.

SET UP: The available energy is given by $E_a^2 = 2mc^2(E_m + mc^2)$ for two particles of equal mass when one is initially stationary. The *minimum* available energy must be equal to the rest mass energies of the products, which in this case is two protons, a K^+ and a K^-. The available energy must be at least the sum of the final rest masses.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: The minimum amount of available energy must be
$E_a = 2m_p + m_{K^+} + m_{K^-} = 2(938.3\text{ MeV}) + 493.7\text{ MeV} + 493.7\text{ MeV} = 2864\text{ MeV} = 2.864\text{ GeV}$

Solving the available energy formula for E_m gives $E_a^2 = 2mc^2(E_m + mc^2)$ and

$$E_m = \frac{E_a^2}{2mc^2} - mc^2 = \frac{(2864\text{ MeV})^2}{2(938.3\text{ MeV})} - 938.3\text{ MeV} = 3432.6\text{ MeV}$$

Recalling that E_m is the *total* energy of the proton, including its rest mass energy (RME), we have

$$K = E_m - \text{RME} = 3432.6\text{ MeV} - 938.3\text{ MeV} = 2494\text{ MeV} = 2.494\text{ GeV}$$

Therefore the threshold kinetic energy is $K = 2494$ MeV $= 2.494$ GeV.

EVALUATE: Considerably less energy would be needed if the experiment were done using colliding beams of protons.

44.50. **IDENTIFY:** Charge must be conserved. The energy released equals the decrease in rest energy that occurs in the decay.

SET UP: The rest energies are given in Table 44.3.

EXECUTE: **(a)** The decay products must be neutral, so the only possible combinations are $\pi^0\pi^0\pi^0$ *or* $\pi^0\pi^+\pi^-$.

(b) $m_{\eta_0} - 3m_{\pi^0} = 142.3\text{ Me V}/c^2$, so the kinetic energy of the π^0 mesons is 142.3 MeV. For the other reaction, $K = (m_{\eta_0} - m_{\pi^0} - m_{\pi^+} - m_{\pi^-})c^2 = 133.1\text{ MeV}$.

EVALUATE: The total momentum of the decay products must be zero. This imposes a correlation between the directions of the velocities of the decay products.

44.51. **IDENTIFY:** Baryon number, charge, strangeness and lepton numbers are all conserved in the reactions.

SET UP: Use Table 44.3 to identify the missing particle, once its properties have been determined.

EXECUTE: **(a)** The baryon number is 0, the charge is $+e$, the strangeness is 1, all lepton numbers are zero, and the particle is K^+.

(b) The baryon number is 0, the charge is $-e$, the strangeness is 0, all lepton numbers are zero and the particle is π^-.

(c) The baryon number is -1, the charge is 0, the strangeness is zero, all lepton numbers are 0 and the particle is an antineutron.

(d) The baryon number is 0 the charge is $+e$, the strangeness is 0, the muonic lepton number is -1, all other lepton numbers are 0 and the particle is μ^+.

EVALUATE: Rest energy considerations would determine if each reaction is endoergic or exoergic.

44.52. **IDENTIFY:** Apply the Heisenberg uncertainty principle in the form $\Delta E\Delta t \approx \hbar/2$. Let Δt be the mean lifetime.

SET UP: The rest energy of the ψ is 3097 MeV.

EXECUTE: $\Delta t = 7.6\times10^{-21}\text{ s} \Rightarrow \Delta E = \dfrac{\hbar}{2\Delta t} = \dfrac{1.054\times10^{-34}\text{ J}\cdot\text{s}}{2(7.6\times10^{-21}\text{ s})} = 6.93\times10^{-15}\text{ J} = 43\text{ keV}.$

$$\frac{\Delta E}{m_\psi c^2} = \frac{0.043\text{ MeV}}{3097\text{ MeV}} = 1.4\times10^{-5}.$$

EVALUATE: The energy width due to the lifetime of the particle is a small fraction of its rest energy.

44.53. **IDENTIFY** and **SET UP:** Apply the Heisenberg uncertainty principle in the form $\Delta E\Delta t \approx \hbar/2$. Let ΔE be the energy width and let Δt be the lifetime.

EXECUTE: $$\frac{\hbar}{2\Delta E} = \frac{(1.054\times10^{-34}\text{ J}\cdot\text{s})}{2(4.4\times10^{6}\text{ eV})(1.6\times10^{-19}\text{ J/eV})} = 7.5\times10^{-23}\text{ s}.$$

EVALUATE: The shorter the lifetime, the greater the energy width.

44.54. **IDENTIFY** and **SET UP:** $\phi \to K^+ + K^-$. The total energy released is the energy equivalent of the mass decrease.

(a) EXECUTE: The mass decrease is $m(\phi) - m(K^+) - m(K^-)$. The energy equivalent of the mass decrease is $mc^2(\phi) - mc^2(K^+) - mc^2(K^-)$. The rest mass energy mc^2 for the ϕ meson is given Problem 44.53, and

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

the values for K^+ and K^- are given in Table 44.3. The energy released then is $1019.4\text{ MeV} - 2(493.7\text{ MeV}) = 32.0\text{ MeV}$. The K^+ gets half this, 16.0 Mev.

EVALUATE: **(b)** Does the decay $\phi \to K^+ + K^- + \pi^0$ occur? The energy equivalent of the $K^+ + K^- + \pi^0$ mass is $493.7\text{ MeV} + 493.7\text{ MeV} + 135.0\text{ MeV} = 1122\text{ MeV}$. This is greater than the energy equivalent of the ϕ mass. The mass of the decay products would be greater than the mass of the parent particle; the decay is energetically forbidden.

(c) Does the decay $\phi \to K^+ + \pi^-$ occur? The reaction $\phi \to K^+ + K^-$ is observed. K^+ has strangeness $+1$ and K^- has strangeness -1, so the total strangeness of the decay products is zero. If strangeness must be conserved we deduce that the ϕ particle has strangeness zero. π^- has strangeness 0, so the product $K^+ + \pi^-$ has strangeness -1. The decay $\phi \to K^+ + \pi^-$ violates conservation of strangeness. Does the decay $\phi \to K^+ + \mu^-$ occur? μ^- has strangeness 0, so this decay would also violate conservation of strangeness.

44.55. **IDENTIFY:** Apply $\left|\frac{dN}{dt}\right| = \lambda N$ to find the number of decays in one year.

SET UP: Water has a molecular mass of 18.0×10^{-3} kg/mol.

EXECUTE: **(a)** The number of protons in a kilogram is $(1.00\text{ kg})\left(\frac{6.022\times10^{23}\text{ molecules/mol}}{18.0\times10^{-3}\text{ kg/mol}}\right)(2\text{ protons/molecule}) = 6.7\times10^{25}$. Note that only the protons in the hydrogen atoms are considered as possible sources of proton decay. The energy per decay is $m_p c^2 = 938.3\text{ MeV} = 1.503\times10^{-10}\text{ J}$, and so the energy deposited in a year, per kilogram, is

$$(6.7\times10^{25})\left(\frac{\ln(2)}{1.0\times10^{18}\text{ y}}\right)(1\text{ y})(1.50\times10^{-10}\text{ J}) = 7.0\times10^{-3}\text{ Gy} = 0.70\text{ rad}.$$

(b) For an RBE of unity, the equivalent dose is $(1)(0.70\text{ rad}) = 0.70\text{ rem}$.

EVALUATE: The equivalent dose is much larger than that due to the natural background. It is not feasible for the proton lifetime to be as short as 1.0×10^{18} y.

44.56. **IDENTIFY:** The energy comes from the mass difference.

SET UP: $\Xi^- \to \Lambda^0 + \pi^-$. $p_\Lambda = p_\pi = p$. $E_\Xi = E_\Lambda + E_\pi$. $m_\Xi c^2 = 1321\text{ MeV}$. $m_\Lambda c^2 = 1116\text{ MeV}$. $m_\pi c^2 = 139.6\text{ MeV}$. $m_\Xi c^2 = \sqrt{m_\Lambda^2 c^4 + p^2c^2} + \sqrt{m_\pi^2 c^4 + p^2c^2}$

EXECUTE: **(a)** The total energy released is $m_\Xi c^2 - m_\pi c^2 - m_\Lambda c^2 = 1321\text{ MeV} - 139.6\text{ MeV} - 1116\text{ MeV} = 65.4\text{ MeV}$.

(b) $m_\Xi c^2 = \sqrt{m_\Lambda^2 c^4 + p^2c^2} + \sqrt{m_\pi^2 c^4 + p^2c^2}$. $m_\Xi c^2 - \sqrt{m_\Lambda^2 c^4 + p^2c^2} = \sqrt{m_\pi^2 c^4 + p^2c^2}$. Square both sides:

$m_\Xi^2 c^4 + m_\Lambda^2 c^4 + p^2c^2 - 2m_\Xi c^2 E_\Lambda = m_\pi^2 c^4 + p^2c^2$. $E_\Lambda = \dfrac{m_\Xi^2 c^4 + m_\Lambda^2 c^4 - m_\pi^2 c^4}{2m_\Xi c^2}$.

$K_\Lambda = \dfrac{m_\Xi^2 c^4 + m_\Lambda^2 c^4 - m_\pi^2 c^4}{2m_\Xi c^2} - m_\Lambda c^2$. $E_\pi = E_\Xi - E_\Lambda = m_\Xi c^2 - \dfrac{m_\Xi^2 c^4 + m_\Lambda^2 c^4 - m_\pi^2 c^4}{2m_\Xi c^2}$.

$E_\pi = \dfrac{m_\Xi^2 c^4 - m_\Lambda^2 c^4 + m_\pi^2 c^4}{2m_\Xi c^2}$. $K_\pi = \dfrac{m_\Xi^2 c^4 - m_\Lambda^2 c^4 + m_\pi^2 c^4}{2m_\Xi c^2} - m_\pi c^2$. Putting in numbers gives

$$K_\Lambda = \frac{(1321\text{ MeV})^2 + (1116\text{ MeV})^2 - (139.6\text{ MeV})^2}{2(1321\text{ MeV})} - 1116\text{ MeV} = 8.5\text{ MeV}\ \ (13\%\text{ of total}).$$

$$K_\pi = \frac{(1321\text{ MeV})^2 - (1116\text{ MeV})^2 + (139.6\text{ MeV})^2}{2(1321\text{ MeV})} - 139.6\text{ MeV} = 56.9\text{ MeV}\ \ (87\%\text{ of total}).$$

EVALUATE: The two particles do not have equal kinetic energies because they have different masses.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

44.57. **IDENTIFY** and **SET UP:** Follow the steps specified in the problem.

EXECUTE: **(a)** For this model, $\frac{dR}{dt} = HR$, so $\frac{dR/dt}{R} = \frac{HR}{R} = H$, presumed to be the same for all points on the surface.

(b) For constant θ, $\frac{dr}{dt} = \frac{dR}{dt}\theta = HR\theta = Hr$.

(c) See part (a), $H_0 = \frac{dR/dt}{R}$.

(d) The equation $\frac{dR}{dt} = H_0 R$ is a differential equation, the solution to which, for constant H_0, is $R(t) = R_0 e^{H_0 t}$, where R_0 is the value of R at $t = 0$. This equation may be solved by separation of variables, as $\frac{dR/dt}{R} = \frac{d}{dt}\ln(R) = H_0$ and integrating both sides with respect to time.

EVALUATE: **(e)** A constant H_0 would mean a constant critical density, which is inconsistent with uniform expansion.

44.58. **IDENTIFY:** $H = \frac{1}{R}\frac{dR}{dt}$.

SET UP: From Problem 44.57, $r = R\theta \Rightarrow R = \frac{r}{\theta}$.

EXECUTE: $\frac{dR}{dt} = \frac{1}{\theta}\frac{dr}{dt} - \frac{r}{\theta^2}\frac{d\theta}{dt} = \frac{1}{\theta}\frac{dr}{dt}$ since $\frac{d\theta}{dt} = 0$. So

$\frac{1}{R}\frac{dR}{dt} = \frac{1}{R\theta}\frac{dr}{dt} = \frac{1}{r}\frac{dr}{dt} \Rightarrow v = \frac{dr}{dt} = \left(\frac{1}{R}\frac{dR}{dt}\right)r = H_0 r$. Now $\frac{dv}{d\theta} = 0 = \frac{d}{d\theta}\left(\frac{r}{R}\frac{dR}{dt}\right) = \frac{d}{d\theta}\left(\theta\frac{dR}{dt}\right)$

$\Rightarrow \theta\frac{dR}{dt} = K$ where K is a constant. $\Rightarrow \frac{dR}{dt} = \frac{K}{\theta} \Rightarrow R = \left(\frac{K}{\theta}\right)t$ since $\frac{d\theta}{dt} = 0 \Rightarrow H_0 = \frac{1}{R}\frac{dR}{dt} = \frac{\theta}{Kt}\frac{K}{\theta} = \frac{1}{t}$.

So the current value of the Hubble constant is $\frac{1}{T}$ where T is the present age of the universe.

EVALUATE: The current experimental value of H_0 is 2.3×10^{-18} s^{-1}, so $T = 4.4\times10^{17}$ s $= 1.4\times10^{10}$ y.

44.59. **IDENTIFY:** The matter density is proportional to $1/R^3$.

SET UP and **EXECUTE:** **(a)** When the matter density was large enough compared to the dark energy density, the slowing due to gravitational attraction would have dominated over the cosmic repulsion due to dark energy.

(b) Matter density is proportional to $1/R^3$, so $R \propto \frac{1}{\rho^{1/3}}$. Therefore $\frac{R}{R_0} = \left(\frac{1/\rho_{\text{past}}}{1/\rho_{\text{now}}}\right)^{1/3} = \left(\frac{\rho_{\text{now}}}{\rho_{\text{past}}}\right)^{1/3}$. If ρ_{m} and ρ_{DE} are the present-day densities of matter of all kinds and of dark energy, we have $\rho_{\text{DE}} = 0.726\rho_{\text{crit}}$ and $\rho_{\text{m}} = 0.274\rho_{\text{crit}}$ at the present time. Putting this into the above equation for R/R_0 gives

$$\frac{R}{R_0} = \left(\frac{\frac{0.274}{0.726}\rho_{\text{DE}}}{2\rho_{\text{DE}}}\right)^{1/3} = 0.574.$$

EVALUATE: **(c)** 300 My: speeding up $(R/R_0 = 0.98)$; 10.2 Gy: slowing down $(R/R_0 = 0.35)$.

44.60. **IDENTIFY:** The kinetic energy comes from the mass difference, and momentum is conserved.

SET UP: $\left|p_{\pi^+ y}\right| = \left|p_{\pi^- y}\right|$. $p_{\pi^+}\sin\theta = p_{\pi^-}\sin\theta$ and $p_{\pi^+} = p_{\pi^-} = p_\pi$. $m_{\text{K}}c^2 = 497.7$ MeV.

$m_\pi c^2 = 139.6$ MeV.

© Copyright 2012 Pearson Education, Inc. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

EXECUTE: Conservation of momentum for the decay gives $p_K = 2p_{\pi x}$ and $p_K^2 = 4p_{\pi x}^2$.

$p_K^2c^2 = E_K^2 - m_K^2c^2$. $E_K = 497.7\text{ MeV} + 225\text{ MeV} = 722.7\text{ MeV}$ so

$p_K^2c^2 = (722.7\text{ MeV})^2 - (497.7\text{ MeV})^2 = 2.746\times10^5\text{ (MeV)}^2$ and

$p_{\pi x}^2c^2 = [2.746\times10^5\text{ (MeV)}^2]/4 = 6.865\times10^4\text{ (MeV)}^2$. Conservation of energy says $E_K = 2E_\pi$.

$E_\pi = \dfrac{E_K}{2} = 361.4\text{ MeV}$.

$K_\pi = E_\pi - m_\pi c^2 = 361.4\text{ MeV} - 139.6\text{ MeV} = 222\text{ MeV}$.

$p_\pi^2c^2 = E_\pi^2 - (m_\pi c^2)^2 = (361.4\text{ MeV})^2 - (139.6\text{ MeV})^2 = 1.11\times10^5\text{ (MeV)}^2$. The angle θ that the velocity of the π^+ particle makes with the $+x$-axis is given by $\cos\theta = \sqrt{\dfrac{p_{\pi x}^2c^2}{p_\pi^2c^2}} = \sqrt{\dfrac{6.865\times10^4}{1.11\times10^5}}$, which gives $\theta = 38.2^\circ$.

EVALUATE: The pions have the same energy and go off at the same angle because they have equal masses.

44.61. **IDENTIFY:** The kinetic energy comes from the mass difference.

SET UP and **EXECUTE:** $K_\Sigma = 180\text{ MeV}$. $m_\Sigma c^2 = 1197\text{ MeV}$. $m_n c^2 = 939.6\text{ MeV}$. $m_\pi c^2 = 139.6\text{ MeV}$.

$E_\Sigma = K_\Sigma + m_\Sigma c^2 = 180\text{ MeV} + 1197\text{ MeV} = 1377\text{ MeV}$. Conservation of the x-component of momentum gives $p_\Sigma = p_{nx}$. Then $p_{nx}^2c^2 = p_\Sigma^2c^2 = E_\Sigma^2 - (m_\Sigma c)^2 = (1377\text{ MeV})^2 - (1197\text{ MeV})^2 = 4.633\times10^5\text{ (MeV)}^2$.

Conservation of energy gives $E_\Sigma = E_\pi + E_n$. $E_\Sigma = \sqrt{m_\pi^2c^4 + p_\pi^2c^2} + \sqrt{m_n^2c^4 + p_n^2c^2}$.

$E_\Sigma - \sqrt{m_n^2c^4 + p_n^2c^2} = \sqrt{m_\pi^2c^4 + p_\pi^2c^2}$. Square both sides:

$E_\Sigma^2 + m_n^2c^4 + p_{nx}^2c^2 + p_{ny}^2c^2 - 2E_\Sigma E_n = m_\pi^2c^4 + p_\pi^2c^2$. $p_\pi = p_{ny}$ so

$E_\Sigma^2 + m_n^2c^4 + p_{nx}^2c^2 - 2E_\Sigma E_n = m_\pi^2c^4$ and $E_n = \dfrac{E_\Sigma^2 + m_n^2c^4 - m_\pi^2c^4 + p_{nx}^2c^2}{2E_\Sigma}$.

$$E_n = \frac{(1377\text{ MeV})^2 + (939.6\text{ MeV})^2 - (139.6\text{ MeV})^2 + 4.633\times10^5\text{ (MeV)}^2}{2(1377\text{ MeV})} = 1170\text{ MeV}.$$

$K_n = E_n - m_n c^2 = 1170\text{ MeV} - 939.6\text{ MeV} = 230\text{ MeV}$.

$E_\pi = E_\Sigma - E_n = 1377\text{ MeV} - 1170\text{ MeV} = 207\text{ MeV}$.

$K_\pi = E_\pi - m_\pi c^2 = 207\text{ MeV} - 139.6\text{ MeV} = 67\text{ MeV}$.

$p_n^2c^2 = E_n^2 - m_n^2c^2 = (1170\text{ MeV})^2 - (939.6\text{ MeV})^2 = 4.861\times10^5\text{ (MeV)}^2$. The angle θ the velocity of the neutron makes with the $+x$-axis is given by $\cos\theta = \dfrac{p_{nx}}{p_n} = \sqrt{\dfrac{4.633\times10^5}{4.861\times10^5}}$ and $\theta = 12.5^\circ$ below the $+x$-axis.

EVALUATE: The decay particles do not have equal energy because they have different masses.

44.62. **IDENTIFY:** Follow the steps specified in the problem. The Lorentz velocity transformation is given in Eq. (37.23).

SET UP: Let the $+x$-direction be the direction of the initial velocity of the bombarding particle.

EXECUTE: **(a)** For mass m, in Eq. (37.23) $u = -v_{cm}$, $v' = v_0$, and so $v_m = \dfrac{v_0 - v_{cm}}{1 - v_0\,v_{cm}/c^2}$. For mass M, $u = -v_{cm}$, $v' = 0$, so $v_M = -v_{cm}$.

(b) The condition for no net momentum in the center of mass frame is $m\gamma_m v_m + M\gamma_M v_M = 0$, where γ_m and γ_M correspond to the velocities found in part (a). The algebra reduces to

$\beta_m\gamma_m = (\beta_0 - \beta')\gamma_0\gamma_M$, where $\beta_0 = \dfrac{v_0}{c}$, $\beta' = \dfrac{v_{\text{cm}}}{c}$, and the condition for no net momentum becomes

$m(\beta_0 - \beta')\gamma_0\gamma_M = M\beta'\gamma_M$, or $\beta' = \dfrac{\beta_0}{1 + \dfrac{M}{m\gamma_0}} = \beta_0 \dfrac{m}{m + M\sqrt{1-\beta_0^2}}$. $v_{\text{cm}} = \dfrac{mv_0}{m + M\sqrt{1-(v_0/c)^2}}$.

(c) Substitution of the above expression into the expressions for the velocities found in part (a) gives the relatively simple forms $v_m = v_0\gamma_0 \dfrac{M}{m + M\gamma_0}$, $v_M = -v_0\gamma_0 \dfrac{m}{m\gamma_0 + M}$. After some more algebra,

$\gamma_m = \dfrac{m + M\gamma_0}{\sqrt{m^2 + M^2 + 2mM\gamma_0}}$, $\gamma_M = \dfrac{M + m\gamma_0}{\sqrt{m^2 + M^2 + 2mM\gamma_0}}$, from which

$m\gamma_m + M\gamma_M = \sqrt{m^2 + M^2 + 2mM\gamma_0}$. This last expression, multiplied by c^2, is the available energy E_{a} in the center of mass frame, so that

$E_{\text{a}}^2 = (m^2 + M^2 + 2mM\gamma_0)c^4 = (mc^2)^2 + (Mc^2)^2 + (2Mc^2)(m\gamma_0 c^2) = (mc^2)^2 + (Mc^2)^2 + 2Mc^2E_m$, which is Eq. (44.9).

EVALUATE: The energy E_{a} in the center-of-momentum frame is the energy that is available to form new particle states.
